Table of Contents

ACR Convergence 2025 Abstract Sessions

Sunday, October 26

10:30 AM – 12:30 PM
Poster Session A
(#0001–0771)

9:30 – 11:00 AM
Plenary Session I
(#0772–0776)

1:00 – 2:30 PM
Oral Abstract Sessions
(#0777–0782) Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases I: Focus on Auto-Inflammatory Diseases
(#0783–0788) Abstracts: Orthopedics, Low Back Pain, & Rehabilitation
(#0789–0794) Abstracts: Patient Outcomes, Preferences, & Attitudes
(#0795–0800) Abstracts: Rheumatoid Arthritis – Etiology and Pathogenesis
(#0801–0806) Abstracts: Systemic Lupus Erythematosus – Treatment I
(#0807–0812) Abstracts: Systemic Sclerosis & Related Disorders-Basic Science

3:00 – 4:30 PM
Oral Abstract Sessions
(#0813–0818) Abstracts: Pain in Rheumatic Disease Including Fibromyalgia
(#0819–0824) Abstracts: Pediatric Rheumatology – Basic Science
(#0825–0830) Abstracts: Professional Education
(#0831–0836) Abstracts: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes II: Look What You Made Me Do (Prediction)
(#0837–0842) Abstracts: Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes I: Advances in Nephritis
(#0843–0848) Abstracts: Systemic Sclerosis & Related Disorders – Clinical I

Monday, October 27

10:30 AM – 12:30 PM
Poster Session B
(#0897–1649)

8:00 – 9:30 AM
Plenary Session II
(#0849–0854)

10:00 – 11:30 AM
Oral Abstract Sessions
(#0855–0860) Abstracts: Antiphospholipid Syndrome
(#0861–0866) Abstracts: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science II: Basic & Translational Research
(#0867–0872) Abstracts: Rheumatoid Arthritis – Animal Models
(#0873–0878) Abstracts: Spondylarthritis Including Psoriatic Arthritis – Treatment I: Therapies
(#0879–0884) Abstracts: Systemic Sclerosis & Related Disorders – Clinical II
(#0885–0890) Abstracts: T Cell Biology & Targets in Autoimmune & Inflammatory Disease
(#0891–0896) Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders I: GCA From Bench to Bedside

1:00 – 2:30 PM
Oral Abstract Sessions
(#1650–1655) Abstracts: Cytokines & Cell Trafficking
(#1656–1661) Abstracts: Health Services Research
(#1662–1667) Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases II: Models and Mechanisms
(#1668–1673) Abstracts: Pediatric Rheumatology – Clinical I
(#1674–1679) Abstracts: Rheumatoid Arthritis – Treatment I: Preventative and Novel Treatments
(#1680–1685) Abstracts: Sjögren's Disease – Basic & Clinical Science

3:00 – 4:30 PM
Oral Abstract Sessions
((#1686–1691) Abstracts: ARP I: Multidimensional Influences on Health in SLE
(#1692–1697) Abstracts: B Cell Biology & Targets in Autoimmune & Inflammatory Disease
(#1698–1703) Abstracts: Genetics, Genomics & Proteomics
(#1704–1709) Abstracts: Healthcare Disparities in Rheumatology
(#1710–1715) Abstracts: Spondylarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes I: Advances in Psoriatic Disease
(#1716–1721) Abstracts: Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes II: Morbidity & Mortality

Tuesday, October 28

10:30 AM – 12:30 PM
Poster Session C
(#1770-2566)

8:00 – 9:30 AM
Plenary Session III
(#1722-1727)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

10:00 – 11:30 PM
Oral Abstract Sessions
(#1728–1733) Abstracts: Immunological Complications of Medical Therapy
(#1734–1739) Abstracts: Osteoarthritis & Joint Biology – Basic Science
(#1740–1745) Abstracts: Pediatric Rheumatology – Clinical II
(#1746–1751) Abstracts: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes I: Breathe (ILD/Pulmonary)
(#1752–1757) Abstracts: Spondylarthritis Including Psoriatic Arthritis – Basic Science
(#1758–1763) Abstracts: Systemic Lupus Erythematosus – Animal Models
(#1764–1769) Abstracts: Vasculitis – ANCA-Associated

1:00 – 2:30 PM
Oral Abstract Sessions
(#2567–2572) Abstracts: Epidemiology & Public Health II
(#2573–2578) Abstracts: Infection-related Rheumatic Disease
(#2579–2584) Abstracts: Innate Immunity
(#2585–2590) Abstracts: Metabolic & Crystal Arthropathies – Basic & Clinical Science
(#2591–2596) Abstracts: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science
(#2597–2602) Abstracts: Systemic Lupus Erythematosus – Etiology and Pathogenesis

3:00 – 4:30 PM
Oral Abstract Sessions
(#2603–2608) Abstracts: ARP II: Perception, Prediction, and Prevention
(#2609–2614) Abstracts: Imaging of Rheumatic Diseases
(#2615–2620) Abstracts: Measures & Measurement of Healthcare Quality
(#2621–2626) Abstracts: Osteoarthritis – Clinical
(#2627–2632) Abstracts: Reproductive Issues in Rheumatic Disorders
(#2633–2638) Abstracts: Spondylarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes II: Advances in Axial Spondylarthritis

Wednesday, October 29

9:30 AM – 11:00 AM
Oral Abstract Sessions
(#2639–2644) Abstracts: Rheumatoid Arthritis – Treatment II: Phenotyping and Personalization
(#2645–2650) Abstracts: Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes III
(#2651–2656) Abstracts: Systemic Sclerosis & Related Disorders – Clinical III

11:30 AM – 1:00 PM
Oral Abstract Sessions
(#2657–2662) Abstracts: Epidemiology & Public Health I
(#2663–2668) Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases III: End Organ Focus on Heart, Lung and Eye
(#2669–2674) Abstracts: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science I: Diagnostics & Therapeutics
(2675–2680) Abstracts: Pediatric Rheumatology – Clinical III
(2681–2686) Abstracts: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes III: Long Live (Comorbidity and Outcomes)
(#2687–2692) Abstracts: Spondylarthritis Including Psoriatic Arthritis – Treatment II: Pathogenesis, Exercise, and Dietary Interventions
(2693–2698) Abstracts: Systemic Lupus Erythematosus – Treatment II
(2699–2704) Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders II

Late-Breaking Abstracts

Friday, October 24

10:30 AM – 12:30 PM
Poster Session C
(#L01–L18) Late-Breaking Abstract Poster

Wednesday, October 29

Oral Session
8:00 – 9:30 AM
(#L19–L24) Late-Breaking Abstracts

Patient Perspectives

Sunday, October 26

10:30 AM – 12:30 PM
Poster Session A

Abstract Embargo Policy

All abstracts accepted to ACR Convergence are under media embargo once the ACR has notified presenters of their abstract's acceptance. They may be presented at other meetings or published as manuscripts after this time but should not be discussed in non-scholarly venues or outlets. The following embargo policies are strictly enforced by the ACR.

Accepted abstracts are made available to the public online in advance of the meeting and are published in a special online supplement of our scientific journal, *Arthritis & Rheumatology*. Information contained in those abstracts may not be released until the abstracts appear online. In an exception to the media embargo, academic institutions, private organizations, and companies with products whose value may be influenced by information contained in an abstract may issue a press release to coincide with the availability of an ACR abstract on the ACR website. However, the ACR continues to require that information that goes beyond that contained in the abstract (e.g., discussion of the abstract done as part of editorial news coverage) is under media embargo until **10:00 AM CT on October 25**. Journalists with access to embargoed information cannot release articles or editorial news coverage before this time. Editorial news coverage is considered original articles/videos developed by employed journalists to report facts, commentary, and subject matter expert quotes in a narrative form using a variety of sources (e.g., research, announcements, press releases, events, etc.).

Violation of this policy may result in the abstract being withdrawn from the meeting and other measures deemed appropriate. Authors are responsible for notifying colleagues, institutions, communications firms, and all other stakeholders related to the development or promotion of the abstract about this policy. If you have questions about the ACR abstract embargo policy, please contact ACR abstracts staff at abstracts@rheumatology.org.

Abstract Reprint (Reproduction) Policy

Copyright law covers all annual meeting abstracts published by the American College of Rheumatology. All rights reserved. No abstracts may be reproduced in any form or by any means without the prior permission of the publisher, except as permitted under section 107 and 108 of the 1976 United States Copyright Act.

For the purposes of this statement, the term "**ACR Abstracts"** refers to all annual meeting abstracts as published in *Arthritis & Rheumatology* and posted online, including the abstracts accepted for presentation during ARP sessions and the late-breaking category.

For the purposes of this statement, the term "**ACR Posters"** refers to the accepted abstract **POSTER PRESENTATIONS** as presented in the poster hall during the annual meeting. **This does not include abstract text published in the online supplement of *Arthritis & Rheumatology*.** All **ACR Posters** are the property of the ACR or the presenting author and cannot be reproduced or distributed without written permission from the ACR and the presenting author.

For the purposes of this statement, the term "reproduce" includes all forms of reproduction, including, but not limited to, print, electronic and photographed formats.

For the purposes of this statement, the term "presenting author" refers to the author who is designated as the individual who will present the work during the ACR's annual meeting, as identified through the abstract submission process.

Approval Process for ACR Abstracts

- Excerpts or the entirety of **ACR Abstracts** may not be reproduced without the prior written permission of the publisher.
- Permission requests for abstract content and other permission inquiries should be addressed to:

  Permissions Department

  c/o John Wiley & Sons, Inc.
  111 River Street
  Hoboken, NJ 07030
  Fax: 201-748-6008
  wiley.com/go/permissions
- Commercial entities seeking permission to reprint must obtain all materials from the author and/or publisher John Wiley & Sons, Inc. The ACR cannot provide any materials.

Approval Process for ACR Posters

- Reprint requests for the actual poster abstract text published in the *Arthritis & Rheumatology* supplement are considered **ACR Abstracts** and must submitted to Wiley (see approval process above).
- Requests to reproduce individual ACR posters, figures from ACR posters, or booklets of poster presentations (e.g., two or more) must be submitted via e-mail to abstractreprints@rheumatology.org.
- Poster reproduction requests must include the following:
  – Abstract ID Number
  – Abstract Title
  – Presenting Author's Name
  – A copy of Presenting Author's written approval (Please Note: An e-mail approval from Presenting Author is acceptable)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Reproducing ACR Abstracts and Posters for Dissemination Prior to ACR Convergence

- Requests to reproduce abstracts for dissemination prior to ACR Convergence *will not be approved*.
- Per the ACR Embargo Policy (see above), academic institutions, private organizations, and companies with products whose value may be influenced by information contained in an abstract may issue a press release to coincide with the availability of an abstract online.
- Permission to issue a press release does not require ACR approval. However, it must comply with the **ACR Embargo Policy;** violation of this policy may result in the abstract being withdrawn from the meeting or other measures deemed appropriate.
- For more information regarding press releases, please contact the ACR public relations department at pr@rheumatology.org.

Reproducing ACR Abstracts and Posters for Dissemination During ACR Convergence

Following approval (see approval process above), an exhibiting organization may:

- Disseminate copies of individual ACR Abstracts from its exhibit space. Booklets of abstracts (e.g., two or more) may not be produced.
- Disseminate information summaries (title/date/time/poster number) of ACR Abstracts from its exhibit space. Summaries may not reference company or product names. Requests for approval must be submitted in writing to abstractreprints@rheumatology.org.
- Presenting authors may disseminate individual copies of their ACR Poster during their assigned poster presentation time.
- Dissemination must be limited to the area directly in front of their assigned poster space and may not interfere with other poster presentations.
- An electronic copy of the poster may be provided via a QR code generated by the presenter and included on the poster

Reproducing ACR Abstracts and ACR Posters for Dissemination After ACR Convergence

ACR Abstracts

Following approval from Wiley (see approval process above), the ACR permits **ACR Abstracts** (i.e., all abstract content published in the online supplement) to be reprinted and disseminated following ACR Convergence.

- Abstracts and booklets of abstracts (e.g., two or more) must include the following statement on the front of the abstract/booklet:
  Abstract(s) reprinted from ACR Convergence held [insert meeting dates]. The American College of Rheumatology does not guarantee, warrant, or endorse any commercial products or services. Reprinted by [insert name of supporting company].
- Booklets cannot contain corporate or product logos or any advertisements. No exceptions.

ACR Posters

Following approval from the presenting author and the ACR (see approval process above), copies of actual ACR poster presentations (i.e., the actual graphic file of the poster) may be reproduced.

1. Reprint requests for the actual poster abstract text published in the *Arthritis & Rheumatology* supplement are considered **ACR Abstracts** and must be submitted to Wiley (see approval process above).

- **IMPORTANT: The ACR does not retain and cannot provide poster presentation images.**
- The following statement must be listed under each Poster reprint:
  Reprinted from ACR Convergence held [insert meeting dates]. The American College of Rheumatology does not guarantee, warrant, or endorse any commercial products or services. Reprinted by [insert name of supporting company].

Use of the ACR Name

The names, insignias, logos and acronyms of the ACR, the ARP, and the Rheumatology Research Foundation are proprietary marks. Use of the names in any fashion, by any entity, for any purpose, is prohibited without the express written permission of the American College of Rheumatology.

Use of the ACR Scientific Program Content

- ACR educational activities are not public events. Information presented at these activities is for the education of attendees and/or purchasers as authorized by the ACR. Any materials or information displayed during these activities are the property of the ACR and the presenter and should not be photographed, copied, photocopied, transferred to electronic formats, reproduced or distributed without written permission of the ACR and the presenter.
- Any use of ACR educational content for commercial purposes, which includes but is not limited to oral presentations, audiovisual materials used by speakers and/or program handouts without written consent from the ACR is prohibited. This policy applies before, during and after each activity.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The ACR will enforce its intellectual property rights and penalize those who infringe upon it.

- The names, insignias, logos and acronyms of the ACR, the ARP and the Foundation are proprietary marks. Use of these in any fashion, by any entity, for any purpose, is prohibited without the express written permission of the ACR

Use of the ACR Disclosure Key

It is suggested when referencing disclosures in the reprints, that the ACR's disclosure key be added to provide adequate context for abstracts:

None: Has no relevant financial relationship to disclose.

1. Advisor or Review Panel member
2. Consultant
3. Employee
4. Officer or Board Member
5. Grant/Research Support
6. Speaker/honoraria includes speakers bureau, symposia, and expert witness
7. Independent contractor
8. Executive role and/or ownership interest
9. Royalties and/or patient beneficiary
10. Intellectual Property / Patents
11. Stock options or bond holdings in a for-profit corporation or self-directed pension plan
12. Private investigator
13. Expert witness
14. Equity interest
15. Other: *specify details*

Abstract Number: 0001

ATG-201, a Novel Steric Hindrance-based Masking CD19xCD3 T-cell Engager (TCE) for the Treatment of B Cell-related Autoimmune Diseases

Gang Bian[1], Tengteng Li[1], Huiling Liu[2], Zaoshun Hu[2], Peng Chen[1], Jay Mei[3] and **Bing Hou**[3], [1]Shanghai Antengene Corporation Limited, Shanghai, China (People's Republic), [2]Antengene (Hangzhou) Biologics, Hangzhou, Zhejiang, China (People's Republic), [3]Antengene Corporation, Shanghai, China (People's Republic)

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0001–0018) B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: CD19-targeted therapies, such as chimeric antigen receptor (CAR)-T or T-cell engagers (TCE), have been approved for the treatment of B cell malignancies. By depleting autoreactive B cells, CD19-targeted therapies have shown early yet promising efficacy in treating patients with B cell-driven autoimmune diseases. However, the clinical application of TCE continues to be greatly hindered by the unfavorable pharmacokinetics, incomplete B cell depletion and toxicity associated with cytokine release syndrome (CRS). Here we developed a "2+1" CD19 x CD3 TCE, ATG-201, for the treatment of B cell driven autoimmune diseases, which utilizes a steric hindrance-based masking technology and a novel fast-on-fast-off CD3 binder, and effectively depletes B cells with minimal risk of CRS.

Methods: ATG-201 was constructed by introducing a novel fast-on-fast-off, conformational epitope-targeted anti-CD3 single chain fragment variable (scFv) to the hinge region of one of the heavy chains of a CD19 monoclonal antibody. It was evaluated in a series of *in vitro* and *in vivo* studies for binding affinity, B cell depletion, cytokine release, anti-disease efficacy and drug developability. The safety and pharmacokinetic (PK) parameters of ATG-201 were evaluated in hCD19/hCD3 knock-in mice, and non-human primates (NHP) using a monkey surrogate TCE antibody.

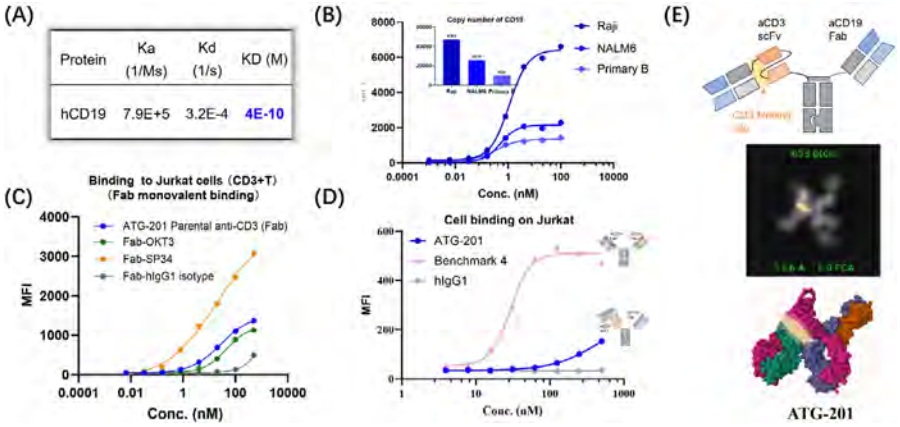

Figure 1. ATG-201 showed limited CD3+ T cell binding before CD19-crosslinking. (A) CD19 protein binding KD of ATG-201 detected by SPR. (B) Binding of ATG-201 to Raji, NALM6 and primary B cells. (C) Monovalent binding of ATG-201's parental anti-CD3 Fab binder to CD3+T cell. (D) Binding of ATG-201 and BMK4 to T cells before CD19 crosslinking. (E) The CD3 binding site is masked by the constant region of the CD19-targeting Fab arm in the absence of CD19 crosslinking by cryo-EM analysis

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

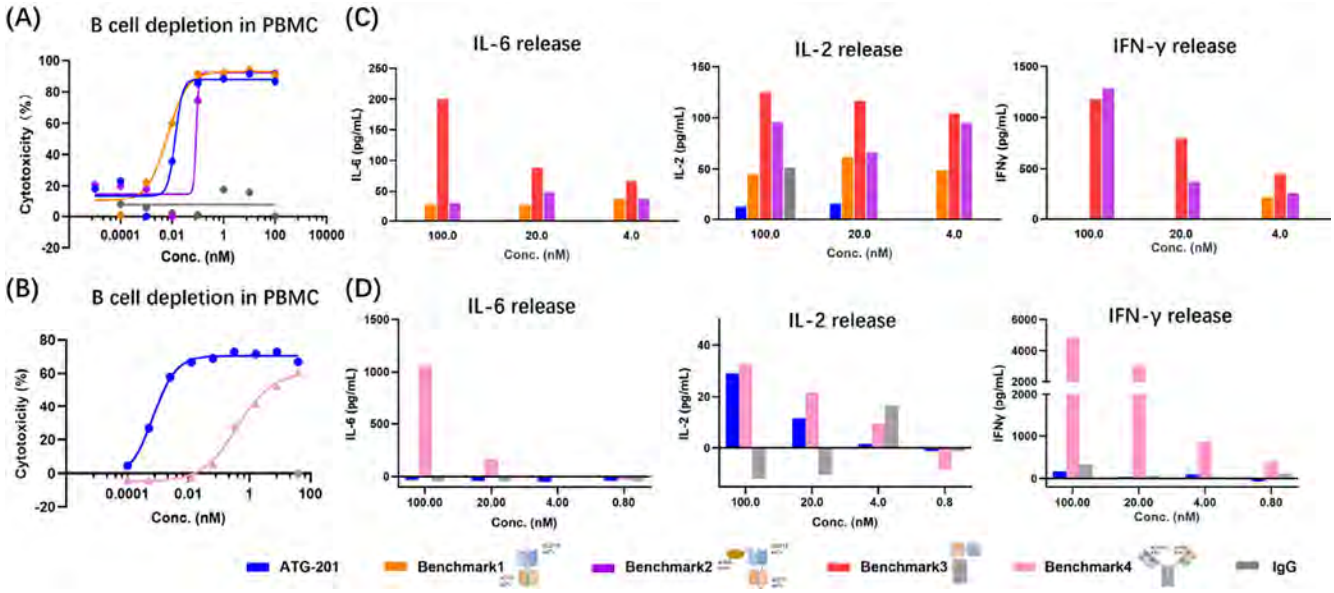

Figure 2. ATG-201 induced enhanced naïve B cell depletion and reduced cytokine release compared to clinical benchmarks. B cell depletion (A, B) and concentration of the indicated cytokines in the supernatant (C, D) of isolated human PBMC incubated with ATG-201 or Benchmarks for 48 hours.

Results: According to cryo-EM data, the CD3 binding site is masked by the constant region of the CD19-targeting Fab arm in the absence of CD19 cross-linking. ATG-201 showed limited CD3+ T cell binding before CD19-crosslinking (Figure 1). It activated T cells and only in the presence of CD19+ cells. ATG-201 demonstrated stronger B cell depletion activity in PBCMs derived from SLE patient and healthy donors with much lower cytokine release compared to benchmark TCEs *in vitro* (Figure 2). Single dose of ATG-201 completely and deeply depleted B cells in blood, bone marrow and spleen of CD34+ cells humanized NDG mice (Figure 3). The mouse surrogate CD19xCD3 TCE demonstrated potent efficacy in MOG-EAE model and MRL-lpr mouse SLE model, with deeper B cell depletion observed compared to CD20-targeted TCE. ATG-201 and its monkey surrogate CD19xCD3 TCE exhibited a favorable pharmacokinetic profile in hCD19/hCD3 knock-in mice and NHP respectively. ATG-201 was stable at high concentration (125mg/ml) and under stress conditions. ATG-201 and its monkey surrogate CD19xCD3 TCE were well tolerated in hCD19/hCD3 knock-in mice and NHP.

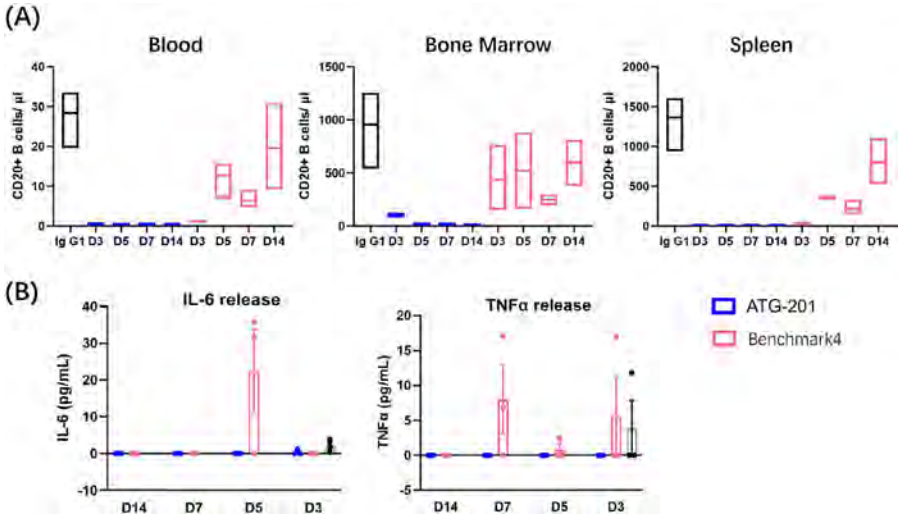

Figure 3. ATG-201 induces complete B cell depletion in CD34+ hematopoietic stem cells humanized mice with reduced cytokine release. CD34+-cell humanized NDG mice were treated with a single dose of 1.5 mg/kg ATG-201 or Bechmark4 (Molar equivalent dose of 1.5 mpk ATG-201). (A) Blood, bone marrow and spleen were collected and analyzed for B cells counts by FACS 3 days (D3), 5 days (D5), 7days (D7), or 14 days (D14) post treatment. (B) Plasma cytokine concentration post treatment.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: ATG-201 demonstrates CD19-dependent CD3 binding and activation, inducing effective B cell depletion and anti-disease activity *in vitro* and *in vivo* with good PK and safety profile, which warrants further clinical evaluation in the treatment of B cell related autoimmune diseases.

Abstract Number: 0002

KITE-363: An Autologous Anti-CD19/CD20 CAR-T Product for the Treatment of Autoimmune Rheumatic Diseases

Brian Kim, Christine Lowe, Francisco Flores, Jeremy Margaitis, Alessandro Calo, Stacey Valny, Anna Konecny, Eva Jaghatspanyan, Sean Yoder, Kenneth Ertel, Simone Filosto, Jodi Murakami and David Barrett, Kite, a Gilead Company, Santa Monica, CA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0001–0018) B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: B-cell dysregulation is a key factor in the development and progression of autoimmune diseases, and B-cell inhibition has been a cornerstone of treatment for decades. Recent studies on B-cell depletion using chimeric antigen receptor (CAR) T-cell therapies in autoimmune diseases highlight the potential for reestablishing immune tolerance and achieving rapid, sustained remission without chronic use of systemic immunosuppressants (Taubmann J, et al. Arthritis Rheumatol. 2024). Both CD19 and CD20 are transmembrane proteins expressed on B-cells with variable expression throughout B cell development and thus, targeting both CD19 and CD20 may provide more comprehensive B-cell depletion than what could be achieved by targeting either antigen alone. KITE-363 is a dual-targeting anti-CD19/CD20 CAR T-cell therapy with 2 costimulatory domains, CD28 and 41BB, and is being evaluated in a Phase 1 clinical study of relapsed/refractory B-cell lymphoma (KT-US-499-0150).

Methods: CD19 and CD20 expression on B cell subsets from healthy donors and patients with systemic lupus erythematosus (SLE) with and without lupus nephritis (LN), systemic sclerosis (SSc), and idiopathic inflammatory myopathy (IIM) were analyzed by flow cytometry. Using a bicistronic lentiviral vector and T cells from patients, we generated anti-CD19/CD20 CAR-T cells (KITE-363). The bicistronic lentiviral vector encodes for an anti-CD19 CAR, containing the FMC63 binder and CD28 costimulatory domain, and anti-CD20 CAR, containing a novel CD20 binder and 41BB costimulatory domain. The final products were characterized via immunophenotyping and functionally assessed in vitro.

Results: Most B cells in the peripheral blood co-expressed CD19 and CD20 ($CD19^+CD20^+$), albeit at variable expression levels. Subsets of both $CD19^+CD20^-$ and $CD19^-CD20^+$ B cells were observed in all autoimmune conditions. Plasmablasts were abundantly $CD19^+CD20^-$, while double negative (IgD^-CD27^-) B cells were enriched for $CD19^-CD20^+$ compared to other B cell subsets. Patient-derived KITE-363 T cell products exhibited high expression of both the anti-CD19 and anti-CD20 CARs and demonstrated CAR- and antigen-specific T-cell functionality including cytokine production, proliferation, and cytotoxicity against autologous B cells and cell lines expressing either CD19 and/or CD20 antigens.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Highly variable expression of CD19 and/or CD20 in B cell subsets, jointly with antigen-specific and B-cell depleting activity of KITE-363, support clinical development of KITE-363 in B cell-mediated auto-immune conditions. With dual-antigen targeting and optimized co-stimulation, KITE-363 has the potential to induce a more comprehensive B-cell depletion and achieve durable, drug-free remission in these diseases. A Phase 1 open-label, multicenter study is underway to evaluate the safety and efficacy of KITE-363 in participants with refractory autoimmune rheumatic diseases.

In Vivo Generation of anti-CD19 CAR T Cells Utilizing Circular RNA Encapsulated in Targeted Lipid Nanoparticles

Xiaoyu Pan[1], Xiaoning Wang[1], Zhihao Chen[1], Xiaowen Zou[1], Siqi Li[1], Jian Ye[1], Fei Lin[1], Yang He[1], **Edo Kon**[2], Peng Zhu[1], Mengyun Chen[1] and Weiyi Zhang[1], [1]RiboX Therapeutics, Shanghai, China (People's Republic), [2]RiboX Therapeutics, Cambridge, MA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0001–0018) B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Chimeric Antigen Receptor (CAR) T-cell therapy has revolutionized cancer treatment and shown promise in addressing autoimmune diseases. However, current *ex vivo* CAR T-cell therapies encounter challenges such as complex manufacturing processes, scalability issues, reliance on viral vectors, and the necessity for lymphodepleting chemotherapy, which limit broader clinical applications. To address these limitations, there is a critical need for an off-the-shelf *in vivo* CAR technology that can simplify delivery and expand therapeutic potential. We have developed tLNP-circCAR, a novel in vivo anti-CD19-CAR circular RNA product delivered via targeted lipid nanoparticles (tLNPs). Preclinical studies in animal models demonstrate its efficacy in B cell depletion, marking a significant advancement towards overcoming existing barriers in CAR T-cell therapy and expanding its applicability to a broader range of diseases.

Methods: tLNP-circCAR encapsulates a circular RNA encoding an anti-CD19-CAR within a tLNP containing a novel ionizable lipid and a T cell targeting domain, enabling efficient transfection of primary human T cells. The functional activity of tLNP-circCAR-mediated CAR T cells was evaluated using multiple *in vitro* and *in vivo* systems.

Results: In activated primary human T cells, circCAR mediated CAR expression lasted up to 9 days. Notably, tLNP-circCAR efficiently engineered non-activated primary human T cells into functional CAR T cells. *In vitro*, these engineered CAR T cells exhibited robust cytotoxicity against autologous B cells and the $CD19^+$ Raji cell line. *In vivo*, utilizing a humanized NOG-PBMC mouse model, a single intravenous dose of tLNP-circCAR resulted in efficient CAR engineering of T cells, leading to complete B cell depletion in the spleen. In humanized NOG-PBMC mice bearing CD19+ NALM-6-Luc lymphoma xenografts, tLNP-circCAR treatment induced complete tumor remission at the dose of sub-microgram per mouse. In

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

cynomolgus monkeys, single dose of tLNP-circCAR treatment achieved remarkable B cell reduction in circulating whole blood, lymph node, bone marrow and spleen.

Conclusion: tLNP-circCAR represents a novel *in vivo* CAR therapy that delivers therapeutic anti-CD19 CAR circular RNA efficiently to human T cells, generating highly functional CAR T cells both *in vitro* and *in vivo*. These results support the further development of tLNP-circCAR for treating B cell disorders, including B cell lymphoma and autoimmune diseases. This innovative approach promises to enhance the accessibility and efficacy of CAR T-cell therapy.

LBL-047, A First-In-Class Anti-BDCA2/TACI Fusion Protein, Inhibits the Function of Both pDCs and B cells

Fengxia Li[1], Jianming Sun[1], Hailin Wang[1], Yan Zhu[1], Xiaoxiao Liu[1], Jing Li[1], Yurong Qin[1], Guojin Wu[1], Jing Guan[1], Min Chen[1], Jordan Zhu[2], Xiaoqiang Kang[1], Xiao Huang[1] and **Hong Ling**[1], [1]Nanjing Leads Biolabs Co., Ltd., Nan Jing, China (People's Republic), [2]Nanjing Leads Biolabs Co., Ltd., Nan Jing

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0001–0018) B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Blood dendritic cell antigen 2 (BDCA2) is specifically expressed on pDCs whose uncontrolled production of type I IFN play a crucial role in the pathogenesis of autoimmune disorders. Litifilimab, an anti-BDCA2 antibody, has demonstrated promising preliminary efficacy and excellent safety profile in patients with cutaneous lupus erythematosus. Meanwhile B-cell activating factor (BAFF) and a proliferation-inducing ligand (APRIL) bind to the transmembrane activator and CAML interactor (TACI) on B cells, facilitating B cell proliferation and differentiation. Targeting this pathway, two TACI based recombinant fusion proteins, such as Povetacicept and Telitacicept, have shown clinical benefits and favorable safety profile in autoimmune disease trials. Therefore, we have developed LBL-047, which simultaneously targets BDCA2 on pDCs and block TACI-mediated signaling on B cells. This dual-targeting approach may hold promise for the treatment of autoimmune diseases.

Methods: LBL-047 was obtained by fusing CRD2 domain of TACI to the N-terminal of the humanized, afucosylated anti-BDCA2 antibody, and the YTE mutation was introduced to extend its half-life. The potency of LBL-047-induced pDCs depletion and pro-inflammatory cytokines inhibition were evaluated in human peripheral blood mononuclear cells (PBMCs). The internalization assay was performed using the BDCA2 overexpressed cell line and measured by flow cytometry. The inhibition of human primary B cells' proliferation and differentiation induced by LBL-047 was evaluated by flow cytometry. The keyhole limpet hemocyanin (KLH)-immunized human $CD34^+$ hematopoietic stem cells- engrafted immunodeficient NCG mouse model (huHSC-NCG model) was used to test the efficacy of LBL-047 in inhibiting the function of pDCs and B cells. The pharmacokinetics (PK), pharmacodynamics (PD) and toxicity of LBL-047 were evaluated in cynomolgus monkeys.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: LBL-047 robustly depleted pDCs and activated BDCA2 downstream signaling pathways, thereby suppressing pDCs produced IFN-α, TNF-α and IL-6. Additionally, LBL-047 mediated potent inhibition of B cells' proliferation and differentiation. When co-bound to BAFF and cell-surface-expressed BDCA2, both LBL-047 and BAFF protein were rapidly internalized into the cells. In KLH immunized huHSC-NCG mouse model, LBL-047 effectively inhibited the function of both pDCs and B cells. LBL-047 also exhibited a linear PK characteristic following single S.C administration in cyno monkeys across 0.3-10 mg/kg, and serum IgM, IgA, and IgG levels were significantly decreased up to 6 weeks in a dose-dependent manner. In a 4-week GLP toxicology study, LBL-047 was shown a favorable safety profile with a NOAEL of 100 mg/kg.

Conclusion: LBL-047 has shown dual immunosuppressive effects, inhibiting simultaneously the function of pDCs and B cells both in vitro and in vivo. In addition, it has demonstrated excellent PK and PD profile, coupled with good safety profile and tolerability in cynomolgus monkeys. Taken together, these findings support the clinical development of LBL-047 and highlight its promise as a therapeutic candidate for autoimmune diseases.

QEL-005: CD19 CAR-Regulatory T cell therapy, a novel approach for the treatment of complex immune mediated inflammatory diseases including Rheumatoid Arthritis and Systemic Sclerosis

Jenny McGovern, Georgios Eleftheriadis, Thomas Grothier, Eva Bugallo Blanco, Anna Koi, Mahsa Nemani, Cameron Allum, Emily Hurley, Daniela Penston, Marc Martinez-Llordella, Luke Devey and Nathalie Belmonte, Quell Therapeutics, London, United Kingdom

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0001–0018) B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid Arthritis (RA) and Systemic Sclerosis (SSc) are immune mediated inflammatory diseases (IMID) where a complex interplay of tissue and immune cell activation drives a chronic loop of inflammation resulting in significant tissue damage. B cell depletion approaches highlight the contribution of B cells in IMIDs, but they are limited to targeting a single immune cell type and carry safety and tolerability risks in certain patient populations. Regulatory T cells (Tregs) are key mediators of immune and tissue homeostasis with an essential role in restraining autoimmunity. Tregs employ a wide array of mechanisms to mediate this effect and therefore can exert control over multiple immune pathways across a broad range of tissues and cell types. In IMIDs driven by complex immune responses and aberrant tissue processes such as RA and SSc, a Treg cell therapy has the unique potential to modulate multiple disease mechanisms with a single drug. In this study we describe the pre-clinical data supporting the development of QEL-005, a novel CD19 CAR-Treg product containing a FOXP3 phenotype lock. Upon infusion these CAR-Treg cells will be activated by B cells in lymph nodes and tissue resulting in a dampening of autoreactive B cell responses including autoantibody production, antigen presentation and B cell cytokine production. Moreover, through bystander suppression, activation of these CAR-Tregs will elicit modulation of other

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

immune cells in the inflamed niche, such as autoreactive T cells and disease-associated monocytes and macrophages. This broader mechanism of action modulating multiple cell compartments differentiates CAR-Tregs from CAR-T and other conventional B-cell depletion assets.

Methods: We generated a construct containing a CAR with an FMC63 aCD19 ScFv binder and a FOXP3 phenotype lock. CD45RA+ Tregs were transduced and expanded for 14 days before cryopreservation. Thawed cells were characterised by flow cytometry to ensure CAR function and Treg stability. The mechanism of action was investigated using co-culture assays with primary human cells.

Results: QEL-005 CD19 CAR Tregs maintain a Treg phenotype, as determined by (i) a panel of Treg markers (ii) maintenance of a demethylated TSDR region, (iii) low levels of cytokine production and (iv) suppression of T cell responses. QEL-005 CAR-Tregs can be activated by CD19, driving antigen-specific proliferation and suppression but with no evidence of cytotoxicity. Culture of QEL-005 Tregs with primary B cells showed a reduction in antigen presentation potential through the depletion of CD80/86 co-stimulatory molecules, a reduction in antibody production and a reduction in B cell cytokine production. In addition, we show that co-culture of CD19 CAR Tregs with T cells and monocytes/macrophages leads to a reduction in their pro-inflammatory potential, demonstrating bystander suppression.

Conclusion: In diseases such as RA and SSc with complex interactions of immune effector and tissue cell types, QEL-005 CD19 CAR-Tregs have the potential to durably restore homeostasis in chronically inflamed tissues with limited risk of drug associated toxicity.

Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Pathogenic autoantibodies are key effectors of inflammation, promoting tissue damage in autoantibody-mediated diseases such as inflammatory myopathies, lupus nephritis, Sjogren's syndrome, antiphospholipid syndrome, and ANCA-associated vasculitis. Antibody degradation using an IgG protease represents a new therapeutic opportunity.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. We present S-1117, a novel pan-IgG protease fused to an effectorless human IgG1 Fc domain and engineered for chronic subcutaneous administration using a proprietary machine learning enabled platform to reduce immunogenicity and augment manufacturability while maintaining potency. S-1117 cleaves and reduces soluble IgG, disrupts IgG effector function, degrades IgG immune complexes (IC), and cleaves the IgG+ B cell receptor (BCR) on surface of memory B cells, reducing IgG+ BCR mediated activation. These features allow S-1117 to simultaneously address multiple mechanisms of autoimmunity.

Methods: Immunogenicity of S-1117 was assessed *in vitro* by major histocompatibility complex (MHC)-associated peptide proteomics (MAPPs) and validated by CD4 T cell proliferation assays. *In vivo*, IgG antidrug antibody (ADA) was quantified in C57BL/6 mice in response to S-1117 protease domain administration vs the parental protease. The polypharmacology of S-1117 was determined through *in vitro* plasma IgG, IgG+ BCR, and IC cleavage, as well as antibody mediated effector function assays. S-1117 function was tested pre-clinically *in vivo* in rabbits and mice.

Results: *In vitro*, S-1117 demonstrates reduced epitope display compared to the wildtype protease by MAPPs. Furthermore, the wildtype protease elicits CD4 T cell proliferation responses from 65% of healthy donors with a response index of 2.60 (magnitude of response over background signal). In comparison, S-1117 demonstrates a reduction in the number of responders to 20% and a 10-fold lower response index.

In vivo, a single dose of S-1117 induces rapid (< 24 hours), deep (>90%), and sustained (over 10 days) reduction of endogenous IgG in rabbits. In mice, repeat dosing of parental protease induced immediate hypersensitivity reactions, causing mortality in 60% of mice and high ADA response. In contrast, all mice treated with the protease domain of S-1117 survived multiple doses without anaphylactic reactions or induction of ADA.

Functionally, S-1117 cleaves all IgG subclasses in human plasma. It directly eliminates IgG effector function and IC-mediated immune cell activation. Moreover, it cleaves the IgG+ BCR on memory B cells in humans *in vitro*, reducing IgG+ BCR driven B cell activation.

Conclusion: S-1117 is a novel pan-IgG protease engineered with our machine learning enabled platform to reduce immunogenicity. It demonstrates rapid, deep, and sustained reduction of IgG levels, IgG effector function, and cleavage of the IgG+ BCR on memory B cells, reducing BCR mediated B cell activation. Advantages of enzymatic degradation, sustained PK, and titratable PD are expected to enable a convenient patient-tailored treatment regimen. Since S-1117 addresses multiple pathogenic mechanisms as a single drug, it has the potential to provide superior clinical outcomes in autoantibody-mediated diseases with complex pathology.

MRT-6160, a VAV1-Directed Molecular Glue Degrader, Attenuates T and B Cell Effector Functions and Inhibits Disease Progression in a Spontaneous MRL-Fas^{lpr} Mouse Model

Adam Cartwright[1], Lucas Gyger[1], Foram Desai[2], Shailee Vora[2], Anna Kostikova[1], Xudong Wang[2], Peter Trenh[2], Katie May[2], Sophia Nguyen[2], Chris King[2], Daniel Lam[2], Xavi Lucas[1], Mary Zlotosch[2], Elisa Liardo[1], Daric Wible[2], Ilaria Lamberto[2], Bradley Demarco[2], Debora Bonenfant[1], Sharon Townson[2], Eswar Krishnan[2], Filip Janku[2], John Castle[1], Laura McAllister[1], Alison Paterson[2] and **Marisa Peluso**[2], [1]Monte Rosa Therapeutics, Basel, Switzerland, [2]Monte Rosa Therapeutics, Boston, MA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0001–0018) B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: VAV1, an immune cell restricted guanine nucleotide exchange factor (GEF) and scaffolding protein, plays a critical role in mediating T- and B-cell receptor activity. Genetic loss of *hVAV1* in CRISPR-based screens confers reduced T-cell effector function and murine (m)VAV1 knockout mice are resistant to T- and T/B-cell mediated autoimmune disease models. MRT-6160 is a highly selective, first-in-class oral VAV1-targeting molecular glue degrader currently being evaluated in healthy subjects [NCT06597799]. Given the role of VAV1 in T- and B-cells, MRT-6160-mediated degradation of VAV1 could have broad therapeutic implications in lymphocyte-driven autoimmune and rheumatic disorders, including primary Sjögren's Syndrome (pSS) and systemic lupus erythematosus (SLE).

Methods: PBMCs from pSS and SLE patients were pre-treated with MRT-6160 prior to TCR or T cell-dependent-like BCR stimulation and assessed for VAV1 levels, IL-2 secretion, and IgG production. Primary human T follicular helper cells and B cells were enriched from allogenic healthy patient PBMCs, treated with or without MRT-6160, co-cultured for 6 days, then assessed for IgG secretion and plasmablast differentiation. MRL-Fas^{lpr} mice were treated with vehicle, prednisone (10 mg/kg, PO QD), anti-CD40L (5 mg/kg, IP Q3D), or MRT-6160 (1 mg/kg, PO QD) from 11 to 18 weeks of age following onset of disease at around 9 weeks of age. Mice were assessed in-life from 9 weeks of age for body weight, lymphadenopathy, skin lesions, proteinurea and autoantibody levels. At the end of the study, organomegaly and kidney histopathological assessments were performed.

Results: MRT-6160 degraded VAV1 in healthy and pSS patient PBMCs, concomitant with an attenuation of TCR stimulation-induced IL-2 and T cell-dependent-like BCR stimulation-induced IgG secretion. Treatment of Tfh and B cell co-cultures with MRT-6160 reduced plasmablast differentiation ($CD38^+CD27^+CD20^-$ cells) of both naïve and memory B cells and concurrently reduced in IgM and IgG respectively. In MRL-Fas^{lpr} mice, whilst blockade of the CD40/CD40L axis had no effect, MRT-6160 inhibited lymphadenopathy and skin lesion formation comparable to prednisone and levels of proteinuria and anti-dsDNA levels were inhibited to a greater extent than prednisone. At study termination, MRT-6160 reduced organomegaly of lymph nodes, spleen and kidneys. In histopathological assessment of the kidneys, MRT-6160 significantly reduced glomerulonephritis and vascular nephritis comparable to prednisone.

Conclusion: MRT-6160-mediated degradation of VAV1 attenuates TCR- and BCR-mediated activation *in vitro* diminishing activation and effector functions of pSS/SLE patient PBMCs and Tfh-mediated differentiation and immunoglobulin production. *In vivo*, MRT-6160 inhibited disease progression and kidney histopathological organ damage in an MRL-Fas^{lpr} mouse model of rheumatic disease. These data demonstrate the therapeutic potential of MRT-6160 in various lymphocyte-driven autoimmune and rheumatic diseases.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0001–0018) B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: B cell depletion is a validated therapeutic strategy in autoimmune disease, but current approaches targeting CD20 may only partially eliminate disease-driving subsets such as early lineage B cells and plasma cells. T-cell engagers (TCEs) that redirect cytotoxic T cells to B-lineage targets offer a promising path to achieve deeper and more durable depletion. XmAb657 is a CD19 x CD3 bispecific antibody specifically engineered for autoimmune indications. CD19 is broadly expressed across the B cell lineage, including on subsets not addressed by CD20-targeted therapies. XmAb657 incorporates a bivalent CD19-binding arm to enhance avidity and improve engagement of CD19+ B cells, while the TCE format facilitates potent T cell–mediated cytotoxicity, including in tissue compartments where conventional therapies may have limited activity. XmAb657 was designed using a clinically validated 2+1 bispecific format and an Fc domain engineered for extended half-life.

Methods: XmAb657 was tested in a human PBMC-based redirected T cell cytotoxicity (RTCC) assay to assess B cell killing, cytokine production (IFNγ), and T cell activation (CD69, CD25). In vivo pharmacokinetics, pharmacodynamics, and tissue depletion were evaluated in cynomolgus monkeys following a single intravenous (IV) or subcutaneous (SC) dose. Peripheral blood, bone marrow, and lymph node B cells and plasma cells were measured for up to 42 days. Extent of lymph node B cell depletion was also assessed by IHC using a non-competing anti-CD19 antibody.

Results: In vitro, XmAb657 induced potent B cell cytotoxicity and T cell activation at low nanomolar concentrations. In cynomolgus monkeys, a single IV or SC dose of XmAb657 led to rapid and sustained depletion of peripheral B cells, and B cell counts were suppressed to levels below reliable quantitation (< 5 B cells/μL blood) for at least 42 days. Tissue analysis

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

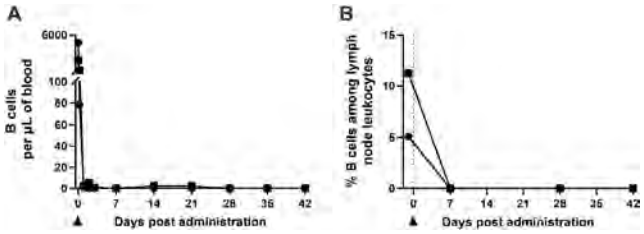

Figure 1. B cell depletion in cynomolgus monkeys (n = 2) following a single intravenous dose of XmAb657. (A) Peripheral blood B cell counts, expressed as absolute cells/µL. (B) Lymph node B cells, expressed as percentage of total leukocytes. B cells were quantified by flow cytometry.

confirmed marked reductions in CD19+ B cells as well as CD19+ plasma cells in both lymph nodes and bone marrow. Serum half-life was approximately 15 days. XmAb657 was well tolerated in cynomolgus monkeys, with no clinical signs consistent with cytokine release.

Conclusion: XmAb657, a CD19 x CD3 bispecific antibody engineered for treatment of autoimmune disease, demonstrated potent in vitro activity and deep, durable depletion of circulating and tissue-resident B cells in cynomolgus monkeys after a single dose. Targeting CD19 may complement other B-lineage–directed approaches by extending depletion to a broader range of B cell subsets. These findings support the ongoing advancement of XmAb657 into first-in-human clinical studies.

KT502, a novel CD19-directed TCE (T-cell engager), leads to rapid and deep B-cell depletion with low cytokine release

Min Bao, John Wang, Jay Zhao and Weihao Xu, Kali Therapeutics, San Mateo, CA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0001–0018) B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Chimeric antigen receptor T-cell (CAR-T) therapies targeting CD19 have shown unprecedented effects in treatment-resistant autoimmune diseases such as systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), and others. However, the limitations in patient selection for CAR-T arise from significant safety concerns, complex logistical hurdles, cost and unsuccessful retreatment if flare occurs. Recently, bispecific antibodies (e.g. Blinatumomab), which may offer an alternative approach to CART with similarly effective B cell depletion but off-the-shelf convenience, have been approved in B cell malignancies and showed impressive efficacy in patients with autoimmune indications in case reports. However, the safety profile and treatment options are not optimized. Therefore, the aim is to develop a novel

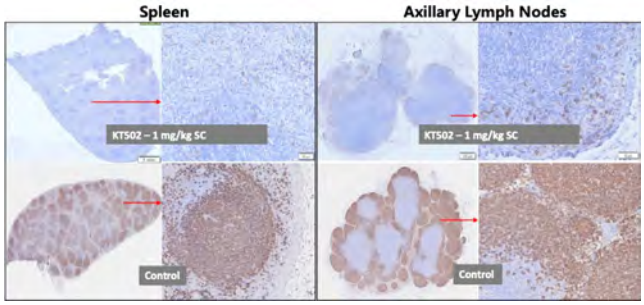

Figure 1: B cell Depletion in Spleen and Lymph Nodes in NHP (CD20 Immunohistochemistry Staining at Day 22)

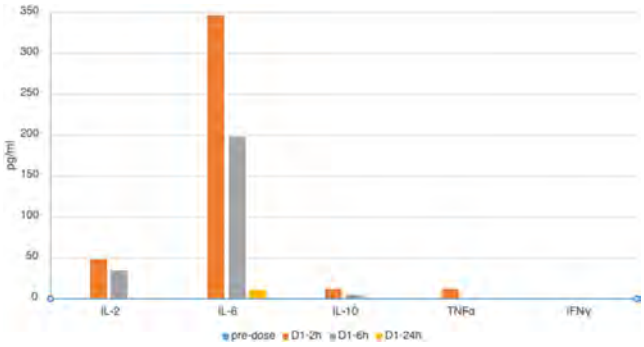

Figure 2: Cytokine Release Following 1 mg/kg SC in NHP (Predose to 24hrs on Day 1)

bispecific antibody targeting CD19/CD3 that can achieve a rapid and deep B cell depletion with an optimized safety profile through subcutaneous injection for the beneficial of patients with autoimmune disorders across multiple therapeutic areas.

Methods: KT502 was selected on an innovative molecular design that maximizes B cell cytotoxicity while minimizes cytokine release through a unique CD3 masking technology. KT502 also has cross-activity with non-human primate (NHP), facilitating preclinical safety and efficacy evaluation. Peripheral blood mononuclear cells (PBMC) from healthy donors were cultured in the presence of KT502 or blinatumomab for 48 hours. Cynomolgus monkeys were treated with KT502 intravenously (IV) or subcutaneously (SC) in the prove-of-concept toxicology study.

Results: In vitro, KT502 exhibits superior potency in B cell killing but lower cytokine release compared with Blinatumomab. In the preclinical study using cynomolgus monkeys, KT502 induced rapid and profound B cell depletion while cytokine release remained low and transient, highlighting KT502's a favorable and differentiated safety from CAR-T therapies and other TCEs with similar target. Following three weekly SC injection of 1mg/kg, robust B cell depletion in spleen and lymph nodes were achieved by day 22 (Figure 1) with no fever or other clinical signs/symptoms observed. The cytokine release syndrome relevant biomarkers were generally low after the initial dose; importantly, all were back to the levels similar to pre-dose within 24 hrs (Figure 2). Furthermore, reductions from baseline for serum IgM, IgA and IgG levels were 65%, 54% and 34%, respectively by day 21.

Conclusion: KT502, a novel CD19/CD3 TCE developed through a unique CD3 masking technology, demonstrated a rapid and deep B depletion in vitro and in NHP study with a favorable and differentiated safety profile. These early findings strongly support the clinical development of KT502 as a potential effective treatment with an optimized safety profile that may also provide patient-friendly treatment option for a broad range of autoimmune diseases. A Phase I first-in-human clinical trial is anticipated to begin in Q1 2026.

Abstract Number: 0012

KT501, a CD19/BCMA/CD3 trispecific antibody, leads to rapid and deep B-cell depletion with well-tolerated safety

Min Bao, John Wang, Jay Zhao and Weihao Xu, Kali Therapeutics, San Mateo, CA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0001–0018) B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Chimeric antigen receptor T-cell (CAR-T) therapies targeting CD19 or B-cell maturation antigen (BCMA) have shown unprecedented effects in treatment-resistant autoimmune diseases such as systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), and others. However, the limitations in patient populations for CAR-T arise from significant safety concerns, complex logistical hurdles and unsuccessful retreatment. Recently, bispecific antibodies (e.g. Blinatumomab and Teclistamab), which may offer an alternative approach to CART with similarly effective B cell depletion but off-the-shelf convenience, have been approved in B cell malignancies and showed impressive efficacy in patients with autoimmune indications in case reports. Furthermore, in some patients, disease may be anchored in the long-lived plasma cells that express BCMA but not CD19. Therefore, the aim is to develop a first-in-class tri-specific antibody targeting CD19/BCMA/CD3 to achieve a rapid and deep B cell depletion with a differentiated safety profile, potentially beneficial for the treatment of autoimmune disorders across multiple therapeutic areas.

Methods: KT501 is a novel IgG-like trispecific T cell engager, designed to bind CD3, CD19, BCMA with high affinity, thereby targeting a broad range of B cell populations. Utilizing an innovative molecular design aimed at maximizing potency while minimizing cytokine release by a unique CD3 masking platform, KT501 has demonstrated robust B cell cytotoxicity and reduced cytokine production in vitro and in non-human primate (NHP) due to its cross activity in NHP.

Results: In vitro, KT501 is more potent in B cell killing and results in lower cytokine release compared with Blinatumomab. In preclinical studies using cynomolgus monkeys, KT501 induced rapid and profound B cell depletion following a single 1 mg/kg intravenous (IV) dose in peripheral blood, bone marrow, spleen and lymph nodes (Figure 1), with minimal cytokine release. Furthermore, a single subcutaneous (SC) administration of 1mg/kg led to reduction from baseline for serum IgA, IgG and IgM levels by 67%%, 44% and 39%, respectively at day 26. In the ongoing repeated dose cyno toxicology study with a wide range of doses (0.01 to 10 mg/kg) by SC injection, KT501 was well tolerated with no fever and other clinical signs/symptoms observed at all dose levels. As presented in Figure 2, after the initial SC administration, peripheral CD20+ B cells were depleted within 24 hrs at the lowest dose of 0.01 mg/kg. Cytokine release syndrome relevant cytokines were transiently increased but all back to the levels similar to pre-dose level within 24 hrs, with no increased cytokines at the subsequent doses.

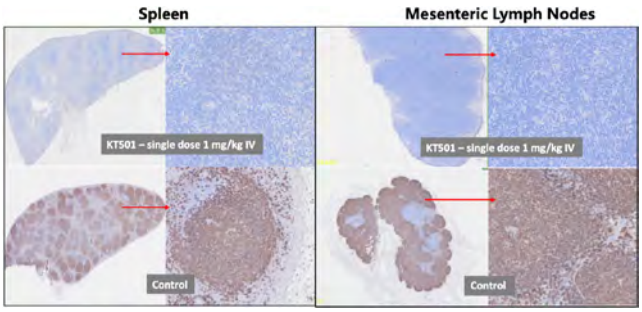

Figure 1: B cell Depletion in Spleen and Lymph Nodes in NHP (CD20 Immunohistochemistry Staining)

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0001–0018) B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: B and T lymphocyte attenuator (BTLA) is an immune checkpoint molecule that contributes to the regulation of T cell, B cell and dendritic cell function through its interaction with its ligand herpesvirus entry mediator (HVEM) on cells *in trans* and on the same cell *in cis*. Here we discovered and characterized SIM0710, which is a novel BTLA agonistic monoclonal antibody without interrupting native HVEM-BTLA interaction.

Methods: The binding activities to human BTLA protein were determined by ELISA and BLI while the blockade of BTLA-HVEM interaction were evaluated by ELISA. Agonistic functionality of SIM0710 was evaluated using a BTLA/SHP2 reporter assay. Antibody-mediated inhibition of HVEM cis-signaling was assessed using a light-driven HVEM-dependent NF-κB assay, while trans-signaling blockade was evaluated in a HVEM-dependent NF-κB assay on CHO-K1-BTLA cells. Diverse *in vitro* functional cellular assays were performed including TLR7/9-mediated IFN-α release in pDCs and modulation of co-stimulatory molecules in LPS-activated mDCs (ELISA or FACS), anti-IgM-stimulated B cell proliferation (FACS) and IL-6 secretion (ELISA), as well as anti-CD3/CD28-activated PBMC proliferation (FACS) and Th1/Th2/Th17/Th22 cytokine profiling (ELISA). *In vivo* efficacy was further assessed in humanized GvHD and TLR7 agonist-induced humanized SLE mouse models.

Results: SIM0710 demonstrates the potential to directly induce co-inhibitory agonistic signaling through BTLA, which can be further enhanced by Fc receptor engagement. Additionally, SIM0710 preserves the formation of anti-inflammatory BTLA/HVEM *cis* complex while simultaneously blocking the pro-inflammatory co-stimulatory signal mediated by HVEM through *trans* BTLA interaction. *In vitro*, SIM0710 effectively inhibited the proliferation of human primary B and T cells with concurrent reduction of IL-6 and multiple Th cytokines. Furthermore, SIM0710 modulated the functions of human primary DCs, including inhibition of the TLR7/9-induced IFN-α secretion from pDC and downregulation of co-stimulatory molecules on mDCs. *In vivo*, SIM0710 improved overall survival in a humanized GvHD mouse model. Notably, SIM0710 also significantly reduced the anti-dsDNA IgG level in the serum of an TLR7-agonist induced SLE model in hu-CD34 HSC NOG-EXL mice.

Conclusion: Taken together, SIM0710 shows broad functional inhibition in diverse pathogenic immune cells and may offer potential therapeutic benefit for treating multiple autoimmune diseases.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0001–0018) B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Autologous CAR T-cell therapies have remarkable clinical activity in autoimmune disease (AD) via B-cell targeting, with many patients achieving durable, drug-free remission. However, safety concerns persist, including toxicities such as cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS). Long manufacturing times and complex logistics that limit patient access also limit broader adoption. Allogeneic natural killer (NK) cell therapy may help address these challenges. NKX019 is an allogeneic, CD19-targeted CAR NK-cell therapy derived from healthy donor peripheral blood mononuclear cells (PMBCs) and cryopreserved for off-the-shelf use. NKX019 expresses a humanized anti-CD19 scFv CAR fused to co-stimulatory (OX40) and signaling (CD3ζ) domains to enhance killing, along with membrane-bound interleukin-15 to support persistence. In a Phase 1 clinical trial for relapsed or refractory B-cell malignancies [NCT05020678], NKX019 demonstrated a favorable safety profile, including no ICANS or life-threatening CRS, as well as encouraging anti-tumor activity. In this study, we evaluate the therapeutic potential of NKX019 in AD.

Methods: NHL patient samples and PBMCs obtained from patients with various B-cell mediated AD (SLE, SSc, IIM, MG, RA, MS) were evaluated to assess depletion of CD19+ B cells, B-cell reconstitution and immune repertoire using flow cytometry and genomic analyses (10X Genomics 5' Single Cell Gene Expression profiling paired with B-Cell Receptor (BCR) sequencing). In vivo studies were performed in NGS mice inoculated with human CD19+ B-cell lymphoma cell lines treated with NKX019 to evaluate activity and biodistribution of NKX019 in tissue samples by bioluminescence imaging (IVIS spectrum) and qPCR, respectively.

Results: NKX019 targets and kills CD19+ cells from patients with NHL and AD. In non-clinical studies, NKX019 potently and selectively depletes B cells from patients with SLE, SSc, IIM, MG, RA, and MS in a dose-dependent manner. In a B-cell lymphoma *in vivo* efficacy model, NKX019 eliminated $CD19^{+}$ lymphoma cells and trafficked to several organs including secondary lymphoid tissue, kidneys and lungs. Translational data from patient samples from the NHL trial demonstrated that NKX019 induces potent and sustained depletion of CD19+ cells from circulation. Following treatment, detailed analyses of the BCR repertoire diversity and phenotypic characterization revealed a shift of the B-cell immune repertoire toward a naïve-dominant profile.

Conclusion: In summary, non-clinical in vitro and in vivo data demonstrated that NKX019 effectively depletes CD19+ cells derived from AD patients and in CD19+ lymphoma models, respectively. In NHL patients, NKX019 induced robust B cell depletion followed by reconstitution of the B cell compartment. These data provide compelling support for NKX019 as a novel therapeutic approach for treatment of B-cell driven AD. NKX019 is currently being evaluated in Phase 1 trials for SLE LN (NCT06557265, Ntrust-1); and SSc, IIM, and ANCA-AAV (NCT06733935, Ntrust-2) and investor-sponsored trials for SLE (NCT06518668) and MG.

CDR111 is a novel CD19 and BCMA dual-targeting T cell engager (TCE) for the treatment of severe and refractory autoimmune diseases

Philipp Richle, Stephanie Jungmichel, Alessio Vantellini, André Fonseca, Anna Howald, Fabian Scheifele, Loredana iuliano, Ariadna Vilarrasa, Romina Doerig, Hannes Merten, Philip Knobel, Daniel Lenherr-Frey, Christian Leisner and Leonardo Borras, CDR-Life, Horgen, Zurich, Switzerland

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0001–0018) B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: B cells and plasma cells are central to the pathogenesis of many autoimmune diseases. While B cell depletion therapies (BCDTs), such as anti-CD20 monoclonal antibodies, have improved outcomes in diseases like systemic lupus erythematosus (SLE), their efficacy is limited by the persistence of plasma cells, leading to disease relapses or refractory cases. Immunotherapies targeting CD19 have revolutionized the treatment of various hematological malignancies. Recently, such therapies have been used in refractory autoimmune diseases with encouraging results. CD19 is a B cell marker expressed from early B cell development through plasma cells, making it an attractive target for broad B cell depletion. However, CD19 targeting BCDT does not address accumulated long-lived plasma cells, leading to persistent autoantibody production despite B cell depletion. B cell maturation antigen (BCMA) is highly expressed on plasma cells, including long-lived plasma cells in lymphoid reservoirs (bone marrow, spleen, lymph nodes). We present a novel TCE designed to target both CD19-positive B cells and BCMA-positive plasma cells. This TCE enables cytotoxic T cells to recognize and eliminate the entire spectrum of B cell lineages, from naïve and memory B cells to plasma blasts and long-lived plasma cells. This dual-targeting approach is designed to overcome a key limitation of current BCDTs by eradicating both the precursors and the ultimate producers of pathogenic autoantibodies.

Methods: Cancer cell lines representing early B cell lineages (CD19+/BCMA-), plasma cells (CD19+/BCMA+), and fully differentiated long-lived plasma cells (CD19-/BCMA+) were co-cultured with isolated T cells and CDR111 for 48h. Peripheral blood mononuclear cells (PBMC) from autoimmune patients and bone marrow (BM) samples from healthy donors were incubated with CDR111. NCG-M mice engrafted with CD34+ human hematopoietic stem cells and treated with toll-like receptor 7 (TLR7) agonist to induce SLE-like symptoms were administered with CDR111.

Results: CDR111 showed potent in vitro killing of all tested cancer cell lines representing the entire B cell compartment. In contrast, CD19-directed control TCE showed no killing of CD19-negative cancer cells, mimicking long-lived plasma cells. Full depletion of B cells and plasma cells was achieved in patient-derived PMBCs. Potent cell killing was observed on plasma cells from BM where BCMA expression is high. CDR111 led to eradication of B cells and plasma cells in peripheral blood, spleen, and bone marrow in the NCG-M mouse model.

Conclusion: CDR111 demonstrates a differentiated approach to treating autoimmune patients. While showing peripheral B cell depletion with controlled cytokine release, it achieves potent plasma cell eradication in lymphoid organs (bone marrow and spleen). CDR111 holds the potential for a true B cell reset, resulting in durable treatment-free disease remission in patients with severe or refractory autoimmune diseases like SLE and rheumatoid arthritis.

Pharmacology Analyses of Sail's In Vivo hCD19 CAR-T Product Reveal Mechanistic Insights Underlying its Optimal Dose Efficiency Profile in Both Healthy Donors and SLE Patient Samples

Siobhan Rice, Sanket Bhagat, Jeremy Burns, Kerry Benenato, Volker Boehnert, Stacie Clark, Manali Deepak Kadam, Deborah Dodge, Paul Durfee, Sarah Gardner, Emilie Giaime, Amber Hoggatt, Khristina Holscher, Kelsey Joyce, Jane Liu, Dinesh Manvar, Paola Quintanilla, Viorel Simion, Akshi Thakkar, Michael Tsui, Jason Wade, Marc Wolfgang, Yi Yao, Vincent Hennemand, Trevor Hallam and Michael Mingueneau, Sail Biomedicines, Cambridge, MA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0001–0018) B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Ex vivo chimeric antigen receptor (CAR) T cell therapy has demonstrated encouraging clinical efficacy in small trials enrolling patients with B cell driven autoimmune diseases (AID), such as Systemic Lupus Erythematosus (SLE). However, existing autologous CAR-T therapies suffer from challenges in manufacturing complexity, scalability and safety. Sail Biomedicines is developing a targeted lipid nanoparticle (tLNP) encapsulating Endless RNA (eRNA^{TM})-encoded hCD19 CAR for in vivo transient reprogramming of pan-T cells.

Methods: Sail's tLNP-eRNA platform was assessed in peripheral blood mononuclear cells (PBMCs) from a cohort of healthy donors and SLE patients in an *in vitro* assay. The mechanistic contribution of various CAR expression variables as well as CD4 and CD8 CAR-T cells to autologous B cell killing was assessed in PBMCs from multiple healthy donors that were depleted of either CD4 or CD8 T cells prior to treatment with tLNP-eRNA. Using humanized mice, *in vivo* engineered T cells were characterized to further understand possible mechanisms underlying the deep B cell depletion observed in blood and lymphoid tissues.

Results: By assessing a large cohort of healthy donors in our in vitro PBMC assay, we determined the CAR expression levels required to achieve maximal B cell killing in terms of frequency of CAR$^+$ T cells, CAR$^+$ T:B ratio and number of CAR molecules per cell. We observed no correlation between the CD4:CD8 ratio of CAR$^+$ T cells and potency of B cell depletion. To investigate the contribution of each T cell subset, we transfected PBMCs depleted of either CD4 or CD8 T cells and found similar dose efficiency relationships in absence of CD4 or CD8 T cells. Healthy donors and SLE patients demonstrated comparable dose-expression and dose-functional potency relationships following treatment with our tLNP-eRNA in vitro. We optimized our dosing regimen in a B cell repopulating humanized mouse model and were able to observe deep B cell depletion in blood and lymphoid tissues, including B cell progenitors in the bone marrow. Detailed immunophenotyping and characterization of in vivo engineering kinetics revealed mechanisms underlying deep depletion of B cells in lymphoid tissues.

Conclusion: Here we explored the mechanisms underlying the optimal dose efficiency profile demonstrated by Sail's pan-T cell tLNP-eRNA. Efficient engineering of both CD4 and CD8 T cells, including T cell memory subsets with tissue migrating potential, likely explains the profound level of B cell depletion in primary and secondary lymphoid tissues and effective immune reset observed *in vivo*. Importantly, *in vitro* tLNP-eRNA engineered CD4 CAR T cells exhibited a comparable capacity to eliminate autologous B cells as CD8 CAR T cells, further supporting our pan-T targeting approach. Moreover, comparable *in vitro* pharmacology relationships in PBMCs from healthy donors and SLE patients suggest a similar dose efficiency profile will be observed in patients. Sail's tLNP-eRNA off-the-shelf IV injectable CAR-T product is poised to transform the care of patients with AID by increasing access, reducing safety risk and negating the need for lymphoablative conditioning while bearing the potential of lentiviral CAR-T efficacy.

Development of a noval '1+1+1' CD19- and BCMA-dual targeted T cell engager for autoimmune diseases

Lin Huan, Hao Ran, Shiyi Wang, Xiaoping Zhang, Bing Yang, Yang He, Dandan Liu, Chenpeng Su, Chuan Chen, Xiaoqian Chen, Kezhen Ye, Liang Tian, Jian Peng and **Zhenping Zhu**, Helixon Therapeutics, New York

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0001–0018) B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: B cells and autoantibodies play a central role in the pathogenesis of various autoimmune diseases. Although CD19-targeted B cell depletion shows promising therapeutic potential, its clinical application is limited by the pharmacokinetic (PK) limitations of BLINCYTO and the high costs associated with CAR-T therapies. Moreover, targeting B cells or plasma cells alone is insufficient to eliminate both pathogenic B cells and autoantibody production. To overcome these challenges, we engineered HXN-1031, an innovative trispecific T cell engager (TCE) capable of dual targeting CD19 and BCMA. This approach seeks to establish a transformative treatment strategy for autoimmune conditions.

Methods: The 1+1+1 format trispecific antibody targeting CD19, BCMA, and CD3 was designed and optimized to meet both activity and druggability criteria. The binding affinity of each arm to its respective target was measured using FACS, while its cytotoxic activity was evaluated in pan-T cell cultures containing $CD19^+$, $BCMA^+$, or mixed cell populations. *In vivo* stability was examined in SD rats, and *in vivo* efficacy was assessed in PBMC-reconstituted mice bearing Raji ($CD19^+$) or H929 ($BCMA^+$) tumor cells.

Results: HXN-1031 exhibits sub-micromolar affinity for CD3 while maintaining nanomolar binding affinity for CD19 and BCMA. The trispecific TCE showed a maximum CD19-positive tumor cell-killing efficacy that is comparable to Blinatumomab and other clinical stage benchmarks, while inducing lower T cell activation and cytokine release. On the other end, HXN-1031 showed high potency in *in vitro* cytotoxicity assays across tumor cells with varying BCMA expression, exhibiting efficacy comparable to the benchmarks. Moreover, it effectively kills both CD19-positive and BCMA-positive cells simultaneously within a mixed cell population while maintaining moderate T cell activation and cytokine release. In contrast, CD19 TCE and BCMA TCE selectively target only B cells or H929 ($CD19^-BCMA^+$) cells, respectively. In animal models, HXN-1031 demonstrates good *in vivo* stability and, as a result, exhibits superior efficacy to Blinatumomab in a CD19-positive tumor model when administered twice per week. HXN-1031 significantly suppresses BCMA-positive tumor growth, showing comparable efficacy to Teclistamab analogue. Additionally, HXN-1031 showed potent efficacy in depleting B cells and plasma cells in cynomolgus monkeys.

Conclusion: HXN-1031 is an innovative T cell engager with finely tuned activity against both CD19 and BCMA, designed to reset the immune system by simultaneously depleting pathogenic B cells and plasma cells. It holds great potential to significantly enhance the clinical efficacy, with the possibility of even curing certain autoimmune diseases.

Background/Purpose: Sjögren's syndrome (SS) is a chronic autoimmune disease characterized by the infiltration of circulating immune cells into the salivary and lacrimal glands. The properties of the peripheral immune cells associated to SS are only partially understood. In this work we aimed to comprehensively characterize the compositional cell changes and the gene expression changes of the circulating immune system associated to Sjögren's Syndrome.

Methods: Peripheral Blood Mononuclear Cells were collected from 32 SS patients and 10 sex and age matched healthy controls. Single cell transcriptome analysis was performed using droplet-based 3' scRNA-Seq technology. After clustering and annotation of the main circulating innate and adaptive immune cell types, compositional differences were tested using the cell frequencies using linear modelling. Alternatively, we used Covariant Neighborhood Analyses to identify compositional changes associated to diseases and not captured by the standard cell clusters. For each cell type, differential gene expression was performed using MAST.

Results: A total of 198,078 peripheral blood cells passed the quality control and were clustered and annotated into 27 immune cell types. SS was associated with an increased abundance of cells from the T compartment, including CD4+-TH2, CD8+TEM and proliferative T. Conversely, SS had significantly less circulating CD4 and CD8+ naive T cells, MAIT, pDC, DC3 and memory B cells compared to healthy controls. CNA analysis identified an independent subpopulation of CD8+ T cells significantly expanded in SS. Differential gene expression analyses revealed transcriptomic changes in all cell compartments, with more significant regulation occurring in specific cell types including NKCD16+, Tregs, TFH, B memory, and CD14+CCL2Hi monocytes. Pathway analysis identified a strong interferon-response signature across many cell types as well as cell-specific aberrant regulatory changes. The CD8+ T cell subpopulation associated to SS through CNA showed a significant enrichment of genes associated to SS risk.

Conclusion: This study provides the largest single cell transcriptomic analysis of circulating immune cells in SS performed to date. The changes both at the compositional and gene expression levels provide a comprehensive characterization of the immunological processes that are altered in the disease.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0019–0048) Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Vasculitis encompasses multiple conditions united by end-organ damage due to an immune-mediated reaction against the vasculature. Leukocytoclastic vasculitis (LCV) is a subtype of cutaneous vasculitis with considerable heterogeneity in etiology, duration, prognosis, and treatment. The pathophysiology underlying LCV remains poorly characterized and targeted treatments are limited.

Methods: 43 skin biopsies with confirmed LCV on histopathology and 5 skin biopsies from healthy controls underwent bulk RNA sequencing. Medical records were reviewed to determine an underlying etiology of LCV, when possible. Differential gene expression analysis and unsupervised hierarchical clustering were performed using DESeq2. Differentially expressed genes were identified with FDR < 0.5, padj ≤ 0.05, and log2FoldChange ≥ 0.5 (upregulated) or ≤ -0.5 (downregulated). Gene ontology enrichment analysis was performed using clusterProfiler. Etiologies with three or more samples were included in comparative analysis. This study was completed under University of Michigan Medical School IRB HUM00261031.

Results: Age at the time of biopsy ranged from 5-85 years old. Etiologies of LCV were unknown (33%), infection (26%), rheumatologic (21%), medications (14%), paraneoplastic (4.7%), and inflammatory bowel disease (IBD) (2.3%). Principal

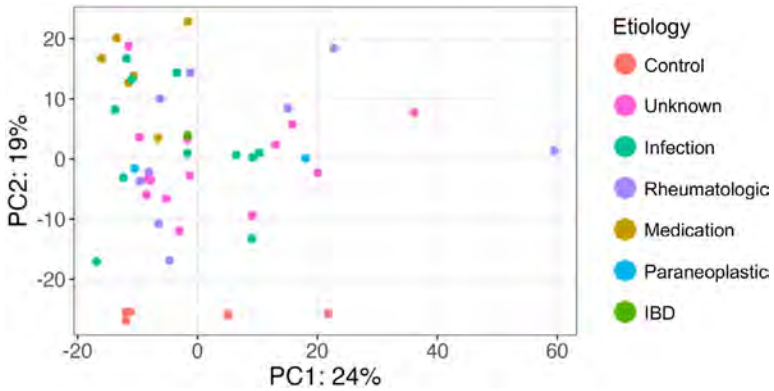

Figure 1. PCA plot of bulk RNA-sequencing data stratified by LCV etiology

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

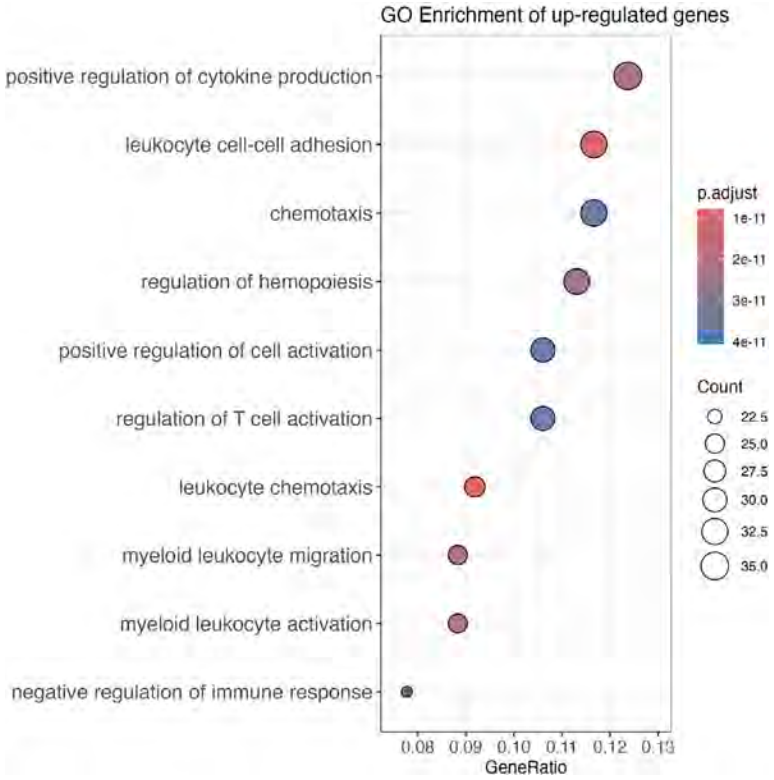

Figure 2. GO biologic process enrichment of 301 common upregulated genes

component analysis showed considerable heterogeneity between LCV samples. 2,246 genes are differentially expressed between all LCV samples and controls (915 upregulated, 1,331 downregulated). Genes upregulated in LCV were enriched for GO biological processes, including leukocyte migration, chemotaxis, and leukocyte cell-cell adhesion. 301 upregulated genes were shared in all LCV etiologies (unknown, infection, rheumatologic, medications) and were enriched for GO biological process of chemotaxis, leukocyte migration, and leukocyte cell-cell adhesion.

Conclusion: Analysis of LCV samples revealed shared upregulation of GO biologic processes related to leukocyte adhesion. Pharmacologic targeting of this pathway may serve as a potential therapeutic treatment for this subtype of vasculitis. Limitations of this study include small sample size and variable availability of associated clinical information. Future work with a larger sample size may validate these findings.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0019–0048) Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Targeted therapies have revolutionized the management of immune-mediated inflammatory diseases (IMIDs), however, there is a substantial number of patients who respond poorly to a given drug. There is a big need to understand the factors that are associated with this heterogeneity. The DoCTIS project aims to characterize molecular variation both at the disease and drug-response levels across six different IMIDs.

Methods: We applied single cell RNA sequencing to 360 samples from 176 patients from six prevalent IMIDs -psoriasis, psoriatic arthritis, Crohn's Disease, ulcerative colitis, rheumatoid arthritis, systemic lupus erythematosus- treated with five different drugs targeting TNF, IL12p40, IL6R, BLySS, IL17 and JAK pathways. All patients were analyzed at two time points including baseline and at the week of clinical response creating an immune landscape of more than two million peripheral immune cells.

Results: We found large inter-disease differences both at the compositional and genetic regulatory programs. ScRNA-Seq analysis revealed large differences at the systemic level between the six IMIDs. We found expected findings, like the predominant interferon response signature affecting multiple cell types in SLE, but also novel findings like strong regulatory differences between diseases with a shared genetic risk like Psoriatic Arthritis and Psoriasis. The impact of each drug was found to be largely disease-specific. Furthermore, we found multiple regulatory features associated with the effect of each drug as well the association to response.

Conclusion: The scRNA-Seq atlas developed in DoCTIS provides a unique resource for the understanding of drug response and disease heterogeneity across immune-mediated inflammatory diseases.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0019–0048) Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Interstitial lung disease (ILD) is clinically present in ~10% of individuals with RA. There is recognized overlap between RA-ILD and idiopathic pulmonary fibrosis (IPF) with shared genetic risk, namely the *MUC5B* rs35705950 promoter variant. Genome-wide association studies (GWAS) in IPF have identified other single nucleotide polymorphism (SNP) risk alleles, but GWAS in RA-ILD have been limited. We aimed to identify novel genetic risk alleles for RA-ILD in a large, multicenter RA cohort.

Methods: We utilized the Veterans Affairs Rheumatoid Arthritis (VARA) registry, a multicenter, prospective cohort of US Veterans with RA. ILD was systematically identified and validated via medical record review. All participants underwent genotyping on banked DNA via the Illumina Global Screening Array. Imputation was performed using the Trans-omics for Precision Medicine (TOPMed) imputation panel on the NHLBI TOPMed imputation server, and filtered for minor allele frequency, missingness, and Hardy-Weinberg equilibrium. Population stratification was accounted by ancestral principal components. GWAS was performed using SAIGE v1.3.0 (R 3.6.3) for MAF >1%. After accounting for linkage disequilibrium (r^2 >0.8), variants reaching a suggestive genome-wide level of significance ($p < 1x10^{-6}$) were investigated using the National Center for Biotechnology Information dbSNP database and National Human Genome Research Institute GWAS Catalog. Plots were generated using LocusZoom. A genetic risk score (GRS) for ILD was calculated using additive counts of the six significant variants weighted by the natural log of the OR compared to an additive model of the *MUC5B* variant alone using logistic regression.

Results: We studied 3295 participants (87% male, mean age 73 years), of whom 345 had RA-ILD. A total of 28,233,561 SNPs were included. ILD signals appeared on chromosomes (chr) 6, 7, 11, 16, 20, and 22 (**Figure 1**). Six SNPs reached the threshold for significant associations with ILD (**Table 1**). As expected, *MUC5B* rs35705950 was the strongest risk variant for RA-ILD (**Figure 2**). In addition to *MUC5B*, we identified 5 novel SNPs. The strongest of these (rs191761566) was an

uncommon variant on chr20 in the *PTPRT* gene, a gene implicated in the STAT3 pathway and that predicts lung cancer response to immune checkpoint inhibitors. *GGT1* (chr22) is associated with IPF, *NUP205* (chr7) contributes to ciliary dysfunction, *PGBD1* (chr6) has been associated with RA and implicated in lung cancer, and rs72786444 (chr16) lies in a predicted enhancer region for *CDH5*, which is expressed in lung endothelial cells. A GRS containing the 6 variants (AUC 0.67 [0.64-0.70) significantly outperformed the *MUC5B* variant alone (AUC 0.57, 0.54-0.59) in discrimination of ILD in patients with RA (p< 0.001).

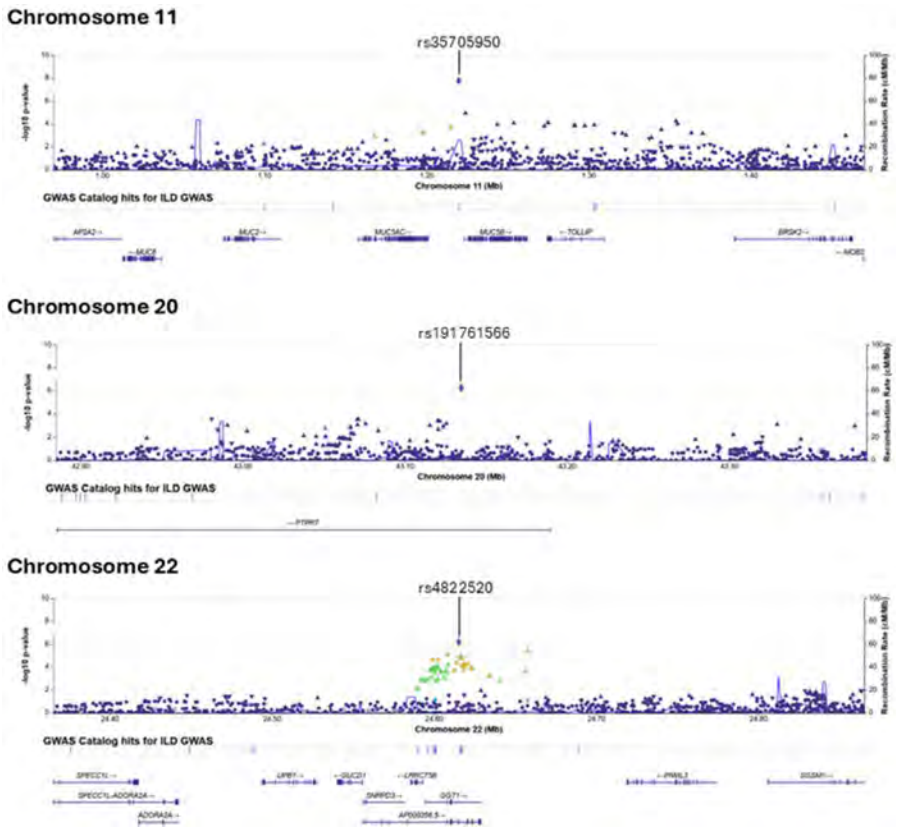

Figure 2. LocusZoom plots for top three risk loci detected by p-value.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Conclusion: In addition to the well-established *MUC5B* promoter variant, this GWAS of ILD in a large RA cohort with validated ILD cases identified several other novel SNPs within genes and regions that have potential pathophysiologic connections to ILD. A GRS containing these SNPs provided significant improvement in ILD discrimination beyond *MUC5B* alone.

Longitudinal Proteomic Effects of Hydroxychloroquine in Individuals at Risk of Lupus: Differential Signatures in Progressors and Non-Progressors

Benjamin Jones[1], Miles Smith[2], Rufei Lu[2], Carla Guthridge[2], Susan Macwana[2], Wade DeJager[3], Nancy Olsen[4], Catriona Wagner[5], Judith James[2], David Karp[6] and Joel Guthridge[2], [1]Oklahoma State University, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma city, OK, [3]Oklahoma Medical Research Foundation, Oklahoma City, [4]Penn State University/Milton S Hershey, Hershey, PA, [5]Oklahoma Medical Research Foundation, Santa Cruz, CA, [6]UT Southwestern Medical Center, Dallas, TX

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0019–0048) Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Hydroxychloroquine (HCQ) is routinely prescribed for treatment of systemic lupus erythematosus (SLE) due to its efficacy at decreasing disease activity/SLE flares and strong benefit:risk ratio. However, the heterogeneity in the molecular mechanism of HCQ responses is not fully appreciated. The Study of Anti-Malarials in Incomplete Lupus Erythematosus (SMILE; NCT03030118), a double-blind, randomized, placebo-controlled trial to evaluate whether HCQ could delay or halt progression to SLE, provides longitudinal samples to characterize molecular differences in individuals who remained stable incomplete lupus erythematosus patients compared to those who gained additional criteria at some point during the 2-year study.

Methods: Baseline, 3 month, and 6 month serum samples from 105 Non-Progressors (did not gain SLICC criteria; 54 HCQ, 51 Placebo) and 54 Progressors (gained 1 or more SLICC criteria, 27 HCQ, 27 Placebo) from the SMILE trial were analyzed using the Olink Explore HT proteomics platform (>5,000 proteins). After stringent quality control, analytes were retained only if the intra-individual coefficient of variation (CV) across multiple visits exceeded the technical CV in $\geq$90% of samples, resulting in 1,490 proteins for downstream analysis. Linear mixed effects models assessed protein changes over time by group. Proteins with nominal $p < 0.2$ were further analyzed by Gene Set Enrichment Analysis (GSEA) using Kyoto Encyclopedia of Genes and Genomes and Gene Ontology pathways.

Results: Proteomic analysis revealed both treatment- and progression-specific signatures. Analysis with GSEA found that both Non-Progressors and Progressors on HCQ showed downregulation of Toll-like receptor, TNF, IL-17 signaling pathways in addition to viral protein interaction pathways (Figure 1A), suggesting that these pathways represent HCQ effects independent of disease trajectory. Additionally, Non-Progressors on HCQ exhibited downregulation of JAK-STAT and

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Pathway enrichment shows treatment and disease-specific signatures. Normalized enrichment scores (NES) for significantly enriched pathways (Q < 0.05), as identified by GSEA using Kyoto Encyclopedia of Genes and Genomes terms (A) and Gene Ontology Biological Process (B), comparing the first 6 months within each group.

Volcano plots showing changes in protein abundance between baseline and 6 months, as determined by linear mixed effects models in (A)Non-Progressors on HCQ, (B) Progressors on HCQ, (C) Non-Progressors on Placebo, and (D) Progressors on Placebo. X-axis indicates the fixed effect coefficient representing the change over time per stratified group, while legends indicate whether the protein was found to be significantly changed at P<0.05 uniquely in the stratified group (red) or in multiple groups (blue).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

MAPK signaling pathways while Progressors on Placebo show an increase in MAPK cascade over the first 6 months (Figure 1B). Progressors on Placebo also had increased inflammatory response pathways, while there was no pathway enrichment observed in Non-Progressors on placebo. IL-6 was uniquely decreased in Non-Progressors on HCQ (Figure 2A), while CCL3 was decreased and SOD2 was increased in Non-Progressors and Progressors on HCQ (Figure 2B). Non-Progressors on Placebo exhibited a decrease in CCL11, contrary to the increase seen in Non-Progressors on HCQ (Figure 2C). Progressors showed an increase in TNF over time (Figure 2D).

Conclusion: Within the first six months of treatment, HCQ exerts both disease-dependent and independent molecular effects, with distinct proteomic and pathway changes in individuals at risk for SLE progression. These findings illustrate the pleiotropic effect of HCQ and offer insight into pathways up-regulated in pre-clinical lupus.

Biobank-scale genetic mapping identifies the shared genetic landscape of rheumatic and cardiovascular disease

Daniel Panyard[1], Daniel Li[2], Pik Fang Kho[2], Rodrigo Guarischi-Sousa[3], Jiayan Zhou[2], Austin Hilliard[4], Christie Bartels[5], Philip Tsao[2] and Themistocles Assimes[2], [1]Stanford University, Sunnyvale, CA, [2]Stanford University, Palo Alto, CA, [3]Palo Alto Veterans Institute for Research, Palo Alto, CA, [4]VA Palo Alto Health Care, Palo Alto, CA, [5]University of Wisconsin School of Medicine and Public Health, Madison, WI

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0019–0048) Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with rheumatic conditions are at increased risk for cardiovascular (CV) problems, striking on average a decade before peers and conferring substantial morbidity and mortality. Understanding the mechanisms underlying this elevated CV risk could lead to improved care for rheumatology patients and novel treatments for CV conditions. While genetic studies have illuminated several mutual risk loci between certain pairs of conditions, these studies have been limited in size, scope, and replication. Our goal was to conduct a comprehensive joint genetic analysis across 8 rheumatic conditions and 8 CV conditions based on two nation-wide data repositories, characterizing the shared genetic risk, loci, and putative causal SNPs.

Methods: We used the Million Veteran Program (MVP; n = 453,878) and UK Biobank (UKB; n = 406,492) EUR cohorts and genome-wide association study (GWAS) statistics based on PheCode definitions of 8 rheumatic (rheumatoid arthritis [RA], lupus [SLE], ankylosing spondylitis [AS], psoriatic arthropathy [PA], regional enteritis, sicca syndrome, ulcerative colitis [UC], and chronic UC) and 8 CV traits (coronary artery disease [CAD], arterial embolism, aortic aneurysm [AA], venous embolism, myocardial infarction [MI], congestive heart failure [CHF], peripheral vascular disease [PVD], and cerebrovascular disease [CVD]) (MVP: Verma et al. 2024, UKB: Zhou et al. 2018) (Figure 1). Genetic heritability (LDSC), global genetic correlation (LDSC), local genetic correlation (HESS), systematic colocalization (coloc, with adaptive locus identification), fine-mapping (SuSiE), and functional enrichment (STRING) were performed for each rheumatic-CV trait pair in a bidirectional replication framework.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

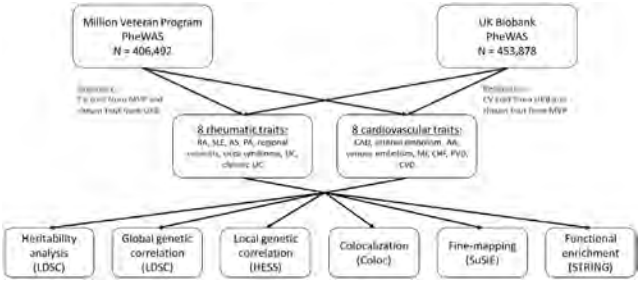

Figure 1. Study design. Genome-wide association study (GWAS) summary statistics from PheWAS performed in both MVP (Verma et al. 2024) and UKB (Zhou et al. 2018) for 16 total rheumatic and CV traits were used. The rheumatic traits included rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), ankylosing spondylitis (AS), psoriatic arthropathy (PA), regional enteritis, sicca syndrome, ulcerative colitis (UC), and chronic UC. The CV traits included coronary artery disease (CAD), arterial embolism and thrombosis, aortic aneurysm, other venous embolism and thrombosis, myocardial infarction MI), congestive heart failure (nonhypertensive) (CHF), peripheral vascular disease (PVD), and cerebrovascular disease (CVD). For the discovery analysis, the CV trait was taken from MVP and the rheumatic trait taken from UKB; the replication analysis reversed this order.

Results: Heritabilities were generally higher in MVP than UKB, particularly for CV traits. A total of 31 significant genetic correlations (false discovery rate [FDR] < 0.05) were identified, all positive. Four rheumatic-CV trait pair genetic correlations replicated in the reverse cohort setup (all involving RA; range: 0.08 – 0.30). A total of 76 regions showed nominal local genetic correlation (P < 0.05), with 23 of those regions at the 6p21.32/6p21.33 locus. All genome-wide-significant SNPs (P < 5e-8) were tested for colocalization (posterior probability for H3 or H4 > 0.8) and fine-mapped (4,773 loci), yielding 25 loci estimated to share the same causal variant (H3) and 26 loci estimated to have different causal variants (H4). These 51 loci were functionally enriched for genes related to antigen processing and peptide presentation (Gene Ontology BP; FDR < 0.05).

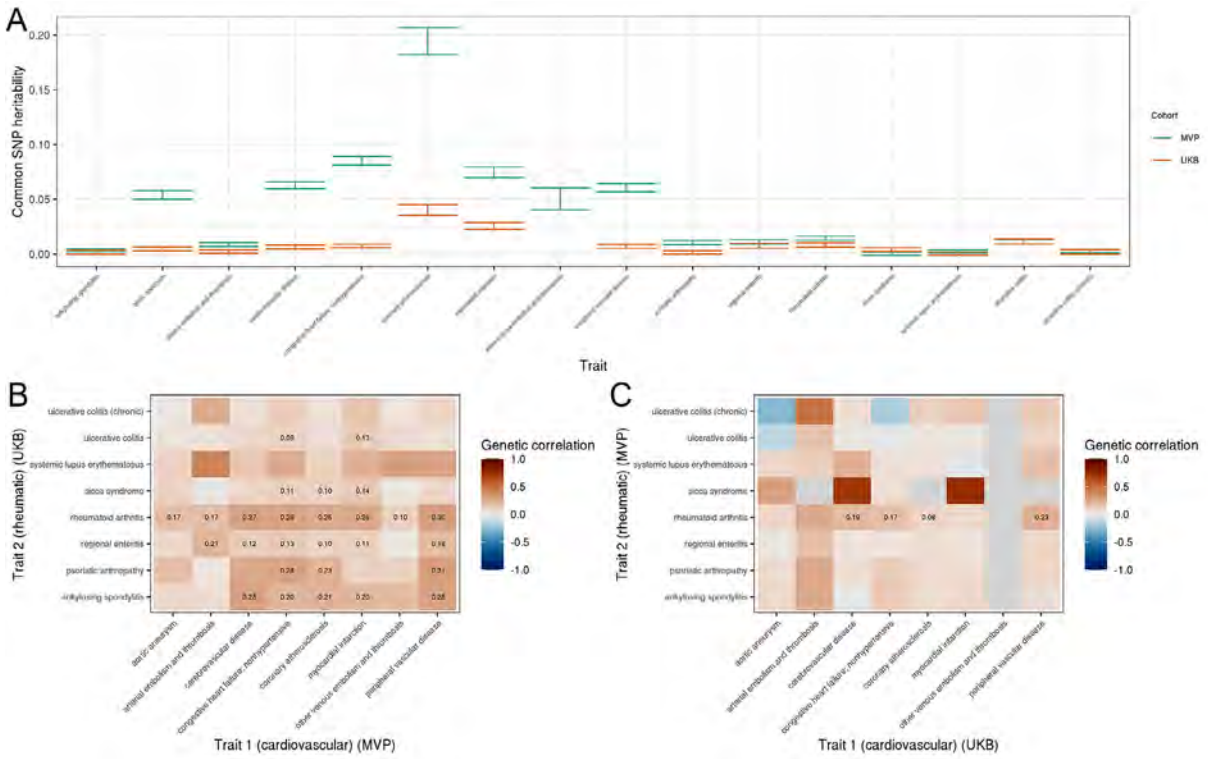

Figure 2. Heritability and global genetic correlation between rheumatic and cardiovascular traits. (A) The heritabilities estimated by LD score regression (LDSC) in a EUR population for each trait (defined by PheCode) are shown by cohort. The pairwise global genetic correlations between each rheumatic and CV trait are shown for both the discovery (B) (CV trait from MVP and rheumatic trait from UKB) and replication (C) (CV trait from UKB and rheumatic trait from MVP) analyses. Statistically significant correlations (FDR < 0.05) are indicated by text showing the estimated correlation in the heatmap. Gray indicates failed estimations (likely due to low heritability in one or both traits).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

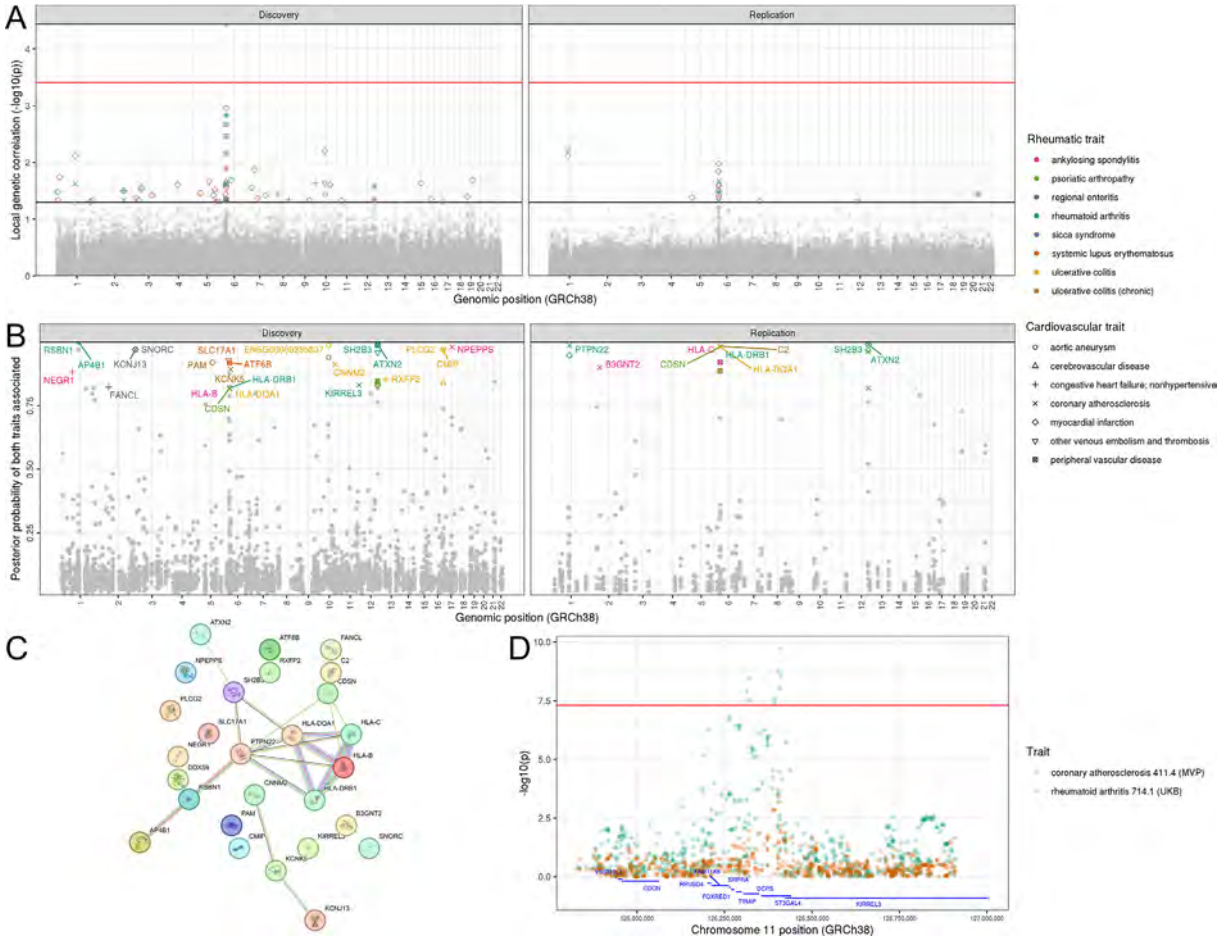

Figure 3. Colocalization and fine-mapping of genetic loci underlying rheumatic and cardiovascular traits. (A) The local genetic correlation for each tested region and for all 128 trait pairs is shown. The color indicates the rheumatic trait, and the shape indicates the CV trait. Significant enrichment of correlated loci with bidirectional replication was found in the 6p21.32/6p21.33 region. (B) The posterior probabilities of both traits being associated (y axis; sum of H3 and H4 coloc hypotheses) for each of the 4,773 tested loci are shown. For significantly colocalized loci (posterior probability > 0.8), the label shows the nearest gene. Insignificant loci are shown as gray points. (C) A functional gene network (STRING) of the genes implicated by the colocalization analysis is shown, including genes from loci either with shared or different casual variants (H3 or H4 > 0.8). (D) The GWAS assocations for the 11p34.1 locus underlying both RA and CAD are shown (results show discovery analysis). The red line indicates the genome-wide significance threshold (5e-8). The blue lines and labels indicate protein-coding genes near the locus (GENCODE).

Implicated loci for RA included *ATXN2* (with CAD, MI, CVD, venous embolism), *SH2B3* (with MI, PVD), *RSBN1* (with CHF), and the 11p34.1 locus near *ST3GAL4* and *KIRREL3* (with CAD).

Conclusion: Our findings support the presence of shared genetic risk between numerous rheumatic and CV conditions, both on the level of mutually implicated genes and of potentially causal variants. Genes related to antigen processing and peptide presentation were enriched among the colocalized loci of rheumatic and CV traits. The strongest shared genetic signal was seen for RA, implicating *ATXN2*, *SH2B3*, *RSBN1*, and the 11p34.1 locus.

Abstract Number: 0025

Expansion and Transcriptional Reprogramming of CD14$^+$ and CD16$^+$ Monocytes in Behçet's Disease

Elio Carmona[1], Rabia Deniz[2], Cemal Bes[3], Haner Direskeneli[4], Ahmet Gul[5] and Amr Sawalha[6], [1]Division of Pediatric Rheumatology, University of Pittsburgh School of Medicine, Pittsburgh, PA, USA, Pittsburgh, [2]University of Health Sciences Basaksehir Çam and Sakura City Hospital, Istanbul, Turkey, [3]University of Health Sciences, Basaksehir Çam and Sakura City Hospital, Istanbul, Turkey, [4]Marmara University, ISTANBUL, Turkey, [5]Istanbul University, Istanbul, Turkey, [6]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0019–0048) Genetics, Genomics & Proteomics Poster

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Behçet's disease (BD) is a chronic, relapsing inflammatory disease characterized by complex immunopathogenesis and limited treatment options. Monocytes are known to play a significant role in BD, with studies indicating alterations in monocyte subsets and functions. However, the detailed transcriptional programs and subset-specific contributions of monocytes to BD pathogenesis remain to be fully characterized. In this study, we leveraged single-cell transcriptomics to uncover monocyte subset-specific immune alterations in BD.

Methods: We performed single-cell RNA sequencing using GEM-X technology (10X Genomics) on PBMCs from 50 individuals (38 BD patients, 12 matched healthy controls). Sample multiplexing was enabled by antibody-based cell hashing. Data preprocessing, normalization, and clustering were performed using Seurat v5. Differential expression, cell composition analyses, and pathway enrichment (GO and GSEA) were conducted to identify disease-associated profiles.

Results: After quality control filtering, we analyzed a total of 251,924 PBMCs, successfully characterizing all major immune cell populations. Focusing on monocyte subsets, we observed significant transcriptional alterations in BD patients. CD14$^+$ monocytes exhibited a significant expansion compared to healthy controls as well as an upregulation of inflammatory and interferon-stimulated genes including *IFI27, IFITM1/2, IFI6*, and *S100A9*. Gene Ontology analysis showed enrichment of cytokine signaling and innate immune activation pathways. Gene Set Enrichment Analysis (GSEA) further highlighted hallmark pathway enrichment for inflammatory response and IL6/JAK/STAT3 signaling, consistent with known BD immunopathology. Similarly, CD16$^+$ monocytes were expanded in BD but exhibited a distinct transcriptional program. Upregulated genes included cytotoxicity-associated effectors (*PRF1, GIMAP4–8*), chemotactic receptors (*CCR5, CX3CR1, CMKLR1*), inflammasome components (*CASP1, PYCARD*), and stress-response genes (*HSPA1A, HSPA6*). Increased expression of immune checkpoints (*CD200R1, SLAMF6, BTLA*) and ISGs (*RSAD2, IFI44L, OAS1*) suggested a pro-inflammatory, non-classical activation state in CD16$^+$ monocytes. Functional enrichment pointed to immune effector functions, cell death, and migration pathways.

Conclusion: Our study provides a comprehensive single-cell map of PBMCs in Behçet's disease, revealing profound transcriptional remodeling of monocyte subsets. While CD14$^+$ monocytes display canonical inflammatory features, we identify an expansion of CD16$^+$ monocytes with a distinct cytotoxic, chemotactic, and interferon-responsive profile. These findings highlight monocyte heterogeneity in BD and uncover candidate pathways that may guide future therapeutic strategies targeting innate immune dysregulation.

Session Date: Sunday, October 26, 2025

Session Title: (0019–0048) Genetics, Genomics & Proteomics Poster

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Immune-mediated inflammatory myopathies (IIMs) are a heterogeneous group of diseases characterized by chronic inflammation, damage and impaired regeneration of the skeletal muscle leading to progressive muscle weakness. Muscle stem cells (MuSCs) play a key role in muscle regeneration, together with other myogenic and non-myogenic stromal cells. However, the exact mechanisms of impaired skeletal muscle regeneration in IIMs are incompletely understood.

Methods: We applied imaging mass cytometry (IMC) to explore the heterogeneity of MuSCs at the single-cell level and characterize cellular alterations of MuSC niches *in situ* in muscle biopsies of IIM patients. Muscle biopsies of patients with dermatomyositis (DM), polymyositis (PM), inclusion body myositis (IBM), and control individuals (CO) were analyzed.

Results: We analyzed a total of 69288 cells, including 57623 stromal cells, of which 14595 MuSCs, and identified 17 stromal cell subpopulations, including four subpopulations of MuSCs. We observed IIM-subtype-specific changes in the frequencies of MuSC subpopulations. $CD56^{hi}$;$CD90^{hi}$;$PAX7^{low}$ MuSCs were particularly upregulated in PM and DM, while $CD82^{hi}$;$PAX7^{low}$ MuSCs were mostly upregulated in IBM muscle biopsies. $GLI1^{hi}$;$PAX7^{hi}$ MuSCs were upregulated only in PM patients and $CD82^{neg}$;$PAX7^{low}$ MuSCs were not changed in frequency compared with CO. Each MuSC subpopulation was characterized by a unique spatial niche. Two MuSC niches were enriched for distinct stromal cells ($CD82^{hi}$;$PAX7^{low}$ and $CD82^{neg}$;$PAX7^{low}$ MuSC niches) and the other two ($CD56^{hi}$;$CD90^{hi}$;$PAX7^{low}$ and $GLI1^{hi}$;$PAX7^{hi}$ MuSC niches) for distinct subsets of immune cells. The $CD82^{hi}$;$PAX7^{low}$ MuSC niche was composed of LECs, while the $CD82^{neg}$;$PAX7^{low}$ MuSC niche was composed of ECs and muscle fibers. The $CD56^{hi}$;$CD90^{hi}$;$PAX7^{low}$ MuSC cellular neighborhood (CN) was enriched in NK cells,

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

HLA-DR$^-$ M2 macrophages, and regenerating muscle fibers, while the GLI1^{hi};PAX7^{hi} MuSC CN was enriched in HLA-DR$^+$ M2 macrophages, HLA-DR$^+$ CD20$^+$ B cells, HLA-DR$^+$ CD28$^-$ T cells, and helper T cells. Furthermore, we identified IIM-subtype-specific perturbations in the cellular interaction network of MuSC populations. The frequencies of MuSC subpopulations correlated with standard histopathological measures of muscle regeneration.

Conclusion: Using spatial proteomics, we unraveled the heterogeneity of MuSCs in DM, PM and IBM patients and identified IIM-subtype-specific changes in the frequencies of the distinct MuSC subpopulations together with unique perturbations in their local niches and cellular interactions. These data might offer potential for therapeutic modulation of individual MuSC subpopulations in IIM, aiming to improve skeletal muscle regeneration and thus combat disabling muscle weakness.

Background/Purpose: Existing methods to produce hyaline cartilage from human induced pluripotent stem cells (hiPSCs) face significant limitations, such as complex culture conditions, instability of the cartilage phenotype, and variability across batches. Our objective was to develop a robust, consistent, and animal component-free (xeno-free) method to generate hyaline cartilage through self-organized multi-tissue organoids (MTOs).

Methods: We developed a xeno-free culture method for differentiating hiPSCs to MTOs in which hyaline cartilage differentiation emerged by 8 weeks in culture. MTOs were cultured under defined conditions for up to 15 weeks, with evaluations conducted at multiple time points. Differentiation into cartilage was characterized by histological analysis for cartilage-specific matrix components. Independent bulk RNA sequencing (bulk-seq) at weeks 8, 11, and 15 was performed to profile

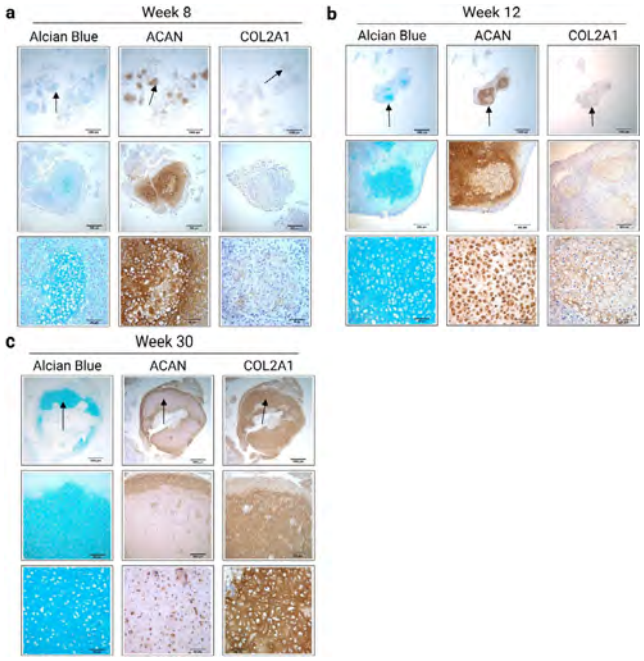

Figure 1. Histology of multi-tissue organoids (MTOs) at 8, 12, and 30 weeks. a. MTOs at 8 weeks show a developing cartilage nodule with diffuse Alcian blue staining (blue) of the early cartilaginous matrix, diffuse labeling for aggrecan (ACAN, brown) in cells and matrix, and type II collagen labeling (COL2A1, brown) in the cartilaginous matrix. Size bars = 1000 μm, 200 μm, 50 μm. Arrows indicate areas magnified in the second and third rows. b. MTOs at 12 weeks show maturing cartilage with increased Alcian blue positive cartilaginous matrix separating chondrocytes, moderate diffuse staining for type II collagen, and diffuse aggrecan labeling. Arrows indicate areas magnified in the second and third rows. Size bars = 1000 μm, 200 μm, 50 μm. c. MTOs after 30 weeks in culture show further maturation to hyaline cartilage morphology with chondrocytes surrounded by an abundant matrix with diffuse Alcian blue and type II collagen staining, and aggrecan staining apparent in the periphery. Arrows indicate areas magnified in the second and third rows. Size bars = 1000 μm, 200 μm, 50 μm.

gene expression changes over time, while single-cell RNA sequencing (scRNA-seq) was independently employed to elucidate cellular heterogeneity and specific differentiation trajectories within the organoids. Both sequencing approaches were essential for thoroughly characterizing hiPSC-derived cartilage.

Results: Histological analysis confirmed robust cartilage formation at 15 weeks, evidenced by intense immunohistochemical staining for collagen type II and aggrecan, indicative of characteristic cartilage extracellular matrix deposition (Fig 1). Bulk-seq analyses comparing weeks 8, 11, and 15 showed significant maturation of cartilage phenotype, with notable upregulation of cartilage-specific genes, including COL2A1 and ACAN ($p< 0.01$), and downregulation of pluripotency markers ($p< 0.001$) by week 15. Further bulk-seq analysis revealed that the gene expression profile of week-15 hiPSC-derived cartilage closely resembled that of developing human cartilage (Fig 2), and was distinct from adult cartilage, suggesting a developmental progression in vitro. Single-cell RNA sequencing identified minimal off-target differentiation, with chondrocytes constituting the majority (>85%) of cells and minimal residual pluripotent cell population (> 3%) (Fig 3). Additional staining exhibited limited pluripotent marker expression across batches, with 6.94 ± 1.65% Oct4+ cells and 17.54 ± 4.68% SSEA4+ cells (Fig 3).

Conclusion: We present a reproducible, xeno-free method for generating high-quality hyaline cartilage from hiPSC-derived MTOs. The integrated use of bulk-seq and scRNA-seq validated the chondrogenic differentiation process, demonstrating stable cartilage phenotype, minimal off-target differentiation, and developmental progression, thus making this approach highly promising for cartilage tissue engineering and the basis for potential clinical applications.

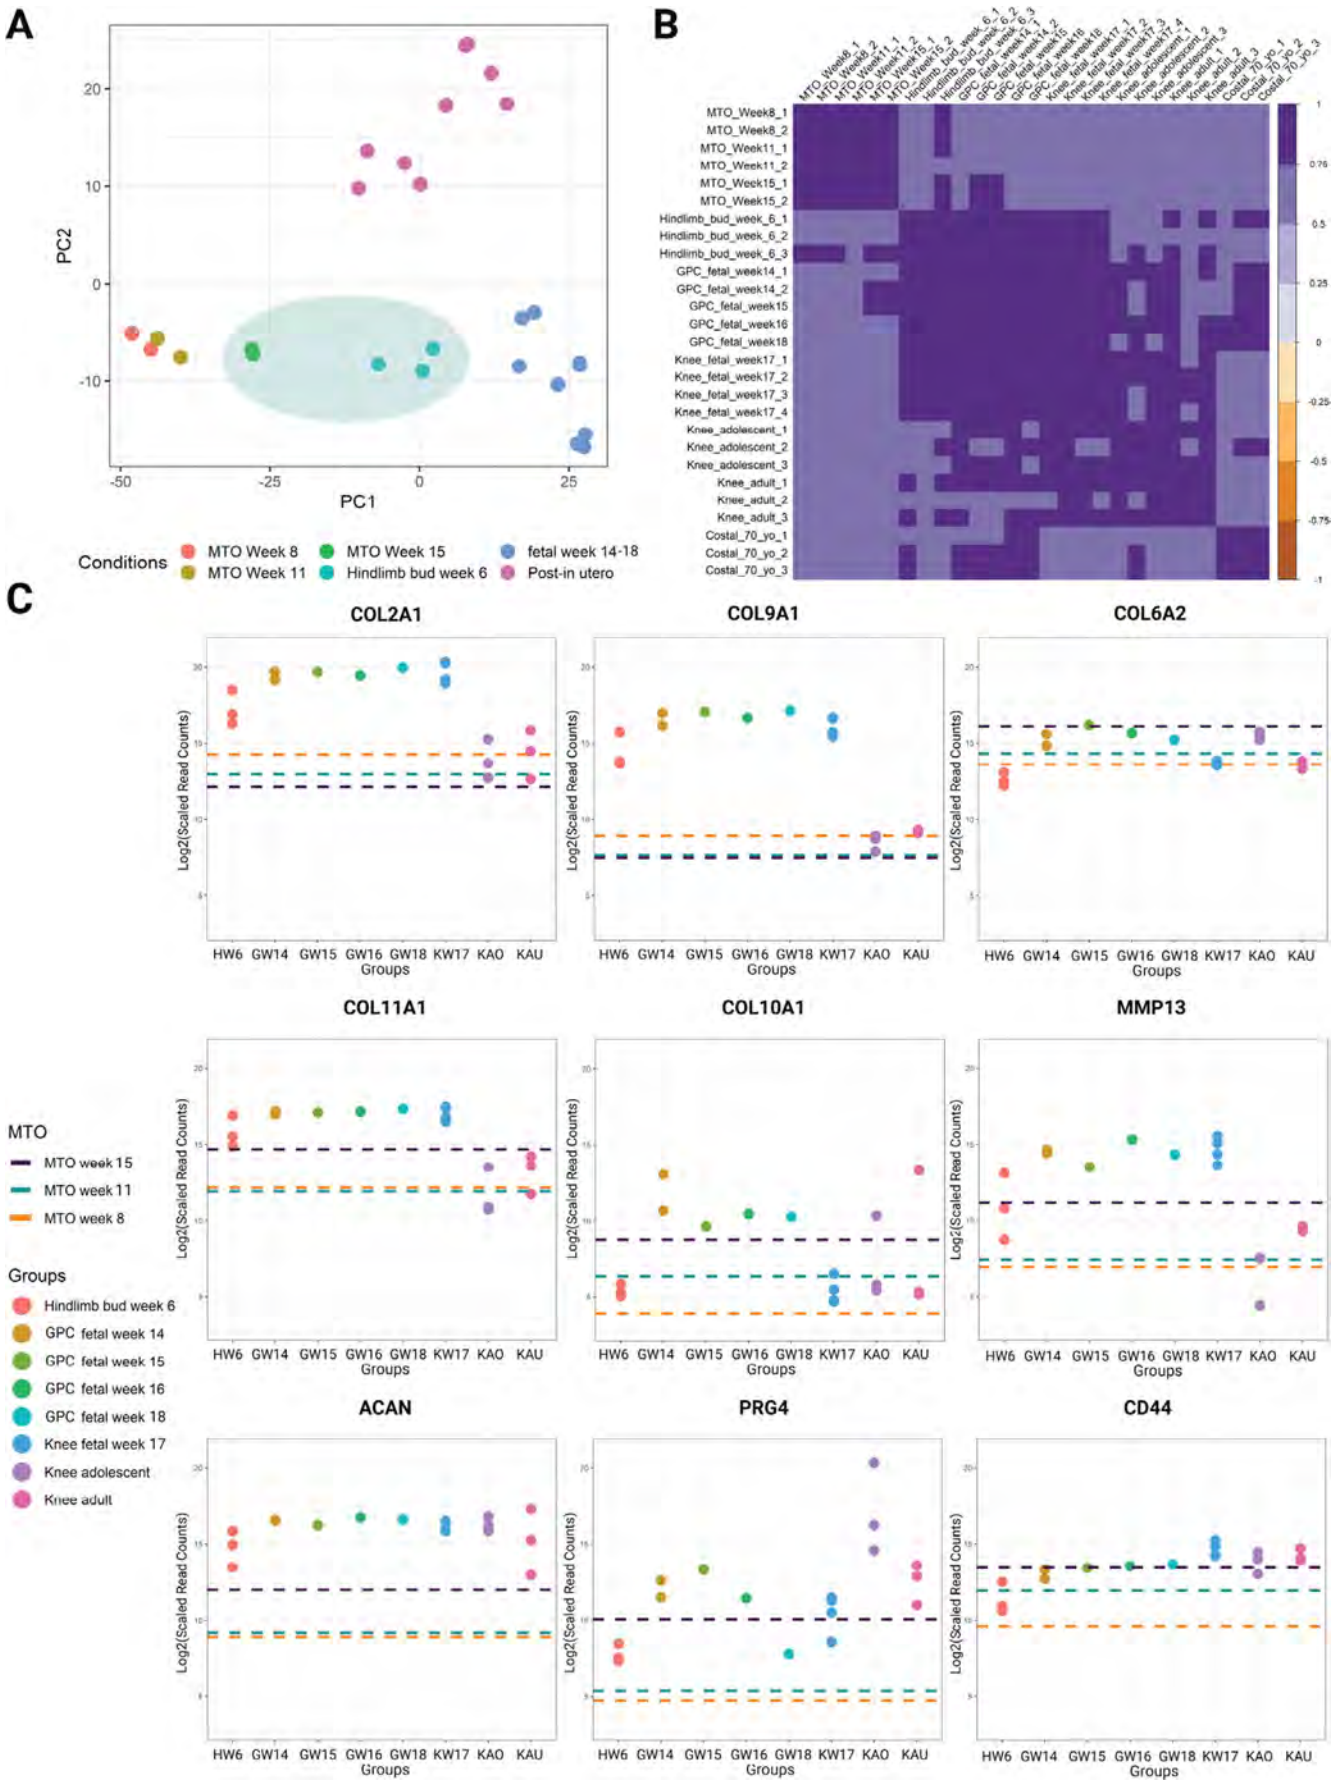

Figure 2. Transcription signatures in MTOs compared to human lower limb bud cartilage at 6 weeks of development (hindlimb bud week-6), fetal weeks 14-17, adolescent knee cartilage (kao), and adult knee and costal cartilage (kau). a. Principal component analysis (PCA) on 325 chondrocyte-specific genes shows closest matching for wk15 MTOs and human lower limb bud cartilage (green ellipse). b. Pearson correlation plot of 325 chondrocyte-specific genes showing closest match for wk15 MTOs and human lower limb bud cartilage, but with overall close matching with all stages of human cartilage. c. Representative comparisons of marker transcripts (COL2A1, COL9A1, COL6A2, COL11A1, COL10A1, MMP13, ACAN, CD44, PRG4) in MTOs and human cartilage at each growth stage. Wk15 MTOs showed closest matches to all stages of human cartilage. MTOs – multi-tissue organoids; GPC – growth plate chondrocytes.

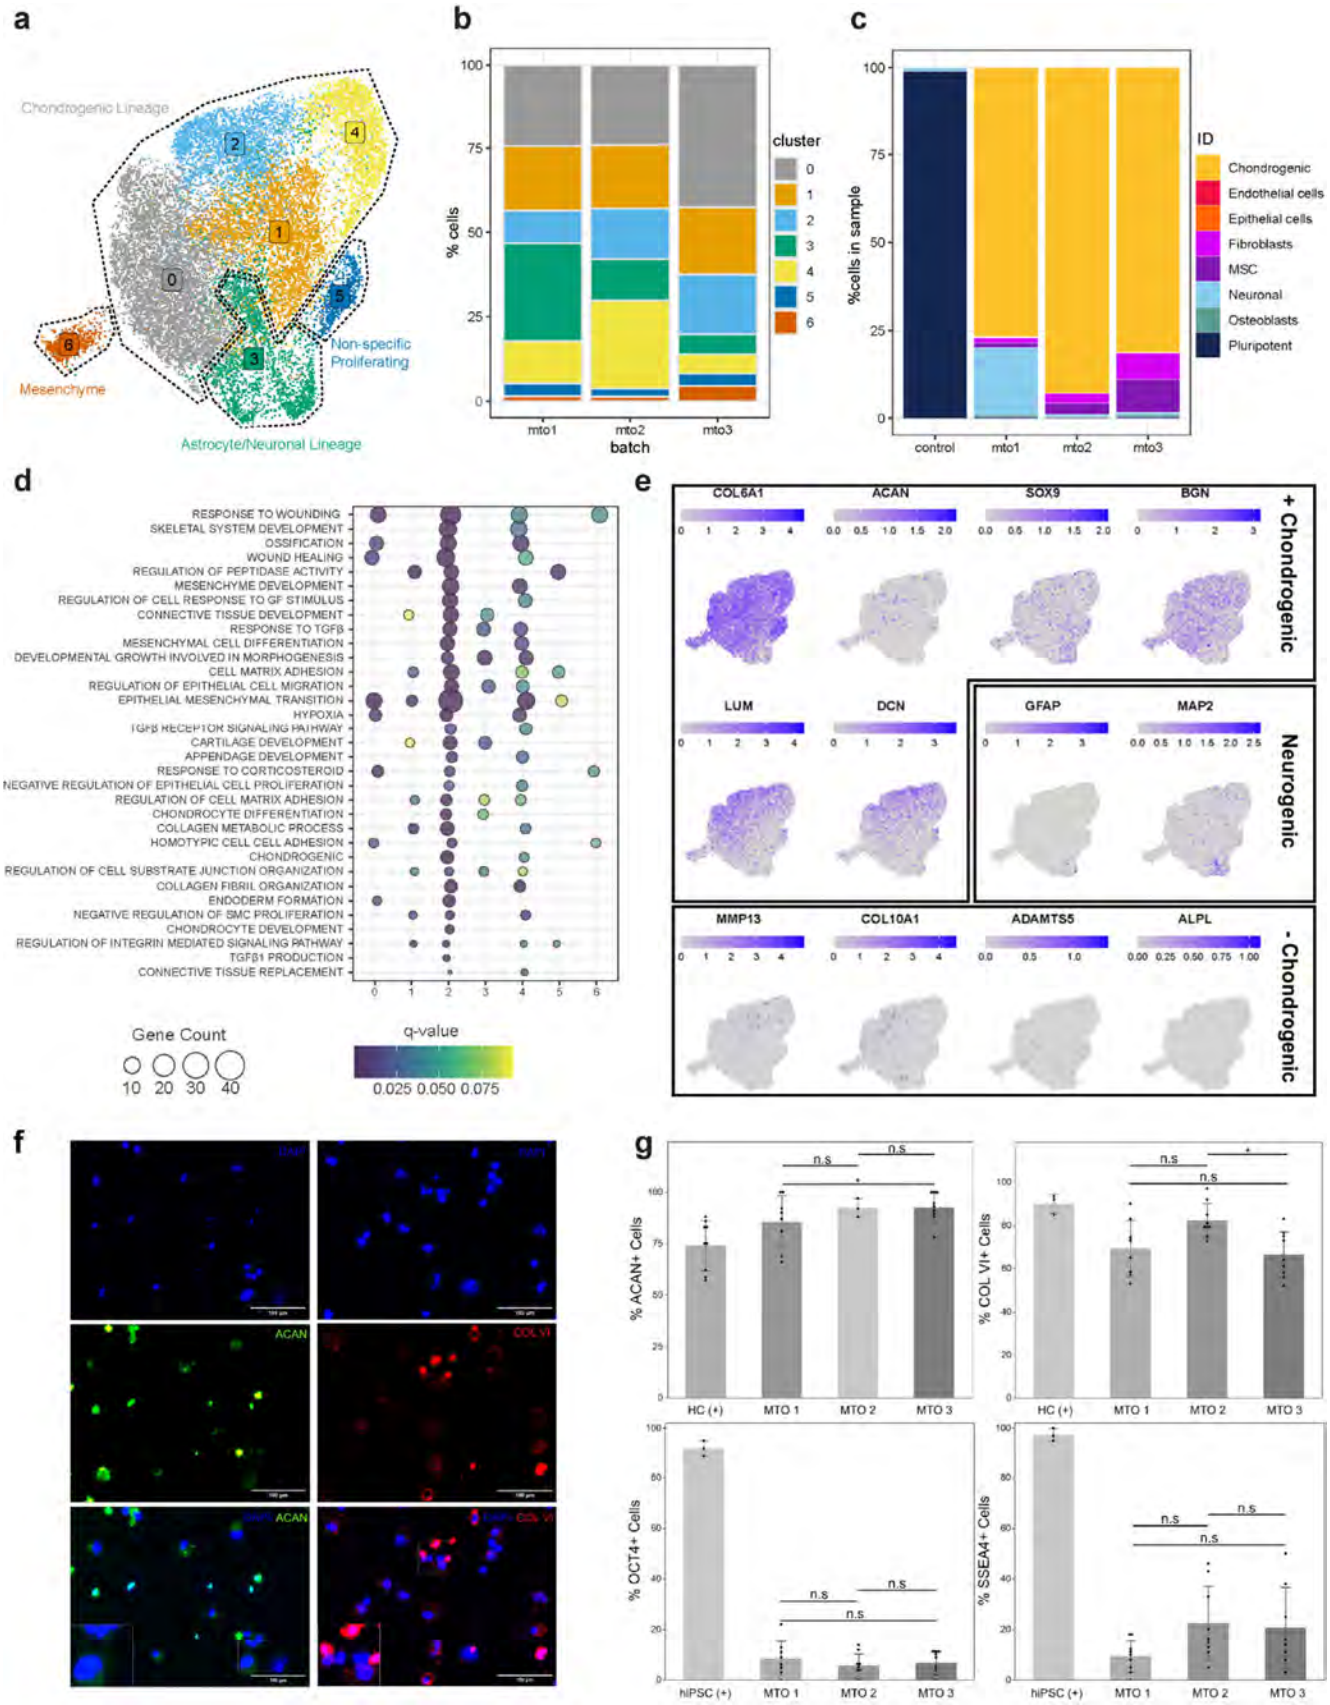

Figure 3. Single-cell RNA-sequencing data showing uniformity of cell populations within and across MTOs. a. Uniform Manifold Approximation Projection (UMAP) and b. Split-bar graph generated using scRNA-seq data of cells derived from 3 batches of MTOs. Results show homogeneity at the cluster levels across the MTO batches, with clusters 0, 1, 2, and 4 representing cells within the chondrogenic lineage, cluster 3 corresponding to neurogenic lineage cells, cluster 5 indicative of non-specific proliferating cells, and cluster 6 containing cells consistent with a mesenchyme phenotype. c. SingleR algorithmic labeling of the unique cell populations found across MTOs at the single cell level in comparison to undifferentiated hiPSC control based on the Human Primary Cell Atlas (HPCA) reference. d. Dot plot depicting enriched biological process terms related to chondrogenesis in the top 300 upregulated marker genes across chondrogenic-lineage clusters. e. Feature plots of positive and negative chondrogenic markers, as well as positive neurogenic markers. f. Immunocytochemistry images of singularized cells of MTOs verifying the expression of chondrogenic markers, type VI collagen (Col VI) and Aggrecan (ACAN) at the protein level, co-stained with DAPI. Scale bar = 100 μm g. Quantification of ICC images of COL VI, ACAN, and pluripotent markers OCT4 and SSEA4. Data represent mean ± SD from each MTO biological replicate (n=8) in comparison to respective positive control (n=3). Statistical significance was assessed by Tukey's HSD test. (* = $p < 0.05$).

Computational and Laboratory Identification of Risk-Driving Alleles on Juvenile Idiopathic Arthritis (JIA)-Associated Haplotypes

Adam He[1], Hannah Ainsworth[2], Kaiyu Jiang[3], Ekaterina Khtovatkova[2], Yanmin Chen[3], Carl Langefeld[4], Charles G Danko[1] and **James N. Jarvis**[5], [1]Cornell University Baker School of Veterinary Medicine, Ithaca, NY, [2]Wake Forest University, Winston-Salem, NC, [3]University of Washington School of Medicine, Seattle, WA, [4]Wake Forest University School of Medicine, Winston Salem, NC, [5]University of Washington Center for Indigenous Health, Seattle, WA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0019–0048) Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Multiple genomic regions are known to confer risk for JIA. However, identifying the SNPs that exert the biological effects that confer risk, and therefore the target genes, is confounded by linkage disequilibrium (LD). LD makes the true risk-driving SNPs statistically indistinguishable from those (the majority) with which they are co-inherited. We used novel analytics and wet lab procedures to identify three SNPs within JIA risk regions whose biological properties make them likely disease-driving variants.

Methods: Our groups have developed independent methods for assessing the likelihood that a SNP on a disease haplotype exerts risk-driving biological effects. The first is an AI-based approach that captures the effect of JIA SNPs on each of the distinct stages of enhancer assembly (as we have previously shown that JIA risk variants are likely to be situated in active or poised enhancers). We trained sequence-to-activity models to predict three different types of genomic data, ATAC-seq, PRO-cap, and PRO-seq, that capture different stages of enhancer assembly. The second method predicts allelic effects on DNA shape/topology, a critical feature of DNA function (e.g., transcription factor binding). To verify the utility of these approaches, we undertook wet lab confirmation of computational predictions using enhancer reporter and DNA pulldown assays.

Results: Using the AI-based method for assessing enhancer (and transcriptional) effects, we identified a SNP within the JIA-associated *IRF1* locus, rs2548998 G to A, as likely to influence transcription. This SNP lies within a large enhancer cluster

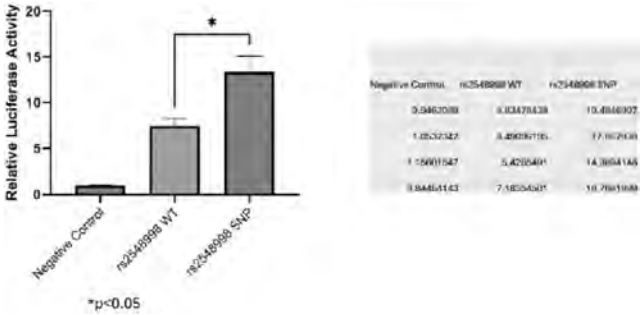

Figure 1 – Results of an enhancer reporter assay performed in CD3/CD28/IL2-activated primary humanCD4+ T cells. We compared the common allele ("rs2548998 WT") with the G to A variant ("rs2548998 SNP"). The SNP showed 2-fold enhancer activity compared with the common allele. Raw data from each of 4 experiments (relative luciferase expression) is shown in the table on the right. The negative control consisted of the green fluorescence protein vector without reporter vector without the enhancer construct inserted.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2 - Identification of proteins with different binding affinity to common allele or allele of single nucleotide polymorphismsidentified via DNA topology analyses as likely to have significant effects on transcription factor binding. (A) Western blot verification of DNA pull-down assay. Nuclear protein extracts from Jurkat cells were incubated with Streptavidin MicroBeads and biotin-labeled probes representing the common allele or allele of rs4147359 (GA, TF CREB1). Nuclear protein extracts from K562 cells were incubated with Streptavidin MicroBeads and biotin-labeled probes representing the common allele or allele of rs7234029 (AG, TF GATA1). (B) The protein levels were quantified using the iBright Analysis System (Thermo Fisher Scientific). Significant differences were marked with an asterisk (*$p < 0.05$; **$p < 0.01$; n=4).

upstream of the *IRF1* transcription start site, marked by both H3K27ac ChIPseq and PROseq-dREG peaks. Using a luciferase enhancer reporter assay, we demonstrated that the rs2548998 G®A allele showed 2x more activity than the common allele in activated primary human CD4+ T cells (**Figure 1)**. We used a DNA pulldown assay to corroborate predictions from DNA topology analyses regarding effects of SNPs' effects on transcription factor binding. We tested 2 SNPs, rs4147359 G to A, within an a CREB1 binding site upstream of *IL2RA* (using nuclei extracted from Jurkat T cells), and rs7234029 A®G, situated in a GATA1 binding site within the first intron of *PTPN2* (using myeloid K562 cells; GATA1 is not expressed in lymphoid cells). **Figure 2** summarizes the results of these experiments. The SNP, rs4147359 G®A reduced CREB1 by approximately 2-fold compared to the common allele ($p< 0.01$), while rs7234029 A®G reduced GATA1 binding by more than 4-fold compared to the common allele ($p< 0.05$).

Conclusion: We demonstrate that, by using a combination of computational techniques that predict different features of DNA/chromatin, and corroborating computational predictions with wet lab techniques, we can identify true risk-driving alleles on JIA risk haplotypes.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0019–0048) Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: IgA vasculitis (IgAV) is a systemic small-vessel vasculitis characterized by immune complex deposition containing aberrantly glycosylated IgA1. While its clinical manifestations are well defined [1], the molecular mechanisms driving disease onset and progression remain poorly understood. Diagnosis still relies on invasive tissue biopsies, underscoring the need for molecular biomarkers to support non-invasive alternatives. Although B cells are central to IgA biology, their role in IgAV pathogenesis remains unclear [2], particularly regarding the regulation of IgA glycosylation [3]. Here, we present the first single-cell RNA sequencing (scRNA-seq) analysis of peripheral B cells in IgAV, with the aim to identify cell subpopulations presenting transcriptional alterations associated with the disease's ethiopathogenesis.

Methods: For this study we recruited 12 Caucasian IgAV patients in the acute phase of the disease and 12 healthy individuals matched by sex, age, and ethnicity to the patients. From the extracted peripheral blood, mononuclear cells were isolated using a density gradient with Ficol and purified the CD19+ B Cells using a magnetic separation kit using MACS® Technology. Single-cell separation and library preparation was carried out using the Chromium platform (10X technologies)

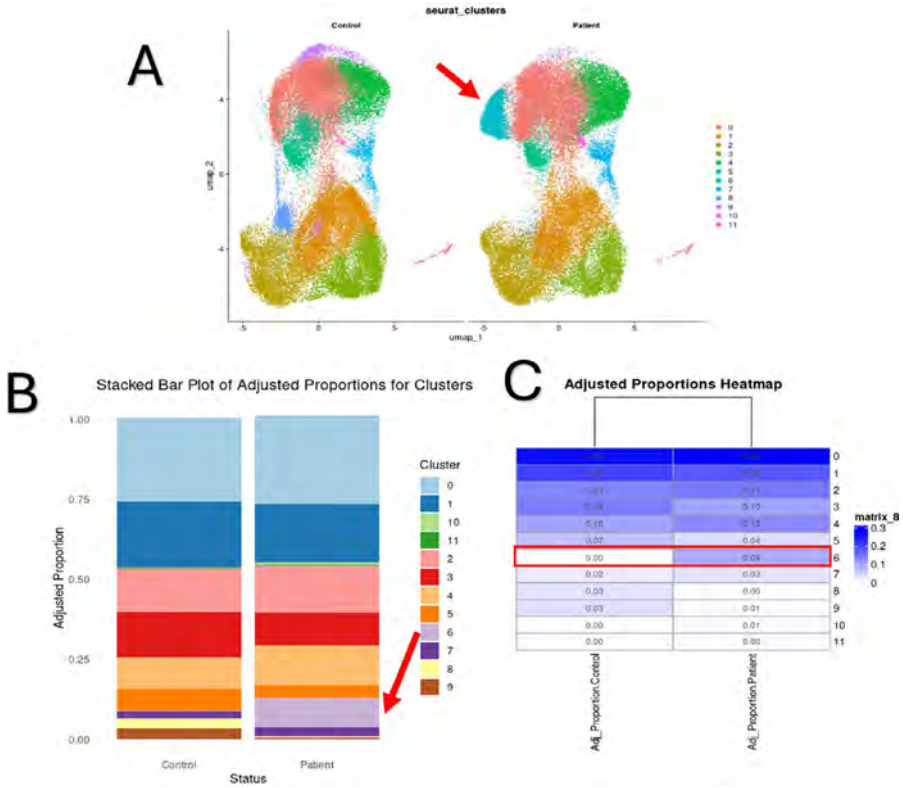

Figure 1. A) UMAP visualization of B cell subpopulations identified by Leiden clustering in IgAV patients and healthy controls. The red arrow indicates the cluster of interest (Leiden cluster 6), which is enriched in IgAV samples. B) Stacked bar plot showing the relative proportions of B cell clusters in each group. Leiden cluster 6, highlighted with a red arrow and box, is overrepresented in IgAV patients. C) Heatmap summarizing B cell cluster proportions across individual samples, further illustrating the expansion of Leiden cluster 6 in IgAV.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Volcano plot of differential gene expression from the B cell subpopulation identified in Leiden cluster 6. Genes highlighted in red are associated with glycosylation pathways implicated in the production of aberrantly glycosylated IgA. Dotted line represents a 0.05 p-value threshold.

and Illumina library preparation kits. Transcriptomic sequencing was carried out on a Novaseq X plus instrument. Raw sequencing data was preprocessed with cellranger and its outputs were analysed with Scanpy and Seurat.

Results: Interestingly, our results reveal for the first time a B cell subpopulation significantly enriched in IgAV patients compared to healthy controls (Fig. 1A). This subset, corresponding to Leiden cluster 6, showed a marked overrepresentation in the IgAV group, as illustrated by both the cluster-wise proportion comparison (Fig. 1B) and the heatmap of cluster proportions (Fig. 1C). Of note, differential gene expression analysis of this population revealed dysregulation of key genes involved in O-glycosylation pathways (Fig. 2), including known regulators of IgA glycosylation. These findings suggest that this B cell subset may contribute to IgAV pathogenesis through the production of aberrantly glycosylated IgA, highlighting its potential relevance as both a mechanistic driver and a biomarker of disease.

Conclusion: Our results reveal, for the first time, a B cell subpopulation with dysregulated glycosylation genes characteristic of IgAV, highlighting its potential as a disease-specific biomarker and a contributor to pathogenic IgA production.

Abstract Number: 0030

Immune-related Diagnoses Associated with *NOD2* Variants in Human Subjects: A Phenome-wide Association Study

John Davis[1], Elizabeth Atkinson[1], Vanessa Kronzer[1], Cynthia Crowson[2], Afsaneh Alavi[3], John Damianos[1], Loftus Edward[1], Joseph Murray[1], Ann Moyer[1] and Filippo Pinto e Vairo[1], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Stewartvillle, MN, [3]Department of Dermatology, Mayo Clinic, Rochester, MN

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0019–0048) Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: The nucleotide-binding oligomerization domain-containing protein 2 (*NOD2*) gene is associated with risk for several inflammatory diseases, including Crohn disease, Blau syndrome, and Yao syndrome (YAOS). Growing awareness of the heterogeneity of *NOD2*-associated conditions has exposed a knowledge gap about the spectrum of *NOD2*-related phenotypes. Our aim was to perform a phenome-wide association study (PheWAS) of *NOD2* variants.

Methods: This study leveraged resources of a population-scale research program with available genomic sequencing data for nearly 100,000 participants recruited in the Midwest, Southeast, and Southwest United States. Participants were 18 to 50 years old, registered as patients at our institution, and had email and web access. Patients were excluded if they had a comorbidity that interfered with study participation, allogeneic bone marrow transplant, active hematological cancer, or non-U.S. residents. Twenty-seven *NOD2* variants were pre-specified based on literature review. A sample of subjects carrying at least one pre-specified *NOD2* variant was identified and matched to *NOD2* variant-unexposed subjects by age, sex, residence, and length of medical records (i.e., >5 years). Subjects' ICD-10 codes were pulled electronically for the prior 5 years and mapped to general PheWAS codes. For this analysis, one code appearance in five years was sufficient to count. PheWAS categories that appeared in fewer than 5 subjects were excluded. Chi-square tests were used to evaluate differences in the frequencies of PheWAS categories between NOD2 variant-exposed and unexposed subjects.

Results: The study included 500 subjects with *NOD2* variants and 500 matched subjects without any *NOD2* variants. The top four were c.2717+158C >T (IVS8+158), c.2782G >A (p.Val928Ile), c.2023C >T (p.Arg675Trp), and c.2938dup (p.Leu980ProfsTer2), with gnomAD allele frequencies 0.109 to 0.015 in descending order. *NOD2* variant-exposed subjects had significantly higher frequencies than *NOD2*-unexposed subjects of twelve PheWAS categories ($p < 0.05$), including 'rheumatoid arthritis and other inflammatory polyarthropathies', 'inflammatory bowel disease (IBD) and other gastroenteritis

Table 1. Phenome-wide association study of *NOD2* variant-exposed subjects and matched *NOD2* variant-unexposed subjects. Shown are selected categories with p<0.10.

PheWAS Category	NOD2 variant-exposed	Unexposed	p-value
Rheumatoid arthritis and other inflammatory polyarthropathies	3.2%	0.6%	0.003
Inflammatory bowel disease and other gastroenteritis and colitis	3.6%	1.2%	0.013
Encounter for long-term (current) use of antibiotics	1.2%	0%	0.014
Other signs and symptoms involving emotional state	1.6%	0.2%	0.019
Acute and chronic tonsillitis	4.0%	2.0%	0.021
Thoracic or lumbosacral neuritis or radiculitis, unspecified	7.0%	4.0%	0.037
Neuralgia, neuritis, and radiculitis NOS	4.2%	2.0%	0.045
Muscular dystrophies and other myopathies	1.2%	0.2%	0.058
Other perinatal conditions of fetus or newborn	3.4%	1.6%	0.062
Disorders of the pituitary gland and its hypothalamic control	2.8%	1.2%	0.071
Psoriasis and related disorders	2.8%	1.2%	0.071
Poisoning by other anti-infectives	6.0%	3.6%	0.076
Benign neoplasm of other endocrine glands and related structures	1.8%	0.6%	0.081
Other disorders of intestine	6.2%	3.8%	0.082
Abnormal movement	8.4%	5.6%	0.083
Other endocrine disorders	1.4%	0.4%	0.094
Venous/cerebrovascular complications in pregnancy and the puerperium	1.4%	0.4%	0.094

and colitis', 'treatment with long-term antibiotics', 'other signs and symptoms involving emotional state', and 'acute and chronic tonsilitis' (Table 1). The most important variants driving the associations for arthritis-related diagnoses were c.2023C >T (p.Arg675Trp) and c.2717+158C >T (IVS8+158) while the most important variants for IBD-related diagnoses were c.2023C >T (p.Arg675Trp), c.2717+158C >T (IVS8+158), and c.2938dup (p.Leu980ProfsTer2) (Tables 2 and 3).

Conclusion: Our findings confirm and expand on previous reports that common *NOD2* variants are associated with an increased risk of immune-related conditions. These include not only IBD and other forms of gastroenteritis and colitis, but also inflammatory arthritis, illnesses requiring long-term treatment with antibiotics, acute and chronic tonsilitis, and other related diagnoses. Further research is underway to illuminate autoinflammatory phenotypes causally related to *NOD2* variants.

Meta-Analysis of Trans-Disease Microbial Biomarkers of Protection and Pathogenesis in Autoimmune Conditions: Results from the AMP AIM Consortium

Kevin Bu[1], Rebecca Blank[2], Alba Boix-Amoros[3], Adam Cantor[4], Jose Scher[5], Jose Clemente[1] and Accelerating Medicines Partnership: Autoimmune and Immune-Mediated Diseases Network (AMP AIM), [1]Icahn School of Medicine at Mount Sinai, New York, NY, [2]NYU Langone Health, New York, NY, [3]Icahn School of Medicine, New York, NY, [4]Icahn School of Medicine, New York, [5]New York University School of Medicine, New York, NY

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0019–0048) Genetics, Genomics & Proteomics Poster

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Autoimmune and immune-mediated diseases (AIMDs) affect over 20 million Americans. The sharp increase in prevalence of these disorders over recent decades suggests that factors other than genetics may be involved in pathogenesis. While the microbiome has been previously investigated as a risk factor, most studies have considered AIMDs in isolation. Here, we hypothesize that analysis across patients with different AIMDs will identify protective and deleterious microbial factors that are unique or shared across diseases.

Methods: As a part of the Accelerating Medicines Partnership-Autoimmune and Immune Mediated Diseases (AMP AIM) consortium, we characterized the microbiome of 126 subjects across six AIMDs: rheumatoid arthritis (RA; n=43), psoriasis (PsO=28), psoriatic arthritis (PsA=28), Sjögren's disease (SjD=10), non-Sjögren's sicca (NSS=12), and systemic lupus erythematosus (SLE=5), as well as 6 healthy controls. Four previously published studies in which data was publicly available were used as validation cohorts (**Table 1**). All studies consisted of 16S rRNA sequencing and were analyzed using QIIME2, the GreenGenes2 taxonomy, and LEfSe. Statistical tests (Wilcoxon Rank-Sum, Kruskal-Wallis) were performed in R 4.4.2 using the base stats library, and comparisons of features across groups was visualized using UpSetR.

Results: Within the AMP AIM cohort, AIMD patients exhibited significantly lower alpha diversity ($p < 0.05$) and significant differences in beta diversity compared to healthy controls for all diseases (except for SLE where p=0.08) (**Figure 1**). LEfSe identified taxa that were differential in disease conditions; *Lawsonibacter* was enriched in SjD patients, while *Anaerotignaceae* and *Othenecus* were depleted in PsO, RA, and SLE patients. Across all six AIMDs, *Phascolarctobacterium* was significantly depleted relative to healthy controls.

In four validation datasets, when comparing disease groups to healthy controls, we observed significantly reduced alpha diversities in one study (Valid2 SjD) and significantly different beta diversities in all four. *Lawsonibacter* was enriched in the affected patients within the Valid1 SLE, Valid2 SjD, and Valid3 RA studies. Conversely, *Anaerotignaceae* and *Othenecus*, were depleted in the Valid1 SLE and Valid2 SjD studies. Additionally, *Phascolarctobacterium* exhibited lower mean abundances in the disease subgroups relative to healthy controls in Valid1 SLE and Valid3 RA studies (although not significantly).

Table 1. Cohort sizes and breakdown of diagnoses in meta-analysis datasets.

Cohort	Author	Journal (Year)	Disease(s)	N (AIMD)	N (healthy)
AMPAIM	N/A	N/A	RA, PsO, PsA, SLE, SjD, NSS	126	6
Valid1 SLE	Su et al.	Gut Microbes (2020)	SLE	37	20
Valid2 SjD	Wang et al.	Cell Reports (2022)	SjD	133	40
Valid3 RA	Yu et al	Front Cell Infect Microbiol (2022)	RA	26	26
Valid4 PsO	Luca	Mendeley Data (2024)	PsO	36	23
	Total			232	109

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Patients with AIMDs exhibit distinct microbiome compositions from healthy controls. (A) Alpha diversity (Shannon index) within the AMP-AIM cohort. (B) PCoA of beta diversity (Unweighted UniFrac) of AMP AIM cohort samples, *p<0.05, **p<0.01.

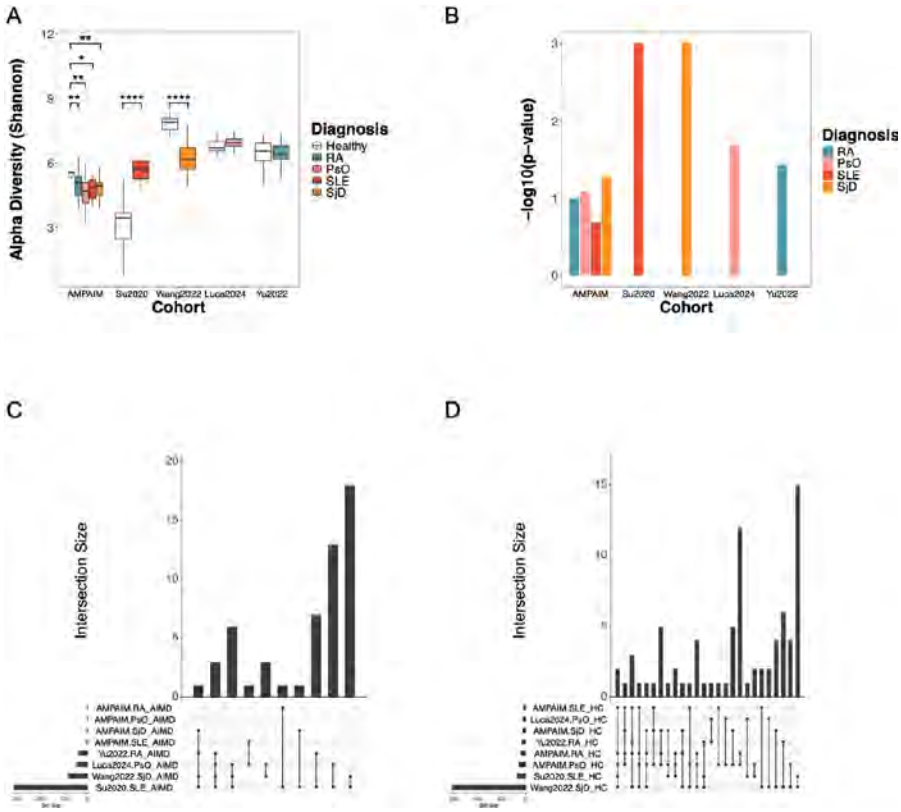

Figure 2. Healthy controls and patients with AIMDs exhibit distinct microbiome compositions across validation studies with overlap in differential taxonomic features. (A) Alpha diversity (Shannon index) of AMP AIM cohort along with 4 validation datasets, broken down by diagnoses. (B) PERMANOVA p-values (negative log-transformed) testing the difference in composition between AIMD and healthy control subgroups within each study for each diagnosis. (C-D) UpSetR plots showing the sizes of intersections of taxa identified as enriched (C) or depleted (D) in disease state relative to healthy controls across AMP AIM and validation cohorts.

Conclusion: In our AMP AIM cohort and across validation studies, comparison of healthy controls and patients with AIMDs revealed differences in alpha diversity, beta diversity, or both. We identified several taxa commonly enriched (*Lawsonibacter*) and depleted (*Phasolarctobacterium, Anaerotignaceae, and Othenecus*) across multiple AIMDs in both AMP AIM and validation studies. Across studies, there was a greater overlap among taxa that were depleted across disease states than among taxa enriched across AIMDs. Our meta-analysis suggests that microbes associated with pathogenesis are likely unique to each disease, potential mechanisms of protection (or lack thereof) tend to be shared.

Abstract Number: 0033

Development and Internal Validation of Two Human Leukocyte Antigen Genetic Risk Scores for Predicting Rheumatoid Arthritis Progression and Anti-Citrullinated Protein Antibody-Positivity

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0019–0048) Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Human leukocyte antigen (HLA) class II genes play a central role in antigen presentation and immune modulation. The shared epitope (SE) region within HLA-DRB1 is a well-established genetic risk factor for rheumatoid arthritis (RA) and is associated with anti-citrullinated protein antibody (ACPA) positivity. RA is a heterogeneous disease, with some individuals developing ACPA positivity years before clinical symptoms, while others seroconvert only after disease onset or remain seronegative. Although prior studies have linked individual HLA alleles with disease risk, there are no composite genetic scores exist that capture HLA-driven risk for key disease features, such as RA stage progression or the emergence of ACPA positivity.

Methods: Using the Accelerating Medicines Partnership (AMP) cross-sectional dataset (n=349, Inamo et. al, *JCI* 2025), we developed two HLA-based genetic risk scores targeting distinct outcomes: (1) natural RA progression across clinical stages (control, at-risk, RA), and (2) ACPA positivity, defined as CCP3.0 and/or CCP3.1 >20 units. At-risk was defined as being either ACPA+ and/or having a first degree relative (FDR) with RA. Genotyping was performed using the Illumina Multi-Ethnic Genotyping Array, and classical HLA alleles were imputed using the TOPMed reference panel. We restricted analyses to participants of European ancestry (n=153, Table 1). Each score was derived using a three-step pipeline: (1) individual regression models performed for each imputed HLA allele, modeling both additive (0/1/2 copies) and heterozygous genotype effects, while adjusting for sex, age, and the first five genetic principal components. For the RA progression score, we used ordinal logistic regression with RA stage (control, ACAP positive at-risk, early seropositive RA) as the outcome, while the ACPA positivity score used a traditional logistic model with ACPA positivity (yes/no) regardless of RA status as the outcome and additionally adjusted for RA status in the model (Figure 1). (2) Markers with FDR-adjusted p-values < 0.05 from likelihood ratio

Table 1. Demographic characteristics of European ancestry participants in AMP. Demographic characteristics are shown for the 153 participants of European ancestry in the AMP study, stratified by original clinical group (control, at-risk, or early RA). Data are presented as mean (standard deviation) for continuous variables and N (%) for categorical variables.

	Control (N=16)	At-Risk (N=53)	RA (N=84)
Age (years)	59.0 (10.7)	59.3 (12.3)	56.9 (15.6)
Female	6 (37.5%)	35 (66.0%)	59 (70.2%)
First Degree Relative with RA	NA	38 (71.7%)	NA
ACPA Positivity*	NA	24 (45.3%)	56 (66.7%)
Rheumatoid Factor Positivity**	NA	6 (11.3%)	NA
Any Smoking History	NA	NA	47 (56.0%)
Body Mass Index (BMI)	NA	NA	27.4 (6.82)

*Positivity defined as ≥ 20 units for CCP3.0 or CCP3.1
**Positivity defined as ≥ 20 units for IgA, IgG or IgM RF

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

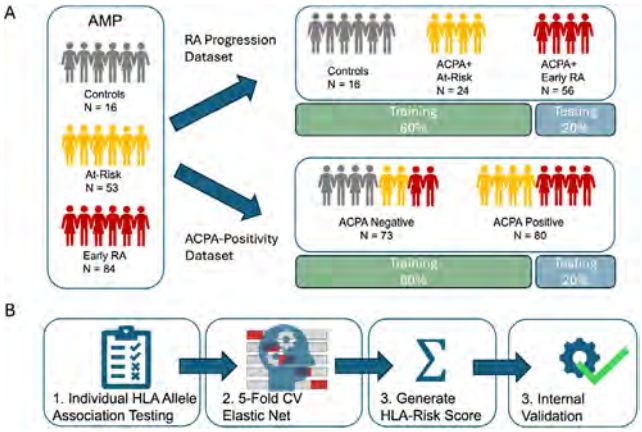

Figure 1. Study design and HLA risk score development pipeline. A. Participants with European ancestry from the AMP cohort were used to train and internally validate (test) a genetic risk score for RA progression and ACPA positivity based on HLA allele markers. The AMP dataset includes controls, at-risk (ACPA-positive and/or first degree relative with RA) individuals, and early RA cases (both seropositive and seronegative). ACPA negative individuals were removed from the at-risk and RA groups in the disease progression risk-score development, while all individuals were used in the ACPA positivity risk-score, but groups defined based on ACPA-positivity status and not the original group. B. Each HLA risk score was constructed using a three-step pipeline: (1) FDR-filtered regression (either ordinal logistic or logistic for the RA progression and ACPA positivity risk scores respectively), adjusting for age, sex, and the first five genetic PCs (RA status was an additional covariate in the ACPA positivity model); to identify outcome-associated HLA allele markers; (2) 5-fold cross-validated elastic net modeling to select and weight markers; and (3) weighted summation of coefficients to compute the HLA risk score. The scores were internally validated with the 20% testing dataset.

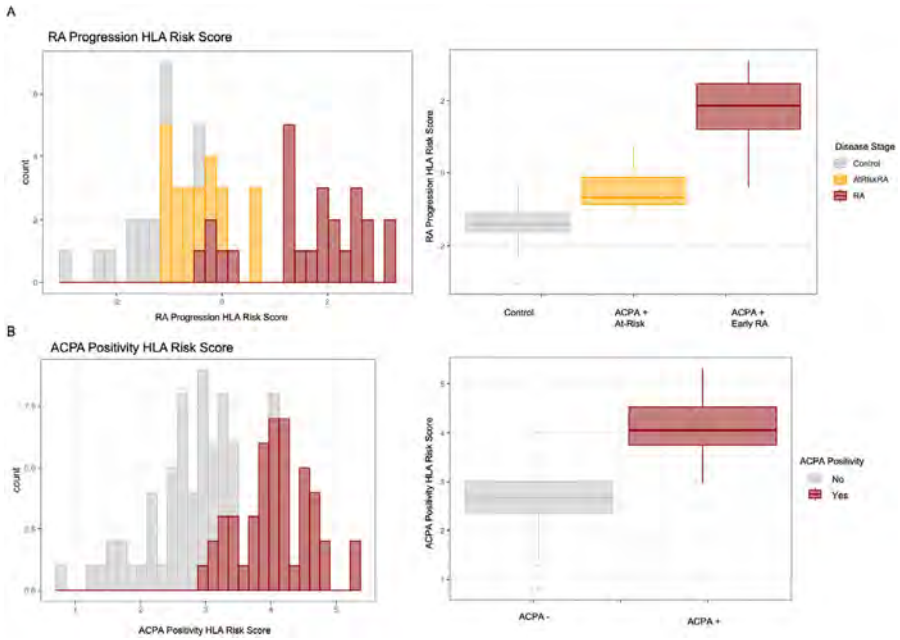

Figure 2. Distribution of Two HLA Risk Scores. A. Histogram and boxplot representations of the RA progression HLA risk score, stratified by disease stage (control, ACPA-positive at-risk, and ACPA-positive early RA), which was the outcome used to train the score. B. Histogram and boxplot representations of the ACPA positivity HLA risk score, stratified by ACPA positivity status (no vs yes), which was the binary outcome used to train the score.

tests were entered into a 5-fold cross-validated elastic net model. (3) Resulting coefficients were used to calculate a weighted genetic risk score. Each score was trained on 80% of the data and tested in the remaining 20%.

Results: Figure 2 depicts the distributions of the two HLA risk scores. The RA progression score showed strong performance with AUCs of 0.900 (early RA vs control), 0.708 (at-risk vs control), and 0.791 (early RA vs at-risk) in the testing set. The ACPA positivity score also demonstrated moderate discriminative ability, with an AUC of 0.671 (ACPA+ vs ACPA–).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Each score included multiple markers beyond traditional SE alleles and incorporated both additive and heterozygous effects, allowing for more nuanced modeling of HLA-driven risk.

Conclusion: We developed and internally validated two HLA-based genetic risk scores that distinguish between stages of RA progression and predict ACPA positivity within a single cross-sectional cohort. These tools provide a foundation for improved HLA-based stratification and may help clarify the genetic mechanisms underlying distinct features of RA development.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0019–0048) Genetics, Genomics & Proteomics Poster

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

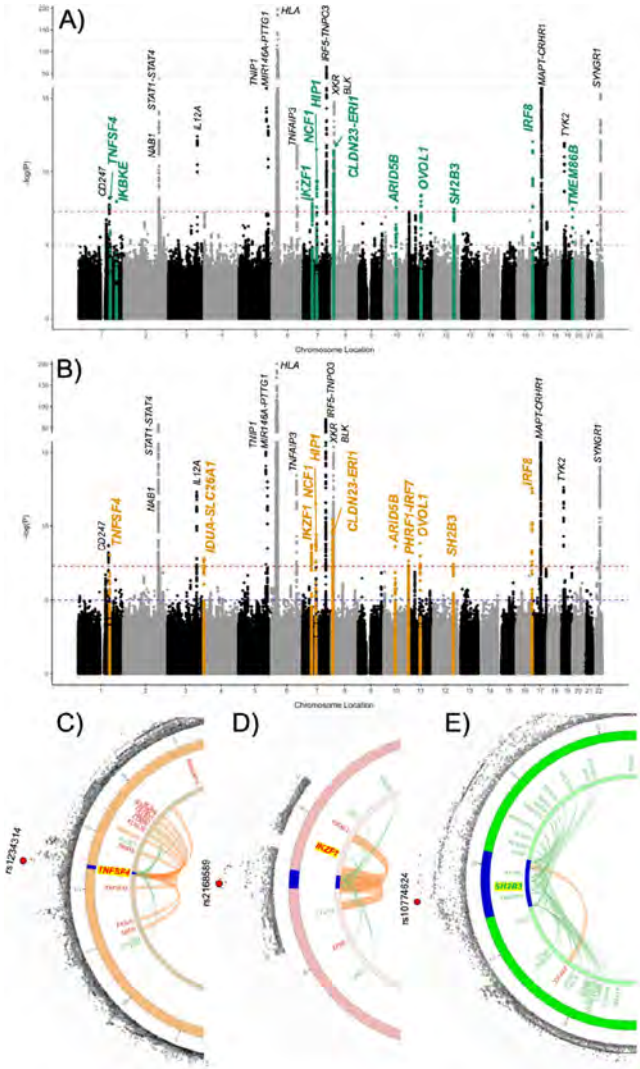

Fig 1. (A-B) The summary statistics of meta-analysis (A) 9,139 EUR cases (green indicates GWS SjD risk loci) or (B) 10,003 EUR+EAS cases (orange indicates GWS SjD risk loci). The -log10(P) for each variant is plotted against genomic locations. Red line indicates GWS (5x10-8) threshold, blue line suggestive threshold (1x10-5). (C-E) Regional maps of the genetic risk locus showing variants associations from the EUR+EAS GWAS shown in B (outer ring; index SNP labeled) and mapped chromatin interactions (orange), eQTLs (green), or both (red) (inner ring) spanning the (C) TNFSF4 (chromosome 1), (D) IKZF1 (chromosome 7), and (E) SH2B3 (chromosome 12) GWS risk loci (indicated as blue in the middle ring).

Background/Purpose: Sjögren's disease (SjD) is a systemic autoimmune condition with a complex genetic architecture. To date, 22 genome-wide significant (GWS) SjD risk loci have been identified, while >100 risk loci have been described in other related autoimmune diseases (Khatri et al. 2022). The objective of this study is to perform large-scale genome-wide association study (GWAS) to identify new GWS SjD risk loci ($p < 5x10^{-8}$; suggestive: $p< 5x10^{-5}$).

Methods: Institutional IRB/EC approval was obtained. GWAS were performed separately using PLINK2 for individuals of European (EUR) (4,855 cases, 25,408 controls) or East Asian (EAS) (561 cases, 1,760 controls) ancestry classified with SjD. After standard quality control, datasets were phased and imputed using the TOPMed reference panel. Data were meta-analyzed using inverse variance-weighted fixed-effect models in METAL with publicly available biobank GWAS summary statistics for cases [Phecode 709.2 (ICD-10 M35.0, ICD-9 710.2)]: Japanese Biobank (303 EAS cases, 175,599 controls [exclusion criteria Phecodes 690-697.99, 708-709]), UK Biobank (511 EUR cases, 397,694 controls [exclusion criteria Phecodes 690-697.99, 708-709]), Estonian Biobank (464 EUR cases, 204,701 controls [exclusion criteria not-cases]), FinnGen (3,309 EUR cases, 484,260 controls [exclusion criteria ICD-10 M30, M31, M32, M33, M34, M35, M36, and ICD-9 136.1, 446, 447.5, 447.6, 710, 725]).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Thirteen novel GWS risk loci were identified: *TNFSF4, IKBKE, IDUA-SLC26A1, IKZF1, NCF1, HIP1, CLDN23-ERI1, ARID5B, PHRF1-IRF7, OVOL1, SH2B3, IRF8*, and *TMEM86B* (Figure 1A and B), with most having been previously implicated in other autoimmune diseases. To investigate the regulatory potential of GWS variants, we analyzed three loci - *TNFSF4, IKZF1*, and *SH2B3* - using FUMA, which integrates chromatin interaction and expression quantitative trait locus (eQTL) data from publicly available immune cell datasets. At the *TNFSF4* locus, GWS variants showed both chromatin interactions and eQTLs with *RABGAP1L, RC3H1, SERPINC1, ZBTB37, DARS2, CENPL, KLHL20, PRDX6, TNFSF4, TNFSF18, FASLG* and *SUCO* (Figure 1C). At the *IKZF1* locus, GWS variants showed both chromatin interactions and eQTLs with *FIGNL1, IKZF1* and *ZPBP* (Figure 1D). At the *SH2B3* locus, GWS variants showed both chromatin interactions and an eQTL with *PPP1CC* (Figure 1E).

Conclusion: By conducting a GWAS using a larger sample size and performing meta-analysis, this study advances the genetic understanding of SjD. Further, SjD risk loci previously established in related autoimmune diseases may be indicative of shared mechanisms of disease. While loci are annotated by the gene closest to the lead variant, this does not necessarily indicate functional relevance. Three loci were evaluated for risk variant impact on chromatin interactions and gene expression changes in immune cells (Figure 1C-D). As both chromatin interactions and eQTLs are often cell-type specific, further analyses across all novel loci and in disease-relevant cell types and tissues are needed. Additional datasets from other SjD clinical partners and biobanks to further increase power are needed to discover novel loci.

Session Date: Sunday, October 26, 2025

Session Title: (0019–0048) Genetics, Genomics & Proteomics Poster

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease that can lead to joint damage and disability. Although methotrexate is the standard first-line treatment, about 40% of patients fail to reach remission/low disease activity and require escalation to bDMARDs. Anti-TNF agents are frequently used, but responses vary and predicting individual treatment responses remains difficult.

Methods: This international multi-centrer prospective observational study, recruited RA patients who were non-responders to synthetic DMARDs and eligible for anti-TNF therapy. Patients were followed from Visit 1 to 5 (∼20 weeks). Due to selective criteria and missing data, 42 of the 55 enrolled patients were analysed. Demographic and clinical characteristics were

Table 1. Baseline age and BMI by EULAR response

Variable	Group	N	Mean	Median	SD	Min	Max
Age (years)	Non-responder	14	44.4	44	9.39	27	57
	Responder	29	51.5	50	18.5	21	84
	NA	12	52.1	55	15.2	28	68
BMI	Non-responder	14	27.3	27.9	4.76	17.3	35.1
	Responder	29	24.4	22.8	4.82	17.0	35.1
	NA	11	26.5	26.7	4.53	19.1	35.1

Table 2. Smoker and gender status by EULAR response

Variable	Category	Non-responder	Responder	NA
Gender	Female (f)	13	22	10
	Male (m)	1	7	2
Smoker	True	5	15	6
	False	9	14	6

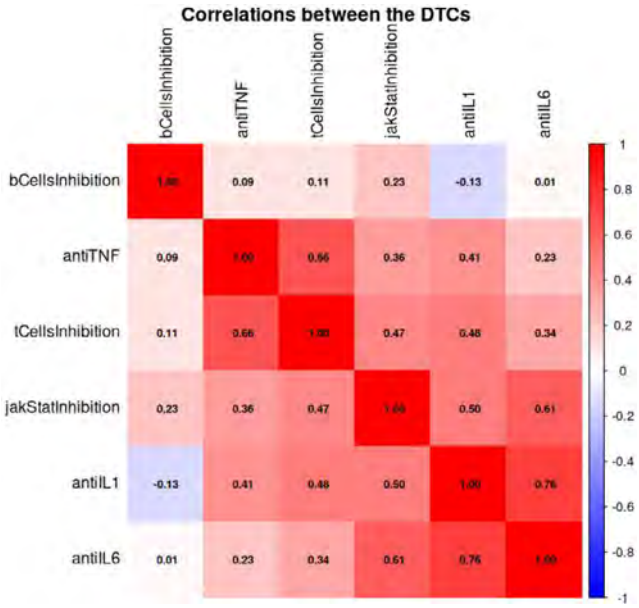

Figure 1. Correlations between the main DMARDs families

recorded at each visit and analysed to assess anti-TNF response in RA. In parallel, pre-treatment transcriptomic profiling (RNASeq by Quantseq method with sequencing depth of ∼20M single-end reads / sample) of synovial biopsies (Visit 2) was performed to provide transcriptomic data, and anti-TNF therapy was initiated thereafter.

Prediction of anti-TNF response via transcriptomic scoring will be presented separately. At baseline, the level of expression of mRNA corresponding to proteins directly involved in the mechanism of actions (Drug Target Complex or DTC (Paul et al., 2019)) of main DMARDs families (BCellInhibitors, AntiIL1, AntiIL6, JakStatInhibitors, AntiTNF, TCellInhibition) have been studied. Treatment response was assessed using the EULAR criteria based on DAS28-CRP, patients were classified as responders (good or moderate), or non-responders. Statistical analysis used Pearson's chi-squared and Wilcoxon rank-sum tests to assess links between baseline traits and treatment response.

Results: Based on the EULAR DAS28-CRP criteria at Visit 5, 32.6% of patients were classified as non-responders and 67.4% as responders (good or moderate). No significant associations were found between treatment response and sex ($p = 0.356$), smoking status ($p = 0.653$), or age ($p = 0.243$). However, BMI was significantly linked to treatment response ($p = 0.049$), suggesting higher BMI may reduce clinical response. Transcriptomic data of DTCs revealed two main observations: (1) transcriptomic profiles of patients are highly heterogeneous, each set of mRNA related to the different DTCs appearing as predominant in similar proportions of patients. (2) two clusters emerged: patients with high B-cell DTC expression tended to show low expression of other DTCs, and vice versa. In contrast, expression levels of non–B-cell DTCs are mutually correlated.

Conclusion: The clinical characteristics and early treatment outcomes align with expectations for this population. Initial analyses suggest that BMI may be associated with therapeutic response, while sex, age, and smoking are not. Early transcriptomic profiling may reveal mechanistic subtypes of RA, with opposing expression patterns between B-cell–related and other DMARDs-related mechanisms. Future analyses will assess the predictive ability of a synovial transcriptomic signature to improve patient stratification and personalize RA treatment.

Abstract Number: 0036

Integrated Analysis of Polygenic and Environmental Risk Scores for Late-Onset Systemic Lupus Erythematosus

Mehmet Hocaoglu[1] and Amr Sawalha[2], [1]University of Pittsburgh Medical Center, Piitsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION

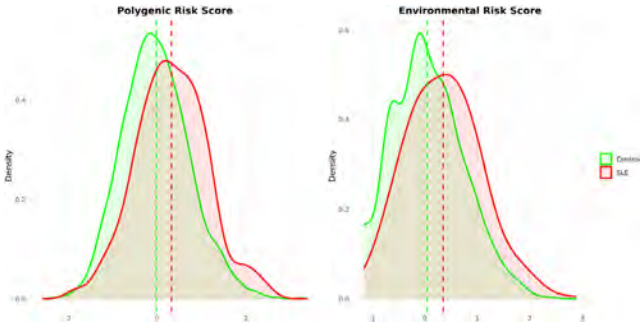
Session Date: Sunday, October 26, 2025
Session Title: (0019–0048) Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Polygenic risk scores (PRS) have been constructed to summarize genetic risk but there is limited research on environment-wide analysis of risk factors for systemic lupus erythematosus (SLE). In this study, we performed an environment-wide association study to construct an environment risk score (ERS) for SLE and compare the risk conferred by ERS and PRS.

Methods: A total of 335 incident SLE cases were identified in the UK Biobank and matched 1:10 with age, sex, and ethnic background 3350 healthy controls. We examined the association between 37 environmental factors and SLE, using a univariate followed by a multivariate analysis. We summed the natural logarithm of the odds ratios (OR) of statistically significant environmental variables in the multivariable model to derive an ERS for SLE. Model discrimination was compared by DeLong`s test. PRS was calculated using the ORs of previously reported SLE genetic risk loci.

Results: The multivariate analysis revealed the association between daily sunlight exposure, depression, sleeplessness, sex hormone binding globulin levels, and air pollution with increased risk of SLE, while moderate physical activity was a protective factor. Increasing quartiles of the newly developed ERS were associated with similar degree of risk for SLE as the PRS. Integrating PRS with environmental factors significantly improved model performance.

Conclusion: We devised an ERS for SLE that summarizes the environmental component of the disease risk. We show that ERS confers a comparable degree of SLE risk as the PRS. Combining genetic and environmental factors could improve risk prediction models in SLE.



Comparison of standardized polygenic and environmental risk scores between SLE cases and matched controls. P values for the mean difference between cases and matched controls for polygenic and environmental risk score are 2.41x10-13 and 1.76x10-13, respectively.

A Proteomic Signature Containing TNF Receptor Superfamily Member 10A (TNFRSF10A) and Growth/differentiation Factor 15 (GDF-15) Improves Prediction of All-cause Mortality Among Individuals with Gout, Beyond Atherosclerotic Cardiovascular and Other Clinical Risk Factors

Natalie McCormick[1], Sharan Rai[2], Chio Yokose[3], Tony Merriman[4], Robert Terkeltaub[5] and Hyon K. Choi[6], [1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital/Harvard Medical School, Boston, MA, [3]Massachusetts General Hospital, Waltham, MA, [4]University of Alabama at Birmingham, Homewood, AL, [5]Retired, San Diego, CA, [6]MASSACHUSETTS GENERAL HOSPITAL, Lexington, MA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0019–0048) Genetics, Genomics & Proteomics Poster

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Gout affects >12 million US adults and is associated with premature all-cause and cardiovascular (CV) mortality which has failed to improve over recent decades, unlike in the general population.[1,2] Comorbidities and treatment inequity contribute, but underlying gout disease-specific mechanisms may also play a role, since the elevated mortality persists with adjustment for cardiometabolic comorbidities, kidney function, BMI, alcohol, all atherosclerotic cardiovascular (ASCVD) risk factors, and serum urate (SU) levels.[1] Since detailed characterisation of the plasma proteome can illuminate mechanisms and risk stratification of premature mortality in gout, we leveraged large-scale proteomics data for a nationwide prospective cohort.

Methods: We studied 2,013 UK Biobank participants with diagnosis of gout and proteomic profiling available (mean age 60 years, 83% males). Proteomic measures (n=2923, via Olink Explore 3072) were quantified from baseline blood samples via Proximity Extension Assay technology. After division into training (80%) and testing (20%) sets, least absolute shrinkage and selection operator (LASSO) regression with 10-fold cross validation was used to identify most robust prognostic proteins and construct a proteomic risk score (signature) for mortality in the training set.

