SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Polymyalgia rheumatica (PMR) is characterized by increases in serum IL-6 and the proportion of Th17 cells in circulating blood. During PMR, IL-6 may originate from circulating monocytes or from the synovial tissue itself. To clarify the role of synovial tissue, we performed experiments using synovial fibroblast (SF) cultures derived from synovial bursae, which are the affected structures in PMR. As secukinumab (SEC) is currently being evaluated in glucocorticoid-dependent PMR, we investigated, in the current study, the impact of IL-17A and SEC on SFs activation.

Methods: SFs were obtained from *ex-vivo* cultures of synovial tissue from the subacromial bursae after arthroscopy in patients with rotator cuff injury. SFs were cultivated *in vitro* with IL-17A (50 ng/mL), IFN-g (2.5 ng/mL) and/or SEC (20 µg/mL) for 24 hours. mRNA expression was analyzed by Bulk RNA sequencing and RT-PCR. The impact of IL-17A on T-cell polarization was assessed by performing co-cultures of SFs and allogenic peripheral blood mononuclear cells (PBMC) activated with anti CD3/CD28 beads. SFs were stimulated with IL-17A or IL-17A + SEC or IgG isotype control for 72 hours, then co-cultures were performed over 7 days. T-cell polarization was analyzed by flow cytometry.

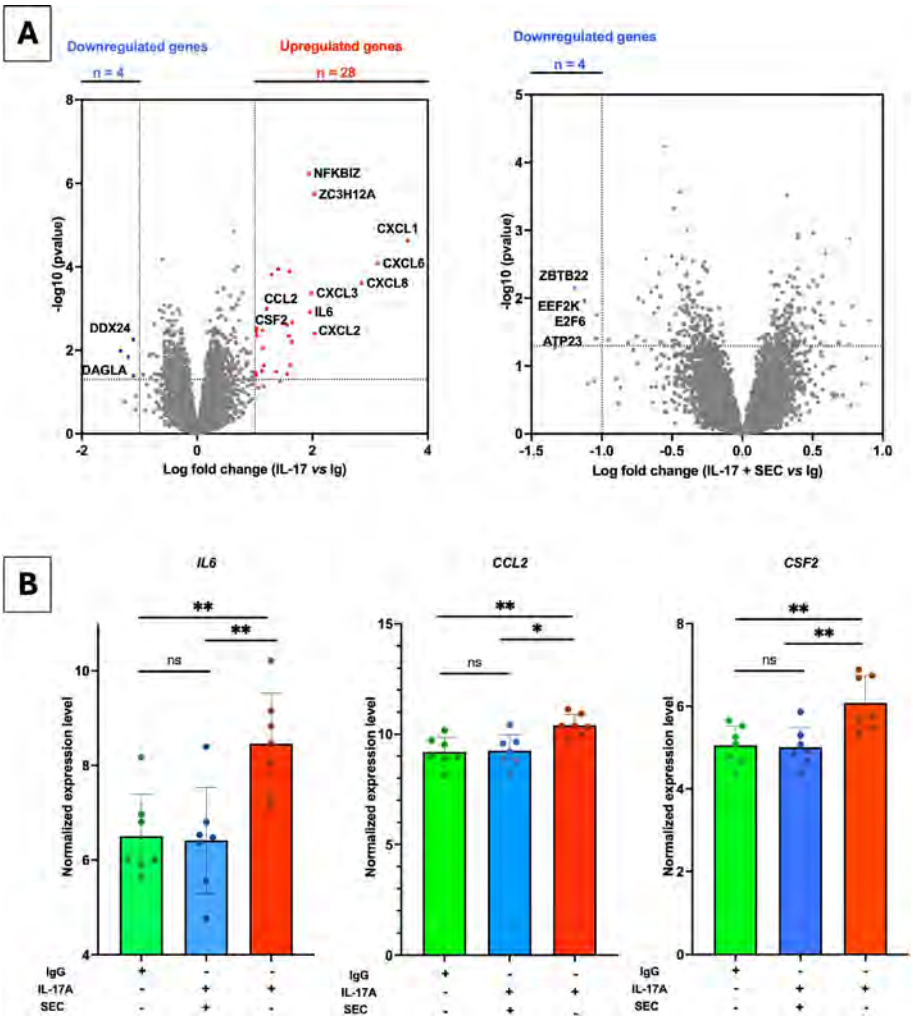

Figure 1: Bulk RNA sequencing results from IL-17A stimulated synovial fibroblasts (n = 8). (A) Volcano plot showing differential gene expression (IL-17A versus IgG; IL-17A + SEC versus IgG). (B) Barplot visualization of IL6, CSF2 and CCL2 gene expression from IL-17A, IL-17A + SEC and IgG stimulated synovial fibroblasts. Columns represent the median, the "whiskers" represent quartiles Q1 and Q3. *: $p < 0.05$, **: $p < 0.01$.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

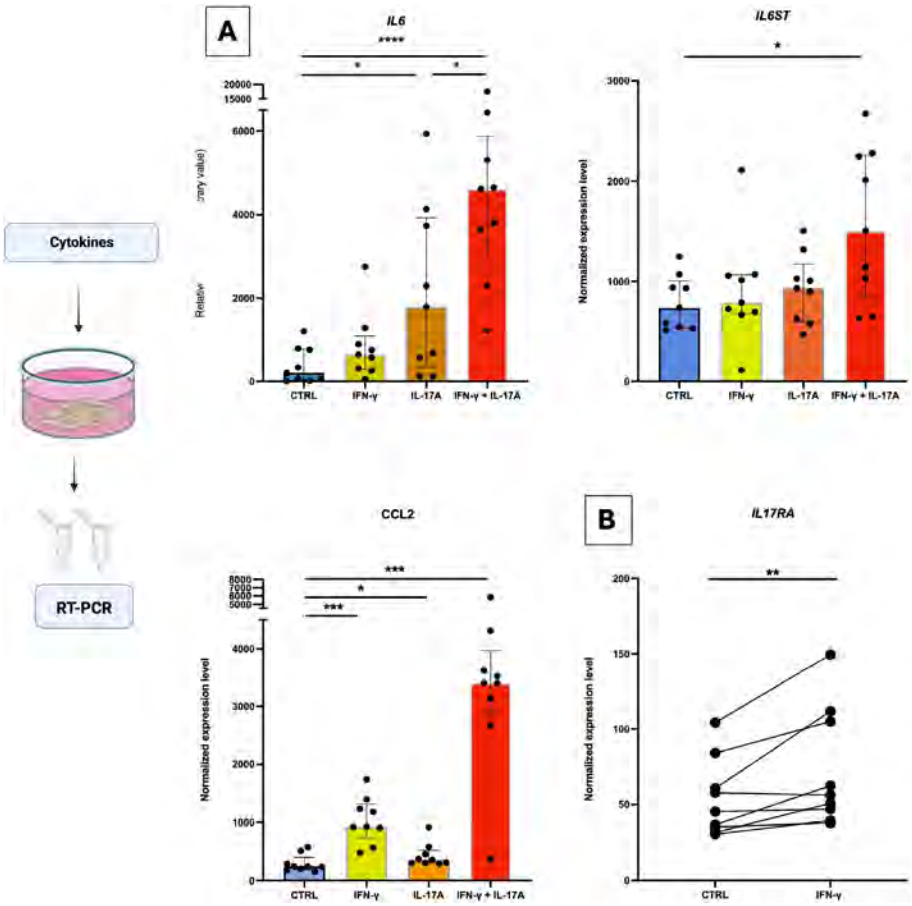

Figure 2: Level of mRNA expression of IL6, IL6ST, CCL2 and IL17RA by synovial fibroblasts after stimulation with IL-17A and/or IFN-γ (n = 9). A: Level of mRNA expression of IL6, IL6ST and CCL2 in synovial fibroblasts after stimulation with IL-17A (50 ng/mL) and/or IFN-γ (2,5 ng/mL). B: Effect of IFN-γ on mRNA expression of IL17RA by synovial fibroblasts. Columns represent the median, the "whiskers" represent quartiles Q1 and Q3. *: $p < 0.05$, **: $p < 0.01$, ***: $p < 0.001$, ****: $p < 0.0001$

Results: The cells obtained through synovial tissue culture exhibited a phenotype fitting with fibroblasts ($CD90^+CD105^+CD73^{int}CD34^-CD45^-$). Bulk RNA sequencing analysis showed increased levels of expression for genes associated with IL-17, PI3k-Akt and the NF-KB signaling pathway. Stimulation with IL-17A led to significant increases in 28 genes, notably *IL6*, *CSF2* (encoding for GM-CSF), and *CCL2*. The addition of SEC led to a significant decrease in these mRNAs, restoring a transcriptomic profile similar to unstimulated SF (**figure 1**). RT-PCR analyses confirmed an increase in the mRNA expression of *IL6*, *CSF2* and *CCL2* in the presence of IL-17A, while no difference was observed for *IL6ST*, *IFNGR1/2*, *IL12A*, *IL23A*, *FAP*, *IL17RA* and *IL17RC* mRNA. Co-stimulation with IL-17A and IFN-g led to a strong increase in mRNA expression of *IL6*, *IL6ST*, and *CCL2* (**figure 2A**). This synergy between IL-17A and IFN-g may be reliant on an increase in *IL17RA* mRNA expression after IFN-g stimulation (**figure 2B**). Co-cultures of SFs with allogenic PBMC were performed after 72h of SFs stimulation with either IgG isotype control, IL-17A or IL-17A+SEC. Compared to SFs pre-treated with IgG or IL-17A+SEC, SFs pre-treated with IL-17A were able to promote Th17 cell polarization without significant increases in the proportions of Th1, Tc1 or Tc17 cells (**figure 3**).

Conclusion: This work highlights the potential role of SFs in PMR via their ability to strongly express *IL6*. SFs are also sensitive to IL-17A and IFN-y, which are two key cytokines in PMR. In response to IL-17A, and with a synergistic effect with IFN-y, SFs strongly express *IL6*, leading to an increase in Th17 polarization. In addition, SFs express other markers such as *CCL2*, suggesting that they may induce the recruitment of $CCR2^+$ monocytes. Finally, SEC can restore a non-inflammatory profile in activated SF, suggesting the potential of IL-17A therapeutic target in PMR.

Background/Purpose: Sarcoidosis is a systemic autoimmune disease with multiorgan involvement. In this study, we analyzed the differences in characteristics in patients with sarcoid myocarditis (cardiac sarcoidosis) and sarcoidosis with other systemic manifestations (other sarcoidosis).

Methods: A retrospective cohort study was performed using TriNetX, a global federated health research network that provides access to electronic medical records across large health care organizations (HCOs). Data was used from 102 HCOs. Patients (>18 years old) were divided into two cohorts, based on the presence of cardiac sarcoidosis (ICD-10 D86.8) or other systemic manifestations of sarcoidosis. 1:1 propensity score matching was performed using 27 different baseline characteristics (Table 1 and Table 2). Kaplan-Meier survival analysis was performed to look at differences in mortality.

Results: 10,296 patients were included in the cardiac sarcoidosis cohort and 160,918 patients were included in the other sarcoidosis cohort before propensity score matching. After propensity score matching, 10,046 patients were included in each cohort.

Univariate analysis before matching showed several significant differences (Table 1 and Table 2). After propensity score matching, there was a significantly higher frequency of black or African American patients with cardiac sarcoidosis (p=0.003), where other sarcoidosis had a significantly higher frequency of white patients (p < 0.001, Table 1). Patients with cardiac sarcoidosis had a significantly increased frequency of hypertension (p=0.007), lung, cutaneous, and lymph node involvement (p< 0.001) and significantly higher frequencies of meningitis (p=0.016), iridocyclitis, arthropathy, and myositis (p< 0.001) (Table 1). The frequency of elevated ESR, CRP, and medication usage was not significantly different (Table 2).

Mortality risk was 10.1% in the cardiac sarcoidosis group vs. 15.8% in the other sarcoidosis group, resulting in a statistically significant risk difference of –5.7%, indicating a lower absolute risk of death in the myocarditis group (Figure 1A). Risk ratio was 0.64 (95% CI: 0.60–0.69) and odds ratio was 0.60 (95% CI: 0.55–0.65), suggesting a ∼40% reduction in the relative

Figure 1A

1 Mortality

Risk analysis

	Cohort	Patients in cohort	Patients with outcome	Risk
1	Sarcoid with myocarditis	10,046	1,017	0.101
2	Sarcoid all - myocarditis excluded	10,046	1,588	0.158

		95% CI	z	p
Risk Difference	-0.057	(-0.066, -0.048)	-11.992	0.000
Risk Ratio	0.640	(0.595, 0.689)	N/A	N/A
Odds Ratio	0.600	(0.552, 0.653)	N/A	N/A

Figure 1B

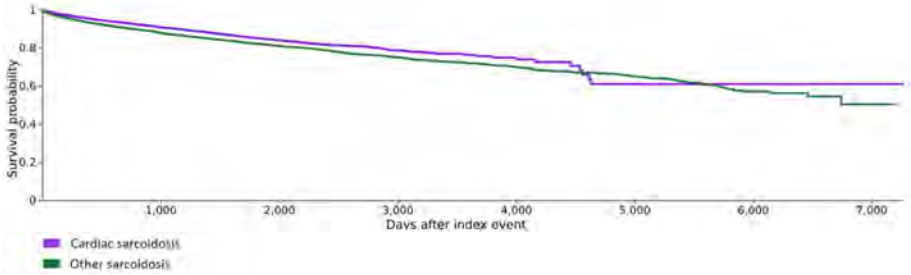

Figure 1A. Mortality Risk Analysis of Patients with Cardiac Sarcoidosis vs. Other Sarcoidosis Figure 1B. Kaplan-Meier Survival Analysis of Mortality in Patients with Cardiac Sarcoidosis vs. Other Sarcoidosis

risk or odds of mortality in the cardiac sarcoidosis group (Figure 1A). Kaplan-Meier survival analysis also showed that the survival probability at the end of study period was higher in those with myocarditis (60.99%) than those without (50.33%) (Figure 1B). The difference was statistically significant (log-rank test $\chi^2 = 33.54$, $p < 0.001$). Cox regression analysis yielded a hazard ratio of 0.79 (95% CI: 0.73–0.86, $p = 0.002$), indicating a 21% lower hazard of death over time in the myocarditis group, with the proportional hazards assumption met.

Conclusion: Black or African American race and several organ-specific sarcoidosis subtypes remained more prevalent in the cardiac sarcoidosis group after matching, suggesting that cardiac sarcoidosis may represent a distinct systemic phenotype with more frequent multiorgan involvement. Contrary to expectations, patients with sarcoid myocarditis demonstrated a lower mortality risk and better survival compared to sarcoidosis patients without myocarditis.

Abstract Number: 1152

Cutaneous Panniculitis in Rheumatology: A Descriptive Cohort Study from a Multidisciplinary Experience

Claudia Campos-Fabre[1], Carlota Ureta-Moneva[1], Elena Sendagorta[1], Jose Rodríguez-Gago[1], Maria José Beato[1], Agustin Remesal[2], Rosa Alcobendas[1], Clara Udaondo[1], Gema Bonilla[3], Laura Nuño[4], Irene Monjo Henry[2], Carolina Tornero[5] and Chamaida Plasencia-Rodríguez[2], [1]La Paz University Hospital, Madrid, Spain, [2]Hospital Universitario La Paz, Madrid, Spain, [3]Hospital Universitario La Paz, Rheumatology, Madrid, Madrid, Spain, [4]Hospital Universitario Puerta de Hierro, Madrid, Spain, [5]Hospital La Paz, Madrid, Spain

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Panniculitis refers to inflammatory disorders of subcutaneous fat that pose diagnostic challenges due to nonspecific clinical features and overlapping histopathological patterns. Although it can occur in immune-mediated diseases (IMIDs), its characterization in rheumatologic settings remains limited. This study aimed to describe the clinical, immunological, histological features and treatments of panniculitis cases jointly evaluated by Rheumatology and Dermatology.

Methods: We conducted a retrospective, observational study of patients diagnosed with panniculitis via electronic health records at Hospital Universitario La Paz between January 2022 and March 2025, during the implementation of a multidisciplinary approach involving adult and pediatric Rheumatology and Dermatology. Patients were identified using the keyword "panniculitis." Data collected included sociodemographics, diagnosis dates, histological pattern (when available), etiology, associated rheumatologic disease, clinical context (initial or subsequent manifestation), lab findings, treatments, and outcomes (remission or recurrence). Statistical analysis was performed using R v4.4.1.

Results: Of 70 patients identified, 63 with cutaneous panniculitis were included (7 pediatric). Most were women (87.3%), with a median age of 49.5 years *(Table 1)*. The leading causes were idiopathic erythema nodosum (EN: 33.3%), Behçet's disease (BD: 11.1%), systemic lupus erythematosus (SLE: 9.5%), infections (15.9%), and sarcoidosis (7.9%).

Panniculitis was the initial manifestation of an IMID in 33.3%. Among BD patients (n=7), it was the first sign in 85.7%; in SLE (n=6), it preceded diagnosis in 50%.

Histopathology was available in 27 cases, with septal panniculitis without vasculitis being most common (55.6%), associated with sarcoidosis, BD, and idiopathic EN. Lobular panniculitis without vasculitis was linked to SLE. Of 35 non-biopsied cases, 26 had idiopathic or infectious causes, likely guiding the decision to omit histology.

Panniculitis achieved remission in 73% (n=46), mainly in idiopathic EN (15) and infectious causes (10), most of whom (98%) responded to symptomatic or antimicrobial therapy. Recurrences occurred in 27% (n=17), linked to idiopathic EN (5), BD (3), SLE (2), autoinflammatory syndrome (AIS: 2), or other IMIDs (5). Of these, 82% required immunomodulatory treatment:

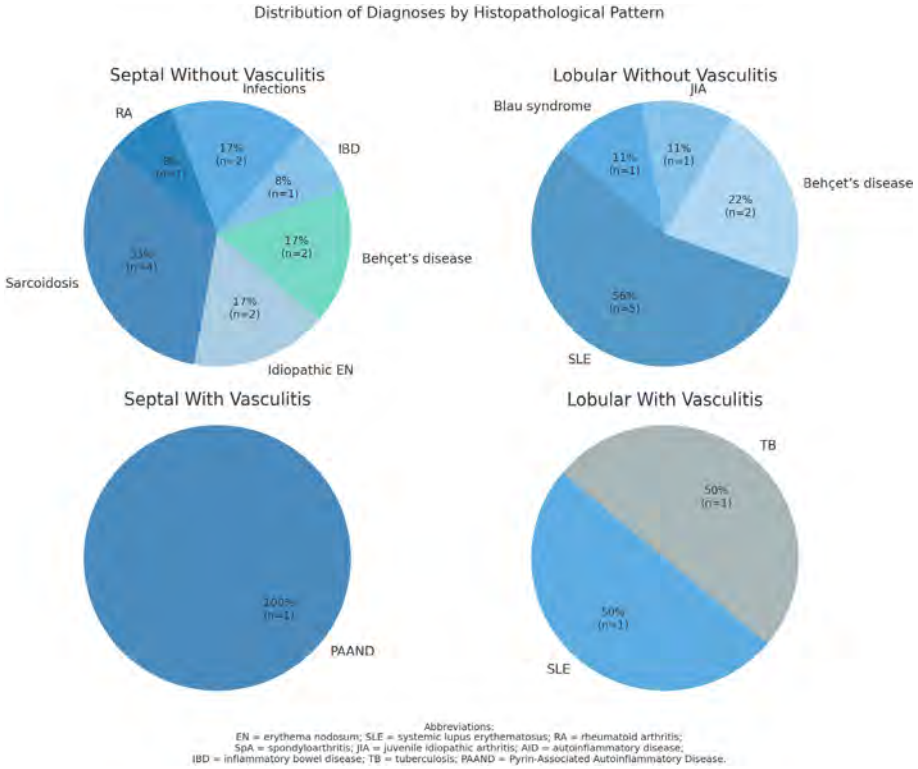

Figure 1. Distribution of diagnoses by histopathological pattern.

Conclusion: Cutaneous panniculitis may be an early or evolving feature of systemic IMIDs, particularly BD and SLE. While idiopathic and infectious cases often remit with symptomatic or antimicrobial therapy, recurrent or immune-mediated forms typically require immunosuppression, including biologics and JAK inhibitors. Multidisciplinary evaluation improves diagnostic accuracy and treatment individualization in complex cases.

Background/Purpose: The novel diagnosis of VEXAS in 2020 led to the proposed possibility of a new category of hematoinflammatory syndromes linking clinically overlapping hematologic and autoinflammatory diseases with multiorgan involvement, laboratory and histopathologic features, and genetic mutation in parallel to the clinical picture of VEXAS syndrome and hemophagocytosis (HLH/MAS)[1, 2]. Lack of definition and standard of care diagnostic and treatment algorithms for this subset of diagnoses pose critical complexities and challenges, given their high morbidity and mortality, hence the need for understanding these disease entities to improve patient outcomes. This study aims to review baseline disease characteristics, diagnostic and treatment approaches, and outcomes at our academic center.

Methods: This is IRB-approved retrospective analysis on all patients 18-89 years old with hematoinflammatory manifestations at University of Florida between 01/01/2020 to 03/31/2025. IDR analysis obtained 162 patients with ICD-10-specific codes for HLH/MAS/VEXAS (D76.1,.3,.2;M04.1,.2,.8,.9) for individual chart review. Inclusion criteria were determined by clinicians' discretion for diagnosis based on HLH 2004/MAS 2016 criteria, histopathology, and/or genetic tests. Subsequent data was collected and analyzed.

Results: Baseline characteristics are summarized (Table 1), with 23 patients meeting criteria for hematoinflammatory diagnosis. Mean age at diagnosis was 40 years. Mean duration of symptoms was 16.35 weeks before diagnosis. Majority were Caucasian(43%), male(57%), and younger age of < 50 years (61%). Most common underlying diagnoses are autoimmune diseases(48%), infection (30%), primarily Epstein-Barr virus (EBV), followed by hematologic etiologies (17%). Constitutional symptoms, such as fever and fatigue, and hematologic findings were present in all patients (Figure 1); gastrointestinal, lymphadenopathy, and dermatologic symptoms in 40%; 91% had at least 3 organ systems involved upon initial presentation. Diagnoses were mainly HLH (48%) and MAS (35%) with fever, elevated ferritin (mean,14,186ng/ml), and cytopenias as most common presentation. Biopsy(78%) and genetic testing (43%)revealed 7 with positive vacuoles and

Figure 2. Treatment received with the corresponding number of patients and prevailing treatment approaches over the past 5 Years following hematoinflammatory diagnosis.

hemophagocytes; 1 with MDS diagnosed with VEXAS after genetic confirmation, and only revealed vacuoles with repeat biopsy after 3 months. Previous treatments comprised majority with csDMARDs.Figure 2 outlines the treatments received following diagnosis-glucocorticoid (100%), Anakinra (43%), and Etoposide (26%). Mean length of stay before discharge was 4 weeks;3 patients died due to infections and hospital complications.

Conclusion: This study provides a heterogeneous presentation of hematoinflammatory syndromes at our center. Due to diagnostic complexities and multiorgan manifestations, clinicians must be cognizant of their broader definitions, familiarize with their most frequent diagnostic associations, and monitor disease indicators (e.g., serial serum ferritin levels, biopsy, etc), if with high clinical suspicion. This leads to earlier recognition and more optimal therapeutic strategies for hematoinflammatory syndromes to improve clinical outcomes.

Abstract Number: 1154

Assessment of Damage Using the igg4-related Disease Damage Index

Eduardo Martin-Nares[1] and Gabriela Hernandez-Molina[2], [1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, [2]Instituto Nacional de Ciencias Medicas y Nutricion, Mexico City, Federal District, Mexico

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: IgG4-related disease (IgG4-RD) is a chronic fibroinflammatory disorder affecting multiple organs, often leading to irreversible damage. Standardized tools like the IgG4-RD Damage Index (DI) are crucial for understanding disease progression and phenotype-specific characteristics, but their performance remains untested in non-Chinese populations. This study aimed to assess damage in Mexican IgG4-RD patients using the IgG4-RD DI.

Methods: We conducted a retrospective study of patients with IgG4-RD who met the 2020 Revised Comprehensive Diagnostic Criteria and/or the 2019 ACR/EULAR Classification Criteria for IgG4-RD. All patients were followed for at least one year. Damage was defined as irreversible organ dysfunction or failure caused by IgG4-RD or by procedures performed for its diagnosis or treatment and persisted for at least six months. Damage was assessed using the IgG4-RD DI at the last follow-up.

Results: We included 70 patients with a mean age of 52.1 ± 15.6 years, of whom 34 (48.6%) were male. The median duration of disease (from symptom onset to last follow-up) was 77.5 months (IQR 54–133).

At the last follow-up, organ damage was detected in 56 patients (80%) based on the IgG4-RD RI. The median DI score for the entire cohort was 1 (IQR 0–3), while for patients with damage it was 2 (IQR 1–3; range 1–9). Figure 1 shows the distribution of IgG4-RD DI scores. The most frequently affected organ-specific domains of the IgG4-RD DI were 'Pancreas' (31.4%), 'Lung' (15.7%), 'Kidney' (11.4%), 'Retroperitoneum/mediastinum' (8.6%), and 'Liver/biliary tree' (8.6%). The 'Others' domain was scored in 26 patients (37.1%), primarily due to partial or total organ resection related to IgG4-RD (22.8%), disease-related or treatment-related diabetes mellitus (15.7%), and damage in other organs (14.3%).

Patients with the head and neck-limited phenotype had lower DI scores (p=0.05). The 'Retroperitoneum/mediastinum' domain was scored more frequently in the retroperitoneal/aortic phenotype (p< 0.001), while the 'Pancreas' domain was scored more frequently in the pancreato-biliary and Mikulicz/systemic phenotypes (p=0.001). The 'Kidney' domain was more commonly scored in the retroperitoneal/aortic phenotype (p=0.01), due to obstructive nephropathy. The proliferative phenotype had more commonly damage in the 'Pancreas' domain (p=0.01), while the fibrotic phenotype in the 'Retroperitoneum/mediastinum' (p< 0.001) and 'Thyroid' domains (p=0.02). There were no significant differences in DI scores or domain involvement between men and women.

Comparing patients with and without damage (Table 1), the former group was less likely to have the head and neck-limited phenotype (20.4% vs. 56.3%, p=0.005; OR: 0.16), and more likely to have elevated IgG levels (60.9% vs. 31.3%, p=0.04; OR: 4.67).

Conclusion: Organ damage is frequent in IgG4-RD, varies by phenotype, and is most common in the pancreas. Elevated IgG levels increase damage risk, while the head and neck-limited phenotype is protective. Organ resections for diagnostic or therapeutic purposes and glucocorticoid toxicity are key contributors to cumulative damage in IgG4-RD.

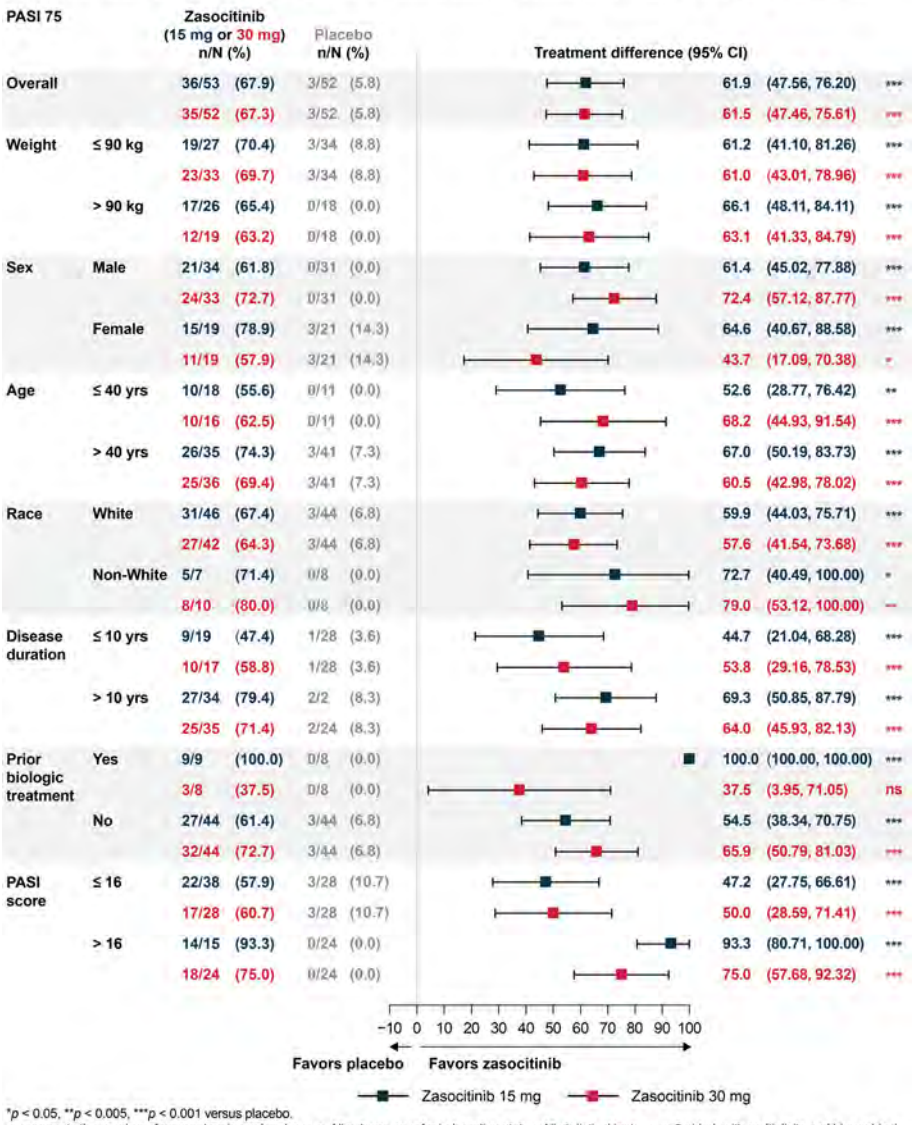
SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Zasocitinib (TAK-279) is an investigational, highly selective and potent, oral, allosteric tyrosine kinase 2 (TYK2) inhibitor. In a phase 2b trial of moderate-to-severe plaque psoriasis, the primary endpoint (psoriasis area and severity index [PASI] 75 response at Week 12) was met with zasocitinib 5 mg, 15 mg and 30 mg once daily; 33% of patients receiving zasocitinib 30 mg achieved PASI 100. The objective of this *post hoc* analysis was to evaluate the influence of baseline characteristics on zasocitinib efficacy in patients with plaque psoriasis.

Figure. PASI 75 response rates were significantly greater in patients treated with zasocitinib 15 mg or 30 mg than in those receiving placebo across all subgroups except for patients receiving zasocitinib 30 mg who had prior biologic treatment.



*$p < 0.05$, **$p < 0.005$, ***$p < 0.001$ versus placebo.
n represents the number of responders in each subgroup. All subgroups refer to baseline status. All statistical tests were 2-sided, with multiplicity and hierarchical testing completed on the primary endpoint only; *p* values for all subgroup analyses are nominal. Owing to the small number of patients in some of the subgroups, data comparisons should be interpreted with caution in some instances.
CI, confidence interval; ns, not significant; PASI, Psoriasis Area and Severity Index.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: This phase 2b, randomized, multicenter, double-blind, placebo (PBO)-controlled, multiple-dose study (NCT04999839) included *post hoc* analyses of Week 12 PASI 75/90/100 responses, Physician Global Assessment (PGA) scores (clear [0] or almost clear [1]) and Dermatology Life Quality Index (DLQI) scores stratified by weight, sex, age, race, disease duration, prior biologics use and baseline PASI. Treatment differences (zasocitinib versus PBO) for all subgroups except prior biologic treatment were calculated using the Mantel–Haenszel method; 95% confidence intervals and *p* values were calculated using the Wald method and Cochran–Mantel–Haenszel test (stratified for prior biologic treatment), respectively. Treatment difference estimates were unadjusted for the subgroup analysis by prior biologic treatment; *p* values were calculated using a chi-square test. For DLQI, a mixed model for repeated measures was used to calculate the least-squares mean, with treatment, visit, treatment-by-visit interaction and prior biologic treatment (not included for the subgroup analysis by prior biologic treatment) as fixed effects and baseline score as the covariate.

Results: Overall, 259 patients were included in this study. PASI 75 response rates with zasocitinib were greater than PBO regardless of **weight** (≤ 90kg: PBO, 8.8%; 15 mg, 70.4%; 30 mg, 69.7%; > 90kg: PBO, 0%; 15 mg, 65.4%; 30 mg, 63.2%, each $p < 0.001$), **sex** (male: PBO, 0%; 15 mg, 61.8%; 30 mg, 72.7%, each $p < 0.001$; female: PBO, 14.3%; 15 mg, 78.9% [$p < 0.001$]; 30 mg, 57.9% [$p < 0.005$]), **age** (≤ 40 years: PBO, 0%; 15 mg, 55.6% [$p < 0.01$]; 30 mg, 62.5% [$p < 0.001$]; > 40 years: PBO, 7.3%; 15 mg, 74.3%; 30 mg, 69.4%, each $p < 0.001$), **race** (White: PBO, 6.8%; 15 mg, 67.4%; 30 mg, 64.3%, each $p < 0.001$; non-White: PBO, 0%; 15 mg, 71.4% [$p < 0.01$]; 30 mg, 80.0% [$p < 0.005$], **disease duration** (≤ 10 years: PBO, 3.6%; 15 mg, 47.4%; 30 mg, 58.8%; > 10 years: PBO, 8.3%; 15 mg, 79.4%; 30 mg, 71.4%, each $p < 0.001$), **prior biologics use** (yes: PBO, 0%; 15 mg, 100% [$p < 0.001$]; 30 mg, 37.5% [$p = 0.055$, not significant]; no: PBO, 6.8%; 15 mg, 61.4%; 30 mg, 72.7%, each $p < 0.001$) and **baseline PASI** (≤ 16: PBO, 10.7%; 15 mg, 57.9%; 30 mg, 60.7%; > 16: PBO, 0%; 15 mg, 93.3%; 30 mg, 75.0%, each $p < 0.001$; **Figure**). PASI 90, PASI 100, PGA 0/1 and DLQI generally improved with zasocitinib treatment versus PBO in almost all subgroups.

Conclusion: Treatment with zasocitinib 15 mg or 30 mg led to greater response rates at Week 12 versus PBO in patients with moderate-to-severe plaque psoriasis, for nearly all baseline characteristics assessed. Phase 3 trials (NCT06088043 and NCT06108544) are ongoing to investigate the efficacy and safety of zasocitinib in larger patient groups.

Abstract Number: 1156

Incidence and Prevalence of Interstitial Pneumonia with Autoimmune Features in a Population-Based Cohort

Elena Joerns[1], Sara Achenbach[1], Cynthia Crowson[2], eva carmona[1], Robert Vassallo[3], John Joerns[1], Vanessa Kronzer[3], John Davis[3] and Elena myasoedova[3], [1]Mayo Clinic, Rochester, [2]Mayo Clinic, Stewartvillle, MN, [3]Mayo Clinic, Rochester, MN

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Interstitial pneumonia with autoimmune features (IPAF) is a type of interstitial lung disease (ILD) with features of autoimmunity, yet patients do not fulfill criteria for any defined systemic autoimmune rheumatic diseases (SARDs) (1). Classification of IPAF requires the presence of interstitial pneumonia and presence of features from at least two of three domains: serological (specific autoantibodies), clinical (signs and symptoms which may be seen in SARDs) and morphological (imaging or biopsy features within the thorax suggestive of ongoing inflammation) (1). While previously thought to be rare

Table 1: Baseline characteristics of the incident IPAF cohort *Elevated above laboratory reference level IPAF – interstitial pneumonia with autoimmune features; SD – standard deviation; UIP – usual interstitial pneumonia

Table 1: Baseline characteristics of the incident IPAF cohort

Baseline characteristic	Total (N=33) n(%)/mean [SD]
Female sex	22 (67)
Age at IPAF incidence, years	70.6 [14.8]
White race	30 (91)
Hispanic ethnicity	0 (0)
Serological domain met	28 (85)

IPAF - interstitial pneumonia with autoimmune features

(2), a recent study revealed that 31% of ILD patients undergoing lung transplant are classified as IPAF (3). Studies of IPAF are limited by its lack of diagnostic criteria and propensity to be studied only at large tertiary referral centers. There are therefore no population-based studies of IPAF, which limits our understanding of its incidence and prevalence.

Methods: We conducted a population-based study to establish the incidence and prevalence of IPAF in a geographically defined area between 2010-2019. Prevalence was calculated on January 1st, 2020. We screened all patients with 2+ ILD codes as well as abnormal autoimmune serologies and/or 2+ codes for Raynaud's syndrome. We excluded all patients with 2+ SARD codes. We performed manual chart review and radiographic review to validate IPAF classification criteria (1) and presence of ILD. We collected data on the presence and specific features of each of the three domains included in IPAF classification: serological, clinical, and morphological (1). Date of IPAF incidence was considered the date of first ILD diagnosis. Descriptive statistics were utilized to describe the baseline characteristics of the cohort. Age- and sex-specific incidence rates were calculated using the number of incident cases as the numerator and census estimates as the denominator. Overall incidence rates were age- and/or sex-adjusted to the 2020 white population of the USA. Confidence intervals for incidence rates were obtained by assuming that the number of incident cases followed a Poisson distribution.

Results: After manual review, a total of 33 patients had confirmed incident IPAF. Table 1 describes the baseline features of those with incident IPAF. The incidence of IPAF was greater in women than in men and increased with age (Table 2). Overall, the annual sex-and age-adjusted IPAF incidence was 3.2 per 100,000 persons. On January 1, 2020, there were 30 patients with prevalent IPAF corresponding to a sex- and age-adjusted IPAF prevalence rate of 26 per 100,000 persons.

Conclusion: To our knowledge, this is the first population-based cohort study of IPAF incidence and prevalence. IPAF is a rare disease, with low prevalence and low incidence rates which are higher in women than men and increase with age. Future studies will expand on the cohort and will include study of phenotypes among IPAF patients and relationship with clinical outcomes.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Herpes zoster (HZ) is common among older adults, with a lifetime risk of 25%. The risk is particularly increased in individuals with immunosuppression such as those with inflammatory rheumatic musculoskeletal diseases (iRMD). In this population, both the underlying disease and immunomodulatory treatments contribute to higher HZ incidence and severity. While the recombinant zoster vaccine (RZV) is recommended for immunocompromised individuals, data on its real-world safety and tolerability in patients with iRMD are still limited.

Methods: Adult patients with rheumatoid arthritis (RA), axial spondyloarthritis (axSpA), and giant cell arteritis (GCA) who were eligible to receive RZV were prospectively included in this ongoing study. Data on demographics, vaccination status, and iRMD diagnosis were collected at first dose visit (FDV). Disease activity and immunosuppressive treatments were assessed at FDV, second dose visit (SDV) and months 3, 6 and 12. Flares, adverse events (AEs), and zoster breakthrough cases were monitored following RZV administration at SDV and months 3, 6 and 12. AEs were categorized by system organ class (SOC) and measured per dose (%). Localized and systemic AEs, including severe AEs (SAEs) and adverse events of special interests (AESIs), were differentiated. A flare was defined as change in DAS-28 >1.2 for RA, ASDAS ≥ 0.9 for axSpA, or clinical signs/CRP ≥ 0.5 mg/dl and/or ≥30 mm for GCA. Descriptive analyses were performed.

Results: A total of 150 patients (age 22-84 years) were included, 32 (21.3%) with a history of HZ). All received RZV at FDV, and 145 (96.7%) also at SDV. Follow-up was completed by 139 (92.7%), 129 (86%), and 100 (66.7%) patients at months 3-, 6-, and 12, respectively, with 295 vaccine doses administered. At least one AE was reported by 108, 105, 30, 22 patients at months 2, 3, 6 and 12, respectively. In total,168, 169, 33 and 25 AEs occurred at those timepoints. Most frequent localized AEs were pain at the injection site (n=102; 34.6%), swelling at the injection site (n=21; 7.1%), and redness at the injection side (n=20; 6.8%). Common systemic AEs included fever (n=49; 16.6%), fatigue (n=34; 11.5%) and musculoskeletal pain (n=31; 10.5%).

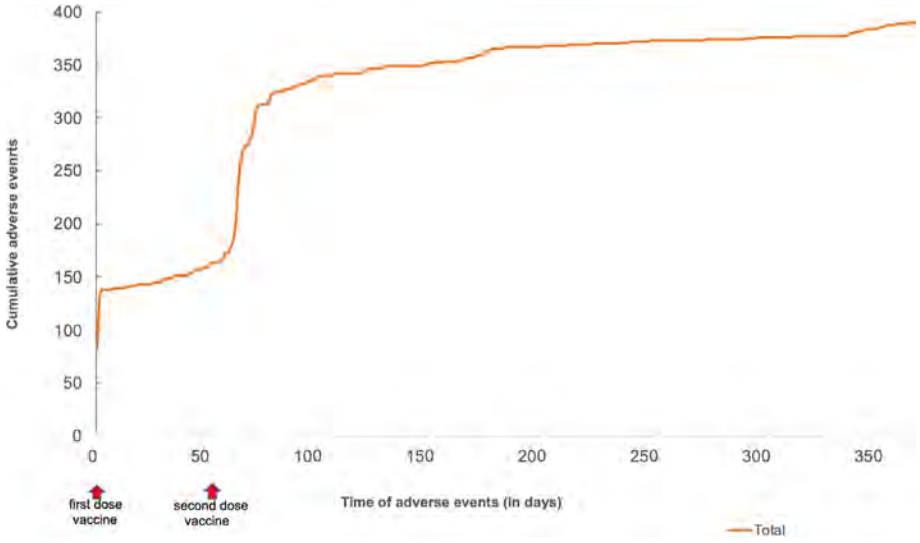

Figure 1: Cumulative adverse events over 12 months

Patients reported 29, 20, 27, and 32 flares at SDV, months 3, 6 and 12, respectively, of which 11 (7.6%), 12 (8.6%), 12 (9.3%) and 13 (13.0%) met predefined flare criteria. Twelve severe AEs (SAEs) occurred (3 flares, 6 malignancies, 3 comorbidities). No AESIs or zoster breakthrough cases were reported.

Conclusion: RZV was well tolerated in patients with iRMD. Most adverse events occurred within a few days after vaccination. Flares were infrequent, and SAEs, including malignancies were considered unrelated. No AESIs or zoster cases were reported. These findings provide reassurance for both rheumatologists and prospective vaccine recipients. They support confidence in RZV safety in this population.

