Methods: We recruited women ≥18 years with validated SLE followed at our hospital. Sociodemographic and SLE disease characteristics, as well as observed and self-report functional status measures (hand grip strength, 4-meter (m) walk test, self-report FRAIL scale, Valued Life Activities self-report disability) were obtained. Participants completed the SARC-F, which includes questions related to strength, assistance walking, rising from a chair, climbing stairs, and falls. Sociodemographic features, SLE disease characteristics, and functional status measures were compared using descriptive statistics between participant groups, with SARC-F scores dichotomized as ≥4 versus < 4 based on established cut points. Pearson correlations and linear and logistic regression were used to evaluate the relationship between the SARC-F as a continuous and dichotomous score with functional status measures, including after adjustment for confounders (i.e., age, race, ethnicity, disease activity, and organ damage).

Results: Of 47 participants, 16 (34%) had SARC-F score ≥4. Participants with SARC-F ≥4 had greater organ damage and worse functional status measures than those with SARC-F < 4 (all p< 0.01). SARC-F continuous scores were significantly correlated with hand grip strength, 4-m walk test, and self-report disability (all p< 0.01) and significantly correlated with all functional status measures (p< 0.01 to p=0.046). Dichotomous SARC-F was significantly associated with 4-m walk test (p< 0.01), including after adjustment for confounders, and there was a trend toward significance with hand grip strength and self-report disability (both p=0.06).

Table 1

Table 1. Sociodemographic and disease characteristics and functional status measures of adults with systemic lupus erythematosus (SLE) with high (≥4) versus low (<4) SARC-F scores

Variable N (%) or mean +/- standard deviation	Overall (N=47)	SARC-F score ≥4 (N=16)	SARC-F score <4 (N=31)	p-value
Age (years)	48.3 (14.5)	47.6 (15.0)	49.6 (14.0)	0.67

Table 2

Table 2. Correlation and association of continuous SARC-F score with functional status measures in adults with systemic lupus erythematosus

Functional measure	Correlation coefficient	p-value	Unadjusted parameter estimate (95% confidence interval)	p-value	Adjusted* parameter estimate (95% confidence interval)	p-value
Hand grip strength	-0.48	<0.01	-1.27 (-1.99, -0.56)	<0.01	-1.21 (-2.39, -0.02)	0.046
4-m walk test	0.73	<0.01	0.50 (0.36, 0.65)	<0.01	0.67 (0.37, 0.97)	<0.01
Valued Life Activities	0.65	<0.01	0.14 (0.09, 0.19)	<0.01	0.12 (0.04, 0.21)	<0.01
Functional measure	Correlation coefficient	p-value	Unadjusted odds ratio (95% confidence interval)	p-value	Adjusted* odds ratio (95% confidence interval)	p-value
Frailty	NA	NA	2.03 (1.33, 3.08)	<0.01	2.40 (1.10, 5.21)	0.03

*Adjusted for age, race, ethnicity, disease activity, and organ damage

Table 3

Table 3. Association of dichotomous SARC-F score (≥4) with functional status measures in adults with systemic lupus erythematosus

	Unadjusted parameter estimate (95% confidence interval)	p-value	Adjusted* parameter estimate (95% confidence interval)	p-value
Hand grip strength	-6.81 (-10.84, -2.79)	<0.01	-6.40 (-13.06, 0.26)	0.06
4-m walk test	2.14 (1.22, 3.05)	<0.01	2.30 (0.52, 4.08)	0.01
Valued Life Activities	0.55 (0.22, 0.88)	<0.01	0.47 (-0.02, 0.97)	0.06

*Adjusted for age, race, ethnicity, disease activity, and organ damage

Conclusion: In this exploratory study of adult women with SLE, SARC-F was significantly associated with multiple functional status measures, suggesting that the SARC-F may be a valid point-of-care screening tool for sarcopenia in women with SLE.

Abstract Number: 0335

Meta-Analysis of the Cost-Effectiveness of Social Media Advertising as a Recruitment Tool

Vladislav Tsaltskan[1], Roel Baez[2] and Gary Firestein[1], [1]University of California San Diego, San Diego, CA, [2]UC San Diego Health, San Diego, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Recruitment of study participants is challenging and can incur significant costs, particularly for studies of rheumatic disease or other rare conditions. Social media advertising is a promising method for recruiting to clinical studies. This approach may improve cost efficiency by targeting specific populations that are more likely to match a study's criteria. Although individual studies evaluating social media as a recruitment tool have been generally favorable, there are no meta-analyses of its cost-effectiveness.

Methods: Studies evaluating costs of recruitment through social media and non-social media methods were identified on MEDLINE and EMBASE. Articles were screened through a two-step process in accordance with PRISMA guidelines. Cost data was then extracted from included articles, normalized for currency and inflation, and a meta-analysis was performed using the Mantel-Haenszel method. The primary outcome was the relative cost-effectiveness of social media compared to non-social media recruitment, defined as the odds ratio of recruiting a participant per US dollar spent on each method. The secondary outcome was the relative cost-effectiveness of social media recruitment compared only to other online recruitment methods.

Results: After completion of the screening process, 23 studies were included in the meta-analysis. All of the included studies evaluated Facebook as a recruiting tool. Two studies also evaluated Instagram and Twitter, and one study each evaluated Youtube, Reddit, Linkedin, and Snapchat. The sample contained a high degree of heterogeneity, requiring the use of the random effects model. The odds ratio of recruiting a participant through social media advertising compared to non-social media methods per dollar spent was 1.97 [95% CI 1.24-3.00, P = 0.004]. This odds ratio conferred a median advantage over other methods of $45.51 [IQR $13.92-134.81] per enrolled participant for social media compared with $74.89 [IQR $6.57-187.15] per participant for other methods. For the secondary outcome, the odds ratio of recruiting a participant through social media compared to other online methods was 1.66 [95% CI 1.02-2.72, P = 0.04].

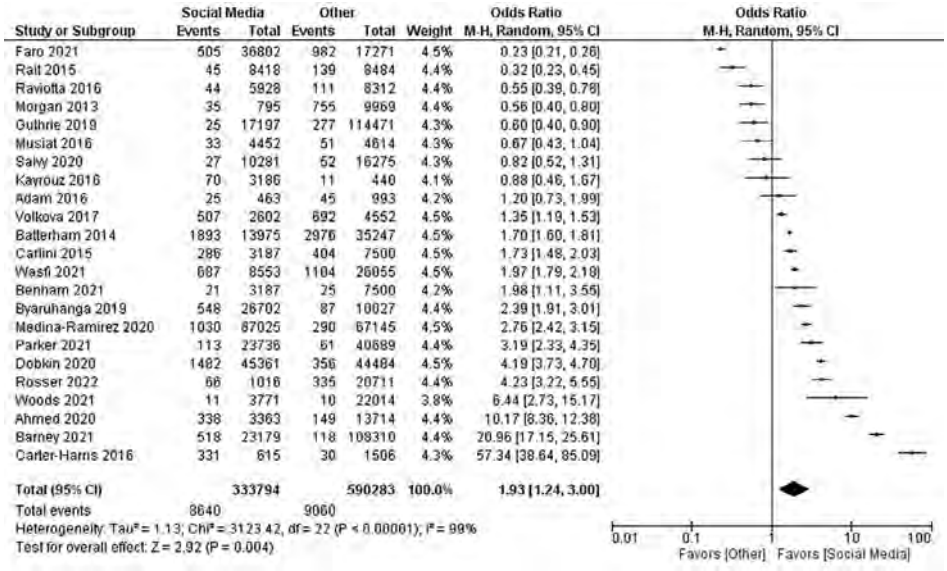

Figure 1: Forest plot of primary outcome.

Conclusion: Social media advertising is approximately twice as cost-effective as other methods of participant recruitment, although the magnitude of cost-effectiveness is varied between studies and populations. Additional data are needed to determine cost-effectiveness for individual rheumatic diseases and for rare conditions. There are also limited data available for newer social media platforms and for difficult-to-reach populations such as non-English speaking or older individuals. However, the data suggest that incorporating social media into clinical research could improve accrual at a lower cost than traditional methods.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Greater understanding of cutaneous signs and symptoms is needed to comprehensively define and measure cutaneous disease activity in lupus erythematosus. Herein, we interviewed dermatologic and rheumatologic experts: (I) to explore perspectives regarding key signs and symptoms for defining disease activity and damage in cutaneous lupus erythematosus (CLE) subtypes (chronic [primarily discoid], subacute and acute [CCLE [DLE]/SCLE/ACLE]) and (II) to explore potential differences and similarities in clinical signs and symptoms across these CLE subtypes.

Methods: This was a non-interventional, mixed-methods research study, integrating qualitative interviews and latent consensus assessments. Board-certified dermatologists (n=11) and rheumatologists (n=10) based in the United States and Europe with ≥5 years' experience in treating CLE were interviewed remotely, using a semi-structured interview guide (Figure 1). Data were evaluated by thematic analysis.

Results: Skin lesions in CLE show a broad spectrum of clinical manifestations and, therefore, it is important to use validated skin scores and to evaluate and distinguish disease activity and damage. The most frequently mentioned signs of disease activity by dermatologists included erythema (11/11) and infiltration/edema (10/11) followed by alopecia (scarring and non-

scarring), malar rash, scaling and dyspigmentation (8/11 for each) (Figure 2A). The rheumatologists also reported erythema (10/10) as the most frequently mentioned signs of disease activity, followed by alopecia (scarring and non-scarring), malar rash, scaling, dyspigmentation and infiltration/edema (Figure 2A). Itch was the most frequently reported symptom by dermatologists (10/11) whereas photosensitivity was the most frequently reported symptom by rheumatologists (8/10; Figure 2B). Erythema and scaling were associated with all subtypes, but infiltration/edema, mucous membrane involvement, alopecia and non-scarring alopecia varied across subtypes (Figure 3). Most clinicians mentioned that CLE progression is often unpredictable, varied across patients and may be influenced by multiple factors including CLE subtype, sun exposure, smoking and medication compliance. The clinical experts characterized remission as the absence of signs and symptoms, with or without medication. CLE remission is negatively influenced by sun exposure and smoking, whereas medication compliance positively impacts duration of remission.

Conclusion: Signs of CLE associated with disease activity may vary across subtypes and must be considered in the definition and measurement of disease activity. Erythema was the most frequently reported sign related to disease activity and was considered relevant across all CLE subtypes.

Impact of Photosensitivity on Quality of Life in Dermatomyositis

Kirubel Gebre[1], Rachita Pandya[2], Julianne Kleitsch[2], Darosa Lim[3], Rui Feng[3] and victoria werth[4], [1]Perelman School of Medicine at the University of Pennsylvania, Lancaster, PA, [2]Philadelphia VAMC, Philadelphia, PA, USA and Department of Dermatology, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, [3]University of Pennsylvania, Philadelphia, PA, [4]University of Pennsylvania, Wynnewood, PA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Photosensitivity (PS) has been documented in dermatomyositis (DM) with symptoms including aggravation of preexisting cutaneous lesions and abnormal transient erythemal responses (Cheong WK et al. 1994). DM has a large negative impact on quality of life (QoL), and DM skin disease activity has been correlated with poorer QoL (Goreshi R et al. 2011). Yet, the impact of PS specifically on QoL in DM has not been well studied. The aims of this study are to examine the impact of PS on QoL and to determine whether there is a relationship between PS-specific QoL measures and degree of cutaneous disease activity in DM.

Methods: Prospectively acquired data from 401 subjects with either classic DM (CDM) or clinically amyopathic DM (CADM) who completed the Skindex-29+3 was used. The Skindex-29+3 is a modified version of the Skindex-29, a validated measure of skin-specific QoL (Chren MM et al. 1997). Two of the three items added to the Skindex-29 relate to PS, items 31 and 33: "I worry about going outside because the sun might flare my disease" and "My skin disease prevents me from doing outdoor activities". The average of these two items comprises the PS subscale. Item 32, "I am worried about my hair loss", is the third added item in the Skindex-29+3. We compared patient responses to cutaneous disease activity using the Cutaneous Disease Area and Severity Index (CDASI), a validated tool for measuring DM disease (Ahmed S et al. 2020). Subject responses were not normally distributed, and group differences were assessed using the Wilcoxon rank-sum test. All three additional items of the Skindex-29+3 were correlated to CDASI activity scores using Spearman correlations. The three items were also correlated to the symptom, emotion, and function subscales of the Skindex-29+3 using Spearman correlations.

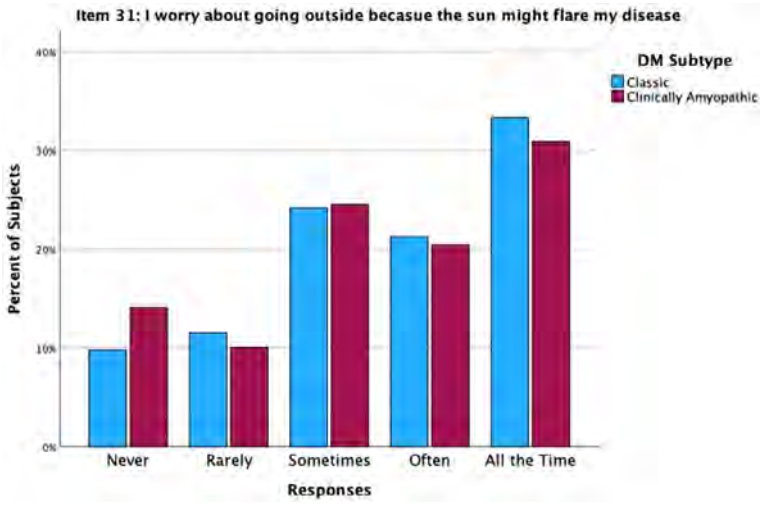

Figure 1. Percent of subject responses to Item 31 by DM subtype

Results: Of 401 subjects, 52% worried "often" or "all the time" about going outside because the sun might flare their disease (Item 31). 42% of subjects reported worrying about their hair loss (Item 32) "often" or "all the time". 39% of subjects reported being prevented from doing outdoor activities (Item 33) "often" or "all the time". There were no significant differences in median responses for Items 31 and 32 between patients with CDM and CADM (p = 0.407, 0.239), but there was a significant difference for Item 33 (p = 0.021), with CDM subjects reporting higher scores. There was a moderate, positive correlation between the PS subscale and both the function and emotion subscales for all subjects (r_s = 0.580, p < 0.001, r_s = 0.527, p < 0.001). There was another moderate, positive correlation between Item 33 and both function and emotion subscales (r_s = 0.611, p < 0.001, r_s = 0.516, p < 0.001). We found a negligible correlation for Items 31, 32, 33, and the PS subscale in relation to CDASI activity scores (r_s = 0.124 p = 0.013, r_s = 0.249 p < 0.001, r_s = 0.183 p < 0.001, r_s = 0.169 p = 0.001).

Conclusion: PS in DM has a significant impact on QoL in CDM and CADM. Concern regarding hair loss is common among subjects with DM. Subjects with CDM experienced greater limitation in participating in outdoor activities when compared to subjects with CADM (p = 0.021). Subjects that experienced greater PS-related concerns and limitations had greater emotional burden and functional impairments.

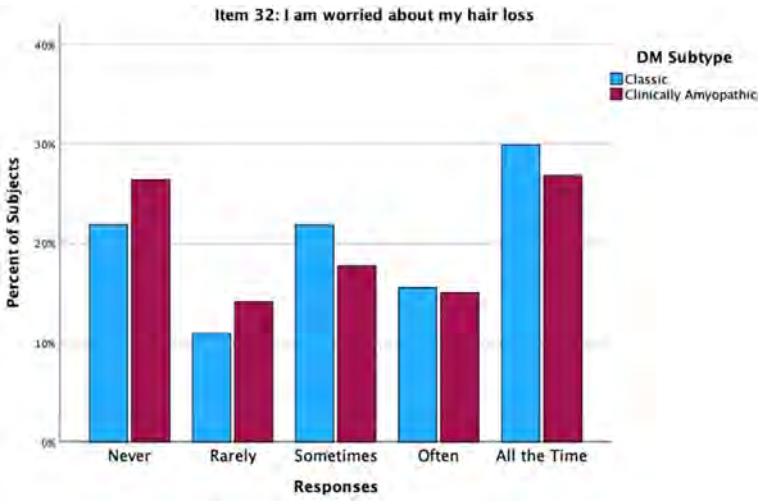

Figure 2. Percent of subject responses to Item 32 by DM subtype

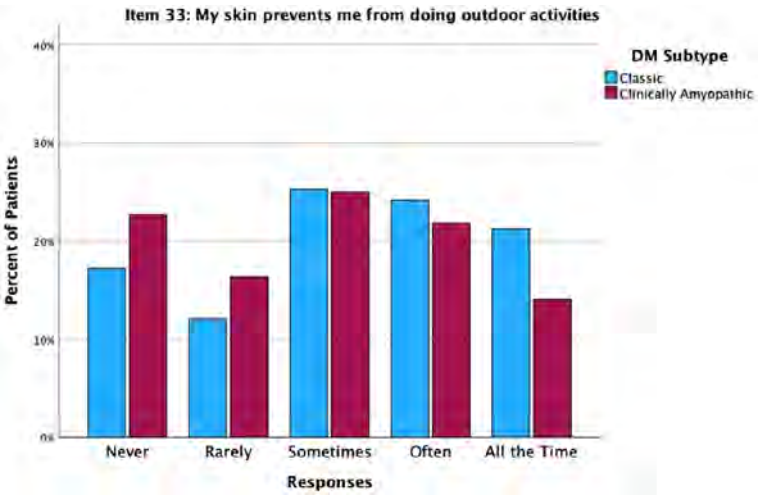

Figure 3. Percent of subject responses to Item 33 by DM subtype. There was a significant difference in the median responses between subjects with classic DM (CDM) and clinically amyopathic DM (CADM), with CDM subjects reporting higher scores (p = 0.021).

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) and spondyloarthritis (SpA), including either Psoriatic Arthritis (PsA) and Ankylosing Spondylitis (AS), are some of the most commonly diagnosed autoimmune rheumatic diseases in rheumatologists' routine clinical practice. Both can lead to joint destruction and substantial disability. Understanding patients' health and functional status is crucial to provide personalized management strategies to optimize disease control and enhance the quality of life. We aimed to compare disease burden in patients with RA, PsA or AS by assessing Patient-Reported Outcome Measurement Information System (PROMIS) Physical Health, Global Mental Health, Physical Function and Fatigue 4a together with Visual Analogue Scale (VAS) Pain.

Methods: Data were obtained in the international COVID vaccination in autoimmune rheumatic diseases study second e-survey (COVAD study). Demographics, AIRD diagnosis, disease activity, PROMIS Global Physical health, PROMIS Global Mental Health, PROMIS Physical Function SF10 and PROMIS Fatigue 4a scores were extracted from the COVAD study

database. For this study, we only included patients with self-reported RA or spondyloarthritis (either PsA or AS) undergoing active treatment with conventional synthetic disease-modifying anti-rheumatic drugs (DMARDs) and/or biologic DMARDs, who answered all the survey questions. Active disease was defined as the patient's perception of their disease as active in the four weeks before the first dose of COVID-19 vaccination. Analysis of Variance with Bartlett's and Tukey's test was used to compare continuous variables between groups.

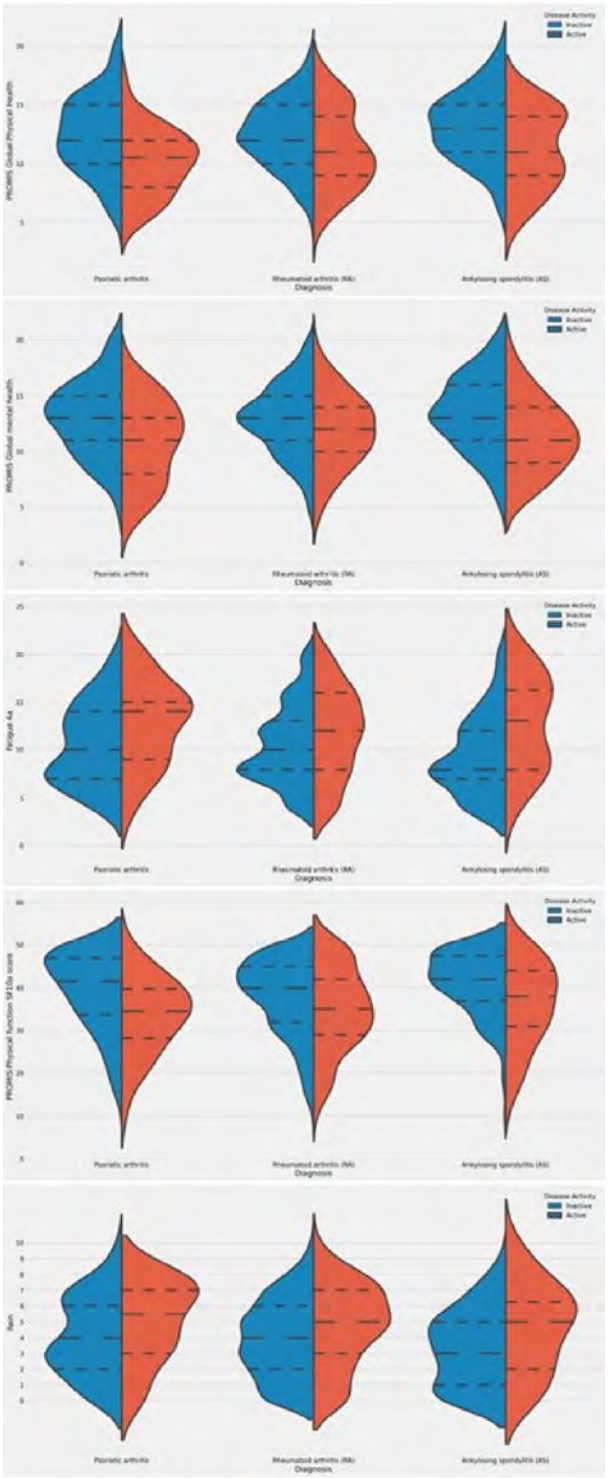

Figure 1. Violin plots showing kernel densities, quartiles and median for Patient-Reported Outcome Measures for patients with RA, PsA and AS, stratified by disease activity status.

PROMIS Global Physical Health	11.05	3.19	10.10	2.76	11.24	3.41	
PROMIS Global Mental Health	11.31	3.26	10.84	3.63	11.89	3.30	
PROMIS Fatigue 4a	12.94	4.87	12.84	4.42	11.75	4.68	
PROMIS Physical Function SF10 Score	35.82	9.62	33.52	8.76	34.90	9.80	
VAS Pain	4.68	2.77	5.0	2.54	4.68	2.61	

Results: From January to June 2022, 1907 patients with RA, female 87.62% (1671/1907), with mean age (±SD) 50.95 ± 13.67, 311 patients with PsA, female 67.20% (209/311), with a mean age of 50.42 ± 12.70, and 343 patients with AS, male 63.27% (217/343), with a mean age of 43.13 ± 12.75 years, responded to the COVAD e-survey. When assessed in those with active disease, neither physical health, global mental health, physical function, fatigue, nor pain were different among groups (Table 1, Figure 1). Patients with inactive AS had higher mean global physical health scores than RA patients (13.13 ± 2.93 VS RA 12.48 ± 2.90, p=0.01, Table 1). Nevertheless, those with inactive RA or PsA showed more severe fatigue (PsA 10.58 ± 2.22, RA 10.45 ± 4.08, vs AS 9.4 ± 4.13, p =0.01 for both). Patients with inactive RA also reported poorer physical function and more residual pain than those with AS (37.79 ± 8.86 VS 41.13 ± 7.79, p< 0.001; 3.87 ± 2.45 VS 3.34 ± 2.39, p=0.01, respectively). Similarly, residual pain was perceived as higher in patients with inactive PsA than those with AS (4.04 ± 2.50 VS 3.34 ± 2.39, p=0.01).

Conclusion: The burden of disease is approximately similar in patients with active RA, PsA or AS. However, patients with inactive RA and PsA report a considerably greater disease burden compared to those with AS.

Longitudinal Glucocorticoid Toxicity in Rheumatic Disease Patients (LONG-TOX) and Associations with Quality of Life and Healthcare Resource Utilization: Interim Analysis from a Prospective Cohort

Naomi Patel[1], Aubree McMahon[1], Grace McMahon[1], Sebastian Perez-Espina[1], Isha Jha[1], Adam Jarvie[1] and John Stone[2], [1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Concord, MA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Glucocorticoids (GCs) continue to be the cornerstone of therapy for many rheumatic diseases, though long-term exposure to GCs has been linked to dozens of potential toxicities. The Glucocorticoid Toxicity Index (GTI) is a validated instrument that quantifies change in GC toxicity longitudinally. The GTI produces two scores: the Cumulative Worsening Score (CWS) and the Aggregate Improvement Score (AIS), which are calculated by evaluation of 9 domains involving clinical, laboratory, and imaging information. We developed a prospective cohort of patients with rheumatic diseases receiving long-term GCs with the goals of assessing longitudinal GC toxicity as measured by the GTI, quality of life (QoL), and healthcare resource utilization to better quantify the personal and societal costs of glucocorticoids.

Methods: We enrolled adults ages 18-89 with any rheumatic disease diagnosis, receiving a GC taper with a starting dose of ≥7.5 mg/day (prednisone or equivalent dose) over an anticipated period of ≥ 3 months. Visits are conducted at baseline, 6, and 12 months and involve assessment of GTI scores, GC use and exposure, patient-reported outcomes including the EQ-5D Visual Analogue Scale [VAS], assessment and quantification of healthcare resource utilization both within Mass General Brigham (MGB) (assessed by an investigator or study coordinator by review of electronic health records) and outside of MGB (assessed by patient survey). Data collection was performed in REDCap and the *Steritas Cloud GTI* app. Patients with available 6-month data are included here. Differences between EQ-5D VAS scores and physician clinic visits were assessed for those with GTI scores above vs. below the median using linear regression, with and without adjustment for disease activity as assessed by Routine Assessment of Patient Index Data 3 (RAPID3) scores. Potential GTI CWS scores ranged from 0 (indicating no toxicity) to 439 (indicating the maximum measurable GC toxicity at 6 months).

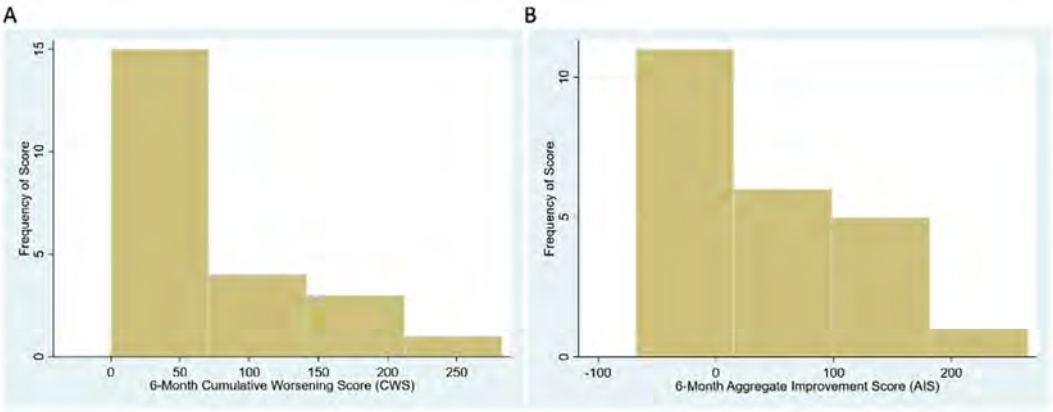

Figure. Glucocorticoid Toxicity Index (GTI) Cumulative Worsening Score (CWS) (A) and Aggregate Improvement Score (AIS) (B) at 6 months.

Table. Differences in healthcare resource utilization and quality of life between those with Glucocorticoid Toxicity Index (GTI) Cumulative Worsening Score (CWS) values above versus below the median.

	GTI CWS above vs. below median, difference (95% CI)	p-value
EQ-5D Visual Analogue Scale		
Unadjusted	3.2 (-1.9, 8.3)	0.21
Adjusted*	2.7 (-2.1, 7.5)	0.26
Physician clinic visits		
Unadjusted	0.0 (-14.8, 14.7)	1.00
Adjusted*	2.1 (-9.8, 14.0)	0.72

Results: Twenty three patients with available 6-month data were included. The 6-month median (IQR) GTI CWS was 63 (29, 121) (Figure). The 6-month median (IQR) GTI AIS was 21 (-19, 113). 21 out of 23 patients (91.3%) had CWS values > 0 at 6 months. The most common individual GTI domains in which patients had an increase in toxicity included Neuropsychiatric (14/23; 61%), Skin (11/23; 48%), Blood Pressure (9/23; 39%), and Body Mass Index (4/23; 17%). The Infection, Myopathy, and Lipid Metabolism domains each indicated toxicity in 3/23 (13%) of patients, and the Glucose Tolerance domain in 2/23 (9%). After adjusting for RAPID3 scores, those with 6-month CWS values > median had 2.7 more clinic visits (p=0.26) and EQ-5D VAS scores that were 2.1 points higher (p=0.72) than those with CWS values < median.

Conclusion: Almost all patients had some degree of GC toxicity at 6 months, based on their GTI scores. Patients with higher GC toxicity had numerically more clinic visits. Quantifying GC toxicity as well as its impact on factors important to both patients and society will be critical to assessing the benefits and cost-effectiveness of steroid-sparing medications moving forward.

Rheumatology Patients' Experiences of a Nationwide Transition to an Adalimumab Biosimilar: A Cross-Sectional Study

Chiara Gasteiger[1], Maria Lobo[2], Robin Stanley[1], Lun Shen Wong[1], Rachel Murdoch[1] and Nicola Dalbeth[1], [1]University of Auckland, Auckland, New Zealand, [2]Department of Rheumatology, Te Toka Tumai Auckland, Auckland, New Zealand

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients are frequently transitioned to biosimilars to reduce the cost burden of biologics. Brand changes can be daunting for patients who have concerns about biosimilar safety, quality, and anticipate a loss of disease control. Therefore, it is crucial to optimize the transition process for patients. To date, patients' experiences with the transition process have not been explored in detail. This study examined rheumatology patients' experiences of a mandatory nationwide brand change to an adalimumab biosimilar.

Methods: People with rheumatic diseases involved in the adalimumab biosimilar brand change in Aotearoa New Zealand were invited to take part in a nationwide online survey. The transition occurred between March and September 2022 and was expected to enable 380 new patients to receive access to adalimumab. Patients were recruited through patient organizations, a rheumatology clinic, and social media support groups between November 2022 and May 2023. Participants reported their satisfaction with the biosimilar, logistics and supply, information and communication, and availability of support, on a 0-10 scale, with 10 indicating high satisfaction. Open-ended questions explored what did and did not go well during the transition.

Results: The sample consisted of 117 participants (48% with rheumatoid arthritis). The mean [SD] overall satisfaction with the transition was 6.2 [3.2]. Participants were least satisfied with the patient support program (mean [SD] 3.4 [3.3]), support (3.4 [3.5]) and information (3.5 [3.2]) received from patient organizations, and training for the biosimilar device (4.9 [3.8]) during the transition period. Participants were the most satisfied with the ongoing supply of the biosimilar during the transition (8.5 [2.2]), the support received from pharmacists (7.5 [2.9]), and how early they were informed before the transition occurred (6.9 [2.8]). After the transition, participants were less satisfied with the quality of the device, and biosimilar safety, efficacy, and the provision of alcohol wipes and sharps bins ($p < 0.05$ for all). Participants appreciated the citrate-free preservative (less injection pain) and the ease of the device. The lack of alcohol wipes and loss of the bio-originator patient support program were viewed negatively.

Conclusion: Patients reported mixed experiences with the mandatory adalimumab biosimilar transition. Future transitions should ensure the availability of alcohol wipes, sharps bins and a patient support program. Patient support organizations could also assist patients by providing information about the biosimilar and training for the new device.

Abstract Number: 0341

Patient Perspectives on the Usability of a Rheumatoid Arthritis Patient-reported Outcomes Electronic Health Record-based Dashboard: A Mixed-Methods Study

Cherish Wilson[1], Catherine Nasrallah[2], Alicia Hamblin[2], Lindsay Jacobsohn[2], Cammie Young[3], Cammie Young[3], Mary Nakamura[4], Andrew Gross[2], Judith Ashouri[2], Brett Dietz[2], Mehrdad Matloubian[2], Jinoos Yazdany[5] and Gabriela Schmajuk[1], [1]UCSF / SFVA, San Francisco, CA, [2]University of California San Francisco, San Francisco, CA, [3]University of California San Francisco, Oakland, CA, [4]UCSF/SFVAHCS, San Francisco, CA, [5]University of California, General Department of Medicine, Division of Rheumatology, San Francisco, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Shared decision making, health literacy, and effective communication around patient-reported outcomes (PROs) are vital components to a treat-to-target approach in rheumatoid arthritis (RA) patients. To enhance these areas of patient care, we developed an EHR-integrated, patient-facing sidecar dashboard application that displays RA outcomes (disease activity, functional status, pain scores), medications, and lab results for use during clinical visits (**Figure**). The

dashboard was rolled out at an academic rheumatology clinic as part of a stepped-wedge pragmatic randomized trial starting in 2021. This study aimed to assess patient perspectives on the usability of the dashboard using a mixed-methods approach.

Methods: Consecutive RA patients whose clinicians used the dashboard during a visit were invited to complete a survey regarding the usability of the dashboard. Using purposive sampling to ensure that a range of usability perspectives were included, a subset of patients was invited to participate in semi-structured interviews to assess their perceptions of the dashboard. Recorded interviews were transcribed verbatim and thematically analyzed using inductive and deductive techniques.

Results: 181 patients responded to the survey. Most patients (79%) were interested in seeing the dashboard again at a future visit and felt that the dashboard helped them talk to their physician about their RA symptoms (76%) and medications (71%; **Table 1**). Many also reported that the dashboard helped them understand more about their disease (71%) and make better decisions about their RA care (67%).

Figure. Screenshot of the rheumatoid arthritis patient-facing sidecar dashboard application, which incorporated historical and real-time EHR data to display trajectories of RA outcomes.Table 1. Selected patient survey questions examining usability of the RA dashboard (N = 181).

Table 1. Selected patient survey questions examining usability of the RA dashboard (N = 181).

Selected survey questions	N	Yes (%)	Somewhat (%)	No (%)	Unsure (%)
Overall					
Would you like to see the dashboard again at your next visit?	181	79%	NA	8%	13%
Patient-provider communication					
Did the dashboard help you talk to your doctor about your arthritis or your symptoms?	180	76%	15%	8%	2%
Did the dashboard help you talk to your doctor about your medicines?	181	71%	14%	10%	5%
Did the dashboard help you talk about things that are important to managing your disease, other than your medicines?	179	61%	17%	17%	4%
Patient knowledge					
Did the dashboard help you understand more about your arthritis?	178	71%	21%	5%	2%
Did the dashboard help you understand more about why you take certain medicines?	179	60%	16%	18%	6%
Shared decision making					
Did the dashboard help you make better decisions about your arthritis care?	176	67%	19%	10%	5%
Do you think using the dashboard helped your doctor to better understand what's most important to you?	175	46%	21%	22%	11%

Table 2. Patients' perceptions about the dashboard: Results of qualitative interviews.

Themes		Sub-themes	Selected quotes
Perceived Benefits	Patient	Knowledge about disease	*"The dashboard helped me understand something that I didn't really understand before."*
		Visualization of disease progression	*"It's easy to get a quick look at how I've been doing and my progress and whether it's good, bad, or the same."*
		Engagement in care	*"The first time that I was ever shown this tool, I latched onto it because it's about me and my recovery."*
		Motivation	*"It gave me hope that, although I'm not there yet, I'm much better than a year and a half ago. That really empowered me."*
	Physician	Access to individual data	*"It's more beneficial for the doctor as far as her being able to recall testing and things like that."*
		Visualization of disease trajectory	*"It's a great visual summary of the disease progression for the doctor."*
	Interpersonal	Goals of care	*"To make a determination whether to change a medication, I need to know: What does my future look like? What are the risks? How have I been doing on this medication for a period of time? The dashboard's helping me figure that out."*
		Trust	*"It showed professionalism and gave me more confidence in the division, that they're capturing data. They're looking at the data in the right way. There's continuity."*
		Focused discussion	*"It gave us a focus... Sometimes we'll go off on tangents that might not necessarily be productive for my health discussion. The dashboard can help keep it on target."*
Concerns		Design	*"The units seemed to be too complicated. I had to read about them on the facing page. Maybe you could put in parentheses "CDAI"."*
		Content	*"It's subjective in a way when you fill out the form about the pain level…I don't know how accurate these questionnaires are to the doctor."*
		Explanation of content	*"[The doctor] did not [explain it]. That's why I said I didn't understand it."*
		Accessibility offline	*"It would be beneficial for the patient to have access to it, especially when you're asking questions about it and I can't answer everything because I don't have access to the application."*
		Technical difficulties	*"Last time the dashboard wasn't accessible. She was trying hard to get in there, and she couldn't open it."*

Similar themes emerged from the qualitative interviews (N = 27; 89% women, mean age 57 years, 74% with self-reported high health literacy; **see Table 2**). Perceived benefits of the dashboard included visualizing disease progression and changes over time, which engaged patients in their care and increased their motivation to control their disease. Patients valued how the dashboard allowed physicians to conveniently access their RA outcome information. On the interpersonal level, patients noted improved communication around goals of care (disease progression and treatment), and increased trust and confidence in their providers. Despite being comfortable with technology, patients also identified some challenges, including that they found it difficult to understand RA outcomes or the dashboard content without some explanation from physicians. Patients also expressed a wish to access the dashboard in-between visits.

Conclusion: In this mixed-methods study, most patients felt that a sidecar dashboard application enhanced their clinical encounters. Positive feedback from patients suggests that routine use of the dashboard has potential to improve patient engagement in RA care. Patients also suggested specific areas for improvement in accessibility, design, and content, which should be considered to further optimize the dashboard.

Abstract Number: 0342

Assessing the Known-group Validity of the IDEOM MSK-Q Using Data from the National Psoriasis Foundation Annual Survey

Lourdes Perez-Chada[1], **George Gondo**[2], Joseph F. Merola[3] and Alice B. Gottlieb[4], [1]Brigham and Women's Hospital, Boston, MA, [2]National Psoriasis Foundation, Alexandria, VA, [3]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [4]Icahn School of Medicine at Mount Sinai, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The IDEOM MSK-Q aims to assess MSK symptoms in individuals with psoriatic disease. It consists of 3 subscales: Intensity of MSK Symptom (3 items), Impact of MSK Symptoms (4 items), and Intensity of Fatigue (1 item). This study sought to evaluate the known-groups validity of the IDEOM MSK-Q.

Methods: Data from a cross-sectional survey of a random sample of individuals with psoriasis was used. To determine the known-groups validity of the IDEOM MSK-Q, we compared the IDEOM MSK-Q score among different groups based on: A). Disease status: patients with psoriasis-only vs psoriasis with PEST ≥ 3 vs PsA; B). PEST score: PEST < 3 vs PEST ≥ 3; and C.) Impact of PsA: Psoriatic Arthritis Impact of Disease (PsAID-9) < 4 vs PsAID ≥ 4. ANOVA and ANCOVA, adjusting for age and sex, were used.

Results: A total of 1,453 participants completed the survey. Equal proportions of participants reported a physician given diagnosis of psoriasis-only (47.9%) and psoriasis with concomitant PsA (47.7%), and 4.4% only having PsA. Participants were mostly female (58.4%) with mild psoriasis (52.3% - BSA 3%). Mean participant age was 54.8 (SD ± 15.73). Among all participants, 61% had a PEST score ≥ 3, indicating the potential presence of PsA. Among individuals with PsA and those with psoriasis-only with a PEST score ≥ 3, 65.5% had a PsAID score > 4 (i.e., unacceptable symptom state). For all

participants, mean scores for the for the Intensity of MSK Symptom, Impact of MSK Symptoms, and Fatigue subscales were 18.4 (SD = ± 13.9), 5.0 (SD = ± 3.3), and 5.01 (SD = ± 3.28).

Results comparing the IDEOM MSK-Q subscales among different disease statues groups were statistically significant. Across all subscales, individuals with PsA scored higher than individuals with psoriasis with PEST score ≥ 3, and those with psoriasis-only (Table 1). These differences were maintained when adjusting for age and sex (see Table 1.)

Unadjusted between group comparison based on PEST score (PEST < 3 vs PEST ≥ 3) were statistically significant for the Intensity of MSK Symptom and Impact of MSK Symptoms subscales. Participants who had a PEST ≥ 3 scored higher across all components of the IDEOM MSK-Q (Table 2) compared to PEST < 3. Similarly, unadjusted group comparison based on PsAID score (PsAID ≤ 4 vs PsAID > 4) suggest that individuals at unacceptable symptom state (PSAID > 4) scored higher on all 3 subscales (Intensity of MSK Symptom, Impact of MSK Symptoms , and Fatigue) (Table2). After adjusting for age and sex, comparisons remained statistically significant (see Table 2).

Conclusion: Results from this study suggest that the IDEOM MSK-Q can discriminate between individuals based on disease status, PEST score, and impact of psoriatic arthritis reflecting it has good known group validity.

Table 1 – Known group validity of the IDEOM MSK-Q by disease status.

	Only PsO with PEST < 3 Mean (95% CI)	Only PsO with PEST ≥ 3 Mean (95% CI)	PsA Mean (95% CI)

Sjögren's Disease Patient Experiences with Dry Mouth and Content Validity of the Xerostomia Inventory

Denise Kruzikas[1], Ann Eldred[2], Shelly Kafka[3], Janet Church[4], Katherine Hammitt[4], Patricia Koochaki[5], Christina O'Donnell[6] and William Thomson[7], [1]AbbVie, Inc., North Chicago, IL, [2]AbbVie, Inc., Lake Bluff, IL, [3]AbbVie, Inc., Norristown, PA, [4]Sjögren's Foundation, Reston, VA, [5]ICON Clinical Research LLC, Raleigh, NC, [6]ICON plc, Raleigh, NC, [7]Department of Oral Sciences, Sir John Walsh Research Institute, Faculty of Dentistry, University of Otago, Dunedin, New Zealand

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Xerostomia (dry mouth) is one of the most prevalent symptoms experienced by patients with Sjögren's Disease (SJD). The Xerostomia Inventory (XI) is a 11-item PRO that has been used primarily to assess the impact of xerostomia on oral health in older populations. The purpose of this study was to identify important symptoms and impacts of dry mouth described by SJD patients and explore the content validity of the XI for use in SJD clinical trials.

Methods: US participants with physician-confirmed diagnosis of SJD were recruited in partnership with the Sjögren's Foundation. Combined concept elicitation (CE) and cognitive interviews (CI) were conducted by telephone or online platform with 29 adult patients experiencing dry mouth due to SJD. CE identified dry mouth symptoms and impacts on activities of daily living. During CI, patients completed the XI and discussed the relevance of each item, clarity of wording, ease of completion, response options, comprehensiveness, and relevancy of the recall period. Interviews were audio-recorded, transcribed, and anonymized. A thematic analysis of the CE data was facilitated by MAXQDA software and a codebook developed from patient interviews. An item-matrix tracker was adopted to capture patient comments on the items and other elements of the XI and to record indicated revisions, additions, or deletions based on patient feedback.

Table 1. Selected Patient Descriptions of Dry Mouth

*"Well, I guess what the Sahara Desert feels like, and **cottonmouth** and everything else you could describe. And it makes it difficult to talk at times; you constantly **bite the inside of your cheek** because there's no saliva. So, if I don't have water I have a **hard time talking**, and I have a **hard time eating**" (Patient 045)*
*"You **can't swallow your food; I can't swallow pills**; I have **difficulty eating dry things**, yeah, just **reading out loud, speaking**. " (Patient 029)*
*"Your **lips are burning**, everything is burning. " (Patient 009)*
*It's like when I drink water or something it's almost as if it **dries up as soon as it gets into my mouth**. It feels like things evap—**liquid evaporates in my mouth** instead of really ingesting it." (Patient 205)*

Results: The study participants were primarily female (96%), White (79%), had a bachelor's degree or higher (90%), with mean age 62.8 years (range 33-74). Over 70% of patients reported experiencing dry mouth daily or all of the time; symptoms included difficulty swallowing (59%), eating (52%), speaking (62%), having an unquenchable thirst (10%), burning (10%), dry mouth (100%) and dry lips (14%) (Table 1). Patients described coping strategies including use of products like mouthwash, gum, or oral melts (76%), and carrying water with them (35%). Patients found XI instructions easy to understand (95%), easy to respond to (79%), the items relevant to their experiences (68-100%), and response options appropriate (85%). XI concepts mapped moderately well to patient-reported symptoms. Items concerning difficulty eating (96%) and swallowing (91%) were highly endorsed by patients. Concepts reported by patients but not included in the XI were dental issues (62%) and speaking difficulties (62%). 50% of patients reported that items about dryness in other anatomical areas in the XI did not fit with a PRO to assess dry mouth. Patients identified regional colloquialisms that should be modified to more general terms. Patient input provided clear directions for item eliminations, additions, and rewording needed to develop a revised XI that is relevant and measures concepts important to SJD patients.

Conclusion: These findings reveal the array of dry mouth symptoms SJD experience and support the need for a PRO that comprehensively assesses patients' experiences. This study demonstrates the utility of a modified XI for assessing dry mouth experienced by SJD patients. Further research can help assess the content validity of a revised XI for use in SJD.

Session Date: Sunday, November 12, 2023

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: We evaluated participants' adherence to protocol-assigned capture of patient-reported outcomes (PROs) and activity tracker data in the context of an ongoing longitudinal study collecting data from rheumatoid arthritis (RA) patients initiating a new biologic or JAKi.

Methods: RA patients in moderate or high disease activity (CDAI >10) and prescribed either upadacitinib (UPA) or adalimumab (ADA) were enrolled during in-office visits at US community rheumatology clinics. To enter the 12-week main study, participants had to successfully complete a 7-day run-in (completion of ≥ 5 of 7 days of daily and weekly PROs) and take their first dose of new treatment within 30 days. Participants completed PROs remotely via app during the main study according to a pre-specified rotating daily assessment schedule that repeated each week and that was anticipated to take 1-3 minutes per day. As an optional component of the study, participants were provided with a Fitbit Versa2 (wearable) device either in clinic or received it by mail.

Table 1. Demographic and clinical characteristics of participants at baseline, by main study eligibility and data completeness (N=299)

	Successfully completed run-in, n=240	Did Not Successfully complete run-in, n=59	Completed main study, n=148	Completed main study and have at least one day wearable data, n=95
Age (years)	52.2 (11.8)	51.2 (12.4)	52.3 (12.0)	51.2 (12.7)

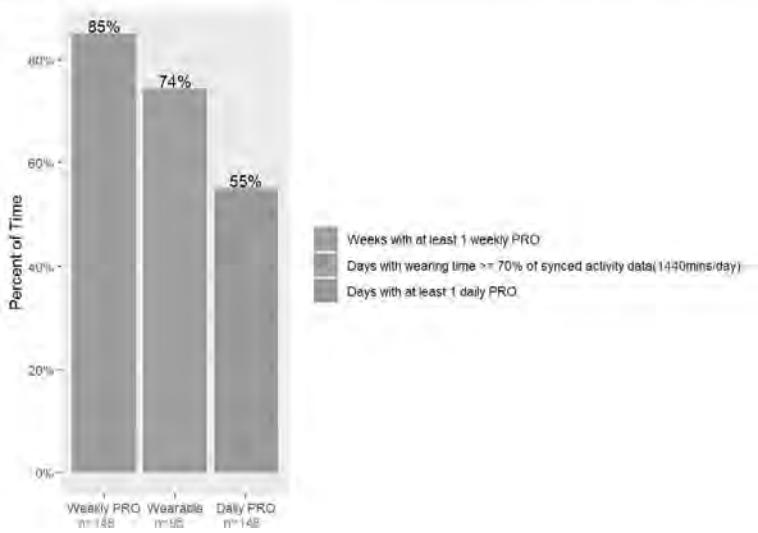
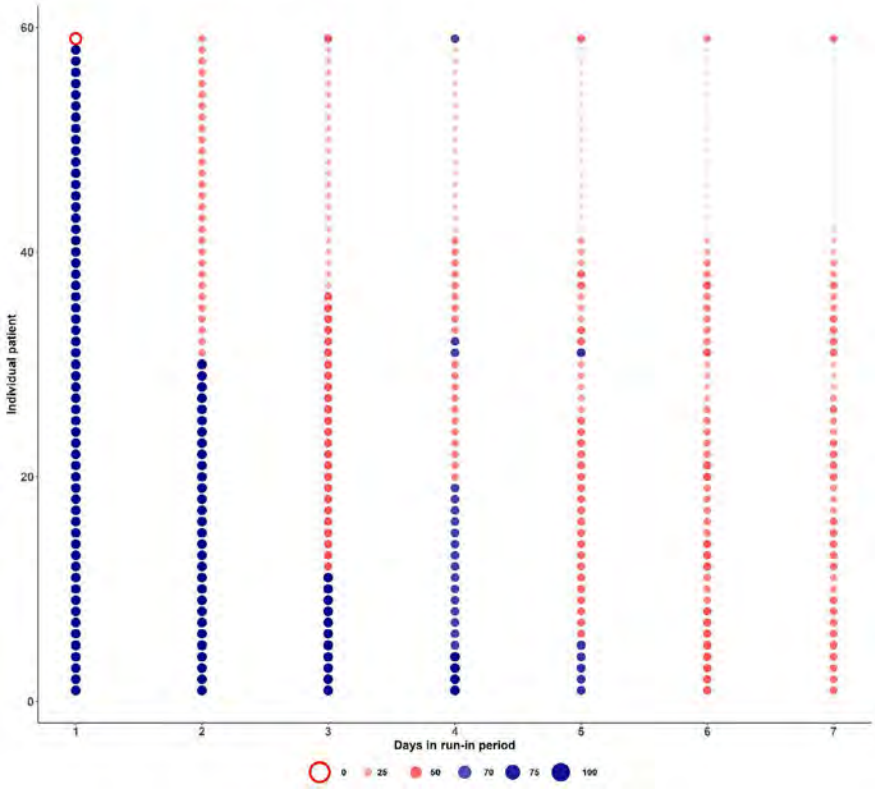
All values shown as mean (standard deviation [SD]), except where indicated as n (percent) Abbreviations: RA, rheumatoid arthritis; DMARDs, disease-modifying antirheumatic drugs; bDMARDs, biologics or biologic DMARDS; csDMARDs, conventional synthetic DMARDs; tsDMARDs, targeted synthetic DMARDs; NRS, numeric rating scale; PROMIS, patient-reported outcomes measurement system; RADAI, rheumatoid arthritis disease activity index; CDAI, clinical disease activity index

Figure 1. Adherence to completing WEAR study tasks by participants providing PRO and wearable data (n=148*)



*n=95 (participants who activated wearable device) for % of days with wearable data PRO = patient-reported outcome

Figure 2. Dot plot of participants who provided one or more day(s) of PRO data during run-in, but did not successfully complete run-in to advance to main study (n=59)



PRO = patient-reported outcome Representative rates of cumulative adherence to data submission show that individuals who did not progress to the main study had a marked drop in adherence as early as day 2. Dot size increases with increasing rate of adherence as shown and at 70% adherence, color of dot changes from red (<70% adherence) to blue (>70% adherence). Each dot in each column represents one participant who did not successfully complete the run-in and advance to the main study (n=59).

Results: A total of 299 patients enrolled and started the run-in. Of these, 240 entered the main study and met all inclusion criteria; at the time of this analysis, 148 participants have successfully completed the main study, with 95 of those (64%) providing both wearable and PRO data. Participants with more pain, fatigue, and worse physical function were more likely to fail the run-in based on inadequate PRO data capture (Table 1). Among the 148 participants who completed the main study, at least once weekly PROs were provided for 85% of weeks (Figure 1), and 83% of participants provided at least once weekly PROs for >= 9 of the 12 main study weeks. Daily PRO data was provided for 55% of days (Figure 1), and 38% of participants provided daily PRO data for at least 70% of all study days. Depending on the day of the week, time taken to complete PRO assessments each day ranged from a median of 1.4 minutes (IQR: 1.1 min – 2.1 min) to 2.1 minutes (IQR: 1.6 min – 3.2 min) among all participants. Among the participants who activated their wearable (n=95 to date), wearable data was provided for 74% of days for >= 70% of each 24-hour period (Figure 1), weekly PRO data was provided for 92% of week, daily PRO data was provided for 59% of days, and 38% of participants provided daily PRO data for at least 70% of all study days. Most patients who failed to meet minimum requirements to successfully complete the run-in did so within 3-4 days of starting the run-in (Figure 2).

Conclusion: Collecting weekly PRO data and daily wearable data for patients on RA treatment is feasible, although requiring daily PROs may be too burdensome in the context of routine care. Building some redundancy into the schedule of patient-generated data capture in order to optimize observations of disease activity and symptom changes over time as part of real-world evidence generation or remote therapeutic monitoring programs is advisable.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Pediatric Rheumatology – Clinical Poster I: JIA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The measurement of disease activity level is of central importance in the evaluation of the patient with juvenile idiopathic arthritis (JIA). The Juvenile Arthritis Disease Activity Score (JADAS) and its clinical version excluding the acute phase reactant (cJADAS) were validated and are increasingly used in clinical trials and routine practice. To allow score interpretation, cutoffs have been developed and subsequently validated for JADAS10 and cJADAS10 in RF- polyarthritis and oligoarthritis. The need to have cutoffs for other arthritis categories is increasingly evident.

To validate the JADAS10 and cJADAS10 disease activity state cutoffs to separate the states of inactive disease (ID), minimal disease activity (MiDA), moderate disease activity (MoDA), and high disease activity (HDA) in children with RF+ polyarthritis, PsA and ERA.

Methods: JIA children from 49 countries included in the EPidemiology, treatment and Outcome of Childhood Arthritis (EPOCA) study were considered. For PsA and ERA, the decision on whether to use oligoarthritis or polyarthritis cutoffs was based on the most frequent pattern of joint involvement at visit. Discriminative ability was assessed by calculating and comparing in each disease activity state the level of pain (0-10 VAS) and functional ability impairment (measured with the Juvenile Arthritis Functional Ability Score, JAFS, 0-45) and the frequency of patients satisfied with current disease state, starting a new medication, and having morning stiffness. Comparisons of quantitative variables among groups were made by Kruskal-Wallis test; Dunn's test was used to assess differences between pairs of patient groups. Percentage data were compared by chi-squared test or Fisher's exact test. Bonferroni's adjustment was applied to explore post-hoc differences between pairs of patient groups.

Results: 309 children with PsA, 959 with ERA, and 382 with RF+ polyarthritis were included. 88% children with PsA and 91% with ERA had oligoarticular disease, at study visit; therefore, oligoarthritis cutoffs were used for these categories.

The level of pain and functional ability was significantly different among the JADAS-based disease states, with pain and JAFS scores increasing progressively from ID to HDA (Kruskal-Wallis test $p < 0.001$). The percentage of patients who prescribed a new medication, with morning stiffness < 15 minutes, and who were satisfied with current disease state were different in the JADAS-based disease states. Paired comparison showed significant discrimination for most comparisons.

Conclusion: Both the JADAS10 and cJADAS10 cutoffs to define disease activity states validated for oligoarthritis and polyarthritis showed good discriminative validity in RF+ polyarthritis, PsA and ERA. These results preliminarily indicate that available cutoffs might be used for these categories of JIA.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Pediatric Rheumatology – Clinical Poster I: JIA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disease of childhood. The emergence of new biologic agents has led to changes in the prognosis and therapeutic approach for these patients. However, the use of biosimilars in adult patients diagnosed with JIA has not been well studied and more evidence is needed on the safety and persistence of these drugs in this patient population.

The aim of this study was to describe the use and assess the safety and persistence of biosimilar disease-modifying antirheumatic drugs (bsDMARDs) compared with original biologics (bDMARDs) in JIA patients older than 16 years.

	bDMARDs N=183	bsDMARDs N= 130	Total N=313
Age at diagnosis, mean±SD	9.7±4.9	11.2±6.1	10.3±5.5

bDMARDs: original biosimilar disease-modifying antirheumatic drugs; bsDMARDs: biosimilar DMARDs; JIA: Juvenil idiopathic arthritis; SD: standard deviation.

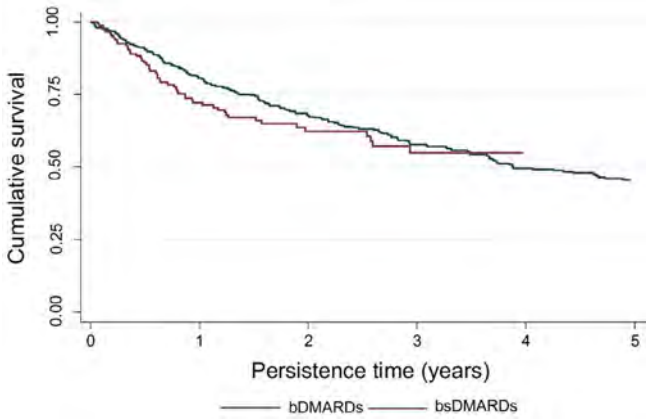
Disease Characteristics, Biologic Therapies, and Reasons for Discontinuation in Adult JIA Patients.

	bDMARDs	bsDMARDs
Total adverse events	400.4 (367.50 - 436.40)	529.6 (444.10 - 631.60)
Serious adverse events	62.4 (50.2-77.6)	51.3 (29.1-90.3)
Fatal	0 (0-0)	0 (0-0)

* Incidence Rate (95% CI) per 1000 Patient-Years

bDMARDs: original biosimilar disease-modifying antirheumatic drugs; bsDMARDs: biosimilar DMARDs.

Incidence rates of adverse events stratified by bDMARDs and bsDMARD*



5-year survival of bDMARD vs. bsDMARD in adult JIA patients.

Methods: Data were obtained from the nationwide prospective registry BIOBADASER (Spanish Registry of Adverse Events of Targeted Therapies in Rheumatic Diseases). All patients diagnosed with JIA and older than 16 years included in the database between 2000 and 2022 were analyzed. Due to the design of the registry, it was not possible to identify each of the JIA subgroups; therefore, we classified them into oligo/polyarticular JIA, enthesitis-related JIA, and psoriatic JIA. Adverse events were coded using the Medical Dictionary for Regulatory Activities (MedDRA) version 13.0. Proportions, means, and standard deviations (SD) were used to describe our population. Drug persistence was calculated using Kaplan-Meier survival curves (KM) until discontinuation for any reason. Incidence rates (IRs) of adverse events and 95% confidence intervals were calculated, and Poisson regression was used to estimate incidence rate ratios (IRRs), adjusting for sex, diagnosis type, age at treatment initiation (≤16 years vs >16 years), and treatment line as confounding variables.

Results: From a total of 313 patients included, 130 (41.5%) patients received bsDMARDs and 183 (58.4%) treatments with bDMRAD. In the bsDMARD group, 43 patients (95.6%) use corticosteroids and 59 patients (96.7%) metotrexate concomitant.Table 1 shows the clinical characteristics, treatment and reason for discontinuation of the studied population according to treatment with bDMARD, bsDMARD and overall. Table 2 shows the IRs for adverse events according to severity. For all adverse events, IR is greater in bsDMARDs compared to bDMARDs, although the latter have a higher IR of serious adverse events. The IRR was 1.33 (95% CI 1.1-1.6) (p=0.004), thus, the risk of adverse events was greater among bsDMARD compared to the original bDMARDs. The KM figure shows that the persistence of bDMARDs and bsDMARDs was similar in the studied population (log rank: 0.78,p-value 0.377).

Conclusion: The most used bsDMARD in adult patients diagnosed with JIA was adalimumab. In this population, there were no differences in 5-year survival rates between bDMARDS and bsDMARDs in JIA adult patients, being ineffectiveness the main reason for discontinuation.

The risk of adverse events was higher in patients treated with bsDMARDs. Although this study allowed us to investigate the long-term safety of biosimilars in JIA, large registries focusing on such patients are needed to better understand rare adverse events.

Towards Effective Shared Decision Making - Development and Validation of a Prediction Model for Personalized Probabilities of Side Effects in the Initial Treatment of Juvenile Idiopathic Arthritis

Jonathan Park[1], Thomas Loughin[2], Andrew Henrey[2] and Jaime Guzman[3], [1]Western University, London, ON, Canada, [2]British Columbia Children's Hospital, Vancouver, BC, Canada, [3]British Columbia Children's Hospital, Vancouver, BC, Canada

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Clinical practice guidelines for Juvenile Idiopathic Arthritis (JIA) emphasize the importance of adapting guideline recommendations to each individual patient through shared decision-making among patients, families, and clinicians. In the initial treatment of non-systemic JIA, a key decision is whether to start NSAIDs and joint injections alone (NSAIDs+/-JI) or in combination with methotrexate (MTX+NSAIDs+/-JI). Effective shared decision making requires patients and families to be informed of reasonable estimates of the likelihood of side effects (SE) with each treatment option. However, there are limited published prediction models for MTX-associated SE and no models comparing MTX+NSAIDs+/-JI

Table 1. Final model for predicting side effects in children with juvenile idiopathic arthritis. The same model calculates risk of side effects with methotrexate (MTX=1) and without (MTX=0)

Predictor	B coefficient (95%CI)
Intercept	1.94 (-1.21, 5.09)
Methotrexate (0=No, 1=Yes)	0.66 (-0.01, 1.33)
Total active joint count	-0.01 (-0.07, 0.04)
Active joint count ≥5	0.26 (-0.65, 1.18)
Male Sex	-0.27 (-0.85, 0.31)
Physician global assessment of disease activity (0 to 10)	-0.03 (-0.19, 0.12)
Disease duration (weeks)	0.00 (0.00, 0.01)
Age (years)	-0.02 (-0.20, 0.16)
Height (cm)	-0.02 (-0.05, 0.02)
Weight (Kg)	0.01 (-0.01, 0.04)
Health related quality of my life scale (0 to 10)	-0.11 (-0.23, 0.02)
Parent global assessment of wellbeing (0 to 10)	0.10 (-0.02, 0.22)
ESR/CRP above normal threshold	0.14 (-0.54, 0.83)
Enthesitis present (0=No, 1=Yes)	0.44 (-0.40, 1.29)
Medication side effects at baseline (0=No, 1=Yes)	1.15 (0.65, 1.65)
Oligoarthritis	-0.19 (-1.18, 0.80)
Polyarthritis RF negative	0.05 (-1.08, 1.18)
Psoriatic arthritis	-0.75 (-2.04, 0.54)
Undifferentiated arthritis	0.35 (-0.65, 1.35)

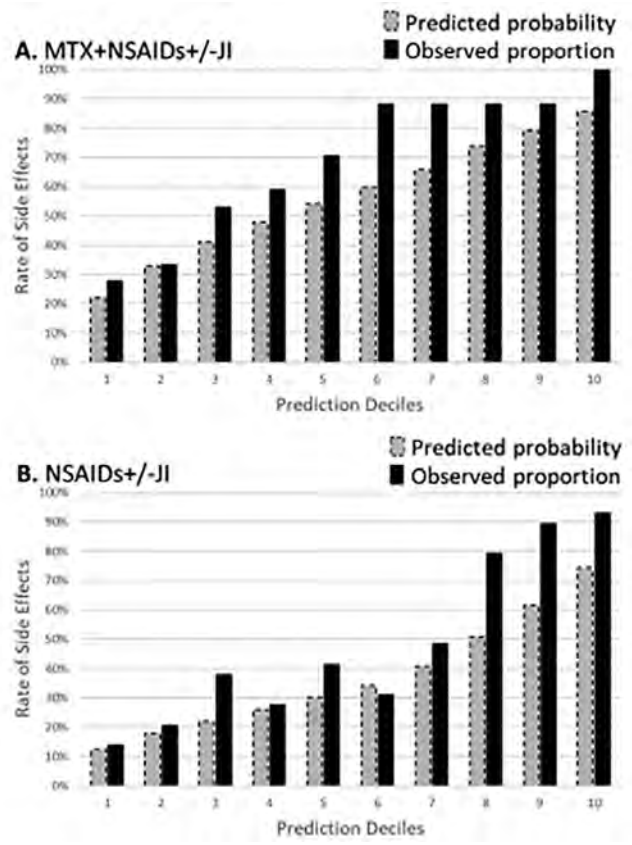

Figure 1. Calibration of prediction models in the validation cohort for probability of side effects for A. MTX+NSAIDs+/-JI and B. NSAIDs+/-JI.

to NSAIDs+/-JI. In this study, we aimed to develop and externally validate a clinical prediction model that provides personalized probabilities of SE comparing NSAIDS+/-JI with and without adding MTX.

Methods: We used data from two Canadian JIA cohorts. Data collected from 2005-2010 in the Research in Arthritis in Canadian Children Emphasizing Outcomes (ReACCh-Out) cohort for model development and data collected from 2017-2020 in the Canadian Alliance of Pediatric Rheumatology Investigators (CAPRI) JIA Registry for external validation. Parents reported SE using standardized lists of symptoms. For model development, we compared various logistic regression models with discrimination accuracy measured with c-index. We measured model calibration by comparing predicted probabilities versus observed rates of SE. Due to the very low frequency of serious SE, models could only predict probabilities for mild-moderate SE. With input from patients, families, and clinicians, we incorporated the models in a Web App that generates a visual aid presenting personalized probabilities of SE when predictor variables are inputted by a clinician.

Results: Patients included for development (n=757) and validation (n=437) had baseline characteristics comparable to most North American JIA inception cohorts. Two-thirds % were female with a median age of 8 years old and more than 75% diagnosed with oligoarthritis, RF-negative polyarthritis or enthesitis related arthritis. The c-indices for the various prediction models in the development cohort were all similar at ~0.67. We chose the final model prioritizing fewer and more easily obtainable variables (Table 1). In external validation, our final model for predicting SE had a c-index of 0.80 (95% CI 0.76, 0.84). Model calibration was acceptable, with similar predicted versus observed SE rates (Figure 1). A Web App was created to present probabilities of SE in pie charts, comparing NSAIDs+/-JI to MTX+NSAIDs+/-JI (Figure 2).

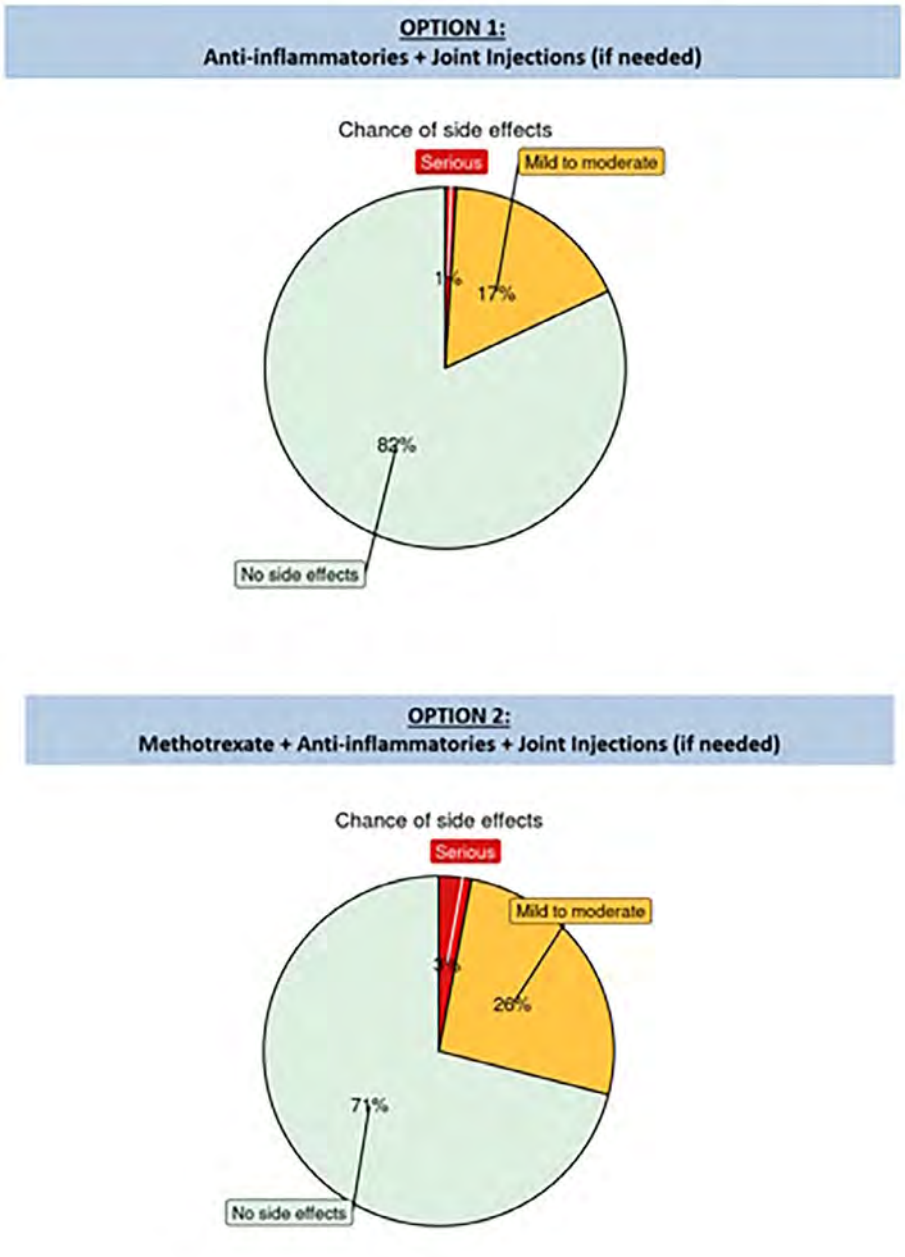

Figure 2. Example of visual representation of predictions for one patient, generated by inputting variables in a Web App.

Conclusion: This study developed and externally validated a prediction model for probability of SE directly comparing two realistic treatment options at the time of JIA diagnosis. Inputting the variables in a Web app will then produce a visual aid to facilitate shared decision-making with families. Future work should add likelihood of treatment response to further aid the decision of choosing an initial treatment option in JIA.

The Use of Ruxolitinib for Improved Disease Control in Systemic Juvenile Idiopathic Arthritis (sJIA) and Recurrent Macrophage Activation Syndrome (MAS)

Kathleen Collins[1], Iman Abutineh[1], Trisha Paul[2], Parul Rai[3], Grant Schulert[4] and **Melissa Hines**[2], [1]University of Tennessee Health Science Center, Memphis, TN, [2]St Jude Children's Research Hospital, Memphis, TN, [3]St Jude Children's Reseaerch Hospital, Memphis, TN, [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Pediatric Rheumatology – Clinical Poster I: JIA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

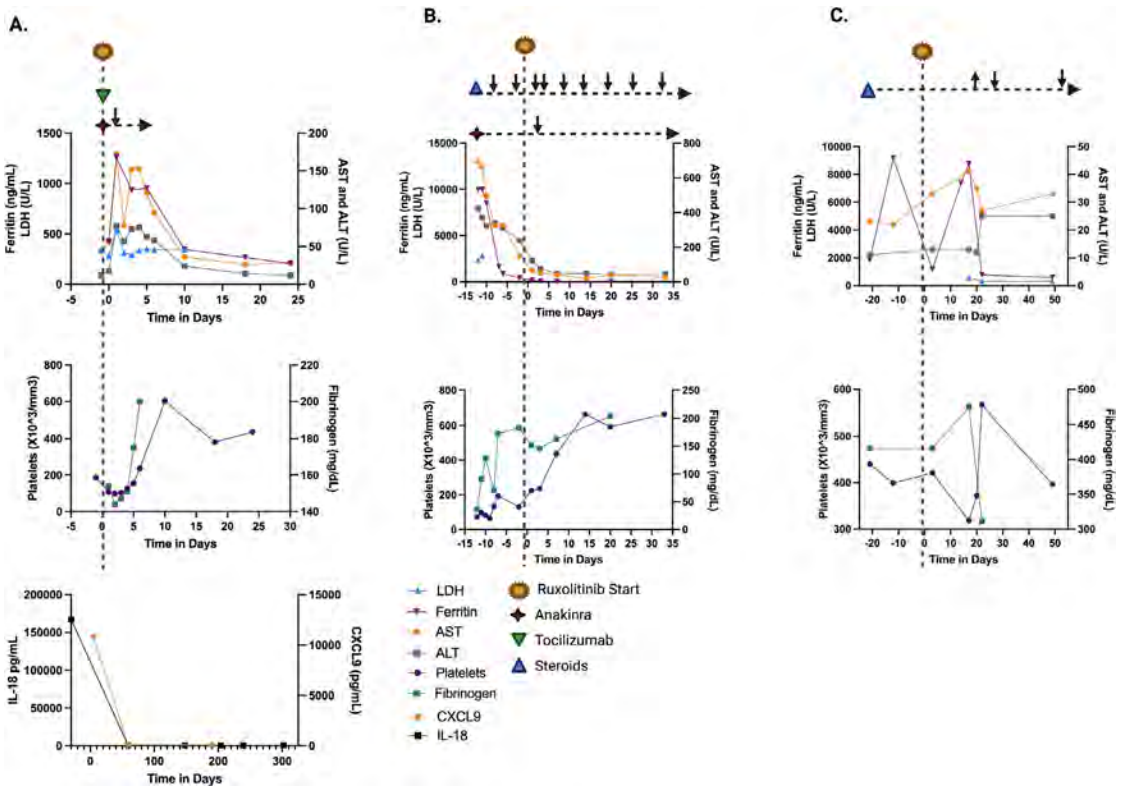

Figure 1. Clinical Details. Day 0 represents first day of ruxolitinib in all patients. Overall, patients had improvement in cytopenias and transaminitis if present. A. On Day 0, patient required ICU admission for MAS with hypotension and fever and was given tocilizumab 800 mg once, ruxolitinib, and anakinra 100 mg q6h (weaned off by day 5). Patient had improvement in ferritin, cytopenias, and transaminitis within 15 days. Patient had significant improvement in IL-18 and CXCL9 levels with continued ruxolitinib monotherapy. B. On day -12, patient was admitted for MAS related to EBV and had initial improvement in ferritin, thrombocytopenia, hypofibrinogenemia and transaminitis with a single dose of rituximab (to aid with EBV clearance), anakinra 12.5 mg/kg/day divided IV q6h and pulse dose steroids (30 mg/kg x 3 days). There was some initial improvement of MAS, but team was unable to wean steroids or anakinra. Ruxolitinib was started which allowed for anakinra to be weaned to 6.25 mg/kg/day SQ dosing by day 3. Patient was discharged on ruxolitinib, anakinra 6.25 mg/kg/day once a day, and 1.5 mg/kg/day prednisolone. While on ruxolitinib, patient continued to tolerate steroid weans as an outpatient. C. Patient was started on ruxolitinib in addition to oral steroids, adalimumab, and mycophenolate for management of SJIA with lung involvement. Patient tolerated slow wean of steroids (methylprednisolone 40 mg/day max to prednisone 15 mg/day) over the course of 4 months. Figure created with GraphPad PRISM and Biorender.

Background/Purpose: The advent of biologics such as IL-1 receptor antagonists has dramatically improved outcomes for children with pediatric rheumatic diseases and hyperinflammation. However, there remains a subset of patients with systemic juvenile idiopathic arthritis (sJIA) who develop life-threatening complications of macrophage activation syndrome (MAS) and interstitial lung disease (ILD) despite treatment with glucocorticoids and IL-1 inhibition. Recent findings point to robust interferon and IL-18 signature as drivers of persistent inflammation in sJIA, suggesting a potential role for inhibition of these pathways using Janus kinase inhibitors, such as ruxolitinib, as a viable therapeutic strategy.

Methods: We completed a retrospective chart review on three patients with sJIA or sJIA-like disease started on ruxolitinib for improved disease control or to allow for glucocorticoid weaning.

Results: Patients ages were 5-15 years of age with 2 females and 1 male (Table 1). Patient A with sJIA-like disease presented with recurrent MAS with fever and hypotension requiring vasopressor support and was treated with ruxolitinib, anakinra, and tocilizumab and MAS was controlled (Figure 1). Anakinra was weaned off prior to discharge home. Ruxolitinib was continued as a single agent and has maintained excellent control of the patient's disease with no further MAS flares or adverse events for the last 10 months. Patient B with previously diagnosed sJIA presented with fulminant MAS secondary to EBV. She was treated with pulse dose steroids and anakinra with some initial stabilization. Ruxolitinib was started due to lack of further improvement in MAS. The addition of ruxolitinib controlled her MAS and steroid and anakinra doses were tapered (Table 2;

Table 1. Patient History, Presentation, and Therapy

	Patient A	Patient B	Patient C
Initial Presentation	Cold autoimmune hemolytic anemia; MAS including hyperferritinemia, cytopenias, hepatosplenomegaly, lymphadenopathy; Uveitis	Arthritis in multiple joints, Systemic inflammation; Fevers; Classic rash	Pleural effusion; Pericardial effusion; Arthritis multiple joints; Elevated ferritin
Age of Initial Presentation	15 years	2 years	17 months
Diagnosis	SJIA-like disease with recurrent MAS and severely elevated IL-18	SJIA	SJIA
Genetic Testing	Primary immunodeficiency, autoimmunity/inflammation, lymphoid malignancy predisposition genetic testing negative for pathogenic variants	None	None
Previous Therapies	Steroid (weaned off 7 months prior presentation) for cold autoimmune hemolytic anemia, anakinra and tocilizumab during MAS flares (last flare 2 weeks prior to presentation). Off all medication at time of last MAS presentation	Stable on every other day anakinra prior to MAS	NSAIDs, steroids, hydroxychloroquine methotrexate, anakinra, and canakinumab. Adalimumab, mycophenolate, and oral steroids were his therapy prior to starting ruxolitinib
Age at Ruxolitinib Initiation	15 years	5 years	10 years
Reason for Starting Ruxolitinib	Single agent to prevent reoccurrence of MAS	To assist with weaning of anakinra and steroids after MAS	Failure of multiple therapies to control disease, development of anti-drug antibodies to adalimumab worsening of SJIA-related lung disease
Current Therapy	Ruxolitinib 20 mg PO BID monotherapy	Anakinra 4.3 mg/kg/dose every other day	Prednisone 0.3 mg/kg/day of PO; Ruxolitinib 25 mg PO BID

Macrophage Activation Syndrome (MAS); Systemic Juvenile Idiopathic Arthritis (SJIA); Interleukin (IL)-18

Table 2. Ruxolitinib Dosing

Patient	A	B	C
Weight (kg)	88.2	18.2	41.1
BSA (m^2)	1.9	1.04	1.48
Starting Medication Dosing	25 mg BID	10mg BID	20mg BID
Weight-based Dosing	0.3 mg/kg/dose	0.5 mg/kg/dose	0.5 mg/kg/dose
BSA-based Dosing	13.5 mg/m^2/dose	10 mg/m^2/dose	13.5 mg/m^2/dose
Titration	Decreased to 20 mg BID	Weaned off	Increased to maximum dose 25 mg

Figure 1). Oral steroids were discontinued 9 weeks after starting ruxolitinib. Ruxolitinib was discontinued at 3 months. Patient was continued on anakinra. Patient C with previously diagnosed sJIA developed sJIA-associated lung disease on canakinumab therapy. Ruxolitinib was added to his therapy (Table 1, 2) due to continued systemic inflammation and inability to wean steroids. Within the 4 weeks the patient reported improvement in joint pain and had no oxygen desaturations with walking. Within 6 weeks, lung function improved with FEV1 increasing from 85% to 91% predicted. Ruxolitinib dose was increased to 25 mg twice a day at 4 months based on patient toleration and to optimize disease control, allowing successful weaning of steroids by 50%. Patients have not had any infectious complications while on ruxoltinib. One adverse event reported was Grade 1 elevated cholesterol. Mean follow-up time is 214 days (146-322). Mean time patients were on ruxolitinib was 189 days (100-322).

Conclusion: Ruxolitinib was well tolerated in these patients with sJIA or sJIA-like disease with no significant adverse events, including cytopenias, transaminitis, or infections. Use of ruxoltinib provided improved disease control as a single agent or in combination with other immunomodulators and allowed reduction of other therapies, such as steroids. Based on our experience, patients may require and can tolerate higher doses than previously used for other indications with titration up and down to affect.

Disease Activity of Juvenil Idiopathic Arthritis in Transitional Care

Karen Carpio Astudillo[1], Daniel clemente Garulo[2], Juan Carlos Lopez-Robledillo[3], Camille Bourgeois Avella[4], Laura Trives Folguera[4], Amparo López López[1], Jose María Alvaro-Gracias[4], Indalecio Monteagudo Sáez[1] and Juan carlos Nieto-Gonzalez[5], [1]Hospital General Universitario Gregorio Marañón, Madrid, Spain, [2]Pediatric Rheumatology Unit, Hospital Niño Jesús, Madrid, Spain, [3]Hospital Infantil Universitario Niño Jesús, Madrid, Spain, [4]Hospital General Universitario Gregorio Marañon, Madrid, Spain, [5]Servicio de Reumatología, Hospital General Universitario Gregorio Marañón, Madrid, Spain

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Pediatric Rheumatology – Clinical Poster I: JIA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile Idiopathic Arthritis (JIA) are a group of heterogeneous arthritis with onset in childhood. According to previous studies, this patients experience an improvement of their disease activity, functionality and even remission as they become young adults [1]. Transitional care units aim to coordinate an uninterrupted follow-up in patients with chronic diseases.[2] Our transitional care unit attend patients from 18 to 25 years old who have been previously diagnosed with any rheumatic disease during childhood. Our primary objective was to describe the disease activity of JIA patients at the transference to our unit and the remission maintenance during follow-up.

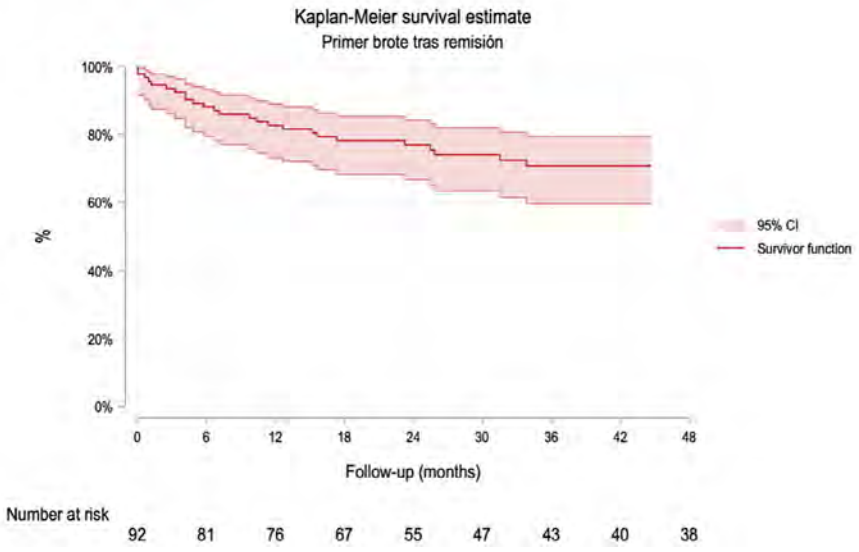
Methods: We conducted an observational retrospective longitudinal study from a cohort of patients with JIA who have been transferred to our transitional care unit. We selected patients with at least one clinical visit and have active follow-up. We collected demographic data, JIA classification, previous treatments and the treatment at time of transfer, articular and ocular flares, remission defined by Wallace criteria[3] and changes in treatment during follow-up.

Results: From December 2016 to December 2021 we received 113 with JIA diagnosis, the mean age at transfer was 19.8 years. Demographic characteristics of patients are shown in Table 1. About 31% of the patients had a flare through the 3 years of follow-up, most of them were women (71.4%). Both oligoarticular (37.1%) and polyarticular (37.1%) and spondyloarthritis (25.7%) had inflamamatory flares in similar proportion.

Table 1. Demographic data from JIA included in the study

	Total (n: 113)	Actives (n:23)	Not Actives (n:90)
Sex (female) n (%)	77 (68.1)	15 (65.2)	62 (68.9)
Age median (SD)	8.22 (5.0)	8.91 (5.1)	8.01 (4.9)
Mean Age at transfer (SD)	19.8 (3.1)	19.18 (1.9)	19.76 (3.3)
sDMARD prior transference (%)	94 (83.2)	22(95.7)	72 (80)
bDMARD prior transference (%)	67 (59.3)	11 (47.8)	56(62.2)
Uveítis	19 (16.8)	8 (16.6)	11 (16.9)
JIA subcategory n (%)			
Oligo persist	39 (34.5)	8 (34.8)	31 (34.4)
Oligo extend	13 (11.5)	1 (4.3)	12 (13.3)
Poly FR -	24 (21.2)	6 (26.1)	18 (20)
Poly FR +	5 (4.4)	1 (4.3)	4 (4.4)
ERA	19 (16.8)	6 (26.1)	13 (14.4)
Systemic	6 (5.3)	0 (0)	6 (6.6)
Psoriatic	7 (6.2)	1 (4.3)	6 (6.6)

Table 2. Kaplan-Meier survival estimate of remission in JIA patients since their transfer to the Transitional Care Unit.



It is important to notice that from 45 patients (38.9%) who had a flare prior to transfer 37.8% had another flare during follow-up. While, 26.5% of the patients who never had a previous flare presented a new flare during this follow-up. Flares during transfer were independent from patient's previous inflammatory activity; and the previous treatment did not influence the risk of flare development.

Conclusion: Flare risk during transfer was independent from previous activity and treatment. The flare frequency was slightly reduced over time (39,8% vs. 31%) (Table 2).

Presentation, Management, and Outcomes of Systemic JIA-Associated Lung Disease: A Single Center Experience

Ana Luiza Altaffer[1], Maria Pereira[2], Marietta De Guzman[2] and Andrea Ramirez[2], [1]Baylor College of Medicine, Texas Children's Hospital, Houston, TX, [2]Baylor College of Medicine, Houston, TX

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a rare and severe complication of systemic juvenile idiopathic arthritis (SJIA) that was recognized relatively recently, and its incidence appears to be rising. Much is still unknown about its optimal management.

Methods: With an institutional review board approval from Baylor College of Medicine, children under 16 years old with SJIA-associated lung disease (SJIA-LD) at Texas Children's Hospital between 2014-2023 were identified. Demographics, clinical features, laboratory, radiographic findings, and therapies were collected and analyzed using standard descriptive statistics.

Results: Six children with SJIA-LD were identified. The median age in years at SJIA diagnosis was 1 (range 0-4), and patients were followed for a median of 30.5 months (range 15-82). There were equal numbers of males and females, most were white (83.3%, vs. 16.7% Black), and most were Hispanic (50.0%, vs. 33.3% not Hispanic and 16.7% not specified). Four patients (66.7%) had no significant medical history prior to SJIA presentation, while 1 patient had Trisomy 21, and another was a former 23-week preterm infant with associated complications, including bronchopulmonary dysplasia with tracheostomy dependence. All patients presented classically with fever, rash, and arthritis; none had respiratory symptoms or clubbing at SJIA diagnosis. The median time from SJIA diagnosis to identification of lung disease was 13 months (range 4-60). Imaging that led to the diagnosis was obtained due to respiratory symptoms in 3 patients (50.0%, of which one occurred in the setting of known rhinovirus) and for asymptomatic screening in 1case (16.7%). Two patients (33.3%) had

incidental ILD on imaging obtained for other reasons. The most frequent pulmonary findings on the initial chest CT were linear opacities (50.0%), while 33.3% had ground-glass opacities. Two patients (33.3%) had pulmonary hypertension, and 1 (16.7%) developed a new oxygen dependence. In addition to corticosteroids, anti-IL1 and anti-IL6 drugs were the most utilized therapies. All patients had their disease course complicated by macrophage activation syndrome (MAS). The disease was difficult to control, and medication changes were common due to disease flares, challenges with the route of administration, infusion reactions, and side effects. At the most recent rheumatology visit, 5 patients (83.3%) were on dual biologic therapy, and 3 patients (50.0%) remained on chronic corticosteroids. No patients died during the study period.

Conclusion: All children in our SJIA-LD cohort were diagnosed with SJIA at an early age and had difficult-to-control disease, including elevated CXCL9 and IL-18 levels. Half of the patients had respiratory symptoms that led to chest imaging, while the other half had no respiratory symptoms. All experienced MAS and required aggressive therapy, often with dual biologics and chronic corticosteroids.

Needs Assessment Survey of Critical Data Element Completion in Telemedicine Visits for Juvenile Idiopathic Arthritis in the Post-Pandemic Period

Kristen Hayward[1], Y. Ingrid Goh[2], Mary Toth[3], Jenny Leal[4], Alice Liu[5], Nidji Naik[5], Jade Singleton[5], Jackson Youn[5] and Esi Morgan[5], [1]Seattle Children's Hospital/University of Washington School of Medicine, Seattle, WA, [2]The Hospital for Sick Children, Toronto, ON, Canada, [3]Nemours Foundation, Orlando, FL, [4]Nationwide Children's, Columbus, OH, [5]Seattle Children's Hospital, Seattle, WA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile Idiopathic Arthritis (JIA) affects 1 in 1,000 children in the United States (US). There is a shortage of pediatric rheumatologists across North America and many patients travel lengthy distances to access subspecialty care. Telemedicine is a potential solution to this distance barrier. Although use of telemedicine has substantially increased since the COVID-19 pandemic, questions remain about the role of virtual visits for monitoring of patients with JIA where hands-on assessments have been the cornerstone for care. Surveys from early in the pandemic indicated that critical data elements (CDE) for Treat-to-Target decision making such as active joint count, physician global assessment (PGA) and patient reported outcomes (PROs) were under-reported in telemedicine relative to in-person visits.[1,2] The global aim of this quality improvement effort is to optimize completion of CDE for JIA patients seen via telemedicine, targeting the

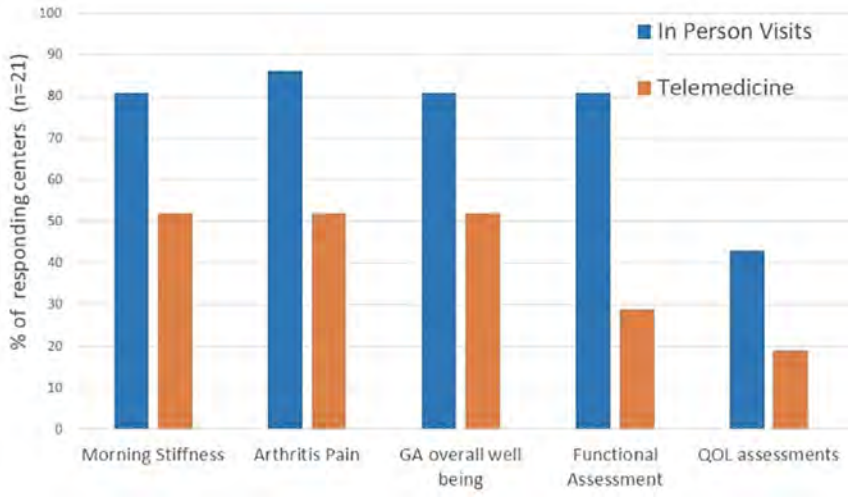

Figure 1: Specific CDE collected during JIA visits by visit modality

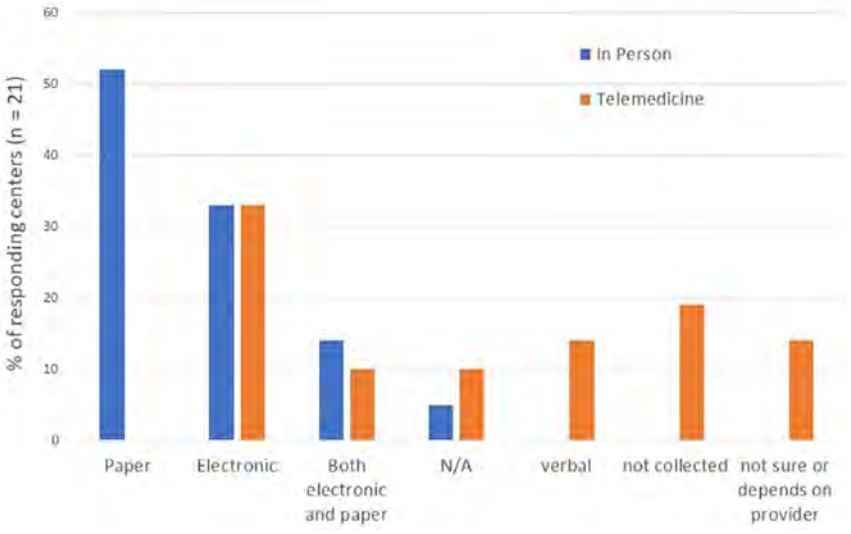

Figure 2: Methods of PRO collection during JIA visits by visit modality

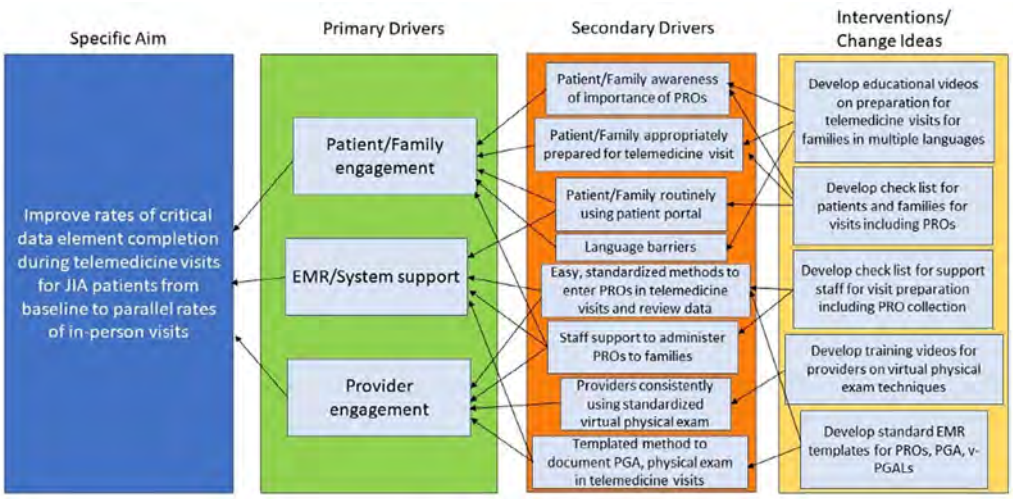

Figure 3: Key Driver Diagram based on PR-COIN network needs assessment survey

same rate as in-person visits. To determine primary drivers of CDE in telemedicine visits as well as to inform ideas for change, we performed a needs assessment of post-pandemic telemedicine practices of the Pediatric Rheumatology Care and Outcomes Improvement Network (PR-COIN) network.

Methods: PR-COIN is a multi-center learning collaborative spanning 24 pediatric centers across the US and Canada. A REDCap survey regarding current telemedicine practices was emailed to the faculty representative for each PR-COIN site in January 2023. Quantitative responses were analyzed with descriptive statistics. Qualitative comments were thematically grouped.

Results: Responses were received from 21/24 sites (88%). Figure 1 demarcates CDE collected by visit modality. Figure 2 notes the methods of PRO collection by visit type. Only 2 sites reported that providers use a standard method to assess active joint counts in telemedicine visits. However, most respondents (15/21) indicated that providers used modifications of the 'video' pediatric Gait Arms Legs and Spine (vpGALS) tool for virtual joint exams.

Reported barriers to CDE collection during telemedicine visits were grouped into three categories of primary drivers: patient engagement, provider engagement and electronic medical record(EMR)/support staff (Figure 3). Opportunities to improve standard collection of CDE included development of educational materials, easy/automated collection methods, enhanced use of support staff, streamlined questionnaires and standardized templates for virtual physical exams.

Conclusion: Despite three years of telemedicine experience, CDE completion for JIA patients in virtual visits lags behind rates for in-person visits. We are currently developing resources including instructional videos, templates and best practices for providers, patients and EMR/support staff to address these gaps. We plan to implement these interventions at network sites using an iterative quality improvement approach and prospectively track rates of CDE completion.

Musculoskeletal Ultrasound Findings in Children with Psoriasis

Laura Nedorezov, Tracy Ting and Patricia Vega-Fernandez, Cincinnati Children's Hospital Medical Center, Cincinnati, OH

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The presentation of juvenile psoriatic arthritis (JPsA) in children with psoriasis can be insidious and poses a diagnostic challenge. Musculoskeletal ultrasound (MSUS) has emerged in recent years as a sensitive and non-invasive imaging modality to detect joint inflammation. A growing number of evidence has shown that adult psoriasis patients without signs of arthritis have findings of subclinical joint pathology on MSUS. These patients with identified imaging abnormalities are more likely to develop active psoriatic arthritis as demonstrated in longitudinal studies. No such research has been performed among children with psoriasis however, highlighting a critical gap in the understanding of pediatric psoriatic disease. The objective of this investigation is to describe MSUS and nail ultrasound findings in children with psoriasis.

Table 1: Demographics and clinical characteristics of the patients studied.

Characteristic	Total, n = 11
Male/female	7/4
Age (years)[a]	11.8 ± 2.4
Ethnicity, n (%)	
Caucasian	7 (63.6)
African American	3 (27.3)
Asian	1 (9.1)
Body mass index (kg/m^2)[b]	18.5 (5.2)
Disease duration (years)[b]	5.4 (7.9)
Psoriasis subtype[c], n (%)	
Plaque	5 (45.5)
Guttate	3 (27.2)
Scalp	5 (45.5)
Palmoplantar	2 (18.2)
Psoriasis Area and Severity Index[b]	2.4 (5.5)
Nail Psoriasis Severity Index[b]	0 (8.0)
Morning stiffness (minutes)[b]	0 (22.5)
Active joint count, n (%)	0 (0)
Beighton score[d] > 5, n (%)	4 (36.4)
Current treatment[c], n (%)	
Topical corticosteroid	7 (63.6)
Topical vitamin D analog	1 (9.1)
Topical calcineurin inhibitor	1 (9.1)
No treatment	3 (27.3)

[a]Mean ± standard deviation
[b]Median (IQR)
[c]Each patient could have more than one disease subtype or treatment identified.
[d]Measure to assess generalized joint hypermobility.

Methods: Grey-scale (B) mode and power Doppler (PD) mode ultrasound were utilized in this cross-sectional study to evaluate joint, enthesis, and nail findings in pediatric psoriasis patients (< 18 years old) without clinical symptoms of arthritis. Exclusion criteria included acute joint injury, trauma, or joint surgery within the last 3 months, on systemic treatment or oral corticosteroids in the last 2 months, or pregnancy. Each subject underwent a full musculoskeletal exam and sonographic evaluation of seven sites bilaterally: a) joints/nails – fingernails, MCP, and IP joints of the second and third fingers, as well as any finger with psoriatic nail involvement, patella, tibiotalar and subtalar joints, b) entheses – quadriceps, proximal and distal patellar tendon, Achilles, and plantar fascia calcaneal insertion. Ultrasound images were assessed using an established

Table 2: Ultrasound characteristics of the studied nails, n = 61.

Wortsman classification[a]		n (%)
Normal		10 (16.4)
I		11 (18.0)
II		34 (55.8)
III		1 (1.6)
IV		5 (8.2)
Nail parameters		**Mean ± SD**
NP thickness (mm)		0.41 ± 0.11
NB thickness (mm)		1.67 ± 0.22
Matrix thickness (mm)		1.33 ± 0.22
Distal extensor tendon thickness (mm)		0.66 ± 0.16
PD grade[b]	PD signal nail bed n (%)	PD signal nail matrix n (%)
0	30 (49.2)	32 (52.5)
1	21 (34.4)	16 (26.2)

[a]Vega-Fernandez P, Ting TV, Oberle EJ, et al. The MUSICAL pediatric ultrasound examination - a comprehensive, reliable, time efficient assessment of synovitis. *Arthritis Care Res (Hoboken)*. 2021;10.1002/acr.24759. doi:10.1002/acr.24759
[b]None of the joints had PD findings of grade 1, 2, or 3.
[c]Wakefield RJ, Balint PV, Szkudlarek M, et al. Musculoskeletal ultrasound including definitions for ultrasonographic pathology. *J Rheumatol*. 2005;32(12):2485-2487.

pediatric-specific scoring system for the joints and semi-quantitative scoring approach for the nails. Enthesitis was evaluated according to the OMERACT definition. Demographic, clinical, and laboratory information was collected when available.

Results: Eleven patients were included until now. Demographic and clinical characteristics are shown in Table 1. The mean duration of the ultrasound exam was 66 minutes. Ultrasound characteristics of the nails studied are displayed in Table 2, and findings of the joints and entheses are shown in Table 3. 51 nails (83.6%) had abnormal nail plate structure per the Wortsman classification, and roughly 20% of nails had increased PD activity in either the nail bed or nail matrix classified as grade 2 or 3. Eight out of 11 patients (72.7%) had a least one grade 2 finding of synovitis on B-mode, with the PIP/DIP, suprapatellar, and anterior subtalar joint recesses most frequently affected. Two patients (18.2%) had enthesopathy involving the lower extremities identified on PD examination.

Conclusion: Subclinical inflammatory abnormalities of the nails, joints, and entheses were identified utilizing MSUS in children with psoriasis who did not have clinical manifestations of arthritis on exam. Ongoing studies involving additional pediatric psoriasis patients and healthy controls is underway to more clearly elucidate the significance of these findings.

Validation of Claims-based Algorithms for Newly Diagnosed Juvenile Idiopathic Arthritis Using Machine Learning Methods

Patricia Hoffman[1], Lauren Parlett[2], Daniel Beachler[2], Daniel Reiff[3], Sarah McGuire[1], Sonia Pothraj[1], Lakshmi Moorthy[1], Cynthia Salvant[4], Dawn Koffman[5], Sanika Rege[5], Cecilia Huang[5], Matthew Iozzio[5], Kevin Schott[2], Kevin Haynes[6], Amy Davidow[7], Stephen Crystal[8], Tobias Gerhard[5], Brian Strom[9], Carlos Rose[10] and Daniel Horton[4], [1]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ, [2]Carelon, Wilmington, DE, [3]University of Alabama at Birmingham, Birmingham, AL, [4]Department of Pediatrics, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ, [5]Rutgers Center for Pharmacoepidemiology and Treatment Science, New Brunswick, NJ, [6]Janssen Pharmaceuticals, Raritan, NJ, [7]New York University, New York, NY, [8]Rutgers University, New Brunswick, NJ, [9]Rutgers, State University of New Jersey, New Brunswick, NJ, [10]Thomas Jefferson University, Philadelphia, PA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Administrative claims databases represent important settings for studying large populations with juvenile idiopathic arthritis (JIA), but prior efforts to validate diagnostic algorithms for JIA using administrative data have been limited to potentially non-generalizable settings (e.g., specific clinics or health care systems). We aimed to develop and validate algorithms for new diagnoses of JIA in a large claims database using rule-based and machine learning-based approaches.

Methods: We performed a cross-sectional validation study using US commercial health plan data (2013-2020). We identified children diagnosed with JIA (ICD-9-CM: 696.0, 714, 720; ICD-10-CM: L40.5, M05, M06, M08, M45) before age 18 following ≥12 months of baseline continuous enrollment without JIA diagnosis or immunosuppression. JIA diagnoses were based on 3 previously validated definitions: 1) rheumatologist's diagnosis plus orders for ≥2 specific laboratory tests; 2) ≥2 outpatient diagnoses 8-52 weeks apart; or 3) 1 inpatient diagnosis. Charts from a random subset of subjects meeting each definition were abstracted and independently adjudicated by clinical experts; discrepancies were resolved by a third expert or, where necessary, consensus. Incident JIA was defined as definite or probable JIA diagnosed in the prior 4 months. Using

data from 1 year before through 1 year after first JIA diagnosis, we then created candidate predictor variables from demographics, diagnoses, medications, procedures, and specialty of clinicians diagnosing JIA. After applying a simulation-based balancing method (Synthetic Minority Oversampling Technique, SMOTE), we selected optimal logistic regression regularization hyperparameters using 10-fold cross-validation. Model variables were used to score observations, and sensitivity, specificity, and positive predictive value (PPV) [95% confidence interval (CI)] were assessed at different thresholds of predicted JIA probability.

Results: Of 182 eligible charts reviewed (92 ICD-9-based, 90 ICD-10-based), 133 had definite/probable JIA (ICD-9 64%, ICD-10 82%). Of JIA diagnoses, 90 were incident (ICD-9 90%, ICD-10 50%). Rule-based algorithms had limited PPV for incident JIA (ICD-9 58%, ICD-10 41%) (Table). Use of machine-learning based algorithms enabled excellent discrimination between incident and prevalent JIA (ICD-9 AUC 0.97, ICD-10 AUC 0.88) and between incident JIA and unlikely JIA (ICD-9 AUC 0.99, ICD-10 AUC 0.94) (Figure 1). Specific predicted probability thresholds yielded excellent test characteristics for

Table. Accuracy of rule-based algorithms for incident JIA. ICD, International Classification of Diseases; Inc., incident; JIA, juvenile idiopathic arthritis; PPV, positive predictive value; Prev., prevalent. Numbers of charts are shown by claims-based definition and adjudicated diagnosis. PPV represents the percentage with definite or probable incident JIA among those meeting the claims-based definition. Specific labs eligible for Definition 1 were antinuclear antibody, rheumatoid factor, anti-cyclic citrullinated protein antibody, and HLA-B27.

	ICD-9-based diagnosis					ICD-10-based diagnosis				
Definition	**Charts**	**Inc. JIA**	**Prev. JIA**	**Not JIA**	**PPV, Inc. JIA**	**Charts**	**Inc. JIA**	**Prev. JIA**	**Not JIA**	**PPV, Inc. JIA**
All definitions combined	92	53	6	33	58%	90	37	37	16	41%
Definition 1: ≥1 rheumatologist's diagnosis + ≥2 specific labs	37	28	2	7	76%	35	18	13	4	51%
Definition 2: ≥2 outpatient diagnoses 8-52 weeks apart	52	24	4	24	46%	50	18	24	8	36%
Definition 3: ≥1 inpatient diagnosis	3	1	0	2	33%	5	1	0	4	20%

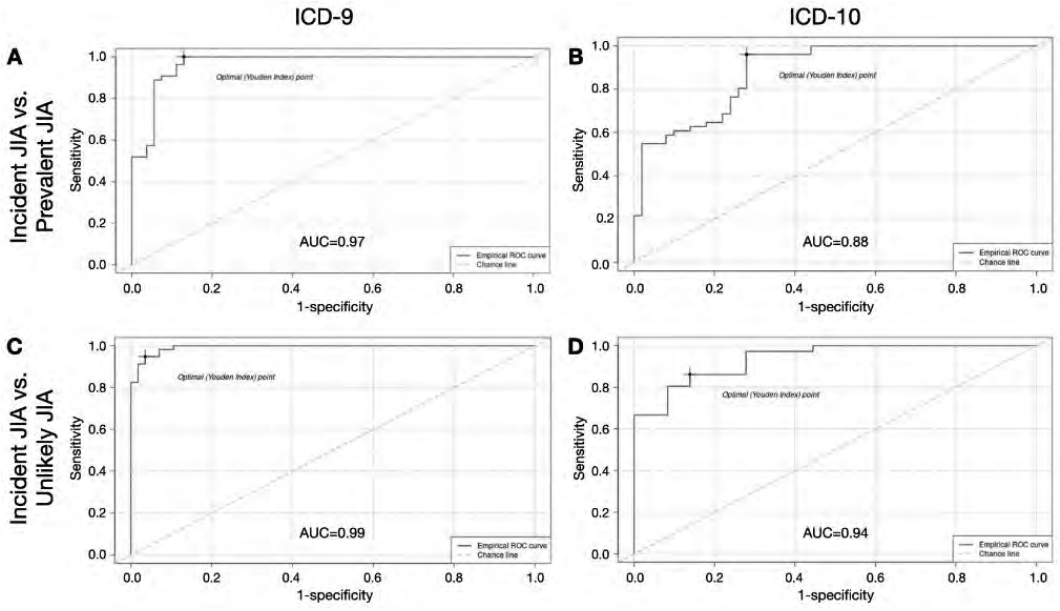

Figure 1. ROC curves for machine learning-based algorithms for incident JIA. AUC, area under the curve; ROC, receiver operating characteristic; ICD, International Classification of Diseases; JIA, juvenile idiopathic arthritis. ROC curves show balance of sensitivity and specificity of machine learning-based algorithms for incident JIA based on comparisons with prevalent JIA (ICD-9 in A, ICD-10 in B) and with unlikely JIA (ICD-9 in C, ICD-10 in D). The Youden Index (dot on ROC curve) represents the maximum value of (Sensitivity + Specificity – 1).

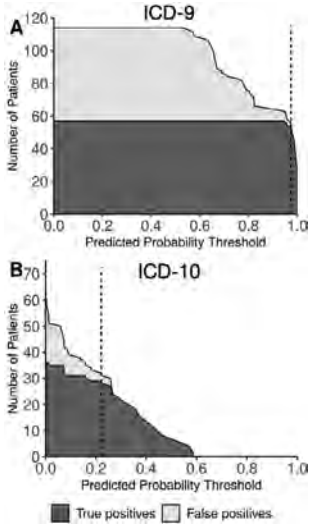

Figure 2. Impact of predicted probability thresholds from machine learning-based models on accuracy of diagnoses of incident JIA compared with unlikely JIA. CI, confidence interval; ICD, International Classification of Diseases; PPV, positive predictive value. Curves show numbers of true positive (dark grey) and false positive (light grey) cases of incident JIA at different thresholds of predicted probability from machine learning-based models comparing children with incident JIA and children unlikely to have JIA based on ICD-9 codes (A) and ICD-10 codes (B). Numbers reflect the total study population, including simulated cases generated by application of a balancing method (Synthetic Minority Oversampling Technique, SMOTE). Threshold values yielding excellent test characteristics (dotted lines) were 0.97 for ICD-9 (sensitivity 95%, specificity 96%, PPV 96% [95% CI 96-100%]) and 0.22 for ICD-10 (sensitivity 81%, specificity 92%, PPV 91% [95% CI 84-97%]).

differentiating incident JIA from unlikely JIA (ICD-9: sensitivity 95%, specificity 96%, PPV 96% [95% CI 96-100%]; ICD-10: sensitivity 81%, specificity 92%, PPV 91% [95% CI 84-97%]) (Figure 2).

Conclusion: Machine learning-based diagnostic algorithms for incident JIA enhanced traditional rule-based algorithms in identifying new diagnoses of JIA using ICD-9 and ICD-10 codes within a large US claims database. External validation of these models is warranted, but these algorithms will facilitate use of administrative data to study JIA diagnosis, management, and outcomes in large populations.

Leu[3], Edwin Lam[3], Yuhua Wang[3], Alberto Martini[5] and Hermine Brunner[6], [1]IRCCS Istituto Giannina Gaslini, UOSID Centro Trial, Genova, Italy, [2]UC Department of Pediatrics, Cincinnati Children's Hospital, University of Cincinnati, Cincinnati, OH, [3]Janssen Research & Development, LLC, Spring House, PA, [4]Janssen Research & Development, LLC, San Diego, CA, [5]Universita degli Studi di Genova, Dipartimento di Neuroscienze, Riabilitazione, Oftalmologia, Genetica e Scienze Materno-Infantili (DiNOGMI), Genova, Italy, [6]Cincinnati Children's Hospital Medical Center, Division of Rheumatology, Cincinnati, OH

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The phase 3, Intravenous Golimumab in Pediatric Participants with Active Polyarticular-Course JIA Despite MTX (GO-VIVA) study demonstrated that golimumab (GLM) 80 mg/m^2 at Week (W) 0, W4 and Q8W thereafter is well-tolerated and effective in children 2 to < 18 years of age with active polyarticular-course juvenile idiopathic arthritis (pcJIA) despite MTX through W52 (NCT02277444). The pharmacokinetics (PK), immunogenicity, efficacy, and safety of GLM in GO-VIVA participants (pts) who continued into the long-term extension (LTE) through W252 are evaluated.

Methods: Pts from GO-VIVA who continued GLM 80 mg/m^2 IV q8w (max dose 240 mg) after W52 were included. PK and immunogenicity were assessed through W244, and safety was assessed through W252. Efficacy measures included JIA ACR response from baseline (start of GLM), clinical Juvenile Arthritis Disease Activity Score based on 10 joints (cJADAS-10) minimal disease activity (cJADAS-10 MDA), inactive disease (cJADAS-10 ID) and remission (≥ 6 continuous months of cJADAS-10 ID). These were analyzed using an intent-to-treat (ITT) approach through W116, due to a protocol amendment instituted during the LTE that limited efficacy data collected after W116. Non-responder imputation was used for missing data.

Results: Of the 127 pts treated, 112 (88.2%) continued into the LTE, and 69 (54.3%) completed GLM through W244 and had a W252 assessment. The most common reasons for discontinuation of GLM treatment through W244 were adverse event (AE) (19%) and withdrawal of consent (7%). W244 median steady-state trough GLM concentration was 0.61 μg/mL (mean ± SD: 0.66 ± 0.569μg/mL; N=31) vs 0.44 μg/mL (mean ± SD: 0.50 ± 0.455 μg/mL; N=93) at W52, indicating that exposure was maintained over time. Median trough GLM concentrations at W244 were similar across different age categories and body weight quartiles. From W52 to W116, the majority of pts had JIA ACR 30 (72%-77%), JIA ACR 50 (71%-76%), and JIA ACR 70 (62%-68%) responses, and approximately 50% had JIA ACR 90. The majority of pts (≥56%) achieved cJADAS-10 MDA, 41%-49% achieved cJADAS-10 ID, and 28-33% achieved remission. Antibodies to GLM were detected in 56 (44.8%) of pts through W244; the majority of titers were < 1:1000. Of these 56 pts, 35 were positive for neutralizing antibodies (Nab) with an overall incidence of NAb of 31% (35/112). No new or unexpected safety issues were identified through W252. AEs and SAEs were reported in 92.1% and 19.7% of pts, respectively. One death (septic shock) occurred.

Conclusion: PK exposure through the end of the LTE was consistent with that observed through W52. Although analyses were limited by protocol modification, data through W116 suggest a therapeutic benefit with additional treatment and achievement of clinically important endpoints for pts who continued in the LTE. GLM was generally well tolerated with an acceptable long-term safety profile through W252.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Pediatric Rheumatology – Clinical Poster I: JIA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Evidence on treatment safety in systemic juvenile idiopathic arthritis (sJIA) is limited. Our objective was to evaluate the safety profile of drugs in the initial 24-months since disease onset.

Methods: Children from Pharmachild were classified into 4 mutually exclusive groups according to the treatment in the first 6 months from sJIA onset. Descriptive data, incidence rates (95% CI), survival curve, log rank test, and Cox multivariate regression model are reported.

Results: A total of 701/992 (71%) sJIA patients were classified as: 1) glucocorticoids (N=161), 2) biologic (b) DMARDS (N=69); 3) conventional synthetic (cs) DMARDs (N=65) and 4) combinations of these drugs (N=406).

In the initial 6 months, bDMARDs and combination therapy had the highest rate of AEs, serious AE and events of special interest. Infections were the most common AEs (N, IR*100PY-95%CI) in bDMARDs group (7, 32.94 [15.70-69.10]). Gastro-intestinal disorders and general disorders were most frequent in the bDMARDs group (6, 28.24 [12.69-62.85]). Kaplan Meier's showed the bDMARDs group experienced more AE and sooner when compared to the other groups (log rank test $p< 0.0001$). The risk of any AE was significantly higher in bDMARDs, hazard ratio (HR) 8.8 (95% CI: 3.5-22.1)

In the following 18 months the number and the risk of any AE was increased in the combination therapy group (HR 4.5; 95% CI: 1.1-18.6).

Conclusion: bDMARDs or combination therapy in sJIA patients was associated with a higher risk of AE in the first six months meanwhile in the following 18 months combination therapy group had the highest risk of AE.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Pediatric Rheumatology – Clinical Poster I: JIA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The Paediatric Rheumatology International Trials Organisation (PRINTO) recently undertook an effort to better harmonize the pediatric and adult arthritis criteria. These provisional criteria are not validated and refinement may be necessary for optimal performance. We aimed to investigate differences amongst youth with clinically diagnosed juvenile SpA who met axJSpA classification criteria who did and did not fulfill the PRINTO provisional enthesitis/spondylitis-related criteria.

Methods: This was a retrospective cross-sectional sample of international youth who had juvenile SpA ascertained by the treating physician. All youth had onset of symptoms prior to age 18 and fulfilled the recently validated axJSpA classification criteria. The axJSpA classification criteria consist of 7 domains: imaging - active inflammation, imaging - structural lesions, pain chronicity, pain pattern, pain location, stiffness, and genetics/family history. A youth with juvenile SpA is classified as having axial disease with a cumulative score of ≥55 (out of 100). To meet the PRINTO criteria for enthesitis/spondylitis-

related arthritis youth must fulfill one of 3 major criteria (Table 1). Data were abstracted from subjects' medical records. All MRI scans underwent central imaging review by at least 2 central raters. Patient demographics, clinical manifestations, and physician and patient-reported outcomes were evaluated using standard descriptive statistics. Differences between groups were compared using Wilcoxon signed-rank test or chi-square as appropriate.

Results: Of 143 patients that met axJSpA criteria, 100 (69%) fulfilled the PRINTO provisional criteria for enthesitis/spondylitis-related arthritis. Thirty-four (23%) did not fulfill any of the 3 major PRINTO criteria due to lack of peripheral disease manifestations. The frequency with which each major and minor criteria were fulfilled is listed in Table 1. Demographics, family history of SpA, location of back pain, and duration of pain were not statistically different between those who did and did not meet PRINTO criteria (Table 2). Those who fulfilled the PRINTO criteria had significantly more morning stiffness lasting ≥15 minutes (p=0.02), peripheral arthritis (p< 0.01), enthesitis (p< 0.01), and HLA-B27 positivity (p=0.02). Patients who did not meet the PRINTO criteria had a significantly higher percentage of pain duration

Table 1. Proportion of JSpA patients with axial disease fulfilling each PRINTO enthesitis/spondylitis-related JIA criterion

PRINTO Criterion		N	N (%)
1. Peripheral arthritis and enthesitis		143	33 (23.1)
	Peripheral arthritis	143	80 (55.9)
	Enthesitis	143	61 (42.7)
2. Arthritis or enthesitis, plus ≥ 3 months of inflammatory back pain and sacroiliitis on imaging		143	56 (39.2)
	Peripheral arthritis or enthesitis	143	108 (75.5)
	≥3 months of inflammatory back pain	143	78 (54.5)
	Sacroiliitis on imaging	143	143 (100.0)
3. Arthritis or enthesitis plus ≥2 of the following: SI joint tenderness; inflammatory back pain; presence of HLA-B27 antigen; acute (symptomatic) anterior uveitis; history of a SpA in a 1st-degree relative.		143	89 (62.2)
	Peripheral arthritis or enthesitis	143	108 (75.5)
	SI joint tenderness	141	95 (67.4)
	Inflammatory back pain	141	94 (66.7)
	Presence of HLA-B27 antigen	136	87 (64.0)
	Acute (symptomatic) anterior uveitis (ever?)	143	8 (5.6)
	History of a SpA in a 1st-degree relative	133	24 (18.1)

Table 2. Clinical features of patients with axial disease

	PRINTO (-)		PRINTO (+)		
	N	N (%) or M(IQR)	N	N (%) or M(IQR)	p-value
Age at reference date	45	14.6 (12.0-16.2)	98	15.2 (12.6-17.0)	0.21
Sex, male	45	26 (57.8)	98	70 (71.4)	0.11

Pain					
Sacral/Buttock	45	25 (55.6)	98	39 (39.8)	0.08
Hip/Groin	45	28 (62.2)	98	63 (64.3)	0.81
Insidious onset	36	28 (77.8)	90	80 (88.9)	0.11
Duration					
≥6 weeks	44	41 (93.2)	94	83 (88.3)	0.38
≥12 weeks	44	35 (79.6)	94	54 (57.5)	**0.01**
Stiffness ≥15 minutes	30	13 (43.3)	79	54 (68.4)	**0.02**
Physical exam findings/Patient medical history					
SI pain with deep palpation or FABER/Mennell/ Gaenslen's maneuver	38	19 (50.0)	89	57 (64.0)	0.14
History of peripheral arthritis	45	6 (13.3)	98	74 (75.5)	**<0.01**
History of enthesitis at any location	45	4 (8.9)	98	57 (58.2)	**<0.01**
HLA-B27 positive	44	22 (50.0)	92	65 (70.7)	**0.02**
Polyarticular course of peripheral arthritis	45	2 (4.4)	98	16 (16.3)	0.06
Acute anterior uveitis	45	0 (0.0)	98	8 (8.2)	0.05

Table 3. MRI imaging features of patients with axial disease

	All		PRINTO (–)		PRINTO (+)		
	N	N (%)	N	N (%)	N	N (%)	p-value
Inflammatory lesions							
Inflammation in subchondral bone marrow	143	126 (88.1)	45	38 (84.4)	98	88 (89.8)	0.35
Inflammation at site of an erosion cavity	143	79 (55.2)	45	25 (55.6)	98	54 (55.1)	0.96
Inflammation in SIJ capsule	143	31 (21.7)	45	10 (22.2)	98	21 (21.4)	0.92
Enthesitis outside SIJ	143	31 (21.7)	45	8 (17.8)	98	23 (23.5)	0.44
Unequivocal inflammatory lesions^	141	124 (87.9)	44	38 (86.4)	97	86 (88.7)	0.70
Structural lesions							
Sclerosis	143	66 (46.1)	45	22 (48.9)	98	44 (44.9)	0.66
Erosion	143	117 (81.8)	45	37 (82.2)	98	80 (81.6)	0.93
Fat lesion	143	18 (12.6)	45	3 (6.7)	98	15 (15.3)	0.15
Fat metaplasia in an erosion cavity	143	13 (9.1)	45	2 (4.4)	98	11 (11.2)	0.19
Ankylosis	143	4 (2.8)	45	0 (0.0)	98	4 (4.1)	0.17
Unequivocal structural lesions#	140	121 (86.4)	44	40 (90.9)	96	81 (84.4)	0.30

Legend. ^Unequivocal evidence of inflammatory lesions typical of axial disease: bone marrow edema in ≥3 SI joint quadrants across all SI joint MRI slices. #Unequivocal evidence of structural lesion(s) typical of axial disease: erosion in ≥3 quadrants or sclerosis or fat lesion in ≥2 SI joint quadrants or backfill or ankylosis in ≥2 joint halves across all SI joint MRI slices.

≥12 weeks (p=0.01). There were no significant differences in the prevalence of inflammatory or structural lesions on MRI between the two groups (Table 3).

Conclusion: A third of children classified with axJSpA remain unclassifiable by the provisional PRINTO enthesitis/spondylitis-related criteria. The clinical and imaging manifestations of axial disease were not significantly different between those who did and did not fulfill the provisional PRINTO criteria. The phenotypic differences between those who were and were not classified by the provisional PRINTO criteria are confined to peripheral disease manifestations. Modification of the second major criterion of the PRINTO provisional criteria may facilitate capture of youth with primarily axial disease.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

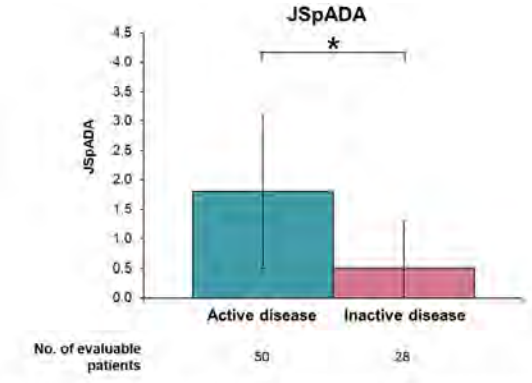
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The juvenile spondyloarthritis disease activity index (JSpADA) is a disease activity assessment tool developed for children with juvenile psoriatic arthritis (JPsA) and enthesitis related arthritis (ERA). This post-hoc analysis investigated the validity of JSpADA for children with ERA and JPsA in a prospective clinical trial setting using data from the JUNIPERA study.

Methods: JUNIPERA (NCT03031782) is a phase 3, placebo-controlled, event-driven withdrawal study investigating the safety and efficacy of secukinumab in pediatric patients with ERA and JPsA. Patients aged 2 to < 18 years who met the International League of Associations for Rheumatology criteria for ERA or JPsA for ≥6 months with active disease (≥3 active joints and ≥1 site of enthesitis) despite treatment with ≥1 non-steroidal anti-inflammatory drug or disease-modifying anti-rheumatic drug were enrolled. Patients received open label secukinumab (75 mg in patients < 50 kg, 150 mg in patients ≥50 kg) weekly for 5 weeks (including Week 0) followed by q4w to Week 12. At Week 12, patients were randomized 1:1 to secukinumab or placebo q4w until disease flare or Week 52. JSpADA consists of 8 equally weighted components (range, 0-8): active joint count, enthesitis count, patient-reported pain, inflammatory markers, morning stiffness, clinical sacroiliitis, uveitis, and back mobility. For this post hoc analysis, the validity of JSpADA was assessed using 3 criteria: discriminatory

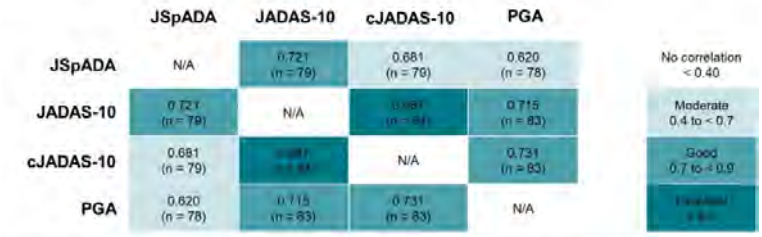


ERA, enthesitis related arthritis; JPsA, juvenile psoriatic arthritis; JSpADA, Juvenile Spondylarthritis Disease Activity; PGA, physician global assessment of disease activity.
* Inactive disease was defined as no joints with active arthritis, CRP level within normal limits, PGA ≤10 mm, absence of patient-reported morning stiffness, and no uveitis; error bars represent SD.
* $P<.0001$

validity based on JSpADA scores at Week 12 among patients with active or inactive disease (defined as no joints with active arthritis, CRP level within normal limits, PGA ≤10, no patient-reported morning stiffness, and no uveitis); convergent validity based on Spearman's correlation between JSpADA and 10-joint Juvenile Arthritis Disease Activity Score (JADAS-10), clinical JADAS-10 (cJADAS-10), and physician global assessment of disease activity (PGA) at Week 12; and responsiveness to change in clinical disease activity based on change in JSpADA scores from Week 12 to Week 52 among patients who had improvement (change in PGA < 0) or worsening (change in PGA >0) of disease activity. Reported *P* values are nominal, and no multiplicity adjustments were made.

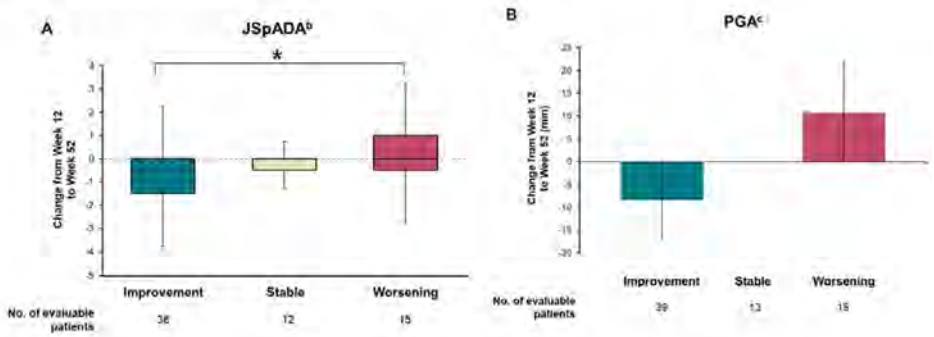
Results: Among the 86 patients included in this analysis, 52 (60.5%) had ERA and 34 (39.5%) had JPsA. At Week 12, patients with active disease had higher mean (SD) JSpADA scores than patients with inactive disease (1.8 [1.3] vs 0.5 [0.8]; *P*< .0001; Figure 1). JSpADA scores showed moderate to good correlation with JADAS-10, cJADAS-10, and PGA scores at Week 12 (Spearman's correlation coefficient; range, 0.62-0.72; Figure 2). Patients with improvements in disease activity from Weeks 12 to 52 as determined by change in PGA scores had greater improvements in mean JSpADA scores over the same time period than patients with worsening in disease activity (–0.8 [1.1] vs 0.4 [1.0]; *P*< .001; Figure 3). Patients with stable disease from Weeks 12 to 52 had minimal change in JSpADA (–0.1 [0.48]).

Figure 2. Spearman's Correlation Coefficients for JSpADA, JADAS-10, cJADAS-10, and PGA Scores for Children with JPsA and ERA at Week 12



cJADAS-10, clinical JADAS-10; ERA, enthesitis related arthritis; JADAS-10, 10-joint Juvenile Arthritis Disease Activity Score; JPsA, juvenile psoriatic arthritis; JSpADA, Juvenile Spondylarthritis Disease Activity; PGA, physician global assessment of disease activity.

Figure 3. Change in (**A**) JSpADA and (**B**) PGA From Week 12 to Week 52 for Children with JPsA and ERA Grouped by Disease Activity[a]



ERA, enthesitis related arthritis; JPsA, juvenile psoriatic arthritis; JSpADA, Juvenile Spondylarthritis Disease Activity; PGA, physicians global assessment of disease activity.
[a] Improvement in disease activity was defined as change in PGA from Week 12 to Week 52 < 0, stable as change in PGA = 0, and worsening as change in PGA > 0.
[b] The horizontal line represents median value, and upper and lower boundaries represent 75th and 25th percentile, respectively. Vertical lines were calculated as the interquartile range × 1.5.
[c] Error bars represent SD.

Conclusion: JSpADA discriminated between active and inactive disease, correlated with other validated disease activity measures, and responded to changes in clinical disease activity in children with ERA and JPsA in the prospective JUNIPERA study.

Baseline Clinical Features and Biomarker Profiles of the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Systemic Juvenile Idiopathic Arthritis Associated Lung Disease (SJIA-LD) Cohort

Esraa Eloseily[1], Autumn Clark[1], Min-Lee Chang[2], MaryEllen Riordan[3], alan Russell[4], Marc Natter[5], Sherry Thornton[6], Yukiko Kimura[7] and Grant Schulert[1], [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Boston Children's Hospital, Boston, MA, [3]Hackensack Meridian Health, Hackensack, NJ, [4]Duke Clinical Research Institute, Duke, NC, [5]Harvard Medical School, Boston, MA, [6]Cincinnati Children's Hospital, Cincinnati, OH, [7]Hackensack Meridian School of Medicine, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic juvenile idiopathic arthritis (SJIA) associated lung disease (SJIA-LD) is an emerging and life-threatening clinical problem with urgent unmet needs including prevalence, pathogenesis, disease biomarkers, influence of biologics, and outcomes. The objective is to define baseline clinical features and biomarker profiles of patients in the CARRA Registry SJIA-LD cohort.

Methods: Existing or newly enrolled CARRA Registry patients with SJIA and suspected, probable, or definite SJIA-LD were included in the cohort. In addition to standard Registry data, lung disease specific data was obtained using a standardized case report form through REDCap Cloud, and biosamples collected when available. Biomarker profiles were determined from plasma using a custom Luminex panel. This study was approved by the DCRI Reliant IRB and/or IRB of all Registry sites.

Results: 37 patients were enrolled in the SJIA-LD cohort, from 16 CARRA Registry sites in the US. 46% had definite (biopsy-proven), 36% probable, and 18% suspected SJIA-LD. Demographic and clinical features are shown in Table 1. Of those who underwent lung biopsy, all had pulmonary alveolar proteinosis (PAP) and interstitial inflammation, and 40% had collagenous fibrosis. 77% had at least one definite episode of macrophage activation syndrome (MAS)

Table 1: Demographic and clinical features of patients in the SJIA-LD cohort (N=37)

Clinical features	Summary or median
Sex	62% F
Age at enrollment*	4.4 years
Age at LD onset*	3.3 years
Age at SJIA onset*	1 years
LD duration**	0.3 (2.1) years
SJIA disease duration**	1 (2.75) years
SJIA duration at LD diagnosis**	1.6 (1.4) years
Clinical features at LD diagnosis	50% cough 50% clubbing 46% tachypnea 36% dyspnea on exertion 23% digital erythema 18% hypoxemia requiring supplemental oxygen
Baseline chest CT findings	55% ground glass opacities 41% peribronchovascular thickening 41% septal thickening 23% peripheral consolidation 23% hilar adenopathy
Pulmonary function tests	50% abnormal DLCO 50% abnormal spirometry 0% abnormal spot pulse oximetry
Broncho alveolar lavage	19% PAP 8% signs of infection
Parent/patient overall well-being score at most recent visit**	1(2)
Parent/subject assessment of disease activity at most recent visit**	1 (4.5)
Overall SJIA physician global assessment at most recent visit**	0.5 (2.5)
Physician global assessment of lung disease (PGALD) at most recent visit**	3.5 (3.75)
Health Related quality of life at most recent visit	26% excellent 22% very good 35% good 17% fair
Biologics ever used	92% Anakinra 65% Canakinumab 65% Tofacitinib 58% Tocilizumab
DMARDs ever used	46% Methotrexate 19% Mycophenolate mofetil
Currently on oral steroids	81 %

*Median, ** Median (IQR)

(including 64% that met the 2016-SJIA-MAS criteria), 73% had more than one MAS episode, and 32% had subclinical MAS. MAS occurred prior to SJIA-LD diagnosis in 68% and coincided with it in 18%.

Across all patient samples, SJIA-LD patients showed significantly increased plasma levels of IL-6, IL-12, IL-18, CXCL9, CD25, CCL11, CCL17, MCP-1, and MCP-3 compared to healthy pediatric controls. Cluster analysis defined 3 distinct groups of SJIA-LD patients. Group 1 (n=7) showed high levels of TNF, IL-6, IL-17, MCP-1 and 3, CCL11, and CCL17; group 2 (n=8) showed high IL-10, IL-12, IL-18, CXCL9, CXCL10, CD25, and CD163; and group 3 (n=10) showed high CCL15 and CCL25 (Figure 1).

Conclusion: Patients in the CARRA SJIA-LD cohort exhibit a broad spectrum of clinical and radiographic features, disease activity, and treatment approaches. Recurrent MAS was common. Patients with SJIA-LD showed multiple distinct plasma biomarker patterns. As an ongoing prospective cohort study of this emerging disease, we will be able to assess clinical features, longitudinal disease progression and trajectories, as well as associated immune biomarkers and cellular populations.

Clinical Characteristics of Patients with Juvenile Idiopathic Arthritis Who Undergo Adalimumab Drug Level Testing and Anti-Drug Antibody Assessment

Chelsea Vallejos[1], Jennifer Cooper[2] and **Ingrid Pan**[1], [1]Children's Hospital Colorado, Aurora, CO, [2]University of Colorado/Children's Hospital Colorado, Denver, CO

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Pediatric Rheumatology – Clinical Poster I: JIA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Adalimumab therapeutic drug monitoring (TDM) using established trough concentrations is not standard practice in JIA patients, unlike IBD. No specific guidelines outline a therapeutic trough level range or clinical indications for monitoring. The aim of this study was to evaluate our institution's current practice of ordering and utilizing adalimumab trough levels for JIA patients.

Table 1: Baseline Demographics and Clinical Characteristics

Variable	All Patients (n = 64)	ADA positive (n = 30)	ADA negative or not tested (n = 34)
Age (years)	11.6 (6.3, 14.1)	11.5 (6.4, 14.1)	11.8 (7.8, 14.1)
Gender (female)	35 (54.7%)	10 (33.3%)	25 (73.5%)

Polyarticular, RF (+)	6 (9.4%)	3 (10.0%)	3 (10.0%)
Polyarticular, RF (-)	11 (17.2%)	7 (23.3%)	4 (13.3%)
Undifferentiated	2 (3.1%)	0 (0.0%)	2 (6.7%)
Disease duration at start of adalimumab (months)	7.6 (1.6, 28.3)	7.6 (1.6, 27.6)	7.1 (1.6, 28.5)
Indication for adalimumab drug level testing			
Inadequate initial response to adalimumab	8 (12.5%)	5 (16.6%)	3 (8.8%)
Loss of clinical response to adalimumab[a]	46 (71.9%)	23 (76.7%)	23 (67.6%)
Other	10 (15.6%)	2 (6.7%)	8 (23.5%)

[a]Loss of clinical response defined as recurrence of joint pain, inflammation, or uveitis flare
Abbreviations: ADA = anti-drug antibody, BSA = body surface area, BMI = body mass index

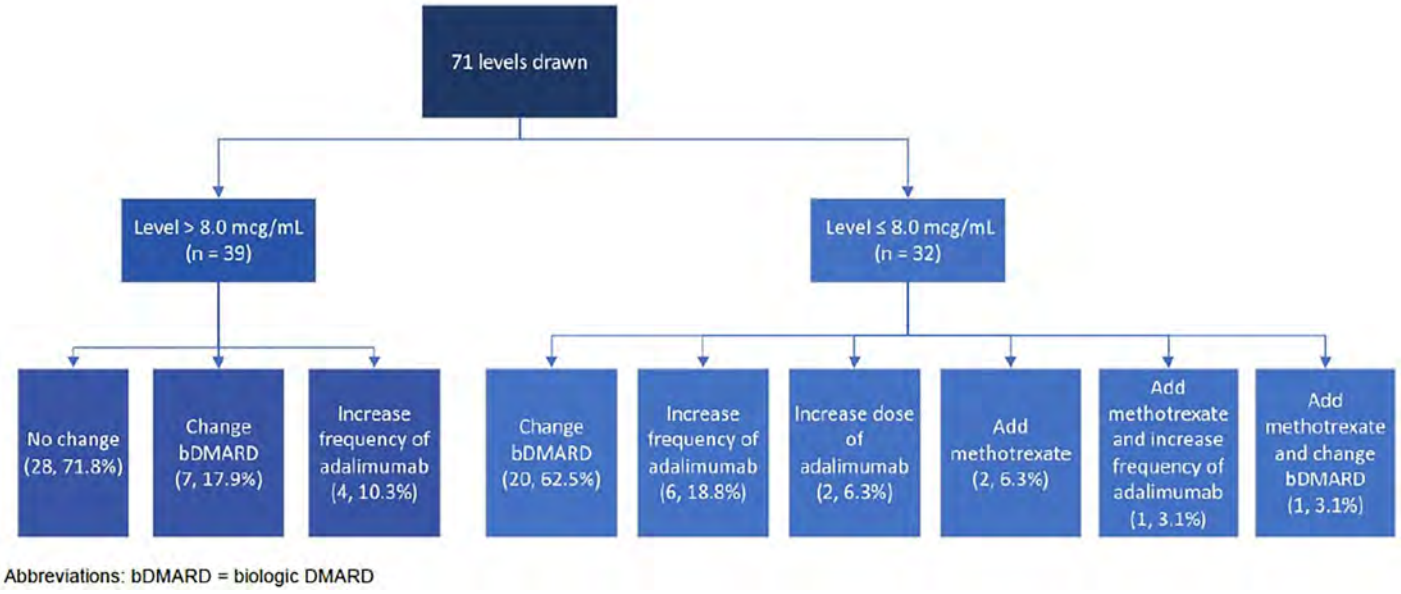

Figure 1: Treatment Changes Based on Adalimumab Trough Level

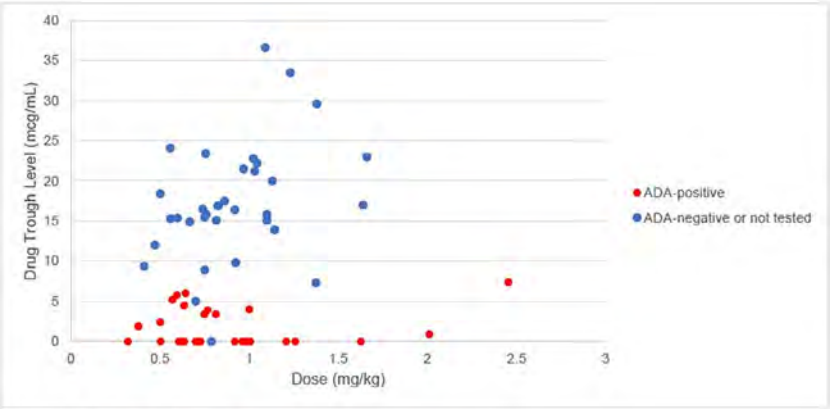
Methods: Asingle-center, retrospective cohort study was completed using an electronic medical system. Non-systemic JIApatients on adalimumab with a minimum of one adalimumab trough drawn at our institution between 1/1/2019 to1/1/2022were included. Patient data, adalimumab dose and frequency, adalimumab trough levels, anti-drug antibody (ADA) activity, and subsequent treatment decisions were collected. The primary objective was to describe the therapeutic outcomes of drug level assessment in patients with JIA. Secondary objectives included indications for trough level testing, incidence of positive ADA activity, and treatment plan changes. Descriptive statistics were performed.

Results: A total of 64 patients with 71 adalimumab trough levels met study inclusion criteria of which 30 patients were ADA positive and 34 patients were ADA negative or not tested (Table 1).The median age was 11.6 years (6.3, 14.1), predominantly female (35, 54.7%) and Caucasian (47, 73.4%).Enthesitis-related arthritis (23, 35.9%) and oligoarticular JIA (22, 34.4%) were the most common subtypes. Common clinical indications for adalimumab drug level testing included loss



Abbreviation: ADA = anti-drug antibody

Figure 2: Adalimumab Dose vs. Trough Level

of response (46, 71.9%) and inadequate initial response to adalimumab (8, 12.5%). Adalimumab troughs resulted at ≤ 8.0 mcg/mL in 32 (45.1%) measurements leading to ADA testing(Figure 1). Of patients tested for ADA, 30 patients were found to be positive. For patients with a level > 8.0 mcg/mL, the most common treatment decision was no change to therapy (28, 71.8%). Switching to an alternative biologic DMARD was the most common change (20, 62.5%) for ADA tested patients. Trough concentrations did not correlate with the dose of adalimumab that patients received (Figure 2).

Conclusion: No distinguishing patterns associated with ADA development were noted. Most trough concentrations collected were due to loss of clinical response to adalimumab. Assessing adalimumab trough concentrations impacted therapy changes, with switching to an alternative biologic DMARD as the most common practice for adalimumab levels ≤ 8.0 mcg/mL. Adalimumab doses did not correlate with trough concentration. Limitations include small sample size and chart review. Further studies are needed to identify the role of TDM in JIA patients.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Pediatric Rheumatology – Clinical Poster I: JIA

Session Type: Poster Session A

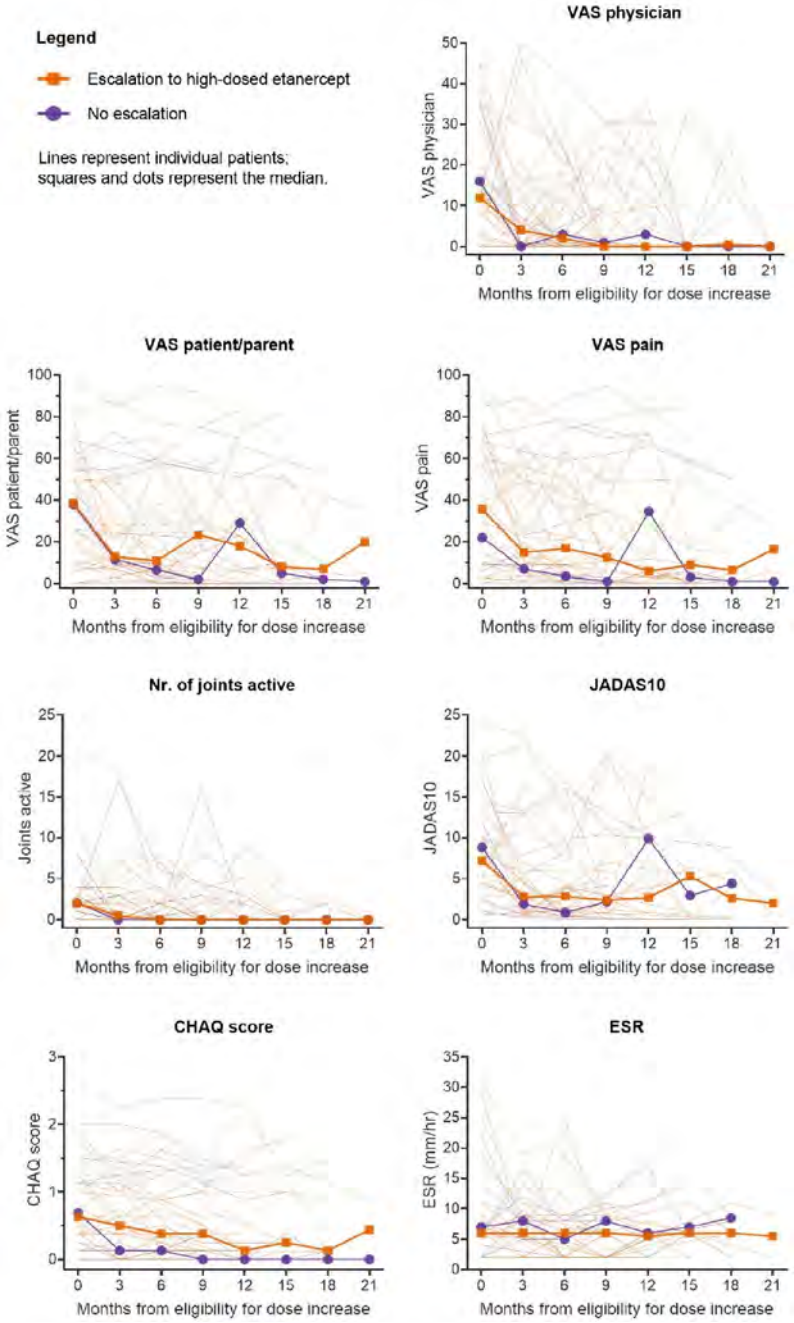
Session Time: 9:00AM–11:00AM

Background/Purpose: The relation between etanercept dose and clinical outcomes of juvenile idiopathic arthritis (JIA) is unclear. Most studies only evaluated doses up to 0.8 mg/kg/week (max 50mg/week),[1] but higher doses are often used off-label in clinical practice. An in-depth description of patients receiving such treatment is lacking. Here, we describe the clinical course of JIA-patients that received high-dose etanercept (1.6 mg/kg/week; max 50mg/week) as part of the Best4Kids trial.

Methods: In a single-blinded treatment-strategy trial, patients with oligoarticular JIA, RF-negative polyarticular JIA or juvenile psoriatic arthritis were randomised across three arms: (1) sequential DMARD-monotherapy (sulfasalazine or methotrexate (MTX)), (2) combination-therapy MTX+6 weeks prednisolone and (3) combination therapy MTX+etanercept.[2]

Figure. Clinical parameters over time after etanercept dose increase (orange) and after not escalating to high-dose etanercept despite eligiblity (purple)

Time-point zero = visit of eligibility for etanercept dose increase



A protocolised treat-to-target approach aiming for inactive disease was used during 24 months follow-up. Treatment was escalated in case of persistent disease-activity or tapered in case of inactive disease. In any treatment-arm patients could eventually escalate from regular to high-dose etanercept alongside MTX 10mg/m^2/week. For comparison we studied patients who did not receive high-dose etanercept due to decisions overriding the trial-protocol by the treating pediatrician and/or the patient/parents.

Results: Of the 94 randomised patients, 32 received high-dose etanercept (69% female, median age 6 years (IQR 4-10), median time from baseline 10 months (7-16), median dose 1.3 mg/kg/week (1.1-1.5)). Follow-up was up to 2 years from baseline (median 24.6 months). Clinical measures of disease-activity decreased largely within 3 months (Figure): median VAS-physician from 12 to 4 (p=0.022), VAS-patient/parent from 38.5 to 13 (p=0.003), VAS pain from 35.5 to 15 (p=0.030), number of active joints from 2 to 0.5 (p=0.12) and JADAS10 from 7.2 to 2.8 (p=0.008). Functional status (CHAQ-score) improved more gradually and ESR remained stable. A comparable pattern of clinical parameters over time was observed in 11 patients (73% girls, median age 8 (IQR 6-9)) who did not escalate to high-dose etanercept despite eligibility according to trial-protocol. In both the high-dose and the comparison group the percentage of patients with inactive disease 6 months after eligibility for dose-increase was 56%. In the high-dose group, 18 out of 32 patients (56%) experienced 26 infectious adverse events (AEs, on average 0.20 events per visit following dose-increase). No serious AEs (SAEs) were recorded after dose-increase. Among the 11 patients who did not receive high-dose etanercept, 4 patients (36%) subsequently experienced 5 infectious AEs (on average 0.11 events per visit); this included one SAE requiring hospitalisation.

Conclusion: Escalation to high-dose etanercept was generally followed by meaningful clinical improvement within 3 months. However, non-escalators experienced comparable improvement. These data do not suggest superior clinical outcomes after etanercept dose increase, while there was a potential trend for more (non-severe) infectious AEs. Larger studies are needed to more closely examine outcomes, adverse events and cost-effectiveness of high dose etanercept.

Abstract Number: 0361

Safety of Golimumab Dose Escalation in Pediatric Autoimmunity: A Single Institution Retrospective Experience

Leah Medrano and Alice Hoftman, David Geffen School of Medicine, UCLA, Los Angeles, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: There is limited data on pediatric golimumab dose escalation, with some data available only in the adult literature. The subcutaneous formulation is not approved for use in pediatric juvenile arthritis. The primary goal of this retrospective analysis was to evaluate for the safety of subcutaneous (SC) golimumab and intravenous (IV) golimumab at escalated doses in children and adolescents with autoimmune diseases. The secondary goal was to gain insight into the efficacy of escalated golimumab dosing in this population.

Table 1. Characteristics, medication details, and side effects of patients initiated on subcutaneous golimumab at age < 18 years and/or receiving escalated subcutaneous dosing. AOM = acute otitis media; IV = intravenous; PNA = pneumonia; SQ = subcutaneous; URI = upper respiratory infection; UTI = urinary tract infection.

	Case 3	Case 5	Case 9	Case 11	Case 12	Case 13
Age at golimumab initiation (years)	19	11	15	13	14	17

Side Effects				
Mild	None	None	None	Nausea, anorexia
Moderate	Pharyngitis, COVID-19	Bronchitis	COVID-19	None
Severe	None	None	None	None

Methods: Patients were identified by retrospective electronic medical record review from a single center pediatric rheumatology clinic. Inclusion criteria encompassed patients with a rheumatologic disease who were treated with IV or SC golimumab at escalated doses or frequency, SC golimumab in patients under the age of 18 years, or combined SC and IV golimumab regimens. IV doses were considered escalated if patients under the age of 18 years received greater than 80 mg/m2/dose or if patients 18 years or older received greater than 2 mg/kg/dose. Increased dose frequency included those receiving IV golimumab at intervals less than every 8 weeks or SC golimumab at intervals less than every 4 weeks.

Results: Thirteen patients were identified. Ten of the patients were female and the average age at initiation of golimumab was 15 years. Average duration of treatment was 28 months. Twelve patients were treated with golimumab for management of juvenile idiopathic arthritis (JIA), 4 of which had associated uveitis, and 1 patient had uveitis without JIA. Patients had insufficient response or intolerance to an average of 2 disease-modifying antirheumatic drugs (DMARDs) and 3 biologic agents or small molecule drugs before initiating golimumab. Golimumab was the first biologic agent used in 1 patient. Positive clinical response to golimumab, based on patient report and clinician assessment, was seen in 10 patients (76.9%). Three patients discontinued high-dose golimumab due to ineffectiveness and 1 discontinued golimumab due to lack of insurance coverage. None discontinued golimumab due to side effects. Mild side effects were reported in 2 patients, including hair loss, fatigue, nausea and decreased appetite. Two patients developed psoriasis after the initiation of golimumab. Mild infections that were seen during golimumab treatment in 8 patients included upper respiratory tract infections, viral gastroenteritis, urinary tract infections, and 2 lower airway infections. There were no serious adverse events.

Conclusion: Our study suggests that dose escalation of golimumab therapy, and SC golimumab administration, are well-tolerated in pediatric rheumatologic diseases and uveitis, with a safety profile similar to that of other biologic agents. Many of our patients (>70%) had positive clinical responses, suggesting that escalated doses may also be effective in patients with refractory disease.

Session Date: Sunday, November 12, 2023

Session Title: Pediatric Rheumatology – Clinical Poster I: JIA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Adverse childhood events (ACEs) are common in children. ACEs are various stressors, including, but not limited to parental incarceration or food and housing insecurity. Our previous work showed that children with arthritis were more likely to be affected by ACEs than healthy children and children with other chronic diseases. To gain a better understanding of the relationship between ACEs and disease outcomes in Juvenile Idiopathic Arthritis (JIA), we screened JIA enrollees from the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry for ACEs.

Table 1: Categorical ACE Scores and JIA Outcomes

	No ACEs	1 ACE	2-3 ACEs	≥4 ACEs	p value
JADAS (median, IQR)	1 (0, 3)	0 (0, 3)	2 (0, 3)	4 (2, 5)	0.005
Physician Global Assessment					
Minimal (n, %)	70 (69%)	21 (66%)	17 (74%)	5 (42%)	<0.001
Moderate (n, %)	20 (20%)	9 (28%)	4 (17%)	0	
Severe (n, %)	12 (12%)	2 (6%)	2 (9%)	7 (58%)	
Patient/Parent Global Assessment					
Minimal (n, %)	57 (55%)	17 (50%)	10 (40%)	2 (18%)	0.004
Moderate (n, %)	26 (25%)	10 (29%)	10 (40%)	1 (9%)	
Severe (n, %)	20 (19%)	7 (21%)	5 (20%)	8 (73%)	
CHAQ					
Minimal (n, %)	62 (65%)	21 (68%)	11 (44%)	4 (44%)	0.2
Moderate (n, %)	24 (25%)	8 (26%)	9 (36%)	2 (22%)	
Severe (n, %)	10 (10%)	2 (6%)	5 (20%)	3 (33%)	
PROMIS Global Health Index T-score (median, IQR)	42 (40, 46)	44 (40, 46)	37 (34, 43)	37 (34, 40)	0.0006
Pain Intensity (median, IQR)	1 (0, 3)	0 (0, 3)	2 (0, 3)	4 (2, 5)	0.005
PROMIS Pain Interference T-score (median, IQR)	47 (41, 54)	48 (44, 52)	57 (50, 61)	54 (48, 63)	0.005
PROMIS Mobility T-score (median, IQR)	56 (46, 59)	59 (52, 59)	47 (40, 59)	45 (38, 59)	0.1

Bivariate relationships between catgerical ACE scores and JIA outcome variables. JADAS, clinical Juvenile Arthritis Disease Activity Score; CHAQ, Childhood Health Assessment Questionnaire; PROMIS Patient-Reported Outcomes Measurement Information System. Physician and Parent Global Assessments were measured by 10-cm visual analog scales with mild, moderate, and severe defined by 25%-ile, 50%-ile, and 75%ile.

Methods: Patients and their families who met inclusion criteria and consented to the study received an ACE screen at CARRA study visits. For participants < 18 years, parents completed the screen; patients ≥18 years completed ACE screen. Demographic and JIA disease data collected in the CARRA Registry were linked to ACE screen data. ACE scores were categorized as 0, 1, 2-3, and ≥4. JIA outcomes examined included disease activity (JADAS), physical impairment (CHAQ and PROMIS Mobility), physician global assessment, patient/parent global assessment, pain intensity scale, PROMIS Pain Interference, and PROMIS Pediatric Global Health Index. Bivariate analyses were conducted to assess for associations between categorical ACE scores, demographics, clinical characteristics and outcomes. Chi-square and Fisher's exact tests were used for categorical variables and Kruskall-Wallis tests were used for continuous variables.

Results: Among 209 participants screened for ACEs, 130 (62%) had none, 38 (18%) had 1, 28 (13%) had 2-3, and 13 (6%) had ≥4. Categorical ACE scores differed by age ($p< 0.001$), race/ethnicity ($p=0.002$), household income ($p< 0.001$), parental education level ($p=0.01$), health insurance status ($p< 0.001$), Area of Deprivation Index national ranking ($p=0.01$), and estimated poverty rate by zipcode ($p=0.002$). Associations between categorical ACE scores and JIA outcomes are described in Table 1. Higher ACE scores were associated with poorer measures of disease activity (JADAS, physician and patient/parent global assessments), higher pain intensity and pain interference, and a poorer PROMIS Global Health Index. While associations with CHAQ and PROMIS Mobility scores did not meet significance, higher proportions of impaired youth were observed among youth with ACE scores of 2-3 and ≥4.

Conclusion: Higher ACE scores were associated with worse JIA outcome measures including disease activity, pain, global health, and patient/parent and physician global assessments. Further work needs to be done to see whether addressing stress around ACEs in youth with JIA can improved disease outcomes.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Refractory systemic juvenile idiopathic arthritis (sJIA) in children can be complicated by repeated episodes of macrophage activation syndrome (MAS) or sJIA-related lung disease (sJIA-LD). Use of allogenic hematopoietic stem cell transplant (HSCT) has been reported in cases of refractory SJIA; however, there is limited data regarding its use in sJIA-LD. The objective of this study was to determine clinical, inflammatory, and pulmonary outcomes 6 months post-transplant in an international cohort of patients with refractory SJIA, recurrent MAS, and sJIA-LD.

Methods: Thirteen patients with refractory sJIA who underwent allogeneic HSCT from 2018-2022 were identified and analyzed. Information regarding sJIA-related treatments prior to transplant, HSCT conditioning regimens, donor HLA matching, pulmonary function tests and chest imaging, pertinent laboratory values, and transplant complications were collected using a standardized case report form. The study was completed with IRB approval from each institution.

Results: Of the 13 patients who underwent allogeneic HSCT for refractory sJIA, 10 patients had recurrent episodes of MAS, and 9 patients had progressive sJIA-LD. All patients in this study had failed treatment IL-1 and IL-6 blockade and received an average of 8 different agents (range 5-13) prior to HSCT. Many patients had received treatment with Janus Kinase inhibitors or emapalumab. The mean maximum IL-18 level prior to HSCT was 251,398 pg/mL (range 64,840-471,860 pg/mL). Most patients received grafts from 10/10 HLA-matched unrelated donors (n=6), or 9/10 HLA matched unrelated donors (n=3). Two patients received grafts from 5/10 or 7/10 HLA-mismatched related donors. Two patients received a second transplant, one for acute graft failure after 32 days and one for relapsed sJIA after one year with donor chimerism of 100%. Post-transplant complications included graft versus host disease (5 patients), bacteremia (3 patients), HHV6 reactivation, (2 patients), EBV encephalitis, CMV reactivation, and infection-triggered MAS (2 patients). One patient died 120 days after transplant due to CMV pneumonitis and multi-organ failure, and another died at day+133 with steroid dependent graft-versus-host disease and CMV pneumonitis. Six months after final transplant, 80% (10/13) of patients showed a complete clinical response, with no active features of sJIA or MAS without any biologic therapy. All patients with available post-transplant IL-18 data had normalized levels 6 months post-HSCT. Most patients (7/9) with sJIA-LD demonstrated improvement in pulmonary function, including improvements on chest CT, reduced need for supplemental oxygen, and reduced clubbing.

Conclusion: A majority of patients who underwent allogenic HSCT for refractory SJIA, recurrent MAS, or sJIA-LD showed a complete response including improvement in clinical and imaging features of lung disease. HSCT may represent a promising approach for highly refractory sJIA and its complications.

Session Title: Pediatric Rheumatology – Clinical Poster I: JIA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The extent to which heterogeneity exists in youth with axial disease and juvenile spondyloarthritis (JSpA) is unclear. In a cross-sectional sample of patients classified as axial disease in JSpA (axJSpA) according to recently validated criteria, we tested for differences in clinical and imaging features amongst males and females.

Table 1. Clinical and imaging features of axJSpA by sex

Feature	Female (n=47) N (%) or median (IQR)	Male (n=96) N (%) or median (IQR)	P-value
Demographics			
Age at axial disease evaluation (n=142)	13.7 (12.0, 16.6)	15.2 (13.0, 17.0)	0.14
HLA-B27 (+) (n=136)	20 (44.4)	67 (73.6)	<0.01
SpA in first-degree relative (n=133)	12 (26.1)	12 (13.8)	0.08
Patient-reported symptoms			
Hip or groin pain (n=141)	25 (54.3)	66 (69.5)	0.08
Hip or groin stiffness (n=126)	12 (31.6)	49 (55.7)	0.01
Lumbar/sacral/buttock pain	37 (78.7)	75 (78.1)	0.93
Arthritis/enthesitis history and/or exam			
Enthesitis (n=136)	16 (36.4)	45 (48.9)	0.17
Peripheral arthritis (n=142)	24 (51.1)	56 (58.9)	0.37
Hip arthritis (current or past) (n=136)	19 (45.2)	46 (48.9)	0.69
Tarsitis (current or past) (n=134)	6 (14.3)	14 (15.2)	0.89
SIJ pain with deep palpation (n=127)	23 (57.5)	53 (60.9)	0.72
Abnormal CRP or ESR (n=126)			
≥1x upper limit normal	11 (26.8)	22 (25.9)	0.91
≥2x upper limit normal	12 (29.3)	41 (48.2)	0.04
Patient/physician-reported outcomes			
Patient pain VAS (n=79)	6.0 (3.0, 8.0)	6.0 (3.5, 7.0)	0.71
Patient global assessment VAS (n=73)	6.0 (3.0, 7.0)	5.0 (3.0, 7.0)	0.61
Physician global VAS (n=94)	2.5 (1.0, 5.0)	3.0 (1.0, 4.0)	0.97
MRI inflammatory/structural lesions			
Subchondral bone marrow edema	36 (76.6)	90 (93.8)	<0.01
Inflammation at site of erosion	27 (57.4)	52 (54.2)	0.71
Capsulitis	13 (27.7)	18 (18.8)	0.22
Joint space enhancement	7 (14.9)	9 (9.4)	0.33
Joint space fluid	5 (10.6)	11 (11.5)	0.88
Enthesitis outside SIJ	3 (6.4)	28 (29.2)	<0.01
Erosion	39 (83.0)	78 (81.2)	0.80
Sclerosis	18 (38.3)	48 (50.0)	0.19
Fatty lesion	6 (12.8)	12 (12.5)	0.96
Fat metaplasia in erosion cavity (backfill)	3 (6.4)	10 (10.4)	0.55
Ankylosis	0 (0.0)	4 (4.2)	0.30
Unequivocal SIJ inflammation (n=141)	36 (76.6)	88 (93.6)	<0.01
Unequivocal SIJ structural lesion(s) (n=140)	40 (87.0)	81 (86.2)	0.90
Axial arthritis in JSpA classification score (range 0-100)	76.0 (60.0, 85.0)	79.0 (68.0, 90.0)	0.07

Legend: JIA (juvenile idiopathic arthritis), SpA (spondyloarthritis), CRP (C-reactive protein), ESR (erythrocyte sedimentation rate), VAS (visual analog scale), MRI (magnetic resonance imaging), SIJ (sacroiliac joint). Sample size indicated for each variable if data incomplete. Unequivocal SIJ inflammation defined as bone marrow edema in ≥3 quadrants across all SIJ slices. Unequivocal SIJ structural lesion(s) defined as erosion in ≥3 quadrants or sclerosis or fat lesion in ≥2 SIJ quadrants or backfill or ankylosis in ≥2 joint halves across all SIJ slices (Weiss PF et al. Arthritis Care Res. 2023).

Methods: This was an international cross-sectional study of youth that met the following criteria: 1) Physician diagnosis of JSpA, 2) Symptom onset prior to age 18 years, 3) Fulfilled criteria for axJSpA. Clinical and magnetic resonance imaging (MRI) data were available from the time when axial disease was first identified; these features were compared between males and females using Pearson's chi-squared and Fisher's exact tests for categorical variables, and Wilcoxon rank-sum tests for continuous variables as appropriate. Multivariate logistic regression was used to assess the association of unequivocal inflammatory and structural lesions typical of axial disease on MRI and sex adjusted for HLA-B27 status and degree of inflammatory marker elevation.

Results: 143 patients met inclusion criteria of which 96 (67.1%) were male, 64.0% were HLA-B27 positive, and 18.1% had a family history of spondyloarthritis in a first degree relative. Clinical and imaging characteristics stratified by sex are displayed in **Table 1.** Male patients had significantly greater prevalence of HLA-B27 positivity ($p< 0.01$), hip/groin stiffness ($p=0.01$), inflammatory markers ≥2x the upper limit of normal ($p=0.04$), pelvic enthesitis ($p< 0.01$), subchondral bone marrow edema ($p< 0.01$), and unequivocal sacroiliac joint inflammation on MRI ($p< 0.01$). There were no statistically significant differences between males and females in peripheral disease manifestations (current or history of) or patient-reported measures. After adjusting for HLA-B27 status and degree of inflammatory marker elevation, the odds of unequivocal inflammatory lesions typical of axial disease (OR 5.70, 95% CI 1.51-21.59), pelvic enthesitis outside the sacroiliac joint (OR 5.92, 95% CI 1.48-23.61) and subchondral bone marrow edema (OR 4.92, 95% CI 1.38-18.12) remained significantly higher in males (**Figure 1A**) but there were no differences between sexes with respect to structural MRI lesions (**Figure 1B**). The median axial disease classification score (range 0-100, classification threshold ≥55) was not significantly higher in males.

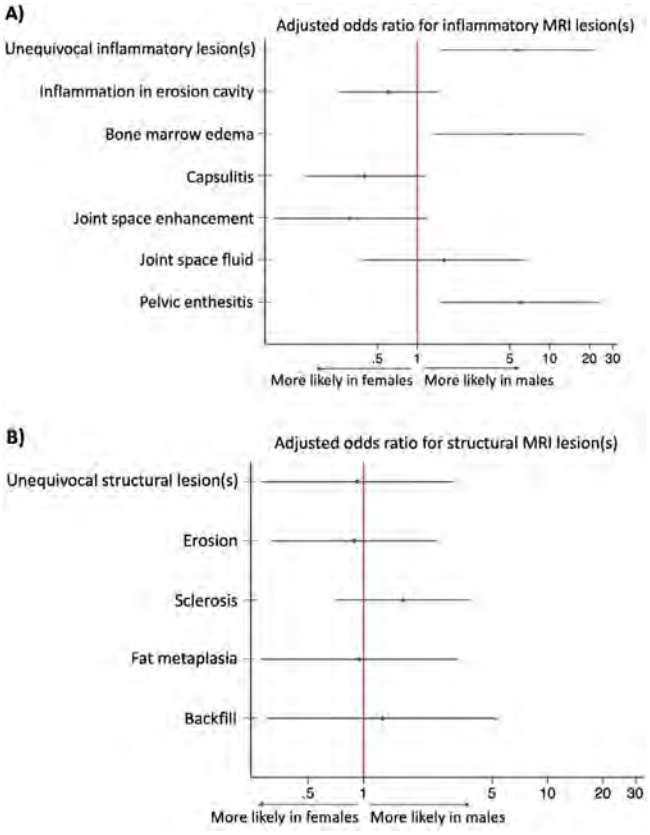

Figure 1. Association of unequivocal (A) inflammatory and (B) structural sacroiliac MRI lesions typical of axial disease and sex, adjusted for HLA-B27 status and degree of inflammatory marker elevation.

Conclusion: In patients with JSpA who met validated criteria for axJSpA the prevalence of HLA-B27 positivity, and serologic and imaging evidence of inflammation were significantly higher in males than females. Further exploration of the mechanisms underlying these differences is warranted, but our findings suggest that stratification by sex should be considered in the design of future studies in axJSpA.

Abstract Number: 0365

Establishing a Multidisciplinary Registry for Temporomandibular Joint Arthritis in Juvenile Idiopathic Arthritis: Insights into Patient Outcomes and Management Challenges

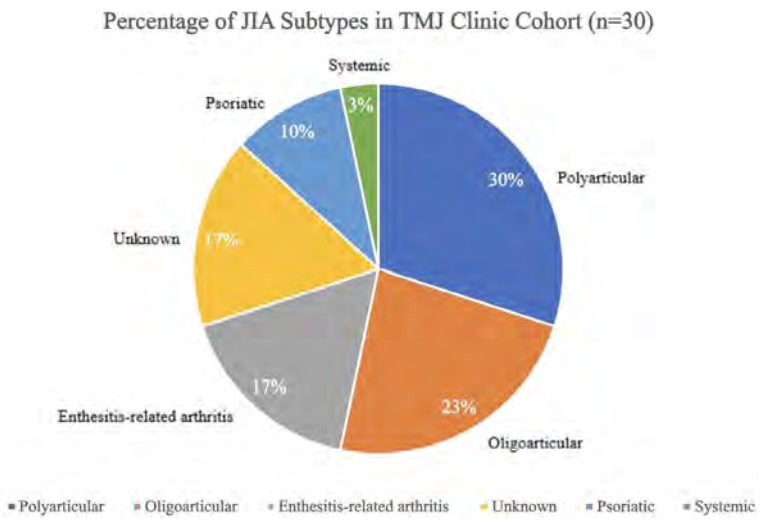
Stacey Tarvin[1], Amy Rakestraw[2], **Jessica Lee**[2], N. Shaun Matthews[3], Susan H. Ballinger[2] and Christina M. Sparks[2], [1]Riley Hospital for Children at Indiana University Health, Indianapolis, IN, [2]Indiana University School of Medicine, Indianapolis, IN, [3]Indiana University School of Dentistry, Indianapolis, IN

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

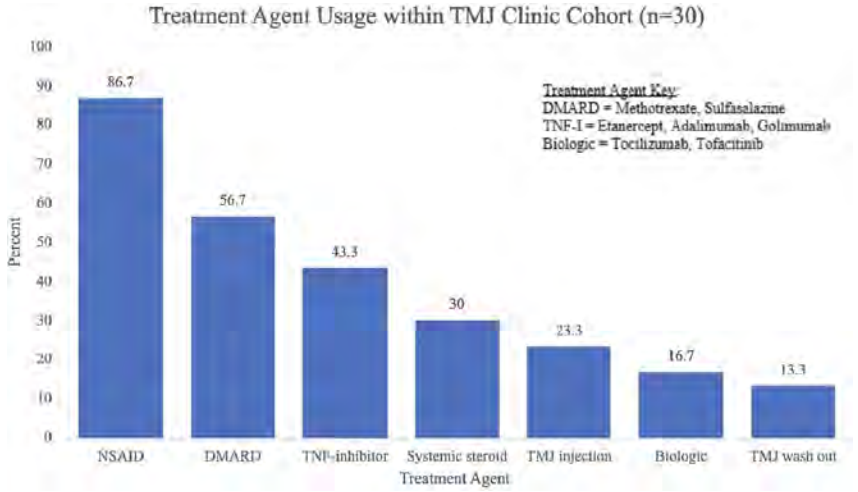
Background/Purpose: Temporomandibular joint (TMJ) arthritis, a condition frequently overlooked in patients with JIA, can result in joint damage if not promptly treated. Such damage presents as pain during joint movement and chewing, as well as mandibular growth abnormalities. Due to minimal symptoms in the early stages, timely diagnosis of TMJ arthritis is challenging without early imaging, often leading to joint damage before detection. This study aims to establish a registry specifically focusing on JIA patients with TMJ involvement. The registry operates within a multidisciplinary clinic, involving pediatric rheumatologists, neuroradiologists, oral maxillofacial surgeons, physical therapists, orthodontists, and pediatric dentists.

Methods: The study enrolled JIA patients referred to the multidisciplinary TMJ clinic for suspected TMJ involvement. Data collection took place during routine care visits, and information was obtained through a combination of prospective and retrospective chart reviews, as well as patient-reported outcomes. The data analyzed in this study were extracted from the participants' initial visit records. Quantitative data was analyzed using descriptive statistics.

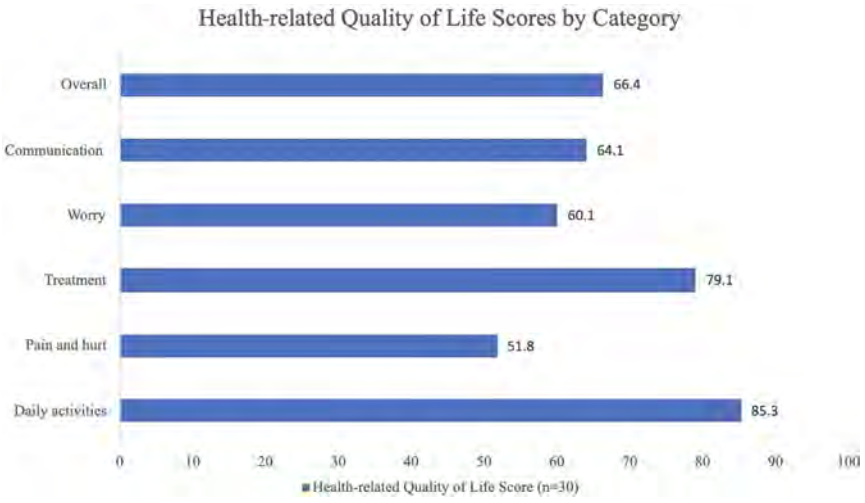
Results: Data from the multidisciplinary TMJ clinic were reviewed involving (n=30) 7 males and 23 females aged 7 to 20 years. The most common diagnoses among participants were polyarticular JIA (30%), oligoarticular JIA (23.3%), and enthesitis-related arthritis (16%) [Figure 1]. The primary reason for referral to the TMJ clinic was jaw, muscle, or neck pain, reported by 86.7% of participants. Before the referral, participants had, on average, tried 2.8 different treatment agents [-Figure 2]. Furthermore, 23.3% of participants had received prior TMJ steroid injections, and 13.3% had undergone a prior TMJ wash-out. Among the 30 patients, 21 had obtained an MRI of their TM joint within 12 months of entering the clinic. During the study visit, participants completed the Pediatric Quality of Life Inventory, a measure of health-related quality of life (HRQOL). The responses were transformed to a 0-100 scale, with higher scores indicating better HRQOL. The average score across all categories (daily activities, pain and hurt, treatment, worry, and communication) was 66.4 [Figure 3]. Participants also reported difficulties in performing various activities based on a patient-specific functional scale. A total of 56 activities were identified, and on average, patients scored 4.9 per activity on a scale of 0 to 10, with 0 indicating complete inability



Percentage of JIA subtypes in TMJ clinic cohort.



Treatment agent usage within TMJ clinic cohort.



Health-related quality of life scores by category.

to perform the activity. Overall, participants reported an average pain intensity score of 3.4/10, and 64% of patients reported affected functionality of their jaws. Additionally, 8 out of the 30 study participants expressed concerns regarding body image.

Conclusion: This data offers valuable insights by capturing outcomes from patients with TMJ arthritis. Our findings indicate that these patients endure TMJ-related pain and experience joint dysfunction that affects their quality of life. The challenges associated with TMJ arthritis highlight the importance of this registry and the ongoing observation of this clinic's cohort.

Active Joint Acoustic Emissions on the Achilles Tendon: A Digital Biomarker of Enthesitis Related Arthritis

Quentin Goossens[1], Miguel Locsin[2], Emily Moise[3], Lori Ponder[4], Omer Inan[1] and Sampath Prahalad[5], [1]Georgia Institute of Technology, Atlanta, GA, [2]Emory University School of Medicine, Atlanta, GA, [3]Georgia Institute of Technolgy, Atlanta, GA, [4]Children's Healthcare of Atlanta, Atlanta, GA, [5]Emory University School of Medicine, Children's Pediatric Institute, Atlanta, GA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile Idiopathic Arthritis (JIA) is a chronic condition in children that causes joint inflammation. Enthesitis-related arthritis (ERA), a subtype of JIA, affects 10-20% of patients and is characterized by enthesitis, leading to substantial joint pain and disability. Diagnosing JIA subtypes is challenging due to insensitive and subjective clinical examinations, patient surveys, non-specific laboratory tests and a lack of pediatric rheumatologists worldwide. Active joint acoustic emission (JAE) sensing, using vibrational stimulation, offers potential to assess the inflammatory status of soft tissues such as the Achilles tendon (AT). Integrating JAEs with machine learning (ML) algorithms can offer valuable insights into tendon health. The aim of this study is to demonstrate the utility of active JAEs as a new digital biomarker for assessing AT involvement in ERA.

Methods: JAEs were recorded from 14 patients diagnosed with JIA that were divided into two subgroups: (1)ERA and symptomatic AT enthesitis (sx ERA), and (2) without ERA and asymptomatic ATs (asx nERA). Symptomatic AT enthesitis was determined by tenderness on clinical examby a physician, while asymptomatic AT showed no tenderness, stiffness, or swelling. To record the JAEs, a setup comprising a miniature vibration motor and an accelerometer was used. The vibration motor provided a harmless input train of burst vibrations, while the accelerometer measured the response of the AT in tiptoe position. The recorded signals were filtered, and 25 bursts were segmented to extract 25 temporal features and the top 3 principal components(PC).Two MLclassifier (logistic regression) was trained using three most salient features and the second and third PCs, respectively. Two subject-wise cross-validation approaches were used to assess the model's generalizability: leave-one-subject-out cross-validation (LOSO-CV) and a 3-fold cross-validation. The latter was performed 10 times with unique combinations to evaluate robustness.

Results: The feature-based LOSO-CV resulted in an 86% accuracy, 83% sensitivity and 88% specificity. The PC-based LOSO-CV resulted in a 71% accuracy, 67% sensitivity and 75% specificity. The corresponding confusion matrices, ROC curves and boxplot of the subject scores are shown in Figure 1. The iterations of the 3-fold cross-validation when

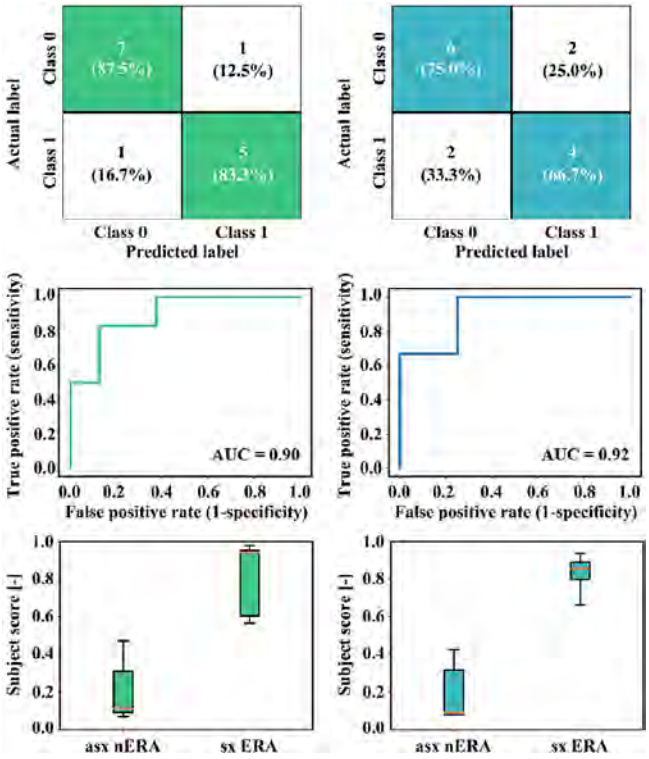

Figure 1 Results of the LOSO-CV. Top row: confusion matrices, middle row: ROC curves, bottom row: box plots of the subjects scores of the correctly predicted subjects generated by the classification algorithm. Left column shows the results of the feature-based classification, right column shows the results of the PC-based classification.

considering the feature-based approach resulted in a 79% mean accuracy (range: 71-93%), a 70% mean sensitivity (range: 50-83%) and an 86% mean specificity (range 75-100%). When considering the PC-based classification, the 3-fold validation resulted in a 76% mean accuracy (range: 64-93%) a 72% mean sensitivity (range: 67-100%) and an 80% mean specificity (range 63-100%).

Conclusion: The presented results lay the foundation in recognizing the potential utility of active JAE technology to identify and label symptomatology on the entheses of the Achilles tendon. While more work needs to be done to increase the sample size and optimize the technology by using training labels validated by gold standard technology, JAEs hold promise as a screening or disease monitoring tool that can be used in clinic or at home and that may help decrease disease morbidity caused by JIA in children.

Adolescents and Young Adults Taking Methotrexate: Knowledge and Behaviours

Matthew Sholdice[1], Heather Bollegala[1], Lauren Heessels[1], Meghan Pancucci[1], KAREN BEATTIE[1] and Michelle Batthish[2], [1]McMaster University, Hamilton, ON, Canada, [2]McMaster Children's Hospital, Hamilton, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: MTX, a first line DMARD, commonly used to treat adolescents and young adults (AYA) with rheumatic diseases (RD), can be hepatotoxic and teratogenic. AYA with RD may face challenges accessing and understanding accurate, reliable information regarding the potential harmful interactions between their medications (e.g., MTX) and certain lifestyle choices they make. The objective of this study was to determine the educational experiences, level of knowledge and informational needs and preferences of AYA taking MTX for RDs, specifically regarding alcohol use and contraception.

Methods: AYA 16-25 years old currently or previously taking MTX completed an anonymous online questionnaire co-designed by AYAs with RD. Links to questionnaires were shared in rheumatology clinics and through patient advocacy groups on social media.

Results: Of 43 respondents, 77% were female, 65% were 19-21 years of age, and 80% had a diagnosis of JIA. In assessing respondent knowledge of MTX, 21% did not know that MTX is a DMARD, 53% were not aware that MTX takes 2-4 months to achieve full effectiveness, 28% did not know that MTX can cause liver damage, and 86% agreed that alcohol should be avoided when taking MTX. The majority (79%) stated that contraception should be used if a female is taking MTX, compared to 64% for a male.

In assessing respondent behaviours, 37% report drinking an average of 1-5 alcoholic drinks weekly, 32% reported drinking ≥3 alcoholic drinks at least once/week, 56% reported that their rheumatologists ask them about their alcohol use at every visit, 21% reported discomfort discussing alcohol use with their rheumatologist, and 18% inaccurately reported alcohol use to their rheumatologist. Past or present sexual activity was reported by 56% of respondents, 93% of which report using contraception. Discomfort discussing sexual activity with their rheumatologist was reported by 28%, and 10% inaccurately reported sexual activity to their rheumatologist. Approximately one quarter were unaware that there is a risk of birth defect while taking MTX.

Respondents reported receiving information about their RD from their rheumatologist/healthcare provider, the internet, and educational pamphlets, which were also their preferred methods of receiving information. One third reported not having access to accurate information regarding managing MTX side effects.

Conclusion: Despite approximately half of AYA reporting drinking alcohol weekly and being sexually active, results suggest almost half of rheumatologists do not routinely discuss these at-risk behaviours with their patients on MTX. Approximately one quarter of respondents reported feeling uncomfortable and/or not being honest with their rheumatologist in discussing alcohol use and sexual activity. Approximately one quarter of AYA report not having access to accurate resources regarding MTX side effects and safe alcohol use. This study identified educational opportunities about MTX for AYAs which can be shared by their rheumatologist/healthcare provider and/or educational pamphlets.

Abstract Number: 0368

Surveying Psychological Resilience and Pain in a Cross-Section of JIA Patients

Daniella Schocken and Tracy Ting, Cincinnati Children's Hospital Medical Center, Cincinnati, OH

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Pain trajectories vary in JIA, with some patients developing chronic pain over the course of their illness. Adaptation and recovery under stressful or traumatic conditions, defined as "psychological resilience," correlates to symptom severity and functioning in other pediatric populations affected by chronic illness. Resilience can be enhanced by therapeutic interventions, making it a potential target for strategies to improve outcomes in disease management. However, psychological resilience has never been studied quantitatively in JIA. This study aimed to apply a validated measure to determine the resilience of children and adolescents with JIA and identify any relationships between pain and resilience in this population.

Methods: 98 children and adolescents with JIA participated in this study, completing the Connor-Davidson Resilience Scale (CD-RISC-25), the PROMIS Pediatric Pain Interference (PPI) Short Form, and the Pain and Symptom Assessment Tool (PSAT). Participants' caregivers provided information regarding participant demographics and psychiatric health history and also completed the CD-RISC-25. Chart review documented participants' case history and clinical status including JIA subtype, date of diagnosis, treatment, pain level, well-being, and active joint count during study participation. Spearman correlation coefficients were calculated to determine relationships between resilience scores and other variables, which were non-parametric. To compare resilience among subgroups of participants, Welch's t-test was used.

Results: Participant resilience scores were normally distributed between 29 and 100 with a mean of 72.93 (sd = 15.96). Comparison of CD-RISC-25 scores to participant age at time of JIA diagnosis (ρ = -0.053, p = 0.60), time elapsed since JIA diagnosis (ρ = 0.10, p = 0.31), and caregiver CD-RISC-25 score (ρ = 0.089, p = 0.38) revealed no statistically significant relationships. Correlations were identified between CD-RISC-25 scores and participants' reported numeric pain intensity rating (ρ = -0.23, p = 0.023), self-assessed well-being (ρ = -0.33, p < 0.001), and PPI (ρ = -0.48, p < 0.001). CD-RISC-25 scores were similar among participants with and without a reported history of depression or anxiety (t = -1.12, p = 0.27). However, for the 18% of participants with PSAT scores consistent with clinical features of juvenile FM (jFM), CD-RISC-25 scores were significantly lower than those seen in the remainder of the study population (t = -3.23, p = 0.0034).

Conclusion: Psychological resilience varied among study participants and was not found to correlate to age at JIA diagnosis, duration of disease, or caregiver resilience. There was no significant difference observed between levels of resilience among participants with and without a reported history of anxiety or depression. In view of the relationships observed between resilience and pain measures among study participants, the differences in resilience of participants with and without clinical features of jFM are compelling. Future research should focus on longitudinal observations to identify whether low psychological resilience may predict the development of secondary FM in JIA patients.

Trajectory of Progression in Transition Readiness in Adolescents with JIA and jSLE

Dorota Borovsky[1], Lauren Heessels[1], Tania Cellucci[2], Liane Heale[1], Julie Herrington[1], KAREN BEATTIE[1] and Michelle Batthish[2], [1]McMaster University, Hamilton, ON, Canada, [2]McMaster Children's Hospital, Hamilton, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: For adolescents, the transition from pediatric to adult rheumatology care is associated with increased health risks, poor disease control and loss to follow-up. Optimizing adolescents' ability to manage their own health independently is of utmost importance and ideally begins years before the actual transfer to adult care. Different models of transition programs to improve patient self-management skills have been proposed and implemented, but best-practices have not been identified. We aimed to assess how a multidisciplinary, patient-centred, individualized approach to improving self-management skills affects changes in transition readiness over time among adolescents with JIA and jSLE.

Methods: Patients 14-18 years old with JIA or jSLE seen in the multidisciplinary pediatric rheumatology transition clinic at McMaster Children's Hospital were invited to participate in a prospective study. At each clinic visit, patients are seen by a pediatric and adult rheumatologist together, as well as a nurse, physiotherapist, and child life specialist. Consenting patients completed the Transition-Q, a validated, self-administered 14-item questionnaire which assesses healthcare self-management skills, at consent and at follow-up (FU) clinic visits. Questionnaires are scored from 0-100 with higher scores reflecting higher skills/independence. Responses to individual questions on the TRANSITION-Q identify areas of need and, in partnership with a member of the healthcare team, goals are set for the next clinic visit. Transition-Q scores were determined at baseline and follow-up visits for all participants and then sub-grouped by age and sex. Clinical characteristics (disease duration, disease activity, quality of life) were collected at baseline.

Results: Of 79 participants who completed the Transition-Q at baseline and ≥1 follow-up, 51 (65%) were female and 64 (81%) had JIA (Table 1). Mean (SD) Transition-Q scores improved by 8.0 (12.7) points between baseline and first FU, and 5.9 (10.1) (n=36) between first and second FU. Overall, 75% of males' Transition-Q scores stayed the same or improved from the baseline to first FU compared to 80% of females. Between the baseline and second FU, 92% (n=11/12) of males improved while 96% (23/24) of females improved. Changes in Transition-Q scores for males and females over the first follow-up period are shown in Figures 1 and 2.

Table 1: Baseline Characteristics

	N	Mean (SD)
Age (years)	79	16.0 (1.2)
Disease duration (years)	69	4.0 (3.9)
Transition-Q (max 100)	79	55.9 (14.6)
Peds QL (max 100)	34	80.7 (20.0)
Physician Global Assessment (max 10)	56	0.4 (1.0)
Patient Global Assessment (max 10)	52	1.4 (2.2)
cJADAS (max 30)	43	1.7 (2.5)

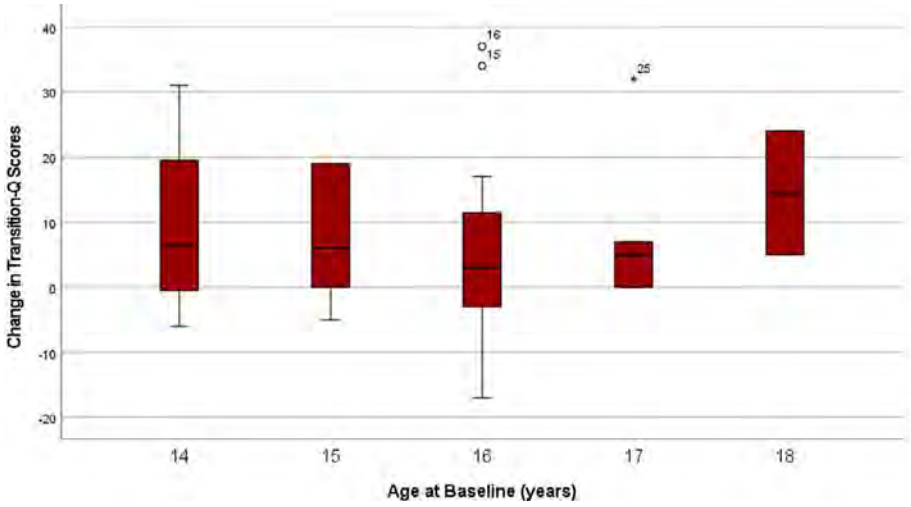

Figure 1: Change in Transition-Q Scores from Baseline to First Follow-Up in Males

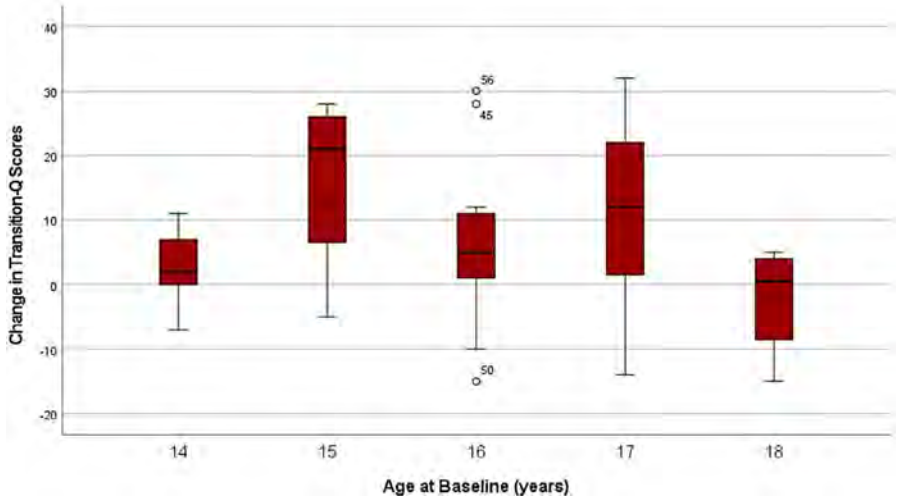

Figure 2: Change in Transition-Q Scores from Baseline to First Follow-Up in Females

Conclusion: In this sample of adolescents with low disease activity, Transition-Q scores improved over time. Males and females do not appear to have the same trajectory of improvement across age groups, and there is considerable variability in improvements within and between age groups. These results suggest that goal setting to improve self-management skills requires an individualized approach within a multidisciplinary clinic. Improvements are evident in adolescents as young as 14, and there is room for ongoing improvement even after adolescents reach 18 years when they transfer to adult care.

Clinical Disease Manifestations Associated with TNF Inhibitor Non-Response in Juvenile Spondyloarthritis

Melissa Oliver[1], Kelly Mosesso[2], Pamela F. Weiss[3], Robert Colbert[4], Matthew Stoll[5] and **Hemalatha Srinivasalu**[6], [1]Indiana University, Indianapolis, IN, [2]Indiana University School of Medicine, Indianapolis, IN, [3]Children's Hospital of Philadelphia, Philadelphia, PA, [4]NIH/NIAMS, Bethesda, MD, [5]University of Alabama at Birmingham, Birmingham, AL, [6]Children's National Hospital, Washington, DC

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Tumor necrosis factor inhibitors (TNFi) are effective in children with juvenile spondyloarthritis (JSpA) and generally represent the first-line choice for biologic therapy. However, not all JSpA patients respond well to TNFi initially (primary non-response) or respond well but lose efficacy over time (secondary non-response). Children who do not respond to initial TNF inhibition are left with limited options. We aimed to identify the clinical characteristics associated with TNFi non-response in JSpA patients.

Methods: Retrospective analysis of JSpA patients and their response to first TNFi agent enrolled in the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry between July 2015 - January 2019. JSpA population included enthesitis-related arthritis, psoriatic arthritis, and undifferentiated spondyloarthritis subtypes. Primary non-response defined as discontinuation of TNFi within the first 3 months of starting. Secondary non-response defined as 1) stopping TNFi AND 2) switching to another biologic or addition of a disease-modifying anti-rheumatic drug (DMARD). Responders were defined those continuing the first TNFi agent for duration of study. Demographic and disease characteristics were compared at 1) baseline visit prior to TNFi start and at 2) time of failure for non-responders or at 4-6 months following TNFi start for responders.

Results: Total of 287 patients met inclusion criteria; 163 TNFi responders and 124 TNFi non-responders. The majority of non-responders were secondary non-responders (91.9%). Median duration prior to initial TNFi failure for non-responders was 274.5 days (IQR:160.5, 433.5). Mean age at TNFi start was 12.5y for non-responders (SD 4.1y) and 12.4y for responders (SD 4.1y) (Table 1). Non-responders were more likely to be female compared to responders, 60.5% vs 48.5% (p=0.04). BMI was higher in non-responders compared to responders, 22.5 vs 21 (p=0.01). Non-responders had more arthritis, enthesitis and sacroiliitis at their baseline visit prior to TNFi start (Table 2) and a post-TNFi start visit (Table 3)

Table 1 Demographics by TNFi response status

Characteristic	Non-responder (N=124)	Responder (N=163)	p value
Sex, Male (n, %)	49 (39.5%)	84 (51.5%)	0.043
Age, y			0.803
Mean (SD)	12.5 (4.1)	12.4 (4.1)

compared to responders. Following initial TNFi therapy for all the non-responders, most patients switched to 2nd TNFi (60.2%), followed by DMARD (35.2%) then another biologic (4.6%).

Conclusion: JSpA patients who did not respond to initial TNFi had more active disease and more axial involvement at baseline prior to starting therapy. Additionally, the non-responders were found to have higher BMI compared to the responders.

Abstract Number: 0371

Assessing Methotrexate Adherence in JIA Using Electronic Health Record-Linked Pharmacy Dispensing Data

Dori Abel[1], David Anderson[1], Michael Kallan[2], Levon Utidjian[1], Joyce Chang[3], Chen Kenyon[1] and Sabrina Gmuca[1], [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA, [3]Boston Children's Hospital, Boston, MA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Pediatric Rheumatology – Clinical Poster I: JIA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The extent to which lack of adherence to prescribed treatment regimens contributes to differential disease outcomes in JIA – and demographic disparities in these outcomes – is unknown, largely because adherence is challenging to assess. Many methods rely on patient or caregiver report, which tend to overestimate adherence. Pharmacy dispensing data offer an objective means of assessing adherence through metrics such as the medication possession ratio (MPR), which measures the proportion of time a patient has medication available. We aimed to link medication adherence

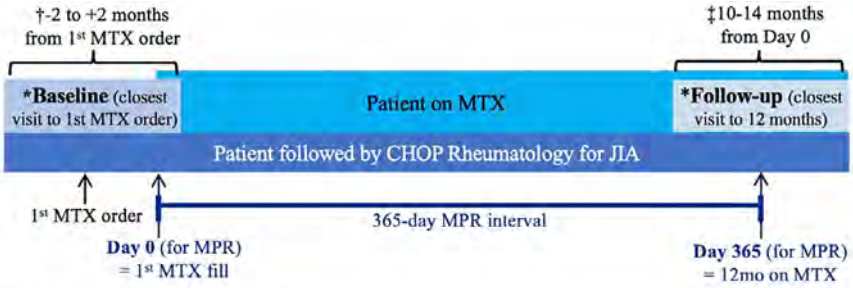

Figure 1. Study design timeline
*Visits from which disease activity data were obtained
†Patients without a visit between -2 and +2 months from the first MTX order were excluded
‡Patients without a visit between the 10- and 14-month window were excluded

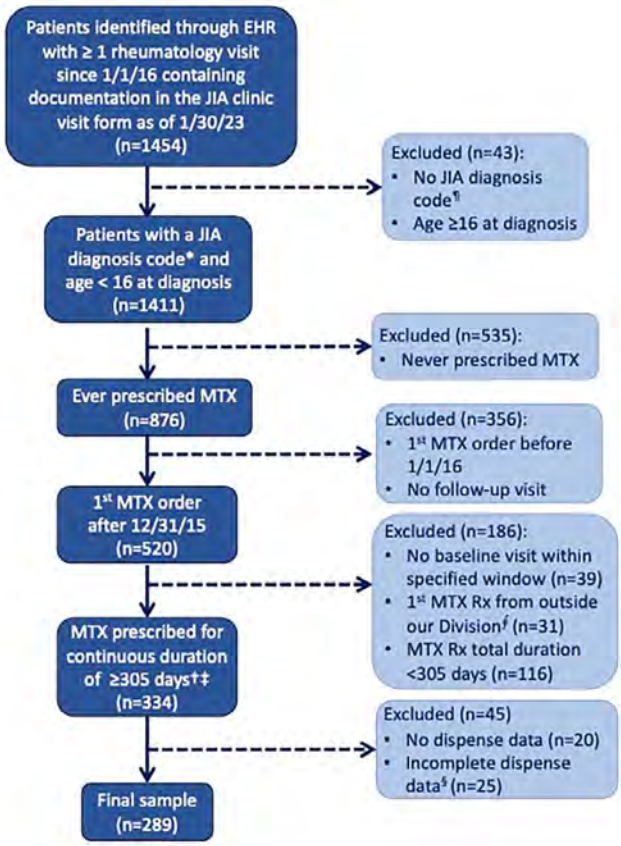

Figure 2. Flow diagram of patient selection into the study sample
*Any diagnosis code within M08, M45, or L40.5
†From prescription orders in the EHR
‡Allowing for 60 days of flexibility to account for follow-up visits that occurred at the 10-month mark
¶Patients with documentation within the JIA visit form but with diagnosis codes of IBD-associated arthritis, reactive arthritis, transient effusion, or Lyme arthritis
ǂOutside institution or different specialty (Gastroenterology, Dermatology)
§Determined by chart review of patients with > 60 days between 1st MTX order and 1st reported dispense

estimates to clinical data in the electronic health record (EHR) to investigate associations between medication adherence, disease activity, and patient characteristics.

Methods: This single-center retrospective cohort study leveraged pharmacy dispensing data from the EHR, provided by Surescripts, to calculate the MPR for MTX for patients with a physician diagnosis of JIA in a large pediatric rheumatology clinic. Surescripts is an information technology company that supports electronic prescriptions and provides this data to subscribing institutions.

All incident users of MTX, treated between January 2016 and May 2022 for ≥12 months with outpatient rheumatology visits within 2 months of the first MTX prescription and after 12 months of follow-up (±2 months) (Figure 1), were included in the sample (Figure 2). MPR was calculated using the total days' supply over a fixed 365-day interval following the initial MTX prescription fill date. Patient-level variables (Table 1), including sociodemographic factors and visit-level clinical factors from the

Table 1. Comparison of baseline characteristics and risk factors between adherence groups

[a]cJADAS = three-variable clinical Juvenile Arthritis Disease Activity Score (range 0,30); [b]Active joint count (sample range 0,33); [c]Physician global assessment of disease activity visual analog scale (range 0,10); [d]Patient/parent global assessment of disease activity visual analog scale (range 0,10); [e]Pain visual analog scale score (range 0,10)

baseline and follow-up visits, were extracted from the EHR. We dichotomized MPRs into optimal adherence (MPR ≥80%) and suboptimal adherence (MPR < 80%) groups. Patient characteristics were compared between the adherence groups using Fisher's exact test for categorical variables and the Wilcoxon rank sum test for continuous variables.

Results: A total of 289 patients were included in the analysis (Figure 2). There was a mean of 9.4 dispenses per patient (SD 3.7) within the first year. Three patients had only 1 MTX dispense reported. The mean MPR was 84.5% (SD 32.3) and the majority (57.1%) of patients were classified as having optimal adherence. Patient race, public insurance, and a lower childhood opportunity index were associated with suboptimal adherence (Table 1). There were no statistically significant associations between adherence and disease activity at baseline, JIA subtype, route of MTX, concomitant use of biologics, or presence of uveitis or a mental health diagnosis.

Conclusion: Our findings demonstrate socioeconomic disparities in adherence to MTX among a cohort of patients with JIA. This method of linking dispense data to clinical data available in the EHR offers an objective approach to assessing adherence to chronic medications, but it should be validated against other methods. Future analyses will investigate associations between patient characteristics, MTX adherence, and disease activity using multivariable models. Qualitative work exploring patient perspectives on mechanisms that influence medication adherence will inform future adherence-focused interventions.

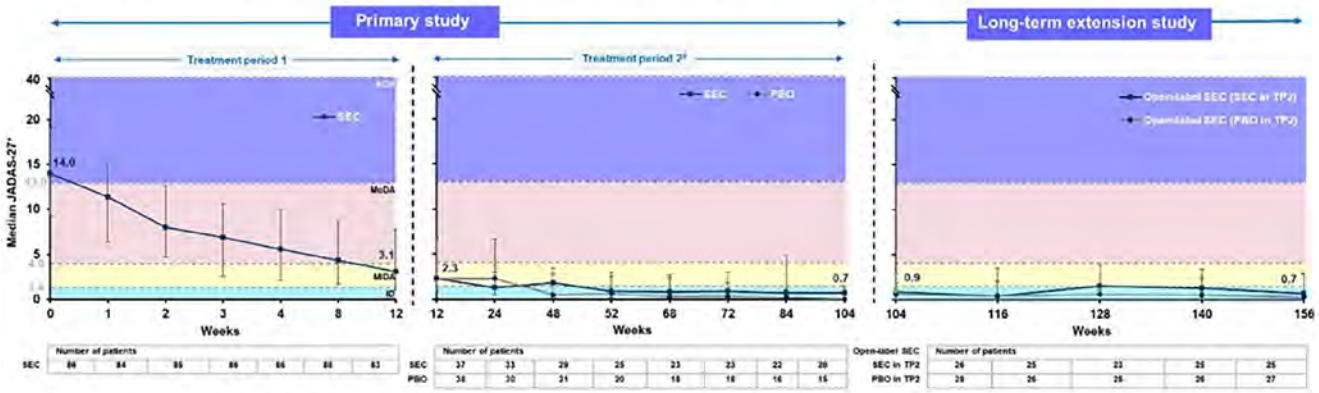
SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Secukinumab has demonstrated efficacy and safety in patients with enthesitis-related arthritis (ERA) and juvenile psoriatic arthritis (JPsA) categories of juvenile idiopathic arthritis (JIA) for up to 2 years.[1] After completion of a 2-year primary study (JUNIPERA), a long-term extension (LTE) study was conducted to evaluate the continued efficacy

Figure. Median JADAS-27 over time in the primary study (TP1 and TP2) and long-term extension study



*JADAS-27 median cut-off values[a]: ID, 0-1.4; MDA, 1.5-4.0; MoDA, 4.1-13.0; HDA, >13.0. JADAS-27 ranges from 0 to 57 (higher scores indicate more disease activity)

[a]Patients received open-label secukinumab in TP1 and were randomized to received placebo or secukinumab in TP2. Patients with placebo who flared in TP2 of the primary study entered TP3 to receive open-label secukinumab. TP2 data presented here (week 12 to week 104) include only TP2 patients.

The upper and lower error bars represent the third (Q3) and first (Q1) quartiles, respectively.

[a]Trincianti et al. *Arthritis Rheumatol*. 2021;73:1966-1975.

HDA, high disease activity; ID, inactive disease; JADAS-27, Juvenile Arthritis Disease Activity Score in 27 joints; MDA, minimal disease activity; MoDA, moderate disease activity; PBO, placebo; SEC, secukinumab; TP, treatment period.

and safety of secukinumab in patients with ERA and JPsA. Here we report the interim efficacy and safety results of the LTE study.

Methods: In the primary study, a total of 86 patients (2 to < 18 years of age) received secukinumab up to week 12 in the open-label period.[1] JIA American College of Rheumatology (ACR)30 responders at week 12 (n=75) were subsequently randomized to secukinumab (n=37) or placebo (n=38) up to week 100 in study period 2. Those who flared after randomization (secukinumab, n=10; placebo, n=21) received open-label secukinumab in study period 3 up to week 100.[1] A total of 55 of 61 patients who had completed the primary study consented to enter the LTE study, among which 54 patients received secukinumab (subcutaneous; 75/150 mg in patients < 50/≥50 kg) every 4 weeks up to 4 years. Patients whose signs and symptoms were not fully controlled, as judged by the investigator in the LTE study, could have dose escalation of their secukinumab dose from 75 mg to 150 mg or 150 mg to 300 mg. Median Juvenile Arthritis Disease Activity Scores (JADAS)-27 were presented up to week 156 for efficacy, and adverse events (AEs) and serious AEs were presented for the entire treatment period up to the cut-off date (02-Feb-2022).

Results: JADAS-27 in the primary study and in the LTE study are presented in the **Figure**. A total of 19 patients had dose escalation in the LTE study: 8 patients from 75 mg to 150 mg and 11 patients from 150 mg to 300 mg. The overall exposure-adjusted incidence rate per 100 patient-years (PY) of treatment-emergent AEs was 98.4 PY in the entire JIA population. The most commonly reported AEs were nasopharyngitis (n=9, 16.7%) and arthralgia (n=8, 14.8%). One major adverse cardiovascular event, not related to the study drug, and 2 cases of uveitis were reported. No cases of Crohn's disease or deaths were reported, and no patient discontinued treatment due to an AE.

Conclusion: With secukinumab treatment, the JADAS-27 inactive disease status was sustained from week 104 to week 156 in patients with JIA who had completed the 2-year primary study and enrolled in the LTE study. Safety data were consistent with adult and pediatric indications, with no new or unexpected safety signals.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Children with oligoarticular JIA are at increased risk of developing uveitis. JIA category, ANA positivity, ≤4 years JIA duration, and < 6 years old at diagnosis are known risk factors. Regular ophthalmic examination is important for screening since uveitis is asymptomatic. Tear fluid is easily obtained and has been used for biomarker studies. This pilot study aims to identify potential tear-based inflammatory markers that can differentiate children with JIA who develop uveitis.

Methods: This prospective cohort study at Cincinnati Children's compared children with JIA-associated uveitis (JIA-U) and JIA without uveitis (JIA-no-U) with oligoarticular subtype. Medical charts were reviewed for demographics, uveitis characteristics, ophthalmic examination, and current treatment. Tear fluid was collected by Schirmer strips. We used advanced proteomic strategies (isobaric tag for relative quantitation [iTRAQ] labeling and nanoLC-MS/MS) to quantify proteins in the left eye of patients with JIA-U and JIA-no-U in duplicate. In those with unilateral JIA-U, the affected eye was used. We reported the log of the mean of the ratios derived from two abundance readings per protein for each subject. Based on a Wilcoxon rank sum exact test we considered a P-value < 0.1 to be significant.

[A]Values determined per SUN criteria, *JIA-U* JIA-associated uveitis, *JIA-no-U* JIA without uveitis; ns: non significant. List of abbreviations: JIA-U: juvenile idiopathic arthritis-associated uveitis, JIA-no-uveitis: JIA without uveitis, YRS: years, N: number

Results: Tear samples of 28 JIA patients were collected (14 JIA-U and 14 JIA-no-U). Demographic and clinical characteristics are summarized (Table 1). Thirteen proteins exhibited differences in tears of 14 children with JIA-U and 14 with JIA-no-U (Table 2). Of these, 8 showed a difference at $p \leq 0.05$. All the proteins were higher in the group of JIA-no-U except for cathepsin D. Cathepsin D and Transitional endoplasmic reticulum ATPase have been associated with the retinal pigment epithelium (RPE) and maintaining the blood-retinal barrier (BRB). As 39% of patients had active arthritis at the time of tear collection, we stratified the analysis by arthritis activity as joint inflammation could affect the presence and level of inflammatory mediators (Table 3). A larger number of proteins differentiated patients with JIA-U and JIA-no-U p who had inactive arthritis (Table 3). Specifically, complement 3, apolipoprotein, S100 proteins, transthyretin, and beta-2 microglobulin have been associated with uveitis.

Conclusion: Uveitis is a vision-threatening disease that warrants exploration of techniques for early detection and treatment. The eye is an immune-privileged organ immunologically shielded by the RPE as part of the BRB. We hypothesize that the immune response proteins identified within the tears of JIA-U patients are by-products of inflammation-induced RPE and BRB breakdown, promoting the inflammatory cascade. Tears of children with JIA-U and JIA-no-U display differential expression of proteins, but it seems to be influenced by arthritis activity. Further study in larger cohorts is needed to verify these results.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Pediatric Rheumatology – Clinical Poster I: JIA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile idiopathic arthritis (JIA) is the most common chronic inflammatory rheumatic disease of childhood and most children require long-term treatment. Adverse events (AE) during treatment may negatively influence disease control and quality of life, and may result in permanent harm.

Table 1. Demographics of patients included in the study

Number of patients	721
Female, n (%)	429 (61.2)
Mean age at baseline	9
JIA category, n (%)	
Oligoarthritis	321 (44.5)
Polyarthritis rheumatoid factor negative	131 (18.2)
Polyarthritis rheumatoid factor positive	26 (3.6)
Enthesitis-related arthritis	116 (16.1)
Systemic arthritis	31 (4.3)
Psoriasis arthritis	46 (6.4)
Undifferentiated arthritis	50 (6.9)
Medications, calculated per visit, no. (%)	
Naproxen	1691 (37.6)
Other NSAID	455 (10.1)
MTX PO	957 (21.3)
MTX SC	1041 (23.1)
Other DMARD	137 (3)
Biologics	967 (21.5)
Systemic glucocorticoids	304 (6.8)
Ocular corticosteroids	128 (2.8)
No Medication	841 (18.7)

NSAID, nonsteroidal anti-inflammatory drug; MTX, methotrexate; DMARD, disease modifying anti-rheumatic drug

In this study, we aim to describe the frequency, seriousness and consequences of physician reported actionable AE in an inception cohort of children with JIA, the Canadian Alliance of Pediatric Rheumatology Investigators (CAPRI) JIA Registry.