Table 1. Associations of a proteomic risk score with all-cause mortality among individuals with gout, training set

	Quintiles of Proteomic Risk Score						
	1=Lowest	2	3	4	5=Highest	Per SD	P-Value of Continuous Score
N Deaths	7	22	50	94	213	386	-
N	323	322	322	322	323	1,612	
Person-Years (PY)	4,479	4,365	4,282	4,076	3,366	20,569	
Rate Ratio, per 1000 PY	1.56	5.04	11.7	23.1	63.3	18.8	-
Multivariable HR, 95% CI*	1.0 (ref)	1.53 (0.65 to 3.60)	2.81 (1.26 to 6.26)	4.40 (2.01 to 9.62)	12.8 (5.82 to 28.0)	2.53 (2.25 to 2.84)	<0.001
Multivariable HR, 95% CI*, + serum urate levels	1.0 (ref)	1.53 (0.65 to 3.60)	2.83 (1.27 to 6.30)	4.42 (2.02 to 9.67)	12.7 (5.79 to 27.8)	2.52 (2.24 to 2.83)	<0.001

HR, hazard ratio; 95% CI, 95% confidence interval.
*Adjusted for age, sex, race, body mass index, diuretic medication use, coronary heart disease, kidney function (eGFR), alcohol consumption, and all other atherosclerotic cardiovascular [ASCVD] risk factors (aspirin use, statin use, anti-hypertensive medication use, systolic blood pressure, diastolic blood pressure, type 2 diabetes, smoking status, total cholesterol levels, and high density lipoprotein cholesterol levels).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 2. Proteomic biomarkers associated with all-cause mortality among individuals with gout, five highest-weighted associations in the proteomic risk score

Protein Name	Hazard Ratio per SD (95% CI)	P_{FDR}
N-terminal prohormone of brain natriuretic peptide (NT-proBNP)	1.38 (1.25 to 1.52)	4.1×10^{-8}
Growth/differentiation factor 15 (GDF-15)	1.61 (1.45 to 1.79)	2.4×10^{-2}
TNF receptor superfamily member 10A (TNFRSF10A)	1.59 (1.43 to 1.77)	4.83×10^{-15}
Proto-oncogene tyrosine-protein kinase receptor Ret (RET)	0.83 (0.75 to 0.91)	1.04×10^{-3}
Glutathione hydrolase 5 proenzyme (GGT5)	1.46 (1.33 to 1.60)	3.3×10^{-13}

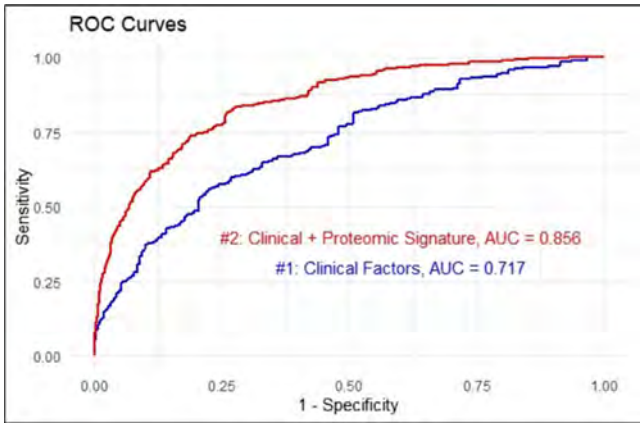

Figure: Receiver operating characteristic curves for discrimination of all-cause mortality with clinical factors and a proteomic signature. AUC= area under the receiver operating characteristic curve. Clinical factors include age, sex, race, body mass index, alcohol consumption, diuretic medication use, coronary heart disease, kidney function (eGFR), atherosclerotic cardiovascular (ASCVD) risk factors (aspirin use, statin use, antihypertensive medication use, systolic blood pressure, diastolic blood pressure, type 2 diabetes, smoking status, total cholesterol levels, high density lipoprotein cholesterol levels), and serum urate levels.

Multivariable Cox models were compared between clinical factors (age, sex, race, alcohol, other ASCVD risk factors, BMI, cardiometabolic comorbidities, kidney function, diuretic medications, and SU levels), with and without the proteomic signature, using area under the receiver operating characteristic curve (AUC). Two-sided DeLong test was used to compare AUCs of each model in training and testing sets.

Results: We documented 469 deaths over 25,751 person-years (PY) of follow-up (18.2 per 1000 PY) in the gout cohort. In the training set (386 deaths), clinical factors alone discriminated mortality with an AUC of 0.717 (95% CI: 0.698, 0.737).

From 790 individually-associated proteins ($P_{FDR} < 0.05$), LASSO regression generated a 76-protein signature of mortality risk; each unit increase in risk score was associated with 2.5-fold greater mortality risk (**Table 1**). Highest-weighted markers in the signature included NT-proBNP, growth-differentiation factor 15 (biomarker of major organ injury, cardiac and cancer risk, and predictive factor for CV disease and mortality), and TNF-R superfamily member 10A (TNFRSF10A) (**Table 2**). Excess TNFRSF10A transduces apoptosis and marked release of multiple inflammatory cytokines (e.g., IL-8, TNF, and CCL20).

Addition of the proteomic signature to the clinical model significantly improved discrimination over the clinical model alone ($P < 0.001$), with AUC of 0.856 (0.844, 0.868) **(Figure)**. Proteomic signature also performed well in the testing set (83 deaths), with AUC 0.672 (0.639, 0.705) for the clinical model alone and 0.812 (0.785, 0.840) for the combined.

Conclusion: Addition of a proteomic signature improves ability to predict risk of all-cause mortality among individuals with gout. The component proteomic biomarkers may allow for risk prediction and stratification, and identification of potential novel therapeutic targets.

DNA Methylation Signatures of Smoking in Labial Salivary Gland Tissue in a Sjögren's Disease Cohort

Priya Bhatt[1], Mary Horton[2], Caroline Shiboski[3], Lisa Barcellos[4], Lindsey Criswell[2], and the Sjögren's International Collaborative Clinical Alliance (SICCA), [1]Mayo Clinic Alix School of Medicine, Toledo, [2]NIH/NHGRI, Bethesda, MD, [3]University of California San Francisco, San Francisco, CA, [4]UC Berkeley, Berkeley

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0019–0048) Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Cigarette smoking has been linked to the development of several autoimmune diseases, including Sjögren's Disease (SjD). Since DNA methylation (DNAm) is altered by cigarette smoking and plays a significant role in autoimmune disease pathophysiology, it may provide some insight into the influence of smoking on SjD progression. Although previous studies have identified genome-wide DNAm changes in whole blood associated with smoking, similar analyses have not yet been conducted in the exocrine glands, which are the primary target tissues in SjD. Salivary glands, in particular, are directly exposed to cigarette smoke and may exhibit distinct epigenetic changes. Here, we aim to compare DNAm in labial salivary gland (LSG) tissue among individuals with different self-reported smoking behaviors.

Methods: We obtained LSG DNAm data from the Sjögren's International Collaborative Clinical Alliance (SICCA) cohort (n = 1,453) that was profiled using the Illumina EPIC v1.0 array (~850,000 CpG sites). We used linear models (limma) to identify sites with differential methylation by smoking status (current v. never smoker, former v. never smoker), adjusting for age, sex, batch effects, SjD status as determined by 2016 ACR-EULAR classification criteria, estimated cell type proportions, and genetic principal components. GO, KEGG, and Reactome pathway enrichment analyses were conducted.

Results: We identified 106,285 differentially methylated sites in current smokers and 13 sites in former smokers at a false discovery rate (q) < 0.05. Of these, 3,891 CpG sites in current smokers and only one in former smokers had at least a 3% average DNAm difference compared to never smokers. These were enriched in pathways related to cellular migration, morphogenesis, and neuronal development. The site cg22103736 (-7.1%, FDR q = 2.3e-29) showed the strongest combination of effect size and significance in both current and former smokers. Cg22103736 is located in *AHRR*, which encodes aryl

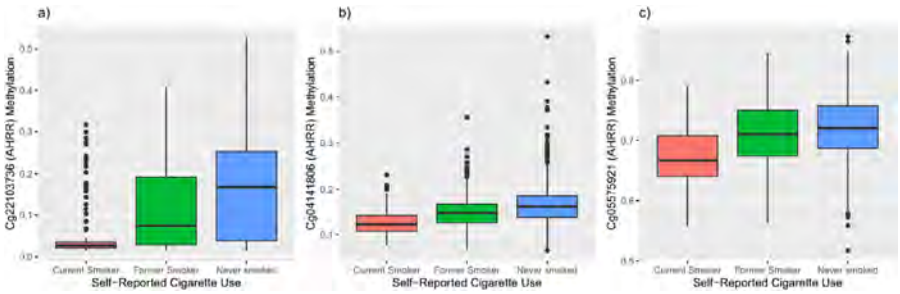

Figure 1. Stepwise relationship between self-reported cigarette use and methylation beta values in AHRR CpGs including a) cg22103736, one of the strongest and most significant differentially methylated positions (DMPs), b) cg04141806, another significant DMP, and c) cg05575921, a DMP that has been widely associated with smoking in whole blood DNAm studies.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

hydrocarbon receptor repressor and is a gene widely linked to smoking-related changes in whole blood DNAm. The median methylation value of cg22103736 among current smokers was very low (0.026) and demonstrated a stepwise increase for former and never smokers (Figure 1a). This trend was replicated in another *AHRR* CpG, cg04141806 (Figure 1b). Interestingly, a well-known CpG within *AHRR* that differentiates smoking behavior in whole blood, cg05575921, did not have as large differences in DNAm between smoking status groups in the gland tissue (Figure 1c).

Conclusion: Our findings suggest that cigarette smoking may significantly perturb normal cellular processes in salivary glands. These changes occur in many more CpGs with stronger and more significant associations in current compared to former smokers. Pathway analysis implicated processes important for fibrosis, such as epithelial-mesenchymal transition and extracellular matrix remodeling, indicating that smoking may exacerbate and accelerate gland atrophy in SjD patients or individuals with xerostomia. The limited number of significant results in former smokers indicates that quitting smoking may allow individuals to acquire DNAm profiles comparable to that of individuals who have never smoked.

Session Title: (0019–0048) Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Severe COVID-19 infection resulting in hospitalization shares features with frequently fatal cytokine storm syndromes (CSS), such as hemophagocytic lymphohistiocytosis (HLH) and macrophage activation syndrome (MAS). Repeatedly, 30-40% of patients in published secondary (beyond infancy) HLH cohorts possess rare heterozygous mutations in established familial HLH (fHLH) genes. These mutations are thought to contribute to CSS via hypomorphic or dominant-negative effects on lymphocyte cytolytic activity. Diminished lymphocyte cytolytic activity results in prolonged lymphocyte with antigen presenting cell engagement yielding increased pro-inflammatory cytokine production contributing to multi-organ system failure.

Table 1: Performance of cytokine scoring systems in total patient cohort

	Total Patients (n = 32)
2016 sJIA/MAS Score: Yes	6/32 (19%)
MS Score, Median (IQR)	-2.5 (-3.0 to -1.4)
Ferritin:ESR > 11.3	27/32 (84%)
Ferritin:ESR > 21.5	13/32 (41%)
Ferritin:ESR, Median (IQR)	18.6 (12.8 to 36.6)
CSS Score: Pos	26/32 (81%)
cHIS Score, Median (IQR)	3 (3 to 4)
Caricchio Score	1/32 (3.1%)

Performance of cytokine scoring systems in total patient cohort. Abbreviations: sJIA - systemic juvenile idiopathic arthritis; MAS - macrophage activation syndrome; MS - MAS/sJIA; IQR - interquartile range; CSS - cytokine storm syndrome score; cHIS - COVID-19-associated hyperinflammatory syndrome

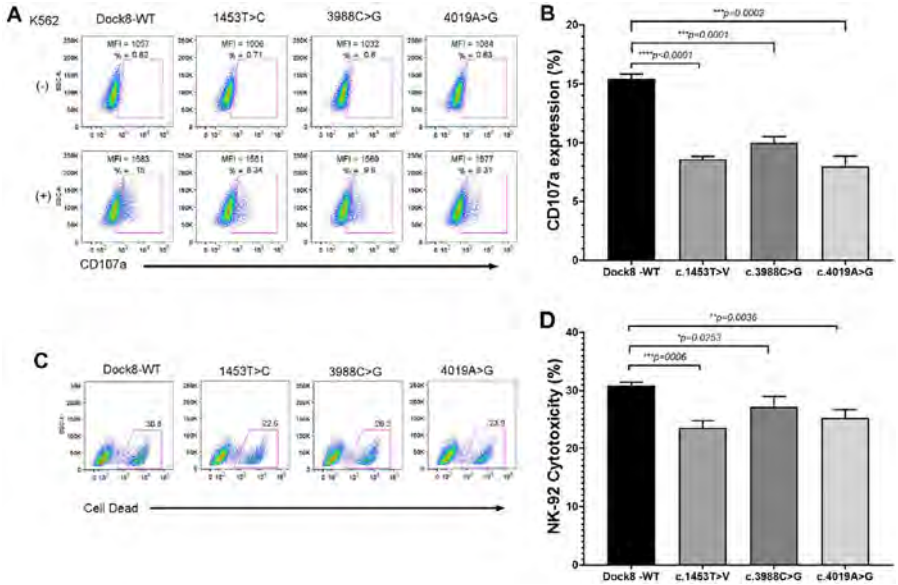
Immunologic rare gene variants identified by whole genome sequencing of COVID-19 clinical trial participants. Abbreviations: fHLH - familial hemophagocytic lymphohistiocytosis; NK - natural killer

Methods: Various published criteria were studied to define CSS among patients (n=32) enrolled in a randomized, double-blinded, placebo-controlled COVID-19 clinical trial exploring interleukin-1 blockade treatment for severe COVID-19. Whole genome sequencing (WGS) was undertaken to explore immunologic gene mutation associations among the first 20 patients



NK cell lytic function of DOCK8 missense variants. A. Flow cytometry plots of CD107a expression on NK-92 cells transfected with WT cDNA or patient-derived DOCK8 variants after co-incubation with K562 target cells. B. Summary plots of CD107a expression from 4 experiments. C. Flow cytometry plots of K562 target cell lysis (death) after incubation with WT DOCK8 or patient-derived variant-expressing NK-92 cells. D. Summary plots NK-92 cell cytotoxicity from 4 experiments.

enrolled in the trial for whom samples for WGS were available. Foamy viral transduction of human NK-92 natural killer (NK) cells with wild-type (control) *DOCK8* cDNA or patient-derived *DOCK8* missense mutations was used to explore NK cell degranulation (CD107a expression) and cytolytic activity against K562 target cells by flow cytometry.

Results: None of the patients met HLH-04 or HScore criteria, but the ferritin to erythrocyte sedimentation rate (ferritin:ESR) ratio and the COVID-19 cytokine storm syndrome score (CSS score) identified 84% and 81% of patients, respectively (Table 1). Rare mutations in fHLH genes were identified by WGS in 6 patients (30%), and 4 patients (20%) possessed rare mutations in *DOCK8* (a novel CSS gene) (Table 2). The 3 patient-derived *DOCK8* missense mutations introduced into NK-92 cells each diminished NK cell cytolytic function and degranulation (Figure). In addition, variants in autoinflammatory and primary immunodeficiency genes were identified in 15% and 60% of patients, respectively (Table 2).

Conclusion: This severe COVID-19 cohort, like others, shares CSS features but is best identified by ferritin:ESR ratio. Rare heterozygous CSS gene (fHLH genes and *DOCK8*) mutations were frequently (45%) identified in this severe COVID-19 cohort, and the *DOCK8* missense mutations may have contributed to CSS in severe COVID-19 patients via diminished lymphocyte cytolytic activity.

Identification Of A Novel, Expressed, Alternatively Spliced FCER1G Protein That Inhibits Receptor Function

Andrew Gibson[1], Jianming Wu[2], Chaoling Dong[1], R. Curtis Hendrickson[1], Travis Ptacek[1], Jeffrey Edberg[1] and **Robert Kimberly**[1], [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Minnesota, Saint Paul, MN

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0019–0048) Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: The Tyrosine Activation Motif (ITAM)-containing FcRg chain, encoded by FCER1G, non-covalently couples with the immunoglobulin binding receptors, -- FcγRI (CD64), FcγRIIIa (CD16), and FcaRI (CD89), -- to initiate intracellular signals and mediate phagocytosis, cytokine production and other functions. While functionally impactful variants have been identified in the ligand-binding alpha-chains of receptors associated with FcRg, variants in the signal-generating FcRg have not been explored. Signal modulation through structural variants at the level of FcRγ would have implications for all FcRγ-associated receptors and their role in the pathogenesis of immune-mediated diseases.

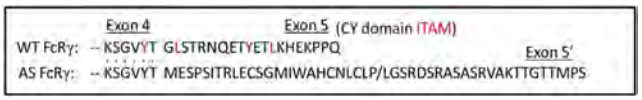

Figure 1. Sequence of FcRγ isoforms. The partial amino acid sequences of WT-FcRγ and AS-FcRγ are shown. Exon 5' in AS-FcRγ replaces exon 5 and encodes a novel cytoplasmic domain with no traditional signaling motifs. The ITAM signaling motif [YxxL(x7)YxxL] present in the WT-FcRγ is highlighted.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

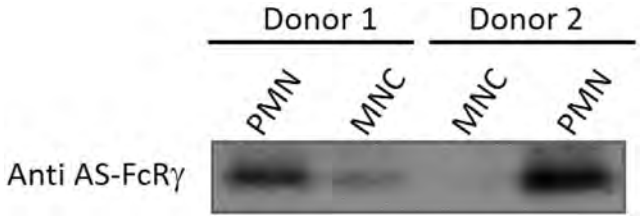

Figure 2. Western blot analysis of FcαR1 immunoprecipitates showing that AS-FcRγ protein pairs with and co-precipitates with FcαR1 in monocytes (MNC) and neutrophils (PMN).

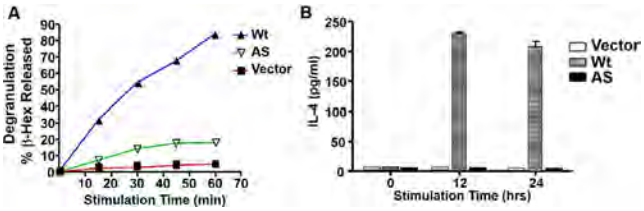

Figure 3. Stimulation of AS-FcRγ chimeric construct. A) Degranulation of β-Hexosaminidase activity. RBL-2H3 cells stably expressing vector alone or a chimeric receptor consisting of the extracellular domain of FcαRI fused to the cytoplasmic domain of WT-FcRγ or AS-FcRγ were stimulated with anti-FcαRI antibody A59 F(ab')2 for the times indicated. Cell degranulation was measured as a percent of total β-Hexosaminidase released by triton X-100 treated cells. B) IL-4 cytokine production. RBL-2H3 cells stably expressing the chimeric receptors were stimulated as outlined above for the indicated times. Cell culture media was then assayed by ELISA for the presence of IL-4 cytokine.

Methods: We carried out *in silico* analyses of whole genome DNA sequence databases based on short read sequencing (eg, gnomAD with ~79,000 genomes) and long-read sequencing (eg, >600 genomes from All of Us, the Arab and Chinese Pangenomes, and local long-read sequenced cohorts). We also assessed whole exome sequences (eg, gnomAD, UK Biobank and Regeneron totally >1M participants) as well as RNA transcript databases. We used Sanger sequencing of cDNAs derived from FcRg mRNAs isolated from local participants to confirm ESTs (eg, BG548748) in circulating immune cells. We used hg38 reference genome to identify genomic DNA and cDNA structural variants at the single nucleotide and larger variant levels.

Results: In the human genome, insertions, deletions and rearrangements of FCER1G are absent, and with the exception of very rare single nucleotide variants (allele frequency < 0.01), the FcRγ protein is monomorphic. Surprisingly, we confirmed that in addition to the canonical FcRγ transcript encoding the classically recognized FcRγ protein, an alternatively spliced (AS) form of FcRg message encodes a translated protein (AS-FcRg) which is expressed in human myeloid cells. AS-FcRγ is able to pair with ligand binding α-chains. The incorporation of the alternate exon 5' in AS-FcRγ creates a novel cytoplasmic domain with a disrupted ITAM signaling motif (Figure 1). The AS-FcRg mRNA is expressed in cell lines (U937, THP-1, HL-60) and in circulating neutrophils, monocytes and platelets, but not in lymphocytes, from normal donors. Co-immunoprecipitation experiments show that AS-FcRg associates with FcaRI in circulating neutrophils and mononuclear cells (Figure 2). An engineered chimeric molecule consisting of the extracellular domain of FcaRI fused to the cytoplasmic domain of AS-FcRg fails to stimulate cellular degranulation and cytokine production (Figure 3)

Conclusion: The AS-FcRg variant is not signaling competent and may represent a novel inhibitory mechanism limiting the ability of Fc receptors to stimulate cellular signaling in myeloid cells with important implications for host defense and antibody-mediated autoimmune diseases, including SLE and RA.

A Genetically Determined, Serine-based and Phosphorylation-dependent Molecular Switch Regulates the Inflammatory Potential of Human Iga

Andrew Gibson[1], Jianming Wu[2], R. Curtis Hendrickson[1], Travis Ptacek[1], Jeffrey Edberg[1] and **Robert Kimberly**[1], [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Minnesota, Saint Paul, MN

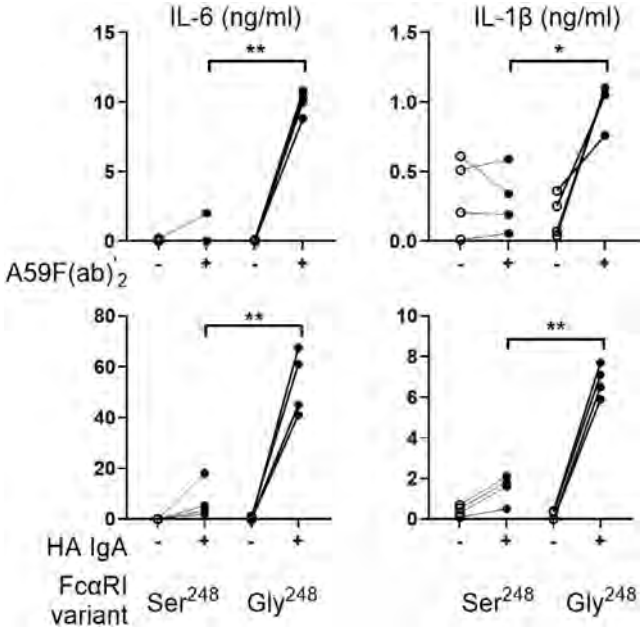
Session Title: (0019–0048) Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Human serum IgA can paradoxically inhibit immune cell activation. Inhibition of such activation, mediated by the inhibitory configuration of the immunoreceptor tyrosine-based activation motif (ITAM) in the Fc receptor common γ-chain (FcRγ), suggests a potential dual role for FcαRI (CD89)-FcRγ signaling pairs. However, in monocytes and neutrophils FcαRI is often expressed in the absence of FcRγ (Launay *et al*,1999). We previously reported a common FcaRI Ser^{248}Gly variant in the cytoplasmic domain of CD89 that affects receptor function in neutrophils. In the absence of FcRg, the Ser^{248} allele does not initiate signaling while the Gly^{248} allele maintains robust signaling. To elucidate the basis for this α-chain functon, we sought allele-specific FcαRI-associated molecules

Methods: To isolate and identify cellular proteins binding to the FcaRI Ser^{248} allele we used an anti-FcαRI affinity column followed by mass spectrometry. We used pull down assays with His6-tagged proteins to confirm direct protein-protein interactions. To test the differential function of the FcaRI Ser^{248}Gly alleles in mononuclear cells, we used freshly isolated human monocytes from donors homozygous for each allele. To investigate the molecular mechanisms underlying differential allele effects, we used the P388D1 murine monocytic cell line stably expressing FcaRI Ser^{248} or Gly^{248} with or without the engineered R^{209}L point mutation in the transmembrane, which abrogates FcRg chain pairing. We also used the U937 human



Sequence variation of FcαRI (S248G) alters IL-6 and IL-1β production in human monocytes . Peripheral blood monocytes (MNC) (n = 4) homozygous for FcαRI Ser248 or Gly248 variants were stimulated with mAb A59 F(ab')2 or heat aggregated IgA (HA IgA). IL-6 and IL-1β release were determined by ELISA at 24 hours following stimulation. * $p < 0.05$; ** $p < 0.01$.

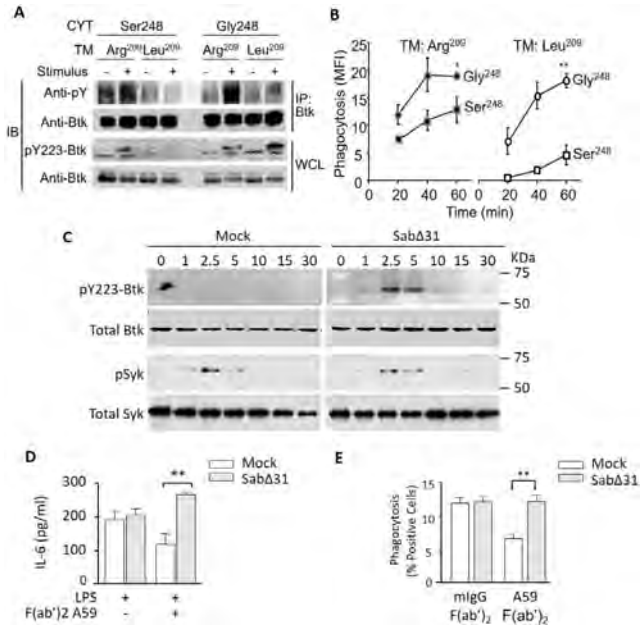
Identification of Sab as an FcαRI-binding protein. (A) A workflow diagram showing steps for isolating and identifying FcαRI variant-specific binding proteins. (B) FcαRI was immuno-isolated from P388D1 transfectants stably expressing human FcαRI-Ser248 or Gly248 using anti-FcαRI A59 F(ab')2-conjugated Sepharose column. The prominent 65KDa co-eluting protein band was subjected to MALDI-Mass Spectrometry analysis for identification. (C) Sab co-precipitates with FcαRI Ser248 independent of FcRγ pairing. (D) His6-Sab specifically pulls down FcαRI-Ser248. Input (1), the unbound flow through (2) and the bound (3) fractions are shown.



The FcαRI Ser248 variant attenuates Btk activation-dependent FcαRI-mediated functions. (A) P388D1 cells expressing FcαRI Ser248 or Gly248 variants with or without the Arg209Leu transmembrane change were stimulated for 3 minutes. Btk immunoprecipitates and whole cell lysates were blotted with anti-phosphotyrosine mAb, 4G10, and anti-pY223 Btk mAb, respectively. (B) The P388D1 transfectants were incubated with A59-opsonized FITC-conjugated Ox RBCs and phagocytosis of the RBCs measured by FITC fluorescence. C,D,E) Dominant negative Sab reverses FcαRI Ser248 failure to signal. C) The U937-SabΔ31 transfectants were opsonized with A59 F(ab')2 and stimulated with GAM F(ab')2 cross-linking for the indicated times. Whole cell lysates of the cells were immunoblotted for phospho-Btk, total Btk and total Syk. For phospho-Syk, phosphorylated proteins were immunoprecipitated using PY20 and immunoblotted for phospho-Syk. D) SabΔ31-expressing U937 cells were stimulated with LPS and A59 F(ab')2 for 24 hours, and secreted IL-6 was measured by ELISA. E) SabΔ31-expressing U937 cells were opsonized for 30 minutes with A59 F(ab')2 and incubated with human IgG-opsonized FITC-conjugated Ox RBC for 1 hour. Internalized RBCs were measured as intracellular FITC fluorescence. * $p < 0.05$; ** $p < 0.01$.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. monocyte cell line, which endogenously expresses FcaRI Ser^{248} to test the effects of the dominant negative truncation of SH3BP5 (SabD31) which is incapable of inhibiting Btk.

Results: FcaRI Ser^{248} does not stimulate production of cytokines by human monocytes while FcaRI Gly^{248} consistently activates cytokine production (Figure 1). FcαRI Ser^{248} specifically recruited Sab (SH3-domain binding protein that preferentially associates with Bruton's tyrosine kinase, Btk), a trans-inhibitor of Btk, in a phosphorylation-dependent fashion, whereas the Gly^{248} variant reciprocally recruited the protein tyrosine kinase Lyn (Figure 2B,C,D). Compared to FcαRI Gly^{248}, FcαRI Ser^{248} recruitment of Sab results in inhibition of Btk phosphorylation/activation (Figure 3A) and suppression of effector functions (Figure 3B) independent of FcRγ-pairing. A dominant negative Sab incapable of binding to Btk fails to inhibit Btk phosphorylation/activation (Figure 3C) and releases FcαRI-mediated inhibition by the Ser^{248}-allele (Figure 3D,E). Ser^{248}-phosphorylation amplifies Sab association and disrupts Lyn binding through an overlapping region containing an unconventional SH3-domain binding motif.

Conclusion: These findings reveal a novel and reversible serine-based phosphorylation-dependent Sab/Lyn switch for regulation of receptor-mediated inhibition/activation that couples FcαRI α-chain to divergent inflammatory properties of human IgA. This genetically determined switch has important implications for the role of IgA in antibody-mediated autoimmune disease and host defense as well as implications for the use of IgA as the backbone for therapeutic antibodies.

Session Title: (0019–0048) Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Our recent study characterized immune endotypes in psoriatic arthritis (PsA) patients using mass cytometry of peripheral blood[1]. We identified an endotype characterized by high levels of CD4+ central and effector memory T cells (cluster 1), which was associated with higher levels of sonographic musculoskeletal inflammation and lower response to biologic therapy compared with the other two endotypes (cluster 2: innate immune cells (ILC) and cluster 3: terminal effector/Th1 cells). Further characterization of these clusters may enhance our understanding of PsA phenotypes. We aim to characterize the proteomic profile of the CD4+ memory T cell endotype in comparison with the other two immune endotypes and identify key proteins and biological pathways associated with disease severity and treatment outcomes.

Pathway enrichment and network visualization of differentially expressed proteins across clusters. (A) Pathways enriched in cluster 1 vs. cluster 2 and (B) pathways enriched in cluster 1 vs. cluster 3 ranked in descending order based on gene ratio; (C) Protein-pathway network plot of the shared enriched pathways characterizing cluster 1 vs. cluster 2 and 3. Coloured diamond nodes = shared pathways, blue circular node = DEPs in C1C2, red = DEP in C1C3 and green = DEP in both comparisons. An olive circular highlight = downregulated protein in C1, pink circular highlight = upregulated protein in C1; (D). Correlation matrix of the relationship between DEPs belonging to the WNT signalling pathway and PsA disease features.

Methods: A total of 30 patients initiating advanced therapies for active PsA were analyzed (9 patients in cluster 1, 11 in cluster 2, and 10 in cluster 3). For each patient, we measured 6402 different serum proteins using an aptamer-based platform. Differential expression analysis was performed between cluster 1 vs. cluster 2 and cluster 1 vs. cluster 3, with significance as $p < 0.05$. Pathway enrichment was performed reusing pathDIP v5, using literature-curated pathways from all 12 database sources. Protein-pathway networks of the shared pathways between cluster 1 vs. cluster 2 and cluster 1 vs. cluster 3 were created using NAViGaTOR v3.

Results: Differential analysis identified 285 proteins in cluster 1 vs. cluster 2 (176 upregulated and 109 downregulated in cluster 2) and 349 in cluster 1 vs. cluster 3 (160 upregulated and 189 downregulated in cluster 1). Pathways shared between these two comparisons (differentially expressed in cluster 1) included WNT signalling, platelet activation, VEGF, PI3K-AKT-MTOR, and MAPK signalling (Figure 1A-C). Additionally, WNT signalling appeared most distinct to the CD4+ memory cell endotype, containing the highest number of DEPs unique to this pathway, whereas other pathways shared multiple proteins. Among the deregulated proteins in the WNT pathway, DKK2, WNT5b, ROR2, FZD7, FZD8, and FZD2, were all proteins upregulated in the CD4+ memory cell endotype and correlated with disease activity measures (Figure 1D).

Conclusion: Given that WNT signalling is known to play a role in PsA pathogenesis, its activity in the CD4+ memory cell endotype may underlie the poorer response to advanced therapy observed in these patients. Overall, these results provide new insights into the biological mechanisms driving PsA and help to define distinct patient subgroups with shared clinical and biological features.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0019–0048) Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: We characterized the spatial distribution of immune cells and identified hub genes within activated molecular networks in key immune cell populations, based on the muscle transcriptome profile of a patient with anti-glycyl tRNA synthetase syndrome.

Methods: Single-cell and spatial transcriptome analyses were performed on muscle biopsy specimens from a male patient in his 40s diagnosed with anti-glycyl tRNA synthetase syndrome. Spatial transcriptomic profiling identified gene expression clusters corresponding to regions of intense inflammation, characterized by immune cell infiltration. Differential gene expression analysis of these immune cell populations was performed using single-cell transcriptomic data. Subsequent molecular network and topological analyses were used to identify hub genes within activated signaling pathways. Validation of hub gene expression was conducted using the publicly available dataset GSE48280, comprising transcriptomic data from patients with idiopathic inflammatory myopathies.

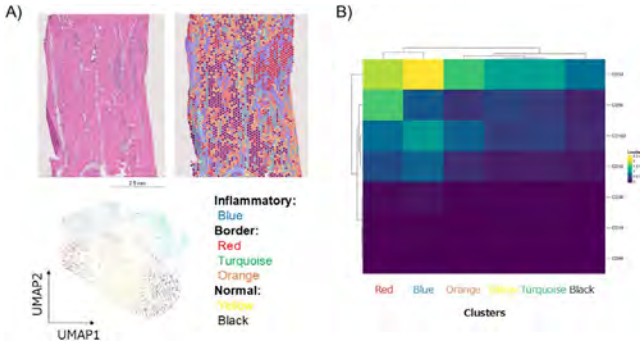

Figure 1. Spatial transcriptomic profiling. A) Six spatial clusters were identified. Blue cluster localized to a region of pronounced inflammation. B) Blue cluster was predominantly composed of $CD14^{+}CD163^{+}$ M2 macrophages.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Single-cell transcriptomic profiling. A) Ten distinct cell clusters were delineated. Black cluster corresponded to CD163-positive M2 macrophages. B, C) Molecular network construction and topological analysis of the top 30 differentially expressed genes in the CD163-positive M2 macrophage cluster identified two hub genes.

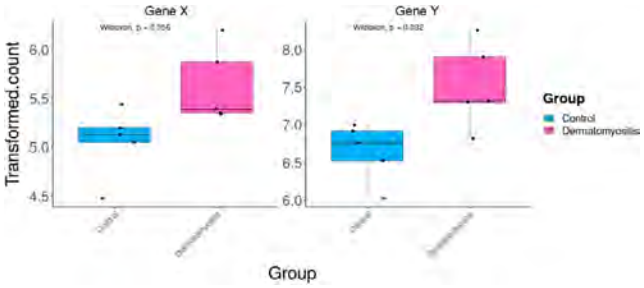

Figure 3. Comparison of the expression of two identified hub genes in muscle biopsy specimens from five healthy subjects and five patients with dermatomyositis. All identified hub genes exhibited a trend toward elevated expression in dermatomyositis patients.

Results: Gene expression profiling of muscle biopsy specimens identified six spatial clusters, one of which localized to a region of pronounced inflammation. This inflammatory cluster was predominantly composed of $CD14^{+}CD163^{+}$ M2 macrophages (Figure 1). Single-cell transcriptomic analysis further delineated 10 distinct cell clusters, including one corresponding to CD163-positive M2 macrophages. Molecular network construction and topological analysis of the top 30 differentially expressed genes in the CD163-positive M2 macrophage cluster identified two hub genes (Figure 2). Validation using the GSE48280 dataset, which includes RNA microarray data from muscle biopsies of five healthy controls and five patients with dermatomyositis, demonstrated that all identified hub genes exhibited a trend toward elevated expression in dermatomyositis patients (Figure 3).

Conclusion: In myositis associated with anti-glycyl tRNA synthetase syndrome, CD163-positive M2 macrophages, characterized by a limited set of hub genes, play a pivotal role in orchestrating the local inflammatory response within affected muscle tissue.

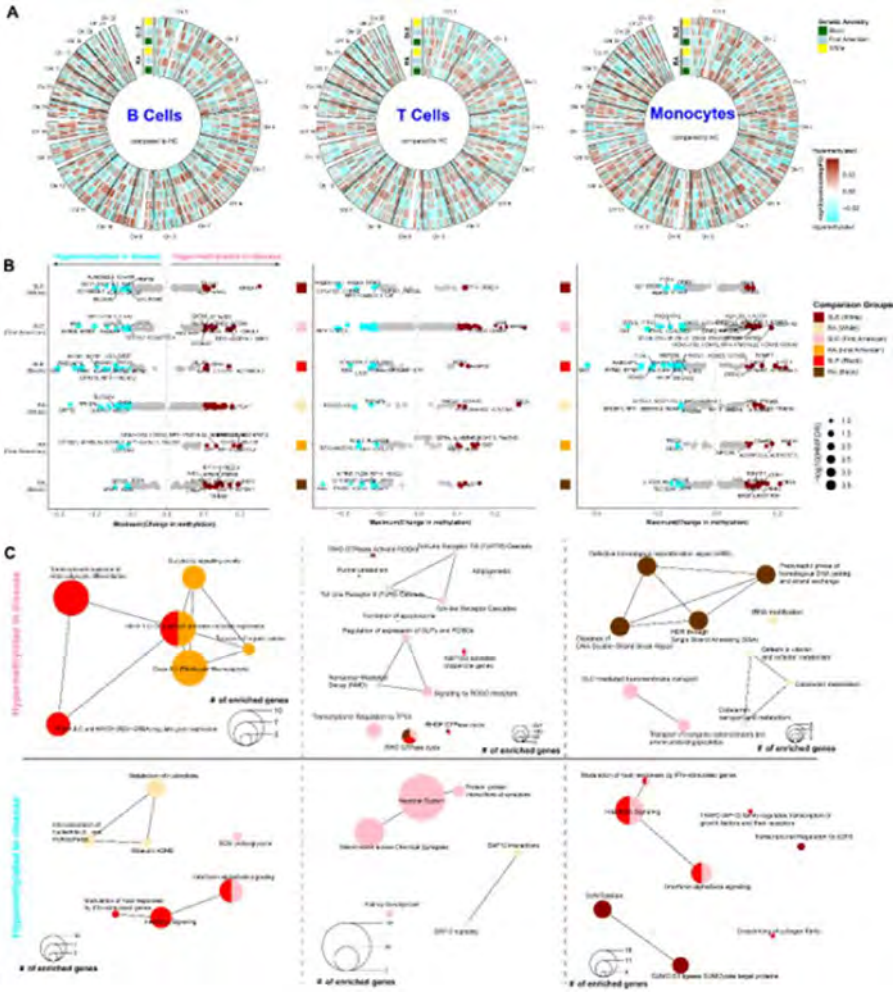
SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0019–0048) Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) are autoimmune diseases with distinct clinical and immunopathological features. Epigenetic modifications, particularly DNA methylation, contribute to immune dysregulation in these diseases. While SLE is characterized primarily by type I interferon (IFN) pathway activation, RA involves complex inflammatory pathways. Both are complex human diseases which share synovitis as a feature. Understanding ancestry-specific methylation patterns in immune cell subsets may elucidate disease mechanisms and explain differences in disease severity and response.

Methods: We performed genome-wide DNA methylation profiling using Infinium MethylationEPIC v1.0 on sorted B cells, monocytes, and T cells from Black (24 SLE and 21 RA), First American (22 SLE and 27 RA), and White (25 SLE and



A, Circular Manhattan plot showing distinct methylation profiles among different genetic ancestries between SLE and RA patients when compared to HC for B, T, and monocytes. B. Differential methylated region analyses for each sorted immune cell population. C. Gene set enrichment analyses of hyper- and hypomethylated genetic regions revealed different cellular pathways unique to disease and genetic ancestry within all three sorted immune cells.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. 24 RA) female patients with SLE or RA and with age-matched healthy controls (n=30/ancestry). Probes above the limit of detections based on negative controls and samples with < 1% poor-quality probes were retained for subsequent analyses. Additionally, probes associated with known single nucleotide polymorphisms were also excluded. Differentially methylated regions were identified and analyzed with respect to immune pathways and ancestry.

Results: Overall, the differences observed in SLE and RA highlight methylation signatures that are unique to both diseases (**Fig 1**). In SLE, B cells and monocytes from Black and First American patients exhibited significant hypomethylation in type I Interferon (IFN) response genes (*MX1, IFITM2, IFITM1, IFI44L*), consistent with IFN hypersensitivity, a signature absent in White patients (**Fig 1 B&C**). First American T cells demonstrated hypermethylation of Toll-like receptor (TLR) response genes (*MYD88* and *TLR9*)., whereas White and Black T cells showed no significant changes in these pathways. In contrast, RA patients showed distinct methylation patterns: White monocytes displayed uniquely hypermethylated regions related to vitamin B12 metabolism (*LMBRD1* and *MMADHC*), and T cells exhibited hypermethylation in TLR-related genes (*MYD88*, *TLR9*, *JUN*, and *IRF7*). AI and Black RA patients displayed minimal methylation alterations in these immune cell types. These findings underscore divergent epigenetic regulation between SLE and RA, with SLE marked by IFN pathway dysregulation predominantly in Black and First American ancestries, and RA characterized by metabolic and TLR pathway methylation changes primarily in WHITE patients (**Fig 1**).

Conclusion: Ancestry-specific DNA methylation signatures in SLE and RA distinct immune pathway involvement. The pronounced type I IFN hypomethylation in Black and First American SLE patients contrasts with the unique methylation of vitamin B12 and TLR-related genes in White RA patients. These results highlight the necessity of incorporating ancestry and disease context in epigenetic studies to better understand autoimmune pathogenesis and guide personalized therapeutic strategies.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0019–0048) Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Previous studies identified single nucleotide polymorphisms (SNPs) that affect hepatocyte and adipocyte response to glucocorticoids (GCs). We aimed to determine if these candidate SNPs impact the risk of metabolic adverse events (AEs) in patients with RA treated with GCs.

Methods: We genotyped participants from the Veterans Affairs RA (VARA) registry, a prospective cohort of RA, using the Illumina GSA v2. Imputation was performed using TopMED Imputation Server. We evaluated 22 candidate SNPs known to impact hepatocyte or adipocyte response to GCs. Among participants initiating a GC course (identified through prescription fill data), Cox proportional hazard models assessed associations between each SNP and composite metabolic AEs (incident diabetes, acute cardiovascular event, or sustained weight gain ≥3kg), censoring 90 days after GC discontinuation, end of follow-up, or death. Models were adjusted for sex, age, and principal components of genetic background and clustered by participant to account for multiple observations per patient. As a negative control, we repeated analyses among participants initiating a DMARD with no GC exposure in the preceding 180 days. Using the Benjamini-Hochberg false discovery rate (FDR), a p-value < 0.0021 was considered significant. SNPs with the strongest associations were screened in the Genotype-Tissue Expression Portal (GTEx) for expression quantitative trait loci (eQTL) in hepatic or adipose tissue to understand the effect of genetically regulated gene expression on the composite outcome. Two sample mendelian randomization (MR) was performed for the effect of rs6495481 on metabolic AEs.

Results: In 2597 VARA participants (88% male, mean age 68 years), there were 1559 prednisone initiations among 994 participants, and 3482 DMARD initiations among 1330 participants unexposed to GCs. Incidence of all metabolic AEs were higher in the prednisone initiation cohort (**Table 1**). In time to event analysis, no SNP reached experiment-wide significance for the primary or secondary outcomes (**Fig. 1)**. The SNP rs6495481 C >T demonstrated the strongest negative association with composite AEs, driven by less sustained weight gain, but did not reach significance (composite OR 0.76, 95% CI 0.63, 0.93, p = 0.007, **Fig. 1, Fig. 2**). rs6495481 was not associated with composite AEs in the cohort unexposed to GCs. In GTEx, rs6495481 is an eQTL for fumarylacetoacetate hydrolase (*FAH)* in several tissues, including the liver. MR demonstrated a strong protective effect of downregulated hepatic gene expression of *FAH* on the risk of composite AEs following GC exposure (Wald ratio 3.74, SE 0.65, p = 9.0 x10^{-9}).

Table 1. Incidence of metabolic adverse events in patients with RA initiating prednisone compared to those unexposed to glucocorticoids initiating a disease-modifying anti-rheumatic drug.

	Group 1 Prednisone Initiation		Group 2 DMARD Initiation (glucocorticoid unexposed)		
	Number of Events	Event Incidence (per 1000 person-years)	Number of Events	Event Incidence (per 1000 person-years)	p-value
Composite Metabolic Adverse Event*	449	353.6	783	76.7	< 0.0001
New-Onset Diabetes	13	9.8	20	2.1	< 0.0001
Acute Cardiovascular Event	152	98.7	344	28.3	< 0.0001
Coronary Artery Disease	44	26.7	116	9.4	< 0.0001
Acute Stroke	16	9.6	51	4.0	0.0036
Heart Failure Hospitalization	112	70.9	180	14.2	< 0.0001
Cardiovascular Death	29	17.2	130	9.9	0.0088
Sustained Weight Gain	357	288.1	579	56.8	< 0.0001

*Composite metabolic adverse events outcome: new-onset diabetes, acute cardiovascular event**, or sustained weight gain

**Acute cardiovascular events: incident coronary artery disease, acute stroke, hospitalization for congestive heart failure, and cardiovascular death, validated in VA and national death index data.

Event incidence rate was calculated using at-risk person-time following each exposure; statistical comparisons were performed using log-rank testing.

Abbreviations: DMARD - disease-modifying anti-rheumatic drug

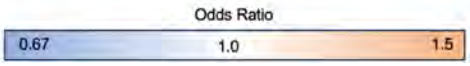

Figure 1. Association of SNPs related to glucocorticoid metabolism with adverse metabolic outcomes in VARA. Bold text indicate p-value < 0.05. No tests reached the experiment-wide significance threshold of 0.0021. Values are hazard ratios from Cox regression model adjusting for age, sex, and population structure. Composite events include new-onset diabetes, acute cardiovascular event, and sustained weight gain. Cardiovascular events include coronary artery disease, acute stroke, congestive heart failure, cardiovascular death.

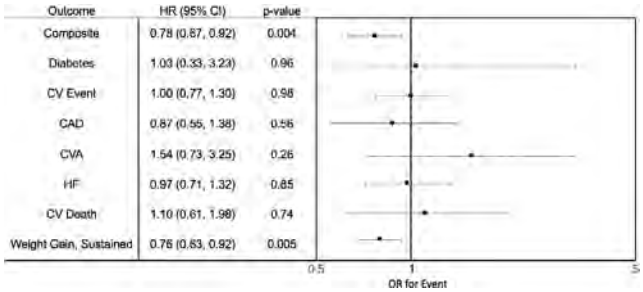

Figure 2. Association of rs6495481 with adverse metabolic outcomes in VARA participants initiating glucocorticoids. Patients with one T allele at rs6495481 (chr15, 80500456, C>T) had lower risk of the composite metabolic adverse event, driven by lower risk for sustained weight gain, but results were not statistically significant at a threshold of p < 0.0021. Confidence intervals are not corrected for the FDR.

Conclusion: Individual genetic variants impacting hepatocyte and adipocyte response to GCs did not meet the experiment-wide threshold for associations with the risk of metabolic AEs in patients with RA initiating prednisone. These analyses may have been underpowered to identify more modest associations. MR results suggest a potential biologic effect of these pathways on GC toxicity. Future studies should assess whether a combination of genetic factors can be combined with clinical factors to identify patients at high risk of metabolic AEs to guide clinical decision making.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0019–0048) Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: The mechanisms underlying female sex bias in autoimmune diseases remain unclear. Recent work has suggested that impaired maintenance of X-chromosome inactivation (XCI) in female murine immune cells can result in systemic lupus erythematosus (SLE)-like phenotypes. *XIST* (X-linked) encodes a long non-coding (lnc) RNA that helps maintain XCI in XX individuals. The Genome-Tissue Expression (GTEx) study has identified genetic variants that are expression quantitative trait loci (eQTL) for *XIST* or its X-linked positive regulator lncRNA *FTX*. This study hypothesized that eQTLs which lead to decreased expression of *XIST* or *FTX* in immune tissue would be positively associated with risk of female-biased autoimmunity.

Table 1. Demographic and Disease Statistics within Penn Medicine Biobank

		Total N=43,590	Male N=21,900	Female N=21,690
Age (yr), median (IQR)		64 (50-74)	68 (57-76)	60 (43-72)
Most Similar Reference Population	AFR	11,268 (25.8%)	4,201 (19.2%)	7,067 (32.6%)
	AMR	698 (1.6%)	303 (1.4%)	395 (1.8%)
	EAS	471 (1.1%)	257 (1.2%)	214 (1.0%)
	EUR	30,284 (69.5%)	16,724 (76.4%)	13,560 (62.5%)
	SAS	570 (1.3%)	295 (1.3%)	275 (1.3%)
	UNKNOWN	299 (0.6%)	120 (0.5%)	179 (0.8%)
Rheumatoid Arthritis		546 (1.3%)	167 (0.8%)	379 (1.9%)
Systemic Lupus Erythematosus		306 (0.7%)	51 (0.2%)	255 (1.3%)
Systemic Sclerosis		147 (0.4%)	32 (0.2%)	115 (0.6%)
Immune Mediated Myopathy (IMM)		89 (0.2%)	25 (0.1%)	64 (0.3%)
Sjögren's Disease		319 (0.8%)	39 (0.2%)	280 (1.4%)

Phenotype definitions:
Rheumatoid Arthritis (RA): 2 outpatient ICD-9 or ICD-10 codes plus a disease modifying anti-rheumatic drug used for RA
Systemic Lupus Erythematosus (SLE): 3 outpatient ICD-9 or ICD-10 codes plus a disease modifying anti-rheumatic drug used for SLE
Systemic Sclerosis (SSc): 2 outpatient ICD-9 or ICD-10 codes
Immune Mediated Myopathy (IMM): 1 inpatient or 2 outpatient ICD-9 or ICD-10 codes
Sjogren's Disease (SjoD): 2 outpatient ICD-9 or ICD-10 codes
Diagnosis assignment (if met multiple algorithms), assigned SSc, then IMM, then SLE, then RA, then SjoD
Abbreviations: IQR – interquartile range. AFR – African; AMR – admixed American; EAS – East Asian; EUR – European; SAS – South East Asian; ICD – International Classification of Disease

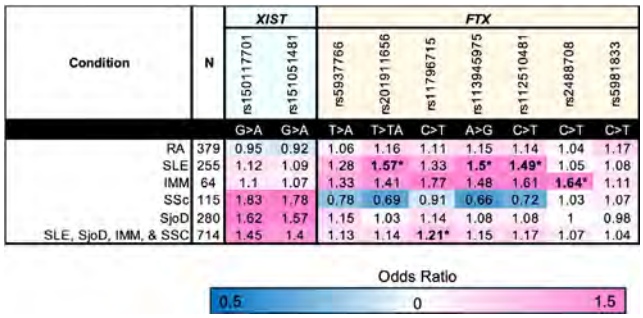

Figure 1. Heat Map of eQTL and sex-biased autoimmune conditions within the Penn Medicine Biobank. eQTLs for FTX were associated with statistically significantly higher odds of systemic lupus, immune mediated myopathy, and pooled sex-biased autoimmune disease. Analysis was performed using logistic regression, adjusted for the first 10 principal components of population structure and restricted to female sex. *Bold font indicates associations with p < 0.05; no associations met the experiment-wide significance threshold < 0.0056. Abbreviations: RA – Rheumatoid Arthritis; SLE – Systemic Lupus Erythematosus; SjoD – Sjogren's Disease: ICD – International Classification of Disease; IMM – Immune Mediated Myopathy; SSc – Systemic Sclerosis; ACR – American College of Rheumatology.

Methods: Participants in this study come from the Penn Medicine Biobank (PMBB), a health system-based biorepository. Participants underwent genotype sequencing using the Illumina Global Sequencing Array v2 by the Regeneron Genetics Center (Tarrytown, NY). Imputation was performed using the TOPMED Imputation Server. eQTLs associated with decreased expression of *XIST* and *FTX* in human splenic tissue were identified using the GTEx portal. Cases were identified using ICD-code and medication algorithms for SLE, systemic sclerosis (SSc), dermatomyositis or polymyositis (immune mediated myopathy, IMM), and Sjögren's Disease (SjoD). RA, a more modestly sex-biased disease not previously associated with X chromosome dosage, was selected as a negative control outcome. Logistic regression was performed to test the association of eQTLs with female-biased autoimmune disease, adjusted for the first 10 principal components of population structure and stratified by female sex. Using the Benjamini-Hochberg false discovery rate, a p-value < 0.0056 was considered significant.

Results: Among 43,590 individuals in PMMB, 21,690 (49.8%) were female (Table 1). By autoimmune condition, 546 (1.3%) had RA, 319 (0.8%) had SjoD, 306 (0.7%) had SLE, 147 (0.4%) had SSc, and 89 (0.2%) had IMM, with a higher prevalence in females compared to males. eQTLs associated with decreased *FTX* in the spleen were associated with increased risk for SLE in females; the strongest associations were for rs201911656 (T >TA) with OR 1.57, but did not meet experiment-wide significance thresholds (p = 0.009, Fig. 1, Table 2). eQTLs associated with decreased *XIST* expression were not statistically significant for individual conditions, including RA (Fig. 1). Examining the risk in diseases previously associated with X chromosome dosage (SLE, IMM, SjoD, and SSc), both *XIST* and *FTX* eQTLs were associated with higher odds of pooled autoimmune disease amongst females, but this result was not statistically significant (*FTX* rs11796715 (C >T) OR 1.21, 95% CI 1.02-1.45, p = 0.03).

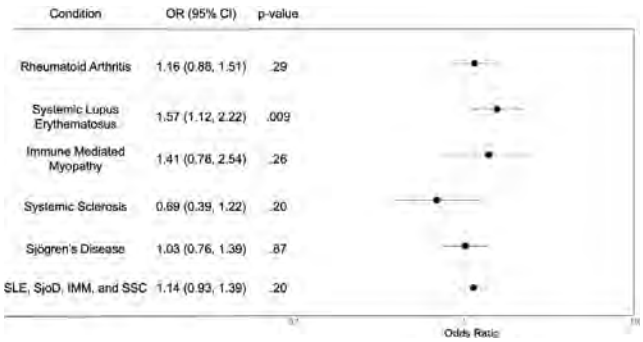

Figure 2. Association with autoimmune disease and FTX eQTL rs201911656. Logistic regression was performed to test the association of eQTL in an additive model with the female-biased autoimmune disease, adjusted for the first 10 principal components of population structure and restricted to female sex. Abbreviations: RA – Rheumatoid Arthritis; SLE – Systemic Lupus Erythematosus; SjoD – Sjogren's Disease: ICD – International Classification of Disease; IMM – Immune Mediated Myopathy; SSc – Systemic Sclerosis; ACR – American College of Rheumatology.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Genetic variation associated with altered expression of regulators of XCI maintenance in immune cells was associated with increased risk for specific female-biased autoimmune disease, but did not reach experiment wide-significance thresholds. These results further suggest that impaired regulation of X chromosome dosage via decreased XIST expression may contribute to the female bias of SLE and other systemic autoimmune diseases.

Abstract Number: 0047

Monocyte Transcriptomic Signatures Uncover Potential Pathogenic Mechanisms of the APOL1 High Risk Genotype (HRG)

Vishnuprabu Pandian[1], Adebola Agboola[1], Sivasubramanian ramani[2], Christele Felix[3], Andrra Nimoni[3], Jasmin Divers[4], Timothy Niewold[5] and Ashira Blazer[2], [1]University of Maryland, Baltimore, Baltimore, Maryland, [2]University of Maryland Baltimore, Baltimore, Maryland, [3]Hospital for Special Surgery, New York, NY, [4]NYU Grossman Long Island School of Medicine, New York, New York, [5]Hospital for Special Surgery, New York, New York

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0019–0048) Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Compared to the low-risk genotype (LRG) the APOL1 high-risk genotype (HRG) confers an increased risk of end stage kidney disease among individuals with systemic lupus erythematosus (SLE). Despite this association, the cellular and molecular mechanisms driving APOL1-mediated cytotoxicity in SLE remain unclear. Monocytes both express APOL1 and are exposed to the SLE inflammatory milieu. This study aimed to define differential pathways of monocyte cytotoxicity in SLE patients stratified by APOL1 genotype.

Methods: THP-1 monocytes were stimulated with IFN-γ, and APOL1 expression was quantified via qRT-PCR and Western blot. Monocytes from SLE patients were isolated using Ficoll density gradient and magnetic bead separation. Blood DNA was extracted from patients and genotyped for APOL1 risk variants. Type-I interferon activity in plasma was assessed using the WISH cell bioassay. RNA-seq was performed on patient's monocytes, and differential gene expression analysis compared high-risk (2 APOL1 variants) and zero-risk groups, followed by gene ontology and pathway enrichment analyses.

Results: Demographic and clinical data from 23 SLE patients were stratified by APOL1 risk allele count (0, 1, or 2). Those with 2 risk variants (n=5) had lower mean eGFR (64 ± 28.5 mL/min/1.73 m^2) and SLEDAI scores (4 ± 2) than patients with 0 (97 ± 15.6; 7.7 ± 5.7) or 1 variant (105.4 ± 18.2; 8.4 ± 6.3). Type I interferon activity, assessed via WISH cell assay, declined with increasing APOL1 variants (mean: 0RV 9.28, 1RV 4.25, 2RV 1.34; p=0.07). IFN-γ treatment of THP-1 monocytes confirmed APOL1 expression, showing 31.1-fold (qRT-PCR) and 2.5-fold (western blot) increases. Transcriptomic profiling revealed that monocytes from high-risk genotype (HRG) patients upregulated genes in TNF-α signaling, coagulation, inflammation, and cholesterol homeostasis. Key upregulated genes included CD5L, TRAP1, HLA-DQA, TNFRSF19, KIR3DL2, and platelet receptor, P2RY12. Conversely, HLA-DRB5, IFNGR2, and TNFSF13B (BAFF) were downregulated in HRG vs low-risk genotype (LRG) monocytes.

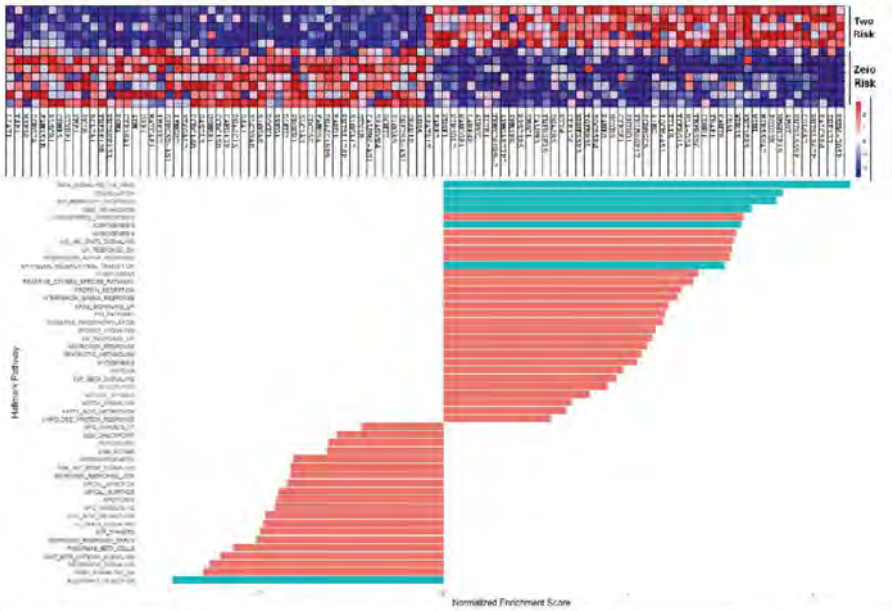
Table-1 Clinical and Demographic Characteristics of SLE Patients Stratified by APOL1 Risk Alleles

	Number of APOL1 Risk Alleles			Full Cohort
Number of Samples (n)	**0 (7)**	**1 (11)**	**2 (5)**	**23**
Demographics				
Age (SD)	45.6 (13.2)	42 (13)	49 (15)	44.7 (13.4)
Female (%)	6 (85.7)	8 (72.7)	4 (80)	18 (78.3)
Male (%)	1 (14.3)	3 (27.3)	1 (20)	5 (21.7)
SLEDAI score (SD)	7.7 (5.7)	8.4 (6.3)	4 (2)	7.2 (5.7)
Proteinuria (%)	43%	55%	40%	49%
eGFR (SD)	97 (15.6)	105.4 (18.2)	64 (28.5)	93.8 (25.8)
Immunology				
ANA Titer (SD)	2(1.3)	1.2 (1)	1.1 (1)	1.4 (1.1)
C3 (SD)	98.6 (30.2)	89.1 (28.8)	108.1 (15.0)	96.1 (28)
C4 (SD)	19 (8.6)	34.6 (38.6)	25.7 (8.8)	27.8 (28.2)
Medications				
Hydroxychloroquine (%)	4 (57.1)	9 (81.8)	5 (100)	18 (78.3)
Prednisone (%)	1 (14.3)	2 (18.2)	4 (80)	7 (30.4)
Mycophenolate (%)	3 (42.9)	4 (36.4)	3 (60)	10 (43.5)
Azathioprine (%)	1 (14.3)	1 (9.1)	1 (20)	3 (13)
Methotrexate (%)	1 (14.3)	0 (0)	1 (20)	2 (8.7)
Benlysta (%)	3 (42.9)	1 (9.1)	1 (20)	5 (21.7)

Demographic, clinical, immunological, and treatment-related characteristics of systemic lupus erythematosus (SLE) patients grouped by the number of APOL1 risk alleles (0, 1, or 2). The full cohort includes 23 patients. Continuous variables are presented as mean (standard deviation), and categorical variables are shown as counts (percentage). Proteinuria is reported as the percentage of patients with documented proteinuria. Medication use reflects the proportion of patients on each treatment at the time of sample collection.

Figure-1 Heatmap and Gene Set Enrichment Analysis of Monocyte transcriptome from Patients with Zero and Two APOL1 Risk Alleles



The top panel displays a heatmap of gene expression profiles from monocytes of patients carrying either zero or two APOL1 risk alleles. Each row represents an individual patient, and each column corresponds to a gene.

The bottom panel shows the normalized enrichment scores (NES) for statistically significant differentially expressed gene sets, with positive NES indicating pathways upregulated and negative NES indicating downregulated in the two-risk group than zero risk. This analysis highlights distinct molecular pathways associated with APOL1 two risk variants.

Conclusion: Our findings indicate that circulating monocytes from HRG SLE patients exhibit a transcriptomic profile characterized by proinflammatory and procoagulant signatures, alongside diminished antigen presentation capacity. These results provide novel insights into how APOL1 risk variants may contribute to cytotoxicity in SLE beyond classical interferon-driven mechanisms.

Abstract Number: 0048

Integrative Spatial Proteomics and Single-Cell RNA Sequencing Unveil Molecular Complexity in Rheumatoid Arthritis for Novel Therapeutic Targeting

Xue Wang[1], Fei Wang[2], Sílvia Sisó[2], Archana Iyer[2], Heather Knight[2], Lori Duggan[2], Yingli Yang[2], Liang Jin[2], Baoling Cui[2], **Yupeng He**[3], Jan Schejbal[2], Lucy Phillips[2], Bohdan Harvey[4] and Yu Tian[2], [1]AbbVie, South San Francisco, CA, [2]AbbVie, Worcester, MA, [3]AbbVie, North Chicago, IL, [4]AbbVie, Cambridge, MA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0019–0048) Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disease characterized by persistent inflammation, fibroblast proliferation and progressive joint damage. Understanding the heterogeneity of RA and identifying therapeutic targets remain challenging using traditional bulk transcriptomics alone, as it lacks the spatial and protein-level resolution needed to fully capture disease and tissue complexities. While scRNA-seq provides a high-resolution of dynamics of gene expression at the single-cell level, it lacks the topographical or spatial context.

Methods: In this study, we applied Laser Capture Microdissection (LCM) coupled with mass spectrometry-based proteomics to analyze histopathological niches of the RA synovium, enabling the identification of protein expression profiles of the diseased synovial lining and sublining microenvironments compared to their healthy counterparts. To enhance our understanding of cellular dynamics within the dissected regions, we further integrated the proteomic dataset with single-cell RNA sequencing (scRNA-seq) and deduced cell type enrichment including T cells, fibroblasts, NK cells, myeloid cells, B cells and synovial endothelial cells.

Results: Using the in-house spatial proteomics workflow, we generated a protein expression abundance dataset containing 3,818 quantified proteins. protein expression changes were more pronounced between disease conditions than between different histopathological compartments. Key pathogenetic RA proteins like membrane proteins (TYROBP, AOC3, SLC16A3, TCIRG1 and NCEH1), and extracellular matrix (ECM) proteins (PLOD2, OGN and LUM) showed different expression patterns in diseased synovium compartments. Integration of scRNAseq and spatial proteomics provide cellular and molecular landscapes of cell type/cluster enrichments in distinct histopathological regions, highlighting fibroblasts enrichment in RA fibrous sublining regions and immune cells enrichment in RA immune sublining regions.

Conclusion: By combining high-resolution spatial proteomics and transcriptomic analyses, we provide novel insights into the molecular mechanisms driving RA and highlight potential protein targets for therapeutic intervention. This integrative approach offers a more comprehensive view of RA synovial pathology and mitigates the limitations of traditional bulk transcriptomics in target discovery.

Abstract Number: 0049

Enhanced Src Homology Region 2 Domain-containing Phosphatase 1 Activity Ameliorates Murine Inflammatory Arthritis Through the Innate Immune System

Jun Li, Katalin Mikecz and **Adrienn Markovics**, Rush University Medical Center, Chicago

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0049–0066) Rheumatoid Arthritis – Animal Models Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Src homology region 2 domain-containing phosphatase 1 (SHP-1) is a cytoplasmic protein tyrosine phosphatase expressed in hematopoietic cells (PMID9069265). SHP-1 is a key negative regulator of adaptive and innate immune cell signaling; its function is critical in preventing and eliminating excessive immune cell activation (PMID12490957). Suboptimal SHP-1 function has been linked to autoimmune and inflammatory diseases (PMID27216862). We reported that genetically and pharmacologically enhanced SHP-1 activity reduced disease severity in a T cell-driven murine model of inflammatory arthritis (PMID32586377). Our objective was to determine if the protective role of enhanced SHP-1 activity is mediated by T cells and the adaptive immunity.

Methods: Proteoglycan-induced arthritis (PGIA) was induced in 12-weeks old female wildtype (WT) and Shp1- overexpressing transgenic (Shp1-Tg) mice. For adoptive cell transfer, unseparated spleen cells, regulatory T cells or conventional T cells were isolated from WT or Shp1-Tg mice and transferred to 12-weeks old female mice with Severe Combined Immunodeficiency (SCID). Collagen antibody-induced arthritis (CAIA) was induced in 12-weeks old female WT and Shp1-Tg mice by an antibody cocktail to collagen II. SHP-1 activity was enhanced by regorafenib (REG) treatment of WT mice with CAIA (20 mg/kg/day). Arthritis incidence and severity were determined by Visual Arthritis Score (VAS). Spleens were harvested to determine inflammatory cytokine gene expression by qPCR. Ankle joint histopathology was quantified. Animal experiments were approved by IACUC #23-059 at Rush University Medical Center. Data analysis software: GraphPad Prism v10.1.2. Statistical significance was set at $p< 0.05$.

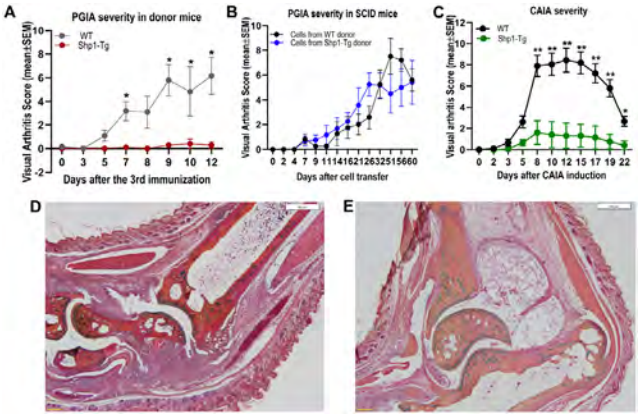

Figure 1. The anti-arthritic effect of SHP-1 overexpression is mediated by the innate immune system. A: Significantly reduced PGIA severity in spleen cell donor Shp1-Tg mice (12-weeks old female, n=10-12/group). B: No significant difference in PGIA severity in spleen cell recipient SCID mice (12-weeks old female, n=6-7/group). C: Shp1-Tg mice show significantly reduced CAIA severity compared to WT mice (n=10/group). D-E: Representative images of the tibiotarsal joint of WT mice with CAIA and treated with vehicle (D) or SHP-1 activator regorafenib (E). Alcian blue/hematoxylin/orange G staining. ($p^*<0.05$, $p^{**}<0.01$;two-way ANOVA followed by Sidak`s multiple comparison).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: In the PGIA adoptive transfer model, SCID mice developed PGIA in each transfer group. PGIA severity in SCID mice was not statistically different following spleen cell transfer or T cell transfer from Shp1-Tg mice, indicating that the protective effect of genetically enhanced SHP-1 activity cannot be transferred by T (or B) cells (Fig 1A-B). In the CAIA model, Shp1-Tg mice showed significantly lower CAIA incidence and severity (Fig 1C) than WT mice. REG treatment of arthritic WT mice significantly reduced CAIA severity. REG treatment also significantly reduced expression of interleukin-1β, IL-6, IL-17 and interferon gamma transcripts. Ankle joint histopathology (synovial thickness, cartilage/bone damage, pannus, inflammatory cell infiltration) was significantly improved after REG treatment (Fig 1D-E).

Conclusion: Enhanced SHP-1 activity was protective/therapeutic in two different murine models of inflammatory arthritis. Since this protective effect was not transferred by spleen cells or T cells from Shp1-Tg mice, it is conceivable that innate immune cells (macrophages, neutrophils) are responsible for the anti-inflammatory effect of enhanced SHP-1 activity. Given the significant role of macrophages and neutrophils in RA, future studies will explore if enhanced SHP-1 activity in these cells can be utilized as a cell-based therapeutic approach in RA.

TL1A expression is upregulated in rheumatic diseases and anti-TL1A antibody reduces disease symptoms and pathological changes in rat collagen-induced arthritis

Preeyam Patel[1], Matthew Siegel[2], Emily Lewis[3], David Giles[3], Justin LaFountaine[3], Joshua Friedman[3] and **Andy Spencer**[3], [1]Spyre Therapeutics, Waltham, [2]Spyre Therapeutics, Menlo Park, CA, [3]Spyre Therapeutics, Waltham, MA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0049–0066) Rheumatoid Arthritis – Animal Models Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: The development of disease-modifying anti-rheumatic drugs (DMARDs) has reduced disease activity in patients living with rheumatic diseases. Despite this, there is continued unmet need for safe and effective agents with improved convenience. TNF-like protein 1A (TL1A) is a pro-inflammatory and pro-fibrotic cytokine. TL1A inhibition has shown proof-of-concept in inflammatory bowel disease (IBD) and is under investigation in additional autoimmune conditions. Spyre Therapeutics is developing half-life extended antibodies targeting TL1A for the treatment of patients with IBD and rheumatic diseases. Animal model and translational data are needed to support the development of TL1A inhibitors in rheumatic diseases.

Methods: Gene expression data from published rheumatoid arthritis (RA), axial spondyloarthritis (axSpA), and psoriatic arthritis (PsA) studies deposited in NCBI GEO were merged and queried to assess TL1A expression in controls and those with rheumatic diseases. To further characterize the role of TL1A in arthritis, the rat collagen-induced arthritis (CIA) model was used to assess the impact of TL1A inhibition on arthritic endpoints. Female Wistar rats were injected with a bovine type II collagen emulsion on days 0 and 7. Antibody treatments were injected (IV) once weekly. Etanercept was injected (IP) every 3 days. Body weight, hind paw volume and arthritis scores were measured twice per week. At study conclusion, X-ray images of the hind paws were taken and scored. Decalcified hind paw sections were scored by a blinded pathologist for cell infiltration, pannus severity, cartilage lesion severity, and bone resorption. RNA sequencing was performed on knee synovium.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: TL1A gene expression is upregulated in the blood of RA and axSpA patients and in skin lesions of PsA patients compared to healthy controls. In the rat CIA model, initiating treatment prior to symptom onset resulted in significantly improved disease activity score and hind paw volume with anti-TL1A antibodies compared to etanercept. Treatment with either anti-TL1A or etanercept improved hind paw X-ray scores relative to control groups with the magnitude of improvement being greater for animals treated with anti-TL1A than with etanercept. Anti-TL1A treatment, but not etanercept treatment, resulted in improvement across all histopathology scores compared to the vehicle control group. When initiated after the development of symptoms, treatment with anti-TL1A and etanercept showed comparable improvements in disease activity score, hind paw volume, and hind paw X-ray score relative to vehicle controls.

Conclusion: TL1A gene expression is increased in the blood of RA and axSpA patients and in skin lesions of PsA patients compared to healthy controls. Anti-TL1A antibody treatment reduced disease symptoms and pathology scores in the rat model of CIA. In this model, anti-TL1A treatment resulted in superior efficacy relative to etanercept when initiated prior to symptom onset and had comparable efficacy to etanercept when initiated at the start of symptom onset. These data support the clinical development of anti-TL1A therapy in rheumatic diseases.

Spp1+ Macrophages Are Specifically Enriched in Arthritic Joints and Associated with Abnormal Bone Metabolism in Collagen-Induced Arthritis Mice

Chenjia He, Xuyang Xia, Heng Xu, Geng Yin and Qibing Xie, West China Hospital, Sichuan University, Chengdu, China (People's Republic)

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0049–0066) Rheumatoid Arthritis – Animal Models Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Synovial fluid (SF) of RA patients contains unique *SPP1*$^{+}$ macrophages that drive pathogenesis by activating fibroblast-like synoviocytes (FLS). Single-cell RNA sequencing (scRNA-seq) data from SF, synovial tissue (ST), and peripheral blood of same RA patient shows *SPP1*$^{+}$ macrophages are enriched in SF and ST but absent in peripheral blood. This limits research on these cells. Previous studies focused on RA patients and lack research on the distribution and functional characteristics of *Spp1*$^{+}$ macrophages in animal models. This study explores the distribution and function of *Spp1*$^{+}$ macrophages in collagen-induced arthritis (CIA) mice, addressing clinical sample limitations and providing insights into RA pathogenesis and therapeutic strategies.

Methods: CIA mouse model was established, and scRNA-seq was performed on joints from CIA and control mice. Sequencing data was annotated and clustered to identify cell populations. Flow cytometry analyzed *Spp1*$^{+}$ macrophage proportions in peripheral blood, spleen, and joints based on established gating strategies. Micro-computed tomography (Micro-CT) was used to assess bone metabolism parameters and their correlation with *Spp1*$^{+}$ macrophage proportions.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Fig. 1 Establishment of the CIA mouse model and single-cell sequencing analysis. A Body weight of CIA and control mice. B Clinical arthritis scores of CIA and control mice. C Hind paws of mice 42 days after primary immunization. D Representative micro-CT images of hind paws and knee joints. E Hematoxylin and Eosin staining of knee joint pathological sections. F Schematic diagram of the study workflow. G t-distributed stochastic neighbor embedding (t-SNE) plot showing single-cell transcriptional profiles of paws from CIA and control mice. H Proportion analysis of cell clusters in CIA versus control mice. *$p < 0.05$, ****$p < 0.0001$.

Results: On day 42 post-immunization, CIA mice showed significant weight loss, higher clinical scores, severe synovial inflammation, and joint destruction compared to controls, confirming successful model induction (Fig. 1A-E). scRNA-seq of paws from one CIA and one control mouse revealed *Spp1*$^{+}$ macrophages specifically in CIA joints, absent in controls (Fig. 1F-H). Flow cytometry showed higher *Spp1*$^{+}$ macrophage proportions in CIA joints than in peripheral blood and spleen (Fig. 2B-C). Proportion of *Spp1*$^{+}$ macrophages in the joints of CIA mice were significantly elevated compared to controls, with no differences in peripheral blood and spleen (Fig. 2E-F). Three-dimensional reconstruction of knee joints showed severe joint surface damage and bone erosion in CIA mice. Bone volume (BV)/tissue volume (TV), bone surface (BS)/TV, trabecular number (Tb.N), and trabecular sepamtion (Tb.Sp) analysis in the proximal tibia showed significant decreases in BV/TV, BS/TV, and Tb.N in CIA mice (Fig. 3A-C), while Tb.Sp was higher (Fig. 3D), indicating bone loss and osteoporosis. Spearman correlation analysis showed *Spp1*$^{+}$ macrophage proportions in joints were negatively correlated with BV/TV, BS/TV, and Tb.N but positively correlated with Tb.Sp (Fig. 3E-H), suggesting a link between elevated *Spp1*$^{+}$ macrophages and bone abnormalities in CIA mice.

Profiling of MT-3534, a Humanized Monoclonal Antibody Targeting Peptidylarginine Deiminase 4, as a Candidate Drug for the Treatment of RA

Hisae Niki[1], Akitoshi Nishizawa[2], Yuuichi Ono[1], Makoto Yamazaki[1], Satoshi Takanashi[3], Keiko Yoshimoto[4], Mitsuhiro Akiyama[3], Tsutomu Takeuchi[5] and Yuko Kaneko[4], [1]Mitsubishi Tanabe Pharma Corporation, Yokohama, Kanagawa, Japan, [2]Mitsubishi Tanabe Pharma Corporation, Fujisawa, Kanagawa, Japan, [3]Keio University School of Medicine, Tokyo, Japan, [4]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Shinjuku-ku, Tokyo, Japan, [5]Saitama Medical University and Keio University, Tokyo, Japan

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0049–0066) Rheumatoid Arthritis – Animal Models Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Although the management of rheumatoid arthritis (RA) has been remarkably improved, there are still patients who have not responded to existing targeted drugs that mainly suppresses inflammatory cytokines. We hypothesize that the pathophysiology mediated by activated neutrophils is responsible for non-response to existing drugs, and inhibiting peptidyl arginine deiminase type 4 (PAD4), which are released by activated neutrophils and plays a key role in the development and progression of RA, could be a new therapy for difficult-to-treat RA. Based on this concept, we have developed MT-3534, a humanized monoclonal antibody that binds to human, mouse, and cynomolgus monkey PAD4, but not to other human PAD family proteins. Non-clinical safety studies in animals have shown no notable adverse events, and a Phase 1 clinical trial is currently ongoing. The objectives of this study were to provide evidence that PAD4-related pathophysiology is the cause of non-response to existing bDMARDs and to profile the anti-arthritic effects of MT-3534 in mouse arthritis models.

Methods: Human plasma PAD4 levels were measured in samples obtained from 29 RA patients treated with TNF inhibitors, IL-6 receptor inhibitors, or abatacept, and 25 healthy controls. Patients were categorized as responders (R) or inadequate responders (IR) to bDMARDs based on their treatment history and disease activity, and plasma PAD4 levels were compared between them. Next, MT-3534 was administered to collagen antibody-induced arthritis (CAIA) and collagen-induced arthritis (CIA) models in mice. Arthritis progression was monitored by scoring the swelling of digits and paws. Various biomarkers in mouse sera and joint homogenates were measured using ELISA. PAD4 in mouse joints was detected using standard immunostaining techniques.

Results: Pre-treatment plasma PAD4 levels in bDMARD-IR patients were higher than that in healthy controls and bDMARD-R patients. After bDMARD treatment, the decrease in plasma PAD4 levels were less in bDMARD-IR patients compared with bDMARD-R patients. In CAIA models, while prophylactic etanercept administration prevented arthritis development but therapeutic etanercept administration did not improve arthritis after arthritis development, MT-3534 suppressed

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

arthritis development and improved developed arthritis equally with prophylactic and therapeutic usage, respectively. Time-course immunostaining of PAD4 in the joints of CIA model mice revealed that MT-3534 worked after neutrophil infiltrated and PAD4 expression increased with arthritis onset. MT-3534 significantly suppressed related biomarkers in the CIA model. Furthermore, it was confirmed that the administration of MT-3534 to mice in which arthritis progressed despite etanercept treatment inhibited the progression of arthritis compared to mice that continued etanercept treatment alone.

Conclusion: MT-3534 inhibited arthritis in mice through a mechanism distinct. The unique mechanism of action of MT-3534 has the potential to fill an unmet medical need in the treatment of RA.

Acknowledgements

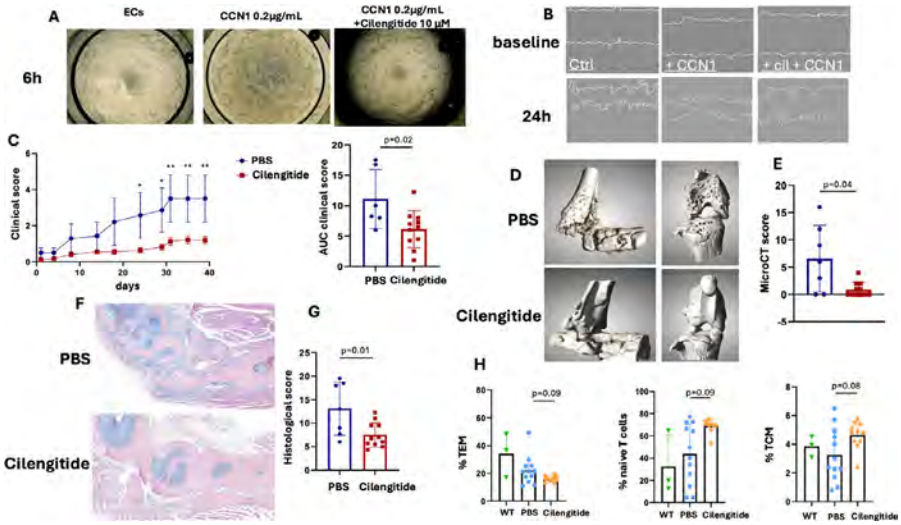
The Integrin Inhibitor Cilengitide Targets CCN1-Mediated Angiogenesis and Reduces Disease Severity in a Preclinical Rheumatoid Arthritis Model

Jérôme Avouac[1], manon lesturgie[2], Virginie Gonzalez[3], Sujeeba Arulananthan[2], Anne Cauvet[3], Francoise Tilotta[4] and Yannick Allanore[5], [1]Hôpital Cochin, AP-HP Centre - Université Paris Cité, Paris, France, [2]INSERM U1016, Paris, France, [3]INSERMU1016, Paris, France, [4]Université Paris Cité, Montrouge, France, [5]Université Paris Cité, Paris, France

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0049–0066) Rheumatoid Arthritis – Animal Models Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: CCN1, a matricellular protein with angiogenic and immunomodulatory properties, is overexpressed in endothelial and synovial tissues of rheumatoid arthritis (RA) patients. Previous findings demonstrated that CCN1 inhibition reduces synovial angiogenesis and structural damages in preclinical arthritis models. However, it remains unclear whether these therapeutic effects of CCN1 inhibition are mediated through a reduction in angiogenesis. This study investigates the ability of Cilengitide, a cyclic pentapeptide integrin inhibitor, to block CCN1-mediated effects on endothelial cells (ECs) and evaluates its potential therapeutic impact in the TNF-dependent Tg197 arthritis model.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



A, Representative images of tube formation at 6 hours in RA endothelial cells (ECs) alone, or following treatment with recombinant CCN1 (0.2 g/mL) with or without Cilengitide (10 M) (4x magnification). B, Representative images of EC migration at baseline and 24 hours in RA ECs alone, or following treatment with recombinant CCN1 (0.2 g/mL) with or without Cilengitide (10 M). C, Experimental arthritis in Tg197 mice receiving IP injections of Cilengitide (10 mg/kg) or PBS (100 L) 3 times weekly. Y-axis shows clinical score and the area under the curve (AUC) of the clinical score (PBS: n=7 mice, Cilengitide, n=11 mice). D, Representative 3D reconstructions of ankles, tarsus and knees of Tg197 mice treated with Cilengitide or PBS. E, Y-axis shows the mean erosion score (from 0 to 16). F, Sections of ankle and tarsus joints from Tg197 mice receiving Cilengitide or PBS stained with hematoxylin (scale bar = 200m). G, Histomorphometric analysis of the area of synovitis and bone destruction. H, Flow cytometry analysis of T cell subsets (effector memory T cells, TEM, naive T cells and central memory T cells, TCM) from the spleen of wild type (WT) mice (n=3) and Tg197 mice treated with Cilengitide or PBS. All data are shown as the means ± SD. Statistical tests: Student's t test for 2-group comparisons, ANOVA with Dunnett's multiple comparisons test for 3-group comparisons. Data are representative of a single experiment.

Methods: The effects of CCN1 inhibition on angiogenesis through Cilengitide were assessed *in vitro* using ECs derived from circulating progenitors. Cells were cultured with CCN1 (0.2 µg/ml), either alone or with Cilengitide (10 µM). We analyzed capillary-like tube formation on Matrigel and EC migration using scratch assay.

For in vivo studies, TNF-transgenic mice (Tg197) received intraperitoneal injections of either Cilengitide (10 mg/kg) or PBS three times weekly. Clinical arthritis scores were monitored bi-weekly, and after six weeks, paws were analyzed using micro-CT and histology. Immune profiling from the spleen of TG197 mice was performed via flow cytometry.

Results: *In vitro*, CCN1 induced capillary-like tube formation and EC migration / invasion, which were significantly inhibited by Cilengitide at a dose of 10µM. (**Figure 1A-B**), strongly supporting that CCN1 effects on ECs are mediated through integrins αvβ3 and αvβ5, which are critical for angiogenesis.

In vivo, Cilengitide significantly improved clinical arthritis scores (**Figure 1C**). The AUC of the clinical score of Cilengitide-injected mice decreased significantly by 55±6% (p=0.020). Micro-CT analysis demonstrated better-preserved joint integrity in Cilengitide-treated mice, with markedly fewer bone erosions compared to controls (**Figure 1D-E**). Histological analysis of hind paw sections confirmed previous results, with significantly less inflammation and structural damage in Cilengitide-treated mice (**Figure 1F-G**).

Flow cytometry showed decreased activation of CD4+ T cells in treated mice, with reduced PD-1 expression, indicating lower exhaustion levels following Cilengitide treatment. CD4+ T cells exhibited a shift in memory subsets, with fewer effector memory T cells and an increase in central memory and naïve T cells (**Figure 1H**).

Conclusion: Cilengitide effectively inhibits CCN1-induced angiogenesis *in vitro*, confirming that CCN1 exerts its effects on endothelial cells through integrins αvβ3 and αvβ5. *In vivo*, Cilengitide significantly reduces clinical, structural, and histological damage in the Tg197 arthritis model while modulating immune profiles. These findings suggest that CCN1's effects in RA,

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. including structural and inflammatory damage, are mediated by its role in promoting pathological angiogenesis. Targeting CCN1 and associated pathways offers a promising therapeutic strategy for RA, complementing current treatments.

Microbial Cues Promote Arthritis and Alter T Cell Selection in SKG Mice

Astha Patel[1], Steven yu[1], Yuka Nakao[1], Mohana Mukherjee[1], Diego Orellana[2], Jose Scher[3], Peter Turnbaugh[1], Renuka Nayak[4] and **Judith Ashouri**[1], [1]University of California, San Francisco, San Francisco, CA, [2]University of California San Francisco, San Francisco, CA, [3]New York University School of Medicine, New York, NY, [4]University of California, San Francisco (UCSF), San Francisco, CA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0049–0066) Rheumatoid Arthritis – Animal Models Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Dysbiosis of the gut microbiota has been linked to rheumatoid arthritis (RA), but it remains unclear whether these microbial alterations are causal or secondary to inflammation, as most patients present after disease onset. The SKG mouse, which develops $CD4^+$ T cell–driven autoimmune arthritis resembling RA including erosive joint disease, rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPAs), and pneumonitis, providing a tractable model to dissect these relationships. Under germ-free (GF) conditions, SKG mice fail to develop arthritis, underscoring the requirement for microbial cues in disease initiation. This model enables dissection of microbiota-dependent versus genetically encoded immune mechanisms, including the largely unexplored gut–thymus axis. We investigated how commensal microbes influence thymic selection, peripheral T cell activation, and tolerance to endogenous antigens.

Methods: GF SKG mice (n=8) and conventionalized GF SKG mice (n=9) received intraperitoneal zymosan injections, and arthritis scores were monitored over time. Clinical scores were assessed blindly, and cumulative disease burden was calculated as area under the curve (AUC); group differences were analyzed using the Wilcoxon test. Immune cell populations in thymocytes, peripheral lymphoid organs and Peyer's patches were analyzed by flow cytometry using FlowJo software,

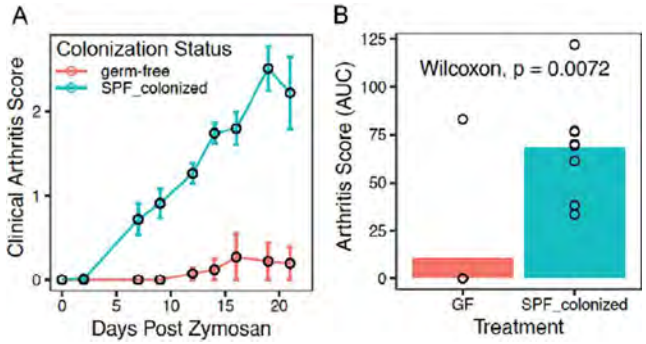

Figure 1. Microbiota are required for arthritis development in SKG mice. Germ-free (GF) SKG mice (n=8) and conventionalized GF SKG mice (n=9) were injected intraperitoneally with zymosan and monitored over time for clinical arthritis scores in a blinded fashion. (A) Blinded longitudinal arthritis scores are shown for each group. (B) Cumulative disease burden, measured by area under the curve (AUC) of arthritis scores, was significantly higher in conventionalized mice (Wilcoxon test, p = 0.0072).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

and group comparisons were made using Student's *t* test. Thymocyte subsets and T cell signaling in thymocytes and peripheral $CD4^+$ T cells were assessed using calcium flux and phospho-flow cytometry.

Results: Only 1 GF SKG mouse developed arthritis, compared to all 9 conventionalized GF SKG mice, which showed significantly higher disease activity (Fig. 1). Conventionalized mice exhibited a significant expansion of T follicular helper (Tfh) cells and a significant reduction in regulatory T cells in Peyer's patches (both $p < 0.001$). In zymosan-free conditions, GF SKG mice showed reduced frequencies of mature $CD4^+$ single-positive (SP4) thymocytes despite normal levels of $CD4^+CD8^+$ double-positive cells, indicating intact positive selection but enhanced negative selection. Thymocytes from GF SKG mice expressed higher CD5, consistent with increased tonic TCR signaling. Accordingly, SKG SP4 thymocytes and peripheral $CD4^+$ T cells from GF mice exhibited more robust signaling responses upon stimulation than their SPF counterparts.

Conclusion: Microbial cues are essential for permissive arthritis in SKG mice and shape both thymic selection and peripheral T cell activation. The enhanced signaling responses in GF-derived T cells, despite reduced basal signaling markers, suggest an unrecognized role for the gut–thymus axis in setting thresholds for T cell reactivity. This model offers a unique opportunity to define how commensals calibrate T cell selection and autoimmune potential.

Abstract Number: 0055

TCR Signaling Thresholds Govern Anergy and Tolerance in ZAP70 Hypomorphic Models of Autoimmune Arthritis

Yuka Nakao, Astha Patel, Letitia Yang, Steven yu, Arthur Weiss and **Judith Ashouri**, University of California, San Francisco, San Francisco, CA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0049–0066) Rheumatoid Arthritis – Animal Models Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: T cell receptor (TCR) signaling strength is a key determinant of immune tolerance and autoimmunity, yet the threshold needed to prevent pathogenic self-reactivity remains poorly defined. ZAP70 is a critical kinase in the TCR signaling cascade, and the SKG and YYAA mice carry distinct hypomorphic ZAP70 mutations—resulting in different degrees of impaired TCR signaling, more severe in SKG. Both strains generate rheumatoid factor (RF) autoantibodies, but only SKG mice develop $CD4^+$ T cell mediated erosive arthritis. This divergence allows us to define how TCR signaling thresholds shape $CD4^+$ T cell fate and identify the minimum signaling needed to maintain tolerance and prevent arthritis.

Methods: SKG and YYAA mice were crossed to Nur77-eGFP reporter mice to quantify TCR signal strength during thymic development and in the periphery. We analyzed expression of Nur77-eGFP, inhibitory receptors, and TCR Vβ repertoire by flow cytometry in thymocyte subsets and peripheral $CD4^+$ T cells. Frequencies of anergic $CD4^+$ T cells ($CD73^+FR4^+$) were compared across genotypes. Functional signaling was assessed via calcium flux and phospho-flow (pERK, pS6) after stimulation.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

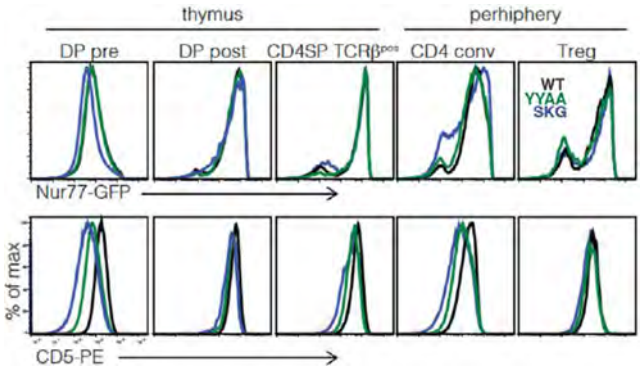

Figure 4. Nur77-eGFP and CD5 expression reveal genotype-dependent differences in TCR signaling across thymic and peripheral CD4$^+$ T cell subsets. Nur77-eGFP serves as a cumulative readout of integrated TCR signaling, while CD5 reflects proximal TCR signal strength. Histograms show expression of Nur77-eGFP (top) and CD5 (bottom) in pre-selection (DP pre; CD69loTCRβlo) and post-selection (DP post; CD69hiTCRβhi) double-positive thymocytes, CD4 single-positive thymocytes (CD4+TCRβpos), peripheral conventional CD4$^+$CD25$^-$ T cells (CD4 conv), and CD4$^+$CD25$^+$ regulatory T cells (Treg) from WTNur (black), YYAANur (green), and SKGNur (blue) mice. Data are representative of ≥ 2 independent experiments with 3 mice per genotype.

Results: Nur77-eGFP expression track with TCR signal strength and reveal genotype-dependent differences in self-reactivity (Fig. 1). In GFPlo thymocytes and peripheral naïve CD4$^+$ T cells, mean fluorescence intensity (MFI) scaled with ZAP70 function: WT > YYAA > SKG. In contrast, GFPhi CD4$^+$ T cells were more abundant in SKG, likely reflecting a more self-reactive repertoire (Fig. 2). Consistent with prior self-antigen encounter, GFPhi CD4 single-positive thymocytes and peripheral CD4$^+$ T cells in SKG and YYAA mice showed dampened signaling upon restimulation, including reduced calcium flux and pERK/S6. Repertoire analysis further supported increased self-reactivity in SKG: TCR Vβ chains recognizing endogenous retroviral superantigens—typically deleted in WT mice—escape deletion in SKG and, to a lesser extent, YYAA. This suggests impaired TCR signaling compromises central tolerance and permits expansion of autoreactive clones. YYAA retain similar or higher frequencies of CD73$^+$FR4$^+$ anergic CD4$^+$ T cells than SKG. Although GFPhi CD4$^+$ T cells from all genotypes upregulate inhibitory receptors (CD5, PD-1, LAG3, TIM-3, FR4), SKG show reduced expression of CD5, PD-1, and FR4 following peripheral self-antigen encounter. In contrast, YYAA more effectively induced these pathways.

Conclusion: TCR signaling strength controls the balance between deletion, anergy, and activation in developing and peripheral CD4$^+$ T cells. Hypomorphic ZAP70 mutations impair thymic selection—altering the TCR repertoire—and

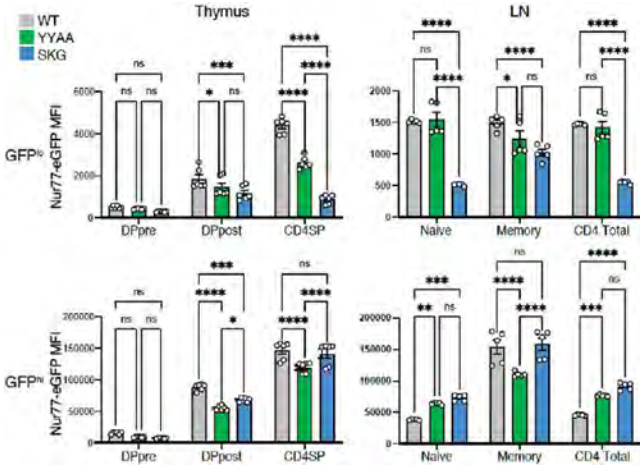

Figure 2. Nur77-eGFP expression in SKG peripheral T cells reflects their increased self-reactivity. Mean fluorescence intensity (MFI) of Nur77-eGFP was quantified in GFPlo (top panels) and GFPhi (bottom panels) thymocyte subsets (left panels; n = 6/genotype) and peripheral CD4$^+$CD25$^-$ T cells from lymph nodes (right panels; n = 5/genotype) in WTNur (gray), YYAANur (green), and SKGNur (blue) mice. GFPlo cells reflect basal/tonic TCR signaling, while GFPhi cells represent cells with higher self-reactivity. In the thymus, GFPlo MFI scales with ZAP70 function (WT > YYAA > SKG), whereas in the periphery, SKG mice exhibit increased GFPhi cells. Statistical significance determined by two-way ANOVA with multiple comparisons. ns: P > 0.05; *P < 0.05; **P < 0.01; ***P < 0.001; ****P < 0.0001. Data pooled from two independent experiments.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

peripheral tolerance. Our findings suggest anergy may serve as an additional central tolerance mechanism when deletion is inefficient. In SKG, defective peripheral tolerance permits self-reactive $CD4^+$ T cell activation and arthritis. In contrast, less impaired anergy and tolerance pathways in YYAA may restrain autoreactive T cells and prevent disease despite RF autoantibody production. These findings highlight a TCR signaling threshold that governs tolerance enforcement and autoimmune risk.

Repository Corticotropin Injection Reduces Inflammation and Bone Turnover Markers in the Murine CIA Model

Maripat Corr[1], Grace Hsueh[2], Aaron place[2], David Lucas[2] and NANCY LANE[3], [1]ucsd, San Diego, CA, [2]ANI Pharmaceuticals, Inc., Baudette, MN, [3]University of California at Davis, School of Medicine, Sacramento, CA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0049–0066) Rheumatoid Arthritis – Animal Models Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Melanocortin receptor agonists, such as adrenocorticotropic hormone (ACTH), are anti-inflammatory with pleotropic functions. We aimed to evaluate the effects of a repository corticotropin injection (RCI; ANI Pharmaceuticals, Inc.), a complex mixture of ACTH, ACTH related peptides and other porcine pituitary derived peptides, on the inflammatory response and bone damage in the mouse CIA model.

Methods: CIA was induced in six-week-old male DBA/1J mice by subcutaneous injection with CFA emulsified with chicken type II collagen, and IFA and collagen on day 21. Mice (n = 15-16 per group) received subcutaneous RCI (ANI Pharmaceuticals, Inc.; 40, or 400 U/kg twice daily), or vehicle days 21-35 (Figure 1A). Changes in hind paw thickness was measured with a caliper, and joints scored (28-point scale). Hind limbs (day 35) were imaged with a micro-computed tomography (CT) scanner, at 9 μm voxel size by standardized methods. Cortical bone analyses were performed on the femoral and tibial diaphysis. Each femur was analyzed at a region of interest 4500 μm proximal to the distal femur growth plate and extended 900 μm proximally. Each tibia was analyzed at a region of interest 4500 μm distal to the proximal tibial growth plate and extended 900 μm distally. CXCL-1 (KC), IL-6, P1NP, CTX-1, and anti-mouse CII antibody levels in sera were determined by ELISA. Statistical analyses were performed by ANOVA followed by post hoc tests.

Results: RCI administration resulted in dose-dependent decreases in ankle swelling in the 40 and 400 U/kg treatment groups compared to vehicle treated [AUC 2.90±39, 1.00±0.19, and 50±0.7, respectively; $F(13, 616)=24$, $P< 0.001$; Figure 1B] and similarly for clinical scores [AUC 47±5.3, 9.4±3.2 and 75±5.9; $F(13,616)=48.59$; $P< 0.0001$; Figure 1C]. There were no differences in the levels of anti-mouse type II collagen antibody generation between the vehicle, 40, or 400 U/kg treatment groups (67680±6637, 68670±8862, 59360±6768 arbitrary units, respectively; P=0.61; Figure 1D). There were lower levels of serum CXCL-1 in the 400 U/kg treatment compared to the vehicle treated group (P=0.016; Figure 1E) and lower levels of IL-6 (P=0.03; Figure 1F). Both serum levels of CTX-1 and PINP were significantly lower in the 400 U/kg treatment compared to the vehicle treated group (P=0.04; Figure 1G and P=0.02; Figure 1H, respectively). MicroCT measures of BV/TV, Tb.Th., and Tb.Sp. were similar between the groups; however, TMD was higher in both the

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

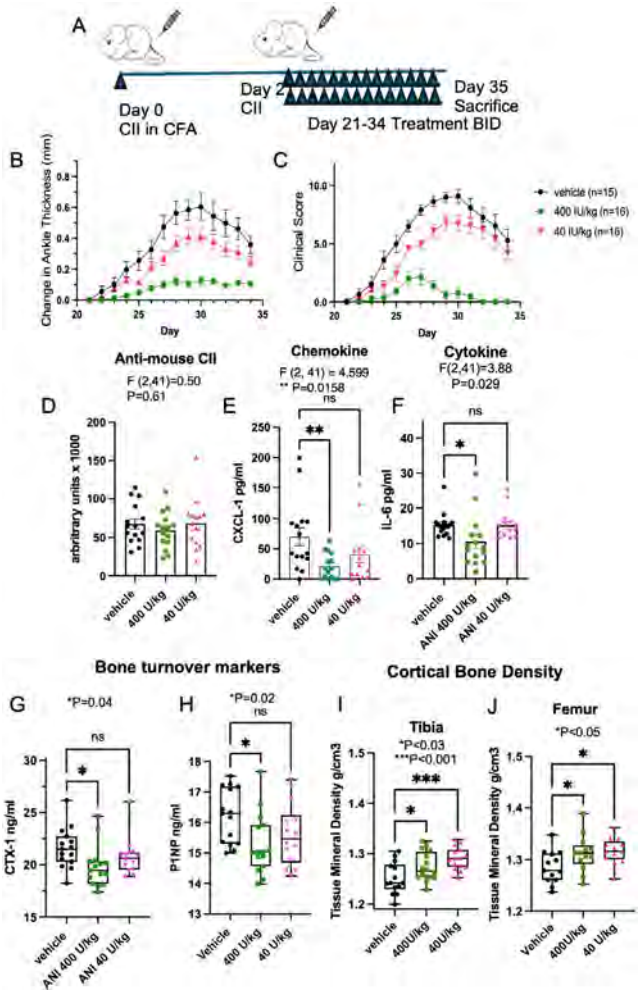

Figure 1. Effects of RCI on CIA. Schematic of experimental protocol (A). DBA/J mice were injected with type II chicken collagen in CFA on day 0 and in IFA on day 21. Starting day 21 mice received RCI or vehicle s.c. injections BID. The ankle widths of the mice were serially measured (B) and the joint inflammation scored (C) demonstrating a reduction in the RCI treated mice compared to vehicle treated. After 14 days of treatment the mice were sacrificed and serum obtained. There were no differences in anti-type II collagen antibody levels (D), but there were reduced serum levels of CXCL-1 (E), IL-6 (F), CTX-1 (G) and P1NP (H) in the 400 U/kg treatment group compared to the vehicle treated mice. Cortical bone density in the tibia (I) and femur (J) of RCI treated mice were greater than the vehicle treated mice.

tibia and femurs in the 40 U/kg and 400 U/kg treatment groups compared to the vehicle treated group ($P < 0.05$; Figure 1I and J).

Conclusion: As monotherapy, RCI significantly reduced CIA-induced joint swelling in male mice. In addition, RCI treatment resulted in a reduction in inflammatory cytokine responses, but no disruption of IgG formation and less bone loss. These findings demonstrate significant reductions in systemic inflammation in the CIA arthritis model with RCI treatment.

TNF Inhibition with Small-molecule Agents Results in Amelioration of Inflammation Similar to that of Anti-TNF Biologics While Preserving TNFR2 Signaling and Maintaining a Suppressive Regulatory T cell Phenotype

Rajesh Singh[1], Bindi Patel[2], Rameshwari Rayaji[2], Archana Sidalaghatta Nagaraja[2], Saranya Chandrasekar[2], Yihong Guan[2], Ritu Kushwaha[2], Yue Tong Lee[2], Cesar Meleza[2], Matthew Epplin[2], Brandon Rosen[2], Manmohan R Leleti[2], Matthew J Walters[2] and Daniel DiRenzo[2], [1]Arcus Biosciences, inc., Santa Clara, CA, [2]Arcus Biosciences, inc., Hayward, CA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0049–0066) Rheumatoid Arthritis – Animal Models Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Anti-TNF biologics are effective in the treatment of inflammatory diseases such as rheumatoid arthritis and psoriasis. However, they can lead to *de novo* inflammation occurrences, termed paradoxical adverse events, driven by inappropriate Th1/Th2/Th17 skewing and suboptimal function of regulatory T cells (Treg). Studies have reported that TNF blocking biologics downregulate both pro-inflammatory TNFR1 and anti-inflammatory TNFR2-mediated signaling. A TNF small molecule inhibitor that blocks pro-inflammatory TNFR1 signaling but spares beneficial TNFR2 signaling has been reported previously and may circumvent these shortcomings of biologic drugs. Herein, we describe the effects of TNF small molecule inhibitors on TNF-mediated inflammatory signaling, inhibition of TNFR1 vs TNFR2 signaling, Treg cell activity and control of murine arthritis.

Methods: NF-κB reporter-expressing HEK293 cells were used to measure cellular potency of TNF small molecule inhibitors. Soluble TNF trimer inhibition and IL-8 secretion were assessed in human umbilical vein endothelial (HUVEC) cells using ELISA and MSD assays. HeLa cells expressing a mutant non-cleavable TNF that allows expression of membrane TNF to activate TNFR2 signaling were generated. For measurement of TNFR1 and TNFR2-specific signaling, NF-κB reporter-expressing K562 cells were stimulated with soluble TNF and membrane TNF-expressing cells. Treg stability and function were evaluated using cytokine and phenotypic marker levels by flow cytometry. The collagen antibody-induced arthritis mouse model was used to demonstrate the activity of TNF signaling blockade.

Results: TNF small molecule inhibitors displayed a concentration-dependent reduction in soluble TNF/TNFR1-stimulated NF-κB activation in HEK293 cells and IL-8 production in HUVEC cells, equivalent to blockade using anti-TNF biologics. Using K562 cells pre-incubated with TNFR1-blocking antibody and co-cultured with membrane TNF-expressing cells, TNFR2-dependent NF-κB activation was retained with small molecule inhibitors but abolished using anti-TNF biologics. TNFR2 signaling has been established to promote Treg functionality *in vitro*. The proliferation of stable FoxP3^{high}Helios^{+} Tregs, and expression of suppressive cytokines IL-10 and TGF-β was retained using TNF small molecule inhibitors but impaired using an anti-TNF biologic. In a murine collagen antibody-induced arthritis model, TNF small-molecule inhibition showed equivalent disease suppression to an anti-TNF biologic but, interestingly, anti-TNF treatment led to enhanced circulating IL-17 levels in the biologic-treated group but not with small-molecule inhibition.

Conclusion: Taken together, these data demonstrate that TNF small-molecule inhibition is effective at inhibiting pro-inflammatory signaling and providing control of murine arthritis like anti-TNF biologics. We also show that TNF small-molecule inhibition has the potential to promote Treg stability and potentially circumvent paradoxical adverse events observed following anti-TNF biologic therapy.

Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Disease flares, or episodic escalating inflammation, is a hallmark of autoimmune diseases, like Rheumatoid Arthritis (RA). They are particularly hard to predict and treat and often signify an overall worsening of disease. The biologic mechanism underpinning disease flares is not well understood, potentially due to limitations of mouse models. Type 1 interferon (IFN) is thought to be a pathogenic cytokine in autoimmune diseases by pre-conditioning cells for hyper-reactive responses during episodic inflammatory challenges. However, type 1 IFN has not been investigated in an in vivo episodic inflammatory arthritis model. Therefore, we tested the hypothesis that loss of type 1 IFN will reduce the flaring inflammation in an episodic zymosan induced arthritis (ZIA) challenge.

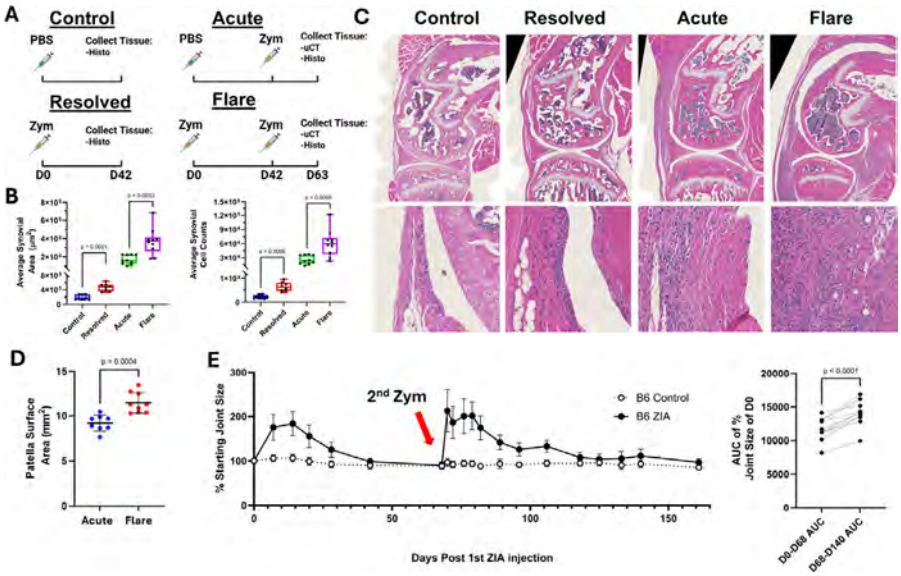

Figure 1. Episodic zymosan induces a joint flare. A) The study design. B) Average synovial area and cell counts via automated histomorphometry, each point is one knee average across 3 anatomic levels in the medial compartment, One-Way ANOVA with Tukey's Post-hoc. C) Representative images of Control, Resolved, Acute and Flare knees. D) uCT analysis of patella bone surface area, t-test. E) Joint widths percent of starting size over time with the 2nd Zym injection at D68 and AUC calculated from D0-D68 vs D68-D140 (right panel, paired t-test). Un-injected contralateral joints used as controls.

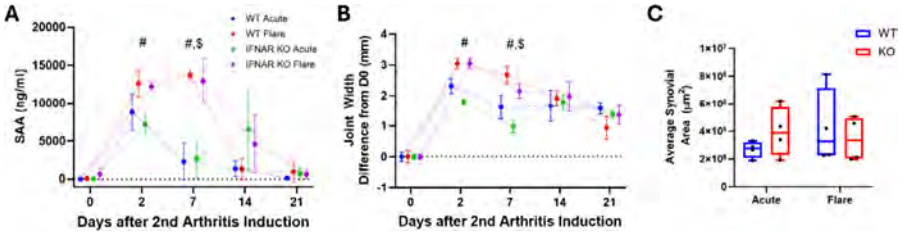

Figure 2. IFNAR1 KO does not modify the flare. A) Serum amyloid A concentration after 2nd ZIA induction at D42. B) Joint widths difference compared to D0 after 2nd ZIA induction at D42. # indicates p<0.05 IFNAR KO Acute vs IFNAR KO Flare; $ indicates p<0.05 WT KO Acute vs WT KO Flare in A and B, repeated one-way ANOVA with Tukey's post-hoc. C) Average synovial area in acute and flaring inflammation between WT and Ifnar1-/-. each point is one knee average across 3 anatomic levels in the medial compartment.

Methods: We performed intra-articular knee injections of 180 μg of zymosan (Zym) or PBS into female C57BL6 and IFN receptor 1 knock out (*Ifnar1-/-*) mice (n=4-10 per group). The same knees were then injected either 42 days or 68 days later with 180 μg of Zym (Fig1 A). Serial cheek bleeds for serum amyloid A (SAA) ELISA and joint widths were collected. After 21 days the mice were euthanized for joint μCT and histology. Patella surface was quantified and automated histomorphometry was performed to measure synovial area and cell counts within the synovium. ANOVA with Tukey's post-hoc, t-test or paired t-test were used to assess differences

Results: In clinically resolved joints, residual elements of synovial pathology were still modestly increased compared to PBS injected controls with some infiltrates and thickening of the synovial lining (Fig. 1B). Strikingly, flaring joints demonstrated a large increase (~2x) in synovial area and cell counts compared to acute inflammation controls demonstrating escalating inflammation after episodic zymosan challenges (Fig 1B-C). Patella surface area is also increased in flared joints suggesting increased bone metabolism (Fig 1D). When Zym was instead re-injected at D68, the trained phenotype persisted as demonstrated by the increased AUC of joint widths (Fig1 E). However, when *Ifnar1* null mice are re-injected at D42 there was no difference in SAA, joint widths or D21 synovial area compared to WT controls (Fig 2A-C).

Conclusion: Our results establish ZIA as a useful model for investigation of training and arthritis disease flare, and demonstrate that type 1 IFN does not play a role in changing joint inflammatory response to episodic zymosan challenges. This is in contrast with the known role of type 1 IFN in controlling many aspects of inflammation in acute and distinct episodic contexts. Further work to dissect mechanisms of training and the temporal and cell specific IFN responses to episodic inflammation is on-going.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic, systemic inflammatory disease that disproportionately affects females over males (3:1). Although sex-based immune differences have been documented, particularly in neutrophil effector functions, the molecular drivers of sex bias in RA remain unclear. Our lab previously implicated N-formylated peptides, danger-associated molecular patterns from bacteria and mitochondria, in RA pathogenesis via activation of formyl peptide receptor 1 (FPR1) on neutrophils. While the related receptor FPR2 regulates sex differences in steatohepatitis, whether FPR1 mediates sex-specific immune responses in arthritis is unknown.

Methods: Male and female C57/BL6 *fpr1*+/+ (WT) and *fpr1*-/- mice were intraperitoneally injected with K/BxN sera at days 0 and 2 for induction of inflammatory arthritis. Joint scores tracking arthritis were recorded by a blinded observer over 7 days. Joints and spleens were harvested for flow cytometry and cytokine expression, respectively. To assess the contribution of hematopoietic versus non-hematopoietic FPR1, bone marrow chimeras were generated by transplanting *fpr1*-/- marrow into irradiated WT male and female recipients, followed by arthritis induction and scoring over 8 days.

Results: FPR1 knockout and wild-type arthritic mice both showed elevated levels of N-formyl methionine in circulation (Figure 1A). Overall arthritis severity was similar between genotypes (Figure 1B). However, when stratified by sex, male *fpr1*-/- mice had worse arthritis than wild-type, while female *fpr1*-/- mice had improved disease (Figure 1C, 1D). There were no significant differences between male and female wild-type mice (Figure 1E). Flow cytometric analysis revealed increased immune cell infiltration in joints of male *fpr1*-/- mice, whereas no major differences were observed in females (Figure 2A-E) and qPCR showed increased TNFa in male KO mice (Figure 2F). To determine whether FPR1 in hematopoietic cells mediated these effects, we performed bone marrow chimera experiments. Female WT mice receiving *fpr1*-/- marrow showed no change in arthritis severity compared to controls (Figure 3A). In contrast, male WT mice receiving *fpr1*-/- marrow developed less severe arthritis than non-chimeric WT males (Figure 3B), suggesting that somatic (non-hematopoietic) FPR1 expression may drive joint inflammation in males.

Conclusion: FPR1 contributes to inflammatory arthritis in a sex- and compartment-specific manner. In females, FPR1 appears to promote inflammation, as its deletion is protective. In males, however, FPR1 deficiency paradoxically worsens arthritis—yet transfer of fpr1-/- bone marrow into WT male hosts reduces disease. These findings suggest that in males, FPR1 expression in non-hematopoietic tissues (e.g., joint stromal or endothelial cells) may exacerbate arthritis, whereas hematopoietic FPR1 may exert a protective effect. Together, our data support a model in which FPR1 plays dual, sex-dependent roles in arthritis pathogenesis, highlighting its potential relevance to understanding sex bias in RA and identifying tissue-specific therapeutic targets.

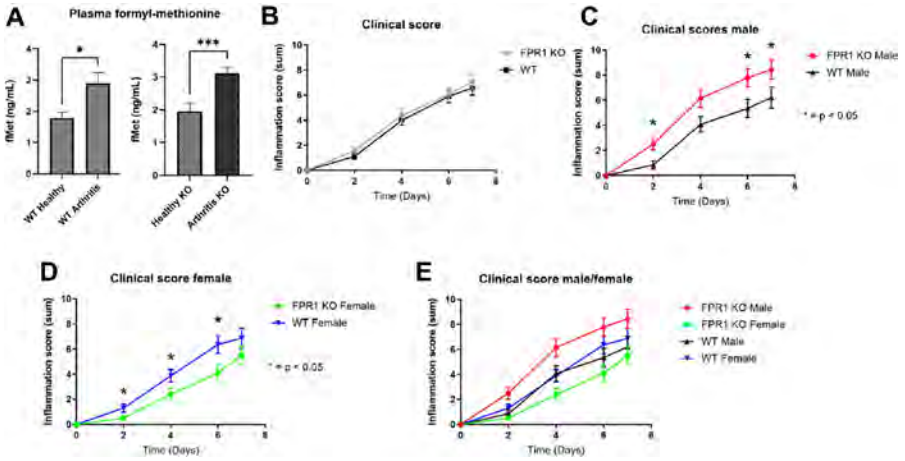

Figure 1. FPR1 worsens arthritis in males while improving arthritis in female mice. Eight to twelve-week-old mice were injected with serum from K/BxN mice on days 0 and 2. Plasma from C57BL/6 wild-type and fpr1-/- (KO) mice at day 0 (WT healthy, Healthy KO) and arthritic wild-type and KO mice at day 7 (WT arthritis, arthritis KO) was analyzed for formylated methionine (fMet) levels by ELISA (A). Mice were followed for 7 days and calculation of paw score (calculated by sum of all 4 paws on scale of arthritis 0-3) was recorded each day by blinded observer. Paw scores were evaluated by segregation by FPR1 genotype (B), genotype and male sex (C), genotype and female sex (D), and all sexes and genotypes (E). n = 10 - 15 mice for each group. * = $p < 0.05$ based on Mann-Whitney t-test.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

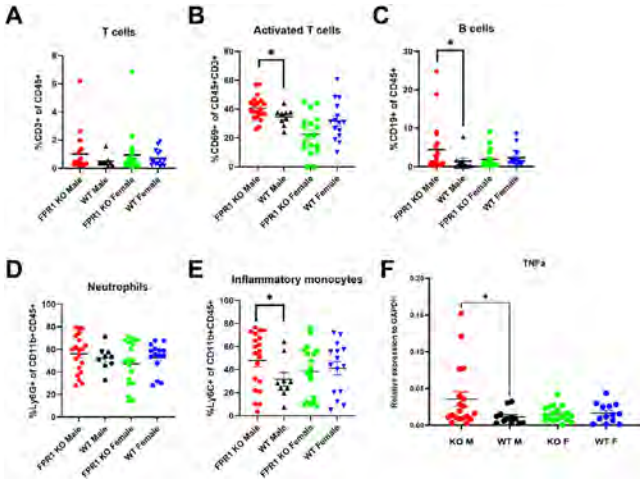

Figure 2. Immune cell infiltration and systemic inflammation are increased in a sex-specific manner mediated by FPR1. On day 7 after induction of serum transfer arthritis in male (M) and female (F) fpr1-/- (KO) and C57BL/6 (WT) mice, mice were sacrificed and one ankle joint was harvested and digested into single cell suspension for flow cytometry. Cells were first selected for CD45 positivity and then stained for markers of T cells (A), activated T cells (B), B cells (C), neutrophils (D), and inflammatory monocytes (E). After sacrifice on day 7, spleens were harvested from all mice for RNA extraction. Quantitative, reverse transcription real-time PCR for TNF-alpha was compared between KO and WT male and female animals (F). * = $p < 0.05$ based on Mann-Whitney t-test.

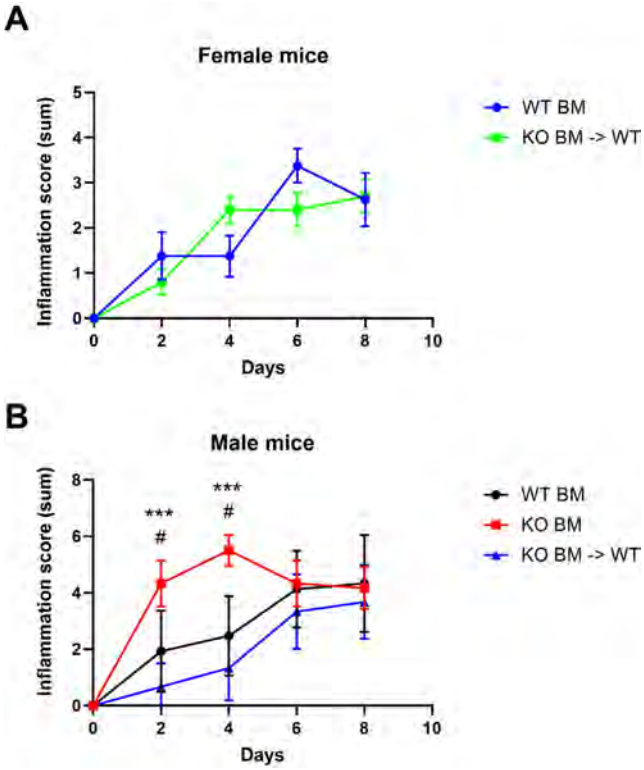

Figure 3. FPR1-deficient bone marrow protects against arthritis in male but not female mice. Arthritis was induced with K/BxN sera in female (A) and male (B) mice as in Figure 1. (A) Female WT mice (blue) were monitored for arthritis severity over 8 days. Bone marrow chimeras were generated by transplant of fpr1-/- bone marrow from female mice into lethally irradiated fpr1+/+ mice. Following engraftment, arthritis was induced with K/BxN serum (KO BM -> WT, green). (B) Similarly to (A), male WT and KO mice were monitored for arthritis severity over 8 days (black and red, respectively) and compared to arthritis development in bone marrow chimera (KO BM -> WT, blue) after successful engraftment and K/BxN sera injection.

Dietary Management of Rheumatoid Arthritis: A Functional Investigation of the Synbiotic Medical Food, SBD121

Ryan Green[1], Daniela Diaz-Infante Morales[1], Alicia Ballok[1], Kristine Kuhn[2], Christopher Ritchlin[3], Mark Charbonneau[1], Eric Schott[1] and Gerardo Toledo[1], [1]Solarea Bio Inc, Waltham, MA, [2]2022 - 2023 / Adult/ University of Colorado, Aurora, CO, [3]University of Rochester Medical Center, Canandaigua, NY

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0049–0066) Rheumatoid Arthritis – Animal Models Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA), affecting approximately 1% of the global population RA is a leading cause of disability worldwide. Despite available treatments, including methotrexate (MTX) and biologics, many patients fail to achieve lasting remission.

RA is associated with intestinal dysbiosis and increased intestinal permeability, two features that associate with local and systemic inflammation in RA. Certain probiotic strains have been shown to benefit patients with RA by reducing disease activity scores, indirect measures of increased intestinal permeability, and some pro-inflammatory measures. These observations highlight the potential of probiotics as a complementary approach for managing inflammation in RA.

To support RA management, we developed SBD121, a synbiotic medical food composed of plant-derived probiotics and prebiotic fibers. This study aimed to evaluate the preclinical efficacy of SBD121 in reducing RA severity, alone and in combination with MTX, as well as to explore its mechanisms of action *in vitro*.

Methods: We examined SBD121 in a collagen-induced arthritis (CIA) mouse model. Mice received SBD121 ($1x10^{10}$ colony forming units) or a water control via oral gavage twice daily for 42 days. Arthritis was induced 28 days after SBD121 initiation, followed by injection with MTX (5 mg/kg) or a vehicle control 3 times weekly. Joint swelling and clinical scores were assessed on days 18, 24, 28, 31, and 35.

To dissect SBD121's cellular effects *in vitro*, human intestinal epithelial cells and immune cells were exposed to SBD121. Barrier integrity (transepithelial electrical resistance), cytokine production (ELISA), and transcriptional responses (RT-qPCR) were measured.

Results: SBD121, co-administered with MTX, significantly reduced RA clinical scores relative to MTX + vehicle in a CIA mouse model. SBD121 alone did not affect clinical score relative to the CIA control.

In vitro, SBD121 improved intestinal barrier integrity without inducing inflammatory cytokine secretion; an effect associated with reduced systemic inflammation. SBD121 also reduced Th17-associated immune cell responses (IL-23, IL-6, IL-8, and CXCL1 secretion).

Conclusion: Here, we have demonstrated that SBD121 potentiates the effects of MTX in a CIA model of RA. Our *in vitro* results suggest that this synergy may be due to attenuated Th17 responses and/or improved intestinal barrier function. Ongoing studies aim to elucidate SBD121's specific effects on articular cells and determine the role of MTX in SBD121-influenced responses. The efficacy of SBD121 in combination with MTX in newly diagnosed RA patients is being evaluated in an ongoing double-blind placebo-controlled clinical trial (NCT06005220).

IL-22 Contributes to Autoantibody-induced Arthritis Via Modulation of Inflammatory Cytokine and Chemokine Expression in the Inflamed Synovium of a Murine Model

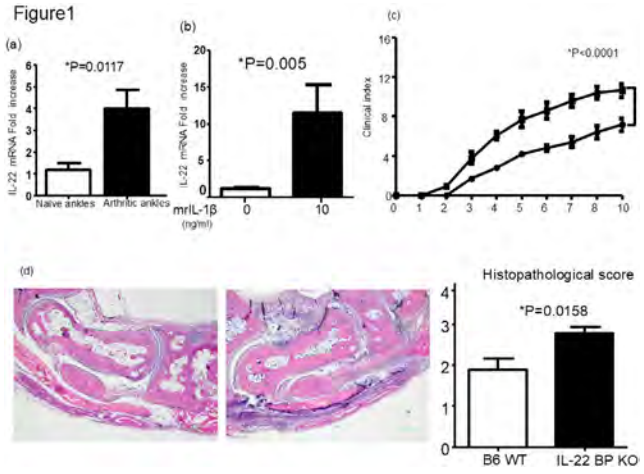
Shinjiro Kaieda[1], Suzuna Sugi[1], Takuma Koga[2], Takashi Kinoshita[1] and Tomoaki Hoshino[1], [1]Kurume university School of Medicine, Kurume, Japan, [2]Kurume Universty School of Medicine, Kurume, Japan

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0049–0066) Rheumatoid Arthritis – Animal Models Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: IL-22 is a key cytokine involved in modulating tissue responses during inflammation and is markedly upregulated in inflammatory diseases, such as psoriasis, inflammatory bowel diseases, and rheumatoid arthritis. IL-22 binding protein (IL-22BP) inhibits IL-22 signaling by binding to it, and treatment with IL-22BP reduces the severity of cutaneous inflammation in psoriatic mice (Front Immunol. 2018;9:1418). Several studies have shown that IL-22 is critical in the pathophysiology of collagen-induced arthritis (CIA), a condition mediated by cellular and humoral immune responses (Arthritis Rheum. 2009;60:390. Arthritis Rheum. 2014;66:1492). IL-22 deficient mice develop less severe arthritis, although the effectiveness of IL-22 neutralizing antibodies in the same models varies depending on the timing of administration. While IL-22 signaling is involved in animal models of CIA, its role in autoantibody-induced arthritis remains unclear. The K/BxN serum transfer model of autoantibody-induced arthritis reflects the effector phase of arthritis and is crucial for innate immunity but not for acquired immunity. This study aimed to assess the role of IL-22 pathway in autoantibody-induced arthritis using IL-22BP-deficient mice.

Methods: C57BL/6 IL-22BP gene-deficient (-/-) mice were subjected to K/BxN serum transfer to induce arthritis, and joint inflammation was assessed histologically in a blinded manner. Murine fibroblast-like synoviocytes (mFLS) were stimulated with recombinant mouse IL-1β or IL-22. mRNA expression levels of IL-22, CXCL1 and IL-1β were analyzed in cultured cells



IL-22BP deficiency exacerbates K/BxN serum transfer arthritis.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Inflammatory cytokines and chemokine expression in inflamed synovial tissue during K/BxN serum transfer arthritis.

IL-22 induces mFLS to produce inflamatory cytokine and chemokine.

using RT-PCR, while protein levels of IL-1β and CXCL1 were examined using ELISA. Additionally, synovial tissue expression of IL-6, IL-1β, TNFα, and CXCL1 mRNA was evaluated using RT-PCR.

Results: IL-22 mRNA expression was significantly elevated in inflamed synovial tissues of mice after K/BxN serum transfer arthritis induction (Fig. 1a). Consistent with *in vivo* data, mFLS can produce IL-22 mRNA after stimulation with recombinant IL-1β (Fig 1b). Disease severity was more pronounced in IL-22BP-/- mice than in wide-type (WT) controls (Fig. 1c). Histomorphometric analysis confirmed these observations, showing significantly higher histopathological scores in IL-22BP-/- mice (Fig. 1d). Consistent with these findings, the expression of pro-inflammatory genes, IL-1β, TNFα, IL-6, and CXCL1, was significantly upregulated in the inflamed synovium of IL-22BP-/- mice compared to WT controls (Fig. 2). Stimulation of mFLS with recombinant IL-22 led to increased expression of IL-1β and CXCL1 at both the mRNA and protein levels (Fig. 3a and b).

Conclusion: The IL-22/IL-22BP axis contributes to autoantibody-induced arthritis by modulating the expression of pro-inflammatory cytokines and chemokines. IL-22 directly induces mFLS to produce IL-1β and CXCL1, thereby exacerbating joint inflammation. Targeting IL-22 signaling may represent a promising therapeutic strategy for rheumatoid arthritis.

Abstract Number: 0062

Neddylation as a Therapeutic Target in Autoimmune Arthritis: Evidence from SKG Mice

Sho Sendo[1], Alfonso Del Peral Fanjul[2], Kazuma Nishisaka[2], Hirotaka Yamada[1], Takaichi Okano[1], Keisuke Nishimura[1], Yo Ueda[1] and Jun Saegusa[2], [1]Kobe University Hospital, Kobe, Japan, [2]Kobe University, Kobe, Japan

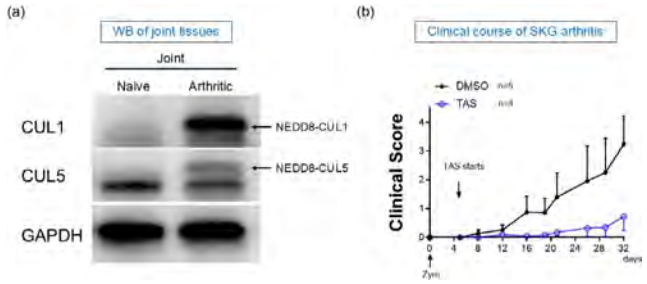
SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0049–0066) Rheumatoid Arthritis – Animal Models Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Neddylation, NEDD8 conjugating process, is a post-translational modification that plays a crucial role in regulating ubiquitination by targeting cullin (CUL)-ring E3 ubiquitin ligases. Our previous research indicated that neddylation is dysregulated in RA FLS, and that its inhibition can reduce arthritis severity in the K/BxN serum transfer model. However, the dysregulation of neddylation in SKG mice remains largely unexplored. This study aims to investigate whether neddylation is dysregulated in arthritic SKG mice and to evaluate its potential as a therapeutic target for arthritis.

Methods: Arthritis was induced in SKG mice through intraperitoneal injection of zymosan. The neddylation status of CUL1 and CUL5, and the relative gene expression of *Nub1* and *Csn1* in joint tissue were compared between arthritic and naïve SKG mice using Western blotting, and RT-qPCR, respectively. In vitro, we assessed the effects of the selective neddylation inhibitor TAS4464 on the induction and maturation of bone marrow-derived dendritic cells (BMDCs), on T cell proliferation, as well as on co-culture T cells with TAS4464-treated BMDCs.

Results: We first investigated the neddylation status in arthritic SKG mice and discovered that the neddylation of CUL1 and CUL5 was upregulated in the joints of arthritic SKG mice (**Figure a**). Gene expressions of *nub1* and *csn1*, negative regulators of neddylation, were decreased in arthritic SKG mice (*Nub1*: 1.03 ± 0.76 and 0.28 ± 0.12; p=0.019, *Csn1*: 1.06 ± 0.59 and 0.50 ± 0.34; p=0.029 for naïve mice and arthritic mice, respectively), which indicated that neddylation systems were dysregulated in the arthritic joints. Subsequently, we assessed the effects of neddylation inhibition on DC differentiation, maturation, and T cell proliferation. The neddylation inhibitor promoted the differentiation of PD-L1-positive DCs (78.7 ± 8.2 % and 91.1 ± 4.7 % for DMSO and TAS4464, respectively; p=0.021), reduced the maturation of MHC II-positive DCs (60.7 ± 10.3 % and 36.9 ± 10.6 % for DMSO and TAS4464, respectively; p=0.008) without altering PD-L1 expression, and had a trend to suppress T cell proliferation (37.8 ± 10.3 % and 13.6 ± 5.5 % for DMSO and TAS4464, respectively; p=0.058). Finally, we assessed the efficacy of neddylation inhibition on arthritis, and revealed the neddylation inhibitor alleviated arthritis severity in SKG mice (**Figure b**).

Conclusion: Upregulated neddylation in inflamed joints could be a novel therapeutic target in autoimmune arthritis.



(a) Representative images of western blotting of CUL1, CUL5 and GAPDH in the joints of naive and arthiritic SKG mice. (b) Clinical scores of zymosan injected SKG mice treated with TAS4464 or DMSO.

Abstract Number: 0063

Effect of alpha-ketoglutarate on Synovial Fibroblasts-Mediated Inflammation in Arthritis

Surabhi Gautam, Vinay Devulapalli, Akash Sathiyamurthi, Jayla Whittaker and Pallavi Bhattaram, Emory University, Atlanta, GA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0049–0066) Rheumatoid Arthritis – Animal Models Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) and related autoimmune joint disease patients exhibit cyclic episodes of resolution and exacerbation of joint inflammation, referred to as flares. Fibroblast-like synoviocytes (FLSs) that are epigenetically and metabolically transformed by chronic inflammation are implicated as the orchestrators of these flares. The tricarboxylic acid cycle (TCA) is the primary energy-producing metabolic pathway that occurs in the mitochondria. Biomolecules (enter the TCA cycle as acetyl-CoA to undergo a series of enzymatic reactions leading to the production of ATP. Another lesser investigated, but highly significant role of the TCA cycle is that its intermediate enzymatic byproducts, like alpha-ketoglutarate (AKG), enter the nucleus to function as an epigenetic modifier that has the potential to inhibit the expression of pro-inflammatory genes. We hypothesized that AKG can be developed as a drug to inhibit the deregulated metabolic and epigenetic state of the RA FLSs and effectively treat RA flares.

Methods: We isolated FLSs from the synovial joints of a transgenic mouse model of inducible human Tumor Necrosis Factor alpha expression (iTNF-tg). We further generated disease states equivalent to homeostasis, inflammatory, and resolution phases of arthritis pathology to mimic the characteristics of the flare pathology in RA patients. We studied the effect of AKG treatment on FLSs from various disease phases. Outcome measures included histological, immunohistochemical, ATP generation, gene expression, epigenetic regulation, cell cycle, and oxidative stress measurements.

Results: Our in vitro results in FLSs from the homeostasis, inflammatory, and resolution phase of the iTNF-tg mouse FLSs showed that AKG inhibited the expression of inflammatory genes. We utilized a luminescence-based assay to measure ATP and reactive oxygen species in live FLSs. Our data suggests that treatment with AKG inhibited the amount of ATP produced by FLSs from all stages. However, the anti-inflammatory and metabolic effects of AKG were maximal during the resolution phase. Our cell cycle analysis and found that AKG did not change the proliferation rate of FLSs. These results suggest that treatment with AKG inhibits inflammation and changes ATP production without altering cell proliferation. We will further discuss the results of our ongoing epigenetic and transcriptomic studies evaluating the in vivo effect of two different forms of dietary AKG treatment (cell-permeable and non-cell-permeable dietary forms) on the inflammatory arthritis features of the iTNF-tg mouse model.

Conclusion: AKG may inhibit RA FLSs' inflammation by downregulating pro-inflammatory gene expression. AKG may show its most effective inhibition of the pathological of RA FLSs during the resolution phase of the disease. Mechanistically, these inhibitory effects may act via blocking the NF-kappaB signaling pathway and cellular senescence pathways. AKG supplementation during the resolution phase of RA may serve as an effective co-treatment with current disease-modifying antirheumatic drugs to prevent the epigenetic deregulation of RA FLSs and thereby the onset of subsequent flares.

Abstract Number: 0064

Sclerostin from marrow adipogenic precursors is essential for bone and joint homeostasis in mice

Tailin He and Yifang Mei, Shenzhen Third People's Hospital, Shenzhen, China (People's Republic)

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0049–0066) Rheumatoid Arthritis – Animal Models Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: A novel mesenchymal subpopulation known as 'marrow adipogenic lineage precursors' (MALPs) has been identified, characterized by the expression of various adipocyte markers while lacking lipid droplets. Serving as precursors for lipid-laden adipocytes, MALPs are predominantly found as pericytes and stromal cells, creating a comprehensive three-dimensional network within the marrow cavity. Nevertheless, the precise mechanisms by which MALPs regulate bone and joint homeostasis under both physiological and pathological conditions remain elusive. Sclerostin serves as a significant inhibitor of bone formation, antagonizing Wnt/β-catenin signaling. Prior research has demonstrated that the use of neutralizing monoclonal antibodies against sclerostin has been shown to enhance bone mass and is being explored as a treatment for osteoporosis. However, it might increase the risk of cardiovascular diseases, potentially because sclerostin plays a role in protecting cardiovascular system. Conditional ablation of sclerostin in MALPs might increase bone mass and promote bone and joint homeostasis, while ameliorating the systemic side effects.

Methods: We assessed the bone mass of conditional knockout (cKO) mice and control mice at various ages utilizing micro-computed tomography (μ-CT), followed by histological analyses. Additionally, we evaluated the osteogenic potential of bone marrow stromal cells (BMSCs) derived from both cKO and control mice *in vitro*. Finally, we established two animal disease models to measure the bone and joint parameters across both groups.

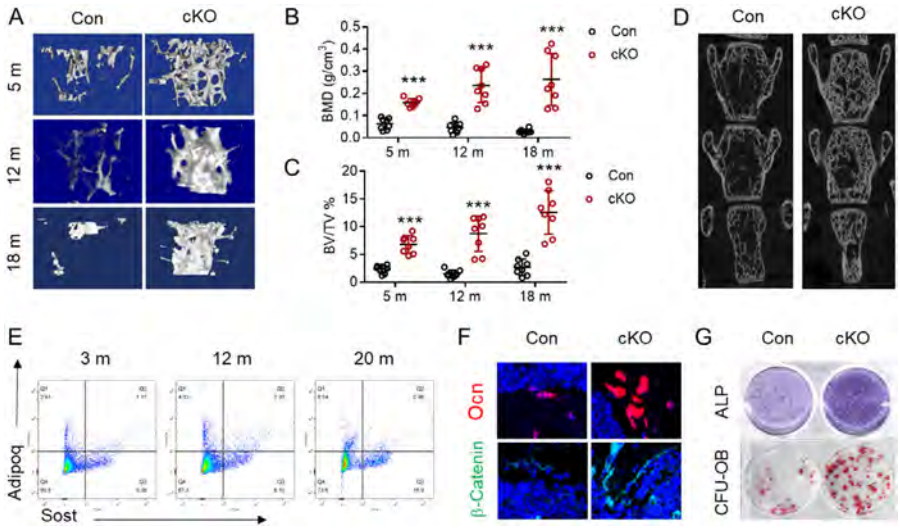

Figure 1. Bone marrow Adipoq+Sost+ cell subpopulation plays an important role in bone formation and BMSC osteogenic differentiation.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Depletion of Sost in MALPs ameliorates osteoporosis and rheumatoid arthritis in mice.

Results: μCT analysis of the skeletal structure indicated that cKO mice demonstrated an increase in bone mass at 5 months of age, particularly within the female group (Figure 1A-C). This phenotype became increasingly pronounced with advancing age. Notably, the spinal bone mass showed a significant increase at 18 months in cKO mice (Figure 1D). Simultaneously, we observed an increase in the proportion of Adipoq^{+}Sost^{+} cells as the mice aged (Figure 1E). Immunofluorescence staining revealed a higher presence of osteoblasts surrounding the trabecular regions, along with an elevated expression of active-β-catenin protein in the bone of cKO mice compared to controls (Figure 1F). The levels of osteogenic marker proteins were markedly enhanced in primary BMSC cultures derived from cKO mice (Figure 1G).

Subsequently, we assessed the impact of sclerostin deficiency in mice subjected to ovariectomy and a collagen antibody-induced arthritis model. The deletion of Sost in MALPs partially mitigated the osteoporotic characteristics associated with estrogen deficiency (Figure 2A, B). Additionally, Sost deletion alleviated the symptoms of collagen antibody-induced arthritis, including ameliorated joint swell (Figure 2C, D), bone erosion (Figure 2E), mechanical pain threshold (Figure 2F), and grip strength (Figure 2G).

Conclusion: We establish that the Adipoq^{+}Sost^{+} cell subpopulation within the bone marrow plays a vital role in the BMSC osteogenic differentiation. This distinct cell population in the bone marrow could serve as a valuable target for therapeutic interventions in osteoporosis and rheumatoid arthritis.

Background/Purpose: Patients with rheumatoid arthritis (RA) experience increased morbidity and mortality due to heart failure with preserved ejection fraction (HFpEF), a condition characterized by diastolic dysfunction largely driven by cardiac fibrosis. However, the underlying mechanisms of HFpEF in RA remain poorly understood. Recent studies from our group have identified the synergistic role of post-translational modifications (PTMs)—specifically citrulline (CIT) and malondialdehyde-acetaldehyde (MAA)—in promoting local inflammation and fibrosis in the joints and lungs of RA patients. Furthermore, these PTMs are increasingly expressed and co-localized in heart tissues of mice with early collagen-induced arthritis (CIA), indicating their potential role in promoting cardiac fibrosis and dysfunction. Therefore, the purpose of this study was to evaluate the temporal relationship between the cardiac expression of these PTMs and cardiac fibrosis in CIA mice.

Methods: Arthritis prone male DBA/1J mice were subjected to CIA (n=8) by standard protocols with saline injections used as control (n=6). Three mice per group were sacrificed at 5 weeks (early CIA) with the remainder sacrificed at 10 weeks (chronic CIA). Prior to being euthanized at 10 weeks, transthoracic echocardiography was performed to assess diastolic function (early to late transmitral diastolic flow [E:A] and myocardial relaxation [E':A'] velocity ratios) and systolic function (left ventricular ejection fraction %). Additionally, bovine serum albumin coupled to fluorescein isothiocyanate (BSA-FITC) was injected into the left ventricle immediately before sacrifice to visualize microvascular leakage. Hearts were resected and myocardial tissues were paraffin-embedded, sectioned, and stained with trichrome to quantify collagen deposition. Statistical comparisons of functional and morphologic features in CIA vs. control mice were performed using Student's t-test.

Results: Though CIT and MAA expression were increased and co-localized in heart tissues from mice with early CIA, (Zhou et al. ACR Convergence 2024, Abst 0032), there were no differences in myocardial collagen deposition in early CIA vs. control mice (**Fig. 1A**). In contrast, we observed significantly increased perivascular and interstitial collagen deposition in chronic CIA vs. control mice (**Fig. 1B**). Mice with chronic CIA also had increased microvascular leakage (**Fig. 2**), impaired diastolic function (**Fig. 3**), and diminished systolic function (**Fig. 3**) vs. controls.

Conclusion: This study is the first to demonstrate that an increase in CIT and MAA deposition in heart tissues precedes the onset of cardiac fibrosis, microvascular leakage and myocardial dysfunction in mice with CIA. Coupled with our recent studies revealing that CIT and MAA synergistically promote the activation of fibroblasts and endothelial cells in vitro, our findings

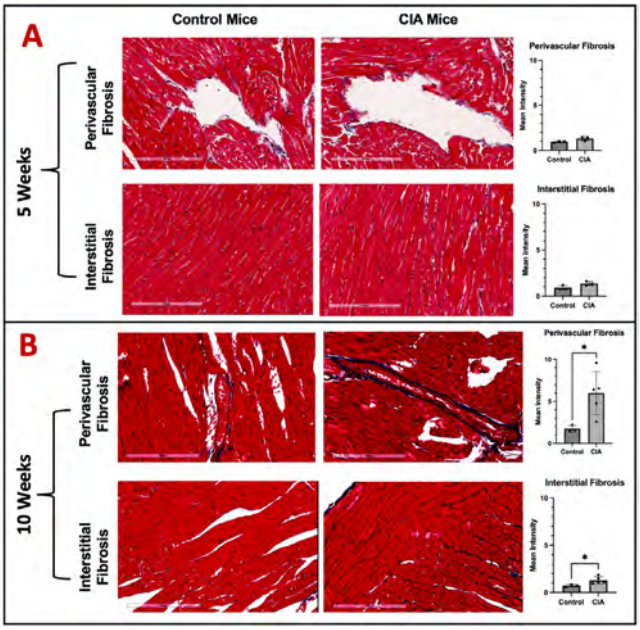

Figure 1. Trichrome Stain Demonstrated Increased Cardiac Fibrosis in CIA Mice at Week 10. Representative image of 20X frame at left ventricle was shown. White scale bar at the bottom indicates 200 μm. Tissue fibrosis (blue) was quantified for control and CIA mice A) 5 weeks and B) 10 weeks post injection. Data shown on graphs are mean ± standard deviation.

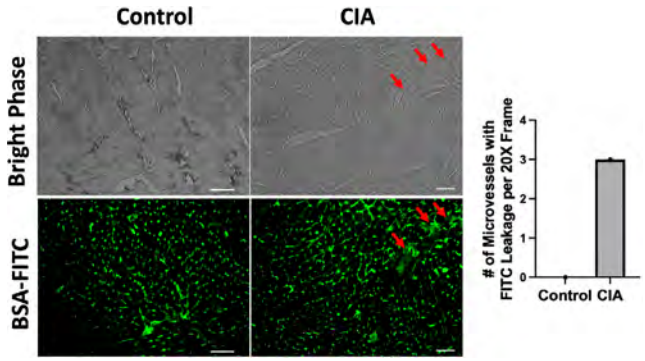

Figure 2. BSA-FITC Revealed Increased Microvascular Leakage in CIA Mice at Week 10. n=1 per group. Representative image of 20X frame at left ventricle was shown. Red arrow points to the sites of micro-vessels with FITC leakage. White scale bar at the bottom indicates 200 μm.

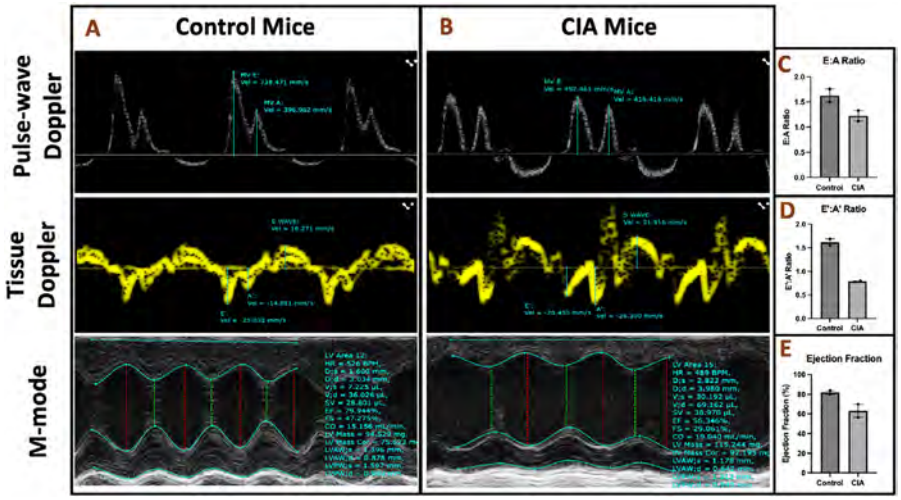

Figure 3. Echocardiography of Collagen Induced Arthritis (CIA) and Control Mice at Week 10. Echocardiography was performed on CIA (n=2) and saline-injected Control Mice (n=2) 10 weeks after the first injection. Raw Echocardiographic data was obtained using Pulse-wave, tissue Doppler, and M-mode, and representative images were shown for: A) Control mice; B) CIA mice. These images were used to measure C) E:A ratio, D) E':A' ratio, and E) Ejection fraction, respectively. Low E:A ratio and E':A' ratio (normal range 1.52 ± 0.40) indicates diastolic dysfunction, and low ejection fraction (normal range 71 ± 11) indicates systolic dysfunction. Data shown on graphs are mean ± standard deviation.

suggest that CIT and MAA together may be significant drivers of cardiac dysfunction in RA. Further research will explore whether inhibitors of CIT, MAA, or their downstream signaling pathways can attenuate cardiac dysfunction in RA.

RA-required synovial tissue-resident monocyte lineage cells are comprised of three distinct subpopulations.

Yidan Wang[1], Samuel Dowling[2], Jessica Maciuch[2], Vanessa Manada De Lobos[2], Meghan Mayer[2], Kainat Mian[1], Tyler Therron[3], Hadijat Makinde[1], Carla Marie Cuda[1], Deborah Rachelle Winter[4] and Harris R Perlman[1], [1]Northwestern University, Chicago, IL, [2]Northwestern University, Chicago, [3]Northwestern Feinberg School of Medicine, Chicago, IL, [4]Northwestern University, Skokie, IL

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0049–0066) Rheumatoid Arthritis – Animal Models Poster

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Tissue-resident monocyte-lineage cell (TRMC) are an extravascular population distinct from circulating monocytes and synovial macrophages and are critical for the development of inflammatory arthritis. Previous fate-mapping results demonstrated that TRMC are at least partially derived from the fetal liver and are traceable using various myeloid-related fate-mapping models, suggesting potential heterogeneity within this population. However, the precise identities and origins of TRMC subpopulations remain unclear.

Methods: We first measured the long-lived and bone marrow (BM)-derived TRMC in bone marrow chimeras (BMC) and parabiosis mice. Next, we used single-cell RNA-sequencing with surface marker detection (CITE-seq) to investigate the heterogeneity of TRMC during homeostasis and their dynamic changes after the synovial disruption induced by clodronate-laden liposome (Clo. Lip) and throughout the progression of RA-like disease in mice. To investigate the dependence of TRMC subpopulations on *Ccr2*, we utilized BMC and parabiosis mice models between CD45.1 B6 and *Ccr2*$^{-/-}$ mice.

Results: We characterized the ontogeny of TRMC, which comprises both bone-marrow (BM)-derived and long-lived populations. Furthermore, CITE-seq identified three TRMC subpopulations, distinguished by TIM4, CX3CR1, and MHCII surface marker expression, each exhibiting distinct functions. TIM4^{+}CX3CR1^{+} TRMC were enriched for pathways involved in synovial hemostasis, whereas MHCII^{+} TRMC were more enriched for inflammatory response pathways, with TIM4^{+} TRMC exhibiting functional features of both.

Clo. Lip modestly reduced the absolute number of TRMC but did not impact proportions or transcriptional profile of TRMC at 7 days post administration. Under steady state, TIM4^{+}CX3CR1^{+} and TIM4^{+} TRMC represented the long-lived population, whereas MHCII^{+} TRMC were BM-derived and dependent on *Ccr2*. During synovial inflammation, BM-derived TRMC expanded up to threefold at the peak of arthritis compared to baseline and replenished the TIM4^{+}CX3CR1^{+} and TIM4^{+} TRMC compartments. Additionally, TIM4^{+} TRMC underwent transcriptional and functional changes resembling MHCII^{+} TRMC during the peak and plateau stages of RA-like arthritis in mice.

Conclusion: These findings underscore the heterogeneity within TRMC and highlight their distinct responses to synovial disruption and potential roles in rheumatoid arthritis (RA). Future therapeutic target strategies should focus on TRMC by targeting their specific subpopulations.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0067–0097) Rheumatoid Arthritis – Etiology and Pathogenesis Poster

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Symptomatic rheumatoid arthritis-related interstitial lung disease (RA-ILD) is prevalent in about 10% of patients with RA and confers a higher mortality compared with RA patients without ILD. Anti-citrullinated protein antibodies (ACPAs) are strongly linked to RA-ILD, suggesting a pathogenic role for citrullinated proteins. Citrullinated histone H3 (Cit H3), a component of neutrophil extracellular traps (NETs), has been identified as a potential biomarker of RA-ILD. Our aim was to quantify and characterize Cit H3 expression in explanted lungs from patients undergoing lung transplant who have RA-ILD compared to patients with other connective tissue disease (CTD)-ILD or idiopathic pulmonary fibrosis (IPF).

Methods: Formalin fixed paraffin embedded explanted lung tissues were obtained from patients with RA-ILD (n=9), other CTD-ILD (n=4) or IPF (n=6). Deceased donor lungs without known pulmonary disease (HC, n=4) were used as controls.

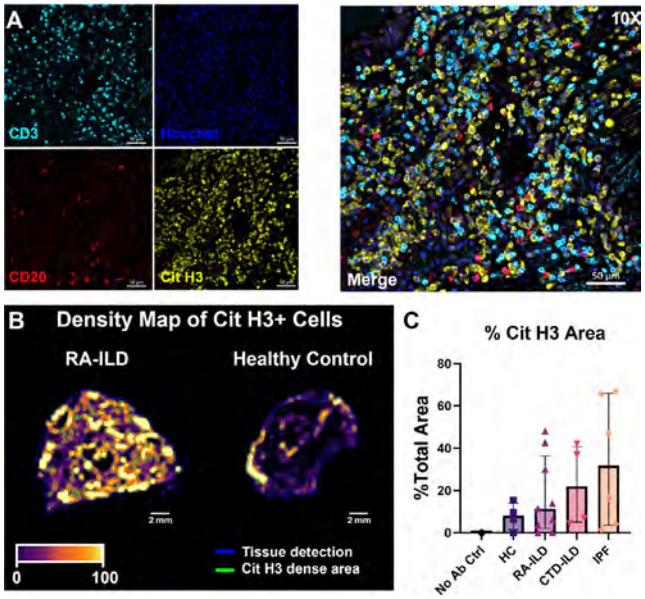

Figure 1: Density of Cit H3+ Cells in RA-ILD, CTD-ILD and, IPF explanted lungs. A) Representative immunofluorescence image of an FFPE section from an RA-ILD explanted lungs to show Cit-H3 (yellow), CD3 (cyan) and CD20 (red). B) Representative density maps of RA-ILD and HC lungs. Maps were generated based on raw cell counts in a 300 μm radius. The blue outline is the tissue based on Hoescht thresholding. The green outline is an area of Cit H3 density with greater than 46 Cit H3+ cells/300 μm radius. C) Percentage of Cit H3 dense areas represented by the Cit H3 dense area (green outline) divided by the total area of the tissue (blue outline). Data are represented as median ±IQR. Kruskal-Wallis test, p values <0.5 noted above columns.

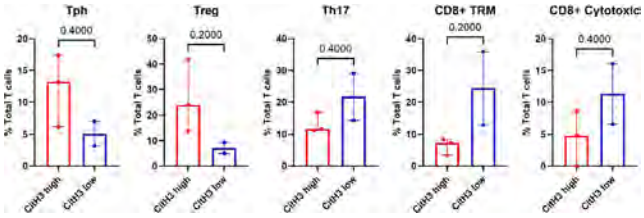

Figure 3: Frequency of T cell subsets based on single cell RNA sequencing of CD45+ immune cells from Cit H3 high and Cit H3 low RA-ILD lung explants. Percentages of T peripheral helper cells (Tph), regulatory T cells (Treg), T helper 17 (Th17) cells, T resident memory (TRM) CD8+cells and, cytotoxic CD8+ T cells in Cit H3 high (n=3) and Cit H3 low (n=2) RA-ILD lung explants. Data are represented as median ±IQR. Mann-Whitney test, p values <0.5 noted above columns.

Results: Cit H3+ cells were identified in explanted lungs with RA-ILD, other CTD-ILD and IPF. A subset of patients in each group had higher Cit H3 density in lung tissue (Fig 1C). In the RA-ILD samples, a portion of the Cit H3+ cells were also NE + indicating the presence of NETs. The average distance of Cit H3+ cells to the nearest CD3+ cells was shorter in RA-ILD (37 μm) vs HC (214 μm) (p=0.008) (Fig 2A). The closer proximity of Cit H3+ cells to CD3+ cells in RA-ILD was independent of the number of CD3+ or Cit H3+ cells present (Fig 2B-C). Single cell RNA sequencing from RA-ILD patients with Cit H3 high (n=3) vs Cit H3 low (n=2) samples revealed non-significant trends in T cell subsets (Fig 3). In the Cit H3 high vs low groups, there were higher percentages of T peripheral helper cells (median 13.2% vs 5.1%, p=0.4) and regulatory T cells (median 23.9% vs 7.3%, p=0.2) and lower percentages of helper 17 cells (median 11.8% vs 21.8%, p=0.4), T resident memory CD8+ T cells (median 7.3% vs 24.5%, p=0.2) and cytotoxic CD8+ T cells (median 4.8% vs 11.3%, p=0.4).

Conclusion: These findings suggest a role for NETs in RA-ILD, highlighting the potential interaction of T cells with NETs. Future direction includes single cell TCR sequencing and spatial transcriptomics to further explore the interplay between T cells and NETs and its impact on the pathogenesis of RA-ILD.

Abstract Number: 0068

Unique Fibroblast-like Synoviocyte Phenotype with Elevated MCSF Expression Induced by TLR5 Activation in Rheumatoid Arthritis

Aryan Patel[1], Osama Al Zoubi[2] and Shiva Shahrara[3], [1]University of Illinois at Chicago, Chicago, [2]University of Illinois at Chicago, Chicago, IL, [3]University of Illinois, Chicago, IL

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0067–0097) Rheumatoid Arthritis – Etiology and Pathogenesis Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disease affecting approximately 1% of the global population, causing significant morbidity and disability. Fibroblast-like synoviocytes (FLS) are key effector cells in RA, contributing to inflammation and exhibiting invasive properties that facilitate joint damage. Despite extensive research, the underlying pathophysiology and immunometabolic dysregulation in RA remain incompletely understood.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. qPCR Data and Heat Map for Gene Markers

Methods: This project aimed to investigate the immunometabolic reprogramming resulting from Toll-like receptor 5 (TLR5) pathway activation in RA FLS, uncovering cellular markers of reprogrammed FLS and exploring cellular crosstalk mechanisms between RA FLS and peripheral blood mononuclear cells (PBMCs). RA FLS were isolated from fresh synovial tissue and treated with flagellin (TLR5 ligand) or PBS (control) for 6 or 18 hours. Gene expression analysis was performed using quantitative reverse transcription polymerase chain reaction (qRT-PCR) and RNA sequencing to assess the change in key inflammatory and cellular markers.

Results: TLR5-activated RA FLS exhibited a unique RSPO3^high/THY1^low signature, characterized by significantly higher expression of RSPO3 (RNA-seq Log2 FoldChange: 3.34, p< 0.0001; qPCR: Mean Fold Change: 7.370, p=0.016), while CD90 (THY1) expression remained unchanged (RNA-seq Log2 FoldChange: -0.16, p=0.15; qPCR: Mean Fold Change: 1.079, p=0.6276). This RSPO3/THY1 phenotype exhibited a significantly higher expression of IL-6 and CCL2, qPCR: 6.31 and 10.05, respectively, supporting its proinflammatory role in the RA joint environment. Additionally, this phenotype was associated with significantly increased expression of Macrophage colony-stimulating factor (MCSF/CSF1) (RNA-seq Log2 FoldChange: 1.84, p< 0.0001; qPCR: Mean Fold Change: 4.959, p=0.0080).

Conclusion: Publicly available single-cell RNA sequencing databases further revealed that CSF1 is almost exclusively expressed by fibroblasts, while CSF1R is nearly exclusively expressed by macrophages, indicating a paracrine axis of fibroblast–macrophage communication that may be central to inflammation and tissue remodeling in RA. This was in contrast to CSF2 and CSF3, which were not significantly expressed in RA FLS.

In conclusion, we have identified a distinct RSPO3^high/THY1^low RA FLS phenotype with elevated CSF1 expression, suggesting a functionally reprogrammed subset of FLS with pro-inflammatory and pro-osteoclastogenic potential. RSPO3, a

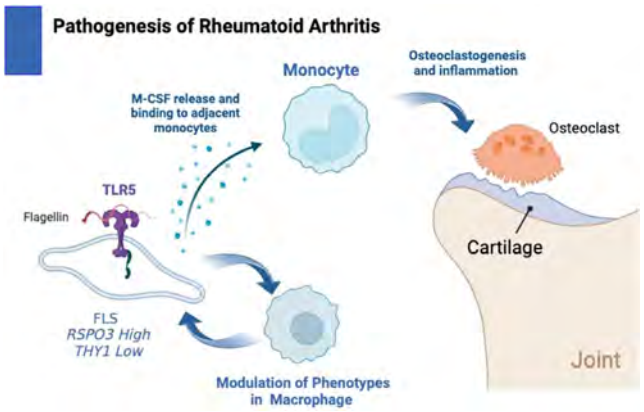
Cell Locations and Heat Map Expression for Unique Phenotype and M-CSF



Pathogenisis Diagram

potent enhancer of Wnt signaling, has been previously reported to be upregulated in the synovium of RA patients and experimental arthritis models. Our study provides insights into the role of TLR5 in activating this invasive phenotype, which may play a crucial role in RA pathogenesis through CSF1-mediated interactions with macrophages, potentially influencing osteoclast differentiation. These findings enhance our understanding of RA pathophysiology and direct us to explore potential interventions to target this fibroblast subset.

Session Title: (0067–0097) Rheumatoid Arthritis – Etiology and Pathogenesis Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: RA synovium displays cellular heterogeneity, with gene expression driving disease pathogenesis. Unbiased cell-specific transcriptomes in RA synovium have previously relied primarily on disaggregated tissues to understand these pathogenic processes, however, this approach can cause cell loss and gene induction. Therefore, we interrogated RA and OA synovial tissue using spatial transcriptomics to investigate spatial and cell-type differences, focusing on lining and sublining regions segmented into fibroblasts and macrophages.

Methods: Fresh frozen synovial tissues from 7 RA and 8 OA patients were prepared for the NanoString GeoMX DSP Whole Transcriptome Assay. Lining and sublining regions were segmented to fibroblasts (vimentin+ CD68-) and macrophages

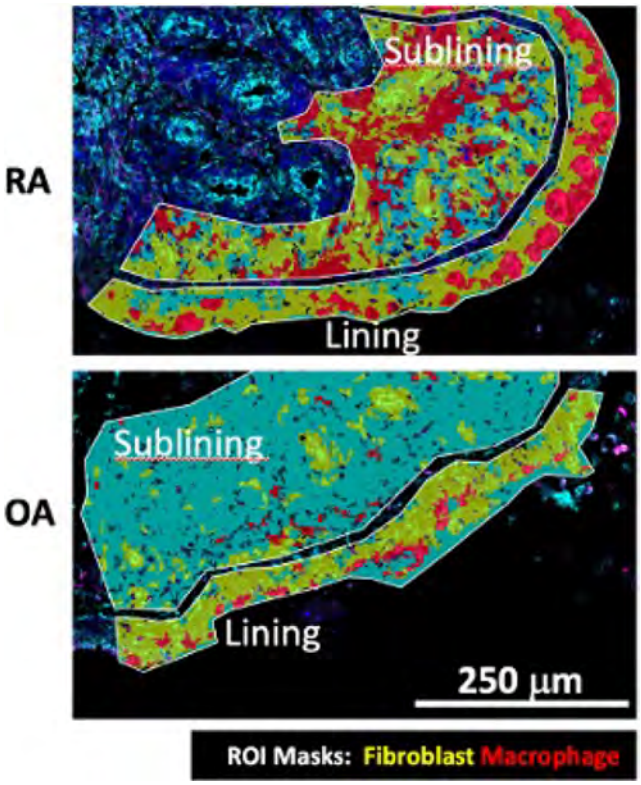

Figure 1. Spatial transcriptomics analysis using NanoString GeoMX DSP Whole Transcriptome Assay. Panel shows examples of RA and OA synovial tissues stained and visualized for fibroblasts (vimentin; yellow-green) and macrophages (CD68; red). The lining and sublining regions were identified as regions of interest (ROI) to quantify gene expression normalized to cell lineage.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

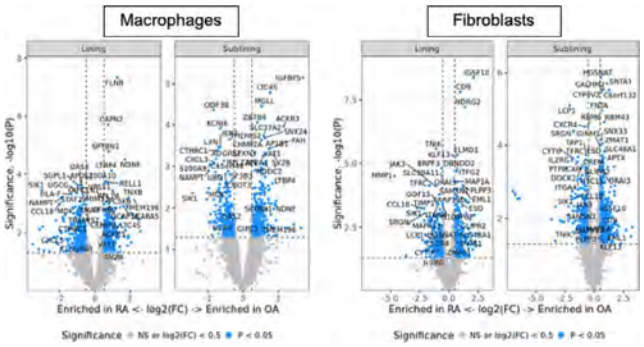

Figure 2. Volcano plots of differentially expressed genes between OA and RA groups for macrophages and fibroblasts in lining and sublining regions. DEGs were identified using linear mixed models (LMM) with a significance threshold of p-value < 0.05 and log2(FC) > 0.5. DEGs in blue are significant genes enriched in RA or OA.

Table 1. Different enriched pathways in lining and sublining fibroblasts from synovial tissue of patients with RA versus OA. Pathways highlighted in bold represent those related to the adaptive immune system. The Reactome pathway analysis was performed using differentially expressed genes in the RA versus OA in lining and sublining fibroblasts (p<0.05). The table displays only pathways that were significantly enriched exclusively in either lining or sublining fibroblasts.

Regions	Representative Enriched Pathways
Lining Fibroblasts (RA vs OA)	• Degradation of ECM • Chemokine receptors bind chemokines • Collagen degradation • IL-10 signaling • Interferon signaling • IL4 and IL13 signaling
Sublining Fibroblasts (RA vs OA)	• **Antigen processing cross-presentation** • **Antigen presentation: folding, assembly and peptide loading of class I MHC** • **Phosphorylation of CD3 and TCR zeta chains** • **Translocation of ZAP-70 to the immunological synapse** • **IL-2 signaling** • **PD-1 signaling** • **Immunoregulatory interactions between lymphoid and non-lymphoid cells** • Platelet activation signaling and aggregation • Elastic fibre formation • RAC1 GTPase cycle

(vimentin– CD68+) (Fig.1). NovaSeq 6000 was used for sequencing. 121 segments passed QC, with 10,363 genes detected and Q3-normalized. A logistic regression (LR) classifier was trained on principal components to find the top 500 genes separating RA from OA. Differentially expressed genes (DEG) were analyzed by linear mixed models (p-value< 0.05 and log2(FC) >0.5), and Reactome pathway analysis (FDR< 0.02).

Results: LR models separation RA from OA found discriminative genes enriched in inflammation and tissue remodeling pathways (e.g., TNF/IL17/IFN signaling, ECM). DEG analysis showed distinct RA vs OA gene signatures across regions and cell types (Fig.2). RA lining fibroblasts had 700 DEG compared with OA lining, with enrichment for 18 pathways that were focused on inflammation and matrix regulation (see Fig.3). RA sublining fibroblasts showed 834 DEG with OA sublining, with enrichment for 29 pathways. Although some inflammatory pathways were identified, sublining fibroblasts also included multiple pathways related to regulation of adaptive immunity (see Fig.3). Spatial comparisons between lining and sublining in RA showed that lining fibroblasts displayed 1176 DEG with 37 enriched pathways, including RAC1 GTPase cycle, collagen biosynthesis/modifying enzymes, and post-translational protein phosphorilation. Therefore, RA lining fibroblasts display a highly activated phenotype compared with sublining cells and help define the aggressive biology of fibroblast-like synoviocytes which are a hallmark in RA. RA lining macrophages showed 628 DEG compared to OA lining, enriched for 60 pathways (e.g., ECM organization, IFN gamma signaling, translation). Surprisingly, even though RA sublining macrophages had 672 DEGs compared to OA, they were only enriched in 2 pathways, suggesting that the differences are random and that sublining macrophages in RA might not drive pathology.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Spatial transcriptomic analysis reveals distinct region- and cell-type-specific transcriptional profiles distinguishing RA from OA synovium. Regional analysis identifies niche-specific fibroblast functions related to inflammation in the lining and adaptive immunity in the sublining were identified, which could help identify subsets as therapeutic targets for patient-specific mechanisms of disease.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0067–0097) Rheumatoid Arthritis – Etiology and Pathogenesis Poster

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: The analysis of synovial tissue has been instrumental in advancing our understanding of Rheumatoid Arthritis (RA) pathogenesis. As an alternative, the identification of serum biomarkers that mirror synovial activity offers a promising and less invasive strategy for diagnosing and monitoring RA. This approach could address existing challenges and significantly enhance the implementation of precision medicine in the management of RA. The objectives of this study were: 1- To characterize synovial tissue-secreted proteins in early RA patients that contribute to serum inflammatory profiles, 2- To identify subsets of early RA patients with distinct serum levels of the protein signature and evaluate their association with disease activity and clinical response to conventional DMARDs (cDMARDs).

Methods: Synovial explants obtained via ultrasound-guided biopsies from 15 early RA patients were cultured *in vitro* for 24 hours to profile secreted proteins using proximity extension assay (PEA) technology (Olink), targeting 92 inflammation-related proteins. Proteomic profiles were also evaluated in serum samples from the same subjects, and correlation studies

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

were performed. Validation of the identified protein signature was performed in an independent cohort of 86 early RA patients, aiming to assess its association with clinical response to cDMARDs.

Results: Eleven synovial-secreted proteins (CXCL6, CXCL9, CXCL11, DNER, FGF-5, IL1α, MCP-1, βNGF, STAMBP, TNF, TNFβ) showed significant correlations with their serum levels in early RA patients. These proteins are involved in biological processes closely linked to RA pathophysiology, such as cell proliferation, cytokine/chemokine signaling, neutrophil chemotaxis and inflammation. Clinically, higher levels of this inflammatory signature were observed in RA patients with active disease, elevated acute-phase reactants and high titres of autoantibodies.

Unsupervised clustering in an independent cohort of 86 early-stage RA patients treated with cDMARDs identified two patient groups with distinctive baseline serum protein profiles. The group with higher levels of the inflammatory signature exhibited higher disease activity and a better clinical response to cDMARDs after 6 and 12 months of treatment. Machine learning algorithms identified clinical and molecular signatures as potential predictors of response to cDMARDs treatment with high accuracy, which was further increased when both features were integrated in a mixed model (AUC: >0.8).

Conclusion: This study identifies a synovial tissue–secreted protein signature that contributes to both the circulating inflammatory profile and clinical characteristics of early RA patients. This signature stratifies early RA patients into subgroups with distinct clinical responses, demonstrating its potential as a robust predictor of therapeutic response to cDMARDs. These findings underscore the value of serum biomarkers reflecting the molecular profile of the synovium to advance personalized medicine in RA.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0067–0097) Rheumatoid Arthritis – Etiology and Pathogenesis Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: This study aimed to identify shared and distinct gene and protein expression profiles associated with clinical features in rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), and SLE with antiphospholipid syndrome (SLE+APS) patients, using integrated multimodal analyses.

Methods: Advanced computational approaches combined clinical data, transcriptomic profiles from peripheral blood mononuclear cells (RNA sequencing), and serum proteomic profiles (proximity extension assays) in 257 RA and 66 SLE patients (20 with SLE+APS). Transcriptomic data were processed and normalized, followed by gene set variation analysis (GSVA) for pathway-level changes. Unsupervised hierarchical clustering identified patient subgroups and gene modules. Correlation analyses explored associations between gene modules, inflammatory protein profiles, and clinical parameters.

Results: Clustering identified three clusters with unique gene expression patterns across 11 gene modules, reflecting different biological pathways. Clinically, C1 was linked to increased cardiovascular (CV) risk in RA and higher disease activity / renal involvement in SLE. C2 exhibited high disease activity and lung involvement in RA and increased CV risk in SLE. C3 showed an intermediate profile, with autoantibody positivity and significant renal involvement, thrombosis and abortions in SLE+APS.

Molecularly, C2 had heightened activity in myeloid cells and inflammation; C1 and C3 displayed increased T and B cell activity. Integrin-mediated cell adhesion pathways were commonly altered. Proteomic analysis supported these findings, revealing the greatest inflammatory protein changes in C2. Correlation analyses revealed relationships among modules related to myeloid cell activity, cell adhesion, inflammation, and T-cell activation correlating with several cytokines and chemokines. Specifically, the IFN response module linked with high IFN-gamma, CXCL10, and MCP-2 levels, while cell adhesion modules connected to several chemokines. Reduced T and B cell activity correlated negatively with increased levels of inflammatory proteins, suggesting different sources of inflammation and immune dysfunction.

Shared genomic modules correlating with clinical profiles included cell cycle regulation with disease activity in RA and SLE, integrin-mediated cell adhesion with CV risk in RA, and myeloid cell activity with CV risk in SLE. Distinct correlations included inflammatory networks and IFN response with disease activity in RA and CV risk in SLE, T cell activity negatively with activity in RA and B cell activity with lung involvement in RA.

Conclusion: Overall, our integrated analysis reveals distinct transcriptomic clusters and molecular heterogeneity in RA, and SLE, driven by inflammation and immune dysregulation. These findings highlight both shared and disease-specific molecular signatures associated with clinical manifestations, providing insights into disease mechanisms and potential therapeutic targets.

Session Title: (0067–0097) Rheumatoid Arthritis – Etiology and Pathogenesis Poster

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Therapeutic advances in RA have introduced effective treatments, including b/tsDMARDs such as Baricitinib. However, its cardiovascular safety profile remains unclear, partly due to the limited scope of existing studies, limiting its optimal positioning within treatment strategies. This study's objective was to conduct clinical-molecular analyses to elucidate the effects of Baricitinib (4mg/day) on the proinflammatory, prothrombotic, and cardiovascular risk profiles of RA patients, in comparison with TNF inhibitors (TNFi) and cDMARDs

Methods: A longitudinal, prospective study was conducted in three RA patient cohorts (n=25 each) who received standard-dose treatment with cDMARDs, TNFi or Baricitinib. All had moderate-severe disease activity (DAS28≥3.2), inadequate response to methotrexate and were naïve to b/tsDMARDs. A control group of 25 age- and sex- matched healthy donors was included.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Clinical-demographic data were collected at baseline and after 6 and 12 months. Carotid ultrasound evaluated atherothrombotic risk.Blood samples were obtained to isolate serum, plasma and monocytes prior to and after treatment. Consequent analyses included: screening for hypercoagulability-associated polymorphisms (Factor V Leiden and prothrombin); quantification of prothrombotic markers (D-dimer, prothrombin F1+2 and TAT complex); transcriptomic monocyte profiling via RNA-seq;and serum proteomic analysis of 276 inflammation- and CV-related proteins using proximity extension assay (Olink/Cobiomic)

Results: At baseline, disease activity was comparable across groups. All treatments led to significant improvements at 6-12 months, although Baricitinib demonstrated superior clinical efficacy, achieving the highest remission rates at both timepoints. Patients exhibited a baseline hypercoagulable state, although all therapies reduced D-dimer levels supporting their capacity to attenuate prothrombotic activity. Genetic hypercoagulability variants were infrequent, while carotid plaque prevalence and traditional CV risk factors were similar among cohorts.

Transcriptomic analysis showed that each therapy induced distinct gene expression changes, with shared effects on inflammation, interferon response and cell metabolism. Proteomic profiling revealed broad molecular shifts, with Baricitinib altering 68 proteins, TNFi 38, and sDMARDs 39. Common changes involved inflammation and vascular remodeling, while Baricitinib uniquely regulated 51 proteins related to cytokine signaling, angiogenesis, and matrix remodeling. Several modulated genes and proteins were linked to known CV risk markers. However, the unique molecular shifts highlight the differential impact of each treatment on CV risk

Conclusion: Baricitinib showed superior clinical efficacy, with higher rates of sustained remission beyond one year. Molecular studies suggest it not only does not increase CV risk but may confer beneficial effects by normalizing gene and protein profiles linked to elevated CV risk.

Background/Purpose: Anti-citrullinated protein antibodies (ACPAs) in rheumatoid arthritis (RA) can be promiscuous, with cross-reactive binding to many antigens containing short motifs, or more private with little cross-reactivity. Also, ACPA reactivity patterns differ among people with RA, including for motif-containing epitopes in important self-antigens like type II collagen and IgG (the latter of which is bound by RA-associated rheumatoid factors, RFs), with limited understanding of the underlying mechanism. The objective of this study was to determine if HLA alleles associate with ACPA reactivity patterns.

Methods: For 100 ACPA+RF+ RA participants, serum IgG binding was quantified by enzyme-linked immunosorbent assay to five citrulline-containing peptides derived from type II collagen (all with citrulline-glycine motifs) and five citrulline-containing peptides derived from IgG1 (four with citrulline-serine motifs). Also, antibody and serum multi-reactivity were evaluated. HLA loci were genotyped, and HLA alleles present differentially in RA participants with high versus low IgG binding to specific peptides as well as with multi-reactivity versus limited reactivity were identified by Fisher's exact test.

Results: Serum IgG multi-reactivity for citrulline-glycine motif-containing collagen peptides was high, at least partially due to promiscuous antibodies. HLA-DQA1*01:02 was present in more participants with anti-citrullinated collagen antibodies and sera multi-reactive with the collagen peptides. In contrast, serum multi-reactivity was low for IgG1-derived peptides due at least in part to more private antibodies. Shared epitope-containing HLA-DRB*04:01 and HLA-DRB*10:01 were present more frequently in participants with some RA-associated RFs that bind citrulline-containing IgG epitopes, irrespective of a citrulline-serine motif. Several HLA alleles associated with specific IgG reactivities.

Conclusion: These findings suggest that specific HLA alleles may contribute to the different reactivity patterns of promiscuous anti-citrullinated collagen antibodies and more private RA-associated RFs. Moreover, to the best of our knowledge, these findings provide the first evidence for a role for HLA-DQA1*01:02 in RA as well as the first HLA association with autoantibody multi-reactivity.