Background/Purpose: Heterozygous loss-of-function mutations in CTLA4 cause a spectrum of immune dysregulation, characterized by hypogammaglobulinemia, autoimmune cytopenias, and lymphoproliferation, yet penetrance and expressivity remain highly variable across cohorts[1-3]

To characterize the clinical, genetic, and therapeutic features of a prospective Chinese cohort with CTLA-4 haploinsufficiency, and to compare their management outcomes with those reported in the largest international series.

Methods: Seven patients diagnosed by whole-exome sequencing underwent systematic evaluation of clinical phenotypes, laboratory parameters, imaging and histopathology, and treatment responses. Data were contrasted against the global 133-patient cohort described by Kuehn et al[1]

Results: All individuals harbored heterozygous CTLA4 variants—four missense and three truncating mutations—exhibiting classical features of immune dysregulation alongside marked phenotypic heterogeneity, even among family

Table1 : Clinical and genetic features of Chinese patients with CTLA-4h

Characteristic	Patient 1	Patient 2	Patient 3	Patient 4	Patient 5	Patient 6	Patient 7
CTLA4 variants	c.155G>T, p.Gly52Val	c.538C>T, p.Leu180Phe	c.347T>A, p.Ile116Asn	c.347T>A, p.Ile116Asn	c.151C>T, p.Arg51Trp	c.436G>A, p.Gly146Arg	c.151C>T, p.Arg51Trp

Table2:Comparison of this cohort with the largest existing cohort

Table2

Feature	Literature Cohort (n=133, global)	Our Cohort (n=7, Chinese patients)
Families / Mutation Types	54 unrelated families; 45 distinct heterozygous CTLA4 mutations (28 novel)	7 families, 7 heterozygous CTLA4 variants, all located in the extracellular domain
Clinical Penetrance	67% (90/133)	71% (7/10 tested, including 3 asymptomatic carriers)
Median Age of Onset	11 years (range <1–59 years)	14 years (range 10–16 years)
Diagnostic Delay	Several cases delayed >10 years, average not systematically reported	2–5 years
Hypogammaglobulinemia	84% (65/77)	100% (7/7)
Lymphoproliferation	73% (62/85)	86% (6/7)
Autoimmune Cytopenias	62% (55/89)	71% (5/7)
Respiratory Involvement	68% (61/90)	29% (2/7)
Gastrointestinal Involvement	59% (53/90)	57% (4/7)
Malignancy Rate	9% (11/133), predominantly EBV-associated lymphomas and gastric cancers	0% (no tumors observed over 6–12 months follow-up)
Key Immunophenotype	Reduced T, B, and NK cell counts; increased Treg percentage	Severe B and NK cell depletion; Treg proportions similar to literature
Preferred Targeted Therapy	Abatacept/belatacept, sirolimus, HSCT	Abatacept + IVIG combination. P6 also received vedolizumab
EBV-related Complications	Frequent EBV reactivation and EBV-driven lymphomas	None observed
Follow-up Outcomes	16% mortality; many HSCT recipients surviving	0% mortality; all patients clinically stable

members with identical genotypes Relative to the international cohort's median diagnostic delay exceeding 10 years, our patients reached genetic confirmation within 2–5 years, enabling earlier initiation of targeted therapy. Nearly all received abatacept (CTLA-4-Ig), achieving sustained disease stabilization and tapering of corticosteroids, complemented by IVIG to correct hypogammaglobulinemia Unlike the 9% malignancy rate observed globally—often EBV-associated—no tumors emerged during 6–12 months of follow-up, suggesting that earlier intervention may mitigate oncogenic risk. Proactive family screening identified asymptomatic carriers, underscoring the value of genetic counseling for at-risk relatives.

Conclusion: This study demonstrates that early genetic screening coupled with prompt abatacept-based immunomodulation and IVIG replacement can markedly shorten diagnostic latency, stabilize multi-system disease, and potentially reduce malignancy complications in CTLA-4 haploinsufficiency. These findings provide a model for precision-medicine approaches in diverse populations.

Abstract Number: 1159

IL-18 Correlates with Pouchot Score and Inflammatory Biomarkers in Adult-Onset Still's Disease: Insights From a Repeated Measures Study

Hadeel Abdul-Rehman[1], Karen Gambina[2] and Bella Mehta[3], [1]Hospital for Special Surgery, New York, NY, [2]Columbia University Medical Center, Islip, NY, [3]Hospital for Special Surgery, Weill Cornell Medicine, Jersey City, NJ

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Adult-Onset Still's Disease (AOSD) is a rare systemic inflammatory disease. Interleukin-18 (IL-18) levels are significantly elevated in AOSD patients[1] and may be a promising indicator of disease activity and potential target for therapeutics. The Pouchot systemic score, used to evaluate disease activity, assigns 1 point to each: fever, rash, pleuritis, pneumonia, pericarditis, hepatomegaly, splenomegaly, lymphadenopathy, leukocytosis (>15,000/μL), sore throat, myalgia, and abdominal pain. The modified Pouchot (mPochout) score replaces splenomegaly and myalgia with arthralgia and hyperferritinemia (>3000 μg/L).

We evaluated the association between serum IL-18 levels and disease activity as measured by Pouchot scores in patients with AOSD to assess the potential of IL-18 as a biomarker.

Methods: Patients were identified by ICD-10 codes, and diagnoses were confirmed by their treating rheumatologist and via chart review by rheumatologists. Pouchot/mPouchot scores were calculated from the same day IL-18 labs were checked.

We used linear mixed-effects models to assess the association between log-transformed IL-18 levels and clinical/serologic markers of disease activity, including Pouchot/mPouchot score, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), and ferritin. Patient ID was included as a random effect to account for repeated measures. Fixed effects included the independent variable of interest (e.g., Pouchot score), with IL-18 as the dependent variable. We also measured intraclass correlation coefficients (ICC).

Table 1. Demographic and Clinical Characteristics

Characteristic	Patient cohort (n=18)[1]	Patient visits (n=38)[2]
Demographics		
Age, mean (SD)	38.1 (15.3)	38.6 (14.8)
Sex, Female, n (%)	13 (72.2%)	24 (63.2%)
Race, White, n (%)	13 (72.2%)	28 (73.7%)
Symptoms		
Fever, n (%)	5 (27.8%)	5 (13.2%)
Rash, n (%)	5 (27.8%)	9 (23.7%)
Pleuritis, n (%)	1 (5.6%)	1 (2.6%)
Pneumonia, n (%)	0 (0%)	0 (0%)
Pericarditis, n (%)	0 (0%)	0 (0%)
Hepatomegaly, n (%)	7 (38.9%)	11 (28.9%)
Splenomegaly, n (%)	2 (11.1%)	2 (5.3%)
Lymphadenopathy, n (%)	2 (11.1%)	2 (5.3%)
Leukocytosis, n (%)	0 (0%)	0 (0%)
Sore throat, n (%)	3 (16.7%)	3 (7.9%)
Myalgia, n (%)	9 (50%)	10 (26.3%)
Abdominal pain, n (%)	4 (22.2%)	4 (10.5%)
Arthritis, n (%)	13 (72.2%)	22 (57.9%)
Hyperferritinemia, n (%)	0 (0%)	0 (0%)
Disease Activity		
Mean Pouchot score (SD)	1.5 (1.1)	1.2 (1.4)
Median Pouchot score (IQR)	1.5 (0-2.1)	1 (0-2)
Mean mPouchot score (SD)	1.9 (1.1)	1.7 (1.4)
Median mPouchot score (IQR)	2 (1-3)	1.5 (1-2)
Lab Values		
Mean ESR (SD), mm/hr	15.62 (12.2)	17.8 (16.9)
Median ESR (IQR), mm/hr	11 (5-17)	11 (5-23)
Mean CRP (SD), mg/dL	0.62 (0.83)	0.9 (1.6)
Median CRP (IQR), mg/dL	0 (0-0.96)	0 (0-1.2)
Mean Ferritin (SD), µg/L	153.6 (128.1)	196.3 (242.5)
Median Ferritin (IQR), µg/L	90 (39.8-212.6)	118.8 (48.7-240.3)
Mean IL-18 (SD), pg/mL	6446.6 (22120)	14041.8 (51295.4)
Median IL-18 (IQR), pg/mL	434 (248-1842.3)	606.5 (275.8-3122.5)

[1]Characteristics summarized by patient; symptoms are reported as present if a patient experienced them across any visit. Lab values are summarized as means of each patient's mean values across visits, or medians of each patient's median values across visits.

[2]Characterisitcs are summarized by individual visit; each visit is treated as an independent observation, and values are calculated across visits

Results: Of the Pouchot score symptoms, arthritis was the most common, followed by hepatomegaly, myalgia, rash, and fever. The mean Pouchot score, mPouchot score, and IL-18 level across all visits were 1.2, 1.7, and 14041.8 pg/mL respectively.

Pouchot scores, ESR levels, and ferritin levels showed significant positive associations with IL-18 levels: ($p< 0.01$, $p < 0.05$, $p < 0.001$). The association between mPouchot scores or CRP with IL-18 levels were not statistically significant.

ICC for the Pouchot, mPouchot, ESR, CRP, and Ferritin models ranged from 0.75-0.84 across models thus indicating 75-84% of variability in IL-18 levels was due to between-subject differences, while 16-25% was due to within-subject variability.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 2. Results of Linear Mixed-Effects Models Assessing the Association Between Disease Activity and Inflammatory Markers with Log-Transformed IL-18 Levels

Variable	Number of patients	Number of visits	Coefficient	Standard error	p-value[1]	ICC[2]
Pouchot	18	38	0.1519	0.0534	**0.00853**	0.79
mPouchot	18	38	0.10618	0.05979	0.0866	0.75
ESR	18	37	0.010263	0.004612	**0.0355**	0.77
CRP	18	37	0.03975	0.04524	0.389	0.73
Ferritin	17	36	0.001082	0.0002265	**0.000111**	0.84

[1]Significant p-values are bolded

[2]The intraclass correlation coefficient (ICC) assesses the proportion of total variance in log-transformed IL-18 levels that can be attributed to between-subject differences

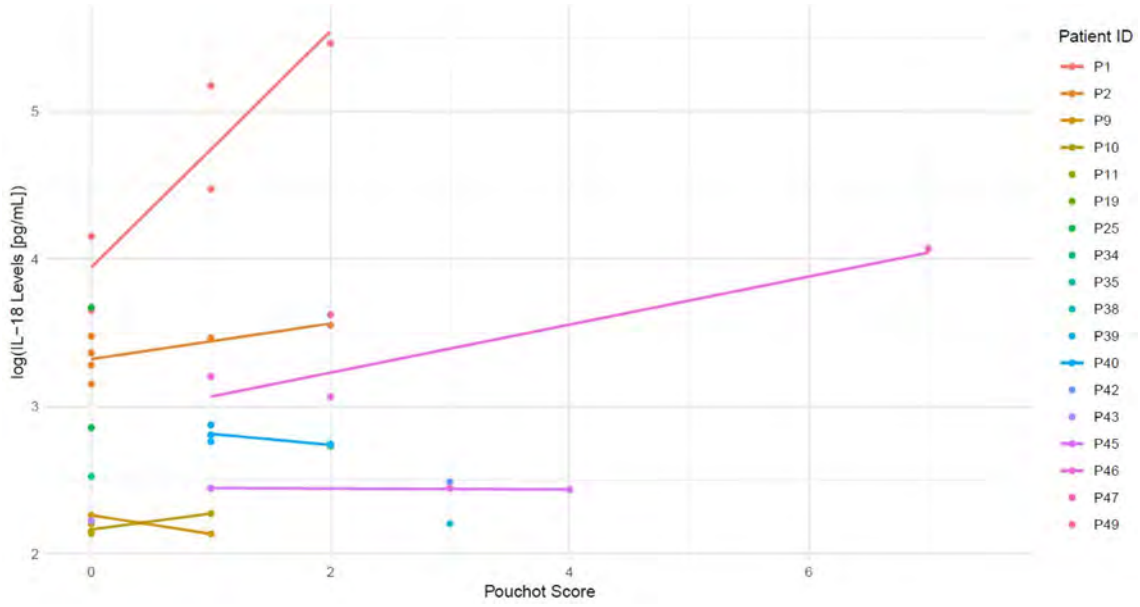

Figure 1: Log-Transformed IL-18 Levels vs Pouchot Score. Data points represent individual visits during which IL-18 levels were checked and Pouchot scores were calculated; different colors correspond to different patients. A line of best fit was constructed for patients that were tested more than once. Higher Pouchot scores indicate more severe disease activity.

Conclusion: These findings suggest the potential utility of IL-18 as a biomarker for disease monitoring in AOSD, particularly in combination with clinical activity scores such as the Pouchot score, given its strong association with disease activity markers and its stable inter-individual variability over time. Given newer potential therapeutics in AOSD, regular IL-18 and disease activity monitoring may be useful in management of these patients.

Abstract Number: 1160

Plasma Adenosine Deaminase 2 as a Potential Disease Activity Biomarker for Sarcoidosis

Jamie Lim[1], Jayanth Doss[2], Jeffrey Shen[2], Rex McCallum[2], Lisa Carnago[3], Hakim Azfar Ali[4], Ravi Karra[5], Kees Frelinger[2], Rishi Rampersad[2], Susan Kelly[2], Amanda Eudy[6], Michael Hershfield[7] and Teresa Tarrant[8], [1]Duke University School of Medicine, Durham, NC, [2]Division of Rheumatology and Immunology, Duke University Department of Medicine, Durham, NC, [3]Division of Rheumatology and Immunology, Duke University Department of Medicine, Duke University School of Nursing, Durham, NC, [4]Division of Pulmonary, Allergy, and Critical Care Medicine, Duke University Department of Medicine, Durham, NC, [5]Division of Cardiology, Duke University Department of Medicine, Durham, NC, [6]Duke University, Raleigh, NC, [7]Division of Rheumatology and Immunology, Duke University Department of Medicine, Department of Biochemistry, Duke University School of Medicine, Durham, NC, [8]Division of Rheumatology and Immunology, Duke University Department of Medicine, Durham Veterans Administration Hospital, Durham, NC

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Sarcoidosis is an inflammatory granulomatous disease of unknown etiology that can affect multiple organ systems. There is currently no standardized approach for measuring sarcoidosis disease activity. Serum tests lack sensitivity, specificity, and correlation with disease activity. Serial MRI, CT, and PET imaging can be used, but these modalities are constrained by cost and radiation exposure for the latter two.

Adenosine deaminase 2 (ADA2) is expressed by and secreted from activated monocytes and macrophages into plasma. ADA2 activity correlates with disease activity in macrophage-activated diseases such as macrophage activation syndrome and tuberculosis, but ADA2 activity in sarcoidosis is less well-characterized. Given that monocyte/macrophage activation plays an important role in sarcoidosis pathogenesis, we hypothesize that ADA2 may serve as a biomarker of disease activity, burden of disease, and treatment response.

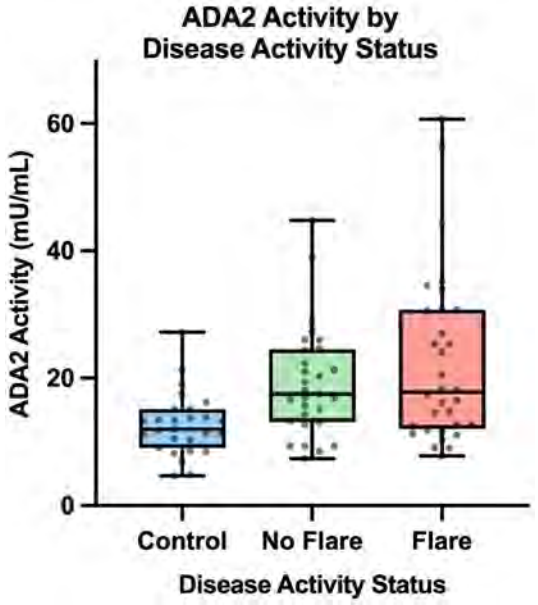

Figure 1. There was a statistically significant difference in plasma ADA2 activity between healthy controls (12.0 mU/mL (IQR 9.0-15.2), n=27), sarcoidosis patients without disease flare (17.5 mU/mL (IQR 13.3-24.4), n=29), and sarcoidosis patients with disease flare (17.8 mU/mL (IQR 12.2-30.7), n=32, p=0.001).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

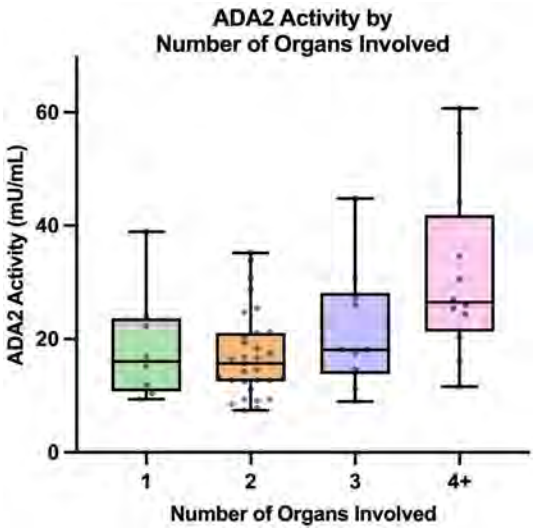

Figure 2. Plasma ADA2 activity was significantly different across groups of patients with sarcoidosis based on the number of organs involved (p=0.01). Median ADA2 activity by number of organs involved: 1 (16.1 mU/mL (IQR 11.2-23.3), n=8), 2 (15.7 mU/mL (IQR 12.5-21.1), n=31), 3 (18.1 mU/mL (IQR 14.7-27.3), n=10), 4+ (26.5 mU/mL (IQR 22.4-39.5), n=12).

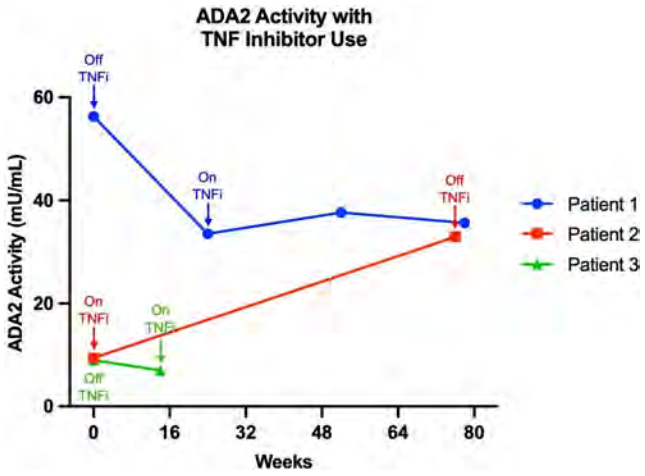

Figure 3. Plasma ADA2 activity in patients with sarcoidosis decreased following TNF inhibitor treatment.

Methods: Patients with sarcoidosis were consented for study under IRB Pro00109933. Plasma samples were collected at enrollment, and disease activity was determined by chart review. Plasma ADA2 activity was measured in the presence of the ADA1 inhibitor erythro-9-(2-hydroxy-3-nonyl)adenine (EHNA) by two independent assays of the inosine and ammonia products using high-performance liquid chromatography (HPLC) and spectrophotometry, respectively. Results of the two assays strongly correlated as measured by the Spearman correlation coefficient (R=0.98, p< 0.0001). Median ADA2 HPLC activity was compared across groups of patients using the Kruskal-Wallis test. For patients with serial ADA2 measurements, ADA2 HPLC activity following TNF inhibitor (TNFi) use was trended.

Results: Sixty-one patients with sarcoidosis were studied. There was a statistically significant difference in ADA2 activity between healthy controls, sarcoidosis patients without disease flare, and sarcoidosis patients with disease flare (Figure 1). There was a statistically significant difference in ADA2 activity across groups of patients with sarcoidosis based on the number of organs involved (Figure 2). Patients with liver, skin, and extrapulmonary lymph node involvement had statistically significantly higher ADA2 activity compared to those without (p=0.0006, p=0.0001, p=0.03, respectively), while patients with cardiac involvement had statistically significantly lower ADA2 compared to those without (p=0.02). Patients with serial

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

ADA2 measurements had decreased ADA2 activity following TNFi treatment (Figure 3) that did not reach statistical significance due to small sample size.

Conclusion: Plasma ADA2 activity is elevated in patients with sarcoidosis, with differences in ADA2 observed based on the number and type of affected organs. There is a possible association between ADA2 activity and treatment response, but a larger sample size is needed to confirm these findings. These results suggest that ADA2 could serve as a plasma-based biomarker for sarcoidosis disease activity.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: To evaluate the efficacy, safety, and tolerability of the antifibrotic agents nintedanib and pirfenidone in the treatment of interstitial lung disease (ILD) associated with rheumatoid arthritis (RA), systemic sclerosis (SSc), and other systemic autoimmune diseases (SADs) fulfilling current criteria for progressive pulmonary fibrosis (PPF).

Methods: A multicentre, longitudinal retrospective observational study was conducted. Data collected included pulmonary function test (PFT) results, adverse events (AEs), tolerability, and drug retention

Results: A total of 132 patients were included (74 women): 27 with RA-ILD (20.5%), 44 with SSc-ILD (33%), and 61 with SADs-ILD (46.5%), including 24 with IPAF, 10 with antisynthetase syndrome, 9 with primary Sjögren's syndrome, 7 with ANCA-associated isolated ILD, 6 with ANCA-associated vasculitis, 3 with SLE, and 2 with sarcoidosis.

Of these, 116 (87.9%) started nintedanib and 16 (12.1%) pirfenidone. The UIP pattern was present in 47.7% (63). Eighty-five percent (112) received combination therapy with a bDMARD, a csDMARD/immunosuppressant, or both. The median post-antifibrotic follow-up was 25 months (IQR 25th–75th: 14–46).

Table 1. Changes in PFTs following initiation of antifibrotic therapy

1A. Rheumatoid arthritis

Before antifibrotics				
	At time of RA-ILD diagnosis mean ± SD (IQR, 25th-75th)	**At time of initiation of initial antifibrotic medication** mean ± SD (IQR, 25th-75th)	**Delta (mean)**	***P* value (95% CI)**
Total sample (N=27)				
%FVC predicted	95.5 ± 14.6 (88.1 – 107.5)	85.6 ± 15 (73 – 97.1)	-8.9%	0.0001 (7.81 to 16.02)
%DLCO predicted	69.1 ± 18.8 (55.4 – 79.5)	54.3 ± 14.8 (44 – 66)	-14.8%	0.0001 (9.53 to 20.16)
After 6 months of treatment				
	At time of initiation of initial antifibrotic medication mean ± SD (IQR, 25th-75th)	**6 months post-treatment** mean ± SD (IQR, 25th-75th)	**Delta (mean)**	***P* value (95% CI**
Total sample (N=24)				
%FVC predicted	88.2 ± 19 (73.7 – 102.7)	89.4 ± 22.7 (74.4 – 105.5)	+1.2%	0.611 (-5.67 to 3.41)
%DLCO predicted	57.4 ± 16.6 (46.2 – 68.1)	61.3 ± 24.9 (40.5 – 79.6)	+3.9%	0.400 (-13.51 to 5.63)
After 1 year of treatment				
	At time of initiation of initial antifibrotic medication mean ± SD (IQR, 25th-75th)	**12 months post-treatment** mean ± SD (IQR, 25th-75th)	**Delta (mean)**	***P* value (95% CI**
Total sample (N=18)				
%FVC predicted	87.5 ± 20.7 (71.8 – 108.6)	92.2 ± 24.8 (76 – 115.8)	+4.7%	0.023 (-8.66 to 0.74)
%DLCO predicted	58.2 ± 17.9 (45.7 – 69.9)	54.4 ± 16.7 (42.7 – 67)	-3.8%	0.175 (-1.82 to -9.25)
After 2 years of treatment				
	At time of initiation of initial antifibrotic medication mean ± SD (IQR, 25th-75th)	**24 months post-treatment** mean ± SD (IQR, 25th-75th)	**Delta (mean)**	***P* value (95% CI**
Total sample (N=9)				
%FVC predicted	89.1 ± 19.7 (71.6 – 111.4)	97.4 ± 19.7 (84.3 – 120.1)	+7.7%	0.037 (-16.07 to 0.66)
%DLCO predicted	60.8 ± 20.3 (43.8 – 81.9)	58.6 ± 15.1 (45.5 – 73.1)	-2.2%	0.621 (-7.67 to -12.07)

1B. Systemic sclerosis.

Before antifibrotics				
	At time of SSc-ILD diagnosis mean ± SD (IQR, 25th-75th)	**At time of initiation of initial antifibrotic medication** mean ± SD (IQR, 25th-75th)	**Delta (mean)**	***P* value (95% CI)**
Total sample (N=44)				
%FVC predicted	80.3 ± 24.9 (58.5 – 96)	71.2 ± 20.4 (54.4 – 79.7)	-9.1%	0.002 (3.46 to 14.56)
%DLCO predicted	56 ± 18.1 (46 – 76.9)	47.9 ± 16.2 (36.2 – 55)	-7.8%	0.005 (2.27 to 11.5)
After 6 months of treatment				
	At time of initiation of initial antifibrotic medication mean ± SD (IQR, 25th-75th)	**6 months post-treatment** mean ± SD (IQR, 25th-75th)	**Delta (mean)**	***P* value (95% CI**
Total sample (N=36)				
%FVC predicted	73.3 ± 18.9 (61 – 80)	79.4 ± 22.7 (61.7 – 87.7)	+6.1%	0.005 (-1.73 to -3.03)
%DLCO predicted	48.8 ± 16.4 (37 – 55)	45.9 ± 15.4 (35.3 – 56.5)	-2.9%	0.254 (-2.71 to 9.87)

Changes in PFTs following initiation of antifibrotic therapy are summarised in Table 2. Across the entire study population, significant declines in PFTs were observed prior to antifibrotic initiation. In patients with RA-ILD, antifibrotic treatment was associated with a significant increase in %CVF at 12 months (+4.7%, p=0.023) and 24 months (+7.7%, p=0.037), while %DLCO remained stable (–3.8% and –2.2%; p=0.175 and p=0.621, respectively). In the SSc-ILD group, %CVF improved consistently (+8.7% at both 12 and 24 months; p=0.024 and p=0.018), whereas %DLCO showed a mild, non-significant decrease (–2.1% and –1.8%; p=0.560 and p=0.427).

In contrast, among patients with other SADs-ILD, %CVF remained stable at 12 months (–0.7%, p=0.665) and declined slightly at 24 months (–3.2%, p=0.103), whereas %DLCO decreased progressively (–3.7% and –5.1%; p=0.422 and p=0.025).

After 1 year of treatment				
	At time of initiation of initial antifibrotic medication mean ± SD (IQR, 25th-75th)	12 months post-treatment mean ± SD (IQR, 25th-75th)	Delta (mean)	*P* value (95% CI
Total sample (N=33)				
%FVC predicted	71.2 ± 18.7 (59.2 – 79.7)	80.2 ± 22.7 (62 – 93.8)	+8.7%	0.024 (-14.29 to 1.10)
%DLCO predicted	48.4 ± 14.3 (39 – 57)	46.3 ± 14.8 (36 – 54.5)	-2.1%	0.560 (-6.03 to 3.33)
After 2 years of treatment				
	At time of initiation of initial antifibrotic medication mean ± SD (IQR, 25th-75th)	24 months post-treatment mean ± SD (IQR, 25th-75th)	Delta (mean)	*P* value (95% CI
Total sample (N=28)				
%FVC predicted	73.8 ± 18.1 (61 – 80)	82.5 ± 24.8 (64.2 – 102.7)	+8.7%	0.018 (-12.82 to -1.34)
%DLCO predicted	48.2 ± 15.3 (36 – 55)	46.4 ± 18.4 (32 – 55)	-1.8%	0.427 (-2.76 to 6.33)

1C. Other systemic autoimmune diseases (SADs)

Before antifibrotics				
	At time of SADs-ILD diagnosis mean ± SD (IQR, 25th-75th)	At time of initiation of initial antifibrotic medication mean ± SD (IQR, 25th-75th)	Delta (mean)	*P* value (95% CI)
Total sample (N=61)				
%FVC predicted	85.4 ± 16.9 (71.5 – 96.5)	80.9 ± 20.8 (68 – 93)	-4.4%	0.031 (0.42 to 8.40)
%DLCO predicted	54.5 ± 13.4 (46.5 – 63.6)	50.8 ± 14.4 (40.6 – 61.8)	-4.8%	0.026 (0.54 to 8.29)
After 6 months of treatment				
	At time of initiation of initial antifibrotic medication mean ± SD (IQR, 25th-75th)	6 months post-treatment mean ± SD (IQR, 25th-75th)	Delta (mean)	*P* value (95% CI
Total sample (N=53)				
%FVC predicted	83.8 ± 18.8 (70.7 – 92.7)	86.4 ± 23.2 (70.6 – 95.5)	+2.6%	0.046 (-6.04 to -0.05)
%DLCO predicted	52.1 ± 13.1 (41.5 – 61.4)	50.7 ± 13 (44.4 – 60)	-1.4%	0.243 (-1.01 to 3.92)
After 1 year of treatment				
	At time of initiation of initial antifibrotic medication mean ± SD (IQR, 25th-75th)	12 months post-treatment mean ± SD (IQR, 25th-75th)	Delta (mean)	*P* value (95% CI
Total sample (N=48)				
%FVC predicted	83.2 ± 18.3 (73.1 – 91.7)	82.5 ± 19.5 (69.7 – 92.5)	-0.7%	0.665 (-2.34 to 3.63)
%DLCO predicted	52.8 ± 13.1 (43 – 62)	49.1 ± 11.6 (41.3 – 58)	-3.7%	0.422 (-1.64 to 3.84)
After 2 years of treatment				
	At time of initiation of initial antifibrotic medication mean ± SD (IQR, 25th-75th)	24 months post-treatment mean ± SD (IQR, 25th-75th)	Delta (mean)	*P* value (95% CI
Total sample (N=40)				
%FVC predicted	83.3 ± 17.7 (73 – 92)	80.1 ± 17.8 (65.2 – 88)	-3.2%	0.103 (-0.68 to 7.12)
%DLCO predicted	52.5 ± 12.9 (43 – 61)	47.4 ± 14.8 (36.2 – 61)	-5.1%	0.025 (0.60 to 8.52)

%pFVC = predicted forced vital capacity; %pDLCO = predicted diffusing capacity for carbon monoxide, corrected for hemoglobin; RTX = rituximab; 6MWT= 6-minute walking test

Data on safety and tolerability are summarised in Table 2. AEs were common across all groups: 81.5% in RA-ILD, 75% in SSc-ILD, and 65.6% in SADs-ILD. Permanent dose reductions due to AEs were more frequent with nintedanib than pirfenidone.

Permanent treatment discontinuation was observed in 52.3% of SSc-ILD, 37% of RA-ILD, and 36.1% of SADs-ILD patients. Discontinuation due to AEs occurred in 31.8%, 18.5%, and 14.8%, respectively. Although these figures suggest lower tolerability in the SSc-ILD

subgroup, differences were not statistically significant in the overall comparison (p=0.100) or in pairwise analyses: p=0.276 for SSc-ILD vs RA-ILD, p=0.055 for SSc-ILD vs SADs-ILD, and p=0.754 for RA-ILD vs other SADs-ILD

Conclusion: Across the three groups, antifibrotic treatment resulted in either PFT stabilisation or a reduced rate of decline. Patients with SSc-ILD appeared to have lower tolerability, but no statistically significant differences were observed.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: There is increasing evidence of the association between interstitial lung disease (ILD) and ANCA positivity without other manifestations of systemic vasculitis. The prognosis of these patients remains uncertain, particularly in terms of their risk of progressing to systemic vasculitis, and the appropriate treatment approach is yet to be established. Our objective was to investigate the clinical characteristics, outcomes, and response to treatment in a cohort of patients with ANCA-positivity with isolated ILD (ANCA-ILD).

Methods: Retrospective study of patients diagnosed with ANCA-ILD at a Pulmonary Interstitial Unit in a tertiary university hospital. Diagnosis was made in cases of ANCA positivity and isolated pulmonary fibrosis, with no apparent development of systemic manifestations over a minimum period of 9 months. Patients were monitored from the date of ANCA-ILD diagnosis until death or the last follow-up

Results: We identified 22 patients (15 men) with a mean age at diagnosis of 66 ± 8 years. Their main clinical features and laboratory data are summarized in Table 1. The predominant radiological pattern was usual interstitial pneumonia (UIP), observed in 59.5% of cases. This was followed by fibrosing non specific interstitial pneumonia (NSIP) in 27% of cases,

Table 1. Main demographic, clinical, functional, serological and treatment-related characteristics of the entire cohort

Number of patients	22
Age (mean ± SD), years	66 ± 8
Women /Men (ratio)	7 (32%) / 15 (68%)
HCRT pattern of ILD	
Usual Interstitial pneumonia (UIP)	13 (59.5%)
Fibrosing non-specific Interstitial Pneumonia (NSIP)	6 (27%)
Combined pulmonary fibrosis and emphysema	2 (9%)
Respiratory bronchiolitis-associated ILD	1 (4.5%)
Median time from ILD diagnosis to ANCA detection, months (IQR 25 th-75 th)	9.5 (9-42.5)
ANCA subtype	
MPO	15 (68.2%)
PR3	3 (13.6%)
Both	4 (18.2%)
%pFVC at diagnosis, mean ± SD	70.4 ±16
%pDLCO at diagnosis, mean ± SD	68 ± 13
Median follow-up, months (IQR 25 th-75 th)	50 (30-70)
Maintained as ANCA-associated isolated ILD	11 (50%)
Progression to systemic vasculitis	11 (50%)
No treatment	2 (9%)
Treatment	20 (91%)
Glucocorticoids	14 (64%)
Immunosuppressants	16 (73%)
Mycophenolate	7 (32%)
Rituximab	9 (41%)

combined pulmonary fibrosis and emphysema in 9%, and respiratory bronchiolitis-associated interstitial lung disease in 4.5%. The median time from ILD diagnosis to ANCA detection spanned 9.5 months, with a range of 9 to 42.5 months. The identified ANCA subtypes were MPO in 68.2% of cases, PR3 in 13.6%, and both subtypes in 18.2%. Initial treatment involved glucocorticoids in 64% of cases and antifibrotic therapy in 59%. After a median follow-up of 54 months (IQR 25th-75th 15 – 90.5), 50% of the patients had developed clinical signs of PAM or GPA-type vasculitis after a median follow-up of 50 months post-ANCA detection (IQR 25th -75th 30-70). These patients received treatment with rituximab (73%) or MMF (27%). None of the patients died, but three developed chronic respiratory failure and became candidates for lung transplantation. Among the remaining 11 patients, who continued with a diagnosis of ANCA-associated isolated ILD and received treatment with low-dose glucocorticoids and antifibrotic therapy (72.7%), 45.5% showed pulmonary progression and required additional immunosuppressive treatment (MMF and, in one case, rituximab). Furthermore, 27.3% developed chronic respiratory failure, and there was an 18.1% mortality rate. No predictive risk factors for the progression to systemic vasculitis were identified. ANCA-MPO levels were notably higher in patients with generalized vasculitis (153±93 versus 76±48; p=0.346). Of the patients with ANCA-PR3, only 57.1% progressed to systemic vasculitis.

Conclusion: Approximately three-quarters of patients initially diagnosed with ANCA-positive isolated ILD showed pulmonary progression, and approximately half eventually developed symptoms of systemic vasculitis during the follow-up period. The use of antifibrotics and immunosuppressants seemed to slow the progression of lung disease

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: IgG4-RD is a rare, chronic, fibroinflammatory disorder characterized by recurrent flares that can affect any organ and lead to permanent tissue damage. Inebilizumab (INEB) is a CD19-specific B cell depleting monoclonal antibody (mAb) approved for the treatment of neuromyelitis optica spectrum disorder (NMOSD) and recently approved for the treatment of IgG4-RD (MITIGATE trial; NCT04540497). Three doses of INEB (days 1, 15 and 183) resulted in an 87% reduction in flare risk compared to placebo-treated participants in the MITIGATE trial. The aim was to evaluate clinical and molecular characteristics of INEB-treated participants who experienced a positively adjudicated and treated IgG4-RD flare during the randomized controlled period (RCP) of the MITIGATE trial.

Methods: Disease history and clinical characteristics of INEB-treated participants (n=7) with an on-study flare were analyzed. B cell counts, IgG4 levels, and other markers were evaluated and compared to the 61 INEB-treated participants who did not flare. Temporal relationships between disease flares, INEB dosing, and changes in biomarker levels were explored.

Table 1: Baseline Disease Characteristics of Inebilizumab-treated Participants with and without On-study Flare

Baseline Characteristics	Participants with flare, N=7	Participants with no flare, N=61
Disease Duration, y, median (min, max)	2.4 (0.1, 10.0)	0.5 (0.1, 20.5)
Prior non-glucocorticoid therapy for IgG4-RD Yes, n (%)	3 (42.9)	14 (23.0)
Number of Organs affected historically, median (min, max)	5 (2, 7)	4 (2, 11)
Number of Organs affected at baseline, median (min, max)	2 (2, 5)	3 (1, 11)
Highest (Ever) IgG4 Serum Concentration (mg/dL), median (min, max)	401.2 (95.1, 2180.0)	721.0 (21.0, 34100.0)
Responder Index Score at Baseline, median (min, max)	4.0 (0, 11)	5.0 (0, 19)
ACR/EULAR Score, median (min, max)	35.0 (25, 58)	40.0 (20, 74)

Results: Overall, the baseline characteristics of the 7 INEB-treated participants who experienced a flare are generally similar to those of the 61 INEB-treated participants who did not (Table 1), with lower historic IgG4 levels, longer duration of disease, and more prevalent prior non-GC therapy noted among the INEB-treated participants who flared. Clinical characteristics of the 7 INEB-treated participants who flared show diversity in disease duration, prior non-GC therapy, organ involvement, highest historic IgG4 levels, baseline Responder Index score, and ACR/EULAR classification criteria scores at study entry (Table 2).

There is no consistent pattern in B cells, immunoglobulins, and other biomarkers among the INEB-treated participants who flared that distinguishes them from the 61 INEB-treated participants who did not flare. Analysis of the timing of biomarker changes (Figure 1) revealed no consistent pattern at the time of flare in INEB-treated participants. Of note:

- Participant 1 discontinued INEB after the first infusion (Day 1), and B cells were fully recovered at the time of flare
- Participant 2 experienced a flare 2 weeks after the first infusion, prior to development of the full pharmacodynamic effects of INEB
- Participant 3 displayed incomplete B cell depletion (>5 cells/μL) at the time of flare despite receiving all prior doses of INEB
- The remaining 4 participants experienced a flare in the setting of deep B cell depletion and reduced IgG4 levels compared to baseline

Conclusion: In this small cohort, baseline clinical and serologic characteristics did not reliably differentiate INEB-treated participants who experienced a flare (n=7) from those who did not (n=61). In INEB-treated participants, no clear patterns of biomarker changes are associated with occurrence of flare. Some participants experienced full apparent pharmacodynamic effect of INEB yet experience a flare. Two INEB-treated participants flared after discontinuing INEB or prior to development of the full pharmacodynamic effect.

Background/Purpose: The effect of systemic TNF inhibition on postprandial glucose homeostasis, a parameter associated with cardiovascular health, remains unclear. This study aims to evaluate the effects of TNF inhibitors (TNFi) on hormones involved in the fine-tuning of postprandial glucose homeostasis: amylin, gastric inhibitory polypeptide (GIP), and pancreatic polypeptide (PP), in patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA), and axial spondylarthritis (axSpA).

Figure 1

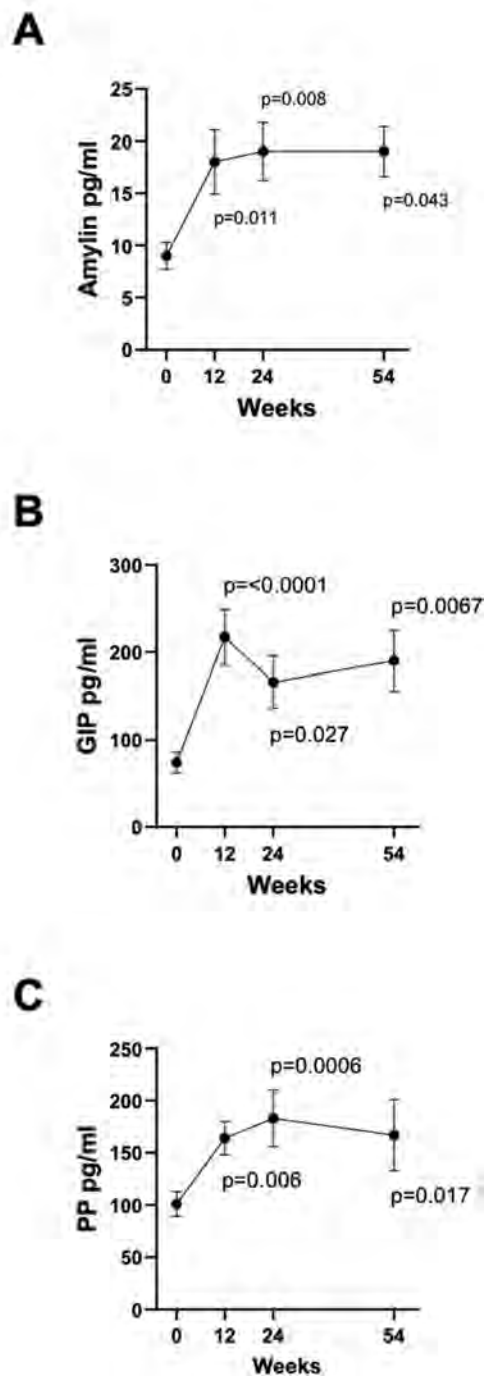

Figure 1. Dot plots showing the changes in plasma concentrations over one year of TNFi treatment in all included patients for (A) amylin, (B) GIP, and (C) pancreatic polypeptide. Data are presented as means ± SEM. p-values indicate statistically significant differences compared to baseline, as determined by mixed-effects analysis for repeated measures with Dunnett's correction for multiple comparisons.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Sixty-four non-diabetic patients (RA, n=22; PsA, n=13; axSpA, n=29) undergoing TNFi therapy were prospectively evaluated at baseline and after 12, 24, and 52 weeks. Assessments included measurements of disease activity, acute-phase reactants, fasting glucose, insulin and C-peptide levels, and insulin resistance as assessed by the updated Homeostatic Model Assessment (HOMA)-2. Serum concentrations of amylin, GIP, and PP were measured at each visit. Multivariable linear mixed-effects models were used to analyze temporal changes in these molecules of glucose metabolism homeostasis.