Methods: For this study, registry data were extracted on December 18, 2021. Recruitment into the CAPRI JIA registry began in February 2017 to prospectively collect information on children within 3 months of JIA diagnosis at 16 participating sites. Core data were collected at every clinic visit including information on actionable AE since previous visit reported by clinicians. An actionable AE was defined as any untoward medical occurrence that requires additional medical visits, investigations, treatment, or a change in arthritis medications, irrespective of its cause. A serious AE was defined as an event that results in death, is life-threatening, requires hospitalization, or results in a significant disability or a congenital anomaly (or requires medical intervention to prevent these).

Results: Patients included in the study were comparable to Western JIA inception cohorts (Table 1). Actionable AE were reported in 261 out of 721 patients (36.2%) at 478 of 4503 visits (10.6%), during a total observation period of 1,207 patient years. The AE rate was 39 per 100 patient years. The serious AE rate was 2.9 events per 100 patient years. The probability that a patient newly diagnosed with JIA will develop an AE during the first year after diagnosis was 34% (95% CI 30-38, Kaplan-Meier estimate). Interestingly, for 67 (25.7%) patients an AE was reported at the study enrolment visit. Most patients (60%) had only 1 visit with an AE but some had multiple visits (range 1-8). The most frequent reported AE were gastrointestinal, primarily nausea and vomiting (n=217, 45.4% of all AE) and abdominal pain (n=51, 10.7%). There were 34 serious AE in 27 patients. The most frequent serious AE were infections with hospitalization (n=9, 0.75 per 100 patient-years), followed by eye surgery (n=5) and gastrointestinal bleed (n=4). There were no reported deaths, malignancies, demyelinating diseases or tuberculosis. More than half (53.8%) of the visits with a reported AE were in patients receiving non-steroidal anti-inflammatory drug (NSAID) either alone or in combination with other medications, most frequently if the combination was

Table 2. List of actionable adverse events

List of adverse events	All/Serious
Most common and/or serious adverse events grouped by system	
Gastro-intestinal symptoms	**315/7**
Nausea/vomiting	217/2
Abdominal pain	51/0
GI bleed	15/4
Epigastric pain	11/0
Mouth ulcers	10/0
Diarrhea	9/0
Appendicitis	1/1
Behavioral symptoms	**39/2**
Mood changes	15/0
Fatigue	8/0
Headaches	7/0
Dizziness	7/0
Anxiety	5/1
Depression	1/1
Cutaneous symptoms	**27/2**
Rash	18/1
Facial edema	2/1
Infections	**14/0**
Musculo-skeletal symptoms	**7/2**
Joint injury	4/1
Fractures	2/1
Respiratory symptoms	**7/1**
Hemoptysis	2/1
Endocrine/metabolic symptoms	**6/3**
Adrenal suppression	2/2
Diabetes type 1	1/1
Laboratory abnormality	**53/2**
Abnormal liver function	28/0
Abnormal blood counts	21/1
Elevated PTT	1/1
Special events	
Anaphylaxis	--
Infection with hospitalization	9/9
Tuberculosis	--
Opportunistic infection	--
Demyelinating disease	--
IBD	1/1
Malignancy	--
GI perforation	--
Complications	
Eye surgery	6/5
Joint surgery	1/0
Macrophage activation syndrome	1/0

with methotrexate. The most common action taken by the clinician reporting an AE was additional treatment (n= 171, 35.8%), followed by stopping medication (n= 122, 25.5%), and by changing dose or route of medication (n= 93, 19.5%).

Conclusion: In our cohort, actionable AE were reported in over a third of JIA patients, but serious AE were rare. Most AE were gastrointestinal and managed with additional treatment. Increasing awareness to these actionable AE is important to improve health outcomes of patients with JIA.

Abstract Number: 0375

Treatment of Methotrexate Intolerance in Juvenile Idiopathic Arthritis Using Eye Movement Desensitization and Reprocessing (EMDR) Can Be Improved by Bi-lateral Alternating Stimulation Tactile (BLAST) Armbands

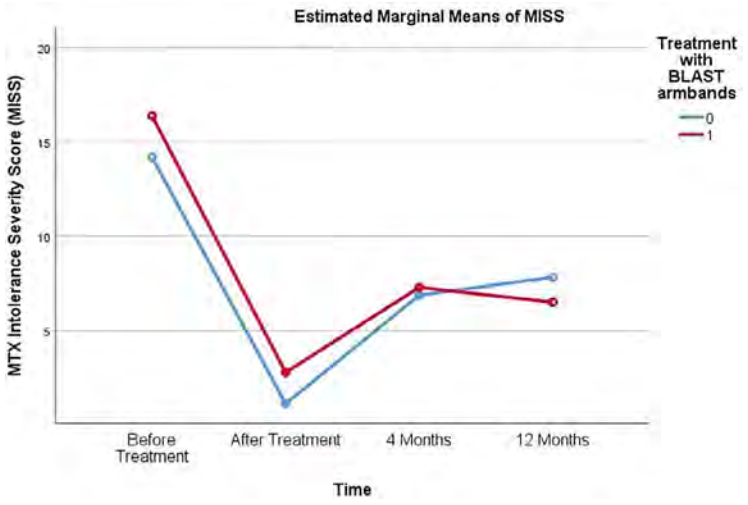
Lea Höfel, Bruno Eppler, Johannes-Peter Haas and **Boris Hugle**, German Center for Pediatric and Adolescent Rheumatology, Garmisch-Partenkirchen, Germany

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Methotrexate (MTX) is commonly used in the treatment of children with juvenile idiopathic arthritis (JIA), and intolerance to the drug frequently leads to discontinuation due to anticipatory and associative gastrointestinal symptoms. Eye Movement Desensitization and Reprocessing (EMDR) is a psychotherapy which has been successfully used in MTX intolerance, however with diminishing efficacy over time. BLAST (bi-lateral alternating stimulation tactile) armbands utilize a similar process to EMDR and have already been used in conjunction with this method.

The aim of this study was to determine if utilization of BLAST armbands could improve and prolong the effect of EMDR on patients with MTX intolerance.

Methods: Consecutive patients admitted to the German Center for Pediatric and Adolescent Rheumatology from October 2016 until March 2023 were included in this study. Inclusion criteria were 1) diagnosis of JIA according to ILAR criteria, 2) age between 8 and 17 years, 3) symptoms of MTX intolerance using the Methotrexate Intolerance Severity Score (MISS) questionnaire and 4) necessity of MTX treatment for at least 6 more months as determined by the treating physician. The standard 8 phase EMDR protocol was adapted for the treatment of MTX intolerance. Treatment started with a structured psychosocial and medical history. Subsequently, five sessions lasting 60 minutes each were held over a time period of 10 – 12 days, concluding with an application of MTX in a clinical setting. The initial 50 patients were treated only with EMDR, as previously published (Höfel et al. Pediatric Rheumatology (2018) 16:11). Subsequent patients were treated with EMDR and BLAST armbands which patients continued to use after the initial treatment sessions.



Estimated marginal means of MISS values over time in the two groups of patients with MTX-Intolerance, treated (1) or not treated (0) with BLAST armbands.

Health-related quality of live was determined using the PedsQL. Measurements of MISS and PedsQL were taken at 4 time points: directly before and after (MISS only) treatment, as well as 4 and 12 months after treatment. Changes in MISS and PedsQL were compared using descriptive statistics and repeated measures ANOVA.

Results: 93 patients with MTX intolerance [median MISS at inclusion: 14 (range 6 - 26)] were included, 50 in group 1 without BLAST armbands and 43 in group 2 which were concurrently treated with BLAST armbands. Directly after treatment, all patients reported marked improvement of MTX intolerance symptoms [group 1: median MISS: 1 (0 – 6), group 2: median MISS: 2 (0 – 11)]. Four months after treatment, median MISS score in group 1 was 5.5 (0-26), and 5 (0-25) in group 2. After 12 months median MISS was 8 (0-33) in group 1, and 6 (0-17) in group 2. A repeated measures ANOVA showed a significant difference between the MISS results ($F(3,105) = 53.7$, $p = .000$). Median quality of life as measured by the PedsQL rose after 12 months from 79.4 to 87.0 in group 1, and from 72.7 to 91.3 in group 2.

Conclusion: Treatment with Eye Movement Desensitization and Reprocessing (EMDR) presents an effective treatment of MTX intolerance, and further significant improvement can be achieved using BLAST armbands. This can facilitate continuation of MTX treatment in patients with MTX intolerance and has the potential to significantly increase quality of life in affected children.

Switching Patterns of Biological and Targeted Synthetic Therapies in Juvenile Idiopathic Arthritis

Daniel clemente Garulo[1], Alina Lucica Boteanu[2], Laura Trives Folguera[3], Antía Asunción García Fernández[2], lydia Abasolo[4], Leticia Leon[5], Juan Carlos López Robledillo[6] and Juan carlos Nieto-Gonzalez[7], [1]Pediatric Rheumatology Unit, Hospital Niño Jesús, Madrid, Spain, [2]Hospital Universitario Ramon y Cajal, Madrid, Spain, [3]Hospital Universitario Infanta Sofía, Madrid, Spain, [4]Hospital Clínico San Carlos, Madrid, Spain, [5]Fundación Investigación Biomédica Hospital Clínico San Carlos, Madrid, Spain, [6]Hospital Universitario Niño Jesus, Madrid, Spain, [7]Servicio de Reumatología, Hospital General Universitario Gregorio Marañón, Madrid, Spain

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: New therapies have improved the therapeutic management of juvenile idiopathic arthritis (JIA), allowing disease control in cases that are refractory or intolerant to methotrexate. However, satisfactory disease control is not achieved in all patients with the first biological and targeted synthetic therapies (ts/bDMARDs) and need switching to another. The choice of ts/bDMARDs for switching is made on an individual basis and influenced by several reasons, mainly the indication for each JIA category, but also previous drug discontinuation causes, concomitant therapy, and comorbidities. Therefore, clinicians are increasingly familiar with the clinical profiles of this treatments and the evidence in halting disease progression. In this study, we aimed to obtain information from real clinical practice about the management of JIA patients to characterize the trends in biologic utilization and switching among JIA categories.

Methods: We conducted a multicentre, observational, longitudinal study of JIA patients, following International League of Associations for Rheumatology (ILAR) classification categories: a) oligoarthritis; b) rheumatoid factor (RF) positive polyarthritis; c) RF negative polyarthritis; d) systemic arthritis; e) psoriatic arthritis; f) enthesitis-related arthritis. Our outcome measure was 'switch' (defined as ≥ 2 ts/bDMARDs courses for therapy). The independent variable was exposure to ts/bDMARDs including: a) TNF inhibitors (infliximab, adalimumab, etanercept, certolizumab, golimumab); b) Other bDMADRs: anti-IL6 (tocilizumab); anti-CTLA4 (abatacept); anti-IL1 (anakinra, canakinumab); anti-IL17 (secukinumab); anti-IL12/23 (ustekinumab); anti-CD20 (rituximab) c) tsDMARDs (tofacitinib). We did a descriptive analysis of the switching, stratified by JIA categories. We also did a bivariate analysis of variables associated with "difficult-to-treat" JIA (≥2ts/bDMARDs with different mechanisms of action)

Table 1. ts/bDMARDs courses and switch among JIA categories.

Oligoarthritis (n=215) N (%)	RF positive polyarthritis (n=16) N (%)	RF negative polyarthritis (n=65) N (%)	Enthesitis-related arthritis (n=39) N (%)	Systemic arthritis(n=44) N (%)	Psoriatic arthritis (n=24) N (%)	
1st ts/bDMARD •Anti-TNF : 99 (100) •Other bDMARDs: 0 •JAKi: 0	1st ts/bDMARD •Anti-TNF : 11 (85) •Other bDMARDs: 2 (15) •JAKi: 0	1st ts/bDMARD •Anti-TNF : 45 (98) •Other bDMARDs : 1(2) •JAKi: 0	1st ts/bDMARD •Anti-TNF : 16 (100) •Other bDMARDs : 0 •JAKi: 0	1st ts/bDMARD •Anti-TNF : 10 (34) •Other bDMARDs : 19 (66) •JAKi: 0	1st ts/bDMARD •Anti-TNF : 21 (100) •Other bDMARDs : 0 •JAKi: 0	
2nd ts/bDMARD •Anti-TNF : 20 (80) •Other bDMARDs : 5 (20) •JAKi: 0	2nd ts/bDMARD •Anti-TNF : 1 (33) •Other bDMARDs : 2 (67) •JAKi: 0	2nd ts/bDMARD •Anti-TNF : 9 (60) •Other bDMARDs : 6 (40) •JAKi: 0	2nd ts/bDMARD •Anti-TNF : 5 (83) •Other bDMARDs : 1 (17) •JAKi: 0	2nd ts/bDMARD •Anti-TNF : 1 (9) •Other bDMARDs : 10 (91) •JAKi: 0	2nd ts/bDMARD •Anti-TNF : 5 (100) •Other bDMARDs : 0 •JAKi: 0	1th switch or 2nd course (n=65)
3nd ts/bDMARD •Anti-TNF : 4 (80) •Other bDMARDs : 0 •JAKi: 1 (20)	3nd ts/bDMARD •Anti-TNF : 2 (100) •Other bDMARDs : 0 •JAKi: 0	3nd ts/bDMARD •Anti-TNF : 4 (67) •Other bDMARDs : 2 (36) •JAKi: 0	3nd ts/bDMARD •Anti-TNF : 1 (100) •Other bDMARDs : 0 •JAKi: 0	3nd ts/bDMARD •Anti-TNF : 1 (17) •Other bDMARDs : 5 (83) •JAKi: 0	3nd ts/bDMARD •Anti-TNF : 2 (100) •Other bDMARDs : 0 •JAKi: 0	2nd switch or 3rd course (n=22)
4nd ts/bDMARD •Anti-TNF : 0 •Other bDMARDs: 1 (100) •JAKi: 0	4nd ts/bDMARD •Anti-TNF : 0 •Other bDMARDs : 0 •JAKi: 1 (100)	4nd ts/bDMARD •Anti-TNF : 0 •Other bDMARDs : 1 (100) •JAKi: 0	4nd ts/bDMARD •Anti-TNF : 0 •Other bDMARDs : 0 •JAKi: 0	4nd ts/bDMARD •Anti-TNF : 2 (67) •Other bDMARDs : 1 (33) •JAKi: 0	4nd ts/bDMARD •Anti-TNF : 1 (50) •Other bDMARDs : 1 (50) •JAKi: 0	3rd switch or 4th course (n=8)
5nd ts/bDMARD •Anti-TNF : 0 •Other bDMARDs : 1 (100) •JAKi: 0	5nd ts/bDMARD •Anti-TNF : 0 •Other bDMARDs : 0 •JAKi: 0	5nd ts/bDMARD •Anti-TNF : 0 •Other bDMARDs : 0 •JAKi: 0	5nd ts/bDMARD •Anti-TNF : 0 •Other bDMARDs : 0 •JAKi: 0	5nd ts/bDMARD •Anti-TNF : 0 •Other bDMARDs : 0 •JAKi: 0	5nd ts/bDMARD •Anti-TNF : 0 •Other bDMARDs : 1 (50) •JAKi: 0	4th switch or 5th course (n=2)

Results: In our cohort of 403 patients with JIA, the mean age at onset was 5.80 ± 4.46 years and 65.84% were females. A total of 235 (58.17%) patients received a bDMARD, with a total of 321 courses. Globally, TNF inhibitors were the most used bDMARDs, with 260 (81%) courses of treatment, although in systemic JIA, as expected, anti-IL1 and anti-IL6 were most used (Table 1). 28% of patients switched bDMARDs and we found a total of 97 ts/bDMARD switches. Of these, 28 (7%) patients met the definition of difficult-to-treat JIA patients. Our analysis identified that systemic JIA was the category with more changes among mechanisms of actions of ts/BDMARDs (p=0.001), representing 39% of the total switches. Long-term disease was also associated with high switching between ts/bDMARDs (p=0.01). Stratified analysis revealed distinct switching patterns in the different JIA categories (Table 1).

Conclusion: In this cohort, approximately a quarter of patients did not respond to the initial ts/bDMARD and need switching to another ts/bDMARD. Our stratified analysis found that the JIA category defines the choice of ts/bDMARD and treatment sequences. This real-world data study can give useful information about treatment patterns and trend for switching in routine clinical practice.

Disease Activity and New Medication Start at Two Consecutive Registry Visits for Patients with Juvenile Idiopathic Arthritis

Melissa Mannion[1], Monica Aswani[2], Kristine Hearld[2], Emily Smitherman[2], Livie Huie[3] and Jeffrey R Curtis[4], [1]University of Alabama at Brimingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]University of Alabama at Birmingham, Gardendale, AL, [4]Division of Clinical Immunology and Rheumatology, University of Alabama, Birmingham, AL

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The goal of treatment for patients with juvenile idiopathic arthritis (JIA) is inactive or minimal disease activity and escalating medication for active disease is recommended. The goal of this analysis is to assess patterns of disease activity at 2 sequential registry visits and associated new medication start.

Methods: Patients with JIA enrolled in the Childhood Arthritis and Rheumatology Research Alliance Registry, a North American multicenter registry, with complete clinical Juvenile Arthritis Disease Activity Scores (cJADAS) at the 6 month and 12-month registry visits were included. Disease activity at each visit was classified according to cJADAS categories (inactive, minimal, moderate, or high) for either oligo- or polyarticular disease course, regardless of JIA categorization. Patient characteristics were determined at the 12-month Registry visit. The primary outcome was new medication (methotrexate or biologic) start at the 12-month visit determined by a clinical site attestation. Stratifying by the respective pairings of 6- and 12-month cJADAS categories, we examined the association between paired cJADAS values, disease activity, and medication changes.

Table 1: Characteristics of patients with JIA by disease activity patterns at 2 consecutive (6-month and 12-month) registry visits. Values are n (row proportion).

	"Persistent Inactive/Minimal" at both visits (60%)	"Improved" Moderate/High then Inactive/Minimal (12%)	"Worsening" Inactive/Minimal then Moderate/High (10%)	"Persistent Moderate/High" at both visits (18%)
New medication start at 6 month visit				
No	1762 (56%)	639 (20%)	232 (7%)	500 (16%)
Yes	22 (12%)	35 (19%)	40 (22%)	89 (48%)
New medication start at 12 month visit				
No	1724 (54%)	648 (21%)	251 (8%)	534 (17%)
Yes	60 (37%)	26 (16%)	21 (13%)	55 (34%)
Sex				
Male (28%)	515 (56%)	176 (19%)	70 (8%)	164 (18%)
Female (72%)	1269 (53%)	498 (21%)	202 (8%)	425 (18%)
Race/Ethnicity				
White (77%)	1424 (55%)	509 (20%)	202 (8%)	435 (17%)

Decline to Answer (1%)	25 (61%)	5 (12%)	4 (10%)	7 (17%)
ILAR Category				
Oligoarticular (36%)	692 (59%)	227 (19%)	97 (8%)	164 (14%)
RF- polyarticular (31%)	541 (53%)	224 (22%)	80 (8%)	184 (18%)
ERA (10%)	134 (41%)	68 (21%)	36 (11%)	89 (27%)
Psoriatic (8%)	137 (51%)	53 (20%)	25 (9%)	56 (21%)
Systemic (7%)	160 (65%)	38(16%)	17 (7%)	30 (12%)
RF+ polyarticular (6%)	73 (40%)	46 (25%)	13 (7%)	50 (27%)
Undifferentiated (2%)	30 (53%)	11 (19%)	3 (5%)	13 (23%)
ILAR – International League of Associations for Rheumatology, RF – rheumatoid factor, ERA – enthesitis related arthritis, Inactive/Minimal disease activity is clinical Juvenile Arthritis Disease Activity Score (cJADAS) <=4 for oligoarticular course and <=5 for polyarticular course, Moderate/High disease activity is cJADAS >4 for oligoarticular course and >5 for polyarticular course				

Results: Our sample included 3325 patients with JIA: 72% were female, 77% were white, 91% were from the US, and two-thirds had oligoarticular (36%) or rheumatoid factor (RF)- polyarticular JIA (31%). The patterns of disease activity across paired visits were: 54% persistent inactive/minimal, 18% persistent moderate/high, 20% "improved" (moderate/high then inactive/minimal), and 8% "worsening" (inactive/minimal then moderate/high)(Table 1). Only 6% of all patients had a new medication start attested after the 6-month Registry visit and 5% at the 12-month visit. A higher percentage of patients with moderate/high disease activity at the 12-month visit started a new medication (9%) compared to those with inactive/minimal disease activity at the 12-month visit (3%) (X^2 $p< 0.0001$). Of those starting a new medication at the 12-month visit, 37% had persistent inactive/minimal disease activity. Notably, 91% of patients with persistent moderate/high disease activity had no medication change at the 12-month visit.

Conclusion: In a large multicenter registry of patients with JIA, starting a new medication was more common for those with moderate/high disease activity at the 12-month visit, but was still uncommon overall. Interestingly, starting a new medication occurred for some patients with persistent inactive/minimal disease and did not occur for most patients with persistent moderate/high disease activity. Our findings suggest that starting a new medication is not driven by longitudinal disease activity scores. Further study is needed to identify reasons for treatment non-escalation among patients with persistent moderate or high disease activity.

Characteristics of Macrophage Activation Syndrome in Systemic JIA Patients Receiving Anakinra as First-line Treatment

Remco Erkens[1], Laura Huber[1], Anouk Verwoerd[1], Greta Rogani[1], Dieneke Schonenberg-Meinema[2], Merlijn van den Berg[2], Wineke Armbrust[3], Elizabeth Legger[4], Sylvia Kamphuis[5], Ellen Schatorjé[6], Esther Hoppenreijs[7], Joost Swart[8], Marc Jansen[1], Jorg van Loosdregt[1] and Sebastiaan Vastert[1], [1]University Medical Center Utrecht, Utrecht, Netherlands, [2]Emma Children's Hospital, Amsterdam University Medical Centers, Amsterdam, Netherlands, [3]University Medical Hospital Groningen, Groningen, Netherlands, [4]University Medical Center Groningen, Groningen, Netherlands, [5]Erasmus University Medical Center, Department of Pediatric Rheumatology, Rotterdam, Netherlands, [6]University Medical Center Radboud, Nijmegen, Netherlands, [7]Radboud University Medical Center, Nijmegen, Netherlands, [8]Wilhelmina Children's Hospital / UMC Utrecht, Utrecht, Netherlands

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Pediatric Rheumatology – Clinical Poster I: JIA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Juvenile Idiopathic Arthritis (sJIA) is a severe inflammatory disease with auto-inflammatory characteristics. The introduction of targeted biologic therapies has revolutionized the treatment and as such improved outcomes for children with sJIA. The IL-1 receptor antagonist, anakinra, is used as first-line treatment for sJIA in the Netherlands since 2008 and has been shown to induce and sustain inactive disease with approximately 50% of patients being able to taper and stop within the first year of disease [Ter Haar 2019 PMID: 30848528]. However, also with this strategy, around 25-30% of patients experience a more refractory disease course, necessitating maintenance therapy. Multiple eposodes of Macrophage Activation Syndrome (MAS), a severe complication of sJIA, has been suggested to be one of the refractory sJIA phenotypes [Erkens 2021 PMID: 34635293]. The EULAR/ACR/PRINTO 2016 MAS classification criteria [Ravelli 2016 PMID: 26314788] have been developed to facilitate the diagnosis of MAS in sJIA. However, there is still a scarcity of data on their performance in sJIA patients treated with biologicals. Recent studies indicate that treatment of sJIA with biologicals might change some clinical and laboratory features of MAS [Schulert 2018 PMID: 28499329]. We therefore aimed to describe the (clinical and laboratory) characteristics of sJIA patients who developed MAS while treated with first-line anakinra and to evaluate whether the 2016 MAS classification criteria are still applicable in these patients.

Methods: In this cohort study, we used both retrospective data (2008-2016) as well as data from a nationwide, prospective multicentre cohort study (Early start of Targeted Treatment in Systemic JIA, ESTIS, 2017 onwards) selecting patients who developed MAS during treatment with first-line anakinra. In total, 15 patients were included with at least 1 year of follow up. We described the demographic, clinical, laboratory and immunologic features of MAS in patients started on recombinant IL-1RA therapy as first-line therapy for sJIA.

Results: We included fifteen patients, with a total of sixteen episodes of MAS. The estimated incidence of MAS was 15.6% in the first year after start of anakinra (7/45 in the prospective nationwide, multicentre cohort study ESTIS in the period 2017-2021). Eleven out of the fifteen patients were female. A significant share (11/16 episodes) of the MAS episodes occurred within 2 months after the onset of sJIA and four episodes (4/16, 25%) were triggered by a primo EBV infection at the onset of MAS. All episodes of MAS met the EULAR/ACR/PRINTO 2016 classification criteria for MAS in sJIA.

Conclusion: While first-line treatment with anakinra in sJIA results in high response rates and minimal corticosteroid use, this strategy does not seem to lower the risk or incidence of MAS in SJIA in the first year of disease. The EULAR/ACR/PRINTO 2016 classification criteria for MAS are applicable to patients treated with first-line anakinra. We recommend to

closely monitor the laboratory features from the classification criteria in (female) patients within the first months after the onset of sJIA and suggest to test all patients at the onset of sJIA on EBV status.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile idiopathic arthritis (JIA) encompasses a group of chronic arthritis that begin in childhood. According to the International League of Associations for Rheumatology (ILAR) criteria, JIA can be divided into seven distinct groups: oligoarthritis, rheumatoid factor (RF) negative and positive polyarthritis, enthesitis related arthritis, psoriatic arthritis, systemic arthritis and undifferentiated arthritis.

Following their visit to the transitional consultation, these patients subsequently undergo clinical follow-up in adult rheumatology.

The objective of this study is to describe the evolution of clinical and analytical findings, as well as treatment data in patients with JIA after the transitional care consultation.

Table 1	Oligoarthritis (n=20)	Enthesitis related arthritis (n=16)	RF negative polyarthritis (n=13)	Systemic arthritis (n=7)	Undifferentiated arthritis (n=6)	RF positive polyarthritis (n=4)	Psoriatic arthritis (n=4)
Diagnosis changes N (%)	2 (10)	-	1(7.7)	1(14.3)	4(66.6)	1(25)	-
New diagnosis	Spondyloarthritis Rheumatoid arthritis	-	Rheumatoid arthritis	Rheumatoid arthritis	Bechet's disease Behçet's disease Psoriatic arthritis Sjögren's disease	Sjögren's disease	-

Diagnosis changes

Table 2	Cumulative incidence at pediatric age N (%)	Cumulative incidence after the transitional care consultation N (%)
Oral/genital thrush	14(20)	5(7.1)
Uveitis	10(14.3)	7(10)
Diarrhea	8(11.4)	4(5.7)
Psoriasis	8(11.4)	4(5.7)
Raynaud phenomenon	6(8.6)	1(1.4)
Antinuclear antibodies (ANA)	40(57.1)	37(52.8)

Cumulative incidence of clinical and analytical manifestations

Table 3	Remission after the transitional care consultation N (%)	New episodes after the transitional care consultation N (%)	Recurrences after the transitional care consultation N (%)
Oral/ genital thrush (n=16)	11(68.7)	2(12.5)	3(18.7)
Uveitis (n=11)	4(36.3)	1(9.1)	6(54.5)
Diarrhea (n=10)	6(60)	2(20)	2(20)
Psoriasis (n=8)	4(50)	-	4(50)
Raynaud phenomenon (n=6)	5(83.3)	-	1(16.6)
ANA (n=42)	5(11.9)	2(4.7)	35(83.3)

Evolution of clinical and analytical manifestations

Methods: Descriptive, longitudinal, and retrospective study conducted on 70 patients diagnosed with JIA based on the ILAR criteria. These patients were followed-up in adult rheumatology consultations after being visited in the transitional consultation at a Spanish tertiary-level hospital. Data pertaining to clinical, laboratory, and treatment aspects were collected from both the adult and transitional consultations.

Results: 70 patients diagnosed of JIA (65.7% women) were included in the study, with a mean age at diagnosis of 9 years old and a mean age at the transitional consultation of 21 years. The average duration of follow-up after the initial diagnosis was 16 years, while the mean duration of follow-up after the transitional consultation was 4 years.

After the transitional consultation, 12.8% of the patients had a change in their diagnosis (table n° 1).

24 patients (34.3%), were lost to follow-up, primarily due to changes in the health department in the majority of cases.

Half of the patients with history of previous uveitis experienced new episodes following the transitional consultation. In contrast, a significant number of patients did not experience recurrences during their follow-up in adult rheumatology appointments (table n ° 3). 100% of the patients who had new flares of uveitis after the transitional consultation had ANA+ in serum.

The frequency of oral and genital thrush, Raynaud phenomenon and diarrhea episodes decreased after the transitional consultation.

Out of the 28 patients who were in remission without treatment during the transitional care consultation, only 1 patient required initiation of therapy during their follow-up in adult rheumatology appointments.

Conclusion: 12.8% of the patients experienced a change in their diagnosis during their follow-up in the adult rheumatology consultation, with the majority of these cases being classified as undifferentiated JIA.

The majority of patients who were in remission without treatment during the transitional consultation did not require treatment during their follow-up in adult rheumatology appointments.

A significant number of patients experienced recurrences of uveitis after the transitional care consultation. However, new cases of uveitis in patients who had not previously experienced episodes were rare during the follow-up in adult rheumatology appointments.

Session Date: Sunday, November 12, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Although the use of patient-reported outcome (PRO) data has grown more common in the care of people with rheumatoid arthritis (RA), the utility of PRO data captured between visits in relation to traditional, physician-derived measures has not been adequately evaluated. We compared changes over time in PRO data captured on a smartphone app against a physician-derived disease activity measure, the Clinical Disease Activity Index (CDAI).

Methods: RA patients in moderate or high disease activity (CDAI >10) and prescribed either upadacitinib (UPA) or adalimumab (ADA) were enrolled in the study from March 2021 to October 2022 during in-office visits at 28 community rheumatology clinics in the US. Patients were prompted to download the ArthritisPower registry smartphone app to complete PROs at home over a 12-week period. Following a mandatory run-in period to verify willingness to provide PRO data, subsequent at-home data collection included disease activity measures as well as symptom measures from the Patient-Reported Outcomes Measurement Information System (PROMIS). Patients returned for a follow-up clinical visit at approximately 3-4 months (follow-up visits permitted at 2-6 months). Rheumatology clinics provided baseline clinical data including CDAI, years since RA diagnosis, prior medications, and follow-up CDAI. A subgroup analysis was restricted to those who stayed on medication with minimal interruptions. Linear regression models adjusted for baseline CDAI and baseline PRO scores were used to test the correlation between follow-up CDAI and follow-up PRO scores.

Results: Of 299 patients recruited, 240 patients (80%) successfully completed the run-in period, and 205 patients started UPA or ADA within 4 weeks and were eligible. A total of 148 patients ("All" cohort) to date have provided baseline and follow-up clinical and PRO data, and 122 (82%) remained adherent (Table 1). Mean CDAI improved 14.4 units for patients who stayed on the medication (Table 2). Correlations between follow-up CDAI and follow-up PROs ranged from 0.38 – 0.56, the strongest of which were for Patient Global Assessment NRS (R=0.56) and Pain NRS (R=0.47) (Table 3). The adjusted R^2 of the overall model showed that changes in PROs explained 52% of the variability in the change in the CDAI.

Table 1. Baseline Characteristics of WEAR Study Participants

Disease Burden, Patient Experiences, and Unmet Needs in Refractory Rheumatoid Arthritis: Insights from 20 Years of Real-World Data

Kristin Wipfler[1], Bobby Kwanghoon Han[2], Sofia Pedro[3], Urbano Sbarigia[4], Federico Zazzetti[5], Anna Sheahan[6], Iris Lin[7], Patti Katz[8], Evo Alemao[9] and Kaleb Michaud[10], [1]FORWARD, The National Databank for Rheumatic Diseases, Omaha, NE, [2]University of Washington, Seattle, WA, [3]Forward, The National Databank for Rheumatic Diseases, Wichita, KS, [4]Janssen Pharmaceutica, Beerse, Belgium, [5]Janssen Research & Development, LLC, Spring House, PA, [6]Janssen, Raleigh, NC, [7]Janssen, Horsham, PA, [8]University of California San Francisco, San Rafael, CA, [9]Janssen Pharmaceuticals, New Hope, PA, [10]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite major advances in RA treatment, a substantial number of patients (estimated at 6-21%[1]) are refractory to multiple advanced therapies. Well-defined refractory RA (reRA) criteria and thoughtful selection of controls are essential to ensure that observed differences are truly due to refractory disease and not to confounding variables. In this study, we aimed to identify factors associated with reRA and characterize differences in disease burden/patient experiences between reRA and matched nonrefractory controls, from over 20 years of real-world data.

Methods: Data were provided by adults with RA in the FORWARD Databank from 1998 to 2019. Participants with no history of biologic (bDMARD) or targeted synthetic DMARD (tsDMARD) use at study entry but with subsequent exposure to one or more of these advanced therapies were included. The reRA group included participants with exposure to ≥3 advanced therapies during observation, with ≥1 TNF inhibitor (TNFi) and ≥1 tsDMARD or non-TNFi bDMARD. The nonrefractory group included participants with continued use of their first advanced therapy for at least two years, and who never

Table 1. Characteristics of FORWARD participants with RA by reRA status at baseline (initiation of first advanced therapy) and follow up (the point of meeting reRA criteria; matched time point for nonrefractory controls).

csDMARD=conventional synthetic DMARD; weak opioid=codeine, tramadol, hydrocodone; strong opioid=morphine, fentanyl, methadone, hydromorphone, oxycodone, oxymorphone; VAS=visual analog scale; PAS-II=Patient Activity Scale II; RDCI=Rheumatic Disease Comorbidity Index; PSD=polysymptomatic distress. Healthcare interactions were in the six month time period preceeding the observation.

exceeded two advanced therapies during observation. Refractory and nonrefractory participants were matched 1:1 on age, sex, RA duration, calendar year, and observation time. Descriptive statistics were calculated at baseline (initiation of first advanced therapy) and at follow up (the point of meeting reRA criteria; matched time point for nonrefractory controls). Significance was assessed with Chi-square and t-tests, as appropriate. Covariates with $p < 0.1$ were included in multivariable logistic regression models for each time point.

Results: Of 6,575 participants who met study inclusion criteria, 718 (10.9%) met reRA criteria. Of those, 692 were matched 1:1 to nonrefractory controls, for a total of 1,384 participants included in the study. In univariate analyses (Table 1), all patient-reported outcomes (PROs) were significantly worse among the reRA group at both time points. Glucocorticoid use, opioid use, Rheumatic Disease Comorbidity Index (RDCI), gastrointestinal (GI) disorder, and polysymptomatic distress (PSD) were also all higher for the reRA group at both time points, and healthcare satisfaction was lower. In multivariable analyses (Figure 1) higher pain, GI disorder, and lower healthcare satisfaction were all associated with future incidence of reRA. Higher education, corticosteroid use, GI disorder, and more rheumatology visits were associated with reRA. History of cancer was associated with nonrefractory status.

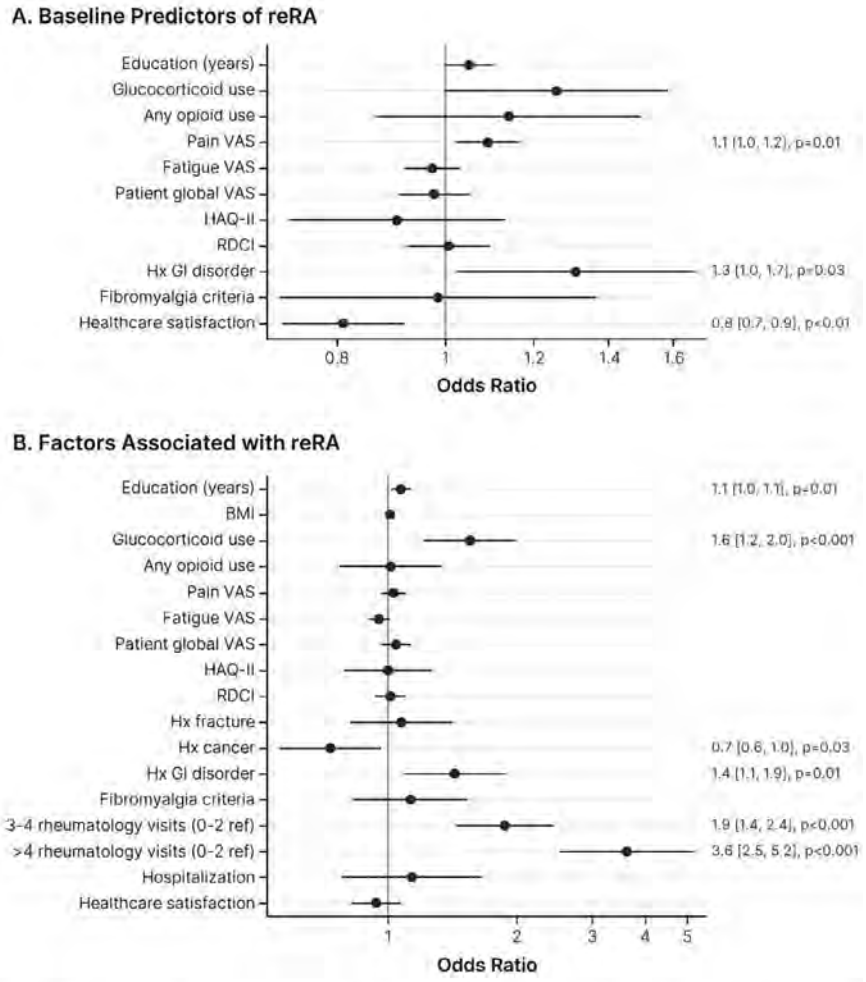

Figure 1. Multivariable logistic regression results for (A) baseline predictors of reRA and (B) factors associated with reRA at the time of meeting reRA criteria. Characteristics with $p<0.1$ in Table 1 were included in each model. Statistically significant ($p<0.05$) covariates have their associated odds ratio [95% CI] and p-value listed. RDCI=Rheumatic Disease Comorbidity Index. Rheumatology visits and hospitalization were within the six month period prior to the observation.

Conclusion: These results demonstrate that reRA is associated with significant disease burden and unmet healthcare needs, as evidenced by lower healthcare satisfaction, higher rates of glucocorticoid and opioid use, greater comorbidity and symptom burdens, and more rheumatology visits. These findings underscore the importance of well-defined reRA criteria and the need for further investigation into this unique RA phenotype to identify targeted treatment strategies and ultimately improve outcomes.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Early detection of difficult to treat (D2T) RA patients as well as better characterization of their long-term course represent unresolved issues. Herein we aimed for a detailed analysis of predictors and assessed for heterogeneity of long-term prognosis within D2T patients.

Methods: This was an analysis from "University of Crete Rheumatology Clinic Registry (UCRCR)", a prospective single center study. We analyzed all patients included form May 2000 until April 2022 and applied the EULAR definition of D2T. Univariate and multivariate analysis of sociodemographic and RA-related characteristics at start of first bDMARDs or tsDMARD were analysed as predictors of D2T. Heterogeneity (HAQ and DAS28 trajectories) withing D2T group was analysed during a follow-up period of 60 months applying latent class trajectory analysis.

Results: 251 out of 1264 patients (19.9%) identified as D2T. Female gender, age at 1st biologic, RF negative, higher RDCI scores, Sicca symptoms, disease duration, higher DAS28 and HAQ at baseline and failure to decrease DAS28 >1.2 at 6 months were all associated with D2T grouping ($p < 0.05$). Patients classified as D2T suffered from osteoarthritis, fibromyalgia, dyslipidemia, hypothyroidism and obesity at significantly higher rates compared to non-D2T patients ($p < 0.05$ for all). Latent class trajectory analysis during 60 months of follow-up, indicated that D2T patients do not constitute a homogenous group; interestingly distinct disease activity trajectory groups could be differentiated while ∼36% of them showed a more favorable outcome but never reaching low disease activity (DAS 28 ESR∼ 3.8 at 60 months) (Figure 1).

Table. Univariate comparisons of selected factors between D2T and non-D2T patients

Table. Univariate comparisons of selected factors between D2T and non-D2T patients

Identification of Contributing Factors to Difficult-to-Treat Rheumatoid Arthritis (D2T RA) in a Cohort of 972 Patients Using a Natural Language Processing (NLP) Approach

Hugo BERGIER[1], Thibaut Fabacher[2], Nathanaël Sedmak[2], Erik Sauleau[2] and **Jacques-Eric Gottenberg**[3], [1]Hautepierre Hospital, Strasbourg, France, [2]Hôpitaux Universitaires de Strasbourg, Strasbourg, France, [3]Rheumatology Department, Strasbourg University Hospital, Strasbourg, France

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Natural Language Processing (NLP), an interdisciplinary field combining artificial intelligence and language science, has gained significant interest in the medical domain for automated collection and structuring of medical data. In this study, we employed an NLP approach to identify and extract the characteristics of patients with D2T RA from their computerized medical records.

Methods: We conducted a monocentric observational retrospective cohort study in our French hospital. Patients were longitudinally recruited over a 5-year period (2015-2020), and their characteristics were retrieved from their electronic health records spanning 2010-2022. Firstly, we performed an NLP phenotyping tool to identify patients who had at least one hospital stay related to RA between 2015 and 2020. The tool relied on CIM-10 coding and the recognition of specific keywords (e.g., "rheumatoid arthritis" or "ACPA") in the medical records to calculate the patient's probability of meeting the RA phenotype. We subsequently employed a named-entity recognition algorithm to identify all drugs associated with RA from the patients' medical reports. The drugs were then arranged in chronological order based on their appearance, and the date of introduction was approximated as the date of first extraction. D2T RA was defined as the failure of at least two targeted therapies (identified by the algorithm retrieving three or more biologics), thereby allowing us to separate our RA cohort into D2T and non-D2T RA groups. Finally, we used another NLP program employing named-entity recognition to retrieve the characteristics of these patients. Specific keywords related to general variables (sex, age at first stay), disease characteristics (presence of joint erosion, DAS28 activity score), and comorbidities were sought in the medical reports using cumulative extraction. The occurrence of these specific tokens was linked to the presence of the respective variable. Finally, a multivariate logistic regression analysis was performed to assess the relationship between variables and the D2T group.

Results: The phenotyping tool identified 972 RA patients, of which 313 were classified as D2T RA and 659 as non-D2T RA. The presence of joint erosions (OR 2.97 CI95% [2.17; 4.08], p< 0.001) and higher disease activity (median DAS28 3.16 vs 2.89) were associated with the D2T group. Female gender, obesity, smoking, anxio-depression, and fibromyalgia comorbidities showed similar proportions in our two groups. Chronic kidney disease (OR=0.66 CI95% [0.44;1.01], p=0.068), cardiac insufficiency (OR 0.52 CI95% [0.38;0.7], p=0.001), liver insufficiency (OR=0.7 CI95% [0.35;1.4], p=0.39), and a history of malignancy (OR=0.62 CI95% [0.47;0.82], p=0.001) were found in higher proportions in the non-D2T group.

Conclusion: NLP facilitates the automated collection of diverse data directly from medical reports using named-entity recognition algorithms. In this study, we demonstrated its application in identifying potential contributing factors to D2T RA. Enhanced understanding of the mechanisms underlying D2T RA and early detection of contributing factors hold promise for improved outcomes and management in this heterogeneous population.

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The formation of neutrophil extracellular traps (NETs) with extrusion of nuclear, granular and cytosolic components from a dying neutrophil, has been described extensively in patients with rheumatoid arthritis (RA), and linked to generation of autoantigens (e.g. citrullinated proteins), inflammation and organ damage. Thus far there have been very few studies describing the effect of treatment in patients with RA on NET formation, and no studies comparing the effects of treatment strategies in (very) early RA. The objective of the study is to assess the effects of different initial treatments on NET formation in patients with early RA.

	Baseline	*Week 12*	*Reduction*	*Week 24*	*reduction*

*Table 1. Results are reported as median (IQR) due to skewedness of the data. Reductions are reported as a percentage reduction compared to baseline. Measurements are marked with * if p<0.05, ** if p<0.01, *** if p<0.001.*

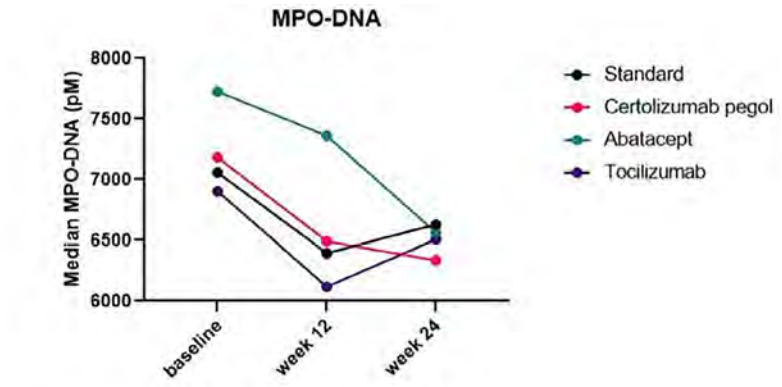

Figure 1:median MPO-DNA over time (pM)

Methods: NORD-STAR is an international, multicenter, open-label, assessor-blinded, phase 4 study where patients with newly diagnosed RA started methotrexate (MTX) and were randomized 1:1:1:1 to a) conventional treatment (either prednisolone tapered to 5mg/day, or sulfasalazine combined with hydroxychloroquine and intra-articular corticosteroids), b) certolizumab pegol, c) abatacept, or d) tocilizumab[1]. This study is a spin-off from the main NORD-STAR study measuring neutrophil biomarkers MPO-DNA (Myeloperoxidase-DNA; NETs) and calprotectin in 24 consecutive Dutch participants and 94 Swedish patients at baseline, 12 weeks and 24 weeks after the start of the treatment. Statistical analysis was done using the Wilcoxon Signed Rank test for paired samples and independent samples median test to compare patients to healthy controls in SPSS version 28.

Results: At baseline patients had elevated levels of NETs and neutrophil activation compared to healthy controls as indicated by calprotectin (median 1080ng/ml vs 133ng/ml, $p< 0.001$) and elevated MPO-DNA (median 7185pM vs 3976pM, $p< 0.001$). Both of the biomarkers decreased significantly at 12 and 24 weeks after treatment in the total group demonstrating reduced neutrophil activity and NET formation. After 24 weeks of treatment, calprotectin was significantly reduced in all groups by up to 93% (Table 1). MPO-DNA showed a more modest reduction of up to 13%, and was relatively similar in all groups, although the reduction in MPO-DNA did not reach statistical significance in the tocilizumab group.

Conclusion: These results indicate highly elevated neutrophil activation and NET formation in recently diagnosed RA patients. All four treatments studied here reduced these detrimental processes within 3 months. The calprotectin reduction seen in this study is in line with an earlier spin-off study[2]. The rapid decline in these markers may have contributed to the minimal radiological progression that was seen in the NORD-STAR trial.

Session Date: Sunday, November 12, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: ERA is considered to be a systemic disorder, but the role of local factors in driving synovial inflammation is increasingly being recognized. These joint-specific factors may modulate disease phenotype. We will study the spatial distribution of swelling (S), tenderness (T) and erosions in a large cohort of ERA patients to assess the existence of joint patterns. Patients treated with MTX were evaluated after 3 and 6 months for joint swelling (JS).

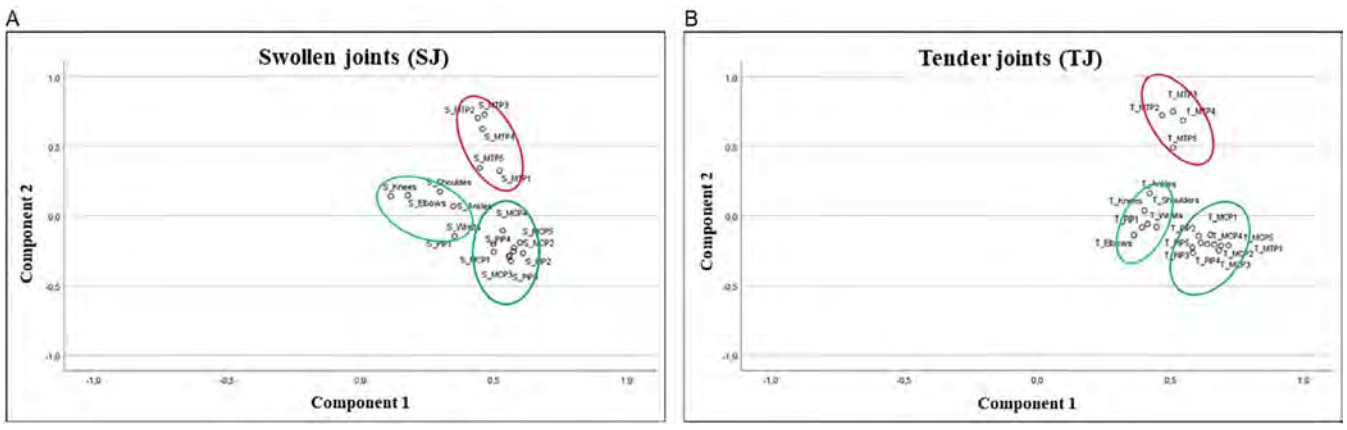

Figure 1 The average spatial distribution of SJ (A) and TJ (B)

Methods: This analysis was based on data from our ERA UCLouvain Brussels cohort. The physician assessed prevalence of baseline SJ and TJ status before DMARD initiation. The association between BL swelling, tender, erosions and disease characteristics was investigated for each individual joint. Remission rates (DAS28-CRP < 2.6) in patients treated with MTX were assessed.

Results: 452 newly diagnosed untreated RA patients were included: mostly female (72.3%), mean age 47.5 years, ACPA/RF positivity 64.8% and 63.3%, erosive disease in 44%, mean DAS28CRP - 4.6 and HAQ - 1.23. In total, 18,080 joints were assessed for swelling and tenderness at baseline, of which 20.4% were SJ and 27.6% were TJ. Wrist was the most frequently S and T joint (in 57% and 50.8% of patients), followed by PIP 2 and 3. Assessment of S and T showed a good correlation for most joints, except for shoulder and MTP1.

We applied PCA on SJ and TJ matrices to assess for potential clusters of joint prone to be concurrently involved in patients (Figure 1). We found three joint clusters: one with MTP1-5, one with hand joints, and one with larger joints. Wrist seemed to locate at the boundaries between fingers and large joints clusters. Analysis for ACPA-positive and ACPA-negative patients found very similar results. The higher rates of bone erosions were observed in the MTP cluster. Erosions were less frequent in the MCP+PIP, and almost absent in large joint, excepted for wrist.

We then divided the patients into 2 subgroups according the swelling for each joint location and compared clinical characteristics. We found that MTP4,5 are more often S in patients younger than 50 years and MCP2-4 in ≥50 years old patients. Swelling in MCP1,3,4 and MTP1,2,5 is associated with erosive disease, whereas swelling of MTPs (MTP1,2,5) is associated with higher frequency of ACPA. Knee swelling more frequently manifest in non-erosive and seronegative disease. Swelling of multiple joints (knee, elbow, shoulder, ankle, wrist, MCP3, PIP 1-2, and MTP5) associates with a higher DAS28CRP, just as higher HAQ score (knee, shoulder, ankle, MCP 1-5, MTP1,5 and PIP1-2).

We analyzed the impact of MTX montherapy on joint swelling. Number of SJs decreased significantly after 6 months: swelling persisted in 36.3%. We found no significant difference in response and JS persistence. We grouped all joints into the previously identified clusters, but no statistical difference in resolution of JS was observed.

Conclusion: This is the first study investigating the spatial distribution of arthritis in a large cohorts of early untreaded RA using unbiased approach. We identify clusters of simultaneously involved joints (hands and fingers cluster, metatarsophalangeal cluster and large joints cluster), supporting the importance of local factors driving synovitis in RA.

Functional Disability and Disease Activity Are Affected by Social Determinants of Health in Patients with Rheumatoid Arthritis

Mohammad Movahedi[1], Kangping Cui[2], George Tomlnson[3], Angela Cesta[3], xiuying Li[3] and Claire Bombardier[4], [1]Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada, [2]Sunnybrook Hospital, Toronto, ON, Canada, [3]University Health Network, Toronto, ON, Canada, [4]University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The relationship between social determinants of health (SDH) (e.g. income, education, and employment status) and disease outcomes in the RA population is not well documented. We aimed to understand the effect of different SDH on disease activity and functional ability.

Methods: All retrospective data were extracted from the Ontario Best Practices Research Initiative- Rheumatoid Arthritis (OBRI-RA) registry for the period January 2008 to April 2022. We conducted adjusted generalized linear mixed models analysis to investigate the effect of baseline SDH on disease activity, using the Clinical disease activity index (CDAI), and functional disability, using the Health Assessment Questionnaire-disability index (HAQ-DI) at 12 months follow-up. The analysis was completed on multiple imputed.

Results: Two thousand six hundred fifty-one patients were identified with a mean (SD) age of 58.1 years (12.9) and 77.8% were female.

Retired patients (compared to unemployed) had higher improvement (difference =-1.62; 95%CI: --3.11,-0.14)and current smokers (compared to never/past) had lower improvement (difference =0.95; 95%CI: -0.02, 1.92)in disease activity (CDAI) at 12 months.

CDAI LDA/remission was less common current smokers (adj ORs: 0.82; 95%CI: 0.68, 0.99) and more common in females (adj ORs: 1.33; 95%CI: 1.12, 1.58).

Compared to unemployed, employed (difference =-0.24; 95%CI: -0.32,-0.16) or retired patients (difference =-0.16; 95%CI: -0.25,-0.07), those with higher house hold income (>50 vs. ≤ 50 CAD) (difference =-0.10; 95%CI: -0.16, -0.04), and post-secondary education (compared to high school or less) (difference =-0.07; 95%CI: -0.11, -0.02) had greater improvement of physical function (Table 1). Caucasian race (compared to non-Caucasian) and alcohol consumption (compared to never use) were also associated with a positive impact on functional ability. In contrast, currently smokers (compared to never/past) had lower improvements in physical function (difference= 0.08; 95%CI: 0.01, 0.14).

Conclusion: Our study suggests that disease activity and functional disability are affected by different SDH factors at 12 months follow-up. These differences in SDH must be understood and addressed by rheumatologists to provide equitable healthcare for all patients with RA.

The Association Between Inflammation, High-Sensitivity Cardiac Troponin T, and Cardiovascular Events in Rheumatoid Arthritis

Brittany Weber[1], Dana Weisenfeld[1], Mary Jeffway[1], Jonathan Coblyn[1], Michael Weinblatt[2], Nancy Shadick[3], Marcelo DiCarli[1] and Katherine Liao[1], [1]Brigham and Women's Hospital, Boston, MA, [2]Harvard Medical School, Waban, MA, [3]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) have a 1.5x excess risk of cardiovascular (CV) disease compared to the general population, attributed to chronic inflammation. In the general population, detectable levels of high sensitivity cardiac troponin (hs-cTnT) are associated with higher risk of major cardiovascular (CV) events (MACE); while this same relationship is expected in RA, we sought to determine whether inflammation may modify this relationship. The objective of this study was to test the association between hs-cTnT with MACE, and further determine whether this relationship may differ by inflammatory states.

Methods: We studied 185 patients in a longitudinal RA cohort with blood samples and hsCRP measured annually, who experienced either a significant increase in hsCRP low→high or decrease in hsCRP high→low, defined as hsCRP≥10 mg/L, in 2 consecutive annual visits. Subjects on statin therapy or lipid-lowering therapy were excluded. Hs-cTnT, a marker of subclinical myocardial injury and routine lipids were measured at baseline; estimated 10-year atherosclerotic CV risk was also calculated at baseline. The primary outcome, MACE was obtained using medical record review from linked electronic health record (EHR) data. Patients were followed from baseline until MACE, death, last EHR encounter or 15 years,

Table 1. Baseline clinical characteristics of RA patients in the study.

Characteristics	hsCRP low→high cohort **n=101**	hsCRP high→low cohort **n=84**
Age, mean (SD)	59.2 (12.7)	57.6 (12.8)
Female (%)	80	89
RA disease duration, median, IQR	16 [8, 27]	14 [8, 28]
Anti-CCP positive, (%)	69	80
DAS28_CRP, median, IQR	3.22 [2.34, 4.09]	5.18 [3.48, 6.56]
Hs-CRP, median, IQR	4.50 [1.67, 8.13]	28.46 [22.08, 44.o09]
Cardiovascular Risk Factors (%)		
Diabetes Mellitus (%)	1	11
Hyperlipidemia (%)	13	14
Hypertension (%)	30	25
Current Smoker (%)	7.1	4.7
ACC/AHA ASCVD Risk*, median (IQR)	4.77 [2.05, 12.35]	4.08 [1.85, 9.15]
Baseline CV Biomarker Data		
Hs-TnT, median, IQR	10.02 [7.57, 14.90]	8.41 [6.71, 12.24]
Detectable hs-cTnT (%)	45.5	44

Anti-CCP indicates anti-cyclic citrullinated peptide; RA, rheumatoid arthritis; RF, rheumatoid factor; hs-CRP, high-sensitivity C-reactive protein; CDAI, clinical disease activity index; hs-cTNT, high sensitivity troponin

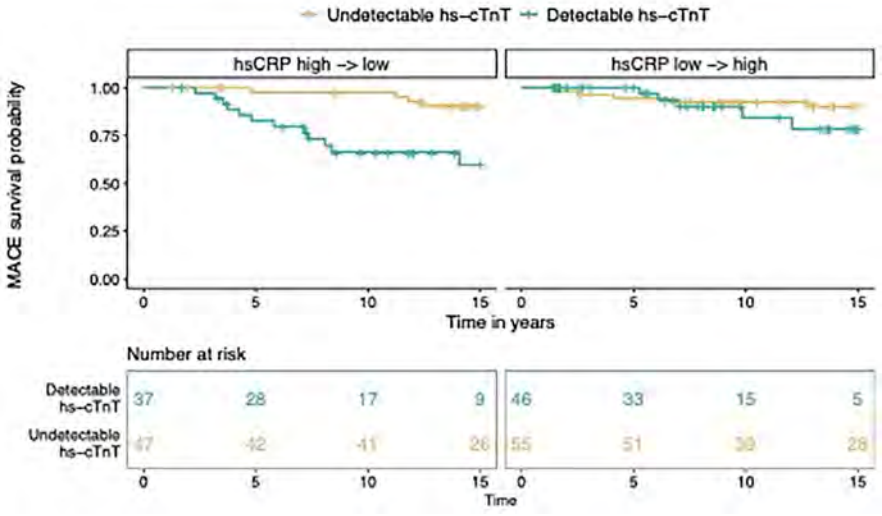

Figure 1. Survival curves for MACE among subjects with and without detectable hs-cTnT at baseline, stratified by cohort: hsCRP high->low cohort and hsCRP low->high.

whichever occurred first. The association between detectable hs-cTnT with MACE were determined using Cox proportional hazards models stratified by cohort status, i.e., hsCRP low→high cohort vs hsCRP high → low cohort; models were further adjusted be CV risk factors including age, sex, hypertension, hyperlipidemia, and smoking.

Results: The mean age was 58 years, 84% female, 74% anti-CCP positive with median RA disease duration of 15 years **(Table 1).** A total of 26 MACE events (14%) occurred during this period. The baseline median hsCRP among the hsCRP low→high cohort was 4.5 mg/dl [IQR 1.7-8.1) and in the hsCRP high→low cohort 28.5 mg/dl [IQR 22-44]. At baseline, in hsCRP low→high cohort, 46% had a detectable hs-cTnT, while 44% were detectable in the hsCRP high→low cohort. Detectable hs-cTnT at baseline was associated with future MACE HR 5.6 (95% CI 1.78-17.6; p=0.003) in the hsCRP high→low cohort with high inflammation at baseline; no association was observed with MACE in the hsCRP low→high cohort with low inflammation at baseline HR 1.84 (95% CI 0.53-6.41; p=0.3) **(Figure 1).** These associations remained after adjusting for CV risk factors.

Conclusion: In this RA cohort with overall low estimated ASCVD risk by standard CV risk scores, detectable hs-cTnT was associated with future MACE independent of traditional CV risk factors among those experiencing a high inflammatory state but not among those in a lower inflammatory state. These findings suggest that hs-cTnT may provide additional info for assessing CV risk among RA patients with overall low estimated ASCVD risk with active inflammation.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) leading cause of death is cardiovascular (CV) disease. RA patients can develop silent myocardial tissue alterations, which result in changes in left ventricular geometry (LVG) and increase CV morbidity and mortality. Echocardiography is a non-invasive tool that can detect subtle geometrical abnormalities. The purpose of this study is to compare the RA disease activity in patients with and without left ventricular geometry abnormalities

Table 1. Demographic Characteristics (n= 156)			
Variable	Patients with LVG abnormalities (n= 52)	Patients with normal LVG (n= 104)	p
Age (years), mean (±SD)	58.3 (8.2)	54.4 (9.1)	0.009
Women, n (%)	50 (96.2)	97 (93.3)	NS
Comorbidities, n (%)			
Active smoking	6 (11.5)	10 (9.6)	NS
Dyslipidemia	14 (26.9)	39 (37.5)	NS
T2DM	11 (21.2)	18 (17.3)	NS
Hypertension	24 (46.2)	32 (30.8)	NS
Obesity	19 (36.5)	27 (26.0)	NS

This table shows a comparison of demographic characteristics and comorbidities between groups. LVG left ventricular geometry; SD standard deviation; T2DM type 2 diabetes mellitus; NS No significative.

Table 2. Disease characteristics (n= 156)			
Variable	Patients with LVG altered (n= 52)	Patients with normal LVG (n= 104)	p
Disease duration (years), median (IQR)	7.7 (3.4-16.6)	7.4 (2.9-13.7)	NS
DAS28-CRP, median (iQR)	3.4 (2.2-4.5)	2.7 (1.9-3.81)	0.022
Lab work-up, median (iQR)			
CRP (mg/dL)	0.8 (0.5-1.0)	0.5 (0.2-1.0)	0.026
ESR (mm/Hr)	26.0 (16.0-39.7)	21.5 (14.0-35.0)	NS
ACPA (U/mL)	27.1 (2.2-192.7)	42.2 (1.6-199.9)	NS
RF IgG (U/mL)	5.8 (2.0-16.9)	4.0 (2.0-11.9)	NS
RF IgM (U/mL)	123.8 (19.2-200.0)	190.4 (34.9-200.0)	NS
RF IgA (U/mL)	40.5 (6.6-179.8)	66.8 (6.3-200.0)	NS
Treatment, n (%)			
Methotrexate	45 (86.5)	78 (75.0)	NS
bsDMARDs	6 (11.5)	14 (13.5)	NS
Prednisone	38 (73.1)	53 (51.0)	0.008

This table shows a comparison of disease characteristics between groups. LVG left ventricular geometry; iQR interquartile range; CRP C reactive protein; ESR erythrocyte sedimentation rate; ACPA anticitrullinated peptide antibody; RF rheumatoid factor; NS no significative.

Methods: Descriptive, comparative, and cross-sectional study. We enrolled RA patients between 40 and 75 years old who fulfilled ACR/EULAR 2010 classification criteria. The disease activity was evaluated by DAS28-CRP. A transthoracic echocardiography was realized. Normal left ventricular geometry was defined as a left ventricular mass index ≤115 g/m^2 for men and ≤95 g/m^2 for women, and a relative wall thickness ≤0.42. Left ventricular abnormalities were considered as any value higher than normal. Normality was assessed by the Kolmogorov-Smirnov test. Variables were described by central tendency and dispersion measures. Differences between groups were analyzed by chi-squared test and Students' t-test or Mann-Whitney U test, accordingly. Statistical significantly was $p \leq 0.05$.

Results: A total of 158 RA patients were included. Demographic characteristics are presented in Table 1. Patients with LVG abnormalities were older (58.3 vs 54.4 years; *p*=0.009). There were no differences in sex and comorbidities (Table 1). The group with LVG abnormalities had higher disease activity (3.4 vs 2.7; *p*=0.022) and C reactive protein levels (0.8 vs 0.5; *p*=0.026). More patients with abnormalities in LVG used prednisone than those with normal LVG (73.1% vs 51.0%; *p*=0.008). There were no differences in disease duration or serology (Table 2).

Conclusion: RA patients with LVG abnormalities had higher disease activity and C reactive protein levels, and current prednisone use than those with normal LVG. Echocardiography may be a useful tool to detect early and subtle LVG abnormalities, particularly in patients with those characteristics.

The Role of anti-CCP3 Antibodies in anti-CCP2 Antibody Negative Patients with Musculoskeletal Symptoms

Andrea Di Matteo[1], Kulveer Mankia[2], Leticia Garcia-Montoya[2], Jacqueline Nam[2], Sana sharrack[3], Michael Mahler[4] and Paul Emery[3], [1]Polytechnic University of Marche, Jesi, Italy, [2]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [3]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, and NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [4]Werfen, San Diego, CA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: To investigate, in primary care, whether testing anti-CCP3 antibodies in anti-CCP2 negative individuals with musculoskeletal (MSK) symptoms, improved the prediction of inflammatory arthritis (IA)/rheumatoid arthritis (RA) progression.

Methods: A total of 469 anti-CCP2 negative individuals who presented to their general practitioner (GP) with new MSK symptoms were included in this study. All participants underwent baseline anti-CCP3 testing (QUANTA Lite CCP3; Inova Diagnostics) and received a questionnaire 12 months after enrolment assessing their disease status. The GPs of those individuals who reported progression to IA/RA were contacted by a rheumatologist to confirm the diagnosis. Univariate and multi-variate analyses were performed to establish variables associated with disease progression.

Results: Both the progression rate towards IA/RA and the prevalence of anti-CCP3 antibodies in anti-CCP2 negative individuals with MSK symptoms were low. Only 61/469 (13.0%) participants reported disease progression of which 43/61 (70.5%) and 13/61 (21.3%) were confirmed to have a diagnosis of IA and RA, respectively. Anti-CCP3 was positive in only 16/469 (3.4%) anti-CCP2 negative individuals. However, interestingly, in univariate analysis, anti-CCP3 positivity was associated with self-reported progression (p< 0.001) and with a diagnosis of IA (p=0.03), but not with a diagnosis of RA (p=0.37). In contrast, when considering antibody levels, anti-CCP3 differed significantly between progressors and non-progressors (p< 0.0001) for all three categories (self-reported progression, IA and RA diagnosis).

At the manufacturer's cut-off (≥20 units) the sensitivity for progression to IA/RA ranged from 8.0-14.0% with high specificity (≥97.0%). The corresponding odds ratios (OR) ranged from 2.4 (95% CI 0.3-20.0) to 7.8 (95% CI 2.8-21.8). Interestingly, when cut-offs were optimized for F-1 score, lower cut-off values (5 units) significantly increased the OR for progression in all three categories. After correcting for confounding factors (age, gender), in multi-variate analysis anti-CCP3 levels remained significantly associated with diagnosis of RA (p=0.02).

Dx	Age	Gender·(male)	Family·history	CCP3·(≥20·units)
Self-reported	***p*<0.0001**	2.6·(1.5-4.8) ***p*=0.0010**	0.8·(0.4-1.5) *p*=0.45	7.5·(2.3-24.0) ***p*=0.0003**
Rheum-IA	*p*=0.0683	2.3·(1.2-4.6) ***p*=0.0113**	1.1·(0.5-2.2) *p*=0.86	3.5·(1.2-11.0) ***p*=0.03**
Rheum-RA	***p*=0.0006**	1.7·(0.4-6.2) *p*=0.3471	1.5·(0.4-5.4) *p*=0.54	2.4·(0.1-18.6) *p*=0.37

Demographic and serological features and their association with disease progression.

Conclusion: The rate of progression to IA/RA in anti-CCP2 negative individuals with MSK symptoms seen in primary care setting was low over a 12-months follow-up period. Our results showed that anti-CCP3 antibody levels have a potential role in improving prediction in IA/RA progression in anti-CCP2 negative individuals with MSK symptoms. Future studies are warranted to validate the cut-off values for anti-CCP3 antibodies with best prediction accuracy in this population.

Statins Influence the Relationship Between ATP-binding Cassette Transporter A1 (ABCA1)-mediated Cholesterol Efflux and Coronary Atherosclerosis in Rheumatoid Arthritis

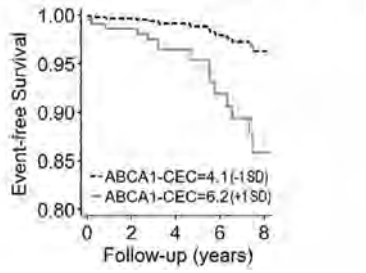
George Karpouzas[1], Bianca Papotti[2], Sarah Ormseth[3], Marcella Palumbo[2], Elizabeth Hernandez[3], Maria Pia Adorni[4], Francesca Zimetti[2], Matthew Budoff[1] and Nicoletta Ronda[2], [1]Harbor-UCLA Medical Center, Torrance, CA, [2]University of Parma, Department of Food and Drug, Parma, Italy, [3]The Lundquist Institute, Torrance, CA, [4]Department of Medicine and Surgery, Unit of Neuroscience, University of Parma, Parma, Italy

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Cholesterol efflux capacity (CEC) is the main antiatherogenic function of high-density lipoprotein (HDL). ATP-binding-cassette A1 (ABCA1) membrane transporter initiates cholesterol export from arterial macrophages to pre-β HDL particles fostering their maturation; in turn, those accept cholesterol through ABCG1-mediated export. Impaired pre-βHDL maturation may disrupt the collaborative function of the two transporters and adversely affect atherosclerosis. Statins exert atheroprotective functions systemically and locally on plaque. We here evaluated associations between ABCA1-CEC, coronary atherosclerosis and cardiovascular risk and the influence of statins on those relationships in rheumatoid arthritis (RA).

Methods: Atherosclerosis (noncalcified, partially or fully calcified, low attenuation plaques) was evaluated with coronary computed tomography angiography in 140 patients without cardiovascular disease and reassessed in 99 after 6.9 ±0.4 years. ABCA1-CEC and ABCG1-CEC were measured in J774 macrophages and Chinese hamster ovary cells respectively as previously described. Cox regression evaluated the association between ABCA1-CEC and cardiovascular risk.

Figure 1 ABCA1-CEC associates with cardiovascular risk in RA



Multivariable negative binomial and robust logistic regression tested associations of ABCA1-CEC and its interactions with statin therapy on coronary plaque burden at baseline and its progression respectively.

Results: ABCA1-CEC inversely correlated with ABCG1-CEC (Pearson r= -0.167, p=0.049). ABCA1-CEC (per SD increment) associated with long-term cardiovascular event risk after adjustments for cardiovascular risk score and baseline plaque burden [HR 2.05 (95% CI 1.20-3.48), Figure 1]. There was an interaction of ABCA1-CEC with time-varying statin use (p=0.038) such that current statin use inversely associated with risk only in patients with ABCA1-CEC below the upper tertile. ABCA1-CEC had no main effect on plaque or plaque progression; instead, ABCA1-CEC (per SD) associated with fewer baseline total plaques (adjusted rate ratio [aRR] 0.81, [95%CI 0.65-1.00]), noncalcified plaques (aRR 0.78 [95%CI

Figure 2. Associations of ABCA1-CEC with baseline atherosclerosis outcomes for the total sample and stratified by statin use. Rate ratios derived from negative binomial regression models indicate the percent change in the outcome associated with one standard deviation unit increase in ABCA1-CEC. All models controlled for ASCVD risk score and high-density lipoprotein cholesterol.*Additionally adjusted for waist circumference †Additionally adjusted for waist circumference and age at diagnosis ‡Additionally adjusted for age at diagnosis.

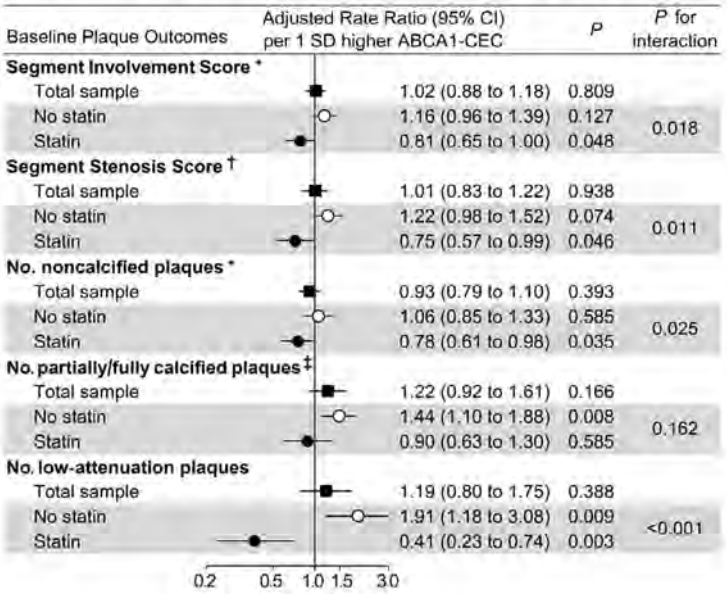


Figure 3. Associations of ABCA1-CEC with coronary atherosclerosis progression for the total sample and stratified by statin exposure during follow-up. Odds ratios derived from binary logistic regression models adjusted for ASCVD risk score, high-density lipoprotein cholesterol, baseline plaque burden, and time between scans *Additionally adjusted for time-averaged C-reactive protein †Additionally adjusted for time-weighted average prednisone dose ‡Additionally adjusted for time-averaged C-reactive protein, waist circumference, and age at diagnosis.

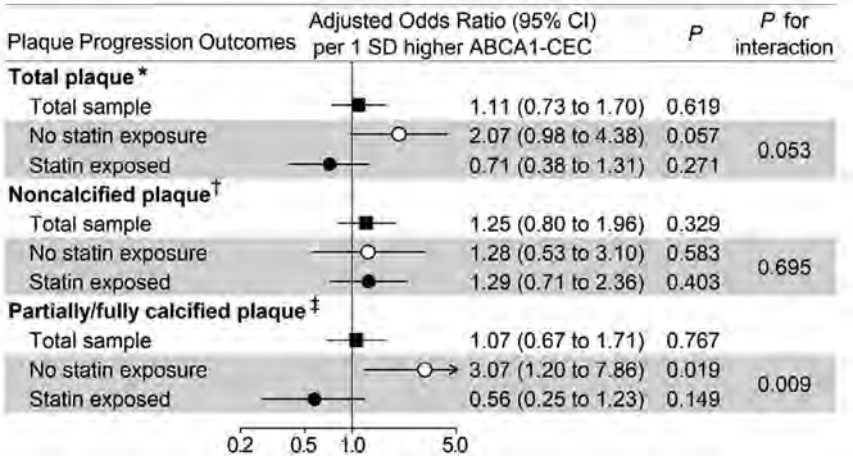

0.61-0.98]), and low attenuation plaques (aRR 0.41 [95%CI 0.23-0.74]) in statin users, and more low attenuation plaques (aRR 1.91 [95%CI 1.18-3.08]) in nonusers (p-for-interaction=0.018, 0.011, 0.025 and < 0.001 respectively, Figure 2). Moreover, ABCA1-CEC (per SD) associated with greater partially/fully-calcified plaque progression (adjusted odds ratio 3.07 [95%CI 1.20-7.86]) only in patients not exposed to statins during follow-up (p-for-interaction=0.009, Figure 3).

Conclusion: In the context of inflammation and impaired pre-β HDL maturation typical of RA, higher ABCA1-CEC may reflect a proatherogenic rather than atheroprotective state, associated with greater coronary atherosclerosis burden, vulnerability and cardiovascular risk. Statin use, by reducing cell cholesterol overload and restoring pre-β HDL maturation may unmask and promote the atheroprotective effect of ABCA1-CEC.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Chronic inflammation contributes to enhanced cardiovascular risk in rheumatoid arthritis (RA). Biologic disease modifying antirheumatic drugs (bDMARDs) control inflammation in many conventional synthetic DMARD non-responders and improve outcomes. We explored whether baseline bDMARD use may influence the impact of disease activity and systemic inflammation on long-term cardiovascular risk in RA.

Methods: We studied 4370 patients free of cardiovascular disease upon registration to *An International Cardiovascular Consortium for people with RA* (ATACC-RA) and followed prospectively. Outcomes included (a) major adverse cardiovascular events (MACE) defined as non-fatal myocardial infarction, non-fatal stroke, or cardiovascular death and (b) any ischemic cardiovascular events (CVE) comprising MACE, coronary revascularization, stable angina pectoris, transient ischemic attack and peripheral arterial disease with or without revascularization. Missing data were imputed using multiple imputation with 10 repetitions.

Figure 1 bDMARD use regulates the effect of inflammation on ischemic cardiovascular risk in patients with RA

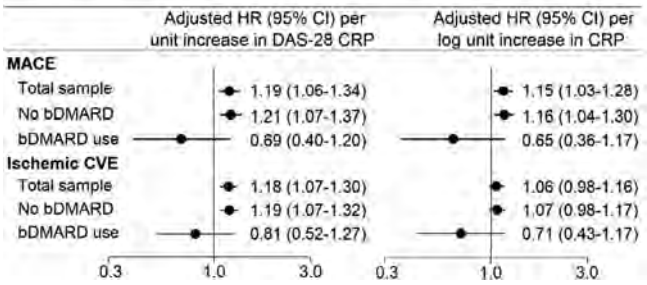

Figure 2 Cumulative probability of (A) Major Adverse Cardiovascular Event (MACE) and (B) any ischemic events in bDMARD users and nonusers at high (+1-SD) and low (-1-SD) baseline DAS28-CRP

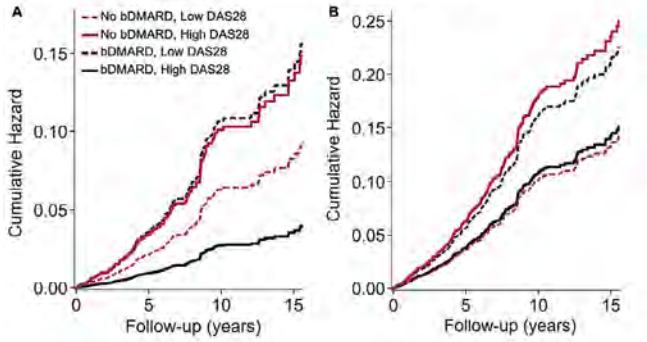

Multivariable Cox models stratified by center evaluated the impact of disease activity (DAS28-CRP), inflammation (CRP), bDMARD use and their respective interactions on CVE risk after adjusting for age, gender, hypertension, diabetes, family history, smoking and total cholesterol to high-density lipoprotein ratio. Two corroborating sensitivity analyses were performed; the first included patients enrolled in the cohort on or after January 1, 2000, when bDMARD use became more prevalent. The second used inverse probability of treatment weights to balance differences in bDMARD treated and untreated patients.

Results: Throughout 26,534 patient years, 239 first MACE and 362 total ischemic CVE were recorded. Among bDMARD nonusers, incidence of MACE and any ischemic CVE was 9.3 (95% CI 8.2-10.6) and 14.2 (12.8-15.8) events/1000PY. Rates for bDMARD users were [5.4 (95% CI 2.9-10.1) and 8.2 (5.0-13.6) events/1000PY. In the entire cohort, DAS-28 CRP and CRP(ln) associated with greater risk of MACE [(adjusted hazards ratio [aHR] 1.19 (95%CI 1.06-1.34), p=0.004 and HR 1.15 (1.02-1.28), p=0.017], while for all ischemic CVE the association was significant for DAS28-CRP [aHR 1.1 (95%CI 1.07-1.30)], but not CRP(ln) [aHR 1.06 (0.97-1.16)]. In bDMARD nonusers, higher DAS28-CRP and CRP(ln) associated with greater risk of MACE [aHR 1.21 (95%CI 1.07-1.37), p=0.002 and aHR 1.16 (1.04-1.30), p=0.009]. However, this was not the case in bDMARD users [p-for-interaction= 0.017 and 0.011 correspondingly, Figures 1 and 2]. In contrast, no significant interaction between DAS28-CRP or CRP and bDMARD use on any ischemic CVE risk was observed (p-for-interaction= 0.167 and 0.237 respectively). Both sensitivity analyses yielded similar results.

Conclusion: Conclusion: Higher disease activity and systemic inflammation at baseline associated with greater risk of MACE in bDMARD nonusers but not in users. This may suggest the presence of additional bDMARD-specific benefits directly on atherosclerotic plaque —such as plaque stabilization— above and beyond effects on systemic inflammation.

Novel Diagnostic Markers for Rheumatoid Arthritis Including Anti-CarP (Carbamylated Protein), Anti-Sa (Citrullinated Vimentin) and Anti-CEP1 (Citrullinated Enolase Peptide1) Are Frequently Positive in Diagnostic Profiles

Jane Yang[1], Rubio Punzalan[1], Lehrhoff Andrew[1], Michael Nappi[1], Vincent ricchiuti[2], Michael Zikry[1] and Kelly Chun[1], [1]Labcorp, Calabasas, CA, [2]Labcorp, Dublin, OH

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite the diagnostic contribution of Anti-CCP3.1 (cyclic citrillunated peptide) antibody and RF (rheumatoid factor) as classified by the 2010 ACR/EULAR RA criteria, approximately one-third of patients with rheumatoid arthritis (RA) are considered "seronegative." Novel markers, Anti-CarP Anti-Sa, and Anti-CEP1 were recently added in order to improve RA diagnosis and characterization. Citrullination and carbamylation are post-translational modifications, and autoantibodies against citrullinated and carbamylated proteins in RA patients may predict the development of RA and may be associated with more active disease and higher risk of developing joint erosions.

Methods: Serum from 28,575 patient samples was analyzed for RF (Roche Integra/COBAS), Anti-CCP3.1 (QUANTA Lite IgG/IgA), and/or enzyme immunosorbent assay (ELISA) lab-developed tests (LDT) for 14-3-3 eta, Anti-CarP, Anti-Sa, and/or Anti-CEP1 in three RA profiles: RheumAssure (RF, Anti-CCP3.1, 14-3-3 eta), RAdx6 (RF, Anti-CCP3.1, 14-3-3 eta, Anti-CarP, Anti-Sa, Anti-CEP1) and SeroNegRAdx4 (14-3-3 eta, Anti-CarP, Anti-Sa, Anti-CEP1).

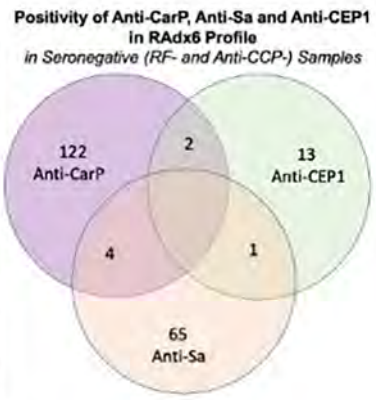
Results: Here, 24,549 RheumAssure, 2672 RAdx6 and 1354 SeroNegRAdx4 were performed and exhibited overall positivity of 28.5%, 35.4% and 19.9%, respectively as shown in Table 1. Novel markers, Anti-CarP, Anti-Sa and Anti-CEP1, added an incremental positivity of 7.7% and 13.5% in RAdx6 and SeroNegRAdx4, respectively. Of note, this additional 7.7%

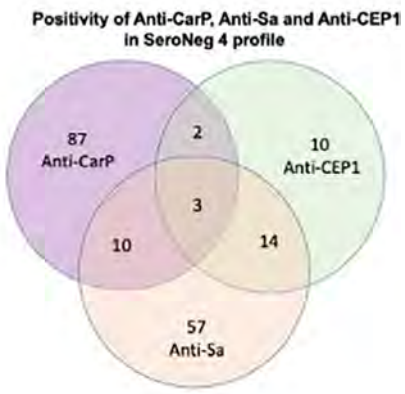
Table 1. Positivity Rates of RA Diagnostic Profiles

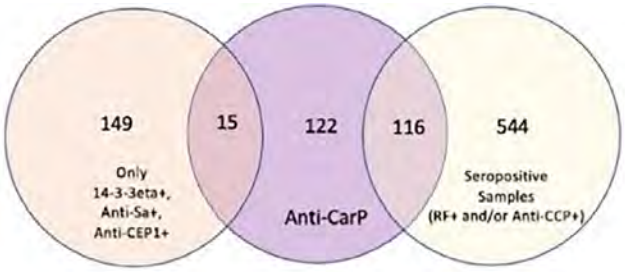
RA Profile	n=	Overall Positivity rate	Positivity rate from conventional markers alone	Incremental positivity from extra marker(s)
RheumAssure (RF, Anti-CCP, 14-3-3eta)	24549	**28.5%**	**24.2%** from RF & Anti-CCP **4.3%** from 14-3-3eta	**N/A**
RAdx6 (RF, Anti-CCP, 14-3-3eta, Anti-CarP, Anti-Sa, Anti-CEP1)	2672	**35.4%**	**24.7%** from RF & Anti-CCP **3.0%** from 14-3-3eta	**7.7%** from Anti-CarP, Anti-Sa, Anti-CarP
SeroNeg 4 (14-3-3, Anti-CarP, Anti-Sa, Anti-CEP1)	1354	**19.9%**	**6.4%** from 14-3-3eta	**13.5%** from Anti-CarP, Anti-Sa, Anti-CarP

Table 2. RAdx6 Positivity Figure 1. Anti-CarP, Anti-Sa & Anti-CEP1 in Seronegative RAdx6 Samples; Figure 2. Anti-CarP, Anti-Sa & Anti-CEP1 in SeroNeg RAdx4 Samples

RAdx6 (RF, Anti-CCP, 14-3-3eta, Anti-CarP, Anti-Sa, and Anti-CEP1)	Count	%
Total	2672	
All negative	1726	64.6%
Any positive (at least one positive)	946	35.4%
Overall RF positivity	559	21.1%
Overall Anti-CCP positivity	307	11.5%
Overall 14-3-3eta positivity	219	8.2%
Overall Anti-CarP positivity	253	9.5%
Overall Anti-Sa positivity	262	9.8%
Overall Anti-CEP1 positivity	137	5.1%
RF positive only	272	13.2%
Anti-CCP positive only	73	3.8%
14-3-3eta positive only	70	2.6%
Anti-CarP positive only	122	4.6%
Anti-Sa positive only	65	2.4%
Anti-CEP1 positive only	13	0.5%
More than one positive	331	12.4%







Overall Anti-CarP positivity	253
Anti-CarP positive only	122
Anti-CarP in Seropositive samples (i.e. RF+ and/or Anti-CCP+)	116
Anti-CarP with only 14-3-3eta+ +/- Anti-Sa+ +/- Anti-CEP1+	15

Figure 3. Anti-CarP Positivity

positivity was seen in 207 (of 2672 total) RAdx6 samples that tested negative for RF, Anti-CCP3.1 and 14-3-3 eta. SeroNegRAdx4 is designed to be useful in patients with high clinical suspicion for RA who have previously tested negative for RF and Anti-CCP. Though clinical histories are not known, almost twice as many, 13.5%, were positive for Anti-CarP and/or Anti-Sa and/or Anti-CEP1. In Table 2, positivity rates of individual markers in RAdx6 are shown where RF was the most frequently positive, followed by Anti-CCP3.1, Anti-Sa, Anti-CarP, 14-3-3 eta, and Anti-CEP1. Concomitant positivity of more than one marker was common, occurring in one third of all positives (331/946, 35.0%). Almost one-quarter (24.7%) of all RAdx6 samples were Seropositive (RF+ and/or Anti-CCP3.1+). In Seronegative samples, the positivity of Anti-CarP, Anti-Sa and Anti-CEP1 (Figures 1 and 2) may be helpful for diagnosis. Figure 3 shows that more than half the time, Anti-CarP is positive in the presence of another RA-specific marker (131/253, 51.8%).

Conclusion: Here, we show the overall positivity rates of three RA profiles. RAdx6 as the most comprehensive RA profile is positive more than one-third of the time. SeroNegRAdx4 offers a potential 20% incremental benefit in diagnosing RA. RF and Anti-CCP3.1 together can detect about a quarter of all positivity observed, but novel markers for RA, Anti-CarP, Anti-Sa and Anti-CEP1, provide additional positivity of 7.7% and 13.5% that may be beneficial in diagnosing early RA and RA in Seronegative patients. Anti-CarP was frequently positive with RF and/or Anti-CCP3.1 and as such, is a useful prognostic marker for erosive disease.

Pulmonary Involvement in Patients with Seropositive and ACPA Positive Rheumatoid Arthritis (RA-ILD) – Novel Screening Protocol for Early Detection of Pulmonary Involvement

Florian Popp[1], Martin Hoffmann[2], **Johannes von Kempis**[3], Martin Welcker[1], Werner von Wulffen[2] and Frank Reichenberger[2], [1]Medizinisches Versorgungszentrum für Rheumatologie Dr. M. Welcker GmbH, Planegg, Germany, [2]Augustinum Klinik München, Department of pneumology, Munich, Germany, [3]Kantonsspital St. Gallen, Division of rheumatology and immunology, St. Gallen, Switzerland

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Seropositive and ACPA positive Rheumatoid Arthritis (RA) is associated with significant cardiovascular and pulmonary comorbidity. However, screening for early detection of pulmonary involvement especially intestitial lung disease (ILD) in patients with seropositive and ACPA positive Rheumatoid Arthritis is not yet established.

Methods: We included a total of 50 consecutive patients with a confirmed diagnosis of seropositive and ACPA positive Rheumatoid Arthritis without symptoms for or known cardiopulmonary disease. For the purpose of this study, we used a noninvasive radiation-free approach to screen for pulmonary, pleural or vascular manifestation of the disease by means of

pulmonary function tests (PFT), cardiopulmonary exercise test (CPET), echocardiography and pleuro-pulmonary transthoracic ultrasound (LUS).

Results: The data of 43 patients (mean age 58.5 years, 81.4% female, 93.02% non-smokers) were available for this analysis, as data collection is still ongoing. With an average disease duration of 10.1 years and with a mean remission of DAS28 ESR 2.3, DAS28 CRP 2.2 or low disease activity (CDAI 6.2, SDAI 6.6), respectively, depending on the used disease activity score, 34.88 % showed an erosive course. A reduced forced vital capacity (FVC ≤80%) on PFT was shown in 3 patients (6.98%), a reduced CO-diffusion capacity (DLCOc-SB ≤80%) in 14 patients (32.56%). In 39% of patients, we found noticeable changes in LUS, 23% with a pattern consistent with ILD. ILD was suspected in 13% with changes on LUS and additional PFT.

Numerous other RA- and ILD-associated parameters were collected in the present study (table 1 and 2).

Other findings included pleural consolidation suspicious for malignancy and pleural effusion on LUS, severe aortic stenosis in bicuspid aortic valve on echocardiography, severe impaired diffusion capacity due to lung emphysema and obstructive lung disease on PFT.

None of the patients showed signs of pulmonary vascular involvement or cardiac ischaemia on echocardiography or CPET.

Conclusion: In conclusion screening of RA-patients for pulmonary involvement with a non invasive, radiation free screening approach may detect a significant number of asymptomatic patients with signs consistent with pulmonary manifestation of rheumatoid arthritis, along with a variety of other cardiopulmonary comorbidities.

Higher Intakes of Red Meat Are Associated with an Increased Risk of Developing Seropositive but Not Seronegative Rheumatoid Arthritis - Results from a Nested Case-Control Study

Rebecka Teresia Bäcklund[1], Isabel Drake[1], Ulf Bergström[1], Michele Compagno[2], Emily Sonestedt[1] and Carl Turesson[1], [1]Lund University, Malmö, Sweden, [2]Lund University, Lund, Sweden

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Healthy eating habits might prevent the development of rheumatoid arthritis (RA). We aimed to examine the relation between adherence to dietary recommendations and the risk of RA.

Methods: A nested case-control study was performed including participants from a population-based survey conducted in 1991-1996. Cases diagnosed with RA from inclusion until December 2016 were identified through register linkage and validated in a structured process. Four controls for each case, matched for sex, year of birth, and year of inclusion, were included. The controls were alive and RA-free when the index person was diagnosed with RA. Diet was assessed using a modified diet history method comprising of a seven-day menu book, a diet history questionnaire, and a complementary diet history interview.

According to the Swedish Dietary Guidelines (SDG) from 2015, a substantial daily intake of vegetables and fruits, fish and wholegrain products is recommended, whereas red meat and added sugars should be limited. Cut-off values for adherence were based on a previously validated Diet Quality Index, except for red and processed meat and added sugars, which were based on the SDG from 2015 and the World Health Organization guidelines from 2015 for sugar intake for adults, respectively.

Table 1. Baseline characteristics.

Fish and shellfish		1.08	0.87 – 1.36	1.10	0.83 – 1.47
Added sugar		1.23	0.98 – 1.53	1.05	0.76 – 1.45
Red and processed meat (g/week)		**1.39**	**1.08 – 1.79**	1.13	0.80 – 1.58

Odds ratio (OR), Rheumatoid arthritis (RA), Standard deviation (SD), Percent of total energy intake (E%), Confidence interval (CI)
* SD for: fibre 0.64 g/MJ; vegetables and fruits 185.6 g/day; fish and shellfish 229.6 g/day; Added sugar 4.28 E%; Red and processed meat: 406.0 g/week

Conditional logistic regression analysis was applied to study the relation between fibers, vegetables and fruits, fish, added sugars and red meat, and RA, with exposures treated as dichotomous (compliant with dietary recommendation or not) and continuous variables per standard deviation. Analyses were stratified for seropositive (positive for rheumatoid factor (RF) and/or anti-cyclic citrullinated peptide antibodies (anti-CCP) and seronegative (negative for RF and anti-CCP) RA. Multivariable models were designed in which covariates (smoking, alcohol and leisure time physical activity) that have been associated with both diet and RA were added. All multivariable models were adjusted for total energy intake and excluded potential misreporters of total energy intake.

Results: In the study population, 204 cases of seropositive RA and 101 cases of seronegative RA were identified (Table 1). Recommended intakes of vegetables and fruits (>400 g/week) and red meat (< 500 g/week) were associated with lower risks of seropositive, but not seronegative RA (Table 2), with similar findings in multivariable-adjusted models (odds ratios (ORs) for seropositive RA 0.59; 95% CI 0.36 – 0.97 and 0.27; 95% CI 0.14 – 0.52, respectively) (Table 3). There were corresponding associations with seropositive RA for continuous variables; for red meat OR 1.39 per SD; 95% CI 1.09 – 1.79, for vegetables and fruits OR 0.64 per SD; 95% CI 0.48 – 0.85) (Table 3). Adherence to recommended intake of fish was associated with an increased risk of RA, in particular seronegative disease, although there was no significant linear association with fish intake (Table 2, 3).

Conclusion: Adherence to recommended intakes of red meat as well as vegetables and fruits were associated with a decreased risk of developing seropositive RA. These results indicate that compliance with dietary guidelines may have differential effects on seropositive and seronegative RA.

Abstract Number: 0395

Prevalence of Objectively Measured Sleep Disturbance in Rheumatoid Arthritis (RA)

Patti Katz[1], Mary Nakamura[2], Sarah Patterson[3] and Katie Stone[4], [1]University of California San Francisco, San Rafael, CA, [2]UCSF/SFVAHCS, San Francisco, CA, [3]University of California San Francisco, Pacifica, CA, [4]University of California San Francisco, San Francisco, CA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Self-reported poor sleep is common in RA, but only a few small studies objectively measuring sleep have been conducted in RA. In general population studies, sleep disorders are associated with poor health outcomes relevant to RA, including lower pain thresholds and higher rates of depression, cognitive impairment, systemic inflammation, and cardiovascular events. We report on the prevalence of objectively-measured sleep disturbances in a longitudinal cohort of individuals with RA.

Methods: Data are from a study of sleep disorders in RA (n=133).At baseline, participants underwent 9 nights of home sleep monitoring. For the first 2 nights, participants wore a WatchPAT™ device (Itamar Medical, Ltd). For the next 7 nights, participants wore an actigraph (GT9X, Actigraph Corp., Pensacola, FL).Participants were followed over 18 months with 3 follow-ups at 6-month intervals. At each follow-up, actigraphs were worn for 7-day periods. WatchPAT monitoring was discontinued early due to the COVID-19 pandemic. The WatchPAT estimates the apnea-hypopnea index (AHI), reflecting the number of apnea or hypopnea episodes/hour of sleep, an indication of obstructive sleep apnea (OSA), and levels and timing of oxygen desaturation (O_2desat). AHI was categorized as normal-mild OSA (< 15) or moderate-severe OSA (≥15). Actigraphs yielded estimates of time in bed, time asleep, and sleep efficiency (SE, time asleep/time in bed).Acceptable SE was defined as ≥85%.Short sleep time was defined as < 7 hours. Analyses examined the frequency of moderate-high OSA, poor SE, and short sleep.

Results: Mean age was 58 ± 13 years, ∼90% female, mean BMI 28 ± 6.Mean disease duration was 16 ± 13 years, self-reported disease activity was relatively low (mean RA Disease Activity Index, RADAI, 3.3 ± 1.9). 31% were currently using glucocorticoids.116 participants had sufficient baseline actigraph data for scoring, 63 completed WatchPAT monitoring, and 58 completed both WatchPAT and actigraph assessments at baseline. Only 9.5% of the sample had normal AHI, while over half had moderate-severe OSA (Table 1).Of those with moderate-severe OSA, fewer than a quarter reported receipt of an OSA diagnosis. 10% had some time at O_2desat < 80%; 40% had >30 minutes with O_2desat < 90%.From actigraphy, mean SE was 83.8% ± 5.7% at baseline, approximately half of participants had SE < 85%, and over half of participants averaged < 7 hours sleep/night; 18% averaged < 6 hours/night (Table 2).Prevalence of poor SE and short sleep was relatively consistent over measurement periods. In the actigraph cohort, 35% had both poor SE and short sleep, 18% had short sleep only, and 16% had poor SE only (Figure 1).Among those with WatchPAT and actigraph assessments, 22% had combined OSA, poor SE, and short sleep. Only 5% had none of the sleep disorders.

Table 1. Characteristics of participants by AHI category (n = 63)

	% (n)	Ever received a diagnosis of OSA, % (n)
Apnea Hypopnea Index (AHI) category		
Normal-mild (>15)	44.4 (28)	3.6 (1)
Moderate-severe (≤15)	55.6 (35)	22.9 (8)
Oxygen Desaturation Index (ODI)		
Any time <80% O_2 saturation	10.3 (6)	
Any time <85% O_2 saturation	43.8% (25)	
>30 minutes <85%	5.3% (3)	
Any time <90% O_2 saturation	76.9% (40)	
>30 minutes	39.6 (23)	
>60 minutes	27.6 (16)	
>120 minutes	13.8 (8)	

Population estimates: General population: 4.2%[1]. Age 60-65: females, 8.2%; males, 14.6%[2].

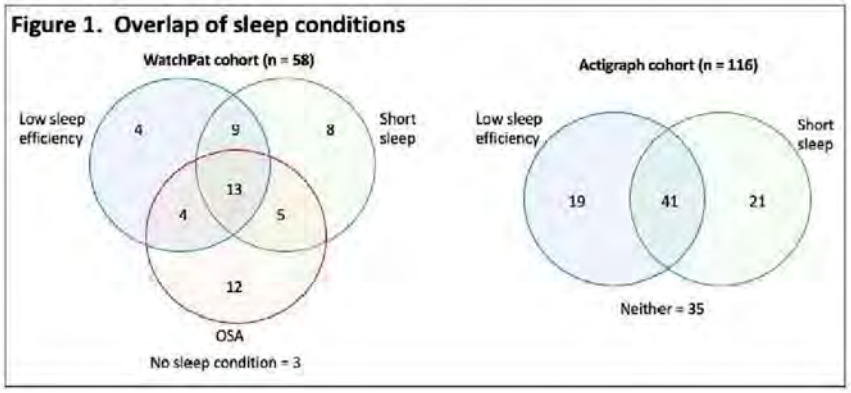
Table 2. Results from Actigraph assessments (n = 116)

	Sleep disturbance	
	Low sleep efficiency (<85%)	Short sleep (<7 hours)
T1 (n = 116)	51.7 (60)	53.5 (62)
T2 (n = 83)	60.2 (50)	57.8 (48)
T3 (n = 64)	48.4 (31)	50.0 (32)
T4 (n = 86)	51.6 (69.8)	59.1 (39)
At any time (n = 116)	69.8 (81)	64.7 (75)
At each measurement time	41.4 (48)	40.5 (47)
% of measurements with disorder	55.6 ± 43.0	53.2 ± 44.3

Figure 1 Overlap among sleep conditions



WatchPAT cohort

One condition only	
• OSA only	12 (21%)
• Low efficiency only	4 (7%)
• Short sleep only	8 (14%)
Two conditions	
• OSA + low efficiency	4 (7%)
• OSA + short sleep	5 (9%)
• low efficiency + short sleep	8 (16%)
All three conditions	13 (22%)
None of the conditions	3 (5%)

Actigraph cohort

Low efficiency only	19 (16%)
Short sleep only	21 (18%)
Both	41 (35%)
Neither	35 (30%)

Conclusion: The majority of this RA sample had at least one sleep disturbance. Given the known association of sleep disturbances with poor health outcomes and potential associations with RA-related factors such as inflammation and disordered cytokine profiles, increased awareness of sleep problems among people with RA may be beneficial. If findings are replicated, screening for OSA may be an important addition to routine care for RA.

Hydroxychloroquine Is Associated with a Decreased Risk of Non-alcoholic Fatty Liver Disease in Patients with Rheumatoid Arthritis: A Population-based, Cohort Study

Hsin-Hua Chen[1] and DER-YUAN CHEN[2], [1]Taichung Veterans General Hospital, Taichung, Taiwan, [2]Center of Rheumatology, China Medical University Hospital, Taichung, Taiwan

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a systemic autoimmune inflammatory disease characterized by chronic destructive arthritis and extra-articular involvement. Prior studies showed patients with RA had a high prevalence of NAFLD (35.2% in men with RA and 22.2% in women with RA). Lim et al. suggested that hydroxychloroquine (HCQ) may decrease the risk of NAFLD[1]. The National Health Insurance Research Database (NHIRD) in Taiwan provided nationwide, population-based claim data to facilitate a longitudinal epidemiologic study.

The aim of the study was to assess the association between HCQ and incident NAFLD in a nationwide RA cohort.

Methods: Using the 2000–2020 NHIRD, we identified 41,791 newly-diagnosed RA patients from 2002 to 2020. After excluding patients with diagnoses of liver diseases (acute/subacute necrosis of liver, chronic liver disease, live abscess/sequelae of chronic liver disease, other disorders of liver, hepatitis B, hepatitis C, alcohol related disorders, alcoholic liver disease) on or before the RA diagnosis date (n = 16,223 patients) and patients with missing data of residence of insured amount (n = 4,110), we included 21,458 patients with RA. A time-varying multivariable Cox regression model was applied to estimate the adjusted hazard ratios (aHRs) with 95% confidence interval (CIs) for the association of NAFLD with the use of HCQ after adjusting potential confounders. Subgroup analyses were conducted based on age (≤50, >50 years) and sex.

Results: The mean ± standard deviation (SD) age was 51.9 ± 14.2 years, and the female-to-male ratio was 3.2. 399 (1.86%) patients developed NAFLD during a mean follow-up period of 8.4 years, with an incidence rate of 2.21 x 10^{-3}. Multivariable time-dependent Cox regression analyses showed that HCQ use was associated with a lower risk of NAFLD (aHR, 0.75; 95% CI, 0.60–0.93; p = 0.007). Other significant predictors for the risk of NAFLD included obesity (aHR, 4.63; 95% CI, 1.47–14.59; p = 0.009), defined daily dose (DDD) of NSAID (per incremental DDD: aHR, 1.03; 95% CI, 1.02–1.05; p < 0.001), prednisolone (Pd) equivalent dose > 5 mg/day (reference: without Pd use; aHR, 2.4; 95% CI, 1.86–3.10; p < 0.001) and Pd equivalent dose ≤5 mg/day (reference: without Pd use; aHR, 0.53; 95% CI, 0.40–0.72; p < 0.001). The association between HCQ and NALFD risk was consistent in patients aged ≤50 years and female patients with RA.

Conclusion: This study revealed that using HCQ was significantly associated with a lower risk of NAFLD, particularly in RA patients aged ≤50 years and in female RA patients.

Obesity Is Associated with Worse Flare Symptoms and Quality of Life in Early Rheumatoid Arthritis: Insights from the RA Flare Questionnaire

Margaret Butler[1], Carlos Aude[2], Clifton Bingham[3] and Vivian Bykerk[1], [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY, [3]Johns Hopkins University, Baltimore, MD

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Elevated BMI has been previously associated with lower RA remission rates and underascertainment of swollen joint counts.1,2 However, a knowledge gap persists regarding the potential impact of elevated BMI on the severity of RA flare symptoms and their effects on quality of life (QOL). Our study addresses this gap, evaluating the influence of BMI on RA flare symptoms and QOL.

Methods: Participants with ≥2 swollen joints and Early/Recent Onset RA (symptoms ≤12/≤24 months) were recruited into the Consortium of Early ArThritis CoHorts-USA Study (CATCH-US) at two centers (New York, Baltimore) between December 2014 and May 2023. Baseline characteristics and patient reported outcomes (PROs) were recorded at each visit.

[1] *p<0.05; **p<0.01; ***p<0.001
[2] CI = Confidence Interval

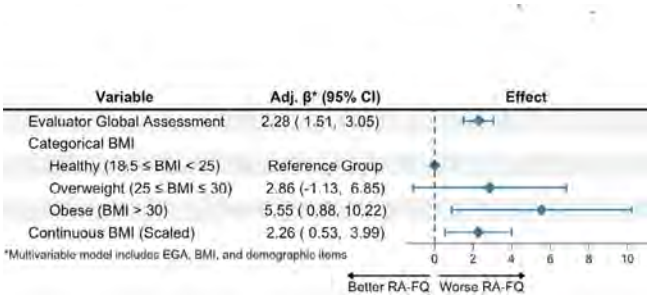

Figure 1. Forest Plot of Adjusted Betas with 95% Confidence Intervals illustrating the impact of Evaluator Global Assessment (EGA) and BMI on RA-FQ scores. BMI is presented as both a categorical and continuous variable; the continuous BMI variable is scaled such that the RA-FQ score is predicted to shift approximately 2.3 points for each standard deviation that the BMI increases/decreases (SD = 5.9).

Flares were determined using the OMERACT RA-Flare Questionnaire (RA-FQ), a PRO that assesses symptoms of Pain, Stiffness, Fatigue, and impacts on Physical Function and Social Participation (items scored from 0 to 10; best to worst); all five scores are summed for an overall score range of 0 to 50. An Evaluator Global Assessment (EGA) score, indicating RA clinical disease activity, was scored by the enrolling rheumatologist between 0 (not active) and 10 (very active). Using a multivariable linear regression model, we tested the correlation between BMI and RA-FQ scores, considering EGA scores and demographic factors as covariates.

Results: Eligible participants (n=134) were mostly female (85%), white (71%), and non-Hispanic (87%); almost half were overweight or obese (46%); median age was 47.3 years and median BMI was 24.3 (**Table 1**). Higher EGA scores ($\beta = 2.3$; $p < .001$) and elevated BMI ($\beta = 0.38$; $p = .01$) emerged as significant predictors of higher RA-FQ scores; EGA was also significantly associated with each RA-FQ subscore, while BMI was significantly associated with four of the five subscores (**-Table 2**). We observed an amplified impact of elevated BMI on RA-FQ scores in obese patients compared to those in healthy weight and overweight categories (**Figure 1**). Age was inversely related to the total RA-FQ score ($\beta = -0.11$; $p = .04$) and Function subscore ($\beta = -0.03$; $p = .01$). No significant associations were found for sex, race, or ethnicity.

Conclusion: Our findings underscore a strong correlation between EGA scores and RA-FQ scores, thereby establishing the concordance of this PRO with clinically assessed disease activity. More importantly, we found that elevated BMI is associated with more severe flare activity and diminished QOL, particularly in obese ERA patients. This result corroborates earlier studies that suggested a systematic underestimation of disease activity in patients with elevated BMI. As such, clinicians should consider patients' BMI and RA-FQ scores when formulating treatment plans for RA flares. Future research will focus on longitudinal analyses to assess the persistence of these associations throughout the course of the disease.

Identification of Disease Activity-related miRNAs Through Artificial Neural Network Analysis in Rheumatoid Arthritis

Milena Rodriguez Alvarez[1], Lissette Delgado-Cruzata[2], **Anna Tryfonos**[1], Nickolas Almodovar[2], Toni-Ann Bravo[2] and Naureen Kabani[1], [1]SUNY Downstate Health Sciences University, Brooklyn, NY, [2]The City University of New York, John Jay College, New York, NY

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) is the result of the complex interplay between genetic, epigenetic, and environmental factors leading to immune dysregulation, synovial membrane inflammation, and disability. MicroRNAs (miRNAs) are non-coding RNA molecules that alter mRNA expression, affecting multiple molecular pathways. Growing evidence suggests that miRNAs are implicated in the onset and development of RA but studies about their association with disease activity are scant. We conducted a pilot study to identify miRNAs differentially expressed in patients with RA and applied Artificial Neural Network (ANN) analysis to build a classificatory model that explored the association between levels of differentially expressed miRNAs and disease activity using Clinical Disease Activity Index (CDAI).

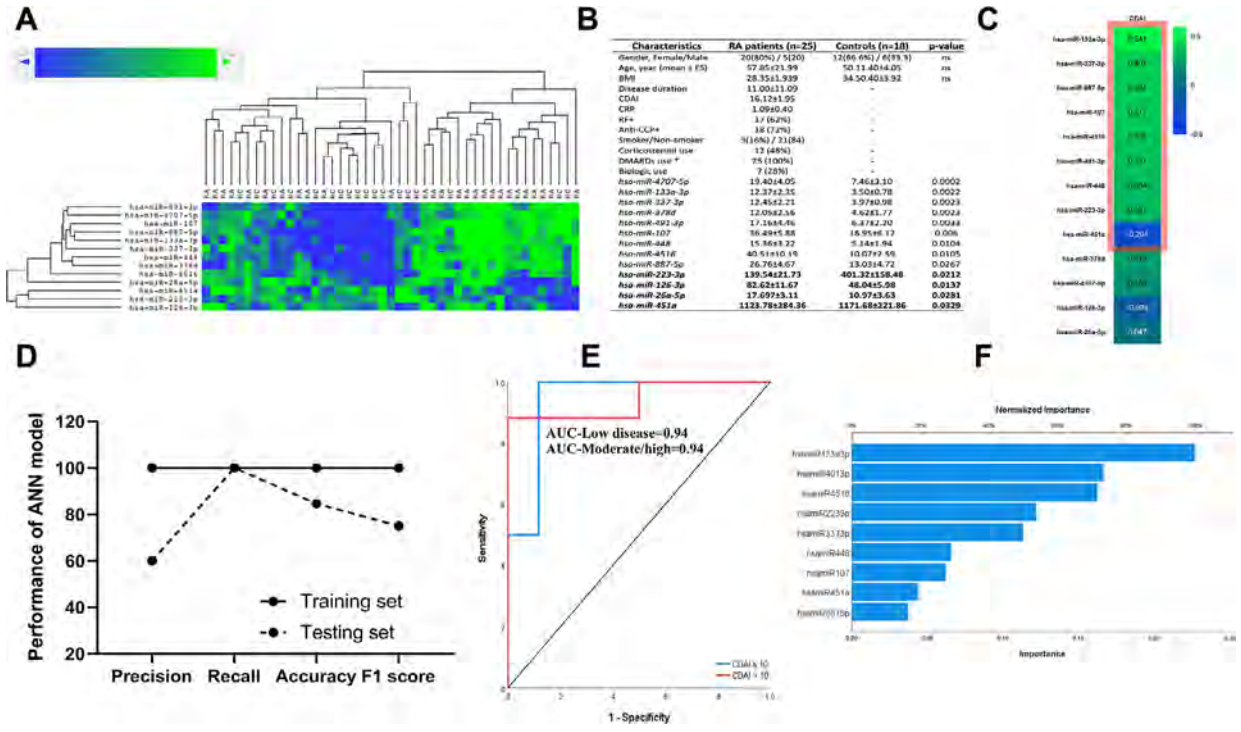

Figure 1: The association of miRNAs with Disease Activity Index in Rheumatoid Arthritis (RA) based on Artificial Neuronal Network (ANN). -A- Unsupervised hierarchical cluster analysis of 13 exosomal miRNA levels in RA patients and healthy controls (HC). -B- Demographics data and miRNA levels in RA patients and HC. -C- Heatmap of Pearson correlation coefficients between 13 miRNAs levels and CDAI numeric values.Statistical significant correlations ($p<0.05$ and/or ES≥0.3) are enclosed in a pink-colored box. -D-. Performance of the ANN model classifying disease activity of RA patients based on miRNAs. -E- ROC curve for the ANN Model and AUC values to predict disease activity levels. -F- Normalized contribution of each miRNAs to the ANN model.

Methods: We recruited 43 subjects, 18 healthy controls (HC), and 25 RA patients. Serum from all participants was collected, exosomes isolated, and miRNAs extracted. Using the Nanostring nCounter miRNA expression panel, levels of 800 miRNAs were determined. We identified 9 miRNAs using nSolver software analysis that had the largest difference (top 10%) between groups and a RA:HC ratio in the top 50%. In subsequent analysis, we also included 4 previously reported RA-relevant miRNAs. The 13 miRNA panel showed good discrimination between RA and HC (Figure 1A). We used the Mann-Whitney t-test to identify mean differences and Pearson correlation to assess the association between miRNA levels and CDAI. ANN analysis was used to build a classificatory model. All analysis was carried out with SPSS v.28, $p \leq 0.05$ was considered statistically significant, and Pearson correlation coefficients were important when $p < 0.05$ and/or the effect size (ES) was moderate or high (ES >0.3).

Results: Of the 13 identified RA-relevant miRNAs in this study (Figure 1A, B), 9 correlated with CDAI (Figure 1C). These 9 miRNAs, ***miR -133a-3p, miR-337-3p, miR -887-5p, miR-107, miR-4516, miR-491-3p, miR-448, miR-223-3p***, and ***miR-451a***, were further selected for the ANN analysis. 70% of the sample was used to train the ANN model and 30% to test it. The training set scored 100% in all performance metrics (Figure 1D), whereas the testing set performed 80% in recall and accuracy, 60% in precision, and 75% in F1 score. The receiver operating characteristic curve (ROC) illustrates the diagnostic ability of the model expressed as low (CDAI≤10) and moderate/high (CDAI >10) disease activity. The area under the ROC curve (AUC) is 0.94 indicating excellent classificatory prediction for the model (Figure 1E). The 4 miRNAs that most contributed to the model were ***miR-133a-3p, miR-491-3p, miR-4516,*** and ***miR-223-3p*** (Figure 1F).

Conclusion: Our study for the first time describes ***miR-133a-3p, miR-491-3p,*** and ***miR-4516*** as differentially expressed in RA. We also described 9 miRNAs not previously correlated with RA disease activity. An ANN model built with these 9 miRNAs had an excellent classificatory capacity for RA patients with low or moderate-high disease activity, therefore providing a new set of potential biomarkers as a starting point to assess RA disease activity and response to treatment in future studies.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I

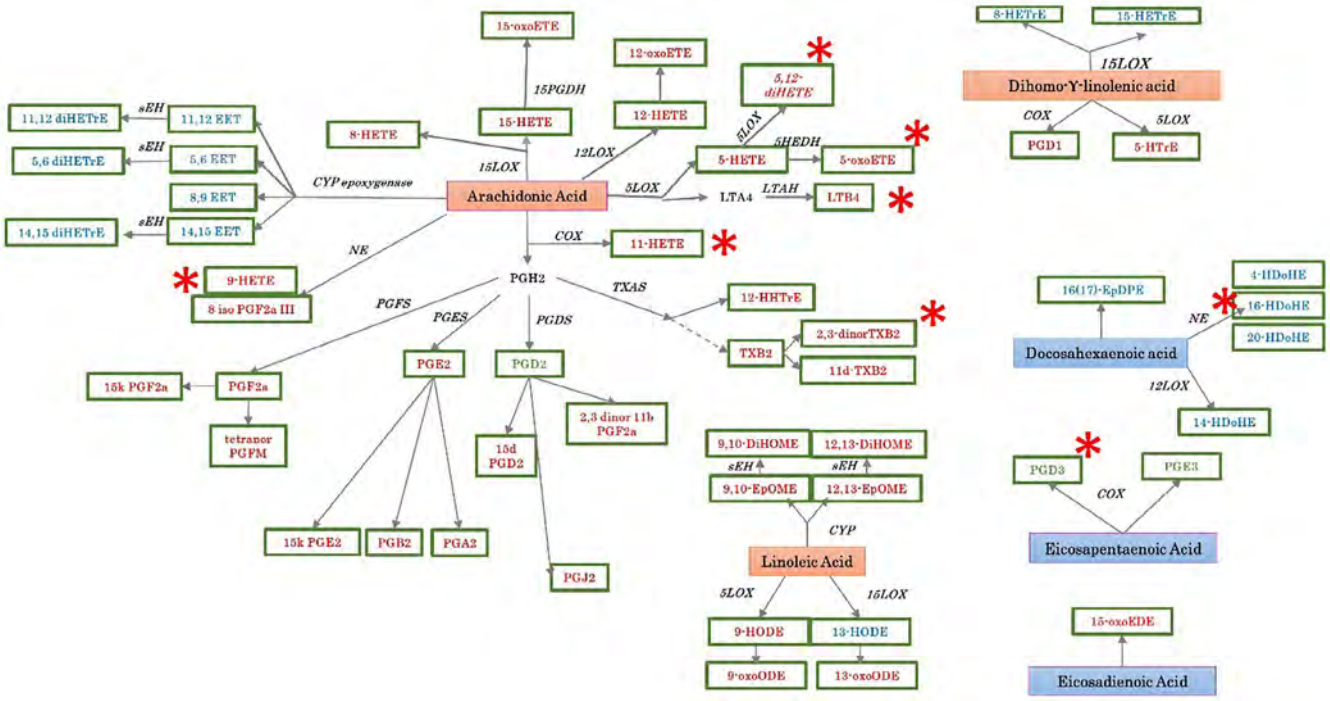
Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Synovial membrane represents the target tissue of Rheumatoid Arthritis (RA) inflammation. Our study aimed to perform a comprehensive quantification of oxylipins and their precursors in synovial tissue specimens of RA patients across disease trajectory.

Methods: 32 patients fulfilling the ACR/EULAR 2010 classification criteria underwent US-guided minimally invasive synovial tissue biopsy of the knee [n=16 patients with DAS28≥4.2 and n=16 patients in sustained (≥12 months) clinical (DAS28≤2.6) and ultrasound remission (Power Doppler negative)]. Oxylipins in synovial tissue were determined by liquid chromatography with tandem mass spectrometry (LC-MS-MS) and were classified into groups according to their precursor: arachidonic acid (AA), LA, ALA, DHA, EPA and DGLA. Moreover, each sample was processed for histology and the synovitis degree was assessed using H&E-based scoring by pathologist blinded on clinical characteristics. Statistical analysis was performed using MetaboAnalyst 5.0 and SPSS software v27.

Results: Among the general panel, 84 different oxylipins were detected in at least one sample and 55 oxylipins remained after eliminating those with less than 50% across the samples (Figure 1). Stratifying RA patients based on the disease status, synovial tissue of active RA was significantly enriched of distinct specialized pro-resolving lipid mediators (SPMs) precursors such as free AA (p=0.0045), free adrenic acid (p=0.0080) and free docosahexaenoic acid (p=0.012) compared to synovial tissue of RA patients in sustained remission. Moreover, considering a threshold ≥4 of oxylipins expression, synovial tissue of active RA showed an 5LOX-derived oxylipins enrichment of 16.087 folds of 5,12-diHETE, 5.7419 folds of LTB4, TXA-derived 34.259 folds of 2,3 dinor TXB2, non-enzymatic -derived 6.192 folds of 16-HDoHE, 5.5097 folds of 9-HETE and, COX-derived oxylipins 4.8275 folds of 11-HETE compared to synovial tissue of RA patients in sustained clinical and ultra-sound remission which was enriched 5.1589 folds of PGD3. Finally, the enrichment of pro-inflammatory SPMs was directly correlated with the histological synovitis degree (R^2=0.473, p=0.006) particularly with the score of synovial hyperplasia (R^2=0.472, p=0.006) and inflammatory infiltrate (R^2=0.466, p=0.007).



Oxylipins observed in at least 50% of the samples by precursor and pathway are shown. Proinflammatory oxylipins are marked on red letters, while anti-inflammatory oxylipins are marked on blue letters. The n-3 polyunsaturated fatty acids (PUFAs) precursors are marked on red squares, while the n-6 PUFAs precursors are marked on blue squares. Those oxylipins with pro and anti-inflammatory reported roles are marked on green letters.

Conclusion: Synovial tissue of RA patients shows a differential enrichment of oxylipins and their precursors which is contingent with the disease status directly mirroring the synovitis degree in terms of synovial hyperplasia and inflammatory infiltrate.

Thresholds of Presenteeism Measurement Instruments for Unacceptable Work Participation and Future Adverse Work Outcomes in Rheumatoid Arthritis

Dafne Capelusnik[1], Sofia Ramiro[2], Elena Nikiphorou[3], Walter P. Maksymowych[4], Marina Nighat Magrey[5], Helena Marzo-Ortega[6] and Annelies Boonen[7], [1]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [2]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [3]King's College London, London, United Kingdom, [4]University of Alberta, Edmonton, AB, Canada, [5]Case Western Reserve University, University Hospitals, Cleveland, OH, [6]NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [7]Care and Public Health Research Institute (Caphri), Maastricht University, Maastricht, Netherlands

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Presenteeism is associated with lower work satisfaction and increased risk of future sick leave in rheumatic diseases. It is generally measured on a continuous scale; however, despite a lower precision, identifying persons with a meaningful level of presenteeism can improve interpretation in clinical studies and might be useful in routine practice. Recently, thresholds of meaning for presenteeism instruments were established for axial spondyloarthritis (axSpA). Our objectives were 1) To identify thresholds for presenteeism instruments that reflect unacceptable work status in patients with RA and whether those thresholds could predict future adverse work outcomes; 2) to assess in patients with RA the performance of presenteeism thresholds previously established in axSpA for the same instruments.

Methods: We used data from the 1-year multinational prospective study on Patient-Reported Outcomes in Employment Study in Rheumatoid Arthritis (RA-PROSE). Thresholds to determine when patients consider themselves in unacceptable work status were calculated at baseline for 4 presenteeism instruments (Work Productivity and Activity Impairment

Table. Optimal thresholds for presenteeism measures and patients correctly classified for unacceptable work status and adverse work outcome during 12 months.

	Optimal threshold (SE/SP)	Correctly classified for unacceptable work status n (%)	Correctly classified for AWO during 12 months n (%)
WPAI presenteeism (0-100)	≥30 (89/70)	66 (73)	57 (69)
	≥40 (78/82)	77 (82)	62 (75)
QQ method (0-10)	<8 (67/55)	53 (56)	49 (59)
	<7 (56/64)	59 (63)	57 (69)
WALS (0-3)	≥0.61 (89/59)	51 (62)	44 (61)
	≥0.75 (67/68)	56 (68)	49 (68)
WLQ 25 (0-100)	≥27 (89/77)	53 (57)	45 (55)
	≥29 (77/80)	57 (61)	46 (56)
Pain (0-10)	≥4 (67/68)	64 (68)	61 (73)

The final thresholds are colored in green and correspond to the one's derived from axSpA. For pain measurement there was no axSpA derived threshold.

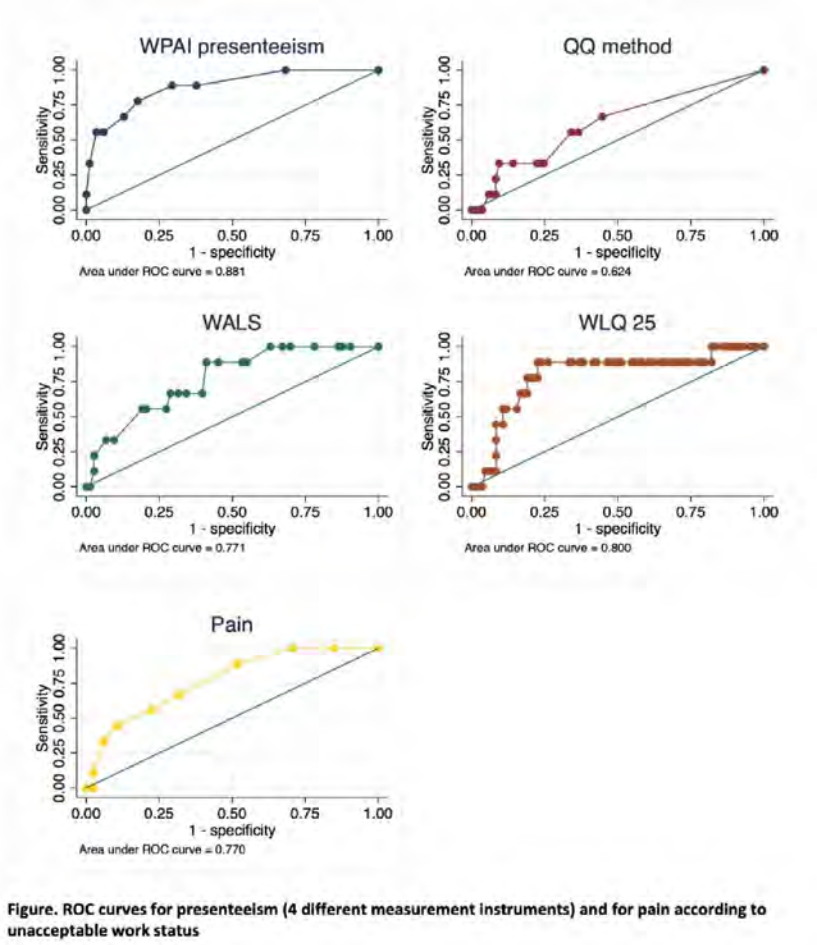

Figure. ROC curves for presenteeism (4 different measurement instruments) and for pain according to unacceptable work status

Figure. ROC curves for presenteeism (4 different measurement instruments) and for pain according to unacceptable work status.

questionnaire -WPAI-, Quality and Quantity method -QQ-, Workplace Activity Limitations Scale -WALS- and Work Limitations Questionnaire -WLQ 25-) and for a patient global assessment of pain.

We created receiver operating characteristic (ROC) using as external criterion addressing one's ability to perform current job satisfactorily. We used different approaches (75th percentile, Youden index, Liu method, nearest to 0.1) to determine the optimal cut-off, while balancing over-under diagnosis (i.e. specificity and sensitivity). Next, accuracy of thresholds to predict future adverse work outcome (AWO) throughout 12 months (defined as sick leave or long-term disability) was assessed. The recently developed presenteeism thresholds for axSpA were also tested.

Results: 105 employed patients were included: 77% females, mean age 48 (SD 9), with a symptom duration of 9.8 (8.7) years. 15% of the patients considered themselves in an unacceptable work status and 7 (8%) had at least one AWO during the 12 months.

All instruments showed good performance vs the external criterion (AUC >0.75) except for the QQ method (AUC 0.62) (figure). The table shows for each instrument (presenteeism and pain) the optimal thresholds and their performance to correctly identify an unacceptable work status and AWO during 12 months for the RA-specific threshold (1st row) and the available axSpA threshold (2nd row). Interestingly, the axSpA thresholds performed better to classify work status as unacceptable and to predict AWO (somewhat lower sensitivity but higher % of correctly classified patients). For adverse work outcome over 12 months, pain and WPAI performed better especially in predicting AWO.

Conclusion: Thresholds for presenteeism and pain representing unacceptable work status have been established for RA. Previously developed thresholds for axSpA showed an even better performance and are therefore the preferred to be used. WPAI performed the best and can be used to identify patients requiring more tailored care in order to avoid future AWO.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid Arthritis is a chronic autoimmune disease characterized by persistent joint inflammation. According to international guidelines, the treatment target should aim to reach the remission state or at least the low disease activity (LDA), evaluated through the disease activity score, including DAS28, CDAI, and SDAI. All the disease activity

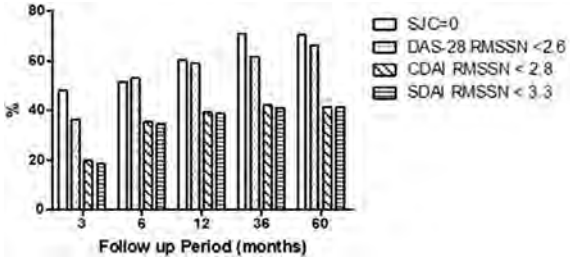

Figure 1. Percentage of patients reaching a SJC=0 and remission status according to DAS28, CDAI, and SDAI definitions up to 5 years of follow-up

composite scores include the swollen joint count (SJC) as the main clinical evaluation. Following this, the ACR/EULAR Boolean criteria were validated with a SJC >1. To the best of our knowledge, no studies have been addressed in the evaluation of no SJC and is association with the other response criteria. The aim of the study is to determine which baseline variables are associated with achieving and maintaining a zero SJC.

Methods: We enrolled RA patients included in the ERA UCLouvain Brussels cohort naïve to DMARDs therapy according to the ACR/EULAR 2010 criteria. Each patient had a complete rheumatological evaluation at baseline and up to 60 months of follow-up. The patient's characteristics including clinical and serological features were collected. The association between swelling, bone erosion, and clinical and disease characteristics was analyzed, aiming at identifying any variables associated with the reaching of SJC=0.

Results: We enrolled 455 RA patients (Male/Female 29.5%/70.5%, medium age 48.8±14.7. At baseline, the mean SJC was 8.70 ±7.44, the mean DAS28 was 4.76±1.38, Age 48.8±14.7, ACPA and RF prevalence was 68.9% and 64.7% respectively. Bone erosions were identified in 45.5% of patients. In figure 1. are reported the percentage of patients reaching a SJC=0 and remission status according to DAS28, CDAI, and SDAI definitions up to 5 years of follow-up. In our cohort at 3 and 6 months, respectively 37.2%, 21.3%, 22.2% and 39.3%, 28.5%, 27.7% of the patients fulfilling DAS28, CDAI or SDAI remission presented at least one SJC. Among all the baseline analyzed features, Baseline Erosion was the strongest predictor of at least one SJ from baseline to 5 years of follow-up: (3 months: 36.2% versus 54.1%; p< 0.001; 6 months: 36.7% versus 54.9%; p< 0.001; 12 months: 39.3% versus 55%; p=0.034; 36 months:43.9% versus 56.2%; p=0.045; 60 months: 47.1% versus 62.8%; p=0.019). Smokers had a lower chance to reach a SJC count at three months (20.8% versus 29.7%; p=0.042), and the female sex had the same association at 60 months of follow-up (65.8% versus 78.2%; p=0.0019). Focusing on long-time follow-up (5 years), including only MTX-treated patients (n=141), the group of subjects who never reached a SJC=0 were characterized by a higher baseline age (52.1±15.7 versus 46.7±15.5; p=0,150), DAS28 (5.08 ±1.38 versus 4.04±1.16; p=0.001), RF prevalence (81.5% versus 62.7%; p=0.08) and baseline erosions (77.8% versus 36.7%; p=0.0004).

Conclusion: We identified an association between baseline disease features and the chance of not reaching a SJC of zero, suggesting how smoking, presence of RF, and baseline erosion may identify a group of patients with clinically persistent joint inflammation, whit a greater risk of not reaching remission. We confirm also that the resolution of SJC is a good practical end point in ERA.

Automated Detection and Quantification of Hand Joint Swelling in Rheumatoid Arthritis: Computer Vision, Deep Neural Network Models, and a Potential Biomarker for Disease Activity Monitoring

Marc Blanchard[1], Jules Maglione[2], Cinja Koller[3], Patrick Hermann[4], David Brüschweiler[3], Arnd Kleyer[5] and Thomas Hügle[6], [1]Dept. of Rheumatology, University Hospital Lausanne (CHUV) and University Lausanne, Lausanne, Switzerland, [2]EPFL, Lausanne, Switzerland, [3]Lausanne University Hospital, Lausanne, Switzerland, [4]ATREON SA, Lausanne, Switzerland, [5]University Hospital Erlangen, Erlangen, Germany, [6]Dept. of Rheumatology, University Hospital Lausanne (CHUV) and University of Lausanne, Lausanne, Switzerland

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: We have previously shown that automated detection and processing of dorsal finger fold patterns from hand photographs can be used as a digital biomarker for joint swelling in rheumatoid arthritis.

In this study, we tested different computer vision and deep learning methods for the automated quantification of dorsal finger folds and diameter of proximal interphalangeal finger joints (PIP) in patients with rheumatoid arthritis. Additionally, the selected model aimed to evaluate the difference in PIP finger joint swelling between healthy individuals and rheumatoid arthritis patients.

Methods: We evaluated the detection and measurement of PIP joint diameter and dorsal finger fold length on hand photographs in 1783 joints of patients with rheumatoid arthritis by canny edge or ridge detection computer vision models or a newly trained convolutional neural network, respectively. The models have been trained to calculate the finger fold index (FFI, potential biomarker for joint swelling), defined as the ratio between pixel length of joint diameter and mean recognized finger folds. In an independent healthy control dataset, the FFI has been calculated to be compared with rheumatoid arthritis PIP joints.

Results: Canny edge and ridge detection were suitable models to detect dorsal finger fold patterns. The prediction of joint diameter and finger fold pixel length was best achieved in a newly trained deep neural network model, where the FFI was predictable in 93% of the images. The accuracy of correct detection of joint diameter measurement was 91%. In 1783 PIP joints of patients with rheumatoid arthritis, the mean FFI was significantly higher than in 168 healthy controls PIP joints (3.42 ± SD 1.04 and 2.15 ± SD 0.68, respectively, p-value < 0.05).

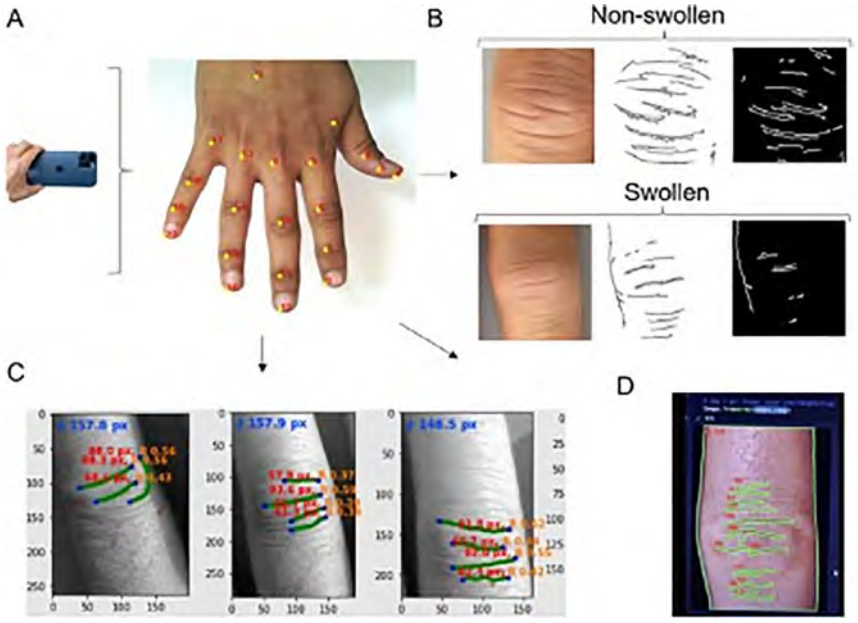

Figure 1: A: Keypoint detection. B: Canny edge detection. C: Metrical analysis with ridge detection. D: Newly trained deep neural network.

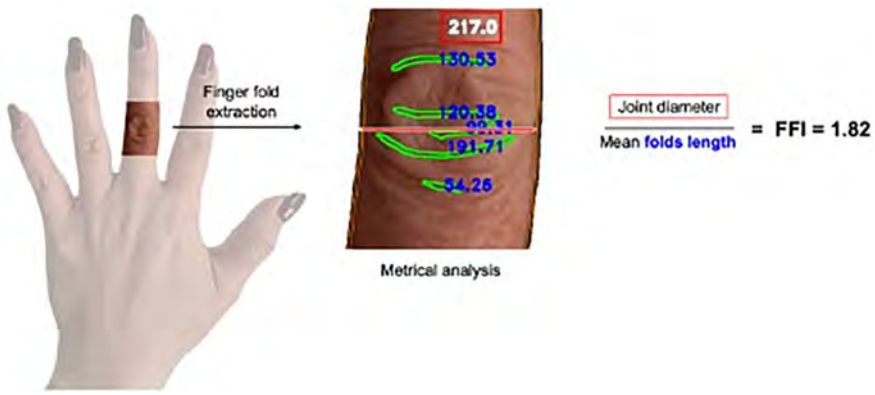

Figure 2: Finger Fold Index (FFI) detection and quantification, from the finger fold extraction (image recognition) to the metrical analysis and calculation (deep neural network).

Conclusion: Finger fold index calculated by a deep neural network model seems a reliable tool for the metrical analysis and thus gradeless detection of swelling in patients with rheumatoid arthritis. Standard deviation for FFI in patients with rheumatoid arthritis was higher than in healthy patients. Therefore, further investigation by stratifying patients into different disease activity levels as well as the correlation of FFI with longitudinal changes of clinical scores on a joint-level and general disease activity is ongoing.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Frailty, defined as an increased vulnerability to stressors and adverse health outcomes, is an emerging concept in RA. Active RA disease gives rise to inflammation, pain, and joint damage leading to functional impairment and morbidity, which cumulatively influences frailty status. However, the association between frailty and RA disease activity is incompletely understood. Given that RA disease activity may impact frailty status but could also be confounded by other health factors, we examined the relationship of disease activity and frailty in a large RA cohort with robust co-variable adjustment.

Methods: A cross-sectional descriptive study was performed on baseline data from the VA Rheumatoid Arthritis (VARA) Registry, a multi-center prospective cohort which began enrolling in January 2003. All participants met ACR criteria for RA. Frailty was measured using the 31-item VA-Frailty Index (VA-FI) which includes diagnostic and procedure codes linked to health-related deficits encompassing morbidity, functional status, cognition and mood, sensory impairment, and other geriatric syndromes from the 3 years prior to enrollment. The VA-FI is a ratio of all deficits and ranges from 0 to 1 with scores >0.2 considered frail. RA disease activity was measured during routine clinical care using the DAS28-ESR. Multivariable logistic regression was used to evaluate the association between frailty and disease activity adjusting for age, sex, disease duration, smoking status, BMI, prednisone use, conventional synthetic DMARD use, and biologic DMARD use, obtained from the registry and linked VA data. Due to collinearity the Rheumatic Disease Comorbidity Index (RDCI) and MDHAQ were not included in the multivariable model.

Results: Of the 2,240 participants studied, 89% were male, mean age was 64.2±10.9 years, mean RA disease duration was 11.1±11.3 years, majority were White (77%), and had moderate RA disease activity (39%). Frailty was observed in 29% of participants at enrollment. Those categorized as frail were older (68.7 vs. 62.3 years), had longer RA disease duration (11.7 vs. 10.9 years), had higher RDCI scores (5.0 vs. 2.7), and higher MDHAQ scores (1.0 vs. 0.8) compared to non-frail participants (Table 1). In the multivariable model, with remission as the reference group, RA disease activity was significantly associated with frailty with the following odds ratios: low disease activity 1.59 (95% CI 1.14-2.21), moderate disease activity 1.65 (95% CI 1.26-2.17) and high disease activity 2.17 (95% CI 1.60-2.94) (p-values all < 0.01) (Table 2). These associations were not attenuated in the adjusted model.

Table 1. Characteristics of the whole cohort and by frailty status measured by the VA Frailty Index. Reported as N (%) or mean (SD).

	Total N = 2,240	Non-frail N = 1,591 (71%)	Frail N = 649 (29%)

*Missing N=257 (12%)

Table 2. Unadjusted (N=2,240) and adjusted (N=2,186) logistic regression models evaluating the relationship between frailty and RA disease activity.

DAS28-ESR Category	OR*	95% CI	p-value	aOR**	95% CI	p-value
Remission	Ref	–	–	Ref	–	–
Low	1.57	1.15-2.15	0.004	1.59	1.14-2.21	0.007
Moderate	1.66	1.29-2.13	<0.0001	1.65	1.26-2.17	<0.0001
High	2.09	1.58-2.76	<0.0001	2.17	1.60-2.94	<0.0001

*Values are odds ratios for predicting frailty.
**Model was adjusted for baseline age, sex, RA disease duration, smoking status, BMI, prednisone use, conventional synthetic DMARD use, and biologic DMARD use.

Conclusion: RA disease activity has a strong, independent association with frailty in Veterans with RA. Point estimates remained consistent between unadjusted and adjusted models suggesting a robust association. Future studies evaluating the longitudinal relationship between these two measures are needed to understand the causal relationships underlying this association and to determine if improving disease activity can impact frailty status.

Persistent Pain and Its Predictors After Start of Anti-TNF Therapy in Rheumatoid Arthritis – Is Line of Treatment Linked to Different Pain Patterns?

Carmen Roseman, Johan Karlsson Wallman, Jon Einarsson, Elisabeth Mogard, Elisabet Lindqvist, Meliha Kapetanovic and **Tor Olofsson**, Lund University and Skåne University Hospital, Lund, Sweden

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Persisting pain with or without inflammation control is a common and debilitating symptom in rheumatoid arthritis (RA). Concerns have been raised that patients with non-inflammatory pain features might accumulate along the treatment path, but data is limited. The aim of this study was to examine prevalence and dynamics of unacceptable pain and unacceptable pain despite inflammation control (refractory pain), as well as predictors of these pain states, comparing TNF-inhibitor (TNFi) treatment lines in established RA.

Methods: RA patients starting a 1st, 2nd or ≥3rd TNFi treatment line 2004-2009 were identified in the South Swedish Arthritis Treatment Group register: N=993 for a 1st TNFi (77% women, mean age 58y, mean disease duration 10y); N=439 for a 2nd TNFi (83%, 56y, 14y); and N=143 for a ≥3rd TNFi (88%, 58y, 16y). A patient could contribute with data to more than one treatment line. Unacceptable pain was defined as >40 mm on a Visual Analogue Scale (VAS; 0-100 mm), according to the Patient Acceptable Symptom State (PASS),[1]and inflammation control captured through CRP < 10 mg/L combined with ≤1 swollen joint (of 28), as previously described.[2] Frequencies of unacceptable and refractory pain were respectively

assessed at 0, 3, 6, 12 and 24 months and compared between treatment lines by Chi-2 test. Potential predictors at start of each TNFi line were estimated in relation to unacceptable/refractory pain at 24 months by logistic regression.

Results: In patients initiating a 1st TNFi, unacceptable pain decreased from 84% to 42% from therapy start to 24 months. Corresponding figures at 24 months were 49% for a 2nd TNFi (p=0.14 vs. 1st) and 63% for a ≥3rd TNFi (p=0.009 vs. 1st) (Figure). Refractory pain at 24 months was 18%, 24% and 26% for a 1st, 2nd and ≥3rd TNFi (2nd and ≥3rd line treatments

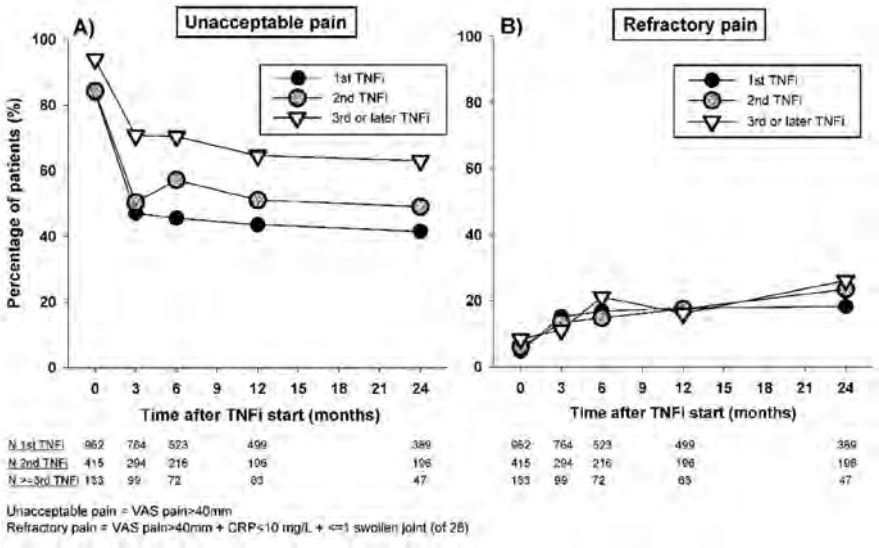

Figure. Frequency of unacceptable pain (A) and refractory pain (B) during 24 months after start of a TNF-inhibitor (TNFi), shown for a 1st, 2nd and ≥3rd TNFi treatment line in RA patients initiating therapy 2004-2009.

Refractory pain: VAS pain >40 mm + CRP<10 mg/L + ≤1 swollen joint (of 28)

Statistically significant estimates ($p<0.05$) are shown in bold font

Univariably significant predictors were adjusted through multivariate models with adjustment covariates chosen based on subject matter knowledge. Covariates with a correlation ≥0.4 or ≤-0.4 were not introduced in the same model. VAS pain, VAS global and HAQ were adjusted for sex, age, disease duration, SJC and CRP. SJC was adjusted for sex, age, disease duration and CRP, whereas CRP and ESR were adjusted for sex, age, disease duration, SJC and VAS pain. TNFi, tumor necrosis factor inhibitor; OR, odds ratio; CI, confidence interval; TJC, tender joint count; SJC, swollen joint count; CRP, C-reactive protein; ESR, erythrocyte sedimentation rate; VAS, visual analogue scale; DAS28, disease activity score with 28 joint count; HAQ, health assessment questionnaire; EQ-5D, EuroQol 5-Dimensions; MTX, methotrexate; NSAID, non-steroid anti-inflammatory drug.

non-significant vs. 1st line). Higher baseline HAQ and VAS pain/global, more tender joints, and lower EQ-5D utility were associated with a higher risk of 24-month unacceptable pain in patients starting both a 1st and later TNFi treatment lines, in adjusted analyses (Table 1). For refractory pain, higher VAS pain/global were the only significant predictors across treatment lines, while for a 1st TNFi refractory pain was also predicted by lower CRP and ESR, as well as higher HAQ (Table 2).

Conclusion: Unacceptable pain at 2 years follow-up is more frequent in later TNFi treatment lines and almost half of this pain load is due to pain indicative of a non-inflammatory mechanism. Predictors of unacceptable pain are largely stable across treatment lines, while for refractory pain they vary with line of treatment. The results suggest a selection of RA patients with intense pain, including non-inflammatory components, in later TNFi treatment lines. This highlights a need for additional pharmacologic and non-pharmacologic therapies that more specifically target various pain features.

Abstract Number: 0405

Clinical Features of Anti-Th/To Antibodies-positive Systemic Sclerosis Patients: A Single-center Retrospective Study

Ko Fujii, Motoki Horii, Natsumi Fushida, Tomoyuki Ikeda, Yasuhito Hamaguchi and Takashi Matsushita, Department of Dermatology, Faculty of Medicine, Institute of Medical, Pharmaceutical and Health Sciences, Kanazawa University, Kanazawa Ishikawa, Japan

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-Th/To antibodies (Abs) have been reported in patients with systemic sclerosis (SSc). The presence of anti-Th/To Abs is detected in 2-5% of SSc cases and is more frequently observed in the limited cutaneous SSc (lcSSc). In the Japanese population, there is a higher incidence of concurrent gastroesophageal reflux disease (GERD) and interstitial lung disease (ILD), although the severity of these complications tends to be milder compared to European and North American populations. Due to the low expression frequency and few case reports on this Abs, there is no consensus on clinical significance of this Abs.

Methods: Thus, to examine the clinical characteristics of patients with anti-Th/To Abs, we retrospectively identified 10 patients by using the serum immunoprecipitation assays between 2001 and 2021.

Results: Among the anti-Th/To positive cases, only lcSSc was observed, and diffuse cutaneous SSc (dcSSc) was not detected.

Compared to 596 cases of Th/To-negative SSc from our hospital, the modified Rodnan total skin thickness score (mRSS) was significantly lower in the anti-Th/To positive group (2.8 [0-9] vs. 10.1 [0-49], $p < 0.05$). Additionally, there was a significantly higher rate of ILD (8/9 vs. 143/596, $p < 0.01$) and Pulmonary arterial hypertension (PAH) (3/9 vs. 41/596, $p < 0.05$) in the anti-Th/To-positive group compared to the negative group. Although there was no significant difference, GERD was more common in the anti-Th/To positive group (63%) compared to the negative group (44.3%). No cases of renal crisis were observed in patients with anti-Th/To positive SSc.

When compared to 170 SSc patients with anti-topoisomerase antibodies, which are known to be frequently associated with ILD, there was no significant difference. However, the anti-Th/To-positive group had a higher rate of ILD.

Conclusion: In conclusion, patients with anti-Th/To antibodies exhibit mild skin sclerosis but have an increased risk of developing organ complications such as ILD and PAH in the future.

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Several therapeutic options are currently available to treat rheumatoid arthritis (RA); however, the response to treatment is highly variable, and not all patients achieve clinical remission. Obesity is suggested to lower the chances of remission, even though a recent observational study has shown that obesity is not associated with reduced response to conventional synthetic anti-rheumatic drugs in patients with early RA. Here, we aim to determine if obesity affects the response to treatment in participants with early RA.

Methods: This report includes 393 Swedish patients from the NORD-STAR study, which is a multicenter, randomized trial on 812 patients with untreated early RA [4]. Participants have been randomized at baseline into 4 arms of treatment: methotrexate combined with (1) prednisolone, (2) certolizumab, (3) abatacept, or (4) tocilizumab. Scores for disease activity and blood samples were measured and collected before randomization and at 24-week follow-up.

Table 1. Disease activity scores and inflammatory parameters at 24 weeks follow-up stratified by baseline BMI. Abbreviations: TJC28, tender joint count; VAS, visual analogue scale of pain; ESR, erythrocyte sedimentation rate.

	BMI (kg/m^2)		
	< 30	≥ 30	P-values
DAS28-ESR	2.2±1.1	2.8±1.2	<0.001
DAS28-CRP	2.1±0.9	2.6±1.0	<0.001
CDAI	5.0±5.3	7.5±6.4	0.001
SJC28	0.7±1.4	0.9±1.4	0.418
TJC28	1.8±3.1	3.0±4.2	0.256
Global VAS, patient, mm	17±18	25±22	<0.001
Global VAS, investigator, mm	8±9	11±11	0.018
ESR, mm/h	11±10	15±16	0.031
CRP, mg/L	2.2±3.1	4.4±7.1	<0.001

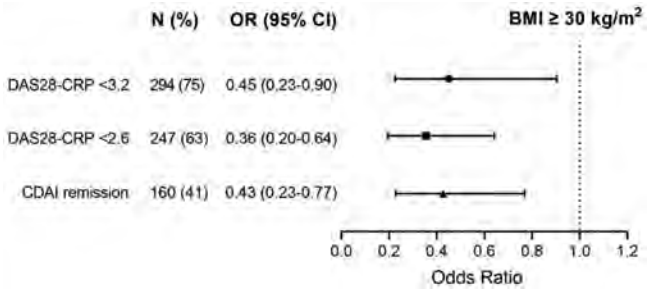

Fig. 1. Multivariable binary logistic regression analysis for response to treatment at 24 weeks according to BMI (reference category: BMI< 30 kg/m2).

Multiple linear regression and binary logistic regression analyses were performed adjusting for sex, baseline age, anti-citrullinated peptide antibody status, current smoking, disease activity score- C-reactive protein (DAS28-CRP), and treatment randomization. The outcomes for this report were: DAS28-CRP ≤3.2 (DAS28-CRP low disease activity), DAS28-CRP ≤2.6 (DAS28-CRP remission) and clinical disease activity index (CDAI) ≤2.8 (CDAI remission).

Results: In total, 75 (19%) participants had obesity at baseline, defined as body mass index (BMI) ≥30 kg/m^2. The percentage of patients with obesity in each treatment group was (1) 25%, (2) 15%, (3) 19% and (4) 19%. At baseline, there were no differences in terms of disease activity indices and inflammation parameters between patients with BMI <30 vs. ≥30 kg/m^2, except for number of swollen joints (SJC28), which was slightly lower in those with obesity (mean±SD, 8±5 vs. 9±5, p=0.018). At 24-week follow-up, patients with obesity had higher disease activity indices and inflammation parameters compared to those with lower BMI (Table 1). Moreover, patients with obesity had a lower chance of achieving response to treatment as measured by DAS28-CRP ≤3.2 (OR 0.5, 95% CI 0.2 - 0.9, p=0.025), DAS28-CRP ≤2.6 (OR 0.4, 95% CI 0.2 - 0.6, p < 0.001) and CDAI remission (OR 0.4, 95% CI 0.2 - 0.8, p=0.006), compared to patients with lower BMI (Fig. 1). BMI-treatment interaction was not significant for any score of disease activity.

Conclusion: In patients with early RA, obesity was not associated with higher disease activity before treatment initiation. However, 24 weeks after treatment, patients with obesity had higher disease activity and lower chances to respond to therapy compared to patients with lower BMI irrespective of treatment.

SESSION INFORMATION

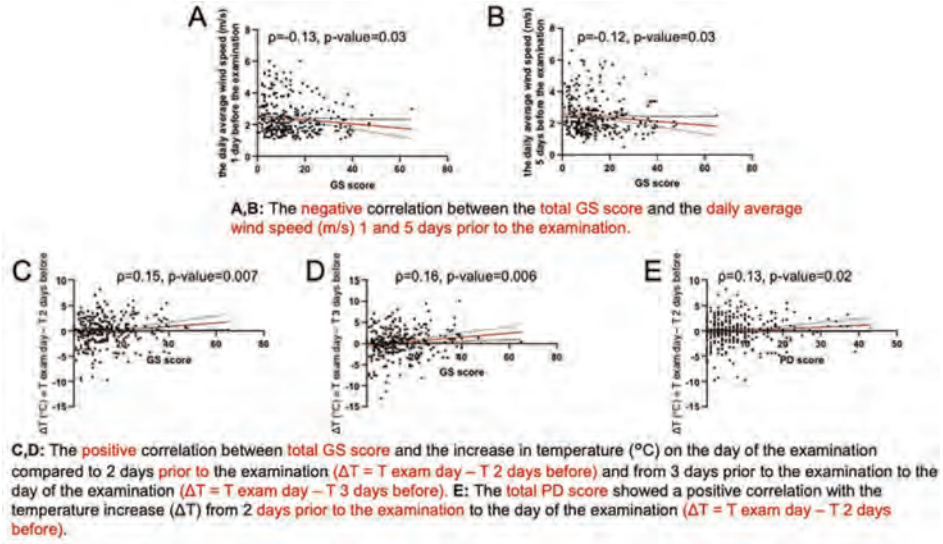
Session Date: Sunday, November 12, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Various environmental factors are involved in the pathogenesis of rheumatoid arthritis (RA), and meteorological conditions such as temperature and atmospheric pressure have also been reported to affect its symptoms. However, studies evaluating its influence based on objective imaging studies are lacking. This study analyzed the correlation between joint ultrasonography scores and meteorological conditions in a multicenter RA cohort to determine whether meteorological conditions contribute to the joint ultrasound findings of RA.



A,B: The negative correlation between the total GS score and the daily average wind speed (m/s) 1 and 5 days prior to the examination.

C,D: The positive correlation between total GS score and the increase in temperature (°C) on the day of the examination compared to 2 days prior to the examination (ΔT = T exam day – T 2 days before) and from 3 days prior to the examination to the day of the examination (ΔT = T exam day – T 3 days before). **E:** The total PD score showed a positive correlation with the temperature increase (ΔT) from 2 days prior to the examination to the day of the examination (ΔT = T exam day – T 2 days before).

Methods: The present study was analyzed from the baseline data from Kyushu Multicenter Rheumatoid Arthritis Ultrasound Prospective Observational Cohort started from 2013. This cohort study recruits active RA patients who require the treatment with biologicalor targeted synthetic disease-modifying anti-rheumatic drugs (b/tsDMARDs). Three hundred eight subjects were evaluated by joint ultrasound synovitis scores [22 joints including bilateral 1^{st} -5^{th} metacarpophalangeal (MCP) joints, proximal interphalangeal (PIP) joints, and wrist joints semi-quantitatively examined by grey-scale (GS) and power Doppler (PD) scores from 0 to 3]. The sum of the GS and PD scores was used as an indicator of individual's ultrasound disease activity. Metrological data [daily mean temperature (°C), daily mean-sea-level barometric pressure (hPa), daily mean vapor pressure (hPa), and daily mean wind speed (m/s)] was obtained from the database issued by the Japan Meteorological Agency (JMA). Spearman's rank correlation coefficient was used for the analysis of the correlation between metrological conditions and ultrasonographic scores.

Results: There was a negative correlation between the total GS score and the daily average wind speed 1 and 5 days before the examination (ρ=-0.13, p-value=0.03, andρ=-0.12, p-value=0.03, respectively). The total GS score exhibited a positive correlation with the increase in temperature on the day of the examination compared to 2 days prior to the examination(ΔT = T exam day–T 2 days before,ρ=0.15, p-value=0.007) and from 3 days prior to the examination to the day of the examination(ΔT = T exam day–T 3 days before,ρ=0.16, p-value=0.006). The total PD score showed a positive correlation with the temperature increase (ΔT) from 2 days prior to the examination to the day of the examination(ΔT = T exam day–T 2 days before,ρ=0.13, p-value=0.02).

Conclusion: Our findings suggest that meteorological conditions, specifically low wind speed, and temperature rise, are associated with the joint ultrasound findings of RA patients. Understanding these correlations could aid in better management and treatment of RA by considering the potential climate impact toward RA disease conditions. Further research and studies are warranted to explore the underlying mechanisms and to validate these findings in larger and more diverse cohorts.

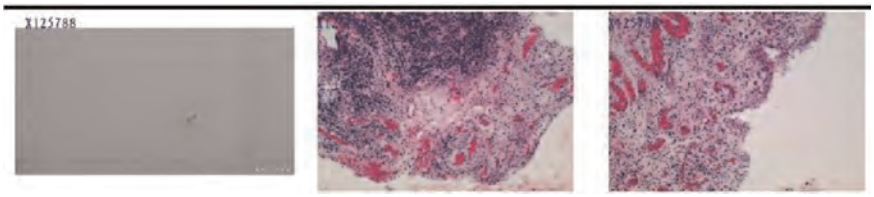
The Role of Synovial Biopsy in Evaluating Rheumatoid Arthritis Acitivity in Patients: Findings from a Study of 30 Patients Treated with Adalimumab

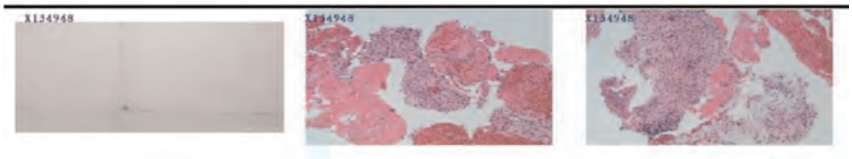
Rui Wu and YIlin Peng, the first affilated hospital of Nanchang University, Nanchang, China

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis(RA)is a chronic autoimmune disease that is characterized by inflammation and destrction of synovial jionts which result in high disabilty. Treat-to-Target is critical to preveting disability and improving outcomes. Accurate evaluation of disease activity is crucial to guide clinical decision-making and develop effective management plan. Synovial biopsy is an emerging tool that can prvide valuable information about the molecular and cellular processes undrlying RA. There is several diffferent types of needles for synovial biopsy. But they maynot be widely available or feasible



F43, acchieved clinical remmision with normal ESR, CRP and high synovial inflammatory score(7 poionts) in right ankel joint synovium which shows proliferation of synovial cells, interstitial edema, neovascularization, lymphoplasmcytic inflitrates, lymphoid tissue hyperplasia, and infiltration (HE).



F62, failed the treatment of adlimumab and MTX with high synovial inflammatory score(6 points) in left knee joint synovium after 3-months adiministration of adalimumab. Under microscope (HE) , it shows proliferation of synovial cells and fibrous tissue, moderate infliltration of lymphoplasmacytic cells, and inflammatory fibrinous exucdate.

for use because of unsuitalbe for small joints or compliated procedure We improved a spring-loaded biopsy needle which can make the procedure easier and safer. This needle now is commonly used in clinical practice in our center. We reports the findings from our study of RA patients treated with adalimumab who underwent synovial biopsy.

Methods: Thrty RA patients who had inadequate response to MTX were treated with adalimumab and assessed using various indicators of disease activity, including DAS28, ESR,CRP, and radiography imaging. Synovial biopsy was also performed to assess the level of synovial inflmmation before and after 3-months administration of adalimumab. The Synovial biopsy scores were compared to the other indicators of disease activity to evaluate their correlation. We improved a novel spring-loaded synovial biopsy needle which can provide more accurate samples. it consists of a small cylindrical outer sheath and an inner stylet that contains a spring-loaded sampling needle. Once the needle is in place, the negative pressure suction mechinism enables the sample to enter the core of the sampling needle and than release the spring which draw back the inner needle and cut sample quickly. The improved synovial biopsy needles provide an easier and safter procedure.

Results: Of the 30 patients, 22 patients responded well to adalimumab, with significant improvement in DAS28, ESR, and CRP levels. But 8 patinets failed to achieve ACR 20. In 22 patients, 6 patients accheive clinical remission with less than 2.6 of DAS 28. Synovial membrane inflammation scores(GSS) were calculated by inflammatory infiltration, stromal activation and synovila lining hyperplasia(0-9). A significant positive correlation between the GSS and DAS28 score was found in RA patients. in 8 patients who failed the treatment of adalimumab, infllltratrion of lymphoplasmcytic cell in the synovial membrane were predominant. But in 4 patiens who accheived clinical remission, GSS sitll remains high level(more than 6).

Conclusion: Our study suggest that a large infiltration of lymphoplasmacytic cells in the synovial mebbrane is a negative predictor for response of adalimumab in RA. Synovial membrane inflammatory scores(GSS) may be a useful tool for assessing disease activity in RA patients and may help indentify patients who need more aggressive treatment even they acchieved clinical remission with DAS 28. The improved spring-loaded synovial biopsy needles can help faciliated more accurate and effective synovial biopsy for assessing disease activity in RA.

Prevalence of Pulmonary Manifestations in Patients with Newly Diagnosed Rheumatoid Arthritis, Psoriatic Arthritis, and Peripheral Spondyloarthritis

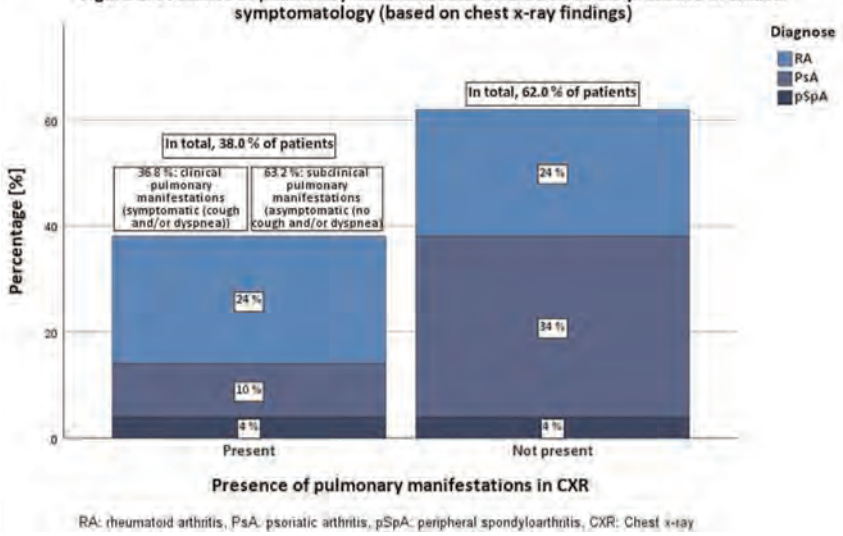
Lone Winter[1], Dirk Skowasch[1], Marcel Weber[1], Daniel Kütting[1], Charlotte Behning[2], Peter Brossart[3], Simon Petzinna[4] and **Valentin Sebastian Schäfer**[3], [1]University Hospital Bonn, Bonn, Germany, [2]Institute of Medical Biometry, Informatics and Epidemiology, University Hospital of Bonn, Bonn, Germany, [3]Clinic of Internal Medicine III, Department of Oncology, Hematology, Rheumatology and Clinical Immunology, University Hospital of Bonn, Bonn, Germany, [4]Clinic of Internal Medicine III, Oncology, Hematology, Rheumatology and Clinical Immunology, University Hospital Bonn, Bonn, Germany

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Pulmonary impairment is a common, yet poorly understood, extraarticular manifestation in rheumatic diseases, which is often inadequately screened and managed. This can result in a substantial increase in morbidity and mortality [1]. While previous studies have mainly focused on rheumatoid arthritis (RA) and to some extent on psoriatic arthritis (PsA), data for patients with peripheral spondyloarthritis (pSpA) are lacking. The aim of this study was to investigate the prevalence of both clinical and subclinical pulmonary manifestations in newly diagnosed patients with RA, PsA, and pSpA. Furthermore, different baseline examination results were compared in order to develop a screening proposal for detecting patients at risk.

Methods: This clinical-prospective, longitudinal cohort study included a diagnostic workup consisting of a questionnaire for patient history, a physical examination, a body plethysmography with diffusion capacity for carbon monoxide (DLCO), a 6-minute walk test, laboratory parameters, and a chest x-ray (CXR) at the time of the initial diagnosis of arthritis disease, and at four additional time points in three-month intervals. This abstract thereby focuses on the baseline characteristics.

Figure 1: Presence of pulmonary manifestations in relation to the presence of clinical symptomatology (based on chest x-ray findings)



RA: rheumatoid arthritis, PsA: psoriatic arthritis, pSpA: peripheral spondyloarthritis, CXR: Chest x-ray

Table 1 Baseline patient characteristics

		Diagnose			
		RA (n = 26)	PsA (n = 24)	pSpA (n = 4)	Control proband (n = 26)
Age [years]	Mean	52.7	46.3	41.3	48.4
	Standard deviation	16.1	12.8	9.0	11.9
Sex	Female	9 (34.6 %)	14 (58.3 %)	1 (25.0 %)	14 (53.8 %)
	Male	17 (65,4 %)	10 (41,7 %)	3 (75,0 %)	12 (46,2 %)
BMI [kg/m²]	Mean	25.1	26.9	26.9	27.0
	Standard deviation	4.1	5.3	8.8	4.1
Smoking	Neversmoker	17 (65.4 %)	14 (58.3 %)	1 (25.0 %)	19 (73.1%)
	Eversmoker	9 (34.6 %)	10 (41.7 %)	3 (75.0 %)	7 (26.9 %)
Chronic cough	Not present	16 (61.5 %)	19 (79.2 %)	2 (50.0 %)	24 (92.3 %)
	Present	10 (38.5 %)	5 (20.8 %)	2 (50.0 %)	2 (7.7 %)
Dyspnea	Not present (NYHA I)	20 (76.9 %)	19 (79.2 %)	2 (50.0 %)	24 (92.3 %)
	Present (NYHA II+)	6 (23.1 %)	5 (20.8 %)	2 (50.0 %)	2 (7.7 %)
Previous pulmonary disease	None	23 (88.5 %)	22 (91.7 %)	3 (75.0 %)	22 (84.6 %)
	Bronchial asthma	2 (7.7 %)	1 (4.2 %)	1 (25.0 %)	1 (3.8 %)
	COPD	0 (0.0 %)	0 (0.0 %)	0 (0.0 %)	1 (3.8 %)
	Interstitial lung disease	1 (3.8 %)	0 (0.0 %)	0 (0.0 %)	0 (0.0 %)
	Sarcoidosis	0 (0.0 %)	1 (4.2 %)	0 (0.0 %)	2 (7.7 %)

RA: rheumatoid arthritis, PsA: psoriatic arthritis, pSpA: peripheral spondyloarthritis, BMI: Body Mass Index, NYHA: New York Heart Association, COPD: chronic obstructive pulmonary disease

Results: In total 54 outpatients (26 RA, 24 PsA, 4 pSpA) and 26 age- and gender-matched controls were examined (tab. 1). Pulmonary impairment, in the sense of a morphologically abnormal CXR, was diagnosed in 19 arthritis patients (38.0 %). Of these, 36.8 % suffered from clinical symptoms such as cough and/or dyspnea. However, 63.2 % of the patients presented subclinical, asymptomatic pulmonary abnormalities (fig. 1). The baseline results of several examinations are illustrated in table 2. An elevation of rheumatoid factor (> 14 IU/ml) showed an association with the manifestation of RA (p = .002) as well as with the presence of pulmonary affection (p = .008). In addition, the mean age of patients with pulmonary abnormalities (57.0 ± 12.8 yrs.) differed significantly from that of patients without such abnormalities (43.9 ± 14.3 yrs.), with a p-value of .002. The association between the activity of arthritis disease, assessed by Disease Activity Score in 28 joints using CRP (DAS28CRP), and CXR findings proved to be significant (p = .011). A DAS28CRP less than 3.2 (remission or low disease activity) indicated non-pathological findings in CXR.

Conclusion: The prevalence of pulmonary manifestations was more than one-third and more than two-thirds presented asymptomatic. The high proportion of asymptomatic patients highlights the need for the implementation of a pulmonary screening at the initial diagnosis of arthritis disease. By alerting physicians, especially in the observed age cohort of 57 years with elevated RF levels, morbidity and mortality could be reduced.

Table 2 Findings in different examinations (physical examination, bodyplethysmography with CO diffusion capacity, laboratory parameters)

		Presence of rheumatic disease		Presence of pulmonary disorders in chest x-ray	
		RA[a]/PsA[b]/pSpA[c] (n=54)	Control proband (n=26)	Present (n=19)	Not present (n=31)
Breathing width	Non-pathological (≥ 3 cm)	18 (33.3 %)	20 (76.9 %)	4 (21.1 %)	13 (41.9 %)
	Pathological (< 3 cm)	36 (66.7 %)	6 (23.1 %)	15 (78.9 %)	18 (58.1 %)
Chest excursion	Non-pathological (≥ 8 cm)	31 (57.4 %)	17 (65.4 %)	10 (52.6 %)	17 (54.8 %)
	Pathological (< 8 cm)	23 (42.6 %)	9 (34.6 %)	9 (47.4 %)	14 (45.2 %)
Restrictive lung disease	Not present	39 (84.8 %)	16 (64.0 %)	15 (88.2 %)	21 (84.0 %)
	Present (FVC < 70 %; TLC < 80 %)	7 (15.2 %)	9 (36.0 %)	2 (11.8 %)	4 (16.0 %)
Obstructive lung disease	Not present	46 (100.0 %)	25 (100.0 %)	17 (100.0 %)	25 (100.0 %)
	Present (FEV1/FVC < 70 %)	0 (0.0 %)	0 (0.0 %)	0 (0.0 %)	0 (0.0 %)
Emphysema	Not present	39 (86.7 %)	19 (76.0 %)	14 (82.4 %)	23 (95.8 %)
	Present (RV > 140 %)	6 (13.3 %)	6 (24.0 %)	3 (17.6 %)	1 (4.2 %)
Diffusion disturbance	Not present	37 (86.0 %)	21 (91.3 %)	13 (81.3 %)	21 (91.3 %)
	Present (DLCO < 60 %)	6 (14.0 %)	2 (8.7 %)	3 (18.8 %)	2 (8.7 %)
C-reactive protein (CRP)	Non-pathological (≤ 3 mg/l)	19 (35.2 %)	19 (86.4 %)	4 (21.1 %)	13 (41.9 %)
	Pathological (> 3 mg/l)	35 (64.8 %)	3 (13.6 %)	15 (78.9 %)	18 (58.1 %)
Rheumatoid factor (RF)	Non-pathological (≤ 14 IU/ml)	31 (66.0 %)	19 (95.0 %)	6 (37.5 %)	21 (77.8 %)
	Pathological (> 14 IU/ml)	16 (34.0 %)	1 (5.0 %)	10 (62.5 %)	6 (22.2 %)
Anti-citrullinated peptide antibodies (ACPA)	Non-pathological (≤ 8 U/ml)	38 (80.9 %)	20 (100.0 %)	12 (75.0 %)	22 (81.5 %)
	Pathological (> 8 U/ml)	9 (19.1 %)	0 (0.0 %)	4 (25.0 %)	5 (18.5 %)

Usefulness of RAPID3 in Assessing Unmet Needs of Patients with Rheumatoid Arthritis in Remission or with Low Disease Activity -a Multicenter Observational Study: T-FLAG Study-

Mochihito Suzuki[1], Nobunori Takahashi[2], Yasumori Sobue[3], yoshifumi Ohashi[1], Ryo Sato[1], Masataka Maeda[1], Hironobu Kosugiyama[1], yusuke Ohno[1], kenya terabe[4], Shuji Asai[1] and Shiro Imagama[1], [1]Nagoya University Graduate School of Medicine, Nagoya, Japan, [2]Department of Orthopedic Surgery, Aichi Medical University, Nagakute, Japan, [3]Japanese Red Cross Nagoya Daiichi Hospital, Nagoya, Japan, [4]Nagoya University, Nagoya, Japan

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Routine Assessment of Patient Index Data 3 (RAPID3) is a patient-reported outcome (PRO) that can be used to assess the condition of rheumatoid arthritis (RA) patients using only a questionnaire that can be completed in a short time. In previous reports, RAPID3 could be used as an assessment similar to Disease Activity Score 28 (DAS28), a common disease activity assessment [1]. However, there are unmet needs in which patients have low satisfaction with treatment, even though they are in remission according to disease activity assessments such as DAS28. To investigate the cause of this discrepancy, we decided to conduct a study using RAPID3 as a subjective patient assessment. The aime of this study was to investigate the discrepancy between disease activity and RAPID3 in RA patients.

Methods: The data for this study were obtained from the Tsurumai-Frailty and Locomotive Syndrome of Rheumatoid Arthritis for Globalization (T-FLAG), an observational study involving three centers. Of the 638 RA patients who completed the PRO questionnaire in 2022, 455 patients with a DAS28-CRP of low disease activity (LDA) or remission (REM) were enrolled. Disease activity was assessed using the RAPID3, DAS28-CRP. PRO assessment was performed using PtGA, Health Assessment Questionnaire Disability Index (HAQ-DI), Kihon checklist (KCL), and the 25-question Geriatric Locomotive Function Scale (GLFS-25). RAPID3 categories were compared in two groups: REM/LDA, and medium and high disease activity (MDA/HDA). Cutoff values for each PRO were detected using ROC analysis.

Results: The mean age (± standard deviation) was 69±14, female was 72%, disease duration was 12±9, RAPID3 was 3.1 ±4.0, DAS28-CRP was 1.65±0.48, HAQ-DI was 0.31±0.55, and KCL was 6.1±4.4. In the disease activity category, 84.5% of patients had RAPID3 and DAS28-CRP in the same category (The disease activity category of RAPID3 was LDA or REM). There were no significant differences in gender, biological and targeted synthetic disease-modifying antirheumatic

Table 1. Baseline characteristic of patients by RAPID3 category

	Total	RAPID3 REM/LDA	RAPID3 MDA/HDA	P value
N, %	445 (100.0)	376 (84.5)	69 (15.5)	
age, year *	69 ± 14	67 ± 14	72 ± 11	0.004

KCL *	6.1 ± 4.4	5.5 ± 3.9	9.7 ± 5.0	< 0.01
GLFS-25 *	16 ± 16	13 ± 13	32 ± 21	< 0.01

RAPID: Routine Assessment of Patient Index Data; REM: remission; LDA: low disease activity; MDA: medium disease activity; HAD: high disease activity; MTX: methotrexate; b/ts DMARDs: biological and targeted synthetic disease-modifying antirheumatic drugs; DAS28: disease activity score with 28 joint counts; CRP: C-reactive protein; TJC: tender joint count; SJC: swollen jointcount; PtGA: patient global assessment; PhGA: physician global assessment; VAS: visual analog scale; HAQ-DI: Health Assessment Questionnaire-Disability Index; KCL: Kihon checklist for frailty; GLFS-25: the 25-question Geriatric Locomotive Function Scale. * Student's t-test † Chi-squared test

Baseline characteristic of patients by RAPID3 category

drugs, C-reactive protein, tender joint count, swollen joint count between the two groups of REM/LDA and MDA/HAD (Table 1). On the other hand, there were significant differences between the two groups in disease duration (11 vs. 16 years), PtGA (5 vs. 39mm), HAQ-DI (0.20 vs. 0.96), KCL (5.5 vs. 9.7), and GLFS-25 (13 vs. 32). The cutoff values for PRO assessment for different disease activity categories of patients were HAQ-DI 0.375 points, KCL 8 points, and GLFS-25 16 points.

Conclusion: In this study of patients with good disease activity control, 84.5% of patients were found to have a concordance between RAPID3 and DAS28 disease activity categories. The discrepancy between DAS28-CRP and RAPID3 may be due to physical dysfunction (HAQ-DI or GLFS-25) or frailty (KCL). Therefore, it is important to achieve clinical remission and improve PRO in RA treatment as an intervention to address unmet needs.

The Impact of Patient-reported Outcomes on Boolean 2.0 Remission Criteria in Rheumatoid Arthritis Patients in Real Clinical Practice -a Multicenter Observational Study: T-FLAG Study-

Mochihito Suzuki[1], yoshifumi Ohashi[1], Yasumori Sobue[2], Ryo Sato[1], Masataka Maeda[1], Hironobu Kosugiyama[1], yusuke Ohno[1], kenya terabe[3], Shuji Asai[1] and Shiro Imagama[1], [1]Nagoya University Graduate School of Medicine, Nagoya, Japan, [2]Japanese Red Cross Nagoya Daiichi Hospital, Nagoya, Japan, [3]Nagoya University, Nagoya, Japan

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The Boolean remission criteria proposed by the The American College of Rheumatology (ACR) and the European College of Rheumatology (EULAR) in 2011 are widely used as remission criteria for rheumatoid arthritis (RA) patients.

Until now, Boolean 1.0, which defined as a score 1 for each of TJC28, SJC28, CRP (mg/dl), and a Patient General Assessment (PtGA) ≤ 1 cm, has been used, but there have been concerns about overtreatment due to its too strict criteria. Therefore, Boolean 2.0, which uses a PtGA ≤2 cm, has recently been shown to be more consistent with Simplified Disease Activity Index (SDAI) remission criteria and has been described to be useful in clinical practice. The purpose of this study was to investigate the relationship between Boolean 2.0 remission and Boolean 1.0 remission and patient-reported outcomes (PRO) in RA patients using real clinical data.

Methods: Among 661 patients who visited the RA outpatient clinic between June and August 2022 (T-FLAG study) and whose patient background could be investigated, including Boolean remission, 308 patients who achieved the Boolean 2.0 remission criteria were included; a group of patients achieving Boolean 1.0 and a group of patients meeting the new criteria of The patient group that achieved Boolean 1.0 and the patient group that achieved Boolean 2.0 but not Boolean 1.0 (Boolean 1.0-2-0) were compared, and logistic regression analysis was performed to determine the background of patients

Table 1. Factors associated with baseline characteristics

	Total (n=308)	Boolean 1.0 (n=276)	Boolean 1.0-2.0 (n=32)	Unadjusted OR (95% CI)	Adjusted OR (95% CI)
age (years)	68.1 (14.1)	68.4 (14.3)	65.6 (12.7)	1.01 (0.99-1.04)

BMI: Body mass index; MTX: Methotrexate; bDMARDs: biological disease-modifying antirheumatic drugs; tsDMARDs: targeted synthetic disease-modifying antirheumatic drugs; DAS28: disease activity score with 28 joint counts; CRP: C-reactive protein; TJC: tender joint count; SJC: swollen jointcount; PtGA: patient global assessment; PhGA: physician global assessment; KCL: Kihon checklist for frailty; GLFS-25: the 25-question Geriatric Locomotive Function Scale; HAQ-DI: Health Assessment Questionnaire-Disability Index. OR: odds ratio. The adjusted model included variables (age and sex). *$p<0.05$ was considered statistically significant.

Factors associated with baseline characteristics

who achieved Boolean 1.0-2.0. The cutoff values of the factors associated with Boolean 1.0-2.0 were calculated by ROC analysis.

Results: The mean age (± standard deviation) of the 308 patients who achieved Boolean 2.0 remission criteria was 68 ± 14 years, 73% were female, disease duration was 11 ± 9 years, DAS28-CRP was 1.40 ± 0.34, Health Assessment Questionnaire-Disability Index (HAQ-DI) was 0.20 ± 0.44, and KCL was 5.0 ± 4.0 (Table 1). Adjusted for age and gender, disease duration, biological disease-modifying antirheumatic drugs (DMARDs), seropositivity, and HAQ-DI were found to be relevant factors. The the 25-question Geriatric Locomotive Function Scale (GLFS-25), a PRO assessment of physical function, and the Kihon Checklist for Frailty Assessment (KCL) were not significantly associated factors. The HAQ-DI cutoff for achieving Boolean 1.0 was 0.25 points (sensitivity, 81.4%; specificity, 40.6%: AUC, 0.619).

Conclusion: RA patients with Boolean 1.0-2.0 were characterized by long disease duration and high use of biologic DMARDs. In addition, only HAQ-DI was involved as PRO assessment.

Abstract Number: 0412

COVID Antibody Response to Third Dose Anti-SARS-COV2 mRNA Vaccine in Patients with Seropositive Rheumatoid Arthritis on Immunosuppressive Therapy

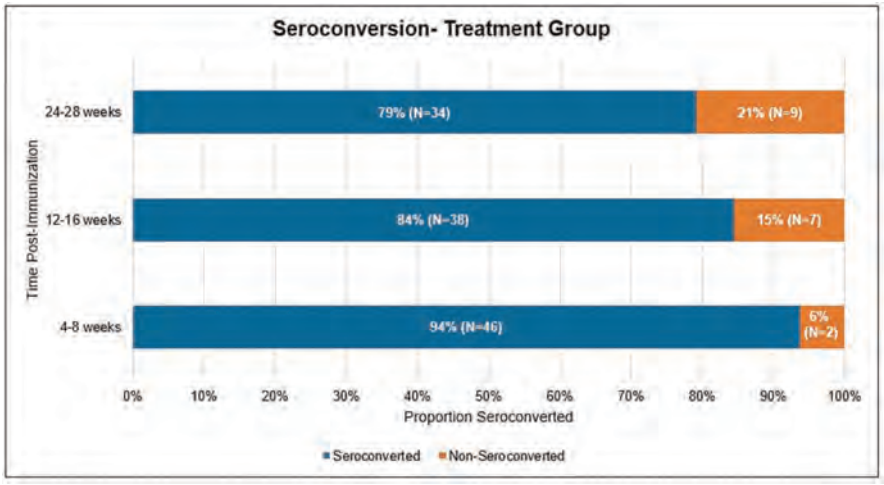
Karthik Kovuru[1], Sylwia Waz[1] and Aarti Malik[2], [1]University of Chicago (Northshore) Internal Medicine Residency, Chicago, IL, [2]Department of Rheumatology, University of Chicago/Northshore University, Chicago, IL

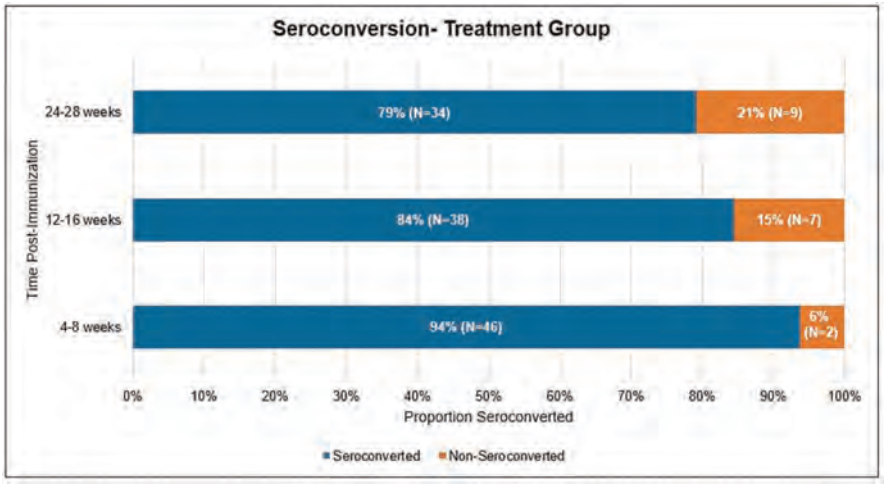
SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with immune-mediated inflammatory diseases on immunosuppressive medications are presumed to be at increased risk for hospital admissions and deaths related to COVID-19 infections. The aim of this study was to better characterize seroconversion response to the third dose of COVID-19 vaccine in patients with seropositive rheumatoid arthritis (RA) on various immunosuppressive therapy classes.

Methods: A prospective cohort study recruited patients with RA on immunosuppressive treatment (n=48) to evaluate immune response to the third COVID-19 vaccine compared to the general population (n=164). Patients with RA in the study group were further characterized into three categories based on their active treatment. These groups were patients on either synthetic DMARD alone, DMARD with biologic, or biologic only. Patients received their third dose of the COVID-19 vaccine of either BNT162b2 (Pfizer) or CX-04414 (Moderna). Serum IgG antibody titers to Anti-S1 spike protein were collected in three different time frames, 4-8 weeks post-immunization (phase 1), 12-16 weeks post-immunization (phase 2), and 24-28 weeks post-immunization (phase 3). Seroconversion was defined as antibody titers above 1500 U/ml. 5 patients were lost in follow-up in the treatment group along with 79 in the control group over course of the study. Sample matching analysis was used to better compare the control and study groups.

Results: In our treatment group, 94% (n=46) of patients seroconverted in phase 1, 84% (n=38) in phase 2, and 79% (n=34) in phase 3. In the control group, 71% (n=74) of patients seroconverted in phase 1, 83% (n=85) in phase 2, and 78% (n=66) in phase 3. After sample matching analysis, patients in the treatment group showed higher rates of seroconversion compared to the control group during phase 1 ($p = 0.01$). A decrease in seroconversion rates over time was observed in both groups.





When evaluating patients on different classes of RA medications, patients on synthetic DMARDs with biologics showed lower rates of seroconversion than the other groups. All therapy classes showed decreased seroconversion rates over time.

Conclusion: Our study revealed that patients with RA demonstrated an adequate response to COVID vaccination despite being on immunosuppressive therapies. Immunogenicity decreases over time after the third COVID-19 vaccine in both immunocompromised and general populations as well as across therapy classes. Patients with RA on immunosuppressive therapies still show adequate levels of seroconversion in the early phase (phase 1) similar to the control group.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite novel treatment strategies in rheumatoid arthritis (RA), approximately 20-30% of patients remain symptomatic. The EULAR definition of difficult-to-treat (D2T) RA has recently been published with significant contributions from our research group (1).Many causes can lead to D2T RA, such as degenerative alterations, psychosocial factors like stress and depression, and central nervous system (CNS) dysfunction, including neuroinflammation and subsequent central pain sensitization. Recent literature suggests that peripheral blood mononuclear cells (PBMCs) can reflect the pathophysiological mechanisms of the CNS. Our main goal was to compare the transcriptomic profiles of PBMCs from D2T RA patients and healthy controls (HC) to identify differences in molecules and signaling pathways to reveal the connection between pain and inflammation.

Methods: This study has been conducted in two centers. 14 D2T RA patients, meeting the 2021 EULAR definition for D2T RA, and 11 HCs were included in Pécs, and 34 D2T RA patients and 20 HCs in Budapest, the data analysis for this group is currently under evaluation. Patients were divided into different subgroups based on their inflammatory and pain parameters. Transcriptomic analysis was performed using total RNA isolated from PBMCs through next-generation sequencing, and the results were evaluated using bioinformatics tools. A clinical examination, including psychology and fMRI experiments, was also conducted.

Results: D2T RA patients exhibited several differentially expressed genes compared to HCs, primarily involved in immune cell migration, activation, cytokine- and chemokine-mediated signaling, and neuronal regulation. Thus far, we have identified 35 upregulated genes, including interleukin 15 (IL-15) and chemokine receptor 2 (CCR2), playing an essential role in maintaining inflammation, and Sortilin1, contributing to neuropathic pain. 28 downregulated genes were found, e.g. tumor necrosis factor alpha-induced protein 3, which controls inflammatory responses. Compared to those with high inflammation and low pain, the subgroup of D2T RA patients with high inflammation and high pain exhibited significant differences in their transcriptomic profiles, particularly in the involvement of Type I Interferon and Interferon-β response. The results of the D2T RA subgroup with high pain and low inflammatory parameters revealed potential pain-related genes, such as the cholesterol-phospholipid efflux protein ABCA1 and EIF2AK2 encoding a serine/threonine kinase. Clinical and fMRI results and their correlation with the transcriptomic data are currently under evaluation.

Conclusion: Our analysis revealed many differences in the transcriptomic profiles of different subgroups of D2T RA patients and HCs. Therefore, PBMC transcriptomics proved to be a useful tool for identifying differentially expressed genes associated with pathophysiological mechanisms involved in inflammatory processes and pain sensitization. Confirming hypotheses generated with this unbiased omics approach can facilitate the development of novel therapies.

Association of a Treat-to-Target Management Approach with Physician and Patient Reported Outcomes Among Real - World Patients with Rheumatoid Arthritis Receiving Advanced Therapy in Europe

Douglas White[1], Aditi Kadakia[2], Oliver Howell[3], Sander Strengholt[4], Emily Goddard[3], Sophie Barlow[3] and Tsutomu Takeuchi[5], [1]Waikato Clinical School, University of Auckland, Hamilton, New Zealand, [2]AbbVie, Inc., North Chicago, IL, [3]Adelphi Real World, Bollington, United Kingdom, [4]AbbVie B.V., Mijdrecht, Utrecht, Netherlands, [5]Keio University School of Medicine and Saitama Medical University, Tokyo, Japan

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease affecting the joints, causing swelling, stiffness, and pain that impact a patient's quality of life. EULAR treatment guidelines suggest using treat-to-target (T2T) for optimal management of RA patients[1] with evidence that T2T is effective when used with advanced therapies (AT)[2]. The clinical benefits of T2T are well studied but evidence for T2T's impact on patient reported outcomes (PROs) is limited. This study aimed to assess the association between T2T, and PROs and clinician reported outcomes (CROs) for RA patients on AT in real world clinical practice.

Methods: Data were sourced from the Adelphi RA XIII Disease Specific Programme™, a cross-sectional survey with retrospective data collection of rheumatologists and their RA patients in France, Germany, Italy, Spain, and the United Kingdom from June 2021 - February 2022. Physicians reported whether a patient was currently on a T2T approach or not. Sensitivity analyses were conducted with T2T defined more stringently, by including patient T2T goals (remission/low disease activity) and consultation frequency (e.g. ≥3 or 4 in the last 12 months) in the definition. PROs were collected through the EQ-5D-5L, EQ-VAS, Health Assessment Questionnaire Disability Index (HAQ-DI) and Functional Assessment of Chronic Illness Therapy – Fatigue (FACIT-F). CROs included physician perceived disease activity (DAS28 scores: remission = < 2.6; low = 2.6–3.2; moderate = 3.3–5.1; high = >5.1), pain and fatigue (none, mild, moderate, or severe). Multivariate regressions (linear regressions for continuous, ordered logistic regressions for ordinal outcomes) were conducted to assess the impact of T2T on PROs and CROs amongst AT patients. The model was adjusted for age, sex, body mass index, Charlson comorbidity index and physician perceived disease severity at diagnosis.

Results: A total of 971 RA patients were receiving AT at the time of data collection of which 610 (63%) were currently following a T2T approach, of these 72% were female vs 65% who were not on T2T, 90% were white/Caucasian vs 86% and mean (standard deviation) age was 50.6 (12.5) vs 53.1 (13.5) years old, respectively. A T2T approach was associated with significantly higher (better) EQ-5D-5L, EQ-VAS, and FACIT-F scores and lower (better) HAQ-DI scores. Patients on T2T experienced problems with activities of daily living less than patients not on T2T (Table 1). T2T was also associated with significantly greater odds of patients being in physician perceived remission and having no pain (Table 2). Despite the association with better FACIT-F scores, T2T was not significantly associated with less physician perceived fatigue.

Conclusion: T2T in RA was associated with significantly better PROs such as overall and domain scores for EQ-5D-5L, HAQ-DI, and FACIT-F. Patients on T2T reported a greater likelihood of being able to conduct daily activities without difficulties or problems compared to those not on T2T. T2T was also associated with better CROs such as remission and no pain.

Table 1: Associated Impact of T2T on Patient Reported Outcomes

PRO		Expected change associated with T2T	Margin Interpretation (On T2T compared to not on T2T)	p-value
EQ- 5D-5L Utility score[1] (n=324)		0.09	Patients on T2T reported 0.09 points higher EQ-5D-5L scores than patients not on T2T	0.001
EQ-VAS[2] (n=325)		9.32	Patients on T2T reported 9.32 points higher EQ-5D VAS scores than patients not on T2T	0.015
HAQ-DI[3] (n=326)		-0.20	Patients on T2T reported -0.20 points lower disability scores than patients not on T2T	0.022
FACIT-F[4] (n=330)		3.18	Patients on T2T reported lower fatigue (3.18 higher FACIT scores) than patients not on T2T	0.033
		Odds Ratio associated with T2T		**p-value**
EQ-5D-5L Domains*	**Mobility** (n=329): (no problems walking)	3.90	Patients on T2T were 32% less likely to have any problems walking	<0.0001
	Self-Care (n=331): (no problems washing or dressing themselves)	3.08	Patients on T2T were 25% less likely to have any problems washing or dressing themselves	0.002
	Usual Activities (n=330) (no problems doing their usual activities)	2.90	Patients on T2T were 25% less likely to have any problems doing their usual activities	0.001
	Pain/discomfort (n=332) (no pain/discomfort)	2.39	Patients on T2T were 17% less likely to have any pain/discomfort	0.004
HAQ-DI Domains†	**Shampoo your hair** (n=327) (without any difficulty)	2.93	Patients on T2T were 23% less likely to report difficulties with shampooing their hair than patients not on T2T	0.001
	Climb up 5 steps (n=330) (without any difficulty)	2.38	Patients on T2T were 20% less likely to report difficulty with climbing steps than patients not on T2T	0.006
	Wash and dry your body (n=332) (without any difficulty)	2.87	Patients on T2T were 21% less likely to report difficulty with washing/drying their body than patients not on T2T	0.002
	Take a tub bath (n=318) (without any difficulty)	2.24	Patients on T2T were 16% less likely to report difficulty with taking a tub bath than patients not on T2T	0.030
	Get on and off the toilet (n=331) (without any difficulty)	2.18	Patients on T2T were 16% less likely to report difficulty with taking a tub bath than patients not on T2T	0.031
	Open car doors (n=332) (without any difficulty)	2.94	Patients on T2T were 22% less likely to report difficulty with opening car doors than patients not on T2T	<0.0001
	Run errands and shop (n=330) (without any difficulty)	3.71	Patients on T2T were 30% less likely to report difficulty with running errands than patients not on T2T	<0.0001
	Get in and out of the car (n=330) (without any difficulty)	2.19	Patients on T2T were 17% less likely to report difficulty with running errands than patients not on T2T	0.021
	Do chores such as vacuuming and yard work (n = 325) (without any difficulty)	2.08	Patients on T2T were 18% less likely to report difficulty with running errands than patients not on T2T	0.040
FACIT-F Domains‡	**I feel fatigued** (n = 328) (not at all)	2.04	Patients on T2T were 17% less likely to report feeling fatigued than patients not on T2T	0.021
	I feel weak all over (n = 328) (not at all)	1.90	Patients on T2T were 16% less likely to report feeling weak all over than patients not on T2T	0.014
	I need help doing my usual activities (n = 330) (not at all)	2.12	Patients on T2T were 18% less likely to report needing help with their usual activities than patients not on T2T	0.016
	I am frustrated by being too tired to do the things I want to do (n=329) (not at all)	2.39	Patients on T2T were 21% less likely to report being frustrated at being too tired than patients not on T2T	0.004
	I have to limit my social activity because I am tired (n=331) (not at all)	2.48	Patients on T2T were 22% less likely to report having to limit social activity due to tiredness than patients not on T2T	0.007

Only PRO domains with best outcomes and significant values included. PRO key (range): Range in brackets indicates for each PRO whether a higher or lower score is a better outcome for patients 1EQ-5D-5L utility score – Germany Tariff (0.0-1.0)=higher; 2EQ-VAS (1.0-100.0)=higher; 3HAQ-DI (0.0-3.0)=lower; 4FACIT-F (0.0-52.0)=higher. Margin outputs are calculated using the regression equation and are the predictions for each group if all other covariates are at their mean value. Margin outputs were calculated for patients on T2T and those not on T2T and the difference has been reported. Odds ratio >1 shows the patient on T2T is more likely to have the outcome = 1 (positive outcome). PRO domain model outcomes: *EQ-5D-5L: 0 = I have problems' (includes 'Slight problems', 'Moderate problems', 'Severe problems', 'Unable to do') 1 = 'I have no problems'. †HAQ-DI: 0 = With difficulty (includes 'With some difficulty', 'With much difficulty' and 'Unable to do'), 1 = 'Without any difficulty'. ‡FACIT-Fatigue: 0 = Presence of fatigue ('Includes a little bit', 'Somewhat', 'Quite a bit' and 'Very much'), 1 – 'Not at all'.

Table 2: Associated Impact of T2T on Physician Perceived Clinical Status

	Odds Ratio associated with T2T	Margin Interpretation (On T2T compared to not on T2T)	p-value
Physician Perceived DAS-28 Remission (n = 971)	1.48	Patient on T2T were 10% more likely to be in remission than patients not on T2T	0.024
Physician Perceived No Current Pain (n = 971)	1.63	Patient on T2T were 11% more likely to have no current pain than patients not on T2T	0.004
Physician Perceived No Current Fatigue (n = 971)	1.15	Patient on T2T were 4% more likely to have no current fatigue than patients not on T2T	0.351

Odds ratio >1 shows the patient on T2T is more likely to have the outcome = 1 (positive outcome). Margin outputs are calculated are calculated from the regression equation seeing the change in outcome for each treatment, while all other covariates are taken as their mean value

Serious Infections Hospital Admissions and Mortality in Patients with Early Inflammatory Arthritis: Results from a Large UK Cohort

Maryam Adas[1], Bechman Katie[1], Mark Russell[1], Ioasaf Karafotias[1], Deepak Nagra[1], Sam Norton[1], Mark Garton[2] and James Galloway[1], [1]King's College London, London, United Kingdom, [2]The Shrewsbury and Telford hospital NHS trust, Shropshire, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: To identify risk of serious infections (SI) according to initial treatment strategy, using conventional synthetic disease modifying anti-rheumatic drugs (csDMARD) and corticosteroids, in patients recruited to the National Early Inflammatory Arthritis Audit.

Methods: An observational cohort study design was used. Population included adults in England with new diagnosis of rheumatoid arthritis (RA), all fulfilling ACR/EULAR 2010 criteria, between April 2018-March 2021. Outcome studied was SI defined by infections requiring hospitalisation (primary admission reason/ nosocomial acquisition) or death (SI stated on death certificate), identified using UK National Health Services (NHS) Digital linkage. Hazard ratios were calculated using single failure Cox proportional hazards models, with confounders adjusted models (age, gender, smoking status, comorbidities, social deprivation) and fully adjusted models included disease factors (seropositivity, 28-joint disease activity score/ DAS28). Individuals were considered at risk from date of RA diagnosis and censored at SI event, death, or March 2021 (whichever was earlier).

Results: 20,060 patients with RA were included. Initial DMARD therapy was known for 19,572 patients, of which 11,966 on MTX based strategy, 2789 on csDMARDs combination strategy and 15,319 on corticosteroids. Baseline characteristics categorized by starting (MTX) strategy were: Mean age was 59.6 (+/-15); 62% were female. Smoking status: 20% current; 30% ex-smokers. Comorbidities: 21% hypertension; 9% diabetes; and 10% lung disease. Rheumatoid Factor/CCP antibodies were positive in 69%. At presentation, median scores were 5.1 (interquartile range IQR: 4.3-6.0) for DAS28, 1.1 (IQR: 0.6-1.7) for health assessment questionnaire (HAQ) and 23 (IQR: 16.0-23.0) for musculoskeletal health questionnaire (MSKHQ). There were 519 SI admissions and 17 SI deaths, corresponding to incidence rates per 100 person-years for admissions: 3.19 [95% CI: 2.93-3.48] and deaths: 0.10 [95% CI: 0.06-0.16]. In fully adjusted models, increasing age predicted both SI admissions and deaths. Being a smoker, having comorbidly (i.e diabetes mellitus, lung disease), disease

activity, symptom burden measured by MSKHQ and disability by HAQ all associated with SI admission. For each 1 unit increase in DAS28, the risk of SI increased by 8% (hazards ratio HR 1.08 [95% CI:1.01-1.16]). Seropositivity did not associate with SI. Methotrexate based strategies 0.75 [95% CI:0.62-0.91] and csDMARDs combination therapy 0.7 [95% CI:0.53-0.94] were significantly related to lower SI admissions. In unadjusted models, corticosteroid was associated with higher SI admissions 1.29 [95% CI:1.10 -1.62], but in fully adjusted model association was no longer significant. csDMARDs strategies were not significantly associated with SI deaths in any of the models.

Conclusion: Patient and disease factors at diagnosis appear to an important predictor of SI. Infection risk appears to be greatest in those with higher RA disease activity. An important limitation is that NEIAA registry does capture data on treatment changes over time and steroids data beyond baseline.

Association Between Sleep Disorders and Rheumatoid Arthritis: A Population-based Cohort Study

Rakesh Kumar[1], Edward Lovering[1], Chanakya Kodishala[2], Sara Achenbach[3], Diego Carvalho[1], Cynthia Crowson[1], John Davis[1] and Elena Myasoedova[1], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic Rochester Minnesota, Rochester, MN, [3]Mayo Clinic, Rochester, MN, Rochester, MN

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Some sleep disorders (SD) are more prevalent in patients with chronic inflammatory diseases, such as Rheumatoid Arthritis (RA). However, most of the research has focused on obstructive sleep apnea (OSA), and less is known about other SD (i.e., insomnia, restless legs syndrome [RLS]). The incidence of SD over time is also not well understood. Therefore, we aimed to examine the incidence of sleep disorders in patients with RA vs comparators without RA over time and by serologic status.

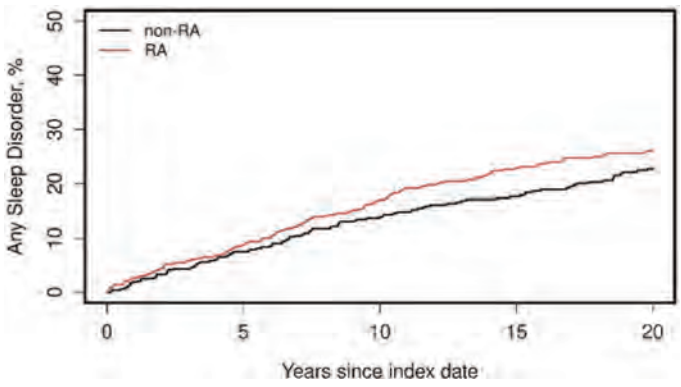

Figure 1. Cumulative incidence of sleep disorders in patients with incident RA in 1980-2009 vs non-RA comparators

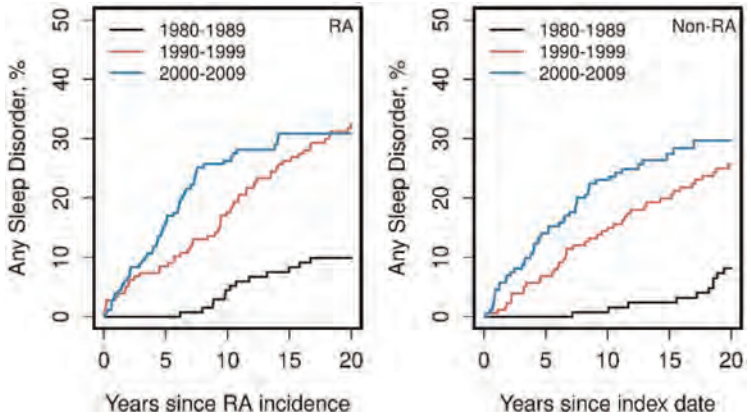

Figure 2. Cumulative incidence of sleep disorders in patients with incident RA in 1980-2009 vs non-RA comparators by decade

Methods: This retrospective population-based cohort study included residents of a geographically defined area, aged ≥50 years when they met 1987 ACR criteria for incident RA in 1980-2009. All these patients were followed until death/ migration or 12/31/2021 and matched 1:1 on age, sex, and calendar year with non-RA comparators. SD were identified based on two ICD 9/10-CM codes and data were abstracted via manual record review. Demographics, medical comorbidities, laboratory data on RA characteristics were collected. We investigated the association between RA and sleep disorders by using Cox models, adjusting for age and sex. P-value < 0.05 was considered significant. All analyses were performed using SAS version 9.4.

Results: A total of 573 patients with RA were studied (mean age 65.5 ±10.3 years, 66% female, 95% White, mean body mass index 28.1 ±6.1 kg/m^2; 62% RF/Anti-CCP positive) along with 573 matched non-RA comparators. At RA incidence/ index date, there were no differences in the prevalence of any SD in patients with RA vs non-RA controls (13% vs 14%, respectively) and by SD subtype: insomnia (6% vs 6%), OSA (7% vs 7%), RLS (2% vs 2%). During a median follow-up of 13.9 years in the RA cohort and 15.1 years in the non-RA cohort, SD developed in 129 patients with and 113 patients without RA. RA patients experienced a borderline increased risk for any SD (age- and sex-adjusted hazard ratio:1.29; 95% CI: 1.00-1.66, p=0.05) (Figure 1). The most common types of SD were OSA and insomnia.

When comparing seropositive and seronegative patients with RA, there was no difference in the development of any SD (HR: 1.17; 0.82-1.67) or OSA (HR: 0.95; 95% CI: 0.59-1.54). However, seronegative patients were more likely to develop insomnia than seropositive patients (HR: 1.81; 95% CI: 1.09-3.03). This association persisted after adjusting for age, sex, smoking and obesity (HR 1.94, 95%CI 1.16-3.27). In addition, the incidence/diagnosis rate of SD increased over time by decade of RA incidence/index date (i.e., 1980-1989, 1990-1999, and 2000-2009) in both cohorts (Figure 2), and this association persisted even adjusting for age, sex, smoking status and obesity.

Conclusion: Our study findings indicate that RA patients tend to experience an increased risk for any SD after the index date. Patients with seronegative RA had significantly higher risk of insomnia compared to seropositive RA patients. The increased incidence rate of SD by decade of RA incidence/ index, likely reflects higher awareness and improved recognition of SD in more recent years. Further research is ongoing by our group to understand the underlying mechanisms for these associations, in order to inform preventive and management options for SD in patients with RA.

The Role of Rheumatoid Arthritis Flare in the Risk of Alzheimer's Disease and Related Dementias: A Population-based Cohort Study

Chanakya Kodishala[1], Tina Gunderson[2], Edward Lovering[2], Rakesh Kumar[2], Cynthia Crowson[2], John Davis[2] and Elena Myasoedova[2], [1]Mayo Clinic Rochester Minnesota, Rochester, MN, [2]Mayo Clinic, Rochester, MN

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) have increased risk for Alzheimer's disease and related dementias (AD/ADRD). Recent studies have reported an association between RA disease activity and risk of AD/ADRD, suggesting that inflammation can be an important contributor to this association. It is unknown whether having more RA flares or spending more time in RA flare increases the risk of AD/ADRD incidence. We examined the role of RA flare and remission on the risk of AD/ADRD.

Methods: This population-based study was conducted on an inception cohort of patients with RA who were residents of a geographic area and aged ≥50 years when they met 1987 American College of Rheumatology criteria for RA in 1980-2014 with follow up until 12/31/2019. Flare/remission status was obtained via medical record review. A worsening of disease status requiring initiation/escalation of therapy or a documentation such as 'flare up', 'ongoing' and 'active' in the medical records was considered a 'RA flare'. While remission was defined as absence of disease activity based on documentation such as 'remission', 'quiescent', 'no activity', or swollen and tender joints (≤1) along with normal inflammatory markers. Visits not classified as flare or remission were counted as intermediate activity. Flares were considered to start on the first date they were documented and to resolve halfway to the next visit where the status was changed (definition 1). In definition 2, 'acute flares' were defined to last ≤6 weeks and patients were considered to have intermediate activity from the 6 week point until the next clinical visit. Incident dementia was defined by presence of two ICD9/10 codes for AD/ADRD at least 30 days apart. Cox models with time-dependent covariates were used to assess the association of RA flares with AD/ADRD, adjusting for age, sex and year of RA.

Results: The study included 771 patients with RA (mean age 65.1 years, 65.4% females). During median follow up of 7.7 years, 77 (10%) patients developed AD/ADRD. During a total of 11,085 medical visits (12 median visits per patient), patients were flaring at 3,608 (32.5%) visits and were in remission at 2,631 (23.6%) visits. Median total duration of time spent in RA flare was 46.4 weeks (IQR: 12.9-137.4). Using definition 1, we found no evidence of a higher risk of incident AD/ADRD when in a RA flare vs remission (HR 1.10; 95% CI: 0.63-1.89). Using definition 2, RA flare was associated with a 2-fold higher risk of AD/ADRD (HR 2.00; 95% CI: 0.93-4.27), but this association did not reach statistical significance. When we examined cumulative time spent in each active flare (using either definition of flare) and intermediate activity, we observed a non-

Table: Association between RA flare and time spent in a flare with incident Alzheimer's disease and related dementias.

	Definition 1	Definition 2
Model 1	Hazard Ratio(95% Confidence Interval)	Hazard Ratio (95% Confidence Interval)
Active flare	1.10 (0.63-1.89)	2.00 (0.93-4.27)
Model 2		
Time spent in active flare (per 1 year increase)	1.03 (0.96-1.10)	1.10 (0.97-1.24)
Time spent in intermediate activity (per 1 year increase)	1.05 (0.98-1.12)	1.03 (0.97-1.10)
Remission	1.00 Reference	1.00 Reference

significant trend towards increased risk (3-5% per year time spent in active flare or intermediate activity) of incident AD/ADRD compared to time spent in a state of remission (Table).

Conclusion: Our findings indicate that flares of RA disease activity are common and may have a detrimental effect on cognitive status. More studies are needed to understand the mechanisms underlying the association between RA and AD/ADRD, and whether tight control of inflammation and improved flare management in patients with RA may confer long term cognitive benefits.