Background/Purpose: RFs are polyclonal autoantibodies which bind the Fc domain of IgGs. Patients with RA and high RF levels experience reduced serum drug concentrations and disease control when treated with Fc-containing biological

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

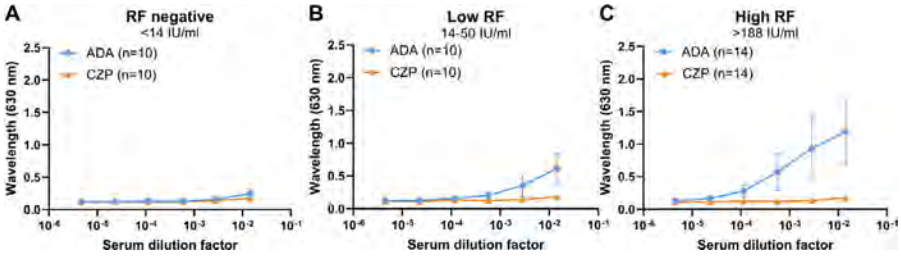

Figure 1. In RA patient sera, RFs bound to Fc-containing ADA but not Fc-free CZP. ELISA assays showed (A) no detectable binding of RF IgM in RF negative (<14 IU/mL) patient sera to ADA (blue) or CZP (orange), (B & C) binding of RF IgM in low RF (14-50 IU/mL) and high RF (>188 IU/mL) patient sera to ADA (blue) but not to CZP (orange). (n=10-14/patient group; n=2 independent experiments; mean±SD)

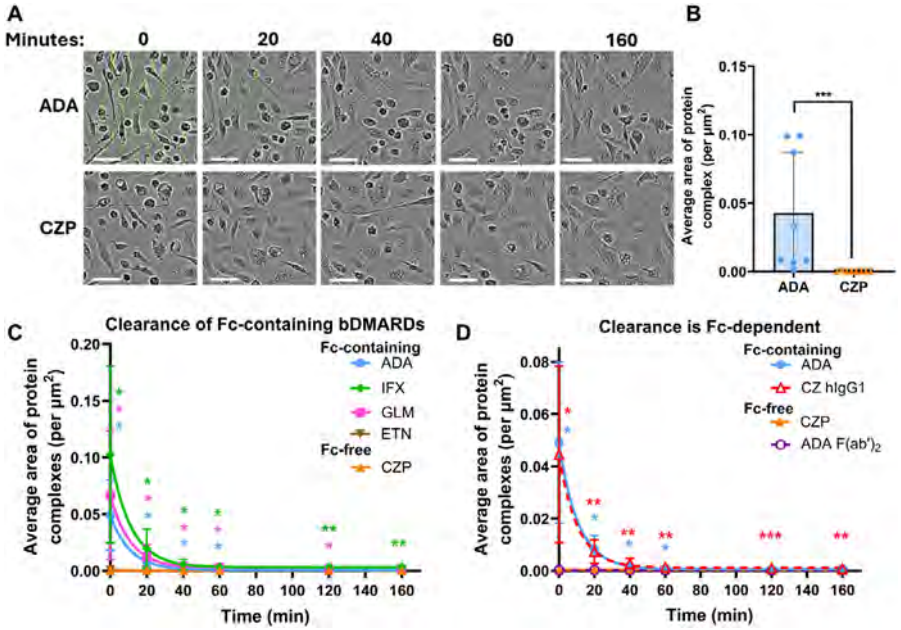
DMARDs (bDMARD). Fc-free certolizumab pegol (CZP) exhibits stable serum drug concentrations and efficacy independent of patient RF levels[1-4]. Previously, we have shown that monoclonal recombinant RF IgMs bind to Fc-containing bDMARDs *in vitro* and form protein complexes that are cleared by human macrophages. Fc-free CZP is not bound and avoids clearance[5-6]. In this study, serum samples from RA patients were classified according to RF level, and the ability of human sera RFs to bind to and clear Fc-containing anti-TNF-α bDMARDs was investigated.

Methods: RF levels in human patient sera were quantified by RF latex agglutination and the sera was classified as "high RF" (>188 IU/ml), "low RF" (14-50 IU/ml) or "RF negative" (<14 IU/ml). bDMARDs [adalimumab (ADA), infliximab (IFX), golimumab (GLM), etanercept (ETN), CZP] were expressed and purified as previously described[5-6]. The CZP variable region sequence was incorporated into a full length human IgG1 to produce Fc-containing certolizumab hIgG1 (CZ hIgG1). ADA was digested with FabRICATOR (Genovis) to produce Fc-free ADA di-Fab (ADA F(ab')$_2$). RF binding to bDMARDs was assessed by ELISA. Live cell imaging of primary human macrophages was performed with an Incucyte microscope (Sartorius).



Protein complexes formed between patient sera RFs, Fc-containing bDMARDs and TNF-α were cleared by human macrophages in vitro. (A) High RF patient sera, bDMARDs and TNF-α were mixed and incubated with primary human macrophages at 4°C. Cells were washed and remaining protein complexes detected with Fab anti-human IgM Fc5µ FITC. Cells were moved to 37°C and imaged for 160 minutes (scale bar=100 µm). Quantification of the protein complex area in the images presented as area of protein complex per µm2 at (B) timepoint 0 minutes (random sampling; n=8/bDMARD; mean±SD), and (C-D) over time (non-random sampling; n=4/bDMARD; mean±SD), * P<0.05, ** P<0.01, *** P<0.001 by (B) paired t-test and (C-D) two-way ANOVA with Dunnett's multiple comparison test (compared to CZP group) on log-transformed data.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: In low and high RF patient sera, RFs bound to Fc-containing ADA by ELISA but not to Fc-free CZP. The magnitude of RF binding to ADA was greater in high RF sera than in the low RF sera. RF negative patient sera had no detectable binding to either bDMARD (**Figure 1**). Human sera RFs formed protein complexes with Fc-containing ADA, IFX, and GLM in the presence of TNF-α, but not with ETN or Fc-free CZP. No complexes formed in RF negative sera. The binding of human sera RFs to bDMARDs was Fc-dependent. Protein complexes formed in high RF sera with Fc-containing ADA and CZ hIgG1, but not with Fc-free CZP or ADA $F(ab')_2$. RF-bDMARD-TNF-α protein complexes were rapidly cleared by primary human macrophages (**Figure 2**).

Conclusion: In RA patient sera, RFs bound to Fc-containing bDMARDs, but not to Fc-free CZP. Serum RF levels corresponded with the magnitude of binding observed. RF binding to Fc-containing bDMARDs drove protein complex formation in the presence of TNF-α, which were cleared by macrophages *in vitro*. These findings provide mechanistic insights into why high RF levels negatively impact Fc-containing bDMARD efficacy, while CZP efficacy is independent of patient RF levels.

Impact of CXCL2 and IL-11 from Rheumatoid Arthritis Synovial Fibroblasts on Angiogenesis and Endothelial Cell Network Formation

Elena Neumann[1], Frederik Loetfering[2], Paula Welbrink[3], Corinna Heck[3], Daria Kuersammer[3], Klaus Frommer[1], Stefan Rehart[4] and Ulf Müller-Ladner[1], [1]Dept. of Rheumatology and Clinical Immunology, Campus Kerckhoff, Bad Nauheim, Justus-Liebig-University, Germany, Bad Nauheim, Hessen, Germany, [2]Justus Liebig University Giessen, Campus Kerckhoff, Bad Nauheim, [3]Justus-Liebig-Universität Gießen, Campus Kerckhoff, Bad Nauheim, Germany, [4]Agaplesion Markus Hospital, Frankfurt, Hessen, Germany

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0067–0097) Rheumatoid Arthritis – Etiology and Pathogenesis Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: In rheumatoid arthritis (RA), hypervascularization contributes to synovial inflammation. RA synovial fibroblasts (RASF) contribute to cartilage and bone erosion but also promote angiogenesis. Activated RASF secrete inflammatory, angiogenesis and matrix remodeling factors including CXCL2 and IL-11. While CXCL2 is primarily recognized for recruiting leukocytes to inflamed tissues, it also promotes angiogenesis. IL-11 is involved in bone resorption and fibrosis. Angiopoietin-2 (ANGPT2) is known to be dysregulated in pathological vessel formation. Therefore the role of CXCL2 and IL-11 in RASF-mediated altered angiogenesis was evaluated.

Methods: In the SCID mouse model of RA, healthy cartilage was subcutaneously co-implanted with RASF. RASF-mediated helix-like vessel (HLV) formation was evaluated after 3-45 days. Implants, RA and osteoarthritis (OA) synovium were stained for ANGPT2 and CXCL2. RASF were stimulated with 0.1 or 1ng/ml IL-1β once or repetitively and ELISA, realtime-PCR and

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

RNAseq performed and supernatants used for 2D tube formation assays (TFA). TFA were performed by seeding HUVEC on Matrigel®. HUVEC were treated with supernatants or CXCL2 (25/50/100ng/ml) or 50ng/ml CXCL2 was combined with the CXCR2 antagonist SB225002 (0.015/0.03/0.06μM) or 10ng/ml IL-11 with/without the IL-11 inhibitor AF-218 (100/250/500ng/ml). To evaluate the role of VEGF, bevacizumab or ECM without VEGF with/without stimulants were used. After 4h, cell network area of TFA was measured using the Keyence BZ-X800© software.

Results: In SCID mice, RASF-specific HLV formation started at d3 and increased until d30. Compared to OA synovium, ANGPT2 was significantly upregulated in RA vessels and implants. RNAseq showed altered signaling pathways of angiogenesis. Repetitive RASF-stimulation significantly reduced IL-1β-induced IL-6, IL-11 and CXCL2 compared to RASF stimulated once (e.g. IL-6: 1^{st}: 5076±1730 vs 3^{rd}: 1890±758pg/ml, p< 0.0001; IL-11: 1^{st}: 451±205 vs 3^{rd}: 69±51pg/ml, p< 0.0001). Repetitive stimulation of HUVEC+15%RASF resulted in a significant IL-6 increase for subsequent stimulations (1^{st}vs.3^{rd}: p=0.02). RASF significantly reduced tube thickness (22.9μm *SD=6.3* to 16.6μm *SD=2.2*) compared to HUVEC alone (p=0.014) but increased ANGPT2 release (4h: 5%, 48h: 14%). IL-1β-stimulated RASF supernatants (1^{st} vs 3^{rd}) reduced HUVEC network area to 78%, p=0.01 vs 77%, p=0.04 (100%: no supernatant-transfer control). CXCL2 decreased the network area (e.g. 50ng/ml: 71% of 100% control, p=0.02; 25ng/ml: 73%, p=0.04). SB225002 partially reversed the CXCL2 effect (0.015: 93%; 0.03: 87%; 0.06: 92%). IL-11 also disturbed the network area (63%, p=0.08) and AF-218 partially reversed the effect (e.g. 250ng/ml: 72%, 500: 90%). Bevacizumab prevented tube formation which could in part be restored by addition of ANGPT2. Addition of ANGPT2 to ECM had a similar effect.

Conclusion: RASF affect vascularization in vitro and in vivo. CXCL2, IL-11 and RASF-derived supernatants altered the HUVEC network. These findings suggest that CXCL2 as well as IL-11 produced by RASF may significantly contribute to the dysregulated angiogenesis involving ANGPT2 observed in RA.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0067–0097) Rheumatoid Arthritis – Etiology and Pathogenesis Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Circulating concentrations of anti-malondialdehyde-acetaldehyde (MAA) antibodies distinguish patients with RA and are detectable years prior to arthritis onset. Recent data demonstrate that anti-MAA antibodies play a pathogenic role in RA by promoting osteoclastogenesis and 'priming' monocytes for pro-inflammatory responses. While

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Clinical and demographic characteristics of participants. Abbreviations: malondialdehyde-acetaldehyde adduct (MAA), immunoglobulin (Ig) Values shown as mean ± standard deviation unless specified.

	RA cases (n = 122)
Age at Diagnosis, years	37.20 ± 7.73
Female sex, n (%)	63 (51.6)
Race, n (%)	
White	66 (54.1)
Black	38 (31.2)
Other	19 (14.7)
Number of pre-diagnosis samples per individual	1.59 ± 0.68
Range of pre-diagnosis samples, years	4.22 ± 5.81
Anti-MAA antibody concentration, all samples (ng/mL)	
IgA	216.5 ± 340.0
IgG	655.9 ± 685.7
IgM	424.1 ± 331.9
Individuals with ≥1 anti-MAA antibody upper quartile measurement, n (%)	
IgA	36 (29.5)
IgG	35 (28.7)
IgM	38 (31.1)
All	8 (6.6)

these data suggest that anti-MAA antibodies are involved in the transition from pre-RA to clinical disease, their pathogenic role remains unknown. We evaluated whether anti-MAA antibody status is associated with differences in serum protein expression during the preclinical stage of RA development.

Methods: We used pre-diagnosis serum samples from RA cases meeting 1987 ACR criteria from the Department of Defense Serum Repository (Zaim et al., *Arthritis Rheum* 2025). Serum was tested for anti-MAA IgA, IgG, and IgM by ELISA, with high anti-MAA for each subtype defined as the upper quartile of all measurements. Olink Proteomics Immune

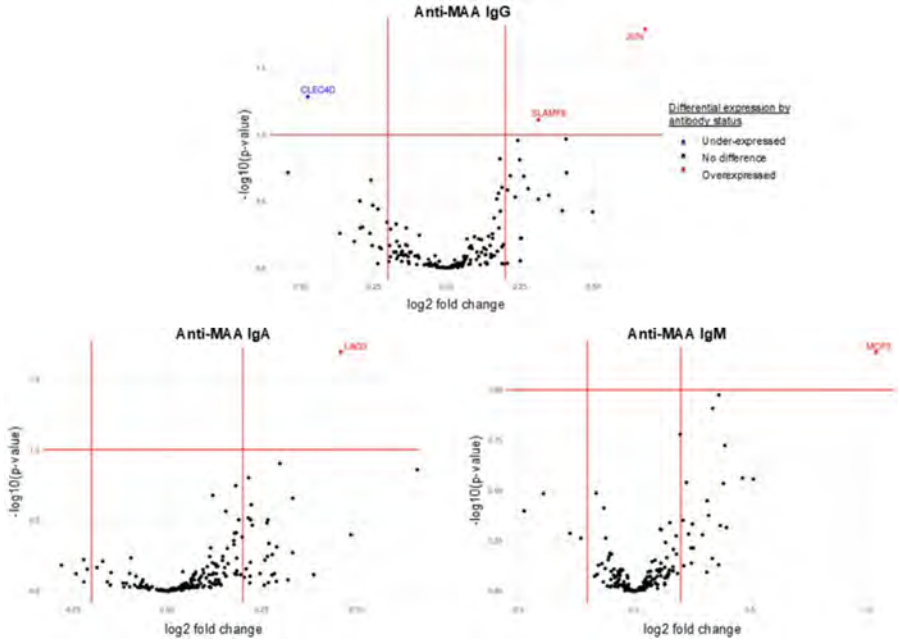

Figure 1. Volcano plots for differential protein expression based on anti-malondialdehyde adduct antibody status. Abbreviations: malondialdehyde-acetaldehyde adduct (MAA), immunoglobulin (Ig)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 2. Proteins differentially expressed based on anti-malondialdehyde antibody status in pre-RA to early RA period. Abbreviations: immunoglobulin (Ig), lymphocyte activation gene-3 (LAG3), transcription factor AP-1 (JUN), signaling lymphocytic activation molecule family member 8 (SLAMF8), C-type lectin domain family 4 (CLEC4D), monocyte-chemotactic protein 3 (MCP3), chemokine C-C motif ligand 7 (CCL7) Negative log2 fold change indicates inverse relationship (CLEC4D).

Protein	Ig Subtype	Log2 FC	Adjusted p-value	General Function & Proposed Relation to RA Pathogenesis
LAG3	IgA	0.381	0.01	T-cell regulation ***RA:*** *Associated with radiographic progression and seropositivity*
JUN	IgG	0.676	0.02	T-cell regulation ***RA:*** *Pro-inflammatory role in macrophage-driven inflammation and bone destruction*
SLAMF8	IgG	0.313	0.08	Immune regulation ***RA:*** *Increased in RA synovial tissue*
CLEC4D	IgG	-0.472	0.05	Cell signaling
MCP3 (CCL7)	IgM	1.039	0.06	Immune regulation ***RA:*** *Increased expression RA serum and synovial fluid; Drives macrophage polarization*

Regulation, Inflammation, and Cell Regulation panels were performed on all samples (n = 197 analytes). The association of each protein (normalized expression value) with anti-MAA antibody status in longitudinally collected samples was tested via linear mixed models accounting for age, race, gender, and time to diagnosis with a subject-level random effect. P-values were adjusted for false discovery rate (FDR) and specific proteins were selected for further evaluation based on FDR-adjusted $p < 0.1$ and absolute log2 fold-change (FC) ≥ 0.2.

Results: A total of 122 participants with RA were included (mean age at diagnosis 37 years, 52% female), all with ≥1 pre-RA sample available (mean 1.59, **Table 1**). For each anti-MAA subtype, ~30% of participants had ≥1 value in the upper quartile at any time (6.6% for all 3 subtypes; **Table 1**). Five proteins were significantly overexpressed in the presence of high anti-MAA isotypes: 1 with IgA, 3 with IgG, and 1 with IgM (**Figure 1, Table 2**); most with established or suspected roles in RA pathogenesis. The largest fold-change was observed with IgM-MAA and macrophage chemotactic protein 3 (MCP3), which is highly expressed in RA synovium and promotes synovitis. The protein associated with IgA-MAA, lymphocyte activation gene-3 (LAG3), inhibits T cell activation, and high serum levels in RA are associated with autoantibody positivity and radiographic progression. IgG-MAA showed the most associations, where the largest was with transcription factor AP-1 (JUN), known to promote synovitis and bone destruction in RA. The only negative association was seen with IgG-MAA and C-type lectin domain family 4D (CLEC4D), a protein thought to have an important role in resolving inflammation.

Conclusion: Anti-MAA antibody status is associated with differences in the serum proteome during the preclinical stages of RA, particularly among mediators of inflammation and immune responses. This differential expression implicates several established pathogenic mechanisms in RA (**Table 2**), suggesting that anti-MAA antibodies may comprise part of a distinct pathophysiologic state leading towards progression of clinical disease during the transition from pre-RA.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0067–0097) Rheumatoid Arthritis – Etiology and Pathogenesis Poster

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Anemia is a prevalent hematologic complication of rheumatoid arthritis (RA) that exacerbates the disease process and severely impacts clinical performance and treatment strategies. We propose to explore the potential molecular changes in RA complicated by anemia (RA_ane) based on transformer architecture and comprehensive multi-omics analysis.

Methods: This study recruited 257 RA patients, 113 controls, and disease comparison groups including 88 systemic lupus erythematosus (SLE) and 37 gout patients. Their plasma samples were collected for metabolomics sequencing, fecal samples for 16S rRNA sequencing, and peripheral blood mononuclear cells were used for transcriptomics, proteomics and phosphoproteomics studies. The transformer architecture and difference analysis were used to obtain overlapping difference features, and 5 machine learning algorithms (k-nearest neighbor algorithm [KNN], support vector machine [SVM], random forest [RF], recursive feature elimination-RF [RFE-RF], and eXtreme gradient boosting algorithm [XGBoost]) were further used to perform significant feature screening and construct clinical diagnostic models.

Results: By integrating the results of the above characterization screen, L-tryptophan, glyceric acid, L-malic acid, ALAS2, CA1, SELENBP1, and RPIA were identified as key biomarkers of RA_ane. Further functional enrichment analyses revealed the core role of the glycine, serine and threonine metabolism (GSTM) pathway in RA_ane and were validated by functional enrichment analyses in other dimensions of multi-omics, in addition to metabolomics and microbiomics analyses of SLE and gout, which indicated that alterations in the GSTM pathway are RA_ane-specific features. Subsequently, we developed and validated multi-omics diagnostic models for RA_ane patients with AUC values ranging from 0.75 to 0.84, and finally, we constructed a molecular map of GSTM-based multidimensional changes in the RA_ane population.

Conclusion: This study demonstrated that GSTM pathway plays a crucial role in RA_ane, shedding light on potential therapeutic interventions.

Abstract Number: 0078

Citrullinated Serum Albumin Is Not an Autoantigen in Rheumatoid Arthritis

Farheen Sultan Shaikh, cecilia mustelin, Xiaoxing Wang and Tomas Mustelin, University of Washington, Seattle, WA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0067–0097) Rheumatoid Arthritis – Etiology and Pathogenesis Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Autoantibodies against citrullinated proteins (ACPAs) are diagnostic of rheumatoid arthritis (RA), an autoimmune disease primarily affecting synovial joints. Proteomic analyses have identified human serum albumin as a target

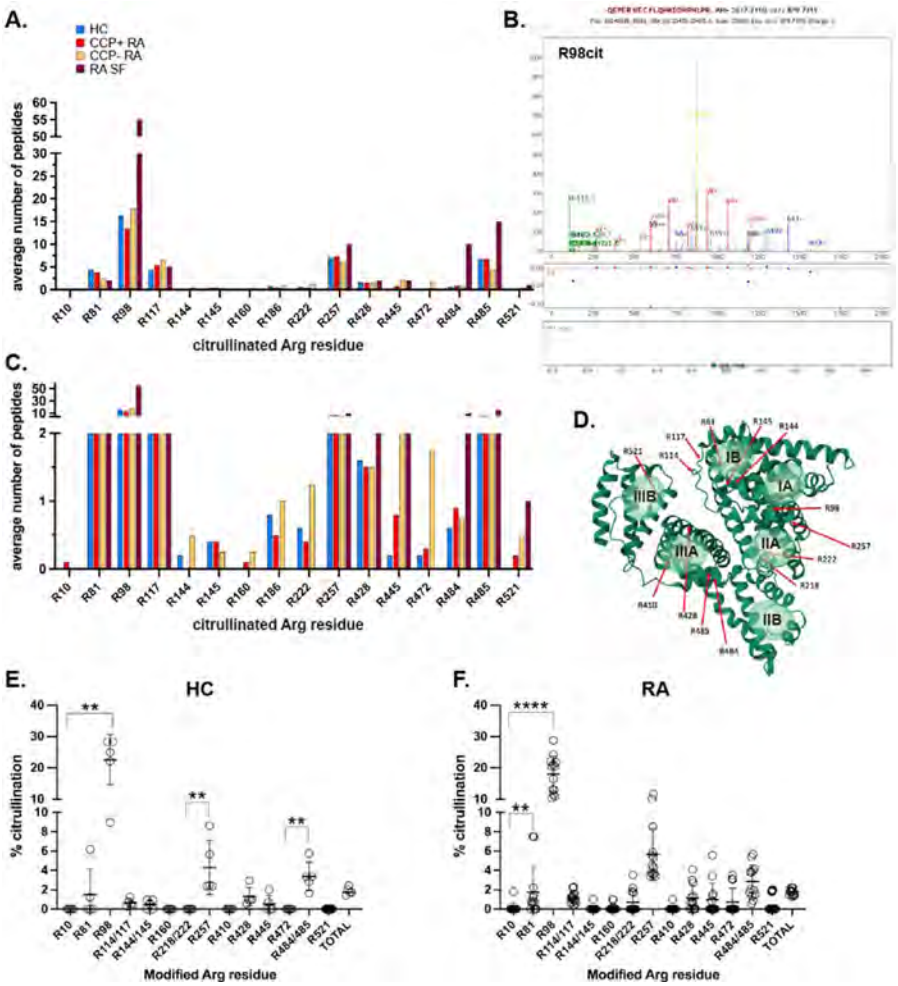

Fig. 1. Summary of mass spectrometry analyses to identify citrullinated Arg residues in albumin. A., Identified sites by the average number of peptides detected in LC-MS/MS experiments in healthy controls (HC, blue bars), CCP-positive RA patients (red bars), CCP-negative RA patients (golden bars), and in synovial fluid from an RA patient (purple bars). B., Mass spectrum for the peptide containing citrullinated R98. C. Same data as in panel A., but with the bottom half of the Y-axis magnified to better visualize the lowest peptide quantities. D., Location of the modified Arg residues in the three-dimensional structure of albumin. The 6 ligand binding pockets are indicated as pale green spheres. E., stoichiometry of Arg citrullination in albumin from healthy donors (HC; n=5) and RA patients (n=13). Statistical significance was assessed using the Mann-Whitney U test. **, p<0.01, ****, p<0.001.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

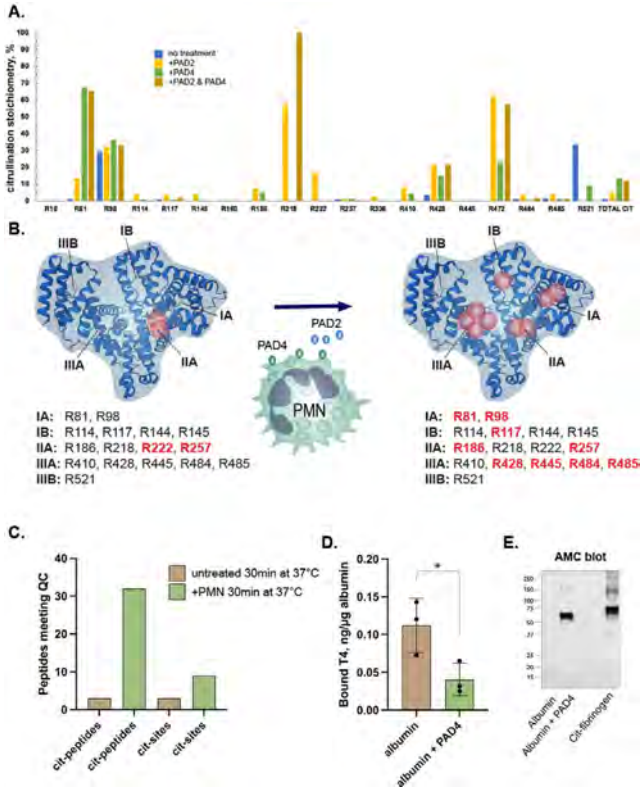

Fig. 2. Citrullination of albumin by PAD2, PAD4, and live neutrophils. A., Stoichiometry of citrullination of albumin at all sites after treatment without (blue) or with PAD2 (golden), PAD4 (green), or both enzymes (tan). B., Arg residues in albumin citrullinated (red) by live neutrophils. C., Numbers of citrullinated sites and peptides in panel B. D., Binding of thyroxin (T4) by albumin treated with (green) or without (brown) PAD4, as indicated. Statistical significance was assessed using the Mann-Whitney U test. E., Anti-modified citrulline (AMC) of albumin treated with PAD4, with citrullinated fibrinogen as a positive control.

of citrullination in RA, and anti-citrullinated albumin antibodies have been reported. This study aimed to characterize the extent and immunological relevance of albumin citrullination in RA.

Methods: Sera from individuals with RA (n = 87), SLE (n = 24), and healthy controls (n = 33) were obtained from the UW Rheumatology Biorepository, and neutrophils were isolated from freshly collected blood samples of RA patients. Anti-CCP status in RA sera was confirmed by ELISA. Neutrophils from RA blood or recombinant PAD2/PAD4 enzymes were used to citrullinate human albumin in vitro. Citrullination was assessed by AMC blotting and LC-MS/MS after in-gel tryptic digestion. Citrullinated and unmodified peptide pairs (14 sites) were tested by ELISA for IgG binding; responses above the 95th percentile of controls were considered positive. Thyroxine binding to native versus citrullinated albumin was measured using competitive ELISA. All protocols were IRB-approved. Mann-Whitney U tests were used for statistical analyses, with $p < 0.05$ considered significant.

Results: This study analyzed serum from 87 RA patients, confirming CCP positivity in 59.5%, and identified 17 citrullinated arginine residues in albumin from both RA patients and healthy donors using LC-MS/MS. Surprisingly, the stoichiometry of citrullination was similar in both groups, suggesting it is a physiological process. Increased citrullination was observed only in RA synovial fluid, albeit at the same sites. The citrullinated residues were surface-exposed and located near ligand-binding pockets, including R81 and R521 near the FcRn binding interface, indicating potential structural or functional consequences. In vitro, PAD2, PAD4, and live RA neutrophils rapidly citrullinated albumin at multiple sites, with PAD4 inducing the most extensive changes. Citrullination significantly reduced thyroxin binding by 64%, suggesting a regulatory role of citrullination in ligand binding. However, ELISA assays showed minimal IgG ACPA reactivity to either physiologically citrullinated albumin or synthetic citrullinated peptides, with only a few RA sera slightly exceeding control thresholds, likely due

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Fig. 3. ELISAs with intact albumin and citrullinated albumin peptides. A., Detection by ELISA of IgG antibodies binding purified albumin. B., Positive control ELISA with the same serum samples detecting IgG binding to citrullinated fibrinogen. Statistical significance was assessed using the Mann-Whitney test. C., Sequence of all peptides used in ELISAs. The unmodified Arg residues are indicated in blue and the citrulline residues in red. D., IgG reactivity in RA sera (n=87) against the indicated citrullinated peptides after subtraction of the reactivity against the unmodified peptide. E., The exact same ELISA using healthy control (HC) sera (n=33). The 95th percentile of the HC distribution for each peptide is indicated as a horizontal dotted line. Statistical significance was assessed using the Mann-Whitney U test between reactivity for each peptide between HC and RA. Note that the statistically significant values all represent lower reactivity in RA than in HC. *, p<0.5; **, p<0.01; ***, p<0.005, ****, p<0.001.

to cross-reactivity of ACPA against other citrullinated proteins. These findings suggest that albumin citrullination is a physiological process and not a major immune target in RA.

Conclusion: Albumin citrullination appears to be a physiological process and is not immunogenic in RA, with similar stoichiometry to healthy controls and minimal ACPA recognition. We conclude that citrullinated albumin is unlikely to contribute significantly to ACPA responses in RA and that immunological tolerance against citrullinated albumin is maintained in RA.

Background/Purpose: Genetic association data, immunohistochemistry, and functional experiments implicate protein arginine deiminase 4 (PAD4) in the pathogenesis of rheumatoid arthritis (RA). This disease is characterized by immunity against epitopes with deiminated arginine (=citrulline) originating from a multitude of intra-and extracellular proteins that are modified in this manner only in RA patients, not in healthy individuals. However, it remains uncertain how, where, and why PAD4 citrullinates these proteins in the RA patients.

Methods: To gain insights into the physical interactions of PAD4 with other cellular proteins, we identified candidate PAD4-associated proteins by mass spectrometry. PAD4 in neutrophils from RA patients and healthy controls co-

D., Negative control staining with secondary antibodies alone. E., PAD4 (green) and myosin-9 (red) in neutrophils treated with 1 µM ionomycin for 30 min at 37°C. F., Magnified view of the third panel, second row, in panel E. G., PAD4 (green) and myosin-9 (red) in a neutrophil undergoing spontaneous cell death by pyroptosis. H., RA neutrophils stained for PAD4 (green) and grancalcin (red) focusing on neutrophils with nuclear PAD4. I. same in neutrophils with cytosolic PAD4. Note that grancalcin is nuclear only when PAD4 is nuclear.

immunoprecipitated with myosin-9, and 20 other proteins, many of which were also present in myosin-9 immunoprecipitates. By immunofluorescence microscopy, myosin-9 co-localized with PAD4 in RA neutrophils, as well as with myosin-9 and myosin light chain 6 in transfected 293T cells. This was confirmed by proximity ligation assays in intact neutrophils.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Inhibition of the motor domain of myosin-9 by blebbistatin resulted in a more diffuse PAD4 location indicating that myosin-9 serves to transport PAD4 within the cells. However, PAD4 translocation to the nucleus involved dissociation from myosin-9. In complex with PAD4, myosin-9 was citrullinated at both N-terminal and C-terminal sites. Citrullinated peptides corresponding to these sites were recognized by IgG autoantibodies in RA patients.

Conclusion: We conclude that at least a portion of intracellular PAD4 in neutrophils interacts physically and catalytically with a myosin-9 containing macromolecular machinery involved in the cell migration and transport of organelles and membrane.

Abstract Number: 0080

The Role of DICAM in Modulating Macrophage Differentiation and Inflammatory Responses via αvβ3 Integrin Signaling in Rheumatoid Arthritis

Hanna Lee[1], Youn-Kwan Jung[2], Sang-il Lee[3], Yun-Hong Cheon[4] and Hyunjin Lim[4], [1]Division of Rheumatology, Department of Internal Medicine, Gyeongsang National University Hospital, Changwon, Changwon-si, Kyongsang-namdo, Republic of Korea, [2]Institute of Medical Science, Gyeongsang National University, Jinju, Jinju, Kyongsang-namdo, Republic of Korea, [3]Department of Internal Medicine and Institute of Medical Science, College of Medicine, Gyeongsang National University and Hospital, Jinju, Republic of Korea, [4]Division of Rheumatology, Department of Internal Medicine, Gyeongsang National University Hospital, Jinju, Jinju, Kyongsang-namdo, Republic of Korea

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0067–0097) Rheumatoid Arthritis – Etiology and Pathogenesis Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disorder characterized by persistent joint inflammation, cartilage destruction, and bone erosion. Among the various immune cells involved in RA pathogenesis, macrophages play a central role by mediating inflammatory responses and tissue damage. Integrins, particularly αvβ3 integrin, are critical regulators of macrophage differentiation and inflammatory signaling via the PI3K/Akt pathway and its downstream effectors, including FOXO3a and IRF7. DICAM (Mxra8), a transmembrane protein, has been identified as a negative regulator of αvβ3 integrin signaling, yet its role in RA remains unclear. This study explores the regulatory function of DICAM in macrophage differentiation and inflammation in the context of RA.

Methods: We utilized the **K/BxN serum transfer mouse model of rheumatoid arthritis** to evaluate whether **DICAM deficiency influences cartilage destruction and macrophage infiltration** in vivo. To investigate the role of DICAM in macrophage signaling in vitro, we employed **THP-1-derived macrophages**. In addition, we performed rescue experiments to confirm whether the regulatory effects of DICAM on macrophage differentiation and inflammatory responses were mediated, at least in part, by suppression of β3 integrin.

Results: Using a K/BxN serum transfer mouse model of RA, we demonstrate that DICAM deficiency exacerbates arthritis severity, cartilage degradation, and macrophage infiltration. In vitro experiments with THP-1-derived macrophages show that DICAM inhibits macrophage differentiation, phagocytic activity, and pro-inflammatory cytokine expression by suppressing αvβ3 integrin expression and downstream PI3K/Akt signaling. Overexpression of DICAM reduced integrin activation,

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. FOXO3a phosphorylation, and IRF7 expression, while knockdown enhanced these processes, promoting an inflammatory macrophage phenotype. Rescue experiments further confirmed that the inhibitory effects of DICAM on macrophage differentiation and inflammatory responses are mediated, at least in part, by the suppression of β3 integrin.

Conclusion: These results, indicating DICAM's protective role in mitigating joint pathology, highlight DICAM as a critical modulator of macrophage function in RA and a potential therapeutic target for reducing inflammation and tissue damage. This study advances our understanding of DICAM's role in RA pathogenesis and its potential as a biomarker and therapeutic intervention.

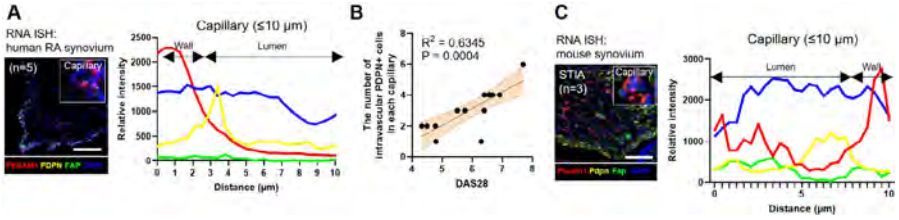
Trans-endothelial Trafficking of Fibroblast-like Synoviocytes Amplifies Synovial Inflammation in Rheumatoid Arthritis

Jaeyeon Kim[1], Sanaz Panahandeh[2], Hieu Nguyen[3], Kainat Mian[4], Hadijat Makinde[4], Kyoung Jae Won[5], Arminja Kettenbach[3], Harris R Perlman[4], Costantino Pitzalis[6] and Nunzio Bottini[7], [1]Cedars Sinai Medical Center, Los Angeles, CA, [2]Cedars-Sinai Medical Center, Los Angeles, [3]Geisel School of Medicine at Dartmouth, Lebanon, NH, [4]Northwestern University, Chicago, IL, [5]Cedars-Sinai Medical Center, Los Angeles, CA, [6]QMUL, Bromley Kent, United Kingdom, [7]Cedars Sinai Medical Center, Beverly Hills, CA

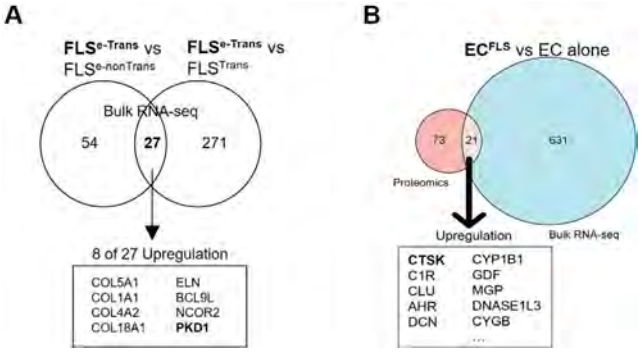
SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0067–0097) Rheumatoid Arthritis – Etiology and Pathogenesis Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: The discovery of circulating fibroblast-like synoviocyte (FLS), known as PRIME cells, in RA patients suggests that synovial FLS may enter the circulation through blood vessels and contribute to systemic inflammation. This study aimed to detect trans-endothelial migration of FLS and dissect the molecular crosstalk between FLS and endothelial cells (EC) during this process and its relevance in rheumatoid inflammation.



(A) Left: trans-EC migration of RA FLS. Representative microscopy of RA (n=5) synovium subjected to RNA in situ hybridization (ISH) for Podoplanin (PDPN, yellow), Fibroblast Activating Protein (FAP, green), Platelet/Endothelial Cell Adhesion Molecule 1 (PECAM1, red), and Hoechst (blue). Scale bar: 100 μm. Right: Representative quantification of ISH intensities through a capillary (≤ 10 micron) wall and lumen in RA synovium. Data were analyzed using Zen (black edition). (B) Correlation between the number of intravascular PDPN+ cells in RA biopsies (n=15) and disease activity score (DAS28). Simple linear regression. P=0.0004. (C) Left: trans-EC migration of mouse FLS. Representative microscopy of serum transfer induced arthritis (STIA) synovium subjected to RNA ISH for Pdpn (yellow), Fap (green), and Pecam1 (red), and Hoechst (blue). Scale bar: 100 μm. Right: Representative quantification of ISH intensities through a capillary (≤ 10 micron) wall and lumen in STIA synovium. Data were analyzed using Zen (black edition).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

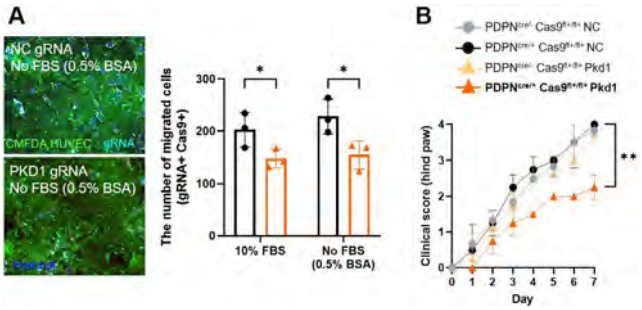


(A) Venn diagram from bulk RNA-seq of trans-EC migrated RA FLS (FLSe-Trans) compared to non-migrated FLS (FLSe-nonTrans) or FLS trans-migrated without EC (FLSTrans), highlighting a shared set of upregulated genes, including polycystin 1 (PKD1). (B) Venn diagram from integrated proteomic and transcriptomic analysis of EC co-cultured with RA FLS (ECFLS) compared to EC alone, highlighting upregulated genes, including Cathepsin K (CTSK).

Methods: Human and mouse arthritic synovium were analyzed using immunofluorescence and RNA in situ hybridization (ISH) to identify trans-endothelial migrating FLS. An in vitro trans-endothelial migration model was established using RA FLS and human umbilical vein ECs (HUVEC), followed by transcriptomics and proteomic analysis. Spatial transcriptomics was performed on RA synovial biopsies. Functional experiments were conducted through gene knockdown in vitro and in vivo.

Results: We identified FLS transmigration through EC layers of capillaries in RA synovium, but not in osteoarthritis (OA), which correlated with RA disease activity. ISH confirmed the presence of intravascular FLS in human and mouse arthritic synovium (**Fig. 1A, B, C**, R^2=0.6, P=0.0004). In vitro trans-endothelial migration assay demonstrated that RA FLS actively transmigrate across EC layers. Bulk RNA-seq of trans-endothelial migrated FLS identified increased expression of polycystin-1 (PKD1) (**Fig. 2A**). Integration of transcriptomics and proteomic data identified cathepsin K (CTSK) as upregulated in EC after transmigration of FLS (**Fig 2B**), Spatial transcriptomics studies showed that PKD1$^+$ FLS are located in close proximity to CTSK$^+$ ECs in RA synovium, supporting a spatially organized induction of CTSK by FLS in EC. In vitro assays confirmed that PKD1 knockdown significantly impaired FLS transmigration across EC layers while PKD1 knockdown in FLS reduced the severity of arthritis in vivo (**Fig. 3A, B**). CTSK knockdown in ECs exposed to FLS impaired angiogenesis while systemic administration of the CTSK inhibitor Odanacatib attenuated joint inflammation and vascular leakage in arthritic mice.

Conclusion: Our findings demonstrate that FLS undergo trans-endothelial migration in RA synovium and identify a mechanism driven by such migration and involving PKD1 and CTSK, which amplifies EC-driven inflammation and RA severity. These results might also provide mechanistic insight into the generation of PRIME cells and highlight FLS–EC spatial interactions as a potential therapeutic target in RA.



(A) Left: representative fluorescence microscopy images from an in vitro trans-EC migration assay of RA FLS transfected with PKD1 gRNA-AF647 (cyan) compared to negative control (NC). HUVEC were loaded with 5-chloromethylfluorescein diacetate dye (CMFDA). gRNA-AF647 is cyan, CMFDA is green, and Hoechst is blue. Right: quantification of trans-EC migrated PKD1 gRNA transfected RA FLS compared to NC gRNA under serum-containing (10% FBS) and serum-free (0.5% BSA) conditions. Each point in A (right) represents an experiment. Two-way ANOVA, Bonferroni's multiple comparison test. *P < 0.05. (B) In vivo electroporation using tweezer electrodes and intra-articular injection of Pkd1 gRNA into joints of PDPNcre/+ Cas9 knock-in (KI) fl+/fl+ mice. Clinical arthritis scores (0 – 4) over time in PDPNcre/+ Cas9 KIfl+/fl+ and control mice following intra-articular injection of PKD1 or NC gRNA. Two-way ANOVA, Bonferroni's multiple comparison test. **P < 0.01.

IBI3011, a Humanized anti-IL1RAP Monoclonal Antibody, Inhibits IL1, IL33, IL36-driven Inflammation Pathway, and Attenuates Inflammation in Preclinical Inflammatory Disease Model

Hongling Tian, Lidan Liang, Chenjuan Zhu, Bin Li, Lei Cao, Meng Ni, Fan Chen, Zhimin Zhang, Min Wu, Tong Liu, **Jinyang Li**, Yao Xiong, Li Li, Shuaixiang Zhou, Enhong Zhong and Huizhong Xiong, Innovent Biologics (Suzhou) Co., Ltd., Suzhou, Jiangsu, China (People's Republic)

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0067–0097) Rheumatoid Arthritis – Etiology and Pathogenesis Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Interleukin 1 receptor accessory protein (IL1RAP) serves as a co-receptor that forms receptor complexes with IL1R1, ST2, and IL36R and mediates signaling pathways triggered by IL1α/β, IL33, and IL36α/β/γ, which implicated in several autoimmune or inflammatory diseases, such as gout, psoriasis, and systemic sclerosis. IBI3011 is a fully humanized IgG1-LALA antibody targeting the extracellular segment of IL1RAP, blocks IL1α/β, IL33, and IL36α/β/γ signaling pathways and without ADCC. IBI3011 has shown potent anti-inflammatory properties in several preclinical models and is currently under development for treatment of gout and auto-inflammatory diseases.

Methods: We evaluated the binding affinity of IBI3011 with human, cynomolgus monkey and mouse IL1RAP in protein level by **Biosensor Layer Interferometry (BLI), and in** cellular level by flow cytometry. The blocking activity of IBI3011 was evaluated via ELISA to quantify target cell activation *in vitro*. Human peripheral blood mononuclear cells (PBMCs) were stimulated with IL1α/β, IL33, or IL36α, respectively, and the secreted inflammatory cytokines were detected. The *in vivo* efficacy of IBI3011 was evaluated in humanized IL1RAP knock-in mice with MSU induced gout and collagen antibody-induced arthritis (CAIA) models. In both studies, mice were treated with IBI3011 or control reagent in a therapeutic fashion, and the blockade efficacy were analyzed by footpad thickness and/or inflammatory cytokines level in footpad tissue.

Results: IBI3011 showed high binding affinity with human and cynomolgus monkey IL1RAP at protein and cellular levels, but not with mouse IL1RAP. For *in vitro* function assay, IBI3011 blocked the inflammatory cytokines TNFα, IFNγ secretion from PBMC when stimulated with IL1α/β, IL33, and IL36α/β/γ. In the acute gout model, IBI3011 demonstrated a dose-dependent inhibition of the gout development in hIL1RAP mice compared to controls, as 10 mg/kg and 20 mg/kg of IBI3011 significantly reduced the thickness and inflammation of the footpad tissues. In the rheumatoid arthritis model, IBI3011 dose-dependently reduced the ankle joint thickness and inhibited the inflammation in joint. The 3 mg/kg and 10 mg/kg dosage groups exhibited significant inhibitory effect on the arthritic joint redness and inflammatory response in mice, while the lower dose of 1 mg/kg showed no significant inhibition, suggesting that IBI3011 can dose-dependently inhibit the initiation of rheumatoid arthritis in the preclinical model.

Conclusion: The *in vitro* study has shown that IBI3011 inhibits the activation of IL1, IL33, and IL36 signaling pathway effectively through blocking the co-receptor IL1RAP. The preclinical mouse models have demonstrated that IBI3011 exerts a dose-dependent anti-inflammatory effect. These preclinical results underscore the potential of IBI3011 as a therapeutic candidate for autoimmune and inflammatory diseases.

Abstract Number: 0083

Confirmatory Factor Analysis of the Plutchik Suicide Risk Scale in Patients with Rheumatoid Arthritis

Pedro Quevedo[1], Javier mora[2], william garcia[2], alejandra Solano[2], **juliana Muñoz**[2] and Daniela Lopez[2], [1]San Rafael Cinic University Hospital, Bogota, Distrito Capital de Bogota, Colombia, [2]san rafael clinic universtity hospital, Bogota, Distrito Capital de Bogota, Colombia

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0067–0097) Rheumatoid Arthritis – Etiology and Pathogenesis Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Prevalence of depression in RA patients ranging from 10% to 25%, making it the most common psychiatric disorder in this population. The Plutchik Suicide Risk Scale is a tool validated in Colombia for assessing suicide risk. It consists of 15 items and evaluates aspects such as suicidal ideation, history of previous attempts, and emotional severity, with a cutoff score of 6 or higher indicating risk. Our Objectives were: To perform an exploratory factor analysis of the Plutchik Suicide Risk Scale in patients with rheumatoid arthritis, and to evaluate the correlation between this score and disease activity and quality of life scales. Additionally, to estimate the prevalence of suicide risk in our population with rheumatoid arthritis.

Methods: A cross-sectional study with ambispective data collection was conducted. Patients over 18 years of age with a diagnosis of rheumatoid arthritis, based on the 2010 ACR/EULAR criteria, and treated at the Rheumatology Department of the Hospital Universitario Clínica San Rafael in Bogotá were included. Patients with major depressive disorder, anxiety disorders, or neurocognitive disorders were excluded. To assess the correlation between the Plutchik scale and the DAS28, HAQ, and CDAI indices, Spearman's correlation coefficient. For the confirmatory factor analysis (CFA), the weighted least squares means and variance adjusted (WLSMV) estimator was applied, as it is suitable for dichotomous items. A theoretical three-factor model was established, and factor loadings, standard errors, and p-values were calculated. Goodness-of-fit

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

measures were then estimated: chi^2, TLI (Tucker-Lewis Index), CFI (Comparative Fit Index), SRMR (Standardized Root Mean Square Residual), and RMSEA (Root Mean Square Error of Approximation). The analysis was performed using MPLUS version 8.11 and RStudio version 4.3.2

Results: A total of 91 patients were included in the study, of whom 78% were women. The mean age was 54 years (±14), and the median disease duration was 60 months (120). The median DAS28 score was 3.5 (2.7), and CDAI score was 12 (14). Quality of life, assessed using the HAQ, showed a median score of 1.1 (IQR: 1.55). The Plutchik Suicide Risk Scale yielded a median score of 3 (4.5). When evaluating suicide risk using the Plutchik scale, 26.3% of our population was found to be at risk. Analysis of the correlation between this scale and disease activity scores showed no statistically significant associations with DAS28 or CDAI However, a significant correlation was observed between suicide risk and quality of life, as assessed by the HAQ (rho = 0.60; $p < 0.001$). The exploratory factor analysis supported a three-factor model, with statistically significant factor loadings for all items except for item P10: "Are you separated, divorced, or widowed?" which had an estimate of 0.19 and a p-value of 0.18. The goodness-of-fit indices indicated acceptable model fit: RMSEA = 0.07, CFI = 0.92, and TLI = 0.91.

Conclusion: The prevalence of suicide risk, according to the Plutchik scale, in our population was 26.3%. A statistically significant correlation was found between this scale and quality of life, demonstrating an acceptable performance of the Plutchik scale in patients with rheumatoid arthritis.

Session Title: (0067–0097) Rheumatoid Arthritis – Etiology and Pathogenesis Poster

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis synovial fibroblasts (RASFs) produce various matrix metalloproteinases (MMPs), cytokines, and chemokines. Histone lysine methylation has been shown to play an important role in the activation of RASFs. We reported that histone lysine methyltransferases (HKMTs), including myeloid/lymphoid or mixed-lineage leukemia 1 (MLL1) and MLL3, are aberrantly expressed in RASFs (PMID: 29465369). MLL1 and MLL3 catalyze histone H3 lysine 4 (H3K4) methylation and are each part of complex proteins associated with Set1 (COMPASS)-like complexes that include

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

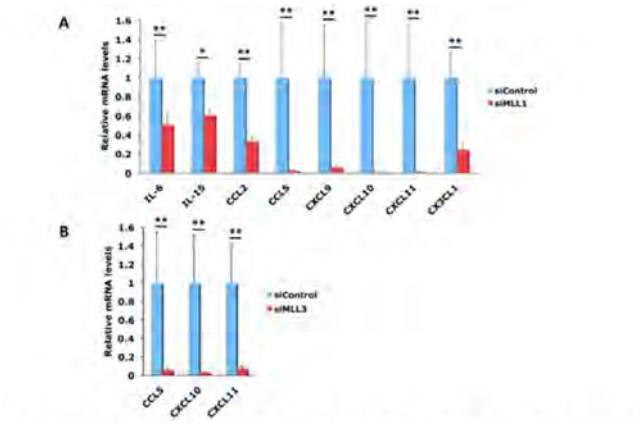

Figure 1. Reduction in mRNA levels of RA-associated genes in RASFs upon siRNA-mediated inhibition of MLL1 (A) or MLL3 (B). Bars shown the mean ± SEM (n=12). Values are expressed as the fold-increase versus the value for control siRNA-treated RASFs. *=P<0.05; **=P<0.01 by Wilcoxon signed-rank test.

WD repeat domain 5 (WDR5) (PMID: 22663077). WDR5 is essential for methylation of H3K4 by MLL1 and MLL3. We investigated the role of MLL1 and MLL3 in RASFs in terms of epigenetic mechanisms of RA pathogenesis.

Methods: Human SFs were isolated from synovial tissues obtained from RA or osteoarthritis (OA) patients undergoing total knee arthroplasty. MLL1 and MLL3 mRNA levels of the above SFs were determined after tumor necrosis factor alpha (TNFα) stimulation. Trimethylation of H3K4 (H3K4me3) is present at the promoters of actively transcribed genes. We investigated changes in mRNA levels of RA-associated genes (matrix-degrading enzymes, cytokines, and chemokines) and H3K4me3 levels in the promoters of these genes upon small interfering RNA-mediated depletion of MLL1 and MLL3 in RASFs. We then determined the levels of H3K4me3 and mRNAs after treatment with MM-102, a WDR5 inhibitor. H3K4me3 levels in the gene promoters were also compared between RASFs and OASFs. Differences between unpaired or paired groups were evaluated using the Mann–Whitney U test or the Wilcoxon signed-rank test, respectively.

Results: MLL1 and MLL3 mRNA levels were significantly higher in RASFs than in OASFs after TNFα stimulation. MLL1 depletion significantly decreased the mRNA levels of several genes of cytokines (IL-6 and IL-15) and chemokines (CCL2, CCL5, CXCL9, CXCL10, CXCL11, and CX3CL1) in RASFs (Figure 1A). Correspondingly, MLL1 depletion significantly reduced H3K4me3 levels in the promoters of the cytokine and chemokine genes in RASFs (Figure 2). These results indicate that MLL1 activates the cytokine and chemokine genes by increasing promoter H3K4me3 levels in RASFs. Interestingly, MLL3 depletion also suppressed the mRNA levels of CCL5, CXCL10, and CXCL11 genes in RASFs (Figure 1B). However, H3K4me3 levels in the promoters of the chemokine genes were not altered by MLL3 depletion in RASFs (Figure 2). Since it has been reported that MLL3 is involved in the generation of H3K4 monomethylation (H3K4me1) in the enhancers of actively transcribed genes (PMID: 24081332), our results suggest that MLL3 may activate CCL5, CXCL10, and CXCL11

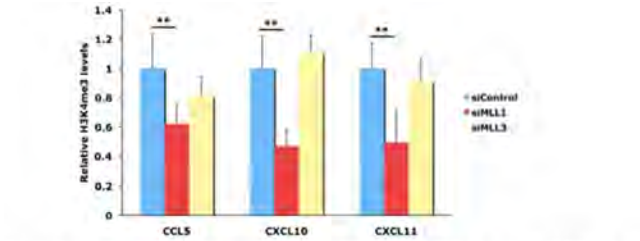

Figure 2. Changes in H3K4me3 levels of CCL5, CXCL10, and CXCL11 genes in RASFs upon siRNA-mediated inhibition of MLL1 or MLL3. Bars shown the mean ± SEM (N=8). Values are expressed as the fold-increase versus the value for control siRNA-treated RASFs. **=P<0.01 by Wilcoxon signed-rank test.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. genes by increasing enhancer H3K4me1 levels. MM-102 significantly decreased promoter H3K4me3 and mRNA levels of CCL5, CXCL9, CXCL10, and CXCL11 genes in RASFs. H3K4me3 levels in the promoters of IL-6, IL-15, CCL2, CCL5, CXCL9, CXCL10, CXCL11, and CX3CL1 genes were significantly higher in RASFs than in OASFs.

Conclusion: This study elucidated the epigenetic mechanism by which MLL1 and MLL3 cooperate to activate chemokine genes in RASFs. These findings may lead to new treatments such as targeting histone methyltransferases for RA.

Session Title: (0067–0097) Rheumatoid Arthritis – Etiology and Pathogenesis Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Interstitial lung disease (ILD) is one of the extra-articular manifestations of rheumatoid arthritis (RA) characterized by inflammation and/or fibrosis. Clinically relevant RA-ILD occurs in approximately 10% of RA patients and is associated with poor prognosis. Recent single-cell RNA-sequencing (scRNA-seq) analysis have revealed the effects of the cellular makeup and molecular pathways on pathological changes in several lung diseases, but little is known about RA-ILD. This study aimed to characterize immune/epithelial cells in RA-ILD through scRNA-seq analysis.

Methods: We processed explant tissues from 5 RA-ILD patients, 3 non-RA connective tissue disease (CTD)-ILD (2 with dermatomyositis (DM) and 1 mixed connective tissue disease (MCTD)), and 4 control patients. CD45+CD31-EpCAM- immune cells and CD45-CD31-EpCAM+ epithelial cells were FACS sorted and subjected to scRNA-seq. Ingenuity pathway analysis was used to perform upstream regulator analysis.

Results: We analyzed 184,814 cells after quality-control filtering and identified 18 distinct cell clusters (Figure 1). By differential abundance analysis, we found that AT2 cells were 65% lower in abundance in RA-ILD lung tissue compared with control lung tissue, and 10% lower in RA-ILD compared with non-RA CTD-ILD. We identified a reciprocal higher abundance of other epithelial cell types (basal cells, club cells, and ciliated cells). We also found fewer FCN1+ CD14+ macrophages and more SPP1+ macrophages in RA-ILD lungs. We calculated the number of differentially expressed genes (DEGs) in each cell cluster between the disease groups (RA vs control and RA vs CTD) and found that AT2 cells, club cells, FCN1+ CD14+ macrophages, FABP4+ macrophages, and SPP1+ macrophage had a higher number of DEGs (Figure 2). Upstream regulator analysis revealed that TNFa was potentially activated as an upstream molecule which drived differential changes in RA-ILD AT2 cells. T cell sub-clustering analysis revealed that peripheral T cells (Tph) are exclusively found in RA-ILD lungs (Figure 3).

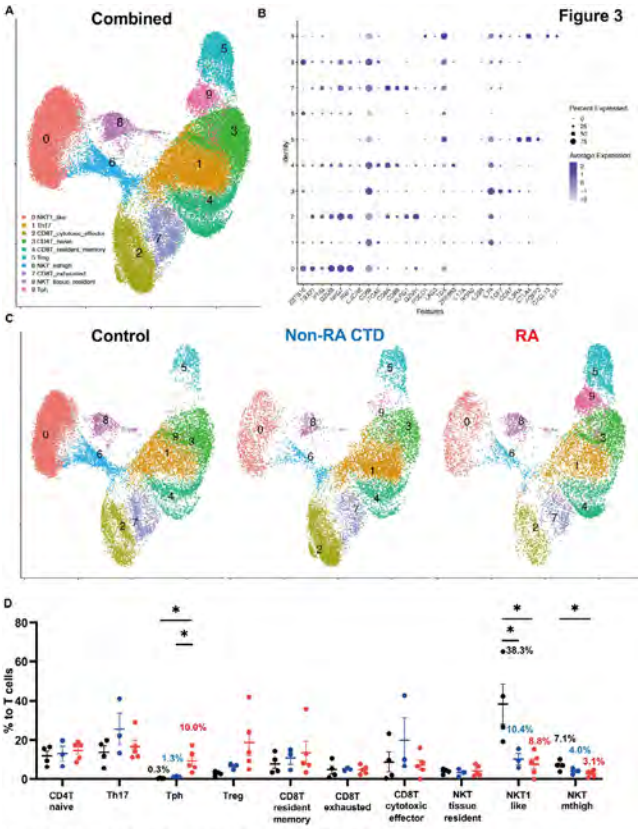

Figure 3. Tph cells were exclusively observed in RA-ILD lungs.
(**A**) UMAP plot of T cell subclusters from 12 combined RA-ILD, non-RA CTD-ILD, and control lungs.
(**B**) Dot plots showing signature gene expression in each clusters.
(**C**) UMAP plot of T cell subclusters colored according to disease status.
(**D**) Differential abundance analysis for each cell clusters among disease groups.

Conclusion: There was heterogeneity in several key cell types, such as AT2 cells, club cells, FCN1+ CD14+ macrophages, FABP4+ macrophages, SPP1+ macrophages, and Tph cells between RA-ILD, non-RA CTD-ILD, and control lungs. An upstream regulator analysis suggested that TNF signaling might be involved in the phenotypic change of AT2 cells in RA-ILD. Our study suggests that immune/epithelial cell abnormalities underlie the pathogenesis of RA-ILD.

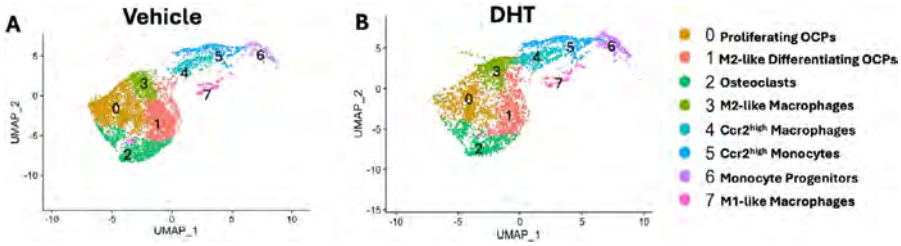

Figure 1. Myeloid Lineage Cells in an Inflammatory Osteoclast Culture. Bone marrow derived cells from a male C57BL/6J mouse were plated and treated with either DHT or vehicle control in osteoclast culture media and collected for single-cell RNA-sequencing. Myeloid lineage populations were subset out from the dataset and defined as 8 unique cluster as illustrated in the uniform manifold approximation and projections (UMAPs) for vehicle-treated (A) and DHT-treated samples (B).

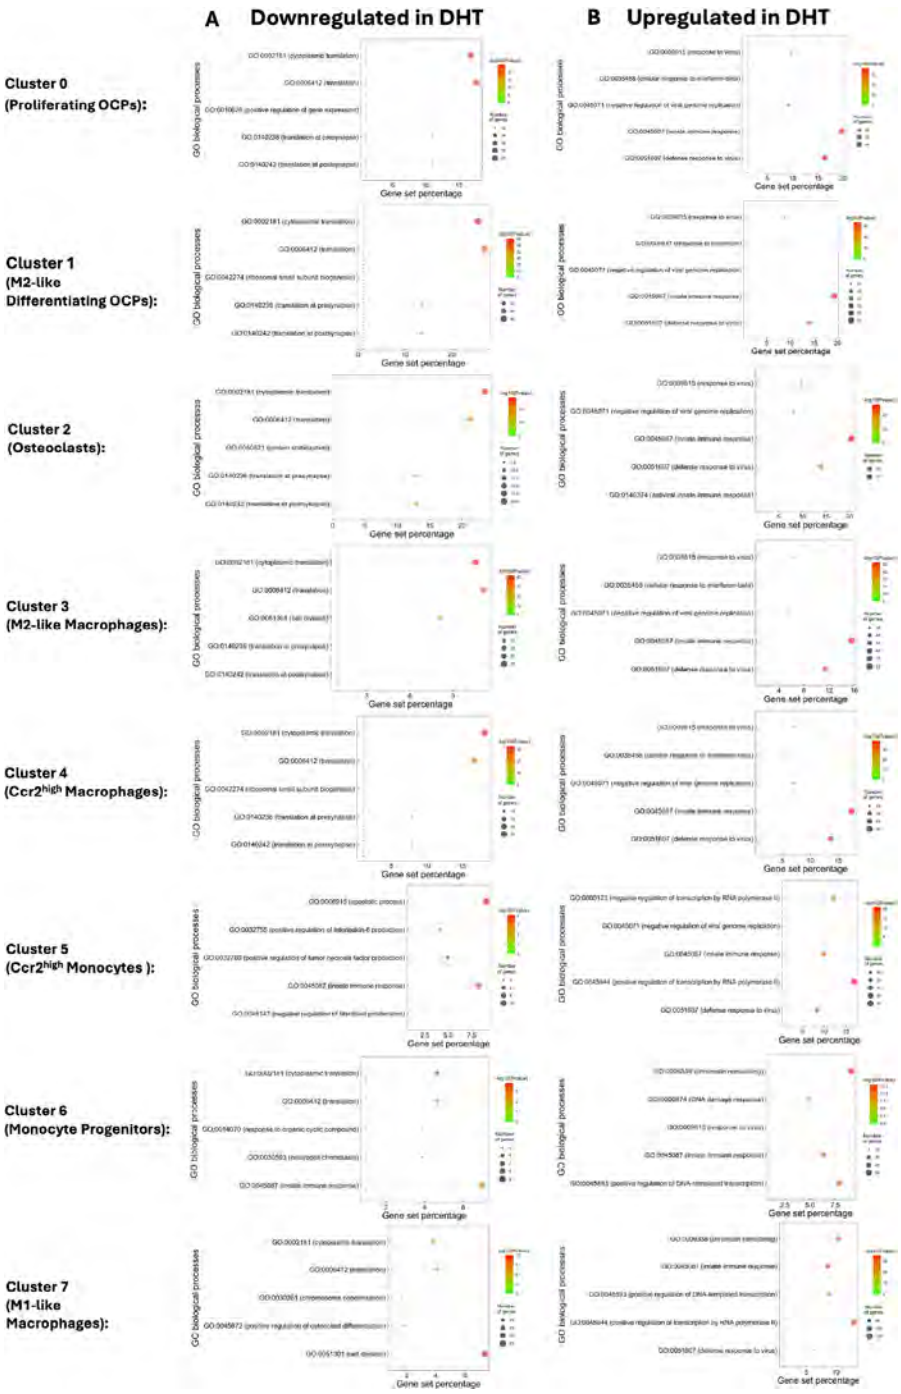

Figure 2. Androgen Treatment Alters the Biological Processes in Myeloid Lineage Cells. Differentially expressed genes (DEGs) between the vehicle and DHT-treated samples in each cluster were used to determine the gene ontology (GO) terms downregulated (A) and upregulated with DHT treatment (B). GO terms that are downregulated with DHT treatment include translation-related terms throughout majority of the clusters and terms that are upregulated with DHT treatment include immune defense response and interferon-related terms throughout majority of the cluster.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 3. Interferon-Related Gene Expression is Increased with Androgen Treatment. Pseudotime trajectory analysis was performed on vehicle-treated (A) and DHT-treated (B) myeloid lineage cells. Cluster 6 (monocyte progenitors) was the root trajectory. Trajectory analysis of the vehicle-treated sample displays the progression of differentiation through monocyte and macrophage populations into differentiating OCPs and osteoclasts. In comparison, the DHT-treated subset illustrates differentiation from monocytes to M2-like differentiating OCPs and osteoclasts, with proliferating OCP clusters determined to be less differentiated. Transcription factor gene expression was analyzed between cluster 3 (M2-like macrophages) to 0 (proliferating OCPs) in the DHT-treated sample (C), and the transcription factor Irf7 was found to be decreased in cluster 0, along with Stat1 and Isg15 (D). In comparison, vehicle-treated cells did not express Irf7 or Isg15 and had lower expression of Stat1 overall. Differentially expressed genes (DEGs) of the DHT-treated sample were exhibited in a volcano plot (E), with Isg15 as the most upregulated DEG. A violin plot illustrates that Isg15 is differentially expressed with DHT treatment in all clusters (F). RT-qPCR of DHT and vehicle-treated cell culture confirmed increased relative expression of Isg15 in DHT-treated cells (G). Plots and analysis were performed with the Cytoscape software and Monocle3, Seurat and EnhancedVolcano R packages. Bars show mean ± standard deviation. Comparisons in RT-qPCR analysis were made with an unpaired t-test. ** = $p<0.01$.

Background/Purpose: Rheumatoid arthritis (RA) is characterized by chronic inflammatory erosions and female predominant disease. Androgen, the dominant sex hormone in males, is protective against bone loss. We have previously shown that androgen limits erosions in a TNF-mediated model of RA and potentially targets osteoclast precursor (OCP). Here, we investigated androgen's effect on osteoclast differentiation and hypothesized that androgen negatively regulates osteoclastogenesis in precursor cells.

Methods: Bone marrow derived cells were harvested from a 3-month-old male C57BL/6J mouse and plated in media containing either 10^{-9}M of 5α-dihydrotestosterone (DHT) or vehicle control and M-CSF. After 48 hours, RANK-L, and human TNFα (hTNFα) were added to media and cells were incubated for 24 hours. Adherent cells were captured with the 10X Genomics Chromium system to undergo single-cell RNA-sequencing (scRNA-seq). Cell typing was determined by the mouse cell atlas and "FindAllMarkers" command in Seurat. Gene ontology (GO) analysis was performed by determining the differentially

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

expressed genes (DEGs) between vehicle and DHT-treated samples in each cluster and submitting them to the DAVID Bioinformatics database. Pseudotime trajectory analysis was performed with the Monocle3 R package. Transcription factor (TF) analysis was performed by generating gene modules between clusters using Monocle3 and the pseudotime dataset. DEGs from this analysis were inputted into the iRegulon package in Cytoscape to determine TFs. DEGs between samples were illustrated in a volcano plot. Using the same cell culture protocol, RT-qPCR was performed on DHT and vehicle-treated samples to compare gene expression.

Results: In the scRNA-seq dataset, 8 clusters were defined as myeloid-lineage cells (Fig. 1A-B). The GO terms that were downregulated with DHT treatment and conserved throughout the clusters included terms associated with translation (Fig. 2A). In comparison, terms upregulated with DHT treatment included innate immune response and response to interferon (Fig. 2B). Pseudotime trajectory analysis of the vehicle and DHT-treated samples showed a difference in differentiation trajectory, where differentiation is decreased in proliferating OCPs with DHT treatment (Fig. 3A-B). TF analysis between our clusters of interest exhibit greater expression of the TF *Irf7* and other interferon-related genes with DHT (Fig 3C-D). The top DEG in the DHT-treated sample for most clusters was *Isg15* (Fig. 3E-F). Relative *Isg15* expression was also significantly increased in DHT-treated OCPs (Fig. 3G).

Conclusion: Androgen treatment in an inflammatory in vitro system of osteoclastogenesis caused a change in the expression of interferon genes and the trajectory of osteoclast differentiation. DHT treatment upregulated interferon signaling, particularly *Isg15* expression, which has been found to negatively regulate osteoclastogenesis (1). This increase in expression may potentially limit differentiation and therefore erosive disease. Further studies will involve examining how androgen targets interferon-related genes and their role in osteoclastogenesis.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0067–0097) Rheumatoid Arthritis – Etiology and Pathogenesis Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Lipid metabolism plays a key role in immune cell plasticity, influencing activation, differentiation and function. Inflammation alters this metabolism, contributing to disease progression. Extensive analyses of these profiles in Rheumatoid Arthritis (RA) using high throughput metabolomics may improve disease characterization.

This study objectives were to analyze circulating lipid and inflammatory profiles of RA patients, explore their association with disease activity and their modulation by b/tsDMARDs and identify mechanisms underlying altered lipid metabolism.

Methods: Clinical data and blood samples were collected from 362 RA patients and age- and sex-matched healthy donors (HDs). Serum lipid profiles were analyzed using Nightingale's NMR spectroscopy (>200 lipid markers). Inflammatory proteins were measured by proximity extension assay (Olink/Cobiomic). A 6-month follow-up was performed in active RA patients treated with TNFi (n=80), IL6Ri (n=27), or JAK inhibitors (n=46). *In vitro* studies in HepG2 liver cells treated with serum from active RA patients included Bodipy staining for lipid accumulation and PCR assays for lipid metabolism gene expression.

Results: Patients were classified as high (n=97) and moderate-low (n=265) disease activity (DAS28). Around 100 lipid markers differed significantly between groups. High activity was associated with reduced levels of most lipids, including apolipoproteins, fatty acids, phospholipids, and total lipid, cholesterol, and triglyceride content. Notably, LDL and VLDL-related proatherogenic markers were reduced. Many lipids negatively correlated with CRP, ESR, ACPAs, RF, cardiovascular risk, and liver enzymes (AST, ALT, GGT).

Some proinflammatory proteins-cytokines, chemokines, and growth factors-were increased in high activity. These also correlated with clinical parameters and the altered lipids identified, indicating a shared dysregulation in high disease activity. At 6-month follow-up, treatment significantly reversed the altered lipid markers and inflammatory proteins, paralleling clinical improvements, including common and specific molecules modulated by each drug.

In vitro HepG2 cells treated with active RA serum showed altered lipid accumulation and dysregulated gene expression compared to HDs. Genes related to lipolysis, β-oxidation, lipid transport and scavenger receptors were over expressed in active RA, whereas genes related to lipogenesis and cholesterol homeostasis were under expressed. These changes were partially reversed by TNFi, IL6Ri or JAKi mirroring *in vivo* effects.

Conclusion: Active RA is characterized by reduced circulating lipids and proinflammatory dysregulation. These changes are partially reversed by biologics and JAKi in parallel with clinical improvement. *In vitro* findings suggest an adaptive hepatic response to inflammation favoring energy mobilization over lipid synthesis, potentially contributing to metabolic dysfunction and CV risk, which may be mitigated by targeted therapies. Ongoing studies aim to further clarify these mechanisms.

Background/Purpose: The mucosal origins hypothesis of RA proposes that immune responses to microorganisms at mucosal sites (e.g. intestine) lead to systemic inflammation and autoimmunity. Little is known about how the fecal microbiome composition and functional capacity may evolve in the pre-clinical period to contribute to development of clinical inflammatory arthritis (IA). The study objective was to compare the fecal microbiome over time among individuals at-risk for RA (ARI) who converted to IA (Converters) versus those who did not (Non-Converters).

Methods: Fecal samples for shotgun metagenomic sequencing of fecal DNA by Illumina NovaSeqX were prospectively collected intermittently over 3 years from ARI, defined as adults with serum cyclic citrullinated peptide antibodies (CCP3 ^{3}20) with no IA at baseline. ARI were grouped into Converters, who developed RA-like synovitis of ^{3}1 joint during follow-up, and Non-Converters. Taxonomic and functional microbiome profiling was performed by MetaPhlAn4 and HUMAnN3. Differential abundance was assessed by MaAsLin3 by mixed linear models. A single baseline and follow up sample from each participant were analyzed. Follow up samples selected were those obtained at the timepoint closest to identification of IA in Converters and the timepoint in Non-Converters that was closest to the median number of days after baseline that Converter follow ups were obtained.

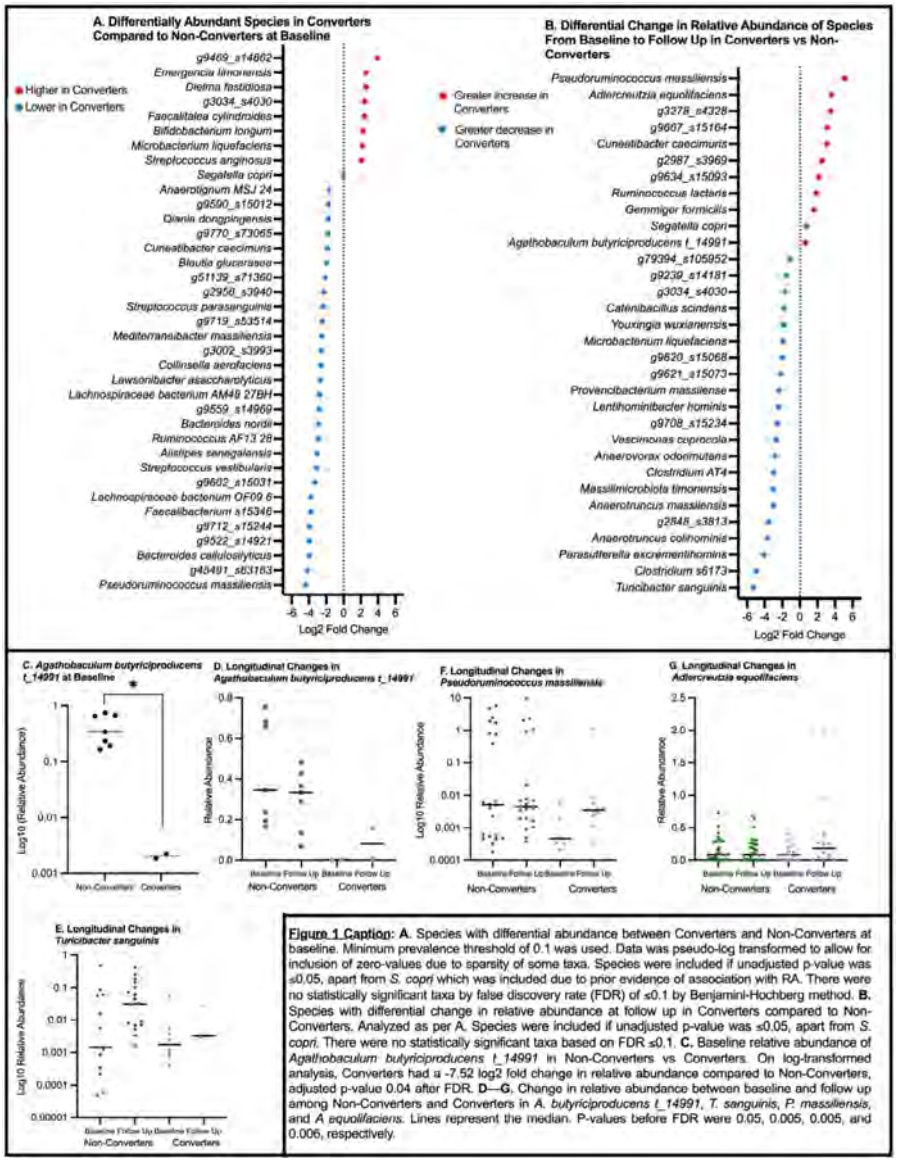

Figure 1: Taxonomic Differences Between Converters and Non-Converters at Baseline and Follow Up

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2: Predicted Functional Gene Features and Pathway Differences Between Converters and Non-Converters at Baseline and Follow Up

Results: There were no significant differences between Converters (n=14) and Non-Converters (n=31) in baseline demographics and labs (**Table 1**). Taxonomic analysis demonstrated -7.5 log2fold lower *Agathobaculum butyriciproducens t_14991* in Converters compared to Non-Converters at baseline; multiple other taxa were differentially abundant but not statistically significant after false discovery rate (FDR) (**Figure 1**). Between baseline and follow up, Converters had a greater increase in *A. butyriciproducens t_14991*, *Pseudoruminococcus massiliensis*, and *Adlercreutzia equolifaciens*; and a greater decrease in *Turicibacter sanguinis*; not significant after FDR. Functional analysis showed significant alterations in fatty acid degradation pathways at baseline among Converters (**Figure 2**). Longitudinally, fatty acid degradation gene features and pathways in Converters changed more significantly over time.

Conclusion: Among a longitudinal cohort of ARI, Converters showed baseline depletion of immunoregulatory bacteria *A. butyriciproducens t_14991*, a short-chain fatty acid (SCFA) producer. Moreover, the trend of changes in several SCFA-producing and starch-metabolizing bacteria in Converters at baseline and over time suggest that Converters harbor gut microbiomes with altered inflammation-regulating capacity compared to Non-Converters. Many of the predicted functional changes at baseline and over time in Converters involve metabolism of immunomodulatory metabolites, including fatty acid degradation pathways. Together, these data indicate complex feedback interactions between the gut microbiome and the

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. host during IA development. Further exploration into longitudinal gut microbiome changes in ARI is needed to better understand potential diagnostic, preventative, and therapeutic applications.

Expansion of PD-1^{hi} Tfh and Tph cells in the peripheral blood of seropositive clinically suspect arthralgia patients: association with progression to rheumatoid arthritis

Maria-Eugenia Miranda-Carus[1], Mariana Gutierrez-Riart[2], Beatriz Nieto-Carvalhal[3], Laura Nuño[2], Alejandro Villalba[1], Diana Peiteado[1], Irene Monjo Henry[1], Marta Novella-Navarro[1] and Eugenio de Miguel[1], [1]Hospital Universitario La Paz, Madrid, Spain, [2]Hospital Universitario La Paz, Madrid, [3]Hospital Universitario La Paz, Mdrid

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0067–0097) Rheumatoid Arthritis – Etiology and Pathogenesis Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Subjects with clinically suspect arthralgia (CSA) are at risk for developing rheumatoid arthritis (RA) and therapeutic interventions may prevent or delay progression. Still, a better identification of potential progressors would minimize exposure to unnecessary treatment. CD4+CXCR5+PD-1^{hi} follicular helper (Tfh) and CD4+ CXCR5-PD-1^{hi}

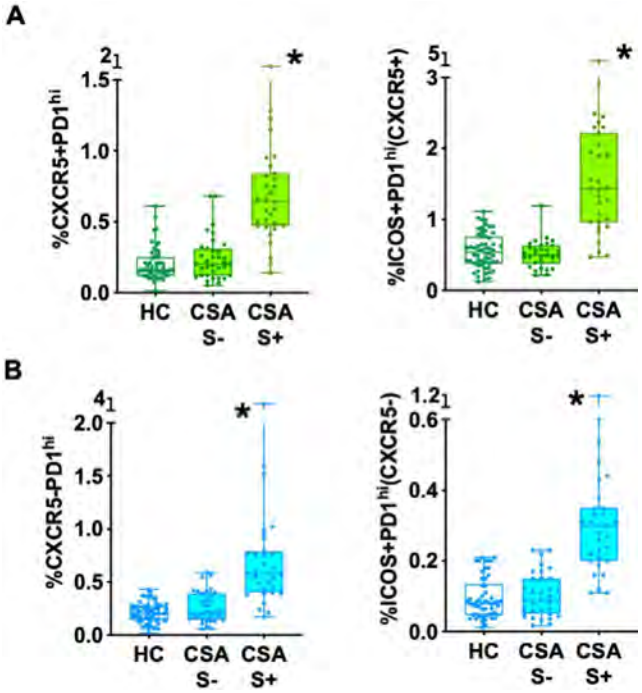

Fig. 1. Frequency of circulating Tfh and Tph cells in HC, seronegative CSA (CSA S-) and seropositive CSA (CSA S+) subjects. A. Frequencies of cTfh (left) and cICOS+Tfh cells(right). B. Frequencies of cTph (left) and cICOS+cTph cells (right)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Relation of the baseline cTfh and cTph cell frequencies with the occurrence of progression to inflammatory arthritis in CSA patients. A-D. Baseline cTfh (A), ICOS+cTfh (B), cTph (C), and ICOS+cTph (D) cell frequencies, in CSA patients who did not progress (non-progressors, NP), vs CSA patients who progressed (progressors, P) to develop inflammatory arthritis. Bars in the left panels represent the median and interquartile range; whiskers represent the maximum and minimum values. *p<0.05, Mann-Whitney test. The right panels show the ROC curves representing the relation of the baseline cTfh (A), ICOS+ cTfh (B), cTph (C) and ICOs+ cTph (D) cell frequencies with the occurrence of progression during the observation period (48 months) (ROC AUC and p values calculated with logistic regression analysis). E. Kaplan-Meier survival curves displaying the probability of progression-free follow-up, stratified using the optimal cTfh cut-off value for progression prediction obtained from the ROC curve.

peripheral helper (Tph) T cells are implicated in RA pathogenesis; characterizing their profile in CSA can enhance our understanding of the RA preclinical stage. Therefore, our objective was to examine the frequencies of circulating Tfh (cTfh) and Tph (cTph) cells in CSA.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Methods: Prospective, non-interventional study in patients with CSA (EULAR definition). Immediately upon initial evaluation, peripheral blood was drawn from each patient and an age/gender-matched healthy control (HC). Ficoll-Hypaque isolated PBMCs were examined by cytometry. Patients were subsequently followed until RA onset or alternatively for up to 48 months.

Results: As compared with HC, patients with seropositive (RF and/or ACPA+) (n=32) but not seronegative (n=37) CSA demonstrated expanded baseline frequencies of cTfh and cTph cells. These frequencies were significantly higher in seropositive CSA patients who progressed to develop classified RA vs those who did not. A cTfh cell frequency > 0.66 predicted progression with a sensitivity of 72% and a specificity of 85%. At the time of RA onset, seropositive progressors (n=18) demonstrated a significant further increase of the cTph but not of the cTfh cell frequency.

Conclusion: Seropositive CSA patients demonstrate increased baseline cTfh and cTph cell frequencies. Higher baseline proportions of cTfh cells associate with progression. This may help identify patients who would benefit from therapeutic interventions directed at delaying or preventing RA onset.

Abstract Number: 0090

Interleukin-36β modulates the progression of rheumatoid arthritis by altering the behavior of rheumatoid arthritis synovial fibroblasts

Marie Svenja Kümmel[1], Mona Arnold-Gräf[2], Selina Ohl[2], Klaus Frommer[3], Nils Schulz[4], Stefan Rehart[5], Ulf Müller-Ladner[3] and Elena Neumann[3], [1]Dept. of Rheumatology and Clinical Immunology, Campus Kerckhoff, Bad Nauheim, Justus-Liebig-University, Germany, Gießen, Germany, [2]Dept. of Rheumatology and Clinical Immunology, Campus Kerckhoff, Bad Nauheim, Justus-Liebig-University, Germany, Bad Nauheim, Germany, [3]Dept. of Rheumatology and Clinical Immunology, Campus Kerckhoff, Bad Nauheim, Justus-Liebig-University, Germany, Bad Nauheim, Hessen, Germany, [4]Kerkchoff Klinik, Dep. of rheumatology, Bad Nauheim, Germany, [5]Agaplesion Markus Hospital, Frankfurt, Hessen, Germany

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0067–0097) Rheumatoid Arthritis – Etiology and Pathogenesis Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis synovial fibroblasts (RASF) play a central role in driving inflammation and promoting cartilage degradation in Rheumatoid arthritis (RA). In our study, we observed that RASF from patients in clinical remission exhibit reduced expression levels of Interleukin-36β (IL-36β). As IL-36β is a pro-inflammatory cytokine involved in immune regulation, we investigated its role in modulating RASF behavior.

Methods: Patients with RA were stratified into remission or active disease groups based on clinical assessments and laboratory markers. RNA sequencing was conducted on RASF isolated from both groups, with and without stimulation using 0.05ng/ml IL-1β. Subsequent analyses included pathway enrichment and identification of the top 50 dysregulated genes. To assess cell adhesion, RASF pre-treated with 1ng/ml IL-1β and/or IL-36β were subjected to a 6-hour assay, followed by quantification of adherent cells after 2 hours. Cell migration was evaluated using transwell assays with 8μm pores and

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

an FBS gradient, comparing pre-stimulated RASF populations based on the stained surface area after crystal violet labeling. Proliferation was determined via BrdU assay 19–24 hours after stimulation with IL-1β, IL-36β, or both. Immunofluorescence staining was employed to analyze IL-36 receptor (IL-36R) expression in synovial tissues from RA patients (active/remission) and individuals with osteoarthritis, with quantification of signal intensity per visual field.

Results: RNA sequencing revealed a marked reduction in IL-36β (-7,14 fold) and its antagonist IL-36Ra (-11,49 fold) in RASF derived from patients in remission compared to those with active rheumatoid arthritis (n=4). Consistent with these findings, elevated IL-36β expression was detected in synovial tissue samples from patients with active disease. Immunofluorescence analysis demonstrated that IL-36 receptor (IL-36R) was predominantly localized to the synovial lining layer across all RA samples, with a more pronounced signal intensity observed in tissues from patients with active RA. Functional assays showed that IL-36β stimulation significantly reduced the adhesive capacity of RASF compared to both unstimulated and IL-1β-stimulated cells ($p < 0.0075, n = 14$). In contrast, IL-36β stimulation led to a significant increase in RASF migration relative to unstimulated controls ($p< 0.002, n=14$), an effect also observed specifically in remission-derived RASF ($p< 0.026, n = 7$). IL-36β treatment increased RASF proliferation compared to IL-1β stimulated cells ($p< 0.009, n=5$), with no significant difference between cells derived from patients with active disease versus remission.

Conclusion: The modulation of adhesion and enhanced migratory capacity of IL-36β-stimulated RASF indicates a potential mechanism by which these cells may more effectively localize to sites of tissue damage in RA. Moreover, the IL-36β-induced increase in RASF proliferation, combined with the diminished IL-36R signal in synovial tissues from patients with active disease, highlights the pathogenic relevance of elevated IL-36β levels in the context of RA progression.

Clonal Hematopoiesis of Indeterminate Potential (CHIP) in Rheumatoid Arthritis: associations with treatment response and comorbidities

Athena Chin[1], susan branford[2], Annabelle Small[3], malcolm Smith[1], monika Kutyna[4], Robert King[5], Susanna Proudman[6], Devendra Hiwase[7] and **Mihir Wechalekar**[8], [1]Flinders Medical Centre, KURRALTA PARK, South Australia, Australia, [2]SA Pathology, Adelaide, [3]Flinders University, Bedford Park, South Australia, Australia, [4]South Australian Health and Medical Research Institute, Adelaide, [5]Flinders Medical Centre, Adelaide, South Australia, Australia, [6]Royal Adelaide Hospital and University of Adelaide, Medindie, South Australia, Australia, [7]Royal Adelaide Hospital, Adelaide, [8]Flinders Medical Centre and Flinders University, Bedford Park, South Australia, Australia

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0067–0097) Rheumatoid Arthritis – Etiology and Pathogenesis Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Clonal hematopoiesis (CH) of indeterminate potential (CHIP) is defined as the detection of recurrent somatic mutations, at a variant allele frequency (VAF) < ![if !msEquation] >< ![if !vml] >< ![endif] >< ![endif] >2%, in genes that are known to drive hematological malignancies (such as *DNMT3A, TET2, ASXL1)* in individuals without hematological abnormalities. CHIP is associated with increased risk of cardiovascular morbidity and all-cause mortality, likely by driving inflammation[1]. We hypothesised that the chronic inflammatory microenvironment in an autoimmune condition such as rheumatoid arthritis (RA) provides selective advantage to CH, thereby promoting an inflammatory state in a self-perpetuating feedback

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. CHIP patients and comorbidities

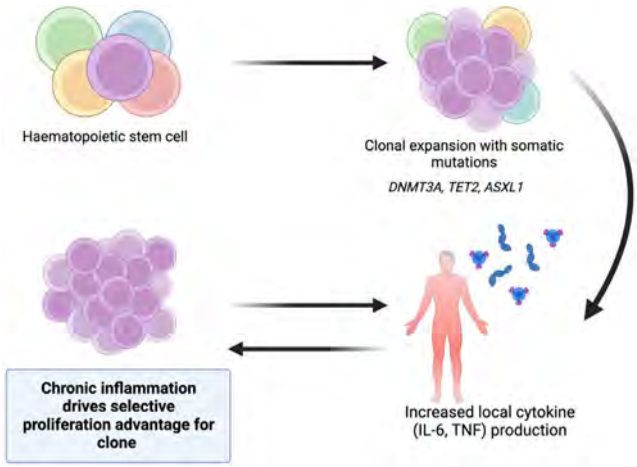
loop. We therefore evaluated the prevalence and pattern of CHIP in RA and its impact on disease activity (DA) and comorbidities.

1. Rossi M, Meggendorfer M, Zampini M, et al. Clinical relevance of clonal hematopoiesis in the oldest-old population. *Blood*. 2021;14doi:https://doi.org/10.1182/blood.2021011320

Methods: DNA was extracted from the peripheral blood of 112 patients with early RA and was analysed for CH using a custom-designed myeloid gene panel. Correlation between CH and disease parameters was performed.

Results: Somatic mutations at VAF levels < ![if !msEquation] >< ![if !vml] >< ![endif] >< ![endif] >0.5% and < ![if !msEquation] >< ![if !vml] >< ![endif] >< ![endif] >2% were detected in 27.7% (31/112) and 9.8% (11/112) RA patients, respectively. RA patients >60years old (53.9%) were more likely to have CHIP (20.5% *vs*. 4.1%; *P*=0.015). This is significantly higher than the reported frequency in an unselected population of 5.6%[2]. The majority of the 48 identified pathogenic variants involved *DNMT3A* (47.9%), *TET2* (16.7%) and *ASXL1* (12.5%). 9/31 (29%) harboured ≥2 variants. Though there was a higher prevalence of CHIP in seronegative patients (11.1%) compared to seropositive (8.2%); this was not statistically significant (p=0.75). Patients with high baseline DA (DAS28-ESR >5.1) and CHIP or ≥2 distinct CH mutations were less likely to



Clonal Haematopoiesis and Chronic Inflammation

SynovAI: A Revolutionary AI Framework for Enhanced Detection and Differentiation of Rheumatoid Arthritis, Osteoarthritis, and Spondyloarthritis via Advanced Ultrasound Imaging

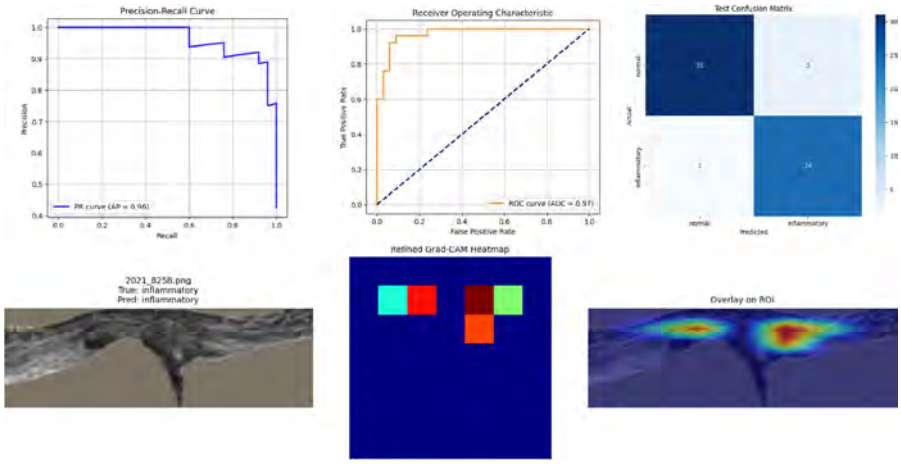
Mojtaba S. Fazli[1], Mariani Diaz Deluna[2], Suzanne Tamang[2] and Robert Fairchild[2], [1]Stanford University, San Francisco, CA, [2]Stanford University, Stanford, CA

SESSION INFORMATION

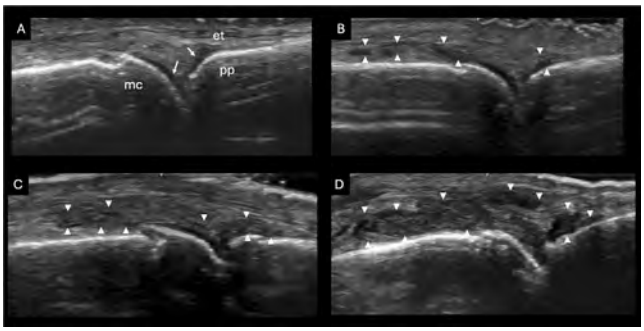
Session Date: Sunday, October 26, 2025
Session Title: (0067–0097) Rheumatoid Arthritis – Etiology and Pathogenesis Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatology musculoskeletal ultrasound (MSKUS) is a powerful technique to identify and differentiate arthritidies joint pathology, yet MSKUS is highly dependent on user experience. Techniques improve ultrasound training, imaging explainability, and aid clinical interpretation can increase the utility of MSKUS. We have begun work on SynovAI, an innovative, next-generation artificial intelligence (AI) framework designed to augment MSKUS interpretation and diagnostic

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Performance of synovial AI on the test set of metacarpophalangeal joints with varying degrees of synovial hypertrophy (top). Image segmentation, grad-CAM heat map, and visualization of the region of interest identified by SynovAI (bottom)



views of the dorsal MCP with normal synovium (A, arrows) and abnormal synovial hypertrophy (B-D, arrowheads). mc= metacarpal head; et = extensor tendon; pp = proximal phalanx.

accuracy. The goal SynovAI is to develop a framework which can identify, quantify, and highlight relevant pathologic features on MSKUS and provide likely rheumatic diagnoses based on the imaging alone, or in combination with clinical data inputs.

Methods: SynovAI framework integrates a suite of pioneering deep learning (DL) strategies designed for maximal diagnostic efficiency and interpretability. The framework begins with (1) an attention-enhanced U-Net architecture that adeptly segments synovial regions of interest (ROI), significantly reducing diagnostic noise. Subsequently, (2) an innovative dual-branch neural network merges global semantic insights derived from a Convolutional Block Attention Module (CBAM)-enhanced ResNet architecture with subtle textural details extracted by a unique diffusion-inspired model, enabling precise discrimination between B-mode ultrasound features. Then, (3) an advanced, attention-based adaptive feature fusion mechanism synthesizes these complementary features into highly robust representations.

Pilot evaluation was conducted on a retrospective clinical dataset of 588 B-mode ultrasound images from dorsal longitudinal metacarpophalangeal (MCP) views, all of which were interpreted by an expert ultrasonographer for the presence or absence of synovial hypertrophy. The dataset was split into 424 training images, 105 validation images, and 59 held-out test images, and reflected real-world clinical variability, including imaging artifacts and inconsistent probe angulation. Training included mixup augmentation, focal loss, gradient clipping, and cosine annealing with warm restarts. Model predictions were further refined via ensemble learning, adaptive thresholding, and test-time augmentation (TTA). Interpretability was enhanced with Grad-CAM visualizations.

Results: On the test set, SynovAI achieved 93.2% accuracy and a macro-averaged F1-score of 0.93, with F1-scores of 0.94 for normal and 0.92 for inflammatory joints. These results highlight SynovAI's strong and consistent performance in detecting early synovial abnormalities in routine ultrasound imaging.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: In this early proof of concept work, SynovAI could identify synovial changes with high accuracy by combining state-of-the-art deep learning methodologies with unparalleled interpretability. We plan to explore identification of associated bony, tendinous, and soft tissue features to synthesize in a predictive model to identify likely diseases, with the addition capability of handling secondary clinical inputs and providing explainable imaging outputs.

Soluble CD13 engages protease-activated receptor 4 to promote synovial inflammation and angiogenesis in rheumatoid arthritis

Chenyang Lu[1], Megan N Mattichak[2], Simin Xu[1], William D Brodie[3], Neha Khanna[2], Hafsa Amin[2], Qi Wu[2], Phillip Campbell[2], David Fox[4] and **Pei-Suen Tsou**[5], [1]Division of Rheumatology, Department of Internal Medicine, Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China, Guangzhou, China (People's Republic), [2]Division of Rheumatology, Department of Internal Medicine, University of Michigan, Ann Arbor, MI, USA, Ann Arbor, [3]Division of Rheumatology, Department of Internal Medicine, University of Michigan, Ann Arbor, MI, Ann Arbor, [4]University of Michigan, Dexter, MI, [5]University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0067–0097) Rheumatoid Arthritis – Etiology and Pathogenesis Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Soluble CD13 (sCD13), the soluble form of aminopeptidase N/CD13, exhibits potent chemoattractant, angiogenic, and arthritogenic properties. While we previously identified certain G protein-coupled receptors (GPCR) including bradykinin receptor B1 as receptors for sCD13 in rheumatoid arthritis (RA), its complete receptor repertoire remains unclear. In this study, we aimed to investigate protease-activated receptor 4 (PAR4) as a novel receptor for sCD13.

Methods: Single-cell RNA sequencing datasets were reanalyzed to determine the expression of PAR4 on synovial cells in RA, which was then validated by immunofluorescence, Wester blotting, and flow cytometry. Induction of PAR4 in human umbilical vein endothelial cells (HUVECs) by TNF-a or IL-1b was assessed by qPCR and Western blotting. PAR4 was overexpressed in RA fibroblast-like synoviocytes (FLS), and cytokine production in sCD13-treated FLS was determined by qPCR and ELISA. The effect of CD13 blocking antibodies (WM15) on proliferation of FLS was dynamically analyzed using the IncuCyte. Effects of PAR4 knockdown or blocker (BMS986120) on the migration and angiogenesis abilities of HUVECs were evaluated by Transwell chambers and tube formation assay, respectively. The binding model of CD13-PAR4 was predicted and constructed using AlphaFold-multimer. Enzymatic inhibitor for CD13, bestatin, was also utilized to assess the enzymatic mechanism of sCD13 activating PAR4. Western blot was performed to identify signaling pathways stimulated by sCD13 in the presence of BMS986120 or WM15. BMS986120 was administered orally to collagen-induced arthritis (CIA) mice and joint inflammation was evaluated.

Results: PAR4 was abundantly expressed in RA synovium, especially in endothelial cells and FLS. While the expression of PAR4 in RA synovium was significantly higher compared to normal and osteoarthritis synovium, it was not induced by TNF-a or IL-1b. In RA FLS, PAR4 overexpression augmented sCD13-mediated proliferation, cytokine production, and ERK1/2 signaling. Both blocking and knocking down PAR4 could suppress sCD13-induced HUVEC migration and angiogenesis *in vitro*. BMS986120 also suppressed sCD13-mediated ERK1/2 phosphorylation in HUVECs. In addition, The CD13-PAR4 interaction involves the center domain of CD13 and the PAR4's pro-peptide region, which needs to be cleaved

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

off for receptor activation. Inhibiting enzymatic activities of sCD13 with bestatin partially reduced sCD13 stimulated migration and angiogenesis of HUVECs. *In vivo*, BMS986120 attenuated joint synovitis and bone erosion in CIA mice.

Conclusion: We identified PAR4 as a second functional sCD13 receptor that mediates proinflammatory signaling in RA FLS and angiogenic responses in endothelial cells, which positions PAR4 as a therapeutic target in RA.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0067–0097) Rheumatoid Arthritis – Etiology and Pathogenesis Poster

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Despite advances in rheumatoid arthritis (RA) treatment, 20–40% of patients do not respond to biologic or targeted synthetic DMARDs (b/tsDMARDs). Understanding each drug's molecular effects may help identify subgroups of patients likely to respond to specific therapies.

Objectives:

1-Characterize the *ex vivo* molecular and cellular effects of JAK (JAKi) and TNF (TNFi) inhibitors on RA immune cells.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

2-Identify, in vivo, RA patient subgroups with distinct baseline levels of drug-specific proteomic signatures and assess their association with clinical response.

Methods: Peripheral blood mononuclear cells (PBMC) and neutrophils from 48 RA patients naïve to b/tsDMARDs were cultured with autologous serum and Baricitinib (JAKi) or Etanercept (TNFi) (10μM) for 24 and 12 hours, respectively. Proliferation, adhesion and NETosis were quantified using specialized kits. Protein changes were assessed via proximity extension assay, analysing a 92-protein inflammation panel in the supernatant. To identify subgroups of patients likely to respond to therapies guided by the identified proteomic signatures, a total of 193 RA patients were included (36 treatment-naïve and 32 previously treated patients initiating JAKi, and 125 treatment-naïve patients starting TNFi) where those proteomic signatures were analysed.

Results: Baricitinib and Etanercept reduced proliferation, adhesion and NETosis in PBMC and neutrophils from naïve RA patients. Each drug modulated distinct inflammatory protein signatures: Baricitinib primarily affected Th17/adaptive immunity while Etanercept targeted acute inflammation.

Unsupervised clustering analysis of JAKi–naïve patients, based on the ex vivo–derived JAKi proteomic signature, revealed two distinct subgroups. Patients with high expression of this signature showed a significantly greater reduction in disease activity (ΔDAS28-CRP) at 3, 6, and 12 months. In contrast, applying the same stratification to non-naïve patients did not predict treatment response. In TNFi-treated naïve patients, the JAKi-associated proteomic signature also stratified into distinct subgroups; however, high baseline levels were not associated with clinical response, supporting the specificity of this signature to JAK inhibitor therapy.

The ex vivo–derived Etanercept proteomic signature effectively stratified TNFi-treated patients, with high baseline levels correlating with improved clinical response at 6 and 12 months. This signature was specific to TNFi and showed no association with treatment response in JAKi-treated patients.

Conclusion: 1. JAKi and TNFi have specific functional and proteomic effects on RA immune cells. 2. Both ex vivo-derived JAKi and TNFi signatures effectively stratified RA patients into subgroups, with each being specific to its respective treatment and not applicable for predicting the clinical response to the other. This highlights the value of drug-specific molecular signatures to personalize and optimize RA treatment strategies.

Abstract Number: 0095

Effect of JAK Inhibitors on Osteoblast Differentiation

Toshihiro Tanioka[1] and Takeo Isozaki[2], [1]Graduate School of Pharmacy, Showa Medical University, Shinagawa-ku,Tokyo, Tokyo, Japan, [2]Graduate School of Pharmacy, Showa Medical University, Tokyo, Tokyo, Japan

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0067–0097) Rheumatoid Arthritis – Etiology and Pathogenesis Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease characterized by chronic inflammation and joint destruction. Among the therapeutic strategies available, Janus kinase (JAK) inhibitors have emerged as an important class of targeted treatments. Currently, five JAK inhibitors are approved for RA treatment in Japan. While their immunomodulatory effects are well-established, their influence on bone metabolism, particularly osteoblast differentiation, remains unclear. This study investigates the effects of different JAK inhibitors on osteoblast differentiation using an in vitro model.

Methods: To assess the impact of JAK inhibitors on osteoblast differentiation, mouse MC3T3-E1 pre-osteoblast cells were cultured in the presence of various JAK inhibitors, specifically Baricitinib (Bari), Peficitinib (Pefi), and Filgotinib (Filgo). The degree of osteoblast maturation was evaluated using Alizarin Red S staining, which detects calcium deposits indicative of mineralized bone matrix, and alkaline phosphatase staining, a marker of osteogenic differentiation. Additionally, the expression of key osteoblast differentiation markers was analyzed to determine molecular correlations with differentiation patterns.

Results: The study revealed distinct effects of different JAK inhibitors on osteoblast differentiation. Bari and Pefi: Both exhibited inhibitory effects on osteoblast maturation, with Bari demonstrating a particularly strong suppression of differentiation. Cells treated with these inhibitors showed reduced mineralization in Alizarin Red S staining and lower alkaline phosphatase activity. Filgo: Unlike Bari and Pefi, Filgo did not inhibit osteoblast differentiation. Even at high concentrations, osteoblasts successfully matured, displaying significant mineralization. Expression of Osterix, a critical transcription factor for osteoblast differentiation, was notably observed in Filgo-treated cells, further supporting its lack of inhibitory effects. FOXM1 Expression: In Filgo-treated cells and control groups, FOXM1 expression increased, suggesting its potential role in osteoblast differentiation. Conversely, FOXM1 levels remained unchanged in cells exposed to Bari and Pefi, reinforcing the hypothesis that JAK signaling influences osteoblast maturation through FOXM1-mediated pathways.

Conclusion: These findings indicate that JAK inhibitors exert differential effects on osteoblast differentiation. Bari and Pefi demonstrated inhibitory activity, whereas Filgo did not affect osteoblast maturation. Furthermore, the regulation of FOXM1 expression by JAK signaling suggests a possible mechanistic link to osteoblast differentiation, warranting further investigation into its role in bone remodeling and therapeutic implications for RA treatment.

Abstract Number: 0096

GLUT1-Dependent Targeting and Enhanced Selectivity of a Glucose-Methotrexate Conjugate in Rheumatoid Arthritis Fibroblast-Like Synoviocytes

Sebastian Makuch[1], Jacek Polański[1] and **Wojciech Tański**[2], [1]Wrocław Medical University, Wrocław, Poland, [2]Wrocław University of Science and Technology, Wrocław, Poland

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0067–0097) Rheumatoid Arthritis – Etiology and Pathogenesis Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disease where fibroblast-like synoviocytes (FLS) play a central role in joint inflammation and destruction. Methotrexate (MTX), a standard treatment, has limitations due to systemic toxicity and variable efficacy. RA-FLS exhibit altered glucose metabolism, notably increased glycolysis and upregulation of glucose transporter 1 (GLUT1), presenting a potential therapeutic target. We developed a glucose-methotrexate conjugate (Glc-MTX) designed to selectively target RA-FLS via GLUT transporters, potentially increasing efficacy and reducing toxicity. This study aimed to evaluate for the first time the in vitro effects of the Glc-MTX conjugate compared to free MTX on proliferation, inflammatory mediator production, and GLUT1-dependent uptake in human RA-FLS.

Methods: Cell proliferation of commercially available primary human FLSs, isolated from the synovial tissues of patients with RA and OA, was assessed using the MTT assay after treatment with Glc-MTX or MTX (doses ranging from 0.01 μM to 10 μM) for 24-48h. For inflammatory response, RA-FLS were stimulated with TNF-α (10 ng/ml) for 48h and treated with Glc-MTX or MTX (0.01 μM to 10 μM) for 24-48h. Levels of key inflammatory mediators (IL-6, IL-8) and matrix-degrading enzymes (MMP-1, MMP-3) in RA-FLS supernatants were quantified by ELISA. To assess GLUT1 dependence, RA-FLS were pre-treated with the selective GLUT1 inhibitor BAY-876 (1 mM) for 60 min before treatment.

Results: MTT assays showed that Glc-MTX inhibited RA-FLS proliferation with an IC_{50} of 2.87 μM, comparable to free MTX (IC_{50}: 2.55 μM). Glc-MTX exhibited greater selectivity for RA-FLS over OA-FLS (IC_{50}: 7.34 μM; Selectivity Index: 2.56) compared to free MTX, which showed higher potency against OA-FLS (IC_{50}: 0.25 μM; Selectivity Index: 0.098). Furthermore, Glc-MTX displayed lower cytotoxic activity against RA-FLS not stimulated with TNF-α compared to those that were stimulated (p=0.013). In TNF-α-stimulated RA-FLS, ELISA results demonstrated that both MTX and Glc-MTX inhibited the secretion of IL-6, IL-8, MMP-1, and MMP-3 compared to stimulated controls, with MTX generally showing stronger inhibition than Glc-MTX at the tested concentrations. Pre-treatment with the GLUT1 inhibitor BAY-876 significantly attenuated the antiproliferative effect of Glc-MTX on RA-FLS, increasing its IC_{50} from 2.87 μM to 12.4 μM ($p< 0.01$), while having minimal impact on the IC_{50} of free MTX (IC_{50}: 2.55 μM without BAY-876 vs. 2.24 μM with BAY-876, $p>0.05$).

Conclusion: The Glc-MTX conjugate inhibits RA-FLS proliferation in vitro with potency similar to MTX but demonstrates significantly improved selectivity over OA-FLS. Both Glc-MTX and MTX inhibited inflammatory and matrix-degrading mediator production. The significant reduction in Glc-MTX efficacy following GLUT1 blockade with BAY-876 confirms its reliance on GLUT1-mediated uptake. These findings show the promising potential of Glc-MTX as a novel, targeted therapeutic strategy for RA. Further in vivo studies are required to fully understand the therapeutic potential of Glc-MTX.

Aberrant Histone Marks Increase the Inflammatory Phenotype of Rheumatoid Arthritis Fibroblast-like Synoviocytes (RA FLS) by Suppressing NUB1 Induction

Yosuke Ono[1], Camilla R.L. Machado[2], Eunice Choi[1], Wei Wang[1], David Boyle[1] and Gary Firestein[2], [1]University of California, San Diego, San Diego, [2]University of California, San Diego, San Diego, CA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0067–0097) Rheumatoid Arthritis – Etiology and Pathogenesis Poster

Session Type: Poster Session A

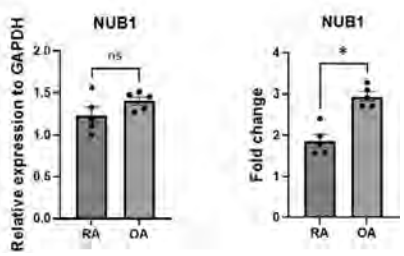
Session Time: 10:30AM–12:30PM

Background/Purpose: Fibroblast-like synoviocytes (FLS) play a central role in cartilage destruction and cytokine production in rheumatoid arthritis (RA). Neddylation, a post-translational modification involving NEDD8 conjugation, is a key regulator of inflammatory signaling. NUB1, a negative regulator of neddylation, is dysregulated in FLS with defective induction after cytokine stimulation that can lead to increased NF-kB activation. Previous studies have shown that this defect is associated with differential histone modification at the NUB1 promoter between RA and osteoarthritis (OA). However, the molecular mechanism of insufficient NUB1 induction in RA remains unclear.

Methods: FLS were isolated from RA and OA synovial tissues and used from passages 4–8. To evaluate mRNA half-life, cells were stimulated with IL-1β (2 ng/mL) for 6 hours, followed by treatment with actinomycin D (10 μg/mL) to interrupt transcription. SNHG12, a long non-coding RNA that binds to NUB1 was depleted with SNHG12 siRNA (knockdown >85). Gene expression was quantified by RT-qPCR after IL-1 stimulation in the presence of EPZ6438 (a histone methylation inhibitor) or MS-275 (an HDAC1/HDAC3 inhibitor).

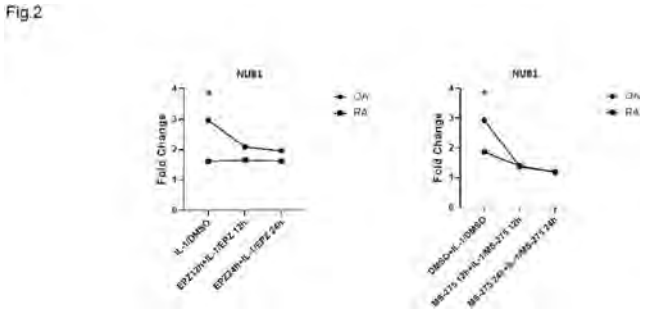
Results: We initially confirmed that NUB1 induction was deficient in RA compared with OA FLS after IL-1 stimulation (Fig. 1). Actinomycin D treatment revealed no significant difference in NUB1 mRNA half-life between RA and OA FLS that might account for this difference, with the half-life for RA=11.3h and for OA=10.7h. In addition, SNHG12 deficiency did not affect NUB1 gene expression or induction in either RA and OA FLS. These findings suggest that the differential expression of NUB1 between RA and OA is likely due to transcriptional differences rather than post-transcriptional regulation. Because NUB1 regulatory regions have distinct epigenetic marks in RA compared to OA, we evaluated this possibility by treated the cells with epigenetic modulators and then stimulated FLS with IL-1 (Fig. 2). IL-1 stimulation resulted in significantly higher

Fig.1



(Fig.1) Reduced induction of NUB1 by IL-1 in RA FLS compared to OA FLS. Basal and IL-1-induced expression of NUB1 in RA and OA FLS is shown. Left: Basal NUB1 mRNA expression in RA and OA FLS, normalized to GAPDH. Right: Fold change in NUB1 expression following IL-1 stimulation (2ng/mL, 6 h), relative to unstimulated (DMSO-treated) cells (RA and OA, n=5 each). Bars represent mean values; individual dots represent biological replicates. Error bars indicate SEM. *; $p < 0.05$, ns; not significant.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



(Fig.2) Reversal of NUB1 differential induction between RA and OA FLS by epigenetic modifiers EPZ6438 (histone methylation inhibitor) and MS-275 (HDAC1/HDAC3 inhibitor). RA and OA FLS were stimulated with IL-1β (2 ng/mL) after pretreatment with epigenetic inhibitors. Fold change was calculated as the ratio of NUB1 expression in IL-1–stimulated cells to that in the corresponding unstimulated control. For the IL-1/DMSO condition, fold change reflects expression relative to DMSO alone. For inhibitor-treated conditions, fold change was calculated relative to cells treated with the same inhibitor without IL-1 stimulation. Circles and squares represent mean fold change for OA and RA FLS, respectively (n = 5 each). *; $p < 0.05$

induction of NUB1 mRNA in OA FLS compared to RA FLS (RA: 1.6-fold, OA: 3.0-fold; $p = 0.01$). EPZ treatment partially reversed this difference (see Fig. 2). MS-275 completely reversed differential induction of NUB1 in OA compared with RA. In addition, 2 week treatment with a DNA methylation inhibitor 5-azacytidine did not alter differential induction of NUB1 in RA compared with OA.

Conclusion: The mechanism of reduced induction of NUB1 in RA FLS is related to differential histone marks in the promoter, most notably histone methylation and acetylation. Because low levels of NUB1 are associated with increased NF-kB activation and cytokine production, this could contribute to increased neddylation and cytokine production in RA FLS. Therapeutic approaches that modify the epigenetic landscape in RA could potentially suppress the inflammatory milieu.

Session Title: (0098–0114) Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Axial Spondyloarthritis (AxSpA) is characterized by both inflammation and new bone formation. Current therapeutic targets aim to control inflammation, however over 40% of patients do not respond to them. The novel deubiquitinase molecule TRABID has been shown to epigenetically control the expression of IL12/23 in the experimental

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

autoimmune encephalomyelitis mouse model. Furthermore, our group has previously shown significantly increased expression of TRABID in inflamed human SpA tissues (bone marrow, synovium and gut). We have also shown that the inhibition of TRABID in monocyte and osteoblast cell culture models significantly supresses cytokine production and bone mineralization respectively. Furthermore, TRABID inhibition in-vivo in curdlan-treated SKG mice significantly suppresses the clinical and histopathological signs of arthritis. Therefore, this study aims to understand the genetic and proteomic mechanisms behind these phenotypes.

Methods: To understand if TRABID can contribute to new bone formation in the spine, facet joint tissues from 5 AxSpA and 5 disease controls were stained using immunohistochemistry to determine TRABID expression patterns. Furthermore, TRABID interactome during osteogenesis was identified by proximity-dependant biotin identification (BioID). Cells were transfected with miniTurbo-tagged TRABID constructs and incubated for 6 days in McCoy's growth or osteogenic media. Biotinylated proteins were enriched using streptavidin beads and identified by mass spectrometry. Biological pathways associated with top significant interactors were identified using PathDip. To assess in-vivo transcriptomic changes induced by TRABID inhibition, 8-week-old SKG mice were injected with curdlan or PBS. For 8 weeks, mice received PBS or high-dose TRABID inhibitor NSC112200 (300mM/kg every 2 days). At 16 weeks, ankle/lymph nodes were collected for RNA extraction and transcriptomic profiling using the murine Nanostring Immunology panel. Pathway analysis for overrepresented gene sets was conducted using Gene Set Enrichment Analysis (GSEA).

Results: We found that TRABID was significantly overexpressed by periosteal cells, osteochondroprogenitor cells that have been shown to promote new bone formation, in the AxSpA facet joints compared to disease controls. Excitingly, we find that TRABID significantly and uniquely interacts with signal transduction, tight junction markers and Rho GTPases during osteogenesis. Moreover, these interactors were predominantly associated with the actin cytoskeleton and membrane bound vesicles. Finally, TRABID inhibition in-vivo significantly altered the expression of genes that belong to antigen processing and presentation pathways in SKG mice. Moreover, these altered genes were found to be associated with the endocytic vesicle membrane and MHC protein complex.

Conclusion: Taken together, our data suggests that TRABID may contribute to new bone formation and inflammation in AxSpA by regulating vesicle transport within the cell. Future work will focus on identifying the exact mechanism by which this process occurs to contribute to AxSpA disease pathology.

Background/Purpose: The management of spondyloarthritis. (SpA) includes controlling disease activity as well as comorbidities such as metabolic syndrome. Metabolic syndrome can be associated with metabolic dysfunction-associated fatty liver disease (MAFLD) or even steatohepatitis (MASH).

The IL-23/TH17 axis plays a central role in the pathophysiology of SpA, but it is also implicated in hepatic steatosis and its progression to fibrosis.

This study aims to evaluate, in an adjuvant-induced arthritis (AIA) rat model, the presence of hepatic inflammation and fibrosis at different stage of arthritis and to assess the effect of early treatment with anti-IL-17A.

Methods: Arthritis was induced in 6-weeks-old male Lewis rats by a subcutaneous injection at the base of the tail with 1.2 mg of inactivated Mycobacterium butyricum suspended in Freund's incomplete adjuvant (AIA groups) at Day 0. At different stages of arthritis (Day 4 post-induction: preclinical phase; Day 11: arthritis onset; Day 30: acute phase; Day 90: resolution phase), intrahepatic inflammation was assessed by measuring mRNA expression of pro-inflammatory cytokines (TNFα, IL-6, IL-17A, IL-23p19, IL-33) using RT-qPCR (delta-delta Ct method, relative expression normalized to GAPDH), and by detecting T lymphocytes (CD3+) and helper T lymphocytes (CD4+) using immunohistochemistry. Fibrosis was evaluated by hepatic TGFβ mRNA expression (RT-qPCR), serum AST/ALT ratio, and histology with picrosirius red staining. The same analyses were performed in non-arthritic control rats and AIA rats treated with secukinumab (20 mg/kg intraperitoneally every three days).

abnormalities associated with SpA but encourage further investigation into the roles of other cytokines, particularly TNF and IL-33, in their pathophysiology.

Results: Compared to controls, AIA rats exhibited early and sustained hepatic inflammation. At preclinical stage, overexpression of TNFα and IL-33 was observed, with additional overexpression of IL-17A and IL-23p19 beginning at arthritis onset ($p < 0.015$). During the acute phase, TNFα, IL-33, and IL-17A remained overexpressed, while only TNFα and IL-33 were still overexpressed at the resolution phase. Hepatic fibrosis was histologically present at all stages ($p < 0.05$), supported by overexpression of TGFβ at Day 11 ($p < 0.001$), Day 30 ($p = 0.06$, NS), and Day 90 ($p < 0.001$). However, the AST/ALT ratio was significantly elevated only during arthritis onset (Day 11, $p < 0.0001$).

Preventive treatment with secukinumab did not alter hepatic pro-inflammatory cytokine genes expression in AIA rats. However, secukinumab increased hepatic CD3+ and CD4+ T cell counts on Day 11 ($p < 0.05$) and TGFβ mRNA expression ($p < 0.01$) compared to untreated AIA rats.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0098–0114) Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: This study aims to:

1. Characterize the NAD^+ metabolome in CIRDs and their association with clinical traits.
2. Evaluate the impact of TNFi therapy on NAD^+ metabolome alterations.
3. Test the potential of a group of NAD^+ boosters to restore NAD^+ alterations and promote anti-inflammatory effects.

Methods: Whole blood samples were collected from 310 subjects: 70 healthy donors (HDs), 80 rheumatoid arthritis (RA) patients, 80 psoriatic arthritis (PsA) patients, and 80 spondyloarthritis (SpA) patients. Key NAD^+ pathway metabolites (NAD^+, NADH, NAM, NMN, NR, NADP and Tryp) were analyzed using two-dimensional Nuclear Magnetic Resonance. A longitudinal analysis in 90 CIRDs patients, 30 from each disease group, assessed NAD^+ metabolome changes after 6 months of TNFi therapy. Peripheral blood mononuclear cells (PBMCs) from 45 patients (15 from each disease group) were treated *ex-vivo* with NAD^+ boosters (NR, NMN, NRT, NRH, and NAR) for 24 hours, followed by intracellular NAD^+/NADH measurement. In parallel, secreted inflammatory mediators were assessed (Olink Inflammation Panel, Cobiomic).

Results: RA, PsA and SpA patients showed reduced NAD^+/NADH ratio and elevated NAM and NMN levels compared to HDs. RA had decreased NAD+ levels, while PsA and SpA displayed increased NADH levels; SpA also had reduced NADP and elevated Trp levels. These disease-specific NAD^+ metabolism alterations correlated with distinct clinical features: in RA, the NAD^+/NADH ratio was negatively associated with DAS28, while NADH and NMN correlated positively with CRP, tender and swollen joint counts (TJC and SJC). Autoantibodies correlated positively with NADH levels. In PsA, the NAD^+/NADH ratio and NAD^+ levels correlated negatively with TJC and SJC, and disease activity (DAPSA) respectively. Uveitis was positively correlated with NAD^+ levels, and psoriasis with NAM levels. In SpA, axial forms had a lower NAD^+/NADH ratio, with positive correlations between ESR and NMN, entesitis and NADH, and dactylitis with Trp. TNFi therapy induced disease-specific changes in NAD^+ metabolites, partially restoring levels toward those seen in HDs. All NAD^+ boosters increased intracellular NAD^+ in patientes PBMCs, with NRH being the most effective. Boosters also reduced inflammatory mediator secretion, showing disease and booster specific effects.

Conclusion: 1-The NAD^+ metabolome was altered in CIRDs, with disease-specific disruption patterns associated with key clinical manifestations.

2-TNFi treatment normalized NAD^+ metabolite levels, indicating a potential role in metabolic rebalancing during therapeutic response.

3- NAD^+ boosters increase intracellular NAD^+ levels and attenuates inflammation, exhibiting both common and disease-specific effects.

Abstract Number: 0101

Enrichment of putative bacteria-reactive gut-derived IL-17+ tissue resident memory helper T cells in arthritic ankles in the SKG mouse model of spondyloarthritis

Benjamin Cai[1], Megan Soon[2], Zewen Kelvin Tuong[2], Mark Morrison[2], Anne-Sophie Bergot[3] and Ranjeny Thomas[4], [1]Frazer Institute, The University of Queensland, Brisbane, Queensland, Australia, [2]Frazer Institute, The University of Queensland, Brisbane, Australia, [3]Frazer Institute, The University of Queensland, Woolloongabba, Queensland, Australia, [4]Frazer Institute, University of Queensland, Brisbane, Queensland, Australia

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0098–0114) Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: In spondyloarthropathy (SpA), arthritis is often associated with gut inflammation. The strong genetic association with HLA-B27 implicates involvement of T cells, but how gut dysbiosis, T cells and SpA are mechanistically linked remain unknown. In the SpA-susceptible ZAP-70W163C SKG mice, Gram-negative dysbiosis is associated with disease severity following curdlan injection. They exhibit defective thymic selection and impaired T cell tolerance, including dysfunctional Tregs, aberrant CD4+CD8+ intraepithelial cytotoxic T lymphocytes, and impaired control of mouse mammary tumour virus (MMTV) superantigen responses. In this study, we investigated the T cell response mediating ileitis and arthritis to gut pathobiont Parabacteroides goldsteinii (*Pg*; a species of Bacteroidaceae enriched in the SKG stool post-curdlan) and its role in mediating ileitis and arthritis in SKG and BALB/c mice.

Methods: Germ-free (GF) SKG and BALB/c mice were orally mono-associated with *Pg* or remained GF for 4 weeks prior to i.p. curdlan injection. CD4+ and CD8+ T cells were FACS-sorted from mesenteric (MLN), popliteal lymph nodes (PLN) at day 6 post curdlan and from ankle joints at day 35 post curdlan. The transcriptome, TCR clonality and usage were analysed by paired scRNA/TCR sequencing combined with CITE-seq using the 10x Genomics pipeline. Bioinformatics analysis was performed using ScanPy, Dandelion, Scirpy pipelines and IEDB database.

Results: At 5 weeks post-curdlan, *Pg*-SKG mice developed ileitis and SpA whilst *Pg*-BALB/c and GF animals were resistant. Naïve T cells, T follicular helper cells (Tfh), early activated T cells, resident-memory T cells (Trm), regulatory Trm cells (Treg-Trm), α4β7 integrin+ T cells were found in the CD4+ compartment, whilst many cell clusters in CD8+ T cells expressed

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

exhaustion-related genes, such as *Hspa1a*, *Tox*, *Lag3* and *Ctla4*. Notably, many α4β7 integrin+ effector T cells were found in *Pg*-SKG ankle and PLN suggestive of their gut origins. Also, IL-17-producing Trm and Treg-Trm cells were enriched in the arthritic ankle joints of *Pg*-SKG mice and exhibited the highest clonality within the CD4+ compartment. These IL-17+ subsets preferentially used TRBV31, TRBV20, and TRBV12-2, of which TRBV12-2 is known to recognize MMTV superantigens. A conserved TCR motif consisted of 14 amino acids was observed across the expanded clones. Structural prediction for this TCR using IEDB database implicated microbial and host-derived proteins, including GPER protein, inner membrane protein YeiH, small nuclear ribonucleoprotein Prp3, and type II secretion system protein GspD in *Chlamydia trachomatis*, as potential reactive antigens.

Conclusion: Gut-derived *Pg* drives ileitis and arthritis in SpA-prone SKG mice by promoting an IL-17+ tissue-resident memory T cell response in the joints. These pathogenic helper T cells may arise from conventional or regulatory T cells in the gut responding to bacterial or viral superantigens in the ankle, providing insight into how gut pathobionts can trigger SpA. Targeting specific TCR motifs, IL-17+ Trm, or their microbial/viral triggers may offer new revenues for treating gut-joint axis inflammation in an antigen-specific manner.

Session Title: (0098–0114) Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Iron metabolism dysregulation has been increasingly recognized as a key factor in the pathogenesis of inflammatory arthritis, with evidence linking altered iron homeostasis to disease progression. However, the mechanisms through which iron dysregulation contributes to inflammation and tissue remodeling in inflammatory arthritis, particularly in ankylosing spondylitis, remain poorly understood. This study aims to investigate the role of iron metabolism dysregulation, particularly the inflammatory mediator SLC39A14, in driving extracellular matrix (ECM) remodeling and ectopic ossification in inflammatory arthritis, using ankylosing spondylitis as a model.

Methods: Primary fibroblasts were isolated from spinal ligament tissues of AS patients, and THP-1 cells were differentiated into macrophages for in vitro studies. The CAIA and SKG mouse models were used, with ferric ammonium citrate (FAC) injected locally in the SKG model to induce iron overload. SLC39A14 conditional knockout (CKO) mice were generated by crossing SLC39A14-flox mice with SCX-cre mice. Ferritin levels and plasma iron concentrations were measured using a colorimetric assay. Immunohistochemistry and immunofluorescence were performed to assess co-localization of Ferritin in fibroblasts and macrophages. CRISPR-Cas9 was used to knock out SLC39A14 in the TTD6 fibroblast cell line, and gene

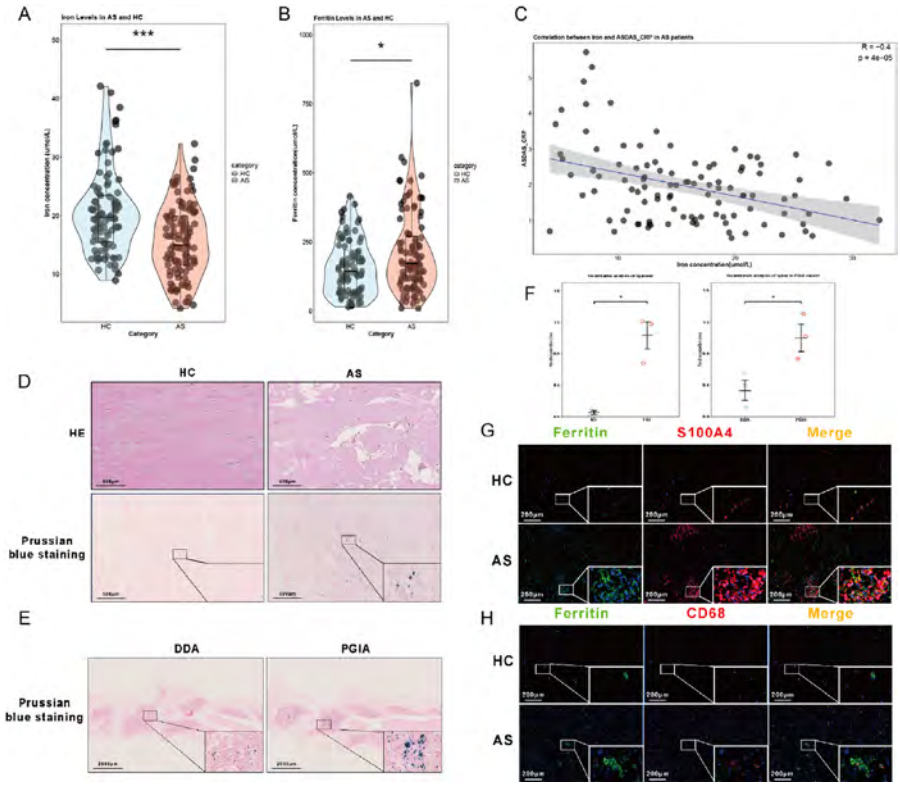

FIGURE 1. Iron Accumulation in Spinal Ligaments of Patients with Ankylosing Spondylitis (AS) (A) Violin plot showing significantly lower serum iron levels in AS patients compared to healthy controls (HC), with statistical significance ($p < 0.05$). (B) Violin plot displaying higher Ferritin concentrations in AS patients relative to HC ($p < 0.05$). (C) Correlation between serum iron levels and ASDAS-CRP scores in AS patients, showing a negative correlation ($r = -0.4$, $p = 4e\text{-}5$). (D) Hematoxylin and eosin (HE) staining and Prussian blue staining of spinal ligament tissues, highlighting iron deposits (blue staining) in AS compared to HC. Scale bars: 50 μm (HE) and 500 μm (Prussian blue). (E) Prussian blue staining of spinal ligaments in the DDA (control group, Dimethyl-dioctadecyl-ammonium) and PGIA (Proteoglycan- induced arthritis) models, showing iron accumulation. Scale bars: 200 μm. (F) Quantification of iron levels and expression of ECM-related genes, demonstrating significant differences ($p < 0.05$). (G) Immunofluorescence staining for Ferritin (green) and S100A4 (red) in spinal ligaments, showing co-localization of Ferritin with activated fibroblasts (S100A4) in AS compared to HC. Scale bars: 200 μm. (H) Immunofluorescence staining for Ferritin (green) and CD68 (red) in spinal ligaments, showing co-localization of Ferritin with macrophages (CD68) in AS compared to HC. Scale bars: 200 μm.

editing efficiency was confirmed by PCR and western blotting. FerroOrange, combined with flow cytometry, assessed iron uptake in treated cells. In vivo, the effects of iron overload were evaluated in the CAIA and SKG models, with western blotting to analyze SLC39A14, Ferritin, and ECM-related proteins.

Results: Our research demonstrated that inflammation-induced iron overload in spinal ligaments led to ECM remodeling and ectopic ossification. Increased Ferritin levels and decreased plasma iron were observed in AS patients, with serum iron negatively correlated with ASDAS-CRP scores, linking iron metabolism to disease severity. TNFα stimulation upregulated SLC39A14 in fibroblasts, promoting excessive ECM deposition. SLC39A14 knockout in fibroblasts inhibited ECM-related gene expression, such as TNC, FN1, and collagen types I and III, highlighting its role in ECM remodeling. Immunohistochemistry showed co-localization of SLC39A14 and Ferritin in activated fibroblasts and macrophages. Single-cell RNA sequencing identified fibroblast subpopulations sensitive to iron accumulation, with elevated ECM gene expression. In vivo, FAC injections in the SKG mouse model induced ectopic ossification in the Achilles tendon, further supporting the role of iron overload in ECM remodeling.

Conclusion: In an inflammatory state, upregulation of SLC39A14 in fibroblasts leads to iron overload, driving ECM remodeling and ectopic ossification in inflammatory arthritis, such as ankylosing spondylitis. Targeting SLC39A14 and modulating iron metabolism may offer potential therapeutic strategies to prevent these pathological changes.

Session Title: (0098–0114) Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Spondyloarthritis (SpA) exhibits strong familial aggregation, with close relatives of patients having a significantly higher risk of developing the disease. This pattern might be driven by an accumulation of common variants that collectively increase disease risk or by rare variants in high linkage disequilibrium (LD) with common risk alleles, amplifying the genetic predisposition in affected families. Our aim was to investigate whether the familial form of SpA is influenced by an excess burden of common risk variants or by rare variants located within SpA-associated loci.

Methods: We examined two independent patient groups: (1) a family-based cohort of 376 SpA patients from 68 French families with at least four affected members, all of whom underwent whole genome sequencing (WGS), and (2) a cohort of 242 French unrelated ankylosing spondylitis (AS) patients with and without a family history of SpA, genotyped on the Illumina CoreExome array. Polygenic risk score (PRS) for AS were calculated using a model developed by Li et al. for Western European population (Li Z et al. doi: 10.1136/annrheumdis-2020-219446). Linear regression was applied to identify PRS-associated factors, and HLA-B27 frequency differences between sporadic and familial cases were analyzed using the chi-square test. We identified 46 coding genes overlapping with SNPs in high LD (r^2 >0.8) with lead SNPs from the 42 known AS-associated loci (Ellinghaus D et al. doi : 10.1038/ng.3528). To examine whether rare variants within these genes contribute to familial SpA, we conducted a rare variant burden test in our family cohort using gnomAD data as controls (Lali R et al. doi: 10.1038/s41467-021-26114-0).

Results: PRS was significantly increased in patients with familial history of SpA (68 probands from multiplex families and 123 patients from the unrelated cohort) compared to 119 sporadic cases (β-estimate (β)± standard error (SE): 0.09 ± 0.03; p-value (p) = 0.004; Figure 1A). However, the HLA-B27 positivity rate was significantly higher in familial cases

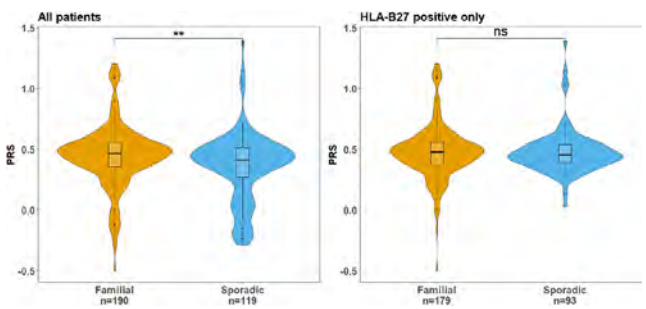

Figure 1 – Distribution of PRS according to family history status in all SpA patients (panel A) or in HLA-B27 positive patients only (panel B)

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

compared to sporadic cases (94.2% vs 78.2%; p = 6x10^{-5}) and the PRS difference was no longer significant when comparing only HLA-B27 positive patients (β ± SE: 0.003 ± 0.03; p = 0.9; figure 1B). Within the familial cohort, PRS was inversely associated with the number of affected family-members (β ± SE: -0.08 ± 0.03; p = 0.03). WGS data from the familial cohort revealed at least one non-synonymous SNPs with a minor allele frequency below 1% in non-Finnish European population and a predicted pathogenicity CADD score above 20 in 19 of the 46 AS-associated coding genes. The rare variant-burden test showed nominal association with familial SpA only for the *PDE4A* gene (p=0.05).

Conclusion: Besides the higher prevalence of HLA-B27, we found no significant accumulation of common AS-associated variants in familial cases of SpA. Furthermore, there was no excess of rare variants in genes within AS-associated loci, with the exception of a nominal association for *PDE4A*. Altogether these results suggest the involvement of other genetic factors, such as rare variants in additional genes, or environmental factors contributing to the strong familial aggregation of SpA.

Session Date: Sunday, October 26, 2025

Session Title: (0098–0114) Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Axial spondyloarthritis (axSpA) is a chronic immune-mediated inflammatory disease with strong genetic predisposition, driven by HLA-B27 and over 100 additional loci identified by genome-wide association studies (GWAS). As most risk variants lie in non-coding regions, pinpointing causal variants and their functional roles remains a major post-GWAS challenge. CARD9 encodes an adaptor protein critical for innate and adaptive immune responses, promoting NF-κB and MAP kinase activation, proinflammatory cytokine production, and Th17 differentiation—key processes in axSpA. Although the CARD9 locus is associated with axSpA, the causal variant(s) and their functional impact are still unknown. The aim of this study was to identify the functional basis for the genetic association of *CARD9* variants with axSpA and its consequences on proinflammatory cytokines production.

Methods: Bayesian fine mapping on the CARD9 locus was conducted using the British subset of the IGAS Immunochip GWAS (*Cortes A et al. doi: 10.1038/ng.2667*). To assess regulatory effects of candidate causal variants, expression quantitative trait *loci* (eQTL) and chromatin accessibility quantitative trait *loci* (caQTL) mappings were performed using RNA-seq

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. CARD9 mRNA expression levels in CD14+ monocytes, CD4+ and CD8+ T cells (panel A) and chromatin accessibility of CD14+ monocyte-specific regulatory region upstream of CARD9 promoter (panel B) according to genotype of SNVCARD9 (axSpA-susceptibility allele : G); ** : p-value <0.01; *** pvalue <0.001.

and ATAC-seq from CD14+ monocytes, CD4+ and CD8+ T cells of 45 individuals (20 axSpA, 35 healthy controls (HC)) (*Brown AC et al. doi: 10.1016/j.xgen.2023.100306*). Transcription factor binding disruption was evaluated via ATAC-seq footprinting with Tobias (*Bentsen M et al. doi: 10.1038/s41467-020-18035-1*) in public CD14+ ATAC-seq data from 41 controls (*Stevens NE et al. doi: 10.1172/JCI171742*).

Finally, TNFα, IL-6 and IL-23 production was measured by flow cytometry in monocytes from 59 axSpA patients before and after stimulation with lipopolysaccharide (LPS) or *Candida albicans* (C.alb) , and associations with candidate variant genotypes were tested using linear regression adjusting for age, sex, cell mortality, stimulation, and biologics use.

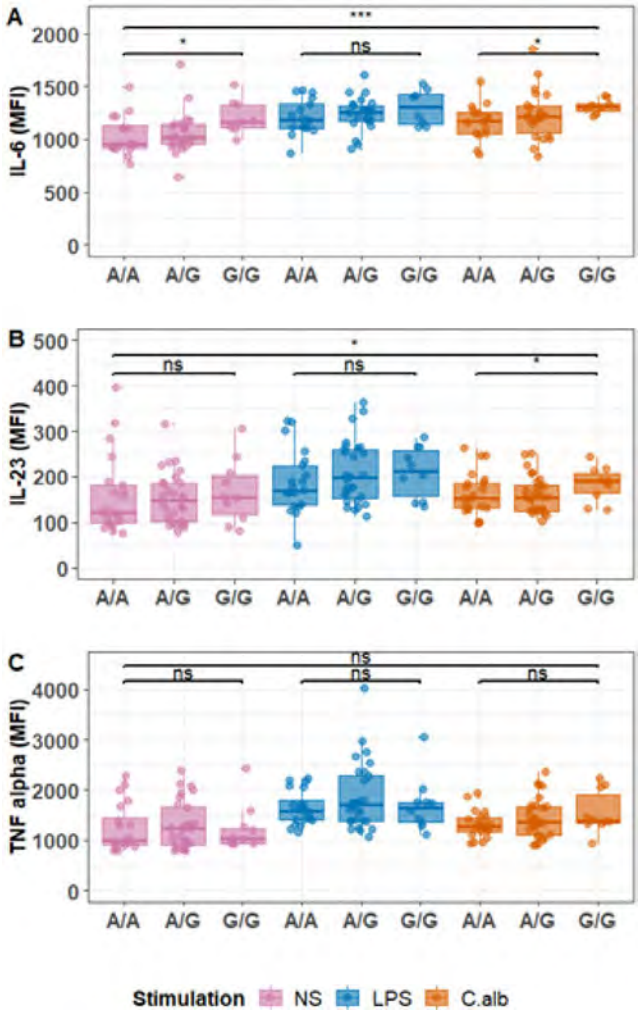

Figure 2. Mean fluorescence intensity (MFI) of IL-6 (panel A), IL-23 (panel B), and TNF alpha (panel C) in monocytes of 59 axSpA patients according to SNVCARD9 genotype in monocytes left unstimulated ("NS") or after stimulation with lipopolysaccharide (LPS) or Candida albicans (C.alb). ns: not significant * : p-value <0.05; *** pvalue <0.001

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Results: Fine mapping in 4,101 axSpA patients and 9,700 HC prioritized one variant -denoted "SNV_{CARD9}"- with >95% posterior probability of causality. This variant lies in a monocyte-specific open chromatin region upstream of the CARD9 promoter. The axSpA-risk G allele was associated with increased CARD9 mRNA expression and with enhanced chromatin accessibility in its surrounding region (figure 1). ATAC-seq footprinting predicted an allele-specific binding of the transcription factor ZBTB24. Functionally, the G allele was associated with a dose-dependent increase in IL-6 (p-value< 0.001) and IL-23 (p-value < 0.05), production but not with TNFα production (Figure 2).

Conclusion: These findings identify "SNV_{CARD9}" as a likely causal variant at the CARD9 *locus* in axSpA, linking increased CARD9 expression and IL-6/IL-23 production to disease risk. This supports the functional role of CARD9 in axSpA pathogenesis and its potential as a therapeutic target in risk allele carriers.

Inflammatory Cytokines, Matrix Metalloproteinases and Bone Markers Expressions Are Modulated in the Joints in the Chronic Murine Model of Imiquimod-Induced Psoriasis

Guillaume LARID[1], Cassandre Dumonteix Moreau[2], Adrien JAMAI[2], Hanitriniaina Rabeony[2], Jean Claude LECRON[2], Elisabeth Gervais[1], Jean François JEGOU[2] and franck MOREL[2], [1]Poitiers University Hospital - Poitiers University - LITEC Laboratory UR 15560, Poitiers, France, [2]Poitiers University - LITEC Laboratory UR 15560, Poitiers, France

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0098–0114) Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Psoriatic disease is a systemic inflammatory condition which encompasses both cutaneous psoriasis (PsO), psoriatic arthritis (PsA) and multiple comorbidities. The chronic Imiquimod (IMQ) induced psoriasiform dermatitis mouse model is a classical model to study psoriasis and has been used in analysing psoriasis associated liver fibrosis. However less is known about joint inflammation and cytokines modification after IMQ psoriasis induction. The objectives of this study were to analyse the expression of cytokines, metalloproteinases and bone markers inside the mice's joints to evaluate the potential of long-term application of IMQ as a new PsA mouse model as well as the involvment of Oncostatin M (OSM).

Methods: Wild type (WT) and OSM-KO male C57BL/6 mice were studied. For the induction of PsO-like inflammation, mice were shaved and depilated on their back before a daily topical application of 62.5 mg of Aldara cream (5% IMQ; Meda) for six consecutive days every other week during 5 (W5) to 9 weeks (W9). Control mice were treated with a similar dose of Vaseline. Mice were euthanized after 5 weeks or 9 weeks of treatment. Knee joints were dissected, collected, rapidly frozen in liquid nitrogen. Total RNA was extracted, reverse transcribed, and transcripts were quantified using the LightCycler-FastStart DNA Master Plus SYBR Green I kit on LightCycler 480 instrument. Samples were normalized to the independent control housekeeping gene, glyceraldehyde 3-phosphate dehydrogenase (GAPDH), and reported according to the ΔΔCT method

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

as RNA fold increase over untreated samples. Comparison were made using Mann Whitney test. p-values < 0.05 were considered significant.

Results: Chronic application of IMQ on the mice skin induced a pro-inflammatory state within the joints as shown by the increased expression of TNF alpha at W5 and W9 in both WT and OSM-KO mice and decreased expression of the anti-inflammatory cytokine PEDF. IL-1 family cytokines seem to be implicated in the initiation of the inflammatory response as suggested by IL1a increase at W5 in the IMQ treated WT mice and the decreased expression at W9 of IL-18. IL10 expression was increased at both W5 and W9 indicating an attempt to regulate joint's inflammation. While at W5 no difference was observed for MMP3, MMP9, and MMP13, a lower expression was found in IMQ treated mice for MMP3 and MMP13 at W9 while no difference were observed for MMP9. Concerning bone turnover, no modification of Sclerostin was found in both groups at W5 and W9 while there was a DKK1 expression decrease only in the WT group at both W5 and W9. M-CSF, an osteoclast differentiation driver, was decreased only at W9 in both groups and at W5 in the WT group only. These results confirm the role of OSM as a modulator of bone biology upon inflammatory conditions. No difference was found at both W5 and W9 for IL1B, VEGFa, MMP9, SOST, TLR7, TRPV1, IL1RA in both groups.

Conclusion: In the long term IMQ induced psoriasis mouse model intra-articular inflammation is observed and modifications of bone cell markers as well as metalloproteinases expression are modulated in a time dependant manner. Those results pave the way to a more detailed analysis of this model which seems a promising new PsA model as well as a PsO to PsA mechanistic model.

Investigation of DNA Methylation Inhibition in a Mouse Model of Ankylosing Spondylitis

Goh Murayama[1], Kurisu Tada[2], Naoto Tamura[3], Eri Hayashi[1], Taiga Kuga[4], Ken Yamaji[5] and **HOSHIKO FURUSAWA**[6], [1]Department of Internal Medicine and Rheumatology, Juntendo University Graduate School of Medicine, Tokyo, Japan, [2]Department of Internal Medicine and Rheumatology, Juntendo University Graduate School of Medicine, Tokyo, [3]Juntendo University School of Medicine, Tokyo, Japan, [4]Juntendo University, Tokyo, Japan, [5]Juntendo University, Department of Internal Medicine and Rheumatology, Tokyo, Japan, [6]juntendo, tokyo, Japan

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0098–0114) Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Ankylosing spondylitis (AS) is a chronic inflammatory disease characterized by enthesitis in axial joints, bone erosion near the entheses, and subsequent irreversible ankylosis due to new bone formation. Although AS has a strong association with HLA-B27, its occurrence in HLA-B27-negative individuals suggests the involvement of epigenetic factors. Decitabine is a DNA methylation inhibitor that induces demethylation and reactivation of silenced genes and is used to treat myelodysplastic syndromes. This study aimed to evaluate the effects of decitabine in a mouse model of spondyloarthritis.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Spondyloarthritis was induced in SKG mice by intraperitoneal injection of β-glucan under SPF conditions. Mice were treated weekly with either decitabine (1 mg/kg/week) or vehicle. Body weight and arthritis scores were monitored until week 12. At week 12, and histological analysis was performed on the limb joints, spine, and tail. At weeks 4, 8, and 12, splenic T cell subsets and cytokine production were analyzed by flow cytometry. DNA methylation analysis was performed on the achilles tendon to identify genes with suppressed methylation by decitabine. Furthermore, to assess the functional effects of decitabine in vitro, splenocyte supernatants from arthritic mice were co-cultured with decitabine, and production of IL-17 and TGF-β was evaluated.

Results: Mice treated with decitabine showed significantly improved arthritis scores compared to the control (vehicle) group. Histological scores of the limb joints and tail at week 12 were significantly improved as assessed by both H&E and toluidine blue staining. Flow cytometry of splenocytes revealed a significant suppression of IL-17 production in mice at weeks 4 and 8. Although the number of regulatory T cells ($CD4+CD25^{+}FOXP3^{+}$) remained unchanged in mice sacrificed at week 12, PD-1 expression on Tregs was significantly reduced. DNA methylation analysis of the Achilles tendon at week 12 revealed significant demethylation of the *FOXP3* and *IL17rd* genes. In vitro experiments showed that stimulation of splenocyte supernatants with IL-2 and anti-CD3/CD28 antibodies, followed by co-culture with decitabine, resulted in a significant increase in TGF-β production as measured by ELISA. After additional 24-hour stimulation with PMA/ionomycin, IL-17 production tended to be suppressed in the decitabine-treated cultures.

Conclusion: DNA methylation inhibitors may alleviate systemic symptoms and arthritis in a mouse model of spondyloarthritis by suppressing IL-17 production and enhancing Treg function.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0098–0114) Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Elastography (EL) is an imaging technique that evaluates the biomechanical properties of tissues. Pathological tissues have different elastic properties compared to healthy tissues.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

In diseases like psoriatic arthritis (PsA), tendon structure and function can be affected, leading to enthesitis, being the Achilles tendon one of the most commonly involved structures. EL allows for the evaluation of tendons´ response to mechanical strain, detecting changes in their elasticity that may indicate inflammation or structural damage. The underlying hypothesis is that Achilles tendon stiffness increases significantly after physical activity in patients with Achilles involvement, while in those without enthesitis, elasticity remains stable.

The purpose of this study is to demonstrate the utility of Achilles elastography (EL-AQ) in the diagnosis of PsA in patients with clinically referred Achilles involvement (PsA-A) or without it, compared to three types of controls.

Methods: Baseline and post-exercise EL-AQ results were compared between PsA and PsA-A patients (diagnosed < 24 months) from four rheumatology centers and three control groups: athletes, non-athletic individuals with normal weight, and overweight/obese subjects, all without known psoriatic disease. Controls were matched to patients by sex and age (±2 years). Baseline and post-exercise comparisons were performed, and correlations between these results, clinical characteristics, and MASEI scores were analyzed. EL-AQ was performed using a General Electric S8 ultrasound machine equipped with a low-frequency linear probe. Tendon stiffness was measured using shear wave elastography, averaging three 1 cm^2 regions of interest within the enthesis of the non-dominant Achilles tendon (controls and PsA patients) or the symptomatic tendon (PsA-A patients). The controlled exercise consisted of 20 minutes on a stationary bicycle at medium resistance with a target of 150% of the resting heart rate.

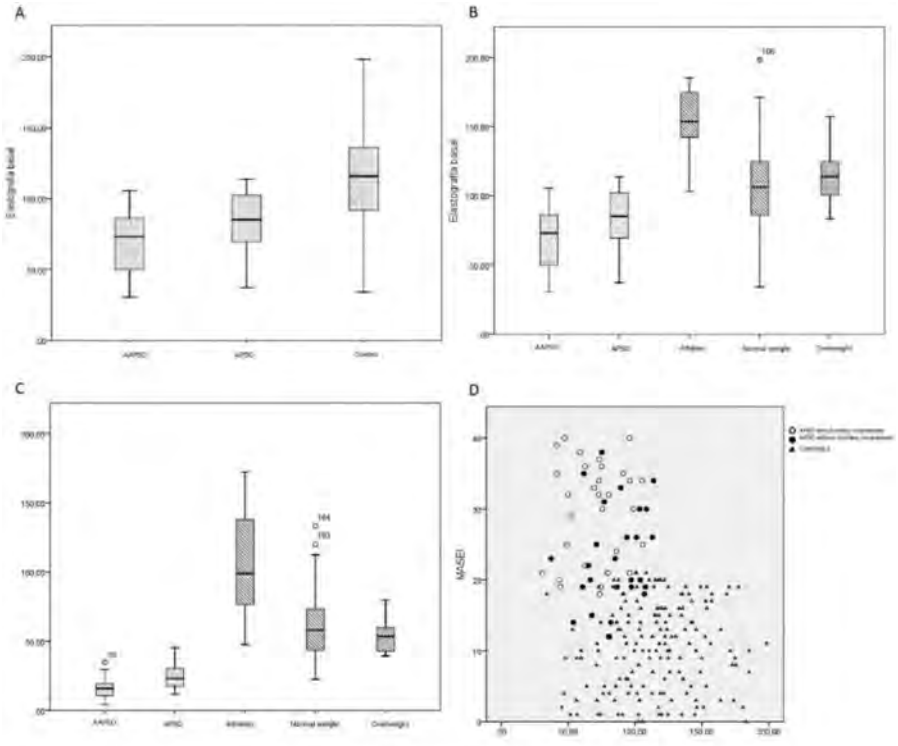

Figure 1A: Comparison of baseline Achilles elastography (EL-AQ) in patients with psoriatic arthritis with Achilles symptoms (PsA-A), PsA without Achilles symptoms (PsA), and all controls.
B: Comparison of baseline EL-AQ in patients and the three control subgroups.
C: Comparison of post-exercise stiffness increase between patients and control subgroups.
D: Correlation between MASEI and baseline EL-AQ in patients and controls.
EL-AQ measurements are expressed in kPa.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: A total of 57 patients (27 PsA, 30 PsA-A) and 171 controls were included. Patients' mean age (SD) = 39.9 (6.7) years. Time since diagnosis = 12 (7) months. Baseline EL-AQ results for controls and patients were 114.6 (32.9) and 77.0 (21.6) kPa, respectively ($p < 0.001$). EL-AQ post-exercise gradients in controls and patients were 65.7 (28.7) and 20.0 (9.3) kPa, respectively ($p < 0.001$). An inverse correlation was observed between MASEI and EL-AQ post-exercise change (Pearson's coefficient -0.445; $p < 0.001$). Among patients, baseline EL-AQ was 70.1 (21.0) in the PsA-A group and 84.7 (19.9) kPa in the PsA group ($p < 0.05$); EL-AQ post-exercise gradient was 15.9 (7.2) in the PsA-A group and 24.5 (9.4) kPa in the PsA group ($p < 0.001$).

Conclusion: Baseline EL-AQ demonstrates discriminatory diagnostic capacity between PsA patients with or without clinical Achilles involvement and healthy controls. Adaptive ability to physical exercise, analyzed via post-exercise EL-AQ gradient, also demonstrated strong discriminatory capacity between patients and control subgroups. EL-AQ should be considered a test of interest for evaluating patients suspected of having PsA with or without Achilles involvement.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0098–0114) Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Psoriatic arthritis (PsA) is a chronic inflammatory disease for which TNFα inhibitors are the standard first-line biologic therapy. Nonetheless, a significant proportion of patients exhibit an inadequate response, requiring a switch to alternative agents. There are several second-line treatment options, such as IL-17 inhibitors, IL-23 inhibitors, or JAK inhibitors. Among these options, IL-23 inhibitors are increasingly used, yet there is no clear guidance to inform their selection in clinical practice. Exploring how TNFα inhibition influences the IL-23 levels may offer valuable insights into whether anti-IL-23 therapies represent a rational and effective choice after anti-TNF failure. This study aims to investigate the effect of anti-TNFa therapy on IL-23 serum levels in PsA patients and explore the mechanistic regulation of IL-23 and other inflammatory markers by TNFa in vitro.

Methods: Serum IL-23 levels were measured by ELISA in a cohort of 40 PsA patients before and after six months of anti-TNFa therapy. In parallel, primary human dermal fibroblasts were cultured and stimulated with recombinant TNFα in the presence or absence of anti-TNFα agents using varying concentrations and exposure times (6h, 24h and 48h). IL-23 expression and other key inflammatory markers were assessed by RT-qPCR to evaluate the impact of TNFα blockade.

Results: Serum IL-23 levels were significantly reduced after six months of anti-TNFα therapy. In vitro, TNFα stimulation induced a robust upregulation of IL-23 expression in dermal fibroblasts which was effectively reversed by anti-TNFα agents. Additionally, anti-TNFα exposure led to a significant decrease in the expression of inflammatory mediators such as IL-6, while genes like IL-17 remained largely unchanged. These findings suggest that TNFα directly promotes IL-23 production in resident skin cells, and that its inhibition downregulates this axis both systemically and at the tissue level.

Conclusion: Our findings demonstrate that anti-TNFα therapy significantly modulates key inflammatory pathways in PsA. Anti-TNFα treatment leads to a notable reduction in IL-23 levels both in vivo and in vitro, highlighting IL-23 as a downstream target of TNF signaling in PsA. Therefore, quantification of IL-23 could serve as a promising biomarker for personalizing biologic sequencing and guiding second-line therapy selection in PsA patients with suboptimal responses to anti-TNFα agents.

Abstract Number: 0109

Application of Psoriatic Arthritis Mouse Models in Preclinical Pharmacodynamic Evaluation

Juan Liang[1] and Yinlian Zhang[2], [1]Gempharmatech, Nanjing, Jiangsu, China, [2]GemPharmatech, Nanjing, China (People's Republic)

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0098–0114) Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Psoriatic arthritis (PsA), a complex inflammatory disorder that affects up to 30% of psoriasis patients. It is marked by clinical heterogeneity and a lack of standardized diagnostic criteria, posing significant challenges in therapeutic development. Despite advancements in targeted therapies, gaps in understanding disease pathogenesis and variable clinical phenotypes highlight the need for robust, translational preclinical models. Here, we established two inducible PsA mouse models to support preclinical drug efficacy testing and accelerate therapeutic discovery.

Methods:

Two distinct PsA models were developed:

1. Mannan-induced PsA model, female BALB/c mice (12-13 weeks) received intraperitoneal mannan injections (every 4 days) combined with a single subcutaneous Complete Freund's Adjuvant (CFA) injection into the hind paw. On day 12, ear and paw tissues were analyzed for histopathology (HE staining, inflammation scoring), qPCR (inflammatory cytokines: *Ifng*, *Il6*, *Il17a*, *Tnf*, *Il23*), and serum cytokines (CBA assay: IL-12, IFN-γ, IL-6).

2. AAV-hIL23-induced PsA model, female NOD ShiLtj mice (8 weeks) were injected intravenously with 1×10^{12} particles/mL AAV-hIL23. Serum hIL-23 levels were monitored weekly (ELISA), and tissues were analyzed at day 35 for histopathology and cytokine expression.

Pharmacodynamic evaluation in the mannan-induced PsA model: Treatment arms included dexamethasone (1 mg/kg, daily oral) and upadacitinib (20 mg/kg, BID oral). In as separate study, PsA was induced with mannan in BALB/c-hIL23AhIL12B mice (GemPharmatech), followed by subcutaneous injection with risankizumab (10 mg/kg, BIW). Disease progression was monitored via psoriasis/arthritis scoring of the ears and hind limbs.

Results: Mannan-induced model, PsA mice exhibited marked ear erythema, paw/ankle swelling, elevated psoriasis/arthritis scores, as well as elevated expression of inflammatory cytokines (*Ifng*, *Il6*, *Il17a*, *Tnf*, *Il23*), and increased serum IL-12, IFN-γ, and IL-6. Histopathology revealed epidermal hyperplasia, inflammatory infiltration, and bone erosion. Both dexamethasone and upadacitinib reduced skin/joint inflammation and disease scores. Risankizumab effectively suppressed skin/joint pathology and disease scores in mannan-induced BALB/c-hIL23AhIL12B mice PsA model. In AAV-hIL23 model, sustained hIL-23 expression (serum, days 14–35) drove progressive skin thickening, elevated psoriasis scores, and arthritis-associated swelling, with upregulated *Il6*, *Il17a*, *Il22*, and *Tnf*.

Conclusion: We validated two inducible PsA models that reproduce key clinical features of human PsA. The mannan-induced model enables the evaluation of small molecules (e.g., JAK inhibitors) and biologics in humanized strains, while

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. the AAV-hIL23 model may provide a platform for IL-23 pathway-targeted therapies. Together, these models help address critical gaps in the preclinical PsA drug development process.

SKG Mice Develop CD4$^+$ T Cell–Driven Psoriasis and Enable Study of Endogenous Antigen-Specific Responses

Yuka Nakao[1], Astha Patel[1], Bahram Razani[2], Steven yu[1], Steven Lazarevsky[2], Marlys Fassett[2] and **Judith Ashouri**[1], [1]University of California, San Francisco, San Francisco, CA, [2]UCSF Department of Dermatology, San Francisco, CA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0098–0114) Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Psoriasis (Pso) and psoriatic arthritis (PsA) are chronic immune-mediated diseases affecting millions, yet early immunologic triggers remain poorly defined. Therapies targeting TNFα, IL-17, and IL-23 help many, but inadequate or transient responses highlight the need to understand upstream mechanisms. CD4$^+$ T cells are central to disease, but early events are hard to study in humans due to genetic variability, late-stage clinical presentation, and limited tissue access. The SKG mouse, with a hypomorphic Zap70 mutation impairing negative selection, develops CD4$^+$ T cell–driven, spontaneous and environmentally induced erosive arthritis with features of RA (RF$^+$, ACPA$^+$, pneumonitis) and spondyloarthritis (skin, eye, gut inflammation, enthesitis). While joint disease is well described, associated skin inflammation is not. Our data reveal psoriatic-like changes reflecting key features of human Pso and PsA. This study aims to define the molecular and cellular mechanisms of Pso skin disease in SKG and characterize the pathogenic TCR repertoire involved.

Methods: Disease was induced by intraperitoneal injection of zymosan into SKG mice or by adoptive transfer of SKG CD4$^+$ T cells into SCID hosts. Psoriasis-like skin disease incidence and clinical arthritis scores were monitored. Skin was evaluated by histology and flow cytometry to assess immune cell infiltration and TCR Vβ repertoire; group differences were analyzed by t-tests and exact permutation tests.

Results: We found that SKG mice develop Pso-like skin inflammation in response to environmental triggers (e.g., zymosan), histologically mirroring human disease with acanthosis, hyperkeratosis, neutrophilic micro abscesses, and lymphohistiocytic

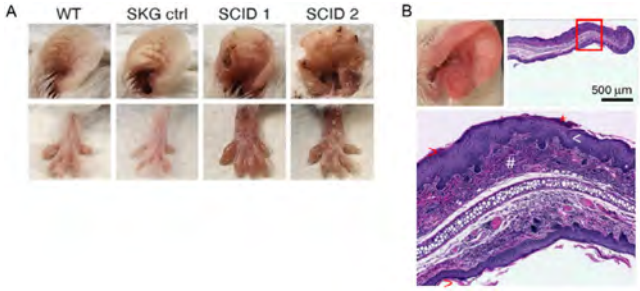

Figure 1. Microbiota are required for arthritis development in SKG mice. Germ-free (GF) SKG mice (n=8) and conventionalized GF SKG mice (n=9) were injected intraperitoneally with zymosan and monitored over time for clinical arthritis scores. (A) Longitudinal arthritis scores are shown for each group. (B) Cumulative disease burden, measured by area under the curve (AUC) of arthritis scores, was significantly higher in conventionalized mice (Wilcoxon test, p = 0.0072).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

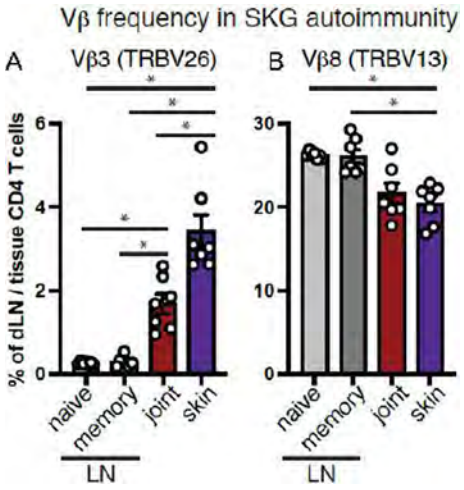

Figure 2. Sag-reactive T cells accumulate in SKG psoriatic skin. Mean frequency (± SEM) of SKG CD4 T cells with Sag-reactive TCR Vβ3 (A) or non-cognate Vβ8 (B) protein usage determined by flow cytometry in LN, joints & skin 5 weeks post zymosan. P value < 0.05 (*) calculated from exact permutation test (A-B).

infiltrates. We demonstrate for the first time that SKG $CD4^+$ T cells alone are sufficient to induce Pso in SCID hosts (Fig. 1), establishing a $CD4^+$ T cell–dependent mechanism of pathogenesis. Flow cytometry shows increased conventional dendritic cells (p=0.02), a trend toward greater neutrophil infiltration and expansion of $V\gamma2^+$ $CD4^+$ T cells—key IL-17 producers implicated in Pso. We identify pathogenic $CD4^+$ T cells enriched for TCR Vβ chains recognizing superantigens (Sags) from an endogenous retrovirus (ERV)—genomic elements that incorporated into the mammalian genome in ancient times and shape innate and adaptive immunity. These Sag-reactive TCRs are significantly enriched in Pso skin relative to peripheral lymphoid organs, while non-cognate Vβs show no enrichment (Fig. 2), supporting an ERV-driven mechanism of tissue-specific autoimmunity.

Conclusion: SKG mice model the chronicity and immune complexity of human Pso, integrating innate (e.g., neutrophil accumulation) and adaptive ($CD4^+$ T cell–driven) pathways without exogenous chemicals. The discovery of Sag-reactive $CD4^+$ T cells recognizing ERV-encoded superantigens in affected skin defines a novel molecular axis of psoriatic autoimmunity. This model provides a robust platform to study disease initiation, antigen-specific responses, and test targeted therapies—advancing translational understanding of Pso and PsA.

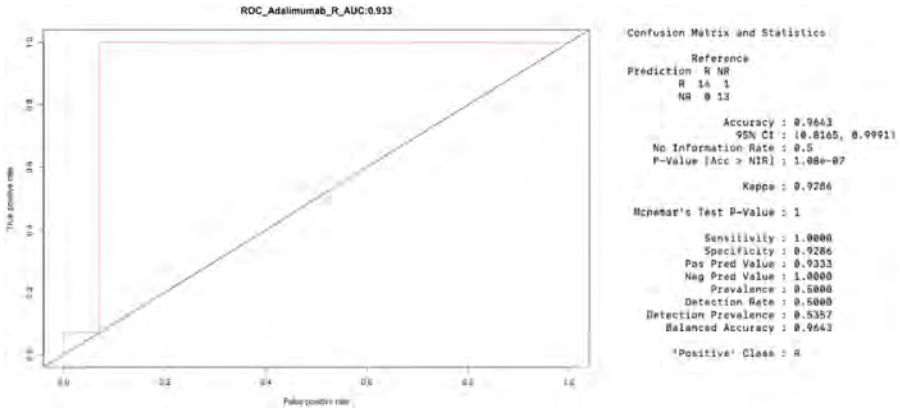

Figure 1: ROC curve displaying the performance of the selected 12-loop signature for PsA responders and non-responders to adalimumab, along with associated statistical matrix.

Background/Purpose: TNF inhibitors (TNFi) have proven efficacy in psoriatic arthritis (PsA) and are commonly prescribed as first line targeted therapy in PsA. However, response to TNFi is unpredictable and many patients fail to respond adequately, with a substantial minority not responding at all. Thus, there is an urgent need for biomarkers that can predict treatment response. Epigenetic chromosome conformation signatures (CCS) using EpiSwitch™ technology have shown predictive potential in various cancers and in predicting a methotrexate response in patients with rheumatoid arthritis [1] but have not been studied in PsA. This work aimed to identify predictive biomarkers of therapeutic response to adalimumab in patients with PsA using baseline peripheral blood CCS.

Methods: Baseline whole blood samples were used from participants in the OPAL Broaden phase III trial (NCT01877668) who received the TNFi adalimumab in the active comparator arm [2]. Response was defined using ACR response at 3 months. Baseline samples and response data were available for 91 participants, with 11 defined as extreme good responders (achieving at least an ACR70 response) and 11 as extreme non-responders (failing to reach at least ACR20 response) selected for the discovery set. Baseline peripheral blood samples underwent genome-wide chromosomal loop screening using the EpiSwitch™ Explorer microarray (Oxford Biodynamics), which consists of $\sim 10^6$ chromatin loops probes. Differential chromatin loops were identified and translated into qPCR assays for further feature reduction and signature refinement using penalised logistic regression.

Results: EpiSwitch™ Explorer microarray analysis of 22 (8 females, 14 males) extreme responders/non-responders, after correcting for biological sex, identified 2,291 chromatin loops (fold change >1.1, p-value < 0.05). Feature reduction narrowed these down to 50 loops, which were further analysed by qPCR in extreme responders/non-responders, as well as in moderate responders (achieving ACR50 but not ACR70 response), and partial responders (achieving ACR20 but not ACR50 response). 30 loops successfully passed the qPCR process. From these, a predictive model for treatment response containing 12 chromatin loop markers was developed, achieving an accuracy of 96.4% and an AUC of 0.93 (Figure 1).

Conclusion: A 12-loop chromosome conformation signature was modelled as a potential biomarker for predicting the therapeutic response to adalimumab in PsA patients in a phase III trial. This model demonstrated 96.4% accuracy and shows promise in correctly identifying not only extreme responders and non-responders, but also moderate/partial responders, highlighting its potential to help select the most effective personalised treatment for every individual. Further validation in an independent cohort is being planned to confirm the accuracy and reliability of these 12 loops as predictive biomarkers for TNFi response in PsA.

Proteome-wide Mendelian Randomization Identifies Therapeutic Targets in Psoriatic Arthritis

Quan Li[1] and **Proton Rahman**[2], [1]University of Toronto, Toronto, Canada, [2]Division of Rheumatology, Craig L. Dobbin Genetics Research Centre, Discipline of Medicine, Memorial University of Newfoundland, St. John's, Canada

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0098–0114) Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: While numerous proteins have been linked to psoriatic arthritis (PsA), the causal nature of these associations remains unconfirmed. This study aims to employ a Mendelian randomization (MR) approach to evaluate whether circulating plasma protein levels, derived from extensive international databases, are causally associated with PsA.

Methods: The study analyzed 1,553 PsA patients and 147,221 controls, all of whom had undergone genome-wide association scans, as identified from the FinnGen consortium. Large-scale plasma protein quantitative trait locus (pQTL) data were sourced from the UK Biobank Proteomics Project (UKB-PPP) (2,923 unique proteins), the INTERVAL study (2,995 unique proteins), and the Icelandic study (Ferkingsatad et al. 2021) with (4,719 proteins). Potential protein candidates were identified based on SNP associations with proteins ($p < 5x10^{-8}$), LD clumping to identify independent pQTLs for each protein ($r^2 < 0.001$), and defining SNPs when the leading SNP was located within 500kb of the transcription site of the protein-coding gene. A two-sample MR was then performed, using the Wald ratio for genes with one SNP and inverse variance weighting (IVW) for genes with more than one SNP. Appropriate MR sensitivity and pleiotropy analyses were conducted.

Results: A total of 19 unique proteins were identified as being associated with the risk of PsA. UKB-PPP dataset revealed four proteins linked to an increased risk of PsA (ATP6V1G2, LTA, HLA-E, APOF) and five proteins associated with a decreased risk (IL12A_IL12B, AGER, MICB_MICA, IL12B, HCG22) (Table 1). The INTERVAL dataset identified five proteins correlated with an elevated risk of PsA (HLA-DRB9, TNXB, HLA-DQB1, HLA-DRB1, HLA-DQA2) and three proteins linked to a reduced risk (IL12B, P4HA2, HLA-DQA1) (Table 1). From Ferkingsatad et al. 2021 dataset, MR identified five proteins significantly associated with PsA (C2,TNXB,HSPA1A and APOF increased PsA risk, while AGER decreased the risk, Table 2).A protein-protein interaction network was constructed using the STRING database, with a required interaction score of >0.4, illustrating the connections among these proteins. Notably, many of these proteins were found within the drug repurposing hub, therapeutic target database, and druggable genome compendium.

Conclusion: This proteome-wide MR study identified 19 unique proteins associated with PsA risk, offering novel insights into the disease's pathogenesis. These prioritized proteins also present potential druggable targets, warranting further investigation to explore novel therapeutic opportunities. More in depth studies are needed to assess the role and utility of these proteins.

ZEB2 and MLCK1 may impair gut barrier integrity in MIF-Deficient SKG Mice

Shaghayegh Foroozan Boroojeni[1], Mansi Aparnathi[2], Akihiro Nakamura[3], Zoya Qaiyum[2] and Nigil Haroon[4], [1]University Health Network/University of Toronto, Toronto, ON, Canada, [2]Schroeder Arthritis Institute, University Health Network, Toronto, ON, Canada, [3]Queen's University, Kingston, ON, Canada, [4]Department of Medicine/Rheumatology, University Health Network, Schroeder Arthritis Institute, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0098–0114) Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Axial Spondyloarthritis (AxSpA) is a chronic inflammatory condition that primarily affects the musculoskeletal system and has multifactorial origins. The majority of AxSpA patients experience gut inflammation, with 60% having microscopic changes and 10% having overt Inflammatory Bowel Disease (IBD). Over the years, researchers have linked many pathways and cell populations to the pathogenesis of gut inflammation in AxSpA. One notable player is the macrophage migration inhibitory factor (MIF), which assumes a crucial role in AxSpA development. In a SpA mouse model (SKG mice), MIF overexpression mirrors key clinical features of AxSpA, while inhibiting or depleting MIF attenuates these symptoms. However, the exact role of MIF in SpA-related gut inflammation is unknown. In this study, we aimed to investigate the effects of MIF on intestinal barrier integrity in SKG mice.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Eight-week-old SKG mice were used for this four-arm study: SKG control mice (WT), SKG mice treated with curdlan (WT_Curdlan), SKG-MIF Knock Out (KO) mice (MKO), and SKG-MIFKO mice treated with curdlan (MKO_Curdlan). After eight weeks of curdlan/vehicle treatment, 16-week-old mice were euthanized. Formalin-fixed paraffin-embedded (FFPE) blocks of the ileum from these mice (n=2/arm) were used for single-cell RNA sequencing (scRNA-seq) Flex Gene Expression assay to investigate the effects of MIF on the expression of genes related to gut homeostasis. These results were validated by Immunohistochemistry (IHC) or qPCR in WT (n=7) and MKO (n=9) mice. Intestinal permeability was assessed in vivo using the FITC-dextran assay. Mice were administered FITC-dextran orally, and serum fluorescence was measured after 4 hours.

Results: scRNA-seq analysis revealed differential expressions of genes potentially related to gut homeostasis: *Zeb2, Mylk, Muc2, Cdh1, Ocln and Cldn7*, across the four arms. As compared to WT mice (± curdlan), downregulation of mucin *Muc2*, adherens junction protein *Cdh1 and* tight junction proteins *Ocln and Cldn7* was observed in MKO mice (± curdlan), which was further confirmed by qPCR and IHC, respectively. These proteins are critical in maintaining gut barrier integrity. Additionally, overexpression of *Zeb2* (a transcriptional repressor of *Cdh1*) and *Mylk* (responsible for endocytosis of occludin from tight junctions) was observed in MKO mice (± curdlan), further validated by IHC. These findings suggest a potential defect in intestinal epithelial regulation in the absence of MIF. Functional assessment of the intestinal barrier using the FITC-dextran assay demonstrated significantly increased intestinal permeability in MKO mice compared to WT controls ($p < 0.05$), consistent with the molecular findings.

Conclusion: MIF maintains gut barrier integrity by regulating the expression of ZEB2 and MLCK1. In the absence of MIF, upregulation of ZEB2 and MLCK1 disrupts the expression of *Muc2*, and function of epithelial tight junction (Cldn7 and Ocln) and adherens junction (Cdh1) markers, contributing to impaired barrier function and increased intestinal permeability in MKO SKG mice. These results highlight the critical role of MIF in maintaining intestinal homeostasis.

Session Title: (0098–0114) Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: The ossification processes observed in ankylosing spondylitis (AS) remain incompletely understood. Substantial evidence from both human and animal studies implicates the Wnt signaling pathway in the excessive

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

endochondral ossification characteristic of AS. Through linkage analysis, we identified a rare variant in the *EXTL3* gene within a family affected by a severe familial form of AS. *EXTL3* is a member of the exostosin gene family and is essential for heparan sulfate biosynthesis.

We generated a mouse model heterozygous for the *Extl3* mutation (*Extl3*$^{mut/+}$) that develops osteoarticular lesions of the sacroiliac joint (SIJ), resembling those found in axial spondyloarthritis (axSpA), along with altered trabecular bone structure in the spine and SIJ. These abnormalities are accompanied by accelerated chondrocyte differentiation, disrupted cartilage architecture in the SIJ, and impaired osteoblast differentiation and mineralization.

Objective

To investigate the role of Wnt signaling and the effects of its modulation in this mouse model of axSpA.

Methods: Immunohistochemical analysis of Tcf1 was performed on SIJs from 6-month-old *Extl3*$^{mut/+}$ mice and wild-type littermates (*Extl3*$^{mut/+}$). In vitro, primary osteoblast and chondrocyte cultures were established at various differentiation stages. RNA sequencing, qPCR, and Western blot (WB) analyses were conducted at different time points.