Results: BMI remained stable throughout the one-year follow-up period. Among patients with RA, disease activity indices, including DAS28-CRP, SDAI, and CDAI, showed significant reductions at 3, 6, and 12 months. Likewise, in patients with axSpA, there was a significant decrease in disease activity, metrological, and functional indices. Finally, in patients with PsA, a significant decrease was observed in the DAPSA index at the 6-month visit, but this improvement was not maintained at the 1-year follow-up. No significant modifications were observed in lipid-related molecules, apart from triglycerides, which showed significantly lower levels after one year of treatment compared to baseline

Serum glucose levels remained consistent with baseline levels after one year of TNFi treatment. Circulating insulin and C-peptide levels remained stable during TNFi treatment. Indices of insulin sensitivity and beta-cell function, as measured by the HOMA-2 index, remained unchanged over the one-year period of TNFi treatment. The interaction analysis showed that changes in insulin resistance indices were consistent regardless of diagnosis (RA, PsA, or AS) or type of TNFi used (adalimumab versus non-adalimumab). Despite this, amylin, GIP and PP levels increased significantly shortly after treatment initiation at week 12 and maintained this significant upregulation at 12-month follow-up (Figure). Importantly, the significance of these findings persisted after adjustment for changes in CRP during the follow-up period. No significant interactions were observed between the specific TNFi used or type of rheumatic disease and changes in amylin and GIP over time. This finding suggests that changes in these hormone levels occur independently of both the TNFi used and the underlying disease.

Conclusion: Systemic TNF inhibition is associated with sustained increases in serum levels of amylin, GIP and PP independent of systemic inflammation. This modulation of postprandial glucose-regulating hormones may contribute to the cardiovascular benefits of TNFi in patients with inflammatory disease.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: A prior analysis found that patients (pts) with psoriatic arthritis (PsA) treated with guselkumab (GUS), an IL-23p19 subunit inhibitor, were approximately 2× more likely to remain persistent with on-label treatment up to 24 months (M) vs first-time subcutaneous (SC) TNFi users.[1] Real-world evidence comparing long-term on-label persistence between GUS and SC TNFi in biologic-naïve and biologic-experienced populations is lacking.

Methods: IQVIA PharMetrics® Plus database (1/1/2011-6/30/2023) was used to analyze treatment persistence among biologic-naïve and -experienced adults with active PsA who initiated GUS/SC TNFi (index date=first claim for GUS/SC TNFi). Analyses were performed separately for biologic-naïve (no prior pre-index biologic claims) and biologic-experienced (≥1 prior pre-index biologic claim) pts. Pts had ≥12M insurance eligibility and no claims for confounding diseases or index medications pre-index date. Baseline characteristics were summarized for the 12M pre-index period. On-label persistence was defined as continued use of index therapy without dose modification (escalation/reduction) per FDA-approved labeling. Propensity score overlap weighting was applied to balance baseline characteristics between the GUS and SC TNFi cohorts. On-label persistence over 24M was compared via weighted Kaplan-Meier (KM) curves and Cox proportional hazards model. For biologic-naïve pts, further adjustment for prior conventional synthetic (cs) and targeted synthetic (ts) disease-modifying antirheumatic drug (DMARD) use was performed.

Results: Among 3,294 pts, 361 GUS pts (49.5 years; 59.8% female) and 2,171 SC TNFi pts (48.3 years; 59.5% female) were biologic-naïve, and 443 in GUS cohort (50.8 years; 61.2% female) and 319 in SC TNFi cohort (48.5 years; 64.3% female) were biologic-experienced. Weighted baseline characteristics were balanced between cohorts, except for prior csDMARD/tsDMARD use among biologic-naïve pts. For biologic-naïve pts, the median time-to-discontinuation was 22.4M for GUS and 9.2M for SC TNFi; weighted KM on-label persistence rates at 6M/12M/18M/24M: 86.2%/73.1%/62.9%/48.9% for GUS vs 63.8%/43.8%/35.3%/28.4% for SC TNFi (all log-rank $p< 0.001$). For biologic-experienced pts, the median time-to-discontinuation was 18.4M for GUS and 7.4M for SC TNFi; weighted KM on-label persistence rates at 6M/12M/18M/24M: 76.9%/57.7%/50.6%/39.5% for GUS vs 58.1%/40.3%/31.1%/23.3% for SC TNFi (all log-rank $p< 0.001$). At 24M, GUS cohort pts were ∼2× more likely to remain persistent vs SC TNFi cohort in both biologic-naïve (HR: 2.36, 95% CI: 1.88-2.98; $p< 0.001$) and biologic-experienced pts (HR: 1.86, 95% CI: 1.46-2.37; $p< 0.001$).

Conclusion: Pts initiating GUS demonstrated statistically significantly higher on-label persistence through 24M than those initiating SC TNFi in both biologic-naïve and biologic-experienced pts with active PsA. Higher long-term on-label persistence may improve disease management outcomes, including functional status and quality of life.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

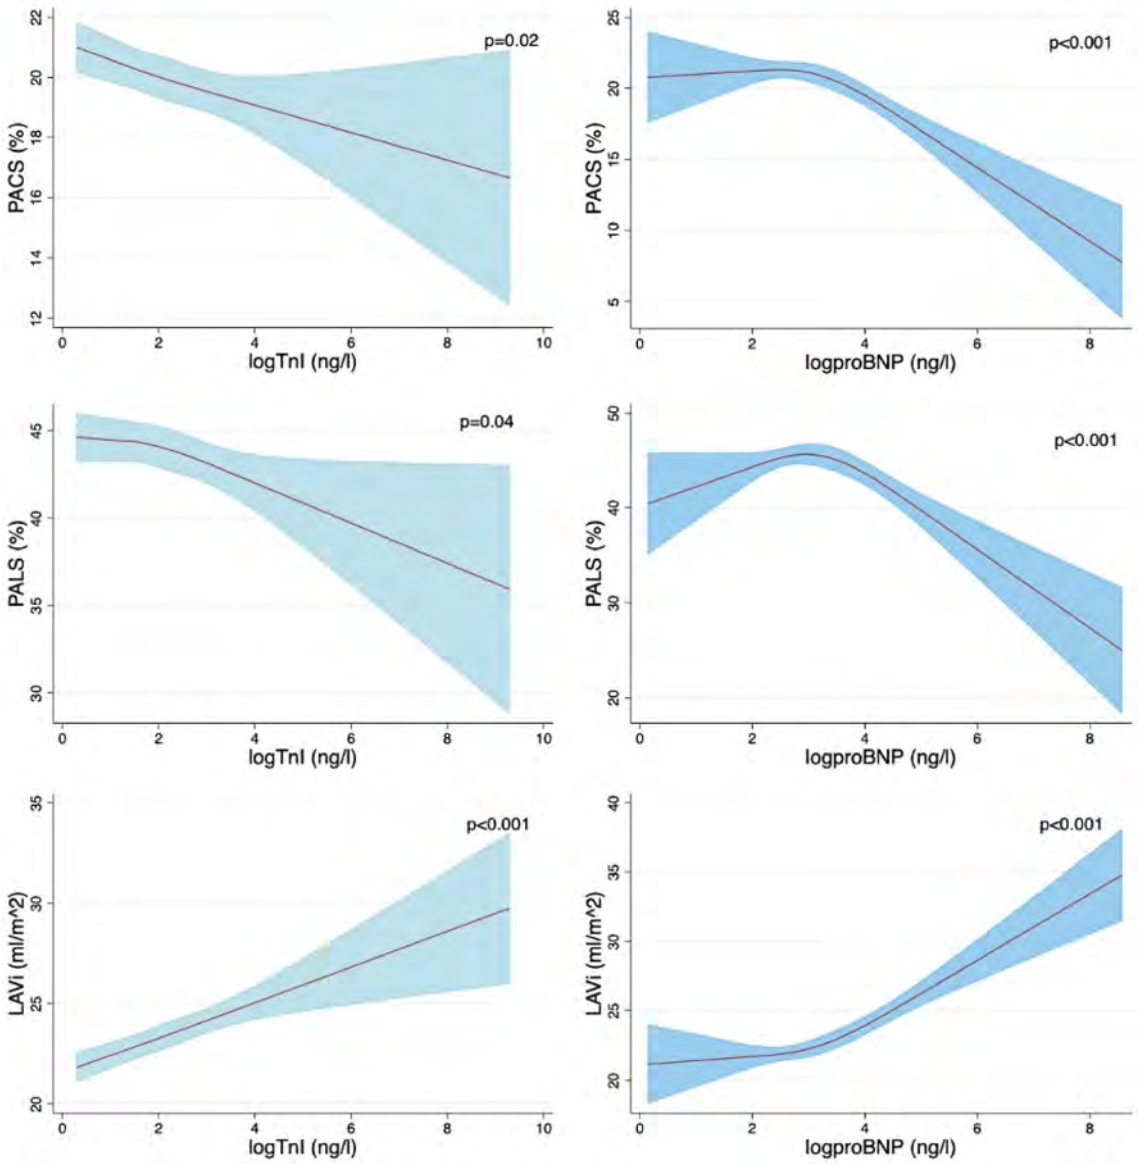
Background/Purpose: Individuals with psoriasis are at increased risk of developing heart disease. Echocardiographic parameters of impaired left atrial (LA) strain (Peak atrial contraction and longitudinal strain (PACS and PALS)) and volume index (LAVi) are associated with increased risk of heart disease. Whether cardiac and inflammatory biomarkers are associated with left atrial impairment in adults with psoriasis is unknown.

The aim of this study was to assess whether plasma levels of high-sensitivity C-reactive protein (hsCRP), high-sensitivity troponin I (hsTnI) and pro-brain natriuretic peptide (proBNP) were associated with LA structure and function in adults with psoriasis.

Methods: This was a cross-sectional analysis of a prospective cohort study of 1,010 participants with psoriasis who underwent echocardiographic examination and had blood samples analyzed from 2021-2024. Those without available measurements of hsCRP (n=27), TnI (n=5) or proBNP (n=17), LA strain (n=23) or LAVi (n=11) were excluded. The population was stratified according to hsCRP, hsTnI and proBNP tertiles, respectively. We used ANOVA, Pearson's Chi^2-test, Kruskal-Wallis test, linear regression and cubic spline models as appropriate to assess the associations between biomarkers, cardiac risk factors and measures of LA structure and function. Biomarkers were logarithmically transformed for the linear regression analyses. In multivariable analyses, models were adjusted for sex, age, package years, BMI >30, hypertension, hypercholesterolemia, diabetes mellitus, chronic kidney disease, ischemic heart disease, heart failure, atrial fibrillation and psoriasis treatment.

Results: We included 927 adults with psoriasis (mean age 54.0 years, 46.5 % women). In the entire cohort, median hsCRP was 1.1 mg/l (IQR 0.5-2.7), median hsTnI was 3.0 ng/l (IQR 1.2-6.0) and the median proBNP was 7.6 ng/l (4.2-14.3). The participants in the highest tertile groups of all three biomarkers were overall older, had more package years and a higher prevalence of hypertension. Furthermore, the highest hsCRP group >1.73 mg/l were predominantly women, had higher

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Cubic spline models analyzing the association between biomarkers and echocardiographic measures of left atrial strain and volume index.

BMI and were less physically active. The highest TnI group >5 ng/l were predominantly men, had a higher prevalence of moderate-to-severe psoriasis, and cardiovascular disease was more prevalent. The proBNP-group >11.5 ng/l had more women and a higher prevalence of cardiovascular disease.

In univariable analyses, higher levels of hsCRP were associated with lower PALS, while higher levels of TnI and proBNP were associated with lower PACS and PALS and higher LAVi. In multivariable analyses, higher levels of TnI and proBNP remained significantly associated with lower PACS and PALS and higher LAVi. (Figure)

Conclusion: In a sample of adults with psoriasis, higher levels of TnI and proBNP were associated with impaired LA structure and function. Given the known association between LA dysfunction and heart disease, these biomarkers may identify individuals with psoriasis at increased risk of cardiac disease.

Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Treatment of IgG4-related disease (IgG4-RD) is recommended for patients with severe organ involvement or for patients with reduced quality of life even in the absence of severe organ involvement. On the other hand, some patients with no severe lesions and acceptable quality of life, especially those with asymptomatic single organ disease, can be followed up without treatment. Therefore, we aimed to investigate the clinical characteristics and outcomes of patients without therapeutic intervention at the time of IgG4-RD diagnosis in single center.

Table 1. Comparison of clinical characteristics at diagnosis between the treatment and observation groups

	Treatment group(n=54)	Observation group(n=26)	P value
Age at diagnosis (years old)#	68.5 ± 10.7	62.7 ± 8.2	< 0.01

Methods: Patients with IgG4-RD diagnosed from 2005 to 2024 according to the comprehensive diagnostic criteria for IgG4-RD revised in 2020 at our institution were included in our study. Clinical characteristics including IgG4-RD Responder Index (IgG4-RD RI) and immunological laboratory findings were retrospectively collected from medical records. In the cases observed without treatment after IgG4-RD diagnosis, we investigated whether the subsequent therapeutic intervention became necessary or not. We then analyzed the predictors of the need for treatment.

Results: Of all 80 cases diagnosed with IgG4-RD, 54 cases (67.5%) were started to treat at diagnosis (treatment group), while 26 cases (32.5%) were observed without therapeutic intervention (observation group).

In the observation group, age at diagnosis was significantly younger and the levels of CRP, IgG, sIL-2R and IgG4-RD RI were lower. Serum IgG4 levels also tended to be lower compared to the treatment group (Table 1). Cases with only glandular and lymph node involvement were more common in the observation group. In contrast, patients with severe organ involvement such as retroperitoneal, renal, pancreatic, pulmonary and orbital lesions were more likely to have started treatment at the time of diagnosis (Figure 1).

Of the 26 cases in the observation group, 7 required therapeutic intervention during the observation period. New organ involvement, including the pancreas, was observed in 5 cases. There were no significant differences in clinical characteristics at the time of diagnosis between the patients with (n=7) and without (n=19) treatment intervention (Table 2). The mean

duration from diagnosis to the initiation of therapeutic intervention was 30 ± 25 months. Among the 19 cases without treatment intervention, 13 cases (68.4%) had multiple organ involvement, such as glandular, lymph node, and pulmonary involvement.

Conclusion: In our study, some cases of IgG4-RD could be observed without treatment, even with multiple lesions. It is important to have an appropriate monitoring strategy to determine the need for therapeutic intervention in IgG4-RD.

Abstract Number: 1168

Interstitial Lung Disease-Associated Antibody Testing and Positivity Rates in Systemic Autoimmune Rheumatic Diseases from a National Reference Laboratory

Karis Lee[1], Min Kyung Lee[2] and Stanley Naides[3], [1]Labcorp, Orlando, FL, [2]Labcorp, Durham, NC, [3]Labcorp, Dana Point, CA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Interstitial lung disease (ILD) is frequent in systemic autoimmune rheumatic diseases (SARDs) and is associated with poor prognosis. The prevalence of ILD is approximately 52% in systemic sclerosis (SSc), 41% in myositis, 23% in Sjögren's syndrome (SS), 21.4% in rheumatoid arthritis (RA), 14.5% in systemic lupus erythematosus (SLE), and 56% in overlap syndromes. While early detection of ILD is crucial, diagnostic imaging is typically limited to high-risk patients. Biomarker testing is a cost-effective method for identifying patients at increased risk of ILD. We examined testing and positivity rates of ILD-associated antibodies in patients with SARDs to assess current screening practices.

Methods: We retrospectively reviewed testing for ILD-associated antibodies (Jo-1, PL-7, PL-12, EJ, OJ, SRP, MDA-5, PM/Scl-100, Ku, and SS-A 52kD) in patients with SSc (N = 87,115), idiopathic inflammatory myopathy (IIM, N = 25,496), myositis (N = 110,645), polymyositis (PM, N = 58,619), dermato(poly)myositis (DM, N = 73,568), SS (N = 365,136), RA (N = 3,837,117), SLE (N = 956,740), and overlap syndromes (N = 104,697) from 2021 through 2024. Patients with interstitial pulmonary disease (N = 190,160) were included for reference. Diagnostic labels reflect provider-assigned ICD-10 codes at the time of testing.

Results: PL-7, PL-12, EJ, OJ, SRP, MDA-5, PM/Scl-100, Ku, and SS-A 52kD were tested in less than 1.7% of patients with SSc, SS, RA, SLE, and overlap syndromes (**Figure 1**). Testing rates for these antibodies ranged from 3.3 – 4.5% in patients with IIM, myositis, or PM, and 5.9 – 6.2% in those with DM. Among patients with SSc, PM/SCL-100 was the second most tested biomarker at 4.2%.

Jo-1 had the highest testing rate across all SARDs, with 6.7 – 9.6% of patients with SSc, IIM, myositis, PM, DM, SS, SLE, and overlap syndromes tested. Jo-1 positivity rates ranged between 0.2 – 1.4% in patients with SSc, IIM, myositis, SS, RA, SLE, and overlap syndromes (**Figure 2**). Jo-1 was positive in 7.0% of patients with PM and 2.9% of patients with DM.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

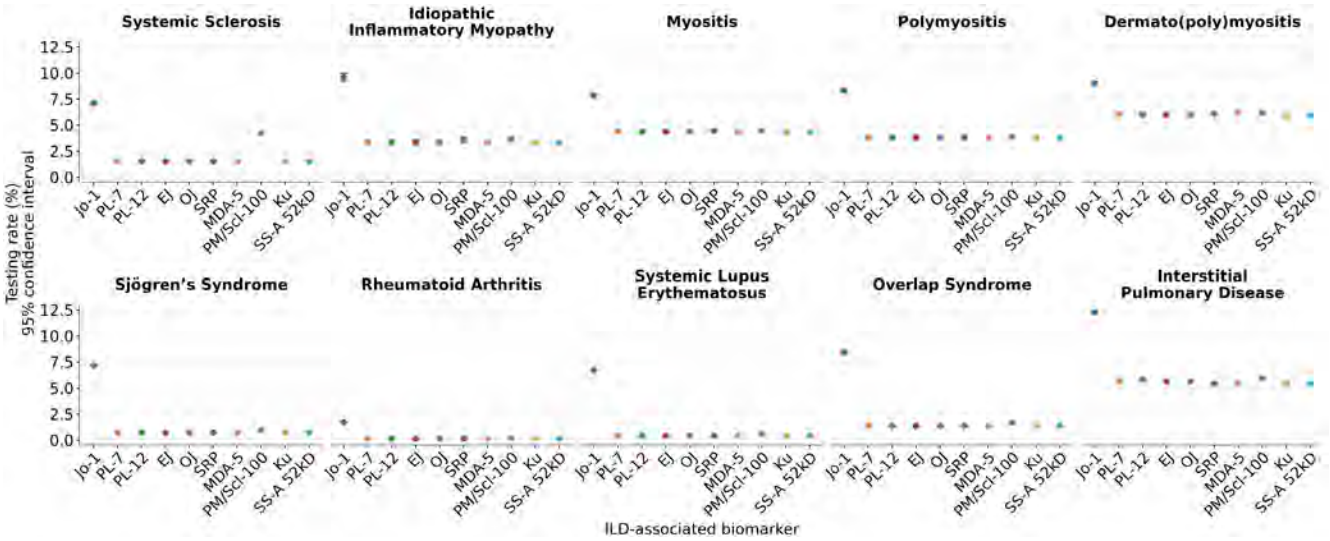

Figure 1. ILD-associated antibody testing rates

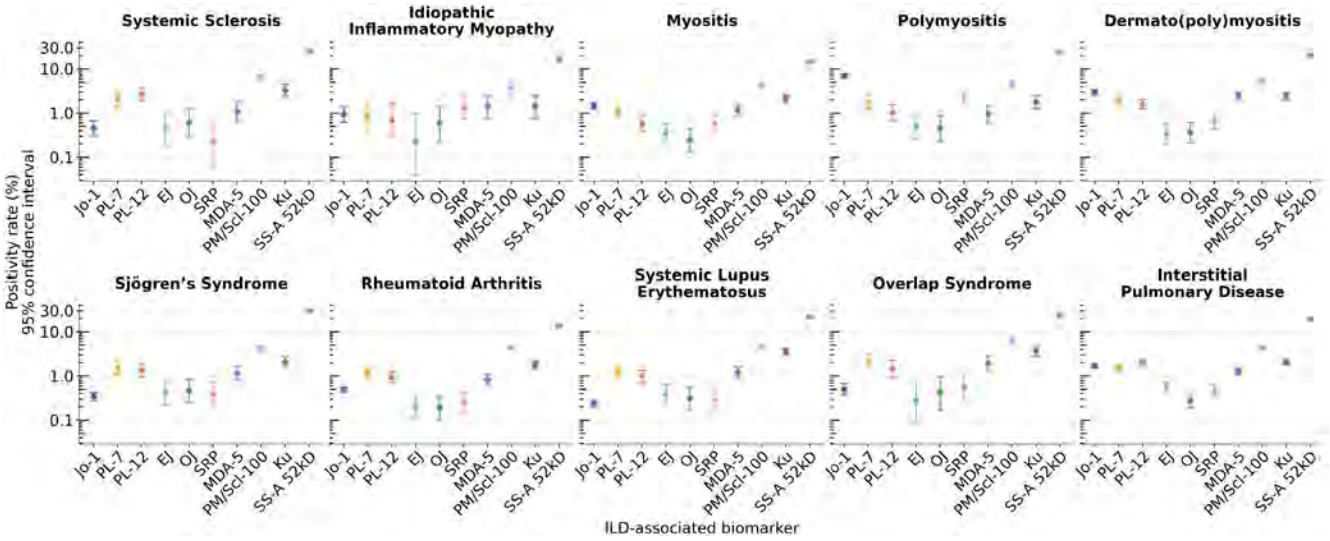

Figure 2. ILD-associated antibody positivity rates

Despite lower testing rates, positivity rates for SS-A 52kD were consistently higher than Jo-1, ranging from 13.7% in RA to 29.8% in SS. PM/Scl-100 also showed higher positivity rates than Jo-1 in all SARDs except PM, ranging from 3.7% in IIM to 6.7% in overlap syndromes. High positivity rates for Ku and PL-7 were also found in patients with SSc (3.3%, 2.1%), IIM (1.4%, 0.8%), myositis (2.2%, 1.1%), SS (2.1%, 1.5%), RA (1.8%, 1.1%), and overlap syndromes (3.8, 2.2%). MDA-5 also had high positivity rates in patients with IIM (1.4%) and in patients with DM (2.5%).

Conclusion: While Jo-1 was the most frequently tested antibody across all SARDs, positivity rates were low among patients with SSc, SS, RA, SLE, and overlap syndromes. In contrast, markers such as PL-7, Ku, and SS-A 52kD that were tested less frequently had higher positivity rates. MDA-5 had positivity rates comparable to Jo-1 among patients with IIM and DM. These findings suggest that incorporating a broader panel of ILD-associated biomarkers along with Jo-1 may facilitate early detection of ILD in patients with SARDs.

Abstract Number: 1169

Periodontitis in neutropenic DADA2 patients

Lorena Wilson[1], Amanda Ombrello[2], Patrycja Hoffmann[3], Cornelia Cudrici[3], Tina Romeo[4] and Daniel L. Kastner[5], [1]National Institutes of Health, Silver Spring, [2]National Institutes of Health, Rockville, MD, [3]National Insitutes of Health, Bethesda, [4]NIH, Bethesda, MD, [5]National Human Genome research Institute (NHGRI), National Institutes of Health (NIH), Bethesda

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Deficiency of adenosine deaminase 2 (DADA2) is an autosomal recessive disease caused by pathogenic mutations in *ADA2*. Severe and refractory neutropenia is a hematologic feature in the phenotypic spectrum of DADA2. Periodontal disease is often recognized as a manifestation of severe neutropenia, but not previously highlighted in neutropenic DADA2 patients.

Methods: Retrospective review of DADA2 patients identified with known periodontal disease and severe neutropenia in the NIH DADA2 cohort. Medical records from 12/18/2005 to 12/01/2024 were reviewed.

Results: Patient 1 (R169Q/deletion in exon 7) is a 57-year-old edentulous female with a 28-year history of neutropenia (ANC = 0), fevers, cervical lymphadenopathy, splenomegaly, and splenectomy. No known history of strokes. Periodontal disease manifested by chronic tooth decay, gingivitis, severe mandibular regression, dental extractions, and poor osseointegration of dental implants. Dental imaging demonstrated severe bone loss. She was treated with cyclosporine, prednisone, and an induction dose of infliximab, followed by adalimumab, with positive treatment response and neutrophil count normalization without periodontitis recurrence.

Patient 2 (H112Q/R34W) is a 44-year-old female with a history of transient neutropenia (ANC = 0.8), Raynaud's, fevers, arthralgia, genital ulcers, livedo reticularis, splenomegaly, and recurrent skin ulcers in lower extremities. No history of strokes. Periodontal disease manifested by extensive painful oral ulcerations and mucositis which correlated with episodes of severe neutropenia. She was treated with adalimumab with resolution of neutropenia and without oral ulcers and fever recurrence.

Patient 3 (R169Q homozygous) is a 43-year-old female with a history of neutropenia (ANC = 0), Raynaud's, two episodes of central retinal artery occlusions leading to right eye blindness, fevers, headaches, arthralgia, livedo reticularis, lymphadenopathy, esophageal necrosis, and common variable immunodeficiency. Periodontal disease manifested by oral ulcers and gingivitis. She was treated with etanercept, response was not observed due to medication discontinuation after patient's decision to withdraw all medical care. Patient expired 07/2024.

Patient 4 (H112Q/R169Q) is a 26-year-old male with a history of neutropenia (ANC = 0.3), fevers, skin rashes, and splenomegaly. Periodontal disease manifested by periodontal abscess and oral ulcers. No history of strokes. He received a hematopoietic stem cell transplant with resolution of DADA2 and periodontitis.

Conclusion: This retrospective review highlights periodontitis in severe neutropenia of DADA2. We hypothesize that DADA2 neutropenia induces IL-23 and IL-17 release by resident macrophages in the gingiva, similar to leukocyte adhesion deficiency. Since the neutropenia of DADA2 is at least partially due to destruction of precursors in the bone marrow, local

cytokine production is unabated, leading to hyperinflammation. To further understand the mechanisms, we plan to conduct careful assessments of DADA2 patients' oral history, dental exams, and when appropriate, gum biopsies.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Haploinsufficiency of A20 (HA20) is a disease at the crossroads between autoinflammation and autoimmunity, caused by heterozygous mutations in TNFAIP3, which encodes the A20 protein, a negative regulator of pro-inflammatory pathways such as NF-κB and NLRP3. Clinically, HA20 can mimic systemic lupus erythematosus, Behçet's disease, inflammatory bowel disease, familial Mediterranean fever, or PFAPA syndrome. Hallmark features include recurrent fever, bipolar aphthosis, skin and gastrointestinal inflammation. Genetic testing is required for diagnosis.

Our study aimed to assess the prevalence of relevant mutations in a cohort with clinically suggestive features, to improve diagnostic precision in daily rheumatology practice.

Methods: Fourteen patients were prospectively recruited from the Rheumatology Department at University Hospital Puerta de Hierro, meeting inclusion criteria based on current literature. Recurrent oral aphthosis before age 30 was required, along with one or more of the following: unexplained fever, genital aphthosis, arthritis/arthralgia, acneiform/pustular/erythema nodosum-like skin lesions, recurrent abdominal pain or diarrhea, or inflammatory ocular disease.

Data collected included demographics, family history, age at symptom onset, mucosal, cutaneous, articular, gastrointestinal, and ocular involvement, and fever episodes. Blood samples were analyzed for ESR, CRP, ANA, ANCA, and anti-dsDNA, and a targeted next-generation sequencing (NGS) panel for autoinflammatory genes including TNFAIP3 was performed. Treatments received were recorded, including NSAIDs, glucocorticoids, colchicine, csDMARDs, bDMARDs, and other targeted therapies.

Table 1, part 1. Demographics, Symptoms, Blood Analysis

Data	n (%) / median (range)
Demographics	
Female sex	12 (86%)
Onset age	17 (1-50)
Family history	9 (64%)
Symptoms	
Mucosal	14 (100%)
Oral aphthae	14 (100%)
Genital aphthae	6 (43%)
Articular	14 (100%)
Arthralgia	14 (100%)
Arthritis	6 (43%)
Abdominal	14 (100%)
Pain	14 (100%)
Diarrhoea	13 (93%)
Elevated calprotectin	2 (14%)
Skin	7 (50%)
Acne	2 (14%)
Folliculitis	4 (29%)
Pustulosis	1 (7%)
Abscesses	3 (21%)
Erythema nodosum	1 (7%)
Ocular	0 (0%)
Chest pain	2 (14%)
Recurrent fever	10 (71%)
Blood analysis	
Elevated reactants	5 (36%)
ANA positivity	5 (36%)
ANCA positivity	0 (0%)
anti-DNAds	3 (21%)

Results: Two patients (14.3%) had mutations identified via NGS: one in RIPK1 and another in PLCG2; no patient in our cohort tested positive for mutation in TNFAIP3.

Both were Caucasian women with first-degree relatives affected by autoimmune disease, but had different ages of onset (29 vs. 5 years).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1, part 2. Treatments

Data	n (%) / median (range)
Treatments	
Glucocorticoids	8 (57%)
NSAIDs	12 (86%)
Colchicine	3 (21%)
cDMARD	10 (71%)
Methotrexate	5 (36%)
Hydroxychloroquine	3 (21%)
Sulfasalazine	2 (14%)
Mycophenolate	1 (7%)
Teriflunomide	1 (7%)
bDMARD	7 (50%)
Adalimumab	6 (43%)
Golimumab	3 (21%)
Certolizumab	2 (14%)
Infliximab	2 (14%)
Etanercept	1 (7%)
Anakinra	3 (21%)
Other	4 (29%)
Tofacitinib	2 (14%)
Upadacitinib	1 (7%)
Apremilast	3 (21%)

Common symptoms included oral aphthae, arthralgia, abdominal pain, diarrhea, and fever. The RIPK1 case showed elevated fecal calprotectin and chest pain, without cutaneous or serologic abnormalities. The PLCG2 patient had acne, folliculitis, elevated acute phase reactants, and ANA positivity.

Both received treatment with NSAIDs, and colchicine in the case of the RIPK1 patient. Cohort characteristics are summarized in Table 1.

Conclusion: In our cohort, despite recruiting patients with matching criteria for HA20, we found presence of two other mutations associated with autoinflammatory syndromes, not related to our target one. This remarks the importance of genetic testing when suspecting autoinflammation, specially in patients with no defined diagnosis, as it shows the clinical overlap between different entities.

Identifying these distinct mutations could refine diagnosis and enable targeted treatment strategies by addressing underlying pathogenic mechanisms.

Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: VEXAS syndrome is an adult-onset autoinflammatory disorder caused by somatic mutations in *UBA1* gene, characterized by systemic inflammation and haematologic abnormalities. Evidence regarding its evolution and approach in real-world settings remains limited.

To aim of this study is to evaluate the clinical progression, inflammatory markers, and treatment response in patients with VEXAS syndrome over a 3, 6, and 12 month-period following diagnosis.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Methods: Observational, ambispective study involving patients with a genetic diagnosis of VEXAS syndrome across rheumatology units in Spain. Follow-up data at 3, 6, and 12 months were collected, including demographic, clinical, laboratory, and treatment related variables. Response rate was defined as complete (RC) (no VEXAS symptoms, CRP ≤10mg/L, prednisone ≤10mg qd), partial (PR)(clinical remission, CRP and prednisone reduction ≥50%) or none (N) (ongoing symptoms, persistent inflammatory markers, no steroid reduction).

Results: Fifty patients (*n*=50) were identified. Follow-up data were available for 25 patients at 3 months, 24 at 6 months, and 19 at 12 months. On the one hand, VEXAS syndrome hallmark symptoms (skin lesions, constitutional syndrome, arthritis, thromboembolic disease, pulmonary and renal involvement) decreased over time ("*Table 1*"). On the other hand, inflammatory markers (CRP, ESR) and haemoglobin levels showed scarce to moderate non-significant improvement. Macrocytosis (MCV > 100 fL) remained persistently elevated ("*Figure 1*").

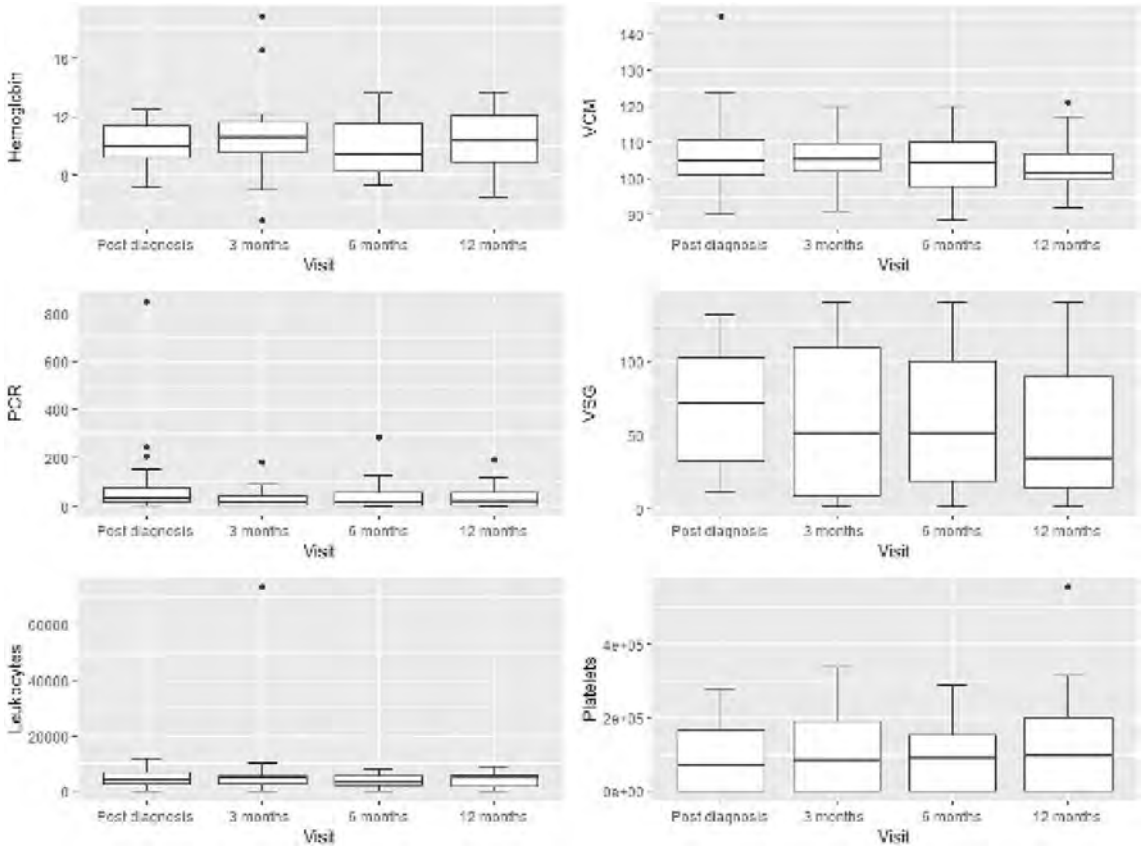

Figure 1. Longitudinal Trends in Inflammatory and Hematologic Biomarkers in Patients with VEXAS Syndrome

At the moment of diagnosis, most frequently prescribed treatments were glucocorticoids (GCs) (92%), azacitidine (28%), MTX and JAK inhibitors (24%), IL-6 inhibitors (16%), and anakinra (18%).

At 3 months, GCs remained the predominant choice of treatment (92%), though both CR and PR were estimated at 38.1%. JAK inhibitors (12%) showed 50% complete response, while IL-6 inhibitors (8%) showed 50% CP and PR response. MTX (16%) showed 75% PR. Anakinra (8%) induced only PR.

At 6 months, glucocorticoids were used in 100% of patients (31.8% CR, 50% PR). IL-6 and JAK inhibitors (both 16.16%) showed 25% CR and 75% PR. MTX (12.5%) maintained a 66.7% PR. Azacitidine (12.5%) showed limited efficacy.

At 12 months, glucocorticoids (100%) continued with 31.8% CR and 50% PR. JAK and IL-6 inhibitors (21.05% each) maintained similar response profiles. MTX (15.58%) still showed 66.7% partial response. Anakinra and azathioprine were discontinued ("*Table 2*").

Two 2 patients underwent allo-HCT, with CR in one case (50%). It has not been possible to lower GCs below 10 mg/day in 1 of the cases after 12 months (partial response 50%).

Conclusion: This multicenter, ambispective study provides real-world data on the disease course and treatment of VEXAS syndrome. GCs remain essential, but seem to lose efficacy over time. IL-6 and JAK inhibitors, especially Ruxolitinib, appear to offer sustained benefit. Despite intensive immunosuppression, inflammatory and haematologic activity persists in many patients. HSCT is a feasible option in selected cases.

Abstract Number: 1172

A Phase II, Single-site, Open-label Study of Zanubrutinib in Patients with igg4-related Disease

Matthew Charles Baker[1], Audra Horomanski[2], Robert Fairchild[3], Yuhan Liu[3], Mariani Diaz Deluna[3], Tobias Lanz[4], Saurabh Gawde[3], Mehdi Khalighi[3], Benjamin Franc[3], Mrudula Penta[3], Nancy Pham[3] and Kip Guja[3], [1]Stanford University, Menlo Park, CA, [2]Stanford University, Palo Alto, CA, [3]Stanford University, Stanford, CA, [4]Stanford University, Stanford

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: IgG4-related disease (IgG4-RD) is a chronic, systemic, immune-mediated disease that is commonly treated with B cell depletion. However, due to potential risks associated with long-term B cell depletion, there is a need for alternative, non-depleting treatment options. Bruton's tyrosine kinase (BTK) plays a critical role in B cell activation and proliferation, and inhibiting BTK is efficacious in B cell driven diseases, without meaningfully reducing B cell numbers. In this phase 2 proof-of-concept study (NCT04602598), we report the efficacy and safety of zanubrutinib in patients with IgG4-RD affecting the lacrimal and/or salivary glands.

Methods: This open-label study was conducted at a single center in the United States. Eligible adult patients with symptomatic IgG4-RD affecting the submandibular and/or lacrimal glands, with prior inadequate response to glucocorticoids, and meeting the 2019 ACR/EULAR Classification Criteria for IgG4-RD, received oral zanubrutinib 80 mg twice daily for up to 24 weeks. The primary endpoint was the change from baseline in the volume of the submandibular and/or lacrimal glands on ^{18}F-fluorodeoxyglucose positron emission tomography/magnetic resonance imaging (FDG-PET/MRI) at Week 24, as determined by two board-certified radiologists blinded to scan order. Secondary endpoints included the change in metabolic activity on FDG-PET/MRI, laboratory parameters such as IgG4 serum concentration, and patient reported outcomes. The Wilcoxon signed rank exact test was used to evaluate changes on imaging.

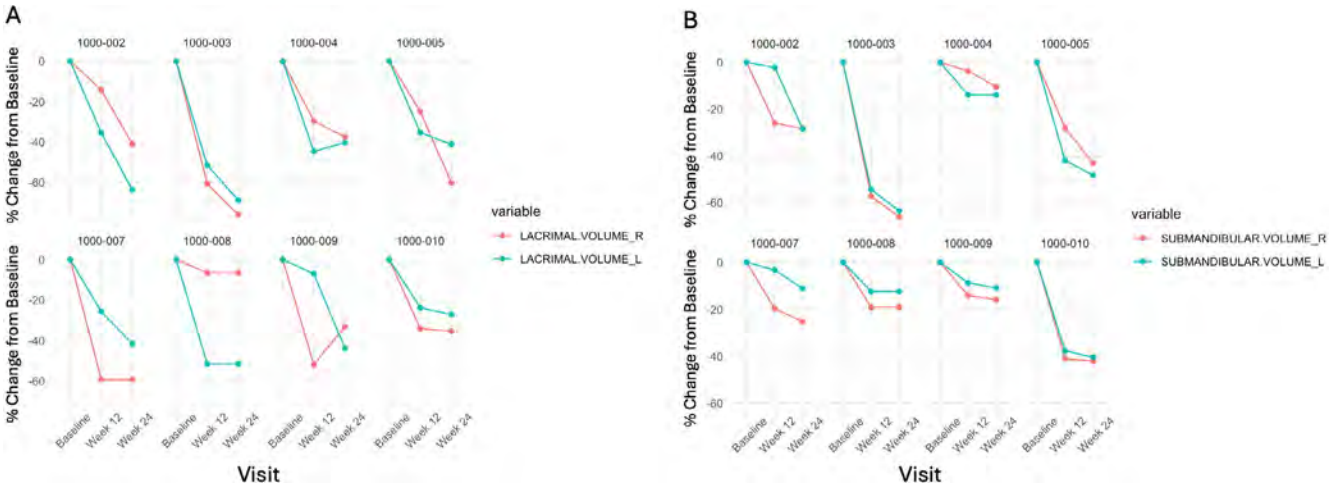

Figure 1. Individual changes in gland volume on FDG-PET/MRI. Panel A shows the percent change from Baseline to Week 12 and Week 24 in lacrimal gland volume for each subject. Panel B shows the percent change from Baseline to Week 12 and Week 24 in submandibular gland volume for each subject. Two subjects who only had Baseline data and terminated early due to adverse events were not included in this analysis. One subject terminated after Week 12 due to worsening IgG4-RD, and the Week 12 imaging data was imputed for Week 24.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

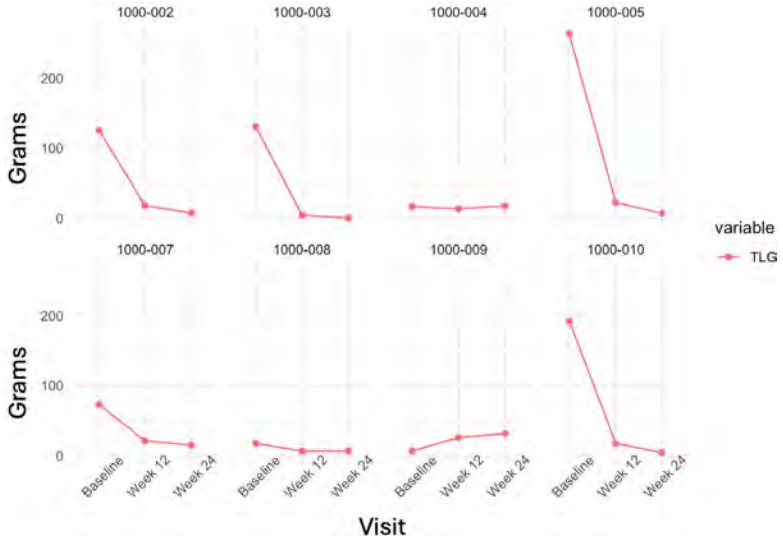

Figure 2. Individual changes in total lesion glycolysis (TLG). TLG is defined as the product of mean standard uptake value (SUVmean) and total metabolic lesion volume (tMLV) of the lacrimal glands, parotid glands, submandibular glands, and regional lymph nodes. Two subjects who only had Baseline data and terminated early due to adverse events were not included in this analysis. One subject terminated after Week 12 due to worsening IgG4-RD, and the Week 12 imaging data was imputed for Week 24.