Synovial Fluid Cell Counts Associated with Joint Histopathology in Rheumatoid Arthritis

Edoardo Spolaore[1], Edward DiCarlo[2], Daniel Ramirez[2], Melanie Smith[2], Amit Lakhanpal[2], Bella Mehta[3], Laura Donlin[2], Susan Goodman[2] and Dana Orange[4], [1]HSS, New York, NY, [2]Hospital for Special Surgery, New York, NY, [3]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY, [4]The Rockefeller University, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: While analysis of synovial fluid white blood cell counts (WBCs) is performed in clinical practice for diagnosing septic arthritis and differentiating noninflammatory from inflammatory forms of arthritis, the connection between features of paired synovial fluid and tissue has not been explored. This study seeks to explore the relationship between paired synovial fluid cell counts, synovial histopathology, clinical features, and disease activity.

Methods: Patients meeting ACR/EULAR 1987 and/or 2010 rheumatoid arthritis (RA) classification criteria were recruited prior to elective total knee arthroplasty. All patients provided written informed consent (HSS IRB # 2014-233). Demographics, RA patient reported outcome measures (PROMs), tender and swollen joints, ESR, CRP, RF, and CCP were collected. Synovial fluid was obtained via arthrocentesis performed immediately before surgery. Absolute and differential cell counts were performed, and synovial histopathology using hematoxylin and eosin (H&E) was performed on tissue. An expert musculoskeletal pathologist scored 14 synovial histologic findings: synovial lymphocytic inflammation, mucoid change, fibrosis, fibrin, germinal centers, lining hyperplasia, polymorphonuclear neutrophils (PMNs), detritus, plasma cells, binucleated plasma cells, Russell bodies, sub-lining giant cells, synovial lining giant cells, and mast cells (available at www.hss.edu/pathology-synovitis). Relationships between synovial fluid and tissue data were measured with Pearson's correlations.

Results: We included 25 patients. Mean age = 68.12 years, mean disease duration = 16.25 years, indicating longstanding disease, mean DAS28-ESR = 4.86 indicating moderate disease activity. Further characteristics of the cohort divided by noninflammatory vs inflammatory synovial fluid (WBC threshold of 2000 cells/microL) are included (Table 1). Synovial fluid WBC was positively correlated with synovial lymphocytic inflammation (SLI), neutrophil infiltration, CRP, and ESR. Of the other synovial histologic features, mucoid degeneration approached significance. Percentage of PMNs in the synovial fluid was positively correlated with PMN infiltration. Percentage of monocytes in the synovial fluid was negatively correlated with PMN infiltration and SLI. Synovial fluid total WBC had no significant correlation with disease activity or PROMs in our cohort. Overview of correlations with associated statistical values included (Table 2, Table 3).

Table 1: Clinical and Histopathologic Characteristics Stratified by Synovial Fluid WBC

1 = mean (SD) 2 = n(%) *Between groups p-value calculated using t-test. RF = rheumatoid factor; CCP = cyclic citrullinated protein; ESR = erythrocyte sedimentation rate; CRP = C Reactive Protein; DAS28 = disease activity score using 28 joints; CDAI = clinical disease activity index; WBC = absolute white blood cell count; Polys% = percentage white blood cells in synovial fluid that are polymorphonuclear neutrophils; Monos% = percentage white blood cells in synovial fluid that are monocytes; Lymphs(%) = percentage white blood cells in synovial fluid that are lymphocytes; PMN = polymorphonuclear neutrophils; Bolded values significant p<0.05

Table 2: Correlations between synovial fluid, synovial histopathology, and blood inflammatory markers using Pearson's Correlation

Absolute Synovial Cell Count			
Variable 1	Variable 2	Adjusted R^2	p - Value
WBC	SLI	0.505	**0.001**
WBC	PMN tissue Infiltration	0.299	**0.009**
WBC	Mucoid Degeneration	0.183	0.01
WBC	CRP	0.338	**0.003**
WBC	ESR	0.238	**0.01**
Differential Synovial Cell Count			
%Polys	Neutrophil tissue infiltration	0.349	**0.02**
%Monos	Neutrophil tissue infiltration	0.294 [Negative Correlation]	**0.03**
%Monos	SLI	0.357 [Negative Correlation]	**0.04**

Table 3: Correlations between synovial fluid WBC and PROMs/disease activity using Pearson's Correlation

Variable 1	Variable 2	Adjusted R^2	p - Value
WBC	DAS28-CRP	0.013	0.27
WBC	DAS28-ESR	-0.013	0.41
WBC	Stiffness	-0.021	0.48
WBC	Pain	-0.035	0.65
WBC	Fatigue	-0.045	0.82
WBC	CDAI	-0.043	0.93

Conclusion: Preliminary results suggest that synovial fluid characteristics are informative and correlate with inflammation in the underlying synovial tissue, but not with disease activity. CRP, present in subclinical synovitis,[1] is strongly correlated with synovial fluid WBC. Further analysis of synovial fluid might increase insight into RA pathophysiology and disease control.

Background/Purpose: Rheumatoid arthritis (RA) is associated with a 2-fold higher risk of venous thromboembolism (VTE) compared with the general population. The immune system and hemostatic system are closely linked by a shared origin. Inflammation affects thrombotic responses by upregulating procoagulants and downregulating anticoagulants and fibrinolysis. Tumor necrosis factor (TNF), an important mediator in the inflammatory pathway, induces a disbalance between the coagulation system and fibrinolytic system, resulting in a hypercoagulable state. In addition, several studies have suggested that some Janus kinase-inhibitors (JAKi) might be associated with an increased risk for VTE. However, the underlying pathogenic mechanisms have yet to be elucidated. Our objective was to compare changes in hemostatic parameters during treatment with TNF-blockers and JAKi in RA.

Methods: Biomarkers for the coagulation system, including D-dimer, fibrinogen, PT, aPTT, F1+2, TAT, F IX and vWF, were prospectively measured in 121 consecutive RA patients: 83 patients treated with aTNF and 38 patients with JAKi. Data were collected at baseline, after 1, 3, and 6 months.

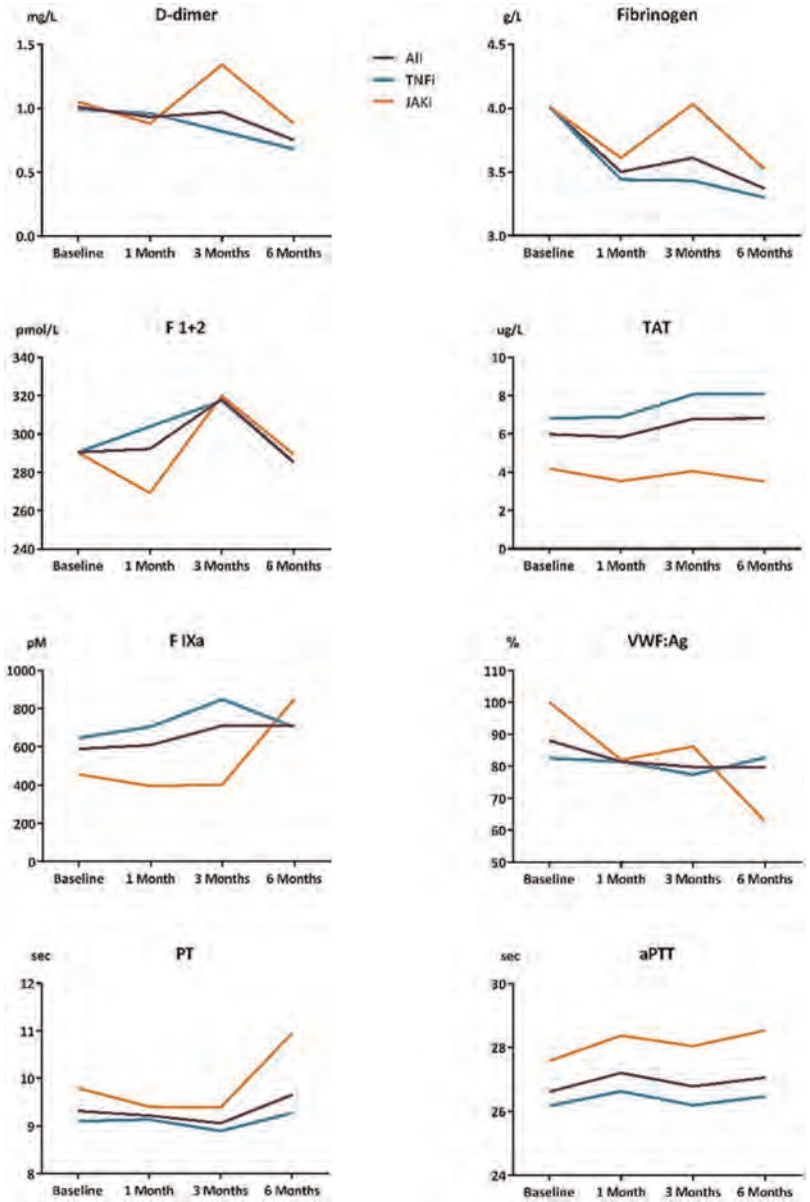

Figure 1: Progression of coagulation markers. F1+2= prothrombin fragment 1+2, VWF= von Willebrand factor, TAT= thrombin-antithrombin complex, FIX= Factor 9, PT = prothrombin time, aPTT = activated partial thromboplastin time.

Results: Mean age for all patients was 57 (±14) years, 76% were female. Mean DAS28-CRP at baseline for TNF-inhibitor group was 3.6 (±1.3) and 4.1 (±1.4) for JAKi group, steadily declining in aTNF users, while decreasing in JAKi users with an intermittent peak at 3 months. Baseline coagulation markers levels were comparable between the groups. D-dimer and vWF levels were slightly higher in the JAKi group (p = 0.30 and p = 0.08, respectively), while F IXa levels were lower (p = 0.17). D-dimer and fibrinogen levels steadily declined in the aTNF group, while fluctuating in the JAKi group, with a peak at 3 months with a subsequent decline thereafter (Figure 1). In aTNF users, TAT increased slightly during follow-up. VWF, PT and aPTT remained relatively stable, while F IXa and F 1+2 showed an increase after 3 months of follow-up, after which they returned to baseline. In JAKi users, D-dimer, fibrinogen, VWF and F 1+2 fluctuated, with a peak after 3 months and then a subsequent decline. F IX and PT initially decreased slightly but increased steadily after 6 months, while TAT and aPTT remained stable during follow-up.

Conclusion: The pro-thrombotic tendency in active RA declined during effective treatment with both aTNF as well as JAKi. A gradually decrease in D-dimer and fibrinogen was seen after 6 months of treatment. The transient increase of coagulation activation in JAKi users at three months coincided with increased disease activity. Altogether, our data suggests that an increased VTE risk in the first six months due to wither treatment aTNF or JAKi seems unlikely. Whether or not the risk increases beyond this time period remains to be investigated.

Associations and Mortality Impact of Machine Learning-derived Quantitative Computed Tomography Parenchymal Lung Features in Rheumatoid Arthritis and non-RA Comparators in a Multicenter Prospective Cohort of Smokers

Gregory McDermott[1], Keigo Hayashi[1], Matthew Moll[1], Michael Cho[1], Kazuki Yoshida[1], Tracy J. Doyle[1], Gregory Kinney[2], Paul Dellaripa[3], Zachary Wallace[4], Elizabeth Regan[5], Gary Hunninghake[1], Edwin Silverman[1], Samuel Ash[1], Raul San Jose Estepar[1], George Washko[1] and Jeffrey Sparks[6], [1]Brigham and Women's Hospital, Boston, MA, [2]University of Colorado Denver, Denver, CO, [3]Brigham and Women's Hospital, Boston, MA, [4]Massachusetts General Hospital, Newton, MA, [5]National Jewish Health, Denver, CO, [6]Division of Rheumatology, Inflammation, and Immunity, Brigham and Women's Hospital and Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Quantitative computed tomography (QCT) methods have been developed to automatically quantify parenchymal lung features on chest CT imaging. There have been limited investigations of QCT in RA participants and non-RA comparators or studies of the mortality impact of QCT features in RA. We hypothesized that RA would be associated with increased interstitial changes and emphysema, as determined by QCT. We also hypothesized that QCT scoring of interstitial and emphysematous lung changes would identify RA patients at higher mortality risk.

Methods: We investigated associations between RA and QCT features in COPDGene, a multicenter cohort study of current or former smokers that excluded participants with known interstitial lung disease or bronchiectasis. We identified participants with and without RA using RA self-report and DMARD use. We assessed the lung parenchyma in each scan using a

k-nearest neighbors classifier that categorizes regions of interest into normal lung, interstitial changes, or emphysema using the local tissue density and distance from the pleural surface. Interstitial changes were subclassified into reticular, subpleural line, linear scar, honeycombing, centrilobular nodule, nodular, and ground glass. Each feature was summed and standardized to total lung volume. We examined associations between QCT features and RA using multivariable linear regression. We dichotomized participants using the 75th percentile for each QCT feature among non-RA participants and investigated mortality associations by RA status and QCT features using Cox regression. We examined multiplicative interactions between RA and continuous interstitial and emphysema percentages and additive interactions between RA status and >75th percentile of QCT features and mortality.

Results: We analyzed 82 RA cases and 8820 non-RA comparators. RA was associated with a lower percentage of normal lung (85.8% vs. 91.0% p=0.0001), increased interstitial changes (7.0% vs. 4.8%, p< 0.0001) and no statistically significant difference in emphysema (2.6% vs. 1.9%, p=0.09) compared to non-RA comparators. In linear regression analyses adjusted for age, sex, smoking status, pack-years, and body mass index, RA was associated with increased interstitial changes (β=1.7±0.5, p=0.0008) but not emphysema (β=1.3±1.7, p=0.44). The combination of RA and >75th percentile of emphysema had significantly higher mortality compared to both non-RA participants (HR 5.86, 95%CI 3.75-9.13) and RA participants (HR 5.56, 95%CI 2.71-11.38) with < 75th percentile of emphysema. There were statistically significant interactions between RA and emphysema for mortality (multiplicative: p=0.014; additive: attributable proportion 0.53, 95%CI 0.30-0.70, p< 0.0001).

Bioinformatics Platform to Study the Genetics of Biologic DMARD Non-responders: Design and Protocol of the RA Non-responders to Treatment (RANT) Study

Gregory McDermott[1], Mary Jeffway[1], Thany Seyok[1], Harrison Zhang[2], Kumar Dahal[1], Dana Weisenfeld[1], Margaret Vella[3], Tracy Johansson[4], Gabriela Schmajuk[5], Kaleb Michaud[6], Cassandra Perry[3], Susanne Churchill[3] and Katherine Liao[1], [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [3]Harvard Medical School, Boston, MA, [4]American College of Rheumatology, Atlanta, GA, [5]UCSF / SFVA, San Francisco, CA, [6]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Although the modern RA treatment armamentarium has led to significant improvements in response rates and outcomes, some RA patients inadequately respond to multiple lines of treatment. The ability to study these "treatment refractory" RA patients is limited by small numbers of patients meeting criteria, even at high volume centers. In the cancer field, the general challenge of engaging small patient subsets for research led to the development of a novel "crowdsourced" bioinformatics research platform to recruit and study extreme outlier responses to chemotherapy from multiple sites/sources. Here we report the adaption of this novel platform to study genetic and clinical risk factors for inadequate response to multiple biologic and targeted synthetic DMARD medications (b/tsDMARDs) in RA.

Methods: RA Non-responders to Treatment (RANT) is a "crowdsourced" cohort study (target size n=300) using a bioinformatics platform investigating genetic and clinical predictors of non-response to b/tsDMARD medications. RA patients who have failed two or more b/tsDMARDs (including at least one TNF inhibitor) are eligible. A combination of traditional and

Figure 1: Study design of RANT study

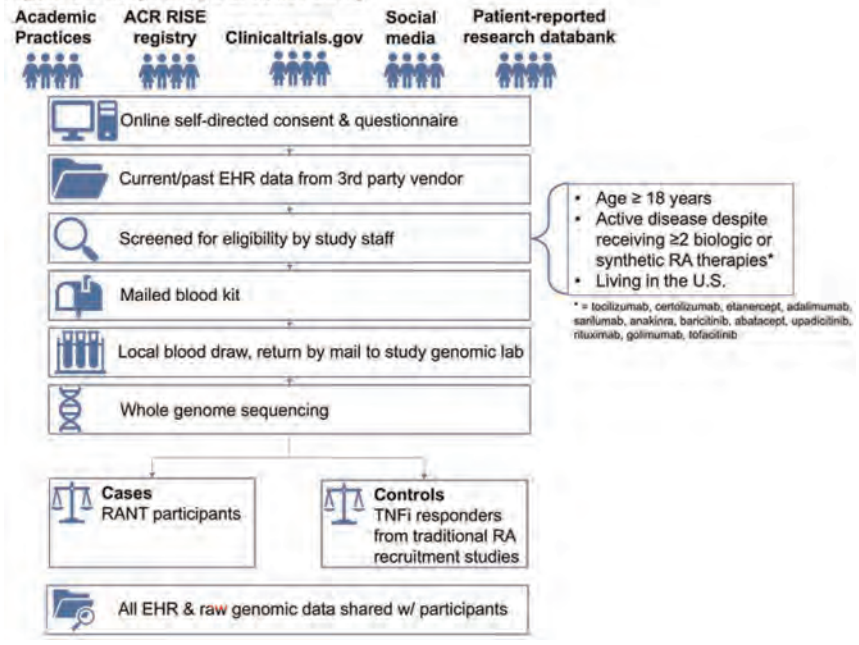

Table 1: Characteristics of RANT study participants and recruitment methods (n=107)

Characteristic	
Age at enrollment (years, mean, SD)	59.8 (12.8)
RA duration (years, mean, SD)	22.0 (12.8)
Female (n, %)	98 (91.6%)
Number of prior b/tsDMARDs (mean, SD)	5.1 (2.2)
Recruitment Method (n, %)	
FORWARD (Patient-reported research databank)	49 (45.8%)
Direct in-person clinic recruitment at academic practices	42 (39.2%)
ACR RISE	8 (7.5%)
Internet search/study website	6 (5.6%)
Clinicaltrials.gov	2 (1.9%)

ACR = American College of Rheumatology; b/tsDMARDs = biologic or targeted synthetic disease modifying antirheumatic drugs; RA = rheumatoid arthritis; SD = standard deviation

multimedia recruitment advertises the study: direct in-person clinic recruitment, dissemination of trial information to patients identified in established RA registries (ACR RISE, FORWARD), and social media publicizing the study to patients and rheumatologists via Twitter and Facebook. Study details are posted for the general public on clinicaltrials.gov.

The study process is detailed in **Figure 1**. Interested patients complete a self-directed online informed consent that includes access to electronic health records though a third-party vendor as well as RA treatment and disease status questionnaires. After study staff confirm eligibility by reviewing patient responses, patients receive a blood sample kit by mail, have blood sample tubes drawn locally, and return the kit by mail to the study genomic lab for whole genome sequencing. Clinical and genetic factors of RA treatment non-responders will be compared to established groups of RA treatment responders from established research cohorts. Patients will receive a copy of their medical records and genetic sequence data.

Results: Baseline characteristics of the first 107 recruited patients are detailed in **Table 1**. The majority were female (91.6%) with mean age 59.8 years and mean RA duration of 22 years. The mean number of b/tsDMARDs prescribed was 5.1 (SD 2.2). The most successful recruitment methods have been through an established patient-reported research databank (45.8%) and direct in-person recruitment of patients in clinic (39.2%).

Conclusion: This protocol describes a "crowdsourced" recruitment and online enrollment/consent procedures to investigate RA treatment non-responders. Similar methods may be useful for investigating rare rheumatology diseases, outcomes, or patient subsets that are difficult to reach or recruit by traditional research methods. Study results will demonstrate the feasibility of these research methods in future rheumatology research and inform the potential clinical and genetic predictors of treatment refractory RA.

Abstract Number: 0422

Electronic Health Record-Based Machine Learning Model for Predicting Disease Activity in Patients with Rheumatoid Arthritis

Zelin Yun[1], Chun Li[2] and Zhanguo Li[2], [1]Peking University People's Hospital, Beijing, China, [2]Peking University People's Hospital, Beijing, China

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is one of the most prevalent chronic inflammatory diseases in which synovitis gradually leads to polyarthritis and joint destruction. Poor response to initial therapy may contribute to progressive disease activity, high costs, and side effects. Given the explosive growth in the number of electronic health records (EHRs), we constructed machine learning models to predict disease activity and assess the effectiveness of treatment prior to the actual start of treatment.

Methods: This multicenter, prognostic study included 1864 patients with RA from 5 tertiary hospitals in China. Electronic health records (EHRs) were collected from 2016 to 2021. The Peking University People's Hospital (PKUPH) cohort was used for training and internal validation. The multicenter cohort was used for external validation. Multi-dimensional variables arranged sequentially (baseline, 3 months, and 6 months after treatment), including demographic features, laboratory tests, and medication history information, were involved in machine-learning model construction. Different algorithms were selected to predict disease activity 6 months after treatment. External validation involved multicenter participants. The Disease Activity Score in 28 joints-Erythrocyte Sedimentation Rate (DAS28-ESR) ≤ 2.6 was categorized as the primary outcome.

Table 1. The baseline characteristics of the study population Data that are not normally distributed are presented as the medians and interquartile ranges (IQRs) unless otherwise indicated. CRP=C-reactive protein; DAS28=disease activity score using 28 joint counts; ESR=erythrocyte sedimentation rate; TJC28=tender joint count (of 28); SJC28=swollen joint count (of 28); PtGA=patient global assessment of disease activity; RF=rheumatoid factor; Anti-CCP=anti-cyclic citrullinated peptide. * indicates a significant difference.

	PKUPH (n=1629)	Multicenter (n=235)	*P* value

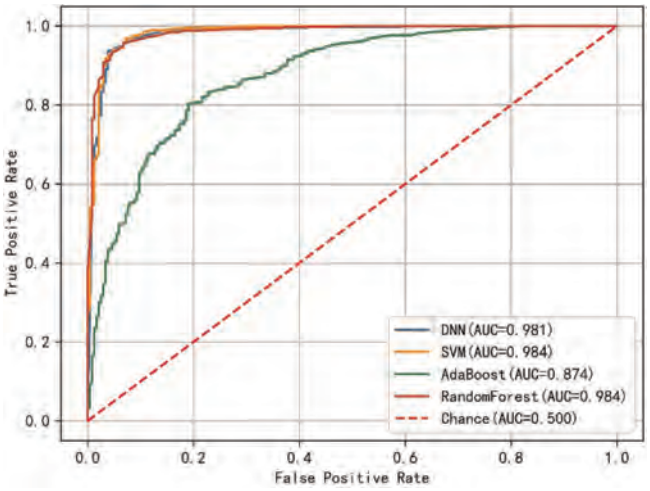

Figure 1. Evaluation of predictive machine learning models using the area under the receiver operating characteristic curve for primary outcome. The area under the receiver operating characteristic curve (AUROC) of machine learning (ML) models is displayed. Different colors were used to represent ML models. The results were attained from tests in the Peking University People's Hospital (PKUPH) cohort. DNN=deep neural network; SVM=support vector machine; AdaBoost=adaptive boosting.

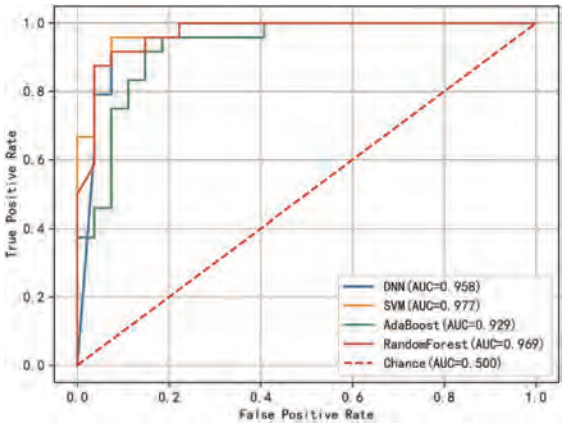

Figure 2. Evaluation of predictive machine learning models using the area under the receiver operating characteristic curve for external validation. The area under the receiver operating characteristic curve (AUROC) of machine learning (ML) models is displayed. Different colors were used to represent ML models. The results were attained from tests in the Peking University People's Hospital (PKUPH) cohort. DNN=deep neural network; SVM=support vector machine; AdaBoost=adaptive boosting.

Results: A total of 1629 patients from Peking University People's Hospital (PKUPH) and 235 multicenter patients were included (number [%] female, 1353 [83.1] vs 197 [84.5]). There were significant differences in disease activity at baseline between the PKUPH and multicenter cohorts at baseline (median [IQRs] DAS28-ESR, 5.4 [4.8, 6.2] vs 6.1 [5.5, 6.7]). For the primary outcome, the best-performing predictive model attained an accuracy of 96.8% and an area under the receiver operating characteristic curve (AUROC) of 0.984 [sensitivity of 98.9%, specificity of 85.2%, positive predictive value (PPV) of 96.9%, and negative predictive value (NPV) of 94.4%]. Notably, in external validation, the best accuracy of 92.7% and AUROC of 0.977 were achieved. We also tested the performance of machine learning models with the secondary outcome (DAS28-ESR >5.1 for high disease activity, >3.2 to ≤5.1 for moderate disease activity, >2.6 to ≤3.2 for low disease activity, ≤2.6 for remission). The DNN model displayed an accuracy of 70.4% and an AUROC of 0.898, which is acceptable.

Conclusion: EHRs including multiple, sequential time nodes can be used to construct and improve machine learning models. Deep learning model can accurately predict the effectiveness of treatment within a moderate sample size. Constructing machine learning models to predict disease activity in patients with rheumatoid arthritis had significant benefits across distinct hospitals.

Detection of Citrullinated Proteins Recognized by a Novel Chimeric Antigen Receptor T_{reg} Therapy in Both Synovial Fluid and Serum from Patients with Rheumatoid Arthritis

Sara Charmsaz[1], Jeff Tracy[1], Elizabeth Whalen[1], John Bui[1], Anne-Renee van der Vuurst de Vries[1], Vivianne Malmström[2] and Michelle Blake[1], [1]Sonoma Biotherapeutics, Seattle, WA, [2]Karolinska Institutet, Stockholm, Sweden

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is one of the most common autoimmune diseases and despite many therapeutic options, an unmet medical need persists for novel therapies in RA. Protein citrullination is a post-translational modification in which arginine is converted to citrulline through a process mediated by the activity of peptidylarginine deiminase enzymes. Citrullination is an important driver of RA pathogenesis and autoantibodies against citrullinated proteins are observed in majority of RA patients. We have developed a novel autologous chimeric antigen receptor (CAR) Treg therapy, SBT777101, that is designed to suppress inflammation in RA patients by utilizing a targeting domain directed against a subset of citrullinated antigens (Van der vurst de vries, ACR 2022). An enzyme-linked immunosorbent assay (ELISA) was developed to characterize the level of CAR-reactive antigens in RA patients.

Methods: An ELISA assay using a capture antibody derived from the binding domain of SBT777101 was used to measure the level of citrullinated proteins in synovial fluid (n = 176 RA, n = 54 non-RA) and serum (n = 130 RA, n = 15 non-RA). Levels of citrullinated proteins as evaluated by the ELISA assay, were compared to the activity produced by the antigen in a CAR-expressing cell-based assay. Additionally, the level of citrullinated antigens were compared to the levels of inflammatory markers in a set of matched serum and synovial fluid samples (n = 50).

Results: In RA patients with active disease, elevated protein citrullination was detected in 84% of synovial fluid samples and in 48% of serum samples (n = 50 matched synovial fluid and serum). Citrullinated antigen in synovial fluid correlated with levels of the antigen in serum (n = 50, Spearman R = 0.41, $p < 0.05$). The levels were higher by 4.6-fold in synovial fluid compared to serum which was reflected by more activity as detected by the CAR-expressing cell-based assay in synovial fluid. Additionally, levels of CAR-specific citrullinated antigens as measured by ELISA significantly correlated with the level of activity measured in the CAR-expressing cell-based assay (n =50, Spearman R = 0.48, $p < 0.05$) and with several markers of inflammation measured in synovial fluid (TNFα, IL1β, IL6, IL12p70, IP10 and MIP1α) and in serum (CRP and IL6) of these patient samples.

Conclusion: In summary, we were able to detect CAR-reactive citrullinated antigens for SBT777101 in synovial fluid and serum and these levels correlated with ability to activate the CAR in a cell-based assay, and with several inflammatory markers both in synovial fluid and serum. The presence of these CAR-reactive citrullinated antigens and inflammatory markers will be further evaluated in an upcoming planned phase 1 study.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The efficacy and safety of upadacitinib (UPA), an oral reversible Janus kinase inhibitor, have been shown in patients (pts) with moderate/severe RA in the SELECT clinical trial program, both as monotherapy and as part of combination therapy[1]. However, real-world (RW) data on UPA in clinical practice are limited. This analysis presents 6-month data on the effectiveness and safety of UPA in pts with moderate/severe RA in RW clinical practice.

Methods: UPHOLD (NCT04497597) is an ongoing, international, observational cohort study of UPA-naïve adults (aged ≥18 years) with moderate/severe RA, who received UPA 15 mg once daily (QD) as per the product label, with the decision to initiate UPA made before study enrollment. This 6-month interim analysis includes data reported between the study start

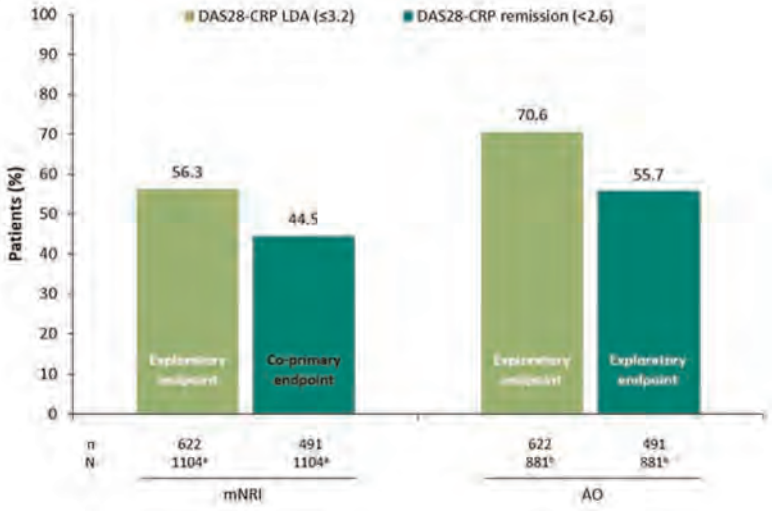
Figure. Proportion of patients who achieved DAS28-CRP LDA and remission at 6 months (mNRI and AO analyses)



[a]Number of patients in the mFAS population (patients within the FAS who completed 6 months of upadacitinib treatment and had DAS28-CRP data available at 6 months [n=881], and those who discontinued the study before 6 months for any reason [n=223]).

[b]Number of patients who completed 6 months of upadacitinib treatment and had DAS28-CRP data available at 6 months.

AO, as observed; DAS28-CRP, DAS of 28 joints using CRP; FAS, full analysis set; LDA, low disease activity; mFAS, modified FAS; mNRI, modified non-responder imputation.

modified FAS (mFAS; all pts within the FAS who completed 6 months of UPA treatment and had DAS28-CRP data available, and pts who discontinued the study before 6 months for any reason). Remission and LDA at 6 months were also analyzed AO in the mFAS population.

Results: Of the 1732 pts enrolled, 1715 received ≥1 UPA dose (FAS), of whom 223 (13%) prematurely discontinued the study before 6 months. The most common primary reasons for discontinuation were AEs and lack of efficacy (n=72 [4.2%] each). Pt demographics and disease characteristics at UPA initiation are summarized in Table 1. Of the 1104 pts in the mFAS, 44.5% (mNRI) and 55.7% (AO) achieved DAS28-CRP remission at 6 months, and 56.3% (mNRI) and 70.6% (AO) achieved DAS28-CRP LDA at 6 months (Figure). Improvements from baseline to 6 months were observed across PROs (Table 2). AEs reported were: any AE (36.4% of pts), serious AEs (4.5%), serious infection (1.7%; most commonly COVID-19), herpes zoster (2.5%), creatine phosphokinase elevation (0.5%), malignancy excluding non-melanoma skin cancer (NMSC; 0.3%), NMSC (0.4%), venous thromboembolic events (0.4%), and deaths (0.3%). No major adverse cardiovascular events were reported.

Conclusion: The results from UPHOLD suggest that UPA 15 mg QD is effective for the treatment of moderate/severe RAin RW practice, with almost half of pts achieving remission at 6 months. The benefit–risk profile of UPA remains favorable in the RW, consistent with that observed in Phase 3 clinical trials[1].

Abstract Number: 0425

Long-term Safety of Rituximab in Rheumatoid Arthritis: A Systematic Review and Meta-analysis

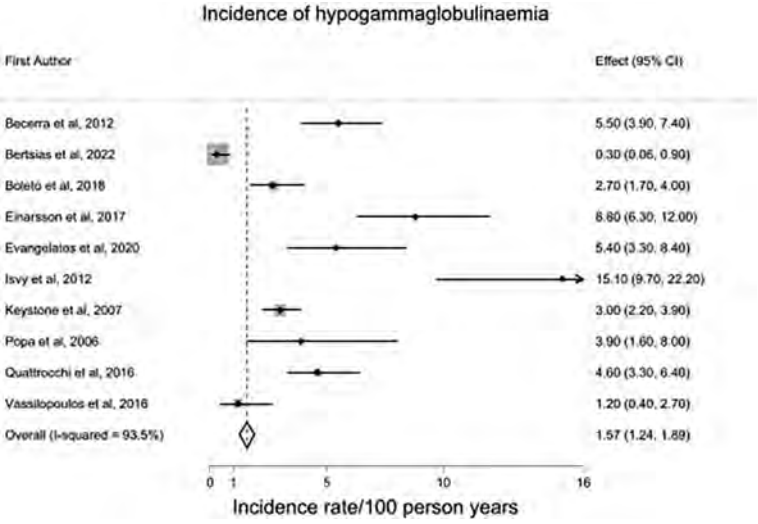
Ioasaf Karafotias, Joshua Rothwell, Maryam Adas, Bechman Katie, Mark Russell, Sam Norton and James Galloway, King's College London, London, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

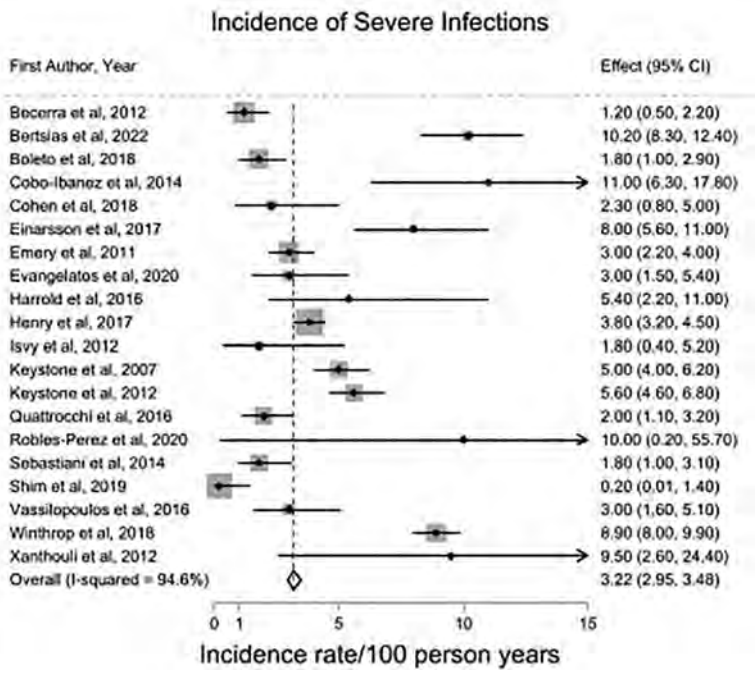
Background/Purpose: Rituximab targets CD20-bearing B cells and is used to treat Rheumatoid Arthritis (RA). Common Variable Immune Deficiency (CVID) is a primary immune deficiency syndrome with immune dysregulation, hypogammaglobulinemia, and recurrent infections. It was hypothesised that iatrogenic B cell depletion could produce a CVID-like phenotype. We sought to evaluate the safety of long-term Rituximab administration in RA patients.

Methods: A systematic review of the Medline/Embase, Web of Science, and Cochrane Library databases was conducted until February 2023. Observational studies in RA populations evaluating the safety of >2 courses of Rituximab, and/or >12 months' exposure to Rituximab were included. Exclusion criteria were case series, short-term exposure to Rituximab, or studies with patients under 16 years of age. Data on adverse events (hypogammaglobulinemia, severe infections, serious adverse events) were extracted. Pooled incidence rates of adverse events were calculated by random-effects meta-analysis.

Results: Twenty-three studies were included, reporting 253 episodes of hypogammaglobulinemia, 964 severe infections, and 1,903 severe adverse events, from a total 19,855 patient-years (PY) exposure. Their pooled incidence rates/100PY were 1.57 [95% confidence interval (95%CI) 1.24-1.89], 3.22 (95%CI 2.95-3.48), and 8.07 (95%CI 7.60-8.54), respectively. Event rates did not increase with longer duration of exposure.



Incidence of hypogammaglobulinemia



Incidence of severe infections

Conclusion: The safety risk of long-term exposure to Rituximab appears to be consistent over time. However, there was high heterogeneity in the outcomes, limited data on use beyond 5 years, and risk of bias was substantial. More research on long-term safety of Rituximab is required to address this.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Some patients with rheumatoid arthritis (RA) need switching therapy between biologic agents (Bio) and Janus kinase inhibitors (JAKi) when efficacy of Bio or JAKi is not enough.

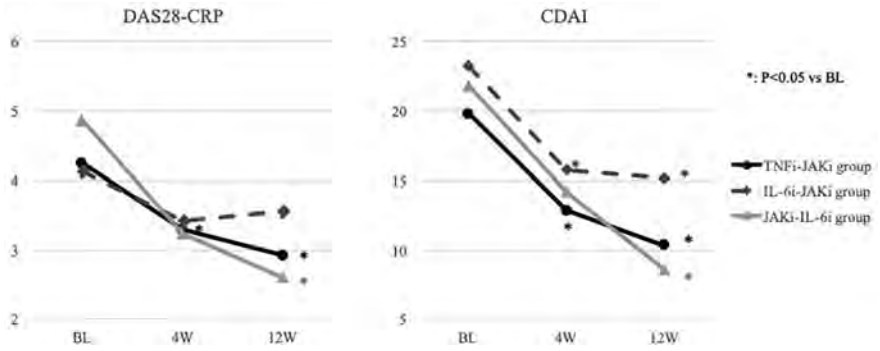

Figure 1: DAS28-CRP and CDAI in three groups for 12 weeks after switching

The aim of this study was to investigate the clinical efficacy of switching therapy between Bio and JAKi in the patients with RA.

Methods: We evaluated inflammatory markers and disease activities for 12 weeks (W) after switching in the patients with RA who received the switching therapy from Tumor Necrosis Factor inhibitors (TNFi) to JAKi (TNFi-JAKi group, N=61; mean age 64.6±12.9 years old), from Interleukin-6 inhibitors (IL-6i) to JAKi (IL-6i-JAKi group, N=33; mean age 64.9±14.7 years old), and from JAKi to IL-6i (JAKi-IL-6i group, N=8; mean age 65.5±14.7 years old).

Results: The mean values of Matrix Metalloproteinase-3 (MMP-3) (ng/ml) of TNFi-JAKi, IL-6i-JAKi, and JAKi-IL-6i groups were 213.5±481.3, 237.5±179.4, and 268.5±138.4 at baseline (BL), and 118.9±126.3 (p=0.148), 183.6 ±192.7 (p=0.279), and 196.2±100.9 (p=0.254) after 4W (vs BL), and 104.0±96.1 (p=0.089), 176.6±120.8 (p=0.123), and 137.4±114.5 (p=0.077) after 12W (vs BL), respectively. The mean Disease Activity Score 28- C reactive protein (DAS28-CRP) of TNFi-JAKi, IL-6i-JAKi, and JAKi-IL-6i groups were 4.22±1.27, 4.13±1.39, and 4.87±1.35 at BL, and 3.28±1.37 (**p< 0.001**), 3.41±1.46 (p=0.805), and 3.24±1.85 (p=0.065) after 4W (vs BL), and 2.99±1.24 (**p< 0.001**), 3.56±1.45 (p=0.115), and 2.60±1.40 (**p=0.005**) after 12W (vs BL), respectively (Figure 1). The mean Clinical Disease Activity Index (CDAI) of TNFi-JAKi, IL-6i-JAKi, and JAKi-IL-6i groups were 19.8±11.8, 23.2±12.7, and 21.8±9.9 at BL, and 12.8±10.4 (**p< 0.001**), 15.7±12.5 (**p=0.020**), and 14.2±13.9 (p=0.228) after 4W (vs BL), and 10.3±9.8 (**p< 0.001**), 15.2±12.6 (**p=0.012**), and 8.6±9.5 (**p=0.017**) after 12W (vs BL), respectively (Figure 1). There were no significant differences in the mean values of MMP-3 for 12W after switching in all groups. The disease activities (both of DAS28-CRP and CDAI) significantly decreased after 4W in TNFi-JAKi group, and after 12W in TNFi-JAKi and JAKi-IL-6i groups (Figure 1). DAS28-CRP and CDAI kept to decrease for 12W after switching in TNFi-JAKi and JAKi-IL-6i groups, however, DAS28-CRP increased and CDAI did not decrease from 4W to 12W after switching in IL-6i-JAKi group (Figure 1).

Conclusion: There have not still been clear indications of the switching therapy between Bio and JAKi in the patients with RA. In this study, it may be considered that the switching therapy from TNFi to JAKi and from JAKi to IL-6i could be effective when RA patients treated with TNFi or JAKi need switching therapy due to insufficient clinical efficacy.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite advances in rheumatoid arthritis (RA) treatment, a significant proportion of patients (10-30%) fail to respond to current medications, including biologics. A better characterization of the molecular effects promoted by the drugs might contribute to the development of personalized therapeutic strategies.

Methods: Peripheral blood mononuclear cells (PBMC) and neutrophils from 10 active RA patients were cultured (24h and 12h, respectively), with autologous serum and with either, etanercept, sarilumab, or baricitinib (all 10 micromolar). Changes in cell proliferation and adhesion in PBMCs and NETosis-derived products in supernatants of cell cultures were measured with specific commercial kits. Protein expression changes promoted by each drug were evaluated in supernatants using proximity extension assay (PEA) technology (Olink), analyzing a panel of 92 inflammation-related proteins. To identify if the proteomic signatures susceptible to being modulated by the drugs were present in patients with active disease, we analyzed the same inflammatory profile in the serum of 180 RA patients.

Results: TNFi, IL6Ri, and JAKinibs inhibited proliferation and adhesion in PBMCs from 70% of RA patients, being TNFi and JAKinibs more effective than IL6Ri. RA Neutrophils treated with autologous serum underwent NETosis, which was equally prevented by all inhibitors. Autologous serum increased the secretion of inflammatory proteins by RA PBMCs and neutrophils, while each drug promoted specific changes in proteomic signatures. Thus, TNFi, IL6Ri, and JAKinibs reduced different sets of cytokines, chemokines, and growth factors, with only three reduced (IL7, TNF, FGF23) by all three inhibitors. Lastly, analysis of the circulating inflammatory proteome revealed that approximately 60% of active RA patients exhibited at least one altered proteomic signature associated with the one modulated ex vivo by any of the drugs. Particularly 20% of patients exhibited an altered proteomic signature modulated ex vivo by the 3 drugs, 20 % with two of them, and 20% with only one precise drug.

Conclusion: The distinctive cellular and molecular changes promoted by TNFi, IL6Ri, and JAKinibs in ex vivo assays of RA immune cells, were consistent with specific altered serum profiles observed in subgroups of active RA patients. Such observations provide compelling evidence regarding the therapeutic potential of each therapy, as it aligns with the specific molecular profile alterations exhibited by individual patients at baseline.

Real World Patterns of Advanced Therapy Tapering in Early Rheumatoid Arthritis: Data from the Canadian Early Arthritis Cohort

Maria Powell[1], Vivian Bykerk[2], Orit Schieir[3], Marie-France Valois[4], Susan Bartlett[5], Louis Bessette[6], Gilles Boire[7], Carol Hitchon[8], Edward Keystone[9], Janet Pope[10], Carter Thorne[11], Diane Tin[12], Glen Hazlewood[1] and Canadian Early Arthritis Cohort (CATCH) Investigators[13], [1]University of Calgary, Calgary, AB, Canada, [2]Hospital for Special Surgery, New York, NY, [3]McGill University, Montréal, QC, Canada, [4]McGill University, Pointe-Claire, QC, Canada, [5]McGill University, Montreal, QC, Canada, [6]Centre de l'Ostéoporose et de Rhumatologie de Québec, Quebec City, QC, Canada, [7]Université de Sherbrooke, Sherbrooke, QC, Canada, [8]University of Manitoba, Manitoba, MB, Canada, [9]Keystone Consulting Enterprises Inc., Toronto, ON, Canada, [10]University of Western Ontario, London, ON, Canada, [11]Southlake Regional Health Centre, Newmarket, ON, Canada, [12]Centre of Arthritis Excellence, Newmarket, ON, Canada, [13]CATCH, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Recent Canadian treatment recommendations suggest offering to taper of biologic or targeted synthetic therapy to patients with rheumatoid arthritis (RA) after they achieve sustained remission (sREM) or low disease activity (LDA) for at least 6 months. This study sought to describe real-world patterns of advanced therapy tapering in a large pan-Canadian cohort of patients with early RA who would be eligible to taper and identify predictors of which patients are reducing their therapy in routine care.

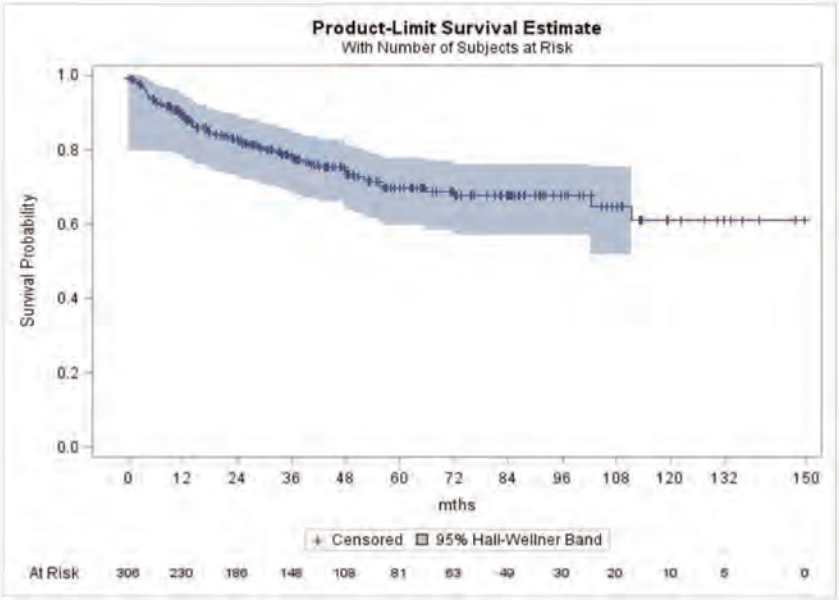

Figure 1: Kaplan Meier Survival Estimates of Time from Rheumatoid Arthritis Sustained Remission or Low Disease Activity to First Advanced Therapy Taper in a Multi-Centre Study Embedded in Routine Care (72 tapered and 234 censored).

Table 1: Multivariable Cox Regression Results - Predictors of Tapering Advanced Therapy in Rheumatoid Arthritis Patients Reaching Sustained Remission or Low Disease Activity in a Multi-Centre Study Embedded in Routine Care (N=306).

Variables	HR	95% CI
Baseline		
Sex: female vs male	0.960	0.556 – 1.660
Education: post-secondary vs. high school degree or less	1.545	0.899 – 2.654
Seropositive (RF or ACPA), %[%]	0.931	0.496 – 1.749
When Sustained Remission / Low Disease Activity First Achieved		
Age, years	1.010	0.990 – 1.029
Disease duration, months	1.001	0.991 – 1.011
Number of Advanced Therapies Tried/Used (>1 vs. 1)	1.080	0.476 – 2.454
Pain (0-10), change of 1	1.004	0.847 – 1.191
Fatigue (0-10), change of 1*	0.852	0.739 – 0.982
Type of advanced therapy		
Non-TNF inhibitor vs TNF inhibitor*	2.732	1.345 – 5.549
JAK inhibitor vs TNF inhibitor	0.750	0.309 – 1.822

Abbreviations
RF (rheumatoid factor)
ACPA (anti-citrullinated protein autoantibodies)
TNF (tumour necrosis factor)
JAK (Janus kinase)

Methods: Data from patients (age >18) enrolled in the Canadian early ArThritis CoHort (CATCH) between January 2007 to August 2022 were analyzed. CATCH is a prospective, observational cohort of patients with early inflammatory arthritis (symptoms < 1 year) treated in rheumatology clinics across Canada. The analysis cohort included patients with a diagnosis of RA according to the 1987 or 2010 ACR/EULAR classification criteria who were prescribed advanced therapy (i.e., tumour necrosis factor (TNF) inhibitors, Janus kinase (JAK) inhibitors, non-TNF inhibitor advanced therapy) and sREM or LDA (using simplified disease activity index or clinical disease activity index) for at least 6 months. Patients were considered taper advanced therapy if they reduced the dose of therapy by at least 25% through dose reduction or dose spacing for a time period of at least 3 months. Survival analysis using the Kaplan-Meier method was used to estimate the median time to taper advanced therapy and Cox regression analysis was used to identify predictors of tapering advanced therapy.

Results: Data were analyzed from 306 RA patients treated with advanced therapy who reached sREM or LDA for at least 6 months. These patients were predominantly white (87%), female (73%), and had seropositive RA (82%) with a mean age of 50 years. At the time of sREM or LDA patients were treated with TNF inhibitors [n=218 (71%)], JAK inhibitors [n=52 (17%)], and non-TNF biologic therapy [n=36 (12%)]. Treatment tapering occurred in 72 (24%) patients and was more frequent for treatment with non-TNF-inhibitors [n=15/36 (42%)] compared to TNF inhibitors [n=51/218 (23%)] or JAK inhibitors [n=6/52 (12%)]. The median time to taper advanced therapy after achieving sREM or LDA was 14 months (IQR: 5, 35 months) (Figure 1). In adjusted Cox regression analyses, treatment with a non-TNF inhibitor was associated with a higher likelihood of tapering (HR: 2.73, 95% CI:1.35, 5.55) and having higher patient reported symptoms of fatigue was associated with a decreased likelihood of tapering (HR 0.89: 95% CI 0.80 – 0.99) (Table 1).

Conclusion: In this real-world study of early RA patients, tapering was attempted in approximately 1 in 4 patients who would be considered eligible based on current recommendations, with a median time of 14 months. Tapering was associated with the type of advanced therapy and was less common in patients with worse fatigue, suggesting real-world decisions to taper are influenced by factors beyond typical measures of RA disease activity.

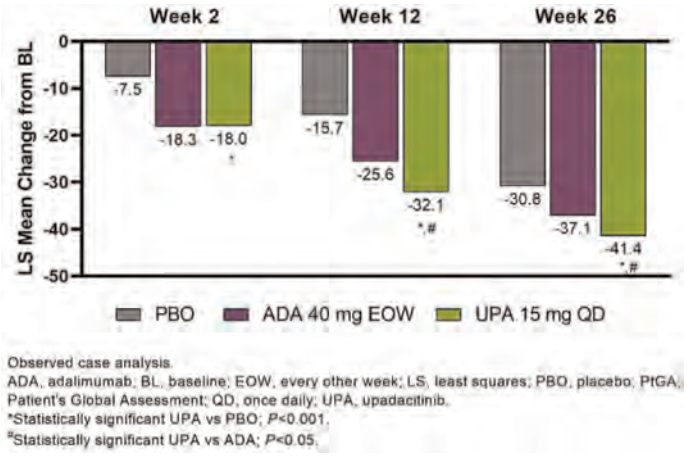
SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Rapid and sustained pain control is an important goal for patients (pts) with rheumatoid arthritis (RA). Control of inflammation in RA does not always eliminate pain, which can have multifactorial causes. Our objective was to assess direct and indirect (ie, by inflammation surrogates) effects of treatment with upadacitinib (UPA) or adalimumab (ADA) vs placebo (PBO) on pain in pts with RA.

Methods: Period 1 of SELECT-COMPARE was a 48-week, randomized, double-blind, phase 3 study with a 26-week PBO-controlled period in pts with RA who had active disease despite methotrexate treatment. Adults (≥18 years) on stable background methotrexate were randomized 2:2:1 to UPA 15 mg once daily, PBO, or ADA 40 mg every other week. Pts with an insufficient response (< 20% improvement in tender joint count [TJC] or swollen joint count [SJC] at week 14, 18, and 22 or if Clinical Disease Activity Index was >10 at week 26) were rescued from PBO to UPA, UPA to ADA, or ADA to UPA; all PBO pts who were not rescued were switched to UPA at week 26. Observed case analysis was performed for change from baseline in Patient's Global Assessment (PtGA) of pain (1–100 mm). A multiple mediator analysis[1] for effect of UPA vs PBO and ADA vs PBO on pain assessed as PtGA of pain or TJC28 was conducted using observed case analysis for week 2 and

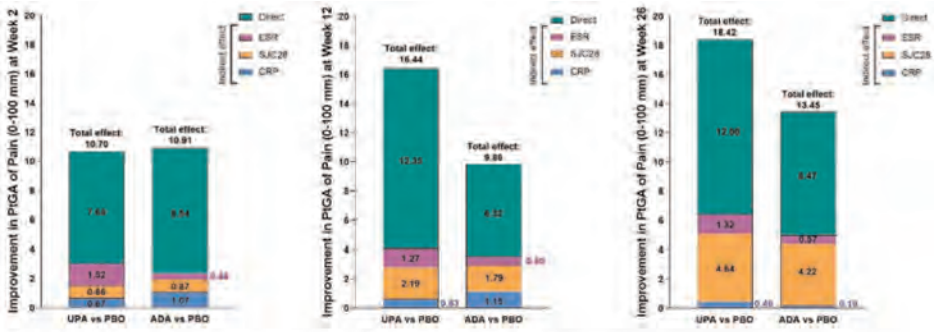


Observed case analysis.
ADA, adalimumab; BL, baseline; EOW, every other week; LS, least squares; PBO, placebo; PtGA, Patient's Global Assessment; QD, once daily; UPA, upadacitinib.
*Statistically significant UPA vs PBO; $P<0.001$.
#Statistically significant UPA vs ADA; $P<0.05$.

Figure 1. Change from Baseline in PtGA of Pain (mm) at Weeks 2, 12, and 26

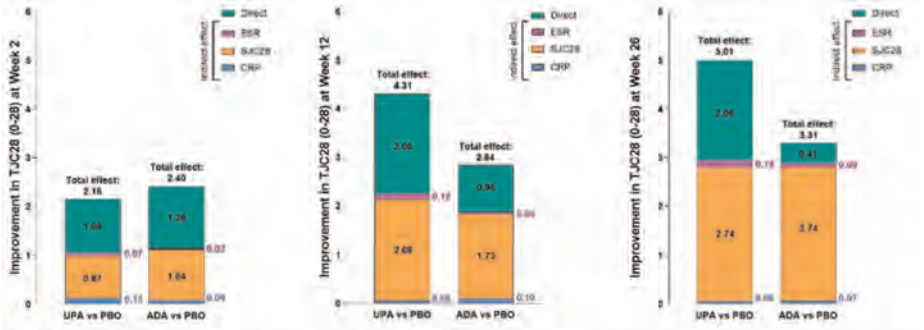
12 analyses and last observation carried forward for data after rescue for the week 26 analysis. Indirect effect of treatment on pain was assessed based on ESR, CRP, and SJC28.

Results: 1629 pts were included in this analysis (UPA, n=651, PBO, n=651, ADA, n=327).PtGA of pain significantly improved with UPA vs PBO from baseline to week 2 (–18.0 [n=639] vs –7.5 [n=624]; *P*< 0.001), week 12 (–32.1 [n=614] vs –15.7 [n=616]; *P*< 0.001), and week 26 (–41.4 [n=478] vs –30.8 [n=305]; *P*< 0.001; **Figure 1**). Improvements in PtGA of pain were also observed with ADA vs PBO at weeks 2 (–18.3 [n=318]), 12 (–25.6 [n=307]), and 26 (–37.1 [n=212]; **Figure 1**). Total and direct effects on PtGA of pain improvement were significantly greater (both *P*< 0.001) with UPA vs PBO as early as week 2 (**Figure 2**) and increased at weeks 12 and 26 (all *P*< 0.001). Total and direct effects on PtGA of pain improvement were also observed with ADA vs PBO (**Figure 2**). Improvement in pain assessed as TJC28 was also significantly greater (all *P*< 0.05) with UPA and ADA vs PBO at weeks 2, 12, and 26; SJC28 showed the greatest indirect effect on pain assessed as TJC28 at weeks 12 and 26 (**Figure 3**). UPA and ADA vs PBO showed similar indirect contributions to improvement in PtGA of pain and TJC28 at weeks 2, 12, and 26, whereas UPA showed a greater direct effect on PtGA of pain and TJC28 at weeks 12 and 26 than ADA (**Figures 2 and 3)**.



Week 2 and 12 data: observed case analysis; week 26 data: LOCF analysis.
ADA, adalimumab; LOCF, last observation carried forward, PBO, placebo; PtGA, Patient's Global Assessment; SJC28, swollen joint count based on 28 joints; UPA, upadacitinib.
Mediation analyses were conducted using the methods of Preacher and Hayes[1]. Estimates for the following effects were generated, controlling for baseline value of PtGA of pain: direct effect of treatment on the outcome of improvement from baseline in PtGA of pain, indirect effects of treatment on the outcome via mediators of change from baseline in ESR/SJC28/CRP, and total effect of treatment on the outcome.

Figure 2. Direct and Indirect Effects of Treatment on Pain Assessed as Improvement in PtGA of Pain at Weeks 2, 12, and 26



Week 2 and 12 data: observed case analysis; week 26 data: LOCF analysis.
ADA, adalimumab; LOCF, last observation carried forward; PBO, placebo; SJC28, swollen joint count based on 28 joints; TJC28, tender joint count based on 28 joints; UPA, upadacitinib.
Mediation analyses were conducted using the methods of Preacher and Hayes[1]. Estimates for the following effects were generated, controlling for baseline value of TJC28: direct effect of treatment on the outcome of improvement from baseline in TJC28, indirect effects of treatment on the outcome via mediators of change from baseline in ESR/SJC28/CRP, and total effect of treatment on the outcome.

Figure 3. Direct and Indirect Effects of Treatment on Pain Assessed as Improvement in TJC28 at Weeks 2, 12, and 26

Conclusion: Both UPA and ADA resulted in rapid and significant improvements in pain vs PBO as early as week 2 in patients with RA. Indirect effects on PtGA or TJC28 pain improvement were similar between UPA and ADA at all time points; however, direct effect on pain was up to two times greater with UPA vs ADA at weeks 12 and 26. These results suggest UPA may be more effective in control of pain, which may be due to either inflammatory or non-inflammatory mechanisms, than ADA in RA.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The Janus Kinase inhibitors (JAKi) drugs are approved for use in adults with moderate to severe rheumatoid arthritis (RA). Real-world studies are necessary as they provide relevant data that complements the information provided by registration clinical trials.

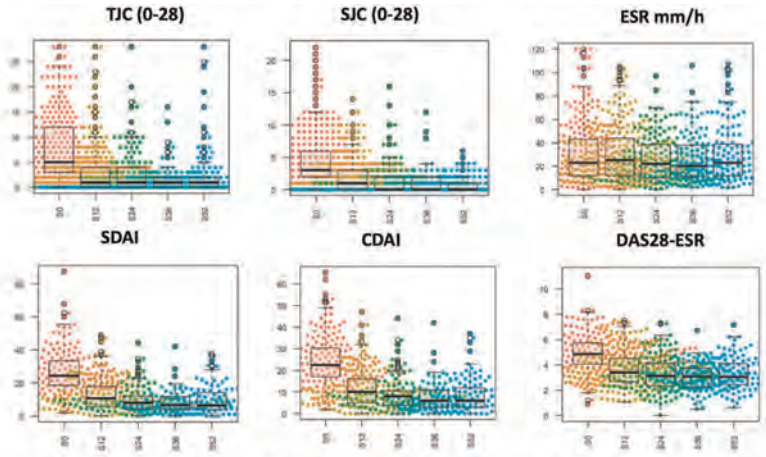

Figure 1. Evolution of parameters and index per week of treatment

For each variable, the mean and standard deviation -mean(sd)- together with the 95% confidence interval for the mean -IC [,] - and the median and interquartile range, median [IQR], were calculated

Table 1. Clinical and epidemiological characteristics of the cohort.

VARIABLE	N (%) [CI 95%]	N
Smoking		248
- No smoker	168 [65.7%] [59.5; 72.0]

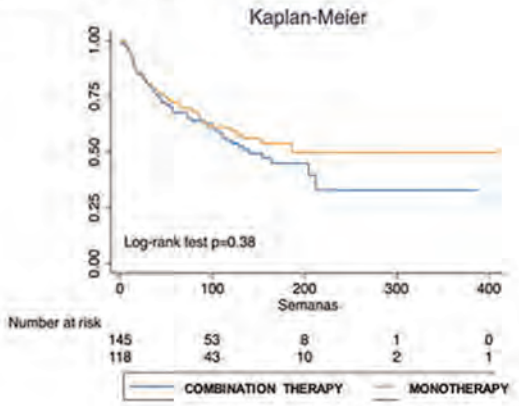
FIGURE 2. Survival of JAKi in monotherapy or combination therapy



Methods: Observational, retrospective, and multicenter study of a cohort of RA patients treated with a JAKi and followed up in n=14 Rheumatology Services, members of the RA Working Group (GT-ARCat) of the Catalan Society of Rheumatology (SCR). Data from patients who underwent JAKi treatment between May 2014 and November 2022 were included. Epidemiological and clinical variables were collected from baseline (S0) to week 52 (S52) of treatment. Analysis of the use of a first JAKi has been performed.

Results: A total of 256 patients (87% women) were included, with a mean age of 57.31 years and a mean time of disease evolution of 12.17 years. The cohort characteristics are detailed in Table 1. 53.5% of the cohort had received baricitinib, 41.8% tofacitinib and 4.7% upadacitinib. No statistically significant differences were observed in the epidemiological and clinical characteristics according to JAKi type. 65.6% of patients had at least one of the following characteristics (age ≥65 years, smoker or former smoker, HT, dyslipidemia, diabetes mellitus, ischemic heart disease, neoplasia, cerebral vascular accident or thrombosis). 36% had undergone ≥ 4 biological therapies (BT). During the follow-up period, treatment with a JAKi was withdrawn in 39.1% (n=100) of the cases included. The main reason for withdrawal was inefficacy in 57% (31% primary, 26% secondary), followed by 26% adverse effects and 17% other reasons. After treatment withdrawal with a JAKi, most patients (31.3%) were started on an anti-TNF drug, followed by an IL6 inhibitor (20.2%) or another JAKi (18.2%). Regarding the efficacy of JAKi treatment, a reduction in activity parameters and indices was observed throughout follow-up period as shown in Figure 1.The proportion of responders at follow-up weeks is detailed in Tables 2 and 3. The comparative analysis between responders and non-responders showed no statistically significant differences in descriptive and disease variables, except for number of previous bDMARDs (2 [RIQ 0.3] vs 2 [RIC 1.4], p=0.041, prior antiTNF use (57.8% vs 76.8%, p=0.011) and rituximab (7.4% vs 23.2%, p=0.003). A higher percentage of patients with DAS28 ≤2.6 was observed in the monotherapy group compared to the combinantion treatment (30.3% vs 17%, p=0.037). The median survival was 3.15 years and higher in monotherapy, although without statistically significant differences, Figure 2.

Conclusion: JAKi have been effective in different RA patient profiles while maintaining a good safety profile. In our cohort, although according to the latest recommendations, the use of JAKi would be limited in more than half of the patients, the withdrawal rate due to adverse effects has been low, although a longer follow-up time would be necessary.

Senescence and Cell Exhaustion in CD4+ and CD8+ Lymphocytes in Rheumatoid Arthritis Patients in Remission Without Treatment

Rodolfo Jiménez-Soto[1], Luis llorente[2], Guadalupe Lima[1], Luisa Alanis Saenz[1], Amairani Gomez Rodriguez[1], Hilda Marin Lopez[1], Erik Cimé-Aké[1] and Juan Jakez-Ocampo[1], [1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, [2]Departamento de Inmunología y Reumatología, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

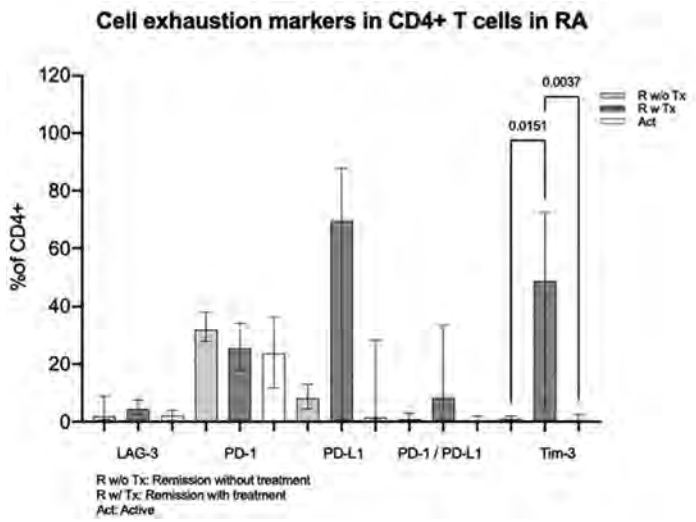
Session Title: RA – Treatments Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: T cells are important among the several risk factors and immunological markers implicated in rheumatoid arthritis (RA). The goal of this study was to look for biological markers of cell exhaustion in CD4+ and CD8+ lymphocytes from RA patients in remission who were not receiving medication.

Methods: A cross-sectional, single-center study was carried out in a tertiary care center in Mexico City. We included 18-year-old patients who met the EULAR/ACR 2010 RA classification criteria. Patients were divided into three groups: G1) remission for 5 years without therapy with DMARDs and/or glucocorticoids; G2) remission on treatment, and G3) active patients. Pregnancy, active infection, cancer, and the presence of other autoimmune diseases (except Sjogren's syndrome) were all exclusion criteria. Relevant clinical and serological parameters were recorded, and a univariate analysis was done with SPSS v29. Flow cytometry with Flow Jo v10 was used to analyze the expression of cell exhaustion markers (CTLA-4, LAG-3, PD-1, PD-L1, and Tim-3).



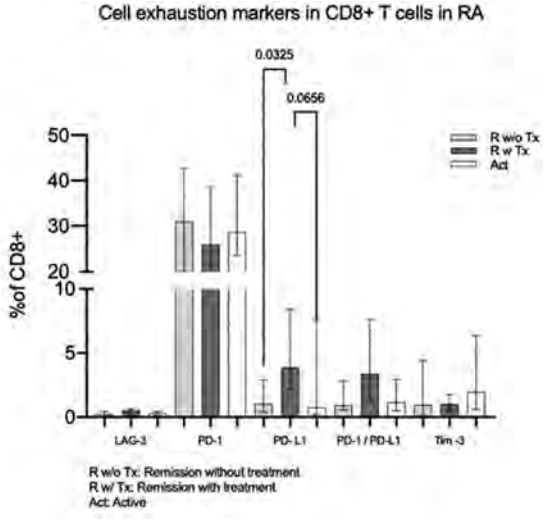


Table 1. Demographic, clinical, laboratory characteristics and treatment of RA patients (n=37).	
Variables	**Total (%) or mean (± SD)**
Age	57.5 (± 12.9)
Female	36 (97.3)
Smoking	5 (13.5)

RF	198.08 (74.75-317.45)	201.05 (97.8-296.1)	86.61 (34.9-108.85)	0.059
Anti-CCP	234.53 (67.4)-336.12	195.5 (14.1-304)	304.94 (256-343)	0.129
***Data are expressed as number (percentage) or median (interquartile range). Statistical analysis: chi-square test for nominal variables and Kruskal-Wallis test used for numerical variables.** **Values shown in bold represent statistically significant p values.** DMARDs: Disease-modifying antirheumatic drugs, HCQ: hydroxychloroquine, MTX: methotrexate, SSZ: sulfasalazine, LFL: leflunomide, RF: rheumatoid factor, NV: not valuable, anti-CCP: anti-cyclic citrullinated peptide antibody, ESR: erythrocyte sedimentation rate, CRP: C-reactive protein.				

Results: We included 37 patients, 12 (32.4%) of whom were in remission without treatment (G1) and were paired with G2 (32.4%) and G3 (35.1%). The majority (97.3%) were female, the mean age was 57.5 (±12.9) years, and only 5 (13.5%) were smokers. Methotrexate (MTX) was used in 16, hydroxychloroquine (HCQ) in 7, sulfasalazine (SSZ) and leflunomide in 5 each. The mean ESR was 8.22 mm/hr (2-36), and the mean CRP was 1.24mg/dL (0.05-8.74), with no major differences detected between the three groups. When the use of DMARDs was analyzed by group, it was 0%, 57.9%, and 42.1% respectively ($p< 0.001$). HCQ use was higher in G3, with 0% vs 28.6% vs 71.4% ($p=0.032$), while SSZ and MTX were more frequent in G2-3, with 0% vs 20% vs 80% and 0% vs 62.5% vs 31.3%, respectively ($p=0.046$ and $p=0.002$). Other drugs showed no significant differences. Rheumatoid factor was positive in all patients, while anti-cyclic citrullinated peptide antibodies were positive in 90%, 71.4%, and 100%, respectively ($p=0.161$). (Table 1) When comparing numeric values between groups, G3 were younger patients and had higher values of ESR and PCR compared to other groups; with ages 64.5 (52.75-73) vs 64.5 (52.5-69) vs 49 (41.5-59.5) years ($p=0.039$), mean ESR of 4 (2-5) vs 2 (2-5.75) vs 14 (4.5-19) mm/hr ($p=0.034$), and mean CPR of 0.24 (0.0875-0.4675) vs 0.27 (0.2-1.43) vs 1.52 (0.5-2.455) mg/dL ($p=0.008$). Other variables were studied; however, no statistical significance was found. (Table 2)Cell exhaustion markers in CD4+ were higher in G2, except for PD-1, with LAG-3, PD-L1, ratio PD-1/PD-L1, and Tim-3 being significant ($p=0.0052$), whereas in CD8+, only the expression of PD-L1 was significantly different ($p=0.0325$) (Image 1). These findings suggest that G2 induces increased cell exhaustion, and treatment may be the primary determining factor. However, the limited sample size may have an impact on the findings.

Conclusion: To the best of our knowledge, this is the first study that assess multiple markers of cell exhaustion in RA patients, with expression perhaps related to remission and/or treatment. Further research with larger sample sizes is required to confirm our findings.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Different guidelines recommend the use of tofacitinib either in monotherapy or combined with methotrexate (combination therapy) in patients with rheumatoid arthritis (RA) with an inadequate response to conventional synthetic DMARDs (csDMARDs) or biologic DMARDs (bDMARDs). Although the evidence originating from clinical trials does not show notable differences in terms of efficacy and safety with both strategies, data from real life is limited.

To evaluate the frequency, predictors of use and survival of tofacitinib in monotherapy compared with combination therapy in a cohort of patients with RA from daily clinical practice in our country.

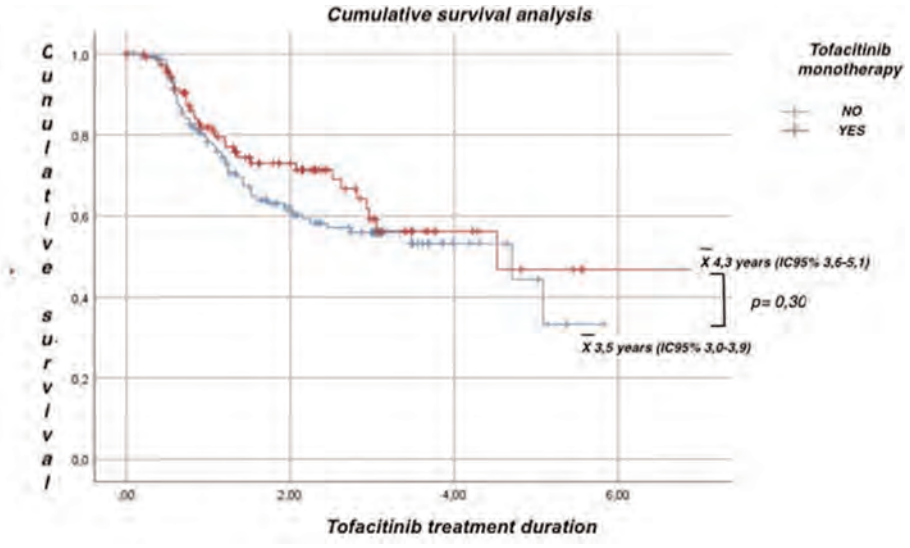
Methods: Longitudinal, observational study which includes a cohort of patients with RA (ACR/EULAR 2010 criteria) from different rheumatology centers who started treatment with tofacitinib. Patients were evaluated at baseline and followed up every six months from the start of medication. Sociodemographic, clinical and treatment data were collected. Chi2 test, Fisher's exact test, Student's T test and Mann Whitney were used according to the nature of the variables. Kaplan-Meier method and the Log Rank test were applied to compare survival of treatment in monotherapy vs. combination therapy. Cox regression analysis was used to evaluate variables associated with lower survival. The incidence of adverse events (AEs) was calculated as events every 100 patients/year (p/y). A $p< 0.05$ was considered significant.

Results: 269 patients were included, 87% female, mean age 56.3 years (SD 13.6), of which 41.3% started treatment with tofacitinib monotherapy. Main reasons for monotherapy use were previous adverse events with csDMARD (16%) and physician's decision (16%). In the univariate analysis, no significant association was found between the use of monotherapy and different sociodemographic and clinical variables. In the multivariate analysis, fewer prior cs-DMARDs combination therapy and prior use of biologic therapy were significantly associated with initiation of tofacitinib monotherapy ($p< 0.05$, both) (table). During follow-up (502.4 patients/year), no statistically significant differences were found in tofacitinib survival between the two groups (figure). Regarding safety, 110 patients (40.9%) had at least 1 AE, the most frequent being infections (57.6%),

	Monotherapy n= 111	Combination n= 158	p
Females, n (%)	98 (88,3)	136 (86,1)	0,7
Age (years), m (SD)	57,4 (12,2)	55,5 (14,5)	0,2
Disease duration (years), *m (IQR)*	12,4 (9,8)	10,6 (8,2)	0,1
Ever Smoking, n (%)	12 (11,4)	26 (17)	0,4
Extra-articular manifestations, n (%)	50 (45)	72 (45,6)	0,9
Rheumatoid nodules, n (%)	22 (19,8)	38 (24,1)	0,4
ILD, n (%)	13 (11,7)	9 (5,7)	0,1
FR positivity, n (%)	95 (85,6)	140 (88,6)	0,4
ACPA positivity, n (%)	96 (90,6)	131 (89,7)	1
Previous therapy with combination of cs-DMARDs	**55 (49,5)**	**103 (65,2)**	**0,01**
Previous therapy with b-DMARDs	**71 (64)**	**81 (51,3)**	**0,04**

*n: number; m: media; SD: standard deviation; *m:* median; IQR: interquartile range; ILD: interstitial lung disease; RF: rheumatoid factor; ACPA: anti-citrullinated protein antibodies; csDMARDS: conventional disease-modifying antirheumatic drugs; b-DMARDs: biologic disease-modifying antirheumatic drugs

Predictors factors of initiation of treatment with tofacitinib monotherapy



Cumulative survival analysis between tofacitinib monotherapy vs. combination therapy

others (16.7%), and gastrointestinal (9.5%). When evaluating the incidence rate (IR) of AEs, no significant differences were found between tofacitinib monotherapy and combination therapy: 47.2 events (100 p/y) (95% CI 38.6-57.5) vs. 38.05 events (100 p/y) (95%CI 31.6-45.7), respectively (p=NS).

Conclusion: In this real-life study, the use of tofacitinib monotherapy was almost 40%, being associated with less prior treatment with csDMARDs and prior use of biologic therapy. Tofacitinib monotherapy demonstrated similar drug survival and safety compared to the use in combination with csDMARDs, and may be a valid option for patients with RA in daily clinical practice.

DMARD Initiation in Older Adults with New Diagnosis of Late-Onset Rheumatoid Arthritis

Jiha Lee[1], Jonathan Martindale[1], Una Makris[2], Namrata Singh[3], Raymond Yung[4] and Julie Bynum[1], [1]University of Michigan, Ann Arbor, MI, [2]UT Southwestern Medical Center and Dallas VA, Dallas, TX, [3]University of Washington, Bellevue, WA, [4]Michigan Medicine, Ann Arbor, MI

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The number of older adults living with rheumatoid arthritis (RA) is growing as the world population is aging. Up to one-third of the older RA population are diagnosed after the age of 65 and have late-onset RA (LORA) which is characterized by more symptomatic and progressive disease. Older adults with RA are less likely to receive optimal treatment despite disease modifying anti-rheumatic drug (DMARD) being effective and generally well tolerated in older adults. In addition, they are prone to the negative effects of glucocorticoids (GCs) which are symptom relieving but not disease modifying. We evaluated the prevalence of and factors associated with disease modifying anti-rheumatic drug (DMARD) initiation and glucocorticoid (GC) use in older adults with new diagnosis of LORA.

Methods: In this retrospective observational study, we identified adults ≥66 years of age with new diagnosis of LORA using 20% Medicare data from 2008-2017. Information on baseline patient characteristics and DMARD initiation during the first 12 months after LORA diagnosis were collected. Concomitant long-term (>90 days) GC use and GC monotherapy (GC use >180 days without any DMARD) was also evaluated. We performed multivariable logistic regression for factors associated with DMARD initiation.

Results: We identified 33,373 older adults with new diagnosis of LORA in continuous fee-for-service Medicare. Average age at LORA diagnosis was 76.7 (SD 7.6), 75.4% were female, 76.9% were non-Hispanic white, and 35.6% had low-income subsidy. Less than one third (28.9%) were initiated on some form of DMARD during the first 12 months after LORA diagnosis. The proportion of older adults initiated on DMARDs was stable between 2009-2015 and ranged between 26.7-30.8%

(Figure 1). Among those on any DMARD treatment (N=9640), 90.1% were initiated csDMARD only, 2.6% on bDMARD only, and 6.8% on both classes of DMARDs. Concomitant long-term GC use was observed in 44.3% of older adults on DMARDs. Among those without DMARD use (N=23,733), 10.8% were on GC monotherapy alone. In multivariable analyses, DMARD initiation was associated with younger age, fewer comorbidities, absence of low-income subsidy status, adjusting for patient sex and race/ethnicity (Table 2).

Table 1: Characteristics of Medicare beneficiaries with new diagnosis of LORA

	No DMARD initiation N=23733	Any DMARD initiation M=9640	p-value
Age at diagnosis, mean (SD)	77.6 (7.9)	14.4 (6.3)	<0.0001

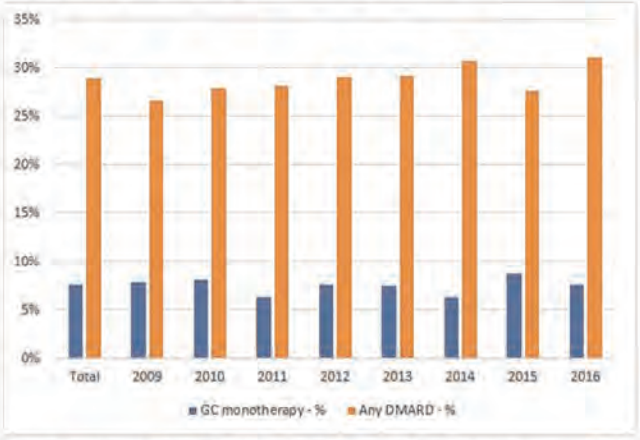
≥6	0.43 (0.39, 0.46)†	0.54 (0.5, 0.59)†

†statistically significant (adjusted model) with p<0.05

Figure 1: Proportion of older adults with DMARD initiation or glucocorticoid monotherapy (without any DMARDs) after new diagnosis of LORA



DMARD=disease modifying anti-rheumatic drugs, GC=glucocorticoids, GC monotherapy=GC use only for >180 days without any DMARD use

Conclusion: DMARD use in older adults with new diagnosis of LORA is low despite current clinical practice guidelines recommending early aggressive initiation of treatment. Concomitant long-term GC use and GC monotherapy use among those on any DMARDs is common, raising concern for suboptimal DMARD use. Further studies are needed to understand drivers of DMARD use in older adults.

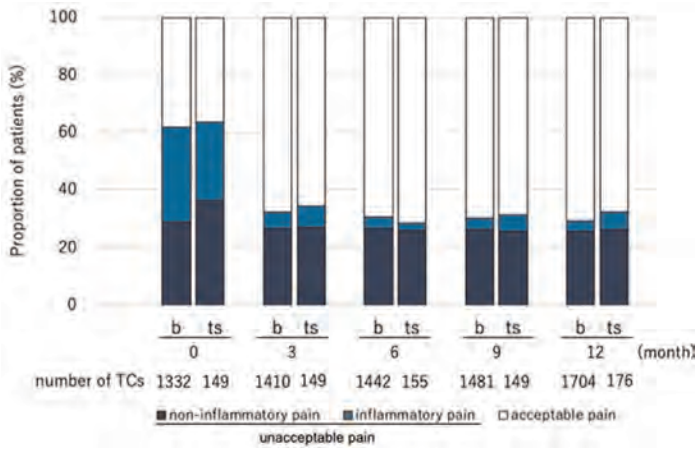
SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Non-inflammatory pain (NIP) is one of the remaining issues in rheumatoid arthritis (RA), and some previous studies suggest that 10-20% of patients with RA remain with NIP even after treatment with biological disease modifying anti rheumatic drugs (bDMARDs). Targeted synthetic DMARDs (tsDMARDs) is reported to improve patient-reported-outcomes including pain, but its effect on NIP is unclear. The aim of this study is to investigate whether tsDMARDs can relieve NIP compared to bDMARDs in RA patients in a longitudinal multicenter cohort study.

Methods: RA patients treated with b/tsDMARDs between 2000 to 2022 and continued the same drug for more than 12 months were included in this study. Unacceptable pain (UP) was defined as patient-visual analog scale (VAS) > 40 mm and was classified to two categories; NIP and inflammatory-pain (IP). NIP was defined as UP with C-reactive protein level < 10 mg/liter. We also assigned a strict definition for NIP (sNIP) as NIP with swollen joint count ≦1. IP was defined as UP without fulfilling the NIP definition. We examined the association between the choice of b/tsDMARDs and the persistence of NIP at month (Mo) 12 using logistic regression model. The frequency of NIP, IP and UP at Mo 0, 3, 6, 9 and 12 were also assessed. Confounding factors (age, sex, disease duration, number of previous b/tsDMARDs, smoking status, stage, class, titer of rheumatoid factor and anti-citrullinated protein/peptide antibodies, dose of methotrexate and prednisolone, the use of painkillers and disease activity at baseline) were adjusted



Time-dependent changes in pain of patients treated with b/tsDMARDs

with inverse probability of treatment weighting estimated by generalized propensity score. Missing data were dealt with multiple imputation to calculate generalized propensity score.

Results: Of 1880 treatment courses (TCs), 1704 TCs were treated with bDMARDs and 176 TCs were treated with tsDMARDs. The rate of UP at baseline was 61.8% in bDMARDs and 63.8% in tsDMARDs. These rates decreased significantly to 32.2% in bDMARDs ($p < 0.001$) and 34.2% in tsDMARDs ($p < 0.001$) at Mo 3, respectively, which remained stable at Mo 12. The rates of IP in both bDMARDs and tsDMARDs also significantly declined at Mo 3, and then remained stable at Mo 12. On the other hand, NIP was present in 28.8% of TCs in bDMARDs and 36.2% of TCs in tsDMARDs at baseline, which remained in 25.6% and 26.1% at Mo 12, respectively (figure). Analysis with sNIP did not change the trend. The proportion of NIP in UP was 46.6% in bDMARDs and 56.8% in tsDMARDs at baseline, which increased to 87.5% and 80.7% at Mo 12. There was no statistically significant difference in frequency of NIP at Mo 12 among b/tsDMARDs in both definitions [NIP: adjusted odds ratio (OR) = 0.79 (95% confidence interval (CI) : 0.53-1.18, p = 0.25), sNIP: adjusted OR = 0.73 (95%CI : 0.46-1.14, p = 0.16)].

Conclusion: In RA patients who were able to continue b/tsDMARDs for 12 months, the effects of tsDMARDs against NIP was comparable to that of bDMARDs. The frequency of RA patients with NIP treated with b/tsDMARDs for 12 months remained 25%, while that of IP were decreased.

Session Title: RA – Treatments Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The ORAL Surveillance study highlighted risks of cardiac events, thromboembolism (VTE), and cancer associated with Janus kinase inhibitors (JAKi). The aim of this study was to understand the effect that these data have had on practice patterns by describing the characteristics of patients initiating advanced therapies for RA including tofacitinib (TOFA), TNF inhibitors (TNFi), and non-TNFi agents before and after the release of safety data in January 2021 and to evaluate characteristics associated with discontinuation among active users at the time that the data was released.

Table 1. Characteristics of Tofacitinib Initiators Before and After January 2021 Oral Surveillance Press Release

Liver disorder (%)	22.8	20.4	0.07

*Categorized using Healthcare Cost and Utilization Project Clinical Classification Software

Methods: This was a national, retrospective study of US Veterans with RA receiving advanced therapies between April 2019 through September 2022. This period was divided into two 664-day periods, one before and one after the January 2021 press release. Eligible patients had ≥1 diagnosis code for RA and initiated a TNFi, non-TNFi, or TOFA. Patient characteristics were defined for each therapy initiation including a comorbidity index (RDCI), and individual comorbidities were categorized using Healthcare Cost and Utilization Project Clinical Classification Software. We tested for interaction within regression models to determine whether changes observed in characteristics (standardized differences) for TOFA users were different from changes observed for the other therapies. We also determined the time to discontinuation for active users at the time of the press release, censoring for death and end of follow-up. We used Cox models adjusted for age, sex, and duration on therapy to evaluate for associations between patient characteristics and therapy discontinuation, testing for interactions with TOFA vs. TNFi.

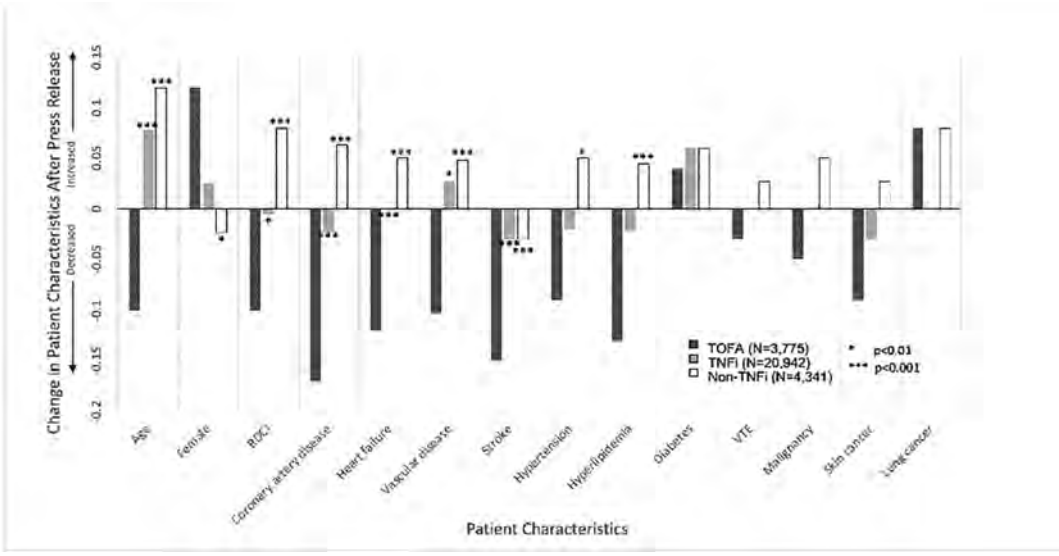

Figure 1. Change in patient characteristics (per 1 SD) by therapy after the January 2021 Oral Surveillance press release. Statistical testing comparing TNFi and non-TNFi therapies to tofacitnib (based on the significance of interaction terms within regression models) are illustrated with asterisks.

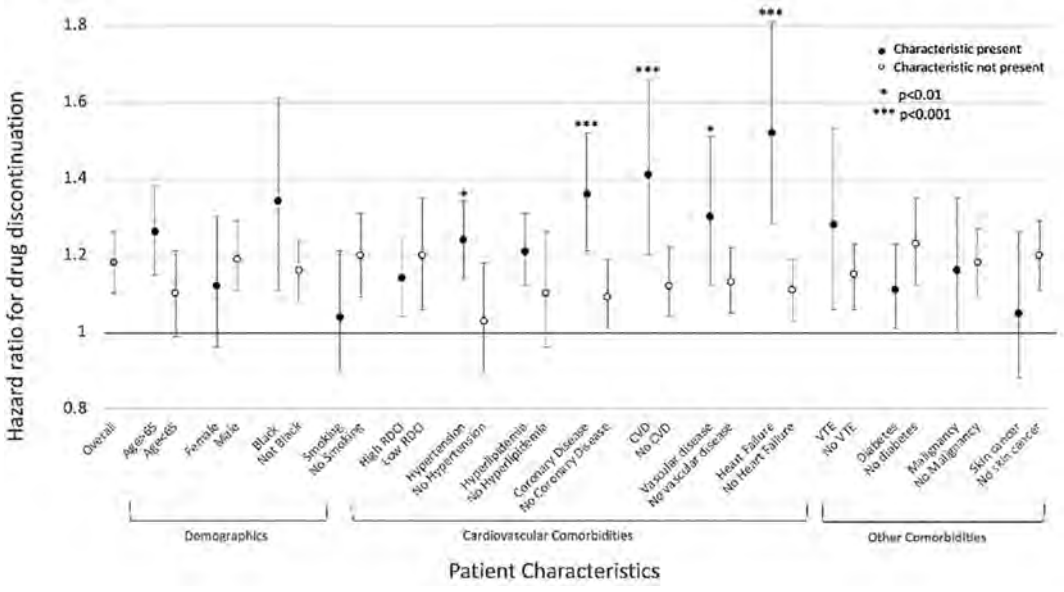

Figure 2. Hazard ratio of discontinuation for tofacitinib compared to TNFi following the ORAL Surveillance press release, stratified by patient characteristic. P-values for multiplicative interactions between tofacitinib and TNFi are illustrated with asterisks. Infliximab and rituximab were excluded because of the length of their dosing cycles.

Results: When comparing patients initiating TOFA before (N=2111) and after (N=1664) January 2021, there were decreases in mean age (64.1 vs 63.0), the proportion of men (20.8% vs 25.9%), mean RDCI score (4.6 vs 4.4), and the proportion with cardiovascular comorbidities and skin cancer (**Table 1**) (all p< 0.01). These changes were significantly different from those observed for patients initiating TNFi or non-TNFi biologic drugs (p for interaction with therapy < 0.05) (**Figure 1**). In contrast, changes in VTE, smoking, and malignancies, including skin cancer, were not significantly different between TOFA initiators and initiators of other therapies. Among active users, the likelihood of discontinuation was higher among TOFA (N=2295, HR: 1.18 [1.10, 1.26], p< 0.001) compared to TNFi (N=12,042). The higher rate of TOFA discontinuation was more pronounced in the presence of cardiovascular comorbidities (**Figure 2**).

Conclusion: Shifts toward younger age, female sex, lower comorbidity, and lower rates of cardiovascular diseases were observed in patients initiating TOFA after the release of safety data. There was a lower proportion of VTE and malignancy as well, which did not reach significance. TOFA users, particularly those with cardiovascular comorbidities, were more likely than TNFi users to discontinue ongoing therapy following the release. These data suggest the ORAL Surveillance trial affected prescribing practices, with particular attention to those at high cardiovascular risk.

Patients with Difficult-to-treat Rheumatoid Arthritis Have Higher Levels of Inflammation on Ultrasound

Ummugulsum Gazel[1], Seyyid Bilal Acikgoz[2], Catherine Ivory[3], Amin Zahrai[3], Ozun Bayindir Tsechelidis[4], Ricardo Sabido-Sauri[1], Elliot Hepworth[1] and sibel aydin[5], [1]University of Ottawa, Ottawa, ON, Canada, [2]University of Ottawa, Rheumatology, Ottawa, ON, Canada, [3]The Ottawa Hospital Research Institute, Ottawa, ON, Canada, [4]Ottawa University, Ottawa, ON, Canada, [5]University of Ottawa - Ottawa, Ottawa, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: With increasing numbers of advanced therapies, rheumatologists frequently see Rheumatoid Arthritis (RA) patients who have failed ≥2 advanced therapies with different mechanisms of action. The management of difficult-to-treat (D2T)-RA patients is challenging, and there is an unmet need to understand the factors leading to D2T-RA. In this analysis, we aimed to compare the disease characteristics and activity of our D2T-RA patients with other RA patients who are starting a new advanced therapies for having active RA.

Methods: Within the ORCHESTRA Clinic (Ottawa Rheumatology CompreHEnSive TReartment and Assessment) at the Ottawa Hospital, all patients with inflammatory arthritis that are planning to initiate a new advanced therapy are assessed in a standardized fashion. Extensive data regarding disease history, medication exposure and disease activity measures are collected; the comorbidity burden is documented and managed. A protocoled ultrasound (US) of 36 joints is conducted at baseline and three-month intervals, until reaching clinical remission. All joints are scored using the Global OMERACT-EULAR Synovitis Score (GLOESS). For this analysis, the D2T-RA definitions were based on the EULAR definition and

patients falling into this category had failed ≥2 biologics therapies[1]. Here we present the results from a pilot exploratory comparative analysis to identify the differences between the D2T-RA patients with the rest of the cohort.

Results: Among 64 RA patients included the study, 18 (28.1%) fulfilled the definition of D2T-RA. Demographic characteristics were similar between two groups, except female sex being slightly higher in D2T-RA patients and having longer disease duration (table). Seropositivity was similar across groups. DT2-RA patients had statistically significant more deformity in their joints than the rest of the group with higher HAQ scores and numerically more erosive disease. There were no differences between groups in terms of comorbidities, except urate levels being but significantly higher in D2T-RA patients (median (IQR): 319 umol/L (98) vs 256 umol/L (103); p=0.05). Regarding disease activity, D2T patients have numerically higher tender joint counts and CDAI scores. The GLOESS scores of D2T-RA patients on US were significantly higher with a trend to have higher Doppler scores (table).

Conclusion: In our D2T RA population, higher disease activity on US suggests an uncontrolled inflammatory process, which may or may not be complicated by centralized pain mechanisms. A greater portion of D2T patients were females, highlighting the importance of incorporating sex into research and understanding the factors leading to poor response in this group.

Table. Comparison of D2T RA patients with others

		D2T: No (N:46)	D2T: Yes (N:18)	p
Disease Features	**RF positive#**	34 (75.6%)	14 (77.8%)	1.000

GLOESS: Global OMERACT-EULAR Synovitis Score

Higher urate levels in D2T-RA may be due to increased disease duration, however, it would be noteworthy to look at the impact of urate crystals joint deposition in resistance to therapies. In addition,to date, fibromyalgia status is self-reported by our participants likely resulting in under-reporting. As this is a significant predictor of D2TRA, we will begin completing the Widespread Pain Index/Symptom Severity Scale in our cohort patients to better understand the predictors of D2TRA in our setting.

Abbreviations: IQR: Interquartile range; NSAID: Non-steroid anti-inflammatory drug; TNF: Tumor necrosis factor

Background/Purpose: Concern has arisen over the safety of Janus kinase inhibitors (JAKi) regarding cardiovascular (CV) outcomes in patients with rheumatoid arthritis (RA) with CV risk factors based on results of the ORAL surveillance trial (1). We compared the risk of major adverse cardiovascular events (MACE) between tumor necrosis factor inhibitors (TNFi), non-TNFi, and JAKi among patients with RA.

Methods: We performed a cohort study using Merative MarketScan databases (2012-2021) of RA patients (including those with pre-existing CV risk factors) identified using ≥1 ICD-9/10 codes, age 18-64 years, who initiated treatment with TNFi, non-TNFi, or JAKi. We used Cox proportional hazards models to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for developing MACE (a composite of myocardial infarction, cardiac arrest, sudden death, stroke, percutaneous coronary intervention, coronary artery bypass graft, identified using ICD-9/10 codes and CPT codes) within 2 years of treatment initiation, adjusting for multiple confounders, including age, sex, region, comorbidity index, frailty (2), healthcare utilization, and surrogates for RA severity. Patients could contribute person-years to multiple drug exposures only if drug escalation mimicked typical clinical practice and were censored if they did not fill a prescription of these drugs for >90 days (>180 days for rituximab due to its longer washout period) or their enrollment ended.

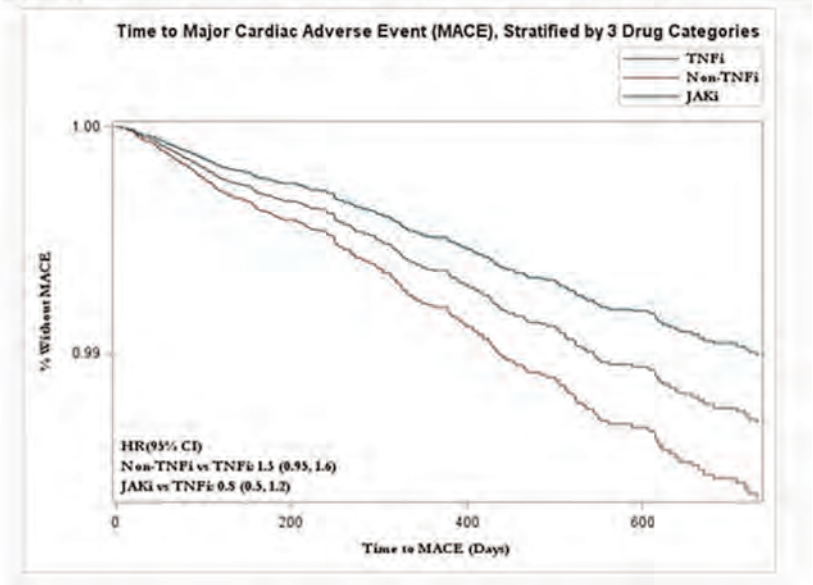
Results: A total of 40,207 patients met eligibility criteria for our study (71% initiated on TNFi, 19% non-TNFi, and 10% JAKi). Most patients were female (78-80%) with the mean age ranging from 47-49 years (Table 1). The median follow-up time was 230 days for TNFi, 190 days for non-TNFi, and 180 days for JAKi. The number of MACE per drug class was highest in non-

Table 2. Number and incidence rate of MACE outcomes within 2 years of initiating biologic drug per 10,000 person-years at risk, stratified by DMARD category

	Raw n of MACE	Incidence rate of MACE /10,000 person-years (95% confidence interval)	Median (IQR) days to MACE (among those with MACE)
TNFi	202 (0.7%)	78 (68, 90)	207 (85, 378)
Non-TNFi	87 (1.0%)	150 (121, 185)	102 (48, 252)
JAKi	20 (0.5%)	66 (40, 102)	180 (94, 271)

Abbreviations: DMARD: disease-modifying antirheumatic drug; JAKi: Janus kinase inhibitors; MACE: Major adverse cardiovascular events; TNFi: tumor necrosis factor inhibitors

Figure 1. Kaplan-Meier curves showing adjusted HR* for incident MACE per different drug class exposures



*Models adjusted for age, sex, Charlson Comorbidity Index, frailty status, healthcare utilization within 12 months prior to starting treatment, days from RA diagnosis to initiating biologic, and disease-modifying antirheumatic drug, nonsteroidal anti-inflammatory drug and opioid fills in 12 months prior to starting treatment and glucocorticoid use 3 months prior to starting treatment)

TNFi exposures (Table 2). In multivariable models, patients taking non-TNFi had an HR (95% CI) 1.3 (0.95, 1.6) compared to those taking TNFi (Figure 1). Patients on JAKi had a similar risk of developing MACE (HR 0.8; 95% CI 0.5, 1.2) compared to those on TNFi, although this was statistically non-significant.

Conclusion: In this large nationwide study, although users of non-TNFi had increased risk of MACE, we did not detect any statistically significant difference overall. However, our study has limitations of residual confounding (e.g., inadequate accounting for RA severity using claims data, the fact that most RA patients initiate treatment with TNFi's before proceeding to non-TNFi's or JAKi's in clinical practice, and the small number of MACE outcomes in the study population). Additional studies with longer follow-up are needed for better assessment of MACE risk to guide clinical care.

Association Between Methotrexate Use and Lymphoma in Rheumatoid Arthritis: A Systematic Literature Review

Swetha Ann Alexander[1], Gordon Starkebaum[2], Diana Louden[2], Grant Hughes[2] and Namrata Singh[3], [1]University of Utah Health, Salt Lake City, UT, [2]University of Washington, Seattle, WA, [3]University of Washington, Bellevue, WA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) patients have an increased risk of developing lymphoma compared to the general population. This increased risk is believed to be linked to higher disease activity. Methotrexate (MTX), a commonly used treatment for RA, has the potential to reduce the risk of lymphoma by lowering disease activity. However, existing research on the association between MTX use in RA and lymphoma development presents conflicting results. This study aimed to conduct a systematic literature review to evaluate this association.

Methods: A comprehensive search was performed in PubMed, Embase, and Cochrane Central Register of Controlled Trials on December 9, 2021. The search included observational studies and randomized controlled trials (RCTs) published in English, focusing on the relationship between MTX use in RA and lymphoma development. Case series and reports were

CI- Confidence Interval; OR- Odds Ratio; RR- Relative Risk; MTX- Methotrexate; HR- Hazard Ratio; DMARD- Disease Modifying Antirheumatic Drug; TNFI- Tumor Necrosis Factor Inhibitor; RA- Rheumatoid arthritis

excluded. Data were extracted from the selected articles by two independent authors using a predefined form, with conflicts resolved by a third reviewer. Quality assessments were conducted.

Results: The search process identified 839 articles, out of which only eight met the eligibility criteria (Figure 1). Table 1 summarizes the characteristics of these studies, which predominantly consisted of observational studies, with one RCT included. The sample sizes ranged from 160 to 20,000 RA patients. Five studies reported odds/hazard ratios for lymphoma occurrence in MTX-exposed versus non-exposed patients. Three studies (one of which was an RCT) compared the risk of lymphoma development in RA patients treated with MTX versus other biological DMARDs. Most studies adjusted for various factors, including age, sex, RA disease activity measures, inflammatory markers, concomitant RA medications, cancer risk factors, and RA-related variables. Six of the eight studies found no significant association between MTX use and lymphoma, while two studies from Japan reported a significant positive association. The included studies were of moderate to high quality, but heterogeneity prevented a meta-analysis.

Conclusion: While conflicting data exist regarding the role of MTX in lymphoma development in RA, the majority of high-quality epidemiological studies reviewed did not support an association between MTX use and lymphoma development. Only two studies, both from Japan, indicated a significant association between MTX use and lymphoma development.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: To prevent infections, EULAR recommends to vaccinate RA patients against streptococcal pneumoniae. PCV13 is a T- cell dependent vaccine whereas PPSV23 induces a T-independent humoral response. Abatacept is a biological DMARD that inhibits T cell activation. We hypothesized that the humoral response after PCV13 vaccination may be more affected under abatacept than after PPSV23. To answer this question, we compared the humoral response 1, 6 and 12 months after vaccination with PCV13/PPSV23 or PPSV23 in RA patients starting abatacept

Methods: We conducted a prospective, multicentre, randomized, open-label study in patients with RA according to ACR/EULAR 2010 criteria, active (DAS28 >3,2) under MTX or leflunomide and proposed to start abatacept. Patients were randomized in 2 groups: the first group (G1) was vaccinated with the PPSV23 and the second group (G2) with PCV13 and PPSV23 8 weeks later. Abatacept was initiated at the same time as vaccination. Patients previously treated with rituximab within the last year were excluded. To measure humoral response, serum was collected 4 weeks after the first vaccine and at 6 and 12 months. A patient was considered as responder if there was a two-fold increase of the antibodies titer for at least 3 of 5 serotypes of interest (1, 3, 14, 7F, 19A) which are the most frequently involved in pneumococcal infections. For the primary endpoint, we compared the rate of responders at one month in G1 and G2 using a Chi-Square test (alpha risk 5% and 80% power). For the secondary end points, we compared humoral response at 6 and 12 months between G1 and G2. A logistic regression was used to identify factors associated with the humoral response at 1, 6 and 12 months. Tolerance of the vaccines (injection site reaction and general reaction) was recorded within the first week and later in a patient booklet. Serious adverse events (SAEs) and related to study participation or study vaccine, were recorded at 1, 6 and 12 months.

Results: Eighty patients were included and randomized in the two groups: 40 in G1 and 39 in G2 because of consent withdrawal for one patient. Characteristics of patients are described in **table 1**. Female were more represented in G1 (82.5%) compared to G2 (64.1%). Lymphocyte count was significantly higher in G1 compared to G2: 1841/mm3 (+/-887) vs

Table 1 : Characteristics of patients at inclusion

Variable	Modality	All population N=79	Group1 PPSV23 N=40	Group 2 PCV 13/PPSV23 N=39

Leflunomide	Yes/ (%)	8 (10.13)	4 (10.00)	4 (10.26)
Steroids	Yes/ (%)	33 (41.77)	16 (40.00)	17 (43.59)
Steroid dose (mg/d)	Mean (±SD)	7.77 (± 2.42)	7.50 (± 2.58)	8.03 (± 2.30)

Table 2: Humoral response after PPSV23 and PCV13/PPSV23 vaccinations, at 1, 6 and 12 months after first dose of vaccine (secondary endpoints). mITT=modified intention to treat; PP= per protocol

Primary Endpoint	Total	PPSV23	PCV13	Chi² test p-value	RR [95% CI]
ITTm: Responders at 1 month (n (% col))	34/79 (43.04)	19/40 (47.50)	15/39 (38.46)	0.42	1.24 [0.74 ; 2.06]
PP: Responders at 1 month (n (% col))	26/64 (40.63)	13/32 (40.63)	13/32 (40.63)	1.00	1.00 [0.55 ; 1.81]

Secondary Endpoints	Total	PPSV23	PCV13/PPSV23	Chi2 test p-value	RR [95% CI]
ITTm: Responders at 6 months (n(% col))	35/79 (44.30)	17/40 (42.50)	18/39 (46.15)	0.74	0.92 [0.56 ; 1.51]
ITTm: Responders at 12 months (n(% col))	25/79 (31.65)	16/40 (40.00)	9/39 (23.08)	0.11	1.73 [0.87 ; 3.45]
PP: Responders at 6 months (n(% col))	27/64 (42.19)	12/32 (37.50)	15/32 (46.88)	0.45	0.80 [0.45 ; 1.43]
PP: Responders at 12 months (n(% col))	20/64 (31.25)	12/32 (37.50)	8/32 (25.00)	0.28	1.50 [0.71 ; 3.17]

1603/mm3 (+/-580). In the mITT, the rate of responders was 47.5% in in G1 and 38.46% in G2 with a RR of 1.23 (IC95%: 0.73-2,06) when comparing responders in PPSV23 vs PCV13 groups (**table 2**). At 6 and 12 months, there was no difference between G1 and G2 in mITT and PP analysis. Logistic regression did not identify factors associated with humoral response at 1 and 6 months. At 12 months, gender (being a male vs female) and PPSV23 vs PCV13/PPSV23 were associated with a better response: OR 3,7 [IC95% 1.2-12] and 3,1 [IC95% 1-9.4] respectively ($p< 0.05$) . 17 infections were reported in G1 and 28 in G2 with 3 severe infections but no pneumococcal infection.

Conclusion: In RA patients treated with abatacept combined with csDMARDs (MTX or LEF), the rate of responders is similar at 1-, 6- and 12-months following vaccination with PCV13 or PPSV23.Abatacept does not seem to impact humoral response of PCV13 in the first 6 months following vaccination.

Baseline T Cell and B Cell-related Markers and HLA-DRB1 Shared Epitope Alleles Predict the Therapeutic Efficacy of Abatacept in Patients with Moderate to Severe Rheumatoid Arthritis

Ting Wang[1], Natalia V. Giltiay[2], Christian Lood[2] and Bobby Kwanghoon Han[2], [1]University of Washington, Seattle, WA, [2]Division of Rheumatology, University of Washington, Seattle, WA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Abatacept, a CTLA-4-Ig fusion protein, is widely used as a treatment for rheumatoid arthritis (RA). However, data on predictive biomarkers associated with therapeutic response to abatacept is still limited. We conducted this study to identify novel biomarkers to predict the therapeutic efficacy of abatacept in patients with moderate to severe RA.

Methods: A total of 23 RA patients, who had an inadequate response to methotrexate and other conventional DMARDs, were enrolled in this study. Responders (n=10) to abatacept were defined as subjects who achieved ACR50 response at week 24. At baseline, week 6, week 14, and week 24, serum levels of soluble CD25, CD27, CD40L, CD80, CXCL10, CXCL13, IL-21, and PD-1 were measured with ProcartaPlex by Luminex, while serum levels of soluble CD83, CD163, and rheumatoid factor (RF) IgM were determined by ELISA. Peripheral blood mononuclear cells (PBMCs) were isolated and analyzed for changes in different T cell and B cell subsets by flow cytometry at baseline, week 14, and week 24. Patients were

also genotyped for human leukocyte antigen (HLA)-DRB1 shared epitope (SE) alleles and classified as SE2 (≥ 2 SE allele, n=8), SE1 (≥ 1 SE allele, n=19) and SE0 (no SE alleles, n=4).

Results: Levels of sCD25, sCD27, sCD83, CXCL13, sPD-1 and RF IgM were significantly decreased at week 14 and week 24 with the treatment of abatacept when compared to baseline, while IL-21 levels were only decreased at week 14 (Table 1). Subjects treated with abatacept had a significant decline in the frequencies of circulating CD4+CXCR5+PD-1hi follicular helper T (Tfh) cells (p=0.0008 and p=0.0001 respectively) and CD4+CXCR5-PD-1hi peripheral helper T (Tph) cells (p=0.0004 and p< 0.0001 respectively) at week 14 and week 24. There was also a significant reduction in other T cell subsets, including CD4+CD25+CD127- regulatory T (Treg) cells, CD4+CD45RA-CCR7+ central memory T cells, and CD4+-CD45RA-CCR7- effector memory T cells. Abatacept also reduced the frequencies of circulating CD19+IgD-CD27+ class-switched memory (SM) B cells (p=0.0239 and p=0.0237, respectively), CD19+CD27hiCD38hi plasmablasts/plasma (PL) B cells (p=0.0249 and p=0.0108, respectively) and CD19+CD11c+ B cells (p< 0.0001 and p=0.012, respectively) at

Table 1. Levels of serum soluble markers before and after treatment with abatacept. Data are displayed as median (interquartile range). Differences between baseline and post-treatment (week 6, week 14, and week 24) were determined by the Wilcoxon matched-pairs signed rank test. ****p<0.0001, ***p<0.001, **p<0.01 and *p<0.05.

	Baseline	Week 6	Week 14	Week 24

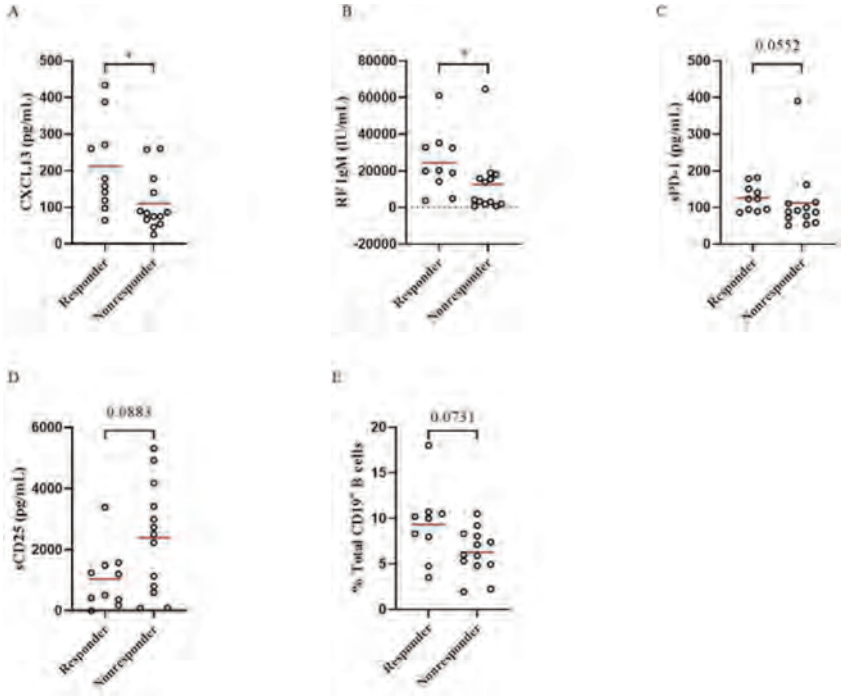

Figure 1. Comparisons in T cell and B cell-related markers between responders and nonresponders. Comparisons of serum levels of CXCL13 (A), RF IgM (B), sPD-1(C), sCD25 (D), and percentages of CD19+CD11c+ B cells (E) in circulation at baseline in patients treated with abatacept. Differences between groups were determined by the Mann-Whitney test. *p<0.05.

week 14 and week 24. Compared to non-responders, baseline levels of CXCL13 (p=0.0178), RF IgM (p=0.0147), sPD-1 (p=0.0552), and the percentages of CD19+CD11c+ B cells (p=0.0731) were higher in the responders, while levels of sCD25 (p=0.0883) tended to be lower in the responders (Figure 1). Responders had a significantly higher percentage of patients with SE2 than non-responders (60% vs 15.38%, p=0.0393). Baseline serum CXCL13 levels were correlated with circulating Tph (r=0.5425, p=0.0075), Treg cells (r=0.4665, p=0.0248), CD19+CD11c+ B cells (r=0.4609, p=0.0309) and RF IgM levels (r=0.6108, p=0.0012).

Conclusion: These findings suggest that baseline CXCL13, RF IgM, sPD-1, CD19+CD11c+ B cell percentages, and HLA-DRB1 shared epitope alleles may be useful markers in predicting response to abatacept in moderate to severe RA patients.

Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Ongoing debate exists regarding the optimal sequence of tumor necrosis factor inhibitors and Janus kinase inhibitors (JAKis) in patients with rheumatoid arthritis (RA) as first-line biologic or targeted synthetic disease-modifying antirheumatic drug (b/tsDMARD) therapy following conventional therapies.The aim of this study was to describe

	ETN	ADA	JAKis
Age, years	54.4 (12.8)	55.5 (12.1)	60.9 (12.5)
Female, n (%)	666 (77)	843 (76)	303 (77)
BMI, kg/m^2	30.4 (7.6)	31.3 (7.9)	30.8 (7.6)
Duration of RA, years	5.9 (7.6)	5.8 (7.3)	8.6 (10.0)
BL disease activity[a]			
CDAI	19.9 (14.3)	18.9 (12.7)	18.8 (13.2)
mHAQ	0.5 (0.5)	0.5 (0.5)	0.5 (0.5)
Patient pain[b]	48.0 (28.8)	49.2 (28.5)	45.2 (29.2)
Disease activity decrease from BL at 6M			
CDAI	6.9 (13.6)	6.4 (12.1)	4.7 (12.3)
mHAQ	0.1 (0.4)	0.1 (0.4)	0.1 (0.4)
Patient pain[b]	9.7 (30.2)	10.6 (28.4)	8.9 (29.5)
Disease activity decrease from BL at 12M			
CDAI	7.4 (13.5)	6.1 (13.0)	5.1 (13.0)

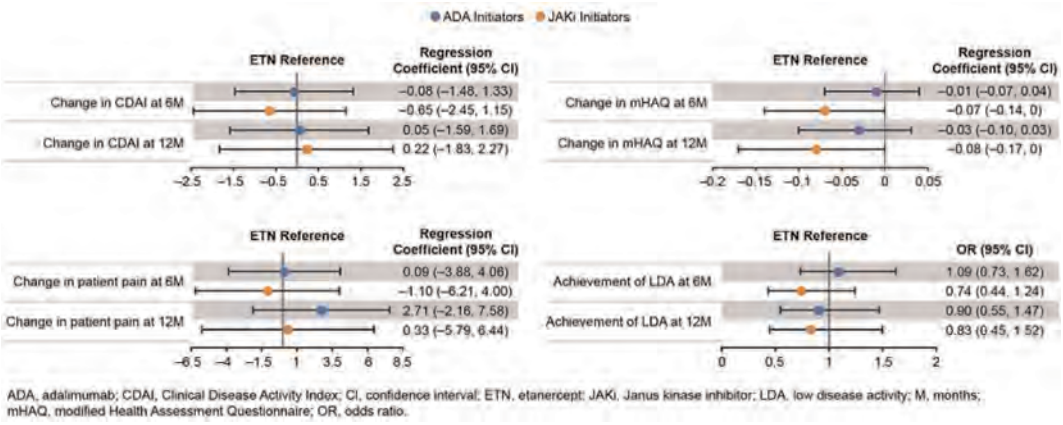
Patient pain[b]	8.8 (29.7)	8.7 (30.1)	7.5 (28.6)
Achievement of LDA[c], %			
6M	43.4	41.9	32.5
12M	41.0	39.6	38.3

[a]Baseline for combined population with 6M and 12M follow-up. [b](range: 0–100). [c]CDAI ≤10 among those with moderate or high disease activity at baseline.
Data are mean (SD) unless otherwise specified.
ADA, adalimumab; BL, baseline; CDAI, Clinical Disease Activity Index; ETN, etanercept; JAKis, Janus kinase inhibitors; LDA, low disease activity; M, months; mHAQ, modified Health Assessment Questionnaire; RA, rheumatoid arthritis; SD, standard deviation.

Patient Description at Time of Initiation and Unadjusted Disease Activity Results



ADA, adalimumab; CDAI, Clinical Disease Activity Index; CI, confidence interval; ETN, etanercept; JAKi, Janus kinase inhibitor; LDA, low disease activity; M, months; mHAQ, modified Health Assessment Questionnaire; OR, odds ratio.

Adjusted Mean Differences in Change in Effectiveness and Patient-Reported Outcomes Relative to Etanercept Initiators

baseline characteristics, effectiveness, persistency, and treatment patterns among first-line b/tsDMARD-naive initiators of etanercept (ETN), adalimumab (ADA), or JAKis (tofacitinib, baricitinib, and upadacitinib).

Methods: Data on patients who initiated b/tsDMARD from 11/2012 to 6/2021 were obtained from the CorEvitas RA Registry, a prospective, multicenter, observational, disease-based registry. Patients ≥18 years with rheumatologist-diagnosed RA and 6- and/or 12-months' (M) follow-up were included. We report descriptive statistics at baseline, persistency on therapy, escalation/de-escalation of therapy, details on patterns of drug switching, and effectiveness outcomes using regression models adjusted for baseline covariates (demographic/socioeconomic/lifestyle characteristics, comorbidities, medication history, disease activity, and patient-reported outcomes). Outcomes were evaluated at 6M and 12M follow-up.

Results: First-line initiators of ETN, ADA, and JAKis with baseline and follow-up visits were identified: 803, 984, and 361 patients at 6M, respectively; 589, 749, and 264 patients at 12M, respectively. Baseline characteristics were similar among ETN, ADA, and JAKi initiators with the exception of disease duration, which was longer among first-line JAKi initiators (mean, 8.6 y) versus ETN (5.9 y) and ADA (5.8 y) initiators. Unadjusted mean improvement in Clinical Disease Activity Index (CDAI) was generally similar between groups at 6M and 12M (**Table**). Adjusted effectiveness results were similar at 6M and 12M (**Figure**). At 6M, 68% of ETN, 69% of ADA, and 67% of JAKi initiators remained on the same therapy; at 12M, 53% of ETN, 57% of ADA, and 57% of JAKi initiators remained on the same therapy. The frequency of switching to another b/tsDMARD was similar across initiators.

Conclusion: In this real-world study in patients initiating first-line b/tsDMARD therapy with ETN, ADA, or JAKis, we did not observe differences in clinical effectiveness/patient-reported outcomes and treatment persistency at 6M and 12M after treatment initiation.

Infliximab Clearance a Predictive Factor of Pharmacokinetic Origin in Relation to Suboptimal Pharmacokinetics and Immunogenicity in United States Based Rheumatology Practices

Elliot Rosenstein[1], Michael Weinblatt[2], Annelie Everts-van der Wind[3], John Conklin[3] and Thierry Dervieux[3], [1]Institute for Rheumatic & Autoimmune Diseases--Atlantic Health System, Far Hills, NJ, [2]Harvard Medical School, Waban, MA, [3]Prometheus Laboratories, San Diego, CA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Infliximab (IFX) has become a mainstay of treatment of many different immune-mediated inflammatory diseases. With the wide range of IFX dosing and dosing intervals, adjustments are often made on clinical parameters without consideration of IFX pharmacokinetics (PK). Measuring clearance (CL) of IFX may be useful for individual dosage adjustment as higher CL is associated with immunogenicity (antibodies to IFX [ATI]), suboptimal exposure (< 8 mg/L at trough) with resultant insufficient neutralization of inflammatory burden. There is paucity of data supporting the notion that optimal PK is achieved in US patients with rheumatic diseases treated with IFX.

Methods: We interrogated a database from a US based clinical PK laboratory offering IFX monitoring and extracted results from patients with rheumatoid arthritis (RA) or juvenile idiopathic arthritis (based on ICD-10 codes beginning with M05, M06 or M08) and having IFX dosing (range 3-10 mg/Kg) and interdose interval provided on test requisition (range 4-8 weeks). Concomitant use of methotrexate was not available. All patient results were de-identified prior to analysis. Serum IFX was measured using a drug tolerant homogenous mobility shift assay. Serum ATI positive status corresponded to titers > 3.1 U/mL. CL, the volume of serum removed each day (expressed as L/day) from drug, was calculated using nonlinear mixed effect models with Bayesian priors using IFX concentrations and ATI status. Minimal effective concentration commensurate with disease control achieved was set at 8 μg/mL, based on prior convention (1). Lower limit of quantification was 1 μg/mL. The impact of lower (< 0.3 L/day), intermediate (0.3-0.8 L/day) and higher clearance (>0.8 L/day) cutoffs on PK parameters was analyzed using Fisher Exact and logistic regression tests.

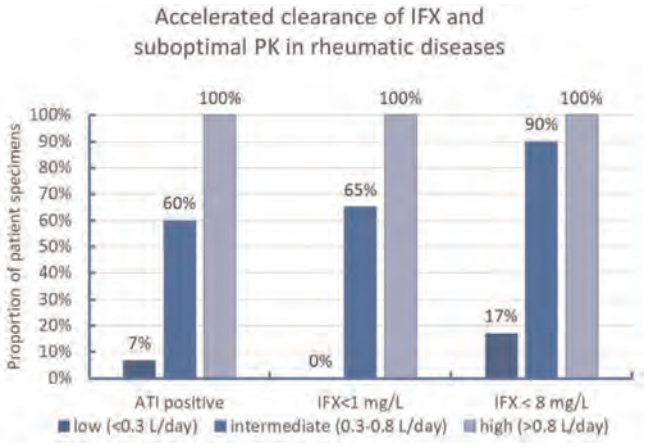

Figure 1

Results: We identified a total of 161 patient specimens ordered by 74 practices and submitted for testing (73% female, mean age =57 [Interquartile range, IQR: 37-69 years]). Median dose was 7.5 mg/Kg normalized to every 8 weeks (IQR: 5-13 mg/Kg every 8 weeks).Median IFX level was 14 μg/mL (IQR: 2.8-28.9 μg/mL), suboptimal exposure (< 8μg/mL) was observed in 36% patients, 22% presented with ATI, 18% had IFX concentration < 1μg/mL. Median CL was 0.231 L/day [IQR: 0.173-0.312 L/day]. Higher and intermediate CL were observed in 2% [3/161] and 25% ([40/161] patient specimens, respectively). Inadequate exposure was observed in most patient specimens having intermediate or high CL and there was little immunogenicity (7%) in the presence of lower CL. In the presence of intermediate or higher CL, there was 47.8 (95%CI: 15.2-150.1) and 23.2 (95%CI: 8.9-60.3) fold higher likelihood of having concentration below 8 mg/L and immunogenicity, respectively (p< 0.001).

Conclusion: This preliminary data suggests that IFX dosing may be suboptimal in a significant proportion of patients with RA and other inflammatory rheumatic diseases. Dose optimization (achieving IFX levels >8 mg/L at trough) might benefit patients who demonstrate inadequate disease control, particularly those who manifest accelerated CL, in part due to immunogenicity.

The Potential of an Oral TNFα Inhibitor with TNFR1 Specificity: Results of a Phase 1b Proof-of-mechanism Trial in Psoriasis

Anna Fishbein[1], Mai Anh Nguyen[2], Ohn Chow[3], Tiago Matos[4], Caroline Dreis[5], Hong Zhang[3], Marion Poirel[6], Johann Gassenhuber[5], Michael Dufault[3], Wagner Frank-Dietrich[7], Laurent Perrin[8], Markus Rehberg[5], Markus Kohlmann[5] and Nassr Nassr[5], [1]Sanofi, Bridgewater, NJ, [2]Sanofi, Berlin, Germany, [3]Sanofi, Cambridge, MA, [4]Sanofi, Amsterdam, Netherlands, [5]Sanofi, Frankfurt, Germany, [6]IT&M Stats, Neuilly-sur-Seine, France, [7]Charité Research Organisation, Berlin, Germany, [8]Sanofi, Montpellier, France

SESSION INFORMATION

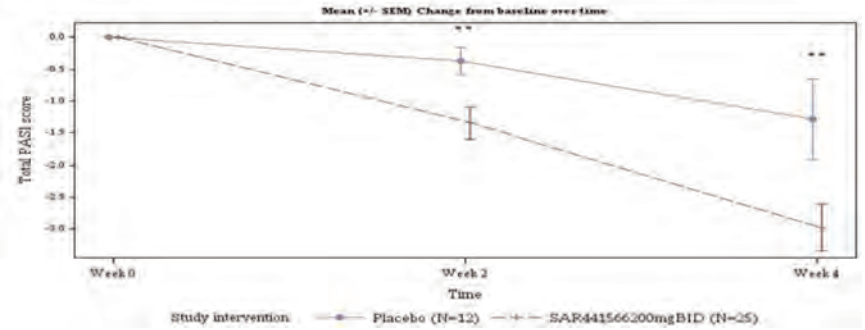
Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: TNFα inhibition is a cornerstone of therapy for rheumatologic disease, yet there is no orally administered TNFα inhibitor available. A novel oral TNFα inhibitor (SAR441566) which specifically inhibits TNFR1 signaling is currently in clinical development. In contrast to biologic TNFα inhibitors, this compound preserves homeostatic TNFR2 signaling. Using SAR441566 in a mouse model of RA (collagen induced arthritis), disease improvement similar to biologic TNFα inhibition was observed*. Based on safety, PK and PD characteristics in first-in-human studies, a phase 1 proof-of-mechanism (POM) trial in psoriasis was conducted. The primary objective was to evaluate tolerability and safety, with secondary/exploratory objectives to assess clinical and biomarker response over 4 weeks of treatment.

Methods: The clinical trial was a double-blind, randomized, placebo-controlled, single-center study with SAR441566, an oral TNFα inhibitor. All participants had dermatologist-diagnosed mild-moderate psoriasis. Peripheral blood biomarkers were assessed by ultra-sensitive immunoassay platform.

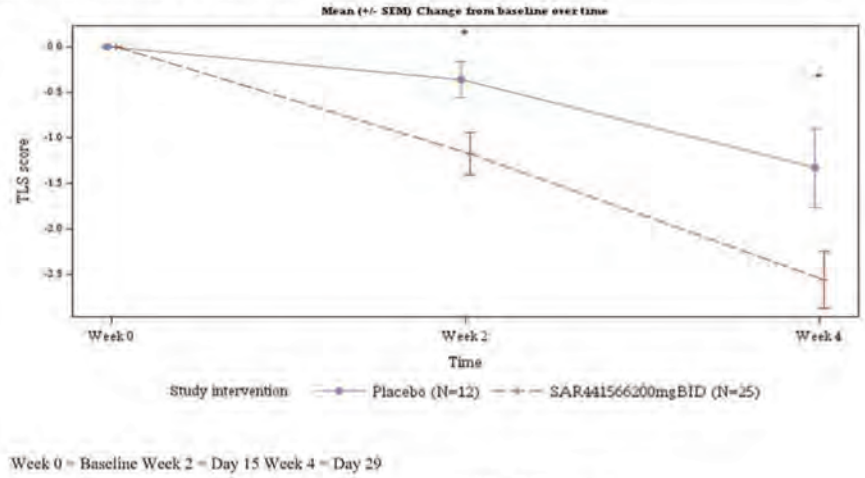
Results: Psoriasis patients recruited to the study randomized to oral TNFα inhibitor (n=26) vs placebo (n=12) were similar in age (μ±SD: 44.2±9.7 vs 40.5±12.5 yrs, p=0.332), race (proportion in %: 96.2 vs 91.7 Caucasian p= 0.565), BMI (26.45 ±2.97 vs 25.98±2.92 kg/m^2, p=0.650), baseline disease severity Investigator Global Assessment (IGA) score (2.42±0.64 vs 2.25±0.45, p=0.407), psoriasis area and severity index (PASI) score (8.91±3.73 vs 7.86±2.53, p=0.382), and target lesion severity (TLS) score (6.83±1.60 vs 7.42±1.40, p=0.280). With regards to safety and tolerability, there were no serious

Figure 1. Time profile of total PASI (psoriasis area and severity index) score for each study intervention group (placebo and SAR441566 200 mg BID)



Comparisons for SAR441566 vs placebo at week 2 demonstrated mean % improvement from baseline (least square means (LSM) ± standard error (SE)) 17.73±2.76 versus 4.12±4.10, with significant improvement from baseline in SAR441566 compared to placebo p= 0.005. Continuous data were summarized using the number of observations available, mean, Standard Deviation (SD), median, standard error of mean (SEM), minimum, and maximum. Categorical and ordinal data were summarized using the count and percentage of participants. Time profile plots and statistical modeling (Mixed model for repeated measures [MMRM]) were used to compare intervention vs placebo. Statistical significance differences between active drug and placebo were reported as a p-value and were calculated either from MMRM model (adjusted mean percentage improvement from baseline) or two-sample t-test for comparing means between the two groups on continuous data or chi-square test for comparing proportions between the two groups on categorical data. p-values <0.05 were considered significant.

Figure 2. Time profile of average TLS (target lesion severity) score for each study intervention group (placebo and SAR441566 200mg BID)

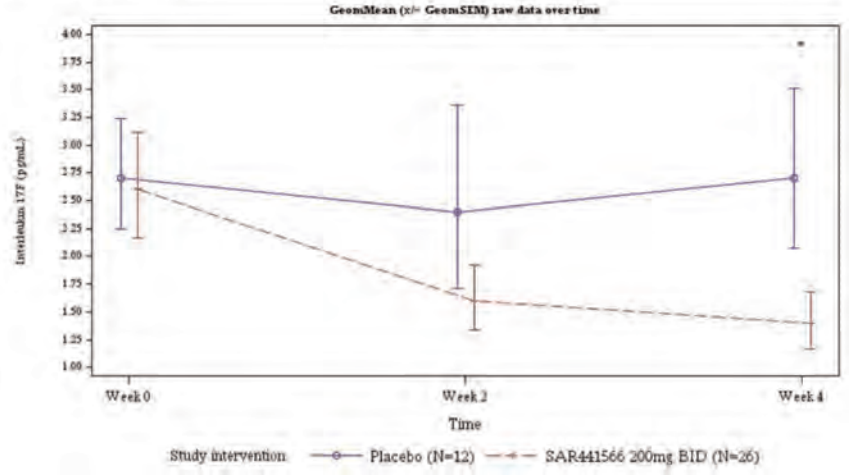


Week 0 = Baseline Week 2 = Day 15 Week 4 = Day 29

*P<0.05, p-value for one-sided test at 5% significance level calculated from MMRM model

Comparisons for SAR441566 vs placebo at week 2 demonstrated adjusted mean % improvement from baseline (least square means (LSM) ± standard error (SE)) 17.06±3.13 versus 6.29±4.68, with significant improvement from baseline in SAR441566 compared to placebo p= 0.032. Statistical significance calculation based on adjusted mean percentage improvement from baseline modeling using Mixed Models for Repeated Measures (MMRM).

Figure 3. Time profile of peripheral blood IL-17F (pg/mL) for each study intervention group (placebo and SAR441566 200mg BID)



Plot shows raw data with geometric mean and geometric standard error. Comparisons for SAR441566 vs placebo at week 2 demonstrated change from baseline in SAR441566, with geometric mean IL17-F levels of 1.65±2.55 vs. 2.39±2.71 pg/mL, p= 0.292, and significant improvement at week 4 1.35±2.55 vs. 2.73±2.44 pg/mL, p= 0.038.

adverse events (SAEs), severe treatment emergent adverse events (TEAEs) or AE of special interest (AESI). All observed TEAEs were grade 1/2 and participants fully recovered. There were few potentially clinically significant abnormalities for vital signs, ECG and laboratory parameters scattered across groups. All were considered not clinically meaningful by the investigator. With regards to clinical response by week 4, patients (N=37) were noted to have significant adjusted mean % improvement in PASI (LSM±SE, 35.09±4.47 vs 15.71±6.33, p=0.009) and TLS (% change 38.18±4.33 vs 20.44±6.18, p= 0.012). The proportion of patients achieving improvement by at least 1 severity level in IGA was 58.3 vs 0%, p=0.003. In addition to improvement in disease severity (PASI and TLS score change from baseline, Figures 1 and 2), Figure 3 depicts improvement in IL-17F.

Conclusion: This phase 1 study demonstrated that this novel oral TNFα inhibitor was safe, well tolerated, and clinically effective, to be further confirmed in larger trials. Limitations include the sample size and homogeneous population. A computational disease platform is being applied to translate psoriasis results to estimate the efficacy of SAR441566 for RA. A phase 2b dose ranging intervention proof-of-concept trial testing efficacy and safety for RA is planned.

Safety, Tolerability, and Pharmacokinetics of a Novel Synthetic Disease Modifying Antirheumatic Drug, TCK-276, After Single Ascending Dose in Healthy Subjects and Multiple Ascending Doses in Patients with Rheumatoid Arthritis

Chie Watai[1], Kazuoki Tsuruda[2], **Yoshinori Tsumura**[1] and Daisuke Tasaki[1], [1]Teijin Pharma Limited, Chiyoda City Tokyo, Japan, [2]Teijin America, Inc., Sausalito, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: TCK-276 is a highly potent, orally active, and selective cyclin dependent kinase 4/6 (CDK4/6) inhibitor that is in development as a novel synthetic disease modifying antirheumatic drug targeting the hypertrophy of synovial fibroblasts. To investigate the safety, tolerability, and pharmacokinetics (PK) of oral doses of TCK-276, we conducted two phase 1 studies in the United States; one was the single ascending dose (SAD) study in healthy subjects and the other is an ongoing multiple ascending dose (MAD) study in patients with rheumatoid arthritis (RA).

Methods: The SAD study was a single-center, randomized, placebo-controlled, double-blind study, which enrolled 48 healthy subjects into 6 cohorts. Six subjects in each cohort received TCK-276 (5, 15, 50, 100, 150, or 185 mg) and 2 subjects in each cohort (total of 12 subjects) received placebo. The MAD study (NCT05437419) is a multicenter, randomized, placebo-controlled, double-blind study, which is planned to enroll a total of 32 RA patients into 4 cohorts. Six patients in each cohort received TCK-276 and 2 patients in each cohort received placebo for 7 days, respectively.

Results: In the SAD study, 5 subjects (10.4%) experienced 7 treatment-emergent adverse events (TEAEs). All TEAEs were mild. Only one TEAE (headache) was considered possibly related to TCK-276 at 150 mg, and all the other TEAEs were considered either unlikely to be related or unrelated. No action was taken for the TEAEs. There were no deaths, serious TEAEs, or TEAEs leading to discontinuation reported during the study. No clinically significant findings were noted in the clinical laboratory evaluations (clinical chemistry, hematology, coagulation, and urinalysis). After administration of 5 to 185 mg TCK-276, geometric mean C_{max}, $AUC_{0\text{-}inf}$, and $t_{1/2}$ values of TCK-276 ranged from 11.5 to 481 ng /mL, 53.9 to 2260 ng*h/mL, and 3.70 to 13.0 h, respectively. Across the 5 mg to 185 mg dose range, an increase in TCK-276 exposure approximately proportional to dose was observed. In the MAD study, a total of 16 patients have been enrolled as of May 26, 2023; 12 patients received TCK-276 (10 mg/day or 25 mg/day for 7 days) and 4 patients received placebo, respectively. There were no safety concerns identified, and the safety review committee concluded that the study can proceed with the next higher dose. PK profiles in RA patients after administration of 10 or 25 mg/day TCK-276 were confirmed to be similar to those in healthy subjects.

Conclusion: Safety results indicated that TCK-276 was well tolerated at a dose of up to 185 mg for a single administration and up to 25 mg/day over 7 days of administration. In addition, no safety concerns have been observed such as anemia, neutropenia, leukopenia, and thrombocytopenia, which are often observed with other CDK4/6 inhibitors. TCK-276 showed faster elimination than other CDK4/6 inhibitors, which may be related to the observed safety profile. Safety, tolerability, and PK of the higher TCK-276 dose cohorts in the MAD study will be available at the presentation. The safety and efficacy of TCK-276 in the treatment of RA will be further evaluated in a phase 2 trial in the future.

Abstract Number: 0445

Comparison of the Efficacy, Safety and Immunogenicity of a Proposed Biosimilar MSB11456 with Tocilizumab Reference Product in Moderate-to-severe Rheumatoid Arthritis: Results of a Randomized Double-blind Study

Anna Zubrzycka-Sienkiewicz[1], Maria Misterska-Skora[2], Małgorzata Socik Pojawa[3], Kamilla Klama[4], Martin Ullmann[5], Corinne Petit-Frere[5], **Andras Illes**[5], Peter Baker[5], Joëlle Monnet[5] and Jan Brzezicki[6], [1]Reumatika - Centrum Reumatologil, Warsaw, Poland, [2]Centrum Medyczne Oporów, Wrocław, Poland, [3]MICS Centrum Medyczne Warszawa, Warsaw, Poland, [4]Solumed Centrum Medyczne, Poznań, Poland, [5]Fresenius Kabi SwissBiosimilars, Eysins, Switzerland, [6]Centrum Kliniczno Badawcze, Elbląg, Poland

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Tocilizumab is an anti-interleukin-6 receptor monoclonal antibody indicated for treating rheumatoid arthritis (RA) and other inflammatory diseases. MSB11456 is a proposed biosimilar to US-licensed tocilizumab and EU-approved tocilizumab. It has already shown equivalent pharmacokinetic (PK), pharmacodynamic (PD) safety, tolerability, and immunogenicity profiles to these products given subcutaneously (SC) as a single dose in healthy volunteers. This is a

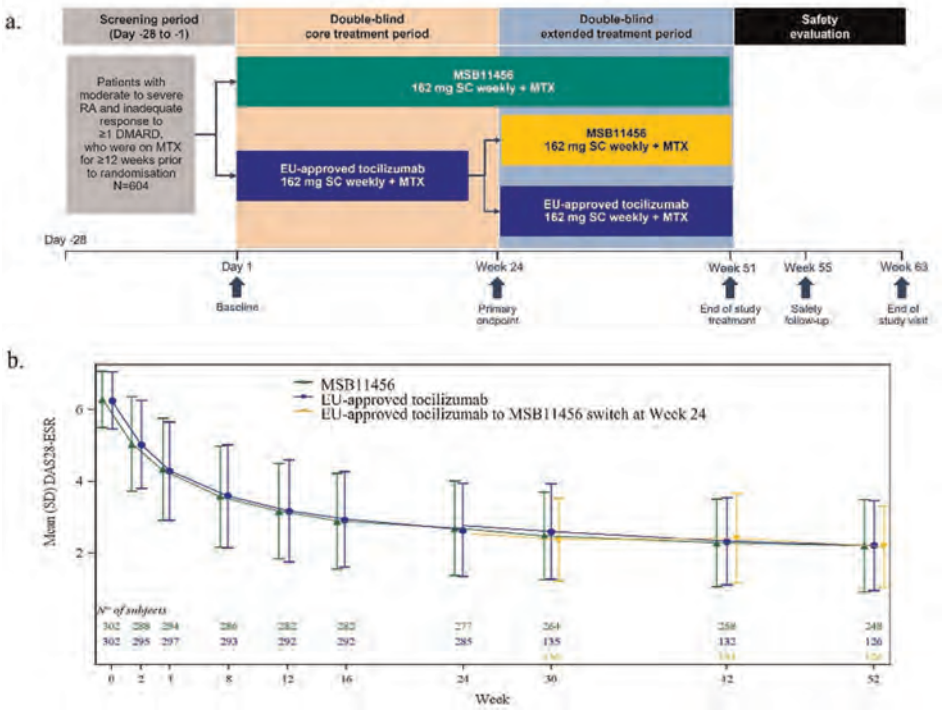

Figure 1: a. Study design; b. Mean DAS28-ESR at various timepoints in patients receiving MSB11456; EU-approved tocilizumab and patients who were switched from EU-approved tocilizumab to MSB11456 at W24 until W52 - All Randomized subjects.

Phase III, multicenter, randomized, double-blind, multiple fixed-dose, parallel group study aiming to compare the efficacy, safety, and immunogenicity of MSB11456 and EU - approved tocilizumab administered SC in patients with moderate-to-severe RA (NCT04512001).

Methods: Patients were randomized to subcutaneous injections of 162 mg MSB11456 or EU - approved tocilizumab for 24 weeks (W). At W24, patients receiving EU-approved tocilizumab were re-randomized to continue their treatment or to switch to MSB11456 up to W52. Those receiving MSB11456 continued MSB11456 until W52. A safety evaluation was conducted up to W63 (Figure 1a).

The primary efficacy endpoint - change from baseline in Disease Activity Score-28 Joint Count (DAS28)-erythrocyte sedimentation rate (ESR) at W24 - was analyzed using analysis of covariance to determine the least squares mean (LSM) difference between MSB11456 and EU-approved tocilizumab; MSB11456 was considered equivalent to EU-approved tocilizumab if the 90% confidence interval (CI) for this difference was entirely within the equivalence interval -0.6 to 0.5. Secondary endpoints were 20% improvement in American College of Rheumatology core set measures (ACR20) at W24 and DAS28-ESR at W12. Additional endpoints included ACR50/70, change in DAS28-C-reactive protein (CRP), Simplified Disease Activity Index (SDAI), Clinical Disease Activity Index (CDAI), evaluation of immunogenicity at various time points up to W55 and safety up to W63.

Table 1: DAS28-ESR - Change from Baseline at Week 24 - (ITT Analysis Set)

Variable Statistic	MSB11456 (N=302)	EU-approved tocilizumab (N=302)	Difference MSB11456 - EU-approved tocilizumab (N=604)
Change from Baseline to Week 24			
LS Mean (SE)[a]	-3.53 (0.106)	-3.54 (0.106)	
95% Confidence Interval[a]	(-3.74, -3.32)	(-3.75, -3.33)	
Number of Imputed Values	25	17	
Difference in Change from EU-approved tocilizumab[a]			
LS Mean Difference (SE)[b]			0.01 (0.104)
90% Confidence Interval[b]			(-0.16, 0.18)

LS = Least squares; SE = Standard error
[a] LS means, standard errors and confidence intervals are from an ANCOVA model based on change from baseline in DAS28-ESR with fixed effects for study drug and previous exposure to biologic treatment for RA [Y / N] and baseline DAS28-ESR as a covariate. Fixed effects were based on IRT.
[b] For the FDA: MSB11456 was considered equivalent to EU-approved tocilizumab if the 90% confidence interval was included in the equivalence interval of [-0.6, 0.5].

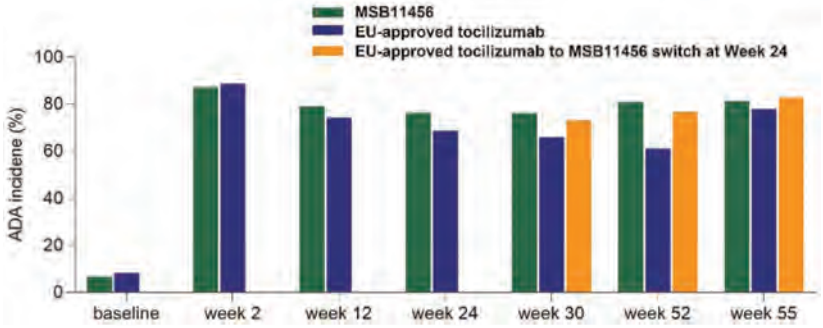

Figure 2: Antidrug antibody (ADA) incidence at various time points in patients receiving MSB11456; EU-approved tocilizumab and patients who were switched from EU-approved tocilizumab to MSB11456 at W24 until W52.

Results: Clinically relevant LSM decreases from baseline in DAS28-ESR were observed as early as W2 and up to W24 with MSB11456 and EU-approved tocilizumab (Figure 1b). As the 90% CI for the LSM difference in the change from baseline in DAS28-ESR between treatments was fully included within the predefined equivalence interval, therapeutic equivalence of MSB11456 and EU-approved tocilizumab was demonstrated (Table 1). The other efficacy endpoint analyses supported this conclusion. Treatment-emergent adverse events (TEAEs) were usually mild or moderate and occurred at similar frequency with both drugs. There were no discernible patterns in terms of the nature, frequency, or other characteristics of serious or treatment related TEAEs to suggest a difference between drugs. Anti-drug antibodies (ADA) incidence was similar among treatment arms (Figure 2). The switch from EU-approved tocilizumab to MSB11456 at W24 had no clinically relevant impact either on efficacy or safety, including immunogenicity.

Conclusion: Equivalent efficacy, and similar immunogenicity and safety profiles of MSB11456 and EU-approved tocilizumab were demonstrated in patients with moderate to severe RA

Abstract Number: 0446

Review of Rheumatoid Arthritis Treatment Landscape During the COVID-19 Pandemic

Rachel Connolly[1], MamTing Thoo[2], Elizabeth Baynton[3] and **Denise Baldock**[3], [1]Ipsos, New York, NY, [2]Ipsos SDN BHD, Kuala Lumpur, Malaysia, [3]Ipsos MORI UK, London, United Kingdom

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: During the COVID-19 pandemic, guidelines were amended with respect to the prescribing of biologic/tsDMARD usage to treat rheumatoid arthritis (RA). In addition, regulatory reviews also ensued gauging the safety & risk parameters of Janus kinase inhibitor (JAKi) usage. The purpose of this study was to analyse any biologic/tsDMARD prescribing shifts in RA during this time, and any possible impacts.

Methods: A multi-country, multi-centre, online, medical chart review study of patients with RA was conducted across January – December 2021 ("2021 cohort") and January – December 2022 ("2022 cohort"), among UK, FR, DE, IT & ES rheumatologists in hospitals and private practices were recruited to collect de-identified data on patients who were recently treated with an advanced therapy (biologic/tsDMARD) as part of their usual care. Physicians were screened for practice duration and patient volume. Rheumatologists abstracted current patient treatment, reasons for prescribing treatments and patient disease score information; patient charts are included in the analysis.

Results: The 2021 cohort consists of 383 sampled physicians who reported on 4999 patients in total. The 2022 cohort consists of 422 sampled physicians who reported on 5161 patients in total.

2022 cohort recorded an increase in biosimilar tumour necrosis factor inhibitor (TNFi) usage among reported patients vs 2021 cohort (31% vs 27%). Alternate available mechanisms of action (MoA) to TNFi recorded a decrease in use to 44% (2022) from 46% (2021) among reported patients; JAKi class share showed minimal change from 24% (2021) to 23% (2022).

In reasons for therapy choice cited by the sampled rheumatologists, the % of reported patients with the following driving metrics have increased from 2021 to 2022: cost/insurance (16% vs 19%), patient request (9% vs 12%), long-term efficacy data available (27% vs 31%) and long-term safety data available (26% vs 29%).

Recorded remission status has decreased from 59% in 2021 cohort to 56% in 2022 cohort.

Conclusion: Comparing the two cohorts in this study data has allowed insight into possible prescribing changes that were beginning to come into view throughout the COVID-19 pandemic and while JAKi regulatory reviews were ongoing: increased prescribing of biosimilar TNFis and decreased prescribing of alternate MoAs. The data shows an increasing desire for long-term safety and efficacy data, patient request, and cost/insurance when physicians are choosing the therapy that their patient is going to be treated with. Interestingly, while the prescribing behaviour of sampled physicians has shifted, disease outcomes of reported patients are not necessarily improving. With patients in this study recording lower remission rates, it may be that the treatment shift away from newer MoA therapies are having an influence. It will be critical to monitor the RA treatment landscape for patient outcomes going forward. Further analysis using comparator cohort is warranted.

Glucocorticoid Use in Rheumatoid Arthritis Patients Initiating Biological or Targeted Synthetic Disease Modifying Anti-rheumatic Drugs (b/tsDMARDs) in Real Life: Data from BIOBADASER

Lucia Otero-Valera[1], Jose María Alvaro-Gracias[2], Jerusalem Calvo[3], Cristina Campos[4], Alicia Garcia Dorta[5], Fernando Sánchez-Alonso[6] and **Isabel Castrejon**[7], [1]Spanish Society of Rheumatology, Madrid, Spain, [2]Hospital General Universitario Gregorio Marañon, Madrid, Spain, [3]Reina Sofia University Hospital, Córdoba, Spain, [4]Rheumatology Unit, Hospital General Universitario de Valencia, Valencia, Spain, [5]Rheumatology Unit, Hospital Universitario de Canarias, Santa Cruz de Tenerife, Spain, [6]Fundación Española de Reumatología, Madrid, Spain, [7]Hospital Universitario Gregorio Marañón, Madrid, Spain

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Glucocorticoids are frequently used as bridging therapy for rheumatoid arthritis (RA) patients starting conventional synthetic DMARDs. Both EULAR and ACR guidelines (1,2), recommend to use the lowest effective dose for the shorter duration possible, ideally less than three months. In addition, glucocorticoids are not recommended when starting a b/tsDMARD. We aim to assess glucocorticoid usage after treatment initiation with bDMARDs and JAKi in RA patients in real life.

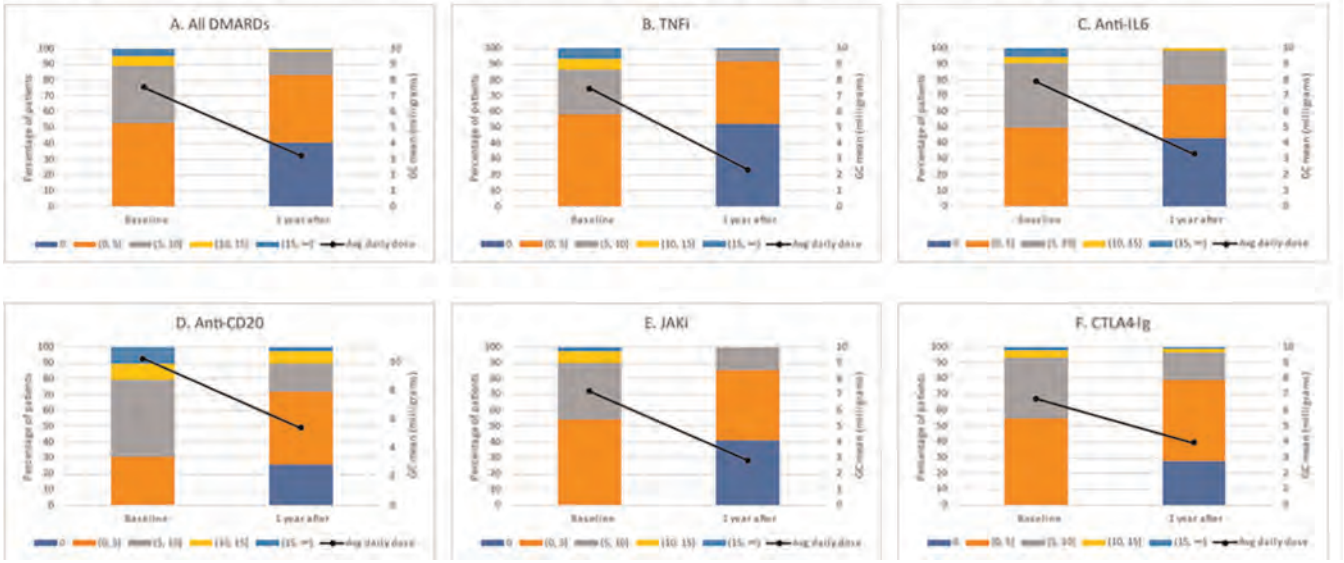
Methods: Data on patients with RA switching from a conventional synthetic DMARD to a first biologic or JAKi enrolled in BIOBADASER 3.0 (a multicenter Spanish Registry on Adverse Events of Advanced Therapies in Rheumatic Diseases) were analyzed. Biologic treatment included TNFi, anti-IL6, anti-CD20, and CTLA4-Ig. Patients with any biologic or JAKi, all in combination with glucocorticoids at therapy initiation were included. As TNFi was the larger group, a random sample was taken for comparison purposes. Descriptive statistics were used to calculate the frequency and average daily glucocorticoid usage according to therapy group, both at baseline and 1 year after treatment initiation. Wilcoxon Singed Rank test was used to compare glucocorticoid dose changes from baseline to 1 year after initiation of the b/tsDMARDs and ANOVA, to compare the mean dose differences across groups.

Results: A total of 432 RA patients met the inclusion criteria and were included in the analysis, 78.2% women, mean age 58.4 (12.2) years old, median disease duration 5.2 years [IQR: 2.1-10.8] and mean DAS28-ESR at baseline 4.72 (1.33). Mean (SD) glucocorticoid daily dose decreased from 7.6 mg (5.8) at baseline to 3.2 (5.5) mg at 1-year follow-up (Figure). Daily dose changes were statistically significant (Wilcoxon Signed Rank test: $p < 0.001$). Mean difference from baseline to one year follow-up was 5.13 for TNFi, 4.59 for anti-IL6, 4.83 for anti-CD20, 4.38 for JAKi, and 2.78 for CTLA4-Ig (ANOVA: p=0.12). The proportion of patients with a decrease in glucocorticoids dose from baseline to one year follow-up after b/tsDMARD initiation was 72.7% for TNFi, 62.2% for anti-IL6, 66.7% for anti-CD20, 67.9% for JAKi, and 60.5% for CTLA4-Ig, and the proportion of patients with no glucocorticoids at one year was 52.1%, 43.2%, 25.6%, 41.1% and 27.9% respectively for each treatment (Table).

Table. Average daily glucocorticoid usage for treatment group

				GC daily doses				
DMARD Drug	**n**		**Mean (SD)**	**No GC [0]**	**[0, 5]**	**(5, 10]**	**(10, 15]**	**(15, ∞)**
TNFi	121	Baseline	7.43 (5.58)	0 (0.0)	71 (58.7)	34 (28.1)	8 (6.6)	8 (6.6)
		1 year after	2.33 (3.49)	63 (52.1)	48 (39.7)	9 (7.4)	0 (0.0)	1 (0.8)
Anti-IL6	74	Baseline	7.89 (7.82)	0 (0.0)	37 (50.0)	30 (40.5)	3 (4.1)	4 (5.4)
		1 year after	3.29 (3.55)	32 (43.2)	25 (33.8)	16 (21.6)	1 (1.4)	0 (0.0)
Anti-CD20	39	Baseline	10.21 (7.41)	0 (0.0)	12 (30.8)	19 (48.7)	4 (10.3)	4 (10.3)
		1 year after	5.38 (5.70)	10 (25.6)	18 (46.2)	7 (18.0)	3 (7.7)	1 (2.6)
JAKi	112	Baseline	7.22 (4.50)	0 (0.0)	61 (54.5)	40 (35.7)	8 (7.1)	3 (2.7)
		1 year after	2.83 (2.85)	46 (41.1)	50 (44.6)	16 (14.3)	0 (0.0)	0 (0.0)
CTLA4-Ig	86	Baseline	6.71 (3.54)	0 (0.0)	47 (54.7)	33 (38.4)	4 (4.7)	2 (2.3)
		1 year after	3.92 (4.21)	24 (27.9)	44 (51.2)	15 (17.4)	2 (2.3)	1 (1.2)
All DMARDs	**432**	Baseline	**7.57 (5.77)**	**0 (0.0)**	**228 (52.8)**	**156 (36.1)**	**27 (6.3)**	**21 (4.9)**
		1 year after	**3.22 (5.48)**	**175 (40.5)**	**185 (42.8)**	**63 (14.6)**	**6 (1.4)**	**3 (0.7)**

Figure. Average daily glucocorticoids usage. A) All DMARDs. B) TNFi. C) Anti-IL6. D) Anti-CD20. E) JAKi. F) CTLA4-Ig



Conclusion: Our data shows that glucocorticoids are frequently used and for longer than 3 months when initiating b/tsDMARDs. Around 2% of patients have glucocorticoid doses over 10mg and 15% over 5mg after one year follow-up. Further studies are necessary to evaluate variables associated with persistent use of glucocorticoids.

Cardioprotective Impact of JAKi, Tofacitinib, on CV Risk in Rheumatoid Arthritis: JAKi CV Risk Impact Study

Ashit Syngle[1], Inderjeet verma[2], Nidhi Garg[3], Kanchan Chauhan[1], Sapna Patyal[1] and Devaansh Syngle[4], [1]Healing Touch City Clinic, Chandigarh, India, [2]Maharishi Markandeshwar University, Mulana, India, [3]Chitkara, Rajpura, India, [4]Healing Touch Foundation, Chandigarh, India

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: RA patients have at least twice the risk of CVD. In fact, CVD is the leading cause of morbidity and premature mortality in RA. Inflammation driven endothelial dysfunction leads to accelerated atherosclerosis and premature CVD in RA. JAKi, tofacitinib, in human aortic endothelial culture inhibits VCAM-1, ICAM-1, TNF-a, IL-1b. However, tofacitinib increases MACE risk in RA patients with ASCVD.

Impact of Tofacitinib on endothelial function in RA patients with inadequate response to csDMARDs in the absence of conventional CV risk factors or pre-existing CVD needs exploration. Endothelial dysfunction (ED), the " sine qua non" for atherosclerosis appearance, is the key promoter of CVD. ED is a barometer for CV health and a seminal target for reducing cardiovascular (CV) risk in RA.

The objective was to prospectively investigate the impact of Tofacitinib (TOFA) on CV risk in active RA in absence of overt CVD or its risk factors.

Methods: 81 consecutive RA patients meeting 2010 Rheumatoid Arthritis Classification Criteria median age 54 years, 81% female, disease duration 14 years, moderate to high activity (DAS28-5.3) who were non-responders to MTX at least 15 mg/week and/or other synthetic DMARDs free of clinical overt cardiovascular disease were randomized 1:1 to receive TOFA 5 mg bid (n=41) or placebo (n=41) for 12 weeks as an adjunct to existing stable antirheumatic drugs. Primary endpoints included endothelial dysfunction assessed by FMD, using Angiodefender, at baseline and after 12 weeks of treatment and occurrence of MACE and VTE throughout the study. The secondary end points included: DAS28, ESR, CRP, HAQ-DI.

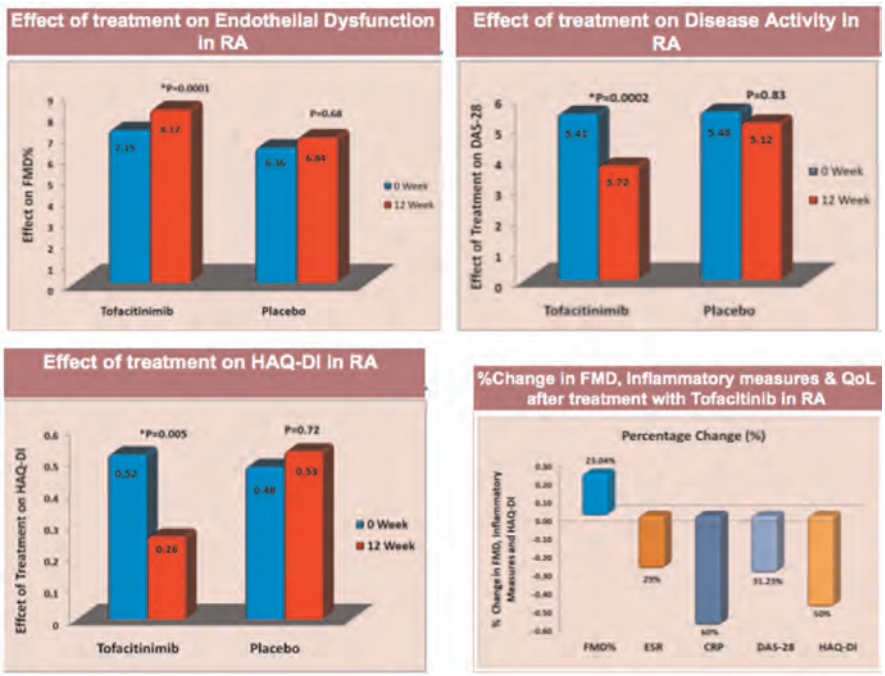

Fig 1. Effect of Tofacitinib treatment on (A) Endothelial dysfunction (B) Disease activity (C) HAQ-DI and (D) % Change

Effect of tofacitinib on 9A) Endothelial Dysfunction (B) Disease Activity (C) HAQ (D) % Change

Results: At baseline, endothelial function was impaired and levels of inflammatory measures were elevated and HAQ-DI was impaired in both groups. After treatment, FMD improved significantly in the tofacitinib group from (6.64 ± 2.13 to 8.17 ± 2.69, p=0.0001) as compared to placebo (6.36 ± 3.01% to 6.84 ± 2.95%, p=0.68) (Fig. 1A). DAS28 (Fig. 1B), ESR and CRP levels improved significantly in tofacitinib group as compared to placebo (p≤0.05). TOFA significantly decreased HAQ-DI (Fig. 1C) values as compared to placebo. There was no MACE or VTE event during the study period in either group. After 12 weeks of treatment, FMD increased by 23.04% where as DAS28, ESR and CRP decreased by 31.23%, 29% and 60% respectively in the TOFA group (Fig 1D). Significant negative correlation was observed between FMD and CRP (0.32, p≤0.05) before and after (r= -0.34, p≤0.05) treatment with TOFA whereas no such correlations were found in placebo group.

Conclusion: TOFA, apart from its anti-inflammatory activity, improves endothelial dysfunction and cardiovascular risk in active RA without clinical overt cardiovascular disease. Thus, JAK inhibition with TOFA has vasculoprotective and cardioprotective effect mediated through anti-inflammatory and probably other mechanisms.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Lymphoproliferative disorders (LPD) in rheumatoid arthritis (RA) (RA-LPD) have unique pathophysiological features. More than half of the cases of RA-LPD undergo spontaneous regression after the discontinuation of disease modifying anti rheumatic drugs (DMARDs), whereas approximately 33% of these cases relapse. Epstein-Barr virus (EBV) infection is especially involved in the pathophysiology of RA-LPD. The current study was conducted with whole RNA transcriptome analysis using the peripheral blood of patients developing RA-LPD to investigate the pathophysiology of RA-LPD.

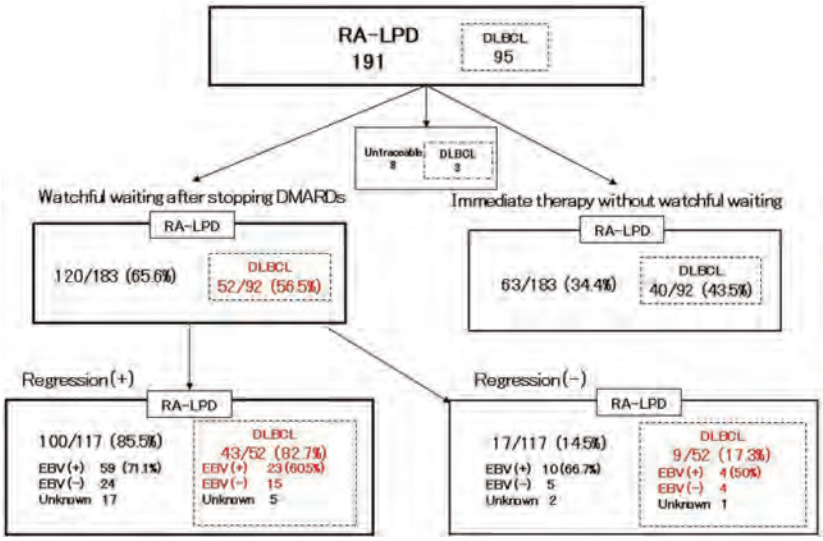

Figure 1. Flow diagram of the study. Cases analyzed in this study are written in red. RA-LPD: lymphoproliferative disorders in rheumatoid arthritis; DLBCL: diffuse large B-cell lymphoma; DMARD: Disease modifying anti rheumatic drug; EBV: Epstein-Barr virus.

Methods: Peripheral blood samples of the patients with RA-LPD were obtained between May 2013 and October 2018 from 30 hospitals in Japan. Whole transcriptome sequencing was performed using the Ion AmpliSeq Human Gene Expression Kit (Thermo Fisher Scientific) and an IonS5 XL sequencer (Thermo Fisher Scientific). The kit covers the expression levels of 20,802 human RefSeq genes (based on UCSC hg19). Differential gene expression analysis was performed by Transcriptome Analysis Console (TAC) software (ver. 4.0.3, Thermo Fisher Scientific) with |FC| > 2-fold difference and at $p < 0.1$. A Gene Set Enrichment Analysis (GSEA) was performed to identify pathways enriched in the Molecular Signatures Database (MSigDB) Hallmark gene set. A nominal p value of < 0.05 and an FDR (false discovery rate) q value of < 0.25 were considered statistically significant.

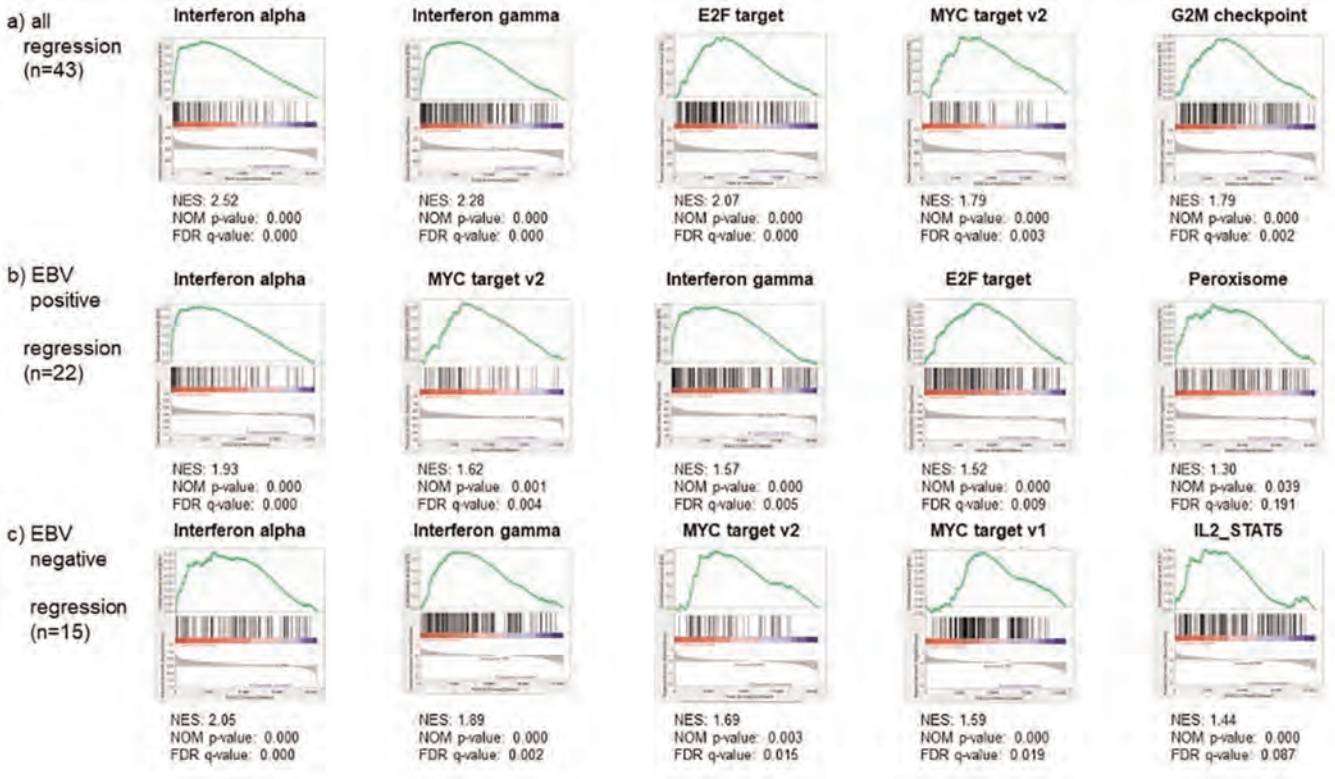

Figure 2. Gene set enrichment analysis (GSEA) in all regression cases (a), regression cases with Epstein-Barr virus (EBV) infection (b), and regression cases without EBV infection (c). Interferon alpha and gamma pathways were upregulated in all regression cases. Interleukin-2- STAT5 was a unique pathway in EBV negative cases.

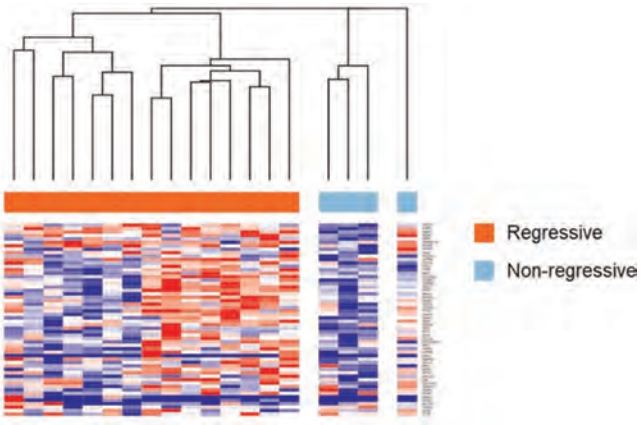

Figure 3. Heatmap showing gene expression related to interleukin 2-STAT5 pathway in cases without Epstein-Barr virus infection. They were highly expressed in regression cases.

Results: In total, 211 cases (191 RA-LPD cases and 20 non-LPD RA cases) were analyzed. The flow diagram of the study is shown in Figure 1. We grouped diffuse large B-cell lymphoma (DLBCL) cases into two groups; regression cases (n = 43), which regressed spontaneously after stopping DMARDs and non-regression cases (n = 9), which did not regress. Gene expression levels were compared between the two groups. GSEA analysis showed that interferon alpha and gamma pathways were enhanced in regression cases (Figure 2a). To investigate mechanisms of regression in EBV-negative cases, we performed further analysis according to EBV infection status. (EBV positive, n= 22; EBV negative, n= 15). The interleukin-2-STAT5 (IL2-STAT5) pathway was enhanced in regression cases without EBV infection, which was suggested to be a unique mechanism for regression in EBV-negative RA-LPD (Figure 2b, c). The heatmap (Figure 3) shows that genes related to IL2-STAT5 were expressed highly in regression cases without EBV infection. Additionally, expression levels of some genes related to the IL2-STAT5 pathway were significantly different between regression and non-regression EBV-negative cases. This result suggests that these genes may serve as new liquid markers for regression in EBV-negative RA-LPD.

Conclusion: The current study showed that interferon-alpha and gamma pathways were upregulated in the regression cases with DLBCL of RA-LPD. Moreover, the study revealed a unique mechanism related to IL2-STAT5 for regression of EBV-negative cases. Our research further suggested new potential markers for regression in EBV-negative cases.

Abstract Number: 0450

Baricitinib versus TNF-inhibitors in Patients with Active Rheumatoid Arthritis After Failure of CsDMARDs: A Pragmatic, Multicenter, Real-Life Study in a Treat-to-Target Setting

Martinus Van de Laar[1], Martijn Oude Voshaar[1], Peter ten Klooster[1], Danyta Tedjo[2] and celine van de laar[3], [1]University of Twente, Hengelo (OV), Netherlands, [2]TiH @ University of Twente, Hengelo (OV), Netherlands, [3]Erasmus School of Health Policy and Management, Erasmus University, Rotterdam, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The EULAR guidelines for Rheumatoid Arthritis (RA) patients advise to use a strategy aiming at a predefined target of disease activity (T2T). If this target is not achieved with csDMARD, adding a TNF-inhibitor (TNFi) or a JAK-inhibitor (JAKi) are advised options in cases with poor prognostic factors, obviously considering contraindications. While randomized clinical trials have provided insight into the relative efficacy and safety of TNFi and JAKi under trial conditions, the generalizability to real-life clinical practice remains unclear.

We aim to demonstrate the non-inferiority (NI) and, in case NI could be shown, subsequent superiority of a T2T strategy using baricitinib versus TNFi, after failure of csDMARDs, in a real-life setting.

Methods: Biologic or targeted synthetic DMARD(b/tsDMARD)-naïve RA patients failing to respond to csDMARDs were eligible if they were pretreated according to T2T principles, had a disease duration ≤5 years and no contraindications to b/tsDMARD. All included patients were treated open label, according the T2T principle, at the discretion of their attending physician with either a TNFi (any type) or baricitinib. Patients were seen at baseline and 12-weekly until final follow-up (48 weeks). Full clinical assessment was performed at each visit and patients completed several PROMs. The primary endpoint was defined as NI of baricitinib versus TNFi with respect to the number of patients achieving ACR50 response at week 12. Subsequently, superiority testing was foreseen in case non-inferiority was shown. For the primary efficacy analysis, the

Table baseline characteristics

		TNFi	Baricitinib	p
		N=102	N=97	
Age		55.2 (13.4)	54.8 (12.0)	0.833

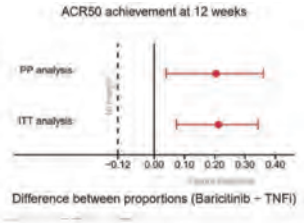

figure 1

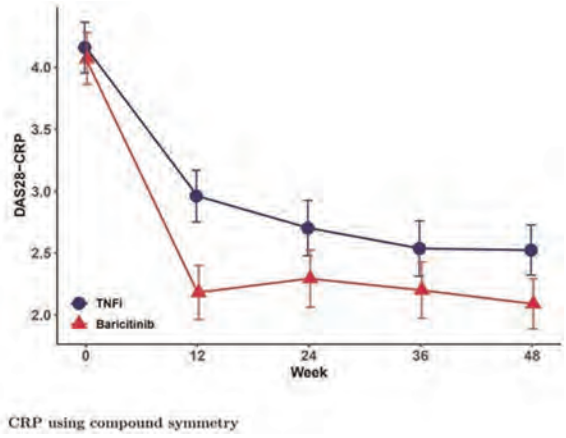

figure 2

ACR50 responses were compared, using 95% confidence intervals calculated using the Wilson score method for the difference in proportions. The non-inferiority margin for baricitinib was set at -12%. Linear mixed models were used to analyze continuous secondary outcomes over the study period of 48 weeks.

Results: 199 patients who received a first dose of either TNFi (n=102) or baricitinib (n=97) were included. Baseline characteristics were comparable between both groups (see table). At 12 weeks, the lower bound of the 95% confidence interval for the difference in the ACR50 response was above zero, in both the per-protocol and intention-to-treat analysis (figure 1). Hence, baricitinib was found to be non-inferior and statistically superior to TNFi in the analysis of the primary endpoint. Moreover, DAS28 remission (DAS28-CRP < 0.6) was achieved in 74% of baricitinib patients compared with 47% of TNFi patients ($p< 0.001$) at 12 weeks. All secondary clinical and PRO -measures over the study period of 48 weeks showed better responses, most often statistically superior, of Baricitinib over TNFi (figure 2 for DAS28-CRP).

Conclusion: Baricitinib was found to be non-inferior as well as superior to TNFi in terms of ACR50 response at 12 weeks in real-world csDMARD refractory RA patients. Analysis of the secondary endpoints on disease activity and PROMs, were consistently in favor of the group that started Baricitinib.

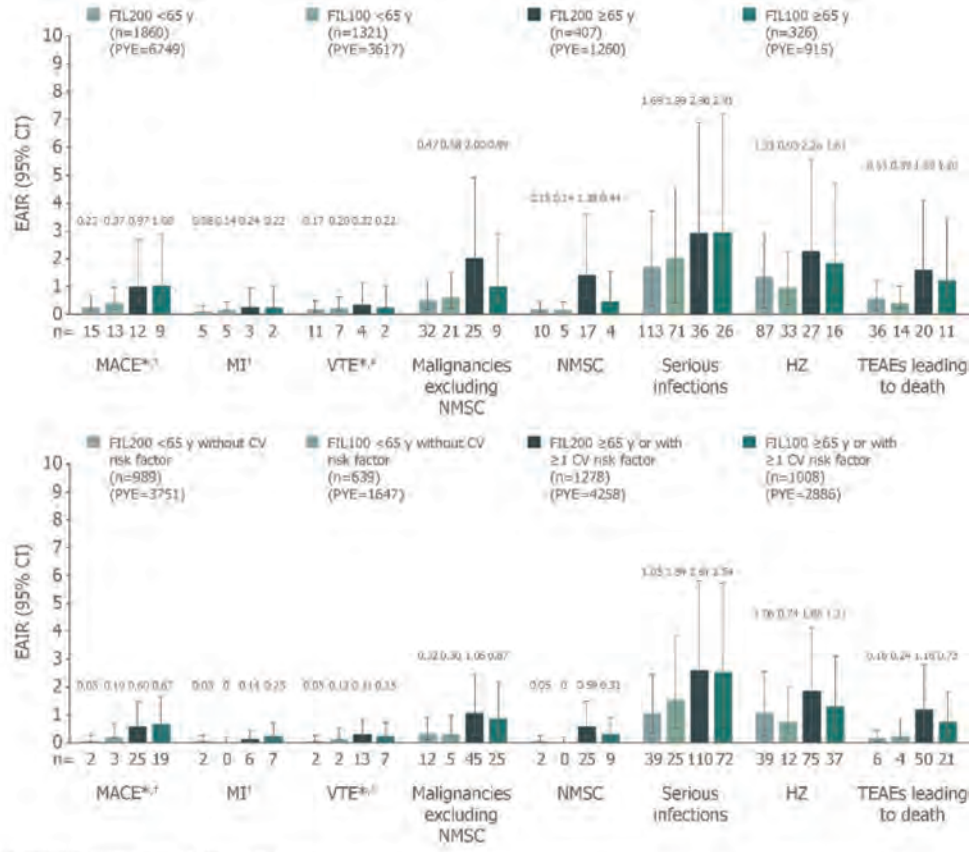
SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Filgotinib (FIL) is an oral Janus kinase 1 preferential inhibitor for the treatment of moderate to severe active RA. A previous pooled analysis reported long-term safety and efficacy for FIL 200 mg (FIL200) vs FIL 100 mg (FIL100) in patients (pts) aged ≥ 65 and < 65 y.[1] The objective of this analysis was to report updated long-term safety and efficacy in 4 subgroups of pts with RA (aged < 65 y, ≥ 65 y, < 65 y without cardiovascular [CV] risk, and ≥ 65 y or with CV risk), treated with FIL200 vs FIL100.

Methods: This *post hoc* analysis pooled data from Phase 2 (DARWIN 1–3; NCT01888874, NCT01894516, NCT02065700) and Phase 3 (FINCH 1–4; NCT02889796, NCT02873936, NCT02886728, NCT03025308) trials. Data for long-term extensions (LTEs) were as of May 2, 2022 (DARWIN 3), and May 6, 2022 (FINCH 4). Analyses were by age (< 65 vs ≥ 65 y) and subgroup (< 65 y without CV risk factor vs ≥ 65 y or ≥1 CV risk factor). CV risk factors were: family history of CV disease; history of dyslipidemia, diabetes mellitus or CV disease; hypertension, ischemic vascular conditions, peripheral vascular disease, extra-articular manifestations of RA; or ever smoked. The as-treated analysis set included data for pts receiving ≥1 FIL dose. Exposure-adjusted incidence rates (EAIRs)/100 patient-years of exposure (PYE) of selected adverse events (AEs), and % of pts achieving Disease Activity Score in 28 joints using C-reactive protein (DAS28-CRP) of < 2.6 or ≤ 3.2 through Week 156 in FINCH 4, are reported.

Results: Baseline characteristics by age have been reported.[1] Baseline disease characteristics by age or CV risk factor were similar for disease severity and concurrent treatment. EAIRs for any treatment-emergent AEs (TEAEs) were generally higher in pts aged ≥ 65 (120.40) vs < 65 y (97.86), and higher in pts aged ≥ 65 y or with CV risk (120.45) vs pts aged < 65 y without CV risk (81.83). Pts aged ≥ 65 y, followed by the broader subgroup with CV risk factors (i.e. ≥ 65 y or ≥ 1 CV risk) had higher EAIRs of serious TEAEs and TEAEs leading to discontinuation vs other subgroups, indicating age is a key risk factor alongside other CV risk factors for developing AEs (data not shown). In pts aged ≥ 65 y, lower incidences of malignancies (excluding nonmelanoma skin cancer [NMSC]), NMSC, herpes zoster (HZ) and TEAEs leading to death were observed with FIL100 than FIL200 (**Figure**). In the broader subgroup with risk factors (i.e. aged ≥ 65 y or ≥ 1 CV risk factor), EAIRs of AEs were generally lower vs pts aged ≥ 65 y, indicating greater influence of age. EAIRs of AEs for subgroups (aged < 65 y without CV risk; ≥ 65 y or ≥ 1 CV risk) for FIL200 and FIL100 are shown (**Figure**). Rates of DAS28-CRP < 2.6 or ≤ 3.2 in all subgroups (FINCH 4) were maintained with FIL100 and FIL200 to Week 156 (**Table**).



EAIRs/100 PYE, censored at time of first event.
*MACE and VTE only included positively adjudicated events with a cutoff of April 3, 2022. †MACE comprised CV events leading to death, MI and stroke; for subcategories of stroke and MI, both fatal and non-fatal events were considered. ‡For VTE subcategories, PE, DVT and 'other' were considered.
DVT, deep vein thrombosis; MACE, major adverse cardiovascular event; MI, myocardial infarction; PE, pulmonary embolism; VTE, venous thromboembolism.

Figure. EAIR of AEs by age and CV risk (safety analysis set, as treated)

Table. DAS28-CRP <2.6 and ≤3.2 from LTE baseline to Week 156, by age, CV risk and FIL dose (safety analysis set, observed values)

	<65 y		≥65 y		<65 y without CV risk factor		≥65 y or with ≥1 CV risk factor	
LTE Week	FIL100 n=944	FIL200 n=1256	FIL100 n=255	FIL200 n=274	FIL100 n=419	FIL200 n=640	FIL100 n=780	FIL200 n=890
	Patients achieving DAS28-CRP <2.6 (%)							
Baseline	46.8	54.5	50.8	59.5	48.2	57.4	47.3	54.0
12	49.0	61.3	55.8	62.0	48.8	65.0	51.3	58.9
24	50.5	62.7	55.2	66.3	48.7	64.7	52.9	62.3
48	51.1	64.2	57.8	65.7	51.6	67.2	53.0	62.4
108	54.2	65.0	58.8	70.2	52.3	67.8	56.7	64.3
156	52.9	64.2	58.9	63.5	51.6	62.9	55.4	64.9
	Patients achieving DAS28-CRP ≤3.2 (%)							
Baseline	66.9	73.7	69.8	74.8	68.8	76.3	66.8	72.2
12	66.8	75.7	71.9	74.4	67.3	80.2	68.2	72.1
24	70.4	78.0	70.4	79.2	70.2	80.4	70.5	76.7
48	71.2	79.1	73.3	78.2	71.4	82.3	71.8	76.4
108	70.4	79.8	75.8	82.0	71.2	82.5	71.6	78.3
156	72.0	81.7	77.8	82.6	70.9	81.6	74.5	82.0

No missing data imputation was performed.

Conclusion: This *post hoc* analysis (in pts ≥ 65 y or with ≥ 1 CV risk factor) suggests that age is an important risk factor in the evaluation of the FIL200 safety profile. Future studies are needed to address the relative contribution of age to traditional CV risk factors. In FINCH 4, efficacy was maintained in all subgroups.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Prognosis for chronic inflammatory arthritis is drastically improved over previous decades and older patients are treated with targeted therapies (TTs) (biological or synthetic targeted therapies). Clinical trials provide mainly information about TTs in patients below the age of 65, so real-life studies are needed to provide more information about TTs in patients over 65 years of age.

The aim of the present study was to compare clinical and therapeutic profile of arthritis patients undergoing TTs and to analyze safety and therapeutic survival according to different age groups.

Table1. Comparative analysis of clinical profile of different age groups at the beginning of TTs.

Variable	40-65 years N=719	≥65 years N=219	P-value
	Mean (SD) / n (%)	Mean (SD) / n (%)	
Age at diagnosis (years)	43 (11)	56 (14)	< 0.001
Age at the beginning of treatment (years)	53 (7)	72 (5)	< 0.001
Time from the diagnosis to the beginning of treatment (years)	10 (10)	17 (12)	< 0.001
Treatment duration (months)	73 (66)	52 (52)	< 0.001

Continuing treatment	559 (77.9%)	158 (72.1%)	0.746
Discontinued treatment by:			
Primary non-response	10 (1.4%)	3 (1.4%)	0.895
Secondary non-response	27 (3.8%)	5 (2.3%)	0.401
Other causes	57 (7.9%)	18 (8.2%)	0.999
Adverse events	65 (9.1%)	35 (15.9%)	0.005
• Infection	11 (1.5%)	8 (3.7%)	0.093
• Malignancy	26 (3.6%)	7 (3.2%)	0.932
1st line treatment	444 (61.8%)	99 (45.2%)	< 0.001
Cycling	85 (11.8%)	29 (13.2%)	0.656
Switching	190 (26.4%)	91 (41.6%)	< 0.001

Methods: We performed an observational cross-sectional study in rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS) patients, older than 40 years old, who started biological or anti-JAK therapy between 2000 and 2022. A comparative analysis and a Kaplan-Meier survival analysis was performed.

Results: 938 patients (62% female) were included in the study, of which 20.3% are PsA, 55.6% RA and 24.1% AS, with a mean age at the beginning of treatment of 57 (10) years and a mean duration of treatment of 68 (64) months. Patients were classified according to the age at the beginning of treatment: 40-65 years and ≥ 65 years of age. 219 patients (23.3%) were over 65 years of age. In table1 we show the comparative analysis between both groups.

Higher proportion of arterial hypertension, diabetes mellitus and dislipemia in patients older than 65 years was observed. Using a logistic regression model, an association between conventional DMARD prescription and patients older than 65 years was found (P< 0.001), being the methotrexate the most used (44.8%). Anti-TNF therapy was the most extended treatment in both groups of patients, and an association between anti-IL6 therapy and older patients than 65 years was observed (P< 0.001). Previous TTs were more frequent in older patients (P=0.002) and treatment duration was lower in

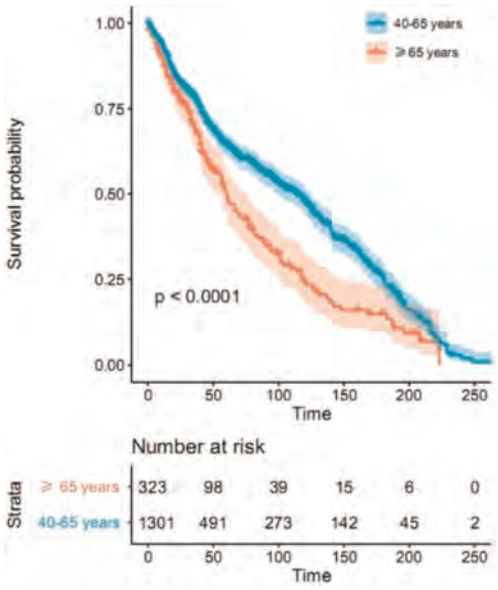

Figure 1

those patients (P< 0.001) (figure1). Adverse events were more commonly found in patients older than 65 years as the reason to TT discontinue (P=0.008), being infections the more frequent.

Conclusion: The use of conventional DMARDs and lower therapeutic survival are more frequent in patients older than 65 years of age.

Adverse events were the main reason of treatment suspension in these patients, with a higher proportion of infections among them in contrast to patients under 65 years old.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with an increased risk of lung cancer compared to the general population. While smoking is a shared risk factor, little is known about the association between use of disease modifying anti-rheumatic drugs (DMARDs) and development of lung cancer. We undertook this study to evaluate the association between use of conventional synthetic (cs) versus biologic (b) or targeted synthetic (ts) DMARDs and incident lung cancer in patients with RA.

Methods: In this retrospective cohort study, we identified Veterans diagnosed with RA in any United States Veterans Affairs facility from 1/1/2002 and 12/31/2018. Criteria for the presence of RA were: two or more International Classification of Diseases Version 9 or 10 (ICD9 or ICD10) diagnosis codes for RA at least 7 days apart but no more than 365 days apart, and a prescription for a csDMARD within 90 days of the first RA diagnosis (index date). The csDMARDs included in these analyses

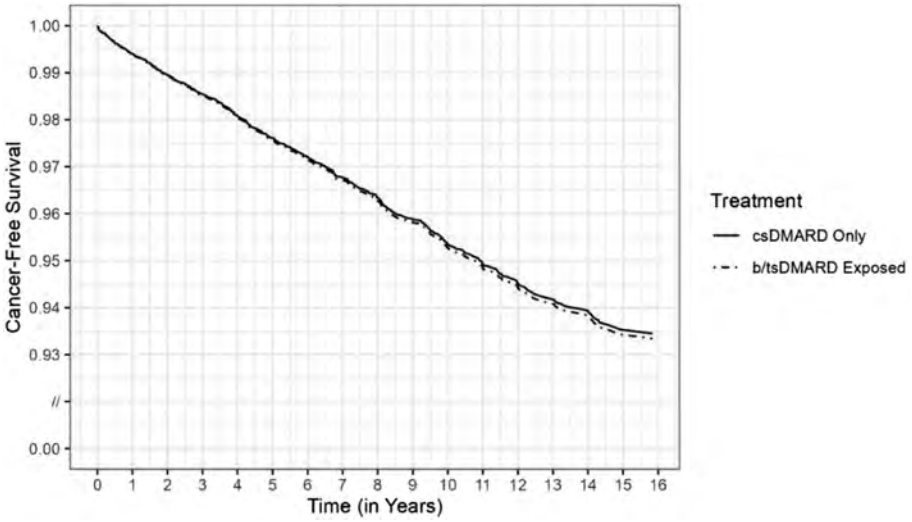

Figure 1. Kaplan Meier curves showing association between use of disease modifying anti-rheumatic drugs and lung cancer.

were: methotrexate, sulfasalazine, leflunomide, and hydroxychloroquine. The bDMARDs included were tumor necrosis factor inhibitors (TNFi) and non-TNFi biologics such as tocilizumab, rituximab, abatacept, and biosimilars; tsDMARDs included tofacitinib and baricitinib. Patients with lung cancer before the diagnosis of RA were excluded. Incident lung cancer was determined by ^{3}2 outpatient ICD9/10 codes, or ^{3}1 ICD9/ICD10/ICDO codes if from inpatient or the oncology raw domain. Drug exposure categories (csDMARD versus b/tsDMARD) were treated as a time-varying variable. Multivariable Cox models were fit to estimate the hazard ratio for developing lung cancer during and following the use of a b/tsDMARD relative to b/tsDMARD-naïve persons adjusting for time-varying age, rheumatic disease comorbidity index (RDCI) and RA interstitial lung disease (RA-ILD, identified using validated administrative algorithms(1)); and baseline sex, race, ethnicity, smoking status, body mass index (BMI), cohort entry (2002-2007, 2008-2013, 2014-2019), rheumatoid factor or anti-CCP positivity, use of opioids, NSAIDs, and steroids. Missing data were imputed using multiple imputation by chained equations.

Results: 26,625 veterans met eligibility criteria, of whom 89% were male and 71% were Non-Hispanic White (**Table 1**). Over a mean (±standard deviation) follow up of 7.0 (±4.5) years, 852 incident lung cancers were detected. The age-standardized incidence among those only on csDMARDs was 4.56 per 1000-person years, compared to 5.33 for those exposed to b/tsDMARDs. In multivariable adjusted models, the hazard ratio for lung cancer in persons who had been treated with a b/tsDMARD was 1.03 (95% confidence interval (CI) 0.87-1.21) relative to those only on csDMARDs (**Figure 1**).

Conclusion: Among Veterans with RA, we observed no evidence of an altered risk of lung cancer associated with different forms of RA treatment. However, incomplete information on cigarette smoking history, along with the relatively short period of follow-up, limit any conclusions that might be drawn.

Rheumatoid Arthritis Disease Activity Indices Assess More Than Inflammation: 29%-36% of Patients with Moderate or High DAS28–ESR or CDAI Have 0 or 1 Swollen Joints, but Positive Screens on MDHAQ FAST4 (fibromyalgia Assessment Screening Tool) And/or MDS2 (MDHAQ Depression Screen) Indices

Theodore Pincus[1], Nicholas Rodwell[2] and Rahel Hunter[1], [1]Rush University Medical Center, Chicago, IL, [2]University of New South Wales, Sydney, Australia

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) therapy is recommended to be intensified according to treat-to-target if DAS28 (disease activity score 28) or CDAI (clinical disease activity index) indicate high/moderate (H/M) activity, although exceptions based on shared decisions are recognized. Comorbid fibromyalgia (FM) and/or depression (DEP) may raise DAS28 and CDAI, independent of inflammation, but often are underrecognized in routine care. A multidimensional health assessment questionnaire (MDHAQ) provides validated feasible screening indices for FM and DEP, FAST4 (fibromyalgia assessment screening tool) (ACR Open Rheum 2019;1:516) and MDS2 (MDHAQ depression screen) (Arth Care & Res 2021;73:120), which agree more than 80% with reference standards, on a single MDHAQ, completed by most patients in 5-10 minutes. We hypothesized that some patients in DAS28-ESR or CDAI H/M vs low/remission (L/R) would have 0 or 1 vs ≥2 swollen joint counts (SJC), but positive vs negative MDHAQ FAST4 and/or MDS2 screens.

Methods: A cross-sectional study at a routine care visit included DAS28 and CDAI. Patients competed an MDHAQ to score patient global assessment, fatigue, 0-3.3 DEP query, self-report 0-54 RADAI painful joint count, 60-symptom checklist (Sx), medical history queries, and FAST4 [positive (+) if 3/4: pain VNS ≥6/10, fatigue VNS ≥6/10, RADAI ≥16/54, and/or Sx

	Total (Row%)(Col%)	SJC 0,1 (Row%)(Col%)	SJC≥2 (Row%)(Col%)	FAST4 FM- MDS2 DEP- (Row%)(Col%)	FAST4 FM+ OR MDS2 Dep+ (Row%)(Col%)	SJC 0,1 & FAST4 FM+ OR MDS2 Dep+ (Row%)(Col%)
DAS28-ESR: Total	128	88 (69%) (100%)	40(31%) (100%)	74(58%)(100%)	54 (42%) (100%)	32 (25%) (100%)
Remission/low(R/L)	76(100%) (59%)	63(83%) (72%)	13(17%) (33%)	52 (68%) (70%)	24 (32%) (44%)	17 (22%) (53%)
Moderate/high(M/H)	52(100%) (41%)	25(48%) (28%)	27(52%) (68%)	22 (42%) (30%)	30 (58%) (56%)	15 (50% of FM+ and/or DEP+) (60% of all M/H and SJC 0,1)
Chi-square			P<0.0001		P=0.003	
CDAI: Total 140	140	95(68%) (100%)	45 (32%)(100%)	79(56%)(100%)	61(44%) (100%)	36 (26%) (100%)
Remission/low(R/L)	61(100%)(44%)	55(90%)(58%)	6(10%) (13%)	50 (82%)(63%)	11(18%) (18%)	9 (15%) (25%)
Moderate/high(M/H)	79(100%)(56%)	40(51%)(42%)	39(49%)(87%)	29(37%)(37%)	50(63%) (82%)	27 (54% of FM+ and/or DEP+) (68% of all M/H and SJC 0,1)
Chi-square			P<0.0001		P<0.0001	

Number of RA patients in DAS28-ESR or CDAI remission/low (R/L) vs moderate/high (M/H), swollen joint count (SJC) 0 or 1 vs ≥2 and MDHAQ FAST4 and MDS2 negative (-) vs FAST4 and/or MDS2 positive (+) for fibromyalgia and/or depression; highlighted numbers focus on patients with DAS28- ESR or CDAI M/H and SJC 0 or 1 and/or FAST4+ and/or MDS2+

≥16/60] and MDS2 [+ if a 0-3 DEP query is ≥2 or positive DEP on Sx). The numbers of patients in H/M vs L/R DAS28-ESR and CDAI, SJC 0/1 vs ≥2 and FAST4 + vs negative (-) and MDS2+ vs - status were analyzed using chi-square statistics.

Results: Median age was 61.3 years, median disease duration 10 years, and 75% of patients were female. DAS28-ESR and CDAI M/H vs L/R differed significantly according to SJC, as expected; R/L included 0/1 SJC in 83% of DAS28–ESR and 90% of CDAI ($p< 0.001$) (Table). However, M/H with 0/1 SJC was seen in 25/52 (48%) by DAS28-ESR and 40/79 (51%) by CDAI. DAS28-ESR and CDAI M/H vs L/R also differed significantly according to FAST4 and MDS2 status, somewhat unexpectedly (Table): 68% of DAS28-ESR L/R were FAST4-,MDS2- while 58% of M/H were FAST4+ &/or MDS2+ ($p=0.003$); 50/61 (82%) of CDAI L/R were FAST4-,MDS2-, while 50/79 (63%) of M/H patients were FAST4+ &/or MDS2+ ($p=< 0.0001$) (Table). Patients classified as M/H but with SJC of 0/1 included 15 for DAS28 (50% of 30 M/H and FAST4+ &/or MDS2+, 60% of 25 with M/H and SJC 0/1, and 29% of all 52 M/H patients), and 27 for CDAI (54% of 50 M/H and FAST4+ &/or MDS2+, 68% of 40 with M/H and SJC 0/1, and 34% of all 79 M/H patients) (Table).

Conclusion: Treat-to-target is a useful guideline for most RA patients. However, a sizable majority in H/M DAS28–ESR or CDAI have 0/1 SJC and may not be candidates for therapy escalation. About half of patients with high index scores and 0/1 SJC have comorbid FM or and/or DEP, which can be feasibly screened for with FAST4 and MDS2 indices on a single MDHAQ. Patients with DAS28-ESR or CDAI H/M vs L/R differed significantly in MDHAQ FAST4+ or - and/or MDS2 + or - indices for FM and DEP. Recognition that FM and DEP may elevate RA index scores is analogous to recognition that an elevated ESR may result from a cause other than inflammation. An MDHAQ, completed by most patients in 5-10 minutes, can help rheumatologists interpret RA index scores.

Rosnilimab, a Novel PD-1 Agonist Monoclonal Antibody, Inhibits Peripheral T Cell Proliferation and Cytokine Secretion and Reduces Circulating PD-1 High Expressing CD4 and CD8 T Cells: Results from a Phase 1 Healthy Volunteer Clinical Trial

Kenneth Luu, Martin Dahl, Eric Hare, Cailin Sibley, Paul Lizzul and Bruce Randazzo, AnaptysBio, San Diego, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: PD-1 pathway mutations increase human susceptibility to multiple autoimmune diseases, and insufficient PD-1 signaling can lead to dysregulated T cell responses. By targeting natural immune regulatory mechanisms to modulate immune cells driving disease, there is an opportunity to dampen the inflammatory cycle and restore immune balance. Rosnilimab is a PD-1 agonist antibody designed to inhibit activated T cells for the treatment of inflammatory diseases, including rheumatoid arthritis (RA).The primary objective of this first-in-human (FIH), healthy volunteer (HV) Phase 1 study was to assess the safety and tolerability of single ascending doses (SAD) and multiple ascending doses (MAD) of rosnilimab. Other objectives included the assessment of pharmacokinetic (PK) profile, immunogenicity, and translational

pharmacodynamic (TPD) endpoints (e.g. PD-1 receptor occupancy (RO), reduction in various T cell populations and associated cytokine signaling).

Methods: This study was conducted at a single study center in the United States with 14 cohorts in SAD and 3 cohorts in MAD. Each cohort had 8 participants (6 active, 2 placebo (PBO)). Treatment cohorts were enrolled sequentially in each SAD/MAD phase. Intravenous (IV) and subcutaneous (SC) routes of administration were assessed in the SAD; SC route was assessed in the MAD.

Results: A total of 144 participants were enrolled; 90 randomized to the active SAD cohorts, 18 to the active MAD cohorts, and 30 and 6 randomized to the SAD and MAD PBO cohorts, respectively. All participants were assessed for safety and PD. Rosnilimab was well tolerated, with no dose-limiting toxicities or deaths. Two serious adverse events (SAEs) were reported in the SAD (obstructive pancreatitis in a PBO-dosed participant; COVID-19 infection in a rosnilimab-dosed participant leading to discontinuation; unrelated to treatment).No SAEs were reported in the MAD. TPD activity was rapid with sustained reduction in quantity and functional activity of PD-1+ T cells. Conventional T (Tcon) cells in the periphery expressing PD-1 were reduced, on average through Day 30 in the SAD where full RO was sustained following rosnilimab dosing, by ∼50% in both CD4+ and CD8+ subsets, in a dose-dependent manner and in correlation with RO.This reduction was maximized on PD-1 high expressing T cells, ∼90% reduction relative to baseline. There was no significant impact on the overall total T cell, Tcon or regulatory T (Treg) cell numbers, thereby resulting in an observed bias in favor of Treg:Tcon cell ratio post-dosing. An antigen-specific functional T cell assay measuring *ex vivo* interferon-gamma release in response to antigen challenge was inhibited up to ∼90% relative to baseline within 30 days following a single dose. Rosnilimab has a favorable PK profile consistent with full RO, a two-week half-life, and exposure nearly dose-proportional in both IV and SC dosing.

Conclusion: Rosnilimab demonstrated favorable safety, PK, and TPD activity. These results demonstrate proof of mechanism in humans and support advancing rosnilimab into a phase 2b study in RA.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Strong clinical predictors for response to biologic and targeted synthetic disease modifying rheumatic drugs (b/tsDMARDs) in rheumatoid arthritis (RA) have yet to be identified. The majority of studies test associations between individual clinical factors, e.g., age, disease duration, with treatment response. Alternatively, individual variables

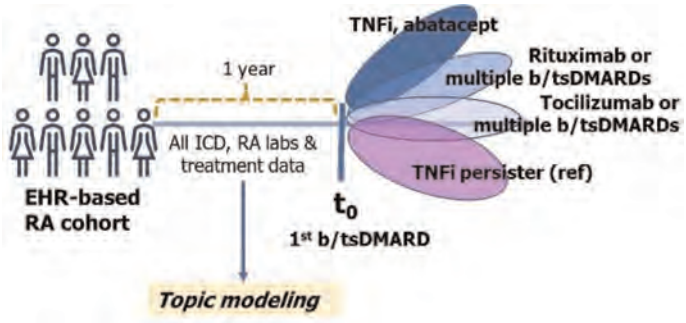

Figure 1. Study design to identify "topics" in an RA cohort using structured electronic health record (EHR) data in the year prior to initiating the 1st b/tsDMARD (t0); subsequent analyses test the associations between the topics and the 4 main treatment patterns after 1st b/tsDMARD identified from a prior study.

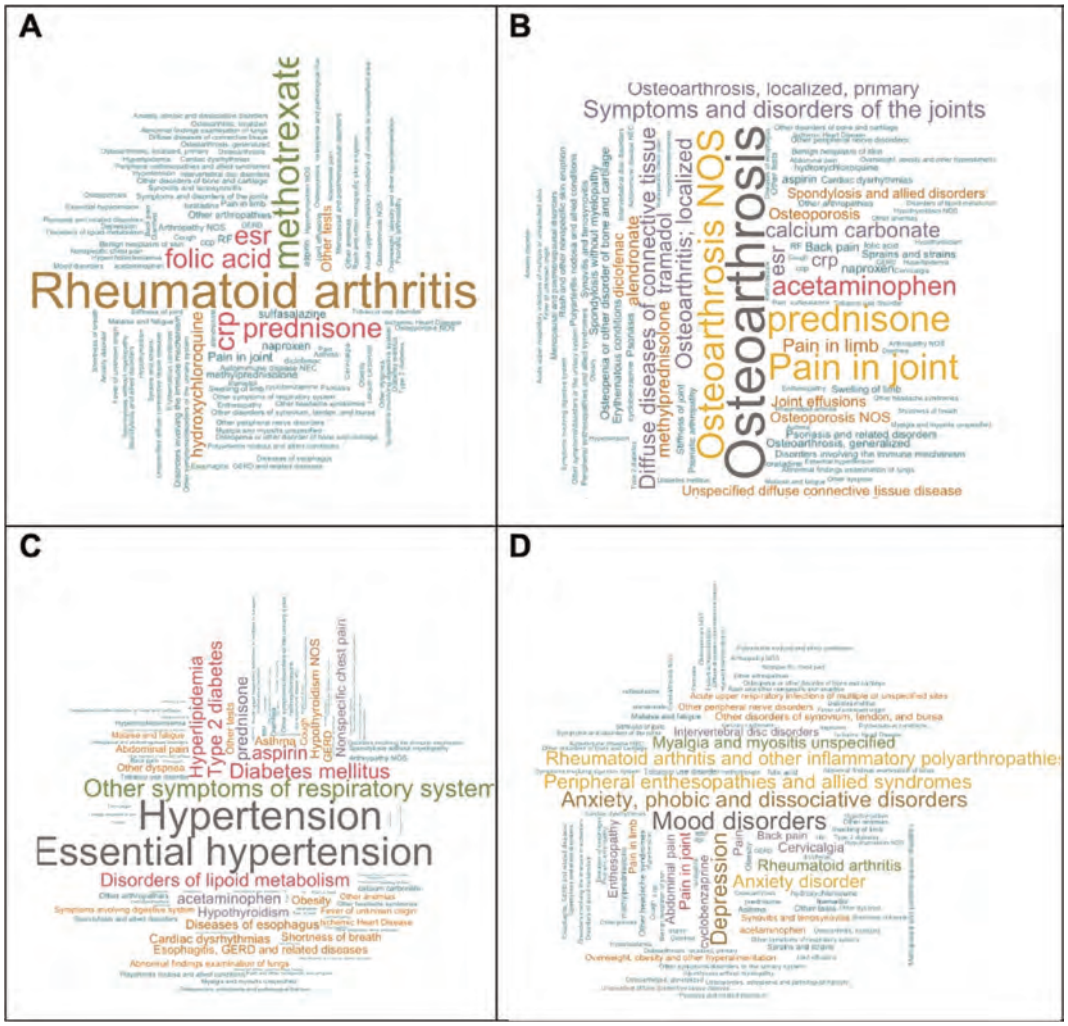

Figure 2. Four main topics identified using all ICD codes, RA-related laboratory data and medications in the year prior to initiating 1st b/tsDMARD named by the predominant features: (A) RA on MTX, (B) arthralgia, (C) hypertension and other CV comorbidities, (D) mood disorders.

can be grouped as a theme or topic, and then tested for association with an outcome, treatment response. Identifying potential topics using a data-driven method can be accomplished using topic modeling. Topic modeling performed on words in a newspaper grouped "music, film, performance" and "market, stock, share" into 2 topics, identifying

Table 1. Association between topics (top row) prior to initiating b/tsDMARD with future RA treatment course.

Treatment course	(A) Early RA		(B) Arthralgia		(C) HTN & CV		(D) Mood disorders	
	OR	p-value	OR	p-value	OR	p-value	OR	p-value
TNFi persisters	REF	-	REF	-	REF	-	REF	-
TNFi to abatacept	1.2	NS	0.56	NS	1.3	NS	0.92	NS
Rituximab	0.18	$1.2x10^{-6}$	1.4	NS	10.3	$1.2x10^{-6}$	0.94	NS
Tocilizumab	0.34	$1.1x10^{-3}$	1.6	NS	3.6	$2.0x10^{-3}$	1.4	NS

NS=not significant

entertainment vs finance-related terms respectively. The objective of this study was to identify the topics in a cohort of RA patients using their electronic health record (EHR) data prior to starting b/tsDMARDs, and to determine the association of these topics to their future b/tsDMARD treatment course.

Methods: We studied subjects from a validated EHR based RA cohort who initiated their 1st b/tsDMARD 2011-2019.In a previously published study, subjects were categorized based on the similarity of their treatment course after their 1st b/tsDMARD: (1) tumor necrosis factor inhibitor (TNFi) persister, (2) TNFi to abatacept, multiple b/tsDMARD and (3) rituximab or (4) tocilizumab (**Figure 1**). Structured EHR data: ICD codes, RA related laboratory data, e.g., anti-CCP, and RA related medication prescription data, e.g., prednisone, methotrexate (MTX), in the year prior to their first b/tsDMARD initiation (t_0) were extracted; all variables had prevalence at least 5%.Latent Dirichlet Allocation (LDA), a topic modeling method, was applied to group the structured EHR data into topics. Multinomial regressions were constructed to test the associations between the 4 topics across the treatment courses in comparison to TNFi persisters (reference group), adjusting for age, sex, self-reported race, and year of 1st b/tsDMARD.

Results: We studied 1102 RA subjects, mean age 53 years, 77% female, 64% rheumatoid factor (rf), 76% were on TNFi at t_0.The LDA model grouped the structured EHR data into 4 main topics: (a) RA on MTX, (b) arthralgia, (c) hypertension (HTN) and cardiovascular (CV) comorbidities, (d) mood disorders (**Figure 2**).Subjects in the RA/MTX topic cluster in the year prior to their 1st b/tsDMARD use had a higher-odds of eventually becoming TNFi persisters compared to those who will belong to the multiple b/tsDMARD/tocilizumab or rituximab groups (**Table 1**). Subjects belonging to the HTN/CV comorbidities topic had a lower-odds of belonging to the TNFi persister group compared to the multiple b/tsDMARD/tocilizumab or rituximab groups. Arthralgias and mood disorders did not associate more strongly with any future treatment course.