To confirm the involvement of Wnt signaling, three Wnt pathway inhibitors—Dkk-1, sFRP2, and PKF 118-310—targeting different components of canonical and non-canonical pathways were applied to osteoblast and chondrocyte cultures. The aforementioned analyses were repeated following inhibitor treatment.

Results: Tcf1 immunostaining was markedly increased in chondrocyte columns and subchondral bone of *Extl3*$^{mut/+}$SIJs. RNA-seq revealed downregulation of Wnt pathway inhibitors *Dkk-1* and *Sclerostin* at late stages of both chondrocyte and osteoblast differentiation. qPCR analysis demonstrated overexpression of Wnt pathway components, including

β-catenin

and *Tcf7*. Accelerated chondrocyte differentiation appeared to involve *Wnt3*, *Wnt4*, *Wnt5a*, and *Wnt5b*.

Overexpression of Tcf1 in *Extl3*$^{mut/+}$ osteoblast cultures was confirmed by Western blot at day 21 (terminal differentiation), and by immunohistochemistry in SIJ cartilage and subchondral bone. Notably, Wnt pathway inhibition, particularly with Dkk-1, reversed the observed phenotypes, including delayed osteoblast and accelerated chondrocyte differentiation.

Conclusion: Our findings demonstrate that the *Extl3* mutation disrupts Wnt signaling in both osteoblasts and chondrocytes. These results align with prior studies in mouse models and human data, reinforcing the critical role of Wnt signaling in the pathological ossification associated with AS. This work highlights potential therapeutic targets aimed at modulating ossification mechanisms in AS.

Dysfunctional Mitophagy Propels Neutrophil Hyperactivity and Thrombosis in Antiphospholipid Syndrome

Ajay Tambralli[1], Emily Becker[2], Kaitlyn Sabb[3], NaveenKumar Somanathapura[1], Srilakshmi Yalavarthi[1], Cyrus Sarosh[4], Jacqueline Madison[1], Yu (Ray) Zuo[1] and Jason S. Knight[1], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, [3]University of Michigan - Ann Arbor, Ann Arbor, MI, [4]University of Michigan, Temperance, MI

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0115–0144) Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Neutrophil hyperactivity and neutrophil extracellular trap (**NET**) release (**NETosis**) contribute to antiphospholipid syndrome (**APS**) pathogenesis. We recently discovered that APS patient neutrophils have more glycolytic flux than healthy neutrophils and that inhibiting glycolysis in mice reduces neutrophil hyperactivity and thrombosis. In addition, our transcriptomic analysis of APS neutrophils identified regulation of autophagosome assembly ($p=1.9E^{-5}$) and ubiquitin-protein ligase activity (p=0.0057) as among the top-upregulated pathways. It has previously been shown that dysfunctional mitochondrial autophagy (**mitophagy**) can enhance glycolysis across various disease contexts. Here, we began to characterize the potential influence of dysfunctional neutrophil mitophagy on the pathogenesis of APS by determining its role in augmenting glycolysis, NETosis, and thrombosis.

Methods: For patient profiling, neutrophils were freshly isolated from healthy controls (n=8) or individuals with primary APS (n=11). For *in vitro* studies, control neutrophils were stimulated with IgG pooled from either controls or individuals with APS who had high-titer anti-β_2GPI IgG. Wild-type C57BL/6 (**WT**) mice and mitophagy-deficient *Pink1*$^{-/-}$ mice were used for animal studies. Thioglycolate-elicited mouse neutrophils were isolated from the peritoneum 16 hours after administration of IgG. Neutrophil mitophagy (MtPhagy), mitochondrial polarization (JC-10), and mitochondrial reactive oxygen species (MitoSOX) were assessed by flow cytometry. NETosis was quantified with SYTOX Green, and glycolytic capacity (the maximal cellular utilization of glycolysis) was assessed using a Seahorse metabolic flux analyzer. Thrombosis was modeled via electrolytic activation of the mouse inferior vena cava.

Results: Compared with controls, APS patients had fewer neutrophils undergoing beneficial mitophagy (66% vs 28%, p< 0.05). In addition, APS patients had more neutrophils with dysfunctional, depolarized mitochondria (11% vs 20%, p< 0.01) and produced more harmful mitochondrial reactive oxygen species (1.3-fold, p< 0.05). The mitophagy activator valinomycin reduced human APS IgG-mediated NETosis to levels seen with control IgG (p< 0.05). Further, compared with neutrophils from WT mice, neutrophils from mitophagy-deficient *Pink1*$^{-/-}$ mice (n=3 mice for each genotype) had increased glycolytic capacity (1.3-fold, p< 0.05) and augmented APS IgG-mediated NETosis (1.4-fold, p< 0.01). Finally, when APS-associated thrombosis was modeled in mice (n=9 WT and n=5 *Pink1*$^{-/-}$), *Pink1*$^{-/-}$ mice developed significantly larger thrombi (mean 5.1 mg vs 8.0 mg, p< 0.01).

Conclusion: APS patient neutrophils demonstrated defective mitophagy and dysfunctional mitochondria. Mice with a baseline defect in mitophagy (*Pink1*$^{-/-}$) phenocopied APS patients by demonstrating more glycolytic flux, NETosis, and thrombosis. Notably, activating mitophagy tempered APS IgG-mediated human NETosis. These results identify dysfunctional mitophagy as a driver of neutrophil hyperactivity and thrombosis in APS, and restoring normal mitophagy could be a promising approach for a future therapeutic intervention.

Cerebral small vessel disease in antiphospholipid syndrome: subtypes and total burden of cSVD on MRI

Chun Li[1], Jianping Guo[2], Yangyi Fan[1], Yu Kang[1] and Xiaodan Hu[1], [1]Peking University People's Hospital, Beijing, China (People's Republic), [2]Peking University People's Hospital, Beijing, Beijing, China

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0115–0144) Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Cerebrovascular diseases are common and severe neurological complications in antiphospholipid syndrome (APS). However, few studies focused on cerebral small vessel disease (cSVD) in APS. We undertook this study to investigate the subtypes, the total burden on MRI and potential risk factors for cSVD in APS.

Methods: We retrospectively analyzed the medical records and brain magnetic resonance imaging (MRI) scans of patients with APS who visited our hospital between January 2015 and July 2022. An age and gender-matched healthy control group were recruited from the Health Care Center affiliated with Peking University People's Hospital. Four major cSVD markers on MRI were assessed, including lacune, enlarged perivascular space (EPVS), microbleed and white matter hyperintensities (WMH). Total cSVD score, ranging from 0 to 4, were rated using validated visual scales. Univariate and multivariate logistic regression model was applied to analyze the association between clinical and laboratory indices and cSVD risks in APS.

Results: Among 132 enrolled patients, 76.5% (101/132) were females with a mean age of 47.0 years. 26.5% (35/132) were primary APS, and 51.5% (68/132) exhibited at least one of the cSVD markers. Lacune was the most frequent cSVD marker [46.2% (61/132)], followed by moderate-to-severe WMH [16.7% (22/132)], EPVS [14.4% (19/132)] and microbleed [12.1% (16/132)]. After adjusting for age, gender and disease duration, the cSVD was significantly associated with hypertension (OR 3. 688, 95%CI 1.17-11.65, P = 0.026), the incidence of thrombosis events (OR 22.145, 95%CI 2.11-232.27, P = 0.010), and the history of stroke (OR 10.709, 95%CI 2.47-46.36, P = 0.002).

Conclusion: In the present study, we observed a high incidence of cSVD in patients with APS. Hypertension, thrombotic events and the history of stroke are risk factors for cSVD in APS.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0115–0144) Antiphospholipid Syndrome Poster

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: It is known that triple positive antiphospholipid syndrome (APS-TP) is related to an increased presence of thrombotic and obstetric manifestations. Triple positivity is referred by the concurrence of anticardiolipin antibodies, anti-beta2 glycoprotein I antibodies and lupus anticoagulant. Up until the definition of the new American College of Rheumatology (ACR)/ European Alliance of Associations for Rheumatology (EULAR) classification criteria, APS was only classified by a laboratory domain and a clinical domain including thrombotic or obstetric events. The addition of other clinical manifestations -thrombocytopenia, cardiac valve afectation, cutaneous, among others- will allow a greater number of patients to be early and systematically detected.

The objective is to analyze the prevalence of other clinical domains in the presence or absence of thrombotic or obstetric events in patients with APS-TP, and to determine the prevalence of the new manifestations included in the 2023 ACR/EULAR classification.

Methods: Cross-sectional descriptive study was carried out in a tertiary care hospital. APS-TP patients diagnosed between 1990 and 2023 were included. Patients under 18 years of age were excluded. Patients were classified into two groups: APS-TP with the presence of thrombotic and/or obstetric events (APS-TP1) and APS-TP with neither thrombotic nor obstetric events but with the presence of another clinical domain (APS-TP2). Sociodemographic, clinical and analytical variables were collected from both groups.

	APS TP-1 36 (70.58)	APS TP-2 15 (29.41)	p-value
Females, n (%)	19 (52.8)	11 (73.3)	0.174
Age, mean (SD)	45 (14.6)	47.06 (17.85)	0.166
Smoking, ever, n (%)	26 (72.2)	9 (60)	0.103
Arterial hypertension, n (%)	19 (52.8)	4 (26.67)	0.125
Dyslipidemia, n (%)	10 (27.8)	6 (40)	0.391
Diabetes mellitus, n (%)	6 (14.63)	2 (13.33)	1.000
Thrombophilia, other (%)	1 (2.8)	1 (6.7)	0.506
Ischemic cardiomyopathy, n (%)	3 (8.3)	1 (6.7)	1.000
Connective tissue disease, n (%)	13 (36.1)	6 (40)	0.750
- SLE, n (%)	12 (33.3)	6 (40)	0.649
- Sjögren syndrome, n (%)	1 (2.78)	0	1.000

SLE: Systemic lupus erithematosus.

Adrenal hemorrhage, n (%)	2 (3.9)	2 (5.6)	0 (0)	0.351

AIHA: Autoinmune hemolytic anemia. TMA: Thrombotic microangiopathy.

** Multivalvular heart disease, nonbacterial thrombotic endocarditis. ** livedo racemosa, livedoid vasculitis. ***cognitive impairment, white matter lesions.*

Figure 2 Prevalence of non-criteria manifestations

Results: A total of 51 APS-TP patients were identified, 36 (70.6%) APS-TP1 patients and 15 (29.4%) APS-TP2 patients. The majority of patients were female (59.3%) with a mean age of diagnosis of 47.2 years (Figure 1). Only 5 patients (9.8%) were classified as catastrophic APS. In the APS-TP1 group, 34 patients (66.7%) presented thrombosis (venous: 20 [58.8%], arterial 12 [35.2%] and

both 4 [11.8%]) and 7 patients (13.7%) presented obstetric events. The most frequent "new domain" in the APS-TP1 group was thrombocytopenia (36.1%), while in the APS-TP2 group was valvular heart disease (46.1%) followed by Raynaud's phenomenon (33.3%). There were no significant differences in any of the observed variables (Figure 2).

Conclusion: In our cohort, the most common clinical manifestation overall was thrombosis. In patients without either thrombosis or obstetric events, the most prevalent manifestations were valvular heart disease and Raynaud's phenomenon. The importance of studying antiphospholipid syndrome in patients with non-thrombotic manifestations is rising, especially in patients who do not meet criteria for other connective tissue diseases. Although some manifestations were exclusive to the thrombotic or obstetric morbidity group (renal microangiopathy, alveolar hemorrhage, bilateral adrenal hemorrhage), we did not find significant differences. This may be influenced by the small sample size, so it could be considered as a further object of study.

Abstract Number: 0118

Single-cell RNA sequencing of skin reveals vascular dysregulation in antiphospholipid syndrome

Ecem Sevim[1], Sumith Panicker[2], Gustaf Wigerblad[3], Stefania Dell'orso[4], Sharon Osgood[2], Leslie Castelo-Soccio[5], Keisuke Nagao[6] and Yogendra Kanthi[7], [1]NIAMS/NIH, Bethesda, MD, [2]NHLBI/NIH, Bethesda, [3]National Institutes of Health, Stockholm, Sweden, [4]National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health (NIH), Bethesda, MD, [5]NIAMS/NIH, Bethesda, [6]NIAMS, Bethesda, MD, [7]National Heart, Lung and Blood Institute, National Institutes of Health, Bethesda, MD

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0115–0144) Antiphospholipid Syndrome Poster

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Antiphospholipid syndrome (APS) is a systemic autoimmune thromboinflammatory disorder defined by persistent antiphospholipid antibodies (aPL) and characterized clinically by macrovascular thrombosis, microvascular disease, and pregnancy morbidity. While aPL-mediated activation of endothelial cells and immune pathways has been established, the molecular drivers of tissue-level vascular dysfunction remain elusive. We performed single-cell RNA sequencing (scRNA-seq) of skin biopsies from patients with APS to identify local cellular and molecular drivers of disease pathogenesis.

Methods: Non-lesional skin biopsies were obtained from the upper thigh of patients with APS (n=6) and healthy controls (n=5). Single-cell suspensions were prepared via enzymatic and mechanical dissociation (Miltenyi Biotec), followed by SYTOX-Green-based FACS for live cell enrichment. Libraries were generated using Chromium Single Cell 5′ HT chemistry (10x Genomics), targeting ~20,000 cells/sample.

Sequencing data were processed with Cell Ranger v8.0.1 and analyzed using Seurat v5 in R for QC, integration, clustering, and annotation. Endothelial cells (ECs) were identified by canonical markers (VWF, CDH5, PECAM1); non-ECs (keratinocytes, immune cells, fibroblasts, pericytes, SMCs) were excluded. Differential gene expression and pathway enrichment analyses were performed comparing APS vs. control ECs.

Results: Four patients with APS had a triple-positive aPL profile; phenotypes included microvascular disease (n=2), macrovascular thrombosis (n=1), and one exhibited both. One APS patient was lupus anticoagulant-positive and had macrovascular disease with cardiac valve involvement; and one patient was positive for LA and anti-cardiolipin IgG with a history of macrovascular thrombosis. None of the patients had skin lesions at the time of biopsy.

Transcriptomic profiling of skin endothelial cells in APS revealed upregulation of genes involved in glycolysis, response to cytokine stimulus, NF-κB signal transduction, mitochondrial metabolism, cAMP signaling, and VEGF response (*ALDOA, PLCG2, NDUFB1, SDF4, PRKAR1A, METAP2, EIF3J*). Concurrently, genes related to RAS signaling, endosomal trafficking, chromatin organization, cell migration, endothelial cell development, tube formation, and barrier establishment were downregulated (*RASGEF1B, RAPGEF6, RBFOX1, BCOR, ZNF366, RNF7, CTS, THSD7A*). These gene expression changes were observed consistently across all six patients with APS compared to healthy controls.

Conclusion: Our single-cell transcriptomic analysis of non-lesional APS skin reveals a metabolically reprogrammed, pro-inflammatory, and stress-responsive endothelial phenotype.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Endothelial cells in APS skin demonstrated upregulation of genes associated with activation and inflammatory signaling, alongside downregulation of pathways involved in vascular homeostasis, signaling regulation, and barrier integrity. Together, these findings reveal a consistent transcriptional signature of endothelial dysfunction in APS skin and highlight opportunities to identify tissue-based biomarkers and potential therapeutic strategies targeting endothelial dysfunction in APS.

Thrombin Generation Assays Inform Hypercoagulability Mediated by Antiphospholipid Antibodies in Children with Systemic Lupus Erythematosus

Elizabeth Sloan[1], Blake Baay[2], Lynnette Walters[2], Paola Sparagana[2], Kristina Ciaglia[1], Simrat Morris[1], Julie Fuller[1], Lorien Nassi[1], Tracey Wright[1] and Ayesha Zia[3], [1]UT Southwestern, Children's Medical Center, and Scottish Rite for Children, Dallas, TX, [2]Scottish Rite for Children, Dallas, TX, [3]UT Southwestern and Children's Medical Center, Dallas, TX

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0115–0144) Antiphospholipid Syndrome Poster

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: In pediatric systemic lupus erythematosus (**SLE**), antiphospholipid antibodies (**aPL**) are independent risk factors for thrombosis. However, data are limited on how aPL impact hypercoagulability. No biomarkers or risk-stratification tools exist to predict thrombosis in aPL-positive pediatric SLE. We aimed to investigate the use of thrombin generation (**TG**) potential to assess aPL-induced hypercoagulability in pediatric SLE patients without a history of thrombosis.

Methods: Three groups of patients were prospectively enrolled: children with SLE and persistently positive aPL (n = 12), children with SLE and persistently negative aPL (n = 20), and children with non-systemic juvenile idiopathic arthritis (**JIA**, n = 20) (**Table 1**). aPL status at enrollment was determined based on historical laboratory data. Participants were excluded if they had a history of thrombosis, known hypercoagulable disorder, or were receiving anticoagulation. Testing for inherited and acquired thrombophilia was performed, and aPL profiles were followed for > 12 weeks. TG assays were performed via the calibrated automated thrombogram method using platelet poor plasma with and without the addition of thrombomodulin, an activator of protein C. TG parameters were compared across the three groups.

Table 1. Demographics of patient cohorts

	SLE with aPL (n=12)	SLE without aPL (n=20)	JIA (n=20)
Age in years (mean ± SD)	14.3 ± 3.5	14.9 ± 2.7	14.6 ± 2.3
Women, n (%)	9 (75%)	19 (95%)	14 (70%)
BMI (mean ± SD)	28.2 ± 6.7	26.9 ± 9.2	25.2 ± 5.3
BMI Percentile (mean % ± SD)	88.4 ± 13.3	78.8 ± 21.8	77.1 ± 24.0
Race, n (%)			
Asian	1 (8%)	0 (0%)	0 (0%)
Black or African American	0 (0%)	3 (15%)	1 (5%)
White	11 (92%)	16 (80%)	19 (95%)
Other	0 (0%)	1 (5%)	0 (0%)
Ethnicity, n (%)			
Hispanic	11 (92%)	14 (70%)	11 (55%)
Non-Hispanic	1 (8%)	6 (30%)	9 (45%)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Thrombin generation assays were performed via the calibrated automated thrombogram method in platelet poor plasma from pediatric patients with SLE with positive antiphospholipid antibodies (aPL), SLE with negative aPL, and JIA. A, Endogenous thrombin potentials (ETP) were similar between all three groups. B, When thrombomodulin was added, ETP was higher in the aPL positive group. C, The aPL positive group showed diminished inhibition of ETP in the presence of thrombomodulin compared to the other groups, which is consistent with activated protein C resistance. D, There was no significant difference in peak thrombin height between groups. E, With the addition of thrombomodulin, the aPL positive group had a statistically significant higher thrombin peak than the JIA group. F, The aPL positive group had diminished peak inhibition in the presence of thrombomodulin, again suggesting activated protein C resistance. ETP and peak parameters were compared between groups by the Kruskal-Wallis test adjusted for multiple comparisons by Dunn's method; *p<0.05, **p<0.01, ***p<0.001.

Table 2. Measures of thrombin generation parameters with and without thrombomodulin in children with SLE and positive aPL, SLE without aPL, and JIA

	Parameter	SLE with aPL	SLE without aPL	JIA	*P*
PPP	ETP, *nM x min*	859.7 ± 130.6	822.9 ± 164.7	830.3 ± 125.8	ns
	Lag time, *min*	4.85 ± 3.23	2.59 ± 0.49	2.51 ± 0.39	< 0.001
	Peak height, *nM*	166.3 ± 24.5	162.0 ± 46.9	145.7 ± 47.1	ns
	Time to peak, *min*	7.90 ± 3.56	5.67 ± 0.84	5.91 ± 0.78	0.020
	Velocity Index, *nM/min*	57.8 ± 18.6	56.9 ± 24.3	46.3 ± 24.6	ns
PPP-TM	ETP, *nM x min*	606.5 ± 114.3	459.3 ± 156.3	435.5 ± 115.7	0.002
	Lag time, *min*	4.54 ± 3.20	2.36 ± 0.48	2.34 ± 0.32	0.001
	Peak height, *nM*	154.1 ± 43.7	122.7 ± 46.7	112.0 ± 35.4	0.028
	Time to peak, *min*	7.02 ± 3.52	4.76 ± 0.59	4.78 ± 0.46	0.009
	Velocity Index, *nM/min*	66.0 ± 25.1	53.1 ± 23.8	48.0 ± 38.4	ns

SLE: systemic lupus erythematosus, aPL: antiphospholipid antibodies, JIA: juvenile idiopathic arthritis, PPP: platelet poor plasma, PPP-TM: platelet poor plasma with thrombomodulin, ETP: endogenous thrombin potential, ns: not significant

Results: The median age of the entire cohort was 15 (range 7 to 18) years. All groups were predominantly female, White race, and of Hispanic ethnicity (**Table 1**). Almost all (92%) of the aPL positive SLE group had positive lupus anticoagulant, and three (25%) had triple aPL positivity. Persistent antiphosphatidylserine/prothrombin IgG and IgM antibodies were present in 58% and 67% of the aPL positive group, respectively. Except for aPL positivity, there were no differences between groups in the presence of inherited or acquired hypercoagulable disorders, including Factor V Leiden, prothrombin mutations, antithrombin, and protein C and S activity. There was no difference in the endogenous thrombin potential (**ETP**) between the groups (p = 0.772) (**Figure 1 A, Table 2**). However, in the presence of thrombomodulin, ETP was higher in the aPL positive group compared to the other two groups (607 ± 114 nM x min vs. 459 ± 156 nM x min vs. 436 ± 116 nM x min, p = 0.002) (**Figure 1 B**). In fact, inhibition of ETP by thrombomodulin was significantly blunted in the aPL positive group versus the aPL negative and JIA groups (25.9% vs. 45.1% vs. 47.4%, p < 0.001) (**Figure 1 C**), suggesting resistance to activated protein C. Change in peak height was also less sensitive to the addition of thrombomodulin in the aPL positive group versus the aPL negative and JIA groups (10.7% vs. 25.8% vs. 26.1%, p < 0.001) (**Figure 1 D-F**). Independent of thrombomodulin, the aPL positive group showed increased lag time (p < 0.001) and time to peak (p = 0.020) (**Table 2**). There were no differences in velocity index between the three groups (p = 0.082).

Conclusion: Our study provides the biologic basis that aPL confer hypercoagulability in pediatric SLE. Activated protein C resistance appears to be an important mechanism of hypercoagulability in aPL-positive pediatric SLE patients, even without thrombosis. TG potential is a potential biomarker of aPL-induced hypercoagulability in pediatric SLE.

Abstract Number: 0120

The Prevalence and Clinical Significance of Heritable Thrombophilia in Antiphospholipid Antibody Positive Patients: Descriptive Results from the Antiphospholipid Syndrome Alliance for Clinical Trials and International Networking (APS ACTION) Registry

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0115–0144) Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Although antiphospholipid antibodies (aPL) are well-established risk factors for thrombosis, heritable thrombophilias (HT) are also associated with venous thromboembolism (VTE). The latter includes deficiencies of the naturally occurring anticoagulants (antithrombin, protein C, and protein S), and factor V Leiden (FVL) and prothrombin (PT) G20210A gene mutations. Methylene tetrahydrofolate reductase (MTHFR) C677T and A1298C polymorphisms are not considered part of the HT screen in clinical practice. The primary objective of this ongoing study was to determine the prevalence of HT in persistently aPL-positive patients. Secondly, we analyzed the association between thrombosis and HT in aPL-positive patients, individually and in combination.

Methods: A web-based data capture system is used to store patient demographics and aPL-related medical history in APS ACTION registry. Inclusion criteria are positive aPL, based on the Revised Sapporo Antiphospholipid Syndrome (APS) classification criteria, tested at least twice within one year prior to enrollment. Patients are followed every 12±3 months with clinical data and blood collection. For this cross-sectional analysis, baseline data were used including demographic, clinical, and HT laboratory (either center-reported [CR] or APS ACTION United Kingdom Core Laboratory [CL] data (following testing in the CL)). When evaluating the results of the HT included (see Table 1), CL were used over CR if both were available; Chi square or Fisher's exact tests were used for comparisons.

Results: Of 1,252 patients recruited as of January 2025, 741 (59%) had at least one CR and/or CL HT result (female: 515 [70%]; mean age at registry entry: 55±13.5; thrombotic APS: 456 [62%]; triple aPL-positive: 273 [37%], lupus anticoagulant with/without aCL or aβ_2GPI: 308 [42%]). The prevalence of each HT and the association with vascular events are shown in Tables 1 and 2, respectively. Homozygosity for the MTHFR C677T and A1286 polymorphisms were reported in 20 (6%) and 4 (1%), respectively, with high homocysteine in 2/20 with MTHFR C677T and none with MTHFR A1298C. In

Table 1. Prevalence of Heritable Thrombophilia and Methylene tetrahydrofolate reductase (MTHFR) C677T and A1298C Polymorphisms Among APS ACTION Registry Patients

Table 2. The Frequency of Arterial/Venous Thrombosis is Patients with Individual Heritable Thrombophilia and Methylene tetrahydrofolate reductase (MTHFR) C677T and A1298C Polymorphisms Among APS ACTION Registry Patients (those with heterozygous MTHFR polymorphisms were not included)

N: 741	Arterial Event*	Venous Event*	No Event
Low Protein C (n: 665)			
- Yes (n: 28)	7 (25%)	18 (64%)	6 (21%)
- No (n: 637)	231 (36%)	272 (43%)	193 (30%)
Low Protein S (n: 653)			
- Yes (n: 42)	12 (29%)	24 (57%)	9 (21%)
- No (n: 611)	219 (36%)	255 (42%)	190 (31%)
Low Antithrombin (n: 687)			
- Yes (n: 42)	18 (43%)	22 (52%)	9 (21%)
- No (n: 645)	231 (36%)	287 (44%)	186 (29%)
Factor V Leiden Mutation (n: 627)			
- Yes (n: 2)	1 (50%)	2 (100%)	0
- No (n: 625)	222 (36%)	276 (44%)	185 (30%)
Prothrombin G20210A Mutation (n: 565)			
- Yes (n: 0)	0	0	0
- No (n: 565)	206 (36%)	244 (43%)	170 (30%)
MTHFR C677T Polymorphism (n: 325)			
- Yes (n: 20)	6 (30%)	8 (40%)	7 (35%)
- No (n: 305)	119 (39%)	128 (42%)	94 (31%)
MTHFR A1298C Polymorphism (n: 280)			
- Yes (n: 4)	1 (25%)	1 (25%)	3 (75%)
- No (n: 276)	108 (39%)	110 (40%)	87 (32%)

*Some patients with both arterial and venous events

Table 3. Comparison of Arterial and Venous Events Between Patients With and Without Heritable Thrombophilia (HT) Among APS ACTION Registry Patients (those with MTHFR polymorphisms were not included)

n= 316	No HT (n= 230)	≥1 HT (n= 86)	*P* value
Arterial Event	86 (37%)	33 (38%)	0.87
Venous Event	88 (38%)	46 (53%)	**0.015**

the subgroup analysis of 316 (43%) patients, we compared those with at least one abnormal HT result (n: 86; excluding heterozygous HT) and those with normal results for all HT assessed (n=230); the former group had significantly more VTE, but not arterial, events (p=0.015) (Table 3).

Conclusion: Based on our large-scale international cohort, up to six percent of persistently aPL-positive patients may have one or more heritable thrombophilia (antithrombin, protein C, or protein S deficiencies, FVL or PT G20210A), which may increase the risk of VTE. Our preliminary results have limitations, including reporting/selection bias, and the lack of information on testing methodology/confirmation and factors that may affect results of naturally occurring anticoagulants, e.g. anticoagulation and pregnancy/puerperium. However, these results and the relatively high frequency of HT in the general population highlight the potential additive risk of HT in aPL-positive patients that may be contributory in the stratification and management of such patients.

Session Title: (0115–0144) Antiphospholipid Syndrome Poster

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: The 2023 ACR/EULAR Antiphospholipid Syndrome (APS) Classification Criteria (CC) focus on IgG and IgM anticardiolipin (aCL) and anti-β_2-glycoprotein-I antibodies (aβ_2GPI). IgA isotypes were excluded due to limited evidence linking isolated IgA positivity to thrombosis, uncertain incremental value beyond established criteria, and a lack of assay standardization. However, emerging data from the general population suggest that individuals with IgA aβ_2GPI may face an elevated risk of atherosclerotic cardiovascular disease, potentially due to impaired cholesterol efflux capacity and endothelial injury. Our primary objective was to compare the demographic, clinical, and laboratory characteristics of aCL

* Thrombocytopenia is defined as platelet count <100,000 per microliter, tested twice at least 12 weeks apart; ** Autoimmune hemolytic anemia is defined as persistent anemia with hemolysis and a positive direct antiglobulin test; *** Neuropsychiatric test proven.
aCL: anticardiolipin antibodies; **aβ_2GPI**: anti-β_2-glycoprotein-I antibodies; **BMI**: body mass index; and **SARD**: systemic autoimmune rheumatic diseases.

and/or aβ_2GPI IgA-positive *versus* IgA-negative patients. A secondary objective was to identify clinical and serological factors independently associated with IgA positivity.

Methods: The APS ACTION registry uses a web-based system to capture patient demographics, APS-related history, and medications. Inclusion requires aPL positivity per Revised Sapporo APS CC, confirmed within one year prior to enrollment. Patients are followed every 12±3 months with clinical assessments and blood collection. For this cross-sectional analysis of baseline data, we first compared demographic, clinical, and laboratory features between IgA-positive (aCL and/or aβ_2GPI IgA ≥20 U; analysis repeated with ≥40 U cutoff) and IgA-negative (< 20 U) patients using chi-square or Fisher's exact tests, based on APS ACTION Core Lab results (BioFlash, Werfen). We then conducted multivariate logistic regression to identify factors independently associated with IgA positivity.

Results: Of 1,252 patients recruited as of January 2025, 706 (56%) had baseline aCL/aβ_2GPI IgA results. Using the ≥20U threshold recommended by the manufacturer, the IgA-positive group (n: 238 [34%]) had significantly higher rates of venous

Table 2: Predictors of Anticardiolipin (aCL) and Anti-β_2-glycoprotein-I antibodies (aβ_2GPI) IgA Positivity Among APS ACTION Registry Patients (Cut-off for positivity ≥20U) (multivariate logistic regression)

Patient characteristics (N = 706)	Adjusted OR (95% CI)	*P* value
Triple aPL-Positivity	**12.34** (7.4740-20.3650)	**<0.0001**
Double aPL-Positivity	**6.56** (3.9800-10.8183)	**<0.0001**
Heart Valve Disease	1.57 (0.8373-2.9354)	0.1600
Thrombocytopenia (<100x109/L)	**1.57** (1.0186-2.4224)	**0.0410**
History of Any Venous Event	1.41 (0.9939-2.0096)	0.0541
History of SLE	**1.54** (1.0521-2.2668)	**0.0265**
History of Any CVD Risk Factor	0.94 (0.6074-1.4602)	0.7886

aPL: antiphospholipid antibodies; **SLE:** systemic lupus erythematosus; **CVD:** cardiovascular disease

events, thrombocytopenia, heart valve disease, and triple/double aPL-positivity. Diabetes, hyperlipidemia, and single aPL-positivity were significantly higher in IgA-negative group (Table 1). In the multivariate analysis, after adjusting for the aPL profile, history of venous events, heart valve disease, thrombocytopenia, systemic lupus erythematosus (SLE), and any traditional cardiovascular disease risk factor, IgA-positivity was significantly associated with triple/double aPL-positivity, SLE, and thrombocytopenia (Table 2). When the IgA positivity cut-off of $\geq$ 40U used: a) there was no change in the univariate results, except that diabetes, and hyperlipidemia no longer differed between the groups; and b) in multivariate analysis, IgA-positivity was significantly associated with triple/double aPL-positivity and history of venous events (data not shown).

Conclusion: In our well-established international cohort of persistently aPL-positive (lupus anticoagulant, aCL IgG/M, and/or aβ_2GPI IgG/M) patients, concomitant aCL/aβ_2GPI IgA-positivity correlates with a more severe clinical and, especially, serological phenotype. Future prospective analysis of the registry will help us further clarify the clinical significance of aCL/aβ_2GPI IgA antibodies in aPL-positive patients.

Abstract Number: 0122

The role of low profile antiphospholipid antibodies and adverse pregnancy outcomes.

Eugenia Chock[1], Tong Wang[2], Areeka Memon[3], Zeyan Liew[4] and Pengfei Guo[4], [1]Yale School of Medicine, New Haven, CT, [2]Yale School of Public Health, New Haven, [3]Yale New Haven Health, New Haven, CT, [4]Yale Center for Perinatal, Pediatric and Environmental Epidemiology, New Haven

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0115–0144) Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Presence of high titer antiphospholipid antibodies (aPLs) confer adverse pregnancy outcomes (APOs). Patients with low titer aPLs often receive conflicting counseling on treatment, many are treated with dual antiplatelet and low molecular weight heparin (LMWH) therapy without clear benefit. We conducted a pilot study to investigate the association of low profile aPLs and APOs.

Methods: We performed a retrospective cohort study using electronic health record (EHR) data of all pregnant women who received aPL testing and hospitalized in a major tertiary care center from 2013 to 2022. Women were categorized into three exposure groups: (1) negative aPLs: anti-cardiolipin ± anti-b2- glycoprotein IgG, IgA, or IgM < 20 GPL/MPL; (2) low profile

Table 1. Characteristics of study population by aPL profile.

Characteristic / Group	Negative aPLs (N=1,938)	Low aPLs (N=96)	High aPLs (N=99)	Overall (N=2,133)

Table 2. Risks of adverse pregnancy outcomes among women with low aPLs.

	Preeclampsia and eclampsia					Late pregnancy loss and stillbirths				
Group	Frequency	Crude OR (95% CI)	p-value	Adjusted OR (95% CI) *	p-value	Frequency	Crude OR (95% CI)	p-value	Adjusted OR (95% CI) ^	p-value
Negative aPLs	360/1938	Ref	Ref	Ref	Ref	200/1938	Ref	Ref	Ref	Ref
Low profile aPLs	17/96	0.96 (0.55, 1.60)	0.891	0.92 (0.49, 1.66)	0.792	8/96	0.62 (0.25, 1.29)	0.219	0.51 (0.20, 1.11)	0.092

aPLs: antiphospholipid antibodies; OR: Odds Ratio, CI: Confidence Interval;
* adjusted for age at delivery, race and ethnicity, history of recurrent pregnancy loss, parity, diabetes, chronic kidney disease, pregnancy-related and gestational hypertension, obesity, rheumatic diseases, aspirin use, low molecular weight heparin use.
^adjusted for age at delivery, race and ethnicity, history of recurrent pregnancy loss, parity, diabetes, chronic kidney disease, pregnancy-related and gestational hypertension, obesity, rheumatic diseases, pre-eclampsia and eclampsia, aspirin use, low molecular heparin use

aPLs, defined as anti-cardiolipin ± anti-ß2- glycoprotein IgG, IgA, or IgM 20-39 GPL/MPL; (3) high profile aPLs, defined as anti-cardiolipin ± anti-ß2- glycoprotein IgG, IgA, or IgM ≥40 GPL/MPL, and/or presence of lupus anticoagulant. The outcomes of interest were: (1) late pregnancy losses and stillbirths; (2) pre-eclampsia and eclampsia. Next, we performed logistic regression to determine the exposure-outcome associations in the low profile aPLs group. The analyses were adjusted for age, parity, obesity, co-morbidities including rheumatic diseases, hypertensive disorders, diabetes, history of recurrent pregnancy losses, aspirin and LMWH use.

Results: We included 2,133 women who were hospitalized during the latter part of pregnancy and tested for aPLs. < 10% of women had positive aPLs and among those, almost half of these women were considered low profile. The mean age of women with low and high profile aPLs was the same (33.7 years of age), Caucasian women constitute more than half in all groups. Most women had private insurance (N=1218; 57.1%). Several conditions were most prevalent in the high-profile group, including obesity (N=56, 56.6%), hypertensive diseases during pregnancy (N=27, 27.3%), and rheumatic diseases (N=41, 41.4%). Women with low profile aPLs were more likely to have history of recurrent pregnancy losses (N=34, 35.4%); smoking (N=150, 7.7%) during pregnancy was most frequent among negative aPL group (Table 1).

Among women with low profile aPLs, the adjusted Odds Ratio (aOR) of pre-eclampsia and eclampsia compared to negative aPL group was 0.92 (95%CI 0.49, 1.66; *p=0.792*), and the aOR of late pregnancy loss and stillbirths was 0.51(95%CI 0.20, 1.11; *p=0.092*) (Table 2).

Conclusion: In the low profile group, the odds of developing the APOs of interest were lower or similar, compared to those with negative aPLs despite treatment with aspirin or LMWH. Women with negative aPLs may be more ill and therefore required inpatient care in this study sample. The limitations of this pilot study include small sample sizes, potential selection bias, and incomplete ascertainment of specific variables. Our findings may not be representative of the general population, but the associations of this pilot study inform additional EHR data collection to improve the limitations above. Future work would include the use of propensity score weighting to account for confounding and to balance the characteristics among groups.

Background/Purpose: Cardiac involvement in antiphospholipid syndrome (APS) includes valvular, coronary, and myocardial manifestations. Valvular involvement is the most frequent, affecting approximately 30% of patients, while myocardial infarction is the second leading cause of death in APS. Although a few studies have examined the progression of valvular disease, data on coronary and myocardial involvement are lacking. Furthermore, the prognostic implications of the different types of APS-related cardiac involvement have not been directly compared. This study aimed to evaluate the long-term prognosis associated with each type of cardiac involvement in APS.

Methods: We conducted a bicentric, retrospective observational cohort study in France, including patients followed at La Pitié-Salpêtrière Hospital (Paris) and Toulouse University Hospital. Patients met the 2023 APS classification criteria and were diagnosed between January 1, 2000, and July 1, 2023. The primary endpoint was the occurrence of a major APS-related complication, defined as death, catastrophic APS (CAPS), admission to intensive care, heart failure, myocardial infarction, or intra-alveolar hemorrhage. Overall survival and incidence of major complications were compared between groups using the log-rank test.

Results: A total of 138 patients were included, of whom 93 were women (67.4%), with a median age of 41 years (IQR 33–52). Cardiac involvement was the initial APS manifestation in 69 patients (50.0%). Compared with those with coronary or myocardial involvement, patients with valvular involvement more frequently had a history of stroke, livedo reticularis, and Sneddon syndrome.

The median follow-up was 6 years (IQR 3–11). During follow-up, 89 patients (64.5%) experienced at least one APS-related complication. The probability of event-free survival was 70% at 1 year and 43% at 5 years. No significant differences in overall or event-free survival were observed across the different types of cardiac involvement. However, patients with myocardial involvement had a significantly higher incidence of arrhythmias ($p = 0.050$), intensive care unit admissions ($p = 0.031$), and hemorrhagic events ($p = 0.046$).

Conclusion: Cardiac involvement in APS is frequent and associated with a substantial risk of adverse outcomes over time. Although overall and event-free survival did not differ significantly across valvular, coronary, and myocardial subtypes, myocardial involvement was independently associated with a higher incidence of severe complications, including arrhythmias, intensive care unit admissions, and hemorrhagic events. These findings underscore the prognostic relevance of the type of cardiac involvement and support the need for stratified risk assessment and targeted management in patients with APS.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0115–0144) Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: To elucidate the molecular and cellular mechanisms underlying Talitacicept therapy in primary antiphospholipid syndrome (PAPS) patients using integrated single-cell RNA and TCR/BCR profiling of paired bone marrow (BM) and peripheral blood (PB) samples.

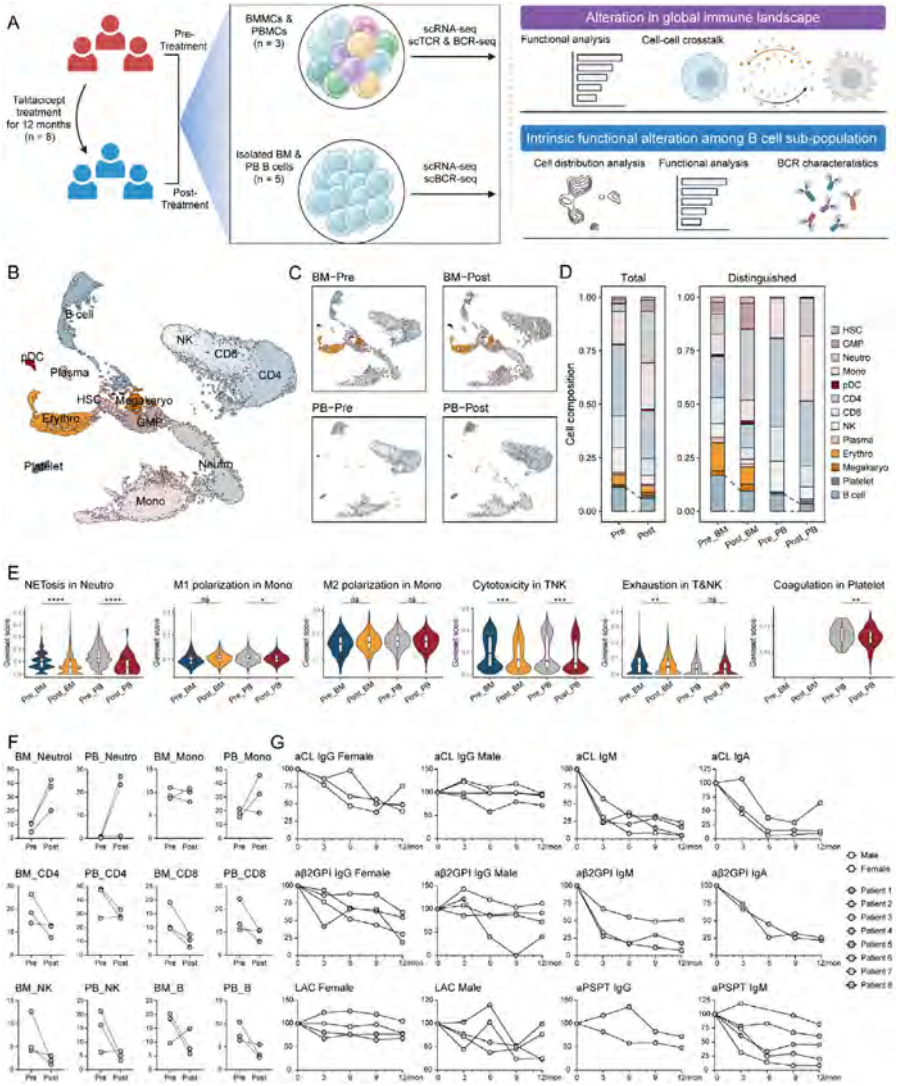

Figure 1: The impact of telitacicept therapy on the overall immune landscape of PAPS patients with therapeutic benefits. A) Schematic diagram of the experimental design for the study. B) Uniform Manifold Approximation and Projection (UMAP) plot depicting 13 immune cell clusters in paired pre- and post- bone marrow (BM) and peripheral blood (PB) samples from PAPS patients who received Talitacicept therapy (n=3). C) Cell-type distribution in UMAP blueprint from distinguished groups, respectively. D) Stacked bar graphs depicting the composition of different cell clusters in Pre- and Post- subjects. Left: celltype from BM and PB samples merged; right: celltype from BM and PB samples distinguished. E) Characteristic cell-type function revealed by geneset score calculated by the UCell Method. Ns: not significant; *: p<0.05; **: p<0.01; ***: p<0.001; ****: p<0.0001. F) Paired pre- and post- celltype composition in each subject reveal change of celltype abundance pre- and post-treatment. G) Longitudinal changes in serum antiphospholipid antibody (aPL) levels in PAPS subjects. Antibody levels were measured at baseline and at 3, 6, 12, and 18 months after initiation of therapy. For each antibody indicator, PAPS subject must have at least one positive test result to be displayed. For aCL IgG, aβ2GPI IgG and LAC, female subjects and male subjects were distinguished in order to be visualized more clearly.

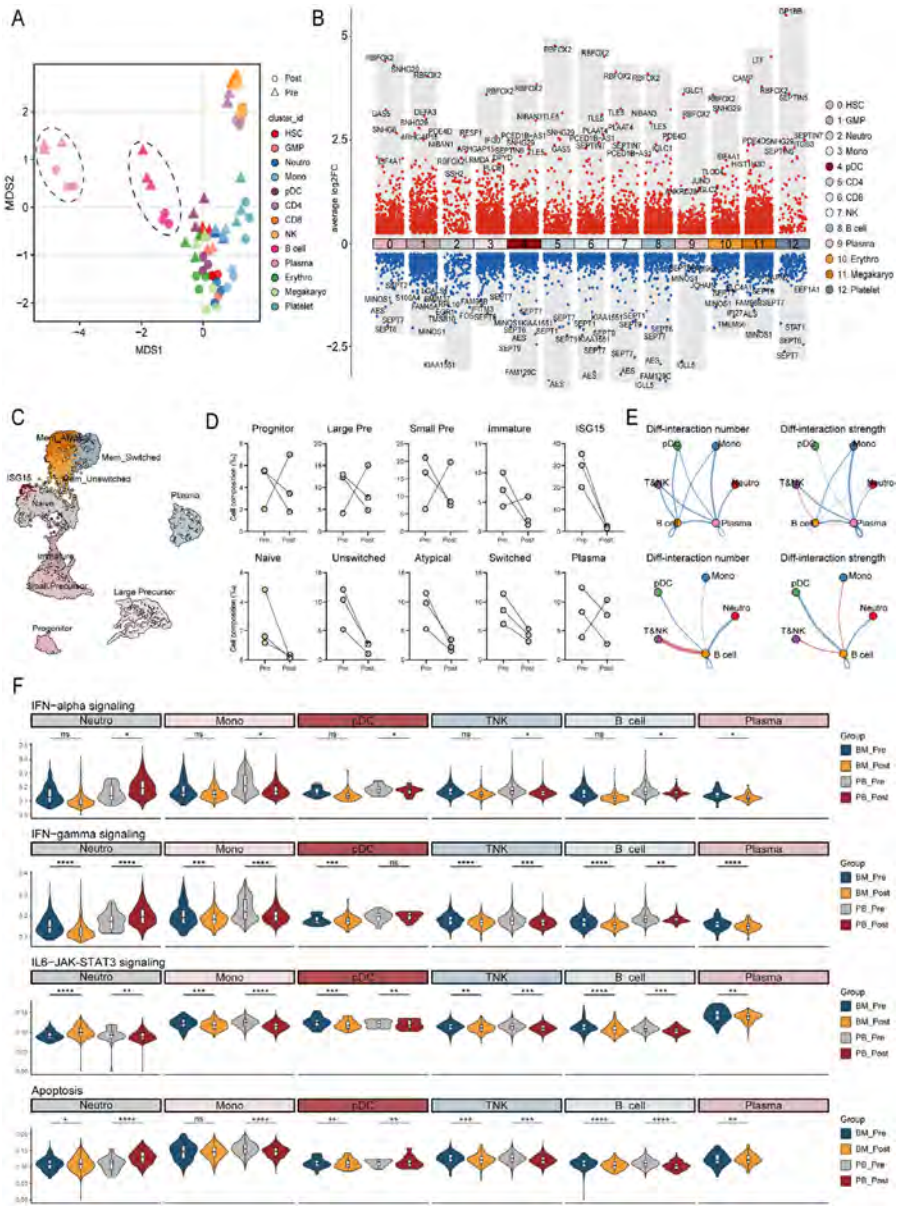

Figure 2: Talitacicept reduces interferon and inflammatory signatures in global immune cell types in PAPS patients. A) Multi-dimensional scaling (MDS) plot showing the differential state between Pre- and Post-groups of each cell type based on aggregated pseudo-bulk form. B) Volcanoplot showing differentially expressed genes (DEGs) in each celltype, DEGs with log2FC > 0.25 and padj < 0.25 were shown. Red refers to genes up-regulated post-talitacicept and blue refers to genes down-regulated post-talitacicept. C) Re-constructed "central-to-periphery" developmental lineage of B cell, including 11 B cell sub-populations. D) Paired Pre- and post- celltype composition in each subject reveal change of B cell sub-population abundance Pre- and post-treatment. E) Circle plot showing differential cell-cell communication network between B/Plasma cells and other immune celltypes to illustrate the changes in the B cells' effects on other immune celltypes after talitacicept therapy. The width of edges represented the relative number of interactions or interaction strength. Red (or blue) colored edges represent increased (or decreased) signaling after talitacicept therapy. F) Characteristic celltype function revealed by geneset score calculated by UCell Method. Ns: not significant; *: p<0.05; **: p<0.01; ***: p<0.001; ****: p<0.0001.

Methods: 8 PAPS patients were recruited to receive standard Talitacicept treatment for 12 months. Clinical data were recorded every 3 months during treatment. Paired BM and PB samples were collected pre-treatment and after the 12-month treatment is completed. In 3 patients scRNA and BCR/TCR sequencing were performed on BMMCs and PBMCs to reveal the global changes in immune landscape; and for the other 5 patients, BM and PB B cells were sequenced to reveal intrinsic change in B cell subpopulations.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 3: Talitacicept influences the intrinsic distribution and molecular characteristics within B cells and reduces the autoreactivity-associated alongside the developmental lineage. A) Uniform Manifold Approximation and Projection (UMAP) plot depicting 12 B cell sub-populations in paired Pre- and post- bone marrow (BM) and peripheral blood (PB) samples from PAPS patients who received Talitacicept therapy (n=5). B) Distribution density of BM and PB B cell sub-population abundance in respective groups. C) Stacked bar graphs depicting the composition of different cell clusters in Pre- and Post- subjects. Left: celltype from BM and PB samples merged; right: celltype from BM and PB samples distinguished. D) Volcanoplot showing differential expressed genes (DEGs) in each celltype, DEGs with log2FC > 0.25 and padj < 0.25 were shown. Red refers to genes up-regulated post-talitacicept, and blue refers to genes down-regulated post-talitacicept. E) Characteristic function alongside B cell lineage revealed by geneset score calculated by the UCell Method. SHM: somatic hypermutation; Ns: not significant; *: p<0.05; **: p<0.01; ***: p<0.001; ****: p<0.0001.

Results: 12 months of standard talitacicept treatment effectively reduced the number of B cells and plasma cells in both BM and PB. The number of neutrophils increased in all 3 patients after treatment, while CD4 T, CD8 T and NK cell showed a coordinated decrease in both BM and PB. However, a male patient with a poor treatment response (defined as no significant decrease in pan-aPL antibodies after treatment) showed an opposite increase in BM B cells. We also confirmed that most aPLs were effectively reduced, but the decline in aCL IgG and aβ2GPI IgG was relatively insignificant in male patients (**-Figure 1**). The differential states of overall transcriptional characteristics revealed that B cells and plasma cells were the most significantly different cell subpopulations. Additionally, DEG (differential expressed gene) analysis showed each celltype presented significant downregulation of abundant interferon and inflammation-related genes. A B cell blueprint was constructed and confirmed that talitacicept effectively cleared most B cell subpopulations. Cellchat analysis indicated that the interactions from B cells and plasma cells toward other immune cells generally decreased after treatment, and UCell scoring also confirmed that the interferon, JAK-STAT pathway and apoptosis levels among global immune landscape were effectively reduced (**Figure 2**). For intrinsic changes in B cell lineage, naive B cells and plasma cells were the main subpopulations that

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

decreased in BM and PB, while the relative proportions of pro-, pre-, and memory B cells increased. Additionally, B cell subpopulations presented similar downregulation of interferon and inflammation-related genes after treatment. Features potentially related with autoimmunity were evaluated, and the V-D-J rearrangement activity was reduced in pro/pre B cells, the activation level of naive B cells and the SHM level in memory B cell stage was reduced, while the autoantibody-related signature in plasma cells decreased as well (**Figure 3**).

Conclusion: Our study revealed the mechanism of talitacicept in treating PAPS patients, including reducing the level of pathogenic antibodies by eliminating mature B cells and plasma cells, inhibiting the interferon and inflammatory pathways among the global immune landscape, and reprogramming autoreactivity-related functions alongside B cell development trajectory. These findings provide important theoretical basis for optimizing the targeted treatment strategy of PAPS.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0115–0144) Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Primary antiphospholipid syndrome (pAPS) is an autoimmune disease that, unlike many other autoimmune diseases, commonly presents with thrombotic events rather than inflammatory manifestations. A peripheral type I interferon (IFN) signature distinguishes patients with pAPS from healthy individuals, but its broader molecular landscape compared with other autoimmune diseases remains unknown.

Methods: We analysed bulk RNA sequencing data from whole blood obtained from patients with pAPS (n=83), systemic lupus erythematosus (SLE; n=249), Sjögren's disease (SjD; n=253), systemic sclerosis (SSc; n=247), and 497 matched healthy controls (HC) from the PRECISESADS project (NCT02890121). We applied supervised pathway enrichment analysis, unsupervised weighted gene co-expression network analysis (WGCNA), and deconvolution analysis to characterise the molecular profile of pAPS.

Results: A total of 85 upregulated and 10 downregulated differentially expressed genes (DEGs) were found in patients with pAPS compared with HC, including genes indicating an overall upregulation of type I and II IFN signalling, complement cascade, and coagulation in pAPS, coupled with differentially enriched neutrophil degranulation and monocyte chemotaxis pathways. However, only 15 of those genes were uniquely differentially expressed in patients with pAPS compared with those with any other of the investigated autoimmune diseases. The comparison between pAPS and SLE revealed 334 DEGs (71 up- and 263 downregulated). Enrichment analysis revealed downregulation of type I and II IFN signalling and

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

complement cascade pathways in pAPS versus SLE. Moreover, type I and II IFN signalling was significantly downregulated in pAPS compared to SjD or even SSc. WGCNA identified 19 modules of co-expressed genes, with pAPS strongly linked only to upregulation of the "IFN" module compared to HC. However, the upregulation of the "IFN" gene module was more pronounced in SLE, SjD and SSc compared with pAPS, supporting a gradient in the upregulation of IFN-related genes across these diseases, as previously shown for APS-SLE[1-2]. Within pAPS, a history of miscarriages was positively associated with the "methylation" module, while thrombocytopenia was negatively associated with the "T cell" and "RNA processing" modules. Deconvolution analysis showed that patients with pAPS exhibited significant alterations in the proportions of neutrophils, NK, naïve T, and memory T, compared to HC. However, these differences were evident in patients with SLE compared to HC.

Conclusion: Patients with pAPS exhibit a distinct molecular profile within the spectrum of systemic autoimmune diseases, marked by a modest activation of interferon signalling.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0115–0144) Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Antiphospholipid syndrome (APS) is a thrombo-inflammatory disorder that causes significant morbidity and mortality, even in children. The 2023 ACR/EULAR classification criteria, which use weighted clinical and laboratory scores, improve specificity (99% vs. 86%) but reduce sensitivity (84% vs. 99%) compared to the 2006 criteria in adults. However, no pediatric-specific criteria exist, and the 2023 criteria have not been validated in children. This multisite North American study aims to assess the performance of both the 2023 and 2006 criteria in pediatric APS.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Patients with pediatric APS and childhood-onset SLE were initially identified by rheumatologists at 5 academic institutions through electronic medical record searches using diagnosis codes. APS diagnosis was determined by documentation of a confirmed diagnosis at age ≤18 by a pediatric hematologist or rheumatologist. SLE controls had a confirmed diagnosis by age 18 and ≥2 antiphospholipid antibody (aPL) test results available. Analyses were performed using Python (v3.10).

Results: We evaluated the performance of the adult 2023 and 2006 APS classification criteria in a well-characterized, multicenter cohort of pediatric patients diagnosed with APS (n=57) and lupus (n=25) (Table 1). When applied to pediatric patients, the 2023 criteria demonstrated improved but similar **specificity** compared with the 2006 version (100% vs. 96%) and reduced **sensitivity** (68% vs. 75%). The 2023 criteria also showed a slightly higher positive predictive value (**PPV**) for diagnosis, reflecting a modest increase in precision (100% vs. 98%), but lower negative predictive value (**NPV**, 58% vs. 63%). The **F1 score**, reflecting overall diagnostic performance, was also lower with the 2023 criteria (0.81 vs. 0.85). ROC analysis favored the 2006 criteria (**AUC** = 0.86 vs. 0.84) (Table 2). Both criteria demonstrated strong agreement (Cohen's kappa = 0.88). Among the 18 APS patients who failed to meet the 2023 criteria (including all 14 who also failed the 2006 criteria), 4 did not reach the clinical criteria threshold, and 14 lacked sufficient laboratory points—8 of whom had only a single positive lupus anticoagulant test. Of the 4 patients meeting the 2006 but not the 2023 criteria, 2 failed to

Table 1. Demographic features, clinical characteristics, and fulfilment of classification criteria in patients with clinical diagnoses of pediatric APS and childhood-onset SLE without APS

	APS (n=57)	Lupus without APS (n=25)

meet clinical and 2 failed to meet lab thresholds. To better understand the profile of missed cases, we compared domain scores between false negatives and the overall cohort. False negatives under the 2006 criteria had significantly lower laboratory scores ($p = 0.033$), suggesting under-recognition of patients with weaker serologic profiles. No significant differences were observed in clinical scores.

Conclusion: Both the 2006 and 2023 APS criteria perform reasonably well in children but with lower sensitivity than in adults. The 2006 criteria are more sensitive—especially for cases with milder, lower-scoring aPL profiles—while the 2023 criteria offer greater specificity. Their high concordance supports the reliability of both systems, but also underscores the need to refine adult-based criteria to better capture true pediatric APS. Our ongoing multisite study (target n=300 across 7 sites), using expert-confirmed diagnoses, will help guide optimal classification in this population.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0115–0144) Antiphospholipid Syndrome Poster

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Some of the rarer manifestations of antiphospholipid syndrome (**APS**), such as cardiac valve disease, remain poorly understood at the molecular level. A previous study profiling skin biopsies from a few patients with marked livedo racemosa preliminarily identified the endothelial cell (**EC**) Hippo-YAP1-CCN2 axis as a key player in APS vasculopathy. Here, we expanded dermal single-cell profiling to include 30 individuals with primary APS, with the goal of identifying unique tissue signatures associated with some of the more poorly understood features of APS, including cardiac valve disease and nephropathy. In this abstract, we focused on the ligand-receptor pairs predicted to be driving cellular communication in the dermis of patients with a history of cardiac valve disease.

Methods: Single-cell RNA sequencing was used to characterize upper-thigh skin biopsies (epidermis removed) from 30 patients with primary APS (including a subset of eight patients with confirmed valve disease) and 14 healthy controls. Cell-cell interaction analysis was performed using CellPhoneDB to identify enriched (i.e., highly correlated)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

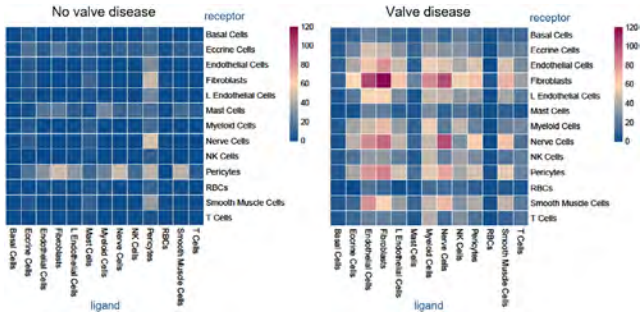

Figure 1: Dermal ligand-receptor analysis of patients with valve disease. Potentially interacting ligands (x-axis) and receptors (y-axis) were compared between APS patients with a history of valve disease (n=8, right panel) and those without (n=22, left panel). The analysis used CellPhoneDB to identify enriched (i.e., highly correlated) ligand-receptor pairs between dermal cell types. Associations with a history of valve disease were tested via logistic regression.

ligand-receptor pairs between ECs and other potentially interacting cell types. Differential expression and pathway enrichment were evaluated using g:Profiler. Associations with a history of valve disease were tested via logistic regression.

Results: Thirteen cell types were detected within the dermis, with endothelial cells representing 18% of the population in primary APS patients, compared with 16% in controls ($p < 0.001$). In patients with valve disease (n=8), versus those without (n=22), endothelial cells showed a markedly increased potential for interactions with myeloid cells, smooth muscle cells, and fibroblasts, amongst others (**Figure 1**). For myeloid cells, highlighted interactions between EC ligands and myeloid cell receptors included CCL23-CCR1, ICAM2-CD209, JAG2-NOTCH1, and DLL1-NOTCH1, with the potential to support inflammatory signaling, leukocyte adhesion, and immune activation. Featured EC interactions with smooth muscle included ANGPT2-TIE2, EDN1-EDNRA, JAG2-NOTCH3, and EFNB1-EPHB6, suggesting increased vascular constriction and remodeling. Notable ligand-receptor interactions between endothelial cells and fibroblasts included PDGFB-PDGFRA, CCL2-CCR2, FN1-ITGA5, and WNT2B-SFRP2, emphasizing fibroblast activation and extracellular matrix (**ECM**) transformation. Finally, pathway analysis underscored the potential for more leukocyte adhesion, angiogenesis, and ECM remodeling in the tissues of APS patients with a history of valve pathology.

Conclusion: Our findings reveal that endothelial cells of patients with a history of valve disease have significant potential—through their production of chemokines, cell adhesion molecules, and ECM-interacting molecules—to engage in proinflammatory and profibrotic interactions with myeloid cells, smooth muscle cells, and fibroblasts. The identified interactions and pathways provide a roadmap for future research into the valvular pathology that causes significant morbidity for some patients living with APS.

Abstract Number: 0128

Defining a Consensus for Critical Data Fields for International Pediatric Antiphospholipid Syndrome Research

Jheel Bhatt[1], Elizabeth Sloan[2], Selcan Demir[3], Mojca Avramovic[4], Seza zen[5], Doruk Erkan[6], Tadej Avcin[7], Delphi collaborators, CARRA SLE-APS Workgroup, PRES SLE Working Party, [1]Advent Health Orlando, Orlando, FL, [2]UT Southwestern, Children's Medical Center, and Scottish Rite for Children, Dallas, TX, [3]Eskisehir Osmangazi University, Eskişehir, Turkey, [4]University Children's Hospital, Ljubljana, Slovenia, [5]Hacettepe University Medical Faculty, Ankara, Turkey, [6]Hospital for Special Surgery, New York, NY, [7]University Children's Hospital University Medical Center Ljubljana, Ljubljana, Slovenia

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0115–0144) Antiphospholipid Syndrome Poster

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Pediatric antiphospholipid syndrome (APS) is a rare, thrombo-inflammatory autoimmune disease characterized by thrombosis and nonthrombotic manifestations in patients with persistent positive antiphospholipid antibodies, with clinical features that differ from adult APS. Current APS classification criteria are derived from adult data, and pediatric APS data collection is fragmented and inconsistent between institutions and regions. This project aims to develop an international consensus that defines critical data fields to facilitate international registry-based pediatric APS research.

Methods: Data fields were compared from existing International Ped-APS Registry and CARRA Registry, which identifies patients with APS within the lupus cohort. The 2023 ACR/EULAR APS classification criteria were reviewed and systematic literature review of pediatric APS between 2003-2024 was conducted to identify potential data elements for future registries (Figure 1). Delphi surveys were completed by physicians with APS experience, which included pediatric rheumatologists, med/peds rheumatologists, adult rheumatologists, and pediatric hematologists representing 12 countries and two caregiver representatives. Items were scored from 1 (not important) to 9 (very critical). Consensus "in" was reached for core items

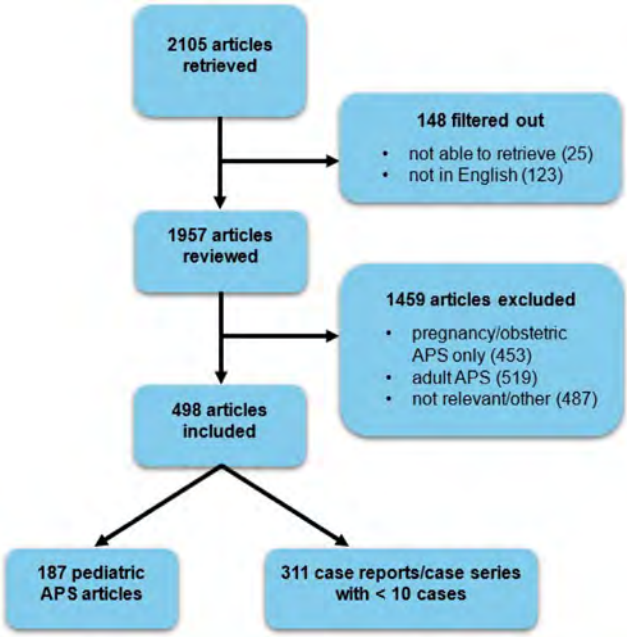

Figure 1. Flow diagram of literature review to identify candidate items

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Flow diagram showing selection process of candidate items for Delphi survey to identify critical data fields in pediatric APS registries

scored > 7 by > 70% of experts, as well as all items included in the adult 2023 APS Classification Criteria. Consensus "out" was reached for items with average score < 5. The remaining items were labeled "equivocal" for voting at a hybrid consensus meeting. During the meeting, items with ≥80% agreement were included in the final dataset (either Core or Expanded),

Table 1: List of consolidated core and expanded clinical datasets

SECTOR	CORE Dataset	Expanded Dataset
DEMOGRAPHICS AND MEDICAL HISTORY	Biologic Sex Year of birth Year of 1st detection of aPL Year of 1st aPL-related clinical manifestation Year of APS diagnosis	Year of the last follow-up visit
FAMILY HISTORY		Family history of APS or other autoimmune diseases (specify which) Family history of thrombosis
UNDERLYING DISEASE	SLE Other autoimmune diseases (specify which)	
CONGENITAL PROTHROMBOTIC STATES:	Presence of hereditary or other acquired thrombophilia (e.g., Factor V Leiden, Prothrombin 20210A mutation, AT deficiency, Protein C/S deficiency, or others - specify)	
ACQUIRED RISK FACTORS FOR THROMBOSIS	Acquired risk factors for thrombosis – any Hormone replacement therapy, estrogen-containing oral contraceptives, on-going IVF Arterial thrombosis Venous thromboembolism Small vessel thrombosis Recurrent thrombosis Microvascular thrombosis on pathology Fetal loss/prefetal loss/preeclampsia Location of thrombosis	Hospital admission Major trauma Surgery Acute severe infection (if yes please specify trigger: viral or bacterial) Cardiovascular risk factors (e.g., arterial hypertension, tobacco smoking, hyperlipidemia, diabetes mellitus, please specify).
HEMATOLOGICAL	Thrombocytopenia Hemolytic anemia/autoimmune hemolytic anemia LA associated hypoprothrombinemia syndrome	
NEUROLOGICAL	Ischemic event, if yes specify (e.g., ischemic stroke, acute hemiplegia) Transient ischemic attack Chorea	Cerebral white matter lesions or changes on MRI, including atypical multiple sclerosis Epilepsy/seizures
SKIN	Livedo racemosa Livedoid vasculopathy	Skin ulcer or cutaneous necrosis Digital ischemia Livedo reticularis
CARDIOPULMONARY	Cardiac valve thickening Cardiac valve vegetation Libman Sachs /noninfectious endocarditis Pulmonary hemorrhage, including pulmonary alveolar hemorrhage and pulmonary capillaritis	Pulmonary hypertension
RENAL	aPL nephropathy chronic/acute	
GASTROINTESTINAL		Budd Chiari syndrome
ENDOCRINE	Adrenal hemorrhage	
MUSKULOSKELETAL		Avascular bone necrosis/osteonecrosis
OPHTHALMOLOGIC	Ischemic retinopathy	
TREATMENT	Anticoagulation therapy (drug, dose, duration) Target INR reached Antiaggregation therapy (drug, dose, duration) Treatment of underlying disease (drug, dose, duration) Immunosuppressive treatment of APS - any Immunosuppressive treatment for APS - specify	Adverse effects of anticoagulation (e.g., bleeding) Other therapy (specify)
FOLLOW UP/OUTCOME	New thrombosis Year of new thrombosis Treatment at the time of new thrombosis development Location of the new thrombosis Treatment of the new thrombosis Identified triggers of new thrombosis Death, related to APS Year of death, related to APS	

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

and items failing to meet consensus were either excluded or revised and re-evaluated when appropriate. Items scoring $\geq$6 were eligible for either Core or Expanded datasets. Items scoring $\geq$ 5 but < 6 were only voted upon for the Expanded dataset.

Results: Thirty-two Delphi surveys were completed in round 1 and twenty-six in round 2. Two caregiver representatives completed a modified Delphi. Of 316 final candidate items (Figure 2), 72 items reached consensus "in", 87 items were consensus "out" and 157 "equivocal" items were discussed at the hybrid consensus meeting (Table 1). Nineteen participants voted upon Core and Expanded Datasets for each "equivocal" item. The final dataset included 60 core data elements and 22 expanded data elements, spanning 18 thematic domains.

Conclusion: Through systematic evaluation of existing registries, literature review, and Delphi process, we have identified several critical variables to inform future pediatric APS registries. By leveraging international expertise and integrating it with patient patient perspectives, we are laying a solid foundation for the development of a harmonized dataset to advance pediatric APS research efforts globally.

Analysis of Antiphosphatidylserine/prothrombin Antibodies as a Predictor of Lupus Anticoagulant in the Pediatric Population

Jonathan Marilao[1], Sean Yates[2] and Elizabeth Sloan[3], [1]University of Texas Southwestern, Dallas, TX, [2]University of Texas Southwestern, Dallas, [3]UT Southwestern, Children's Medical Center, and Scottish Rite for Children, Dallas, TX

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0115–0144) Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Antiphospholipid Syndrome (**APS**) is a systemic thromboinflammatory autoimmune disease characterized by thrombotic or obstetric events occurring in individuals with persistently positive antiphospholipid antibodies (**aPL**). Recently, research in adult populations has shown that antiphosphatidylserine/prothrombin antibodies (**aPS/PT**) are a reliable predictor of lupus anticoagulant (**LA**). These findings have yet to be reproduced in the pediatric population. We aim to ascertain the sensitivity, specificity, negative predictive value, and positive predictive value of aPS/PT to anticardiolipin (**aCL**), anti-beta-2 glycoprotein I (**aβ2GPI**), and LA in the pediatric population.

Methods: A retrospective chart review was performed of pediatric patients from 2019 to 2024 who had a full aPL panel (aPS/PT, aCL, aβ2GPI, LA) obtained as part of their medical evaluation for suspected or diagnosed conditions potentially related to aPL positivity. A cut-off of 40 units was used for aPL positivity for all antibodies. LA positivity was determined in accordance with international guidelines, and LA values obtained on anticoagulation were excluded. Sensitivities, specificities, negative predictive values, and positive predictive values were calculated with 95% confidence intervals.

aβ2GPI IgA	5	1.68%
Triple positivity‡	10	3.36%

aPL: antiphospholipid antibodies. SD: standard deviation. aPS/PT: antiphosphatidylserine/prothrombin; LA: lupus anticoagulant. aCL: anticardiolipin. aβ2GPI: anti-beta-2 glycoprotein I.
**aPS/PT, aCL, and aβ2GPI titers ≥ 40 units*
†LA positivity determined by clinical laboratory data, in accordance with international guidelines
‡Triple positivity: positive LA, aCL, and aβ2GPI.

Results: Our cohort included 298 patients who underwent aPL testing (**Table 1**). The majority of patients were female (72.4%), white (56.7%), and non-Hispanic (62.8%). Mean age at time of laboratory evaluation was 13.5 ± 4.3 years. Almost half (45%) of the cohort were diagnosed with a rheumatologic disease, most commonly systemic lupus erythematosus (n=89). Twelve patients (4%) had confirmed APS. Twenty patients with rheumatologic disease experienced at least one thrombotic event (**Table 2**). In the entire cohort, 30 patients (10.1%) had positive aPS/PT IgG and 56 (18.8%) had positive aPS/PT IgM (**Table 1**). Positive aPS/PT IgG and IgM showed high specificity (IgG 96.9%, 95%CI 94.0-98.4%; IgM 89.5%, 95%CI 85.1-92.7%) and low to moderate sensitivity (IgG 53.7%, 95%CI 38.8-67.9%; IgM 70.7%, 95%CI 54.0-80.9%) for

aCL IgM	58.33%	91.96%	23.33%	98.13%	83.33%	84.27%	18.18%	99.18%
aCL IgA	66.67%	90.51%	6.67%	99.63%	66.67%	82.03%	3.64%	99.59%
Triple Positive	80%	92.36%	26.67%	99.25%	90%	83.68%	16.07%	99.59%

aPS/PT: antiphosphatidylserine/prothrombin. LA: lupus anticoagulant. aCL: anticardiolipin. aβ2GPI, anti-beta-2 glycoprotein I; PPV: positive predictive value. NPV: negative predictive value.
**Triple Positive: positive LA, aβ2GPI, and aCL*

LA positivity (**Table 3**). The negative predictive value of both aPS/PT IgG and IgM were high (>90%) for LA, aCL, and aβ2GPI. Ten patients were triple positive for LA, aCL, and aβ2GPI, and aPS/PT IgG was highly specific (92.4%, 95%CI 88.7-94.9%) and moderately sensitive (80%, 95%CI 49.0-96.5%). Negative predictive value of aPS/PT IgG and IgM for triple positivity exceeded 99%.

Conclusion: Overall, the high specificity combined with the strong negative predictive values of aPS/PT IgG and IgM highlights the ability to use such antibodies to rule in the presence of LA and other aPL when positive and to confidently exclude them when negative. These findings align with previous adult literature and highlight the usefulness of aPS/PT as a predictor of lupus anticoagulant in the pediatric population. As anticoagulation can affect the interpretation of LA, positive aPS/PT, when associated with a positive LA, offers a useful alternative to monitor LA regardless of patients' anticoagulation status. Additionally, with institutional variation in the conduct of LA, aPS/PT may provide a more comparable measure for multicenter research collaborations.

Background/Purpose: Antiphospholipid antibody syndrome (APS) is a common cause for acquired thrombophilia. The group termed 'seronegative' APS has not made any headway in the revised APS ACR 2023 criteria as no new antibodies were included. Increased levels of Plasminogen activation inhibitor -1 (PAI-1) has been observed in patients with connective tissue disease. It may account for the increased risk of thrombotic events in APS the form of a second hit or function independently as a risk factor for thrombosis. We assessed the role of PAI-1 in antiphospholipid syndrome in relation to the presence of criteria antiphospholipid antibodies (aPL).

Methods: A case control study was done at a tertiary level Rheumatology centre in North India between September 2022 and 2024. The primary objective was to compare PAI-1 levels between those with APS (aPL+ APS), patients with thrombosis or obstetric morbidity but with antibody profile not satisfying criteria as put forward by the modified Sapporo criteria (aPL-APS) and healthy controls. An SLE group without APS or aPL was also included. Adults (age > 18 years) who had clinical

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

features of APS as per the Modified Sapporo criteria were enrolled. Plasma levels of PAI-1 was estimated by sandwich ELISA. To obtain a power of 0.99 and a confidence interval of 0.95, a sample size of 24 was required in each group. Plasma tPA levels were also estimated in each group. Comparison between the 4 groups was done by ANOVA. Analysis was done using IBM SPSS statistics for windows [Version 26.0].

Results: Sixty-three cases of APS (females 84%) with mean age 35.2 (±8.9) were included. This included 38 aPL+APS and 25 aPL-APS cases (Table 1). Twenty-five SLE cases and 27 healthy controls were also included. **Plasma PAI-1 levels were higher in aPL+APS compared to healthy controls (16.3 vs 10.6 ng/ml; p-0.03)**. The PAI-1 levels were similar among aPL-APS group, SLE controls and healthy controls. No specific aPL antibody (anticardiolipin, anti-β2GP1 or lupus anticoagulant) showed any association with PAI-1 levels. **PAI 1 level was a positive predictor of thrombosis [OR 1.11 (1.01 – 1.22); p – 0.03]**. This association remained significant after adjusting for age, gender, BMI, presence of SLE, presence of antiphospholipid antibodies and prednisolone intake (Table 2). There was no dichotomy in risk for arterial or venous thrombosis. Those with recurrences did not have higher PAI-1 levels [OR 1.07 (95% CI 0.98 – 1.17), p 0.09]. Higher PAI-1 levels reduced the risk of obstetric APS (n= 20) [OR 0.90 (0.82- 0.99). p =0.03]. Plasma tPA was higher in both antiphospholipid groups and SLE compared to healthy controls. It did not have any effect on thrombosis. There was a poor correlation between tPA and PAI-1 levels (r-0.11).

Conclusion: Plasminogen activation inhibitor 1 is an independent contributor of thrombosis in APS. Targeting PAI-1 directly or by drug repurposing may improve outcomes in APS.

Libman-Sacks Endocarditis in APS: A Case-Control Study of Clinical and Serologic Features

Kyla Rodgers[1], Cyrus Sarosh[2], Srilakshmi Yalavarthi[3], Emily Becker[4], Yiran Shen[5], Kaitlyn Sabb[4], Peter Hagan[4], Ajay Tambralli[5], Jacqueline Madison[5], Yu (Ray) Zuo[5] and Jason S. Knight[5], [1]University of Michigan, Whitmore Lake, MI, [2]University of Michigan, Temperance, MI, [3]Division of Rheumatology, Department of Internal Medicine, University of Michigan, Ann Arbor, [4]University of Michigan, Ann Arbor, [5]University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0115–0144) Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Libman-Sacks endocarditis (LSE) is an inflammatory phenomenon, typically involving the mitral or aortic valve, that affects some patients with systemic lupus erythematosus (SLE) and/or antiphospholipid syndrome (APS). These thrombotic vegetations can cause valve failure or become a nidus for bacterial endocarditis. The pathophysiologic mechanisms underlying LSE, including the role played by specific APS-associated autoantibodies (aPL), are poorly understood. Here, we set out to define any unique clinical characteristics of patients with a history of LSE. We also sought preliminary evidence of inflammatory pathways more likely to be activated in these patients.

Methods: We identified cases of LSE from an academic cohort of approximately 300 patients with durably positive aPL testing; roughly 75% of the cohort met criteria for APS. All available TTE and TEE reports were reviewed to identify APS patients with and without valve disease. Those with TTE/TEE evidence of LSE and/or those who had undergone valvular replacement

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

for LSE were selected as cases (n=10). Patients with positive blood cultures or with valve thickening without vegetation were excluded. Age- and sex-matched controls were randomly selected from the cohort of APS patients with normal TTE/TEE results (n=20). Clinical characteristics, including comorbid conditions and standard laboratory results (e.g., platelet count, complement levels), were noted. Plasma levels of selected aPL were measured by ELISA. We also assessed biomarkers tending to track with activation of endothelial cells (E-selectin), platelets (P-selectin), and neutrophils (calprotectin).

Results: In our patient population, the average age was 47.9 years in the case group and 47.8 years in the control group. In both groups, 80% of patients were female, and 20% had SLE. LSE most frequently involved the mitral valve (90%), followed by the aortic valve (10%). Overall, 60% of patients required valve surgery. Patients with LSE were significantly more likely to have a history of hypertension (80% vs. 25%, p=0.007), catastrophic APS (30% vs. 0%, p=0.039), and white matter hyperintensities (70% vs. 25%, p=0.045) than those without; significant differences were not found in the rates of hyperlipidemia (30% vs. 5%), venous thrombosis (60% vs. 50%), or stroke (70% vs. 40%). Patients with LSE tended to have lower platelet counts (mean 225 K/μl vs. 289, p=0.028), as well as lower complement C4 levels (mean 19.6 mg/dl vs. 25.5, p=0.029). LSE patients were more likely to have positive testing for anti-β_2GPI IgG and anti-PS/PT IgG; however, these differences were not statistically significant. Though E-selectin and calprotectin levels were not statistically different between the groups, P-selection was increased in the LSE patients (mean 32.2 ng/ml vs. 25.0, p=0.035).

Conclusion: Durably aPL-positive patients with a history of LSE were more likely to have a history of hypertension, catastrophic APS, and white matter hyperintensities, as compared to those without. They also tended to have lower platelet counts and complement C4 levels. Candidate biomarker testing suggests that platelet activation likely deserves further study as a contributor in the pathogenesis of aPL-associated LSE.

Abstract Number: 0132

Increased Expression of Gas6 and Its Tyrosine Kinase Receptor Tyro3 Are Associated with Antiphospholipid Syndrome

Fanshu Li, Ranran Yao, Fanlei Hu, **Liling Xu** and Chun Li, Department of Rheumatology and Immunology, Peking University People's Hospital, Beijing, China (People's Republic)

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0115–0144) Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Growth arrest specific protein 6 (Gas6) is a member of the vitamin K-dependent protein family. It participates in apoptosis, inflammatory response and immunomodulation by binding to its receptors Tyro3, Axl and Mer (TAM). Previous studies have suggested that Gas6 is able to affect the coagulation system by regulating platelet and vascular cell function through the TAM signaling pathway. However, its role in antiphospholipid syndrome (APS) is unclear. This research focuses on the expression level and clinical significance of Gas6 in APS to further understand the role of Gas6/TAM signaling pathway in the pathogenesis of APS.

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: 102 patients diagnosed APS with Sydney criteria were recruited from the Department of Rheumatology and Immunology at Peking University People's Hospital. 104 healthy volunteers were enrolled as control. Among them, the serum Gas6 concentrations of 92 APS patients were determined by ELISA, and the relationship between Gas6 and clinical characteristics was analyzed. The expression of TAM receptor on the surface of peripheral blood monocytes in 10 APS patients was further examined. The results were analyzed by Mann-Whitney U test, Kruskal-Wallis test followed by Dunn's posttest for multiple comparisons and Spearman's rank correlation test as appropriate. $p < 0.05$ was considered significant.

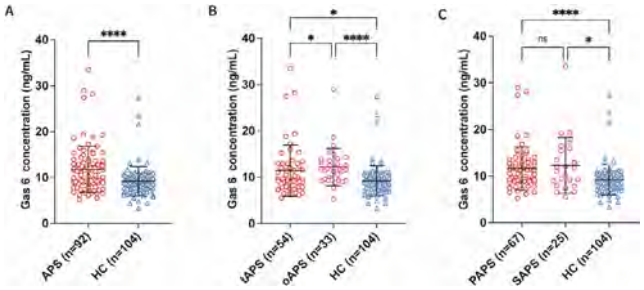

Fig.1. A) Serum Gas6 concentration was significantly higher in antiphospholipid syndrome (APS) patients than in healthy controls (HC) ($p < 0.0001$). B) Serum Gas6 concentration was significantly higher in both thrombotic antiphospholipid syndrome (tAPS) ($p = 0.0203$) and obstetric antiphospholipid syndrome (oAPS) ($p < 0.0001$) patients, and the concentration in the oAPS was significantly higher ($p = 0.0476$). C) Serum Gas6 concentration was significantly higher in both primary antiphospholipid syndrome (PAPS) ($p < 0.0001$) and secondary antiphospholipid syndrome (SAPS) ($p = 0.0008$) patients, and there was no significant difference between them ($p > 0.9999$).

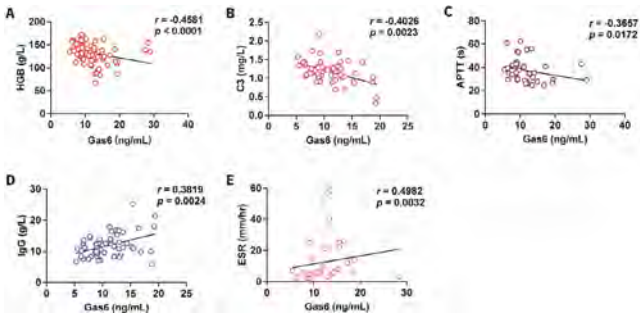

Fig.2. Correlation analysis between serum Gas6 concentration and clinical features in APS patients, which showed negative correlation with HGB (A), C3 (B), APTT (E), and positive correlation with IgG (C) and ESR (D).

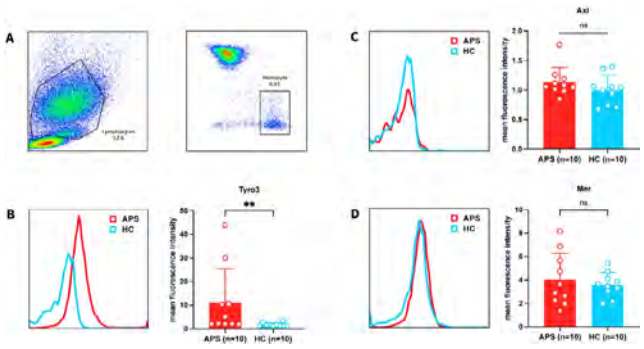

Fig.3. A) Monocytes in the peripheral blood of APS patients were sorted by CD14 and CD16. B) The expression level of Tyro3 on the surface of monocytes in the peripheral blood of APS was significantly higher than HC ($p = 0.0015$). C/D) There was no significant difference in the expression levels of Axl ($p = 0.2176$) and Mer ($p = 0.9705$) between APS and HC.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Compared to HC, APS patients had higher serum expression of Gas6 (11.81±5.02 vs. 9.22±3.22 ng/mL, $p < 0.0001$) (Fig.1A). Furthermore, serum Gas6 concentrations in patients with thrombotic APS (tAPS) and obstetric APS (oAPS) were analyzed. While oAPS was higher than tAPS (12.21 ± 4.057 vs. 11.42 ± 5.537 ng/mL, $p = 0.0476$) (Fig.1B). And serum Gas6 concentrations in tAPS ($p = 0.0203$) and oAPS ($p < 0.0001$) were significantly higher than in HC. In PAPS (11.63 ± 4.655 ng/mL, $p < 0.0001$) and SAPS (12.28 ± 5.973 ng/mL, $p = 0.0008$), serum Gas6 concentrations were higher than in HC, with no significant difference between PAPS and SAPS ($p > 0.9999$) (Fig. 1C). Next, the correlation between patients' serum Gas6 concentrations and clinical features was explored. The results showed that patients' serum Gas6 concentrations showed negative correlation with HGB ($r = –0.4581$ $p < 0.0001$), C3 ($r = –0.4026$ $p = 0.0023$), and APTT ($r = –0.3657$ $p = 0.0172$), and positive correlation with IgG ($r = 0.3819$ $p = 0.0024$) and ESR ($r = 0.4982$ $p = 0.0032$) (Fig.2). Moreover, Gas6 concentration was higher in patients with low C3 ($p = 0.0015$) and low C4 ($p < 0.0001$) than in patients with normal complement, and were also higher in ANA-positive patients than in ANA-negative patients ($p = 0.0101$). The expression level of Tyro3 on the surface of peripheral blood monocytes in APS (MFI: 11.01 ± 14.44) was significantly higher than HC (MFI: 1.744 ± 0.7233, $p = 0.0015$) (Fig. 3B). For Axl (MFI: 1.136 ± 0.2480 vs. 0.9975 ± 0.2477, $p = 0.2176$) and Mer (MFI: 4.022 ± 2.257 vs. 3.576 ± 1.049, $p = 0.9705$), no significant differences were detected between APS and HC (Fig. 3C/D).

Conclusion: Serum Gas6 was significantly overexpressed in APS patients and correlated with parameters of inflammation, immunity and coagulation, suggesting that the Gas6/TAM signaling pathway may play a potential role in APS.

Background/Purpose: Cardiovascular disease (CVD) in antiphospholipid syndrome (APS) is driven by antiphospholipid antibody-mediated immunothrombotic mechanisms and traditional cardiovascular risk factors (CVRFs). Although the EULAR recommendations for cardiovascular risk management highlighted the importance of CVRF control, CVRF target achievement and the differences between primary APS (PAPS) and systemic lupus erythematosus (SLE)/APS remain uncertain.

In the context of the SUrvey of Cardiovascular Disease Risk Factors-SURF in SLE and APS project (1), this study aimed to assess the prevalence and control of traditional CVRFs in a multi-centre group of SLE/APS and PAPS patients across four continents.

Methods: CVRF data were collected from medical records in 17 centres from 11 countries between 2015 and 2020 (extended to 2022 due to COVID-19 pandemic). We evaluated the prevalence of traditional CVRFs, and individual's cardiovascular risk (low/moderate/high/very-high) using the Systematic Coronary Risk Evaluation (SCORE) algorithm. Target attainment was assessed for the following CVRFs: blood pressure (BP) (< 140/90 mm Hg), lipids, smoking, and body mass index (BMI) according to 2016 European Society of Cardiology guidelines, as well as a composite CVRF (at least two, three, and all four CVRF targets of BP, smoking, low-density lipoprotein [LDL], BMI). An additional BP target of < 130/80 mmHg was assessed according to the 2022 EULAR recommendations for cardiovascular risk management. Multivariable regression models were applied.

Results: 1003 patients meeting the Sydney APS criteria (median age 47.0 years, females: 77.7%, White: 66.2%, median disease duration 11.0 years) were included; 539 with PAPS and 464 with SLE/APS (additionally fulfilling 2012 ACR SLE classification criteria). We found a high CVRF prevalence (hypertension 41.0%, hyperlipidemia 34.3%, obesity 32.1%, current smoking 19.3%) and inadequate individual (BP < 130/80 mm Hg, body mass index [BMI], lipids) and multiple CVRF control in the entire APS cohort.

Higher prevalence of hypertension (50.4% vs 32.8%, p< 0.001) and hyperlipidemia (39.7% vs 29.7%, p=0.001) was observed in SLE/APS versus PAPS, but a lower prevalence of current smoking (15.9% vs 22.3%, p=0.012). Patients with PAPS had worse target attainment than SLE/APS patients for smoking (no current smoking) (77.7% vs 84.1%, p=0.012), BP < 130/80 mmHg (47.9% vs 56.6%, p=0.007) and ≥2 CVRF targets in the entire group, and additionally for BMI, LDL, triglycerides and ≥3 CVRF targets in the high/very high CVD risk subgroup. In multivariable analysis, age, sex and arterial thrombosis history, were the main independent predictors of ≥3 and four target attainment.

Conclusion: In this large real-world survey, high prevalence and suboptimal CVRF control were observed in APS, highlighting the need for increased CVD risk awareness, especially in PAPS, a clinical entity with frequently under-recognised cardiovascular risk compared to SLE.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0115–0144) Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Emerging evidence implicates neutrophil activation and neutrophil extracellular trap (**NET**) formation (i.e., NETosis) in amplifying APS-associated thromboinflammation. Gasdermin D (**GSDMD**), a substrate of inflammatory caspases that is best known for forming membrane pores during macrophage pyroptosis, can also support interleukin-1β (**IL-1β**) release and NETosis by neutrophils. Based on preliminary data demonstrating elevated inflammatory caspase activity in APS neutrophils, we investigated the potential role of neutrophil GSDMD in APS pathophysiology.

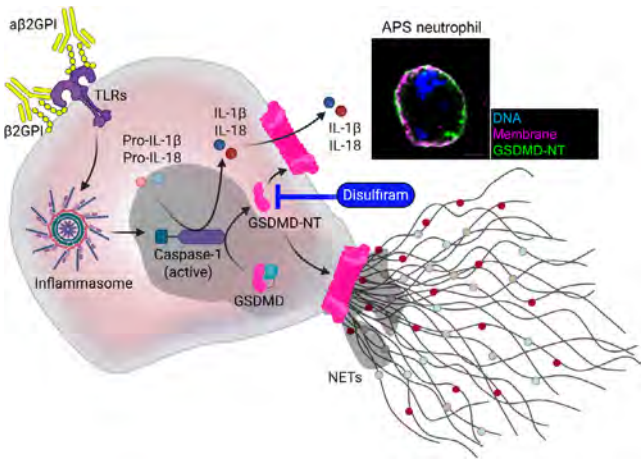

Figure 1. Schematic illustration depicting the role of active GSDMD in promoting the release of mature interleukins and NETs in APS neutrophils.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: NETosis was measured with the SYTOX Green assay and/or citrullinated histone H3-based quantification. Cleaved, pore-forming N-terminal GSDMD (**GSDMD-NT**) was identified using flow cytometry, immunoblotting, and confocal microscopy. Caspase-1 activity was measured with a luminescent assay. Plasma IL-1β, IL-18, and calprotectin were quantified by ELISA. *In vitro*, neutrophils were treated with inhibitors of GSDMD (disulfiram, necrosulfonamide) or caspase-1 (VX-765), followed by exposure to IgG fractions from controls or APS patients or affinity-purified anti-β2GPI. GSDMD-deficient (*Gsdmd*$^{-/-}$) mice were assessed in the context of APS IgG-accelerated venous thrombosis in the inferior vena cava (IVC).

Results: Compared with healthy controls (n=13), neutrophils from patients with primary APS (n=25) exhibited a 3-fold increase in caspase-1 activity ($p< 0.0001$), as well as a 4-fold higher formation of cleaved, pore-competent GSDMD-NT ($p< 0.01$). A 2.8-fold rise in plasma IL-18 levels ($p< 0.01$) was also appreciated in the same patient cohort. Notably, both neutrophil caspase-1 activity ($r=0.52$, $p=0.0058$) and plasma IL-18 ($r=0.41$, $p=0.031$) positively correlated with neutrophil GSDMD-NT, as did plasma calprotectin ($r=0.64$, $p=0.0024$), a biomarker of neutrophil activation and NET formation. *In vitro*, the exposure of control neutrophils to APS patient IgG significantly increased caspase-1 activity (2.5-fold, $p< 0.05$), GSDMD-NT formation (3-fold, $p< 0.01$), IL-1β secretion (3-fold, $p< 0.01$), and NETosis (3-fold, $p< 0.0001$). Confocal microscopy demonstrated that APS IgG triggered the preferential accumulation of GSDMD-NT in neutrophil plasma membranes. Furthermore, blocking GSDMD-NT cysteine-191, which is required for efficient pore formation, with either disulfiram or necrosulfonamide prevented neutrophil activation by APS IgG; the inhibition of caspase-1 with VX-765 was similarly protective. Compared with wild-type mice, *Gsdmd*$^{-/-}$ mice (n=5) exhibited a 2-fold reduction in plasma IL-1β ($p< 0.01$, n=5) and developed significantly smaller thrombi in response to APS IgG-associated thrombosis (mean 3.1 mg versus 7.6 mg, $p< 0.01$).

Conclusion: By releasing IL-1β, NETs, and other inflammatory mediators, GSDMD pores may play a crucial role in linking innate immunity to immunothrombosis in APS (**Figure 1**). Since GSDMD deficiency and inhibition (with repurposed agents like disulfiram) reduce neutrophil activation in APS models, targeting GSDMD could offer a new approach for managing inflammation-driven thrombosis that may not respond to anticoagulation alone.

* Only lupus anticoagulant positive
** Before the event, an INR of 7.6 was converted to an INR of 1 with K-vit due to vaginal bleeding.

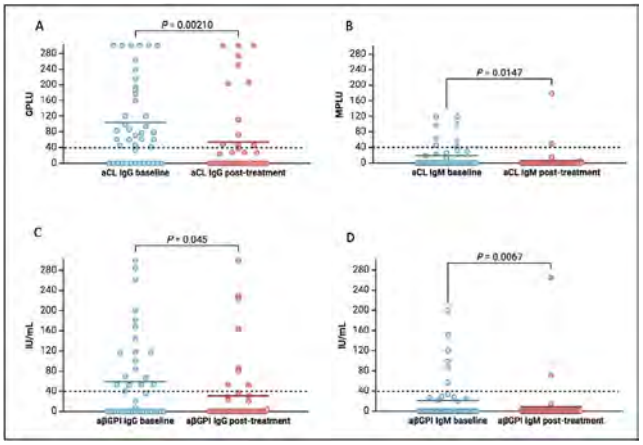

Figure 1 Change in aPL titers 6-12 months after rituximab

Background/Purpose: Rituximab treatment has been shown to be effective in non-thrombotic manifestations of APS and refractory catastrophic APS (CAPS). However, there are conflicting results regarding the change in aPL titers and limited data on the effect on thrombotic recurrence. The aim of this study was to evaluate the change in aPL titers over time, thrombotic recurrence and mortality rates, and treatment-related adverse events in APS patients treated with rituximab.

Methods: This retrospective single center study included 43 patients with thrombotic APS (11 with primary APS, 32 with SLE+APS) who received at least 1 cycle of rituximab (1000 mg on days 0 and 15). Baseline demographic, clinical, and serologic characteristics, aCL IgG/IgM and anti-β2-glycoprotein-I (aβ2GPI) IgG/IgM titers at 6 to 12 months of rituximab treatment were reviewed. The positivity threshold for aCL and aβ2GPI IgG/IgM was accepted as >40 GPL/MPL units or >99th percentile.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: The demographic, clinical, and serologic characteristics of the patients are summarized in Table 1. The median follow-up period after rituximab was 3.5 (IQR: 5.8) years. Whilst the majority of patients were treated with rituximab for thrombotic APS, there were also patients who were received rituximab for lupus nephritis or non-renal SLE (Table 1). After 6-12 months of rituximab treatment, aPL positives decreased: aCL IgG from 29 (67.4%) to 13 (30.2%), aCL IgM from 9 (20.9%) to 2 (4.7%), aβ2GPI IgG from 22 (51.2%) to 9 (20.9%), and aβ2GPI IgM from 9 (20.9%) to 2 (4.7%). There was also a statistically significant decrease in aPL antibody titers (Figure 1). Five patients developed new events after rituximab and details are shown in Table 2. Five patients died during follow-up. Causes of death were sepsis in 1, traumatic intracranial hemorrhage in 1, and lupus nephritis in 1. One patient died due to recurrence of pulmonary hemorrhage 38 months after rituximab and 1 patient was lost due to treatment-refractory CAPS at 6th month of rituximab. Bacterial infections were observed in 15 patients (4 required hospitalization and 1 lost after ICU admission), COVID infections in 7 (2 required hospitalization), herpes zoster in 3. Finally, 2 patients developed allergic reactions, none of which were considered anaphylaxis.

Conclusion: In patients with thrombotic APS, rituximab treatment may prevent thrombotic recurrence with a significant decrease in aPL titers. It is noteworthy that 4 of 5 patients who developed recurrence after rituximab were not receiving effective anticoagulant therapy. These data suggest that under consideration of infectious complications, rituximab may be an effective alternative in high-risk APS patients with recurrent thrombosis.

Abstract Number: 0136

Beyond Thrombosis: Histological Spectrum, Predictors and Outcomes of Renal Involvement in Primary Antiphospholipid Syndrome: A Single-Centre Cohort Study

RITESH KUMAR MISHRA[1], SUBIN PHILIP[2], RIZWANA NAUSHAD[2], AISHWARYA GOPAL[3], Chengappa Kavadichanda[2], CHRISTINA MARIASELVAM[2], RAJESH N G[2], Molly mary Thabah[3] and VIR SINGH NEGI[2], [1]JAWAHARLAL INSTITUTE OF POSTGRADUATE MEDICAL EDUCATION AND RESEARCH, Bhubaneswar, India, [2]JAWAHARLAL INSTITUTE OF POSTGRADUATE MEDICAL EDUCATION AND RESEARCH, PUDUCHERRY, Puducherry, India, [3]JAWAHARLAL INSTITUTE OF POSTGRADUATE MEDICAL EDUCATION AND RESEARCH, PUDUCHERRY, India

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0115–0144) Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Renal involvement in primary APS is underrecognized and histologically diverse, encompassing both vascular and glomerular pathology. We aimed to describe the histopathology, outcomes of biopsy-proven renal disease among primary APS and predictors of renal involvement.

Methods: Among 233 patients with primary APS (revised Sapporo criteria, 2006), Renal abnormalities defined as proteinuria >0.5 g/day and/or elevated serum creatinine with or without hematuria—were identified. Clinical, serological, histopathological and direct immunofluorescence (DIF) data were analyzed. Renal lesions were classified as per the Renal Pathology Society-2023 consensus definitions for aPL- nephropathy.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Nineteen patients (8.15%) had renal abnormalities, Of these, 11 patients underwent kidney biopsy (Table 1). The median age of the biopsied cohort was 27 years (23.5-38), with 63.6% female. Hypertension was present in 63.6%. Median serum creatinine was 1.6 mg/dL (0.75-2.35), and UPCR was 4.4 g/g (1.76-7.5).

Renal biopsy findings were diverse (Figure 1A), with glomerular injury more frequent than aPL nephropathy. The major glomerular finding was glomerulosclerosis and ischemic wrinkling of GBM (a sequela of TMA) seen in 27%, followed by basement membrane thickening, while interstitial inflammation was present in 64% and mesangial expansion in 73% (Table 2).

S. No	Age/ Sex	Extra-renal APS manifestation	HTN	UPCR/ S. Creatinine	anti-β2GP1 anti-cardiolipin IgG/IgM titers	LAC	Renal biopsy findings	Treatment	Outcomes	Follow-up duration
1	36F	Recurrent pregnancy losses, AIHA, Thrombocytopenia, Stroke, DVT, Mitral regurgitation	+	10/2.3	High/Neg Low/Neg	+	Membranous nephropathy, Hypertensive vascular changes	Pulse Steroids, Inj CYC, MMF maintenance, Warfarin	50% proteinuria reduction at 6 months	1y

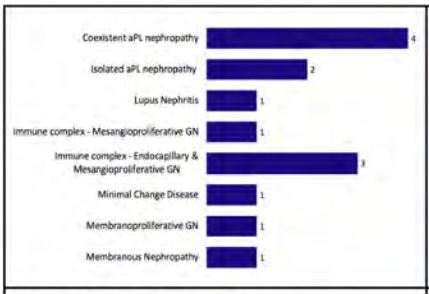

Figure 1A: Spectrum of renal biopsy diagnosis in primary APS

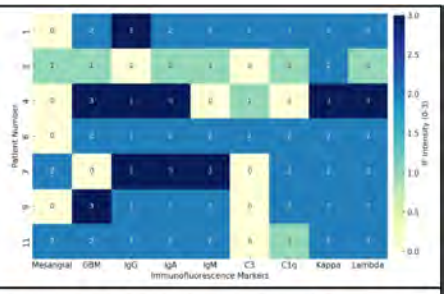

Fig 1B: Heatmap depicting DIF staining pattern in primary APS with proliferative GN

Isolated Antiphospholipid nephropathy (aPL-N) was seen in 2/11 patients. Acute or chronic TMA like lesions with immune deposits or inflammatory cells seen in 4/11 patients (54.5%). Acute TMA lesions were seen in one patient, chronic lesions seen in four, while one patient had acute with chronic TMA change (Table 2). DIF was positive in most, with a full-house pattern observed in two patients, despite no lupus manifestations (Figure 1B).

Treatment included warfarin (n=9, 81.8%), RAAS blockade (n=10, 90.9%), corticosteroids (n=4, 36.4%), and MMF (n=3, 27.3%). In the biopsied group (n=11), at a median 2-year follow-up, four (36.4%) achieved complete proteinuria remission (UPCR < 0.5 g/g), two (18.2%) had partial reduction, and one (9%) patient showed resolution of AKI.

Of all 19 APS with renal manifestations, five had CKD and only one progressed to dialysis-dependent ESRD.

On univariate analysis, arterial thrombosis ($p = 0.002$) and cutaneous ulcers ($p = 0.0009$) were significantly associated with renal involvement. On multivariable logistic regression, cutaneous ulcers independently predicted renal involvement (OR:19.5, 95% CI: 1.37-277.8, p=0.028), suggesting microvascular skin–renal overlap.

Conclusion: Renal abnormalities were identified in 8.2% of patients with primary APS. Only a minority of biopsied patients met strict histological criteria for aPL nephropathy. Most biopsies showed glomerular immune deposits or interstitial inflammation, pointing to immune-mediated renal injury in APS patients. The histologic overlap with SLE supports a pathologic continuum. Given the multitude of renal biopsy findings in Primary APS, it calls for individualized, pathology-driven treatment. Renal outcomes were favorable, with a low incidence of dialysis-requiring CKD.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0115–0144) Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Primary Antiphospholipid Syndrome (APS) a systemic autoimmune prothrombotic disorder with long-term consequences. While secondary APS is well studied, large real-world cohorts of primary APS remain scarce. We characterised the clinical, serological, and damage profiles of patients with primary APS and identified predictors of irreversible damage using the Damage Index for APS (DIAPS).

Methods: This retrospective study included 233 primary APS patients meeting the 2006 Sydney criteria for primary APS. Clinical features, antibody profiles, obstetric outcomes, and DIAPS were analyzed. High damage was defined as DIAPS ≥3. Subgroup analyses were performed in thrombotic APS (n=185) and obstetric-only APS (n=48). Multivariable logistic regression was used to identify predictors of high damage.

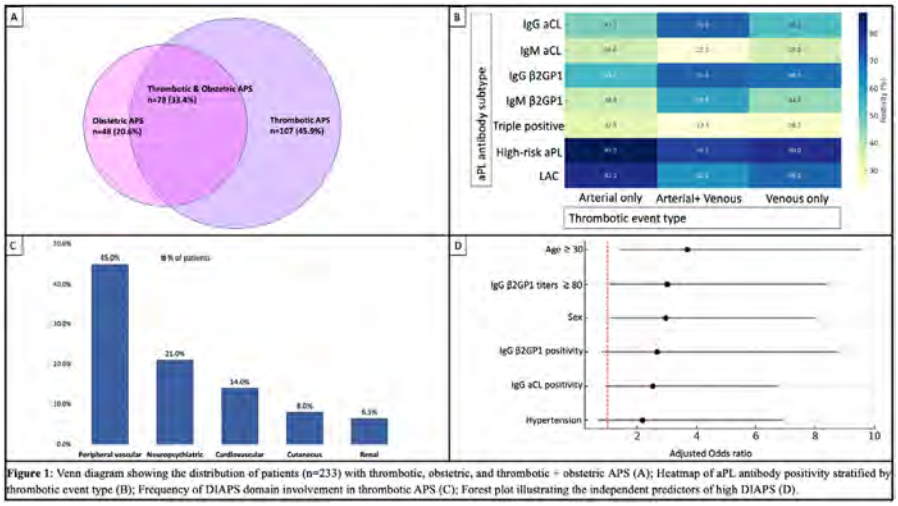

Figure 1: Venn diagram showing the distribution of patients (n=233) with thrombotic, obstetric, and thrombotic + obstetric APS (A); Heatmap of aPL antibody positivity stratified by thrombotic event type (B); Frequency of DIAPS domain involvement in thrombotic APS (C); Forest plot illustrating the independent predictors of high DIAPS (D).

TABLE 1: Manifestations of primary APS in a single center cohort of 233 patients, grouped as per the 2023 ACR/EULAR classification for APS

IgG aCL	23 (74.2)	73 (47.4)	**0.01***
IgG aCL High titers (≥80)	10 (32.3)	27 (17.5)	0.10
IgM aCL	9 (29.0)	63 (40.9)	0.30
IgM aCL High titers (≥80)	0 (0.0)	8 (5.2)	0.41
IgG β2GP1	26 (83.9)	89 (57.8)	**0.01***
IgG β2GP1 High titers (≥80)	15 (48.4)	21 (13.6)	**0.00***
IgM β2GP1	11 (35.5)	67 (43.5)	0.53
IgM β2GP1 High titers (≥80)	0 (0.0)	5 (3.2)	0.68
Lupus anticoagulant	14 (45.2)	82 (53.2)	1.0
Triple positive	13 (41.9)	39 (25.3)	0.08
High risk aPL	27 (87.1)	121 (78.6)	0.30
Single aPL positive	5 (16.1)	43 (27.9)	0.26

Results: Clinical spectrum: Over a median follow-up of 5.1 years (range 0.5–12.7), 107 (45.9%) had thrombotic-only APS, 78 (33.4%) had both thrombotic and obstetric APS, and 48 (20.6%) had obstetric-only APS (Fig. 1A). In the thrombotic subgroup (n=185), median age was 29 years (range 14–63), and 82.2% were female. Venous thrombosis occurred in 106 (57.8%), arterial events in 63 (34%), microvascular involvement in 27 (14.5%), and CAPS in 4 (1.7%) patients. Neurological manifestations seen were stroke/TIA: n=39 (21.1%); CVT: n=27 (14.6%); Chorea in n=3 (1.2%). Cardiac involvement included valvular lesions in 19 (8.1%), MI in 8 (4.3%). Hematological features included thrombocytopenia in 65 (27.8%) and AIHA in 16 (6.8%) (Table 1). Renal involvement (n=19, 8.2%) included aPL nephropathy (n=10) and immune-mediated glomerular injury (n=9).

MI, cutaneous ulcers, and arterial thrombosis were more frequent in males ($p< 0.05$). Arterial events were numerically more common in patients with triple positivity, LAC, or high-risk aPL profiles (Fig.1B).

In obstetric-only APS (n=48), the median number of pregnancies was 3 (IQR 2–3.25), with a high burden of first-trimester loss and adverse outcomes such as preeclampsia or low birth weight in 22.2%.

Serological: Of the total 233 patients, 178 (76.4%) had high-risk aPL profiles, 57 (24.5%) were triple-positive, and 83 (35.6%) had single aPL positivity.

Damage Index: The median DIAPS score was 1.0 (IQR 0–2, range 0–6); 65.9% had some damage and 17.8% had high damage. The most frequently involved domains were peripheral vascular (44.9%), neuropsychiatric (21.1%), cardiovascular (14.1%), and cutaneous (8.1%) (Figure 1C).

On multivariable analysis, age ≥30 (OR 3.9, 95% CI 1.5–10.1), male sex (OR 3.0, 95% CI 1.1–8.0), and IgG β2GP1 high titers (OR 3.0, 95% CI 1.1–8.4) independently predicted high DIAPS (Figure 1D). Hypertension showed a trend in the univariate analysis (table 2) but did not retain statistical significance in the multivariate model for prediction of high damage index.

Conclusion: This large single-center cohort highlights the clinical heterogeneity and damage burden in primary APS. Notably, CVT rates were higher than reported in international APS cohorts. Older age, male sex, and high IgG β2GP1 titers independently predicted irreversible damage. These findings underscore the need for early risk stratification to guide personalized monitoring and care.

Abstract Number: 0138

Evaluating Artificial Intelligence for Diagnosing Antiphospholipid Syndrome in Pulmonary Embolism Case Reports: A Prompt-Based Analysis

Sami Rabah and Xiangyi Kang, Lincoln Medical Center, New York, NY

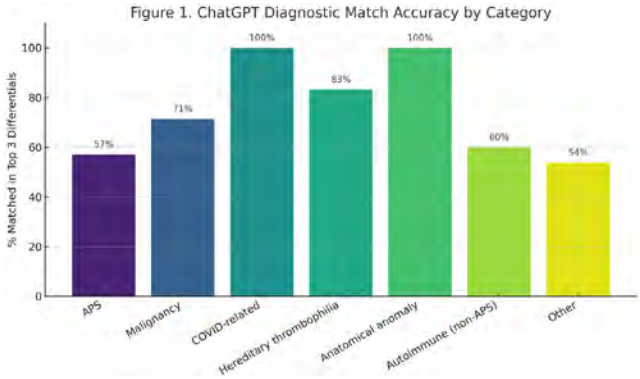
SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0115–0144) Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Antiphospholipid syndrome (APS) is a complex autoimmune prothrombotic disorder that can present with venous or arterial thromboses, often masquerading as unprovoked pulmonary embolism (PE). The use of artificial intelligence (AI) to assist in diagnostic reasoning is expanding, but its precision in recognizing rare or overlapping disorders like APS remains underexplored.

Methods: We reviewed 958 PubMed entries related to pulmonary embolism and included only English-language case reports with full-text access, adequate clinical detail, and documented APS-related diagnostic testing. Fifty cases met the inclusion criteria. Each case was blinded to the final diagnosis and analyzed using GPT-4 (ChatGPT), which was instructed to list its top three differential diagnoses, assess the likelihood of APS, and indicate whether APS antibody testing was warranted. Final diagnoses were recorded separately for performance assessment.

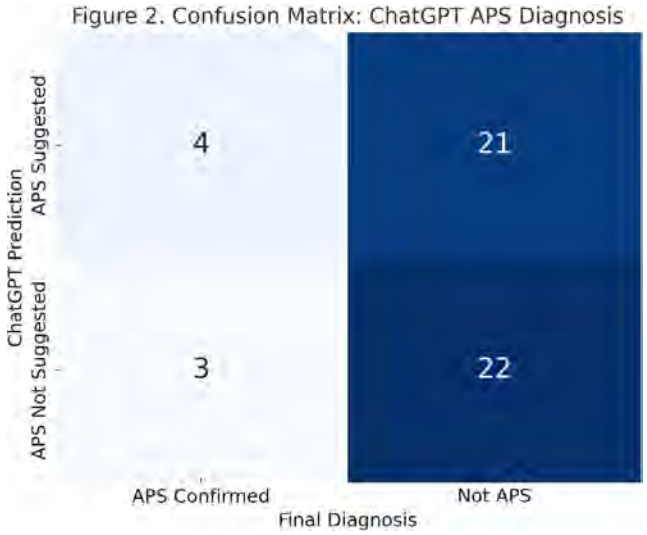
Results: Among the 50 included cases, 7 had a confirmed diagnosis of APS. ChatGPT correctly identified APS in 4 of 7 cases (sensitivity 57%) and incorrectly suggested APS in 21 non-APS cases (specificity 51%). Overall diagnostic accuracy was 52%, with a positive predictive value (PPV) of 16%, a negative predictive value (NPV) of 88%, and an F1 score of 0.25.

ChatGPT also correctly recommended APS antibody testing in all 7 APS cases and withheld testing in 19 of 43 non-APS cases, yielding a testing recommendation sensitivity of 100% and specificity of 44.2%. Additionally, in 73% of all cases, ChatGPT correctly included the final diagnosis—APS or otherwise—within its top three differential diagnoses,



Bar chart showing the percentage of cases in which ChatGPT correctly included the final diagnosis category within its top three differentials. Categories include APS, malignancy, hereditary thrombophilia, anatomical anomalies, COVID-related thrombosis, autoimmune (non-APS), and other causes.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Heatmap illustrating true positives, false positives, true negatives, and false negatives based on whether ChatGPT suggested APS in each case. The matrix is based on 50 PE case reports, 7 of which were confirmed to be APS.

demonstrating consistent clinical reasoning across a wide range of thrombotic etiologies including hereditary thrombophilia, malignancy, infection, and anatomical anomalies. Performance by diagnosis category is summarized in Figure 1, and APS classification performance is illustrated in the confusion matrix (Figure 2).

Conclusion: ChatGPT-4 demonstrates potential in supporting differential diagnosis generation in complex PE cases. While it overcalls APS in some instances, it consistently identifies relevant thrombotic mechanisms and reliably flags cases warranting APS testing. These findings support the growing role of artificial intelligence in complex diagnostic workflows and highlight the importance of structured prompt design in enhancing model accuracy and clinical relevance.

Background/Purpose: Antiphospholipid syndrome (APS) is a systemic autoimmune disorder characterized by the persistent presence of antiphospholipid antibodies (aPL) along with clinical manifestations such as venous or arterial thrombosis and obstetric morbidity, including recurrent pregnancy loss and preeclampsia. Among aPL isotypes, IgG antibodies (particularly those targeting cardiolipin and β2-glycoprotein I) are well established as the primary pathogenic drivers and are central to current classification criteria. In contrast, the clinical relevance of IgM antibodies (especially when coexisting with IgG) is less well understood and often underrecognized in clinical settings. Determining whether concurrent IgM positivity confers additional clinical risk is key to enhancing diagnostic precision, prognostic evaluation, and clinical management in APS.

To determine whether the added aPL IgM positivity is associated with a more severe clinical phenotype in patients with aPL IgG positive APS.

Methods: A cross-sectional, multicenter study was conducted at two European tertiary care centers: Reina Sofía University Hospital (Cordoba, Spain) and Ospedale San Giovanni Bosco (Turin, Italy). Patients with confirmed APS, according to the revised Sydney classification criteria, were included and stratified based on the presence or absence of concurrent IgM positivity. Clinical, immunological, and therapeutic data were collected from electronic medical records. Valvular involvement (valvulopathy) was assessed by transthoracic echocardiography in accordance with institutional protocols. Univariate

Table 1. Clinical, immunological, and treatment characteristics of IgG+ versus IgG+IgM+ APS patients. ANA: antinuclear antibody; ASA: acetylsalicylic acid; VKA: vitamin K antagonist; HTN: hypertension; HCQ: hydroxychloroquine. Valvulopathy was assessed by transthoracic echocardiography according to institutional protocols.

Variable	IgG+ (n = 65)	IgG+IgM+ (n = 35)	p-value

analyses were followed by multivariate logistic regression to identify independent associations, adjusting for the Global Antiphospholipid Syndrome Score (GAPSS), a validated tool for APS risk stratification.

Results: Among the 100 patients included, 65 were classified as IgG+ only and 35 as IgG+IgM+. No statistically significant differences were found between groups in age, sex, systemic lupus erythematosus (SLE) prevalence, or thrombotic burden. However, the IgG+IgM+ group had a significantly higher median GAPSS (13 vs. 10; p=0.04) and a markedly increased prevalence of echocardiographically confirmed valvulopathy (17% vs. 2%; p< 0.01). Detailed clinical and serological comparisons are shown in Table 1. In multivariable analysis, IgM positivity remained independently associated with valvulopathy (OR: 12.5; 95% CI: 1.73–274.5; p=0.03), after adjusting for potential confounders including GAPSS and the presence of SLE. The wide confidence interval highlights statistical uncertainty, limiting the precision and interpretability of this association.

Conclusion: The presence of IgM aPL in patients with IgG-positive APS defines a clinically distinct subgroup, characterized by greater valvular involvement despite similar thrombotic profiles. These findings suggest that IgM antibodies may contribute to a more complex, organ-specific disease phenotype and support their inclusion in APS risk stratification and therapeutic decision-making. Future research should explore the role of other isotypes, such as IgA, to comprehensively characterize their contribution to APS manifestations.

Outcome Of Patients With Non-Criteria Manifestations Of Primary Antiphospholipid Syndrome Treated With Immunosuppressants -A Single Centre Study

Sindhuja Rajendran[1], ashish mathew[2], sukesh chandran nair[3], john mathew[2] and ruchika goel[2], [1]Christian Medical College ,Vellore, Madurai, Tamil Nadu, India, [2]Christian Medical college , Vellore , India, Vellore, Tamil Nadu, India, [3]Christian,Medical College ,Vellore ,India, Vellore, Tamil Nadu, India

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0115–0144) Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Non-criteria manifestations occur in 24% in Primary antiphospholipid syndrome (PAPS) . The efficacy of immunosuppressants in patients with above condition is not certain due to paucity of evidence. This stuyd aims to evaluate the outcome of patients who have been treated with immunosuppressive drugs for treatment of non-criteria manifestations of PAPS.

Methods: Patients with the diagnosis of APS or probable APS, attending our clinics between 2010 to 2024 were screened. Among these those satisfying the APL domain of ACR/EULAR 2023 criteria and had at-least one non criteria manifestation not attributable to any other defined CTD or disease and have been treated with immunosuppressive therapy were included. Data regarding clinical presentation, laboratory abnormality, treatment and response were included.

The primary outcome was the clinical improvement or resolution of the presenting manifestation after initiation of therapy.

Comparison of response to therapy in patients receiving Rtx and mycophenolate/ azathioprine

Results: Of the 334 patients screened ,a total of 44 patients 28 females, mean age 38±13 (SD) years satisfied the inclusion criteria. The most common non-criteria manifestation was thrombocytopenia (24, 54%) followed by AIHA (12,27%) (Table-1). Rituximab was the most common immunosuppressant used in 19(43%) followed by mycophenolate (18 (40%). 90% received antiplatelet and anticoagulants. During a median follow up of 32 months (IQR: 20-63), 80% patients responded to treatment. The best response was noted among patients with thrombocytopenia. Response rates of all manifestations is depicted in Table 2.

Major adverse events included death in 2 patients due to sepsis and pneumocystis carinii pneumonia, in patients receiving rituximab and 1 death due to sepsis, disseminated TB, Ca breast in patients receiving MMF

Conclusion: Among the patients with PAPS with non criteria manifestation, the best response to immunosuppression was observed in those presenting with AIHA and thrombocytopenia. All manifestions except LAHPS and skin ulcers showed similar response with rituximab as well as mycophenolate/ azathioprine

Abstract Number: 0141

Cytokine profiles in antiphospholipid syndrome

Xiangjun Liu[1], Yuzhou Gan[2], Chun Li[3], Jianping Guo[4], lei zhu[5] and yuan jia[3], [1]Peking University, Beijing, Beijing, China, [2]University of Michigan, Ann Arbor, MI, [3]Peking University People's Hospital, Beijing, China (People's Republic), [4]Peking University People's Hospital, Beijing, Beijing, China, [5]Affiliated Nantong Rehabilitation Hospital of Nantong University, Nantong, China (People's Republic)

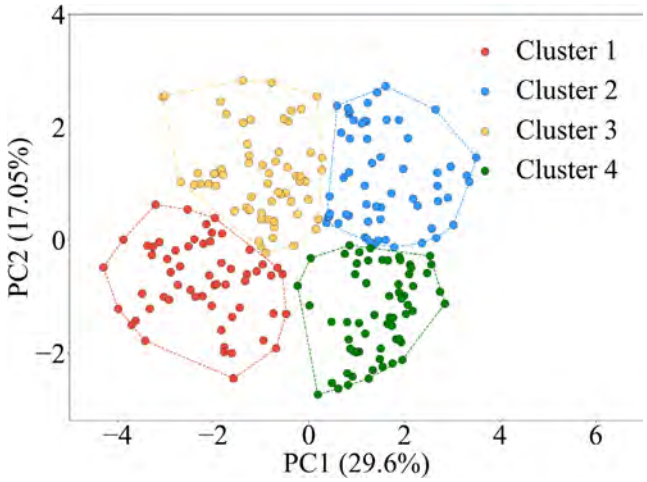
SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0115–0144) Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Antiphospholipid syndrome (APS) is an autoimmune disease with unknown etiology. Inflammatory-mediated tissue damage plays an important role in APS. This study aimed to investigate the cytokine profiles in patients with APS.

Methods: Serum samples were collected from 250 patients with APS and 129 healthy controls (HCs). Serum concentrations of 11 cytokines, including interleukin (IL)-2, IL-4, IL-5, IL-6, IL-8, IL-10, IL-12p70, IL-17, interferon (IFN)-α, tumour necrosis factor (TNF) -a, and IFN-γ,were measured by multiplex bead array assay. Principal component analysis (PCA) and K-means clustering were performed to stratify APS patients into distinct subgroups based on their cytokine profiles. Subsequent comparative analyses assessed differences in clinical manifestations and laboratory parameters across the identified clusters.

Results: Compared withHCs, APS patients displayed significantly increased levels of IL-2 (p = 0.040), IL-1β (p<0.001), IL-12p70 (p <0.001), IL-8 (p <0.001), IL-6 (p <0.001) and IFN-γ(p=0.012), and significantly decreased levels of IL-5 (p<0.001), IL-17 (p=0.007) and TNF-α (p=0.002). The patients with thrombotic APS had significantly higher levels of IL-6 (p < 0.0001), IL-10 (p = 0.005) and TNF-α (p = 0.01), compared to patients with obstetric APS. Unsupervised clustering identified four distinct subgroups (**Fig. 1**): Cluster 1 (N=59) with globally suppressed cytokines except moderate IL-8; Cluster 2 (N=61) exhibiting pan-hypercytokinemia; Cluster 3 (N=62) showing elevated TNF-α/IL-6/IL-10/IL-5 with suppressed IFN-γ/IL-17/IL-12p70/IFN-α/IL-2/IL-4; and Cluster 4 (N=68) characterized by IL-2/IL-4 overexpression (**Fig. 2**). Clinically, Cluster 2 correlated with higher aGAPSS scores, while Cluster 4 was enriched for primary APS (p< 0.05).



PCA scatter plot in patients with APS.

Risk Factors for Antiphospholipid Syndrome-associated Nephropathy: A Retrospective Cohort Analysis

Xiaohan Wei[1], Zhixia Yang[2], Haoyu Pan[2], Yuying Fan[2], Jinyi Qian[2], Shuyi Yu[2] and Hui Shi[3], [1]Shanghai JiaoTong University, Shanghai, China (People's Republic), [2]Department of Rheumatology and Immunology, Ruijin Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China, Shanghai, Shanghai, China (People's Republic), [3]Shanghai Jiaotong University Affiliated Ruijin Hospital, Shanghai, China (People's Republic)

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0115–0144) Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: To identify independent clinical and laboratory risk factors associated with antiphospholipid syndrome-associated nephropathy (APSN) and highlight the clinical importance of early screening in high-risk patients.

Methods: This retrospective cohort study included patients with antiphospholipid syndrome (APS) consecutively enrolled in the APS-Shanghai database between January 2021 and March 2025. All patients were classified based on the 2023 ACR/EULAR criteria. Biopsy-confirmed APSN was used as the diagnostic endpoint. Clinical and laboratory data were extracted from the electronic medical record system. Differences between APSN and non-APSN groups were analyzed, and multivariate logistic regression was performed to identify independent risk factors. All statistical analyses were conducted using SPSS version 29.0.

Results: Among 208 APS patients included, 32 (15.4%) were diagnosed with biopsy-confirmed APSN. Compared with patients without renal involvement, those with APSN had a significantly higher prevalence of hypertension, valvular heart

Multivariate analysis			
Value Heart Disease	1.001	**0.040**	2.720(1.049-7.055)
Thrombocytopenia	1.298	**0.002**	3.664(1.601-8.386)
Stroke	1.373	**0.002**	3.948(1.673-9.313)

disease, thrombocytopenia, ischemic stroke, and cerebrovascular stenosis. Laboratory differences included higher serum creatinine, lower estimated glomerular filtration rate (eGFR), reduced complement C3 levels, and a higher positivity rate for IgA anti-cardiolipin antibodies. Multivariate logistic regression identified three independent clinical predictors of APSN: valvular heart disease (OR = 2.720, 95% CI: 1.049–7.055, P = 0.04), thrombocytopenia (OR = 3.664, 95% CI: 1.601–8.386, P = 0.002), and stroke (OR = 3.948, 95% CI: 1.673–9.313, P = 0.002). These findings suggested that APS patients with these features are at increased risk of developing APSN and may benefit from early screening, including renal function monitoring and consideration for renal biopsy, even in the absence of overt renal symptoms.

Conclusion: This study identified valvular heart disease, thrombocytopenia, and stroke as independent risk factors for APSN. These findings underscore the importance of vigilant renal evaluation in APS patients with systemic vascular involvement and support the role of renal biopsy in clarifying occult nephropathy in high-risk individuals.

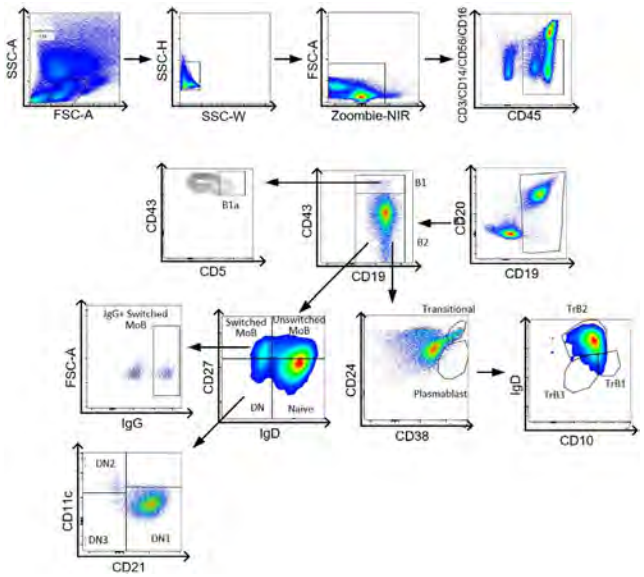

Figure 1. Gating strategies of peripheral B cells from PBMCs.

Background/Purpose: Background: Antiphospholipid syndrome (APS) is a systemic autoimmune disorder characterized by the presence of pathogenic antiphospholipid antibodies (aPL) in the setting of venous or arterial thrombosis, pregnancy morbidity, and other morbid manifestations. B cells are central to APS pathogenesis through their role in aPL production. However, despite their pathogenic importance, the phenotypic and functional characteristics of circulating B cells in APS remain incompletely understood. In this study, we applied high-dimensional spectral flow cytometry to comprehensively characterize the activation profiles of circulating B cells in patients with APS.

Methods: Methods: We developed a 26-color spectral flow cytometry panel to deeply characterize circulating B cell subsets and their activation states in patients with APS. The panel was designed based on established literature and included markers for B cell development, activation, memory, homing, and regulatory phenotypes. Peripheral blood mononuclear cells (PBMCs) were isolated from APS patients (n=37) fulfilling the 2023 ACR/EULAR APS classification criteria and age-

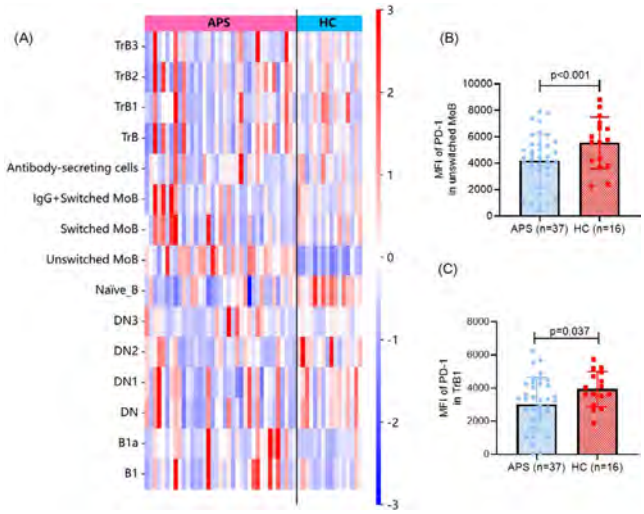

Figure 2. Altered proportions of B cell subsets and reduced PD-1 expression on unswitched memory and transitional B1 cells in APS patients. (A) Heatmap showing the relative percentages (Z-score normalized) of B cell subsets in peripheral blood from patients with antiphospholipid syndrome (APS, n = 37) and healthy controls (HC, n = 16). Subsets include transitional B cells (TrB, TrB1–TrB3), memory B cells (MoB, switched and unswitched), antibody-secreting cells, naïve B cells, double-negative B cells (DN, DN1-DN3), and B1 cells (B1, B1a). (B) Median fluorescence intensity (MFI) of PD-1 on unswitched memory B cells is significantly lower for APS patients versus HCs. (C) PD-1 MFI on transitional B1 cells is also reduced in APS patients.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Baseline Demographic Characteristics of APS Patients and Healthy Controls

	APS (n=37)	HC (n=16)	p
Gender (Female, n%)	33 (89.2)	14 (87.5)	1
Age (mean± SD)	47.9±13.5	43.2±17.9	0.353

and sex-matched healthy donors (n=16). Samples were stained and analyzed using a 5-laser Cytek Aurora spectral flow cytometer. Manual gating was performed using FlowJo software to define major B cell subsets, including naïve, transitional, memory, double-negative, and plasmablast populations. Activation markers such as CD86, CD95, CD69, and HLA-DR were assessed across subsets. Statistical analyses were conducted using SPSS to compare APS patients with healthy controls, with significance defined as $p < 0.05$.

Results: Among the patients, 25 (67.6%) were diagnosed with primary APS, while 12 (32.4%) had APS associated with systemic lupus erythematosus (SLE). Gating strategies were shown in **Fig. 1**. Compared with healthy controls, patients with APS exhibited an increased proportion of B1a cells ($CD5^+CD43^+$) (0.30% of $CD19^+CD20^+$B cells [0.15, 0.44] vs. 0.14 [0.08, 0.22], p=0.010) and unswitched memory B cells ($CD27^+IgD^+IgM^+$) (30.52% of $CD19^+CD20^+$B cells [21.68, 36.79] vs. 12.19 [9.59, 17.58], p< 0.001). In contrast, the proportion of naïve B cells ($CD27^-IgD^+IgM^+$) was significantly reduced in APS patients (46.21% of B cells [42.34, 58.44] vs. 63.01 [57.51, 72.64], p< 0.001) (**Fig. 2A**). Moreover, the expression of the key checkpoint regulator PD-1 was reduced on transitional B1 cells ($CD10^{hi}IgD^{hi}CD24^{hi}CD38^{hi}$) and unswitched memory B cells in APS patients (**Fig. 2B-C**).

Conclusion: High-dimensional profiling of circulating B cells in APS patients reveals distinct alterations in subset distribution and activation states, including increased B1a and unswitched memory B cells and reduced naïve B cells, alongside diminished PD-1 expression on key populations. These results provide novel insights into B cell dysregulation in APS and raise the possibility that augmenting PD-1 signaling or modulating specific B cell subsets could represent future therapeutic strategies for this complex autoimmune disorder.

Abstract Number: 0144

Duration of Anticoagulation in Antiphospholipid Antibody-positive Patients: Results from an AntiPhospholipid Syndrome Alliance for Clinical Trials and InternatiOnal Networking (APS ACTION) Survey

Zeynep Belce Erton[1], Joann Vega[2], Hannah Cohen[3] and Doruk Erkan[2], on Behalf of the APS ACTION Duration of Anticoagulation Working Group, [1]Hospital for Special Surgery, Brooklyn, NY, [2]hospital for special surgery, New York, NY, [3]University College London Hospitals NHS Foundation Trust, London, United Kingdom

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0115–0144) Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: APS ACTION is a multidisciplinary, international research network focused on developing collaborative studies to improve antiphospholipid syndrome (APS) diagnosis and management. There is limited prospective evidence guiding the optimal duration of anticoagulation in thrombotic APS, particularly across varied antibody profiles, levels, and thrombosis risk

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1: APS ACTION Survey Responses on Anticoagulation Discontinuation in Standardized Venous Thromboembolism (VTE) and Arterial Thrombosis (AT) Scenarios, Stratified by aPL Profile and VTE and AT Risk Factors

VTE Scenario: 50-year-old female; with no other systemic autoimmune disease; with history of lower extremity deep vein thrombosis without pulmonary embolism 12 months ago, which was treated with low-molecular-weight-heparin transitioned to warfarin. For scenarios with concomitant VTE risk factors, i.e., high-risk profile or no high-risk profile, the risk factor is no more present.

AT Scenario: 55-year-old male; with no other systemic autoimmune disease; with history of acute ischemic stroke 12 months ago, treated with low-dose aspirin followed by warfarin; with no evidence of atherosclerosis or cardiac embolic source. For scenarios with concomitant cardiovascular disease risk factors, i.e., high-risk profile or no high-risk profile, the risk factor is well-controlled.

aPL Profile (Units)	% of Respondents who Would Stop Anticoagulation For VTE Scenarios Median (range)*	% of Respondents who Would Stop Anticoagulation For AT Scenarios Median (range)*
Triple aPL-positive		
-IgG (+/- IgM) 40-79 or ≥80	10 (3-13)	5 (3-13)
-IgM Only 40-79 or ≥80	13 (6-29)	5 (3-17)
Double aPL-positive		
-LA + aCL or aβ$_2$GPI IgG (+/- IgM) 40-79 or ≥80	10 (3-17)	7 (4-14)
-LA + aCL or aβ$_2$GPI IgM Only 40-79 or ≥80	16 (7-31)	9 (4-21)
-aCL and aβ$_2$GPI IgG (+/- IgM) 40-79 or ≥80	23 (10-42)	12 (7-25)
-aCL and aβ$_2$GPI IgM Only 40-79 or ≥ 80	42 (20-58)	24 (10-46)
Single aPL-positive		
-LA	18 (13-27)	15 (3-20)
-aCL IgG (+/- IgM) 40-79 or ≥80	30 (17-45)	20 (13-37)
-aCL IgM Only 40-79 or ≥80	43 (33-63)	27 (20-63)
-aβ$_2$GPI IgG (+/- IgM) 40-79 or ≥80	30 (13-43)	18 (10-33)
-aβ$_2$GPI IgM Only 40-79 or ≥80	41 (28-69)	30 (20-63)

*The number of respondents for each scenario ranged from 26 to 31; the median and range of responses were calculated based on different VTE/AT risk profiles and/or aCL/aβ$_2$GPI levels, in accordance with 2023 ACR/EULAR APS Classification Criteria. **LA:** lupus anticoagulant; **aCL / aβ$_2$GPI**: anticardiolipin antibodies / anti-β$_2$-glycoprotein-I antibodies

factors. The objective of this survey was to evaluate clinical decision-making practices among APS ACTION members regarding the duration of anticoagulation for secondary thrombosis prevention in APS, using standardized clinical scenarios.

Methods: A cross-sectional electronic survey was distributed to APS ACTION members in April 2025. Participants were asked to assess whether they would discontinue long-term anticoagulation in patients with different scenarios designed, based on the clinical and laboratory domains of the 2023 ACR/EULAR APS Classification Criteria. Each scenario was stratified by aPL profile (triple, double, or single-positive), aCL/aβ$_2$GPI isotype (IgG +/-IgM, or IgM only), and aCL/aβ$_2$GPI level (40–79U or ≥80U), as well as by venous thromboembolism (VTE) and arterial thrombosis (AT) risk profiles (Table 1). Descriptive statistics summarize the proportion of clinicians favoring discontinuation across scenarios.

Results: Fifty-nine APS ACTION members involved in patient care received the survey, and 31 (53%) (mean years in practice 25 ± 12, rheumatologists: 21 [68%], hematologists: 3 [10%],and other: 7 [22%]) responded. When stratified by aPL profile, anticoagulation discontinuation rates were the lowest in triple aPL-positive patients, with only 10–16% willing to stop in different VTE and 7% in AT scenarios. In double aPL-positive patients, discontinuation rates were lower for lupus anticoagulant (LA)-positivity, and higher when LA was negative, particularly for IgM-only profiles (10-42% would stop anticoagulation for different VTE and 7-28% for AT profiles). Single aPL-positive patients demonstrated the highest likelihood of discontinuation (lowest for LA-positive patients); depending on the aPL and thrombosis risk profiles, rates of discontinuation of anticoagulation were 13-69% for VTE and 3-63% for AT (Table 1).

Conclusion: Among APS ACTION members, anticoagulation discontinuation decisions in thrombotic APS vary significantly depending on the aPL profile, thrombosis type, and concomitant thrombosis risk factors at the time of the event. Clinicians were more likely to stop anticoagulation in VTE than AT scenarios, in patients with IgM-only profiles, and in the absence of a positive LA test. These findings highlight areas of variability in clinical practice and underscore the need for risk-stratified controlled studies to inform anticoagulation duration in diverse APS phenotypes.

Session Title: (0145–0174) Epidemiology & Public Health Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Cancer is highly prevalent and a leading cause of death for patients with Idiopathic Inflammatory Myopathies (IIM). Evaluating cancer type and stage at diagnosis for patients with IIM is paramount to identify and target critical factors to decrease cancer morbidity. Prior work in the US has focused on assessment of cancer risk by comparing

Table 1: Demographics of patients with IIM ICD code(s) who had cancer by NCCR (n=876)

Description	Number	%
Sex		
Male	361	41.2
Female	515	58.8

subgroups within IIM, from clinical settings. This study seeks to use a statewide population-based approach to assess cancer incidence and stage at diagnosis in patients with IIM compared to the general population.

Methods: The Cancer Information and Population Health Resource (CIPHR) is a linked dataset of the North Carolina Central Cancer Registry (NCCR) and insurance claims that cover approximately 55% of the total population of NC from Medicaid, Medicare fee for service, Medicare advantage and private insurance plans (2003-2020). Patients with IIM were selected from administrative datasets utilizing prior validated methodologies (i.e., 1 ICD-9 [710.3-4] or -10 [M36.0, M33.0-2,9, M60.8, M60.9 if associated with J99.1, J84.9 or J84.1] associated with a hospitalization or two codes [ICD-9 (710.3-4) or -10 (M33.0-2,9, G72.4]) which are between 30 days to 365 days. Once identified in claims the IIM cohort was linked to the NCCR. This abstract is focused on description of the linked cohort.

Results: A total of 6531 patients with IIM were identified from claims, of whom 876 developed an initial cancer with a mean age of 64 years. Most patients had a first and only tumor (69%) and almost half developed cancer after the first IIM ICD code date (43%). Of patients with IIM who developed cancer, the majority were female (59%), non-Hispanic white (70%), and had an urban residence (67%). A quarter (26%) of patients with IIM had a Surveillance, Epidemiology and End Result (SEER) stage of distant, although the most frequent stage was localized (40%, Table 1). The most common type of cancer for

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

women was breast cancer (19%) followed by lung (13%) then colorectal. The most frequent cancer for men was prostate (28%), then lung (12%) followed by melanoma (8%, Table 2).

Conclusion: A NC population-based assessment of cancer development in patients with IIM (a rare disease), is feasible and will enable the calculation of standardized incidence ratios which will identify those cancer types that are more likely to occur in patients with IIM, enabling future efforts for targeted screening.

Abstract Number: 0146

Association Between Frailty and Delirium and Hospitalization Outcomes Among Older Adults with Rheumatic Diseases

Bhavik Bansal[1], Yehseo Jung[2], Abdulla Damluji[3], Parag Goyal[4] and Namrata Singh[5], [1]UT Southwestern Medical Centre, Dallas, TX, [2]University of Washington, Seattle, WA, [3]Johns Hopkins, Baltimore, [4]Weill Cornell, New York, [5]University of Washington, Bellevue, WA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0145–0174) Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: We investigated the association of frailty and delirium, both independently and in combination, with in-hospital mortality and non-routine discharge (i.e. when a patient is discharged to a destination other than their home, such as transfers to rehabilitation centers, or nursing homes) among hospitalized older adults with rheumatic diseases.

Methods: We performed a retrospective study using data from the Nationwide Inpatient Sample (NIS), spanning 2016 to 2022. Adults aged 65 and older with a primary diagnosis of select rheumatic diseases (rheumatoid arthritis. systemic lupus, polymyalgia rheumatica, psoriatic arthritis, giant cell arteritis, spondyloarthropathy) were identified using ICD-10 codes. Frailty and delirium were ascertained using the Hospital Frailty Risk Score (HFRS) (categorized into three levels: low (< 5), moderate (5–15), and high (>15) frailty risk) and ICD-10 diagnostic codes, respectively. Multivariable logistic regression was used to assess the association of delirium and frailty both individually and combined with co-primary outcomes: in-hospital mortality and non-routine discharge. Each model was adjusted for demographic characteristics (age, sex, race and insurance status) and comorbidities. In a subgroup analysis, we evaluated these associations among patients with RA.

Results: Among 938,595 weighted hospitalizations of older adults with rheumatic diseases, 2.6% were classified as highly frail and 3.5% experienced delirium (**Table 1**). The mean age was 76.0 years, and 74.6% were female. Patients with RA comprised 70% of the cohort (**Table 2**). Both delirium and high frailty independently increased the odds of in-hospital mortality: delirium was associated with an OR of 4.99 (95% CI: 4.16–5.99) and high frailty with an OR of 6.80 (95% CI: 5.45–8.48). The combined presence of delirium and high frailty conferred the highest risk of mortality (OR: 16.2, 95% CI: 11.5–22.9). A similar pattern was observed for non-routine discharge, with elevated odds for delirium alone (OR: 3.14, 95% CI: 2.95–3.35), high frailty alone (OR: 5.69, 95% CI: 5.26–6.16), and both together (OR: 11.1, 95% CI: 8.78–14.0) (**Figure 1**). These associations remained significant across subgroup analyses.

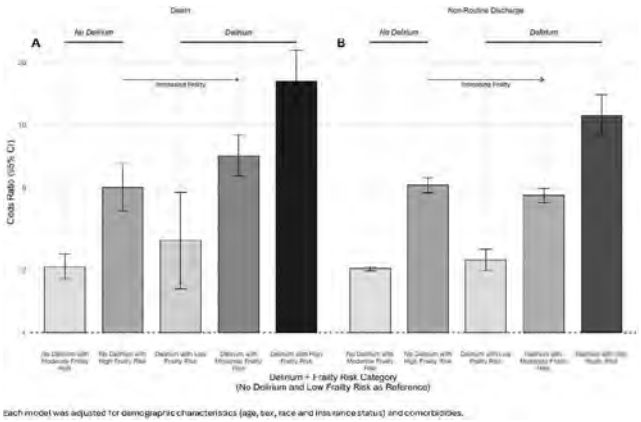

Figure 1. Multivariable analyses evaluating the association between frailty and delirium on a) in-hospital mortality and b) non-routine discharge among hospitalized older adults with rheumatic diseases.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Among hospitalized older adults with rheumatic diseases, both frailty and delirium were independently linked to poorer outcomes, including higher in-hospital mortality and increased likelihood of discharge to a non-home setting. Notably, patients with both conditions faced the greatest risk. These findings underscore the potential value of proactively identifying frailty and delirium during hospitalization, as doing so could help clinicians better support safe transitions out of the hospital.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0145–0174) Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: A total of 98.8% of French citizens are registered in the National Health Data System (SNDS), which includes claims data of all reimbursed health-related expenditures such as medication, professional healthcare services, and eligibility for full reimbursement of care related to chronic diseases (named Long-Term Disease (LTD) status).

The identification of rheumatoid arthritis (RA) patients in the SNDS is generally based on the presence of at least one RA-related ICD-10 code (International Classification of Diseases, 10th Revision) recorded during hospitalization and/or as part of an LTD status. Based on these criteria, annual mapping by the French health insurance system estimated an RA prevalence of 0.47% in the adult population in 2022. (1)

However, inclusion based on a single RA code may lack specificity, potentially leading to an overestimation of RA prevalence. Conversely, RA patients who are neither hospitalized nor covered by LTD status may not be identifiable using these criteria.

The PREST study aims to refine algorithms for improving the estimation of RA prevalence in France. Additionally, it seeks to analyze care pathways of identified patients and explore factors associated with disease management.

Methods: Data were extracted from the SNDS covering the period 2010–2022, using the following criteria: hospitalization records and/or LTD status with ICD-10 codes M05 or M06, and/or the dispensing of csDMARDs (conventional synthetic Disease-Modifying Antirheumatic Drugs) or b/tsDMARDs (biologic/targeted synthetic DMARDs).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Different RA identification algorithms were applied including additional criteria based on disease-management pathways.

Various combinations of these criteria were applied to define multiple subgroups. Corresponding RA prevalences were estimated for 2019.

Results: The data extraction identified 914,278 adult patients alive on January 1, 2019, who met at least one of the following criteria: RA LTD status (N=281,441), hospitalization with RA ICD-10 code (N=205,232), or treatment for RA without differential diagnosis (N=390,564). Patients without RA coding but with a differential diagnosis were excluded.

Among them, 355,350 met the standard definition corresponding to a prevalence of 0.70%. The new algorithms yielded highly variable prevalence estimates depending on the criteria.

The most stringent combination (patients with M05 or M06 codes receiving RA treatment) identified 249,240 cases (0.49%). Broadening the criteria to include untreated patients with at least two RA ICD-10 codes identified 275,694 patients (0.54%). Including previously excluded patients who had diagnostic procedures associated with an RA code or treatment further increased the number of identified patients to 392,974 (0.77%).

Conclusion: Depending on the identification criteria, RA prevalence in the French adult population in 2019 ranges from 0.49% to 0.82%, with the true prevalence most likely falling within this range. A previous study, EPIRHUM, conducted a general population survey in 2000 and reported an underestimated prevalence of 0.31% (2).

The significant variation in prevalence based on the identification criteria highlights the complexity of identifying RA in the SNDS.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0145–0174) Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) and spondyloarthritis (SpA), are chronic inflammatory rheumatic diseases. Despite significant advancements in their management through novel therapies, some patients continue to experience flares or therapeutic resistance. Environmental factors, particularly smoking and air pollution, are known contributors to disease activity and progression. However, the role of air pollutants in exacerbating these diseases remains debated, especially in SpA.

Methods: This prospective study included 94 patients with stable RA (DAS28 < 3.2) or SpA (BASDAI < 4) recruited between January and May 2023. All patients were on stable biological therapies. Air pollutant levels (PM2.5, PM10, NO2, and O3) were obtained from AtmoSud, a regional air quality monitoring body. Exposure was calculated based on the patient's residential location over a 6-month period, with a focus on the 2 months preceding the first flare for patients experiencing disease exacerbations. Statistical analyses, including logistic regression and ROC curve analysis, were used to explore the relationship between pollutant levels and disease flares.

Results: : Sixty-one patients (65%) experienced at least one flare during the study period. Patients with flares had significantly higher exposure to PM10 (29 μg/m3 vs. 18.4 μg/m3, p=0.0003) and PM2.5 (11.7 μg/m3 vs. 8.5 μg/m3, p=0.0004). Conversely, lower exposure to ozone (O3) was associated with flares (71.9 μg/m3 vs. 104.6 μg/m3, p=0.0004). No significant differences were found for NO2 exposure. The multivariate analysis confirmed these associations, and ROC curves identified flare thresholds of 20.6 μg/m3 for PM10 and 9.5 μg/m3 for PM2.5.

Conclusion: Our findings highlight the role of air pollution, particularly particulate matter (PM2.5 and PM10), in triggering disease flares in patients with RA and SpA. These results support the need for stricter air quality standards to mitigate the impact of environmental factors on inflammatory rheumatic diseases.

Abstract Number: 0149

Effect Of Osteoporosis And Opioid Use On Mortality And Unplanned Healthcare Utilization Among Patients With Rheumatoid Arthritis

Viengneesee Thao, Molly Moore Jeffery, Nafisseh Warner and **Elena myasoedova**, Mayo Clinic, Rochester, MN

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0145–0174) Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with rheumatoid arthritis (**RA**) have a 2-fold increase in risk for osteoporosis compared to the general population. About 30-50% of RA patients experience fragility fractures, while pain management frequently includes prescription opioids, despite a paucity of long-term data on safety and efficacy. The impact of osteoporosis and

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

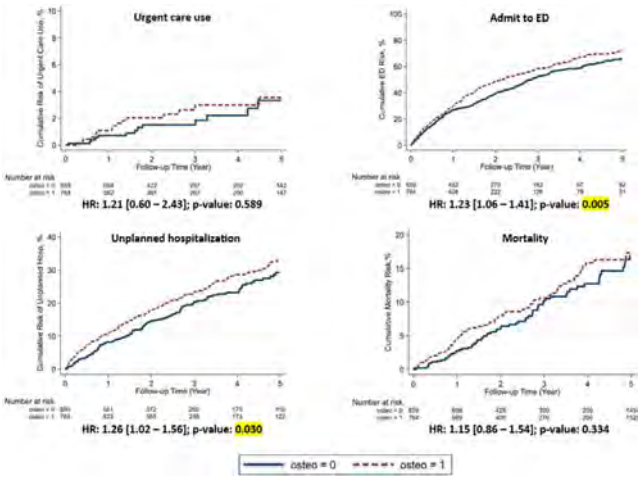

Figure 1: Cumulative risk of mortality and unplanned healthcare utilization among individuals with RA, 1:1 matched osteoporosis vs. no osteoporosis

opioid use on healthcare utilization and mortality in persons with RA is not well defined. We aimed to 1) compare mortality and unplanned healthcare use in those with RA with vs. without osteoporosis, and 2) compare 30-day mortality and unplanned healthcare use in those with RA and osteoporosis with vs. without opioid use.

Methods: This is a retrospective cohort analysis using the OptumLabs Data Warehouse, a large administrative claims database containing de-identified health information. We included commercially insured and Medicare Advantage beneficiaries, ≥50 years old, with RA. The outcomes included mortality and unplanned healthcare use, i.e. ED use, unplanned hospitalization, and urgent care. We identified persons with a diagnosis of RA between 1/1/2005-12/31/2023. For aim 1, we categorized those with RA by osteoporosis diagnosis status (1 inpatient or 2 outpatient claims with a diagnosis of osteoporosis, or at least 1 medication fill for an antiosteoporotic medication). For aim 2, we included everyone with a diagnosis of RA and osteoporosis, and categorized individuals by whether or not they had at least one opioid fill.

We 1:1 propensity score (PS) matched individuals based on the following variables: age, sex, race/ethnicity, geographic location, insurance type, comorbid conditions of interest, including the Elixhauser comorbid index, and use of glucocorticoids. After matching, a standardized mean difference < 0.10 was deemed acceptable. Cox proportional hazards regression was used to compare individuals with osteoporosis and without, in terms of mortality and unplanned healthcare use. Logistic regression was used to compare individuals with an opioid fill to those without a fill, in terms of 30-day mortality and unplanned healthcare use. As a sensitivity check we repeated our analysis using inverse probability of treatment weighting (IPTW) instead of propensity score matching.

Results: Among individuals with RA (862 matched pairs), those with osteoporosis had higher ED use [hazard ratio (HR): 1.23, 95% confidence interval (CI): 1.06 – 1.41; p-value = 0.005] and unplanned hospitalizations [HR: 1.26, 95% CI: 1.02 – 1.56; p-value = 0.03] compared to those without osteoporosis (Figure 1). The IPTW model showed similar results. Among individuals with RA and osteoporosis; the PS matched model did not yield any differences in mortality or healthcare utilization; however, the IPTW model (644 with an opioid fill vs. 189 without a fill) showed that those with an opioid fill had higher 30-day ED use [HR: 5.82, 95% CI: 1.77 – 19.19; p-value = 0.004] compared to those without a fill.

Conclusion: The presence of osteoporosis in RA and opioid use in patients with osteoporosis and RA pose a significant risk for unplanned healthcare utilization. Effective prevention and management of osteoporosis in RA, as well as judicious use of opioids can help prevent these unfavorable outcomes.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0145–0174) Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV), include Granulomatosis with Polyangiitis (GPA), Microscopic Polyangiitis (MPA), and Eosinophilic Granulomatosis with Polyangiitis (EGPA).

Mortality rates are scare, Sims et al observed a morality rate of 38.4/1000 person-years (PY) between 2002-2017 (during 3385 PY of follow-up). Moreover, this depends on the AVV subtype, severity of the cohorts studied and their different classification criteria.

Our aim is to determine the mortality rate and the main causes of death in patients with GPA, MPA, and EGPA in a region of northern Spain.

Methods: Observational study of AAV from January 1, 2000, to December 31, 2024, in a northern Spanish. Classification of AAV was based on the 2022 ACR/EULAR criteria. Mortality rates were expressed as cases by 10^6 habitants/year (95% IC) and the Case Fatality rate expressed as percentage (95% IC) of deceased patients. Rates of mortality are expressed as the exposure-adjusted incidence rate (EAIR) per 100 person-years (PY). We defined two patient groups: **1) Study group** (deceased patients) and **2) Control group** (surviving patients) to compare the main clinical characteristics between these two groups. In addition, we evaluated the principal causes of death among the different types of ANCA-associated vasculitis.

	MPA	GPA	EGPA
MORTALITY RATE cases/10^6 inhabitants/ year (95% CI)	2.8 (1.7-4)	1.8 (0.9-42.7)	0.1 (-0.1-0.2)
CASE-FATALITY RATE (%), 95% CI	38.8% (20.1-57.5)	31.9% (14-49.9)	1% (-1-3)
EAIR cases/100 PY	7.9	3.86	0.6

TABLE. Comparison of Mortality and Case-Fatality Rates by ANCA Vasculitis Subtypes.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

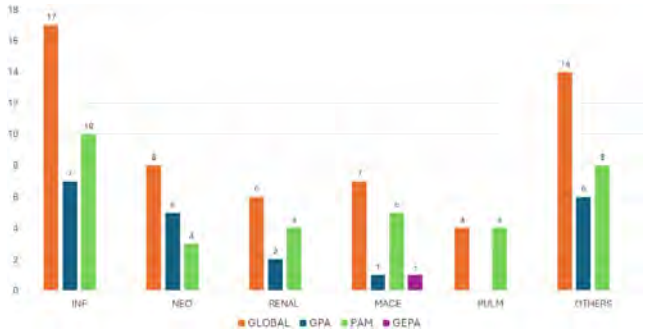

FIGURE. Main causes of death by ANCA Vasculitis Subtypes.

Results: We included 194 patients (99 men/95 women); mean age, 63.7±14.6 years, distributed as follows: GPA (n=67; 34.5%), MPA (n=69; 35.6%), and EGPA (n=28; 14.4%). Death was observed in 56 patients (28.9%); MPA (n=34; 60.7%), GPA (21; 37.5%), and EGPA (1; 3.5%).

After a mean of 6±5.4 years of follow up; in AAV group the overall mortality rate was 5.5 per 10^6 inhabitants/year (95% CI: 3.8-7.1); EAIR of 4.6/100 PY and the overall case-fatality rate was 32.5% (95% CI: 21.9-43.1).

Among the AAV subtypes, MPA showed the highest mortality and case-fatality rates with 2.8/10^6 inhabitants/year (95% CI: 1.7-4); EAIR: 7.9/100 PY and 38.8% (95% CI: 20.1-57.5), respectively. GPA followed with a mortality rate of 1.8/10^6 inhabitants/year (95% CI: 0.9-42.7); EAIR: 3.86/100 PY and a case-fatality rate of 31.9% (95% CI: 14-49.9). EGPA had low rates: a mortality rate of 0.1/10^6 habitants/year (95% CI: –0.1-0.2); EAIR: 0.6/100 PY and a case-fatality rate of 1% (95% CI: –1-3) **(Table)**.

The main causes of death were infections (n=17; 30%), neoplasia (n=8; 14%), major adverse cardiac events (MACE); (n=7; 13%), renal complications (n=6; 11%), and non-infectious pulmonary complications (n= 4; 7%). Infections were the most frequent cause of death in both GPA and MPA. In EGPA, the only cause of death was MACE.

Statistically significant differences were observed between the study group (deceased patients) and the control group (survivors), particularly regarding clinical manifestations associated with a higher risk of mortality, such as pulmonary and renal involvement.

Conclusion: Mortality rates and case-fatality rates in patients with AAV remain relatively high. mortality rate was higher in MPA and lower in EGPA. The most common causes of death were infections (30%), neoplasia (14%), and MACE (13%). Life-threatening organ involvement, such as pulmonary or renal disease, increases mortality risks.

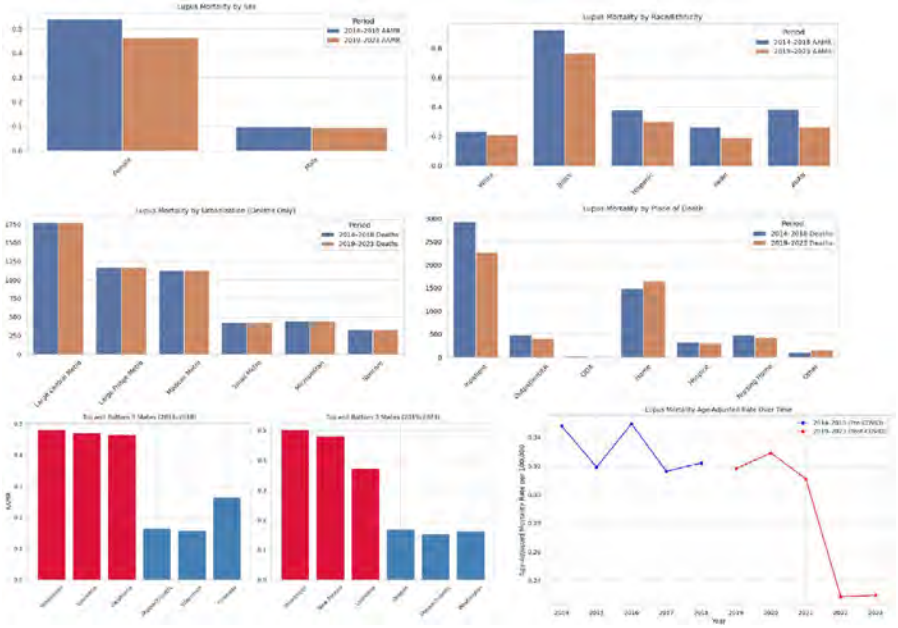
Session Title: (0145–0174) Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic multisystem autoimmune disease with high morbidity and mortality. The impact of the COVID-19 pandemic on SLE-related deaths in the United States has not been comprehensively evaluated.

Methods: : We analyzed national mortality data from the CDC WONDER database for all deaths attributed to SLE (ICD-10 code M32) from 2014 to 2023. Data were stratified by sex, race/ethnicity, age group, state, urbanization level, and place of death. We defined two periods for analysis: pre-COVID (2014–2018) and post-COVID (2019–2023), and compared age-adjusted mortality rates (AAMRs) between periods.

Results: A total of 11,150 SLE-related deaths occurred, with 5,889 pre-COVID and 5,261 post-COVID. The national AAMR declined from 0.3496 to 0.2828 per 100,000, a 19.1% reduction. Women comprised over 85% of deaths, with AAMRs decreasing from 0.5399 to 0.4629. Male AAMRs remained lower (0.0981 to 0.0936). By race, Black individuals consistently had the highest AAMRs (0.9245 to 0.7649), followed by Hispanic (0.3820 to 0.3019), American Indian/Alaska Native (0.3846 to 0.2638), Asian (0.2632 to 0.1906), and White individuals (0.2323 to 0.2103). Mortality rates increased with age,



Graphs showing differences in pre vs post COVID state, urbanization, gender, race and place of death Lupus Mortality

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. peaking at 1.10 per 100,000 among those ≥85. Home deaths increased from 25.2% to 31.3%, while inpatient deaths declined from 49.9% to 43.3%. The highest AAMRs were observed in Mississippi and Louisiana; the lowest were in Washington and Massachusetts.

Conclusion: SLE mortality declined in the post-COVID era, with persistent disparities by sex and race. The shift in place of death suggests changes in healthcare access and utilization. These findings underscore the need for targeted, equitable strategies to improve lupus outcomes across populations.

Abstract Number: 0152

Exploring internet use and health information behaviour in patients with inflammatory rheumatic musculoskeletal diseases (RMD)

Ioana Andreica[1], Sulafa Chikh Mohamad[2], Dieter Wiek[3], Birgit Barten[3], Iulia Roman[4], Anja Kremser[5], David Kiefer[6], Philipp Sewerin[1], Uta Kiltz[7] and Xenofon Baraliakos[7], [1]Rheumazentrum Ruhrgebiet Herne; Ruhr-Universität Bochum, Germany, Herne, Germany, [2]Rheumazentrum Ruhrgebiet, Ruhr-Universität Bochum, Herne, Germany, [3]Deutsche Rheuma Liga, Germany, Bonn, [4]Rheumazentrum Ruhrgebiet, Ruhr-Universitét Bochum, Herne, Germany, [5]Rheumazentrum Ruhrgebiet, Herne, Germany, [6]Ruhr-Universitét Bochum; Private practice of rheumatology, Hattingen, Germany, Herne, Germany, [7]Rheumazentrum Ruhrgebiet Herne, Ruhr-University Bochum, Herne, Germany

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0145–0174) Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Digital health literacy has recently become a focus of patient-centred recommendations, not only as a key social determinant of health, but also as a tool for evaluating the successful implementation and accessibility of eHealth interventions (1). In line with the overarching goal of empowering patients in their disease management, telemedicine and digital health tools are gaining ground (2). However, there is a gap in understanding the accessibility, usability and comprehensibility of available digital resources and the actual level of digital health literacy among patients with RMD. This study aims to assess the ability of patients with RMD to search for and select relevant disease-related information for self-management.

Methods: In this cross-sectional study, patients diagnosed with rheumatoid arthritis (RA), psoriatic arthritis (PsA) or axial spondyloarthritis (SpA) were consecutively recruited from a tertiary centre. Patients completed a structured questionnaire covering internet access, search strategies, understanding and use of online disease-related information. Patients were

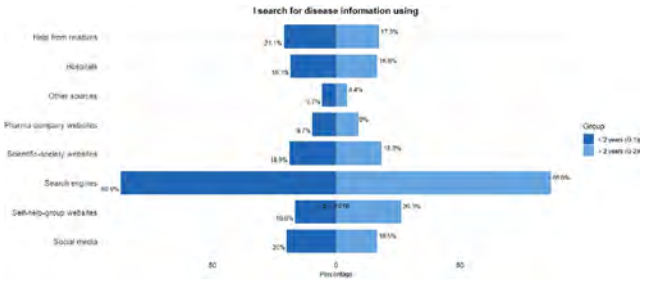

Figure 1.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

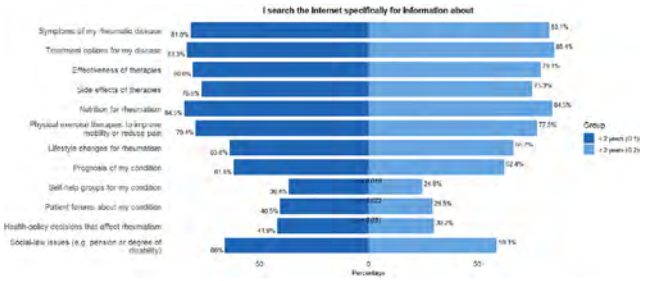

Figure 2.

categorised according to disease duration: early disease (< 2 years; Group 1, G 1) and long-standing disease (> 2 years from diagnosis; Group 2, G 2). Descriptive statistics and chi-squared tests were used for group comparisons. The study was conducted in collaboration with the patient's research partners from the German Rheumatology Patient Association (Deutsche Rheumaliga).

Results: A total of 705 patients were recruited (53.8% RA, 25.5% axSpA and 20.7% PsA) with a mean disease duration of 9.7 ± 10.5 years and a mean age of 53.7 years. The majority were female (62.7%).

Out of 705 patients, 552 (78.3%) indicated that they had searched for disease-related information on the internet. Most patients reported mainly using their smartphones (80.3%), with higher use of smartphones among patients with early vs. long-standing disease duration (86.5% vs 77.4%, respectively, $p < 0.05$). The predominance of information sources accessed is shown in Figure 1. Patients with early disease (G1) consulted the internet more frequently, with 19.3% searching several times a week, compared to 8.2% of patients with a long-standing disease (G 2). The majority found online content understandable (79.8%) and would seek clarification from their rheumatologist if in doubt (83.7%). Two-thirds (68.2%) reported using the information in their daily lives, with no significant difference between groups. Notably, patients in G 1 were more likely to investigate community, social and regulatory issues ($p< 0.05$), with 36.4% (G1) vs 24.8% (G2) looking for self-help groups, 40.5% (G1) vs 29.5% (G2) for patient forums and 41.9 % (G1) vs 30.2 % (G2) for health policy decisions, Figure 2.

Conclusion: Searching for health information online is common among patients with RMD and is used as a supplement to regular outpatient consultations. The vast majority of recruited patients, especially those in the early stages of their disease, actively seek online information and feel competent to use it. High smartphone usage highlights the need for mobile-optimised, evidence-based resources

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0145–0174) Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Patient-Reported Outcome Measures (PROMs) are integral to shared decision-making and quality improvement in rheumatology. They are recommended for monitoring treatment response, assessing quality of life, and supporting clinical care. Scientific societies as EULAR have promoted standardized of PROM collection through data set recommendations and an Outcome Measures Library with instruments and validation data https://oml.eular.org/. This study aimed to: (1) develop and implement an electronic PROM (ePROM) system within BIOBADASER, a multicenter registry of advanced therapies; (2) analyze initial results post-implementation; and (3) evaluate usability and patient satisfaction.

Methods: A core set of validated and feasible PROMs was selected based on the International Consortium for Health Outcomes Measurement (ICHOM) recommendations and expert consensus. These were incorporated into a web-based application designed for patient self-completion via internet-enabled devices (smartphone, tablet, computer). Patients initiating advanced therapies were invited to participate. A pilot phase involving six centres was conducted from December 2023 to June 2024, followed by full-scale implementation across all centres. Descriptive statistics summarized demographic, clinical, and PROM data.

Results: From December 2023 to November 2024, 136 patients were invited to participate; 95 (70%) accessed the system, and 81 (60%) completed the questionnaires. Participants were predominantly female (64.2%) with a mean age of 50.9 years. The most common diagnoses were rheumatoid arthritis (35.8%), spondyloarthritis (19.8%), and psoriatic arthritis (17.3%). TNF inhibitors were the most frequently initiated therapy (72.8%). RAPID3 scores indicated high disease activity (mean 13.3 ± 6.8). Most patients reported minimal problems with mobility (69.1%), self-care (82.7%), usual activities (59.2%), and anxiety/depression (67.9%). The mean global health score was 55.6. Regarding usability, 81% experienced no or slight difficulty using the system, 79% found the instructions clear or very clear, and 80.2% were quite or very satisfied. A majority (66.7%) preferred online reporting over paper-based methods, and 87.6% felt comfortable using digital devices.

Table 1. Demographic and clinical characteristics of patients using the ePROMs system

		Total
Number of patients, n		81
Female (%)		52 (64.2)
Age, mean (SD)		50.9 (10.2)
Diagnoses, n (%)		
Rheumatoid arthritis		29 (35.8)
Spondyloarthritis		29 (19.8)
Psoriatic arthritis		14 (17.3)
Other		32 (27.1)
Comorbidities		
Smoking habit, n (%)		
Never smoker		47 (58.0)
Current smoker		20 (24.7)
Former smoker		11 (13.6)
Body mass index, n (%)		
Underweight		6 (7.4)
Normal weight		28 (34.6)
Overweight		25 (30.9)
Obesity		14 (17.3)
Unknown		8 (9.9)
Hypercholesterolemia, n (%)		14 (17.3)
Hypertension, n (%)		15 (18.5)
Charlson comorbidity index, n (%)		
0		46 (56.8)
1		27 (33.3)
2		8 (9.9)
Initiated b/tsDMARD treatments, n (%)		
Anti TNFs		59 (72.8)
JAK inhibitors		9 (11.1)
Anti IL17A		7 (8.6)
Anti 12/23		2 (2.5)
Inhib Blys		1 (1.2)
CTLA4-Ig		3 (3.7)
PROMs		
Pain VAS (0-10), mean (SD)		5.6 (2.9)
Fatigue VAS (0-10), mean (SD)		4.9 (3.4)
Patient Global Assessment VAS (0-10), mean (SD)		4.9 (2.9)
MDHAQ (0-3), mean (SD)		2.7 (1.8)
RAPID3, mean (SD)		13.3 (6.8)
Tender joint count, mean (SD)		7.8 (7.9)
Quality of life (EQ5D-5L), n (%)		
Mobility	I have no problems in walking about	27 (33.3)
	I have slight problems in walking about	29 (35.8)
Self-care	I have no problems washing or dressing myself	41 (50.6)
	I have slight problems washing or dressing myself	26 (32.1)
Usual activities (work, study,	I have no problems doing my usual activities	15 (18.5)
housework, family or leisure)	I have slight problems doing my usual activities	33 (40.7)
Pain / discomfort	I have no pain/slight or discomfort	37 (44.9)
	I have moderate pain or discomfort	18 (22.2)
	I have severe/extreme pain or discomfort	22 (26.1)

Table 2. Patient experience with the electronic PROMs system and level of satisfaction

Usability and level of satisfaction		
Do you think PROMs help improve your care?	Somewhat	19 (23.5)
	Quite	27 (33.3)
	Very much	13 (16.1)
Number of questions	Appropriate	31 (38.3)
	Many questions but manageable	42 (51.9)
	Too many questions	2 (2.5)
Difficulty to complete	No difficulty	54 (66.7)
	Sligh difficulty	12 (14.8)
	Too difficult	2 (2.5)
Clarity of questions	Slightly	6 (7.4)
	Quite	43 (53.1)
	Very much	21 (25.9)
Level of satisfaction with questionnaires	Quite satisfied	50 (61.7)
	Very satisfied	15 (18.5)
Online reporting system better or worse	Same	10 (12.4)
than paper reporting	Somewhat better	9 (11.1)
	Better	54 (66.7)
Level of comfort using technology and	Quite comfortable	35 (43.2)
electronic devices	Very comfortable	36 (44.4)
Do you feel it is adequate to complete the PROMs every 3 months?	Yes	63 (77.8)

Conclusion: The ePROM system was feasible, well accepted, and effective for remote disease monitoring. Patients expressed high satisfaction and a preference for digital tools, supporting the integration of ePROMs into rheumatology registries to enhance personalized, patient-centred care.

Abstract Number: 0154

Incidence and Prevalence of Connective Tissue Diseases with Interstitial Lung Disease (CTD-ILD) in the United States

Diana Martins[1], George Mu[2], Elaine Irving[3], Roger A. Levy[4], Nisha Bhatt[5] and **Keele E. Wurst**[6], [1]GSK, Epidemiology, Toronto, ON, Canada, [2]GSK, Statistics, Collegeville, PA, [3]GSK, Clinical, Stevenage, United Kingdom, [4]GSK, Specialty Care, Global Medical Affairs, Collegeville, PA, [5]GSK, Global Medical Affairs, Collegeville, PA, [6]GSK, Immunology and Emerging Epidemiology, Durham, NC

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0145–0174) Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Despite the high disease burden and reduced quality of life for patients with CTD-ILD, data on its incidence and prevalence – particularly by CTD subtype (RA, SSc, SLE, IIM, MCTD and pSS) – remains limited. This study describes the incidence and prevalence of CTD-ILD and its subtypes in the US.

Methods: This retrospective cohort study (GSK Studies 223907, 224023) of two large US databases (Optum® de-identified Electronic Health Record data set [Optum® EHR], and MarketScan® Commercial and Medicare Databases [MarketScan]) identified adults with CTD-ILD subgroups of interest between January 2018 and December 2023, using ICD-10 diagnosis codes and algorithms, in a two-step process: 1) identifying individuals with CTD, and 2) identifying ILD on or within 365 days before or after the CTD diagnosis. Index date: the later date of the first CTD or ILD diagnosis. Identified CTD-ILD cases were classified as prevalent. Of those, incident cases required a 1-year enrolment prior to index with no ILD claims during this "washout" period. Incidence was presented per 100,000 person-years (PY) and prevalence per 100,000 persons (comprising crude rates, including stratification by age and sex, and age- and sex-adjusted rates).

Table 1. Crude and adjusted incidence (per 100,000 person-years) of CTD-ILD – overall and in CTD-ILD subgroups of interest – in US Optum® EHR and MarketScan databases. *Overall captures any CTD-ILD (no duplicates), using ICD-10 diagnosis codes. Patients may be captured in more than 1 CTD subtype but will contribute only once to the CTD-ILD overall column. CI, confidence interval; CTD, connective tissue diseases; EHR, electronic health record; ICD-10, International Classification of Diseases 10th Revision; IIM, idiopathic inflammatory myositis; ILD, interstitial lung disease; MCTD, mixed connective tissue disease; pSS, primary Sjögren's syndrome; RA, rheumatoid arthritis; SLE, systemic lupus erythematosus; SSc, systemic sclerosis.

Male	12.4 (11.9, 12.9)	7.3 (6.9, 7.7)	1.9 (1.7, 2.1)	1.3 (1.1, 1.5)	2.5 (2.3, 2.8)	0.7 (0.6, 0.9)	1.2 (1.0, 1.4)
Age 18–64	20.7 (19.8, 20.7)	10.0 (9.7, 10.4)	4.6 (4.4, 4.8)	4.6 (4.3, 4.8)	3.6 (3.4, 3.8)	2.2 (2.0, 2.3)	3.3 (3.1, 3.5)
Age 65+	134.8 (128.9, 140.7)	89.4 (84.6, 94.2)	17.9 (15.7, 20.0)	15.2 (13.2, 17.2)	10.0 (8.4, 11.6)	5.6 (4.4, 6.9)	20.8 (18.5, 23.1)
Age- and sex-adjusted prevalence (95% CI)	44.5 (43.8, 45.6)	27.0 (26.1, 27.8)	7.3 (6.9, 7.8)	6.7 (6.3, 7.1)	5.0 (4.6, 5.3)	2.9 (2.6, 3.1)	6.9 (6.5, 7.4)

Results: Among all patients with CTD-ILD identified (N=20,276 Optum® EHR and N=9342 MarketScan), most were female (Optum® EHR: 74.1%; MarketScan: 76.0%), with median (interquartile range) age of 65 (56, 73) years (Optum® EHR) and 56 (49, 63) (MarketScan), and had RA-ILD (Optum® EHR: 57.4%, MarketScan: 53.2%). In Optum® EHR, race of patients was 73.2% Caucasian, 16.8% Black, 2.6% Asian, and 7.4% had missing race. Race of patients was not captured in MarketScan.

Age- and sex-adjusted rates for CTD-ILD overall were 9.4 (Optum® EHR) and 10.7 (MarketScan) per 100,000 PY for incidence (**Table 1**), and 45.1 (Optum® EHR) and 44.5 (MarketScan) per 100,000 persons for prevalence (**Table 2**). Age- and sex- adjusted incidence varied by CTD subtype in Optum® EHR (0.7 [MCTD-ILD] to 5.6 [RA-ILD]) and MarketScan (0.7 [MCTD-ILD] to 6.6 [RA-ILD]) (**Table 1**). This variation also existed for adjusted prevalence rates (**Table 2**). Crude stratified rates were approximately double in females versus males, and ≥3 × higher in ages 65 and older versus 18–64 years, across all CTD-ILD subtypes (**Tables 1** and **2**). Incidence and prevalence rates increased over the study period.

Conclusion: The scarcity of US data on CTD-ILD epidemiology underscores the importance of investigating ILD in patients with CTD, and vice versa, to aid diagnosis and intervention, particularly in older patients and females, where CTD-ILD incidence and prevalence rates are highest. Overall, CTD-ILD incidence and prevalence rates were highest for RA-ILD, corresponding to the higher rates of RA compared with other CTD subtypes. Importantly, findings for age- and sex-adjusted rates were similar between these two large US databases capturing different US patient populations. These prevalence data suggest that 116,000–118,000 individuals in the US have CTD-ILD (based on 2023 adult population estimated at 262.1 million). These novel data highlight a substantial healthcare burden, especially in older patients and females.

Abstract Number: 0155

Effect Modification of Cigarette Smoking on the Relationship between Post Traumatic Stress Disorder and Rheumatoid Arthritis Risk

Kelsey Coziahr[1], Harlan Sayles[1], Tate Johnson[1], Joshua Baker[2], Punyasha Roul[3], Grant Cannon[4], Gary Kunkel[5], Bryant England[1] and Ted Mikuls[1], [1]University of Nebraska Medical Center, Omaha, NE, [2]University of Pennsylvania, Philadelphia, PA, [3]UNMC, Omaha, NE, [4]University of Utah and Salt Lake City VA, Salt Lake City, UT, [5]Salt Lake City VA, Salt Lake City, UT

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0145–0174) Epidemiology & Public Health Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Post-traumatic stress disorder (PTSD) is associated with increased systemic inflammation that may increase the risk of developing autoimmune disorders such as rheumatoid arthritis (RA). The prevalence of cigarette smoking, an established risk factor in RA, is substantially higher in patients with PTSD than in the general population. We aimed to quantify the association between PTSD and the risk of developing RA in U.S. veterans, examining whether this association is confounded or modified by smoking.