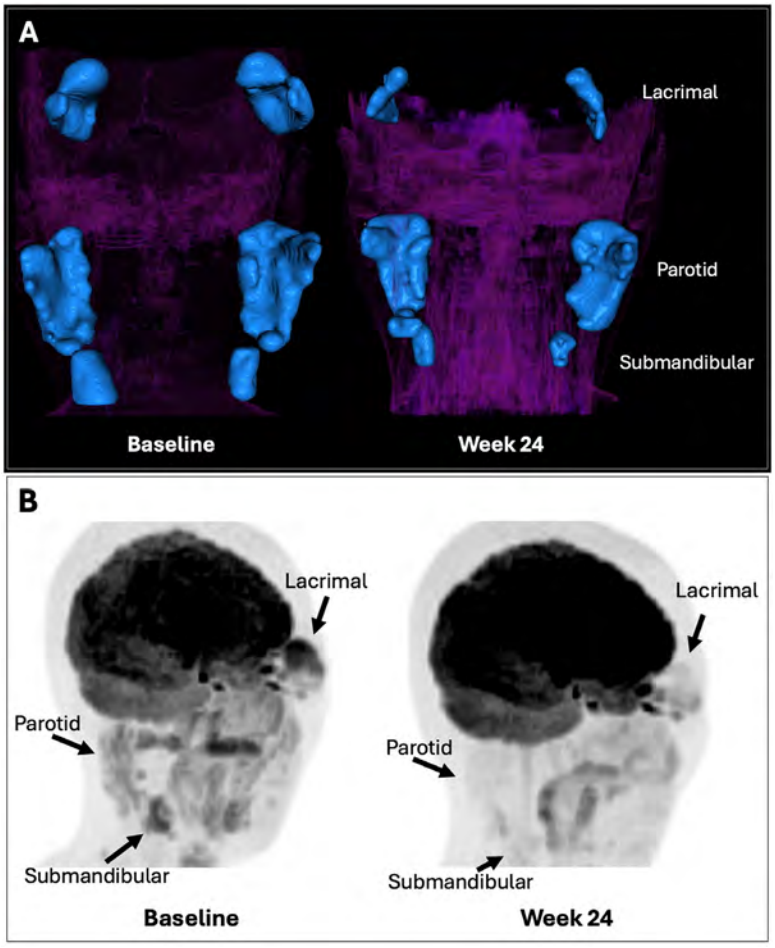

Figure 3. Change in gland volume and metabolic activity on FDG-PET/MRI. Panel A shows MRI 3D volumetric segmentation and rendering of the lacrimal, parotid, and submandibular glands at Baseline and Week 24. Panel B shows FDG-PET maximum intensity projection (MIP) images in right anterior oblique orientation (SUV scale 0-7), demonstrating hypermetabolism in all glands at Baseline, which significantly improves after treatment.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Results: Ten patients were enrolled; most were male (70.0%), Asian (60.0%), and with a median age of 58 (range, 38-74) years. Prior treatments included prednisone (10 patients), azathioprine (2 patients), and rituximab (5 patients); for rituximab-treated patients, the mean (standard deviation [SD]) time since last dose was 2.5 years (1.5). No patients were receiving glucocorticoids or a steroid-sparing immunosuppressive treatment at the time of enrollment or during the study. The mean (SD) number of organs ever affected by IgG4-RD was 4.4 (1.4), and all patients had both lacrimal and submandibular gland disease. At Week 24, the mean (SD) percent changes from baseline were -45.4% (17.4) for lacrimal gland volume ($p < 0.001$) and -30.0% (18.6) for submandibular gland volume ($p < 0.001$) (**Figure 1**). In addition, reductions were observed in all measures of metabolic activity, including a mean (SD) change from baseline in total lesion glycolysis of -91.6 grams (98.5; $p = 0.05$) (**Figure 2**). Representative FDG-PET/MRI images are shown in **Figure 3**. The mean (SD) change in the serum IgG4 concentration over 24 weeks was -417.0 mg/dL (410). All patients had at least one treatment-emergent adverse event (TEAE), most of which were mild, and there was one serious TEAE from COVID-19.

Conclusion: Treatment with zanubrutinib alone, without the need for glucocorticoid induction or other background immunosuppression, significantly reduced both lacrimal and submandibular gland volume and metabolic activity on FDG-PET/MRI, as well as reduced serum IgG4 concentrations, with an acceptable safety profile. Given these results, zanubrutinib warrants further investigation as a treatment for IgG4-RD.

Abstract Number: 1173

Prevalence of Coronary Artery Involvement in IgG4-Related Disease Detected by Non-Gated Cross-Sectional Imaging

Matthew Charles Baker[1], Lauren Taylor[2], Haziq Siddiqi[2], Jison Hong[2] and Brian Pogatchnik[2], [1]Stanford University, Menlo Park, CA, [2]Stanford University, Stanford, CA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: IgG4-related disease (IgG4-RD) classically presents with a mass or diffusely enlarged organ, but it also affects blood vessels of all sizes. Coronary artery involvement (CAI) is well described but understudied. Prior work demonstrated CAI in 13 out of 361 (4%) IgG4-RD patients, however it was limited by lack of standardized screening for the evaluation of CAI[1]. The goal of our study was to establish a conservative estimate of the true prevalence of CAI by screening IgG4-RD patients that had prior cross-sectional imaging of the chest, regardless of whether CAI was clinically suspected.

Methods: IgG4-RD patients were identified using the STAnford medicine Research data Repository by searching all adult patients seen at Stanford University between 2/28/09 and 3/1/2023 with any clinical document containing "IgG4-related disease," "IgG4-RD," or "IgG4 disease." Each chart was manually reviewed to verify the diagnosis. Cases were categorized as definite, probable, or possible IgG4-RD[2]. We included all patients with prior non-gated CT chest imaging. A radiologist with expertise in IgG4-RD and vasculitis reviewed the scans, and patients who had features concerning for possible CAI

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Cohort selection.

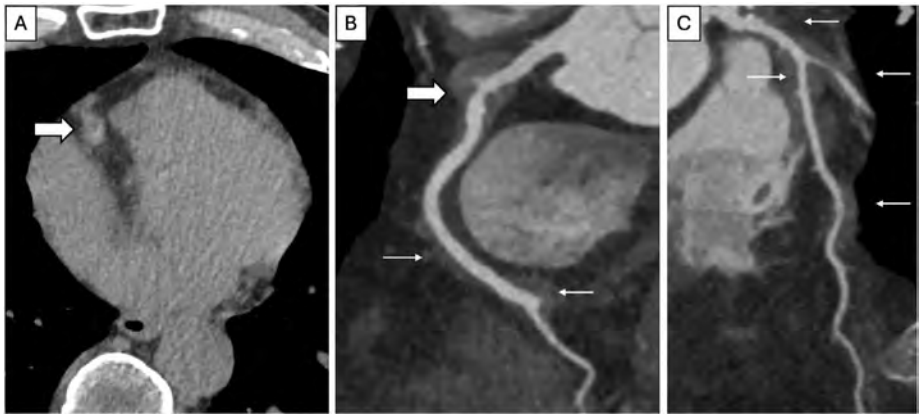

Figure 2. IgG4-RD coronary artery involvement on computed tomography. Panel A demonstrates suspected right coronary artery thickening on a non-gated chest CT without IV contrast (large arrow), which is confirmed on gated CT angiography (Panel B; large arrow). Panel C demonstrates additional sites of disease, including the left main, left anterior descending, and proximal left circumflex (small arrows), which were not clearly apparent on the initial CT.

were recommended to obtain a gated CT of the heart or chest. After reviewing the confirmatory imaging, we calculated the prevalence of CAI, as well as the positive predictive value (PPV) for detecting CAI.

Results: Of the 250 IgG4-RD patients in the full cohort, 130 patients (52.0%) had prior non-gated chest imaging (**Figure 1**). Twenty patients (15.4%) had findings concerning for possible CAI. Four of the 20 patients could not be contacted due to departure from our healthcare system or death. Of the 16 remaining patients, 3 had a negative gated CT angiography (CTA) of the chest or heart, 4 had a positive gated CTA, and 7 had prior gated CTA studies obtained after the original non-gated CT chest, which were subsequently reviewed and were positive (representative images of CAI are shown in **Figure 2**). Additionally, 2 patients had such profound results on the initial non-gated CT chest they were deemed definitely positive without the need for a confirmatory gated CTA. As **Table 1** demonstrates, patients with CAI were older (70 years

Investigational agent**	13 (10.0)	12 (10.6)	1 (7.7)

*Based on screening or confirmatory imaging. **Investigational agents include inebilizumab, zanubrutinib, rilzabrutinib, and obexelimab. SD = standard deviation; y = year; kg = kilogram; m = meter.

vs 63 years), more likely to be male (77% vs 49%), more likely to be current smokers (23% vs 3%), more likely to have multiorgan disease (100% vs 58%), and had higher serum IgG4 concentrations (mean peak value 973 mg/dL vs 456 mg/dL). In total, 13 out of 16 patients who screened positive were confirmed to have CAI, resulting in a PPV of 81.3%. The prevalence of CAI in this cohort of patients was 13 out of 130 (10.0%).

Conclusion: By reviewing non-gated CT chest imaging to screen for IgG4-RD CAI, we observed a prevalence of CAI of 10% in our cohort. This is higher than what has been previously reported and likely represents a conservative estimate. Our results suggest that CAI is relatively common in IgG4-RD, and future studies are needed to determine which patients should be screened for CAI and whether the approach described herein has adequate sensitivity to be implemented as a screening test.

High Prevalence of Autoimmunity in Rosai Dorfman Disease: A Multinational Study

Mitali Sen[1], Gordon Ruan[2], Samuel Reynolds[3], Haadi Ali[3], Xi Yang[3], Diana Morlote[1], Aishwarya Ravindran[1], Lauren Shea[1], Matthew Koster[4], Jithma Abeykoon[2], Hind Salama[5], Xin-Xin Cao[6], Asra Ahmed[3], Ronald Go[2] and Gaurav Goyal[1], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Mayo Clinic, Rochester, [3]University of Michigan, Michigan, [4]Mayo Clinic, Rochester, MN, [5]National Guard Health Affairs, Riyadh, Saudi Arabia, [6]Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China (People's Republic)

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Rosai-Dorfman Disease (RDD), formerly known as sinus histiocytosis with massive lymphadenopathy, was initially thought to be inflammatory or autoimmune in nature. The discovery of MAP-ERK pathway mutations has since reclassified RDD as a histiocytic neoplasm. However, autoimmune diseases have been commonly reported, and recent consensus guidelines recognize "immune-related RDD" as a distinct subtype. Given its clinical overlap with autoimmune diseases, a deeper understanding of RDD's immunologic profile is increasingly important for rheumatologists.

Methods: We performed a retrospective chart review of histologically confirmed RDD cases from five international referral centers. Using a standardized data collection form, we gathered data on patient demographics, patterns of organ involvement, driver mutations, autoimmune serologies, and treatment outcomes of autoimmune diseases.

Results: We identified 162 patients with RDD diagnosed from Jan 2003- Jan 2025. Median age at diagnosis was 48 years (range, 7-85) with nine patients diagnosed before age 18. Cohort was 64.8% female and racial distribution was 34.6% Black, 33.3% White, and 24.7% Asian (Table 1). Multisystem involvement was noted in 53.7% of cases, with common sites including skin/subcutaneous tissue (49.4%), lymph nodes (39.5%), and bone (33.9%).

Autoimmune diseases were present in 29 patients (17.9%), among which, the most common were systemic lupus erythematosus (6, 20.7%) and rheumatoid arthritis (5, 17.2%) (Figure 1). Autoimmune disease was more frequent in multisystem vs single organ RDD (62% vs 38%, p=0.3). Mean ESR and CRP were higher in patients with autoimmune disease (37.1 mm/Hr and 53.5 mg/L) vs patients without autoimmune disease (25.5 mm/Hr and 39.4 mg/L). Autoantibodies were detected in 44 of 94 tested (46.8%), most commonly ANA in 33.3% (29/87) (Figure 2).

Tissue-based next generation sequencing was performed in 102 patients (62.9%), revealing KRAS mutation (11.7%), MEK mutations (9.3%), other mutations (16.7%) and no mutation (25.3%). No significant association was observed between mutational status and autoimmunity.

Autoimmune disease preceded RDD diagnosis in 19 cases (11.7%). Treatment data were available for 22 of 29 patients with autoimmune disease: 11 (50%) were stable off treatment, 10 (45.5%) were stable on DMARD therapy, and 1 (4.5%) had active disease despite multiple DMARDs.

Median follow-up for the entire cohort was 29.8 months (IQR 10.4–61.4). Eight deaths were reported in the cohort, none among patients with autoimmune disease.

Autoantibodies in patients with RDD (% of patients positive)

Conclusion: This multi-center cohort highlights the clinical and molecular diversity of RDD. It also reveals a high prevalence of autoimmunity in RDD, both in terms of autoimmune disease (17.9 %) and positive autoantibodies (46.8 %), which is higher than general population rates of approximately 3% and 16% respectively. There was a trend toward association of autoimmune disease with multisystem RDD and with higher inflammatory markers at the time of RDD diagnosis. Overall, findings highlight the need for investigation into shared pathogenesis and potential therapeutic strategies that could target both RDD and autoimmune diseases.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: GCA and PMR are closely related, immune-mediated chronic inflammatory diseases often occurring concurrently in individuals over 50.[1,2] While glucocorticoids (GC) are the mainstay of treatment, relapses are common, and long-term use causes significant side effects, highlighting the need for GC-sparing therapies.[2]

Secukinumab (SEC), a monoclonal antibody that selectively neutralizes interleukin-17A, has shown efficacy and safety in various immune-mediated diseases.[3] In the TitAIN phase 2 study, SEC resulted in a higher sustained remission rate in patients with GCA than in placebo (PBO) at week 28, with effects lasting for 52 weeks; safety was consistent with its known safety profile.[4]

This post hoc analysis evaluated SEC vs PBO in the subgroup of GCA patients with PMR symptoms within 12 weeks prior to and/or at baseline (BL).

Methods: TitAIN was a randomized, double-blind, PBO-controlled, multicenter, phase 2 study in patients aged ≥50 years with new-onset or relapsing GCA (unequivocal cranial symptoms of GCA and/or symptoms of PMR) who were naive to biological therapy and receiving GCs at BL with a prednisolone equivalent dose of 25–60 mg/day.[4] Patients were assigned (1:1) to receive 300 mg SEC or PBO subcutaneously once a week up to week 4 and every 4 weeks thereafter. In both arms, prednisolone dose was tapered to 0 mg over a 26-week period.[4]

Results: In the TitAIN study, 27 patients received SEC and 25 received PBO; 44.4% (12/27) of patients in the SEC arm vs 32.0% (8/25) in the PBO arm had PMR symptoms and were included in this post hoc analysis.

Among patients with PMR symptoms, 58.3% (7/12) in the SEC arm vs 12.5% (1/8) in the PBO arm were in sustained GCA remission at week 52, consistent with a previous finding in the overall study population (59% vs 8%).[4]

Overall, only 3.7% (1 of 27) in the SEC arm vs 24.0% (6/25) in the PBO arm experienced PMR symptoms post BL up to week 52. In the subgroup of patients with PMR symptoms, only 8.3% (1/12) in the SEC arm had PMR symptoms post BL compared to 50.0% (4/8) in the PBO arm. Data for new-onset and relapsing GCA subgroups are presented in Table 1.

Table 1. Results at 52 weeks for the overall GCA population and the subgroup of GCA patients with PMR symptoms from the TitAIN study

	Secukinumab		Placebo	
	All patients N=27	Patients with BL PMR* N=12	All patients N=25	Patients with BL PMR* N=8
Sustained remission of GCA at week 52				
Total	16/27 (59.3%)	7/12 (58.3%)	2/25 (8.0%)	1/8 (12.5%)
New-onset GCA	15/23 (65.2%)	6/9 (66.7%)	1/19 (5.3%)	0/5 (0)
Relapsing GCA	1/4 (25.0%)	1/3 (33.3%)	1/6 (16.7%)	1/3 (33.3%)
Post-BL PMR symptoms up to week 52				
Total	1/27 (3.7%)	1/12 (8.3%)	6/25 (24.0%)	4/8 (50.0%)
New-onset GCA	1/23 (4.3%)	1/9 (11.1%)	4/19 (21.1%)	2/5 (40.0%)
Relapsing GCA	0/4 (0)	0/3 (0)	2/6 (33.3%)	2/3 (66.7%)

Data is presented as observed.
*Patients who had PMR reported within 12 weeks prior to and/or on the first day of study treatment in 1) GCA medical history eCRF, 2) Signs and symptoms eCRF at screening or BL, 3) AE summary eCRF page
AE, adverse event; BL, baseline; eCRF, electronic case report form; GCA, giant cell arteritis; PMR, polymyalgia rheumatica.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

All GCA patients with PMR symptoms had ≥1 adverse event (AE), in both arms. The most common AEs were consistent with those reported in the study population.[4] Serious AEs were reported in 8.3% of patients (n=1; facial paralysis) in the SEC arm and 37.5% (n=3; gastrointestinal pain, dizziness, and chronic obstructive pulmonary disease) in the PBO arm.

Conclusion: This post hoc analysis showed a numerical reduction in patients with PMR symptoms with SEC treatment compared to PBO. The safety profile of SEC was similar to the overall GCA study population and consistent with its known safety profile. These results support the development of SEC for PMR. A phase 3 trial (NCT05767034) is evaluating the efficacy and safety of SEC in relapsed patients with PMR.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Post-inflammatory pigment alteration (PIPA) following resolution of psoriasis plaques is an important, neglected problem that disproportionately impacts people of color.[1-3] VISIBLE, an ongoing Phase 3b study evaluating guselkumab for moderate-to-severe psoriasis across all skin tones, is designed to collect PIPA data.

Methods: Total 211 participants were randomized (3:1) to receive guselkumab or placebo with placebo crossover to guselkumab at Weeks 16, 20, and every 8 weeks (q8w) thereafter. Through Week 48, clinician-reported Psoriasis Area Severity Index (PASI) responses and patient-reported outcomes (Skin Discoloration Impact Evaluation Questionnaire [SDIEQ], Dermatology Life Quality Index [DLQI], and Patient-Reported Outcomes Measurement Information System-29 [PROMIS-29]) were collected. Standard and cross-polarized photographs were obtained and analyzed for skin tone evenness.

Results: Mean PASI improvement was ∼95% at Week 48 for the guselkumab randomized groups. Correlation coefficients were higher for SDIEQ and DLQI versus SDIEQ and PASI at Week 48, indicating high impact of skin discoloration on quality of life (QoL). SDIEQ had moderate (r=0.4116) and weak (r=0.3204) correlations with PROMIS-29 anxiety and depression measures, respectively, whereas Week 48 PASI did not correlate with either PROMIS-29 outcome.

Conclusion: Impact of PIPA on QoL is much greater than skin clearance as measured by PASI. Awareness of patient concerns about PIPA will enable clinicians to better counsel patients starting psoriasis treatment. The study is limited by variations in photograph quality. PIPA due to psoriasis highly impacts QoL in people of color. Discussing PIPA before starting

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. treatment is imperative and its effect should be explicitly measured. While there are objective ways to quantify PIPA, further planned analyses of mechanistic changes will help identify factors predictive of PIPA outcomes.

Background/Purpose: Familial Mediterranean Fever (FMF) is an autoinflammatory disease mainly treated with colchicine. Anakinra, an interleukin-1 receptor antagonist, is used for colchicine-resistant cases. However, data on the safety of Anakinra during pregnancy is limited. This study aims to evaluate pregnancy outcomes of FMF patients who received at least one dose of Anakinra during pregnancy.

Methods: A retrospective single-center study was conducted to analyze clinical data and pregnancy outcomes of FMF patients who received Anakinra during pregnancy.

Results: This study included data from 27 pregnancies involving 19 mothers. The average maternal age at pregnancy was 31.5 ± 3.95 years. The most common genotype among mothers was homozygous M694V, observed in %72.2 (13/18) of cases. Amyloidosis was present in %15.8 (3/19) of mothers. In %51.9 (14/27) of the pregnancies, mothers were on Anakinra treatment prior to pregnancy, while in the remaining pregnancies Anakinra treatment was started during pregnancy.

Out of the 27 pregnancies, 26 resulted in delivery, and one is still ongoing at 15 weeks of gestation. Among the terminated pregnancies, 26 babies were born, one of whom was stillborn. The frequency of cesarean section was 80.8% (21/26), and the rate of preterm birth was 34.6% (9/26), with an average gestational age at birth of 36.6 ± 3.3 weeks. Assisted reproduction techniques were utilized in %30.4 (7/23) of the pregnancies.

The most common maternal complication during pregnancy was preeclampsia (5/23) followed by bleeding (2/23), hypertension (2/23), gestational diabetes (1/23), and cerebrovascular event (1/23).

Intrauterine growth restriction was reported in %18.5 (5/27) of the pregnancies. The rate of neonatal ICU hospitalization was %16.7 (4/24) among babies. It was reported that %34.8 (8/23) of the babies were small for gestational age. Mean weight, length, and head circumference of the babies were 2.8 ± 0.76 kg, 46.5 ± 6.2 cm, and 33.8 ± 3.8 cm, respectively. The average Apgar scores at first and fifth minutes were 7.8 ± 1.4 and 9.0 ± 1.1, respectively.

The average current age of the children is 75.3 ± 45.9 months, with a mean weight of 26.7 ± 11.4 kg and mean height of 116.4 ± 22.8 cm. Among these children, the most common chronic condition was allergic conditions (4/9), followed by growth hormone deficiency (1/9), PFAPA (1/9), torticollis (1/9), and a heart murmur (1/9).

Conclusion: Although complications such as preeclampsia and intrauterine growth restriction were observed, no lasting sequelae were reported in the children, and the majority of pregnancies resulted in live births with favorable outcomes. Anakinra appears to be safe during pregnancy, with no major teratogenic effects identified. However, long-term follow-up is warranted to fully assess potential outcomes.

Figure 1: Global, geographical distribution of panellists

Table 1: Statements which achieved stable consensus or stable disagreement regarding JAKi use in RMDs.

A. Current uses of JAK inhibitors
JAK inhibitors have an important role in the management of rheumatoid arthritis.
JAK inhibitors have an important role in the management of ankylosing spondylitis.
JAK inhibitors have an important role in the management of psoriatic arthritis.
JAK inhibitors may have an important role in the management of atopic dermatitis.
JAK inhibitors should be reserved for second or subsequent treatment lines.
JAK inhibitors have utility as a corticosteroid sparing agent.
When the treatment target has been achieved, patients may be maintained on JAK inhibitors.
B. Potential uses of JAK inhibitors beyond currently approved indications
JAK inhibitors have a potential role in the management of psoriasis.
Combination therapy with another targeted synthetic or biologic DMARD should only be used when there is substantial evidence on efficacy and safety from clinical trials.
Combination therapy should only be used when there is substantial evidence on efficacy and safety from clinical trials.
C. Potential uses of a specific class of JAK inhibitors: TYK2 inhibitors
TYK2 inhibitors have a potential role in the management of psoriatic arthritis.
TYK2 inhibitors have a potential role in the management of psoriasis.
D. Acquisition and access to JAK inhibitors
JAK inhibitors are currently accessible for patients who have an indication for these agents in my country.
The availability of generic JAK inhibitors may lead to their wider use.
The availability of generic JAK inhibitors may broaden the indications for which they are used.
The availability of generic versions of existing JAK inhibitors may increase their use in the early stages of conditions for which they are indicated.
The availability of generic JAK inhibitors may broaden the off-label indication for which they could be used.
JAK inhibitors should be prescribed exclusively by specialists in the condition being treated.
JAK inhibitors may be prescribed by non-specialists.
Monitoring for JAK inhibitors may be undertaken by non-specialists in the condition being treated provided there is an agreement with the specialist and agreed guidelines are followed.
Cross-disciplinary education initiatives are important to ensure effective prescribing of JAK inhibitors in people with multiple conditions who may benefit from their use

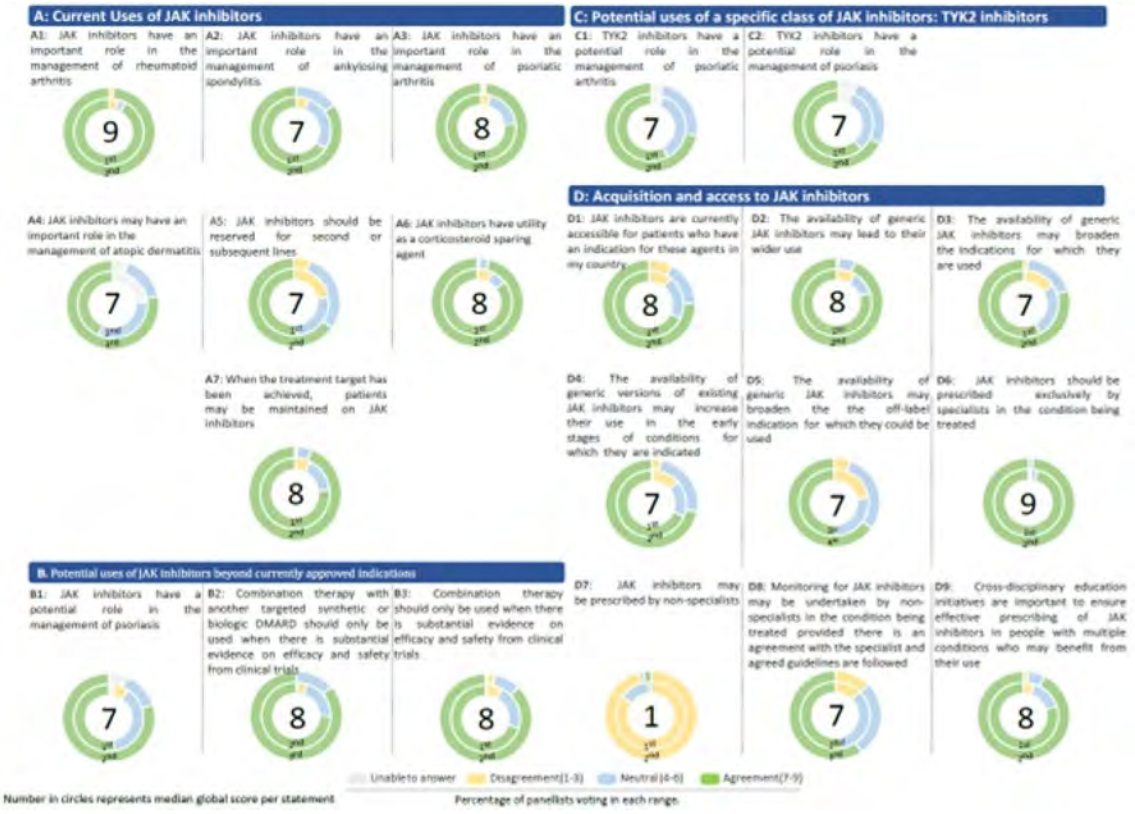

Figure 2: Detailed outcomes for statements achieving stable consensus in the overall global analysis.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: The development of advanced therapies such as JAK inhibitors (JAKi) has expanded treatment options available for patients with rheumatic and musculoskeletal diseases (RMDs). Case reports and scientific studies are increasingly demonstrating the potential scientific rationales regarding JAKi use for broader indications. Defining current and anticipated prescribing habits may help predict the future treatment paradigm and understand key evidence gaps. This study aimed to capture global discussions on the evolution of JAKi use within (1) current indications and (2) new indications where JAKi may have potential place in therapy as identified by unmet medical need, external global expert opinion and literature evidence using a modified Delphi approach.

Methods: A 4 round modified Delphi study was conducted with 178 Panellists from 23 countries worldwide. Global experts formed the academic and steering committees. Systematic and scoping reviews on published literature of JAKi use in RMDs were conducted to inform initial statements alongside committee expertise. Panellists ranked statements on a Likert scale of 1-9, provided comment on statement stringency and suggestions. Stable statement consensus or stable disagreement was considered as a median score of ≥7 or ≤3 from two consecutive rounds, respectively. Statements were presented in ≥2 rounds and wording amended based on panellist suggestions, confirmed by committees.

Results: Panellists (n=178) participated from: Americas (n=30), Europe (n=40), Eastern Mediterranean (n=35), South-East Asia (n=19), Africa (n=27), and Western Pacific (n=27) (Figure 1). Statements were grouped into the following categories: Current Uses of JAKi, Potential uses of JAKi beyond currently approved indications, Potential uses of a specific class of

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

JAKi: TYK2 inhibitors or Acquisition and access to JAKis (Figure 2/Table 1). Of the 79 statements presented, 20 reached stable consensus, and one reached stable disagreement, with >250 comments. Consistent themes included the important role of JAKi in current indications, that the availability of generic JAKi may lead to their wider use, lack of RCT data on potential new indications and accessibility. Opinion stratification across key differentiators including geography, national income and treatment practice highlighted great heterogeneity in responses, particularly in relation to cost, JAKi adoption in earlier stages of indicated conditions, and potential expansion of their use more broadly.

Conclusion: Based on available literature evidence and global expert consensus, this study highlights global consensus characterization of current uses and the evolution of JAKi use in RMDs. Clinicians were in consensus that JAKi have an important role in the management of current indications. Additionally, opinion showed availability of generic JAKi may lead to their wider use and may broaden the indications for which they are utilised.

Efficacy and Safety of Ruxolitinib in Adult Patients With Refractory Connective Tissue Disease-Associated Macrophage Activation Syndrome

Jingjing Li[1], Ran Wang[1], Jie Chen[1], Antao xu[1], Yakai Fu[1], Yanwei Lin[1], Xiaodong Wang[1], Shuang Ye[2], Fang Du[1] and **Qiong Fu**[3], [1]Department of Rheumatology, Renji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China, Shanghai, China (People's Republic), [2]Renji Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China, Shanghai, Shanghai, China (People's Republic), [3]Renji Hospital, Shanghai, Shanghai, China

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Macrophage activation syndrome (MAS) is a rare and life-threatening complication of connective tissue diseases (CTDs), with approximately 30% of cases being refractory to standard therapeutic protocols. Ruxolitinib, a Janus kinase 1/2 inhibitor, has emerged as a potential therapeutic option for refractory MAS. This study aimed to evaluate its efficacy and safety in patients with refractory CTD-associated MAS (CTD-MAS).

Methods: A meticulous chart review was conducted on 20 patients with refractory CTD-MAS who received ruxolitinib in our institution. Data from ruxolitinib-naïve CTD-MAS patients served as historical controls. Clinical and laboratory parameters, therapeutic response, and survival outcomes were analyzed. The efficacy and safety of ruxolitinib were evaluated, and survival rates were compared to historical controls.

Results: The cohort of 20 patients with refractory CTD-MAS included 17 females and 3 males, with underlying conditions comprising adult-onset Still's disease (n = 13), systemic lupus erythematosus (n = 4), and other connective tissue diseases (n = 3) (Table 1). At the initiation of ruxolitinib treatment, all patients exhibited active diseases. The survival rate was

*Ruxo: ruxolitinib; IVIG: intravenous immunoglobulin; AOSD: adult-onset Still's disease; SLE: systemic lupus erythematosus; CTD: connective tissue diseases.

significantly higher in the ruxolitinib group (19/20, 95%) than in historical controls (13/21, 62%) (P = 0.011) (Figure 1). Partial response (PR) was observed in 9 patients at the first scheduled response assessment (week 1), and the first complete remission (CR) was documented at week 2. Two additional patients progressed from PR to CR during the third week, and one patient improved from no response (NR) to PR. By week 8, 50% (10/20) and 30% (6/20) of ruxolitinib-treated patients had achieved partial and complete responses, respectively. Four patients exhibited no response to treatment, including the patient who died of complications (Figure 2). Ruxolitinib therapy led to rapid and significant clinical and laboratory parameter improvements. By week 8, the median daily glucocorticoid dose decreased from 2.7 mg/kg/day to 0.5 mg/kg/day. Cytomegalovirus infection occurred in 20% (4/20) of patients.

Conclusion: Ruxolitinib demonstrated substantial efficacy and tolerability in patients with refractory CTD-MAS, leading to significant clinical improvement and a notable reduction in glucocorticoid dependence. These findings support the potential role of ruxolitinib as a salvage therapy for refractory CTD-MAS, warranting further investigation in prospective clinical studies.

Abstract Number: 1180

Gender-Based Clinical Differences in Behçet's Syndrome: Findings from a 24-Year Cohort in a Non-Endemic and Multiethnic Country

Rafael Bassara Macedo[1], Pedro Araujo[2], Fabio Specian[1], Carolina Ejnisman[3], Barbara Bayeh[3], Percival Degrava Sampaio Barros[3], Thiago Freitas[4], Rafael Cordeiro[5] and Henrique Giardini[4], [1]Rheumatology Division, Hospital das Clinicas da Faculdade de Medicina da Universidade de Sao Paulo (USP), Sao Paulo, Sao Paulo, Brazil, [2]Universidade de São Paulo, Sao Paulo, São Paulo, Brazil, [3]Rheumatology Division, Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, Sao Paulo, SP, Brazil, Sao Paulo, Brazil, [4]Rheumatology Division, Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, Sao Paulo, SP, Brazil, São Paulo, Brazil, [5]Rheumatology Division, Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, Sao Paulo, SP, Brazil, São Paulo, Sao Paulo, Brazil

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II

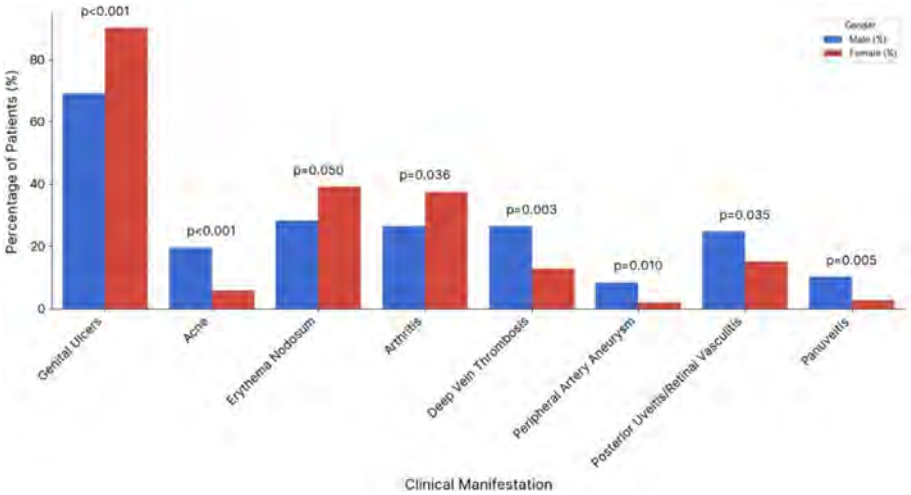
Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Behçet's syndrome (BS) is a multisystemic inflammatory condition that affects both genders, although gender-related differences in disease manifestations may vary across regions. Studies report severe manifestations more commonly in men. However, gender-based differences in South America, a non-endemic region, have been less studied.

Methods: This is a retrospective analysis of a prospective, single-center, multiethnic cohort of patients with BS from January 2000 to December 2024. Patients were diagnosed according to the International Study Group and/or the International Criteria for Behçet's Syndrome. Categorical variables were analyzed using the chi-square test or Fisher's exact test, while continuous variables were compared using unpaired Student's t-test.

Results: Among 369 patients evaluated, 303 were included, of whom 117(38.6%) were male and 186(61.4%) were female. The mean age at symptom onset was 27.4±11.4 years, with males presenting at 25.9±10.4 years and females at 28.3 ±12.0 years (p=0.075). The mean age at diagnosis was 31.6±10.4 years, with no significant difference between sexes (p=0.082). The most prevalent clinical manifestations were oral ulcers (99.3%), genital ulcers (81.5%), pseudofolliculitis (51.5%) and erythema nodosum-like lesions (35%). Female patients more frequently presented genital ulcers (89.2%



Clinical Manifestations by Gender in Behçet's Syndrome

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

vs. 69.2%; $p< 0.001$), erythema nodosum-like lesions (39.2% vs. 28.2%; $p=0.050$) and arthritis (38.2% vs. 26.5%; $p=0.036$). Conversely, male patients more often exhibited acne (19.7% vs. 5.9%; $p< 0.001$), deep vein thrombosis of the limbs (26.5% vs. 12.9%; $p=0.003$), caval vein thrombosis (7.7% vs. 2.2%; $p=0.020$), peripheral artery aneurysms (8.5% vs. 2.2%; $p=0.010$), arterial occlusions (11.1% vs. 4.3%; $p=0.023$), posterior uveitis/retinal vasculitis (24.8% vs. 15.1%; $p=0.035$) and panuveitis (10.3% vs. 2.7%; $p=0.005$). Azathioprine use was more common among males (75.2% vs. 64%; $p=0.041$). Fibromyalgia was significantly more prevalent in female patients (18.3% vs. 1.7%; $p< 0.001$). No gender differences were observed regarding the use of other medications or comorbidities.

Conclusion: This is the largest cohort in South America to evaluate gender-specific features in BS. Male patients were more likely to exhibit severe manifestations, consistent with existing literature. Female patients showed a higher prevalence of mucocutaneous lesions, arthritis, and fibromyalgia. Although these manifestations are often considered benign, they can significantly affect quality of life. The higher prevalence of fibromyalgia in women may reflect the general higher incidence of this condition in females, but arthritis may also trigger central nervous system sensitization, making women more susceptible. This hypothesis requires further investigation. The higher use of azathioprine in male patients suggests the need for more aggressive immunosuppression due to the severity of their symptoms. This difference may also reflect a more conservative treatment approach for women, given the perceived milder nature of their manifestations.

Abstract Number: 1181

Clinical Relevance of Tumor Necrosis Factor Superfamily Cytokines

Robert Corty[1], Gul Karakoc[1], Ahmad Jawdat[2], Hui Yu[3], Jonathan Mosley[4], Michael Stein[1], Vivian Kawai[5] and Participants and investigators of All of Us Research Program and FinnGen study, [1]Vanderbilt University Medical Center, Nashville, TN, [2]University of Alabama at Birmingham, Birmingham, [3]University of Miami, Miami, [4]UT Southwestern Medical Center, Dallas, [5]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: The tumor necrosis factor superfamily (TNFSF) includes 48 proteins involved in immune activation, inflammation, and cell death and represent an area of intense focus in current drug development efforts. However, the proteins are difficult to measure in large clinical populations, thus the clinical relevance of many of these proteins in human disease is not well characterized and the potential effects of drugs targeting them is largely unknown. The ability to associate genetically driven variability in protein levels with phenotype risk provides an opportunity to determine the potential relevance of TNFSF proteins using large populations with both genotype and clinical information available.

Methods: To define the clinical manifestations associated with TNFSF members, we examined genetic models for 38 TNFSF proteins available in the UK Biobank pQTL web portal (http://uk-ppp.gwas.eu). We estimated genetically determined levels of TNFSF proteins in participants of European ancestry in the Vanderbilt University Medical Center biobank (BioVU) and in the All of Us Research Program (AoU). We performed a phenome-wide association study (PheWAS) in each biobank to define clinical associations for TNFSF levels adjusted for sex, age, and 5 principal components; and significant associations (P-value$\leq 5x10^{-5}$) in BioVU and AoU were combined in a meta-analysis. We examined proteins with significant associations in the meta-analysis (P-value $\leq 5x10^{-5}$) using a Mendelian randomization (MR) approach. We used genetic predictors of

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

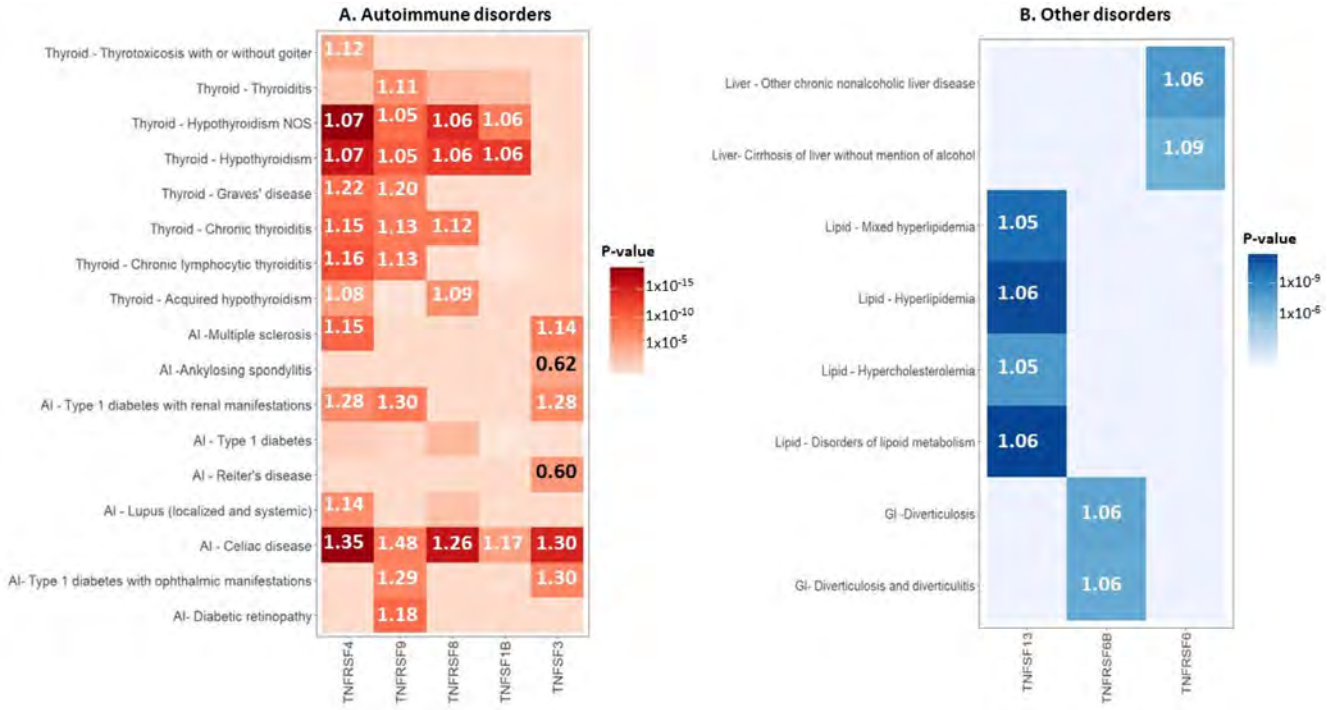

Figure 1: Heatmaps showing the association between genetically predicted levels of tumor necrosis factors super family proteins (TNFSF) with (A) Autoimmune disorders and (B) Others disorders. Darker shades represent more significant associations (P =2.2x10-19 for hypothyroidism NOS and P =1.8x10-12 for disorders of lipoid metabolism). Odds ratios (OR) for significant associations (P ≤5x10-5) are shown in each tile and OR<1 are shown in black fonts.