Conclusion: Topics derived from the structured EHR data of RA subjects prior to their 1st b/tsDMARD identified 2 topics differentiating future TNFi persisters vs those requiring multiple b/tsDMARDs.Topic modeling can provide an alternative method to study potential predictors for outcomes in RA and other rheumatic conditions.

Biologic Disease Modifying Antirheumatic Drug Use in Immune Checkpoint Inhibitor-Treated Cancer Patients with Rheumatoid Arthritis: Utilization and Overall Survival

Deanna Jannat-Khah[1], Jeffrey R Curtis[2], Fenglong Xie[3], Ashish Saxena[4] and Anne Bass[5], [1]Hospital For Special Surgery, New York, NY, [2]Division of Clinical Immunology and Rheumatology, University of Alabama, Birmingham, AL, [3]University of Alabama at Birmingham, Birmingham, AL, [4]Weill Cornell Medicine, New York, NY, [5]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: There is a dearth of knowledge around the safety of biologic disease modifying antirheumatic drugs (bDMARDS) in immune checkpoint inhibitor (ICI)-treated rheumatoid arthritis (RA) patients with cancer. The goal of this study was to quantify the association between bDMARD use after ICI initiation and overall survival (OS) in RA patients with metastatic non-small cell lung cancer (mNSCLC), melanoma and urothelial cancer.

Methods: We used a curated Medicare claims dataset that consists of a 100% sample of patients with RA. We included patients ≥ 66 years of age with both a diagnosis of RA and of mNSCLC, melanoma or urothelial cancer, who initiated nivolumab, pembrolizumab or atezolizumab 2015-2019 and who received an intravenous (IV) bDMARD at some time during the year prior to ICI initiation. ICI and DMARD use were identified using J and C codes. We limited the study to IV bDMARDs because the timing of administration can be accurately ascertained. Patients with mNSCLC, melanoma and urothelial cancers were required to have two claims associated with the relevant ICD-9-CM or ICD-10-CM codes. RA was defined as having two claims associated with an ICD-9-CM or ICD-10-CM diagnosis code for RA. Patients who took a specific bDMARD after ICI initiation were compared to patients who took the same bDMARD in the year prior, but not in the year after ICI initiation. Kaplan Meier (KM) curves and cox proportional hazard models (CPHM) (un-adjusted, age and ICI adjusted) were created to measure OS from first ICI initiation. Patients were followed through 12/31/2019 and were censored at time of death or last recorded visit in the database.

Results: A total of 6350 ICI-treated RA patients with mNSCLC, melanoma, and urothelial cancer were identified. Of these, only 466 (7.3%) received an IV bDMARD in the year prior to ICI initiation. 166/466 (35.6 %) took the same DMARD in the 1 year after ICI initiation. Overall median follow up was 186.5 days (IQR 76, 355). Patients who took a bDMARD prior to ICI only were more likely to be female than those who continued/initiated that bDMARD after ICI initiation (63.3% vs 51.2%, p= 0.011) (Table1). Figure 1 displays the KM curves comparing patients who continued/initiated a TNFi after ICI initiation to those who took a TNFi only prior to ICI initiation (1A, log rank p-value 0.02) and a similar analysis for Rituximab (1B; p-value 0.06). In CPHM for mNSCLC, patients who took an IV TNFi only prior to ICI initiation had worse OS than those who continued/initiated a TNFi after ICI initiation (Table 2). Adjusted models for other cancers and other IV DMARDS were not statistically significant.

Conclusion: Few RA patients with mNSCLC, melanoma, and urothelial cancer use IV bDMARDS in the year prior to ICI initiation, even among those who were previously receiving them before their cancer diagnosis. Patients who continued/initiated an IV TNFi after ICI initiation appear to have better OS than patients who take a TNFi only prior to ICI initiation. However, this may reflect unmeasured differences between these two groups, such as the use of concomitant chemotherapy, number of prior cancer treatments or comorbidities, which we will address in further analyses.

Drug Switching Due to Inefficacy in Rheumatoid Arthritis Patients Treated with Biological and Targeted Therapies. Daily Clinical Experience

Maria Rodriguez Laguna[1], Zulema Rosales-Rosado[2], Cristina Vadillo-Font[1], Jose Pierre Otazu-Moudelle[1], Inés Pérez Sancristóbal[1] and lydia Abasolo[2], [1]Hospital Clinico San Carlos, Madrid, Spain, [2]Hospital Clínico San Carlos, Madrid, Spain

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The treatment of Rheumatoid Arthritis (RA) has undergone an enormous change in the last two decades with the use of biological Disease Modifying Drugs and targeted therapies (ts/bDMARDs). These drugs are widely used in clinical practice, but we have scarce information about the switching between them in these conditions due to inefficacy. Our objective is to evaluate the incidence rate of switching due to inefficacyas well as the factors associated to switching due to inefficacy.

Methods: We conducted an observational longitudinal retrospective study. Subjects: all patients with recent onset RA diagnosed between January 1st 2007 and December 31st 2015 followed in outpatient clinic at Hospital Clinico San Carlos until January 1st 2022, which used any ts/bDMARDs during at least 3 months. Main outcome: Switching of the ts/bDMARD (suspension and change to a different ts/bDMARD) due to inefficacy. Covariables: sociodemographic, clinical and treatment. Statistical analysis: incidence rates of switching due to inefficacy (IR) per 100 patient-years were estimated using survival techniques with their respective 95% confidence interval [CI]. A multivariate Cox regression analysis was used to evaluate the risk factors of switching due to inefficacy. Results were expressed as HR with their 95% CI.

Table 1. Baseline sociodemographic characteristics.

Variables	N= 186
Women, n (%)	152 (81.72)
Age; media ± SD	52.37 ± 13.8
Smokers (n= 177), n (%)	31 (17.51)
Positive rheumatoid factor + (n=184), n (%)	119 (64.67%)
Positive anti-citrullinated protein antibodies + (n=181); n (%)	101 (55.8)
ESR (n=), media ± SD mm/h	41.55 ± 28.42
ts/bDMARDS; n (%)	
TNF inhibitor	213 (61.38)
Rituximab	50 (14.41)
Abatacept	31 (8.93)
IL6 inhibitor	25 (7.20)
JAK inhibitor	28 (8.1)
Combined treatment, n(%)	
Methotrexate	96 (51.61)
NSAIDs	156 (83.87)
Glucocorticoids	66 (35.48)

Table 2. Incidence rates of drug switching due to inefficacy per 100 *patient year in RA patients treated with biological and targeted therapies.

	SWITCHING			
	Patients/year	N	IR	95%CI
Total	918.12	88	9.95	7.77-11.81

JAK inhibitor	51.38	4	7.78	2.92-20.74

Table 3. Multivariate analysis of drug switching due to inefficacy in RA patients treated with biological and targeted therapies.

	SWITCHING		
	HR	95%CI	P
Age < 46 years	0.98	0.97-1.01	0.22
Male	0.45	0.21-0.98	0.04
≥3 courses of treatment	1.72	1.07-2.76	0.025
By ts/bDMARDs			
TNF inhibitor	1	-	-
Rituximab	0.68	0.33-1.39	0.296
Abatacept	1.78	0.97-3.27	0.060
IL-6 inhibitor	0.79	0.31-1.98	0.61
JAK2 inhibitor	0.70	0.23-2.10	0.52

Results: 186 patients were included (927.86 patient-years), 81.72% were women with a mean age of 52.38±13.80. Characteristics at baseline are shown in table 1. The 186 patients received 347 courses of ts/bDMARD treatment of which 88 were switched due to inefficacy (25.36%) with an IR of inefficacy of 9.58 [7.77-11.81]. The most frequent ts/bDMARD group was TNFi (61.38%), specifically Etanercept (21.90%). IRs of switching due to inneficacy are shown in table 1, we found a higher IR in the female sex (IR 10.67 [8.57-13.28]), younger patients (IR 13.50 [10.37-17.59], subsequent courses of treatment (IR 14.34 [10.70-19.20]), with the concomitant use of corticoids (IR 10.22 [8.14-12.83]), and with the use of certain ts/bDMARDs (IR Abatacept 23.38 [12.58-43.45], IR anti-IL6 10.43 [4.68-23.23], IR anti-TNF 9.54 [7.39-12.32], IR JAKi 7.78 [2.92-20.74], IR Rituximab 6.06 [3.15-11.65]). In the multivariate analysis (table 2) we found a higher risk for switching due to inefficacy in patients receiving the third or posterior course of treatment (HR 1.72 [1.07-2.77]) and a tendency in patients in treatment with abatacept compared to anti-TNF (HR 1.79 [0.98-3.28]); the male sex was a protective factor for switching due to inefficacy (HR 0.46 [0.21-0.98]).

Conclusion: Switching of ts/bDMARDs in daily clinical practice due to inefficacy appears with certain regularity (25.36%) with an estimated IR of 9.58. We have found higher switching rates of ts/bDMARDs due to inefficacy in the female sex, younger patients, subsequent courses of treatment, concomitant use of corticoids as well as with some ts/bDMARDs in specific (Abatacept and anti-IL6). Patients receiving the third or posterior course of treatment had a higher risk of switching due to inefficacy meanwhile the male sex acted as a protective factor; treatment with abatacept seemed to have a higher risk to switching due to inefficacy but it did not reach statistical significance.

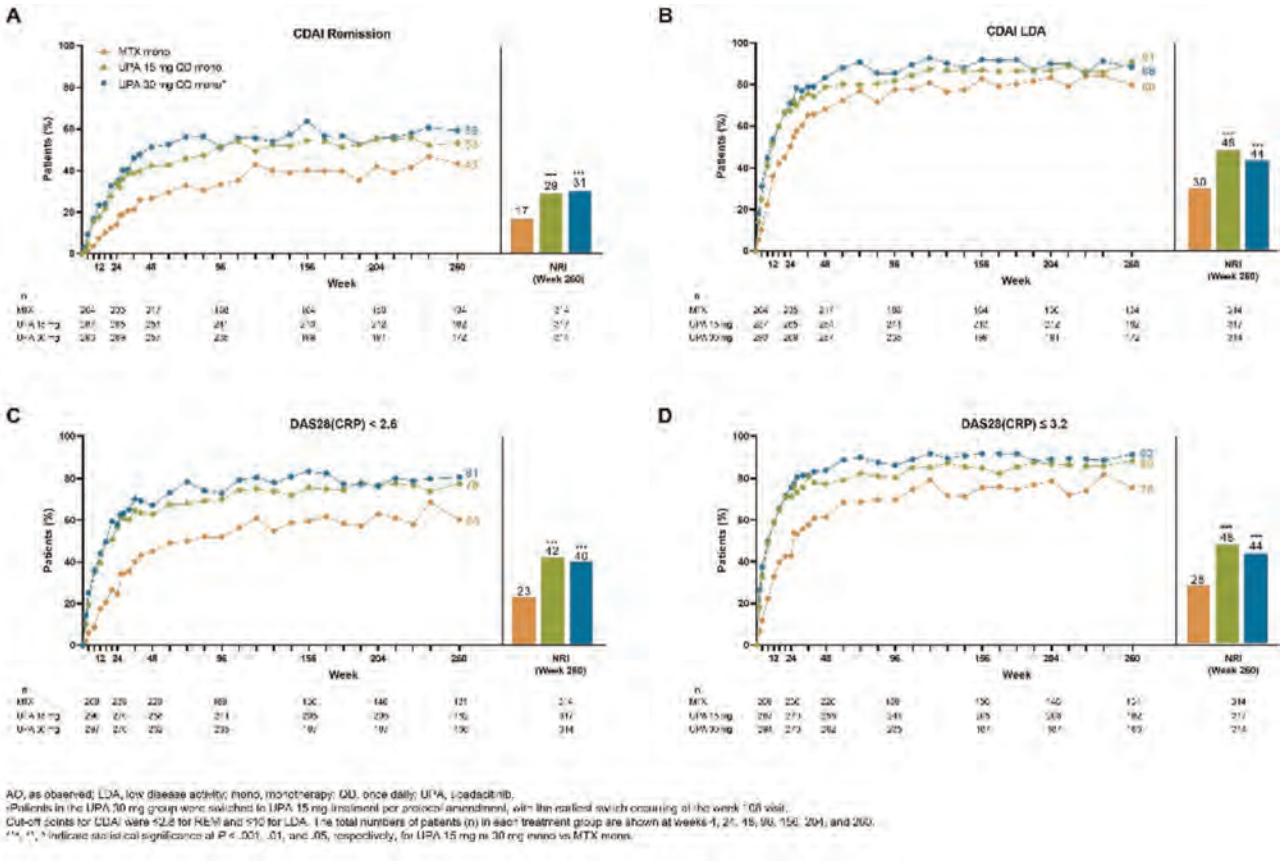
SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: RA – Treatments Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

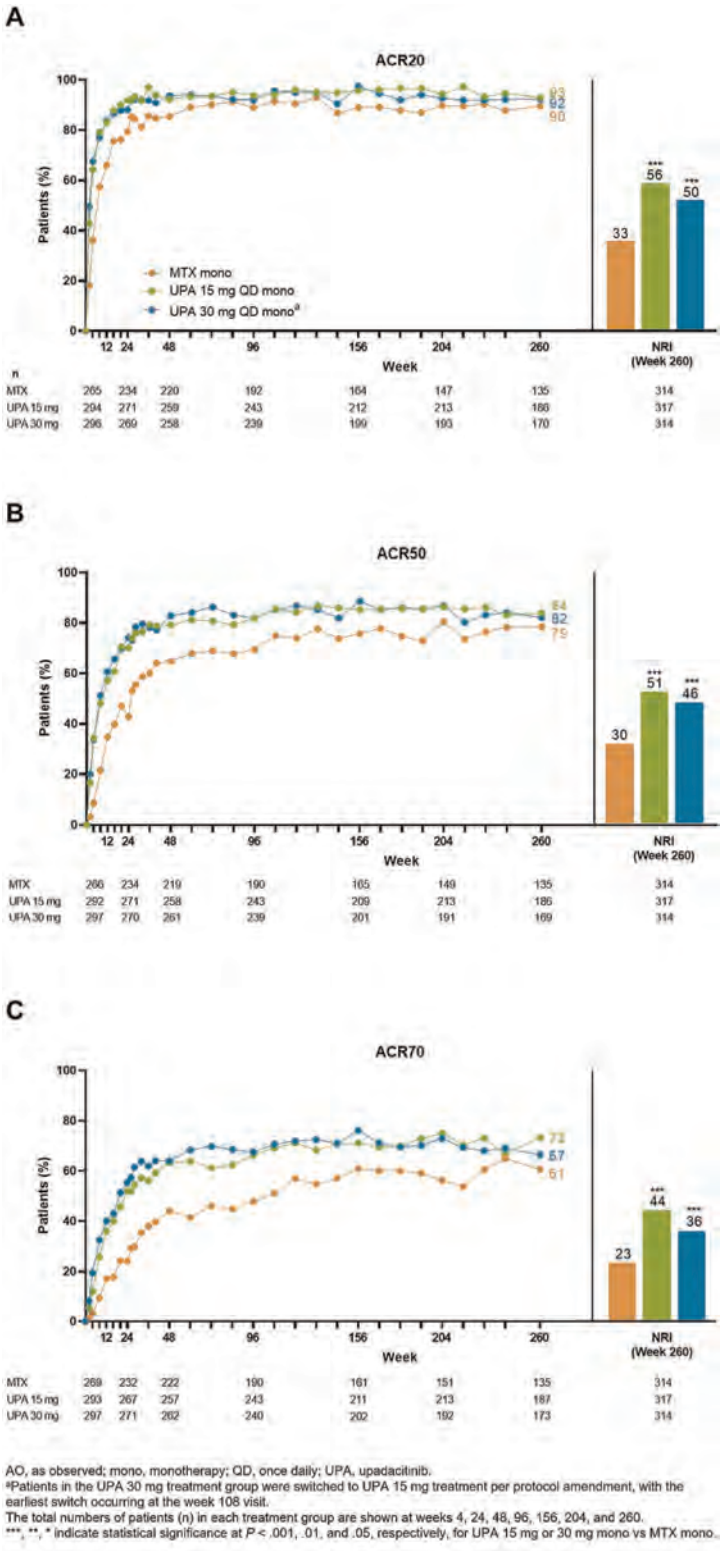
Background/Purpose: To evaluate the efficacy and safety of upadacitinib (UPA) monotherapy vs MTX monotherapy over 5 yrs among MTX-naïve patients with moderately to severely active RA in the long-term extension (LTE) of the phase 3 SELECT-EARLY trial.

Methods: Patients were randomized 1:1:1 to receive once daily UPA 15 mg or 30 mg or MTX (titrated up to 20 mg/wk by wk 8).[1] At wk 26, patients who did not achieve CDAI remission (≤2.8) with < 20% improvement from baseline in TJC or SJC received rescue therapy (addition of MTX to insufficient responders in the UPA groups and addition of UPA 15/30 mg [by re-randomization] to insufficient responders in the MTX group). For patients who did not achieve CDAI remission but had ≥20% improvement in TJC and SJC at wk 26, background RA medications were optimized while patients remained on their original study drug. Per protocol amendment, all patients receiving UPA 30 mg were switched to the approved 15 mg dose, with the earliest switch occurring at wk 108. Efficacy assessments were evaluated over 5 yrs and are reported



AO, as observed; LDA, low disease activity; mono, monotherapy; QD, once daily; UPA, upadacitinib.
*Patients in the UPA 30 mg group were switched to UPA 15 mg treatment per protocol amendment, with the earliest switch occurring at the week 108 visit.
Cut-off points for CDAI were ≤2.8 for REM and ≤10 for LDA. The total numbers of patients (n) in each treatment group are shown at weeks 4, 24, 48, 96, 156, 204, and 260.
*, **, *** Indicate statistical significance at $P < .001$, .01, and .05, respectively, for UPA 15 mg or 30 mg mono vs MTX mono.

Figure 1. Proportions of Patients Achieving CDAI or DAS28(CRP) Disease Activity States Through 5 Years (AO, NRI)



AO, as observed; mono, monotherapy; QD, once daily; UPA, upadacitinib.
[a]Patients in the UPA 30 mg treatment group were switched to UPA 15 mg treatment per protocol amendment, with the earliest switch occurring at the week 108 visit.
The total numbers of patients (n) in each treatment group are shown at weeks 4, 24, 48, 96, 156, 204, and 260.
***, **, * indicate statistical significance at $P < .001$, .01, and .05, respectively, for UPA 15 mg or 30 mg mono vs MTX mono.

Herpes zoster	7 (0.8)	41 (3.9)	33 (4.5)	12 (4.1)
Malignancies (excluding NMSC)	8 (0.9)	6 (0.6)	8 (1.1)	5 (1.7)
NMSC	0	4 (0.4)	8 (1.1)	6 (2.1)
CPK elevation[d]	12 (1.4)	68 (6.4)	106 (14.3)	14 (4.8)
MACE (adjudicated)[e]	3 (0.3)	3 (0.3)	4 (0.5)	1 (0.3)
VTE (adjudicated)[f]	5 (0.6)	3 (0.3)	4 (0.5)	1 (0.3)
Neutropenia	15 (1.7)	34 (3.2)	41 (5.5)	11 (3.8)
Lymphopenia	28 (3.3)	17 (1.6)	23 (3.1)	6 (2.1)
Anemia	37 (4.3)	45 (4.2)	28 (3.8)	8 (2.7)
GI perforation (adjudicated)	0	0	4 (0.5)	0
COVID-19	23 (2.7)	34 (3.2)	6 (0.8)[g]	39 (13.3)[g]
All deaths[h,i]	8 (0.9)	6 (0.6)	9 (1.2)	5 (1.7)
Deaths ≤30 days after last dose	1 (0.1)	3 (0.3)	8 (1.1)	3 (1.0)
Deaths >30 days after last dose	7 (0.8)	3 (0.3)	1 (0.1)	2 (0.7)

AE, adverse event; CPK, creatine phosphokinase; GI, gastrointestinal; NMSC, nonmelanoma skin cancer; PY, patient-years; QD, once daily; UPA, upadacitinib.
[a]Treatment-emergent adverse event is defined as any adverse event with an onset date that is after the first dose of study drug, and no more than 30 days after the last dose of study drug. Data include patients receiving UPA or MTX monotherapy, censored at either time of rescue to UPA + MTX or with addition of background conventional synthetic DMARD.
[b]UPA 30 mg exposure was censored at time of dose switch to the approved 15 mg dose. Safety outcomes following the switch from UPA 30 mg to UPA 15 mg are reported separately (last column).
[c]Opportunistic infections exclude herpes zoster and tuberculosis (TB). No cases of TB were reported on MTX monotherapy during the study, while 2 cases were reported for each the UPA 15 mg and 30 mg mono groups.
[d]Most CPK events were asymptomatic and transient.
[e]Defined as cardiovascular death, non-fatal myocardial infarction, and non-fatal stroke
[f]Includes pulmonary embolism and deep vein thrombosis.
[g]Given the timing of the study, the lower rate of COVID-19 observed in the UPA 30 mg group is due to the majority of patients in this group having been switched to UPA 15 mg by the onset of the COVID-19 pandemic (and, conversely, why rates are higher in the UPA 15 mg switched from 30 mg group).
[h]Five of these deaths were COVID-19-related: 2 on UPA 30 mg mono and 3 on UPA 15 mg mono switched from UPA 30 mg mono.
[i]Additionally, 1 death occurred in a patient receiving UPA 30 mg plus background MTX, and 2 deaths (both COVID-19-related) occurred in patients on background MTX who switched from UPA 30 mg to UPA 15 mg.

as observed (AO) for patients who received continuous monotherapy with UPA 15/30 mg or MTX. Results at wk 260 are also reported by randomized group for all patients, applying NRI for patients who were rescued or discontinued, with nominal *P* values. Treatment-emergent adverse events (TEAEs) per 100 patient-yrs were summarized over 5 yrs for those receiving monotherapy.

Results: Of 945 patients randomized and treated, 775 (82%) completed wk 48 and entered the LTE on study drug. Of these 775 patients, 255 (27%) discontinued study drug during the LTE due to the following primary reasons: TEAEs (9%), withdrawal of consent (7%), lack of efficacy (2%), lost to follow-up (3%), or other reasons (6%). Patients receiving UPA consistently demonstrated higher achievement of disease activity targets over 5 yrs compared with MTX (**Figure 1, 2**). In AO analyses, 53%/59% of patients attained CDAI remission with UPA 15/30 mg vs 43% on MTX at wk 260. NRI analyses also showed better CDAI, DAS28(CRP), and ACR/20/50/70 responses with UPA relative to MTX at wk 260 (nominal $P < .001$). Most TEAEs were numerically most frequent in patients receiving UPA 30 mg (**Table**). The rates of serious infections, herpes zoster, CPK elevation, nonmelanoma skin cancer (NMSC), and neutropenia were

numerically higher with UPA than MTX. The overall rates of MACE, VTE, malignancy excluding NMSC, and lymphopenia were comparable across treatments. Rates of death were similar between UPA 15 mg and MTX but numerically higher with UPA 30 mg. Overall, the observed safety profile of UPA over 5 yrs was consistent with earlier results from this trial and the integrated phase 3 safety analysis.[1-3]

Conclusion: UPA 15 mg or 30 mg showed better clinical responses vs MTX in patients with RA throughout the 5-yr trial. Higher rates of several AEs, including serious infection, herpes zoster, and CPK elevation were observed with UPA compared to MTX. When used as monotherapy in MTX-naïve patients, UPA has better long-term efficacy vs MTX and a favorable benefit-risk profile.

Knowledge Related to Fertility and Infertility Treatments Among Women with Systemic Rheumatic Disease

Sanjana Adurty[1], Lucy Masto[2], Amaya Smole[2], Caroline Siegel[2], Sarah Lieber[3], Jonah Levine[2], Bessie Stamm[2], Lisa Mandl[3], Michael Lockshin[3], Medha Barbhaiya[3] and Lisa Sammaritano[3], [1]Weill Cornell Medical College, New York, NY, [2]Hospital for Special Surgery, New York, NY, [3]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Reproductive Issues in Rheumatic Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Fertility awareness is low in the population and is influenced by disparities in race, ethnicity, and socioeconomic status. Because systemic rheumatic disease (SRD) contributes to decreased fertility, identifying knowledge gaps and underlying factors among affected women is a key step towards improved counseling on fertility therapies. Here, we use a previously published instrument to determine whether fertility knowledge is affected by having an SRD or by other medical or sociodemographic factors.

Methods: We enrolled women ages 18-65 seen ≥2 times by a Hospital for Special Surgery rheumatologist from 2020-2022 in the Rheumatology Women's Reproductive Health and Wellness Cohort; cohort enrollment is ongoing. This is an interim analysis that includes women aged 18-45 years with self-reported SRD, to whom we administered the Fertility & Infertility Treatment Knowledge Score (FIT-KS) (1). Using descriptive statistics, we compared FIT-KS scores in women with SRD to scores of reproductive-aged women in the general population, as previously published by Kudesia et al. Among women with SRD, we compared those with a total score ≥19 on the FIT-KS ("high scorers") and those who scored < 19 ("low scorers") in terms of sociodemographic, lifestyle, medical, and reproductive factors.

Results: In this interim analysis, 142 reproductive-aged women with SRD completed the FIT-KS, with a median total score of 18 (62% correct out of 29 questions) (Table 1). Compared to women in the general population, women with SRD were more frequently non-White (p=0.04) and Hispanic/Latina (p=0.02), more highly educated (p< 0.01), and less likely to have

Table 1. Fertility awareness among reproductive-aged women with SRD compared to a previously published sample of reproductive-aged women in the general population in the United States of America[1,2]

IVF twinning rate ***(21-35%)***	36 (25)	37 (31)	*0.28*
Live birth rate per thawed egg after OC ***(≤10%)***	20 (14)	42 (36)	***<.001***

1. The fertility knowledge of women from the general population is based on data previously published by Kudesia et al
2. All results are reported as N (%) unless noted otherwise
3. P-values were derived from chi-squared testing, which was performed if at least 80% of expected values were ≥5
4. Scores are reported as each population's median number of questions answered correctly, with the corresponding percentage of correctly answered questions denoted in parenthesis. Of note, there were a total of 29 questions on the FIT-KS, of which 21 related to natural fertility to comprise the natural fertility sub-score, and 8 related to infertility treatments to comprise the infertility treatment sub-score.
5. Not enough granularity of data was provided regarding the previously published sample of the general population to be able to perform statistical analysis comparing FIT-KS scores between the two populations.
6. Each of the rows in this section of the table represents an individual question on the FIT-KS. Results are presented as the number (%) of individuals in each population who answered the question correctly.
7. Correct answers to each question are denoted in parentheses.

had successful pregnancies (p< 0.01). The SRD population was more aware of the risks of infertility due to smoking (p=0.03), sexually transmitted infections (p=0.01), and being underweight (p< 0.01). Women with SRD were more frequently correct about success rates for in vitro fertilization (IVF) for women older than 44 years (p=0.02) but less frequently correct about success rates per thawed egg after oocyte cryopreservation (OOC) (p< 0.01). Compared to high scorers on the FIT-KS, low scorers were more frequently Hispanic/Latina (p=0.03) and more likely to have considered OOC (p=0.03) (Table 2).

Conclusion: Compared to a previously reported sample of women in the general population, women with SRD performed qualitatively better on the FIT-KS, with greater knowledge of modifiable infertility risk factors and IVF, but less knowledge of OOC. Among women with SRD, those with decreased fertility awareness were more frequently Hispanic/Latina and more open to OOC. Future multivariate analysis is planned, but our results suggest a relationship between demographic characteristics and fertility awareness and highlight important knowledge gaps among women with SRD, particularly related to options for fertility preservation.

Table 2. Characteristics of women with SRD who had high versus low scores on FIT-KS[1]

Variable[2]	High Scorers (N=70)	Low Scorers (N=72)	*p-value*[3]
Sociodemographics and Lifestyle

1. A high score was defined as a total score ≥19 on the FIT-KS, which marked the 75th percentile of scores reflected in the general population, as previously published by Kudesia et al.
2. All results are reported as N (%) unless noted otherwise.
3. P-values were calculated using chi-squared testing. Values were only calculated for variables for which at least 80% of the expected values were ≥5.
4. Inflammatory arthritis: Adult Onset Still's Disease, JIA, PsA, RA, spondyloarthritis (i.e. AS, IBD-related arthritis, ReA), inflammatory arthritis - not otherwise specified
5. Lupus and lupus-like conditions: APS, SLE, MCTD, SS, UCTD
6. Vasculitis, myositis, and SSc: Behcet's, myositis (i.e. DM, PM, IBM, or other inflammatory muscle disease), SSc, CREST, vasculitis (including ANCA-associated vasculitis, GCA, Takayasu's vasculitis, PAN)
7. Other autoinflammatory conditions: autoinflammatory syndrome (i.e. CAPS, TRAPS, FMF), IgG-4-related disease, PMR, sarcoidosis
8. Teratogenic medications: CYC, LEF, MTX, MMF, nintedanib, thalidomide, warfarin
9. Gynecologic comorbidities: polycystic ovarian syndrome, endometriosis, uterine fibroids, gynecologic cancer
10. Other ART: oral/injectable medications for ovarian stimulation, intrauterine insemination, and in vitro fertilization

Self-esteem as a Determinant of Sexual Function in SLE Patients

María Espinosa-León[1], Daniela Marengo-Rodríguez[2], Monserrat Ibarra-Velasco[2], Ana Barrera-Vargas[2] and Javier Merayo-Chalico[3], [1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, [2]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubiran, Mexico City, Mexico, [3]Reumátika, Centro de Vanguardia en Reumatología de la Ciudad de México, Mexico City, Mexico

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Reproductive Issues in Rheumatic Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatic diseases, and specifically SLE, present with greater sexual dysfunction than other chronic diseases. Sexual dysfunction (SxD) is multifactorial and comprises disease-related factors, psychological factors, hormonal imbalance, and treatment. Self-esteem has an association with mental and physical health in SLE patients, however, its impact has not been studied as a determinant of SxD.

We aimed to assess the association between body self-esteem, global self-worth and sexual functioning in SLE patients.

Methods: We performed a transversal study in a tertiary care center in Mexico City. Patients ≥18 years old who fulfilled EULAR/ACR criteria for SLE were included. Body self-esteem was assessed by the Body Self-esteem Scale (BSS) and global self-worth by the Rosenberg´s Self-Esteem Scale (RSES). Sexual function was assessed by the CSFQ-14 questionnaire. Disease activity was measured by SLEDAI and disease-associated damage by SLICC index. Relevant demographic, clinical and serological characteristics were recorded. We used univariate and multivariate analysis to assess association between self-esteem and SxD. Statistical analysis was performed using SPSS V.25.

Results: We included a total of 280 patients, in whom self-esteem was analyzed. Most patients were female (87%), the mean age was 41 (±12 years) and mean BMI was 25.6 (±4.9kg/m^2). Mean SLEDAI and SLICC scores were 2.45 (±2.72) and 0.8 points (±1.04), respectively. A correlation between body self-esteem and SxD was found in both genders. Interestingly, the correlation was higher in men than in women (r=0.45, p=0.008 *vs* r=0.25, p=0.0001,

Table 1. Clinical, demographic, and laboratory variables of patients with Systemic Lupus Erythematosus (SLE)

Table 1. Clinical, demographic, and laboratory variables of patients with Systemic Lupus Erythematosus (SLE)			
Variables	**SxD mean ± SD**	**No-SxD mean ± SD**	**Comparison (p value)**
BMI, kg/m2	25.2 ±4.6	26.1±5.5	0.16
PDN dose	4.6 ±8.7	3.8 ±6.1	0.42
Body Attractive (Total AC), points	37.2 ±13.8	46.8±8.6	**<0.0001**
Body Satisfaction (Total SC), points	151.2 ±35.7	162.7±29.1	**< 0.006**
Body self-esteem (EAC), points	188.4 ±44.9	207.9±40.1	**<0.0001**
Global self-worth, points (Rosenberg)	21.8 ±5.0	34.4±6.4	**<0.0001**
SLEDAI score, points	2.4±2.7	2.3±2.5	0.71
SLICC DI, points	0.8 ±1.0	0.6±0.9	0.09
C3 levels, mg/dL	111.6 ±30.3	117.1 ±32.8	0.19
C4 levels, mg/dL	22.1 ±10.3	20.7 ± 10.9	0.34
anti-dsDNA antibodies, IU/mL	151.1 ±752.4	36.1 ±63.5	0.16
*Values shown in bold represent statistically significant p values.			

respectively). In addition, a correlation was established between global self-worth and SxD for both men and women (r=0.4, p=0.006 *vs* r=0.18, p=0.004) respectively. Interestingly, both scales (BSS and RSES) showed a moderate correlation with SxD in men with SLE (r=0.45, p=0.008 and r=0.47, p=0.006, respectively). Although this correlation was also found in women (between BSS, RSES and SxD), it was weaker than in men (r=0.25, p=0.0001 and r=0.18, p=0.004)

Other clinical and laboratory variables were studied, such as prednisone, cyclophosphamide, obesity, depression, body self-esteem, SLEDAI and SLICC damage index; however, no statistical significance was found (Table 1).

The multivariate analysis showed that age (0.96, 95% CI 0.94-0.98, p=0.003), lower RSES score (1.08, 95% CI 1-1.14, p=0.01) and leukocytes (1.19, 95% CI 1-1.40, p=0.02) were independently associated with SxD. Although there was a trend for an association with lower BSS, it did not reach statistical significance (1.00, 95% CI 1-1.15, p=0.055).

Conclusion: To our knowledge this is the first study to evaluate self-esteem (with two different scales) as a determinant of sexual function in SLE patients, showing a greater impact in male population. Given the complexity of sexual function in SLE patients and the various factors that can affect it, it is important to consider additional psychosocial aspects, such as self-esteem, to help us identify and address potential problems early on, leading to better quality of life through timely interventions.

Breastfeeding Intention in Systemic Lupus Erythematosus Patients

Susana Villamizar Pérez[1], **Nicole Josianne Paris**[1], Melissa Serna Góngora[1], Ariel Brener[1], Jerson Claros[1], Maria Pia Izaguirre Germain[1], Barbara Pérez Cepas[2], Marina Micelli[3], Gabriel Sequeira[1] and Eduardo Mario Kerzberg[1], [1]Hospital Dr. JM Ramos Mejia, Ciudad Autonoma de Buenos Aires, Argentina, [2]Hospital medico policial Churruca Visca, Ciudad Autonoma de Buenos Aires, Argentina, [3]RELESSAR, CABA, Argentina

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Reproductive Issues in Rheumatic Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Breastfeeding in systemic lupus erythematosus (SLE) has received little attention and the limited data available suggest that women with SLE have lower breastfeeding rates and sustain it for less time than the general population. This study aimed to assess the knowledge about breastfeeding in patients with SLE, estimate the breastfeeding intention rate, and consider the impact that SLE activity and the information on lactation provided by hydroxychloroquine and prednisone patient information leaflets (PILs) could have on breastfeeding intention.

Methods: A cross-sectional study was performed through an anonymous, closed, multiple-choice survey. Outpatients with SLE (meeting EULAR/ACR 2019 classification criteria) treated at a public hospital, aged 18 or older, and of childbearing age were surveyed. The authors conducted the surveys during medical consultations. Personal data (age, level of education) and past pregnancy and lactation experience were collected. Prior knowledge about breastfeeding in SLE was evaluated. Patients were asked about a) their intention to breastfeed in the event of a pregnancy and b) their intention to breastfeed in the event of active SLE. They were requested to read hydroxychloroquine and prednisone PILs and asked whether they thought it was possible to breastfeed while taking these medications. Finally, they were given updated information brochures on the subject. All patients signed written consent forms. The study was approved by the Bioethics Committee.

Results: The survey was answered by 72 patients with a mean age of 34 (SD 9) years old. Thirteen (18%) had at least primary education, 35 (49%) had high school education, and 24 (33%) had higher education. Twenty-nine (40%) had no children, 13 (18%) had had children before being diagnosed with SLE, and 30 (42%) had had at least one child after the diagnosis. Thirty-nine patients (54%) had previous breastfeeding experience.

Table 1: Level of knowledge about breastfeeding in SLE

n :72 patients	Yes	No	Unknown
Is it possible to breastfeed with SLE?	44 (61%)	7 (10%)	21 (29%)
Do SLE medications allow breastfeeding?	24 (33%)	16 (22%)	32 (45%)
Does breastfeeding benefit patients with SLE?	5 (7%)	10 (14%)	57 (79%)
Does breastfeeding with SLE benefit the infant?	25 (35%)	13 (18%)	34 (47%)

In the event of a new pregnancy, 64 patients (89%) would choose to breastfeed. However, in the event of active SLE, 47 patients (65%) would take the best available medication and not breastfeed,19 (27%) would opt for less effective medications that allow breastfeeding, and 6 (8%) would prefer not to take medication and breastfeed.

After reading the prednisone PILs, 47 patients (65%) considered it was possible to breastfeed while taking that drug, but only 20 (28%) said that the same applied to hydroxychloroquine.

Conclusion: Most patients considered it was possible to breastfeed and intended to do so, but this percentage would decrease in the event of active disease. Over 70% of the respondents considered it was unsafe to breastfeed after reading the hydroxychloroquine PIL. Information on breastfeeding should be reinforced for patients with SLE.

Session Title: Reproductive Issues in Rheumatic Disorders Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Pregnancies complicated by systemic lupus erythematosus (SLE) are known to be at high risk for adverse pregnancy outcomes (APOs). Previous studies have shown that active SLE and/or glucocorticoid use were risk factors for APOs. In American College of Rheumatology guideline for reproductive health, the importance for preconception care has been indicated. However, the evidence of the need for preconception care has not well revealed, especially whether it influences pregnancy outcomes. Therefore, we evaluated the impact of preconception care for SLE patients on pregnancy outcomes.

Methods: We used the data of SLE patients who were managed from the planning for pregnancy to delivery from March 2006 to March 2023 in our institution. Preconception care strategy was defined as all of the following: 1) counseling, 2) contraception and control moderate or high disease activity, 3) assessment of risk factors for maternal and fetal adverse event, 4) change to pregnancy-compatible medications. We retrospectively evaluated the associatio

Results: 42 cases in 30 SLE patients were included in our study. The preconception care strategy was completed in 34 cases (81.0%), while the remaining cases resulted in conceiving before completion of preconception care. In preconception care group, mean glucocorticoid dose and the rate of increasing dose of glucocorticoid during pregnancy was significantly lower than non-preconception care group (Table 1, P=0.01, < 0.01). As for disease activity parameters, only SLEDAI at first trimester was significantly lower in preconception care group (Table 2, P=0.01). However, there was no significant difference in other disease activity parameters between these two groups. Table 3 showed pregnancy outcomes with or without preconception care. Mean gestational age at delivery and mean birth weight of newborns was significantly higher in preconception care group (P=0.03 and < 0.01), and the rate of APOs or NICU administration was significantly lower in these group (P=0.04 and 0.03). The rates of preterm birth, low birth weight, or SGA tend to be lower in preconception care group (P=0.06, 0.053, and 0.06).

Table 1. Patients characteristics on preconception care. Values are presented as the mean ± standard deviation or number (%). #Wilcoxon rank sum test; ##Fisher's exact test. *P < 0.05.

Abstract Number: 0464

Adverse Pregnancy Outcomes in Sjogren's Disease Compared to Controls: An Interdisciplinary Approach with Maternal Fetal Medicine

Lauren Tesoriero[1], Jennifer Kidd[1], Julie Piccione[1], Izmirly peter[2], Meredith Akerman[1], Steven Carsons[1], Patricia Rekawek[1] and Julie Nusbaum[1], [1]NYU Long Island School of Medicine, Mineola, NY, [2]NYU, New York, NY

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Reproductive Issues in Rheumatic Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Outside of the known association of Ro antibody with congenital heart block (CHB), little is known about adverse maternal outcomes, and even less about neonatal outcomes, in patients with Sjogren's Disease (SjD).Few studies of pregnancy in SjD have been conducted in collaboration with Maternal Fetal Medicine (MFM). With an interdisciplinary approach, we aim to describe maternal and neonatal outcomes of pregnancies in SjD compared to a 1:3 matched control population.

Methods: This was a retrospective cohort study of pregnant patients who had prenatal care and delivered at NYU Langone Hospital-Long Island from 01/2018-12/2022.SjD patients were matched 1:3 with non-SjD controls by gestational age and maternal age. Inclusion criteria for SjD patients were diagnosis by the 2016 ACR/EULAR Criteria or by rheumatologist evaluation, with available pregnancy data. Exclusion criteria for SjD patients were concurrent autoimmune disease (i.e. SLE); antibodies to dsDNA, Smith, or aPL; or unavailable pregnancy records. Controls were excluded if they had major maternal medical comorbidities, major fetal anomalies in pregnancy, prior adverse pregnancy outcome (APO), or delivery elsewhere. Many outcomes of interest are rare, and a composite of grouped outcomes was utilized. All component details of composites are included below (Table 3) and were verified by a MFM specialist. The primary outcome was a composite of APO between the two groups. Secondary analysis included the following composite outcomes: maternal hypertensive, adverse maternal antenatal, adverse delivery, maternal infectious, and adverse neonatal. Statistical analysis of maternal demographics, maternal outcomes, and neonatal outcomes was performed using two sample t-test for continuous variables and Fisher's exact test for categorical variables, with significance p value of < 0.05.

Results: 48 patients were included: 12SjD patients and 36 controls. SjD patients were more likely to be prescribed aspirin (50% vs 5.6%, p = 0.002) and hydroxychloroquine (33.33% vs 0%, p=0.003), while other demographics were comparable (Table 1).The APO composite score was significantly increased in SjD patients (25% vs 2.8% p=0.04) with SjDAPO of 1 preterm birth, 1 fetal growth restriction, and 1 limb anomaly; non-SjD had 1 cardiac anomaly (Table 3).There were no cases of CHB in either group. SjD patients were more likely to be delivered by cesarean delivery(CD) (75% vs 25%, p= 0.004) (Table 2). There were no other significant differences in adverse maternal or neonatal outcomes (Table 2, Table 3).

Table 1: Demographics

Variable	Patients with SjD (n=12)	Non-SjD Controls (n=36)	p-value
Age (years)*	35.58 ± 4.44	34.19 ± 4.20	0.33

* Reported as mean ± standard deviation

Table 3: Composite Outcomes

Composite Outcomes	Patients with SjD (n=12)	Non-SjD Controls (n=36)	p-value
Adverse pregnancy[1]	3 (25%)	1 (2.78%)	0.04
Maternal infectious[2]	0 (0%)	0 (0%)	N/A
Maternal hypertensive[3]	3 (25%)	3 (8.33%)	0.156
Adverse delivery[4]	2 (16.67%)	7 (19.44%)	1.000
Adverse maternal antepartum[5]	2 (16.67%)	3 (8.33%)	0.587
Adverse neonatal[6]	0 (0%)	4 (11.11%)	0.560

All outcomes reported as n (percent)
1. **Adverse pregnancy composite:** Miscarriage, intrauterine fetal death, Fetal complication (intrauterine growth restriction and congenital anomalies [cardiac, lung, renal, neurologic, gastrointestinal, genitourinary, limb, hydrops, neural tube defect, thickened nuchal translucency]), Fetal heart block, Preterm birth (gestational age <37weeks)
2. **Adverse infectious composite:** Chorioamnionitis, Endometritis, Mastitis, Wound infection
3. **Maternal hypertensive composite:** Gestational hypertension, Preeclampsia, Eclampsia, HELLP (hemolysis, elevated liver enzyme, low platelet) syndrome, Postpartum preeclampsia
4. **Adverse delivery composite:** 3rd/4th degree laceration, Episiotomy, Cesarean delivery for fetal intolerance of labor, Postpartum hemorrhage, Shoulder dystocia, Placenta accreta spectrum, Retained placenta, Blood transfusion, Hysterectomy, Intensive care unit admission, Maternal death
5. **Adverse maternal antepartum composite:** Venous thromboembolism, Gestational diabetes, Vasa previa, Placenta Previa, Placental abruption
6. **Adverse neonatal composite:** Neonatal intensive care unit admission, Neonatal complications (infection [sepsis, pneumonia, neonatal necrotizing enterocolitis], respiratory problem [mechanical ventilation, RDS], neurologic [seizures, hypoxic ischemic encephalopathy, intraventricular hemorrhage]) Neonatal demise, Birthweight less than 2500 grams, Umbilical cord arterial blood gas pH <7.0, APGAR (appearance, pulse, grimace, activity, and respiration) 5 minute score <7

Conclusion: There was an increased risk of APO in SjD patients compared to controls. No significant difference in neonatal outcomes was noted, adding an important contribution to the limited knowledge of neonatal outcomes in SjD. A significantly increased rate of aspirin use and of CD among patients with SjD was noted and calls for further study. Larger sample size, an interdisciplinary approach with MFM, and the use of rigorous definitions of perinatal outcomes would improve upon our existing knowledge of pregnancy in SjD. Our study suggests that clinicians should consider closer monitoring and early collaboration with MFM specialists for the pregnancies of SjD patients.

Abstract Number: 0465

The Effects of Post-Dobbs Abortion Policy on Rheumatology Clinical Practice: A Survey of Rheumatologists

Mehret Birru Talabi[1], Bonnie Bermas[2], Irene Blanco[3], Ashira Blazer[4], Megan Clowse[5], Cuoghi Edens[6], Leslie Pierce[7], Catherine Wright[1] and Rosalind Ramsey-Goldman[3], [1]University of Pittsburgh, Pittsburgh, PA, [2]UT Southwestern, Dallas, TX, [3]Northwestern University, Chicago, IL, [4]Hospital for Special Surgery, New York, NY, [5]Duke University, Chapel Hill, NC, [6]University of Chicago, Chicago, IL, [7]University of Pittsburgh, Raleigh, NC

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Reproductive Issues in Rheumatic Disorders Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: In June 2022, the U.S. Supreme Court's decision in *Dobbs v. Jackson Women's Health* removed the federal constitutional right to abortion, returning abortion policy to individual states. Approximately one-third of states have since banned or planned to greatly restrict abortion access. We distributed a confidential online survey to a sample of U.S.-based rheumatologists to learn how the *Dobbs* decision might affect clinical practice around teratogen prescribing, abortion referrals, and perceived vulnerability to criminalization.

Methods: This study was designated as exempt by the University of Pittsburgh Institutional Review Board. QR codes to the survey were disseminated in November 2022: 1) at a plenary session about reproductive health at the American College of Rheumatology (ACR) national meeting; 2) via Twitter by study investigators during the ACR national meeting. Results were analyzed by descriptive statistics or chi-square tests, which compared responses by practice in abortion-restricted or protected states.

Results: Most respondents (N=152) identified as female (80.3%), practiced in academic settings (76.3%), and were in their early careers (fellows: 13.2%, < 10 years of independent practice: 47.4%). Approximately 47% of respondents practiced in abortion-restricted states. Half of respondents reported that one or more of their patients had ever become pregnant while using a teratogen (e.g., methotrexate, mycophenolate), and 34% had ever recommended abortion to a patient before *Dobbs*. Rheumatologists in abortion-restricted states were more comfortable referring a patient for abortion without fear of reprisal prior to *Dobbs* than post-*Dobbs* (83.1% and 34.8%, respectively; $p< 0.001$). Rheumatologists in abortion-restricted vs protected states were marginally more likely to report that they had changed or planned to change how often they prescribed methotrexate (13.0% vs 5.3%, p=0.146) and/or mycophenolate (8.7% vs 1.32%, p=0.05) to reproductive-age patients.

Conclusion: Our results suggest that rheumatologists' prescribing patterns may change in the context of the nationwide abortion restriction, particularly in abortion-restricted states; reproductive-age females with rheumatic diseases may therefore have less access to evidence-based treatments such as mycophenolate and methotrexate [2-5]. Limitations of the current study include uncertain representativeness of the sample: the response rate cannot be calculated due to social media dissemination, and rheumatologists who had more interest in reproductive health issues may have been more likely to respond to the survey. Nonetheless, our findings underscore an urgent need for data to inform a concerted public health response that protects the health and well-being of females with rheumatic diseases.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Reproductive Issues in Rheumatic Disorders Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: There are limited data on the impact of the postpartum period (PP) on the activity of inflammatory rheumatic disorders (IRD), and the data available on the impact of breastfeeding on the activity of IRD are contradictory. The objectives of this analysis were to describe disease activity and treatments received during the PP period and breast-feeding frequency and its possible impact on IRD activity.

Methods: A descriptive study from a French multicenter prospective observational cohort (GR2) studying pregnant women with IRD i.e. rheumatoid arthritis (RA) and spondylarthritis (SpA) confirmed by a rheumatologist was conducted (NCT 02450396). Data were collected during several regular pre-conception visits, visits during pregnancy and visits around 6- and 12-months PP, from October 2014 to October 2022. Disease activity was assessed with DAS28-CRP for RA and

bDMARDS (%)	15/92 (16.3)	39/91 (42.9)	6/91 (6.6)
MTX (%)	0/91	30/91 (33.0)	4/91 (4.4)
CORTICOTHERAPIE (%)	12/94 (12.8)		12/94 (12.8)

Legends: Date are expressed in number and percentages. SpA : Spondylarthritis; RA : rheumatoid arthritis; PP : post-partum; bDMARDs : biological Disease-Modifying AntiRheumatic Drugs ; MTX : Methotrexate.

BASDAI and ASDAS for SpA. Flares were defined according to physician judgment. The change in disease activity was investigated by paired Student's t-tests and Mac-Nemar Chi-2 tests for paired data, as appropriate. Subgroup bivariate comparisons by IRD pathology were performed according to patients' breastfeeding status at 6-months PP by Kruskal-Wallis tests for continuous variables and Fisher exact tests for categorical variables. There was no imputation of missing data.

Results: Overall, 218 pregnant patients were analyzed: 124 with SpA and 94 with RA. The mean age was 31.8 ± 5.0 and 32.8 ± 5.0 years, respectively for SpA patients and RA patients (**Table 1**). In SpA patients, there were no significant differences in terms of activity (flares, BASDAI and ASDAS) at 6 months PP compared to during pregnancy. However, CRP level was significantly higher during pregnancy compared to 6 months PP (7 mg/L vs 3.2 mg/L; p = 0.014) (**Table 2**). RA patients presented significantly more flares in the first 6 months PP compared to pregnancy (62.0% vs 43.5% p = 0.02).Disease activity measures were similar between both SpA and RA patients who still breastfed at six months PP and patients who never breastfed or stopped before 6 months.

After one-year PP, among SpA patients, the number of flares were significantly higher than during pregnancy (40.3% vs 13.4%; p < 0.001). For RA patients, the mean activity and the number of flares were not different during pregnancy and at one year PP. Regarding treatment, about 40% of SpA and RA patients resumed bDMARD during PP, mainly in the first month PP (**Table 3**). For SpA, all bDMARDs were TNF inhibitors except for one treatment with belimumab (patient with SpA and systemic lupus erythematosus). For RA, among bDMARDs prescribed, 38/45 (84.4%) were TNF inhibitors (tocilizumab, abatacept and JAK inhibitors were the remaining).

Conclusion: RA patients presented significantly more flares in the first 6 months of postpartum compared to pregnancy while SpA patients remained stable. Yet, in both diseases, only about 40% of the patients resumed bDMARD during postpartum period. Breastfeeding was not associated with an increase or decrease in disease activity in SpA and RA patients.

Abstract Number: 0467

Cardiovascular Events During Pregnancy: Implications for Adverse Pregnancy Outcomes in Individuals with Autoimmune Rheumatic Diseases and Antiphospholipid Syndrome

Rashmi Dhital, Rebecca Baer and Christina Chambers, University of California San Diego, La Jolla, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Reproductive Issues in Rheumatic Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoimmune rheumatic diseases (ARD) and antiphospholipid syndrome (APS) are autoimmune conditions with increased risks of cardiovascular complications as well as negative pregnancy consequences. We recently found significantly higher risks for acute cardiovascular events (CVEs) during pregnancy and postpartum in women with ARD and APS compared to individuals without such conditions. However, the impact of such CVEs on adverse pregnancy outcomes (APOs) is not well known. The primary aim was to compare APOs between individuals with ARDs, primary APS and those without either condition, based on the presence or absence of acute CVEs during pregnancy.

Methods: We used the Study of Outcomes in Mothers and Infants (SOMI) database (2005-2020), an administrative population-based birth cohort in California. The main outcomes were APOs, which included preterm birth (PTB) and small-for-gestational age (SGA). Preterm birth was sub grouped as spontaneous, provider initiated, early preterm birth (< 32 weeks), and late preterm birth (32 – 36 weeks). We compared APOs between individuals with or without acute CVEs during pregnancy, after categorizing them into three groups: those with ARDs, those with primary APS, and those with no ARDs or APS. We calculated relative risks (aRR) and 95% confidence intervals (CIs), adjusting for age at delivery, race/ethnicity, primary payer, maternal education, maternal pre-pregnancy body mass index, preexisting hypertension, preexisting diabetes, hyperlipidemia, smoking, alcohol use, drug use, and depression.

Table 1. Comparison of adverse pregnancy outcomes (APOs) in individuals with or without an acute cardiovascular event during pregnancy, stratified by presence of an autoimmune rheumatic disease (ARD) or primary antiphospholipid syndrome (APS), 2005 – 2020 (n= 7,031,432) *ARD: autoimmune rheumatic disease, APS: antiphospholipid syndrome, CVEs: cardiovascular events, APOs: adverse pregnancy outcomes Risks were adjusted for: age at delivery, race/ethnicity, payer for delivery, maternal education, maternal pre-pregnancy body mass index, preexisting hypertension, preexisting diabetes, hyperlipidemia, smoking, alcohol use, drug use, and depression.

	No ARD or APS (n= 7,004,334)			Any ARD (n=19,340)			Primary APS (n=7,758)

Spontaneous	2,151 (12.5)	337,885 (4.8)	2.2 (2.1, 2.3)	79 (29.5)	2,042 (10.7)	2.6 (2.1, 3.2)	61 (14.2)	652 (8.9)	1.3 (1.03, 1.8)
Provider initiated	1,053 (6.1)	116,555 (1.7)	3.2 (3.0, 3.4)	28 (10.5)	823 (4.3)	2.6 (1.7, 3.7)	22 (5.1)	268 (3.7)	1.3 (0.8, 2.0)
Small for gestational age	1,954 (11.4)	622,516 (8.9)	1.2 (1.1, 1.3)	52 (19.4)	2,657 (13.9)	1.2 (0.9, 1.6)	61 (14.2)	726 (9.9)	1.3 (1.02, 1.7)

Results: Pregnant individuals with an ARD (26.9%) or primary APS (21.3%) had significantly higher APOs as compared to women without these conditions (15.2%). The presence of acute CVEs during pregnancy further increased the adjusted risk of an APO by 1.8-fold for ARD, 1.3-fold for primary APS and 1.6-fold for those without an ARD or APS. Among individuals with an ARD, more than half (53.4%) with CVEs experienced APOs, compared to 26.6% without CVEs (aRR 1.8, 95% CI 1.5 to 2.1). The increased risk of APOs in ARD pregnancies with CVEs was primarily driven by higher rates of PTB, which was 41.0% in ARD patients with CVEs compared to 15.6% in those without CVEs during pregnancy (RR: 2.3, 95% CI 1,9, 2.7), whereas the rate of SGA was similar among ARD patients with and without CVEs. Among ARD patients with CVEs, 12.7% experienced early PTB, while 2.7% of those without CVEs had early PTB (RR 4.5, 95% CI 3.2 to 8.5) (**Table 1**).

Conclusion: Pregnant individuals with an ARD or APS had higher rates of APOs than those without these conditions. Acute CVEs during pregnancy further increased the risk of an APO, regardless of ARD or APS diagnosis. These findings highlight the need for close monitoring and management of pregnant women, not only for adverse outcomes, but also for cardiovascular risks and events, in order to identify those at the highest risk for adverse outcomes. This need is particularly significant for individuals with ARDs, as 53.4% of our population with an ARD and CVE in pregnancy experienced an APO.

Abstract Number: 0468

Patients with Autoimmune Skin Diseases Are at Increased Risk of Adverse Pregnancy Outcomes

Heejo Keum[1], Bonnie Bermas[2], Shivani Patel[1], Benjamin Chong[1] and Heidi Jacobe[1], [1]University of Texas Southwestern Medical Center, Dallas, TX, [2]UT Southwestern, Dallas, TX

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Reproductive Issues in Rheumatic Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Increased rates of adverse pregnancy outcomes (APOs) have been reported in association with rheumatologic diseases such as systemic lupus erythematosus (SLE), dermatomyositis (DM), and rheumatoid arthritis (RA). However, little is known about pregnancy outcomes in patients with autoimmune skin diseases (ASDs). We aimed to determine the frequency of APOs in patients with ASDs. We hypothesized that similar to rheumatic diseases, patients with ASDs would have a higher frequency of APOs than the general population.

Methods: This case-control study was conducted using the TriNetX US Collaborative Network, a database of electronic medical records of 94 million patients in the United States. Pregnant patients aged 15-44 years between January 1, 2016 and December 31, 2021 were included. Pregnancies were identified using International Classification of Diseases, Tenth Revision, Clinical Modification (ICD-10-CM) indicating pregnancy endpoints. Cases consisted of patients with at least one ASD diagnosed prior to the end of pregnancy. The ASDs identified were alopecia areata, bullous pemphigoid, cicatricial pemphigoid, dermatitis herpetiformis, cutaneous lupus erythematosus, epidermolysis bullosa acquisita, morphea, pemphigus foliaceus, pemphigus vulgaris, vitiligo, and amyopathic DM. There were 2 control groups: 1) healthy controls without ASDs, SLE, or RA and 2) disease controls defined as patients with SLE or RA. For all cases and controls, patients with hidradenitis suppurativa or other common autoimmune diseases such as Hashimoto's thyroiditis and Type 1 diabetes were excluded. The primary outcomes were APOs defined as spontaneous abortion, gestational hypertension, preeclampsia/

Table 1. Baseline characteristics of patients with ASDs, controls, and disease controls after propensity score matching

Characteristics	Patients with ASDs (N=3,654)	Controls (N=3,654)[1]	SLE (N = 2147)[2]	RA (N = 889)[3]

Preterm birth	62 (2.9)	119 (5.5)	0.5 [0.4-0.7]	<0.001	22 (2.5)	37 (4.2)	0.6 [0.4-1.0]	0.05

eclampsia, gestational diabetes, intrauterine growth restriction (IUGR), preterm premature rupture of membranes (PPROM), and preterm birth. Patients with ASDs and controls were 1:1 propensity score matched by age, race, ethnicity, comorbidities, obesity, and substance use. For each outcome, risk ratio (RR) with a 95% confidence interval (CI) was calculated.

Results: 3,654 patients with ASDs were matched to 3,654 healthy controls (Table 1). Patients with ASDs were more likely to have spontaneous abortions (RR=1.5 [1.4-1.7], P< 0.001), and preeclampsia/eclampsia (RR=1.2 [1.0-1.3], P=0.04) than healthy controls (Table 2). When compared to women with SLE, women with ASDs were less likely to have preeclampsia/eclampsia (RR=0.7 [0.6-0.9, p=0.001), have a preterm birth (RR= 0.5 [0.4-0.7], P< 0.001), PPROM (RR=0.6 [0.4-0.9], P=0.004), or an infant with IUGR (RR=0.6 [0.5-0.8], P< 0.001), and more likely to have a spontaneous abortion (RR=1.2 [1.1-1.3], P=0.003). Patients with ASDs had similar risks for APOs as patients with RA (Table 3).

Conclusion: These results suggest that patients with ASDs have increased rates of adverse pregnancy outcomes compared to healthy controls and are similar in risk to RA. In contrast, those with SLE have a greater frequency of APOs indicating that all these groups may benefit from multidisciplinary care with maternal-fetal medicine specialists. Further studies will be helpful to identify mechanisms behind increased risk of adverse pregnancy outcomes in patients with ASDs.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Reproductive Issues in Rheumatic Disorders Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Pregnancies in patients with systemic lupus erythematosus (SLE) are at greater risk of preeclampsia. Hydroxychloroquine (HCQ) is recommended during SLE pregnancy to control disease activity. Some studies have suggested that HCQ may reduce the risk of preeclampsia and hypertensive disorders of pregnancy, although results are conflicting. We studied HCQ use in SLE pregnancy in a large integrated health system to investigate whether HCQ reduces the risk of preeclampsia in a diverse patient cohort.

Methods: SLE was defined as ≥2 coded visits ≥7 days apart (ICD9: 710.0, ICD10: M32.1, M32.9). Individuals with full pregnancy histories derived from the electronic health records occurring in 2011-2020 were included. Data from all healthcare encounters, labs and pharmacy records were accessible. Qualifying SLE-coded encounters were required to occur before last menstrual period date (LMP) prior to pregnancy. We included pregnancies lasting until at least 20 gestational weeks. Pregnancies were considered HCQ-exposed if at least two fills covered the exposure window (3 months pre-LMP through 1st trimester), and unexposed if there were no fills overlapping with this time. Preeclampsia and eclampsia (PE/E) were defined in the pregnancy database and included all ICD-coded visits during pregnancy and labor and delivery documentation. All analyses were stratified by parity (primipara vs multipara). To account for possible confounding by indication, we estimated propensity scores (PS) as a function of age, BMI, race/ethnicity, neighborhood deprivation index, pre-pregnancy morbidity (diabetes, hypertension, nephritis) and medication ((corticosteroids, azathioprine), and antiphospholipid antibody (aPL) status. We estimated risk ratios (RR) and 95% confidence intervals using PS adjusted Poisson regression stratified by parity and by pre-pregnancy hypertension to investigate effect modification.

Results: 18% of SLE pregnancies had a PE/E diagnosis; among primiparous: 24% in HCQ exposed vs 21% in unexposed, and 14% and 15% among multiparous exposed and unexposed, respectively. Approximately 20% of the pregnancies had ≥1 aPL antibody, 16% had pre-existing hypertension, and 20% had a history of nephritis in the study cohort of 399 SLE pregnancies. (Table 1). In PS-adjusted models among primipara we found a null association (1.06, 95% CI: (0.57, 1.97)). Among multipara the RR was 0.76 (0.35, 1.64). Examining effect modification by pre-pregnancy hypertension, we found that among those with pre-pregnancy hypertension, ≥2 HCQ fills (vs no fills) was associated with a RR of 0.70 (95% CI (0.39, 1.25)), compared to RR=1.12 (0.57, 2.20) among those without pre-existing hypertension.

Conclusion: SLE patients using HCQ shortly before and early in pregnancy generally were comparable to those who did not use HCQ, although some small differences were observed. Confounding by disease activity was accounted for by including pre-pregnancy treatment with corticosteroids and azathioprine. We consistently observed RRs near or below the null of 1.0.

Demographics and clinical characteristics for singleton deliveries (live and stillbirth) in patients with systemic lupus erythematosus by HCQ fills (exposed defined as at least two fills overlapping three months pre-LMP through first trimester and unexposed is no fills)

Educational Intervention to Increase Contraception Screening and Documentation for Reproductive-Aged Women Seen in an Academic Rheumatology Clinic

Caroline Siegel[1], Deanna Jannat-Khah[1], Avi Mikhaylov[1], Erika Abramson[2], Nancy Pan[1] and Lisa Sammaritano[3], [1]Hospital for Special Surgery, New York, NY, [2]Weill Cornell Medicine, New York, NY, [3]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Reproductive Issues in Rheumatic Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Only one-third of reproductive-aged women with rheumatic disease (RD) are prescribed effective contraception, even if prescribed teratogenic medications (Talabi et al. *Arthritis Care Res*. 2019). Contraception counseling and documentation are important steps to improve effective contraception use in at-risk patients; however, in a nationwide study, less than 10% of women with SLE or RA had contraception documented in a structured electronic health record (EHR) field (Clowse et al. *Arthritis Care Res*. 2023). The aim of this quality improvement (QI) initiative was to increase the rate

of provider screening and documentation of contraception use for female patients aged 18-45 seen in an academic rheumatology clinic from our baseline of 11% to 50% by 24 weeks.

Methods: We administered a survey to clinic staff including demographic information, professional credentials and years of experience, and barriers to contraception documentation and desired interventions. We conducted 6 Plan-Do-Study-Act (PDSA) cycles including educational presentations and motivating reminders for clinic staff, devised to address the "vital few" barriers (representing 80% of responses) identified.

The primary outcome measure was the percentage of the study population with contraception use documented in the structured EHR field. The primary balancing measure was the percentage of the study population with smoking status documented in the structured EHR field. The primary process measure was percentage of contraception documenters who

Table. Demographic and Professional Characteristics of Baseline Survey of Rheumatology Clinic Staff

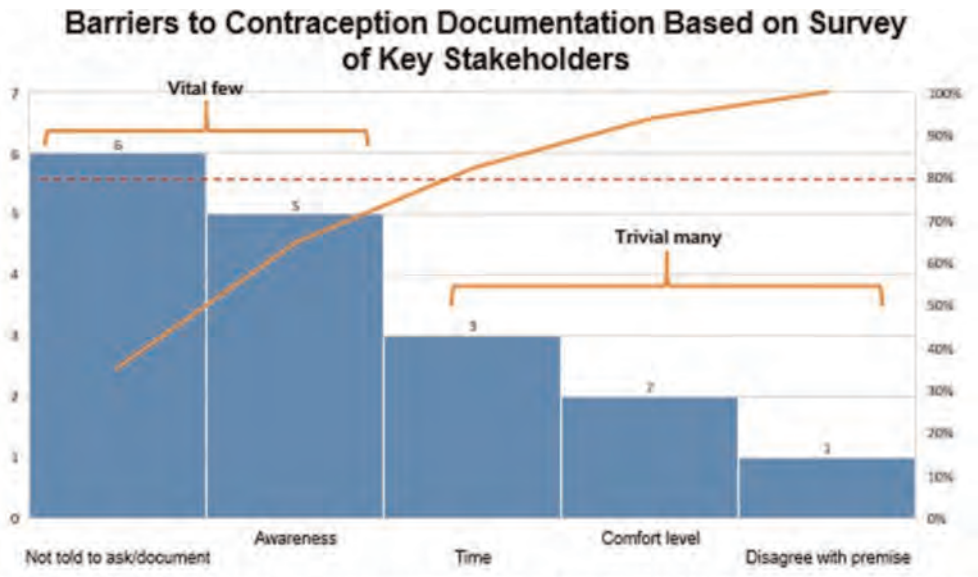

Figure 1. Pareto chart demonstrating responses to survey administered to rheumatology clinic staff at study baseline regarding barriers to contraception screening and documentation.

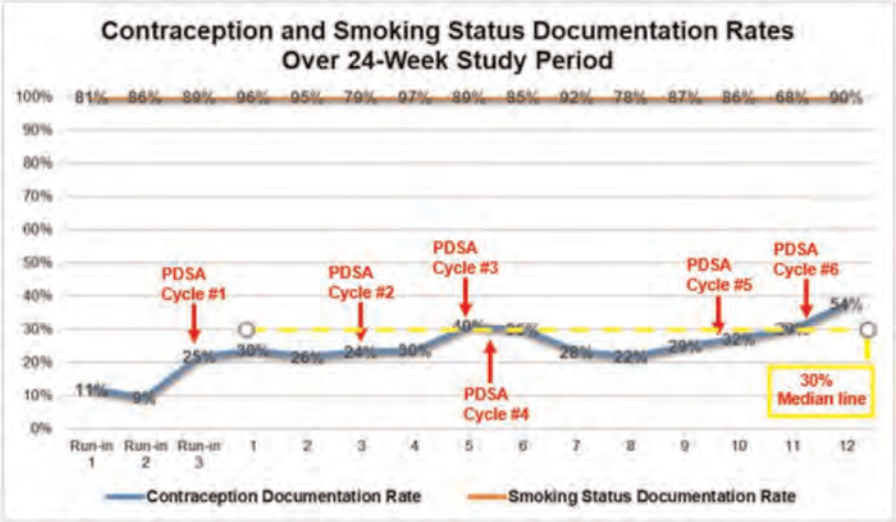

Figure 2. Run chart demonstrating primary outcome measure (i.e. contraception documentation rate) and balancing measure (i.e. smoking status documentation rate) every 2 weeks over 24-week study period.

were non-MD clinical staff, as the intervention focused on this group. We tracked primary outcome, process, and balancing measures at 2-week intervals over 24 weeks; we tracked primary outcome and balancing measures on a run chart.

Results: Baseline survey respondents (n=17) were 65% female; 47% White and 29% Asian/Indian; 82% Not Hispanic/Latino; 53% Registered Nurses/Personal Care Assistants and 47% Rheumatology Fellows [**Table**]. The "vital few" barriers to contraception documentation were not having been told to document this information and lack of awareness of this EHR field [**Fig. 1**]. The intervention most frequently suggested by respondents (47%) was education.

Interventions included an introductory educational session with documentation instruction and scripts to guide screening (PDSA #1), email reminders from nursing leadership (PDSA #2 and #5), and interim educational sessions (PDSA #3, #4, #6). Over 24 weeks, the rate of contraception documentation increased from 11% to 54% (median 30%) and the median smoking status documentation rate was 88% (68%-97% range) [**Fig. 2**]; the median rate of non-MD clinical staff documenters was 92% (70%-100% range).

Conclusion: A multi-cycle educational intervention designed based on key stakeholder feedback led to an increase in the contraception documentation rate from 11% to 54% for reproductive-aged women seen in our rheumatology clinic over 24 weeks. Future phases of this QI initiative will focus on encouraging rheumatologists to provide contraceptive counseling and referrals to women's health providers for patients who are prescribed teratogenic medications.

Knowledge and Misconceptions About Contraception Among Individuals with Inflammatory Arthritis and Lupus-like Diseases

Caroline Siegel[1], Medha Barbhaiya[2], Lucy Masto[1], Amaya Smole[1], Bessie Stamm[1], Jonah Levine[1], Sarah Lieber[2], Lisa Mandl[2], Michael Lockshin[2] and Lisa Sammaritano[2], [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Reproductive Issues in Rheumatic Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatologists do not consistently provide contraceptive counseling for patients with systemic rheumatic disease (SRD). As contraception considerations may differ based on SRD, we compared contraception knowledge between individuals with reproductive capacity who have inflammatory arthritis (IA) or lupus-like diseases.

Methods: Women aged 18-65 years seen by a rheumatologist at our academic center ≥2 times from 2020-2022 were enrolled in the Rheumatology Women's Reproductive Health and Wellness Cohort. This analysis included participants who completed a contraception knowledge assessment and self-reported IA or lupus-like disease. We excluded participants >50 years of age and those who self-reported menopause/premature ovarian failure, hysterectomy and/or oophorectomy, and/or infertility. We used descriptive statistics to compare the frequency of correct responses between participants with IA and lupus-like diseases.

Results: Of 812 cohort participants, 658 (81.0%) responded to contraception questions; 249 with reproductive capacity (mean age 36.3 ± 7.5 years; 99.2% self-reporting woman as gender identity) who self-reported IA (n=147) or lupus-like disease (n=102) were included in this analysis. Patients with IA vs. lupus-like diseases were more frequently White race (82.5% vs. 69.7%, p=0.04) and less frequently Hispanic/Latinx ethnicity (7.5% vs. 15.7%, p=0.04). 93.2% reported Bachelor's degree or higher education level and 61.1% were married/partnered, with no differences between groups.

There were no differences in the frequency of correct responses about contraception effectiveness between patients with IA and lupus-like disease. Many participants overestimated the effectiveness of methods with low (1-10%) 1-year failure rates: 50.2% for depot medroxyprogesterone acetate [DMPA], 33.7% for estrogen-containing birth control pill [BCP], patch, or vaginal ring, and 28.1% for the progestin-only pill. In terms of methods with high (11-30%) 1-year failure rates, 66.7% overestimated effectiveness of barrier methods [**Table 1**].

Compared to individuals with IA, those with lupus-like disease more frequently responded "true" (i.e., correct response) that BCPs are contraindicated for women with antiphospholipid antibodies (aPL) (54.9% vs. 30.6%, p< 0.001). Participants with lupus-like disease vs. those with IA less frequently responded "false" (i.e., correct response) that BCPs (81.4% vs. 93.2%, p=0.004) and subdermal implants (82.4% vs. 91.2%, p=0.04) are contraindicated for women with any rheumatic disease [**Table 2**].

Conclusion: In a sample of highly educated individuals with reproductive capacity and IA or lupus-like disease, approximately half responded incorrectly about effectiveness of moderately/highly effective contraceptive methods. Compared to those with IA, more patients with lupus-like disease endorsed SRD-specific contraindications to BCPs: half correctly noted BCPs should not be taken by patients with aPL but one-fifth incorrectly noted BCPs should not be taken by anyone with SRD. Our results highlight important misconceptions about contraception that can inform patient education and counseling efforts.

Table 1. Knowledge about Contraception Effectiveness of Women with IA and Lupus-like Disease

	Overall (N=249)	IA (N=147)[1]	Lupus-like (N=102)[2]	p-value
Correct Responses[3]

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Reproductive Issues in Rheumatic Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Individuals with systemic rheumatic disease (SRD) underutilize effective contraception even when prescribed teratogenic medications. As disease-related factors may impact contraception choice, we evaluated the association between contraception use and both SRD diagnosis and teratogenic medication use in patients with inflammatory arthritis (IA) or lupus-like diseases.

Methods: Women aged 18-65 years seen by a rheumatologist at our academic center ≥2 times from 2020-2022 were enrolled in a Reproductive Health and Wellness Cohort. This analysis included participants with self-reported IA or lupus-like disease. We excluded participants >50 years of age and those who self-reported menopause/premature ovarian failure, hysterectomy and/or oophorectomy, and/or infertility. We used descriptive statistics to evaluate demographics, medications, and contraception use, stratified by disease and teratogenic medication use.

Results: Of 812 cohort participants, 658 (81.0%) responded to contraception questions; 249 with reproductive capacity (mean age 36.3 ± 7.5 years, 99.2% self-reporting woman as gender identity) who self-reported IA (n=147) or lupus-like disease (n=102) were included in this analysis. Patients with IA vs. lupus-like disease were more frequently White (82.5% vs. 69.7%, p=0.04) and less frequently Hispanic/Latinx (7.5% vs. 15.7%, p=0.04). 94.8% had private insurance and 61.5% were married/partnered, with no differences between groups.

Compared to individuals with IA, those with lupus-like diseases less frequently used the birth control pill, patch, or vaginal ring (14.7% vs. 31.5%, p=0.003) and more frequently used barrier methods, fertility awareness or withdrawal (30.5% vs. 17.5%, p=0.02); groups did not differ in terms of permanent contraception, intrauterine device, or subdermal implant use [**Table 1**].

Compared to participants not taking teratogenic medication (n=197), those who were (n=52) more frequently reported that their rheumatologist had ever discussed contraception (44.2% vs. 21.8%, p=0.001) and more frequently reported permanent contraception use (8.0% vs. 1.1%, p=0.02). Of those taking teratogenic medication, 44.0% reported use of barrier methods, fertility awareness/withdrawal, or no contraception; frequency of any reversible method or no contraception use did not differ based on teratogen use [**Table 2**].

Conclusion: Among individuals with IA or lupus-like diseases and reproductive capacity seen in an academic rheumatology center, less than half used moderately/highly effective contraception. Although patients taking vs. not taking teratogenic medication were more likely to have discussed contraception with their rheumatologist, they were no more likely to use effective contraception; nearly half used less effective or no contraception. Compared to patients with IA, those with lupus-like diseases less commonly used estrogen-containing methods and more commonly used less effective contracep-

Table 1. Contraception and Teratogen Use in Women with IA and Lupus-like Disease

	IA (N=147)[1]	Lupus-like (N=102)[2]	p-value

Abstract Number: 0473

The Number of Rheumatoid Arthritis Patients Who Give up Pregnancy Due to the Disease Is Decreasing

Ryo Inoue[1], Sakiko Isojima[1], Toshihiro Matsui[2], Shigeto Tohma[3] and Nobuyuki Yajima[4], [1]Division of Rheumatology, Department of Medicine, Showa University School of Medicine, Shinagawa City, Tokyo, Japan, [2]NHO Sagamihara National Hospital, Kanagawa, Japan, [3]NHO Tokyo National Hospital, Dallas, TX, [4]Showa-Universtiy of Medicine, Tokyo, Japan

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Reproductive Issues in Rheumatic Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Biologics have been shown not to be a disruption in pregnancy, and the reproductive health care environment surrounding rheumatoid arthritis patients has improved significantly. In this study, we attempted to assess changes in attitudes toward pregnancy among female rheumatoid arthritis patients of childbearing age using a questionnaire.

Methods: A cross-sectional study using the NinJa database conducted at 49 sites in 2020, a database of RA patients in Japan collected from April 1, 2020 to March 31, 2021. We selected women under 50 years of age who answered a questionnaire on changes in the desired number of children due to the presence of rheumatoid arthritis. Of these, we excluded those who answered that they already had the desired number of children or that they did not want to have children. We compared the percentage of patients who reported that the onset of rheumatoid arthritis had reduced their desire for children in the three groups based on the time of onset of the disease ("before 2000," "2001-2011," and " after 2012"). We also evaluated the stratification by age at onset (24 years and younger, 25 to 34 years, and 35 years and older), the reasons why respondents answered that they wanted fewer children.

Results: Of 15553 patients, 468 were selected, of which 188 were excluded, leaving 280 eligible cases. The number of patients who reported that the onset of rheumatoid arthritis reduced the desired number of children was 57% (20/35) for onset before 2000, 47% (63/133) for onset between 2001 and 2011, and 35% (39/112) for onset after 2012. Within each group, when further divided into three groups according to age at onset, especially in the 25-34 age group, the percentage of patients who reported a reduction in the desired number of children decreased with the time of onset.

We analyzed the reasons for the 122 patients who indicated that they wanted to have fewer children, and found that the most common reason was "I am worried about my ability to take care of my children" (40%: 49 patients). The next most common reason was "I am worried about the effects of the medication on my child" (25%: 30 patients).

Conclusion: In this study, the desired pregnancy outcome was particularly improved in the 25-34 age group, who are likely to be thinking about pregnancy and childbirth in the near future, possibly due to improvements in the treatment environment, such as an increase in the number of drugs available during pregnancy and the accumulation of information on pregnancy complicated by rheumatoid arthritis. On the other hand, the reasons behind the decrease in pregnancy desire may include limitations in physical function and financial burden, which will be an issue to be addressed in the future.

Abstract Number: 0474

Acute Cardiovascular Events During Pregnancy and Delivery in Patients with Autoimmune Rheumatic Diseases (ARDs): An Analysis of National Inpatient Sample

Karun Shrestha[1], Prakriti Subedi[1], Manoj Ghimire[1], Sajana Poudel[2], Kalpana Ghimire[1], Sai Keerthi Parvatheneni[1], Mrunalini Dandamudi[1], Laura Pedraza[1], Luisa Brito[1] and Liliya Gandrabur[3], [1]Department of Internal Medicine, St. Barnabas Hospital, SBH Health System, Bronx, NY, [2]Department of Internal Medicine, John H Stroger Jr Hospital of Cook County, Chicago, IL, [3]SBH Health System, Forest Hills, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Reproductive Issues in Rheumatic Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE), rheumatoid arthritis (RA) & vasculitis are autoimmune rheumatic diseases (ARDs) with systemic involvement. Management of women with ARDs during pregnancy presents unique clinical challenges. Previous studies have indicated that individuals with ARDs are at an increased risk of experiencing significant cardiovascular (CV) events during delivery. Long-term CV risks associated with ARDs are well-documented but less is known about the acute CV complications during delivery. This study aims to investigate the outcomes of CV complications during delivery hospitalizations for women with ARDs.

Methods: NIS (2016-2019) was used to identify delivery hospitalizations among birthing individuals with diagnoses of SLE, RA and systemic vasculitides (medium & small vessel vasculitis) using International Classification of Diseases (ICD-10) codes. The primary outcomes were CV events such as preeclampsia, peripartum cardiomyopathy (PPCM), heart failure (HF), stroke, cardiac arrhythmias and venous thromboembolism (VTE). We also assessed mortality, length of stay and total cost of hospitalization. Statistical analysis was performed in STATA v.17.A multivariable logistic regression model was used to understand the association between ARDs and acute peripartum cardiovascular complications. Statistical significance was defined by the two-sided t-test with a p value < 0.05.

Results: We identified 3,470,086 weighted delivery hospitalizations [mean age 29.14 years, 95% Confidence interval (CI), 29.05-29.24)]. Among them, 5900(0.17%) had SLE, 4895(0.14%) had RA, and 325(0.009%) had vasculitis. After adjusting for age, race, insurance, income and co-morbidities; SLE remained an independent risk factor for peripartum cardiovascular complications such as preeclampsia (OR 1.5; 95% CI, 1.1-2.1), arrhythmia (OR 3.17; 95% CI, 1.73-5.79), and venous thrombosis (OR 8.4; 95% CI, 2.9-22.1). Vasculitides was identified as an independent risk factor for preeclampsia

(OR 4.7; 95%CI, 2-11.3), stroke (OR 513.3; 95% CI, 114-2284), heart failure (OR 24.17; 95% CI, 4.68-124.6) and peripartum cardiomyopathy (OR 66.7; 95% CI, 8.7-509.4. However, RA was found to be a risk factor for pre-eclampisa only(OR 1.5; 95% CI, 1.05-2.1).

The study also revealed significantly higher in-hospital mortality among pregnant women with SLE (0.17% vs. 0.0001%, p< 0.001) and vasculitis (1.54% vs. 0.0001%, p< 0.001) compared to women without ARDs. Individuals with SLE had a longer mean length of hospital stay compared to those without SLE (3.7 days vs. 2.5 days, p< 0.001), as did individuals with vasculitis compared to those without vasculitis (4.7 days vs. 2.5 days, p< 0.001). The mean cost of hospitalization was also

Prevalence of Endometriosis and Polycystic Ovarian Syndrome in Patients with Rheumatic Diseases in the United States

Sabahat Usmani[1], Catherine Lavallee[2], Maria Antonelli[3] and Cuoghi Edens[4], [1]Weiss Memorial Hospital, Chicago, IL, [2]Virginia Tech Carilion School of Medicine, Roanoke, VA, [3]MetroHealth System, Cleveland, OH, [4]University of Chicago, Chicago, IL

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Reproductive Issues in Rheumatic Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Endometriosis (ENDO) and Polycystic Ovarian Syndrome (PCOS) are underdiagnosed, often debilitating conditions with unknown etiologies that, like rheumatic diseases, affect reproductive-aged women. Recent studies suggest an association between ENDO across autoimmune diseases; PCOS has not been examined. The purpose of our study is to determine the prevalence and association of these conditions in patients with rheumatologic diseases in a large ambulatory population.

Table 1. Polycystic Ovarian Syndrome and Endometriosis Prevalence by Rheumatic Disease and Age

Rheumatic Disease	PCOS All ages	PCOS 10-49yo	ENDO All ages	ENDO 10-49yo
JIA	10.0%	11.1%	6.3%	2.3%
PsA	5.1%	6.1%	3.5%	3.3%
RA	2.5%	6.8%	3.5%	6.5%

SSc	1.99 (1.85-2.13)	3.48 (3.09-3.90)	2.82 (2.62-3.02)	5.34 (4.65-6.10)
All Rheum disease of Interest	2.21 (2.18-2.24)	4.31 (4.24-4.38)	4.38 (4.33-4.43)	13.34 (13.15-13.54)

Juvenile idiopathic arthritis (JIA) Psoriatic arthritis (PsA) Axial spondyloarthritis (AS) Rheumatoid arthritis (RA) Systemic lupus erythematosus (SLE) Mixed or undifferentiated connective tissue disease (CTD) Inflammatory Myositis (IM) Sjogren's disease (SD) Systemic Sclerosis (SSc)

Methods: Utilizing the secure cloud-based platform, IBM® Explorys®, we conducted a retrospective cross-sectional study of females, ages 10-49, from the United States with PCOS or ENDO and rheumatic diseases using pooled deidentified data from multiple US health-care systems using Epic® electronic medical record platform, collected from 1999 to 2022. Rheumatic diseases examined: Juvenile idiopathic arthritis (JIA) Psoriatic arthritis (PsA) Axial spondyloarthritis (AS) Rheumatoid arthritis (RA) Systemic lupus erythematosus (SLE) Mixed or undifferentiated connective tissue disease (CTD) Inflammatory Myositis (IM) Sjogren's disease (SD) Systemic Sclerosis (SSc).Females in the IBM® Explorys® platform with no rheumatic diseases served as the control group representing the general population. Chi-squared test and odds ratio (OR) were calculated.

Results: RA was present in 1% of the Explorys® population, in line with established epidemiologic data, serving as validation of the data set. The prevalence of PCOS and ENDO in the general population was under 2%, regardless of age.900,600 women had one of the queried rheumatic diseases, with 194,200 ages 10-49. In those with a rheumatic disease, 3% and 3.9% had PCOS and ENDO, in those 10-49 prevalence was 3.9% and 5.8%, respectively. Table 1 contains prevalence for each specific rheumatic disease. SD had the highest ENDO prevalence and SD, JIA, AS, and CTD the highest prevalence of PCOS. There is evidence that there is an association between each unique rheumatic disease or as a whole with ENDO ($p< 0.0001$) and PCOS ($p< 0.0001$).

If age 10-49 with a rheumatic disease, the odds of having PCOS was 4.3 (4.24-4.38) times higher than in the general population with the odds of having ENDO 13.34 (13.15-13.54).In this demographic, SD, AS and CTD had the highest likelihood of both ENDO and PCOS, which can be found in Table 2.Across all ages, JIA and CTD had the highest likelihood of PCOS and ENDO. SLE also had one of the highest likelihoods of having ENDO across all ages.

Conclusion: Increased prevalence and evidence of association exist between rheumatic diseases and both PCOS and ENDO compared to the general population when examined in a large electronic medical record platform. Additionally, there is an increased likelihood of having PCOS or ENDO in all rheumatic diseases analyzed. Future studies are needed to identify the mechanisms contributing to these findings of PCOS and ENDO in patients with rheumatic diseases as well as increased awareness of these underdiagnosed conditions amongst those who care for these patients to aid in their diagnosis and care.

Factors Associated with the Need for Assisted Reproductive Therapies in a Spanish Cohort of Patients with Rheumatic Diseases

Antía García-Fernández[1], Fernando Rengifo-García[1], Raquel Senosiain-Echarte[1], Miguel álvaro-Navidad[1], Miguel A Gonzalez-Gay[2] and Juan A Martínez-López[1], [1]Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain, [2]IDIVAL and School of Medicine, UC, Santander; Department of Rheumatology, IIS-Fundación Jiménez Díaz, Madrid, Santander, Spain

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Reproductive Issues in Rheumatic Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatic diseases (RMD) have a lower pregnancy rate, with infertility being one of the main causes. The rate of assisted reproductive therapies (ART) and the factors associated with the need for ART in patients with RMD are not fully identified.

Methods: Retrospective study of patients with RMD followed up in a specialized pregnancy clinic in Madrid, Spain. Patients with RMD who attended the clinic from December 2012 to January 2023 were included. After one year trying to conceive, patients were referred for ART. Each episode of pregnancy counseling was included as a case. Carriers of autoantibodies, anti-Ro and antiphospholipid (aPL) antibodies, without defined disease, were excluded. Factors associated with the need for ART (ART group) were compared with patients who did not require ART (no ART group). Categorical variables were described as proportions and/or percentages, while continuous variables were shown as mean and standard deviation (SD). The Mann-Whitney U test, Student t test and $\chi 2$ test were used to compare data (ART and non-ART groups), when appropriate. A multivariate logistic regression model was plotted to identify factors associated with need of ART.

Results: 259 cases in 202 patients were included. Fifty-two cases, in 39 patients, of autoantibody carriers were excluded. Sixty-one of 259 (23.6%) cases required ART. The main characteristics and univariate analysis are reported in Table 1. The most frequent diagnosis was the combined RA-JIA group (28.6%). There was a low frequency of comorbidities, including previous nephritis, and 62.7% of the cases had never been pregnant. The patients who required ART were older, more frequently with dyslipidemia. A higher rate of patients in the non-ART group had previously delivered a newborn, but there was no difference from prior miscarriage. There were no differences regarding immunosuppressive treatment, but there was a higher prescription of hydroxychloroquine, aspirin, and heparin in the ART group. In the multivariate analysis (Table 2), older age was associated with the need for ART, while previous delivery of a newborn was the main protective factor for not needing ART.

198 (76.4%) cases became pregnant. The pregnancy rate was lower among the ART group (39/61, 63.9%) compared to the no ART group (159/198, 80.3%), p=0.008. Among the 61 (23.6%) cases who did not become pregnant, the main reason in the ART group was ART failure (9/21, 42.9%) and in the no ART group it was the interruption of the desire for pregnancy (17/39, 43.6%) and active disease (8/39, 20.5%), p= 0.03.

Conclusion: In our cohort, the ART rate was 23.5% and maternal age was the main factor associated with the need for ART, while a history of a previous newborn was associated with a lower risk of needing ART.

Session Title: Reproductive Issues in Rheumatic Disorders Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Many women with chronic rheumatic inflammatory diseases (CRID) stop tumor necrosis factor inhibitors (TNFi) treatment once pregnancy is confirmed to avoid potential adverse fetal events but taking the risk of inflammatory flare.

The aim of the study was to compare in real life settings the pregnancy outcomes of two treatment strategies among women with CRID: to continue TNFi vs. stop TNFi upon pregnancy diagnosis.

Methods: the French nationwide health insurance database (*Système National des Données de Santé*) was used to emulate a target trial in adult women, with CRID (i.e., rheumatoid arthritis, psoriatic arthritis or spondyloarthritis), having started a singleton pregnancy between 2008 and 2017, and and being treated with TNFi upon pregnancy diagnosis. We compared the frequency of unfavorable pregnancy outcomes (malformations, obstetrical complications, and infections) between the treatment strategies at pregnancy diagnosis, using inverse probability weighted marginal models.

	OUTCOMES	TNFI CONTINUE (N = 584)[$]	TNFI STOP (N=1497)[$]	RELATIVE RISK (CONTINUE VS. STOP) 95% CI
	Live births	505 (86.6%)	1327 (88.6%)	0.9 [0.9 - 1.0]
	Spontaneous abortion (GA < 22 WG or birth weight < 500g)	11 (1.9%)	50 (3.3%)	0.6 [0.3 - 1.2]
	Intrauterine fetal death (GA >=22 WG or birth weight >=500g)	6 (1.1%)	8 (0.5%)	2.0 [0.8- 5.3]
	Medical termination of pregnancy	4 (0.6%)	15 (1.0%)	0.6 [0.2 - 2.4]
	Preterm birth (GA between 22 and 37 among live birth)	37 (6.4%)	108 (7.2%)	0.9 [0.6 - 1.3]
	Small for GA (< 10th percentile)	52 (8.9%)	139 (9.3%)	0.9 [0.7 - 1.4]
	Cesarean delivery	115 (19.8%)	337 (22.5%)	0.9 [0.7- 1.1]
	Eclampsia/Pre-eclampsia	6 (1.0%)	21 (1.4%)	0.7 [0.3 - 1.6]

	Severe infection (requiring hospitalization) during the first year of life	51/486 (10.6%)	119/1293 (9.2%)	1.2 [0.8 - 1.7]
	NCIU admission for more than 48h in infants born after 37 WG	6/486 (1.3%)	24/1293 (1.9%)	0.7 [0.3 - 1.9]
INFANTS				

$: Weighted pseudopopulation; Abbreviations: GA = gestational age; WG = weeks of gestation

Results: A total of 2082 singleton pregnancies of CRID women (579 RA and 1503 SpA) exposed to TNFi 6 weeks after last menstrual period were identified; among them, in 1497 (72%) TNFi was discontinued.

Mean (SD) age of women at the start of pregnancy was 31 (5) years and mean (SD) disease duration was 4 (5) years. Continuation of TNFi was not associated with increased frequencies of unfavorable obstetrical nor infant outcomes, and interestingly, the proportion of maternal severe infections (i.e., requiring hospitalization) was significantly lower in the 'continue' group (1(0.2%) vs. 19 (1.3%), with an adjusted risk ratio = 0.2 [0.1 - 0.6]).

Conclusion: In pregnant women with CRID treated with TNFi until pregnancy diagnosis, unfavorable obstetrical outcomes were not different to those observed when TNFi were maintained, and maternal severe infections were less frequent, when compared with a strategy of stopping TNFi.

The Long-term Neurodevelopmental Outcome of Children Born to Women with Systemic Sclerosis: Assessment Through a Self-reported Questionnaire by the Mothers and Nneuropsychiatric Evaluations of the Children

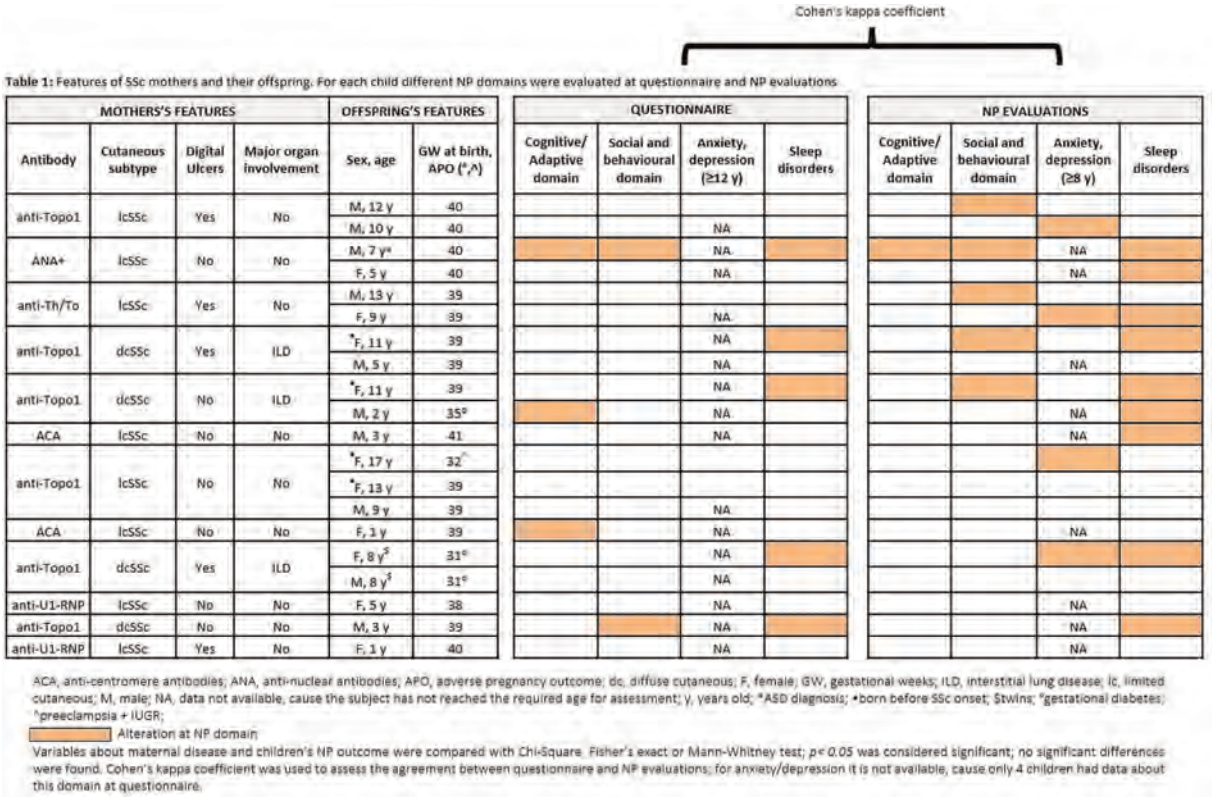
Maria Grazia Lazzaroni[1], Eleonora Pedretti[1], Liala Moschetti[1], Marzia Bendoni[2], Lucrezia Visconti[2], Anna Molinaro[2], Cecilia Nalli[3], Franco Franceschini[3], Paolo Airò[1], Jessica Galli[2], Elisa Fazzi[2], Angela Tincani[4] and Laura Andreoli[5], [1]Rheumatology and Clinical Immunology, ASST Spedali Civili of Brescia, University of Brescia, Brescia, Italy, [2]Unit of Child and Adolescent Neuropsychiatry, ASST Spedali Civili of Brescia, University of Brescia, Brescia, Italy, [3]Rheumatology and Clinical Immunology, ASST Spedali Civili of Brescia, Department of Clinical and Experimental Sciences, University of Brescia, Brescia, Italy, [4]Rheumatology and Clinical Immunology, ASST Spedali Civili of Brescia, University of Brescia, Gussago, Italy, [5]University of Brescia, Brescia, Italy

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Reproductive Issues in Rheumatic Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The long-term neuropsychiatric (NP) outcome of children born to mothers affected by autoimmune diseases (AIDs) represents a controversial topic, with few studies[1-3] reporting a possible increased prevalence of NP alterations. We focused on the neurodevelopment (ND) of children born to Systemic Sclerosis (SSc) mothers, starting with the creation of an ad-hoc questionnaire regarding different aspects of children's ND administered to consecutive SSc mothers in 2021[4]. We further investigated the long-term NP outcome of SSc offspring by offering a comprehensive pediatric NP evaluation.

Methods: SSc mothers (ACR/EULAR 2013 criteria) who previously completed the questionnaire[4] were allowed to have their children aged < = 18 years undergo a clinical NP evaluation including:

Table 1: Features of SSc mothers and their offspring. For each child different NP domains were evaluated at questionnaire and NP evaluations



Cohen's kappa coefficient

Table 1: Features of SSc mothers and their offspring. For each child different NP domains were evaluated at questionnaire and NP evaluations

MOTHERS'S FEATURES				OFFSPRING'S FEATURES		QUESTIONNAIRE				NP EVALUATIONS			
Antibody	Cutaneous subtype	Digital Ulcers	Major organ involvement	Sex, age	GW at birth, APO (*,^)	Cognitive/ Adaptive domain	Social and behavioural domain	Anxiety, depression (≥12 y)	Sleep disorders	Cognitive/ Adaptive domain	Social and behavioural domain	Anxiety, depression (≥8 y)	Sleep disorders

ACA, anti-centromere antibodies; ANA, anti-nuclear antibodies; APO, adverse pregnancy outcome; dc, diffuse cutaneous; F, female; GW, gestational weeks; ILD, interstitial lung disease; lc, limited cutaneous; M, male; NA, data not available, cause the subject has not reached the required age for assessment; y, years old; *ASD diagnosis; •born before SSc onset; §twins; °gestational diabetes; ^preeclampsia + IUGR;

Alteration at NP domain

Variables about maternal disease and children's NP outcome were compared with Chi-Square, Fisher's exact or Mann-Whitney test; $p < 0.05$ was considered significant; no significant differences were found. Cohen's kappa coefficient was used to assess the agreement between questionnaire and NP evaluations; for anxiety/depression it is not available, cause only 4 children had data about this domain at questionnaire.

(1) cognitive/adaptive functioning (Griffiths Mental Development Scales -GMDS-III-; Wechsler Scale for corrected age -WISC-III; Vineland Adaptive Behavior Scales -VABS-II-)

(2) behavioral/social problems (Child Behavior CheckList -CBCL-, fulfilled by the mothers; Youth Self Report -YSR-, for children [3] >=11 years)

(3) anxiety/depression/somatic disorders (Self-administered psychiatric scales for children/adolescents -SAFA-A/D/S- [3] >=8 years)

(4) sleep disorders.

Cohen's kappa coefficient was used to evaluate the agreement between questionnaire answers and NP test results.

Results: 23 SSc mothers reported 39 children aged < = 18 years, 37/39 were proposed for NP evaluation and 20 agreed to be evaluated (F/M 1:1; median age 8 [6-11] years). The mothers had reported at least one alteration in the questionnaire for 7 children (Table 1); one already had a diagnosis of autism spectrum disorder (ASD). At NP evaluations were recorded:

(1) normal scores for cognitive/adaptive functioning in all children, except the one with ASD
(2) an increased risk of developing behavioral/social problems especially in extra-academic/social activities in 3/20 at CBCL and in 3/6 at YSR
(3) an increased risk of developing depression in 4/11
(4) sleep disorders in 9/20

Features of mothers and their offspring are shown in Table 1. The agreement between questionnaires and NP evaluation was moderate for cognitive/adaptive functioning and sleep disorders (k 0.5 and 0.6 respectively) and weak for behavioural/social problems (k 0.2).

Conclusion: At NP evaluation, children born to SSc mothers showed normal cognitive skills but a tendency toward an impairment in the behavioral/social area. Mothers seldom recognized such a difficulty, according to the self-reported questionnaire.

In the setting of preconception counseling, it is important to inform SSc mothers about possible NP symptoms in their children and to seek for a specialist evaluation in case of doubts. Indeed, with the help of specialists, most NP problems can be overcome if detected early.

Exploring Reproductive Experiences with Women Enrolled in the Vasculitis Pregnancy Registry

Catherine Sims[1], Christine Yeung[2], Heather Tam[3], Joyce Kullman[4], Amanda Eudy[5], Renee Borchin[6], Cristina Burroughs[6], Megan Clowse[7] and Peter Merkel[2], [1]Duke University School of Medicine, Durham, NC, [2]University of Pennsylvania, Philadelphia, PA, [3]Vasculitis Patient Powered Research Network, Stanford, CA, [4]Vasculitis Foundation, Kansas City, MO, [5]Duke University, Raleigh, NC, [6]University of South Florida, Tampa, FL, [7]Duke University, Chapel Hill, NC

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Reproductive Issues in Rheumatic Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: There are limited data on the reproductive health and experiences of women with vasculitis. This study engaged women with vasculitis to understand their perspectives about pregnancy and breastfeeding.

Methods: The Vasculitis Pregnancy Registry (VPREG) is an international, online, prospective, patient-reported registry within the Vasculitis Patient-Powered Research Network (VPPRN). The VPREG team partnered with the Vasculitis Foundation and patient research partners to develop two qualitative interview guides to prompt discussions of reproductive experiences with i) women who had live births; and ii) women who had non-live births. The guides included closed-ended scale items and open-ended prompts to elicit participant experiences. The interviews, performed by a rheumatologist, explored topics including pregnancy, medication choices to treat vasculitis, disease activity levels, patient-physician relationships, experiences with delivery, and breastfeeding. Participant responses were evaluated using thematic analysis.

Results: The 18 participants were located in North America, ranged in age from 25-43 years, and most had more than one pregnancy (n=11) (**Table 1**). Anti-neutrophil cytoplasmic antibody-associated vasculitis was the most common diagnosis (n=10) followed by Takayasu's arteritis (n=4), Behçet's disease (n=2), IgA vasculitis (n=1), and relapsing polychondritis (n=1). Almost all pregnancies ended in a live birth (n=17).

Table 1. Patient Characteristics among Women with Vasculitis and a History of Pregnancy

Mean age at enrollment (range)	33 years (25-43)
Country of origin	United States: 14 Canada: 4
Type of vasculitis	ANCA-associated vasculitis: 10 (55.6%) *-Granulomatosis with polyangiitis: 8* *-Microscopic polyangiitis: 1* *-Eosinophilic granulomatosis with polyangiitis: 1* Takayasu's arteritis: 4 (22.2%) Behçet's disease: 2 (11.1%) IgA vasculitis: 1 (5.6%) Other/suspected: 1 (5.6%)
First pregnancy	No: 11 (61.1%) Yes: 6 (33.3%) No response: 1 (5.5%)

Figure 1. Women utilized a broad range of resources for information about pregnancy and breastfeeding

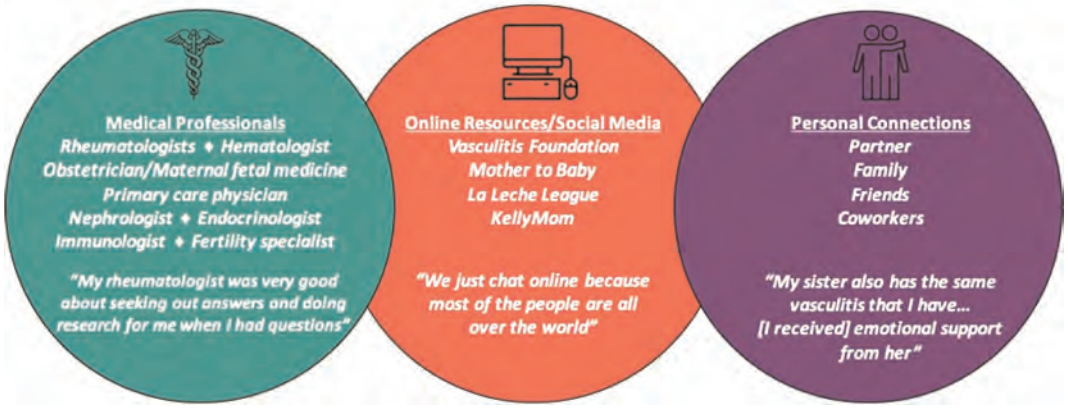

Figure 1 displays the variety of resources patients with vasculitis accessed to gather information about their reproductive health

Figure 2. Emergent themes in the reproductive journey for women with vasculitis

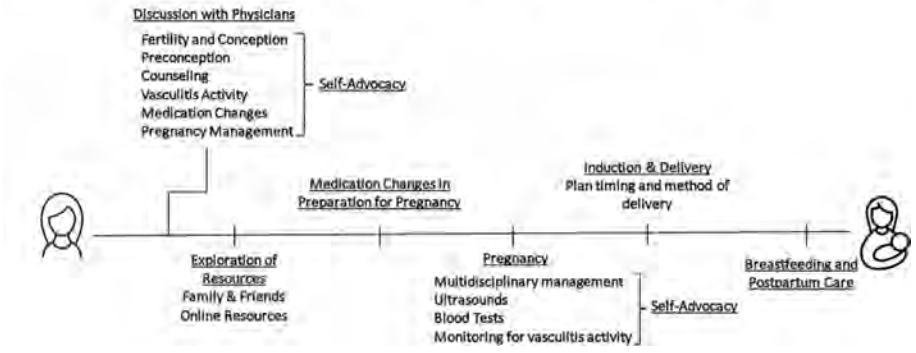

Figure 2 summarizes the emergent themes along the reproductive timeline of patients with vasculitis

Four major themes emerged from interviews: 1) Women sought information about pregnancy from a range of sources, including their physicians, social media, and online forums (**Figure 1**); 2) Women cited discussions with family and physicians as important when deciding about treatment of vasculitis during pregnancy; 3) Women with vasculitis developed skills of self-advocacy during pregnancy to optimize communication between medical providers; and 4) Women with vasculitis had positive reproductive experiences with the majority reporting no flares of vasculitis, feeling "very well", and having "no pain" related to their vasculitis (**Figure 2**). Women who required changes to their medications to pursue their reproductive goals, identified physicians and family members as important participants in these conversations. Women described proactively gathering information about pregnancy and vasculitis from multiple sources, but ultimately decided their physician's perspective was the most influential. All women that used social media and online resources reported it did not impact or determine their reproductive decisions.

Conclusion: Women with vasculitis value the recommendations of their rheumatologists during reproductive healthcare discussions. Self-advocacy was frequently described during pregnancy because women felt they needed to act as liaisons among multiple specialists to ensure proper medical treatment. This study found that patients prioritize their relationships and conversations with physicians when planning for pregnancy.

Non-random Sampling in Rheumatology Randomized Controlled Trials: Evidence of Concerning Trial Conduct?

Victoria Le[1], Mats Junek[2], Mike Putman[3], Maximilian Casey[1], Kenrick Manswell[1], Jay Goldsher[1], Elizabeth Nettleton[1], Desh Nepal[1] and Sanket Shah[1], [1]Medical College of Wisconsin, Milwaukee, WI, [2]McMaster University, Hamilton, ON, Canada, [3]Division of Rheumatology, Medical College of Wisconsin, Milwaukee, WI

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Research Methodology – Interprofessional Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Non-random sampling of baseline variables in randomized controlled trials (RCTs) may be due unintentional errors, stratified randomization strategies, or data fabrication. Prior studies have suggested that non-random sampling may occur in up to 15% of RCTs in anesthesiology and have led to high profile retractions of fabricated data. No similar studies have been conducted in the field of rheumatology.

Methods: A PRISMA compliant systematic review was conducted to identify rheumatology RCTs published between 2010 and 2022 and met the following criteria: >20 patients per arm, first publication of trial data, ≥5 extractable variables, 2-5 trial arms, and studied a rheumatic disease. Baseline demographic and clinical variables from randomized arms were extracted. Monte Carlo simulations (50,000 per variable) were performed to calculate p values for individual baseline variables, which

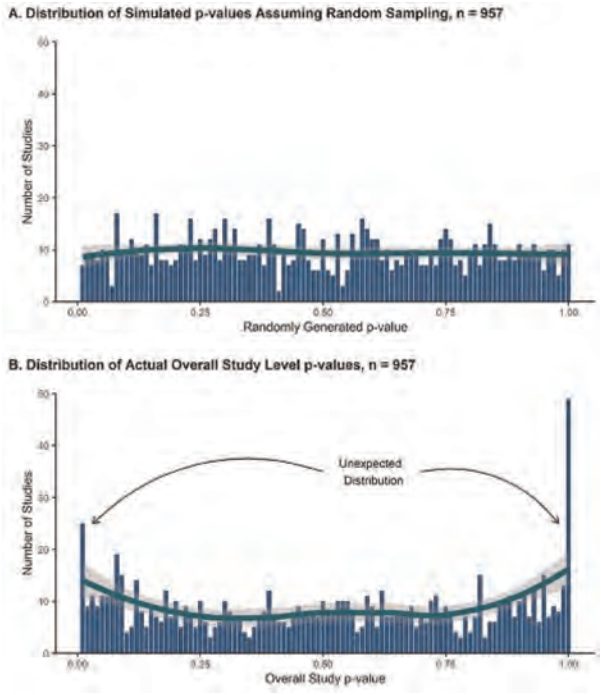

Image 1. (A) Distribution of Simulated p-values Assuming Random Sampling (B) Distribution of Actual Overall Study Level

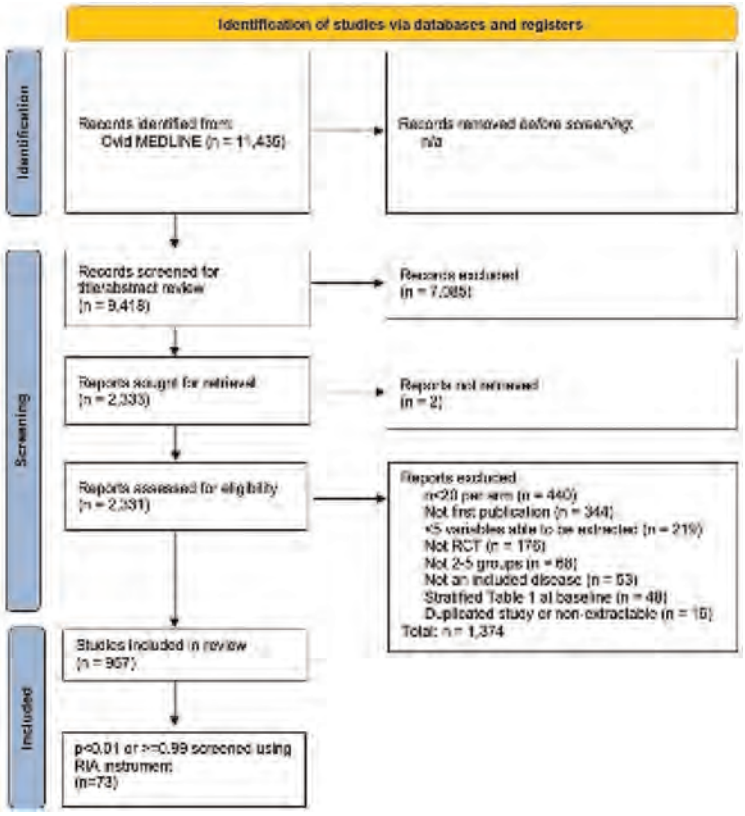

Image 2. Identification of studies via databases and registers

were then used to calculate an overall trial p-value using the Fischer-Stouffer method. The distribution of participant summary p-values, which should be uniform under conditions of true random sampling, was graphed. RCTs with trial p-values ≤ 0.01 or ≥ 0.99 underwent further scrutiny using a modified version of the Research Integrity Assessment (RIA) Checklist. Integrity concerns for individual metrics (No, Some, Significant Concerns) and overall (Low, Moderate, High Concern) were assessed.

Results: We identified 11,435 RCTs, 2,313 of which underwent full text review. Of these, 957 met inclusion criteria, from which 19,799 baseline variables were extracted. A uniform distribution of trial p-values would have produced approximately 19 studies with p values < 0.01 or >0.99; our search identified 73 such studies (Figure 1). Using the RIA checklist, 64 (87.7%) studies were found to be lacking across at least one metric of study integrity. The most common items among trials with high integrity concerns included trials not being prospectively registered (21, 28.8%) and reporting ethics approval number (20, 27.4%). None of the studies were retracted or had letters of concern written. Based on the RIA findings, 28 (38.4%) trials were rated as having a high level of data integrity concerns, 3 (4.1%) had moderate data integrity concerns, and 42 (57.5%) had low data integrity concerns.

Conclusion: Non-random sampling has occurred in nearly 1 out of every 100 rheumatology randomized controlled trials. The majority of studies were assessed as being of low risk of threats to their integrity, but 27 out of 957 studies (2.8%) had moderate to high concern of problematic conduct. Understanding common themes within these studies will assist in identifying areas that require further scrutiny in evidence synthesis and implementation.

Table 1: Summary statistics of threats to individual research integrity based on the Research Integrity Assessment checklist (RIA) and overall assessment by RIA reviewers, n = 73

Table 1: Summary statistics of threats to individual research integrity based on the Research Integrity Assessment checklist (RIA) and overall assessment by RIA reviewers, n = 73

Variable	High concern (n=28)	Moderate concern (n=3)	Low concern (n=42)
Not prospectively registered	21 (28.8%)	2 (2.7%)	50 (68.5%)
Ethics approval number not reported	20 (27.4%)	2 (2.7%)	51 (69.9%)

Automatically Detect Finger Joint Center and Angle on Hand X-ray: A Deep Learning Model

Yuan Gao[1], Juan Shan[2], Raj Ponnusamy[2], Jordan Blackadar[3], Carmine Guida[2], Jeffrey Driban[4], Timothy McAlindon[5] and **Ming Zhang**[1], [1]Boston University, Boston, MA, [2]Pace University, New York, NY, [3]Photo Diagnostic System, Boston, MA, [4]Tufts Medical Center, Boston, MA, [5]Tufts Medical Center, Arlington, MA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Research Methodology – Interprofessional Poster

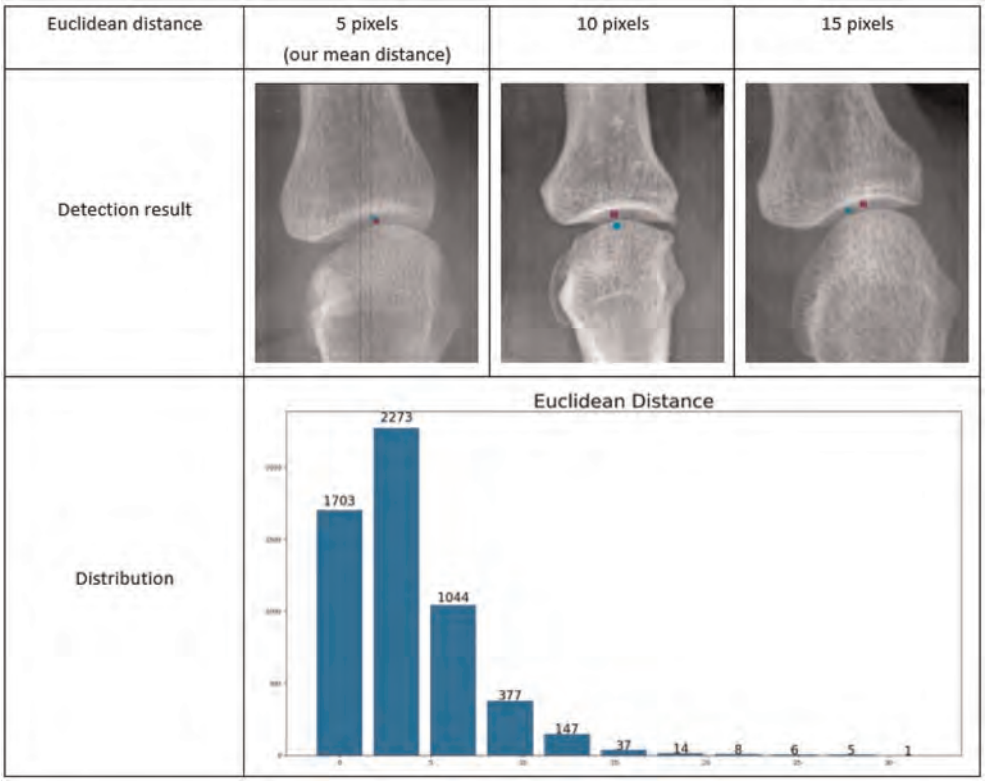
Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

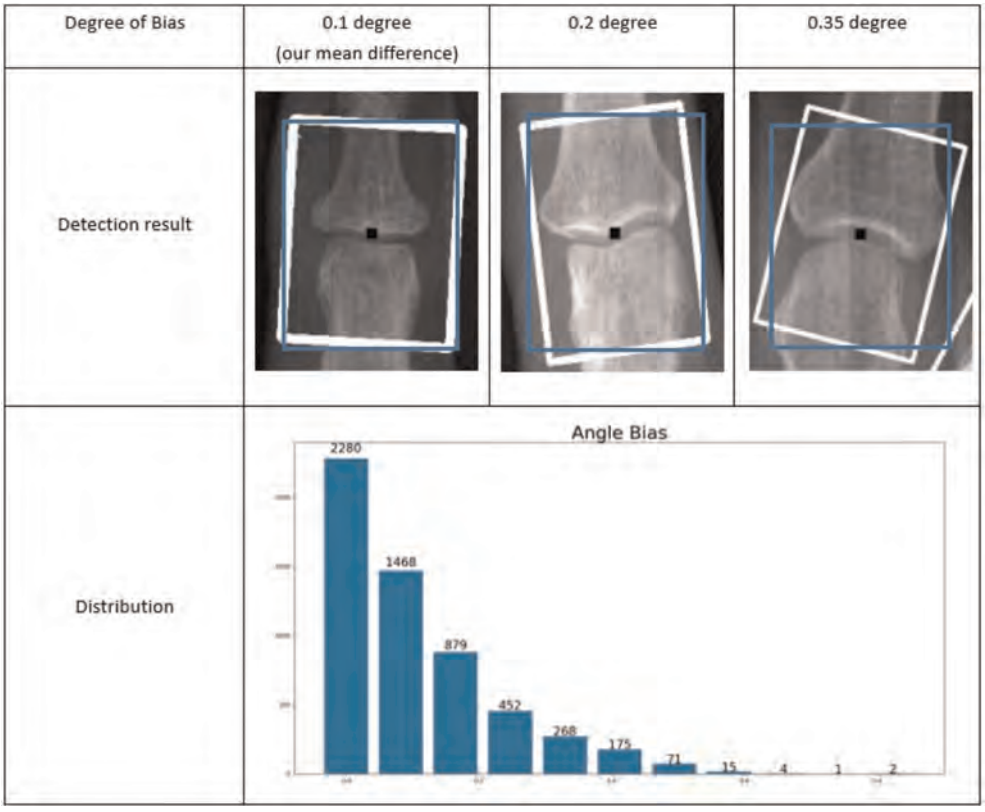
Background/Purpose: Hand osteoarthritis (OA) is the second most common anatomic region for OA. The diagnosis and evaluation of hand OA heavily rely on subjective assessments conducted by experienced physicians, primarily utilizing clinical examinations and radiographs. However, the interpretation of radiographs is prone to considerable variability, leading to challenges in objectively assessing hand OA. This abstract presents the development of an automated approach using deep learning and convolutional neural networks (CNN) to localize joint hand centers and measure angles, offering a potential solution to the Joint Space Width (JSW) estimation and hand OA assessment.

Methods: We selected 3,557 hand X-ray images from the Osteoarthritis Initiative (OAI). Two readers performed manual annotations of the twelve finger joints on each hand, the distal interphalangeal (DIP), proximal interphalangeal (PIP), and metacarpophalangeal (MCP) joints. Each joint was enclosed within a bounding box measuring 180*180 pixels. To enhance the diversity of the training data for the machine learning model, we employed various image augmentation techniques, including rotation, flipping, scaling, cropping, and mosaic. The data was split into training, validation, and test sets in a 7 : 1.5: 1.5 ratio. Utilizing the YOLOv5 architecture, the model was trained for 100 epochs using stochastic gradient descent (SGD) as the optimizer. The model output provided each joint's position in coordinate form, which calculate the rotation and inclination angles of the DIP, PIP, and MCP joints. Specifically, we connected the center points of the DIP and PIP joints to derive the slope as the rotation angle of the DIP joint. Similarly, by connecting the PIP and MCP joints, we obtained the slope representing the rotation angle of the MCP joint. The rotation angle of the PIP joint was computed as the average of these two slopes. Leveraging the joint positions and the computed angles, we selectively cropped image patches from the original hand X-ray images, ensuring the joints were vertically oriented. This vertical orientation is crucial for accurately calculating the joint space width in subsequent steps.

Results: In our evaluation process, our testing set has an average Euclidean distance (between the detection center and human annotation center) of 5.1 pixels (Figure 1). The mean error (absolute distance) in the test set for the angle estimation step is 0.144 degrees (Figure 2). Interestingly, we encountered 21 human annotation errors within the dataset during the initial training of YOLOv5, resulting in a human error rate of 0.5%, while the model successfully identified 5 out of the 6 human errors in the test set, leading to machine error rate of 0.2%. This indicates that our model exhibited a lower error rate than manual annotations.



Examples of Euclidean Distance between the manual label (purple) and computer-generated (green) result



Angle difference between a manual label (white box) and computer-generated (blue box) results

Conclusion: Our deep-learning approach successfully detects each finger joint its rotation angle. Moreover, our model shows a lower error rate than manually labeling the joints. It also exhibits high accuracy and holds promise in reducing inter-observer variability during hand OA evaluation. In future studies, we intend to develop an automatic JSW detection algorithm and explore the correlation between clinical symptoms and JSW.

Preference and Relative Sensitivity of Indicators Reporting Response Rate in Pharmaceutical Trials of Psoriasis and Psoriatic Arthritis

Jingru Tian[1], Shuntong Kang[2], Dingyao Zhang[3] and Qianjin Lu[4], [1]Institute of Dermatology, Chinese Academy of Medical Sciences and Peking Union Medical College, Nanjing, China, [2]Department of Dermatology, Hunan Key Laboratory of Medical Epigenomics, The Second Xiangya Hospital, Central South University, Nanjing, China, [3]Graduate Program in Biological and Biomedical Sciences, Yale University, New Haven, CT, [4]Hospital for Skin Diseases, Institute of Dermatology, Chinese Academy of Medical Sciences and Peking Union Medical College, Changsha, China

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Research Methodology – Interprofessional Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Numerous indicators have been proposed to evaluate the efficacy for randomized clinical trials (RCTs) of psoriasis (Pso) and psoriatic arthritis (PsA), but the comparability and correlation remain unknown. To evaluate the preference and relative sensitivity of the mostly widely used indicators that report response rate, and to provide advice for the primary endpoint selection for Pso and PsA.

Methods: We conducted a systematic search including 3 databases and 4 registries to identify all pharmacological intervention-controlled RCTs of Pso. Bayesian hierarchical linear mixed model assessed the relative discriminations and provided a ranking of these indicators.

Results: Altogether 326 RCTs met our inclusion criteria, with 285 and 65 records on Pso and PsA, respectively. We found evidence of significant differences between indicators. Psoriasis Area and Severity Index (PASI) 50, PASI 75 and Investigator's Global Assessment (IGA) 0,1 were powerful indicators to reveal the pharmacological efficacy in most RCTs of Pso(-Figure 1). In contrast, PASI 125, Dermatology Life Quality Index (DIQI) 0,1 and Numerical Rating Scale (NRS) 4 were not preferred under different circumstances. Additionally, PASI 50, PASI 75 and PASI 90 seemed to be the most effective in nearly all types of pharmacological RCTs of PsA (Figure 2). However, due to their extremely sensitivity, American College of Rheumatology (ACR) 20 was also recommended to avoid exaggerating the therapeutic advantages of interventions. Instead, ACR 50, ACR 70 and Minimal Disease Activity (MDA) were the least sensitive, but they were supposed to be more cautious in evaluating disease changing. Indicator preference was slightly altered by disease severity, intervention type and administration method(Table 1).

Conclusion: The impressionable efficacy discrimination ability of indicators highlights the importance of flexibility and comprehensiveness when choosing primary outcome(s). As for trials that are only evaluated by indicators with extremely sensitivity, attention should be paid to the outcome interpretation to avoid the exaggeration of treatment efficacy.

Jones[1] and Neil Basu[3], [1]Aberdeen Centre for Arthritis and Musculoskeletal Health (Epidemiology Group), University of Aberdeen, Aberdeen, United Kingdom, [2]University of Aberdeen, Aberdeen, United Kingdom, [3]University of Glasgow, Glasgow, United Kingdom

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: PsA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Co-morbid fibromyalgia has been shown to be an important influence on non-response in patients with some inflammatory arthritides. Around 1 in 5 patients with PsA have been estimated to have co-morbid fibromyalgia. Here we examine to what extent meeting criteria for fibromyalgia or reporting symptoms typical of fibromyalgia is an important determinant of non-response to a biologic or targeted synthetic (b/ts) DMARD, taking into account other predictors of non-response.

Table. Fibromyalgia and other predictors of treatment response

		Model 1[1] N = 125	Model 2[2] N = 116
Variable		**OR (95% CI)[3]**	**OR (95% CI)[3]**
Polysymptomatic distress (FMness)	0-31	0.66 (0.40, 1.08)[4]	-
FM ACR2016 criteria		-	0.29 (0.08, 0.99)
csDMARD (current)		2.58 (1.01, 6.61)	2.61 (0.92, 7.44)
Patient global score (Arthritis)	0-10	1.27 (1.04, 1.55)	-
Physician global (skin disease activity)	0-10	1.28 (1.05, 1.57)	1.42 (1.10, 1.85)
Symptom duration (joints), years		-	0.79 (0.63, 0.98)
Steroids (current)		0.42 (0.15, 1.13)	0.40 (0.13, 1.24)
Nail onycholysis (current)		-	3.07 (1.11, 8.50)
Index of Multiple Deprivation (Based on area of residence)	Decile 1-4[5]	Reference	Reference
	Decile 5-7	1.36 (0.41, 4.50)	1.58 (0.37, 6.73)
	Decile 8-10	3.15 (1.03, 9.60)	3.46 (1.05, 11.38)
Sensitivity		41.0%	54.6%
Specificity		88.4%	94.0%

[1] Polysymptomatic distress forced into model
[2] FM ACR2016 criteria forced into model
[3] Odds Ratio (per unit increase unless otherwise specified)
[4] Odds Ratio per 5-unit increase in FMness
[5] Least Deprived

Methods: Data included were from BSR-PsA (January 2023 download), a prospective registry of patients with PsA who meet CASPAR criteria, recruited across Great Britain. In this analysis we include those newly commencing a bDMARD/tsDMARD (having not previously taken the same agent). The association between patient characteristics and treatment response (PsARC) was determined by logistic regression. The fibromyalgia polysymptomatic distress score (FMness) (*Model1*) or fibromyalgia 2016 (FM2016) criteria (*Model2*) was forced into the model and then other predictors of poor outcome which improved the fit of the model were determined using a stepwise procedure. There were 12 candidate variables across social/demographic/economic, clinical and patient-reported outcome domains.

Results: 148 patients were included with median age 52 years, 29% male, 52% obese with a median FMness score of 12 and 29% met FM criteria. They had a median disease duration of 7 years, a median Quality of Life score (PsAQoL) of 12, physician global (musculoskeletal and skin) of 5.1, Disease Activity in Psoriatic Arthritis (DAPSA) 34 and 57% had ≥1 comorbidity. Follow-up was at a median of 6 months (IQR 4.9-6.7) at which point 28% fulfilled PsARC. Multivariable regression models showed that patients meeting FM2016 (OR 0.3 95% CI (0.1, 0.99) or with fibromyalgia symptoms (OR 0.7, 95% CI (0.4, 1.1) per 5 unit increase in FMness (Table) were less likely to meet PsARC after accounting for other predictors of response accepted into the model (living in a less deprived area, concurrent therapies, shorter symptom duration, nail onycholysis, poorer physician and patient global measures).

Conclusion: PsA patients with features of fibromyalgia, particularly those meeting current fibromyalgia criteria, commencing b/tsDMARDs, are considerably less likely to meet response criteria, independently of other predictors of outcome. They are likely to benefit from additional management specifically targeted to their fibromyalgia symptoms.

Higher Levels of High-sensitivity CRP Are Associated with Future Risk of Developing Psoriatic Arthritis Among Patients with Psoriasis: A Prospective Cohort Study

Lihi Eder[1], Vinod Chandran[2], Cheryl Rosen[3], Richard J. Cook[4] and Dafna Gladman[5], [1]Women's College Research Institute, Division of Rheumatology, University of Toronto, Toronto, ON, Canada, [2]Schroeder Arthritis Institute, Krembil Research Institute, University Health Network and Division of Rheumatology, Department of Medicine, University of Toronto, Toronto, ON, Canada, [3]Division of Dermatology, Toronto Western Hospital, Toronto, ON, Canada, [4]Department of Statistics and Actuarial Science, University of Waterloo, Waterloo, ON, Canada, [5]Schroeder Arthritis Institute, Krembil Research Institute, Toronto Western Hospital, Department of Medicine, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: PsA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Simple and accessible biomarkers that predict the development of psoriatic arthritis (PsA) among psoriasis patients are critically needed to improve early detection of high-risk individuals. High-sensitivity C-Reactive Protein (hs-CRP) is a biomarker of systemic inflammation. We aimed to assess whether higher levels of hs-CRP are associated with risk of future development of PsA among patients with psoriasis.

Methods: We analyzed data from a prospective cohort of patients with psoriasis without PsA at enrollment. Participants were assessed annually by a rheumatologist for signs and symptoms of PsA. Information on patient demographics, psoriasis features, medications and musculoskeletal symptoms was collected using standard protocols. hs-CRP levels were measured in serum samples collected at baseline using standard commercial assays in a hospital laboratory. The differences in

Table 1 - Baseline patient characteristics

Variable	All (N=589)	Developed PsA (N=57)	No PsA (N=532)
Age (years)	47.3 (13.5)	48.6 (12.2)	47.2 (13.7)

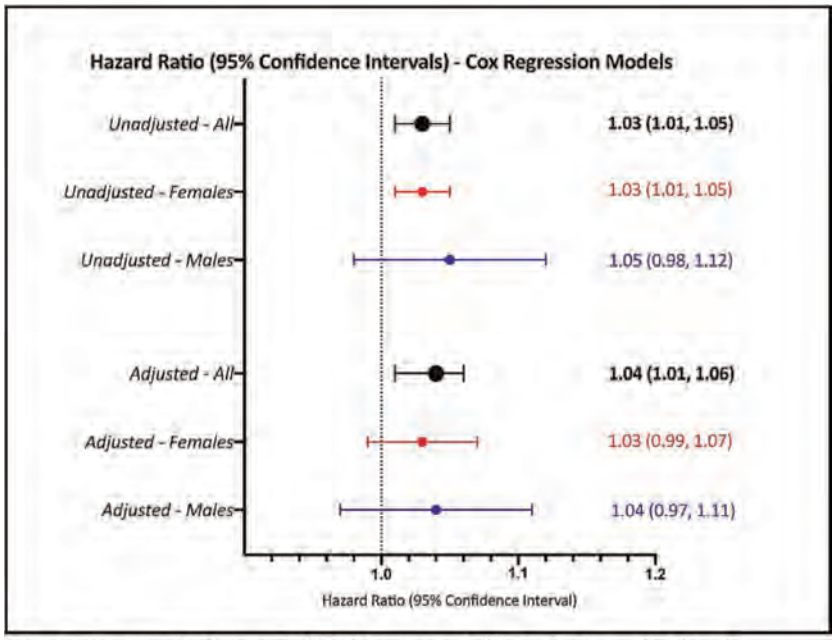

Figure 1: The association between hsCRP and development of PsA by Cox proportional hazards models. Univariate and multivariable regression models adjusted for age, sex, psoriasis duration, PASI, nail lesions, BMI, pain, FACIT-fatigue, use of biologics, and use of non-biologic systemic therapy/UV therapy

average hs-CRP levels were assessed across pre-defined patient groups using t-test. The association between hs-CRP levels and risk of future development of PsA was assessed using multivariable Cox proportional hazards model adjusted for known risk factors for PsA.

Results: A total of 589 patients with psoriasis followed from 2006 to 2019 were analyzed. Mean duration of follow up was 7.5 years. 57 patients developed PsA during the follow up period (incidence of 1.2 events per year). Mean level of hsCRP was 3.1±5.5 mg/L. Patient characteristics are shown in **Table 1**. Significantly higher levels of hs-CRP at baseline were found in patients with arthralgia (4.2±8.53 vs. 2.71±3.67 mg/L), obesity (4.75±4.95 vs. 2.45±5.61 mg/L) and in females (3.92 ±7.13 vs. 2.51±3.68 mg/L); see **Table 2**. Higher hs-CRP levels were associated with future development of PsA in univariate analysis (hazard ratio (HR) 1.03, 95% Confidence Interval (CI) 1.01, 1.05, p=0.002). This association remained significant in the multivariable regression analysis (HR 1.04, 95% CI 1.01, 1.06, p=0.008). Similar effect size was seen in males and females (**Figure 1**). No significant interaction was found between hs-CRP and sex or BMI.

Conclusion: Higher levels of systemic inflammation, as measured by hs-CRP, identify patients with psoriasis at high risk of future development of PsA.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: PsA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Sex differences have been reported in pathophysiology, clinical manifestations, and treatment responses in several rheumatic diseases, including psoriatic arthritis (PsA).[1] Although PsA is equally prevalent in male and female patients, it is important to understand sex-specific outcomes related to physician assessment of disease activity and patient-reported outcomes (PROs).[1]Previous research also suggests there may be a differential response to therapy with TNF or IL-17 inhibition in male and female patients. Deucravacitinib is a first-in-class, oral, selective, allosteric inhibitor of tyrosine kinase 2 approved in multiple countries for adults with plaque psoriasis.[2,3] Here, we further characterize the effect of deucravacitinib on PsA disease activity by sex as derived from physician assessments and PROs.

Methods: Patients with PsA (N=203) were randomized 1:1:1 to placebo, deucravacitinib 6 mg once daily (QD), or deucravacitinib 12 mg QD in this phase 2 study. Outcomes were reported descriptively by sex. Composite changes in PsA disease activity were assessed by the achievement of ACR 20/50/70 and Minimal Disease Activity (MDA) and by mean changes in Psoriatic Arthritis Disease Activity scores. Mean change from baseline scores were calculated for physician assessments of specific disease domains including both Tender and Swollen Joint Counts, Leeds Enthesitis Index, and Leeds Dactylitis Index. Mean change from baseline scores were calculated for PROs included HAQ Disability Index (HAQ-DI), Patient-Reported Outcomes Measurement Information System (PROMIS)-Fatigue, and Subject Global Assessment of Pain (Pain).

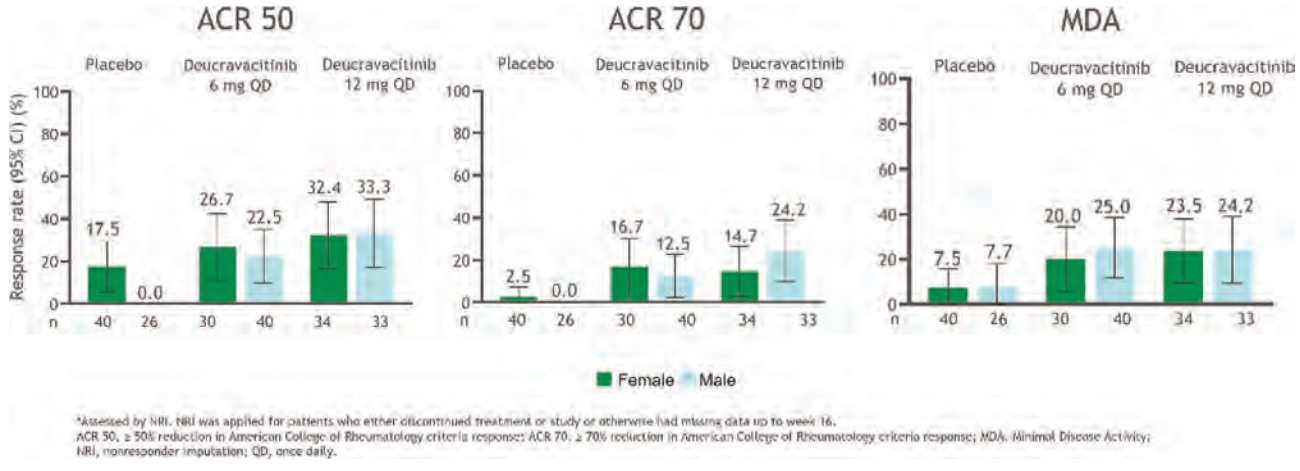

Figure 1. Disease activity measures: ACR 50, ACR 70, and MDA response rate by sex (a)

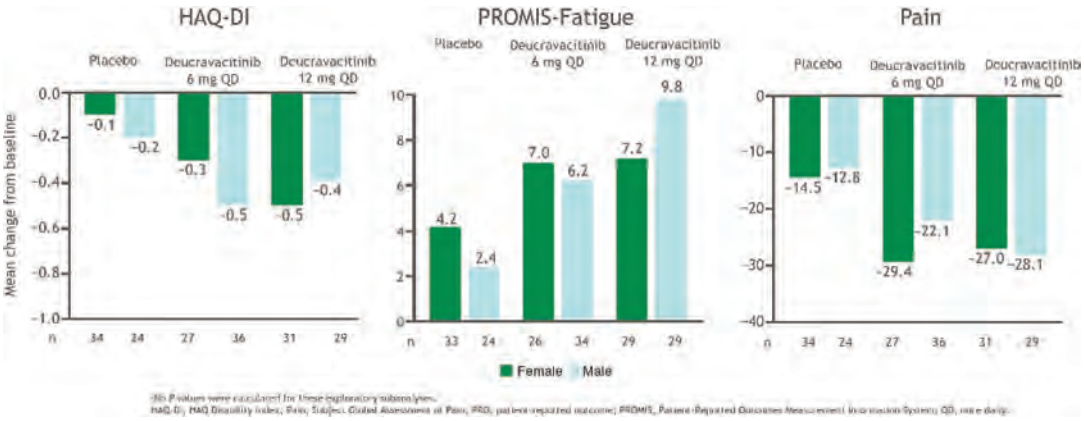

Figure 2. PROs: mean change from baseline in HAQ-DI, PROMIS-Fatigue, and Pain scores by sex (a)

Median (range)	11.5 (1.6–31.4)	5.2 (1.2–18.0)	6.5 (1.6–33.8)	5.2 (1.8–16.4)	6.9 (1.8–31.8)	5.9 (1.4–18.3)

BSA, body surface area; HAQ-DI, HAQ Disability Index; PASI, Psoriasis Area and Severity Index; QD, one daily.

Results: Baseline characteristics were balanced between sexes and are shown in the **Table**. A higher percentage of patients of both sexes treated with deucravacitinib achieved ACR 50, ACR 70, and MDA responses at week 16 compared with placebo (**Figure 1**). In addition, a greater mean change from baseline HAQ-DI, PROMIS-Fatigue, and Pain scores occurred in patients treated with deucravacitinib compared with placebo among both sexes (**Figure 2**). Treatment-associated responses were generally similar between sexes in disease activity assessments and PROs.

Conclusion: Patients treated with deucravacitinib more frequently achieved reductions in disease activity measures and had greater changes from baseline scores for PROs compared with patients who received placebo. Deucravacitinib has comparable effects on PsA disease activity and PROs for the instruments assessed after 16 weeks of treatment in male and female patients.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: PsA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriasis is a chronic, immune-mediated inflammatory skin disease that affects over 2.5% of the global population. Approximately 25% of psoriasis patients also have a form of inflammatory arthritis called psoriatic arthritis (PsA). Current methods for evaluating skin disease activity, like Psoriasis Area and Severity Index (PASI), are subjective and

prone to intra- and inter-rater variability. A metabolomics-based approach can elucidate psoriatic disease pathogenesis and provide potential objective biomarkers. Therefore, we aimed to use solid phase microextraction (SPME) with liquid chromatography coupled with mass spectrometry (LC-MS) with the hypothesis that serum metabolites are associated with skin disease activity.

Methods: Serum samples from PsA patients (n=151, summary of demographics and disease characteristics shown in Table 1) with active skin disease and a range of PASI scores were selected. Patients were classified into 3 groups of psoriasis activity based on PASI- low (PASI 1-4.8) n=56, moderate (PASI 5-9.8) n=45, and High (PASI 10.1-54.6) n=40. SPME devices were prepared in-house and used to conduct the sample preparation, followed by positive and negative ion mode data acquisition via an untargeted approach using LC-MS. Associations between the levels of each metabolite and PASI scores was evaluated using 8 Machine learning (ML) models including support vector machine (SVM), random forest, and Naïve Bayes (NB) with varied feature sizes of 1-80. These models were summarised using Area Under Receiver Operator Characteristic curves (AUROC) for performance. Statistically significant metabolite features were tentatively identified.

Results: ML models were able to distinguish between low and high PsA severity with Area Under Curve (AUC) score as low as 0.745 for 10 features, and as high as 0.813 for 40 features. Trends were similar for other disease activity comparisons. A SVM model with 10 features were able to predict between low and high severity PsA with AUC = 0.862, and p-value < 0.05. Table 2 provides a summary of the results of the analyses. The features of interest used in best performing models were associated with dysregulation of fatty acid metabolism when predicting between low PASI versus moderate or high PASI.

Table 1: Summary of disease characteristics and patient demographics

Total = 151 patients		
LOW PASI 1-4.8 Ages 18-75	**MODERATE** PASI 5-9.8 Ages 19-73	**HIGH** PASI 10.1-54.6 Ages 22-81
28 M	28 M	28 M
28 F	27 F	12 F
56 TOTAL	55 TOTAL	40 TOTAL

Table 2: Top 10 Tentatively Identified Metabolites for Low vs High PASI Disease Activity

m/z	Ret. Time (min)	Adduct	Monoisotopic Mass	Tentative Identification
412.4147	14.784	$[M+NH4]^+$	394.3811	Ximenic Acid; 1 other hit
546.3528	14.588	$[M+Na]^+$	523.3638	Platelet-activating factor; 6 other hits
544.3373	13.349	$[M+Na]^+$	521.3481	LysoPC(0:0/18:1(9Z)); 5 other hits
116.0708	0.603	$[M+H]^+$	115.0633	Proline
427.1938	5.737	$[M+NH4]^+$	409.1584	dermatan L-iduronate; 1 other hit
496.3397	12.948	$[M+Na]^+$	473.3505	Clupanodonyl carnitine; 5 other hits
373.2735	9.793	$[M+H]^+$	372.2664	Cervonoyl ethanolamide
520.3398	12.332	$[M+H]^+$	519.3325	LysoPC(0:0/18:2(9Z,12Z)); 1 other hit
370.2950	8.204	$[M+NH4]^+$	352.2614	MG(18:3(6Z,9Z,12Z)/0:0/0:0); 8 other hits
289.1409	5.124	$[M+Na]^+$	266.1518	pentadeca-5,7,9-trienedioic acid; 8 other hits

Some metabolites tentatively identified include eicosanoids with anti- or pro-inflammatory properties, like 12-Hydroxyeicosatetraenoic acid, which was previously implicated in joint disease activity in PsA. Other tentatively identified features belong to classes such as bile acid metabolites, oxidized phospholipids, N-acrylamide, and long-chain fatty acids.

Conclusion: An untargeted metabolomics approach was employed to analyze potential differences in serum metabolome of PsA patients of varying skin disease activity. Confirmation and validation of the tentatively identified circulating metabolites should be conducted to reveal potential biomarkers of PsA disease activity.

A Comparative Study of Serositis Between Inpatients with Psoriatic Arthritis and Rheumatoid Arthritis

Ashmia Saif[1], Priyanka Dongare[2], Meghan Beard[3], Yunhan Liao[4], Xiaoyue Zhang[4], Qingping Yao[5] and Asha Patnaik[6], [1]Stony Brook University Hospital, Syosset, NY, [2]Stony Brook University Hospital, Highland, NY, [3]Stony Brook Southampton, Moriches, NY, [4]Biostatistical Consulting Core - Renaissance School of Medicine at Stony Brook University, Stony Brook, NY, [5]Stony Brook University, Stony Brook, NY, [6]Stony Brook University Medical Center, East Setauket, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: PsA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoimmune diseases such as rheumatoid arthritis (RA) and psoriatic arthritis (PsA) can causes erositis including pericarditis and pleuritis. However, the rate of serositis in PsA is not defined, though several case reports have described pleuropericardial involvement. The prevalence of pericarditis in RA ranges from 30% to50%. This study aimed to estimate the frequency of pleuropericarditis in PsA vs RA.

Methods: A retrospective chart review of hospitalized patients with RA and PsA was conducted between 2013 and 2021. The frequencyof pericarditis or pleuritis was compared between RA and PsA patients. This study was approved by the Institutional Review Board of Stony Brook University.

Results: There were a total of 113 inpatients aged 18 and 65 (Table 1). These patients were divided into two groups: 57 patients with RA (Group 1) and 56 with PsA (Group 2). Of the 57 RA patients, 48 patients had pericardial or pleural effusions and 46 were determined to have idiopathic etiology. Of the 56 PsA patients, 42 had pericardial or pleural effusions and 23 were considered idiopathic. Approximately 41% of PsA patients had idiopathic pericardial or pleural effusions as compared with 81% RA patients. This shows a statistically significant difference between the two groups ($P < 0.0001$).

Conclusion: This study suggests that both RA and PsA patients can cause pleuropericarditis, and the frequency of idiopathic etiology in RA may be two-fold higher than PsA. Further study using a larger cohort of patients is warranted to accurately estimate the rate of serositis.

Table 1: comparison of pleuropericardial involvement between psoriatic arthritis and rheumatoid arthritis

Factors Associated with Work Productivity Among Individuals with Psoriatic Arthritis (PsA) and Psoriasis (PsO): The Role of Patient Reported Outcomes and Disease Severity

Nancy Shadick[1], Kumiko Schnock[2], Vivi Feather[3], Ruogu Li[2], Jing Cui[1], Shivani Patel[2], Sabrina Goutier[1], Muibat Yussuff[2], Lourdes Perez-Chada[2], Michael Weinblatt[4] and Joseph Merola[5], [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Mass General Brigham, Boston, MA, [4]Harvard Medical School, Waban, MA, [5]Harvard Medical School, Brigham and Women's Hospital, Newton, MA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: PsA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with Psoriatic Arthritis (PsA) and Psoriasis (PsO) have an increased rate of work loss due to their disease compared the general population; however, little is known about the impact of their illness on work productivity among those who remain employed. Our goal was to evaluate the differential effect of self-reported disease symptoms and severity on the ability to work.

Methods: Data from study subjects who participated in the Cohort of Psoriasis and Psoriatic Arthritis Registry (COPPAR), a prospective, longitudinal registry of adult subjects with PsA or PsO at a large academic medical center, were analyzed. Demographics and disease characteristics of the study subjects were summarized by diagnosis (PsA vs. PsO) and compared using univariate statistics. Work Productivity and Activity Impairment (WPAI) survey data were collected at baseline and assessed in three binary domains: missed work, impaired work productivity, and impaired daily activity due to their illness. All subjects had disease severity measured by the Psoriasis Area and Severity Index (**PASI**), and self-reported disease

Table 1. Employed Study Subjects' Characteristics in the COPPAR Registry

	PsA (N=113)	PsO (n=67)	*P* value

SD: Standard Deviation, IQR: Interquartile Range. DMARD: Disease-Modifying Antirheumatic Drug, BSA: Body Surface Area, PGA: Physician's Global Assessment, PASI: Psoriasis Area and Severity Index, SF-12: The 12-Item Short Form Health Survey, DLQI: Dermatology Life Quality Index, PHQ-8: The Eight-Item Patient Health Questionnaire Depression Scale, PROMIS: Patient-Reported Outcomes Measurement Information System, EQ-5D: European Quality of Life- 5 Dimensions, WPAI: Work Productivity and Activity Impairment #Each WPAI element is binary. % Yes are reported.

*Pain is assessed by a 3-level scale pain question in European Quality of life-5D (EuroQol-5D) where 0 represents the patient has no pain or discomfort, and 2 represents that the patient has extreme pain or discomfort. [b]Fatigue is assessed by a 5-level scale question from the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-Fversion 4) questionnaire where 0 represents that the patient does not feel fatigued at all and 4 represents that the patient feels very tired. [c]Itch is assessed by a numeric itchiness rating scale where 0 represents no itch, and 10 represents the worst imaginable itch.

Table 2: Association between WPAI Scores and Demographic, Disease Severity, and Symptom Related Covariates in the COPPAR Registry

	Multivariate Model*								
	Missed Work Hours			Work Productivity Impaired			Daily Activity Impaired		
Covariates	OR	95% CI	p	OR	95% CI	p	OR	95% CI	p
Diagnosis (PsA vs. PsO)	0.41	(0.14, 1.24)	0.11	1.98	(0.69, 5.71)	0.21	3.73	(1.39, 10.02)	**0.01**
Pain[a]	2.43	(0.87, 6.82)	0.09	6.94	(2.41, 19.98)	**<0.001**	5.6	(2.16, 14.53)	**<0.001**
Fatigue[b]	2.17	(1.42, 3.3)	**<0.001**	2.39	(1.56, 3.65)	**<0.001**	2.16	(1.45, 3.22)	**<0.001**
Itch[c]	0.99	(0.81, 1.2)	0.89	1.3	(1.07, 1.57)	**0.01**	1.12	(0.94, 1.34)	0.22
PASI[d]	0.96	(0.87, 1.06)	0.40	1.05	(0.92, 1.19)	0.47	1.01	(0.91, 1.13)	0.79

*Adjusted for age, gender, and race. [a]Pain is assessed by a 3-level scale pain question in European Quality of Life-5D (EuroQol-5D) where 0 represents the patient has no pain or discomfort, and 2 represents that the patient has extreme pain or discomfort. [b]Fatigue is assessed by a 5-level scale question from the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F version 4) questionnaire where 0 represents that the patient does not feel fatigued at all and 4 represents that the patient feels very tired. [c]Itch is assessed by a numeric itchiness rating scale where 0 represents no itch, and 10 represents the worst imaginable itch. [d]PASI: Psoriasis Area and Severity Index

symptoms were assessed as the amount of overall pain, degree of skin itch, and fatigue measured on a rating scale. Symptoms and disease severity variables, along with demographics, were tested in logistic regression models to determine their associations with WPAI outcomes.

Results: Of 288 cohort subjects who completed the WPAI survey, 180 (63%) subjects were currently employed (113 PsA and 67 PsO subjects). Study subjects had a mean age of 49.7 years, 45.3% female, and 85.8% White (Table 1). The mean disease duration was 22 years for PsA and 15 years for PsO (p=0.04). PsO subjects had more severe skin disease, while PsA subjects were more likely to be on biologic therapies (Table 1). In univariate analyses, there were no statistically significant differences in missed work between PsA and PsO subjects (15.93% vs. 19.40%, p=0.55), but PsA subjects reported more impaired work productivity (44.25% vs. 25.37%, p=0.01) and impaired daily activities outside of work hours (53.10% vs. 20.9%, p< 0.001). However, the adjusted regression model showed that study subjects who had missed work reported more fatigue ([Odds Ratio (OR)]:2.17, p< 0.001). Study subjects who had impairment in work productivity reported more pain (OR:6.94, p< 0.001), fatigue (OR:2.39, p< 0.001), and itch (OR:1.3, p=0.01). Study subjects who reported daily activity impairment outside of work hours reported more fatigue (OR:2.16, p< 0.001), pain (OR:5.6, p< 0.001) and were more likely to have PsA than PsO (OR: 3.73 p=0.01). Of note, the PASI score was not associated with any of the three WPAI impairment domains.

Conclusion: While employed individuals with PsA reported more impaired work productivity than those employed who had PsO, impairment was driven by pain, itch, and fatigue rather than arthritis diagnosis and skin disease severity. Eliciting these symptoms may help rheumatologists better tailor interventions to improve an individual's capacity to work.

Abstract Number: 0489

Prediction of Low Disease Activity in Patients with Psoriatic Arthritis Treated with Secukinumab in Real World – Data from a German Observational Study

Asmir Vodencarevic[1], Jan Brandt-Juergens[2], Daniel Peterlik[1], Benjamin Gmeiner[1] and **Uta Kiltz**[3], [1]Novartis Pharma GmbH, Nürnberg, Germany, [2]rheumatologische Schwerpunktpraxis, Berlin, Germany, [3]Rheumazentrum Ruhrgebiet, Herne, Germany

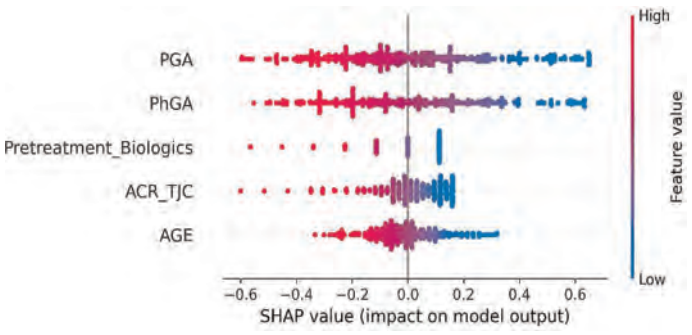
SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: PsA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Secukinumab (SEC) proved to be an effective treatment for patients with psoriatic arthritis (PsA) in previous randomized clinical trials [1]. There is only limited knowledge on prediction of low disease activity (LDA) and treatment strategy in PsA patients under SEC treatment in routine clinical care.

Using real-world data from the German non-interventional study AQUILA [2], the main objectives were (1) to predict LDA in individual PsA patients treated with SEC through machine learning methods and (2) to identify the most important predictors and their influence on the prediction using explainable artificial intelligence (XAI).

Methods: Data of 1041 PsA patients from the AQUILA study were used. Thirty-three demographic, clinical and treatment parameters at baseline (BL) served as input data to develop prediction models. LDA was defined as physician global assessment (PhGA) ≤ 2 at week (w) 16 (+/- 6 w). Samples were divided into training (70%) and validation (30%) cohorts. Ten different prediction models were applied and compared. Model performance was measured using area under the receiver operating characteristic curve (AUROC) which represents the probability that a randomly selected patient with LDA will have higher prediction to achieve LDA than a patient with moderate/high disease activity. Additionally, sensitivity and specificity of the prediction model were computed and express the proportion of correctly identified patients who reach or don't reach LDA at w16, respectively. Shapley XAI estimated importance and impact of each predictor based on how it affected the change in individual prediction [3].

Results: The most influencing predictor was patient global assessment (PGA) at BL, followed by PhGA, number of pretreatments with biologics, tender joint count and age (Figure 1 A). AUROC of the best prediction model was 0.68 in validation cohort. Sensitivity and specificity were 0.62 and 0.64, respectively. Applied XAI approach showed that lower BL values of



A: Main predictors at baseline and their direction of influence based on Shapley values [3]

B: Explanation of patient-individual prediction of 79% using baseline data

all main predictors have higher probability of reaching LDA at w16. The highest probability was evident in biologic-naive patients (Figure 1 A). The approach also provided visual explanations of patient-individual predictions: Variables with values shown in green color increased probability of reaching LDA at w16, whereas red ones showed the opposite effect (Figure 1 B).

Conclusion: A promising prediction model accuracy of LDA in PsA patients treated with SEC could be reached and validated. Identified main predictors at BL, such as PGA and number of pretreatments with biologics, and their direction of influence on the prediction mostly match the existing clinical knowledge [4]. The analysis showed that XAI can provide useful clinical insights in patient-individual predictions, potentially guiding PsA treatment decisions in future.

Racial/Ethnic Differences in Psoriatic Arthritis Patient Responses Regarding Disease Burden, Treatment, and Communication with Care Team

Iris Navarro-Millán[1], Gail Kerr[2], Jeffrey Carter[3], Laura Simone[4] and **Marykate Nelson**[5], [1]Weill Cornell Medicine, Hospital for Special Surgery, New York, NY, [2]Washington DC VAMC/Georgetown and Howard Universities, Washington, DC, [3]PRIME Education, Boynton Beach, FL, [4]PRIME, Omaha, NE, [5]PRIME Education, Drexel Hill, PA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: PsA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The purpose of this study was to examine differences in perceptions of psoriatic arthritis (PsA) disease burden as well as various aspects of care across racial/ethnic groups.

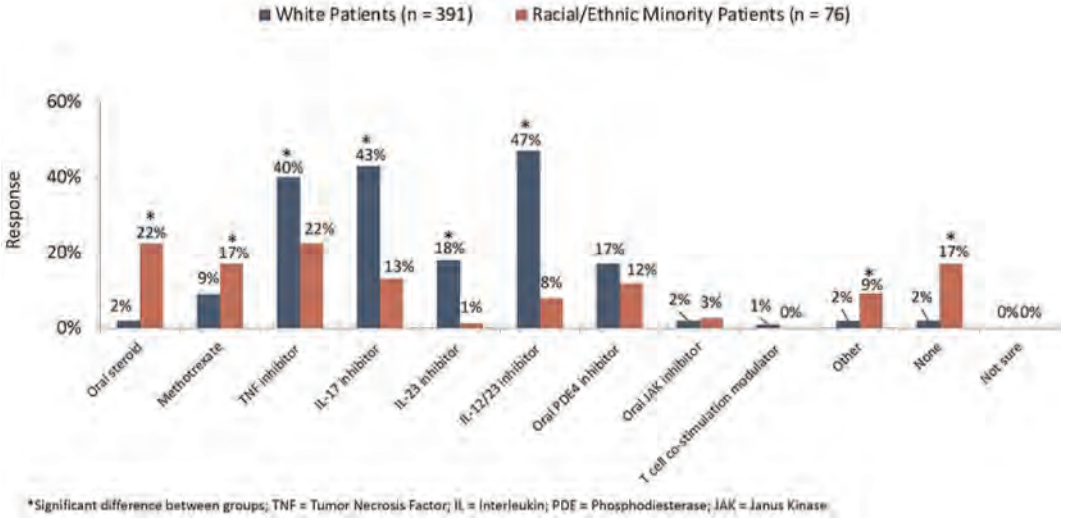
Methods: Survey questions assessing PsA patient insights regarding their disease burden and quality of care were developed. From September to October 2022, surveys were deployed to 455 PsA patients either through a leading advocacy organization email list (n = 420) or an additional national patient survey organization (n = 35). Self-reported race/ethnicity was recorded. If patients selected both "white" and another racial/ethnic group, they were included in both groups in the analysis.*P* values were calculated using the chi-square or Fisher's Exact tests for counts less than 5.

Results: The age of patients ranged from 28 to 91 years. Three hundred ninety-one identified as white and 76 identified with a racial/ethnic minority group (29 African American/Black, 20 Asian/Pacific Islander, 14 Hispanic/Latinx, 8 Native American/Alaska Native, 5 "Other").

Racial/ethnic minority PsA patients were less likely to be diagnosed within 12 months from the onset of symptoms (50% vs 71%; $P < 0.001$) and more frequently uninsured (8% vs. 1%; $P < 0.001$) compared to white patients. Racial/ethnic minority patients more often had self-described severe disease vs. white patients (41% vs. 14%; $P < 0.001$) and extreme impact on quality of life and emotional well-being (25% vs. 6%; $P < 0.001$).

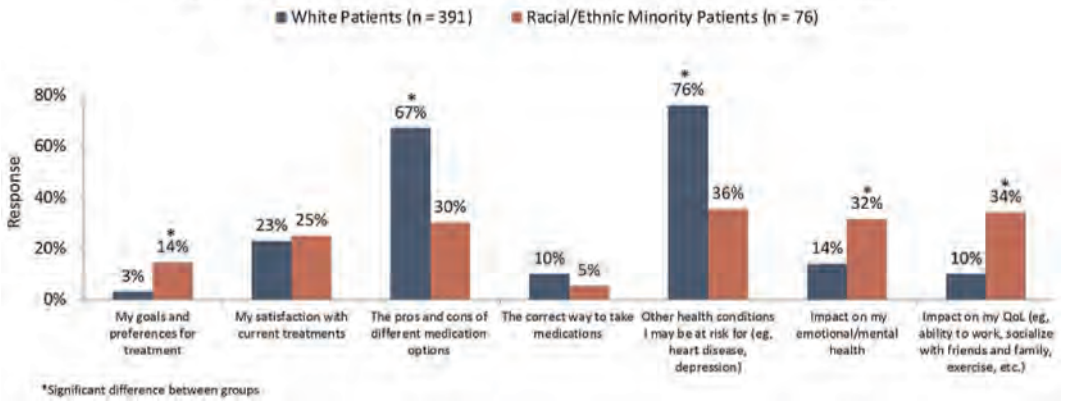
Regarding treatment, racial/ethnic minority PsA patients were less often prescribed a biologic and more frequently received oral glucocorticoids, methotrexate, or no prescription medications compared to white PsA patients (Figure 1). Also less frequent among racial/ethnic minority patients were high levels of knowledge/familiarity with targeted agents such as injectable biologics or oral small molecule inhibitors (42% vs. 81%; $P < 0.001$) and high satisfaction with treatment (39% vs. 77%; $P < 0.001$). Financial barriers to managing PsA were four-fold more common in racial/ethnic minority patients (26% vs. 7%; $P < 0.001$); the difference in concern for risks of medications was similarly significant (29% vs. 3%; $P < 0.001$).

Figure 1. Patients' Response to the Question: "Which Prescription Therapies Are You Currently Taking For PsA?"



*Significant difference between groups; TNF = Tumor Necrosis Factor; IL = Interleukin; PDE = Phosphodiesterase; JAK = Janus Kinase

Figure 2. Patients' Response to the Question: "Which of the Following Do You Wish You Had More Time To Discuss With Your PsA Care Team?"



*Significant difference between groups

Gaps in communication with the PsA care team were also observed. Racial/ethnic minority patients were less likely to feel that they were very/extremely involved in shared decisions regarding their care (60% vs. 82%; $P < 0.001$). When asked what they wished they had more time to discuss with their care team, racial/ethnic minority PsA patients requested various aspects of the impact of the disease as well as goals and preferences for treatment (Figure 2). Notably, the advantages and disadvantages of different treatment options and comorbidities were a lower priority in racial/ethnic minority patients despite a higher percentage of comorbid disease (Figure 2).

Conclusion: These survey findings confirm racial/ethnic disparities across the spectrum of PsA disease from time to diagnosis to treatment, and underscore the dissatisfaction with overall care. There is a need for more time to be spent on educating individuals with PsA to enable shared decisions and improved understanding of therapeutic options.

Abstract Number: 0491

Arthralgia with Risk of Progression to Psoriatic Arthritis in a Large Cohort of Patients: Role of Ultrasound

rodrigo garcía salinas[1], Jonatan Mareco[2], Santiago Ruta[2], RONALD PEREZ[2], Felica Almada[2] and Sebastián Juan Magri[3], [1]Arthritis and Spondyloarthritis Unit, Hospital Italiano de La Plata, National University of La Plata, La Plata, Argentina, [2]Hospital Italiano de La Plata, La Plata, Argentina, [3]Hospital Italiano La Plata, Melchor Romero, Argentina

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: PsA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The psoriasis- to- psoriatic arthritis (PsA) transition offers a unique opportunity to identify individuals at increased risk of developing PsA and to implement preventive strategies. **Objectives**: To estimate the frequency of arthralgia with risk of progression to PsA (ARP-PsA) in a large cohort of patients and to estimate the incidence of PsA at one year in ARP-PsA patients analyzing clinical, laboratory and imaging predictor variables.

Methods: Prospective cohort study, include patients over 18 years of age who were admitted consecutively for arthralgias, to the¨Reuma-check program. In this, the baseline included: laboratory, X-rays, ultrasound (US) with power Doppler (PD) and clinical interview. Sociodemographic data, clinical and clinimetry (global VAS, joint count, HAQ) were collected. Each evaluator (laboratory, imaging and clinical) were blinded to the data of the other studies. Presence of psoriasis (Pso) and family history (FH) were investigated. Patients with previous diagnosis of PsA were excluded. The ARP-PsA was defined as those patients with arthralgia plus Pso and/or FH. This group was evaluated at one year to estimate if they developed PsA. Statistical analysis: descriptive statistics, Chi2 test, Fisher's exact test, Student's T test and Mann Whitney was performed. A multivariate logistic regression: dependent variable the final diagnosis of PsA at year.

Results: A total of 1419 patients with arthralgia were included between July 2017 and March 2022, 8.4% (95% CI: 7-10) met ARP-PsA criteria. Of these 119 patients 34 developed PsA at 1 year (29%, 95%CI: 20-37). The clinical, laboratory and imaging characteristics between ARP-PsA patients who did and did not develop PsA are shown in table 1 (univariate analysis). Of the ARP-PsA patients who had only Pso (n 32), only family history (n 70) or both combine (n 17) developed PsA at 1 year: 57%, 11% and 53% respectively. Longer duration of psoriasis was associated with the development of

Clinical, laboratory and imaging characteristics between ARP-PsA patients who did and did not develop PsA

PsA: median years:15 vs 3. In multivariate analysis, the predictor variables for progression from ARP-PsA to PsA at one year were: combination of Pso plus FH (OR: 32; CI 95%: 1.2-1026), synovitis by PDUS (OR: 31; CI 95%: 1.1-967), US enthesopathy findings (OR: 470; CI 95%: 13-1600) and tender joint count (OR 0.2 CI95% 0.05-0.6).

Conclusion: The frequency of patients at risk of progression to PsA (arthralgia plus PsA and/or FH) in our cohort was 8.4%, of whom 29% developed PsA at 1-year follow-up. The main predictor variables were US findings (synovitis and enthesopathy), as well as the combination of Pso plus FH, a lower number of tender joints, and a longer duration of the Pso.

Axial Spondyloarthritis in Patients with Late-Onset Chronic Low Back Pain (Older Than 45 Years). Axial Spa or Psoriatic Disease with Axial Involvement?

rodrigo garcía salinas[1], Gisel Reyes[2], Rosario Jaldín Céspedes[2], Felica Almada[2] and Sebastián Juan Magri[3], [1]Arthritis and Spondyloarthritis Unit, Hospital Italiano de La Plata, National University of La Plata, La Plata, Argentina, [2]Hospital Italiano de La Plata, La Plata, Argentina, [3]Hospital Italiano La Plata, Melchor Romero, Argentina

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: PsA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose:

It is known that patients diagnosed with axSpA do not subsequently meet the classification criteria. The Objectives are: To estimate the diagnostic prevalence of axSpA in patients who started low back pain over 45 years of age and to analyze the clinical, laboratory and imaging differences with patients who started it before that age.

Methods: Methods: Observational and cross-sectional study, which included patients older than 18 years with a diagnosis of axial spondyloarthritis performed between 2017 and 2021. At baseline, all patients underwent: blood tests, HLA B27, X-rays and MRI of the sacroiliac joint, enthesis ultrasound, sociodemographic data, level of education and habits were also recorded. Axial spondyloarthritis symptoms, age of onset, delay to diagnosis, characteristics of low back pain, characteristics of axial spondyloarthritis, NSAIDs intake and response, VAS pain and night pain, morning stiffness time. In addition, BASDAI, BASFI, MASES and HAQ scores were used. The symptom evaluator was unaware of the results of the complementary studies that were collected by another observer. The MRIs recorded the presence of any lesion and classified it into acute (edema) and chronic (fatty changes, erosions, sclerosis, and bone bridges) lesions.

Tabla 1: Patientes´Features.

Results: Results: One hundred sixteen patients with a diagnosis of axial spondyloarthritis were included, whose characteristics are summarized in Table 1. The prevalence of patients who started low back pain after the age of 45 was 31.28% (95% CI 20-36). The relevant differences were: female sex (51% vs 29% p 0.03), smoking (38% vs 57% p 0.07), psoriasis (42% vs 17% p 0.007), good response to NSAIDs (52% vs 73% p 0.03), HLA-B27 (+) (32% vs %54 p 0.04), more than 4 characteristics of axial spondyloarthritis (35% vs 54% p 0.08), BASFI (5.1 vs 4.5 p 0.05), delay to diagnosis in months (40 vs 93 p 0.002). No differences were found in terms of disease activity and imaging (MRI or X-rays). In the logistic regression analysis, the variables that were independently associated were: male sex (OR 0.2 IC95% 0.06- 0.8), psoriasis (OR 4.8 IC95% 1.1-29), and shorter delay to diagnosis (OR 0.9 IC95% 0.96 -0.99).

Conclusion: The prevalence of diagnosis of axial spondyloarthritis in patients who started low back pain after the age of 45 was 28%. The characteristics of these patients were: female sex, higher frequency of psoriasis, and shorter delay to diagnosis. This study shows that the older age at the onset of low back pain and the association with psoriasis could show a group of patients with axial involvement in the context of psoriatic disease.

Axial Disease Activity in Psoriatic Arthritis Is Higher in Patients with Carotid Plaque

Rosa Arvizu-Rivera[1], Valeria Gonzalez-Gonzalez[2], Dionicio A. Galarza-Delgado[3], Iris Colunga[3], José Ramón Azpiri-López[3], Victor Beltran[4], Angel Arias Peralta[5] and Jesus Alberto Cardenas-De la Garza[6], [1]Hospital Universitario \"Dr. José Eleuterio Gonzalez\", Escobedo, Mexico, [2]Universidad Autónoma de Nuevo León, Monterrey, Mexico, [3]Hospital Universitario UANL, Monterrey, Mexico, [4]Rheumatology Service Hospital Universitario "Dr. José Eleuterio González", Monterrey, Mexico, [5]Medicine Faculty, Universidad Autonoma De Nuevo Leon, Monterrey, Mexico, [6]Hospital Universitario "Dr. José Eleuterio González", San Nicolas, Mexico

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: PsA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Approximately half of the patients with psoriatic arthritis (PsA) present with axial disease. Previously, it was reported that PsA-patients with axial involvement present a higher cardiovascular risk compared with those without the axial disease. Additionally, it has been reported that axial disease is higher in patients with axial spondyloarthropathies, and carotid plaque (CP) identified by ultrasound than in patients without CP. The objective was to compare the Bath Ankylosing Spondylitis Metrology Index (BASMI) between PsA-patients with and without CP.

Methods: A cross-sectional and comparative study that included PsA patients aged 30 to 75 years old who fulfilled the 2006 Classification Criteria for PsA. Patients with previous cardiovascular atherosclerotic disease were excluded. B-mode carotid ultrasound was performed on all patients by a board-certified radiologist blinded to clinical information. Carotid plaque (CP) was defined as a carotid intima–media thickness (cIMT) ≥1.2 mm or a focal narrowing ≥0.5 mm of the surrounding lumen, and an increased cIMT was defined as a value ≥0.8 mm. Axial disease activity was measured using the BASMI in all patients.

Table 1. Demographic characteristics.

Characteristics	PA patients without CP (n=38)	PA patients with CP (n=32)	*p*-value
Age, years, ± SD	52.3 ± 9.4	56.3 ± 12.2	**0.012**
Women, n (%)	20 (52.6)	17 (53.1)	NS
Diabetes, n (%)	4 (10.5)	13 (40.6)	**0.003**
Hypertension, n (%)	15 (39.5)	18 (56.3)	NS
Dyslipidemia, n (%)	15 (39.5)	17 (53.1)	NS
Obesity, n (%)	16 (42.1)	12 (37.5)	NS
Active smoking, n (%)	10 (26.3)	5 (16.1)	NS
Time of evolution, years, median (IQR)	5.5 (3.2-10.2)	6.0 (3.0-14.0)	NS
DAPSA, median (IQR)	13.0 (6.1-19.1)	10.3 (5.3-21.1)	NS
PASI, median (IQR)	0.75 (0.0-2.2)	0.20 (0.0-3.0)	NS
NAPSI, median (IQR)	0.0 (0.0-4.0)	0.0 (0.0-10.0)	NS
BASMI, median (IQR)	2.8 (2.4-3.4)	3.4 (2.4-4.2)	**0.016**

PsA, psoriatic arthritis; SD, standard deviation; IQR, interquartile range; NS, no significative.

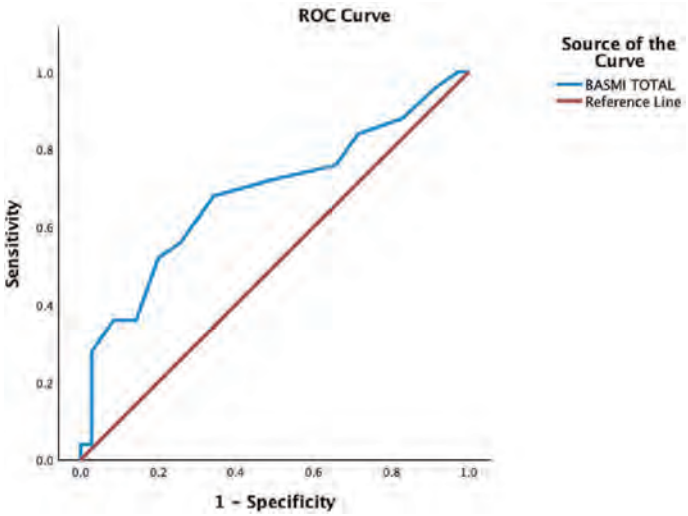

Figure 1. ROC analysis to evaluate the best cut-off point of BASMI to identify CP.

Results: A total of 70 patients with PsA were included, the mean age was 55 ± 11.47, the disease evolution of PsA was 7.95 ± 7.08 years, and the mean BASMI of all patients included was 3.09 ± 0.99. The prevalence of type 2 diabetes mellitus was higher in patients with PsA and CP (10.5% vs 40.6%, *p*=0.003). There was no difference between the prevalence of obesity and other cardiovascular risk factors, including smoking, obesity, hypertension, and dyslipidemia. BASMI was higher in PsA patients with CP in comparison to those patients without CP (3.4 vs 2.8, *p*=0.016). In a subanalysis, the Youden Index between CP and BASMI was assessed to determine the best cut-off point to identify CP, which resulted in a cut-off point of a BASMI of 2.9 with a sensitivity of 68% and a specificity of 65.7% (CI 0.541 - 0.826, *p*=0.012), Figure 1.

Conclusion: Patients with PsA and CP present higher axial disease activity compared to PsA patients without CP. A BASMI of 2.9 or higher may identify patients who would benefit from non-invasive screening for subclinical atherosclerosis.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: PsA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Triglyceride Glucose Index **(**TyG) is a surrogate marker positively correlated with atherosclerotic burden in patients with psoriatic arthritis (PsA). Atherosclerotic index of plasma (AIP) levels have not been evaluated in patients with subclinical atherosclerosis and PsA. The objective was to compare levels of AIP and TGI between PsA-patients with and without carotid plaque (CP).

Table 1. Demographic characteristics.

Characteristics	PsA patients with CP (n=36)	PsA patients without CP (n=52)	*p*-value
Age, years, ± SD	57.7 ± 9.8	54.9 ± 6.3	**0.006**

PsA, psoriatic arthritis; CP, carotid plaque; SD, standard deviation; IQR, interquartile range; NS, no significative; DAS28-CRP, 28-joint Disease Activity Score based on C-reactive protein; PASI, psoriasis area severity index; NAPSI, nail psoriasis severity index; DAPSA, disease activity in psoriatic arthritis; AIP, atherogenic index of plasma; TGI, triglyceride-glucose index; cIMT, carotid intima-media thickness.

Methods: Cross-sectional study that included PsA-patients aged 40 to 75 years old who fulfilled the 2006 Classification Criteria for PsA. Patients with previous cardiovascular disease were excluded. Carotid ultrasound was performed on all study participants. The presence of carotid plaque (CP) was defined as diffuse carotid intima-media thickness (cIMT) ≥1.2 mm or focal thickness ≥0.5 mm. Subclinical atherosclerosis was defined as the presence of CP or an increased cIMT (≥0.8mm). Cardiovascular disease risk was evaluated using the algorithm: FRS-Lipids. AIP was defined by Log (TG/HDL-C) mg/dL. TGI was defined by Log (Fasting triglyceride (mg/dl) x fasting glucose (mg/dl)/2. The distribution between groups was assessed with the Kolmogorov-Smirnov test. Comparisons with Chi-square or Fisher's exact test and Student's t-test or Mann Whitney's U-test, accordingly. The correlation between the AIP, TGI, cIMT, and FRS-Lipids was assessed by Spearman's correlation coefficient. A value of $p \leq 0.05$ was considered statistically significant.

Results: A total of 88 patients with PsA were included, mostly women (n=46, 52.3%), the mean age was 53 ± 11.3, median disease duration of PsA was 5.0 (3.0-10.7) years. Median AIP was 0.44 (0.31-0.66) and TGI 3.8 (3.6-4.0) of all patients included. The most prevalent cardiovascular risk factor was dyslipidemia (n= 36, 41.4%). Patients with carotid plaque and PsA presented higher TyG compared to the group without carotid plaque (p=0.010). (Table 1).

Table 2. Association between cardiovascular algorithm, cIMT and index.

	AIP	TGI
FRS-Lipids	rs=0.618 *p*=0.000	rs=0.569 *p*=0.000
cIMT	rs=0.254 *p*=0.020	rs=0.271 *p*=0.013

TGI, triglyceride-glucose index; AIP, atherogenic index of plasma; FRS, Framingham Risk Score; cIMT, carotid intima-media thickness.

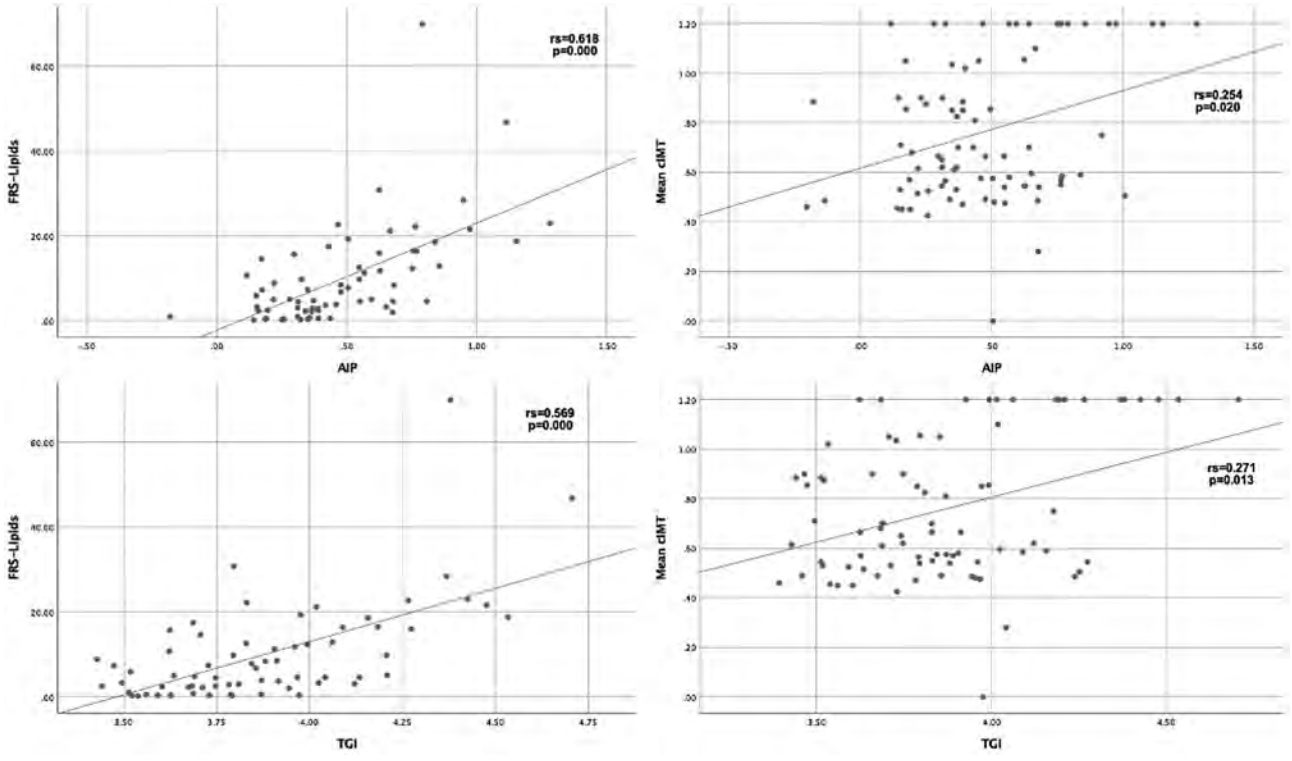

Figure 1. Scatterplots of the association between cardiovascular algorithm, cIMT and index.

Conclusion: AIP is not elevated in patients with PsA and subclinical atherosclerosis. However, TyG levels are increased in PsA-patients and CP. Prospective studies are needed to evaluate the performance of these surrogate markers to predict CV events in these patients.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: PsA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: EISER is a cross-sectional, multicenter, observational, SER-GETECCU cooperative study involving 13 Spanish hospitals whose main objective was to estimate the prevalence of undiagnosed Inflammatory Bowel Disease (IBD) in patients with spondyloarthritis (SpA), including axial (axSpA) (radiographic axSpA-r and non-radiographic; axSpA-nr) and psoriatic arthritis (PsA).

Methods: We selected patients ≥18 years of age from the NHS Rheumatology Department, SpA diagnosed according to CASPAR criteria for PsA and ASAS for axSpA. Patients under treatment with biologics were excluded. Patients currently treated with systemic steroids or in the previous 30 days were not included. Patients over 50 years of age were included if a colonoscopy wasn't performed in the last three years or, if a colonoscopy was performed but did not meet the criteria of valid colonoscopy.

Patients were recruited by the rheumatologist who collected demographic, clinical and treatment data. A fecal calprotectin (FC) determination was performed using the Quantum Blue rapid test. FC was assessed and all patients with a FC ≥80 µg/g underwent an endoscopic study by the gastroenterologist. Patients in whom the result of the endoscopic study was normal underwent to an endoscopic capsule study or magnetic resonance imaging.

Table 1: Sociodemographic and general data of all patients included in the study.

General and sociodemographic data n (%)	
Number of patients	559
Male	285 (51.0%)
Female	274 (49.0%)
Mean age of participants*	52.2 ± 12.6
Mean age of diagnosis*	42.0 ± 13.2
Mean time of disease progression*	12.3 ± 11.6
Smoking status	
Never	271 (48.5%)
Past	186 (33.2 %)
Current	102 (18.3%)
Alcohol consumption	
No	333 (59.6%)
Yes	226 (40.4%)

*mean ± standard deviation

Table 2: Type and activity of patients enrolled in the study.

Disease information n (%)	
Type Spondyloarthritis (SpA)	
Axial psoriatic arthritis	17 (3.0%)
Peripheral psoriatic arthritis	200 (35.8%)
Mixed psoriatic arthritis	55 (9.8%)
Radiographic Axial Axial Spondyloarthritis	207 (37.0%)
Non radiographic Axial Axial Spondyloarthritis	80 (14.3%)
Spondyloarthritis Baseline Activity (SpA)	
BASDAI*	3.6 ± 2.3
DAPSA*	10.4 ± 8.3
ASDAS_PCR*	2.3 ± 1.0
ASDAS_VSG*	2.4 ± 1.0
Global assessment of the disease between 0 and 10*	4.1 ± 2.7
Quality of life (EuroQol-5D-5L)	
Health status between 0 and 100*	67.5 ± 19.5

*mean ± standard deviation

Results: A total of 559 patients were included, 51.0% of whom were men. The mean age of the participants was 52.2 years, with a mean age at diagnosis of 42 years. Mean time of disease evolution was 12.3 years (Table 1).

Regarding the type of SpA, the most frequent form was axSpA-r (37.0%), followed by peripheral PsA (35.8%; Table 2). Concerning disease activity data in axSpA BASDAI 3.6, ASDAS_PCR 2.3, ASDAS_VSG 2.4 and of patients with PsA DAPSA of 10.4 (Table 2). Global assessment and mean health status reported by patients was 4.1 (0 to 10 scale) and 67.5 (0 to 100 scale; Table 2), respectively.

A total of 47.0% of patients with PsA had FC≥80 μg/g vs. 53% of axSpA (80% axSpA-r vs. 20% axSpA-nr). The mean FC values were higher in the case of axSpA-r (395.06 μg/g) compared to the other groups (305.52 μg/g for the axSpA-nr and 306.19 μg/g for the PsA subgroup).

Overall, 10.0% of the patients had a family history of IBD and 14.6% had clinical manifestations compatible with IBD, the most common clinical manifestations were asthenia (50.0%), abdominal pain (15.6%) and chronic diarrhea (14.1%). A total of 189 colonoscopies were performed (167 in patients with FC≥80 μg/g, of which 39.7% presented some pathological finding, mostly: aphthous ulcers (65.9%), superficial ulcers (20.5%) and mucosal erythema (13.6%), mainly located in terminal ileum (41.3%).

Finally, 23 patients were diagnosed with IBD (4.4%): 22 diagnosed with Crohn's disease (95%), 1 unclassifiable IBD (5%). Of the 23 patients diagnosed with IBD, 17.4% had a family history of IBD, 30.4% had clinical symptoms compatible with IBD and 82.6% had a colonoscopy with some type of pathological finding.

Conclusion: The finding of elevated fecal calprotectin levels in patients with SpA, followed by an appropriate complementary study (endoscopic and/or radiological), allows the detection of a relevant subgroup of patients who meet diagnostic criteria for IBD.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: PsA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The atherogenic index of plasma (AIP) is a predictor of atherosclerosis and coronary heart disease. In patients with systemic lupus erythematosus and rheumatoid arthritis, AIP is correlated with increased cardiovascular risk measured by Framingham's risk score. The correlation between AIP and calculated cardiovascular risk has not been studied in PsA-patients. To evaluate the correlation between AIP and six cardiovascular risk scores in patients with PsA.

Methods: Cross-sectional study that included PsA-patients aged 40 to 75 years who fulfilled the 2006 Classification Criteria for PsA. Patients with previous cardiovascular disease were excluded. AIP was defined by log (TG/HDL-C) mg/dL, and levels ≥0.21 were considered as high AIP. Cardiovascular disease risk was evaluated using 6 algorithms: ACC/AHA 2013, FRS-Lipids, FRS-BMI, RRS, QRISK3, and SCORE2. The Kolmogorov-Smirnov test was performed to evaluate the distribution of variables. The correlation between the AIP and cardiovascular risk algorithms was assessed by Spearman's correlation coefficient. A value of $p \leq 0.05$ was considered statistically significant.

Results: A total of 94 patients with PsA were included, mostly women (n=52, 55.3%), the mean age was 53 ± 11.2, the disease duration of PsA was 5.0 (2.0-10.0) years, and the median AIP of all patients included was 0.49 (0.35-0.67). The median of each algorithm was: FRS-BMI 15.0 (6.7-27.8), FRS-Lipids 7.4 (3.0-16.4), SCORE 1.0 (1.0-3.0), QRISK3 5.6 (2.4-12.5),

Table 1. Correlations between cardiovascular risk algorithms and AIP.

	FRS-Lipids	FRS-BMI	SCORE	RRS	QRISK3	ACC/AHA 2013
AIP	rs=0.619 *p*=0.000	rs=0.427 *p*=0.000	rs=0.341 *p*=0.003	rs=0.538 *p*=0.000	rs=0.460 *p*=0.000	rs=0.641 *p*=0.000

AIP, atherogenic index of plasma; FRS, Framingham Risk Score; BMI, body mass index; RRS, Reynolds Risk Score.

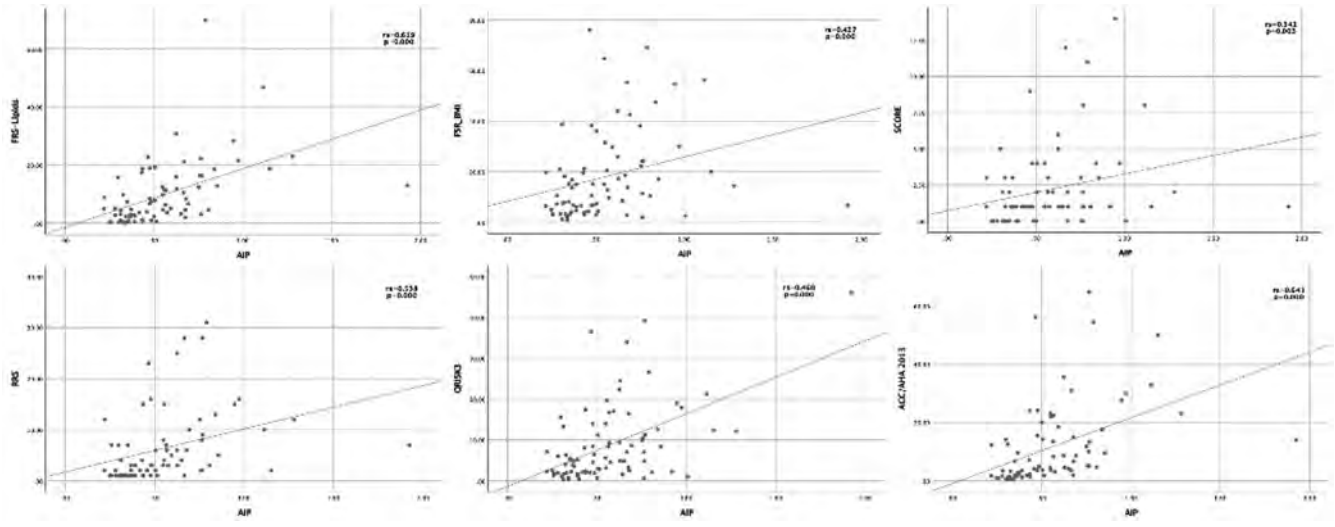

Figure 1. Scatterplots of the correlations between cardiovascular risk algorithms and AIP.

RRS 3 (2.0-7.5) and ACC/AHA 2013 5.3 (2.1-14.5). The most prevalent cardiovascular risk factor was dyslipidemia (n= 41, 43.6%). All cardiovascular risk algorithms presented a high positive correlation between AIP levels and cardiovascular risk. The calculator with the highest correlation was ACC/AHA 2013 (rs=0.641, *p*=0.000). (Table 1 and Figure 1).

Conclusion: In patients with PsA, higher values of AIP are associated with increased cardiovascular risk irrespective of the algorithm used. High AIP values could identify patients who would benefit from a non-invasive evaluation for subclinical atherosclerosis.

Effects and Tolerability of Low to Moderate Biomechanical Stress During Leisure Sport Activity in Patients with Psoriasis and Psoriatic Arthritis

Filippo Fagni[1], Melek Yalcin Mutlu[1], Ioanna Minopoulou[1], Selahattin Alp Temiz[2], Manuel Krieter[3], Georg Schett[4], Arnd Kleyer[5], David Simon[1] and **Axel Hueber**[6], [1]Friedrich-Alexander-Universität (FAU) Erlangen-Nürnberg & Universitätsklinikum Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology / Deutsches Zentrum Immuntherapie, Erlangen, Germany, [2]University Hospital Erlangen and Friedrich-Alexander University (FAU) Erlangen-Nürnberg, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany, [3]Department of Dermatology, Klinikum Nürnberg, Paracelsus Medical University, Nürnberg, Germany, [4]Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany, [5]University Hospital Erlangen, Erlangen, Germany, [6]Division of Rheumatology, Klinikum Nürnberg, Paracelsus Medical University / Friedrich-Alexander-Universität (FAU) Erlangen-Nürnberg & Universitätsklinikum Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology, Nürnberg, Germany

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: PsA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: International guidelines advise physical activity as complementary measure to drug treatment for patients with RA. However, this can hardly be extrapolated for PsA, for which excessive physical strain areas has been implicated in the pathogenesis of enthesitis (so-called "Deep Koebner phenomenon"). This raises the question whether physical activity should be at all recommended in PsA, and if yes what type of activity and intensity are safe. Hence, determining safe thresholds for exercise in PsA is of high importance. In this context, we aimed to assess the effects of mechanical strain on the entheses of psoriatic patients exposed to low-moderate physical activity through badminton, which exerts considerable mechanical stress on the extremities.

Methods: A prospective study was conducted on a cohort of patients with PsA fulfilling CASPAR criteria and PsO recruited at the department of rheumatology of the Erlangen University Clinic and of the Nürnberg Hospital. Participants underwent physical examination of 29 entheses and US of the entheses at the lateral humeral epicondyle, inferior patellar pole, and Achilles tendon bilaterally before and after a 60-minutes badminton session through two rheumatologists (AH, AK). Two blinded expert readers scored US scans to assess entheseal pathology according to OMERACT criteria (MYM, FF). Data on clinical history, therapy, physical activity habits, disease activity, and pain before and after exercise were collected. A follow-up assessment of pain and adverse events was performed one week afterwards by telephone.

Table 1: Baseline characteristics of PsA and Psoriasis patients

	PsA	Psoriasis
n (% female)	7 (14%)	9 (33%)
age (yrs) (mean (SD))	39,3 (10,3)	44,1 (10,9)
disease duration (mean (SD))	16,9 (14,2)	24,3 (14,8)

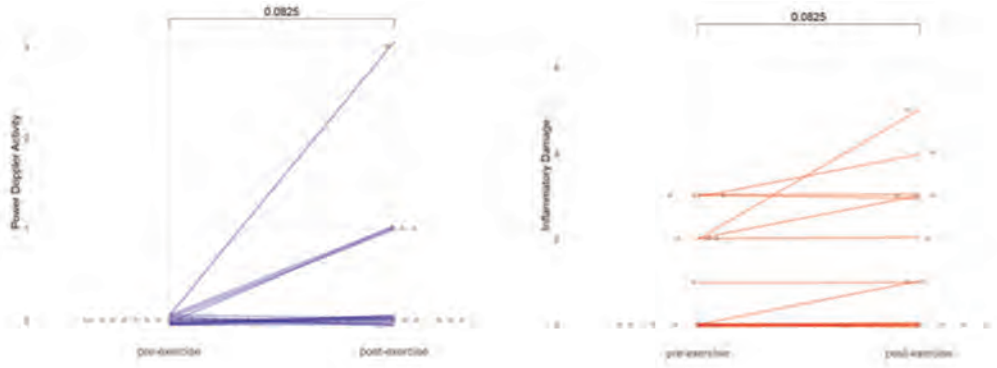
Erosions	0/96	0/96

SPARCC: Spondyloarthritis Research Consortium of Canada enthesitis score; MASES: Maastricht Ankylosing Spondylitis Enthesitis Score; LEI: Leeds Enthesitis Index; IQR: interquartile range,



A Paired t-test revealed no significant difference in the frequency of inflammatory changes (p = 0.08) and Power Doppler activity (p = 0.08) in the pre- and post-exercise measurements.

Figure 1: Spaghetti plots depicting the frequency of individual inflammatory ultrasound changes (right panel) and power Doppler ultrasound signals (left panel) before and after training.

Results: Seven patients with PsA and 9 PsO patients were included. A total of 196 grayscale and power Doppler (PD) US scans were acquired. Baseline clinical characteristics are reported in Table 1. After training, no significant change in median VAS pain nor in tender entheses emerged (Table 2). Baseline US showed structural and inflammatory changes in 15/96 and 17/96 entheses, respectively. After training, 4 patients (2 PsA, 2 PsO) developed a grade-1 Power-Doppler at 6 entheses (Figure 1), which remained non-tender. After one week, median VAS pain remained stable (0,5 cm (0,0-3,0)). Only one untreated PsA participant with active disease at baseline experienced new-onset arthritis in three joints. A single adverse event (disc protrusion) was reported by one PsO patient.

Conclusion: Our findings show that low-moderate mechanical strain on entheses, as in the context of leisure physical activity, is likely to be well tolerated by patients with psoriasis and PsA and might not lead to an increase in disease activity. As the only flare in our cohort was observed in an untreated PsA patient, immunomodulatory therapy could possibly offer some protection against mechanically-induced inflammation. Larger controlled studies are needed to validate our findings and define which physical activity thresholds are safe in PsA. Generating this data is crucial to inform management decisions and ultimately develop evidence-based guidelines for physical activity in PsA.

Abstract Number: 0498

Biological Therapies for Psoriasis and Psoriatic Arthritis- effects on Future Risk Development of Major Adverse Cardiovascular Events (MACE)

Arad Dotan[1], Niv Ben-Shabbat[1], Abdulla watad[2], Dennis McGonagle[3] and **Howard AMITAL**[2], [1]Department of Medicine 'B'. Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, Tel-Hashomer, Israel, Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Israel, [2]Sheba Medical Center, Ramat Gan, Israel, [3]Leeds Biomedical Research Centre, University of Leeds, Leeds, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: PsA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Major adverse cardiovascular events (MACE) are known comorbidities and consequences of psoriasis (PsO) and psoriasis arthritis (PsA). Previous studies underlined the potential of immunomodulatory agents decreasing MACE incidence in patients with PsO and PsA.

We aimed to assess the risk of developing MACE in patients with pre-existing PsO treated with different treatment regimens; topical treatment, methotrexate and biologic disease-modifying anti-rheumatic drugs (bDMARDs), including antiTNFα, anti-IL17 and anti-IL12/23 agents and JAK inhibitors.

Methods: We conducted a retrospective exploratory study using real-world data from the databases of 'Meuhedet', the third-largest Israeli health maintenance organization, covering approximately 1.3 million subjects. A total of 55,780PsO and 5,223 PsA patients were diagnosed between January 2000 and January 2020 and 244,012 healthy controls were included. We performed Cox proportional hazards regression analysis adjusted for factors including sex, body mass index, age at PsO diagnosis, diagnosis of type 2 diabetes mellitus, dyslipidemia, and hypertension. To gain further insight into the

influence of different types of bDMARDs on the risk of MACE, we undertook a comprehensive logistic regression analysis which included the accumulative constatives of the different types of bDMARDs and the mean quantity per month with the same adjustments as in the cox analysis.

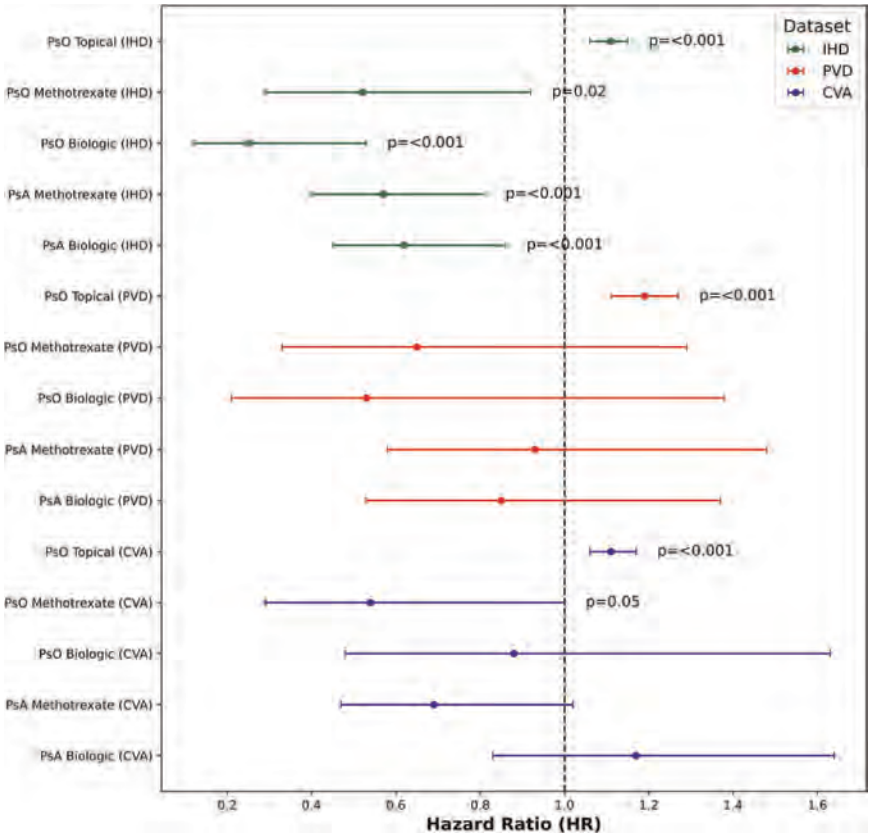
Results: After implementing the exclusion criteria, our study comprised 216,896 participants, with 52,632PsO and 1,592 PsA patients and 162,672 matched controls, contributing a total of 2,261,815 patient-years. PsO and PsA patients treated with methotrexate or bDMARDs showed a significantly lower MACE risk compared to health matched controls (HR: 0.45-0.68, p-value: < 0.001). However, patients receiving topical therapy exhibited a marginally increased MACE risk com-

Combined Univariate and Multivariate Cox Regression Results

	Univariate				Multivariate			
Variable	HR[1]	Lower 95% CI[2]	Upper 95% CI	P-Value	HR	Lower 95% CI	Upper 95% CI	P-Value
PsO Topical	1.13	1.09	1.17	<0.001	1.14	1.10	1.18	<0.001
PsO Methotrexate	0.51	0.33	0.80	<0.001	0.45	0.29	0.70	<0.001
PsO Biologic	0.46	0.29	0.74	<0.001	0.46	0.29	0.74	<0.001
PsA Methotrexate	0.70	0.53	0.92	0.01	0.64	0.48	0.85	<0.001
PsA Biologic	0.66	0.51	0.84	<0.001	0.68	0.53	0.88	<0.001

[1] HR: Hazard ratio

[2] CI: Confidence interval



Green, red, and blue represent data points from 'IHD', 'PVD', and 'CVA' datasets, respectively. Circles symbolize Hazard Ratio (HR) values with lines showing the 95% confidence interval. A black dashed line at HR=1. Data points may have a 'p' value, indicating the HR's statistical significance. Only 'p' values ≤0.05 are shown.

pared to health matched controls (HR: 1.14, p-value: < 0.001) **(Table 1)**. Individual outcomes constituting the composite of MACE, including cerebrovascular accidents, ischemic heart disease, and peripheral vascular disease, showed similar trends**(Figure 1)**.In the logistic regression analysis of PsO and PsA patients exclusively treated with biological treatments, we observed stronger cardioprotective properties of anti-IL-12/23 and anti-IL-17 compared to anti-TNF. Importantly, increased mean monthly quantity of anti-TNF was associated with higher risk of developing MACE (OR=1.12, p=0.042, 95% CI [1.01, 1.24]).In contrast, total quantity of anti-IL 17, anti-IL 12/23, and JAKi reduced risk of developing MACE (OR = 0.98, p = 0.024, CI [0.96, 0.99]).

Conclusion: Our findings suggest that systemic anti-inflammatory treatments for PsO and PsA, including bDMARDs and methotrexate, provide cardioprotective effects. Our study also highlights potential cardiovascular benefits of anti-IL17 and anti-IL12/23 biological agents compared to anti-TNF treatments. This information can assist clinicians and patients in making informed decisions about these therapeutic agents.

Durability of Response Among Patients with Psoriatic Arthritis (PsA) Using Biological or Targeted Synthetic Disease-Modifying Antirheumatic Drugs in the CorEvitas PsA/Spondyloarthritis Registry

Alexis R Ogdie[1], Chao Song[2], Nicole Middaugh[3], Maya Marchese[3], Melissa Eliot[3], Silky Beaty[4], **Robert Low**[4] and Philip J. Mease[5], [1]University of Pennsylvania, Philadelphia, PA, [2]UCB Pharma, Duluth, GA, [3]CorEvitas, LLC, Waltham, MA, [4]UCB Pharma, Smyrna, GA, [5]Swedish Medical Center/Providence St. Joseph Health and University of Washington School of Medicine, Seattle, WA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: PsA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Improvement in both joint and skin manifestations is an important goal in the treatment of psoriatic arthritis (PsA). This study describes durability of 50% improvement in the modified American College of Rheumatology (mACR50) over 24 months and associated factors of response among patients (pts) with PsA initiating biological/targeted synthetic disease-modifying antirheumatic drugs (b/tsDMARDs) in the CorEvitas PsA/Spondyloarthritis Registry – a prospective, non-interventional North American research registry.

Methods: Pts who initiated b/tsDMARDs (March 2013–February 2022) and achieved mACR50 at 6 (±3) months post-initiation were followed until the first occurrence of loss of treatment response (defined as earliest occurrence of b/tsDMARD discontinuation, non-biologic addition, or loss of mACR50), last study visit, or 24 months post-achievement. The mACR50 response measure, which did not require laboratory results, was validated to have high correlation with ACR50 in the CorEvitas registry.[1]

Pt and clinical characteristics, including disease activity and pt-reported outcomes (PROs), were assessed at treatment initiation (index) and time of mACR50 achievement. Percent (95% confidence interval [CI]) maintaining treatment response at 6, 12, 18, and 24 months along with median time to loss of response were reported. Unadjusted proportional hazards

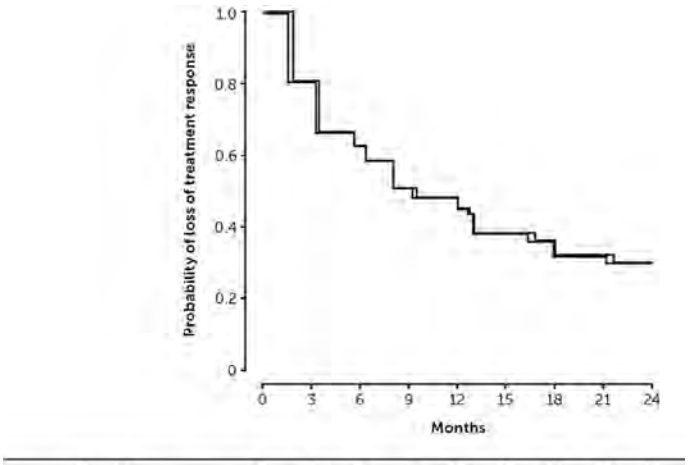
regression models for interval-censored outcomes were used to identify predictors of mACR50 response durability. A multivariable-adjusted regression model was used to calculate hazard ratios (HRs) to evaluate associations between pt characteristics and loss of response over follow-up.

Results: The analysis included 189 b/tsDMARD initiations. Mean (standard deviation [SD]) age was 53.0 (13.3) years. Overall, 52% of pts were female, 89% were white, 86% were overweight/obese, 58% pts were biologic-naïve. Mean (SD) PsA disease duration was 5.9 (7.6) years, with 8.1 (9.3) years since symptom onset.

At mACR50 achievement, improvements in disease activity and PROs were observed. However, 8% of mACR50 achievers still had moderate/high disease activity according to the Clinical Disease Activity Index for Psoriatic Arthritis (cDAPSA) and 20% had not reached Minimal Disease Activity.

Over the 24-month follow-up, 37% (95% CI: 31%, 43%) lost response at 6 months, 52% (95% CI: 45%, 58%) at 12 months, and 70% (95% CI: 65%, 75%) at 24 months (**Figure 1**, **Table 1**). Median time for loss of mACR50 was 9.3 months (95% CI: 7.5, 13.0).

Multivariable-adjusted analysis showed that higher EuroQol-5D (EQ-5D) score at achievement of mACR50 (0.1 unit increase, HR=0.8 [95% CI: 0.67, 0.96]) and having a college education (HR=0.5 [95% CI: 0.30, 0.83]) were associated with lower risk of initial mACR50 loss (**Table 2**).



Months	0	3	6	9	12	15	18	21	24
Number remaining at risk (n)	189	185	155	122	110	92	82	76	72

N= 189. mACR50: 50% improvement in the modified American College of Rheumatology response. Calculation of the mACR50 response correlates with calculation of the ACR50 response, but with the removal of laboratory measures (erythrocyte sedimentation rate [ESR] and C-reactive protein [CRP]).[1]

Figure 1. Kaplan-Meier Curve of Estimated Time Until Loss of mACR50 Treatment Response

Table 1. Description of Time Until Loss of mACR50 Treatment Response

	Months (95% CI) to loss of response			Percent (95% CI) maintaining treatment response			
	25th percentile	Median	75th percentile	6 months	12 months	18 months	24 months
All initiators (N=189)	3.4 (1.8, 3.7)	9.3 (7.5, 13)	NA (21.6, NA)	62.8 (56.6, 69.3)	48.1 (42.1, 54.5)	31.9 (26.7, 37.7)	30.1 (24.8, 35.2)

NA: As 30% maintained response at 24 months (the end of follow-up), the 75th percentile of time to loss of response could not be calculated; mACR50: 50% improvement in the modified American College of Rheumatology response.

Table 2. Hazard Ratios Assessing the Association Between Loss of Treatment Response and Patient and Disease Characteristics

	Unadjusted[a]		Adjusted[b]

Combination Therapy with cDMARD (Reference: Monotherapy)				
Polytherapy	1.14 (0.76, 1.69)	0.532	1.27 (0.92, 1.75)	0.148

*The significance level was set at p<0.05. [a]Univariate model where each predictor was tested one at a time; [b]Models were adjusted for age, sex, college education, work status, BMI, BSA, fatigue, EQ-5D, and combination therapy; model variables were selected based on univariate regression results and clinical knowledge. BMI: body mass index; BSA: body surface area; cDMARD: conventional disease-modifying antirheumatic drug; CI: confidence interval; EQ-5D: EuroQol-5D; HR: hazard ratio; VAS: Visual Analog Scale.

Conclusion: Among pts with PsA who achieved mACR50 after b/tsDMARD initiation, approximately one third lost treatment response at 6 months, and two thirds lost treatment response at 18- and 24-months post-achievement. A higher EQ-5D score, denoting greater health status, was associated with longer durability of mACR50, following the initial response.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: PsA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Selecting patients with the highest probability of long-term retention of biological treatments is important from a clinical and cost-effectiveness point of view. In this work, we analyzed the Kaplan-Meier curve of golimumab retention in patients with rheumatoid arthritis (RA) and spondyloarthropathies (SpA, including axial SpA plus psoriatic arthritis [PsA]) fitted to a two-phase exponential decay curve, to identify the moment the curve changes from fast to slow decay, and to study factors related to golimumab retention at that moment, i.e, the patient profiles most likely to retain golimumab in the long term.