Methods: We conducted a nested, case-control study using national Veteran Health Administration data from 2006-2019, identifying patients with incident RA (≥2 diagnostic codes, rheumatologist diagnosis, positive autoantibody or DMARD fill, plus ≥365 days in VA care before a DMARD fill or RA ICD code). Cases were matched to non-RA controls on the date the RA algorithm was fulfilled, at a ratio up to 1:10 by age, sex and year of VA enrollment. PTSD and other mental health disorders (OMH; i.e., bipolar disorder, depression, anxiety and substance use) were identified retrospectively and defined by the presence of ≥2 ICD9/10 codes. Conditional multivariable logistic regression was used to examine the association of PTSD (± OMH) and OMH (without PTSD) with RA, adjusting for race, ethnicity, urban/rural residence, smoking status, and BMI and including an interaction term for RA status and smoking. Based on initial results, additional models were stratified by ever vs. never smoking status and included age, sex, and year of VA enrollment as covariates in addition to those noted. Separate models were used to examine associations in subgroups defined by sex and seropositivity status (RF and/or aCCP).

Results: Patients included in this analysis (n=357,361; n=32,884 with RA) had a mean age of 53 years, 87% were male, and 70% had ever smoked. Among RA cases, 76% were RF or aCCP positive. PTSD, OMH, and smoking were all more frequent in patients with RA than controls (**Table 1**). In multivariable analyses, there was evidence of a highly significant smoking-PTSD interaction (p< 0.001). In subsequent multivariable analyses stratified by ever smoking status, the association of PTSD (vs. no PTSD or OMH) with RA was higher in never smokers (aOR 1.54; 95% CI 1.41, 1.69) than ever smokers (aOR 1.20;

No MH Diagnosis	575 (53)	38,724 (68)	*Referent*
Other MH (No PTSD)	308 (29)	11,760 (21)	1.61 (1.40, 1.86)
PTSD	197 (18)	6,118 (11)	1.94 (1.64, 2.29)

* Models adjusted for age, sex, year of VA enrollment, race, ethnicity, urban/rural residence, BMI; Abbreviations: PTSD, post-traumatic stress disorder; MH, mental health; RA, rheumatoid arthritis; OMH, Other Mental Health; aOR, adjusted odds ratio

95% CI 1.16, 1.25). Similar associations, though lower in magnitude, were observed for OMH (**Table 2**). PTSD-related risk remained quantitatively higher in never vs. ever smokers in subgroups defined by sex and seropositivity with a higher risk observed for seronegative RA (**Table 3**).

Conclusion: In addition to validating prior reports demonstrating an increased risk of RA attributable to both PTSD and cigarette smoking, these results suggest that the relationship of PTSD with RA disease susceptibility is modified, rather than being confounded, by smoking status with a greater contribution to RA risk in never smokers. PTSD also appears to be more closely associated with the development of seronegative RA. These results highlight a complex relationship between PTSD and OMH with RA development and call for research into how mental health may influence the development of distinct RA phenotypes.

Abstract Number: 0156

Heat Exposure and Acute Care Utilization among Individuals with Rheumatic Conditions: A Time Series Framework for Identifying Delayed Associations

Leah Santacroce[1], Jamie Collins[1], Ana Valle[2], Rebecca Summit[3], Paul Dellaripa[4] and Candace Feldman[1], [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Brookline, MA, [3]Brigham & Women's Hospital, Boston, MA, [4]Brigham and Womens Hospital, Boston, MA

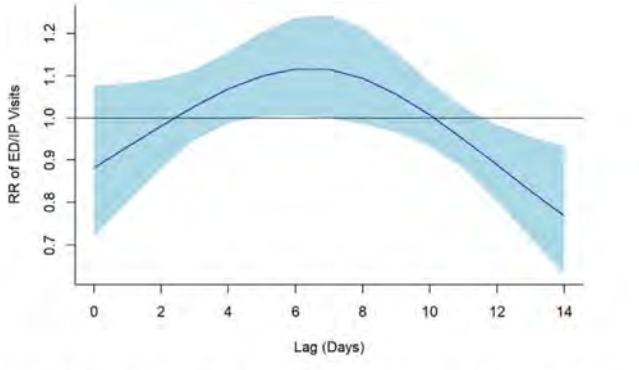
SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0145–0174) Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Temperature and air pollution are increasing each year across the US. There is growing interest in studying how the effects of high temperature impact patients with rheumatic conditions. We aimed to provide a framework using time series methods to assess whether specific days of high heat contributed to acute care utilization (emergency department [ED] and inpatient [IP] visits) among individuals with rheumatic conditions.

Methods: We identified patients with ≥ 2 ICD-10 codes for rheumatic conditions in a multi-hospital center in Massachusetts. We obtained temperature and relative humidity from the National Oceanic Atmospheric Administration and air quality data from the Environmental Protection Agency. Acute care use was defined as ED or IP visits with a primary diagnosis code for a rheumatic condition or heat related illness (e.g. heat stroke, dehydration) from January 1, 2022, to October 1, 2024.

We used distributed lag non-linear time series models to estimate the effects of high temperature on risk of acute care utilization. These models allow for non-linear associations between exposures and outcomes and delayed effects using lags. We allowed the effect of temperature to be distributed over 14 days (lag days) with a cubic spline and fit a quasi-Poisson model adjusted for relative humidity, air quality index, day of week and time.

Results: 16,131 patients met inclusion criteria. 79% were white, 71% female, and the median age was 63. There was an average of 1.2 (SD 1.1) ED and IP visits with a primary diagnosis of rheumatic condition or heat related illness per day across all patients. Over the 3 summers in the study period there were 38 days that reached 90+ Fahrenheit (°F) and 12 days that reached 95+ °F. In the distributed lag non-linear models, we found significant associations between temperatures of 87°F



The dark blue line represents the relative risk and the light blue shading represents the 95% confidence interval at a day where the temperature reaches 95°F compared to 60°F.

Figure 1. Relative risk of acute care utilization among individuals with rheumatic conditions at each lag day after the temperature reaches 95°F.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Relative Risk of acute care utilization among individuals with rheumatic conditions at different temperatures and lag days.

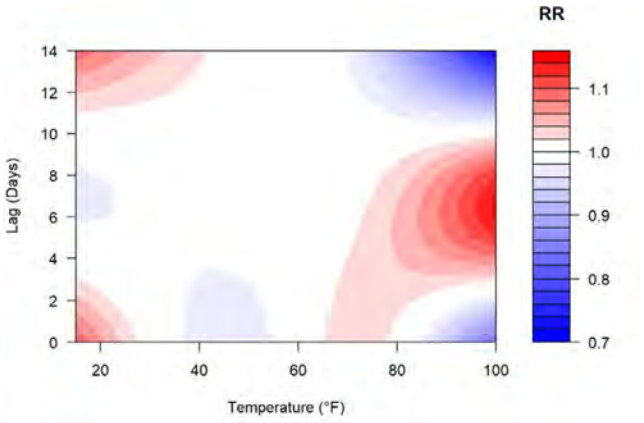
Temperature (°F)	Day 5	Day 6	Day 7
	Relative Risk (95% CI)		
92	1.09 (1.005, 1.176)	1.10 (1.005, 1.203)	1.10 (0.998, 1.206)
93	1.09 (1.005, 1.185)	1.10 (1.005, 1.214)	1.10 (0.999, 1.218)
94	1.10 (1.004, 1.194)	1.11 (1.005, 1.226)	1.11 (0.999, 1.230)
95	1.10 (1.004, 1.204)	1.12 (1.006, 1.238)	1.11 (0.999, 1.243)
96	1.10 (1.003, 1.214)	1.12 (1.006, 1.251)	1.12 (0.999, 1.256)
97	1.11 (1.002, 1.224)	1.13 (1.005, 1.263)	1.13 (0.999, 1.270)
98	1.11 (1.001, 1.234)	1.13 (1.005, 1.276)	1.13 (0.999, 1.284)
99	1.12 (1.001, 1.245)	1.14 (1.005, 1.290)	1.14 (0.999, 1.298)

Snapshot of relative risk and 95% confidence interval at various temperatures and lag days, revealing a small but statistically significant increase in risk of acute care use as temperatures increase, and higher risk ratios at higher temperatures.



Red coloring indicates a higher relative risk of acute care use, white represents a null risk, and blue coloring indicates a lower relative risk. Colors are shown at all possible temperatures and lag days after exposure day, compared to 60°F.

Figure 2. Contour plot with relative risk of temperature effects on acute care utilization among individuals with rheumatic conditions.

to 99°F with increased risk of acute care utilization at lag days 5 and 6. **Figure 1** shows the lag-response curve at 95°F which provides relative risks for each lag day. When the maximum temperature reaches 95°F on a given day, we see that there is no effect on utilization on that day or the next few days, but there is a trend toward higher risk of utilization on days 4-9 with statistical significance at days 5 and 6, which decreases around day 10. The relative risk of an ED or IP visit 6 days after the temperature reached 95°F was 1.12 (95% CI 1.01, 1.24) **(Table 1)** compared to a day when the temperature was 60 °F. **Figure 2** shows a contour plot of the relative risks at all possible lag days and temperatures, with darker red indicating higher risk of acute care utilization.

Conclusion: In this population of patients with rheumatic conditions, we found a modest delayed effect of high temperature on increased risk of acute care use for heat related illness and rheumatic conditions. The geographic areas where these patients lived have milder summers than other parts of the US, which may have limited our ability to detect risks associated with persistently high heat. As temperatures rise further, modeling approaches such as distributed lag non-linear models will become increasingly important to assess climate-related health risks among individuals with rheumatic conditions.

Influence of Outpatient Clinic Visits on Receipt of the COVID-19 Vaccine among People with Autoimmune Rheumatic Diseases

Lesley Jackson[1], Nicole Wright[2], Rahima Begum[3], Fazlur Rahman[1], Rena Patel[1], Kenneth Saag[4], Jeffrey Curtis[5] and Maria I. (\"Maio\") Danila[6], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Tulane University School of Medicine, New Orleans, LA, [3]University of Alabama at Birmingham, Birmingham, [4]The University of Alabama at Birmingham, Birmingham, AL, [5]Foundation for Advancing Science, Technology, Education and Research, Birmingham, AL, [6]University of Alabama at Birmingham (UAB), Birmingham VA Medical Center, Birmingham, AL

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0145–0174) Epidemiology & Public Health Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatologists and primary care providers (PCPs) are some of the most trusted clinicians for people living with autoimmune rheumatic diseases (AIRD), and they may influence the vaccine decision-making process during outpatient visits. We aimed to determine the factors associated with receipt of a COVID-19 vaccine during the immediate follow-up interval after either rheumatology or PCP clinic visits.

Methods: We used electronic health records (EHR) to conduct a retrospective cohort study of established patients with AIRD at our institution seen from 12/8/2020 through 1/8/2024. We conducted two separate cohort analyses in patients who had 2+ clinic visits in the observation period with (1) rheumatology or (2) a PCP. The primary outcome of "post-visit vaccination" was defined as receipt of a dose of the COVID-19 vaccine during the 8-day interval after a rheumatology or a PCP clinic visit (i.e., the day of visit + 7 days post-visit). We built multivariable logistic regression models to identify factors independently associated with post-visit vaccine receipt. Secondarily, we conducted a self-controlled case series (SCCS) analysis to

Table 1. Characteristics of individuals with a rheumatology clinic visit stratified by presence or absence of a COVID-19 vaccine occurring during the post-visit interval. Bold denotes p<0.05 for comparisons between the 2 groups.

Characteristic	Presence of clinic visit without associated vaccine post-visit, N=2188	Presence of clinic visit and receipt of vaccine post-visit, N=440	p-value
Sex, female, N(%)	1781 (81.4)	367 (83.4)	0.3
Age, mean (SD)	58.1 (14.7)	60.6 (13.4)	**0.0004**
Age groups (years), N (%)			0.08
<50	598 (27.3)	96 (21.2)

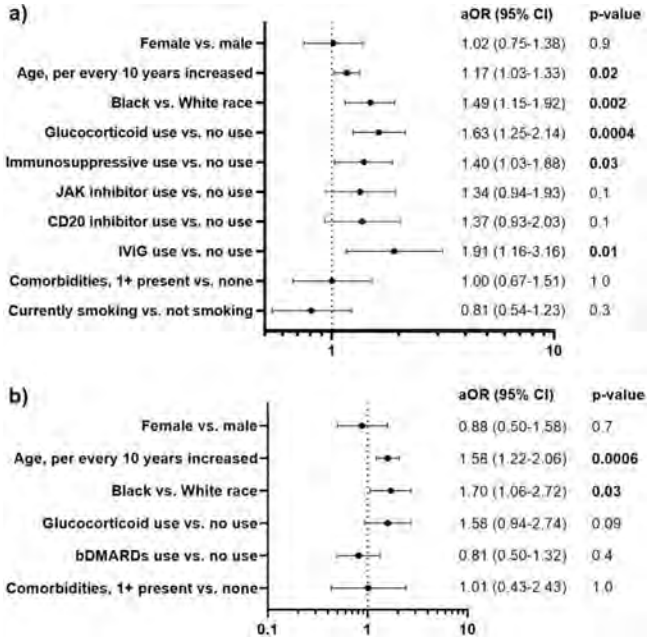

Figure 1. Results of multivariable logistic regression model with odds ratio (OR) and 95% confidence intervals (CI) for covariates associated with receipt of a COVID-19 vaccine during the 8-day post-visit interval after an outpatient a) rheumatology clinic visit or b) primary care clinic visit. Model includes all relevant covariates of biological significance (e.g., sex, age) and those with p<0.25 in the univariable analysis. OR and CI presented on a logarithmic scale. aOR, adjusted odds ratio; IVIG, intravenous immunoglobulin; JAK inhibitor, janus kinase inhibitor.

compare receipt of COVID-19 vaccination during the 8-days post-visit "hazard interval" vs. 8-days pre-visit "control interval", and censored at the time of their vaccine receipt or death during these intervals.

Results: We identified 2,628 individuals with rheumatology (**Table 1**) and 493 individuals with PCP clinic visits, of whom 440 (16.7%) and 119 (24.1%) received a COVID-19 vaccine in the 8-day post-visit interval, respectively. In the multivariable logistic regression model examining the outcome following rheumatology visits, older age (OR=1.17, 95% CI 1.03 – 1.33, for every 10-year increase), Black race (OR=1.49, 95% CI 1.15 – 1.92), and use of glucocorticoids (OR=1.63, 95% CI 1.25 – 2.14), immunosuppressives (OR=1.40, 95% CI 1.03 – 1.88), and intravenous immunoglobulin (OR=1.91, 95% CI 1.16 – 3.16) were associated with higher odds of post-visit vaccine receipt (**Figure 1a**). Among eligible patients with PCP clinic visits, only older age (OR=1.58, 95% CI 1.22 – 2.06) and Black race (OR=1.70, 95% CI 1.06 – 2.72) were associated with a post-visit vaccine receipt (**Figure 1b**). In the SCCS analysis, there were significantly higher rates of vaccine receipt during the post-visit hazard interval compared to each person's control interval following rheumatology (IRR=1.87, 95% CI 1.62 – 2.18, p< 0.0001) and PCP clinic visits (IRR=3.81, 95% CI 2.75 – 5.36, p< 0.0001); among only patients who received a vaccine, the rates were similar.

Conclusion: In this cohort study of patients with AIRD, we found that older age, Black race, and use of certain high-risk medications were associated with higher odds of COVID-19 vaccination in close proximity to a visit with a rheumatologist or PCP. While both PCP and rheumatology clinic visits were associated with more post-visit COVID-19 vaccinations, our results suggest that rheumatologists may be focusing vaccination efforts among those with certain high-risk patient characteristics such as older age or greater immunosuppression burden. Effective interventions aimed at improving vaccine uptake could be implemented at or soon after a clinic visit.

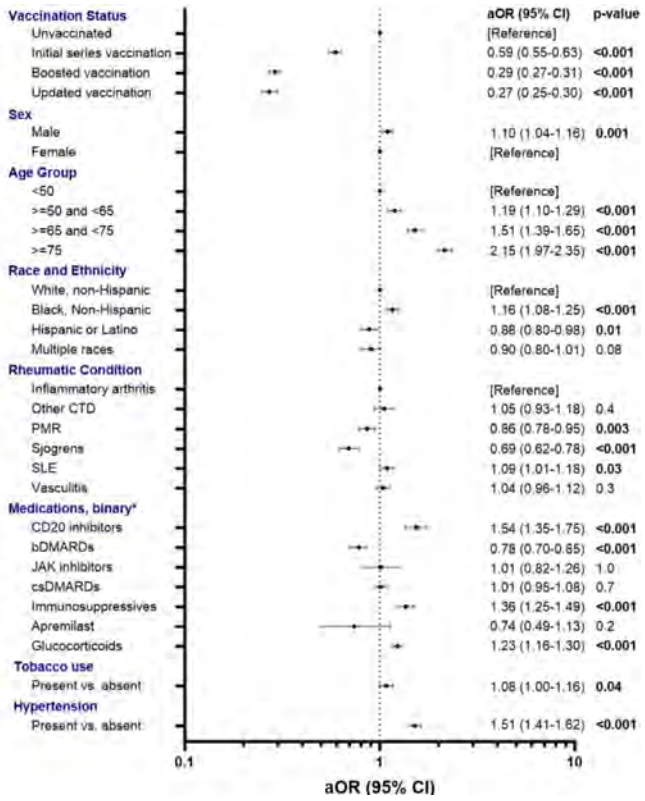

Figure 1. Results of multivariable logistic regression model with odds ratio (aOR) and 95% confidence intervals (CI) adjusted for covariates associated with COVID-19 related hospitalization. OR and CI presented on a logarithmic scale. Model was adjusted for: vaccination status, sex, age, race and ethnicity, rheumatic condition, medication use, tobacco use, presence of hypertension, Charlson Comorbidity Index, and social vulnerability index. *categories defined by presence vs. absence of medication. bDMARDs, biologic disease modifying anti-rheumatic drugs; csDMARDs, conventional synthetic disease modifying anti-rheumatic drugs; JAK inhibitor, janus kinase inhibitor; PMR, polymyalgia rheumatic; SLE, systemic lupus erythematosus.

Background/Purpose: People with autoimmune rheumatic diseases (AIRD) are at higher risk for serious complications and poor outcomes from COVID-19 infection. Data is lacking on outcomes related to the 2023-2024 updated COVID-19 vaccine in this population. We aimed to assess the association between vaccination status and COVID-19-related hospital admissions.

Methods: We conducted a retrospective cohort analysis using electronic health record (EHR) data from the National Clinical Cohort Collaborative (N3C) COVID-19 Enclave among people with AIRD and incident positive COVID-19 testing (i.e., positive SARS-CoV-2 polymerase chain reaction (PCR), antigen, or antibody test or COVID-19 diagnostic code) between December 2020 and December 2023. Eligible patients were adults age ≥18 years with ≥2 International Classification of Diseases (ICD)-10 codes for AIRD occurring at least 30-days apart. We defined time-varying vaccination status as: unvaccinated (i.e., no vaccine record on file), initial series completed (i.e., received two mRNA vaccine doses or 1 Janssen dose of the COVID-19 vaccine), boosted (i.e., received initial vaccination series and a booster or bivalent dose), or updated vaccinated (with 1+ updated 2023–2024 COVID-19 vaccine). We defined the primary outcome as presence of an inpatient hospitalization occurring during the period 3 days before and up to 14 days after positive SARS-CoV-2 testing, and allowed for repeat hospitalizations. We conducted a multivariable logistic regression model and adjusted for repeating measures and participating site. Covariates included sex, age, race and ethnicity, AIRD category, AIRD-related medication use, tobacco use, presence of hypertension, obesity, modified Charlson comorbidity index (excluding AIRD), and social vulnerability index (SVI).

Results: Our cohort included 54,848 people with AIRD, including 41,383 (75%) females, with median (IQR) age 62 (50-73) and 39,766 (73%) White non-Hispanic race (**Table 1**). Of these, 5,775 (11%) had received an updated 2023-2024 COVID-19 vaccine. After adjusting for relevant covariates, people with AIRD who had received a booster or an updated vaccine dose had 71% (adjusted odds ratio [AOR]=0.29, 95% confidence interval [CI] 0.27-0.31) and 73% (AOR=0.27, 95% CI

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

0.25-0.30) lower odds of COVID-19-related hospitalization compared to unvaccinated people, with similar odds comparing to those with initial series alone (**Figure 1**). In addition, male sex, older age, Black non-Hispanic race, having systemic lupus erythematosus, exposure to CD20 inhibitors, immunosuppressives, or glucocorticoids, current tobacco use, having hypertension, more comorbidities, and higher SVI were associated with an increased odds of COVID-19-related hospitalization.

Conclusion: After accounting for important covariates, we observed a substantially decreased independent odds of COVID-related hospitalization among people with AIRD that received a booster or updated 2023-2024 COVID-19 vaccine compared to initial series alone or unvaccinated statuses. Updated vaccinations appear to continue to provide significant protection for this vulnerable population and should be supported by providers, policy makers, and patient advocacy groups.

Abstract Number: 0159

Prenatal and Early-Life Environmental Exposures in Juvenile-Onset Systemic Autoimmune Rheumatic Diseases

Takuma Ohnishi[1], Megan Zhao[1], Min Shi[2], Adam Schiffenbauer[3], Sharon Jackson[3], Anna Jansen[1], Nastaran Bayat[4], Payam Farhadi[1], Christine Parks[2], Clarice Weinberg[2], Frederick Miller[5] and **Lisa Rider**[6], [1]National Institutes of Health/National Institute of Environmental Health Sciences, Bethesda, MD, [2]National Institutes of Health/National Institute of Environmental Health Sciences, Research Triangle Park, NC, [3]National Institute of Health/National Institute of Dental and Craniofacial Research, Bethesda, MD, [4]National Institutes of Health/National Institute of Environmental Health Sciences, Gaithersburg, MD, [5]National Institutes of Health/National Institute of Environmental Health Sciences, Chapel Hill, NC, [6]National Institute of Environmental Health Sciences/National Institutes of Health, Environmental Autoimmunity Group, Bethesda, MD

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0145–0174) Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic autoimmune rheumatic diseases (SARDs), including juvenile idiopathic arthritis (JIA), systemic lupus erythematosus (SLE), idiopathic inflammatory myopathies (IIM), and systemic sclerosis (SSc), are characterized by immune dysregulation. While genetic predisposition contributes to disease susceptibility, environmental exposures, including those during the prenatal period and early childhood, may potentially influence disease risk. Evidence regarding these early-life factors is limited and inconsistent. This study aimed to examine associations between early-life environmental exposures and juvenile-onset SARDs.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table. Associations between prenatal and early-life environmental factors and participant role

	Probands vs Unrelated controls Odds ratio (95% Confidence Interval)
Prenatal factors	
Delivery by Cesarean section	1.31 (0.68-2.58)
Premature birth (< 37 weeks)	2.08 (0.74-6.73)
Gestational hypertension	4.81 (0.80- 92.59)
Preeclampsia, eclampsia, or toxemia	8.72 (0.98-1150)
Gestational diabetes	2.00 (0.62-7.72)
Rho(D) immune globulin usage	1.06 (0.32-3.77)
Flu or fever for more than 5 days	0.75 (0.15-4.16)
Placenta previa or placental abruption	5.46 (0.53-737)
Total number of pregnancy complications	1.57 (1.14-2.24)†
Prenatal parental smoking	4.81 (1.30-24.29)‡
Maternal smoking	1.81 (0.25-36.95)
Paternal smoking	7.43 (1.66-55.68)†
Early-life factors	
Birth order	1.00 (0.78-1.30)
Breast feeding	1.02 (0.41-2.45)
Soy formula (≥ 2 weeks)	1.06 (0.48-2.46)
Passive smoke exposure*	4.88 (1.38-23.51)‡
Active cigarette smoking	2.13 (0.10-326.7)

*Household smoking before age at diagnosis for probands or reference age for unrelated controls. Reference date is the proband's date of diagnosis.

†P ≤ 0.01, ‡P ≤ 0.05

Methods: A case-control study included 124 probands with juvenile-onset SARDs diagnosed within 5 years (99 with juvenile IIM, 16 with JIA, 5 with SSc, and 4 with SLE), their same gender, close-in-age unaffected siblings (n=121), and demographically matched unrelated controls without autoimmune disease (n=90). The proband's date of diagnosis served as the reference date for their siblings and matched controls. Participants resided in the United States or Canada. Parents of pediatric patients completed questionnaires on pregnancy complications, parental smoking during pregnancy, early-life exposures, and active smoking history. Paired analyses between probands and their siblings were performed using conditional logistic regression models adjusted for age. Probands and controls were compared by logistic regression analysis, adjusting for potential confounding variables including age, sex, race, ethnicity, and education level.

Results: The median age at reference date was 7.4 years for probands, 8.4 years for siblings, and 9.2 years for controls. Sex and race distributions did not differ significantly among groups: 62% of probands and siblings were female compared to 66% of controls; 85% of probands and siblings were White compared to 87% of controls. No significant differences in pregnancy complications or early-life exposures were observed between probands and their siblings. However, compared to controls, juvenile-onset SARDs were associated with multiple pregnancy complications (OR 1.57, CI:1.14–2.24), but not with any specific complication (Table). Prenatal parental smoking was also significantly associated with juvenile-onset SARDs (OR 4.81, CI:1.30–24.29). While maternal smoking rates were similar between groups, paternal smoking was more frequent in probands compared to controls (OR 7.43, CI:1.66–55.68). Early-life exposures, such as birth order, breastfeeding and soy formula use, did not differ significantly between probands and controls. Passive smoke exposure before reference age was also associated with juvenile-onset SARDs (OR 4.88, CI:1.38–23.51). Active smoking was uncommon, with one proband and two siblings reporting tobacco use.

Conclusion: The number of pregnancy complications was associated with juvenile-onset SARDs, without an association with a specific complication. Parental smoke exposure during prenatal and early-life periods was strongly associated with SARDs. These findings highlight the importance of pregnancy and early-life factors in these diseases.

Abstract Number: 0161

Risk Factors and Clinical Predictors of Lung Cancer in Systemic Sclerosis: A Matched Case-Control Study from a Michigan Cohort

Madiha Naqsh Siddiqui[1], Yen Chen[1], Rosemary Gedert[2], Suiyuan Huang[2], Dinesh Khanna[2] and John Varga[2], [1]University of Michigan, Ann Arbor, [2]University of Michigan, Ann Arbor, MI

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0145–0174) Epidemiology & Public Health Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Malignancies are one of the leading causes of non-systemic sclerosis-related mortality in patients with systemic sclerosis (SSc)[1], with lung cancer being the most common type[2,3,4]. Although factors such as prolonged immunosuppression[4], family history of malignancy[5], and smoking[6] have been implicated, findings have been inconsistent. We conducted a matched case-control study to investigate clinical, serological, and treatment-related risk factors associated with lung cancer among patients with SSc in a Michigan-based cohort.

Methods: Data were extracted retrospectively using DataDirect, a self-service tool that retrieves information from the electronic medical record system by identifying relevant International Classification of Diseases (ICD) 9 and 10 codes for SSc and lung cancer (710.1, 162.9 and M34.0, M34.1, M34.2, M34.8, M34.9, C34.00-C34.92, respectively) and/or listed diagnosis in the medical record. Inclusion criteria included adults aged 18 or older who were actively followed by rheumatology at the University of Michigan and had a confirmed diagnosis of SSc, either by fulfillment of the ACR classification criteria or through clear documentation in a rheumatologists' note. Exclusion criteria were patients aged under 18, lack of active follow-up at the University of Michigan, localized scleroderma, or secondary lung cancer (metastatic, with a primary site other than lung). Using these criteria, we identified 102 patients: 51 SSc patients with lung cancer (cases) and 51 age-

* Test is not applicable due to fewer than 2 non-missing levels in case or control, or both. [a] Paired T test. [b] McNemar test. [c] Bowker's symmetry test.					

Table 1: Baseline Characteristics.

matched SSc patients without lung cancer (controls). Paired t-tests, McNemar's and Bowker's symmetry tests were used to assess baseline differences. Conditional logistic regression was then performed to examine associations with lung cancer.

Results: Baseline patient data characteristics are summarized below in table 1. Compared to controls, cases had significantly higher rates of diffuse cutaneous SSc (72.5% vs. 39.2%, p=0.0036), former smoking (64.7% vs. 27.5%, p=0.0009), presence of lung nodules on CT chest (87.5% vs. 61.2%, p=0.0164), and immunosuppressive therapy use (89.4% vs. 56.9%, p=0.0006). Mean DLCO% was significantly lower in cases (48.7% vs. 61.1%, p=0.0011). In multivariable

Table 2: Conditional logistic regression results

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

analysis (table 2), former smoking (OR 8.22, 95% CI: 2.39 – 28.27, p=0.0008), glucocorticoid use (OR 14.50, 95% CI: 3.46 – 60.77, p=0.0003), and nodules on chest CT (OR 3.2, 95% CI: 1.17 – 8.74, p=0.0232) were independently associated with lung cancer. Diffuse cutaneous subtype was a risk factor, while limited cutaneous SSc was protective (OR 0.14, 95% CI: 0.04 – 0.49, p=0.0017). DLCO% was inversely associated with lung cancer risk (OR 0.95 per % increase, 95% CI: 0.92 – 0.99, p=0.0065). Cases had 1300% higher odds of death (OR 14%, 95% CI: 3.34 – 58.77, p=0.0003).

Conclusion: In this matched cohort, lung cancer in SSc was significantly associated with diffuse cutaneous subtype, prior smoking history, nodules on CT chest, reduced DLCO, and glucocorticoid exposure. In contrast, limited cutaneous SSc conferred a protective effect. These findings underscore the importance of clinical phenotype and treatment history in assessing malignancy risk in SSc patients and support the need for targeted cancer screening protocols.

Abstract Number: 0162

Clinical Relevance of Systematic Comorbidity Screening in Autoimmune and Inflammatory Diseases

Martin Michaud, Caroline Arlet, Jean Alain Bournazeau, François de Maupeou, Julie Gaston, Stephanie Mermet, Helene Coulier, Marie Oustalet, Christophe Raspaud, Cédric Maurice, Sophie Recipon, Claire Verplancken, Kim Paricaud and Leonardo Astudillo, Clinique Saint Exupery, TOULOUSE, France

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0145–0174) Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Chronic autoimmune and inflammatory diseases are associated with an increased prevalence of various comorbidities, which may impact both prognosis and therapeutic strategies. EULAR recommends systematic identification, prevention and screening of key comorbid conditions in this population.

Methods: Since January 1st, 2025, the PREDIRE cohort has included consecutive adult patients with chronic autoimmune or inflammatory diseases undergoing a multimorbidity assessment during a one-day hospitalization. Collected data include sociodemographic and anthropometric characteristics, medical history, current treatments, cardiovascular risk factors, osteoporosis risk, and infectious risk evaluation (including dental follow-up and vaccination status). At the end of the assessment, individualized recommendations are issued for both the patient and their primary care physician.

Results: A total of 46 patients were included, with a mean age of 64.2 (±15.2) years . Autoimmune or inflammatory diseases were giant cell arteritis (26%), polymyalgia rheumatica (13%), sarcoidosis (8.7%), Behçet's disease, systemic lupus erythematosus, systemic sclerosis , spondyloarthritis (6.5%), Sjogren disease (4.3%), ANCA-associated vasculitis (4.3%), or rheumatoid arthritis, familial mediterranean fever, or retroperitoneal fibrosis (2.17% each). The median duration of the disease was 2 years (IQR: 1–7).

Regarding cardiovascular comorbidities, 21.7% had a history of major cardiovascular event, 38.1% had hypertension and 10.9% had diabetes.

Diabetes	10,8
Cancer	8,69
Osteoporosis	13
Lipid lowering therapy (%)	28,2
Anti-platelet therapy (%)	19,5
Anti-osteoporotic drug (%)	15,2

Patient Characteristics

Obesity was observed in 26% of patients, while 28.2% were overweight. Physical inactivity was reported in 34.7% of patients.

Active smoking was reported in 19.5% of cases and 28.2% had a history of smoking.

	All patients (n=46)
Metabolic syndrome (%)	19,5
Undiagnosed diabetes (%)	0
Undiagnosed or uncontrolled Hypertension (%)	36,9
Cardiovascular disease risk (%)	
Very High	34,7
High	30,47
Low to moderate	26
Very low	8,7
LDL-cholesterol target levels achievement (%)	19,5
Undiagnosed risk to sleep apnea (%)	21,7
Physical activity profile (%)	
Inactive	34,7
Active	60,8
Very active	4,3
Undiagnosed osteopenia (%)	30,4
Undiagnosed osteoporosis (%)	15,2
Vitamin D insufficency (%)	65
Low calcium intake (%)	71,7
Anti-osteoporotic drug need (%)	26
Dental care to complete (%)	21,7
Cancer screening to complete (%)	54,3
Vaccine calendar to complete (%)	84,7

Screening Outcomes

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Cardiovascular risk, estimated using the SCORE2 algorithm, showed that 65.2% of patients were at high or very high risk. Target LDL cholesterol levels were achieved in only 19.5% of patients.

A risk of sleep apnea was identified in 21.2% of patients.

While osteoporosis was previously known in 13% of patients, the assessment revealed newly diagnosed osteopenia in 34% and osteoporosis in 15.2%. Vitamin D deficiency was identified in 65% of patients, and inadequate calcium intake was noted in 71.7% of cases. Despite being indicated, osteoporosis treatment was lacking in 26% of patients.

Dental follow-up was indicated in 21.7% of patients. Vaccination schedules needed updating in 84.7% of patients.

In 54.3% of cases, cancer screening was outdated or incomplete, warranting an update of the recommended evaluations

Conclusion: The first data from the PREDIRE cohort highlight the high burden of comorbidities among patients with chronic autoimmune and inflammatory diseases. The implementation of a standardized, one-day multimorbidity screening approach allowed for the early identification of unrecognized or under-managed comorbid conditions, particularly in cardiovascular, bone, infectious, and cancer-related domains. These findings support the clinical utility of systematic comorbidity screening in improving patient care and guiding personalized preventive strategies.

Trends in hospitalization and outcomes among patients admitted with Adult-onset Still's disease in the United States: INSIGHTS FROM THE NATIONAL INPATIENT SAMPLE (2016-2022)

Mohammed Akram[1], Muhammad Sohaib Asghar[2], Woo Joo Lee[2], Basmah Fayaz Yousuf[3], Carmen Tormo Carillo[4] and Savier Aleman Rama[4], [1]HCA Aventura, Aventura, FL, [2]AdventHealth Sebring, Sebring, FL, [3]SUNY Downstate Health Sciences University, New York, NY, [4]HCA Florida Aventura Hospital, Aventura, FL

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0145–0174) Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Adult-onset Still's Disease is a rare systemic autoinflammatory disorder characterized by spiking fever, arthralgia/arthritis, skin rash, and elevated inflammatory markers (ferritin). Estimated incidence ranges from 0.16 to 0.4 cases per 100,000 persons and is associated with significant morbidity during systemic flares requiring inpatient management. There is a lack of research related to hospitalization trends and outcomes of patients with this disease within the United States. Hence, we conducted this analysis from national databases to investigate the hospitalization trends of Adult Onset Still's Disease pre and post COVID-19 pandemic era.

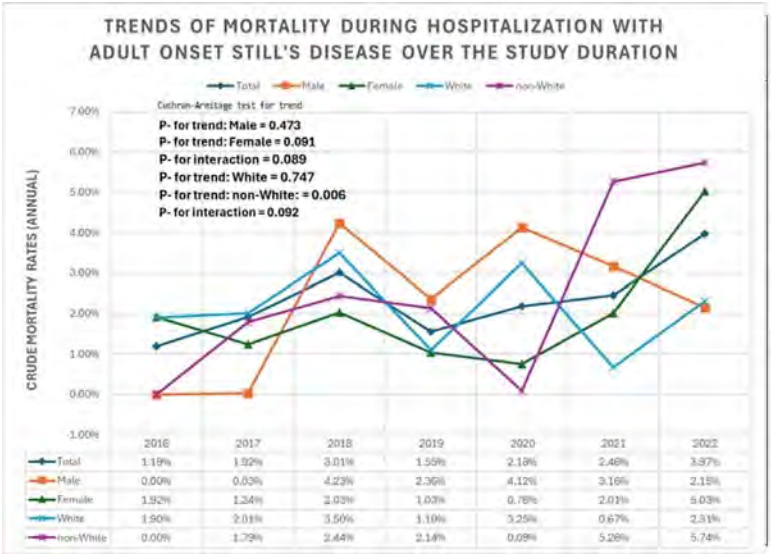
Hospital location							

Methods: We used the National Inpatient Sample (NIS), a database that includes a subset of hospital discharges in 50 states, to identify patients with adult-onset Still's disease who were admitted to the hospital due to any cause. Patients who were admitted in the years 2016 to 2022 (including the COVID-19 pandemic) were enrolled in the study. Adult-onset Still's disease was defined based on the ICD-10 code M06.1. Patients were excluded based on age cut-off of < 15 years,



Top 20 listed primary reasons of admission (Unweighed)

1.	2895	M061	Adult-onset Still's disease
2.	1044	A419	Sepsis, unspecified organism
3.	125	J189	Pneumonia, unspecified organism
4.	124	R509	Fever, unspecified
5.	119	D761	Hemophagocytic lymphohistiocytosis
6.	100	U071	COVID-19
7.	94	N179	Acute kidney failure, unspecified
8.	65	N390	Urinary tract infection, site not specified
9.	60	A4189	Other specified sepsis
10.	55	L03116	Cellulitis of left lower limb
11.	50	I214	Non-ST elevation myocardial infarction (NSTEMI)
12.	49	I130	Hypertensive heart disease and CKD stage 1-4
13.	40	A4151	Sepsis due to Escherichia coli [E. coli]
14.	39	K529	Noninfective gastroenteritis and colitis, unspecified
15.	39	I110	Hypertensive heart disease with heart failure
16.	35	I2699	Pulmonary embolism without acute cor pulmonale
17.	35	Z5111	Encounter for antineoplastic chemotherapy
18.	34	M1712	Unilateral primary osteoarthritis, left knee
19.	30	K7200	Acute and subacute hepatic failure without coma
20.	29	I313	Pericardial effusion (noninflammatory)

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. and as well as juvenile rheumatoid arthritis identified as M08.2 were not included in the analysis. Discharge weights were applied to estimate national level representation. Adjusted hospital costs were reported for inflation in the year 2022 according to the U.S. Department of Labor inflation index for Medical Care Consumer Price Index (CPI) for cost-based analysis. Cochrane-armitage and Jonckheere-Terpstra test were applied as indicated to analyze the trends over the study period for in-hospital mortality rates, length of stay, inflation adjusted hospitalization costs respectively.

Results: There were a total of 1827 unweighted and 9135 weighted hospital discharges reported with a history of adult onset's still disease on payer information through healthcare cost and utilization project (HCUP). Among these admissions over a span of 7 years within NIS databases, 40% were males and 60% females, 58% were white by ethnicity. In-hospital mortality rate was 2.3%, and the trend shows an increase amongst non-White population, especially after the COVID-19 pandemic (P=0.006). The most common primary reason of admission remains sepsis following adult-onset Still's disease complications. Hospitalization costs and length of stay were found higher with male gender (p=0.001 & 0.006 respectively), and non-White population (p=0.001 & 0.005 respectively). Among non-White population, length of stay and hospitalization costs were found highest in Asians/Pacific Islanders population. Also, the mean age of these patients were comparatively higher than other races (50 vs 42 years), as opposed to White population with a mean age of 52 years (p< 0.001).

Conclusion: Sepsis was the most common primary reason for admission. Overall in-hospital mortality was low (2.3%) but increased significantly among non-White populations. Male gender and non-White race were associated with higher hospitalization costs and lengths of stay. Among subgroups, Asian/Pacific Islander patients had the highest resource use and were older at admission than other non-White groups.

Abstract Number: 0164

Online Patient Survey on the Impact of Extreme Weather Events on Autoimmune and Rheumatic Diseases

Iazsmin Ventura[1], Tamiko Katsumoto[2], **Natasha Powell**[3], Elena Adams[4] and Olivia Casey[5], [1]Section of Rheumatology, University of Chicago, Chicago, [2]Division of Immunology and Rheumatology, Stanford University, Millbrae, CA, [3]University of Chicago Pritzker School of Medicine, Chicago, [4]New Rochelle High School, New Rochelle, [5]Autoimmune Association, Eastpointe

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0145–0174) Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: The impact of climate change on autoimmune and rheumatic diseases remains poorly understood. However, emerging evidence suggests extreme weather events, often related to climate change, may be associated with disease flares, hospitalizations, and disruptions in access to medical care. This pilot study, the first retrospective online survey of its kind, investigates associations between extreme weather events, patient demographics, and self-reported disease flares.

Methods: An online survey was distributed to U.S. individuals with autoimmune and rheumatic diseases, collecting data on demographics, diagnoses, self-reported flares, and exposure to extreme weather events (e.g., floods, wildfires). It also assessed healthcare utilization, treatment disruptions, mental health impacts, and barriers to medical access post-extreme

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

weather. Respondents were grouped based on whether their disease flare occurred within 90 days of their most severe extreme weather event or not. Chi-square analyses examined associations between flares, demographics, weather events, and healthcare access.

Results: Among 155 participants, 88 participants (57%) reported having a disease flare within the period investigated. Participants with polymyalgia rheumatica (50% vs. 10.5%, p = 0.004) and rheumatoid arthritis (24% vs. 9.8%, p = 0.045), were more likely to experience flares within 90 days of their most severe extreme weather event exposure when compared with individuals who did not have the specified disease. Conversely, those with Raynaud's phenomenon (2.7% vs. 14.9%, p = 0.046) and Sjogren's disease (2.8% vs 14.8%, p = 0.052) were less likely to experience a flare within 90 days of their most severe extreme weather event.

Additionally, participants who were unable to store medication safely (75% vs. 10.4%, p < 0.001) or who had trouble remembering key details of the event (60% vs. 20.8%, p = 0.044) following their most severe extreme weather event were more likely to experience flares within 90 days of this event compared to individuals who did not have those characteristics.

Finally, participants who identified as Black (33.3% vs. 10.3%, p = 0.018) were more likely to experience flares within 90 days of their most severe extreme weather event compared to individuals who did not identify as Black.

Conclusion: Difficulty storing medication, specific diseases (polymyalgia rheumatica, rheumatoid arthritis), and identifying as Black were associated with increased flare risk within 90 days following extreme weather events. These findings point to possible mechanisms—like improper medication storage—and reinforce evidence that climate change disproportionately affects vulnerable populations, including racial and ethnic minorities. This exploratory project lays the foundation for future research and education aimed at improving patient resilience to climate change. Next steps include developing a shorter survey focused on the timing and location of severe weather events and flares, and expanding survey dissemination in the U.S. and internationally to better understand the link between severe weather and autoimmune disease flares.

Session Title: (0145–0174) Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Anti-diabetic medications often have effects on other conditions. GLP1 agonists (GLP1a) have shown protective effects on OA outcomes in trials and short-term trial emulations, but many patients stop treatment and long-term outcomes are unknown. To assess the effectiveness of GLP1a accounting for treatment discontinuation or switching, we selected SGLT2 inhibitors (SGLT2i) as an active comparator, which have pleiotropic effects and are

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Five-Year Risk Ratios, and Risk Differences for Knee Replacement (KR) and Osteoarthritis (OA) Outcomes

Comparison	Outcome	Analysis	Risk Ratio (95% CI)	Risk Difference per 1,000 (95% CI)
GLP1a vs. SGLT2i	KR	PP	1.18 (1.05, 1.33)	8.5 (15.4, 2.5)
		ITT	1.00 (1.00, 1.00)	0.0 (0.0, 0.0)
	OA	PP	1.16 (1.10, 1.23)	23.3 (33.2, 15.1)
		ITT	1.00 (1.00, 1.00)	0.2 (0.1, 0.3)
Semaglutides vs. SGLT2i	KR	PP	1.05 (0.78, 1.12)	-2.5 (-14.5, 5.2)
		ITT	1.00 (1.00, 1.00)	0.0 (0.0, 0.0)
	OA	PP	0.96 (0.88, 1.10)	-6.4 (-19.7, 14.2)
		ITT	1.00 (1.00, 1.00)	0.1 (0.0, 0.2)
Non-Semaglutide GLP1a vs. SGLT2i	KR	PP	1.23 (1.09, 1.41)	11.4 (4.8, 17.9)
		ITT	1.00 (1.00, 1.00)	0.1 (0.0, 0.1)
	OA	PP	1.19 (1.12, 1.27)	27.1 (16.9, 35.5)
		ITT	1.00 (1.00, 1.00)	0.2 (0.1, 0.3)

Risk ratios and risk differences estimates were adjusted for baseline and time-varying confounders that included demographics, diabetes, hypertension, hyperlipidemia, chronic kidney disease, COPD, obesity, knee pain, ACL/meniscus injury history, and use of NSAIDs/opioids, insulin, metformin, statins, and DPP4 inhibitors.

efficacious in several diseases. We compared the effectiveness of GLP1a vs. SGLT2i on the 5-year risk of knee replacement (KR) and OA, using per-protocol analyses to account for treatment discontinuation or switching, addressing limitations of prior intention-to-treat (ITT) analyses that assumed sustained treatment and ignored time-varying confounding.

Methods: We emulated a target trial using 2015–2022 Merative MarketScan Commercial Claims data, including persons aged 45-65 initiating GLP1a or SGLT2i GLP1a with at least 1 year of continuous enrollment and a washout period (with no prior use of either drug). Exclusions included a prior diagnosis of fibromyalgia, rheumatoid arthritis, or any claims for KR (the primary outcome) or OA (the secondary outcome) before drug initiation. Baseline and time-varying confounders included in the model are shown in the Table 1. We used parametric g-formula for per-protocol analyses, modeling time-varying hazards with pooled logistic regression to estimate cumulative risks of treatment with GLP1a SGLT2i vs. SGLT2i. GLP1a, accounting for censoring due to discontinuation, switching, loss to follow-up, or study end (5 years). Of GLP1a, because semaglutides cause greater weight loss than earlier GLP1a, they may be uniquely beneficial in OA. Thus, we carried out sensitivity analyses to assess 5-year outcome risk comparing semaglutides vs. SGLT2i and non-semaglutide GLP1a drugs vs. SGLT2i. We further carried out ITT analyses to highlight the impact of non-adherence on risk estimates.

Results: Among 323,445 eligible individuals (129,603 GLP1a initiators and 193,842 SGLT2i initiators, mean age 55, 49% male, 61% with diabetes [72% GLP1a, 53% SGLT2i]), per-protocol analyses showed that 5-year risk of KR was 18% greater in GLP1a users vs. SGLT2i users (Table 1; risk ratio = 1.18, risk difference: 8.5 more KR cases per 1,000 in GLP1a initiators). For OA, GLP1a users had a 16% greater risk (Table 1: risk ratio = 1.16; risk difference: 23.3 more OA cases per 1,000 in GLP1a initiators). In contrast, sensitivity analyses showed no significant KR or OA risk differences for semaglutides vs. SGLT2i, whereas non-semaglutatides vs. SGLT2i showed reduced risks in SGLT2i users (Table 1). ITT analyses, ignoring drug discontinuation or switching, showed no significant differences for either outcome (Table 1).

Conclusion: GLP1a's increased risk of KR and OA onset compared with SGLT2i, suggesting SGLT2i may have previously unrecognized therapeutic effects in OA. Semaglutides and SGLT2i showed similar effects on KR and OA despite semaglutide's well-recognized weight loss effects. Our results also suggest that ITT analyses may not accurately reflect long term risks of drugs on OA outcomes, especially for drugs where discontinuation or switching is common.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0145–0174) Epidemiology & Public Health Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Environmental influences affect the human body throughout life, from conception to old age. The influence of air pollution and fine dust particles on systemic diseases, particularly rheumatoid arthritis (RA), has been studied in various regions, but has not yet been comprehensively recorded for Germany. Therefore, the aim of this study is to describe the associations between air pollution and the prevalence and disease activity of RA in Germany.

Methods: In the German National Cohort (NAKO) Health Study, medical histories and examination findings were collected from a total of 204,729 individuals (18-69 years of age) in a population sample from 18 study centers between 2014 and 2019. In addition, 23,456 individuals underwent a clinical hand examination of 20 joints for pain and swelling by trained examiners (Level 2 subcohort), enabling the calculation of DAS28 as a measure of rheumatic disease activity. Cumulative and daily air pollution levels were made available for the NAKO study regions by the Environmental Data Unit in Munich (air pollutants (UBA: particulate matter particle size (PM) 2.5, PM10, nitrogen oxide (NO2), and ozone (O3)) to the nearest 1 km from the place of residence on a daily basis; air pollutants (ELAPSE: PM2.5, NO2, O3, black carbon (BC)) to the nearest 100 m for 2010. The analyses were adjusted for age, sex, smoking status, BMI, and income.

Results: RA was known in 4033 individuals of the total cohort (1.97%) and 426 individuals (1.82%) of the Level 2 cohort. Disease activity in the cohort was low (mean DAS28 1.37, standard deviation 1.03). The occurrence of RA was positively associated with age (10-year OR = 1.65 [95% CI: 1.59-1.71]) and female sex (OR = 2.67 [2.46-2.90]). Individuals with RA were on average 57 years old (vs. 50 years old in those without RA), and 71% were female (50%). 39% (vs. 44%) reported never smoking, 36% (vs. 32%) reported previously smoking, and 18% (vs. 20%) were currently smoking.

Table 1

Table 1: Effect sizes of environmental influences on the incidence of RA evaluated in the Level 1 cohort (n = 204,729) and the DAS28 evaluated in the Level 2 RA cohort (n = 426). All effect sizes refer to scaled variables (mean 0, variance 1).

Variables with 95% confidence interval	Odds Ratio for RA n= 204,729 (Level 1 Cohort)	Mean change DAS28 n=426 (Level 2 RA Cohort)
PM2.5 (2010)	0.99 [0.95;1.03]	0.13 [0.03;0.22]
NO2 (2010)	0.93 [0.90;0.97]	0.08 [-0.01;0.17]
O3 (2010)	1.02 [0.98;1.06]	-0.08 [-0.19;0.03]
Black Carbon (2010)	0.94 [0.90;0.98]	0.07 [-0.02;0.17]
PM2.5 (2017)	1.01 [0.97;1.05]	0.14 [0.02;0.25]
PM10 (2017)	1.01 [0.97;1.05]	0.14 [0.03;0.26]
NO2 (2017)	0.93 [0.89;0.97]	0.10 [0.01;0.19]
O3 (2017)	1.03 [0.99;1.07]	-0.12 [-0.21;-0.03]

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The historical (ELAPSE) and daily (UBA) environmental pollution levels of the respective place of residence showed a strong association with DAS28. Fine dust particle pollution for PM2.5 and PM10, NO2, and BC were positively associated with RA disease activity. In contrast, ozone pollution showed a negative association with disease activity. There was no clinically relevant effect of particulate matter pollution on the frequency of RA for PM2.5 and PM10, NO2, and BC for either the current or historical measurements, although the frequency was lower at higher ozone levels.

Conclusion: A clinically relevant association of disease activity with all air pollutant exposures for RA was demonstrated in the population sample of over 200,000 individuals. However, a relevant association between air pollutant exposure at the current place of residence and the occurrence of RA could not be demonstrated. The cross-sectional results presented here will also be prospectively examined in the NAKO cohort for 20 years to provide stronger conclusions regarding causality, particularly with regard to the different frequencies observed in the study centers.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0145–0174) Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune, systemic disease with a rising U.S. healthcare burden. Utilizing Global Burden of Disease (GBD) 2021 estimates, we analyzed sex, age, and state specific trends in prevalence, incidence, Disability-Adjusted Life Year (DALY), and death, including attributable smoking burden.

Methods: We performed a descriptive analysis with GBD 2021 estimates for RA in all 50 U.S. states and District of Columbia from 1990 to 2021. Age-standardized prevalence, incidence, DALY, and death rates were stratified by sex and age group. Choropleth maps were created to display geographic disparities, and box plots were employed to compare inter-state variation and gender differences. States were also grouped based on the magnitude and temporal trends of smoking-attributable RA DALY percentages.

Results: Montana, Wyoming, and New Mexico consistently ranked among the top three states for overall RA burden, with Montana showing highest age-standardized prevalence (464.73 per 100,000) and DALY rate (73.17). The District of Columbia, California, and Mississippi reported the lowest prevalence and DALY rates. RA burden increased progressively with age.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

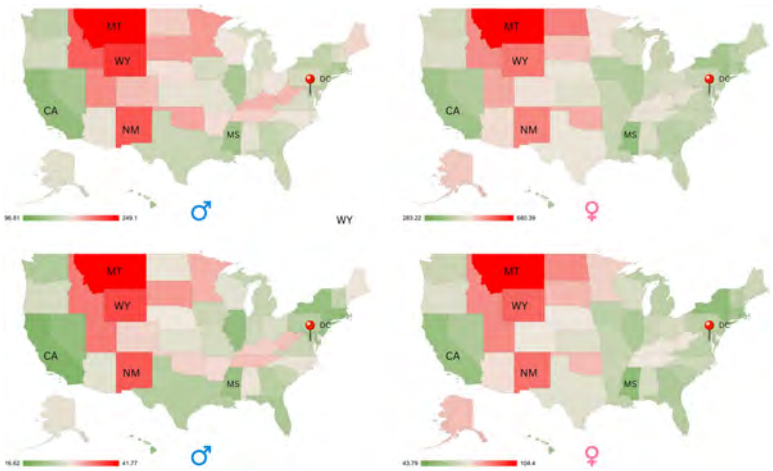

Figure 1: U.S. state-level choropleth maps showing the age-standardized burden of rheumatoid arthritis (RA) by sex. The top row depicts age-standardized prevalence rates in males (left) and females (right). The bottom row shows age-standardized DALY (disability-adjusted life year) rates in males (left) and females (right). Color gradients range from green (lower burden) to red (higher burden). Montana consistently shows the highest burden across both prevalence and DALY measures, especially among females. In contrast, states such as California and the District of Columbia demonstrate lower burden. Across all maps, females show higher RA burden compared to males, highlighting persistent sex-based disparities.

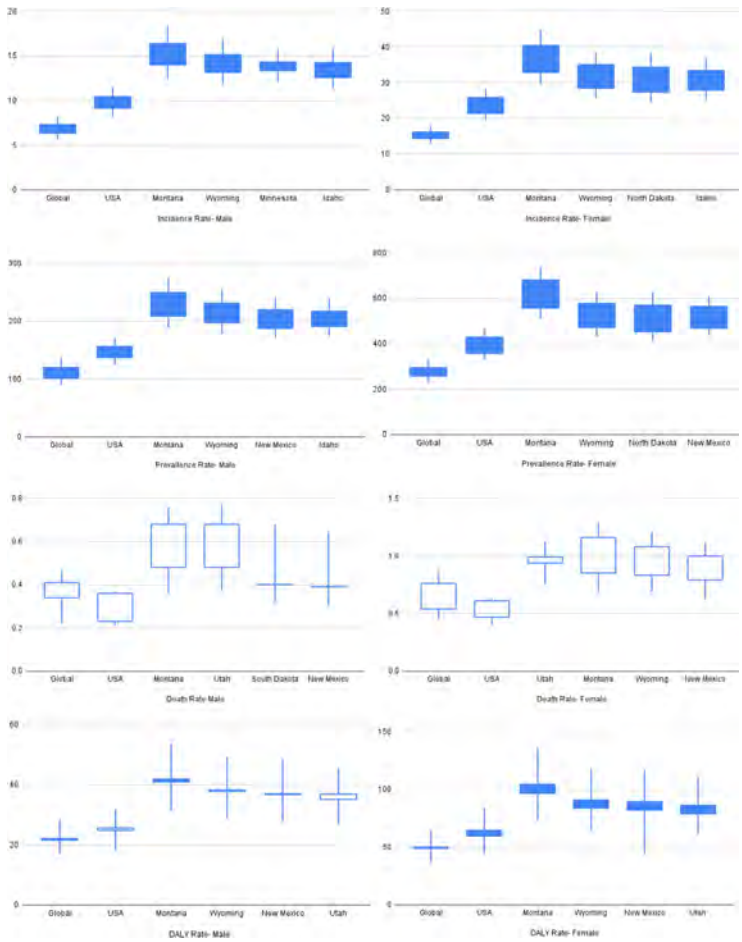

Figure 2: Boxplots illustrating age-standardized burden of rheumatoid arthritis (RA) from 1990 to 2021 across global, U.S., and high-burden states by sex and metric. The plots compare male (left column) and female (right column) data across six domains: incidence rate, prevalence rate, death rate, and DALY rate. Each box represents the interquartile range (IQR) of the metric, with the filled boxes indicating an increase and unfilled boxes indicating a decrease between 1990 and 2021. The central vertical whisker spans the widest confidence interval limits (i.e., from the lowest lower bound to the highest upper bound of both years), indicating the maximum possible uncertainty range over time. The x-axis includes Global, USA, and the top four high-burden U.S. states identified for each metric. Notably, Montana and Wyoming appear consistently among the highest for most metrics, particularly in females, who show greater overall burden across incidence, prevalence, DALY, and death.

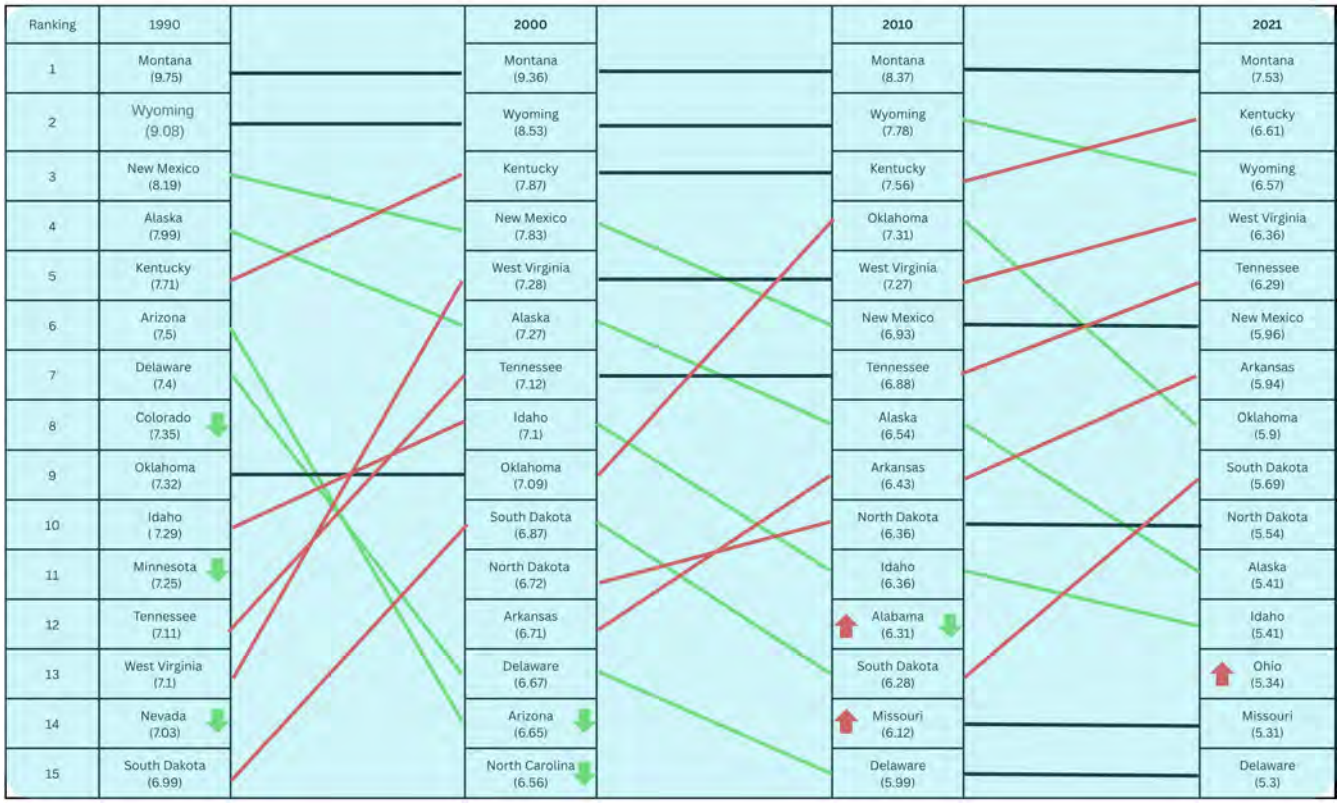

Figure 3: Trends in the top 15 U.S. states by age-standardized DALY rate attributable to smoking-related rheumatoid arthritis (RA) from 1990 to 2021. Each column represents rankings by year (1990, 2000, 2010, 2021), with corresponding DALY rates in parentheses. Black lines indicate unchanged rank from one time point to the next. Green lines indicate a decrease in rank (i.e., improvement/lower disease burden). Red lines indicate an increase in rank (i.e., worsening disease burden). Green downward arrows denote states that were ranked in the top 15 in respective time frame but dropped out by 2021. Red upward arrows denote states that entered the top 15 in respective time frame by 2021. This visualization reflects geographic and temporal disparities in smoking-attributable RA burden across the U.S., highlighting states with persistently high burden (e.g., Montana, Kentucky) and those showing worsening trends (e.g., Arkansas, South Dakota).

The 55+ group had the highest rates across all parameters (DALY: 162.8; incidence: 46.98; prevalence: 1014.63; death: 2.16), while individuals under 20 had minimal burden (DALY: 4.44; death: 0.00).Females had consistently higher burden than males across all states and age groups. For example, Montana's female DALY rate was 104.4 compared to 41.77 for males.

Smoking-attributable RA DALY rates showed an overall national decline but remained highest in states such as Montana, Kentucky, and Wyoming, which consistently ranked in the top three from 1990 to 2021. West Virginia, Tennessee, and New Mexico remained within the top 10, highlighting regions of persistent burden. Meanwhile, states such as Colorado, Minnesota, and Nevada showed significant improvement, dropping out of the top 15. In contrast, Arkansas, Kentucky and South Dakota climbed the ranks, reflecting worsening trends in smoking-related RA burden in those regions.

Conclusion: Substantial disparities in RA burden exist across U.S. states, with consistently high rates observed in Montana, Wyoming, and Kentucky. These differences are further amplified by sex- and age-specific trends, with older adults and females bearing a disproportionate burden. While smoking-attributable RA DALY percentages have declined nationally, several states—particularly Kentucky, Arkansas, and Missouri—continue to show persistently high or worsening burden, suggesting gaps in tobacco control. Conversely, states such as Colorado and Minnesota demonstrate improving trends.

These findings highlight the urgent need for state-specific, gender- and age-sensitive strategies to mitigate RA burden and address modifiable risks like smoking. Targeted interventions may include stricter tobacco control policies, tailored public health campaigns, improved telehealth access for rheumatologic care, and early screening integrated into primary care for high-risk groups. Focused, equitable efforts are critical to narrowing geographic and demographic disparities in RA outcomes across the U.S.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0145–0174) Epidemiology & Public Health Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: RA-associated lung disease (RA-LD), including RA-associated interstitial lung disease (RA-ILD) and RA-associated bronchiectasis (RA-BR), is a serious extra-articular manifestation of RA that significantly contributes to morbidity and mortality. Although previous studies have documented the adverse clinical outcomes associated with RA-LD, its impact on hospitalization risk is insufficiently investigated, particularly for RA-BR.

Methods: We conducted a retrospective matched cohort study of patients enrolled in the biobank of a large U.S. health care system, comparing RA-LD cases to RA comparators without lung disease (RA-no LD), matched by calendar date, age, sex, and RA duration at the index date. The index date was defined as the later date of the RA or ILD/BR diagnosis for RA-LD cases, and the matched date for RA-no LD comparators. Patients with RA met the 2010 ACR/EULAR classification criteria. RA-LD cases were verified by medical record review and chest imaging for clinically-apparent RA-ILD and/or RA-BR. The primary outcomes were overall and respiratory hospitalizations. Secondary outcomes included emergency department (ED) visits and intensive care unit (ICU) admissions. Incidence rates were calculated per 100 person-years. Incidence rate ratios (IRRs) with 95% confidence intervals (CI) were estimated using multivariable Poisson regression models, comparing RA-LD cases vs. RA-no LD comparators as well as for RA-ILD and RA-BR cases vs. RA-no LD comparators, with adjustment for the propensity score as a covariate.

Results: We analyzed 221 RA-LD cases (151 RA-ILD and 70 RA-BR) and 980 matched RA-no LD comparators (**Table 1**). RA-LD patients had higher rates of overall hospitalization (60% vs. 41%, p< 0.001) and respiratory hospitalization (23% vs. 6%, p< 0.001), along with higher proportions of ED visits (57% vs. 48%, p=0.02) and ICU admissions (36% vs. 20%, p< 0.001, **Table 2**). RA-LD patients had a shorter time from the index date to first hospitalization (median 922 vs. 1,217 days, p=0.01) compared to RA-no LD comparators. They also had a shorter time to first respiratory hospitalization (median 1,588 vs. 2,253 days, p=0.009), including RA-ILD (median 1,707 vs. 2,253 days, p=0.03) and RA-BR (median 1,436 vs. 2,253 days, p=0.04). RA-LD, including RA-ILD and particularly RA-BR, had higher risks of overall hospitalization (adjusted IRR 1.73, 95%CI 1.57-1.91) and respiratory hospitalization (adjusted IRR 5.13, 95%CI 3.80-6.94, **Table 3**). RA-ILD was associated with an increased risk of ICU admissions (adjusted IRR 1.99, 95%CI 1.81-2.18).

Table 1. Baseline characteristics of RA-LD cases and RA-no LD comparators

Characteristics	RA-LD cases (n=221)	RA-no LD comparators (n=980)
Demographics		
Age, years (mean and SD)	63.9 (11.3)	62.3 (10.5)
Female sex, n (%)	165 (75)	743 (76)
Race		
Asian	3 (1)	13 (1)
Black	14 (6)	54 (6)
White	191 (86)	853 (87)
Other	8 (4)	37 (4)
Frailty Index, mean (SD)	0.2 (0.04)	0.1 (0.04)
Smoking		
Smoking status, n (%)		
Past	126 (57)	454 (46)
Current	15 (7)	61 (6)
Pack-years, median (IQR)	5 (0-22.5)	0 (0-12.1)
Comorbidities		
Diabetes	9 (4)	49 (5)
Heart failure	15 (7)	31 (3)
Cardiovascular disease	20 (9)	44 (4)
Solid tumor cancer	7 (3)	6 (1)
Leukemia or lymphoma	17 (8)	36 (4)
RA characteristics		
RA duration, years (median and IQR)	9.0 (0.7-18.9)	6.4 (1.8-15.0)
Seropositive	180 (81)	618 (63)
Glucocorticoids, n (%)	113 (51)	355 (37)
Any DMARDs, n(%)	136 (62)	542 (56)
csDMARDs, n (%)	108 (49)	411 (42)
bDMARDs, n (%)	82 (37)	283 (29)
tsDMARDs, n (%)	5 (2)	23 (2)
Serious infection within 365 days prior to index date, n (%)	10 (5)	18 (2)
Health care utilization		
Any hospitalization within 365 days before index, n (%)	47 (21)	107 (11)
Number of outpatient visits within 365 days before index, Median (IQR)	11 (4-23)	6 (2-15)

bDMARDs, biological disease-modifying antirheumatic drugs; csDMARDs, conventional synthetic disease-modifying antirheumatic drugs; DMARDs, disease-modifying antirheumatic drugs; IQR, interquartile range; RA-LD, rheumatoid arthritis-associated lung disease; RA-no LD, rheumatoid arthritis without lung disease; SD, standard deviation; TNFi, tumor necrosis factor inhibitor; tsDMARDs, targeted synthetic disease-modifying antirheumatic drug

Table 2. Acute care outcomes, comparing RA-LD cases and RA-no LD comparators

Variable	RA-LD (n=221)	RA-no LD (n=980)	P value
Emergency Department			
Any visit, n (%)	127 (57)	474 (48)	**0.02**
Overall Hospitalization			
Any hospitalization, n (%)	132 (60)	401 (41)	**<0.001**
Number of hospitalizations, median (IQR)	3 (1-5)	2 (1-3)	**0.001**
Time to first hospitalization (days), median (IQR), among those with any hospitalization	922 (269-1,959)	1,217 (430-2,231)	**0.01**
Length of stay of first hospitalization, median (IQR), among those with any hospitalization	4 (2-7)	3 (2-6)	0.15
Total length of stay of all hospitalizations, median (IQR), among those with any hospitalization	14 (5-33)	6 (4-21)	**0.001**
Respiratory Hospitalization			
Any respiratory hospitalization, n (%)	50 (23)	62 (6)	**<0.001**
Number of respiratory hospitalizations, median (IQR)	1 (1-2)	1 (1-1)	**0.009**
Time to first respiratory hospitalization (days), median (IQR), among those with respiratory hospitalization	1,588 (624-2,409)	2,253 (1,170-3,951)	**0.009**
Length of stay of first respiratory hospitalization, mean (SD), among those with respiratory hospitalization	6 (3-11)	4 (2-9)	0.25
Intensive Care Unit			
Any intensive care unit hospitalization, n (%)	79 (36)	196 (20)	**<0.001**
Invasive ventilation, n (%)	20 (9)	39 (4)	**0.002**

Table 3. Incidence rate ratios for acute care outcomes, comparing RA-LD cases to RA-no LD comparators

	Incidence rate (per 100 patient-years)	Multivariable** RR (95%CI)
Outcome: ED visit		
RA-no LD comparators	22.2	1.0 (Ref)
RA-LD cases	29.0	0.95 (0.86-1.04)
RA-no LD comparators	22.2	1.0 (Ref)
RA-ILD cases	28.3	0.94 (0.84-1.05)
RA-BR cases	30.8	0.96 (0.82-1.12)
Outcome: Hospitalization		
RA-no LD comparators	14.9	1.0 (Ref)
RA-LD cases	32.9	**1.73 (1.57-1.91)**
RA-no LD comparators	14.9	1.0 (Ref)
RA-ILD cases	33.2	**1.78 (1.59-1.98)**
RA-BR cases	32.3	**1.63 (1.39-1.90)**
Outcome: Respiratory hospitalization		
RA-no LD comparators	0.9	1.0 (Ref)
RA-LD cases	5.4	**5.13 (3.80-6.94)**
RA-no LD comparators	0.9	1.0 (Ref)
RA-ILD cases	5.6	**5.36 (3.88-7.40)**
RA-BR cases	5.0	**4.59 (2.93-7.01)**
Outcome: Intensive care unit		
RA-no LD comparators	12.9	1.0 (Ref)
RA-LD cases	41.5	**1.68 (1.53-1.84)**
RA-no LD comparators	12.9	1.0 (Ref)
RA-ILD cases	54.6	**1.99 (1.81-2.18)**
RA-BR cases	11.8	**0.62 (0.48-0.79)**

*RA-LD cases and RA-no LD comparators were matched by calendar date, age, sex, and RA duration at index date of RA-LD diagnosis.
**Adjusted for propensity score that included smoking status, pack-years, Frailty Index, Charlson Comorbidity Index score, serostatus, glucocorticoids, csDMARDs, bDMARDs, previous serious infection, previous hospitalization, and health care utilization.

Conclusion: RA-LD was associated with higher risks of overall hospitalization, respiratory hospitalization, and ICU admissions than RA-no LD comparators. RA-BR had a similarly elevated hospitalization risk as RA-ILD, illustrating an unreported unmet need in this population. These findings highlight the need for targeted strategies to prevent and manage acute care utilization in RA patients with lung involvement.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0145–0174) Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Interstitial lung disease (ILD) is a serious pulmonary manifestation that can occur across all connective tissue disorders (CTD). Aberrant immune-mediated inflammation and fibrosis leads to symptoms like dyspnea, cough, and respiratory failure, making ILD a major contributor to CTD morbidity and mortality. To better understand unmet therapeutic needs, characterization of real-world patient burden and treatment patterns is required. While epidemiologic studies have typically focused on single CTD populations, this study describes patient characteristics, comorbidities, and treatment utilization across a broad range of CTD-ILDs using a large electronic health record (EHR) database.

Methods: This retrospective cohort study (GSK Study 219992) used an Optum® de-identified EHR dataset of an incident cohort of patients with CTD-ILD diagnosed from 2018–2023. Published definitions and algorithms were used to identify CTD subtypes (RA, SSc, SLE, idiopathic inflammatory myopathies [IIM], MCTD, SS). Diagnoses of ILD after or within 365 days prior to CTD diagnosis were identified, with index being the first valid ILD diagnosis date within the study period. Baseline was 1 year prior to index. Patient follow-up was until death, discontinuation, or end of study period (Dec 31, 2023). Outcomes included baseline comorbidities and clinical characteristics, and treatment use.

Results: Baseline characteristics of eligible US patients with CTD-ILD by CTD subtype are shown in **Table 1**. ILD was diagnosed within ±1 year of CTD diagnosis in most patients (54–83%). Patients with RA and SLE were most likely to receive an ILD diagnosis >1 year after CTD (46% and 41%, respectively). Overlap with other CTD subtypes occurred in 11–38% of patients. The most frequently reported ILD symptom during the baseline period was dyspnea across all CTD subtypes (56–66%).

Around 25% of patients in each CTD subtype had ≥3 comorbidities (**Table 2**). There was a high burden from infections requiring hospitalization (29–45% by CTD subtype), of which ∼60% were due to acute respiratory infection.

Table 1. Patient and clinical characteristics at baseline. IQR, interquartile range.

		IIM ILD	MCTD ILD	RA ILD	SLE ILD	SSc ILD	SS ILD

Figure. Treatment use by CTD-ILD type at baseline and 12 months. IS comprised cyclophosphamide, mycophenolate, azathioprine, methotrexate, calcineurin inhibitors, leflunomide; TNFi comprised etanercept, adalimumab, infliximab, golimumab, certolizumab pegol; anti-IL-6 comprised tocilizumab, sarilumab; anti-fibrotic agents comprised pirfenidone, nintedanib; JAK inhibitors comprised tofacitinib, baricitinib, upadacitinib. IVIG, intravenous immunoglobulin; JAK, Janus kinase; TNFi, tumor necrosis factor inhibitor.

At baseline, 31–55% of patients were not receiving any oral/IV glucocorticoids (GC), immunosuppressants (IS), or advanced therapies across CTD subtypes. GC and IS were the most common treatments across all CTD-ILDs at any time (**Figure**). There was an increase in therapy following ILD diagnosis, with the proportion of patients receiving any treatment increasing from 45–70% at baseline to 74–88% in the first year. Even at the peak of treatment use in the first year, 12–26% of patients did not receive any oral/IV GC, IS, or advanced therapies. A trend of decreasing proportions of patients receiving any treatment was observed after the first year.

Conclusion: Patients with CTD-ILD suffer considerable chronic comorbidities that often have overlap with other CTDs, leading to high disease burden on healthcare systems and complex clinical management. Symptom burden and infections requiring hospitalization were high, highlighting a need for earlier diagnosis and treatment initiation. The observation that treatment use tended to decrease after the first year suggests an unmet need for optimal therapeutic management remains.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0145–0174) Epidemiology & Public Health Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Although rheumatoid arthritis (RA) is a known risk factor for heart failure (HF), a limited number of studies has explored the association based on HF subtype (ischemic and non-ischemic), RA serostatus, or use of biologic or targeted synthetic disease-modifying anti-rheumatic drugs (b/tsDMARDs).

We aimed to evaluate the association between RA and subsequent risk of HF, focusing on ischemic and non-ischemic HF, as well as the role of RA serostatus (seropositive RA [SPRA] , seronegative RA[SNRA]) and the use of b/tsDMARDs.

Methods: This retrospective cohort study utilized nationwide population data from the National Health Insurance Service (NHIS) of Korea. The study analyzed 46,975 RA patients (33,424 SPRA, 13,551 SNRA) diagnosed in 2010–2017, along with 140,925 matched non-RA patients in a control group. Participants were followed from 1 year after RA diagnosis (to mitigate surveillance bias) until December 31, 2020. The primary outcome was newly diagnosed HF, classified as ischemic or non-ischemic.

Results: During follow-up, 615 new HF cases were identified (238 in the RA group, 377 in the control group). The RA patients had a higher risk of overall HF (adjusted hazard ratio (aHR) 1.97, 95% confidence interval (CI) 1.64-2.26), and risk was more prominent for ischemic HF (aHR 2.24, 95% CI 1.86-2.71) than non-ischemic HF (aHR 1.36, 95% CI 0.97-1.90). SPRA was associated with a higher risk than SNRA for overall HF (aHR 2.13, 95% CI 1.78-2.55 for SPRA and 1.59, 1.19-2.11 for SNRA compared to the control group) and non-ischemic HF (aHR 2.31, 95% CI 1.03-5.17 for SPRA and 0.71, 0.32-1.51 for SNRA) but not for ischemic HF (aHR 2.37 for SPRA and 1.94 for SNRA). Risk for HF was more prominent for bDMARD users than non-users for overall (aHR 3.16 vs. 1,89), ischemic (3.53 vs. 2.16), and non-ischemic HF (2.39 vs. 1.28). The effect of tsDMARDs could not be determined due to an insufficient number of HF events in these users.

Conclusion: This study demonstrates that RA was associated with both ischemic and non-ischemic HF, and that the association was stronger for ischemic HF. While the risk for ischemic HF was higher for both SPRA and SNRA, the risk for non-ischemic HF was higher only for SPRA and not for SNRA. bDMARDs do not seem to reduce but may instead increase the risk of HF.

The Association Between Short-Term Trajectory Of Atmospheric Particulate Matter 10 (PM10) Concentration And Hyperuricemia

Sunggun Lee[1], Minyoung Her[1], Seong-HO Kim[1], Yong-Gil Kim[2] and Ji Seon Oh[2], [1]Department of Internal Medicine, Haeundae Paik Hospital, Inje University College of Medicine, Busan, Republic of Korea, [2]Division of Rheumatology, Department of Internal Medicine, University of Ulsan College of Medicine, Asan Medical Center, Seoul, South Korea, Seoul, Republic of Korea

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0145–0174) Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: The association between high atmospheric particulate matter concentration and gout flare has been reported[1], but the causality and mechanism of this association remain unknown. We studied the association between trajectories of particulate matter concentration and hyperuricemia.

Methods: The seventh Korean National Health and Nutrition Examination Survey (2016–2018) linked air pollution concentration data was used. Trajectories of atmospheric particulate matter ≤10 μm (PM_{10}) concentrations from the day of serum uric acid measurement to 14 days prior (a total of 15 days) were clustered based on measures selected from principal component analysis. Hyperuricemia was defined as ≥7.0 mg/dL for men and ≥6.0 mg/dL for women. The association between the prevalence of hyperuricemia and quartiles of mean PM_{10} concentration or trajectories of PM_{10} concentration in the previous 15 days was modeled using generalized additive models, including age, sex, household income, obesity, chronic kidney disease, alcohol intake, mean temperature (spline), and mean relative humidity (spline). The associations were tested using weighted logistic regression models.

Results: The prevalence of hyperuricemia was 20.5% (95% confidence interval [CI], 19.2%–21.9%) in men and 6.1% (95% CI 5.5%–6.8%) in women. Mean PM_{10} concentration in the 15 days was 48.6 ng/mL (95% CI 47.4–49.9). There were three short-term trajectories of atmospheric PM_{10} concentrations: decreasing (N=4289, 32%), increasing (N=4724, 34%), and rapidly increasing (N=4688, 34%) (figure 1). There was no significant association between hyperuricemia and quartiles of mean PM10 concentration in prior 15 days; Q1: reference, Q2: odds ratio [OR] 0.81 (95% CI 0.69–0.96), Q3: OR 0.89 (95% CI 0.74–1.07), and Q4: OR 0.86 (95% CI 0.71–1.04). However, the short-term trajectory of PM10 levels was significantly associated with hyperuricemia. Compared with the decreasing trajectory, the increasing (OR 0.88 [95% CI 0.76–1.00], P = 0.056) and rapidly increasing (OR 0.85 [95% CI 0.74–0.97], P = 0.018) trajectories were negatively associated with hyperuricemia. When the association was analyzed using weighted generalized linear models, there was a similar trend for negative association between hyperuricemia and the rapidly increasing trajectory; decreasing trajectory: reference, increasing trajectory: OR 0.93 (95% CI 0.79–1.09, P-value 0.251), rapidly increasing trajectory: OR 0.89 (95% CI 0.75–1.07, P-value 0.081). In the receiver operating characteristic curve analysis, model discrimination was significantly better using the GAM model (Model 1 in figure 2, $P < 0.001$).

Conclusion: Compared with decreasing trajectory, rapidly increasing trajectory of atmospheric PM_{10} concentration was associated with lower prevalence of hyperuricemia. The results suggest that the mobilization of urate crystals may be the cause of gout flares associated with air pollution. This hypothesis must be validated through longitudinal studies.

Cancer Screening for Patients with Rheumatic Diseases: A Scoping Review

Teresa Xiao[1], Namrata Singh[2] and Pankti Reid[3], [1]University of Chicago, Chicago, IL, [2]University of Washington, Bellevue, WA, [3]University of Chicago Medical Center, Chicago, IL

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0145–0174) Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: There is minimal guidance on specific cancer screening practices for rheumatic diseases (RDs) other than for myositis. The aim of this scoping review was to evaluate the available evidence on the risk of cancer for various RDs and associated risk factors.

Methods: We evaluated cancer associations and risk factors associated with incident cancer development for key systemic RDs: RA, SSc, and SS. We conducted a comprehensive literature search via PubMed to identify relevant publications with the following search terms: ''systemic sclerosis'' or ''Sjogren's disease'' or ''rheumatoid arthritis'' and ''cancer'' or ''malignancy'' or ''risk'' or ''risk factors.'' Data for cancer associations was limited to meta-analyses. Associated risk factors for incident cancer were obtained from meta-analyses and retrospective/prospective observational studies.

Results: We reviewed 19 manuscripts: 6 for cancer associations and 13 for risk factors. There were 3 meta-analyses for RA, 3 for SSc, and 1 for SS that reflected standardized incidence ratios (SIRs) for cancer. SS had 6 publications describing risk factors associated with cancer, followed by SSc (4) and RA (3). SSc was most commonly associated with liver cancer or lung cancer, RA with lymphoma and SS with hematologic malignancies, in particular non-Hodgkin's lymphoma (Table 1). Incident cancer risk for SSc was most commonly associated with anti-transcriptional intermediary factor 1 (TIF-1γ) positivity (Table 1).

Table 1. Cancer associations and risk factors for incident cancer in SSc, RA, and SS.

Rheumatic Disease	Cancer Associations	Risk factors for Incident Cancer	References
SSc	Liver cancer (SIR 4.36) Lung cancer (SIR range 3.14-3.18)	Anti-TIF-1-γ (OR 19.5) Anti-RNA polymerase III (OR 10.9) Anti-Scl-70 (OR 2.55) Anti-U1 RNP (OR 5.54) ILD (HR 2.85)	Onishi et al., 2013 Zhang et al., 2013 Sieiro Santos et al., 2022 Sakr et al., 2018 Hsu et al., 2021
RA	Lymphoma (SIR range 2.26-3.21)	RF and anti-CCP positivity (HR 6.29)* ILD (HR 3.25)*	Simon et al., 2015 Chatzidionysiou et al., 2022 Brooks et al., 2024
SS	Non-Hodgkin's lymphoma (SIR 13.71)	Low C3 levels (HR 36.65) Low C4 levels (HR 39.70) Lymphocytopenia (HR 16.47)	Zhang et al., 2022 Solans-Laque et al., 2011

*associated with lung cancer specifically
SSc = systemic sclerosis; RA = rheumatoid arthritis; SS = Sjogren's syndrome; Anti-TIF-1-γ = anti-transcriptional intermediary factor 1 gamma antibody; anti-Scl-70 = scleroderma antibody or anti-topoisomerase I antibody; Anti-U1 RNP = anti-U1 ribonucleoprotein antibody; ILD = interstitial lung disease; RF = rheumatoid factor; anti-CCP = anti-cyclic citrullinated peptide antibody

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

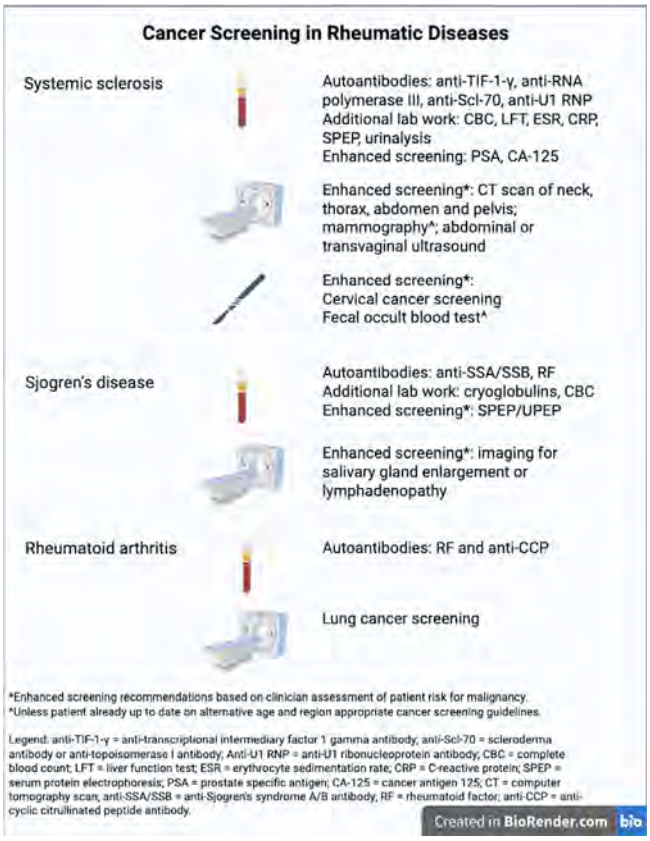

Figure 1. Cancer screening in rheumatic diseases.

RF and anti-CCP positivity were associated with lung cancer for patients with RA (Table 1). SS literature identified the highest cancer association with low complement levels and lymphocytopenia (Table 1). For RA and SSc, interstitial lung disease (ILD) was identified for both as a risk factor associated with malignancy.

Conclusion: RA, SSc, and SS are uniquely associated with different cancers. High-powered prospective studies to inform evidence-based, expert driven screening guidelines are needed to identify effectiveness of various cancer screening recommendations and guide appropriate clinical care.

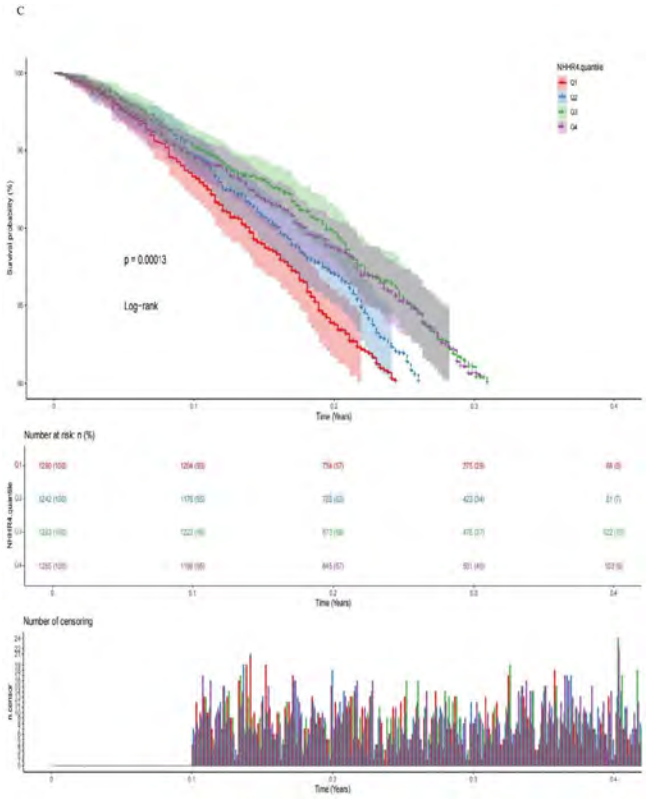

Figure 2 presents the survival analysis of RA patients. Panel A shows the survival area plot, illustrating the survival probabilities of RA patients over time. Panel B displays the survival contour plot, showing the survival probability at specific time points for RA patients. Panel C presents the survival curves by NHHR quartiles (Q1-Q4), highlighting the impact of different groups on survival probability. In Panel A, the color gradient (from red to blue) reflects changes in RA values over time. Higher RA values (red) are associated with higher survival probabilities, while lower RA values (blue) correspond to lower survival probabilities. In Panel B, S(t) represents the survival probability at various time points, ranging from 0 to 1. The color bar indicates different intervals of the survival function, with colors transitioning from purple to yellow, representing survival probabilities from low to high. Panel C features survival curves at the top: Q1 in red, Q2 in blue, Q3 in green, and Q4 in purple. The middle section shows the risk table, displaying the number of individuals at risk for each group (Q1, Q2, Q3, Q4) at each time point, with the remaining proportion for each group in parentheses. The bottom section represents censored events, with a histogram displaying the censoring status at different time points, color-coded by quartile group. Differences between survival curves across groups were tested using the Log-rank test.RA,Rheumatoid arthritis.

Background/Purpose: The Non-High-Density Lipoprotein Cholesterol to High-Density Lipoprotein Cholesterol Ratio (NHHR) has emerged as a promising marker for atherosclerosis, yet its relationship with all-cause mortality in individuals with rheumatoid arthritis (RA) remains poorly understood. This study aims to explore the association between NHHR and mortality in adults with RA.

Methods: Data from the National Health and Nutrition Examination Survey (NHANES) spanning 2007 to 2016 were analyzed, with participants stratified into quartiles based on their NHHR levels. Key covariates included age, gender, body mass index (BMI), C-reactive protein (CRP), and the presence of comorbidities. Subgroup analyses were conducted to assess how the association between NHHR and mortality risk varied across different age groups, sexes, and comorbidity profiles, with interaction effects tested using likelihood ratio tests. Multivariable Cox proportional hazards models were applied to estimate the relationship between NHHR and all-cause mortality risk. Kaplan-Meier survival curves were generated to visualize survival differences among NHHR quartiles, and restricted cubic spline models were employed to explore potential non-linear associations. Sensitivity analyses were also performed to evaluate the robustness of the findings by excluding extreme NHHR values.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

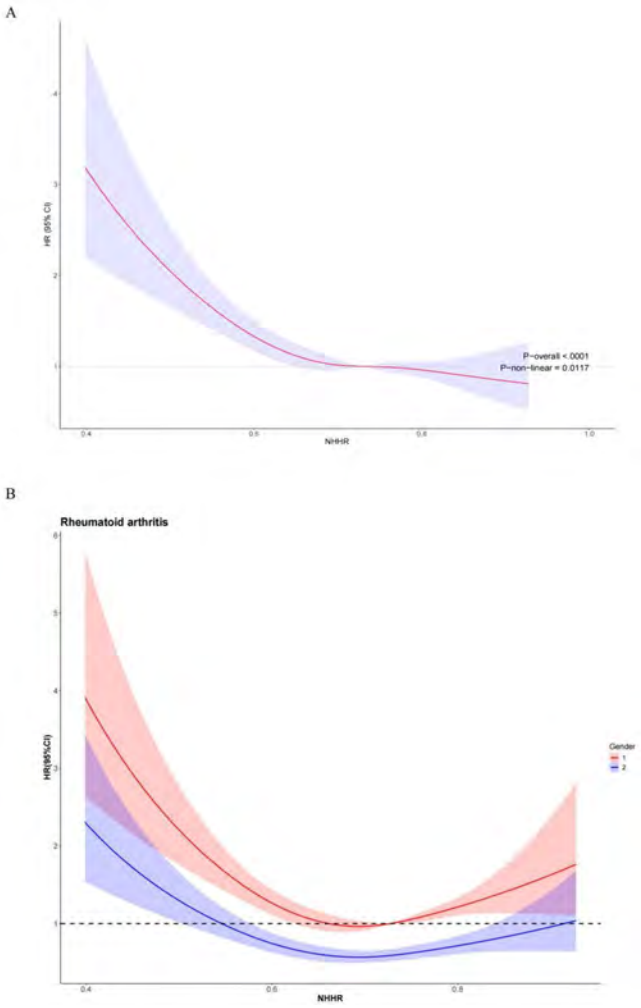

Figure 4 illustrates the relationship between NHHR and all-cause mortality in patients with rheumatoid arthritis using restricted cubic splines (A), with stratified analyses by gender (B), race (C), and education level (D). The analysis was adjusted for age, gender, race/ethnicity, marital status, education level, household poverty-to-income ratio, BMI, CRP, smoking, alcohol consumption, hypertension, diabetes, stroke, coronary heart disease, and cancer history. Solid and dashed lines represent the estimated values and their corresponding 95% confidence intervals, respectively. BMI: Body Mass Index; CRP:C-reactive protein,HR: Hazard Ratio. Gender group: 1 represents Male, 2 represents Female. Race group: 1 represents Mexican American, 2 represents Non-Hispanic Black, 3 represents Non-Hispanic White, 4 represents Other Hispanic, 5 represents Other Race. Education level group: 1 represents Less than 9th grade, 2 represents 9-11th grade, 3 represents High School, 4 represents Some college or AA degree, 5 represents College graduate or above.

Results: Significant variations in baseline characteristics were observed across NHHR quartiles, including differences in age, BMI, cholesterol levels, and comorbidities. Higher NHHR values were associated with increased BMI, total cholesterol, and CRP levels, while individuals in the lowest NHHR quartile showed a higher prevalence of hypertension, diabetes, and coronary heart disease (CHD). NHHR was inversely associated with CHD and showed a positive association with diabetes, though the latter lost significance after adjusting for covariates. A U-shaped relationship was identified between NHHR and all-cause mortality in RA patients, with a risk threshold around 0.575. Kaplan-Meier analysis indicated improved survival with increasing NHHR levels (Log-rank P=0.00013), particularly among older adults (HR = 0.18) and cancer survivors (HR = 0.18). The initial associations were attenuated after covariate adjustment, and sensitivity analyses confirmed the robustness of the findings (bias = −0.024).

Conclusion: NHHR has emerged as a valuable prognostic marker in RA, demonstrating a U-shaped relationship with all-cause mortality, with a critical threshold of 0.575. Its predictive capacity supports the early identification of high-risk individuals, enabling personalized interventions to enhance patient survival and optimize RA management strategies.

Abstract Number: 0174

Genetic and Environmental Risk Factors and Incident Rheumatoid Arthritis

Xuesen Zhao[1], Puran Nepa[2], Hui Yu[3], Laura Daniel[2], Vivian Kawai[4], Michael Stein[5], Yan Guo[3] and Cecilia Chung[3], [1]University of Miami, Miami, FL, [2]University of Miami, Research Service, Miami VA Healthcare System, Miami, FL, [3]University of Miami, Miami, [4]University of Alabama at Birmingham, Birmingham, AL, [5]Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0145–0174) Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: While some studies have linked air pollution to risk for rheumatoid arthritis (RA), U.S.-based studies utilizing nationwide exposure data remain limited and often exclude the combined effect of genetic factors. Given the rising pollution level, it is essential to integrate environmental and genetic factors to better identify individuals at risk for RA and to inform prevention strategies.

Methods: This case-control study used data from NIH *All of Us v8* (AoU). We included participants with short read whole genome sequencing (srWGS) data. A case of RA was defined by three criteria: a) 3 or more encounters with RA-related ICD-9/10 codes, b) prescription of RA-specific medications, c) exclusion of patients with other concurrent autoimmune diseases. Incident RA cases required at least 1 year of electronic health record (EHR) preceding their earliest RA diagnosis. Control subjects did not meet any of the three criteria and had at least 1 year of EHR before their last recorded ICD codes. Cases and controls were 1:10 frequency-matched on age, sex, race, and the duration from the earliest to the latest recorded encounter. Genetic risk was quantified by a polygenic risk score (PRS) based on 92 RA-related genetic variants.

Table 1. Multivariate Cox Regression Analyses of Risk Factors for RA onset adjusted for demographics and smoking history

Variable	Unit	HR (95% CI)	P
PRS		1.25 (1.12, 1.40)	<0.001
Age	Year	1.00 (0.99, 1.01)	0.822
Sex: Male vs Female		1.05 (0.78, 1.42)	0.738
Race: White vs Black		2.10 (1.55, 2.83)	<0.001
Income: 100-150 vs <25	Thousands per year	0.35 (0.22, 0.56)	<0.001
Income: ≥150 vs <25	Thousands per year	0.35 (0.20, 0.60)	<0.001
Income: 25-50 vs <25	Thousands per Year	0.63 (0.45, 0.88)	0.007
Income: 50-100 vs <25	Thousands per Year	0.45 (0.32, 0.64)	<0.001
Education: Advanced Degree vs Less than High School		0.51 (0.26, 0.99)	0.048
Education: College Graduate vs Less than High School		0.64 (0.34, 1.20)	0.164
Education: High School vs Less than High School		0.79 (0.43, 1.43)	0.435
Education: Some College vs Less than High School		0.81 (0.45, 1.44)	0.469
Smoked 100 cigarettes: Yes vs No		1.19 (0.93, 1.51)	0.16
PM2.5 - Local Conditions	Micrograms/cubic meter (LC)	1.38 (1.30, 1.46)	<0.001
Sulfur dioxide	Parts per billion	1.10 (1.06, 1.15)	<0.001
Ozone	Parts per billion	1.10 (1.03, 1.17)	0.003
Lead (TSP) STP	Micrograms/cubic meter (25 C)	6.76 (2.00, 22.82)	0.002
Average Ambient Pressure	Millimeters (mercury)	1.00 (0.99, 1.01)	0.405
Nitrogen dioxide (NO2)	Parts per billion	0.93 (0.90, 0.96)	<0.001

*PRS: Polygenic Risk Score; TSP: Total Suspended Particles; STP: Standard Temperature Pressure; LC: Local Conditions; HR: Hazard Ratio; CI: Confidence Interval; P: P-value

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

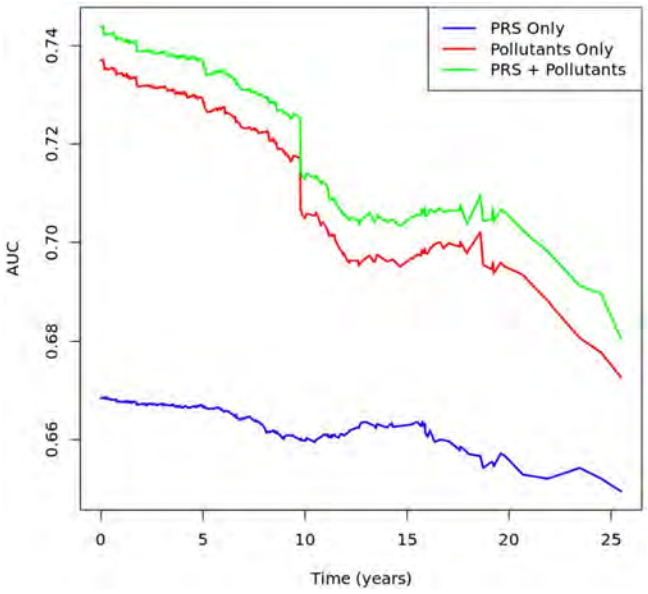

Figure 1. Time-Dependent AUC curves comparing the predictive performance of PRS-only, air pollutants-only, and the combined models for RA risk, adjusted for demographics and smoking history. All models exhibited a general decline in AUC over time. The combined model and air pollutants-only model showed notable decreases around years 10 and 20, whereas the PRS-only model maintained a relatively stable AUC throughout the follow-up period. *PRS: Polygenic Risk Score; AUC: Area Under Curve.

Environmental exposures were assessed using annual average air pollutant concentrations from Environmental Protection Agency AirData (1980–2024), aggregated at the 3-digit ZIP code level. Only exposure data preceding RA diagnosis for cases and prior to the last condition entry for controls were included. Variables selected by the LASSO and Elastic Net Cox models using 5-fold cross-validation were used to fit the final Cox model, adjusting for demographics and smoking history. Integrated Area Under the Curve (iAUC) was computed by the weighted average of time-dependent AUCs with 95% bootstrap confidence intervals (CI) in R v4.4.0.

Results: 283 cases of incident RA and 2,830 matched controls were included. PRS was significantly associated with increased risk of incident RA (HR = 1.25, CI: 1.12-1.40). Among air pollutants, lead showed the strongest association (HR = 6.76, CI: 2.00-22.82), followed by particulate matter ($PM_{2.5}$) (HR = 1.38, CI: 1.30-1.46), SO_2 (HR = 1.10, CI: 1.06-1.15) and ozone (HR = 1.1, CI: 1.03-1.17). Conversely, NO_2 exposure was associated with a reduced RA risk (HR = 0.93, CI: 0.90-0.96). Higher income levels and more advanced education were linked to reduced risk of RA incidence. Smoking history and ambient pressure showed no significant association. The combined model of PRS and air pollutants achieved the highest integrated AUC (iAUC = 0.72, CI: 0.70-0.76), outperforming models with PRS only (iAUC = 0.66, CI: 0.64-0.70).

Conclusion: Integrating PRS with air pollutants enhances the prediction of RA incidence. Notably, lead and $PM_{2.5}$ exhibited the strongest associations with increased risk for RA. These findings underscore the importance of combined genetic and environmental assessments in identifying individuals at elevated risk for RA.

Abstract Number: 0175

Patient Satisfaction with a New Patient Video Triage Program

Adam Dore[1] and Yue Yin[2], [1]Allegheny Health Network, Pittsburgh, PA, [2]Allegheny Health Network, Pittsburgh

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0175–0198) Health Services Research Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: To assist with lowering new rheumatology patient appointment wait times, our division initiated a New Patient Video Triage Program in 2023. In this program, we found the average wait time for a new video triage appointment was less than half of an in-person new patient appointment. However, it was not understood if patients had a positive experience with a new patient video triage visit. Given this, we initiated a patient questionnaire to better understand the patients' satisfaction of the new patient video triage visit.

Methods: Patients completing a video visit through our New Patient Video Triage Program between March, 2024 and February, 2025 were asked to complete a patient satisfaction questionnaire. The questionnaire (Table 1) included 7 questions and basic demographic information. The answers were received anonymously. Descriptive statistics were initially reported. Continuous variable was reported as mean and standard deviation, while categorical variables were reported as frequency and percentage. ANOVA or t-test were conducted to compare continuous variables between groups. Fisher's exact test was conducted to examine the association between categorical variables. To control the Type I error rate, Benjamini-Hochberg correction was used to adjust *p* values. All statistical analyses were conducted under alpha level .05 via SAS 9.4.

Results: 208 surveys were completed. Most of those responding were female (83%) and identified as white/Caucasian (95%). The majority were extremely satisfied with the overall experience of the appointment (81%), the timeliness of the appointment being scheduled (67%), the attentiveness shown towards the patients' concerns (89%), the amount of time spent with the provider (86%), and the outcome of the appointment (74%). Almost all who responded would recommend a similar new patient video visit to others (96%) and only 14% of patients had technology issues during the visit (Table 2).

Table 1: Patient Questionnaire

How satisfied are you with your overall experience with this appointment?
☐ Extremely Satisfied ☐ Satisfied ☐ Somewhat Satisfied ☐ Disappointed

How satisfied are you with the timeliness of your appointment being scheduled?
☐ Extremely Satisfied ☐ Satisfied ☐ Somewhat Satisfied ☐ Disappointed

How satisfied are you with the attentiveness shown towards your concerns?
☐ Extremely Satisfied ☐ Satisfied ☐ Somewhat Satisfied ☐ Disappointed

How satisfied are you with the amount of time you spent with the provider?
☐ Extremely Satisfied ☐ Satisfied ☐ Somewhat Satisfied ☐ Disappointed

How satisfied are you with the outcome of your appointment?
☐ Extremely Satisfied ☐ Satisfied ☐ Somewhat Satisfied ☐ Disappointed

Would you recommend a similar New patient video visit to other patients?
☐ Yes ☐ No

Did you experience any technology issues during your visit?
☐ Yes ☐ No

If willing to share, please provide the following:

Age

Sex

Race

Table 2: Descriptive Statistic Results

Variable	Mean(std)/frequency(percent)
Age	53.15(14.68)
Sex	
Female	171(83.41%)
Male	34(16.59%)
Race	
Black	8(4.85%)
White	157(95.15%)
Overall experience	
Disappointed	7(3.38%)
Somewhat satisfied	3(1.45%)
Satisfied	29(14.01%)
Extremely satisfied	168(81.16%)
Scheduling timeliness	
Disappointed	9(4.35%)
Somewhat satisfied	11(5.31%)
Satisfied	47(22.71%)
Extremely satisfied	140(67.63%)
Attentiveness towards patients' concerns	
Disappointed	5(2.42%)
Somewhat satisfied	1(0.48%)
Satisfied	17(8.21%)
Extremely satisfied	184(88.89%)
Provider time spent with patient	
Disappointed	2(0.97%)
Somewhat satisfied	3(1.45%)
Satisfied	23(11.11%)
Extremely satisfied	179(86.47%)
Outcome of appointment satisfaction	
Disappointed	8(3.85%)
Somewhat satisfied	8(3.85%)
Satisfied	39(18.75%)
Extremely satisfied	153(73.56%)
Recommendation of a similar appointment to others	
No	9(4.35%)
Yes	198(95.65%)
Any technology issue	
No	178(85.58%)
Yes	30(14.42%)

According to Table 3, except the timeliness of scheduling, all survey items were significantly associated with the patients' overall recommendation of a similar appointment to others (all $p = .0008$), indicating that patients who would not recommend the video visit to others were more likely to be disappointed in the other four aspects and patients who would

Table 3: Variable Comparison for Patients' Recommendation to Others

Variable	Recommend to others		P value
	No	Yes	
Age	53.50(16.95)	53.10(14.66)	1.0000
Sex

Extremely satisfied	0(0%)	167(84.77%)	
Scheduling timeliness			
Disappointed	2(22.22%)	7(3.55%)	.0558
Somewhat satisfied	2(22.22%)	9(4.57%)	
Satisfied	2(22.22%)	45(22.84%)	
Extremely satisfied	3(33.33%)	136(69.04%)	
Attentiveness towards patients' concerns			
Disappointed	4(44.44%)	1(0.51%)	.0008
Somewhat satisfied	1(11.11%)	0(0%)	
Satisfied	4(44.44%)	13(6.60%)	
Extremely satisfied	0(0%)	183(92.89%)	
Provider time spent with patient			
Disappointed	1(11.11%)	1(0.51%)	.0008
Somewhat satisfied	3(33.33%)	0(0%)	
Satisfied	5(55.56%)	18(9.14%)	
Extremely satisfied	0(0%)	178(90.36%)	
Outcome of appointment satisfaction			
Disappointed	6(66.67%)	2(1.01%)	.0008
Somewhat satisfied	2(22.22%)	6(3.03%)	
Satisfied	1(11.11%)	38(19.19%)	
Extremely satisfied	0(0%)	152(76.77%)	

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

recommend the video visit to others were more likely to be satisfied in the other four areas. Experiencing a technological issue during the video visit was not significantly associated with the satisfaction of the appointment (all $p > .05$).

Conclusion: Our New Patient Video Triage Program previously showed success in lowering rheumatology new patient wait times. Reassuringly, in this study we have shown that most patients completing the new patient video triage visit and questionnaire were extremely satisfied with the visit and would recommend a similar appointment to others. Having technological issues during the appointment did not impact the patient's satisfaction and there was not one area that led to overall satisfaction or dissatisfaction. Given these findings, we plan to continue utilizing new patient video triage appointments.

Abstract Number: 0176

Development and Validation of an Accurate Patient Reported Outcome Measure-based Disease Activity Score to Enable Remote Monitoring in RA

Agnes Looijen[1], Paco Welsing[2], Sytske Anne Bergstra[3], Annette van der Helm-van Mil[3] and Pascal de Jong[4], [1]Erasmus MC, Rotterdam, Netherlands, [2]Department of Rheumatology and Clinical Immunology, University Medical Center Utrecht, Utrecht University, Utrecht, Netherlands, Utrecht, Netherlands, [3]LUMC, Leiden, Netherlands, [4]Erasmus University Medical Center, Rotterdam, the Netherlands, Rotterdam, Netherlands

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0175–0198) Health Services Research Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: For RA patients, regular monitoring of disease activity is essential, but in-person assessments may not always be feasible due to the increasing pressure on our healthcare system. One solution might be the implementation of 'patient-reported outcome measures' (PROMs) to remotely monitor the disease activity. Previous research combining multiple PROMs showed moderate diagnostic accuracy ('Area Under the Receiver Operating Characteristic curve' (AUC-ROC) of 0.76) in detecting a disease flare. However, these individual PROMs may include items unrelated to disease activity, hindering optimal discrimination.

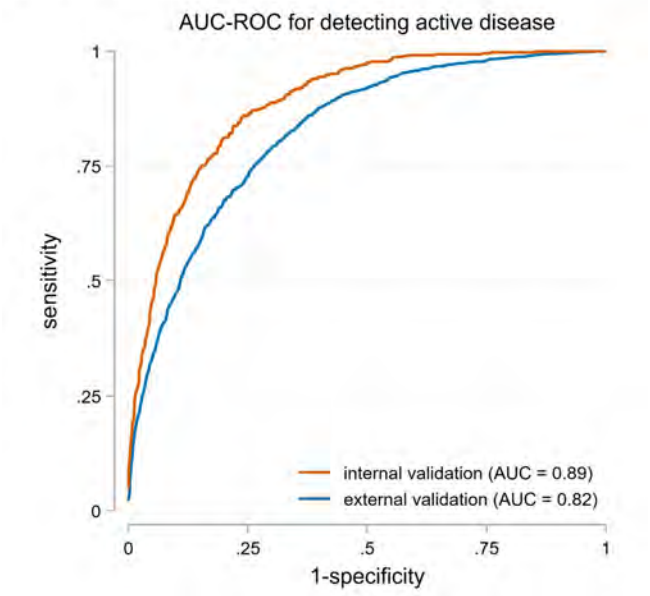
Therefore, our aim was to develop a model composed of a selection of independent PROM-items, that accurately represents the disease activity score in patients with RA.

Methods: Data from early and established RA patients in the 'treatment in the Rotterdam Early Arthritis Cohort' and 'TApering strategies in Rheumatoid Arthritis' trials were used and randomly split (1:1) into development and internal validation cohorts. For external validation data from RA patients in the 'Leiden Early Arthritis Clinic' were used. Patients were included if they met the 1987 or 2010 RA criteria and had at least one PROM-item and the DAS44 measured at the same time point.

With 'Least Absolute Shrinkage and Selection Operator' regression, a model was developed using age, sex, disease duration, and individual PROM-items (HAQ-items, pain (numeric rating scale (NRS) 0-10), general health (visual analogue (VAS) 0-100 millimeters (mm)), and fatigue (VAS 0-100mm)) to predict the DAS44. The final model was evaluated for its ability to detect active disease (DAS44 >2.4) using the AUC-ROC. Sensitivity and specificity where then assessed across thresholds based on: (I) the Youden index, (II) DAS44 >2.4, and thresholds for (III) 95% sensitivity and (IV) 95% specificity in the development cohort.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 1. Receiver operating characteristic curve for the internally and externally validated model which adequately reflects the disease activity score in patients with RA.



Abbreviations AUC, area under the curve; RA, rheumatoid arthritis

Table 1. Sensitivity and specificity for different thresholds of the model in the internal validation cohort

	Threshold[1]	Sensitivity	Specificity
Youden index	1.93	78	82
DAS44 threshold	2.40	52	94
95% sens[1]	1.40	97	53
95% spec[1]	2.43	49	94

[1]*Defined in the development cohort*
Abbreviations: DAS, disease activity index; Sens, sensitivity; Spec, specificity

Results: The development and internal validation cohorts included, 423 early and 187 established RA patients with 5802 visits; active disease was present in 20% of these visits. The external validation cohort included 793 patients with 2467 visits, and in 38% of those visits active disease was present. The final model included 12 of the 26 potential variables (age, sex, disease duration, 7 HAQ-items, NRS pain, and VAS general health) and showed an excellent discriminative ability (AUC-ROC=0.89 for internal validation, 0.82 for external validation) (**see figure 1)**. **Table 1** summarizes the sensitivity and specificity for the different thresholds. Using the Youden index (1.93), the sensitivity for detecting active disease is 78% and the specificity is 82%.

Conclusion: A combination of age, sex, disease duration, VAS general heath, NRS pain and seven HAQ-items is able to adequately differentiate between well-controlled and active disease with excellent diagnostic accuracy, even after validation in an external dataset. This could support remote monitoring of RA patients.

Session Title: (0175–0198) Health Services Research Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Artificial intelligence (AI) is transforming rheumatology care, with innovative tools now empowering physicians and health professionals (HPRs). Our survey examines how adult and pediatric rheumatologists, and HPRs

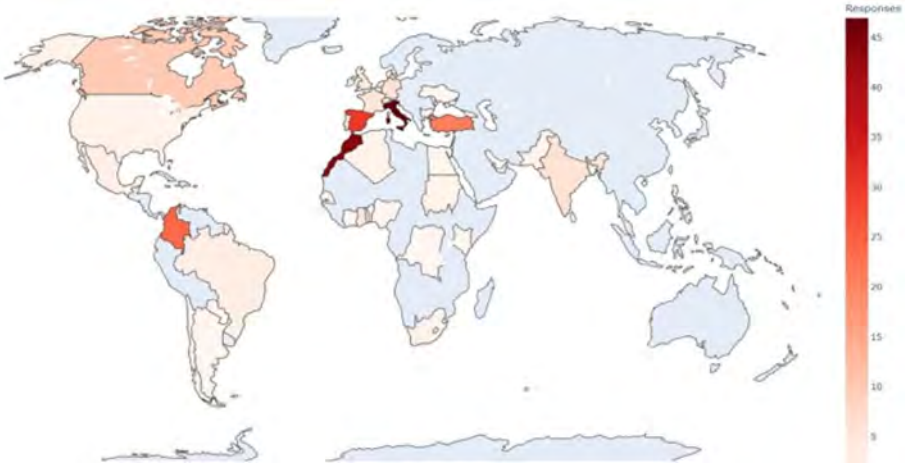

Figure 1 . Geographic distribution of survey respondents

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

currently perceive and utilize AI tools in rheumatology clinical and research environments, by identifying their experiences, concerns, and unmet needs.

Methods: An international, cross-continental online survey following CROSS & CHERRIES frameworks was shared in March 2025 to gather perspectives from the adult and paediatric rheumatology community. The questionnaire included 27 questions, both multiple-choice and open-ended, in four sections: sample characteristics, AI usage and applications, opinions and concerns, and expectations for AI implementation in clinical practice and research.

Results: By early May 2025, a total of 263 respondents (63.5% female) from 43 countries completed the survey, including rheumatologists, paediatric rheumatologists, and HPRs (figure 1). Median age of responders was 38 [IQR 32–48.5] years; only a minority of participants primarily worked in paediatric rheumatology (52, 19.8%), as HPRs (24, 9.1%), or mainly in research rather than clinical practice (54, 20.5%).

Most respondents (220, 83.7%) reported using large language models (LLMs) for medical purposes, commonly for text editing (176, 66.9%), brainstorming (137, 52.1%), summarizing papers (133, 50.6%), and manuscript writing assistance (115, 43.7%); only 30 (11.4%) respondents had never used LLMs. Attitudes towards AI were predominantly positive, with 204 (81.4%) expressing optimism regarding AI's efficacy and safety. However, up to 151 (58.1%) participants emphasized the need for strict AI regulation in medicine.

AI literacy was highly valued, with 214 (81.6%) rating it as very or extremely important, with 92 (35.5%) having or having had subscriptions to AI models/tools. Respondents favoured LLM use for practical tasks: email drafting (191, 72.9%), copy-editing (191, 74%), generating manuscript sections (136, 51.9%), and facilitating reference access (157, 59.9%). Substantial support existed for integrating AI into peer review, assisting reviewers (118, 45%) and editors (112, 42.7%). Respondents indicated AI's greatest future impact in research (212, 80.6%), diagnosis (183, 69.6%), and administrative tasks (177, 67.3%).

Key concerns included ethical issues (176, 67.2%), lack of trust in AI-generated decisions (181, 69.1%), and insufficient training (156, 59.5%). Respondents supported AI integration into rheumatology practice, with only 5 (1.9%) not recommending AI tools to colleagues.

Conclusion: Pilot results suggest the rheumatology community is recognizing AI's transformative potential whilst acknowledging the need for appropriate governance frameworks. AI tools are widely used and positively perceived by rheumatology and pediatric rheumatology professionals. However, concerns about ethics, trust, and training highlight the need for clear guidance and targeted education to support safe integration into clinical and research practice.

Abstract Number: 0178

Prevalence and factors associated with virtual rheumatology care utilization in a national population of Veterans with RA

Beth Wallace[1], Yuqing Gao[2], Shirley Cohen-Mekelburg[2] and Akbar Waljee[2], [1]Michigan Medicine, VA Ann Arbor Healthcare System, Ann Arbor, MI, [2]VA Ann Arbor Healthcare Center, Ann Arbor

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0175–0198) Health Services Research Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Up to half of RA patients receive virtual rheumatology care, which is associated with high satisfaction but potentially lower quality. We aimed to identify factors associated with virtual RA care utilization in a real-world cohort seen at the Veterans' Health Administration, where telehealth services are established, well-integrated, and available across sites.

Methods: This retrospective cross-sectional study used national VA administrative claims to identify patients who a) met a validated claims-based definition of RA, b) had ≥1 rheumatologist visit for RA in 2022-2023 (study period). We compared demographics and treatment characteristics stratified by proportion of rheumatology care for RA received virtually (virtual proportion: 0, < 0.2, 0.2-0.5, 0.51-0.9, >0.9). To investigate factors associated with virtual proportion, we used zero-one inflated beta regression to account for the bounded nature of proportion data and excess zeros/ones. We estimated average marginal effects of age, sex, RA duration, log-transformed cumulative glucocorticoid (GC) dose and distance to rheumatologist's VA site, number of unique DMARDs, all-cause in-person office visits, MTX and biologic use. We performed a sensitivity analysis limited to those with ≥2 rheumatologist RA visits.

Results: We analyzed 11,703 patients, of whom 4964 (42.4%) had a virtual rheumatology visit, 3895 (33.2%) had virtual proportion >0.2, and 1661 (14.2%) had virtual proportion >0.5. As virtual proportion increased, age and distance to rheumatologist increased, and proportion of male patients, MTX, biologic, and GC use, number of DMARDs, and rheumatology and

Table 1: Population characteristics stratified by proportion of rheumatology care for RA received virtually

	Virtual Proportion					P for trend
	0	≤ 0.2	0.2-0.5	0.51-0.9	>0.9	
N (%)	6739 (57.5)	1069 (9.1)	2234 (19.1)	909 (7.8)	752 (6.4)	–
Age, mean (SD) years	65.9 (11.3)	66.2 (10.8)	65.1 (11.8)	65.1 (11.8)	66.8 (12.2)	0.0005
Male sex, N(%)	5306 (79)	845 (79)	1690 (76)	701 (77)	600 (80)	0.0193
Distance to rheumatologist, mean (SD) miles†	79 (74)	72 (69)	78 (72)	87 (71)	108 (83)	<0.0001
RA duration, mean (SD) years	7.1 (2.6)	7 (2.5)	7.1 (2.6)	7 (2.5)	7.2 (2.5)	0.2218
MTX use, N (%)	2586 (38)	495 (46)	878 (39)	443 (49)	253 (34)	<0.0001
Biologic use, N (%)	3601 (53)	713 (67)	1388 (62)	534 (59)	378 (50)	<0.0001
GC use, N (%)	2911 (43)	600 (56)	1023 (46)	435 (48)	265 (35)	<0.0001
Cumulative GC dose, mean (SD) mg prednisone equivalent	524 (1188)	818 (1500)	607 (1278)	644 (1258)	502 (1198)	<0.0001
Cumulative GC days' supply, mean (SD)	74 (171)	111 (197)	83 (177)	88 (179)	72 (166)	<0.0001
Unique DMARDs, mean (SD)	1.5 (1)	1.9 (1)	1.6 (1)	1.7 (1)	1.3 (1)	<0.0001
Rheumatologist visits*, mean (SD)	4.1 (2.2)	7 (2.3)	5.3 (2.8)	6.4 (3.3)	3.2 (2.7)	<0.0001
Total in-office visits, mean (SD)	24 (18)	31 (20)	24 (20)	22 (18)	15 (15)	<0.0001

†missing for 200 patients *in-person and virtual combined

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 2: Variables significantly associated with virtual care proportion in a zero-inflated beta regression

	Primary analysis		Sensitivity analysis	
	Average effect on proportion	95% CI	Average effect on proportion	95% CI
Age, per year	0.14	0.06 – 0.22	0.12	0.05 – 0.20
In-office visits, per visit	-0.55	-0.65 – -0.44	-0.42	-0.52 – -0.32
Driving distance, per log unit increase	4.2	3.3 – 5.1	3.8	3.0 – 4.6
DMARD use, per additional medication added	-2.3	-3.5 – -1.1	-1.4	-2.5 – -0.4

All variables assessed during 2022-2023

in-office visits decreased. However, distance to rheumatologist and MTX use did not differ significantly for virtual proportion 0.2-0.5 vs 0 (p=0.17, 0.43 respectively), and biologic use, GC days' supply, and GC dose did not differ significantly for virtual proportion >0.9 vs 0 (p=0.10, 0.72, 0.61 respectively).

The average change in virtual proportion per incremental increase in each predictor was examined (Table 2). Virtual proportion was associated with an average increase of 0.14 percentage points per year of age (95% CI 0.06-0.22), and 4.2 points per unit increase in log-transformed site distance (approximately 2.7-fold increase in miles, 95% CI 3.3-5.1). Virtual proportion was associated with an average decrease of 2.3 percentage points per additional unique DMARD (95% CI 3.5 to -1.1) and 0.55 points per additional all-cause in- office visits (95% CI: -0.65 to -0.44). Sex, GC dose, RA duration, and MTX and biologic use did not show significant associations. Our sensitivity analysis showed similar findings.

Conclusion: In a real-world cohort of RA patients with access to telehealth, virtual RA care was common and associated with older age, female sex, greater distance from rheumatology site, fewer in-office visits, and lower DMARD and GC use. Initial findings suggest trends may vary across levels of utilization. Limitations include those associated with claims data (e.g. confounding by indication) and cross-sectional design limiting causal inferences. Further work is needed to identify factors affecting virtual care utilization for RA and their impact on clinical outcomes.

Digital Divide in Rheumatology: Patterns of Technology and AI Adoption Across Generations of Specialists

CARLA F DIONELLO[1], ANA F PADUA[2], Claudia Marques[3], BRUNA L PORTO[4], LEONARDO R CAMPOS[5], RODRIGO OLIVEIRA[6], GUSTAVO GM BALBI[7], RODRIGO LUPPINO-ASSAD[6], YURE G AZEVEDO[8], LUIZ F DIPE[9], BRUNO BORDALLO[5], Cleandro Pires[10], Licia Maria Henrique da Mota[10] and PAULA MONTINA[10], [1]FEDERAL UNIVERSITY OF RIO DE JANEIRO - UFRJ, RIO DE JANEIRO, Rio de Janeiro, Brazil, [2]SANTA CASA MG, BELO HORIZONTE, Minas Gerais, Brazil, [3]Hospital das Clinicas - Universidade Federal de Pernambuco - UFPE, Recife, Pernambuco, Brazil, [4]UNIVATES, SÃO LEOPOLDO, Rio Grande do Sul, Brazil, [5]UFF, Rio de Janeiro, Rio de Janeiro, Brazil, [6]FMRP-USP, Ribeirão Preto, Sao Paulo, Brazil, [7]UFJF, JUIZ DE FORA, Minas Gerais, Brazil, [8]SCR, SOBRAL, Ceara, Brazil, [9]GRUPO AMIL, SÃO PAULO, Sao Paulo, Brazil, [10]UNB, Brasilia, Distrito Federal, Brazil

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0175–0198) Health Services Research Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: The integration of digital tools and artificial intelligence (AI) in rheumatology practice has advanced rapidly. However, disparities in adoption across generations of specialists remain underexplored. This study investigates patterns of digital technology and AI usage among Brazilian rheumatologists, stratified by years since medical graduation.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: A nationwide, self-administered, anonymous questionnaire was distributed to rheumatologists affiliated with the Brazilian Society of Rheumatology. The survey included 14 binary-use items related to electronic health records (EHR), AI-assisted tasks, telemedicine, cloud-based collaboration, and scheduling tools. Respondents were categorized into four groups based on time since graduation: 3–10, 10–20, 20–30, and >30 years. Descriptive statistics, Pearson's correlations, one-way ANOVA, chi-square tests, principal component analysis (PCA), and K-means clustering were performed.

Results: A total of 454 responses were analyzed. EHR usage demonstrated a significant negative correlation with years since graduation ($r = –0.33$, $p < 0.001$). Use of AI for text generation was also inversely correlated ($r = –0.17$, $p < 0.01$). ANOVA revealed significant variation across graduation strata in EHR usage ($p < 0.0001$), AI-assisted writing tools ($p < 0.001$), and cloud-based collaboration platforms ($p < 0.01$). Chi-square testing confirmed an association between experience level and AI writing tool adoption ($\chi^2 = 26.2$, $p < 0.0001$).

PCA explained 57.9% of the variance (PC1 = 34.9%, PC2 = 23.1%), and K-means clustering identified three distinct user profiles:

- **Cluster 0** (n=49): Low digital engagement, with 83.7% having >30 years since graduation.
- **Cluster 1** (n=96): High engagement across EHR and AI, predominantly 10–30 years since graduation (69.8%).
- **Cluster 2** (n=179): Intermediate engagement, with mixed generational representation (35.2% >30 years).

A regression model between EHR use and graduation time showed $R^2 = 0.11$ ($p < 0.001$), supporting a generational trend.

Conclusion: A digital divide exists in rheumatology, with more recent graduates demonstrating greater engagement with EHRs and AI tools. These findings highlight the importance of targeted training and support for senior rheumatologists to bridge gaps in digital literacy and optimize care delivery.

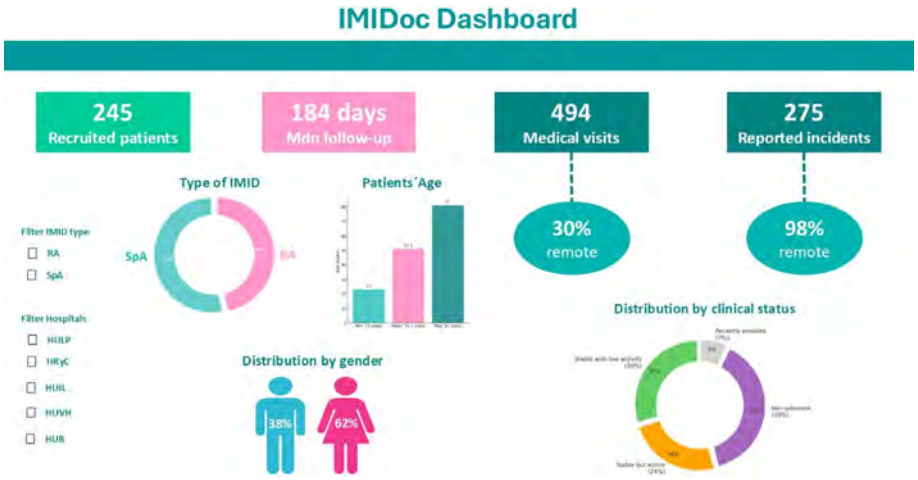
SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0175–0198) Health Services Research Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) and spondyloarthritis (SpA) are immune-mediated inflammatory diseases (IMIDs) characterized by joint and spinal inflammation, leading to functional impairment. Their management requires close monitoring and effective communication between patients and healthcare providers. Digital health tools can help overcome current gaps in care by facilitating follow-up and interaction, especially within mixed care models that combine in-person and remote visits. Our aim was to evaluate the clinical implementation of a mixed care model using a digital tool called IMIDOC®, designed for both patients and healthcare professionals.

Methods: This prospective, multicenter study was conducted under the FIS PI22/00777 project. In its initial phase, IMIDOC was developed as a mobile app for patients and a web-based platform for clinicians. Patients can report health-related outcomes (PROs), clinical incidents, access educational content, and manage appointments and medication reminders. The clinician interface allows tracking of patient progress and timely intervention. In the clinical phase, 260 patients with RA or SpA receiving biological or targeted synthetic DMARDs (b/tsDMARDs) were scheduled for protocolized mixed follow-up for up to 12 months.

Results: Between April and October 2024, 245 patients were recruited (62% women; mean age 51.5 ±11.5 years; 47% RA, 53% SpA). The median follow-up time was 184 days (IQR 75–229). A total of 275 clinical incidents were reported (19% flares, 11% infections, 29% medication-related, 41% other), 98% of which were resolved remotely (77% via messaging, 23% via phone); only 2% required in-person visits. The median resolution time was 1 day (IQR 0–3). Among 494 medical visits, 29% were conducted remotely and 71% in person. A total of 15,011 PRO questionnaires were completed (6324 for RA, 8687 for SpA). In RA, the most frequent PROs were p-NAD (15%), p-NAT (14%), and p-VAS (14%); in SpA, p-NAD (11%), p-painful entheses (11%), and p-VAS (12%). Based on PRO-derived disease activity, 30% of patients were stable with low activity, 24% were stable but active, 39% were non-adherent, and 7% were recently enrolled. There were 609 consultations with educational materials, and at least 63% of patients accessed these resources, most commonly those related to joint self-assessment, the role of the rheumatologist, and early signs of disease. The app's usability was rated 81 on the System Usability Scale (SUS).



IMIDoc Dashboard

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: The mixed care model supported by the IMIDOC tool represents a feasible and effective strategy for managing RA and SpA, combining digital and clinical components to enhance real-time monitoring, patient empowerment, and remote resolution of incidents

Launch of the National Tele-Rheumatology Program (NTRP) to Expand Rheumatology Care to Rural Veterans

Cherish Wilson[1], Catherine Nasrallah[2], Gary Tarasovsky[3], Alicia Hamblin[4], Asia Williams[5], Broderick Flynn[5], Bernard Ng[6] and gabriela Schmajuk[7], [1]UCSF / SFVA, San Francisco, CA, [2]University of California San Francisco (UCSF), San Francisco, CA, [3]SFVA, San Francisco, [4]UCSF, San Francisco, CA, [5]Lexington VA, Lexington, [6]Lexington VA, University of Washington, Seattle, [7]University of California, San Francisco, and San Francisco Veterans Affairs Medical Center, San Francisco, CA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0175–0198) Health Services Research Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Given the nationwide shortage of rheumatologists, particularly in rural areas, many Veterans Affairs (VA) facilities have struggled to hire or retain specialists, resulting in greater reliance on non-VA (i.e., community-based) care. While non-VA care can expand access, it also increases costs for the VA and contributes to fragmented care for Veterans. To address these challenges, we launched the VA National Tele-Rheumatology Program (NTRP) in collaboration with the VA Office of Rural Health. In this study, we describe the implementation and early evaluation of the NTRP using the RE-AIM framework.

Methods: The NTRP is a centrally-managed and scalable telehealth model designed to deliver virtual rheumatology care across the country. The program launched in July 2024 with 3 clinical teams, each consisting of a rheumatologist and a Telehealth Clinical Technician with a shared nurse and pharmacist. The NTRP coordinates services and care delivery from a single site that triages and manages care for multiple outlying facilities. To recruit facilities into the program, NTRP leaders targeted sites with a high proportion of Veterans living in rural areas (according to Rural-Urban Commuting Area codes) and high expenditures on non-VA rheumatology care. Our initial evaluation used program records and data from the VA Corporate Data Warehouse to report on facility participation and characteristics (Adoption), Veteran enrollment and demographics (Reach), and non-VA care cost metrics (Implementation; **Figure 1**).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. RE-AIM Domains, Measures, and Strategies Used in the NTRP

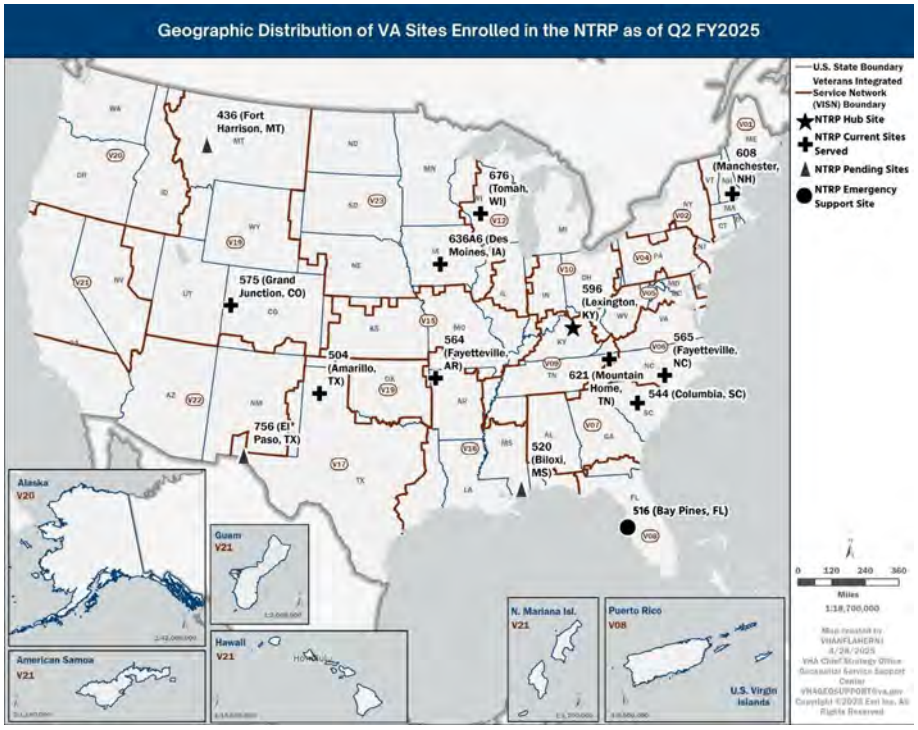
DOMAIN	ADOPTION	IMPLEMENTATION	REACH	EFFECTIVENESS	MAINTENANCE
DESCRIPTION	Site engagement and staff capacity	Program delivery and operational consistency	Rural Veteran access and service utilization	Clinical outcomes and care experience	Sustainability, scalability, and resource planning
KEY MEASURES	• Site/staff participation • Funded roles • Enrolled sites	• Delivery fidelity • Workflow alignment/ mapping • Resource use	• Rural Veteran enrollment • Demographics • Encounter counts	• Clinical metrics • Veteran-reported outcomes • Satisfaction with program	• Sustainability planning • Continuation intentions • Resource planning
KEY STRATEGIES	• Engage high-cost, rural-serving VA sites • Partner with local champions to drive uptake	• Reduce burden and expand access via centralized scheduling and telehealth • Adapt workflows to site infrastructure	• Target high-need rural areas • Ensure diverse enrollment and reduce access barriers	• Monitor clinical outcomes and Veteran satisfaction using standardized tools	• Assess site commitment, funding shifts, and stakeholder support for long-term sustainability

*RE-AIM domains are presented in A-I-R-E-M order to reflect the operational flow of the National Tele-Rheumatology Program (NTRP), beginning with system-level adoption and ending with long-term maintenance.



Geographic Distribution of VA Sites Enrolled in the NTRP as of Q2 FY2025

Results: Adoption: 13 facilities were recruited, most of which were located in the Southern U.S. (61.5%). Facility-level rurality ranged from 9.0% to 75.0% (**Figure 2**). Reach: 1,099 Veterans (83.2% male, 83.6% White, and mean (SD) age of 63.6 (15.1) years) received care through NTRP, 47.6% of whom lived in rural or very rural areas. Implementation: Among 7 enrolled sites with complete cost data, non-VA care expenditures for rheumatology care in Quarter 2 (Q2) of Fiscal Year (FY) 2024 averaged $289,361. These expenditures dropped by 43.2% in Q2 FY2025 (**Figure 3**).

Conclusion: In its first year, NTRP had significant adoption and reach across rural geographies. Early evaluation suggests that non-VA care expenditures rapidly decrease at participating facilities. Although we anticipate that the NTRP will lead to reduction in total costs for rheumatology care, additional evaluation is needed to determine whether savings in non-VA care

A Joint Effort: Implementing Depression Screening in a Safety-net Rheumatology Clinic

Clare Grossman[1], Jay Chhabra[1], Ximena Gonzalez Sanchez[1], Karina Brito[1], Jacqueline Friskey[1], Brent Abel[2] and Mary Margaretten[2], [1]University of California San Francisco, San Francisco, CA, [2]Zuckerberg San Francisco General Hospital, UCSF, San Francisco, CA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0175–0198) Health Services Research Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Comorbid depression is common in patients with autoimmune diseases and is associated with increased healthcare utilization and death. Despite American College of Rheumatology recommendations for annual depression screening, it is often lacking in rheumatology practices, particularly in safety-net settings. We aimed to implement workflows for depression screening with appropriate mental health follow-up referrals in an urban, safety-net rheumatology clinic using the Institute for Healthcare Improvement's Model for Improvement.

Methods: This was a quality improvement project conducted by an interprofessional team of medical students, nurses, medical assistants (MAs), and a rheumatologist. Data were collected from workflow observations, stakeholder interviews, and Patient Health Questionnaire-9 (PHQ-9) forms, a validated tool to screen for depressive symptoms in multiple languages used by primary care at our institution. Patients literate in English, Spanish, or Chinese presenting to rheumatology clinics

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

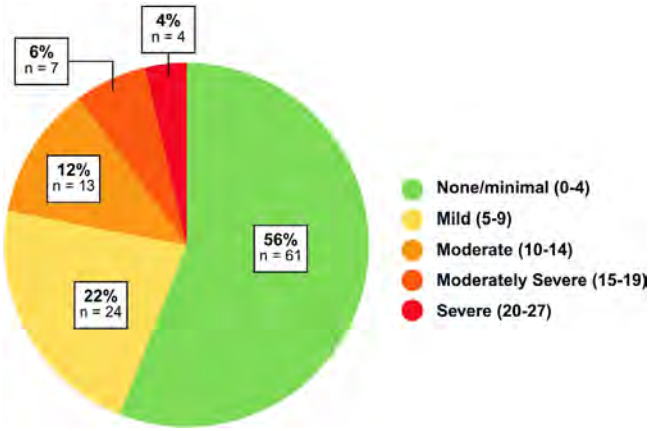

Figure 1. Severity of Depressive Symptoms Among 109 Patients Screened with PHQ-9

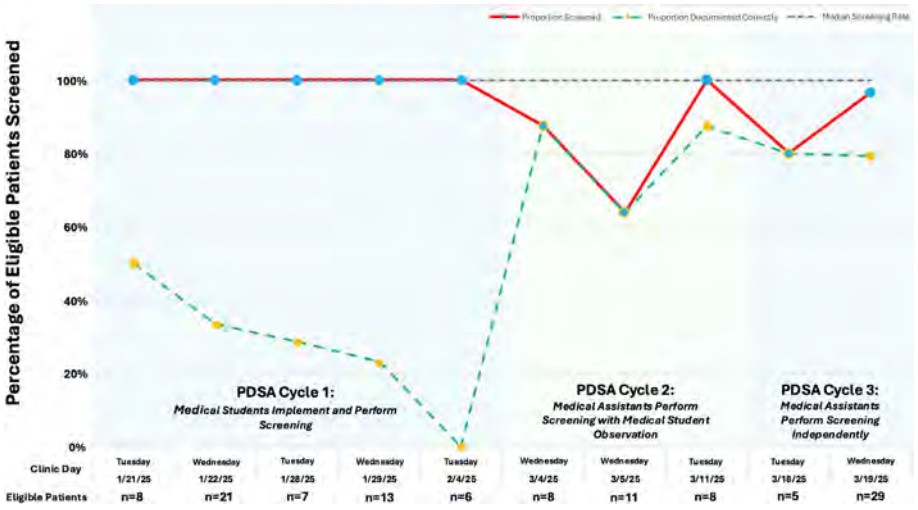

Figure 2. Rates of PHQ-9 Screening and Documentation After Workflow Implementation in a Safety-net Rheumatology Clinic Across Three PDSA Cycles (Jan - Mar 2025)

were eligible for screening, unless screened within the past 12 months. A standardized protocol for PHQ-9 collection, documentation, and follow-up was developed. PHQ-9 scores were documented in the electronic medical record (EMR) and a retrospective chart review was conducted to assess accuracy and completeness of documentation. Language concordant educational materials were created for patients who scored >4 on the PHQ-9. Referrals to behavioral health and primary care notification were made for scores ≥10; patients endorsing suicidal ideation were assessed for immediate safety needs and brought to psychiatric emergency services if needed. Implementation occurred over three plan-do-study-act (PDSA) cycles: first by students, then by MAs with student observation, and finally by MAs independently.

Results: We identified 117 patients eligible for screening. One patient declined screening and was excluded. Of the remaining 116 patients, 109 (94%) were screened for depressive symptoms and 48 (44%) screened positive (PHQ-9 >4), with 24 (22%) having PHQ-9 scores ≥ 10 that corresponded to moderate or severe symptoms (Fig. 1). Ten patients endorsed passive suicidal ideation and received timely safety assessments. All patients who screened positive were offered appropriate follow-up based on their PHQ-9 scores. Screening rates varied across PDSA cycles: 100% in the first, 82% in the second, and 94% in the third cycle. Correct documentation in the EMR went from 29% to 96% to 84% across the three cycles (Fig. 2). In qualitative follow-up interviews, clinic staff reported high acceptability of the new workflow and confidence in managing depression screening.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Screening for depressive symptoms in patients with rheumatic diseases and providing appropriate mental health follow-up in rheumatology clinics at a safety-net hospital is feasible. Although managing positive screens required staff training and interdepartmental coordination, clear protocols allowed for smooth implementation. Iterative workflow improvements can enable screening rates to remain high and improve documentation.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0175–0198) Health Services Research Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Timely access to current rheumatology guidelines at the point of care presents a significant challenge. Large Language Models (LLMs) offer potential solutions, but their propensity for "hallucinations" raises safety concerns. The primary objective of this study was to develop and evaluate a novel Retrieval-Augmented Generation (RAG) system, the first of its kind specifically for adult rheumatology, integrating European Alliance of Associations for Rheumatology (EULAR) and American College of Rheumatology (ACR) guidelines to provide clinicians with timely, evidence-based recommendations.

Methods: Seventy-four clinically relevant EULAR and ACR management guidelines for adult rheumatology were selected and processed. A RAG system was implemented using the LangChain framework, voyage-3 embedding model, and a Qdrant vector database, see **Figure 1**. For evaluation, 740 guideline-specific questions were generated. Answers were produced by an LLM (ChatGPT-o3-mini) with context retrieval (RAG) and without (baseline). Performance was assessed by an LLM-as-a-judge (Gemini 2.0 Flash) using a 5-point Likert scale across five dimensions (relevance, factual accuracy, safety, completeness, conciseness) and by determining preference. Wilcoxon signed-rank and Binomial tests were used for statistical analysis. Two blinded rheumatologists independently validated a random 15% sample of questions.

Results: The LLM-as-a-judge evaluation revealed that the RAG system significantly outperformed the baseline system across all criteria ($p < 0.001$). The RAG system was significantly preferred by the LLM-as-a-judge in 92.8% of comparisons ($p < 0.001$), **Table 1** Manual evaluation by rheumatologists confirmed these findings, with significant improvements in accuracy, safety, and completeness for the RAG system ($p < 0.001$), which was preferred in 71.2%-74.8% of comparisons ($p < 0.001$), **Table 2**.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

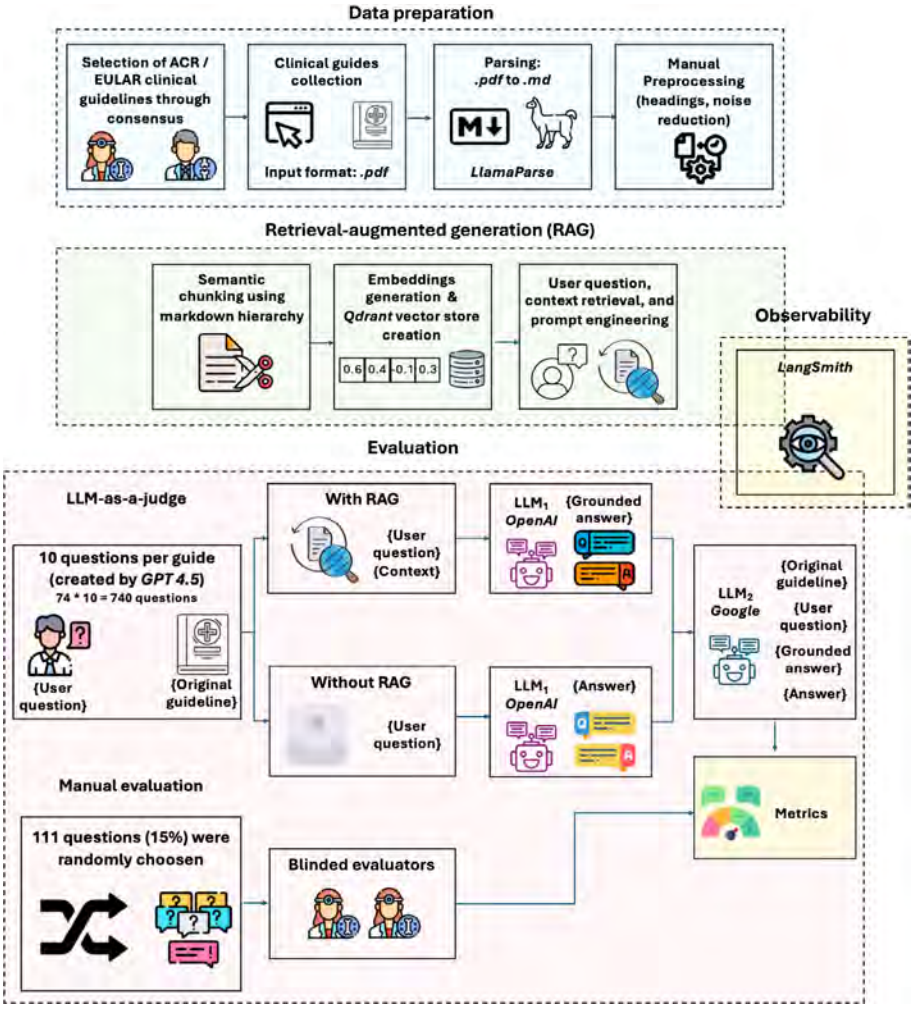

Figure 1: Walkthrough of the entire process—from initial creation to final evaluation—of the RAG architecture proposed

Conclusion: This study successfully developed and validated a RAG system integrating EULAR and ACR guidelines for adult rheumatology. The system significantly enhances the quality and reliability of LLM-generated answers, providing a robust foundation for AI-driven clinical decision support tools. Such tools have the potential to improve guideline adherence and evidence-based practice in rheumatology by offering clinicians rapid, context-aware access to recommendations.

Neurocognitive Complications of Lupus: A Multidisciplinary Program Model for Advanced Diagnostics, Management, and Clinical Research

Douglas Wilcox[1], Matthew Baum[2], Sophie Lebiedz[2], John Sullivan[2], Margaret Naclerio[2], Jonathan Zurawski[2], Bonnie Glanz[2], Rohit Bakshi[2], Tanuja Chitnis[2], Shamik Bhattacharyya[3] and Karen H. Costenbader[4], [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston, [3]Brigham and Women's Hospital, Malden, MA, [4]Harvard Medical School and Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0175–0198) Health Services Research Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Neurological symptoms in lupus are common and occur in the majority of patients with SLE. Although neuropsychiatric lupus (NPSLE) can involve the entire nervous system, cognitive slowing and fatigue are more common and functionally limiting symptoms. There is currently no clear standardized, multidisciplinary approach to the

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

evaluation and management of these patients. Further, there is an urgency to better understand the features and potential mechanisms of cognitive changes in patients with lupus to open new therapeutic avenues and standards of care.

Our objective was to create a multidisciplinary Neuro-Lupus Program to comprehensively assess patients through advanced second-tier diagnostics, manage patients through multidisciplinary collaborations, and to build a clinical research database to investigate cognitive concerns in patients with SLE.

Methods: Patients with a diagnosis of SLE and any neurocognitive symptoms or concerns can be referred to the Neuro-Lupus Program. Patients are initially evaluated by a dedicated lupus neurologist, where they undergo a standardized neurologic history and exam. This is followed by referral for a full neurocognitive evaluation by a clinical psychologist and evaluation by a trained expert autoimmune disease psychiatrist. Patients then undergo advanced brain imaging using a high-resolution 7T MRI scan to evaluate for subtle inflammatory changes, including leptomeningeal enhancement, cortical atrophy, and brain lesions. Patients with abnormalities on MRI are evaluated further with CSF studies through a dedicated lumbar puncture clinic. We additionally have access to refer appropriate lupus patients for FDG PET-CT brain, TSPO-PET CT brain, vascular imaging, and EEG. For the clinical research arm, following patient consent, matched serum and CSF samples are added to a biorepository for future studies investigating cognitive changes in NPSLE.

Results: At our center, we have recruited and evaluated 30 patients with lupus and neurocognitive concerns in a 6-month period (Table 1). Full neurocognitive evaluation revealed previously undiagnosed mild cognitive impairment and dysexecutive function in a significant portion (88%) of patients presenting with "fatigue" or "cognitive fog". Advanced imaging demonstrated previously undescribed leptomeningeal enhancement in 26% of patients with cognitive symptoms who underwent a 7T MRI brain scan. Despite the presence of significant cognitive changes and leptomeningeal enhancement, none of the CSF studies revealed an abnormally high white cell count or protein. Similarly, median neurofilament light chain (NfL) values, a serum biomarker for neuronal injury, was within the reference range.

Conclusion: In conclusion, our novel multidisciplinary Neuro-Lupus Program brings together neurologists, psychiatrists, rheumatologists, clinical psychologists, and radiologists to better support, evaluate, manage, and understand the complex but important cognitive impact of SLE on our patients. Future work will be aimed at leveraging our unique biobank and diagnostic studies to better understand the cellular and molecular pathways that may underly cognitive impairment in patients with lupus.

Table 1. Demographics and clinical characteristics of patients with SLE referred to the Neuro-Lupus Program

	Total number of patients (n=30)

Promoting Health Services Research Rigor and Reproducibility using CodeMapper: A novel tool for harmonization, collaboration, and precision

Emily Holladay[1], Nick McCormick[2], Robert Matthews[3], Shanette Daigle[4], Fenglong Xie[5], Tapan Mehta[1] and Jeffrey Curtis[6], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Auburn University, Auburn, AL, [3]Foundation for Advancing Science Technology Education and Research, Hoover, [4]Foundation for Advancing Science, Technology, Education and Research (FASTER), Hoover, AL, [5]The University of Alabama at Birmingham, Birmingham, AL, [6]Foundation for Advancing Science, Technology, Education and Research, Birmingham, AL

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

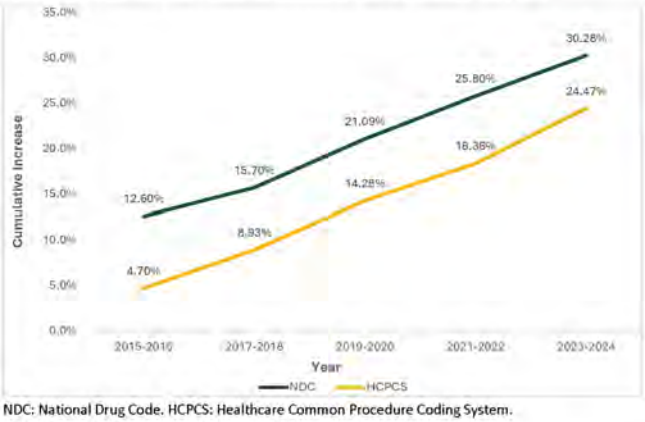
Session Title: (0175–0198) Health Services Research Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Medication, procedure, and diagnosis coding using structured data is fundamental to using real-world data to support clinical research, impacting cohort selection, patient recruitment, and outcome measurement. Source vocabulary systems (e.g. ICD-10-CM, HCPCS, RxNorm) are updated regularly, and incorporating these changes into existing code sets is essential yet challenging to manage, particularly in multidisciplinary settings. To address this need, we developed CodeMapper, an informatics tool designed to facilitate routine code updates and interdisciplinary collaboration. Our objective was to quantify medication, procedure, and diagnosis changes over time to assess the importance of maintaining updated code sets and provide a foundation for tool development.

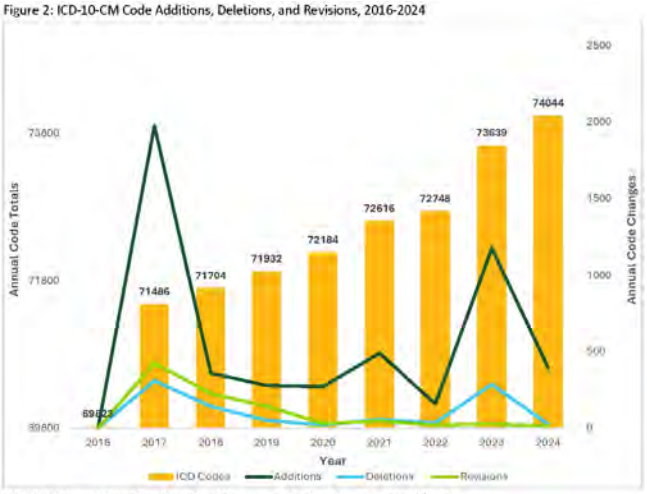
Figure 1: HCPCS and NDC Code Cumulative Increases by Two-Year Intervals, 2015-2024



NDC: National Drug Code. HCPCS: Healthcare Common Procedure Coding System.
Note: Percent increases do not include deleted or revised codes.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 2: ICD-10-CM Code Additions, Deletions, and Revisions, 2016-2024



ICD-10-CM: International Classification of Diseases, Tenth Revision, Clinical Modification.

Figure 3: CodeMapper Interface

Methods: We analyzed codes using the International Classification of Diseases, Tenth Revision, Clinical Modification (ICD-10-CM) codes from the National Center for Health Statistics and National Drug Codes (NDC) from First Data Bank (2015 to 2024). We also assessed Healthcare Common Procedure Coding System (HCPCS) codes from Centers for Medicare & Medicaid Services from inception through 2024. We summarized code changes over time and visualized trends using figures.

Results: Between 2015 to 2024, 2,911 new HCPCS codes were added. These additions accounted for approximately 25% of all HCPCS codes (Figure 1). Similarly, notable increases in the number of NDC codes occurred from 2016-2024 with a median (IQR) of 20510.0 (20424.0, 22275.0) NDC codes added per two-year period (Figure 1). Similar changes were also observed for ICD-10-CM codes with a median of 377.5 (276.0, 833.0) additions, 54.5 (30.0, 214.5) deletions, and 38.5 (24.0, 184.5) revisions occurring annually (Figure 2). Revisions describe the changes occurring in naming, coding granularity, and numbering.

Given these substantial changes over time in standardized coding systems, we developed CodeMapper, a new web-based informatics tool integrating current and historical diagnostic, procedural, medication, and laboratory codes. With semi-

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

annual source vocabulary updates, this tool helps maintain the code sets described above and offers the ability for interdisciplinary teams to collaborate and refine code lists for use in current or future research (Figure 3).

Conclusion: Regular updates to medical coding systems are essential to support accurate research findings. The potential to under-ascertain codes within structured data is high, particularly in multi-year longitudinal studies where code sets may be fixed at the time of protocol development yet will under-capture medications, procedures, and diagnoses as they change over time. Maintenance and integration of current and complete source vocabularies are critical for rigorous and generalizable clinical research both for trials and real-world evidence using observational electronic health record or claims data.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0175–0198) Health Services Research Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Use of telemedicine has increased substantially. Our overall goal was to assess the utility of a standardized video joint exam and infrared thermal imaging as virtual tools to determine joint status during telemedicine visits.

Methods: Adults and children aged ≥4 and with an established diagnosis of inflammatory arthritis and suspected active inflammation in at least one knee, ankle/subtalar, elbow, or wrist joint were enrolled. A joint exam performed by the in-person clinician during routine visits was recorded as the gold standard of joint status. On the same day, participants completed a clinical research visit consisting of completion/obtainment of: 1. a questionnaire, 2. thermal images of hands, wrists, elbows, knees, ankles and feet, and 3. a standardized video joint exam. A follow-up research visit was conducted along with a clinical visit ≥3 months later. All the data collected except the clinical joint exam and assessment recorded by the in-person clinician was used to simulate "virtual visits" for "virtual" physicians to review. In order to determine the added value of each component of patient-generated data, the virtual physicians recorded their impression of the 72 joint exam and physician global assessment (PGA) sequentially: 1. after viewing the results of the patient questionnaire, primary rheumatologist's interval history, and lab results (if available), 2. after viewing the video joint exam, and 3. after viewing the thermal images and thermal imaging report. Interrater reliability statistics were calculated by cohort, joint, and review type (history only, history + video,

history + video + thermal), and include both baseline and follow-up assessments. Sensitivity and specificity were calculated by joint, cohort, review type, time (baseline and follow-up) and reviewer seniority.

Results: We enrolled 100 adults and 101 children (Table 1). At every virtual assessment (history only, history + video, and history + video + thermal report), there was a significant positive correlation between in-person and virtual physicians regarding the PGA. Regarding total active joint counts, there was a significantly positive correlation between in-person and virtual physicians at every assessment, except for when the adult virtual doctors were provided with history only (Table 2). Regarding the sensitivity and specificity for detecting inflammatory arthritis in the virtual setting, sensitivity was low and generally did not improve as more information was provided (13-83% for pediatric providers, and 0-58% for adult providers). However, specificity was high at nearly every time point assessed (57-97% for pediatric providers and 52-86% for adults). Agreement between the virtual physicians generally decreased as more information was added (Figure 1).

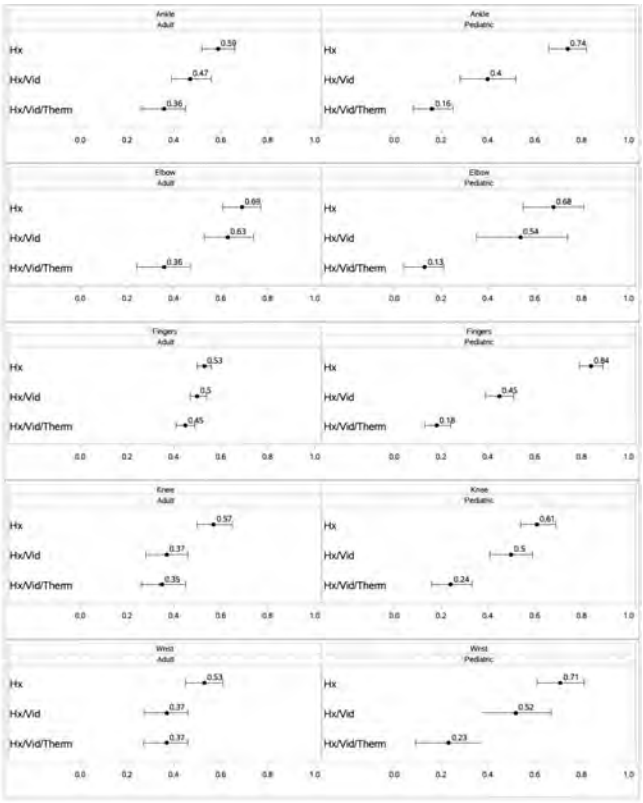

Figure 1. Kappa (95% CI) By Level of Information Among Adult and Pediatric Patients

Conclusion: Our study showed that history complemented with asynchronous video exam reviewed by rheumatologists led to moderately consistent assessment as in-person providers. Thermal imaging results did not yield additional benefit towards accurate joint assessment in the present study.

Abstract Number: 0187

Message Testing in Online Recruitment Advertisements for a National Rheumatoid and Psoriatic Arthritis Study

Matthew Kearney[1], Sarah Hopkins Gillespie[1], Stephanie Chen[1], Tyler Cavin[2], Christine Lindsay[3], Christopher Ritchlin[4], Jennifer Seifert[5], Susan Goodman[6], Jessica Fishman[1] and Alexis Ogdie[7], [1]University of Pennsylvania, Philadelphia, PA, [2]University of Rochester, Rochester, NY, [3]Self, prosper, TX, [4]University of Rochester Medical Center, Canandaigua, NY, [5]University of Colorado and Oklahoma Medical Research Foundation, Aurora, CO, [6]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY, [7]Department of Medicine, Perelman School of Medicine at the University of Pennsylvania, Wilmington, DE

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0175–0198) Health Services Research Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background/Purpose: Study recruitment procedures have increasingly included paid advertisements using social media. However, it is unclear which types of message framing will be the most effective for recruitment. The most common types of messages use an altruistic messages (contribute to the study out of a desire to help others) or simple informational message. **We aimed to** compare the effectiveness of two social media message frames - altruism and empowerment - versus attention-matched control in recruiting participants into the Accelerating Medicines Partnership Autoimmune and Immune-Mediated Diseases (AMP AIM) study, a multi-site study focused on rheumatoid arthritis, psoriatic arthritis, and psoriasis.

Methods: Between September 2024 and February 2025, we posted three Facebook advertisements to recruit study participants. Ads featured the question "Do you have RHEUMATOID ARTHRITIS or PSORIATIC ARTHRITIS?" and used one of three messages: 1) Altruism ("Make a difference by joining the arthritis study!"); 2) Empowerment ("Become a partner. Your voice matters!"); and 3) Attention-matched control ("Consider joining the arthritis study,"). Ads were linked to recruitment websites with matching messages. After pilot testing with altruism ads to focus the scope of impressions, all three ad sets were run concurrently. Facebook users randomly received one of the three ads, but not multiple. Outcomes included impressions (ad views), clicks, engagement (website visitors), and completed submissions. Regression modeling evaluated predictors of completed submissions and website visits. Analyses were conducted using StataSE (version 15).

Results: Over 39 total ad-days (pilot phase=18 days; final phase=21 days, 7 days/ad type), AMP AIM recruitment advertisements collectively generated 1,332,969 views and reached 617,206 unique Facebook users. Across both phases, 13 individuals submitted their information to learn more about the study through the AMP AIM website. Although altruism ads received 7 submissions, the most of any ad group, these submissions were all during the pilot phase. During the final phase when all three ads were run concurrently, all 6 submissions received were from individuals shown the attention-matched control ads – and zero from the altruism or empowerment ads. However, when compared to the attention-matched control ads and after controlling for study phase, regression modelling suggested that both the empowerment and altruism ads received significantly more Facebook impressions ($p < .001$), more ad clicks ($p < .001$), and more AMP AIM website visits ($p = .017$).

Conclusion: Message framing significantly affects attention, engagement, and recruitment. We learned that altruism and empowerment frames increased impressions and clicks but, ultimately, did not improve recruitment. All submissions during the final phase came from attention-matched control ads, suggesting simpler messages may better prompt action. In

Advertisement	Impressions (# of views)	Engagement (# of clicks)	Reach (# of sessions)	Contacts (# of submissions)
Attention-matched control	228,056	2,015	453	6
Altruism 	271,870	2,145	442	7 (only in pilot)
Empowerment	216,816	1,968	428	0

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. addition, traditional engagement metrics alone may not fully capture recruitment effectiveness. Additional research to compare these and other message frames among additional subpopulations could help to better inform effective strategies for recruitment.

Investigating Canadians' information needs related to lupus: A Google Trends analysis of online search query data

Taylor Williamson[1], Emily Shantz[1], Susan Elliott[1], Christine Sperling[2], Karen H. Costenbader[3] and **May Choi**[4], [1]University of Waterloo, Waterloo, Canada, [2]None, Calgary, Canada, [3]Harvard Medical School and Brigham and Women's Hospital, Boston, MA, [4]University of Calgary, Calgary, AB, Canada

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0175–0198) Health Services Research Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: A lack of knowledge surrounding SLE has been identified as a main challenge for patients, particularly those seeking a diagnosis or recently diagnosed. Subsequently, many turn to online sources for information, where they risk encountering misleading or even endangering mis- or disinformation. Hence, we investigated the public awareness of SLE and how this varies spatially across Canada using health geographical approaches to examine Google Trends (GT) data, a tool for assessing public knowledge and information.

Methods: This research employs a health geographical approach to exploring spatial and temporal trends in information-seeking behaviours and associated knowledge gaps related to SLE in Canada. Using GT, relative search volumes (RV), associated topics and queries were collected from 2004-2024, using keywords for "lupus" (Fig1). The top 25 search terms were collected from each province and territory, and these search terms were analyzed thematically. The research process leveraged an integrated knowledge translation approach, in which a patient partner living with SLE was a key part of the research team.

Results: Search volumes for the search term "lupus" in Canada hit an all-time peak in October 2015 (RV=1.0) (Fig2,Table). This peak occurred in all provinces simultaneously, correlating with celebrity Selena Gomez's SLE diagnosis. Additional peaks were observed across Canada in July 2009 (RV=0.58), September 2016 (RV=0.69), and September 2017 (RV=0.78), all of which were correlated with milestones in the development and eventual approval of belimumab for SLE. Similarly, a peak in August 2016 (RV=0.66) was associated with positive Phase II trials for voclosporin. A national peak in June 2010 (RV=0.60) was associated with the 9th International Congress on SLE held in Vancouver, Canada. There was a marked trough across all Canadian provinces in November and December 2020 (RV=0.28), perhaps reflecting that SLE-related concerns were overshadowed by the ongoing COVID-19 pandemic. Overall, interest was highest in Newfoundland (RV=1.0), New Brunswick (RV=0.83), and Manitoba (RV=0.80), though the top related topics and queries varied spatially among provinces. The most frequently searched terms typically fell within the following themes: causes of lupus, diagnosis,

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Fig. 1.0 Search Interest Over Time: Comparing "Lupus" and "SLE" on Google Trends

Fig. 1.1 Regional Distribution of search interest for "lupus" across Canada and Related Queries

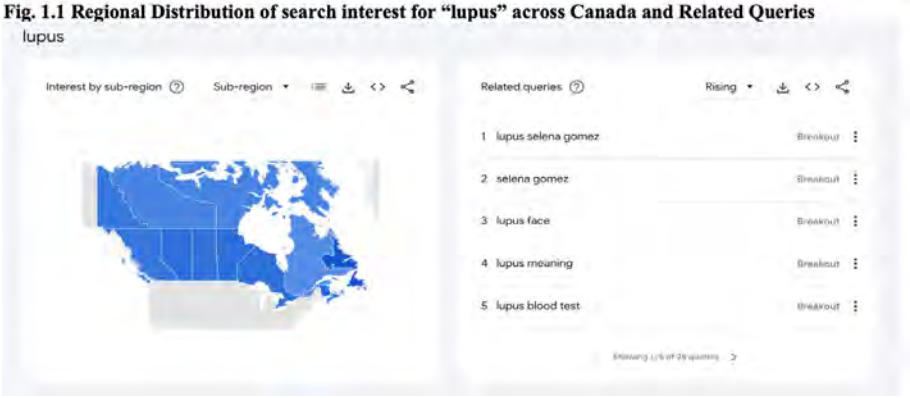

Figure 1. Google Trends dashboard displaying 1.0) search interest over time and 1.1) regional distribution across Canada

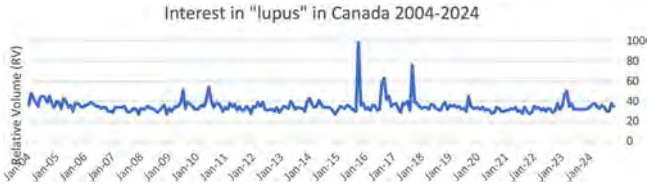

Figure 2. Relative Volume (RV) for the search term "lupus" across Canada (2004-2024)

symptoms, medication, and treatment. Some search terms were spatially unique, only appearing in one province, including search terms in French ("lupus maladie", Quebec), and Indonesian ("penyakit lupus", Newfoundland) languages.

Conclusion: An understanding of the information needs of the general public related to SLE, and how they vary spatially, is critical for designing and implementing targeted and effective patient education interventions. To this end, these research results will be shared and triangulated with the knowledge needs of advocacy organizations and the realities of lived SLE experience, through a deliberative dialogue with key stakeholders from across Canada. This research and deliberative

Table. Timeline, Key Events & Major Peaks, Search for "Lupus" (Canada 2004–2024)

Time Period	Peak/Trough	Associated News/Events
July 2009	Peak (0.58)	GSK announces positive Phase 3 study results for Benlysta News headlines speculate that musician Michael Jackson struggled with lupus prior to his death

"try It, You'll Love It": Patterns of AI Scribes Use Among Rheumatologists

Megan Creasman[1], Jing Li[2], Augusto Garcia-Agundez[3], gabriela Schmajuk[4] and Jinoos Yazdany[3], [1]UC San Francisco, San Francisco, CA, [2]University of California, San Francisco, San Francisco, CA, [3]UCSF, San Francisco, CA, [4]University of California, San Francisco, and San Francisco Veterans Affairs Medical Center, San Francisco, CA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0175–0198) Health Services Research Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Heavy documentation contributes to clinician workload and burnout. Rheumatology carries one of the highest documentation burdens among Internal Medicine (IM) subspecialties. While recent advances in artificial intelligence (AI) have led to the development of AI scribes that can produce structured clinical notes in real time, little is known about how rheumatologists use these tools. The implementation of AI scribes across a large ambulatory academic health system provided a unique opportunity to compare the adoption, retention, and utilization patterns of AI scribes by rheumatologists compared to other physicians.

Methods: Data from Dec 2024-May 2025 was collected to capture AI scribes use. Ambulatory physicians were eligible to access AI scribes and became "live users" after completing a training; live users became "active users" if they used AI scribes at least once in the preceding 30 days. Provider adoption was defined as the ratio of live users to all eligible providers. Retention was defined as the ratio of active to live users in the preceding 30 days. To assess utilization, live users were categorized based on the percentage of eligible encounters that used AI scribes in the past 30 days: low (< 30%), medium (30–70%), and high (>70%). Fisher's exact test was used to compare the proportion of high utilizers between rheumatology vs. IM physicians and rheumatology vs. non-IM physicians. Outcome measures tracked the average weekly time spent on EHR activities per provider, comparing the 90 days prior to the date each physician became a "live user" to the post AI scribes period.

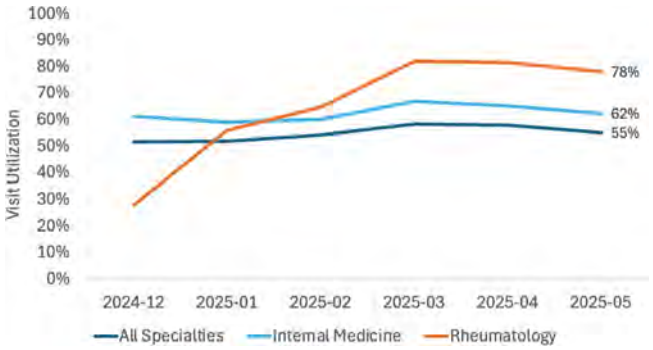

Figure 1. Visit Utilization in in Rheumatology, IM and Non-IM Specialties

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

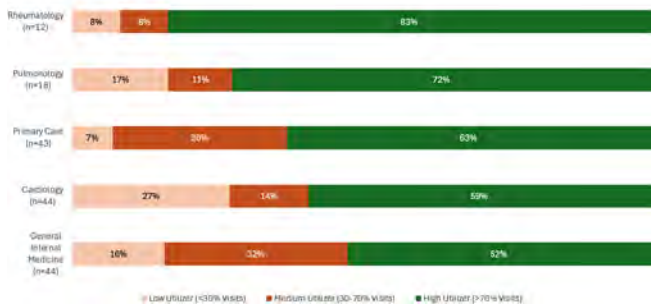

Figure 2. Top Five IM Specialties by Provider Visit Utilization

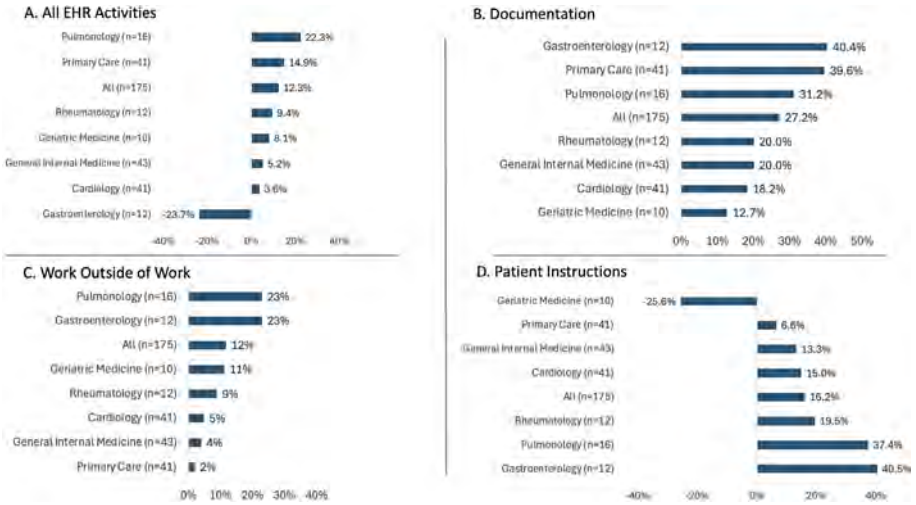

Figure 3. Outcomes by IM Specialty

Results: 2477 physicians were eligible to start using AI scribes; by the end of the observation period 888 (37%) had become live users. Adoption by rheumatologists was 41% (12/29) compared to 49% for all other IM physicians (224/455, 15 specialties). Of IM sub-specialties Rheumatology was 10th by adoption rate. Among rheumatologists, retention was 100%, slightly higher than the 94% retention seen across IM. Rheumatology live users used AI scribes for more of their encounters (78%) than any other IM specialty (62%) and non-IM physicians (55%; see Figure 1). Rheumatology had the largest percentage of high utilizers of all IM specialties (83% vs. 52%; see Figure 2). By Fisher's exact test Rheumatology had a numerically higher but not statistically significant proportion of high utilizers than IM (83% vs. 72%, p=0.5) and a significantly higher proportion than non-IM physicians (83% vs. 42%, p=0.006). Live users from IM specialties and rheumatology decreased mean time spent in all EHR activities, documentation, work outside of work, and patient instructions; rheumatologists had slightly less time savings except in patient instructions (see Figure 3).

Conclusion: Approximately half of rheumatologists adopted AI scribes, emerging as the highest users per encounter among IM subspecialties. Retention was consistently high across all specialties, including rheumatology, underscoring sustained engagement. Rheumatologists enjoyed time savings across all four outcome measures. Future research should investigate the implications of AI scribes on rheumatologist well-being and the patient experience.

Abstract Number: 0190

Health literacy and comorbidity burden: a cluster analysis in a national cohort of people with inflammatory arthritis

Mrinalini Dey[1], James Galloway[2], Andrew Cope[2], MAYA BUCH[3], Richard Osborne[4], Sam Norton[2] and Elena Nikiphorou[2], [1]Centre for Rheumatic Diseases, King's College London, London, United Kingdom, [2]King's College London, London, United Kingdom, [3]UNIVERSITY OF MANCHESTER, MANCHESTER, United Kingdom, [4]La Trobe University, Melbourne, Victoria, Australia

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0175–0198) Health Services Research Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Health literacy is a social determinant of health in people with chronic diseases, including inflammatory arthritis (IA). We aimed to assess the association between health literacy and comorbidity burden.

Methods: The National Early Inflammatory Arthritis Audit (NEIAA) is an observational cohort comprising adults with IA, recruited since 2018. Patients with confirmed IA, within NEIAA, were invited to complete an online survey (March to May 2024), including the Health Literacy Questionnaire (HLQ); Work Productivity and Activity Impairment questionnaire; Generalised Anxiety Disorder (GAD-2); Patient Health Questionnaire (PHQ-2); socio-demographics, employment and education; self-reported disease activity. Comorbidity data were extracted from the NEIAA for: diabetes mellitus, hypertension, lung disease, depression, and stomach ulcers.

The survey was distributed to 3300 individuals with those responding matched to original records within NEIAA.

Agglomerative hierarchical clustering using Ward's method was applied. Health literacy, socio-demographics and comorbidity profile were compared between clusters.

Results: A total of 995 patients with IA were included. The median age was 59 years (IQR 50-67) and 66% were female.

A five-cluster approach was deemed optimal for characterising the sample. The cohort was clustered according to normalised HLQ scores: "Highest" n=90; "High" n=190; "Moderate" n=296; "Low" n=270; "Lowest" n=149 (Figure 1 and Table 1).

The "highest" health literacy cluster had highest mean age (63.4, SD 11.4), lowest proportion of females, and least likely to have ever smoked. The cluster with "lowest" health literacy had the lowest mean age (53.9, SD 11.8) and highest proportion of females (Table 1).

Table 1: Outcomes presented by health literacy cluster. Higher mean scores for Patient Health Questionnaire (PHQ-2) and Generalised Anxiety Disorder (GAD-2) denote higher levels of depression and anxiety, respectively. SD= standard deviation.