TNFSF proteins as instrumental variables and summary statistics for clinical diagnoses as outcome in an inverse-variance weighted regression (IVWR). We tested horizontal pleiotropy using Egger regression. A P-value< 0.05 was considered significant in the IVWR and an intercept P-value ≤0.05 suggested pleiotropy.

Results: Genetically predicted levels of twelve proteins were significantly associated with at least one clinical diagnosis in either biobank. In the meta-analysis, higher levels for TNFRSF4, TNFRS9, TNFRSF8, and TNFRSF1B increased the risk of several thyroid and autoimmune diseases including lupus; higher levels of TNFSF3 were associated with a reduced risk of both ankylosing spondylitis and Reiter's disease (**Fig. 1A**). TNFSF13 increased the risk for dyslipidemias, TNFRSF6B for diverticulosis and TNFRSF6 for non-alcoholic liver disease (**Fig. 1B**). In the IVWR analyses, TNFRSF4 (P-value =1.5x10^{-5}) and TNFRSF8 (P-value=0.02) were associated with autoimmune thyroiditis without evidence of horizontal pleiotropy (intercept P-value >0.05 for both proteins).

Conclusion: Genetic predisposition to higher levels of several TNFSF proteins is associated with increased risk of autoimmune, metabolic, hepatic, and gastrointestinal disorders and may identify potential therapeutic targets.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Sarcoidosis is an inflammatory disease characterized by non-necrotizing granulomatous inflammation that can affect any organ. Approximately 5% of patients with sarcoidosis develop clinically significant cardiac sarcoidosis (CS), but up to one-fourth may have clinically silent cardiac involvement. A definitive diagnosis of CS requires histologic evidence of granulomas in cardiac tissue. Due to the limited sensitivity and infrequent use of cardiac biopsies, the pursuit of a tissue diagnosis is not routinely performed. There is a paucity of data on biopsy-confirmed CS, particularly among Black patients, a population at higher risk for this disease. We aimed to characterize a cohort of Black patients with biopsy-proven CS and describe their clinical features and outcomes.

Table 1: Characteristics of the definite cardiac sarcoidosis in Black patients

Variables	Mean ± SD or number (%)

CS: Cardiac Sarcoidosis, LVEF: Left Ventricular Ejection Fraction, MRI: Magnetic Resonance Imaging, PET: Positron Emission Tomography, SD: Standard Deviation

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We conducted a retrospective study via review of electronic medical records. Patients with CS in our institution's cardiac sarcoidosis database (2014 - 2025) were identified. Black patients with biopsy-proven CS (referred to as definite CS as per the Heart Rhythm Society criteria) were included in our study. We assessed demographic, clinical presentation, diagnostic evaluation, immunosuppression, heart replacement therapies, and outcomes.

Results: Amongst 306 definite or probable CS patients, 17 Black patients had definite CS. The diagnosis was established through histopathology from endomyocardial biopsy (n = 12) or explanted heart tissue (n = 5). Demographic and clinical characteristics are summarized in Table 1. Most patients (94%) had heart failure with reduced ejection fraction, with 71% having severe left ventricular systolic dysfunction (ejection fraction < 30%). In 53% of the patients, CS was the first diagnosis of sarcoidosis. Isolated cardiac sarcoidosis was diagnosed in 18% of the patients. Almost 60% had increased multifocal uptake on PET scans at diagnosis. The median initial dose of prednisone was 40 mg (range: 20–80 mg), and the median duration of treatment was 1 year (range: 0–11 years). Mycophenolate was the most frequently used (41%) steroid-sparing agent for immunosuppression, followed by methotrexate (24%). Adalimumab and infliximab were used as second-line steroid-sparing agents (18%). Seven patients ultimately received heart transplants. Post-transplant immunosuppression typically included prednisone, mycophenolate, and tacrolimus. Over a median duration of seven years, five patients died (three of these had not received any maintenance immunosuppression), one was lost to follow-up, and the rest were clinically stable or in remission. There was no recurrence of CS in any of the patients who received heart transplantation.

Conclusion: To our knowledge, this is the largest descriptive cohort of biopsy-proven CS in Black patients. One-third of the patients in our study were diagnosed with CS after heart transplantation, which highlights the challenge in making a definitive diagnosis. Given the rarity of definite CS, multi-institutional registry study would be useful to characterize disease presentation and diagnosis.

Abstract Number: 1183

Risk of Inflammatory Bowel Disease in Psoriatic Arthritis Patients Treated with IL-17 Inhibitors

Rusudan Tskitishvili[1], Abdallah Hussein[2], Irakli Tskhakaia[3], Nanuka Tsibadze[3], Eric Osgood[2] and Humaira Khan[4], [1]Virtua Health, Camden, NJ, [2]Virtua Health, Camden, [3]Jefferson Health - Einstein, Philadelphia, PA, [4]Virtua Health, Voorhees

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Psoriatic arthritis (PsA) is a chronic, progressive inflammatory arthritis that significantly impairs quality of life and contributes to substantial morbidity. Interleukin-17 (IL-17) plays a central role in PsA pathogenesis. Although anti–IL-17 therapies have shown clinical efficacy in PsA, clinical trials have reported cases of new-onset inflammatory bowel disease (IBD) or exacerbation of pre-existing IBD. Given these concerns, this study aimed to investigate whether treatment with IL-17 inhibitors is associated with a higher risk of IBD in a large real-world cohort of PsA patients, compared with other treatment options.

Methods: This was a retrospective observational analysis utilizing the TriNetX research network, which includes data from over 130 million patients globally. The study population consisted of 11,287 patients with psoriatic arthritis (PsA) treated with IL-17 inhibitors and 51,328 PsA patients receiving other therapies, such as other biologic DMARDs (bDMARDs), conventional synthetic DMARDs (csDMARDs), targeted synthetic DMARDs (tsDMARDs), or NSAIDs. Outcomes were evaluated

K51 – Ulcerative colitis
K52 – Other and unspecified noninfective gastroenteritis and colitis

Appendix 1. Inclusion and Exclusion Criteria, Matching Criteria and Outcomes with Corresponding ICD-10 and RxNorm Codes

both before and after propensity score matching for demographic and clinical factors. The risks of developing Crohn's disease, ulcerative colitis, and other or unspecified noninfective gastroenteritis and colitis were assessed between January 1, 2015, and April 1, 2025 (Appendix 1).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: After propensity score matching, 8 931 patients were included in each group. The overall cohort's mean ± SD age was 51 ± 12.9 years, with 57.586% female and the majority White (75.21%) and not Hispanic or Latino (72.064%). Matching achieved balance across cohorts ($P < 0.05$) (Table 1, Table 2). The IL-17 inhibitor–treated cohort demonstrated a slightly lower risk of developing Crohn's disease compared with the non–IL-17i cohort (Relative risk (RR) 0.723, 95% CI: 0.524 – 0.998, $p = 0.0475$). In contrast, the IL-17i group showed a significantly lower risk of developing ulcerative colitis (RR 0.562, 95% CI: 0.414– 0.763, $p < 0.01$) and other or unspecified noninfective gastroenteritis and colitis (RR 0.761, 95% CI: 0.673– 0.861, $p < 0.01$).

Conclusion: This study suggests that treatment with IL-17 inhibitors in patients with psoriatic arthritis does not appear to increase the risk of developing or exacerbating Crohn's disease. Additionally, IL-17 inhibitors may be associated with a decreased risk of developing ulcerative colitis and other unspecified noninfective gastroenteritis and colitis compared to other treatment options. Further research is warranted to better understand the mechanisms underlying these observations.

Abstract Number: 1184

Does Blocking IL-17 Treat Recalcitrant Uveitis? Explorative Study on the Use of Ixekizumab to Manage Patients with Uveitis

Sergio Schwartzman[1], Stephen Anesi[2], Yasmin Massoudi[2], Monica Schwartzman[3] and Peter Chang[2], [1]Weill Cornell Medical Center, New York Presbyterian Hospital, and Hospital for Special Surgery, New York, NY, [2]MERSI, Waltham, [3]Hospital for Special Surgery/New York Presbyterian Hospital-Weill Cornell Medical Center, New Rochelle, NY

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Non-infectious uveitis can exist as a primary autoimmune disease or can be a manifestation of an underlying systemic illness. Despite the availability of new therapies, there are few medications approved for the management of uveitis. The purpose of this study was to determine the efficacy and safety of Ixekizumab, an IL-17A targeting human monoclonal antibody in patients with recalcitrant non-infectious intermediate, posterior, panuveitis, or chronic steroid-dependent anterior noninfectious uveitis.

Methods: This was a 24-week prospective, open-label, proof-of-concept exploratory study. The study was designed with two treatment arms of Ixekizumab. Both arms were treated at Week 0 with a loading dose of 160mg of Ixekizumab. Subjects in Arm 1 were then treated with biweekly dosing of 80mg SC Ixekizumab. Subjects in Arm 2 were assigned to a regimen of 80mg SC every four weeks. All subjects began an oral steroid taper starting with 60mg of prednisone alongside the loading dose at Week 0.

Primary Endpoint: A four-point composite endpoint was used to evaluate for visual acuity, control of inflammation, tapering of medication therapy and cystoid macular edema, scored .yes/no" (Suhler et. al., 2013). Control of inflammation was defined as either achieving clinical quiescence, referring to anterior chamber cells and flare of 0.5+ or less as well as vitreous haze of 0.5+ or less, or by achieving a greater than two step reduction in both AC cells and flare"

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

.Secondary Endpoints: The NEI VFQ-25 questionnaire was utilized to gain a standardized insight on each patient's subjective visual functioning throughout each timepoint of the trial, with a higher score indicating better function and lesser impact of visual impairment from uveitis on daily life. Intraocular pressure was monitored for changes, as one goal for the use of steroid-sparing immunomodulatory therapy for patients with uveitis is to avoid steroid-induced ocular hypertension

Results: The trial was closed to recruitment prematurely due to an overall lack of clinical response. Only two participants completed the entire duration of the study without being discontinued from Ixekizumab and/or without receiving additional rescue therapy. All other subjects required rescue therapy between Week 8 and Week 20. Additionally, all patients in Arm 2 assigned to a maintenance dose of Ixekizumab dosing every 4 weeks, were reassigned to Arm 1 due to inadequate clinical response to Q 4 week dosing.

Conclusion: In this study, the efficacy of Ixekizumab for the management of recalcitrant uveitis was explored. None of the nine subjects enrolled met the criteria for clinical response, and all but two patients necessitated rescue therapy and/or discontinuation of the investigational treatment. The lack of efficacy resulted in early study termination.

There are a number of potential explanations for the lack of response. The first is that IL-17A may not be the effector cytokine target in the patients studied. This population was clinically heterogeneous both in terms of the uveitis studied and underlying disease. It is possible that the dose of therapy utilized was suboptimal. Lastly, the number of patients may have been insufficient to detect a statistically benefit.

Background/Purpose: Inflammatory lung disease (ILD) in Still's disease (SD) has recently been described. Pulmonary arterial hypertension (PAH), a rare subtype of pulmonary hypertension (PH), is a potentially life-threating complication of SD. It is crucial to differentiate PAH (group 1 PH), characterized by progressive remodeling of small pulmonary arteries, from PH associated with interstitial lung disease (PH-ILD), which falls under group 3 PH and results primarily from parenchymal lung involvement and hypoxic vasoconstriction. Although in the context of SD both mechanisms, PH-ILD and PAH, may be involved, PAH has rarely been reported. This work reports a large cohort of PAH in adults with SD.

Methods: We identified 16 adult SD patients with PAH (PAH+ group, PAH was confirmed by right heart catheterization in all patients) by a call for observations from the CRIIMIDIATE network and a search of the French PH network registry. Patient characteristics and disease evolution were retrospectively compared with those of 111 SD controls without PAH (PAH-) followed in a reference center.

Results: The profile of patients in the PAH+ and PAH- groups differed (**Table**): 100% versus 69.4% female (p=0.006), 75% versus 17.1% Black (p< 0.0001), more active SD both at diagnosis and throughout the disease course, and more likely to present MAS (62.5% vs 14.4%, p< 0.0001), which was recurrent (i.e. ≥ 2 episodes) in most cases (7/10 patients), and exhibit eosinophilia during the disease course (68.7% vs 7.2%, p< 0.0001). Twelve patients in the PAH+ group presented mild radiological parenchymal features on the CT scan (interlobular septal thickening, non-specific ground-glass opacities) that could not explain PH. For the 84/127 patients with genetic typing, the HLA-DRB1*15 allele was more prevalent in

Table 1A. Characteristics of Still's disease patients with and without pulmonary arterial hypertension (PAH) 1In some patients, the disease developed in childhood (systemic juvenile idiopathic arthritis), but symptoms persisted and/or recurred in adulthood. 2The radiological parenchymal involvement was mild in the 12 patients of the PAH+ group: interlobular septal thickening in all cases, ground-glass opacities of non-specific nature in half of the cases (please see main text and figure 1 for details). The radiological parenchymal involvement was mild to moderate on the CT scan for the 3 patients of the PAH- group who had parenchymal involvement (please see supplementary tables 16 and 17 for details). Importantly, no patient in either group presented with pulmonary alveolar proteinosis and endogenous lipoid pneumonia. 3Including one patient with PAH in whom myocarditis developed in the context of major eosinophilia up to 8,000/mm3. 4Among the population with PAH, 7 patients had multiple (≥2) episodes of MAS, and 1 had a refractory episode of MAS over several months associated with uncontrolled PAH that led to death. csDMARDs, conventional synthetic disease-modifying anti-rheumatic drugs–IL, interleukin–IQR, interquartile range–JAK, Janus kinase–MAS, macrophage activation syndrome–PAH, pulmonary arterial hypertension–10N, 10 times above normal

Table 1B (table continued). Characteristics of Still's disease patients with and without pulmonary arterial hypertension (PAH) 5Eosinophilia was defined as absolute eosinophil count ≥ 700/mm3 or eosinophils ≥10% of the total white blood cell count, measured on at least two occasions (Lerman et al, Arthritis Care & Research. 2023). 6Some patients had several lines of treatment. 7Drug reactions to IL-1 and/or IL-6 inhibitors were all confirmed by a dermatologist and/or an allergologist, and included rashes atypical for SD (e.g. nonevanescent, pruritic, urticarial, a fortiori in the presence of blood eosinophilia), or acute reactions (respiratory distress, swelling or Quincke edema during or near the time of medication administration). Two patients in the HTAP+ group met the criteria for DRESS syndrome (RegiSCAR for DRESS ≥ 4) (Kardaun et al, Br J Dermatol. 2013). Local reactions at the injection site were not included in this category, as they are common with subcutaneous biotherapies. csDMARDs, conventional synthetic disease-modifying anti-rheumatic drugs–IL, interleukin–IQR, interquartile range–JAK, Janus kinase–MAS, macrophage activation syndrome–PAH, pulmonary arterial hypertension–10N, 10 times above normal

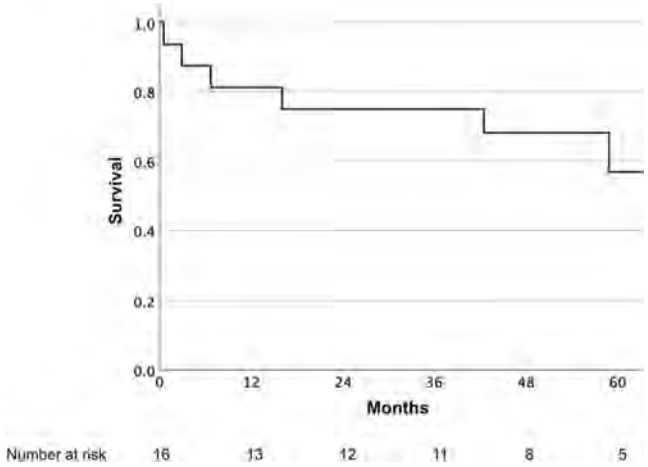

Figure. Overall survival after pulmonary arterial hypertension diagnosis in patients with Still's disease (n=16). Overall survival at 1 and 3 years was 81% and 75%, respectively.

PAH+ than PAH- patients (8/11 [72.7%] vs 22/51 [30.1%], p=0.014). The groups did not differ in treatment, except for methotrexate (81.2% vs 50.4%, p=0.029), canakinumab (50% vs 21.6%, p=0.026) or immunosuppressant agents (56.2% vs 10.8%, p< 0.0001) that were more often used in the PAH+ group, reflecting a more active underlying SD. There was higher frequency of drug reactions to interleukin 1 (IL-1) and/or IL-6 inhibitors in PAH+ than PAH- patients (37.5% vs 7.2%,

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

p=0.002). Mortality was higher in PAH+ than PAH- patients (37.5% vs 0.9%, p< 0.0001), all deaths related to SD flare (**Figure)**.

Conclusion: PAH develops on the same background as other manifestations of SD-related ILD (i.e., in patients with MAS, especially when recurrent; eosinophilia; and carrying the HLA-DRB1*15 allele). Female sex and Black ethnicity seem to be risk factors. This work reinforces the association of the HLA-DRB1*15 allele with severe forms of SD and raises the question of treatment optimizations to better control both SD and its complications. The fact that PAH can be isolated in SD, i.e., it can occur in the absence of major parenchymal involvement, should encourage physicians to screen for it using echocardiography in cases of unexplained dyspnoea, before confirmation by catheterization. The existence of PAH has major therapeutic implications, since it requires the addition of vasodilating agents to targeted and non-targeted immunomodulating therapies.

Increased Adoption of IL-1 Pathway Inhibition and the Steroid-sparing Paradigm Shift: Temporal Trends in Recurrent Pericarditis Treatment From the RESONANCE Patient Registry

Paul Cremer[1], Michael Garshick[2], Sushil Allen Luis[3], Ajit Raisinghani[4], Brittany Weber[5], Vidhya Parameswaran[6], Allison Curtis[6], **Sue Gibbons**[6], Allan Klein[7], John Paolini[6] and RESONANCE Study Group, [1]Cleveland Clinic, Shaker Heights, OH, [2]NYU Langone Health, Tenafly, NJ, [3]Department of Cardiovascular Medicine, Mayo Clinic, Rochester, MN, [4]Division of Cardiology, Department of Medicine, Sulpizio Cardiovascular Center, University of California San Diego, San Diego, CA, [5]Brigham and Women's Hospital, DEDHAM, MA, [6]Kiniksa Pharmaceuticals, LEXINGTON, MA, [7]Cleveland Clinic, Cleveland, OH

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Recurrent pericarditis (RP) is a chronic autoinflammatory disease mediated by IL-1 that requires long-term treatment. While the 2015 European Society of Cardiology Guidelines position IL-1 pathway inhibition only after corticosteroids, complications associated with long-term steroid use underscore the importance of steroid-sparing strategies. Rilonacept, an IL-1a and IL-1b cytokine trap, is the only FDA-approved treatment for RP (available since April 2021). RESONANCE, an ongoing 5-year non-interventional US registry of patients (pts) with RP, has collected real-world data from pts cared for by cardiologists with a focus on pericardial disease, with a goal of informing contemporary RP clinical management.

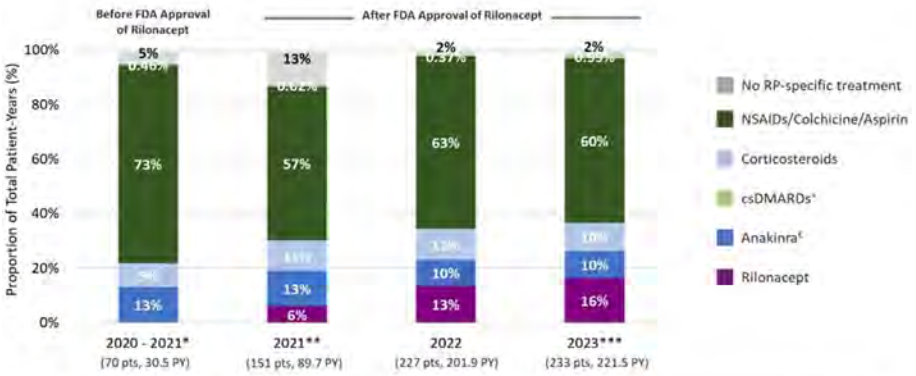
Methods: From a database cut-off (DCO) on 21 December 2023, patient demographics and disease characteristics are reported for 242 active RP pts (excluding RHAPSODY prior participants) at 20 US sites (median [Q1:Q3] 2.1 [1.5:2.6] years and 556 patient-years [PY] of observation). Complete medication class use data were available for 239 pts (total 546 PY). Proportional medication class use prior to initiating rilonacept was analyzed annually across the observation period.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Mean (standard deviation) age at DCO was 50.2 (16.6) years; 58.1% were female. Median [Q1:Q3] disease duration at DCO from index pericarditis episode was 3.1 [2.2:5] years. Median [Q1:Q3] number of prior recurrences at enrollment was 3 [2:5]. Prior to rilonacept availability, NSAIDs/Colchicine/Aspirin represented the highest proportion of treatment (73% of PY); steroid use was 9% of PY, IL-1 pathway inhibition (anakinra) was 13% of PY, and conventional synthetic disease modifying antirheumatic drugs (csDMARDs) were 0.46% PY (no RP-specific treatment was 5% of PY) (**Fig 1**). In the years since rilonacept availability, proportional IL-1 pathway inhibition use has increased, from 13% of PY in 2020-21 to 26% of PY in 2023, driven by an increase in rilonacept use (6%, 13%, 16% of PY in 2021, 2022, and 2023, respectively). Over that same period, proportional NSAIDs/Colchicine/Aspirin use (57%-63% of PY) has been consistently 6-times more than proportional steroid use (10%-11% of PY). Among pts who initiated rilonacept (n=81), similar proportions transitioned from NSAIDs/Colchicine/Aspirin as from corticosteroids (**Fig 2**), a robust trend observed each year. Of those pts transitioning from corticosteroids, 1/3 had used corticosteroids for < 30 days and 1/3 for >6 months.

Conclusion: Real-world data from the RESONANCE registry reveal a temporal shift in RP management in US centers with RP-focused cardiologists, with increased proportional IL-1 pathway inhibition use since rilonacept availability in 2021. Advancing beyond 2015 guideline recommendations, IL-1 pathway inhibition is often being used as steroid-sparing treatment, i.e., after colchicine instead of chronic corticosteroids.

Figure 1. Proportion of Medication Class Use# Over Time (by patient-years)



*Prior to Rilonacept approval; **Partial year after Rilonacept commercial availability April 1, 2021 – Dec 31, 2021; ***Partial year until data cut-off of Dec 21, 2023
#Not mutually exclusive, patients could contribute patient years to multiple medication classes
+Includes azathioprine, methotrexate, hydroxychloroquine/Plaquenil, sulfasalazine
€ 22.2% of patients using anakinra went on to use rilonacept; of those, 40% used anakinra for <30 days.
Total absolute pt counts: Rilonacept (n=81); Anakinra (n=45), Corticosteroids (n=79), NSAIDs/colchicine/aspirin (n=216), csDMARDs (n=8)
csDMARDs: conventional synthetic disease modifying antirheumatic drugs; PY: patient-years; Pts: patients

Figure 2: Proportion of Prior Medication Class Use# 1 Month before initiating Rilonacept (by patient)

*Partial year after Rilonacept approval April 1, 2021 - Dec 31, 2021; **Partial year until data cut-off of Dec 21, 2023
#Patients on multiple medication classes at the same time were bucketed into one medication class by the following hierarchy: Anakinra, csDMARDs, Corticosteroids, NSAIDs/Colchicine/Aspirin, No RP-specific treatment
+Includes azathioprine, methotrexate, hydroxychloroquine/Plaquenil, sulfasalazine
¥31% of pts used corticosteroids for 30 days or less; 34% used corticosteroids for 6 months or more
€40% of pts used anakinra for 30 days or less
csDMARDs: conventional synthetic disease modifying antirheumatic drugs; Pts: patients

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: The associations between various myositis-specific antibodies (MSAs), rapidly progressive interstitial lung disease (RP-ILD), and mortality in antisynthetase syndrome (ASS) have been previously reported in several studies, although limited by small sample sizes. RP-ILD has been recognized as a major risk factor for increased mortality in ASS. This study aimed to systematically assess MSAs and clinical factors associated with RP-ILD and mortality in ASS.

Methods: We conducted a systematic review and meta-analysis of cohorts identified through PubMed, MEDLINE, Embase, and Scopus. Studies enrolling individuals with ASS and evaluating risk factors for RP-ILD and mortality were included from inception to December 2024. The primary outcomes were the incidence of RP-ILD and mortality. Pooled risk ratio (RR) and 95% confidence interval (CI) were calculated using a random-effect, generic inverse variance method of DerSimonian and Laird.

Results: A total of 19 studies comprising 1,971 patients were included, with 17 studies analyzed for mortality and 5 for RP-ILD. Random-effects meta-analysis revealed that factors associated with increased mortality included age over 50 years (risk ratio [RR], 2.86; 95% confidence interval [CI], 1.50–5.43; $I^2 = 0\%$), with a mean difference (MD) of 7.74 years (95% CI, 4.15–11.34), male sex (RR, 1.44; 95% CI, 1.01–2.05; $I^2 = 0\%$), malignancy (RR, 7.59; 95% CI, 3.87–14.30; $I^2 = 0\%$), RP-ILD (RR, 4.90; 95% CI, 1.84–13.08; $I^2 = 0\%$), anti-OJ antibody positivity (RR, 3.03; 95% CI, 2.19–4.18; $I^2 = 0\%$), and anti-PL7 antibody positivity (RR, 1.65; 95% CI, 1.16–2.35; $I^2 = 0\%$). Only anti-Ro52 antibody positivity was associated with an increased risk of RP-ILD (RR, 2.75; 95% CI, 1.18–6.40; $I^2 = 38\%$), with moderate heterogeneity. RP-ILD and mortality were observed in 33.3% and 16.3% of the pooled cohort, respectively.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

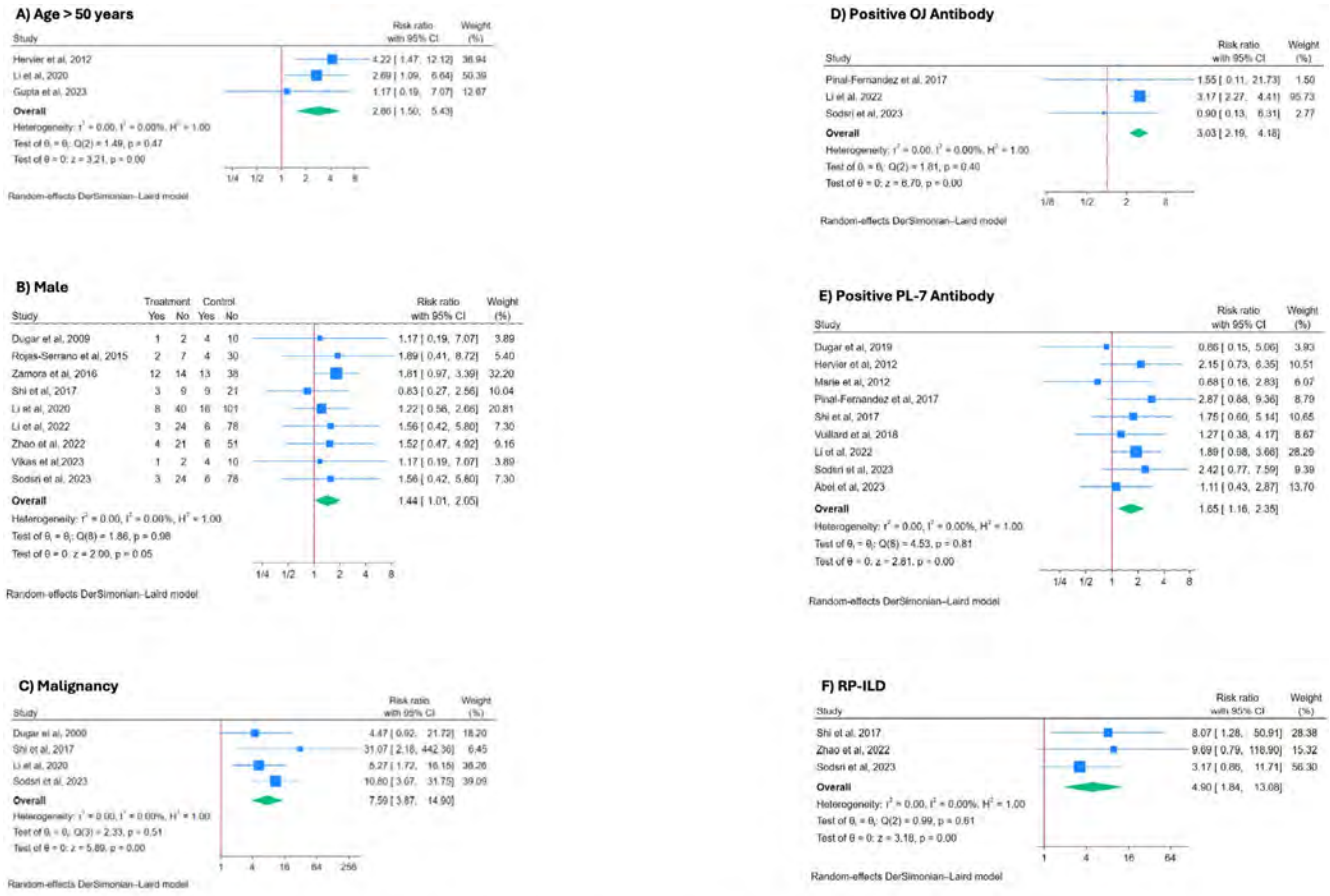

Figure 1: Forest plots of the meta-analysis of the factors affecting mortality risk

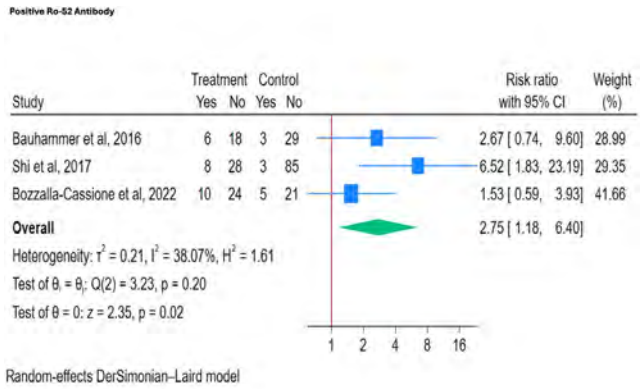

Figure 2: Forest plots of the meta-analysis of the serologies affecting RP-ILD risk

Conclusion: Anti-Ro52 antibody positivity was significantly associated with RP-ILD in ASS. Increased mortality was associated with age over 50 years, male sex, malignancy, RP-ILD, and positivity for anti-OJ and anti-PL7 antibodies. These findings highlight the potential role of MSAs in stratifying disease severity in ASS. However, given the limited number of studies and observed heterogeneity, these results should be interpreted with caution.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Diffuse idiopathic skeletal hyperostosis (DISH) is often characterized by new bone formation along the right anterolateral spinal column, particularly in the thoracic region (1, 2). We aimed to investigate the influence of the anatomical right-sided position of the aorta on the localization of osteoproliferation in patients with DISH.

Methods: Computed tomography (CT) examinations involving the thoracic region, performed between 2014 and 2024, were re-evaluated for DISH by an experienced musculoskeletal radiologist in patients whose reports included the terms "dextrocardia," "situs inversus," or "right aortic arch." Those under 18 years of age, with inadequate imaging, or "with dextrocardia and a left aortic arch" were excluded. Patient sex and age at the time of imaging were recorded. The Resnick and Niwayama criteria were used to identify classical DISH (1), while the Kuperus criteria were applied for early-stage DISH (2).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Of the 214 patients reviewed, a total of 83 patients were included in the final analysis. Imaging modalities included chest CT (n=60), cardiac CT (n=10), thoracic CT angiography (n=6), thoracoabdominal CT (n=4), and spinal CT (n=3). Of the final cohort of 83 patients 60% were male, with a mean age of 33 ± 18 years at the time of CT. Of these, 58 had dextrocardia with a right aortic arch, while 25 had levocardia with a right aortic arch. Changes consistent with DISH were observed in 8 of 83 patients (9.6%) with a right aortic arch. Early DISH findings were detected in seven of these eight patients (87.5%). All osteoproliferative changes were localized to the left side, except in one patient, where they were present on both the upper right thoracic and lower left thoracic regions. Sex distributions were similar between patients with DISH (62.5% male) and those without DISH (60% male), but the mean age at imaging was significantly higher in the DISH group (61 ± 11 years vs. 30 ± 16 years, $p< 0.001$). The age distribution of patients in the DISH group was as follows: one patient (12.5%) was under 50, two patients (25%) were between 50 and 60, four patients (50%) were between 61 and 70, and one patient (12.5%) was between 71 and 80 years of age.

Conclusion: In classic DISH patients with right-sided osteoproliferation, this localization has been shown to be more closely related to the position of the aorta rather than the heart. The inverse relationship between aortic wall stress and DISH localization may serve as a guide for future studies aimed at preventing osteoproliferation development due to repetitive mechanical stress elsewhere.

Period III: Dec 2020–May 2021
Period IV: June 2021–November 2021
Period V: December 2021–01July 2022

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: In this retrospective analysis, patients with SjD (NCT02962895), RA (NCT03574545) and SLE (NCT03656562), who received at least one dose of ianalumab 300 mg or placebo on top of background therapies, between Dec 2019 - Jul 2022, and had anti-spike IgG, and/or anti-nucleocapsid IgG, and/or nucleocapsid antigen were included (Fig 1). Symptomatic SARS-CoV-2 infection was defined by treatment-emergent adverse events (AEs). Patients without reported SARS-CoV-2 AEs but with increased anti-nucleocapsid or nucleocapsid antigen levels were considered asymptomatic. Clinical outcomes included the incidence and severity of SARS-CoV 2–related AEs. Anti-spike IgG titers after exposure to SARS-CoV-2 antigen (virus/vaccine) were evaluated to assess the serological response (Fig 1).

Results: Overall, 123 and 28 patients who received ianalumab and placebo, respectively, were included. Of them, 74 (ianalumab: 72; placebo: 21) had anti-spike IgG, and/or anti-nucleocapsid IgG and/or nucleocapsid antigen data. The crude IRs of SARS-CoV-2 infection (not accounting for the different lengths of observation time/time at risk of SARS-CoV-2 infection) were 31.9% (23/72) and 9.5% (2/21), in the ianalumab and placebo groups, respectively.The observation time-adjusted IRs of SARS-CoV-2 infection were comparable between ianalumab and placebo groups (27 vs. 21 patients/100 patient-year). Most of the infected patients were asymptomatic in the ianalumab (17/23) and placebo (2/2) groups. Symptomatic infections in the ianalumab group (26.1%, 6/23) were mild to moderate in severity, and all patients fully recovered (Fig 2).

Among the patients who received SARS-CoV-2 vaccine during this period and had available post-vaccination anti-spike IgG titer data (ianalumab: 10; placebo: 2), all mounted a serological response. Post-vaccination, anti-spike IgG titers were slightly lower in the ianalumab group during treatment, increasing during the follow up, reaching comparable levels to the placebo group after B cell recovery.

Conclusion: This analysis suggests that ianalumab treatment did not seem to increase the risk of severe SARS-CoV-2 infection in patients with SjD, RA or SLE. Both ianalumab and placebo groups mounted a serological response to SARS-CoV-2 vaccine, which improved during the follow-up even before B-cell recovery. Limitations include small sample size, imbalance in the patient number and observation time, varying risks, geographical regions, SARS-CoV-2 variants and vaccine availability.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: This study aimed to explore the clinical characteristics, treatment, and prognosis of IgG4-related disease (IgG4-RD) patients with comorbid autoimmune diseases (AIDs).

Methods: A total of 879 treatment naïve IgG4-RD patients from Peking Union Medical College Hospital were retrospectively included in this study. IgG4-RD Patients with comorbid autoimmune diseases were classified into the AID-positive (AID-Pos) subgroup, while those without autoimmune diseases were classified into the AID-negative (AID-Neg) subgroup. Additionally, AIDs were classified as systemic or organ-specific. The clinical features, laboratory findings, treatment regimens, and long-term prognosis were compared among the AID-Pos and AID-Neg groups, and the characteristics of AIDs were also explored.

Results: The prevalence rate of AIDs in IgG4-RD patients was 9.67% (85/879), including 47 cases of systemic AIDs and 38 cases of organ-specific AIDs. The types of comorbid AIDs were diverse, such as vitiligo (15 patients), systemic vasculitis (12 patients), psoriasis (12 patients), Hashimoto's thyroiditis (11 patients), and rheumatoid arthritis (10 patients). Most AIDs

PSO: Psoriasis; HT, Hashimoto's thyroiditis; RA, Rheumatoid arthritis; PBC, Primary biliary cirrhosis; T1DM, Type 1 Diabetes Mellitus; UCTD, Undifferentiated connective tissue disease; SpA, Spondyloarthritis; pSS, Primary Sjögren's syndrome; ARF, Acute rheumatic fever; AIHA, Autoimmune hemolytic anemia; APS, Antiphospholipid syndrome; GBS, Guillain-Barré syndrome; GD, Graves' disease; NMOSD, Neuromyelitis optica spectrum disorders; PP, Palmoplantar pustulosis; PMR, Polymyalgia rheumatica; UC, Ulcerative colitis.

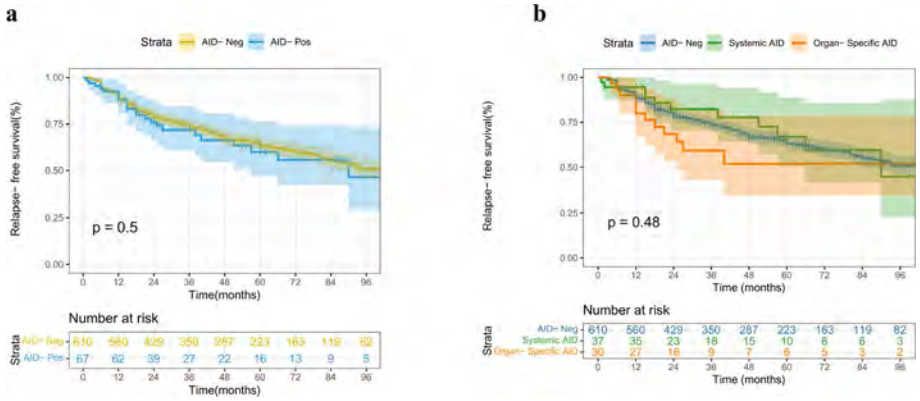

Figure 3 The prognoses of IgG4-RD patients with or without AIDs during follow-up. (a) IgG4-RD patients in AID-Pos group or AID-Neg group; (b) IgG4-RD patients in systemic AID group, Organ-Specific AID group or AID-Neg group.

occurred before or simultaneously with IgG4-RD. Among AID-Pos subgroup patients, 75 (88.2%) had only one type of AID. AID-Pos subgroup patients had lower serum IgG4 levels than AID-Neg subgroup patients (6017 [2729;13900] vs 9176 [3956;18100], p=0.004). Compared with AID-Neg subgroup patients, those with systemic AIDs had higher level of

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

erythrocyte sedimentation rate (40 [22.5; 74.] vs 18.0 [10.0;52.0] mm/hr, adjusted p < 0.001) and higher serum IgG1 level (11500 [8355;13575] vs 8700 [7215;11000] mg/L, adjusted p=0.002). There was no significant difference in treatment regimens and long-term prognosis between AID-Pos and AID-Neg subgroup patients.

Conclusion: IgG4-RD patients can complicate with other AIDs. Compared with AID-neg subgroup patients, IgG4-RD patients with comorbid AIDs have lower serum IgG4 levels, while the clinical characteristics, treatment, and prognosis were similar between two subgroups.

Abstract Number: 1191

Effect of ER Stress Inhibition With 4-Phenylbutyric Acid on Disease Phenotype in a Mouse Model of Myositis

Alfredo Guzman, Elizabeth Bagley, Rita Spathis, Madison King, Kanneboyina Nagaraju and Melissa Morales, Binghamton University, Johnson City, NY

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1191–1220) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Dysregulation of the ER stress and interferon (IFN) pathways play a major role in the pathophysiology of autoimmune myositis. Upregulation of ER stress markers and type 1 IFN stimulated genes (an IFN 'signature') are present in myositis patients, and this IFN signature is related to disease activity. While the role of IFNα/β in myositis has been extensively studied, including clinical trials aimed at inhibiting type 1 IFN expression, the ER stress pathway—characterized by the accumulation of misfolded proteins and the activation of the unfolded protein response (UPR)—remains less explored. Therefore, we investigated the therapeutic efficacy of the ER stress inhibitor, 4-phenylbutyric acid (4PBA) in a myositis mouse model.

Methods: Myositis was induced in 21-day old female mice by removal of doxycycline from their water. Mice were randomized into 4 groups (n=10-17/group); Healthy controls (C57BL/6), myositis no treatment, myositis + 150 mg/kg 4PBA, and myositis + 300 mg/kg 4PBA. 4PBA was administered daily as a cherry syrup oral suspension at 150 mg/kg and 300 mg/kg body weight respectively for seven weeks. Treatment groups were evaluated based on survival time, body weight, muscle strength and function, and expression levels of ER stress markers CHOP, GADD34, Grp78, and Xbp1, and type 1 IFN stimulated genes (ISG) Ifit1, Irf7, Isg15, and Mx1.