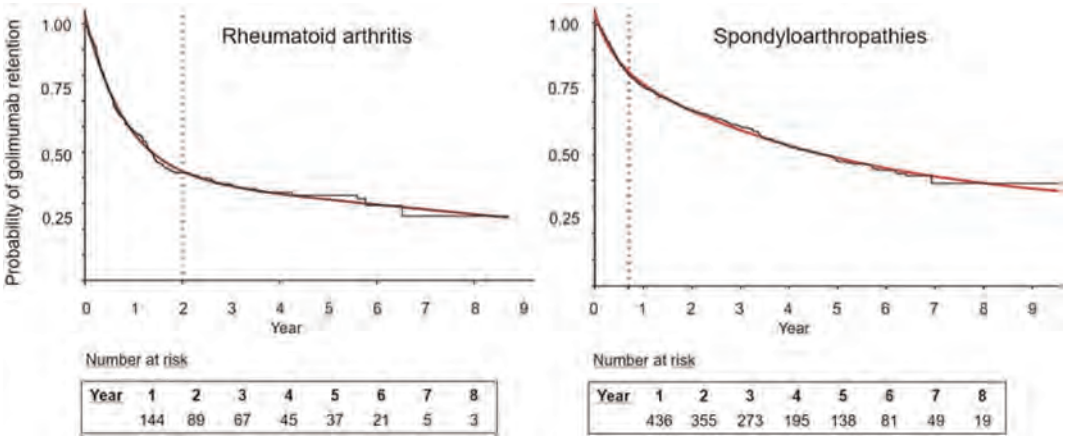
Methods: Data were retrospectively analyzed from the BIOBADASER registry. The Kaplan–Meier retention curve of golimumab was fitted to a two-phase exponential decay curve using GraphPad Prism version 9.3.1 for Windows, and the change in the trend of the curve from fast to slow decay (i.e, from high to low golimumab discontinuation rate) was identified with the formula:

$$Retention_0 - SpanFast = Retention_0\ (Retention_0 - Plateau) * PercentFast * 0.01$$

($Retention_0$ = retention value when time is zero, Plateau = retention value at infinite times, PercentFast = fraction of the span (from $Retention_0$ to Plateau) where the decay is fastest).

Variables associated with retention at the moment of the decay change were studied with Cox-regression analysis. Furthermore, the retention rates at that moment by subgroups of combination of the different variables identified in the Cox regression were calculated. Axial SpA and PsA showed similar curves and were analyzed together as a group (SpA group).

Results: A total of 267 patients with RA and 618 with SpA were included. The Kaplan-Meier curve fitted to a two-phase exponential decay curve for RA and for SpA yielded a coefficient of determination (R^2) = 0.99 and identified month 24 and month 8 as the moment the curve changed from fast to slow decay for RA and for SpA respectively (figure). By Cox regression analysis, second/third line of therapy, older age and use of glucocorticoids at golimumab initiation were associated with golimumab discontinuation at month 24 in RA. In SpA, factors associated with golimumab discontinuation at month 24 in RA. In SpA, factors associated with golimumab discontinuation at month 8 were female sex, second/third line of therapy and disease activity > median at golimumab initiation. Tables 1 and 2 show the retention rates at month 24 (RA) and at month 8 (SpA) stratified by the variables identified in the Cox regression.



Kaplan Meier curve showing probability of golimumab retention. The red line represents the fit of the Kaplan-Meier survival curve to the exponential two-phase decay equation model

Table 1. Retention rate of golimumab at month 24 in RA patients by combination of variables identified in the Cox regression analysis

			Yes:	27.8 (7.0 – 48.6)
	≥ 65:	27.5 (10.8 – 44.2)	No:	63.6 (35.2 – 92.0)
			Yes:	12.2 (0.0 – 27.3)

(*) Only four patients in this group. Confidence intervals were not calculated; (**) Only one patient in this group, who reached month 24; (***) This group comprised nine patients, five discontinued golimumab before month 24 and the remaining four were on golimumab therapy but had not reached a follow-up of 24 months at the time of study analysis.

Table 2. Retention rate of golimumab at month 8 in SpA patients by combination of variables identified in the Cox regression analysis

Sex	Line of therapy		Disease activity at golimumab initiation	
Men: 86.0 (82.3 – 89.7)	First line:	91.5 (86.8 – 96.2)	< median:	93.2 (87.5 – 98.9)
			> median:	88.9 (79.7 – 98.1)
	Second line:	86.6 (80.3 – 92.9)	< median:	88.9 (81.1 – 96.7)
			> median:	83.7 (72.7 – 94.7)
	Third or subesquent line:	78.7 (71.1 – 86.3)	< median:	83.0 (72.2 – 93.8)
			> median:	81.5 (71.1 – 91.9)
Women: 75.7 (70.6 – 80.8)	First line:	81.5 (73.1 – 89.9)	< median:	94.1 (86.3 – 100.0)
			> median:	78.9 (66.0 – 91.8)
	Second line:	78.3 (70.1 – 86.5)	< median:	76.5 (62.2 – 90.8)
			> median:	78.0 (66.4 – 89.6)
	Third or subesquent line:	67.7 (58.1 – 77.3)	< median:	80.0 (65.7 – 94.3)
			> median:	64.9 (50.0 – 79.8)

Conclusion: The golimumab retention curve changes from fast to slow decay at month 24 in RA and at month 8 in SpA. After that moment, the rate of golimumab discontinuation slows. The probability of retention of the different patient profiles calculated might allow a better identification of patients with higher probability of retention in the long-term to be treated with golimumab. The study is limited by the low number of patients in several subgroups of RA.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: PsA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Data are still scarce about risk factors predicting the occurrence and course of uveitis in spondyloarthritis (SpA). We aimed to examine associations between demographic, clinical, and/or laboratory characteristics of SpA with the occurrence and the course (including eye damage and recurrence rate) of uveitis.

Methods: Characteristics (at disease diagnosis and ever-present) from all SpA patients in 3 tertiary rheumatology-clinics (1/2018-1/2023) were retrospectively recorded. Comparisons were made between patients with and without uveitis, as well as between subjects with uveitis rate [episodes/year] above the median uveitis rate in the whole cohort and those without persistent uveitis. In multivariable models, age, gender, and variables that were statistically significant in univariate analyses were included.

Results: 264 AxSpA and 369 PsA patients were enrolled. In AxSpA, uveitis occurred in 11.7% and was associated (multivariable analysis) with HLA-B27 (OR = 4.15, 95% CI 1.16-14.80, p=0.028) and ever-present peripheral arthritis (OR 3.05 (1.10 – 8.41, p=0.031;) (Table 1). In PsA, uveitis was reported in 2.7% of patients and was associated with SpA family history (p=0.023; 6.35 (1.29-31.27), axial disease at diagnosis (p=0.038; 5.61 (1.01-28.69) and disease duration (. p=0.004; 1.12 (1.04-1.21) (Table 2). Median uveitis rate was 0.205 for AxSpA and 0.285 for PsA. No associations were found between those above the above rates and demographic/clinical/laboratory characteristics. Permanent vision damage was seen in 16.1% of AxSpA and 30% of PsA patients, all of them with recurrent uveitis.

Conclusion: Uveitis in SpA is associated with specific characteristics. Permanent eye damage is not rare, especially in those with recurrent uveitis.

Developing Electronic Health Record Algorithms to Accurately Identify Psoriatic Arthritis Patients

Paras Karmacharya[1], **Avery Fortier**[1], Georgina Sellyn[1], Alexis R Ogdie[2] and Leslie Crofford[3], [1]Vanderbilt University, Nashville, TN, [2]University of Pennsylvania, Philadelphia, PA, [3]Vanderbilt University Medical Center, Melbourne, AR

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: PsA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a chronic, progressive inflammatory disease of the skin and musculoskeletal system, affecting over half a million US adults. With relatively uncommon diseases such as PsA, electronic health records (EHR) offer an opportunity to better understand long-term outcomes in the real-world setting. EHR are an efficient and cost-effective tool that allows for the identification of a large number of patients in the real-world setting for clinical and translational research. However, the clinical heterogeneity of PsA along with a lack of clear diagnostic criteria or tests poses a diagnostic challenge. This also translates into a difficulty in identifying PsA patients in the EHR. Identifying PsA patients accurately in the EHR is crucial to study long-term outcomes in PsA in the real-world setting. Therefore, the objective of this study was to develop EHR algorithms to accurately identify patients with PsA.

Methods: We used a de-identified version of Vanderbilt's EHR called the Synthetic Derivative (SD containing ~3.5 million subjects) to identify our PsA cohort. The SD includes longitudinal clinical data over several decades (1993-2021) with all information available in the EHR. We screened the SD for adult patients (≥18 years of age) with one International Classification of Diseases, Ninth or Tenth Revision (ICD 9/10) code for psoriatic arthritis or any psoriatic arthritis keyword in the problem list (**Figure 1**). Of the 5,636 potential PsA cases, we randomly selected 200 for chart review

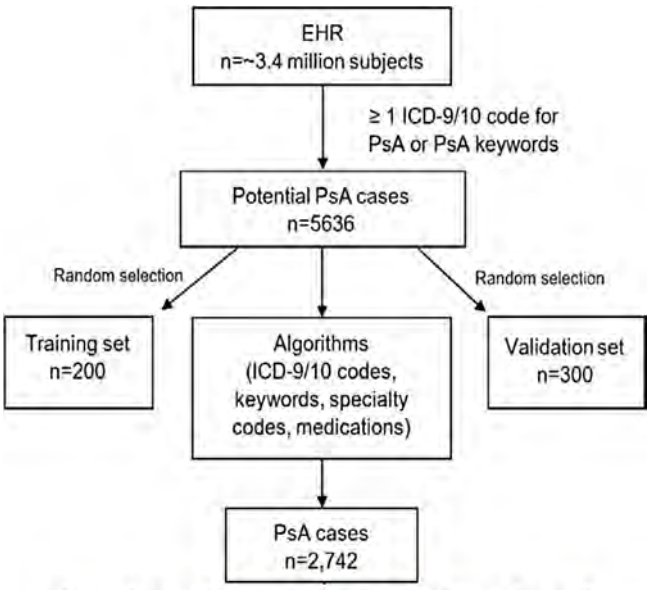

Figure 1. Development of EHR algorithms for PsA
n= number of individual patients

Figure 1. Development of the electronic health record algorithms for psoriatic arthritis

to identify their true disease status and to serve as a training set and a separate random set of 300 as the validation set. A rheumatologist diagnosis of PsA or fulfillment of CASPAR criteria based on manual chart review was used as the reference standard. Potential algorithm components decided *a priori* were ICD 9/10 codes for PsA and psoriasis, ICD 9/10 codes for PsA by rheumatology and dermatology, keywords for PsA in the problem list, and use of disease-modifying antirheumatic drugs (DMARDs). Positive predictive value (PPV) and sensitivity, along with the F-score (harmonic mean of PPV and sensitivity), were calculated.

Table 1. Performance of high-performing algorithms using specialty and medications in addition to PsA ICD 9/10 codes

Algorithm	PPV in training set	PPV in validation set	Sensitivity	F-score (training set)
≥ 4 counts ICD 9/10 counts	90%	93%	71%	0.79
≥ 1 count by a rheumatologist	95%	95%	51%	0.66
≥ 4 PsA ICD 9/10 counts **OR** ≥ 1 count by a rheumatologist	**91%**	92%	**81%**	**0.86**
≥ 4 PsA ICD 9/10 counts **AND** ever DMARD use	91%	93%	67%	0.77

Table 2. Baseline characteristics of the psoriatic arthritis electronic health record cohort (n=2,742)

Baseline characteristics	Mean (SD)
Age, years	50.2 (13.5)
Female, no. (%)	1602 (58.4)
Race, no. (%)	
White	2453 (89.5%)
African American	54 (2.0%)
Hispanic	30 (1.1%)
Asian	28 (1.0%)
Alaskan/Indian	4 (0.2%)
Missing/unknown	189 (6.9%)
No. of PsA ICD codes	15 (16)
BMI (kg/m^2)	29.9 (7.3)
Years of follow-up	8 (5)
PsA Medications Ever*	
Conventional DMARDs	1956 (71.4%)
TNFi	1834 (66.9%)
PDE4	460 (16.8%)
JAKi	112 (4.1%)
IL-17i	504 (18.4%)
IL-23i	109 (4.0%)
Abatacept	111 (4.1%)

SD= standard deviation, PsA= psoriatic arthritis, ICD= International Classification of Diseases, BMI= body mass index
*Adds to more than 100% because these are medication ever used

Results: The best-performing algorithms in the training and validation sets are shown in **Table 1**. Using the best performing algorithm of ≥ 4 PsA ICD 9/10 codes OR at least 1 ICD 9/10 code by a rheumatologist (PPV of 91%, sensitivity 81%, F-score 0.86), we identified 2,742 PsA patients. The mean age of the EHR cohort was 50.2 (SD 13.5), 58.4% female, and the majority (89.5%) were white, with a mean follow-up of 8 (SD 5) years (**Table 2**).

Conclusion: We have successfully developed an EHR algorithm using ICD-9/10 codes, demonstrating a PPV of 92% in internal validation. This rule-based algorithm represents a useful tool for clinical and translational research to identify PsA patients efficiently and accurately in an EHR. The EHR-based PsA cohort will enable longitudinal, de-identified chart review for further sub-phenotyping, and pragmatic clinical studies that pave the way for personalized treatment approaches.

Spinal Inflammation a Dominant Pathology in Psoriatic Arthritis: Characterization and Quantification by *In-Vivo* ^{18}F-FDG Total-Body PET/CT Imaging

Siba Raychaudhuri[1], Yasser Abdelhafez[2], Dario Mazza[2], Smriti K Raychaudhuri[3] and Abhijit Chaudhari[4], [1]UC Davis, School of Medicine/ VA Medical Center, Sacramento, Davis, CA, [2]University of California Davis, Sacramento, CA, [3]VA Sacramento Medical Center, Mather, CA, [4]UC Davis School of Medicine, Sacramento, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: PsA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Right and Moll recognized the presence of spinal inflammation/axial disease in psoriatic arthritis (PsA) in their seminal work in 1973. The prevalence of axial disease in patients with PsA varies with disease duration. The Total Body (TB)-PET/CT with the ^{18}F-FDG radiotracer captures glucose metabolism across the entire body, and provides standardized measures as surrogates for degree of inflammation such as SUVmax. The objective of this study was to apply high-sensitivity TB ^{18}F-FDG PET/CT imaging to identify and characterize the spectrum of spinal inflammation in patients with PsA.

Methods: We prospectively recruited 25 PsA patients (6 female, 19 male; mean age of 51.4±16.4 years), as per CASPAR criteria. Among them, 8 patients had inflammatory low back pain (LBP). All subjects underwent a single-time point ^{18}F-FDG TB-PET/CT using 1/5th the standard radioisotope dose (78.2±4.9 MBq) *(Abdelhafez Y,et al .J Nucl Med. 2022(10):1579-1585)*.

Degree of inflammation was quantified by using maximum standardized uptake value ratio corrected by the background level (rSUVmax).Qualitative changes in the joints (atlantoaxial, apophyseal, costovertebral/costotransverse, and sacroiliac) and entheses (cervical/thoracic/lumbar supra- and interspinous ligaments) were also evaluated.

Results: In one or more of the described sites PET imaging demonstrated abnormality in 21 (84%) patients. Notable changes respectively were observed in atlantoaxial **(Figure 1),** apophyseal, costovertebral/ costotransverse, and sacroiliac joints **(Figure 2)** in 15 (60%), 18 (72%), 11 (44%), and 5 (20%) patients in variable combinations.

20% patients(5/25) demonstrated sacroiliitis by PET imaging, among them the involvement was unilateral in three and bilateral but asymmetric in two patients **(Figure 2).** A patient with PsA with inflammatory LBP for >5 years had no evidence of sacroiliitis on MRI but demonstrated unilateral pronounced sacroiliitis on PET.

Increased ^{18}F-FDG uptake suggestive of active inflammation on PET imaging was observed in cervical, thoracic, and lumbar spine enthuses **(Figure 3**) in 14 (56%), 17 (68%), and 15 (60%) patients, respectively. Overall, spinal enthesitis was evident in 80% (20/25) patients.

Quantification of the total spinal inflammatory load (rSUVmax) could be measured in each patient, the summed rSUVmax/patient was on average 7.3±3.1 for all the described sites.

Conclusion: TB-PET/CT scan is an US FDA approved technology. We observed spinal inflammation to be a dominant pathology in PsA : i. Our findings provide direct in-vivo evidence that enthesitis could be the primary pathology for axial inflammation in PsA; spinal enthesitis was observed in 80% of patients. In majority of the patients this pathology was clinically occult, as only about one third of the patients reported back pain. ii. Non-radiographic axial disease in PsA remains unaddressed. Here we have demonstrated this condition in PsA and we provide TB-PET/CT as a biomarker tool to diagnose this

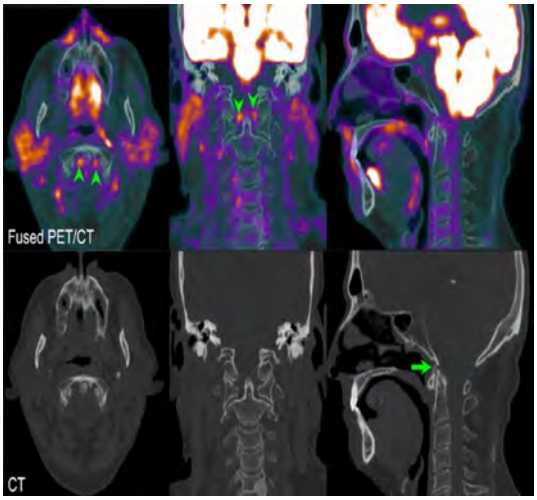

Figure 1. Changes in atlanto-axial articulation. Fused 18F-FDG PET/CT sections (top row) and their corresponding low-dose CT (bottom row) extracted from TB-PET/CT for a 62-year-old man with PsA in axial (left), coronal (middle) and sagittal (right) views. Images demonstrate intense FDG uptake with rSUVmax 1.7 at the alar ligaments (arrowheads) with evidence of ossification of the anterior atlanto-occipital membrane on the CT (arrow).

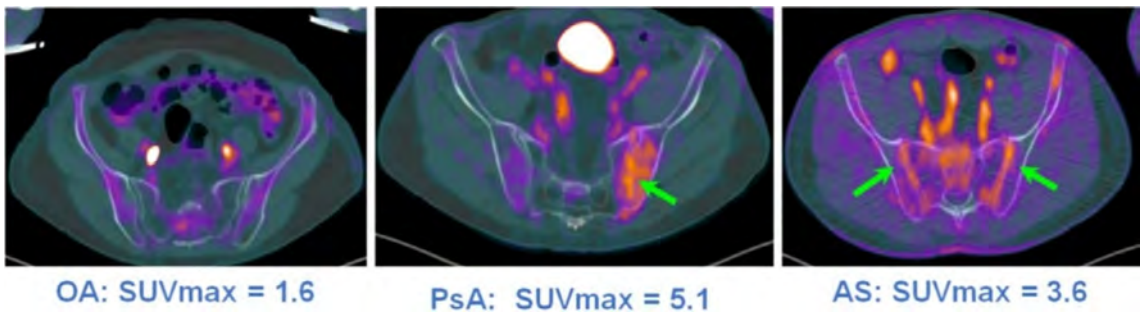

Figure 2. Asymmetric sacroiliac inflammation in Psoriatic arthritis. PET-CT imaging is capable of Identifying and providing in vivo quantitative measures of the degree of inflammation (SUVmax) as shown in this figure. Compared to osteoarthritis (OA) marked unilateral SI joint inflammation can be been in psoriatic arthritis (PsA) and bilateral symmetric inflammation of SI joints in ankylosing spondylitis (AS).

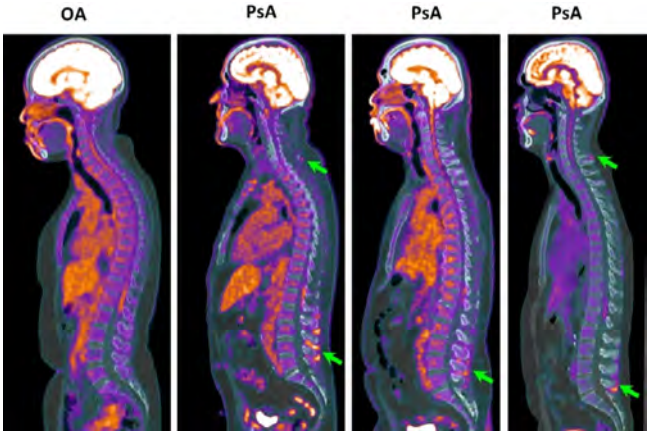

Figure 3. PET-CT in Diagnosis of Psoriatic Arthritis Axial Disease. Enthesitis at multiple levels in the spine (green arrows) with or without sacroiliitis is an interesting finding in the psoriatic arthritis (PsA) patients by total body the PET-CT imaging. Where as in osteoarthritis (OA) spinal inflammation could not be detected. Involvement of the inter-/supra-spinous ligament are marked by the green arrows.

condition. iii. In-vivo TB-PET imaging provided the total inflammatory burden (rSUVmax) of the whole spine thus demonstrating the ability of TB-PET/CT as a quantitative tool for assessing disease severity and for therapeutic response.

Abstract Number: 0504

Burden of Disease of Psoriatic Arthritis in Latin America: A Systemic Review of Literature

Wilson Bautista-Molano[1], Linda Ibata[2], Susan Martinez[2] and Andrea Chacon[2], [1]University Hospital Fundación Santa Fe de Bogotá, Bogotá, Colombia, [2]InValue Health Solutions, Bogotá, Colombia

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: PsA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a chronic inflammatory pathology that generates a substantial and progressive deterioration of functionality and quality of life. It is associated with comorbidities such as cardiovascular disease, metabolic diseases and a significant compromise of mental health. In Latin America, information regarding the disease is limited. This study reviews the burden of disease (disease activity, function, clinical manifestations, comorbidities, patient-reported outcomes, quality of life, and use of health resources) in adults diagnosed with PsA in Latin America.

Methods: A SLR of the literature was carried out to determine the burden of PA in Latin America, under a qualitative and quantitative approach, following the PRISMA report. Publications in PUBMED, EMBASE, Cochrane Database of Systematic Reviews – CDSR, LILACS, Scielo, Redalyc, conference abstracts and grey literature, were reviewed. The full texts of potentially eligible studies were assessed independently, extracting in each the data requested by a pre-specified data collection

instrument. Quality was assessed according to the type of study. Risk of bias assessment was performed with the instrument validated for cross-sectional studies, for cohort studies the instrument validated (CLARITY tool) was used. The Joanna Briggs quality tool was used for economic evaluations. To reduce publication bias, we searched grey literature.

Results: We identified 692 references, selecting 50 studies: 41 cross-sectional, 4 economic studies, 4 cohort studies and 1 systematic review. The information comes mainly from Brazil, Argentina and Mexico. The estimated disease prevalence for Latin America ranges from 0.004% to 0.08% (95% CI 0.02–0.20). The disease duration was reported with a mean of 7.2 years (95% CI 6.94-7.52). DAS28 scored between mild to moderate disease activity (mean 3.01–3.51). Lower activity was reported in patients with normal body weight *versus* those who were overweight or obese. Disability assessed using the HAQ-DI reports data of 1.1 ±0.7. Patients treated with biologics had fewer impairments in function than those treated with NSAIDs, without treatment or with DMARD. The SF-12 health survey, report averages of 43 (physical component) and 42-45 (mental component). In a registry, 39.6% of these were employed. The greater the severity of the disease, the lower the employment rate (mild:50%, moderate:38.7%, severe:38.5%). Twelve studies reported frequency of medication use, 30.3% (6.2%-42.5%) receiving corticosteroids, 47.8% (38.5%-82.4%) methotrexate, 38.3% (9.2%-40.6%) leflunomide and 23.5% (8%-56.2%) biologics.

Table 2| Measures of function and disability in patients with psoriatic arthritis in Latin America

Abstract Number: 0505

Factors Associated with Minimal Disease Activity in Psoriatic Arthritis: Insights from a Registry-Based Study

Shashank Cheemalavagu[1], Yuxuan Jin[2] and M. Elaine Husni[3], [1]Cleveland Clinic Foundation, Cleveland, OH, [2]Cleveland Clinic, Cleveland, OH, [3]Cleveland Clinic / Department of Rheumatic and Immunologic Diseases, Cleveland, OH

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: PsA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Achieving minimal disease activity (MDA) is an important treatment goal in psoriatic arthritis (PsA), as it leads to improved clinical outcomes and quality of life for patients. However, the impact of specific clinical factors and therapies on long-term MDA status requires further investigation. The aim of this study was to identify treatment factors associated with minimal disease activity (MDA) status in PsA patients.

Methods: We utilized data from a tertiary care psoriatic disease biorepository, collecting patient- and physician-reported outcomes and clinical information longitudinally. Adult PsA in the registry for more than one year with at least two evaluations of MDA status were included. A multivariable logistic regression model was constructed to investigate factors associated with long-term MDA status. Candidate predictors included: PsA duration (at the most recent recorded visit), gender, baseline MDA status, number of completed visits in the registry, number of medication regimen switches, and seven medication class-related variables (use of TNFi, IL-17i, IL-12/23i, IL-23i, JAKi, oral DMARD only, and combination biologic and oral DMARD). The outcome of interest was long-term MDA status, defined MDA status at the most recent registry visit. Continuous variables were summarized using medians and IQR, while categorical variables were summarized using counts and frequencies. Model results were presented using odds ratios and 95% confidence intervals for likelihood of being in non-MDA status at the most recent registry visit. All tests were two-sided, assuming an alpha level of 0.05.

Results: The analysis included 164 PsA patients with an average duration of PsA of 20.4 years, of whom 56% were female. Approximately 75% of patients were not in MDA at baseline, while approximately 54% of patients were not in MDA at their most recent evaluation. Baseline MDA status showed the most significant association with long-term MDA status. Patients in MDA at baseline had an 84% lower likelihood of being in non-MDA status at their most recent evaluation compared to patients not in MDA at baseline (OR 0.16, 95% CI: 0.06, 0.46, $p = 0.001$). In other words, patients in MDA at baseline were much more likely to be in MDA long-term. The use of IL-17 inhibitors (OR 3.38, 95% CI: 1.08, 10.59, $p = 0.036$) or oral DMARDs alone (OR 2.51, 95% CI: 1.01, 6.26, $p = 0.048$) during the registry period decreased the likelihood of long-term MDA status. No other medication or continue variable had a significant effect on the final MDA status.

Table 1: Demographic and Disease Characteristics of the PsA Study Cohort

Variable	Level	Total(n=164)	N
PsA Duration. Median [25th:75th]		20.4 [12.7;37.0]	146
Age at PsA Diagnosis. Median [25th:75th]		31.9 [20.3;44.3]	146

	Yes	66 (40.2%)	
Number of Completed Visits. Median [25th:75th]		4.00 [2.00;5.00]	164
Most Recent MDA Status. N (%)	Non-MDA	89 (54.3%)	164
	MDA	75 (45.7%)	

[1] Number of times medication regimen was different from the prior registry visit

DMARD, disease modifying anti-rheumatic drugs; IL-17i, interleukin-17 inhibitor; IL-12/23i, interleukin-12/23 inhibitor; IL-23i, interleukin-23 inhibitor; JAKi, janus kinase inhibitor; MDA, minimal disease activity; TNFi, tumor necrosis factor inhibitor

Table 2: Analysis of Multivariable Logistic Regression Model Results in the Psoriatic Arthritis Study Cohort

Variable	Level	OR (95%CI)	P-value
PsA Duration (years)[1]	12.7–37	1.19 (0.68, 2.08)	0.538
Gender	F (v M)	1.12 (0.51, 2.46)	0.786
Baseline MDA	MDA (v non-MDA)	0.16 (0.06, 0.46)	0.001
Number of Visits	2–5	1.11 (0.53, 2.35)	0.782
Number of Medication Switches	0–2	1.48 (0.69, 3.2)	0.317
Ever on TNFi	Yes (v No)	1.51 (0.49, 4.63)	0.468
Ever on IL-17i	Yes (v No)	3.38 (1.08, 10.59)	0.036
Ever on IL-12/23i	Yes (v No)	0.68 (0.18, 2.63)	0.576
Ever on IL-23i	Yes (v No)	1.03 (0.18, 5.8)	0.970
Ever on JAKi	Yes (v No)	1.31 (0.23, 7.54)	0.761
Ever on DMARD alone	Yes (v No)	2.51 (1.01, 6.26)	0.048
Ever on Biologic + DMARD	Yes (v No)	1.07 (0.45, 2.56)	0.877

[1] For PsA duration, number of visits, and number of medication switches, OR reflects the IQR increase

IQR, interquartile range; OR, odds ratio

Conclusion: This registry-based study provides insights into factors associated with minimal disease activity in PsA patients. Baseline MDA status is a key predictor of long-term MDA status, emphasizing the importance of achieving early MDA. The use of IL-17 inhibitors and oral DMARD alone were associated with a decreased likelihood of achieving MDA. These findings can assist in risk stratification and guide clinicians in selecting therapies for improved psoriatic disease control.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: PsA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: In patients with psoriatic arthritis (PsA), discordance between physicians and patients when assessing disease activity has been described as frequent, mainly in European and North American studies. This discordance may negatively impact treatment adherence and shared decision-making processes. Culture and beliefs influence patients' perceptions of health.

The purpose of this study was to evaluate the concordance between patient- (PGA) and physician-global assessment (PhGA) of PsA disease activity and its association with demographic and disease characteristics in a multinational group of patients from Arab countries.

Methods: This multicentric multinational cross-sectional study was conducted in thirteen Arab countries by the Arab League of Associations of Rheumatology (ArLAR) research group (ARCH). During a single routine visit, patients and physicians rated PsA disease activity on a numeric scale from 0 (no activity) to 10 (worse activity). In addition, demographic and disease data were collected, as well as PGA and PhGA for psoriasis (PsO) activity, Health Assessment Questionnaire (HAQ), Fibromyalgia Rapid Screening Tool (FiRST), Patient Health Questionnaire (PHQ4) and Disease Activity in Psoriatic Arthritis (DAPSA). First, the correlation between PGA and PhGA for PsA and PsO disease activity was assessed statistically

using the Spearman correlation coefficient and graphically using the Bland and Altman method. Second, concordance between the PGA and PhGA PsA activity (defined as a difference between -2 and 2) was calculated and correlated with demographic and disease factors using multivariable binary logistic regression.

Results: The study included 554 patients from thirteen countries: mean age 45 years (SD 13), 57% females, median disease duration four years (IQR 2-9); 89.2% had skin PsO, and 43.5% had nail PsO. The disease was active overall: mean DAPSA was 19.3 (SD 16.1), HAQ 1.1 (SD 0.8), and PHQ4 3.3 (SD 2.9). The screening test for widespread pain was positive in 18.4% of patients (Table 1). The mean PGA for PsA activity was 4.7 (SD 2.5) versus a PhGA of 3.9 (SD 2.4). Similarly, PGA for psoriasis activity was 4.0 (SD 2.8), and PhGA was 3.1 (SD 2.6). The correlation between PGA and PhGA was strong for PsA activity (r= 0.738) (with good agreement on Bland and Altman (Figure 1)) and moderate for psoriasis activity (r=0.613). Among 554 patients' measurements, 358 (84.2%) were in concordance with the physician's global assessment (Figure 2). In the multivariable analysis, concordance was independently associated with a high CRP (OR 2.32 [95%CI 1.33; 4.02] and DAPSA category (better concordance in patients in remission (OR 1.02 (95%CI 1.01; 1.03]).

Table 1. Patients' and disease's characteristics.

Characteristic	N or Mean or Median	% or SD or IQR
Number of patients (N)	554	
Age, years (mean, SD)	45.5	13.2
Gender (N, %)		
- Male	221	39.9
- Female	318	57.4
- Missing	15	2.7
Education (N, %)		
- None	13	2.3
- Elementary	99	17.9
- Secondary	164	29.6
- University	263	47.5
- Missing	15	2.7
BMI category (N, %)		
- Underweight	9	1.6
- Healthy	135	24.4
- Overweight	206	37.2
- Obese	189	34.1
- Missing	15	2.7
Current smoking (N, %)	99	17.9
PsA duration (median, IQR)	4	2 - 9
PsA diagnostic delay (median, IQR)	1	0 - 3
Skin psoriasis (N, %)		
- Yes	494	89.2
- No	45	8.1
- Missing	15	2.7
Nail psoriasis (N, %)		
- Yes	241	43.5
- No	298	53.8
- Missing	15	2.7
Psoriasis duration (median, IQR)	12	6 - 21
PGA for PsA activity (mean, SD)	4.7	2.5
PGA for PsA pain (mean, SD)	4.7	2.7
PGA for psoriasis activity (mean, SD)	4.0	2.8
PhGA for PsA activity (mean, SD)	4.0	2.4
PhGA for psoriasis activity (mean, SD)	3.1	2.6
DAPSA score (mean, SD)	19.3	16.1
HAQ score (mean, SD)	1.1	0.8
PHQ4 total score (mean, SD)	3.3	2.9
FiRST positive screening (5/6) (N, %)		
- Yes	102	18.4
- No	450	81.2

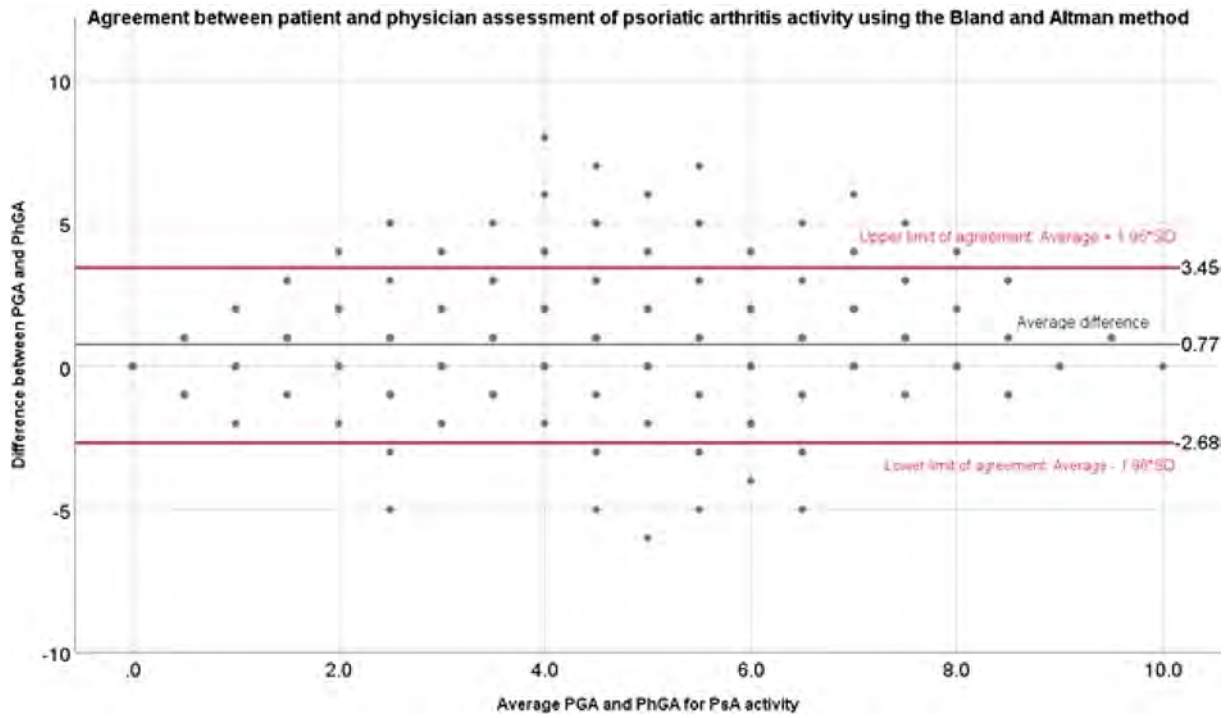

Figure 1. Agreement between PGA (Patient) and PhGA (Physician Global Assessment) of PsA activity using the Bland and Altman plot. Each dot is the difference between PGA and PhGA for a specific patient.

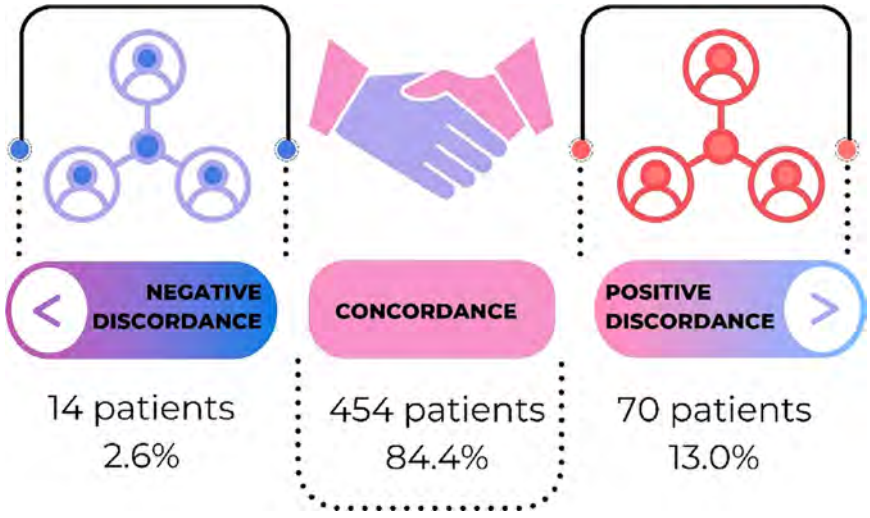

Figure 2. Concordance between PGA and PhGA of PsA activity, defined by a difference (PGA – PhGA) comprised between -2 and +2 (total available = 538 pairs)

Conclusion: In this unselected sample of patients from Arab countries, there was a strong concordance between PGA and PhGA of PsA activity. This raises questions about patient expectations and pain perceptions in Arab countries. Concordance was stronger for PsA than PsO, indicating that rheumatologists may be more comfortable assessing joints than skin. The patient's evaluation of disease activity needs to be taken into account when considering the disease management plan, especially in patients who are not in remission.

Abstract Number: 0507

The Use of PSAID-12 in Remote Monitoring Correlates with In-person Clinical Examination Findings in Psoratic Arthritis

Antoni Chan and NiSoe Nwe, Royal Berkshire NHS Foundation Trust, Reading, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: PsA
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Patient-reported outcome measures (PROMs) are important tools for evaluating disease activity, functional status, and quality of life in patients with psoriatic arthritis (PsA). The Psoriatic Arthritis Impact of Disease (PSAID) questionnaire is a commonly used PROM. The Psoriatic Arthritis Response Criteria (PSARC) is a composite measure that assesses changes in disease activity based joint pain, swelling and general health. The objective of this study was to assess the correlation between remote PSAID-12 and in-person tender, swollen joint and pain in patients with PsA attending the clinic.

Methods: This study was a cross-sectional, observational study of patients with PsA meeting CASPAR critieria. Patients were recruited consecutively from clinic and completed the PSAID-12 questionnaires 14 days prior to their clinic visit digitally or by paper. Demographic and clinical data, including age, gender, disease duration, medication were collected. The tender (68 joint) and swollen (66 joint) count as well as the Likert Pain Score was conducted in-person in the clinic. The primary outcome was the correlation between PSAID-12 and tender, swollen joint and Likert Pain Score. Descriptive statistics was used to summarise the demographic and clinical characteristics of the study population. Pearson correlation coefficients were calculated to assess the correlation between PSAID-12 and tender joint, swollen joint and pain scores.

Results: The total number of patients in the study was 235. The female:male ratio was 1.0:0.8. The mean disease duration was 27 years (range 2 months to 54 years). The mean age was 52 years (range 18 to 86 years). The number of patients on cs DMARDs were 201/235 (85.5%) and bDMARDs 84/235 (35.7%). The mean PSAID-12 score was 4.1 (SD 2.5). The number of patients in remission (PSAID-12 < 1.4) was 48 (21%), low disease activity (PSAID-12, 1.4- 4) 71 (30%), moderate disease activity (PSAID-12, 4-6.7) was 83 (35%), active disease (PSAID-12 > 6.7) was 33 (14%), tender joint count 11.7 (SD 14.8), swollen joint count 6.1 (SD 10.1) and Likert Pain Score 4.6 (SD 2.6). There was a positive correlation between the pre-clinic PSAID-12 score and the in-person calculated tender joint count ($r=0.58$, $p < 0.05$, figure 1)swollen joint count ($r= 0.51$, $p < 0.05$, figure 2) and the Likert pain score ($r=0.84$, t-score 22.7, $p< 0.05$, figure 3).

Conclusion: This real-world clinic study confirms the findings from the previous PSAID-12 validation studies where the PSAID-12 correlation with Pain VAS was $r = 0.83$, tender joint count was $r = 0.57$ and swollen joint count was $r = 0.40$. Our study has shown very similar results. This provides evidence that the PSAID-12 score may be used as a PROM for remote monitoring

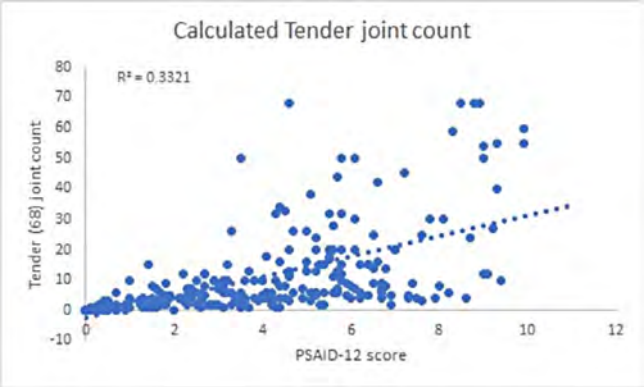

Figure 1. Correlation between remote PSAID-12 and in-person calculated tender (68) joint count

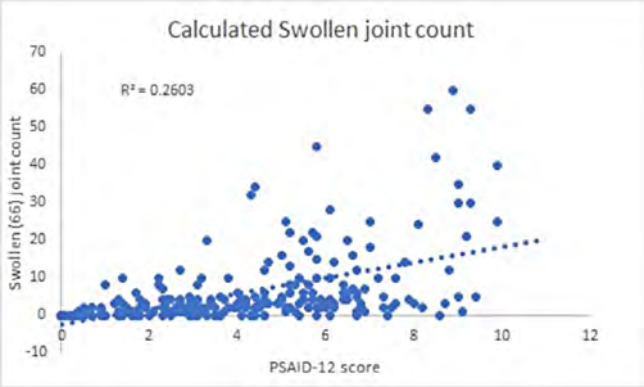

Figure 2. Correlation between remote PSAID-12 and in-person calculated swollen (66) joint count

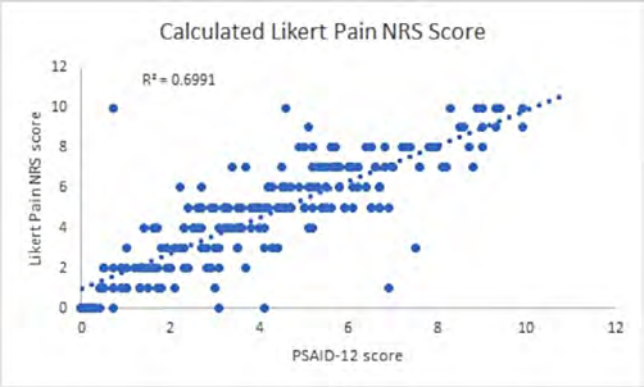

Figure 3. Correlation between remote PSAID-12 and in-person Likert Pain NRS score assessment

during the longer intervals between in-person clinic reviews. Using PSAID-12, one-fifth of patients were in PsA remission and may be suitable for a remote or tele-consultation which will reduce the need to travel to hospital for an in-patient review. The results of this study may help to improve the understanding of the relationship between these remote monitoring and in-person assessments and their utility in clinical practice for assessing disease activity and functional status in patients with PsA.

Assessment of Pain Outcomes in a Phase 2 Trial of a Selective, Allosteric Tyrosine Kinase 2 Inhibitor, Deucravacitinib, in Patients with Active PsA

Philip J. Mease[1], Lihi Eder[2], Alexis R Ogdie[3], Atul Deodhar[4], Subhashis Banerjee[5], Miroslawa Nowak[5], Jiyoon Choi[6], Thomas Lehman[7] and Vibeke Strand[8], [1]Swedish Medical Center/Providence St. Joseph Health and University of Washington School of Medicine, Seattle, WA, [2]Women's College Research Institute, Division of Rheumatology, University of Toronto, Toronto, ON, Canada, [3]University of Pennsylvania, Philadelphia, PA, [4]Division of Arthritis and Rheumatic Disease, Oregon Health & Science University, Portland, OR, [5]Bristol Myers Squibb, Princeton, NJ, [6]Bristol Myers Squibb, Lawrenceville, NJ, [7]Bristol Myers Squibb, Philadelphia, PA, [8]Stanford University, Palo Alto, CA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: PsA

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Pain is commonly cited by patients with PsA as affecting their daily activities and quality of life and may differ by sex[1]. In addition to neurological pathways, pain signaling involves many cytokines, some of which are tyrosine kinase 2 (TYK2) mediated and involved in PsA pathogenesis. Deucravacitinib is a first-in-class, oral, selective, allosteric inhibitor of TYK2 approved in multiple countries for adults with moderate to severe plaque psoriasis.[2,3] Deucravacitinib was efficacious vs placebo (PBO) in a phase 2 trial in patients with active PsA, and certain cytokine levels associated with pain signaling were reduced with deucravacitinib vs PBO, demonstrating the downstream effects of TYK2 inhibition on these

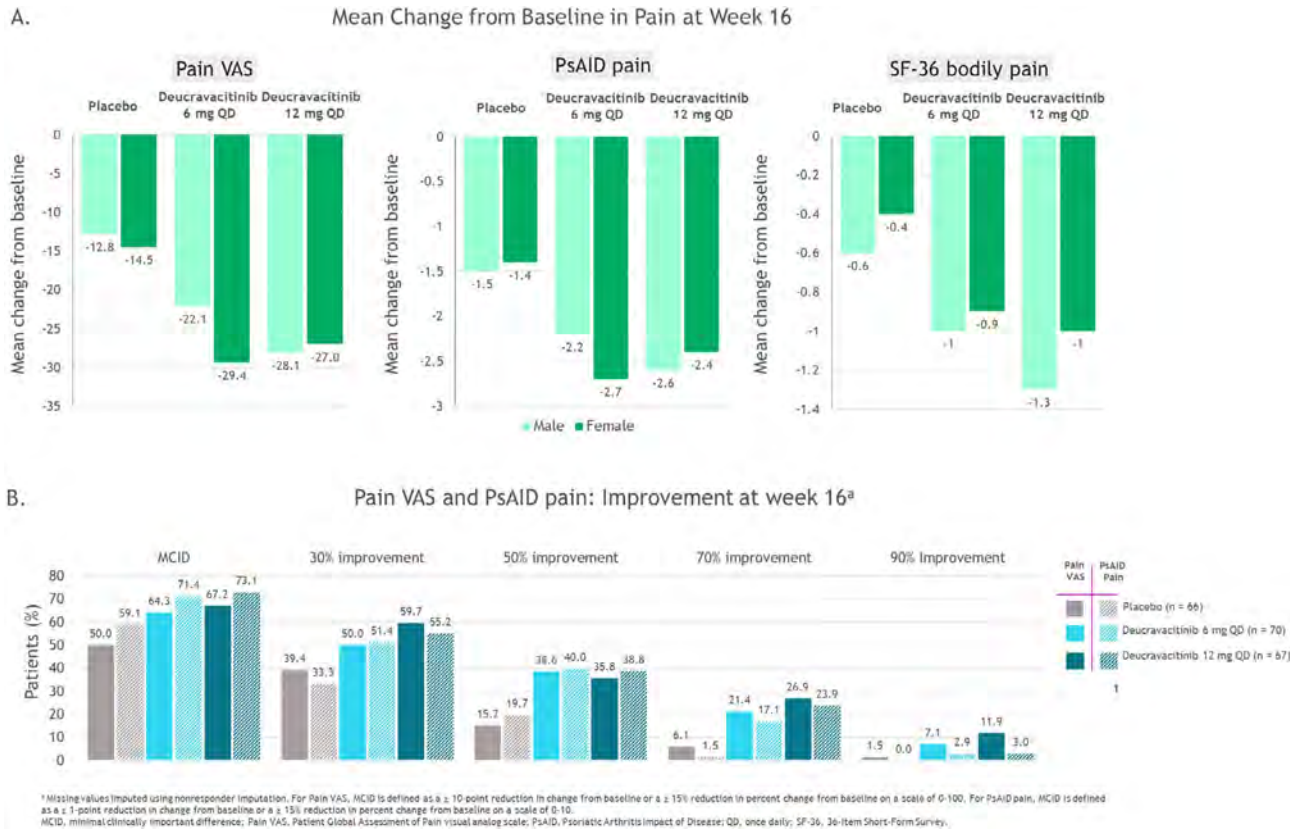

Figure 1. Mean change in pain from baseline (A) and percentage of patients who reported improvements in Pain VAS and PsAID at week 16 (B)

pathways.[4,5] Here, we characterize the effect of deucravacitinib on pain across different instruments by sex, and alignment across those pain instruments, in patients in the phase 2 PsA trial (NCT03881059).

Methods: Patients with PsA (N=203) were randomized 1:1:1 to PBO, deucravacitinib 6 mg once daily (QD), or deucravacitinib 12 mg QD. Three instruments assessed pain up to week 16: (1) Patient Global Assessment of Pain visual analog scale (Pain VAS), scored from 0-100; (2) Psoriatic Arthritis Impact of Disease (PsAID) pain instrument, scored from 0-10; and (3) 36-Item Short Form Survey (SF-36) Bodily Pain questionnaire, in which patients rated their pain on a 6-item scale from "none" to "very severe." Mean change from baseline (BL) in pain scale scores by sex, the proportion of patients who reported meaningful improvements in pain, and correlation among pain scales and disease efficacy measures were evaluated.

Results: Mean Pain VAS score was 64.1, and mean PsAID pain score was 6.4 at BL; scores were similar across groups. At BL, pain assessments strongly correlated with the Psoriatic Arthritis Disease Activity Score (PASDAS) and Patient Global Assessment of Disease Activity **(Table)**. Mean improvements in pain for all 3 measures and percentages of patients reporting improvements in Pain VAS and PsAID pain scores were greater with deucravacitinib compared with PBO **(Figure 1)**.

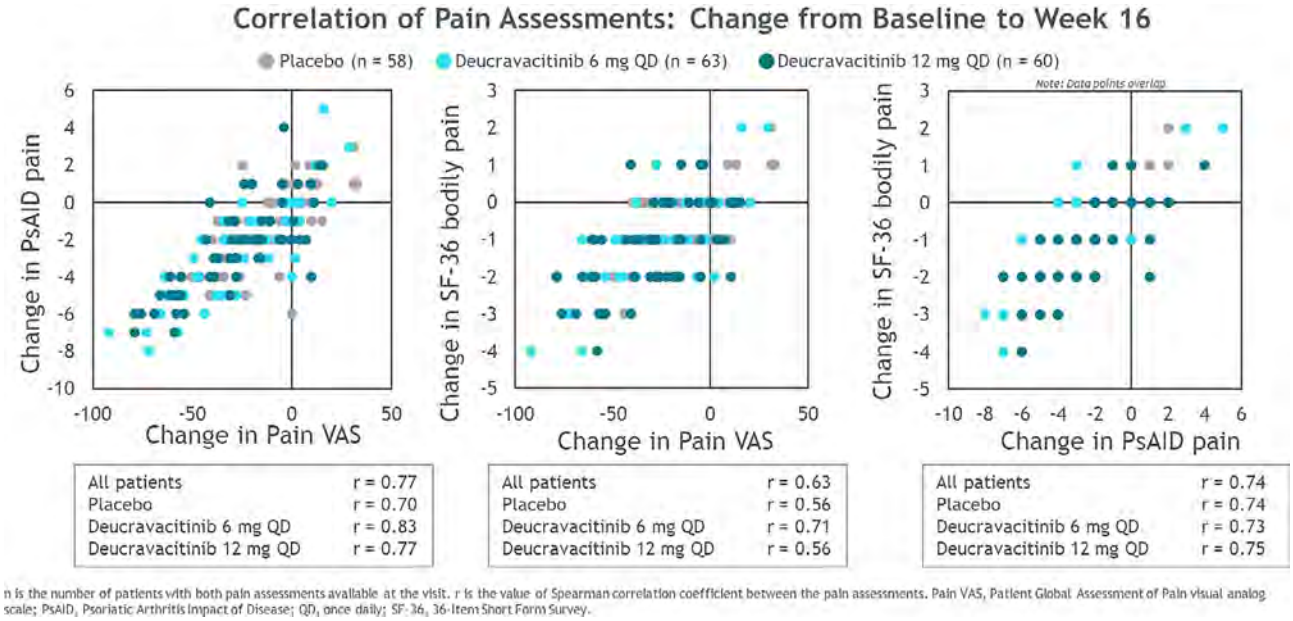

Figure 2. Correlation of pain assessments: Change from baseline to week 16

Table. Correlations between pain assessments at baseline and other baseline disease activity measures

	Pain measurements			Disease activity measurements

Strength of association:
None: 0.0–0.1
Weak: 0.1–0.3
Medium: 0.3–0.5
Strong: 0.5–1.0

Spearman rank correlation coefficient was used unless otherwise noted. [a]Only in patients with a score of > 0 at baseline. [b]Pearson rank correlation coefficient. CRP, C-reactive protein; DAPSA, Disease Activity in Psoriatic Arthritis; DAS28, Disease Activity Score - 28 joint; HAQ-DI, Health Assessment Questionnaire - Disability Index; LEI, Leed's Enthesitis Index; Pain VAS, Patient Global Assessment of Pain visual analog scale; PASDAS, Psoriatic Arthritis Disease Activity Score; PGA, Physician Global Assessment; PsAID, Psoriatic Arthritis Impact of Disease; PtGA, Patient Global Assessment of Disease Activity; SF-36, 36-Item Short Form Survey; SJC, swollen joint count; SPARCC, Spondyloarthritis Research Consortium of Canada; TJC, tender joint count.

Similar improvements in pain were observed in both male and female patients. Pain assessments correlated with one another both at BL **(Table)** and over time through week 16, with some divergent responses to pain questions also observed **(Figure 2)**.

Conclusion: A higher proportion of patients with PsA treated with deucravacitinib reported clinically meaningful improvements in pain compared with PBO. Patient-reported pain assessments had moderate correlation with one another. No consistent differences were observed between male and female patients in reported mean improvements in pain.

Abstract Number: 0509

Assessment of Direct and Indirect Impact on Pain and Fatigue Outcomes in a Phase 2 Clinical Trial of Deucravacitinib, a Selective, Allosteric Tyrosine Kinase 2 Inhibitor, in Patients with Active PsA: A Mediation Analysis

Philip J. Mease[1], Lihi Eder[2], Alexis R Ogdie[3], Atul Deodhar[4], Subhashis Banerjee[5], Ying-Ming Jou[5], Miroslawa Nowak[5], Thomas Lehman[6] and Vibeke Strand[7], [1]Swedish Medical Center/Providence St. Joseph Health and University of Washington School of Medicine, Seattle, WA, [2]Women's College Research Institute, Division of Rheumatology, University of Toronto, Toronto, ON, Canada, [3]University of Pennsylvania, Philadelphia, PA, [4]Division of Arthritis and Rheumatic Disease, Oregon Health & Science University, Portland, OR, [5]Bristol Myers Squibb, Princeton, NJ, [6]Bristol Myers Squibb, Philadelphia, PA, [7]Stanford University, Palo Alto, CA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I: PsA

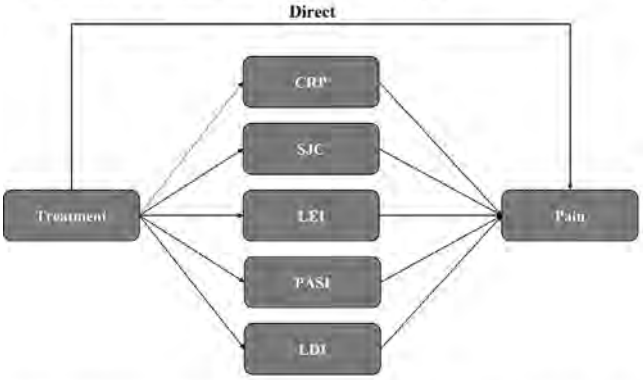
Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Tyrosine kinase 2 (TYK2) is an intracellular kinase involved in key cytokine pathways linked to PsA pathophysiology. Several of these pathways are intertwined with those that mediate pain signaling and fatigue, symptoms that patients with PsA commonly cite as negatively affecting quality of life and daily activities. Deucravacitinib is a first-in-class, oral, selective, allosteric TYK2 inhibitor approved in multiple countries for the treatment of adults with plaque psoriasis. In a phase 2 trial in patients with active PsA, deucravacitinib treatment resulted in a reduction in pain and fatigue as well as the levels of key cytokines, vs placebo (PBO)[1]; deucravacitinib has also demonstrated efficacy vs PBO in patients with SLE receiving standard background therapy. Previous studies have shown the effects of therapeutic interventions on pain may have both direct and indirect contributions. Here, we apply a mediation analysis of data from the phase 2 PsA trial (NCT03881059) to characterize and quantify the potential direct effects of deucravacitinib on pain and fatigue vs. observable indirect effects achieved through improvements in available clinical endpoints associated with inflammation or swelling.

Methods: All data included are from week 16 observations in the phase 2 trial of deucravacitinib (6 mg QD and 12 mg QD pooled) v. PBO in patients (N=203) with active PsA. Improvements in pain and 5 clinical endpoints associated with inflammation or swelling were included in the initial mediation model. These endpoints included C-reactive protein (CRP), swollen joint

Figure 1. Mediation model in the full analysis. Treatment is represented by a binary variable (deucravacitinib 6 mg QD and 12 mg QD pooled vs PBO). Pain was measured by the patient's assessment of arthritis pain



CRP, C-reactive protein; LDI, Leeds Dactylitis Index; LEI, Leeds Enthesitis Index; PASI, Psoriasis Area and Severity Index; QD, once daily; SJC, swollen joint count.

Figure 2. Direct and indirect effects of deucravacitinib treatment on pain and fatigue in patients with PsA in the refined model

PASI, Psoriasis Area and Severity Index; SJC, swollen joint count.

Table. Direct and indirect effects of treatment on pain and fatigue, and proportion of effect mediated by PASI and SJC

	Pain, %	Fatigue, %
Direct	50.8	48.5
Indirect		
Total	**49.2**	**51.5**
PASI	31.0 (P 0.0246)	34.3 (P 0.0534)
SJC	18.7 (P 0.0553)	16.9 (P 0.1355)

PASI, Psoriasis Area and Severity Index; SJC, swollen joint count.

count (SJC), Psoriasis Area and Severity Index (PASI), Leeds Enthesitis Index (LEI), and Leeds Dactylitis Index (LDI) (**-Figure 1**). The relative contribution of each parameter to the improvement in pain was derived and used to develop a refined model including only those parameters which reached or neared statistical significance. The same methodology was repeated for fatigue.

Results: In the initial model, the strongest indirect mediators of both pain and fatigue with deucravacitinib treatment were SJC and PASI (**Table**). The following parameters were not significantly associated with the mediation of pain or fatigue: CRP, LEI, LDI. In the refined model, the total observable indirect effects of deucravacitinib on pain and fatigue were calculated to be 49.2% and 51.5%, respectively, derived from improvements in SJC and PASI. The remaining, potentially direct, effect on pain and fatigue improvement is calculated to be 50.8% and 48.5% respectively. (**Figure 2**).

Conclusion: Improvements in pain and fatigue in patients with PsA treated with deucravacitinib may be attributable to both direct and indirect mechanisms. PASI- and SJC-mediated improvements in pain and fatigue contributed the most to the observed indirect effects. Further investigation into the potential direct effect of deucravacitinib on pain and fatigue are needed.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Bimekizumab (BKZ) is a monoclonal IgG1 antibody that selectively inhibits IL-17F in addition to IL-17A. In the phase 3 studies BE MOBILE 1 and 2, BKZ demonstrated sustained improvements to Week (Wk) 52 in patients (pts) with active non-radiographic (nr-) and radiographic axial spondyloarthritis (r-axSpA; i.e., AS).[1,2]

Here, we report the impact of BKZ in pts with axSpA on key pt-reported symptoms (spinal pain, stiffness, and fatigue).

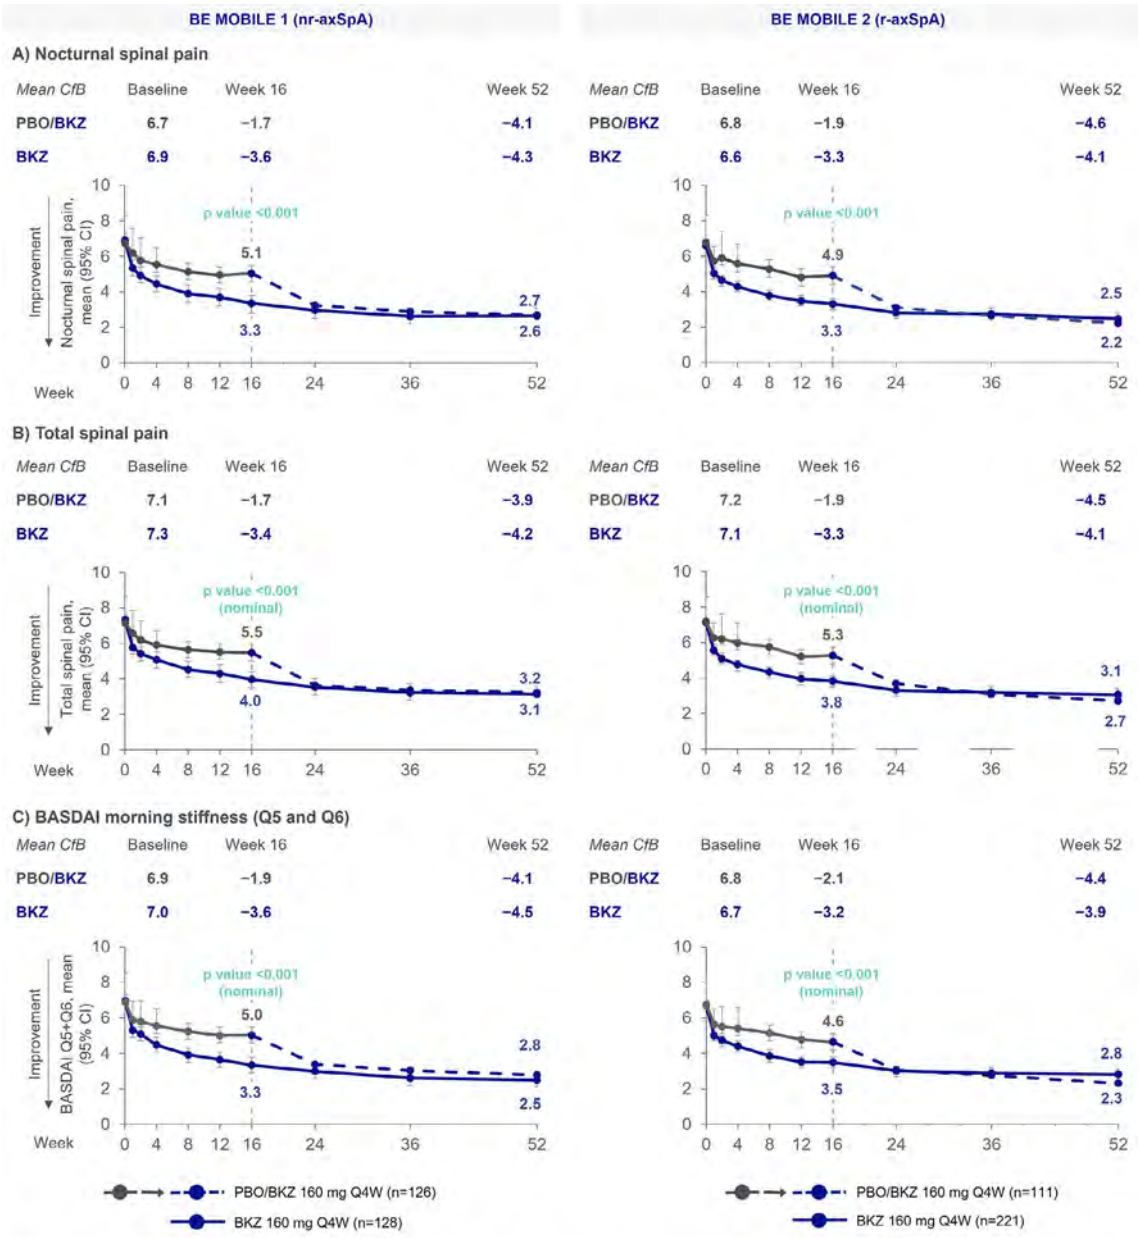
Methods: BE MOBILE 1 (NCT03928704) and 2 (NCT03928743) both comprised a 16-wk double-blind period followed by a 36-wk maintenance period. Pts were randomized to receive subcutaneous BKZ 160 mg every 4 wks (Q4W) or placebo (PBO); from Wk 16 all pts received BKZ 160 mg Q4W.

We report mean nocturnal and total spinal pain, and BASDAI morning stiffness (mean of BASDAI questions 5 and 6), as well as mean change from baseline (CfB) in Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue scores to Wk 52; missing values were imputed using multiple imputation. Least squares mean difference (LSMD) is reported for FACIT-F at Wk 16. Proportion of pts achieving low levels of pain (total and nocturnal spinal pain score: ≤2 and ≤4) and a meaningful improvement in fatigue (FACIT-F score: ≥8 point increase from baseline [BL]), analyzed post hoc, are also reported; missing values were imputed using non-responder imputation.

Results: 254 pts with nr-axSpA (BKZ: 128; PBO: 126) and 332 with r-axSpA (BKZ: 221; PBO: 111) were randomized; 86.6% (220/254) and 89.8% (298/332) pts completed to Wk 52, respectively. Across both studies, mean BL scores for all reported outcomes indicated high disease burden (**Figure 1**).

At Wk 16, BKZ-randomized pts achieved greater improvements in mean nocturnal and total spinal pain (nominal), and BASDAI morning stiffness (nominal) vs PBO (all $p < 0.001$; **Figure 1**). Mean scores were further improved to Wk 52 among BKZ-randomized pts and among pts who switched from PBO to BKZ at Wk 16 (PBO/BKZ), responses approached those of BKZ-randomized pts. Similarly, at Wk 16 a higher proportion of BKZ- vs PBO-randomized pts achieved low nocturnal and total spinal scores (**Figure 2**); at Wk 52 these improvements were similar across BKZ-randomized and PBO/BKZ pts.

At Wk 16, BKZ-randomized pts achieved greater improvements in FACIT-F scores vs PBO (mean CfB [nominal p value]: nr-axSpA: 8.5 vs 3.9 [< 0.001]; r-axSpA: 8.4 vs 5.0 [0.015]; LSMD: nr-axSpA: 4.2; r-axSpA: 2.2) with similar improvements at Wk 52 among BKZ-randomized and PBO/BKZ pts (mean CfB: nr-axSpA: 10.9 vs 9.2; r-axSpA: 9.9 vs 9.5). Similarly, a higher proportion of BKZ-randomized pts achieved a ≥8 point improvement from BL compared with PBO at Wk 16 (**Figure 3**);responses at Wk 52 were similar across PBO/BKZ and BKZ-randomized pts.



Randomized set. Multiple imputation. P values calculated at Week 16 for nocturnal spinal pain were part of a hierarchical gatekeeping strategy and used reference-based multiple imputation. P values without any multiplicity adjustment are indicated as nominal p values and should not be used as an indication of statistical significance. Error bars represent 95% CI. Spinal pain scores range from 0–10 with lower scores reflecting better health status. BASDAI morning stiffness score assessed as mean of BASDAI questions 5 and 6; scores range from 0–10 with lower scores reflecting better health status. BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; BKZ: bimekizumab; CfB: change from baseline; CI: confidence interval; nr-axSpA: non-radiographic axial spondylarthritis; PBO: placebo; Q4W: every 4 weeks; r-axSpA: radiographic axial spondylarthritis.

Figure 1. Improvement in mean (A) nocturnal spinal pain, (B) total spinal pain scores, and (C) BASDAI morning stiffness (questions 5 and 6) to Week 52 (MI)

Conclusion: BKZ treatment resulted in clinically meaningful improvements in spinal pain, morning stiffness, and fatigue to Wk 52 in pts across the full disease spectrum of axSpA, who had a similar and high disease burden at BL. These findings emphasize the benefit of BKZ on clinical symptoms which are important to pts and have a substantial impact on their daily lives.[3]

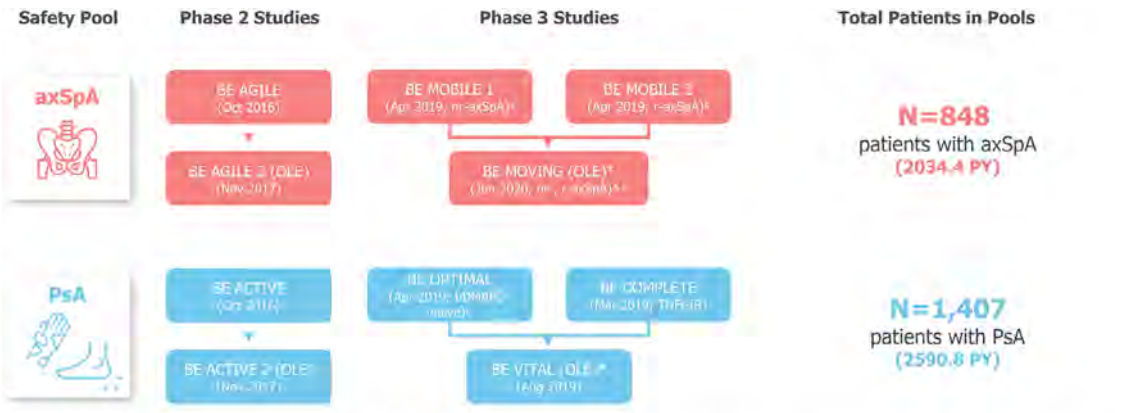
Session Date: Sunday, November 12, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Bimekizumab (BKZ) is a monoclonal IgG1 antibody that selectively inhibits IL-17F in addition to IL-17A. A previous analysis of pooled safety data from the placebo-controlled period of four phase 3 trials was conducted in patients (pts) with axial spondyloarthritis (axSpA) and psoriatic arthritis (PsA) to Week (Wk) 16.[1] Here, we present long-term pooled safety data for BKZ in axSpA and PsA pt populations, across phase 2b/3 trials and all study periods.



Actual study start dates provided. *Study ongoing. [a] Patients with nr-axSpA met ASAS classification criteria. Patients with radiographic sacroiliitis were excluded; [b] Patients with r-axSpA met modified New York criteria and fulfilled ASAS classification criteria, therefore the terms raxSpA and AS may be used interchangeably;[7] [c] BE OPTIMAL also included an adalimumab treatment arm. Patients randomized to this arm are not included in the PsA safety pool. The PsA (and axSpA) safety pool only includes patients who received ≥1 dose of BKZ 160 mg Q4W.

BE AGILE: NCT02963506; BE AGILE 2: NCT03355573; BE MOBILE 1: NCT03928704; BE MOBILE 2: NCT03928743; BE MOVING: NCT04436640; BE ACTIVE: NCT02969525; BE ACTIVE 2: NCT03347110; BE OPTIMAL: NCT03895203; BE COMPLETE: NCT03896581; BE VITAL: NCT04009499.

Abbreviations: AS: ankylosing spondylitis; ASAS: Assessment of SpondyloArthritis international Society; axSpA: axial spondyloarthritis; bDMARD: biologic DMARD; BKZ: bimekizumab; nr-axSpA: non-radiographic axSpA; PsA: psoriatic arthritis; pt: patient; PY: patient-year; Q4W: every 4 weeks; r-axSpA: radiographic axSpA; SARS-CoV-2: severe acute respiratory syndrome coronavirus 2; TEAE: treatment-emergent adverse event; TNFi-IR: tumour necrosis factor inhibitor inadequate response; Wk: week.

Figure. Two safety pools (axSpA, PsA) of patients treated with BKZ 160 mg Q4W from phase 2b/3 studies

Table. Summary of TEAEs

	axSpA	PsA
TEAEs[a] n (%) [EAIR/100 PY]	BKZ 160 mg Q4W (N=848; exposure 2034.4 PY)	BKZ 160 mg Q4W (N=1,407; exposure 2590.8)
Any TEAE	752 (88.7) [136.9]	1,170 (83.2) [139.6]
Severe TEAEs	66 (7.8) [3.4]	90 (6.4) [3.6]
Study discontinuations due to TEAEs	54 (6.4) [2.7]	79 (5.6) [3.1]
Drug-related TEAEs[b]	393 (46.3) [28.9]	504 (35.8) [26.7]
Serious TEAEs	97 (11.4) [5.1]	148 (10.5) [6.1]
Deaths	3 (0.4) [0.1]	3 (0.2) [0.1]
Most common TEAEs[c]		
Nasopharyngitis	146 (17.2) [8.2]	180 (12.8) [7.7]
SARS-CoV-2 infection	133 (15.7) [6.8]	201 (14.3) [8.2]
Upper respiratory tract infection	94 (11.1) [5.0]	136 (9.7) [5.6]
Oral candidiasis	70 (8.3) [3.7]	103 (7.3) [4.2]
Headache	56 (6.6) [2.9]	72 (5.1) [2.9]
Diarrhea	48 (5.7) [2.4]	75 (5.3) [3.0]
Safety topics of interest

Without prior history	11 (1.5) [0.6][n]	0

Data to the most recent data-cut (July 2022) shown; includes all patients who received ≥1 dose of BKZ 160 mg Q4W. [a] Defined according to MedDRA v19.0. [b] Per investigator assessment; [c] TEAEs occurring in ≥5% of patients in both the axSpA and PsA patient pools, respectively; [d] Defined by omission, non -systemic infections were reported; [e] One serious fungal infection was reported – a 59-year-old female patient with oropharyngeal candidiasis was hospitalized to achieve candidiasis control 10 months and 18 days after initiation of BKZ. BKZ was temporarily discontinued. The infection resolved with antifungal treatment, including fluconazole and clotrimazole. BKZ was restarted approximately one month later; [f] Includes events described as drug -related hepatic disorders, excluding liver neoplasms; [g] n=847; [h] n=1405; [i] Three patients with axSpA experienced cardiac disorders (AMI, ventricular arrythmias, and cardiac arrest); [j] Three patients with PsA experienced an ischemic stroke, while two patients experienced an AMI; [k] Neutropenia includes additional preferred terms identified based on UCB-defined search criteria; [l] Includes the preferred terms uveitis, iridocyclitis and iritis; [m] n=130; [n] n=718. ALT: alanine transaminase; AMI: acute myocardial infarction; AST: aspartate aminotransferase; axSpA: axial spondyloarthritis; BKZ: bimekizumab; EAIR: exposure-adjusted incidence rate; MACE: major adverse cardiovascular event; NEC: not elsewhere classifiable; PsA: psoriatic arthritis; PY: patient-years; Q4W: every four weeks; SARS-CoV-2: severe acute respiratory syndrome coronavirus 2; SIB: suicidal ideation or behavior; TEAE: treatment-emergent adverse event; ULN: upper limit of normal.

Methods: We report two pooled analyses, each comprising three phase 2b/3 trials, and their open-label extensions, in pts with active axSpA (non-radiographic [nr]-axSpA and radiographic [r]-axSpA, i.e., ankylosing spondylitis)[2] and active PsA, respectively (**Figure**).[1,3–5]

The number, proportion, and exposure-adjusted incidence rates (EAIRs) per 100 pt-years (PY) of treatment-emergent adverse events (TEAEs) are reported for all pts who received ≥1 dose of BKZ 160 mg every four weeks (Q4W). Data are reported to the most recent data-cut (July 2022) across all treatment periods.

Results: The axSpA and PsA safety pools included 848 pts (2034.4 PY) and 1,407 pts (2590.8 PY), respectively. The most frequently reported TEAEs in pts with axSpA and PsA were nasopharyngitis, SARS-CoV-2 infection, and upper respiratory tract infection (**Table**). See **Table** for safety topics of interest.

Fungal infections were reported in 375 pts (axSpA: 161 [19.0%]; PsA: 214 [15.2%]), leading to discontinuation in 19 pts (7 axSpA [0.8%], 12 PsA [0.9%]); no fungal infections were systemic in nature. Most fungal infections were oral, and the vast majority of oral fungal infections were mild to moderate in severity (axSpA: 162 [99.4%]; PsA: 231 [99.6%]). Two pts experienced severe oral fungal infections (axSpA: 1 [0.1%]; PsA: 1 [0.1%]), which resolved in both cases with treatment. *Candida* fungal infections were seen in a similar proportion of pts with axSpA and PsA (**Table**).

Serious infections and infestations occurred in 59 pts (axSpA: 29 [3.4%]; PsA: 30 [2.1%], **Table**). One serious fungal infection (oropharyngeal candidiasis) was reported in a pt with PsA (1 [< 0.1%]), which resolved with treatment (further details provided in **Table**).

Adjudicated IBD (definite or probable) occurred in 16 pts with axSpA (EAIR/100 PY: 0.8) and 7 pts with PsA (EAIR/100 PY: 0.3). Uveitis occurred in 25 pts with axSpA (EAIR/100 PY: 1.2), while no uveitis cases were reported in pts with PsA (**Table**).

Fourteen pts experienced an adjudicated major adverse cardiovascular event (axSpA: 4 [EAIR/100 PY: 0.2]; PsA: 10 [EAIR/100 PY: 0.4]). Five pts experienced events adjudicated as suicidal ideation/behavior (axSpA: 3 [EAIR/100 PY: 0.1]; PsA: 2 [EAIR/100 PY: 0.1]), while no cases of active tuberculosis were reported (**Table**).

Conclusion: The long-term safety profile of BKZ in pts with axSpA and PsA is consistent with prior studies.[1] As expected, due to inhibition of IL-17, oral candidiasis featured among the safety signals reported.

Factors Associated with Treatment Pathways in Early Axial Spondyloarthritis: A Multistate Analysis of the 10-year Follow-up of the DESIR Cohort

Elodie Portier[1], Sylvie chevret[2], Adeline Ruyssen-Witrand[3], Anouk Walter-Petrich[2], Maxime Dougados[4] and Anna Molto[5], [1]Hôpital Cochin, Paris, France, [2]Saint Louis Hospital, Paris, France, [3]Toulouse University Hospital, Toulouse, France, [4]Rheumatology Department, Cochin Hospital; INSERM (U1153): Clinical Epidemiology and Biostatistics, University of Paris, Paris, France, [5]HOPITAL COCHIN AP-HP, Service de Rhumatologie, Paris, France

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Current recommendations for the management of patients with axial spondyloarthritis (axSpA) emphasize the need of individualized strategy in the therapeutic decision. Thus, many factors seem to impact this strategy.

The objectives of the study were to describe the therapeutic strategies observed in axSpA, and to assess the factors associated with treatment changes over time.

Methods: This study included patients with axSpA from the French prospective cohort DESIR, with a scheduled 10-year follow-up. A multi-state model with 4 ordered treatment states ("none", "non-steroidal anti-inflammatory drugs (NSAID)", "conventional synthetic DMARD (csDMARD)", "TNF inhibitors (TNFi)") was defined, with 6 possible transitions. Estimation of the restricted mean sojourn times spent in each state from the state occupation probabilities was performed. Then, predictors of those transitions were assessed by multivariable Cox models.

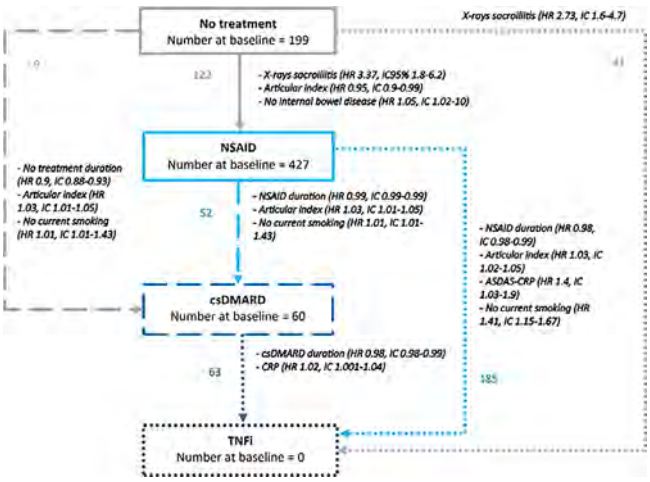

Figure: Multistate model representation. Each arrow corresponds to a possible transition (n=6). Number at baseline denotes the number of patients who started from the state at baseline. The number of events and factors significantly associated with each transition in the multivariable analysis are written near to the corresponding arrow. NSAID refers to non-steroids anti-inflammatory drugs, csDMARD stands for conventional synthetic Disease Modifying Anti-Rheumatic Drug, and TNFi for tumor necrosis factor inhibitors.

Results: 686 (96.9%) of the 708 patients who had more than one visit were analyzed. At cohort entry, 199 (29.0%) were untreated, 427 (62.2%) received NSAID, and 60 (8.7%) received csDMARD and none TNFi.

Over the 10 years of follow-up, patients mostly received NSAID (46.4% of the time) followed by TNFi (24.4% of the time). In multivariable analysis (**figure**), presence of sacroiliitis on radiography, internal bowel disease and articular index were associated with transition to NSAID. Duration in the previous state was often a significant protective factor associated with transition to csDMARD or TNFi. Finally, the several disease activity outcomes were associated with most transitions.

Conclusion: This was the first study using a multistate model to easily represent the different states, detailing the transitions across them, and their associated factors. Different time profiles of axSpA patient management were identified, including abstention up to a significant proportion of patients treated with csDMARD.

Impact of Pregnancy on Sacroiliac Imaging in Women with Axial Spondyloarthritis: Results of the Analysis of the DESIR Cohort

Elodie Portier[1], Maxime Dougados[2], Adeline Ruyssen-Witrand[3] and Anna Molto[4], [1]Hôpital Cochin, Paris, France, [2]Rheumatology Department, Cochin Hospital; INSERM (U1153): Clinical Epidemiology and Biostatistics, University of Paris, Paris, France, [3]Toulouse University Hospital, Toulouse, France, [4]HOPITAL COCHIN AP-HP, Service de Rhumatologie, Paris, France

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Axial spondyloarthritis (axSpA) is typically characterized by imaging (radiographs or MRI) abnormalities of the sacroiliac joints (SIJ). Also, inflammatory lesions of the SIJ have been observed in healthy women post-partum. However, the impact of pregnancy on imaging abnormalities in women with axSpA is unknown.

The objective of this study was to evaluate impact of pregnancy on SIJ imaging in patients with early axSpA.

Methods: Women with axSpA from the French prospective cohort DESIR were included, with a follow-up of 5 years. Description of demographic and disease criteria, and SIJ imaging abnormalities at baseline was performed in all women, then according to antecedent of pregnancy. Secondly, changes on imaging over time were analyzed in the 38 women who were nulligravidae at baseline and became pregnant during follow up, using paired-test and then mixed models.

Results: 381 patients were included in the analysis. At baseline, women nulligravidae (142, 37%) were younger and had higher education level than other women with axSpA. Presence of sacroiliitis on MRI and X-ray were more frequent in women nulligravidae (16.9% vs 9.9%, p = 0.046 and 33.8% vs 19.4%, p = 0.0016, respectively) **(table 1).**

Table 1: Imaging characteristics of women with axSpA according to antecedent of pregnancy at baseline, and statistical analysis with Student test or Chi-square (for continuous and binary variables, respectively).

Imaging criteria *Mean (sd) or number (%)*	Nulliparous (N = 142)	Non-nulliparous (N = 232)	P-value*
X-ray criteria			
X-ray sacroiliitis	24 (16.9%)	23 (9.9%)	**p = 0.046**
New York score on right sacroiliac joint	0.72 (1.1)	0.61 (0.95)	NS
New York score on left sacroiliac joint	0.59 (1.02)	0.56 (0.96)	NS
Any erosion in the sacroiliac joints	28 (19.7%)	27 (11.6%)	**p = 0.031**
Any joint widening in the sacroiliac joints	0	2 (0.9%)	NS
Any sclerosis in the sacroiliac joints	27 (19%)	29 (12.5%)	NS
Any partial or total ankylosis in the sacroiliac joints	3 (2.1%)	3 (1.3%)	NS
MRI criteria			
Sacroiliitis on MRI	48 (33.8%)	45 (19.4%)	**p = 0.0016**
SPARCC score	3.6 (6.74)	2.42 (5.12)	NS
≥ 3 fatty lesions on MRI	12 (8.45%)	7 (3.02%)	**p = 0.013**
≥ 3 erosions on MRI	4 (2.82%)	4 (1.72%)	NS
≥ 5 fatty lesions and/or erosions on MRI	11 (7.75%)	5 (2.16%)	**p = 0.0086**
Number of any lesions on sacroiliac joint (0 to 144)	1.65 (3.51)	1.95 (4.55)	NS
Number of enthesitis (0 to 12)	0 (0)	0 (0)	NA
Number of erosions (0 to 40)	0.8 (1.53)	0.71 (1.57)	NS
Number of fatty lesions (0 to 40)	0.96 (9.52)	0.51 (1.74)	NS
Number of sclerosis (0 to 40)	0.125 (0.59)	0.38 (1.26)	**p = 0.03**
Number of partial or total ankylosis (0 to 24)	0.07 (0.64)	0.06 (0.53)	NS

Table 2: Imaging characteristics in women with axSpA who had first pregnancy during follow up, with description before/after delivery and paired-test with Mc Nemar of Student test (for binary and continuous variables, respectively).

Imaging criteria *Mean (sd) or number (%)*	Before pregnancy (N = 38)	After delivery (N = 38)	P-value
Radiographic criteria			
X-ray sacroiliitis	8 (21.1%)	9 (23.7 %)	p = 0.37
New York score on right sacroiliac joint	0.66 (1.06)	0.67 (0.86)	p = 1
New York score on left sacroiliac joint	0.67 (1.07)	0.95 (0.95)	**p = 0.037**
Any erosion in the sacroiliac joints	9 (23.7%)	9 (23.7%)	p = 0.48
Any joint widening in the sacroiliac joints	0	3 (7.9%)	NA
Any sclerosis in the sacroiliac joints	6 (15.8%)	9 (23.7%)	p = 0.13
Any partial or total ankylosis in the sacroiliac joints	1 (2.6%)	2 (5.3%)	p = 0.48
MRI criteria			
Sacroiliitis on MRI	18 (47.3%)	2 (5.2%)	p = 0.074
SPARCC score	3.94 (7.63)	0.39 (0.74)	p = 0.15
≥ 3 fatty lesions on MRI	4 (10.5%)	1 (2.6%)	p = 1
≥ 3 erosions on MRI	1 (2.6%)	0	NA
≥ 5 fatty lesions and/or erosions on MRI	1 (2.6%)	1 (2.6%)	p = 1
Number of any lesions on sacroiliac joint (0 to 144)	1.81 (3.36)	1.8 (2.92)	p = 0.1
Number of enthesitis (0 to 12)	0 (0)	0 (0)	NA
Number of erosions (0 to 40)	0.84 (2.36)	0.42 (0.7)	p = 1
Number of fatty lesions (0 to 40)	0.97 (2.01)	1 (2.02)	p = 0.15
Number of sclerosis (0 to 40)	0 (0)	0.26 (0.86)	p = 0.29
Number of partial or total ankylosis (0 to 24)	0 (0)	0 (0)	NA

When focusing on incident pregnancies, these patients had more sacroiliitis on X-ray and MRI at baseline than patients nulligravidae at the end of follow-up and patients with past pregnancy, but had lower BASFI and ASDAS-CRP. Only left SIJ was statistically different after delivery, with mean scores of 0.67 and 0.95 before and after delivery (**table 2**). No impact of pregnancy on continuous imaging score was found with the different mixed models.

Conclusion: Pregnancy does not seem to aggravate imaging of axSpA women when comparing imaging according to the antecedent of pregnancy. Following axSpA patients who had first pregnancy showed mild increase of left sacroiliitis score on X-ray after delivery, but not enough to be considered as "worsening".

Difficult-to-treat Axial Spondyloarthritis Is Associated with Psoriasis and Comorbidities: Results from a Nationwide Study

Olivier FAKIH[1], Maxime Desmarets[2], Bérenger Martin[2], Clément Prati[1], Elisabeth Monnet[2], Daniel Wendling[3] and frank Verhoeven[1], [1]Service de rhumatologie, CHU de Besançon, Besançon, France, [2]INSERM CIC-1431, Besançon, France, [3]Besançon University Hospital, Besançon, France

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: An increasing number of targeted therapies are available for the treatment of SpA. However, some patients retain active disease despite several lines of treatment. This has led to the emergence of the concept of difficult-to-treat axial SpA (D2T-axSpA), inspired by similar reasoning in rheumatoid arthritis (D2T-RA). This study aimed to determine the cumulative incidence and identify the factors associated with D2T-axSpA.

Methods: This study used the French National Medico-Administrative Database Système National des Données de Santé (SNDS), which includes administrative data, long-term illnesses (LTIs), outpatient care, medication consumption, and hospitalizations for 97% of the French population. All patients newly benefiting from the LTI #27 "severe spondyloarthritis" with associated diagnostic code M45 (AS), between 2010 and 2013, were included. The use of LTI allowed us to build a cohort of patients with supposedly active disease, the SNDS having no data on disease activity. All patients with active SpA despite NSAID treatment and therefore requiring DMARDs were theoretically newly enrolled in the LTI scheme. The end date of follow-up was December 31, 2018.

Similar to the EULAR definition of D2T-RA, D2T-axSpA was defined as the failure of three biologic/targeted synthetic DMARDs (b/tsDMARDs) or two b/tsDMARDs with different modes of action. Comorbidities and extra-musculoskeletal manifestations (EMM) were identified using previously described algorithms.

A comparison of characteristics between the D2T-axSpA and non-D2T-axSpA groups was performed using t-tests for quantitative variables, and Chi-2 for qualitative variables. Multivariate analysis adjusted for age and b/tsDMARD exposure duration was performed using logistic regression analysis.

Results: 23062 patients were included. 10928 (47.39%) patients received at least one b/tsDMARD during the study period. Uveitis was observed in 82 (0.36 %) patients. This can be explained by the algorithm used, which detects only hospitalized patients. There was also a lack of sensitivity for the detection of smoking and obesity. The rates of other comorbidities and EMM were similar to those reported in previous studies.

During follow-up, 2176 were classified as D2T-axSpA, representing 9.44% of all patients and 19.91% of patients who received at least one b/tsDMARD. To limit selection bias, comparisons were restricted to D2T-axSpA and non-D2T-axSpA patients who had received at least one b/tsDMARD. In the univariate analysis, peripheral involvement and psoriasis were significantly more frequent in the D2T-axSpA group (Table 1). There was a significant increase in smoking, obesity, hypertension, and depression in the D2T-axSpA group. These results were confirmed by the multivariate analysis, with the highest

Table 1: Comparison of sociodemographic characteristics, extra-musculoskeletal manifestations, and comorbidities between D2T-axSpA and non-D2T-axSpA patients who received at least one b/tsDMARD.

Characteristic	D2T-axSpA (n=2176)	Non-D2T-axSpA (n=8752)	p

Dose Adjustment of Tumor Necrosis Factor Inhibitors Does Not Correlated with Radiographic Progression in Patients with Ankylosing Spondylitis

Bon San Koo[1], Seo Young Park[2], Ji Hui Shin[3], Seunghun lee[3], kyung bin Joo[3] and Tae-Hwan Kim[4], [1]Inje University Seoul Paik Hospital, Seoul, South Korea, [2]Korea National Open University, Seoul, South Korea, [3]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [4]Department of Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Among patients with ankylosing spondylitis (AS) treated with tumor necrosis factor (TNF) inhibitors, tapering the dose of TNF inhibitors may be considered for patients with low disease activity. While several studies have examined the relationship between tapering of TNF inhibitors and disease activity, few have investigated the relationship between tapering TNF inhibitors and radiographic progression. This study aimed to analyze the correlation between the total dose of TNF inhibitors and radiographic progression over a defined period of time, using a defined daily dose (DDD).

Methods: This retrospective study evaluated the electronic medical records of patients with AS between January 2001 and December 2018. The study included AS cohort patients from a single center who had modified Stoker Ankylosing Spondylitis Spinal Score (mSASSS) records for more than 2 years after starting TNF inhibitors. The patients were divided

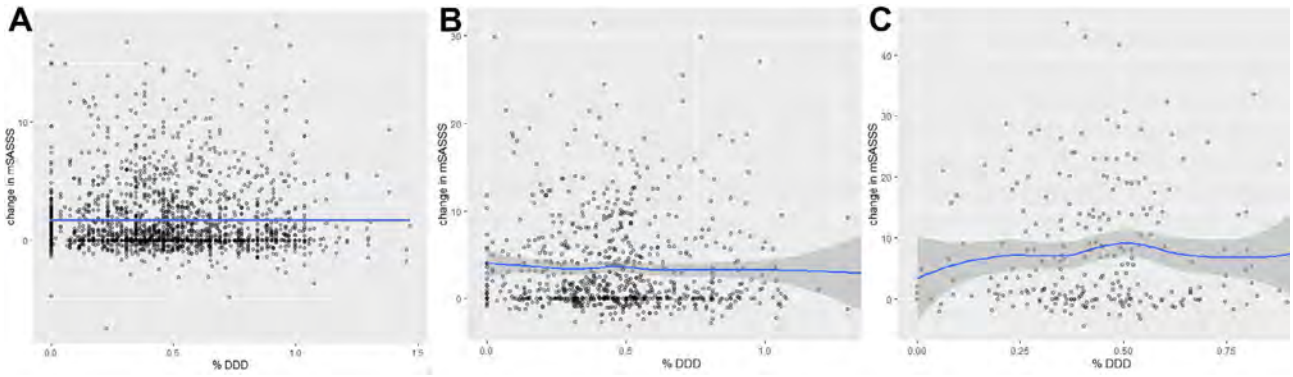

Figure 1. Scatterplot of defined daily dose (%DDD of TNF inhibitors) and change in modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS) at each interval (A: 2-year interval, B: 4-year interval, C: 8-year interval)

into follow-up periods of 2 years, 4 years, and 8 years, and the %DDD of TNF inhibitors during each period was calculated. The correlation between the percentage of DDD and changes in mSASSS was analyzed using a linear mixed model at 2-year, 3-year, and 8-year intervals. Subgroup analysis was also performed by dividing the baseline mSASSS into three groups (mSASSS ≤24, mSASSS >24 and ≤48, mSASSS > 48).

Results: A total of 559 patients were included in the study. The Pearson correlation coefficients of %DDD and changes in mSASSS were -0209 for the 2-year interval, -0.0301 for the 4-year interval, and 0.0315 for the 8-year interval (Figure 1). In linear mixed models, %DDD and the changes of mSASSS at 2 years (β=-0.134, 95% CI -0.629 – 0.362), 4 years (β =-0.733, 95% CI -2.258 – 0.792), and 5 years (β=1.235, 95% CI -5.230 – 7.701) were not statistically significant in any interval (p = 0.597, p = 0.345, p = 0.707, respectively).In the subgroup analysis divided by baseline mSASSS, the correlation between %DDD and the changes of mSASSS was not statistically significant.

Conclusion: There was no correlation between the doses of TNF inhibitors and the changes of mSASSS. Although this study was a retrospective, our findings suggest that dose adjustment of TNF inhibitors may not be correlated with radiographic progression in patients with AS.

Drivers of Treatment Intensification in Patients with Axial Spondyloarthritis and High Disease Activity: Results from a Clinical Practice Registry

Casper Webers[1], Rabab Nezam El-Din[1], Marin Been[1], Harald Vonkeman[2] and Astrid van Tubergen[1], [1]Department of Internal Medicine, Division of Rheumatology, Maastricht University Medical Centre, Maastricht, Netherlands, [2]Department of Rheumatology, Medisch Spectrum Twente and University of Twente, Enschede, Netherlands

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: In the management of axial spondyloarthritis (axSpA), treatment intensification (TI) is recommended in patients with high disease activity (HDA). However, in practice, in most patients who are in an HDA state, treatment is not changed. Possibly, other factors than disease activity, such as disease impact and acceptability of current health state, drive the decision for TI. Our objective was to explore which patient- and disease-related determinants are associated with TI in axSpA patients with HDA.

Methods: In this cross-sectional observational study, one time point per patient was used from SpA-Net, a multicentre registry for SpA. Only patients in an HDA state (defined as Ankylosing Spondylitis Disease Activity Score [ASDAS]≥2.1) were included. The outcome (TI) was defined as 1) a higher dose or shorter interval of the same drug, 2) a switch of the current drug to another drug or 3) addition of a new drug to the current treatment regime; and only due to inefficacy of the current treatment. Only anti-inflammatory drugs (NSAIDs, conventional synthetic/biologic/targeted synthetic DMARDs [cs/b/tsDMARDs], corticosteroids) were considered. Primary determinants were ASDAS, Assessment of SpondyloArthritis international Society Health Index (ASAS HI) and physician global (PhGA). Education, peripheral symptoms and skin

Table. Logistic regression analyses of treatment intensification in patients with axSpA and ASDAS≥2.1

	Univariable (n=119)			Multivariable physician-centered* (n=111)			Multivariable patient-centered (n=111)

Sex, female	1.02	0.48-2.20	0.95	0.84	0.31-2.25	0.72	0.93	0.37-2.32	0.88
ASDAS	1.76	0.96-3.26	0.07	1.65	0.78-3.47	0.19	1.81	0.90-3.62	0.10
PhGA (0-10)	1.92	1.43-2.57	<0.01	1.74	1.24-2.46	<0.01	N/A		
ASAS HI (0-17)	1.05	0.94-1.17	0.36	†§			†§		
Education, high	1.27	0.59-2.77	0.54	†			†		
Peripheral symptoms	4.87	2.03-11.68	<0.01	2.76	0.99-7.70	0.05	5.11	2.00-13.05	<0.01
BSA ≥3%	2.03	0.12-33.44	0.62	†			†		

*PhGA and PASS according to physician were only considered for the physician-centered model, in separate models. Only the PhGA-model is shown here. †Variable with p>0.20 in univariable regression, not included in multivariable model. §Not associated with TI if forced in multivariable model (physician-centered model: OR 0.97 [0.85-1.10], p=0.64; patient-centered model: OR 1.02 [0.90-1.14], p=0.79). BSA, Body Surface Area; N/A, not applicable; PhGA, physician global.

involvement were also considered as determinants. Acceptable symptom state according to patient (PASS-patient) or physician (PASS-physician) were included in sensitivity analyses. The association between determinants and TI was investigated with multivariable logistic regression. Both physician-centered and patient-centered models were generated.

Results: In total, 119 patients in an HDA state were included. Mean age was 50.4 (SD 13.5) years, symptom duration 20.1 (13.2) years and 65 patients (54.6%) were female. The majority were currently in an acceptable state (PASS-patient 57.1%, PASS-physician 66.7%). TI was conducted in 40 patients (33.6%). Patients in which TI was not applied were older, less often employed and more likely to be on biological treatment at time of ASDAS≥2.1. In physician-centered regression analyses, the physician-based determinants were very strong and independent drivers for TI (OR_{PhGA} = 1.74 [95%CI 1.24-2.46]; $OR_{PASS\text{-}physician}$ = 27.0 [4.18-174.0]) while patient-based determinants (ASDAS, ASAS HI, education) were not associated with TI (Table). In patient-centered regression analyses, only peripheral symptoms were associated with TI. PASS-patient was not associated with TI in any of the models (OR = 1.22 [0.34-4.45] when added to the patient-centered model).

Conclusion: In practice, treatment is intensified in only a minority of patients with axSpA and HDA. Physician-centered factors seem to be driving this decision to change treatment, independently of (ASDAS-based) disease activity. Further research is needed to better understand these decisions.

Which ASDAS Cut-Off Corresponds Best to Treatment Intensification in Patients with Axial Spondyloarthritis in Daily Practice?

Casper Webers[1], Rabab Nezam El-Din[1], Marin Been[1], Harald Vonkeman[2] and Astrid van Tubergen[1], [1]Department of Internal Medicine, Division of Rheumatology, Maastricht University Medical Centre, Maastricht, Netherlands, [2]Department of Rheumatology, Medisch Spectrum Twente and University of Twente, Enschede, Netherlands

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: In patients with axial spondyloarthritis (axSpA) and high disease activity (typically defined as Ankylosing Spondylitis Disease Activity Score [ASDAS]≥2.1), it is recommended to adapt treatment. However, this recommendation is not always followed in practice. The ASDAS was developed for research, and it is unknown how it performs in daily practice. Possibly, the cut-off of 2.1 as currently endorsed is too strict in this setting. Our objective was to investigate which ASDAS cut-off values correspond best with treatment intensification (TI) in practice.

Methods: Data were used from a prospective multicentre Dutch registry for patients with SpA (SpA-Net). Patients with axSpA and ≥1 ASDAS measurement in 2016-2022 were included. TI was defined as 1) higher dose or frequency of the same drug, 2) switch to another drug or 3) addition of a new drug to the current treatment regime; due to inefficacy. Only anti-inflammatory drugs (NSAIDs, conventional synthetic/biologic/targeted synthetic DMARDs [cs/b/tsDMARDs], corticosteroids) were considered. Single patients could contribute multiple TI events. Receiver operating characteristic (ROC) curve analyses were conducted to estimate the ability of ASDAS to discriminate between TI/non-TI (Area Under the Curve [AUC]), and identify the ASDAS cut-off that discriminates best in this real-world population, with corresponding sensitivity and specificity. Analyses were conducted with (1) all observations and (2) the first observation per patient per calendar year.

Results: In total, 328 patients with 2,010 ASDAS measurements were included. Median follow-up was 2.5 (IQR 1.0-4.3) years. Mean age was 50.2 (SD 14.0) years, 149 (45.4%) were female, and mean ASDAS was 2.3 (SD 1.0). Approximately two-thirds of patients (211/328, 64.3%) were on biological/targeted synthetic DMARDs (b/tsDMARDs) at some point during follow-up. TI was applied after 218/2,010 ASDAS measurements (10.8%), and mean ASDAS was higher at TI timepoints than at non-TI timepoints (3.1 [SD 1.0] versus 2.3 [SD 1.0]). When all ASDAS measurements were included for analysis, the AUC was 0.72 (95%CI 0.68-0.75) with an optimal ASDAS cut-off of 2.7 (sensitivity 68%, specificity 66%). Results were similar when only one measurement was used per patient and calendar year (1,069 ASDAS measurements; AUC 0.75, ASDAS cut-off 2.7). Over the years, the ASDAS cut-off was consistently higher than 2.1, however with a decreasing trend (Table).

Conclusion: In daily practice, TI is associated with a higher ASDAS cut-off value than the recommended one (≥2.1). Possibly, rheumatologists believe the recommended cut-off to be too stringent or consider other factors than disease activity when making treatment decisions. Regardless, the cut-off seems to be gradually decreasing, suggesting increased uptake of axSpA management recommendations.

Table. ROC analysis of TI and ASDAS, by calendar year (one measurement per patient per year)

	2016 (n=56)	2017 (n=175)	2018 (n=221)	2019 (n=206)	2020 (n=132)	2021 (n=133)	2022 (n=117)
AUC (95% CI)	0.67 (0.39-0.95)	0.82 (0.73-0.91)	0.75 (0.66-0.84)	0.70 (0.59-0.81)	0.71 (0.59-0.82)	0.73 (0.60-0.86)	0.77 (0.64-0.91)
Optimal cut-off*							
ASDAS	2.34	2.76	2.67	2.70	2.35	2.40	2.53
Sensitivity	0.75	0.78	0.78	0.67	0.94	0.88	0.80
Specificity	0.65	0.76	0.65	0.68	0.56	0.59	0.71

If patients had multiple ASDAS measurements in a calendar year, the first measurement was used. *According to Liu index (maximize product of sensitivity x specificity). AUC, Area Under the Curve; Receiver operating characteristic, ROC; TI, treatment intensification.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Elevated baseline (BL) CRP levels can predict treatment response in patients (pts) with AS. Tofacitinib is a Janus kinase inhibitor for the treatment of AS. This post hoc analysis evaluated the impact of BL CRP levels on tofacitinib efficacy and safety in pts with AS.

Fig. ASAS20 response rates over time by BL CRP

[a]To W12: P2; W16: P3

[b]To W12: P2; W48: P3

[c]P2: tofacitinib 2, 5, or 10 mg BID to W12; P3: 5 mg BID to W48

[d]Pts with events/100 pt-years

AE, adverse event; BID, twice daily; BL, baseline; CI, confidence interval; ELV, elevated; HZ, herpes zoster; IR, incidence rate; n, number of pts with an event within risk period (on treatment); N, number of pts in safety analysis set; NML, normal; P, Phase; PBO, placebo; pt, patient; SAE, serious adverse event; SI, serious infection; TEAE, treatment-emergent adverse event; W, Week

Methods: Post hoc analysis of pooled data from placebo (PBO)-controlled, randomized, double-blind trials (NCT01786668, Phase [P]2, 16 weeks; NCT03502616, P3, 48 weeks) in pts with AS on ≥ 1 dose of tofacitinib or PBO (P3: PBO-treated pts switched to tofacitinib after Week [W]16), by BL CRP: normal (NML) < 5 mg/L; elevated (ELV) ≥ 5 mg/L. Tofacitinib 5 mg twice daily (BID) efficacy was assessed to W12/W16–48 (P3). Endpoints: Assessment of SpondyloArthritis international Society (ASAS) 20/40, Bath AS Disease Activity Index (BASDAI) 50, AS-Disease Activity Score-CRPinactive disease (ASDAS-CRP ID), and least squares mean change from BL (Δ) in nocturnal pain and Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F). Safety was assessed to W16 and W48.

Results: Of 372 pts, 30.4/69.6% had NML/ELV BL CRP. Both groups had generally similar BL characteristics; more pts with ELV CRP were male, current smokers, and had prior biologic DMARD use. At W12, ASAS20 response was greater for tofacitinib vs PBO in both groups (Fig); efficacy maintained to W48. At W12, the difference in response from PBO for tofacitinib was numerically greater for ELV vs NML CRP for ASAS20 (44.7% vs 15.9%), ASAS40 (34.6% vs 17.3%), BASDAI50 (33.8% vs 15.3%), ASDAS-CRP ID (9.5% vs 8.2%), Δnocturnal spinal pain (-2.1 vs -1.4), and ΔFACIT-F (5.2 vs 3.5). For tofacitinib, rates of treatment-emergent adverse events and infections to W16 trended numerically higher for tofacitinib vs PBO in pts with NML CRP, but were similar to PBO in pts with ELV CRP (Table). There were few serious adverse events, serious infections, or herpes zoster across groups and no deaths. Limitations: small sample size, differences in BL characteristics.

Conclusion: Regardless of BL CRP, at W12, tofacitinib was more efficacious vs PBO; and across endpoints, the differences in response from PBO for tofacitinib were numerically greater in pts with ELV vs NML CRP. Tofacitinib safety rates were consistent with PBO in pts with ELV CRP, but trended higher for tofacitinib vs PBO in pts with NML CRP.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Bimekizumab (BKZ), a monoclonal IgG1 antibody, selectively inhibits IL-17F in addition to IL17A. BKZ has demonstrated clinical efficacy and safety up to 3 years (yrs) in patients (pts) with active AS (i.e., radiographic axial spondyloarthritis)[1] in the phase 2b study BE AGILE and its open-label extension (OLE).[2]

Here, we report 5-yr results of BKZ in BE AGILE and its OLE.

Methods: The dose-ranging BE AGILE study (NCT02963506) consisted of a 12-week (wk) double-blind, placebo-controlled period, then a dose-blind period to Wk 48 where pts received BKZ 160 or 320 mg every 4 wks (Q4W).[2] Pts completing Wk 48 were eligible to enter the OLE (NCT03355573) where all pts received BKZ 160 mg Q4W to Wk 256.

Treatment-emergent adverse events (TEAEs; MedDRA v19.0) are reported for BKZ exposure from Wk 0–256. Efficacy is reported from Wk 0–256 for pts enrolled in BE AGILE entering the dose-blind period (dose-blind set [DBS]) and Wk 48–256 for pts enrolled in the OLE with ≥1 efficacy measurement at OLE entry (OLE full analysis set [FAS]). Analyses used non-responder imputation (NRI; pts who did not enter the OLE were considered non-responders from Wk 48), observed case methodology, or multiple imputation (MI).

Results: 296/303 (97.7%) pts randomized in BE AGILE entered the dose-blind period; 265/303 (87.5%) completed to Wk 48. Of 255/303 (84.2%) pts who entered the OLE at Wk 48, and received ≥1 BKZ dose, 202/255 (79.2%) completed to Wk 256.

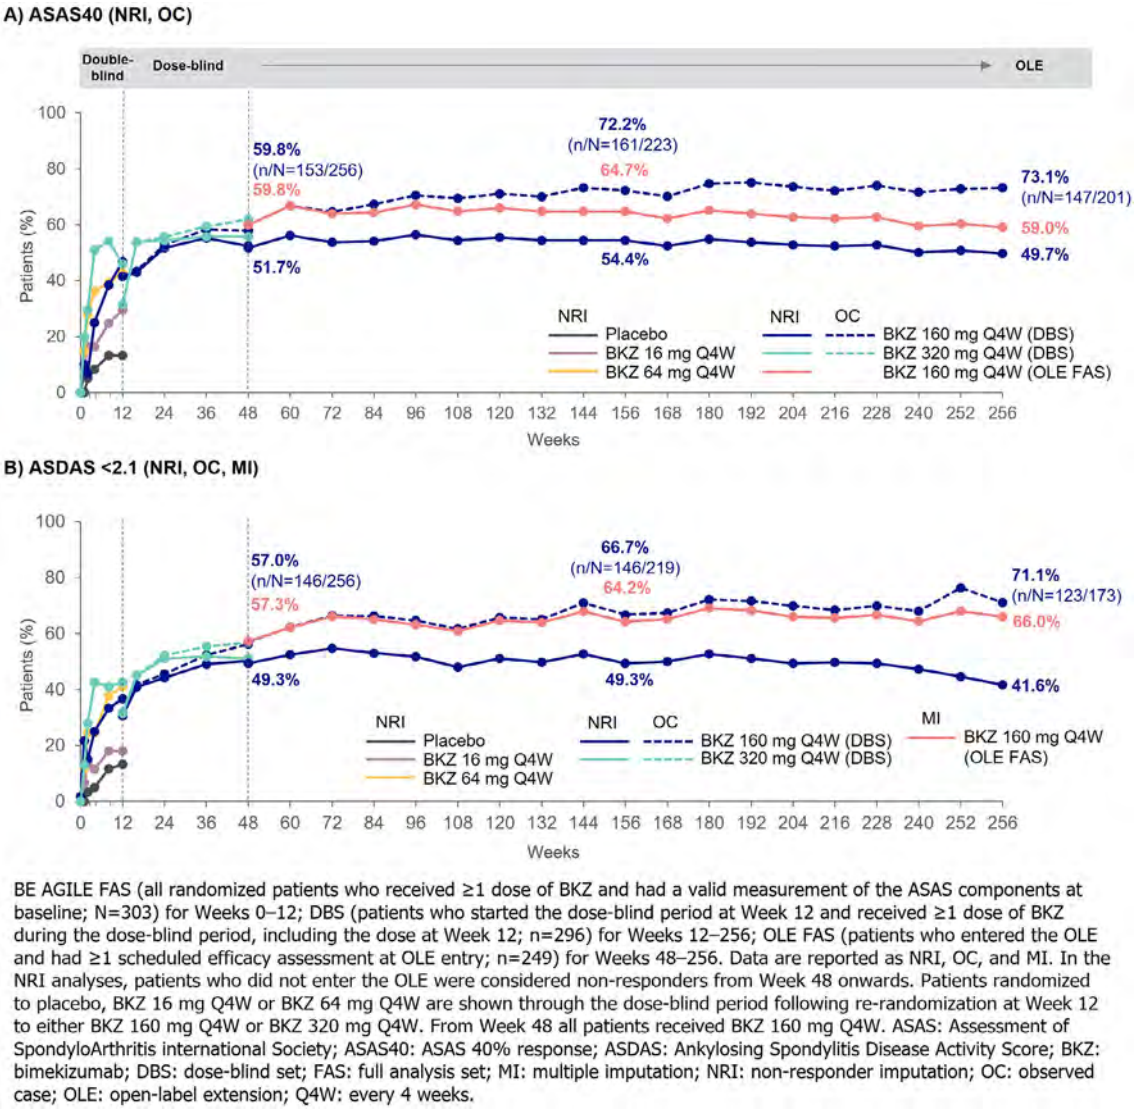
Table. Safety to Week 256 for exposure to BKZ in BE AGILE and the OLE

TEAEs[a] n (%) [EAIR/100 PY]	**BE AGILE and OLE** Weeks 0–256 **Total (N=303; exposure 1,231 PY)**
Any TEAE	289 (95.4) [134.6]
Study discontinuations due to TEAEs	43 (14.2) [3.5]
Drug-related TEAEs	160 (52.8) [21.8]
Serious TEAEs	58 (19.1) [5.2]
Deaths	3 (1.0) [0.2][b]
Safety topics of interest	
Fungal infections[c]	74 (24.4) [7.4]
Candida infections by preferred term[d]	30 (9.9) [2.6]
Oral candidiasis	25 (8.3) [2.2]
Skin *Candida*	4 (1.3) [0.3]
Vulvovaginal candidiasis	2 (0.7) [0.2]
Candida infection	1 (0.3) [0.1]
Oropharyngeal candidiasis	1 (0.3) [0.1]
Serious infections and infestations	17 (5.6) [1.4]
Neutropenia	4 (1.3) [0.3]
Adjudicated SIB	1 (0.3) [0.1]
Injection site reactions	2 (0.7) [0.2]
Definite and probable IBD[e]	10 (3.3) [0.8][f]
With prior history	2 (0.7)
Without prior history	8 (2.6)
Uveitis[g,h]	9 (3.0) [0.7][i]
With prior history	3 (1.0)
Without prior history	6 (2.0)

Safety set. TEAEs occurring on placebo treatment are not included. All patients received BKZ 160 mg Q4W during the OLE (Weeks 48–256) after completing BKZ 160 mg or 320 mg Q4W at Week 48 in BE AGILE.
[a] Defined according to MedDRA v19.0. [b] There was one death in BE AGILE (cardiac arrest) and two in the OLE (cardiac arrest, road traffic accident). Neither were considered treatment related. [c] Other than *Candida* infections, fungal infections included *Tinea* and not elsewhere classified infections, and were localized to the skin, scalp, ear, mouth, tongue, nails, vulva, and feet; none were systemic. [d] All *Candida* infections were mild to moderate, none were systemic. [e] Includes the preferred terms Crohn's disease, colitis ulcerative, and colitis. [f] Four patients had IBD TEAEs in BE AGILE; none of these cases occurred from Weeks 0–12 in patients who were treated with placebo. [g] Includes the preferred terms iritis, iridocyclitis, and uveitis. [h] Uveitis was not a safety topic of interest in this study and is included as an extra-musculoskeletal manifestation. [i] Two uveitis cases occurred during BE AGILE; one case was in a placebo-treated patient during Weeks 0–12. BKZ: bimekizumab; EAIR: exposure-adjusted incidence rate; IBD: inflammatory bowel disease; OLE: open-label extension; PY: patient-years; Q4W: every 4 weeks; SIB: suicidal ideation and behavior; TEAE: treatment-emergent adverse event.

From Wk 0–256, exposure adjusted incidence rates (EAIRs) per 100 pt-yrs were 134.6 for any TEAE and 5.2 for serious TEAEs (**Table**). EAIR of *Candida* infections over 256 wks (2.6) was lower than in Wk 0–48 (7.5).[1] All *Candida* infections were mild or moderate; 1 oral candidiasis event led to discontinuation. No systemic fungal infections were reported. Over 256 wks, EAIRs of serious infections and infestations (1.4) and injection site reactions (0.2) remained low. EAIRs of IBD (0.8) and uveitis (0.7) were also low.

At the OLE entry visit (Wk 48), around half of the DBS (n=296) achieved ASAS40 (51.7%) and ASDAS < 2.1 (49.3%); 49.7% and 41.6% achieved these endpoints at Wk 256, respectively (NRI; **Figure 1**). Similar results were seen in the OLE FAS (n=249) for ASAS40 (NRI; Wk 48: 59.8%; Wk 256: 59.0%) and ASDAS < 2.1 (MI; 57.3%; 66.0%).



BE AGILE FAS (all randomized patients who received ≥1 dose of BKZ and had a valid measurement of the ASAS components at baseline; N=303) for Weeks 0–12; DBS (patients who started the dose-blind period at Week 12 and received ≥1 dose of BKZ during the dose-blind period, including the dose at Week 12; n=296) for Weeks 12–256; OLE FAS (patients who entered the OLE and had ≥1 scheduled efficacy assessment at OLE entry; n=249) for Weeks 48–256. Data are reported as NRI, OC, and MI. In the NRI analyses, patients who did not enter the OLE were considered non-responders from Week 48 onwards. Patients randomized to placebo, BKZ 16 mg Q4W or BKZ 64 mg Q4W are shown through the dose-blind period following re-randomization at Week 12 to either BKZ 160 mg Q4W or BKZ 320 mg Q4W. From Week 48 all patients received BKZ 160 mg Q4W. ASAS: Assessment of SpondyloArthritis international Society; ASAS40: ASAS 40% response; ASDAS: Ankylosing Spondylitis Disease Activity Score; BKZ: bimekizumab; DBS: dose-blind set; FAS: full analysis set; MI: multiple imputation; NRI: non-responder imputation; OC: observed case; OLE: open-label extension; Q4W: every 4 weeks.

Figure 1. Efficacy responses to Week 256

Mean reductions from BL to Wk 48 in ASDAS (3.9 to 2.1) and BASDAI (6.5 to 3.0) in the DBS were sustained or further decreased to 2.1 and 2.5, respectively, at Wk 256 (MI); responses in the OLE FAS from Wk 48 to Wk 256 were similar (MI; ASDAS: 2.0 to 1.9; BASDAI: 2.8 to 2.4).

Mean BASFI and ASQoL improvements from BL to Wk 48 were sustained to Wk 256 in the DBS (MI; **Figure 2**), and from Wk 48 to Wk 256 in the OLE FAS (MI; BASFI: 3.0 to 2.6; ASQoL: 3.3 to 2.6).

Conclusion: The long-term safety profile of BKZ in pts with AS was consistent with previous observations, with no new safety signals identified after 5 yrs of exposure.

Clinical efficacy, including improvements in signs and symptoms, disease activity, physical function, and health-related quality of life, was maintained up to 5 yrs of BKZ treatment. To our knowledge, this is the first report of NRI ASAS40 data up to 5 yrs in pts with AS exposed to novel treatments.

Abstract Number: 0520

How Do Early Disease Activity and Early Clinical Response Associate with Long-Term Outcomes with Ixekizumab in Radiographic Axial Spondyloarthritis?

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The ASAS-EULAR recommendations for the management of axial spondyloarthritis (axSpA) advise that a patient be assessed for biological disease-modifying anti-rheumatic drug (bDMARD) treatment response after at least 12 weeks of treatment[1]. The recommended treatment target for axSpA is inactive disease (ID) or low disease activity (LDA)[2], as together defined by an Ankylosing Spondylitis Disease Activity Score (ASDAS) <2.1[3]. This analysis aimed to explore the association between treatment response at Week (W)12 and W24, and attainment of the ASDAS < 2.1 treat-to-target (T2T) recommendation at W52 in patients with radiographic (r-) axSpA treated with ixekizumab (IXE).

Methods: This post hoc analysis included patients randomly assigned to IXE 80mg every 4 weeks (N=81) from COAST-V (NCT02696785), a Phase 3 trial that investigated the efficacy of IXE in bDMARD-naïve patients with r-axSpA. The proportion of patients who achieved the ASDAS < 2.1 target response at W52 was evaluated among those in ID, LDA, high disease activity (HDA) or very high disease activity (VHDA) at W12 or W24. The proportion of patients who achieved ASDAS< 2.1 at W52 was also measured among those who attained meaningful clinical response at W12 or W24, as defined by a clinically important (CII, ΔASDAS ≥1.1) or a major improvement (MI, ΔASDAS ≥2.0) in ASDAS, improvement of ≥50% in Bath Ankylosing Spondylitis Disease Activity Index score (BASDAI50), or achievement of BASDAI < 4. Patient and disease characteristics are described according to responses at W12 or W24 and W52. Non-responder imputation was used to handle missing data.

Results: Of the 81 patients, 34 (42%) were in ID or LDA at W12 (8 ID, 26 LDA) and most of these patients met the ASDAS < 2.1 target at W52 (ID=100%, LDA=85%; Figure 1A). 47 patients achieved ASDAS CII at W12 and of those, 33 (70%) were in ID or LDA at W52 (Figure 1B). Similarly, most patients who met the ASDAS MI, BASDAI50 or BASDAI< 4 clinical response measures at W12 met ASDAS < 2.1 at W52 (81–94%; Figure 1B). 37 patients (46%) were in ID or LDA at W24 (13 ID, 24 LDA) and of those, 29 (78%) had already achieved ASDAS < 2.1 at W12 (Table 1), and most also met ASDAS < 2.1 at W52 (ID=100%, LDA=79%; Figure 1A). 52 patients achieved ASDAS CII at W24 and among them, 37 (71%) were in ID or LDA at W52 (Figure 1B). Most patients who met the ASDAS MI, BASDAI50 or BASDAI< 4 clinical response measures at W24 met ASDAS < 2.1 at W52 (80–89%; Figure 1B). Patients who did not meet ASDAS < 2.1 at W12 were more likely to be older, female, or with a longer symptom duration versus those who did, and 8 of these 47 patients (17%) subsequently achieved ASDAS < 2.1 at W24 (Table 1). 39 patients were in HDA or VHDA (ASDAS ≥2.1) at both W12 and W24 (Table 1), and 9 (23%) of these patients (11% of the 81 included patients) met the ASDAS < 2.1 target at W52.

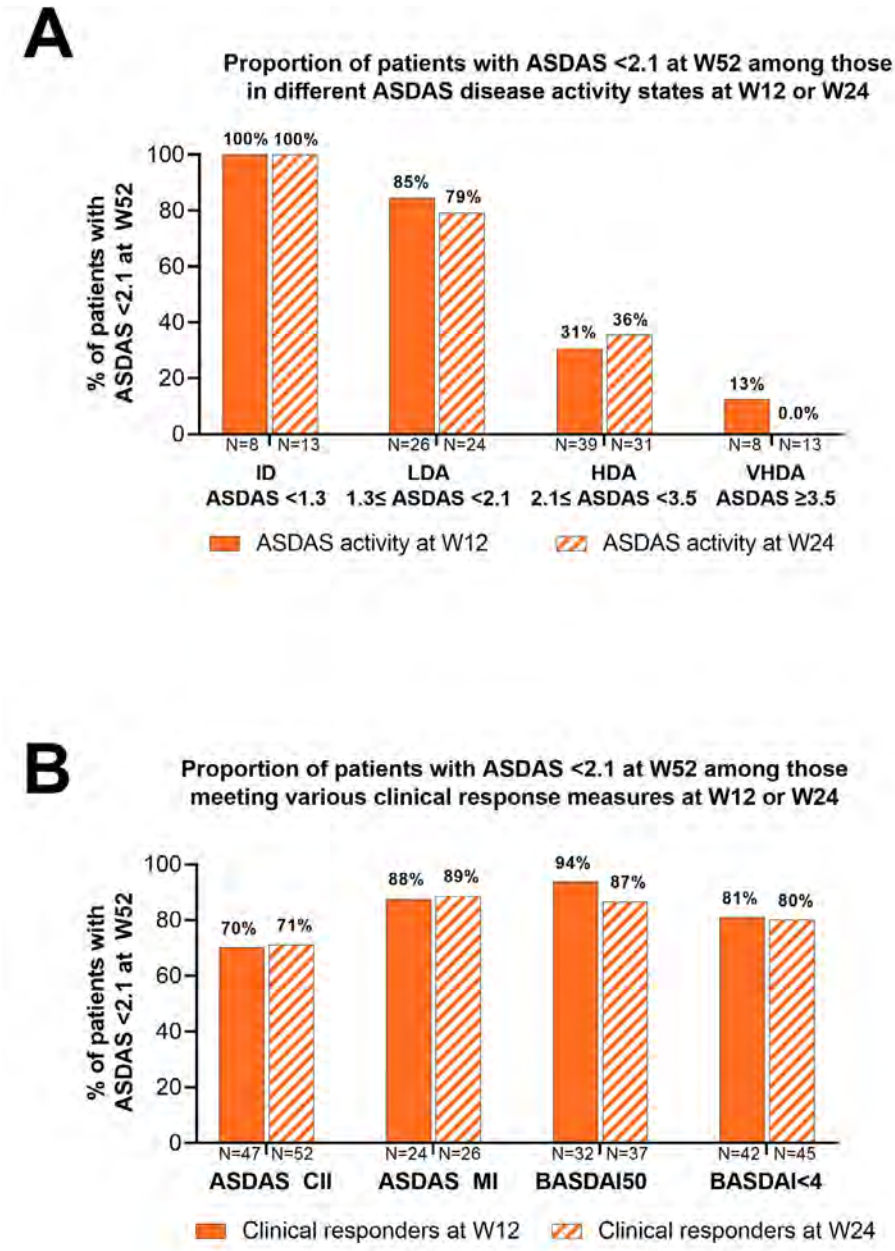

Figure 1. The proportion (%) of IXE-treated patients that achieved ASDAS <2.1 at Week 52 among those meeting specific response criteria at Week 12 or Week 24

Percentage values are rounded. ASDAS <2.1 represents the treatment target of ID or LDA. ASDAS CII is a change ≥1.1 units, ASDAS MI is a change ≥2.0 units. BASDAI50 represents an improvement of ≥50% of the BASDAI score from baseline. A BASDAI score less than 4 is not considered active disease.

Abbreviations: ASDAS= Ankylosing Spondylitis Disease Activity Score; BASDAI=Bath Ankylosing Spondylitis Disease Activity Index; CII=Clinically Important Improvement; HDA=High Disease Activity; ID=Inactive Disease; IXE=ixekizumab; LDA=Low Disease Activity; MI=Major Improvement; VHDA=Very High Disease Activity; W=Week

Conclusion: These data regarding IXE-treated patients with r-axSpA reinforce the current ASAS-EULAR and T2T recommendations, in that those who achieved ASDAS CII or ASDAS < 2.1 at W12 and/or W24 were highly likely to attain the treatment target of ID or LDA at W52.

Table 1. Baseline demographics and disease characteristics of patients that had ASDAS <2.1 or ASDAS ≥2.1 at Week 12 and/or Week 24

	Week 12 ASDAS <2.1 (N=34)		Week 12 ASDAS ≥2.1 (N=47)	
	Week 24 ASDAS <2.1 (N=29)	Week 24 ASDAS ≥2.1 (N=5)	Week 24 ASDAS <2.1 (N=8)	Week 24 ASDAS ≥2.1 (N=39)
Age, years	35.0 (10.1)	38.2 (9.8)	42.1 (11.5)	45.5 (12.3)
Female, n (%)	1 (3.4)	0 (0)	2 (25.0)	10 (25.6)
HLA-B27+, n (%)	28 (96.6)	5 (100.0)	8 (100.0)	34 (87.2)
Symptom duration, years	9.9 (6.6)	14.2 (10.4)	16.2 (13.1)	20.3 (11.8)
MRI-SIJ+, n (%)	15 (51.7)	2 (40.0)	2 (25.0)	8 (20.5)
CRP+, n (%)	21 (72.4)	2 (40.0)	5 (62.5)	24 (61.5)
ASDAS at baseline	3.7 (0.8)	3.5 (0.3)	3.6 (0.7)	3.8 (0.7)
ASDAS at week 12	1.5 (0.4)	1.9 (0.2)	2.5 (0.2)	2.9 (0.4)
ASDAS at week 24	1.4 (0.4)	2.5 (0.3)	1.6 (0.3)	2.9 (0.7)

Data are mean (standard deviation) unless stated otherwise.
Abbreviations: ASDAS=Ankylosing Spondylitis Disease Activity Score; CRP+=SERUM C reactive protein nephelometry >5.0 mg/L, HLA-B27=Human Leukocyte Antigen B 27; MRI-SIJ+=Magnetic resonance imaging of the sacroiliac joints, Spondyloarthritis Research Consortium of Canada score ≥2

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The clinical manifestations of axial spondyloarthritis (axSpA) limit physical function and work productivity, posing an economic burden to patients (pts) and society.[1] Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits IL-17F in addition to IL-17A, demonstrated sustained efficacy in controlling disease activity up to Week (Wk) 52 in pts with non-radiographic (nr-) and radiographic (r-)axSpA (i.e., AS)[2] in the phase 3 studies BE MOBILE 1 and 2, respectively.[3] This analysis assessed the impact of BKZ on work productivity and activity impairment (WPAI) at Wk 16 and Wk 52 in pts across the full disease spectrum of axSpA.

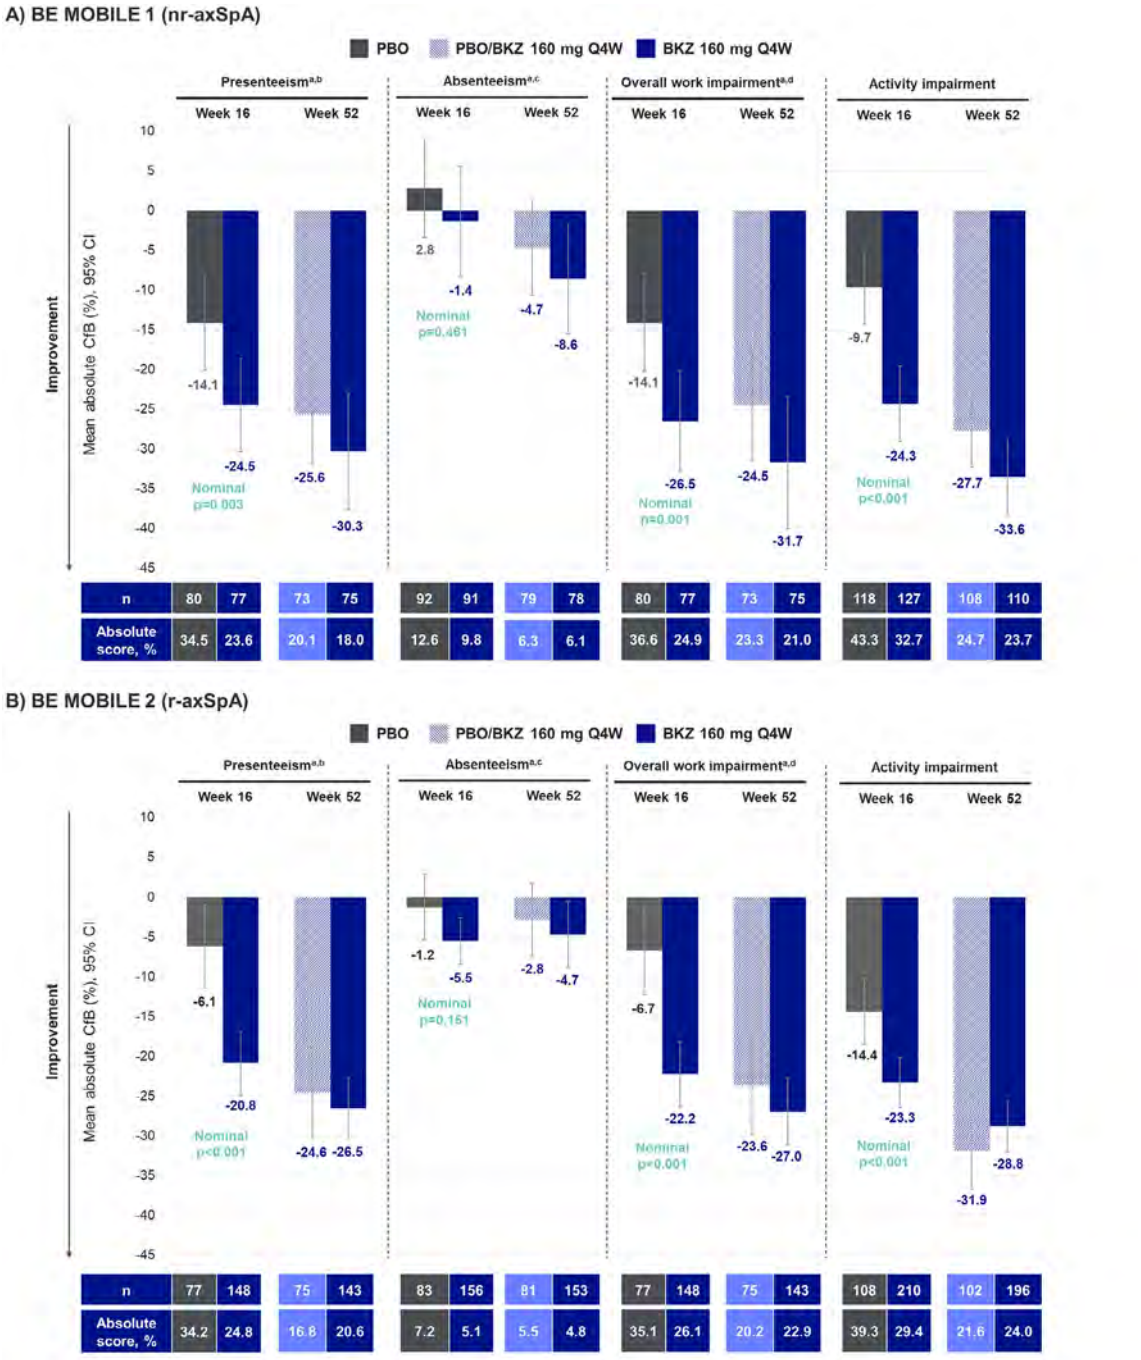
Methods: The parallel BE MOBILE 1 (NCT03928704) and 2 (NCT03928743) studies comprised a 16-wk double-blind period followed by a 36-wk maintenance period.[3] Pts were randomized to subcutaneous BKZ 160 mg every 4 wks (Q4W) or placebo (PBO). All pts received BKZ 160 mg Q4W from Wk 16. We report mean change from baseline (BL) at Wk 16 and 52 in WPAI Specific Health Problem scores,[4] which assess disease impact on pts' impairment while at paid work (i.e., presenteeism), work time missed (i.e., absenteeism, including sick leave), overall work impairment (composite of presenteeism and absenteeism) and daily activity impairment (outside paid work). Observed case data are reported.

Results: Almost 75% of pts were employed at BL (nr-axSpA BKZ: 95/128 [74.2%], PBO: 93/126 [73.8%]; r-axSpA BKZ: 161/221 [72.9%], PBO: 82/111 [73.9%]). Pts had substantial overall work impairment at BL, with presenteeism contributing most to this (**Table**).

Table. Baseline employment and WPAI-SHP item scores (OC)

	BE MOBILE 1 (nr-axSpA)		BE MOBILE 2 (r-axSpA)	
	PBO/BKZ 160 mg Q4W N=126	BKZ 160 mg Q4W N=128	PBO/BKZ 160 mg Q4W N=111	BKZ 160 mg Q4W N=221
Employment, n (%)	93 (73.8)	95 (74.2)	82 (73.9)	161 (72.9)
WPAI-SHP item score, mean % (SD)				
Presenteeism[a,b]	47.1 (20.9) (n=84)	49.2 (25.1) (n=86)	42.3 (23.4) (n=74)	46.1 (24.9) (n=149)
Absenteeism[a,c]	11.6 (26.7) (n=93)	12.8 (25.0) (n=95)	10.9 (26.9) (n=82)	11.5 (23.6) (n=161)
Overall work impairment[a,d]	49.1 (21.5) (n=84)	52.2 (26.6) (n=86)	43.9 (24.5) (n=74)	49.2 (25.6) (n=149)
Activity impairment	53.4 (21.7) (n=126)	57.3 (22.9) (n=128)	54.1 (24.2) (n=111)	53.3 (23.6) (n=221)

Randomized set. OC data reported. WPAI-SHP item scores are expressed as a percentage, with higher numbers indicating greater impairment and less productivity. [a] Absenteeism, presenteeism, and overall work impairment were assessed only in patients who were employed at baseline. [b] Impairment while at paid work due to axSpA; [c] Work time missed due to axSpA. [d] Overall work impairment is a composite of absenteeism and presenteeism. axSpA: axial spondyloarthritis; BKZ: bimekizumab; nr-axSpA: non-radiographic axSpA; OC: observed case; PBO: placebo; Q4W: every 4 weeks; r-axSpA: radiographic axSpA; SD: standard deviation; WPAI-SHP: Work Productivity and Activity Impairment Questionnaire Specific Health Problem.



Randomized set. OC data reported. Error bars represent 95% CI. WPAI-SHP item scores are expressed as a percentage, with a greater reduction indicating greater improvement. Week 16 nominal p values are calculated using ANCOVA with baseline WPAI-SHP item score as covariate and treatment, region and either MRI/CRP classification at baseline (nr-axSpA) or prior TNF inhibitor exposure (r-axSpA) as fixed effects. [a] Absenteeism, presenteeism, and overall work impairment were assessed only in patients who were employed at baseline. [b] Impairment while at paid work due to axSpA; [c] Work time missed due to axSpA. [d] Overall work impairment is a composite of absenteeism and presenteeism. ANCOVA: analysis of covariance; axSpA: axial spondyloarthritis; BKZ: bimekizumab; CfB: change from baseline; CI: confidence interval; CRP: C-reactive protein; MRI: magnetic resonance imaging; nr-axSpA: non-radiographic axSpA; OC: observed case; PBO: placebo; Q4W: every 4 weeks; r-axSpA: radiographic axSpA; TNF: tumor necrosis factor; WPAI-SHP: Work Productivity and Activity Impairment Specific Health Problem.

Figure. Mean absolute change from baseline in WPAI-SHP items at Week 16 and Week 52 (OC)

At Wk 16, mean reductions from BL (i.e., absolute improvement) were greater in BKZ- vs PBO-randomized pts for presenteeism (nr-axSpA: –24.5% vs –14.1%, nominal p=0.003; r-axSpA: –20.8% vs –6.1%, nominal p< 0.001), overall work impairment (nr-axSpA: –26.5% vs –14.1%, nominal p=0.001; r-axSpA: –22.2% vs –6.7%, nominal p< 0.001) and activity impairment (nr-axSpA: –24.3% vs –9.7%; r-axSpA: –23.3% vs –14.4%; nominal p< 0.001; **Figure**). Mean improvements in overall work impairment were sustained or further improved to Wk 52 in BKZ-randomized pts (nr-axSpA: –31.7%; r-axSpA: –27.0%); pts who switched from PBO to BKZ at Wk 16 reached similar levels of improvement to BKZ-randomized pts at Wk 52. Similar trends were seen in presenteeism and activity impairment (**Figure**).

Mean BL absenteeism scores were low compared with other WPAI items (**Table**), leaving limited room for improvement. At Wk 16, no clear separation was seen for improvements in absenteeism between BKZ-randomized pts and PBO; this response improved or was sustained in BKZ-randomized pts at Wk 52 (**Figure**). Absenteeism may also have been impacted by the COVID-19 pandemic.

Conclusion: BKZ treatment resulted in substantial improvements in overall work and activity impairment at Wk 16, with further improvements at Wk 52 in pts across the full disease spectrum of axSpA.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: SURPASS, a phase 3b randomized controlled study in patients with radiographic axial spondyloarthritis (r-axSpA), found low spinal radiographic progression over 2 years with no significant difference between the secukinumab (SEC) and adalimumab biosimilar (SDZ- ADL) treatment arms.[1,2] Baseline (BSL) radiographic damage (presence of syndesmophytes) and elevated C-reactive protein (CRP) levels have been identified as predictors of radiographic progression in r-axSpA.[3] This study evaluated the effect of SEC and SDZ-ADL on spinal radiographic progression in subgroups of patients based on the presence of syndesmophytes and elevated high-sensitivity CRP (hsCRP) levels at BSL, from the SURPASS study.

Methods: Biologic-naïve patients with active r-axSpA and with hsCRP ≥5 mg/L and/or ≥1 syndesmophyte(s) on spinal radiographs were randomized (1:1:1) to SEC (150 or 300 mg; dose-blinded) or SDZ-ADL (40 mg; open label). Patients were categorized into the following subgroups at BSL: hsCRP ≥5 mg/L (CRP+), hsCRP < 5 mg/L (CRP–), presence of syndesmophyte(s) (Synd+), absence of syndesmophyte(s) (Synd–), and CRP+Synd+. The proportion of patients with no radiographic progression (change from BSL in modified Stoke Ankylosing Spondylitis Spinal Score [mSASSS] ≤0.5), mean change from BSL in mSASSS, and proportion of patients with no new syndesmophytes(s) in each subgroup at week 104 (all as observed) are reported.

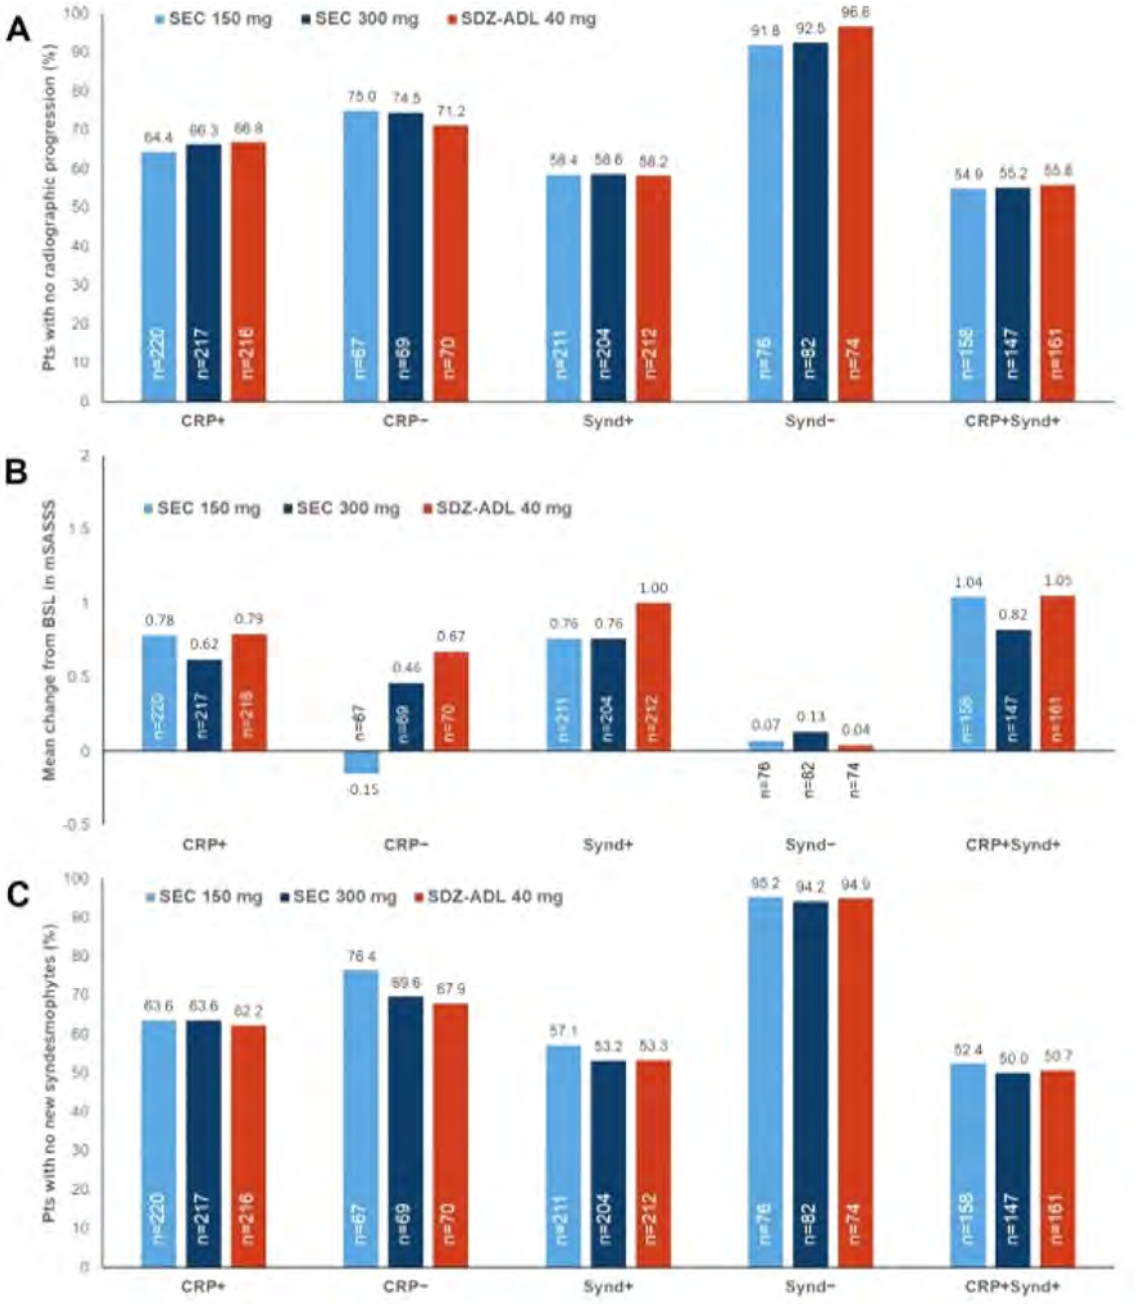
Results: Of the 859 patients, 653 (76%) were CRP+, 627 (73%) were Synd+, and 466 (54%) were CRP+Synd+ at BSL. Demographic and BSL disease characteristics were largely balanced across subgroups and treatment arms, except for the Synd– group in which mean age, proportion of male patients, and mean time since diagnosis were lower than in other subgroups (**Table 1**). All radiographic outcomes at week 104 were similar across treatment arms; however, differences were observed between subgroups irrespective of the treatment arm. The Synd– subgroup followed by the CRP– subgroup showed the least progression in all radiographic outcomes (as indicated by the higher proportion of patients with no radiographic progression and no new syndesmophytes, and lower mean change from BSL in mSASSS), across treatment arms (**Figure 1**). The CRP+Synd+ subgroup followed by the Synd+ subgroup and the CRP+ subgroup had higher radiographic progression compared with the Synd– and CRP– subgroups (**Figure 1**).

Conclusion: Spinal radiographic progression over 2 years was low with no notable difference between SEC and SDZ-ADL arms regardless of the presence or absence of specific predictive factors for progression (syndesmophytes/elevated CRP). Expectedly, patients from subgroups without predictive factors (especially Synd–, followed by CRP–) had lowest rates of radiographic progression. The presence of syndesmophytes is a stronger predictor than the presence of an elevated CRP.

Table 1. Demographic and baseline disease characteristics by subgroup

Characteristics, mean values unless specified otherwise	CRP+ N=653	CRP− N=206	Synd+ N=627	Synd− N=232	CRP+Synd+ N=466
Age (years)	40.7	46.4	45.0	34.2	43.4
Male, %	80.1	73.3	82.1	68.5	84.3
BMI (kg/m²)	27.3	27.2	27.6	26.4	27.6
Time since first diagnosis of r-axSpA (years)	6.3	8.0	7.6	4.3	7.2
mSASSS	16.2	17.8	22.5	0.1	22.5
Number of syndesmophytes	6.8	7.6	9.6	0.0	9.5
BASDAI	7.2	6.9	7.1	7.2	7.2
hsCRP (mg/L)	26.1	2.6	19.9	22.0	25.8
HLA-B27 positive, %	82.4	77.7	81.2	81.5	82.0

CRP+, hsCRP ≥5 mg/L; CRP−, hsCRP <5 mg/L; Synd+, presence of syndesmophyte(s); Synd−, absence of syndesmophyte(s)
BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BMI, body mass index; HLA-B27, human leukocyte antigen B27; hsCRP, high-sensitivity C-reactive protein; mSASSS, modified Stoke Ankylosing Spondylitis Spinal Score; r-axSpA, radiographic axial spondyloarthritis



BSL, baseline; mSASSS, modified Stoke Ankylosing Spondylitis Spinal Score; Pts, patients; SDZ-ADL, adalimumab biosimilar; SEC, secukinumab
A patient was considered to have a syndesmophyte if at least one reader assessed mSASSS score of ≥2 for any individual vertebral corner

Figure 1. Radiographic outcomes at week 104 by subgroup: A) Patients with no radiographic progression (change in mSASSS ≤0.5), B) Mean change from BSL in mSASSS, C) Patients with no new syndesmophytes

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

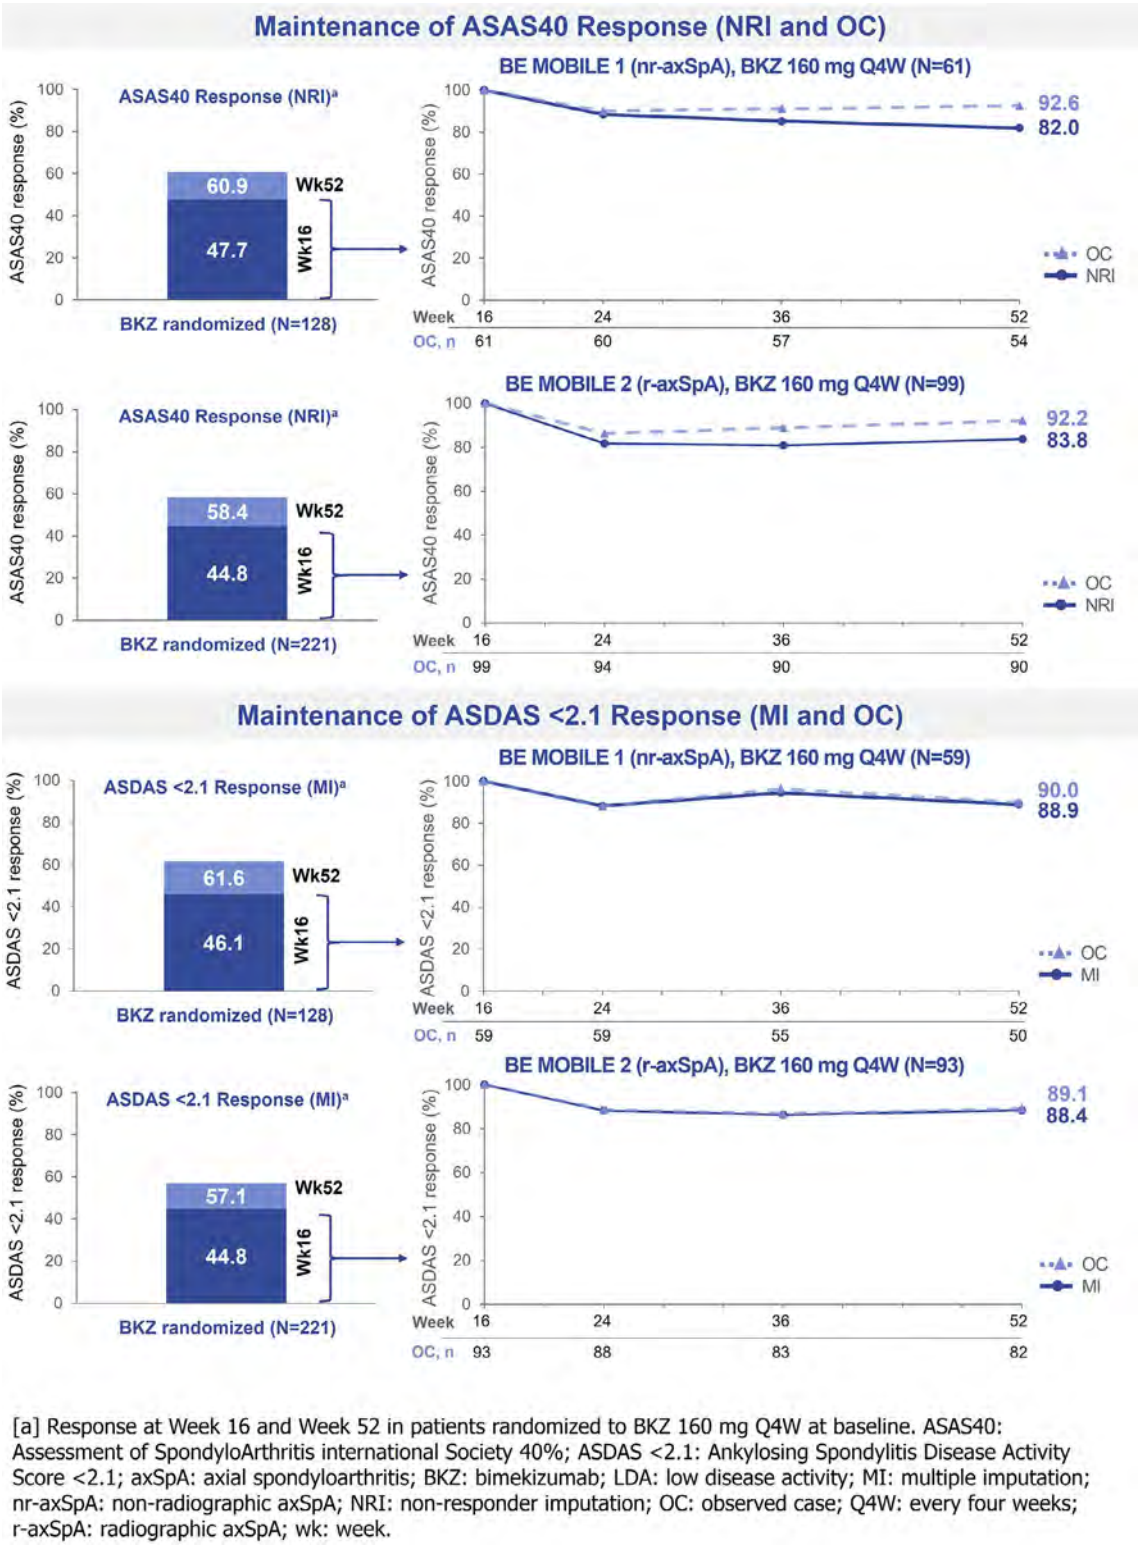
Background/Purpose: Axial spondyloarthritis (axSpA) is a chronic rheumatic disease which requires optimal management and disease control. Patients (pts) can experience loss of response in the long term and maintenance of response is an internationally recommended treatment target.[1]

Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits IL-17F in addition to IL-17A, has demonstrated sustained clinical efficacy to Week (Wk) 52 in pts across the full disease spectrum of axSpA in the phase 3 studies BE MOBILE 1 and 2.[2]

Here, we report the maintenance of stringent clinical responses through 1 year of treatment with BKZ in pts with non-radiographic axSpA (nr-axSpA) and radiographic-axSpA (r-axSpA, i.e., AS).[3]

Methods: In BE MOBILE 1 (NCT03928704; nr-axSpA; pts met ASAS criteria for axSpA) and BE MOBILE 2 (NCT03928743; r-axSpA; pts fulfilled ASAS and modified New York criteria for r-axSpA), pts were randomized to receive subcutaneous BKZ 160mg every 4 wks (Q4W) or placebo (PBO) to Wk 16. From Wks 16–52, all pts received BKZ 160mg Q4W.[4,5]

Assessment of SpondyloArthritis international Society ≥40% improvement (ASAS40) and Ankylosing Spondylitis Disease Activity Score (ASDAS) < 2.1 (low disease activity [LDA]) or < 1.3 (inactive disease [ID]) responses to Wk 52 were assessed among BKZ-randomized pts who responded at Wk 16. Non-responder imputation (NRI), and multiple imputation (MI) were



[a] Response at Week 16 and Week 52 in patients randomized to BKZ 160 mg Q4W at baseline. ASAS40: Assessment of SpondyloArthritis international Society 40%; ASDAS <2.1: Ankylosing Spondylitis Disease Activity Score <2.1; axSpA: axial spondyloarthritis; BKZ: bimekizumab; LDA: low disease activity; MI: multiple imputation; nr-axSpA: non-radiographic axSpA; NRI: non-responder imputation; OC: observed case; Q4W: every four weeks; r-axSpA: radiographic axSpA; wk: week.

Figure. Maintenance of ASAS40 and ASDAS LDA (ASDAS <2.1) through 52 weeks of BKZ 160 mg Q4W among Week 16 ASAS40 and ASDAS LDA responders, respectively, from BE MOBILE 1 and 2

used for missing ASAS40 and ASDAS data, respectively. Observed case (OC) data and Wk 16 and Wk 52 responder rates for all BKZ-randomized pts (NRI or MI) are also reported.

The number of treatment-emergent adverse events (TEAEs) to Wk 52 are reported for pts who received ≥1 dose of BKZ.

Results: A total of 128 and 221 pts were randomized to BKZ 160mg Q4W in BE MOBILE 1 and 2, respectively. At Wk 16, 47.7% and 44.8% of these pts achieved the primary endpoint, ASAS40, and this increased to 60.9% and 58.4% at Wk 52 (NRI, **Figure**). Of pts that achieved ASAS40 at Wk 16, 82.0% and 83.8% maintained this response at Wk 52 (NRI, **Figure**).

ASDAS LDA was achieved by 46.1% and 44.8% of BKZ-randomized pts at Wk 16 of BE MOBILE 1 and 2, respectively; this increased to 61.6% and 57.1% at Wk 52 (MI, **Figure**). Of pts that achieved ASDAS LDA at Wk 16, 88.9% and 88.4% maintained this response at Wk 52 (MI, **Figure**).

At Wk 16 of BE MOBILE 1 and 2, ASDAS ID was achieved by 18.8% and 16.4% of BKZ-randomized pts, respectively; and this increased to 25.2% and 23.4% at Wk 52 (MI). Among Wk 16 ASDAS ID responders, ASDAS ID was maintained by 79.2% and 75.1% at Wk 24, 85.3% and 71.7% at Wk 36, and 88.0% and 58.7% at Wk 52 (MI).

To Wk 52 of BE MOBILE 1 and 2, 183/244 (75.0%) and 249/330 (75.5%) pts reported ≥1 TEAE whilst receiving BKZ, respectively; 9 (3.7%) and 20 (6.1%) reported serious TEAEs.

Conclusion: Dual inhibition of IL-17F and IL-17A with BKZ provided robust maintenance of stringent clinical responses from Wk 16 to Wk 52 across the full disease spectrum of axSpA.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Acute anterior uveitis (AAU) is the most common extra-musculoskeletal manifestation in axial spondyloarthritis (axSpA), affecting more than a third of patients. However, long-term interventional placebo-controlled studies are lacking due to ethical challenges. This study aimed to evaluate anterior uveitis flares rate in patients with axSpA who are at high risk of recurrent uveitis when treated with the PEGylated Fc-free TNF inhibitor certolizumab pegol (CZP) compared with standard non-biologic care.

Methods: In the C-VIEW study (NCT03020992), CZP was administered to patients with a high risk of uveitis flares (i.e., those with active axSpA, human leukocyte antigen-B27 [HLA-B27] positivity, and a history of recurrent AAU [≥2 AAU flares in total; ≥1 in the year prior to baseline]). This was an open-label, multicenter study where patients received CZP for 96 weeks; data up to Week 48 were used in the present analysis. The number of AAU flares in C-VIEW were compared to those seen in matched high-risk patients with non-biologic standard care from two North American axSpA centers who were followed up for 48 weeks. Inverse probability weighting (IPW) was performed to adjust for potential confounders, followed by Poisson regression, adjusted for follow-up time, to test the effect of treatment with CZP.

Results: A total of 89 patients received CZP and completed the C-VIEW study, while 66 bio-naïve patients (40 from the University of California, San Francisco and 26 from the University of Toronto) qualified as comparator with no exposure to biologic therapy during the 48-week follow-up period. All patients were HLA-B27 positive and had at least one episode of AAU before the baseline visit. Symptom duration and baseline CRP levels were similar in the two groups. Following IPW, there were no statistically significant differences in mean BASDAI and distribution of ASDAS disease activity states at baseline between the CZP treatment and comparator groups. Conventional synthetic DMARD use was similar between groups at baseline and during follow-up. The mean number of AAU flares (mean ± standard deviation) was significantly lower ($p < 0.001$) with CZP (0.42±0.81) than in the matched comparator population (1.3±1.47). In the final model after IPW, there was an 87% reduction in AAU flares ($p \leq 0.001$) associated with CZP treatment (**Table**).

Table. Results of the final model after IPW

	AAU flares, mean (SD)	p value	RR	95% CI	Bootstrap 95% CI
CZP (n=89)	0.42 (0.81)	–	–	–	–
Comparator (n=66)	1.3 (1.47)	**<0.001**	0.13	(0.08, 0.24)	(0.05, 0.33)

IPW was performed to adjust for potential confounders, followed by Poisson regression, adjusted for follow-up time. All patients were HLA-B27 positive and had a history of uveitis with at least one episode in the preceding year. AAU: acute anterior uveitis; CI: confidence interval; CZP: certolizumab pegol; IPW: Inverse probability weighting; RR: relative risk ratio; SD: standard deviation; SE: standard error.

Conclusion: This matched control study supports the benefit of CZP over standard non-biologic treatment in reducing anterior uveitis flares among high-risk patients with axSpA, highlighting its potential as a promising therapeutic option in managing this debilitating ocular manifestation in axSpA.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

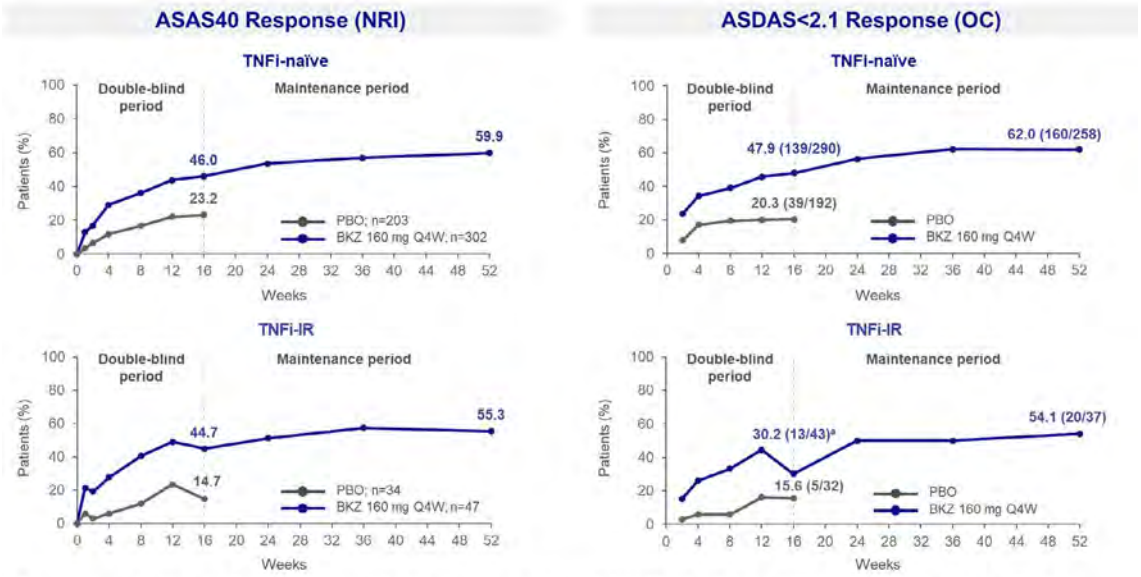
Background/Purpose: In patients (pts) with axial spondyloarthritis (axSpA), tumor necrosis factor inhibitors (TNFi) are the usual first line biologic treatment, yet many pts may experience loss of response over time, and some are intolerant to TNFis.[1] Typically, response to second line biologics is limited in TNFi-inadequate responders (IR).

Bimekizumab (BKZ) is a monoclonal IgG1 antibody that selectively inhibits IL-17F in addition to IL-17A. In the phase 3 BE MOBILE 1 and 2 studies, BKZ treatment resulted in rapid and sustained improvements in efficacy outcomes through 52 weeks (wks) in pts with active non-radiographic (nr-)axSpA and radiographic (r-)axSpA (i.e., AS).[2,3] In studies of BKZ in psoriatic arthritis, similar efficacy between TNFi-naïve and TNFi-IR pts were observed.[4] Here, we report the efficacy of BKZ in TNFi-naïve or -IR pts with active nr-axSpA and r-axSpA through Wk 52 across multiple key endpoints.

Methods: In BE MOBILE 1 (nr-axSpA; NCT03928704) pts met Assessment of SpondyloArthritis international Society (ASAS) classification criteria and in BE MOBILE 2 (r-axSpA; NCT03928743) pts fulfilled modified New York and ASAS criteria. Pts were randomized to receive subcutaneous BKZ 160 mg every 4 wks (Q4W) or placebo (PBO) then BKZ 160 mg Q4W from Wk 16. This post hoc analysis reports pooled mean efficacy data, including disease activity, MRI inflammation,

physical function, and quality of life (QoL), through Wk 52 of BE MOBILE 1 and 2, stratified by TNFi status (naïve/IR). TNFi-IR pts are defined as those who experienced loss of efficacy, contraindication or intolerance to prior TNFi treatment.

Results: This pooled analysis included 505 TNFi-naïve and 81 TNFi-IR pts. 302/505 (59.8%) TNFi-naïve and 47/81 (58.0%) TNFi-IR pts were randomized to BKZ.



Data are pooled from BE MOBILE 1 and 2. Data reported using OC (ASDAS <2.1) or NRI (ASAS40). Data from PBO-randomized patients not included from Wk 16 onwards. [a] 7 patients were identified as being responders at Week 12 and non-responders at Week 16; all were male and 6 were patients with r-axSpA. Of these participants, 6 became responders again at Week 24. All ASDAS differences in these patients between Week 12 and Week 16 were less than 1. ASAS40: Assessment of SpondyloArthritis international Society 40 response; ASDAS<2.1: Ankylosing Spondylitis Disease Activity Score <2.1; BKZ: bimekizumab; IR: inadequate responder; LDA: low disease activity; NRI: non-responder imputation; OC: observed case; PBO: placebo; Q4W: every four weeks; TNFi: tumor necrosis factor inhibitor.

Figure. Achievement of ASAS40 and ASDAS<2.1 (LDA) over 52 weeks in TNFi-IR and TNFi-naïve patients, pooled across BE MOBILE 1 and 2

Table. Pooled efficacy endpoints across BE MOBILE 1 and 2 in TNFi-naïve and -IR patients

	Week 16				Week 52	
	BE MOBILE 1 and 2 TNFi-naïve		BE MOBILE 1 and 2 TNFi-IR		BE MOBILE 1 and 2 TNFi-naïve	BE MOBILE 1 and 2 TNFi-IR
	PBO N=203	BKZ 160 mg Q4W N=302	PBO N=34	BKZ 160 mg Q4W N=47	BKZ 160 mg Q4W N=302	BKZ 160 mg Q4W N=47
ASDAS-CRP CfB [MI] mean (SE)	−0.7 (0.1)	−1.5 (0.1)	−0.6 (0.1)	−1.6 (0.1)	−1.8 (0.1)	−1.9 (0.2)
BASDAI CfB [MI] mean (SE)	−1.7 (0.1)	−3.0 (0.1)	−1.6 (0.4)	−2.7 (0.3)	−3.6 (0.1)	−3.7 (0.3)
SPARCC MRI SIJ CfB [OC][a] mean (SD)	−0.9 (7.3)[b]	−5.3 (8.4)[c]	1.4 (6.0)[d]	−5.6 (13.4)[e]	−5.9 (9.1)[f]	−6.9 (12.2)[e]
Berlin MRI Spine CfB [OC][a] mean (SD)	−0.2 (1.5)[g]	−1.4 (3.2)[h]	0.4 (1.3)[i]	−0.5 (1.9)[e]	−1.7 (3.6)[j]	−1.2 (2.1)[e]
BASFI CfB [MI] mean (SE)	−1.1 (0.1)	−2.3 (0.1)	−0.5 (0.3)	−2.2 (0.3)	−2.8 (0.1)	−2.9 (0.3)
Nocturnal spinal pain CfB [MI] mean (SE)	−1.7 (0.2)	−3.4 (0.2)	−2.1 (0.5)	−3.3 (0.3)	−4.1 (0.2)	−3.9 (0.3)
ASQoL CfB [MI] mean (SE)	−2.8 (0.3)	−5.1 (0.3)	−2.4 (0.6)	−4.2 (0.6)	−5.8 (0.3)	−4.7 (0.6)

Data are pooled from BE MOBILE 1 and 2. Data reported using OC or MI. Data from PBO-randomized patients not included from Wk 16 onwards. [a] Only patients enrolled in the SIJ and spine MRI substudy and with ≥1 post-baseline record for the respective variable are included; [b] n=95; [c] n=144; [d] n=13; [e] n=15; [f] n=130; [g] n=94; [h] n=140; [i] n=12; [j] n=127. ASDAS-CRP: Ankylosing Spondylitis Disease Activity Score C-reactive protein; ASQoL: Ankylosing Spondylitis Quality of Life; BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; BASFI: Bath Ankylosing Spondylitis Functional Index; BKZ: bimekizumab; CfB: change from baseline; IR: inadequate responders; MI: multiple imputation; MRI: magnetic resonance imaging; OC: observed case; PBO: placebo; Q4W: every four weeks; SD: standard deviation; SE: standard error; SIJ: sacroiliac joints; SPARCC: Spondylarthritis Research Consortium of Canada; TNFi: tumor necrosis factor inhibitor.

At Wk 16, the proportion of pts achieving ASAS40 and AS Disease Activity Score (ASDAS)< 2.1 (low disease activity) were higher in BKZ-randomized TNFi-naïve/-IR pts vs PBO. In both TNFi-naïve/-IR continuous BKZ-treated pts, responses were similar and increased to Wk 52 (**Figure**). Similar substantial reductions from baseline in ASDAS-CRP and MRI inflammation by Wk 16 were also achieved with BKZ vs PBO in both TNFi-naïve and IR pts; in continuous BKZ-treated pts this was sustained or further improved through 52 wks. Comparable improvements in physical function, nocturnal spinal pain and ASQoL were observed through 52 wks with BKZ in TNFi-naïve/-IR pts(**Table**).

Conclusion: Across the full disease spectrum of axSpA, BKZ treatment resulted in clinically relevant improvements in key efficacy outcomes vs PBO, including suppression of inflammation and improvements in physical function and QoL, regardless of prior TNFi exposure. The improvements with BKZ at Wk 16 were sustained to Wk 52. **References:1.** Noureldin B. Rheumatology (Oxford). 2018;57(suppl 6); **2.** Boel A. Ann Rheum Dis. 2019;78:1545–9; **3.**Baraliakos X. SESSION INFORMATION

Session Date: Sunday, November 12, 2023

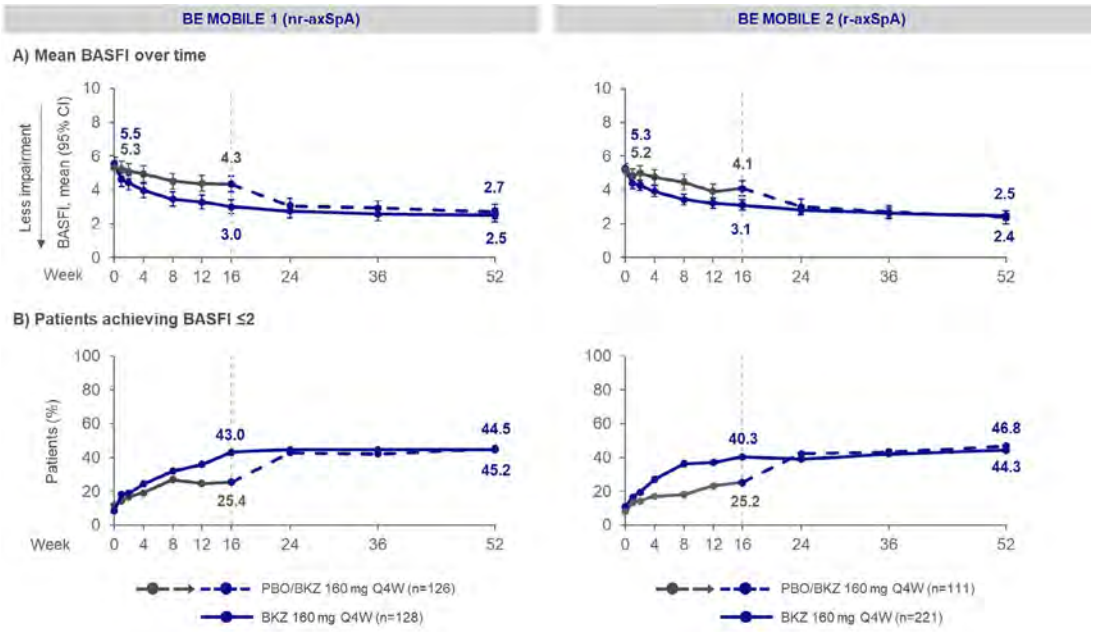
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

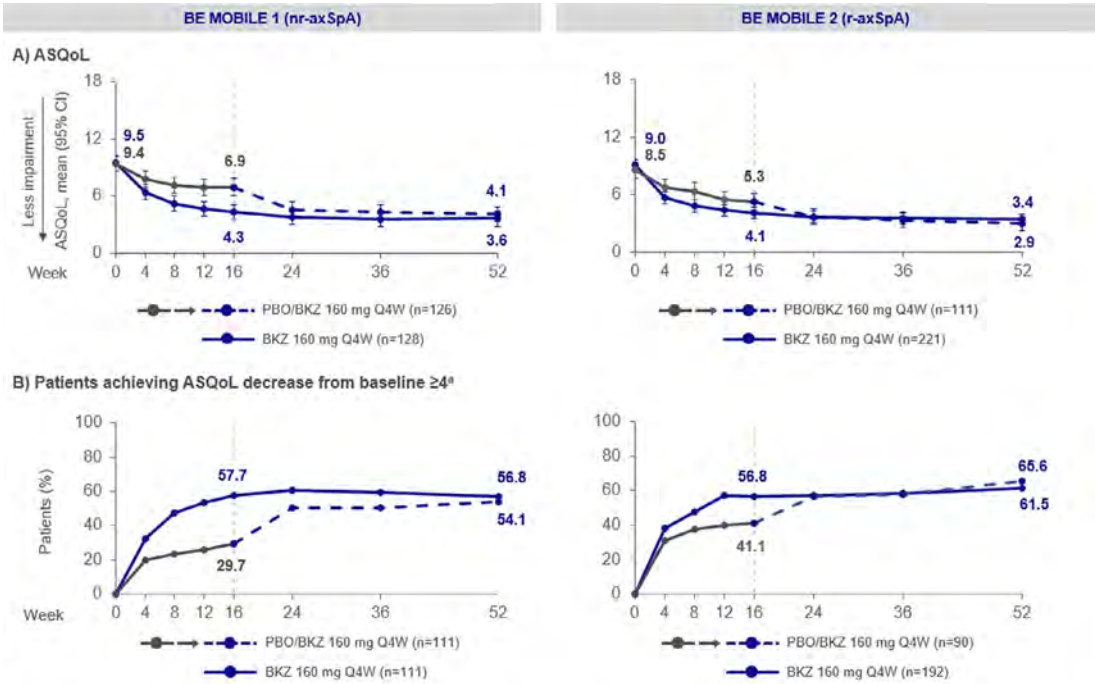
Background/Purpose: Axial spondyloarthritis (axSpA) severely impairs physical function and health-related quality of life (HRQoL).[1] Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits IL-17F in addition to IL-17A, met all primary and ranked secondary endpoints at Week (Wk) 16 in patients (pts) with axSpA in the phase 3 studies BE MOBILE 1 and 2; efficacy was sustained to Wk 52.[2]

Here, we assess the impact of BKZ on physical function and HRQoL in pts with axSpA to Wk 52.



Randomized set. Mean BASFI reported with MI and proportion of patients achieving BASFI ≤2 with NRI. Error bars represent 95% CI. BASFI scores range from 0–10 with a higher score reflecting greater impact on physical function. BASFI: Bath Ankylosing Spondylitis Functional Index; BKZ: bimekizumab; CI: confidence interval; HRQoL: health-related quality of life; MI: multiple imputation; nr-axSpA: non-radiographic axial spondyloarthritis; NRI: non-responder imputation; PBO: placebo; Q4W: every 4 weeks; r-axSpA: radiographic axial spondyloarthritis.

Figure 1. (A) Mean BASFI (MI) and (B) proportion of patients achieving BASFI score ≤2 (NRI) to 52 weeks



Randomized set. Mean ASQoL reported with MI and proportion of patients achieving ASQoL improvement ≥4 with NRI. ASQoL scores range from 0–18 with a higher score reflecting greater impact on HRQoL. [a] Reported for patients with baseline ASQoL score ≥4. ASQoL: Ankylosing Spondylitis Quality of Life Questionnaire; BKZ: bimekizumab; HRQoL: health-related quality of life; MI: multiple imputation; nr-axSpA: non-radiographic axial spondyloarthritis; NRI: non-responder imputation; PBO: placebo; Q4W: every 4 weeks; r-axSpA: radiographic axial spondyloarthritis.

Figure 2. (A) Mean ASQoL (MI) and (B) ASQoL improvement of ≥4 points (NRI) from baseline to Week 52

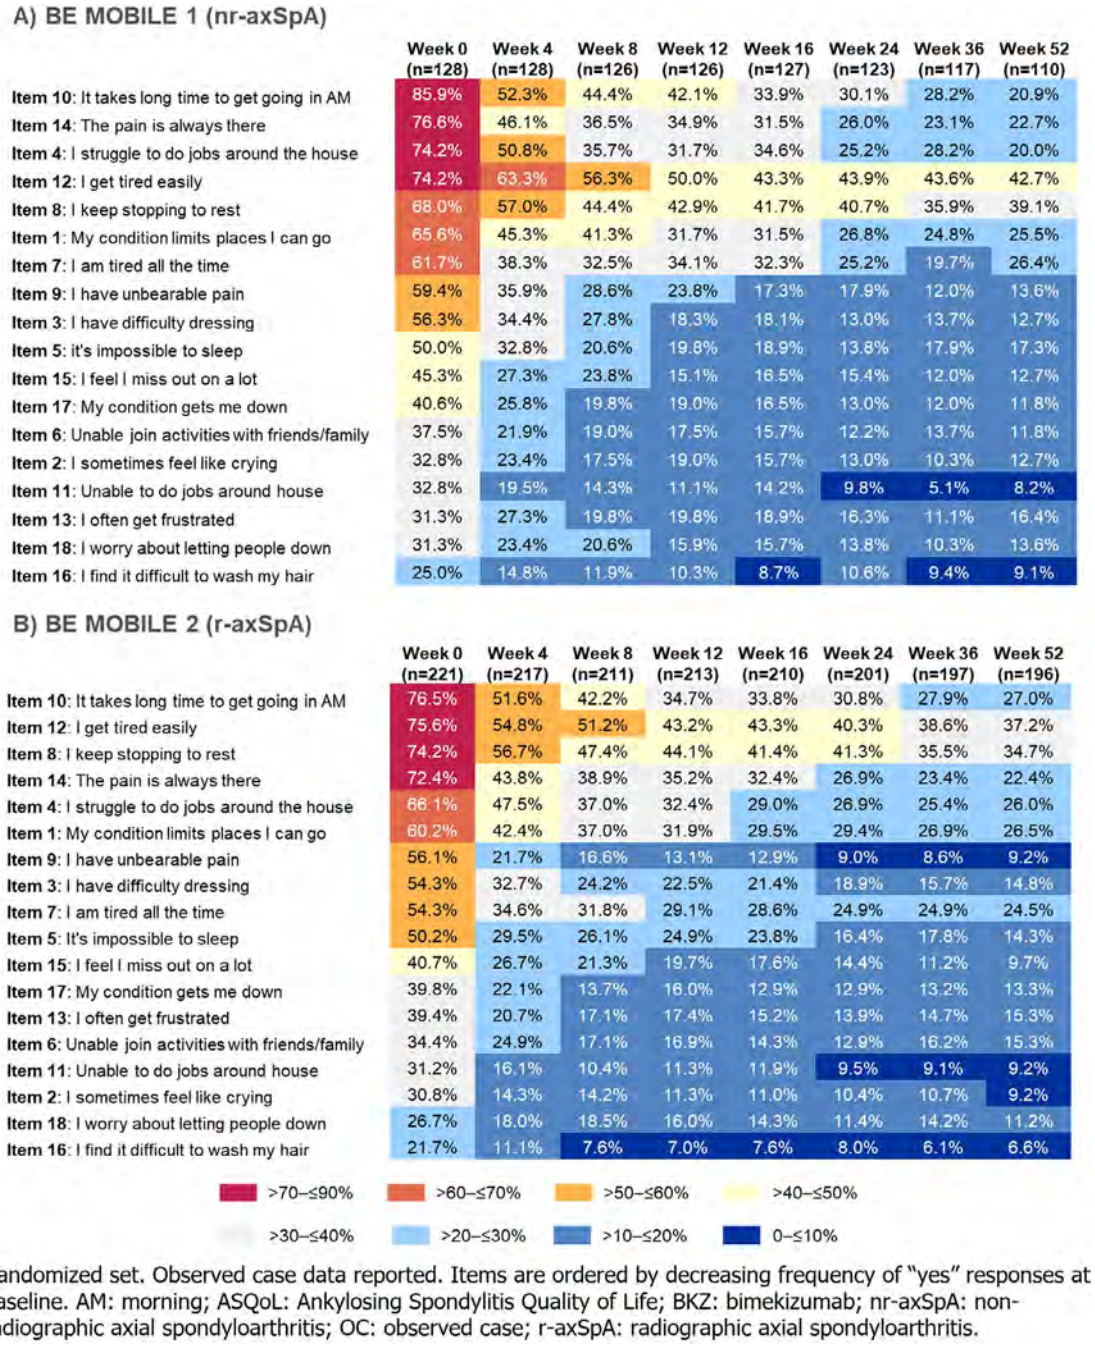


Figure 3. Proportion of BKZ-randomized patients providing "yes" responses to individual ASQoL items (OC)

Methods: BE MOBILE 1 (NCT03928704; non-radiographic [nr-] axSpA) and 2 (NCT03928743; radiographic [r-] axSpA; i.e., AS)[3] were randomized, placebo (PBO)-controlled trials comprising a 16-wk double-blind period followed by a 36-wk maintenance period. Pts were randomized to subcutaneous BKZ 160 mg every 4 wks (Q4W) or PBO; from Wk 16 PBO-randomized pts switched to BKZ 160 mg Q4W (PBO/BKZ). Physical function was assessed by BASFI (0–10) and HRQoL by AS quality of life questionnaire (ASQoL; 0–18).

We report mean BASFI and ASQoL scores to Wk 52 with multiple imputation (MI), and proportion of pts achieving low BASFI score (≤2) and clinically relevant ASQoL improvement (≥4-point reduction from baseline [BL])[4] with non-responder imputation. Proportion of BKZ-randomized pts impacted by each ASQoL item (i.e., responded "yes") to Wk 52 is reported as observed.

Results: 254 pts with nr-axSpA (BKZ: 128; PBO: 126) and 332 with r-axSpA (BKZ: 221; PBO: 111) were randomized. Mean BL BASFI and ASQoL indicated impaired physical function and HRQoL (**Figure 1A, 2A**).

At Wk 16, significantly greater reductions from BL (i.e., improvement) in BASFI and ASQoL were observed in BKZ-treated pts vs PBO ($p< 0.001$; reference-based MI). Mean scores remained low or decreased at Wk 52 in both BKZ-randomized vs PBO/BKZ pts for BASFI (nr-axSpA: 2.5 vs 2.7; r-axSpA: 2.5 vs 2.4) and ASQoL (3.6 vs 4.1; 3.4 vs 2.9; **Figure 1A, 2A**).

A higher proportion of BKZ- vs PBO-treated pts achieved BASFI ≤2 and ≥4 ASQoL reduction from BL at Wk 16; these proportions were sustained or improved to Wk 52, and were similar among BKZ-randomized vs PBO/BKZ pts for BASFI ≤2 (nr-axSpA: 44.5% vs 45.2%; r-axSpA: 44.3% vs 46.8%) and ≥4 ASQoL reduction from BL (56.8% vs 54.1%; 61.5% vs 65.6%; **Figure 1B, 2B**).

ASQoL items impacting ≥66% of BKZ-randomized pts with nr-axSpA and r-axSpA at BL were items 10 (it takes a long time to get going in the morning; 85.9% and 76.5%), 14 (pain is always there; 76.6% and 72.4%), 12 (I get tired easily; 74.2% and 75.6%), 4 (I struggle to do jobs around the house; 74.2% and 66.1%), and 8 (I keep stopping to rest; 68.0% and 74.2%). Reductions from BL were seen in the proportion of pts responding "yes" to each ASQoL item through 52 wks of BKZ treatment; the greatest reductions at Wk 52 were in items 10 (nr-axSpA: –65.0%; r-axSpA: –49.5%) and 14 (–53.9%; –50.0%; **Figure 3**).

Conclusion: BKZ resulted in high proportions of pts achieving improvements in physical function and HRQoL through 52 wks of treatment across the full disease spectrum of axSpA.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Pain and fatigue have been identified by patients (pts) as key features of PsA, driving the impact on their health-related quality of life.[1] Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits IL-17F in addition to IL-17A, has demonstrated meaningful improvements in pain and fatigue outcomes to 16 weeks (wks) vs placebo (PBO) in pts with active PsA.[2,3] In this study, pt-reported pain and fatigue outcomes are reported up to 1 year from two phase 3 studies of BKZ in pts with PsA.

Methods: BE OPTIMAL (NCT03895203) and BE COMPLETE (NCT03896581) were two phase 3 trials assessing BKZ in pts with active PsA who were biologic DMARD (bDMARD)-naïve or had inadequate response or intolerance to 1–2 TNF-α inhibitors (TNFi-IR), respectively. Both trials had a 16-wk double-blind, PBO-controlled phase.

Table. Patient-reported symptoms at Week 40/52

	BE OPTIMAL (bDMARD-naïve)		BE COMPLETE (TNFi-IR)	
Patient-reported symptom	PBO/BKZ 160 mg Q4W (n=281)	BKZ 160 mg Q4W (n=431)	PBO/BKZ 160 mg Q4W (n=133)	BKZ 160 mg Q4W (n=267)
	Week 52		Week 40[a]	
FACIT-Fatigue CfB,[b] mean (SE) [MI]	5.5 (0.5)	5.3 (0.4)	4.4 (0.8)	6.0 (0.6)
FACIT-Fatigue MCID,[c] n (%) [NRI]	139 (53.7)	208 (54.3)	54 (44.6)	146 (58.4)
	Week 52		Week 52	
PtAAP CfB,[d] mean (SE) [MI]	−31.8 (1.8)	−30.4 (1.4)	−29.5 (2.7)	−32.2 (1.8)
PtAAP 30, n (%) [NRI]	188 (66.9)	277 (64.3)	71 (53.4)	178 (66.7)
PtAAP 50, n (%) [NRI]	158 (56.2)	243 (56.4)	56 (42.1)	152 (56.9)
PtAAP 70, n (%) [NRI]	122 (43.4)	183 (42.5)	42 (31.6)	117 (43.8)

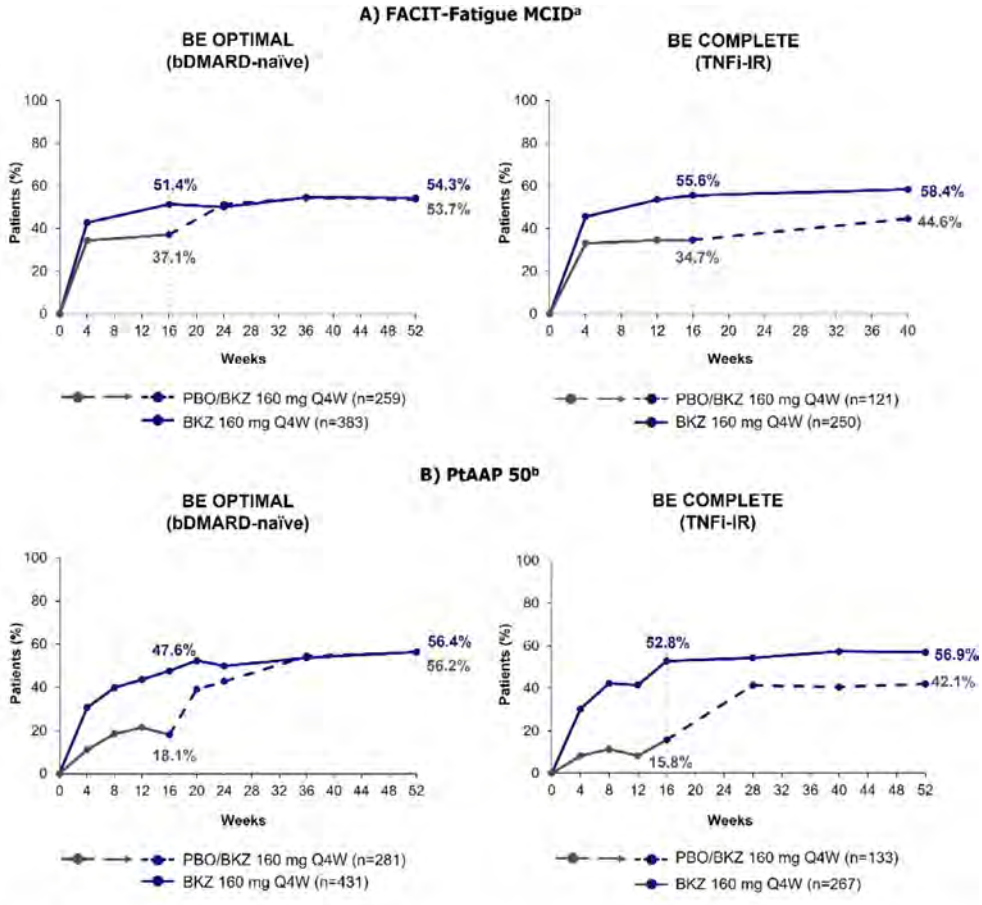
Randomized set. FACIT-Fatigue score ranges from 0 to 52, with 52 being the best possible score. PtAAP 100 mm VAS ranges from 0 to 100, with 0 representing "no pain" and 100 "most severe pain". PtAAP 30/50/70 represent clinically important improvements in patient-reported pain. [a] FACIT-Fatigue values not collected at Week 52; only collected to Week 40 for BE COMPLETE; [b] OC FACIT-Fatigue baseline values (SD): BE OPTIMAL PBO/BKZ 36.0 (10.2) BKZ 37.8 (9.6); BE COMPLETE PBO/BKZ 36.3 (9.9) BKZ 35.3 (10.5); [c] FACIT-Fatigue MCID defined as score increase from baseline ≥4 in patients with FACIT-Fatigue ≤48 at baseline; BE OPTIMAL PBO/BKZ n=259; BKZ n=383; BE COMPLETE PBO/BKZ n=121; BKZ n=250; [d] OC PtAAP baseline values (SD) BE OPTIMAL PBO/BKZ 56.8 (23.2) BKZ 53.6 (24.3); BE COMPLETE PBO/BKZ 61.7 (24.6) BKZ 58.3 (24.2).

bDMARD: biologic DMARD; BKZ: bimekizumab; CfB: change from baseline; FACIT-Fatigue: Functional Assessment of Chronic Illness Therapy—Fatigue; MCID: minimum clinically important difference; MI: multiple imputation; NRI: non-responder imputation; OC: observed case; PBO: placebo; PtAAP 30/50/70: ≥30/50/70% improvement in Patient's Assessment of Arthritis Pain; Q4W: every 4 weeks; SD: standard deviation; SE: standard error; TNFi-IR: inadequate response or intolerance to TNF-α inhibitor; VAS: visual analog scale.

Pts in BE OPTIMAL were randomized 3:2:1 to subcutaneous (sc) BKZ 160 mg every 4 wks (Q4W), PBO, or reference (sc adalimumab [ADA] 40 mg Q2W). At Wk 16, PBO pts switched to receive BKZ until Wk 52 (PBO/BKZ); pts receiving BKZ or ADA continued their dosing until Wk 52. BE OPTIMAL ADA data are not reported here. Pts in BE COMPLETE were randomized 2:1 to sc BKZ 160 mg Q4W or PBO. Along with BE OPTIMAL Wk 52 completers, pts who completed Wk 16 of BE COMPLETE were eligible to enter an open-label extension, BE VITAL (NCT04009499); PBO pts switched to BKZ (PBO/BKZ) on entry (36 wks of BKZ treatment to Wk 52); BE COMPLETE plus BE VITAL is referred to as 'BE COMPLETE' hereafter.

Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-Fatigue) subscale Minimum Clinically Important Difference (MCID; ≥4-point improvement from baseline [BL]) and change from BL (CfB), along with Pt's Assessment of Arthritis Pain (PtAAP) CfB and clinically important improvements (≥30/50/70%), are reported up to 1 year. BE COMPLETE FACIT-Fatigue values were collected to Wk 40 only. Non-responder and multiple imputation (NRI, MI) were used for missing binary and continuous variables.

Results: Overall, 770/852 (90.4%) and 347/400 (86.8%) pts completed Wk 52 of BE OPTIMAL and BE COMPLETE, respectively.



Randomized set. [a] FACIT-Fatigue MCID defined as score increase from baseline ≥4 in patients with FACIT-Fatigue ≤48 at baseline; [b] PtAAP 100mm VAS ranges from 0 to 100, with 0 representing "no pain" and 100 "most severe pain"; PtAAP 50 represents a clinically important improvement in patient-reported pain. bDMARD: biologic DMARD; BKZ: bimekizumab; FACIT-Fatigue: Functional Assessment of Chronic Illness Therapy—Fatigue; MCID: minimum clinically important difference; NRI: non-responder imputation; PBO: placebo; PtAAP 50: ≥50% Improvement in Patient's Assessment of Arthritis Pain; Q4W: every 4 weeks; TNFi-IR: inadequate response or intolerance to TNF-α inhibitor.

Figure. (A) FACIT-Fatigue MCID and (B) PtAAP 50 responders up to Week 40/52 [NRI]

At Wk 16, BKZ-treated pts achieved greater improvements in pain and fatigue outcomes vs PBO pts (**Figure**); improvements were sustained from Wk 16 to Wk 52 on BKZ treatment. For PBO/BKZ pts, pain and fatigue outcomes improved following switch to BKZ (**Table**).

Of pts with FACIT-Fatigue ≤48 at BL, FACIT-Fatigue MCID was achieved by 208/383 (54.3%) BKZ and 139/259 (53.7%) PBO/BKZ pts at Wk 52 in BE OPTIMAL, and 146/250 (58.4%) BKZ and 54/121 (44.6%) PBO/BKZ pts at Wk 40 in BE COMPLETE (**Table**, **Figure**). At Wk 52, PtAAP 50 was achieved by 243/431 (56.4%) BKZ and 158/281 (56.2%) PBO/BKZ pts in BE OPTIMAL, and 152/267 (56.9%) BKZ and 56/133 (42.1%) PBO/BKZ pts in BE COMPLETE.

Conclusion: Treatment with BKZ resulted in sustained improvements in pt-reported pain and fatigue from Wk 16 up to 1 year in both bDMARD-naïve and TNFi-IR pts with active PsA, with clinically meaningful improvements observed in over half of pts. Improvements in pt-reported pain and fatigue were similar between the two studies, demonstrating consistent responses in bDMARD-naïve and TNFi-IR pts.

Abstract Number: 0528

Risk of Cardiovascular Disease Associated with Long-term Use of NSAIDs in Ankylosing Spondylitis

Seong-Kyu kim[1], Ji-Won kim[1], Jun Sik Yoon[2], bo young Kim[3], Hwajeong Lee[1], Sung-Hoon Park[1] and Jung-Yoon Choe[1], [1]Daegu Catholic University School of Medicine, Daegu, South Korea, [2]Busan Paik Hospital, Inje University College of Medicine, Busan, South Korea, [3]Daegu Catholic University Medical Center, Daegu, South Korea

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is associated with increased cardiovascular disease, but there are limited data as to whether prolonged treatment with non-steroidal anti-inflammatory drugs (NSAIDs) increases the cardiovascular risk in AS patients. We aimed to examine the risk of cardiovascular disease associated with long-term use of NSAIDs in a large real-world AS cohort.

Methods: A nationwide population-based cohort of patients with AS and matched controls without AS were analysed. The primary outcome was cardiovascular disease, a composite outcome of ischemic heart disease, stroke, or congestive heart failure. Long-term use of NSAIDs was defined as use of NSAIDs for more than 365 cumulative defined daily doses. The association between long-term use of NSAIDs and incident cardiovascular disease was examined using a multivariable Cox proportional hazards regression model in both AS and non-AS populations.

Results: Among 19,775 patients with AS and 59,325 matched controls without AS, there were 1,663 and 4,308 incident cases of cardiovascular disease, showing an incidence of 16.9 and 13.8 per 1,000 person-years, respectively. Long-term use of NSAIDs increased the risk of cardiovascular disease in non-AS controls (adjusted hazard ratio [aHR], 1.64; 95% CI, 1.48–1.82). In contrast, long-term use of NSAIDs did not increase the risk of cardiovascular disease in AS patients (aHR, 1.06; 95% CI, 0.94–1.20; adjusted for age, sex, socioeconomic status, body mass index, smoking status, hypertension, diabetes, hyperlipidemia, and tumor necrosis factor inhibitor use).

Conclusion: Prolonged NSAID treatment in AS patients may not be as harmful as in the general population regarding cardiovascular risk.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Individualized treatment strategies are of high importance in the treatment of patients with axial spondyloarthritis (axSpA). IL-17A inhibition has demonstrated good efficacy on axSpA. Nevertheless, approx. 30% of the patient will not achieve remission after initiation of systemic therapy. Therefore, the identification of patient characteristics leading to higher response rates to bDMARD treatments are important to guide treatment choice and its adjustments in clinical routine care to promote an improved outcome. An adapted machine learning approach (cluster analysis) is used to analyze baseline (BL) patient characteristics to detect clinical patterns of disease activity in axSpA patients treated with secukinumab (SEC) in a non-interventional trial.

Methods: Data from 621 patients enrolled in the German non-interventional AQUILA study with active axSpa, whose first SEC treatment occurred no more than 4 weeks prior to BL, was analyzed. All patients were included, irrespective of treatment response We identified patient groups by applying an extended version of the machine learning method of hierarchical density-based clustering (HDBSCAN) to BL data, where features included patient and disease characteristics variables as well as standardized patient-reported outcome (Table 1).Feature groups with high numbers of missing values were initially excluded, and subsequent clustering was performed to achieve the stepwise integration of all features. At each step, an additional feature group was included in a re-clustering using a complete subset of subjects. This led to a further split of some of the original clusters. For every final cluster, disease activity over the course of the study was visualized including patient and physician-derived assessments.

Results: The machine learning approach resulted in the categorization of 7 clusters of patients and outliers (n=139, cluster -1)(Fig.1). The primary focus of this analysis lies on medially relevant clusters, which exhibit similar characteristics including little prior and ongoing therapy, but differ in their sex (cluster 5: n=89, female; cluster 6: n=172, male, Fig. 2A). While women had a significantly higher subjective ASAS-HI (p=.003, Fig 2B), BASDAI was comparable in both groups at BL. At week

Table 1: Overview of dataset characteristics of 621 axSpA patients at baseline, across all 7 clusters. *Total n can differ from 621 in table, due to missing values; ** Chronic heart failure, stroke, or coronary heart disease

Baseline Criteria	Total n=621*
Age, [years] (median) (n=621)	47.8
BMI, [kg/m²] (median) (n=605)	26.9
Active smokers (n=545)	205
Ex-smokers (n=545)	70
bDMARD-naïve	227
Previous TNF	394
Previous IL-23	4
Previous csDMARDs	212
csDMARDs Concomitant	77
MTX Concomitant	61
Comorbidity: Depression (n=586)	70
Comorbidity: Uveitis (n=603)	35
Comorbidity: Cardiovascular** (n=609)	43
PhGA (median) (n=563)	6.2
PGA (median) (n=378)	6.1
ASAS (median) (n=549)	8.0
CRP [mg/dl] (median) (n=302)	5.0
BASDAI (median) (n= 510)	5.4

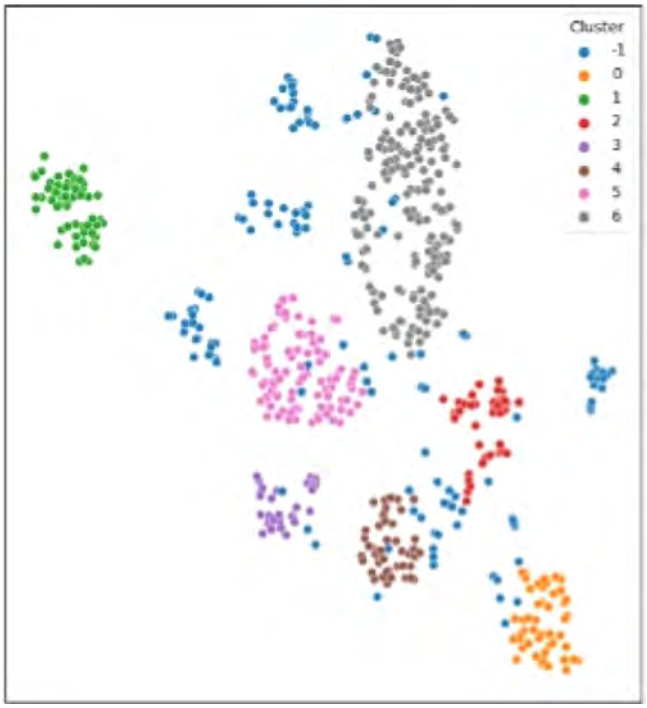

Figure 1 Result of multistage clustering of BL characteristics of 621 active axSpA patients. The clustering reveals 7 clusters and outliers (cluster –1). Important cluster characteristics: 5, predominantly female; 6, predominantly male. The scatterplot of the patient characteristics is created by the dimension reduction TSNE to 2 dimensions and thus has arbitrary units on the axes.

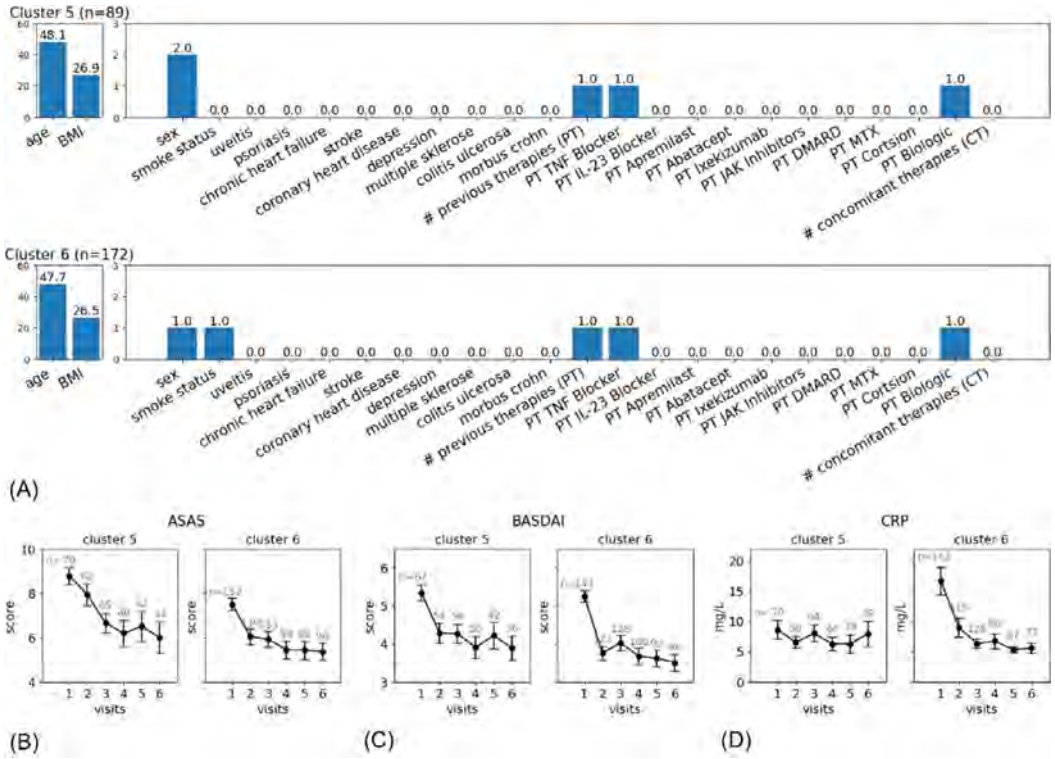

Figure 2 (A) Median BL characteristics of patients of cluster 5 and cluster 6 (B) Mean ASAS with standard error of patients of cluster 5 and cluster 6 over the course of the study up to W52 (visit 6). Cluster 5 has significantly higher values at BL (p=.003). (C) Mean BASDAI with standard error of patients of cluster 5 and cluster 6 over the course of the study up to W52 (visit 6). (D) Mean CRP with standard error of patients of cluster 5 and cluster 6 over the course of the study up to W52 (visit 6). Cluster 6 has significantly higher values at BL (p=.04) and a stronger improvement over trail (BL – V6, p=.001).

52 disease activity (ASAS-HI and BASDAI, Fig 2B, 2D) did not differ significantly between both groups. At BL CRP was significantly higher among male patients (p=.04, Fig 2C) and showed stronger improvement after one year of SEC treatment (p=.001, Fig 2C), leading to a comparable mean outcome (4.0 vs. 3.9).

Conclusion: We present a machine learning approach applied to the heterogeneous axSpA cohort from AQUILA. Differences were found in the two clusters which differ primarily in sex. At BL, female patients had higher subjective ASAS-HI while male axSpA patients showed higher CRP values whereas BASDAI was comparable. No differences in disease activity remain at week 52. This initial difference in disease perception between male and female groups converges to similar outcomes after 1 year of SEC therapy, emphasizing the treatment's effectiveness across sexes.

Impact of Upadacitinib on Wearable Device-Measured Physical Activity in Patients with Ankylosing Spondylitis from the SELECT-AXIS 2 Trial

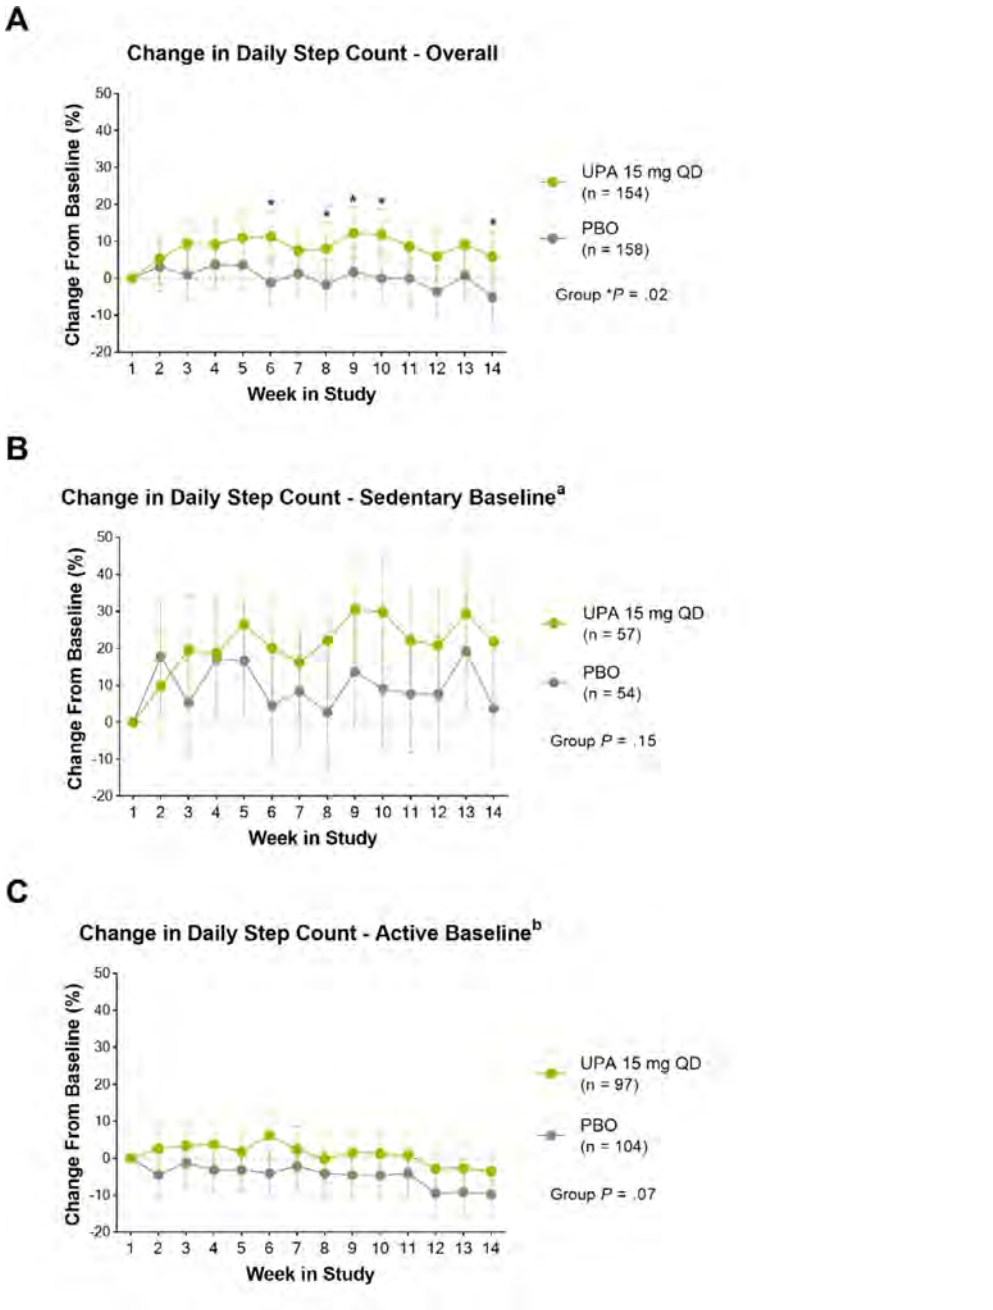
Jeffrey Curtis[1], Rebecca Grainger[2], Dan Webster[3], Jie Shen[4], Ana Biljan[5], Anna Shmagel[4], Peter Wung[4] and Philip J. Mease[6], [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Otago, Wellington, New Zealand, [3]AbbVie, Inc., Libertyville, IL, [4]AbbVie, Inc., North Chicago, IL, [5]AbbVie, Inc., Buffalo Grove, IL, [6]Swedish Medical Center/Providence St. Joseph Health and University of Washington School of Medicine, Seattle, WA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Physical activity is associated with reduced pain, improved mobility and physical function in people with ankylosing spondylitis (AS) and plays a crucial role in AS management. Despite this, the impact of pharmacologic interventions on physical activity is rarely measured or reported in clinical research. Wearable technology enables passive collection of objective physical activity data. We previously demonstrated high levels of wearable device adherence in patients with active AS in the SELECT-AXIS 2 phase 3 trial and reported this cohort's baseline physical activity patterns.[1] Here, we evaluated the effect of upadacitinib (UPA) vs placebo (PBO) on physical activity in this patient cohort through 14 weeks (wks).