Cluster by health literacy	Highest n=90	High n=190	Moderate n=296	Low n=270	Lowest n=149
Age (Mean, SD)	63.4 (11.4)	57.1 (14.7)	57.9 (13.4)	56.9 (12.6)	53.9 (11.8)
Gender (% female)	62.2	65.8	65.6	66.0	69.8
Smoking status (%)					
Current smoker	8.9	5.3	3.7	11.5	10.7
Ex-smoker	22.2	23.7	30.4	30.0	26.2
Never smoker	53.3	45.3	44.3	39.3	42.3
Unknown	15.6	25.8	21.6	19.3	20.8
PHQ-2 (Mean, SD)	0.7 (1.3)	0.9 (1.3)	1.5 (1.6)	1.8 (1.6)	2.5 (1.9)
GAD-2 (Mean, SD)	0.9 (1.4)	1.0 (1.4)	1.5 (1.7)	1.8 (1.7)	2.6 (2.0)
Self-reported disease activity (0-100; Mean, SD)	27.9 (26.6)	29.5 (26.4)	35.5 (27.7)	40.3 (26.9)	59.4 (28.2)

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

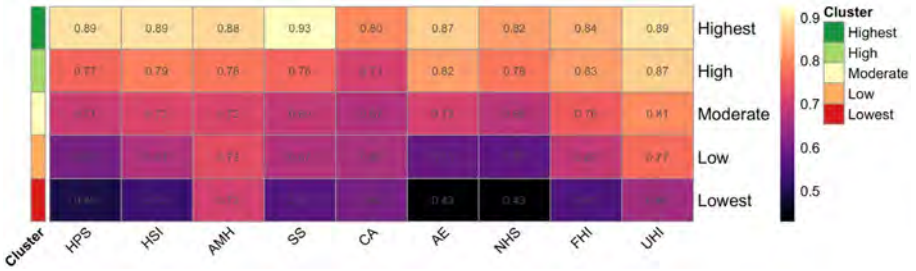

Figure 1: Normalised Health Literacy Questionnaire (HLQ) scores by cluster (0-1 scale). The HLQ has nine domains: 1. HPS: Feeling understood and supported by healthcare providers; 2. HSI: Having sufficient information to manage health; 3. AMH: Actively managing my health; 4. SS: Social support for health; 5. CA: Appraisal of health information; 6. AE: Ability to actively engage with healthcare providers; 7. NHS: Navigating the health-care system; 8. FHI: Ability to find good health information; 9. UHI: Understanding health information well enough to know what to do.

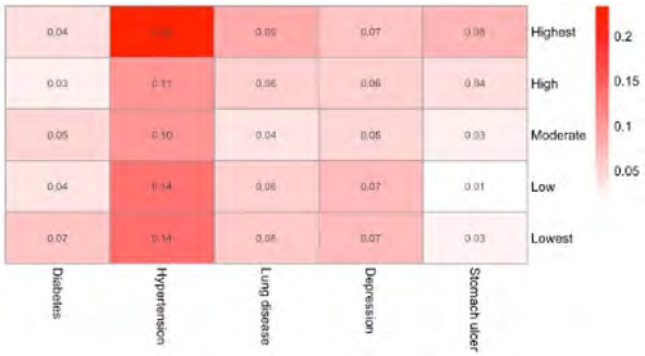

Figure 2: Mean comorbidity prevalence by health literacy cluster.

Anxiety and depression (as measured by GAD-2 and PHQ-2) were 3.6x and 2.9x higher respectively in the "lowest" compared to "highest" health literacy cluster. Self-reported disease activity was also twice as high in the "lowest" compared to "highest" health literacy cluster.

The "highest" health literacy cluster had the highest prevalence of all comorbidities, aside from diabetes, which was most frequent in the "lowest" health literacy cluster (Figure 2). The two lowest health literacy clusters had relatively high prevalence of hypertension and depression. Of the recorded comorbidities, only prevalence of hypertension and stomach ulcer were significantly different between the five clusters (p=0.02 and p=0.05 respectively).

Conclusion: The "lowest" health literacy cluster had almost four times greater anxiety and depression and twice as high self-reported disease activity, compared to the "highest" health literacy cluster. Our results suggest higher health literacy associated with older age, greater comorbidity prevalence, but lower likelihood of smoking, mental health symptoms and disease activity.

Older individuals likely have more comorbidities and more frequent contact with healthcare services which may increase overall engagement and understanding of health information. Our results will inform policy and management strategies in assessing and modifying health literacy, as well as multimorbidity, in the context of IA.

Abstract Number: 0191

Advanced Therapy Use in RA Patients with Moderate Disease Activity in a Large NHS Foundation Trust in South London, UK

Aoibhinn Kelly[1], Maddalena Rupnik[2], Nasra Ahmed[1], **Mrinalini Dey**[3] and Elena Nikiphorou[4], [1]King's College Hospital NHS Foundation Trust, London, United Kingdom, [2]Faculty of Medicine and Dentistry, Queen Mary University of London, London, United Kingdom, [3]Centre for Rheumatic Diseases, King's College London, London, United Kingdom, [4]King's College London, London, United Kingdom

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0175–0198) Health Services Research Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Moderate disease in rheumatoid arthritis (RA) is defined as a 28-joint disease activity score (DAS28) of 3.2-5.1(MDAS). As per the National Institute for Health and Care Excellence (NICE, TA 715, TA 744 & TA 676), patients with moderate RA failing ≥2 conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs) should be assessed for eligibility for a TNF-inhibitor, upadacitinib or filgotinib [1].

We aimed to assess compliance with NICE guidance on moderate RA management in a diverse area of London.

Methods: All patients with confirmed RA (EULAR/ACR 2010 criteria [2]) seen in the last 18 months were extracted from the electronic records (Epic) of King's College Hospital NHS Foundation Trust. Patients with recorded MDAS and previously receiving ≥2 csDMARDs were included. Exclusion criteria were: temporarily stopping advanced therapy (eg due to malignancy or infection); commencing a biologic or targeted synthetic DMARD (b/tsDMARD) not specified in TA 715, 744 or 676; no recorded DAS28 or components.

Patients were analysed in two groups:

i) those on a biologic via the moderate RA pathway;

ii) those not on a biologic.

All patients in group I were automatically eligible for inclusion.

Table 1: Summary of characteristics of included patients with rheumatoid arthritis (RA), including those commenced on advanced therapy via the moderate RA pathway during the 18-month study period.

	Patients on advanced therapy via moderate RA pathway n=87	Patients not on advanced therapy		
		Moderate RA (DAS28 3.2-5.1) n=6	DAS28 <3.2 or >5.1 n=224	No face-to-face assessment n=20
Gender				
Female (%)	53 (55)	3 (50)	165 (73)	11 (55)
Age (SD)	53 (14.7)	63 (8.0)	61.7 (16.1)	58 (17.0)
Hospital site (% total in column)				
Tertiary hospital (n=162)	47 (54.0)	1 (16.7)	105 (46.9)	9 (45)
District general hospital (n=175)	40 (46.0)	5 (83.3)	119 (53.1)	11 (55)
Advanced therapy (%)

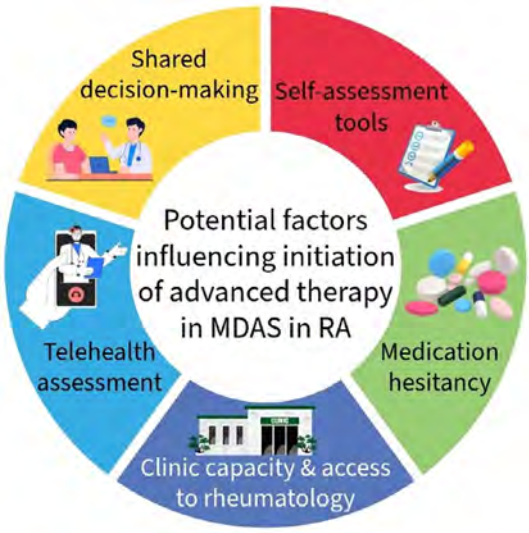

Figure 1: Summary of potential reasons for commencing or delaying advanced therapy in the setting of moderate disease activity (MDAS) in people with rheumatoid arthritis (RA). Possible reasons identified from this study include medication hesitancy (due to previous side-effects), telehealth assessments with no disease activity scores completed, and delays in accessing clinic appointments especially in rural or district hospitals. Mitigating factors may include the use of self-assessment tools in conjunction with telehealth and increased shared decision-making.

For group II, a random sample of 250 patients were reviewed in depth for encounters in which MDAS was recorded. If MDAS was present, reasons for not starting advanced therapy were extracted from Epic, if available. Other data extracted included demographics, DAS28, comorbidities and treatment history.

Results were summarised using descriptive statistics. Reasons for delaying therapy were summarised using narrative synthesis.

Results: In total, 87 patients commenced advanced therapy via the moderate RA pathway (mean age [SD]: 53 [14.7]; 55% female), most commonly adalimumab (n=70) (Table 1).

Of the 250 patients not on a b/tsDMARD, 20 had no recorded DAS (5% (n=13) did not attend a rheumatology appointment; 3% (n=7) had telephone encounters). 2% (n=6) had MDAS documented on ≥1 occasions (3.23-4.23), 50% female and mean age 63 (SD 8.0).

In all six MDAS cases, no offer of advanced therapy was recorded. One patient with MDAS had "apprehension about starting new medications" due to previous DMARD side-effects. Three patients with MDAS were subsequently assessed via telephone, precluding DAS assessment (Figure 1).

Conclusion: Our results demonstrate good compliance with NICE on escalation to advanced therapies in patients with MDAS. Increased telehealth usage limits assessment of joints and suitability for treatment escalation, especially in district hospitals. Self-assessment tools, to complete prior to telephone appointments, may mitigate this. Clinicians may be reluctant to discuss advanced therapies if patients demonstrate medication hesitancy.

Shared decision-making, appropriate triage for telehealth assessment and greater use of self-assessment tools are vital in facilitating discussions and commencement of advanced therapy in moderate RA.

Session Title: (0175–0198) Health Services Research Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatic and musculoskeletal diseases (RMDs) are chronic conditions that require complex, multidisciplinary care. Since 2020, digital health applications (DiGAs) have been available for prescription and reimbursement in Germany, offering potential support for patient self-management. However, data on patient awareness, willingness to use,

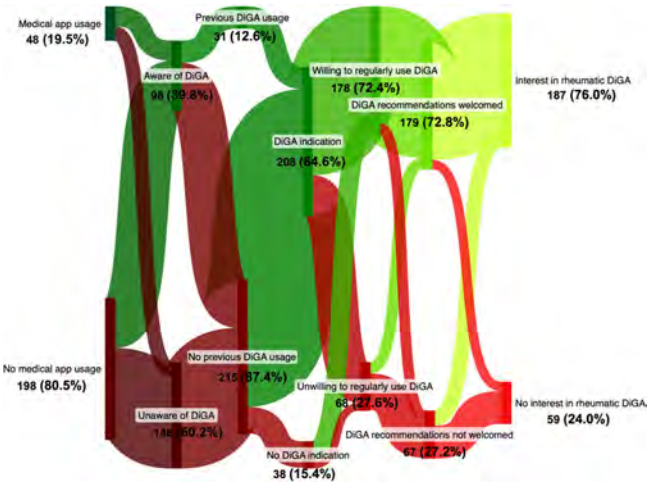

Figure 1: Sankey diagram illustrating patients' medical app usage, DiGA awareness, DiGA usage, DiGA indications, willingness to use DiGAs, interest in receiving DiGA recommendations, and interest in a rheumatology-specific DiGA.

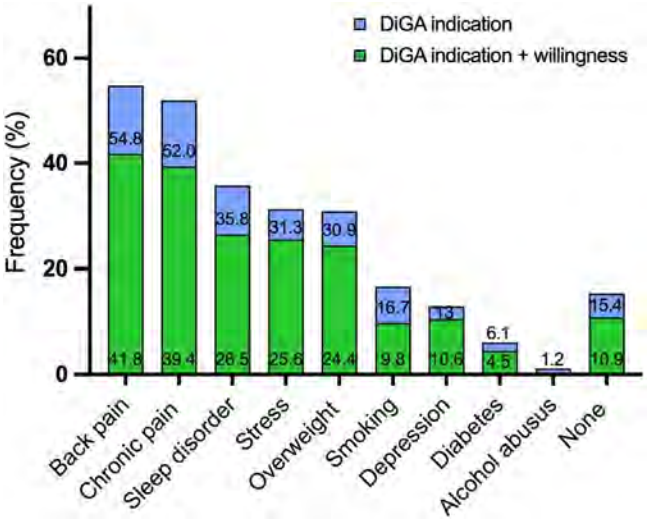

Figure 2: Patient-reported comorbidities that represent indications for approved prescribable digital health applications (DiGAs). Participants were allowed to select multiple comorbidities. Light blue depicts the proportion of patients with the reported respective indication. Green depicts the proportion of patients with the reported respective indication and reported willigness to regularly use a DiGA.

suitability, and actual adoption of DiGAs among individuals with RMDs remain limited. This study aimed to evaluate both the potential and actual adoption of DiGAs by patients with RMDs.

Methods: A national cross-sectional survey was conducted between February 17 and April 8, 2025, across multiple German rheumatology outpatient clinics. Adult patients presenting to the clinics were invited to complete an anonymous electronic REDCap questionnaire.

Results: A total of 246 patients completed the survey (mean age 50.4 years; 71.1% female). Most participants were treated at a university hospital (59.8%), primarily for rheumatoid arthritis (41.1%), psoriatic arthritis (18.3%), or axial spondyloarthritis (10.2%) (**Table 1**). Regarding digital health usage (**Figure 1**), 9.5% of patients reported prior medical app usage, 39.8% were aware of DiGAs, and 12.6% had previously used a DiGA. Additionally, 84.6% of patients reported at least one comorbidity corresponding to an approved DiGA indication; the most frequently reported indications were back pain (54.8%), chronic pain (52.0%), and sleep disorders (35.8%), see **Figure 2**. Importantly, 72.4% of patients expressed willingness to regularly use a DiGA, and 72.8% would welcome active DiGA recommendations from their rheumatologists or insurance providers. Finally, 76.0% expressed interest in a rheumatology-specific DiGA.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: The majority of patients reported comorbidities potentially addressable with DiGAs and expressed interest in regular use. However, only a minority had previously used a DiGA. These findings highlight the need for enhanced implementation strategies to fully leverage the potential of digital health applications.

Evaluation of electronic health record and efficiency tool utilization by pediatric subspecialists

Samantha Coss[1], Alison Brittain[2], Jennifer Lee[3], Julie Young[1], Ivana Stojkic[1], John Mahan[4] and Alysha Taxter[5], [1]Nationwide Children's Hospital, Columbus, OH, [2]Nationwide Children's Hospital, Canal Winchester, OH, [3]Department of Gastroenterology, Nationwide Children's Hospital, Columbus, OH, [4]Department of Nephrology, Nationwide Children's Hospital, Columbus, OH, [5]Nationwide Children's, Columbus, OH

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0175–0198) Health Services Research Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Excessive interaction with the electronic health record (EHR) is frequently cited as a common source of physician burnout. The administrative burden and extended documentation time required by EHR systems can significantly contribute to physician fatigue and discontent. This study evaluated EHR utilization across pediatric subspecialties.

Methods: This is a cross-sectional study evaluating EHR utilization data from 8 pediatric subspecialties at a quaternary medical center. Three months of outpatient EHR provider action logs from spring 2024 were evaluated. We assessed factors associated with EHR utilization including the percentage of time reviewing the chart, writing notes, addressing in-basket tasks, managing orders as well as measures of efficient EHR usage including the percentage of notes manually typed, percentage of same day chart closure, and the use of efficiency tools were recorded. Time actively using the EHR was

Table 1: Rheumatology and Pediatric Subspecialist Electronic Health Record Utilization Metrics

	Rheumatology	Other Pediatric Subspecialists	p-value
Time in EHR[a]	53 [48, 56]	34 [23, 44]	<0.01
% time writing notes	54% [52, 60]	53% [44, 59]	0.71
% time chart review	17% [17, 20]	18% [15, 23]	0.89
% time in Basket	16% [13, 18]	13% [9, 18]	0.23
% time Orders	12% [11, 13]	13% [10, 17]	0.33

Legend:
[a]Time in EHR is calculated by minutes spent actively using the system (clicking, scrolling, typing)/Number of appointments
[b]Non-business work hours measured by average minutes per month outside of 7AM to 530PM
EHR: Electronic Health Record

normalized by number of clinic appointments. Non-business work hours were measured by average minutes per month utilizing the EHR outside of 7AM to 530PM. Providers were stratified by greater than or less than 5 half-day sessions of clinic per week to assess differences in EHR utilization based on clinical load. Summary statistics are reported. Comparisons were made between groups using Wilcoxon rank-sum test.

Results: 127 provider logs were assessed across 8 specialties, with a median of 17 [10, 33] providers per specialty. Nine pediatric rheumatologists spent a median of 53 [48, 56] minutes within the EHR per patient appointment, whereas other subspecialists spent a median of 34 [23, 44] minutes ($p< 0.01$) (Table 1). The percentage of time completing non-documentation tasks within the EHR and rates of same day chart closure were similar between rheumatology and other subspecialists. The use of diagnosis and level of service speed buttons, quick actions, and chart review filters did not differ between rheumatologists and other subspecialists. All rheumatologists but only 68% of other subspecialists utilized chart search ($p=0.04$). There was no difference in EHR utilization metrics when stratifying by the number of clinic sessions within subspecialty departments (Table 2).

Conclusion: Pediatric rheumatologists spend significantly more time per appointment within the EHR than other subspecialty providers, and the majority of this extra time is spent on documentation. Leveraging new tools such as ambient listening and other artificial intelligence tools may lessen documentation burden and improve EHR utilization, potentially decreasing burnout rates and improving workforce retention.

Abstract Number: 0194

Evaluation of a Home-based Therapeutics Service: Feasibility, Patient and Caregiver Experience, and Cost

Xiaohui Xin, Andrea Low, Sow Ling Yee, Miao Miao Liu, Christina Tan, Daphne Ng and **Siaw Ing Yeo**, Singapore General Hospital, Singapore, Singapore

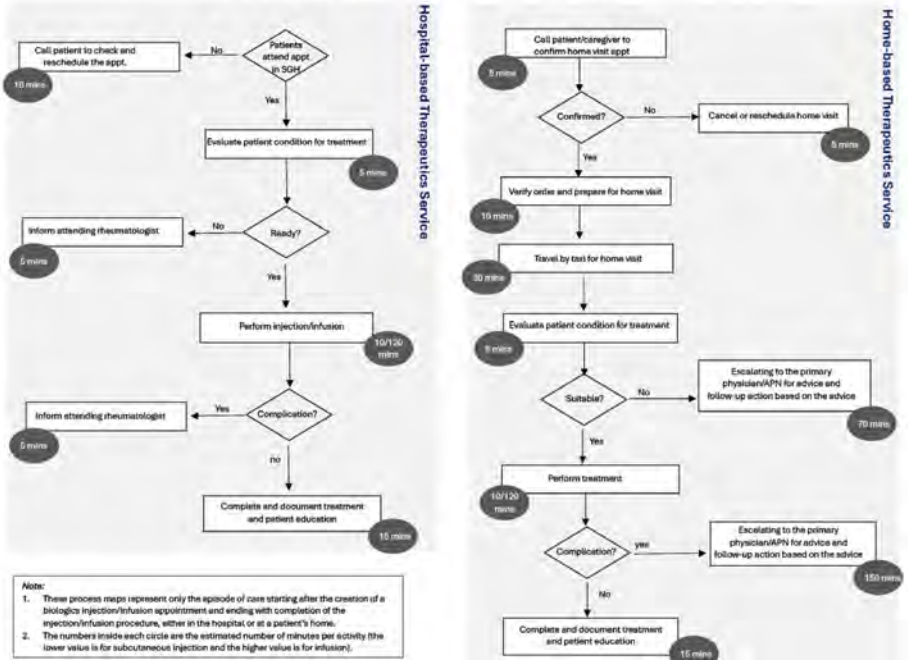
SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0175–0198) Health Services Research Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: The home-based therapeutics service (HTS) by a community nurse is part of an ongoing larger initiative—Community Therapeutics Programme (CTP)—spearheaded by the Rheumatology and Immunology Department in Singapore General Hospital. CTP is an innovative healthcare initiative designed to deliver specialist therapeutic infusions (e.g. anti-TNF inhibitors, tocilizumab, zoledronic acid) and subcutaneous injections (e.g. anti-TNF inhibitors, denosumab) within community settings by providing direct HTS and empowering primary care providers (General Practitioners and Polyclinics) to offer these treatments. It aims to address several challenges faced by patients and by healthcare systems: long waiting times for procedures, inconvenience, higher cost of frequent hospital visits for patients and their caregivers, and the strain on inpatient hospital resources.

This observational study assesses the feasibility, patient and caregiver experience, and cost of the HTS.

Methods: This evaluation included all patients referred to the HTS by their attending rheumatologists from March 2023 (the start of the CTP) to February 2025. Feasibility was assessed by tracking patients requiring urgent return to hospital-based therapeutics. Patient and caregiver feedback on their experience with the HTS was collected via anonymous online surveys,

FIGURE 1. PROCESS MAPS OF HOSPITAL-BASED VERSUS HOME-BASED THERAPEUTICS SERVICES



23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

rating overall experience and specific aspects (convenience, timeliness, scheduling, and comfort) of the HTS. Cost comparison between the HTS and hospital-based care was conducted using time-driven-activity-based-costing (TDABC) method (process maps shown in Figure 1).

Results: The HTS served 230 patients during the evaluation period, administering 867 treatments: 623 subcutaneous injections to 185 patients and 244 therapeutic infusions to 45 patients. No patient needed urgent transfer to hospital-based care. Only three infusions out of the 867 procedures (0.3%) needed rheumatologist consultation: two for pre-infusion stabilisation of blood pressure and one for post-infusion monitoring of side effects that resolved within three days.

We received 258 completed service evaluation survey responses (223 by patients and 35 by caregivers), covering 111 intravenous infusion and 147 subcutaneous injection procedures, respectively. The feedback was overwhelmingly positive with 95-98% of respondents agreeing that HTS was convenient, timely, comfortable, and easy to arrange.

Cost analysis using TDABC revealed significant savings: the average HTS cost was SGD136 for a subcutaneous injection and SGD260 for a therapeutic infusion, compared to SGD286 and SGD915 respectively for hospital-based alternatives. This translated into total savings of SGD253,270 (SGD93,450 from 623 injections and SGD159,820 from 244 infusions). Even in the three rare cases requiring rheumatologist consultation, the average cost of an infusion in HTS remained more than SGD300 cheaper than that of a hospital-based infusion.

Conclusion: HTS is a safe and less costly service compared to hospital-based therapeutics with overwhelming satisfaction from both patients and caregivers.

Abstract Number: 0195

Utility of Repeat ANA Testing

Michael Luggen[1] and **Sila Mateo Faxas**[2], [1]University of Cincinnati College of Medicine, Cincinnati, OH, [2]Good Samaritan Hospital, Cincinnati, OH

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0175–0198) Health Services Research Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: The ANA by immunofluorescence is a sensitive screening test for most systemic auto-immune rheumatic diseases (SARDs). A negative result is oftentimes sufficient to exclude a diagnosis. However, when diagnostic uncertainty persists, repeat testing is sometimes performed. The utility of a subsequent positive result is not clear. Only one previous study has examined the predictive value of a subsequent positive test after an initial negative result and found that only 1.1% of such patients developed a SARD. The purpose of this study was to attempt to validate this result in a different population of patients followed longitudinally and specifically evaluated by a rheumatologist, something that had not been done previously.

Methods: All patients aged ≥18 years seen at the University of Cincinnati Medical Center who tested negative for ANA initially and subsequently tested positive and who were evaluated by a rheumatologist on one or more occasions between April 2015 and April 2024 constituted the study population. Clinical diagnoses were established by board-certified

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

rheumatologists and independently verified through comprehensive electronic medical record review by a second rheumatologist.

Results: Of 4129 patients who underwent ANA testing and were evaluated by a rheumatologist during the study period, 296 (7.2%) had discordant results. Among these, 103 patients (2.5% of total cohort) had an initially negative ANA followed by a subsequent positive one. Records were reviewed before and after the positive result to determine if the diagnoses had been revised. In only 4 patients or 3.8% of cases did a positive result lead to a change in diagnosis. The revised diagnoses in these 4 patients were: UCTD (1), SLE (1), Sjogren's (1), undifferentiated inflammatory arthritis (1).

Conclusion: Repeat ANA testing after a negative result in patients suspected of having connective tissue disease infrequently results in a new diagnosis. Such testing is not cost-effective and should be discouraged in clinical practice guidelines.

Abstract Number: 0196

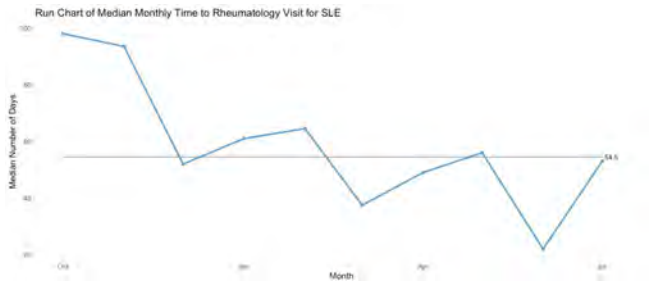
Increasing Timely Rheumatology Evaluation for High Risk Lupus Patients

Steven Taylor[1] and Elena Weinstein[2], [1]University of Colorado, Denver, CO, [2]University of Colorado, Englewood, CO

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0175–0198) Health Services Research Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: The rheumatology workforce shortage presents many challenges to the delivery of rheumatology care. Improving timely access to rheumatology for patients with life or organ threatening conditions such as SLE is one of the most important challenges. Our institution has a significant mismatch between number of referrals for new evaluation and number of new patient spots within our clinic. Further complicating the challenge of scheduling a prompt evaluation for these patients is the complex and multisystem nature of SLE. Literature

suggests less than half of these referrals have inflammatory rheumatic disease (Feuchtenberger, 2016) and delays in SLE care lead to worse outcomes (Kernder, 2021). Therefore, we developed a quality improvement (QI) project to improve the time from referral to first rheumatology appointment, in this report we describe the results of our first iteration of the project.



Run Chart of monthly days until rheumatology appointment for lupus patients

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Our study was deemed IRB exempt as a QI initiative. We implemented the Model for Improvement framework in our project (Langley, 2009). The aim statement of the project is to reduce the time from referral entry to first visit with a rheumatologist by 20% in which a diagnosis of SLE is coded. Data was collected from the medical record including ICD10 codes associated with the initial visit, date of initial visit, and date of the referral order. The first Plan, Do, Act, Study (PDSA) cycle focused on referral management. In the baseline state referrals were evaluated by a registered nurse (RN) reviewing the chart for appropriateness for rheumatology visit. That protocol did not include a mechanism to identify high risk phenotypes. Therefore, the referral process was changed to a hybrid of RN and rheumatologist review. The rheumatologist was instructed to evaluate appropriateness of referral and to risk stratify timing of the appointment. Statistical analysis was performed in R, tests of significance were Student's T and Mann-Whitney-Wilcoxon.

Results: The first PDSA cycle was started in February of 2024, with the addition of physician review on February 19th. From October 1, 2023, to July 1, 2024, there were 4,405 referrals to rheumatology, of which 123 had a diagnosis of SLE on the first visit. The median time from referral order to first appointment was 60.5 (±59.2) days for all referrals, and 60 (±57.2) days for SLE appointments. From October 1 to February 19 the median time to appointment was 70 (±67.3) days (n 707), and from February 19 to July 31 it is 5a5 (±42.5) days (n 539) $p \leq 0.05$. For SLE appointments the median time to appointment was 69±63 days (n 73) before intervention while the time after intervention was 51±38.9 (n 50) $p \leq 0.05$. A run chart for monthly time to evaluation is included in figure 1.

Conclusion: By incorporating physician review into the referral evaluation process, we were able to decrease the time to appointment by 26% for SLE patients. Confounding our study was an expansion of our clinical faculty in January 2024 and April 2024 by 1 full time equivalent. The next iterations of our project will focus on alternative processes to further improve access for patients with high-risk disease states while reducing reliance on manual chart review. This is an area of critical need in rheumatology.

Rheumatoid arthritis (RA) patients who screen positive for anxiety, depression, and/or fibromyalgia are more likely to report problems with sleeping, memory, and/or social activities than to have an abnormal rheumatoid factor or ACPA

Theodore Pincus[1], Juan Schmukler[1] and Tengfei Li[2], [1]Rush University Medical Center, Chicago, IL, [2]Rush, chicago, IL

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0175–0198) Health Services Research Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: A symptom checklist and screening indices for anxiety (ANX), depression (DEP), and/or fibromyalgia (FM) on patient questionnaires such as a multidimensional health assessment questionnaire (MDHAQ) facilitate recording symptoms as formal medical history data, not available prior to information technology. MDHAQ data may be informative to address two problems in RA: a. primary RA symptoms of joint pain and functional disability may be seen in patients with comorbid joint damage and/or patient distress, which may elevate RA core data set measures and indices in the absence

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Order of 60 symptoms among all patients	Symptom	All patients	ANX, DEP, and/or FM pos	ANX, DEP, and FM neg
2	Back pain	46%	62%	38%
3	Problems with sleeping	43%	75%	25%
5	Neck pain	38%	60%	40%
7	Headaches	33%	57%	43%
8	Unusual fatigue	28%	73%	27%
10	Anxiety	28%	100%	0%
15	Shortness of breath	25%	74%	26%
17	Depression	22%	100%	0%
18	Problems with memory	21%	81%	19%
21	Dizziness	19%	77%	23%
22	Problems with thinking	18%	87%	13%
25	Heartburn	17%	73%	27%
26	Cough	17%	56%	44%
27	Palpitations	15%	75%	25%
28	Problems with social activities	15%	92%	8%

Prevalence of self-report of symptoms in 173 patients with rheumatoid arthritis on a multidimensional health assessment questionnaire (MDHAQ), including the order in all patients (symptoms reflecting inflammatory activity are such as joint pain as #1 are excluded) according to positive screening on 1 of 3 MDHAQ indices for anxiety (ANX), depression (DEP) and or fibromyalgia (FM)

of inflammatory activity; b. rheumatoid factor (RF) or anti-cyclic citrullinated proteins (ACPA) are found in only 67-69% of RA patients (Meta-analysis: Nishimura et al Ann Int Med. 2007;146(11):797-808). Formal recording of specific symptoms may be analogous to laboratory testing to inform management decisions. The prevalence of non-inflammatory symptoms in RA patients with positive versus negative screens on MDHAQ ANX, DEP, and FM indices was analyzed.

Methods: All patients seen in the study setting complete an MDHAQ, which includes a 60-symptom checklist to record a review of systems and screen for adverse events of high-risk medications. The prevalence of each symptom was computed in all patients and compared in those who screened positive versus negative for any of the 3 MDHAQ indices, MAS2 (MDHAQ anxiety screen), MDS2 (MDHAQ depression screen) and/or FAST4 (fibromyalgia assessment screening tool). The 15 most common non-inflammatory-based symptoms reported by all patients were identified, after excluding symptoms likely to result from inflammation, e.g., joint swelling, muscle pain, muscle weakness, dry eyes, dry mouth, although recognizing that the included and excluded symptoms might have an inflammatory or noninflammatory origin in certain individual patients. The prevalence of each symptom was then compared in patients who screened positive for MAS2 for ANX , MDS2 for DEP, and/or FAST4 for FM versus negative for all 3 indices.

Results: Among all 173 RA patients, 40-50% reported neck pain, headaches, unusual fatigue, anxiety (by definition), dyspnea, depression (by definition), and problems with memory, 20-40% reported dizziness, problems with thinking, heartburn, cough, palpitations, and 15-19% problems with social activities (Table). Each of these symptoms was reported by more than 50% of patients who screened positive for ANX , DEP, or FM, and by fewer than 50% in those who screened negative (Table). More than 70% of patients who screened positive for ANX, DEP, and/or FM reported problems with thinking, memory, sleeping, and unusual fatigue, in addition to anxiety and depression (by definition), higher than the prevalence of rheumatoid factor or ACPA in RA.

Conclusion: Symptoms on a computer checklist can function as clues to the likelihood of ANX , DEP, or FM in patients with RA who may have elevated DAS28, CDAI, or RAPID3, but little or no inflammation, analogous to laboratory tests. The prevalence of symptoms in >70% of RA patients with ANX, DEP, and/or FM is higher than the prevalence of RF or ACPA in RA in a meta-analysis. This information can inform more rational patient management toward improved care and outcomes.

Variation in RA disease activity measure assessment and treatment change documentation in virtual vs in-office rheumatology visits

Yasmin Khader[1], Rocio Bautista Sanchez[2], Arati Kelekar[2], Marianne Kerski[2], David Wallace[2], Olivia Dickinson[3], Shirley Cohen-Mekelburg[3], Bryant England[4], Joshua Baker[5], Grant Cannon[6], Daniel Clauw[7] and Beth Wallace[8], [1]University of Michigan/VA Ann Arbor, Ann Arbor, [2]VA Ann Arbor/University of Michigan, Ann Arbor, [3]VA Ann Arbor, Ann Arbor, [4]University of Nebraska Medical Center, Omaha, NE, [5]University of Pennsylvania, Philadelphia, PA, [6]University of Utah and Salt Lake City VA, Salt Lake City, UT, [7]University of Michigan, Whitmore Lake, MI, [8]Michigan Medicine, VA Ann Arbor Healthcare System, Ann Arbor, MI

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0175–0198) Health Services Research Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: RA requires resource-intense management, with a joint exam recommended every 3-6 months to monitor disease activity. Frequent in-person visits are burdensome for patients and exacerbate access issues, contributing to long wait times and suboptimal care. Up to half of RA patients receive virtual rheumatology care, which can improve access and treatment adherence when added to office care. We know little about virtual care practices of RA management and how they compare to in-office practices. We aim to compare documentation of disease activity measure (DAM) assessment and treatment changes at virtual vs in-office RA visits in a large academic health system.

Methods: We conducted a retrospective cross-sectional study of a convenience sample of RA patients seen at University of Michigan rheumatology clinic from 2021-2024. We required a) a documented RA diagnosis in a clinical note by an attending rheumatologist during the study period, b) ≥1 office and ≥1 virtual visit during the study period to limit selection bias by

Table 1: Characteristics of the study cohort, stratified by virtual care utilization (ratio of virtual rheumatology visits to all rheumatology visits)

	Low virtual care (≤0.33)	High virtual care (>0.33)	p value

TJC: tender joint count; SJC: swollen joint count, PtGA: patient global assessment, ProvGA: provider global assessment, HAQ: health assessment questionnaire; GC: glucocorticoid

disease activity/severity. We extracted patient- and visit-level data from the electronic medical record using a standardized collection form. We used descriptive statistics to evaluate a) patient-level characteristics stratified by virtual care utilization (at/below vs above the mean ratio of virtual to total visits), b) visit-level documentation of disease activity measures (DAMs) and DMARD or glucocorticoid (GC) changes.

Results: We reviewed 330 visit notes (111 virtual, 219 office) for 64 RA patients seen by 3 rheumatology attendings during the study period. At the patient level, median (IQR) office and virtual visit counts were 1 (1-2) and 4 (2-4) respectively (Table 1). Mean (SD) virtual care utilization was 0.34 (0.16) and similar across attendings. Demographics and rheumatology clinic contact were similar across levels of virtual care utilization. Patients with higher virtual care utilization had higher rates of fibromyalgia (3.2 vs 9.0%, $p < 0.0001$), seropositivity (80.7 vs 87.9%, $p < 0.0001$), RA duration (median 14 vs 21 years, p 0.0002), and TNF inhibitor use (54.8 vs 30.3%, p 0.05).

All attendings were less likely to document DAMs at virtual vs. office visits ($p < 0.0001$) (Table 2). Patient-reported DAM documentation was low in both settings (total N = 1). We saw significant between-provider differences in joint count documentation at both virtual and office visits, inflammatory marker and treatment change documentation at virtual visits (p 0.004 DMARD, 0.005 GC), and DMARD change documentation at office visits (P 0.038). Attending 3 was less likely to change treatment at virtual vs in-office visits (p 0.05); documentation was consistent across settings for attendings 1 and 2 (all $p \geq 0.1$).

Conclusion: In a sample of RA patients seen both virtually and in-office, we saw variation in DAM and treatment change documentation a) between settings across attendings, b) across attendings in each setting. Patient-reported DAM collection was low overall. Further work is needed to confirm these findings, and to develop and test provider-facing interventions to improve DAM collection and treatment optimization in the virtual setting.

Pain Phenotypes and Social Determinants of Health in Chronic Chikungunya Arthritis: A Cross-Sectional Study

Abebawork Adem[1], Alfonso Sucerquia[2], Jose Forero[3], Juan Alzate[2], Larry Moreland[4], Gary Firestein[5], Andres Cadena[6] and Aileen Chang[7], [1]George Washington University, Washington, DC, DC, [2]The George Washington University, Arlington, [3]The George Washington University, Arlington, VA, [4]University of Colorado, Denver, CO, [5]University of California, San Diego, San Diego, CA, [6]Clinica de la Costa, Barranquilla, Colombia, [7]The George Washington University, Washington

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0199–0209) Infection-related Rheumatic Disease Poster

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Chronic chikungunya arthritis (CCA) is a long-term sequela of chikungunya virus infection marked by persistent pain, disability, and reduced quality of life. While nociplastic, neuropathic and nociceptive pain types have been described in other diseases, they remain understudied in CCA. This study aimed to classify pain phenotypes and evaluate clinical and social determinants associated with each phenotype among individuals with CCA.

Methods: We conducted a cross-sectional analysis of 117 participants enrolled in a clinical trial for CCA in an underserved population. Pain types were categorized using the PainDETECT Questionnaire and the Nociplastic-Based Fibromyalgia Features (NFF) tool. Disease activity and function were assessed using the Chikungunya Disease Activity Score (CHIK-DAS), Disease Activity Score-28 (DAS-28), Health Assessment Questionnaire (HAQ), and arthritis flare score. Social determinants

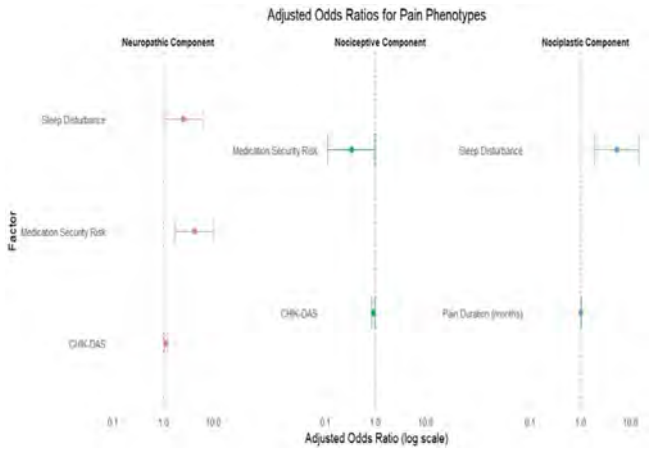

Figure 1. Adjusted Odds Ratios (AORs) for Factors Associated with Pain Phenotypes in Chronic Chikungunya Arthritis. Forest plot showing multivariable-adjusted associations between clinical and social factors and the presence of neuropathic, nociceptive, and nociplastic pain components. Odds ratios are plotted on a log scale with 95% confidence intervals. Medication insecurity and higher CHIK-DAS scores were significantly associated with neuropathic pain, while nociplastic pain was linked to longer pain duration and sleep disturbance. Nociceptive pain was inversely associated with CHIK-DAS and medication security risk.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

of health (SDOH) were measured using a validated 10-item instrument. Bivariate analyses and multivariable logistic regression were used to examine associations between pain phenotypes and clinical/SDOH variables.

Results: Participants were predominantly female (78.6%), with a median age of 58 years and a median pain duration of 8.6 years. Nociplastic pain was the most prevalent phenotype (79.5%), followed by neuropathic (48.7%) and nociceptive (25.6%) pain. Nociplastic pain was significantly associated with longer pain duration (aOR = 1.02, 95% CI: 1.00–1.04) and sleep disturbance (aOR = 5.27, 95% CI: 1.92–14.44). Neuropathic pain was linked to higher disease activity (aOR = 1.12, 95% CI: 1.03–1.21), sleep disturbance (aOR = 2.47, 95% CI: 1.02–5.96), and medication insecurity (aOR = 4.17, 95% CI: 1.69–10.27). Nociceptive pain was inversely associated with CHIK-DAS (aOR = 0.91, 95% CI: 0.84–0.98) and less frequent among participants with medication insecurity (aOR = 0.33, 95% CI: 0.11–0.96) (Figure 1). Clinical burden was highest in those with nociplastic pain, while social vulnerability was more prominent in those with neuropathic components.

Conclusion: Pain in CCA is multidimensional, with nociplastic and neuropathic phenotypes predominating and associated with greater disease activity and functional impairment. Medication insecurity and sleep disturbance were key predictors of neuropathic pain, while nociplastic pain appeared more driven by chronicity and central sensitization. Incorporating SDOH screening and phenotype-specific assessments like CHIK-DAS may improve pain management strategies in post-viral arthritis.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0199–0209) Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Infections and malignancies are two of the most feared side effects of biologic therapies. Giant cell arteritis (GCA) is a vasculitis which affects older people in whom the risk of infection and malignancies is higher.

Our aim was to assess severe infections and malignancies that occurred during the follow-up of a series of patients with (GCA) treated with tocilizumab (TCZ).

TABLE. Severe infections and malignancies documented in the 471 GCA patients treated with tocilizumab.

Methods: Multicentre study of 471 patients diagnosed with GCA and treated with TCZ. The diagnosis of GCA was performed between 2014 and 2020 according to: a) 1990 ACR criteria, b) temporal artery biopsy, and/or **c)** imaging evaluation techniques. Rate of infections and malignancies are expressed as the exposure-adjusted incidence rate (EAIR) per 100 person years (PY).

Results: We studied 471 patients (342 women; mean age, 74±9 years) treated with TCZ. The phenotypic distribution was: cranial GCA (cGCA) (n=217; 46%), mixed GCA (mixGCA) (n=174; 37%), and extracranial GCA (ecGCA) (n=80; 17%).

After 25.3±21.7 months of follow-up, 63 (13.4%) patients had severe infections (6.4 EAIR/100 PYs), which were more frequent in cGCA (n=44; 20.3%) **(Table)**. The most frequent infections were: urinary tract infection (n=14; 3%), bacteriemia/sepsis (n=9; 1.9%), varicella zoster virus infection (n=6; 1.3%), pneumonia (n=6; 1.3%), upper respiratory tract infection (n=5; 1.1%), cellulitis (n=5; 1.1%), abscess (n=4; 0.8%), septic arthritis (n=2; 0.4%), osteomyelitis (n=2; 0.4%), septic bursitis (n=1; 0.2%), meningitis (n=1; 0.2%), pyelonephritis (n=1; 0.2%), pericarditis due to *Lysteria* (n=1; 0.2%), candidiasis (n=1; 0.2%), and *Cytomegalovirus* infection (n=1; 0.2%).

Four (0.8%) patients developed a neoplasia (0.4 EAIR/100 PYs). The most frequent malignancies were: bladder cancer (n=1), colon cancer (n=1), lung cancer (n=1), and myelodysplastic syndrome (n=1).

Conclusion: In this wide series of TCZ in GCA of clinical practice, although TCZ is a relatively safe therapy in GCA, in our series, severe infections were observed in a non-negligible percentage rate of patients, being more frequent in cGCA. Neoplasms were rarer.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0199–0209) Infection-related Rheumatic Disease Poster

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with immune-mediated inflammatory diseases (IMIDs) receiving Janus Kinase Inhibitors (JAKi) are at increased risk of herpes zoster reactivation. The adjuvanted recombinant zoster vaccine (HZ/su) was recently approved in Europe; however, IMID patients were not included in the pivotal clinical trials. This study presents the largest real-world analysis of the immunogenicity and safety of HZ/su in IMID patients, compared to healthy controls.

Methods: We conducted a prospective, multicenter cohort study in Madrid, Spain, between March 2022 and March 2025. Vaccine response was defined as a fourfold or greater increase in antibody titers at follow-up compared to pre-vaccination levels, in line with clinical trial criteria.

Results: A total of 93 IMID patients and 107 healthy controls were enrolled. The mean age was 54 ± 10 years in the patient group and 61.8 ± 1.5 years among controls. Previous herpes zoster reactivation was reported in 9% of participants. A humoral immune response was observed in 51.4% of healthy controls, compared to 30% of patients. Immunogenicity was not influenced by other factors, including concomitant treatment with methotrexate, prednisolone, or the treatment line. No serious adverse events or major disease flares were reported.

Conclusion: IMID patients receiving JAKi therapy showed a reduced immunogenic response to the HZ/su vaccine compared to healthy individuals, likely influenced by concurrent immunosuppression. The vaccine was well tolerated, with a very low rate of adverse events. These findings support a strong recommendation for HZ/su vaccination in this vulnerable patient population, and advocate for varicella zoster vaccination prior to starting JAKi treatment.

Session Date: Sunday, October 26, 2025

Session Title: (0199–0209) Infection-related Rheumatic Disease Poster

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with autoimmune inflammatory rheumatic diseases (AIIRD) are at increased risk of infections due to both immune system dysfunction and the use of immunosuppressive therapies. Vaccination is a key preventive strategy to reduce infection-related morbidity and mortality in this population. This study aimed to develop evidence-based vaccination recommendations for adults with AIIRD in Saudi Arabia, based on international guidelines (ACR, EULAR, CDC, WHO), current literature on vaccine safety and efficacy, and expert consensus. The recommendations address vaccine timing, safety, and immunogenicity, covering both live and non-live vaccines, and emphasize a personalized approach that balances optimal protection with the risk of disease flares and treatment considerations.

Methods: A Delphi consensus method was used to develop expert-based vaccination recommendations for patients with AIIRD. A multidisciplinary panel comprising rheumatology, infectious disease, and immunology specialists participated in a structured, three-round process. This included an initial open-ended survey, followed by quantitative rating of statements on a 10–100 scale, with ≥70% agreement required to establish consensus. Statements not reaching consensus were revised and re-evaluated. Data collection was conducted via Word documents and Google Sheets, and both online and in-person meetings supported iterative discussion and finalization of recommendations.

Results: A review of current literature and consensus guidelines revealed that inactivated influenza vaccination is safe and generally effective in patients with AIIRD, even while receiving immunosuppressive therapy. Patients on methotrexate demonstrated improved vaccine immunogenicity when the drug was withheld for 1–2 weeks post-vaccination, without a significant increase in disease flares. For those on rituximab, delaying therapy for at least 2 weeks after vaccination may enhance immune response if disease activity permits. Vaccination is strongly recommended for patients on prednisone ≤10 mg/day and conditionally recommended at higher doses due to potentially reduced efficacy. Use of TNF inhibitors and JAK inhibitors did not significantly impair immune responses, supporting vaccine administration without treatment interruption. Despite

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. modest reductions in immunogenicity in certain subgroups, partial protection remains clinically beneficial, reinforcing the importance of annual influenza vaccination in our population.

Conclusion: Vaccination plays a vital role in reducing infection-related risks in patients with AIIRD. We present comprehensive recommendations aligned with international guidelines, highlighting the preference for non-live vaccines, the contraindication of live vaccines in immunosuppressed patients, and the importance of individualized vaccination plans. It underscores the need to enhance physician awareness and patient education to improve vaccine uptake and calls for future research to optimize vaccine responses and expand immunization strategies in Saudi population.

Session Title: (0199–0209) Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Cytomegalovirus (CMV) infection is a well-recognized complication in immunocompromised individuals, yet there islimited evidence guiding surveillance strategies in patients with rheumatic diseases on immunosuppressants. This study aimed to identify risk factors for CMV infection and define a high-risk subgroup warranting active screening among patients receiving prolonged, high-dose glucocorticoids.

Methods: We retrospectively analyzed 2,343 patients with rheumatic diseases who received ≥30 mg/day of prednisolone-equivalent glucocorticoids for ≥28 consecutive days at nationwide tertiary referral centers in South Korea. Clinical, laboratory, and immunosuppressant data were collected during a 28-day lead-in period from the high-dose glucocorticoid initiation. The observation period was one year following the lead-in period. Quantitative CMV PCR or pp65 antigenemia tests were performed at the discretion of the treating physician. Cox proportional hazard model was used to identify independent predictors of 1-year CMV infection. Kaplan–Meier curves were used to present a CMV infection-free survival by risk group.

Results: During the follow-up of 2131 person-years, 223 (9.7%) patients underwent CMV testing. Of these, 104 (46.6%) were diagnosed with CMV infection, and 33 (31.7%) of them met criteria for CMV disease. Multivariable analysis identified female sex (HR 0.53 [95% CI 0.33–0.83]), Sjögren's syndrome (HR 3.17[1.35–7.44]), hypertension (HR 1.66 [1.10–2.51]), diabetes (HR 1.96 [1.29–2.98]), interstitial lung disease (HR 3.21 [2.09–4.92]), renal impairment (azotemia: HR 2.02 [1.27–

3.21]; hemodialysis: HR 53.79 [1.84–7.81]), previous solid organ transplantation (HR 14.43 [5.44–38.31]), use of lymphocyte-targeting immunosuppressants (HR 2.16 [1.39–3.35]), rituximab (HR 2.02 [1.11–3.68]), leukopenia (lymphocyte < 800/μL; HR 1.96 [1.25–3.07]), anemia (Hb < 8 g/dL; HR 3.10 [1.76–5.46]), and thrombocytopenia (platelet< 150k; HR 1.68 [1.04–2.73]) as independent risk factors (Table 1). The final model demonstrated strong discriminatory performance with AUCs ranging from 0.799 to 0.891 throughout the follow-up period. High-risk patients identified by the model showed a significantly higher incidence of CMV infection than those in the low-risk group (HR 14.82 [9.687 – 22.67]) (Figure 1). Of 34 CMV disease cases, 11 (32.4%) died within one year. Disease risk was significantly associated with lymphopenia and elevated CMV titers (antigenemia >10 or PCR >1000).

Conclusion: This risk stratification model identifies patients at increased risk for CMV infection who may benefit from active surveillance. Prospective validation is needed to optimize CMV monitoring strategies in this high-risk population.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Immunogenicity and safety summary for the chikungunya virus-like particle vaccine development programme

Lauren Tindale[1], Jason Richardson[1], Deborah Anderson[1], Jason Mendy[2], Sufia Muhammad[2], Tobi Loreth[1], Victoria Jenkins[3], **Krystal Valenzuela**[4], Benedetto Simone[5], Patrick Ajiboye[2] and Lisa Bedell[4], [1]Bavarian Nordic Canada Inc., Toronto, Canada, [2]Bavarian Nordic, Inc., San Diego, [3]Bavarian Nordic Belgium, Brussels, Belgium, [4]Bavarian Nordic, Inc., Durham, [5]Bavarian Nordic Berna GmbH, Thoerishaus, Switzerland

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0199–0209) Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Chikungunya virus (CHIKV) is a threat to public health and a risk for travellers to endemic countries. Typical acute symptoms include fever, arthralgia, myalgia, fatigue, and headache. Debilitating arthralgias may persist for months or years. We report aggregated safety and immunogenicity data from five clinical trials for a CHIKV virus-like particle (VLP) vaccine, which has been approved for use by the US FDA in February 2025.

Methods: To date, the CHIKV VLP vaccine development programme has included three phase 2 and two phase3 trials across multiple sites in the US, which enrolled participants 12 to 95 years of age. Participants received a single dose of CHIKV VLP vaccine or placebo. The safety population included 3141vaccinated and 675 placebo participants from five trials and the immunogenicity evaluable population included 2829 vaccinated and 607 placebo participants from four trials. Immunogenicity was assessed by measuring CHIKV serum neutralising antibody (SNA) titres (NT80) at selected time points; SNANT80 ≥100 is the surrogate marker likely to predict protection. Immunogenicity and safety were assessed through Day 183 post vaccination.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Immunogenicity findings showed robust responses, with a seroresponse (SNA NT80 ≥100) as early as Day 8 (47%), peaking at Day 15 (96%) and Day 22 (97%; primary endpoint), and lasting through Day183 (85%).In phase 3 trials, the seroresponse rate and geometric mean titre was significantly higher in the vaccine group than the placebo group at all time points. CHIKV VLP vaccine demonstrated a favourable safety profile across trials. Most AEs were mild or moderate; events primarily consisted of injection site pain, headache, fatigue, and myalgia. Solicited and unsolicited events of arthralgia were reported at similar rates between vaccinated and placebo participants. SAEs occurred in < 1% of participants, with no vaccine-related deaths. Overall, no safety signals were detected.

Conclusion: CHIKV VLP vaccine offers a VLP-based vaccine option for immunisation against CHIKV disease. The data analysed demonstrate the strong immunogenicity and favourable safety profile of CHIKV VLP vaccine; rapid and durable SNA NT80 responses support the potential for this vaccine to protect individuals ≥12 years of age from disease caused by CHIKV.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0199–0209) Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: In 2023, Spain approved the inactivated varicella zoster virus (VZV) vaccine in individuals over 50 years of age with immunosuppressive conditions, including rheumatology patients due to both immune system alterations and immunosuppressive therapies. It is anticipated that the proportion of vaccinated patients will increase in the coming years, resulting in fewer herpetic events and associated complications.

Our objective is to describe a population of rheumatology patients eligible for VZV vaccination and to analyze vaccination uptake and incidence of herpetic events.

Methods: We conducted a retrospective, observational, descriptive study of patients followed at a tertiary care Rheumatology Department. Between January 2021 and June 2024, patients were referred for vaccination prior to initiating biologic,

targeted synthetic, or immunosuppressive therapy. Demographic and clinical characteristics were recorded. A subanalysis of herpetic events and their incidence before and after the vaccine was performed.

Results: 431 patients (66.1% female) were referred for VZV vaccination, most commonly with Rheumatoid Arthritis (34.1%). The mean age at treatment initiation was 51.49 ± 13.81 years (Table 1). The most frequently initiated therapy was anti-TNF agents (25.29%), followed by JAK inhibitors (20.6%).

Of these, 171 patients (39.7%) received the VZV vaccine, primarily women with rheumatoid arthritis. Among vaccinated patients, JAK inhibitors were the most commonly initiated treatment (41.52%), with Upadacitinib used in 31 cases. The annual proportion of patients vaccinated against VZV increased from 10.87% in 2021 to 66.67% in 2024 (Figure 1).

29 herpetic events occurred in 23 patients, yielding an incidence of 0.06 events per patient over a mean follow-up of 10.81 years. Of these, 21 were women and 8 were receiving JAK inhibitors.

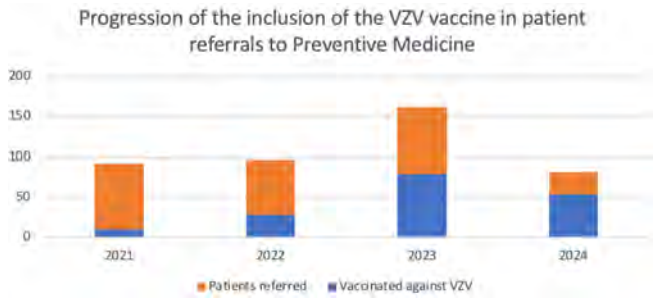

Figure 1. Annual Proportion of Patients Referred to Preventive Medicine Who Received VZV Vaccination.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Among vaccinated individuals, 22 herpetic events were recorded, with 18 occurring prior to vaccine administration and 4 events reported post-vaccination. The majority of herpetic episodes were cutaneous monometameric (60.7%), followed by multimetameric cutaneous involvement (10.7%).

The incidence of herpetic events in the vaccinated group was 0.02 events per patient (2.33% of vaccinated patients). In contrast, the incidence in unvaccinated patients was higher, at 0.05 events per patient (5.8% of the unvaccinated population).

Conclusion: 39.7% of patients referred for pre-biologic varicella zoster virus (VZV) vaccination received it, with uptake increasing progressively over the study period. The most frequent treatment initiated were JAK inhibitors.

29 herpetic events were documented in 23 patients, most of which were mild. Among these 23 patients, 18 had been vaccinated, with only 4 herpetic events occurring after vaccine administration.

The incidence of herpetic events among unvaccinated patients was 0.05 events per patient, corresponding to 5.8% of that subgroup. In contrast, the incidence in the vaccinated cohort was reduced to 0.02 events per patient, affecting 2.33% of vaccinated individuals. These findings support a potential protective role of VZV vaccination in reducing herpes zoster events in immunocompromised rheumatology patients.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0199–0209) Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Recombinant zoster vaccine (RZV), represents a major advancement in the prevention of herpes zoster in autoimmune rheumatic diseases (ARD) patients. However, RVZ efficacy depends on strong cellular and humoral

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

immune response. Intravenous cyclophosphamide (IVCYC) is a potent immunosuppressive agent known to impair both arms of the immune system. Therefore, it is important to evaluate the impact of IVCYC on RVZ humoral immunogenicity in ARD patients, and to explore factors that may influence vaccine response.

Methods: This was a subgroup analysis of ARD patients (≥18 years) currently receiving IVCYC (ARD-IVCYC) enrolled in a phase 4 randomized placebo-controlled prospective study. Healthy immunocompetent adults ≥50 years (CG) and patients not treated with IVCYC (ARD-No IVCYC) were included as comparison groups (1:4 ratio). ARD-IVCYC patients were randomized in two groups: P1 (vaccine) and P2 (placebo). CG and P1 received RZV (D0 and D42); P2 initially received placebo, followed by RZV (D84 and D126). Humoral response to RZV was defined as anti-gE concentration (ELISA) ≥4-fold the pre-vaccination level and evaluated at baseline and 6 weeks after second dose. GMT was also calculated. Disease activity was assessed using ARD-specific activity indices. Adverse events (AEs) were recorded.

Results: 42 ARD-IVCYC, 168 CG and 168 ARD-no IVCYC individuals were included. Among ARD-IVCYC, 34% were treated according to the EuroLupus protocol, 54% National Institutes of Health (NIH) regimen, and 10% followed the CYCLOPS protocol for vasculitis. The median cumulative dose of IVCYC was 3 g (3-4.5). Groups were comparable for sex ($p< 0.05$), although ARD-IVCYC and ARD-No IVCYC were younger than CG (40 vs. 40 vs. 52 years, $p< 0.001$). ARD diagnoses were similar between ARD-IVCYC and ARD-No IVCYC groups ($p >0.05$), except for a higher frequency of vasculitis in the former (10.8% vs. 0%, $p< 0.001$). Regarding immunogenicity, ARD-IVCYC and ARD-No IVCYC had comparable humoral response but lower than CG (91.9% vs. 91.1% vs. 99.4%, $p < 0.002$). Post-immunization GMT were alike in ARD-IVCYC and ARD-No IVCYC groups but both significantly lower than CG [7.53 (95% CI 5.09–11.15) vs. 6.64 (95% CI 5.58-7.91) vs. 13.2 (95% CI 12.0–14.58) mUI/mL, $p < 0.001$]. Among ARD-IVCYC patients, those with post-RZV anti-gE titers < 7.53 mUI/mL more frequently used mycophenolate mofetil (33% vs 5.3%, p=0.042), with no differences in age, diagnosis, glucocorticoid, or other therapies compared to those with titer ≥7.53 mUI/mL ($p >0.05$). Flare rates were similar between vaccine (P1) and placebo (P2) groups (25% vs. 22.7%, p=0.592). Local and systemic AEs were less frequently reported by ARD-IVCYC compared to CG after both RZV doses ($p< 0.05$). No severe AEs were reported.

Conclusion: Our findings demonstrate that IVCYC is safe and, unexpectedly, does not exert a more detrimental effect on the humoral response to RZV than other immunosuppressive agents used in ARD, particularly MMF. Although the response rate was high, the lower immunogenicity compared to controls, despite the younger age, reinforces the need for close surveillance for HZ risk. (ClinicalTrials NCT05879419).

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0199–0209) Infection-related Rheumatic Disease Poster

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: There have been over 777 million cases of acute COVID-19 infections worldwide as of April 2025. Although many patients recover, an estimated 10-30% of patients continue to experience a constellation of symptoms labelled "Long COVID" or PASC. Major symptoms include fatigue, cognitive dysfunction, post-exertional malaise, and sleep disturbances. Exact pathophysiology of PASC remains unclear but there are data suggesting a potential role of inflammation and autoimmunity in persistence of symptoms. In the absence of effective treatments, patients are inquiring about the role of diet given burgeoning data linking microbiome dysbiosis to dysregulated host immune responses and autoimmune diseases. We assessed the feasibility of a 12-week anti-inflammatory diet (Long COVID Anti-Inflammatory, LC-ITIS) among patients with PASC and explored diet-induced changes in clinical symptoms and inflammatory makers.

Methods: Patients with a confirmed COVID-19 infection and persistence of $\geq$2 of the 3 new symptoms (sleep disturbances, brain fog, fatigue $\geq$ 5 on VAS) for $\geq$ 12 weeks after the infection were recruited. LC-ITIS diet was similar to previously established RA anti-inflammatory (RA-ITIS) diet from our group which has shown correlation between gut microbiome/metabolome and clinical response [Coras R et al. Clin Transl Med 2022;12:e959]. LC-ITIS diet emphasized foods rich in anti-inflammatory nutrients and those with favorable omega-6:Omega-3 fatty acid profile (e.g. flax/chia seeds, miso). Foods such as highly processed foods, added sugar, and nightshade vegetables were restricted. Clinical outcomes, dietary adherence, and inflammatory makers were measured (Table 1). Data were analyzed using ANOVA and mixed-effects model. Statistical analyses were performed in SPSS.

Table 1. LC-ITIS Diet Regimen and Assessment Timeline

Table 2. Clinical Outcomes

	Wk -2	Wk 0	Wk 2	Wk 5	Wk 8	Wk 12	F
Total FAS	35.1 ± 6.7	32.9 ± 7.4	32.7 ± 8.4	30.1 ± 8.2	29.1 ± 6.8	28.4 ± 7.9	$F_{(5,41)}$ = 10.45**
BDI	17.9 ± 7.7	14.7 ± 8.0	13.1 ± 6.9	12.9 ± 8.3	12.8 ± 7.0	12.6 ± 6.8	$F_{(5,53)}$ = 7.84**
PROMIS IB Sleep Disturbances T score	58.6	57.5	55.9	54.7	54.7	53.2	$F_{(3,33)}$ = 3.31*
MOCA	26.1 ± 2.9		27.6 ± 2.1			27.5 ± 1.8	$F_{(2,31)}$ = 8.50*

Means and standard deviations are reported. FAS 10-35 (10-21: no fatigue; 22-50: substantial fatigue; Minimally important difference: 4 points); BDI 0-63 (0-13: minimum depression; 14-19: mild depression; 20-28: moderate depression; 29-63: severe depression); PROMIS 8B Sleep Disturbances T score 50 = average US population, higher T = worse sleep; MOCA no cognitive dysfunction >26; **p<0.001; *p<0.01

Results: Two patients dropped out at Week 0 (Wk0) before starting the diet. All remaining 21 patients completed 2 weeks of LC-ITIS diet with pre- and post-assessments. Majority (71%) completed 12 weeks of diet and assessments. Patients were 66% women, 57% Caucasians, and 24% Hispanics with a mean age of 53.3 ±15 (range 25-78). By the end of the study, 50% reported that they changed their dietary habits significantly. The self-reported adherence rate was high at 91% at Wk2 and maintained at 94% through Wk12 (≥6 on a 0-10 scale; moderate to very well). The mean BMI decreased from 28.8 to 27.8 over 12 weeks. Many, 69% and 49%, found diet instruction and diet easy/very easy to follow, respectively. There were significant clinical improvements in fatigue, sleep, cognitive function, and depressive mood with LC-ITIS diet (Table 2). Inflammatory marker results are excluded in this report.

Conclusion: This is the first pilot study assessing the effect of anti-inflammatory diet on clinical outcomes in patients with PASC. The diet adherence rate was very high among these patients despite significant fatigue and brain fog. Our initial findings demonstrate feasibility and potential symptom relief benefits of anti-inflammatory diet in a disease with no effective treatment. This finding should be evaluated in a larger randomized controlled trial.

Abstract Number: 0208

Current practices and challenges in tuberculosis screening and preventive treatment among patients with rheumatic diseases: A multiregional physician survey in China

Xu Wang, Lifan Zhang and Lidan Zhao, Peking Union Medical College Hospital, Beijing, China (People's Republic)

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0199–0209) Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: This study aimed to assess the current clinical practices of tuberculosis (TB) infection screening and TB preventive treatment (TPT) among patients with rheumatic diseases, identify challenges physicians face during diagnosis and treatment, and explore potential strategies for improvement.

Methods: A well-structured questionnaire was designed and distributed to nationwide physicians from multiple disciplines, including but not limited to rheumatology, infectious diseases, and tuberculosis departments.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: A total of 443 valid responses were collected and analyzed. 76% of the respondents were from general hospitals, and 71% of the respondents had treated patients with rheumatic diseases complicated by active TB in the past year. Approximately 60% of the respondents reported routinely performing TB infection screening at the initial visit of patients with rheumatic diseases. Target populations primarily included those scheduled to receive tumor necrosis factor-alpha inhibitors or Janus kinase inhibitors, and those with a history of TB exposure or previous TB infection. Common preferred screening methods included chest imaging (15.58%), the tuberculin skin test (18.06%), and interferon-gamma release assays (58.69%). Reasons for not conducting routine screening included patients' financial burden (50.57%), perceived low risk of infection (53.45%), and minimal impact on treatment decisions (46.55%). The majority of physicians (74.49%) indicated they would recommend TPT for patients with latent TB infection, and a 3-month combination regimen of isoniazid with rifampicin was mostly preferred (60.95%). However, poor treatment adherence due to long duration and adverse drug reactions was frequently reported. Although most physicians acknowledged the necessity and safety of TPT, concerns remained regarding individualized efficacy and potential risks. Key barriers identified included poor patient compliance, drug-related side effects, and a lack of robust clinical evidence.

Conclusion: Implementing TB infection screening and preventive treatment in patients with rheumatic diseases remains suboptimal, with multiple practical challenges. Enhancing professional training, improving awareness of clinical guidelines, strengthening patient education, and optimizing screening and treatment strategies may improve feasibility and effectiveness in clinical settings. Future efforts should focus on multicenter studies and policy support to standardize and promote TB infection management, thereby improving the overall quality of care for patients with rheumatic diseases.

A Retrospective Safety Analysis Based on Platelets in Arthrocentesis and Joint Injections in Cancer Patients

Yuanteng Li[1], Cheuk Leung[2], Heather Lin[2], Angeles Lopez-Olivio[3] and Jean Tayar[3], [1]MD Anderson Cancer Center, Houston, TX, [2]MD Anderson Cancer Center, Houston, [3]The University of Texas, MD Anderson Cancer Center, Houston, TX

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0199–0209) Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Arthrocentesis and joint injections are commonly performed to diagnose and to treat rheumatic conditions such as crystal-induced arthritis, septic arthritis, and inflammatory arthritis. While generally safe, these procedures carry risks of iatrogenic infection and bleeding (Courtney 2005, Dooley 2002), particularly in cancer patients, who often have leukopenia and thrombocytopenia from chemotherapy or are on anticoagulation therapy (Ahmed 2012). Despite proposed thresholds for prophylactic transfusions (e.g., 20,000 and 10,000/microliter) in more invasive procedures, specific guidelines on the safety of arthrocentesis in cancer patients remain lacking (Kaufman 2015, Avvisaati 2003).

Methods: We conducted a retrospective cohort study of patients who underwent arthrocentesis or joint injections between 2006 and 2016 at MD Anderson Cancer Center. Baseline demographic information, clinical characteristics (e.g. primary cancer diagnosis, smoking status, comorbidities and etc), and clinical outcomes were collected up to 12 weeks post-procedure. The primary outcome was bleeding, and the secondary outcome was iatrogenic infection. To evaluate the safety

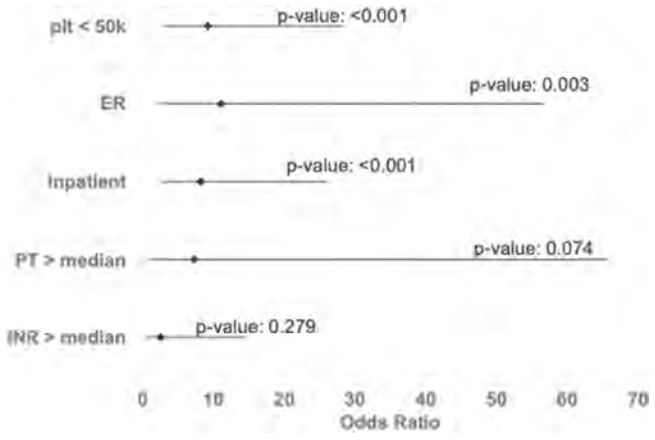
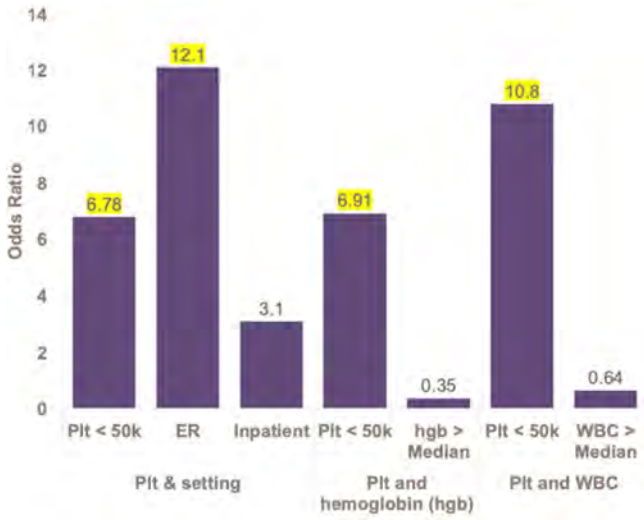
Demographics after exact matching 1:2. The absolute standardized differences were less than 10% for all 5 categories after exact matching, indicating good balances on the matching factors.



Odds of septic arthritis vs. patient characteristics based on univariable logistic regression with 95% confidence interval

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Odds of Septic Arthritis based on low platelet count and setting, hemoglobin, and WBC based on multivariable analysis with α at 0.05. Highlighted Odds Ratio have a p-value < 0.05.

of arthrocentesis and joint injections in thrombocytopenic patients (platelet count ≤50,000/μL), we performed exact matching on sex, age, cancer type, anti-platelet, and anti-coagulant drugs use in a 1:2 ratio with patients with normal platelet count (≥140,000/μL) to compare the outcomes between the two patient groups.

Results: Among 95 arthrocentesis in thrombocytopenic patients and 760 in patients with normal platelet counts, no cases of bleeding or iatrogenic infection were observed in either group. After matching, thrombocytopenic patients (n=89) and controls (n=174) were comparable in demographic and clinical characteristics. Univariable analysis showed that initial visits to the ER and inpatient were associated with higher risk of septic arthritis. However, hemoglobin greater than the median and white blood cell greater than the median are associated with a lower risk of septic arthritis. Finally, thrombocytopenic patients had a higher risk of initial septic arthritis, while even adjusting for white blood count (OR 10.8; 95% CI: 2.9-39.8; P< 0.001).

Conclusion: Arthrocentesis and joint injections appear safe in cancer patients with thrombocytopenia, as no bleeding or iatrogenic infections were observed. However, the higher incidence of septic arthritis in thrombocytopenic patients underscores the importance of microbiological analysis of synovial fluid. These findings support the safety of these procedures while highlighting the need for vigilance in high-risk patients.

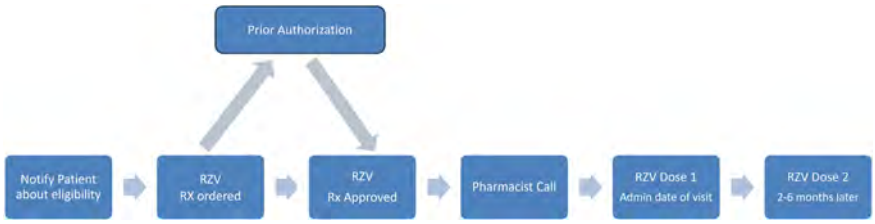

Figure 1: Process Map for RZV Dose 1 Adminstration

Background/Purpose: Despite guideline recommendations, recombinant zoster vaccine (RZV) uptake remains low among immunocompromised individuals younger than 50 years of age, notably those with rheumatoid arthritis (RA). Previous institutional efforts, including patient and physician education, demonstrated increased willingness to receive the vaccine but the impact was limited. Additional strategies to increase uptake were warranted. Our aim was to increase RZV uptake among RA patients ages 18-49 from 10% to 15% by January 2025 through a targeted partnership with specialty pharmacy.

Methods: We defined our baseline cohort as RA patients ages 18-49 years seen at a tertiary care clinic from July 2023 to December 2023. Prior patient and physician educational interventions increased baseline RZV uptake from 6.7% to 10.3% (January 2024 to May 2024). Root cause analysis identified vaccine access as a major barrier. Starting June 2024, we partnered with Stanford Specialty Pharmacy, that is located near the clinic, to develop a coordinated vaccine delivery pathway aligned with rheumatology visits. Our improvement team included clinic nurses, patient care coordinators (PCC), pharmacists, and rheumatologists. A comprehensive workflow was established including communication regarding eligibility, RZV prescription with obtaining prior authorization, pre-visit vaccine counseling, and RZV administration on date of clinic visit (Figure 1). In November 2024, a separate workflow was created to coordinate the second vaccine dose within 2-6 months post-first dose (Figure 2). To minimize barriers to vaccine access, validated parking was provided in collaboration with Stanford Medicine Transportation Services. The primary outcome was the proportion of eligible patients to receive at least 1 dose of RZV following intervention during June 2024 to January 2025. The secondary outcome was completion of 2 dose series following implementation (November 2024). Barriers to RZV were collected from telephone encounters between patient and pharmacist.

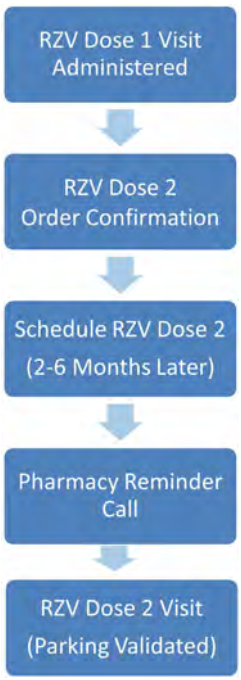

Figure 2: Process Map for RZV Dose 2 Adminstration

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Among the baseline cohort (n=137), 15.3% received at least one RZV dose between June 2024 and January 2025, meeting the intervention goal. Following implementation of the workflow for dose #2 of RZV, 5 of 9 eligible patients (55.5%) completed the two-dose series by May 2025. Common barriers to vaccination included reproductive considerations (n=5) including in vitro fertilization, pregnancy, or breastfeeding as well as insurance authorization issues (n=5), and vaccine hesitancy (n=3).

Conclusion: A targeted partnership with specialty pharmacy significantly improved RZV uptake among RA patients ages 18-49 years, which included direct outreach to the patients from the pharmacists. Prior to scaling the intervention to patients with various rheumatologic conditions, it is critical to investigate and address population-specific barriers to enhance vaccine uptake in this high-risk group.

Initial Results From a Single-Center Quality Improvement Initiative Using the Shingrix Rheumatology Immunization Dashboard Within the Veterans Health Administration

Alexandra Do[1], Lisa Matsumoto[1], Cherish Wilson[2], Gary Tarasovsky[3], gabriela Schmajuk[4] and Jennifer Barton[5], [1]Oregon Health and Science University, Portland, [2]UCSF / SFVA, San Francisco, CA, [3]UCSF, San Francisco, [4]University of California, San Francisco, and San Francisco Veterans Affairs Medical Center, San Francisco, CA, [5]VA Portland Health Care System/OHSU, Portland, OR

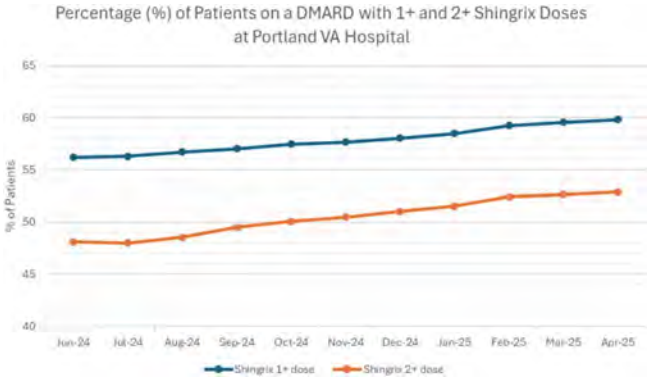
SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0210–0232) Measures & Measurement of Healthcare Quality Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

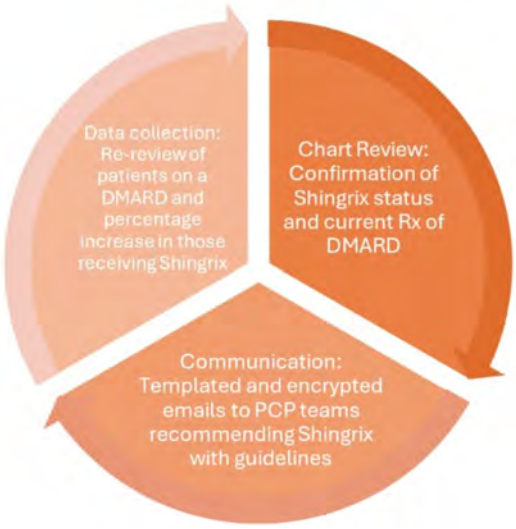
Background/Purpose: Disease-modifying antirheumatic drugs (DMARDs) are used to treat many rheumatologic diseases by modulating the patient's immune system. However, patients on DMARDs are more susceptible to infection, including varicella zoster or shingles. ACR guidelines state adults aged 19 and older who are prescribed DMARD therapy should receive two doses of the Shingrix vaccine to protect against shingles. We aimed to improve Shingrix vaccine immunization among Veterans on DMARDs at the VA Portland Health Care System (VAPORHCS) using a medication safety dashboard.

Methods: We accessed the Rheumatology Medication Safety Shingrix Dashboard developed by the San Francisco VA Measurement Science QUERI, which was available to us as part of a wait-list control randomized trial. Using data from the dashboard, we identified patients who received a DMARD through the VA Portland Health Care System and reviewed EHR charts to confirm medication use and Shingrix vaccination status or refusal. Templated, secure emails were sent to the patients' VA primary care providers and nurse care managers, highlighting the importance of Shingrix (Figure). Progress was tracked from June 2024 to April 2025 via the dashboard to monitor changes in the proportion of patients with immunizations and through chart review of patients whose PCPs were emailed, to confirm whether they received the Shingrix vaccine.

Results: From June 2024 to April 2025, the percentage of patients on a DMARD who received at least one dose of Shingrix increased from 56.2% to 59.8%—an overall rise of 3.6% (Graph). The percentage of patients fully vaccinated (both doses) increased from 48.1% to 52.9%, representing a 4.8 percentage point gain over the same period.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License





Study design

On a monthly basis, the proportion of patients receiving only one dose rose by 0.013%, while those completing both doses increased by about 0.018% per month. Over the 11-month period, there is an increase of 6.4% in one-dose coverage and a 9.9% increase in two-dose coverage. The gap between the first and second Shingrix doses steadily declined over 11 months, from 8.1% in June 2024 to 7.0% in April 2025, demonstrating that patients who received the first dose of the vaccine also went on to get the second dose. During the period when the majority of emails to PCP teams were sent out — November to April 2025 — we observed an increased proportion of patients receiving at least one dose of Shingrix. This suggests that outreach to PCPs was effective, as many reported they were unaware of the lowered age recommendation for Shingrix in patients on a DMARD.

Conclusion: The use of a safety dashboard, combined with targeted outreach to primary care providers was associated with a steady increase in the administration of Shingrix among Veterans on DMARDs. We plan to expand the use of these dashboards to promote other recommended immunizations within this population. Prompt implementation of EHR-based dashboards can boost quality improvement efforts by delivering key metrics and actionable insights directly to clinicians.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0210–0232) Measures & Measurement of Healthcare Quality Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Therapeutic decisions during pregnancy in women with autoimmune rheumatic diseases (ARDs) such as SLE, APS, RA, and Sjögren's syndrome require a personalized approach due to heterogeneous risk profiles and complex disease interactions. We developed and validated a treatment recommendation algorithm based on a comprehensive meta-analysis of over 100 studies assessing predictive biomarkers, clinical factors, and treatment outcomes during pregnancy in ARDs.

Methods: Using PRISMA guidelines, we performed a systematic review and meta-analysis to identify evidence-based therapeutic associations across ARDs. Key biomarkers were mapped to treatment responses, including lupus anticoagulant (LAC), anti-β2GP1, anti-cardiolipin, anti-SSA/Ro, anti-dsDNA, complement components (C3/C4, sC5b-9), NLR, disease activity indices, and prior pregnancy loss or thrombosis. We assigned intervention thresholds and created a decision matrix matching biomarker-risk profiles with pharmacologic and non-pharmacologic strategies, including hydroxychloroquine (HCQ), low-dose aspirin (AAS), low molecular weight heparin (LMWH), corticosteroids, and immunosuppressives.

Table 1. Biomarker-Guided Therapeutic Recommendations in Pregnant Patients with Autoimmune Rheumatic Diseases

Biomarker/Clinical Factor	Recommended Therapy	Justification (Effect Size / Evidence)
Lupus Anticoagulant (LAC) + high-titer aPLs	Low-dose aspirin (AAS) + LMWH	OR 1.29 for reducing adverse pregnancy outcomes (APOs)
Anti-SSA/Ro positive	Hydroxychloroquine (HCQ)	Reduces fetal AV block recurrence risk from 18% to 7.5%
SLEDAI > 4 or hypocomplementemia	Corticosteroids ± Azathioprine	Controls lupus activity and prevents flares during pregnancy
Elevated NLR or Chemerin	Consider an anti-inflammatory adjustment or close monitoring	Indicators of subclinical inflammation
Prior pregnancy loss or thrombosis	AAS ± LMWH depending on aPL profile	Secondary prophylaxis in obstetric APS

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: The calculator integrates 9 core biomarker-based indications for treatment. For instance, the presence of LAC and high-titer antiphospholipid antibodies indicated LMWH+AAS (OR for APO reduction: 1.29); anti-Ro positivity triggered HCQ to prevent fetal AV block (risk reduction from 18% to 7.5%). Active lupus (SLEDAI >4 or hypocomplementemia) prompted corticosteroid and azathioprine use; elevated NLR or chemerin levels served as adjunctive inflammation markers. Each therapeutic output is supported by published OR/RR values and is adjustable to disease context and trimester.

Conclusion: We present a personalized therapeutic calculator to optimize pregnancy outcomes in ARD patients. It translates biomarker profiles into actionable treatment recommendations with literature-based justification. The tool is undergoing academic licensing and is not publicly available. Future trials will evaluate its implementation impact in multidisciplinary care models.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0210–0232) Measures & Measurement of Healthcare Quality Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Autoimmune rheumatic diseases (ARDs) such as systemic lupus erythematosus (SLE), antiphospholipid syndrome (APS), rheumatoid arthritis (RA), and Sjögren's syndrome significantly increase the risk of adverse pregnancy outcomes (APOs), including preeclampsia, fetal restriction (intrauterine growth restriction (IUGR)), fetal loss, and preterm birth. Traditional risk factors do not fully explain these complications. We aimed to develop and validate a predictive model for obstetric risk stratification in pregnant women with ARDs, using a systematic review and meta-analysis of over 150 studies.

Methods: We conducted a systematic search across PubMed, Embase, Web of Science, and Scopus, selecting studies that evaluated biomarkers and clinical predictors of APOs in pregnant women with ARDs. Key variables included lupus anticoagulant (LAC), anti-β2GP1, anti-cardiolipin, complement activation (C3/C4, sC5b-9), neutrophil-to-lymphocyte ratio (NLR), anti-SSA/Ro antibodies, disease activity indices (SLEDAI, DAS28), and clinical history (nephritis, chronic hypertension, prior fetal loss). Data from eligible studies were pooled using random-effects meta-analysis. Predictive weights were assigned to variables based on odds ratios and integrated into a point-based risk calculator.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1. Predictive Biomarkers and Clinical Variables Included in the Obstetric Risk Stratification Model for Autoimmune Rheumatic Diseases

Predictor	Effect Size (OR)	Clinical Interpretation
Lupus anticoagulant (LAC)	~12.5	Strongest predictor of adverse pregnancy outcomes
Chronic hypertension	5.8	Strong risk factor for preeclampsia
Active lupus (SLEDAI >4)	2.9	Associated with preterm birth
Prior lupus nephritis	↑	Increases APO risk, esp. with proteinuria
Hypocomplementemia (C3/C4 low)	↑	Reflects active immune complex deposition
NLR >2.9	AUC = 0.71	Predicts maternal-fetal complications
Anti-SSA/Ro positivity	–	Indicates risk for fetal heart block, integrated if present
History of pregnancy loss	↑	Included as cumulative clinical risk

Results: The model incorporates 12 high-evidence predictors. LAC conferred an OR of ∼12.5 for APOs >12 weeks; chronic hypertension an OR of 5.8 for preeclampsia; and active lupus an OR of 2.9 for preterm birth. The presence of nephritis and low complement levels significantly increased APO risk. NLR >2.9 yielded an AUC of 0.71 for predicting maternal-fetal complications. Each variable was scored to produce a cumulative risk score, stratifying patients into low, moderate, or high-risk categories. Internal validation showed a sensitivity of 81% and a specificity of 74% for predicting APOs. (Table 1)

Conclusion: We developed a robust, evidence-based calculator that stratifies obstetric risk in pregnant women with ARDs. This tool integrates clinical, serologic, and inflammatory markers and has potential to guide early interventions and personalized monitoring. The model is currently under academic licensing and not yet publicly available. Future prospective validation is planned to support clinical implementation.

Background/Purpose: Patients with inflammatory arthritis (IA), including rheumatoid arthritis (RA) and spondyloarthritis (SpA), are at elevated risk for comorbidities, complicating disease management. Despite rheumatology societies recommending periodic comorbidity reviews, their integration into routine care remains challenging. This study aimed to (i) assess baseline compliance with comorbidity management recommendations among patients with IA, and (ii) identify clinical action items resulting from a physician-led global review.

Methods: We conducted a retrospective cohort study of adults with RA or SpA who underwent a standardized global review at Hôpital Cochin, Paris, between June 2017 and March 2025. The review adhered to EULAR recommendations for comorbidity management in rheumatic diseases and included assessments for cardiovascular risk, bone health, infections, and malignancy (1). Descriptive statistics were used to summarize patient characteristics and actions taken.

Results: The cohort included 458 patients (RA: 187, SpA: 271) with a mean disease duration of 17.4 years (SD 12.9) as detailed in Table 1. Among RA patients, 84.5% were female, with a mean age of 55.0 years (SD 15.4) and mean DAS28 of 2.7 (SD 1.3). Among SpA patients, 42.8% were female, mean age 48.6 years (SD 13.3), and mean ASDAS 1.8 (SD 1.0). Among all patients, corticosteroids were used by 14.7%, and biologics by 63.1%.

Cardiovascular history included ischaemic heart disease in 3.5%, diabetes in 4.8%, and hypertension in 22.5% of the total population, with comparable rates across the RA and SpA subgroups. Active smoking was reported in 19.3% of RA and 24.0% of SpA patients. LDL levels were above target in 40.5% and 47.5%, and obesity (BMI >30 kg/m^2) affected 10.9%

Table 1: Baseline Characteristics

Characteristic	n	Total (n=458)	n	RA (n=187)	n	SpA (n=271)
Age, years, mean (SD)	458	51.2 (14.5)	187	55.0 (15.4)	271	48.6 (13.3)
Gender, female	458	274 (59.8%)	187	158 (84.5%)	271	116 (42.8%)
Diseases duration, years, mean (SD)	449	17.4 (12.9)	185	17.0 (12.2)	264	17.7 (13.5)
Disease activity, mean (SD)

Table 2: Clinical Actions Triggered by Global Review Findings

Action Item	n	Total (n=458)	n	RA (n=187)	n	SpA (n=271)
New Cardiology Referral for Symptoms of Cardiac Insufficiency	454	16 (3.5)	186	8 (4.3)	268	8 (3.0)
New Cardiology Referral for increased risk of ischemic heart disease	444	25 (5.6)	182	13 (7.1)	262	12 (4.6)
Recommended family physician follow-up for blood pressure management	438	78 (17.8)	174	32 (18.4)	264	46 (17.4)
Referral to Dietician	452	71 (15.7)	184	32 (17.4)	268	39 (14.6)
Referral to Physiotherapy	453	57 (12.6)	185	19 (10.3)	268	38 (14.2)
Vaccination prescribed	456	285 (62.5)	186	120 (64.5)	270	165 (61.1)

*Unless otherwise specified, values represent number (percentage).

and 13.8% in RA and SpA patients, respectively. New cardiology referrals were initiated for 25 (5.6%) patients due to high ischaemic risk as seen in Table 2.

Regarding bone health, vitamin D deficiency was present in 75.1% of the overall population. Fractures were reported in 14.4% of RA patients and 6.7% of SpA patients, while a DXA-based definition of osteoporosis was seen in 18.2% vs. 15.5% respectively.

In terms of vaccination coverage, adherence was 54.0% for influenza, 53.4% for pneumococcal, and 55.7% for diphtheria-tetanus-polio (DTP) vaccines, as per French recommendations. The global review led to a vaccine prescription in 62.5% of cases.

Malignancy screening adherence was 48.0% for colon, 39.4% for skin, 83.6% for breast, and 87.2% for cervical cancer.

Conclusion: Our findings underscore the gap between recommended and actual comorbidity management in IA. The global review revealed areas needing intervention and generated actionable steps to address care gaps. Importantly, this model demonstrates that systematic screening can be feasibly implemented in routine rheumatology clinical practice.

Background/Purpose: Patients with inflammatory arthritis (IA), including rheumatoid arthritis (RA) and spondyloarthritis (SpA), face elevated risk for comorbidities that complicate disease management. Although rheumatology societies recommend periodic comorbidity reviews, few studies have assessed the effectiveness of this resource- and time-intensive intervention. This study aimed to assess the impact of a structured global review on comorbidity management in patients with IA.

Methods: We conducted a retrospective cohort study of adult patients with RA or SpA who completed two global reviews at Hôpital Cochin, Paris, between June 2017 and March 2025. The global review followed a standardized protocol aligned with EULAR recommendations for comorbidity management in rheumatic diseases, assessing cardiovascular, bone, infection, and malignancy risk (1). For cardiovascular and malignancy domains, recommendations were provided to the general practitioner, while specific prescriptions were issued when vaccination or bone health interventions were indicated.

Table 2- Comparison of Comorbidity Management at Baseline and Follow-up, N=63

	Baseline	F/U	P value
Cardiovascular domain			
Heart Score, median (IQR)	**1.3 (0.9, 3.0)**	**4.3 (1.5, 7.0)**	**<0.001**
LDL above target	52.7	62.3	0.149
Triglycerides >1.7 mmol/L	21.8	21.8	1.000
Hypertensive in clinic	26.7	32.8	0.724
BMI≥25 kg/m^2	**43.5**	**54.0**	**0.046**
BMI≥30 kg/m^2	14.5	19.0	0.248
Active Smoking	23.8	19.0	0.371
Osteoporosis domain			
Vitamin D deficiency (<75nmol/L)	**81.5**	**43.1**	**<0.001**
Patients with BMD testing	88.9	96.8	0.074
T score spine, median	-1.0 (-2.1, 0.2)	-0.8 (-1.9, 4.5)	0.506
T score hip, median	-1.1 (-2.2, -0.4)	-1.0 (-1.8, -0.6)	0.684
Medication Use			
Lipid-lowering agent	10.9	15.4	0.134
Anti-hypertensive medications	23.8	25.8	1.000
Osteoporosis medication	4.8	4.8	1.000
Infection prevention in agreement with recommendations			
Dentist follow-up	75.8	82.5	0.423
Influenza vaccination	**40.7**	**66.1**	**0.004**
Pneumococcal vaccination	58.9	66.1	0.472
DTP vaccination	**57.4**	**73.0**	**0.037**
Malignancy screening in agreement with recommendations			
Colon cancer screening	51.4	57.5	0.424
Dermatology follow-up	**45.2**	**58.7**	**0.043**
Mammography	100	94.4	1.00
Pap smears	87.0	84.0	1.00

Baseline characteristics were determined using simple statistics. Comorbidity management at the second review was compared to the first using McNemar's test for categorical variables and Wilcoxon signed-rank test for continuous non-normally distributed data.

Results: The cohort included 63 patients (RA: 17, SpA: 46) with a mean disease duration of 21.2 years (SD 14.2), and mean time between visits of 4.1 years (SD 1.5). Among RA patients, 94.1% were female, mean age 58.0 years (SD 16.5), mean DAS28 2.7 (SD 1.8). Among SpA patients, 30.4% were female, mean age 51.8 years (SD 11.7), and mean ASDAS 1.7 (SD 0.8). Corticosteroids use was low (4.8%), while 63.5% of patients received biologics.

Despite 52.7% of patients having elevated LDL, 26.7% being hypertensive, and 43.5% being overweight at baseline, no significant improvement was seen in cardiovascular risk management at follow-up. In contrast, with respect to bone health, there was a significant improvement in rates of vitamin D deficiency from 81.5 to 43.1% ($p< 0.001$). Vaccination adherence improved: influenza coverage increased from 40.7% to 66.1% ($p=0.004$), and DTP from 57.4% to 73.0% ($p=0.037$). Compliance with skin cancer screening rose from 45.2% to 58.7% ($p=0.043$). Adherence to mammography and Pap smear guidelines remained high (>80%) at both time points, suggesting a ceiling effect. No change was observed in colorectal cancer screening rates.

Conclusion: A single structured global review led to meaningful improvements in vaccination coverage, vitamin D deficiency correction, and skin cancer screening among IA patients. However, cardiovascular risk management did not improve, potentially due to the absence of direct prescriptions. These findings support the utility of global reviews while highlighting the need for better coordination in managing complex comorbidities in patients with IA.

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic and complex autoimmune disease that requires adequate treatment adherence to control disease activity and prevent complications. However, adherence rates among SLE patients are generally low, influenced by multiple personal, social, and clinical factors. This study aims to evaluate adherence to oral pharmacological treatment in SLE patients, analyze factors associated with therapeutic compliance, and identify patient profiles with low adherence levels.

Methods: This was an observational, cross-sectional, analytical study conducted on a cohort of 115 SLE patients followed at the Rheumatology outpatient clinic of a tertiary hospital in northern Spain. Adherence to oral treatment was assessed using the Compliance Questionnaire on Rheumatology (CQR), a validated tool for evaluating therapeutic adherence in rheumatologic diseases. Good adherence was defined as a CQR score ≥ 80. Statistical analysis included descriptive statistics and Chi-square tests to identify significant associations between adherence and the studied variables.

Results: Among 115 SLE patients, 105 were women (91.30%), with a mean age of 53.35 ± 14.27 years and an average disease duration of 14.27 ± 14 years. Sociodemographic and clinical factors influencing adherence were analyzed (Table 1), identifying risk profiles with lower compliance. Overall adherence was suboptimal, with only 58.26% achieving a CQR score ≥ 80. Women had higher adherence (73.33%) than men (60.0%). University-educated patients adhered better (81.48%) than those with primary education (50.0%). Married individuals showed the highest adherence (75.36%), while divorced and widowed patients had the lowest (50.0% and 25.0%, respectively). Employment favored adherence (80.0%), surpassing unemployed or retired patients (65.0%). Patients without comorbidities adhered better (81.25%) than those with comorbidities (70.71%). Medication burden influenced adherence, with higher rates in those taking one (75.34%) or two drugs (71.43%) compared to those on three or more. Significant associations were found between adherence and sex ($p = 0.0278$), education ($p = 0.0439$), employment ($p = 0.0316$), and comorbidities ($p = 0.0402$). Marital status ($p = 0.0944$) and medication count ($p = 0.2959$) showed no significant correlation. Low adherence profiles included male sex, lower education, unemployment, comorbidities, and divorced/widowed marital status.

Conclusion: This study highlights the low treatment adherence rates among SLE patients, driven by sociodemographic and clinical factors. Findings emphasize the need for targeted interventions in vulnerable subgroups, including men, individuals with lower educational attainment, unemployed patients, and those with comorbidities.

Development of the American College of Rheumatology Implementation Guide for Integrating Patient Reported Systemic Lupus Erythematosus Quality Measures

Catherine Nasrallah[1], Christine Hariz[2], Shanthini Kasturi[3], Wambui Machua[4], Jinoos Yazdany[5], Christie Bartels[6], Kate Chiseri[7], Starla Blanks[7], Patti Katz[8], Cherish Wilson[9], April Jorge[10], Beth Radtke[11], Tom Tack[7] and Shivani Garg[12], [1]University of California San Francisco (UCSF), San Francisco, CA, [2]University of California San Francisco (UCSF, San Francisco, CA, [3]Tufts Medical Center, Boston, MA, [4]Piedmont Healthcare, Atlanta, GA, [5]UCSF, San Francisco, CA, [6]University of Wisconsin School of Medicine and Public Health, Madison, WI, [7]American College of Rheumatology, Atlanta, GA, [8]UCSF, San Rafael, CA, [9]UCSF / SFVA, San Francisco, CA, [10]Massachusetts General Hospital, Boston, MA, [11]ACR, Atlanta, GA, [12]University of Madison, School of Medicine and Public Health, Madison, WI

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0210–0232) Measures & Measurement of Healthcare Quality Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex disease that presents unique care challenges. To improve high-quality patient-centered care, the American College of Rheumatology (ACR), developed evidence-based quality measures related to using patient reported outcome measures (PROMs) in SLE. This study aimed: 1) To conduct qualitative interviews with practices that had implemented ACR-recommended SLE PROMs as part of the pilot evaluation, using the Consolidated Framework for Implementation Research (CFIR) and 2) To synthesize implementation findings to inform the development of the SLE Quality Measures Implementation Guide for national dissemination.

Methods: Using purposive sampling, we invited five community-based rheumatology practices representing geographically diverse clinical settings to pilot the routine collection of SLE PROMs, including measures of physical function (RAPID-3 or MDHAQ) and depression (PHQ-8). After the pilot, rheumatologists and medical staff from each practice participated in qualitative virtual interviews, guided by the CFIR, to identify barriers and facilitators to implementing SLE PROMs and explore resources needed to improve the collection and use of the measures in clinical care. Recorded interviews were transcribed and analyzed thematically using deductive and inductive techniques to identify themes. Subsequently, insights from

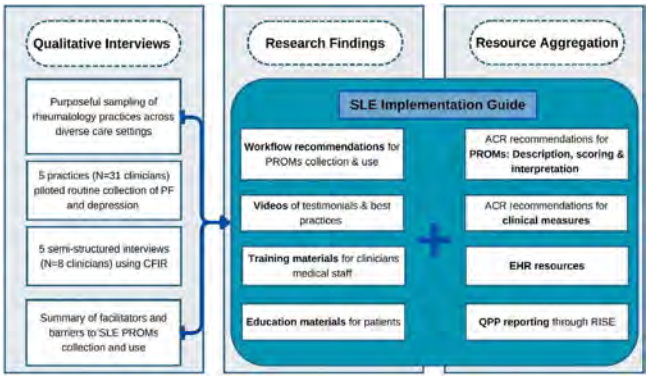

Figure1: Workflow for Developing the SLE Implementation Guide

Table 1. Characteristics of Pilot Practices.

	P1	P2	P3	P4	P5
Geographic region	East South Central	West South Central	South Atlantic	East South Central	South Atlantic
EHR type	NextGen	NextGen	NextGen	NextGen	NextGen
Total number of clinicians at the practice	3	9	12	6	24
Number of clinicians engaged in the pilot	3	8	12	6	2
Number of patients with SLE diagnosis	566	703	883	999	771
Physical function (PF)					
Measure	RAPID3	Full MDHAQ	HAQ	Full MDHAQ	Full MDHAQ
Unique patients PF collected per practice report	>150	65	50	>150	35
Range of scores	0-8	1-8	0-8	1-10	0-8
Depression					
Depression Measure	PHQ8	PHQ8	PHQ8	PHQ8	PHQ8
Unique patients PHQ8 Responses	12	41	30	183	0
Unique patients' depression tools collected per practice report	>150	65	58	>150	35

Table 2: Barriers and Opportunities of SLE PROMs Collection: Findings from Qualitative Interviews

CFIR domain	Barriers	Opportunities
Process	1. Patient identification gaps in check-in workflow 2. Inconsistent collection of PROMs by medical staff 3. Staff oversight in recording scores in EHR 4. Inconsistent discussion of survey results with patients 5. Increased administrative burden	1. Standardizing PROMs integration into SLE patient check-in 2. Scheduling reports to flag upcoming SLE visits 3. Improving patient education about care process 4. Streamlining PROM training and workflows 5. Maintaining consistent PROM collection
Innovation	1. Patient difficulty with score and statement interpretation 2. Physician difficulty interpreting survey score 3. Engaging older patients in mental health discussion 4. Length of the PF forms 5. PHQ-8 questions potentially triggering for patients	1. Normalizing mental health discussions among clinicians 2. EHR templates supporting data entry in the EHR 3. Short questionnaires (PHQ8) 4. Enhancing clinical decision-making 5. Promoting patient-centered care 6. Strengthening patient-clinician rapport 7. Improving patient satisfaction and wellbeing
Individual characteristics	1. Patient survey fatigue 2. Patient privacy concerns and data-sharing resistance	1. Staff commitment and collaboration 2. Reinforcing mental health care and symptom awareness.
Inner setting	1. Unstructured EHR documentation 2. Manual data entry and scoring 3. Communication gaps between MAs and physicians 4. Physicians time constraints 5. Staff turnover and training burden	1. Electronic collection of measures (Phreesia, iPad) 2. Automatic data transmission into structured EHR fields 3. Automatic PROM reminder alerts 4. Enhancing patient awareness of PROM collection 5. Providing mental health resources for patients with high PHQ8 scores
Outer setting	1. Referral delays to mental health care 2. Limited availability of local mental health facilities 3. High cost of physical and occupational therapy 4. Insurance limitations for mental health coverage	1. Proactive referrals for mental health and therapy based on scores 2. Data collection supporting insurance authorization of treatment

interviews, combined with ACR guidelines and other resources, informed the development of an SLE Quality Measures Implementation Guide (Figure 1).

Results: Thirty-one clinicians engaged in the pilot evaluation across five practices (Table 1). Qualitative Interviews with representatives from each practice (N=8) revealed key insights into the innovations, resources, recommendations, best practices, and challenges related to SLE PROMs collection and use (Table 2). Despite challenges with workflow integration, clinician and medical staff engagement, and limited resources, both patients and clinicians supported using PROMs in routine care. PROMs effectively assessed mental health and physical function through standardized workflows, enhanced communication, and EHR integration. These findings informed the development of an online SLE Quality Measures Implementation Guide, designed to aide clinicians and care teams with implementing the recommended measures into clinical practice. Sections include recommended detailed instructions for use of ACR-recommended SLE PROMs, downloadable PROMs, workflow recommendations and scoring guidance. Reflecting themes from interviews, the guide also includes videos on best practices, patient education materials, staff training resources, and validated translations of PROMs in Spanish and Chinese.

Conclusion: This study assessed the implementation of ACR-recommended SLE PROMs in five rheumatology practices and used the findings to develop the SLE Quality Measures Implementation Guide. This guide supports rheumatologists and care teams with integrating PROMs into routine practice by offering guidance and practical strategies for collecting the measures to guide clinical decisions and advance patient-centered care.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0210–0232) Measures & Measurement of Healthcare Quality Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Lupus affects up to 1.5 million people in the US with significant health disparities in care and outcomes that call for care delivery innovation. Similar disparities in HIV were addressed using a globally-endorsed Care Continuum model with steps including measuring linkage and retention in specialty care by visits and labs. The Continuum led to evidence-based interventions that improved disease control including an effective Electronic Health Record (EHR) outreach intervention. Given prior success, we aimed to adapt a care retention intervention for SLE. Our objectives were to convene patients, clinicians, public health leaders, and community partners to adapt and design a pilot intervention to address SLE Care Continuum gaps.

Methods: We convened 8 focus groups (3 patient, 3 healthcare, and 2 external rheumatology/public health advisory group meetings) to discuss interventions for care retention in lupus. Participants included 10 patients with SLE, 7 rheumatologists, 2 RNs, 2 primary care physicians, 2 patient advocates, and 3 public health experts. Groups spanned 4 US states, 5 academic centers, 2 countries. Focus groups were a series of 60–90-minute virtual meetings. Transcripts were analyzed using NVivo software for content analysis.

Based on suggestions, experts at one academic center co-designed an EHR (Epic) workbench to highlight clinic patients with SLE lacking: (a) rheum clinic visit scheduled or completed in > 6 months or (b) recent laboratory tests (CBC, creatinine, urinalysis protein, complement, dsDNA every 6 months for SLE, 3 months for lupus nephritis. We added hydroxychloroquine (HCQ) and steroid indicators per 2023 ACR SLE clinical quality measures. Inclusion required age ≥18 and at least 1 rheumatologist lupus code; patients without any rheumatology clinic visits (e.g., receiving outside care) were excluded.

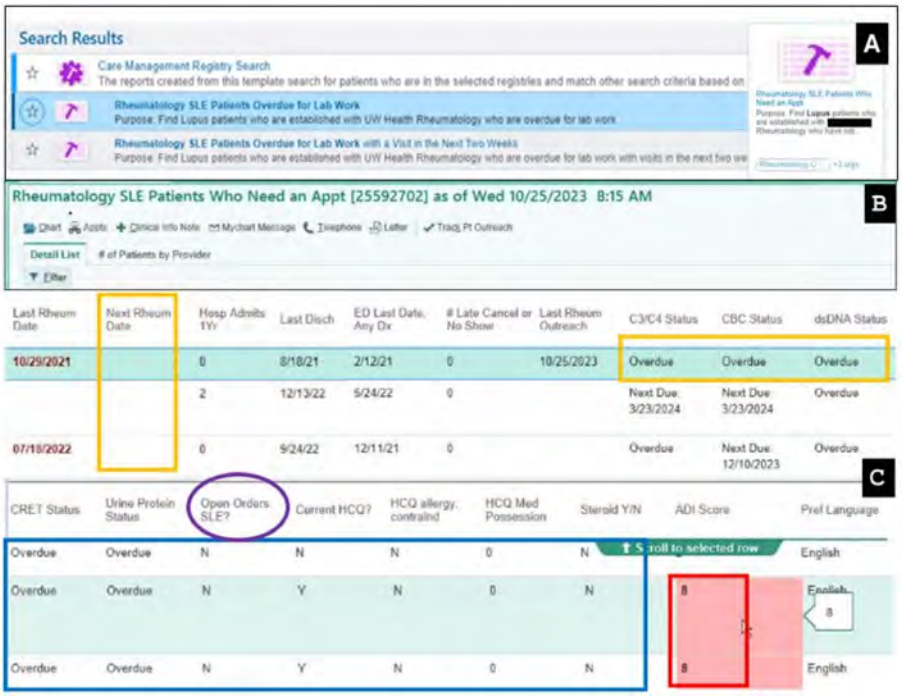

Figure 1: Three Workbench views include 34 columns with selected features shown in A-C. (A) Search panel to specify visit or lab list, (B) Overdue visit and lab list (yellow) with next and last visit dates plus ER and hospital dates, and (C) Other indicators for nephritis, open orders (purple circle), kidney test, HCQ, and steroid indicators (blue box), and adverse Area Deprivation Index (ADI) neighborhood (red) plus preferred language for instance.

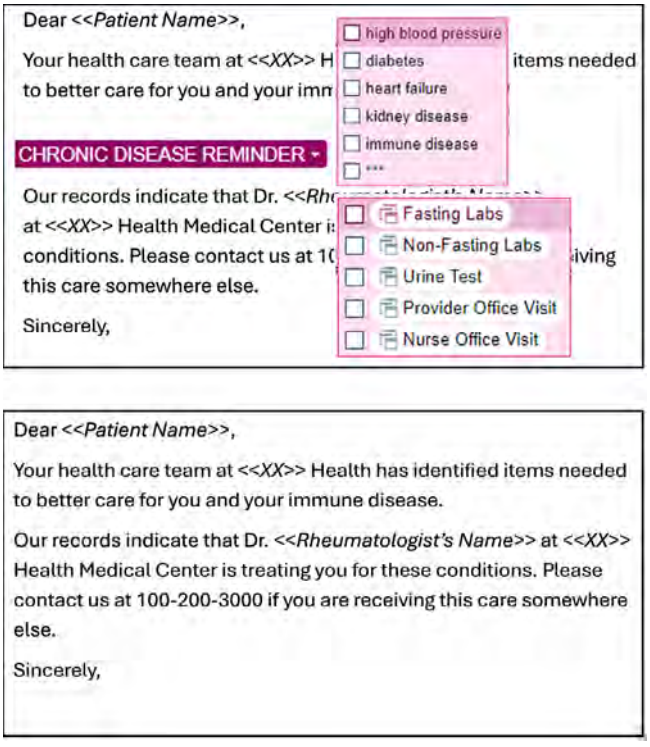

Figure 2: Chronic Disease Outreach Letter staff view (top) and patient view (bottom).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

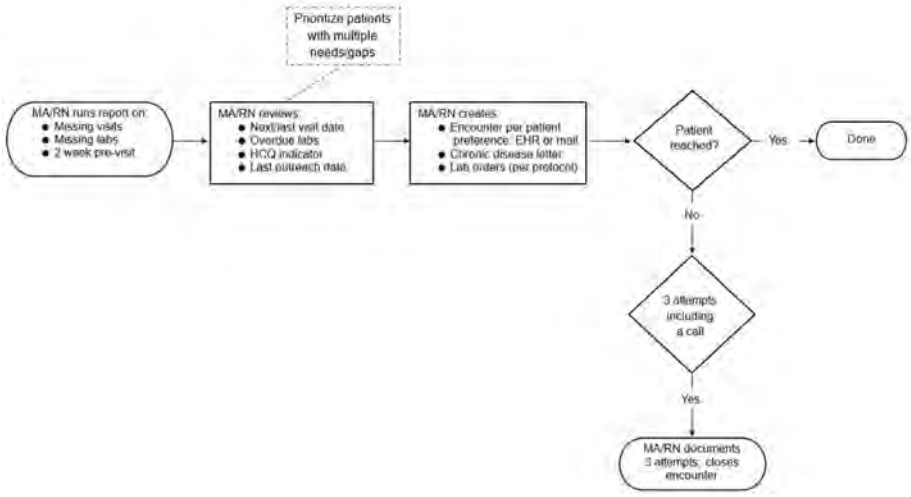

Figure 3: Process flow diagram for using the Lupus Outreach Workbench

Results: Advisors shared desires for patient reminders and outreach for due visits, labs and refills and consistent clinical personnel to address potential barriers (i.e., "patient navigator"). While many supported dedicated patient navigators, clinicians noted low resources and staff turnover as limitations. Based on this input, we designed an EHR staff outreach intervention with potential to scale to other clinics and staff.

Three workbench views (Fig 1a-c) included those lacking: 1) visits, 2) lupus labs, or 3) lacking labs with upcoming visits within 2 weeks (to aid pre-visit planning). The workbench also displays all three 2023 ACR lupus clinical quality measures: hydroxychloroquine use, kidney lab testing, and prednisone reduction.

Outreach tools consisted of modifying an existing chronic disease outreach letter to indicate a need to call for a visit or labs (*Fig 2*). Letters could be sent via EHR portal or mail by patient preference; subsequent contacts included calls by RN/MA outreach staff workflow (*Fig 3*).

Conclusion: Advisors guided adapting a proven EHR outreach intervention for care retention in SLE. Using an EHR workbench and a staff workflow with a simple chronic disease outreach letter, we created tools to address SLE care retention. The workbench also displays all three 2023 ACR lupus quality measures for use in future studies.

Abstract Number: 0219

Increased Engagement With the RISE Registry Clinician Dashboard Is Associated With Improving Performance on Some but Not All Rheumatology Quality Measures

Jing Li[1], Jessica Fitzpatrick[2], Jinoos Yazdany[2] and **gabriela Schmajuk**[3], [1]University of California, San Francisco, San Francisco, CA, [2]UCSF, San Francisco, CA, [3]University of California, San Francisco, and San Francisco Veterans Affairs Medical Center, San Francisco, CA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0210–0232) Measures & Measurement of Healthcare Quality Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Previous studies have shown that quality measure performance tends to improve after practices join the ACR's Rheumatology Informatics System for Effectiveness (RISE) registry, but the underlying drivers of this improvement remain unclear. One potential factor is access to the RISE web-based clinician dashboard, which provides detailed performance data to support quality improvement. Although many practices access the dashboard, its impact on quality improvement is not well understood. This study evaluated whether year-over-year changes in dashboard engagement were associated with changes in performance on 6 rheumatology-specific quality measures.

Methods: We included practices that reported any of the 6 selected measures in both 2021 and 2022. Included measures are shown in **Table 1**. Using audit log data, dashboard engagement was categorized into 4 levels: Most engaged: ≥2 sessions/month and ≥1 measure-action/month for ≥6 months; Moderately engaged: Some sessions and measure-actions, but below "most" threshold; Minimally engaged: >1 session, 0 actions; No engagement: 0 – 1 session, no actions. Practices were classified based on change in engagement level from 2021 to 2022 (increased, decreased, or no change). For each measure, we calculated performance change and visualized differences across engagement change groups using box plots. Analyses were stratified by baseline performance (above or below the 2021 median). We conducted linear regression analyses to test the association between engagement change and performance change, adjusting for baseline performance, EHR vendor, and an interaction term between engagement change and baseline performance.

Results: Among the 181 practices, most were single-specialty groups, and nearly half used the NextGen EHR (**Table 2**). At baseline, 13% were most engaged, 44% were moderately engaged, 23% were minimally engaged, and 20% had no dashboard engagement. Between 2021 and 2022, 57% of practices had no change in engagement, 26% decreased, and 17%

Table 1. Rheumatology-specific measures included in this study

Measure ID	Measure short name	Measure description
ACR10	Hepatitis B (HBV) screening	Percentage of patients initiating a new conventional or biologic DMARD with HBV screening (HBV surface antigen) in the preceding 12-month period.
ACR14	Gout Serum Urate (SU) target	Percentage of patients with gout on urate lowering therapy for at least 12 months with most recent serum urate at target of < 6 mg/dL.
ACR15	Hydroxychloroquine (HCQ) dosing	Percentage of patients receiving HCQ with an average daily dose at ≤ 5 mg/kg/day.
QPP176	TB screening	Percentage of new biologic DMARD users with a TB test completed in the preceding 12-month period.
QPP177	RA disease activity assessment	Percentage of RA patients with disease activity assessments at ≥ 50% of visits during the measurement year.
QPP178	RA functional status assessment	Percentage of RA patients with at least one functional status assessment during measurement year.

Amazing Charts	13 (7.2)	3 (10.0)	6 (5.8)	4 (8.5)
Other	36 (19.9)	4 (13.3)	22 (21.2)	10 (21.3)

Disclaimer: This data was supported by the ACR's RISE registry. Views expressed represent those of the authors, not necessarily the ACR.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

increased. Practices that increased their engagement showed greater improvements in performance on certain measures, specifically HBV safety screening, gout serum urate (SU) target, and HCQ dosing (**Figure**). These effects were most evident among practices with below-median baseline performance. Linear regression results aligned with these findings, showing increased engagement to be associated with greater improvements in gout and HCQ measures, although these associations did not reach statistical significance.

Conclusion: Increased engagement with the RISE dashboard from one year to the next was associated with modest performance gains in selected rheumatology quality measures. Prior studies have shown steady improvements in multiple measures after practices join the registry, and these findings suggest that greater use of the dashboard may support quality improvement efforts, especially among lower-performing practices. Additional studies with larger sample sizes are needed to clarify causal pathways and identify strategies to maximize the dashboard's impact on clinical performance.

Abstract Number: 0220

National Implementation of a Medication Safety Dashboard to Improve HLA-B*58:01 Testing Among Allopurinol Users in the Veterans Health Administration

Alissa Becerril[1], Jing Li[2], Cherish Wilson[3], Gary Tarasovsky[4], Abimbola Fadairo-Azinge[5], Mary Whooley[4] and **gabriela Schmajuk**[6], [1]UCSF, san francisco, CA, [2]University of California, San Francisco, San Francisco, CA, [3]UCSF / SFVA, San Francisco, CA, [4]SFVA, San Francisco, [5]UCSF, San Francisco, [6]University of California, San Francisco, and San Francisco Veterans Affairs Medical Center, San Francisco, CA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0210–0232) Measures & Measurement of Healthcare Quality Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Allopurinol can cause life-threatening severe cutaneous adverse reactions, especially in patients who carry the HLA-B58:01 allele. Because this allele is more common among Southeast Asian and African American individuals, the 2020 American College of Rheumatology Gout Guidelines conditionally recommend genetic testing for these groups before starting allopurinol. To support safer prescribing, we developed and evaluated a national electronic dashboard to promote HLA-B58:01 testing among at-risk allopurinol users in the U.S. Veterans Health Administration (VHA).

Methods: We identified allopurinol users in the VHA using data from the Corporate Data Warehouse. A dashboard was built using Microsoft PowerBI to display patient identifiers, HLA-B58:01 testing status, and self-reported race/ethnicity (**Figure 1**). The dashboard launched nationally in April 2023, and all VHA rheumatologists were notified by email. Dashboard use at each facility was tracked through PowerBI activity logs. Facilities were excluded if they were pilot sites (n=6), used a different EHR (Cerner; n=6), lacked structured fields for HLA-B58:01 testing (n=50), or had no recorded dashboard sessions (n=11).

The main outcome was the weekly percentage of allopurinol users with self-reported Asian or African American race who had completed HLA-B*58:01 testing, between October 2022 and April 2023 (pre-launch) and May 2023 to April 2024 (post-launch). Facilities were categorized as high or low engagement based on how often they used the dashboard after launch (≥20% of weeks vs. < 20%). We used a two-group interrupted time series (ITS) analysis to compare trends in testing between high- and low-engagement facilities.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table. Percentage of HLA-B*58:01 testing among allopurinol users with self-reported Asian and African American race, overall and by engagement group, at the beginning and the end of the study period.

Facility	Week 1 Mean (SD)	Week 80 Mean (SD)
All Facilities (N=57)	1.57 (5.20)	3.00 (6.31)
High Engagement (n=18)	3.09 (8.98)	5.06 (10.08)
Low Engagement (n=39)	0.87 (1.47)	2.05 (3.21)

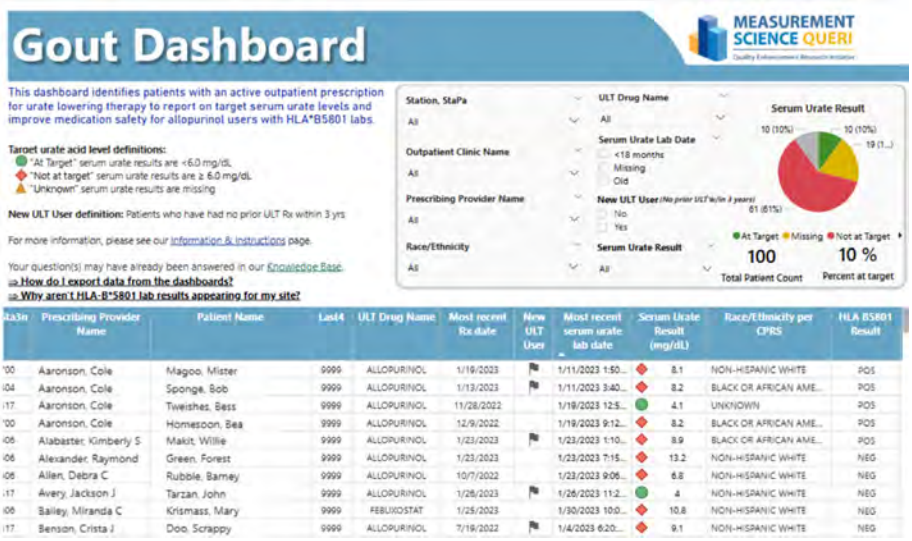

Figure 1. Simulated gout dashboard displaying fictitious patient data for monitoring HLA-B*58:01 testing and serum urate levels. This example shows how users can filter and visualize patient-level data, including urate-lowering therapy use, recent lab results, and HLA-B*58:01 testing status.

Results: The analysis included 57 VHA facilities (86% classified as high complexity), serving 45,500 at-risk allopurinol users. Patients were 97% male, with a mean age of 67.3 years; 88.5% were African American and 11.5% were Asian. Overall, HLA-B*58:01 testing increased from 1.6% at baseline to 3.0% at the end of the study (**Table**). ITS analysis showed a significantly faster increase in testing at high-engagement sites compared to low-engagement sites (post-intervention trend difference: +0.024 percentage points/week, 95% CI: 0.002–0.047; p = 0.03; **Figure 2**).

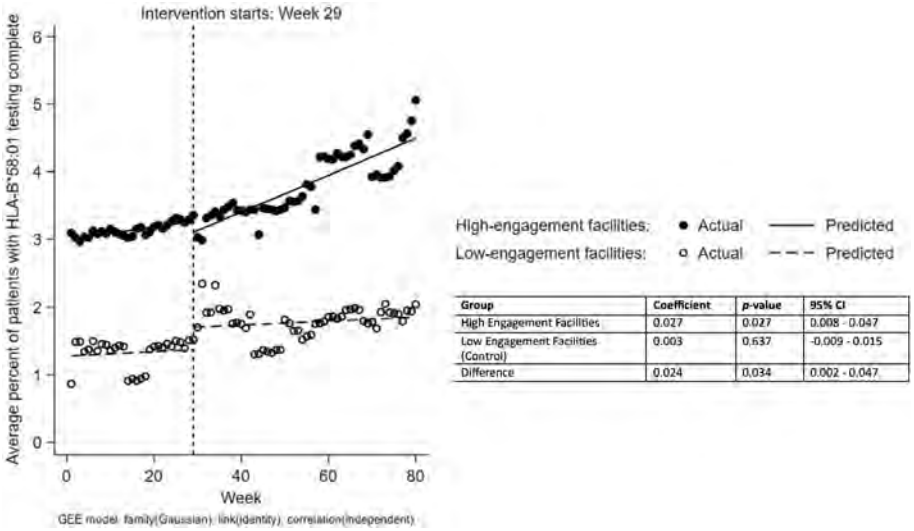

Figure 2. Interrupted time series (ITS) assessing HLA-B*58:01 testing pre- and post-dashboard launch for high vs low-engagement facilities.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Although overall testing rates remained low, implementation of a national dashboard was associated with modest but significant increases in HLA-B*58:01 testing—especially at facilities that regularly used the tool. Future studies should assess testing in an incident user cohort of patients. Ongoing work should focus on maintaining clinician engagement, improving dashboard usability, and assessing the long-term impact on patient safety.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0210–0232) Measures & Measurement of Healthcare Quality Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Clinical guidelines recommend the use of disease activity measures (DAMs) in rheumatoid arthritis (RA) management. Measurement of DAMs is also a critical component of clinical and epidemiologic research in RA. The Veterans Affairs RA (VARA) registry is a prospective cohort study of Veterans with RA that is active at 16 VA Medical Centers. A VARA goal is to systematically collect and document eight DAM components for participants at each in-person clinic visit **(Table1)**. A multimodal intervention was initiated to enhance DAMs collection. This report details preliminary results following three months of implementation of this planned 12-month program.

Methods: This intervention involved three phases: 1) baseline; 2) development: and 3) implementation (**Table 1**). Key activities included qualitative interviews with site investigators to confirm availability of electronic health record (EHR) tools for DAM collection, provision of additional EHR tools if needed, development of monthly just-in-time lists of VARA participant appointments, and monthly provider-specific feedback on DAMs collection performance and comparison to VARA registry overall performance. Verification and retrieval of documented DAM components in the EHR was accomplished through data extraction of note text form the VA Corporate Data Warehouse. Performance at each encounter, by provider and by VARA site over the 3-month implementation phase was compared to baseline performance using chi square testing.

Table 1. Demographic Information and Quality Improvement Program Study Design to Improve Collection of Disease Activity Measures (DAMs) in Clinic Notes for RA Patients in VARA Registry

Phase	Baseline	Program Development	Implementation*
Dates	March - August 2024	September - December 2024	January - March 2025
Phase Duration	6 Months	4 Months	3 months
Clinic Notes	1750	1057	769
Unique Patients	1231	916	728
Unique Providers	119	97	98
Age Project Start	67.2±10.4	67.3±10.5	66.7±10.4
Male Gender (%)	80.2%	81.8%	79.9%
Disease Duration	17.3±13.0	17.0±12.8	16.9±12.3
Activities	▪ Baseline Data Collection ▪ No other Activities	▪ Meeting with VARA Principal Investigators to discuss project goals ▪ Interviews of VARA Site Principal Investigators by Projected Director ▪ Protocol Development ▪ Development of Monthly Patient Lists of Future Rheumatology Clinic Appointments for RA patients Enrolled in VARA ▪ Development of Monthly Site Reports of DAMs collections on individual RA Patients aggregated by Provider	▪ Distribution of Monthly Pending Clinic Visit Reports ▪ Distribution of Monthly Performance Reports ▪ Continuous Feedback ▪ Review of Provider Performance by VARA Site Principal Investigator ▪ Provider Survey of Barriers and Facilitators of DAMs Collection

Outcome Measure Analysis of Each Electronic Medical Record Clinic Note for Each of the Following Factors		
Disease Activity Measure (DAM) Components	**Summary DAM Components**	**Composite DAMs**
Clinical DAM Components	Any DAM Element	DAS_28
Tender Joint Count	All Clinical DAM Element	DAS_28-CRP
Swollen Joint Count	Both ESR & CRP	CDAI
Patient Global Assessment	All 8 DAM Elements	RAPID_3
Provider Global Assessment		Any Composite DAM
Global Pain Score		
Multi-Dimensional Health Assessment Questionnaire		
2 Laboratory DAM Components		
Erythrocyte Sedimentation Rate (ESR)		
C-reactive Protein (CRP)		

*First 3 months of 12-month quality improvement process to improve DAMs collection in RA Patients Enrolled in the VARA registry.

Results: Between March 2024 through March 2025, 3,576 in-person rheumatology clinic visits occurred in 1,436 RA patients enrolled in VARA who were seen by 135 unique providers. The distribution of these visits and basic demographic information on these patients during the baseline, development, and implementation phases are listed (**Table 1**). Compared to baseline values, there was a significant increase in the documentation of individual DAM components, combined DAM components, and composite DAMs during the implementation phase with increases ranging from 5.8% to 10.4% (**Table 2**). Analyses limited to the 44 providers completing ≥5 clinical notes during both the baseline and implementation phases demonstrated an increase in the number of providers successfully documenting DAMs in >50% of encounters (**Table 3**). A separate analysis of DAMs collection by all providers at each VARA site also showed improvement in the number of VARA sites successfully documenting DAMs (**Table 3**).

Conclusion: This multimodal intervention increased DAM collection and documentation in clinical notes, expanded the number of providers consistently collecting DAMs, and enhanced the performance at VARA registry sites during an initial 3-month intervention phase. Ongoing monitoring will determine if additional performance improvement occurs through sustained intervention over a 12-month follow-up. This work demonstrates that collaborative actions in a multi-center registry

Table 2. Documentation of Specific Disease Activity Measure (DAM) Components and Composite DAMs in Clinic Notes During Baseline and Implantation Phases

	Study Time Period			
	Baseline (N=1750)	Intervention (n=769)	Change from Baseline	p-value*
DISEASE ACTIVITY MEASURE (DAM) COMPONENTS				
Clinical DAM Components

Table 1. Disease Activity Measurement Components Ranked by Difficulty of Collection based on Rheumatology Provider Responses. CRP, C-Reactive Protein; ESR, Erythrocyte Sedimentation Rate; MDHAQ, Multi-Dimensional Health Assessment Questionnaire; VARA, Veterans Affairs Rheumatoid Arthritis Registry

	Full Population N = 64		Provider Response by VARA Site Performance				
			High-Performing Sites n = 29		Low-Performing Sites n = 35		
How difficult is it for you to collect the...	Some Difficulty†	No Difficulty‡	Some Difficulty†	No Difficulty‡	Some Difficulty†	No Difficulty‡	p-value*
MDHAQ	67.2%	32.8%	55.2%	44.8%	77.1%	22.9%	0.06
Erythrocyte Sedimentation Rate (ESR)	53.1%	46.9%	48.3%	51.7%	57.1%	42.9%	0.48
C-Reactive Protein (CRP)	53.1%	46.9%	48.3%	51.7%	57.1%	42.9%	0.48
Patient Global Assessment	42.2%	57.8%	27.6%	72.4%	54.3%	45.7%	0.03
Patient Pain Score	23.4%	76.6%	17.2%	82.8%	28.6%	71.4%	0.29
Swollen Joint Count	21.9%	78.1%	17.2%	82.8%	25.7%	74.3%	0.41
Tender Joint Count	20.3%	79.7%	17.2%	82.8%	22.9%	77.1%	0.58
Physician Global Assessment	18.8%	81.3%	17.2%	82.8%	20.0%	80.0%	0.78

† "Some Difficulty" includes the following survey responses: slightly difficult, moderately difficult, very difficult, extremely difficult.
‡ "No Difficulty" includes the following survey response: not difficult at all.
* Chi-square comparison of provider responses at high- versus low-performing VARA sites.

Background/Purpose: Collection of disease activity measures (DAMs) is a key component of high-quality care for rheumatoid arthritis (RA) patients. This study surveyed rheumatology providers at Veterans Affairs RA (VARA) registry sites to identify barriers and facilitators for collecting and documenting DAMs.

Methods: The VARA registry is multicenter, prospective cohort study of US Veterans with RA who receive care within the Veterans Health Administration. A provider survey was developed to investigate barriers and facilitators for collecting and documenting DAMs [tender joint count (TJC), swollen joint count (SJC), Physician Global Assessment (PGA), Patient Global Assessment (PtGA), pain score (PS), Multi-Dimensional Health Assessment Questionnaire (MDHAQ), Erythrocyte Sedimentation Rate (ESR), C-Reactive Protein (CRP)] for RA patients at each VARA site. Survey questions were then independently evaluated and refined by 5 expert reviewers. The final 42-question survey was administered to 92 VA rheumatology providers at 16 VARA sites. Sites were designated as high- or low-performing based on whether the percentage of site notes that documented all 6 clinical DAMs (TJC, SJC, PGA, PtGA, PS, MDHAQ) for VARA participants was above or below the mean of the 16 VARA sites from 3/2024 to 3/2025. Responses were scored using 5-point Likert scales. Responses were grouped into "no difficulty or barrier" and "some difficulty or barrier" categories for DAM barrier questions and "very helpful" and "less helpful" categories for DAM facilitator questions due to clustering of responses at the low and high ends of the barrier and facilitator scales respectively. Results were reported as descriptive statistics, and provider responses from high- and lower-performing sites were compared using chi-square testing.

Table 2. Barriers to Collecting Disease Activity Measures Ranked by Provider Response Frequency. CPRS, Computerized Patient Record System; CRP, C-Reactive Protein; DAMs, Disease Activity Measures; ESR, Erythrocyte Sedimentation Rate; VARA, Veterans Affairs Rheumatoid Arthritis Registry.

	Full Population N = 64		Provider Response by VARA Site Performance				
			High-Performing Sites n = 29		Low-Performing Sites n = 22		
In your clinical setting, how significant are the following barriers to collecting DAMS?	Some Barrier†	No Barrier‡	Some Barrier†	No Barrier‡	Some Barrier†	No Barrier‡	p-value*
ESR and CRP labs are not drawn prior to clinic visit.	90.6%	9.4%	93.1%	6.9%	88.6%	11.4%	0.54
DAMs forms are available but not completed.	75.0%	25.0%	72.4%	27.6%	77.1%	22.9%	0.66
There is insufficient time to collect DAMs data.	70.3%	29.7%	58.6%	41.4%	80.0%	20.0%	0.06
Rheumatology fellows do not consistently collect or document DAMs for VARA patients they see in clinic.	65.6%	34.4%	55.2%	44.8%	74.3%	25.7%	0.11
Lack of research support staff in clinic to assist with collecting DAMs.	65.6%	34.4%	51.7%	48.3%	77.1%	22.9%	0.03
There is insufficient time to document DAMs in CPRS.	59.4%	40.6%	51.7%	48.3%	65.7%	34.3%	0.26
Veterans who require DAMs assessments are not identified.	53.1%	46.9%	37.9%	62.1%	65.7%	34.3%	0.03
VARA patients who require DAMs are seen by non-VARA providers.	46.9%	53.1%	44.8%	55.2%	48.6%	51.4%	0.77
DAM forms are not available in the clinic.	40.6%	59.4%	31.0%	69.0%	48.6%	51.4%	0.16
Templates for DAMs entry are not available for use in CPRS notes.	26.6%	73.4%	17.2%	82.8%	34.3%	65.7%	0.12
I am not aware of the goal to collect DAMs for all VARA patients.	14.1%	85.9%	10.3%	89.7%	17.1%	82.9%	0.44
I am not adequately trained to assess and document DAMs.	4.7%	95.3%	3.4%	96.6%	5.7%	94.3%	0.67

† "Some Barrier" includes the following survey responses: slightly significant, moderately significant, very significant, extremely significant.
‡ "No Barrier" includes the following survey response: not a barrier.
* Chi-square comparison of provider responses at high- versus low-performing VARA sites.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 3. Facilitators of Collecting Disease Activity Measure Ranked by Provider Response Frequency. Note: the "N" and "n" of the full population and high- and low-performing sites excludes providers who responded, "not currently available at my site." CPRS, Computerized Patient Record System; CRP, C-Reactive Protein; DAMs, Disease Activity Measures; ESR, Erythrocyte Sedimentation Rate; VARA, Veterans Affairs Rheumatoid Arthritis Registry.

	Full Population			Provider Response by VARA Site Performance						
				High-Performing Sites*			Low-Performing Sites*			
At your VARA site, how helpful are the following facilitators in completing DAMs?	N	Very Helpful†	Less Helpful‡	n	Very Helpful†	Less Helpful‡	n	Very Helpful†	Less Helpful‡	p-value*
VARA patients are seen in a rheumatoid arthritis specific clinic.	22	72.7%	27.3%	14	100.0%	0.0%	8	25.0%	75.0%	<0.01
Having standardized templates for VARA patients within CPRS.	57	66.7%	33.3%	26	76.9%	23.1%	31	58.1%	41.9%	0.13
Having printed DAM forms available in clinic.	62	66.1%	33.9%	28	71.4%	28.6%	34	61.8%	38.2%	0.42
ESR and CRP labs are routinely drawn on all VARA patients prior to clinic visit.	45	64.4%	35.6%	23	69.6%	30.4%	22	59.1%	40.9%	0.46
Having research support staff assisting with collecting DAMs.	34	61.8%	38.2%	16	56.3%	43.8%	18	66.7%	33.3%	0.53
Having research support staff assisting with documenting DAMs.	35	60.0%	40.0%	18	50.0%	50.0%	17	70.6%	29.4%	0.21
Identifying upcoming VARA patient appointments prior to the visit.	49	51.0%	49.0%	23	39.1%	60.9%	26	61.5%	38.5%	0.12
Ensuring providers are made aware of the goals to collect DAMs on all VARA patients.	61	50.8%	49.2%	28	57.1%	42.9%	33	45.5%	54.5%	0.36
Routine provider training on the collection of DAMs.	56	42.9%	57.1%	26	46.2%	53.8%	30	40.0%	60.0%	0.64
Ensuring that VARA patients are only seen by VARA providers.	41	36.6%	63.4%	19	42.1%	57.9%	22	31.8%	68.2%	0.50
The availability and usability of the VARA Rheumatoid Arthritis Dashboard.	53	30.2%	69.8%	27	25.9%	74.1%	26	34.6%	65.4%	0.49

† "Very Helpful" includes the following survey responses: quite helpful, essential.
‡ "Less Helpful" includes the following survey response: not helpful, slightly helpful, moderately helpful.
* Chi-square comparison of provider responses at high- versus low-performing VARA sites.

Results: 66 providers (71.7%) from 15 sites (93.8%) submitted survey responses. Providers at both high-and low-performing sites reported the MDHAQ, ESR, CRP, and PtGA were the most difficult DAMs to collect (**Table 1**). Providers at both high- and low-performing sites reported the most common DAM barriers were labs not being drawn prior to clinic visits, DAM forms not being completed, insufficient time, inconsistent DAMs assessment by fellows, and lack of research support staff (**Table 2**). Providers at low-performing sites cited two barriers more often than high-performing sites: lack of research support staff (77.1% vs. 51.7%; p=0.03) and failure to identify Veterans requiring DAMs assessments (65.7% vs. 37.9%; p=0.03). Among all respondents, the most common DAM facilitators were having an RA-specific clinic, using standardized DAM templates, using printed DAM forms, drawing labs before clinic visits, and having research support staff (**Table 3**). Providers at high-performing sites noted having an RA-specific clinic as a facilitator more often than low-performing sites (100.0% vs. 25.0%; p< 0.01).

Conclusion: Our rheumatology provider survey identified several modifiable barriers and facilitators for DAMs collection and documentation for RA patients. These results will inform future VARA registry QI efforts and may provide useful information to improve DAMs collection and documentation in other healthcare systems.

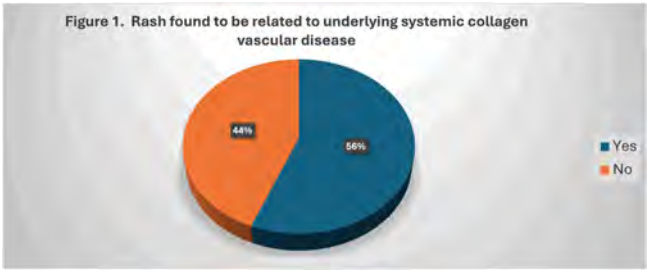
SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0210–0232) Measures & Measurement of Healthcare Quality Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Collagen vascular diseases (CVD) often present with skin manifestations, but it is not always clear whether these changes are directly related to the underlying autoimmune condition. Therefore, a collaborative effort between rheumatologists and dermatologists is imperative to distinguish dermatoses related to systemic CVD versus dermatoses unrelated to systemic CVD. By promptly identifying systemic CVD with skin involvement, early changes in therapies can lead to better outcomes. The goals of this study were to 1) identify the percentage of dermatoses that were associated with systemic CVD, 2) identify and describe the frequency of immunosuppressive therapy modifications after patients' first rheumatology-dermatology combined clinic (RDCC) visit.

Methods: All patients who were evaluated at the RDCC between February 2023 to February 2025 were included in this study. Patients were assessed simultaneously by one of two rheumatologists and one dermatologist. A retrospective study chart review was performed using the electronic medical records. Data collection included RDCC pre-clinic diagnosis and systemic CVD treatment, as well as post-clinic diagnosis and systemic CVD treatment. Secondary outcomes were autoimmune serologies, skin biopsy frequency, rates of clinical photography, and topical therapies. The data was analyzed using descriptive statistics. The IRB reviewed and approved the study (#2023-15460).

Results: A total of 98 patients were identified. Of these, 56% had dermatoses related to systemic CVD, while 44% had dermatoses unrelated to systemic CVD (Figure 1). At the end of the first RDCC visit, 43% of the patients had a change in immunosuppressive therapy, with the majority receiving an additional immunosuppressant or dose escalation of current therapy (Figure 2). Of the 62 patients with positive autoimmune serologies, the most common was antinuclear antibody (ANA), followed by anti-SSA antibody and anti-RNP antibody (Figure 3). Skin biopsies were performed in 22% of the cases, and clinical photography was recorded in 91% of the cases.



The post-clinic diagnoses include Systemic lupus erythematosus/ Cutaneous lupus erythematosus (25.6%), non-CVD (17.4%), Rheumatoid arthritis (10.2%), Scleroderma (10.2%), Psoriatic arthritis (9.18%), Dermatomyositis (8.2%), Undifferentiated connective tissue disease (6.1%), Sjogren's syndrome (3.1%), Sarcoidosis (3.1%), Mixed connective tissue disease (2%), Erythema nodosum (1.0%), Panniculitis (1.0%), Morphea (1.0%), Raynaud's (1.0%), Ankylosing spondylitis (1.0%).

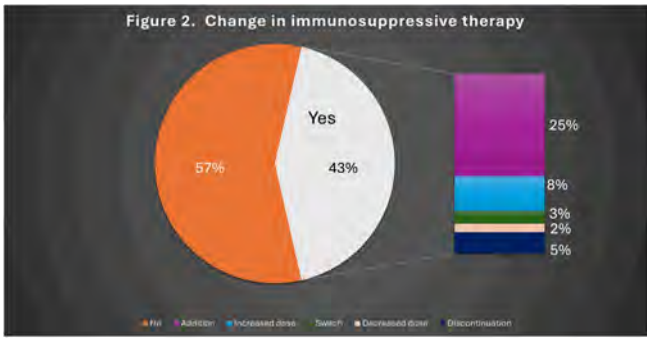

Figure 3. The serologies of patients seen in the RDCC

Positive autoimmune serology	N=62
ANA	50
SSA	21
RNP	16
RF	9
Centromere	8
CCP	4
MDA5	1
PR3	1
MPO	1

ANA: Anti-nuclear antibody, SSA: anti-SSA/Ro antibody, RNP: anti-RNP antibody, RF: Rheumatoid factor, Centromere: anti-centromere antibody, CCP: anti-cyclic citrullinated peptide, MDA5: anti-melanoma differentiation-associated protein 5, PR3: anti-proteinase 3 antibody, MPO: anti-myeloperoxidase antibody

Conclusion: The RDCC was designed to streamline communications between rheumatologists and dermatologists, to improve diagnostic accuracy and timely management in patients with suspected systemic CVD with skin involvement. Based on our clinic experience, over half of the patients referred for dermatoses had underlying systemic CVD. This finding suggests there may be some diagnostic uncertainty when either field refers to the other and highlights the benefit of a combined clinic. The diagnostic uncertainty becomes more evident in patients with positive ANA or anti-SSA antibodies. Moreover, there was a change in immunosuppressive therapy in almost half of the patients after their initial RDCC visit, demonstrating the importance of timely management changes made possible through our RDCC.

Table 1: Demographic data of patients in post-intervention analysis.

Demographic	Count (n=48)	Percentage
Sex		
Female	44	91.7%
Male	4	8.3%
Race		
White	33	68.8%
Black	5	10.4%
Latino	10	20.8%

Background/Purpose: Annual screening for pulmonary hypertension (PH) in patients with Systemic Sclerosis (SSc) reduces mortality. The American College of Radiology, European Society of Cardiology/European Respiratory Society, and the 6th World Symposium of PH all recommend yearly screening with 1) Pulmonary Function Testing (PFT) with diffusing capacity for carbon monoxide (DLCO), 2) Transthoracic Echocardiogram (TTE), and 3) B-natriuretic peptide (BNP). However, clinician adherence is variable, with one study reporting rates as low as 34% (Pauling JD *et al*.).

We previously conducted a retrospective study assessing PH screening in our quaternary medical center, presented at ACR 2024. Based on these findings, we implemented a quality improvement (QI) intervention consisting of a departmental presentation outlining our adherence rates and a streamlined electronic order set for all three tests.

Methods: To evaluate the impact of this intervention, we analyzed screening compliance over a six-month period (September 17, 2024 to March 17, 2025). Inclusion criteria matched our prior study: 1) rheumatologist-diagnosed SSc, 2) age over 18 years at diagnosis, 3) seen in our rheumatology clinics, and 4) no prior PH diagnosis.

We reviewed charts for completed PFTs, TTEs, and BNPs. "Full compliance" was defined as completion of all three tests within 12 months prior or 6 months after an outpatient visit. "Ever compliant" was defined as completion of at least one of these tests, maintaining consistency with our prior methodology.

Results: A total of 48 patients met these criteria, accounting for 70 outpatient visits. Demographically, 91% (44) of patients were female, 68.8% (33) White, 10.4% (5) Black, and 20.8% (10) Latino (Table 1). At the visit level, 74% (52) had at least one screening test completed, and 20% (14) had all three tests completed. Individually, 48.6% (34) of visits had a PFT, 67.1% (47) a TTE, and 30% (21) a BNP (Figure 1).

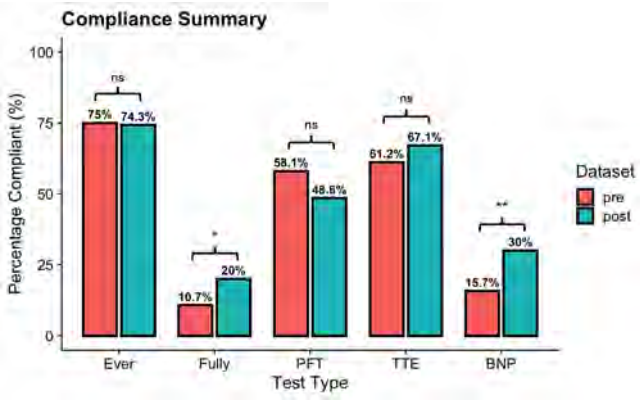

Figure 1: Percentage compliance with recommended testing per appointment. "Ever" indicates completion of at least one of the three tests (PFT, TTE, BNP), while "Fully" indicates completion of all three within 12 months prior to or 6 months after the visit. Compliance is also shown for each individual test. Bars represent pre-intervention (red) and post-intervention (teal) proportions. p-values reflect two-proportion Z-tests comparing pre- and post-intervention groups. *$p < 0.05$, **$p < 0.01$

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 2: Pre- & post-intervention analysis using two-proportion Z test. *p < 0.05, **p < 0.01

Metric	Pre (%)	Post (%)	Difference (%)	z-stat	p-value
Ever Compliant	75	74.3	–0.7	0.125	0.90
Fully Compliant	10.7	20	+9.3	-2.234	0.0255*
PFT	58.1	48.6	–9.5	1.529	0.126
TTE	61.2	67.1	+5.9	-0.981	0.326
BNP	15.7	30	+14.3	-2.619	0.009**

Comparing pre- and post-intervention periods using a two-proportion Z test (Table 2), full compliance increased significantly from 10.7% to 20% (z=-2.234, p=0.0255), and BNP testing improved from 15.7% to 30% (z=-2.619, p=0.009). Changes in PFT, TTE, and ever-compliant rates were not statistically significant.

Conclusion: Our QI intervention significantly improved adherence to full, guideline-based PH screening and BNP testing in SSc patients. Barriers remain for PFT and TTE completion, which require additional efforts in patient scheduling and follow-through. Future interventions will target these challenges through patient education materials and streamlined coordination support.

Abstract Number: 0225

Positive anxiety, depression and/or fibromyalgia screening on validated MDHAQ indices is seen in 30-50% of routine care patients with all rheumatic diagnoses

Juan Schmukler[1], Tengfei Li[2] and Theodore Pincus[1], [1]Rush University Medical Center, Chicago, IL, [2]Rush, chicago, IL

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0210–0232) Measures & Measurement of Healthcare Quality Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Comorbid anxiety (ANX), depression (DEP), and fibromyalgia(FM) are reported as more common in patients with rheumatoid arthritis (RA) and other rheumatic diagnoses than in the general population. These comorbidities are associated with elevated RA indices such as DAS28 and CDAI designed to assess inflammatory activity. However, formal recognition of ANX, DEP, and/or FM is largely limited to research studies, as multiple patient questionnaires are not feasible in busy routine care. Three validated indices within a multidimensional health assessment questionnaire (MDHAQ), MAS 2 - MDHAQ anxiety screen, MDS2 - MDHAQ depression screen, and FAST4 - fibromyalgia assessment screening tool, agree >80% with reference questionnaires. We analyzed the prevalence of positive MDHAQ screening for comorbid ANX, DEP, and/or FM on MDHAQ indices in unselected routine care patients with any rheumatic diagnosis seen at an academic medical center.

Methods: All patients with all diagnoses at the study site are asked to complete an MDHAQ at each rheumatology visit prior to seeing a health professional. The prevalence of positive screening on the MDHAQ indices for ANX, DEP, and FM was computed according to ICD-10 diagnoses. Diagnoses with fewer than 20 patients were grouped as "other inflammatory" (other inflam) or "other noninflammatory" (other non-inflam).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table: Proportion of patients in each category who screen positive or negative for any of the 3 MDHAQ indices for anxiety, depression, and/or fibromyalgia and each individual index

1º Diagnosis	n	% ANX, DEP, &/or FM pos	% Anxiety pos	% Depression pos	% FM pos	% ANX, DEP, & FM neg
Inflammatory diagnoses						
Myositis	21	48%	38%	33%	10%	52%
Sjogren syndrome	45	47%	33%	27%	24%	53%
Polymyalgia rheumatica	22	45%	18%	27%	27%	55%
Systemic lupus erythematosus	215	45%	33%	23%	22%	55%
Psoriatic arthritis	40	45%	33%	30%	25%	55%
Rheumatoid arthritis	366	43%	25%	23%	27%	57%
Spondyloarthropathy	29	38%	31%	21%	28%	62%
Other inflammatory	54	37%	17%	15%	26%	63%
Systemic sclerosis	23	35%	35%	9%	9%	65%
Vasculitis	27	30%	19%	22%	7%	70%
Crystal arthritis	50	30%	20%	20%	12%	70%
Non-inflammatory diagnoses						
Other non-inflammatory	152	52%	39%	31%	24%	48%
Osteoarthritis	238	46%	32%	25%	31%	54%
Bone mineral disorders	55	42%	36%	24%	18%	58%
Total without primary FM	1337	44%	30%	24%	25%	56%
Primary FM	60	78%	55%	55%	53%	22%
Totals – all pts	1397	45%	31%	25%	26%	55%

Results: In 1337 patients, excluding 60 with primary FM, positive screening for MAS2 ANX, MDS2 DEP and/or FAST4 FM was seen in 587 (44%), including 399 (30%) for MAS2 ANX, 321 (24%) for MDS2 DEP, 328 (25%) for FAST4 FM; 750 patients (56%) screened negative for all the 3 indices (Table). Among diagnosis categories, a positive screen for **any** of the 3 indices ranged from 52% in patients with "other non-inflammatory" diagnoses, excluding primary fibromyalgia, to 30% in crystal diseases and vasculitis, for ANX from 39% in “other non-inflammatory" diagnoses to 19% in “other-inflammatory” diagnoses, for DEP from 33% in myositis to 9% in systemic sclerosis to, and for FM from 31% in OA to 7% in vasculitis (Table). The totals were raised by only 1% with inclusion of 60 patients with primary FM, reflecting a high prevalence of 1 , 2, or 3 positive screens in all other diagnosis categories (Table). Among all patients with a positive MDHAQ screening index for ANX, DEP, and/or FM, one of the 3 was positive in 271 (43%), 2 of the 3 in 214 (34%), and all 3 in 149 (24%) (Figure).

Conclusion: In 1337 patients seen in routine care (excluding 60 with primary FM), positive screening on MDHAQ indices was seen in 30% for ANX, 24% for DEP, 25% for FM, and 44% for any of the 3 indices. Positive screening is common, and affects assessment, management, and outcomes of all rheumatic diseases. An important limitation involves data from only one setting, as variation is likely according to cultural and socioeconomic variables in different settings. An MDHAQ, completed by most patients in 5-10 minutes prior to seeing a rheumatologist and available in the February 2025 release of the Epic electronic medical record (EMR), provides a feasible strategy to screen for ANX, DEP, and FM in all patients.

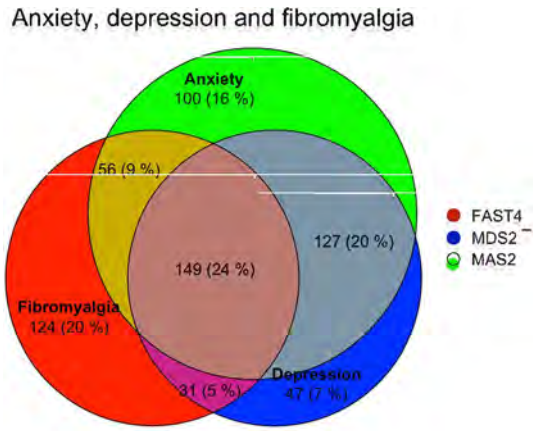

Figure: positive screening for anxiety, depression and fibromyalgia in rheumatology patients with all diagnoses seen in routine rheumatology care.

Abstract Number: 0226

Integration of the 5Ms of Geriatrics in a Novel Geri-Rheumatology Clinic

Justin Levinson[1] and Christie Bartels[2], [1]University of Wisconsin- Madison, Madison, WI, [2]University of Wisconsin School of Medicine and Public Health, Madison, WI

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0210–0232) Measures & Measurement of Healthcare Quality Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Geriatric integrative care models, such as the Perioperative Optimization of Senior Health (POSH) initiative, have shown improved outcomes (PMID: 29299599), yet there remains limited adoption in specialty clinics such as Rheumatology. This study aims to assess the findings of a novel Geri-Rheumatology clinic by a dual rheumatologist-geriatrician at an academic medical center. To test our hypothesis that an interplay of chronic inflammation and cardiovascular disease (CVD) risks impact rheumatology patients who have been shown to have higher rates of cognitive impairment (PMID: 39542002), we aimed to evaluate associated risk factors in older patients compared to peers without inflammatory conditions.

Methods: In this quality improvement pilot from August 2023 through November 2025, new Geri-Rheumatology referrals for ages >55 years were offered a geriatric evaluation using validated screening tools performed by Montreal Cognitive Assessment (MoCA) certified practitioners preceding their rheumatology visit (Figure1). The 5M's of Geriatrics were integrated through clinical assessments of Mobility (Short Physical Performance Battery [SPPB]), Mind (MoCA), Medications (polypharmacy and anti-cholinergic burden), Multicomplexity (medical and social history assessment), and Matters Most, by appropriate counseling and referrals. Patients could opt-in to the full geriatric assessment or certain elements. Cognitive risk factors of sleep apnea, depression, anxiety, and disease activity were assessed along with CVD medical history. Patients with primary diagnosis codes for rheumatologic diseases (ex. SLE, RA) were compared to those with non-inflammatory codes (ex. OA, Positive ANA, Osteoporosis).

Table 1. Geriatric Assessment of Rheumatologic vs Non-Inflammatory Cohorts by MoCA Score

	Normal Cognition (MoCA >25)		Mild Cognitive Impairment (MoCA 18-25)		Moderate Cognitive Impairment (MoCA 10-17)		Overall	
	Rheumatologic Diagnosis	Non-Inflammatory Diagnosis	Rheumatologic Diagnosis	Non-Inflammatory Diagnosis	Rheumatologic Diagnosis	Non-Inflammatory Diagnosis	Rheumatologic Diagnosis	Non-Inflammatory Diagnosis

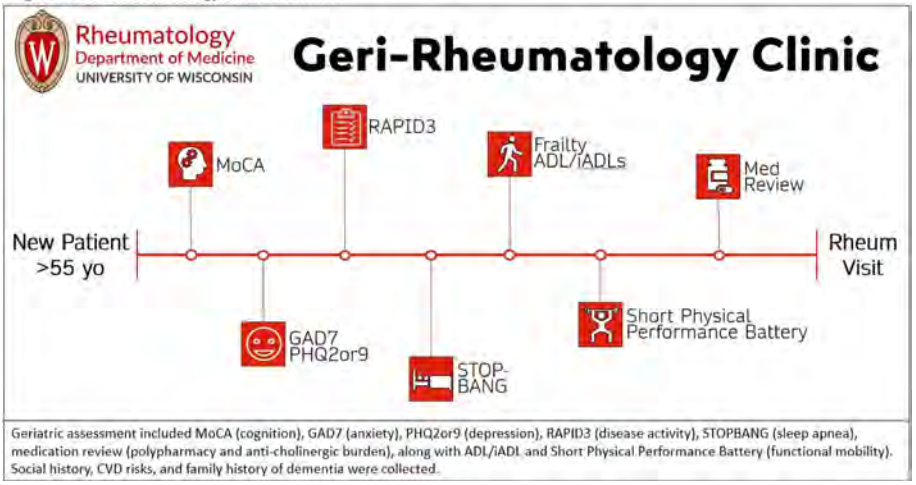
Figure 1. Geri-Rheumatology Clinic Workflow



Geriatric assessment included MoCA (cognition), GAD7 (anxiety), PHQ2or9 (depression), RAPID3 (disease activity), STOPBANG (sleep apnea), medication review (polypharmacy and anti-cholinergic burden), along with ADL/iADL and Short Physical Performance Battery (functional mobility). Social history, CVD risks, and family history of dementia were collected.

Results: A total of 77 patients completed a MOCA assessment and are included in this evaluation. With a cut off for Cognitive Impairment of ≤25, 35% (27) showed cognitive impairment with 3.9%(3) showing moderate impairment. While cognitive impairment frequencies were similar between rheumatologic and non-inflammatory cohorts, rheumatologic patients had higher baseline rates of CVD comorbidities (Table1). Lower MOCA scores were similar between cohorts and inversely related to age. The most common impairments were in Visuospatial, Attention, and Recall domains (Table2).

Polypharmacy (≥ 5 medications) was found in 73% vs 62% (p=0.44) of the rheumatologic and non-inflammatory cohorts, respectively. The average overall anti-cholinergic burden was 2.2 medications. The geriatric assessment led to 24 memory clinic, 12 physical therapy, and 15 sleep study referrals.

Conclusion: With a growing geriatric population, this study adds to the body of knowledge informing care for older rheumatology patients. Nearly 1/3 of patients were offered referral to memory clinic for further evaluation. Clinicians should consider cognitive screening for this high-risk group as dementia affects patient outcomes, counseling, and medication adherence. Limitations were small cohort size and that patients self-selected involvement; no patients had severe impairment likely due to difficulties with visit attendance or consent. Future studies should expand this cohort to evaluate long-term outcomes.

Abstract Number: 0227

Malignancy Screening of Dermatomyositis Patients in the Penn State Registry of Inflammatory Myopathies (PRIMO)

Katrina Gonzales[1], William DeKryger[2], Deepika Pugalenthi Saravanan[2], Esha Tulsian[2], Peri Newman[3], Jacob Colello[2], Galen Foulke[4] and Nancy Olsen[5], [1]Penn State College of Medicine, Hummelstown, PA, [2]Penn State College of Medicine, Hershey, PA, [3]Penn State Health/ Penn State College of Medicine, Hershey, PA, [4]Penn State Health, Hershey, PA, [5]Penn State University/Milton S Hershey, Hershey, PA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0210–0232) Measures & Measurement of Healthcare Quality Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Dermatomyositis (DM) is an immune-mediated myopathy characterized by muscle weakness and skin rash that carries an elevated risk of associated malignancy within 5 years of diagnosis [1]. While the link between DM and malignancy is well established, no consensus guidelines exist regarding advanced malignancy screening beyond standard age appropriate US Preventive service task force (USPSTF) and American Cancer Society recommendations. Given the variability of practices among providers, we sought to explore institutional trends and barriers to obtaining malignancy screenings for adult DM patients.

Methods: We conducted a retrospective review of patients enrolled from 2010-2020 in our previously established registry, the Penn State Registry of Inflammatory Myopathies (PRIMO). Inclusion criteria were diagnosed at age >18, DM diagnosis confirmed through ACR/EULAR criteria, and presentation within 3 years of diagnosis. Descriptive statistics were used to summarize results.

Table 1 - Demographics and Antibody Panel

Malignancy Screenings: X-axis = Malignancy Screening Type, Y-axis = Number of tests ordered

Results: A total of 65 patients met inclusion criteria. Patients were predominantly female (78.5%), with mean age at diagnosis of 55.3 years. In 69.8% of initial encounters, malignancy risk and/or need for screening was documented. CT thorax (72.3%) and CT abdomen/pelvis (66.2%) were the most commonly completed screenings with 42.8% undergoing PET CT. Regarding USPSTF screenings, 29% and 37.4% of eligible patients completed colonoscopy and mammogram respectively. All patients with high risk antibody profiles received advanced screening. Notably, 15.4% of patients had no advance testing completed or documented. Rheumatologists (25, 43.1%), dermatologists (29, 50.0%), and primary care physicians (19, 32.8%) were the most common ordering providers. Insurance approval and financial concerns were leading reasons why ordered tests were not completed. Malignancy was present in 18.8% of patients and included breast, lung, gastrointestinal, hematologic, and gynecologic cancers. The average time between first DM evaluation and malignancy diagnosis was 27.6 months.

Conclusion: Our data highlights the variability that exists among cancer screening practices in DM. While those with the highest risk disease subtypes were identified and screened, many others were not recommended for advanced screening and clinical decision making was not well documented. Furthermore, USPSTF screenings were not commonly ordered by specialists, drawing attention to the need for collaboration. Given the morbidity and mortality that accompanies malignancy, efforts should be made to overcome barriers to screening. Future efforts should focus on collaborations with other institutions to expand participant diversity, adopting insights from primary care screening practices, assessing patient and provider perspectives, and developing practical quality improvement initiatives to trial in the clinical environment.

Abstract Number: 0228

Bridging the Gap: Leveraging Econsultation to Improve Access to Quality Gout Care

Laura Nichols[1] and Steven Taylor[2], [1]University of Colorado, Aurora, CO, [2]University of Colorado, Denver, CO

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0210–0232) Measures & Measurement of Healthcare Quality Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: In the context of the rheumatology workforce shortage, eConsultation holds significant potential to address some challenges through supporting primary care providers in managing rheumatologic conditions. Gout is a useful prototype for implementation of eConsults considering uric acid as a biomarker, the common nature of gout, and well-defined treatment regimens. This quality improvement project aimed to evaluate the current impact of gout eConsults on improvements in uric acid, consistency of consultation, conversion to in-person visits, and milage and travel cost savings.

Methods: Data from 93 gout consults received between 5/18/2018 – 9/16/2024 at a single academic site were reviewed. Data was collected regarding uric acid levels, the type of recommendation provided, as well as whether the patient was seen in-person by rheumatology. Consults were categorized based on whether patients were evaluated with eConsult only, immediately converted to in-person visit, or subsequently converted to an in-person visit. Duplicate eConsults and patients who were never seen due to cancellations or scheduling errors were excluded from analysis. Milage saved and travel cost saved were calculated based on the distance between the patient's zip code and the medical center and the average IRS milage compensation from 2018-2024 ($0.599/mile).

Results: Forty-nine eConsults did not require an in-person visit.Twenty-five patients were converted to an initial in-person visit. Six additional patients were subsequently converted to an in-person visit. Average uric acid levels decreased over the monitoring period in patients treated by all three pathways (Table 1). Patients triaged to in-person visits compared to eConsult generally had a higher baseline uric acid level (8.2 versus 7.9), but lower levels (5.1 versus 6.0) at 1 year. Average 2-way milage saved for patients with eConsult was 45.6 miles. Average cost savings was $27.31 (Figure 1). Formal categorization of qualitative data was not performed for this quality improvement study. However, there was notable heterogeneity in responses, such as interval of checking uric acid. Limitations include missing values for uric acid.

Conclusion: eConsults resulted in decreased uric acid from baseline as well as both mileage and travel cost savings for patients. Though there were likely intrinsic differences between in-person and eConsult patient populations at baseline, the lower uric acid levels with in-person visits suggest there is room for improvement with current eConsultation practices.

Table 1: Change in uric acid over time for eConsultation and in-person visits

	BASELINE URIC ACID	URIC ACID AT 6 MONTHS	URIC ACID <6 AT 6 MOS N (%)	URIC ACID AT 1 YEAR	URIC ACID <6 AT 1 YEAR N (%)	MOST RECENT URIC ACID
E-CONSULTATION ONLY N=49	7.9	6.5	11 (22%)	6.0	14 (29%)	6.7
INITIAL IN-PERSON EVALUATION N=25	8.2	5.9	9 (36%)	5.1	14 (56%)	5.8
CONVERSION TO IN-PERSON EVALUATION N=6	8.7	7.2	1 (17%)	6.6	2 (33%)	6.1

Figure 1: Travel distance (2-way) and associated travel costs for patients

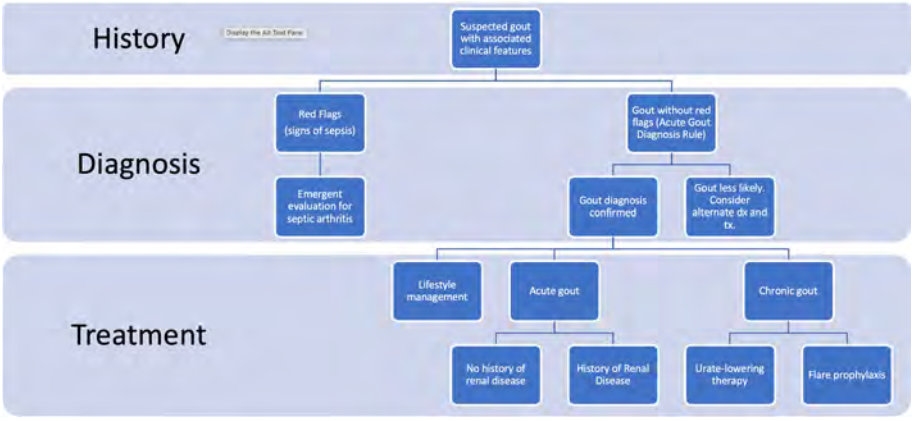

Figure 2: Schematic for point-of-care diagnostic and therapeutic algorithm

Future quality improvement directions include: standardization of gout eConsult recommendations utilizing tools such as a division-wide consult smart phrases, point-of-care treatment algorithms for referring clinicians such as in Figure 2, and pairing of eConsults with other care-delivery models such as pharmacy or nursing-led gout clinics. Analysis of cost savings and milage savings represent unique metrics for monitoring quality improvement.

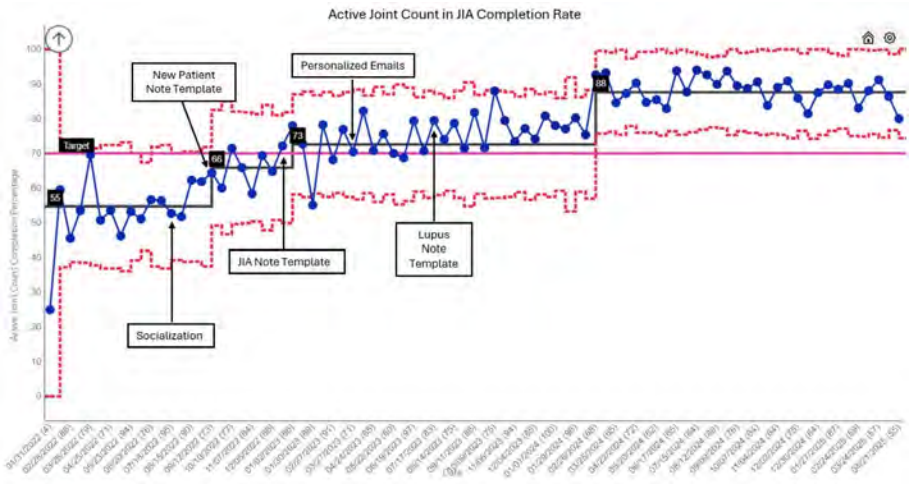

Figure 1: Active Joint Count in JIA Completion Rate P chart

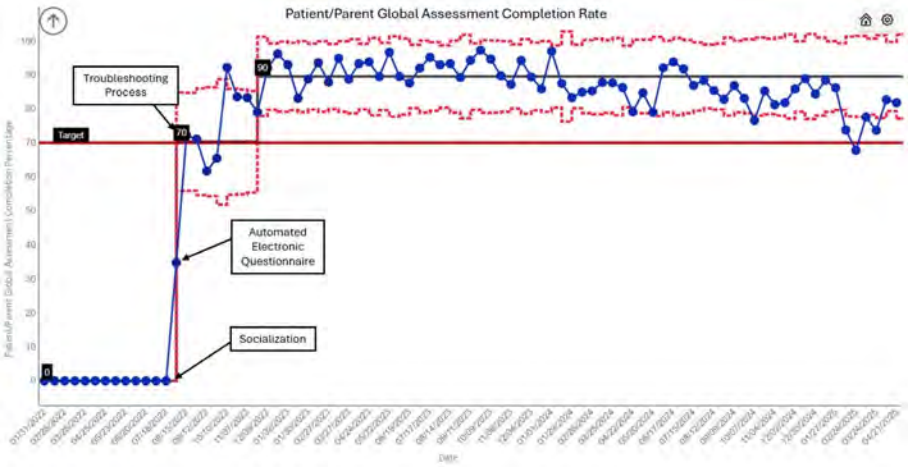

Figure 2: Patient/Parent Global Assessment Completion Rate P Chart

Background/Purpose: A systematic approach to clinical data collection is critical to enhancing patient outcomes, enabling research and quality improvement initiatives, and benchmarking performance. This quality improvement project aimed to increase the rate of discrete data captured during eligible outpatient visits in a pediatric rheumatology clinic from a mean documentation rate of 0-55% of visits to 70% of visits for each data element.

Methods: Division-wide consensus identified data variables essential for patient care and research, including active joint count in JIA, physician global assessment of disease activity in JIA, patient/parent global assessment, clinical juvenile arthritis disease activity score (cJADAS) in JIA, and patient health questionnaire-9 (PHQ-9) score for depression screening in lupus. Patient-reported data were collected via an automated paperless workflow using a virtual interface, with discrete storage in the electronic medical record (EMR). A semi-structured documentation strategy incorporating hyperlinks, disappearing reminders, and auto-populated fields was created to prompt provider-reported data collection. A flexible "choose your own adventure" approach provided structure for data collection while maintaining the personalization providers desired. The essential data elements were grouped as exam data and outcomes data relevant to specific disease and were easily accessed as a link in the EMR. Providers had the options of using a standard note template with embedded data elements or a personalized template or copied forward note to which the essential data elements could be manually added. The EMR automatically calculated cJADAS from its components utilizing an existing functionality. Other interventions included consensus meetings, provider education and individual provider performance feedback. The Model for Improvement guided implementation through Plan-Do-Study-Act cycles, and outcomes were analyzed using statistical process control (SPC).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

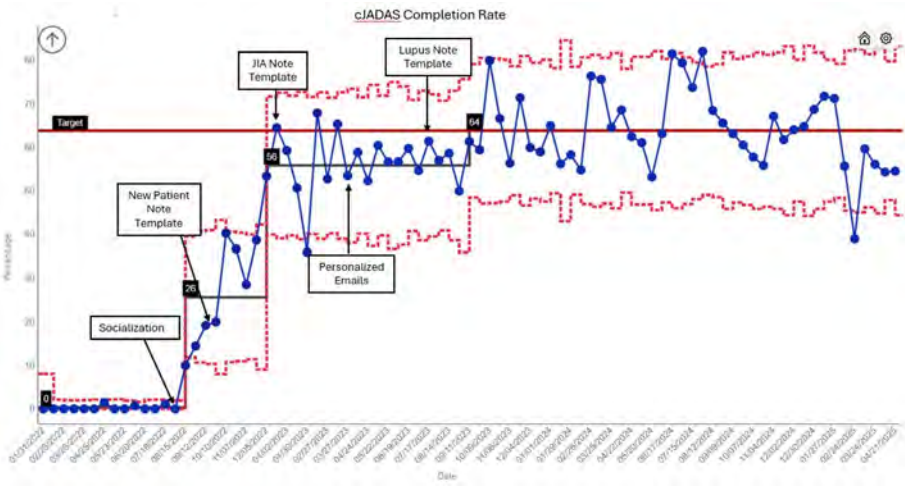

Figure 3: cJADAS Completion Rate P Chart

Results: From January 2022 to March 2024, completion rates improved significantly: active joint count in JIA rose from 55% to 88% (Figure 1), physician global assessment in JIA from 32% to 76%, patient/parent global assessment from 0% to 90% (Figure 2), cJADAS in JIA from 0% to 64% (Figure 3), and PHQ-9 in lupus from 57% to 84% of visits. All mean shifts met criteria for special cause variation using SPC methods. The target completion rate of 70% was achieved in all but one data element (cJADAS). All gains were sustained through April 2025.

Conclusion: A high rate of standardized discrete data collection in a pediatric rheumatology clinic was achieved and maintained using automated electronic patient questionnaires, a flexible documentation strategy, and existing EMR functionalities. These interventions have potential to be adapted to other data elements and across institutions to improve rates of discrete data collection for patient care, research, and quality improvement in pediatric rheumatology.

An Epic Journey – Therapeutic Drug Monitoring at an Academic Center

Puja Khanna[1] and Michael Rice[2], [1]Division of Rheumatology, University of Michigan, Ann Arbor, MI, [2]Division of Gastroenterology, University of Michigan, Ann Arbor, MI

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0210–0232) Measures & Measurement of Healthcare Quality Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Non-oncologic use of immunomodulatory agents is increasing. These drugs have a narrow, patient-specific therapeutic index, making therapeutic drug monitoring essential for safe prescribing. However, monitoring parameters vary widely, often influenced by the managing clinician's expertise and the complexity of patients with multiple comorbidities (1). In rheumatology, this challenge is compounded by ambiguous guidelines from professional societies and regulatory bodies, as well as high monitoring costs and frequency that affect patient preferences (2). Inconsistency in recommendations about how best to monitor for adverse effects impacts which ones clinicians adhere to. Our objective

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Patients being monitored by Specialty

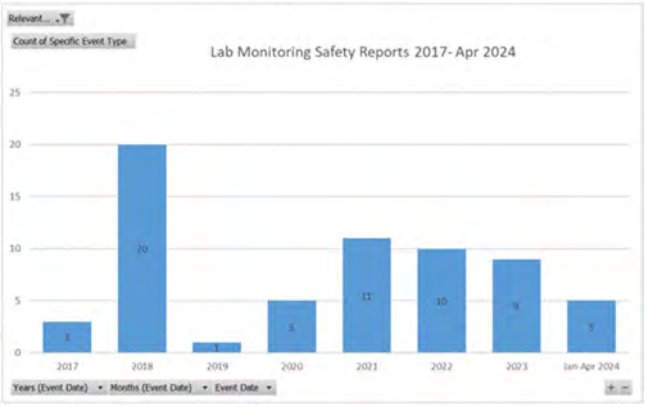
Table 1. Medication Monitoring Root Cause Analysis

GAPS IN Workflows
Significant process variability across sites and within specialties
Multiple management structures; work decentralized across multiple clinics
Accountability for work not well defined
Roles often not clearly defined; no overall process owner
Communication gaps arise due to fragmented documentation systems and absence of of standardized workflows
Lab results retrieval and entry can be time consuming as several patients have their labs done in the community
Significant inefficiencies emerge as workload increases
No best practice to share

Figure 2. Rates of Safety Reports



was to create an evidence-based best practice paradigm for clinicians and operationalize a dynamic program for supporting care teams to avoid adverse outcomes at a tertiary care academic practice.

Methods: A large interdisciplinary steering committee was formed to assess laboratory monitoring across eight Internal Medicine specialties, with Rheumatology taking the lead due to its high patient volume. Stakeholder focus groups were conducted (among clinicians, nursing, IT, pathology, pharmacists, medical assistants and patient support advocates) to identify gaps, areas of improvement, and achieve consensus on a minimum standard of streamlined processes. A standardized laboratory monitoring policy was instituted to establish the workflows unique to each subspecialty and then operationalized at

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

the height of COVID in 2021. Epic©, the electronic medical record (EMR), was leveraged to build a single unified platform. Smartsets were designed to facilitate efficient lab ordering, reduce manual data retrieval for staff and attain timely review of integral results.

Results: Baseline data revealed 7,747 patients enrolled in various inconsistently monitored programs across IM specialties in 2020 (Figure 1). Root cause analysis identified approximately 5 % missed enrollments and several workflow gaps in the medication monitoring (Table 1). In the followup PDCA, over 16,000 patients are now being monitored for both medication safety and disease activity at our institution. We saw an incremental decline in the volume of safety events (Figure 2) from the inception of this initiative.

Conclusion: Ensuring patient safety is essential to delivering optimal care for patients with complex conditions requiring high-risk medications. Our experience at a large academic center demonstrates how the EMR can be leveraged with the support of a multi-disciplinary collaborative team to ensure successful implementation of a standardized platform to attain this longitudinal goal. A dashboard is in development for each specialty to explore the quality of key monitoring metrics in a sustainable manner.

A Quality Improvement Project to Explore the Implications of the 2020 ACR Gout Guideline Recommendations for HLA-B5801 Testing

Sarah Anstett[1], Brian Coburn[2], Carlos Garcia-Gonzalez[3], Max Krall[1], Akash Gupta[4], Riya Madan[5], Stephanie Lee[6], Tania Aguila[1], Adam Mayer[7], Elise Breed[2], Preethi Thomas[8], Nora Sandorfi[1], Anupama Shahane[1] and Rachel Dayno[1], [1]University of Pennsylvania, Philadelphia, PA, [2]Hospital of the University of Pennsylvania, Philadelphia, PA, [3]University of Pennsylvania, Philadelphia, [4]Hospital of University of Pennsylvania, Philadelphia, PA, [5]University of Pennsylvania Medical Center, Philadelphia, PA, [6]University of Pennsylvania and Children's Hospital of Philadelphia, Philadelphia, PA, [7]University of Pennsylvania/Children's Hospital of Philadelphia, Philadelphia, PA, [8]UNIVERSITY OF PENNSYLVANIA, Conshohocken, PA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0210–0232) Measures & Measurement of Healthcare Quality Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: The presence of the HLA-B5801 allele increases the risk of life-threatening allopurinol hypersensitivity syndrome (AHS). The 2020 ACR gout management guidelines conditionally recommend HLA-B5801 testing before starting allopurinol in populations more likely to have this allele, including African Americans and individuals of Southeast Asian descent (FitzGerald et al, Arthritis Care Res 2020). While intended to reduce harm, these guidelines could result in delayed

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Fishbone diagram examining barriers to testing HLA-B5801

or untreated gout in these high-risk populations if appropriate systems are not in place. This project aims to identify beliefs, practices, and consequences of HLA-B5801 testing to inform future strategies that ensure prompt urate-lowering therapy (ULT) initiation for all individuals.

Methods: Data collection included a chart review and provider survey. The chart review was conducted at two academic rheumatology clinics from October 1, 2023 to September 30, 2024. All new patients and hospital discharge visits with a diagnostic code for gout (M10.XX, M1A.XX) during this period were reviewed. Manual chart review collected self-identified race as listed in the electronic health record, consideration of ULT, length of allopurinol treatment, HLA-B5801 testing, and ULT prescribing/dispensing details. A local survey of rheumatology providers assessed HLA-B5801 testing practices, perceived testing frequency, barriers, and future testing intentions. The chart review and survey results informed the creation of a fishbone diagram to identify targets for quality improvement interventions (Figure 1).