Results: Untreated myositis mice had significantly reduced weight gain, muscle function and strength compared to BL/6 mice. 150 mg/kg 4PBA treatment resulted in an improvement in survival of myositis mice, with 76% surviving to the end of study compared to 59% and 63% for the untreated myositis and 300 mg/kg 4PBA treatment groups, respectively. Expression levels of the ER stress markers CHOP, GADD34, Grp78, and Xbp1, and type 1 IFN score, which were significantly elevated in untreated myositis mice, were noticeably decreased in skeletal muscle of 150 mg/kg 4PBA treated mice. However, significant increases in CHOP (p = 0.023) expression were observed in the higher dose treatment group compared to the untreated myositis group. Neither dose significantly improved muscle function.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Overall, we observed that treatment with 150 mg/kg 4PBA improved survival and showed a trend to lowering the ER stress and IFN signature, but this did not translate to functional improvement. Furthermore, 300 mg/kg did not improve any of the measures tested but instead increased the signature of selected markers. While the exact mechanisms for this dose-dependent effect are unknown, higher doses may lead to toxicity or off-target effects.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1191–1220) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Although herpes zoster vaccination has been evaluated in immunocompromised populations, studies assessing vaccine immunogenicity and safety in idiopathic inflammatory myopathies (IIM) are restricted to H1N1 and SARS-CoV-2 and no data are available for the recombinant zoster vaccine (RZV). Thus, the objectives are to compare immune response of RZV in IIM patients and healthy control group (CG), and evaluate the vaccine safety profile, the influence on IIM disease activity and factors associated with vaccine responsiveness.

Methods: This prospective, randomized, placebo-controlled study included 70 immunosuppressed IIM patients (>18y) and 280 healthy controls (≥50y), all receiving two RZV doses (6 weeks apart). IIM patients were randomized 1:1 to receive vaccine (P1) or placebo (P2), with P2 subsequently vaccinated after unblinding at D84. Serum anti-glycoprotein E (anti-gE) antibody levels were measured by in-house GSK ELISA at baseline and 6 weeks post-second dose. Humoral response was defined as an anti-gE concentration ≥4-fold the pre-vaccination level. Geometric mean titers (GMTs) and Factor Increase (FI), as the ratio of post-vaccination to pre-vaccination titers were calculated. Adverse events were recorded using a standardized questionnaire. Disease activity was evaluated at baseline and 6 weeks after each RZV and placebo doses through clinical scores [Myositis Disease Activity Assessment Visual Analogue (MYOACT), Manual Muscle Test (MMT), Health Assessment Questionnaire (HAQ) and Modified Medical Research Council (mMRC) Dyspnea Scale] and serum muscle enzymes (ALT, AST, LDH, CK).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1 - Humoral response rates after 12 weeks and anti-gE IgG titers before (D0) and after two doses of recombinant zoster vaccination in overall IIM patients and Control group

	Humoral response	Geometric mean titer (GMT)			Factor increase in GMT
	D84	D0	D84	p (D0 vs D84)	D0 to D84
IIM (P1 +P2), n=86	52 (78.8)	0.27 (0.2-0.4)	5.1 (3.43-7.47)	<0.001	18.5 (11.7-29.1)
CG, n=280	278 (99.3)	0.22 (0.2-0.3)	11.8 (10.9-12.8)	<0.001	53.0 (45.8-61.3)
p (IIM vs CG)	<0.001	0.269	<0.001	-	<0.001

IIM - idiopathic inflammatory myopathies; CG – control group GMT – Geometric mean titers (AU/mL); Frequencies of humoral response are presented as number (%) and they were compared using two-sided chi-square test between ARD and CG at D84. Ig-gE IgG titers and factor increase in GMT are expressed as geometric means with 95% confidence interval (95%CI). Data regarding anti-gE titers were analyzed using ANOVA with repeated measures and 2 factors [2 groups (ARD vs. CG), at 2 time points (D0 and D84)], followed by Bonferroni's multiple comparisons at neperian logarithm (ln)-transformed data. GMT and factor increase in GMT were compared using Mann-Whitney test for intergroup comparisons in ln-transformed data at pre-specified time points (D0 and D84). All analyses were two-sided. P1 – IIM patients who received the RZV on the day of randomization (D0) and after 6 weeks (D42) P2 – IIM patients who initially received placebo and were vaccinated 12 weeks after randomization, on D84 and after 6 weeks (D126)

MYOACT-Myositis Disease Activity Assessment Visual Analogue, pPGA Patient global assessment, phPGA- Physician Global Assessment MMT-Manual Muscle Test, HAQ- Health Assessment Questionnaire, mMRC Modified Medical Research Council (mMRC) Dyspnea Scale Results are expressed in medians (interquartile range) and n (%). Continuous data were compared using Mann-Whitney test, and categorical variables with the chi-square or Fisher's exact tests, as appropriate, always as two-sided analyses. P1 – IIM patients who received the RZV on the day of randomization (D0) and after 6 weeks (D42) P2 - IIM patients who initially received placebo and were vaccinated 12 weeks after randomization, on D84 and after 6 weeks (D126)

Results: Seventy IIM patients (54 dermatomyositis, 16 antisynthetase syndrome) and 280 individuals in control group (CG) were analyzed. Groups were balanced for sex (p >0.05), although IIM were slightly younger (54 vs. 55y; p=0.022). At D84, the humoral response rate was significantly lower in IIM compared to CG (78.8% vs. 99.3%, p< 0.001%). IIM patients exhibited markedly lower post-vaccine GMT (5.1 vs 11.8 mUI/mL, p< 0.001) and factor increase (FI) (18.5 vs. 53.0, p< 0.001) (Table 1). A trend toward reduced response with mycophenolate mofetil (MMF) was observed (30.8% vs. 57.1%, p=0.069) but not confirmed in multivariate analysis. Adverse events were less frequent in IIM vs CG (71.4 vs 88.9%, p=0.001), including local (65.7 vs. 83.9%, p< 0.001) and systemic reactions (38.6 vs. 61.4%, p=0.001). Disease activity

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

metrics were comparable between groups (p >0.05), [patients VAS (p=0.308), physicians VAS (p=0,285, MMT (p=0.711), MYOACT (0,510), CPK (p=0,403) and DHL (p=0.065) (Table 2).

Conclusion: In immunosuppressed IIM patients, RZV showed good short-term immunogenicity and safety, with no disease worsening. However, reduced post-vaccination antibody titers suggest a potential risk for diminished long-term protection, highlighting the need for continued monitoring. (ClinicalTrials NCT05879419).

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1191–1220) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Interstitial lung disease (ILD) is a frequent complication of idiopathic inflammatory myositis (IIM) and systemic sclerosis (SSc), ranging from subclinical ILD to rapidly progressive respiratory failure. Despite advancing immunosuppressive and antifibrotic therapies, many progress to end-stage respiratory failure and may require lung transplantation. Unlike idiopathic pulmonary fibrosis (IPF), data on lung transplant outcomes for IIM and SSc patients remain limited. The aim of this study was to compare clinical characteristics and lung transplant outcomes in patients with IIM and SSc to IPF.

Methods: We retrospectively analyzed clinical data collected in patients with ILD diagnosed with IIM, SSc, and IPF who underwent bilateral lung transplant between January 1, 2014 and April 30, 2024 at the Vancouver General Hospital, and between January 1, 2012 and December 31, 2024 at the Centre hospitalier de l'Université de Montréal. All IIM and SSc patients satisfied their respective ACR classification criteria.

* Continuous variables were analyzed using the Kruskal-Wallis test, followed by post-hoc pairwise comparisons with Dunn's test for significant results. Categorical variables were assessed using the Chi-squared test, with pairwise comparisons conducted using Fisher's Exact test and Bonferroni correction for significant results

**Does not include corticosteroids, intravenous immunoglobulin and hydroxychloroquine

Univariate analyses were performed for continuous and categorical data. Survival was assessed with Kaplan-Meier analysis, and incidence of chronic lung allograft dysfunction (CLAD) and malignancy were assessed with Poisson regression.

Results: We included 18 IIM, 24 SSc, and 64 IPF patients. Among IIM patients, 50% were anti-melanoma differentiation-associated protein 5 (MDA5) positive, 39% had anti-synthetase syndrome, and 50% had anti-Ro52. Among SSc patients, anti-Scl-70 was found in 33%, anti-centromere in 4.2%, and anti-RNA polymerase III in 4.2%. Patients with IIM and SSc were younger at the time of ILD diagnosis and lung transplantation, more likely to be female, less likely to have a smoking history, and had fewer comorbidities than IPF patients (Table 1). SSc patients had significantly lower diffusing capacity for carbon monoxide (DLCO) and longer ILD duration before transplant than IIM and IPF patients (Table 1).

Usual interstitial pneumonia (UIP) was predominant in IPF explant pathology, and nonspecific interstitial pneumonia (NSIP) was predominant in IIM and SSc (Table 2).

IIM patients had higher rates of urgent transplant, intensive care unit (ICU) admission, and prolonged post-transplant ICU/hospital stays (Table 2). At 1-year follow-up, forced vital capacity (FVC) was significantly lower in IIM and SSc patients compared to IPF. SSc patients had a significantly higher rate of non-pulmonary infections requiring hospitalization. Over long-term follow-up, all groups shared comparable post-transplant survival (Figure 1), rejection, pulmonary infection, and malignancy rates.

* Continuous variables were analyzed using the Kruskal-Wallis test, followed by post-hoc pairwise comparisons with Dunn's test for significant results. Categorical variables were assessed using the Chi-squared test, with pairwise comparisons conducted using Fisher's Exact test and Bonferroni correction for significant results
** Analyzed with Kaplan Meier survival analysis
*** Analyzed with Poisson incidence analysis

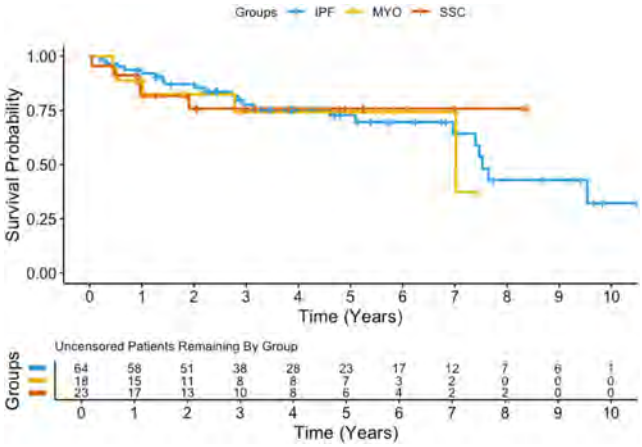

Figure 1. Kaplan Meier survival curve for IIM, SSc and IPF patients.

Conclusion: This study is the first to compare short- and long-term lung transplant outcomes from a combined cohort of IIM, SSc, and IPF patients. IIM patients required more urgent transplants and prolonged ICU stays, and SSc patients experienced higher rates of non-pulmonary infections. However, long-term post-transplant survival and complication rates were comparable across all groups. These findings suggest that lung transplantation remains a viable option for carefully selected IIM and SSc patients with advanced ILD, despite their distinct clinical challenges.

Risk of Calcinosis with Proton Pump Inhibitor Use in Adult Dermatomyositis and Systemic Sclerosis

Antonia Valenzuela[1], Nicolás González[2], José Rojas[3], Martin Fuentes[3], Srijana Davuluri[4], Brian Lee[5], David Fiorentino[6] and Lorinda Chung[4], [1]Pontificia Universidad Catolica de Chile, Santiago, Chile, [2]Pontificia Universidad Católica de Chile, Santiago de Chile, Chile, [3]Pontificia Universidad Católica de Chile, Santiago de Chile, Chile, [4]Stanford University, Stanford, CA, [5]Stanford University, Stanford, [6]Department of Dermatology, Stanford University Medical Center, Stanford, CA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1191–1220) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Calcinosis is a painful, debilitating manifestation in connective tissue diseases. Recent findings suggest a link between proton pump inhibitor (PPI) use and calcinosis in systemic sclerosis (SSc), but this association has not been studied in dermatomyositis (DM). This study aims to evaluate the relationship between PPI use and the presence of calcinosis in patients with DM and to confirm this association in SSc.

Methods: We conducted a retrospective, cross-sectional study using DM and SSc cohorts from Pontificia Universidad Católica de Chile. Adults meeting ACR/EULAR criteria for DM or SSc were included. Clinical data, PPI exposure, and presence of calcinosis was extracted from electronic medical records. PPI exposure score was calculated as described by Host et al.(1) as total duration of use in years multiplied by total daily PPI equivalent dose. Logistic regression was used to assess the association between PPI use and calcinosis, adjusting for clinical variables that were significant in univariate analysis as well as potential confounders.

Results: A total of 107 patients with SSc and 83 with DM were included. Calcinosis was present in 23 SSc patients (21.5%) and 18 DM patients (21.7%). Among SSc patients, those with calcinosis had significantly longer median disease duration from both Raynaud's phenomenon (RP) onset (12 vs. 3 years) and first non-RP symptoms (5 vs. 2.5 years), higher prevalence of digital ulcers (52.2% vs. 22.6%, p=0.0151), more frequent gastroesophageal reflux disease (GERD) symptoms (86.9% vs. 57.1%), greater PPI use (95% vs. 72.6%, p=0.02), and a markedly higher median PPI exposure score (4580 vs. 293, p< 0.0001). In DM, patients with calcinosis had a higher frequency of ulcers (27.8% vs. 1.54%, p=0.0003), but no significant differences in PPI use, although a numeric trend toward longer PPI exposure was noted (3.7 vs. 0.1 years, p=0.08). In multivariate analysis of the SSc cohort, adjusting for disease duration from first RP, longer disease duration (OR 1.11, 95% CI 1.04–1.19, p=0.0013), PPI use for 5–10 years (OR 7.41, 95% CI 1.2–45.6, p=0.03), and PPI use for more than 10 years (OR 16.4, 95% CI 2.5–107.7, p=0.0036) were significantly associated with calcinosis. In contrast, PPI use for less than 5 years was not associated with calcinosis.

Conclusion: Prolonged PPI use was significantly associated with calcinosis in patients with SSc, confirming its role as a potentially modifiable risk factor. No significant association was found in DM, although a trend toward longer PPI use in those with calcinosis warrants further study. These findings raise important questions about the long-term safety of PPI therapy in

Abstract Number: 1195

Discordance between Immunoblot and ELISA in the detection of Jo-1 and Ro/Ro-52 Autoantibodies

Antonia Valenzuela[1], Sebastián Andrés Cerda Acevedo[2] and Francisco Vera Gutiérrez[2], [1]Pontificia Universidad Catolica de Chile, Santiago, Chile, [2]Pontificia Universidad Católica de Chile, Santiago de Chile, Chile

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1191–1220) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Autoantibodies play a key role in the diagnosis, classification, and prognosis of idiopathic inflammatory myopathies (IIM). Among the most relevant are myositis-specific antibodies (MSAs), such as anti-Jo-1, and myositis-associated antibodies (MAAs), such as anti-Ro/Ro-52. Accurate serological detection using techniques such as Enzyme-Linked Immunosorbent Assay (ELISA) or immunoblot, is essential. However, in clinical practice, discordance between these methods is frequently observed. We aim to evaluate the discordance between ELISA and immunoblot in detecting Jo-1 and Ro/Ro-52 autoantibodies, and the clinical relevance of discordant results in a real-world cohort.

Methods: A retrospective, cross-sectional study was conducted on patients from a tertiary health center (Red de Salud UC Christus), who underwent testing for antinuclear antibodies (ANA), nuclear extractable antigen (ENA), and a myositis autoantibody panel within a +/-1 year interval, from March 2020 to March 2021 and had at least one clinic visit. ANA was detected using indirect immunofluorescence on HEp-2 cells, ENA by ELISA, and the myositis autoantibody panel by a 16-antigen line immunoassay/immunoblot. Demographic, clinical, and laboratory variables were collected through review of electronic medical records.

Results: A total of 112 patients met the inclusion criteria. 69 (61.6%) were female, with a mean age of 54.4 (±17.3) years. ANA was positive in 63 patients (53.4%), with the most frequent titer being 1/80 dilution, with AC-4,5 pattern (n=27, 23%). Jo-1 autoantibodies were detected exclusively by ELISA in 4 patients, exclusively by immunoblot in 5, and by both methods in 3. Ro/Ro-52 autoantibodies were positive exclusively by ELISA in 4 patients, exclusively by immunoblot in 14, and by both in 1. The discordance rate between ELISA and immunoblot was 8% for Jo-1 and 17% for Ro/Ro-52. Among the 3 patients with concordant Jo-1 positivity on both tests, all had dermatomyositis (DM)—two met definite and one met possible ACR/EULAR classification criteria. Of the 4 patients with positive Jo-1 on ELISA but negative on immunoblot, only one had DM; the remaining three had no autoimmune disease. In contrast, all patients who were Jo-1 negative on ELISA but

Clinical diagnoses and classification criteria according to Jo-1 and Ro/Ro-52 antibody result concordance and discordance between ELISA and immunoblot.

positive on immunoblot had confirmed autoimmune conditions (Table 1). The one patient who had Ro positivity on ELISA and Ro-52 positivity on immunoblot was ultimately diagnosed with thyroid cancer. Finally, no correlation was observed between ANA patterns (nuclear or cytoplasmic) and specific autoantibodies identified by the other methods.

Conclusion: Our findings highlight a significant rate of discordance between ELISA and immunoblot in the detection of autoantibodies, particularly for Ro/Ro-52. Notably, immunoblot-identified Jo-1 positivity alone was more consistently associated with confirmed autoimmune diagnoses than ELISA alone. These results underscore the importance of using complementary serological methods in the diagnostic workup of suspected IIM, and caution against relying solely on a single testing modality.

Session Title: (1191–1220) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Table 1. Health-related outcomes, satisfaction, and health care utilization of FORWARD participants with IIM with and without chronic opioid use.

Characteristics	Participants without chronic opioid use (n=109)	Participants with chronic opioid use (n=43)	p value
Fatigue (0-10)	4.1 ± 3.3	5.6 ± 3.1	**0.01**
Pain (0-10)	2.8 ± 2.6	6.1 ± 2.7	**<0.001**
Patient global disease activity (0-10)	3.2 ± 2.2	4.9 ± 2.8	**<0.001**
HAQ-II (0-3)	0.9 ± 0.7	1.2 ± 0.7	**0.007**
SF-36 Physical component summary (0-100)	39.4 ± 10.9	31.2 ± 9.2	**<0.001**
SF-36 Mental component summary (0-100)	50.6 ± 10.6	45.5 ± 14.8	0.07
Health satisfaction (0-4)	2.1 ± 0.1	1.7 ± 0.2	0.06
Rheumatologist visits (>2) *	36 (39.1%)	14 (40%)	1.0
ER visits (≥1) *	16 (34%)	12 (50%)	0.2
General practitioner visits (>2) *	10 (11.8%)	7 (21.2%)	0.2

Abbreviations: HAQ-II, Health Assessment Questionnaire-II; SF-36, 36-Item Short Form Health Survey; VAS, Visual Analogue Scale
** In the last 6 months*

Table 2. Factors associated with chronic opioid use among individuals with IIM on univariable and multivariable logistic regression models.

Variables	Univariable logistic regression model		Multivariable logistic regression model	
	OR (95% CI)	p value	OR (95% CI)	p value
Age	0.99 (0.96 – 1.01)	0.4	1.01 (0.97 – 1.06)	0.5
Female (%)	1.01 (0.42 – 2.40)	1.0	1.20 (0.29 – 5.03)	0.8
Non-White race (%)	4.98 (1.85 – 13.40)	**0.001**	4.71 (0.96 – 23.25)	0.06
Ever smoker (%)	4.31 (2.01 – 9.23)	**<0.001**	4.16 (1.41 – 12.25)	**0.01**
Body mass index	1.04 (0.98 – 1.10)	1.9		
Education level (years)	0.86 (0.72 – 1.03)	0.1		
Total annual income ($)	0.99 (0.99 – 0.99)	**0.01**	0.99 (0.99 – 1.00)	0.2
Symptom duration (years)	1.03 (0.98 – 1.10)	0.2		
Dermatomyositis	0.62 (0.28 – 1.35)	0.2		
Polymyositis/IMNM	1.38 (0.66 – 2.87)	0.4		
Rheumatic Disease Comorbidity Index (0-9)	1.39 (1.12 – 1.73)	**0.003**		
Osteoarthritis	1.64 (0.68 – 3.94)	0.3		
Depression	2.34 (1.08 – 5.09)	**0.03**	1.17 (0.31 – 4.45)	0.8
Anxiety	1.27 (0.54 – 2.97)	0.6		
Hypertension	1.26 (0.62 – 2.57)	0.5		
Diabetes mellitus	1.70 (0.61 – 4.72)	0.3		
Myocardial infarction	0.82 (0.16 – 4.24)	0.8		
Cancer	0.84 (0.33 – 2.17)	0.7		
Renal disease	3.27 (1.03 – 10.38)	**0.04**	4.34 (0.79 – 23.92)	0.1
Pulmonary disease	3.78 (1.75 – 8.18)	**0.001**	3.81 (1.25 – 11.60)	**0.02**
GI disease	3.56 (1.65 – 7.68)	**0.001**	1.95 (0.66 – 5.76)	0.2
Cardiac disease	1.40 (0.59 – 3.33)	0.4		
Fibromyalgia	2.83 (1.32 – 6.04)	**0.007**	1.76 (0.53 – 5.80)	0.4

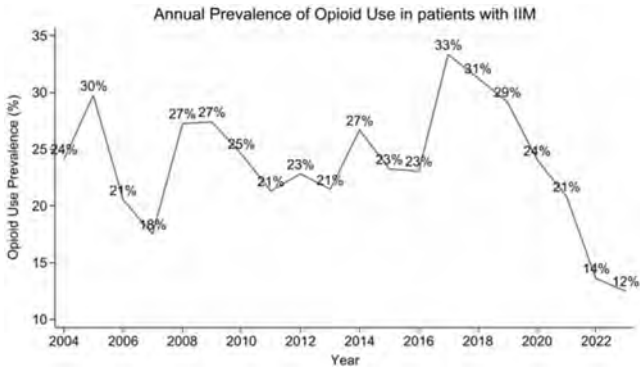

Figure 1. Annual prevalence of opioid use in individuals with IIM (2004 – 2023).

Background/Purpose: Idiopathic inflammatory myopathies (IIM) can be associated with significant pain and functional impairment. While the use of opioids has been documented in other inflammatory disorders, data regarding opioid use in patients with IIM are scarce. Given the risks of long-term opioid therapy, understanding the prevalence and predictors of chronic opioid requirements in this patient population is crucial for developing appropriate pain management strategies.

Methods: We used the FORWARD Databank - a longitudinal prospective registry of adults with rheumatic diseases in the US. Participants included in this study had a physician diagnosis of IIM and completed comprehensive semiannual questionnaires reporting sociodemographic features, pain, fatigue, physical function, disease activity, use of opioids/other medications, and health services at serial visits. Chronic opioid use was defined as documentation of opioid use in participant surveys on ≥2 consecutive study visits, amounting to a cumulative duration of opioid use of ≥ 90 days. Fischer's exact and Student's T tests were used to compare healthcare utilization, satisfaction, and outcomes between participants with and without chronic opioid use. The observation at enrollment was used for non-chronic opioid users while the first-reported opioid use observation was used for chronic opioid users. Logistic regression was used to determine variables associated with chronic opioid use. We calculated the annual prevalence and temporal trends of opioid use among participants with at least 90 days of follow-up defining use as documentation of opioid use at ≥1 visit within a given year between years of 2004-2023.

Results: Out of 210 participants with IIM, 152 (mean age ± SD, 55.4 ± 1.4, 80.5% female, and 85.8% White) with at least 90 days of follow-up were included. The participants were followed for a mean duration of 4.9 ± 0.4 years. A total of 43 participants with IIM (28.3%) were found to have chronic (90+ days) opioid use. Participants with chronic opioid use were more likely to have history of smoking, non-White race, lower annual income, and were more likely to have comorbid depression, fibromyalgia, pulmonary and gastrointestinal disorders, with a higher rheumatic disease comorbidity index. Chronic opioid use was associated with worse fatigue, pain, patient global disease activity, disability, and quality of life (Table 1). On multivariable logistic regression, history of smoking and presence of comorbid pulmonary disease were significantly associated with increased odds of chronic opioid use (Table 2). The prevalence of opioid use was relatively stable at 20% - 33% between 2004 and 2017 with a downward trend between 2017-2023 (Figure 1).

Conclusion: Approximately one in three individuals with IIM are chronic opioid users. Smoking history, comorbid pulmonary disease, and poor health-related outcomes are associated with chronic opioid use among individuals with IIM. Further studies evaluating pain mechanisms and alternate pain management strategies in IIM patients are needed.

Abstract Number: 1197

Genetic Profiling of Idiopathic Inflammatory Myopathies in Indian Patients Reveals Genotype-Phenotype Correlation

Bandana Jassal[1], Aishwarya Dhall[1], Mohammed Faruq[2], Danveer Bhadu[1], Uma Kumar[1] and Mehar Chand Sharma[1], [1]All India Institute of Medical Sciences, New Delhi, New Delhi, Delhi, India, [2]Institute of Genomics and Integrative Biology, New Delhi, Delhi, India

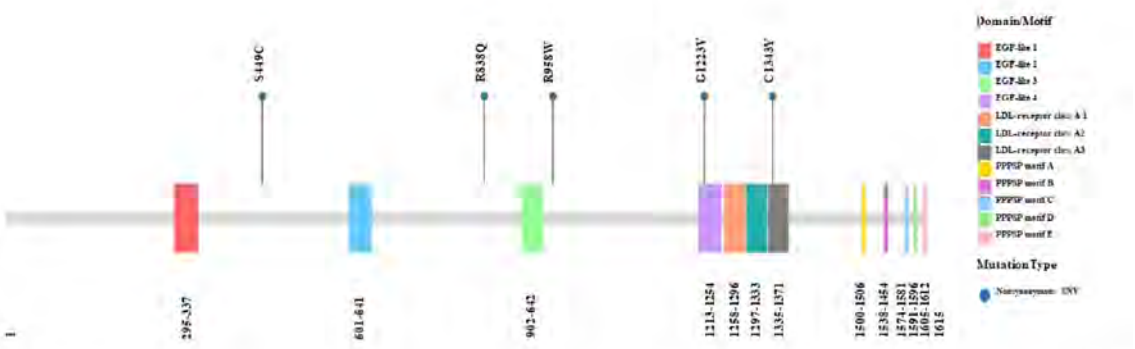
SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1191–1220) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Idiopathic inflammatory myopathies (IIMs) are rare autoimmune muscle disorders with complex genetic underpinnings. Most genetic studies have focused on limited populations. This study explores genetic risk factors in Indian IIM patients, integrating clinical, serological, and histopathological features to enhance understanding of its pathogenesis.

Methods: Genomic DNA was isolated from EDTA blood and libraries were prepared using the SureSelect XT HS2 protocol and sequenced on the Illumina NextSeq 2000 (2×150 bp). Variants were prioritized based on quality, frequency, predicted impact, and pathway relevance then selected variants were validated by Sanger sequencing using custom-designed primers and standard PCR. Frequently mutated genes were assessed for phenotype associations.

Results: A total of 91 prioritized variants were identified across 86 IIM cases, with mutations present in 68.6% (59/86). Of these, 4.4% were classified as pathogenic, 14.3% as likely pathogenic, and 81.3% as variants of uncertain significance (VUS). Most were nonsynonymous SNVs (80.2%), followed by frameshift deletions (5.5%), stopgain mutations (4.4%), and others. Notably, 25.3% were novel variants. Seventeen genes harbored ≥2 variants or at least one pathogenic/likely pathogenic variant, with five genes (*CFTR, COL1A1, HBB, LRP5*, and *WDFY4*) meeting both criteria for further evaluation. Among these, *LRP5* carried five nonsynonymous SNVs across IIM subgroups. Domain mapping revealed key mutations within or

Figure 1. Mapping of *LRP5* variants identified in the IIM Cohort



Schematic representation of the *LRP5* protein (1–1615 amino acids) showing the positions of prioritized variants identified in the IIM cohort.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Comparison of characteristics of IIM Patients With and Without LRP5 Variants: This table presents a univariate comparison between idiopathic inflammatory myopathy (IIM) patients carrying prioritized LRP5 variants (n = 5) and those without such variants (n = 81). Clinical, histopathological, serological, and diagnostic variables are shown as counts with corresponding percentages. Statistical significance was assessed using Fisher's exact test. Results are expressed as p-values with corresponding odds ratios (OR) and 95% confidence intervals (CI) in parentheses.

Variables	Patient with LRP5 variant	Patient without LRP5 variant	pvalue (OR[95%CI])
n(%)	5(5.8)	81(94.2)	NA
Gender, n(%)			
Female	4(80)	47(58)	0.6442 (2.9 [0.3-27.1])

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1191–1220) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Treatment of anti-synthetase syndrome (ASyS) presents clinical challenges: myositis can lead to permanent disability and severe organ involvement is life-threatening.

Methods: We treated three patients with multidrug-resistant severe anti-Jo-1 positive ASyS with blinatumomab 143μg and added rituximab (RTX) 1000mg for maintenance therapy. Patient 1, 67-year-old female, had reoccurring myositis and new interstitial lung disease (ILD). Patient 2, 36-year-old male, suffered from progressive ILD and myocarditis. Patient 3, 47-year-old male, had debilitating myositis. All patients were unresponsive to at least three immunosuppressants including rituximab.

Results: Blinatumomab induced complete depletion of $CD19^+$ B cells in circulation and muscle tissue (Figure 2) and profound decreases in anti-Jo-1 titers. Blinatumomab induced glucocorticoid-free remission with normalization of muscle enzymes, improvement of muscle strength (Figure 1) in all patients.

Patient 1 showed an increase in CD19+ B cells and recurrence of myositis 4 months after blinatumomab. We re-started blinatumomab plus RTX and reinduced clinical remission followed by maintenance therapy with RTX (follow-up six months).

Patient 2 showed ongoing remission of myositis and improvement of ILD for six months after blinatumomab and repeated RTX.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Patient 3 demonstrated ongoing remission for 6 months after blinatumomab and RTX.

Adverse events: cytokine release syndrome (CRS) grade 3 (same day recovery) and respiratory infection in patient 3. No neurotoxicity occurred.

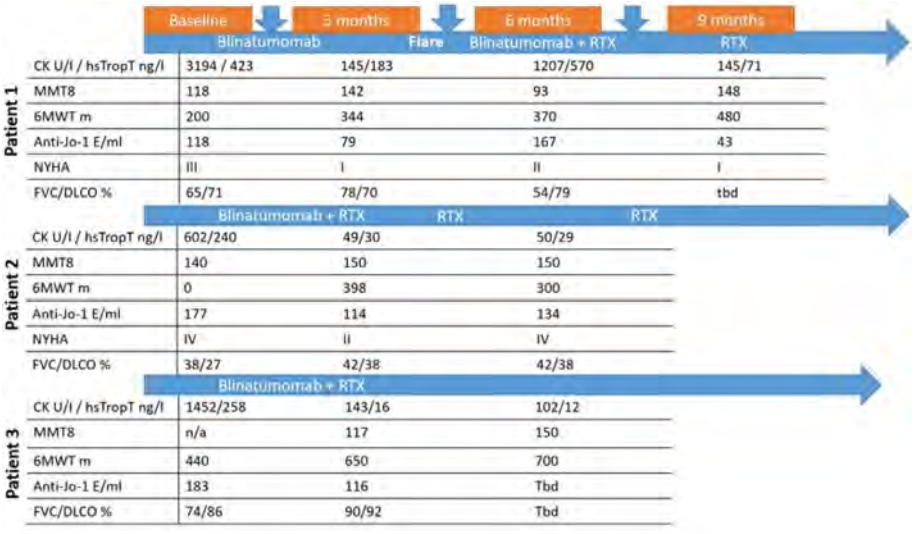

Figure 1: Clinical and serological follow-up including schedule of maintenance treatment

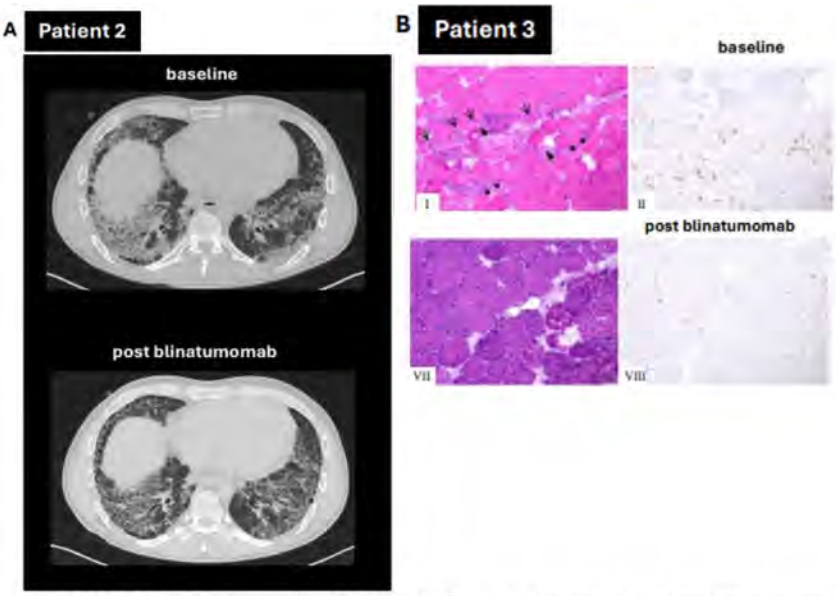

Figure 2: A: Radiologic comparison of ILD in HRCT at baseline (upper) and post blinatumomab. (lower). **B:** Histology of muscle biopsy at baseline I – II and post blinatumomab VII – VIII. **I)** H&E, magnification 200x. Perimysial and endomysial round cell infiltrates (arrows) as well as preferential perifascicular atrophy of muscle fibers (asterisk). In addition, muscle fiber necrosis (arrowhead) and regenerating muscle fibers (dots). **II)** Immunohistochemistry with anti-CD8 and slight counterstaining with hemalum, magnification 200x. Numerous CD8-positive T cells in the perimysial and endomysial infiltrate. **VII)** H&E, magnification 200x. After therapy, there are only minor signs of perifascicular atrophy. Pronounced round cell infiltrates, fiber necrosis or myophagic reactions are no longer present. **VIII)** Immunohistochemistry with anti-CD8 and slight counterstaining with hemalum, magnification 200x. Single CD8-positive T cells in the perimysial and endomysial infiltrate.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: This is the first report on treating patients with severe, treatment-refractory ASyS with blinatumomab. When followed by RTX, glucocorticoid-free remission remained stable for up to 10 months follow-up. Combining blinatumomab with RTX may offer potential in treatment-refractory ASyS patients.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1191–1220) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic autoimmune rheumatic diseases (SARDs) are a major cause of interstitial lung disease (ILD), with high prevalence in inflammatory idiopathic myopathy (IIM), systemic sclerosis (SSc), and rheumatoid arthritis (RA). In clinical practice, ILD assessment relies primarily on high-resolution CT (HRCT), as surgical lung biopsy is infrequently performed in SARDs-ILD. This study aims to evaluate the correlation between radiologic patterns at diagnosis and histopathologic findings in explanted lung tissue from SARDs-ILD patients undergoing lung transplantation.

Methods: Patients with ILD secondary to IIM, SSc, or RA who underwent lung transplantation between January 1, 2014 and April 30, 2024 at Vancouver General Hospital and between January 1, 2012 and December 31, 2024 at the Centre hospitalier de l'Université de Montréal were included. Agreement between HRCT and histologic diagnoses was assessed using kappa (κ) statistics with predefined coefficient weights: complete agreement (same diagnoses, κ=1), partial agreement (overlapping terms, for example, NSIP vs. NSIP/UIP κ=0.5), or no agreement (different terms, κ=0). The HRCT-histopathology relationship was visualized using an Alluvial chart (*Flourish, UK*).

Results: The study included 70 patients (18 IIM, 24 SSc, and 28 RA) (Table 1). RA patients were older at transplant, more likely to have a smoking history, and less likely to be female compared to IIM and SSc. IIM patients were more likely to require emergency lung transplant. At initial presentation, nonspecific interstitial lung disease (NSIP) was the predominant HRCT

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

pattern in IIM (55.6%) and SSc (75%) patients, while usual interstitial lung disease (UIP) was most common in RA (57.1%) (Table 2). On explant pathology, NSIP remained the primary tissue diagnosis in SSc (62.5%), followed by mixed NSIP/UIP (20.8%) and UIP (12.5%). In RA, UIP was the most frequent histopathologic pattern (50%), followed by mixed NSIP/UIP (25%) and NSIP (17.9%) (Table 2). Cohen's κ analysis with custom coefficient weight demonstrated moderate agreement between HRCT and histology for SSc (κ = 0.42, p=0.02) and RA (κ = 0.46, p=0.002). In contrast, IIM showed insignificant correlation (κ = 0.14, p=0.4), with explant pathology distributed across all six diagnostic patterns. Notably, 50% of IIM patients undergoing transplant had anti-MDA5 dermatomyositis with rapidly progressive ILD clinically, and either diffuse alveolar damage (DAD) or unclassifiable end stage fibrosis on explant.

Conclusion: This study demonstrates moderate radiologic-histologic correlation in SSc- and RA-associated ILD. However, IIM-ILD shows significant histopathologic heterogeneity that poorly correlates with HRCT patterns, particularly in anti-MDA5 positive patients who uniformly exhibited rapidly progressive ILD with diffuse alveolar damage. The major limitation of the study is that explant lungs often have extensive damage from chronic disease and infections, obscuring the original histologic pattern. Despite the limitation, these findings highlight the dynamic radiologic and histologic evolution of ILD in IIM-ILD.

Table 1. Baseline patient demographics pre-transplant.

Table 1. Baseline patient demographics pre-transplant.

Variables	IIM (n=18)	SSc (n=24)	RA (n=28)
Demographics			
Age at SARD diagnosis, median [IQR]	46.4 [40.0, 51.0]	46.0 [38.9, 56.4]	52.5 [40.6, 58.9]
Age at ILD Diagnosis, median [IQR]	46.4 [39.6, 51.1]	48.5 [40.2, 55.8]	56.0 [49.2, 60.9]
Age at lung transplant, mean [IQR]	53.4 [48.2, 58.5]	57.2 [47.7, 62.1]	62.5 [54.7, 68.2]

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1191–1220) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Idiopathic Inflammatory Myopathies (IIM) are a group of heterogeneous connective tissue diseases including dermatomyositis (DM), polymyositis (PM), anti-synthetase syndromes (ASS), immune-mediated necrotizing myopathies (NM), and overlap syndromes (OS). These diseases are the most severe connective tissue diseases, with a high mortality rate of 30%. These diseases represent the connective tissue disorders with the highest mortality risk compared to the

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

general population, with reported standardized mortality ratios ranging from 1.56 to 7. No study has evaluated the SMRs for OS and IMNM.

The aim of this study was to evaluate the comparative mortality figure in IIM and its subgroups in a real-life setting.

Methods: A retrospective study was conducted using the MIIRTALITY cohort, including patients followed for IIM from 2010 to 2022. Patients were included if they had more than one year of follow-up or early death, were diagnosed between 2010 and 2020, and met the 2017 EULAR and/or 2019 ENMC classification criteria. They were then categorized into five subgroups: DM, PM, ASS, NM, and OS.

Crude mortality rates were calculated for the study population, and expected mortality rates were obtained from the French National Institute of Statistics and Economic Studies (INSEE). Comparative Mortality Figures (CMFs) were computed as the ratio of observed to expected deaths, adjusting for differences in age structure between the study and reference populations. CMFs were preferred over standardized mortality ratios (SMRs) due to the limited size of the IIM subgroups.

Results: A total of 225 patients were included: 83 with dermatomyositis (DM; 36.9%), 14 with polymyositis (PM; 6.2%), 55 with antisynthetase syndrome (ASS; 24.4%), 24 with immune-mediated necrotizing myopathy (IMNM; 10.7%), and 49 with overlap syndrome (OS; 21.8%). The median age at diagnosis was 59 years [IQR 46–69], with a predominance of female patients (n = 133, 59.1%). The median follow-up duration was 4 years [IQR 2–7]. An associated malignancy was identified in 29 patients (12.8%).

During follow-up, 33 patients died, corresponding to an overall mortality rate of 14.7%. The Comparative Mortality Figure (CMF) for the total IIM cohort was 3.49 (95% CI: 2.25–5.40). CMFs by subgroup were as follows: DM, 5.45 (95% CI: 3.42–8.67); PM, 24.23 (95% CI: 3.89–151.08); ASS, 1.51 (95% CI: 0.48–4.79); IMNM, 1.44 (95% CI: 0.35–5.90); and OS, 2.58 (95% CI: 1.14–5.89).

Conclusion: Patients with DM, PM, and OS demonstrated a significantly increased risk of mortality compared to the general population. No excess mortality was observed in patients with ASS or IMNM.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1191–1220) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Lung involvement is the most frequent and severe extramuscular complication of Idiopathic Inflammatory Myopathy (IIM). The utility of pulmonary function test (PFT) monitoring for predicting long-term outcomes in IIM-associated interstitial lung disease (IIM-ILD) and assessing treatment efficacy in clinical trials remains unclear.

We aimed to evaluate the association between 1-year changes in PFTs and long-term outcomes, including 10-year mortality and lung transplant, in patients with IIM-ILD.

Methods: A prospective cohort of adult IIM-ILD patients was analyzed retrospectively. ILD was defined as per ATS criteria using chest HRCT, and myositis was classified according to either myositis-specific autoantibodies and/or the 2017 EULAR/ACR IIM classification criteria. Baseline was defined as the first rheumatology visit. Inclusion criteria required baseline and follow-up PFTs 6–18 months apart. Changes in forced vital capacity (FVC)% and diffusing capacity (DLCO)% were calculated as annualized values: [ΔFVC or ΔDLCO ÷ interval in months] × 12. Cox regression identified associations between PFT trends and outcomes, adjusting for age, sex, smoking, baseline FVC%, and interval from baseline to the first PFT. Kaplan-Meier analysis compared survival by FVC% trends, HRCT patterns, and IIM subsets.

Table 1. Association of One-Year FVC Change and Baseline DLCO with 10-Year Mortality and Transplant-Free Survival in IIM-ILD. Univariate Cox regression analysis showing that absolute and relative FVC declines ≥5% were significantly associated with increased mortality and adverse outcomes. Baseline DLCO was also a strong predictor of transplant-free survival.

Table 1. Univariate analysis of the association between **FVC** estimated change over a year and baseline **DLCO** and 10-year mortality or pulmonary event-free survival (all-cause death or lung transplant).

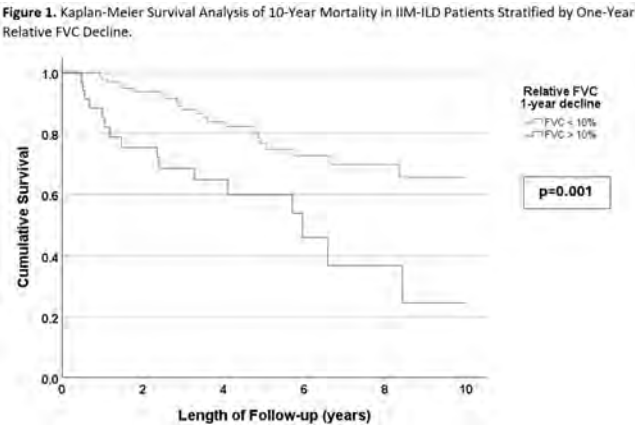

Figure 1. Kaplan-Meier Survival Curves Stratified by One-Year Relative FVC Decline in IIM-ILD. Patients with ≥10% relative FVC decline demonstrated significantly worse 10-year survival.