Methods: Patients with active AS with an inadequate response or intolerance to biologic DMARDs (bDMARD-IR) were randomized to receive UPA 15 mg once daily or PBO.[2] As part of the study design, patients were required to wear a medical-grade wrist-worn actigraphy device during the 14-wk, PBO-controlled portion of the study. For inclusion in physical activity

analyses, patients needed to have at least 3 adherent days (defined as 16 hrs per day of device usage) out of the first 7 days after trial entry. The percent change from the first wk of the study (defined as baseline) in mean daily steps was evaluated over 14 wks. Changes in physical activity were also assessed in the subsets of patients who demonstrated an active (≥5000 steps per day per day) or sedentary lifestyle (< 5000 steps per day) at baseline. Group-wise nominal *P* values for



PBO, placebo; QD, once daily; UPA, upadacitinib.
[a]Defined as <5000 steps per day, as previously reported (Tudor-Locke C, et al. *Sports Med*. 2004;34:1–8).
[b]Defined as ≥5000 steps per day.
Group-wise nominal *P* values for comparison of UPA vs PBO groups were calculated by mixed model repeated measures (MMRM) analysis, with comparisons at each week performed by one-way analysis of variance (ANOVA). Fixed effects in the MMRM model included treatment, visit, treatment-by-visit interaction, and baseline step count.
*, indicates nominal statistical significance at *P* <.05 for UPA 15 mg vs PBO.

Figure 1. Percent Change From Baseline in Physical Activity Through 14 Weeks in the SELECT-AXIS 2 Study Cohort

comparison of UPA vs PBO groups through 14 wks were calculated by mixed model repeated measures analysis, with comparisons at each wk performed by one-way analysis of variance.

Results: Of 420 total patients, physical activity data were collected from 394 participants, and 312 (UPA, n=154; PBO, n=158) met minimal adherence criteria based on their first 7 days of study participation. In these patients, adherence was 83.5% of study days through 14 wks.[1] Patients treated with UPA had numerically higher mean daily step counts than those treated with PBO, with an 11-percentage point improvement vs PBO at wk 14 (mean absolute difference of 345 steps per day; $P < .05$) (**Fig 1A**). In patients with a sedentary lifestyle at baseline, a 22% improvement in the mean daily step count was observed with UPA from baseline to wk 14 compared to a 4% improvement with PBO (mean absolute difference of 264 steps per day), although these differences were not significant (**Fig 1B**). Patients with an active lifestyle at baseline also showed numerically better maintenance of their daily step counts over 14 wks with UPA compared to PBO where step counts declined over time (**Fig 1C**).

Conclusion: In bDMARD-IR AS patients, UPA treatment led to numerically greater improvements compared to PBO in physical activity as measured by a wearable device over 14 wks, especially in sedentary patients. These findings support the utility of passively collected actigraphy measurements to monitor the effect of a targeted therapy on physical activity and further exploring possible heterogeneous effects on step count depending on baseline activity.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: To investigate the effects of anti-tumor necrosis factor (anti-TNF) treatment on lipid profiles and identify risk factors for elevated total cholesterol (TC) after the treatment in ankylosing spondylitis (AS) patients.

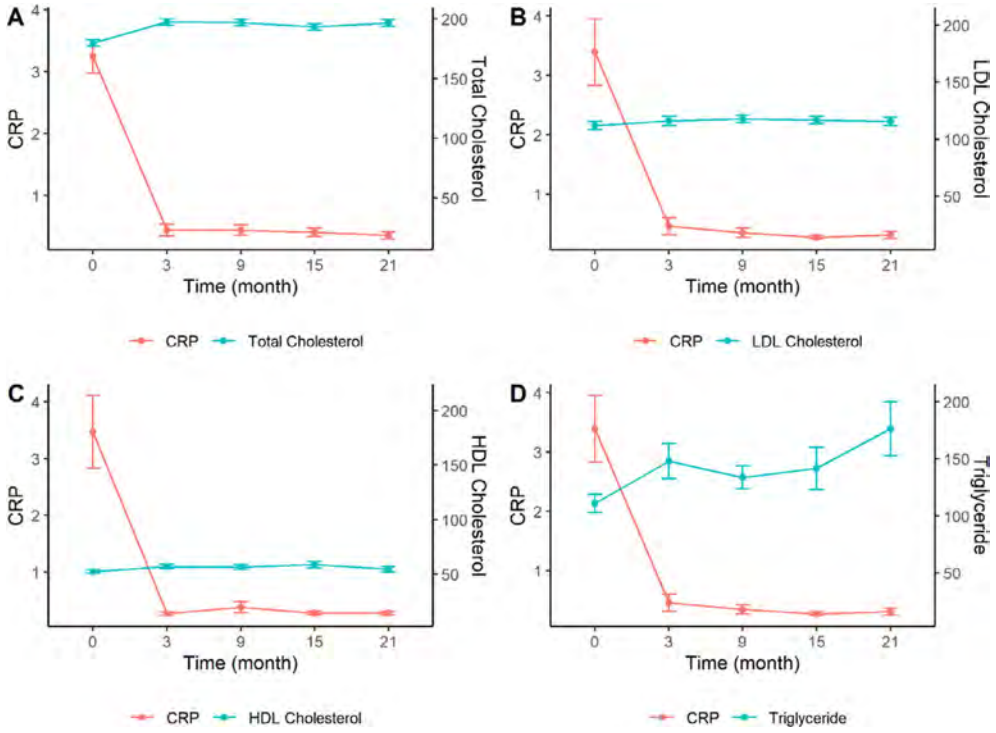

Figure 1. Changes in CRP and lipid particles after anti-TNF treatment. CRP, c-reactive protein; TNF, tumor necrosis factor; HDL, high-density lipoprotein; LDL, low-density lipoprotein

Table 1. Risk factors for increased total cholesterol after 3 months of anti-tumor necrosis factor treatment

TNF, tumor necrosis factor; mSASSS, modified stoke ankylosing spondylitis spinal score; BASDAI, Bath ankylosing spondylitis disease activity index; CRP, c-reactive protein; ESR, erythrocyte sedimentation rate; LDL, low-density lipoprotein; HDL, high-density lipoprotein; TG, triglyceride;

Methods: A retrospective cohort study analyzed AS patients who received first-line anti-TNF treatment. Patients excluding underage and those on lipid-lowering agents, with at least nine months of follow-up were included. One-way ANOVA with repeated measures assessed the impact of anti-TNF inhibitors on disease activity and lipid profile (TC, Low-density lipoprotein [LDL], High-density lipoprotein [HDL], and triglycerides [TG]). Univariable and multivariable linear regression identified risk factors for elevated TC after 3 months of anti-TNF treatment.

Results: A total of 320 AS patients were enrolled (78.4% male, mean age 34.3 ± 10.8 years). TC and TG levels significantly increased particularly within the first 3 months of anti-TNF treatment, while LDL and HDL levels did not show significant changes. Changes in inflammatory markers and lipid particles (TC, LDL, TG) were strongly correlated over time, but HDL showed no significant correlation. Older age, higher baseline ESR, and lower baseline LDL levels were identified as risk factors for elevated TC after 3 months of anti-TNF treatment.

Conclusion: In AS patients, anti-TNF treatment has been found to increase lipid particles, potentially due to its anti-inflammatory effects. Future research should explore the clinical implications of dyslipidemia, particularly the occurrence of cardiovascular events, following anti-TNF treatment in AS patients.

Factors Associated with Cause-specific Discontinuation of Long-term Anti-tumor Necrosis Factor Agent Use in Patients with Ankylosing Spondylitis

bora nam[1], Nayeon Choi[2], Bon San Koo[3], Jiyeong Kim[2], Ji-Hui Shin[1], Seunghun lee[4], kyung bin Joo[4] and Tae-Hwan Kim[1], [1]Department of Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [2]Biostatistical Consulting and Research Lab, Medical Research Collaborating Center, Hanyang University, Seoul, South Korea, [3]Inje University Seoul Paik Hospital, Seoul, South Korea, [4]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-tumor necrosis factor (TNF) agents have proven to be effective in treating Ankylosing spondylitis (AS). However, a significant number of patients discontinue or switch their anti-TNF agent for various reasons. Previous studies have been limited in scope, primarily focusing on drug retention rates or utilizing cohorts with short follow-up durations. The objective of this study is to investigate the factors associated with cause-specific discontinuation of long-term anti-TNF agent use in patients with AS.

Methods: AS patients who initiated the first-line anti-TNF agent between 2004 and 2018 and continued the treatment for at least 2 years were enrolled in the study. Patients with concomitant inflammatory bowel disease were excluded. The index date was defined as the date of initiation of the first-line anti-TNF agent, and the observation period lasted until the last visit, discontinuation of the first-line anti-TNF agent, or September 2022. The reasons for discontinuation of the first-line anti-TNF agent were categorized into 1) clinical remission, 2) lack of efficacy, 3) adverse events, and 4) other reasons including loss to follow-up, cost, or reimbursement issues. The cumulative incidence function curve was used to visualize the cumulative

failure rates over time for each specific reason. Univariate and multivariate cause-specific hazard models were utilized to identify factors associated with cause-specific discontinuation of the first-line anti-TNF agent.

Results: A total of 429 AS patients were included in the study, with 121 on adalimumab (ADA), 176 on etanercept (ETN), 89 on infliximab (INF), and 43 on golimumab (GLM). The median overall survival on the first-line anti-TNF agent was 10.6 (7.9-14.5) years. Among the patients, 103 (24.0%) discontinued the first-line anti-TNF agent, with 36 (34.9%) due to

inefficacy, 31 (30.1%) due to sustained clinical remission, 15 (14.6%) due to adverse events, and 21 (20.4%) due to other reasons. Patients treated with ETN had a lower risk of discontinuation due to sustained clinical remission compared to those on ADA (Hazard ratio [HR] 0.45 [0.21-0.99], P=0.048). Higher baseline BASDAI (HR 1.31 [1.04-1.65], P=0.023) and use of INF were associated with a higher likelihood of discontinuation due to inefficacy compared to ADA (HR 4.53 [1.45-14.16], P=0.009). Older age was related to an increased risk of discontinuation due to infection-related adverse events (HR 1.07 [1.02-1.12], P=0.005), and current smoking was a risk factor for discontinuation due to other reasons (HR 6.22 [1.82-21.28], P=0.004).

Conclusion: Several factors influencing cause-specific discontinuation of long-term anti-TNF treatment were identified in our study. Further investigation is needed to understand the underlying reasons for these phenomena. This knowledge is valuable for improving personalized medicine in the management of patients with AS, as it allows for more informed decision-making and the customization of treatment plans based on individual patient characteristics.

Remission in Axial Spondyloarthritis: Is There a Difference Between NSAIDs and b/tsDMARDs in Daily Practice?

Francesco Natalucci[1], Pauline KRUG[2], Angela DE SOUSA LEITE[2], Tatiana Sokolova[3], Patrick Durez[4], Maria S. Stoenoiu[2] and **Adrien NZEUSSEU TOUKAP**[5], [1]UCLouvain University, Sermoneta, Italy, [2]Cliniques Universitaires Saint-Luc, Brussels, Belgium, [3]Université Catholique de Louvain, Brussels, Belgium, [4]UCLouvain, Brussels, Belgium, [5]Cliniques universitaires Saint-Luc, St.-Lambrechts-Woluwe, Belgium

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Randomized-controlled trials (RCTs) done in axial spondyloarthritis (axSpA) patients have shown that remission in axSpA (including nonradiographic axSpA) patients treated without b/tsDMARDs (TNFα blockers, IL-17A blockers, JAK inhibitors)(BIOL) occurs infrequently. Few are known about remission rate (RR) with large cohort in daily clinical practice.

The purpose of this study was to assess the remission rate (RR) in axSpA patients in the real life, and to compare the RR in axSpA patients on NSAIDs to RR for those on BIOL.

Methods: This cross-sectional study reviewed clinical data from a single center from 01/2013 to 01/2023. Last visit available for clinical assessment was evaluated. Disease activity was measured using the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), and the Ankylosing Spondylitis Disease Activity Score (ASDAS) using the C-reactive protein. Remission was defined as BASDAI < 4 and ASDAS < 1,3.

Results: Data from 873 axSpA patients were reviewed. 529 were men (60.3 %). In the entire cohort, 653 BASDAI and 409 ASDAS were recorded. The RR according to the BASDAI was 46.7% (n =305), and 20.3 % for the ASDAS (n = 83). To look for the treatment-related RR, we stratified by the treatment (NSAIDs vs Biologics). We had 441 patients on NSAIDs

Table: Distribution of ASDAS values in both groups.

	ASDAS < 1.3	ASDAS ≥ 1.3 < 2.1	ASDAS ≥ 2.1 ≤3.5	ASDAS > 3.5
NSAIDs (n = 158)	N = 34 (21.5%)	N = 35 (22.2%)	N = 60 (38%)	N = 29 (18.4%)
BIOL (n = 251)	N = 49 (19.5%)	N = 58 (23.1%)	N = 93 (37.1%)	N = 51 (20.3%)

(250 men, 56.7 %) and 432 on BIOL (279 men, 64.6 %). 287 BASDAI were available for NSAIDs and 366 for BIOL. 132 patients on NSAIDs (46 %) and 173 on BIOL (47.3%) were in remission for BASDAI. Regarding ASDAS (table below), data from 158 patients on NSAIDs and 251 on BIOL were available. Out of them, 34 (21.5 %) and 49 (19.5 %) were in remission for NSAIDs and BIOL respectively. Chi-square test: p = NS.

Conclusion: Based on the ASDAS, The overall RR in our axSpA cohort was around 20%, even in the NSAIDs group. When we added patients on low disease activity (LDA) according to the ASDAS score, the overall proportion of patients with inactive disease or LDA was quite the same in both groups and slightly above 40 %. In daily practice, we should probably better define the remission in axSpA.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The recent recommendations from EULAR-ASAS for Axial Spondyloarthritis (AxSpA) call for decreasing biologic (b)DMARDs after an extended period of remission. This is especially relevant in underdeveloped countries, where patients pay out of pocket for their healthcare and are exposed to higher risks of opportunistic infections with bDMARD therapy. Despite sharing the same issues of infections and expenses, there is no clear evidence for the tapering strategy of targeted synthetic DMARDs in AxSpA. We aimed to study whether TOFA can be tapered in patients with AxSpa, assess the risk of flares, time to flare, and factors associated with flares.

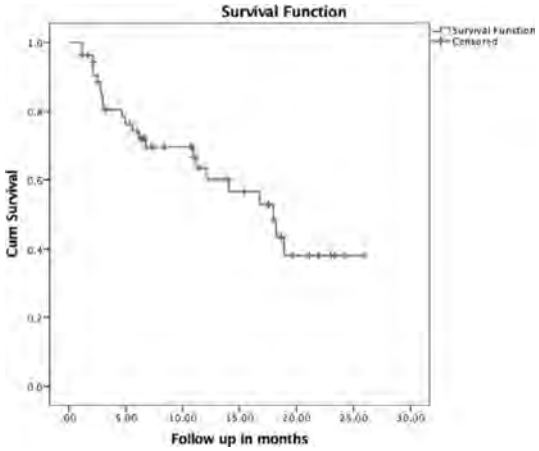
Methods: Patients with AxSpA (ASAS criteria) on tofacitinib (TOFA) in remission or low disease activity (ASDAS CRP < 2.1) state for at least three months, were gradually tapered off TOFA. The drug was tapered at the treating physician's discretion, with each visit accompanied by an evaluation of the disease activity. Co-treatment with conventional(c) DMARDs, but not bDMARDs was permitted. Tofacitinib was resumed at the previous dose in case of flares, defined at the treating physician's discretion.

Flare-free survival was visualized by Kaplan-Meir curves. To determine factors associated with flares, covariates with a p-value of < 0.2 on univariate analysis (age, radiographic disease, cDMARD use in the past, ASDAS CRP > 3.5 at baseline) were included for multivariate Cox regression modelling. Data are expressed as median and interquartile range.

Results: The study included 54 patients, aged 38 years(29.75–46.75), 75% males, and a disease duration of 6 (9–17.5) years. Three-fourths had radiographic disease, and 30 of 44 (68.1%) were HLA-B27 positive. Amongs the extra-articular features,uveitis was observed in 9(16.7%).

Before TOFA initiation, ASDAS-CRP was 3.1(2.4-3.5), 24 (44.4%) had used cDMARDs, and 20 (37%) had used bDMARDs. Reasons for shifting to TOFA were an inadequate response to cDMARD or bDMARD in 36 (66.7%) cases; financial considerations with bDMARD therapy in 14 (26%), and adverse drug reactions in four (7.4%). TOFA was started at a full dose of 70 mg/week in 47 (87%), and 41 (76 %) received concomitant sulfasalazine but no bDMARDs were used with TOFA.

ASDAS CRP was 0.3 (0.9-1.7) at 3 months (3-5.25) of full dose TOFA. During tapering, 23 (42.6%) patients flared, with the median time to flare being 18 months (CI 12.5-23.4)(Figure 1,2). All patients who flared re-attained remission after restoring the TOFA dose to the previous dose.



Kaplan Meir survival analysis with time from onset of TOFA dose tapering and flare as the event

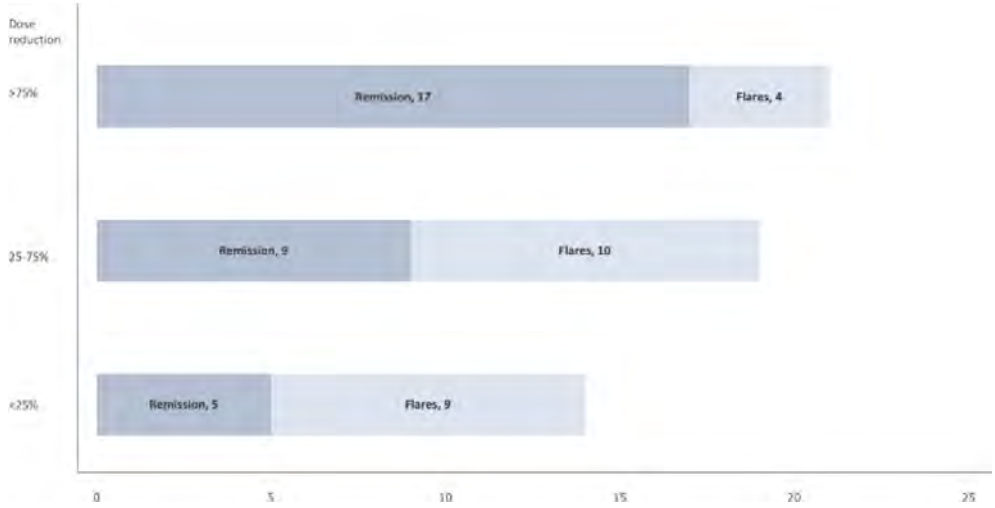


Figure 2: Outcomes stratified by dose tapering of Tofacitinib

At a median of 7.3 months (3-17.4) of TOFA tapering, 39 (70%) were in remission with4 (10.5%) on >75%, 32(84.2%) on 25-75% and 2(5.2%) on >25% of full TOFA dosage.

In multivariate Cox regression, radiographic disease [0.01, 7(1.6-31)], prior cDMARD [0.02, 0.3(0.1-0.8)] and ASDAS CRP >3.5 prior to initiation of TOFA [0.005, 3.4(1.4-8.1)] use were linked with flare.

Conclusion: This real-world data provides proof of concept that TOFA tapering is viable in the management of AxSpA. Flares can be managed by increasing the dose of TOFA to the previous effective level. This can pave the way for randomized controlled studies to determine the optimum tapering strategy, as well as long-term cohort studies to see the effects on radiographic progression.

Pharmacologic Treatment of Ankylosing Spondylitis in a Large Urban Medical Center: Effects of Socioeconomic Status, Race/Ethnicity and Sex

EA TROY[1], ZT Chan[1], WL GALLANTER[2], EM Adams[3], Mina Al-Awqati[2] and Huan Chang[1], [1]University of Illinois at Chicago; Jesse Brown VA Medical Center, Chicago, IL, [2]University of Illinois at Chicago, Chicago, IL, [3]Jesse Brown VA Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is estimated to affect up to 1,647,500 Americans, resulting in significant disability and lost productivity for affected individuals. Biologic medications reduce disease activity and improve functional outcome in those with AS, but they are expensive and may be difficult to access. Individuals of lower socioeconomic status (SES), minorities (specifically African American or Latinx), and women may be less likely to receive biologic treatment, resulting in poorer functional outcomes The objective of this study was two-fold: 1) to develop a multi-ethnic longitudinal AS cohort for analysis of clinical features, demographics, SES, race/ethnicity, sex and treatment patterns and 2) to analyze the effects of these factors on the prescription of a biologic agent.

Methods: Data from the electronic medical record of an urban academic health system were analyzed between January 1, 2010 and September 12, 2020.Subjects had at least one ambulatory encounter and diagnostic codes of M45 (ICD-10) or 720 (ICD-9). Independent variables included insurance information, address with zip code, race/ethnicity and sex. Social Deprivation Index (SDI) was utilized as a measure of SES. Patients were removed from the analysis if they were in a correctional facility or did not list a residential address in the chart. The dependent variable was prescription of at least one biologic medication. Multivariate logistic regression was performed using R Statistical Programming Software.

Results: Our cohort included 430 patients total; 423 were included in the multivariate analysis. Seven patients were removed due to lack of SDI information. Non-Hispanic Blacks made up 30% of the cohort, with Latinx and Non-Hispanic Whites representing 21% and 30% respectively (Fig 1). Women made up 37% of the cohort (Fig 2). Men were prescribed biologic agents more often than women. Non-Hispanic Blacks and Latinx had increased odds of receiving biologic therapy

compared with Non-Hispanic Whites. Insurance status and SDI did not affect the odds of receiving a biologic agent. The odds of receiving biologic therapy decreased 0.962 (CI 0.946, 0.978) with each year of age (Fig 3).

Conclusion: In a large multiethnic cohort of patients with AS, biologic therapy was prescribed more often for males, Non-Hispanic Blacks and Latinx. Low SES, measured by SDI, and insurance status did not affect the odds of receiving a biologic agent. This study suggests that SES did not prevent patients with AS from receiving biologic therapy. The reasons for differential prescribing by race/ethnicity would benefit from further study.

Session Date: Sunday, November 12, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Before COVID pandemic, rheumatologists were not confident with telehealth for the need to adquire new technology, need of specific training and poorer reimbursement (1). Two groups of rheumatoid arthritis (RA) patients have been identified in a study of PROMS-based telehealth use (2): the keen and the reluctant.

Explore the degree of acceptance of asynchronous telehealth followup with whatsapp platform chatbot among our controlled AxSPA patients under biological therapy, and to search for a patient profile more prone to telehealth consultation

Methods: A prospective study with retrospective control was performed, choosing AxSPA patients under biological therapy with stable disease, visited in our center from 01/01 to 30/11/2021. We recruited 62 patients, but finally include 60 (2 quit for personal reasons). We offered them two teleconsultation visits (using their personal mobile), every f4 months, and a presential final visit one year after inclusion. The chatbot sends PROMS (BASDAI, VAS for patient global disease assessment,

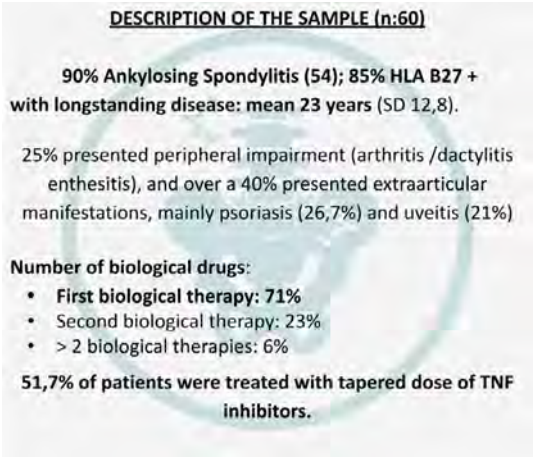

Image 1

ASDAS, and 3 questions for extraarticular disease), and feedback and schedule for the following visits. In the case of lab test or PROMs deviation or when the patient asks for contact, it is phoned by nurse/doctor who solves the question and/or arranges an additional presential visit. We collect patient and disease characteristics (age, gender, educational level, employment, disease activity, duration and treatments), and patient´s satisfaction and preferences in the final visit.

Results: We included 60 patients (Image 1).

At inclusion 93,3% were at remission/LDA by ASDAS/BASDAI-RCP and 4 patients were considered clinically controlled in spite of higher scores. At follow-up 3 patients with reduced dose needed to increase to standard dose of biological drug. There was no worsening from basal to final visits according BASDAI, BASFI, ASDAS-RCP or AsQOL.

Patients final VAS score (1-10) assessment of telehealth consultation was high: mean 9,14 (DS 1,498); 91.7% ≥ 8 and 76.7% ≥ 9.

83,3% preferred telehealth follow-up. There was a trend towards telehealth preferences in higher educational levels, and active working (86% vs 70%) but not statistically significant. We found no correlation with gender, age and disease characteristics tested.

Conclusion: Asynchronous teleconsultation seems promising, not inferior to presential consultation and preferred for follow-up by our AxSpa patients with stable disease with biological drugs . We met some "reluctant patients", that were more inactive working and with lower educational levels, but the differences were not significant. Further reserarch is needed with this telehealth model in other age and disease populations (RA), in order to characterize the reluctant and keen patients.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Before COVID pandemic, telehealth use for the followup of rheumatic disease patients had been limited, but nowadays it appears as a more sustainable model of consultation, as it seems to be time and resources sparing for the patiens and the healthcare system.

Prove that the use of asynchronous telehealth followup with whatsapp platform chatbot among our controlled AS patients under biological therapy, was less time (and resource) consuming for the patient and the system.

Methods: A prospective study with retrospective control was performed, choosing AxSPA patients under biological therapy with stable disease, visited in our centre from 01/01 to 30/11/2021. We recruited 62 patients, but 2 quit for home moving or personal reasons. We offered them 2 teleconsultation visits (using their personal mobile), every 4 months, and a presential final visit one year after inclusion. The chatbot sends PROMS (BASDAI, VAS for patient global disease assessment, ASDAS, and 3 questions for extraarticular disease), and feedback and schedule for the following visits. In case of lab test or PROMs deviation or when the patient asks for contact, it is phoned by nurse/doctor who solves the question and/or arranges an additional presential visit. We collect patient and disease characteristics (age, gender, educational level, employment, disease activity, duration and treatments), patients preferences, and number of presential visits and phone calls from the year previous to inclusion.

Results: We included 60 patients (83,3% men), mean aged 48,22 years (SD 12,128), 36% under 45 years at inclusion. 83.3% were active working and only 10 patients were jobless or retired. They were Ankylosing Spondylitis (AS) (90%), HLA B27 positive (85%) with longstanding disease (mean 23 years, SD 12,8), and were receiving the first (71%), or the second (23%) biological therapy (51,7% tapered anti-TNF). 25% presented peripheral impairment, and over 40% extraarticular manifestations.

At inclusion 93,3% were at remission/LDA by ASDAS/BASDAI-RCP and 4 patients were considered clinically controlled in spite of higher scores. At followup 3 patients with reduced dose needed to increase to standard dose of biological drug, with no other need of treatment change. There was no worsening from basal to final visits according BASDAI, BASFI, ASDAS-RCP or AsQOL. Patients final VAS score (1-10) assesment of telehealth consultation was high: mean 9,14 (DS 1,498) and 83,3% preferred telehealth followup.

In this study we spared 62% presential visits (Only needed 70, 60 scheduled and 12 additional). Patients estimated time needed for presential consultation was 90 +/- 30 minutes including approach to hospital and waiting times. For the health-care team, time needed for whatsapp consultation was 1/3 from the needed for presential consultation.

Conclusion: Asynchronous telehealth followup with whatsapp platform chatbot in our controlled AxSPA patients under biological therapy resulted time sparing for the patient and the system, as it reduces time in presential consultation. The use of this model of telehealth approach in an enviroment different from a clinical study is needed for more precise saving estimates.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite multiple pharmacological options for axSpA are available, still one out of three patients do not achieve the recommended treatment target (1), highlighting the need to understand better the difficult-to-treat (D2T) axSpA profile. The aim of this study was to identify the characteristics of D2T-axSpA patients compared to "good responders" (GR) and determine predictive factors for D2T-axSpA.

Methods: Data from an observational prospective cohort recruiting consecutively patients diagnosed of axSpA initiating the first bDMARD from La Paz University Hospital between 2004 and 2019 were analysed. Patients were classified as D2T if they failed to at least two b/tsDMARDs or as GR if they continued treatment with the first bDMARD for at least 3 years or stopped it due to disease control. Clinical characteristics, laboratory tests, concomitant treatment and disease activity measures prior to starting the first bDMARD (baseline) and after 6 months were collected. Also, b/tsDMARD courses were registered. Chi-square or Fisher test and unpaired t-student were used for descriptive analyses. Logistic regression models

Table 1. Stratified characteristics. Results are shown as absolute numbers (percentages) or mean ± standard deviation.

	D2T (n=42)	GR (n=59)	p value
Age (years)	40.7±11	44.7±12.4	0.1
Male sex	21 (50)	38 (64.4)	0.1
Current smoking habit	13 (31)	7 (11.9)	<0.05*
Symptom duration until first bDMARD (year)	5.5±7.7	10.5±10.7	<0.01*
HLA-B27 +	27 (64.3)	48 (82.8)	<0.05*
Enthesitis	40 (95.2)	35 (59.3)	<0.001*
IBD	6 (14.3)	2 (3.4)	<0.05*
Comorbidities			
Hypertension	20 (47.6)	15 (25.4)	<0.05*

CRP (mg/L)	5.9±7.9	1.7±2.7	<0.01*

(*): statistically significant differences (p<0.05), IBD: inflammatory bowel disease, NSAIDs: nonsteroidal anti-inflammatory drugs, ASDAS: Ankylosing Spondylitis Disease Activity Score, BASDAI: Bath Ankylosing Spondylitis Disease Activity Index, TJC: tender joint count, PtGA: patient global activity, PhyGA: physician global activity, CRP: C-reactive protein.

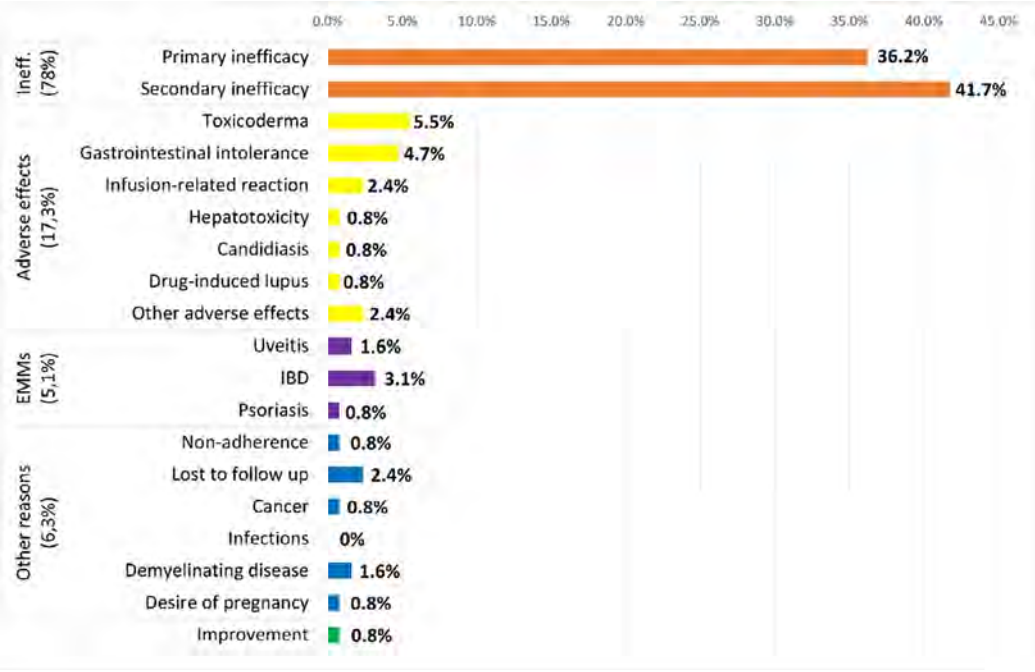

Figure 1. Reasons for b/tsDMARD discontinuation in D2T-axSpA patients.

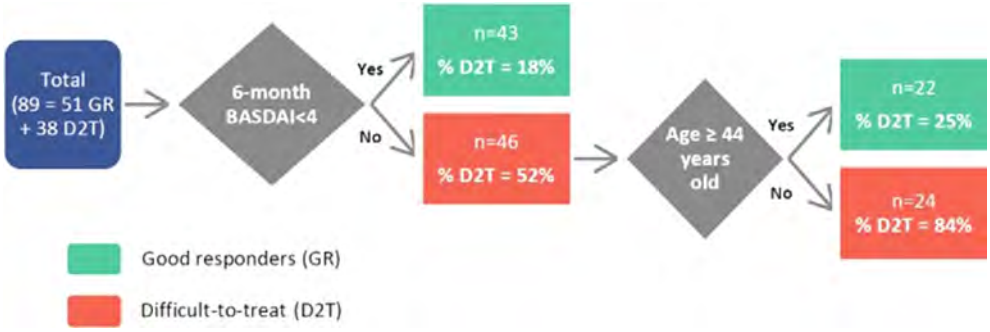

Figure 2. CART predicting probability of D2T-axSpA patients. The value at the terminal node represents the most frequently expected value (D2T vs. GR).

were used to identify associated factors with D2T-axSpA. Finally, a Classification And Regression Tree ('CART') was created to predict D2T-axSpA.

Results: Out of 101 patients included, 42 (41.6%) were classified as D2T and 59 (58.4%) as GR. D2T patients were more frequently HLA-B27 negative and smokers, had significant shorter symptom duration and more enthesitis, IBD, concomitant NSAIDs and comorbidities (hypertension, dyslipidemia, depression or anxiety and fibromyalgia) (**Table 1**). However, no significant differences were found in age, sex, BMI, dactylitis, arthritis, uveitis, psoriasis, concomitant csDMARDs, diabetes mellitus or cardiopathy. Furthermore, while no differences were found for disease activity composite measures (ASDAS, BASDAI) and CRP or ESR at baseline, D2T patients had greater scores in BASDAI questions for pain and morning stiffness, TJC, PtGA and PhyGA. After 6 months of starting the first bDMARD, the scores for all disease activity measures, including ASDAS, BASDAI, CRP and ESR were significantly higher in D2T patients. Reasons for b/tsDMARDs discontinuation in D2T patients are shown in **Figure 1**. Two different multivariable models were obtained due to collinearity between ASDAS and BASDAI/CRP.These multivariable logistic regression models showed that 6-month BASDAI (odds ratio [OR]=1.49, p=0.001) and 6-month CRP (OR=1.15, p< 0.05) or 6-month ASDAS (OR=3.16, p< 0.001) were independently associated with D2T-axSpA. The CART model (**Figure 2**), incorporating 6-month BASDAI and age at diagnosis, demonstrated the best predictive performance, with an area under the curve (AUC) of 0.84 (95% confidence interval 0.87-1).

Conclusion: D2T-axSpA patients often have known predictors of poor therapeutic response (smoking and HLA-B27 negative) and worse response to first bDMARD already after 6 months. Disease activity at this point is independently associated with failure to consecutive b/tsDMARDs. The proposed CART model is simple to apply and useful for predicting D2T-axSpA after 6 months of bDMARD therapy.

Impact of Extreme Baseline BASDAI and/or Maastricht AS Enthesitis Score on Treatment Response to Upadacitinib in Patients with Axial Spondyloarthritis

Maxime Dougados[1], David Bulbin[2], Heather Jones[3], Tianming Gao[4], Anna Shmagel[5], Thomas Poznanski[6], Abhijeet Danve[7] and Karl Gaffney[8], [1]Université de Paris, Paris, France, [2]Geisinger Health System, Danville, PA, [3]AbbVie, Inc., Mettawa, IL, [4]AbbVie, Inc., North Chicago, IL, [5]AbbVie, Inc., Long Grove, IL, [6]AbbVie, Inc., Plainfield, IL, [7]Yale University, New Haven, CT, [8]Norfolk and Norwich University Hospital NHS Trust, Norfolk, United Kingdom

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Axial SpA (axSpA) and FM manifest with overlapping clinical features such as pain, fatigue, and stiffness, yet their treatment is distinctly different. FM is a comorbidity with axSpA in 4–21% of patients (pts), and extreme BASDAI pain and fatigue scores have been suggested as surrogate markers for FM[1]. The Janus kinase inhibitor upadacitinib (UPA) is approved for the treatment of AS and non-radiographic axSpA (nr-axSpA), and has demonstrated efficacy in pts with axSpA in the Phase 3 SELECT-AXIS 2 study through 14 weeks (wks) of treatment[2,3]. The objective of this post hoc analysis was to compare the baseline (BL) characteristics of pts with extreme or non-extreme BL BASDAI and/or Maastricht AS Enthesitis Score (MASES) and to assess the efficacy of UPA vs placebo (PBO) in these subgroups.

Methods: The SELECT-AXIS 2 program was comprised of 1 study of pts with active nr-axSpA (PBO-controlled for 52 wks) and 1 study of pts with active AS and inadequate response to biologic DMARDs (PBO-controlled for 14 wks). Pts with a concomitant diagnosis of active FM according to the treating physician were excluded. The primary endpoint in both studies was ≥40% improvement in Assessment of SpA international Society score (ASAS40) at wk 14. Subgroup analysis was performed on pooled data: 'extreme BASDAI' was defined as a score of ≥8 for ≥3/5 BASDAI components, and 'extreme MASES' was defined as a score of ≥10; cutoffs reflected the top quartile range of each measure. Demographics and disease characteristics were summarized descriptively. Efficacy measures were evaluated at wk 14 and reported using non-responder imputation incorporating multiple imputation to handle missing data due to COVID-19; statistical comparisons were adjusted for screening high-sensitivity CRP level and study.

Results: Overall, 732 pts were evaluated, including 275 with extreme scores (PBO, n=135; UPA, n=140) and 457 with non-extreme scores (PBO, n=230; UPA, n=227). At BL, of the 275 extreme pts, 232 (84.4%) met BASDAI criteria only, 19 (6.9%) met MASES criteria only, and 24 (8.7%) met both criteria. Compared with non-extreme pts, more extreme pts were female, ≥40 years old, and had higher BL rates of anxiety/depression (validated cutoff scores from EuroQol-5D-5L, 43.9% vs 22.2% for extreme vs non-extreme pts with UPA), pain (Pt's Assessment of Pain, 8.4 and 6.8, respectively), and fatigue (Functional Assessment of Chronic Illness Therapy-Fatigue, 21.7 and 30.5, respectively; Table). Regardless of extreme or non-extreme scores at BL, UPA demonstrated improvement across multiple disease activity outcomes vs PBO at wk 14 including ASAS40 ($p< 0.0001$; Figure). Extreme pts reported a numerically lower efficacy response within both UPA and PBO treatment groups at wk 14 vs non-extreme pts.

Conclusion: Pts with axSpA and extreme BL BASDAI/MASES reported higher BL rates of anxiety/depression, pain, and fatigue than those with non-extreme scores. UPA demonstrated greater efficacy than PBO among pts with both extreme and non-extreme BL BASDAI/MASES scores.

The Impact of Baseline BMI and Physical Activity on Upadacitinib Treatment Response: A Post Hoc Analysis of Patients with Ankylosing Spondylitis from the SELECT-AXIS 2 Study

Angela Crowley[1], Lori Siegel[1], Pendleton Wickersham[2], Heather Jones[3], Dan Webster[4], Anna Shmagel[5], Ana Biljan[6], Uta Kiltz[7] and Philip Helliwell[8], [1]Illinois Bone and Joint Institute, Gurnee and Hinsdale, IL, [2]Methodist Hospital, Baptist Medical Center and CHRISTUS Santa Rosa Hospital - Westover Hills, San Antonio, TX, [3]AbbVie, Inc., Mettawa, IL, [4]AbbVie, Inc., Libertyville, IL, [5]AbbVie, Inc., Long Grove, IL, [6]AbbVie, Inc., Buffalo Grove, IL, [7]Rheumazentrum Ruhrgebiet, Herne, Germany, [8]University of Leeds, Leeds, United Kingdom

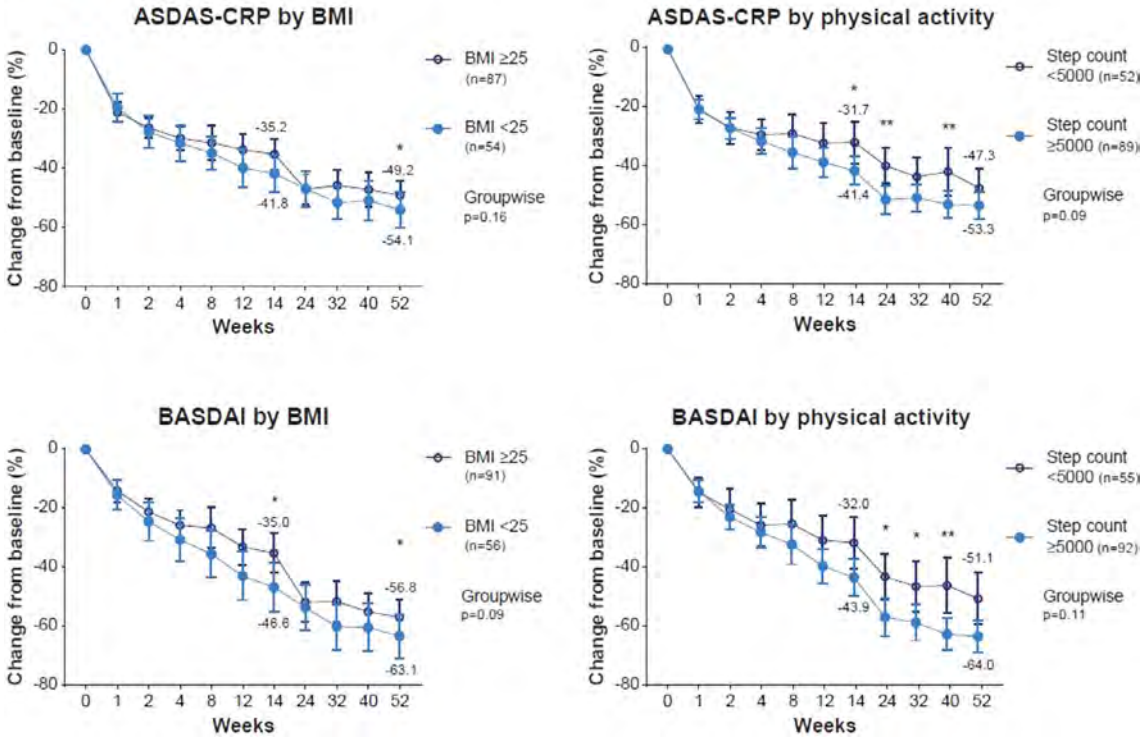
SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: In patients (pts) with AS, higher BMI has been linked to higher disease activity[1]. However, given that BMI can be a poor indicator of body composition, using BMI alongside digital devices that can measure physical activity (PA) may be a more comprehensive measure of fitness. To better understand the impact of BMI and PA on treatment response, we evaluated outcomes in pts with AS treated with upadacitinib (UPA) 15 mg once daily through 52 weeks (wks) of the Phase 3 SELECT-AXIS 2 trial (NCT04169373), stratified by baseline (BL) BMI and level of PA[2].

Methods: Pts with active AS and inadequate response to biologic DMARDs in SELECT-AXIS 2 were required to wear a wrist-worn actigraphy device that remotely monitored PA during the 14-wk, placebo-controlled portion of the study. In this post hoc analysis, we evaluated Ankylosing Spondylitis Disease Activity Score with CRP (ASDAS-CRP) and BASDAI scores at wk 52 among pts who received continuous UPA for 52 wks stratified by BL PA (inactive [< 5000 steps/day] or active [≥5000 steps/day])[3] and BMI (overweight/obese [BMI ≥25 kg/m^2] or healthy weight/underweight [BMI < 25 kg/m^2]). BL step count was calculated by mean daily step counts for wk 1 in pts with at least 3 days of wearable device adherence, and at least 16 hours/day of wear time. One-way analysis of variance was used to investigate the association of ASDAS-CRP and BASDAI scores at each time point through wk 52 with each BL category; significant variables ($p< 0.05$) were then analyzed using a mixed model for repeated measures. A Student's t-test with Welch's correction was used to assess ASDAS-CRP or BASDAI scores in each combination of BL BMI and PA.

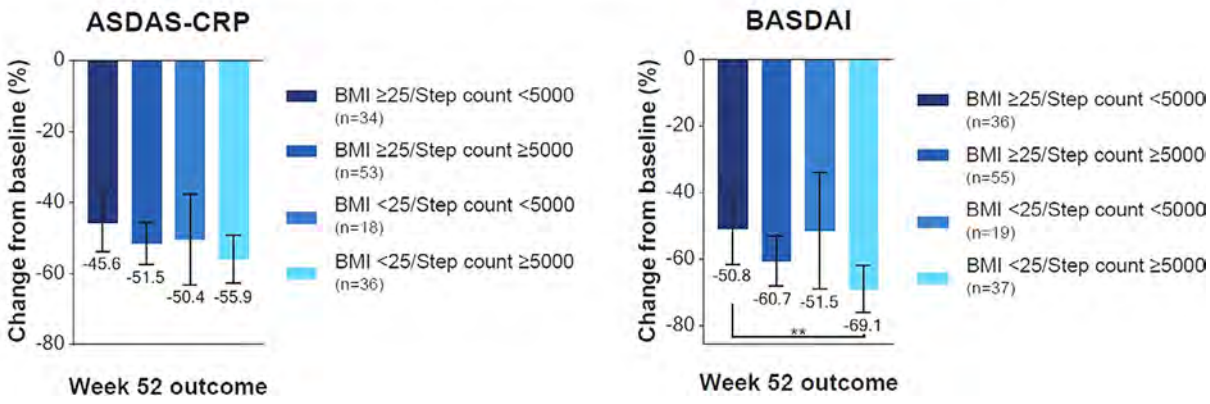
Results: Data were available from 141 pts for ASDAS-CRP and 147 pts for BASDAI who wore the actigraphy device. While no statistical differences in change from BL in ASDAS-CRP or BASDAI were observed between subgroups at wk 52, pts who were healthy weight/underweight or active at BL demonstrated a trend toward greater reduction in ASDAS-CRP and BASDAI scores at most time points from wk 8 onwards vs pts who were overweight/obese or inactive (Figure 1). When BL subgroups were considered concurrently, pts who were healthy weight/underweight and active at BL achieved significantly greater reduction in BASDAI scores over 52 wks vs pts who were overweight/obese and inactive (nominal p< 0.01;

Figure 1. Change from baseline in ASDAS-CRP and BASDAI stratified by baseline BMI or physical activity levels



*p<0.05; **p<0.01. As observed data, excluding missing data due to COVID-19. Error bars denote 95% confidence intervals. ASDAS-CRP, Ankylosing Spondylitis Disease Activity Score with CRP; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BMI, body mass index.

Figure 2. Change from baseline in ASDAS-CRP and BASDAI among each stratified combination of baseline BMI and physical activity



**p<0.01. As observed data, excluding missing data due to COVID-19. Error bars denote 95% confidence intervals. ASDAS-CRP, Ankylosing Spondylitis Disease Activity Score with CRP; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BMI, body mass index.

Figure 2). No significant differences were reported between pts with any other combination of BL BMI and PA for ASDAS-CRP or BASDAI.

Conclusion: Pts with active AS receiving UPA for 52 wks who were active or healthy weight/underweight at BL generally experienced greater decreases from BL in ASDAS-CRP and BASDAI vs pts who were inactive or overweight/obese. Pts with active AS receiving UPA who were active tended to have numerically greater improvements in disease activity vs pts who were inactive, regardless of BMI. BMI and PA together may offer a more clinically relevant way to determine outcomes than either measure alone.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Data regarding the adoption of the treat-to-target (T2T) approach aiming at inactive disease (ID), or low disease activity (LDA) in axial (axSpA) and peripheral Spondyloarthritis (perSpA) in real-world clinical practice is scarce. Our aims were to assess the level of disease activity of SpA patients in real-world practice, the extent of T2T strategy implementation and the reasons of possible non-implementation.

Methods: Cross-sectional study of all consecutive patients with SpA who visited the outpatient department or the one-day infusions' clinic of our hospital during a 7-month period (6/2021-12/2021). Detailed patient, disease and treatment characteristics were collected, as well as disease activity of axial (using ASDAS-CRP), peripheral (DAPSA) and extraarticular manifestations. Additionally, physicians filled-in questionnaires regarding treatment intensification or not (and reasons) in patients not in target at the specific visit. Multivariable logistic regression analysis was employed to identify predictors of therapy intensifications in patients not in target.

Results: We analyzed243 patients (54% males; AxSpA:187, perSpA:56)with median (IQR) age of 52 (42-61) and disease duration 4.1 (2.1-12.3) years. The main therapy in the majority of the patients (83%) was a biologic (b-)DMARD.In patients with AxSpA, median (IQR) ASDAS-CRP was 2.4 (1.7-3.1), while in perSpA patients, median (IQR) DAPSA score was 26 (12.4-36.2). Low disease activity or inactive disease (LDA/ID), taking into account axial and/or peripheral as well as extra-articular manifestations was found in 26% and 25% of the patients in AxSpA and perSpA respectively.

Of the patients not having at least LDA (N=181), 82 (45%) had their treatment intensified. Physician-documented reasons of non-intensification are shown in Figure. In multivariable analysis, the type of patients' main therapy [OR(95%CI) for non-bDMARD vs bDMARD:12.2 (4.8-41.4)], physician's VAS score [OR:1.22 (1.10-1.27)]and patients' VAS global score [OR:1.08 (1.02-1.12)]were predicting therapy intensifications in patients not in target.

Conclusion: In this real-world study, the majority of SpA patients had high disease activity levels. T2T strategy was implemented in approximately half of those patients, especially those on non-biologic main therapy and high physician VAS score.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: AxSpA Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-IL17 agent secukinumab (SEC) has been proven effective and is widely used in the treatment of spondyloarthritis (SpA) patients alternatively to tumor necrosis factor inhibitors (TNFis). Our aim was to compare treatment retention and clinical responses at 2 years in SpA patients starting therapy with SEC versus TNFis in routine clinical care.

Methods: This was an analysis from UCRCR Registry, which is a prospective single center study. For the present study we analyzed all consecutive patients with axial (AxSpA) or peripheral SpA (pSpA), including psoriatic arthritis (PsA) starting or switching bDMARD therapy, either a TNFi or SEC from 1/2016 till 12/2022. We excluded patients with IBD-related SpA, patients starting ustekinumab (or apremilast) and patients switching from a bio-originator to a biosimilar TNFi or vice versa. We compared disease activity scores improvement at 6 months using linear regression analysis and treatment retention using Kaplan-Meier survival curves with log-rank test and Cox regression, adjusting for diagnosis (AxSpA vs pSpA,), presence of psoriasis, age, sex, disease duration, treatment line, co-administered csDMARDs (yes/no), smoking status (ever/never) and rheumatic disease comorbidity index (RDCI).

Results: A total of 644 patients with SpA started/switched bDMARD (SEC:214, TNFis:430). SEC was the ≥3rd bDMARD in 49% of patients compared to 31% of TNFis (p< 0.001). AxSpA was the diagnosis in 62% patients starting SEC and 74% starting TNFis while psoriasis was more common with SEC (51% vs 33.5% in TNFis). Monotherapy was more common with

SEC compared to TNFis (66% vs 58%, p=0.04). All other patients' characteristics at baseline, including extraarticular manifestations (except psoriasis), comorbidities' indices and sociodemographics were similar in the two groups. Baseline disease activity in both AxSpA and peripheral SpA was also comparable in patients starting SEC and TNFi.

Unadjusted 2-year treatment retention was higher in patients receiving SEC compared to TNFi both overall (SEC: 60%, TNFi: 45%, p=0.004) and separately in AxSpA (SEC: 59.5%, TNFi: 48%, p=0.039) and pSpA patients (SEC: 61%, TNFi: 36.5%, p=0.020).

In adjusted analysis, SEC administration was an independent predictor for higher bDMARD retention overall [HR (95%CI) =0.61 (0.45-0.84), p=0.002] and separately in AxSpA [HR=0.65 (0.45-0.95), p=0.025] and in pSpA [HR=0.54 (0.31-0.93), p=0.028].

Mean BASDAI and ASDAS improvements at 6, 12, 18 and 24 months of treatment were similar in patients with AxSpA receiving SEC or TNFis [at 6 months, mean(SD) δBASDAI:0.9 (2.2) vs 1.3 (2.2) respectively (p=0.49) and δASDAS: 0.5 (0.9) vs 0.6 (1.0), p=0.75]. Similarly, in patients with pSpA, δDAPSA was comparable in the two groups at all timepoints [at 6 months, mean (SD)δDAPSA: 12.3 (21) vs 8.1 (11), p=0.294]. Adjusted analyses provided similar results to the unadjusted analyses in both axial and peripheral SpA.

Conclusion: In real-world SpA patients, administration of Secukinumab results in similar clinical responses but higher treatment retention compared to TNFis.

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: To diagnose Systemic Lupus Erythematosus (SLE), one must understand the phenotype specter and interpret clinical, serological, radiological, and histopathological data, as well as exclude mimicking conditions. As diagnostic criteria for SLE currently are not within reach, patients are selected for research by classification criteria created to define homogeneous SLE-cohorts comparable across studies. This requires high specificity, which typically compromise the sensitivity. The new 2019 European Alliance of Associations for Rheumatology /American College of Rheumatology (ACR) classification criteria for SLE (2019 EA criteria) appears to be significantly more sensitive than the 1997 ACR criteria when applied on cohorts from referral centers/registries, especially for recent onset SLE. However, further studies are needed to confirm this highly promising sensitivity-improvement, not least in population-based SLE cohorts. We established a population-based cohort including all new-onset SLE cases during 1999-2017 in an area of 2.9 million inhabitants in Norway. Then we estimated the sensitivity of 1997 ACR- and 2019 EA criteria for adult cases diagnosed during 2000-2015.

Table 1A Comparative sensitivity of classification criteria in the adult incident SLE study population (2000-2015, N=647) N, number of cases in the study population; n1, number of cases fulfilling the criteria; n2, total number of cases at visit

Methods: The cohort included all cases (all ages) ICD-10 coded as SLE in the study area during 1999-2017. All cases were chart-reviewed to confirm/reject SLE diagnosis and assess classification-criteria items at time of diagnosis, and prospectively. At study end, 84% vs. 94% of cases in the total incident cohort fulfilled 1997 ACR- vs. 2019 EA criteria. Applying SLE diagnosis as "gold standard", sensitivity of 1997 ACR- vs. 2019 EA criteria was compared at diagnosis, at two years disease duration, and at study end, in adult incident SLE cases diagnosed during 2000-2015. All tests were two-sided and a 5% significance level was used. We applied 2015 as study end to have complete two-year data, and 2000 as study start as 29 cases diagnosed in 1999 lacked complete follow-up data due to technical reasons.

Results: After chart-review the population-based adult SLE cohort included 647 cases with new-onset disease diagnosed during 2000-2015. In this cohort the 2019 EA criteria showed higher sensitivity than the 1997 ACR criteria at diagnosis (91.2% vs. 77.2 %), also when stratified for sex (Table 1A). The sensitivity of the 2019 EA criteria was also superior to the 1997 ACR criteria after two years disease duration and at end of study, for both female-and male subjects (Table 1A). The sensitivity of the 2019 EA criteria was not significantly different for the female vs. the male population (Table 1B).

Conclusion: We provide new evidence for excellent sensitivity of the 2019 EA criteria for new-onset SLE, from a presumably complete population-based cohort. More than 90% of the SLE-cohort cases met the 2019 EA criteria already at time of diagnosis. Stratified for sex, almost all female subjects meeting the 2019 EA criteria during study period did so at time of diagnosis (91.2 % out of 94.2%). The corresponding numbers for the male population was 85% out of 92%.One possible implication for future clinical studies might be capture of almost all SLE patients early in their disease course, which may have important implications for studies on treatment.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-dsDNA antibodies (ADA) are traditionally measured by ELISA and are associated with Lupus nephritis (LN). Testing by immunoline assay (IL) provides additional information on antibodies to dsDNA, nucleosomes and histones which are all dsDNA associated proteins. Co-positivity for these antibodies in various combinations may have an association with diagnosis of LN, especially proliferative LN. This study aimed to assess if ADA by IL show similar association with proteinuria (i.e. lupus nephritis; LN) and proliferative LN (PRLN) as by ELISA and if co-occurrence with the other 2 antibodies have any impact on association with LN or PRLN.

Methods: Autoantibody profiles on IL and ADA values by ELISA (Euroimmune, Germany) of 2151 Indian SLE patients (F:M=1968:183; mean age=27.56 years) from the INdian SLE Inception Cohort for REsearch (INSPIRE cohort) at baseline were used. Among patients with LN (defined as per EULAR 2019 criteria; n=835), renal biopsy was available for 549 patients (337 PRLN; class III, IV, Mixed class III+IV and IV+V in 117, 149, 45 and 26 respectively). Autoantibodies against dsDNA (by both methods), nucleosomes and histones were tested for association with LN and PRLN either in isolation or in combination. Chi-square test was used to find association of individual and combination of autoantibodies with LN and PRLN. The results are expressed as Odds ratio (95% CI). A p-value< 0.05 was considered significant.

Results: ADA on ELISA and IL tested positive in 1499 (69.68%) and 843 (39.19%) patients respectively. A total of 1685 (78.33%) patients tested positive for ADA by at least one method and 749 (34.82%) patients tested positive by both the methods. Anti-nucleosome and anti-histone antibodies were positive in 950 (44.16%) and 791 (36.77%) patients. ADA results (ELISA & IL respectively) showed significant association with LN (1.55 (1.27-1.88); p< 0.001 & 1.31 (1.1-1.56); p< 0.001) and PRLN (2.64 (1.94-3.59); p< 0.001 & 2.74 (2.16-3.48); p< 0.001) but this association disappeared when re-tested after omitting the co-positivity for anti-nucleosome and anti-histone antibodies. Positivity for the other 2 antibodies either in isolation or in combination also didn't show any association with LN and PRLN.

Double positivity for ADA (IL) and anti-nucleosome antibodies showed a significant association (1.62 (1.06-2.48); p< 0.05) with PRLN. Triple antibody positivity in both the groups (ELISA & IL respectively), showed significant association with LN (1.5 (1.24-1.82); p< 0.001 & 1.45 (1.18-1.78); p< 0.001) and PRLN (2.4 (1.89-3.05); p< 0.001 & 2.73 (2.13-3.49); p< 0.001). (Table-1)

Table – 1. Association of antibodies to dsDNA, nucleosomes and histones (alone or in combination) with proteinuria and proliferative lupus nephritis

Anti-ds DNA	Anti-Nucleosome	Anti-Histone	LN (n=835)	OR (95%CI)	p-value	PRLN (n=337)	OR (95%CI)	p-value
+ (ELISA)	Not taken into account	Not taken into account	628	1.55 (1.27-1.88)	<0.001*	284	2.64 (1.94-3.59)	<0.001*
+ (IL)	Not taken into account	Not taken into account	360	1.31 (1.1-1.56)	<0.001*	202	2.74 (2.16-3.48)	<0.001*
+ (ELISA)	-	-	225	1.13 (0.93-1.38)	0.22	77	0.84 (0.64-1.11)	0.23
+ (IL)	-	-	68	0.96 (0.7-1.31)	0.81	28	0.99 (0.66-1.52)	0.99
+ (ELISA)	+	-	88	0.84 (0.64-1.11)	0.23	42	1.1 (0.78-1.57)	0.58
+ (IL)	+	-	50	0.95 (0.66-1.36)	0.78	30	1.62 (1.06-2.48)	0.035*
+ (ELISA)	-	+	40	1.01 (0.68-1.53)	0.93	16	1.0 (0.58-1.73)	0.99
+ (IL)	-	+	25	1.24 (0.73-2.10)	0.43	13	1.61 (0.86-3.03)	0.14
+ (ELISA)	+	+	275	1.5 (1.24-1.82)	<0.001*	149	2.4 (1.89-3.05)	<0.001*
+ (IL)	+	+	217	1.45 (1.18-1.78)	<0.001*	131	2.73 (2.13-3.49)	<0.001*

ELISA = Enzyme Linked Immunosorbent Assay; IL = Immunoline Assay; LN = Lupus Nephritis (presence of proteinuria); PRLN = Proliferative Lupus Nephritis; OR = Odds Ratio; CI = Confidence Interval

*p-value is significant

Positive predictive value (PPV) of ADA by ELISA for LN vs PRLN were 41.89% & 42.7% respectively as compared to ADA by IL (18.94% & 23.96% respectively). These were lower than the PPV for triple antibody positivity for LN and PRLN for ADA by ELISA (45.99% & 45.78% respectively) and for ADA by IL (24.87% & 27.63% respectively).

Conclusion: Anti-dsDNA antibody positivity in isolation (ELISA or IL) doesn't have any association with LN or PRLN. Their association with LN and PRLN appears only when antibodies to nucleosomes and histones are co-positive with them and the odds of developing renal involvement increase significantly.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Early diagnosis remains an unmet need for SLE patients across the world. Reasons for delay in diagnosis differ in various geographic regions and largely depend on accessibility to medical care. We report the time to diagnosis, its determinants and the referral pattern from India.

Methods: Members of the Lupus special interest group developed a questionnaire including a pilot run to understand the referral pattern and variables affecting time to diagnosis of Lupus. Patients fulfilling the SLICC criteria for SLE diagnosed after Jan 2022 were included. All patients provided written informed consent. All centres received permission from their ethics committees. Their socio demographic profile as per modified Kuppuswamy scale(2022), health care referral pattern, organ systems affected and disease related parameters at diagnosis were recorded. The data was categorised into early and late diagnosis based on median time taken for diagnosis and the differences were explored using Chi-square, univariate and multivariate logistic regression.

Results: Nine centres provided data for 348 patients for this study, four were Government university teaching hospitals(n=191), 3 private university teaching hospitals (n=116) and 2 from single specialty clinics (n=41). Figure 1 represents an overview of centres which participated in the current study and the home states from where the patients were enrolled. Patients originated from both rural (48%) as well as urban areas(52%).

Table 1: Sociodemographic and clinical factors associated with early or late diagnosis (n=348)

Table 2: Multivariate Analysis - Time taken for diagnosis >7months

Variables	Adjusted Odd Ratio(CI)
Education	
Literate	-
Illiterate	2.28(1.00,5.41)
Place of residence (home state)	
South India	-
North India	5.44(1.87,18.7)
Eastern states	2.13(0.79,5.90)
Renal Lupus	1.87(0.90,3.93)

Figure: Map of India depicting participant centres and states from where patients originated

The mean age of SLE patients was 28.48±10.92 years, 93% were women and 57% were married. The median time to diagnosis was 7 months(IQR 3::18), about one third [92(30.4%)] were diagnosed within 3 months and 55(18.2%) within one month. In about 38%, the diagnosis was beyond 12 months. Renal involvement at diagnosis was observed in 19.3% (69/348).The mean SLEDAI-2k at diagnosis (n=232) was 12.13+ 6.85 and in 33/232(14.2%) SLEDAI was <4.

The mean Kuppuswamy scale was 12.39+6.55 reflective of lower middle class patient population. In the univariate analysis, illiteracy (uOR=1.81, 95%CI:0.99,3.35), renal involvement (uOR=1.87,95%CI:0.90,3.93) and lower family income (p=0.05) were found to be associated with delayed diagnosis.(table1) However, in the multivariate analysis only illiteracy (AOR=2.36,95%CI:1.02,5.66) remained significantly associated with delayed diagnosis.(table2)

The referring practitioners were largely another graduate or postgraduate doctor (87%). No referral was made by a medical field worker. The family size, employment and marital status did not influence the time to diagnosis, however, the regional differences were evident.(p=0.001) Almost half patients were self-financing (56.6%) ,with one-third (36.9%) utilising private medical insurance and < 2% receiving government health insurance.

Conclusion: Very early diagnosis (within 3 months of symptom onset) was made in about a third of SLE patients. Time taken for diagnosis was longer in those with low literacy and differed in geographic regions of our country.

Abstract Number: 0546

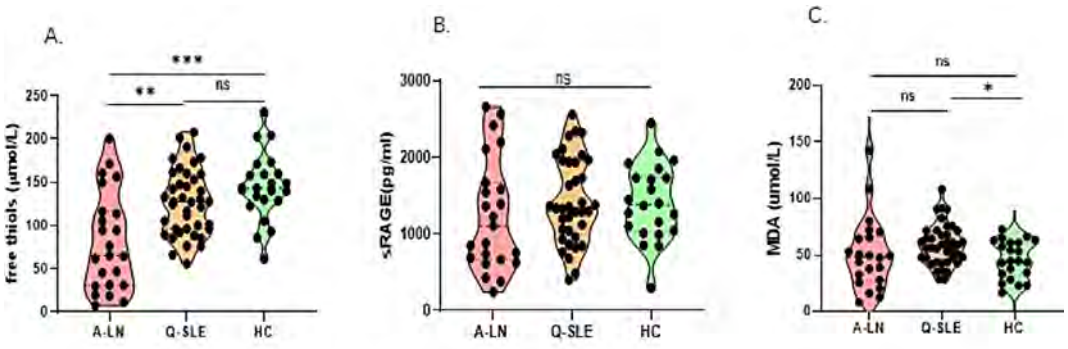
Markers of Oxidative Stress in Systemic Lupus Erythematosus Patients with Nephritis

Lu Liu, Karina de Leeuw, Suzanne Arends, Berber Doornbos-van der Meer, Harry van Goor and Johanna Westra, University Medical Center Groningen, Groningen, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus nephritis (LN) is regarded as one of the most severe manifestations of systemic lupus erythematosus (SLE). This inflammation in the kidneys may lead to excessive production of reactive oxygen species (ROS), which can induce oxidative stress, creating a pathogenic loop. Potential biomarkers of oxidative stress are plasma-free thiols, soluble receptors for advanced glycation end-products (sRAGE), and malondialdehyde (MDA). To analyze whether levels of thiols, sRAGE and MDA are different in SLE, and especially in active LN. Moreover, associations between oxidative stress biomarkers and clinical characteristics were investigated.

Methods: Forty-seven SLE patients with quiescent disease (Q-SLE) without renal involvement, 23 SLE patients with active proliferative LN, who previously participated in Dutch Lupus Nephritis studies and 23 healthy controls (HC) were included. Of the SLE patients with active LN follow-up samples were also analyzed. Thiols levels were measured as previously described. sRAGE levels were measured by ELISA. MDA levels were measured by Lipid Peroxidation (MDA) Assay Kit. Clinical parameters, including



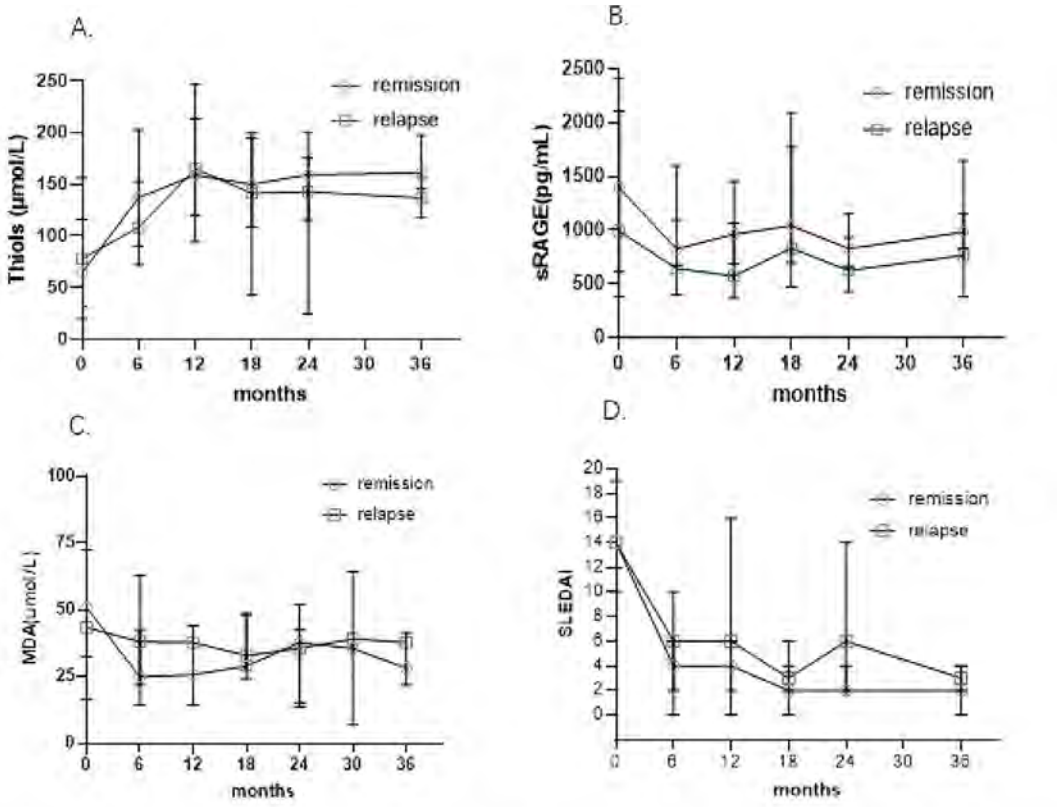
(A) Plasma-free thiols levels. (B) sRAGE levels (C) MDA levels
A-LN: active Lupus Nephritis, Q-SLE: quiescent systemic lupus erythematosus, HC: healthy control.
sRAGE: soluble receptor for advanced glycation end-products, MDA: malondialdehyde

Figure 1. Levels of thiols, sRAGE and MDA at baseline

disease activity using the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) score, were documented. Longitudinal changes in thiols, sRAGE, and MDA levels were compared to clinical parameters using generalized estimating equations (GEE).

Results: Demographic characteristics are shown in Table 1. Thiols levels were significantly lower in active LN (at baseline) and Q-SLE patients compared to HC (Figure 1A). There was no significant difference in sRAGE levels among the groups (Figure 1B). Q-SLE patients exhibited significantly elevated levels of MDA compared to HC (Figure 1C). In SLE patients with LN, changes over time in thiols, sRAGE, MDA and SLEDAI during the 36-month follow-up are shown in Figure 2. We divided the patients into relapse and remission subgroups, defined as having remission when SLEDAI was < 5 during follow-up. Six patients experienced a flare-up resulting in a recurrence rate of 26%. In the univariate GEE model, changes of thiols were negatively correlated with SLEDAI ($p < 0.001$). Changes in sRAGE and MDA were positively correlated with SLEDAI ($p = 0.035$ and $p = 0.016$, respectively).

Conclusion: Levels of thiols are significantly reduced in patients with Q-SLE and active LN compared to HC. In Q-SLE, levels of MDA were increased compared to HC. During follow-up of SLE patients with LN, thiols levels are significantly negatively correlated to SLEDAI. sRAGE and MDA levels are slightly positively correlated with SLEDAI. These results indicated



(A) Median plasma-free thiols levels; (B) Median sRAGE levels; (C) Median MDA levels; (D) Median SLEDAI levels;
Pink lines represent remission group, green lines represent relapse group; Each dot with vertical lines indicate median with error.
sRAGE: soluble receptor for advanced glycation end-products, MDA: malondialdehyde, SLEDAI: Systemic Lupus Erythematosus Disease Activity Index

A Spatially-resolved Single Cell Resolution Atlas of Pediatric Lupus Nephritis Uncovers Complex Interactions Between Stromal and Infiltrating Immune Cells

Shaun Jackson[1], Nicholas Hasle[2], Elizabeth Nguyen[3], Robyn Reed[2] and Patrick Danaher[4], [1]Seattle Children's Research Institute / University of Washington, Seattle, WA, [2]Seattle Children's Hospital/University of Washington, Seattle, WA, [3]Seattle Children's Research Institute, Seattle, WA, [4]Nanostring, Inc., Seattle, WA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The molecular and cellular heterogeneity of human Lupus Nephritis (LN) at the kidney tissue level makes it challenging to identify key disease drivers and therapeutic targets. Single-cell transcriptomics (scRNA-Seq) has advanced our understanding of LN pathogenesis, but tissue dissociation eliminates all spatial information and several rare cell types (such as podocytes) are under-represented using droplet-based scRNA-Seq protocols. Using a technical advance in spatial transcriptomics, we generated a spatially-resolved, single cell resolution atlas of childhood-onset lupus nephritis.

Methods: Using the CosMx Spatial*Molecular Imager* (Nanostring), we generated single cell-resolution spatial transcriptomic data on archived kidney biopsy tissue from 8 pediatric Class III/IV LN patients and 2 health controls.

Results: After data QC and cell segmentation, we identified a total of 447,892 cells, which were assigned to 33 reference cell types (Fig. 1A). Visualizing spatial relationships provided robust evidence of the accuracy of cell annotation, such as the colocalization of fenestrated glomerular endothelial cells, mesangial cells, and podocytes within glomeruli (Fig. 1B, C).

As predicted by the biology of immune complex glomerulonephritis, the proportion of mesangial cells was broadly increased in LN, while relative podocyte numbers declined (Fig. 2A, B). Analysis of differential gene expression demonstrated that SLE induced broad transcriptional changes in resident glomerular cells (Fig. 2C). For example, glomerular endothelial cells downregulate expression of *TEK* (encoding the angiopoietin-1-binding TEK receptor tyrosine kinase), the angiopoietin-1/TEK signal regulator *DUSP1* (Dual Specificity Phosphatase 1), and *CLEC1A*(encoding the C-type lectin domain family 1 member A), suggesting altered glomerular endothelial function and cross-talk with surrounding mesangial matrix. Amongst the upregulated genes in LN mesangial cells, *TAGLN*, encoding transgrelin, is a marker for proliferating mesangial cells responding to

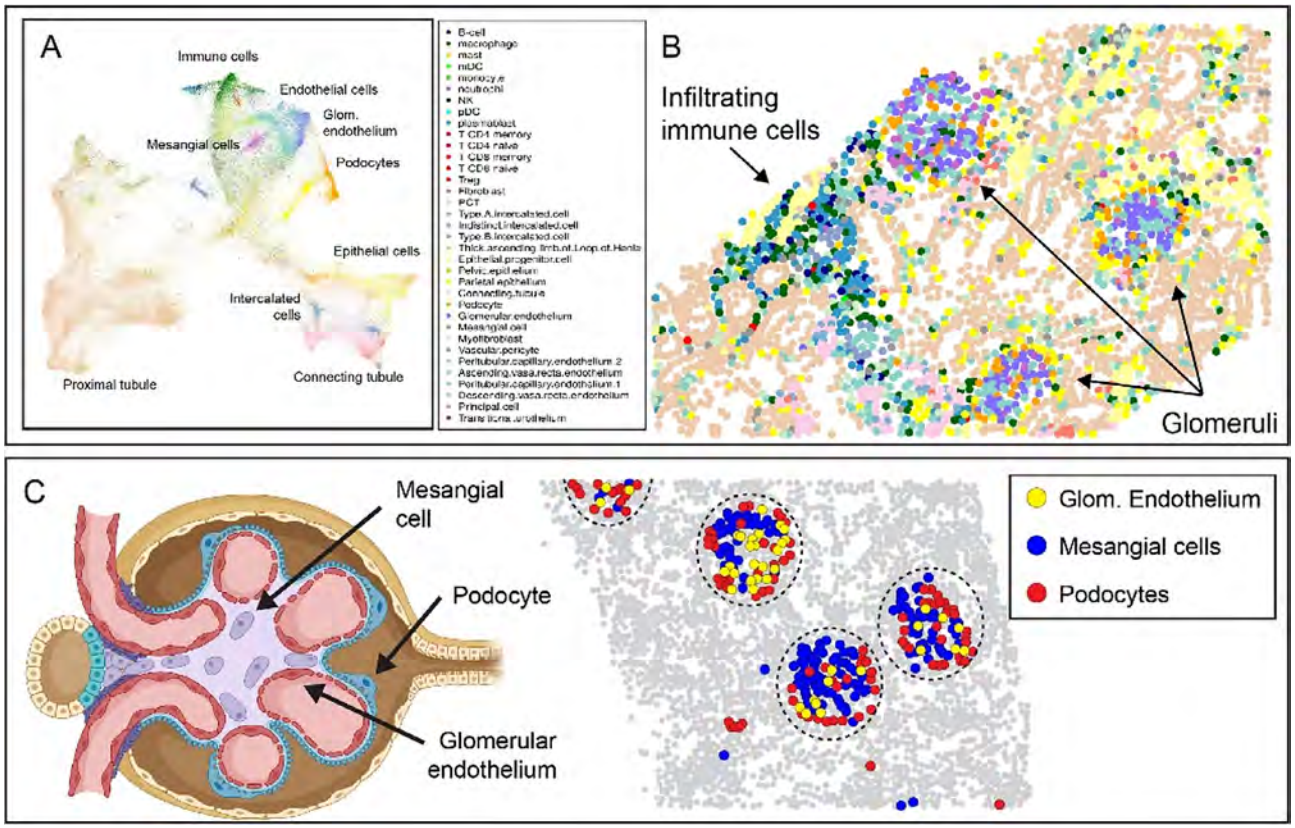

Figure 1: (A) UMAP projection of immune and renal cell subsets in LN. (B) Spatial relationships with each dot indicating a single cell. Arrows denote glomeruli and infiltrating tubulointerstitial immune cells. (C) Left: Illustration showing major glomerular cell types. Right: Glomerular cell types are spatially confined to glomerular structures (dashed circle), with podocytes (red) predominantly located peripherally outside mesangial and endothelial cells. Grey dots: unlabeled cells.

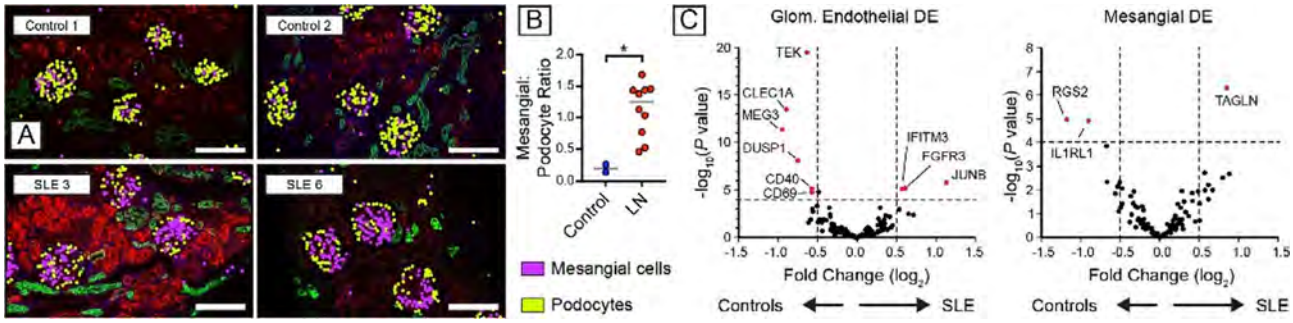

Figure 2: (A) Representative image showing mesangial hypercellularity in proliferative LN relative to controls. (B) Increased mesangial cell:podocyte ratio in LN. (C) Volcano plot showing differentially expressed genes (DEG) in childhood-onset LN relative to healthy controls.

(B) Image showing the computational identification of kidney regions (defined as: i) inside glomeruli; ii) bordering glomeruli; iii) within the kidney tubulointerstitium; and i) within immune hotspots). Left panel: cell types. Right panel: kidney spatial regions. (C) Distribution of infiltrating immune cells into kidney spatial regions in LN.

tissue injury. Mesangial cells in LN also upregulated collagen molecules (*COL3A1, COL1A2, COL4A1, COL6A*), matrix metalloproteinases and inhibitors (*MMP14, MMP19, TIMP1*), and chemokines (*CSF1*, CXCL9).

Focusing on immune cell infiltrates, LN was characterized by the relative expansion in B cells, plasma cells, and plasmacytoid dendritic cells (pDCs) within the kidney parenchyma (Fig. 3A). Notably, individual immune lineages traffic to specific regions in LN kidneys (Fig. 3B, C), while the transcriptional signatures of these cells also varied as a function of tissue location (not shown).

Conclusion: Spatial transcriptomics is a powerful tool to uncover the heterogeneity of LN. Our data highlight how gene expression in resident kidney cells and infiltrating immune cells varies as a function of both disease state and spatial location. The identification of new pathogenic mechanisms may inform the development of new targeted therapies.

Clinical and Interferon Biomarkers to Exclude Imminent Autoimmune Disease in ANA Positive Individuals

Md Yuzaiful Md Yusof[1], Sabih Ul-Hassan[1], Zoe Wigston[1], Antonios Psarras[2], Jack Arnold[1], Lucy Carter[3], Paul Emery[4] and Ed Vital[1], [1]University of Leeds, Leeds, United Kingdom, [2]Oxford University, Oxford, United Kingdom, [3]University of Leeds, Hartlepool, United Kingdom, [4]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, and NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Many rheumatologists find it challenging to safely discharge "At-Risk" ANA-positive people at the first visit due to lack of cardinal signs and prediction tools. "Watch and wait" approach is not cost-effective and delay appropriate care of non-immune pathology. We previously showed that higher IFN-Score-B and family history were predictive of progression to meeting classification criteria at 12-months[1]. However, classification criteria may undergo revision and not capture all significant outcomes. Our study objectives were to describe the 3-year outcomes of At-Risk cohort and assess discriminative ability of baseline clinical and IFN-Score-B in predicting various progression endpoints at 1 and 3 years.

Methods: We conducted a prospective cohort study in At-Risk people (ANA-positive ≥1:80, new referral with non-specific symptoms of ≤1 year and treatment naïve). Patients were assessed at baseline, then annually for 3 years. We used multiple RMD classification criteria, including the revised 2019 EULAR/ACR for SLE, and need for therapy, to group patients as below: i) Absolute non-progressor (ANP) (no clinical criteria); ii) Undifferentiated CTD (U-CTD) (≥1 clinical criteria but not full RMD criteria). This group was subdivided into those requiring immunosuppressant (IS) excluding antimalarials only and those who did not; iii) Year 1 progressor (meeting criteria for RMD by 1 year); iv) Late progressor (meeting criteria for RMD in Years 2-3); v) Clinically significant disease (CSD) (progressor OR U-CTD on IS). Bloods were analysed for two IFN-stimulated gene expression scores previously described[2]. Discrimination of single or combined clinical and IFN-Score-B markers were assessed using ROC curve analyses.

Results: Of 148 patients, mean (SD) age was 47 (15) years, 132 (89%) were female, 107 (72%) were Caucasians, 48 (32%) had a family history of RMD, 56 (38%) were anti-dsDNA+ and 8 (6%) had low C3 and/or C4. No. of clinical criteria at baseline were 0 (30%), 1 (64%) and 2 (6%). Outcomes were: Year 1 progressors: 21 (14%) [SLE=14; pSS=6; AS=1]; Late progressors: 12 (8%) [SLE=10; pSS=1; AS=1] of which only 2/12 in Year 3; U-CTD on IS: 8 (5%); U-CTD on antimalarials only: 20 (14%); U-CTD not on therapy: 50 (34%) and ANP: 37 (25%). Thus, 41 (28%) was classified as CSD by 3-year. For the prediction of Year 1 progressor, in addition to baseline IFN-Score-B and family history, multivariable regression showed no. of clinical criteria was associated with increased risk, OR 7.8 (95% CI 1.7-36.3). Table 1 showed that combined baseline

Table 1: Discrimination of single or combined clinical and IFN-Score-B markers

Progression Criteria	No. of Progressors (n/N)	No. of Progressors with available samples (n/N)	AUC (95% CI) for IFN-Score-B Only	AUC (95% CI) for Combined Markers (IFN-Score-B + FH of RMD + No. of Clinical Criteria)	Sensitivity, Specificity	PPV, NPV	Accuracy
Year 1 SLICC Classification	21/148	20/122	0.81 (0.72, 0.91)	0.89 (0.83, 0.96)	45%, 98%	82%, 90%	89%
Year 1 ACR/EULAR Updated Classification	26/148	25/122	0.73 (0.64, 0.81)	0.81 (0.73, 0.91)	36%, 98%	82%, 86%	85%
Year 1 CSD	26/148	24/122	0.76 (0.66, 0.87)	0.86 (0.77, 0.95)	42%, 98%	83%, 87%	87%
Year 3 SLICC Classification	33/148	31/122	0.64 (0.52, 0.76)	0.77 (0.67, 0.87)	29%, 97%	75%, 80%	80%
Year 3 ACR/EULAR Updated Classification	36/148	34/122	0.64 (0.52, 0.76)	0.76 (0.67, 0.86)	26%, 97%	75%, 77%	77%
Year 3 CSD	42/148	40/122	0.59 (0.48, 0.70)	0.74 (0.64, 0.83)	30%, 96%	80%, 74%	75%

markers (IFN-Score-B, family history and no. of clinical criteria) had good accuracy in predicting various definitions of progression at Years 1 and 3 as per AUROC.

Conclusion: About a quarter of At-Risk people developed CSD by 3-year, mostly did so within Year 1. Combined baseline clinical and IFN biomarkers had high specificity and could be used to risk stratify new ANA-positive referrals to rheumatology to exclude imminent or future disease/requirement of immunosuppressant. A validation study with cost-effectiveness analysis of these markers is in progress and would help translate their use in clinical practice.

Development of Customized Digital Cognitive Assessment Battery: A Pilot Use Case in SLE Patients

Priyanka Srivastava[1] and **Liza Rajasekhar**[2], [1]International Institute of Information Technology, Hyderabad, India, [2]Nizam's Institute of Medical Sciences, Madhapur, India

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Reported prevalence of cognitive dysfunction (CD) in SLE varies from 3%-88%1.Variability may be due to use of tools insensitive to population characteristics like literacy, improper control groups and effect of psychological health. We developed a language agnostic computerized cognitive test battery to evaluate CD in SLE.

Methods: Patients fulfilling the 2012 classification criteria for SLE and their randomly chosen care-givers, attending outpatient services, able to provide written consent and sustain the duration of cognitive testing (CT) were enrolled as cases and controls respectively.

CT included 1 paper-and-pencil Montreal Cognitive Assessment (MoCA), and 4 modified computerized tests: attention network tests (ANT) for executive control; sustained attention to response task (SART) for continuous task performance, picture naming for language proficiency, and n-back for working memory (WM), which used familiar images like truck, bag, fan instead of numbers or colors. Developed with PsychoPy experiment design software, participants' response time and accuracy was recorded. Depression, anxiety, stress, and trait anxiety were assessed using patient health questionnaire (PHQ-9), generalized anxiety disorder scale (GAD-7), perceived stress scale (PSS-4) and short state-trait anxiety inventory (STAI-T) respectively. Institutional Ethics committees approved the study. Scores were compared between groups using Mann Whitney U test with Bonferroni correction.

Results: Twenty-one SLE patients and 20 controls were enrolled. There was no difference in mean age (cases 27.7(6.5) controls 28(8.3) years) between groups. Mean duration of illness in cases was 61.8(42.5) months and mSLEDAI was 0. Table 1 shows mean scores of CT and psychological scales. Cases had reduced commission error (inappropriate

response to a no-go stimulus), and increased accuracy for no-go conditions, but with overall response latency in SART (effect size, r= .43 , -0.43, -0.40 respectively). Cases had significantly higher GAD scores (effect size (r=-0.36) with overall 23% reporting moderate generalized anxiety symptoms. (Figure 1).

Harnessing Machine Learning to Predict Neuropsychiatric Events in Systemic Lupus Erythematosus

Nursen Cetrez[1], Julius Lindblom[1], Raffaele Da Mutten[2], Dionysis Nikolopoulos[2] and Ioannis Parodis[1], [1]Karolinska Institutet, Stockholm, Sweden, [2]Karolinska Institutet and Karolinska University Hospital, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Neuropsychiatric systemic lupus erythematosus (NPSLE) is linked to increased morbidity, mortality, and adverse health-related quality of life. Early disease, a history of NPSLE, aPL positivity, and high disease activity are considered risk factors for NPSLE. However, there is currently no reliable clinical tool to predict neuropsychiatric flares. Recent advancements in machine learning (ML) have demonstrated great potential in aiding clinical decision-making across various medical disciplines. Therefore, we aimed to assess the reliability and effectiveness of ML applications in predicting NPSLE flares within a large cohort of patients with active SLE, yet no ongoing active severe NPSLE.

Methods: We analysed data from five phase III trials (BLISS-52, BLISS-76, BLISS-NEA, BLISS-SC, EMBRACE) after exclusion of patients with baseline neuropsychiatric BILAG score A (N=3638). Neuropsychiatric flares were defined as a transition from BILAG score C, D, or E to score A or B, or from score B to score A in the neuropsychiatric domain of the classic BILAG index throughout a 52-week long follow-up. After constructing panels of variables based on expert knowledge, we employed ML methodology to develop predictive models utilising the least absolute shrinkage and selection operator (LASSO) as well as multivariable logistic regression analysis. A stratified split was applied to the data to partition the study population into a training (70%; N=2547), and a test set (30%; N=1091). The training set was used in model development while the internal validation was developed by a 10 times 10-fold cross validation. The test set was used for validation of the built model, and the performance of the two models was demonstrated using area under the curve (AUC) of the receiver operating curves (ROC), accuracy with a 95% confidence interval (CI), sensitivity, and specificity metrics.

Results: A total of 105 SLE patients (2.89%) experienced a neuropsychiatric flare during follow-up. Knowledge-driven feature selection included a history of NPSLE, disease duration, aCL positivity, clinical SLEDAI-2K, sex, age, and the use of antimalarials. The LASSO and multivariable logistic regression models demonstrated comparable performance, with an AUC of 0.80 and 0.80, sensitivity of 0.61 and 0.61, and specificity of 0.83 and 0.82, respectively. Moreover, both algorithms exhibited appropriate calibration on the test dataset.

Conclusion: The integration of traditional risk factors for NPSLE into ML-based models can predict neuropsychiatric involvement in SLE with high specificity and modest sensitivity. We herein propose a pragmatic, robust, and highly accurate prediction tool forecasting neuropsychiatric flares in patients with SLE. The utilisation of this ML-based tool holds promising prospects for improving patient care and outcomes in real-world settings.

Monogenic Lupus: Clinical Phenotypes and Genetic Mutations in a Cohort of Pediatric Patients

Keerthi Vardhan Yerram[1], Kavitha Shanigaaram[1], Gaurang Sudhir Deshpande[1], Akshay Parikh[1], Arjun Ramavath[1], Nanditha Gollakota[1], Ramesh Manthri[1] and Liza Rajasekhar[2], [1]Department of Clinical Immunology and Rheumatology, Nizams Institute of Medical Sciences, Hyderabad, India, [2]Nizam's Institute of Medical Sciences, Madhapur, India

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Monogenic lupus is associated with specific gene mutations, most commonly reported in TREX1, DNASE1L3, DNASE2, and SAMHD1. However, their phenotypes are not well reported.

Methods: Patients < 16 years of age, satisfying classification criteria for SLE (SLICC 2012) or incomplete lupus1 (ILE)(ANA (titer ≥1:80) and any 1 of acute/ subacute/ chronic cutaneous lupus, oro-nasal ulcers, alopecia, synovitis, serositis, neurologic or renal manifestation or 2 of hematologic, immunologic manifestations, family history of autoimmune rheumatic

Table 1- Genetic Mutations and Lupus Presentation Categories in Study Patients

Nomenclature	Number of patients	Genetic mutation
Complete lupus (fulfilling SLICC classification criteria)	1	C1QA , Exon 3, c.622C>T(p.Gln208Ter)
Incomplete lupus (fulfilling criteria for incomplete lupus)	2	IFIH1,c.281A>G (p.Tyr94Cys) C1QB,Exon 3,c.371C>A (p.Ala124Asp)
Lupus like disease (not fulfilling criteria)	3	DNASE1L3,Exons 1-2,chr3:g.(58207142_58210877)del CFI,Exon 4,c.562G>A (p.Gly188Arg) ACP5 Exon 4,c.407del, (p.Phe136SerfsTer23)

disease (AIRD) or lupus-like disease(LLD) as per treating physicians opinion, in whom a monogenic cause was suspected due to consanguinity in parents, young age of onset, familial history, recurrent infections, skeletal abnormalities were subjected to clinical exome sequence. Data was retrieved from outpatient and inpatient records. Those with pathogenic variants or with variant of unknown significance but with the same mutation identified in parents were analysed.

Results: Clinical exome revealed mutations in 6 of 7 patients tested (Table 1). The mean age of the patients was 5.3 years(range 2-12) and mean duration of follow-up was 10.8 months (range 4- 21). One patient with a mutation in C1QA gene fulfilled the SLICC-CC (acute cutaneous lupus, oral ulcers, myelitis, lupus nephritis). She also experienced recurrent infections (thigh cellulitis and thumb abscess).

Two patients met the criteria for ILE. One had AIHA, ILD, and low complements and shared a heterozygous mutation in the IFIH1 gene with her mother. The other had oral ulcers, discoid rash, and mutation in C1QB mutation.

Three patients had LLD. One had DAH (diffuse alveolar haemorrhage) and mutation in DNASE1L3 gene, another had urticarial skin rash and low complements with a mutation in CFI gene, and third had AIHA (autoimmune hemolytic anemia), leucopenia, and spondyloenchondroplasia with mutation in ACP5 gene. All, except patient with DNASE1L3 mutation, were ANA positive. None had a family history of AIRD.

Conclusion: We report on 6 patients with mutations in C1QA, C1QB, DNASE1L3, CFI, IFIH1, and ACP5. In 3 with known mutations for monogenic lupus (C1QB, DNASE1L3, ACP5) SLE SLICC criteria were not met. One child presented with DAH. Others had lupus-like autoimmune features and features atypical for ILE eg ILD. Monogenic lupus will allow better research into pathways of disease.

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) suffered from an increasing risk of cardiovascular diseases (23·3 events per 1000 patient-years). Antiphospholipid antibodies (aPLs), including anticardiolipin antibodies (aCL), anti-β2 glycoprotein I antibodies (aβ2GPI), and lupus anticoagulant (LA), increase the risk of thrombotic events in antiphospholipid syndrome, but the impact of aPLs on SLE patients was not yet determined. In this multi-center prospective study, we aimed to determine the association between aPLs and future atherosclerotic cardiovascular disease (ASCVD) risk in SLE.

Methods: Seven aPL isotypes (aCL IgG/IgM/IgA, aβ2GPI IgG/IgM/IgA, and LA) were measured based on international guidelines at SLE diagnosis and during follow-up. Clinical manifestations, disease activity status and organ damage were collected. Future ASCVD events were defined as new onset nonfatal myocardial infarction, nonfatal stroke, coronary or peripheral artery revascularization, or cardiovascular death.

Results: Among the 1573 recruited SLE patients, 525 (33.4%) had positive aPLs. LA had the highest prevalence (324 [20.6%]), followed by aCL IgG (249 [15.8%]), aβ2GPI IgG (199 [12.7%]), aCL IgA (58 [3.7%]), aβ2GPI IgM (83 [5.3%]), aβ2GPI IgA (58 [3.7%]), aCL IgM (92 [5.8%]). 116 (7.37%) patients developed ASCVD during the mean follow-

Table 1. Proportion of ASCVD in SLE patients with different isotypes of aPLs

	ASCVD, n (%)	HR	95% CI	p
Anti-phospholipid antibodies (n=525)				
Anticardiolipin antibodies (n=299)	66(22.1)	6.07	4.19-8.77	<0.001

up of 4.51±2.32 years and 92 patients were aPLs positive. In univariate Cox regression analysis, both aPLs (HR=7.81, 95% CI, 5.00-12.24, p< 0.001) and traditional risk factors of cardiovascular disease were associated with future ASCVD events (Table 1). Kaplan-Meier plots suggested a potential trend towards ASCVD in positive versus negative aPLs antibodies. More importantly, anticoagulant or antiplatelet therapy can reduce ASCVD risk in SLE patients with positive aPLs (HR=0.57, 95% CI,0.25-0.93, P=0.026) (Figure 1). In multiple Cox regression analysis, aCL IgG (HR=1.95, 95% CI, 1.25-3.00, p=0.003), aCL IgM (HR=1.83, 95% CI, 1.03-3.20, p=0.039), and LA (HR=5.13, 95% CI 3.23-8.20, p< 0.001) positivity remained independently associated with ASCVD; traditional risk factors for ASCVD, including smoking, gender, age and hypertension, also play an independent role in SLE patients (Figure 2).

Conclusion: SLE patients with positive aPLs, especially positive aCL IgG/IgM and LA, warrant more care and surveillance of future ASCVD events during follow-up. Antithrombotic therapy has a protective effect on future ASCVD.

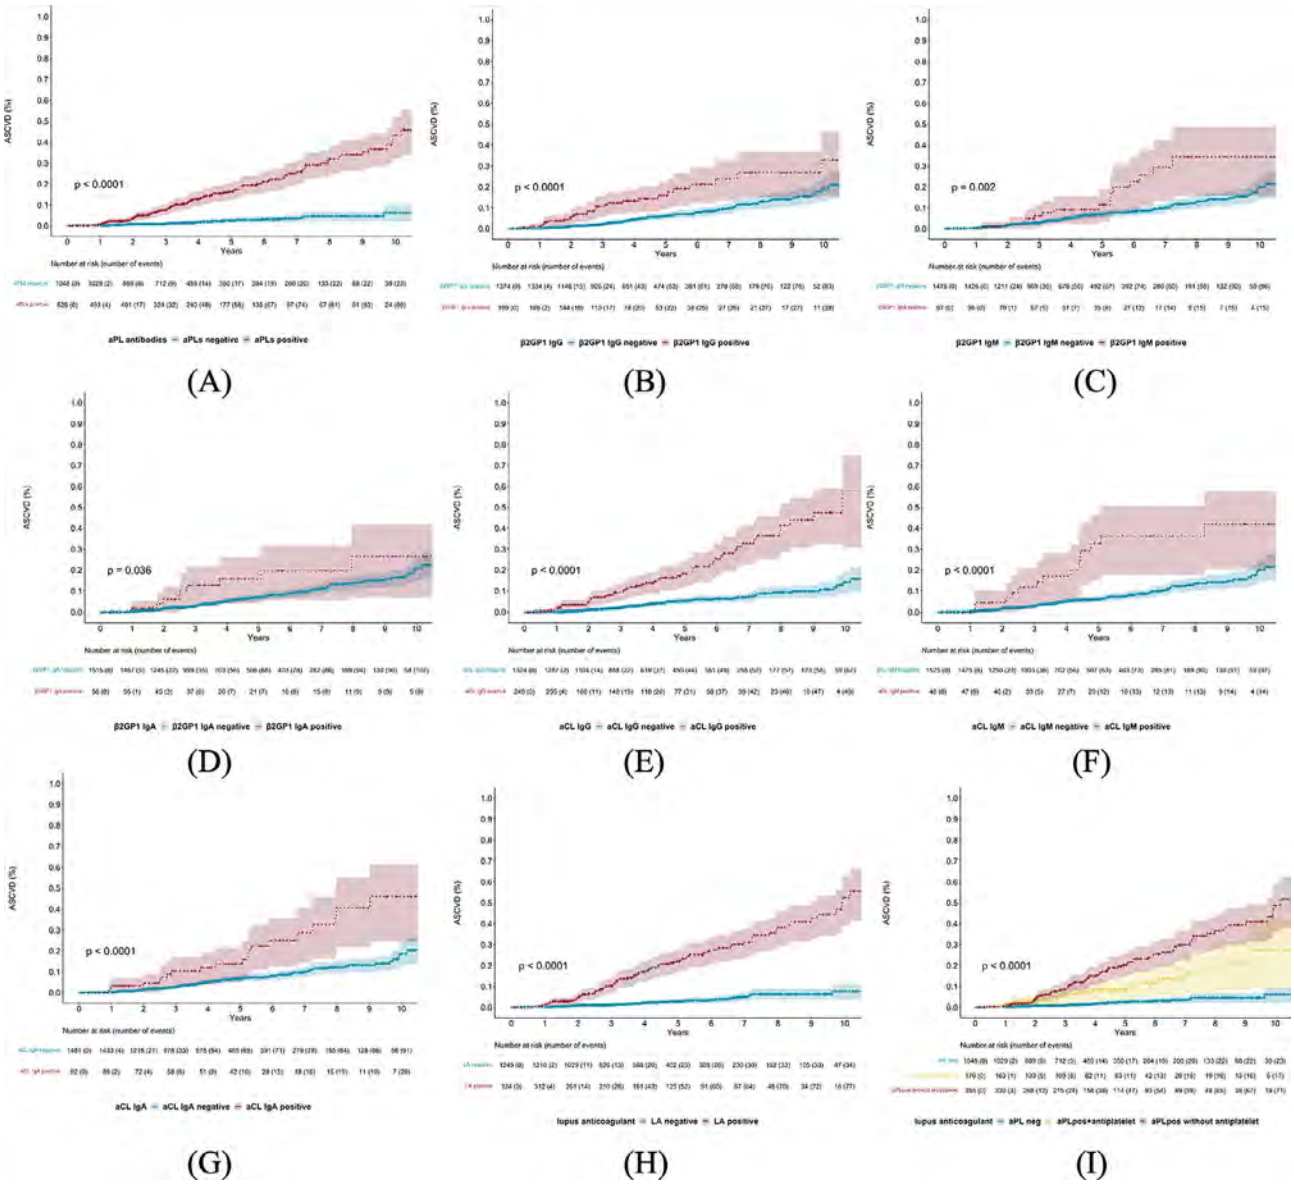

Figure 1. Cumulative probability of ASCVD in patients with or without aPLs (A), aβ2-GPI IgG antibody (B), aβ2-GPI IgM antibody (C), aβ2-GPI IgA antibody (D), aCL IgG antibody (E), aCL IgM antibody (F), aCL IgA antibody (G), and LA (H). (I) Cumulative probability of ASCVD in aPLs negative patients, aPLs positive patients with anticoagulant or antiplatelet therapy, and aPLs positive patients without anticoagulant or antiplatelet therapy.

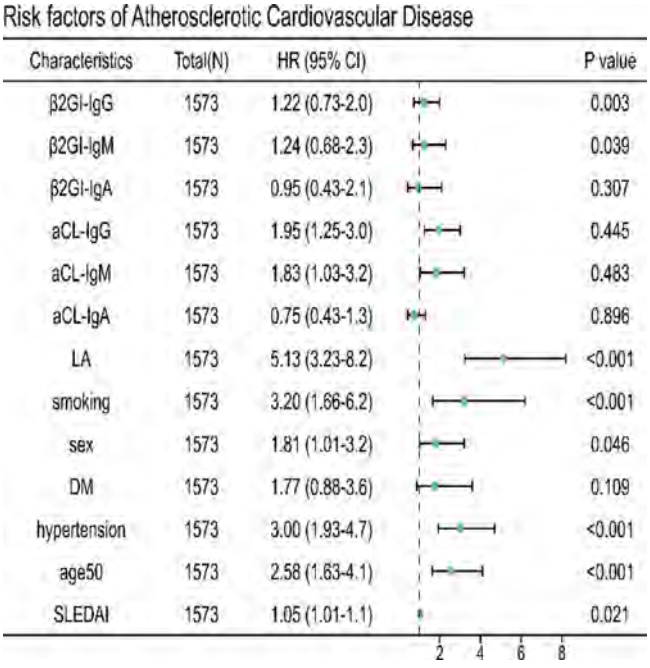

Figure 2. Risk factors of ASCVD in SLE patients.

Serum Isolevuglandin IgG Antibody Concentrations Are Increased in Patients with Systemic Lupus Erythematosus versus Control Subjects and Associated with Lower 24-hour Blood Pressure

Anastasiia Phothisane[1], Shahensha Shaik[1], Qiong Wu[1], Olivia Posey[1], Sean Davies[2], Jaya Krishnan[1], David Patrick[3], C. Michael Stein[1] and Michelle Ormseth[1], [1]Vanderbilt University Medical Center, Nashville, TN, [2]Vanderbilt University, Nashville, TN, [3]Department of Veterans Affairs, Nashville, TN

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) have a 2-3-fold increased risk of cardiovascular events. A major risk factor for this is hypertension. We previously demonstrated that downstream products of oxidative stress, isolevuglandins (isoLGs) promote hypertension and autoimmunity in SLE. IsoLGs covalently bind to lysine residues, leading to increased tissue damage, inflammation, and formation of autoantigens. The purpose of this study is to determine if anti-isoLG IgG antibodies are increased in patients with SLE and associated with disease activity and blood pressure (BP).

Methods: This cross-sectional study included 23 SLE and 30 control subjects. Subjects wore an ambulatory BP monitor for 24 hours with diurnal measurements every 15-30 minutes and nocturnal measurements every 30 minutes. Serum-isoLG IgG antibody concentrations were measured using a sandwich ELISA as previously published. One SLE serum sample was

used on all plates to normalize for plate-to-plate variability. Data were compared by chi square (categorical) or Mann-Whitney U (continuous) tests. Correlation was conducted by Spearman rho and linear regression analysis with anti-isoLG IgG antibody concentrations log-transformed to normalize residuals.

Results: Patients with SLE and control subjects were of similar age, race, and sex. Disease activity in SLE patients was low to moderate (mean SLEDAI=4). Most 24-hour BP parameters were significantly elevated in SLE versus control subjects (**-Table 1**). Serum anti-isoLG IgG antibody concentrations were increased in SLE (median [interquartile range]: 1.30 units [0.93, 1.70 units]) versus control subjects (0.91 units [0.73, 1.28 units], P=0.007; **Figure 1**). Anti-isoLG IgG antibody concentrations were significantly inversely associated with office and diurnal systolic BP (**Table 2**) in patients with SLE but were not significantly associated with BP in control subjects or disease activity and damage in SLE (SLEDAI: rho=0.156, C4: rho=-0.320, SLICC: rho=0.338). SLE patients not taking anti-hypertensive drugs were examined separately due to impact of the anti-hypertensives on BP and anti-isoLG IgG antibody concentrations were strongly significantly inversely associated with office and 24-hour BP measurements (**Table 2**). For example, every 20% increase in anti-isoLG IgG concentration was associated with a 10 mmHg decrease in 24-hour systolic BP, P=0.004. This remained significant after adjustment for age (P=0.03).

Conclusion: Serum concentrations of anti-isoLG IgG antibodies are increased in SLE versus control subjects. Anti-isoLG IgG antibody concentrations were inversely associated with 24-hour BP measurements. Given prior mechanistic studies demonstrating that cellular isoLGs promote hypertension, it is possible that in SLE, isoLG antibodies could help clear these hypertension-inducing antigens. Future work will further evaluate this mechanism and the role of anti-isoLG IgG antibodies as markers of BP and cardiovascular risk.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease marked by varied disease activity, underscored by complex immune dysregulation, including altered immune mediators and accumulation of autoantibody (AutoAb) specificities. This study seeks to determine an optimal panel of analytes that distinguish SLE patients with active disease and refine a Lupus Disease Activity Index (L-DAI).

Methods: We procured samples from patients with classified SLE on dates of low disease activity (< 4, range 0-3, n=162) or active disease (≥4, range 4-30, n=162) defined by the hybrid SLEDAI (hSLEDAI). Race/sex/age-matched healthy control (Ctrl) samples (n=81) were also evaluated. Plasma immune mediators (n=33) were evaluated by microfluidic immunoassay and serum AutoAb specificities, including dsDNA, chromatin, Ro/SSA, La/SSB, Sm, SmRNP, and RNP, were assessed by xMAP assay. The L-DAI is the sum of log-transformed, standardized immune mediators, weighted by the Spearman r correlation coefficient of mediator levels vs. either hSLEDAI scores or number of AutoAb specificities associated with clinical disease activity. Log-transformed mediator levels were further evaluated using random forest applied machine learning modeling to determine an optimal subset of analytes to inform the L-DAI.

Results: As expected, SLE patients with active disease demonstrated differences in clinical and serologic features, as well as increased use steroids. Random forest modeling of immune mediators comparing low vs. active disease, including clinically and/or serologically active vs. quiescent disease and Ctrls informed a variable importance ranking (**Fig. 1**, mean ± SD, top 21 mediators shown). Forward selection (adding mediators to top mediator, IFN-α [red]) and backward elimination (subtracting mediators from total [blue]), in combination with univariate analysis (**Fig. 1**), yielded a combination of 9 mediators (in red, **Fig. 1**) that best informed the L-DAI. The L-DAI 9, whether weighted by hSLEDAI or number of AutoAbs, significantly ($p \leq 0.05$) differentiated SLE patients with Low vs. Active disease, including clinically/serologically active/quiescent disease (vs. Ctrls, **Fig. 2**), with strong correlation between the weightings (Spearman r=0.990, $p < 0.0001$). An average composite L-DAI differentiated SLE patients with low, active, and clinically/serologically active/quiescent disease (vs. Ctrls, **Fig. 3**). There was enhanced distinction of low/moderate/high risk regions for active disease after application of decision curve analysis, with large (>0.8) Cohen's effect size and AUC=0.795 ($p < 0.0001$) in distinguishing clinical/serologic active/quiescent disease activity, and significant correlation (Spearman r=0.407, $p < 0.0001$) with concurrent clinical disease activity (hSLEDAI scores) (**Fig. 3**).

Conclusion: We have refined the L-DAI to characterize SLE patients with active clinical and/or serological disease vs. those with low/quiescent disease. Treat-to-target approaches using a sensitive and objective biomarker surrogate for clinical disease activity has the potential to help improve clinical disease management and prevent organ damage in SLE.

Evaluation and Management of the "False Positive" ANA and Undifferentiated Connective Tissue Disease Amongst Rheumatologists

Neha Gupta[1], Sarah Ford[2], Lane Scheiber[2], Tangada Rao[2] and Abhishek Nandan[2], [1]Virginia Commonwealth University Health Systems, Richmond, VA, [2]Virginia Commonwealth University Health Systems; Veterans Affairs Medical Center, Richmond, VA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The management of a positive anti-nuclear antibody (ANA) is one of the most common consultations in rheumatology outpatient practice. The prevalence of a positive ANA in the general population is far greater than that of connective tissue diseases (CTDs), including systemic lupus erythematosus (SLE). There are no guidelines on management of a positive ANA without a clear diagnosis. This study seeks to understand how rheumatologists navigate such scenarios.

Methods: We reached out to 40 practicing rheumatologists using an anonymized, case-based survey using multiple choice questions with branching logic. Demographic information was obtained. We used American College of Rheumatology/European Alliance of Associations for Rheumatology (ACR/EULAR) criteria for SLE to design the cases.

In two cases, patients had a high titer ANA but met no ACR/EULAR criteria for SLE. These cases represent a false-positive ANA (FP-ANA). Two additional cases had patients with low-positive ANA titers, morning-dominant joint stiffness for one hour with a normal musculoskeletal exam, and one ACR/EULAR criteria for SLE. These two cases represent undifferentiated connective tissue disease (UCTD). A final case had isolated thrombocytopenia along with a positive ANA (ITP-UCTD).

Participants were asked if they would obtain ANA sub-serologies or discharge the patient from practice. Of those obtaining sub-serologies, they were asked when follow-up should be arranged, if routine labs are to be obtained at follow-up, and if they would start hydroxychloroquine (HCQ). In each case if sub-serologies were requested, they always returned negative.

Results: 21 out of 40 rheumatologists participated. Work setting: 47% academic, 53% non-academic. Years in practice: 52% with 1-10 years, 24% with 10-20 years, and 24% with more than 20 years. 57% of participants worked in suburban areas. Practice characteristics were not significant in case decision-making.

A mean of 81% of participants in the FP-ANA cases obtained sub-serologies, while the rest chose to discharge the patient without further work-up. Despite negative sub-serologies, 87.5% of participants wished to continue to follow up. One of these cases is detailed in Figure 1.

In all three UCTD cases, all participants obtained sub-serologies. A mean of 55% of participants started HCQ. All participants chose to follow the patient long-term. The ITP-UCTD case is detailed in Figure 2.

Conclusion: Our study suggests that there is substantial variability in how rheumatologists manage the "false-positive ANA" and UCTD. Based on the data, many participants obtain ANA-specific antibodies for a high-titer ANA even when no clinical criteria are met. Most rheumatologists would continue to follow all patients with a positive ANA, although the decision to start HCQ was variable among responders in the cases. Yet, clinical practice guidelines on these practices are lacking. Balancing

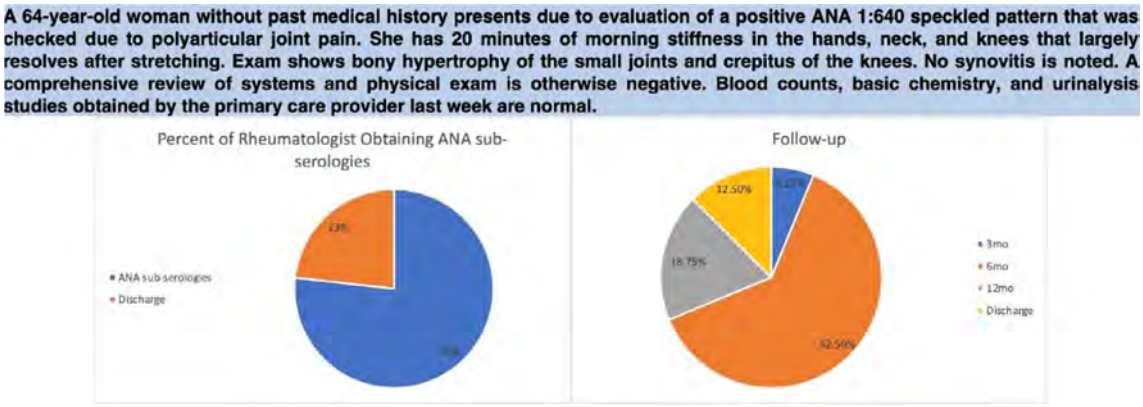

Figure 1: A representative case of a positive ANA patient without ACR/EULAR criteria for CTD. Pie charts show the percentage of participants that would pursue further ANA sub-serologies. Of those obtaining sub-serologies (which returned negative), the additional pie chart shows the distribution of when follow-up was chosen to be arranged.

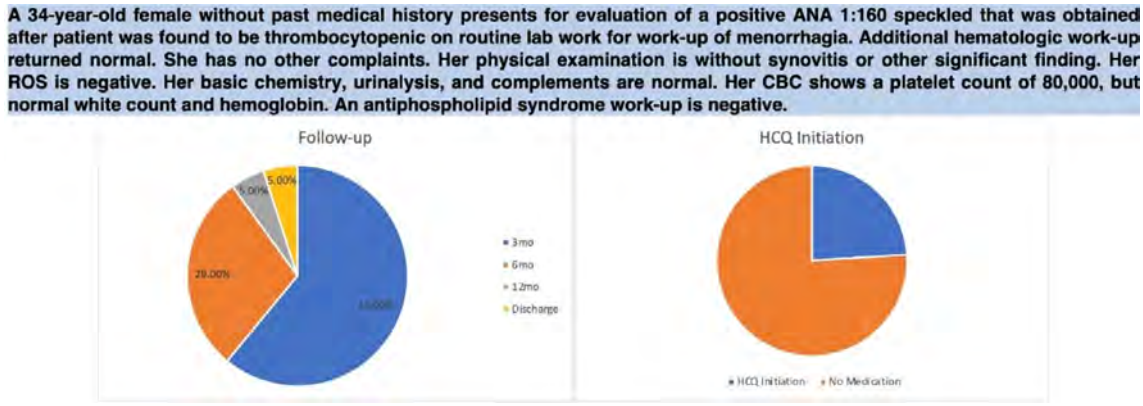

Figure 2: A representative case of a positive ANA patient with thrombocytopenia. All participants chose to obtain sub-serologies, which were negative. Pie charts show the percentage of participants electing to initiate HCQ therapy and the distribution of when follow-up was chosen to be arranged.

the economic costs of continued follow up visits and lab testing in these cases with the risk of developing a defined CTD is a complicated endeavor for most rheumatologists. Further studies and evidence are needed to guide decision making in such scenarios.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus nephritis (LN) is an autoantibody-mediated disease that can activate C1q and the classical complement pathway. Pathogenic anti-C1q antibodies (PACAs) are often present, amplifying classical pathway inflammation and contributing to progressive kidney damage. Elevated C4d and reduced C4 are markers of classical complement activation and consumption, respectively. For LN patients in the CLUES/UCSF Study, C4d/C4 ratio positively correlated with PACAs and urine protein-creatinine ratio (UPCR). To validate this correlation, the Sanguine Bio study was conducted.

Methods: Samples were collected from 40 LN patients (plus 20 healthy controls) from the CLUES/UCSF Study and 24 LN patients (plus 10 healthy controls) from Sanguine Bio. In the CLUES/UCSF Study, systemic lupus erythematosus (SLE) diagnoses were confirmed by study physicians according to either of the following definitions: (a) meeting ≥4 of the 11 ACR revised classification criteria for SLE as defined in 1982 and updated in 1997 or (b) meeting 3 of the 11 ACR criteria along with having SLE confirmed by a study rheumatologist. Complement activation and consumption (C4d, C4), exploratory biomarkers in plasma and urine, and UPCR were evaluated.

Results: Sanguine Bio samples from a subset of LN patients demonstrated elevated C4d/C4 compared to healthy controls, indicating classical complement pathway activation (**Figure**). Urinary biomarkers of LN correlated with C4d/C4 ratio in these patients.

Conclusion: In these LN patients, C4d/C4 ratios were elevated and correlated with LN biomarkers in blood and urine, supporting classical complement activity. These data support an ongoing, phase 1b study of ANX009 with the goal of assessing safety, tolerability, and pharmacodynamics of repeat doses of subcutaneous ANX009 with standard of care in adults with LN. ANX009 is an anti-C1q antigen binding fragment targeting LN patients with evidence of classical complement activity (elevated C4d/C4).

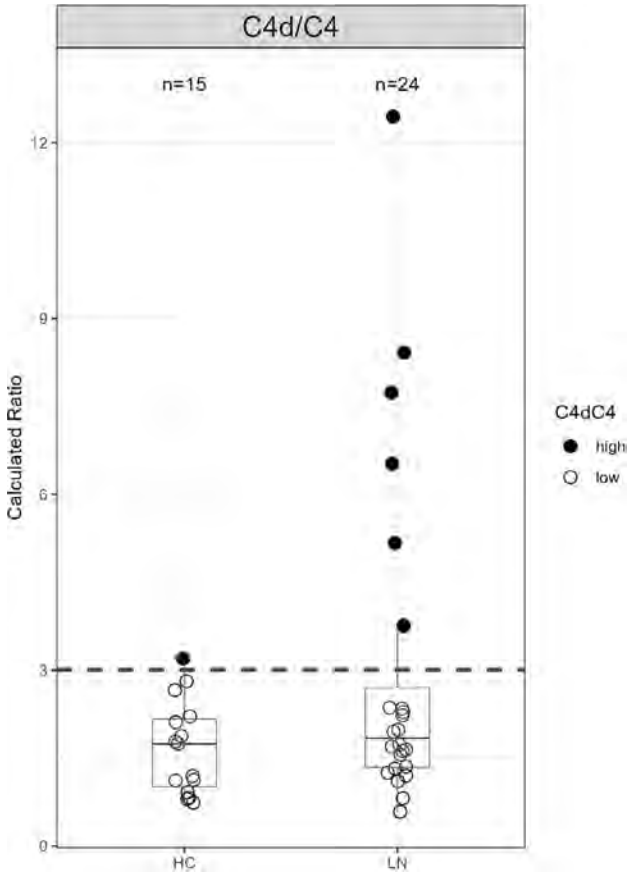

Figure. A Subset of Patients with LN Demonstrated Elevated C4d/C4 Over Healthy Controls

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Cell-bound complement activation products (CB-CAPs), when part of a multi-analyte assay with algorithm (MAP), are valuable SLE diagnostic biomarkers. Levels of erythrocyte-bound complement activation products have been associated with SLE disease activity. The clinical and serologic phenotype of longitudinal MAP-positive patients has not been well described. Herein, we assessed the relationship between longitudinal MAP results with clinical and laboratory variables.

Methods: This was a longitudinal study of adult SLE patients (2012 SLICC or ACR/EULAR criteria) with ≥2 routine clinic visits from June 2020 to July 2022. Patients completed the polysymptomatic distress scale. The rheumatologist scored the PGA and SLEDAI scores. Autoantibodies including ANA and anti-RNA binding proteins were measured by ELISA. Anti-dsDNA was measured by immunofluorescence using the Crithidia luciliea assay. CB-CAPs were analyzed by flow cytometry. The multi-analyte assay panel (MAP) was determined using a 2-tier algorithm. Chi-square and ANOVA tests were used to analyze differences in demographic and disease history between persistently MAP positive, MAP negative, and patients with changing MAP positivity. Serologies and clinical variables at follow-up visits were compared using generalized linear models.

Results: In this longitudinal cohort of 113 patients with 175 follow-up visits (90% female, 62% Black, mean age 45) 65% were consistently MAP positive, 20% were negative, and MAP positivity changed in 15%. Persistent MAP-positive patients were younger and more often of the Black race. There was no difference in MAP positivity based on disease duration. Significantly more MAP-positive patients met ACR/EULAR criteria and had higher total ACR/EULAR scores. Patients who remained MAP positive were more likely to have a history of acute cutaneous lupus but there was no difference in other historical manifestations between groups (Table 1).

When evaluating longitudinal associations, patients with persistent MAP positivity had higher total SLEDAI scores, but there was no difference in the clinical SLEDAI. Therapy was comparable across groups except for greater use of belimumab, rituximab, and cyclophosphamide in persistent MAP-positive patients. Patients who remained MAP positive reported higher rates of depression, but a similar burden of polysymptomatic distress and fatigue. A greater number of lupus-specific serologies were present in those with MAP positivity (Table 2).

Table 1. Demographics and Disease History of the SLE patient cohort

	Overall Patients (N = 113)	MAP remains positive (N = 73)	MAP remains negative (N = 23)	MAP changing positivity (N = 17)	p-value
Demographics					
Age, mean (SD)	44.6 (14.3)	42.1 (15.0)	47.1 (12.9)	52.0 (10.2)	0.0227

SLEDAI Rash	17.1% (30/175)	21.6% (24/111)	9.3% (4/43)	0.0% (0/10)	18.2% (2/11)	0.0601
Patient reported symptoms						
Polysymptomatic distress score, mean (SD), N	9.3 (6.7), 159	8.8 (6.7), 99	10.8 (6.6), 40	9.1 (5.1), 10	7.8 (7.3), 10	0.3985
Fatigue (moderate/severe)	48.0% (72/150)	46.4% (45/97)	54.3% (19/35)	55.6% (5/9)	33.3% (3/9)	0.6473
Depression	36.5% (54/148)	45.7% (43/94)	21.6% (8/37)	11.1% (1/9)	25.0% (2/8)	0.0136

Conclusion: Identifying endotypes of SLE is key to advancing personalized medicine. In this cohort of patients with SLE, most patients had static MAP results. MAP results changed between visits in a subset of patients; although there was not a distinct clinical, demographic, or laboratory phenotype in those patients. Patients with consistent MAP positivity reported more depression and had a greater burden of disease activity as measured by the ACR/EULAR score and greater use of biologic and cytotoxic therapy. Combining longitudinal MAP scores with assessments of SLE activity may provide important prognostic information. Larger studies are ongoing to evaluate the relationship between individual CB-CAPs and disease activity.

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Cognitive impairment (CI) is one of the most common manifestations of Neuropsychiatric Systemic Lupus **Erythematosus** (NPSLE). Studies have reported that SLE patients with different NPSLE syndromes have alterations in the cerebrospinal fluid or their serum levels of various cytokines and proteases (analytes) that can lead to neuroinflammation. However, studies focused on analytes in CI are scarce. In this study, we investigated the ability of various serum analytes to discriminate SLE patients with CI from those without impairment.

Methods: Two hundred ninety individuals 18-65 years old who met the 2019 EULAR/ACR classification criteria for SLE were included. Cognitive ability was measured by psychometrists utilizing the 1-hr ACR-Neuropsychological Battery (ACR-NB), and the scores were standardized by age and gender to operationally classify patients' performance into CI (z-score of ≤-1.5 in two or more domains) and non-CI. At the time of the neuropsychological assessment patients provided blood samples. The serum levels of nine analytes (IL-6, IL-10, IFN-γ, MMP-9, NGAL, S100A8/A9, S100B, TNF-α, and TWEAK) were determined using ELISA. The data were randomly partitioned into a training (70%) and a test (30%) sets. A predictive regression model was performed to evaluate the measured analytes' ability to discriminate SLE patients with CI from patients without impairment. The optimal cut-off values to discern between CI and non-CI for each analyte were

Table. 1. AUC of measured analytes serum levels to discriminate SLE patients with CI from those without CI.

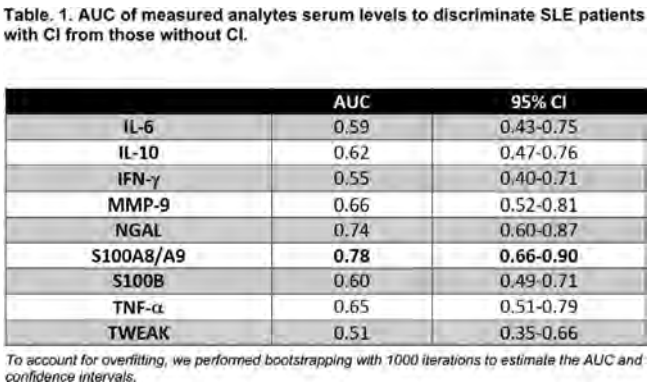

Table. 1. AUC of measured analytes serum levels to discriminate SLE patients with CI from those without CI.

	AUC	95% CI
IL-6	0.59	0.43-0.75
IL-10	0.62	0.47-0.76
IFN-γ	0.55	0.40-0.71
MMP-9	0.66	0.52-0.81
NGAL	0.74	0.60-0.87
S100A8/A9	**0.78**	**0.66-0.90**
S100B	0.60	0.49-0.71
TNF-α	0.65	0.51-0.79
TWEAK	0.51	0.35-0.66

To account for overfitting, we performed bootstrapping with 1000 iterations to estimate the AUC and confidence intervals.

Table 2. MMP-9, NGAL, S100A8/A9, and various combinations ability to discriminate SLE patients with CI from those without CI.

Table 2. MMP-9, NGAL, S100A8/A9, and various combinations ability to discriminate SLE patients with CI from those without CI.

Analyte	Sn (%)	Sp (%)	PPV (%)	NPV (%)
MMP-9 (≥ 78.42 pg/mL)	78	32	71	41
NGAL (≥ 141.47 pg/mL)	42	69	70	35
S100A8/A9 (≥ 2367 ng/mL)	29	**86**	**82**	36
Analyte Combination				
S100 A8/A9 and MMP-9	38	87	86	40
S100 A8/A9 and NGAL	35	74	47	63
S100 A8/A9 and NGAL and MMP-9	15	89	48	61

For those analytes with the highest AUC (MMP-9, NGAL, and S100A8/A9) optimal cut-off values to discern between CI and non-CI were obtained by Youden's index, Sensitivity (Sn), specificity (Sp), positive predictive value (PPV), and negative predictive value (NPV).

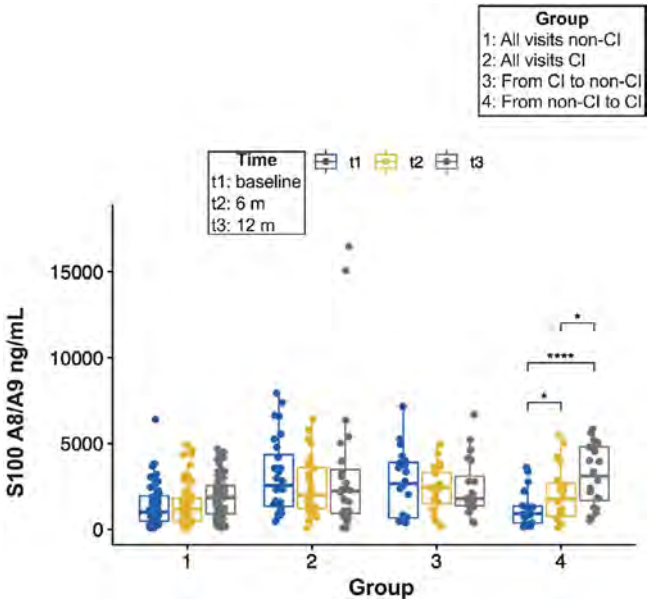

Figure 1. Pairwise comparison of S100A8/A9 serum levels between time points. P-values were adjusted using the Bonferroni multiple-testing correction method. Significant differences are indicated by asterisks (* $p \leq 0.05$, **** $p \leq 0.0001$). Non-significant differences are not displayed.

obtained by Youden's index, and their sensitivity (Sn), specificity (Sp), and predictive values were calculated. For patients that had completed cognitive assessment at 6 and 12 months (n=125, 43%), pairwise comparisons of the S100A8/A9 serum levels between time points were performed.

Results: Of 290 patients, 40% had CI (n=116). Overall, no differences in demographic or clinical characteristics were observed between patients with and without CI. S100A8/A9 had the highest AUC (0.79, 95% CI: 0.66-0.90) (Table 1) and displayed the greatest discriminative ability (Sp 86% and PPV 82%) (Table 2) to differentiate between patients with and without CI. Compared to the predictive ability of S100A8/A9 alone, the improvement of S100A8/A9 combined with other analytes was marginal, except for a mild increase in Sn and Sp with MMP-9 (Table 2). Cognitive status remained unchanged for most of the patients with 6- and 12-month follow-up visits (57 and 28 remained in the non-CI and the CI groups, respectively, whereas 20 with CI changed to non-CI and 20 from non-CI to CI). S100A8/A9 serum levels increased over time in group 4 (from non- CI to CI) and there was a trend to reduced levels from the baseline and 6-month visits to the 12-month visit in group 3 (from CI to non-CI) (Figure 1).

Conclusion: In this large cohort of well-characterized SLE patients, amongst all measured analytes, S100A8/A9 had the greatest discriminatory ability in differentiating between SLE patients with and without CI. Replication of these findings is needed to confirm the utility of S100A8/A9 as a biomarker for CI in SLE. Research into the underlying mechanisms is also needed.

Development of Charlson Comorbidity Index (CCI) Comorbidities and CCI Score in Danish Nationwide Cohort of 3,178 Patients with Newly Diagnosed Systemic Lupus Erythematosus

Renata Baronaite Hansen, Copenhagen Research Center for Autoimmune Connective Tissue Diseases, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Comorbidity risk is remarkably increased in patients with Systemic Lupus Erythematosus (SLE) compared with the general population. A better understanding of comorbidity development in SLE is needed to improve the prognosis in SLE patients. We assessed the accrual of comorbidity utilizing the Charlson Comorbidity Index (CCI) in a large nationwide cohort of patients with SLE compared with matched population controls.

Methods: We assembled a cohort of adult patients with incident SLE using ICD diagnosis codes registered in the Danish National Patient Register (DNPR) from January 1996 to July 2018 (n=3,178). The date of the first SLE registration in the DNPR was considered the baseline. SLE patients were age, - and sex-matched to 60,090 population controls randomly selected from the Danish Civil Registration System. Comorbidities (during outpatient and inpatient care) were identified using DNPR. We estimated the CCI score, number of CCI comorbidities and cumulative prevalence (%) of CCI comorbidities, stratified by sex, at baseline (SLE diagnosis) and at the end of follow-up (FU) (death, emigration or July 2018) in patients with SLE and controls.

Results: 84% of SLE patients and non-SLE controls were female; mean age at baseline was 47 years. *Mean CCI scores* were 2.3 times higher in SLE patients vs controls at baseline (0.7 vs 0.3) and 1.9 times higher at the end of FU (1.7 vs 0.9). Similarly, the CCI scores were about 2-3 times higher in SLE patients than controls in the 1-2, 3-4 and ≥ 5 *score categories*, both at baseline and the end of FU (Table 1). Males had higher scores than females in all the above categories.

Table 1. Baseline (SLE diagnosis) and end-of-follow-up CCI scores, stratified by sex, in patients with incident SLE compared with matched general population controls, followed during January 1996 - July 2018

CCI score*	SLE n= 3178		PC n= 60090	
	Baseline n (%)	End of follow-up n (%)	Baseline n (%)	End of follow-up n (%)
1-2				
All	807 (25.4)	1088 (34.2)	8239 (13.7)	13371 (22.3)
Females	637 (23.8)	913 (34.1)	6534 (12.9)	10939 (21.6)
Males	170 (34.0)	175 (35.0)	1705 (18.0)	2432 (25.7)
3-4				
All	180 (5.7)	474 (14.9)	1339 (2.2)	3950 (6.6)
Females	134 (5.0)	362 (13.5)	963 (1.9)	2925 (5.8)
Males	46 (9.2)	112 (22.4)	376 (4.0)	1025 (10.8)
≥ 5				
All	58 (1.82)	304 (9.57)	569 (0.95)	2910 (4.84)
Females	39 (1.46)	222 (8.29)	396 (0.78)	2108 (4.16)
Males	19 (3.8)	82 (16.4)	173 (1.83)	802 (8.46)

CCI: Charlson Comorbidity Index; PC: population control.

*The original version of the CCI contains 19 comorbidities (we excluded the rheumatologic disease category). The CCI score is calculated by summing the assigned weights for each comorbidity, e.g., assigned weight is 1 for cerebrovascular disease, 2 for moderate or severe renal disease, 3 for moderate or severe liver disease, and 6 for metastatic solid tumor (Charlson ME et al., 1987).

Table 2. Number of CCI comorbidities at baseline (SLE diagnosis) and at the end of follow-up, stratified by sex, in patients with incident SLE compared with matched general population controls, followed during January 1996 - July 2018

Number of CCI Comorbidities*	SLE n= 3178		PC n= 60090	
	Baseline n (%)	End of follow-up n (%)	Baseline n (%)	End of follow-up n (%)
0				
All	2133 (67.1)	1312 (41.3)	49943 (83.1)	39859 (66.3)
Females	1868 (69.8)	1181 (44.1)	42722 (84.4)	34643 (68.4)
Males	265 (53.0)	131 (26.2)	7221 (76.2)	5216 (55.1)
1				
All	707 (22.3)	909 (28.6)	7506 (12.5)	11625 (19.4)

Males	16 (3.2)	78 (15.6)	110 (1.2)	548 (5.8)

CCI: Charlson Comorbidity Index; PC: population control.

* The original CCI version contains 19 comorbidities (Charlson ME et al., 1987). The Rheumatologic disease category is excluded; "Any tumor without metastasis" is combined with "Leukemia and lymphoma".

Number of CCI comorbidities

Fewer SLE patients than controls had no CCI comorbidities at baseline: 67% vs 83%, and at the end of FU: 41% vs 66% (Table 2). Two out of ten SLE patients had at least one CCI comorbidity at baseline vs one out of ten controls. Moreover, compared with controls, patients with SLE were 2-3 times more likely to have 2, 3 and 4 CCI comorbidities, at baseline and the end of FU.

Cumulative prevalence of CCI comorbidities

The cumulative prevalence of myocardial infarction, congestive heart failure, and peripheral vascular, cerebrovascular, chronic pulmonary and liver diseases was 2-4 times higher in patients with SLE than controls, at baseline and the end of FU (Table 3). Of note, in SLE patients, the cumulative prevalence of all the above comorbidities, as well as diabetes and peptic ulcer, doubled by the end of FU compared with baseline. Relative to controls, renal disease was the most prevalent comorbidity in SLE, with baseline and end-of-FU prevalence 8.6 and 6.5 times higher in SLE patients vs controls. Baseline and end-of-FU prevalence of malignancy was similar in SLE and controls. Most CCI comorbidities were more prevalent in males than females.

Table 3. Cumulative prevalence of CCI comorbidities at baseline (SLE diagnosis) and at the end of follow-up in patients with incident SLE compared with matched general population controls, followed during January 1996 - July 2018

CCI comorbidity*	SLE n= 3178		PC n=60090	
	Baseline n, %	End of FU n, %	Baseline n, %	End of FU n, %
Myocardial infarction	92 (2.9)	186 (5.9)	850 (1.4)	1872 (3.1)
Congestive heart failure	74 (2.3)	222 (7.0)	528 (0.9)	1843 (3.1)
Peripheral vascular disease	185 (5.9)	366 (11.5)	853 (1.4)	2243 (3.7)
Cerebrovascular disease	228 (7.2)	501 (15.8)	1622 (2.7)	4326 (7.2)
Chronic pulmonary disease	274 (8.6)	588 (18.5)	2877 (4.8)	5755 (9.6)
Renal disease	218 (6.9)	518 (16.3)	487 (0.8)	1485 (2.5)
Diabetes without chronic complications	89 (2.8)	213 (6.7)	1361 (2.3)	3054 (5.1)
Diabetes with chronic complications	42 (1.3)	107 (3.4)	538 (0.9)	1337 (2.2)
Liver disease, mild	64 (2.0)	142 (4.5)	410 (0.7)	863 (1.4)
Liver disease, moderate/severe	9 (0.3)	33 (1.0)	81 (0.1)	291 (0.5)
Peptic ulcer disease	85 (2.7)	174 (5.5)	1009 (1.7)	1851 (3.1)
Hemiplegia/ paraplegia	10 (0.3)	21 (0.7)	92 (0.2)	179 (0.3)
Dementia	13 (0.4)	60 (1.9)	204 (0.3)	1059 (1.8)
Malignancy without metastases*	168 (5.3)	478 (15.0)	2856 (4.8)	7632 (12.7)
Metastatic solid tumor	11 (0.4)	89 (2.8)	257 (0.4)	1431 (2.4)
AIDS	0	0	29 (0.1)	41 (0.1)

CCI: Charlson Comorbidity Index; PC: population control; FU: follow-up; AIDS: Acquired Immunodeficiency Syndrome.
* The original CCI version contains 19 comorbidities (Charlson ME et al., 1987). The Rheumatologic disease category is excluded; "Any tumor without metastasis" is combined with "Leukemia and lymphoma" into "Malignancy without metastases".

Conclusion: The baseline and end-of-follow-up cumulative prevalence of myocardial infarction, congestive heart failure, and renal, peripheral vascular, cerebrovascular, chronic pulmonary and liver diseases was substantially increased in patients with SLE compared with matched general population controls. The CCI scores and the number of CCI comorbidities were about 2-3 times higher in SLE patients than controls, at baseline and at the end of follow-up.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I

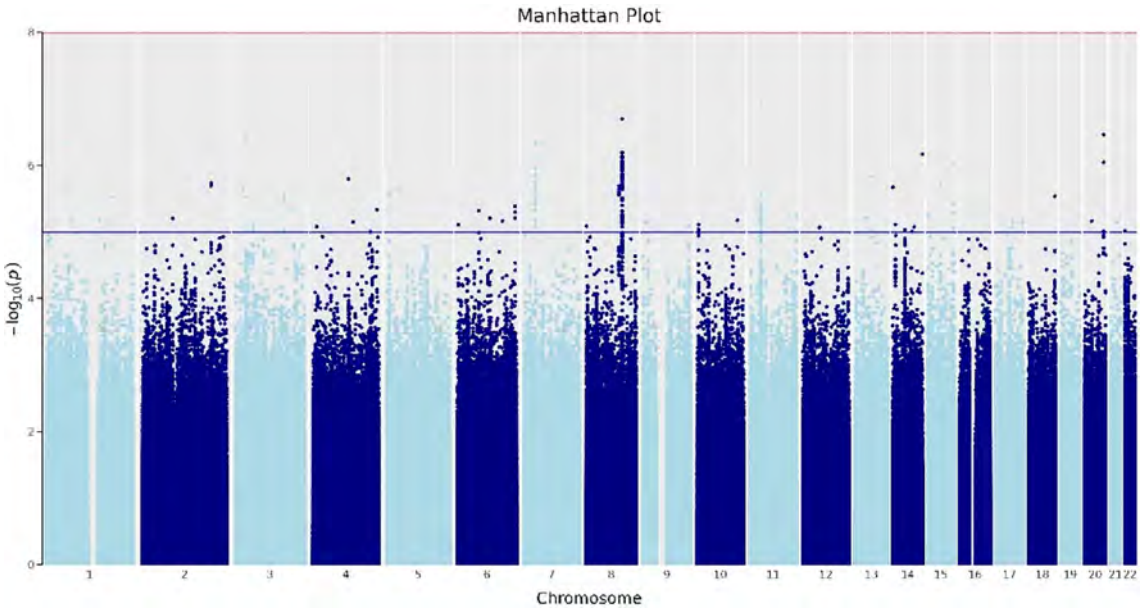
Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus nephritis (LN) is one of the most common and severe manifestation of SLE. Risk factors for lupus nephritis and renal function decline are not well understood. We completed a genome wide association study (GWAS) of LN in a multi-ethnic cohort of children and adults with SLE.

Methods: We included SLE patients from dedicated Lupus clinics and the SLICC cohort. All patients met ACR and/or SLICC SLE classification criteria and were genotyped on a multi-ethnic Illumina array. Ungenotyped SNPs were imputed to TopMed, and principal components for ancestral estimation were generated using both 1000 Genomes and GRAF-pop. LN was defined by SLE criteria and confirmed on kidney biopsy in 75%. Kidney function (estimated glomerular filtration rate, eGFR) was calculated using the Schwartz Bedside formula for measures < 18 years and CKD-EPI (without race) for >18 years of age and collected longitudinally over time. Wilcoxon rank sum or Chi-square tests were used to compare characteristics between LN and Non-LN patients. We completed GWAS of LN in marginal and multivariable adjusted regression models with principal components for ancestry, sex and cohort site.

Results: The study included 2981 patients with SLE, 88% female, 46% of European ancestry and 27% childhood-onset SLE. LN was present in 45%. People with LN were younger at diagnosis, and more likely of African American or East Asian ancestry than those without LN. People with LN had significantly lower within-person mean eGFR, greater eGFR variability



Manhattan Plot for LN, adjusted for PC, sex and site

Table: Characteristics of LN and Non-LN patients

Patient Characteristics	All SLE Patients (n=2981)	LN SLE Patients (n=1351)	Non-LN SLE Patients (n=1630)	P-value

Within-Person eGFR Variance*	106.6 [51.4, 198.7]	137.2 [69.6, 268.6]	87.2 [43.1, 156.4]	$2.2e^{-16}$
eGFR slope ml/min/1.73m^2/y*	-0.53 [-2.00, 0.48]	-0.67 [-2.26, 0.36]	-0.53 [-1.83, 0.67]	$2.3e^{-02}$

* data available for N= 2740

and slope over time compared to those without LN (Table). GWAS of LN demonstrated a peak on chromosome 8, intronic to *ATP6V1C1*, yet did not reach a genome-wide significance ($p < 5x10^{-8}$).

Conclusion: A GWAS of LN in a multiethnic cohort of children and adults with SLE, did not identify a significant locus. The top signal was on chromosome 8, intronic to *ATP6V1C1*. We will complete GWAS of repeated eGFR measures, as it is a more informative outcome that we expect will improve power for detecting genetic loci for LN.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-Ro antibodies can be detected in 40% of patients with systemic lupus erythematosus (SLE) and have been associated with various clinical manifestations of the disease as well as maternal-fetal complications. The aim of this study was to describe the frequency of anti-Ro antibodies in SLE patients and to assess their association with disease characteristics, maternal-fetal complications, treatment, morbidity and mortality.

Methods: Retrospective observational study. Data from SLE patients of the National Registry of the Argentine Society of Rheumatology (RELESSAR) were used. Sociodemographic data, comorbidities, disease characteristics, maternal-fetal complications, SLE morbidity and mortality, activity and damage scores were recorded.

Statistical analysis: Descriptive statistics. Appropriate tests (Chi2, Fisher, Student's t-test or Wilcoxon), and univariate/multivariate logistic regression analyses were conducted to identify factors associated with presence of anti-Ro antibodies.

Corticosteroids	0.49	0.25-0.92	**0.032**
Methotrexate	0.75	0.6-1	**0.036**

OR = Odds Ratio; **CI 95%**= Confidence Interval 95%; **Anti-Sm** = Anti-Smith antibodies; **Anti-RNP** = Anti-ribonucleoprotein antibodies.

Results: A total of 1513 patients were included. Patient characteristics are shown in **Table 1**. Anti-Ro antibodies were requested in 88% (n=1331), of which 41% (n=552) were positive. Characteristics of patients with positive and negative Anti-Ro antibodies can be observed in**Table 2.** Anti-Ro antibodies were associated with hypocomplementemia (p< 0.05), anti-La antibodies (< 0.001), anti-Sm antibodies (p< 0.001), anti-RNP antibodies (p< 0.001) and Sjogren's syndrome (p< 0.001). Also were associated with Raynaud's phenomenon (p< 0.004), pericarditis (p< 0.005) and interstitial pneumonitis (p< 0.02). More infections (p< 0.01) and a greater use of corticosteroids (p< 0.04) and methotrexate (p< 0.04) were observed. Univariate analysis in patients with Anti-Ro determination is shown in **table 3**. In the multivariate model, the independent variables were anti-Sm antibodies (OR 1.9, 95% CI 1.4-2.5), anti-La antibodies (OR 48, 95%CI 26-99), chronic thyroiditis (OR 1.9, 95%CI 1.3-2.7) and the use of methotrexate (OR 0.66, 95%CI 0.5-0.9).

Conclusion: In this SLE patients, anti-Ro positivity was associated with the presence of other antibodies, chronic thyroiditis and methotrexate use, but not with any specific clinical profile, maternal-fetal complications or SLE-related morbidity and mortality.

HDL-Cholesterol Efflux and the Complement System Are Linked in Systemic Lupus Erythematosus

Ivan Ferraz Amaro[1], Maria García-González[1], Fuensanta Gómez-Bernal[1], Juan Carlos Quevedo-Abeledo[2], Yolanda Fernández-Cladera[1], Agustín F González-Rivero[1] and Miguel A Gonzalez-Gay[3], [1]Hospital Universitario de Canarias, Santa Cruz de Tenerife, Spain, [2]Hospital Doctor Negrín, Las Palmas de Gran Canaria, Spain, [3]IDIVAL and School of Medicine, UC, Santander; Department of Rheumatology, IIS-Fundación Jiménez Díaz, Madrid, Santander, Spain

SESSION INFORMATION

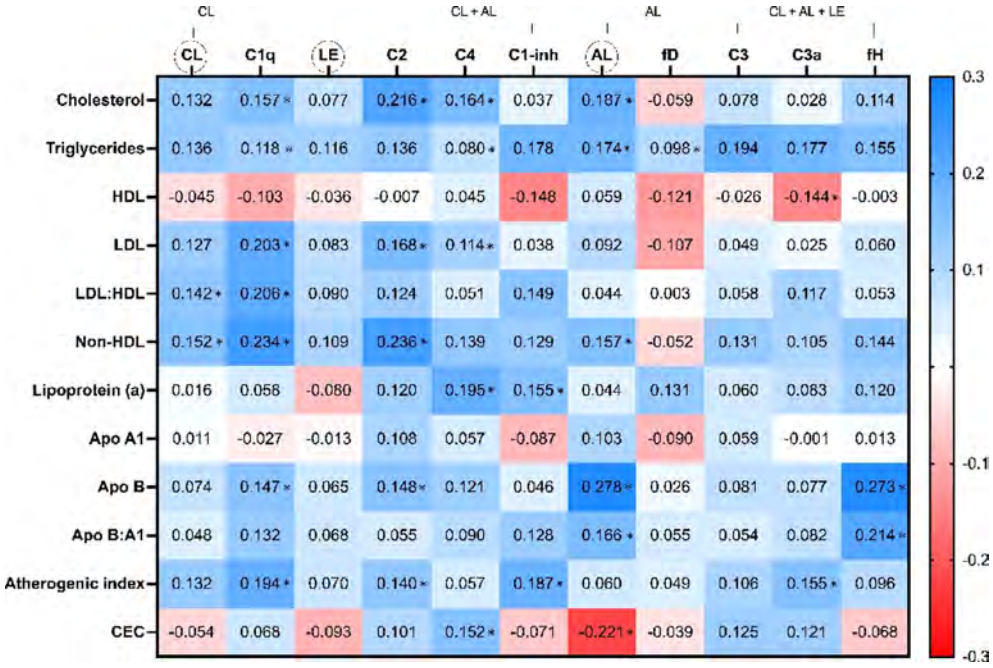
Session Date: Sunday, November 12, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Cholesterol efflux capacity (CEC), the ability of high-density lipoprotein (HDL) cholesterol to accept cholesterol from macrophages, has been linked to cardiovascular events. Systemic lupus erythematosus (SLE) is characterized by the consumption of complement (C) proteins, and has been associated with an increased risk of cardiovascular disease. CEC is reduced in SLE patients compared to controls. In the present work, our objective was to analyze whether the disruption of C influences CEC in patients with SLE.

Methods: New generation functional assays of the three pathways of the C system were performed in 207 patients with SLE. Additionally, serum levels of inactive (C1q, C2, C3, C4, factor D) and activated (C3a) molecules, and regulators (C1-inhibitor and factor H) of C system were measured. CEC, using an in vitro assay, and lipoprotein serum concentrations were assessed. Multivariable linear regression analysis was performed to assess the relationship between C system and CEC.

Results: Overall, no associations were found between disease characteristics or comorbidity and CEC. Only the use of methotrexate showed a significant relationship to CEC (beta coef. 3 [95%CI 0.8-4], p=0.005). Besides, the presence of hypertension and Katz index showed a trend to be associated with CEC, although, in these cases, statistical significance was not reached.

The univariable association of these lipid pattern related molecules with the cascades and individual components of the C system is exposed as Spearman's Rho correlation coefficients in **Figure 1**. In this sense, many associations were found in the univariable analysis. Most of them turned out to be positive (blue in the heatmap). The strongest, with a coefficient greater than 0.2, were found between C1q (classical pathway) and the serum levels of LDL, LDL:HDL ratio, and non-HDL cholesterol; between C2 (classical and alternative pathway) and total cholesterol and non-HDL cholesterol; and between the



Heat map of the relationship of lipid profile molecules and complement pathways and individual elements. CL: classical, AL: alternative, LE: lectin, HDL: high density lipoprotein cholesterol, LDL: low density lipoprotein cholesterol, Apo: apolipoprotein, CEC: cholesterol efflux capacity, fH: factor H, fD: factor D. Cell numbers represent Spearman's Rho correlation coefficients. Significant correlations (p inferior to 0.05) are marked with an asterisk.

Multivariable analysis of the relationship of complement system pathways and components to cholesterol efflux capacity.

Complement routes and elements are considered the independent variable.
Multivariable analysis is adjusted for hypertension, Katz index, methotrexate, azathioprine, statins intake and total cholesterol, HDL, lipoprotein (a), triglycerides and apolipoproteins A1 and B serum levels.

Multivariable analysis of the relationship of complement system pathways and components to cholesterol efflux capacity

functional test of the alternative pathway and apolipoprotein B and CEC. The molecules most associated with the activation of the three pathways were apolipoprotein B and the Apo B:ApoA1 ratio. CEC was significantly and positively associated with C4, but negatively with the alternative pathway functional assay. However, the functional test of the lectin pathway showed no association with any of the lipid pattern molecules.

The association of C functional assays and individual C elements with CEC is represented in **Table 1**. We performed a multivariable analysis controlling for hypertension, Katz index, methotrexate, azathioprine (disease related data that had a p value inferior to 0.20 in relation to CEC), statins intake, and all lipids profile molecules that were not derived from a formula (to avoid collinearity). After this adjustment, the functional assay of the alternative route showed a significant and negative relationship with CEC (beta coef. -0.02 [95%CI -0.04- -0.002], p=0.030). This was also de case for C2 and C3, in which the associations were found to be positive and statistically significant (**Table 1**).

Conclusion: C system and CEC are interconnected in patients with SLE.

Urinary Neutrophil Gelatinase-associated Lipocalin (NGAL) as a Mediator of the Association Between Particulate Matter Exposure and Disease Activity in Systemic Lupus Erythematosus

Ji-Hyoun Kang[1], Hyemin Jeong[2], Sung-Eun Choi[2], Dong-Jin Park[2], Han Joo Baek[3], Hyo-Jin Choi[4], Jae Hyun Jung[5] and Shin-Seok Lee[2], [1]Chonnam National University Hospital, Gwangju, South Korea, [2]Chonnam National University Medical School & Hospital, Gwangju, South Korea, [3]Gil Medical Center, Gachon University College of Medicine, Inchon, South Korea, [4]Gil Medical Center, Gachon University College of Medicine, Incheon, South Korea, [5]Korea University Ansan Hospital, Ansan-si, South Korea

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Neutrophil gelatinase-associated lipocalin (NGAL) is an acute-phase glycoprotein increased by inflammatory stimuli, oxidative stress, and tissue injury. Although NGAL is associated with global and renal disease activity in systemic lupus erythematosus (SLE), it is not known whether particulate matter (PM) affects NGAL levels and lupus activity in these patients. Thus, we investigated the mediating role of NGAL in the association between PM_{10} and $PM_{2.5}$ exposure and lupus activity in a prospective, longitudinal cohort.

Methods: The study enrolled 386 patients from three metropolitan regions in Korea. The daily average PM_{10} and $PM_{2.5}$ concentrations were measured using portable air quality monitors and based on data from the National Ambient Air Monitoring System. Urinary NGAL (uNGAL) was measured at the time of enrollment and at 12 months, and disease activity was evaluated using the SLE Disease Activity Index 2000 (SLEDAI-2K) every 3 months for 1 year. Mixed Cox proportional hazard regression was performed to evaluate the associations of PM_{10} and $PM_{2.5}$ with uNGAL and SLE disease activity.

Results: Changes in PM_{10} and $PM_{2.5}$ were associated with changes in uNGAL ($\beta = 1.038$, 95% confidence interval [CI]: 1.017–1.059, $p < 0.001$; $\beta = 1.030$, 95% CI: 1.001–1.045, $p = 0.013$, respectively), and with changes of SLEDAI-2K scores of > 8 over 1 year in SLE patients ($\beta = 0.097$, 95% CI: 0.048–0.146, $p < 0.001$; $\beta = 0.100$, 95% CI: 0.054–0.146, $p < 0.001$, respectively). In addition, changes in uNGAL were significantly associated with changes in SLEDAI-2K scores of > 8 ($\beta = 1.000$, 95% CI: 1.000–1.002, $p = 0.043$).

Conclusion: The association between PM exposure and SLE disease activity may be partially explained by uNGAL levels.

Risk Factors for Immune Thrombocytopenia in Systemic Lupus Erythematosus and Generation of a Predictive Model to Assess Its Risk of Development

Irene Carrión-Barberà[1], Jesús Cornudella Lema[2], Sergio Vázquez Montes de Oca[3], Francesc García Pallarols[1], Jordi Monfort[1], Blanca Sánchez-González[1] and TAREK CARLOS SALMAN MONTE[4], [1]Hospital del Mar, Barcelona, Spain, [2]Faculty of Medicine, Pompeu Fabra University, Barcelona, Spain and Faculty of Medicine, Autonomous University of Barcelona, Barcelona, Spain, [3]Biomedical Informatics Research Group, IMIM, Barcelona, Spain, [4]Hospital del Mar/Parc de Salut Mar-IMIM, Barcelona, Spain

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease with a wide variety of manifestations including immune thrombocytopenia (ITP), which has been described in 7-40% of SLE patients.

The aims of our study are to determine the prevalence of ITP in the cohort of patients with SLE from Hospital del Mar, to identify those risk factors associated with its development, and to build a predictive model capable of evaluating the risk of suffering ITP in these patients.

Methods: A case-control study was conducted in which 407 medical records of patients with SLE were reviewed. 34 had developed ITP (cases) and were matched by sex and age with 2 controls with SLE without ITP.

To build the model, the cases whose ITP was posterior to SLE diagnosis and their controls were selected. The model consists of a Random Forest run on a cohort of 66 patients. The variables used were those that showed the greatest disparity in frequency of appearance between both groups. The model was trained with 70% of the cohort and tested with the remaining 30%. The scores obtained were calculated by means of the average of the results obtained after 1000 executions.

Results: Table 1 describes the characteristics and differences between cases and controls and Figure 1 the characteristics used to build the model. The prevalence of ITP in our cohort was 8.35% and it was diagnosed at an age of 43.14 ± 17.11 years. No significant differences were found in demographic variables between groups. At the diagnosis of SLE, controls presented a higher prevalence of arthritis (p-val = 0.02), while cases presented a higher proportion of hemolytic anemia (p-val = 0.04). Throughout the disease, cases presented a greater presence of lupus anticoagulant (p-val = 0.01), anticardiolipin (p-val = 0.044) and anti-β2-glycoprotein 1 antibodies (anti-β2GP1) (p-val = 0.003). In turn, cases had a significantly higher SLICC than controls (p-val = 0.02). Regarding treatment, cases received mycophenolic acid (MPA) (p-val = 0.02) and azathioprine (AZA) (p-val = 0.045) more frequently.

The variables that showed the most disparity and importance for the model were hemolytic anemia, low C4, low C50, anticardiolipin and anti-β2GP1, which were more frequent in cases, and oral ulcers, arthritis and Raynaud's phenomenon (RP) in controls.

The model presented a sensitivity of 87.53%, a positive predictive value of 81.92%, a specificity of 80.50%, an area under the curve (AUC) of 83.92% (Figure 2), and an accuracy of 83.68%.

Conclusion: Patients with SLE who develop ITP seem to have a different phenotype than those who do not, presenting with less arthritis and more hemolytic anemia at diagnosis, as well as higher positivity for antiphospholipid syndrome antibodies throughout the disease. Having developed ITP was associated with higher SLICC and receiving treatment more frequently with MPA and AZA, probably indicating a more severe disease.

We have created a predictive model capable of evaluating the risk of developing ITP in patients with SLE. By combining 8 variables (hemolytic anemia, low C4, low C50, anticardiolipin, anti-β2GP1, oral ulcers, arthritis, and RP), the model correctly predicts 87.53% of patients with SLE who will develop ITP with an accuracy of 83.68%.

Table 1: Characteristics of cases and controls. * Indicates statistically significant differences between cases and controls (95% confidence level). a Indicates mean ± standard deviation. b SLEDAI-1 point. ITP: immune thrombocytopenia. APS: antiphospholipid syndrome. Anti-β2GP1: anti-β2-Glycoprotein 1 antibodies. ACA: anticardiolipin antibodies. SLEDAI: systemic lupus erythematosus disease activity index. SLICC: systemic lupus international collaborating clinics damage index.

Insulin Resistance and the Complement System Are Linked in Patients with Systemic Lupus Erythematosus

José María Viotti-Serra[1], Maria García-González[1], Fuensanta Gómez-Bernal[1], Juan Carlos Quevedo-Abeledo[2], Yolanda Fernández-Cladera[1], Agustín F González-Rivero[1], Miguel A Gonzalez-Gay[3] and Ivan Ferraz Amaro[1], [1]Hospital Universitario de Canarias, Santa Cruz de Tenerife, Spain, [2]Hospital Doctor Negrín, Las Palmas de Gran Canaria, Spain, [3]IDIVAL and School of Medicine, UC, Santander; Department of Rheumatology, IIS-Fundación Jiménez Díaz, Madrid, Santander, Spain

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) patients more commonly have insulin resistance (IR) than control subjects. Recent studies have revealed that the complement (C) system is not only a mediator of the immune system but is also related to the pathogenesis of atherosclerosis in the general population. Given that the C alteration is a characteristic of SLE, in the present work we set out to analyze if there is a relationship between the C system and IR in patients with SLE.

Methods: New generation functional assays of the three pathways of the C system were performed in 225 non-diabetic patients with SLE. In addition, the serum levels of inactive (C1q, C2, C3, C4, factor D), activated (C3a) and regulators (C1 inhibitor and factor H) molecules of the C system were evaluated. Insulin and C-peptide serum levels were measured, and insulin resistance and indices of beta cell function were calculated using the homeostatic model assessment –HOMA–. Metabolic syndrome criteria fulfillments were applied. Multivariable linear regression analysis was performed to assess the relationship between C system and IR indices and the presence of metabolic syndrome.

Results: C system pathways functional tests and individual elements showed significant relationships with IR indices in the univariable and multivariable analysis (Table 1). In this regard, after multivariable analysis that included age, hypertension, dyslipidemia, BMI and the use of statins and prednisone, serum C3a and factor H values were associated with higher HOMA2-IR levels. In contrast, after adjusting for covariates, no relationship was found between system C and the HOMA2-B% index expressing β-cell function.

Seventy-five (33%) patients fulfilled the definition of metabolic syndrome using the NCEP ATP III criteria. As expected, patients with metabolic syndrome were significantly older, used statins and antihypertensive treatment more frequently, suffered more commonly obesity and dyslipidemia, and had higher values of BMI and abdominal circumference. Regarding disease-related data, in the univariable analysis, patients with metabolic syndrome had more accrual damage measured through the SDI score, and less frequently were taking hydroxychloroquine when the study was performed.

Beta coefficients are expressed using HOMA2-IR and HOMA2-B% as the dependent variables.
Linear regression analysis is adjusted for age, hypertension, dyslipidemia, body mass index and the use of statins and prednisone.
HOMA2-IR is calculated using insulin and glucose serum levels; HOMA2-B% is calculated with circulating C peptide and glucose.
Significant p values are depicted in bold.

According to the NCEP ATP III definition, metabolic syndrome is present if three or more of the following five criteria are met: waist circumference over 102 cm (men) or 88 cm (women), blood pressure over 130/85 mmHg, fasting triglyceride (TG) level over 150 mg/dl, fasting high-density lipoprotein (HDL) cholesterol level less than 40 mg/dl (men) or 50 mg/dl (women) and fasting blood sugar over 100 mg/dl. Metabolic syndrome is considered the dependent variable in this analysis. NCEP ATP III criteria for metabolic syndrome could not be calculated in 2 of 225 patients. Multivariable analysis is adjusted for age, prednisone and hydroxychloroquine intake. Significant p values are depicted in bold.

Besides, SLE patients with metabolic syndrome had some differences in C system routes functional assays and inactive and active individual C elements. With respect to this, in the univariable analysis, patients with metabolic syndrome exhibited higher serum levels of C1q, factor D, C3, C3a and C1-inh (Table 2). Besides, in the multivariable analysis, after adjustment for covariates, serum levels of C1q and C3 were associated with a higher odds ratio for the presence of metabolic syndrome (Table 2).

Conclusion: IR and metabolic syndrome are positively and independently related to higher serum levels of some serum C elements in patients with SLE with a predominant role of the alternative pathway elements.

Abstract Number: 0566

Characterization of Disease Activity Using a Novel Physiologic Biomarker in Pediatric SLE

Sangeeta Sule, Olivia Lamanna, Kevin Jackson, Sun-Young Ahn, Tineer Ahmed and Julia Finkel, Children's National Hospital, Washington, DC

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex inflammatory disease involving many organ systems. To better understand and treat SLE, two phenotypes have been proposed. Type 1 is defined by signs of autoreactivity and inflammation such as nephritis, arthritis, and rash. The Type 2 state is thought to result from cytokine mediated

peripheral and central (nociplastic) changes causing fatigue, sleep disturbance, and widespread pain, which often overlap with the manifestations of fibromyalgia (FM). While the grouping of patients based on symptoms and the clinical/serological components of disease is an established practice in the field, the application of this approach is limited by the tools available to assess and measure patient disease activity.

Methods: We performed phenotype testing on 12 patients (ages 13-21y) diagnosed with SLE being seen at the Children's National Multidisciplinary Lupus Clinic. All patients met the ACR diagnostic criteria for SLE. This approach employs a novel medical device invented at Children's National Hospital. This device is a novel integration of non-invasive and innocuous neuroselective electrical stimulation with infrared pupillometry (nPRD) to activate specific sensory nerve fiber types and allows for an objective quantified characterization of sensory nerve fiber activity. This technology measures the impact of

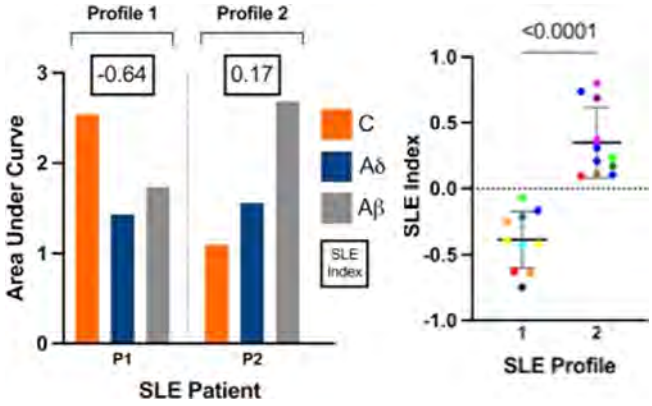

Figure 1. Distinct nociceptive profiles detected in SLE cohort by nPRD. (left) Showing nPRD-derived AUC measures of C, Ad, and Ab fibers and SLE Index scores of patients with SLE. Patients are categorized into "Profile 1" and "Profile 2" as indicated. (right) Showing the SLE Index measures for Profile 1 and Profile 2. Statistics: unpaired t-test, significance is as indicated.

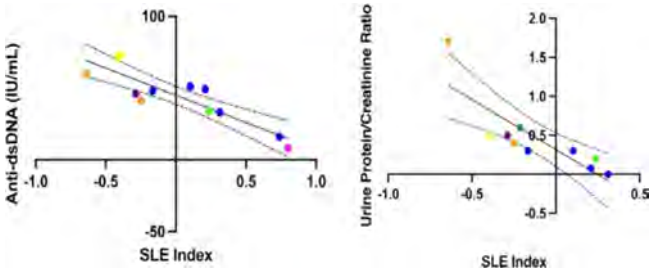

Figure 2. Anti-dsDNA antibodies and urine protein/creatinine ratio correlate with SLE Index. Plot showing line of best-fit and 95% confidence band of simple linear regression of the SLE Index with anti-dsDNA antibody (n=10) and the urine protein/creatinine ratio (n=7).

Table 1. Summary of correlation coefficients and significance of SLE Index with correlates. Statistical significance and strength indicated by *.

Correlate	r	r^2	P value
Anti-dsDNA	-0.8925	0.7965	0.0005 ***
Urine Protein/Creatinine Ratio	-0.8284	0.6863	0.0213 *

Urine Creatinine	-0.6909	0.4774	0.0269 *
C4	0.5520	0.3047	0.0505
C3	0.3987	0.1589	0.1772
Composite SLEDAI-2K	-0.4329	0.1874	0.1598

SLE-associated inflammation on sensory nerve fiber activity. The relationship of the nPRD-derived AUC for each of the three sensory fibers (Aβ, C and Aδ) at a given time are compared using a ratio (e.g., $[AUC_{A\delta}\text{-}AUC_C]/AUC_{A\beta}$) to derive a quantitative index, which is the primary measurement endpoint. This index is used as the clinical output to contextualize the type and intensity of nociceptive processing. The data were analyzed using student's t-tests and Pearson's Correlation.

Results: Using our novel technology and method we observed two overarching and significantly different SLE physiologic phenotypes ($p< 0.001$, Figure 1). P1 has relatively increased C fiber sensitivity and decreased Aδ fiber sensitivity, which has been designated "profile 1". P2 has a dominating Aβ fiber with less pronounced C and Aδ measures, which has been designated "profile 2".Nociceptive profile 1 aligns with SLE Type 1 (active disease) whereas, nociceptive profile 2 aligns with SLE Type 2 (FM and/or nociplastic).

We then correlated our SLE Index to the SLEDAI-2K composite score and specific serological components, which are shown in **Figure 2** and summarized in **Table 1**. These data demonstrate a statistically significant correlation to four parameters expected to be elevated or decreased in the SLE Type 1 active state.

Conclusion: Our preliminary data support the potential of our novel, objective, physiologic measure to characterize and quantify SLE disease activity. These findings will be verified in future studies.

N-Terminal Pro-Brain Natriuretic Peptide Correlates Strongly with Cardiovascular Damage in Systemic Lupus Erythematous (SLE): A Cross-sectional Study

Karim Sacre[1], Evelyne Vinet[2], Christian Pineau[2], Arielle Mendel[3], Fares Kalache[3], Louis Pierre Grenier[3], Thao Huynh[3] and Sasha Bernatsky[4], [1]Université Paris Cité, Paris, France, [2]McGill University Health Centre, Montréal, QC, Canada, [3]McGill University Health Centre, Montreal, QC, Canada, [4]Research Institute of the McGill University Health Centre, Montreal, QC, Canada

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiovascular (CV) disease represents the leading cause of death in SLE. Traditional risk factors are less accurate at identifying cardiovascular risk in SLE than in the general population. N-Terminal pro-Brain Natriuretic Peptide (NT-proBNP) is a key biomarker to detect heart disease and predict cardiac outcomes, in non-lupus populations. We assessed NT-proBNP in a large cross-sectional sample of unselected SLE patients and investigated associations with CV damage.

Methods: Adults meeting ACR SLE classification have been consecutively enrolled in our Lupus Clinic cohort. Patients were followed yearly with evaluations of drugs, SLICC Damage Index (SDI), SLEDAI-2K, and other measures including cardiovascular risk factors. NT-proBNP (pg/mL) levels were measured in serum collected at annual research visits between March

2022 and April 2023. The main outcome was CV damage defined as any CV SDI events. Cross-sectional associations between NT-proBNP and this outcome were evaluated using multivariable logistic regression model.

Results: Overall, 270 SLE patients (91% female 91%, median age of 50.7 [1st quartile- 3rd quartile: 39.6-62.1] years) from the MUHC cohort were included. At NT-proBNP assessment, median disease duration was 17.7 years [11.6-27.2] and median SLEDAI-2K and SDI scores were 2 [0-4] and 1 [0-3] respectively. Characteristics of patients are given in Table 1. Thirty-three (12%) patients had CV damage including coronary artery disease (n=14), cerebral vascular accident (n=12), chronic pericarditis (n=6), valvular diseases (n=5), cardiomyopathy (n=3) and peripheral artery disease (n=1). The median [1stquartile- 3rd quartile] NT-proBNP serum level was 95 [54-185] pg/mL. NT-proBNP levels were higher in patients with CV damage (281 [140-856] versus 84 [50-147] pg/mL in those without CV damage, P< 0.001) and were especially high in patients with more than one CV damage item (989 pg/mL [734–1725] versus 194 [122-327] pg/mL in those with one CV damage item only, P< 0.0001). The ROC curve for NT-proBNP demonstrated strong associations with CV damage (AUC 0.78, 95% CI 0.69-0.87). The threshold providing the best discrimination for those with/without CVD was 133 pg/mL, with a sensitivity of 79% (95% CI 64-91) and a specificity of 70% (95% CI 64-76). In multivariate analyses, hypertension (OR 3.3, 95% C 1.2-9.0), dyslipidemia (OR 3.6, 95% CI 1.3-9.6) and NT-proBNP >133 pg/mL (OR 7.0, 95% CI, 2.6-19.1) were strongly associated with CV damage. CV damage was less frequent in SLE patients on hydroxychloroquine (OR 0.3, 95% CI 0.1-0.8). Increased NT-proBNP levels were themselves associated with age (OR 4.2, 95% CI 2.2-8.3), smoking (OR 1.9, 95% CI 1.0-3.5), reduced eGFR (4.1, 95% CI 1.3-13.1), prior pericarditis/pleuritis (OR 2.5, 95% CI 1.4-4.5) and aPL antibodies (OR 2.6, 95% CI 1.4-4.9)

Conclusion: Serum NT-proBNP levels correlate with CV damage in SLE. Future evaluations are needed to identify the usefulness of NT-proBNP in tailoring treatments to prevent CV burden in SLE. The novel associations of NT-proBNP levels with pericarditis/pleuritis and aPL antibodies suggest new avenues for research to better understand what drives CV risk in SLE.

Comparison of Plasma Protein Profiles and Endothelial Function in Patients with Pediatric-Onset Systemic Lupus Erythematosus and Healthy Controls

Liyoung Kim[1], Gabrielle Alonzi[1], Marina Barguil Macedo[2], Pamela F. Weiss[3], Jane Newburger[4], Karen Costenbader[5], Christian Lood[2] and Joyce Chang[1], [1]Boston Children's Hospital, Boston, MA, [2]University of Washington, Seattle, WA, [3]Children's Hospital of Philadelphia, Philadelphia, PA, [4]Boston Children's Hospital, Boston, MA, [5]Brigham and Women's Hospital and Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with pediatric-onset systemic lupus erythematosus (pSLE) have elevated cardiovascular (CV) risk associated with accelerated atherosclerosis that begins in childhood. Endothelial dysfunction may be one of the earliest atherosclerotic precursors, but the role of endothelial function assessment for CV risk stratification in pSLE is unclear. We compared non-invasive endothelial function testing and plasma protein profiles between patients with pSLE and controls and evaluated associations between protein expression and endothelial dysfunction.

Methods: Forty-four pSLE subjects, aged 9–21 years without active Raynaud's, were recruited from pediatric rheumatology clinics at two tertiary centers. We recruited 24 age and sex-matched controls without chronic conditions from siblings of rheumatology patients, dermatology clinic or primary care network. Demographic data, traditional CV risk factors and clinical disease activity scores were collected. Endothelial function, quantified as the log-transformed reactive hyperemia index (LnRHI), was measured by peripheral arterial tonometry (EndoPAT, Itamar Medical). We measured plasma markers of neutrophil (myeloperoxidase (MPO)-DNA, neutrophil elastase-DNA, and calprotectin) and endothelial activation (ICAM-1, VCAM-1) hypothesized to induce endothelial injury, as well as a 96-target proteomic proximity extension assay (CVD-II panel, Olink[â]). We used linear regression models and Mann-Whitney U tests to evaluate differences in LnRHI and plasma biomarkers, respectively. Spearman rank correlation coefficients (r) were used to evaluate clinical factors and biomarkers associated with LnRHI in pSLE subjects.

Results: Compared to controls, pSLE subjects were more likely to report Black race, lower parental education and lower household income (Table 1). pSLE subjects also had more CV risk factors, including family history of CVD, higher body mass index and triglyceride levels, lower high-density lipoprotein (HDL), and lower physical activity scores compared to controls. Of note, 75% of the pSLE cohort had low or inactive disease (SLEDAI-2K score≤ 4).Endothelial function testing revealed higher (better) average lnRHI in pSLE subjects vs. controls (b 0.26, p< 0.01), regardless of disease activity (Fig 1), and with adjustment for body surface area (BSA) (for finger size) and HDL (b 0.30, p< 0.01). There was no significant increase in neutrophil/endothelial activation markers or CVD-related proteins in subjects vs. controls. Conversely, median MPO-DNA and VCAM-1 levels were higher in controls (Fig 2). Only BSA and diastolic blood pressure were significantly associated with lnRHI (r 0.32, p=0.03, and r-0.32, p=0.04, respectively).

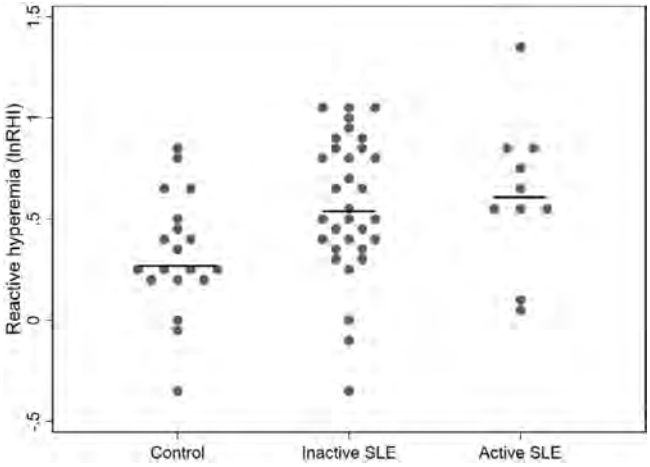
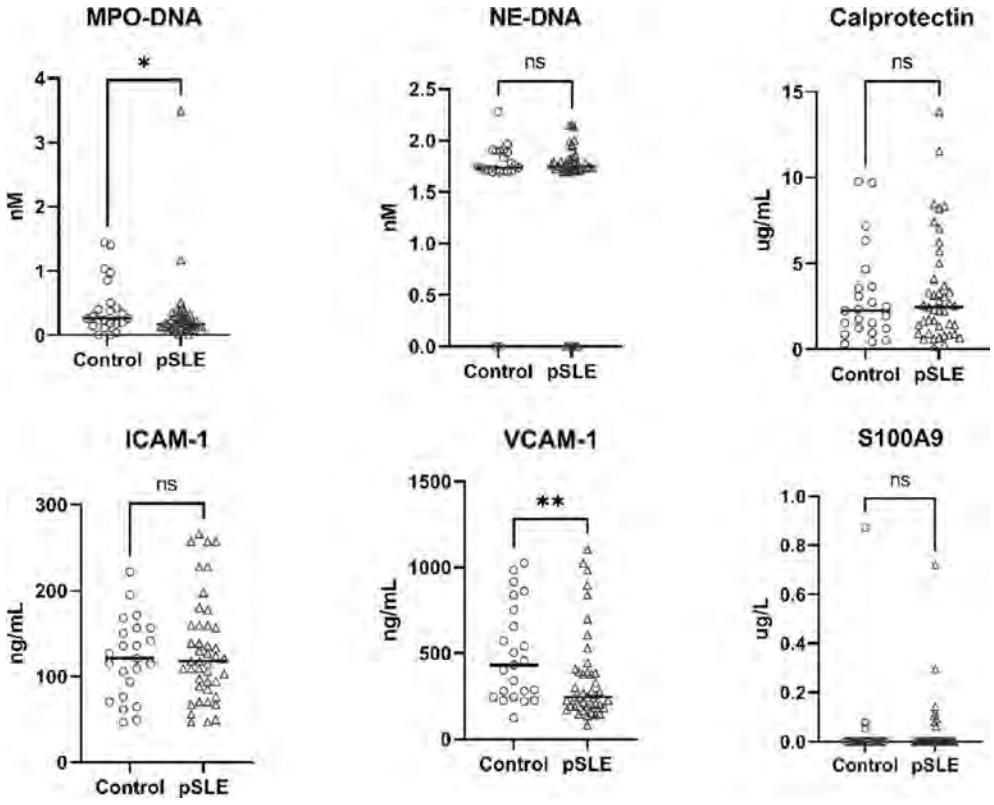
Fisher's exact or Mann-Whitney U tests were used to compare clinical characteristics between pSLE subjects and controls. ^ BMI-for-age-and-sex percentiles are used for ages 2-19 years. * Obesity defined by BMI 95th percentile for subjects 2-19 years old, or BMI >30 kg/m2 in subjects 20 years or older. †SLEDAI <5, low disease activity; 6–10, moderate; 11–19, high; maximum, 105 #The area under the curve (AUC) was calculated as a measure of long-term burden. ‡ Disease-modifying anti-rheumatic drugs (DMARDs) include mycophenolate mofetil, methotrexate, tacrolimus, and azathioprine.

Conclusion: Our results unexpectedly demonstrated better endothelial function and lower MPO-DNA levels in children with pSLE compared to controls despite greater CV risk factors. This might be attributed to low SLE disease activity and/or effects of treatment. Further studies to understand how disease activity and immunomodulatory medications modify endothelial health in children with pSLE may provide insight into potential mechanisms of endothelial dysfunction and ideal disease activity targets.



Mean differences in baseline reactive hyperemia (LnRHI) between 42 pSLE subjects and 19 controls with evaluable peripheral arterial tonometry tracings. Both subjects with low/inactive SLE (SLEDAI-2K≤ 4) and active SLE (SLEDAI-2K> 4) had statistically significant higher average LnRHI values compared to controls (p=0.01 and p< 0.01, respectively).



Selected plasma biomarkers of neutrophil extracellular traps (myeloperoxidase [MPO]-DNA complexes, neutrophil elastase [NE]-DNA, neutrophil activation (calprotectin, S100A9), or endothelial activation (VCAM-1, ICAM-1) in 43 pSLE subjects at enrollment compared to 23 controls with evaluable samples, using Mann-Whitney U tests. * p<0.05; ** p<0.01

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: S100, a damage-related molecular pattern factor, was reported to be a biomarker associated with disease activity in SLE. Additional hydroxychloroquine, which could regulate IFN signature, was found to modulate serum S100 in patients with SLE. However, what SLE pathophysiology S100 reflects remains unclear. The study aimed to determine the usefulness of S100 as a biomarker of SLE pathogenesis.

Methods: This single-center, retrospective, observational study enrolled patients with SLE admitted to our hospital between January 2016 and December 2021. The SELENA-SLEDAI, SLE-DAS, and lupus low disease activity state scale were used to measure disease activity. Serum cytokines reported to associated with SLE activity (TNF-α, IL-8, monocyte

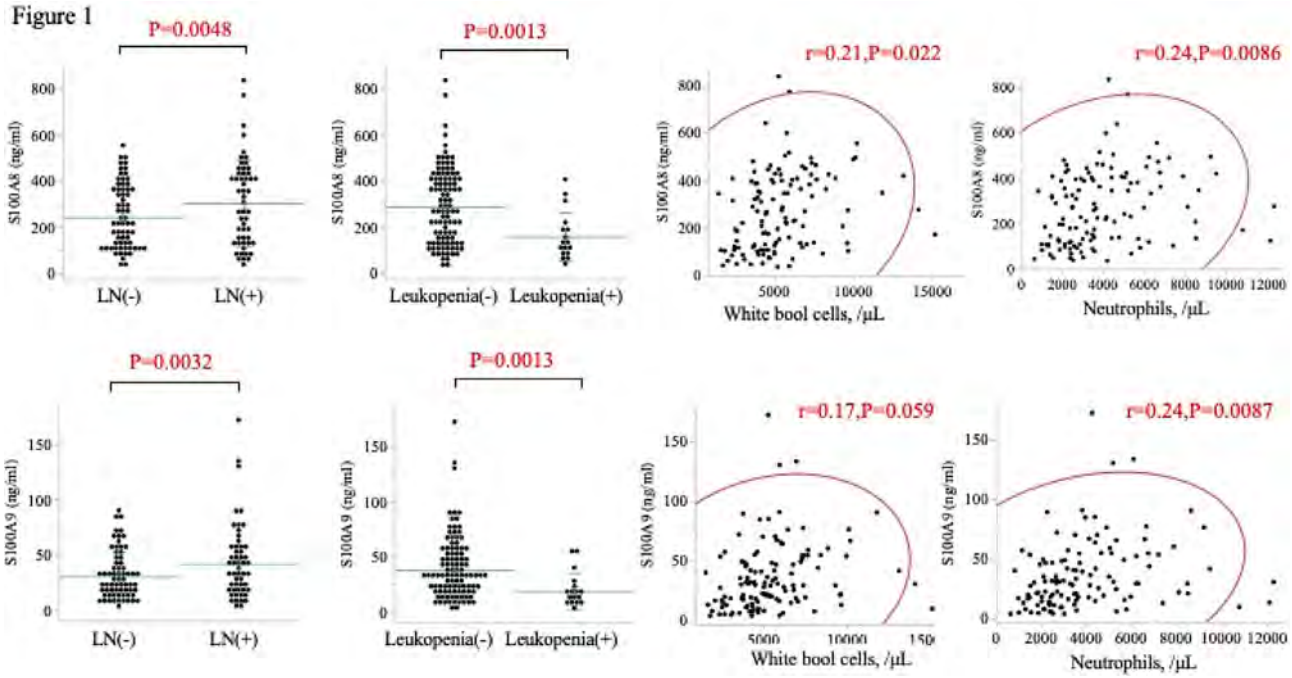

Figure 1. Association of serum S100 protein levels with lupus nephritis, immunological biomarkers, and leukopenia P-values were determined using the Mann–Whitney U test or Pearson's correlation coefficient (r).

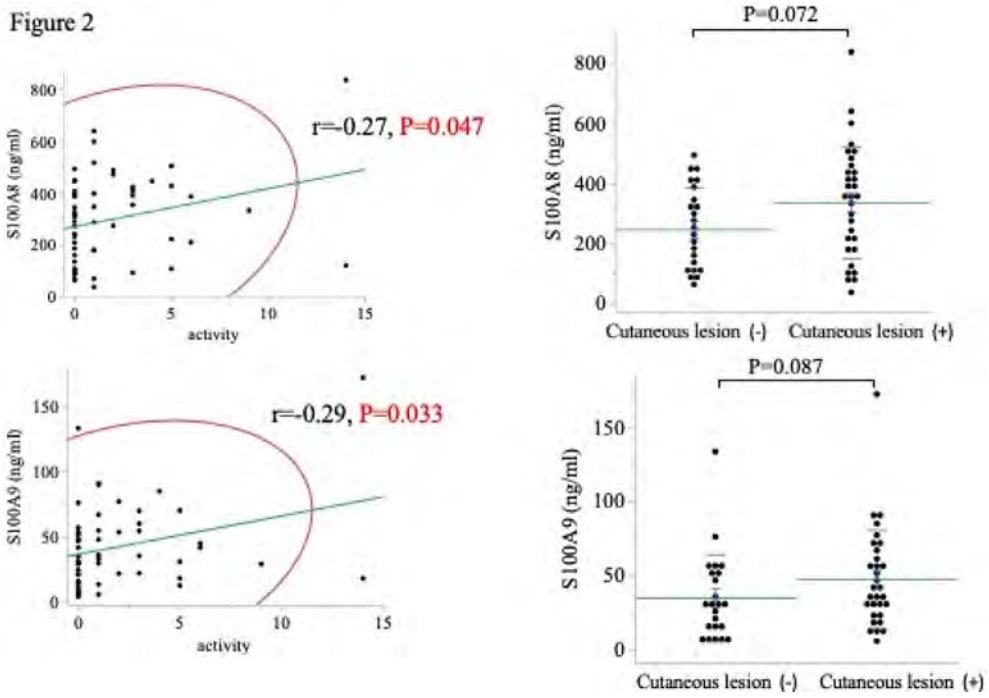

Figure 2. Association of serum S100 protein levels with cutaneous lesions in patients with SLEDAI scores of 1–4 (n = 54) For statistical analysis, the Mann–Whitney U test was used for the presence of lesions, and Pearson's correlation coefficient (r) was used for the association with CLASI activity.

chemoattractant protein-1, IL-1ra) were measured by multiplex Luminex assay, and serum S100A8 and S100A9 by ELISA. The correlation between these biomarkers and organ involvements was analyzed.

Results: Overall, 120 patients (9 men and 111 women; mean age, 40.5 years) were included. Table 1 shows the patient's characteristics when measuring serum S100A8, S100A9, and cytokines. The level of TNF-α, IL-8, monocyte chemoattractant protein-1, and IL-1ra were not associated with type of organ involvements. Renal involvement was related to the level of S100 A8 and A9 (Figure 1). S100A8 and A9 levels correlated with leukocyte and neutrophil counts positively and were significantly lower in patients with leukopenia (Figure 1). The SLEDAI score showed a slightly negative correlation with S100A8 levels, but not with S100A9 levels, whereas S100A9 levels showed a slightly positive correlation with the CLASI activity score ($r = 0.19$, $P = 0.039$). S100A8 levels positively correlated with IL-1ra levels ($r = 0.19$, $P = 0.039$) and S100A9 with IL-8 and IL-1ra levels (IL-8; $r = 0.30$, $P = 0.022$ and $r = 0.53$, $P < 0.0001$). Regarding SLEDAI scores of 1–4 ($n = 54$), patients with higher S100A8 and S100A9 levels tended to have higher SLE-DAS scores. S100A8 and S100A9 levels were higher in patients with cutaneous lesions, which correlated with the CLASI activity score (S100A8, $r = 0.27$, $P = 0.047$; S100A9, $r = 0.29$, $P = 0.033$; Figure 2).

Conclusion: Serum TNF-α, IL-8, monocyte chemoattractant protein-1, and IL-1ra were not associated with organ lesions. However, S100 was significantly associated with renal and skin lesions, which are strongly suggested to be associated with IFN.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoantibodies and auto reactive B cells participate on the pathogenesis of systemic lupus erythematosus (SLE), affecting various organs and tissues, including the nervous system, referred as neuropsychiatric SLE (NPSLE). The B-lymphocyte stimulator (BLyS) cytokine, which induces B cell proliferation and survival, may play an important role in NPSLE manifestations. In this study, we examine BLyS levels in SLE patients with well-defined NPSLE symptoms as compared to SLE patients without NPSLE and individuals with depression and cognitive impairment and healthy controls.

Methods: We included 75 SLE patients from the Rheumatology outpatient unit and 53 age and sex matched controls (20 with primary depression, 14 with mild cognitive impairment and 9 healthy controls). SLE patients were selected based on the presence of depression (N=25), cognitive impairment (N=25) or absence of neuropsychiatric (NP) manifestations

(N=25). SLE patients that have been prescribed belimumab or rituximab were excluded. SLE patients and controls had similar age and sex distribution. A complete clinical, laboratory and neurological evaluation was performed in all subjects. Mood disorders were determined through Beck Depression (BDI)). Cognitive evaluation was evaluated by Automated Neuropsychological Assessment Metrics (ANAM), *Montreal Cognitive Assessment* (*MoCA*) and formal cognitive testing. BLyS concentrations were evaluated in serum samples with Quantikine Elisa (R&D Systems, USA), following the manufacturer's instructions and with minimum detectable levels of2.68 pg/mL. All measurements were made on a single occasion. Data were analysed using the Mann-Whitney U test, with a p value < 0.05 considered significant.

Results: Active disease was observed in 23 (30.7%) SLE patients. Seventy (93%) were on immunosuppressant medication [Prednisone with doses ≥7.5 mg/day in 55 (73%), hydroxychloroquine in 57 (76%), azathioprine in 30 (40%), mycophenolate in 20 (26%). BLyS serum concentrations were significantly increased in SLE patients when compared to controls (p=0.005). BLyS serum concentration from 25 individuals with SLE and depression were significantly increased when compared to 25 SLE without NP manifestations (p=0.042), and the 20 healthy individuals with primary depression (p=0.017). No significant difference between primary depression and healthy controls was observed. BLyS serum concentration from 25 individuals with SLE and cognitive impairment were significantly increased when compared to 25 SLE without NP manifestations (p=0.003), and the 14 healthy controls with mild cognitive impairment (p=0.016). No significant difference between mild cognitive impairment controls and healthy controls was observed.

Conclusion: SLE patients with depression and cognitive impairment had higher BLyS levels when compared to SLE patients without NP manifestations and healthy controls with NP diagnoses. BLyS may play a role in NPSLE pathogenesis.

A Polygenic Risk Score for Systemic Lupus Erythematosus (SLE) Discriminates Between Patients with Lupus and Individuals Without Lupus and a Positive Antinuclear Antibody Test

Gul Karakoc[1], Ge Liu[1], Jacy Zanussi[2], Cecilia Chung[2], Jorge Gamboa[1], Jonathan Mosley[1], Nancy Cox[1], C. Michael Stein[1] and **Vivian Kawai**[1], [1]Vanderbilt University Medical Center, Nashville, TN, [2]University of Miami, Miami, FL

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: A positive ANA (ANA-POS) test is present in almost all patients with SLE and is also frequently present in other autoimmune (AI) diseases and in the general population. Genetic factors play an important role in the risk for SLE and a polygenic risk score for SLE (PRS_{SLE}) is significantly different in patients with SLE compared to controls. However, several studies have reported immunologic findings or clinical features of incomplete lupus in ANA-POS patients without SLE, raising concern for increased genetic risk of SLE in these patients. Thus, a clinically important question is whether a PRS_{SLE} differs among patients with SLE and individuals without SLE who have a positive ANA test.

Methods: We built a PRS_{SLE} using a Bayesian framework with continuous shrinkage using summary data from the largest SLE genome-wide association analysis (GWAS) in individuals of European ancestry. Then, we calculated the PRS_{SLE} in individuals who were tested for ANA as part of their clinical care and had genome-wide interrogation in BioVU - a biobank that links de-identified genetic and electronic health record data at Vanderbilt. We defined 5 different groups: patients with SLE (SLE), patients with other AI diseases who had a positive (AI-ANA-POS) or a negative (AI-ANA-NEG) ANA test, and individuals without an AI disease who had a positive (ANA-POS) or a negative (ANA-NEG) ANA test. A positive ANA was defined as a titer of 1:80 or higher. The PRS_{SLE} was standardized and compared between patients with SLE and the other 4 groups. A P-value ≤ 0.0125 (0.05/ 4 comparisons) was considered significant. To test the ability of the PRS_{SLE} to discriminate patients with SLE among those with a positive ANA test, we selected individuals (n=4,086) with a positive ANA (SLE, ANA-POS and AI-ANA-POS), and trained two predictive models (PRS_{SLE} alone, and PRS_{SLE}, sex, and age) using a 70% of the sample as training set. Then, we calculated the area under the curve (AUC) of the Receiver Operating Characteristic (ROC) curve in the remaining sample (testing set). Continuous variables were analyzed using Wilcoxon rank-sum test.

Results: We studied 10,032 individuals of European ancestry with ANA results. Patients with SLE had a higher proportion of female patients and were younger compared to the other groups (all P< 0.0125) (Table). The PRS_{SLE} was higher is the SLE group compared to all other groups: AI-ANA-POS (P=1.8E-11), ANA-POS (P=3.7E-20), AI-ANA-NEG (P=1.5E-21), and

Table: Demographic characteristics and distribution of the polygenic risk score for SLE (PRS_{SLE}) in BioVU individuals tested for antinuclear antibodies

	SLE	AI ANA POS	ANA-POS	AI ANA NEG	ANA-NEG
Total count	662	1341	2083	1587	4359
Female (%)	578 (87.3%)	1002 (74.7%) P=1.2E-10	1428 (68.6%) P=4.2E-21	998 (62.9%) P=1.7E-30	2453 (56.3%) P=5.7E-52
Age (years)	48.7 [36.7, 59.8]	55.1 [40.7, 65.0] P=8.9E-08	56.2 [43.4, 66.7] P=5.4E-15	53.7 [41.0, 63.4] P=5.0E-06	53.6 [41.4, 63.9] P=3.9E-08
PRS_{SLE}	0.23 [-0.35, 0.99]	-0.10 [-0.61, 0.62] P=1.8E-11	-0.15 [-0.71, 0.47] P=3.7E-20	-0.22[-0.74, 0.49] P=1.5E-21	-0.23 [-0.72, 0.43] P=1.2E-28

SLE: systemic lupus erythematosus, AI-ANA-POS: individuals with an autoimmune disease with a positive ANA test, ANA-POS: individuals without an autoimmune disease with a positive ANA test, AI-ANA-NEG: individuals with an autoimmune disease with a negative ANA test, ANA-NEG: individuals without an autoimmune disease with a negative ANA test. PRS_{SLE} are shown as z-scores distributions. P-values represent the comparison between the SLE group and each of the other groups for a specific variable. Data are shown as counts (percentage) and median [interquartile range]

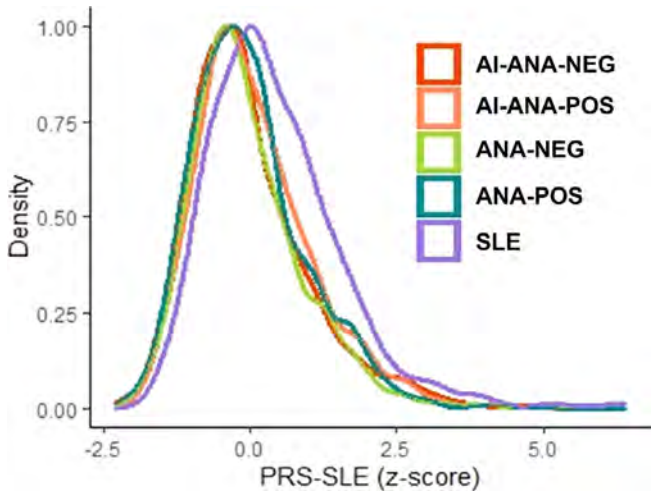

Figure 1: Distribution of the standardized Polygenic Risk Score for SLE (PRS SLE) in individuals who had an ANA test performed as part of their clinical care in BioVU.

ANA-NEG (P=1.2E-28). (Figure and Table). The PRS_{SLE} discriminated patients with SLE from those with a positive ANA test (AUC = 0.61, 95%CI [0.57, 0.66]) and the inclusion of age and sex resulted in a higher AUC (0.66, 95%CI [0.62, 0.70]) (P=0.02)

Conclusion: Patients with SLE have a higher PRS_{SLE} compared to individuals with a positive ANA test. The PRS_{SLE} had a modest discriminative ability to distinguish patients with SLE among those with a positive ANA result, and this increased when age and sex were also included in the model.

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: CD163 is a glycosylated membrane protein expressed in monocytes and macrophages that phagocytize the hemoglobin/haptoglobin complex. As a result of proinflammatory stimuli, CD163 is shedded from the cell membrane and becomes soluble CD163. Therefore, it has been shown that serum (s) and urine (u) levels of soluble CD163 increase in acute or chronic inflammatory diseases. sCD163 and uCD163 are considered as potential biomarkers

Table 1. Serum and urine levels of CD163 across study groups

Table 1 Serum and urine levels of CD163 across study groups

Biomarker	Active LN (n=20)	Inactive LN (n=10)	P	Extrarenal active SLE (n=15)	P	Healthy control (n=20)	P

LN lupus nephritis, SLE systemic lupus erythematosus, SD standard deviation

Figure 1. Serum and urine levels of CD163 after treatment

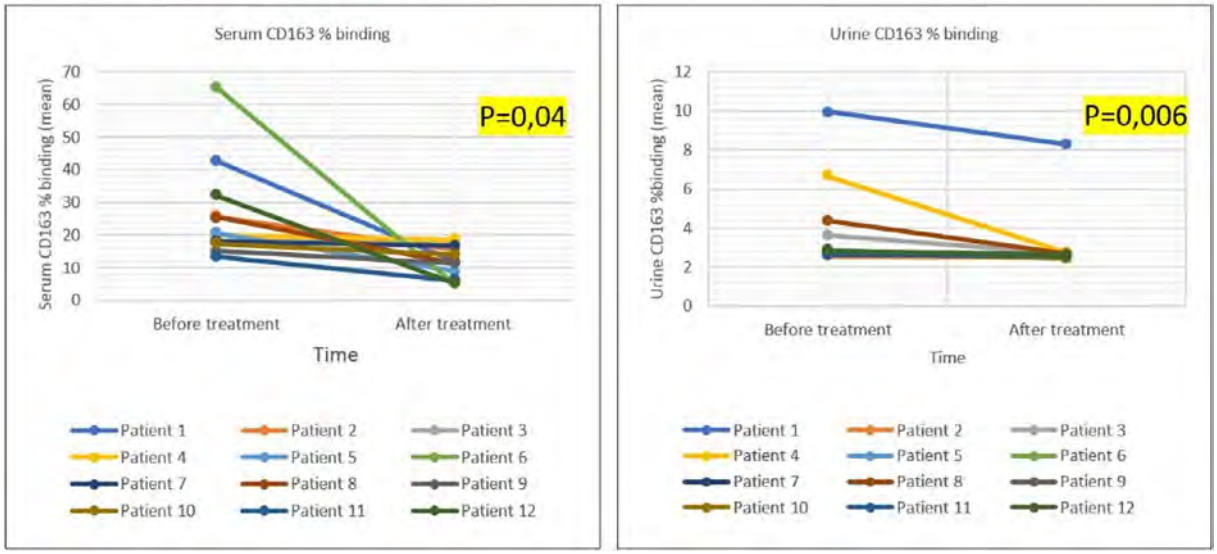

Figure 1. Serum and urine levels of CD163 after treatment

reflecting disease activity in patients with systemic lupus erythematosus (SLE).We aimed to investigate the association of serum and urine soluble CD163 levels and renal CD163 expression with disease activity in patients with lupus nephritis (LN).

Methods: Serum and urine levels of CD163 of 45 SLE patients (active renal 20, active non-renal 15, inactive 10) and 20 healthy volunteers were tested by ELISA. Control samples were taken from 12 active renal patients after six months of treatment and 30 renal biopsy specimens were examined for CD163 expression.

Results: Of 45 participants, 37 (82.2%) were female, with a median disease duration of 113 (1-436) months and a mean age of 38,9±13 (18-68) years. Both the frequency of uCD163 positivity and its levels were significantly higher in the active LN group compared to the inactive LN (p=0,007 and 0.02 respectively) and active non-renal SLE (p=0,001 and 0.023 respectively) groups (Table 1). sCD163 and uCD163 levels of 12 patients with active LN were significantly reduced after treatment (p=0,04 and p=0,006) (Figure 1). CD163+ macrophage expression in kidney biopsies of patients with active LN correlated with sCD163 (r= 0.597 and p=0.01) and uCD163 (r=0.507 and p=0.045) levels.

Conclusion: uCD163 is a promising biomarker that can differentiate active LN from inactive LN and active extrarenal SLE changing in line with treatment response. Correlation of both s and uCD163 with CD163+ macrophage expression in biopsies suggests that it may be used as an activity parameter in patients with lupus nephritis histopathologically. Further studies are awaited to confirm these results.

Presence of Mediterranean Fever Gene Variants Provides Protection from the Development of Lupus Nephritis in Patients with Systemic Lupus Erythematosus

Yushiro Endo[1], Tomohiro Koga[1] and Atsushi Kawakami[2], [1]Department of Immunology and Rheumatology, Division of Advanced Preventive Medical Sciences, Nagasaki University, Nagasaki, Japan, [2]Nagasaki University, Nagasaki, Japan

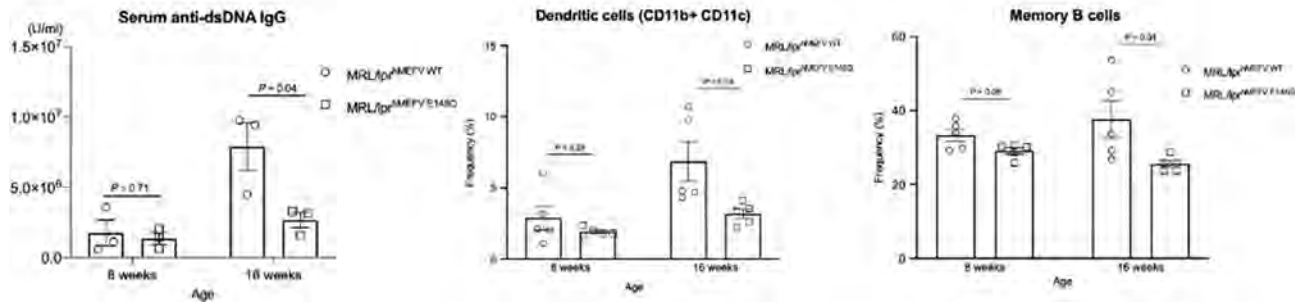
SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Previous studies showed that the prevalence of variants in *Mediterranean Fever* (*MEFV*) genes was lower in adult patients with SLE compared to healthy population and thatlow prevalence of coexistence of FMF and SLE was observed in several large FMF cohorts, suggesting that a potential protective effect of the presence of *MEFV* variants and/or FMF from SLE. Also, existence of *MEFV* variants have been suggested to modify clinical phenotypes of SLE. In particular, the presence of the E148Q variant in the exon 2 of *MEFV* gene may be protective for the development of lupus nephritis among adult patients with SLE. However, all these reports showing a relationship between SLE and *MEFV* gene are limited to those in the Mediterranean region, where *MEFV* exon 10 variants are relatively common.

Methods: We conducted a retrospective analysis of 55 Japanese SLE patients between January 2008 and April 2020 at Nagasaki University Hospital. We examined whether they have *MEFV* variants by next-generation sequencing in the whole region of *MEFV*. and compared clinical characteristics of the patients based on the presence or absence of *MEFV* variants. We introduced a partial segment of human exon 2 of the MEFV gene with or without E148Q variant, which is common variant in MEFV gene, into MRL/lpr mice and compared those phenotypes between MRL/lpr mice expressing the wild-type MEFV gene (MRL/lpr$^{hMEFV\ WT}$) and those expressing the E148Q variant (MRL/lpr$^{hMEFV\ E148Q}$).

Factors associated with the development of lupus nephritis in SLE patients in multiple regression analysis

End point	Variables		Odds rate (95% CI)	P-value
Lupus nephritis	Age at onset	1 increase	1.013 (0.963 to 1.065)	0.63
	Male gender	Presence	0.754 (0.053 to 10.741)	0.84
	Low CH50	Presence	4.758 (0.869 to 26.052)	0.07
	Anti-dsDNA Ab positive	Presence	5.159 (0.761 to 34.950)	0.09
	Total count number of *MEFV* variants	1 increase	0.359 (0.137 to 0.942)	0.04



Results: A total of 33 out of 55 patients with SLE had one or more variants in exon 1–5 of *MEFV*, whereas none of the patients had a mutation in exon 10. Patients with *MEFV* variants exhibited significant lower presence of lupus nephritis than those without *MEFV* variants (P=0.007). We counted the total number of *MEFV* variants exhibited in each patient. The total number of *MEFV* variants in patients with lupus nephritis was significantly lower than those without lupus nephritis (P=0.006). Among the factors analyzed including age at onset, male gender, low CH50, anti-dsDNA Ab positive, and the total count number of *MEFV* variants, only the total count of MEFV gene variants were significantly associated with the presence of lupus nephritis (odds ratio [OR] 0.359, $p< 0.05$). Consistent with the data from patients with SLE, *MRL/lpr*$^{hMEFV\ E148Q}$ showed the tendency of less severality in lupus nephritis (not statistically significant) and showed significantly less autoantibody production ($p< 0.05$). These observed differences in disease phenotypes were suggested to be attributed by reduced induction of dendritic cells ($p< 0.05$) followed by a decrease in memory B cells ($p< 0.05$).

Conclusion: Presence of *MEFV* variant can modify clinical type of SLE and be a protective factor against the development of lupus nephritis.

Type I IFN-associated Regulation of Immune Checkpoint Genes in Patients with SLE

Kanwal Zahid Siddiqi[1], Amanda Hempel Zinglersen[2], Katrine Kjær Iversen[1] and Søren Jacobsen[2], [1]Copenhagen Research Center for Autoimmune Connective Tissue Diseases (COPEACT), Department of Rheumatology 4242, Rigshospitalet, University Hospital of Copenhagen, Copenhagen, Denmark, [2]Copenhagen Research Center for Autoimmune Connective Tissue Diseases, Center for Rheumatology and Spine Diseases, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Aberrant activation of type I IFN, and subsequent adverse clinical implications, have been widely discussed in relation to SLE. With the lack of consistent data to support an association between disease activity and type I interferon, we hereby explore an alternative role of type I interferon in SLE pathogenesis. Continuous exposure to type I IFN is implicated in regulating immune checkpoint genes *in vitro* and in the context of a viral infection. Based on these findings, we investigated whether IFN exposure also regulates immune checkpoint genes in SLE, using bulk RNA-seq analysis.

Methods: We measured whole blood RNA-seq in 34 patients fulfilling the 2019 EULAR/ACR classification criteria for SLE and 15 age- and gender-matched healthy controls (HC). SLE disease activity was determined according to the SLE Disease Activity Index 2000 (SLEDAI-2K) score[1]. Whole blood samples were collected in PAXgene blood tubes (Qiagen) and analyzed for mRNA expression levels of 24 immune checkpoint genes and 12 type I IFN-stimulated genes using NanoString nCounter Technology. All expressions levels were represented as $\log_2$ fold change relative to HC. A compound type I IFN gene expression score (IGS) was calculated based on the median $\log_2$ fold change of type I IFN-stimulated gene expression and patients were grouped according to low or high IGS (IGS >1). Statistical analyses were performed using R version 3.6.1. and SPSS version 25.

Table 1. Demographics, laboratory, and clinical characteristics of SLE patients SLEDAI-2K: SLE Disease Activity Index 2000; ANA: anti-nuclear antibodies; dsDNA: double-stranded DNA; Sm: Smith. *: Azathioprine, mycophenolate mofetil, cyclophosphamide, rituximab, and/or methotrexate.

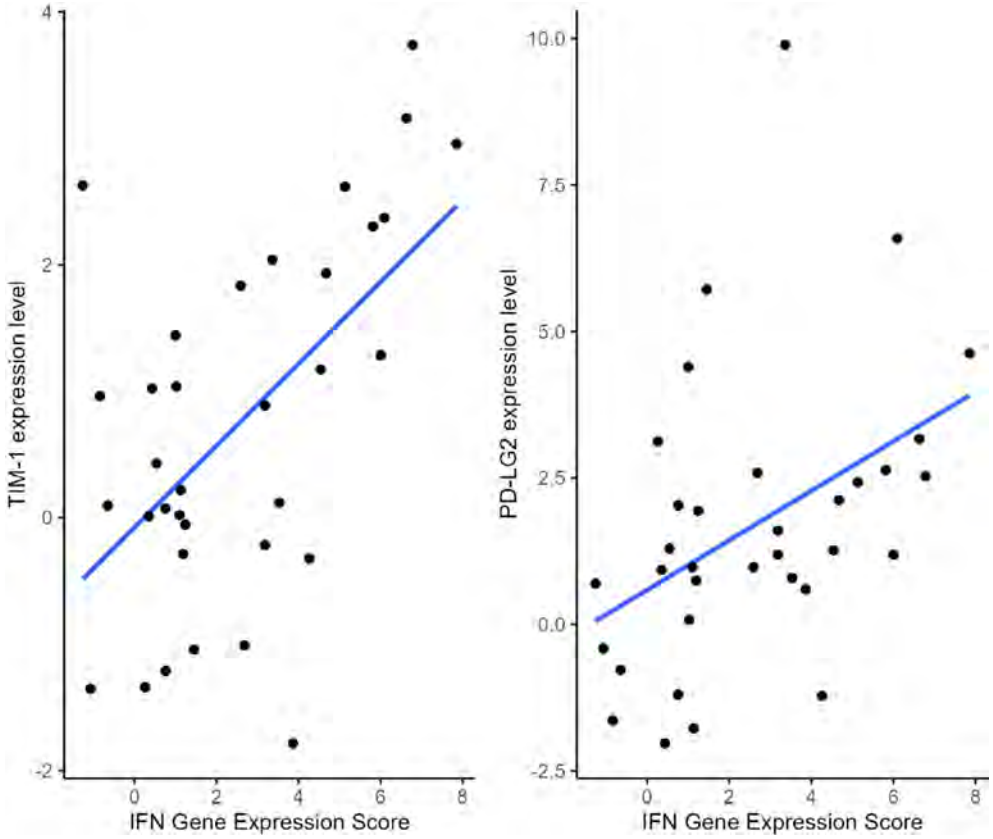

Figure 1. Whole blood gene expression in SLE patients. Scatterplot showing association between mRNA expression of immune checkpoint genes TIM-1 (left) and PD-LG2 (right). Regression lines were determined by a generalised linear model analysis.

Results: Demographic and clinical characteristics of SLE patients are detailed in **Table 1**. Twenty-four SLE patients (70%) had a high IGS. We found that genes coding for the immune checkpoints TIM-3 and PD-LG2 were upregulated in SLE patients with a high IFN score compared with HC; $\log_2$ fold changes were 0.36 and 0.89 and P-values were 0.0046, 0.0042 for TIM-3 and PD-LG2 respectively. Expression of the immune checkpoint genes paralleled the expression of the IGS but only for those patients who had a high expression of type I IFN stimulated genes (**Figure 1**). This was confirmed by a generalized linear model analysis showing a significant positive association between the IGS and expression of TIM-3 and PD-LG2 in SLE patients (P= 0.0001 and 0.006, respectively).