Results: We identified 78 patients who fit our criteria (Table 1). Of those, 47% of Black patients (n=14) and 75% of Asian patients (n=3) had HLA ordered (Table 2). Among Black and Asian patients who started allopurinol, HLA-B5801 testing was ordered for 50% (n=7) of patients on allopurinol for ≤6 months and for 57% (n=8) who had never received allopurinol. Of the patients who had never received allopurinol, 25% (n=2) started low dose allopurinol the same day HLA-B5801 testing was ordered while the remainder waited for results. Of the 20 survey responses, 100% reported awareness of ACR guidelines; 60% reported consistently ordering HLA-B5801 testing. The majority (85%) felt comfortable discussing race/ancestory to guide testing. Among the 8 providers who did not routinely order testing, there were concerns about delaying ULT initiation, thought that testing would not impact management, and challenges with ordering the test.

Conclusion: Providers demonstrated variable practices and beliefs surrounding HLA-B5801 testing. This may reflect uncertainty about implementing a race- or ancestry-based recommendation in clinical practice. Future goals for our quality improvement project are to reduce barriers for HLA-B5801 ordering so high-risk populations for the HLA-B5801 allele may be promptly and safely started on appropriate ULT.

Hydroxychloroquine Blood Testing in Lupus: The Michigan Medicine Experience

Zeinab Saleh[1], Michelle Kahlenberg[2], Wendy Marder[1], Emily Somers[1] and Internal Medicine Clinical Experience & Quality team, [1]University of Michigan, Ann Arbor, MI, [2]Michigan Medicine, Ann Arbor, MI

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0210–0232) Measures & Measurement of Healthcare Quality Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

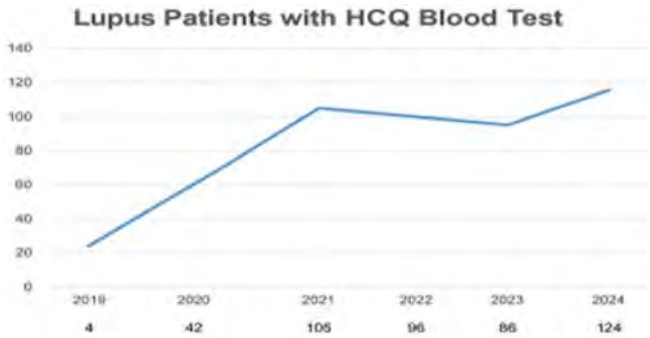
Background/Purpose: Measuring hydroxychloroquine (HCQ) blood levels in patients with systemic lupus erythematosus (SLE) can assess medication adherence and determine whether concentrations fall within the therapeutic or toxic ranges. Despite this potential, HCQ monitoring has not been incorporated into routine SLE care, largely due to the absence of standardized clinical cut-offs and formal guidelines from rheumatology associations (e.g, the American College of Rheumatology and the European Alliance of Associations for Rheumatology). Our objectives are twofold: (1) to provide evidence-informed recommendations for monitoring HCQ blood levels in adult SLE patients on therapy for at least six months, and (2) to evaluate HCQ levels in our lupus population at Michigan Medicine (MM).

Methods: We conducted a systematic review using PubMed, Embase, and Cochrane databases (from inception to October 2024), applying MeSH terms and keywords related to lupus and hydroxychloroquine. A multidisciplinary team—including representatives from rheumatology, dermatology, ophthalmology, nursing, pharmacy, pathology, the Internal Medicine Clinical Experience & Quality team, and a patient advisor—held six teleconferences, reached consensus, and developed institutional recommendations for HCQ blood level monitoring. In parallel, our continuous improvement specialist and data analyst assisted in extracting data from our adult lupus patient population.

Michigan Medicine HCQ Blood Level Target Range Guidelines		
	Whole Blood	Serum
Severen non-adherence	< 200 ng/mL	< 100 ng/mL
Partial non-adherence or Sub-therapeutic	200-750 ng/mL	100-400 ng/mL
Therapeutic or Target range	750-1200 ng/mL	400-600 ng/mL
Supra-therapeutic	> 1200 ng/mL	> 600 ng/mL

Michigan Medicine HCQ Blood Level Target Range Guidelines

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Number of Michigan Medicine lupus patients with HCQ blood tested between 2019 and 2024

	Number of Patients (Total 457, from 2019-2024)
Severe non-adherence	65
Partial non-adherence or Sub-therapeutic	284
Therapeutic or Target range	68
Supra-therapeutic	40

HCQ Blood Level Distribution in Our Patient Cohort

Results: (1) Our team defined target HCQ blood level ranges for four clinical categories: severe non-adherence (frequent interruptions or complete discontinuation), partial non-adherence (occasional missed doses) or subtherapeutic levels, therapeutic levels, and supra-therapeutic levels (associated with potential retinal toxicity). These guidelines are now posted on PolicyStat, Michigan Medicine's centralized platform for institutional policies, procedures, and guidelines (Figure 1).

(2) From January to July 2024, only 4% of adult lupus patients managed by MM Rheumatology had their HCQ blood levels tested. However, utilization has steadily increased since the test was introduced in 2019 (Figure 2). Figure 3 illustrates the distribution of HCQ levels among our tested patients.

Conclusion: Our work provides clinicians with practical, consensus-based guidance for monitoring HCQ blood levels in patients with SLE. We are actively engaging stakeholders- including rheumatologists, ophthalmologists, dermatologists, nurses, and patients- to raise awareness of the benefits of HCQ level monitoring in improving long-term outcomes. Our goal is to increase testing among HCQ-treated lupus patients from 4% to 25% within the next six months.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: While both SGLT2 inhibitors and GLP-1 receptor agonists improve glycemic control in type 2 diabetes (T2D), their safety profiles, particularly regarding hypoglycemia and infection risk, may differ in patients with inflammatory conditions. This study compared these outcomes in patients with T2D and inflammatory polyarthropathy treated with either drug class.

Methods: This retrospective cohort study analyzed data from the TriNetX global health research network, identifying adult patients with T2D and inflammatory polyarthropathy receiving either SGLT2 inhibitors (n=3,377) or GLP-1 receptor agonists (n=4,733). After propensity score matching (n=2,838 per group), we evaluated the incidence of hypoglycemia, respiratory infections, urinary tract infections, sepsis, and other infection-related outcomes over a 5-year follow-up period.

Results: Patients treated with SGLT2 inhibitors experienced higher rates of sepsis (8.1% vs 5.9%, HR 1.609, 95% CI 1.318-1.965, p< 0.001) and acute kidney injury (16.9% vs 13.6%, HR 1.371, 95% CI 1.216-1.547, p< 0.001) compared to those on GLP-1 receptor agonists. Hypoglycemic events were more common in the SGLT2 inhibitor group (1.8% vs 1.1%, HR 1.594, 95% CI 1.028-2.472, p=0.036). The SGLT2 inhibitor cohort also showed higher rates of endocarditis/valve disorders (3.8% vs 2.9%, HR 1.478, 95% CI 1.098-1.990, p=0.043) and bacteremia (3.4% vs 2.4%, HR 1.627, 95% CI 1.205-2.196, p=0.001). Pneumonia incidence was similar between groups. Acute respiratory distress was more frequent with SGLT2 inhibitors (11.0% vs 6.7%, HR 1.699, 95% CI 1.480-1.949, p< 0.001).

Conclusion: In patients with T2D and inflammatory polyarthropathy, treatment with GLP-1 receptor agonists was associated with lower risks of serious infections, acute kidney injury, and hypoglycemia compared to SGLT2 inhibitors. These findings suggest that GLP-1 receptor agonists may offer a more favorable safety profile in this specific patient population. Clinicians should consider these differences when selecting glucose-lowering agents for patients with T2D and inflammatory arthritis.

Background/Purpose: Small fiber neuropathy (SFN) is a common complication of sarcoidosis, affecting about one third of patients. The current gold standard for diagnosis combines patient history and a skin biopsy to quantify small nerve fibers. Corneal confocal microscopy (CCM) is now being used with more frequency to evaluate nerve fibers in the cornea, specifically in diabetic neuropathy. However, further research is needed to validate the role of CCM in sarcoidosis. Our study focused on CCM and how it can be utilized as an accurate, non-invasive diagnostic tool for SFN in patients with sarcoidosis.

Methods: This study is a subset analysis of a larger study to better characterize SFN in sarcoidosis. A total of 12 patients with sarcoidosis who completed CCM analysis were included in the study. We categorized sarcoidosis patients into two groups: those with a physician impression of neuropathy (PIN) and those without a physician impression of neuropathy (non-PIN). A third group, healthy age-matched controls without sarcoidosis from a database, were added for comparison. CCM was performed to determine corneal nerve fiber density, length and tortuosity and corneal nerve branch density.

Results: CCM data was collected on 12 patients with sarcoidosis, 8 of who had PIN and 4 of who had non-PIN. The mean age of patients in the PIN group was 52.8 years with 87.5% females. The non-PIN group averaged 47.25 years old with 50% females. The healthy control group had a mean age of 51.3 years with no data on sex. One-way ANOVA analysis revealed a difference in corneal nerve fiber density (CNFD) approaching significance (p = 0.05) between the three groups. Post-hoc comparison using two-sample t-test to assess for between-group differences revealed a statistically significant difference in CNFD (p = 0.03), and a difference in corneal nerve branch density approaching statistical significance (p = 0.05) between

Table 1. One-way ANOVA test analyzing group differences in corneal nerve fiber density (CNFD), corneal nerve branch density (CNBD), corneal nerve fiber length (CNFL), and corneal nerve fiber tortuosity (CNFT) among three groups: health controls (HC), patients without a clinical impression of peripheral neuropathy (non-PIN), and patients with a clinical impression of neuropathy (PIN). The difference in CNFD is approaching statistical significance between the groups (p = 0.05).

	HC (N=12)	Non-PIN (N=4)	PIN (N=8)	P-value
CNFD				
Mean (SD)	30.0 (4.99)	23.4 (5.98)	20.3 (11.0)	0.0543
Median [Min, Max]	29.2 [22.3, 39.6]	21.9 [18.7, 31.2]	15.6 [12.5, 37.5]	
CNBD				
Mean (SD)	73.1 (25.9)	59.4 (16.5)	39.8 (38.1)	0.0696
Median [Min, Max]	69.5 [43.8, 125]	56.2 [43.7, 81.2]	28.1 [0, 106]	
CNFL				
Mean (SD)	22.7 (3.76)	19.8 (4.60)	16.8 (8.48)	0.11
Median [Min, Max]	22.3 [18.6, 29.0]	18.4 [16.1, 26.2]	16.3 [5.18, 29.7]	
CNFT				
Mean (SD)	13.8 (1.98)	18.8 (7.95)	14.3 (5.26)	0.21
Median [Min, Max]	13.6 [9.63, 16.9]	16.2 [12.9, 29.8]	12.7 [9.00, 23.5]	
Missing	2 (16.7%)	0 (0%)	0 (0%)	

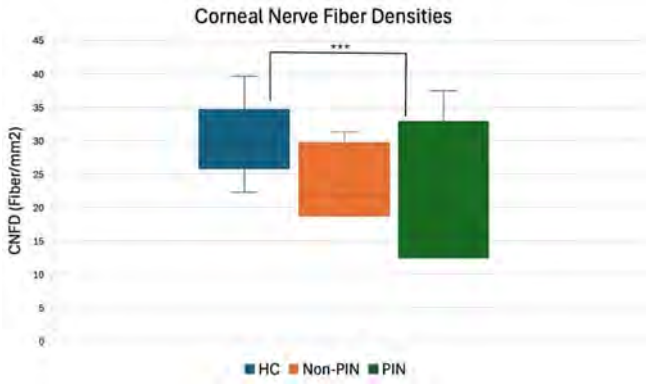

Figure 1. Corneal nerve fiber densities (CNFD) among healthy controls (HC), patients without a clinical impression of peripheral neuropathy (non-PIN), and patients with a clinical impression of neuropathy (PIN). A statistical difference was noted between healthy controls and PIN groups (p= 0.03).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

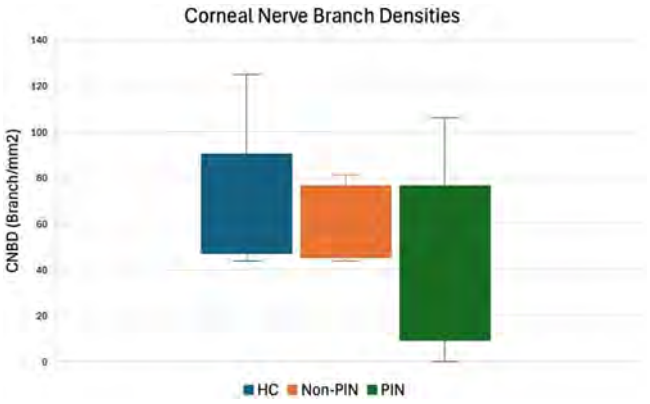

Figure 2. Corneal nerve branch densities (CNBD) among healthy controls (HC), patients without a clinical impression of peripheral neuropathy (non-PIN), and patients with a clinical impression of neuropathy (PIN). Though no statistically significant difference was found among the groups, there was a trend towards significance between HC and PIN groups (p = 0.05).

age-matched controls and PIN patients. However, there was not a difference in corneal nerve fiber length or corneal nerve fiber tortuosity between the two groups. There was no statistical difference noted in any of the measures between healthy controls and the non-PIN group or when comparing the PIN and the non-PIN groups.

Conclusion: CCM is a non-invasive method to capture images of small nerve fibers as a marker for SFN. Primarily used in diabetic neuropathy, our study findings indicate CCM can provide diagnostic data in patients with sarcoidosis and features of SFN, especially when analyzing CNFD. Interestingly, though not statistically significant, non-PIN patients trended toward having low corneal nerve fiber and branch densities, similar to PIN patients. Due to the low number of patients in our study, further research will be needed to validate the use of CCM as a screening tool for SFN in sarcoidosis patients.

Mortality Trends due to Hypertension Related Deaths in Elderly Patients with Inflammatory Polyarthropathy: A CDC WONDER Analysis of 21 Years

ZAUHA FAWAD MEMON[1], Sibgha Fawad Memon[2], Matia Fawad Memon[2], **REHAN ISHAQUE**[3], AHMAD SANAN[4] and MUHAMMAD MUGHEES[5], [1]Peoples University of Medical and Health Sciences for Women, Tando Allahyar, Sindh, Pakistan, [2]Peoples University of Medical and Health Sciences for Women, Tando Allahyar, Pakistan, [3]LIAQUAT UNIVERSITY OF MEDICAL AND HEALTH SCIENCES, Jam Shoro, Sindh, Pakistan, [4]KHYBER MEDICAL COLLEGE, Peshawer, Pakistan, [5]Bahria University health Sciences, KARACHI, Pakistan

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Inflammatory polyarthropathy (IPA) is a group of chronic autoimmune disorders, common among older adults and contribute significantly to systemic inflammation and cardiovascular risk . These conditions are associated with systemic inflammation, which leads to an elevated risk of cardiovascular diseases, notably hypertension (HTN). Recent

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

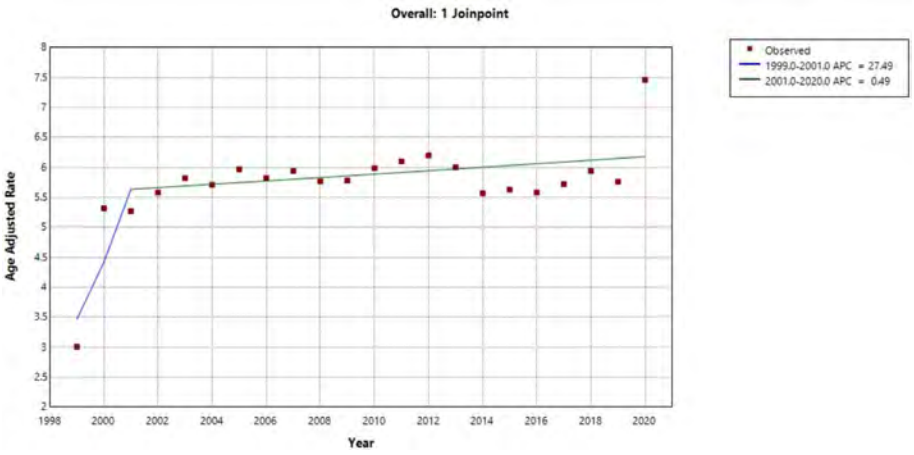

Figure 1: showing an overall increase in mortality trend due to Inflammatory Polyarthropathy and Hypertension

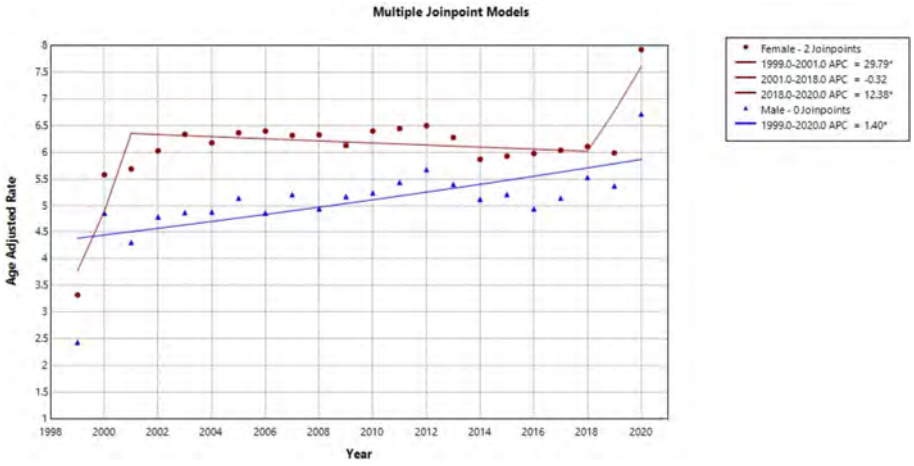

Figure 2: Showing disparities in mortality trends between sexes, with constant rise seen in males, and females demonstrating a biphasic pattern

studies suggest that people with IPA like rheumatic arthritis (RA) are 48% more likely to develop cardiovascular disorders than the general population. Emerging research underscores the role of immune-mediated inflammation in pathogenesis of HTN among patients with IPA. This study explores mortality rates due to IPA in patients with (HTN) patients aged 55 or above to inform prevention and care strategies.

Methods: We conducted a retrospective population-based study using the Centers for Disease Control and Prevention's Wide-ranging Online Data for Epidemiologic Research system (CDC WONDER) death certificate data (1999-2020). Subjects with Inflammatory polyarthropathy and Hypertension (HTN) were selected. Age-adjusted mortality rates (AAMRs) per 100,000 were calculated, and trends were assessed using Joinpoint regression to estimate annual and average annual percent changes (APC, AAPC). Rates were stratified by year, gender, race/ethnicity, region, and urbanization.

Results: A total of 91,168 deaths were reported to be associated with Inflammatory polyarthropathy and hypertension between 1999-2020, of which males accounted for 35.68% and female accounted for 64.32%. The overall age-adjusted mortality rate (AAMR) increased from 3.01 in 1999 to 7.46 in 2020 (AAPC: 2.78, $p < 0.050810$). Females had a higher age-adjusted mortality rate than males (6.15 vs 5.17).

Racial/ethnic disparities were apparent. Black or African American population had the highest AAMR (10.97 in 2020) (AAPC: 1.12, $p < 0.565390$). Asian or Pacific Islander had an overall similar trend (AAPC: -0.67, $p < 0.170487$). The trend in White people (AAPC: 2.90, $p < 0.017643$) remained almost consistent with sudden spike in 2020 (AAMR 7.18). Hispanic people had an overall upward trend (AAPC: 3.03, $p < 0.013721$).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Geographically, all four U.S. Census regions showed statistically significant incline, most prominent in the Northeast (AAPC: 4.03) and South (AAPC: 2.75) regions.

Both Urban and rural populations witnessed a substantial rise, however, it was more pronounced in rural population (AAPC: 3.30, $p < 0.021351$) as compared to urban (AAPC: 2.50, $p < 0.083213$)

Conclusion: Over the last 2 decades, mortality due to inflammatory polyarthropathy in patients with hypertension has remarkably increased. These findings highlight the need for targeted public health interventions and equitable access to address these disparities.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: T cell engagers (TCEs) are a promising therapeutic strategy to treat autoimmune diseases (AID). However, long-term data remain limited.

Methods: Patients with treatment-refractory AID were treated with the CD19 TCE blinatumomab or the BCMA TCE teclistamab. Eligibility criteria for blinatumomab were (i) diagnosis of rheumatoid arthritis (RA), (ii) ACPA/RF positivity or B-cell infiltration of the synovium, (iii) DAS28-ESR >3.2 and (iv) failure of ≥ 3 bDMARDs/tsDMARDs. Eligibility criteria for teclistamab: (i) diagnosis of AID according to respective diagnostic criteria, (ii) presence of characteristic autoantibodies, (iii) active disease based on respective criteria and ascertained by three specialists and (iv) failure of ≥ 2 immunosuppressants.

Results: 24 patients received TCE therapy. Most (18/24) had previously failed B cell depletion. 14 RA patients received blinatumomab (2–3 cycles, cumulative dose 77–189µg). 10 patients received teclistamab [systemic sclerosis (SSc), N=3, idiopathic inflammatory myositis (IIM) N=2, IgG4-related disease (IgG4-RD) N=2, primary Sjogren's-Syndrome (SjS) N=1,

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Safety of blinatumomab and teclistamab in autoimmune disease. (A) Overview of adverse events during blinatumomab therapy. (B) Overview of adverse events during teclistamab therapy.

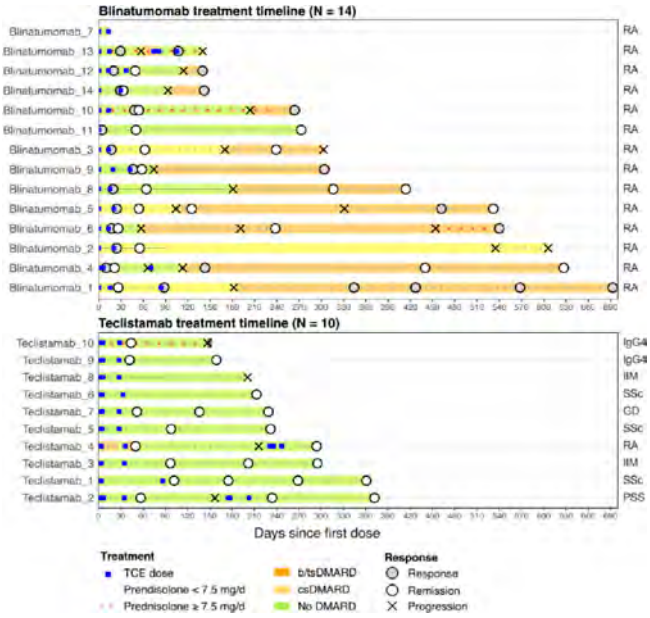

Figure 2. Durability of response. (A) Blinatumomab and (B) teclistamab treatment timeline.

Graves disease (GD) N=1, RA N=1]. Teclistamab was administered s.c. (d1: 0.06 mg/Kg; d3: 0.3 mg/Kg; d5: 1.5 mg/Kg, week 4: 1.5 mg/Kg). Treatment with TCEs was well tolerated (Fig. 1). No high-grade CRS and no ICANS occurred.

In patients treated with blinatumomab, low-grade (1-2) CRS was observed in 3/14 cases.

Transient hypogammaglobulinemia occurred in one patient. Mild infections occurred in 4 patients; no severe infections were observed. In patients treated with teclistamab, low-grade CRS occurred in 8/10 cases and resolved upon tocilizumab infusion. Hypogammaglobulinemia occurred in 9/10 patients and resolved after a median of 2 [range: 1-5] immunoglobulin infusions. 3 severe infections were observed, which fully resolved (viral gastroenteritis, *Clostridium difficile* infection, urinary tract infection). Mild upper respiratory tract infections occurred in 8/10 patients.

All patients showed initial clinical and serological response. In blinatumomab-treated RA patients, average DAS28-CRP decreased from 5.13 to 2.6, leading to DAS remission in 9/14 patients at month 3. After a median response to blinatumomab of 3.8 months, 13/14 patients progressed and required further therapy; one patient stayed in remission (Fig. 2).

In patients treated with teclistamab, disease specific autoantibodies seroconverted or markedly decreased. Serum IgG4 and CRP normalized and organ manifestations of IgG4-RD improved. At 3-month follow-up, mRSS decreased on average by 10, ESSDAI decreased from 34 to 12, CDASI improved from 22 to 5 and MMT8 increased from 138 to 150. DAS28 decreased from 5.59 to 2.1. Interstitial lung disease improved (median KCO of 45% to 53% at month-3 follow up). In the patient with GD, endocrine orbitopathy reverted.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

6/10 patients treated with teclistamab maintained clinical response (median: 9 months), 3/10 patients progressed after a median of 5.2 months, one patient showed initial non-response (Fig. 2).

Conclusion: Our data substantiate an overall favorable safety profile and clinical efficacy of TCEs, warranting further investigation as treatments in different AIDs.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Monogenic autoinflammatory diseases are rare innate immunity disorders characterized by recurrent episodes of fever and systemic inflammation. They are most often described in childhood, although adult-onset cases have been reported. Clinical, genetic, and phenotypic expression varies by geographic region, and correlations between genotype and symptomatology have been described.

Undefined autoinflammatory syndrome (uSAID) is characterized by recurrent episodes of inflammation similar to monogenic autoinflammatory diseases with no diagnosis or genetic alterations detected.

The purpose of this study is to describe the characteristics of autoinflammatory diseases managed in rheumatology and to analyze genotype–phenotype correlations in patients with Familial Mediterranean Fever (FMF).

Methods: Descriptive, longitudinal, retrospective study of patients with monogenic autoinflammatory diseases and uSAID in the Rheumatology Department of a tertiary hospital. Demographic, diagnostic and clinical data were registered throughout the disease course. Laboratory, Autoinflammatory Disease Activity Index (AIDAI) and therapeutic data at the last visit were collected. Student's T-test and Pearson correlation matrix were applied for analytical modeling.

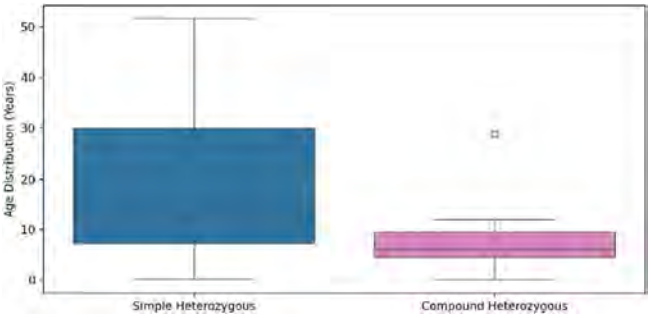

Figure 1. Distribution of symptom onset age according to FMF patient genotype.

Results: 70 patients were studied (60% female), with a median age at symptom onset of 10.3 years (±14.9) and at diagnosis of 18.4 years (±15.3). Table 1 describes their demographic, clinical and laboratory features.

A positive correlation was observed between amyloid levels and ESR, and more strongly with CRP. Higher levels of amyloid, CRP, and ESR were associated with older age at symptom onset, diagnosis, and beginning of follow-up. Female sex was linked to higher ESR levels and later diagnosis (median in males 13 vs. 31 years in females). Additionally, higher AIDAI scores were associated with requirement for anti-IL1 therapy.

Table 2. Classification criteria and treatment according to FMF patient genotype.

Variable	Compound Heterozygous (n=15) n(%)	Simple Heterozygous (n=17) n(%)	Homozygous (n=3) n(%)
Meets Eurofever/PRINTO classification criteria	12(80)	7(41)	2(67)

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Among FMF patients, 15 (41%) were compound heterozygotes (symptom onset at 5.6 years [SD 6.8]), 17 (47%) simple heterozygotes (symptom onset 12.8 years [SD 16]), and 3 (8%) homozygotes (symptom onset 13 years [SD 14.5]). Table 2 shows FMF patient characteristics according to genotype. Symptom onset was statistically significantly earlier in compound than in simple heterozygotes (p = 0.0137; see Figure 1).

18 MEFV gene mutations were identified in FMF patients. The most frequent were c.2082G >A (p.Met694Ile) (25%), c.442G >C (p.Glu148Gln) (19%), and c.2080A >G (p.Met694Val) (16%).

Among patients with uSAID, 22% were in remission without treatment, 11% received colchicine, and 61% required biologic therapy.

Conclusion: -Amyloid levels were correlated with the need for anti-IL1 therapy; female sex was associated with later diagnosis and higher ESR levels.

-FMF was the most frequent disease, being c.2082G >A (p.Met694Ile) the most common MEFV mutation observed.

-FMF patients with compound heterozygosity showed more typical clinical features with a higher proportion of patients meeting classification criteria, and symptom onset was statistically significantly earlier than in simple heterozygotes.

-Most patients uSAID did not respond to colchicine and required biologic therapy, mainly anakinra.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Eosinophilic gastrointestinal disorders (EGIDs) are a group of disorders characterized by marked eosinophilic infiltration of the gastrointestinal (GI) tract resulting in organ dysfunction and onset of GI symptoms. They may present isolated or as part of systemic diseases including eosinophilic granulomatosis with polyangiitis (EGPA) and hypereosinophilic syndrome (HES).

Table 1. Patients' characteristics and clinical, laboratory, and treatment data before MEPO

PATIENTS' CHARACTERISTICS			
	EGPA (n=23)	HES (n=25)	TOTAL (n=48)
Male sex, n (%)	15 (65)	12 (48)	27 (56)

Other	-	-	MMF	-	-	-	-	-
Therapeutic management of flare	Switch to MEPO 300, add OCS 25 mg/d	Increase OCS to 25 mg/d, add MTX and RTX	Add OCS 25 mg/d, add topic CS for GI	Add OCS 40 mg/d and MMF	Increase OCS to 10 mg/d	Add CS (iv bolus followed by OCS 50 mg/d)	Switch to MEPO 300, increase OCS to 25 mg/d	Add OCS 40 mg/d (short course)

Legend: EGPA: Eosinophilic Granulomatosis with Polyangiitis; HES: Hypereosinophilic syndrome; GI: gastrointestinal; AEC: Absolute Eosinophil Count; OCS: Oral Corticosteroids; MMF: Mycophenolate Mofetil; RTX: Rituximab; iv: intravenous

Mepolizumab (MEPO), an anti-interleukin 5 monoclonal antibody, is approved for both of these conditions; however, data are limited regarding its role in managing GI involvement.

The aim of this study is to retrospectively evaluate the efficacy of MEPO on EGPA and HES-related GI involvement.

Methods: This was a retrospective cohort study conducted among centres referring to the European EGPA Study Group. Inclusion criteria: age $\geq$ 18 years; diagnosis of EGPA ([1], [2]) or HES ([3]); GI manifestations confirmed by histology or imaging; start of MEPO any dosage (ie 100 mg/month sc, 300 mg/month sc, 750 mg/month iv) for uncontrolled GI manifestations.

Data were collected from disease onset until MEPO start (t0), at 1 (t1), 3 (t3), 6 (t6), 12 (t12), and 24 (t24) months, as well as during flares (defined as exacerbations of GI symptoms requiring therapeutic escalation).

Outcomes included symptom improvement, absolute eosinophil count (AEC) reduction, flare occurrence, and corticosteroid (CS)-sparing.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Data are presented as n (%) or median (IQR). Wilcoxon or McNemar tests were used as appropriate. Flare rates (flares/patient-month) pre- and post-MEPO were compared using incidence rate ratio (IRR) with 95% CI ($p< .05$).

Results: Forty-eight patients were included [23 EGPA, 25 HES; median age at onset: 38 (30-51) years; median age at diagnosis: 43 (33-55) years; median diagnostic delay: 12 (3-44) months]. At baseline, all the patients had active GI involvement, with a median peak AEC of 3857 (1593-9743) cells/μL. Overall, 46 patients (96%) had a history of CS use prior to MEPO. Median time from diagnosis to MEPO start was 5 (1-49) months (Table 1).

Median AEC significantly decreased by t1 [t0: 805 (482-1805) cells/μL; t1: 115 (60–223); $p< .001$] and remained low through t24 [70 (23–108) cells/μL; $p< .001$]. By t24, a significant decrease in the proportion of patients with active GI symptoms (65% to 12%, $p< .001$) and oral CS (OCS) use (85% to 46%, $p=.001$) were seen. Median prednisone equivalent daily dose decreased from 11.3 (5-25) mg/day at t0 to 0 (0-2.5) mg/day at t24 ($p< .001$) (Table 2).

During follow up, 8 patients experienced a GI relapse [4 EGPA, 4 HES; median time to event: 9 (4-23) months]. All were on a stable MEPO dose, 3 were on OCS (2 tapering) and 1 on MMF. The AEC increased AEC in only 1 case. All flares were managed by adjusting CS therapy; additionally, MEPO dose was increased in 2 cases and immunosuppressive therapy was added in 2 others (Table 3). The flare rate decreased from 0.021 to 0.0049 flares per patient-month after MEPO initiation (IRR 0.23, 95% CI 0.11–0.49, $p=.0001$), representing a 77% reduction.

Conclusion: MEPO effectively controlled GI symptoms and reduced CS use in the majority of EGPA and HES patients.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: IgG4- related disease (IgG4-RD) is a chronic, progressive, immune-mediated fibrotic disease with limited treatment options. Rilzabrutinib is an orally available, reversible, inhibitor of Bruton's tyrosine kinase (BTKi). We conducted an open label proof-of-concept safety and efficacy study of rilzabrutinib orally twice daily in patients diagnosed with active IgG4-RD. As of Jan 2, 2025, the cumulative exposure to rilzabrutinib in interventional clinical trials is estimated to be 1186 participants and 672 patient-years (PY). Across the completed and ongoing studies in multiple indications (IgG4-RD, immune thrombocytopenia, warm autoimmune hemolytic anemia, focal segmental glomerulosclerosis/minimal change disease, pemphigus vulgaris, asthma, atopic dermatitis, and chronic spontaneous urticaria) rilzabrutinib was well tolerated, including at single and multiple doses

Methods: The safety of rilzabrutinib was evaluated in a 52-week, phase 2 proof-of-concept study (NCT04520451) including adult patients with active IgG4-RD. Two cohorts were included. Cohort A included participants in the United States and Cohort B included participants in Canada, France, Italy, and Spain. Safety parameters included spontaneously reported treatment emergent adverse events (TEAE), serious TEAE, TEAE leading to discontinuation, adverse events of special interest (AESI), and death

Results: The most frequently reported TEAEs by primary SOC (≥20% of participants) were: Gastrointestinal disorders (16 of 27 [59.6%], infections and infestations (12 of 27 [44.4%]), skin and subcutaneous tissue disorders (11 of 27 [40.7%]) and nervous system disorders (8 of 27 [29.6%]) (Table). Overall, 2 of 27 (7.4%) participants experienced serious TEAE (1 participant with campylobacter infection; and 1 death due to aspiration pneumonitis while hospitalized for acute kidney injury, reported as not related to study intervention, in a participant with history of chronic kidney failure, oesophagitis, and hiatal hernia). Overall, 5 of 27 (18.5%) reported TEAEs leading to permanent treatment discontinuation (Table). There were no reports of pregnancy, symptomatic overdose, tuberculosis, or uveitis; nor drug related AESI associated with other BTKi: major hemorrhagic events, severe or serious cytopenia, or atrial fibrillation.

Table: Summary of adverse events and the most common adverse events (>20%) reported during the study

Summary of adverse events	Cohort A (N = 13)	Cohort B (N = 14)	Overall (N = 27)
Participants with at least one TEAE	10 (76.9)	13 (92.9)	23 (85.2)
Participants with at least one Serious TEAE	1 (7.7)	1 (7.1)	2 (7.4)
Participants with TEAE leading to death	0 (0.0)	1 (7.1)	1 (3.7)
Participants with TEAE leading to permanent Study intervention discontinuation	2 (15.4)	3 (21.4)	5 (18.5)
Participants with treatment emergent AESI	4 (30.8)	3 (21.4)	7 (25.9)
TEAE reported in ≥20% of participants			
System Organ Class (SOC)			
Participants with at least one TEAE	10 (76.9)	13 (92.9)	23 (85.2)
Gastrointestinal disorders	8 (61.5)	8 (57.1)	16 (59.3)
Infections and infestations	5 (46.2)	6 (42.9)	12 (44.4)
Skin and subcutaneous tissue disorders	3 (23.1)	8 (57.1)	11 (40.7)
Nervous system disorders	4 (30.8)	4 (28.6)	8 (29.6)

Treatment emergent adverse events that started on or after the first dose of rilzabrutinib.
Adverse events are coded using the MedDRA 27.1
n (%) = number and percentage of participants with at least one TEAE by SOC and PT.
Percentages are based on the number of Participants in the Rilzabrutinib Treated Population.
TEAEs: Treatment emergent adverse events (TEAEs) AESI: Adverse event of special interest
NB: 1 participant accounts 1 serious TEAE, 1 TEAE leading to permanent study intervention discontinuation and 1 death

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Although this study included participants with a multi-organ, chronic, relapsing disease, with the exception of the unrelated fatal event, the safety profile was consistent with that reported for other clinical trials of rilzabrutinib. No participant experienced a TEAE associated with other BTKi, e.g., bleeding, cytopenia, or atrial fibrillation.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

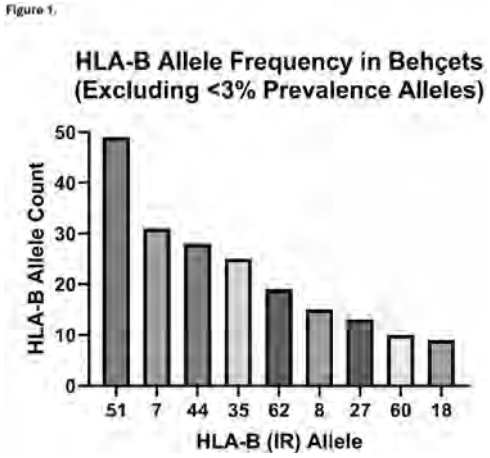
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Behçet's disease (BD) is a chronic systemic disease with heterogenous clinical presentations. The strongest genetic risk factor and diagnostic biomarker for BD is the class I major histocompatibility complex antigen HLA-B51. Although best studied in 'Silk-Road' populations, B51's prevalence in BD varies considerably across different racial/ethnic groups (Capittini, et al. *Dis Markers*, 2021). The genetic risks in American populations with BD are limited. This study

Figure 1.



Values represent HLA-B allele count from total of 285 alleles (144 Behçet's patients, 3 missing copies). Excluded the following HLA-B alleles representing <3% prevalence, but still present at least once: HLA-B: 13, 37, 38, 39, 41, 42, 45, 46, 47, 48, 49, 50, 55, 56, 57, 58, 61, 63, 65, 67, 71, 72, 75, 77.

bDMARD (SpA)	10 (20.8)	28 (29.2)
tsDMARD	2 (4.2)	2 (2.1)
Glucocorticoids	38 (79.2)	77 (80.2)
B27+	2 (4.2)	10 (10.4)
B44+	3 (6.3)	**22 (22.9)***
B7+	5 (10.4)	**25 (26.0)***
B35+	6 (12.5)	18 (18.8)
B8+	1 (2.1)	12 (12.5)

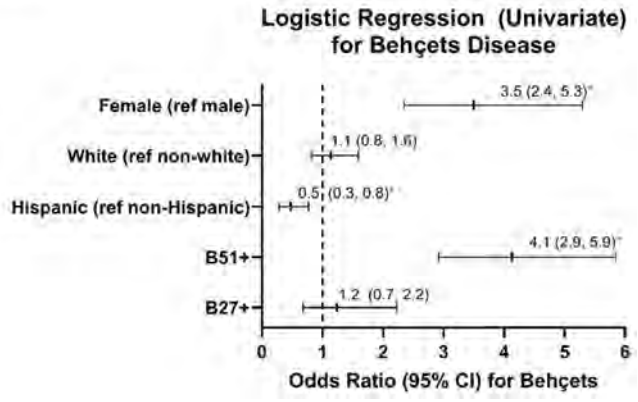
Values represent n (%) for categorical variables, and mean (SD) for continuous variables. Race, ethnicity, and gender are self-reported by the patient. *p<0.05, by Chi-Squared testing comparing B51(+) vs (-) AAPI=Asian American/Pacific Islander, DMARD=disease modifying anti-rheumatic drug, csDMARD=conventional synthetic DMARD, bDMARD=biologic DMARD (RA=bDMARDs for RA, SpA=bDMARDs for spondyloarthritis, including IL17i, IL12/23i, IL23i), tsDMARD=targeted synthetic DMARD.

describes the associations between HLA-B alleles and demographics in a diverse BD population from a large urban academic medical center in Los Angeles County.

Methods: Inclusion criteria required that patients had HLA-B allele testing (by sequence-specific oligonucleotide-polymerase chain reaction typing) conducted in routine clinical care, and were identified as having BD with ≥2 ICD-9/10 codes for BD. A sensitivity analysis with a more restrictive cohort (≥2 ICD-9/10 codes for BD, plus ≥1 rheumatology encounter, plus ≥1 DMARD prescription) was performed, and had similar demographic/genetic features. HLA-B alleles evaluated in the analysis included known relevant alleles (B51, B27), and the other 3 alleles of highest frequency.

Results: There were 144 identified BD patients, with B51 positivity in 33% (48 patients), versus a B51 prevalence of 11% among 2614 non-rheumatic controls (p< 0.0001). Amongst the BD patients, the alleles of highest frequency were B51 (49), B7 (31), B44 (28), and B35 (25) (Figure 1). Comparing B51(+) versus B51(-) BD patients, the groups were similar by age, gender, race/ethnicity and use of disease modifying agents (Table 1). However, there were higher percentages of B7(+) and B44(+) patients in the B51(-) group (Table 1). 35% of BD patients identified as white and compared to non-white BD patients had similar rates of B51(+), but a higher rate of B27(+) (16% vs 4%, p=0.01). White BD patients compared to white non-rheumatic controls had significantly higher B51(+) and B27(+). Non-white/Hispanic BD patients compared to

Figure 2.



Univariate logistic regressions for the outcome of Behçet's Disease diagnosis.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

non-white/Hispanic controls had significantly higher B51(+). The unadjusted odds ratios (OR) for BD (yes/no) demonstrated B51(+) 4.13 (95% CI 2.92, 5.85), female gender 3.5 (2.35, 5.30), and Hispanic ethnicity 0.48 (0.29, 0.77) (Figure 2). B51, gender, and Hispanic ethnicity remained significant in a multivariate model, and interaction terms were non-significant.

Conclusion: In a large diverse U.S. urban academic medical center, BD was significantly associated with B51(+) and was present in ~1/3 of BD patients. B51(+) did not differ significantly between race or ethnicity. White BD patients had significantly higher rates of B27(+) than non-rheumatic white controls, and non-white BD patients. This data shows that U.S. BD patients may have lower B51(+), and higher female prevalence than in Silk-Road BD populations, which may reflect different genetic/environmental risks for BD. Limitations include selection bias (patients had to have clinically indicated HLA-B allele testing), and misclassification bias utilizing ICD codes (though sensitivity analysis demonstrated similar baseline/genetic features).

Abstract Number: 0241

Efficacy and Safety of JAK Inhibitors in Behçet's Syndrome: A Systematic Literature Review

Bercemhan Sulu[1], Sinem Nihal Esatoglu[1], Ibrahim Hatemi[2], Aykut Ferhat Celik[3] and Gulen Hatemi[1], [1]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey, [2]Istanbul University-Cerrahpasa / Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Gastroenterology, Istanbul, Turkey, [3]Istanbul University-Cerrahpasa / Cerrahpasa Medical Faculty / Department of Internal Medicine / Division of Gastroenterology, Istanbul, Turkey

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Tumor necrosis factor inhibitors (TNFi) are a key treatment modality for major organ involvement, one of the main contributors to morbidity and mortality, as well as for resistant mucocutaneous and articular manifestations that significantly impair quality of life in Behçet's Syndrome (BS). In cases of inadequate response, and with emerging evidence on the involvement of multifactorial immune mediators and activation of the Janus kinase (JAK) signaling pathway in BS, JAK inhibitors (JAKi) have been introduced through pilot studies and case reports. We aimed to investigate the efficacy and safety profile of JAKi through a systematic literature review.

Methods: The systematic literature review was registered in PROSPERO under the identification number CRD420251000172. All articles published in PubMed, EMBASE, and the Cochrane Library up to March 6, 2025, that reported the use of JAKi in patients with BS and provided treatment outcomes were included. The search was conducted using the keywords: "Behçet AND (JAK OR tofacitinib OR baricitinib OR upadacitinib OR filgotinib OR Janus)." Two independent investigators (BS and SNE) screened 306 articles, and a total of 18 articles, reporting on 91 patients, along with one case report from our center, were included. Four patients (4.3%) had a prior history of JAKi use.

Results: Among the included patients, 16 (17.4%) received upadacitinib, 49 (53.3%) received tofacitinib, and 31 (33.7%) received baricitinib. The primary indication for initiating JAKi therapy was uveitis in 18 patients (19.6%), vascular involvement in 22 (23.9%), and gastrointestinal involvement in 46 (50%). The remaining 5 patients received JAK inhibitors due to refractory mucocutaneous and/or articular involvement. Nearly all patients had previously failed conventional treatments and

ICBD	28/83 (33.7)	20/48 (41.7)	8 (25.8)	0
Unmet criteria	6/83 (7.2)	4/48 (8.3)	1 (3.2)	2/8 (25)
Indication for JAKi initiation				
Eye	19 (20.6)	15 (30.6)	0	4 (25)
Vascular	22 (23.9)	5 (10.2)	17 (54.8)	0
Gastrointestinal	46 (50)	27 (55.1)	14 (45.2)	9 (56.3)
Mucocutaneous and/or articular	5 (5.4)	2 (4.1)	0	3 (18.8)
Treatment n/N (%)				
Prior use of TNFi	52/91(57.1)	25/49 (51.0)	17 (54.8)	15/15 (93.3)
Concomitant IS therapy	50/82 (61.0)	22/47 (46.8)	28 (90.3)	3/8 (37.5)
The Remission Rates n/N (%)				
Gastrointestinal				
Clinical	38/46 (82.6)	19/27 (70.4)	11/14 (78.6)	9/9 (100)
Endoscopic	19/38 (50)	12/22 (54.5)	6/9 (66.7)	1/7 (14.3)
Ocular	15/18 (83.3)	12/15 (80)	N/A	3/3 (100)
Vascular	20/22 (90.9)	5/5 (100)	15/17 (88)	N/A

57.1% at least one anti-TNF monoclonal antibody. The remission rates were 82.6% and 50% for gastrointestinal involvement in terms of clinical and endoscopic remission, respectively; 83.3% for ocular involvement; and 90.9% for vascular involvement. The relapse rates were 2.2% for gastrointestinal and 16.7% for ocular involvement (Table 1). Serious adverse events were reported in 6 patients (6.5%), including two cases of anemia, one of pneumonia, and three cases of herpes zoster. No thrombotic events were reported in any patient.

Conclusion: JAK inhibitors are promising targeted synthetic DMARDs for patients with BS who show inadequate response to TNF inhibitors, particularly in cases with major organ involvement. However, randomized controlled trials are needed to establish their true efficacy and safety profile.

Figure: Pericardial characterization prior to rilonacept initiation in RESONANCE

	Patients who had CMR prior to rilonacept initiation (N=46)	Patients who did not have CMR prior to rilonacept initiation (N=57)
Type of institution		
Academic medical center, patients, % (n/N)	46% (45/97)	54% (52/97)
Non-Academic medical center, patients, % (n/N)	17% (1/6)	83% (5/6)
Disease characteristics		
Number of recurrences prior to rilonacept initiation, median [Q1, Q3]	2 [1,3]	1 [1,2]
Steroid use prior to rilonacept initiation, patients, %	52%	32%
Disease duration at rilonacept initiation, years, median [Q1, Q3]	1.0 [0.5, 2.9]	0.9 [0.4, 2.9]

Background/Purpose: Recurrent pericarditis (RP) is a chronic autoinflammatory disease (mediated by IL-1) that requires long-term treatment, and selection of therapy is guided by multiple factors. Cardiac magnetic resonance (CMR) imaging characterizes pericardial inflammation and may inform RP management. Rilonacept, an IL-1α and IL-1β cytokine trap, is the only FDA-approved treatment for RP. We analyzed all CMR use prior to rilonacept initiation in RESONANCE, a US observational RP registry.

Methods: CMR use data were analyzed from 103 active pts at 22 sites (19 academic medical centers [AMCs], n=97; 3 non-AMC sites, n=6) who initiated rilonacept during RESONANCE up to Sep 9, 2024 (223.9 pt-yrs in median [Q1:Q3] 2.2 [1.4, 3.0] yrs).

Results: In 103 pts initiating rilonacept (mean [SD] age 49.7 [17.0] yrs, 56% female; median observation 0.8 [0.4, 1.0] yrs), median disease duration was 1.0 [0.4, 2.9] yr, with 1.5 [1, 2] prior recurrences. 45% (46/103) of pts had CMR before rilonacept initiation, 98% (45/46) of whom were managed at AMCs; 59% (27/46) showed pericardial inflammation. 54% (52/97) of rilonacept initiators at AMCs and 83% (5/6) at non-AMCs did not have CMR (**Figure**). Those having CMR had similar disease duration (1.0 [0.5,2.9] yr) but more prior recurrences (2 [1, 3]) and more prior steroid use (52%) than those not having CMR (0.9 [0.4, 2.9] yrs; 1 [1, 2]; 32%).

Conclusion: Recurrent pericarditis is a chronic disease that requires long-term treatment, and selection of therapy is guided by multiple factors. While CMR has utility amongst expert cardiologists in diagnosis, pericardial characterization, and monitoring, it was obtained in more clinically complex RP pts; real-world data indicate that pericardial imaging with CMR prior to rilonacept initiation was performed primarily at AMCs but in less than half of AMC patients (pericardial inflammation was present in approximately half); clinical criteria informed rilonacept initiation in the remainder.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic autoinflammatory diseases (SAIDs) are rare disorders characterized by recurrent episodes of fever, serositis, gastrointestinal symptoms, arthritis, and/or skin lesions. In adult-onset SAIDs, clinical manifestations are often less pronounced and differ from typical pediatric features. The incidence and prevalence of adult-onset SAIDs remain unknown due to variations in classification criteria and heterogeneous population samples.

Our objectives were: (a) to estimate the incidence of adult-onset SAIDs in a well-defined population, (b) to describe their demographic and clinical features, and (c) to document associated genetic variants.

Methods: We included all patients diagnosed with SAIDs with onset in adulthood (≥16 years of age) from January 1st, 2000 to December 31st, 2024 in Cantabria, Northern Spain. Patients were classified according to Yamaguchi and/or Fautrel criteria for adult-onset Still disease (AOSD) and Eurofever/PRINTO classification criteria for the remaining SAIDs. Annual incidence rates were calculated as cases per 100,000 inhabitants.

Table. Demographic, clinical, and laboratory characteristics of 45 patients with adult-onset SAIDs

	Adult-onset SAIDs (n=45)
Demographic features	
Age at diagnosis (years), *mean±SD*	45.2 ± 16.4
Sex (women), *n (%)*	24 (53.3%)
Clinical manifestations	
Duration of symptoms after diagnosis (months), median [IQR]	3 [1-24]
Fever, n(%)	40 (88.9%)
Skin rash, n(%)	35 (77.8%)
Mucocutaneous ulcers, n(%)	7 (15.6%)
Arthralgia/arthritis, n(%)	40 (88.9%)
Ocular, n(%)	8 (17.8%)
Pleuropericarditis, n(%)	7 (15.6%)
Neurologic, n(%)	6 (13.3%)
Gastrointestinal, n(%)	12 (26.7%)
Asthenia, n(%)	37 (82.2%)
Constitutional syndrome, n(%)	16 (35.6%)
Lymphadenopathies n(%)	17 (37.8%)
Macrophage activation syndrome n(%)	0 (0%)
Laboratory parameters	
CRP (mg/dL), median [IQR]	54 [19-120]
ESR (mm/1st hour), median [IQR]	45 [13-75]

Abbreviations: CRP (creatinine reactive phosphate), ESR (erythrocyte sedimentation rate).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure. Classification of 45 patients with adult-onset SAIDs.

Results: We included 45 patients (24 women/21 men; mean age: 45.2±16.4 years). The mean annual incidence was 0.32 cases per 100,000 inhabitants, and the prevalence was 7.6 cases per 100,000. Patients were classified into the following SAIDs (Figure): AOSD (n=26), Cryopyrin-Associated Periodic Syndromes (CAPS) (n=5), Syndrome of Undifferentiated Recurrent Fever (SURF) (n=3), Familial Mediterranean Fever (FMF) (n=4), Pyogenic Arthritis, Pyoderma Gangrenosum, and Acne Syndrome (PAPA) (n=2), YAO Syndrome (n=2), VEXAS (n=2), Schnitzler Syndrome (n=1). The demographic and clinical features are summarized in Table.

The most common manifestations were recurrent fever (88.9%), arthralgia/arthritis (88.9%), asthenia (82.2%), and rash (77.8%). The median time from symptom onset to diagnosis was 3 [1-24] months. Genetic variants were identified in the following genes: NLRP12 (n=3), NOD2 (n=2), NLRP3 (n=2), MEFV (n=4), CD2BP1 (n=2), UBA1 (n=2), WDR1 (n=1), TNFAIP3 (n=1), BTD (n=1), SCL40A1 (n=1), SLC29A3 (n=1), NLRC4 (n=1).

Conclusion: Over a 20-year period, the mean annual incidence of adult-onset SAIDs was 0.46 cases per 100,000 inhabitants, with a prevalence of 11 cases per 100,000 in a well-defined population in Northern Spain. A similar gender distribution was observed, with AOSD being the most common condition.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Anifrolumab is a human monoclonal antibody targeting the type I interferon receptor, approved for the treatment of systemic lupus erythematosus (SLE), with demonstrated efficacy in managing cutaneous involvement. However, its potential role in non-systemic subacute and chronic cutaneous lupus remains undefined, as its use in this setting is off-label.

This study aimed to assess the effectiveness and safety of anifrolumab in patients with non-systemic subacute or chronic cutaneous lupus in routine clinical practice.

Methods: This multicenter study evaluated patients with non-systemic subacute or chronic cutaneous lupus treated with anifrolumab. Given that non-systemic lupus represents an off-label indication, informed consent was obtained from all participants.

Cutaneous involvement was assessed using the Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI), evaluating both disease activity (CLASI-A, score range: 0–70) and damage (CLASI-D, score range: 0–56). The primary outcome was the reduction in CLASI-A and CLASI-D scores. Comparisons were conducted between baseline and months 1, 3, and 6 using Wilcoxon's signed-rank test.

Furthermore, considering the role of natural killer (NK) cells in the pathogenesis of cutaneous lupus, we analyzed NK cell dynamics in three patients over the study period.

Results: A total of 10 patients (8 females, 2 males) with cutaneous lupus treated with anifrolumab were included in the analysis (TABLE). The diagnoses were discoid lupus (n=7) and subacute lupus (n=3). The mean disease duration prior to anifrolumab initiation was 32.9±30.2 months.

Patient	Age/sex	Type of cutaneous lupus	Prior therapies	Systemic therapies concomitant with anifrolumab	Baseline CLASI-A score	CLASI-A score at last follow-up (months)	CLASI-A score change (% change)	Baseline CLASI-D score	CLASI-D score at last follow-up (months)	CLASI-D score change (% change)	Adverse events
1	61/M	Discoid lupus	Topical glucocorticoids, hydroxychloroquine	None	9	0 (3)	9 (100)	14	14 (3)	0 (0)	None
2	44/M	Discoid lupus	Topical glucocorticoids, hydroxychloroquine	Hydroxychloroquine	33	11 (3)	22 (66.7)	25	23 (3)	2 (8)	None
3	66/F	Discoid lupus	Topical glucocorticoids, oral glucocorticoids, hydroxychloroquine, methotrexate	Oral glucocorticoids	22	10 (2)	12 (54.5)	3	2 (2)	0 (0)	None
4	56/F	Discoid lupus	Topical glucocorticoids, hydroxychloroquine, methotrexate, azathioprine, belimumab, rituximab	Hydroxychloroquine, azathioprine	20	1 (14)	19 (95)	8	2 (14)	6 (75)	None

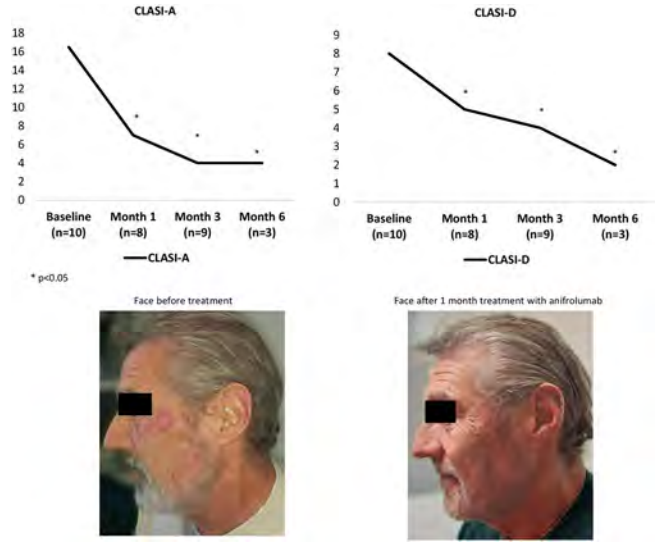

FIGURE 1. Clinical improvement of cutaneous lupus in patients treated with anifrolumab.

Before starting anifrolumab, patients had received the following treatments: topical glucocorticoids (n=10), hydroxychloroquine (n=10), methotrexate (n=7), oral glucocorticoids (n=5), chloroquine (n=3), azathioprine (n=2), belimumab (n=2), rituximab (n=2), mepacrine (n=1), thalidomide (n=1), apremilast (n=1), and mycophenolate mofetil (n=1).

Anifrolumab was administered at a dose of 300 mg intravenously every 4 weeks, either in combination with other therapies (n=9) or as monotherapy (n=1). All patients experienced a rapid and significant improvement in cutaneous disease activity (CLASI-A and CLASI-D) following anifrolumab initiation (FIGURE 1).

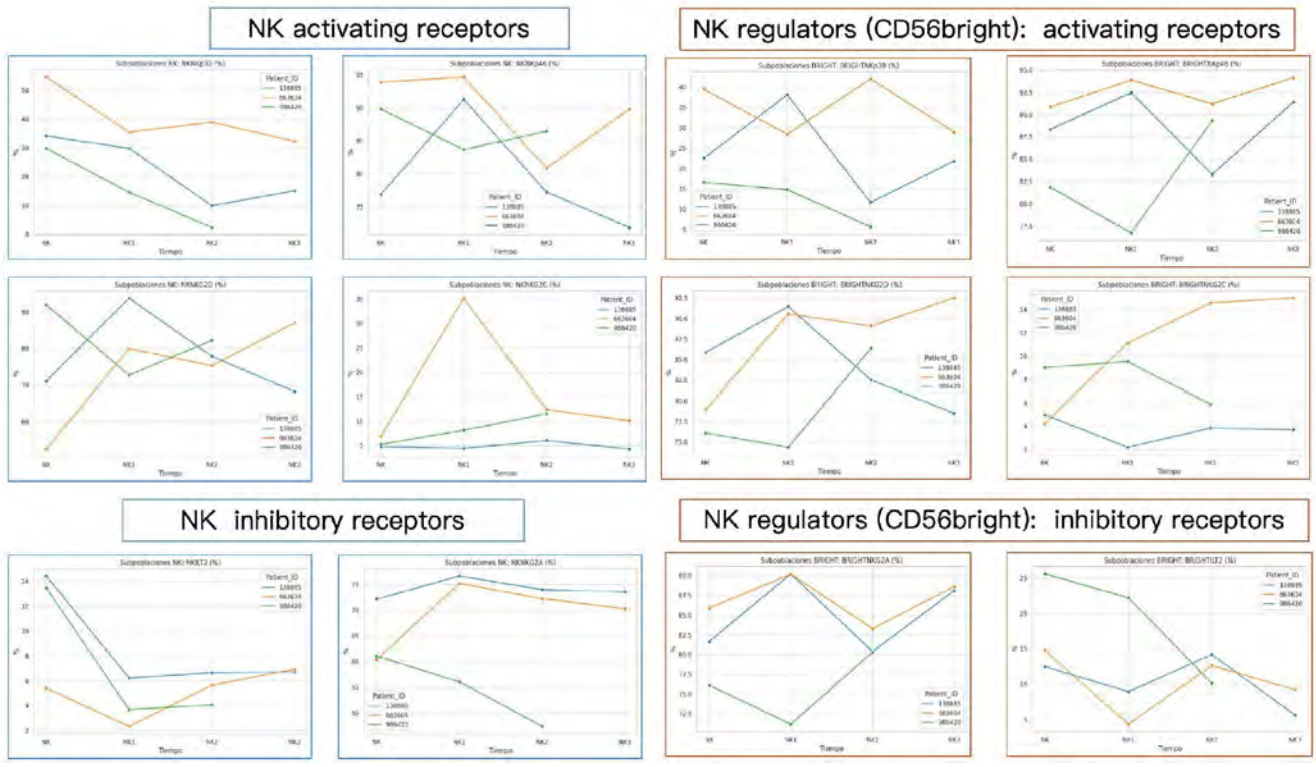

FIGURE 2.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. During a mean follow-up of 5.3±4.6 months, the median [IQR] CLASI-A score decreased from 16.5 [12.7–21.5] to 1 [1–3.2] (p=0.032), while the median [IQR] CLASI-D score decreased from 8 [4.2–9.7] to 4 [2.5–6.7] (p=0.044). No adverse effects were reported during follow-up. Additionally, an upregulation trend in inhibitory markers was observed in NK cell subtypes among the three patients in whom this analysis was performed (FIGURE 2).

Conclusion: Anifrolumab appears to be an effective and well-tolerated treatment for patients with refractory non-systemic cutaneous lupus.

Predictors of Arterial Stiffness in Connective Tissue Diseases: Insights from the Lupus Extended Autoimmune Phenotype (LEAP) Cohort Study

cristiana Sieiro[1], Sarah Dyball[2], Ellen Bruce[3], Ben Parker[4] and Ian Bruce[5], [1]Univrsity of Manchester, Manchester, United Kingdom, [2]University of Manchester, Manchester, United Kingdom, [3]Manchester University NHS FT, The Kellgren Centre of Rheumatology, Manchester, United Kingdom, Manchester, [4]NIHR Manchester CRF, Manchester Royal Infirmary, Manchester, United Kingdom, [5]Centre for Public Health, Faculty of Medicine, Health and Life Sciences, Queen's University, Belfast, Manchester, United Kingdom

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Connective tissue diseases (CTDs), including systemic lupus erythematosus (SLE), systemic sclerosis (SSc), and Sjögren's disease (SjD), are associated with an increased risk of cardiovascular disease (CVD), driven by chronic inflammation and immune dysregulation. Arterial stiffness, measured by carotid-femoral pulse wave velocity (cfPWV) and augmentation index (AIx), serves as a reliable marker of cardiovascular health and a predictor of adverse cardiovascular events. However, factors associated with arterial stiffness in CTD populations remain poorly defined.

This study aimed to assess arterial stiffness, measured by pulse wave velocity (PWV) and augmentation index (AIx), in individuals with CTDs including systemic lupus erythematosus (SLE), systemic sclerosis (SSc), primary Sjögren's disease (SjD), undifferentiated connective tissue disease (UCTD), mixed connective tissue disease (MCTD), and/or overlap and idiopathic inflammatory myositis (IIM), compared to healthy controls (HC) and to identify factors associated with arterial stiffness in this population.

Methods: Participants from the Lupus Extended Autoimmune Phenotype (LEAP) cohort were enrolled in the study, which included patients with a diagnosis of a CTD and age- and gender-matched healthy controls. Sociodemographic data, CVD risk factors, and treatment details were collected for each participant. To identify independent associations with carotid-femoral pulse wave velocity (cfPWV) and brachial and aortic augmentation index (Aix), multivariate linear regression models were used.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: We enrolled 382 CTD patients (167 with SLE, 75 with SjD, 53 with UCTD, 25 with SSc, 17 with overlap/MCTD, and 17 with myositis) and 28 healthy controls. Median age was 51 ± 21 years old. 357 (93%) patients were female. SLE patients were prescribed immunosuppressive treatment, antimalarial and oral steroids treatment significantly more often ($p < 0.0001$) than those with other diagnoses.

Patients with SSc diagnosis had a higher cfPWV compared with other CTDs ($\beta = 0.40$, $p = 0.04$). Across all CTDs, increased cfPWV was associated with age ($\beta = 0.04$, $p = 0.002$), systolic blood pressure (SBP) ($\beta = 0.01$, $p = 0.001$), diastolic blood pressure (DBP) ($\beta = 0.09$, $p = 0.002$), and aortic AIx ($\beta = 0.09$, $p < 0.0001$). Aortic Aix was associated with male gender ($\beta = 6.73$, $p < 0.0001$), age ($\beta = 0.32$, $p < 0.0001$), DBP ($\beta = 0.39$, $p = 0.01$) and mean arterial pressure (MAP) ($\beta = 0.73$, $p < 0.0001$). In addition, AIx brachial ($\beta = 0.08$, $p < 0.0001$), cfPWV ($\beta = 0.15$, $p = 0.03$), and central blood pressure ($\beta = 0.49$, $p < 0.0001$) were positively correlated with aortic AIx. Conversely, heart rate ($\beta = -0.44$, $p < 0.0001$) and diastolic reflection area ($\beta = -0.13$, $p < 0.0001$) showed significant negative associations. Brachial AIx was associated with age ($\beta = 0.46$, $p = 0.02$) as was a diagnosis of SSc SSc was ($\beta = 12.67$, $p = 0.03$). Of note, anti-Scl70 antibodies across all CTDs had a negative association with brachial AIx ($\beta = -1.64$, $p = 0.08$).

Conclusion: Arterial stiffness in patients with CTDs are particularly associated with blood pressure parameters, heart rate, and a diagnosis of SSc diagnosis.

Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Intestinal Bowel Diseases (IBD), including Crohn's (ChD), and Ulcerative Colitis (UCD), along with Celiac (CID), diseases are chronic inflammatory conditions that primarily affect the gastrointestinal tract with systemic complications such as compromised bone health. These disorders are frequently associated with malabsorption of essential nutrients critical for bone metabolism. Chronic inflammation further exacerbates bone loss by promoting osteoclast activation and impairing osteoblast function through elevated levels of pro-inflammatory cytokines leading to higher prevalence of osteopenia, osteoporosis, and fragility fractures, even at a younger age. Additionally, long-term corticosteroid therapy

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

contributes to reduced BMD and increased fracture risk Understanding the interplay between intestinal immune activity and skeletal health is essential for effective prevention and monitoring strategies. This study primary aims to assess the innovative 5-year fracture risk (FR) in these patients using the Radiofrequency Echographic Multi-spectrometry (REMS) technology and, secondarily, determine which condition has the greatest impact on fracture risk.

Methods: The 5-year FR was assessed using a REMS-based algorithm that automatically integrates both quantity and quality parameters. Specifically, by combining the REMS T-score with the Fragility Score (FS), the system identifies 7 distinct risk categories, each corresponding to a progressively increasing probability of fracture. To ascertain the impact of each pathology on the likelihood of experiencing an incident fracture, a logistic regression was performed.

Results: A cohort of 63 Caucasian patients (both genders), with ChD (n = 19, median age: 61 yo, 42.1% women < 65 yo), CID (n = 38, median age: 47.8 yo, 73.7% women < 65 yo), and UCD (n = 6, median age: 71 yo, 25% women < 65 yo) diseases underwent REMS scans at femoral neck. The FR analysis on hips showed that in ChD and UCD patients were mostly classified into high-risk classes (R5-R7), as follows: 21.1% (R5), 10.5% (R6), and 21.1% (R7), and 33.3% (R5 and R7), respectively. Conversely, in CID, patients were never classified in the high-risk level: R1 (23.7%), R3 (44.7%), and R4 (5.3%)). The logistic regression revealed a strong and statistically significant association between IBD and CID and high-risk fracture, with UCD OR = 5.5 (95% CI = 5.5, $p < 0.001$), followed by ChD (OR = 3.1% CI = 3.1-3.1, $p < 0.0001$) and by CID (OR = 1.3, 95% CI = 1.3-1.3, $p < 0.0001$) groups. Notably, the FS was higher in the IBD patients compared to CID group (42.51 and 29.2 for ChD and UCD, respectively), thus supporting the hypothesis that a steroids-based therapy in these patients can negatively affect the trabecular architecture.

Conclusion: This study highlights a significant link between these conditions and increased fracture risk, with UCD having the greatest impact, followed by ChD, while CID posed a comparatively lower risk. Furthermore, these findings emphasize the importance of early, targeted monitoring of bone health in these patients. The integration of bone quantity and quality parameters could enhance fracture risk prediction and support cost-effective strategies to prevent osteoporotic fractures in USA.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Nintedanib was approved in the US for the treatment of chronic fibrosing interstitial lung diseases (ILDs) with a progressive phenotype (progressive pulmonary fibrosis [PPF]) in 2020. We used US claims data to evaluate the characteristics and treatment patterns of patients with PPF treated with nintedanib.

Methods: We analysed claims data from 2019 to 2022 in the Optum Clinformatics Data Mart database. PPF was identified based on ≥1 of these criteria: a) ≥2 encounters with ICD-10 diagnosis code for 'interstitial lung disease with progressive fibrotic phenotype', ≥1 to 365 days apart; b) fibrotic ILD (≥2 encounters with relevant ICD-10 diagnosis codes, ≥1 to 365 days apart) and a progressive fibrosing phenotype (met ≥1 proxy criterion for progression after diagnosis of fibrotic ILD). Patients with idiopathic pulmonary fibrosis were not included. Analyses were based on data from patients who were newly prescribed nintedanib after identification of PPF in 2020 or 2021. Patients were followed from nintedanib initiation until death, the end of continuous insurance coverage (30-day gap permitted), or the end of the study.

Results: Among the 333 patients newly prescribed nintedanib after identification of PPF in 2020 or 2021, mean age was 72 years; 55.9% were male; 65.5% were White; 81.7% had Medicare. The nintedanib dose at initiation was 150 mg twice daily in 74.8% of patients. Among the patients for whom information on provider was available, the provider at initiation of nintedanib was a pulmonologist in 72.8%, internist in 17.4%, a rheumatologist in 1.8%, a family practitioner in 0.9%, and a different provider in 7.0% of patients. Over a mean follow-up of 463 days, nintedanib was discontinued in 47.2% of patients and interrupted in 40.5% of patients. The mean time to first interruption or discontinuation of nintedanib was 134 days. The mean time between the first interruption and re-starting nintedanib was 34 days. After initiating nintedanib, oxygen therapy was prescribed for 72.1% of patients, systemic corticosteroids for 45.4%, mycophenolate for 13.2%, hydroxychloroquine for 6.9%, methotrexate for 2.4%, rituximab for 2.1%, and tocilizumab for 1.8%; 1.5% underwent lung transplantation. Among patients who initiated nintedanib, 79 (23.7%) died during the follow-up period.

Conclusion: This analysis of a claims database showed that among US patients with PPF prescribed nintedanib, comedication use was high, with 72.1% of patients later prescribed oxygen. Almost half of patients initiated on nintedanib discontinued it over a mean follow-up of about 15 months.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Anti-Ku antibodies are rare myositis-associated antibodies directed against a DNA-binding heterodimer involved in DNA repair. Anti-Ku positivity may be associated with a distinct clinical phenotype in autoimmune diseases and, when present in isolation from other autoantibodies, may represent a distinct clinical syndrome. The current literature primarily includes studies on Asian and Caucasian populations, with limited data available on Hispanic individuals. We aim to describe the clinical and serological characteristics of Hispanic patients with anti-Ku positivity.

Methods: We conducted a cross-sectional study at the "Dr. José Eleuterio González" University Hospital in Monterrey, Mexico, between February 2016 and December 2023. Patients were identified by moderate or strong positivity for anti-Ku antibodies using the EUROLINE Autoimmune Inflammatory Myopathies panel. Demographic, clinical, and serological data were obtained from medical records. Patients with weak or borderline positivity, duplicated entries, or insufficient follow-up were excluded. This study was approved by our institution's ethics committee (RE24-00004).

Results: Eight patients were included, with a median age of 46 (IQR: 32.5 – 64.75). Seven (87.5%) were women. Three patients were diagnosed with anti-Ku syndrome. Other rheumatic diagnoses included overlap syndrome (systemic lupus erythematosus (SLE)/rheumatoid arthritis (RA), n=3), systemic sclerosis (SSc), and SLE (n=1 each). Clinical characteristics are detailed in Table 1.

In our cohort, all patients reported articular involvement during their clinical evolution. Skin involvement (alopecia, malar rash, and hyperpigmentation) appeared in seven patients. Sicca symptoms and Raynaud's were present in five (62.5%) and four (50%) patients, respectively. Cardiac and lung involvement each occurred in two patients.

Anti-Ro52 was the most common overlapping antibody (50%). We identified three antibody subgroups: anti-Ro-52 ± MDA5/NXP2/U1-RNP (n=4), often associated with Raynaud's and cardiac involvement, including the cohort's only death; isolated anti-Ku (n=3), with predominantly articular and sicca symptoms, and anti-cN1A (n=2), associated with SLE and cutaneous features.

Woman	65	Anti-Ku syndrome	Arthralgia	59	Alopecia	No	No	Yes	Yes	Yes	No	Yes	No	Leflunomide Prednisone	No	5
Woman	31	SLE	Paresthesia Lower extremity muscle weakness	29	Photosensitivity Malar rash Skin hyperpigmentation	Yes	Yes	Yes	No	Yes (oral ulcers)	No	No	CN-1A	Hydroxychloroquine Leflunomide Prednisone Azathioprine Methotrexate	No	7

Compared to international cohorts, our patients shared similar articular symptom prevalence (France: 83%, Italy: 86%, Germany: 80%) and Raynaud's rates (Portugal: 40.7%, France: 43%, Italy: 66.7%, ours: 50%). However, ILD was less frequent (25%) than in other international cohorts (up to 58%). All patients received corticosteroids. Immunosuppressants included methotrexate (n=3), azathioprine, mycophenolate mofetil, hydroxychloroquine, and leflunomide (n=2 each).

Conclusion: Clinical manifestations largely mirrored data from other international cohorts, particularly in articular and Raynaud's symptoms. Antibody clustering may reveal phenotypes with distinct prognoses. Our findings highlight the need to consider autoantibody profiles in risk stratification and individualized treatment. Larger studies are needed to better define clinical implications in this population.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: The 2023 EULAR criteria for systemic sclerosis reaffirm the diagnostic value of nailfold videocapillaroscopy (NVC), particularly the presence of giant capillaries and capillary loss to detect scleroderma pattern. However, their presence in non-rheumatic patients with cardiovascular risk factors (CVRFs), such as overweight/ obesity (OBE), remains underexplored.

The main objective of the study was to evaluate the existence of differences in capillaroscopic findings, in patients with OBE compared to patients with normal weight.

Methods: Longitudinal unicentric observational study carried out in 2020 and 2025, in which the frequency of pathological findings in capillaroscopy is estimated in subjects without rheumatic disease or Raynaud's phenomenon and compared by presence of OBE (body mass index >26) and normal weight. Exclusion criteria included having Raynaud's phenomenon or any rheumatological disease, as well as having a CVRF other than OBE.The variables collected were: sociodemographic, weight, height and body mass index, cardiovascular complications, autoimmunity, lipid profile, treatments, tortuosities and NVC alterations (ramified capillaries, enlarged capillaries, giant capillaries, haemorrhages and density loss). The NVC was performed again after 5 years, in 2025, to verify evolution.

For the statistics, measures of central tendency and dispersion were used for quantitative variables, and frequencies and percentages for qualitative variables. The outcome variable was OBE yes/no, and the X^2 test and Fisher's test were used to compare variables.

Results: 78 subjects were included (78,2% men, mean age 48±13 years), 39 with only obesity as a CVRF and 39 healthy controls without CVRF. The predominant vascular or thrombotic complication was abortion in 15.4% of the subjects, followed by stroke in 2,6% of participants. The presence of tortuosities was observed in 82.1% of the participants, subsequently 44.9% ramified capillaries, 35.9% enlarged capillaries, 33.3% haemorrhages, 28.2% density loss and 26.6% giant capillaries.

A statistically significant association was found between OBE and the presence of all the NVC findings, especially giant capillaries and density loss ($p < 0,001$).

These OBE patients were classified as having a scleroderma pattern and remained asymptomatic throughout. Five years later, the analytical and capillaroscopic studies were repeated, revealing the same NVC changes, with no development of rheumatologic pathology in any of them.

Conclusion: Scleroderma-pattern capillaroscopic findings may occur in non-rheumatic patients with OBE. These results underscore the importance of clinical context in interpreting NVC findings and suggest a potential overlap between metabolic and autoimmune microvascular damage.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Autoinflammatory diseases(AIDs) are characterized by recurrent inflammatory episodes resulting from alterations in regulatory genes, activating the innate immune system. Although these diseases primarily occur in children, an increasing number of cases are reported in adults.

This study aimed to identify demographic, clinical, analytical, and therapeutic response factors contributing to diagnosing AIDs in adults in a clinical setting. Additionally, we sought to establish a correlation between these variables and the outcomes of genetic analysis.

Methods: A multicenter observational study was conducted involving adult patients (≥16 years) diagnosed with AID and followed up in rheumatology departments in Spain. Demographic, clinical, genetic, analytical, and therapeutic response data were collected. Genetic analysis was performed using Sanger or exome sequencing. Descriptive and relational comparative analyses were conducted using IBM SPSS statistical software.

Results: The study included 117 patients (57 females) with a mean age at diagnosis of 45.3±18.1 years and a mean time to diagnosis of 62 months; 15.4% had a family history of AID.

The most frequently diagnosed conditions (table)were adult-onset Still disease(AOSD) (43.6%), undifferentiated AID(UAID) (12.8%), and familial mediterranean fever(FMF)(12.8%).

The most common clinical manifestations included musculoskeletal symptoms(88%), fever(83.8%), asthenia(76.1%), cutaneous manifestations(75.2%), constitutional syndrome(40.2%), abdominal pain(30.8%), lymphadenopathy(29.9%), atypical chest pain(29.1%), oral aphthosis(25.6%) and ocular abnormalities(17%).

The mean C-reactive protein (CRP) level was 88.1 mg/L.

Genetic sequencing was performed for 93 patients(79.3%), with 64.4% of them showing heterozygous findings, including variants of uncertain significance (VUS)(n=35) and pathogenic variants(n=22).

Abbreviations: Autoinflammatory disease (AID), adult-onset Still disease(AOSD), undifferentiated autoinflammatory disease (UAID), familial mediterranean fever(FMF), cryopyrin-associated periodic syndrome(CAPS), syndrome of undifferentiated recurrent fever (SURF), tumor necrosis factor receptor periodic syndrome(TRAPS), STING-associated vasculopathy with onset in infancy (SAVI).

Treatment approaches included corticosteroids (GC)(82.1%) with a complete response(CR) of 43.7%, NSAIDs(54.7%) with a CR of 6.2%, methotrexate (MTX)(51.3%) with a CR rate of 31.6%, colchicine(49.6%) with a CR of 15.4%, anakinra(33.3%) with a CR of 38.5%, anti-IL-6(20.4%) with a CR of 58.3%, anti-TNF(19.6%) with a CR of 26.1%, canakinumab(10.2%) with a CR of 58.3%, and JAK inhibitors(6.7%) with a CR of 37.5%.

A significant relationship ($p < 0.05$) was found between carriers of VUS or pathogenic genetic variants and the presence of affected relatives, oral aphtosis, testicle pain, neurological and digestive manifestations. CR to GC and MTX was significantly higher in non-carriers.

Conclusion: This study identified AOSD, UAID and FMF as the most common in adults. Nevertheless, the genetic analysis was not performed in all patients, therefore monogenic AIDs may be underdiagnosed. Musculoskeletal symptoms, fever, asthenia and cutaneous manifestations were prevalent and anti-IL6 and canakinumab treatments showed the highest CR rates.

Genetic variants were linked to family history, oral aphtosis, testicle pain, neurological and digestive manifestations while non-carriers had higher CR to GC and MTX. Although the sample size was limited, these findings may assist in detecting monogenic AIDs in adults

Abstract Number: 0251

Impact of Mepolizumab on Idiopathic Hypereosinophilic Syndromes: Preliminary Analysis of a Monocentric Retrospective Cohort

Jacopo Mora[1], Francesca Regola[1], Paola Toniati[2], Giulia Fontana[1], Alessia Gatti[1], Ilaria Cavazzana[3] and Franco Franceschini[4], [1]Rheumatology and Clinical Immunology Unit – ERN ReCONNET, ASST Spedali Civili and University of Brescia, Brescia, Lombardia, Italy, [2]Rheumatology and Clinical Immunology Unit – ERN ReCONNET, ASST Spedali Civili of Brescia, Brescia, Lombardia, Italy, [3]Rheumatology and Clinical Immunology Unit, Clinical and Experimental Sciences Department, ERN ReCONNET, ASST Spedali Civili of Brescia and University of Brescia, Brescia, Italy, Brescia, Lombardia, Italy, [4]University of Brescia, Brescia, Brescia, Italy

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Idiopathic hypereosinophilic syndromes (iHES) are a group of disorders characterized by persistent eosinophilia and eosinophil-mediated organ damage. Mepolizumab, an anti-interleukin-5 monoclonal antibody, has proven effective in reducing eosinophilic burden, controlling clinical manifestations in various forms of iHES, and decreasing the reliance on glucocorticoids (GCs). This study aims to evaluate the clinical and steroid-sparing efficacy of mepolizumab in a monocentric retrospective cohort of patients with iHES.

Methods: We analyzed a cohort of patients diagnosed at our Center according to the 2023 refined diagnostic criteria and classification for HES (1). Only patients diagnosed with iHES and treated with mepolizumab were included. Descriptive statistics included medians (1st-3rd IQR). Differences were assessed using the Wilcoxon test (significance: $p \leq 0.05$). Variables were analyzed immediately prior to mepolizumab initiation (t0) and at 1 (t1), 3 (t3), 6 (t6), 12 (t12), 18 (t18), and 24 (t24) months post-treatment.

Table 1. Clinical manifestations from iHES onset to diagnosis. Abbreviations: ENT = Ear, Nose, and Throat; SVT = superficial venous thrombosis; PTE = pulmonary thromboembolism; BAL = bronchoalveolar lavage; DVT = deep venous thrombosis.

Symptoms	Patient 1	Patient 2	Patient 3	Patient 4	Patient 5	Patient 6	Patient 7
General	Fever		Fever		Fever		Loss of weight > 5%

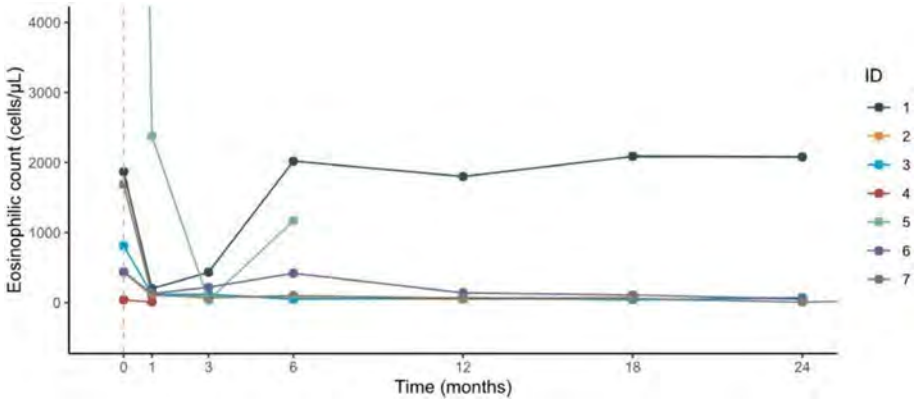
Table 2. Eosinophil count and glucocorticoid daily dosage at t0 (immediately prior to mepolizumab initiation) and at different time points (each representing the number of months) after mepolizumab initiation.

Time points	t0	t1	t3	t6	t12	t18	t24
	Eosinophil count (cells/μl)						
Patient 1	1871	200	435	2020	1800	2090	2080
Patient 2	436	100	100	70	48	80	
Patient 3	810	120	120	50	70	40	70
Patient 4	40	10					
Patient 5	25010	2380	32	1170			
Patient 6	440	130	220	420	140	110	50
Patient 7	1690	112	69	101	60	60	10
Median (1st-3rd IQR)	810 (438-1250)	120 (106-125)	110 (77-117)	260 (76-380)	70 (60-70)	80 (60-80)	60 (40-62)
	Glucocorticoid daily dosage (mg/day)						
Patient 1	0	0	0	0	0	25	5
Patient 2	5	5	5	0	0	0	
Patient 3	55	5	2.5	0	0	0	0
Patient 4	38.5	5					
Patient 5	50	50	25	0			
Patient 6	37.5	37.5	0	10	2.5	2.5	2.5
Patient 7	12.5	10	7.5	7.5	2.5	0	0
Median (1st-3rd IQR)	27 (2-51)	5 (5-9)	2.5 (0-10)	0 (0-0)	0 (0-0)	0 (0-6)	0 (0-2.5)

Results: Seven patients were enrolled [3 males, 4 females; median age at HES onset: 49 (35-59) years; median age at diagnosis: 49 (37-59) years; median diagnostic delay: 4 (1-26) months]. Clinical features at onset are reported in Table 1. At HES onset, median eosinophil count (EC) was 6910 (5685-16525) cells/μl and all patients showed hypereosinophilia. The median time from diagnosis to mepolizumab initiation was 5 (1-18) months, with a median follow-up of 24 (12-24) months. Six patients had received GCs prior to mepolizumab and were still on steroid therapy at the time of initiation. Furthermore, patient 2 had been treated with cyclosporine A for lichenified trunk eczema. At t0, 1 patient showed eosinophilia and 3 hypereosinophilia. A marked decrease in EC was observed as early as t1 [median t0: 810 (438-1250) cells/μl; median t1: 120 (106-125) cells/μl; p: 0.0156], which was maintained at the last available follow-up [median at last follow-up: 70 (30-625) cells/μl; p: 0.0469]. At t6, 2 patients showed a significant rebound in ECs. In patient 1, hypereosinophilia persisted from t6 onward, and both GCs and dupilumab were introduced at t18. Patient 6 was hospitalized at t6 and later died from septic shock (notably, with a history of substance abuse) (Table 2; Graphic 1). Overall, the median percentage reduction in EC was 89 (78-92) % (p: 0.0469). During follow-up, GCs were discontinued in 5 patients and later reintroduced in 3 cases due to HES relapses. The comparison of GC daily dose at t0 and at the last available follow-up showed a significant reduction [median at t0: 27 (2-51) mg/day; median at last follow-up: 0 (0-4) mg/day; p: 0.0469] (Table 2). The number of HES



Graphic 1. Eosinophil count trend over time, from t0 (immediately prior to mepolizumab initiation) to t24. For Patient 5, an outlier value of 25010 cells/μl was excluded to improve graphical readability; however, the overall trend line was maintained to reflect the general trajectory.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. relapses before (n: 9) and after (n: 4) initiation of mepolizumab showed a trend toward statistical significance, although not reaching it (p: 0.0780).

Conclusion: Preliminary findings from our cohort suggest that mepolizumab may be effective in achieving clinical control and reducing GC dependence in patients with iHES.

Capillaroscopic Signatures in Autoimmune Rheumatic Diseases: Unveiling Patterns in Systemic Sclerosis, Polyautoimmunity, and PAH

María Paula Carrillo[1], Juan Esteban Bedoya-Loaiza[1], Claudia Ibáñez-Antequera[1], Laura Gallego[1], Alejandro Escobar[1], Adriana Rojas-Villarraga[2] and **Jairo Cajamarca-Baron**[3], [1]Fundacion universitaria de ciencias de la salud, Bogota, Distrito Capital de Bogota, Colombia, [2]Fundacion Universitaria de Ciencias de la salud, Bogota, Distrito Capital de Bogota, Colombia, [3]Fundacion universitaria de ciencia de la Salud, Bogota, Distrito Capital de Bogota, Colombia

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Nailfold capillaroscopy is a fundamental tool in rheumatology for assessing capillary morphology, allowing the differentiation between primary and secondary Raynaud's phenomenon, identifying risks associated with systemic sclerosis, and exploring vascular alterations in various autoimmune diseases. This study aimed to describe capillaroscopic patterns in a cohort of patients with autoimmune disorders.

Methods: A cross-sectional, observational, and descriptive study was conducted in 136 patients with autoimmune rheumatic diseases. Sociodemographic, clinical, and capillaroscopic data were collected using the RedCap platform; images were obtained with the Smart G-Scope device and processed using Capillary.io software. Statistical analysis was performed using STATA 18.

TABLE . Summary of the frequencies of the most relevant capillaroscopic findings in autoimmune diseases

Disease	Reduced density	Avascular areas	Giant capillaries	Microhemorrhages	Tortuosities	Flame-shaped or helmet hemorrhage	Perivascular edema
Systemic sclerosis	+++	+	+++	+++	++	++	+
Inflammatory myopathy	+++	+	+++	+++	+++	+++	+
Sjögren's syndrome	++	-/+	+++	+++	+	+	+
Systemic lupus erythematosus	++	-	++	+++	+	+	+
Rheumatoid arthritis	+	-	+	++	++	-/+	+
Vasculitis	-	-	+	++	+	-	-

Frequency -: 0%; -/+: 0–10%; +: 10–30%; ++: 30–50%; +++: >50%

Summary of the frequencies of the most relevant capillaroscopic findings in autoimmune diseases

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: The cohort included 136 patients, mostly women (86.76%), with a median age of 59 years. Systemic sclerosis was the most prevalent disease (50.74%), followed by Sjögren's syndrome and systemic lupus erythematosus; 24.2% presented with polyautoimmunity. Pulmonary arterial hypertension (PAH), confirmed or suspected, was found in 25 patients (18.3%). Capillary dilations (91.91%), giant capillaries (51.47%), and decreased capillary density (41.98%) were documented, particularly in systemic sclerosis. Microhemorrhages were observed in 58.82% of patients, most frequently in those with systemic sclerosis (49 out of 69 patients, 71.01%), followed by inflammatory myopathy (3 out of 5 patients, 60%) and Sjögren's syndrome (16 out of 29 patients, 55.17%). Tortuosity was the most frequent morphological abnormality (26.47%) (See Table). In inflammatory myopathy, all patients exhibited at least one type of abnormal capillary morphology, with arborized capillaries being the most common. Systemic sclerosis, in turn, showed the greatest diversity and number of abnormal capillary forms. The most frequently observed pattern was nonspecific, followed by the active pattern in systemic sclerosis and inflammatory myopathies. The nonspecific pattern (n=50, 36.76%) was the most common overall, prevalent in all diseases except systemic sclerosis and inflammatory myopathy, where the active pattern predominated (n=27, 39.13% and n=3, 60%, respectively), reflecting greater microvascular aggressiveness in these conditions. Patients with positive ANAs had reduced capillary density (Fisher's exact = 0.018), as did those with polyautoimmunity (p = 0.043), who also showed a higher number of microhemorrhages per millimeter (p = 0.020). Patients with PAH exhibited a higher number of capillary dilations per millimeter (p = 0.022) and reduced capillary density (≤6 capillaries/mm; p = 0.0444).

Conclusion: These findings support the use of videocapillaroscopy as a diagnostic and prognostic tool not only in systemic sclerosis but also in broader autoimmune contexts like polyautoimmunity and PAH.

Ophthalmology Screening for Asymptomatic Uveitis in Sarcoidosis Patients: A Single-Center Investigation

Justin Nguyen[1], Philip Bucur[2], Sai Patel[2], Aamer Syed[2], Thomas Iden[3], Jessica McLaughlin[2], Neha Gupta[2], Jordana Kron[2], Kelly Gwathmey[2], Ryan Canissario[2], Vaishali Patel[2] and Huzaefah Syed[2], [1]Virginia Commonwealth University Medial Center, Richmond, VA, [2]Virginia Commonwealth University Medical Center, Richmond, VA, [3]Virginia Commonwealth University Medical Center, Richmond

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Asymptomatic ocular involvement must be considered in any patient with sarcoidosis. If left untreated, severe complications, including vision loss, can occur. As a result, sarcoidosis patients without ocular symptoms are frequently referred to ophthalmology for uveitis screening. However, the frequency of these patients being diagnosed with asymptomatic uveitis remains uncertain. Additional referrals may burden the healthcare system, leading to longer wait times. In this retrospective, descriptive analysis, our primary objective was to determine how many patients with non-ocular sarcoidosis developed asymptomatic uveitis after their new-patient sarcoidosis visit. Secondary objectives included determining the number of referrals made to ophthalmology, the number of patients following ophthalmology or optometry, and the number of patients who developed any ocular manifestations of sarcoidosis over time.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

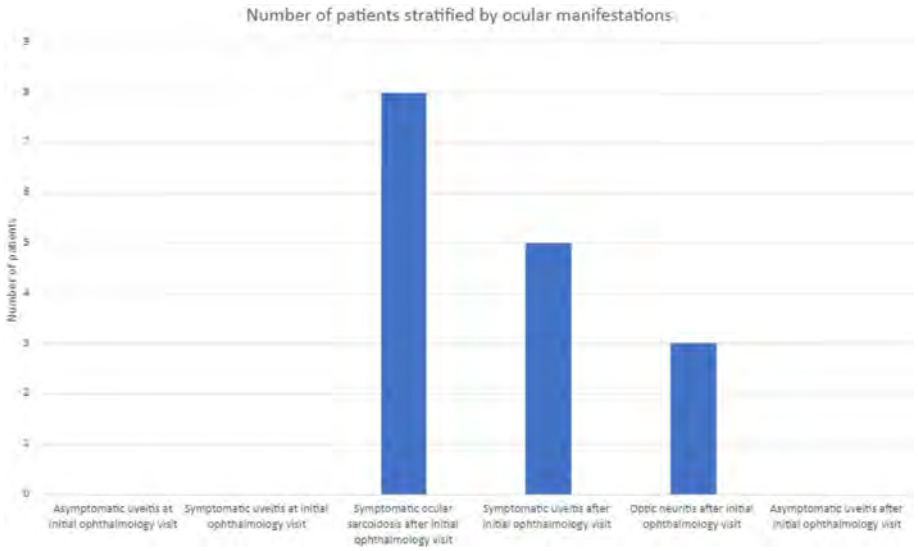

Table 1: Patient Demographics and Ophthalmologic Outcomes

Category	Variable	Patients with Sarcoidosis (N = 856)	Percentage (%) of Total
Age	Years, mean ± SD	53.3 ±12.6	
Sex	Male, n (%)	360	57.9
	Female, n (%)	496	42.1
Race	White	407	47.5%
	Black	420	49.1%
	Hispanic	2	0.2%
	Asian	2	0.2%
	Other	25	2.9%
Ophthalmology Stats	Total Internal Ophthalmology Referrals	158	18.5 %
	Total Patients Established with Ophthalmology	419	48.9 %
	Patients Established with Internal Ophthalmology	43	5.0 %
	Patients Established with External Ophthalmology	376	43.9 %

Methods: Using our institution's Data Repository of Pulmonary Sarcoidosis (DROP Sarcoidosis) database, we filtered 2,387 sarcoidosis patients for those with ocular involvement, resulting in 998 patients. This list was further filtered to exclude patients with new patient visit notes mentioning ocular disease not reflected in the database, patients with optic neuritis, and those who eventually received a diagnosis other than sarcoidosis. We then reviewed new and follow-up patient visits occurring from Oct 10, 2019, until November 8, 2024. We searched key phrases in the electronic medical record to determine if patients had a history of ocular involvement and manually reviewed our institution's internal ophthalmology records.

Results: Our study consisted of 856 patients, with an average age of 53.3 ± 12.6 years. Among our patients, 57.9% were female and 42.1% male, with demographics of 49.1% black, 47.5% white, 0.2% Hispanic, 0.2% Asian, and 2.9% other races. Over an average of 34 months, no patients had asymptomatic uveitis on referral to ophthalmology. However, 8 of the 856 (0.9%) patients developed symptomatic manifestations of ocular sarcoidosis. This included 5 patients developing symptomatic uveitis and 3 patients developing optic neuritis. Additionally, 158 (18.5%) patients were referred internally to ophthalmology. Meanwhile, 419 (48.9%) patients were already following either internal ophthalmology or eye care (ophthalmology or optometry) externally.

Conclusion: Our analysis challenges the necessity of ophthalmology referral for primary screening of uveitis in newly diagnosed sarcoidosis patients. However, some patients subsequently developed ocular manifestations, which may support an indication for new patient referrals when symptoms occur. Patients who are established with ophthalmology may benefit from timely evaluation when ocular symptoms do arise.

Comparative Outcomes in MAGIC Syndrome versus Relapsing Polychondritis Alone: A Propensity-Matched Analysis

Justin Riley Lam[1], Emmanuel Otabor[2], Laith Alomari[2], Michael Hamilton[2], Maxim Barnett[2], Shahrzad Abdollahi[3] and Irene Tan[4], [1]Albert Einstein Medical Center, Philadelphia, PA, [2]Jefferson Einstein Hospital Philadelphia, Philadelphia, PA, [3]Jefferson Einstein Hospital, Philadelphia, PA, [4]Einstein Healthcare Network Philadelphia - Jefferson Health, Bala Cynwyd, PA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: MAGIC syndrome, a rare overlap of relapsing polychondritis (RP) and Behçet's disease manifestations, remains poorly characterized compared to isolated RP. Behçet's-associated features such as recurrent mucosal ulcerations and ocular inflammation may amplify systemic inflammatory burden. Given its hybrid nature involving vascular, mucosal, and cartilaginous inflammation, MAGIC may carry heightened risk for both airway and systemic complications. We aimed to compare clinical outcomes between patients with MAGIC syndrome and those with RP alone.

Methods: Using the TriNetX Global Collaborative Network, we conducted a retrospective cohort study identifying adults (≥18 years) diagnosed with RP. Cohort 1 (n=374) included patients with RP and concomitant features of Behçet's disease, identified using ICD-10 codes for iridocyclitis or uveitis, recurrent oral ulcers, and genital ulcers (MAGIC syndrome). Cohort 2 (n=3,313) included patients with RP without these features. After 1:1 propensity score matching for demographics and comorbidities, 361 patients per cohort were analyzed. Outcomes over three years included thrombosis, vision loss, stroke, tracheal stenosis, gastrointestinal (GI) bleeding, inflammatory markers (CRP, ESR), and immunosuppressive or biologic therapy utilization. Risk analyses and Kaplan-Meier survival curves were performed.

Results: Following matching, baseline characteristics were well-balanced. Rates of thrombosis (3.3% vs 3.3%; p=0.994), vision loss (2.9% vs 2.9%; p=0.953), stroke (3.4% vs 4.3%; p=0.571), and GI bleeding (3.9% vs 3.1%; p=0.539) were similar between MAGIC and RP groups. Tracheal stenosis occurred more frequently in MAGIC (3.9% vs 3.0%) and was associated with a significantly increased hazard ratio (HR 4.18, 95% CI 1.19–14.66; p=0.015). Median CRP levels trended higher in MAGIC (31.3 vs 19.1 mg/L; p=0.055), while ESR was similar (24.6 vs 22.5 mm/hr; p=0.501). Use of non-biologic immunosuppressants (e.g., mycophenolate mofetil, azathioprine) was more common in RP, whereas biologic therapy (e.g., infliximab, tocilizumab) use was higher in MAGIC, though neither difference reached statistical significance.

Conclusion: Patients with MAGIC syndrome demonstrated similar risks of thrombosis, stroke, vision loss, and GI bleeding compared to matched RP patients. However, the significantly increased incidence of tracheal stenosis in MAGIC highlights a possible pathophysiologic overlap involving vasculitis, mucosal inflammation, and cartilaginous involvement—potentially accounting for increased airway compromise. These findings support vigilant airway surveillance and raise the possibility that MAGIC represents a more aggressive RP phenotype with unique clinical considerations.

Abstract Number: 0255

Clearing the Smoke: Association Between Cannabis Use and Autoimmune Disease Incidence in a Retrospective Cohort Analysis

Justin Riley Lam[1], Emmanuel Otabor[2], Laith Alomari[2], Esteban Kosak Lopez[2], Maxim Barnett[2] and Shahrzad Abdollahi[3], [1]Albert Einstein Medical Center, Philadelphia, PA, [2]Jefferson Einstein Hospital Philadelphia, Philadelphia, PA, [3]Jefferson Einstein Hospital, Philadelphia, PA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Cannabis use has increased substantially in the past decades, with legalization expanding across the U.S. Despite its known therapeutic potential, the immunomodulatory effects of cannabis remain unclear. Prior studies suggest cannabis may influence immune responses, potentially affecting autoimmune disease risk. However, epidemiological evidence on its long-term impact on autoimmune disease incidence is limited. We evaluate the association between cannabis, use and the incidence of autoimmune diseases, inflammatory markers, and major adverse health outcomes, including all-cause mortality and cardiovascular events, using a large-scale retrospective cohort analysis.

Methods: A retrospective cohort study was conducted using TriNetX Global Collaborative Network data. Two cohorts were defined: cannabis users (ICD-10: F12) and non-users, matched 1:1 via propensity scoring based on demographics, comorbidities, and social determinants. The primary outcomes included the incidence of autoimmune diseases (e.g., rheumatoid arthritis), inflammatory markers (CRP, ESR), major adverse cardiovascular events (MACE), and all-cause mortality. Statistical analyses included risk ratios, Kaplan-Meier survival analysis, and t-tests for laboratory outcomes.

Results: Among 229,366 matched patients, cannabis use was associated with a lower incidence of certain autoimmune conditions, including Hashimoto's thyroiditis (RR: 0.512, $p < 0.001$), rheumatoid arthritis (RR: 0.817, $p = 0.020$), type 1 diabetes (RR: 0.810, $p = 0.002$), and vitiligo (RR: 0.735, $p = 0.046$). (Figure 1.) However, inflammatory markers (CRP, ESR) were significantly elevated in cannabis users ($p < 0.001$), and cannabis use was linked to an increased risk of MACE (RR: 1.195, $p < 0.001$) and all-cause mortality (RR: 1.670, $p < 0.001$). (Figure 2.)

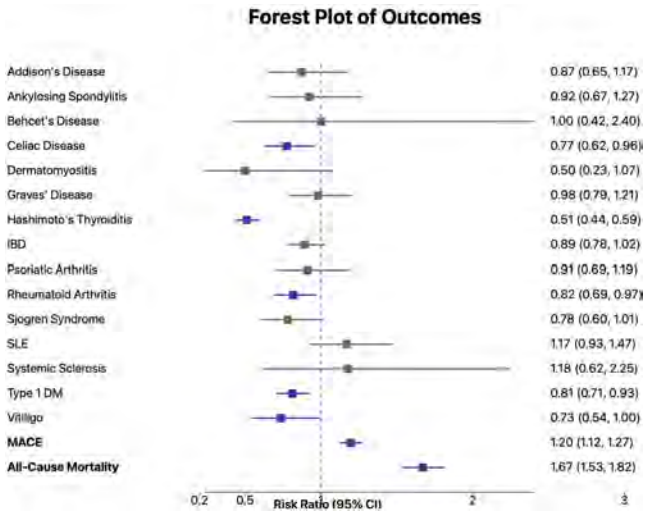

Figure 1. Forest Plot of Outcomes

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

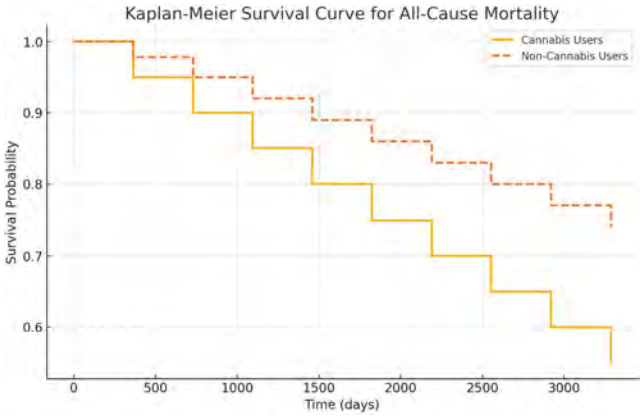

Figure 2. Kaplan-Meier Curve for All Cause Mortality

Conclusion: Cannabis use was associated with significantly increased inflammatory markers, higher risk of major adverse cardiovascular events (MACE), and elevated all-cause mortality. While there appeared to be a decreased incidence of certain autoimmune diseases among cannabis users, this finding should be interpreted with caution. The lower observed rates may reflect underdiagnosis or underreporting, potentially influenced by changing patterns of healthcare engagement amid rising cannabis legalization and widespread use. As cannabis use becomes increasingly normalized, it is essential to critically evaluate both its potential harms and the risk of diagnostic oversight. Prospective research is needed to clarify causality and guide evidence-based clinical and public health recommendations.

The Role of Extracorporeal Membrane Oxygenation in Cardiopulmonary Dysfunction Due to Rheumatologic Diseases: A Systematic Review

Kari Falaas[1], Lyubov Tiegs[2] and Elie Gertner[3], [1]University of Minnesota, Minneapolis, [2]University of Minnesota, Mineapolis, [3]Regions Hospital, St. Paul, MN

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatologists are increasingly involved in the management of patients with severe manifestations of rheumatologic disease treated with Extracorporeal Membrane Oxygenation (ECMO). A 2020 systematic review, reviewing the use of ECMO in rheumatology from 1999 to 2018, found a survival rate of 93% (in 27 of 29 patients). The use of ECMO has steadily increased since then. This systematic review documents the current status of ECMO use in patients with complications of rheumatologic diseases.

Methods: A systematic review was conducted following Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) 2020 guidelines, covering studies from January 2019 to January 2025 (Figure 1). The initial search identified 2,695 studies from 4 different databases. Inclusion criteria included patients requiring ECMO for rheumatologic disease complications with documented outcomes. Studies were excluded if they lacked outcome data, were not published in

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart outlining the process of screening and selection.

English, letters to the editor, secondary sources, or ECMO for non-rheumatologic indications. Data extracted included patient characteristics, ECMO indications and details, therapy type, outcomes, and complications.

Results: A total of 145 studies were included in the final analysis, encompassing 734 patients who received ECMO. The average age of patients was 32.2 years (range: 7 weeks to 70 years), with 340 (46%) females. The most common indications for ECMO were diffuse alveolar hemorrhage, severe interstitial lung disease, myocarditis, cardiac arrest, and massive pulmonary embolism. The most frequent rheumatologic diagnoses were anti-neutrophil cytoplasmic antibody (ANCA) vasculitis, inflammatory myositis, systemic lupus erythematosus (SLE), anti-glomerular basement membrane disease, and antiphospholipid syndrome. There were 482 patients treated with venovenous (VV) ECMO, 236 with venoarterial (VA) ECMO, and 10 were transitioned between VA and VV. ECMO duration ranged from 1 day to 123 days. Common therapies included glucocorticoids, cyclophosphamide, and plasmapheresis. Infection was the most frequent complication during hospitalization. In terms of outcomes, 362 patients were successfully bridged to recovery, 54 patients underwent successful transplants and survived, 304 patients died, and 3 patients remained on ECMO at the time of publication.

Conclusion: ECMO remains a potential and viable option for the severe manifestations of rheumatologic disease, serving as a bridge to either recovery or transplant. In this review, 416 patients survived due to ECMO who likely would have otherwise

Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Guselkumab (GUS), a dual-acting interleukin (IL)-23 inhibitor that potently neutralizes IL-23 and binds to CD64 (a receptor on cells that produce IL-23), is currently approved in the United States for treatment of ulcerative colitis (UC) and worldwide for the treatment of plaque psoriasis and psoriatic arthritis. While GUS has been shown to be safe in Crohn's disease (CD) and UC, safety results have only been reported in individual trials to date. To characterize the overall

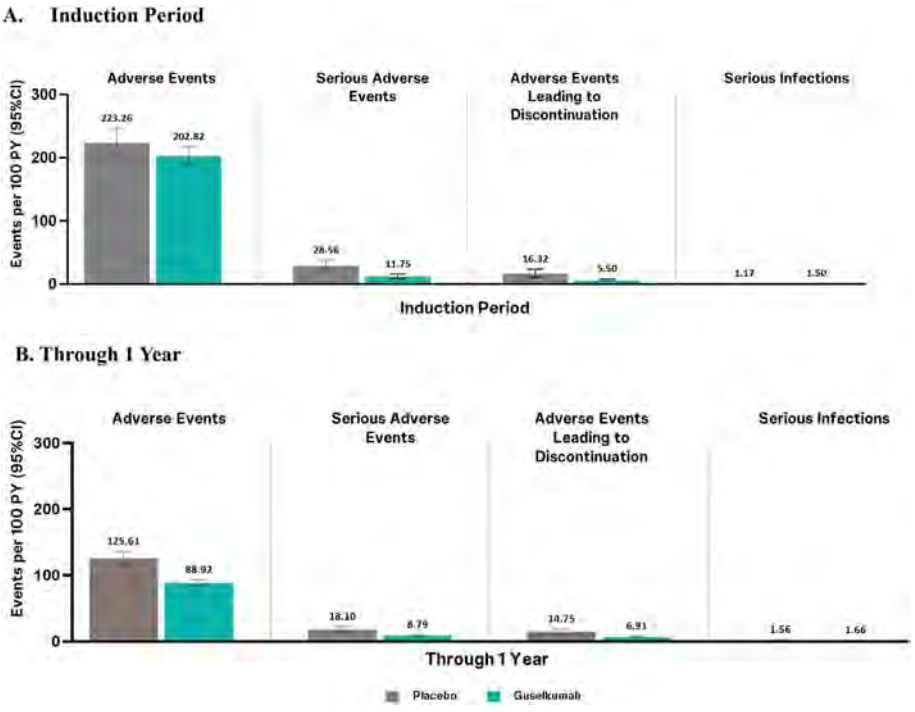

Figure 1. Key safety events in phase 2/3 IBD clinical studies during the induction period (Week 0-12) (A) and through 1 year (B)

Abbreviations: AEs=adverse events; CI=confidence interval; GUS=guselkumab; IBD=inflammatory bowel disease; MedDRA=Medical Dictionary for Regulatory Activities; PBO=placebo; PY=participant-years; SAE=serious AE; TB=tuberculosis.

[a]Ulcerative colitis: (0-12 weeks) CNTO1959UCO3001 QUASAR Induction Study 1 and Induction Study 2 (VEGA not included due to no PBO control); Crohn's disease (0-12 weeks): CNTO1959CRD3001 GALAXI 1, GALAXI 2, GALAXI 3 and CNTO1959CRD3004 GRAVITI.

[b]Ulcerative colitis: includes data up to the first dose of guselkumab for participants who were initially treated with placebo; includes data at or after 12 weeks from the last induction dose of guselkumab for participants who were treated with guselkumab in induction and were rerandomized to placebo in the Maintenance Study, up to the dose adjustment for participants who had a dose adjustment. Crohn's disease: includes data up to the time of rescue or crossover.

[c]Ulcerative colitis: CNTO1959UCO3001 QUASAR (through induction Week 20 for participants who did not enter the Maintenance Study and did not receive treatment at induction Week 12; through induction Week 32 for participants who did not enter the Maintenance Study and received treatment at induction Week 12; through maintenance Week 44 for participants who entered the Maintenance Study); CNTO1959UCO2002 VEGA through Week 38 (guselkumab monotherapy arm only); includes all guselkumab data and data up to 12 weeks from the last induction dose of guselkumab for participants who were randomized to placebo in the Maintenance Study. Crohn's disease: CNTO1959CRD3001 GALAXI 1, GALAXI 2 and GALAXI 3, and CNTO1959CRD3004 GRAVITI through Week 48; includes data from the first dose of guselkumab onward for participants who were rescued or crossed over from placebo.

[d]Confidence interval based on an exact method assuming that the observed number of events follows a Poisson distribution.

[e]Clinically important hepatic disorders are defined as hepatic disorder AEs reported as SAEs or AEs leading to discontinuation of study intervention.

Note: Includes all participants who were treated.

Note: Participants are counted only once for any given event, regardless of the number of times they actually experienced the event. Adverse events are coded using MedDRA Version 26.0

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. IV and SC, Weeks 0-12 [VEGA excluded due to no PBO control]) and through 1 year (GALAXI, GRAVITI, QUASAR, & VEGA). In this pooled analysis, safety events were normalized to 100 participant-years (PY) of follow-up with corresponding confidence intervals.

Results: Through Week 12, 1703 participants were treated with GUS with 399.9 PY of follow-up. Rates of adverse events (AEs) were similar between participants treated with GUS (200 mg IV or 400 mg SC) and PBO (**Figure 1A**). AEs occurred at a rate of 202.82/100 PY and 223.26/100 PY, serious AEs at 11.75/100 PY and 28.56/100 PY, AEs leading to study agent discontinuation at 5.50/100 PY and 16.32/100 PY, and serious infections at 1.50/100 PY and 1.17/100 PY, for GUS and PBO, respectively.

Through 1 year, 2057 participants were treated with GUS, with 1752.1 PY of follow-up. Rates of AEs, serious AEs, AEs leading to discontinuation, and serious infections, were no higher in GUS-treated than PBO-treated participants (**Figure 1B**). Through 1 year, no anaphylactic or serum sickness reactions were reported, and rates of malignancy, opportunistic infection, major adverse cardiovascular event, and clinically important hepatic disorders were low (**Table 1**). In GUS-treated participants, one participant (from an endemic region) reported active tuberculosis, and 2 deaths (acute myocardial infarction in a participant with pre-existing cardiovascular risk factors and non-suicidal gunshot wound, respectively) occurred.

Conclusion: Through 1 year of treatment, GUS demonstrated a favorable safety profile comparable to PBO in participants with CD and UC. No new safety concerns were identified.

Abstract Number: 0258

Performance characteristics of anti-Collagen II antibodies for diagnosing inflammatory and non-inflammatory diseases: a systematic review and meta-analysis

Karyssa Stonick[1], Marcela ferrada[2], Alice Fike[3], Kaitlin Quinn[3], Benjamin Turturice[3], Casey Stein[4] and Peter Grayson[5], [1]National Insitute of Arthritis and Musculoskeletal and Skin Diseases, Bethesda, MD, [2]University of Maryland, Bethesda, MD, [3]National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health (NIH), Bethesda, MD, [4]NIAMS, NIH, Chevy Chase, MD, [5]National Institutes of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health (NIH), Chevy Chase, MD

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Anti-collagen II (Col2) antibodies have been clinically and experimentally associated with relapsing polychondritis (RP), rheumatoid arthritis (RA), and other diseases. Whether anti-Col2 antibodies are directly involved in disease pathogenesis in humans or represent a marker of cartilage disease remains unknown. The purpose of this study was to synthesize and evaluate the current evidence in the literature on the prevalence and diagnostic performance of anti-Col2 antibodies across all the diseases in which it has been studied.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: A systematic review and meta-analysis was performed on diagnostic performance of anti-Col2 antibodies across a broad spectrum of diseases and studies in accordance with the recommendations of the Cochrane Collaboration and the Preferred Reporting Items for Systematic Reviews and Meta-Analyses. The study was registered in PROSPERO (April 1, 2025; CRD# 1023286). A PubMed search for articles measuring anti-Col2 antibodies in human serum was completed using the terms ((anti-collagen II) OR (collagen II antibodies)) AND (human)). Additionally, snowballing was used to identify articles not captured in the original search. Two independent investigators classified each article into one of four categories: inflammatory diseases with cartilage involvement, inflammatory diseases without cartilage involvement, non-inflammatory

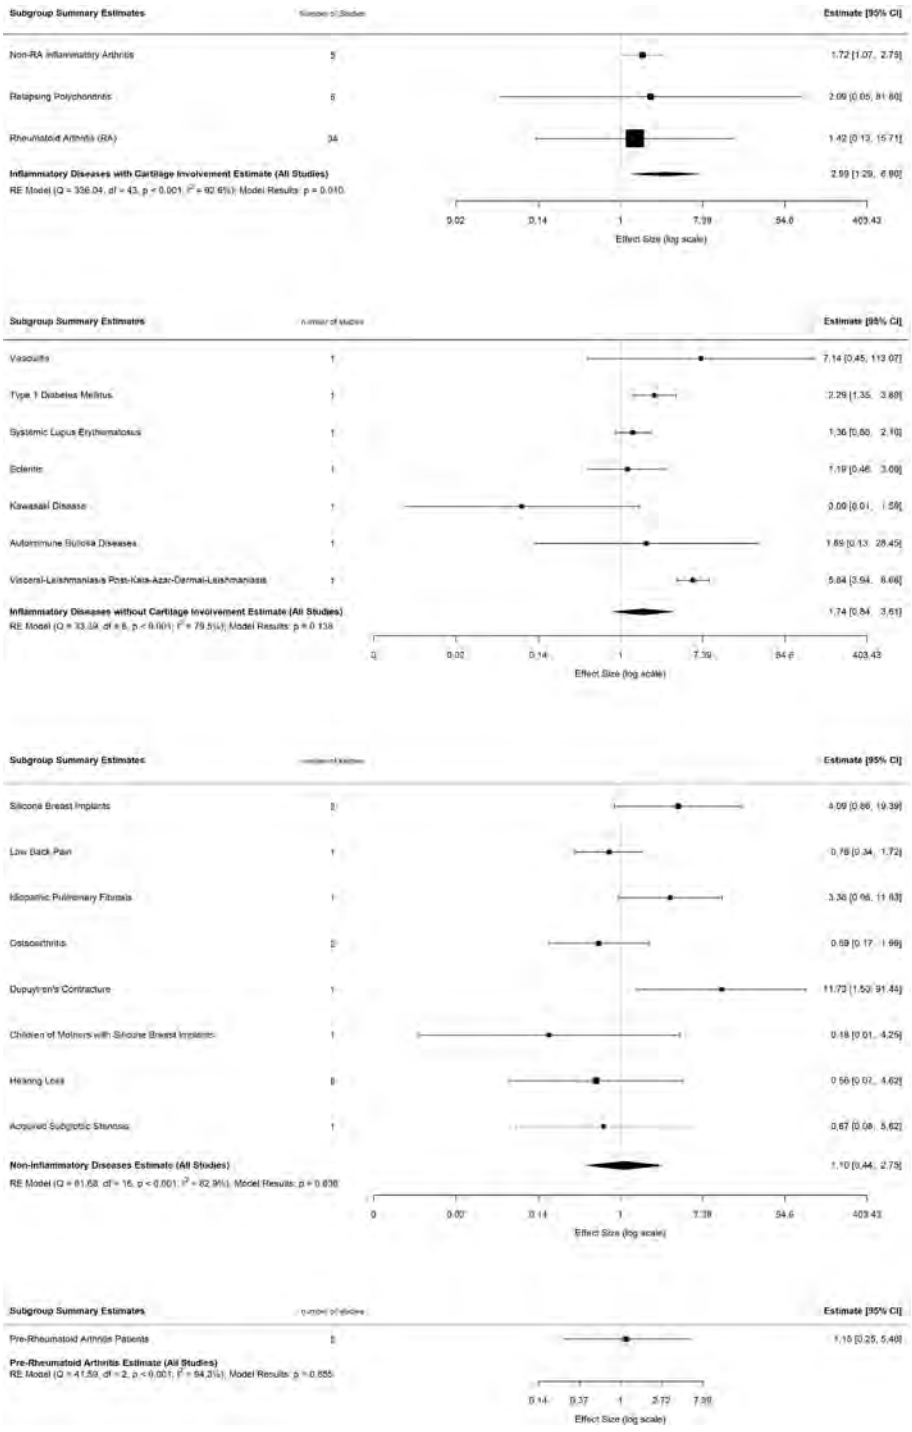

Figure 1: Forest plots summarized by disease within each composite disease subgroup. The risk ratio (RR) is the probability of anti-col2 antibody positivity in the disease versus control groups.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

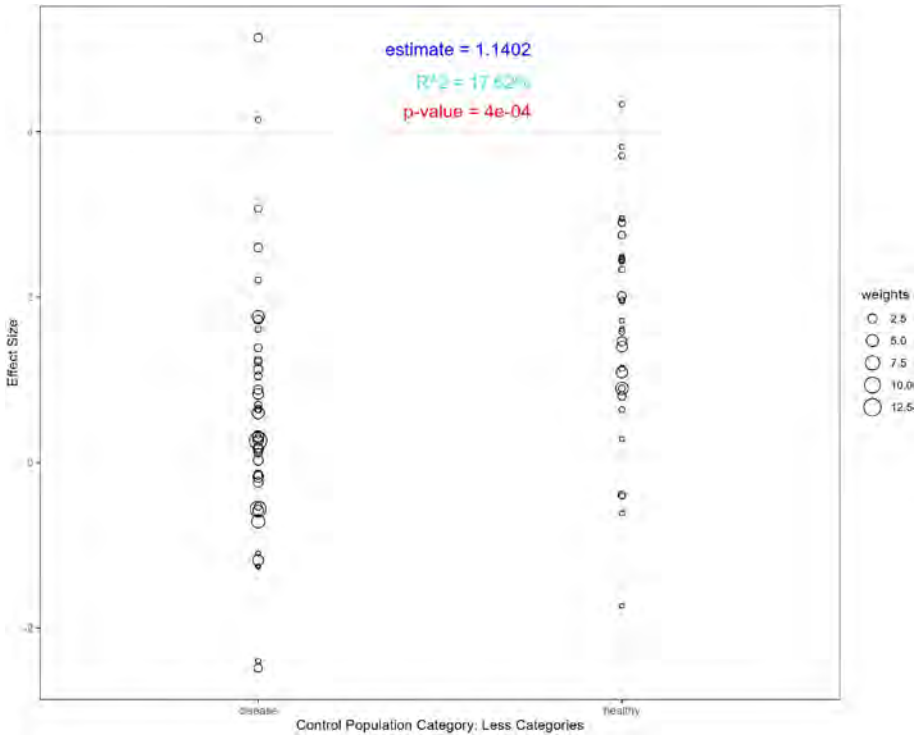

Figure 2: Differences in Composition of the Control Population Explains a Proportion of Heterogeneity Between Studies

diseases, and pre-RA patients. Forest, funnel, and meta-regression plots were generated to evaluate individual study risk ratios (RR) and pooled disease category RR, study bias, and inter-study heterogeneity.

Results: Out of 2443 reviewed articles, 72 were selected for analysis. Prevalence of anti-Col2 antibodies was significantly associated with the group of inflammatory diseases with cartilaginous involvement (RR 2.99; 95% CI: 1.29, 6.91; p=0.01); however, it was not significantly associated with most of the specific diseases contained in this category, including RP or RA (**Figure 1**). There was no significant association between anti-Col2 antibody positivity and inflammatory diseases without cartilage involvement (RR: 1.74, 95% CI: 0.84, 3.61, p = 0.138), non-inflammatory diseases (RR: 1.10, 95% CI: 0.44, 2.75, p = 0.84) or the pre-RA group (RR: 1.15, 95% CI: 0.25, 5.40, p = 0.86) (**Figure 1**). Studies that used healthy rather than disease controls reported increased effect sizes (Beta-estimate = 1.14, I^2=17.08%, p=0.0004) (**Figure 2**).

Conclusion: Anti-Col2 antibodies have been indiscriminately detected in several diseases where there is inflammation of cartilage. As such, Anti-Col2 antibodies are more likely a marker of inflammatory cartilage damage rather than a driver of disease pathogenesis. Clinical use of these antibodies to diagnose specific conditions, such as RP, is not advisable.

Inhaled pirfenidone as an innovative therapeutic approach to treat autoimmune ILD and other forms of Progressive Pulmonary Fibrosis: Phase 2b Study Design

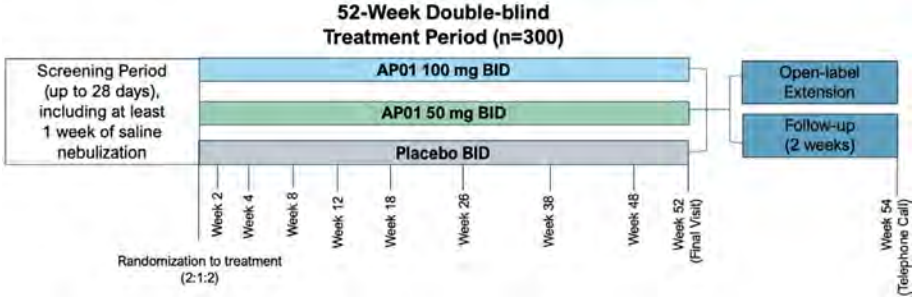
Kristin Highland[1], Colin Reisner[2], Allison Trucillo[3], Deepthi Nair[4], Felix Woodhead[4], Howard Lazarus[4], Craig Conoscenti[4] and Martin Kolb[5], [1]Cleveland Clinic, Shaker Heights, OH, [2]DevPro Biopharma, Basking Ridge, NJ, [3]Avalyn Pharma, Austin, TX, [4]Avalyn Pharma, Cambridge, MA, [5]McMaster University, Hamilton, ON, Canada

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Progressive Pulmonary Fibrosis (PPF) is an increasingly recognized condition, defined in 2022 to address the progression of pulmonary fibrosis in patients with interstitial lung diseases (ILDs) other than idiopathic pulmonary fibrosis (IPF). PPF is a characteristic feature of autoimmune ILD. Oral pirfenidone has shown positive signals in some studies without reaching the primary endpoint, but treatment with oral pirfenidone is also associated with significant adverse events and a poor tolerability profile. This study aims at exploring the efficacy and safety of inhaled pirfenidone which might be a promising therapeutic approach considering the local drug delivery into the lungs and the subsequent reduced systemic exposure.

Data from the AP01-002 (ATLAS) Study of inhaled pirfenidone in IPF demonstrated efficacy and improved safety compared to that seen historically with oral pirfenidone. The AP01-005 long term extension study allowed new patients with PPF to enter the study and showed a trend toward FVC stabilization. The AP01-007 (MIST Study) is designed to study the efficacy and safety of AP01 (inhaled pirfenidone) in patients with PPF including autoimmune ILD patients.

Methods: MIST is a prospective randomized placebo-controlled trial comparing two doses (100mg BID and 50mg BID) of inhaled pirfenidone with placebo over 52 weeks. Patients will be eligible if they meet at least one of the following criteria for progression of ILD within the 24 months prior to screening: a relative decline in the FVC of at least 10% of the predicted value, a relative decline in the FVC of ≥5% to less than < 10% of the predicted value accompanied by worsening of respiratory symptoms or an increased extent of fibrosis on HRCT; or worsening of respiratory symptoms and an increased extent of fibrosis on HRCT. Patients will remain on stable background immunosuppression, and up to 30% of patients will remain on background nintedanib therapy. 300 patients will be recruited in 14 countries, including the US.



MIST phase 2b Study Design

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: The AP01-007 (MIST Study) is designed to study the efficacy and safety of AP01 (inhaled pirfenidone) in patients with PPF including autoimmune ILD patients. The primary endpoint is the change in the annual rate of decline in FVC in the AP01 treatment groups as compared to placebo. In addition, efficacy will be measured in secondary endpoints of time to progression, change in fibrotic scores via quantitative HRCT, and change from baseline QoL. Safety outcomes will be assessed as well. Cough will be analyzed through cough questionnaires, which should allow differentiation of cough related to PPF vs. aerosol inhalation via nebulization.

Conclusion: MIST is the first study to analyze the novel concept of inhaled medications in autoimmune ILD. In addition to the safety and efficacy endpoints, MIST will examine the presence of cough in this population of patients.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: VEXAS syndrome is a recently identified, severe systemic hemato-inflammatory disease with a complex and heterogeneous clinical presentation. The disease is associated with significant morbidity and mortality, with most patients experiencing recurrent flares or persistent symptoms despite anti-inflammatory therapy. Accurate and standardized measures of disease activity are critical for understanding disease progression, optimizing management, and conducting effective clinical trials. Before developing a disease activity instrument, it is essential to define disease activity, such as VEXAS flare. The absence of universally accepted definitions of VEXAS flare has significantly hindered these efforts. Developing consensus criteria for a VEXAS flare will promote consistency in research, the evaluation of therapeutic interventions, and most importantly will improve patient care.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: A 9-member international expert advisory committee, including both hematologists and rheumatologists, developed a consensus definition of VEXAS flare using modified Delphi methodology. Clinical manifestations of VEXAS syndrome were identified by a systematic literature review. Committee members developed a conceptual framework for flare definition, proposed revisions, and voted on changes until consensus was reached (defined as ≥75% concurrence). To facilitate revisions, a moderator amended VEXAS flare definition text, synthesizing similar proposed changes, and providing multiple drafts for consideration for dissimilar proposals.

Results: A total of 4 revision rounds were conducted from May to July of 2024, and consensus was reached on the definition of VEXAS flare as an active inflammatory manifestation of VEXAS syndrome requiring escalation in glucocorticoid therapy. Three categories of flare were established: **A)** recurrence of a prior documented VEXAS manifestation; **B)** development of a new VEXAS-defining inflammatory sign; or **C)** development of an inflammatory sign not meeting criteria for categories A or B. The panel agreed upon the need for an independent adjudication committee to aid in the determination of flares, particularly in the context of category C manifestations, during clinical trials.

Conclusion: A consensus definition of VEXAS flare provides uniform criteria for defining and characterizing recurrence of VEXAS disease activity. Future efforts will focus on refining this definition through its application and performance in clinical trials.

This abstract has been accepted for publication by the European Alliance of Associations for Rheumatology (EULAR). The definitive copyedited version is available online at: www.ard.eular.org

Randomized Confirmatory Basket Trial: Performance Evaluation of a Simulated Application Example in Rare Disease Using Real World Data

Daphne Guinn[1], **Linchen He**[2], Yuru Ren[1], Valeriy Korostyshevskiy[1] and Robert Beckman[1], [1]Georgetown University, Washington, [2]Novartis, East Hanover

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Basket trials group together participants who share a common biomarker or disease pathway across several diseases or phenotypes in a single clinical study. Such trial designs may substantially increase efficiency of clinical development, especially in rare diseases with the challenges of limited resources and high operation costs. Rituximab, a monoclonal antibody targeting the CD20 antigen on B-cells, is used as a treatment option for several rare

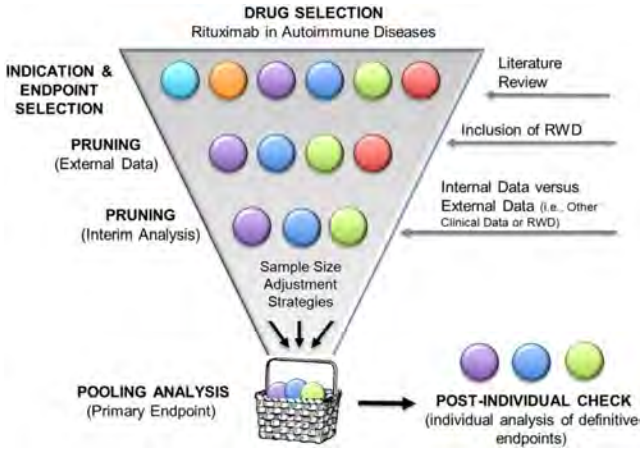

Figure 1. Randomized confirmatory basket designs. Cartoon shapes represent putative indications. The design is a funnel proceeding from top to bottom with the indicated steps shown on the side of the funnel. After indication and endpoint selection by literature review, RWD is used to optimize the choice of indications and other detailed study design features. A pruning process subjects possible indications to a high interim bar to decrease heterogeneity. After this pruning, the resulting pooled indications continue until study maturity. A pooled analysis on pooled data by the definitive endpoint is applied and followed by an additional pruning step to individual indications if the pooled analysis is positive, which enables stricter control of the false positive rate by individual indications.

autoimmune diseases including autoimmune hemolytic anemia (AIHA), thrombotic thrombocytopenic purpura (TTP), and idiopathic thrombocytopenic purpura (ITP), as it effectively depletes B-cells which are often implicated in the production of autoantibodies causing these conditions.

Methods: We utilized real world data (RWD) of off-label use of rituximab together with literature data for a design of a randomized confirmatory basket trial of steroid therapy +/- rituximab in multiple rare auto-immune diseases. The adaptive basket design removes disease indications where the therapy does not appear to be benefitting patients at interim analysis, pools the remaining indications in the primary analysis, and then performs an indication-by-indication post check, again discarding indications that do not appear to benefit patients (Figure 1). We simulated this basket design under numerous scenarios varying design parameters based on RWD and literature information and assessed power, efficiency, and benefit of a basket trial investigating k indications compared to k parallel, independent Phase 3 designs, given the false positive rate of the entire trial controlled at 0.025k. Efficiency was defined as the number of true positive results confirmed per patient enrolled. A false positive event was considered to have occurred if the study resulted in approval of one or more indications where experimental therapy was not beneficial.

Results: Information from RWD influenced our selection of indications for the simulated trial and led us to increase the sample size due to more realistic estimates of clinical benefit. Literature information alone resulted in poor study performance. Using the RWD information together with literature information, we were able to design a basket trial of three auto-immune indications that had robust performance across plausible clinical scenarios, and up to a 46-132% improvement in development efficiency with comparable control of the false positive rate when compared to parallel clinical studies.

Conclusion: RWD can be useful when performing design optimization of complex basket trial designs in rare auto-immune disease. Rigorous, efficient confirmatory basket trial designs are feasible.

Preclinical Characterization of ABB071 – a Humanized anti-CD180 Antibody that Modulates Multiple Pro-inflammatory Immune Pathways for the Treatment of Autoimmune and Inflammatory Disorders

Margaret McDaniel, Brenda Stevens, Socheath Khim, Alan Wahl, Che-Leung Law and Edward Clark, Abacus Bioscience, Seattle, WA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: CD180 is a Toll-like receptor (TLR) homolog expressed on antigen-presenting cells (APCs): B cells, dendritic cells, monocytes, and macrophages. While the extracellular domain of CD180 is structurally similar to other TLRs, intracellular signaling is distinct from classical TLRs as CD180 lacks a TIR domain. Instead, CD180 signaling leads to pleiotropic downstream immune responses, including PI3K activation and downregulation of type I interferon (IFN)-associated inflammation. In mice, treatment with an agonistic anti-CD180 antibody is therapeutic in multiple models of lupus.

Methods: We utilize RNA-sequencing and transcriptional analysis of human B cells stimulated with humanized anti-CD180 monoclonal antibody to characterize CD180 signaling and predict diseases that may show therapeutic effect with anti-CD180 treatment. Mouse models of rheumatic disease are used to support these disease predictions.

Results: To support clinical development of anti-CD180 therapy, we have humanized G28-8, a mouse anti-human CD180 monoclonal antibody. Humanized G28-8 (hzG28-8), including the lead drug candidate ABB071, have retained primate CD180 cross-reactivity and functional profiles of the parent G28-8.

RNAseq analysis revealed an inverse correlation between genes regulated by ABB071 in B cells from normal donors to genes differentially expressed in B cells from patients with rheumatic disease. Several genes upregulated in B cells from lupus patients, e.g., TLR7 and IRF5, were downregulated in ABB071 treated B cells. In contrast, genes downregulated in B cells from lupus patients, e.g., PNPT1 and DNASE1L3, were induced by ABB071. These results suggest a genetic connection between CD180 biology and the pathogenesis of autoimmune and inflammatory disorders.

Suppression of IFN-stimulated genes (ISGs) was used to evaluate the therapeutic potential of ABB071. ABB071 inhibited ISGs induced by ligands for TLR7, TLR8, TLR9, cGAS-STING, as well as IFNα in B cells from normal donors. The effects of ABB071 against TLR7/8 ligand and IFNα was also observed in B cells from SLE patients. In addition, ABB071 down-modulated baseline expression of several genes in the type I IFN pathway including IFNAR1/2, IRF5, and IL-15.

A mouse model of imiquimod-induced psoriasis was used to validate the role of CD180 signaling in suppressing inflammatory disease. Mice treated with anti-CD180 had reduced overall PASI scoring (psoriasis severity scoring), as well as reduced levels of key inflammatory cytokines in the skin. The safety margin of CD180 targeting in mice was confirmed by the finding that anti-CD180, up to 50 mg/kg, did not result in observable clinical side effects or increase in circulating proinflammatory cytokines such as IL-6, TNFα, and IFNɣ.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Conclusion: In contrast to most current approved therapies designed to neutralize individual cytokines or their receptors globally in patients, targeting CD180 is a novel strategy focusing the therapeutic actions on one of the most relevant subsets of immune cells, the APCs, to simultaneously suppress multiple key pro-inflammatory pathways. This study provides the rationale for clinical development of ABB071 in the treatment of autoimmune and inflammatory diseases.

Abstract Number: 0263

A Multicenter Retrospective Case Series of Patients with Susac Syndrome Treated with Rituximab

Michelle Benjamin[1], Mattia Wruble Clark[2], Shamik Bhattacharyya[3], Audra Horomanski[1] and Kristin Galetta[4], [1]Stanford University, Palo Alto, CA, [2]Mass General Brigham, Somerville, MA, [3]Brigham and Women's Hospital, Malden, MA, [4]Stanford Medical Center, Palo Alto

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Susac Syndrome (SuS) is a rare immune-mediated vasculo-occlusive disease characterized by a triad of encephalopathy, hearing loss, and branched retinal artery occlusions. Deficits can be permanent and there is limited data to guide treatment. Here, we describe the treatment trajectories of a series of patients with SuS treated with rituximab.

Methods: A retrospective chart review of patients with SuS treated with rituximab and followed in neurology and/or rheumatology clinics at three tertiary care centers in the United States was performed.

Results: Eight patients -- 4 (50%) females, 7 (87.5%) with the complete SuS triad, median age of 47 years (range 21-66 years) -- were included. There were 11 instances of rituximab treatment (1 patient received 3 distinct courses) -- 8 (72.7%) for ≥ 6 months (3 are ongoing) and 3 (27.3%) for < 6 months. Co-treatment with prednisone occurred in 10 (90.9%) instances -- all 7 instances of rituximab ≥ 6 months reached steroid freedom; all 3 instances of rituximab < 6 months saw a decrease in daily prednisone dose by ≥ 30mg, but none reached steroid freedom. Mycophenolate mofetil (MMF) co-treated patients continued at the same dose, decreased, and weaned off MMF completely over 4 (36.4%), 2 (18.2%), 4 (36.4%) instances of rituximab treatment respectively. In the 4 (36.4%) rituximab instances involving co-treatment with intravenous immunoglobulin G (IVIg), the total monthly IVIg dose was decreased over 2 (50.0%) rituximab instances and weaned off completely over 1 (25.0%) instance. Additional co-treatments included methotrexate and azathioprine in 1 instance each, both of which were weaned off completely during rituximab treatment. No patients were co-treated with cyclophosphamide (though 1 was treated cyclophosphamide before rituximab initiation).

Conclusion: In this case series of patients with SuS, rituximab facilitated steroid freedom and tapering of other immunotherapeutic agents. These initial findings provide evidence supporting the use of rituximab in SuS.

Abstract Number: 0264

Seeing Beyond the Eye: Subclinical Audio-Vestibular Involvement in Vogt-Koyanagi-Harada Disease

Mohamed Tharwat Hegazy, Rania Yacoub, Sarah Sheta, Rana Hussein Amin and Noha Khalil, Faculty of Medicine, Cairo University, Cairo, Egypt

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Vogt-Koyanagi-Harada disease (VKH) is a systemic disease that affects the central nervous system, ocular, and integumentary system. It causes bilateral granulomatous uveitis, dysacusia ranging from tinnitus, vertigo to hearing loss, and skin abnormalities such as poliosis, vitiligo, and alopecia. The present criteria only mention tinnitus as an ear finding, despite some studies reporting vestibular and cochlear involvement in individuals with VKH. Also, the diagnostic criteria for VKH do not include hearing loss as an auditory finding

Methods: Our study is one of the unique prospective studies in VKH. We aimed to evaluate the clinical and sub-clinical audio-vestibular (AV) involvement in VKH, and to compare between eye and AV response to treatment. Our patients were recruited and followed for 6 months. All our patients were assessed with emphasis on eye and AV evaluation {using Pure Tone Audiometry (PTA), Transient Evoked Otoacoustic Emission (TEOAE), positioning, spontaneous nystagmus, and caloric tests}. Laboratory investigations included CBC, ALT, AST, Creatinine, ESR, and CRP

Results: 100 patients with VKH were included. 63 cases with Active uveitis: Anterior 23/63 (35.5%), intermediate 10/63 (15.9%), posterior 4/63(6.3%), pan uveitis **40.3%25/63 (**, symptomatic patients had symptomatic (clinical) AV involvement either audiological 18/26 (69.2%), vestibular 1/26 (3.8%), or both 7/26 (27%), while **40 asymptomatic patients had subclinical AV involvement:** audiological 26/40 (65%), vestibular 2/40 (5%), both 12/40 (30%). The 63 cases with active uveitis). 26 55.5% (35/63**) had subclinical**, and 15/63 (24.2%) had clinical AV involvement. The 37 patients with no uveitis, **14/37 (40.5%)** had subclinical and 11/37 (29.7%) had clinical AV involvement. This group with subclinical AV involvement and no eye activity is very important, as without evaluating the AV system, those patients would have been missed without treatment till damage occurs. Patients received treatment according to the activity by different lines of management **(Table 1). After 6 months:** Follow-up (F/U) for ocular response: Complete response in 33/63 (52.4%), Partial response in 12/63 (19%), No response in 6/63 (9.5%), Worsening in 8/63 (12.7%), Lost F/U in 4/63 (6.3%). Follow up for AV response:

Table 1: The medications used as single treatments or in combinations.

Medication	Number of patients using this medication
Low dose steroid <10 mg/day	17
Medium dose steroid (10-20 mg/day)	35
High dose steroid >20 mg/day	33
Methotrexate	50
Mycophenolate mofetil	7
Azathioprine	23
Cyclosporine	9
Leflunomide	1
Adalimumab	14
Infliximab	1
Rituximab	3

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 2: Base line characteristics of Uveitis and Audio-vestibular involvement and follow-up

	Baseline							Follow-up of organ involvement								
Uveitis	Active Uveitis						No Uveitis	Complete response	Partial response	No response	Worsening	Lost F/U				
	63 (%)						37 (%)									
	Anterior	Intermediate	Posterior	Panuveitis				33/63 (52.4%)	12/63 (19%)	6/63 (9.5%)	8/63 (12.7%)	4/63 (6.3%)				
	23 (35.5%)	10 (15.9%)	4 (6.3%)	35 (55.5%)												
Audio-vestibular involvement (AV)	AV involvement 66 (%)						No AV 34 (%)									
	Symptomatic 26/66 (39.4%)			Subclinical 40/66 (60.6%)				Symptomatic 26/66 (39.4%)				Subclinical 40/66 (60.6%)				
	Audio	Vestibular	Both	Audio	Vestibular	Both		Improve	No Improve	Worsening	Lost F/U	Improve	No Improve	Worsening	Lost F/U	
	18/26 (69.2%)	1/26 (3.8%)	7/26 (27%)	26/40 (65%)	2/40 (5%)	12/40 (30%)		15/26 (57.7%)	6/26 (23.1%)	4/26 (15.4%)	1/26 (3.8%)	28/40 (70%)	4/40 (10 %)	3/40 (7.5%)	5/40 (12.5 %)	

subclinical improvement 28/40 (70%), subclinical no improvement 4/40 (10%), subclinical worsening 3/40 (7.5%), lost F/U 5/40 (12.5%), clinical improvement 15/26 (57.7%), clinical no response 6/26 (23.1%), clinical worsening 4/26 (15.4%), lost F/U 1/26 (3.8%). Regarding the group of patients with normal eyes at base line with AV involvement and received treatment: subclinical improvement 10/14 (71.4%), subclinical no improvement 1/14 (7.1%), subclinical worsening 1/14 (7.1%), lost F/U 2/14 (14.3%), clinical improvement 8/11 (72.8%), clinical no response 1/11 (9%), clinical worsening 2/11 (18.2%) **(Table 2)**

Conclusion: Subclinical AV (40%) involvement is common and more than symptomatic cases and even present in about 40% of cases without uveitis. So, early detection of subclinical AV involvement is important to allow early treatment before damage. We recommend adding AV involvement in the diagnostic criteria of VKH and not only tinnitus

Influence of Menopausal Status on Coronary Artery Calcium Burden and Cardiovascular Computed Tomography Abnormalities in Inflammatory Arthritis

Mohammed Mohammed[1], Bindee Kuriya[2], Lihi Eder[1], Elsie Nguyen[3], Shadi Ahktari[4], Paula Harvey[5], Wei Wu[6] and Sohan Shahab[7], [1]University of Toronto, Toronto, ON, Canada, [2]University of Toronto - Toronto, Toronto, ON, Canada, [3]University of Toronto, Toronto, [4]University of Toronto Department of Medicine and Women's College Hospital, Toronto, Canada, [5]University of Toronto Department of Medicine and Women's College Hospital, Toronto, ON, Canada, [6]University of Toronto, Toronto, Canada, [7]Women's College Research Institute, Women's College Hospital, Toronto, Canada

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with inflammatory arthritis (IA) have increased cardiovascular risk. Coronary artery calcium (CAC) scoring by computed tomography (CT) detects early coronary disease and structural abnormalities. While sex and menopause influence CVD risk, their impact on coronary and extra-coronary CT findings in IA is unclear

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table. Multivariable-adjusted odds ratios for elevated coronary artery calcium score in post-menopausal women compared to men with inflammatory arthritis patients.

	Unadjusted OR (95% CI)	Adjusted OR (95% CI)
Post-menopausal status	0.541 (0.367-0.798)	***0.314 (0.188-0.526)***
Age, years	1.085 (1.061-1.110)	***1.113 (1.081-1.147)***
Disease duration, years	1.017 (1.001-1.034)	1.007 (0.989-1.026)
CRP, mg/L	1.024 (0.999-1.050)	***1.034 (1.006-1.063)***
Hypertension	2.739 (1.800-4.167)	1.682 (0.998-2.835)
Diabetes	4.221 (1.970-9.041)	***2.453 (1.001-6.014)***
Dyslipidemia	2.277 (1.475-3.515)	1.475 (0.818-2.659)
Smoking History	1.975 (1.341-2.910)	***2.028 (1.283-3.204)***
Obesity (BMI>30)	1.567 (1.058-2.320)	1.308 (0.814-2.103)

Methods: We conducted a cross-sectional analysis using data from the U of T CardioRheum Network (2017–2023). Eligible participants were aged >40 years with confirmed IA, and no prior CVD. The primary outcome was total CAC category (0, 1–100, >100); secondary outcomes included plaque distribution and other CT-detected abnormalities. Multivariable logistic regression assessed associations with post-menopausal status, adjusting for confounders.

Results: Among 594 IA patients, 31% were male (mean age 57.3), 14% pre-menopausal female (46.1), and 54% post-menopausal female (61.7). Males were more likely to have AS/PsA (71%) compared to pre-menopausal (38%) and post-menopausal females (30%), while RA was more prevalent in post-menopausal females (70%, $p< 0.001$). Males had more CVD risk factors and higher Framingham scores (44% vs. 11% post- and 1.5% pre-menopausal females, $p< 0.0001$). Both female groups had higher joint counts, global, and pain scores (all $p< 0.05$). DMARD use was highest in post-menopausal females (92%), though biologics were more common in males (58%) and pre-menopausal females (54%) than post-menopausal females (45%) ($p=0.01$). Corticosteroid use was also higher in post-menopausal females (25%, $p=0.01$). CAC >100 occurred in 28% of males, 19% of post-, and 1.4% of pre-menopausal females ($p< 0.0001$). Post-menopausal females had more aortic calcification (44%), aortic enlargement (23%), and pericardial effusion (8%) (all $p\leq0.001$), while males had more left main and right coronary calcification ($p\leq0.001$). In multivariable models, post-menopausal females had lower odds of elevated CAC vs. males (OR 0.31, 95% CI 0.19–0.53). Independent predictors of CAC >100 included older age, higher CRP, smoking, and diabetes. Post-menopausal women had lower odds of CAC in specific coronary territories (left main, right, and circumflex arteries), but there were no adjusted differences in aortic involvement.

Conclusion: Sex and menopausal status significantly influence both coronary and extra-coronary abnormalities detected by CT in IA patients. While men exhibit greater coronary plaque burden, post-menopausal women show a distinct pattern of vascular and structural abnormalities. These findings support a sex-specific approach to cardiovascular risk stratification in IA.

Background/Purpose: Proton pump inhibitors (PPIs) are one of the most prescribed medications around the world. Recent research has increasingly identified adverse reactions in patients with long-term prescription of PPIs, including the risks of enteric infection with Clostridium difficile, osteoporosis, malignancy, ischemic stroke, myocardial infarction, and dementia. Autoimmune diseases (ADs) comprise disorders caused by an imbalance of the immune system, which leads to damage to individual tissues. The administration of medications is one of the most important factors in the induction of ADs. Some medications change the composition of the gastrointestinal microbiota, which may cause development of various diseases. Alteration of the gut microbiome can play a pathogenic role in the development of ADs.

Methods: This is a nationwide, retrospective study. We used the global, multicenter research network (TrinetX) database from 83 large healthcare organizations across multiple countries. We included patients within the age of 18-45 with a diagnosis of gastroesophageal reflux disease (GERD), or dyspepsia, from January, 2000 through September, 2024, using the International Classification of Disease-10 codes. We compared GERD, or dyspepsia patients on PPIs (Esomeprazole, Dexlansoprazole, Lansoprazole, Pantoprazole, Omeprazole, Rabeprazole, Vonoprazan), with GERD, or dyspepsia patients not on PPIs. We used 1:1 propensity score matching that accounted for demographic variables (age, gender, race); diagnoses (gastrointestinal, endocrine, nervous system, neoplastic); medication use (CNS, cardiovascular, dermatological, gastrointestinal, hormonal, musculoskeletal, genitourinary, antineoplastic agents). Index event was determined as simultaneous appearance of dyspepsia, or GERD, and PPI use in patients' charts. Outcome of interest was the incidence of autoimmune conditions, including Sjogren's Syndrome, Scleroderma, Rheumatoid Arthritis, Dermatomyositis, Polymyositis, SLE,

Table 2. Risks of autoimmune conditions in patients (18-45) who were on chronic PPI therapy versus not on PPI therapy

Outcome	Groups	Overall Risk, %	Risk Ratio	Overall Risk, %	Risk Ratio
	Before Propensity Score Matching			After Propensity Score Matching	
Systemic Sclerosis	PPI	0.117 (1,124/ 958,503)	3.562 (3.196-3.97) p-value < 0.0001	0.122 (471/387,262)	2.591 (2.184-3.075) p-value < 0.0001

Antiphospholipid Syndrome, Granulomatosis with Polyangiitis (GPA), Giant Cell Arteritis, Psoriatic Arthritis, Behcet Disease, Ankylosing Spondylitis. Patients displaying these outcomes before the index event were excluded from the analysis. Risk ratios with 95% confidence intervals were calculated for each outcome. A two-sided p-value less than 0.05 was considered statistically significant.

Results: We identified 948,767 GERD, or dyspepsia patients taking proton pump inhibitors (PPIs) and 1,427,586 patients not taking PPIs. At baseline, the mean age of diagnosis was 29.5 ±8.26 years for those on PPIs and 26.9±8.96 not on PPIs. Female patients were predominant in PPI group. After propensity score matching, patients on PPIs showed higher risk of developing autoimmune conditions compared to those not using PPIs (Table 2).

Conclusion: Patients with GERD, or dyspepsia, using PPI therapy have higher risks for autoimmune disease development, compared to those patients, not on PPI therapy. Further research is warranted to elucidate the pathways through which alterations in the gut microbiota contribute to the pathogenesis of autoimmune diseases.

Pharmacosurvellience study of FDA Adverse Event Reporting System (FAERS) events of Secukinumab and Guselkumab

NUR BARLAS[1], Sait Barlas[1] and Emre Adalier[2], [1]Florida State University College of Medicine, Cape Coral, [2]University of Pavia School of Medicine & Surgery, Pavia, Italy

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Interleukin-17 (IL-17) and interleukin-23 (IL-23) inhibitors have revolutionized treatment for psoriatic arthritis, axial spondyloarthritis, and moderate-to-severe plaque psoriasis. IL-17 inhibitors block the pro-inflammatory cytokine IL-17, while IL-23 inhibitors target the Th17 pathway via IL-23. Secukinumab (Cosentyx), an IL-17 inhibitor, was FDA-approved in 2015, and Guselkumab (Tremfya), an IL-23 inhibitor, received approval in 2017. Both classes are highly effective, but their distinct mechanisms lead to different safety profiles, guiding treatment choices—especially in patients with comorbidities.

Methods: The FAERS system gathers information on adverse events and medication errors.

We conducted a pharmacovigilance study using the FAERS database to evaluate adverse events (AEs) associated with Secukinumab and Guselkumab. Post-marketing reports from 2015 to 2024 were analyzed using disproportionality analysis. Reporting odds ratios (RORs) were calculated to assess drug-event associations. An ROR >1 indicates a stronger association of the drug with the adverse event compared to the other. An ROR < 1 indicates a weaker association of the drug with the adverse event.

Results: As of December 2024, there were a total of 143,401 and 23,064 reported adverse events (AEs) for Secukinumab and Guselkumab, respectively. Secukinumab was associated with a significantly higher ROR of several adverse events compared to Guselkumab, including liver injury (ROR 13.01, 95% CI 6.41–26.42), pericarditis (ROR 12.78, 95% CI 6.41–

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Interleukin-17 and interleukin-23 inhibitors mechanism of action

ROR Results of Secukinumab and Guselkumab

25.47), hypercholesterolemia (ROR 9.31, 95% CI 5.00–17.35), type 2 diabetes mellitus (ROR 8.49, 95% CI 4.97–14.48), gastrointestinal disorder (ROR 6.26, 95% CI 4.79–8.18), hypertension (ROR 5.42, 95% CI 4.34–6.78), sinusitis (ROR 4.85, 95% CI 4.02–5.85), depression (ROR 2.99, 95% CI 2.34–3.83), asthma (ROR 2.24, 95% CI 1.55–3.24), and lower respiratory tract infection (ROR 2.11, 95% CI 1.83–2.43). Notably, Guselkumab showed higher odds of cerebrovascular accident (ROR 0.68, 95% CI 0.55–0.85) and myocardial infarction (ROR 0.45, 95% CI 0.36–0.57), indicating these were more frequently reported with Guselkumab. There was no statistically significant difference in the risk of pneumonia (ROR 0.97, 95% CI 0.89–1.06) or death (ROR 1.14, 95% CI 0.99–1.31) between the two agents.

Conclusion: This FAERS-based analysis highlights the distinct adverse event profiles of Secukinumab and Guselkumab. Secukinumab showed higher RORs for liver injury, pericarditis, hypercholesterolemia, type 2 diabetes, GI disorders, hypertension, sinusitis, and depression. Guselkumab was more strongly associated with cerebrovascular accidents and myocardial infarctions. No significant differences were found for pneumonia or mortality. These findings underscore the need for individualized risk assessment when choosing between IL-17 and IL-23 inhibitors and highlight the importance of further research into their long-term safety.

TABLE. Case reports and literature review of patients with uveitis treated with Janus Kinase Inhibitors

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

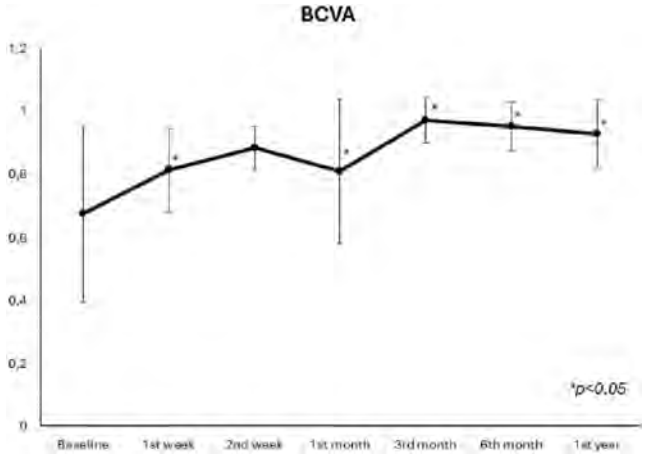

FIGURE 1. Rapid improvement of best corrected visual acuity (BCVA) following the start of JAKINIB

Background/Purpose: Non-infectious uveitis may be related to several immune-mediated diseases (IMIDs). Those that are refractory to conventional therapy or biologics may lead to severe ocular damage. Janus Kinase inhibitors (JAKINIB) had shown efficacy in refractory cases.

The objectives were to assess the efficacy and safety of JAKNIBs in patients with refractory uveitis due to IMIDs, and to review the updated literature.

Methods: Multicenter study of 18 patients with refractory uveitis due to IMIDs treated with different JAKNIBs. Our ocular variables evaluated were best corrected visual acuity (BCVA), anterior chamber cells and presence of cystoid macular edema, and they were recorded from baseline up to 1 year treatment.

We included patients with non-infectious uveitis treated with JAKNIBs for the literature review searched on PubMed, Embase and the Cochrane library up to 1st December 2024.

Results: We studied 18 patients from Spain and 13 cases from the literature were reviewed. They were 24 women and 7 men. There were panuveitis (n=12), anterior (n=17;), intermediate (n=1) and posterior uveitis (n=1).

26 patients with uveitis were secondary to IMIDs while 5 cases were idiopathic. The main underlying IMIDs were spondylarthritis (n=14) and juvenile idiopathic arthritis (n=6) **(Table)**.

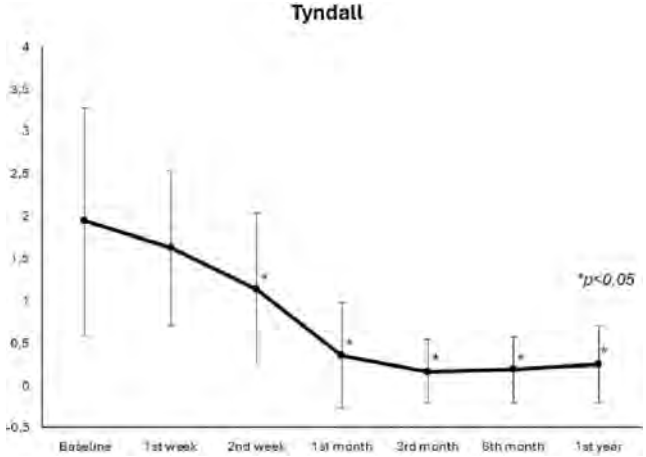

FIGURE 2. Decrease of Tyndall following the initiation of JAKNIB

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

They received treatment with conventional (n=26) or biological immunosuppressive drugs (n=27) before the JAKNIBs therapy. The JAKINIB most widely used was Upadacitinib (n= 17).

Complete clinical improvement was recorded after starting JAKNIBs treatment. 28 patients presented a complete improvement while the remaining patients showed partial improvement.

In the multicenter study, BCVA showed a rapid and maintained improvement **(Figure 1)** after 13 months of follow-up. From 14 patients with Tyndall + at baseline, 4 of them had a partial decrease in the first month (n=4) and resolved by the sixth month **(Figure 2)**. Two patients had cystic macular edema at baseline, resolved at 3 months of follow-up. No serious adverse effects were found.

Conclusion: Treatment with JAKNIBs in uveitis due to different IMIDs may be effective and safe, even in refractory to previous biological drugs patients.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: VEXAS syndrome is a rare disease caused by somatic mutations in *UBA1* gene. Different mutations in this gene appear to be associated with specific phenotypes, potentially influencing disease severity and progression. This work aims to describe the clinical, phenotypic, and laboratory characteristics of a Spanish cohort of patients with confirmed VEXAS syndrome and to evaluate associations between *UBA1* mutations, manifestations and mortality.

Methods: An observational, ambispective study conducted across rheumatology units in Spain, identifying patients with genetically confirmed VEXAS syndrome. Demographic, clinical, laboratory, and outcome data were collected. Statistical analyses were performed using standardized tests (significance set at $p < 0.05$).

Results: A total of 50 patients with VEXAS syndrome were identified, all male and of Caucasian origin. The mean age at symptom onset was 68.05 years (SD±10.24) and the mean age at diagnosis was 73.49 years (SD±8.72). The mean diagnostic delay was 5.79 years (SD±4.4). "*Table 1*" summarizes the most common initial misdiagnoses.

The most frequent clinical manifestations included cutaneous lesions (88%), arthritis, constitutional symptoms, non-infectious fever, (76% respectively), and chondritis (48%). Other hallmark features of the syndrome, such as pulmonary involvement, thromboembolic disease associated with VEXAS, and renal impairment, were observed in 38%, 32%, and 22% of the patients (see "*Table 2*").

Laboratory findings revealed anemia in 47 patients (94%), with macrocytosis in 41. The mean hemoglobin level was 9.89 g/dL (SD±2), and the mean MCV was 107.3 fL. Additionally, 23 patients (46%) presented with leukopenia (mean leukocyte count 5337/mm^3) and 22 (44%) with thrombocytopenia (mean platelet count 136950/mm^3). MDS was present in 44% of the cases, while MGUS was identified in 26% (see "*Table 2*").

Genetic analysis identified the leucine variant as the most frequent UBA1 mutation (40%, n=20), followed by threonine (36%, n=18) and valine (16%, n=8). Four patients harbored other UBA1 mutations, two of which were classified as VUS (c.1798A >G, p.Thr600Ala and c.209T >A, p.Leu70His), previously unreported. Significant associations were found between leucine and MGUS, threonine and thrombocytopenia, and valine and renal involvement. Non-significant numerical trends included leucine with Sweet's syndrome (inverse with medium-vessel vasculitis), threonine with thromboembolic disease, and valine with multisystemic involvement ("*Image 1*").

"Table 1". Most common initial misdiagnoses.

Previous diagnosis	*n*
Seronegative arthritis	9
Relapsing polychondritis	7
Rheumatic polymyalgia	5
Sweet's síndrome	4
Systemic lupus erythematosus	3
Medium vessel vasculitis	3

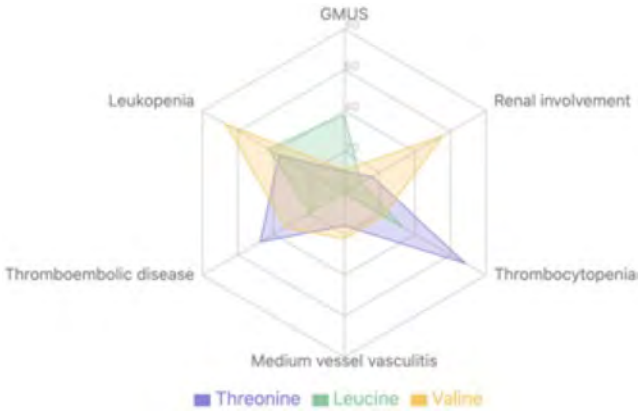
LCV	10 (20%)	5 (35%)	3 (16.66%)	2 (25%)	
Constitutional syndrome	38 (76%)	14 (70%)	15 (83,33%)	6 (75%)	
Non infectious fever	38 (76%)	13 (65%)	14 (77.77%)	8 (100%)	
Arthritis	38 (76%)	17 (85%)	14 (77.77%)	4 (50%)	
Chondritis	24 (48%)	11 (55%)	11 (61.11%)	2 (25%)	
Perichondritis	24 (48%)	11 (55%)	11(61.11%)	2 (25%)	
Nasal chondritis	8 (16%)	3 (15%)	4 (22.22%)	1 (12.5%)	
Ocular lesions	28 (56%)	8 (40%)	9 (50%)	2 (25%)	
Pulmonary involvement	19 (38%)	6 (30%)	7 (38.88%)	5 (62.5%)	
Tromboembolic disease	16 (32%)	4 (20%)	9 (50%)	3 (37.5%)	
Periorbital edema	13 (26%)	3 (15%)	7 (38.88%)	3 (37.5%)	
Renal involvement	11 (22%)	2 (10%)	4 (22.22%)	**5 (62.5%)**	**<0.01**
Splenomegaly	9 (18%)	5 (25%)	3 (16.66%)	1 (12.5%)	
Hepatomegaly	5 (10%)	1 (5%)	3 (16.66%)	1 (12.5%)	
Hypoacusis	9 (18%)	2 (10%)	5 (27.77%)	1 (12.5%)	
Medium vessel vasculitis	7 (14%)	0 (0%)	3 (16.66%)	2 (25%)	
Orchitis	5 (10%)	1 (5%)	3 (16.66%)	1 (12.5%)	
Epididymitis	4 (8%)	0 (0%)	3 (16.66%)	1 (12.5%)	
Cardiac involvement	3 (6%)	1 (5%)	1 (5.55%)	1 (12.5%)	
Anemia	47 (94%)	18 (90%)	18 (100%)	7 (87.5%)	
Leukopenia	23 (46%)	10 (50%)	7 (38.88%)	6 (75%)	
Thrombocytopenia	22 (44%)	7 (35%)	**13 (72.22%)**	2 (25%)	**<0.05**
MDS	22 (44%)	7 (35%)	8 (44.44%)	4 (50%)	
MGUS	13 (26%)	**8 (40%)**	2 (11.11%)	1 (12.5%)	**<0.05**
MM	7 (14%)	4 (20%)	1 (5.55%)	2 (25%)	



"Image 1". Mutations and main clinical associations.

Mortality occurred in 11 patients (22%), with only 6 deaths (12%) related to VEXAS activity. Periorbital edema was significantly associated with VEXAS-related death (5/6, p=0.006). No significant mortality differences were found between UBA1 variants.

Conclusion: Patients with VEXAS syndrome in this cohort are predominantly older males presenting with cutaneous, constitutional, and articular symptoms, reflecting a "*rheumatologic profile*". Specific genotype-phenotype correlations were identified (leucine: MGUS, threonine: thrombocytopenia, valine: renal involvement), along with potential severity markers (periorbital edema: mortality).

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: IgG4-related disease (IgG4-RD) is a rare immune-mediated condition characterized by fibrosclerosing inflammation, elevated serum and tissue IgG4 levels, and heterogeneous clinical manifestations. Several classification criteria have been proposed, including ACR/EULAR (2019) (1), Umehara (2011) (2), and Okazaki (2012) (3). The objective of this study is to analyze the concordance and differences among the main IgG4-RD classification criteria.

Methods: Observational multicenter study of patients diagnosed with IgG4-RD by expert rheumatologists across 25 Spanish hospitals. The ACR/EULAR, Umehara, and Okazaki classification criteria were applied to determine which patients fulfilled each set. Concordance between the criteria was assessed using PABAK index (prevalence- and bias-adjusted kappa). A Venn diagram was used to represent the overlap among the different criteria, illustrating how many patients fulfilled only one, shared more than one, or met none. Notably, patients who did not fulfill any of the established classification criteria but were diagnosed with IgG4-RD based on expert clinical judgment were categorized as having an exclusive clinical diagnosis. In addition, clinical, demographic, and laboratory data were analyzed for each subgroup.

Results: We include 68 patients (43 men/25 women) diagnosed as IgG4-RD by expert rheumatologists; mean age was 54.4 years. Of them 37 (54.4%) met Okazaki and ACR/EULAR criteria; 16 (23.5) were classified based exclusively on clinical criteria and 13 (19.1%) met Umehara. Concordance between criteria was variable. PABAK showed low-moderate agreement between ACR/EULAR and Umehara (PABAK 0.264), and between Umehara and Okazaki (PABAK 0.441), while the exclusive clinical criterion showed significant discordance, with negative PABAK values (**Table 1**). Patients classified according to Umehara showed a higher prevalence of pancreatic involvement (47.1%), whereas those classified by ACR/EULAR had more glandular involvement (32.4%). In contrast, the exclusive clinical group exhibited a less typical profile, with lower prevalence of pancreatic involvement (6.2%). Serum IgG4 levels were highest in the Umehara group (303.4 mg/dL). Additional clinical, laboratory, and complementary characteristics are shown in **Table 2**. When comparing the two most recent criteria, ACR/EULAR and Okazaki, no statistically significant differences were observed. According to the Venn diagram (**Figure**), only 8 patients met the three criteria simultaneously, 14 met only the Okazaki criteria, 9 met only ACR/EULAR, and none met exclusively Umehara criteria. The greatest overlap was between ACR/EULAR and Okazaki, with 15 patients meeting both sets of criteria.

Conclusion: Concordance among classification criteria was low. These results highlight the inherent challenges in diagnosing IgG4-related disease. Currently available criteria appear to prioritize different aspects of the disease, which may limit their ability to capture the complexity of the clinical picture and hinder their consistent application in clinical practice. A new universally accepted classification criteria for IgG4-related disease are still an unmet need.

Table 1. Concordance of Classification Criteria: PABAK (95% CI) Between ACR/EULAR, Umehara, Okazaki, and Exclusive Clinic

PABAK IC 95%	ACR/EULAR	Umehara	Okazaki	Exclusive Clinic
ACR/EULAR	-			
Umehara	0.264 (0.03 – 0.49)	-		
Okazaki	0.176 (-0.06 – 0.40)	0.441 (0.22 – 0.65)	-	
Exclusive Clinic	-0.558 (-0.68 – -0.29)	-0.294 (-0.45 – -0.05)	-0.558 (-0.68 – -0.29)	-

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: IgG4-related disease (IgG4-RD) is a systemic fibroinflammatory entity that can involve almost every organ, with characteristic histological features. Its pathogenesis remains poorly understood, clinical features are heterogeneous and unspecific, and recently released classification criteria have poorer performance in early recognition of the disease. Therefore, regrettably IgG4-RD continues to be underdiagnosed. Our objetives were a) To evaluate the clinical characteristics of patients diagnosed with IgG4-RD; and b) to compare it with other large series.

Reference	Cases	Sex Female (F)/ Male (M)	Age, median [IQR] or mean±SD	Diagnosis criteria	Number of organs affected	Level of serum IgG4 (mg/dL), median [IQR]
Lanzillotta et al. Rheumatology 2020	131	F (n=36), M (n=95)	62 [53-70]	-Umehara: possible (46%), probable (2%), definitive (52%)	-1 organ (26%) -More of 1 organ (74%)	224 [115-382]
An et al. Orphanet J Rare Dis 2022	127	F (n=35), M (n=92)	63 [55-69]	-Umehara: possible (82.6%), probable (2.3%), definitive (11.8%)	-1 organ (20%) -2-4 organs (68%) -More of 5 organs (9%)	980 [390-1520]
Zongfei et al. Clin Rheumatol 2021	102	F (n=25), M (n=77)	62 [54.1-65.8]	-Okazaki (100%)	Median [IQR]: 2 [1-3]	399 [199-776]
Wang et al. Arthritis Res Ther 2018	215	F (n=67), M (n=148)	54 [46-62]	-Umehara: possible (47.9%), probable (4.7%), definitive (47.4%)	-1-2 organs (36%) -3-4 organs (47%) -5 or more organs (17%)	896 [350-1860]
Inoue et al. Medicine (Baltimore) 2015	235	F (n=189), M(n=46)	67	-Symptoms+laboratory+image/ Compatible histology (100%)	-1 organ (41%) -2 or more organs (59%)	470 [ND]
Wallace et al. Arthritis Rheumatol 2015	125	F (n=49), M (n=76)	50,3±14.9	- Symptoms+laboratory+image/ Compatible histology (100%)	-1 organ (38%) -2 organs (24%) -3 or more organs (38%)	ND
Current series	68	F (n=25), M (n=48)	54 ± 15,16	-Okazaki: 51,4% -Umehara: possible (5,9%), probable (5%), definitive (45,6%) -ACR/EULAR 2020 (51.4%) -Symptoms+laboratory+image/ Compatible histology (23,6%)	-1 organ (26%) -2 organs (26%) -3 or more organs (46%)	109 [49.5-188]

TABLE. Main features of the patients with IgG4-RD in series of more than 100 patients and in current series

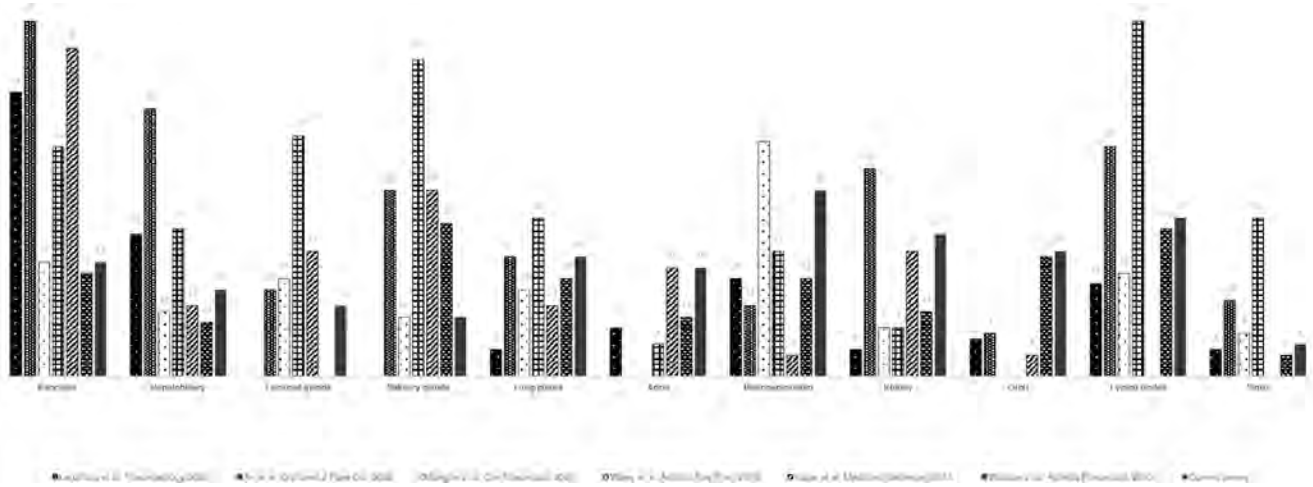

FIGURE. Involved organs in series of more than 100 patients and in current series. Data are in %

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Observational multicenter study of patients diagnosed with IgG4-RD and literature review. Diagnosis was made accordingly to these criteria: a) Okazaki; b) Umehara; c) ACR/EULAR 2020; and/or d) clinical, laboratory and imaging suggestive findings (1-3). For the literature review, we searched PubMed and the Cochrane library from its inception until 30 November 2024, selecting those series with the largest number of patients.

Results: We studied 78 patients diagnosed with IgG4-RD (48 males/25 females, mean±SD age; 54.4±15 years). The main affected organs were lymph nodes (n=29; 42,6%), retroperitoneum (n=23; 33.8%), kidney (n=18; 26.5%), orbit (n=16; 23.5%), aorta (n=14; 20.5%), lung/pleura (n=15; 22.%), pancreas (14; 20.6%), salivary glands (n=11; 16.1%), ear nose and throat (n=9; 16.6%), lacrimal glands (n=9; 13.2%), liver/biliary duct (n=11; 16.1%), pachymeninges (n=3; 5.5%), mesenterium (n=2; 3.7%) and other 9 (n=16.6%). IgG4 values were above 135mg/dL in 23 (33,8%) patients (median 109 mg/dL [IQR 49,5-188]). Median values of CRP and ESR were 2.6 mg/dL [IQR 0.77-13.6] and 29 mm/h [IQR 11-56], respectively. In the literature review, 6 series of more than 100 patients each were selected. The main data from the different series are listed in table. The figure shows the most frequently affected organs in the different series. The pancreas and salivary glands were less frequently involved in our series. In contrast, aortic, retroperitoneum and lung/pleura were more frequently involved than in most of the other series.

Conclusion: IgG4-RD is a very heterogeneous disease with involvement of virtually every organ of the anatomy, usually presenting with involvement of more than one organ. Despite the name of the entity, serum IgG4 is not always elevated.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Ocular involvement is a potential severe complication of Behçet's Disease (BD). The traditional classification, by the International Study Group (ISG, 1990) requires the mandatory presence of recurrent painful oral ulcers, whereas the International Criteria for BD (ICBD, 2013) uses a scoring system without mandatory oral ulcers.

Our objective was to assess the frequency and type of ocular manifestations accordingly to these classification criteria and compare the sensitivity and concordance of ISG versus ICBD, focusing on the impact of including or excluding ophthalmologic involvement and highlighting therapeutic implications.

Methods: Observational study of 142 BD, diagnosed by expert rheumatologists in Northern Spain (January 1980-November 2023). ISG and ICBD criteria were applied to these patients. Ocular manifestations included anterior, intermediate and posterior uveitis, panuveitis, dry eye, scleritis, episcleritis, and peripheral ulcerative keratitis (PUK). Proportions for each ocular manifestation were compared between the two classification sets, and p-values were provided to assess statistical significance. We calculated proportions for each ocular feature, assessed statistical significance (p-values), and evaluated sensitivity and concordance (Cohen's Kappa, Prevalence and Bias Adjusted Kappa - PABAK) when ocular involvement was included or excluded.

ICBD criteria showed greater sensitivity than ISG, specially due to the absence of oral ulcers in certain patients. Classifying these additional patients by ICBD facilitated the initiation of on-label biologic treatments (e.g., monoclonal anti-TNF), potentially improving the management of BD, particularly for those with ocular involvement and without oral ulcers.

Results: We studied 142 patients diagnosed as BD by expert rheumatologists, 84 met the ISG criteria while 116 met the ICBD criteria. Therefore, there were 32 additional patients with ICBD (**Table 1)**.

Among ISG-classified patients (n=84), ocular lesions were present in 49 patients (58.3%), while among ICBD-classified patients (n=116), 55 patients (47.4%) had ocular involvement (p=0.13). The frequency of uveitis (n=42; 50% ISG vs. n=47; 40.5% ICBD; p=0.18), and subtype (anterior, posterior, or panuveitis) were similar in both groups. With ocular inclusion, the non-adjusted Kappa was 0.405 (95% CI: 0.176–0.634), and the PABAK was 0.788, indicating strong agreement; without ocular inclusion, these values decreased to 0.443 (95% CI: 0.326–0.561) and 0.408 respectively, as shown on **Table 2**. Of the 32 patients classified as BD exclusively by ICBD, 7 were on anti-TNF therapy (3 infliximab, 4 adalimumab) and 2 on apremilast; 5 had uveitis and not oral ulcers with 1 receiving infliximab.