Results: The study included 149 patients (mean age 50.5 ± 12.9 years, 63% female, 85% White). Based on serology, ASyS was the most frequent IIM subset (73.2%), followed by dermatomyositis (10.7%) and polymyositis (8.7%). Mean baseline FVC was 67.5 ± 19.3%, and DLCO was 54.2 ± 19.4%. The HRCT ILD pattern was nonspecific interstitial pneumonia (NSIP) in 85 (57.0%) patients, usual interstitial pneumonia (UIP) in 31 (20.8%) and organizing pneumonia in 2 (1.4%). After a median follow-up of 4.4 years, 41 (27.5%) had died and 6 (4%) had undergone lung transplant.

Both absolute and relative FVC declines of ≥5% over 1 year were significantly associated with higher mortality (HR 2.03 and 2.01; [p=0.03]) and lower transplant-free survival (HR 1.90 [p=0.048] and 1.87 [p=0.050]). Relative FVC declines ≥10% or ≥15% over 1 year showed even stronger associations with mortality (HR 2.83 [p=0.002] and 2.96 [p=0.002], respectively). Conversely, stable or improved absolute FVC was linked to lower mortality (HR=0.49, p=0.04). Baseline DLCO, but not its subsequent decline, was associated with transplant-free survival (HR 0.96, p< 0.001) (**Table 1**). Multivariate analysis revealed similar results. Survival was significantly worse among patients with relative FVC decline > 5%, > 7.5%, >10%, >12.5%, and > 15% (p< 0.05) (**Figure 1**). No significant differences in survival were observed between ASyS and other IIM subsets, or UIP and other HRCT patterns.

Conclusion: FVC decline, even at a threshold as low as 5%, is a significant predictor of long-term mortality and lung transplant in IIM-ILD. However, the 10% threshold, showing stronger associations with outcomes, should be incorporated as an outcome measure in IIM-ILD clinical trials. Routine PFT monitoring from IIM-ILD provides valuable prognostic information, enabling improved risk stratification and individualized treatment planning.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1191–1220) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Interstitial lung disease (ILD) is a common and severe complication of idiopathic inflammatory myopathies (IIM), adversely impacting clinical outcomes. While the ACR/CHEST guideline recommends ILD screening in IIM patients with specific risk factors (Table 1), validation of these predictors in diverse populations remains limited. This study evaluated the utility of ACR/CHEST risk factors for ILD development in a Hong Kong IIM cohort (MyoHK).

Methods: MyoHK was a multicentre observational cohort that collected longitudinal data from IIM patients from 7 rheumatology centers in Hong Kong. IIM patients with at least 6 months of follow-up data were analyzed after excluding patients with unknown myositis-specific or myositis-associated antibodies (MSA/MAA). Data was reviewed from Jan 2024 to Feb 2025. Demographic, clinical, and serological data at IIM diagnosis were recorded. ILD was confirmed by compatible CT thorax findings or histology. The time between IIM and ILD diagnosis was determined. Multivariable regression was performed to identify the independent predictors of ILD.

Results: A total of 665 patients were analyzed and 503 (75.6%) had at least one clinical or serological risk factor for developing ILD at IIM diagnosis. More than half (53.7%) of IIM patients had ILD and 28.6% had no respiratory symptoms including cough, dyspnoea, or Velcro crackles at onset (Figure 1). There were more female patients in the IIM-ILD group (73.3% vs 63.6%, p=0.007) but there was no difference between mean age at diagnosis (55.6 ± 12.5 vs 56.7 ± 15.8, p=0.35) and median follow-up duration (73 (interquartile range: 27 – 130.5) vs 54 (27 – 131) months, p=0.651). Over 60% of ILD were diagnosed within 6 months of IIM diagnosis but ILD preceded IIM diagnosis in 62 (17.4%) patients.

Table 1. Risk factors for ILD screening in 2023 ACR/CHEST guideline [1]

Clinical Risk factors	Arthritis / Arthralgia, Ulcerative Lesions, Mechanic's hands
Serological Risk factors	Anti-synthetase (Jo-1, PL7, PL12, EJ, OJ, KS, Ha, Zo), anti-MDA5, anti-Ku, anti-Pm/Scl, anti-Ro52 antibody positivity

Presented in absolute number (percentage) unless otherwise specified.			

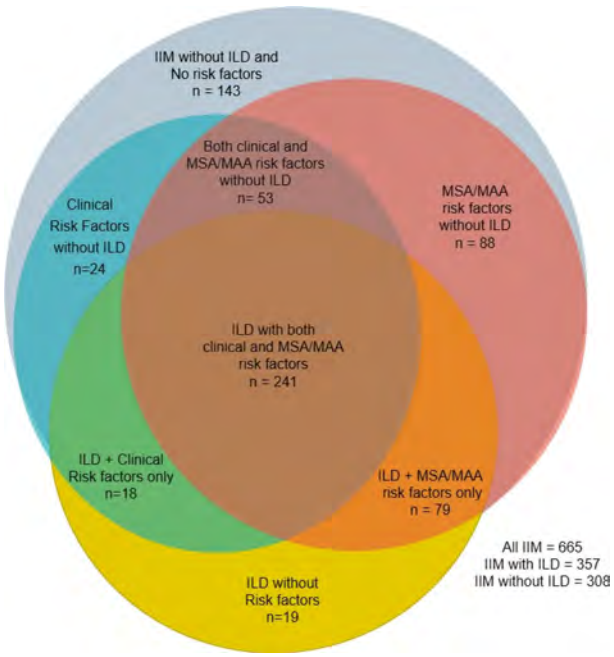

Figure 1. Distribution of clinical and serological risk factors and occurrence of ILD among IIM patients

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Arthritis (57.7% vs 21.8%, p< 0.001), ulcerative lesions (12.9% vs 1.6%, p< 0.001), and mechanic's hands (25.2% vs 4.9%, p< 0.001) were more common in IIM-ILD group (Table 2). Regarding MSA/MAA status, antibodies against MDA5 (28.0% vs 2.9%, p< 0.001), Jo1 (23.8% vs 2.9%), PL7 (11.2% vs 5.2%, p=0.005), EJ (7.3% vs 1.3%, p< 0.001) and Ro52 (62.7% vs 28.9%, p< 0.001) were more frequently identified among ILD patients. Independent risk factors for ILD development in line with the ACR/CHEST guideline included anti-MDA5 positivity (Odds ratio (OR):12.3, 95% CI: 4.8 - 31.0), anti-Jo1 positivity (OR: 6.8, 95% CI: 2.7 – 12.2), anti-EJ positivity (OR: 5.7, 95% CI: 1.37 – 23.6), anti-Ro52 positivity (OR: 2.8, 95% CI: 1.7 – 4.6), mechanic's hands (OR: 2.5, 95% CI: 1.1 – 5.7) and arthritis (OR: 1.8, 95%CI:1.1 – 3.2). Fever (OR: 2.27, 95% CI = 1.5 – 4.9) and Raynaud's phenomenon (OR: 2.1, 95%CI: 1.0 – 4.4) were identified as additional risk factors for ILD development. Only 5.3% of ILD patients lacked guideline-recommended risk factors.

Conclusion: The study validated the risk factors from ACR/CHEST guidelines in IIM patients in Hong Kong. However, the absence of respiratory symptoms or guideline-specified risk factors could not exclude the possibility of ILD, underscoring the need for clinical vigilance.

Rituximab in Treatment Refractory vs Treatment Naive Anti Signal Recognition Particle (SRP) Myositis A Case Series

Israrul Haque[1] and Parasar Ghosh[2], [1]Institute of Postgraduate Medical Education and Research(IPGMER), KOLKATA, India, [2]Dept of Clinical Immunology and Rheumatology, IPGMER & SSKM HospitalGovt of West Bengal, Kolkata, India, Kolkata, West Bengal, India

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1191–1220) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Anti-Signal Recognition Particle (Anti-SRP) Myositis is a form of Polymyositis. Available consensus guidelines recommend initial combination therapy of high dose corticosteroids and Methotrexate and addition of Rituximab (RTX) within 6 months of starting therapy.

Methods:

Objectives:

1. Comparison of non-rituximab vs Rituximab therapy in treatment naïve Anti-SRP Myositis patients.

2. Comparison of Rituximab in Treatment refractory vs Treatment naïve anti-SRP Myositis patients.

Methods: It is a Single centre retrospective study. Patients satisfying EULAR/ACR classification criteria for Idiopathic Inflammatory Myopathy AND anti-SRP antibody in moderate to high titer were defined as cases. Patients with concomitant presence of any other Myositis specific antibody (MSA) in moderate to high titer were excluded. Complete remission (CR) was defined as MMT increase of ≥ 20% *from baseline in Manual Muscle testing* (*MMT* —— 8) AND normalisation of CPK while

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 2: Comparison of Rituximab Therapy in Treatment refractory and Treatment naive anti-SRP myositis patients.

Table 2: Comparison of Rituximab Therapy in Treatment Refractory and Treatment Naïve SRP Myositis Patients

	RTX in Treatment Refractory (N=8)	RTX in Treatment Naive (n=5)	't' value, df	P value
Complete remission (CR)at 6 Months	5/8 (62.5%)	5/5 (100%)	Z value=-1.5612	0.118, NS
Partial remission (PR) at 6 Months	3/8 (32.5%)	0	Z value=-1.5612	0.118, NS
Mean MMT-8 at baseline (SD)	95.25 ± 25.82	90.20 ± 8.07	0.4185, df=11	0.683, NS
Mean MMT-8 at 6 Months after RTX (SD)	114.38 ± 20.21	108.80 ± 14.81	0.5311, df=11	0.605, NS
Mean Change in MMT-8 from baseline at 6 months (SD)	16.13 ± 3.31	18.60 ± 6.84	0.884, df=11	0.395, NS
Mean CPK at baseline (SD), Units/liter	2617.50 ± 2507.67	5405.80 ± 2706.57	1.894, df=11	0.084, NS

partial remission was defined as ≥ 20% *increase in MMT* —— 8 but elevated CPK (>2 times of ULN). Patient with ≥ 20% worsening in MMT from highest value and/or > 3 times increase in CPK from lowest value while on standard of care therapy were defined asrefractory cases.

Results: A total of 13 patients of SRP Myositis were included. Out of 13 cases-8 cases initially received Immunosuppressants other than Rituximab (defined as initial non-rituximab therapy group) while 5 cases initially received Rituximab (defined as initial Rituximab Therapy group). In initial non-rituximab therapy group, 3 received Methotrexate, 2 received monthly Cyclophosphamide therapy for 6 months, 2 received Mycophenolate Mofetil and 1 received Azathioprine. All 8 cases relapsed after Complete or partial remission during follow-up and met the criteria of refractory disease. Refractory patients received Inj. Rituximab 1 gm two doses. In initial Rituximab therapy group cases received Rituximab 1 gm two doses and did not receive any other conventional DMARD (C-DMARDs).

Conclusion:

1. Complete remission (CR) at 6 months is higher in initial rituximab therapy group in treatment naïve anti-SRP Myositis patients. However, both groups showed similar improvement in MMT-8, reduction in CPK, and corticosteroid dose reduction at 6 months after starting therapy.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

2. RTX therapy is equally effective at 6 months in treatment refractory and treatment naïve patients in terms of improvement in MMT and reduction in CPK. Treatment-naïve patients had significantly greater corticosteroid needs throughout the treatment period.

Abstract Number: 1204

Validity and reliability of a new ultrasound-based semiquantitative echogenicity grading scale for myositis.

Takeshi Yoshida[1], Didem Saygin[2] and **Jemima Albayda**[3], [1]Johns Hopkins Hospital, Baltimore, MD, [2]Rush University Medical Center, Chicago, IL, [3]Johns Hopkins University, Baltimore, MD

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1191–1220) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: The Heckmatt grading scale has been widely used as a semiquantitative assessment method for grading muscle echo intensity (EI) on ultrasound; however, this was originally developed for muscular dystrophies in the 1980s. Concerns have been raised regarding poor agreement among assessors and inadequate capture of changes seen with acute myositis. In this study, we test the reliability and construct validity of a new 4-point, semiquantitative grading scale developed for myositis, which defines increases in muscle EI relative to surrounding structures and incorporates changes in muscle architecture that occur with inflammation and damage.

Methods: Ultrasound images of deltoid, biceps brachii, and rectus femoris muscles of myositis patients and controls, obtained from 2015 to 2018 were included in this study. Two experienced raters and one less experienced rater, who had received a two-hour lecture and one training session before the assessment, independently assessed the images. We defined the Hopkins myositis grading scale as follows;

- Grade 1: *Normal - muscle EI equal to or lower than the overlying fat, with clear contrast to perimysial septation and fascia*
- Grade 2: *Mildly Abnormal - muscle EI is slightly increased, may be higher than that of overlying fat layer but lower than that of fascia, but perimysial septations remain well-defined*
- Grade 3: *Moderately Abnormal - muscle EI is high but is still less echogenic than fascia, with loss or blurring of contrast to perimysial septation*
- Grade 4: *Severely Abnormal - muscle EI is very high, equal to or nearly equal to fascia, potentially accompanied by acoustic shadows*

Construct validity was evaluated using Spearman's correlation between each grading system and muscle strength, as well as quantitative muscle EI. Interrater and intrarater reliability were evaluated using Cohen's kappa. Cohen's kappa was interpreted as substantial for 0.60-0.80 and almost perfect for 0.80-1.00.

Results: A total of 349 images from 61 myositis patients (26 inclusion body myositis (IBM) and 35 non-IBM myositis), and 222 images from 37 healthy controls were included. The Hopkins myositis grading scale demonstrated good correlations with both muscle strength and EI, ranging between rho 0.55 - 0.62, better than the Heckmatt scale (Table). In

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

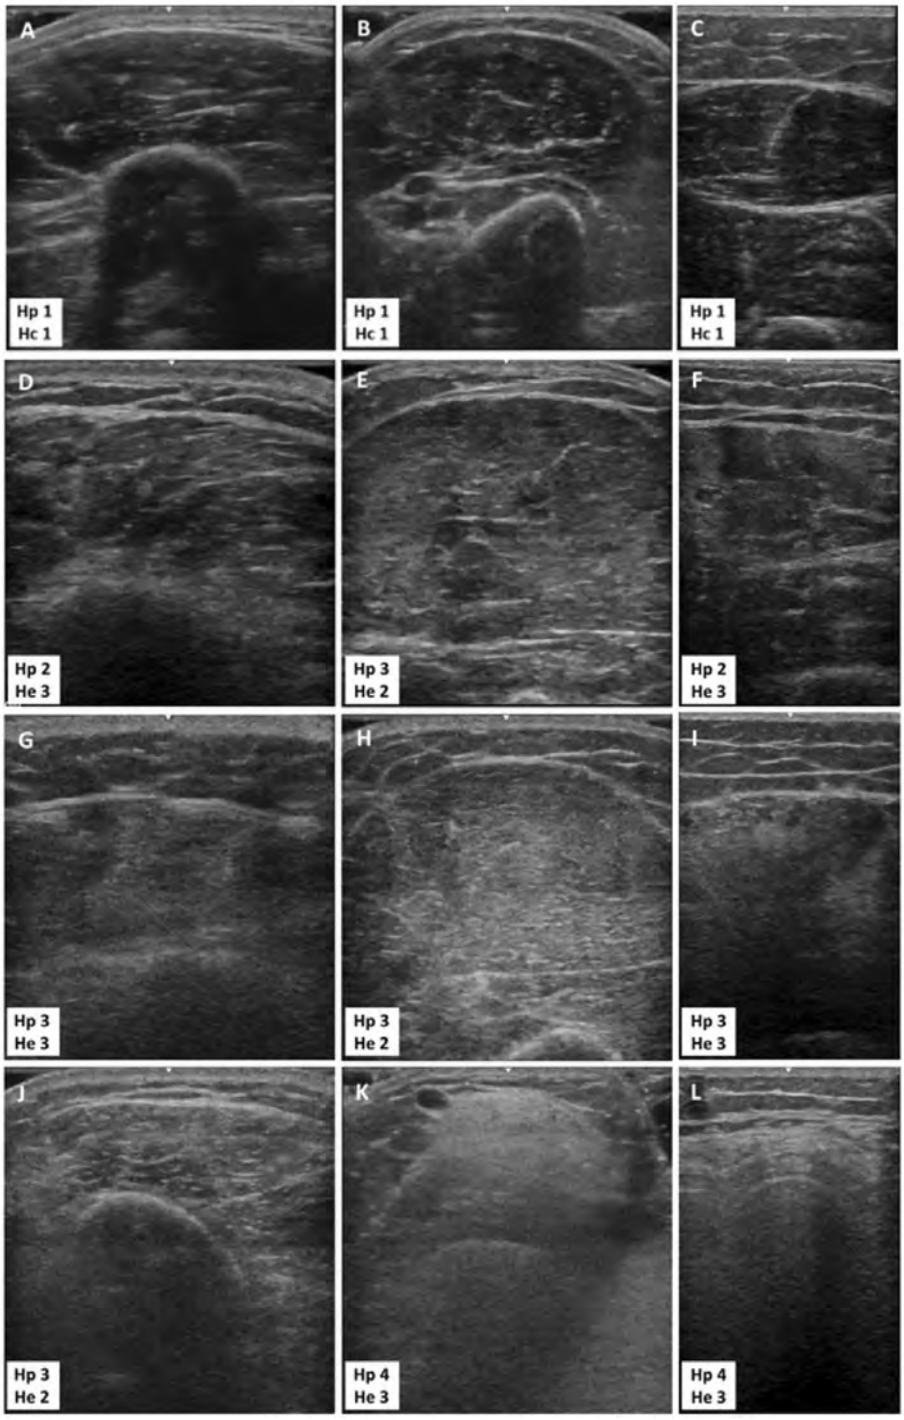

Figure 1. The Hopkins myositis grading scale in healthy controls (A-C) and myositis patients (D-F: immune mediated necrotizing myopathy, G-I: Anti-synthetase syndrome, J-L: inclusion body myositis). A, D, G, J: deltoid. B, E, H, K: biceps brachii. C, F, I, L: rectus femoris. Abbreviation: Hp: the Hopkins myositis grading scale, He: the Heckmatt grading scale.

myositis patients, interrater reliability of the Hopkins myositis grading scale demonstrated substantial agreement (Cohen's kappa 0.62 - 0.65) while the Heckmatt scale had fair agreement (Cohen's kappa 0.28 - 0.36). Similarly, intrarater reliability of the Hopkins myositis grading scale was almost perfect and better than the Heckmatt scale (0.78-0.85 vs 0.67).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Validity and reliability of the Hopkins myositis grading scale and the Heckmatt grading scale.

Subject		Assessment method	Interrater reliability, κ (% agreement)			Intrarater reliability, κ (% agreement)	
			Rater 1/2	Rater 1/3	Rater 2/3	Rater 1	Rater 2
Myositis	Total	Modified Heckmatt	0.62 (75.1)	0.643 (76.3)	0.647 (77.5)	0.846 (89.7)	0.78 (86)
		Heckmatt	0.365 (59.7)	0.358 (57.2)	0.277 (51.1)	0.67 (82.2)	0.669 (80.4)
	Non-IBM	Modified Heckmatt	0.578 (74.2)	0.621 (76.4)	0.592 (75.9)	0.839 (89.9)	0.747 (85.4)
		Heckmatt	0.324 (57.9)	0.388 (59.6)	0.251 (52.7)	0.698 (83.1)	0.575 (77.5)
	IBM	Modified Heckmatt	0.651 (76.2)	0.651 (76.2)	0.704 (79.5)	0.836 (88.9)	0.8 (86.7)
		Heckmatt	0.37 (61.5)	0.281 (53.3)	0.267 (48.4)	0.629 (82.2)	0.738 (83.3)
Healthy control		Modified Heckmatt	0.384 (73.1)	0.445 (77.4)	0.358 (76.3)	0.693 (85.1)	0.551 (82.5)
		Heckmatt	0.242 (53.2)	0.394 (63.4)	0.16 (50.5)	0.667 (79.2)	0.589 (78.9)

Subject	Assessment method	Muscle strength, ρ		QMUS, ρ	
		Rater 1	Rater 2	Rater 1	Rater 2
Total	Modified Heckmatt	-0.569	-0.551	0.626	0.559
	Heckmatt	-0.425	-0.523	0.296	0.566
Non-IBM	Modified Heckmatt	-0.540	-0.5	0.517	0.408
	Heckmatt	-0.349	-0.455	0.236	0.46
IBM	Modified Heckmatt	-0.517	-0.54	0.71	0.717
	Heckmatt	-0.498	-0.516	0.343	0.639

Conclusion: In myositis patients, the Hopkins myositis grading scale which incorporates more specific parameters to aid in assessing changes in muscle EI and architecture, showed excellent validity and reliability and showed improvements over the original Heckmatt scale. Notably, the less experienced rater demonstrated interrater reliabilities comparable to those of the experienced raters, suggesting that appropriate training can be sufficient for accurate assessment.

Session Title: (1191–1220) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Swallowing dysfunction -dysphagia- is a frequent and debilitating symptom in neuromuscular disorders, leading to malnutrition, cachexia, aspiration pneumonia and death. Identification of the underlying pathophysiological mechanisms is important for diagnosis and treatment. As standard assessments have limitations, novel imaging techniques are needed. In the present study, we investigated the utility of real-time MRI and quantitative muscle ultrasound for characterizing dysphagia in two different neuromuscular disorders.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Quantitative muscle ultrasound (QMU) of orofacial muscles in IBM and OPMD patients. Heatmap of echogenicity (A) and muscle thickness (B) obtained by QMU. I1-I18 are individual IBM patients, O1-O13 are individuals with OPMD. Color codes represent z-scores, with echogenicity z-scores between 1.5 and 2 considered borderline abnormal, z-scores ≥ 2 considered abnormal and z-scores > 3 considered as severely abnormal. Muscle thickness z-scores -1.5 were considered abnormal. White represents missing data. (C) shows exemplary QMU findings of the tongue muscle. Echogenicity was analysed using histogram based grey-scale analysis and manually selected ROI, demarcated by the dotted green line (I), the dotted blue line delineates the border between the subcutaneous fat layer and muscle. Normal echogenicity of the tongue muscle in an IBM patient (II) and moderate signs of fibrosis and fatty infiltration in the tongue muscle of an OPMD patient (III).

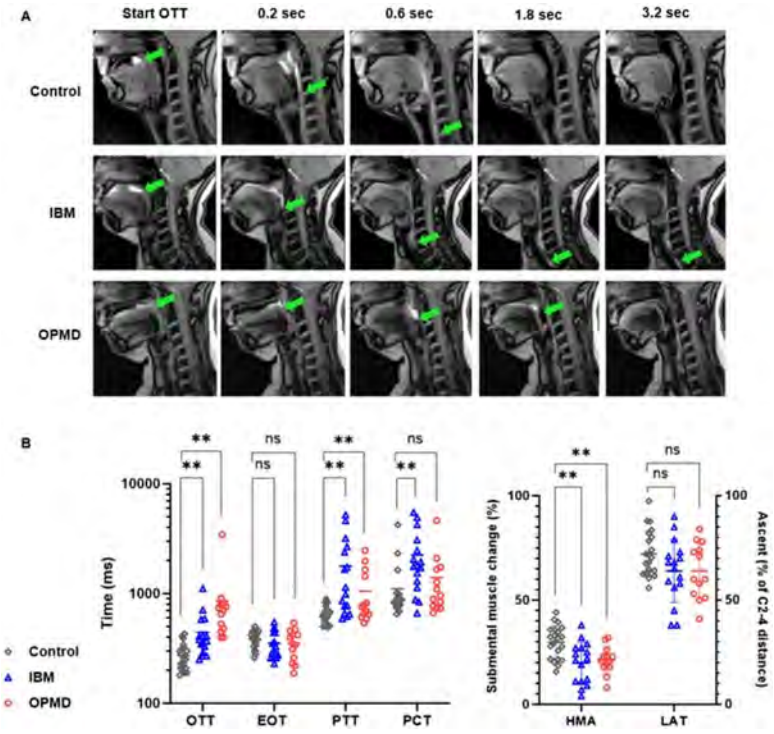

Figure 2. Real-time MRI assessment of swallowing in patients with IBM and OPMD versus control subjects. A. RT-MRI at a resolution of 40 ms with exemplary findings in a control subject (upper row), an IBM patient (middle row) and an OPMD patient (bottom row). Images were selected at start of oral transit time (OTT) and subsequently 0.2 sec, 0.6 sec, 1.8 sec and 3.2 sec. Note how swallowing one bolus of pineapple juice (bright contrast, bolus head is marked by a green arrow) is completed in the control subject at 1.8 sec, while the IBM patient shows pharyngal retention and a cricopharyngeal bar at 1.8 sec and 3.2 sec. The OPMD patient shows a prolonged oral phase of swallowing until 1.8 sec after start of OTT, while the pharyngeal phase is unaffected and swallowing is completed by 3.2 sec. These RT-MRI sequences can be viewed in movie format in Supporting Information Movies S1 and S2. B. RT-MRI shows a significantly prolonged OTT in patients with OPMD and to a lesser extent also in patients with IBM. The pharyngeal phases of swallowing (PTT and PCT) are significantly impaired in patients with IBM and in a few patients with OPMD. No differences between the cohorts were found for esophageal opening time (EOT). Hyoid-mental approximation (HMA) is significantly reduced in both diseases. No differences to controls were observed for relative laryngeal elevation (LAT). Variables were tested using t-tests and compared to a non-myopathic control group.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 3. T1 mapping of swallowing muscles in patients with IBM and OPMD versus control subject. A. Selected T1 weighted MRI sequences (upper row) and T1 maps (middle and bottom row) obtained for head and neck region of a 71 y.o. control subject, a 64 y.o. IBM patient and a 61 y.o. OPMD patient. The bottom row outlines the manually placed regions of interest (dotted green lines) of the tongue muscles in the coronal sequences and the geniohyoid muscles in the sagittal sequences for analysis of mean T1 values. B. T1 mapping reveal significantly lower T1 values of tongue muscle in OPMD patients indicating a higher fat content. T1 values of geniohyoid muscle and masseter muscle show no significant differences between patients and controls. Variables were tested using t-test. C. The reduced T1 values of the tongue in quantitative MRI correlate significantly with increased echogenicity of the tongue on ultrasound in OPMD patients (Spearman r = -0,52; p = 0,005), both methods thereby indicating fibrosis and fatty infiltration of the tongue muscle.

Methods: This prospective cohort study included 18 patients with inclusion body myositis (IBM, 33% female, age 68.9 ± 7.7 years) and 13 with oculopharyngeal muscular dystrophy (OPMD, 62% female, age 55.9 ± 7.0 years) from two European Neuromuscular research centers (Nijmegen, NL; Göttingen, DE). Swallowing function was studied using real-time MRI (RT-MRI), FEES (flexible endoscopic evaluations of swallowing) and clinical assessments. T1-mapping and quantitative muscle ultrasound (QMUS) were used to analyze tissue properties in swallowing muscles. Outcomes were compared between the two muscle diseases. RT-MRI values were also compared to 22 age- and sex-matched non-myopathic controls.

Results: RT-MRI revealed significantly prolonged oral transit times in OPMD vs. controls (difference between means= 581.2 ms, 95% CI 225.9-936.4, p=0.002). Pharyngeal transit time was significantly prolonged in IBM vs. controls (difference between means= 1132.8 ms, 95% CI 482.2-1783, p=0.001). A cricopharyngeal bar as a well-established morphological indicator of dysphagia was identified in 80% patients with IBM compared to 53% in OPMD. Fatty degeneration of the tongue in OPMD significantly correlated between MRI-T1 values and ultrasound echogenicity (Spearman`s ρ= -0.52, p=0.005). ROC revealed excellent discrimination between diseases by combining RT-MRI, T1-mapping and QMUS (AUC= 0.95, 95% CI 0.86-1.00), while FEES and clinical assessments failed to differentiate specific patterns of dysphagia.

Conclusion: This study supports the value of novel MRI and ultrasound techniques for clinical use by identifying the pathophysiology and severity of impaired swallowing. Differentiating the phenotypes of dysphagia can aid in the diagnosis and treatment of affected patients.

Overexpression of lymphotoxin in autophagy-deficient mice as model for inclusion body myositis

Juliane Bremer[1], Judith Nagel[2], Jana Zschüntzsch[3], Kamil K Zajt[1], Tayfun Palaz[1], Thomas Blank[4], Aylin Ikis[1], Laura A Fischer[3], Anna SM Sensmeyer[3], Lara Wiechers[3], Josef J Reichelt[3], Kai P Hofmann[5], Monika J Wolf[6], Corinna Leuchtenberger[7], Priyanka Tripathi[1], Claudia Einer[8], Hans Zischka[2], Ulrike Rothermel[7], Anna L Eck[7], Regina Reimann[9], Veronika Kana[6], Elisabeth Rushing[6], Adriano Aguzzi[6], Marco Prinz[4], David Liebetanz[3], Francesca Odoardi[3], Chao-Chung Kuo[1], Joachim Weis[1], Florian Kraft[1], **Jens Schmidt**[10] and Mathias Heikenwälder[7], [1]University Hospital RWTH Aachen, Aachen, Germany, [2]Technical University of Munich, München, Germany, [3]University Medical Center Göttingen, Göttingen, Germany, [4]University of Freiburg, Freiburg, Germany, [5]DKFZ Heidelberg, Göttingen, Germany, [6]University Hospital Zürich, Zürich, Switzerland, [7]DKFZ Heidelberg, Heidelberg, Germany, [8]Helmholtz Munich, München, Germany, [9]University Hospital Zürich, Zürich, Germany, [10]Immanuel University Hospital Rüdersdorf, Brandenburg Medical School, Rüdersdorf bei Berlin, Germany

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1191–1220) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Inclusion body myositis (IBM) is a progressive muscle disorder characterized by inflammation and degeneration with altered proteostasis. To better understand the interrelationship between these two features, we aimed at establishing a novel preclinical IBM model.

Methods: First, we used quantitative PCR to determine expression of pro-inflammatory chemo- and cytokines including lymphotoxin (LT)-signaling pathway components in human skeletal muscle tissue diagnosed with myositis. Based on these results we generated a mouse model that we analyzed at the histological, ultrastructural, transcriptional, biochemical, and behavioural level. Lastly, we subjected this model to anti-inflammatory treatments.

Results: After confirming and extending previous data on activation of lymphotoxin (LT)-signaling in human myositis, we generated distinct transgenic mouse lines co-expressing LTa and -b in skeletal muscle fibers. Transgenic mice displayed chronic myositis accompanied by dysregulated proteostasis, including an altered autophagolysosomal pathway. Related genes were temporarily up- and later downregulated, possibly in a compensatory fashion. Therefore, we genetically impaired autophagy in skeletal muscle cells. Autophagy impairment alone induced a pro-inflammatory transcriptional state, but no obvious cellular inflammation. However, the combination of LT-driven myositis with autophagy impairment induced the full spectrum of characteristic molecular and pathological features of IBM in skeletal muscle, including protein aggregates with typical ultrastructural morphology and mild mitochondrial pathology. Our attempts to treat the pathology by subjecting these mice to corticosteroids or anti-Thy1.2 antibodies mirrored recent treatment failures in humans, i.e., none of these treatments resulted in significant clinical improvement of motor performance or the transcriptional profile of muscle pathology.

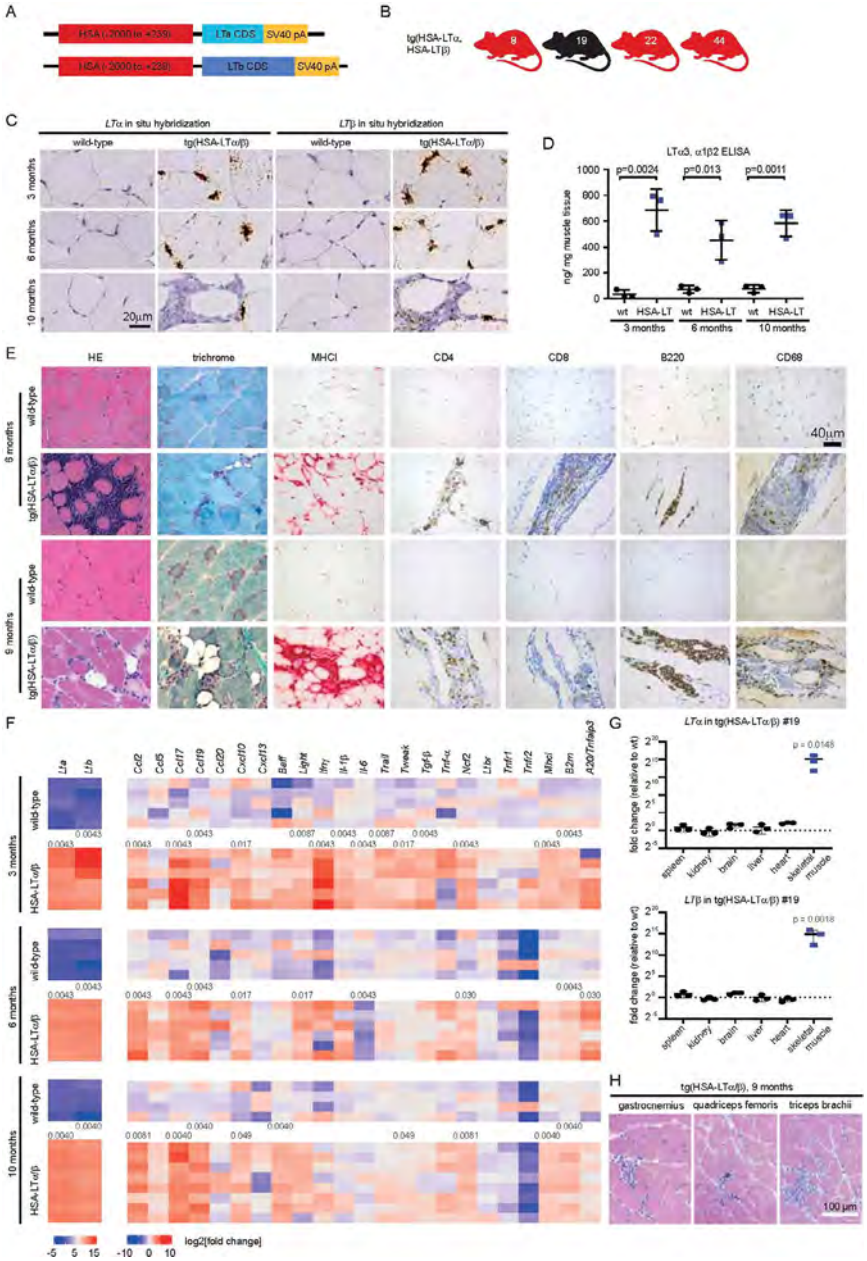

Figure 1. Generation, histology and chemo-/cytokine expression of HSA-LT/ transgenic mice. (A) Schematic drawing of the transgenic constructs of the coding sequences (CDS) of LT and LT both being cloned downstream of the human skeletal muscle actin (HSA) promoter (-2000 to +239) followed by an SV40 poly A site. (B) Four founder mice carrying both transgenes, HSA-LT and HSA-LT and transmitting them through the germline were obtained (line #8, #19, #22, #44). (C-D) LT and LT transgene expression was detected in quadriceps muscle fibers of HSA-LT/ #19 mice by RNA in situ hybridization of paraffin sections (brown signal) in the muscle fibers at 3, 6 and 10 months of age and also in inflammatory infiltrates in skeletal muscle, shown at 10 months of age (C). LT ELISA with skeletal muscle tissue homogenate from indicated time points and genotypes. Data are shown as ng LT3/LT12/LT21 protein per mg total protein. Statistical significance was tested using two-tailed Student's t-test. (E) Histologically, HSA-LT/ transgenic mice show endomysial inflammatory infiltrates and occasional muscle fiber necrosis. Especially at the age of 9 months, there is fibrosis and partial replacement by fatty tissue within the endomysium. Fiber size variation is also increased in transgenic mice (H&E and trichrome). In addition to the normal MHCI localization on endomysial capillaries seen in wild-type mice, transgenic mice display focal sarcolemmal MHCI upregulation (red signal). The inflammatory infiltrates are mostly composed of B220+ B cells and CD68+ macrophages and - to a lesser extent - of CD4+ and CD8+ T cells (brown signals). (F) Heatmap of chemo- and cytokine expression in HSA-LT/ transgenic mice determined by quantitative PCR of quadriceps femoris muscle tissue at 3, 6 and 10 months of age. P-values were determined using two-tailed Mann-Whitney tests. In case of significant differences between wild-type and transgenic mice, the p-values are displayed between the group of wild-type and transgenic line of the respective age group. (G) Quantitative PCR determining LT and LT expression in different organs of HSA-LT/ transgenic mice. P-values were determined using the ANOVA test with Šídák's multiple comparison test, significant differences compared to wild-type are displayed. (H) HE-stained sections of three different muscles from 9 months old HSA-LT/ mice.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Behavioural and histological consequences of autophagy depletion in lymphotoxin-induced chronic myositis. (A) Breeding scheme to obtain HSA-LT/+ Ckmm-Cre+ Atg5fl/fl (HSA-LT;CreAtg5) mice. (B-C) Muscle volume was determined by magnetic resonance imaging (MRI) at 3 and 6 months of age of male and female HSA-LT;CreAtg5 compared to Ckmm-Cre+ Atg5fl/fl (CreAtg5) mice. Representative MRI (FLASH) images and 3D reconstructions of calf muscles are shown along with volumetric quantification. Muscle atrophy was observed in HSA-LT;CreAtg5 compared to CreAtg5 mice. Two-sided unpaired student's t-test was used to determine p-values. (D-F) Histological and immunohistochemical analysis for inflammatory markers revealed chronic myositis in HSA-LT;CreAtg5, but not in CreAtg5 mice, characterized by endomysial infiltrates composed of CD4+ and CD8+ T cells, B220+ B cells and CD68+ macrophages (brown signals) as previously observed in HSA-LT/ transgenic mice. Sarcolemmal upregulation of MHCI were detected in HSA-LT;CreAtg5, but MHCI was either not (1 of 4) or expressed weakly/ only on single fibers (3 of 4) in CreAtg5 mice (red signal). Quantification is shown in F. P-values were determined using the ANOVA test with Šídák's multiple comparison test. (G-H) Motor performance of CreAtg5 and HSA-LT;CreAtg5 mice was determined by the grip strength test (G) and by the hanging wire test (H). Groups were compared using the two-sided unpaired student's t-test. P-values are shown.

Conclusion: In summary, these data provide evidence that inflammation and autophagy disruption play a synergistic role in the development of IBM-like muscular pathology. Furthermore, once established, IBM-like pathology in these mice, as in human IBM patients cannot be reverted or prevented from progression by conventional means of immunosuppression. We expect that this novel mouse model will help to identify future treatment modalities for IBM.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 3. IBM-like myositis in mice is resistant to anti-inflammatory treatments. (A) Timeline of treatment. Density of CD3+ T cells in the liver of untreated mice and after treatment; for anti-Thy1.2 (B) and prednisolone (C) treatment. P-values were determined using two-tailed Students t-tests. Grip strength of mice at day 150. The results show genotype-dependent differences, but no treatment effect after prednisolone (D) and anti-Thy1.2 (E) treatment. (F) The heatmap shows expression examined by qPCR relative to the respective untreated controls (treated compared to untreated wild-type, HSA-LT/ and HSA-LT;CreAtg5, respectively) – here in case of prednisolone treatment. Except for a significant downregulation of Cxcl10, Ncf2 and Gpx2 following prednisolone treatment of HSA-LT/ mice compared to untreated HSA-LT/ and non-significant trends for some other genes, there was a counterintuitive upregulation of Ccl5 in treated compared to untreated HSA-LT;CreAtg5 mice, but otherwise stable gene expression. n.d. = not determined. Mann-Whitney-U test was performed as statistical test since some values were not normally distributed. P-values are only displayed in case of statistical significance between untreated and treated mice. Behavioral phenotypes and gene expression patterns following these treatments were stable (see also Supplementary figures).

Abstract Number: 1207

Cutaneous and Muscular Disease Trajectories in Adult Patients with Dermatomyositis

Jesus Valencia[1], Will Kelly[1], Sean Tackett[2], Amanda Finney[1], Jemima Albayda[1], Julie Paik[3], Lisa Christopher-Stine[1] and Chris Mecoli[4], [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins University, Baltimore, [3]Johns Hopkins Rheumatology, Baltimore, MD, [4]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1191–1220) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Dermatomyositis (DM) is a rare autoimmune disease characterized by cutaneous manifestations and proximal muscle inflammation.[1,2] Notably, the clinical course of muscular and cutaneous disease in DM is highly variable. Some patients may exhibit predominant muscle disease while up to 20% of patients are categorized as clinically amyopathic and present with skin manifestations in the absence of muscle disease.3 However, most clinical trials require both muscle and skin involvement to be eligible.4 Our center has observed that even DM patients who are not amyopathic at presentation will often have improvement in muscle activity before skin activity, which prevents patients from being eligible for clinical trials given the lack of both muscular and skin involvement. Our study aims to characterize the clinical trajectory of muscular and cutaneous disease activity in patients with DM.