The median (range) SLEDAI-2K scores were 4.0 (0–10) and 2.0 (0–5) for the high and low IGS SLE patients, respectively. A generalized linear model analysis showed that SLEDAI-2K scores did not associate with the expression of TIM-3 and PD-LG2, arguing against the notion that differential expression of immune checkpoint genes in high IGS SLE patients may be related to disease activity.

Conclusion: This study revealed differential mRNA expression of immune checkpoint genes TIM-1 and PD-LG2 in a type I IFN-associated manner, which did not associate with disease activity. These results are in line with previous observations that type I IFN activity does not necessarily reflect SLE disease activity. With this, we suggest that persistent type I IFN activation perhaps regulates inhibition of immune cells in SLE patients and other rheumatic diseases characterized by such type I IFN activation.

Abstract Number: 0575

The Real-World Utility of a Lupus Activity Monitoring Panel in the United States Community Rheumatologist Practice

Andrew Concoff[1], Laura Moore-Schiltz[2], Vijay Nadipelli[3], Tyler O'Malley[1], Karen Worley[4], Allison Petrilla[2], Debra Zach[1], Scott B. Robinson[2], Sara Taiyari[5], Barton Jones[2] and Bernard Rubin[6], [1]Exagen, Vista, CA, [2]Inovalon, Bowie, MD, [3]GlaxoSmithKline, Philadelphia, PA, [4]GlaxoSmithKline, US Value Evidence and Outcomes, Cincinnati, OH, [5]GlaxoSmithKline, Collegeville, PA, [6]GlaxoSmithKline, US Medical Affairs and Immuno-inflammation, Durham, NC

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with active SLE have periods of uncontrolled disease activity that are associated with a greater risk for developing irreversible organ damage. Current standard of care (SoC) testing does not adequately monitor disease activity, and there is a lack of widespread real-world application of these tests, making it difficult to provide individualized care. To help address this, the lupus activity monitoring panel, comprising a blood test, is designed to assess SLE disease activity by measuring SLE-related biomarkers more comprehensively than SoC tests (see **Table 1** footnote). This observational, retrospective cohort study (GSK Study 217538) describes patient and provider characteristics of those who received the lupus activity monitoring panel test and those who received SoC tests.

Methods: Adults with an SLE diagnosis who received at least two lupus activity monitoring panel tests (cases) or at least one set of SoC tests (C3/C4 and anti-dsDNA; controls) between July 1, 2016, and December 31, 2021, were identified in the United Rheumatology-Normal Integrated Community Evidence repository (cases may have also received SoC tests). Eligible

patients were linked to administrative medical and pharmacy claims data from Medicare, managed Medicaid and commercial plans. Patients had continuous enrollment for 6 months pre-index (index=first recorded panel/SoC test) and 6 months post index. For cases and controls, patient and provider characteristics were assessed descriptively as mean and standard deviations (SD) for continuous variables and frequencies and proportions for categorical variables.

Results: The mean (SD) age for cases (N=75) and controls (N=616) was 57.5 (15.7) and 61.0 (15.1) years, 61% and 54% were white, and 71% and 78% had Medicare or Medicaid insurance, respectively; ≥90% of patients were female (**Table 1**). Both groups had mean baseline Deyo-Charlson Comorbidity Index scores of 2.4; the most common comorbidities were hypertension (cases, 53%; controls, 59%) and depression (cases, 27%; controls, 20%; **Table 2**). Approximately half of patients had moderate SLE, and most received ≥1 SLE therapy (cases, 60%; controls, 65%) with antimalarials most commonly prescribed. The lupus activity monitoring panel or SoC index test was ordered at a clinic with only 1 provider for 42% of cases compared with 15% of controls (**Table 3)**. The lupus activity monitoring panel was most frequently used by providers seeing 50 to < 75 patients with SLE/index year, whereas SoC testing was most common in larger practices (**Table 3**).

Table 1. Demographic characteristics measured on index date among patients with at least 6 months of continuous enrollment post index. *The lupus activity monitoring panel consists of six specialized biomarkers including: erythrocyte-bound C4d, anti-dsDNA by chemiluminescent immunoassay, complement C3 and C4, platelet-bound C4d, and the anti-C1q biomarker. NR, not reportable.

Measure	Cases* N=75	Controls N=616
Age at index date (years), mean (SD)	57.5 (15.7)	61.0 (15.1)
Age group, n (%)		
18–39 years	14 (19)	63 (10)
40–64 years	24 (32)	229 (37)

Disease severity*, n (%)		
Mild	19 (25)	157 (25)
Moderate	42 (56)	351 (57)
Severe	14 (19)	108 (18)
Outpatient rheumatologist visits, mean (SD)	1.6 (2.1)	1.6 (1.9)
Length of time on biologic and/or immunosuppressant prior to index date (months), mean (SD)**	32.1 (27.9)	32.7 (21.9)

Table 3. Provider characteristics among patients with at least 6 months of continuous enrollment post index.

Measure	Cases	Controls
Number of provider(s) at site where index lupus activity monitoring panel or SoC test was ordered, n (%)	**52 (100)**	**367 (100)**
1 provider	22 (42)	56 (15)
>1 provider	30 (58)	311 (85)
Index visit provider SLE patient volume/index year, n (%)	**46 (100)**	**367 (100)**
<50 patients/index year	12 (26)	77 (21)
50 to <75 patients/index year	19 (41)	100 (27)
≥75 patients/index year	15 (33)	190 (52)

Conclusion: This is the first real-world study to describe use of the lupus activity monitoring panel by community-based rheumatologists and offers initial insights into the heterogeneity of this population. There is a need to further understand the lupus activity monitoring panel use in the context of SLE care management and to educate providers on appropriate use of the unique tests included in the lupus activity monitoring panel.

Enhancing Systemic Lupus Erythematosus Diagnosis: Comparative Performance Characteristics of TC4d and Anti-T-Cell Antibodies with Conventional Biomarkers

Andrew Concoff[1], Vasileios Kyttaris[2], Vaneet Sandhu[3], Tyler O'Malley[4], Giorgio Casaburi[4], Sudha Kumar[4], Chau Ching Liu[5], Susan Manzi[6] and Joeseph Ahearn[5], [1]Exagen, Los Angeles, CA, [2]BIDMC, Boston, MA, [3]Loma Linda University, Loma Linda, CA, [4]Exagen, Vista, CA, [5]Allegheny Health Network, Pittsburgh, PA, [6]Lupus Center of Excellence, Autoimmunity Institute, Allegheny Health Network, Pittsburgh, PA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic, systemic autoimmune disease, affecting multiple organ systems with varying severity among patients. SLE presents a diagnostic challenge due to its protean clinical manifestations. Current standard of care biomarkers such as anti-dsDNA, anti-Smith, and complement proteins C3/C4 have limited discriminatory power characterized by poor sensitivity in incipient cases of SLE. This study aims to compare the clinimetric performance of T-cell bound complement split product C4d (TC4d) and anti-T-cell antibodies IgG (TIgG) and IgM (TIgM) with conventional biomarkers in differentiating Systemic Lupus Erythematosus (SLE) from clinically relevant controls (CRCs).

Methods: A total of 230 patients were included in the analysis (SLE = 80; CRC = 150) (Table 1). SLE patients were required to meet either the 1997 ACR, 2012 SLICC, or 2019 ACR/EULAR classification criteria for SLE; CRCs were required to have a clinical diagnosis with an associated ICD-9/ICD-10 code to confirm clinical diagnosis as enumerated in the Table 1 caption. A comprehensive machine learning pipeline integrating feature selection, multiple model architectures training, and cross-validation (CV) techniques was employed to compare the relative diagnostic performances of TIgG, TIgM, and TC4d to conventional SLE biomarkers. The robustness and generalizability of the pipeline were validated through permutational hold-out (HO) predictions, mitigating the risk of overfitting the models developed.

Results: The SLE cohort had a higher proportion of females (96.3% vs. 77.3%), younger age (mean [SD]: 47.1 [13.9] vs. 53.6 [14.3] years), and fewer Caucasians (65.0% vs. 82.7%) as compared to the CRC group (Table 1). Cumulative ROC analysis derived from multiple 10-fold CV models showed the diagnostic performances of TC4d (AUC = 0.86), TIgG (AUC = 0.81), and TIgM (AUC = 0.78) outperformed C3 (AUC = 0.77), anti-dsDNA (AUC = 0.76), anti-Smith (AUC = 0.72), and C4 (AUC = 0.70) (Figure 1, A). While the specificity of TIgG, TIgM, TC4d compared to conventional biomarkers were

CRC [N=150] consists of the following: Rheumatoid Arthritis [N=42]; primary Sjögrens syndrome [N=31]; chronic localized pain [N=15]; osteoarthritis [N=11]; fibromyalgia syndrome [N=10]; psoriatic arthritis [N=7]; spondyloarthritis [N=6]; UCTD [N=5]; inflammatory arthritis [N=3]; polymyalgia rheumatica [N=3]; Stills disease [N=2]; systemic sclerosis (limited) [N=2]; ANCA-associated vasculitis [N=2]; gout [N=2]; dermatomyositis [N=1]; Crohns [N=1]; enteropathic arthritis [N=1]; juvenile idiopathic arthritis [N=1]; MCTD [N=1]; cutaneous lupus [N=1]; polymyositis [N=1]; sarcoidosis [N=1]; autoimmune thyroiditis [N=1]

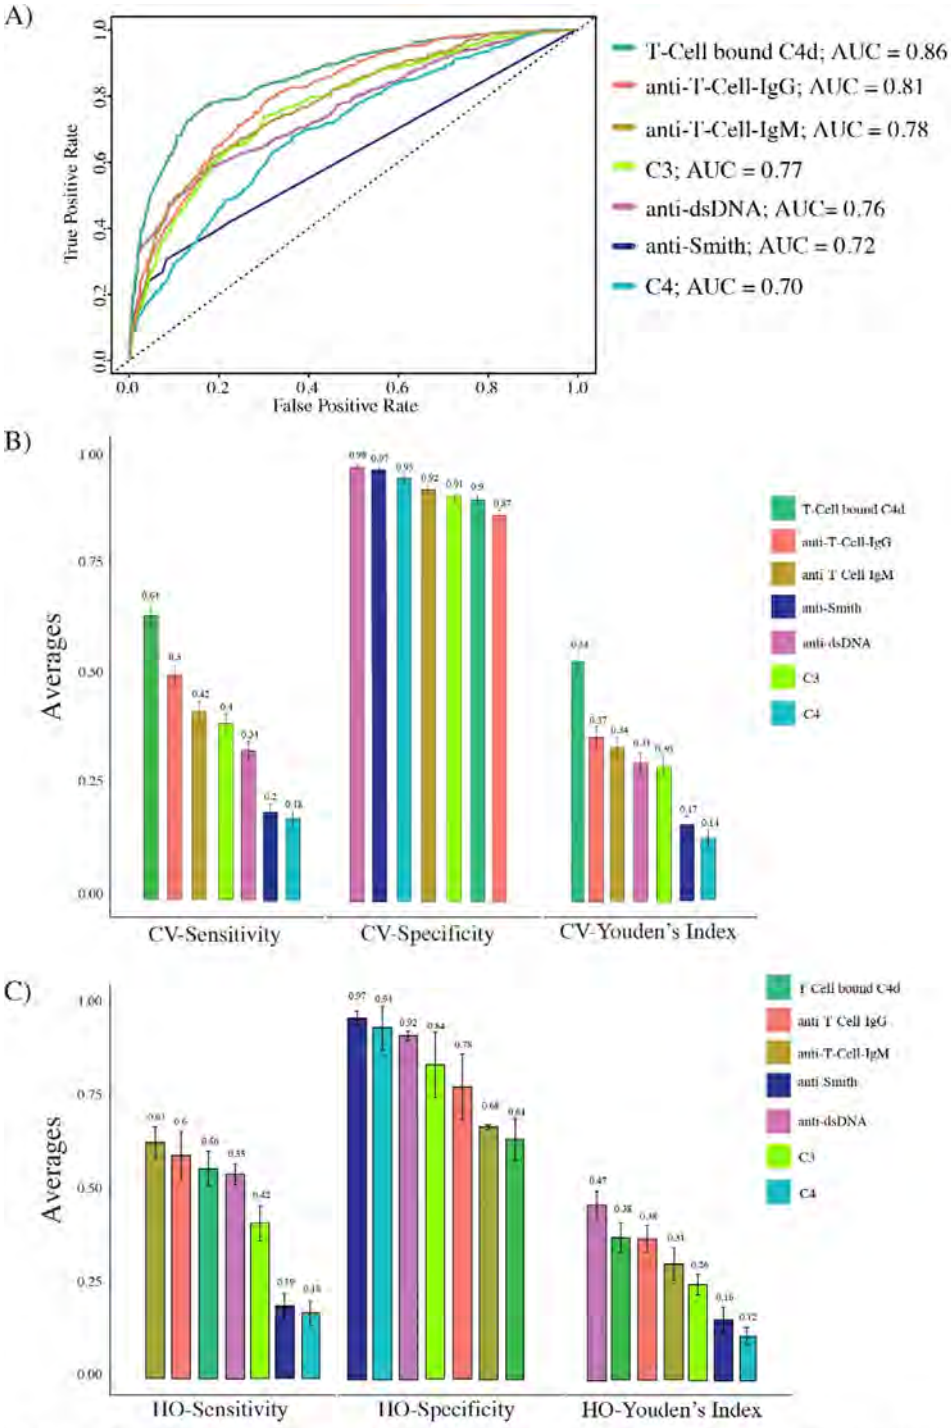

Figure 1. Comparative Performance Characteristics of TC4d and, Anti-T-Cell Antibodies, and conventional biomarkers predicting SLE from CRC samples. A) Cumulative ROC curves depicting top 10-CV models per marker. Individual biomarker AUCs are reported in the legend representing average performances of the 10-CV models in cross validation. B) Average Sensitivity, Specificity and Youden's Index (Sensitivity + Specificity -1) during cross-validation for the individual as well as combined biomarker performances at thresholds maximizing F-1 scores (the harmonic mean of Precision and Recall which aims to balance the two with maximum benefits). Average performance results are reported on top of individual bar charts per biomarker respectively. C) Average Sensitivity, Specificity and Youden's Index (Sensitivity + Specificity -1) of the hold-out data (unseen data) for the individual biomarker performances at thresholds maximizing F-1 scores. Average performance results are reported on top of individual bar charts per biomarker respectively.

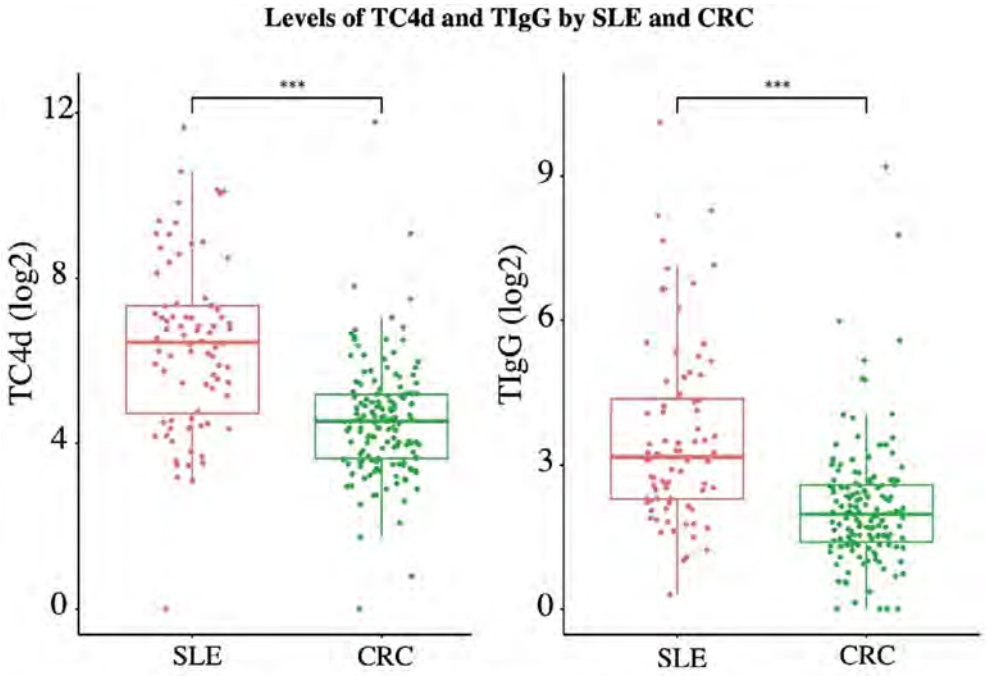

Figure 2. Blood level comparisons of TC4d and TIgG between SLE and ORD samples. The figure presents the log2 blood levels of TC4d and TIgG in SLE and ORD samples. Whisker plots depict the interquartile range, median, minimum, and maximum for each group. Outliers, where present, are represented as individual points beyond the whiskers. A significant difference between groups is indicated by ***$P<$ 0.0001 (Wilcoxon test).

similar in CV models, the sensitivity for SLE in both 10-CV and HO partitions were significantly higher for TIgG, TIgM, and TC4d compared to conventional biomarkers (Figure 1 B, C). Comparing median blood levels of TC4d and TIgG confirmed a statistically significant difference between SLE and CRC ($P<$ 0.0001) (Figure 2), further highlighting their intrinsic discriminatory power.

Conclusion: The study demonstrates the potential of TIgG, TIgM, and TC4d as sensitive and specific biomarkers for the diagnosis of SLE with improved diagnostic performance relative to conventional biomarkers. These findings suggest an opportunity for improved diagnostic accuracy that could yield timely treatment initiation and improved patient outcomes in SLE. However, further studies are needed to validate the results among larger, more diverse patient cohorts and to determine how T cell antibodies and TC4d biomarkers may improve upon existing integrated diagnostic biomarker solutions. Future efforts will explore the potential of T-Cell biomarkers to predict disease progression and as surrogates of treatment response.

Background/Purpose: Intrinsic signaling of intracytoplasmic TLRs (7 and 9) and MyD88 in B cells (BC) plays an important role in the development and pathogenesis of Systemic Lupus Erythematosus (SLE). Different genetic polymorphisms of TLR7 and TLR9 have been associated with the development of lupus nephritis (LN). In patients with SLE there is a higher expression of TLRs 7, 9 and MyD88 in their peripheral blood mononuclear cells (PBMCs) compared to healthy subjects. There is scarce information about the expression of TLR7, 9 and MyD88 in B cell subsets in patients with LN.

We aimed to analyze the expression of intracytoplasmic TLRs (7 and 9) and MyD88 in different subsets of BC from patients with lupus nephritis.

Methods: We included adult patients who fulfilled the ACR/SLICC 2012 classification criteria for SLE. They were stratified in 2 groups: those who had active LN (cases) proven by renal biopsy (LN class III/IV +/- V) or laboratory parameters (decreased filtration rate, proteinuria >500mg/24 hours or active urinary sediment) and those with active SLE (SLEDAI 2K: ^{3}6) but without renal involvement for the last 5 years (controls). Exclusion criteria included prior treatment with anti CD20 drugs.

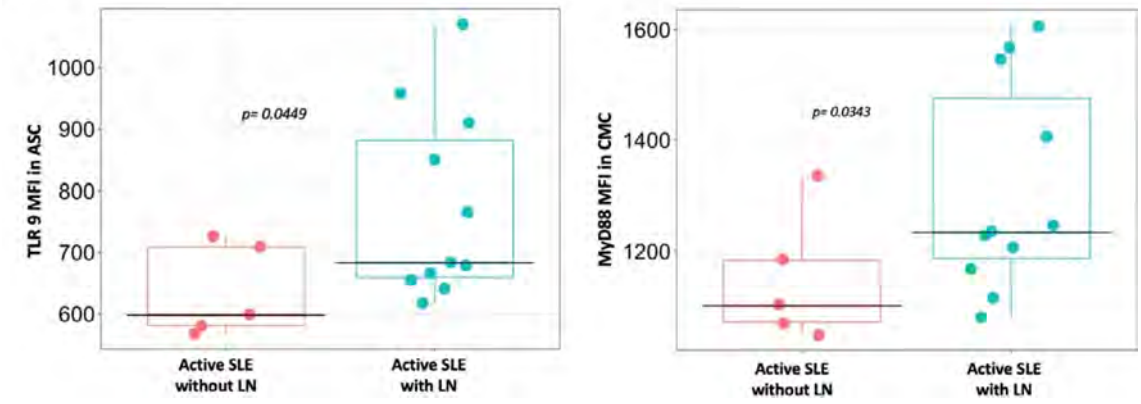
Using multiparametric flow cytometry we measured the expression of TLRs 7, 9 and MyD88 in BC subsets from a peripheral blood sample. The BC subsets evaluated were: age-associated B cells (ABC) [$CD19^{pos}CD21^{neg/lo}$ $CD11c^{hi}$ Tbet ^{pos}], antibody-secreting cells (ASC) [$CD19^{pos}$ $CD27^{hi}$ $CD38^{hi}$], classic memory cells (CMC) [$CD19^{pos}$ $CD27^{pos}$ IgD $^{pos/neg}$], double negative cells (DNC) [$CD27^{neg}$ IgD ^{neg}], naive cells (NC), non classic memory cells (NCMC) [CD27 ^{neg}] and transitional cells (TrC) [CD21 $^{neg/lo}$]. All samples were acquired in a BD LSR Fortessa flow cytometer and data were analyzed by support of the flow jo software.

Table 2.

Variable	Active SLE without LN n=5 (31.3%)	Active LN n=11 (68.7%)	P – value
TLR 9 MFI in ABC, A.U	2317 (2022 – 2344)	1948 (1288 – 2108)	0.0562
MyD88 MFI in ABC, A.U	1208 (1082 –1365)	1312 (1244 – 1654)	0.0902
TLR 9 MFI in ASC, A.U	**598 (581 – 709)**	**683 (660 – 880.5)**	**0.0449**
MyD88 % in ASC, %	0.57 (0.15 – 0.58)	1.33 (0.34 – 1.99)	0.0902
MyD88 MFI in ASC, A.U	1166 (1154 – 1383)	1341 (1256 – 1578)	0.0726
MyD88 MFI in CMC, A.U	**1101 (1071 – 1183)**	**1234 (1186 – 1476)**	**0.0343**
MyD88 MFI in NC, A.U	1091 (1053 – 1094)	1116 (1083 – 1349)	0.0902
TLR 7 % in NCMC, %	1.68 (1.11 – 5.98)	0.66 (0.44 – 1.74)	0.0562
MyD 88 MFI in TrC, A.U	939 (897 – 943)	1061.5 (948.8 – 1281.2)	0.0646

ABC: Age-associated B cells. ASC: Antibody-secreting cells. A.U: Arbitrary units. CMC: Classic memory cells. MFI: Mean fluorescence intensity. NC: Naive cells. TrC: Transitional cells. %: percentage. Data are expressed as median (interquartile range).

Figure 1.



MFI expressed in A.U. Only statistically significant (p=<0.05) data shown.

Absolute cell numbers and percentage of cells positive for TLR7, 9 and MyD88 expression was measured as well as mean fluorescence intensity (MFI) for each molecule in each of the B cell subset assessed. Comparisons were made between groups by using the Mann–Whitney U test.

Results: A total of 16 patients with active SLE were included. Eleven of them (68.7%) were assigned as cases (with LN) and 5 of them (31.3%) as controls (without LN). The majority (93.8%) were women. Their main demographic, clinical and laboratory features are depicted in Table 1.

In general, we observed increased expression of TLR 9 and MyD88 in BC subsets from patients with lupus nephritis than those without renal involvement (Table 2). Particularly, we found enhanced TLR 9 expression (MFI) in antibody-secreting cells (ASC) [active SLE with LN: 683 A.U (660 – 880.5), active SLE without LN: 598 A.U (581 – 709); p=0.0449], as well as higher MyD88 expression (MFI) in classic memory cells (CMC) [active SLE with LN: 1234 A.U (1186 – 1476), active SLE without LN: 1101 A.U (1071 – 1183); p=0.0343]. This information is reflected on the box-plots below (Figure 1).

Conclusion: Our preliminary data suggests that patients with lupus nephritis are characterized by enhanced expression of TLR 9 and MyD88 in specific B cell subsets, particularly of the effector humoral compartment, which might be involved in the pathogenesis of renal damage in SLE.

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Tissue damage in LN is mediated by immune complex activation of the classic complement pathway (PMID 23929771). In a study of LN, renal C5b-9 deposition was more frequent in nonresponders (45.5%) than responders (13%) (PMID 34996855). Additionally, complement mediated upregulation of endothelial cell adhesion molecules is seen in the dermal blood vessels of nonlesional skin (NLS) from patients with active SLE (PMID 9336415). In diseases with systemic complement activation (SCA), such as atypical hemolytic uremic syndrome, extensive C5b-9 deposition is seen in NLS (PMID 25893747). This supports hypothesis that NLS C5b-9 deposition is a biomarker for disease activity and evidence of SCA in LN

Figure 1. Positive Immunohistochemical C5b-9 staining in non-lesional skin biopsy of patient with active LN.

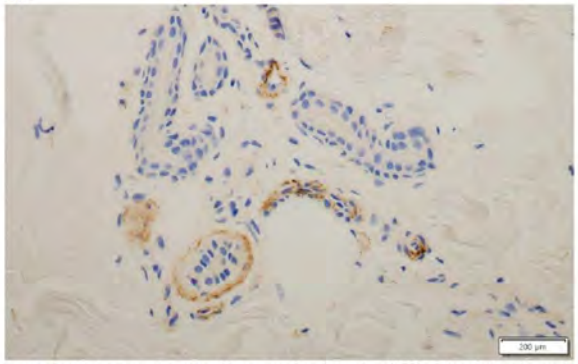

Image demonstrates extensive fine granular deposits of C5b-9 involving the endoluminal aspect of the microvasculature, specifically capillaries and venules Evidence of systemic complement pathway activation is based on counting the number of microvessels encompassing capillaries, venules, arterioles and small arteries showing endothelial and subendothelial deposition of C5b-9.

Table 1. Patient demographics and disease characteristics.

	C5b-9 positive (n=6)	C5b-9 negative (n=10)	P-value
Female	4(66.7)	8 (80)	0.60
Age, Year	32.8(9.2)	40.5(11.9)	0.15

Data are mean (SD) or n (%).
P values are evaluated using SPSS with t tests or Chi Square tests of independence. IFTA=Interstitial fibrosis tubular atrophy. ISN/RPS=International Society of Nephrology and Renal Pathology Society. NIH=National Institute of Health. SELENA SLEDAI=Safety of Estrogens in Systemic Lupus Erythematous National Assessment SLE Disease Activity Index. *Adjusted dsDNA calculated by dividing value by reference upper limit of normal. *a* one person LN Class missing. *b* 3 people without light microscopy details available. *c* 5 people with electron microscopy not available. *d* one person unable to provide urine due to being anuric.

Table 2. Sensitivity and specificity of significant microvascular C5b-9(i.e. 10 or more positive staining vessels) in nonlesional skin biopsy for active LN compared to traditional biomarkers of LN disease activity.

	Sensitivity (%)	Specificity (%)
Significant levels of microvascular C5b-9 Deposition(i.e. 10 or more positive vessels)	62.5	87.5
Elevated dsDNA	100	42.8
Hypocomplementemia	75	57.1
Pyuria	87.5	62.5
Hematuria	87.5	100
uPCR >0.5	100	57.1

Hematuria greater than 5 rbc/hpf. Pyuria greater than 5 wbc/hpf. Hypocomplementemia and dsDNA determined by testing laboratory's reference values.

Methods: Sixteen LN patients without TMHA consented to 4 mm NLS deltoid biopsies, were ≥18 years of age, met ACR SLE classification criteria, and a history of biopsy proven LN or undergoing first clinically indicated renal biopsy. In those undergoing renal biopsy, skin biopsy was performed within 7 days. Formalin fixed paraffin imbedded skin samples were stained for C5b-9 via diaminobenzidine technique and reviewed by dermatopathologist experienced in assessing microvascular C5b-9(PMID 33058948); she was blinded to clinical history. Classification as active LN required an activity index (AI) of ≥1 on biopsy or urine protein creatinine ratio (uPCR) $\geq$ 0.7 and albumin $\leq$ 3.7 g/dL. Inactive LN required AI of 0 or a uPCR ≤0.7, albumin ≥3.7 g/dL and no escalation of care by treating physician. Clinical, demographic, and lab parameters were compared between individuals based on presence of evidence of SCA as determined by demonstrating ≥ 10 blood vessels with endothelial or subendothelial C5b-9 deposition in NLS(PMID 33058948)

Results: Sixteen patients included: 12 females, mean age 37 years, 4 Black, 2 White, 2 Asian, 5 Hispanic and 3 other with clinical characteristics in Table 1. Of the 16 patients, 8 had active LN and 6(37.5%) were positive for endothelial C5b-9 deposition (Figure 1). Of those with SCA compatible C5b-9 deposition, 5 of 6 (83%) had active LN. Of those without significant C5b-9 deposition, 3 of 10 had active LN. Five of 8 active LN patients and 1 of 8 inactive LN patients demonstrated SCA compatible C5b-9 (p= 0.04). These findings demonstrate that SCA is present in LN and is significantly more common in active disease. Cutaneous evidence of SCA as demonstrated by quantitative C5b-9 assessment in microvessels has greater specificity, 87.5%, for active LN than pyuria, low complements, elevated dsDNA, and proteinuria (Table 2). uPCR was significantly higher in LN patients with C5b-9 deposition (4.92 vs 1.19; p =0.007). C5b-9 deposition was not associated with a higher AI, interstitial fibrosis, dsDNA, or lower complements (Table 2)

Conclusion: This is the first study to demonstrate evidence in NLS of levels of microvascular C5b-9 indicative of SCA in LN. C5b-9 deposition indicative of SCA is statistically more common and demonstrated greater specificity than historical biomarkers in active LN. Findings support a potential role for microvascular C5b-9 assessment in NLS as biomarker for LN activity. Long term follow up needed to assess if NLS evidence of SCA associates with less treatment response or poor outcomes in active LN

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Ischemic stroke is 2-3 times more common in patients with SLE as compared to the general population, and genetic susceptibility in the *STAT4* and *HLA-DRB1* genes have been reported to contribute to stroke in SLE. But few studies have investigated the distribution of stroke sub-types in SLE, and to our knowledge, none if they are associated with known susceptibility genes. We therefore investigated the distribution of ischemic stroke sub-types, classified according to the Trial of Org 10172 in Acute Stroke Treatment (TOAST) system(1), among patients with systemic lupus erythematosus (SLE).

Methods: Among 665 SLE patients fulfilling ACR -97 criteria for SLE, we identified 69 patients with ischemic stroke. Medical charts were retrieved and brain, cardiac and vascular imaging at the time of the first stroke were examined. Classification was performed according to TOAST: large-artery atherosclerosis (LAA), cardioembolism (CE), small-artery occlusion (SAO), stroke of other determined etiology (OC) and stroke of undetermined etiology (UE). Occurrence of the anti-phospholipid syndrome/antibodies (APS/aPL) were documented. Evaluators were blinded to genotypes. General population controls (N=658) and SLE patients free from previous cerebrovascular disease (N= 517) were used as comparators. Genetic susceptibility in the signal transducer and activator of transcription factor 4 (*STAT4*) gene, defined by the single nucleotide polymorphism (SNP) rs10181656(G), and the Human Leukocyte antigen (HLA)-DRB1 alleles were explored.

Table 1

Distribution of ischemic stroke subtypes in patients with SLE according to TOAST classification

Ischemic stroke subtypes	N (%)	Age in years at first event (median, range)
Any ischemic stroke	56 (100%)	52 (17-84)
Large artery artherosclerosis (LAA)	7 (12%)	55 (34-67)
Small arterial occlucion (SAO)	9 (16%)	63 (51-84)
Cardioembolic stroke (CE)	12 (21%)	57 (23-70)
Other determined etiology (OE), all APS	19 (33%)	42 (18-74)**
Undetermined etiology (UE)	9 (16%)	56 (25-73)

**Patients with OE/APS strokes were younger, as compared to all other stroke subtypes, p=0.003

Results: 56/69 patients with ischemic stroke had charts with sufficient information for TOAST classification. Median age was 52 (17-84) years, 91% were female. TOAST classification and age at first stroke is presented in Table 1. All strokes classified as OC were attributed to APS/aPL. Strokes of OE/APS and CE origin were associated with the *STAT4* risk genotype as presented in Table 2 and Figure 1. HLA-DRB1 alleles were not associated with stroke sub-types (data not shown).

Conclusion: The majority (54%) of ischemic strokes among 56 SLE patients were of APS/aPL or CE origin. These two subtypes were associated with genetic susceptibility in the *STAT4* gene. We also noted that patients with APS/aPL associated strokes were younger than other sub-types, median 42 years. *STAT4* genotype could, in addition to antiphospholipid antibodies and echocardiography, add information about stroke risk and help identify patients who will benefit from prophylactic anticoagulation treatment.

Table 2

Associations of the risk allele, STAT4 single nucleotide polymorphism (SNP) rs10181656 (G), in SLE patients with ischemic stroke overall and stroke subtypes, specified according to the TOAST classification

Stroke type	MAF %	OR (95% CI) vs. Controls N=658 RAF 22.1 %	p-value vs. Controls	OR (95% CI) vs. Non-stroke SLE, N=517 RAF 31.9 %	p-value vs. Non-Stroke SLE
Any ischemic stroke N=56	**33.7**	**3.3 (2.2-4.9)**	**<0.0001**	**2.0 (1.3-2.9)**	**0.0005**
Small artery occlusion N=9	27.8	1.4 (0.5-3.8)	0.57	0.8 (0.3-2.3)	0.71
Large artery occlusion N=7	21.4	1.0 (0.3-3.5)	1.00	0.6 (0.2-2.1)	0.56
Cardioembolic stroke N=12	**70.8**	**8.6 (3.5-20.8)**	**$1.8x10^{-8}$**	**5.1 (2.1-12.5)**	**$6.7x10^{-5}$**
Other determined etiology (all APS) N=19	**60.5**	**5.4 (2.8-10.5)**	**$3.2x10^{-8}$**	**3.2(1.7-6.3)**	**0.0003**
Undetermined etiology N= 9	33.3	1.8 (0.7-4.7)	0.28	1.1 (0.4-2.8)	0.92

Performance of Conventional Cardiovascular Risk Scores in Identifying Subclinical Atherosclerosis in Systemic Lupus Erythematosus

Gayathri MS, Aishwarya Gopal, Molly Mary Thabah, Christina Mariaselvam, jaiveer Singh and Chengappa Kavadichanda, Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry, India

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiovascular disease (CVD) is a major cause of mortality in systemic lupus erythematosus (SLE). Role of conventional risk scores which predict cardiovascular events, to detect subclinical atherosclerosis in SLE is not established. In this study we assessed the performance of QRESEARCH database risk score-3 (QRISK3), Systemic COronary Risk Evaluation (SCORE), WHO (World Health Organization), Framingham (FRS) and modified Framingham(mFRS) CVD scores in subclinical atherosclerosis and determine clinical associations of the same

Methods: In this single centre cross-sectional analytical study, we enrolled 108 female SLE patients (without CVD) aged 40-60 years and 108 age matched healthy controls. Demography, disease activity, autoantibodies, steroid dose were noted. Subclinical atherosclerosis was defined by presence of either carotid plaque or abnormal carotid intima media thickness (cIMT) on ultrasound. CVD risk scores (QRISK3, SCORE, WHO, FRS and mFRS) were assessed. Agreement between scores was determined using kappa coefficient

Table 1: Comparison of disease parameters between SLE patients with and without subclinical atherosclerosis

Variable	SLE with subclinical atherosclerosis (n=55)	SLE without subclinical atherosclerosis (n=53)	p value
Age in years (mean± SD)	46.8± 6.6	45±5.2	0.39
Body mass index, (mean± SD)	26.5±5.1	26.3 ±4.7	0.59
Diabetes, n (%)	12(21.8)	10(18.9)	0.7
Hypertension, n (%)	14(25.5)	14(26.4)	0.9
Age at onset of first SLE symptoms, (mean± SD)	39± 9.45	37.9± 7.3	0.32
Disease duration in months (median, IQR)	84(81)	84(72)	0.88
Treatment duration in months (median, IQR)	72(93)	72(78)	0.65
Clinical SLEDAI (median, IQR)	0(0-8)	0(0-8)	0.59
SLEDAI>6, n (%)	5(9.1)	3(5.7)	0.5
SLICC-ACR damage index (median, IQR)	0(0-3)	0(0-2)	0.37
Renal involvement ever, n (%)	**24(43.6)**	**37(69.8)**	**0.006**
CNS involvement ever, n (%)	9(16.4)	5(9.4)	0.28
Any thrombotic manifestation, n (%)	3(5.5)	2(3.8)	0.67
Cumulative steroid dose mg (mean± SD)	14273± 11088	13360 ±10330	0.8
Anticardiolipin IgG antibody, n (%)	8(14.5)	3(5.7)	0.13
Anticardiolipin IgM antibody, n (%)	2(3.6)	5(9.4)	0.2
Anti Beta2 GPI IgG antibody, n (%)	7(12.7)	8(15.1)	0.69
Anti Beta2 GPI IgM antibody, n (%)	7(12.7)	5(9.4)	0.6
Lupus anticoagulant, n (%)	8(14.5)	5(9.4)	0.46
Any antiphospholipid antibodies (aPL) positive n (%)	22(40)	16(30.2)	0.28
Triple positive aPLs, n (%)	**3(5.5)**	**0**	**0.04**

Results: Mean age of patients was 46±6 years, median duration of SLE was 72(93)months, median SLEDAI 0(0-8) and SLICC-ACR damage index was 0 (0-3) (Table 1).Subclinical atherosclerosis was present in 55 (51%) SLE [abnormal cIMT-44(41%) and plaque- 17(16%)] and in 52 (48%) controls [abnormal cIMT-46(42%) and plaque 12(11%)].Mean cIMT was comparable (0.62 ±0.2 cm) in cases and controls. All CVD risk scores had low sensitivity but good specificity to identify subclinical atherosclerosis in patients and controls (Table 2). Area under the curve (AUC) of the receiver operating characteristic curve (ROC), with subclinical atherosclerosis as outcome, showed that all scores had poor discriminatory capacity (Fig 1). In SLE, WHO and FRS had moderate agreement (kappa coefficient k 0.53), QRISK3 and mFRS had substantial agreement (k 0.65) with subclinical atherosclerosis, whereas in controls with FRS and QRISK3, and SCORE and WHO had substantial agreement (k 0.66 and 0.7 respectively) (Table 3). Proportion of patients having triple positive antiphospholipid antibodies were significantly higher in SLE with subclinical atherosclerosis than without (5.5% vs 0, p=0.04). Renal involvement was significantly less in SLE with subclinical atherosclerosis than without (43.6% vs 69.8%, p=0.006)

Conclusion: Prevalence of subclinical atherosclerosis was comparable in SLE and controls (51% vs 48%), though carotid plaques were significantly more prevalent in SLE (17% vs 11%). Sensitivity of conventional CVD scores in detecting subclinical atherosclerosis in SLE was poor. Hence, until further scores are validated, screening for subclinical atherosclerosis using carotid ultrasound should remain gold standard

Abstract Number: 0581

Performance Characteristics of a Novel, Fully Automated Multiplexed Immunoassay Microarray Prototype for the Serological Detection of Eleven IgG Autoantibodies Commonly Found in Connective Tissue Diseases

Daphne Bijlsma, Ewa Lukasik, Michael Hausmann, **Gerber Gomez**, Christine Ginocchio and Emmanuel Moreau, Quotient Suisse SA, Eysins, Switzerland

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Detection of autoantibodies is key for the identification and prognosis of patients with connective tissue diseases (CTD); however, some current testing methods are manual, time-consuming, and fragmented, highlighting the need for the development of new fully automated diagnostic tools. We report the performance characteristics of MosaiQ Aiplex CTD prototype, (Quotient Suisse, Eysins, CH), a new planar microarray (MA) immunoassay designed for use with the fully automated, continuous random access, high throughput MosaiQ system for qualitative serological detection of eleven IgG autoantibodies commonly found in CTD (dsDNA, SS-A 60, TRIM21, SS-B, Sm, Sm/RNP, U1RNP, Jo-1, Scl-70, Centromere B, Ribosomal P).

Methods: Each MA consists of two wells, each enclosing an epoxy-silane functionalized glass chip, framed in a plastic chassis (Figure 1). Antigens probes were printed in duplicate, except in triplicate for dsDNA. One side of the MA was printed, leaving the other side available for future addition of antigens. MA were assembled into magazines and loaded in the MosaiQ 125 instrument and read by the on-board Radio Frequency Identification (RFID) antenna. Key information (i.e., number of MA, lot number, expiry date) is transmitted to the instrument which evaluates the adequacy of resources to execute the selected test order and alerts user when any replacement of reagents is required. MAs are released from the magazine and automatically processed in the system where they undergo sample/buffer/reagent addition and removal to generate a final spot signal for interpretation by the instrument.

Results: A cohort of 123 individual serum samples, of which 20 were obtained from blood donations and the rest from a CTD sample bank, were tested in 6-8 replicates with the investigational device, across 3 instruments and 3 MA lots (except for U1RNP which was tested on two lots) and compared with the results obtained with a CE-marked device. Table 1 shows that across analytes the total positive, negative, and overall percent agreement (PPA, NPA and OPA) respectively, were 82.5% (95% CI 80.7-84.2), 94.6% (95% CI 93.9-95.1), and 91.6% (95% CI 91.1-92.4). Rates of indeterminate and invalid results were 0.3% and 2.1%, respectively.

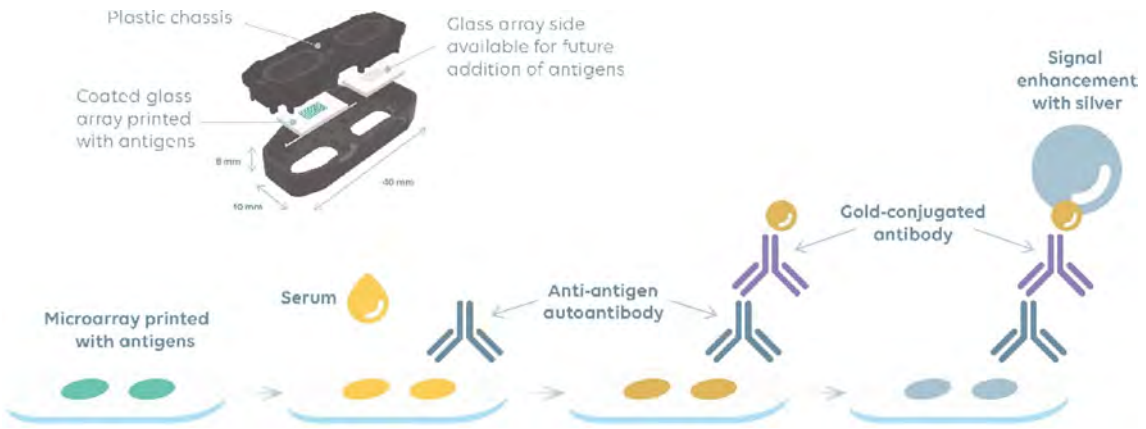

Figure 1. Microarray and assay's reactions

Table 1

Performance of MosaiQ Aiplex CTD Microarray Prototype

Concordant results n	Discordant results n	True Positive n	True Negative n	False Positive n	False Negative n	Indeterminate n (%)	Invalid n (%)	PPA % (95% CI)	NPA % (95% CI)	OPA % (95% CI)
6,608	592	1,506	5,280	304	320	36 (0.3)	158 (2.1)	82.5 (80.7-84.2)	94.6 (93.9-95.1)	91.6 (91.1-92.4)

PPA: positive percent agreement, NPA: negative percent agreement, OPA: overall percent agreement, CI: confidence interval

Conclusion: These preliminary results support the performance of the MosaiQ MA technology platform and Aiplex CTD prototype device for the serological qualitative detection of IgG autoantibodies commonly found in CTD. Clinical studies to further evaluate the performance of the investigational device are ongoing. Future versions of the MA are planned to expand the number of analytes included. The MosaiQ System has the potential to advance CTD testing by increasing laboratory efficiency and productivity by automatically analyzing multiple autoantibodies simultaneously and processing large number of samples per day.

Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE is a chronic disease that progressively reduces patients' health-related quality of life.[1] In a post hoc analysis of the TULIP trials, patients with SLE reported improvements in patient-reported outcome measures over 52 weeks.[2] Here, we evaluated the long-term impact of anifrolumab treatment on the Short Form 36 Health Survey version 2 (SF-36v2) in patients receiving standard therapy from the placebo-controlled, phase 3 long-term extension (LTE) trial.[3]

Methods: Adult patients with moderate to severe SLE (1997 ACR criteria) who completed a 52-week TULIP-1 or TULIP-2 trial could enroll in the 3-year LTE study (NCT02794285). Patients included in this analysis were randomized to intravenous anifrolumab 300 mg or placebo every 4 weeks in TULIP-1/-2 and continued in the same treatment group in the LTE, in addition to standard therapy. Proportions of patients classified as responders (defined by positive changes in responses from baseline greater than or equal to the minimum clinically important differences [MCIDs]) in Physical and Mental Component Scores (PCS/MCS) and SF-36v2 individual domains (acute recall) were analyzed for each treatment group using a Cochran–Mantel–Haenszel approach from Weeks 52 to 208. MCIDs were defined as changes from baseline ≥2.5 for PCS and MCS scores and ≥5 for all SF-36v2 domains.[2]Patients with baseline PCS ≤73.01 and MCS ≤67.15 scores and those with each baseline SF-36v2 domain score ≤95 were included in each respective analysis. Domain scores were non-normalized and scaled from worst to best (0–100).

Results: The proportion of PCS responders treated with anifrolumab (n=257; **Figure A**) increased over time from 51% at Week 52 to 56% at Week 208, whereas the proportion of responders decreased in the placebo group (n=112; **Figure B**) from 45% to 38%. The proportion of MCS responders was sustained for patients on anifrolumab with a 1% increase over 3 years, but decreased by 10% for patients on placebo. Proportions of SF-36v2 responders treated with anifrolumab were

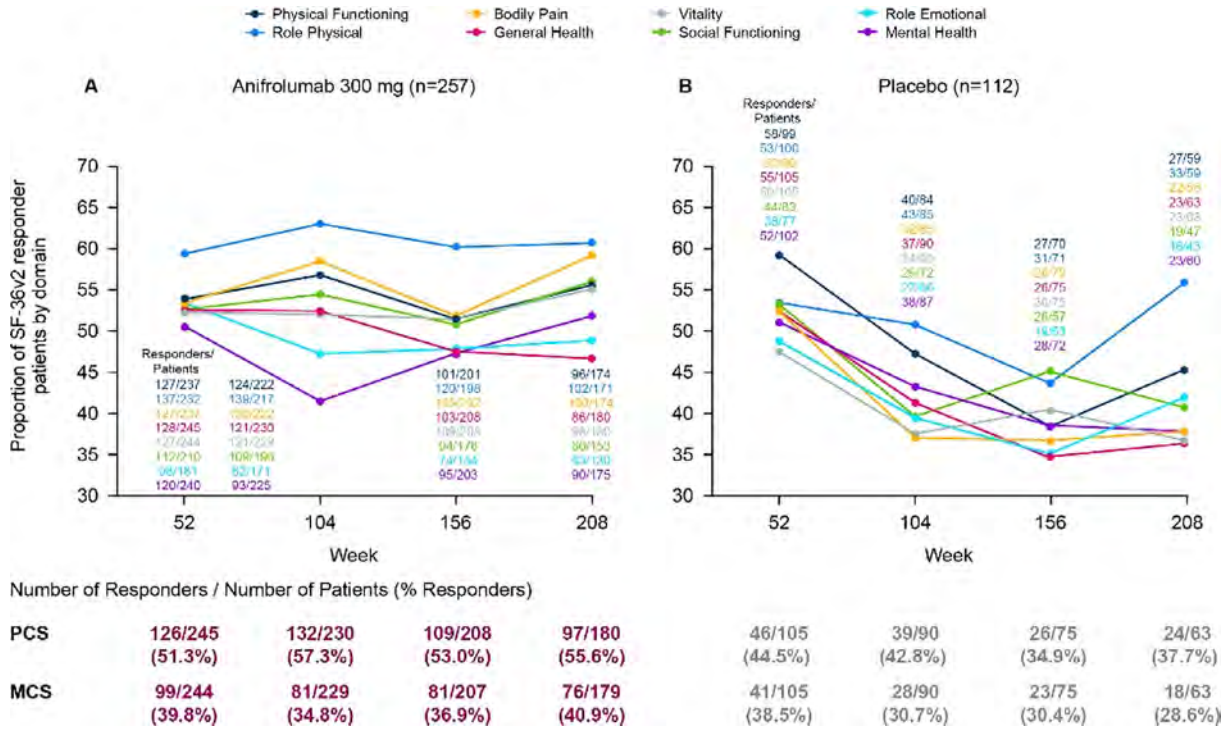

Figure. The Proportions of PCS, MCS and SF-36v2 by Domain Responder Patients by Treatment Group Throughout the TULIP-LTE Study. A) Anifrolumab 300 mg; B) Placebo. CMH, Cochran–Mantel–Haenszel; GC, glucocorticoids; IFN, interferon; LTE, long-term extension; MCS, Mental Component Score; PCS, Physical Component Score; SF-36v2, Short Form 36 Health Survey version 2; TULIP, Treatment of Uncontrolled Lupus via the Interferon Pathway. Percentages of responders were calculated using a stratified CMH approach (stratification factors: SLEDAI-2K score at screening [<10 points vs ≥10 points], Week 0 GC dose [<10 mg/day vs ≥10 mg/day] and type I IFN gene signature test result at screening [high vs low]). Responders were defined as positive changes in responses from baseline greater than or equal to the minimum clinically important differences.

generally maintained throughout the 3-year LTE period, with 47%–61% of patients reporting improved domain scores at Week 208. In all SF-36v2 domains except for General Health and Role Emotional, similar or higher proportions of anifrolumab-treated patients were responders at Week 208 compared with Week 52. In contrast, the proportions of responders receiving placebo decreased over time in all domains except Role Physical, ranging from 36%–56% at Week 208.

Conclusion: Patients with SLE treated with anifrolumab had sustained improvements in PCS, MCS, and most SF-36v2 individual domains over the 3-year LTE period. This was not observed in patients on standard therapy alone, despite the higher dropout rates and survivor bias observed in the placebo group.[3] These results support the long-term benefit of anifrolumab on self-reported, clinically important, health status outcomes across multiple domains.

Therapeutic Potential of Imvotamab, a CD20-Targeted Bispecific IgM T Cell Engager, for the Treatment of Refractory Autoimmune Disease Patients

Racquel Domingo-Gonzalez[1], Isabelle Baribaud[2], Miho Oyasu[1], Sivani Pandey[1], Maya Leabman[1], Genevive Hernandez[1], Albert Candia[1], Stephen Carroll[1], Bruce Keyt[1], Maya Kotturi[1], Carrie Brodmerkel[2] and Mary Beth Harler[2], [1]IGM Biosciences, Inc., Mountain View, CA, [2]IGM Biosciences, Inc., Doylestown, PA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: B cell depletion therapy (BCDT) with conventional IgG antibodies (e.g.rituximab) has been used to treat autoimmune (AI) disease for several decades. However, many patients do not achieve long term disease control or remission. Failure of these therapies to fully deplete tissue-resident B cells may result in persistent reservoirs of pathogenic clones that contribute to the ongoing generation of autoantibodies and disease activity. Bispecific IgM antibody T cell engagers (TCEs) are exciting drug candidates with the potential to deplete tissue-resident target cells more effectively through T cell-dependent cellular cytotoxicity (TDCC) and complement-dependent cytotoxicity compared to conventional BCDT mechanisms of action. Imvotamab (IGM-2323) is an engineered high-affinity, high avidity bispecific anti-CD20 IgM antibody TCE that has been evaluated for the treatment of non-Hodgkin's lymphoma (NHL). Given the preliminary clinical profile of imvotamab in NHL, which shows durable response rates and a favorable safety profile, we evaluated its potential to deplete peripheral and tissue-resident B cells in preclinical models of AI disease.

Methods: The ability of imvotamab, rituximab (anti-CD20 IgG1) and a bispecific CD20xCD3 IgG TCE to deplete B cells in the context of AI disease was assessed using an ex vivo TDCC assay. Human peripheral blood mononuclear cells (PBMCs) from healthy donors and patients with AI disease, including SLE, RA, and multiple sclerosis (MS)were utilized. B cell killing, T cell activation status, and cytokine release were assessed. The in vivo activity of a surrogate cynomolgus monkey cross-reactive CD20xCD3 IgM bispecific TCE, IGM-2324, was evaluated for depletion of B cells in peripheral blood and tissues of cynomolgus monkeys. B cell depletion in blood was measured by flow cytometry and in tissues by immunohistochemistry (IHC).

Results: Imvotamab induced killing of B cells in PBMCs from both AI patients and healthy donors. The maximum killing of B cells and half maximal effective concentration (EC50) were comparable between imvotamab, rituximab, and the bispecific CD20xCD3 IgG TCE. Importantly, no hyper-active responses were noted for T cell activation and cytokine release following treatment of PBMCs with imvotamab or the bispecific IgG TCE from healthy volunteers and AI patients. Evaluation of tissue-resident B cells in cynomolgus monkeys following treatment with IGM-2324 resulted in significant reductions in peripheral and tissue-resident B cells. IGM-2324 treatment led to the depletion of not only high and moderate tissue-resident CD20-expressing B cells, but also B cells that expressed low levels of CD20.

Conclusion: Our preclinical data suggests that imvotamab can effectively target and kill peripheral B cells from AI patients. Moreover, a CD20xCD3 IgM bispecific TCE can penetrate tissues and mediate direct killing of CD20-expressing target cells in vivo. Clinical studies with imvotamab in patients with autoimmune diseases, including RA and SLE, are planned to evaluate the therapeutic benefit of this mechanism.

Targeting Key Components of SLE Pathogenesis with the Multifaceted Immunomodulatory Properties of Cenerimod, a Selective S1P1 Receptor Modulator

Thomas Hoyler[1], Daniel Strasser[1], Ouali Berkani[2], Peter Cornelisse[1], Mark Murphy[1] and **Marianne Martinic**[1], [1]Idorsia Pharmaceuticals Ltd., Allschwil, Switzerland, [2]IDORSIA, Allschwil, Switzerland

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: In SLE, aberrant lymphocyte activation and autoantibody production result in deposition of immune complexes and contribute to tissue damage. Cenerimod, a highly selective $S1P_1$ receptor modulator with a biased signaling, shows potential therapeutic effect in SLE through its immunomodulatory effects on lymphocyte trafficking, inflammation, and autoantigen transport. Preclinical and clinical data suggest that cenerimod may halt the vicious circle of autoimmunity, ultimately preventing organ damage in SLE.

Methods: A murine model of SLE (MRL/lpr mice) and a proof-of-mechanism murine model for antigen transportation were used to evaluate the effects of cenerimod on leukocyte distribution, autoantibody titers, inflammation, and antigen transport, using flow cytometry, ELISA, and histology.[1-3] Leukocytes, autoantibodies, and inflammation biomarkers were further assessed in two phase 2 clinical studies of once-daily cenerimod (0.5, 1, 2, or 4 mg) versus placebo in patients with SLE (NCT02472795 and NCT03742037 [CARE]).[3-5] In the first phase 2 study, patients were treated for 12 weeks. In the CARE study, treatment was for 12 months; patients assigned to cenerimod 4 mg were re-randomized to placebo or cenerimod 2 mg at Month 6.

Results: In rodent disease models, cenerimod reduced the migration of dendritic cells to the draining lymph node, which was accompanied by reduced T cell proliferation and pro-inflammatory cytokine secretion. Furthermore, in the MRL/lpr lupus mouse model, treatment with cenerimod led to significant disease amelioration, evidenced by a reduction of tissue-infiltrating lymphocytes, lower titers of autoantibodies, and reduced levels of inflammatory cytokines. This was associated with reduced signs of pathology in the kidneys, improved kidney function, and increased survival.

In the 12-week phase 2 clinical trial, treatment with cenerimod decreased circulating T and B lymphocytes, decreased autoantibody levels, and reduced secretion of pro-inflammatory IFN-a. These findings were supported in the CARE study, which showed that cenerimod 4 mg improved clinical indices of disease activity and reduced pro-inflammatory cytokines.

Conclusion: Both preclinical and clinical research provide evidence that cenerimod is a promising immunomodulatory drug candidate that addresses three critical aspects of SLE pathogenesis: migration of autoreactive lymphocytes, release of pro-inflammatory cytokines and chemokines, and continuous autoimmune priming. The $S1P_1$ receptor modulator cenerimod may effectively interrupt this pathogenic circle of SLE autoimmunity. The ongoing OPUS Phase 3 program (NCT05648500, NCT05672576) is designed to further investigate the safety and efficacy of cenerimod at a dose of 4 mg for the treatment of SLE in adults.

The Impact of Impaired Vagus Nerve Activity and Transcutaneous Vagus Nerve Stimulation (tVNS) on Arterial Stiffness in Systemic Lupus Erythematosus (SLE)

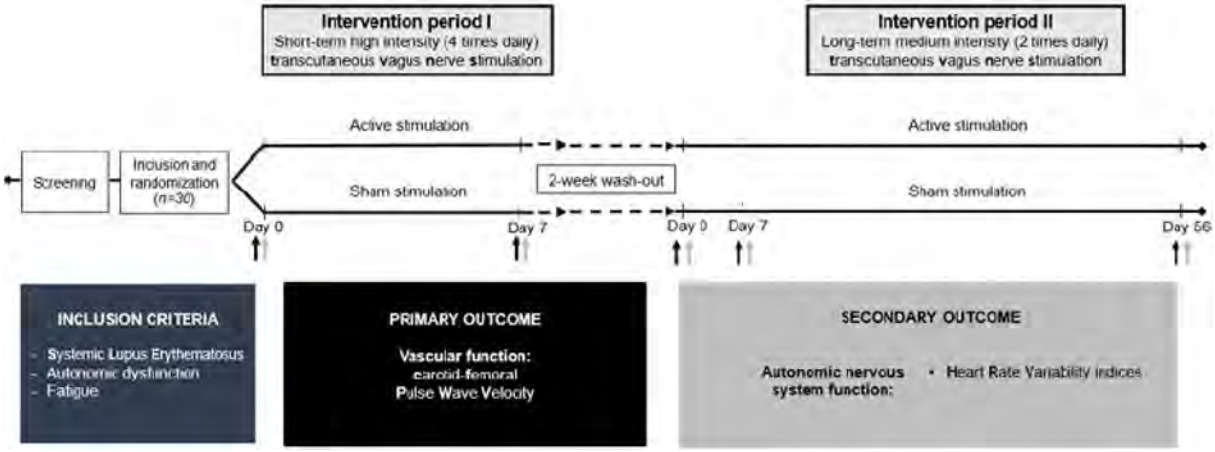
Tobias Schmidt[1], Christina Brock[2], Jesper Fleischer[3], Søren Jacobsen[1] and Amanda Hempel Zinglersen[1], [1]Copenhagen Research Center for Autoimmune Connective Tissue Diseases, Center for Rheumatology and Spine Diseases, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark, [2]Department of Gastroenterology and Hepatology, Aalborg University Hospital and Clinical Institute, Aalborg, Denmark, [3]Steno Diabetes Center Aarhus, Aarhus University Hospital, Aarhus, Denmark

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

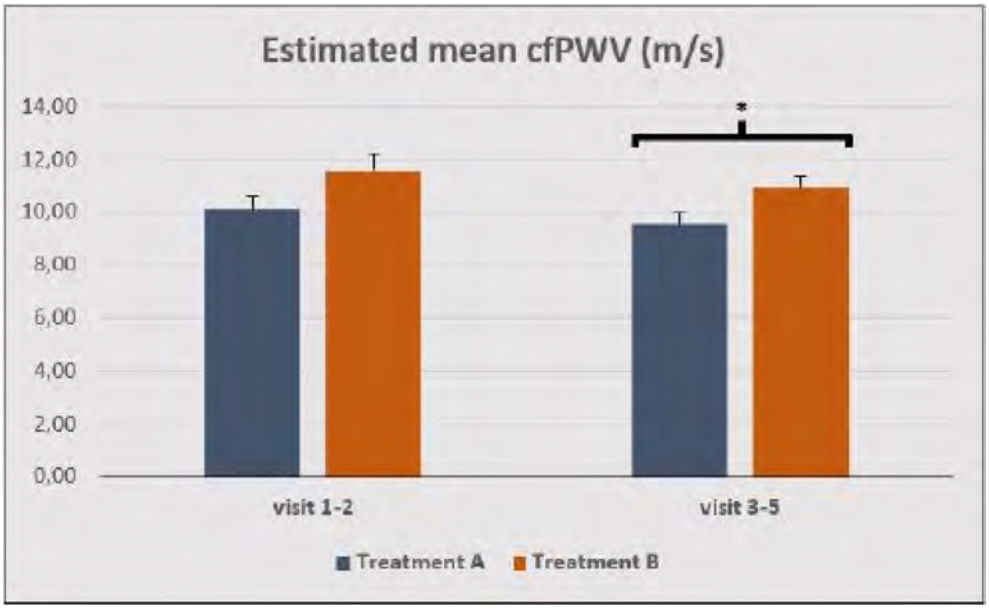
Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic inflammatory autoimmune disease with an increased risk of atherosclerosis. The development of atherosclerosis in SLE cannot be fully explained by traditional risk factors but may be partially due to chronic inflammation. SLE is associated with abnormal autonomic function i.e., decreased parasympathetic vagus nerve activity. Impaired vagal activity may impact disease severity through an impaired vagally mediated inflammatory reflex, which may lead to increased inflammation, and possibly to stiffening of conduit arteries

i.e., increased arterial stiffness. In SLE patients, we aim to determine whether impaired vagus nerve activity is associated with arterial stiffness and whether the latter can be diminished by increasing vagal activity through transcutaneous vagus nerve stimulation (tVNS).

Methods: This is a blinded sub-study (n=30) of an ongoing double-blinded, randomized, sham-controlled study investigating the effects of tVNS on SLE (n=58). In the first intervention period, patients were randomized to self-administration of either active or sham bilateral tVNS at the cervical vagus nerve for 120 seconds 4 times daily for seven days. After a stimulation-free two-week wash-out period, tVNS was self-administered for 120 seconds 2 times daily for eight weeks in the second intervention period. Pulse wave velocity (PWV), which is a gold standard method for non-invasive arterial stiffness assessment, pulse wave velocity (PWV), was recorded at two arterial sites, i.e., carotid-femoral PWV (cfPWV). Autonomic function was assessed using a VagusTM device that measured 5-min resting heart rate variability. Data was analyzed using a linear mixed model in SPSS.



Overview of the systemic lupus erythematosus (SLE)-vagus nerve stimulation (VNS) study.



Estimated mean (±SE in error bars) carotid-femoral pulse wave velocity (cfPWV) between groups during visits 1-2 and visits 3-5 (n=30). The mean difference in cfPWV between groups is based on estimated means. The groups displayed a mean difference in cfPWV during visits 3-5 (p=0.04).

Pairwise comparisons of differences between groups at visit 3-5 (n = 30)

Group	Variable	Mean diff.	[95% CI]	P-value
A vs. **B**	*cfPWV, m/s*	-1,38	[-2,72 ; -0,05]	0,04 *
	HRV indices			
A vs. **B**	*SDNN, ms*	13,33	[4,59 ; 22,06]	0,003 **
A vs. **B**	*RMSSD, ms*	13,21	[4,71 ; 21,72]	0,003 **
A vs. **B**	*LF, ms²*	83,67	[-123,98 ; 291,32]	0,4
A vs. **B**	*HF, ms²*	153,22	[56,35 ; 250,09]	0,002 **
A vs. **B**	*TP, ms²*	364,05	[19,91 ; 708,20]	0,04 *
A vs. **B**	*LF/HF ratio*	0,07	[-1,53 ; 1,39]	0,9

Mean difference (Mean diff.) between groups is based on estimated marginal means.
Mean diff. is illustrated with a negative value if overall mean of A is smaller than B.
** Mean diff. values between groups are considered significant (p<0.05).*
*** Mean diff. values between groups are considered significant (p<0.01).*

Pairwise comparisons of mean differences between groups during visits 3-5 (n=30): cfPWV, carotid-femoral pulse wave velocity; HF, high-frequency power; HRV, heart rate variability; LF, low-frequency power; RMSSD, root mean square of successive differences between normal heartbeats; SDNN, SD of all NN intervals; TP, total power.

Results: The groups were divided into A or B. However, the main study was still blinded at the time of this thesis, thus Group A was selected as the active treatment group for purpose of a meaningful discussion. Group-A (n=17) and group-B (n=13) were similar in age (51.6±14.1, 46.6±17.6 years), sex (94.1%, 86.4% females), and in the prevalence of hypertension and hypercholesterolemia. In unadjusted analyses, higher baseline cfPWV correlated with lower degrees of autonomic function in all but one measure ($p< 0.05$). During the second and longer intervention period (8 weeks), Group-A displayed a lower cfPWV, i.e., less stiff arteries, than Group B (mean difference 1.38 m/s, p=0.04).

Conclusion: In SLE, autonomic dysfunction was associated with arterial stiffness at baseline. Arterial stiffness was reduced with Treatment A, indicating a reduced the risk of vascular disease with vagus nerve stimulation in SLE. However, this needs to be verified after unblinding the main study.

Therapeutic Drug Monitoring of Azathioprine and Tacrolimus in SLE Pregnancies: Preliminary Results from the LEGACY Cohort

Reem Farhat[1], Arielle Mendel[2], Isabelle Malhamé[3], Joo Young (Esther) Lee[4], Luisa Ciofani[5], Sasha Bernatsky[6] and Evelyne Vinet[2], [1]McGill University, Montréal, QC, Canada, [2]McGill University Health Centre, Montréal, QC, Canada, [3]McGill University Health Centre, Montreal, QC, Canada, [4]McGill University, Montreal, QC, Canada, [5]McGill University Health Center, Montreal, QC, Canada, [6]Research Institute of the McGill University Health Centre, Montreal, QC, Canada

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Pregnant SLE women still face an unacceptably high risk of maternal and fetal morbidity, particularly when their disease is active. How to personalize SLE therapies to optimize pregnancy outcomes remains unknown. Though guidelines strongly recommend azathioprine (AZA) and tacrolimus (TAC) in specific SLE pregnancy scenarios, evidence to guide drug monitoring in this context is non-existent. Our aim is to evaluate the characteristics of SLE pregnancies according to the levels of AZA metabolites and TAC trough levels at the first pregnancy (baseline) visit.

Methods: LEGACY is a prospective cohort enrolling unselected SLE pregnancies ≤16 6/7 gestational weeks at 7 Systemic Lupus International Collaborating Clinics. We record demographics, disease activity, and drugs. In addition, whole blood samples are collected at baseline to determine AZA metabolites (e.g., erythrocyte-free 6-thioguanine, 6-TG) and trough TAC levels if applicable. The present study included Montreal LEGACY participants prescribed either AZA or TAC ≥3 months prior to their first pregnancy visit. We characterized AZA metabolite and TAC levels as continuous and categorical variables (i.e., non-adherent, sub-therapeutic, therapeutic, and supra-therapeutic, using established cut-offs in nonpregnant populations). We defined patients as non-adherent if they had undetectable or barely detectable levels despite appropriate dosing.

Results: Of 70 LEGACY pregnancies enrolled in Montreal, 23 (33%) and 6 (9%) were prescribed AZA and TAC, respectively. Among those prescribed AZA, only 9% had therapeutic levels, while 91% were subtherapeutic or non-adherent (Table 1). Compared to those with therapeutic levels, pregnancies with subtherapeutic or non-adherent AZA levels were more likely to occur in women of non-Caucasian ethnicity/race, on steroids, with longer SLE duration, and with prior lupus nephritis (Table 2). Among those prescribed TAC, 50% (3/6) had therapeutic levels, while 33% (2/6) and 17% (1/6) were subtherapeutic and supra-therapeutic, respectively. No patients on TAC were identified as non-adherent. Less than half (43%) of pregnancies non-adherent to AZA were in Lupus Low Disease Activity State (LLDAS) at baseline. Of the pregnancies with subtherapeutic TAC levels, 50% (1/2) were not in LLDAS, while all (4/4) pregnancies with therapeutic or supra-therapeutic TAC levels were in LLDAS at baseline.

Table 1. Number of pregnancies and mean drug dose at baseline visit according to AZA metabolite (6-TG) and TAC trough levels

		Non-adherent	Sub-therapeutic	Therapeutic	Supra- therapeutic
AZA (n=23)	**Pregnancies**, n (%)	7 (30)	14 (61)	2 (9)	-
	AZA dose in mg/kg, mean ± SD	2.5 ± 0.5	1.9 ± 0.5	2.0 ± 0.2	-
TAC (n=6)	**Pregnancies**, n (%)	-	2 (33)	3 (50)	1 (17)
	TAC dose in mg/kg, mean ± SD	-	0.04 ± 0.02	0.04 ± 0.02	0.03 ± 0

Table 2. Baseline maternal characteristics stratified according to AZA metabolite (6-TG) and TAC trough levels

		AZA (n=23)			TAC (n=6)		
		Non-adherent (n=7)	Sub-therapeutic (n=14)	Therapeutic (n=2)	Sub-therapeutic (n=2)	Therapeutic (n=3)	Supra-therapeutic (n=1)
Age in years, mean ± SD		34.0 ± 4.1	33.8 ± 3.9	29.0 ± 0.7	30.3 ± 3.3	31.3 ± 4.1	32.4 ± 0
Race/ Ethnicity, n (%)	Caucasian	1 (14)	4 (29)	2 (100)	2 (100)	2 (67)	1 (100)
	Hispanic	-	-	-	-	1 (33)	-
	Black	2 (29)	3 (21)	-	-	-	-
	Asian	2 (29)	5 (36)	-	-	-	-
	Arabic	1 (14)	-	-	-	-	-
Education in years, mean ± SD		15.7 ± 3.5	16.7 ± 3.1	17.0 ± 1.4	19.0 ± 1.4	14.3 ± 1.5	16.0 ± 0
Disease duration in years, mean ± SD		10.3 ± 6.5	10 ± 6.9	5.3 ± 0.7	9.3 ± 0	4.2 ± 1.1	3.8 ± 0
LLDAS, n (%)		3 (43)	10 (71)	-	1 (50)	3 (100)	1 (100)
Prior or current lupus nephritis, n (%)		5 (71)	5 (36)	-	2 (100)	1 (33)	-
Steroid use, n (%)		2 (29)	1 (7)	-	-	-	-

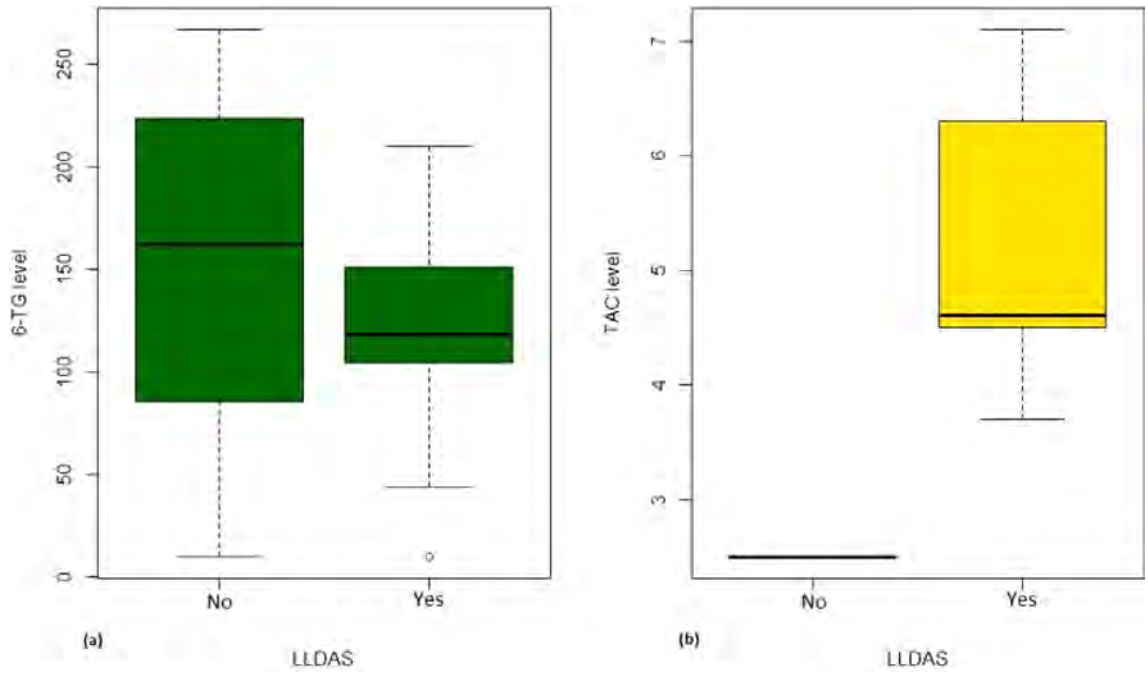

Figure 1. Boxplot of 6-TG levels [pmol/8×108 RBC] (a) and TAC trough levels [ng/ml] (b) according to LLDAS

Conclusion: We observed that most SLE pregnancies prescribed AZA had sub-therapeutic levels, with nearly a third identified as non-adherent. Pregnancies with lower AZA and TAC levels may be less likely to achieve LLDAS. Despite low numbers, our preliminary results suggest the value of personalized drug monitoring as a novel approach to precision medicine in pregnant SLE women, that might improve efficacy, safety, and adherence in a high-risk population.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The clinical effectiveness of 6-month IV BEL use in SLE has previously been described in a post hoc pooled analysis from six OBSErve cohort studies.[1] Here we present expanded post hoc analysis of eight pooled OBSErve studies investigating the long-term effectiveness of BEL on reducing oral CS (OCS) use and achieving low disease activity (LDA) and remission, which are important treatment targets for SLE to minimize irreversible organ damage.[2,3]

Methods: This was a post hoc pooled analysis (GSK Study 219649) of data from eight OBSErve studies in Argentina, Canada, Germany, USA, Russia, Saudi Arabia, Spain, and Switzerland. Clinician-reported data were captured for adults with SLE at IV BEL initiation (index) and at 6–24 months after index. All studies captured 6 months of data after index, with Argentina and USA data extending up to 24 months after index. Enrollment was 6 months post index for all studies except Argentina and n=284/501 USA patients (pts) who enrolled 12 months after index. The primary objective was to describe the proportion of pts achieving a daily OCS dose ≤10 mg, ≤7.5 mg, ≤5 mg, or 0 mg at 6, 12, 18, or 24 months after index. Secondary objectives included: the proportion of pts who maintained their 6-month post index daily OCS dose threshold over time; and the proportion of pts achieving LDA (modified Lupus Low Disease Activity State; SLEDAI score ≤4 with no worsening of clinical manifestations and OCS dose ≤7.5 mg/day[4]) or remission (modified Definition Of Remission In SLE; SLEDAI score=0 and OCS dose ≤5 mg/day[5]) at 24 months after index.

Results: Data from 959 pts were included. Most pts were from the USA (52.2%), Germany (10.6%), and Argentina (8.4%). At enrollment, the mean age was 41.5 years, 89.5% were female, 64.6% were White (N=878 only); 55.2% had SLE for ≥5 years before enrollment.

At index, median (interquartile range) OCS dose was 10.0 (5.0, 20.0) mg/day; 14.5% were receiving an OCS dose of >20 mg/day and 41.0% >10 mg/day. The proportion of pts receiving OCS dose ≤7.5 mg/day increased from 38.5% at index to 69.4% at 6 months, 80.0% at 12 months, 83.7% at 18 months, and 92.1% at 24 months (data after 6 months for pooled Argentina/USA only; **Figure 1A**). A similar trend was seen among those who were receiving >10 mg/day at index (**-Figure 1B**). Over 87% of pts maintained the same OCS low dose threshold at 12, 18, and 24 months as at 6 months after index (**Figure 2**). At index (N=447), 0.4% of pts were in LDA state and 0.2% in remission. At 24 months, 18.2% and 12.9% achieved LDA and remission, respectively (**Table**).

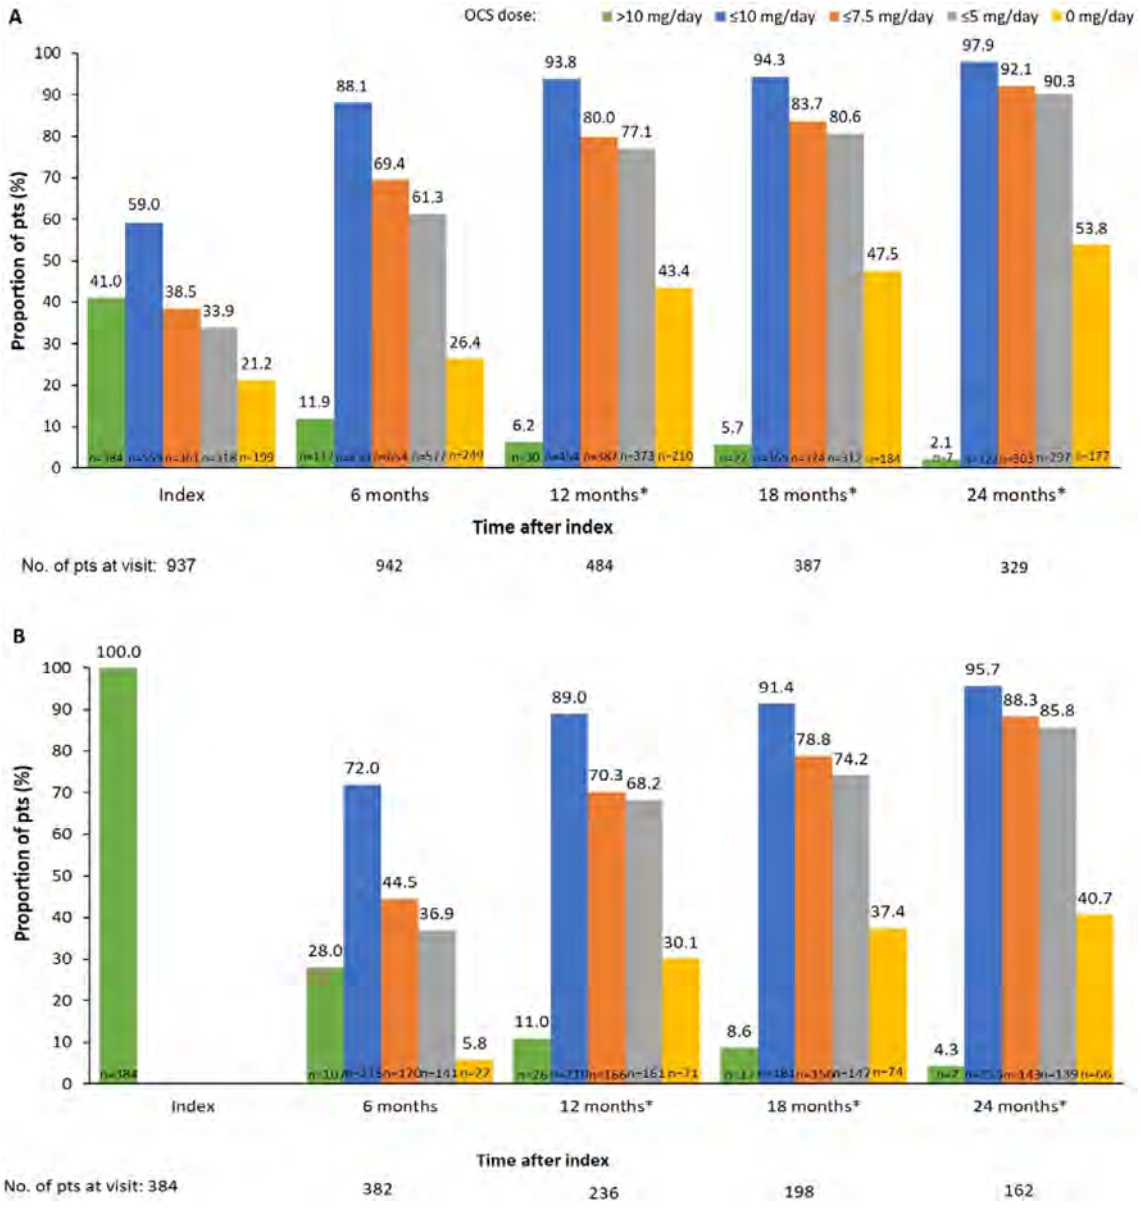

Figure 1. Summary of OCS use at index and 6, 12, 18, and 24 months after index among all pts (A) and patients receiving OCS >10 mg/day at index (B). OCS dose=prednisone equivalent. *Among pooled pts in Argentina and the USA where data were captured beyond 6 months post index.

Conclusion: These data demonstrate a steroid-sparing effect of long-term BEL use, which was evident from 6 months and maintained over 24 months, as well as an improvement of disease activity indices in pts with SLE, further supporting the effectiveness of IV BEL in real-world SLE clinical management.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: SLE – Treatment Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Rituximab (RTX) is increasingly being employed to treat refractory systemic lupus erythematosus(SLE). Though the drug is effective there is a high risk of adverse events including infections. Most studies have focused on short term(< 1 year) safety, whereas long term follow-up data is sparse. This study was designed to look at the frequency and predictors of infections in patients with SLE receiving RTX who are on long term follow up.

Abbreviations: RTX-Rituximab, MPS-Methyl prednisolone, IS-Immunosuppressants, MMF-Mycophenolate mofetil, MACE-Major adverse cardiac event

Methods: This was a single-centre retrospective observational study. Data of SLE patients who received at least 1 gram of RTX were abstracted from the case record forms of the department's biologic registry. Patients were followed up at 3-6 monthly intervals and disease activity, infectious and non-infectious adverse events during or after RTX induction were documented. For those patients who did not have follow up for ≥ 1 year, the last available date of follow-up was considered for this study. Demographic, baseline organ involvement, laboratory data, treatment details were collected. Glucocorticoid

exposure was assessed in terms of cumulative steroid (prednisolone) dose, standardized steroid dose (glucocorticoid intake per month of exposure) and number of times the patient received pulse IV methylprednisolone. A 'serious adverse event' was defined according to guidelines by International Council on Harmonisation (ICH) 1994. The primary outcome was the occurrence of a serious infection. Secondary outcomes included mortality, time to first serious infection, minor infections and other adverse events.

Results: A total of 76 SLE patients (median age 29 years, 83% females) were included. The median follow-up duration was 27.0 (10-49) months amounting to 177.33 person-years of follow-up. Baseline data of the patients is represented in table 1. Forty-five patients (59.2%) had at least one adverse event. Among these, non-infectious events occurred in 4 (5.26%). Infusion reactions occurred 3 (3.9%), one requiring discontinuation of therapy. One patient had worsening of pre-existing pulmonary artery hypertension. There were 43 (56.6%) patients who had infectious events, 16 of 76 (21.05%) were serious infections amounting to 9.02 infections per 100 person-years of follow-up. Majority(53%) of infections occurred after 1 year of RTX infusion. Site of infections and microrganisms implicated are detailed in table 2. There were total 8 deaths resulting in a mortality rate of 4.5 per 100 person-years of follow-up. All deaths except one were due to serious infection. Male sex, younger patients, CKD**,** previous cyclophosphamide use, higher cumulative dose of cyclophosphamide, refractory lupus nephritis, higher SLICC ACR damage index at baseline was associated with serious infections (table 1). On binary logistic regression younger age(B 95% CI) and presence of disease damage(B 95% CI) emerged as significant predictors of serious infections (table 3).

Conclusion: Serious infections following RTX are common and result in mortality in SLE. More than 50% of them occur after 1 year of RTX administration. Infections arise from common and rare opportunistic organisms. Juvenile lupus and presence of damage at baseline predispose to infections.

Abstract Number: 0589

A Comparative Evaluation of IgA2 Anti-dsDNA Antibodies and Clinical Outcome in Two Clinical Trials of Belimumab After Rituximab in SLE

Muhammad RA Shipa[1], Daniel McCluskey[1], Laura Cooney[2] and Michael Ehrenstein[1], [1]University College London, London, United Kingdom, [2]Immune Tolerance Network, Seattle, WA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: SLE – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: We have shown that serum IgA2 anti-dsDNA antibody levels is a biomarker of response to belimumab after rituximab in SLE (BEAT-lupus trial) (1). We sought to confirm these findings in the CALIBRATE trial where 43 patients with lupus nephritis refractory to conventional therapy were randomised to receive either rituximab, cyclophosphamide, and then belimumab (RCB) for 48 weeks, or rituximab and cyclophosphamide (RC) (2).

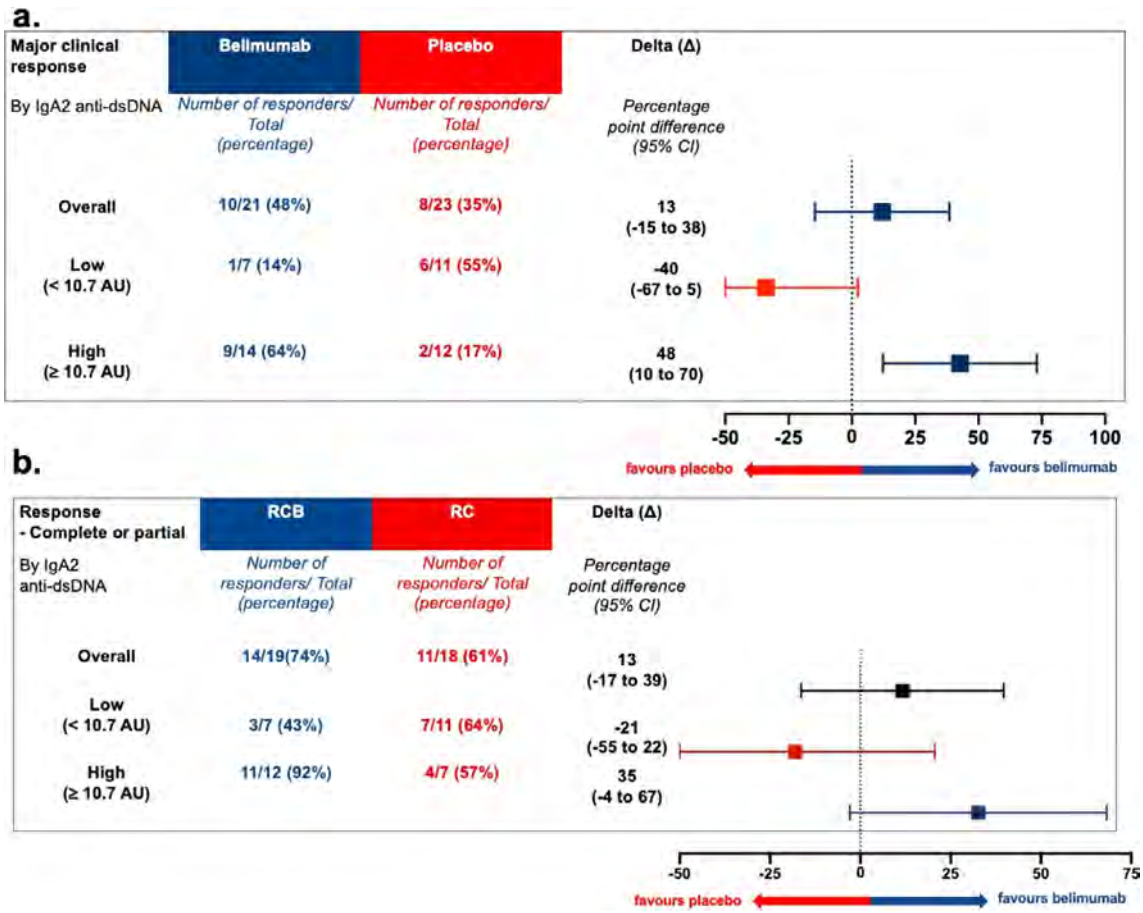

Figure 1a-b - Patients with high baseline serum IgA2 anti-dsDNA antibody levels were more likely to respond at 1 year to belimumab after rituximab compared to rituximab therapy: (a) BEAT-LUPUS and (b) CALIBRATE trial. Baseline serum IgA2 anti-dsDNA antibody levels were categorised into high or low levels (the optimal cut-point was derived from the Area under the Receiver operator characteristic (ROC) curve (AUROC) analysis (= 10.7 arbitrary units/AUs). RCB = belimumab after rituximab and cyclophosphamide, RC = rituximab and cyclophosphamide

Methods: All patients met the ACR classification criteria for SLE. Serum IgG, IgA1 and IgA2 anti-DNA antibodies were assayed by ELISA. We performed a post-hoc modified intention to treat analysis of the CALIBRATE trial so that the clinical outcome data could be matched with the BEAT-lupus trial.

Results: The intention-to-treat analysis of both the BEAT-lupus and CALIBRATE trials revealed a 13% difference in outcome at 1 year favouring belimumab after rituximab compared to rituximab. This difference increased to 35% in those patients in the CALIBRATE trial with elevated serum levels of IgA2 anti-dsDNA antibodies, the corresponding value in the BEAT-lupus trial was a 48% difference (1) (Figure 1a-b).

Matching previously published data from the BEAT-LUPUS trial (1), serum IgA2, but not IgA1, anti-dsDNA antibodylevels decreased at 48 weeks only in patients who received belimumab (p=0.002) (Figure 2a-b). Serum IgA2 anti-dsDNA antibodies increased after cessation of belimumab therapy. There was no significant difference in serum IgG anti-DNA antibody levels between the two arms of the CALIBRATE trial (Figure 2c). Serum IgA1 anti-dsDNA antibody levels in the CALIBRATE

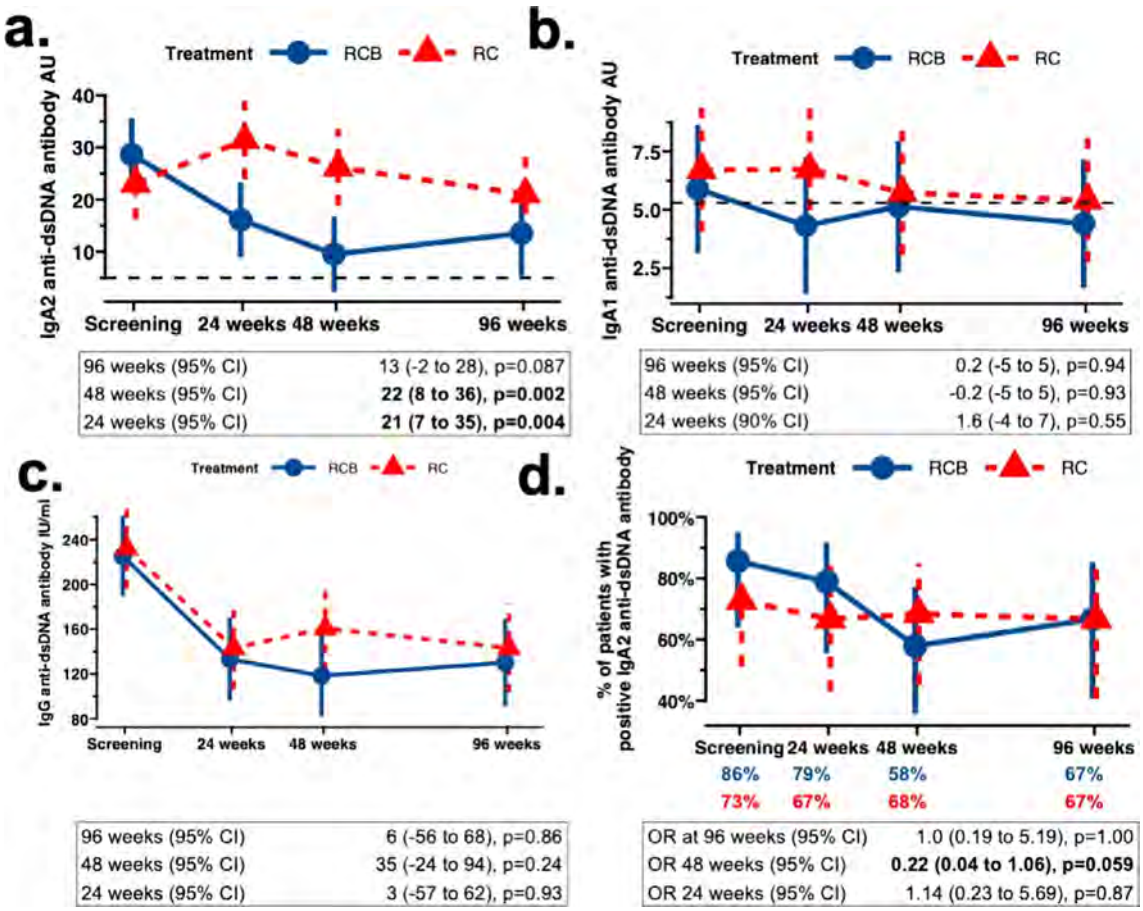

Figure 2a-d - Belimumab after rituximab decreased serum IgA2 anti-dsDNA antibody levels compared to rituximab therapy (CALIBRATE trial). Longitudinal change of (a) serum IgA2 anti-dsDNA antibodies, (b) serum IgA1 anti-dsDNA antibodies, and (c) serum IgG anti-dsDNA antibodies stratified by treatment i.e., RCB = belimumab after rituximab and cyclophosphamide versus RC = no belimumab after rituximab and cyclophosphamide. A generalised longitudinal linear mixed-effect model was fitted with random patient effect to account for clustering by patients and fixed effect of treatment group intercepting with trial times and adjusted for screening IgA2 anti-dsDNA antibody values, age, gender, and concomitant prednisolone (yes or no) to calculate expected difference at 24, 48, and 96 weeks. Estimated mean with 95% confidence intervals (95%CIs) are shown; p values are provided. The horizontal black dotted lines where shown indicate upper limit of normal (3 standard deviation above the mean of healthy control samples). (d) Proportion of patients who were positive† for IgA2 anti-dsDNA antibodies at each time point. Odds ratio (OR) of seronegative reversion for IgA2 anti-dsDNA antibodies at each time points with RCB (if positive for IgA2 anti-dsDNA antibodies at baseline) compared to RC group. †Positivity of IgA2 anti-dsDNA antibody was defined as 3 standard deviations above the mean values of healthy control samples (=5.4 arbitrary units).

trial were less than IgA2 anti-DNA antibody levels and remained close to healthy control values, consistent with our previous observation that the former is low in lupus nephritis (1).

At baseline, 18/21 patients (86%) in the RCB group and 16/22 patients (73%) in the RC group were positive for serum IgA2 anti-dsDNA antibodies. The percentage of patients with positive IgA2 anti-dsDNA antibodies reduced to 58% in the RCB group at 48 weeks (Figure 2d). The odds ratio of reversion to seronegativity in belimumab treated patients with positive IgA2 anti-dsDNA antibodies was 0.22 at 48 weeks (95% CI 0.04–1.06; p=0.059); a similar sero-reversion rate was noted in the belimumab arm of the BEAT-LUPUS trial (1).

The overall response rate in the CALIBRATE trial (74% - RCB arm, 61% - RC arm) was higher than the BEAT-LUPUS trial (48% - belimumab arm, 35% - placebo arm). Patients in the CALIBRATE trial received almost twice as much prednisolone in the first 48 weeks compared to the BEAT-LUPUS trial (Figure 3) which could reflect the slightly different patient populations (CALIBRATE- refractory lupus nephritis; BEAT-lupus – refractory lupus: 20/52 patients had lupus nephritis) and explain the difference in outcome.

Conclusion: Data from two independent trials confirm IgA2 anti-dsDNA antibody levels as a predictive biomarker of response to belimumab after rituximab in SLE. Cessation of belimumab therapy after rituximab led to a rise in IgA2 anti-dsDNA antibody levels providing a mechanistic rationale for continuation of therapy.

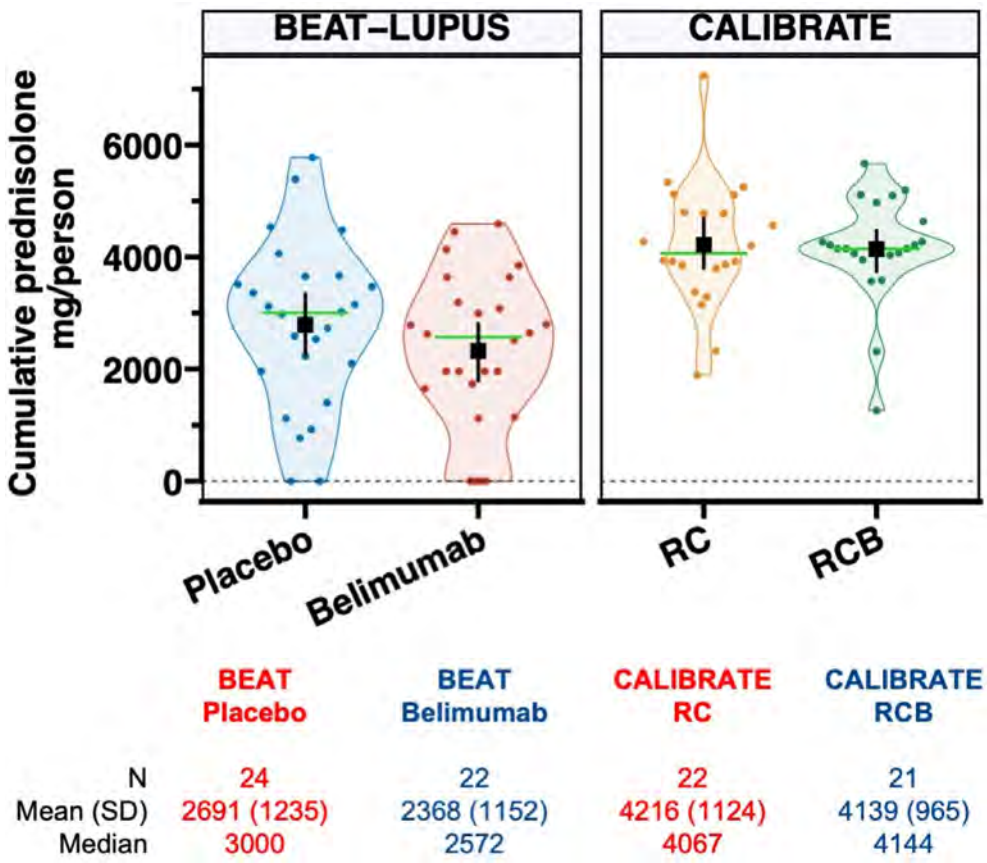

Figure 3 – Cumulative dose of prednisolone in the CALIBRATE and BEAT-lupus trials. Cumulative dose of prednisolone in the treatment arms in the BEAT-LUPUS and CALIBRATE trials over 52 and 48 weeks, respectfully. The black boxes and lines indicate mean values with 95% confidence interval, green horizontal lines indicate median values. RCB = belimumab after rituximab and cyclophosphamide. RC = no belimumab after rituximab and cyclophosphamide.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Sodium-glucose co-transporter 2 inhibitors (SGLT2i), originally approved as oral hypoglycemic agents for type 2 diabetes (T2D), have been shown to reduce progression to end-stage renal disease (ESRD), as well as heart failure and overall mortality. Those with systemic lupus erythematosus (SLE) were excluded from trials and thus the potential benefits for these patients are unknown. We conducted a simulated clinical trial comparing renal, cardiovascular, infectious, and mortality outcomes among patients with both SLE and T2D starting SGLT2i vs. dipeptidyl peptidase 4 inhibitors (DPP4i) in a large real-world administrative dataset.

Methods: We identified a cohort of patients with both SLE and T2D, age ≥ 18 years within administrative data from 92 hospitals across the United States (TriNetX) using billing claim algorithms. All patients initiated either an SGLT2i or DPP4i between 2014 and 2023. SGLT2i recipients were 1:1 propensity score (PS) matched to DPP4i recipients on demographic and clinical factors, also identified by billing codes. Cox models estimated hazard ratios (HRs) and 95% confidence intervals (CIs) for the endpoints: 1) acute kidney injury (AKI), chronic kidney disease (CKD), end-stage renal disease (ESRD), 2) heart failure, myocardial infarction, stroke, 3) infections, specifically urinary tract and genital infections, severe sepsis, 4) emergency visits, hospitalizations and all-cause mortality.

Results: **Table 1** shows the SLE/T2D populations before and after PS-matching. Of the 3,749 PS-matched patients starting SGLT2i and 3,749 starting DPP4i, mean age was 58.3 (±11.2) years; 86.9% were females. In follow-up over 7.95 (±14.5) mean years, SGLT2i vs DPP4i recipients had significantly reduced risks of developing AKI (HR 0.65; 0.56-0.75), CKD (HR 0.74; 0.66-0.82), ESRD (HR 0.40; 0.27-0.59), and heart failure (HR 0.80; 0.71-0.90) (**Table 2**). SGLT2i use was also associated with decreased future emergency visits (HR 0.82; 0.77-0.88) and hospitalization (HR 0.68; 0.53-0.89). Risk of genital infection was elevated (HR 1.29, 1.12-1.49), but urinary tract infections (HR 0.90; 0.75-0.91) and severe sepsis (HR 0.61; 0.45-0.84) were reduced. We found no significant differences in all-cause mortality, diabetic ketoacidosis, or lower limb amputation between SGLT2i versus DPP4i use (**Table 2**).

Conclusion: In this real-world head-to-head simulated randomized trial in a large population of patients with SLE and T2D from 2014-2023, SGLT2i use compared to DPP4i use was associated with significantly reduced risks of developing AKI, CKD, ESRD, hospitalization, and heart failure. Genital infection risk was elevated, but risks of emergency visits, hospitalizations, urinary tract infections, and severe sepsis were also reduced for SGLT2i users. Overall mortality was not different.

Baseline Characteristics of Patients with Systemic Lupus Erythematosus and Type 2 Diabetes Started on either SGLT2i (n=3,749) or DPP4i (n=3,749) before and after PS-Matching

Outcomes	HR (95% CI)
Acute Kidney Injury	0.65 (0.56, 0.75)
Chronic Kidney Disease	0.74 (0.66, 0.82)
End-Stage Renal Disease	0.40 (0.27, 0.59)
Heart Failure	0.80 (0.71, 0.90)
Myocardial Infarction	0.95 (0.74, 1.21)
Stroke	0.97 (0.80, 1.18)
Urinary Tract Infection	0.83 (0.75, 0.91)
Genital Infection	1.29 (1.12, 1.49)
Sepsis	0.61 (0.45, 0.84)
Diabetic Ketoacidosis	1.05 (0.67, 1.64)
Emergency Department Visit	0.82 (0.77, 0.88)
Hospitalization	0.68 (0.53, 0.89)
All-cause Mortality	0.84 (0.67, 1.04)

Hazard Ratios (with 95% Confidence Intervals) for Outcomes after PS-Matching among Patients with Both Systemic Lupus Erythematosus and Type 2 Diabetes Started on SGLT2i (n=3,749) versus DPP4i (n= 3,749) and Followed for a Mean of 7.95 (±14.5) Years

Thus, SGLT2i appear safe and effective for those with SLE and T2D. Given high risks of cardiovascular and renal disease in patients with SLE, further trials and studies should investigate whether SGLT2i should be used for patients with SLE without T2D.

Abstract Number: 0591

Despite Dramatic Expansion of Approved Biologics in SLE, Unmet Needs Remain

Ryan Rex, Maxine Yarnall and Sawyer May, Spherix Global Insights, Exton, PA

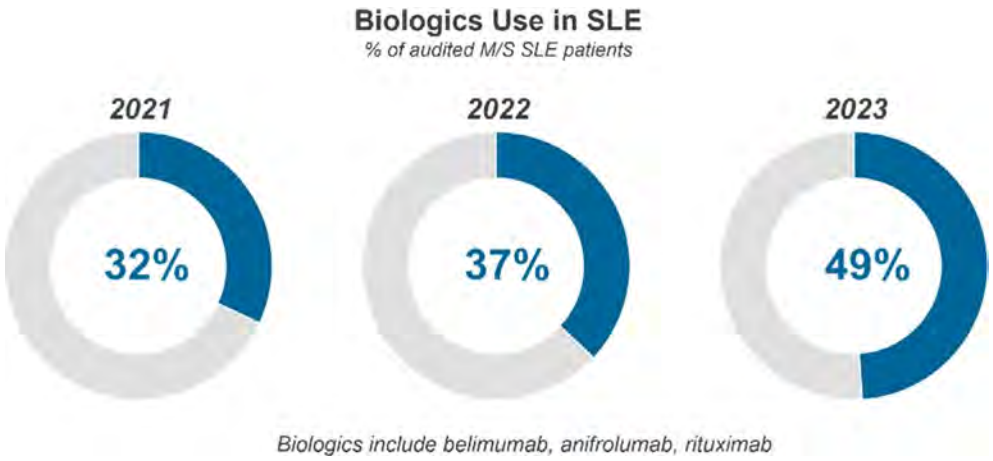
SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: This study was conducted to uncover real-world treatment patterns among moderate to severely active systemic lupus erythematosus (SLE) patients in the US.

Methods: 1,011 records from SLE patients with moderate and severely active disease were collected in collaboration with 297 US rheumatologists via an online survey platform from March 31 through May 5, 2023.

Results: Study results reveal that the use of biologics in SLE has substantially increased over the past three years – marking a dramatic expansion of biologic use in moderate-to-severe SLE in a relatively short period of time.

37% of audited patients are currently on FDA-approved biologic belimumab for their moderate-to-severe SLE, substantially up from levels observed in 2022 (28%) and 2021 (21%) and increasingly driven by the drug's anticipated efficacy, steroid-sparing ability, safety profile, and recent lupus nephritis (LN) indication. 8% of audited moderate-to-severe patients are



currently on FDA-approved biologic anifrolumab compared to 3% noted in the 2022 audit.* Like belimumab, rheumatologists were most compelled to prescribe anifrolumab due to its perceived efficacy, steroid-sparing effect, and safety profile.

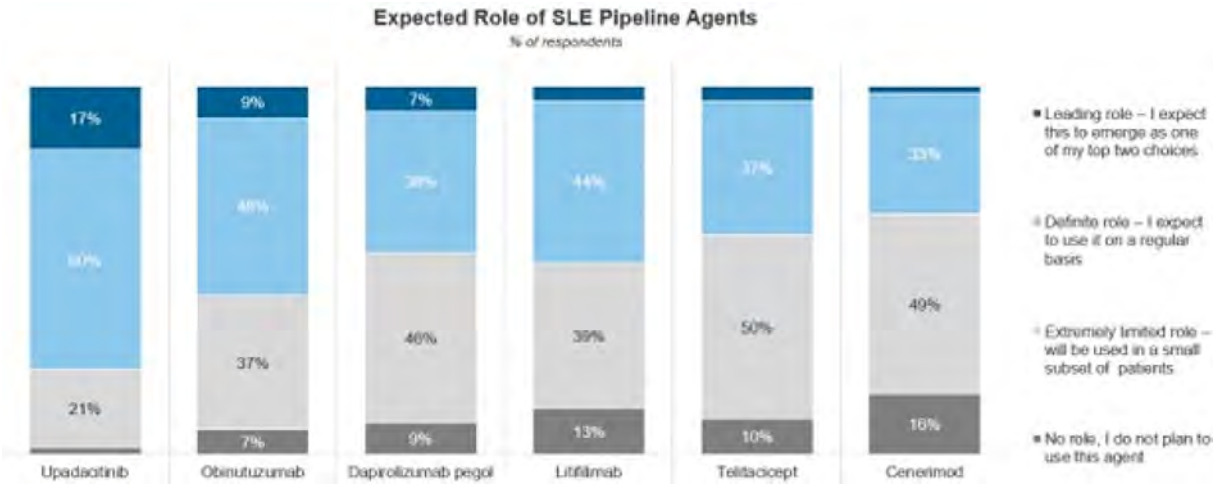
Commonly used "off label" biologic rituximab, on the other hand, is seeing a year-over-year decline in patient share with rheumatologists (4% of moderate-to-severe patients in 2023, 6% in 2022 and 11% in 2021) and physicians are considering fewer of their patients as potential candidates for the drug.

Notably, rheumatologists have also been using fewer other off-label agents in SLE over the same period, likely due to the availability of recently approved SLE agents along with safety concerns associated with the Janus kinase (JAK) inhibitor class, which has shown a steep decline in off-label use for SLE since 2021.

While the majority of rheumatologists express satisfaction with patients' response to approved biologics belimumab and anifrolumab, it is notable that only 18% of rheumatologists agree with the statement "*I am satisfied with the treatment options available to me in SLE*," underscoring the remaining unmet need for new pharmacologic treatment options.

The robust SLE pipeline – which consists of over 40 drugs in development – provides promising future treatment options for SLE. Of the SLE pipeline agents in or entering Phase III, rheumatologists expect upadacitinib to play the most important role if approved with 77% of rheumatologists saying the drug will play a leading or definite role.

While rheumatologists have been lessening their use of off-label JAK inhibitors in SLE, upadacitinib is a drug rheumatologists have experience using in a host of other rheumatic conditions, which could revitalize use of JAKs in SLE if approved.



Conclusion: Rheumatologists are increasingly using approved biologics in their moderate-to-severe SLE patients, however an unmet need for new pharmacological treatments remains. Despite the lessening of off label use of the JAK class many rheumatologists believe upadacitinib could provide significant value to their treatment armamentarium if approved.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: SLE – Treatment Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The international SLE Prospective Observational Cohort Study (SPOCS) collected data on patients with moderate to severe SLE disease activity from June 2017 through November 2022. A unique aim of SPOCS is to evaluate relationships between various aspects of SLE and type I IFN gene signature (IFNGS) status.

Objectives: To assess medication use among SPOCS patients over 36 months.

Methods: Patients enrolled in SPOCS were ≥18 years old with moderate to severe active SLE (SLEDAI ≥6 or clinical SLEDAI ≥4) and received standard therapy with ≥6 months of systemic SLE treatment beyond non-steroidal anti-inflammatory drugs and analgesics. All patients met ACR or Systemic Lupus International Collaborating Clinics (SLICC) SLE classification criteria. Medication use data were collected over 36 months during patients' biannual clinic visits. In this analysis, we report the proportions of patients receiving antimalarials, immunosuppressants (IS), biologics (belimumab or rituximab), or glucocorticoids (GCs), as well as daily oral GC dosage (mg/day) and proportions of patients receiving low (>0 to ≤7.5 mg/day) or high (>7.5 mg/day) oral GC dosages. Medication use was also stratified by baseline IFNGS (high vs low).

Results: At baseline, most patients (n=826; IFNGS-high [70.8%], low [29.2%]) were receiving antimalarials (81.1%), 21.2% were receiving biologics, and 54.8% were receiving IS (Table). From baseline to 36 months, the proportions of patients taking antimalarials remained stable while the use of biologics and IS moderately increased. At baseline, 65.0% of patients were taking GCs and the proportion was largely stable over time. However, the proportion administered oral GC >7.5 mg/day increased from 26.0% at baseline to 44.3% at 6 months and 45.7% at 12 months, and then declined with time but did not reach the baseline level. The mean (SD) dose of oral GC increased from 6 (7.1) mg/day at baseline to 10 (8.7) mg/day at 6 months and then was stable over time. Across the study period, IS, biologics, and GCs were generally administered

Table. Medication use among SPOCS patients from baseline through 36 months. GC, glucocorticoid; SD, standard deviation. aGC use current or since previous visit. bOral GC daily dose derived from cumulative dose over treatment interval. cGroup sizes differ because oral GC use could be reported without dose information.

n (%)	Baseline n=826	6 months n=663	12 months n=542	18 months n=479	24 months n=426	30 months n=441	36 months n=409
Antimalarials	670 (81.1)	537 (81.0)	447 (82.5)	398 (83.1)	351 (82.4)	362 (82.1)	341 (83.4)

IFNGS high	531 (70.8)	392 (69.9)	277 (65.8)	236 (67.4)	201 (66.1)	206 (66.9)	190 (65.1)
IFNGS low	219 (29.2)	169 (30.1)	144 (34.2)	114 (32.6)	103 (33.9)	102 (33.1)	102 (34.9)
Mean (SD) oral GC dosage (mg/day)[b]	6.0 (7.1)	9.8 (8.7)	10.3 (9.4)	10.7 (10.4)	8.8 (7.6)	9.2 (8.5)	9.8 (17.4)
Dosage group among oral GC users[c]	**n=457**	**n=377**	**n=258**	**n=201**	**n=166**	**n=155**	**n=154**
Oral GC >0 to ≤7.5 mg/day	338 (74.0)	210 (55.7)	140 (54.3)	116 (57.7)	104 (62.7)	97 (62.6)	103 (66.9)
Oral GC >7.5 mg/day	119 (26.0)	167 (44.3)	118 (45.7)	85 (42.3)	62 (37.3)	58 (37.4)	51 (33.1)

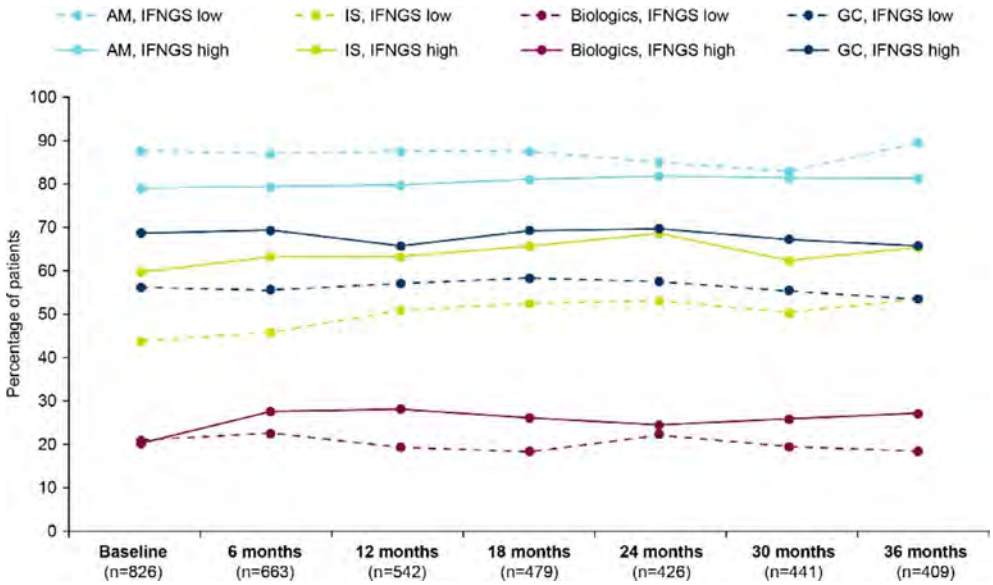

Figure. Medication use by IFNGS status from baseline through 36 months. AM, antimalarials; IFNGS, type I interferon gene signature; IS, immunosuppressants; GC, glucocorticoid.

to greater proportions of IFNGS-high than low patients (Figure). Mean oral GC daily doses were similar between IFNGS-high and low groups throughout the study period except at the final visit. At 36 months, IFNGS-low patients received a lower mean (SD) oral GC daily dose compared with IFNGS-high patients (7 [4.9] vs 11 [20.6] mg/day).

Conclusion: Overall, the increase in oral mean daily GC dose in the first 6 months was maintained through 36 months despite standard therapy, stable antimalarial use, and moderate increases in use of biologics and IS. Although the proportion of GC use was largely stable over time, those on oral GC >7.5 mg/day increased initially and then declined but did not return to the baseline level. In addition, IFNGS-high status was associated with more immunomodulatory therapy compared with those with IFNGS-low status. Together, these data indicate that additional therapies are needed to avoid high-dose GC use among patients with SLE. SPOCS will provide opportunities to increase our understanding of real-world treatment and to identify educational needs within the lupus community.

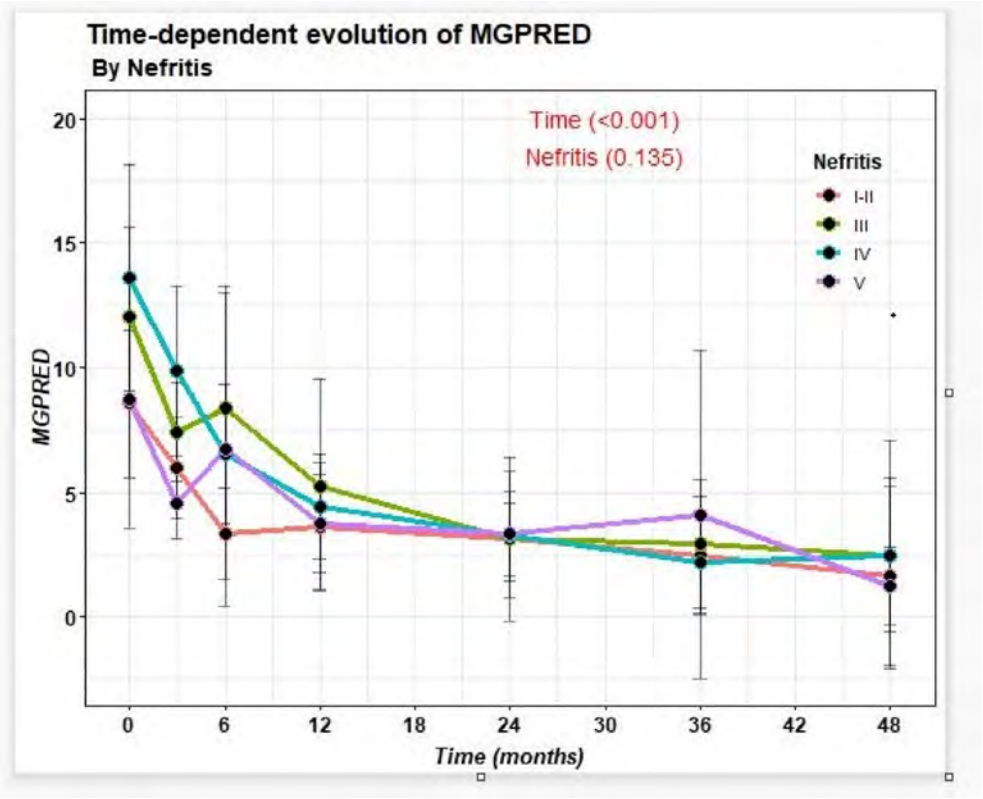
SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Belimumab (BLM) is a B-cell stimulating factor (BlyS) monoclonal antibody, approved in 2022 for the treatment of lupus nephritis (NL) and since 2011 for systemic lupus erythematosus (SLE).

Objectives. To describe the demographic characteristics, efficacy and safety of BLM in real clinical practice in patients with lupus nephritis.

Age at SLE diagnosis (years)* *	26.9 (20.2-35.5)
Age at BLM starts (years)* *	37.7 (30.4-47.8)
Gender (female) n, (%)	88 (81.5)
Time from diagnosis until BLM start (years)**	8.6 (5-15.5)
ANA positive, n (%)	102 (94.4)
DNA positive, n (%)	76 (75.2)
Antiphospholipidic syndrome, n (%)	16 (14.8)
Articular involvement, n (%)	84 (77.8)
Hematologic involvement, n (%)	53 (51)
Skin involvement, n (%)	52 (48.6)
Cyclophosphamide, n (%)	59 (11.3)
bDMARD, n (%)	22 (20.4)
cDMARD pre BLM, n (%)	108 (100)
- Hydroxychloroquine	99 (91.7)
- Azathioprine	39 (36.1)
- Mycophenolate mofetil/mycophenolic acid	71 (65.7)
- Tacrolimus/cyclosporine	13 (12)

** Median (IQR).



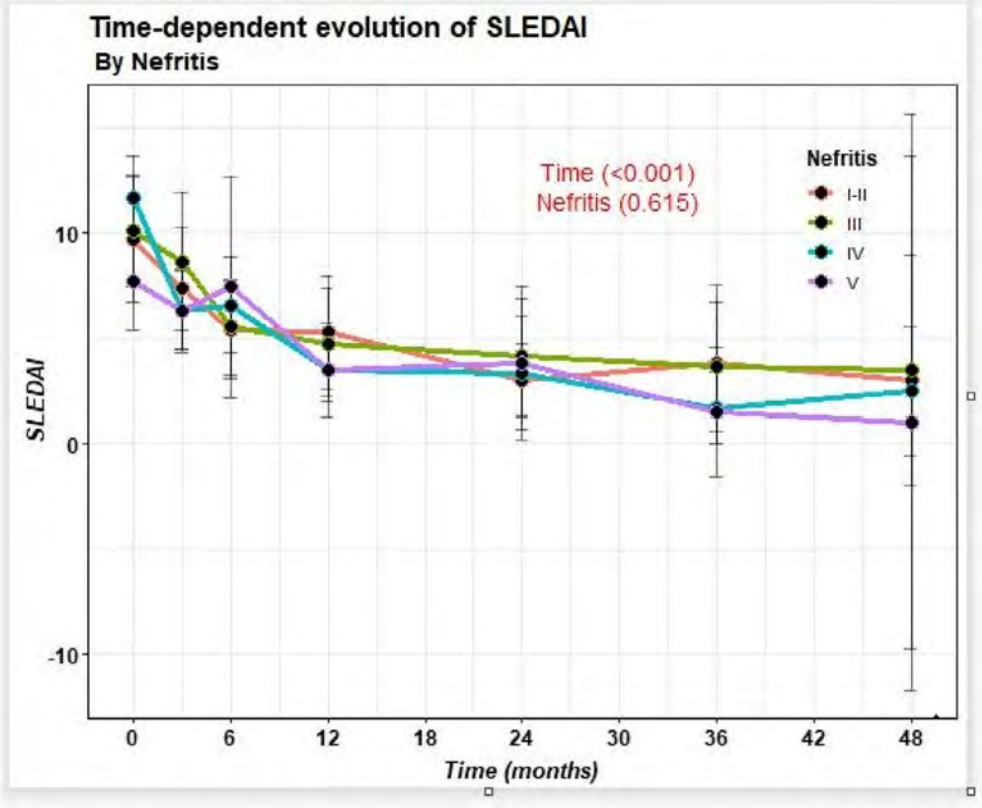
Methods: A descriptive, retrospective study of patients with lupus nephritis confirmed by biopsy from the Spanish multicenter registry of patients treated with BLM. Demographic, analytical and previous and concomitant treatment with belimumab were collected. To assess efficacy, analytical variables (anti-DNA, C3, C4), Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) scale, and steroid doses at baseline and throughout follow-up were analyzed. Renal improvement was considered when a 24-hour proteinuria of less than 0.5 grams was reached. Safety profile of BLM was analyzed.

Results: We included 108 patients, 81.5% women, with a mean age at diagnosis of SLE of 26.9 years (20.2-35.5).The most frequent nephritis class was IV (47 patients, 43.5%), followed by class III (23 patients, 21.3%), V (19 patients, 17.6%) and I-II (19 patients, 17.6%). The time of evolution of the disease until the onset of BLM was 8.6 years (5-15.5).62 patients (57.4%) started BLM subcutaneously (SC), 33 patients (30.6%) intravenously (IV) and 13 patients (12%) change from IV to SC route. Baseline characteristics are summarized in Table 1

The median proteinuria in 24 hours was 1.0 (0.5 to 2.5). The median number of pre-BLM cDMARD uses was 2.0 (2.0-3.0), with antimalarials being the most commonly used (91.7%). 39 and 22 patients received cyclophosphamide and bDMARD prior to BLM respectively, being Rituximab (RTX) the most commonly bDMARD used. 107 patients received prednisone at the time of starting BLM with a median dose of 7.5 (5-1.5) mg.

74.4% of patients improved after BLM in terms of reduction of proteinuria, with last 24-hour proteinuria of 0.2 (0.1-0.9) grams. A decrease in prednisone dose and SLEDAI improvement (Figure 1) was observed from baseline to last follow-up. On the other hand, a decrease in anti-DNA and an increase in C3 and C4 were observed.

21 patients (19.4%) discontinued treatment mainly due to ineffectiveness; 4 patients stopped BLM because of nephritis improvement. The median time on treatment for patients who had to discontinue BLM was 9 (6-24) months. In terms of safety, 28 patients had infections, most of them mild, being urine infection the most reported. One patient died due to meningitis. There were no tumors.



Conclusion: In this cohort of LN treated with BLM in real world settings, we observed an improvement of 24-hour proteinuria, SLEDAI, decrease of anti-DNA and increase of complement, despite of the administration route. No new safety alarms were reported.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite recent advances, the current state of SLE therapeutics remains largely empirical with existing immunosuppressive treatments failing to induce remission in over 40% of patients. There is currently a paucity of tools that would predict response to treatment and guide therapeutic choices.

Methods: Whole blood transcriptome samples were obtained from 95 patients with moderate to severe SLE at baseline, 1 month and 6 months after initiation of treatment with cytotoxic agents (cyclophosphamide, mycophenolate mofetil), mycophenolate mofetil/anti-CD40 antibody, rituximab or belimumab. Disease activity was assessed using the SLEDAI-2K. Response to treatment was defined as achievement of Low Disease Activity State (LLDAS) or remission at 6 months. Differentially expressed genes (DEGs) were identified using the DEseq2. Weighted correlation network analysis (WGCNA) was applied to detect modules of co-expressed transcripts. Abundances of cell types were assessed by CIBERSORTx.

Results: Out of 95 patients the majority were women (93.7%) with a mean [SD] age at SLE diagnosis of 42.9 [13.6] years and a mean disease duration [SD] at sampling of 5.1 [7.2] years. At baseline, mean SLEDAI [SD] was 9.4 [5.7] and active lupus nephritis (LN) was the most common treatment indication (24%), followed by active neuropsychiatric SLE (NPSLE)

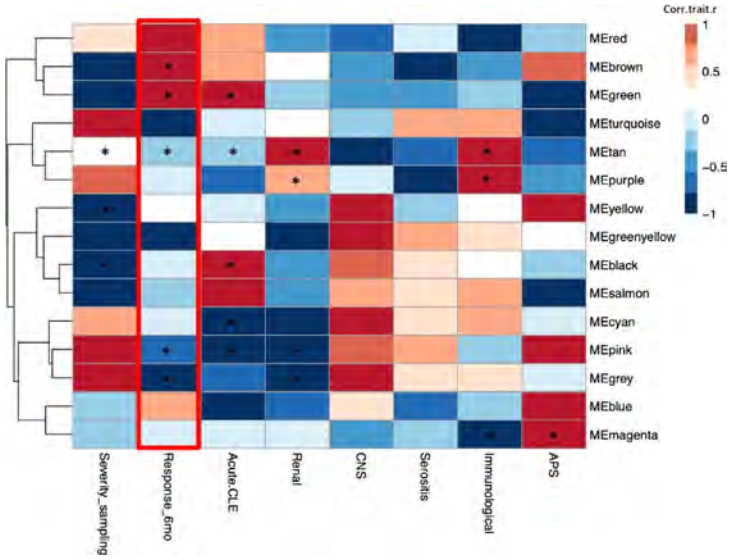

Figure 1. WGCNA module eigengene (ME) correlations to clinical features uncover the brown and green gene modules which are associated with 6 month-response to treatment. Severity_sampling: Presence of moderate or severe disease at sampling timepoint as defined by BILAG Glossary Definition combined with expert physician judgement (DB, GB); Response_6mo: Response to treatment 6 months after treatment initiation; Acute.CLE: Presence of acute cutaneous SLE at any time during the disease course; Renal: Presence of renal manifestations, as defined in the EULAR/ACR SLE classification criteria, at any time during the course of the disease; CNS: Presence of neurological features, as defined in the EULAR/ACR SLE classification criteria, at any time during the course of the disease; Serositis: Presence of polyserositis, as defined in the EULAR/ACR SLE classification criteria, at any time during the course of the disease; Immunological: Presence of immunological disturbances, as defined in the EULAR/ACR SLE classification criteria, at any time during the course of the disease; APS: Antiphospholipid Syndrome. * p-value < 0.05.

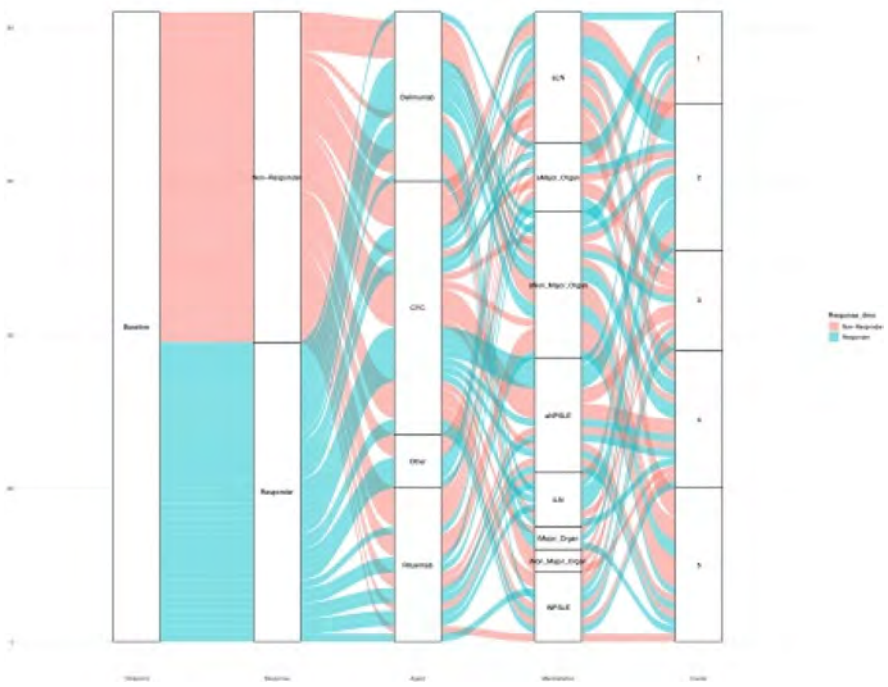

Figure 2. K-means clustering of the baseline samples based on module eigengene (ME) defined the cluster 2, enriched for responders. aLN: Active LN; aMajor_Organ: Active major organ involvement other than LN or NPSLE; aNon_Major_Organ: Active non-major organ involvement; aNPSLE: Active NPSLE; iLN: Inactive LN; iMajor_Organ: Inactive major organ involvement other than LN or NPSLE; iNon_Major_Organ: Inactive non-major orgen involvement; iNPSLE: Inactive NPSLE.

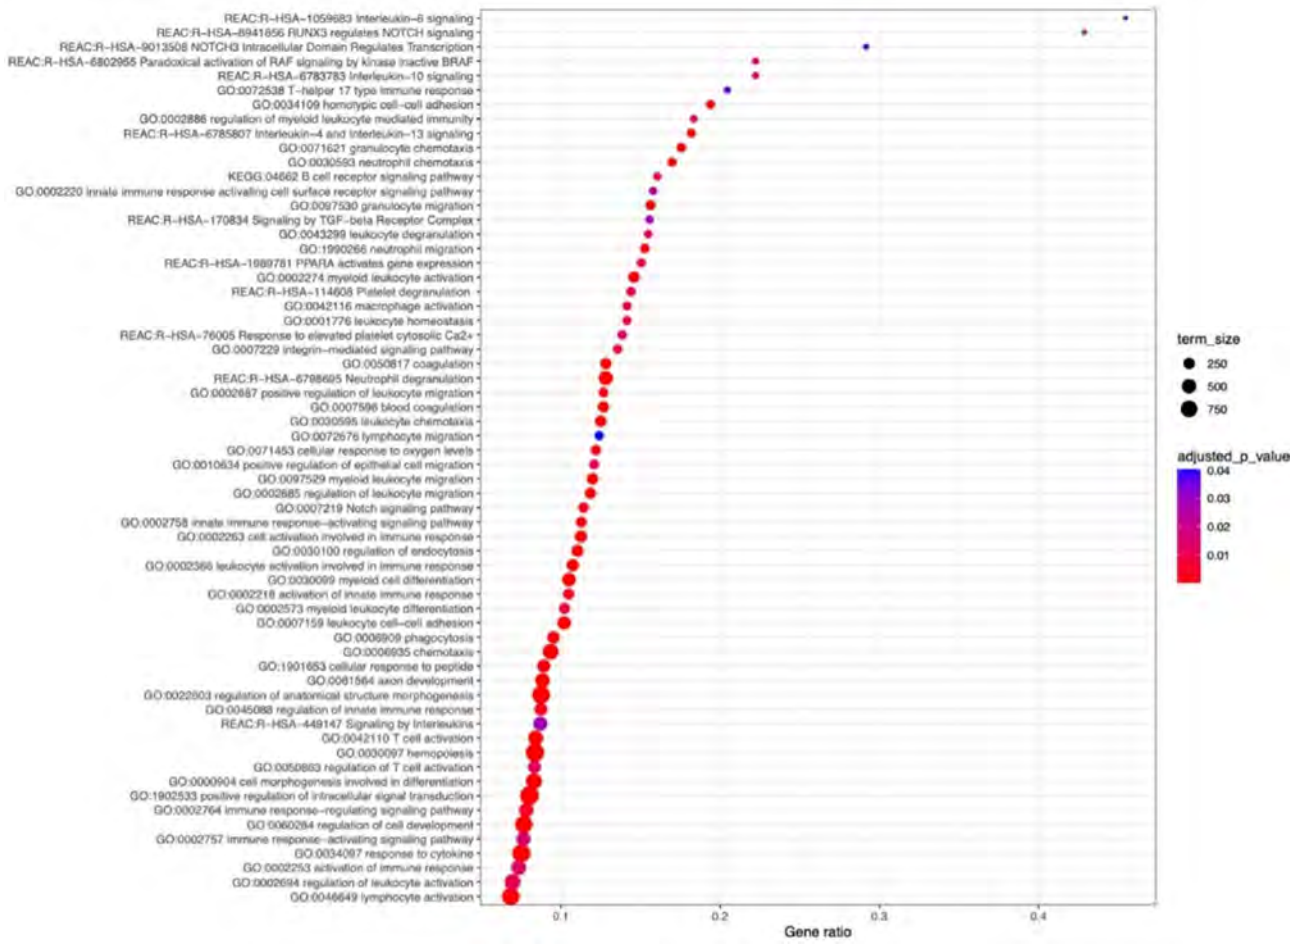

Figure 3. Functional enrichment analysis of the upregulated DEGs resulting from the comparison of responders versus non-responders 1 month after treatment initiation.

(20%). Cyclophosphamide was the most frequently used immunosuppressive agent (n=46), followed by belimumab (n=24) and rituximab (n=21). Forty-three patients responded to treatment. WGCNA-generated modules (Figure 1.) that positively correlated with response to treatment at 6 months ($p = 0.005$, $p = 0.04$) were enriched in biological processes that included type I interferon, pattern recognition receptor signaling, and neutrophil degranulation. Unsupervised clustering of the baseline samples, based on the module eigengene, revealed a respondent rich patient subset (Cluster 2), which was characterized by high prevalence of active LN (Figure 2.). The transcriptional landscape of "resistant" disease was dominated by disturbances related to p53-signaling pathway. Upregulation of pathways linked to neutrophil degranulation, Th17 responses, IL6 mediated responses, TGF-beta, PPARA, and NOTCH signaling differentiated the one-month-transcriptional profile of responders compared to non-responders (Figure 3.).

Conclusion: Baseline molecular fingerprints related to innate immunity correlated with 6-month response to treatment in SLE. Aberrances linked to p53-signaling decisively shaped the transcriptional signature of "resistant" disease.

Renal Involvement in Patients with Systemic Lupus Erythematosus Treated with Anifrolumab Compared with Placebo over a 4-Year Period

Richard A. Furie[1], Kenneth Kalunian[2], Eric Morand[3], Ian Bruce[4], Susan Manzi[5], Gelareh Atefi[6], Gary Bryant[6], Micki Hultquist[7], Raj Tummala[7], Gabriel Abreu[8], Catharina Lindholm[8] and Hussein Al-Mossawi[9], [1]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY, [2]University of California San Diego, La Jolla, CA, [3]Monash University, Centre for Inflammatory Diseases, Melbourne, Australia, [4]University of Manchester, Manchester, United Kingdom, [5]Lupus Center of Excellence, Autoimmunity Institute, Allegheny Health Network, Pittsburgh, PA, [6]BioPharmaceuticals Medical, AstraZeneca, Wilmington, DE, [7]BioPharmaceuticals R&D, AstraZeneca, Gaithersburg, MD, [8]BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden, [9]BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: SLE – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: In patients with SLE, nephritis is present in 50%–60% during the first 10 years of disease.[1] Renal involvement is associated with poor clinical outcomes including increased morbidity and mortality.[1,2] Anifrolumab is a human mAb to the type I IFN receptor that is approved for the treatment of SLE.[3] In this post hoc analysis of the phase 3 TULIP long-term extension (LTE) trial of anifrolumab, we assessed renal outcomes in patients with SLE with or without evidence of SLEDAI-2K renal involvement at baseline.[4]

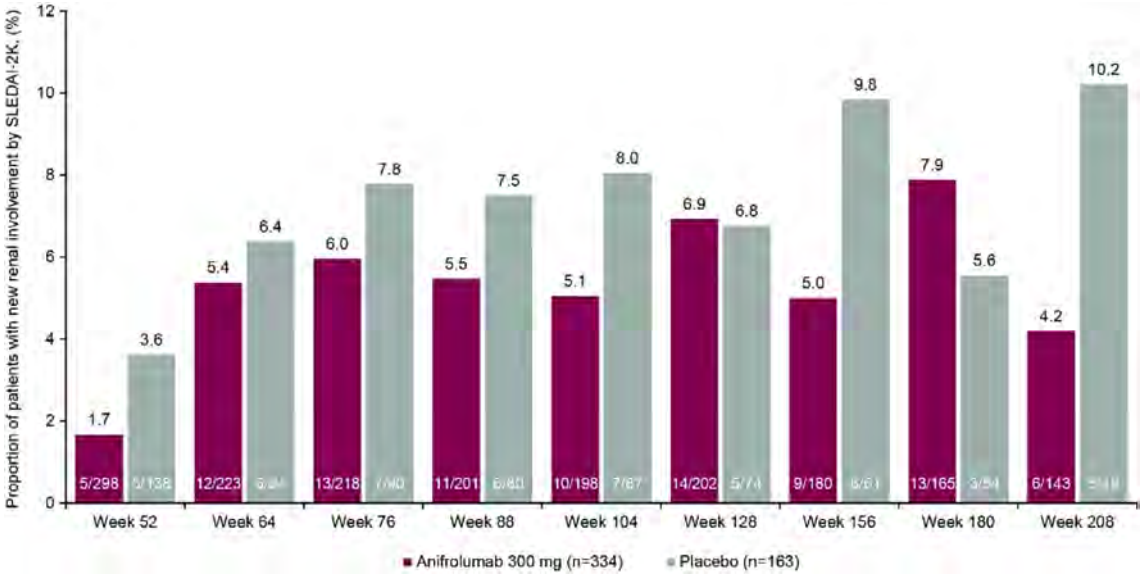

Figure. New Renal Involvement During the LTE Period Among Patients With No Renal Involvement at TULIP Baseline. No renal involvement was defined as renal SLEDAI-2K score =0. New renal involvement was defined as renal SLEDAI-2K score >0. For measuring no renal involvement, percentages are based upon all patients in the full analysis set. For measuring new renal involvement, percentages are based upon all patients in the full analysis set with no involvement at baseline and according to the number assessed at each timepoint thereafter; patients are missing due to either discontinuation, withdrawal, or missing data. Baseline means baseline of the phase 3 feeder studies, ie, the last non-missing measurement prior to dose administration on Day 1.

Methods: Adults with moderate to severe SLE (1997 ACR criteria) despite standard therapy who completed the 52-week, multicenter phase 3 TULIP-1 (NCT02446912) or TULIP-2 (NCT02446899) trials could reconsent to participate in the randomized, placebo-controlled, double-blind, 3-year extension (NCT02794285). The TULIP-1 and TULIP-2 trials excluded patients with active, severe lupus nephritis, serum creatinine >2 mg/dL, or urine protein/creatinine ratio >2 mg/mg. We identified patients with renal involvement below the threshold for exclusion at baseline, or patients without renal involvement, who were randomized to receive intravenous anifrolumab 300 mg or placebo across the TULIP-1/-2 and LTE periods (or would have continued the same treatment in the LTE if not discontinued during TULIP-1/-2). SLEDAI-2K renal domain involvement was assessed from baseline through Week 208.

Results: At TULIP baseline, the proportions of patients with SLEDAI-2K renal involvement were balanced between treatment groups (anifrolumab 6.7% [24/358] vs placebo 8.4% [15/178]). Of patients with baseline renal involvement and available data, a greater proportion of patients achieved renal improvement at LTE study entry (Week 52) with anifrolumab vs placebo (70.6% [12/17] vs 50.0% [6/12]). A greater proportion of patients with baseline renal involvement continued treatment to Week 208 with anifrolumab vs placebo (33.3% [8/24] vs 6.7% [1/15]), and renal improvement at Week 208 was achieved by more patients who received anifrolumab (90.0% [9/10]) vs placebo (0% [0 patients with available data at this timepoint]). Of all patients included in this analysis, ≤1/358 in the anifrolumab group and ≤3/178 in the placebo group experienced new renal activity greater than the baseline score at any timepoint during the study period. In patients with no baseline renal involvement, lower proportions of patients had new renal activity with anifrolumab vs placebo at all timepoints up to Week 208, except for Weeks 128 and 180 (**Figure**).

Conclusion: In the small subgroup of patients with renal involvement at baseline, more

patients treated with anifrolumab remained in the study and achieved SLEDAI-2K renal improvement compared with placebo over the 4-year TULIP-LTE trial. Of patients with no renal involvement at baseline, fewer patients had new renal activity with anifrolumab compared with placebo.

Deucravacitinib, an Oral, Selective, Allosteric Tyrosine Kinase 2 Inhibitor, in a Phase 2 Trial in Systemic Lupus Erythematosus (SLE): Achievement of Sustained SRI(4), BICLA and Dual Responses over 48 Weeks

Richard Furie[1], Cristina Arriens[2], Kenneth Kalunian[3], Marilyn Pike[4], Ronald van Vollenhoven[5], Coburn Hobar[6], Ayanbola Elegbe[6], Samantha Pomponi[6], Subhashis Banerjee[6], Shalabh Singhal[6], Thomas Wegman[7] and Eric Morand[8], [1]Northwell Health, Manhasset, NY, [2]Oklahoma Medical Research Foundation and University of Oklahoma Health Sciences Center, Department of Arthritis & Clinical Immunology, Oklahoma City, OK, [3]University of California San Diego, La Jolla, CA, [4]MedPharm consulting, Inc., Raleigh, NC, [5]Amsterdam University Medical Centers, Amsterdam, Netherlands, [6]Bristol Myers Squibb, Princeton, NJ, [7]Bristol Myers Squibb, Beaver Falls, PA, [8]Monash University, Centre for Inflammatory Diseases, Melbourne, Australia

SESSION INFORMATION

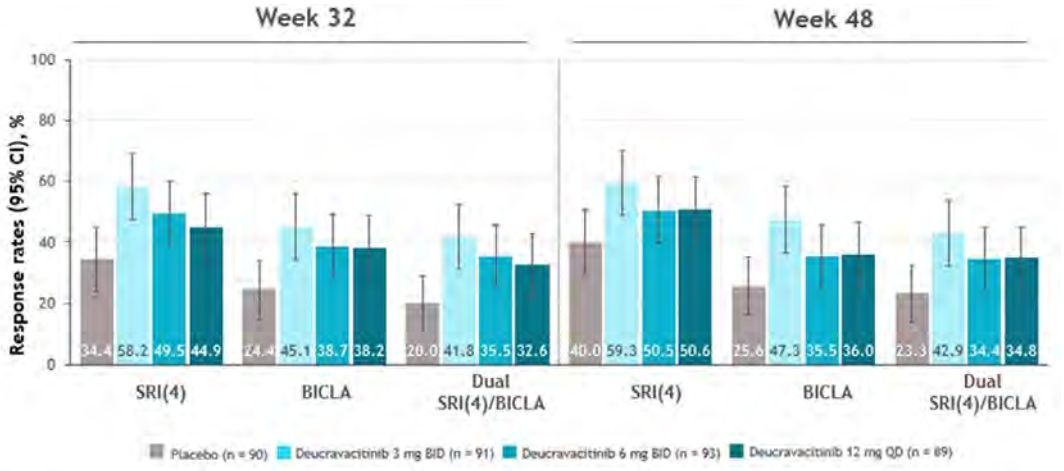
Session Date: Sunday, November 12, 2023

Session Title: SLE – Treatment Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Deucravacitinib is a first-in-class, oral, selective, allosteric tyrosine kinase 2 inhibitor approved in multiple countries for the treatment of adults with plaque psoriasis. In a phase 2 trial (NCT03252587) in patients with SLE receiving standard background therapy, deucravacitinib demonstrated efficacy vs placebo across multiple endpoints, including Systemic Lupus Erythematosus Responder Index-4 (SRI[4]) responses at week 32 (primary endpoint) and week 48 (secondary endpoint) as well as British Isles Lupus Assessment Group–based Composite Lupus Assessment (BICLA) responses at week 48 (secondary endpoint).[1] Given that discordance between SRI(4) and BICLA responses has been reported with other agents,[2] this post hoc analysis further evaluated efficacy, time to response, and sustained responses with deucravacitinib vs placebo for SRI(4) and BICLA in the phase 2 trial.



BICLA, British Isles Lupus Assessment Group–based Composite Lupus Assessment; BID, twice daily; QD, once daily; SRI(4), Systemic Lupus Erythematosus Responder Index-4.

Figure 1. SRI(4), BICLA, and dual SRI(4)/BICLA response rates at weeks 32 and 48

Methods: This 48-week, double-blind trial randomized 363 patients with active SLE 1:1:1:1 to placebo or deucravacitinib 3 mg twice daily (BID), 6 mg BID, or 12 mg once daily. Endpoints included the proportions of patients achieving SRI(4), BICLA, or simultaneous (dual) SRI(4)/BICLA responses at weeks 32 and 48, time to onset of responses, and proportions of patients with sustained responses through week 48 (responder at every visit from weeks 32 through 48). BICLA response, and therefore dual response, was measurable at the first visit after steroid taper completion (week 24 [day 168]). Analyses were descriptive.

Results: At weeks 32 and 48, SRI(4), BICLA, and dual response rates were numerically higher with deucravacitinib vs placebo **(Figure 1)**. Median time to onset of SRI(4), BICLA, and dual responses were shorter with deucravacitinib vs placebo, such that median times to onset of dual response were 196 to 282 days with deucravacitinib but was not reached for placebo **(Table)**. Patients treated with deucravacitinib had a numerically higher likelihood of attaining SRI(4), BICLA, or dual SRI(4)/BICLA responses versus placebo at week 32, week 48, or sustained responses from week 32 through week 48 **(Figure 2)**.

Conclusion: Deucravacitinib elicited higher response rates and faster time to SRI(4), BICLA, and dual responses vs placebo. Patients were more likely to sustain their treatment responses from weeks 32 through 48 with deucravacitinib vs placebo. Furthermore, there was consistency between SRI(4) and BICLA responses for patients treated with deucravacitinib. These data support the robust efficacy of deucravacitinib across multiple SLE response indices.

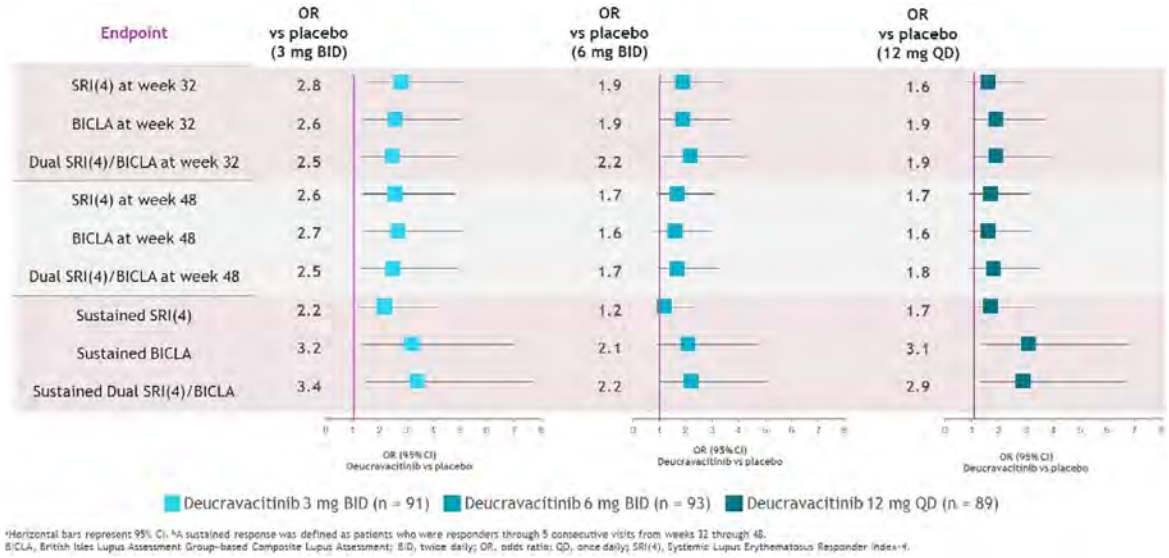


Figure 2. ORs versus placebo (a) for SRI(4), BICLA, and dual SRI(4)/BICLA at week 32, week 48, and sustained responses (b)

Table. Median time to first response for SRI(4), BICLA, and dual SRI(4)/BICLA

Outcome	Placebo (n = 90)	Deucravacitinib 3 mg BID (n = 91)	Deucravacitinib 6 mg BID (n = 93)	Deucravacitinib 12 mg QD (n = 89)
SRI(4)	116 (112, 144)	85 (85, 113)	92 (85, 138)	111 (85, 115)
BICLA	284 (176, NE*)	172 (170, 198)	224 (176, 286)	194 (170, 259)
SRI(4)/BICLA dual response	NE* (250, NE*)	196 (170, 225)	282 (198, NE*)	196 (171, NE*)

*Some points were deemed "not estimable" because they exceeded the time period of the study (48 weeks/336 days).
BICLA, British Isles Lupus Assessment Group–based Composite Lupus Assessment; BID, twice daily; NE, not estimable; QD, once daily; SRI(4), Systemic Lupus Erythematosus Responder Index-4.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE is a systemic autoimmune disease requiring long-term treatment. In this placebo-controlled phase 3 TULIP long-term extension (LTE) study,[1] the impact of anifrolumab in addition to standard therapy on total and organ-specific disease activity was assessed over 4 years in patients with moderate to severe SLE.

Methods: TULIP-LTE (NCT02794285) was the first randomized, placebo-controlled, double-blind, 3-year extension study in SLE. Patients with SLE (1997 ACR criteria) on standard therapy who completed a TULIP trial through the 52-week treatment period could enroll in the LTE. Treatment groups used in this analysis were patients randomized to receive intravenous anifrolumab 300 mg or placebo every 4 weeks in TULIP-1/-2 who continued the same treatment (or would have continued if not discontinued during TULIP-1/-2) in the LTE (anifrolumab 300 mg: n=358; placebo: n=178). Proportions of patients with a ≥4-point reduction in total SLEDAI-2K score from Week 0 (baseline) to Week 208 were compared between treatment groups using summary statistics. Proportions of patients with a SLEDAI-2K improvement (patients with improvement [n_1] /

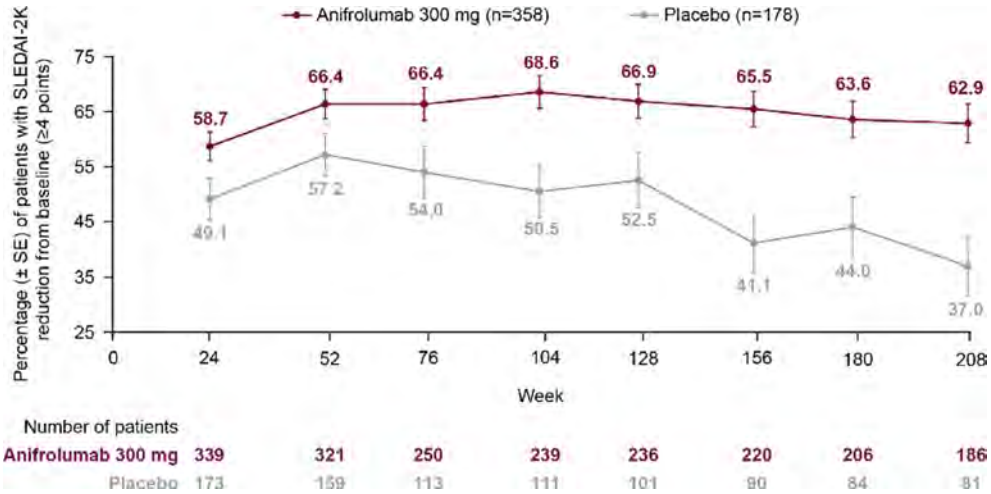

Figure. Percentage (± SE) of Patients With a SLEDAI-2K ≥4-point Reduction From Baseline* During the TULIP and LTE Period. LTE, long-term extension; SE, standard error; SLE, systemic lupus erythematosus; SLEDAI-2K, SLE Disease Activity Index 2000. *Analysis includes patients with a SLEDAI-2K score ≥4 at TULIP baseline (Week 0) and data with discontinuation due to worsening/lack of efficacy non-improvement imputation.

patients with baseline involvement and available data at the timepoint [n_2]) were further analyzed by organ domain (mucocutaneous, musculoskeletal, immunological, hematological/fever) during the TULIP and LTE periods; SLEDAI-2K improvement was defined as a lower organ domain score than at baseline.

Results: The proportion of patients who achieved a ≥4-point reduction in SLEDAI-2K score from baseline was greater with anifrolumab vs placebo from Week 52 (66.4%, [95% confidence interval: 60.9–71.5] vs 57.2% [49.2–65.0]) to Week 208 (62.9% [55.5–69.9] vs 37.0% [26.6–48.5]), and the difference between the treatment groups increased over time (**Figure**). Baseline organ involvement was similar between treatment groups in the mucocutaneous and musculoskeletal domains (anifrolumab 300 mg vs placebo: 96.6% vs 95.5% and 93.0% vs 93.8%, respectively). Immunological and hematological/fever baseline involvement were higher in the anifrolumab group compared with placebo (65.6% vs 58.4% and 15.4 vs 9.0%, respectively). Mucocutaneous, musculoskeletal, immunological, and hematological/fever SLEDAI-2K improvements generally occurred more frequently in the anifrolumab group compared with placebo from Week 52 (73.5% [n_1/n_2: 227/309] vs 60.9% [92/151]; 67.9% [201/296] vs 64.9% [96/148]; 28.8% [61/212] vs 17.2% [16/93]; and 81.6% [40/49] vs 80.0% [12/15]) up to Week 208 (79.8% [142/178] vs 58.7% [44/75]; 71.8% [122/170] vs 56.0% [42/75]; 32.1% [36/112] vs 14.6% [6/41]; and 72.4% [21/29] vs 42.9% [3/7]). By the end of the LTE period, many patients had missing data in the placebo group, due to lack of organ involvement and/or no available data at the timepoint.

Conclusion: Compared with placebo, anifrolumab was associated with long-term, sustained ≥4-point reductions in SLEDAI-2K over the 4-year TULIP and LTE period and, despite the higher drop-out rates in the placebo group, greater improvements were seen in disease activity for individual organ domains.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Litifilimab is a humanized IgG1 mAb targeting BDCA2, a receptor expressed on plasmacytoid dendritic cells (pDCs), that negatively regulates the production of Type I IFN and proinflammatory chemokines and cytokines.[1,2] In the Phase 2 LILAC study of litifilimab (NCT02847598), Part A (participants with SLE, active arthritis and rash) and Part B (participants with active CLE, with or without SLE) met their primary endpoints at Weeks (W) 24 and 16, respectively.[1,2] We evaluated the effects of litifilimab on IFN gene signature (IFNGS) scores from whole blood samples, serum IFNα concentrations, and other serum cytokine concentrations in LILAC participants.[3,4]

Methods: Expression of 22-gene panel IFNGS scores and concentrations of IFNα and other cytokines were examined over time in the modified intent-to-treat population (Part A N=120, Part B N=132) with available data at baseline (BL) and ≥1 post-BL visit. Treatment effects were estimated using a mixed model repeated measures approach. In Part A, IFNα concentration changes over time were compared with W24 total active joint counts and CLASI-A scores (Spearman rank correlations) and SLE Responder Index (SRI-4) status. In Part B, Pearson correlations between percent changes in CLASI-A score and IFNGS score were estimated and the dose-response relationship was estimated using a previously described MCP-Mod method.[2]

Results: As too few participants were IFNGS-low at BL, only data for the IFNGS-high subgroups are described. Litifilimab induced rapid, substantial, and sustained reductions in 22-gene IFNGS scores and IFNα concentrations that were greater (nominal $P< 0.05$) vs placebo (PBO) with litifilimab 150 mg (Part B) and 450 mg (Parts A and B) (**Table 1** and **Figure 1**). In Part A, TNFα and IL-10 concentrations were reduced (nominal $P< 0.05$) with litifilimab 450 mg at W24 (**Table 1**); no strong evidence of this was seen in Part B. Change in IFNα concentration and change in total active joint count with litifilimab 450 mg in Part A were correlated (Spearman correlation estimates: PBO –0.15 [95% CI: –0.41, 0.16]; 450 mg 0.34 [0.07, 0.55]), as were changes in IFNα concentration and CLASI-A score (PBO –0.01 [–0.34, 0.31]; 450 mg 0.35 [0.10, 0.58]) at W24. A trend of greater median IFNα concentration reduction in W24 SRI-4 responders relative to non-responders was seen with litifilimab 450 mg. Confirmation of these findings in larger sample sizes is warranted. In Part B, the dose-response relationship was similar to that observed with the clinical responses (**Figure 2**) and percent change in CLASI-A score was correlated with percent change in IFNGS score in all treatment groups.

Table 1. Primary efficacy endpoints and changes from BL in 22-gene panel IFNGS score and IFNα concentration for the IFNGS-high subgroup (modified intent-to-treat population). Data are LS means unless otherwise specified. Variations in n within each group at any timepoint are the result of missing samples and/or different analysis populations. *Assessed in participants who met the joint count inclusion criterion for Part A: ≥4 tender joints and ≥4 swollen joints according to a 28-joint assessment (≥4 swollen joints must have been in PIP, MCP, or wrist joints; participants were not required to have coexistent swelling and tenderness of individual joints);1 †total active joint count is the sum of the tender joint count and the swollen joint count; ‡ratio between the GM fold change from BL in the litifilimab arm and the GM fold change from BL in the placebo arm; values <1 favor litifilimab. BL, baseline; CI, confidence interval; CLASI-A, Cutaneous Lupus Erythematosus Disease Area and Severity Index–Activity; GM, geometric mean; GMR, geometric mean ratio; IFNGS, interferon gene signature; LS, least squares; PBO, placebo

Conclusion: Litifilimab induced a rapid, substantial, and sustained reduction in 22-gene IFNGS scores and IFNα concentrations, and reductions in some biomarkers correlated with clinical responses. These results further support the mechanism of action for litifilimab and the role of Type I IFN and pDCs in SLE and CLE.[5,6]

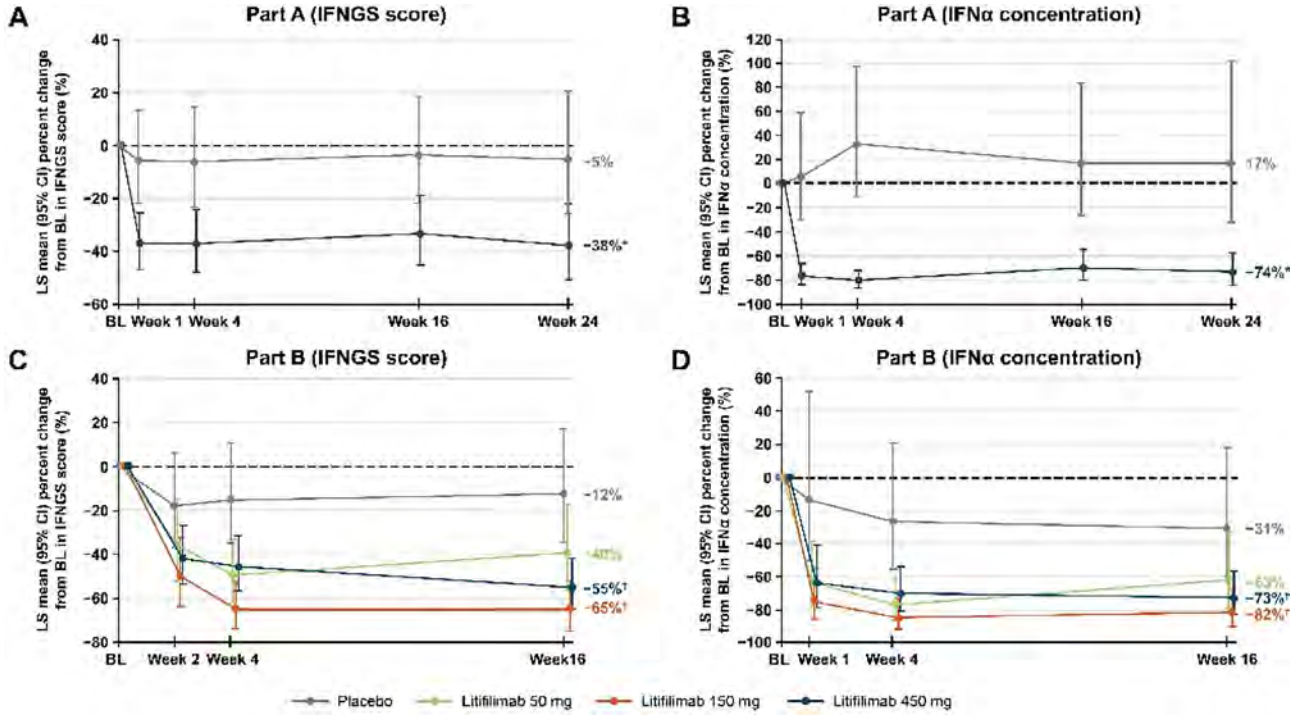

Figure 1. Change in IFNGS score and IFNα concentration over time in Part A (A and B) and Part B (C and D) of the Phase 2 LILAC study for the IFNGS-high subgroup. *At Week 24 (Part A), nominally significant (P<0.05) changes from BL in 22-gene panel IFNGS score and IFNα concentration were demonstrated for the litifilimab 450-mg group relative to placebo using GMRs; †at Week 16 (Part B), changes in IFNGS score and IFNα concentration were nominally significant (P<0.05) for the litifilimab 150- and 450-mg groups relative to placebo using GMRs. BL, baseline; CI, confidence interval; GMR, geometric mean ratio; IFNGS, interferon gene signature; LS, least squares

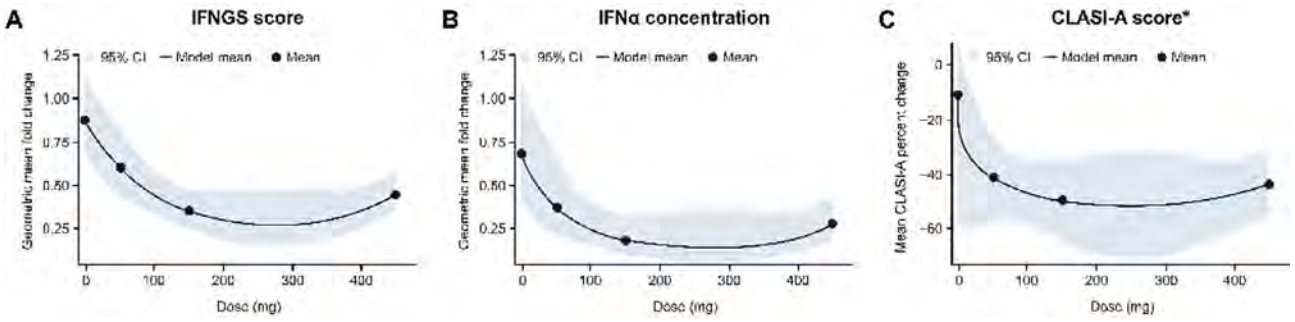

Figure 2. MCP-Mod analysis from Part B of the Phase 2 LILAC study for fold change in IFNGS score (A), fold change in IFNα concentration (B), and percent change in CLASI-A score (clinical response; C) at Week 16 for the IFNGS-high subgroup. Dose-response relationships are based on the MCP-Mod method. The MCP-Mod method uses a two-step process: a multiple comparison step to test for the presence of a significant dose-response relationship, in which placebo serves as a dose of 0 mg, and a modeling step to fit the best dose-response curve. Further details can be found in Werth VP, et al (2022).2 *CLASI-A data include participants with missing baseline biomarkers data. CI, confidence interval; CLASI-A, Cutaneous Lupus Erythematosus Disease Area and Severity Index–Activity; IFNGS, interferon gene signature; MCP-Mod, multiple comparison procedure–modeling

Targeted Inhibition of Cathepsins Limits the Intracellular Complement Activation in Lupus Nephritis Podocytes

Ana Kunzler[1], Meenakshi Jha[1], Masataka Umeda[2], Rhea Bhargava[2], Maria Tsokos[1], George Tsokos[2] and Abhigyan Satyam[2], [1]Beth Israel Deaconess Medical Center, Boston, MA, [2]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a multisystem autoimmune disease that leads to damage to several tissues and organs. Inflammation of the kidney is one of the most severe manifestattions of SLE that leads to lupus nephritis (LN). Podocytes are critical for the maintenance of the glomerular filtration barrier and are injured in many kidney diseases including LN. The pathogenesis of LN involves the activation of the complement system and deposition of immune complexes. While the established pathways of complement activation are well-known, recent studies have revealed that complement component C3 can undergo activation within the cell. Specifically, proteases belonging to the cathepsin family have been shown to cleave C3 and C5, thereby introducing a novel pathway for complement activation. In this study, we investigated the production and activation of complement within the podocytes in LN, focusing on the role of cathepsin inhibition as a potential therapeutic tool to reduce intracellular complement activation

Methods: Human immortalized podocytes were cultured on engineered cell-derived decellularized matrix (DCM) coated plates (Adv. Funct. Mater. 2020, 30(44):1908752*)*. Podocytes were then exposed to IgG from patients with LN or to hypoxia. Cathepsin was inhibited *in vitro* and *in vivo* using nanoparticles (NP) loaded with E64d, a cathepsin inhibitor, and tagged with a nephrin antibody. MRL*lpr,* lupus-prone mice, and MRL*MpJ* control mice, received E64d or empty NP intravenously weekly starting at ages between weeks 8 and 12, followed by tissue harvesting at week 19. Differences at the levels of specific proteins, including C3, C3d, C5b9, and IgG, between E64d-treated and empty NP groups were analyzed. Due to non-normality of residuals, the Wilcoxon-Mann-Whitney test was used for statistical comparison. A p-value < 0.05 was considered significant.

Results: Human podocytes exposed to LN IgG or to hypoxia displayed increased production of C3, C4, C5b9, and C3 activation products. In parallel, podocytes produced cathepsins, and cathepsin inhibition using E64d NP curbed the intracellular C3 activation. There were no significant differences observed in C3 deposition between E64d-treated *vs* empty NP-treated mice, in either MRL*lpr* or MRL*MpJ* mice. The production though of C3d and the deposition of IgG were significantly decreased in the MRL*lpr* and MRL*MpJ* mice treated with E64d NP ($p< 0.05$).

Conclusion: Targeted inhibition of cathepsins in podocytes using E64d-loaded and nephrin antibody-tagged NP effectively reduced intracellular C3 activation in human podocytes exposed to LN IgG or hypoxia, as well as in MRL*lpr* and MRL*MpJ* mice. Furthermore, E64d-loaded NP treatment showed a significant decrease in IgG deposition in the mice. This study sheds light on the production of complement components by podocytes and their cathepsin-dependent intracellular activation. More importantly, our experiments indicate that targeted inhibition of complement activation in podocytes averts the deposition of IgG.Our findings have implications for the development of novel treatment strategies for LN and related autoimmune kidney diseases.

Identification of Subsets of SLE Patients Responsive to Baricitinib by Transcriptomic Analysis at Baseline

Prathyusha Bachali[1], Amrie Grammer[2] and Peter Lipsky[2], [1]AMPEL BioSolutions, Redmond, WA, [2]AMPEL BioSolutions, Charlottesville, VA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Baricitinib is an inhibitor of Jak1 approved for treatment of rheumatoid arthritis, atopic dermatitis, alopecia areata and Covid-19. A phase 2 trial showed success in treating SLE (NCT02708095), but it did not meet its primary endpoint in phase 3 trials(NCT03616964, NCT03616912). To understand the possible dichotomy between these trial results and identify patients with SLE potentially responsive to baricitinib, baseline transcriptomic analysis was carried out in patients enrolled in the phase 2 trial. The goals of this study were to identify the transcriptomic profile of SLE patients who were responsive to baricitinib and the impact of the agent on gene expression abnormalities.

Methods: Baseline whole blood samples from 272 SLE patients from the phase 2 baricitinib trial were utilized for this analysis. These patients had active disease determined by SLEDAI-2K >/=6 and involvement of skin and joints. Patients were randomized to placebo, or one of two doses of baicitinib (2 of 4 mg once daily). Clinical response was determined by perectage of patients resolving skin or joint involvement at 24 weeks using the SLEDAI-2K instrument. RNAseq was performed and analyzed by Gene Set Variation Analysis (GSVA) using 32 informative gene modules and a machine learning (ML) model tested and validated on 3,166 lupus patients from 17 datasets.

Results: ML analysis of GSVA scores from baseline samples of 272 patients yielded 8 subsets (Figure 1). Subset A had the fewest molecular abnormalities, whereas Subset H had the most disturbances in immune function, including enrichments in the IGS, immunoproteasome, IL-1/ inflammasome pathway, and neutrophil/granulocyte genes and lymphopenia. Clusters B-G had intermediate degrees of abnormal enrichment in specific gene modules. No significant differences in baseline demographic characteristics were noted between the subsets. There were significant but modest differences between subsets in baseline anti-DNA and complement C3 and C4, but no differences in SLEDAI-2K scores. Significant clinical responses to baricitinib were confined to subsets D and G (Figure 2). Effect sizes of responses in these groups were > 30%. Other subsets had higher placebo responses and no additional response to baricitinib. Treatment with baricitinib

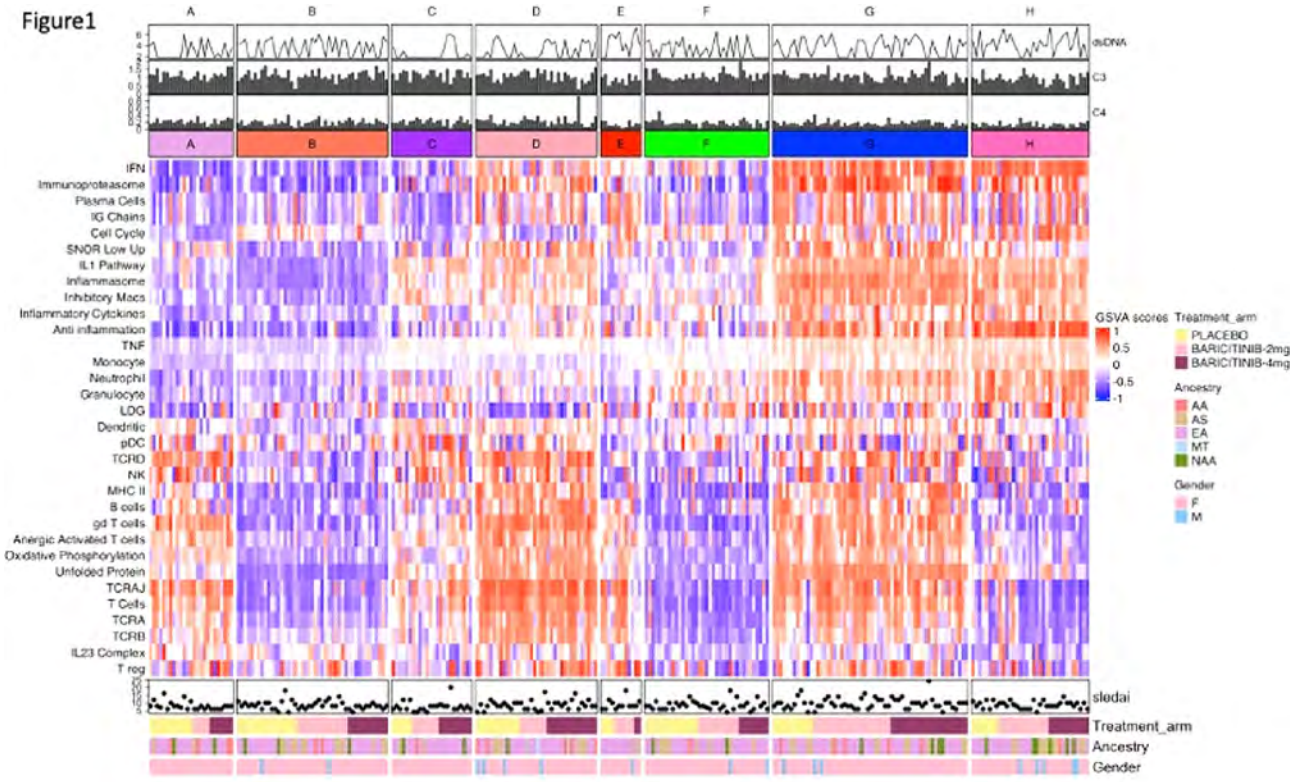

Figure1: Random Forest classifier revealed 8 SLE subsets in 272 baseline lupus samples.
Model weights from random forest (ML) model built on 3166 lupus samples[2183-train,983-test] using 32 gene informative signatures were used to classify the 272 baseline samples into 8 lupus subsets [A-H] ordered by "the least abnormal" to "the most abnormal" immunologic activity. The 8 lupus subsets are visualized by ComplexHeatmap in R.

resulted in significant decreases in the interferon, immunoproteasome, inflammasome, monocyte, granulocye and inflammatory cytokine signatures among others, with improvement observed within 4 weeks of treatment onset. (Figure 3).Notably, gene modules downstream of JAK1, JAK2 and TyK2 were significantly decreased by baricitinib, but not placebo treatment.

Figure2

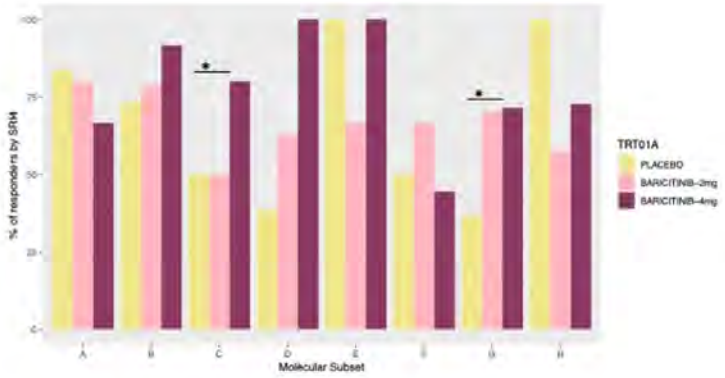

Figure2: Clinical response of lupus patients in lupus subsets by SRI4 reveals a significant response to the Baricitinib 4mg in subset D & G. Statistical differences between samples received Placebo and two doses (2mg,4mg) of Baricitinib is calculated by Chi-square test (* pval < 0.05)

Figure3

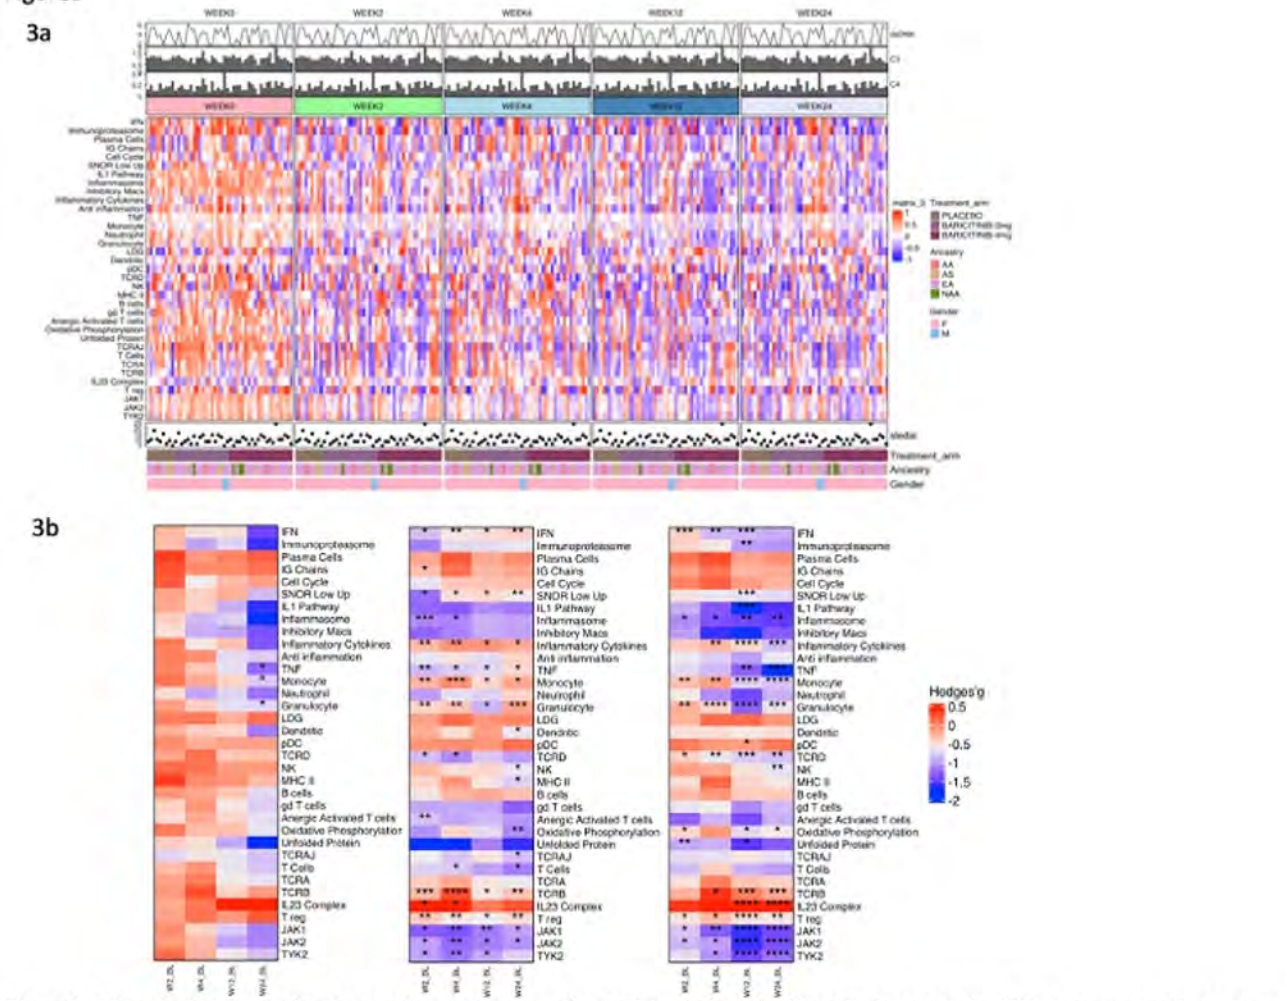

Figure3. Timeseries analysis of samples in lupus subset G explains significant decrease in IFN, Immunoproteasome, Inflammasome, Monocyte, Inflammatory cytokines, TNF, JAK1, JAK2, and TYK2 signatures. 3a)GSVA scores of samples from subset G across week0, week4, week12, week24 were visualized using ComplexHeatmap in R. 3b) Hedges' g effect sizes of cellular and process gene modules for week4, week12, and week24 compared to week0 in pateints treated with Placebo, and two doses of Baricitinib were calculated. The heatmap visualizes the increased gene expression (> 0) in red and decreased gene expression (< 0) in blue. Welch's t-test p values are referred by * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$, **** $p < 0.0001$

Conclusion: Transcriptomic analysis of of baseline samples using GSVA scores from informative gene modules and ML successfully clustered patients into subsets that exhibited differences in response to baricitinib treatment. Treatment with baricitinib altered gene expression profiles in a manner consistent with the known action of the agent. Gene expression based subsetting may be useful to enrich trials for responsive patients and monitor the impact of therapy.

Selective Disposition of Voclosporin, Cyclosporine, and Tacrolimus in Renal Tissue

Simon Zhou[1], Krishani Kumari Rajanayake[2], Miao He[2], Bo Wen[2], Ankhbayar Lkhagva[2], Ernie Yap[3], Duxin Sun[2], Jennifer Cross[1], Kory Engelke[1] and Robert B. Huizinga[4], [1]Aurinia Pharmaceuticals Inc., Rockford, MD, [2]University of Michigan, Ann Arbor, MI, [3]Aurinia Pharmaceuticals Inc., Edmonton, AB, Canada, [4]Reformation Consulting Services, North Saanich, BC, Canada

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The calcineurin inhibitors (CNI) cyclosporine (CSA) and tacrolimus (TAC) were revolutionary when first introduced for solid organ transplant. Voclosporin (VCS), a novel CNI, is the first oral therapy approved for the treatment of active lupus nephritis. Unlike CSA and TAC, VCS has demonstrated consistent pharmacokinetics and pharmacodynamics, eliminating the need for therapeutic drug monitoring. Further, VCS is associated with a more favorable metabolic profile and has not been associated with electrolyte disturbances.

Emerging evidence indicates small molecule therapies display differential disposition within organ tissues. This suggests that CNIs may be differentially distributed and retained in the kidney, potentially explaining differences in their efficacy and safety. Here we assessed in mice and humans the disposition of each CNI in the kidney relative to its systemic drug exposure.

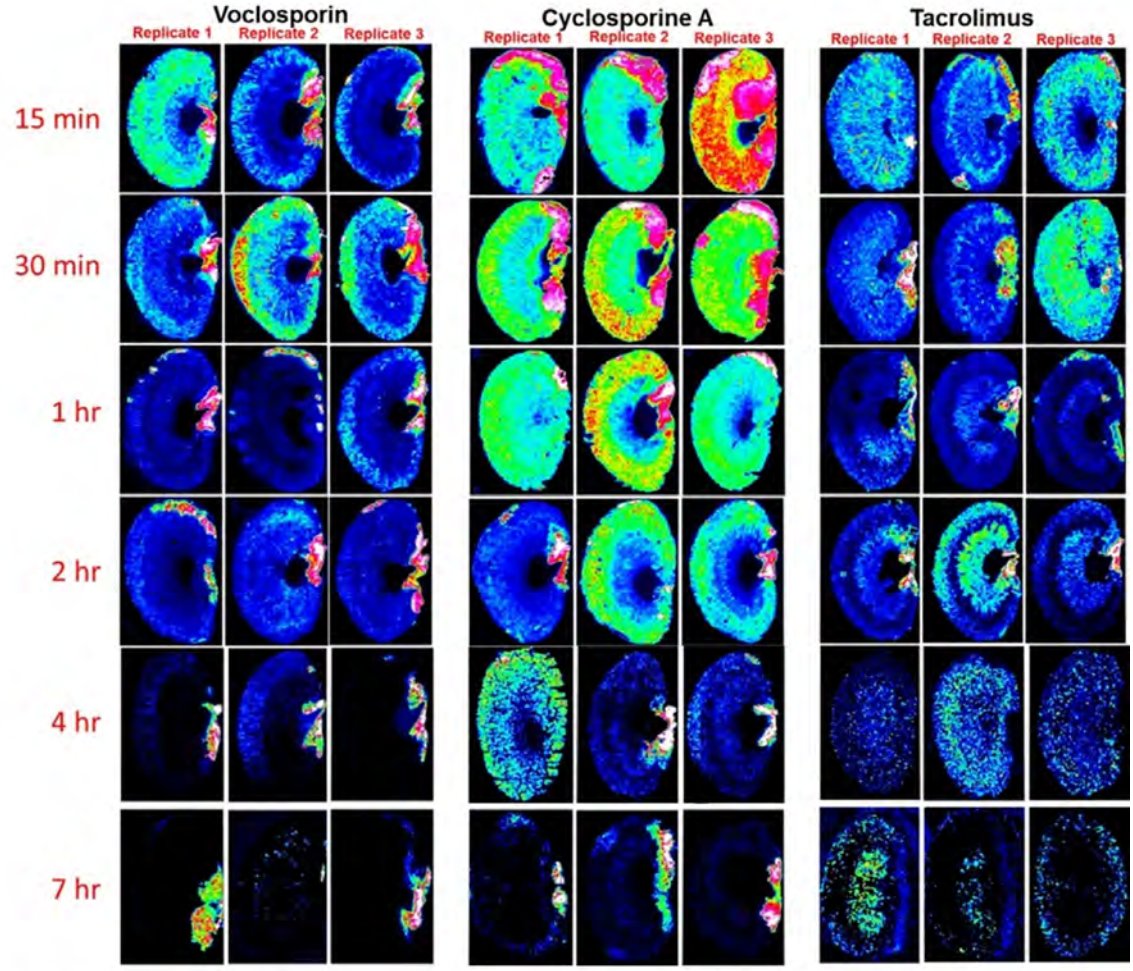
Methods: Single 30 mg/kg doses of CSA, TAC and VCS were administered intravenously (IV) to mice. Following IV administration, kidneys were collected at various time points, flash frozen in liquid nitrogen, and stored at -20 ^{0}C. Sections of kidney tissue were mounted on indium tin oxide coated glass slides. Matrix of 10 mg/mL α-Cyano-4-hydroxycinnamic acid in 85% acetonitrile/13% ethanol + 2% water + 0.1% trifluoroacetic acid was sprayed on the tissue, dried for 10 minutes, and subjected to Matrix-assisted Laser Desorption and Ionization Mass Spectrometry Imaging (MALDI-MSI). The systemic and renal clearance (CLr) in humans of CSA and TAC were obtained from literature; pharmacokinetic data on VCS was obtained from data on file. Renal secretion of each drug was compared to its expected passive filtration based on glomerular filtration rate (GFR), fraction unbound in plasma (fu), and respective systemic drug exposure.

Results: MALDI-MSI demonstrated significantly higher concentrations of drug and more diffuse tissue disposition of CSA in mouse kidney compared to VCS (Figure 1). CSA was retained up to 2 hrs post-administration. Higher concentrations and more diffuse disposition of TAC was also noted compared to VCS at 15 and 30 min; TAC was distinctively retained in the cortex and medulla. VCS had moderate distribution in the cortex and was rapidly excreted with low levels present in the kidney after 1 hr.

According to published data, CSA has a measured renal CLr of 1.48 mL/min in humans, representing approximately 10% of expected passive filtration of 12.5 mL/min (Table 1). TAC has a CLr of 0.014 mL/min representing < 2% of expected passive filtration of 1.25 mL/min. VCS has a CLr of 7.82 mL/min representing approximately 200% of its expected passive filtration rate of 3.75 mL/min.

Conclusion: MALDI-MSI revealed differential retention and distribution of CSA, TAC and VCS in mice, consistent with their CLr in humans. Higher drug exposure and >90% renal reabsorption was observed for CSA and TAC, whereas renal handling of VCS suggested significant tubular secretion. The higher rate of secretion and lower overall renal exposure to VCS

Figure 1. MALDI-MSI of voclosporin, cyclosporine, and tacrolimus in mouse kidney over time



CSA, cyclosporine; K, potassium; Tac, tacrolimus; VSP, voclosporin.

Table 1. Published pharmacokinetic data in humans

	CL	CL/F	fu	Expected CLr (GFR*fu)	CLr
Cyclosporine A	210-240 mL/min	500-600 mL/min	10%	12.5 mL/min	1.48 mL/min
Tacrolimus	37.5 mL/min	NA	1%	1.25 mL/min	0.014mL/min
Voclosporin	NA	1060 mL/min	3%	3.75 mL/min	7.82 mL/min

Dual Blockade of ICOS and CD28 with Acazicolcept (ALPN-101) Reveals Non-Redundant Roles of T Cell Co-Stimulation Pathways in Systemic Lupus Erythematosus

Elizabeth Repash, Tiffany Blair, Amanda Enstrom, Lawrence Evans, Susan Debrot, Katherine Lewis, Armand Bankhead, Stanford Peng and Stacey Dillon, Alpine Immune Sciences, Inc., Seattle, WA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: CD28 and inducible T cell costimulator (ICOS) play nonredundant roles in T cell activation and inhibiting these pathways can ameliorate an (auto)immune response. Systemic lupus erythematosus (SLE) is characterized by the dysregulation of T and B cell activation. Transcriptional analyses have revealed upregulation of CD28 and ICOS ligand/receptor genes in SLE[1], but single pathway inhibition has not proven clinically effective in SLE and related diseases.[2,3] Acazicolcept is an Fc fusion protein of a human variant ICOS-ligand (ICOSL) domain designed to block CD28 and ICOS simultaneously. We conducted *in vitro* assays with healthy donor (HD) and SLE patient PBMCs to analyze acazicolcept or comparators to suppress inflammatory mediators that promote disease pathogenesis. Additionally, acazicolcept was evaluated in a SLE mouse model.

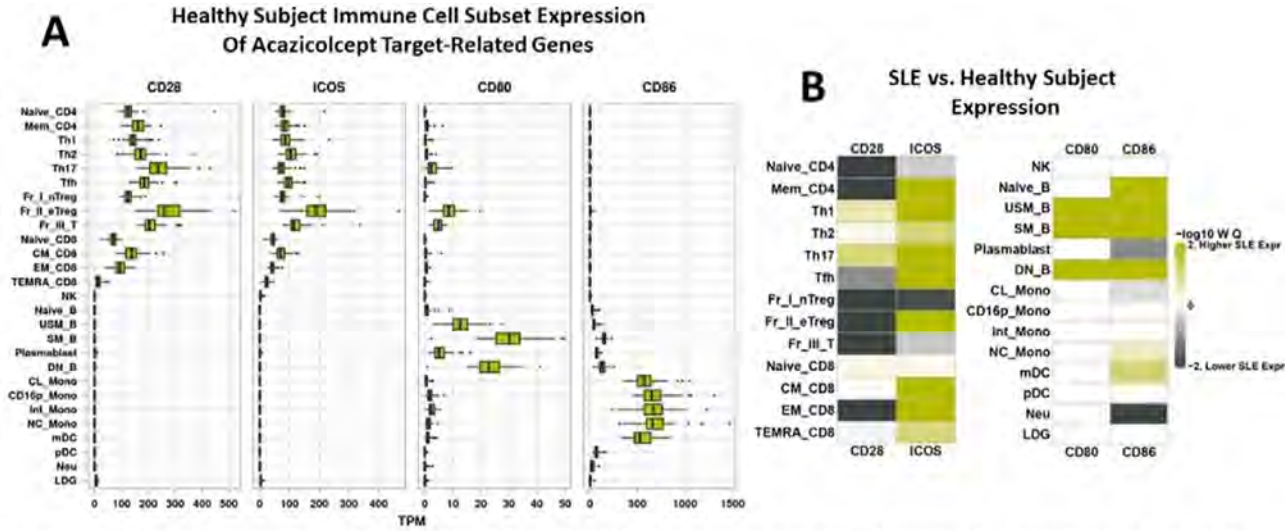

Figure 1: RNA-Seq expression of acazicolcept target-related genes in sorted PBMC subsets reported by Ota *et al.* **A** Transcripts per million (TPM) expression values for healthy sample immune cell subsets. **B** TPM values were $\log_2$ transformed and converted to z-scores for SLE vs. healthy donor comparison. Heat map colors represent negative $\log_{10}$ q-values from Wilcoxon tests between ~60 SLE and ~70 healthy subjects with positive (*green*) values representing higher SLE patient expression and negative (*black*) values representing lower SLE patient expression. White heat map values indicate either non-significance (q-values ≈1) or low expression (healthy subject median expression ≤ 10). TPM values displayed were upper quartile normalized.

Methods: HD or SLE PBMCs were stimulated with artificial antigen presenting cells expressing CD80, CD86, ICOSL and anti-CD3 (OKT3) for 48h with 100 nM of Fc control protein, acazicolcept, or comparators directed against CD28 (abatacept, [CTLA-4-Ig]) or ICOS (prezalumab [anti-ICOSL mAb]) or combined abatacept/prezalumab. Supernatants and cells were analyzed for cytokine production and gene expression. Acazicolcept was compared *in vivo* to abatacept (CTLA4-Ig) in a bm12 induced mouse model of lupus[4]. C57BL/6 recipient mice were treated 2x/wk with acazicolcept or abatacept (N=12), from Days 0-93. Serum anti-double stranded (ds) DNA antibody concentrations were measured, and frozen kidney sections collected on Day 100 wereanalyzed for IgG deposition.

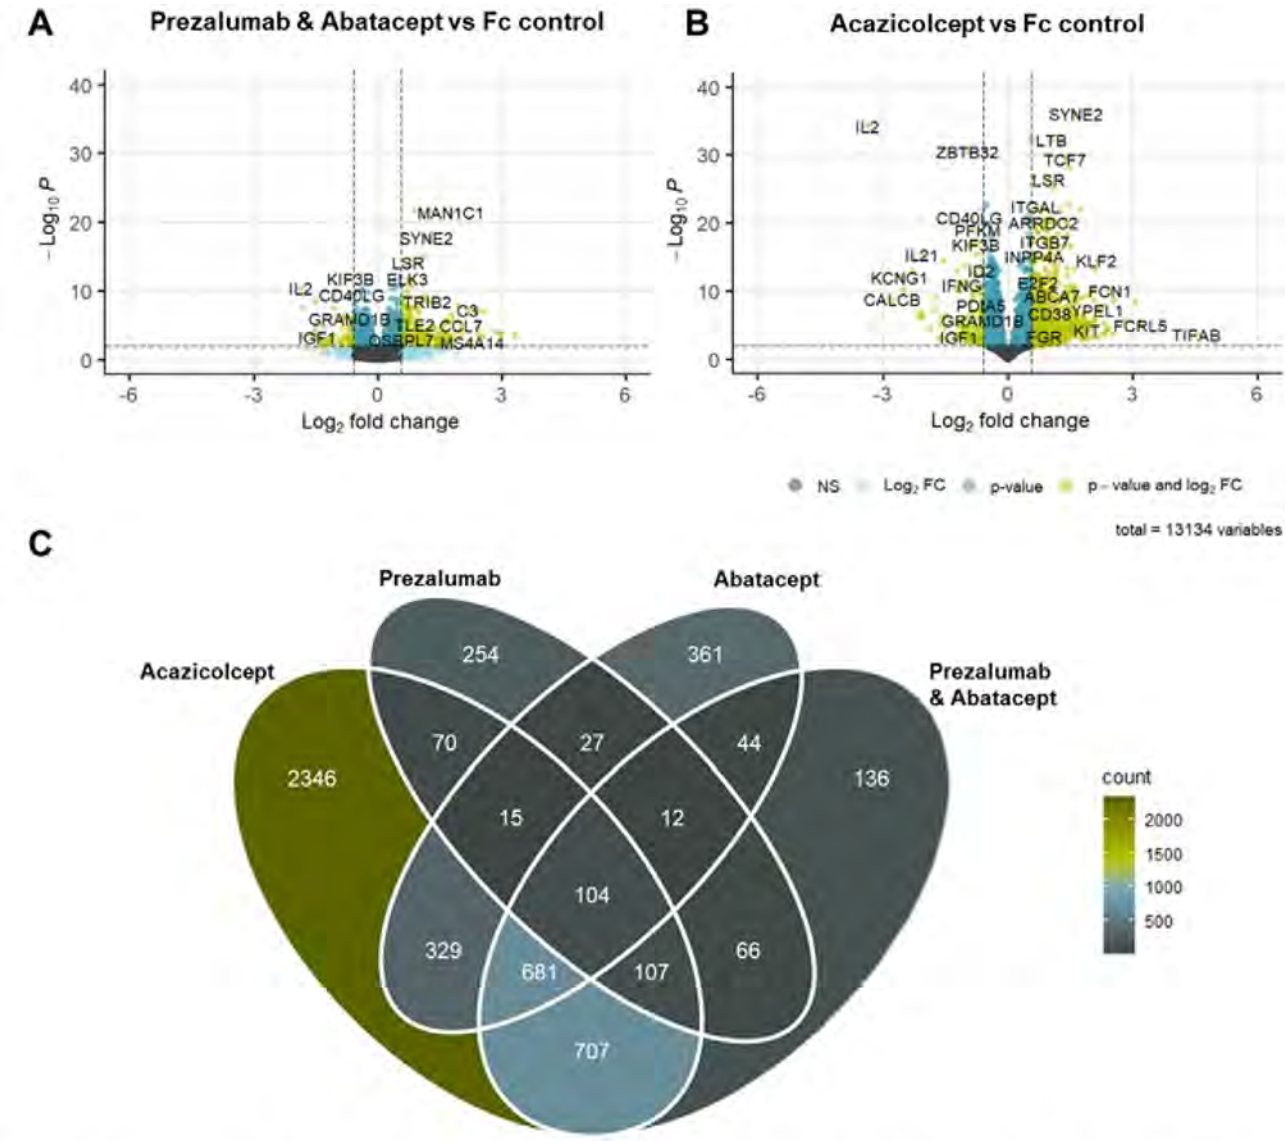

Figure 2: Acazicolcept potently downregulates genes associated with T cell activation in SLE donor PBMC stimulated with K562 cells expressing anti-CD3 (OKT3), CD80, CD86 and ICOSL. Volcano plots display differentially expressed genes from the following comparisons: **A** prezalumab and abatacept vs Fc control and **B** acazicolcept vs Fc control. Green dots represent differentially expressed genes that pass significance threshold with a p value < 0.001 and a $\log_2$ fold change cutoff with an absolute value greater than 0.58. Light blue dots pass the p value cutoff but not the fold change threshold, dark blue dots pass a fold change cutoff but not the p value threshold, and gray dots are not significant. **C** Venn diagram featuring differentially expressed genes (threshold $\log_2$ fold change > 0.58 or < -0.58 with a p value < 0.001) derived from the individual comparisons of acazicolcept, prezalumab, abatacept, or prezalumab & abatacept versus Fc control.

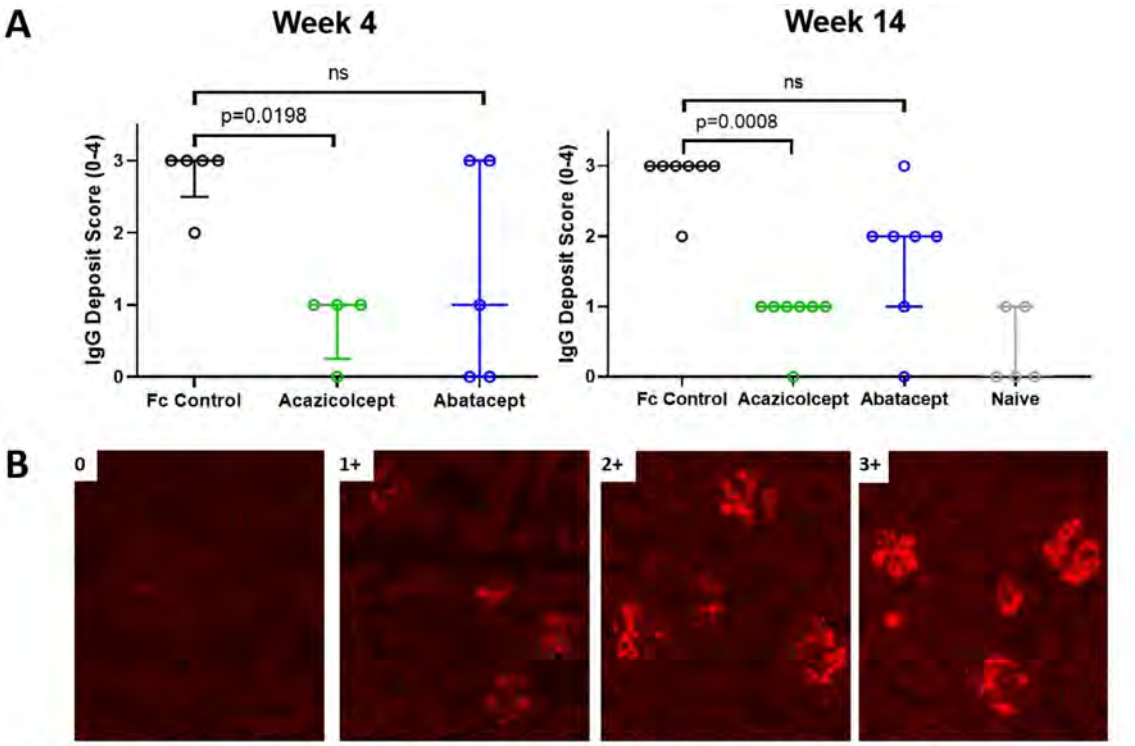

Figure 3: Acazicolcept significantly reduces glomerular IgG deposition in the bm12 induced mouse model of lupus. At termination (week 4 and week 14), kidneys were harvested from each mouse and frozen, sectioned, and stained with anti-mouse IgG antibody. The extent of mouse IgG staining indicating immune complex deposition was semi-quantitatively scored; the glomerular IgG deposit scores for each kidney collected for each treatment group at week 4 (left)and week 14 (right) are plotted in **A**. Representative sections (original magnification, 10X) for each score are shown in **B**. Data shown in **A** are from individual mice; horizontal bars and vertical error bars represent the group median ± interquartile range, respectively. Statistically significant differences between treatment groups were assessed via Kruskal-Wallis test with uncorrected Dunn's test; p values <0.05 were considered statistically significant.

Results: Acazicolcept more potently suppressed expression of genes associated with T cell activation than the abatacept or prezalumab comparators, alone or combined. Gene expression analyses revealed distinct transcriptional profiles between PBMC from HD vs. SLE patients (**Fig 1**), in agreement with previously published findings. Furthermore, acazicolcept suppressed pro-inflammatory cytokine production and inhibited pathways associated with immune activation including Th1 and Th2 activation and IL-17 signaling (**Fig 2**). In the bm12 model, acazicolcept significantly reduced serum titers of anti-dsDNA autoantibodies compared to Fc control on Weeks 2 and 6. IgG deposition scores in the kidneys of acazicolcept-treated mice were significantly lower than the Fc control group at Weeks 4 (p=0.0198) and 14 (p=0.0008), while these scores in the abatacept-treated mice were not significantly different than the Fc control group (**Fig 3**).

Conclusion: Taken together, these and previous findings indicate that simultaneously inhibiting ICOS and CD28 pathways may result in significant disease amelioration in lupus-related inflammation/autoimmunity, with activity superior to agents targeting only one of these pathways. These observations provide further support for the clinical evaluation of acazicolcept for treatment of SLE; a Phase 2 trial of acazicolcept in SLE is ongoing (NCT04835441/Synergy).

Antiphospholipid Antibodies as Potential Predictors of Disease Severity and Poor Prognosis in Systemic Lupus Erythematosus Associated Thrombocytopeinia

Mehret Birru Talabi[1], Bonnie Bermas[2], Irene Blanco[3], Ashira Blazer[4], Megan Clowse[5], Cuoghi Edens[6], Leslie Pierce[7], Catherine Wright[1] and Rosalind Ramsey-Goldman[3], [1]University of Pittsburgh, Pittsburgh, PA, [2]UT Southwestern, Dallas, TX, [3]Northwestern University, Chicago, IL, [4]Hospital for Special Surgery, New York, NY, [5]Duke University, Chapel Hill, NC, [6]University of Chicago, Chicago, IL, [7]University of Pittsburgh, Raleigh, NC

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: SLE – Treatment Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Thrombocytopenia (TP) is a common hematologic abnormality in systemic lupus erythematosus (SLE). Severe thrombocytopenia is correlated with disease activity and a worse prognosis of SLE associated thrombocytopenia (SLE-TP). Antiphospholipid antibodies (aPLs)have been proven to cause low platelet count through various mechanisms. However, the impact of aPLs on SLE-TP remains a matter of debate. In this multicenter prospective study, we aim to investigate the role of aPLs on disease severity and prognosis of SLE-TP.

Methods: All SLE patients fulfilled the 2019 the American College of Rheumatology (ACR) / the European League Against Rheumatism(EUALR) classification criteria for SLE. Antiphospholipid syndrome (APS) was diagnosed according to the revised 2006 Sapporo APS classification criteria. TP was defined as a platelet count<100×10^9/L, and patients with TP due to other causes were excluded. aPLs were tested following international guidelines (anticardiolipin, anti-β2 glycoprotein I antibodies and lupus anticoagulant). Demographic characteristics, platelet count, clinical manifestations, disease activity, and autoantibody profiles were collected at baseline. Severity of thrombocytopenia was categorized into mild, moderate, and severe group. Relapse was defined as the loss of remission. Bone marrow punctures indicated impairment of megakaryocyte maturation.

Results: A total of 371 SLE-TP patients with complete follow-up data were enrolled, out of which 199 (53.6%) were aPLs positive and 48 (24.1%) were complicated with APS. Baseline comparison showed that SLE-TP with aPLs had lower baseline platelet counts (62.0×10^9/L *vs*. 76.0×10^9/L, *P*=0.003), and a higher proportion of moderate to severe cases (17.1% *vs*. 9.9%; 23.6% *vs*. 13.4%, *P*=0.002). SLE-TP patients with aPLs had lower platelet counts at their lowest point (37.0×10^9/L *vs*. 55.0×10^9/L, *P*=0.002).In addition, the increasing number of aPLs types was associated with the decrease of baseline and minimum values of platelets (*P* < 0.001; *P*=0.001). SLE-TP carrying aPLs had a lower prevalence of arthritis (39.7% *vs*. 45.3%, *P*=0.019) and serositis (14.6% *vs*. 25.0%, *P*=0.011).Among aPLs carriers, there was a higher positivity rate for ANuA (18.1% *vs*. 10.5%, *P*=0.038), whereas it was lower for anti-RNP antibody (33.7% *vs*. 51.2%, *P*=0.001). During a median 5.47-year follow-up of 326 SLE-TP patients with complete treatment data (181 aPLspositive, 55.5%), SLE-TP carrying aPLs hada higher relapse rate(58.6% *vs*.45.5%, *P*=0.019) and lower complete response (CR) rate (85.6% *vs*.87.6%).

Table 1. Baseline characteristics, profile of autoantibodies, and clinical manifestations of 371 SLE-TP patients.

	aPLs+ (n=199)	aPLs- (n=172)	*P*
Female, n (%)	173(86.9)	157(91.3)	0.183

HGB($\times10^{12}$/L), median (25%-75%)	119 (101-136)	119 (103-131.8)	0.751
Anti-double stranded DNA (anti-dsDNA) antibody, n (%)	47 (23.6)	59 (34.3)	**0.023**
Anti-Sm antibody, n (%)	42 (21.1)	51 (29.7)	0.058
Anti-RNP antibody, n (%)	67 (33.7)	88 (51.2)	**0.001**
Anti-SSA antibody, n (%)	108 (54.3)	109 (63.4)	0.076
Anti-SSB antibody, n (%)	25 (12.6)	31 (18.0)	0.143
Anti-ribosomal P protein (anti-RibP) antibody, n (%)	48 (24.1)	36 (20.9)	0.464
Anti-nucleosome antibody (ANuA), n (%)	36 (18.1)	18 (10.5)	**0.038**
Anti-histone antibody (AHA), n (%)	38 (19.1)	25 (14.5)	0.243

Furthermore, the analysis of 61 SLE-TP with qualified bone marrow reports found that there was no significant difference in ratio of granulocytes to red blood cells (G/E), the total number of megakaryocyte and categories (granulosa, naked nuclear, and plate producing cells).

Table 2. The minimum PLT value during follow-up and the treatment response of 326 SLE-TP patients with different aPLs.

	aPLs+(n=181)				aPLs-(n=145)	*P*
	1 aPL+ (n=69, 38.1%)	2 aPLs+ (n=46, 25.4%)	3 aPLs+ (n=66, 36.4%)	aPLs+ total		
Minimum PLT count($\times10^9$/L), median (25%-75%)	45 (23-73.5)	29.5 (8.75-69.5)	31.5 (13.5-50)	37 (15-63.5)	55 (25.5-76)	**0.002**
Severe(<20×10^9/L), n (%)	14 (20.3)	18 (39.1)	21 (31.8)	53 (29.3)	28 (19.3)	
Moderate(20-50$\times10^9$/L), n (%)	25 (36.2)	12 (26.1)	27 (40.9)	64 (35.4)	42 (29.0)	**0.01**
Mild(50-100$\times10^9$/L), n (%)	30 (43.5)	16 (34.8)	18 (27.3)	64 (35.4)	75 (51.7)	
Latest PLT count($\times10^9$/L), median (25%-75%)	122 (84.5-210)	133.5 (85.75-218.75)	100.5 (63.75-166.75)	117 (77-204.5)	136 (82-206)	0.312
CR, n (%)	63 (91.3)	38 (82.6)	54 (81.8)	155 (85.6)	127 (87.6)	
R, n (%)	1 (1.4)	2 (4.3)	7 (10.6)	10 (5.5)	1(0.7)	**0.01**
NR, n (%)	5 (7.2)	6 (13.0)	5 (7.6)	16 (8.8)	17 (11.7)	
Loss of CR or R, n (%)	38 (55.1)	25 (54.3)	43 (65.2)	106 (58.6)	66 (45.5)	**0.019**

Note: CR, complete response,is defined as any platelet count of at least 100×10^9/L. R, response, is defined as any platelet count between 30 and 100×10^9/L and at least doubling of the baseline count. NR, nonresponse,is defined as any platelet count lower than 30×10^9/L or less than doubling of the baseline count. Loss of CR or R, platelet count below 100×10^9/L or bleeding (from CR) or below 30×10^9/L or less than 2-fold increase of baseline platelet count or bleeding (from R) 1 aPL+, single aPL positive. 2 aPLs+, double aPLs positive. 3 aPLs+, triple aPLs positive.

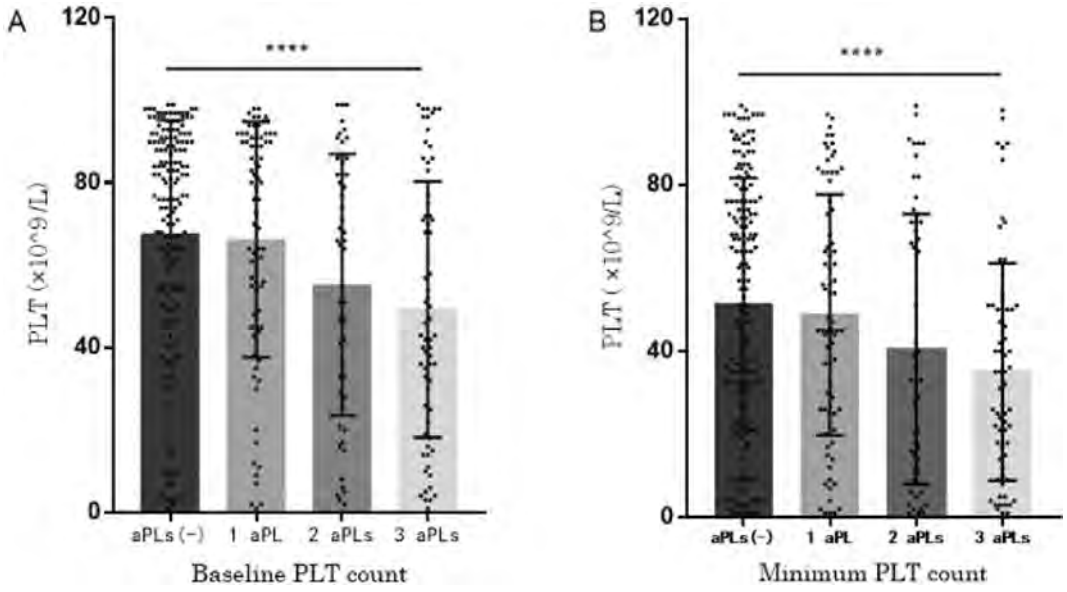

Figure. (A). Baseline platelet count of SLE-TP with different aPLs. (B) Minimum platelet count of SLE-TP with different aPLs.