Table 1: Main clinical features according to different diagnosis criteria focusing on the ocular manifestations and biological treatments.

	Expert Diagnosis (N=142)	ISG criteria (N=84)	ICBD criteria (N=116)	ISG vs ICBD p value
Demographic data				
Age, mean (SD)	36.4 (13.9)	35 (12.8)	37 (13.2)	
Gender, n (%)				
Male	73 (51.4)	41 (48.8)	57 (49.1)	0.80
Female	69 (48.6)	43 (51.2)	59 (50.9)	0.59
Clinical Manifestations n (%)				
Oral aphthosis	135 (95.1)	84 (100)	115 (99.1)	0.99
Recurrent (3 times/year)	115 (81)	72 (85.7)	102 (87.9)	0.80
Genital aphthosis	88 (62)	67 (79.7)	88 (75.8)	0.63
Skin manifestations	91 (64.1)	74 (88.1)	79 (68.1)	0.01
Ocular lesions	60 (42.3)	49 (58.3)	55 (47.4)	0.13
Uveitis	52 (36.6)	42 (50)	47 (40.5)	0.18
Anterior	20 (14.1)	20 (23.8)	20 (17.2)	0.25
Intermediate	3 (2.1)	0	2 (1.7)	0.51
Posterior	14 (9.9)	11 (13.1)	13 (11.2)	0.68
Panuveitis	14 (9.9)	10 (11.9)	11 (9.5)	0.58
Unilateral	29 (20.4)	25 (29.8)	28 (24.1)	0.37
Bilateral	23 (16.2)	17 (20.2)	19 (16.4)	0.49
Dry Eye	8 (5.6)	7 (8.3)	8 (6.9)	0.71
Scleritis	0	0	0	0.99
Episcleritis	4 (2.8)	3 (3.6)	4 (3.4)	0.99
PUK	1 (0.7)	1 (1.2)	1 (0.86)	0.90
Joint manifestations	87 (61.3)	52 (61.9)	71 (61.2)	0.99
Neurological manifestations	29 (20.4)	13 (15.4)	22 (18.9)	0.65
Vascular manifestations	19 (13.4)	9 (10.7)	17 (14.6)	0.54
Complementary tests n (%)				
Pathergy test positive	7 (5)	6 (7.1)	6 (5.1)	0.78
HLA 51 Positive	51 (36)	25 (29.7)	38 (32.7)	0.76
Treatment n (%)				
Anti- TNF treatment	36 (25.3)	28 (33.3)	35 (30.1)	0.63
Infliximab	15 (10.5)	12 (14.2)	15 (12.9)	0.78
Adalimumab	20 (14.1)	15 (17.8)	19 (16.3)	0.78
Etanercept	1 (0.7)	1 (1.2)	1 (0.8)	0.99
Apremilast	10 (7)	7 (8.3)	9 (7.7)	0.88
Anti-IL6r (Tozilizumab)	1 (0.7)	0	0	0.99

Conclusion: ICBD criteria showed greater sensitivity than ISG, specially due to the absence of oral ulcers in certain patients. Classifying these additional patients by ICBD facilitated the initiation of on-label biologic treatments (e.g., monoclonal anti-TNF), potentially improving the management of BD, particularly for those with ocular involvement and without oral ulcers.

Table 2: Metrics for Modified Classification Criteria: Concordance Analysis After the Addition or Exclusion of Ocular Manifestations in All Patients.

	With Ocular Involvement	Without Ocular Involvement
Non adjusted Kappa (CI 95%)	0.405 (0.176 - 0.634)	0.443 (0.326 - 0.561)
Specific agreement + (CI 95%)	94.2% (72.1% - 83.1%)	74.4% (67.2% - 80.5%)
Specific agreement - (CI 95%)	44.4% (22.1% - 43.6%)	65.0% (56.1% - 72.9%)
Global agreement + (CI 95%)	89.4% (58.8% - 74.1%)	70.4% (62.5% - 77.3%)
Bias and prevalence indices		
Bias index	-10.6%	-29.6%
Bias adjusted Kappa	0.386	0.393
Prevalence index	81.0%	15.5%
Prevalence and bias adjusted Kappa (PABAK)	0.788	0.408

Abstract Number: 0273

Effector CD8+ T cells and PD-1hi CXCL13hi CD4+ T cells contribute to recurrent immune checkpoint inhibitor mediated inflammatory arthritis

Synat Keam[1], Yuanteng Li[2], Yanshuo Chu[1], Jean Tayar[3], Huifang Lu[4], Michael Wu[5], Sandeep Agarwal[6], Nitin Jain[7], Pavlos Msaouel[1], Adi Diab[2], Cara Haymaker[1], Linghua Wang[1], Roza Nurieva[8] and **Sang Kim**[9], [1]The University of Texas MD Anderson Cancer Center, houston, [2]MD Anderson Cancer Center, Houston, TX, [3]The University of Texas, MD Anderson Cancer Center, Houston, TX, [4]UT MD Anderson Cancer Center, Houston, TX, [5]Baylor College of Medicine, Houston, [6]Baylor College of Medicine, Houston, TX, [7]The Universty of Texas MD Anderson Cancer Center, Houston, [8]University of Texas MD Anderson, Houston, TX, [9]Yale University, Branford, CT

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Immune checkpoint inhibitor (ICI) therapy is associated with life- and/or organ-threatening immune-related adverse events, including inflammatory arthritis (ICI-IA). However, the mechanisms behind ICI-IA, especially when it recurs, have not been fully elucidated. Thus, longitudinal sample analyses provide valuable information to understand disease pathogenesis. The purpose of the study is to elucidate mechanisms of ICI-IA by analyzing longitudinal synovial fluid (SF) samples.

Methods: SF samples were collected from six ICI-IA patients at the first and second occurrences of the IA flare and analyzed with single-cell RNA sequencing (scRNAseq), scTCRseq, scBCRseq, and flow cytometry. SF samples from cancer-naïve osteoarthritis (OA) patients were used as negative controls.

Results: SF effector $CD8^+$ T cells and PD-1^{hi} $CXCL13^{hi}$ $CD4^+$ T cells were clonally expanded, implying their role in ICI-IA pathogenesis. Ninety three % of the top 10 expanded effector $CD8^+$ T cell clones were shared between the first and second ICI-IA flare, with 47% of them are being expanded in the second IA flare. For PD-1^{hi} $CXCL13^{hi}$ $CD4^+$ T cells, half of the top 10 clones were shared between first and second ICI-IA flares, and 60% of shared clones were expanded in the second IA flare. Effector $CD8^+$ T cells and PD-1^{hi} $CXCL13^{hi}$ $CD4^+$ T cells produced inflammatory cytokines including IFNg, TNFa, and IL-21, especially in the second ICI-IA. Trajectory inference analysis demonstrated that effector $CD8^+$ T cells were positioned after tissue-resident memory T cells and effector memory T cells. The trajectory within the $CD4^+$ T cells indicated that recently activated $CD4^+$ T cells have the developmental potential to become PD-1^{hi} $CXCL13^{hi}$ $CD4^+$ T cells. Effector $CD8^+$ T cells and PD-1^{hi} $CXCL13^{hi}$ $CD4^+$ T cells interact with each other and with myeloid immune cells via chemokines (CXCL9/10/11/13, CCL5) and cytokines (MIF, IL-2/7/15/21). Age-associated B cells, B cell population expanded in autoimmune diseases, were seen expanded in the second ICI-IA flare.

Conclusion: Effector $CD8^+$ T cells and PD-1^{hi} $CXCL13^{hi}$ $CD4^+$ T cells play a pivotal role in ICI-IA disease pathogenesis. These cells were more clonally expanded and produced more inflammatory cytokines in the second ICI-IA flare, implying immune memory responses. Understanding of these cells will shed light on therapeutic targets for ICI-IA and biomarkers to predict development or recurrence of ICI-IA, an emerging disease entity in rheumatology and oncology.

Abstract Number: 0274

Transplant-free survival in patients with systemic autoimmune rheumatic diseases and progressive pulmonary fibrosis in the ILD-PRO Registry

Sonali Bracken[1], Aparna Swaminathan[2], Jeremy M Weber[3], Megan L Neely[4], Scott Palmer[4], Erin Wilfong[5], Ann Chauffe[6], Elizabeth Volkmann[7] and ILD-PRO Registry investigators, [1]Duke University Medical Center, Durham, NC, USA, Apex, NC, [2]Duke University Medical Center and Duke Clinical Research Institute, Durham, NC, USA, Durham, NC, [3]Duke Clinical Research Institute, Durham, NC, USA, Durham, [4]Duke University Medical Center and Duke Clinical Research Institute, Durham, NC, USA, Durham, [5]Vanderbilt University Medical Center, Nashville, TN, USA, Nashville, TN, [6]Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, CT, USA, Newberry, FL, [7]Division of Rheumatology, Department of Medicine, University of California, David Geffen School of Medicine, Los Angeles, CA, USA, Los Angeles, CA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Progressive pulmonary fibrosis (PPF) is known to be associated with high mortality, but there are few data on the course of PPF in patients with interstitial lung disease (ILD) due to systemic autoimmune rheumatic diseases (SARDs). We evaluated time to death or lung transplant among patients with SARDs and PPF.

Methods: The ILD-PRO Registry enrolled patients who had an ILD other than idiopathic pulmonary fibrosis, reticular abnormality and traction bronchiectasis (with or without honeycombing) on HRCT, and met criteria for ILD progression within the prior 24 months. Patients were followed prospectively while receiving usual care. The Kaplan–Meier method was used to analyze time to death or lung transplant over 24 months in patients with the following SARDs: rheumatoid arthritis (RA), systemic sclerosis (SSc), idiopathic inflammatory myopathies (IIMs), interstitial pneumonia with autoimmune features (IPAF), mixed or undifferentiated connective tissue disease (CTD), Sjögren's disease, and other SARDs.

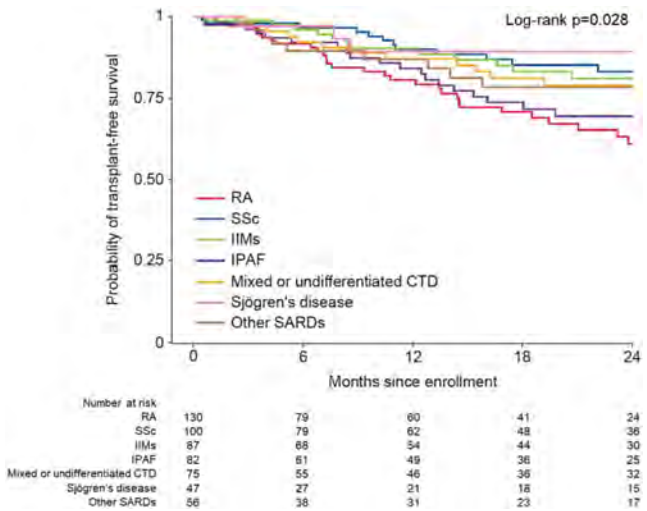

Figure. Kaplan-Meier estimate of time to death or lung transplant among patients with SARDs and PPF in the ILD-PRO Registry.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table. Characteristics of patients with SARDs and PPF at enrollment in the ILD-PRO Registry

	RA (n=130)	SSc (n=100)	IIMs (n=87)	IPAF (n=82)	Mixed or undifferentiated CTD (n=75)	Sjögren's disease (n=47)	Other SARDs (n=56)
Age, years	70 (62, 75)	60 (52, 70)	62 (53, 72)	74 (65, 77)	61 (54, 69)	71 (59, 76)	65 (51, 70)
Female	56.2	77.0	64.4	51.2	80.0	78.7	80.7
Ever smoker	48.5	26.0	39.1	47.6	36.0	31.9	39.3
FVC % predicted	61.7 (49.4, 71.5)	67.5 (53.2, 78.7)	62.0 (47.0, 72.7)	62.2 (47.6, 75.5)	60.6 (49.4, 69.8)	65.3 (55.9, 79.4)	66.7 (48.2, 76.9)
DLco % predicted	38.8 (29.6, 48.3)	38.2 (29.7, 51.8)	35.6 (27.4, 46.4)	36.3 (29.5, 47.3)	36.2 (25.9, 46.8)	45.4 (33.9, 55.4)	40.2 (30.4, 51.9)

Data are median (Q1, Q3) or % of patients with available data.

Results: A total of 577 patients in the ILD-PRO Registry had SARDs: 130 (22.5%) RA, 100 (17.3%) SSc, 87 (15.1%) IIMs, 82 (14.2%) IPAF, 75 (13.0%) mixed or undifferentiated CTD, 47 (8.1%) Sjögren's disease, and 56 (9.7%) other SARDs. Patient characteristics at enrollment are summarized in the Table. The probability of transplant-free survival at 24 months was 60.8% for RA, 83.0% for SSc, 80.9% for IIMs, 69.3% for IPAF, 78.8% for mixed or undifferentiated CTD, 89.2% for Sjögren's disease and 78.2% for other SARDs (Figure).

Conclusion: Patients with SARDs and PPF enrolled in the ILD-PRO Registry had a high probability of death or lung transplant over the following two years. The probability of transplant-free survival varied by type of SARD, with the worst survival in patients with RA and IPAF.

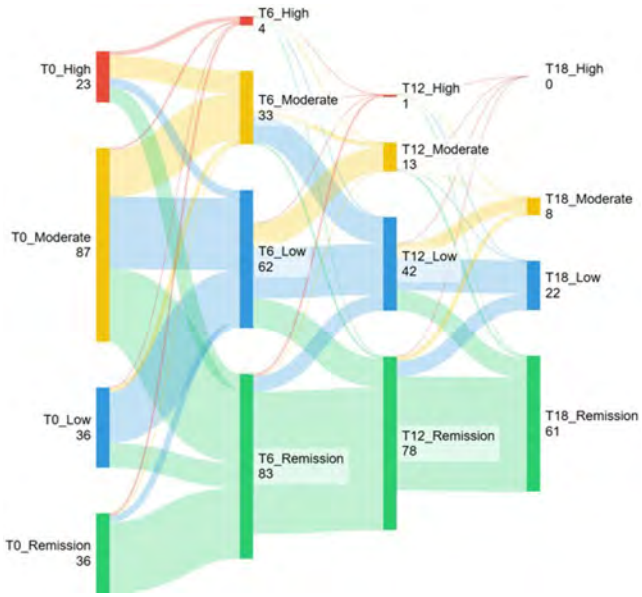
SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: A new subcutaneous formulation of infliximab (CT-P13) has recently become available for the treatment of inflammatory rheumatic diseases (IRDs), psoriasis and inflammatory bowel diseases. To date there are no real-life data on the use of this product nor is any real-world effectiveness evidence available in rheumatological settings. This study aims to provide a snapshot of subcutaneous infliximab (scIFX) use in IRDs evaluating treatment persistence and any factor able to influence drug retention rate (DDR).

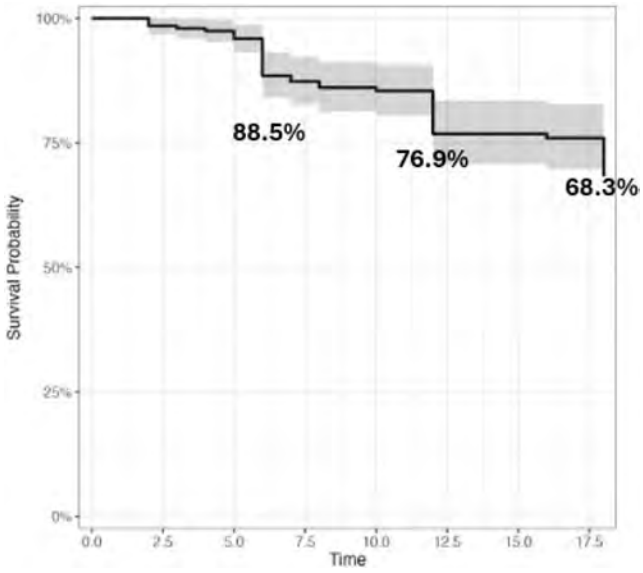
Methods: We conducted a multicentric observational retrospective study enrolling consecutive adult patients with immune-mediated diseases treated with scIFX for at least 6 months. Disease status was assessed with standard activity indexes according to diagnosis (i.e. DAS28 for rheumatoid arthritis (RA), DAPSA for Psoriatic Arthritis (PsA), ASDAS-CRP for Axial Spondyloarthritis and clinician's evaluation for the other conditions). Treatment persistence was assessed using the DRR at 6, 12, and 18 months. Factors influencing DRR were identified using the Log-Rank test.

Results: A total of 201 patients were included [134 women (66.7%), mean±SD age 49.9±13.8 years (range 18-82)]. Sixty-six (32.8%) patients had a diagnosis of AxSpA, 68 (33.8%) of PsA, 18 (9%) of RA, 18 (9%) of Behçet's disease (BD), 10 (5%) of Takayasu arteritis (TA), 16 (8%) of Juvenile Idiopathic Arthritis (JIA) (16; 8%) and 5 (2.5%) of other IRDs. Patients were treated with scIFX for a median duration of 14.0 months (IQR 13). Among them, 71 (35.3%) were treated with IFX as first-line biologic, 75 (37.3%) as second-line biologic and 55 subjects were treated as third or more line of treatment. Ninety-five (47.3%) patients were treated with intravenous (iv)IFX before switching to scIFX. Figure 1 shows our cohort disease status variations after scIFX start at the different timepoints. While starting scIFX, an induction regimen was used in 74 patients (78.3%), while 32 patients started scIFX every other week without any loading dose. The DRR for scIFX (Figure 2) was



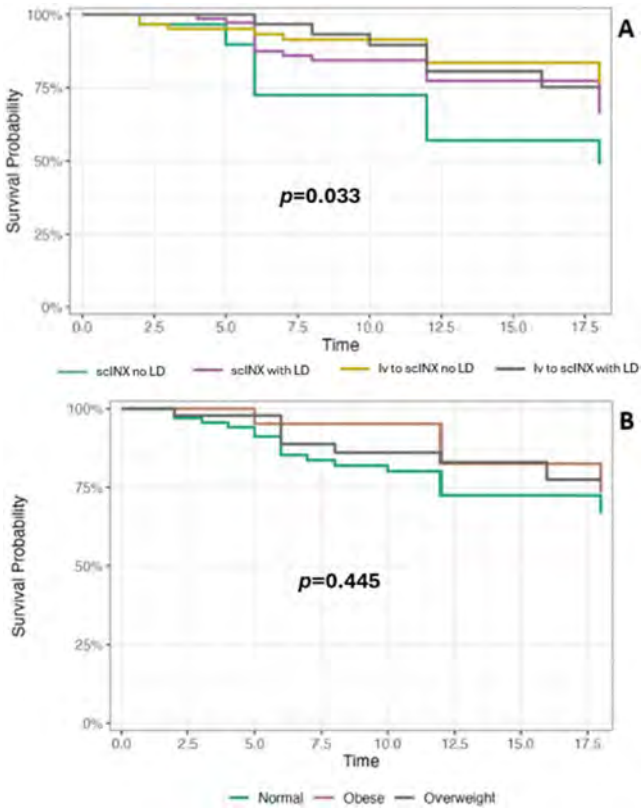
Disease status variation during the observation period.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



scIFX drug retention rate of the whole cohort

88.5% at 6 months, 76.9% at 12 months, and 68.3% at 18 months (Figure 2). DRR was significantly higher in patients switching from ivIFX than directly stating with scIFX (p=0.038). Patients starting scIFX without loading dose had a significant lower DRR (p=0.033) than those who underwent a loading dose both subcutaneously or intravenously (Figure 3A). Patients starting scIFX (no previous ivIFX) had a similar DRR regardless of the line of biologic treatment (p=0.066). Similarly, there were no differences in DRR among BMI classes in the whole cohort (p=0.445) (Figure 3B). Forty-seven subject (23.4%) discontinued scIFX during the observation time. Concerning safety, 21 patients (10.4 %) experienced adverse events.



A: Drug Retention rate according to scIFX initiation (switchers from ivIFX vs new scIFX treatments) and according to the performance of a loading dose (LD vs no-LD) at the start of treatment. B: Drug retention rate according to BMI classes.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: The study results suggest that scIFX provides sustained effectiveness over time for the treatment of IRDs. While factors such as line of treatment or BMI class do not affect DRR, the use of an induction dose appears to predict better treatment persistence.

Abstract Number: 0276

Plasma Proteomic Profiling Identifies Inflammatory Proteins and Pathways Associated With Non-idiopathic and Idiopathic Retroperitoneal Fibrosis

Thomas Pelowitz, Benjamin Hur, Kenneth Warrington, Jaeyun Sung and Matthew Koster, Mayo Clinic, Rochester, MN

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Retroperitoneal fibrosis (RPF) is a rare fibroinflammatory disease of the retroperitoneum that can lead to obstructive uropathy and other life-threatening complications. While RPF can arise secondary to malignancy, IgG4-related disease, or vascular inflammation, many cases remain idiopathic. Despite increasing awareness, diagnosis remains challenging due to reliance on non-specific imaging or invasive biopsy. Blood-based biomarkers capable of accurately distinguishing RPF from healthy individuals are needed to facilitate earlier and less invasive diagnosis.

Methods: Plasma from 45 individuals with RPF (Non-idiopathic: IgG4-related = 9, malignancy-associated = 3, Erdheim-Chester disease = 4, inflammatory abdominal aortic aneurysm = 4; Idiopathic = 19) and 6 healthy (non-disease) controls were profiled using the SomaLogic SomaScan 7K Assay, which quantifies over 7,000 proteins per sample. Differential abundance analysis was performed using linear regression analysis, adjusting for clinical and demographic covariates (e.g., age, sex, BMI, creatinine levels, platelet counts, hemoglobin, and IgG4 levels). Proteins significantly more or less abundant in RPF cases compared to control as well as idiopathic RPF compared to non-idiopathic RPF (significance criteria: $P < 0.05$ and mean fold-change $\geq 25\%$) were identified. A machine learning pipeline was trained to distinguish RPF cases, and its performance was estimated across 100 bootstrap iterations.

Results: A total of 176 plasma proteins were differentially abundant between RPF patients and controls while controlling potential confounders. Proteins notably elevated in RPF included those associated with inflammation and immune dysregulation (e.g., Ferritin, Serum amyloid A [SAA], and T-cell immunoglobulin and mucin domain-containing protein 3 [TIMD3]). Pathway enrichment analyses found that these differentially abundant proteins mainly participated in fibrosis-related inflammatory tissue remodeling processes, such as cytokine-chemokine signaling, apoptosis, interleukin signaling, and integrin-mediated cell adhesion pathways. We also identified protein differences amongst etiological subtypes of non-idiopathic RPF. Additionally, 80 proteins showed differential abundance between idiopathic and non-idiopathic forms of RPF, including chemokine ligand 7 (CCL7) and junction adhesion molecule-like 1 (JAML1). Non-idiopathic RPF subtype-specific analyses further identified proteins uniquely elevated within subtypes compared to controls. Finally, an Extra-Trees classifier trained on these plasma protein profiles demonstrated potential in distinguishing RPF cases from controls, achieving a mean ROC-AUC of 0.81.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: This study identifies key inflammatory proteins and immune-related pathways significantly associated with RPF. In all, these plasma-derived proteins offer promising candidates for minimally invasive diagnostics, as well as provide insight into systemic inflammatory mechanisms underlying RPF pathology. Looking ahead, follow-up studies incorporating disease controls will be necessary to further validate specificity and clinical utility.

Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Interleukin 1 receptor associated kinase 4 (IRAK4) degradation may modulate toll-like receptor signaling and alleviate symptoms in rheumatoid arthritis and atopic dermatitis.[1,2] BGB-45035, an orally administered CDAC, targets IRAK4 and in animal models, demonstrated a PK/PD association with suppression of IL-33–induced skin inflammation.

Table 1. TEAEs Occurring in ≥3 Participants by Preferred Term (Parts A-C; Safety Analysis Set [N=116])

Table 2. BGB-45035 Geometric Mean (CV% GM) PK Parameters After Single- and Multiple-Dose Administration

Cohort A1-6: SAD		
Dose	C_{max}, ng/mL	$AUC_{0\text{-}inf}$, ng·h/mL
X	44.1 (48.4)	2560 (40.3)
3X	103 (67.6)	6370 (59.2)
6X	149 (57.6)	11,300 (57.6)
12X	202 (64.6)	15,400 (12.2)
18X	350 (35.4)	28,500 (41.1)
30X	388 (36.1)	33,700 (42.2)

Cohort B1-4: MAD				
Dose	T_{max}, h	C_{max}, ng/mL	$AUC_{0\text{-}tau}$, ng·h/mL	AR AUC
X	4.00	190 (34.1)	2680 (26.5)	6.05 (17.6)
2X	4.00	265 (36.6)	4130 (18.1)	5.18 (54.5)
4X	4.00	455 (39.5)	6790 (22.8)	5.03 (30.1)
6X	4.00	369 (68.7)	5920 (55.2)	5.20 (10.5)

Cohort C1-3: MAD				
Dose	T_{max}, h	C_{max}, ng/mL	$AUC_{0\text{-}tau}$, ng·h/mL	AR AUC
2X	4.00	340 (40.7)	5100 (20.4)	6.38 (18.9)
4X	4.00	596 (28.8)	9810 (28.8)	6.86 (43.7)
6X	4.00	658 (26.6)	11,783 (30.0)	7.67 (45.2)

Geometric mean (CV% GM) values are rounded to three significant digits. T_{max} values are presented as median.

AR AUC, accumulation ratio for day 14/day 1 area under the plasma concentration-time curve over the last 24-hour dosing interval; $AUC_{0\text{-}inf}$, area under the plasma concentration-time curve from time zero extrapolated to infinity; $AUC_{0\text{-}tau}$, area under the plasma concentration-time curve over a dosing interval; C_{max}, maximum observed plasma concentration; CV% GM, geometric coefficient of variation; MAD, multiple ascending dose; PK, pharmacokinetic; SAD, single ascending dose; T_{max}, time to maximum plasma concentration.

This first-in-human study of BGB-45035 has 6 parts, data from parts A–C are reported. Parts A (single ascending dose [SAD]) and B (multiple ascending dose [MAD]) were in healthy participants; part C assessed MAD in healthy Chinese participants (China only). Objectives were to assess the safety, tolerability, PK, and PD of BGB-45035.

Methods: Participants were aged 18-55 years, with a body mass index of 18-32 kg/m^2. Parts A-C were double-blind and placebo controlled. Part A (SAD) comprised 6 cohorts (X, 3X, 6X, 12X, 18X, 30X dosages); in each cohort, 6 participants received BGB-45035, and 2 participants received placebo. Participants were randomized (5:1) to BGB-45035 or placebo. Parts B and C (MAD) comprised 4 cohorts (X, 2X, 4X, 6X dosages) and 3 cohorts (2X, 4X, 6X dosages), respectively. Participants in both parts were randomized (3:1) to BGB-45035 or placebo once daily (QD) for 14 days. Adverse events and serious adverse events (SAEs) were monitored. PK parameters were estimated from plasma concentration data. PD assessments included IRAK4 protein concentration extracted from whole blood and cytokine production from ex vivo stimulated from whole blood.

Results: As of April 7, 2025, 80 participants (all men) were enrolled in parts A (n=48; median age 29 [range, 20-54] years) and B (n=32; median age 28 [range, 19-54] years) and 36 were enrolled in part C (median age 27 [range, 18-44] years). All active doses were generally well tolerated. No dose-dependent toxicity was observed; no safety signals were identified. Upper respiratory tract infection was the most common treatment-emergent adverse event, all were mild in severity (**-Table 1**). One SAE, delirium, was considered severe but not treatment-related, and led to treatment discontinuation.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

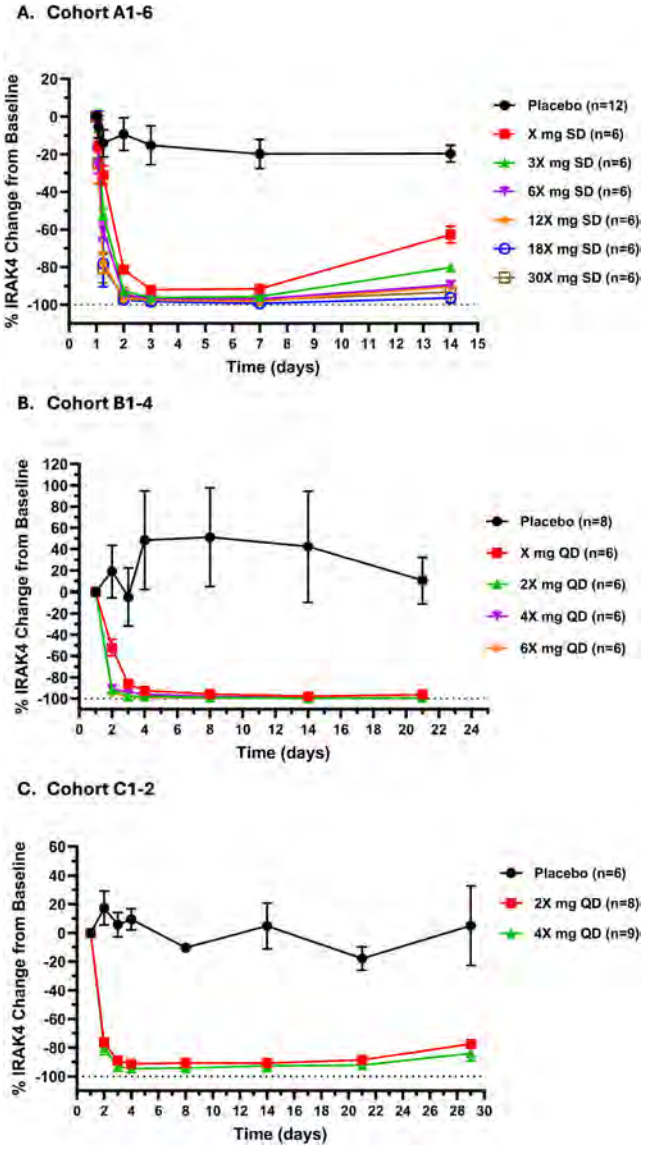

Figure 1. Mean Percent Reduction of IRAK4 in Part A-C

Dose-dependent PK increases were observed with doses of X-30X, with maximum concentration observed at a median of 4 hours and a mean terminal half-life ($t_{1/2}$) ranging from 58.5 to 95.6 hours across dosage groups (**Table 2**). Consistent with $t_{1/2}$, a ≈5-6–fold increase in exposure was observed on day 14 with BGB-45035 QD dosing. Substantial IRAK4 degradation was observed via whole blood assay after BGB-45035 dosing (**Figure 1**).

Conclusion: BGB-45035 is a potent IRAK4 degrader that was generally well tolerated in healthy participants, with a favorable safety and PK profile over a 14-day dosing period. This supports continued evaluation of BGB-45035 as a therapy for autoimmune diseases.

Abstract Number: 0278

Classic and Clinically Amyopathic Dermatomyositis: Autoantibody Positivity

Xiwei Yang[1], Shae Chambers[2], Aretha On[1], Hammad Ali[2], Touraj Khosravi[3], Lais Lopes Almeida Gomes[2], Rui Feng[4] and Victoria Werth[5], [1]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA, [3]Department of Dermatology, Perelman Shool of Medicine, University of Pennsylvania, Philadelphia, PA, [4]Center for Clinical Epidemiology and Biostatistics, University of Pennsylvania, Philadelphia, Pennsylvania, Philadelphia, PA, [5]University of Pennsylvania, Wynnewood, PA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0233–0279) Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Dermatomyositis (DM) is an idiopathic inflammatory myopathy subclassified as classic (CDM) and clinically amyopathic (CADM). It can involve myositis-associated (MAA) and myositis-specific (MSA) autoantibodies. Many MSA are associated with specific DM subsets, which helps in disease monitoring and prognostication. However, few studies have compared the positivity rates of all commonly tested MAA and MSA in CDM versus CADM.

Methods: We performed a retrospective cross-sectional review of CDM and CADM patients in our IRB-approved DM database at the University of Pennsylvania who had myositis autoantibody testing between April 01, 2016 and October 31, 2024. MAA included anti-SSA, -Pm-Scl, -Ku, -U1-RNP, -U2-RNP, and -U3-RNP. MSA included anti-Jo-1, -PL-7, -PL-12, -EJ, -OJ, -Mi-2, -SRP, -TIF-1γ, -NXP-2, -MDA5, and -SAE. ANA status was also recorded. The relation between DM subtype and autoantibody positivity rate was assessed using chi-square and Fisher's exact tests with $\alpha = 0.05$.

Results: We identified 320 patients tested at mean age 52.6 ± 14.4 years; 198 (62%) were CDM and 122 (38%) CADM. MSA positivity rate was 47% (94/198) in CDM vs. 40% (49/122) in CADM, $p = 0.20$. Though typically seen in CADM, anti-MDA5 was comparably positive in CDM (8%, 13/166) and CADM (10%, 10/97), $p = 0.49$. Although anti-NXP2 was more common in CDM (10%, 16/162) than in CADM (5%, 5/94), the difference was not statistically significant ($p = 0.20$). Anti-TIF-1γ was the most common MSA in both subtypes (CDM 17%, 29/169; CADM 22%, 21/97). MAA positivity rate was 29% (48/168) in CDM vs. 26% (26/100) in CADM, $p = 0.65$. Anti-SSA was the most common MAA in both subtypes (CDM 21%, 33/159; CADM 19%, 18/94). ANA was positive in 63% (90/143) CDM vs. 49% (42/85) CADM, $p = 0.045$. Of the patients with negative myositis panels, 26/53 (49%) CDM and 13/36 (36%) CADM were ANA positive.

Conclusion: We found that MSA and MAA positivity rates did not differ significantly between CDM and CADM ($p > 0.05$), whereas ANA was significantly more common in CDM ($p < 0.05$). A sizeable portion of DM was ANA positive despite negative MSA and MAA, which suggests that there may be other DM-related autoantibodies not yet discovered. These results reiterate that DM management requires integrating clinical and lab findings and should not solely depend on autoantibody status.

Background/Purpose: IgG4-related disease (IgG4-RD) is a progressive, systemic, fibroinflammatory disease characterized by unpredictable and recurring flares, leading to organ damage and decreased quality of life. Inebilizumab is a humanized, glycoengineered, CD19-directed, monoclonal antibody that depletes CD19+ B cells, including plasmablasts and some plasma cells, effectively in a targeted manner. MITIGATE (NCT04540497) is an international, randomized, blinded, placebo-controlled Phase 3 trial that evaluates the safety and efficacy of inebilizumab as treatment for IgG4-RD. The aim is to evaluate the safety and efficacy of inebilizumab across various baseline disease characteristic subgroups of participants enrolled in the study.

Methods: Adult participants who met the ACR/EULAR Classification Criteria for IgG4-RD with a score ≥20 were enrolled in the study. Eligible participants had a history of multiorgan IgG4-RD and had experienced an IgG4-RD flare that required glucocorticoid treatment during the screening period. Additional eligibility criteria and study design have been previously reported (Stone et al, 2024). The primary endpoint (time to first adjudication committee (AC)-determined and investigator-treated IgG4-RD flare during the RCP) and all key secondary endpoints were met in the overall study population. This post

Table 1: Baseline Disease Characteristics

Subgroup	PBO, N=67	INEB, N=68	Overall, N=135

CD20 B cell count				
< Median	6/33 (18.2)	16/26 (61.5)	7.54 (2.25, 25.21)	.0010
≥ Median	5/24 (20.8)	21/35 (60.0)	5.72 (1.73, 18.91)	.0043
Prior Maintenance Therapy				
Yes	0/12 (0.0)	6/11 (54.5)	N/A[c]	N/A[c]
No	15/55 (27.3)	34/57 (59.6)	3.94 (1.78, 8.72)	.0007

[a]Flare-free, corticosteroid-free complete remission is defined as the absence of evident disease activity at week 52; defined as an IgG4-RD Responder Index score of 0 or determination by the investigator that no disease activity is present (on the basis of physical, laboratory, pathology, or other evidence), no AC-determined flare during the RCP of the trial, and no corticosteroid treatment for flare or disease control beyond the protocol required prednisone taper.
[b]P-values should be interpreted with caution due to the questionable reliability of the statistical test based on the small sample sizes.
[c]Not estimable due to 0% response in placebo arm.

hoc subgroup analysis evaluated safety and efficacy of inebilizumab across baseline characteristics: disease duration, IgG4 serum level, ACR/EULAR score, CD20 B-cell count, and prior maintenance therapy.

Results: 135 participants were randomized and received at least one dose of inebilizumab (n=68) or placebo (n=67). Baseline disease characteristics were generally well balanced between the 2 treatment groups for subgroups (Table 1). Inebilizumab treatment substantially reduced the risk of flare relative to placebo in all subgroups (Table 2), with each subgroup exhibiting a hazard ratio similar to the overall study population. Annualized flare rates were reduced by inebilizumab relative to placebo in all subgroups. Proportions of participants achieving flare-free, treatment-free complete remission or flare-free, corticosteroid-free complete remission at Week 52 were increased by inebilizumab in all subgroups with sufficient representation to permit analysis (Table 3). No subgroup exhibited safety findings that were substantially different from those observed in the overall population.

Conclusion: The MITIGATE trial demonstrates the consistent benefit and safety of inebilizumab across all baseline disease characteristic subgroups analyzed. Inebilizumab represents a viable treatment option for all patients, regardless of their IgG4-RD baseline disease characteristics.

Abstract Number: 0280

Sera from dermatomyositis patients induce muscle weakness via activation of type I interferon (IFN) receptors

Suchada Kaewin[1], Cecilia Leijding[2], Kristofer Andreasson[2], Helene Alexanderson[3], Stefano Gastaldello[1], Ingrid Lundberg[2] and **Daniel C. Andersson**[2], [1]Karolinska Institutet, inst fysiologi och farmakologi, Stockholm, Sweden, [2]Karolinska Institutet, Stockholm, Sweden, [3]Karolinska University Hospital, Stockholm, Sweden

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0280–0305) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Dermatomyositis (DM) is a major subtype of idiopathic inflammatory myopathies (IIMs) and characterized by muscle weakness, systemic inflammation and cutaneous lesions. Expression of type I interferon (IFN)-stimulated genes have been found in muscle, skin tissue and peripheral blood cells which links to disease activity in DM patients. However, the mechanisms of muscle weakness in DM are incompletely understood. For instance, it is unclear to what degree systemic factors, eg IFN signalling, contribute to muscle weakness and disease phenotypes. This study aims to investigate whether inhibition of type I IFN signaling protects DM serum-induced muscle weakness and to determine the effects of IFN-a and/or IFN-b on muscle force generation.

Methods: An experimental platform was used in which isolated mouse muscles were exposed to DM patient serum or healthy control serum. Flexor digitorum brevis (FDB) muscles were isolated from healthy C57BL/6JRj mice and exposed to 10% dilution of serum from healthy controls or serum from DM patients for 24 hours. To determine whether inhibition of type I IFN protect DM serum-induced muscle weakness, an IFN-a/b receptor 1 (IFNR) blocking antibody was used. Isolated FDB muscles were pre-incubated with IFNAR1 antibody for 2 h and thereafter muscles were incubated in serum from DM patients with or without IFNAR1 antibody. To investigate the effect of IFN-a and/or IFN-b on muscle force generation, FDB muscles were incubated in 10% healthy control serum containing of 1,000U/ml of IFN-a and/or IFN-b. Muscle force was measured before and after incubation in a paired fashion.

Results: Serum from DM patients, but not from healthy controls, induced a decline in FDB muscle force. Treatment with an anti-IFN1R antibody protected from the DM serum-induced muscle force decline. Surprisingly, neither IFN-a nor IFN-b affected force production when incubated for 24h in isolation with the muscles. However in combination, IFN-a together with IFN-b, induceed a marked reduction in muscle force, which was rescued with addition of an IFN1R blocking antibody.

Conclusion: Serum from DM patients contain factors that can induce muscle weakness. One mechanism for this effect is mediated by pathways dependent on type I IFN Receptor signaling.

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are a heterogeneous group of systemic autoinflammatory diseases that affect muscle tissue, often leading to muscle atrophy, weakness and myalgia. While IIM patients frequently present with myositis-specific or myositis-associated autoantibodies, less is known about the presence and function of natural anti-cytokine autoantibodies (ACAAs). Some studies report their presence in healthy individuals, suggesting a role in tissue homeostasis and regeneration, while others have found elevated levels in autoimmune diseases. The aim of this study was to measure serum levels of ACAAs directed against interleukin-6 (anti-IL-6) in IIM patients and assess their potential impact on IL-6 signalling, a pathway associated with inflammation-induced muscle wasting.

Methods: Serum samples were collected from 44 consecutive IIM patients treated at the Department of Rheumatology, University Medical Centre Ljubljana, and from 36 healthy controls (HC, Fig. 1). Patients were stratified into treatment-naive (n=13) and previously treated groups (n=31). ELISA was used to quantify serum IL-6 (BioLegend), soluble IL-6 receptor (sIL-6R, Proteintech), and anti-IL-6 levels (in-house ELISA). To assess the functional effects of anti-IL-6 antibodies, sera were mixed with recombinant human IL-6 (rhIL-6) and applied to a reporter gene assay (RGA, SVAR Life Science) that detects IL-6 signalling pathway activity. In treatment-naive patients, the relationship between RGA activity and markers of muscle damage was evaluated.

Results: Serum IL-6 levels were significantly higher in IIM patients than in HC, while sIL-6R levels showed no significant difference. Anti-IL-6 levels tended to be lower in IIM patients, but this difference did not reach statistical significance (p=0.08). RGA activity, indicating IL-6 signalling pathway activation, was markedly higher in IIM patients (p< 0.0001) and tended to be higher in individuals with low anti-IL-6 levels (Fig. 2). To rule out interference from endogenous IL-6 present in serum samples, control experiments were performed without the addition of recombinant human IL-6 (rhIL-6), confirming that the observed increase in RGA activity was not due to endogenous IL-6. Treatment status had no significant effect on the measured parameters, although treatment-naive patients exhibited higher IL-6 and lower anti-IL-6 levels. Among these patients, those with higher RGA activity tended to have lower manual muscle test scores and higher serum creatine kinase (CK) levels (Fig. 3).

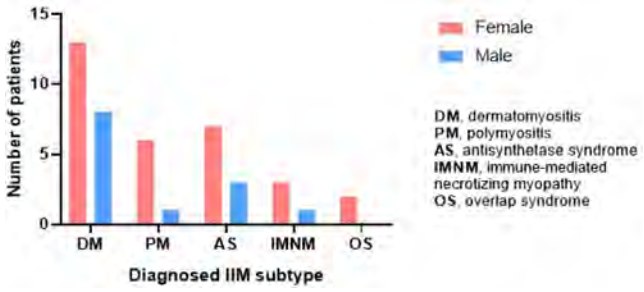

Figure 1: Number of IIM patients included in the study.

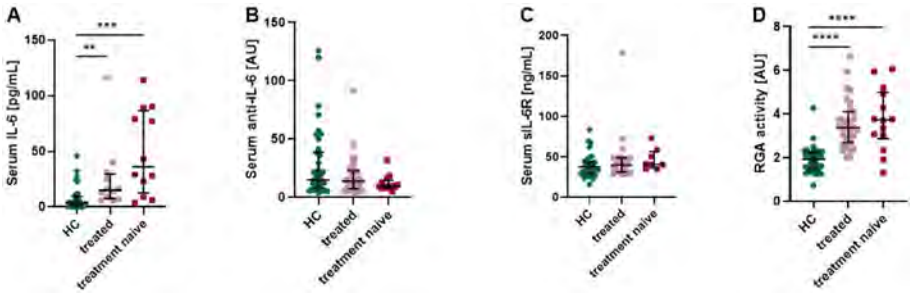

Figure 2: Serum levels of IL-6 (Fig. 2A), anti-IL-6 autoantibodies (Fig. 2B), soluble IL-6 receptor (Fig. 2C) and serum RGA activity (Fig. 2D) in treatment-naive or treated IIM patients and healthy controls. Kruskal-Wallis test: ** p<0.01; *** p<0.001; **** p<0.0001.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

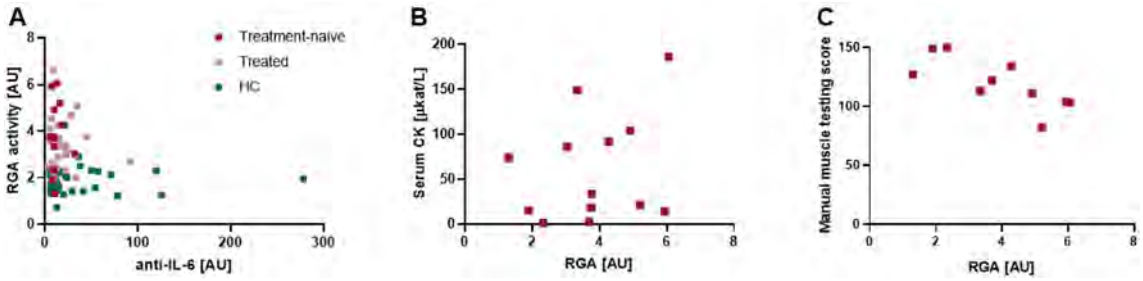

Figure 3: Correlation of RGA activity with anti-IL-6 autoantibodies in serum of treatment-naive or treated patients and healthy controls (Fig. 3A). Correlation of serum creatine kinase levels (Fig. 3B) and manual muscle testing score (Fig. 3c) with RGA activity in treatment-naive patients.

Conclusion: Sera from IIM patients showed enhanced IL-6 signalling activity, independent of the treatment status and serum IL-6, or sIL-6R levels. Based on the inverse relationship between anti-IL-6 levels and RGA activity, we hypothesise that these autoantibodies may neutralise IL-6 signalling. In treatment-naive patients, elevated RGA activity was associated with markers of muscle damage, indicating a pathological role of IL-6 signalling activity in muscle function in these patients.

Session Date: Sunday, October 26, 2025

Session Title: (0280–0305) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: The six myositis core set measures (CSMs) are widely utilized to assess disease activity in idiopathic inflammatory myopathies (IIM). However, their association with how the patient feels and functions, and minimal thresholds for clinically meaningful improvement, remain undefined.

We aimed to evaluate the validity, meaningfulness, and minimal clinical thresholds of change in CSMs in relation to symptoms, function, and quality of life in patients with IIM.

Methods: Adults with IIM were enrolled in a 6-month prospective observational study. Monthly data collected included CSMs (patient global assessments, Health Assessment Questionnaire [HAQ] and creatine kinase [CK]) and patient-reported outcome measures (PROMs) such as pain and fatigue (VAS), Short Form-36 (SF-36), and PROMIS-Physical Function (PROMIS-PF). Physician measures, including MMT-8 (scale 0-80), MDAAT, and physician global assessments, were

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Longitudinal correlations between core set measures (CSMs) and outcome measures using linear mixed models adjusted for age, sex, and race. Most CSMs showed strong associations with patient-reported outcomes and other clinical metrics, supporting their validity in tracking disease activity in IIM.

Table 1. The correlation of the myositis CSMs with other myositis CSMs and outcome measures during the follow-up period, using a linear mixed model, adjusted for sex, age, and race.

gathered every three months. Baseline and longitudinal associations were evaluated using Spearman correlation and linear mixed models. Responsiveness, effect sizes, and clinically important differences (CID) were assessed using patient- and physician-reported change at 6 months as anchors.

Results: Fifty patients (mean age 51.6 ± 14.9, 60% females) were enrolled, including 48% dermatomyositis, 12% polymyositis, 18% necrotizing myopathy, and 22% anti-synthetase syndrome. Most CSMs demonstrated strong baseline and longitudinal associations with key patient- and clinician-reported outcome measures, including pain, fatigue, physical function, and quality of life. CK showed weaker associations at baseline, but significant longitudinal correlations with most outcome measures (**Table 1**). In patients with improvement in absolute percentage change in the CSMs and TIS over 6 months, corresponding positive trends were observed in quality of life (PCS, MCS), fatigue (VAS), pain (VAS), and physical function (PROMIS-PF) (**Figure 1**). Specifically, greater improvements in patient and physician global assessments, disability (HAQ-DI), and muscle strength (MMT) were associated with incremental gains in quality of life and physical function measures, along with reductions in fatigue and pain).In patients who improved based on the patient global impression of change (PtGIC) and physician global impression of change (PhGIC) anchors, significant improvements were observed in physician global disease activity, MMT, HAQ-DI, CK, and extra-muscular disease activity, with moderate to large effect sizes. The CIDs according to PtGIC were 2.1 for physician global disease activity, 1.4 for extra-muscular disease activity, 1.7 for patient global disease activity, 4.2 for MMT, 0.5 for HAQ, and 1475 IU/L for CK levels. Similar results were observed for physician-reported improvement (**Table 2**.

Conclusion: Myositis CSMs showed strong validity and responsiveness, reflecting meaningful changes in patient symptoms, function, and quality of life, and supporting their utility in IIM clinical trials and practice. CIDs were defined for all CSMs, improving their interpretability and application in clinical trials and routine care.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0280–0305) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Idiopathic inflammatory myopathies (IIM; including dermatomyositis, polymyositis, and inclusion body myositis) are heterogenous systemic inflammatory conditions that cause significant disability and morbidity. The study of these rare diseases (prevalence of 10-20/100,000) is limited by our ability to accurately classify cases with a high positive predictive value (PPV). Rule-based algorithms that rely on ICD codes have been used to identify IIM prevalence based on administrative claims and IIM hospitalizations with reported PPVs of 90% or higher. The objective of this study was to apply published rule-based ICD-based algorithms to electronic health record (EHR) data to identify IIM cases to build an IIM cohort.

Methods: Data was extracted from a multihospital EHR system. We identified patients with $\geq$1 ICD 9/10 codes for IIM (359.7*, 710.3, 710.4, G72.4*, M33.*, M36.*) between 1/1/2000 - 9/6/2024; from this set, a random sample of 250 patients were selected for chart review. Subjects were classified as having "definite", "probable", "possible", or "unlikely" IIM per the 2017 EULAR/ACR Classification Criteria. ICD codes were extracted for all subjects. The performance of 8 previously published rule-based algorithms for IIM were compared against "definite" cases of IIM from chart review. Algorithms developed using ICD-9 codes were updated to map to ICD-10 codes. Reviews were performed by two independent reviewers (ALV, AV) and discrepancies were adjudicated by a blinded third reviewer (RLC). As the goal was to create an IIM cohort for study, the key performance characteristic of interest was PPV. Specificity, sensitivity, and negative predictive value (NPV) were also calculated.

Results: We identified 5706 patients with $\geq$1 IIM ICD 9 or 10 code from the EHR. The prevalence of definite IIM in this cohort was 34.8% (Table 1). M33.* (dermatopolymyositis) was the most common code (35.2%) in the cohort. The highest PPV achieved was 65% with $\geq$2 IIM ICD codes in the outpatient setting within 2 months (Algorithm 1) and IIM ICD codes used $\geq$2 times between 30 and 365 days (Algorithm 7, Table 2). Algorithm 7 classified 67.8% of definite IIM cases. The algorithm achieving the highest specificity at 94% had low sensitivity (16%) (Algorithm 5, Table 2).

Rheumatol Adv Pract. 2022;6(3):rkac102; with the exclusion of interstitial lung disease and less specific codes (M60.8 for Other Myositis, M60.9 for Myositis unspecified). Algorithms 3, 4, 7 based on Smoyer-Tomic et al. BMC Musculoskelet Disord. 2012;13:103; mapped to ICD 10 codes.

Conclusion: The best performing rule-based IIM algorithms correctly classified 65% of definite IIM cases. The lower performance from prior reports may be due to the different patient populations and lack of direct mapping of ICD-9 codes to ICD-10 codes. Future directions include considering a broader range of EHR data including IIM treatments or data extracted using natural language processing related to IIM characteristics to improve the ability to accurately classify IIM cases at high PPV (≥80%); a crucial first step for IIM studies.

Abstract Number: 0284

Glucocorticoid Tapering and Relapse Risk in Anti-ARS Antibody-Positive Myositis: A Retrospective Study in a Single-Center Cohort Treated with Immunosuppressants

Ayaka Inoue[1], Takashi Yamane[2], Noriaki Yasuda[3] and Takahisa Ohnishi[1], [1]Kakogawa Central City Hospital, Kakogawa, Japan., kakogawa-cho, kakogawa city, Hyogo, Japan, [2]Kakogawa Central City Hospital, Kobe, Hyogo, Japan, [3]Kakogawa Central City Hospital, Kakogawa, Japan

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0280–0305) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Anti–synthetase syndrome is generally responsive to glucocorticoid (GC) therapy, though relapse frequently complicates tapering. Prolonged GC use is associated with adverse events and decreased quality of life, yet the optimal maintenance dose to prevent relapse remains unclear. While immunosuppressants (IS) are often used in combination with GC to prevent disease recurrence, the risk of flare in patients treated with both remains insufficiently understood.

Methods: We retrospectively reviewed patients with anti–aminoacyl–tRNA synthetase (anti–ARS) antibody-positive myositis, identified by enzyme immunoassay (LSI Medience), treated at our institution between April 2018 and September 2024. Among 45 patients identified, 37 who received GC and had ≥26 weeks of follow-up were included. Clinical characteristics, relapse, GC tapering, and IS use were analyzed. Multivariate Cox proportional hazards, ROC curve, and Kaplan–Meier analyses were performed.

Results: Of the 37 patients, 21 were female (57%) with a mean age of 64 years; 33 had interstitial lung disease. Methylprednisolone pulse therapy was given in 10 cases; the average initial prednisolone (PSL) dose was 39 mg/day (0.7 mg/kg). IS was used in 36 of 37 cases (97%).

Table 1. Predictive Factors for Relapse in Patients with Anti-ARS Antibody Syndrome: Univariate and Multivariate Cox Proportional Hazards Models

Table 1. Predictive Factors for Relapse in Patients with Anti-ARS Antibody Syndrome: Univariate and Multivariate Cox Proportional Hazards Models

A. Baseline Clinical and Disease Characteristics

Variable	Univariate HR (95% CI)	p-value	Multivariate HR (95% CI)	p-value
Disease duration (days)	1.00 (0.99 – 1.001)	0.18	—	—
Arthritis	1.25 (0.53 – 2.97)	0.61	0.93 (0.37 – 2.35)	0.88
Mechanic's hands	1.10 (0.43 – 2.93)	0.83	1.47 (0.53 – 4.00)	0.46
Raynaud's phenomenon	3.89 (1.33 – 11.40)	0.013	3.80 (1.18 – 12.30)	0.026
Fever	3.61 (1.27 – 10.27)	0.016	—	—
ILD	25.66 (0.07 – 10093)	0.36	0 (N/A)	0.98

* Multivariate for ILD, arthritis, mechanic's hand, and Raynaud's phenomenon

B. Initial Treatment-Related Factors

Treatment	Univariate HR (95% CI)	p-value	Multivariate HR (95% CI)	p-value
Days to concomitant IS initiation	1.01 (1.00 – 1.02)	0.029	1.01 (1.00 – 1.03)	0.018
mPSL pulse therapy	1.28 (0.47 – 3.53)	0.63	1.63 (0.52 – 5.06)	0.401
Daily PSL dose at baseline	1.58 (0.29 – 8.74)	0.6	—	—
Daily PSL dose at 26 weeks	1.06 (0.91 – 1.26)	0.44	1.06 (0.88 – 1.26)	0.546
Daily PSL dose at 52 weeks	1.15 (0.90 – 1.47)	0.28	—	—

*Multivariate for age, Days until concomitant IS induction, mPSL pulse therapy, and Daily PSL(mg/kg).

Abbreviations: IS:immunosuppressants, mPSL:methylprednisolone:, PSL:prednisolone, HR:hazard ratio, CI:confidence interval

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Prednisolone Dose at Relapse in Anti-Jo-1 and Non-Jo-1 Anti-ARS Antibody Groups

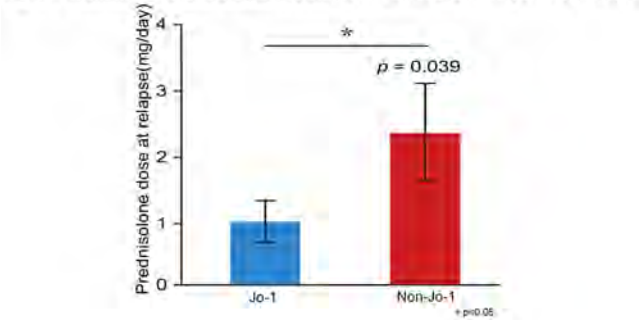

Figure2:Kaplan–Meier Curve for Relapse-Free Survival According to Prednisolone Dose at Week 26 (<3 mg/day vs ≥3 mg/day)

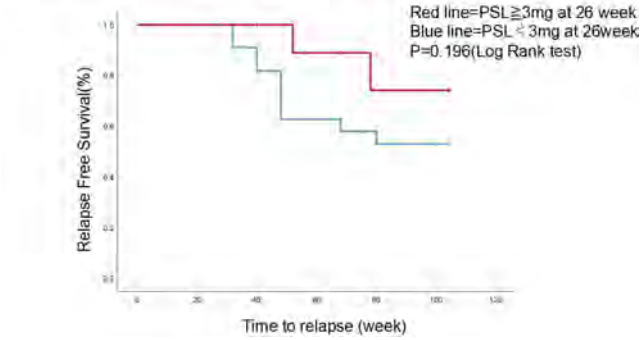

Anti–Jo–1 antibodies were positive in 9 patients, non–Jo–1 in 26, and untyped in 2. Relapse occurred in 5 Jo–1-positive (56%) and 16 non–Jo–1 (62%) patients (p = 1.00). No relapses were observed in the Jo–1 group when PSL reached 5 mg/day, while 5 relapses occurred in the non–Jo–1 group. The mean PSL dose at relapse was significantly lower in the Jo–1 group (1.0 vs. 4.3 mg/day; p = 0.039).

In multivariate Cox analysis, Raynaud's phenomenon (HR 3.8; 95% CI 1.18–12.3; p = 0.026) and longer interval until IS initiation (HR 1.01; 95% CI 1.00–1.03; p = 0.018) were independently associated with relapse. ROC analysis identified 1.55 mg/day as the optimal PSL cutoff to predict non-relapse (sensitivity 66.7%, specificity 68.8%). Relapse was more common in patients tapered to < 5 mg/day than those on ≥5 mg/day. KM analysis from week 26 to 104 showed a trend toward more relapse in patients < 3 mg/day (log-rank p = 0.196).

Conclusion: In this IS-treated cohort, Jo–1-positive patients were able to maintain remission on lower GC doses, with no relapses observed when PSL was tapered to 5 mg/day. However, relapse was more frequent in patients tapered below 5 mg/day, and a possible trend toward increased relapse was also observed below 3 mg/day. Although nearly all patients received IS, delayed initiation was associated with increased relapse risk. These findings support early immunosuppressant use and strategic tapering guided by clinical risk factors such as the presence of Raynaud's phenomenon and timing of IS initiation. Tapering GC doses to 3 mg/day may be possible with caution, although relapse risk should be carefully monitored in anti–synthetase syndrome.

Abstract Number: 0285

Delayed-Onset Myopathy in Dermatomyositis: A Retrospective Cohort Study

Connor Buechler[1], Nawang Singhe[2], Lindsey Wanberg[2], Cody Rasner[2], Joseph McGrath[2], Karen Baker-James[2], Rebecca Freese[2] and David Pearson[3], [1]University of Minnesota, Mendota Heights, MN, [2]University of Minnesota, Minneapolis, MN, [3]Department of Dermatology, University of Minnesota, Minneapolis, MN

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0280–0305) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Amyopathic dermatomyositis (ADM) is a subset of DM in which cutaneous findings occur without muscle disease for >6 months after diagnosis. However, there is limited data on the mean time to onset of muscle symptoms in classic DM (CDM). Differentiating ADM and CDM may affect treatment, screening for comorbidities including malignancy and interstitial lung disease, and clinical trial inclusion.

Methods: We performed a retrospective cohort study of adult DM patients at an academic tertiary referral center to determine the mean time to onset of muscle symptoms in CDM and characterize the presentation of patients who develop muscle symptoms >6 months after diagnosis. Patients were reviewed to confirm diagnostic and demographic details, including the timing of muscle symptom onset relative to first cutaneous or pulmonary symptom onset and the time from presentation to formal diagnosis.

Results: 223 patients with DM were identified, of which the majority had CDM (172; 77%). 154 CDM patients had a clearly identifiable date of symptom onset. Median time to muscle symptoms was 0 months, with 24 (15.6%) developing muscle symptoms >6 months after first symptom onset. The onset of muscle symptoms in the delayed group ranged from 6.4 months to 42.4 months (median 13.3 months). Those with late onset muscle symptoms did not differ demographically from typical CDM or ADM patients, but they experienced a higher rate of ILD (33%) than either typical CDM (29%) or ADM (18%) patients and lower rate of DM-related death (0%) than either typical CDM (11%) or ADM (5.8%) patients. Those with late onset muscle symptoms also experienced a longer mean delay from presentation to diagnosis (8.4 months) than either ADM (4.3 months) or typical CDM (1.9 months) patients (ANOVA p=0.024).

Conclusion: Our results suggest that even patients diagnosed with ADM should be monitored for muscle weakness and pain. This study sheds further light on a subpopulation of DM patients with potentially disparate outcomes from either CDM or ADM, which could affect counseling, treatment, and clinical trial inclusion.

Abstract Number: 0286

Anifrolumab for Treatment of Refractory Juvenile Dermatomyositis in Adult Patients

Connor Buechler[1] and David Pearson[2], [1]University of Minnesota, Mendota Heights, MN, [2]Department of Dermatology, University of Minnesota, Minneapolis, MN

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0280–0305) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Juvenile dermatomyositis (JDM) is an autoimmune connective tissue disorder with a chronic, relapsing course that can persist into adulthood. Current therapies exhibit widely variable efficacy. While JDM pathogenesis remains incompletely understood, continuous activation of type-I interferon (IFN) signaling is thought to play a key role, leading to changes including activation and infiltration of CD4+ and CD8+ T-cells, mitochondrial dysfunction, microvascular remodeling, and reduced muscle stem-cell repair and proliferation. IFN activity has been shown to correlate with histological and clinical measures of disease activity. Anifrolumab, a monoclonal antibody that blocks the type I IFN receptor IFNAR1, has been approved for treatment of SLE and is currently undergoing a phase III trial in adult DM, with some case reports and series showing encouraging prospects.

Methods: Clinical data were extracted to complete a retrospective case series.

Results: Three female patients with JDM, ages 22, 24, and 48, were seen in the adult dermatology clinic. They had failed to obtain durable control of cutaneous JDM through combinations of methotrexate, mycophenolate, hydroxychloroquine, intravenous/subcutaneous immune globulin, or prednisone. Two had also failed systemic janus kinase inhibitors (JAKi), two had failed rituximab, one had failed quinacrine, one had failed azathioprine, one had failed cyclophosphamide, and one had failed cyclosporine. After initiation of anifrolumab at 300 mg per month alongside existing therapies, each patient saw remarkable improvement in cutaneous disease. Each patient was able to reduce systemic glucocorticoids and taper other therapies, including cessation of prior intravenous or subcutaneous immune globulin in two cases and JAKi in one case.

Conclusion: These encouraging results illustrate the relationship between type-I IFN modulation and JDM as well as the promise of anifrolumab as a rescue medication for refractory cases. As there are no current FDA-approved therapies for refractory cutaneous JDM, these cases also highlight the need for further systematic investigation into type-I IFN modulation in JDM therapy.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0280–0305) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Vasculopathic manifestations of idiopathic inflammatory myopathies (IIM) such as interstitial lung disease (ILD), calcinosis, skin ulcers, mechanic's hands, are characterized by immune-mediated vascular damage. However, operational definitions of activity/complete clinical response (CCR) underscore vasculopathy as a domain that impacts therapeutic decisions. Different subsets of neutrophils had been described as key regulators of activity in IIM. The "low-density granulocytes" (LDGs) in patients with vasculopathy, produce higher amount of neutrophil extracellular traps (NETs), correlate with IL18 and are found more frequently in different tissues from patients anti-MDA5 positive; a clinical subtype with predominance of vasculopathic features. A different unexplored subset are the neutrophils that migrate from sites of inflammation to the vascular system, known as reverse transendothelial migration (rTEM), characterized by the expression of CD54high, CXCR1low. The role of innate immune cells subsets in immune-mediated IM vasculopathy is unknown. The aim of this study was to address the role of neutrophil and monocyte subsets in the vasculopathic features of patients with IIM.

	Active with vasculopathy (n= 7)	Active without vasculopathy (n= 7)	Inactive with vasculopathy (n= 18)	Inactive without vasculopathy (n= 18)	P value

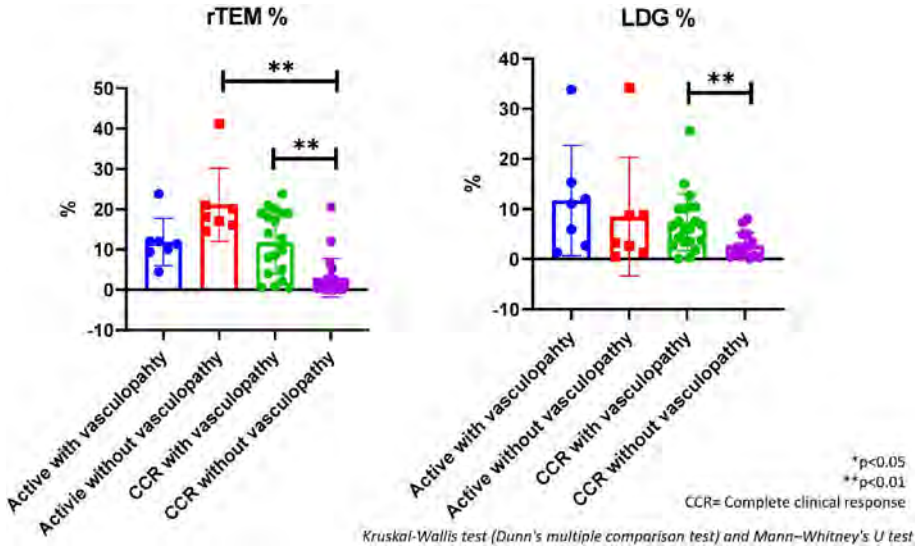
Clinical features of the fifty patients included in the study

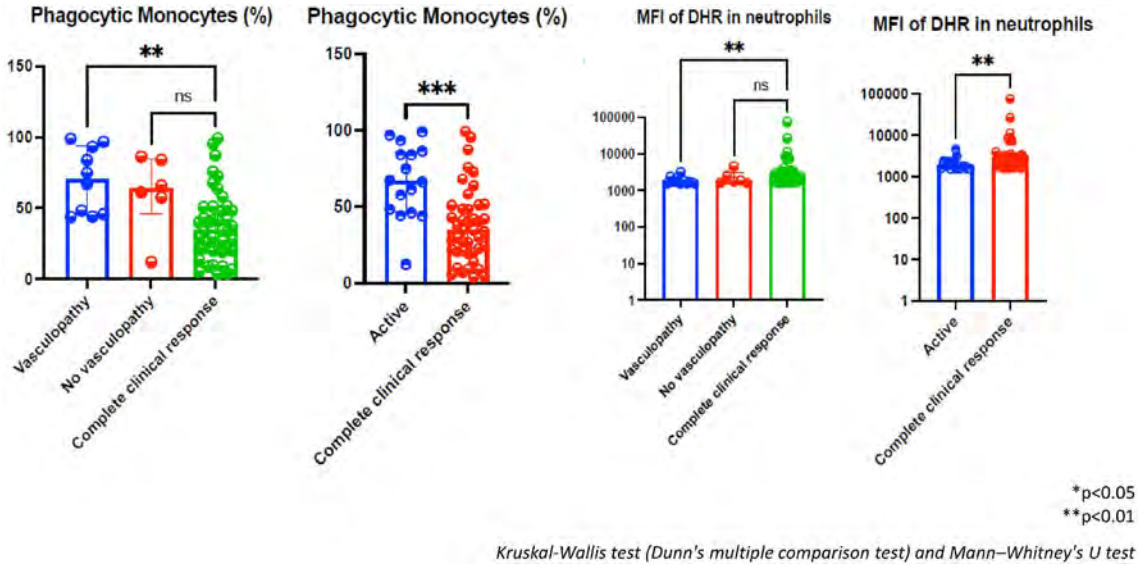
23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



IIM patients with CCR and vasculopathy exhibit a significantly increased percentage of LDGs and rTEM compared with patients in CCR without vasculopathy (9.54% (2.9-29.18) vs 0.7% (0.48-2.32); p=0.0092) / (19.7% (9.85-23.8) vs 2.4% (0.99-2.88)

Methods: : A single-tertiary center cross-sectional study was performed. Fifty patients with definite IIM diagnosis according to ACR/EULAR 2017 criteria from the institutional (MYOTReCSZ) cohort were included, 25 patients with vasculopathy (7 with active IIM and 18 with CCR) who were compared with 25 patients without vasculopathy (7 with active IIM and 18 with CCR). Vasculopathy was defined as the presence of interstitial lung disease, calcinosis, ulcers, mechanic's hands or hiker's feet. Disease activity was defined as MMT8 < 136 and/or CDASI >6. Immunophenotyping of neutrophils (LDGs: $CD66b^{pos}CD14^{neg}$, rTEM: $CD15^{pos}CD16^{hi}CD54^{hi}CXCR1^{lo}$) and monocytes (Classical monocytes: $CD14^{hi}CD16^{neg}$, Non-classical monocytes: $CD14^{pos}CD16^{hi}$, Intermediate Monocyte: $CD14^{hi}CD16^{pos}$) was performed using flow cytometry, as well as phagocytosis and respiratory burst assays evaluation with pHRhodo and DHR123 assays, respectively.

Results: IIM patients with CCR and vasculopathy exhibit a significantly increased percentage of LDGs and rTEM compared with patients in CCR without vasculopathy (9.54% (2.9-29.18) vs 0.7% (0.48-2.32); p=0.0092) / (19.7% (9.85-23.8) vs 2.4% (0.99-2.88); furthermore, monocyte's phagocytosis is increased in vasculopathy group compared with CCR patients (70%



Monocyte's phagocytosis is increased in vasculopathy group compared with CCR patients (70% (45.35-94.08) vs 34.5% (20.3-50.7); p=0.0012). IIM patients with vasculopathy displayed a markedly greater reduction in respiratory burst activity compared with patients, IN CCR, indicating a distinct functional impairment in this subgroup. (1703 IMF (1547-2279) vs 2736 IMF (1946-3217); p=0.005).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(45.35-94.08) vs 34.5% (20.3-50.7); p=0.0012). IIM patients with vasculopathy displayed a markedly greater reduction in respiratory burst activity compared with patients, IN CCR, indicating a distinct functional impairment in this subgroup. (1703 IMF (1547-2279) vs 2736 IMF (1946-3217); p=0.005).

Conclusion: The expansion of LDGs and rTEM, along with the increased monocyte phagocytosis and reduced respiratory burst in neutrophils, phenotypically and functionally differentiate the innate immune profiles of IIM patients with vasculopathy.

Predictors and Characteristics of Objective Flares in Adult Dermatomyositis

Didem Saygin[1], York Wang[2], Kathryn C. Fitzgerald[3], Jemima Albayda[4], Julie Paik[5], Eleni Tiniakou[6], Brittany L Adler[2], Andrew Mammen[7], Lisa Christopher-Stine[4] and Chris Mecoli[2], [1]Rush University Medical Center, Chicago, IL, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, [4]Johns Hopkins University, Baltimore, MD, [5]Johns Hopkins Rheumatology, Baltimore, MD, [6]UT Health Science Houston, Houston, TX, [7]NIH, Bethesda, MD

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0280–0305) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Dermatomyositis (DM) is a chronic systemic autoimmune disease with a heterogenous clinical course. Flares often lead to increased morbidity, health care utilization, and reduced quality of life. Understanding risk factors and clinical features of flares can inform individualized therapeutic and monitoring strategies. In this study, we aim to determine the predictors and characteristics of flares in patients with DM.

Methods: Patients who were seen at the Myositis Center outpatient clinic and fulfilled the 2017 EULAR/ACR Classification Criteria for DM were included. Two authors manually reviewed all notes to ascertain any increase in disease activity and the context in which it occurred. Patient symptoms, physical exams, labs, imaging findings, and medication changes were recorded for each encounter. Objective flare was defined as evidence of active disease on exam or ancillary testing (worsening/new weakness, rash, inflammatory arthritis, pulmonary function test [PFT] or lung imaging findings concerning for worsening/new myositis-related lung disease) that resulted in an increase in immunosuppressive therapy. Increased disease activity within 6 months of diagnosis were not counted, nor were increases in disease activity within 3-6 months after tapering immunosuppression. The characteristics of participants and flares were summarized using descriptive statistics. We assessed the association between covariates and time to first flare using Cox proportional hazards models.

Results: A total of 637 patients with DM (75.4% female; 77.1% White; average age at diagnosis of 48.7 [±13.7]) were included. The patients had an average follow up of 7.9 years (± 4.6), during which time 35.5% (n=226) had at least one flare. Among patients with flare, DM rash documented on exam was the most common finding (75.7%), followed by muscle weakness (58.4%), new/worsening findings on PFTs and/or lung imaging (19.0%) and inflammatory arthritis (12.4%). The

majority of the patients who self-reported rash, weakness, dyspnea, joint swelling and dysphagia fulfilled the definition of objective flare (**Figure 1)**. In univariate Cox proportional hazards model, Black race, anti-synthetase (ASYS) autoantibody and shorter time to diagnosis were significantly associated with increased flare risk. On multivariable model, Black race and time to diagnosis remained associated with flare risk **(Table 1)**. Among patients who experienced a flare, the odds of being diagnosed with cancer within 6, 12, or 24 months were significantly lower, suggesting that most flares do not herald a cancer diagnosis. Of the 71 patients diagnosed with cancer after their dermatomyositis diagnosis, 5 (7%) experienced a flare within 6 months of their cancer diagnosis, 8 (11%) within 12 months, and 10 (14%) within 24 months.

Conclusion: In this tertiary care center cohort of patients with DM, approximately one third of the patients experienced at least one flare. Patient-reported symptoms of increased disease activity are often indicative of objective flare. Black race and shorter time to diagnosis were associated with increased risk of flares. Understanding these factors can inform clinicians about timely intervention and improved patient outcomes.

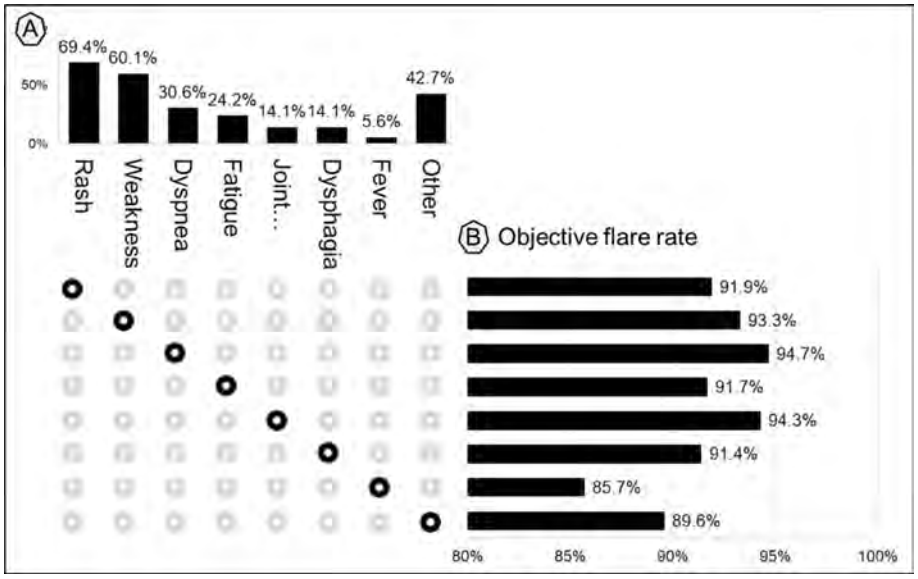

Figure 1. Frequency of symptoms reported by patients with DM (A) and proportion of patients who met the objective flare criteria based on self-reported symptom (B).

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0280–0305) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Recent progress has been made in developing myositis outcome assessments, response and classification criteria, and consensus in the design and conduct of clinical trials through the International Myositis Assessment and Clinical Studies Group (IMACS). However, critical deficiencies remain for data standardization across myositis registries. While the National Institute of Health (NIH) Common Data Elements (CDEs) Repository has been developed to facilitate consistent data collection and data sharing, few myositis-specific or autoimmune disease CDEs currently exist. Here, we developed CDEs for myositis core set activity measures (CSMs) using novel data science strategies to support myositis research interoperability.

Methods: Dictionaries of several myositis registries were examined to understand how myositis CSMs are captured across databases. We used the Linked data Modeling Language (LinkML), an open-source data modeling framework for creating schemas for structured, linked data to develop computable CDEs. Information and metadata of CDEs were captured in a machine-readable format that leverages existing standards for data standardization and reuse. The Observational Health Data Science and Informatics (OHDSI) application Athena-OHDSI Vocabularies Repository (Odysseus Data Services, Inc.)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Flow diagram of the project steps.

Table 1. Myositis Core Set Activity Measure CDEs: Comments received, solutions presented, and consensus rating for CSM CDEs

CSM	CSM characteristics	Comments Received on CDEs	Planned Solutions	Consensus on CDEs
Physician/ Patient/Parent global disease activity	10-cm VAS on overall disease activity	- Add numeric rating scale: used more than VAS - Change nomenclature from Likert to ordinal scale - Likert scale rarely used	- 21-point numeric rating scale added - Ordinal scale terminology used and made optional	100%
HAQ/CHAQ	20-item patient-reported daily-life activities questionnaire assessing disability	- Include scoring of domains when aides/devices are used - Pain VAS not used in Europe	- Adjusted scoring to include aides/devices - Made pain VAS an optional element	100%
MMT-8	Muscle strength measure by manual muscle testing, assessing eight key muscle groups	- Include instructions on how to perform the test - Specify left/right and dominant side - Include image or URL of the form	- Added instructions - Added a question to specify the dominant side and laterality of the test -Plan to create persistent URL of IMACS website with detailed instructions and link to it in CDE	100%
Extra-muscular Global Disease Activity/MDAAT	10-cm VAS on overall disease activity excluding muscle disease	No comments	No revision	100%
Serum muscle enzymes	Laboratory results of serum creatine kinase, aldolase, AST, ALT, LDH, and creatinine	- SGOT and SGPT terminology used more commonly in Europe than AST and ALT - Aldolase not commonly available in Europe - Change form name or remove creatinine, as it is not a muscle enzyme - Add age, sex, and race of the individual	- SGOT and SGPT added to the naming of AST and ALT - Results of enzymes were made optional - Form name changed to Serum muscle enzymes and metabolites - Age and sex were added	100%
CMAS	Performance-based tool assessing muscle strength, endurance, and	No comments	No revision	100%

Table 2. Myositis measures prioritized by expert panelists (n=22) for future CDE development

Form Name	% Endorsement for CDE Development (n/N)
ACR-EULAR IIM Response Criteria	100.0% (22/22)
EULAR-ACR IIM Classification Criteria	72.7% (16/22)
Myositis Damage Index	72.7% (16/22)
PROMIS Pain Interference Short Form 6a	68.2% (15/22)
Physician Patient/Parent Global Damage	59.1% (13/22)
Functional Index-3	54.6% (12/22)
Timed Up-and-Go and Sit-to-Stand tests	54.6% (12/22)
Swallowing Questionnaire	50.0% (11/22)
PROMIS FACIT Fatigue	45.5% (10/22)
PROMIS Fatigue Short Form 7a	45.5% (10/22)
Preliminary Criteria for Worsening of Myositis (Disease Flare Criteria)	45.5% (10/22)
IBM Functional Rating Scale	36.4% (8/22)
Six-minute Walk test, Two-minute Walk test	33.3% (7/22)
ENMC Classification Criteria for IBM	31.8% (7/22)
Provider and Patient Skin Activity	31.8% (7/22)
Cancer screening form	31.8% (7/22)
Initial muscle magnetic resonance imaging and biopsy	27.3% (6/22)
PROMIS-57 Adult profile	27.3% (6/22)
Quantitative muscle testing	23.8% (5/22)
Thigh muscle magnetic resonance imaging	23.8% (5/22)
PROMIS 49 Pediatric Profile	22.7% (5/22)
PROMIS Physical Function Shore Form 8b	22.7% (5/22)
IMACS Core-01A and 01B form (core demographics, clinical subgroups, myositis autoantibodies, clinical features, medications)	22.7% (5/22)
Dermatomyositis Disease Symptom Questionnaire	19.1% (4/22)
SkinDex29	13.6% (3/22)

Abbreviations: FACIT: Functional Assessment of Chronic Illness Therapy; IBM: Inclusion Body Myositis; ENMC: European Neuromuscular Centre.

was utilized to map CDEs to the Observational Medical Outcomes Partnership (OMOP) vocabulary. After development of draft CDEs for myositis CSMs, a hybrid conference was held to discuss results, reach consensus on the coding of myositis CSM CDEs, and to prioritize additional forms for development of CDEs. An international panel of 13 myositis experts and 11 discussants, including adult/pediatric rheumatologists, neurologists, dermatologists, physical therapists, and patients/patient advocates, attended the consensus conference. The Delphi method and modified nominal group technique were used in tandem as consensus methods for each CDE. Comments from participants were received via an open survey on REDCap and discussed, followed by electronic voting to reach consensus. Participants also ranked additional myositis measures for future CDE development.

Results: A standardized workflow has been established for creation of CDEs in myositis and other autoimmune diseases (Figure). CDEs for all myositis CSMs were drafted, except CHQ-P50 due to its restrictive licensing. After receiving several comments on each CDE and holding discussions to improve the coding of the CSM CDEs, 100% agreement among participants was reached for all CDEs (Table 1). The prioritized measures for future CDEs included IIM Response, Classification and Flare Criteria, damage measures, task-oriented physical function measures, and patient-reported outcome measures via PROMIS instruments among others (Table 2).

Conclusion: Leveraging broad multispecialty expertise in myositis and patient communities through IMACS and data science expertise of the National Library of Medicine (NLM), the first myositis-specific CDEs have been developed to accelerate the ability to conduct interoperable myositis clinical studies and therapeutic trials.

Abstract Number: 0290

Comparison of Organ Damage and Survival in Anti-synthetase Syndrome and Other Idiopathic Inflammatory Myopathies: An Analysis of Patients from Turkey

Ezgi Sahin[1], Omer Uludag[2], yasemin yalcinkaya[3], Bahar Artim Esen[4], Ahmet Gul[3] and Murat Inanc[3], [1]Istanbul University Istanbul Faculty of Medicine, Istanbul, Turkey, [2]Istanbul University, Istanbul Faculty of Medicine, Division of Rheumatology, Istanbul, Turkey, [3]Istanbul University, Istanbul Faculty of Medicine, Division of Rheumatology, Istanbul, Istanbul, Turkey, [4]Istanbul University, Istanbul, Istanbul, Turkey

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0280–0305) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Idiopathic inflammatory myopathies (IIMs) are rare autoimmune diseases characterized by muscle weakness, often involving other organs such as the skin, lungs, and heart. Defined subtypes include dermatomyositis (DM), anti-synthetase syndrome (ASS), polymyositis (PM), immune necrotizing myopathy (IMNM), and inclusion body myositis (IBM). ASS exhibits distinct clinical, serological, and prognostic features.This study aims to compare the prognosis and clinical characteristics of patients with ASS and other IIMs (OIMM) in our cohort.

Methods: Data of 122 IIM patients fulfilled Bohan and Peter criteria and 2017 myositis classification criteria with myositis-specific antibody results who were followed up in our clinic between 1991 and 2024 were retrospectively analysed. The patients were divided into two groups, those with ASS and those with OIMM and their clinical and laboratory characteristics damage progress and survival rates were compared.

Results: A total of 35 patients (28.7%) were diagnosed with ASS. In this cohort, 85.7% of ASS and 59.8% of OIIM were female (p = 0.011). The median age at diagnosis was 47 years in ASS and 46 years in OIMM. The mean follow-up period

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

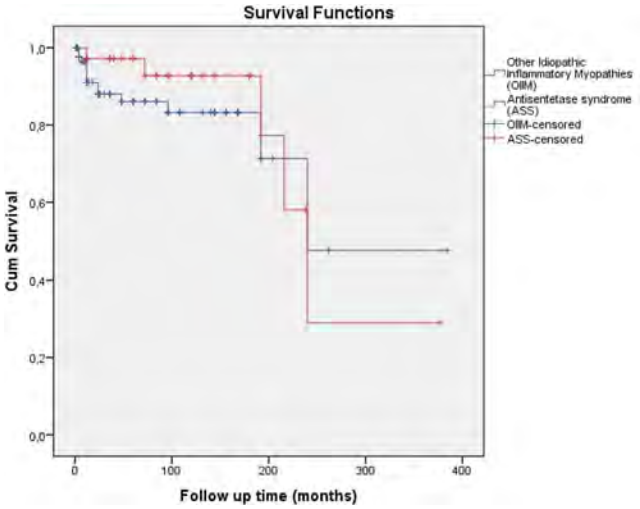

Figure 1: Comparison of survival rates by Kaplan-Meier analysis (Mantel Cox Log Rank test χ^2=0.679 df=1, p=0.410).

was 84.48±77.95 months. In these patients, anti-Jo-1 was positive in 88.6%, anti-PL-7 in 8.6%, and anti-KS in 2.8%. The frequency of mechanic's hand (ASS: 11.4%; OIMM: 1.1%; p = 0.024), arthritis (ASS: 51.4%; OIMM: 21.8%; p = 0.003), and ILD (ASS: 68.6%; OIMM: 21.8%; p< 0.001) were significantly higher in the ASS. Dysphagia was frequent in the OIMM (ASS: 8.6%; OIIM: 37.9%; p = 0.003). Anti-Ro-52 positivity was also higher in the ASS (ASS: 42.9%; OIIM: 21.8%; p = 0.034). At the time of diagnosis, median CRP, leukocyte, and neutrophil values were higher in the ASS. The median myositis damage index (MDI) of the ASS group was higher than the OIMM in the sixth month of the follow-up (median MDI: 3 vs. 2, p = 0.046) Comparing the ASS group with other autoantibody based subgroups, a difference was observed between the ASS and the TIF-1 gamma-positive patients in terms of damage progression at the sixth month (median MDI: 3 vs 1.5, p = 0.033) While ILD was observed at a high prevalence in the ASS malignancy was predominant in anti-TIF-1gamma positive patients (ILD: 72.7% vs 3%, p < 0.001; malignancy: 20% vs 35.3%, p = 0.045) In the last assessment there was no difference between the OIMM and ASS for MDI. The mortality rate was 14.3% in the ASS and 14.9% in the OIIM **(Figure 1)** It was found that there was no difference in survival rates between the ASS and OIMM.

Conclusion: The ASS has significant clinical differences from OIMM. Among these patients, mechanic's hand, arthritis, and ILD are more prevalent, whereas dysphagia is less common. Inflammatory markers like CRP, leukocyte, neutrophil levels, and anti-Ro-52 positivity are more frequent at baseline in the ASS. In the early follow-up period, higher organ damage was developed in patients with the ASS compared to the OIIM. This difference was due to the rapid development of significant ILD in most of the patients with ASS. These findings highlight the unique clinical features and different disease progression trajectories of ASS, providing insight into possible differences in the management strategies for IIM subtypes.

Acute Onset Inflammatory Myositis: Clinical Features and Survival

Gollakota Nandita[1], Madhuri Challa[2], Phani Kumar D[3], Meghna Gavali[4] and Liza rajasekhar[5], [1]NIMS, Hyderabad, Hyderabad, Telangana, India, [2]Nizams institute of medical sciences, hyderabad, Andhra Pradesh, India, [3]NIMS, Hyderabad, Telangana, India, [4]nizam's institute of medical sciences ,Hyderabad, Hyderabad, Telangana, India, [5]Nizam's Institute of Medical Sciences, Hyderabad, Telangana, India

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0280–0305) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Idiopathic inflammatory myopathies (IIMs) are characterized by subacute onset symmetric proximal muscle weakness, with occasional extra-muscular involvement, leading to significant morbidity and mortality. Acute onset inflammatory myositis with seasonal variation has been documented[1], but the role of infectious or environmental triggers in temporal clustering remains uncertain. We report on cases of acute myositis observed over a two-year period, with temporal clustering .

Methods: Records of patients admitted with acute-onset (< 8 weeks), severe, symmetrical proximal muscle weakness between January 2023 and April 2025, unrelated to toxin exposure were reviewed and patients followed up. Demographics, clinical features, antibody profile (Euroimmun line immunoblot, 16 antigens), muscle biopsy, diagnosis, and outcomes were recorded. Patients with a dermatomyositis (DM) specific rash and/or myositis specific antibodies

(MSA), perifascicular atrophy (PFA), or MXA staining on muscle biopsy were classified as dermatomyositis. Those not meeting 2016 ACR/EULAR subtypes were labeled unclassified acute myositis.

Categorical data were reported as percentages, continuous as means/medians. Cox regression identified factors associated with survival and outcomes.

Results: Of 51 incident inflammatory myositis cases admitted, 33 (19 female) had acute-onset myositis, with clustering noted during September 2023–January 2024 and October–December 2024. The median (IQR) MMT-8 score was 68 (52–83). 9 patients were classified as DM. 3 of 11 non-survivors had DM and 8 unclassified acute myositis. Survivors had higher baseline MMT-8 scores and less frequent endomysial inflammation on biopsy (Table 1).

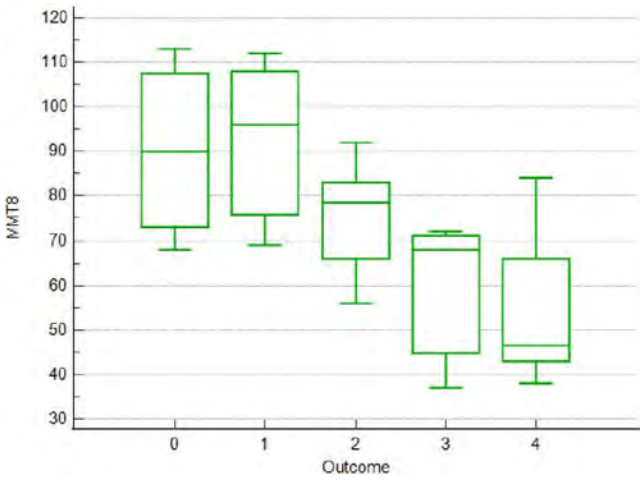

Figure 1- Box and Whisker Plot Depicting MMT-8 amongst various groups(0-Off all medication, 1- Tapering doses of DMARDs, 2- Tapering doses of Steroids, 3-Hiking in IS, 4- Non-Survivors

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Survivors were followed for a median (IQR) 61.2 (25–73) weeks. At follow-up, 4 patients were off therapy, 13 remained stable on tapering steroids or immunosuppressants, and 4 experienced flares requiring treatment escalation. Follow-up data were unavailable for 1 patient. Lower baseline MMT-8, presence of dysphagia, and MSA positivity were associated with flares or clinical worsening (Table 2).

There was higher frequency of Gottron's lesions and PFA positivity in the DM group ;prodromal symptoms and clinical improvement in the unclassified myositis group.

Conclusion: Two clusters of acute myositis observed over two years included 9 patients with dermatomyositis . There was considerable mortality which was linked to lower MMT-8 scores and endomysial inflammation . In most survivors immunosuppression was either being tapered off or stopped. Lower MMT-8, dysphagia, and MSA positivity predicted the need for escalating therapy.

Patterns and Predictors of Longitudinal Trajectories of Pain in Individuals with Inflammatory Myopathies

Haley Zimmerman[1], Ethan Ritz[2], Kristin Wipfler[3], Kaleb Michaud[4] and Didem Saygin[1], [1]Rush University Medical Center, Chicago, IL, [2]Rush Research Informatics Core, Rush University Medical Center, Chicago, IL, [3]FORWARD, The National Databank for Rheumatic Diseases, Omaha, NE, [4]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0280–0305) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) have historically been considered a disease of painless weakness. However, recent studies indicate that most patients with IIM experience pain that interferes with their daily activities. Despite the high prevalence and burden of pain, longitudinal pain trajectories of patients with IIM are currently unknown. Understanding the temporal course of pain in these patients can inform clinicians about risk stratification and assist with long-term pain management. In this study, we aimed to explore longitudinal changes in pain levels and to examine the relationship between changes in pain and various clinical variables in individuals with IIM.

Methods: The FORWARD Databank is a longitudinal prospective registry of adults in the US with rheumatic diseases. The Databank includes patient-reported biannual forms related to their socio-demographics, disease activity and subtypes, comorbidities, symptoms including pain levels (21-point numeric rating scale), and medications. We identified participants with IIM diagnosis in FORWARD who had pain scores at ≥2 time points. Pain trajectories over time were fit using latent class mixed models with the lcmm package in R version 4.4.3. Pain was modeled as an ordinal outcome, using the "thresholds" link function. The model included a fixed effect for time and included random intercepts and slopes for each participant. Akaike Information Criterion (AIC) and Bayesian Information Criterion (BIC) were used to determine the optimal number of latent classes. We compared the baseline characteristics of the two groups with chi square test and t test/Fisher's exact test where appropriate. To further examine the factors associated with change in pain levels over time, univariate and multivariable linear mixed models were performed.

Results: A total of 147 individuals with IIM (mean age of 54.6 [±13.8], female 78.9%) were included in the study. Two groups were identified: improving (57%; n=84) and stable longitudinal pain trajectories (43%; n=63) **(Figure 1)**. Pain levels of the improving group started at 4.31 and improved by 0.14 per year. The pain trajectories were in line with longitudinal change in patient global disease activity. The participants with improving pain trajectory had worse baseline pain levels, patient global disease activity, fatigue and disability, and more commonly reported joint swelling, rash, photosensitivity, and muscle weakness than those in stable group **(Table 1)**. Baseline demographics, disease subgroups, socioeconomic variables, and comorbidities, including osteoarthritis and fibromyalgia, were generally comparable between the two trajectory groups. Younger age, higher BMI, analgesic use and higher patient global disease activity were significantly associated with increase in pain levels over time in multivariable models **(Table 2)**.

Conclusion: Pain levels improved over time in nearly 60% of the individuals with IIM, while the rest had stable pain levels. Individuals with improving pain trajectory were more likely to have active disease. A close link between pain trajectories and myositis disease activity suggests that pain could be a clinical manifestation of IIM.

Background/Purpose: Sporadic inclusion body myositis (sIBM) is an autoimmune disease manifesting with muscle degeneration, inflammatory infiltrates and inclusion vacuoles. Diagnosis of sIBM is hampered by its imprecise characteristics, at times indistinguishable from other Idiopathic Inflammatory Myopathies, but may now be assisted by detection of sIBM-specific autoantibodies targeting muscle antigen Mup44, identified as cytosolic 5'-nucleotidase 1A (cN-1A; Mup44; NT5c1A). This study evaluated sensitivity and specificity of an anti-cN-1A IgG serological assay in sera from patients with and without sIBM.

Methods: Serum from patients with clinically and pathologically diagnosed sIBM (n=68) and from suspected sIBM (encompassing biopsy readings of possible, probable and doubtful sIBM patients, n=15), as well as from patients with other forms of myositis [including dermatomyositis (DM; n=4), polymyositis (PM; n=7); unspecified myositis without sIBM (n=94), muscle atrophy (n=1), myonecrosis (n=4)], systemic lupus erythematosus (n=33), scleroderma (n=20), Sjögren's syndrome (n=20), rheumatoid arthritis (n=20) and from healthy controls (n=254) were tested for anti-cN-1A IgG using an anti-cN-1A ELISA (full-length antigen, EUROIMMUN).

Results: Anti-cN-1A was most frequent among definite sIBM (41.2%). The overall specificity was 96.3% with individual specificities from 90% (scleroderma) to 100% (PM or DM).

Conclusion: The presence of anti-cN-1A in serum appears to be disease-specific for sIBM. These antibodies are found at a moderate prevalence but are only rarely detected in other autoimmune conditions. Thus, anti-cN-1A ELISA may support the diagnostics of sIBM and accelerate the diagnosis, where muscle biopsy is delayed or unfeasible.

autoantibodies (MSA) and myositis-associated autoantibodies (MAA) can now be identified in up to 70% of IIM patients. Clinical validation of multi-specific immunoassays, especially regarding the clinical relevance of low-titer positive MSA/MAA in the setting of a malignancy, remains to be determined.

Methods: Using an electronic database, we identified all patients for whom a myositis panel was assessed through the Eastern Ontario Regional Laboratory Association from June 2019 to October 2024. This myositis panel included 18 autoantibodies detected by a semi-quantitative (autoantibodies are reported in terms of low, moderate and high titers) immunoblot assay (EUROIMMUN Medizinische Labordiagnostika AG, Lübeck Germany). We performed a retrospective chart review examining clinical characteristics of the subset of patients with low titers of MSA/MAA and a history of malignancy.

Results: We identified 166 patients with low titer positive MSA or MAA antibodies from 1478 patients with a myositis panel result. In total, 38 patients had a history of malignancy and 7 patients (18%) were clinically true positives, meaning their positive MSA/MAA was clinically associated with a diagnosis of IIM [Table 1]. IIM diagnoses included cancer-associated (n=2), amyopathic dermatomyositis (n=1), dermatomyositis (n=2), antisynthetase syndrome (n=1), and immune mediated necrotizing myopathy (n=1). The majority (58%) of underlying malignancies in clinically false positives (n=31) were gastrointestinal (n=5), skin (n=7) and breast (n=6). Proximal weakness was present in 71% of clinically true positive cases, whereas interstitial

lung disease presented most commonly (32%) among those with clinically false positives [Table 2]. A large proportion of clinically false positives were found to be anti-Mi2-alpha (3%) or -beta (19%) positive, anti-PL7 positive (23%), or anti-NXP2 positive (13%) [Table 3]. From the 11 patients (29%) identified with multiple positive MSA/MAA, 2 had clinically true positives.

Conclusion: In patients with an underlying malignancy, a positive MSA/MAA at low titer identified by multi-specific immunoassay had a corresponding clinical positive in only 18% (n=7/38) of cases, and 18% (n=2/11) of those with multiple positive MSA/MAA. The most common false positives identified were anti-Mi2-beta (19%), anti-PL7 (23%) and anti-NXP2 (13%). Further studies are needed to understand the clinical significance of low positive titer MSA/MAA in the setting of a past or present malignancy.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0280–0305) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Fatigue significantly impacts quality of life in idiopathic inflammatory myopathies (IIM) but remains poorly understood. This study aimed to identify the key determinants of fatigue in IIM through comprehensive analysis of disease-specific, psychological, and sociodemographic factors.

Methods: Cross-sectional data from the global e-survey "Collating the Voice of people living with autoimmune diseases" were analysed. Fatigue was measured using the Visual Analogue Scale for Fatigue (VAS-F) and reported as mean±SD. Regression models were constructed to identify factors influencing fatigue across three domains: disease-associated, psychological, and sociodemographic **[Fig 1 A]**. Hierarchical cluster analysis using Euclidean distance and Ward's D2 linkage was performed to identify distinct patient subgroups.

Results: Among 11,541 respondents **[Fig 1 B]**, 1,193 (10.33%) had IIM, with fatigue significantly higher in IIM (6.04 ± 2.36) compared to healthy controls (4.11± 2.64), p< 0.001) **[Fig 1 C]**. Within IIM subtypes, overlap myositis (OM) reported the highest fatigue (6.63±2.29) and antisynthetase syndrome (ASyS) the lowest (5.25± 2.28) **[Fig 1 D]**. Disease factors explained the greatest variance in fatigue (R^2=0.43), with disease activity, disease damage, pain, lung involvement, dermatomyositis (DM), inclusion body myositis (IBM), necrotizing autoimmune myositis (NAM), OM, polymyositis (PM) significantly associated with higher fatigue **[Fig 2 A]**. Younger age reduces fatigue risk. Among psychological factors (R^2=0.31), depression, fibromyalgia, and chronic fatigue syndrome increased fatigue; while greater self-efficacy and subjective well-being were protective **[Fig 2 B]**. For sociodemographic variables (R^2=0.19), female gender was associated with higher fatigue while non-Caucasian ethnicity, higher family functioning and household income were protective **[Fig 2 C]**. A

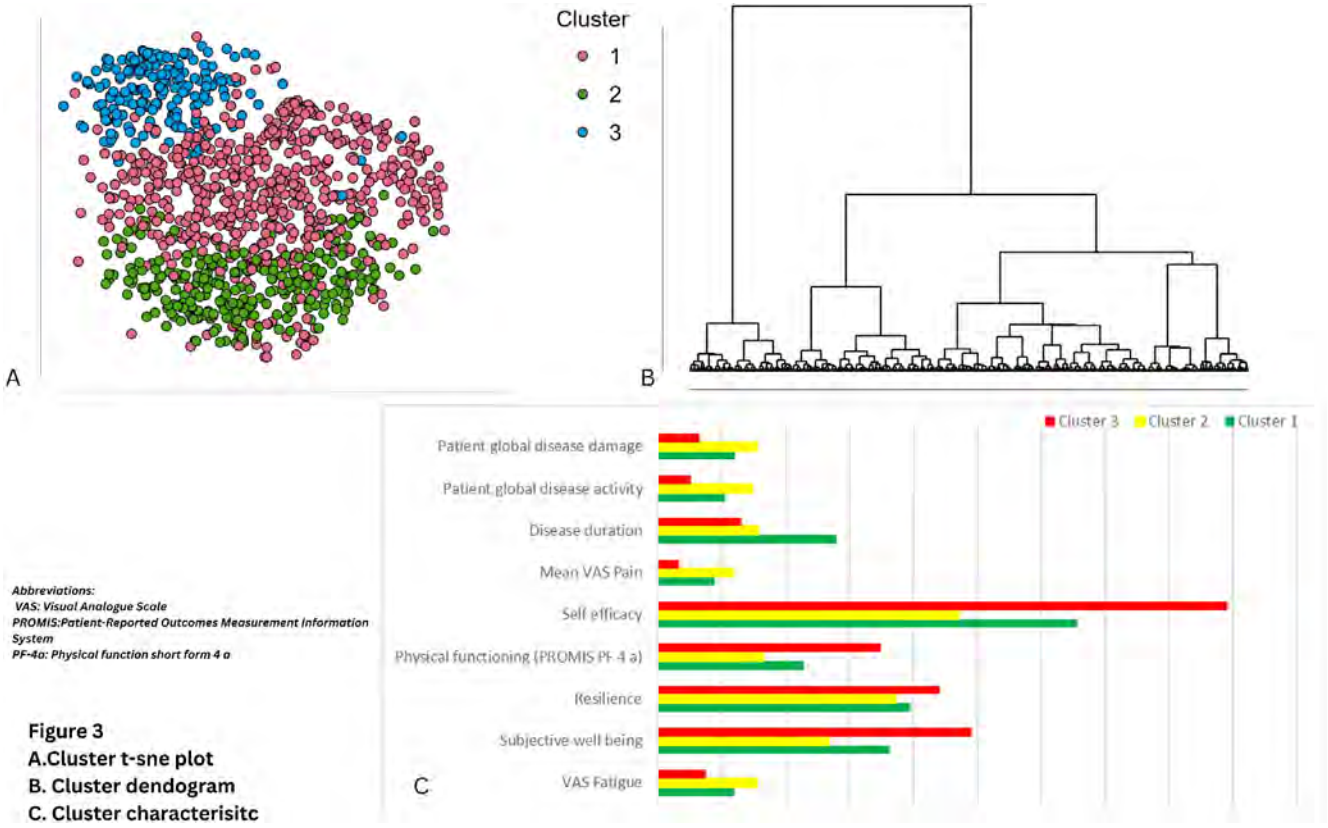

Figure 3 A.Cluster t-sne plot B. Cluster dendogram C. Cluster characterisitc

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

composite interventional model was made where younger age, presence of basic co-morbidity, higher disease activity and damage, certain IIM subtypes (DM, NAM, OM) and high pain scores had higher fatigue scores. Shorter disease duration, higher self-efficacy, better satisfaction with life, higher resilience and non Caucasian ethnicity had lower fatigue scores **[Fig.2D]**. Cluster analysis **[Fig 3]** identified three distinct patient subgroups: Cluster 3 (predominantly DM) showed lower fatigue (3.76±2.21) and comorbidity burden, while Clusters 1 and 2 (primarily IBM, OM, and ASyS) demonstrated intermediate (6.01±2.04) and high (7.74±1.70) fatigue and disease burden, respectively.

Conclusion: Fatigue in IIM emerges as a complex multidimensional phenomenon driven by disease-specific, psychological, and sociodemographic factors. Our findings highlight the importance of integrating these domains in clinical assessment and developing targeted interventions to address fatigue in IIM patients.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0280–0305) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Autoimmune inflammatory myopathies (IMs) comprise a diverse group of diseases that primarily affect the muscles and often involve the lungs, skin, and joints. Among them, patients with autoantibodies against aminoacyl-tRNA synthetases develop a distinct clinical entity known as antisynthetase syndrome (ASyS), characterized by inflammatory myopathy, pulmonary fibrosis, arthritis, Raynaud's phenomenon, and mechanic's hands. The most common antisynthetase autoantibody, anti-Jo1, targets histidyl-tRNA synthetase (HARS).

Recent studies have demonstrated that autoantibodies can penetrate muscle fibers and disrupt the function of their target autoantigens. In ASyS patients, this process induces a distinct transcriptomic profile that recapitulates the effects of pharmacologic inhibition of HARS with histidinol.

This study aims to examine the localization of anti-Jo1 antibodies and their cognate antigen, HARS1, in muscle biopsies from anti-Jo1–positive ASyS patients and diseased controls.

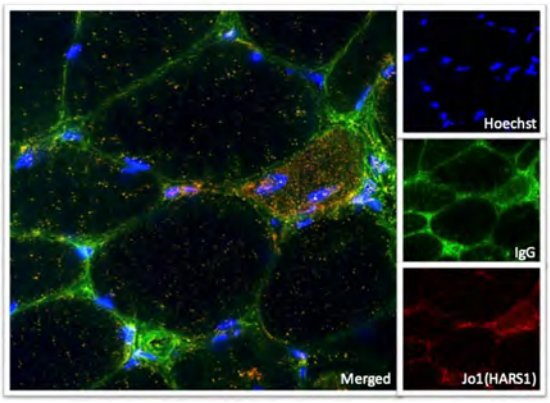
Figure 1.



Direct immunofluorescence showing the aggregation of HARS1 and internalized antibodies in a muscle biopsy of a patient with antisynthetase syndrome and anti-Jo1 (HARS1) autoantibodies

Methods: We performed direct immunofluorescence for IgG and HARS1 staining on 10 µm-thick unfixed muscle sections from patients with anti-Jo1 autoantibodies and those with other forms of inflammatory myopathy. Images were acquired using a Leica SP8 high-resolution confocal microscope.

Results: We observed co-aggregation of HARS1 and internalized IgG in muscle biopsies from ASyS patients with anti-Jo1 autoantibodies (Figure 1). This pattern was not detected in samples from patients with other forms of myopathy.

Conclusion: Our data suggest that antibodies from anti-Jo1 patients induce HARS1 aggregation in the cytoplasm of muscle fibers. Notably, similar HARS1 aggregation has been observed in patients with HARS1 mutations and Charcot-Marie-Tooth (CMT) disease. In CMT, this aggregation disrupts HARS1 function, resulting in errors in peptide translation.

Session Date: Sunday, October 26, 2025
Session Title: (0280–0305) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Dermatomyositis (DM) is a multisystemic immune mediated disease presenting with heterogeneous clinical features. Disease monitoring in DM relies in part on biomarkers of muscle disease activity such as creatinine kinase (CK) which may be unreliable especially in patients with predominant extra-muscular involvement. Novel proteomic platforms have the potential to identify inflammatory biomarkers for personalized monitoring.The objective of this study was to determine whether the Olink Target 96 Inflammation panel could identify proteins associated with disease activity in DM.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. *Autoantibodies measured with Euroimmun line immunoassay

Methods: Six DM patients from a multicenter inflammatory myopathy registry with available longitudinal biobanked sera were identified. All patients met the 2017 EULAR/ACR criteria for adult idiopathic inflammatory myopathy. Disease activity at each timepoint was categorized based on the International Myositis Assessment and Clinical Study (IMACS) physician global assessment (PhGA) as low (PhGA 0-3) or moderate/high (PhGA 4-10). The IMACS core set measures necessary to calculate the 2016 ACR/EULAR Total Improvement Score were extracted. Serum samples were analyzed using proximity

extension technology (Olink Proteomics Inc., Watertown, MA), simultaneously targeting 92 proteins involved in inflammatory processes. Results were reported as normalized protein expression (NPX) values (log2 scale) with higher NPX values representing higher protein concentration in the sample. Paired comparisons of NPX results were made using t-tests with Benjamini-Hochberg correction for multiple testing.

Results: Six female DM patients with ages ranging from 34 to 53 years were included (**Table 1**). Clinical features at timepoint 1 included rash (n=6), muscle weakness (n=5), interstitial lung disease (n=5), Raynaud's (n=3), arthritis (n=1) and dysphagia (n=1). Median CK was 326 U/L (range 41-6039 U/L). Autoantibodies included anti-MDA5, -TIF1y, -Mi2, -Ro52, and -Ku. At the first timepoint, 5 patients had moderate/high disease activity and at the second timepoint, 5 patients had low disease activity. Eleven proteins were significantly upregulated when results were compared based on disease activity status (moderate/high vs. low) (**Figure 1**). The strongest modulation (ΔNPX) was observed for monocyte chemoattractant proteins, MCP-2 (3.0, adj. p=0.02), MCP-1 (2.4, adj. p=0.02), MCP-4 (2.2, adj. p=0.02), and C-X-C motif chemokine 11 (CXCL11, –3.0, adj. p=0.05). Additional upregulated proteins (ΔNPX) included PD-L1 (1.27, adj. p=0.05) and CD40 (0.92, adj. p=0.05). Other proteins with significant upregulation (all adj. p=0.05) were CX3CL1 (1.57), CCL11 (1.42), IL-4 (1.1), IL-15RA (0.9) and CSF-1 (0.61).

Conclusion: Using longitudinal serum inflammatory profiles, we identified proteins upregulated when patients with DM have moderate/high disease activity. Those included chemokines involved in monocyte and T-cell recruitment that could represent potential biomarkers for disease monitoring. Further studies on a larger number of DM patients are required to understand the potential of longitudinal proteomic analyses to improve personalized monitoring in DM.

Session Date: Sunday, October 26, 2025

Session Title: (0280–0305) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are characterized by symmetrical proximal muscle weakness. Accurate and reliable assessment of muscle strength is important for diagnosis, monitoring, and clinical trials. Manual Muscle Testing (MMT) is widely used due to its simplicity but has notable limitations, particularly in inter-rater reliability. (1) Isokinetic dynamometry, the gold standard, is accurate but impractical for routine use. Hand-held dynamometry (HHD) offers a portable and objective alternative, and studies have shown that HHD outperforms MMT in intra-rater reliability and clinical responsiveness in IIM. However, prior studies were limited by homogenous evaluator profiles. (2)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

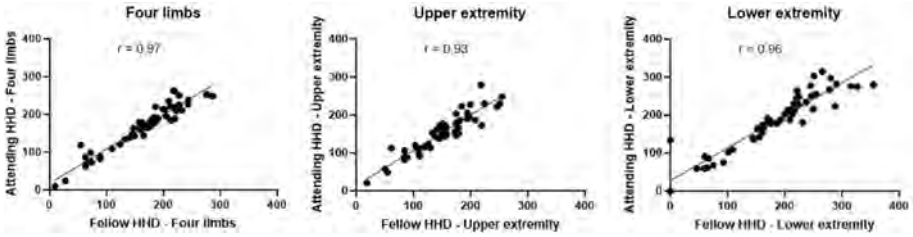

Figure 1:- Correlation plots for handheld dynamometry measurements of fellows and attending for upper and lower extremities as well as four-limb measurement.

Severity of weakness (n)	MMT9 score	Combined* handheld dynamometry in lbs of force, mean± SD (range)
Normal (20)	160	218 ± 30 (156-267)
Mild (12)	150 to <160	174 ± 38 (89-241)
Moderate (9)	140 to <150	126 ± 41 (74-183)
Severe (5)	<140	50 ± 31 (10-86)

* Mean of four-limb combined fellow and attending readings

Figure 2:- Combined fellow and attending handheld dynamometry readings across four MMT9 scores grading severity of weakness

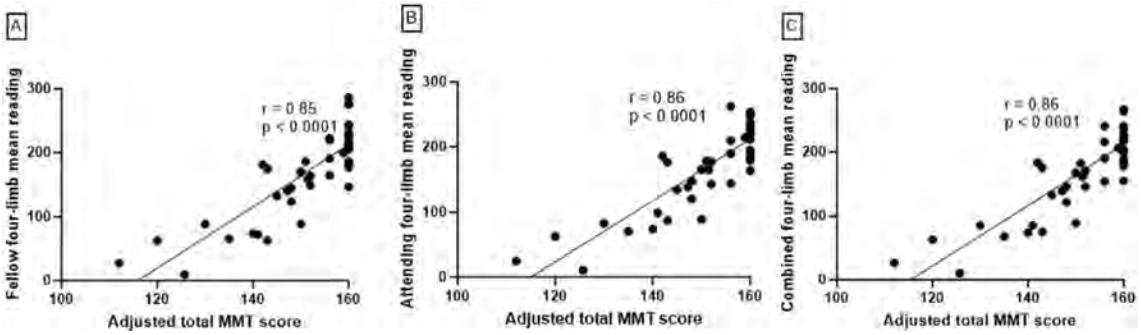

Figure 3: Correlation of adjusted total MMT score with four-limb HHD readings performed by fellow (A), attending (B), and the mean of both (C).

Methods: This study was aimed to evaluate the inter-rater reliability of HHD and its correlation with MMT scores. Forty-six patients who were evaluated at the University of Pittsburgh Myositis Center between July 2020 and March 2021 and classified as IIM (DM/PM/NM) as per 2017 EULAR/ACR Classification criteria were included. Muscle strength of bilateral deltoid and iliopsoas groups was assessed using a Micro FET2 dynamometer and MMT of 9 muscle group (MMT-9). HHD was conducted sequentially by two blinded examiners—one experienced male attending and one female rheumatology fellow who underwent a 20 minute training on assessing HHD. Inter-rater reliability was analysed using intraclass correlation coefficients (ICCs) and Pearson correlation.

Results: In the cohort of 46 patients, the mean age was 56 years with 80% (n=37) females and 80% (n=37) Caucasians. Dermatomyositis (n=23) and necrotizing myopathy (n=12) were the most common subtypes of IIM. The mean MMT score in the combined cohort was 151.Physician assessment showed excellent inter-rater reliability: ICCs were 0.92 (upper extremity), 0.93 (lower extremity), and 0.95 (four-limb) among the fellow and attending. Correlation coefficients were strong across patient subgroups stratified by sex and race. The correlation between HHD and MMT scores was also strong [r = 0.85 (fellow), r=0.86 (attending)], with consistent findings for both upper and lower extremity muscle groups. A ceiling effect was noted with MMT, as HHD captured a wide range of values even at maximum MMT score. Variability was greater in iliopsoas testing, likely due to the influence of examiner strength when assessing stronger muscle groups. Subgroup analysis of DM and non-DM patients revealed similar reliability and correlation patterns.

Conclusion: This study confirms the high inter-rater reliability of HHD in assessing muscle strength in IIM, even among raters with different levels of clinical experience and gender. HHD correlated well with MMT and demonstrated additional utility in detecting subtle strength variations, supporting its clinical application in myositis care and research.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0280–0305) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) present with diverse clinical features and disease courses. The myositis autoantibody line blot immunoassay (LIA) has advanced IIM diagnostics and is widely adopted across multiple specialties. We explored its predictive value in real-world, broader clinical settings.

Methods: A retrospective observational study of consecutive patients received the myositis autoantibody LIA testing in the National Taiwan University Hospital (NTUH) System from April 2021 to March 2023. All patients received the LIA testing via EUROLINE Autoimmune Inflammatory Myopathies 16 Ag kit. Patient demographics, including the presenting symptoms and IIM diagnosis subtypes, LIA details and the associated diagnostic work-up results were extracted from the electronic medical records (EMR). Two adult rheumatologists (TY and PH) were involved for the clinical review.

Based on the presence of IIM and the LIA results, we categorized the autoantibody status of the each patients into: true-positive (TP, IIM+Autoantibody+), false-positive (FP, IIM-Autoantibody+), false-negative (FN, IIM+Antoantibody-), true-negative (TN, IIM-Antoantibody-) and calculated the clinical predictive values.

True negative	342 (50.5%)

Variables of the study population: median (Q1, Q3) or number (%).

IIM: idiopathic inflammatory myopathy.

We further determined the LIA testing indications for each patients into: *suspected IIM* (presented with manifestations across multiple clinical domains), *single clinical domain* (*pulmonary, muscular, joint, skin, cardiovascular*) and *autoimmune work-ups*. We then analyzed autoantibody positive predictive value (PPV) based on the LIA testing indication categories. All analysis were performed using R software.

Results: A total of 677 patients were included. One hundred sixty-two patients were diagnosed with IIM and the most common subtypes ere dermatomyositis (73, 45.1%), anti-synthetase syndrome (45, 27.8%) and polymyositis

Figure 1. Myositis Autoantibody Line Blot Immunoassay (LIA) Clinical Performances, Stratified by Testing Indications. Heatmap demonstrating positive predictive value and positive likelihood ratio of myositis LIA, stratified by testing indications. Both the highest PPV and LR+ were seen in the suspected IIM category. IIM: idiopathic inflammatory myopathy. PPV: positive predictive value. LR+: positive likelihood ratio.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

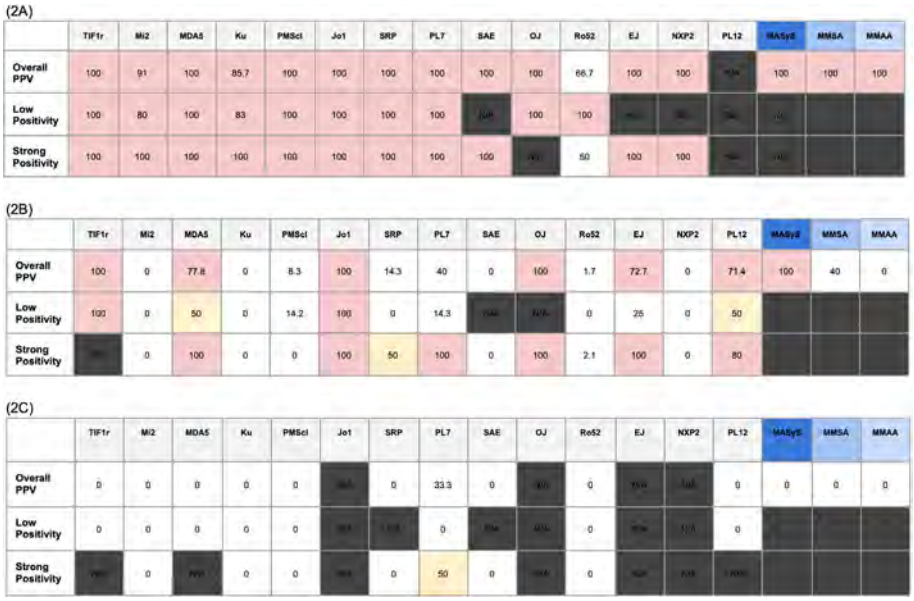

Figure 2. Myositis Autoantibody Positive Predictive Value (PPV), Stratified by LIA Testing Indications. Heatmap demonstrating PPV for individual autoantibody PPV(%) among the cases with LIA tested for (2A) Suspected IIM, (2B) Pulmonary manifestations and (2C) autoimmune work-ups. Multiple autoantibody positivity was distinguished from single antibody positivity. Overall positivity PPV included PPV of both low and strong positivity. MMSA: presence of more than one myositis specific antibody. MASyS: presence of more than one anti-aminoacyl-tRNA synthetase antibody. MMAA: presence of more than one myositis associated antibody. N/A: non-applicable.

(24, 14.8%)(Table 1). LIA demonstrated overall sensitivity 80.2% and specificity 66.4%. *Suspected IIM* exhibited the highest PPV (95.9%) and positive likelihood ratio than any entities from *single clinical domain* or *autoimmune work-ups* (Figure 1)

Among patients diagnosed with IIM, 19.7% were LIA negative while MDA5 (11.1%), multiple MSA (9.9%) and TIF1r (9.3%) were the most commonly positive autoantibodies. While PPV of most autoantibodies were high for *suspected IIM* even at low positivity (Figure 2A), autoantibodies with higher PPV for *pulmonary manifestations* (Figure 2B) were multiple coexisting anti-aminoacyl-tRNA synthetase antibodies, TIF1r and MDA5. Autoantibody PPV was low for cases tested for *joint, skin manifestations* and *autoimmune work-ups* (Figure 2C).

Conclusion: Pre-test clinical assessment is valuable under wider clinical applications as the diagnostic accuracies increase with pre-test probability. Autoantibody positive predictive values vary with specific autoantibodies and clinical Indications. Further studies are necessary to elucidate whether myositis autoantibody positivity in cases tested for single clinical domain manifestations, in particular the pulmonary manifestations, would predict and/or associate with disease course and treatment response.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0280–0305) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Anti-synthetase syndrome (ASyS) is a rare, heterogeneous inflammatory myopathy characterized by presence of anti-aminoacyl transfer RNA synthetase autoantibodies with multisystem disease manifestations including myositis, inflammatory arthritis, and "mechanic's hands" rash.1 Other forms of idiopathic inflammatory myopathy, mainly dermatomyositis, are associated with increased risk of malignancy.2 Although ASyS has been presumed to have low associated malignancy risk, reports of malignancy have been presented.3 The goal of this study was to describe the incidence and types of malignancy in a cohort of ASyS patients.

Methods: A retrospective observational study was conducted by reviewing medical records of adults diagnosed with ASyS across 3 sites at the same institution. Charts were reviewed to identify whether malignancy of any type was diagnosed around the time of ASyS diagnosis defined as up to 5 years before or after. Demographic, clinical, radiologic, and immunologic data, including ILD patterns and myositis-specific antibodies, were collected and descriptive statistics were performed. Incidence rates per person-years are calculated for three intervals: 5 years before, 5 years after, and 5 years before and after ASyS diagnosis.

Characteristic	Total (N=40)
Age	
Age at ASyS diagnosis, mean (SD)	61.7 (13.86)

Malignancy categories and types in the cohort of patients with anti-synthetase syndrome diagnosed with malignancy within 5 years of anti-synthetase diagnosis

Results: A total of 236 patients diagnosed with ASyS were identified with 40 (17%) receiving a diagnosis of malignancy within 5 years of ASyS diagnosis. Of these, 18 (45%) and 22 (55%) occurred before and after ASyS diagnosis, respectively. Demographics, disease characteristics, potential malignancy risk factors, and trialed therapies of the identified cohort with concurrent malignancy are outlined in Table 1. The incidence of malignancy was 1.8 per 100 person-years, slightly higher post-ASyS diagnosis (2.03/100 person-years) than pre-ASyS diagnosis (1.57/100 person-years) (Table 2). The most common category of malignancy was solid tumors (47.5%) followed by skin cancer (42.5%). The most common individual cancer type was squamous cell carcinoma (20%), followed by basal cell carcinoma (12.5%), of the skin. Identified malignancies and their frequencies are shown in Table 3.

Conclusion: Malignancy was seen in 17% of ASyS within a period of 5 years prior to and 5 years after diagnosis of their rheumatic disease with incidence 1.8 cases per 100 person-years. Comparison to rates in the general population and further elucidation of disease and treatment characteristics associated with risk of malignancy is warranted.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0280–0305) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: The mevalonate (MVK) pathway synthesizes isoprenoids that mediate post-translational protein modifications via prenylation. Deficient protein prenylation due to decreased mevalonate kinase (MK) activity leads to innate immune activation and autoinflammatory disorders. Patients using statins, HMG-CoA reductase inhibitors, may present with myopathy. However, the precise pathogenesis of prenylation deficiency-associated inflammation and myotoxicity remains unclear. We identified a rare homozygous pathogenic variant in the *HMGCS1* gene (c.265C >T, p. Arg89Trp), encoding for HMG-CoA synthase, the first enzyme in the MVK pathway, in two siblings presenting with necrotizing myopathy, arthropathy/arthritis, and susceptibility to infections.

Methods: Single-cell RNA sequencing **(**scRNA-seq) was conducted on PBMCs obtained from affected siblings, an unaffected sibling (wild-type), the mother (heterozygous) and unrelated healthy control. Muscle biopsies from affected siblings were used for bulk RNA sequencing. Using spectral flow cytometry, whole blood and/or PBMCs from affected individuals were assessed for IFN-g, IL-1b and IL-6 expression in monocytes, while IFN-g, granzyme B and perforin were assessed on NK and T cells.

Results: ScRNA-seq data evidenced an expansion of activated monocyte and cytotoxic populations in the affected but not in the unaffected brother, suggesting monocytes, T and NK cells as drivers of inflammation. Since muscle biopsies of the affected brothers revealed a strong IFN-g signature and IL-1 and IL-6 are crucial for inflammasome formation, we investigated these cytokines and inflammatory markers in LPS-stimulated myeloid subsets, and IL-12-stimulated NK cells and T cells of affected and unaffected controls. Percentage of IL-1b^{+} and IL-6^{+} non-classical monocytes (NCM) were significantly elevated in the affected siblings. IFN-g levels were increased in all monocyte subpopulations of the affected siblings, consistent with the IFN-g signature observed in the muscle biopsies. Monocytes expressing inflammatory markers, such as CD64, Siglec-1, and CD11c, were increased with a marked expression in NCM. Classical monocytes (CM), intermediate monocytes (IM), and NCM of the affected siblings presented lower PSGL-1 levels, aligned with the observed inflammatory responses, suggesting an infiltration of activated monocytes into muscle tissues. We observed a decrease in NK cells in affected donors, while T cells, specifically Th1 and Th17 cells, were expanded. Further, T cells presented elevated IFN-g expression in affected siblings, correlating with T cells infiltration seen in muscle tissue. Notably, T cells of the affected donors showed higher expression of granzyme B and perforin but decreased CD107a, indicating these cells were activated but with diminished degranulation activity.

IFN-g, IL-1 and IL-6 release is increased in non-classical monocytes of HMGCS1 homozygous siblings.

Conclusion: Our data provide strong evidence that monocytes and T cells may play a pivotal role in the pathogenesis of inflammation and necrotizing myositis in patients with *HMGCS1* deficiency, with NCM and cytotoxic T cells presenting the most proinflammatory profile suggesting an important role of these cells in sustaining *HMGCS1* mutation-associated auto-inflammatory disorder.

Abstract Number: 0302

Urine Kynurenine Pathway Biomarkers Correlate with Disease Activity and Damage Core Set Measures in JDM

Shannon O'Connor[1], Hermine Brunner[1], Josh Gunn[2], Payam Farhadi[3], Carley Phillips[4], Lisa Rider[5], Alexei Grom[1] and Sheila Angeles-Han[6], [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Ethos R&D, Newport, KY, [3]National Institutes of Health/National Institute of Environmental Health Sciences, Bethesda, MD, [4]Cincinnati Children's Hospital Medical Center, Cincinnati, [5]National Institute of Environmental Health Sciences/National Institutes of Health, Environmental Autoimmunity Group, Bethesda, MD, [6]Cincinnati Children's Hospital, Cincinnati, OH

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0280–0305) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Juvenile dermatomyositis (JDM) is an autoimmune vasculopathy affecting muscle, skin, and vasculature. Core set measures (CSM) assess disease activity and damage, and guide treatment. However, CSMs can be time consuming and provider dependent. Type I and II interferon (IFN) signatures correlate with disease activity. Some metabolites in the urine of children with rheumatic diseases reflect IFN activity. We aim to assess correlations between CSMs of disease activity and damage and urinary metabolites reflective of IFN activity kynurenine pathway, oxidative stress, intracellular micronutrient status, or neurotransmitter production in JDM. We hypothesize that urine metabolite concentrations correlate with JDM clinical disease.

Methods: This was a cohort study at the National Institutes of Health in collaboration with Cincinnati Children's. Inclusion criteria: a) definite or probable JDM per Bohan and Peter criteria in patients ≤18 yrs; and b) disease activity and damage CSMs performed within 3 days of urine and blood collection. Ethos R&D measured concentrations of 10 urine metabolites via mass spectrometry, normalized by urine creatinine. Absolute values of Spearman's rank correlation coefficient were calculated for each urine biomarker-CSM pair and each serum/plasma biomarker-CSM pair then sorted by the root mean square (RMS) to determine individual strongest disease predictors. Activity and damage CSMs were separated, and RMS calculated to determine predictors for activity and damage.

Table. Patient demographics and clinical characteristics at time of sample collection. Patients were in varying stages of their disease course.

Characteristics	Category	Frequency (n=33)	Percentage
Mean Age (years) (Standard Deviation)		11.6 (4.8)	
Mean disease duration (years) (Standard Deviation)		3.2 (3.6)	
Sex	Female	25	75.8
Race	White	27	81.8
	African American	3	9.1
	Asian	3	9.1
Ethnicity	Not Hispanic or Latino	29	87.9
	Hispanic or Latino	4	12.1

Myositis Associated Autoantibodies	Ro	7	21.2
	U1RNP	1	3.0
	PM/Scl	1	3.0
Calcinosis	Present	15	45.5

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

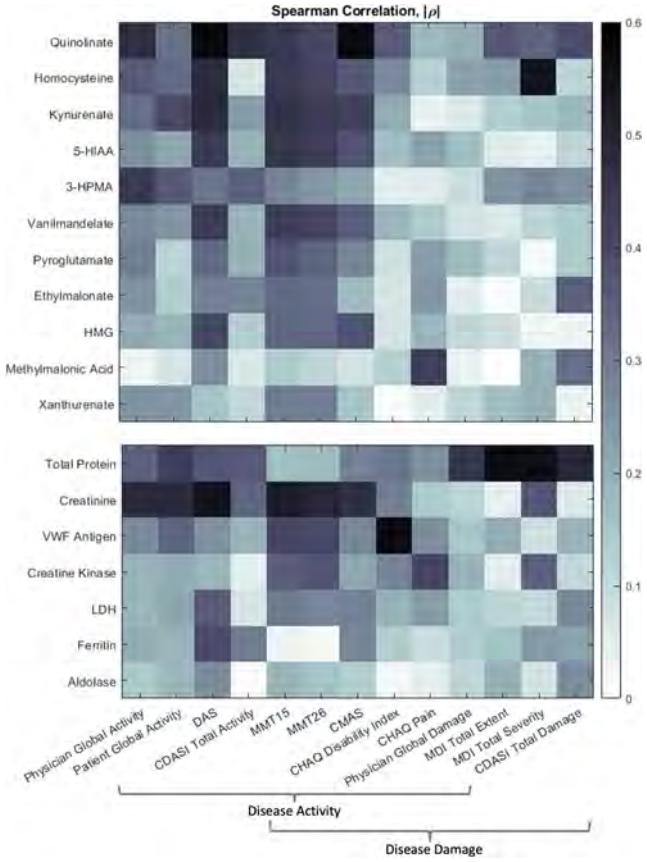

Figure 1. Heatmap of the absolute value of Spearman's rank correlation coefficient calculated for each urine biomarker-core set measure (CSM) pair (top block), and each serum or plasma biomarker-CSM pair (bottom block) for comparison. Urine metabolites are sorted from top to bottom by the root mean square (RMS) of Spearman's rank correlation coefficient to demonstrate the individually strongest predictors of disease activity and damage. VWF = von Willebrand Factor; LDH = lactate dehydrogenase. CDASI = Cutaneous Dermatomyositis Disease Area and Severity Index; CHAQ = Childhood Health Assessment Questionnaire; CMAS = Childhood Myositis Assessment Scale; DAS = Disease Activity Score; MDI = Myositis Damage Index; MMT = Manual Muscle Testing.

For each CSM, we performed linear regression with independent coefficients for each urine metabolite. CSM values were plotted against predicted CSM values and R^2 was calculated. We excluded patients with urine metabolite concentrations with a Z-score >5 (n=1).

Results: Demographics and clinical characteristics of 33 patients are shown in Table.

Figure 1 shows urine metabolites and plasma biomarkers predictive of disease activity and damage across the CSMs. Quinolinate (QA) (RMS=0.42), homocysteine (HYCS) (RMS=0.35) kynurenate (KYNA) (RMS=0.34), and 5-HIAA (RMS=0.31) are most predictive of disease activity and damage. QA (RMS=0.44,0.38), KYNA (RMS=0.36. 0.28), HYCS (RMS=0.34, 0.33), 5-HIAA (RMS=0.32, 0.27), and vanilmandelate (VMA) (RMS=0.31, 0.25) correlate best with activity and damage measures, respectively.

Creatinine (RMS=0.44, 0.33), von Willebrand Factor Antigen (VWF Ag) (RMS=0.35, 0.32), and total protein (RMS=0.31, 0.39) correlate best with disease activity and damage measures, respectively. Urine biomarkers outperform serum/plasma biomarkers, namely total protein (RMS=0.36) and VWF Ag (RMS=0.31).

Urine biomarkers showed strong correlations with CSMs in linear regression models (Figure 2), highest for MMT26 (R^2=0.74), DAS (R^2=0.70), MMT15 (R^2=0.67), and Physician Global Activity (R^2=0.65).

Conclusion: We report strong correlations between clinical measures of JDM disease activity and damage and 10 urine metabolites, many in the kynurenine pathway. 5 of these reflect disease status individually. This first step toward identifying

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1: Ratios of Muscle Enzymes to CK during the study

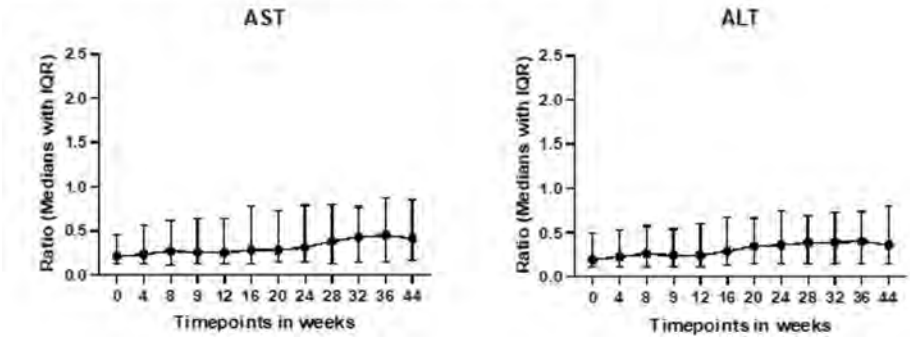

Figure 1. Stability of Muscle Enzyme-to-CK Ratios Over Time in IIM Patients. Median enzyme-to-CK ratios (AST/CK and ALT/CK) remained consistent throughout the study, supporting proportional enzyme release from muscle.

Table 1. Comparison of Muscle Enzyme Abnormalities Based on Hepatotoxic Medication Use. Median values of CK, AST, ALT, and corresponding enzyme-to-CK ratios in patients on hepatotoxic medications versus those not on such medications, including a sub-analysis by methotrexate use. No significant differences were observed between groups.

Table 1: Comparison of Muscle Enzyme Abnormalities Based on Hepatotoxic Medication Use:

Muscle enzyme level (x ULN)	Patients on any hepatotoxic medications (n=109)	Patients not on hepatotoxic medications (n=38)	P value (Mann-Whitney Test)
CK	3.32 (1.23-10.49)	4.07 (0.58-7.85)	0.42
AST	1.18 (0.79-2.29)	1.28 (0.63-1.85)	0.65
ALT	1.2 (0.7-2.1)	1.1 (0.6-1.9)	0.35
AST/CK	0.35 (0.2-0.75)	0.42 (0.22-1)	0.32
ALT/CK	0.32 (0.19-0.79)	0.41(0.2-0.87)	0.52
	Patients *on* Methotrexate (n=83)	**Patients *not* on Methotrexate (n=19)**	
CK	3.4 (1.4-10)	4.8 (0.5-10)	0.84
AST	1.3 (0.8-2.1)	1.5 (0.61-2.3)	0.73
ALT	1.2 (0.8-2.1)	1.1 (0.6-1.9)	0.31
AST/CK	0.34 (0.21-0.64)	0.42 (0.14-0.93)	0.78
ALT/CK	0.32 (0.19-0.67)	0.33 (0.11-1)	0.97

Table 2. Model-Predicted AST and ALT Levels Based on CK Values in IIM Patients. Estimated AST and ALT (in xULN) across CK categories, derived from a predictive model using $\log_{10}$-transformed CK values. Values include means, 95% confidence intervals of the mean, and expected value ranges.

Table 2: Expected Muscle Enzyme Values Based on Continuous CK Levels

Continuous CK (xULN)	AST (xULN)		ALT (xULN)	
	Mean (95% CI of mean)	95% CI of Expected Values	Mean (95% CI of mean)	95% CI of Expected Values
< 1	0.63 (0.58 – 0.68)	0.28 – 1.42	0.60 (0.54 – 0.66)	0.20 – 1.79
1-2	0.84 (0.77 – 0.93)	0.38 – 1.88	0.84 (0.75 – 0.94)	0.34 – 2.03
2-3	0.96 (0.87 – 1.07)	0.41 – 2.26	1.00 (0.88 – 1.13)	0.38 – 2.61
3-4	0.98 (0.87 – 1.10)	0.19 – 5.08	0.95 (0.82 – 1.10)	0.35 – 2.54
4-5	1.11 (0.97 – 1.26)	0.52 – 2.38	1.12 (0.96 – 1.30)	0.42 – 2.99
5-10	1.42 (1.29 – 1.57)	0.65 – 3.10	1.41 (1.25 – 1.58)	0.48 – 4.15
10-15	2.01 (1.81 – 2.24)	0.96 – 4.23	1.97 (1.74 – 2.25)	0.69 – 5.61
15-20	2.70 (2.35 – 3.09)	1.08 – 6.75	2.63 (2.24 – 3.10)	0.90 – 7.73
≥20	4.08 (3.78 – 4.42)	1.59 – 10.52	3.03 (2.76 – 3.32)	0.97 – 9.42

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are characterized by elevated muscle enzymes, including creatine kinase (CK), aldolase, aspartate aminotransferase (AST), alanine aminotransferase (ALT), and lactate dehydrogenase (LDH). While CK is a relatively specific marker of muscle injury, AST and ALT are also indicators of liver damage, complicating interpretation- particularly in patients receiving potentially hepatotoxic medications. Distinguishing muscle-related enzyme elevations from true liver injury remains a key clinical challenge.

We aimed to develop a predictive model for estimating liver enzyme levels based on CK values in IIM patients, assisting in the differentiation between muscle-derived enzyme elevations and true hepatotoxicity.

Methods: This study analyzed data from adult participants in the Rituximab in Myositis (RIM) trial, a multicenter, randomized, double-blind, placebo-controlled trial in patients with refractory dermatomyositis (DM) or polymyositis (PM). Patients with known liver disease were excluded. Data on CK, AST, and ALT were collected across 11 visits over 44 weeks. Enzyme values were standardized as multiples of the upper limit of normal (xULN). Concurrent medication use, including potentially hepatotoxic agents such as methotrexate, acetaminophen, and NSAIDS, was documented.

All enzyme values were incorporated into a repeated measures mixed model as $\log_{10}$-transformed variables to normalize distributions and satisfy model assumptions. Predicted enzyme levels and their 95% confidence intervals (CI) were derived from the model and subsequently back-transformed to xULN to facilitate clinical interpretation.

Results: The study included 147 patients (49% DM, 51% PM), with a mean age of 49 ± 11.3 years; 75% were female and 71% were White. Muscle enzyme-to-CK ratios remained stable over time (median range 0.19–0.87), reflecting consistent proportional release **(Figure 1)**.

There were no significant differences in CK, AST, ALT, or enzyme-to-CK ratios between patients receiving hepatotoxic medications and those who were not. Similar results were observed in a sub-analysis comparing methotrexate users to non-users (**Table 1**).

ALT and AST levels were predicted from CK using model-derived formulas: $ALT = 0.480 \times \log_{10}(CK) + 0.186$ ($R^2 = 0.78$) and $AST = 0.598 \times \log_{10}(CK) + 0.204$ ($R^2 = 0.82$). Expected enzyme levels across CK categories are summarized in **Table 2**. For example, for CK levels between 2 and 3 times the ULN, the estimated ALT and AST values were 1.0 and 0.96 xULN, respectively. Estimated AST and ALT based on CK levels were similar in DM vs. PM patients.

Conclusion: A CK-based predictive model can allow reliable estimation of AST and ALT in IIM patients, providing a valuable framework for distinguishing muscle-related enzyme elevations from potential liver injury. The use of hepatotoxic medications did not significantly influence liver enzyme levels in this cohort. This model can potentially aid clinicians in interpreting liver enzyme elevations in the context of active muscle disease.

Abstract Number: 0304

Concordance for myositis-specific autoantibody detection between commercial enzyme-linked immunosorbent assay and line blot assay: a multi-center study across the Asia-Pacific region

Takahisa Gono[1], Vidya Limaye[2], Latika Gupta[3], Vikas Agarwal[4], Ho So[5], JASMIN RAJA[6], Warren Weng Seng Fong[7], Supraporn Wangkaew[8], Andrea Low[9], Akihiro Murakami[10], Kimiko Hasegawa[10], Takuya Isayama[11] and Masataka Kuwana[1], [1]Nippon Medical School Graduate School of Medicine, Tokyo, Japan, [2]Royal Adelaide Hospital, Adelaide, South Australia, Australia, [3]School of Infection, Inflammation and Immunology, College of Medicine and Health, University of Birmingham; Royal Wolverhampton NHS Trust; Centre for Musculoskeletal Research, School of Biological Sciences, The University of Manchester, Manchester; Francis Crick Institute, London, Birmingham, UK, United Kingdom, [4]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, Uttar Pradesh, India, [5]Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Hong Kong, Hong Kong, [6]University Malaya, Subang Jaya, Malaysia, [7]Singapore General Hospital, Singapore, [8]Maharaj Nakorn Chiang Mai Hospital, Chiang Mai, Thailand, [9]Singapore General Hospital, Singapore, Singapore, [10]Medical & Biological Laboratories co., ltd., Tokyo, [11]Medical & Biological Laboratories co., ltd., Tokyo, Japan

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0280–0305) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: RNA/protein immunoprecipitation (IP) assays remain the "gold standard" for myositis-specific autoantibody (MSA) detection. However, the requirements for large-scale cell culture and radioisotopes limit its availability to specialized laboratories. Clinical practice has shifted toward commercial enzyme-linked immunosorbent assay (ELISA) and multianalyte line blot assay (LBA), yet their reliability is inadequately established. Our study provides the comprehensive evaluation of concordance between two widely used commercial assays against IP assays, establishing evidence-based guidelines for MSA testing in clinical practice.

Table 1

Table1. Comparison of MSA results between ELISA and LBA

	Cutoff value of LBA	Positive percentage agreement	Negative percentage agreement	Total percentage agreement	Cohen's kappa	Grade of agreement*
Anti-synthetase (n=521)						
Anti-Jo-1	LBA 1+	0.96	0.99	0.98	0.92	Almost perfect
	LBA 2+	0.89	0.99	0.99	0.93	Almost perfect
	LBA 3+	0.80	1	0.98	0.88	Almost perfect
Anti-PL-7	LBA 1+	0.89	0.97	0.97	0.62	Substantial
	LBA 2+	0.83	0.98	0.98	0.74	Substantial
	LBA 3+	0.81	1	0.98	0.66	Substantial
Anti-PL-12	LBA 1+	0.83	0.99	0.99	0.84	Almost perfect
	LBA 2+	0.70	0.99	0.98	0.79	Substantial
	LBA 3+	0.61	1	0.98	0.75	Substantial
Anti-EJ	LBA 1+	0.95	0.99	0.99	0.95	Almost perfect
	LBA 2+	0.91	0.99	0.99	0.93	Almost perfect
	LBA 3+	0.78	1	0.99	0.85	Almost perfect
Anti-MDA5 (n=491)**	LBA 1+	0.93	0.99	0.99	0.91	Almost perfect
	LBA 2+	0.74	0.99	0.97	0.83	Almost perfect
	LBA 3+	0.59	0.99	0.96	0.70	Substantial
Anti-Mi-2 (n=521)	LBA 1+	0.67	0.98	0.97	0.52	Moderate
	LBA 2+	0.53	0.99	0.98	0.58	Moderate
	LBA 3+	0.20	0.99	0.98	0.31	Fair
Anti-TIF1-γ (n=491)**	LBA 1+	0.89	0.99	0.99	0.90	Almost perfect
	LBA 2+	0.79	0.99	0.98	0.84	Almost perfect
	LBA 3+	0.68	0.99	0.98	0.78	Substantial

* The grade of the agreement was defined based on a previous manner: the kappa values were 0-0.2 in slight agreement, 0.21-0.4 in fair agreement, 0.41-0.6 in moderate agreement, 0.61-0.8 in substantial agreement, and 0.81-1.0 in almost perfect agreement.
**Thirty samples were unable to be tested because of limited serum volume.
MSAs, myositis specific autoantibodies; ELISA, enzyme-linked immunosorbent assay; LBA, multianalyte line-blot assay; ARS, aminoacyl-tRNA synthetase; MDA5, melanoma differentiation-associated gene 5; TIF1, transcriptional intermediary factor

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Sera from patients with idiopathic inflammatory myopathies (IIMs) were collected across the Asia-Pacific region. Anti-Jo-1, anti-PL-7, anti-PL-12, anti-EJ, anti-melanoma differentiation-associated gene 5 (MDA5), anti-Mi-2, and anti-transcriptional intermediary factor (TIF) 1-γ antibodies were centrally measured using commercial ELISA kits (MBL, Tokyo, Japan) and LBA systems (EuroImmun, Lübeck, Germany). Positive percentage agreement (PPA), negative percentage agreement (NPA), and Cohen's kappa were calculated to assess concordance between the two assays. Discordant results were further validated using RNA/protein IP assays.

Results: A total of 521 sera from patients with dermatomyositis (DM; n = 180), amyopathic DM (n = 44), juvenile DM (n = 7), polymyositis or immune-mediated necrotizing myopathy (n = 197), inclusion body myositis (n = 57), and IIM-not-otherwise-specified (n = 36) were collected from Australia (n = 200), India (n = 83), Hong Kong (n = 35), Japan (n = 152), Malaysia (n = 21), Singapore (n = 20), and Thailand (n = 10). The highest PPA at the 1+ cutoff value for LBA was observed for anti-Jo-1 (0.96), followed by anti-EJ (0.95), anti-MDA5 (0.93), anti-TIF1-γ (0.89), anti-PL-7 (0.89), anti-PL-12 (0.83), and anti-Mi-2 (0.67). Kappa values indicated strong agreement for anti-Jo-1, anti-PL-12, anti-EJ, anti-MDA5, and anti-TIF1-γ, but lower agreement for anti-PL-7 and anti-Mi-2 (Table 1). PPA at the cutoff value of 2+ or 3+ for LBA was numerically lower for all MSAs, whereas NPA remained high in all (0.99-1). The validation analysis using IP assays in sera with discordant results between ELISA and LBA at the 1+ cutoff value revealed a high rate of false-positives for anti-PL-7 (7/9 samples) and anti-Mi-2 (6/6 samples) antibodies with LBA. The false-positive rates decreased at the 3+ cutoff value for anti-PL-7 (0/9) and anti-Mi-2 (1/6).

Conclusion: LBA demonstrates discordance in PPA based on the cutoff values across all MSAs. Clinicians should interpret LBA results with caution, particularly when evaluating antibodies to PL-7 and Mi-2.

Abstract Number: 0305

From Movement to Meaning: Exploring Physical Function in IBM with Actigraphy

Vaidehi Kothari[1], Eaman Alhassan[2], Kevin Renz Ambrocio[1], Bonny Rockette-Wagner[3], Chester V. Oddis[1], Kendrea (Focht) Garand[1] and Rohit Aggarwal[4], [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh Medical Center, Pittsburgh, PA, [3]University of Pittsburgh, PITTSBURGH, [4]University of Pittsburgh, Rheumatology and Clinical Immunology, Pittsburgh, United States of America, Pittsburgh, PA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0280–0305) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Inclusion body myositis (IBM) is a progressive and severe inflammatory muscle disease that primarily affects adults over 50 years of age. It presents with asymmetric weakness, particularly in the quadriceps and finger flexors, and leads to significant disability over time. Standard clinical measures may not fully capture real-world activity and function. Actigraphy, a non-invasive tool for monitoring continuous physical activity, has been utilized in other myopathy subtypes but

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1: Baseline characteristics of enrolled patients

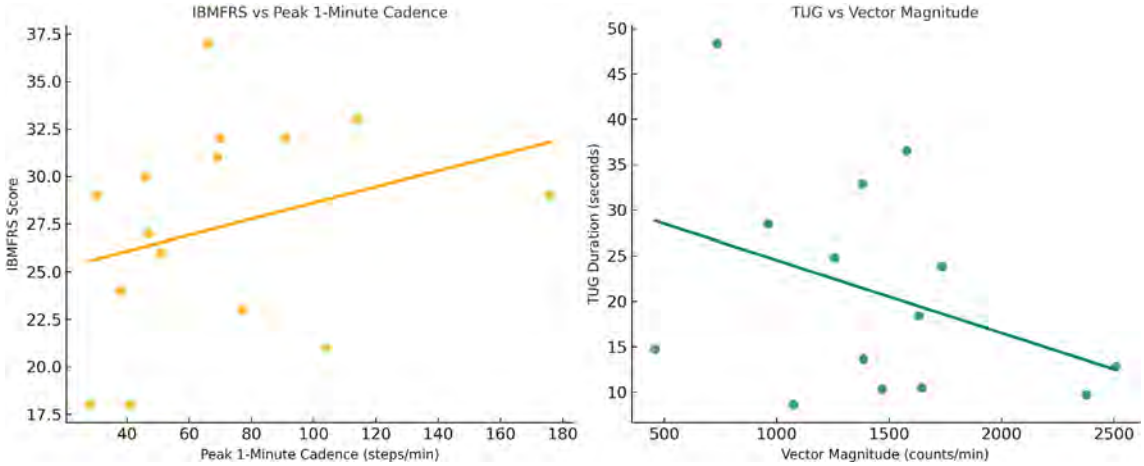
Parameter	n	Median (IQR)	Mean ± SD	95% CI	Min	Max
Demographics						
BMI (kg/m²)	15	26.00 (24.50–29.00)	26.40 ± 2.95	24.77–28.03	21	31
Age at visit (years)	15	73.00 (69.50–76.00)	72.53 ± 5.91	69.26–75.81	60	83
Age at symptom onset (years)	15	65.00 (60.00–69.00)	65.13 ± 5.90	61.86–68.40	57	74
Age at diagnosis (years)	15	69.00(65.50–74.00)	68.93 ± 5.62	65.82–72.05	60	77
Disease Duration (years)	15	8.00 (6.00–9.50)	8.60 ± 3.76	6.52–10.68	4	17
Physical Function Outcome measures						
IBMFRS Score	15	29.00 (23.50–31.50)	27.33 ± 5.61	24.22–30.44	18	37
TUG (seconds)	14	16.57 (11.05–27.55)	20.97 ± 12.02	14.02–27.91	8.61	48.33
Actigraphy						
MVPA (%)	15	19.55 (13.68–25.00)	19.72 ± 9.80	14.29–25.14	0.18	36.97
Vector Magnitude counts per minute	15	1386.20 (1165.65–1638.60)	1436.21 ± 539.63	1137.37–1735.05	458.7	2507.5
Steps per minute	15	7.40 (4.75–7.80)	6.91 ± 2.69	5.42–8.40	2.6	11.7
Peak 1 min cadence	15	66.00 (43.50–84.00)	69.87 ± 39.22	48.15–91.58	28	176

Table 2: Correlations between clinical assessment outcomes and Actigraphy parameters

Measure	MVPA (%)	Vector Magnitude counts per minute	Steps per minute	Peak 1-min cadence
IBMFRS	0.25 (p=0.37)	0.26 (p=0.34)	0.29 (p=0.30)	0.41 (p=0.13)
TUG	-0.30 (p=0.26)	-0.36 (p=0.20)	-0.32 (p=0.26)	-0.31 (p=0.28)

remains understudied in IBM, where it may offer valuable additional insights. This study examined the relationship between clinical assessments and actigraphy-derived activity metrics in individuals with IBM.

Methods: We conducted a pilot prospective cohort study at an academic center. Participants met the European Neuromuscular Center Classification (2024) and the ACR classification criteria (2017) for IBM. Assessments included the IBM Functional Rating Scale (IBMFRS), Timed Up and Go (TUG), and wrist-worn actigraphy (24/7 for seven consecutive days). Using Spearman's rank-order correlation, we assessed relationships between the clinical assessments (IBMFRS and TUG) and four actigraphy-derived metrics: percentage of time in moderate-to-vigorous physical activity (%MVPA), vector magnitude counts per minute (VM), average daily steps per minute, and peak 1-minute cadence.



Correlation Graphs

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Fifteen participants (60% male, mean age 72.5 ± 5.9 years) completed the study. The mean age of symptom onset was 65.1 years, and the mean age at diagnosis was 68.9 years, indicating a diagnostic delay of ~3.8 years. The average disease duration at enrollment was 8.6 years. Participants' IBMFRS scores averaged 27.3 ± 5.6, and mean TUG time was 21.0 ± 12.0 seconds, indicating moderate impairment. Actigraphy revealed substantial limitations in daily activities, with a mean MVPA of 19.7%, VM of 1436.2 counts/min, average daily steps of 6.9/min, and peak 1-minute cadence of 69.8 steps/min (Table 1).

IBMFRS was moderately correlated with peak 1-minute cadence ($\rho = 0.41$, $p = 0.13$) and average daily steps per minute ($\rho = 0.29$, $p = 0.30$). TUG duration was inversely correlated with VM ($\rho = -0.36$, $p = 0.20$) and steps per minute ($\rho = -0.32$, $p = 0.26$), suggesting that higher physical activity is associated with better mobility (Table 2).

Conclusion: Actigraphy metrics, particularly peak 1-minute cadence and steps per minute, demonstrated promising correlations with functional outcomes in IBM. These findings support the potential of accelerometry to capture real-world physical function and highlight the need for validation in larger, diverse myositis cohorts to establish clinical relevance and utility.

Direct Assessment of Intestinal Permeability as a Risk Factor for Multiple Joint Osteoarthritis in Community Cohorts of Humans and Pet Dogs

Liubov Arbeeva[1], Virginia Kraus[2], Richard Loeser[3], Yvonne Golightly[4], Hiroko Enomoto[5], Masataka Enomoto[5], Duncan Lascelles[5] and **Amanda Nelson**[6], [1]University of North Carolina, Chapel Hill, Carrboro, NC, [2]Duke University, Durham, NC, [3]University of North Carolina, Chapel Hill, NC, [4]University of Nebraska Medical Center, Omaha, NE, [5]North Carolina State University, Raleigh, NC, [6]University of North Carolina at Chapel Hill, Chapel Hill, NC

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0306–0336) Osteoarthritis – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Increased intestinal permeability (IP) is common in chronic inflammatory diseases, and can be measured indirectly (e.g., with blood markers such as lipopolysaccharide, LPS), or directly (through measurement of ingested and excreted sugars). The goal was to determine cross-sectional associations between directly measured IP and radiographic multiple joint osteoarthritis (rMJOA) in community cohorts of humans and pet dogs.

Methods: Data were from the Johnston County Health Study (JoCoHS) and a parallel study in pet dogs from North Carolina State University (NCSU). JoCoHS participants (n=96, mean age 55 yrs, 63% females, 57% White) provided radiographs, clinical, and demographic data. Similar data were collected from an independent cohort of pet dogs (N=110, mean age 8 yrs). rMJOA was defined as 3+ unique appendicular joint sites involved in both cohorts.

BMI= Body Mass Index; MJOA; rMJOA= radiographic multiple joint osteoarthritis; LPS=lipopolysaccharide

For direct IP assessment, humans fasted overnight followed by ingestion of 10g lactulose and 5g 12C-mannitol; sugars excreted in urine at baseline, 3- and 5-hours post-ingestion were measured using high-performance liquid chromatography (HPLC)–tandem mass spectrometry (Mayo). Lactulose:mannitol (L:M) ratio was calculated based on the percentage of administered dose of each sugar molecule in urine at 3- and 5-hours post-ingestion.

IP in dogs was also assessed after an overnight fast, followed by oral iohexol at a dose of 2.0 mL/kg (Omnipaque-350, GE Healthcare Ireland, Ireland). HPLC was used to analyze iohexol concentration in serum at baseline, 1, 2, and 4 hours post-iohexol ingestion (NCSU).

Sugars excreted at each time point and L:M at 5 hours in humans, and iohexol absorbed in dogs, were evaluated for participants with and without rMJOA using boxplots, comparing those with and without MJOA and by number of sites with rOA. Regression models adjusted for sex, age, body mass index (BMI), Charlson Index, and medications were used to examine the association of the mannitol excretion (log transformed) at 5 hours with rMJOA in humans; a similar approach used body composition score (BCS), age and rMJOA status in pet dogs.

Results: The overall prevalence of increased IP (L:M ≥ 0.1, PMID33865841) was low in JoCoHS participants. The expected associations between IP (L:M ratio) and LPS, age, and BMI were seen in humans, indicating that the test performed as expected (data not shown). Mannitol excretion was slightly higher in those with rMJOA at 3 and 5 hours (**Fig1**). In regression models, mannitol excretion at 5 hours was lower in women but not statistically significantly associated with rMJOA (**Table 1**).

In dogs, higher serum iohexol was not associated with BCS (a measure of obesity), age, or rMJOA status. IP measured by serum iohexol was numerically but not significantly increased at 4 hours (**Fig1**). IP (L:M ratio at 5 hours for humans; total time-integrated serum iohexol at 4 hours in dogs) was increased when more joint sites were involved (**Fig2**).

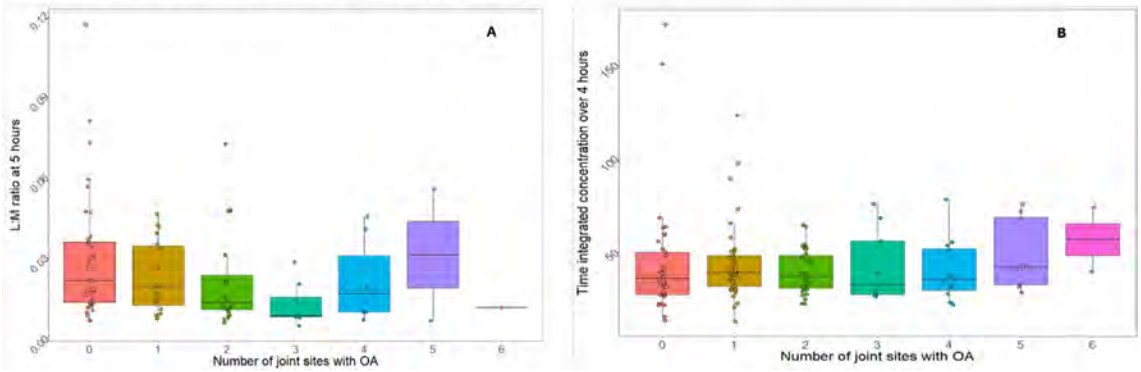
Figure 2: Radiographic osteoarthritis joint count vs (A) urine L:M ratio at 5 hours in 96 humans and (B) serum iohexol time integrated concentrations at 4 hours in 110 dogs



Conclusion: No associations were observed between increased IP and rMJOA in humans or pet dogs, likely due to limited sample size and cross-sectional data. Increased IP was infrequent in both cohorts, although a few outliers were noted (primarily in individuals with comorbidities and medication use).

Cytokine Profiling of Molecular Endotypes of Knee Osteoarthritis: Insights from the IMI-APPROACH cohort

Monica T. Hannani[1], Jaume Bacardit[2], Jonathan Larkin[3], Virpi Glumoff[3], Morten A. Karsdal[1], **Anne-Christine Bay-Jensen**[1], Ali Mobasheri[3] and Christian Thudium[4], [1]Nordic Bioscience A/S, Herlev, Denmark, [2]Newcastle University, Newcastle upon Tyne, United Kingdom, [3]University of Oulu, Oulu, Finland, [4]Nordic Bioscience, Herlev, Denmark

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0306–0336) Osteoarthritis – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: There has been a surging interest in characterizing subpopulations of osteoarthritis (OA) to facilitate recruitment of the right subgroups for drug development. The APPROACH consortium discovered three biomarker-based endotypes driven by i) structural damage to bone and cartilage, ii) connective tissue inflammation, and iii) low tissue turnover in 295 knee OA (KOA) participants at baseline. There is a need to gain a deeper understanding of the endotypes of OA to unveil the clinically actionable potential of such patient subgroups. The purpose of this study was to further characterize the three endotype subgroups through cytokine-profiling.

Methods: 277 participants from APPROACH fulfilling the ACR criteria for KOA were included. The three endotypes of structural damage, inflammation, and low tissue turnover previously defined by 19 serum and urine biomarkers reflecting bone and cartilage turnover and inflammation were considered at the month six, 12, and 24 visits. 24 cytokines were measured with Luminex Multiplex Immunoassays. Cytokines with ≤ 50% missing values were considered, resulting in 15 included

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

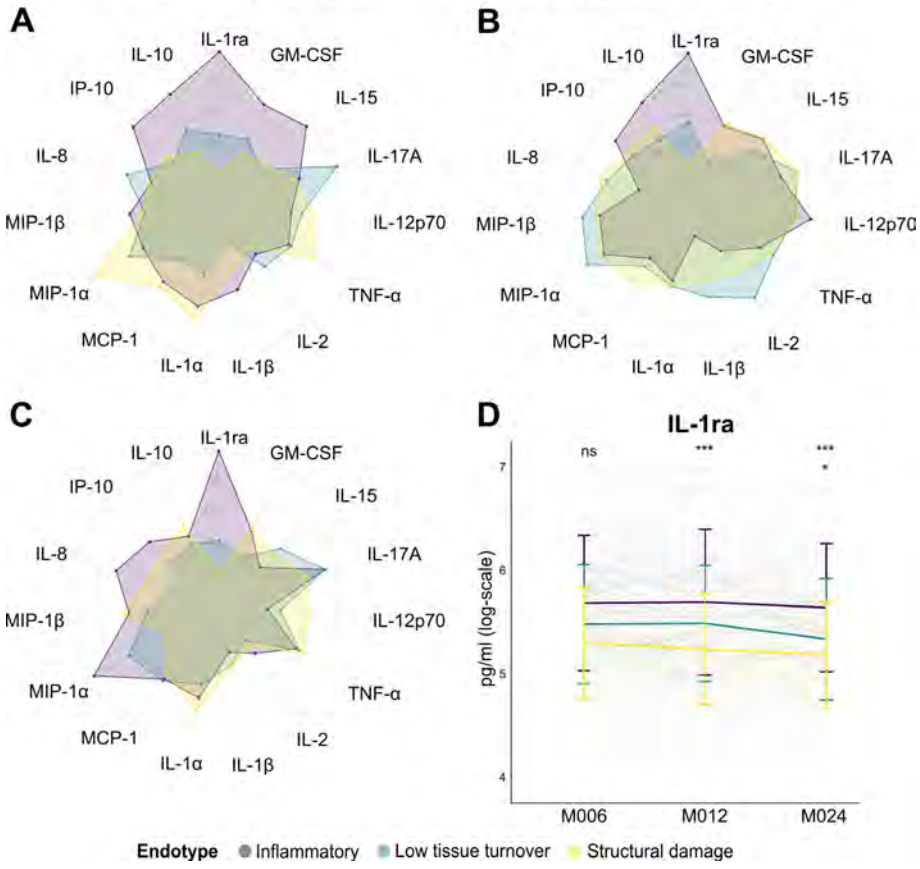

Figure 1. **Cytokine profiles of molecular endotypes of knee osteoarthritis participants from APPROACH at the A) six (M006), B) 12 (M012), and C) 24 (M024) month visits. Log-transformation and sex-specific z-score scaling was performed on the measurements (min-max normalized values shown). D) Longitudinal measurements of interleukin-1 receptor antagonist (IL-1ra) for each participant and endotype means with standard deviations. Differences between endotypes were estimated with a linear-mixed model, adjusting for age, sex, and BMI. P-values were Benjamini-Hochberg-adjusted for multiple testing. ns, no significance between any comparisons; *, p = 0.047 between inflammatory and low tissue turnover endotypes; ***, p < 0.001 between inflammatory and structural damage endotypes.**

markers. Cytokine levels were log-transformed, trimmed for extreme outliers (Winsor's and Tukey's rule), and sex-specific z-score scaling was performed. Cytokine-profiles of each endotype and visit were visualized using min-max normalized median concentrations. Percent changes in geometric mean cytokine concentrations between the endotypes were computed with linear mixed-effects models (LMMs), adjusting for age, sex, and BMI based on non-z-score scaled, log-transformed cytokine levels. P-values were Benjamini-Hochberg-adjusted for multiple testing. Intra-class correlations (ICCs) of the cytokines levels over time were estimated.

Results: Cytokine-profiling across the visits of the KOA endotypes revealed fluctuating longitudinal cytokine expression patterns (Fig. 1A-C). 8/15 cytokines exhibited good longitudinal stability (ICC > 0.75), with the highest ICCs achieved for MCP-1 of 0.89 (95% CI: 0.87, 0.91) and the anti-inflammatory cytokine interleukin-1 receptor antagonist (IL-1ra) of 0.88 (95% CI: 0.85, 0.90). IL-1ra was the only cytokine with differential levels between the endotypes (Fig. 1D). At month 12, a mean change of IL-1ra of 36% (95% CI: 19%, 54%; p-value < 0.001) was found for the inflammatory endotype relative to structural damage, while it was 40% (95% CI: 22%, 59%; p-value < 0.001) at month 24. At month 24, a mean change of IL-1ra of 21% (95% CI: 10%, 31%; p-value = 0.047) was found for the inflammatory endotype relative to low tissue turnover.

Conclusion: This study further characterized the three KOA by an independent modality from which the endotypes were originally defined. We showed that the cytokine panel was associated with longitudinal fluctuations across the endotype

subgroups but found that IL-1ra was persistently and differentially associated with the inflammatory endotype. These results may indicate an intriguing pathobiological involvement of the anti-inflammatory cytokine IL-1ra in OA subgroups driven by an inflammatory molecular endotype.

Session Title: (0306–0336) Osteoarthritis – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Unstructured data in physician notes can be incredibly valuable, especially for understanding patient-reported outcomes (PROs), which are often mentioned in these notes.

In this study, we explore an Artificial Intelligence technique to efficiently extract patient-reported pain in Osteoarthritis (OA) patients by prompt engineering Large Language Models (LLMs). Prompt engineering is the process of designing inputs in LLMs to help to get insights from unstructured data. Our objective is to apply prompt engineering techniques to extract/predict patient-reported pain in physician notes in OA patients.

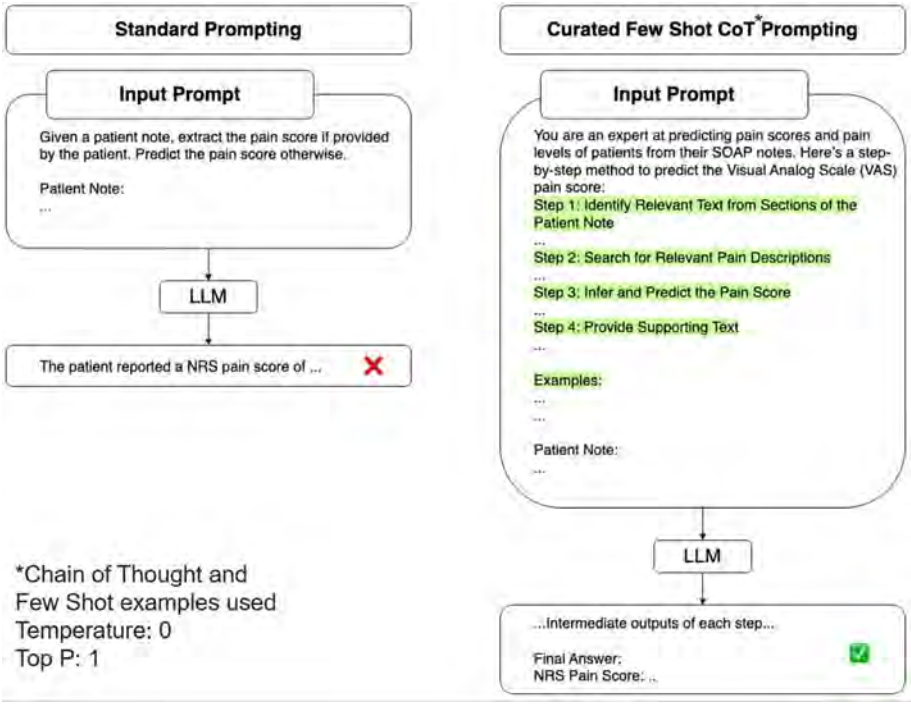

Figure 1

Methods: We used notes from patients with osteoarthritis at Internal Medicine screening (IM) and Orthopedic visits(ortho) enrolled in a registry before Total Knee Arthroplasty. A trained abstractor extracted pain scores (0-10) where they were explicitly stated. For notes without explicit scores, a board-certified IM physician estimated it based on the content. Notes were processed using the Llama 3.2-90B model, with a prompt engineered to extract 0-10 pain scores. **(Figure 1)**. Prompt engineering techniques, such as Chain of Thought and Few Shot examples, were employed. Outside of the visits, patients reported a 0–10 pain score **(Table 1)**. We calculated Kendall's Tau-b to measure ordinal correlation between the LLM predictions, abstractor scores when present and patient reported pain. Physician predictions were analyzed for notes without scores.

Results: There were 159 patients in this study with corresponding ortho and IM notes. We identified 133 IM notes and 66 ortho notes that explicitly stated pain scores **(Figure 2)**. In comparisons between pain scores extracted via a trained abstractor and the LLM, we observed a strong correlation in IM notes ($\tau = 0.81$) and an even stronger correlation in ortho

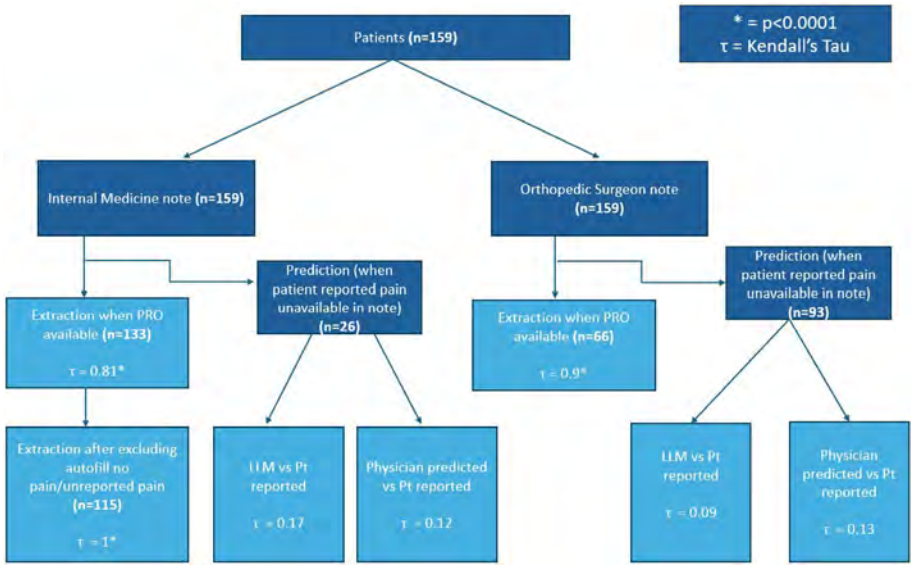

Figure 2

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

notes (τ = 0.99). In IM notes, 18 had a pain score written as 0 because the question was unanswered by patients, causing the EMR system to default to zero. In most cases, the LLM recognized and flagged these abnormalities. We then excluded the default zero and had a perfect correlation (τ = 1).

For notes lacking explicit pain scores, the LLM predicted scores for 26 IM notes and 93 ortho notes. When comparing LLM-predicted pain scores to patient-reported pain scores obtained outside of the visit, the correlations were weak (IM: τ = 0.17, p = 0.30) (Ortho: τ = 0.09, p = 0.30). When a board-certified physician was asked to predict the scores, the correlation remained weak (IM: τ = 0.12, p = 0.46) (Ortho: τ = 0.13, p = 0.12).

Conclusion: When patient pain is explicitly documented in the chart, large language models (LLMs) can accurately extract this information, offering a potential time-saving tool for abstracting data from clinical notes. In contrast, when pain scores are not explicitly documented, LLM predictions are less accurate but still comparable to the performance of physicians attempting to infer scores from the same unstructured text. LLMs represent an efficient method for extracting information from clinical notes which may have variability in documentation when relevant data exist in unstructured form, opening new pathways for leveraging this information in both clinical care and research.

A Composite Cumulative Cartilage Damage Metric Predicts Incident Symptomatic Knee OA: Data from the Osteoarthritis Initiative

Julieann Patarini[1], Timothy McAlington[2], Jonggyu Baek[1], Emily Kirillov[3], Nhung Vo[3], Michael Richard[3], Ming Zhang[4], Matthew Harkey[5], Grace Lo[6], Shao-Hsien Liu[1], Kate Lapane[1], Charles Eaton[7], James Mackay[8] and **Jeffrey Driban**[9], [1]UMass Chan Medical School, Worcester, MA, [2]UMass Chan School of Medicine, Arlington, MA, [3]Tufts Medical Center, Boston, MA, [4]Boston University, Westford, MA, [5]Michigan State University, East Lansing, MI, [6]Baylor College of Medicine / MEDVAMC, Houston, TX, [7]Brown University, Pawtucket, RI, [8]University of Cambridge; Norwich Medical School, San Diego, CA, [9]University of Massachusetts Chan Medical School, Marlborough, NH

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0306–0336) Osteoarthritis – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Cartilage defects are a hallmark of OA progression. We previously developed a composite MRI-based metric that combines cartilage damage from 6 anatomical regions throughout a knee. This cumulative damage metric relates to radiographic knee OA severity and reflects the accumulation of damage attributable to OA over the course of the disease. Cumulative damage is a sensitive biomarker for detecting cartilage changes; however, morphological cartilage changes typically occur later in the disease process. It remains unclear whether this composite score represents clinically meaningful pathways relevant to early stages of OA and can identify people before the onset of OA. We evaluated whether our cumulative damage composite metric is prognostic of incident symptomatic knee OA over the subsequent three years.

Methods: We analyzed a convenience sample within the Osteoarthritis Initiative of participants without symptomatic knee OA. Pain assessments and radiographs were collected annually. Using Magnetic resonance images from the initial visit, we combined 6 regional cartilage damage index measures (intra-reader ICC ≥ 0.84) to calculate a composite score, referred

Notes. (a). Relative risks adjusted for age, gender, and body mass index. (b). Relative risks for disease activity as a continuous measurement are per 1 unit. Bold = statistically significant associations. * Only unadjusted relative risks are reported because of the limited sample size within each stratum.

to as the cumulative damage metric. A cumulative damage metric of 0 approximated the average value for a reference sample (n=197, 53% had moderate-severe radiographic knee OA, average [SD] WOMAC pain score = 5.0 [3.6]); lower (negative) values indicate milder disease, while greater values indicate worse disease. The outcome was incident symptomatic knee OA (the combined state of frequent knee pain and radiographic OA [Kellgren-Lawrence Grade ≥ 2]) within three years after the cumulative damage measurement. We used logistic regression with repeated measures to assess the association between cumulative damage (continuous measure and tertiles) and incident symptomatic knee OA, adjusting for gender, age, and body mass index.

Results: Among 913 knees (n=572 participants), most were female (56%), white (82%), and had a mean age of 61 (SD=9) and body mass index of 29.4 (SD=4.5) kg/m^2. Cumulative damage ranged from -9.4 to 13.3 (higher values = worse cartilage damage). Knees that developed incident symptomatic OA had greater cumulative damage (2.0 [3.4] vs. 0.6 [3.3]); the adjusted relative risk per 1 unit increase was 1.09 (95% confidence interval: 1.06-1.13; Table). More specifically, the tertile with the worst cumulative damage – analogous to damage typically observed among knees with radiographic OA (Table) – was associated with a greater risk for incident symptomatic knee OA.

Conclusion: Greater cumulative damage, especially severe damage typical of knees with radiographic OA, is associated with a higher risk of incident symptomatic OA.

Abstract Number: 0310

Evaluate Safety, Tolerability, and Pharmacodynamics of a Single Intra-Articular Injection of GNSC-001 Gene Therapy in Subjects with Knee Osteoarthritis: 12-month Results from DONATELLO

Annahita Keravala[1], Philip Conaghan[2], shanna jackson[1], sharmila Vijay[1], Thomas Chalberg[3], **Jeyanesh Tambiah**[4] and Laurie Halligan[1], [1]Genascence, Palo Alto, CA, [2]University of Leeds, Leeds, United Kingdom, [3]Genascence Corp, Palo Alto, CA, [4]Genascence, San Diego, CA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0306–0336) Osteoarthritis – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: IL-1 contributes significantly to osteoarthritis (OA) pathology, driving inflammation and cartilage degradation. Prior therapies targeting IL-1 have shown limited success due to inadequate drug delivery and retention in joints. GNSC-001, a recombinant adeno-associated virus (rAAV) encoding the IL-1 receptor antagonist (IL-1Ra) transgene, is designed to provide sustained, local inhibition of IL-1 activity after a single intra-articular (IA) injection. The DONATELLO Phase 1b trial was initiated to evaluate the safety, dosing and pharmacodynamic effects of GNSC-001. Effects of immune conditioning with short regimens of corticosteroids (CS) were also investigated. Results from the 12-month primary follow-up period are reported.