Conclusion: SLE-TP with positive aPLs had more severe disease condition and a higher recurrence rate, which suggests that we should implement more proactive management strategies and maintain vigilance towards relapse in SLE-TP patients with positive aPLs.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: SLE – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Belimumab (BLM) is an IgG-1l anti-BAFF monoclonal antibody effective in patients with systemic lupus erythematosus (SLE), being used increasingly. However, there are no published data on dose optimization in responder patients.

Aim: to assess the prevalence of dose optimization in patients with SLE treated with BLM in our country, its modalities and its impact on disease activity control.

Methods: Retrospective longitudinal and multicenter study of SLE patients, treated with

BLM in Spanish rheumatology departments. Demographic and clinical features, activity (SLEDAI), treatments and outcomes (remission (DORIS -2021) and low disease activity (LLDAS) were collected at baseline (pre-optimization) (VB), at 6 (V6M) and at 12 months (V12M) post-optimization. A comparative analysis was performed pre- and post-optimization.

Table. BLM optimization

Table 1: Differences pre and post belimumab dosage optimization

	VB (pre)	V6M (post)	V12M (post)
SLEDAI, median (p25-p75)	0 (0-2)	2 (0-49)	0 (0-2)
PGA (0-3), median (p25-p75)	0,33 (0-0,5)	0,28 (0-0.48)	0,2 (0-0.4)
DORIS remission, n/total (%)	15/26 (57.7%)	14/22 (63.6%)	12/19 (63.2%)
LLDAS, n/total (%)	23/26 (88.5%)	20/22 (90.9%)	17/19 (89.5%)
CRP, median (p25-p75)	1.65 (0.4-5.5)	1.63 (0.46-4.14)	0.7 (0.25-3.9)
C3 or C4 low, n/total (%)	5/26 (19.2%)	11/25 (44%) #	7/20 (35%) #
Anti-DNA positive, n/total (%)	5/26 (19.2%)	2/24 (8.3%)	0/20 (0%)
Active serology, n/total (%)	8/29 (27.6%)	13/24 (54.2%)	7/20 (35%)
DAMARD, n/total (%)	17/26 (65.4%)	14/25 (56%)	10/20 (50%)
Glucocorticoids (GC), n/total (%)	15/26 (57.7%)	12/24 (50%)	8/20 (40%) #
GC dose, median (p25-p75)	2.5 (0-5)	2,5 (0-5) #	5 (0.62-8.75)

VB (pre): basal visit (pre-optimization); V6M: visit at 6 months post-optimization; V12M: visit at 12 months post-optimization.
p significant
DORIS: Definition of Remission in SLE. PGA: Physician Global Assessment. LLDAS: Lupus Low Disease Activity State. CRP: C Reactive Protein. DMARD: Disease Modifying Antirheumatic Drugs.

Results: 324 patients with SLE (98%, ACR-97 or SLICC-12 criteria) treated with BLM were included; 91% women; mean age (±DS): 42.4 (±12.9) years. Median follow-up follow-up: 3.2 years (p25-p75) (1.4-5.9). A total of 29 patients (8.9%) were optimized. Median time to optimization 2.7 (1.77-4.48) years. Mean time on optimization: 11.36 (±2.5) months. Optimization modalities: increase of the interval in 9 patients with subcutaneous BLM (from 7 days to 10-21 days of interval between doses) and in 6 patients with intravenous (ivBLM) (from a 4-week to a 5- 6-weeks). Dose reduction per administration (all ivBLM) in 16 patients (from 10mg/kg to 5-9 mg/kg).

Pre-optimization status (VB): 15/26 (57.7%) in DORIS-21 remission and 23/26 (88.5%) in LLDAS. LLDAS. Only 1 patient had lupus nephritis. Detailed description of other baseline characteristics are displayed in Table 1. After optimization, 2/24 (8.3%) and 3/22(13.6%) patients lost remission-DORIS in V6M and V12M, respectively, but with no statistically significant differences with respect to VB; regarding to LLDAS, 2/23(8.7%) and 2/21(9.5%) did so in V6M and V12M, respectively, but also without statistically significant differences with respect to VB. Out of 11/23(47.8%) and 9/21(42.9%) moved from SLEDAI 0 to SLEDAI >0 in V6M and V12M, respectively. In terms of disease activity, no significant differences were found pre- and post-optimization in any of the measures, except for hypocomplementemia ($p = 0.0276$) (Table 1). Changes in activity did not lead to relevant changes in treatment, thus only one patient returned to the baseline dose of BLM and only one patient started DMARD. Significantly fewer patients received GC in V12M, even though the median dose of GC was higher in V12M (5 (0.62-8.75) vs. 2.5 (0-5) in VB) (Table 1).

Conclusion: It is possible to optimize doses of BLM without relevant changes in disease activity, at least in the short term, in a significant percentage of patients, and the most of them maintain the optimized dose. However, the increased clinical or serologic activity is possible in some patients. This makes a tighter post-optimization follow-up advisable.

More studies, with a larger number of patients and longer follow-up time, will be required to confirm these results and to analyse more robust outcomes.

Determining the ECG Cut-off Point in Systemic Lupus Erythematosus Patients Undergoing Hydroxychloroquine Therapy

Carmen Lasa[1], Alba Herrero-Morant[2], Jon Zubiaur[3], Adrián Margarida[4], Raquel Pérez[3] and Ricardo Blanco[5], [1]Hospital Universitario Marqués de Valdecilla, IDIVAL., La Cavada, Spain, [2]Hospital Universitario Marqués de Valdecilla, Ontinyent, Spain, [3]Hospital Universitario Marqués de Valdecilla, Santander, Spain, [4]Hospital Universitario Marqués de Valdecilla., Santander, Spain, [5]Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) is a widely used drug in Systemic Lupus Erythematosus (SLE) that can cause cardiac alterations such as arrhythmic events in the short-term and dose-dependent cardiomyopathy in the medium to long-term. The cardiological implications of HCQ accumulation in these patients in the medium to long-term is unknown.

Methods: Single university hospital observational study of all consecutive SLE patients who had an electrocardiogram (ECG) at baseline and at least one ECG at follow-up. New conduction disturbances were assessed by ECG, defined as atrio-ventricular block, bundle branch block or QT interval prolongation. ECGs were extracted from the medical record and interpreted at baseline and for 15.2 years (95%CI 13.24-17.16) of follow-up. We defined cumulative HCQ (cHCQ) as the total grams of HCQ that had been administered. A ROC curve analysis was performed to determine the optimal cut-off point for sensitivity and specificity.

Results: We studied 105 (93 female/12 male) SLE patients with a mean (±SD) age of 61.8±14.9 years. The mean daily dose of HCQ in our sample was 256 mg per day **(Table)**. The ROC curve showed a moderate diagnostic ability for new conduction disturbances with an area under the curve of 0.69 (95% CI 0.59 - 0.77) **(Figure).** The highest efficacy cut-off point was cHCQ: 4097g (Sensitivity 15%; Specificity 100%) and the optimal cut-off point was cHCQ: 901g (Sensitivity 85%; Specificity 52.9%). This cut-off point was reached with a mean HCQ treatment in our sample of 9.7 years. High grade atrio-ventricular block was found in 5 patients. In all of them the cHCQ dose was over 901g.

Conclusion: According to our study, 901g of cumulative HCQ dose is a good cut-off point for performing a protocolized ECG to rule out cardiac conduction disturbances in patients with SLE and chronic HCQ treatment. This is equivalent to 9.7 years of treatment with the mean HCQ dose use in our sample.

Table 1. Clinical characteristics of systemic lupus erythematosus patients.

General characteristics	Global (N=105)
Current age (mean ± SD)	61.8 ± 14.9
Years of SLE evolution (mean ± SD)	16.3 ± 10.3

Risk of Damage Progression with Belimumab versus Oral Immunosuppressant Use in Patients with Systemic Lupus Erythematosus

April Jorge[1], Baijun Zhou[1], Yuqing Zhang[2] and Hyon K. Choi[3], [1]Massachusetts General Hospital, Boston, MA, [2]Division of Rheumatology, Allergy, and Immunology, Department of Medicine, Massachusetts General Hospital, Boston, MA, [3]Massachusetts General Hospital and Harvard Medical School, Lexington, MA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: SLE – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Belimumab was approved for the treatment of non-renal SLE in 2011 and has been previously associated with a lower risk of damage progression when compared with prior 'usual care.' We sought to determine the risk of damage progression with belimumab versus alternative SLE immunosuppressants in a contemporary real world setting.

Methods: We identified all adults with SLE (defined by ≥2 ICD codes >30 days and < 2 years apart) in a United States multicenter electronic health record (EHR) database, TriNetX. We identified all patients who initiated belimumab, azathioprine (AZA), methotrexate (MTX), or mycophenolate (MMF) between 3/2011 and 8/2021. We designed and emulated a pragmatic target trial to compare the risk of damage progression with initiation of belimumab vs. AZA, belimumab vs. MTX, and belimumab vs MMF. For each comparison, eligible patients had never used the direct comparator but could have used other immunosuppressants and did not have lupus nephritis prior to the index date of treatment initiation. To emulate randomization, we used propensity score overlap weighting to balance baseline covariates, including demographics, geographic region, treatment initiation year, comorbidities including CKD, congestive heart failure, obesity, cardiovascular disease, the Charlson comorbidity index, tobacco use, SLE severity index (Garris C. *J Med Econ* 2013), SLE disease duration, baseline SLICC damage index score (categorized as 0, 1, or ≥2), medication use including glucocorticoids, hydroxychloroquine, and other immunosuppressants, and healthcare utilization. We assessed the outcome of damage progression defined by an increase

in the SLICC damage index (SDI), which was adapted to administrative data using ICD codes. We conducted an intention-to-treat analysis and a per-protocol analysis using pooled logistic regression where we adjusted for adherence to assigned treatment with inverse probability of treatment weighting. We also assessed the mean change in the SDI at three years among patients with ≥3 years of follow-up using linear regression.

Results: We compared 2,434 and 5,644 initiators of belimumab and AZA, (**Table 1**), 2,163 and 7,224 initiators of belimumab and MTX, and 2,431 and 6,350 initiators of belimumab and MMF, respectively. In each comparison, covariates were balanced after propensity score overlap weighting. 95% were female; the mean age was 44 years. 53% had a baseline SDI of zero. After

Belimumab	309	0.85 (0.72, 0.98)	0.08 (-0.06, 0.22)	
Belimumab vs. Mycophenolate				
Mycophenolate	857	1.31 (1.19, 1.43)	Ref	<0.01
Belimumab	301	0.85 (0.70, 0.99)	-0.47 (-0.64,-0.29)	

5 years, over 41% in each treatment group developed ≥1 new damage item on the SDI. The risk of damage progression was lower with belimumab than mycophenolate (HR 0.74 [95% CI 0.67-0.83]; **Table 2**), but there was no difference in the risk of damage progression between belimumab and AZA or belimumab and MTX. Similarly, belimumab was associated with a lower 3-year change in SDI when compared with MMF, but there was no difference when compared with AZA and MTX (**Table 3**).

Conclusion: In this real world EHR-based SLE cohort, after accounting for baseline covariates associated with the risk of organ damage, belimumab was associated with a lower risk of damage progression than MMF but not AZA or MTX use. Limitations include the use of administrative claims to identify components of the SDI.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: SLE – Treatment Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: We have previously shown that CD19 CAR T cell therapy leads to stable drug-free remission of treatment-resistant SLE (1,2). Based on these findings we addressed the question whether disease-specific autoimmunity resolves in a sustainable way in CD19 CAR T cell- treated SLE patients. We also asked the question whether CD19 CAR T cell therapy affects long-term vaccination responses

Methods: Patients with treatment-resistant SLE received a single infusion of 1 million CD19 CAR T cells per kilogram body weight. CAR T cells were manufactured from autologous T cells and transfected with the lentiviral vector MB-CART19.1 (Miltenyi) encoding the CD19 CAR. Immunosuppressive treatment was stopped before CAR T cell infusion. Standard conditioning treatment (1g/m2 cyclophosphamide, 75 mg fludarabine) was done before CAR T cell infusion. SLE disease activity was sequentially monitored over at least one year with a maximum of up to two years. Autoantibodies (reactivities against double stranded (ds) DNA, single stranded (ss) DNA, nucleosomes, secondary necrotic cells, Smith antigen and Ro60 antigen) were measured at baseline, 3 months after CAR T cell therapy and at last follow-up (1-2 years after CAR T cell therapy). In addition, vaccination responses against measles, mumps, rubella, varicella zoster virus (VZV), Epstein Barr virus (EBV), tetanus and pneumococcus (PC) were assessed. All the antibody measurements were done by commercial ELISA. Anti-dsDNA antibodies were additionally measured by radioimmunoassay (RIA).

Results: Between March 2021 June 2023 8 SLE patients received treatment with CD19 CAR T cell therapy. Five patients had a follow up of more than one year post CAR T cell infusion. All 8 patients fulfilled DORIS remission criteria at time of writing the abstract (June 2023), had a SLEDAI-2K equal to zero and were off glucocorticoid therapy and any other

Figure 1 A

	dsDNA RIA	dsDNA	ssRNA	NUC	SNEC	Sm	Ro60

Follow Up (1-2 years)	0 [0; 0]	0 [0; 0]	0 [0; 0]	0 [0; 257]	0 [0; 0]	0 [0; 0]	0 [0; 84]

Figure 1 B

	Measles	Mumps	Rubella	Tetanus	VZV	EBV	PC
Before CAR T cells	636 [168; 1278]	196 [83; 980]	11 [8; 49]	0.97 [0.07; 1.38]	1367 [306; 2000]	32.4 [0; 49.1]	11.8 [3.5; 31.6]
Follow Up (1-2 years)	461 [50; 827]	67 [46; 255]	10 [6; 30]	1.33 [0.07; 1.96]	770 [290; 1214]	33.7 [0; 46.7]	13.1 [8.4; 105]

immunosuppressive medication. Autoantibodies against dsDNA (4/5), ssDNA (4/5), nucleosomes (5/5), secondary necrotic cells (4/5) and Smith antigen (3/5) disappeared after CD19 CAR T cell therapy with the exception of nucleosome antibody response in one patient and remained negative until the last follow-up (12-24 months after treatment) (Table 1A). Also RIA-based detection of anti-dsDNA antibodies showed sustained seroconversion. Ro60 activity, which was found in one patient, remained stable throughout the observation period but did apparently no impact disease activity. In contrast to autoantibodies, antibody reactivities against measles, mumps, rubella, VZV, EBV, tetanus and PC remained stable 12-24 months after treatment (Table 1B).

Conclusion: CD19 CAR T cells therapy lead to a sustained disappearance of autoantibodies in SLE patients, while vaccination responses remained stable. This observation suggests that the main cellular source of autoantibodies in SLE are CD19+ plasmablasts, which are depleted by CD19 CAR T cells, while antibodies related to vaccination responses appear to predominantly stem from CD19-negative plasma cells. The selective and sustained abrogation of disease specific autoimmunity without affecting vaccination responses provides a favorable combination for the safety and efficacy of CD19 CAR T cell therapy in SLE.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: SLE – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Cenerimod is an orally active, selective sphingosine 1-phosphate (S1P) 1 receptor modulator under investigation for the treatment of systemic lupus erythematosus (SLE). In the Phase 2 CARE study (NCT03742037), patients treated with cenerimod 4 mg showed reduced disease activity versus placebo after 6 months.[1]

Type-1 interferon (IFN-1) activation is a robust biomarker of SLE disease activity, and an elevated IFN-1 signature associates with autoantibodies and more active disease. Cenerimod reduces plasma levels of IFN-α and leads to decreased circulating B and T cells in patients with SLE, suggesting effects on innate and acquired immune responses.

Table 1. Resolution of alopecia and arthritis (assessed by SLEDAI) at Month 6 by baseline IFN-1 gene expression signature. IFN-1, interferon 1. Overall population refers to all randomized patients.

		IFN-1 gene expression signature		Overall
	Treatment group	High	Low	population
Alopecia	Cenerimod 4 mg, n (%)	10/26 (38.5)	8/31 (25.8)	19/60 (31.7)
	Placebo, n (%)	4/28 (14.3)	2/30 (6.7)	7/62 (11.3)
Arthritis	Cenerimod 4 mg, n (%)	20/35 (57.1)	12/43 (27.9)	33/83 (39.8)
	Placebo, n (%)	15/40 (37.5)	16/38 (42.1)	32/84 (38.1)

Here the efficacy of cenerimod in patients with high IFN-1 gene expression signature and high anti-dsDNA antibody levels is presented, as reported at EULAR 2023.[2]

Methods: CARE randomized 427 patients with SLE to once-daily cenerimod (0.5, 1, 2, 4 mg) or placebo. At month (M) 6, patients on 4 mg cenerimod were re-randomized to placebo or cenerimod 2 mg for the remaining 6 months; other groups continued their initially assigned treatment to M12. The primary endpoint was change from baseline to M6 in SLEDAI-2K score modified to exclude leukopenia (mSLEDAI-2K) due to the mechanism of action of cenerimod.

Subgroup analyses were performed in patients with high IFN-1 gene expression signature (based on expression of *IFI27*, *RSAD2*, *HERC5*, and *IFIT1*) or anti-dsDNA levels ≥30 IU/mL.

Results:

At baseline, 207/408 patients (51%) in CARE had high IFN-1 gene expression signature [including 36 (45%) and 40 (50%) on cenerimod 4 mg and placebo, respectively], and 86/426 (20%) had anti-dsDNA antibody levels ≥30 IU/mL [21 (25%) and 15 (17%) for cenerimod 4 mg and placebo, respectively]. There was an association between high IFN-1 gene expression signature and high anti-dsDNA levels, with more than 75% of patients with anti-dsDNA levels ≥30 IU/mL having high IFN-1 gene expression signature.

Cenerimod 4 mg resulted in decreased levels of anti-dsDNA antibodies and IFN-a protein at M6 versus baseline. In patients with high IFN-1 gene expression signature or high anti-dsDNA, 4 mg cenerimod led to greater reductions of disease activity versus placebo, as measured by mSLEDAI and SRI-4 at M6.

More patients with high IFN-1 gene expression signature at baseline had resolution of arthritis and alopecia at M6 in the treatment arm versus patients with the low IFN-1 gene expression signature (Table 1).

Conclusion: Treatment with cenerimod 4 mg resulted in greater reduction of disease activity versus placebo at M6 in patients with baseline high IFN-1 gene expression signature or high anti-dsDNA antibody levels. Cenerimod treatment also reduced levels of IFN-α protein and anti-dsDNA antibodies in these patients. Two Phase 3 studies designed to evaluate the treatment effect of cenerimod 4 mg in SLE are underway.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Autologous hematopoietic stem cell transplantation (HSCT) has benefitted some patients with autoimmune disease (AD) but is associated with toxicity and treatment-related mortality. Autologous HSCT is an option, particularly in scleroderma, a disease associated with high mortality. We aimed to describe individuals undergoing autologous HSCT for AD, including scleroderma, and to evaluate mortality post-HSCT.

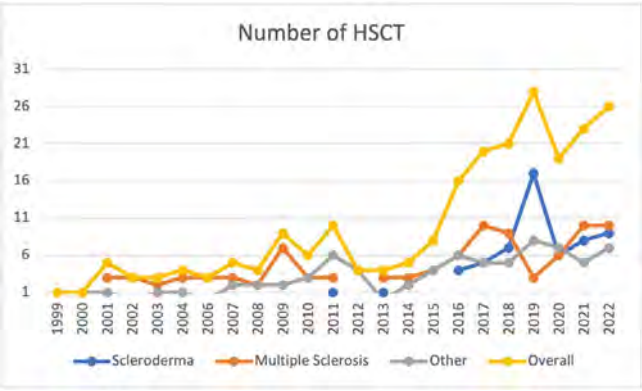

Figure 1. Number of HSCT performed at two Canadian tertiary care centers, per year, overall and stratified by indication.

Methods: CAN-AIM is a team funded to do high-priority research projects for Health Canada and other stakeholders. We employed chart review to analyze data from blood and marrow transplant programs at two Canadian tertiary care centres. We included consecutive adults (18+) who underwent autologous peripheral blood HSCT for AD from 1999-2022. Patient characteristics were summarized using median/interquartile range (IQR) or frequency/percentage. We calculated the mortality rate per 1,000 person-years (PY), calculated from index date (HSCT) to death, loss to follow-up, or end of study. Overall survival was calculated for 2 and 5 years after transplant. To compare mortality in scleroderma versus other AD, we calculated adjusted hazard ratios (aHR) with 95% confidence intervals (CI), adjusting for age at transplant, sex, time from AD diagnosis to HSCT, and calendar year.

Results: We studied 228 individuals who underwent HSCT, most commonly for multiple sclerosis (42%) and scleroderma (26%). Over half of the sample (54%) were women. The median age at HSCT was 40 (IQR 33-49), with a median time between AD diagnosis and HSCT of 4.7 years (IQR 2.4-9.1). The frequency of HSCT for AD increased across the years, and although numbers sharply decreased in 2020 (due to COVID), it is on the rise again (Figure 1). Over a median follow-up of 3.9 years (IQR 1.7-6.5), 28 of 228 patients died (23 deaths/1,000 PY). Less than a third (27%) of deaths were due to AD progression/relapse (5.7 per 1,000 PY). 35% were due to HSCT complications (defined as occurring within the first 100 days, including respiratory complications, n=3; multi-organ failure, n=2 and infections, n=2), and 38% were due to late events that occurred beyond the 100 days post-HSCT (sudden death, infection, organ failure, and cancer) including late HSCT toxicity. We observed similar results for males versus females (Figure 2). Survival at 2 years post-HSCT was 94% and 89% at 5 years, and slightly lower for scleroderma (Table 1). There was a trend in univariate analyses (HR 0.45, 95% CI 0.18-1.09) for worse survival in scleroderma (half of the deaths were due to disease relapse), which disappeared after controlling for sex, age, time since diagnosis, and calendar year (adjusted HR 0.98, 95%CI 0.32-2.95).

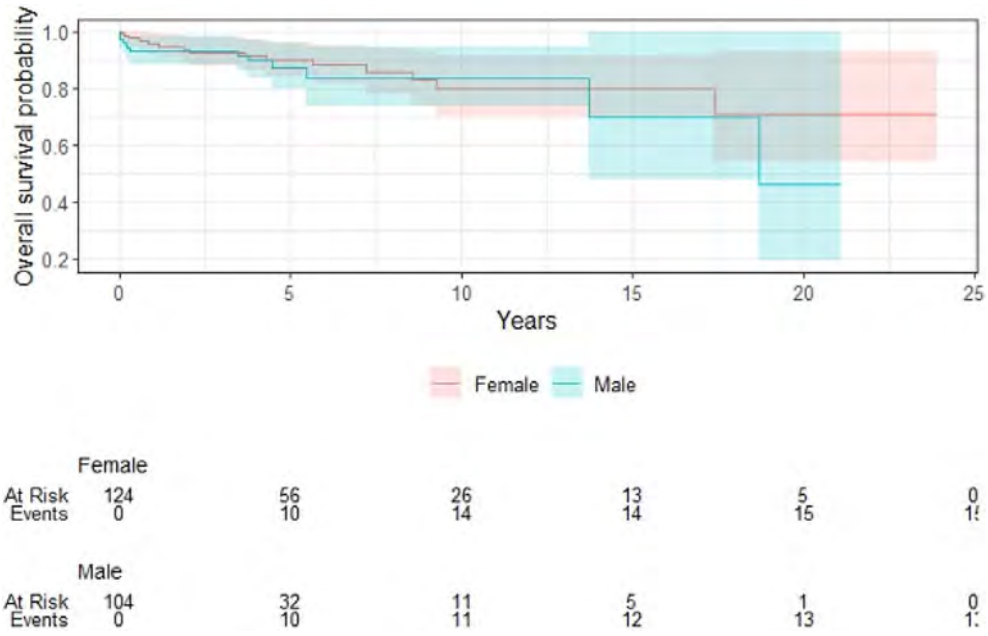

Figure 2. Kaplan-Meier curve estimating survival time between date of transplant and death or last follow-up (censor) from the transplant program, stratified by biological sex.

Table 1. Overall survival (95%CI) at 2 and 5 years after HSCT, stratified by sex at birth and restricted to scleroderma patients.

	Overall	Male	Female	Scleroderma
100 days	96.0% (93.5%-98.6%)	94.2% (89.9%-98.8%)	97.6% (94.9%-1.00%)	98.3% (95.1%-1.00%)
2 years	93.6% (90.4%-96.9%)	93.2% (88.5%-98.2%)	93.8% (89.4%-98.4%)	92.2% (85.0%-99.9%)
5 years	88.9% (84.3%-93.9%)	87.4% (79.7%-95.7%)	89.9% (84.0%-96.2%)	68.6% (49.0%-96.1%)

Conclusion: Adults undergoing HSCT for AD have a high survival rate of up to 5 years. A trend to worse outcomes in scleroderma may be due to differences in demographics (i.e. age distribution), time trends, and/or other factors.

Abstract Number: 0610

Nailfold Capillaroscopy for Prediction of Novel Severe Organ Involvement in Systemic Sclerosis

Cristiana Sieiro Santos[1], Rúben Rego Salgueiro[2], Clara Moriano Morales[3], Carolina Álvarez Castro[3] and Elvira Díez Álvarez[3], [1]Complejo Asistencial Universitario de León, León, Spain, [2]ULS Guarda, Guarda, Portugal, [3]CAULE, León, Spain

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Nailfold capillaroscopy (NFC) has been suggested as a potential biomarker of disease severity in systemic sclerosis (SSc). Several studies report the association between capillary loss and disease severity however, the association of NFC abnormalities with novel severe organ involvement/progression in SSc has not been evaluated. We aim to evaluate the association of nailfold capillaroscopy (NFC) with novel major organ involvement/progression in SSc.

Methods: Follow-up data from patients with SSc registered between 2000 and 2022 were analysed. Patients underwent NFC at baseline. Novel severe organ involvement/progression was defined as new or progressive involvement of peripheral vasculature, lungs, heart, skin, gastrointestinal, kidney, musculoskeletal at 12 and 24 months of follow-up. The following NFC parameters were evaluated: capillary density, haemorrhages, enlarged and giant capillaries, avascular areas, organization of capillary architecture and scleroderma pattern (early/active/late). Logistic regression modelling was run to assess associations between NFC parameters and the occurrence of novel severe organ involvement and/or progression and risk factors.

Results: 113 patients with SSc were included, 70 patients (61%) developed novel overall severe organ involvement/progression: 39 patients (56%) during the first 12 months and 31 patients (44%) from 12 to24 months of follow-up. 11% of patients developed novel peripheral vascular involvement, 21% developed novel interstitial lung disease (ILD), 11% had progression of known ILD, 6% had novel pulmonary hypertension, 11% had skin progression, 10% had novel heart involvement, 10% had novel gastrointestinal involvement, 6% had scleroderma renal crisis and 13% had novel musculoskeletal involvement. Table 1 summarizes the associations between NFC and novel severe organ involvement/progression during follow-up. Loss of capillary density was associated with overall severe organ involvement (p 0.002), peripheral vascular involvement (p 0.03), new ILD (p 0.04) and skin progression (p 0.01); avascular areas were associated with overall severe organ involvement (p 0.03), new ILD (p 0.03) and progression of ILD (p 0.02) and scleroderma pattern was associated with overall severe organ involvement (p 0.03), peripheral vascular involvement (OR p 0.04), new ILD (p 0.004), progression of ILD (p 0.03) and skin progression (p 0.04).

Novel severe involvement or progression	Loss of capillary density	P value	Haemorrhages	P value	Enlarged capillaries	P value	Avascular areas	P value	Scleroderma pattern	P value
Overall future organ involvement	**3.21 (1.02-5.45)**	**0.002**	1.82 (0.82-4.52)	0.82	1.09 (0.52-3.23)	0.72	**2.1 (1.34-6.23)**	**0.03**	**1.82 (1.12-4.25)**	**0.03**

Demographics and Clinical Features Associated with Small Bowel Hypomotility in Systemic Sclerosis

Jenice Cheah[1], Jamie Perin[2], Michael Hughes[3], Julie Paik[4], Christopher Mecoli[2], Laura Hummers[4], Ami Shah[5], Fred Wigley[6] and Zsuzsanna McMahan[7], [1]University of California Los Angeles, Los Angeles, CA, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Tameside and Glossop Integrated NHS Foundation Trust & The University of Manchester, Manchester, United Kingdom, [4]Johns Hopkins University, Baltimore, MD, [5]Department of Medicine, Division of Rheumatology, Johns Hopkins University School of Medicine, Ellicott City, MD, [6]Department of Rheumatology, Johns Hopkins Medicine, Baltimore, MD, [7]Johns Hopkins Rheumatology, Lutherville, MD

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The gastrointestinal (GI) tract is the second most commonly affected organ in patients with systemic sclerosis (SSc). It is estimated that the small bowel is involved in up to 50% of SSc patients at tertiary referral centers. Although some patients have mild disease, some have severe complications and may require total parenteral nutrition (TPN) to sustain life. Our aim was to identify demographic and clinical features associated with SSc patients who have delayed small bowel transit to better characterize patients at risk for this complication.

Methods: SSc patients with GI symptoms were prospectively enrolled in our study and underwent a scintigraphy-based whole gut transit (WGT) study. A cross-sectional analysis was then performed comparing demographic and clinical features between patients with and without objective small bowel transit delay by WGT. We also compared UCLA GIT 2.0 symptoms between these patient groups. Univariate logistic regression models were used to examine clinical features associated with delayed small bowel transit and a multivariable model was created using significant variables from our cross-sectional analysis and known confounders to further evaluate these associations.

Results: Of 131 patients enrolled in this study, 24 (18%) had delayed small bowel transit (defined at < 49% emptying at 6 hours). Patients with delayed small bowel transit were less likely to be female [79%, (19/118) vs. 93% (99/118); p=0.05], to be white [67%, (16/105) vs. 84% (89/105); p=0.05], and to have sicca symptoms [68% (15/107) vs. 89% (92/107);

Multivariable model evaluating the association between SSc clinical features and delayed small bowel transit after adjusting for sex and race

Covariate	Univariate model; OR (95% CI)	Multivariate model; OR (95% CI)
Maximum MRSS	1.05 (1.00, 1.11)†	1.05 (0.99, 1.11)
Myopathy	2.47 (0.91, 6.72)	2.53 (0.89, 7.22)
Cardiac involvement (≥2)	3.54 (1.00, 12.52)†	2.54 (0.64, 10.07)
Tendon friction rub	3.53 (0.90, 13.85)	2.76 (0.66, 11.58)
Sicca symptoms	0.26 (0.09, 0.76)†	0.29 (0.10, 0.90)†
Dead	3.76 (1.19, 11.94)†	
Pulmonary fibrosis	0.96 (0.35, 2.62)	0.84 (0.30, 2.42)
Pulmonary function parameters		
DLCO % predicted	0.97 (0.95, 1.00)†	0.97 (0.95, 1.00)
Anti-RNA polymerase III	7.00 (0.88, 55.41)	3.79 (0.33, 43.25)

†Statistically significant

SSc = Systemic sclerosis; WGT= whole-gut transit scintigraphy study; MRSS = modified Rodnan Skin Score; Cardiac involvement = maximum Medsger cardiac severity score ≥ 2; Normal DLCO = diffusing capacity of carbon monoxide >60%

p=0.01]. Those with delayed small bowel transit were more likely to have low (worse) mean DLCO (51% vs. 68%, p=0.03) and were more likely to die [26% (6/15) vs. 9% (9/15); p=0.02]. In the univariate analyses, we determined that a higher modified Rodnan skin score [Odd's ratio (OR)=1.05, confidence interval (CI) 1.00-1.11, p=0.05], more cardiac involvement (OR=3.54, CI 1.00-12.52, p=0.05), less sicca symptoms (OR=0.26, CI 0.09-0.76, p=0.02), and lower DLCO (OR=0.97, CI 0.95-1.00, p=0.03) were associated with delayed small bowel transit. In the multivariable model, sicca symptoms (OR=0.29, CI 0.10-0.90, p=0.03) remained negatively associated with delayed small bowel transit.

Conclusion: These findings suggest delayed small bowel transit in SSc is associated with a high mortality and a specific clinical phenotype. Recognizing patients at risk for delayed small bowel transit is important for clinical care and in the design of future studies evaluating this high-risk group.

COVID Vaccinations and Infections Among Individuals with Systemic Sclerosis: A Scleroderma Patient-centered Intervention Network (SPIN) Cohort Study

Kimberly Lakin[1], Jessica Gordon[1], Yin Wu[2], Linda Kwakkenbos[3], Marie-Eve Carrier[2], Richard Henry[2], Christopher Denton[4], Luc Mouthon[5], Robert Spiera[6] and Brett Thombs[2], [1]Hospital for Special Surgery, New York, NY, [2]Lady Davis Institute for Medical Research, Jewish General Hospital, Montreal, QC, Canada, [3]Radboud University, Nijmegen, Netherlands, [4]University College London, London, United Kingdom, [5]Hopital Cochin - Paris University, Paris, France, [6]Hosptial for Special Surgery, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: We previously surveyed individuals with systemic sclerosis (SSc) enrolled in Scleroderma Patient-centered Intervention Network (SPIN) Cohort between April-May 2021 to determine COVID-19 vaccination rates, adverse reactions, and vaccine hesitancy. The purpose of the present study was to extend analyses through June-July 2022 and assess (1) COVID vaccination rates, including boosters; (2) vaccine-related adverse events from primary series and booster vaccine doses; (3) peri-vaccination immunosuppressive (IS) medication management; (4) vaccine hesitancy and perceptions; and (5) rate and severity of self-reported COVID-19 in SSc.

Methods: Participants were adults with SSc enrolled in the SPIN Cohort, which includes 47 centers from seven countries. Participants from the SPIN Cohort, including those who did and did not complete the 2021 survey, were invited to complete the second survey from June 1 to July 4, 2022. The survey included items related to COVID-19 history, COVID-19 vaccinations, and perceptions related to COVID-19 vaccines. Participants were considered "fully vaccinated" if they had completed a primary vaccine series and received at least one booster dose.

Results: 544 participants answered the 2021 survey only, 101 answered the 2022 survey only, and 388 answered both. Participant characteristics are shown in Table 1. 437 of 489 (89%) participants who completed the 2022 survey received a booster dose. 18 of 31 (58%) participants who were vaccine hesitant in 2021 were vaccinated by the 2022 survey. Adverse events following primary vaccine and booster doses are shown in Table 2. SSc symptom worsening was reported after the first and second vaccine dose in 6% (53 of 960 and 39 of 657, respectively) and after the booster dose in 4% (17 of 437) (Table 2). Of 157 patients taking methotrexate (MTX) or mycophenolate (MMF), 129 (82%) held those at the time of booster vaccination. Of 58 individuals not fully vaccinated, 29 (50%) were worried that the vaccine would cause an SSc flare; 19 (33%) indicated that they did not have enough information to decide about vaccination. 172 of 489 (35%) from the 2022 survey reported a history of COVID-19 (Table 3), 114 (66%) of which occurred after completing a primary vaccine series. 9 (5%) were asymptomatic, 66 (44%) had mild symptoms, 82 (48%) had moderate symptoms, and 15 (9%) required hospitalization. Of those 15 hospitalized individuals, 9 (60%) were taking at least one IS medication, 11 were fully vaccinated, 3 were partially vaccinated, and 1 was unvaccinated at the time of hospitalization.

Conclusion: Most participants were fully vaccinated, and a majority held their MTX or MMF post-booster vaccination, which is aligned with recent American College of Rheumatology Guidance. Most vaccine-hesitant participants were concerned regarding risk of SSc flare; however, few vaccinated participants reported an SSc flare following primary (6%) or booster

a. Indicates at least one COVID infection. 11 participants had two infections, and 1 participant had three infections; b. Fully vaccinated indicates the participant completed a primary vaccine series and had received at least one booster dose. c. N = 488. For the group of no history of COVID, N = 316. d. N=453, for the group with history of COVID, N = 155, and for the group of no history of COVID, N = 298; e. Includes prednisone and/or methylprednisolone or prednisolone; f. The following four variables were not available among the Survey 2 only participants, so N = 388.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: No quantitative and objective methods for measuring skin hardness have been established. Japanese technology leads the world in the tactile sensor field, and SOFTGRAM has received an award from the Going-Global Innovations Competition 2019.This study aimed to verify whether SOFTGRAM, a device that can measure elastic modulus using the Hertz elastic contact theory, could be used to evaluate skin hardness in systemic sclerosis (SSc). As a far-reaching effect, this study might be one of the triggers to progress a diagnosis with medical artificial intelligence systems for various diseases.

Methods: Skin score according to the modified Rodnan's total skin thickness score and elastic modulus of the skin using SOFTGRAM were measured for 20 patients with SSc and 20 healthy controls on 8 parts, both of the cheeks, forearms, fingers, and hands (Figure 1). Five observers shared to measure skin score 320 times (40 participants × 8 parts). Elastic modulus was measured 1600 times (40 participants × 8 parts × 5 times each). As an additional examination to compare differences among observers, the skin score of another healthy control was measured 40 times (5 observers × 8 parts). Elastic modulus was measured 200 times (5 observers × 8 parts × 5 times each).

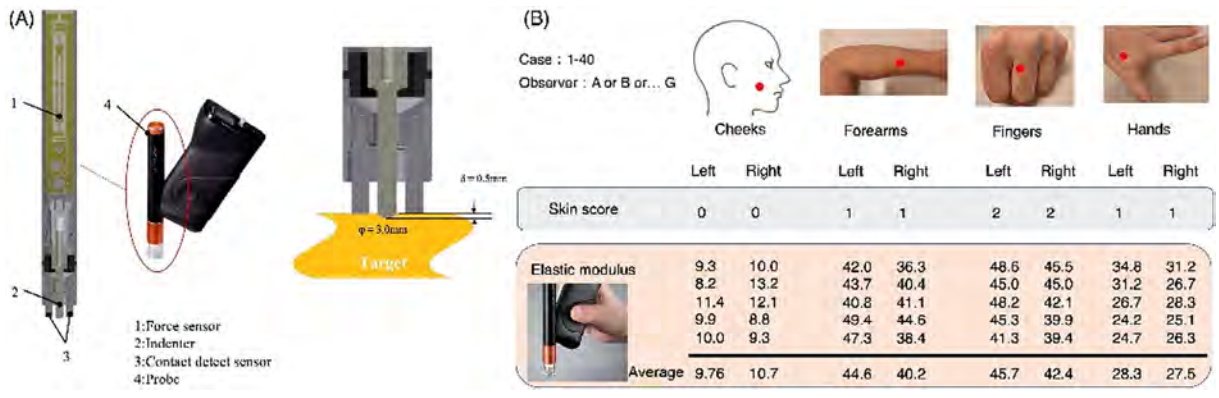

Figure 1. (A) Sensing device. (B) Measurement points and an example.

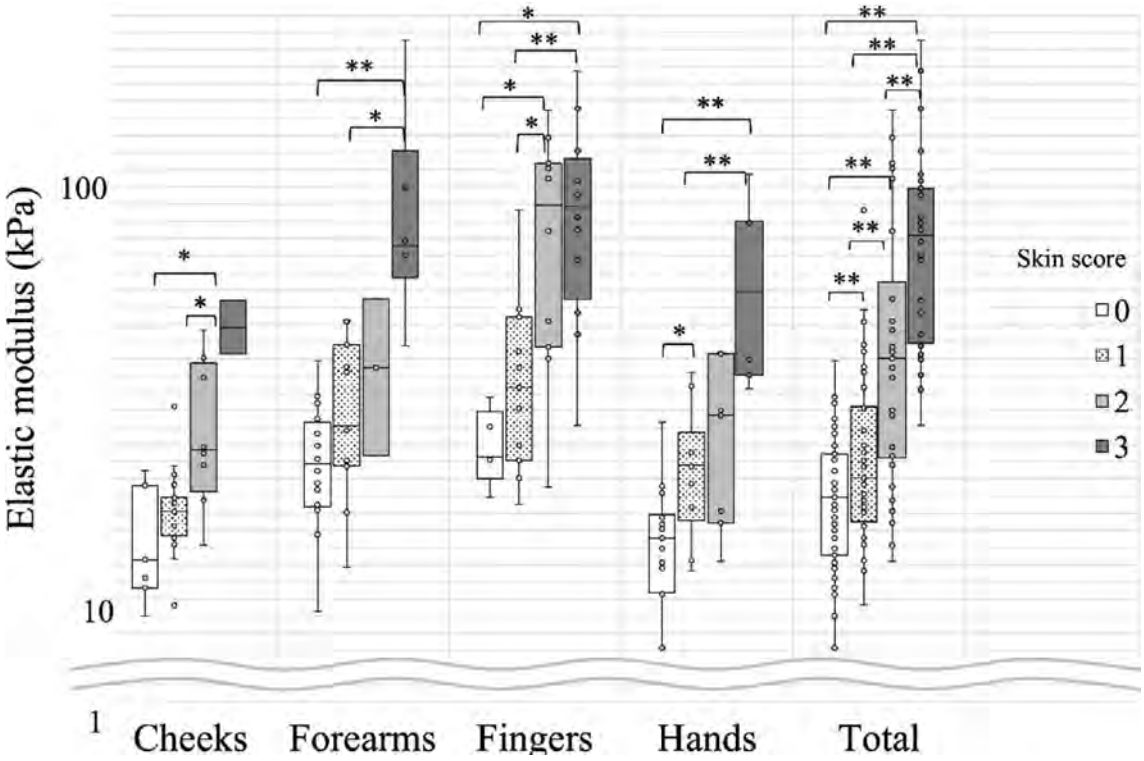

Figure 2. Correlation between elastic modulus (logarithmic scale) with SOFTGRAM and skin score of 40 participants (*p<0.05, **p<0.01).

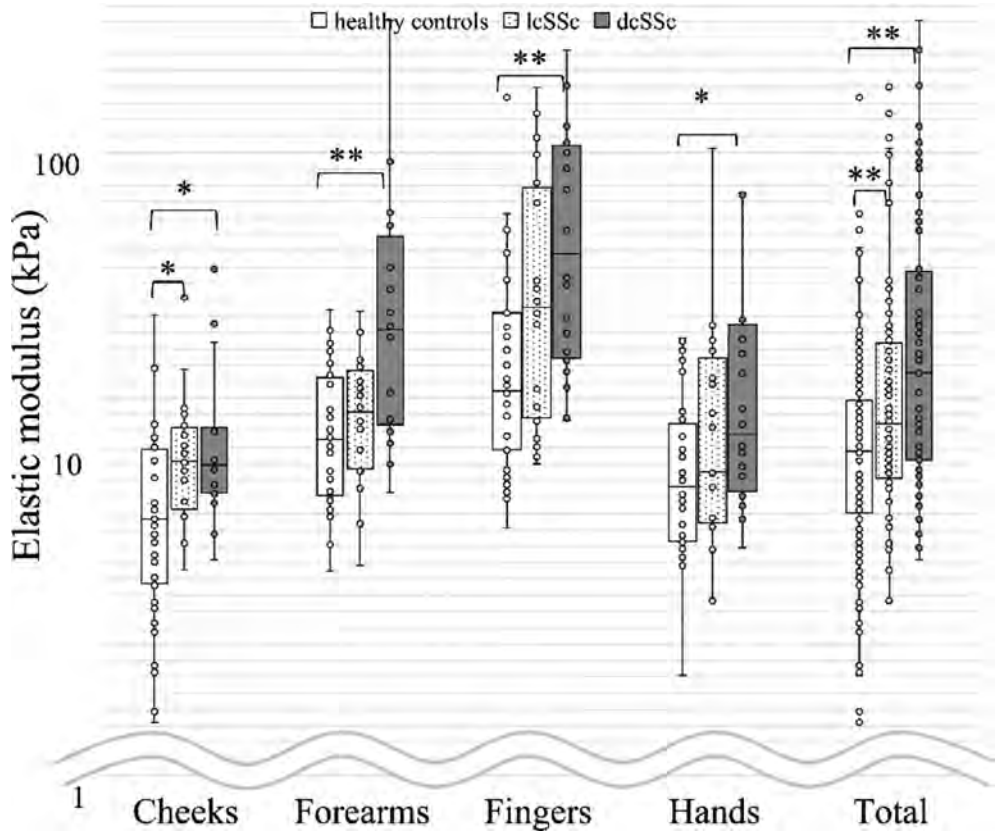

Figure 3. Elastic modulus of healthy controls, lcSSc, and dcSSc patients (*p<0.05, **p<0.01).

Results: Data were collected from 20 healthy Japanese controls (1 male and 19 females; 63.2±12.3 years old), 10 lcSSc patients (10 females; 65.9±6.3 years old), and 10 dcSSc patients (1 male and 9 females; 58.8±14.9 years old).Our findings reveal a significant correlation between elastic modulus and skin score (correlation coefficient=0.67, $p< 0.001$; Figure 2). Furthermore, we observed significant differences in elastic modulus among healthy controls, limited cutaneous SSc, and diffuse cutaneous SSc (22.6±15.7 vs. 32.0±27.7 vs. 44.8±39.8, $p< 0.001$; Figure 3). Intraobserver reliabilities were sufficient in 6 of 7 observers; however, interobserver was less satisfactory.It would be because elastic modulus depended on the skin position and the power and speed to push by SOFTGRAM. Regarding the skin position, bone hyperreflection might affect elastic modulus. If SOFTGRAM is improved to measure only the more shallow parts, the effect of bone hyperreflection might be minimal.

Conclusion: SOFTGRAM has many advantages compared to previous methods. This study showed the practicality of SOFTGRAM as an accurate measurement method of skin hardness but also revealed points to be improved. SOFTGRAM will have further improvements, and sensing devices will be able to useful especially for clinical trials and research.

Self-Reported Sexual Dysfunction and Perceptions of Rheumatologist Engagement on This Issue in Patients with Systemic Sclerosis

Liza Morales[1], Robert Spiera[2], Jessica Gordon[1], Deanna Jannat-Khah[1] and Kimberly Lakin[1], [1]Hospital for Special Surgery, New York, NY, [2]Hosptial for Special Surgery, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Few studies have investigated the prevalence and risk factors of sexual dysfunction among individuals with systemic sclerosis (SSc). The purpose of this study is to define, among individuals with SSc, (1) the prevalence and risk factors associated with sexual dysfunction, (2) the frequency of discussions regarding this subject, and (3) patient-perceived barriers to those discussions.

Methods: We developed the Sexual Function in SSc Questionnaire (SFSScQ) to anonymously survey individuals with self-reported SSc regarding their sexual function and sexual health discussions with their MD rheumatologist. Participants were asked to complete the SSFSScQ and to complete the Female Sexual Function Index (FSFI) or the International Index of Erectile Function (IIEF) Questionnaire based on self-reported sex. Participant characteristics between those with vs. without self-reported sexual dysfunction were compared using Fisher's Exact test. Agreement to statements regarding potential barriers to sexual function conversations were compared between those who reported feeling satisfied vs. not satisfied with sexual

Table 1. Bivariate comparison between participants with systemic sclerosis who self-reported sexual dysfunction and participants who did not by characteristics and demographics.

health discussions using Fisher's Exact test. Univariable and multivariable logistic regression were performed to assess factors associated with sexual dysfunction.

Results: 41 participants completed the SFSScQ; 30 (73%) also completed the FSFI or IIEF. 26 (63%) participants reported sexual dysfunction. Clinical characteristics of those with vs. without self-reported sexual dysfunction are shown in Table 1. In both unadjusted and adjusted regression models, age, sex, race, SSc subtype, and time since SSc diagnosis were not predictors of sexual dysfunction. Self-reported sexual dysfunction was not associated with the presence of sexual dysfunction on the scored questionnaires (p=0.431); 25% of individuals who self-reported sexual dysfunction did not meet scored questionnaire criteria (Table 2). 36 (88%) of 41 participants had never discussed sexual health with their rheumatologist, of whom 23 (64%) self-reported sexual dysfunction. 19 (46.3%) participants agreed that having conversations with their rheumatologist regarding sexual function was important. Most (33 (81%)) were not satisfied with the sexual health discussions they have had to-date (Table 3). Patients who were satisfied (vs. not satisfied) with their sexual health discussions more often felt comfortable discussing sexual function with their rheumatologist (p=0.012), believed their rheumatologist makes time to discuss sexual function (p=0.003), and felt that their rheumatologist has been helpful regarding sexual function (p=0.002) (Table 3).

Conclusion: A majority of participants with self-reported SSc indicated that they experience sexual dysfunction but have never discussed sexual health with their rheumatologist. No patient-level factors were identified as independent predictors of sexual dysfunction; however, our sample size is small. Self-reported sexual dysfunction was not associated with sexual dysfunction determined by scored questionnaires, suggesting that SSc sexual dysfunction may encapsulate disease specific complaints not captured by surveys designed for other populations.

Abstract Number: 0615

Prevalence of Barrett's Esophagus in Patients with Systemic Sclerosis

FNU Rida Ul Jannat[1], Devanshu Verma[1] and Laila Sakkal[2], [1]West Virginia University Hospital, Morgantown, WV, [2]West Virginia University, Morgantown, WV

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Gastrointestinal manifestations of systemic sclerosis are common and include luminal dysmotility. Esophageal aperistalsis (scleroderma esophagus) presents with dysphagia and reflux; and can predispose patients to esophagitis, theoretically increasing the risk for Barrett's esophagus, which is a known risk factor of esophageal adenocarcinoma. However, no current data is available in literature regarding the risk of Barrett's esophagus or esophageal adenocarcinoma in patients with SS.

Methods: A retrospective cohort study was conducted using the multi-institutional research network TriNetX. All patients with systemic sclerosis (age 16 and above) were identified. Prevalence and incidence proportion of Barrett's esophagus were calculated for the year 2022.

Table 1: Baseline characteristics of patients with Systemic Sclerosis and Barrett's Esophagus before and after propensity score matching.

Variables	Before the propensity score match			After the propensity score match		
	SS cohort Mean±SD or Number (%)	Control cohort Mean±SD or Number (%)	SMD	SS cohort Mean±SD or Number (%)	Control cohort Mean±SD or Number (%)	SMD

Baseline characteristics of patients with Systemic Sclerosis and Barrett's Esophagus before and after propensity score matching

Propensity matched analysis was then performed, utilizing age, gender, race, presence of GERD, and history of smoking as covariates, to compare rates of BE diagnosis at index endoscopy in patients with and without SS who underwent EGD during the study time period.

Results: A total of 60,907 patients with SS were identified in the research network. The prevalence and incidence proportion of Barrett's esophagus in patients with SS during 2022 were calculated to be 3.96% and 0.39% respectively. Incidence rate of BE diagnosis in the cohort was 0.000014 cases/ person day. The prevalence and incidence rate of Barrett's esophagus in patients without SS during the same period was 0.54% and 0.074% respectively.

Patients with SS who underwent EGD examinations were identified and 1:1 propensity score matching was performed to identify a control cohort of patients without SS who underwent index EGD during the study period (10,808 patients in each cohort). In PSM analysis, the risk of Barrett's esophagus diagnosis at index esophagogastroduodenoscopy (EGD) was not different between patients with systemic sclerosis compared to patients without SS who underwent EGD for any indication [3.67% vs 3.37 %, RR: 1.09 (0.95 – 1.25)]. However, the risk of BE esophagus diagnosis at any time during follow up was higher in patients with SS [8.11% vs 6.17%, RR: 1.32 (1.19-1.45)]. No difference was noted in rates of esophageal cancer diagnosis in the two cohorts [0.86% vs 0.96%, RR: 0.89 (0.68-1.18)].

Conclusion: The prevalence and incidence rate of BE diagnosis in patients with SS is high. Provider vigilance is advised, and EGD screening and proton pump inhibitor therapy should be considered in patients with SS with upper GI symptoms.

Abstract Number: 0616

Does Systemic Sclerosis Affect the Interpretation of Mammograms? A Retrospective Cohort Study

Lea Meir[1], Tegveer Sandhu[2], Weiwei Chi[2] and **Gabriela Santiago**[2], [1]Icahn School of Medicine, New York, NY, [2]Icahn School of Medicine at Mount Sinai, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Sclerosis is an autoimmune disorder marked by thickened and hardened skin. Cutaneous cutis, the deposition of insoluble calcium salts in the skin and subcutaneous tissues, occurs frequently in patients with systemic sclerosis. Breast mammography is a screening tool used to detect breast cancer. Approximately 10% of all patients have abnormal mammograms with areas of calcification, which may be a sign of malignancy. There has been no formal study to date evaluating the mammograms of patients with systemic sclerosis. This study compared the mammograms and breast biopsies of systemic sclerosis patients with that of age matched controls.

Methods: Patients diagnosed with systemic sclerosis and with mammograms done at Mount Sinai Hospital between 01/01/2017 and 01/11/2022 were identified using the Reports function in Epic. The results of these mammograms and subsequent breast biopsy results were analyzed. Participants' race/ethnicity, serologic markers, clinical features, use of immunosuppressive medications, and duration of systemic sclerosis diagnosis were determined by chart review. These results were compared to age matched controls with abnormal mammograms and breast biopsies. The primary outcome was the frequency of false positive abnormal mammography findings. Sub-analysis was performed among the patients with systemic sclerosis comparing patients with malignancy found on breast biopsy to those with benign findings. Chi Square analysis and Independent Sample T test were used to check for statistical significance.

Results: Of the patients with systemic sclerosis, more than a third of these patients (36%) were found to have had calcifications on their mammograms. 29/152 (19%) were found to have abnormal breast mammograms and were referred for breast biopsy. Of these patients, 34.5% were diagnosed with a malignancy after completing their breast biopsy. 65.5% of the scleroderma patients were found to have false positive screening mammograms versus 67% of the age-matched control group. Sub-analysis within the scleroderma cohort found no statistically significant differences in serologic markers or clinical features amongst patients with breast cancer compared to those without breast cancer. Of the systemic sclerosis patients found to have had true malignancies, only 1 (10%) was taking hydroxychloroquine, while 10 (52.6%) of patients with false positive mammograms were taking hydroxychloroquine. There were no other statistically-significant differences in terms of medication usage.

Conclusion: Approximately 1/5th of patients with systemic sclerosis were found to have abnormal breast mammograms. There were no significant differences in the rate of false positive mammograms in patients with systemic sclerosis and healthy controls.

Pulmonary Rehabilitation in Connective Tissue Disease-Related Interstitial Lung Diseases

Rosemary Gedert[1], Suiyuan Huang[2], Maya Sabbagh[2], Melissa McInroy[2], Steven Huang[2], Dinesh Khanna[2] and Vivek Nagaraja[3], [1]University of Michigan, Onsted, MI, [2]University of Michigan, Ann Arbor, MI, [3]Mayo Clinic Arizona, Scottsdale, AZ

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a common manifestation of connective tissue disease (CTD)[1]. Pulmonary rehabilitation (PR) can be utilized to improve dyspnea and quality of life in patients with chronic lung conditions, including both obstructive and restrictive lung diseases[2]. This study aims to determine if PR can be a useful therapy to improve dyspnea and hall walk in CTD-ILD.

Methods: Patients at a tertiary center who were referred to PR rheumatology as the standard of care were enrolled in this study. To determine the outcomes of patients who underwent PR, pulmonary function tests (PFTs), 6-minute walk test (6MWT), and patient-reported outcomes (PROs) including PROMIS Dyspnea, St George Respiratory Questionnaire

Table 1: Baseline Demographics. *Three subjects did not fall into the CTD types above. One patient had high titer anti-CCP, one had Sjogren's and Polymyositis, one had Undifferentiated CTD.

Variable	Statistics (n=21)
Age (year), Mean (Standard Deviation)	65.5 (8.0)
Type of CTD, n (%)	
Systemic Sclerosis	16 (76.2%)
Rheumatoid Arthritis	2 (9.5%)

Baseline	45.3 (12.6)

Table 2: Average 6MWD and PROMIS dyspnea scores were recorded at baseline and 8 weeks after starting PR. Mean (Standard Deviation) is reported in table above.

Primary Outcome Measures	Baseline	Week 8	Difference	p-value
6MWD (meters), n=18	402.3 (114.3)	447.3 (94.8)	45.1 (63.0)	**0.007**
PROMIS Dyspnea				
Characteristics, n=21	17.2 (11.7)	15.5 (9.2)	-1.7 (7.7)	0.26
Severity, n=21	52.3 (7.5)	51.6 (6.3)	-0.6 (4.5)	0.59
Functional Limitation, n=21	54.3 (7.4)	52.4 (9.2)	-1.9 (4.9)	0.09
Secondary Outcome Measures				
LCQ, n=21	16.2 (3.7)	17.2 (3.6)	0.9 (1.8)	**0.03**
Physical, n=21	5.4 (1.0)	5.8 (0.9)	0.4 (0.6)	**0.01**
Psychological, n=21	5.4 (1.4)	5.7 (1.4)	0.3 (0.7)	0.06
Social, n=21	5.5 (1.4)	5.7 (1.4)	0.2 (0.6)	0.17
SGRQ, n=19	41.2 (17.7)	39.3 (15.9)	-1.9 (10.5)	0.23
Symptom, n=19	51.7 (18.1)	42.2 (15.8)	-9.6 (14.4)	**0.01**
Activity, n=20	29.5 (15.1)	29.4 (14.3)	-0.04 (11.4)	0.49
Impact, n=20	12.5 (8.2)	11.4 (7.8)	-1.1 (4.3)	0.28

(SGRQ), and Leicester Cough Questionnaire (LCQ) were collected before and at 8 weeks after PR. 21 patients were included in the data analysis. P< 0.05 was considered statistically significant.

Results: The baseline characteristics are shown in Table 1. Following PR, there was a statistically significant improvement in 6MWT (Table 2). Improvement in scores was observed in LCQ and the symptom domain of the SGRQ. Trends were noted in PROMIS Dyspnea scores.

Conclusion: In CTD-ILD patients, an 8-week course of PR led to improvements in functional capacity (6MWT) and certain quality of life domains (LCQ and symptom domain of SGRQ). Future studies are required to determine the longer-term benefit of PR in CTD-ILD patients and if these improvements are sustained.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Although 50% of patients with systemic sclerosis (SSc) present with interstitial lung disease (ILD) at baseline, new onset of ILD can also occur later in the disease. We aimed to compare the phenotypes and prognostic outcome between incident and prevalent ILD in SSc.

Table 1. Baseline characteristics of SSc patients according to the ILD status

	ILD prevalent group (n=5042)	ILD incident group (n=1080)	ILD negative group (n=5359)	P value between 3 groups	P value ILD prevalent vs ILD incident
Age, years, mean±SD	57 ± 13	57 ± 14	54 ± 14	**<0.01**	0.39

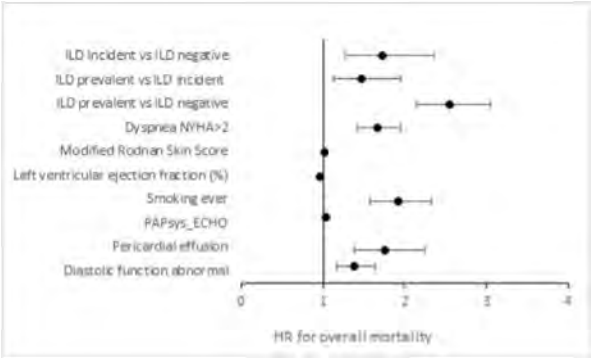

Figure 1. Multivariate prediction model of mortality in the ILD incident and ILD prevalent groups.

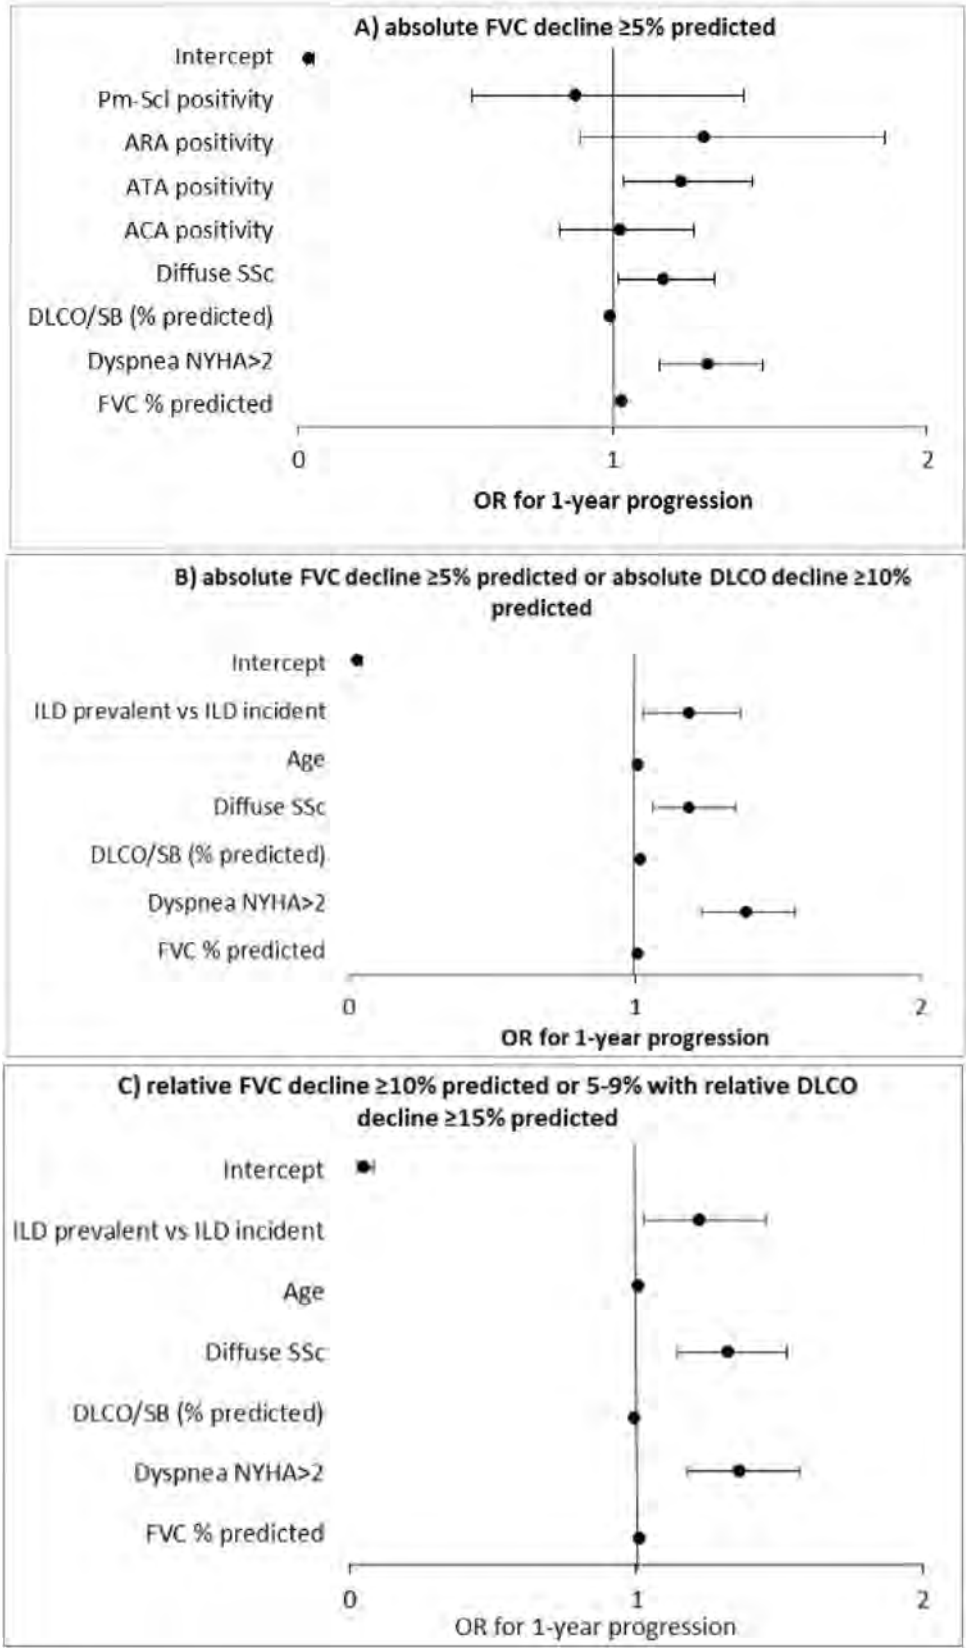

Figure 2. Multivariate prediction models of functional progression of SSc-ILD according to three definitions used.

Methods: SSc patients from the EUSTAR database were eligible if classified according to the 2013 ACR/EULAR criteria, with available information for ILD on high-resolution computed tomography (HRCT) at baseline and follow-up visits. Patients with pulmonary arterial hypertension on right heart catheterization were excluded.

Based on HRCTs, our population was divided in 3 groups: patients with ILD at baseline (ILD prevalent), patients with new onset of ILD during the follow-up (ILD incident) and patients who remained ILD negative (ILD negative). Disease features were compared between these groups.

ILD groups were tested as a predictor of mortality using multivariable Cox regression with backward selection.

Functional progression of ILD at 12±3 months intervals represented the secondary endpoint. Three different definitions of progression were applied: (A) absolute FVC decline ≥5% predicted, (B) absolute FVC decline ≥5% predicted or absolute DLCO decline ≥10% predicted and (C) relative FVC decline ≥10% predicted or 5-9% with relative DLCO decline ≥15% predicted. Logistic regression with backward selection was used to identify independent predictors, comparing prevalent vs incident ILD.

Known predictors of SSc-ILD progression and mortality were chosen as covariates from the literature and based on expert opinion.

Results: We analyzed 11481 SSc patients, including 5042 (44%) ILD prevalent, 1080 (9%) ILD incident and 5359 (47%) ILD negative patients. In comparison to the prevalent group, the ILD incident group was characterized by a milder functional impairment, higher prevalence of peripheral vascular manifestations, arthritis and smoking ever (Table 1).

During median 3.8 (IQR 1.8-7.3) years follow-up, 753/10157 deaths were recorded, more frequent in the ILD prevalent (67%) compared to ILD incident (22%) or ILD negative (11%)groups ($p < 0.01$ by Log-rank test).

In the Cox regression model adjusted for covariates (Fig.1), the ILD prevalent group showed higher risk of mortality in comparison to both ILD incident (HR 1.47, 95% CI 1.12-1.95) and ILD negative (HR 2.55, 95% CI 2.14-3.05) groups. Notably, the ILD incident had higher risk of mortality than the ILD negative group (HR 1.73, 95% CI 1.27-2.35).

ILD progression was variably observed among 7337 follow-ups of 2803 SSc-ILD patients (in 25% vs 35% vs 19% observations, according to the respective abovementioned definitions).

In comparison to the ILD incident group, the ILD prevalent group showed a higher risk of ILD progression evaluated by definition B (OR 1.18, 95% CI 1.03-1.37) and C (OR 1.21, 95% CI 1.02-1.45) after adjustment for covariates, but it was not confirmed for definition A (Fig.2).

Conclusion: Incident ILD carries a higher risk of mortality compared to ILD negative cases, despite representing a milder phenotype compared to prevalent ILD. Therefore, screening for SSc-ILD should be continued during the follow-up after a negative baseline.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: There is no established consensus on defining the clinical course and the outcomes of systemic sclerosis-associated interstitial lung disease (SSc-ILD), both among experts and in the literature. Most proposed definitions of progression or severity of SSc-ILD are based on research data from idiopathic pulmonary fibrosis and are not fully validated for SSc-ILD. The aim of our study is to collect the available evidence about definitions of severity, progression and outcomes in SSc-ILD.

Methods: A systematic search of the literature was performed according to the PRISMA guidelines, to identify all papers including definitions of SSc-ILD severity, progression and outcome (PROSPERO registration CRD42022379254). Medline, Embase and Web of Science databases were searched up to December 31st, 2021.Randomized clinical trials, cross sectional or longitudinal studies were included if they focused on SSc or on cohorts in which data on SSc patients could be extracted, considered ILD as primary target (representing at least one of population, exposure, outcome) and included at least 10 adult patients. Exclusion criteria were papers not in English, non-human non-clinical studies, ILD onset as an outcome, literature reviews and no full-text availability.

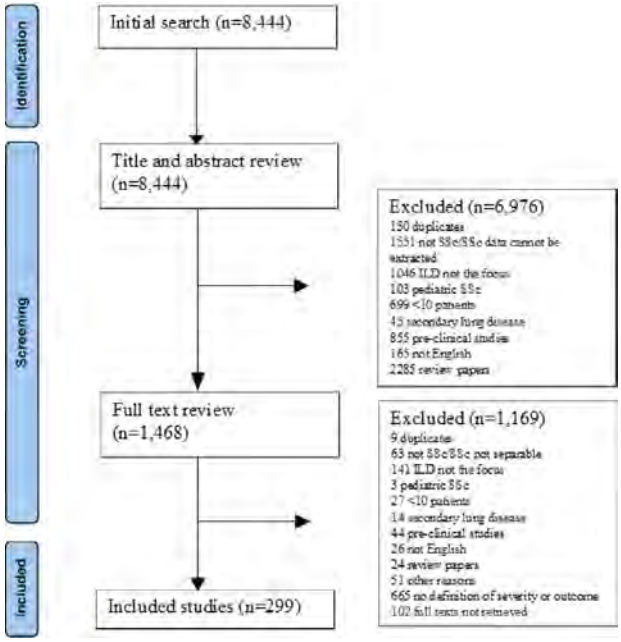

Figure 1. PRISMA flow diagram of studies selection. ILD, interstitial lung disease; SSc, systemic sclerosis.

Results: Out of 8,444 papers identified by the primary literature search (Fig. 1), 299 original research manuscripts including 35'463 patients with SSc-ILD were finally selected. Mean age was 52 years (range from 32 to 66 years), 72.5 % were females. The mean disease duration ranged from 2 to 10 years.

A definition of SSc-ILD severity was included in 138 (46%) papers (Fig. 2). Most papers (52%) used the extent of ILD on high resolution computed tomography (HRCT) to assess severity, mostly through visual quantification, either alone or in combination with pulmonary function tests (PFTs) data. The second most frequently used tool for severity was PFTs, based on forced vital capacity (FVC) in 30 (22%), on combination of FVC and diffusion of the lung for carbon oxide (DLCO) in 15 (11%) and on DLCO in 11 (8%) papers.

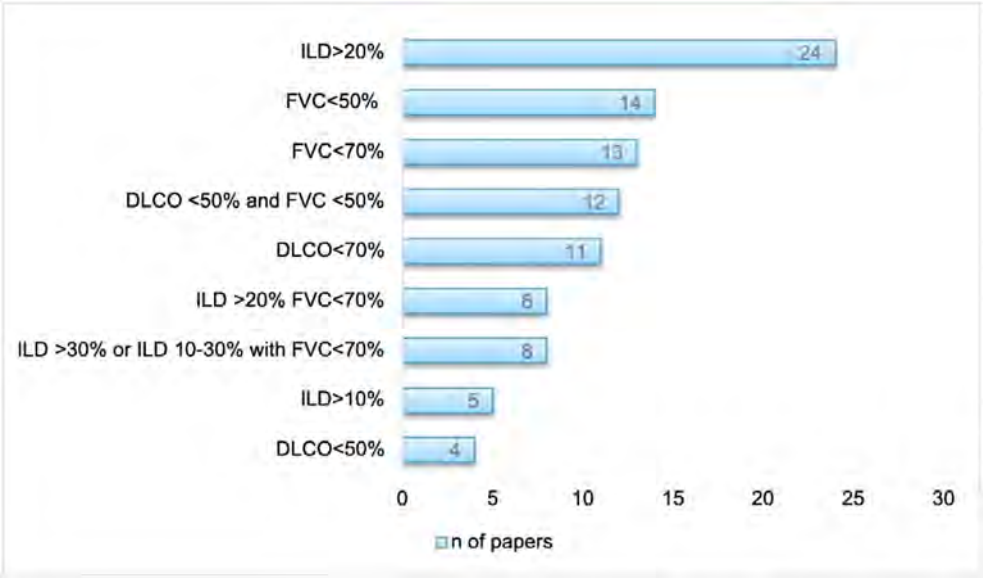

Figure 2. Number of studies stratified by the core of most commonly used definition of SSc-ILD severity.

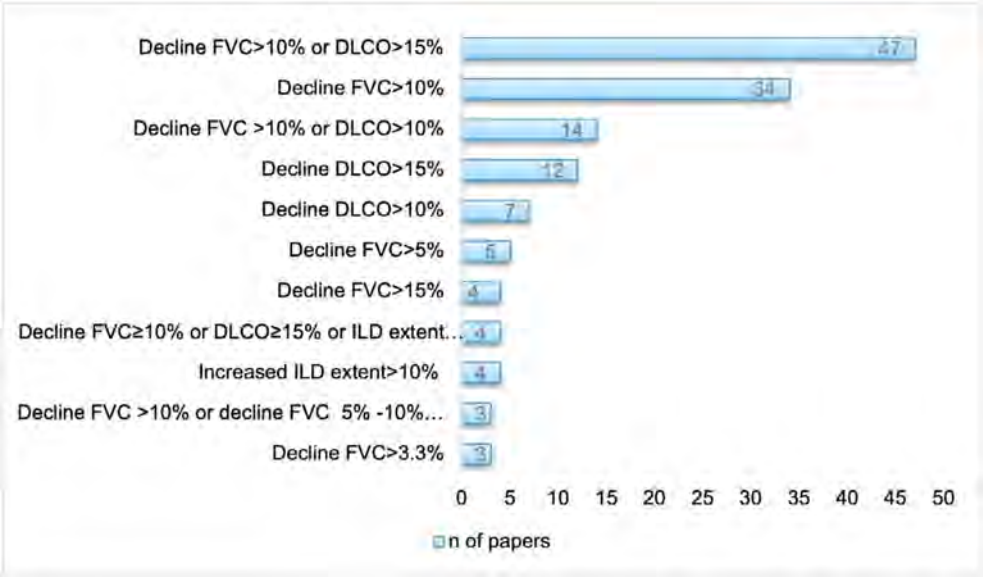

Figure 3. Top candidate definitions of SSc-ILD progression.

Sixty-four of 181 studies (35%) provided a definition of SSc-ILD progression referred to changes in FVC and DLCO, 51 (28%) in FVC, 23 (13%) in DLCO, 19 (10%) in ILD extent on HRCT, 7 (4%) to combination of PFTs and HRCT changes, 5 (3%) to combination of PFTs, clinical signs and HRCT data, 12 (7%) to other aspects (Fig.3). The timing to evaluate for SSc-ILD progression was also heterogeneous, including the re-assessment at 6 (5.5% papers), 12 (32.6 %), 24 (16.6%), 36 (10.5%), 60 (3.3%), or more than 60 months (7.2%).

The long-term outcomes recorded included mortality (131 papers, both ILD and non ILD-related), hospitalization (4 papers), end-stage ILD (5 papers), lung transplantation (2 papers) and infections (1 paper). Non-primarily ILD-related outcomes, such as malignancy, were also identified (4 papers).

Conclusion: our study showed large heterogeneity in definitions of SSc-ILD progression, severity, and outcome. This emphasizes the need to develop a standardized, consensus definition of severe SSc-ILD, to link a disease specific definition of progression as a surrogate outcome for clinical trials and clinical practice.

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Patient-Reported Outcomes Measurement Information System-29 version 2.0 (PROMIS-29v2) is a patient-centered questionnaire used to assess health-related quality of life (HRQoL). PROMIS-29v2 has shown validity and responsiveness to change in patients with systemic sclerosis (SSc) but has not yet been described specifically in early SSc. This study's aim was to describe PROMIS-29v2 outcomes and clinical associations in the Collaborative National Quality and Efficacy Registry (CONQUER), which is a multi-center US-based registry of patients with early limited cutaneous (lc) and diffuse cutaneous (dc) SSc.

Methods: Patients enrolled in CONQUER meet 2013 ACR-EULAR Classification criteria for SSc and have a disease duration of less than 5 years from their first non-Raynaud SSc symptom. Baseline results of the PROMIS-29v2 domains of physical function (PF), ability to participate in social roles/activities or social function (SF), pain interference, fatigue, anxiety/fear, sleep disturbance, and depression were described for the entire CONQUER cohort and compared between patients with lcSSc and dcSSc using two-sample t-tests. Pearson's correlation assessed the relationship between patient clinical characteristics and PROMIS-29v2 domain scores.

Results: Baseline data were available for 536 participants. Of these, 368 (68.7%) had dcSSc (Table 1). Disease duration from first non-Raynaud's symptom was 2.6 [1.3, 3.8] years for the whole group and was not significantly different between lcSSc and dcSSc. Individuals with dcSSc had worse PF, SF and pain interference, but significant differences were not seen for fatigue, anxiety/fear, sleep disturbance and depression (Table 1). Female participants had significantly higher anxiety/fear, 54.1 (95% CI 40.3, 60.3) versus 44.1 (40.3, 57.5) for males, p=0.001 (Table 2). PF score was worse (lower) in participants with digital ulcers, restrictive lung disease (RLD, defined as FVC < 70% or TLC < 80%) and pulmonary hypertension. The presence of digital ulcers correlated with worse scores in multiple domains, including PF, SF, pain interference and

depression/sadness. RLD correlated with worse PF and SF. Higher mRSS was weakly correlated with PF, r = -0.38 (95% CI -0.45, -0.3) and SF, r = -0.27 (-0.35, -0.19) in the whole group and in the dcSSc group (Table 3). Statistically significant correlations of variable strengths were seen with the UCLA SCTC GIT 2.0 score in all domains (Table 3). The strongest correlations for GIT were seen with fatigue, r = 0.53 (0.46, 0.59); pain interference, r = 0.46 (0.39, 0.52), and SF, r = -0.42 (-0.48, -0.34). Musculoskeletal manifestations including the presence of large or small joint contractures, tendon friction rubs, proximal muscle weakness, calcinosis and the use of ambulatory aids were associated with worse scores in multiple domains (data not shown).

Table 1

Table 1: Demographics and Baseline Characteristics of Patients that Completed the PROMIS-29v2 at Baseline.

	Overall (N = 536)	Limited cutaneous[1] (N = 168)	Diffuse cutaneous[1] (N = 368)	P-value
Age (years)	53.7 [42.7, 63.5]	54.6 [42.1, 65.9]	53.5 [42.9, 62.3]	0.228[3]
Female	438 (81.7%)	145 (86.3%)	293 (79.6%)	0.063[4]

Sleep disturbance	55.5 [53.3, 57.6]	55.5 [53.7, 57.5]	55.5 [53.3, 57.6]	0.632[3]
Fatigue	55.2 [48.6, 62.7]	53.2 [46.0, 60.7]	55.2 [48.6, 62.7]	0.075[3]
Anxiety/fear	53.8 [40.3, 59.6]	51.8 [40.3, 59.6]	53.8 [40.3, 59.6]	0.726[3]
Depression/sadness	48.9 [41.0, 56.0]	48.9 [41.0, 55.9]	48.9 [41.0, 57.3]	0.063[3]

Unless otherwise specified, all variables are as recorded at baseline.
[1] SSc subtype is defined as whether the patient has ever been diagnosed as having diffuse SSc. Otherwise, the patient is assumed to have limited SSc.
[2] Pulmonary hypertension is diagnosed using a right heart catheterization in patients who were symptomatic.
[3] Two-sample t-test
[4] Chi-square test of independence

Table 2

PROMIS-29v2 is a standardized questionnaire that assesses health related quality of life related to seven domains: physical function, social role, pain interference, sleep disturbance, fatigue, anxiety, and depression. Each question is scored on a scale from 1 to 5. The scores for each domain are averaged to produce a T-score, which has a mean of 50 and a standard deviation of 10 for the general population. For physical function and social role, a score higher than 50 is a better outcome. For pain interference, sleep disturbance, fatigue, anxiety, depression, a higher score is a worse outcome.
PROMIS-29v2 domain scores are compared between each subgroup using a two-sample t-test.

Table 3

Table 3: Correlation of PROMIS-29 Domain Scores with Patient Characteristics in Systemic Sclerosis.

	Physical function	Ability to participate in social roles/ activities	Pain interference	Sleep disturbance	Fatigue	Anxiety/fear	Depression/ sadness
Disease duration since date of first non-Raynaud's symptom to baseline (years)	0.14 (0.06, 0.22)	0.16 (0.07, 0.24)	-0.17 (-0.25, -0.09)	-0.06 (-0.14, 0.03)	-0.08 (-0.17, 0)	-0.09 (-0.18, -0.01)	-0.09 (-0.17, -0.01)
Age at baseline (years)	-0.12 (-0.2, -0.03)	-0.02 (-0.11, 0.06)	-0.02 (-0.1, 0.07)	0.01 (-0.07, 0.09)	-0.07 (-0.16, 0.01)	-0.14 (-0.22, -0.06)	0 (-0.08, 0.09)
mRSS at baseline	-0.38 (-0.45, -0.3)	-0.27 (-0.35, -0.19)	0.28 (0.2, 0.36)	0.08 (-0.01, 0.16)	0.16 (0.08, 0.25)	0.06 (-0.03, 0.14)	0.17 (0.08, 0.25)
FVC % predicted at baseline	0.28 (0.2, 0.36)	0.2 (0.12, 0.28)	-0.09 (-0.18, -0.01)	-0.1 (-0.18, -0.02)	-0.13 (-0.21, -0.05)	-0.08 (-0.16, 0.01)	-0.04 (-0.13, 0.04)
UCLA SCTC GIT 2.0 score Overall at baseline	-0.39 (-0.46, -0.32)	-0.42 (-0.48, -0.34)	0.46 (0.39, 0.52)	0.12 (0.04, 0.2)	0.53 (0.46, 0.59)	0.34 (0.26, 0.41)	0.39 (0.31, 0.46)

Summary statistics are Pearson Correlation (95% Confidence Interval).

Conclusion: We describe the use of PROMIS-29v2 to assess quality of life in an early US-based SSc cohort. Diffuse disease, higher mRSS, musculoskeletal manifestations, presence of digital ulcers, RLD and UCLA SCTC GIT scores were associated with reduced HRQoL as measured by PROMIS-29v2. Multivariable analysis and assessment of longitudinal change are underway.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Scleroderma renal crisis (SRC) is a life-threatening vascular manifestation of systemic sclerosis (SSc) occurring in up to 5% of SSc patients. This condition continues to have significant morbidity and mortality despite the advent of angiotensin converting enzyme (ACE) inhibitors. We identified risk factors associated with SRC in addition to evaluating its management and outcomes in consecutively diagnosed patients in a large Australian tertiary referral hospital [St Vincent's Hospital Melbourne (SVHM)].

Methods: 17 incident SRC cases were diagnosed at SVHM between 2012-2022. Patient demographics, SSc disease manifestations, and SRC treatments were determined using data prospectively collected in the Australian Scleroderma Cohort Study supplemented by chart review. Differences between those with SRC (n=17) and those without SRC (n=466) were assessed using logistic regression analyses to determine the risk factors associated with SRC.

Results: There were 483 SSc patients included in this study, their demographics and disease characteristics are presented in Table 1. 17 (3.5%) of the cohort experienced SRC during our 10 year study period.

The median SSc disease duration at SRC onset was 2.5 (IQR 1-4) years. At SRC presentation, 16 patients (94.12%) presented with a systolic blood pressure (SBP) >140mmHg (median SBP = 169 (IQR 153-182)mmHg) and a median creatinine of 120 (IQR 80-156) µmol/L. Peak creatinine occurred at a median of 11 (IQR 5-14) days post SRC diagnosis, with SBP

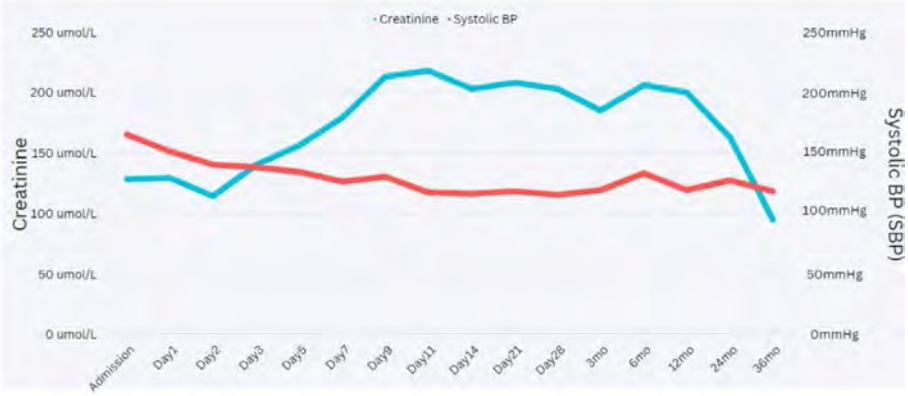

Figure 1: Mean systolic blood pressure and creatinine post SRC onset

Table 1: Demographics and disease characteristics of SSc patients at SVHM

	SVHM SRC patients (n=17)	SVHM SSc patients (n=466)
Male	10 (58.82%)	59 (12.80%)
Diffuse subclass	11 (88.24%)	114 (24.46%)
Centromere positive	0 (0%)	231 (49.57%)
ANA – nucleolar	7 (41.18%)	116 (24.89%)
Scl70 positive	7 (41.18%)	80 (17.17%)
RNAP III positive	8 (47.06%)	59 (14.71%)*
ANCA positive	1 (5.88%)	22 (4.72%)
Myocardial involvement	2 (11.76%)	27 (5.79%)
ILD	6 (35.29%)	134 (28.76%)
Raynauds phenomenon	15 (88.24%)	462 (99.14%)
Digital ulcers	11 (64.71%)	225 (48.28%)
Telangiectasia	3 (17.65%)	440 (94.42%)
Calcinosis	3 (17.65%)	199 (42.70%)
PAH	3 (17.65%)	76 (16.31%)

*401/466 patients had RNA polymerase III Ab tested

peaking at onset of SRC. Nine (52.94%) SRC patients had evidence of acute neurologic and cardiac complications including retinopathy (n=2), encephalopathy (n=6), and acute cardiac failure (n=3).

In terms of SRC management, all patients received ACE inhibitors, with a median of 3 anti-hypertensive agents required to manage hypertension. Adjuvant anti-hypertensive agents used included calcium channel blockers (most commonly amlodipine), moxonidine, and prazosin.

Complications of SRC included acute hemofiltration required in 3 (17.65%) patients, while 3 (17.65%) patients (including 2 patients that needed acute hemofiltration) required ongoing renal replacement therapy. During our observation period, 7 (41.18%) SRC patients died at a median of 2.75 (IQR 0.74-7.25) years after SRC onset, with at least 2 deaths attributable directly to complications of SRC.

Patients with SRC were more likely to be male (OR 9.73, 95% CI 3.57-26.56), have diffuse disease (OR 23.16, 95% CI 5.22-102.80), and have antibodies to Scl70 (OR 3.34, 95% CI 1.24-9.04) or RNA polymerase III (RNAP III) (OR 5.15, 95% CI 1.91-13.89).

Conclusion: In our case series, peak serum creatinine was most likely to occur 11 days after peak SBP. Refractory hypertension was a near universal feature, with adequate SBP control often requiring multiple anti hypertensives and often taking more than 7 days to achieve.

Over half of the cases of SRC in our series were negative for RNAP III, highlighting the importance of remaining vigilant for SRC, particularly in patients with diffuse disease subtype and Scl-70 antibodies.

The frequency of patients requiring renal replacement therapy (18%) in our cohort is lower than 25-81% reported in other Western countries.

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Pulmonary involvement is major causes of mortality in patients with systemic sclerosis (SSc). The breath-holding test (BHT), rapid bedside test, is a useful surrogate marker of pulmonary capacity in SSc patients. This study aimed to develop a machine learning (ML) model to predict pulmonary parameters, using real-time data of oxygen saturation (SpO2) and pulse rates obtained during the BHT in SSc patients.

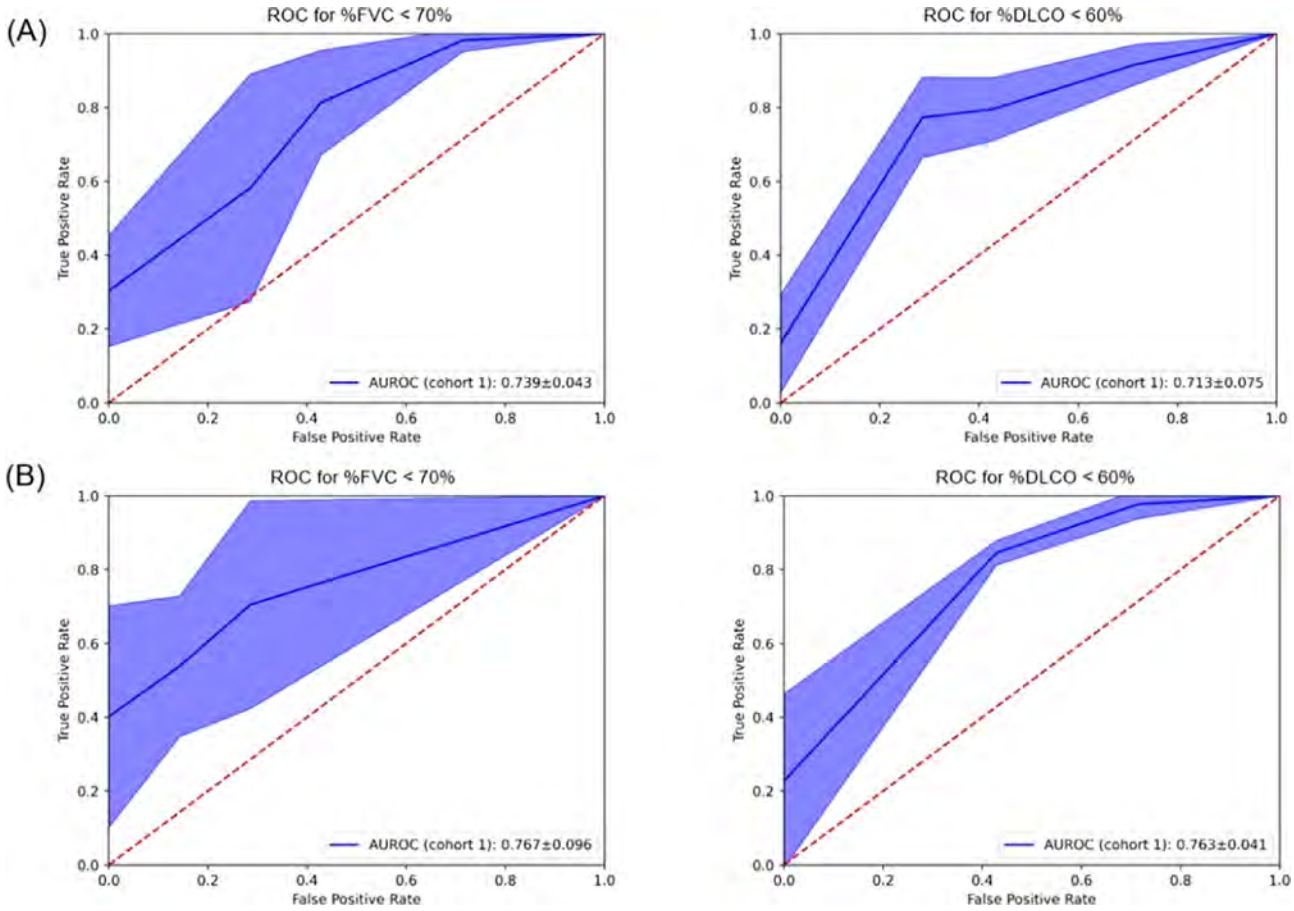

Figure 1. Receiver Operating Characteristic curves of the machine learning algorithm in the internal 4-fold cross validation using data from SpO2 and pulse rates (A) and only SpO2 (B) in breath-holding test.

Methods: Two prospective SSc cohorts were recruited for the study. Cohort 1 (n = 72) was for training a ML model and collected from August 2020 to February 2021, while Cohort 2 (n = 84) was for external validation of the established model and collected from April 2022 to September 2022. Real-time values of SpO2 and pulse rates were obtained during the BHTs and 6-min walking tests (6MWT) in Cohort 1, while the same data were collected during BHT in Cohort 2. The random forest classifier was applied to predict pulmonary functions (Forced vital capacity, FVC; diffusion capacity of carbon monoxide, DLCO), using data on SpO2 and pulse rates. In addition, demographic information such as age, gender, and body mass index, modified Rodnan skin score was also concatenated to the input feature. The validity of the ML model was evaluated using the Receiver Operating Characteristic (ROC) curve and the Area Under the ROC Curve (AUROC).

Results: A total of 72 subjects were enrolled in Cohort 1 and 84 subjects in Cohort 2, respectively. There was an overlap of 36 subjects between Cohort 1 and 2. In 4-fold cross-validation evaluation from Cohort 1, the ML algorithm using data from BHT showed AUROC of 0.739 ± 0.043 for %FVC < 70%, and 0.713 ± 0.075 for %DLCO < 60%, respectively (Figure 1A). A model using only SpO2 during BHT values showed a comparable AUROC to predict FVC and DLCO (AUROC for %FVC; 0.767 ± 0.096, and %DLCO; 0.763 ± 0.041, respectively) (Figure 1B). The ML model using data from 6MWT showed similar performance compared with BHT (AUROC for %FVC; 0.780 ± 0.040 and %DLCO; 0.754 ± 0.099, respectively). Cohort 2, an external validation cohort, showed similar AUROC (For %FVC, 0.686; for %DLCO, 0.669).

Conclusion: Our ML models showed the potential to discriminate decreased pulmonary function in SSc patients using data from SpO2 and pulse rates during the BHT and 6MWT. Our results suggest that BHT, when combined with SpO2 monitoring, can be useful to detect impaired lung capacity in SSc patient in whom a pulmonary function test is difficult to perform. (NCT04484948)

Nailfold Capillaroscopy in Patients with Systemic Sclerosis-Associated Interstitial Lung Disease (SSc-ILD) Treated with Nintedanib

Vanessa Smith[1], Christopher Denton[2], Ariane Herrick[3], Carina Ittrich[4], Margarida Alves[5] and Maurizio Cutolo[6], [1]Ghent University Hospital, Gent, Belgium, [2]University College London, London, United Kingdom, [3]University of Manchester, Salford, United Kingdom, [4]Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach an der Riss, Germany, Biberach an der Riss, Germany, [5]Boehringer Ingelheim International GmbH, Ingelheim am Rhein, Germany, [6]Laboratory of Experimental Rheumatology, Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, IRCCS San Martino Polyclinic, Genova, Italy

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Microvascular damage is part of the pathogenesis of systemic sclerosis and is associated with internal organ involvement. Nintedanib is a tyrosine kinase inhibitor approved for the treatment of SSc-ILD. The SENSCIS trial was a placebo-controlled trial of nintedanib in patients with SSc-ILD. We assessed absolute changes in nailfold videocapillaroscopy (NVC) measures in a sub-study of the SENSCIS trial.

Methods: The SENSCIS trial enrolled patients with SSc with first non-Raynaud symptom in the prior ≤7 years and an extent of fibrotic ILD on high-resolution computed tomography ≥10%. Patients were randomized to receive nintedanib or placebo. In a sub-study, NVC was performed at baseline and weeks 12, 24, 36 and 52 [Smith et al. Autoimmun Rev

2020;19:102458]. Images from all 8 fingers were assessed by a central reader. Data were summarized by patient for mean capillary density (number of capillaries/mm), mean number of giant capillaries, mean number of abnormal shapes, and the percentage of fingers with microhemorrhages. These data are presented descriptively as the mean (SD) across patients.

Results: Of 576 patients in the SENSCIS trial, 120 participated in the NVC sub-study. At baseline, among the patients in the sub-study, mean (SD) age was 53.2 (11.9) years, 73.3% were female, median time since first non-Raynaud symptomwas 3.4 years, 50.0% had diffuse cutaneous SSc, mean (SD) modified Rodnan skin score was 11.4 (8.8), 59.2% were taking mycophenolate. Mean (SD) capillary density was 5.4 (1.8) capillaries/mm. The mean (SD) number of giant capillaries was

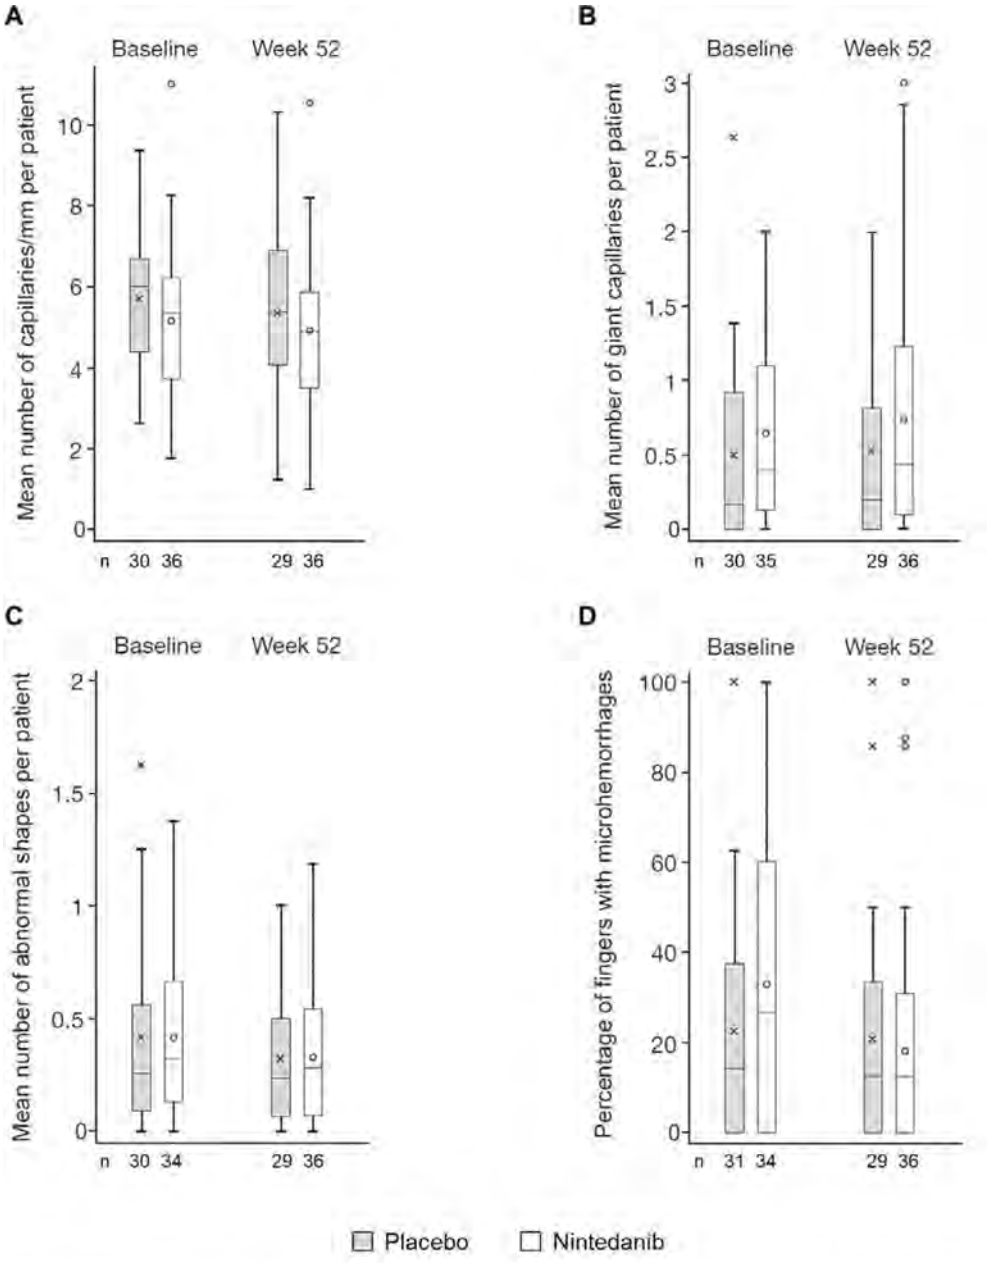

Figure. (A) Mean capillary density per patient, (B) mean number of giant capillaries per patient, (C) mean number of abnormal shapes per patient and (D) percentage of fingers with microhemorrhages at baseline and week 52 in the placebo and nintedanib groups.

0.6 (0.6) and the mean (SD) number of abnormal shapes was 0.4 (0.4). The mean (SD) percentage of fingers with microhemorrhages was 28.0 (30.4). There were no notable changes in mean capillary density, the mean number of giant capillaries, the mean number of abnormal shapes, or the percentage of fingers with microhemorrhages over 52 weeks in either the placebo or nintedanib groups (Figure).

Conclusion: In a sub-study of the SENSCIS trial in patients with SSc-ILD, NVC showed no notable changes in the mean number of microvascular abnormalities over 52 weeks in either the placebo or nintedanib groups. These analyses were limited by the small number of patients providing data at baseline and week 52. Further evaluation is needed to assess whether there were differences in capillaroscopic characteristics in patients whose disease did or did not progress, as has been observed in previous studies [Avouac et al. Semin Arthritis Rheum 2017;47:86-94; Vanahecke et al. Rheumatology (Oxford) 2022:61:4384-96].

Outcomes in Systemic Sclerosis-Associated Interstitial Lung Disease (SSc-ILD) Based on Serological Profiles: Focus on Anti-Centromere Antibody (ACA) and Anti-RNA Polymerase III (ARA) Antibodies

Elizabeth Volkmann[1], Shervin Assassi[2], Christopher Denton[3], Rozeta Simonovska[4], Steven Sambevski[5] and Elana Bernstein[6], [1]University of California Los Angeles, Los Angeles, CA, [2]University of Texas McGovern Medical School at Houston, Houston, TX, [3]University College London, London, United Kingdom, [4]Mainanalytics GmbH, Sulzbach (Taunus), Sulzbach, Germany, [5]Boehringer Ingelheim International GmbH, Ingelheim am Rhein, Germany, [6]Division of Rheumatology, Department of Medicine, Vagelos College of Physicians and Surgeons, Columbia University Irving Medical Center, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoantibody profiles are associated with organ involvement and outcomes in patients with SSc. Anti-topoisomerase I antibody (ATA) positivity has been associated with a greater risk of developing SSc-ILD, while positivity for ACA or ARA has been associated with a lower risk. No prior studies have assessed the rate of progression of SSc-ILD in subgroups by ACA or ARA status in the context of a clinical trial. The purpose of this post-hoc analysis of the SENSCIS trial was to determine whether participants with ACA or ARA experience progression of SSc-ILD.

Methods: The SENSCIS trial enrolled participants with SSc with first non-Raynaud symptom in the prior ≤7 years and an extent of fibrotic ILD on high-resolution computed tomography (HRCT) ≥10%. Participants were randomized to receive nintedanib or placebo, stratified by ATA status. We analyzed the rate of decline in forced vital capacity (FVC) (mL/year) over 52 weeks in subgroups by ACA status and ARA status (based on central laboratory data) at baseline. Exploratory interaction

p-values were calculated to assess potential heterogeneity in the effect of nintedanib versus placebo between the subgroups. We also analyzed the rate of decline in FVC (mL/year) over 52 weeks in participants who were negative for ATA, ACA and ARA.

Results: Among 549 participants with available data, 5.8% were ACA positive. Compared with ACA negative participants, ACA positive participants were older, had a lower mean modified Rodnan skin score (mRSS), and a lower proportion had diffuse cutaneous SSc (Table). Among 528 participants with available data, 18.6% were ARA positive. Compared with ARA negative participants, a greater proportion of ARA positive participants had diffuse cutaneous SSc (Table). In the placebo arm, the adjusted rate (SE) of decline in FVC (mL/year) over 52 weeks was numerically greater in participants who were ACA negative than positive (-94.8 [14.3] vs -61.5 [54.5]) and numerically greater in those who were ARA negative than positive (-99.1 [15.9] vs -62.7 [31.6]). The effect of nintedanib versus placebo on reducing the rate of FVC decline was numerically more pronounced in participants who were ACA positive than negative (difference 96.6 mL/year [95% CI –65.7, 259.0] vs 34.8 [-5.1, 74.6]) or ARA positive than negative (difference 68.5 mL/year [95% CI –25.8, 162.8] vs 26.9 [-16.8, 70.7]), but the interaction p-values (>0.05) did not indicate heterogeneity in the effect of nintedanib between these subgroups. In the placebo arm, the rate of decline in FVC (mL/year) over 52 weeks, and the effect of nintedanib versus placebo in reducing the rate of FVC decline, were similar between the subset of patients who were negative for ATA, ACA and ARA and the overall trial population (Figure).

Conclusion: While the results of these post-hoc analyses should be interpreted with caution given the small number of participants who were ACA positive, the results suggest that patients who are ACA positive or ARA positive can experience SSc-ILD progression and should be monitored closely. The effect of nintedanib on slowing FVC decline was numerically more pronounced in participants with SSc-ILD who were ACA positive or ARA positive.

Table. Baseline characteristics by autoantibody status in the SENSCIS trial.

	Overall trial population (n=576)	ACA positive (n=32)	ACA negative (n=517)	ARA positive (n=98)	ARA negative (n=430)	ATA, ACA and ARA negative (n=127)

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: RP and its ischaemic complications are a major cause of morbidity in SSc. Non-pharmacological measures to minimise cold exposure can play a vital role in managing RP. This study sought to compare the efficacy of heated gloves compared with routine practice in SSc.

Table 1. Baseline characteristics of participants with SSc (n=26).

Characteristic	Value
Age, years, mean (SD)	62.5 (10.0)
Female, n (%)	23 (88.5)
SSc subtype	
- dcSSc	6 (23.1)
- lcSSc	20 (76.9)
Duration of SSc, years, median (IQR)	16.5 (11.8, 28.8)
Duration of RP, years, median (IQR)	18.5 (13.0, 34)
Digital ulcers (current), n (%)	8 (30.8)
Pitting scars, n (%)	14 (53.8)
Pharmacological treatment for RP, n (%)	13 (50.0)
Active smoker, n (%)	1 (3.8)
Baseline RCS score (1-10), mean (SD)	5.1 (2.2)

RCS: Raynaud Condition Score; RP: Raynaud's phenomenon; dcSSc: diffuse cutaneous systemic sclerosis; lcSSc: limited cutaneous systemic sclerosis

Table 2. Descriptive statistics and linear mixed model analyses comparing routine practice and heated glove use.

Outcomes	Mean (SD)	Median (IQR)	Min, Max	Linear Mixed Model Results			
				Est (95% CI)	P-value	Adjust period effect Est (95%CI)	Adjust period effect P-Value
Primary							
Mean RCS (1-10)							
Routine practice	4.43 (2.2)	4.34 (2.7, 5.7)	1.2, 8.7				
Heated gloves	2.9 (2.0)	2.4 (1.2, 3.7)	1.0, 8.5				
Routine practice vs Heated gloves				-1.57 (-2.50, -0.65)	0.001	-1.51 (-2.28, -0.75)	<0.001
Secondary							
Mean number of attacks (n/day)							
Routine practice	2.44 (1.4)	2.14 (1.3, 3.3)	0.4, 6.4				
Heated gloves	1.79 (1.2)	1.71 (1.0, 2.8)	0.0, 4.1				
Routine practice vs Heated gloves				-0.65 (-1.09, -0.21)	0.005	-0.64 (-1.09, -0.19)	0.007
Mean attack duration (mins)							
Routine practice	100.76 (98.3)	86.82 (31.0, 109.8)	12.5, 389.7				
Heated gloves	63.71 (76.0)	31.96 (14.9, 71.0)	1.1, 253.9				
Routine practice vs Heated gloves				-37.05 (-67.82, -6.29)	0.020	-36.01 (-67.05, -4.97)	0.025
CFHS (0-90)							
Routine practice	12.81 (18.0)	5.50 (2.0, 10.8)	0.0, 67.0				
Heated gloves	12.73 (16.9)	6.00 (1.0, 14.0)	0.0, 52.0				
Routine practice vs Heated gloves				-0.08 (-2.26, 2.11)	0.945	-0.04 (-2.14, 2.05)	0.970
HAQ-DI (0-3)							
Routine practice	0.71 (0.6)	0.50 (0.3, 0.8)	0.0, 2.4				
Heated gloves	0.68 (0.6)	0.50 (0.3, 0.8)	0.0, 2.3				
Routine practice vs Heated gloves				-0.03 (-0.13, 0.08)	0.587	-0.03 (-0.13, 0.08)	0.609

RCS: Raynaud Condition Score, CFHS: Cochin Hand Function Scale, HAQ-DI: Health Assessment Questionnaire-Disability Index

Methods: A single centre, randomized crossover trial was undertaken in patients with SSc according to 2013 ACR/EULAR classification criteria. The study was conducted during winter and participants were randomized into two groups. Group GR (Gloves/Routine practice) commenced treatment with heated gloves for 28 days followed by 28 days of usual practice (which could include use of non-heated gloves). There was a one week washout between heated gloves and routine care. Group RG (Routine practice/Gloves) followed the same protocol in reverse order. Patients were advised to continue their pharmacotherapy. Data was collected via patient diary and included a daily Raynaud's Condition Score (RCS), hours gloves worn, RP attack details, and adherence to pharmacotherapy. Cochin Hand Function Scale (CHFS) and HAQ-Disability Index (HAQ-DI) score were collected at baseline and at each period end. The primary outcome measure was RCS, averaged over 28 days for each participant for heated glove use versus routine practice. Power calculation indicated a sample size of 22 required to achieve 90% power for detecting a minimal clinically important difference of 1.4 in RCS determined by Khanna *et al*. at a significance criterion of $\alpha = 0.05$. To determine if the timing of active treatment influenced response between

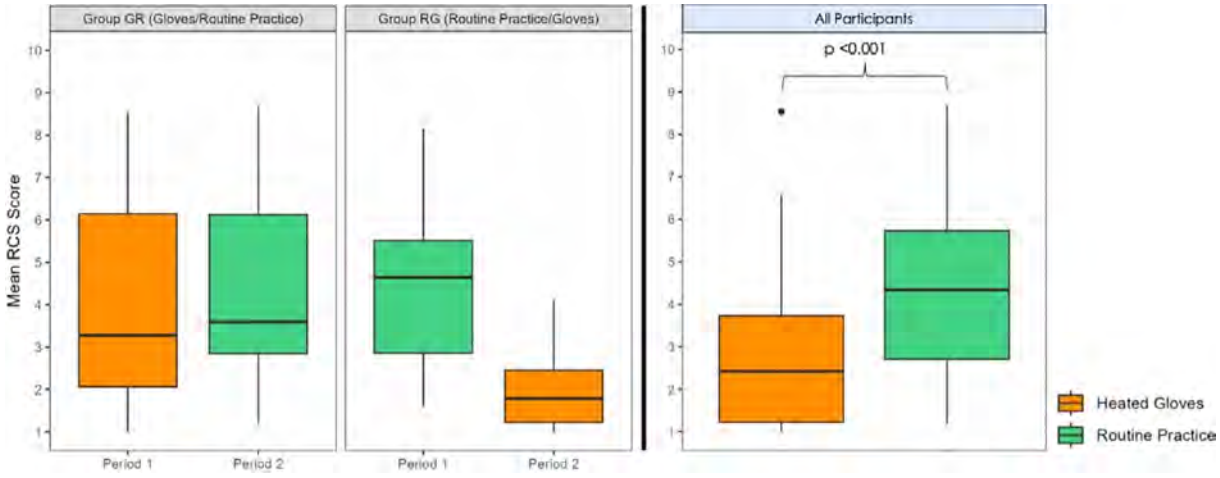

Figure 1. Boxplots of participant mean (SD) RCS score by intervention for crossover groups and all participants combined. P-value shown for linear mixed model results comparing mean RCS for heated gloves and routine practice.

groups, a linear mixed effects model was fitted to the average RCS and adjusted for period effect. The model was repeated for secondary outcomes including mean number and duration of RP attacks, CHFS and HAQ-DI score. RCS, CHFS and HAQ-DI analyses were baseline adjusted.

Results: Twenty-six participants completed the trial (Table 1). Two participants were withdrawn due to insufficient data, one following baseline visit and one from the GR group at washout. Mean hours of glove wearing per day was 4.77 in the GR group and 2.68 in the RG group. From the period and baseline adjusted model, the combined heated gloves groups had a 1.51 unit lower mean RCS score compared to routine practice (95%CI (-2.28, -0.75), P< 0.001) (Table 2, Figure 1). From the period-adjusted model, the heated gloves group had a 0.64 reduction in mean number of attacks (95%CI (-1.09, -0.19), P=0.007). For the mean duration of attacks, there was no significant period effect (0.377) but there was interaction between period and treatment (P=0.027). From the period adjusted model, the heated gloves group had 37.05 minutes lower mean attack duration compared to the control group (95% CI (-67.05, -4.97), P=0.025). There was no difference in CHFS score (95%CI (-2.14, 2.05), P=0.970) or HAQ-DI score (95%CI (-0.13, 0.08), P=0.609) between treatment periods. Reported side effects included skin dryness (2 participants) and intolerance to glove heat (2 participants).

Conclusion: Heated gloves resulted in a statistically and clinically significant reduction in daily RCS. Heated gloves are an effective and safe intervention for reducing RP symptoms in SSc and may be a useful alternative/adjunct to current practice.

Clinical Features of Anti-hUBF Antibodies-positive Patients: A Single-center Retrospective Study

Natsumi Fushida, Motoki Horii, Kie Mizumaki, Natsuki Numata, Yasuhito Hamaguchi and Takashi Matsushita, Department of Dermatology, Faculty of Medicine, Institute of Medical, Pharmaceutical and Health Sciences, Kanazawa University, Kanazawa Ishikawa, Japan

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-human upstream-binding factor (hUBF) antibodies (Abs) have been reported predominantly in patients with connective tissue diseases (CTDs) but have also been reported in non-CTDs such as hepatocellular carcinoma. Because of the low frequency of expression and few case reports on this Abs, there is no consensus on the clinical significance of this Abs. Thus, we aimed to examine the clinical features of patients with anti-hUBF Abs.

Methods: Serum samples were collected from 1042 patients clinically suspected of CTDs. The presence of anti-hUBF Ab was screened by Immunoprecipitation (IP) assays. AutoAbs associated with various CTDs were identified by specific indirect immunofluorescence staining, enzyme-linked immunosorbent assay, or IP assay. Clinical characteristics of systemic sclerosis (SSc) patients were first analyzed among patients positive for anti-hUBF Abs or negative for this Abs. We next compared the clinical features among three subgroups: Anti-hUBF Abs, anti-centromere Abs (ACA), and anti-topoisomerase I (topo I) Abs. Statistical analyses were performed at a 0.05 significance level using SPSS version 27 (IBM, Tokyo, Japan).

Results: Of 1042 patients, 19 (1.82%) were positive for anti-hUBF Abs. Of the 19 patients, 10 were diagnosed with undifferentiated connective tissue disease (UCTD), 6 were SSc, and 3 were others. Of the 10 patients with UCTD, 5 were referred to our hospital suspected of SSc. All 5 patients did not fulfill the 2013 American College of Rheumatology/European League Against Rheumatism classification criteria, but 3 of them got 7 points which was a relatively high score. Of the 6 patients with SSc, anti-hUBF-positive patients had a significantly lower modified Rodnan total skin thickness score (mRSS) than those with anti-hUBF-negative patients (2[0-2] vs 7[0-49], $p< 0.01$). Compared with anti-topo I Abs, anti-hUBF-positive patients had a significantly lower mRSS (2[0-2] vs 13[0-42], $p< 0.01$) and lower incidence of scleroderma renal crisis (0/6 vs 8/184, $p< 0.01$). Whereas compared with ACA, anti-hUBF-positive patients had a higher incidence of interstitial lung disease (ILD) but there was no significant difference (4/6 vs 19/239).

Conclusion: Anti-hUBF Abs were positive predominantly in CTDs and UCTD. In CTDs, SSc had a high ratio and they seemed to have lower mRSS and higher incidence of ILD. In UCTD, they should be followed up carefully because they might be CTDs in the future.

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Despite the progress in understanding the patient heterogeneity in systemic sclerosis (SSc) based on SSc-specific antibodies, better risk stratification is needed. SSc non-specific antibodies might represent surrogate markers to improve the stratification of SSc patients. Here, we aim to evaluate the prevalence of anti-Ro/SSA antibodies in the largest available cohort of established SSc patients and study their association with disease phenotype and clinical outcomes, focusing on lung involvement.

Methods: Patients from the EUSTAR database fulfilling the ACR 2013 classification criteria for SSc with available data on anti-Ro/SSA antibodies were included. Clinical characteristics of patients with or without anti-Ro/SSA antibodies were compared at baseline using t-test and chi-squared according to the distribution of the variable. The progression of lung fibrosis was defined (i) in patients with lung fibrosis (FVC%decline from baseline of ≥ 10% or an FVC%decline of 5-9% in association with aDLCO% decline of ≥15%)or (ii) by a decline of FVC >5% in patients with lung fibrosisor (iii) by the development of lung fibrosis de novo (on HRCT scan). Prognostic factors for lung fibrosis progression and death during the follow-up were tested by multivariate Cox proportional hazards regression. Covariates were selected according to literature evidence. Multiple imputation was used to impute missing data in these models.

Results: Among the 4.421 patients fulfilling the inclusion criteria, 661 (15.2%) had positive anti-Ro/SSA antibodies. Anti-Ro/SSA antibodies were more frequently observed among Asians and Africans and less prevalent in Caucasians (Table 1). Anti-Ro/SSA antibodies were positively associated ($p<0.001$) with anti-SSB, anti-U1RNP antibodies, and rheumatoid factor. Patients with anti-Ro/SSA antibodies more frequently presented with muscular involvement (18% vs 12.5%, $p<0.001$), PAPs >45 mmHg on echocardiography (9.2% vs. 6.5%, $p=0.058$) and lung fibrosis on HRCT (56.2% vs 47.8%, $p=0.001$). Specifically, the percentage predicted of DLCO in patients with lung fibrosis was significantly lower in patients with anti-SSA antibodies (59.0±18.6% vs. 61.9±20.2, $p=0.041$). Over a median follow-up of 2.4 years [95CI: 2.2-2.9], anti-SSA antibodies did not predict lung fibrosis progression ((i) HR: 1.03 [0.8-1.33], (ii) HR: 1.05 [0.83-1.31] and (iii) HR: 0.98 [0.72-1.32] or death (HR: 1.27 [0.8-2]).

Conclusion: In the large EUSTAR cohort, anti-SSA antibodies are detected in 15% of SSc-patients and are associated with more severe lung involvement. These data support the inclusion of anti-SSA antibodies in clinical practice for better SSc-patient risk stratification.

Table1: Comparison of SSc-patients with and without anti-Ro/SSA antibodies

	Patients with anti-Ro/SSA antibodies (n=641)	Patients without anti-Ro/SSA antibodies (n=3580)	P value

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) affects around 50% of patients with systemic sclerosis (SSc) and is the main cause of mortality. Preliminary data from small cohorts suggest ILD may occur even in very early SSc (veSSc, prescleroderma). The main aim of this study is to assess the prevalence and the characteristics of ILD in veSSc and to identify possible predictors of ILD development during follow-up.

Methods: This is a longitudinal cohort study of a single EUSTAR center. We included patients with veSSc, defined as Raynaud's phenomenon and/or at least one of puffy fingers, antinuclear antibodies (ANA), abnormal capillaroscopy, not fulfilling the 2013 ACR/EULAR classification criteria for SSc at baseline. ILD was diagnosed by expert radiologists on high-resolution computer tomography of the chest, which was performed yearly. We analyzed the clinical and spirometry parameters of ILD cases at baseline and during follow-up. Standardized mean difference (SMD) was used to compare patient groups with and without ILD. Cox regression analysis was used to identify risk factors for development of ILD in veSSc. Covariates were chosen according to previous literature and expert opinion.[1]

Results: In our cohort of 737 patients, we identified 159 patients with veSSc. Among these, 25 (15.7%) patients had ILD (Table 1). There were 9 ILD cases (5.7%) at baseline and 16 cases were first detected at follow-up. All of these patients fulfilled the classification criteria during the follow-up period, 10/16 at the visit when ILD was diagnosed. The groups with- and without ILD were imbalanced as measured by SMD: patients with ILD were older, had a longer disease duration (measured

since the first occurrence of Raynaud phenomenon) and more often elevated inflammatory markers, especially ESR (Table 1). There was a significant association between ILD at baseline and a reduced diffusing capacity for carbon monoxide (defined as DLCO < 70% of predicted) (p=0.007, Fisher's test). However, we neither found an association between ILD at baseline and a low forced vital capacity (FVC< 80% of predicted), nor with specific antibodies (anti-centromere, anti-Scl70

Table 1. Characteristics of the patients with- and without ILD during the follow-up period.

	Overall	No ILD	ILD	SMD
n	159	109	25	
Age (median [IQR])	48.00 [35.00, 60.00]	46.00 [34.00, 57.00]	61.00 [53.00, 71.00]	1.116
Male gender (%)	17 (10.7)	11 (10.1)	3 (12.0)	0.061
Baseline visit only (%)	51 (32.1)	38 (34.9)	5 (20.0)	0.338
Disease duration (years) (median [IQR])	3.33 [1.23, 9.92]	3.25 [1.31, 10.42]	9.17 [7.67, 31.00]	0.819
Fulfilled criteria during follow-up (%)	27 (18.9)	20 (18.3)	1 (11.1)	0.205
Raynaud phenomenon (%)	143 (89.9)	100 (91.7)	20 (80.0)	0.342

Dyspnea NYHA III or IV (%)	8 (5.5)	2 (2.0)	6 (26.1)	0.741
6-MWT (distance in m) (median [IQR])	585.00 [513.25, 670.50]	602.50 [524.25, 679.25]	515.50 [406.75, 571.75]	0.743
Desaturation ≥4% in the 6-MWT (%)	11 (10.4)	5 (6.4)	6 (25.0)	0.528
Lung involvement HRCT > 20%	2 (8.7)	0 (NaN)	2 (8.7)	NaN
Abnormal diastolic function (%)	18 (13.4)	12 (12.8)	6 (33.3)	0.504
Esophageal symptoms (%)	50 (31.6)	35 (32.4)	9 (36.0)	0.076
Cigarette smoking ever (%)	36 (51.4)	27 (57.4)	6 (31.6)	0.539

*Specific antibodies were considered: anti-centromere, anti Scl-70 and anti-RNA Polymerase III antibodies

ILD interstitial lung disease; SMD standardized mean difference; n number; ANA anti-nuclear antibodies; Ab antibodies; CRP C-reactive protein; ESR erythrocyte sedimentation rate; FVC forced vital capacity; DLCO diffusing capacity of the lungs for carbon monoxide; NYHA New York Heart Association; 6-MWT 6-minutes walking test; HRCT high resolution computer tomography;

	HR	95% CI	P-Value
DLCO < 70%	2.761	1.056 to 7.216	0.038
Esophageal symptoms (reflux)	1.925	0.844 to 4.390	0.120

DLCO diffusing capacity of the lungs for carbon monoxide; ILD interstitial lung disease; HR hazard ratio

Figure 1. A reduced DLCO (<70%) predicts development of ILD (Cox regression model with the outcome ILD at follow-up).

or anti-RNA polymerase III), presence of puffy fingers or a short disease duration. Only a DLCO< 70% at baseline was a predictor for developing ILD during the follow-up period (HR 2.761, 95% CI 1.056 to 7.216, p=0.038), whereas the presence of reflux symptoms was not significant in the regression model with these two covariates (Figure 1).

Conclusion: After a first analysis of ILD in veSSc, we observed that ILD occurs even in these very mild cases. Therefore, screening for ILD is important even in veSSc. A reduced DLCO < 70% at baseline was not only associated with ILD at baseline, but also predicted the development of ILD at follow-up.

Abstract Number: 0629

Negative Affect, Anxiety and Fatigue Moderate the Association Between Pain Intensity and Physical Function in People with Systemic Sclerosis

Daniel Whibley[1], Yen Chen[1], Anna Kratz[1], Dinesh Khanna[1] and Susan Murphy[2], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan, Plymouth, MI

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Pain is a common symptom of systemic sclerosis (SSc), affecting over 80% of those living with the condition, with over a third experiencing pain of moderate or severe intensity. Pain intensity is strongly associated with physical functioning in SSc, however psychosocial moderators of this association are understudied. If modifiable psychosocial factors decouple the pain intensity-physical functioning association, addressing them may help diminish physical limitations attributable to SSc-related pain. Accordingly, this study examined psychosocial factors as potential moderators of the pain intensity-physical function association in SSc.

Methods: This cross-sectional observational study used baseline data from a trial examining the effectiveness of a web- and app-based intervention for fatigue management for people with SSc (ClinicalTrials.gov identifier NCT04908943). Participants were $\geq$18 years old with any SSc subtype, with a mean score $\geq$4 on the Fatigue Severity Scale. A questionnaire battery captured information about demographic, clinical and psychosocial factors. Pain intensity was assessed using the PROMIS Global Pain item (average pain past 7 days; 0-10 Numeric Rating Scale); physical function was assessed with the PROMIS short-form v2.0 Physical Function 4a. Psychosocial factors examined as potential moderators were positive and negative affect (Positive and Negative Affect Schedule), resilience (Connor-Davidson Resilience Scale), and PROMIS measures of anxiety, depression, fatigue, sleep disturbances, and self-efficacy. Linear regression was used to quantify the association between pain intensity and physical function, with interaction terms added for each moderator in separate models, adjusted for age, SSc subtype, and disease duration.

Results: Of 174 people recruited to the trial, 173 were randomized and included. 93% were female, sample mean age 54.5 (standard deviation (SD) 11.7). Most were white (83%), non-Hispanic/non-Latino (87%), and married (65%). 47% had diffuse cutaneous SSc, 35% limited,13% overlap, and 5% other/unsure. Mean (SD) pain intensity was 4.9 (2.3) and mean physical function T-score was 38.5 (1.2 SD below the general US population). There was a linear association between pain intensity and physical function, with pain intensity explaining 31% of variability in physical functioning, adjusted for age, SSc subtype, and disease duration. Statistically significant interaction effects were identified for level of negative affect, anxiety, and fatigue. In all cases, higher psychosocial symptom levels were associated with a stronger, negative association between pain intensity and physical functioning.

Conclusion: Negative affect, anxiety and fatigue moderated the association between pain intensity and physical functioning. Compared to those with lower levels of these psychosocial symptoms, those with higher levels experienced poorer physical functioning at higher pain intensities. If replicated, these findings would support longitudinal studies to examine whether addressing high levels of negative affect, anxiety and fatigue improve physical functioning of people with SSc-related pain.

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Digital ischemic ulcers (DIU) develop in 36-44% of patients with systemic sclerosis (SSc).[1,2]Prior international observational studies have evaluated characteristics of digital pitting and ulcers in their SSc patient populations; however, these studies do not necessarily reflect the US SSc patient population. We examined the prevalence of digital ischemic complications in a US-based longitudinal registry and evaluated clinical factors and patient reported outcomes associated with current digital pitting scars (DPS) and DIU.

Methods: We conducted a cross-sectional study utilizing the Collaborative National Quality and Efficacy Registry (CONQUER), a US-based, prospective, multi-center cohort of adults with SSc who meet 2013 ACR/EULAR Classification Criteria, with a disease duration ≤ 5 years from first non-Raynaud's symptom at enrollment. At study enrollment, clinicians recorded the presence of DPS and DIU, and demographic, clinical, laboratory variables, and patient reported outcomes were collected. Multivariable-adjusted logistic regression models were designed using directed acyclic graphs.

Results: Among 772 eligible CONQUER participants, 166 (22%) had at least one DPS and 47 (6%) had active DIU at enrollment (Tables 1 and 2). Half of the participants with DPS were prescribed calcium channel blockers. Participants with DPS had worse PROMIS-29 v2.0 social function and pain scores, and participants with DIU had worse physical function, depression, social function, and pain scores. In our multivariable logistic regression model, younger age and male sex were associated with DPS (OR for female sex 0.50, 95% CI: 0.30 to 0.84 and OR for increased age by 5-year increments 0.90, 95% CI: 0.83 to 0.98, Figure). Race, tobacco use, abnormal nailfold capillaries, presence of telangiectasias, mRSS, disease subtype, disease duration, hypertension, and autoantibody status were not associated with DPS.

Conclusion: Digital ischemic complications were associated with impaired quality of life among patients with SSc, specifically in the domains of social function and pain. Younger age and male sex were associated with presence of digital pitting scars.

Safety of Radiotherapy for Malignancy in Systemic Sclerosis. a Systematic Review

Aos Aboabat[1], Mohammed AlDohan[2], Patrick Cheung[2], Ani Orchanian-Cheff[3] and Sindhu Johnson[4], [1]University of Toronto, Toronto, ON, Canada, [2]Odette Cancer Centre, Sunnybrook Health Sciences Centre, University of Toronto, Toronto, ON, Canada, [3]Library and Information Services, University Health Network, Toronto, ON, Canada, [4]Division of Rheumatology, Department of Medicine, Schroeder Arthritis Institute, Krembil Research Institute, Toronto Western and Mount Sinai Hospitals; Institute of Health Policy, Management and Evaluation, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a chronic autoimmune disorder with higher risks of malignancies. Concerns regarding offering radiotherapy (RT) to SSc patients stem from the potential to worsen SSc manifestations and RT-specific toxicity. Through systematic review of the literature, we evaluated the effect of RT on SSc-manifestations and RT-specific adverse

Methods: MEDLINE, Embase, Cochrane Database of Systematic Reviews and Cochrane Central Register of Controlled Trials were searched using subject headings and text words for systemic sclerosis and RT. Inclusion criteria were a physician-based diagnosis of SSc, development of cancer after SSc diagnosis, and exposure to RT. The outcomes were SSc manifestations (cutaneous thickening by mRSS or physicians' clinical assessment, pulmonary fibrosis, flare of SSc) and RT-related toxicity (acute and late).

Results: The search yielded 25 articles, comprising 12 case reports, 3 case series, 5 retrospective cohort studies, and 5 case-control studies. A total of 121 SSc patients who received RT were included, with a mean age of 54.9 years, and 73.6% were female. Indications for RT were breast (N = 46), intrathoracic (N = 7), head and neck (N = 4), genitourinary (N = 3), colorectal (N = 3), and central nervous system (N = 1) cancers. The intent of RT was curative (88.7%) and (11.3% palliative. Post-RT 36/39 (92.3%) did not develop worsening skin thickening, 1/39 (2.6%) had minimal worsening of skin thickening and 2/39 (5.1%) had progressive skin thickening beyond the radiation port. Following RT, 36/39 (92.3%) did not develop SSc-related pulmonary complications, 1/39 (2.6%) developed pulmonary fibrosis, and 1/39 (2.6%) diffuse alveolar hemorrhage. Acute RT adverse effects were reported in 57 patients, with severe acute adverse events observed in a minority. Late non-severe RT adverse effects (Grade 1 and 2 toxicities) included seromas and telangiectasias, whereas late severe adverse effects (Grade 3- 5) included dysphagia, laryngeal edema, radiation pneumonitis, esophageal stricture and small-bowel obstruction. The frequency of grade 3-5 toxicity in cohort studies ranged between 15%-24%.

Conclusion: The majority of SSc patients did not develop worsening SSc-related manifestations following RT, suggesting that RT can be safely administered. A minority experienced acute severe RT-related adverse effects. However, the risk of severe late RT-related adverse effects may be high, underlining the need for close follow-up during and after RT. A larger prospective controlled study is needed to confirm these findings and to identify potential risk factors for adverse outcomes in SSc patients undergoing RT.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Few studies have evaluated mouth opening (MO) in systemic sclerosis (SSc). None have studied MO trajectories.

Methods: We performed a multicentre study patients enrolled in the French national SSc cohort with at least one MO assessment, described patients based on MO baseline measure, modelized MO trajectories, and associated MO measures with SSc prognosis.

Results: 1101 patients were included in the study. Baseline MO was associated with disease severity. Kaplan Meier analysis showed that MO < 30mm was associated with a worse 30-year-survival ($p< 0.01$) and higher risk of pulmonary arterial hypertension occurrence ($p< 0.05$). Individual MO trajectories were heterogenous between patients. The best model of MO trajectories using latent process mixed models showed that 88.8% patients had a stable MO trajectory, and clustered patients into 3 groups which were predictive of SSc survival ($p< 0.05$). and interstitial lung disease (ILD) ($p< 0.05$). It highlighted a cluster of 9.5% patients with diffuse SSc (dcSSc) ($p< 0.05$) and a high but decreasing MO over one year ($p< 0.0001$) at higher risk of a poor survival and ILD occurrence.

Conclusion: MO, which is a simple and reliable measure, is predictive of disease severity and survival in SSc. Although it remains stable in most SSc patients, dcSSc patients with high but decreasing MO are at risk of poor survival and ILD occurrence.

Abstract Number: 0633

Prediction of Progressive Fibrosing Interstitial Lung Disease in Systemic Sclerosis Patients: Insight from the CRDC Cohort Study

Min Hui[1], Xinwang Duan[2], Jiaxin Zhou[3], Mengtao Li[3], Qian Wang[4], Jiuliang Zhao[1], Yong Hou[1], Dong Xu[5] and xiaofeng Zeng[4], [1]Department of Rheumatology, Peking Union Medical College Hospital, Beijing, China, [2]Department of Rheumatology, The Second Affiliated Hospital of Nanchang University, Beijing, China, [3]Peking Union Medical College Hospital, Beijing, China, [4]Department of Rheumatology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China, [5]Department of Rheumatology, Peking Union Medical College, Beijing, China

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

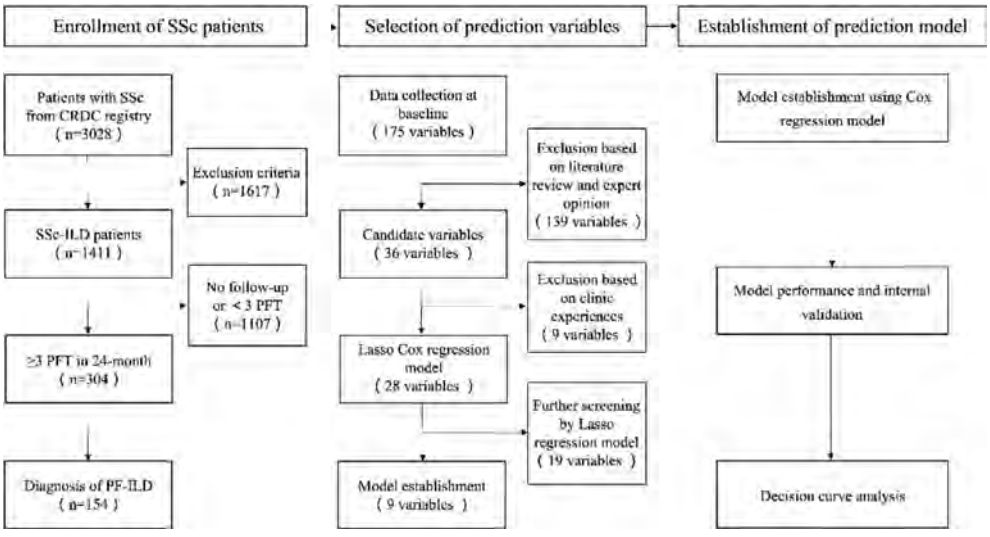
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) patients can develop progressive fibrosing interstitial lung disease (PF-ILD), linked to a poor outcome. This study aims to establish a reliable prediction model of PF-ILD in SSc-ILD patients, to achieve early risk stratification, and to help better preventing disease progression.

Methods: Three hundred and four SSc-ILD patients registered on Chinese Rheumatism Data Center (CRDC) database since January 2008, with no less than three pulmonary function tests within 6-24 months, were included. The major outcome was development of PF-ILD, which was defined as an absolute annualized forced vital capacity (FVC) decline ≥5% predicted. We collected data at baseline and compared differences between SSc patients with PF-ILD (SSc PF-ILD) group and SSc patients without PF-ILD (SSc non-PF-ILD) group. Lasso regularization regression was performed for further screening. Multivariable Cox regression were used to construct the prediction model, which were presented as nomogram and forest plot.



Flow chart showing the study design

Results: SSc-ILD patients were divided into SSc PF-ILD group (n=154) and SSc non-PF-ILD group (n=150). Compared with SSc non-PF-ILD group patients at baseline, SSc PF-ILD patients were at older age (48.5±11.9 years vs 44.9 ±11.3 years, p< 0.001), had more male patients (9.7% vs 6.0%, p=0.012), more diffused SSc (dcSSc) subtype (58.4% vs 32.7%, p< 0.001), and a significant higher incidence of hyperlipidemia (31.2% vs 8.7%, p< 0.001), smoking history (18.2% vs 5.3%, p< 0.001), arthritis (38.3% vs 24.7%, p< 0.001), shortness of breath (84.4% vs 80.0%, p< 0.001) and anti Scl-70 antibody positivity (53.2% vs 40.0%, p< 0.001), as well as more serum IgA deficiency (11.0% vs 5.3%, p< 0.001). The use of cyclophosphamide (CYC) and/or mycophenolate mofetil (MMF) were less common in SSc PF-ILD group compared with SSc non-PF-ILD group (58.4% vs 68.7%, p< 0.001). Based on the results of univariable Cox analysis and Lasso regularization regression, a 9-variable prediction model was constructed, including age≥50 years, hyperlipidemia, smoking history, dcSSc subtype, arthritis, shortness of breath, serum IgA deficiency, positive anti-Scl70 antibody and usage of CYC/MMF. C-index for the model was 0.874, while the Brier scores were 0.144 after bootstrap resampling internal validation.

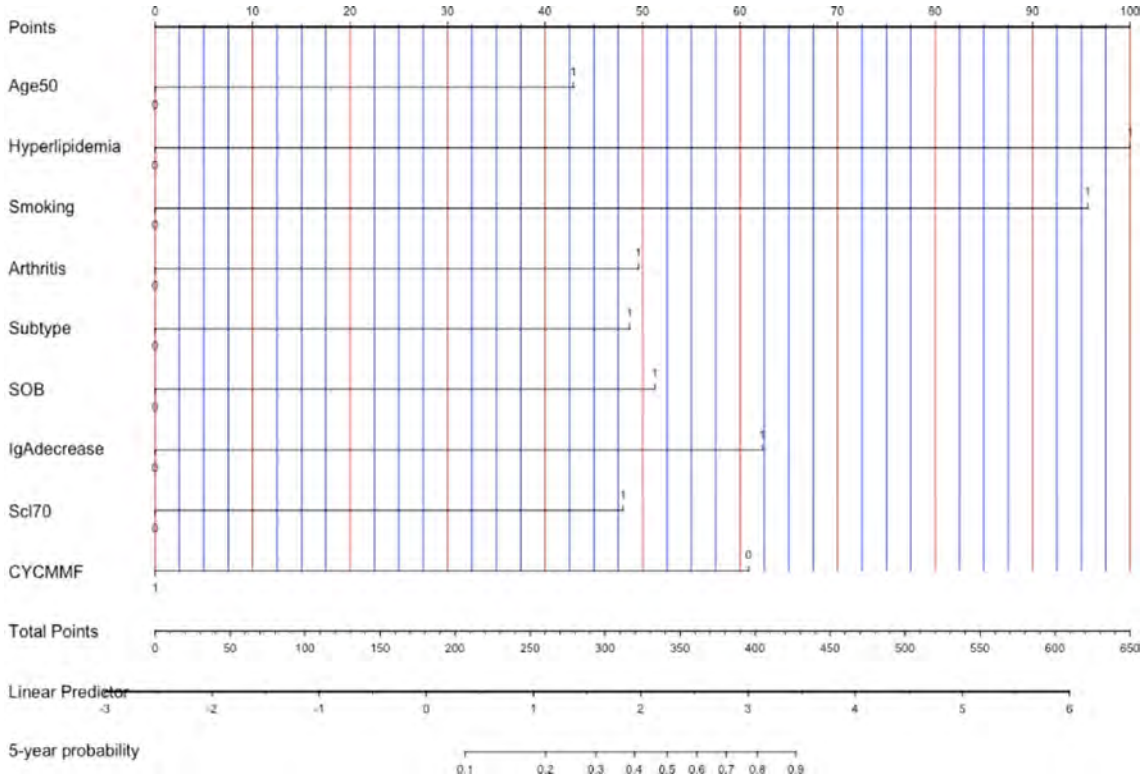
Baseline demographic and clinical characteristics of the SSc-ILD patients analyzed for PF-ILD risk in univariate Cox proportional hazards regression analysis



Nomogram predicting the probability that a systemic sclerosis patient with interstitial lung disease (ILD) will develop PF-ILD

Conclusion: This study developed the first prediction model for PF-ILD in SSc-ILD patients based on data from CRDC database, and internal validation showed favorable accuracy and stability of the model.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Anaemia in systemic sclerosis (SSc) is under-studied and under-characterised. Its prevalence amongst SSc patients is not well described, nor are its effects on outcomes and survival. The aim of this study was to report the prevalence and nature of anaemia in a large national SSc cohort, and the associations with SSc disease manifestations, malignancy, hospitalisations, and mortality.

Methods: Data prospectively collected between 2007 and 2019 as part of the Australian Scleroderma Cohort Study (ASCS) were used. All ASCS patients meeting 2013 SSc ACR/EULAR criteria were included. The prevalence of anaemia (defined as ever having a haemoglobin < 120 g/L for females and < 130 g/L for males) and severe anaemia (defined as ever having a haemoglobin < 80 g/L) were calculated. The median lowest haemoglobin ever was calculated, as was the median time to anaemia diagnosis from SSc disease onset. Anaemia status by sex and disease subclass was also assessed. Proportions of anaemic patients who experienced gastric antral vascular ectasia (GAVE), interstitial lung disease (ILD), pulmonary arterial hypertension (PAH), angina/acute myocardial infraction (AMI), malignancy, hospitalisation, and death were calculated. P-values were generated by chi square test for categorical variables, and by Wilcoxon rank-sum test for continuous variables. Survival analysis was performed using Kaplan-Meier survival estimates.

Table 1. Prevalence of anaemia in the whole cohort, and by sex and disease subclass. Values are expressed as number (%). Abbreviations: SSc – systemic sclerosis.

	Anaemia	No anaemia	*p-value*
Overall (n=1,929)	741 (38.4%)	1,188 (61.6%)	
Female (n=1,648)	619 (37.6%)	1029 (62.4%)	0.036
Male (n=276)	122 (44.2%)	154 (55.8%)	
Limited SSc (n=1,367)	487 (35.6%)	880 (64.4%)	<0.001
Diffuse SSc (n=460)	221 (48%)	239 (52%)	

Table 2. Proportions within the whole cohort, and by anaemia status, of patients who also experienced other systemic sclerosis manifestations/ comorbidities ever, were hospitalised at least once for reasons other than DU, and died within the follow up period. Values are expressed as number (%). Abbreviations: GAVE - gastric antral vascular ectasia, PAH - pulmonary arterial hypertension, ILD – interstitial lung disease, AMI – acute myocardial infraction, DU – digital ulcers.

	Whole cohort n = 1,929	Anaemia n=741	No anaemia n=1,188	*p-value*
GAVE ever	212 (11%)	124 (16.7%)	88 (7.4%)	<0.001
PAH ever	184 (9.5%)	116 (15.7%)	68 (5.7%)	<0.001
ILD ever	526 (27.3%)	251 (33.9%)	275 (23.1%)	<0.001
Angina/AMI ever	220 (11.6%)	126 (17.3%)	94 (8.0%)	<0.001
Malignancy ever	436 (22.6%)	195 (26.3%)	241 (20.3%)	0.002
Ever hospitalised (for reasons other than DU)	1048 (55.2%)	519 (70.8%)	529 (45.4%)	<0.001
Death within the follow up period	338 (17.6%)	219 (29.6%)	119 (10.1%)	<0.001

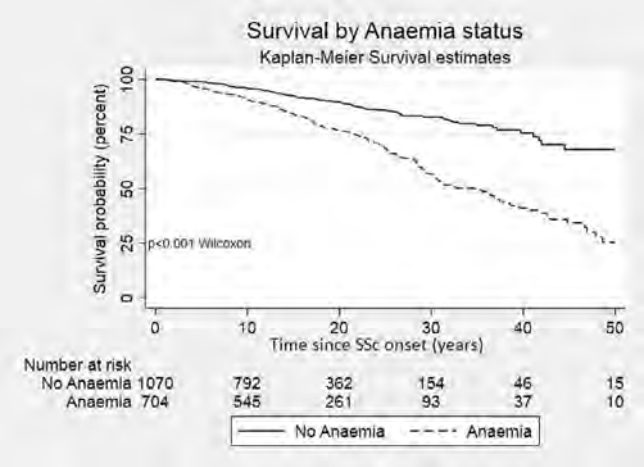

Figure 1. Survival from the first non-Raynaud's symptom onset to death according to anaemia status. Abbreviations: SSc - systemic sclerosis.

Results: Of 1,929 patients, 38.4% experienced anaemia (Table 1) and 1.3% experienced severe anaemia. Anaemia affected 44.2% of males and 37.6% of females (p= 0.036). The proportion of patients with diffuse SSc who had anaemia was 48%, compared to 35.6% of those with limited SSc (p< 0.001). The median lowest ever haemoglobin recorded was 125 g/L (interquartile range (IQR): 114 -133) amongst the whole cohort, and 110 g/L (IQR: 101-116) amongst the anaemic group (p< 0.001). The median time to anaemia diagnosis from SSc disease onset was 10.49 years (IQR: 3.91-19.46). More anaemic patients experienced GAVE compared to non-anaemic patients (16.7% vs. 7.4%, p< 0.001) (Table 2). Similarly, PAH occurred more often in anaemic patients (15.7% vs. 5.7%, p< 0.001), as did ILD (33.9% vs. 23.1%, p< 0.001), angina/AMI (17.3% vs. 8%, p< 0.001), and malignancy (26.3% vs. 20.3%, p= 0.002). More anaemic patients were hospitalised ≥ 1 time (for reasons other than digital ulcers) compared to non-anaemic patients (70.8% vs. 45.4%, p< 0.001). Death within the follow up period occurred more often in the anaemic group (29.6% vs. 10.1%, p< 0.001). Survival was significantly worse in those with anaemia (p< 0.001, Figure 1).

Conclusion: To our knowledge, this is the first study to report prevalence of all-cause anaemia in a large SSc cohort. The prevalence of anaemia in the ASCS was substantial at 38.4%. Severe anaemia was rare. A greater prevalence of anaemia was seen in male patients and in those with diffuse disease. Frequencies of GAVE, cardiopulmonary disease, and malignancy, were higher in anaemic patients, as were hospital admissions and mortality. These findings may guide clinical practice, prompting clinicians to be vigilant for concomitant anaemia in SSc, and to monitor more closely for these associations.

Session Date: Sunday, November 12, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Childhood-onset systemic sclerosis (SSc) is a rare autoimmune multisystemic condition with immune, fibrotic, and vascular manifestations. Although progress has been made in recognizing this condition in children, pediatric outcomes are not well described. We report on clinical characteristics and long-term outcomes of pediatric patients diagnosed with SSc at our center.

Table 1: Demographics and Clinical Characteristics of Patients with Systemic Sclerosis at a Large Tertiary Center

Gastrointestinal	13 (87)	5 (71)	18 (82)
Cardiac	3 (20)	0	3 (14)
Renal	0	0	0

Methods: Under IRB approval, we retrospectively reviewed patients with SSc between 2005 to 2023; 91% of patients fulfilled the 2013 EULAR/ACR classification criteria. Patients with SSc overlap syndrome who also fulfilled the 2017 EULAR/ACR juvenile dermatomyositis (JDM) classification criteria or 2012 SLICC criteria for lupus (SLE) were included. Demographics, clinical features, diagnostic findings, and outcomes were collected.

Results: A total of 22 patients were diagnosed with SSc: 15 (68%) classified as SSc between 2005-2022 and 7 (32%) classified as SSc overlap syndrome between 2015-2023 (n=4 with JDM overlap, n=1 with SLE, n=1 with Sjogren's, and n=1 patient with both JDM and SLE features). Table 1 summarizes patient's demographics and clinical characteristics. Six patients (27%) were diagnosed more than 24 months after symptom onset.

ANA was positive in 82% of patients, and 32% had Scl-70 antibody. No patients had anti-centromere or Pol III antibodies. U1-RNP or U3-RNP antibodies and hypocomplementemia were noted in overlap syndrome. Most patients had typical cutaneous, vascular, and musculoskeletal features at presentation. Pulmonary involvement was seen in 68% of patients, and 3 (all non-overlap) had worsening of their disease at their last visit. Gastrointestinal (GI) involvement was seen in 82% of patients; GERD and esophageal dysmotility being most common. Eleven patients (50%) had active or worsening GI disease at their last visit. Three patients developed cardiomyopathy with heart failure, and 2 required ICD placement. No patients developed renal disease throughout their course.

Patients received a range of immunomodulatory therapies (Figure 1); 20 (91%) received corticosteroids with 13 (59%) remaining on corticosteroids at their last visit. No patient with overlap syndrome received cyclophosphamide, however these patients were more likely to be on a biologic agent.

Figure 1: Percentage of Patients by Treatment

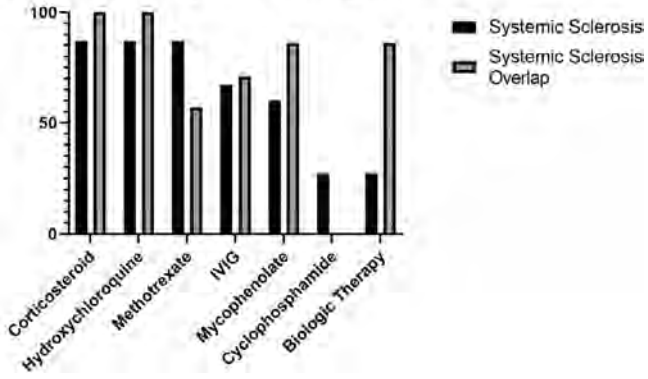

Figure 1: The most common biologic therapy includes rituximab (6 patients total) and tocilizumab (4 patients total).

Table 2: Adverse Events in Patients with Systemic Sclerosis at a Large Tertiary Center

	Systemic Sclerosis (n=15)	Systemic Sclerosis Overlap Syndrome (n=7)	Total (n=22)
Infections (%)			
Cellulitis	3 (20)	1 (14)	4 (18)
UTI	3 (20)	3 (43)	6 (27)
STI	1 (7)	1 (14)	2 (9)
Pneumocystis jirovecii pneumonia	0	1 (14)	1 (5)
Bacteremia	1 (7)	1 (14)	2 (9)
Concern for Mood Disorder (%)	4 (27)	2 (29)	6 (27)
Suicidal Ideation	2 (13)	1 (14)	3 (14)
Pregnancy (%)	1 (7)	0	1 (5)
Death (%)	1 (7)	1 (14)	2 (9)

Three patients had interruptions in care due to insurance or financial reasons. Other adverse events are shown in Table 2. Out of 12 eligible patients, 5 were successfully transitioned to an adult scleroderma center of excellence, 3 to other adult rheumatologists, and 4 did not have any transition records available at the time of the study.

Conclusion: Childhood-onset SSc and SSc overlap syndrome are rare and potentially life-threatening autoimmune conditions, and this cohort addresses a gap in knowledge about long-term outcomes. Cardiopulmonary and GI involvement remained a significant source of morbidity despite multimodal therapy. Treatment including corticosteroids was well tolerated. Defining the differences in clinical course and prognosis between juvenile SSc and SSc overlap syndrome are limited by the nature of the study, the small cohort, and variability in available treatments at the time of caring for the patient.

Chasing Pain: Investigating Somatosensory Profiles in Patients with Rheumatological Diseases Using Quantitative Sensory Testing

Claus Juergen Bauer[1], Ruth Sophie Schrapper[2], Simon Petzinna[3], Charlotte Behning[4], Tim T.A. Bender[5], Peter Brossart[1], Martin Muecke[6] and Valentin Sebastian Schäfer[1], [1]Clinic of Internal Medicine III, Department of Oncology, Hematology, Rheumatology and Clinical Immunology, University Hospital of Bonn, Bonn, Germany, [2]University of Bonn, Bonn, Germany, [3]Clinic of Internal Medicine III, Oncology, Hematology, Rheumatology and Clinical Immunology, University Hospital Bonn, Bonn, Germany, [4]Institute of Medical Biometry, Informatics and Epidemiology, University Hospital of Bonn, Bonn, Germany, [5]University Hospital of Bonn, Bonn, Germany, [6]Universital Hospital of Aachen, Aachen, Germany

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Pain is a prominent symptom in numerous rheumatological diseases. In order to allow for a standardized quantification and the assessment of nociceptive and non-nociceptive submodalities of various afferent nerve fiber groups and central pathways, and to identify sensitive plus or minus signs like hyperalgesia or hypesthesia, the "Quantitative Sensory Testing" (QST) protocol was developed. This tool, established by the German Neuropathic Pain Research Network

Fig. 2 Results of the linear modelling for Mechanical Detection Threshold (MDT) and Vibration Detection Threshold (VDT)

(DFNS), generates somatosensory profiles [1]that can serve as a valuable tool for guiding targeted pain management strategies. This study investigates variations in somatosensory profiles between healthy individuals and patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA), axial spondyloarthritis (SpA), systemic sclerosis (SSc).

Methods: Twenty patients of each disease group (RA, PsA, SpA and SSc) and 20 healthy individuals were enrolled in this monocentric five-armed study, which received ethical approval under Institutional Review Board #065/20. Each of the 100 participants underwent the standardized QST procedure for the creation of a somatosensory profile. QST included both small fiber mediated stimuli and large fiber mediated stimuli incorporating all categories depicted in figure 1. Additional clinical data (including laboratory values, joint manifestations, and pain and disease activity assessments) was collected via standardized questionnaires (BASDAI, PASDAS, CDAI and mRSS). Data was analyzed by using linear modelling and standardized z-scores.

Results: A preliminary data analysis of all 100 study participants was performed. As shown in figure 2, all patient groups presented with increased mechanical detection thresholds ($p \leq 0.045$ for RA, PsA, SpA and SSc). Furthermore, RA, PsA and SpA patients showed diminished vibration perception ($p \leq 0.033$ for RA, PsA and SpA). A higher prevalence of allodynia was seen in all patient groups, as in 5% of patients with SSc, 15% of RA, 25% of PsA, and 15% of all SpA patients, compared with 0% in the control group.

Additionally, the study showed that people with systemic sclerosis notice cold and cold pain stimuli much earlier than healthy individuals ($p=0.023$).

Conclusion: Allodynia, mechanical detection and vibration are perceived through A β-fibers. Considering that all these three modalities showed deviations within the somatosensory profiles, A β-fibers seem to be most severely affected from rheumatological diseases. Accordingly, further research on the role of A β-fibers, particularly in allodynia, is thought to be supportive in the improvement of targeted and personalized pain management. Systemic sclerosis patients' particular susceptibility to cold stimuli is explained given the presence of Raynaud's syndrome.

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The 2022 ESC/ERS Guidelines recommend comprehensive risk stratification at diagnosis of pulmonary arterial hypertension (PAH) to guide optimized management.[1]Several risk stratification tools have been developed with data derived mainly from patients with idiopathic PAH. However, patients with systemic sclerosis (SSc)-associated PAH have a worse prognosis. We aimed to assess the performance of current risk stratification tools to predict mortality in SSc-PAH by adding variables specific to SSc.

Methods: We included SSc patients from the EUSTAR database who were diagnosed with PAH by right heart catheterization (RHC) between 2001-2021 (Project Number: CP122). PAH was defined as a mean pulmonary arterial pressure >20 mmHg, pulmonary artery wedge pressure ≤15 mmHg and pulmonary vascular resistance >2 WU. We excluded patients with previous PAH-specific treatment and meaningful interstitial lung disease (ILD), defined as an extent of ILD >20% on HRCT or FVC < 70% in patients with missing quantification. We applied four different approaches:

(I) **2022 ESC/ERS 3-strata:** Three risk groups based on the mean of up to 17 risk parameters from the guidelines graded 1-3 representing low-high risk

(II) **2022 ESC/ERS 4-strata:** Equals no. (I), but divides the intermediate-risk group into two groups

(III) **COMPERA 2.0:** Four risk groups based on the mean of WHO-functional class (FC) and/or six-minute walk distance (6MWD) and NT-proBNP graded 1-4 representing low-high risk.[2]

(IV) **REVEAL Lite 2:**Three risk groups based on six weighted variables (WHO-FC, systolic blood pressure, heart rate, 6MWD, NT-pro-BNP, and eGFR)[3]

We performed Cox regression adjusted for general and SSc-specific factors associated with worse outcome based on expert opinion and published literature (age, male sex, anti-centromere antibodies, digital ulcers, DLCO and limited ILD). Harrell's C-index and ROC analysis with area under the curve (AUC) were applied to compare the performance and discriminating ability of the models with >0.7 defined as acceptable.

Results: Of 890 patients who had RHC, 367 were eligible. Among these, 87% were females, mean age was 66 years, and 83% had limited cutaneous SSc.

In univariable analysis, only COMPERA 2.0 and REVEAL Lite 2 had acceptable predictive value with a C-index >0.7 (table). Adjusted for general and SSc-specific variables, all models were acceptable (table, fig. 1).Numerically, COMPERA 2.0 and REVEAL Lite 2 were the most accurate to predict mortality (table, fig. 1). Hazard ratios increased with higher risk scores (fig. 2). However, COMPERA 2.0 and REVEAL Lite 2 did not significantly discriminate the lower risk groups (fig. 2).

Conclusion: In SSc-PAH, we suggest that risk stratification at time of PAH diagnosis should take general and SSc-specific variables into account. The COMPERA 2.0 and REVEAL Lite 2 risk stratification models perform best when used as stand-alone tools. Neither requires invasive measurements, making them easily applicable in clinical practice. Importantly, these models identify patients in the high-risk group where aggressive upfront treatment is recommended.

Table: Harrell's C-index and AUC in the four approaches

	Univariable analysis		Multivariable analysis	
	C-index	AUC (p=0.04)	C-index	AUC (p=0.27)
ESC/ERS 3-strata	0.64	0.64	0.71	0.71
ESC/ERS 4-strata	0.66	0.67	0.72	0.72
COMPERA 2.0	0.72	0.72	0.76	0.75
REVEAL Lite 2	0.73	0.72	0.78	0.73

Session Date: Sunday, November 12, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Pulmonary arterial hypertension (PAH) patients can be stratified as low, intermediate, or high risk of 1-year mortality based on clinical, biochemical and haemodynamic prognostic variables measured at diagnosis. In 2022, the European Society of Cardiology (ESC) and European Respiratory Society (ERS) updated their risk assessment method which is intended to guide therapeutic strategy over time.(1)

Methods: We evaluated incident systemic sclerosis-associated PAH (SSc-PAH) in a large combined cohort of Singaporean and Australian patients. We applied the 2022 ESC 3- and 4-strata risk assessment at baseline and first follow up (within 2 years), respectively. Kaplan-Meier survival analyses and Cox proportional hazards regression models were used to evaluate survival according to risk score.

Results: At baseline (n = 200), the majority of SSc-PAH (72.2%) were intermediate risk according to the 2022 ESC 3-strata risk assessment, based on ten variables. At follow-up, according to the 4-strata risk assessment (based on three variables: WHO functional class, serum N-terminal pro-brain type natriuretic peptide and six-minute walk distance), half (53.5%) of the

cohort were classified as low or intermediate-low risk (Figure 2). The 2022 4-strata risk model at follow up demonstrated statistically significant differences in survival between risk groups with low risk having better survival, and a change in risk category from high or intermediate risk to low or lower risk was associated with an improvement in survival (Figure 1). All three individual parameters were significantly associated with mortality at baseline and/or follow up and included WHO functional class, serum N-terminal pro-brain type natriuretic peptide and six-minute walk distance (Table 1).

Conclusion: The 2022 ESC risk assessment strategy at baseline and follow up accurately predicts survival in SSc-PAH and is sensitive to change. Treatment decisions for SSc-PAH should include risk assessments, aiming to achieve low risk status according to the 2022 ESC guidelines as this is associated with improved outcome.

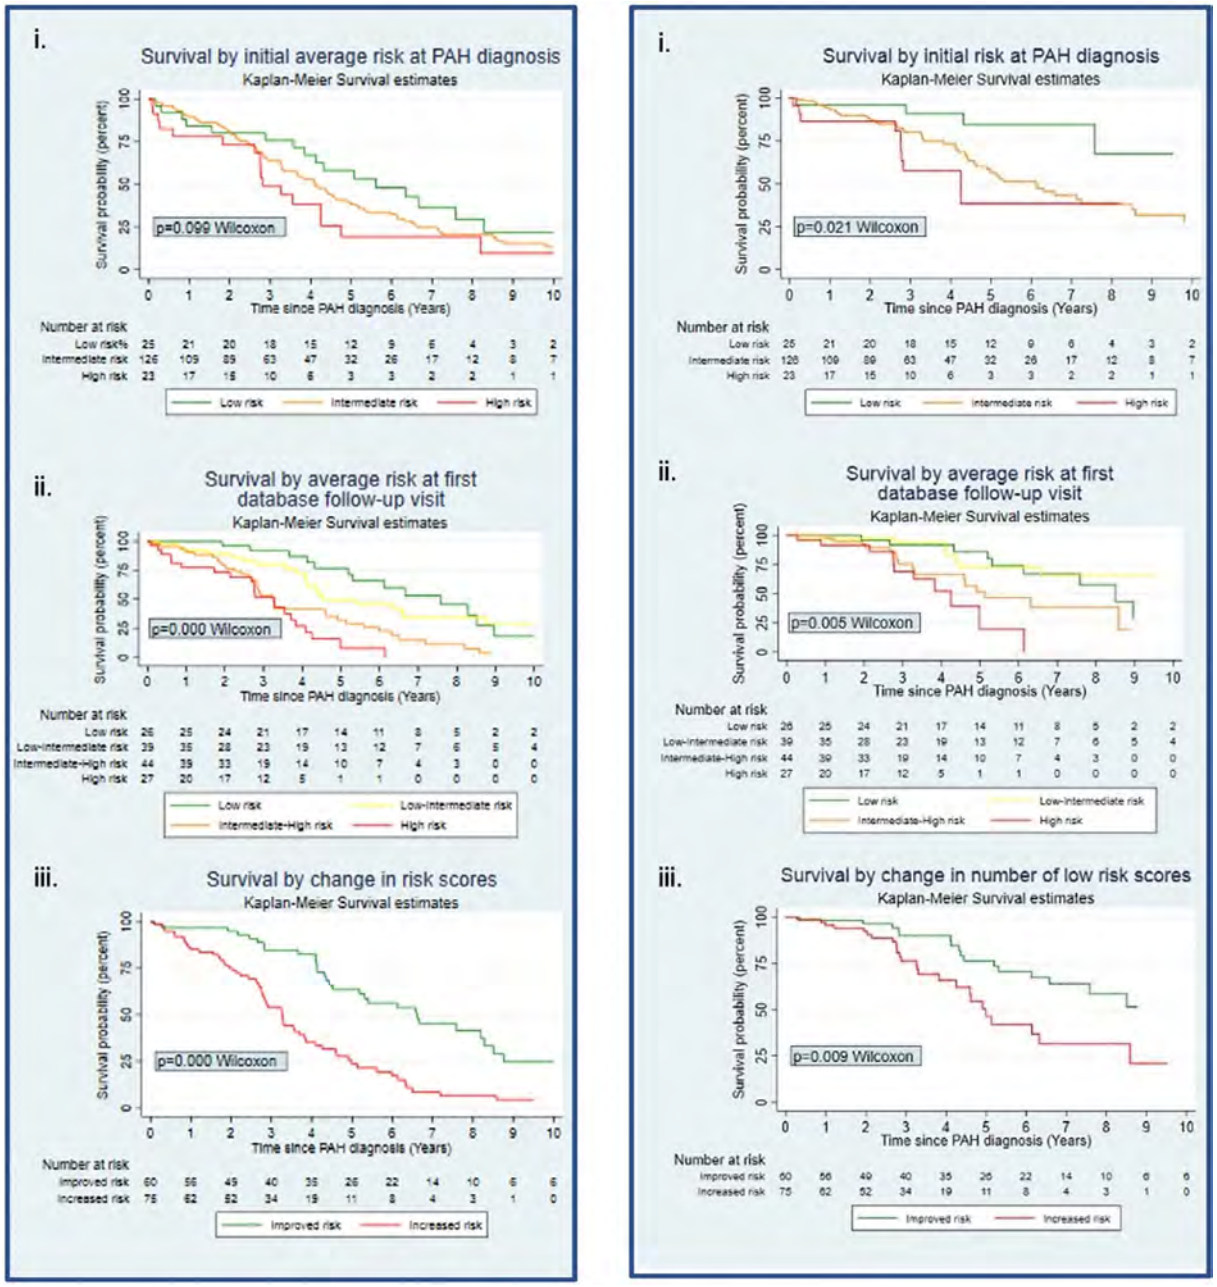

Figure 1. Kaplan-Meier survival curve according to 2022 ESC risk score from PAH diagnosis to mortality applied at i. PAH diagnosis, ii. First follow up and iii. Change in risk score: a.) All-cause mortality b.) PAH-related mortality

Evaluating Esophageal Dysmotility by Scintigraphy in Systemic Sclerosis: Subsets and Phenotypes

Antonio Salas[1], Lisa Yanek[2] and Zsuzsanna McMahan[3], [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Johns Hopkins University School of Medicine Department of Medicine, Baltimore, MD, [3]Johns Hopkins Rheumatology, Lutherville, MD

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Gastrointestinal (GI) dysmotility affects most patients with systemic sclerosis (SSc), and the esophagus is the most commonly affected region. While most SSc patients are negatively impacted by esophageal dysmotility, significant heterogeneity exists (i.e., absent contractility, ineffective esophageal motility). Importantly prior studies demonstrate that esophageal manometry is useful for risk stratification. For example, absent contractility associates with a more severe extraintestinal clinical phenotype of SSc, (e.g., diffuse cutaneous disease, lower diffusing capacity of the lungs for carbon monoxide (DLCO) values and more severe Raynaud's) while ineffective esophageal motility associates with a milder SSc clinical phenotype. However, manometry can be difficult to obtain due to poor access to the study, and its invasive nature limits tolerability among patient subgroups (i.e., cardiopulmonary complications). Scintigraphy offers a non-invasive alternative to manometry in characterizing motility. We therefore sought to determine (1) whether distinct SSc clinical features associate with decreased esophageal transit on scintigraphy; and (2) how such features compare to the previously described extraintestinal clinical phenotypes described in patients with absent contractility and ineffective esophageal motility on manometry.

Methods: Clinical and demographic features and patient reported outcomes were compared between patients with and without delayed esophageal transit on scintigraphy. Patients were part of a prospective cohort of patients who had clinical data and blood samples collected every 6 months during clinical visits. Scintigraphy-based whole gut transit was used to measure transit time and the percent emptying in each part of the gut from the esophagus to the colon. Medsger scores were used to evaluate SSc disease activity, UCLA-GIT scores were used to evaluate GI symptoms, and the COMPASS-31 survey was used to evaluate symptoms of dysautonomia.

Results: Among 131 patients in our cohort, 79 (60%) had delayed esophageal transit and 52 (40%) did not. Patients with delayed esophageal transit were more likely to have diffuse scleroderma [24 (32%) vs. 11 (22%); p=0.024]. Esophageal transit time negatively correlated with DLCO values (correlation coefficient: -0.317; p=0.014) and % esophageal emptying at 10 seconds was positively correlated with DLCO values (correlation coefficient: 0.339; p=0.0173). Secretomotor symptoms were negatively associated with esophageal transit time (correlation coefficient -0.223; p=0.041). Interestingly, patients with delayed esophageal transit had a higher median (IQR) diarrhea GIT score [0.5 (0-1) vs. 0 (0-1); p=0.050].

Conclusion: Our results suggest that esophageal scintigraphy is a useful tool that can identify patients with a more severe SSc phenotype. Furthermore, patients with delayed esophageal transit on scintigraphy have similar clinical characteristics to SSc patients with absent contractility diagnosed on manometry. Further studies are needed to determine whether esophageal scintigraphy may serve as non-invasive tool to identify SSc patients who may have specific GI and extraintestinal complications.

Table 1. Clinical, demographic, and antibody data of our cohort separated by presence of esophageal transit delay.

Clinical and demographic features	Total (n)	Delayed esophageal transit (n=79)	No delay in esophageal transit (n=52)	P-value
Sex (female), n (%)	131	70 (88.61)	48 (92.31)	0.488
Age at time of WGT, mean (± SD)	131	57.02 (12.5)	55.67 (12.8)	0.552

Multidisciplinary and Multiparametric Evaluation of Sarcopenia in Patients with Systemic Sclerosis

Marco Di Battista[1], Alessandra Rossi[1], Gaia Pisano[1], Riccardo Morganti[2], Alessandra Della Rossa[3] and Marta Mosca[4], [1]Rheumatology Unit, University of Pisa, Pisa, Italy, [2]Section of Statistics, University of Pisa, Pisa, Italy, [3]University of Pisa, Rheumatology Unit, Pisa, Italy, [4]Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a chronic autoimmune disease with a heterogeneous clinical expression that heavily affects the functionality and quality of life of patients. Sarcopenia is an insidious complication of SSc, often poorly recognized and underdiagnosed, but difficult to manage and with important prognostic repercussions. The aim of this study was to evaluate the prevalence of sarcopenia in subjects with SSc, trying to obtain a characterization as complete as possible through a multidisciplinary approach.

Methods: Consecutive adult SSc patients were evaluated by a multidisciplinary team of rheumatologists, nutritionists and physiotherapists to identify the presence of sarcopenia according to the diagnostic algorithm proposed by the EWGSOP2 consensus in 2019. After completing the SARC-F questionnaire, generally used for the case finding, the patients' muscle strength was measured with the hand grip test and the 5-times sit to stand test (5STS). Subsequently, the confirmation of a possible sarcopenia was obtained by measuring the appendicular skeletal muscle mass (ASSM) by bioimpedance vector analysis (BIVA), a method also used to identify subjects with a state of malnutrition. Finally, the severity of sarcopenia was assessed using the following physical performance tests: short performance physical battery (SPPB - composite score of balance tests, 4m linear walk and 5STS), time up and go (TUG - static balance and dynamic) and gait speed.

Results: Thirty-three SSc patients (87.8% female, mean age 61.2 ± 12 years) were evaluated. The SARC-F questionnaire resulted pathological in 9 of them, whereas for the evaluation of muscle strength pathological values were observed in 42.4% and in 45.4% of the hand grip and 5STS tests, respectively. The ASSM/height ratio was used for the evaluation of muscle mass and was found pathologically reduced in 37.2% of patients. Finally, physical performance tests had pathological results in 27.2% of SPPB, 9% of TUG and 15.1% of gait speed tests. According to the definitions proposed by the EWGSOP2, in our cohort sarcopenia was found in 13 (39.4%) SSc patients, of which 5 (15.1%) presented a severe form. In addition, BIVA found malnutrition in 12 patients and this happened in combination with a sarcopenic state in 75% of cases. Malnourished subjects had significantly lower hand grip strength values (p=0.007), worse SPPB scores (p=0.03), and longer TUG times (p=0.05).

Conclusion: Sarcopenia emerges as a relatively frequent complication in SSc, with important repercussions on the physical-dynamic sphere and a profound interrelationship with nutritional status. A multidisciplinary approach is essential for an accurate diagnosis of sarcopenia in potentially high-risk individuals such as those with SSc.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The occurrence of lower limbs macrovascular complications configuring lower extremities arterial disease (LEAD) has been reported in Systemic Sclerosis (SSc) patients. Recently, digital ulcers (DUs), pulmonary arterial hypertension (PAH), steroid use and active smoking/having stopped ≤3 years were identified as factors associated with lower limbs amputation in a single-centre SSc cohort[1]. Our aim was the estimation of LEAD prevalence in: (i) the overall SSc cohort and (ii) at-risk patients according to the above-mentioned features.

Methods: Consecutive SSc patients attending our centre for scheduled visits between October 2022 and April 2023 were included. Patients without known LEAD with ≥1 feature associated to lower limb amputation, as described above[1] were referred for lower extremities arterial Doppler ultrasonography (DUS) performed by a single expert vascular surgeon.

Results: Among 192 SSc patients evaluated (93% females, 81% limited cutaneous involvement, 45% anti-centromere), 18 (9%) were previously diagnosed with LEAD, requiring revascularization interventions in 8 (44%) and amputations in 5 (28%). As compared to the remaining 174, they were older (median[1st-3rd quartile]: 75[69-79] vs 62[51-70] years; p< 0.001), had a longer disease duration (20[15-27] vs 12[6-19] years; p:0.004), higher frequency of DUs (90% vs 54%; p:0.001), especially at lower limbs (67% vs 12%; p< 0.001), more comorbidities (Charlson Comorbidity Index: 6[5-7] vs 3 [2-5]; p< 0.001), and were more frequently treated with prostanoids (67% vs 31%; p:0.002) and steroids (61% vs 31%; p:0.010).

At least 1 LEAD risk factor was identified in 124/174 patients (71%) (DUs (77%); steroid use (40%); smoking (26%); PAH (5%)). Among 41 patients so far evaluated by DUS, LEAD was detected in 13 (32%) (**Table 1**): 10 were asymptomatic (stage I), 2 reported mild claudication (stage IIa), 1 reported pain also at rest (stage III). 10/13 were already on treatment with anti-

Table 1. Characterization of LEAD findings on DUS in 13 patients. Variables are expressed as n (%).

	Occlusion	Stenosis	Intimal thickening	Calcifications
Proximal arteries	0 (0)	5 (39)	6 (46)	6 (46)
Femoral arteries	0 (0)	5 (39)	5 (39)	6 (46)

Endothelin-antagonists	6/28 (21.4)	3/13 (23.1)	1.000
PDE5-inhibitors	3/28 (10.7)	0/13 (0.0)	0.539
Selexipag	1/28 (3.6)	0/13 (0.0)	1.000
Steroids	9/28 (32.1)	4/13 (30.8)	1.000
Immunosuppressive therapy	7/28 (25.0)	4/13 (30.8)	0.719
Statins	4/28 (14.3)	5/13 (38.5)	0.113
Anticoagulants	2/28 (7.1)	2/13 (15.4)	0.579

platelets/anti-coagulants, in the remaining 3 patients low dose aspirin was added; the patient with LEAD stage III was referred to angiographic study. As compared to 28 patients with a normal DUS, no differences were observed in clinical-demographic features (**Table 2**).

Conclusion: Based on these preliminary data, in our SSc cohort the prevalence of diagnosed LEAD stands at 9%. However, by selecting at-risk SSc patients (DUs, PAH, steroid use and smoking), LEAD signs on DUS were detected in 32% of them, mostly free from lower limb symptoms and traditional CV risk-factors. This underlines the need to implement the diagnostic/therapeutic work-up of SSc patients by performing lower extremities arterial DUS and including vascular surgeons in the multidisciplinary team dedicated to SSc patients.

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) patients with clinical features of another connective tissue disease (CTD) may have different clinical characteristics from patients with SSc alone. Our aim was to compare the clinical characteristics and survival of patients with SSc, SSc-overlap and SSc-mixed connective tissue disease (MCTD).

Table 1: Demographics and clinical characteristics

Table 1: Demographics and clinical characteristics

	SSc (n=2131)	SSc-overlap (n=250)	SSc-MCTD (n=164)	P value
Diffuse SSc, n (%)	666 (31.3)	45 (18.5)	21 (20.2)	<0.001
Female, n (%)	1786 (84.9)	220 (89.4)	151 (92.1)	0.008

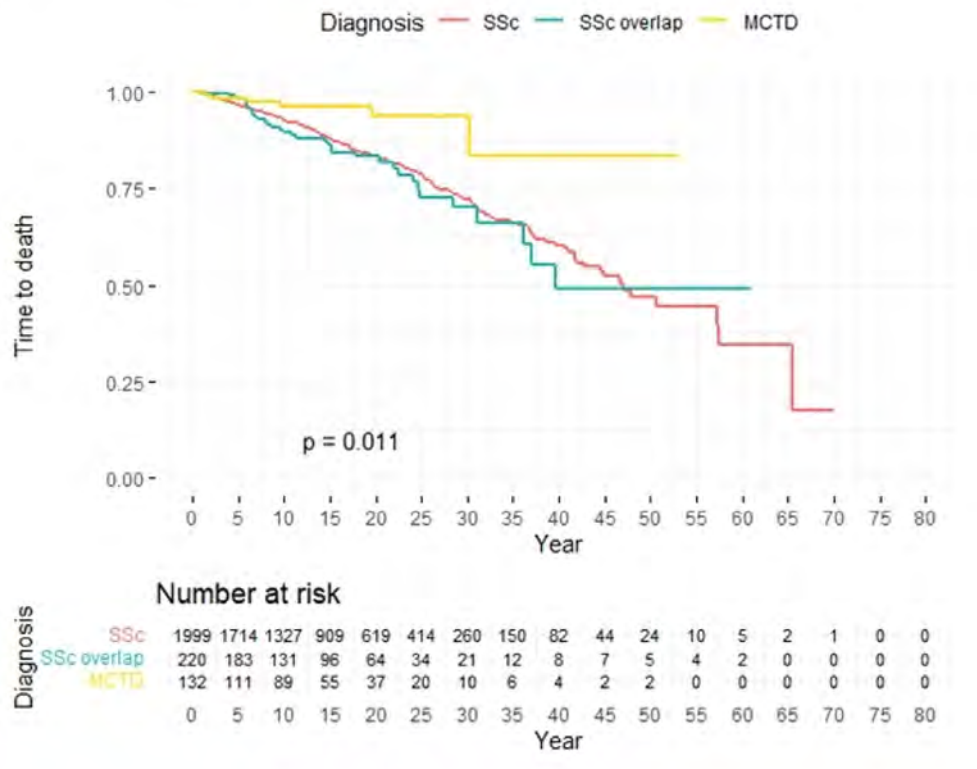
Rheumatoid factor	129 (20.0)	35 (33.0)	33 (47.1)	<0.001
Immunomodulators, n (%)	1236 (59.7)	216 (88.2)	145 (89.5)	<0.001

Methods: This retrospective cohort study included SSc, SSc-overlap and SSc-MCTD patients from Australia, Hong Kong, Malaysia, Singapore, and Thailand. SSc patients fulfilled the 2013 ACR-EULAR SSc classification criteria; SSc-overlap patients also fulfilled the criteria for another CTD which included rheumatoid arthritis, systemic lupus erythematosus, or inflammatory myositis; SSc-MCTD patients had anti-RNP antibody positivity and at least 3 of the following features (per Alargon-Sergovia criteria): swollen hands, synovitis, myositis, Raynaud phenomenon (RP) and acrosclerosis/sclerodactyly. Univariate comparison of clinical characteristics among groups was performed by analysis of variance or chi-square testing. Survival analysis was performed using Kaplan-Meier curves.

Results: Among 2545 patients (11.3% from Singapore, 5.3% from Malaysia, 3.8% from Thailand, 3.3% from Hong Kong and 76.3% from Australia), 250 (9.8%) had SSc-overlap syndrome, 164 (6.4%) had SSc-MCTD and 2131 (83.7%) had SSc. SSc-overlap and SSc-MCTD, respectively, occurred more frequently in the Asian (SSc-overlap: 13.2%-17.9%; MCTD: 8.3%-31.8%) vs Australian (SSc-overlap: 8.2%; MCTD: 3.7%) cohorts. SSc patients were more likely to have diffuse cutaneous SSc, significantly higher modified Rodnan skin score (11.2 ± 9.8 in SSc vs 9.0 ± 9.0 in SSc-overlap vs 6.5 ± 7.2 in SSc-MCTD, p< 0.001), gastrointestinal involvement, higher % predicted forced vital capacity (89.0 ± 22.8 in SSc vs 84.6 ± 23.5 in SSc-overlap vs 80.1 ± 19.9 in SSc-MCTD, p< 0.001) and digital ulcerations as compared to SSc-overlap and SSc-MCTD patients. Arthritis and myositis were significantly more prevalent in SSc-overlap and SSc–MCTD than in SSc

Figure 1: Survival by diagnosis group



Comparison	KM analysis	Univariate Cox regression		
	Log-rank test p value*	HR (95% CI)	P value	Omnibus P value
SSc vs SSc overlap	0.6082	0.903 (0.640, 1.273)	0.5586	0.0220
SSc vs MCTD	0.0053	2.886 (1.326, 6.282)	0.0076	
SSc overlap vs MCTD	0.0053	3.198 (1.386, 7.379)	0.0064	

* adjusted for multiple comparison (BH method)

Figure 1: Survival by diagnosis group

patients. RP was more frequent in SSc-MCTD than in SSc and SSc-overlap patients. At baseline, more patients with SSc (27.7%) and SSc-overlap (21.2%) were in NYHA III/IV than MCTD (15.3%; p< 0.001). There was no significant difference in the frequency of interstitial lung disease and pulmonary arterial hypertension in the 3 groups. Anti-centromere antibody was more frequently seen in SSc patients, and anti-topoisomerase I antibody in SSc-overlap and SSc patients; other antibodies including anti-PM/Scl, double-stranded DNA, rheumatoid factor, anti-Ro, anti-La and Jo-1 were significantly less frequent in the SSc group compared to the SSc-overlap and SSc-MCTD groups. SSc-MCTD and SSc-overlap patients were also more likely to receive immunomodulators than SSc patients (Table 1). Overall survival was better in SSc-MCTD than SSc or SSc-overlap (p=0.011) (Figure 1).

Conclusion: Our study showed significant differences in the clinical characteristics and survival outcomes in patients with SSc, SSc-overlap and SSc-MCTD.

Session Date: Sunday, November 12, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: In clinical practice, we often wait for progression of interstitial lung disease (ILD) in systemic sclerosis (SSc) to initiate or escalate therapy. Similarly, progressive SSc-ILD patients are recruited into trials to enrich for further progression. These strategies assume that patients with recent ILD progression have a higher risk for further progression. Here, we assessed whether ILD progression predicts subsequent progression using four definitions of progressive disease.

Methods: We included all SSc patients from two expert SSc centers who had ILD on HRCT and consecutive annual forced vital capacity (FVC) measurements. For the primary analysis, ILD progression was defined as absolute FVC decline ≥5% over 12 months. Patients were grouped into progressors (FVC ≥5% decline) and non-progressors (all others). At the next annual

follow up visit, all patients were again assessed for ILD progression. In secondary analyses, we applied other definitions of progression such as:

1. 2022 ATS/ERS/JRS/ALAT PPF guideline criteria with (1) worsening of respiratory symptoms; (2) absolute decline in FVC ≥5% or in DLCO ≥10% and (3) disease progression on HRCT over 12 months
2. INBUILD PF-ILD criteria with (1) FVC decline ≥10%, (2) FVC decline >5%-< 10% and worsening of respiratory symptoms or an increased extent of fibrosis on HRCT, or (3) worsening of respiratory symptoms and an increased extent of fibrosis within 24 months
3. Composite criteria with decline in FVC ≥10%; or FVC ≥5%-9% and DLCO >15%.

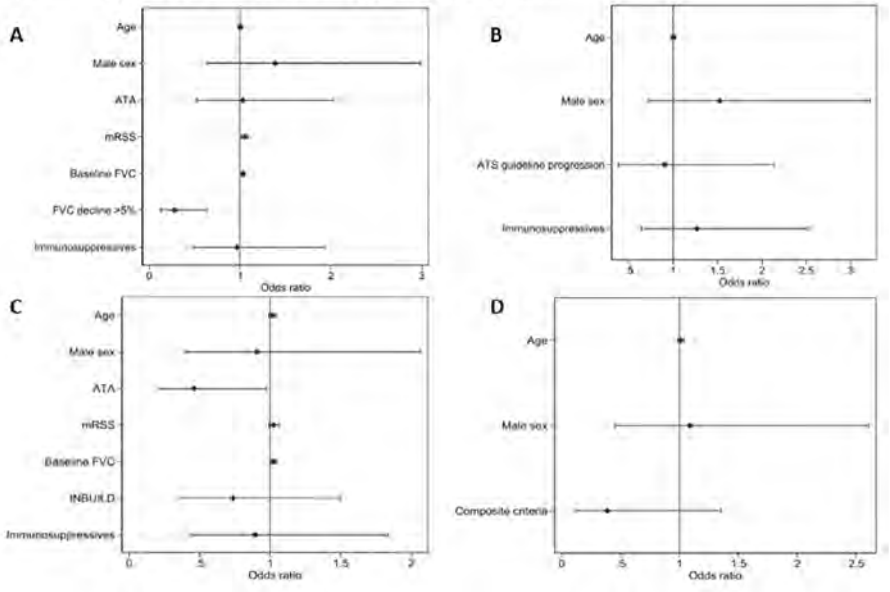
Multivariable logistic regression was applied, adjusting for known risk factors of ILD progression, including treatment.

Results: In total, 231 SSc-ILD patients were included (Table 1). At 12 months, 71 (30.7%) showed FVC decline >5% and were classified as progressors. In multivariable logistic regression ILD progression was significantly protective for further progression at the next annual follow-up (Odds Ratio 0.28, 95%CI 0.12-0.63, p=0.002, Figure1a). When other definitions of

Table1: Baseline characteristics and death of patients fulfilling different definitions for ILD progression

	FVC decline>5% N=71	PPF N=39	PF ILD N=89
Male sex, n (%)	20 (28)	11 (28)	27 (30)
Age at onset, y (SD)	49 (14.8)	49 (13.5)	48 (13.0)
Disease duration<3y, n (%)	9.4 (11.2)	7.8 (8.8)	7.9 (8.9)
dcSSc, n (%)	36 (51)	22 (56)	46 (52)
ATA, n (%)	33 (47)	20 (51)	38 (43)
CRP↑, n (%)	7 (14)	2 (9)	7 (11)
FVC, % (SD)	93 (19.6)	88 (18.9)	89 (20.4)
DLCO, % (SD)	66 (16.3)	61 (16.4)	65 (17.7)
Functional class 3&4, n (%)	9 (19)	5 (18)	11 (18)
ILD>20%, n (%)	17 (26)	15 (44)	27 (34)
Ground glass, n (%)	28 (42)	22 (59)	44 (51)
O_2 desaturation, n (%)	6 (14)	6 (30)	9 (16)
Immunosuppressives, n (%)	20 (28)	18 (46)	38 (44)
Death, n (%)	32 (45)	18 (46)	39 (44)

Figure 1: Multivariable logistic regression for ILD progression using definitions of ILD progression (A) FVC decline >5%, (B) Guideline criteria; (C) INBUILD criteria and (D) composite criteria



ATA: anti-topoisomerase I antibody; mRSS: modified Rodnan skin score; FVC: forced vital capacity

progression were applied, similar results were obtained: 39 (19%) fulfilled the PPF guideline criteria, 89 (39%) the PF-ILD criteria and 33 (14%) the composite criteria. Multivariable regression analysis adjusted for age, sex and treatment (PPF), for age and sex (composite) and for age, sex, anti-Topoisomerase I antibody (ATA), modified Rodnan skin Score (mRSS), baseline FVC and treatment (PF-ILD) showed the same direction as the primary analysis (Figure1b-d).

Conclusion: SSc-ILD progression does not predict further progression using any definition of ILD progression. These results challenge current treatment practice, since waiting for progression to initiate or escalate treatment does not seem to be the adequate strategy.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Progression of interstitial lung disease (ILD) reduces long-term survival in patients with systemic sclerosis (SSc), and aggressive treatment and tight monitoring should be considered. Conversely, identifying stable SSc-ILD patients over time is important in clinical practice to avoid overtreatment and facilitate inclusion into clinical trials. The objective was to determine predictive factors for stable ILD in SSc.

Methods: We included all SSc patients who had ILD on HRCT from two expert SSc centers with well characterized SSc cohorts. Consecutive annual lung function tests including forced vital capacity (FVC) and diffusing capacity for carbon monoxide (DLCO), and comprehensive serial clinical and imaging assessments were evaluated. Patients were defined as long-term stable ILD if no progression was observed over three years, using the following definitions for ILD progression:

(A) FVC decline ≥5% over 12 months

	All N=231	Stable ILD using		
		No FVC decline>5% N=75	No PPF N=133	No PF-ILD N=105
Male sex, n (%)	55 (24)	19 (25)	27 (20)	22 (21)
Age at onset, y (SD)	48 (14.6)	47 (13.8)	48 (15.5)	48 (15.4)
Disease duration<3y, n (%)	67 (31)	19 (28)	28 (23)	20 (21)
dcSSc, n (%)	94 (41)	24 (33)	42 (32)	31 (30)
Anti-topoisomerase I Ab, n (%)	83 (37)	24 (33)	46 (36)	34 (34)
CRP↑, n (%)	28 (18)	10 (20)	18 (26)	13 (18)
Reflux disease, n (%)	142 (63)	43 (59)	74 (58)	60 (59)
Arthritis, n (%)	18 (17)	3 (11)	6 (11)	5 (12)

Desaturation at six min walking test			

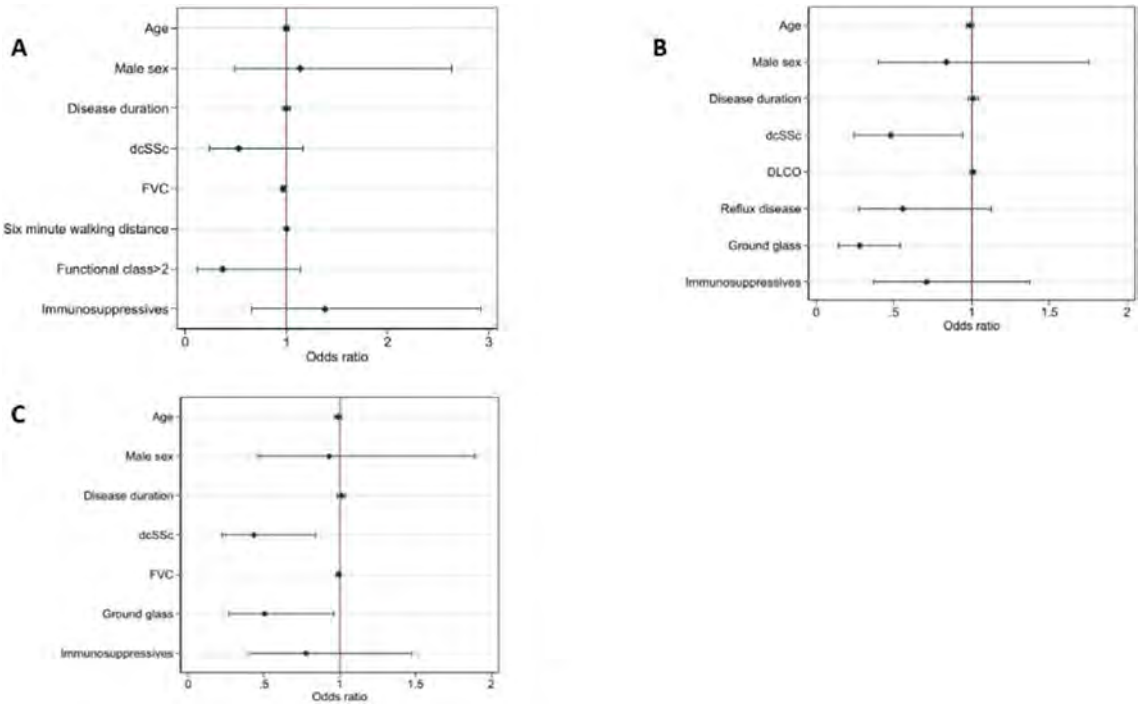

Figure 1: Variables predicting stable ILD using (A) FVC ≥5% decline, (B) PPF and (C) PF-ILD assessed with multivariable logistic regression

(B) 2022 ATS/ERS/JRS/ALAT guideline progressive pulmonary fibrosis (PPF) criteria with (1) worsening of respiratory symptoms; (2) absolute decline in FVC ≥5% or in DLCO≥10% and (3) disease progression on HRCT over 12 months

(C) INBUILD progressive fibrosing ILD (PF-ILD) criteria with (1) relative FVC decline ≥10%, (2) relative FVC decline ≥5-< 10% and worsening of respiratory symptoms or an increased extent of fibrosis on HRCT, or (3) worsening of respiratory symptoms and an increased extent of fibrosis within 24 months.

Multivariable logistic regression was applied, adjusting for known risk factors for ILD progression, including treatment, to identify predictors of stable ILD.

Results: In total, 231 SSc-ILD patients were included (Table 1). We identified 75 (32%) patients with stable ILD over mean three years defined by no FVC decline≥5%, 133 (58%) defined by no PPF guideline criteria and 105 (45%) by no INBUILD PF-ILD criteria. Factors predicting long-term stable ILD varied in univariable logistic regression depending on which definition was applied and no consistent factors could be identified (Table 2). Multivariable logistic regression models also varied based on the applied definition. Stable ILD as defined by no FVC >5% decline was predicted by lower baseline FVC (Figure 1A). Stable ILD defined by no PPF criteria and no PF-ILD criteria was significantly predicted by the absence of dcSSc and of ground glass opacities on HRCT (Figure 1B and C).

Conclusion: Long-term stable ILD in SSc occurs but varies based on which definition is applied. Prediction of stability is challenging, highlighting the necessity of comprehensive disease assessment and monitoring.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: We have previously shown that short term progression of interstitial lung disease (ILD) in systemic sclerosis (SSc) is associated with mortality. However, it is less clear how multiple progressive ILD events over years affect mortality. The objective was to determine the number of progressive SSc-ILD events over three years and assess its impact on mortality.

Methods: We included all SSc patients from two expert SSc centers with well characterized SSc cohorts who had ILD on HRCT, consecutive annual lung functions including forced vital capacity (FVC) and diffusing capacity for carbon monoxide (DLCO) and comprehensive serial clinical and imaging assessments available. ILD progressive events were observed over a follow-up period of 3 years segregated in no, 1 or >1 progressive event using:

(A) FVC ≥5% decline over 12 months

(B) 2022 ATS/ERS/JRS/ALAT guideline progressive pulmonary fibrosis (PPF) criteria with (1) worsening of respiratory symptoms; (2) absolute decline in FVC ≥5% or in DLCO ≥10% and (3) disease progression on HRCT over 12 months

(C) INBUILD progressive fibrosing ILD (PF-ILD) criteria with (1) relative FVC decline ≥10%, (2) relative FVC decline ≥5-< 10% and worsening of respiratory symptoms or an increased extent of fibrosis on HRCT, or (3) worsening of respiratory symptoms and an increased extent of fibrosis within 24 months

(D) Composite decline with FVC ≥10% decline; or FVC ≥5%-9% and DLCO ≥15% over 12 months

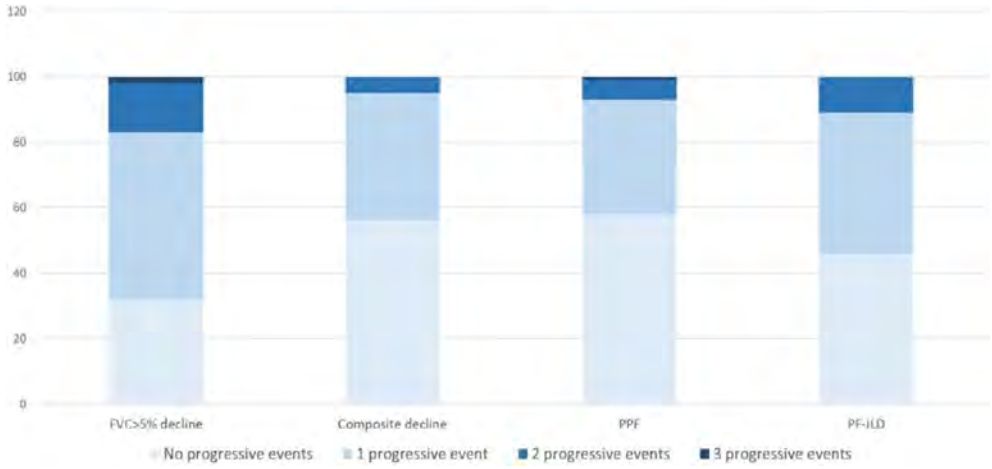

Figure 1: Prevalence of number of progressive events applying different definitions of progressive ILD

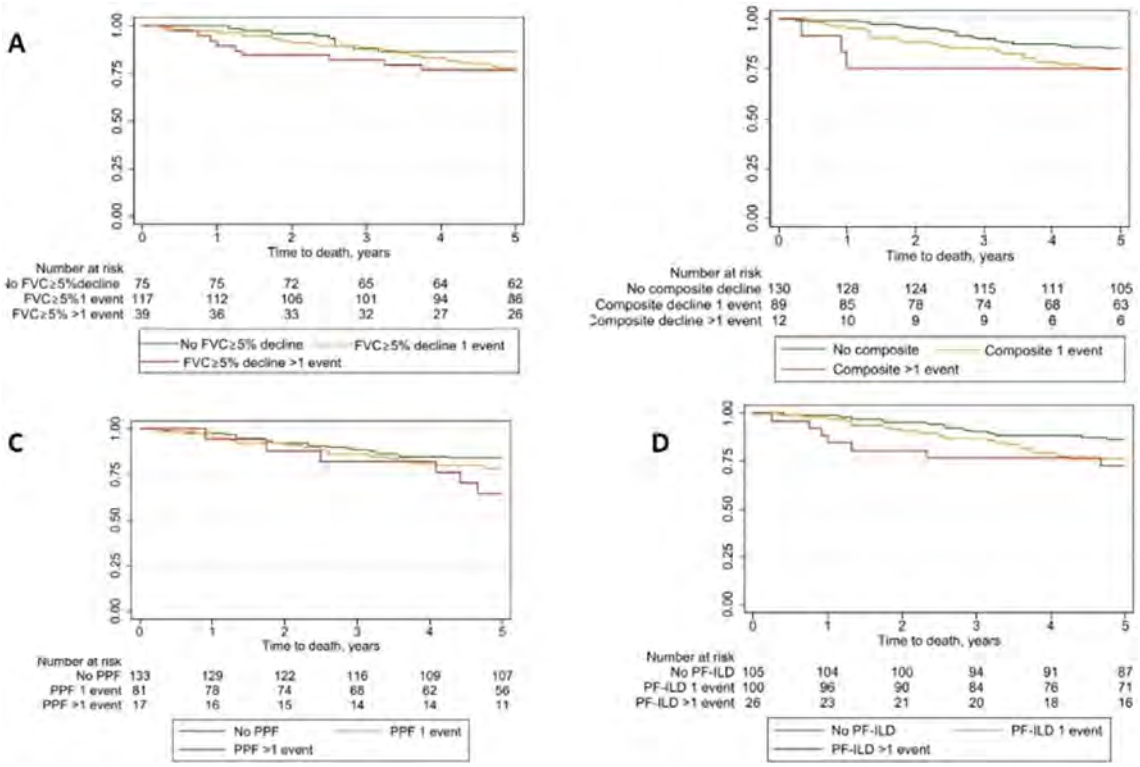

Figure 2: Survival estimates segregated by number of progressive events using FVC ≥5% decline (p=0.008); (B) composite decline (p=0.015), (C) PPF (p=0.169) and (D) PF-ILD (p<0.001)

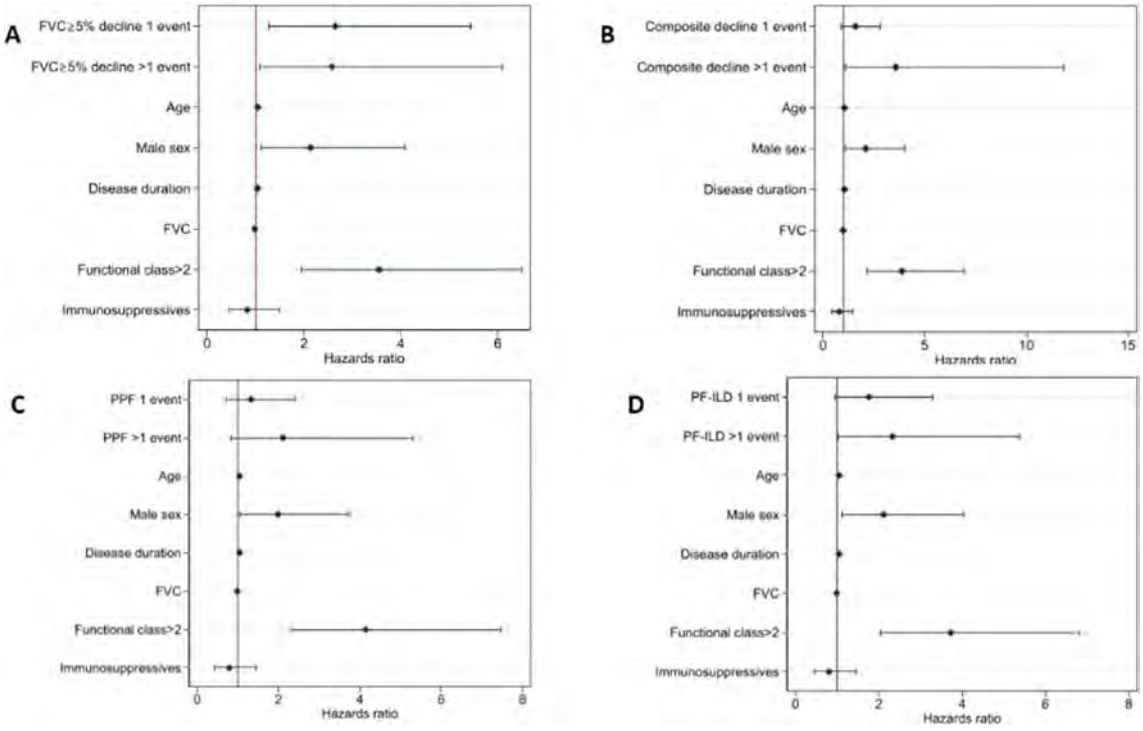

Figure 3: The impact of number of progressive ILD events using (A) FVC ≥5% decline; (B) Composite decline; (C) PPF and (D) PF-ILD on mortality compared to no even

Survival was assessed with Kaplan-Meier survival estimates. Multivariable Cox regression was applied, adjusting for known risk factors including treatment to identify the impact of multiple progressive ILD events on mortality.

Results: In total, 231 SSc-ILD patients were included. The number of progressive events varied depending on the applied definition, with FVC ≥5% decline showing >1 event over 3 years in 17%, compared to 5% using composite decline, 7% using PPF and 11% using the PF-ILD criteria (Figure 1). Over the observation period of 7.7 (SD3.9) years, 81 (35%) died. When assessing the impact of number of events on survival by Kaplan Meier estimates, we found significant difference for FVC ≥5% decline, composite decline, PF-ILD but not PPF (Figure 2).When assessing the impact of number of progressive events on mortality compared to no progression adjusted for other known risk factors, we identified that >1 events of PF-ILD and composite decline were associated with increased mortality (Figure 3).

Conclusion: ILD progression has a major impact on long-term outcome with even one event of FVC≥5% decline reducing long-term survival, but with multiple events further reducing survival. It is therefore of high importance to prevent progression in SSc-ILD to improve survival.

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Individuals with self-identified Black race have a higher incidence of systemic sclerosis (SSc), develop SSc at a younger age, and have a more severe clinical phenotype than their White counterparts. To understand the roles autoantibodies may play in driving racial variation in disease severity, we compared autoantibody distribution and associated phenotypes between cohorts of Black and White individuals from the US multicenter Genome Research in African American Scleroderma Patients (GRASP) cohort and the Johns Hopkins Scleroderma Center cohort, respectively.

Methods: 803 Black and 2178 White patients with SSc had systematic autoantibody testing for anti-centromere (ACA), anti-RNA-polymerase III (POLR3), anti-Scl70, anti-PMSCL, anti-NOR90, anti-ThTo, anti-Ku, anti-U3RNP, and anti-Ro52 using the Euroimmun platform and anti-U1RNP using a commercial ELISA assay. 93.7% and 94.2% of individuals in the Black and White cohorts met 2013 ACR/EULAR criteria for SSc. Autoantibody frequency was compared between the two groups. To assess the effect of autoantibodies on the association between race and clinical outcomes, odds ratio coefficients for race from multivariable models including and excluding autoantibodies were compared. Multivariable logistic regression analyses were performed to assess the association between each autoantibody and clinical outcomes. Clinical outcomes included common manifestations of SSc, and organ-specific disease severity.

Figure 1: Comparison of Autoantibody Distributions between Black and White Individuals with SSc

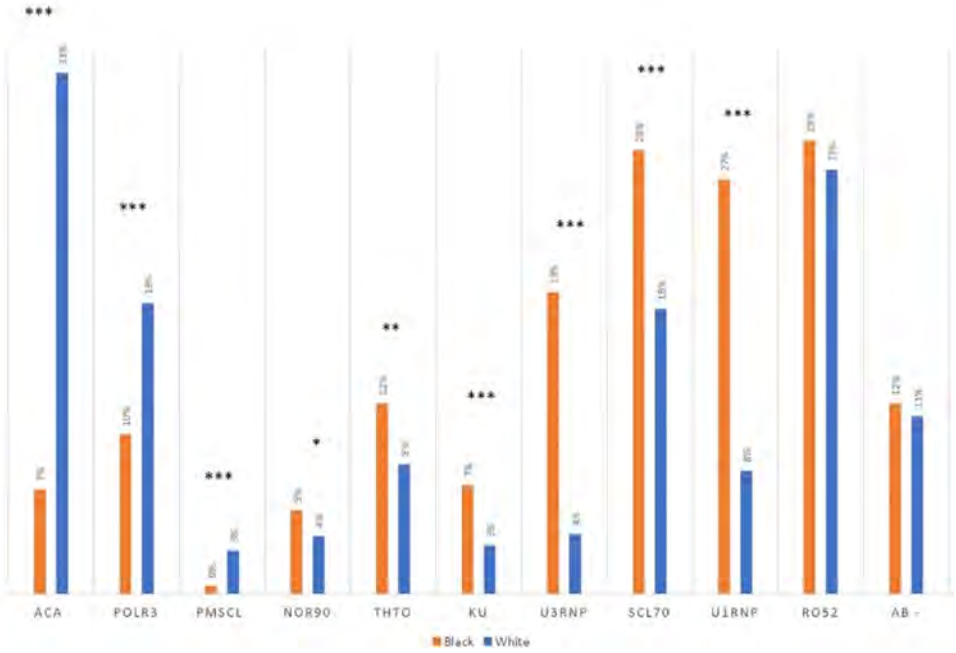

Figure 1: Distribution of autoantibodies among individuals in Black and White cohorts who underwent autoantibody testing. Numbers do not add up to 100% due to autoantibody overlap. ACA=anti-centromere antibody, POLR3=anti-RNA polymerase III, anti-Scl70=anti-topoisomerase, Ab negative refers to a group that underwent Euroimmun testing and testing for U1RNP but was not positive for any detectable antibodies. Comparison of autoantibody frequency using Chi-squared testing and Fisher's exact testing was done as appropriate. * $p<0.05$, ** $p<0.005$, *** $p<0.0005$.

Results: Comparing these self-reported racial groups, the Black cohort had a higher mean modified Rodnan skin score and higher rates of pulmonary fibrosis; Black individuals had higher rates of severe Raynaud's phenomenon, skin, gastrointestinal and lung disease. Statistically significant differences were seen in autoantibody distribution between the Black and White cohorts (Figure 1). Among the Black cohort, anti-Scl70 (28%), anti-U1RNP (27%), and anti-U3RNP (19%) were most common while the White cohort was enriched for ACA (33%) and anti-POLR3 (19%). In multivariable models, anti-Scl70 was associated with diffuse skin disease, severe cutaneous disease, pulmonary fibrosis and severe lung disease (Table 1). Anti-U3RNP was associated with diffuse skin disease, telangiectasias, calcinosis, and severe Raynaud's phenomenon. Anti-POLR3 was associated with severe skin and renal disease. Adjusting for autoantibodies decreased the effect of race on clinical outcome by 17%, 10% and 10% for FVC< 70%, severe lung and heart disease respectively; it increased the effect of race by 18% for severe skin and 44% for severe kidney disease (Table 2).

Conclusion: This study is the largest systematic analysis of autoantibody responses and associated clinical phenotypes in a geographically diverse population of Black individuals with SSc. Black and White individuals with SSc had distinct autoantibody distributions. Antibodies common in the Black cohort (anti-Scl70, anti-U1RNP, anti-U3RNP, anti-ThTo) commonly associate with severe skin disease and interstitial lung disease. However, differences in autoantibody distributions explain only a small fraction of the racial effects on clinical outcomes for FVC< 70%, severe lung and heart disease.

Table 1a and 1b: Multivariable regressions assessing association between autoantibodies and clinical outcomes were conducted. These models controlled for the covariates of sex, age of symptom onset, disease duration, race and diffuse skin disease (for non-cutaneous outcomes). Pulmonary, cardiac and vascular analyses also controlled for history of smoking. Autoantibodies included ACA, POLR3, PMSCL, Ku, ThTo, Nor90, U1RNP, U3RNP, Ro52. Statistically significant associations were seen for ACA, POLR3, U3RNP, Scl-70 and PMSCL, the data for which is included in this table. Conversely, no statistically significant associations were seen for Ku, ThTo, Nor90, U1RNP, and Ro52. Analyses in Table 1a assess the associations between autoantibodies and common clinical outcomes in SSc. Analyses in Table 1b evaluate the association between autoantibodies and organ specific disease severity as defined by a Medsger severity score of 3 or 4. * p<0.05, ** p<0.005, *** p<0.0005 † Covariate of smoking status (ever versus never smoked cigarettes was included in the multivariate analysis)

Table 2: Ratio of odds: Multivariable regressions were done. Model A refers to a multivariable regression assessing association between race and clinical outcomes controlling for the covariates of sex, age of symptom onset, disease duration, and diffuse skin disease. Pulmonary, cardiac and vascular outcomes controlled for history of smoking. Model B refers to multivariable regression assessing association between race and clinical outcomes, controlling for the previous covariates, as well as the tested antibodies (ACA, POLR3, PMSCL, Ku, ThTo, Nor90, U1RNP, U3RNP Ro52). Ratio of odds refers to the ratio between the coefficient for race in Model B and the coefficient for race in Model A. Upper and lower bounds of the ratio of odds are calculated based on 5000 random samples of the data. * statistical significance