Methods: Patients with DM satisfying the ACR/EULAR 2017 classification criteria were prospectively enrolled between 2019 and 2025 at a large United States tertiary academic medical center. Patients included in this study were adult patients (≥18 years old at DM symptom onset), had clinical active disease as defined by Manual Muscle Testing-8 (MMT-8) < 142 and Cutaneous Dermatomyositis Disease Area and Severity Index-Activity (CDASI-A) >6 and at least 3 consecutive visits over 24 months (Figure 1). Demographic data, DM disease history, serologic status and treatment history were obtained through

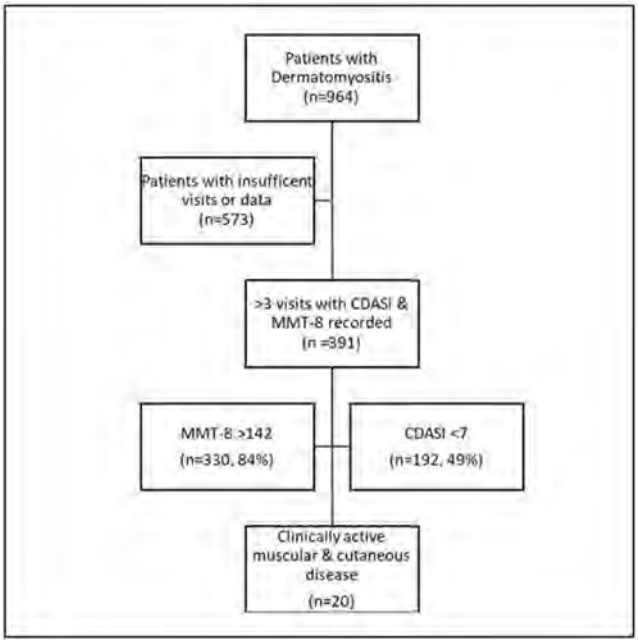

Figure 1. Of the 391 DM eligible cohort, 330 (84%) of patients did not meet muscle criteria whereas 199 (51%) met cutaneous criteria, suggesting most patients are not eligible for many clinical trials due to lack of weakness.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. prospective discrete data capture at each clinical visit. Outcomes included the percentage of patients who achieved improvement of their cutaneous and muscular disease as measured by the CDASI-A (decrease in 40%) and MMT-8 scores (near normalization of strength, ≥142).[5]

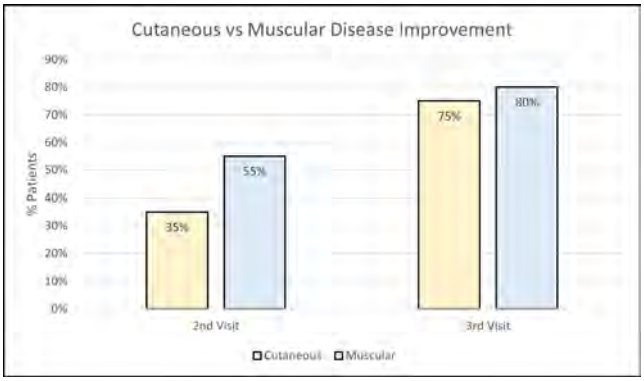

Figure 2. Cutaneous vs Muscular Disease Improvement Over Time

Table 1. Demographic and Disease Characteristics

Characteristic	Inclusion Group (n=20)	
Female sex, No. (%)	19 (95%)	
Age at DM symptom onset, mean (SD), yr	46.0 (18.0)	
Age at DM diagnosis, mean (SD), yr	46.8 (18.5)	
Age at baseline visit, mean (SD), yr	51.8 (17.9)	
Race/Ethnicity, No. (%)		
Asian	1 (5%)	
Black	4 (20%)	
Hispanic/Latino	0 (0%)	
White	15 (75%)	
CDASI-A Score Baseline, median (IQR)	9.0 (8.0-13.5)	
MMT-8 Score Baseline, median (IQR)	132 (122-137)	
Autoantibody positivity, No. (%)		
Mi-2 (line blot/ELISA)	0 (0.0%)	
NXP2 (IVTT IP)	11 (57.9%)	
MDA5 (line blot)	1 (5.6%)	
SAE1 (line blot)	0 (0.0%)	
TIF1Y (ELISA) >32	3 (30.0%)	
Medication History	**Prior Use [No. (%)]**	**Medication at Most Recent Visit [No. (%)]**
Hydroxychloroquine	4 (20%)	2 (10%)
Azathioprine	7 (35%)	0 (0%)
IVIG	4 (20%)	13 (65%)
Jak inhibitor	3 (15%)	1 (5%)
Methotrexate	15 (75%)	3 (15%)
Mycophenolate	9 (45%)	8 (40%)
Rituximab	6 (30%)	3 (15%)
Subcutaneous Ig	0 (0%)	1 (5%)
Systemic steroids (prednisone, methylprednisolone)	10 (50%)	6 (30%)
No systemic oral medications or intravenous immunoglobulin	3 (15%)	3 (15%)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: 20 patients with adult DM met the inclusion criteria (95% female, 75% White; mean age at DM diagnosis 47) with demographics outlined in Table 1. The baseline visit was on average five years after DM onset. Baseline median CDASI activity was 9 (IQR 8.0-13.5) and baseline median MMT-8 was 132 (IQR 122-137). From the baseline visit to the second visit (median 5 months after baseline), the median CDASI-A improved from 9 to 8 whereas the MMT-8 improved from 132 to 144. Only 7 (35%) patients experienced cutaneous improvement, whereas 11 (55%) patients experienced strength improvement. By the 3rd visit (median 10 months after baseline) median CDASI-A improved to 5 and MMT-8 improved to 146. At this time, 15 (75%) patients achieved cutaneous improvement, and 16 (80%) patients achieved muscular improvement (Figure 2). The median time to improvement for cutaneous disease was 6.5 months (IQR 5-11) whereas median time to improvement for muscular strength was 5 months (IQR 3-9.5).

Conclusion: At our U.S. tertiary academic medical center, most adult dermatomyositis (DM) patients present with relatively preserved muscle strength but more active skin disease. As a result, many are ineligible for clinical trials that require significant muscle weakness. Longitudinal data indicate that muscle symptoms often improve before skin symptoms, and the delay between disease onset and referral to a tertiary center may further hinder clinical trial recruitment.

Session Date: Monday, October 27, 2025
Session Title: (1191–1220) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Juvenile dermatomyositis (JDM) is an inflammatory vasculopathy characterized by muscle weakness and systemic inflammation. This study aimed to investigate the clinical utility of neutrophil activation markers, specifically calprotectin (S100A8/A9) and myeloperoxidase (MPO)-DNA complexes, as potential biomarkers for muscle inflammation and predictors of long-term outcomes in JDM.

Methods: Plasma levels of calprotectin and MPO-DNA were quantified using ELISA in JDM (n = 36), juvenile idiopathic arthritis (JIA, n = 13), and healthy controls (HCs, n = 21). Disease severity and muscle function were assessed using the Childhood Myositis Assessment Scale (CMAS), Physician Global Assessment (PGA), and Manual Muscle Testing 8 (MMT8).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Neutrophil activation levels in JDM and associations with disease activity markers. (A, B) Levels of calprotectin (A) and MPO-DNA (B) in plasma among different groups. (C) Correlation of calprotectin with CMAS, MMT8, and PGA muscle score. (D) ROC curves comparing the performance of calprotectin, MPO-DNA and CK levels in distinguishing active from remission states in JDM patients based on CMAS. Active disease was defined as a CMAS ≤ 47. (E-F) PGA muscle scores (E) and CMAS (F) in JDM patients stratified into three groups based on neutrophil activation marker levels. Group 0: low level of both calprotectin and MPO-DNA; Group 1: elevated level of either biomarker; Group 2: elevated levels of both biomarkers. Statistical analyses by Kruskal-Wallis test, Spearman correlation and Mann-Whitney U test with * p<0.05, ** p<0.01, and *** p<0.001.

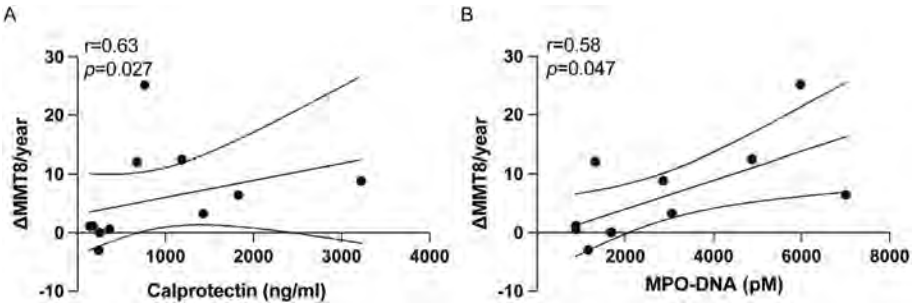

Figure 2. Correlations of neutrophil activation markers and disease progression in JDM. (A-B) Correlation analysis between plasma levels of calprotectin (A) and MPO-DNA (B) and MMT8 progression in JDM. Statistical analyses by Spearman correlation.

Results: JDM patients exhibited significantly higher plasma calprotectin and MPO-DNA levels as compared to HCs (p=0.0008 and p=0.0048, respectively) (Figures 1A-B). Calprotectin levels correlated with muscle function scores (CMAS r=-0.682, p=0.0002; MMT8 r=-0.59, p=0.005; and PGA muscle scores r=0.452, p=0.014) (Figure 1C). ROC analysis demonstrated that baseline calprotectin and MPO-DNA levels could distinguish active disease with high accuracy (AUC = 0.85

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

and 0.80, respectively) (Figure 1D). Further stratification showed that patients with elevated levels of both markers had significantly worse disease activity and muscle involvement (Figures 1E-F). Notably, higher baseline levels of these markers correlated with improved MMT8 scores over time (r=0.634, p=0.027; r=0.582, p=0.047) (Figures 2A-B), indicating a predictive role in muscle recovery.

Conclusion: Calprotectin and MPO-DNA represent promising biomarkers for muscle inflammation and functional outcomes in JDM. These results suggest that neutrophil activation plays a key role in JDM pathogenesis and may provide insights into disease monitoring and treatment strategies.

Abstract Number: 1209

Beyond Muscle Strength: Functional Performance Measures Enhance Assessment of Disease Activity in Juvenile Dermatomyositis

Jia Shi[1], Alexander Carpenter[2], Christopher Wong[2], Qian Wang[3], Christian Lood[4] and Susan Shenoi[5], [1]University of Washington, Seattle, WA, [2]Division of Rheumatology, Seattle Children's Hospital and Research Center, Seattle, [3]Peking Union Medical College Hospital, Beijing, Beijing, China (People's Republic), [4]University of Washington, Division of Rheumatology, Seattle, [5]Seattle Children's Hospital and Research Center, Mercer Island, WA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1191–1220) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: To evaluate the measurement properties of functional performance measures (FPMs)—broad jump (BJ) and 10-meter run (10MR)—for assessing muscle function and disease activity in children with juvenile dermatomyositis (JDM), and to assess their added value alongside conventional clinical tools.

Methods: This longitudinal cohort study included 39 children with JDM. BJ and 10MR were assessed alongside standard clinical scores. Construct validity and responsiveness were assessed through cross-sectional and longitudinal analyses (linear mixed-effects models, LMMs).

Results: FPMs correlated significantly with established disease activity and muscle function measures (Figure 1). While 10MR and BJ demonstrated moderate responsiveness (standardized response mean = -0.56 and 0.31, respectively), longitudinal analyses (Figure 2) confirmed that changes in FPMs closely tracked with improvements in Childhood Myositis Assessment Scale (CMAS) and manual muscle testing (MMT8) over time. Within the clinically inactive disease (CID) group, functional heterogeneity was evident (Figure 3A). Cluster analysis based on CMAS and MMT8 identified a subgroup with relatively low strength scores and poor FPM performance (Figures 3B-C), while a more comprehensive four-variable clustering using BJ, 10MR, CMAS, and MMT8 further stratified CID patients into three distinct phenotypes (Figure 3D). Notably, one subgroup exhibited high CMAS/MMT8 scores but reduced FPMs, suggesting residual functional impairment not captured by traditional assessments. Low internal consistency (Cronbach's α =0.44) further suggested that FPMs capture distinct dimensions of muscle function beyond CMAS/MMT8.

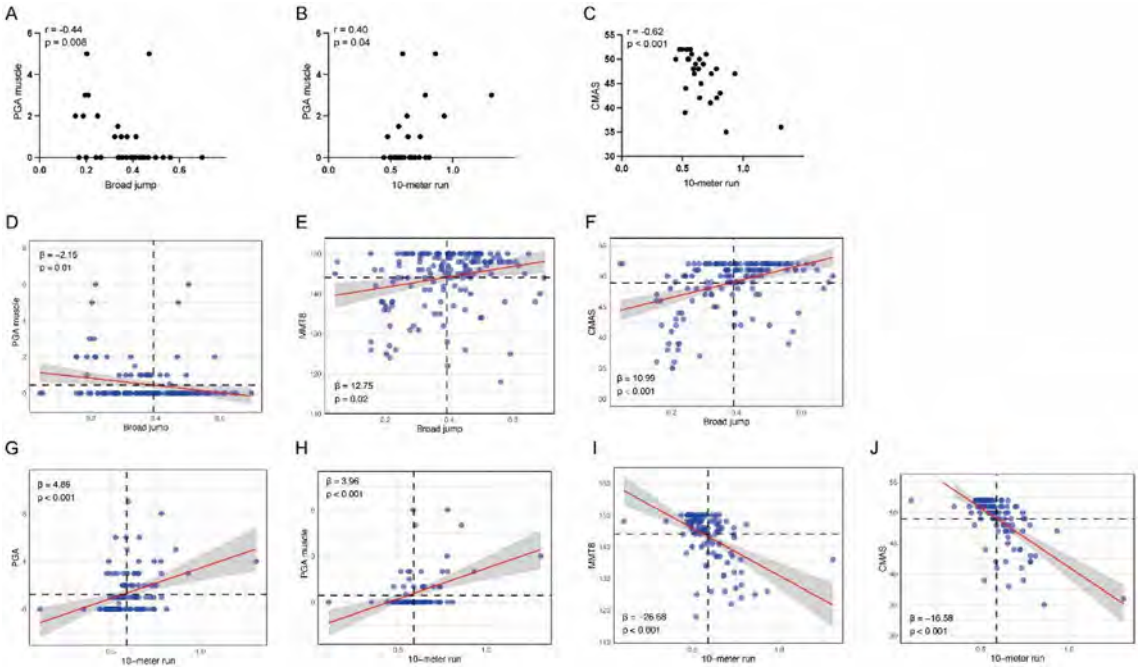

Figure 1. Relationship between FPMs and disease activity scores in JDM. (A-C) Correlation of baseline FPMs (BJ and 10MR) with PGA Muscle (A-B) and CMAS (C). (D-F) Relationship between broad jump and disease activity scores (PGA Muscle, MMT8, and CMAS) across all follow-up data. (G-J) Relationship between the 10-meter run and disease activity scores (PGA, PGA Muscle, MMT8, and CMAS) across all follow-up data. The red line represents the linear regression model fitted to the data, with the shaded area indicating the 95% confidence interval. The regression coefficient (β) and p-value are annotated on the plots. Statistical analyses were performed using Spearman correlation (A-C) and LMM (D-J).

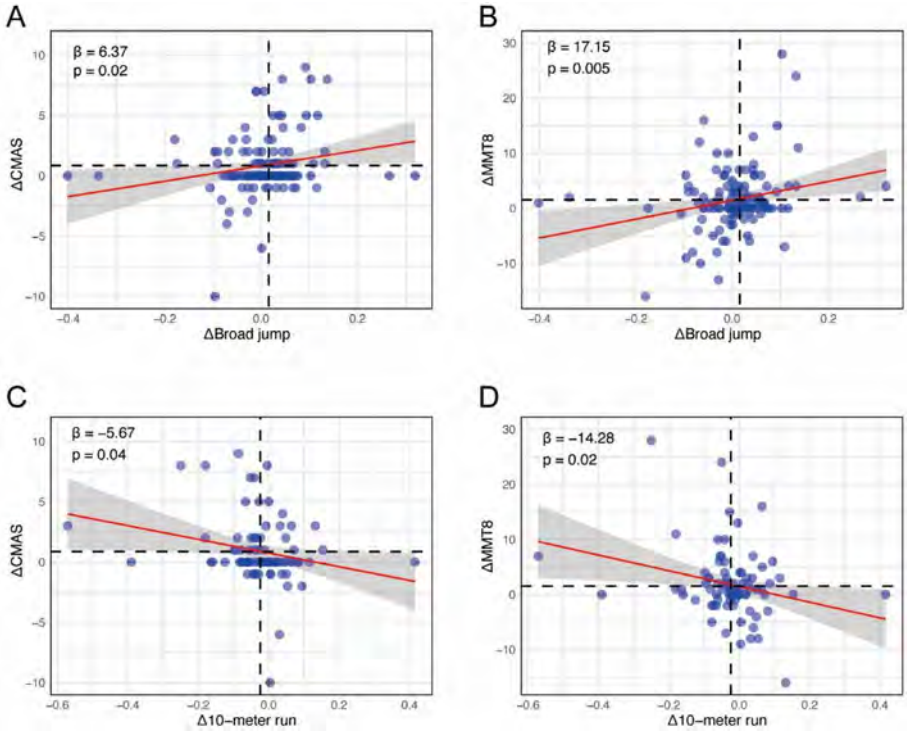

Figure 2. Change in FPMs and disease activity scores between follow-up visits in JDM. (A-B) Relationship between changes in BJ and changes in disease activity scores (ΔCMAS and ΔMMT8, respectively) across all follow-up data. (C-D) Relationship between changes in 10MR and changes in disease activity scores (ΔCMAS and ΔMMT8, respectively) across all follow-up data. The red line represents the linear regression model fitted to the data, with the shaded area indicating the 95% confidence interval. The regression coefficient (β) and p-value are annotated on the plots. Statistical analyses were performed using LMM.

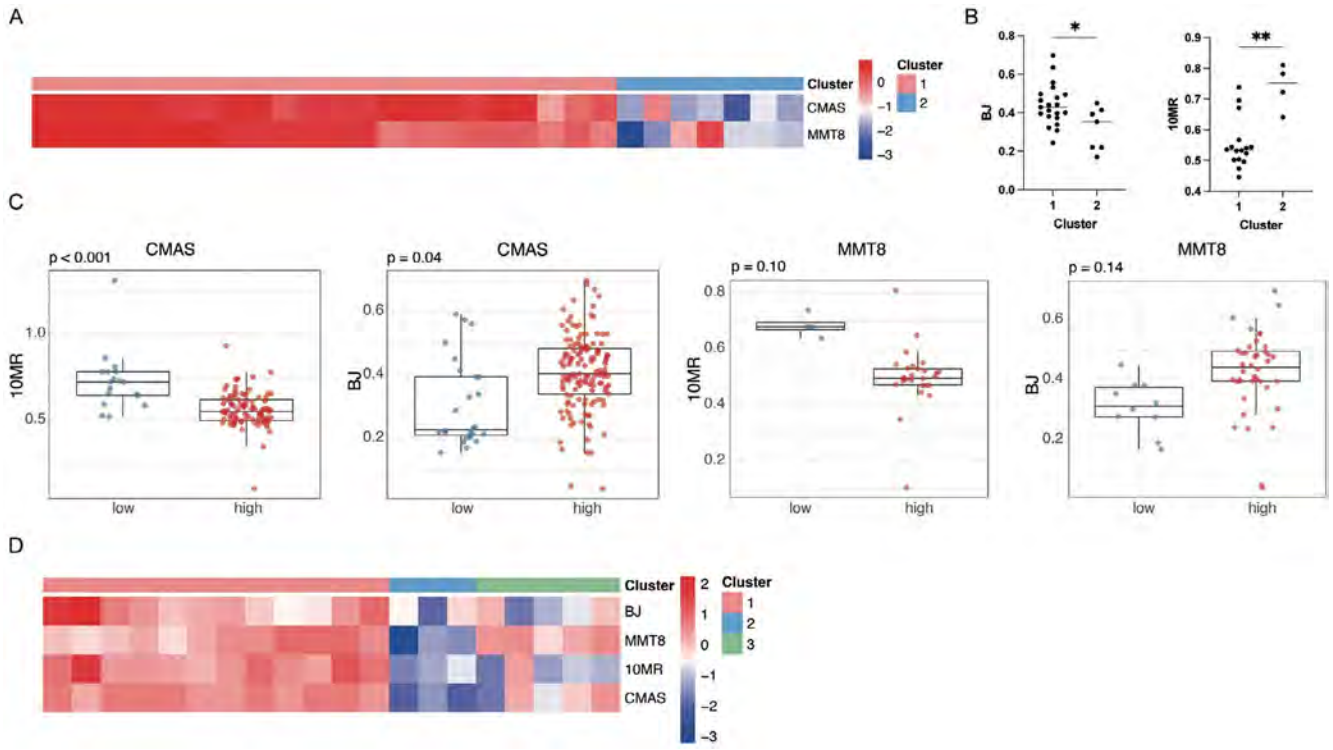

Figure 3. Evaluation of CMAS, MMT8 and functional performances in patients with JDM in clinically inactive disease (CID). (A) Heatmap depicting two patient clusters within the CID group, based on CMAS and MMT8 scores. (B) Comparisons of BJ and 10MR performance between Cluster 1 and Cluster 2. (C) Comparisons of 10MR and BJ performance between high and low CMAS groups, as well as high and low MMT8 groups, in CID patients across all follow-up data. (D) Heatmap depicting three patient clusters within the CID group, based on CMAS, MMT8 scores, BJ and 10MR (inverted). Statistical analyses were performed using the LMM and Mann-Whitney U test with * p<0.05 and ** p<0.01.

Conclusion: FPMs are quick, non-invasive, and clinically feasible tools that demonstrate good measurement properties. By capturing dynamic aspects of muscle function overlooked by CMAS and MMT8, FPMs may enhance clinical assessment and support individualized management in JDM.

Artificial Intelligence-based Capillaroscopy and Laboratory Biomarkers to Predict Disease Activity in Idiopathic Inflammatory Myopathies: Preliminary Data from the Capiami Cohort

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1191–1220) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background/Purpose: Nailfold videocapillaroscopy (NVC) is a valuable non-invasive tool for assessing microvascular damage in autoimmune diseases. However, its application in idiopathic inflammatory myopathies (IIM) remains limited, partly due to variability in interpretation. Artificial intelligence (AI)-based software offers the potential for objective, standardized capillaroscopic analysis. The CapIAMI project aimed to explore the role of automated NVC evaluation in IIM patients across a large international cohort.

Methods: We conducted an ambispective, observational, international, multicenter study including patients diagnosed with IIM according to established criteria. Standardized NVC images were analyzed using Capillary.io, an AI-based platform extracting quantitative microvascular parameters. Clinical data, laboratory values (CPK, aldolase, LDH, CRP, ESR, and ferritin), and autoantibody profiles were collected at the time of NVC. Disease activity was determined based on clinical

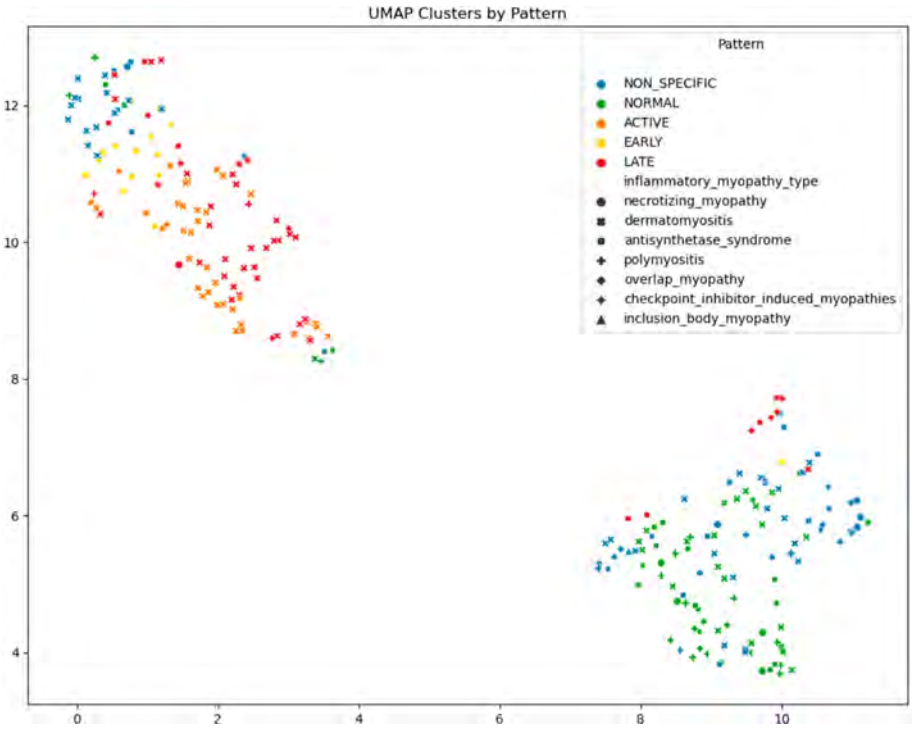

Figure 1. UMAP projection of capillaroscopic variables from CapIAMI patients. Each dot represents an individual capillaroscopy, coloured by capillaroscopic pattern and shaped by IIM subtype. The figure shows distinct clustering based on microvascular characteristics, supporting the potential of AI-assisted stratification in idiopathic inflammatory myopathies.

Table 1. Cohort & Key Clinical Features

Parameter	Value
Patients (n)	272
Age, median (IQR)	58.0 years (41.3–67.0)
Female (%)	68.2 %
Ethnicity (%)	Caucasian 56.2; Latin American 37.7; African American 3.0; Asian 2.6; African 0.4
IIM Subtype (%)	Dermatomyositis 53.7; Antisynthetase syndrome 15.8; Overlap myopathy 11.8; Polymyositis 7.7; Necrotizing autoimmune myopathy 4.0; Inclusion-body myopathy 0.7; Checkpoint inhibitor–induced myopathy 0.4
Active disease (%)	49.3 %
Manifestations (%)	Myositis 80.5; Cutaneous involvement 42.7; Articular symptoms 29.3

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 2. Autoantibody Positivity

Autoantibody	n (%)	Autoantibody	n (%)
Anti–Ro-52	86 (31.6 %)	Anti–SRP	12 (4.4 %)
Anti–Mi-2	54 (19.9 %)	Anti–RNP	10 (3.7 %)
Anti–PM/Scl	36 (13.2 %)	Anti–EJ	9 (3.3 %)
Anti–TIF1γ	28 (10.3 %)	Anti–PL-7	9 (3.3 %)
Anti–Jo-1	26 (9.6 %)	Anti–HMGCR	8 (2.9 %)
Anti–MDA-5	26 (9.6 %)	Anti–KS	5 (1.8 %)
Anti–NXP-2	22 (8.1 %)	Anti–Ha/YRS	4 (1.5 %)
Anti–SAE	20 (7.4 %)	Anti–OJ	2 (0.7 %)
Anti–Ku	20 (7.4 %)	Anti–Zo	2 (0.7 %)
Anti–PL-12	18 (6.6 %)		

evaluation. Predictive models were developed using machine learning algorithms, with performance assessed by cross-validation metrics.

Results: A total of 272 IIM patients from 25 centers were included. The median age was 58.0 years (IQR 41.3–67.0), and 68.2 % were female. Ethnic distribution was 56.2 % Caucasian, 37.7 % Latin American, and 6.0 % other groups. Dermatomyositis was the predominant subtype (53.7 %), followed by antisynthetase syndrome (15.8 %) and overlap myopathy (11.8 %) (Table 1). Clinically active disease was present in 49.3 % of patients. The most frequent active manifestations were myositis (80.5 %), cutaneous involvement (42.7 %), articular symptoms (29.3 %) and interstitial lung disease (ILD) (24.26%) (Table 1).

Patients with active disease exhibited significantly higher serum CK and aldolase, elevated CRP (all $p < 0.05$) and increased prevalence of ILD and late-scleroderma NVC pattern (both $p < 0.001$). Autoantibody profiles are detailed in Table 2. The most prevalent specificities were anti–Ro-52 (31.6 %), anti–Mi-2 (19.9 %) and anti–PM/Scl (13.2 %), with lesser frequencies for other myositis-specific and myositis-associated antibodies.

Combining AI-derived capillaroscopic metrics with laboratory biomarkers yielded an overall precision of 0.746 in cross-validated predictive models. Capillary tortuosity, ramification abnormalities, megacapillary presence and hemorrhagic patterns constituted the principal predictive features, with capillary ramification ($p = 0.005$) and average limb width ($p = 0.026$) remaining independent predictors. UMAP embedding of these features demonstrated clear segregation of early-, active- and late-scleroderma–like patterns from non-specific/normal patterns (Fig. 1).

Conclusion: Automated NVC analysis combined with conventional laboratory biomarkers improves the prediction of disease activity in IIM patients. These preliminary findings underscore the added value of standardized capillaroscopic evaluation as a complementary tool in clinical practice. Further validation in larger cohorts is needed to confirm and expand these observations.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1191–1220) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) involve muscle inflammation. MicroRNAs (miRNAs), such as miR-133a-3p and miR-1-3p, play a key role in gene regulation and muscle repair. Their dysregulated expression contributes to IIM pathogenesis, making them potential biomarkers and therapeutic targets. This study evaluates the expression of miR-133a-3p and miR-1-3p in IIM vs. healthy controls (HC), and the association with muscle involvement and disease-related features, and the impact of initial immunosuppressive therapy.

Methods: 60 patients with IIM were included: 19 males; mean (SD) age 59.1 (12.9) years; disease duration 2.5 (3.5) years; 20 dermatomyositis (DM)/ 25 polymyositis (PM), both without statin history/ 15 statin-induced immune-mediated necrotizing myopathies (IMNM). Follow-up at 6 months of immunosuppressive therapy included 13 patients (5 DM, 5 PM, 3 IMNM) with early disease (disease duration 0.9 (1.3) years). Furthermore, 33 age-/sex-matched HC were included (10 males, age 58.3 (13.4)). Body composition was examined using bioelectric impedance analysis (BIA-2000-M). Total RNA was extracted from plasma with miRNeasy Serum/Plasma Advanced kit (Qiagen). Quantitative PCR was performed using 6 miRCURY LNA

Table 1.

Table 1: Expression of miR-133a-3p and miR-1-3p in IIM and HC

IIM / HC cohorts	miR133a-3p mean (SEM) [log10_RQ to max]	miR-1-3p mean (SEM) [log10_RQ to max]
IIM (n=60)	1.225 (0.074)	1.018 (0.066)

Significant correlations are highlighted in bold (p<0.05). trends missing the level of statistical significance are highlighted in italics (p = 0.05-0.1).
Abbreviations: MYOACT, Myositis disease aktivity assessment visual analogue scale; MMT-8, Manual Muscle Testing-8; CK, Creatine Kinase; LD, lactate dehydrogenase; PED, Prednisone Equivalent Dose; RQ, Relative Quantification

miRNA PCR assays (Qiagen) with miR-103-3p, miR-191-5p, and let-7a-5p as endogenous controls. miRNA concentration analysis was performed using GenEx software (Multid Analysis AB). Data are presented as mean (SEM).

Results: The expression of miR-133a-3p and miR-1-3p was significantly higher in IIM vs. HC, in all IIM subsets vs. HC, and particularly in IMNM vs. DM and PM (Table 1) and correlated with increased muscle damage markers (CK, LD, myoglobin), decreased muscle strength (MMT8), and shorter disease duration (Table 2). After 6 months of immunosuppressive therapy, miR-133a-3p and miR-1-3p levels significantly decreased, alongside disease activity (MYOACT) and muscle damage markers, while muscle strength (MMT-8) improved (Table 3). A greater miR-133a-3p decrease correlated with a larger decrease in CK (p=0.003; r=0.780) and LD (p=0.030; r=0.623), and strength improvement (p=0.043; r=0.591). Similarly, larger miR-1-3p reduction correlated with greater CK decrease (p=0.010; r=0.705). Higher baseline miR-133a-3p and/or miR-1-3p predicted greater muscle strength improvement (p=0.043; r=0.591) and larger reductions in CK (p=0.007;

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

r=0.727 and p=0.017; r=0.671), LD (p=0.010; r=0.707 and p=0.075; r=0.532), and myoglobin (p=0.059; r=0.584, respectively).

Conclusion: The expression of miR-133a-3p and miR-1-3p were significantly higher in IIM vs. HC, in all IIM subsets vs. HC, particularly in IMNM than in DM and PM, reflecting greater muscle damage. The levels were highest in early disease with high activity and declined after 6 months of immunosuppressive therapy, mirroring reduced muscle damage markers and improved strength. Our study demonstrated both miR-133a-3p and miR-1-3p as a potential biomarker of disease activity and muscle damage in IIM, and a potential predictor of initial treatment response in IIM.

Session Date: Monday, October 27, 2025
Session Title: (1191–1220) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are a group of rare and heterogeneous diseases. One of the greatest challenges in IIM management is defining and predicting disease flares, which are inconsistently characterized across studies(1–2). The aim of the study was to identify predictors of relapse in a retro-prospective, multicenter IIM cohort during the first two years of disease.

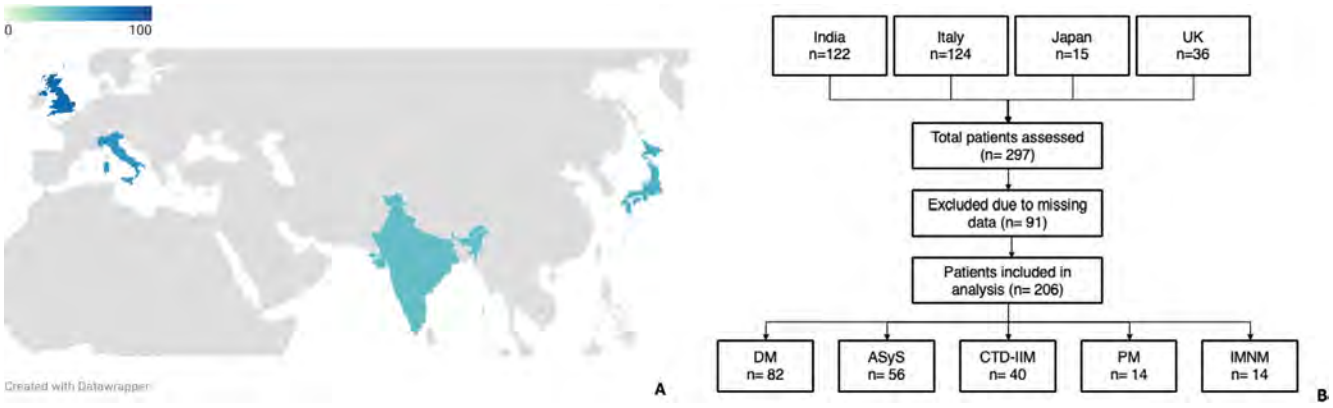

Figure 1A: Percentage of non-monophasic patients in participating centers. 1B: Workflow chart of patients' selection

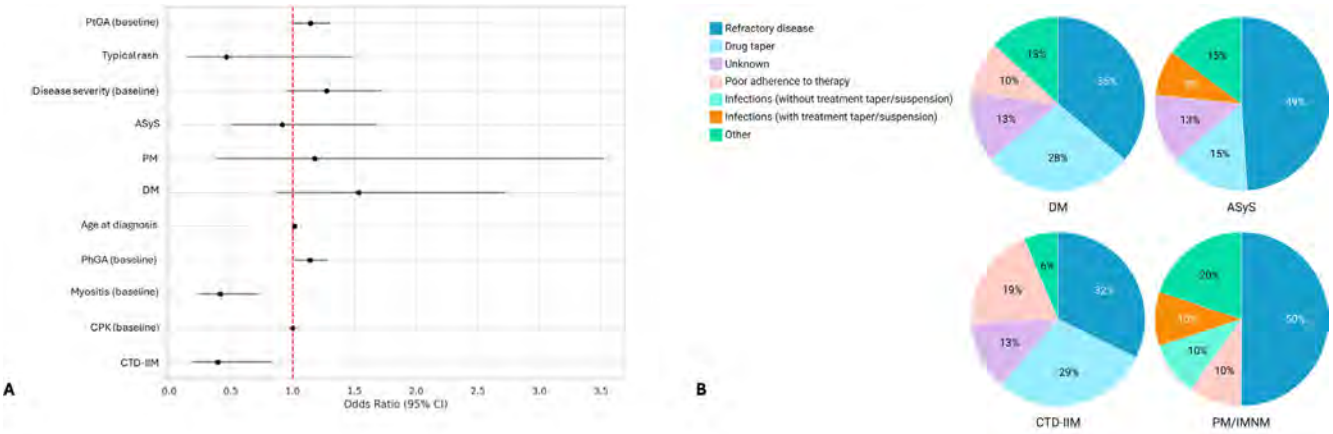

ASyS: anti-synthetase syndrome; CPK: creatine phosphokinase; CTD-IIM: connective tissue disease-associated idiopathic inflammatory myopathy; DM: dermatomyositis; PM: polymyositis; PhGA: Physician global assessment; PtGA: Patient global assessment.

Figure 2A: Clinical predictors of chronic/relapsing disease in IIM. 2B Causes of relapses in different IIM subsets

Methods: Patients with IIM subsets—dermatomyositis (DM), polymyositis (PM), antisynthetase syndrome (ASyS), connective tissue disease-associated IIM (CTD-IIM), or immune-mediated necrotizing myopathy (IMNM)—were included if aged ≥18 years and had ≥2 years of follow-up. Relapse was defined as any worsening of disease activity requiring escalation of immunosuppressive therapy and/or glucocorticords (GC). Patients were classified as monophasic (M; 0 relapses), polycyclic (P; ≥1 relapse), or chronic continuous (CC; persistent activity) (2). Clinical characteristics across subgroups were compared using chi-square, Mann–Whitney U, or Student's t-test. Predictors were identified through multivariable logistic regression.

Results: Of 297 screened patients, 206 were included (155 F; median age at diagnosis: 46.9 years), distributed as follows: DM (82; 39.8%), ASyS (56; 27.2%), CTD-IIM (40; 19.4%), PM (14; 6.8%) and IMNM (14; 6.8%).

Over the first 2 years, disease trajectories were M in 40.8% of patients (n=84), P in 32.5% (n=67) and CC in the remaining (n=55, 26.7%). PM and IMNM demonstrated a higher propensity for CC or P patterns (64.2% vs 35.8%, p=0.326) although autoantibodies were not predictive.

Among 139 documented relapses, muscle involvement predominated (61.9%), with subtype-specific patterns: PM/IMNM (88.9% muscle), DM (68.4% muscle and skin), and ASyS (61.4% ILD). Refractory disease was primarily associated with

ASyS: anti-synthetase syndrome; CPK: creatine phosphokinase; CTD-IIM: connective tissue disease-associated idiopathic inflammatory myopathy; DM: dermatomyositis; ILD: interstitial lung disease; IMNM: immuno-mediated necrotizing myopathy; IVIG: intravenous immunoglobulins; LDH: lactate dehydrogenase; MAA: myositis associated autoantibodies; MMT8: manual muscle testing 8; MSA: myositis specific autoantibodies; PhGA: Physician global assessment; PM: polymyositis; PtGA: Patient global assessment; SGOT: Serum Glutamic-Oxaloacetic Transaminase; SGPT: Serum Glutamic Pyruvic Transaminase.

relapse (43.2%), followed by treatment-related factors (see Figure 2B). Most relapses (56.5%) occurred while patients were on low-dose GC (≤5mg/day or none) with 44.7% developing within 6 months of stable dosing. Relapses occurred equally during short-term (≤3 months) and long-term (>1 year) stable immunosuppressive therapy (30.2% each).

23265205, 2025, 59, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

P/CC disease was associated with a more severe phenotype— including elevated muscle enzymes and higher global assessment scores (Ph and Pt). Patients with relapsing patterns more often received low-dose GC at disease onset (< 0.25 mg/kg; 78.9% vs 21.1%, p=0.019) and intravenous immunoglobulin therapy (26.0% vs 10.0%, p=0.004). Multivariable analysis confirmed baseline muscle involvement, CPK levels, and PtGA as independent predictors of relapse.

Conclusion: In this multicentric cohort, relapses occurred in two-thirds of patients, often during a vulnerable period on low-dose GC and within six months of stable therapy. High baseline CPK and PtGA, along with low initial GC dose, independently predicted relapse. These findings highlight the potential value of flare predictors and advocate for standardized definitions of disease activity/relapse in IIM.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1191–1220) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: HRCT is used as a surrogate for important histopathological findings when evaluating patients with interstitial lung disease (ILD). Quantitative imaging analysis (QIA) using CT texture-based scores were shown to associate with lung physiology and patient reported outcomes in IIM-ILD. The current work aims to examine changes in HRCT patterns of IIM-ILD as they transition from one pattern to another during follow-up, and compare transition patterns of IIM-ILD to that of ILD related to systemic sclerosis (SSc-ILD).

IIM-ILD subgroup of patients with 2 year interval between baseline and follow up to match follow up time in SLS II
Mean±SEM of the probabilities of moving from one pattern to another pattern

Methods: We evaluated changes in the quantitative extent of ground glass, fibrotic pattern and normal lung obtained at baseline and follow-up in HRCT scans. Patients with ILD confirmed by HRCT and on immunosuppressive treatment were included from 2 longitudinal IIM-ILD cohorts. In each within-patient baseline to follow-up HRCT pair, we calculated the transitional probability expressed as a proportion of voxels representing a particular pattern of ILD that changes from the initial pattern to another pattern at follow-up, the denominator being the total number of voxels within the initial pattern at baseline. Net improvements in ground glass and fibrotic patterns were determined by subtracting unfavorable transitional probabilities from favorable ones and statistically analyzed with the null hypothesis of net improvement being 0. In order to compare transitional probability with SSc-ILD, we selected IIM-ILD patients with comparable follow up time between HRCTs to the Scleroderma Lung Study II (SLS II) for which transitional probability had previously been reported using similar methodology (PMID:31430058).

Results: Transitional probability was calculated in 70 IIM-ILD patients that had baseline and follow-up HRCT scans adequate for voxelwise registration. The cohort included 53% antisynthetase and 37% dermatomyositis associated ILD patients with a mean disease duration of 3.5 years (Table 1). Mean transitional probability for each transition pattern is shown in Figure 1. Fifty-five percent of baseline ground glass and 46% of baseline fibrosis transitioned to a normal pattern. Net probabilities of improvement for both ground glass to normal transition ($P_{GG \rightarrow NORML}$ - $P_{NORML \rightarrow GG}$) and fibrosis to normal transition ($P_{Fibro \rightarrow NORML}$ - $P_{NORML \rightarrow Fibro}$) were significant (mean 0.44 and 0.39 respectively, $p < 0.0001$ for both). We compared transitional probabilities of 36 IIM-ILD patients with those in SLS II (Table 2). Favorable transitional probabilities ($P_{GG \rightarrow NORML}$, $P_{Fibro \rightarrow NORML}$, $P_{Fibro \rightarrow GG}$) were significantly greater in IIM-ILD compared to SSc-ILD patients whereas the majority of SSc-ILD remained stable. Unfavorable transitional probabilities ($P_{NORML \rightarrow GG}$, $P_{GG \rightarrow Fibro}$ and $P_{NORML \rightarrow Fibro}$) were overall low in both groups, showing a slight trend to be greater in the IIM-ILD compared to the SSc-ILD group (2/3 comparisons not statistically significant).

Conclusion: Transitional scoring assessment of ILD demonstrated that significant portions of ground glass and fibrotic patterns at baseline transitioned to a normal pattern with treatment in both IIM and SSc patients with ILD. However, IIM-ILD had significantly greater proportions of favorable transition patterns than SSc-ILD.

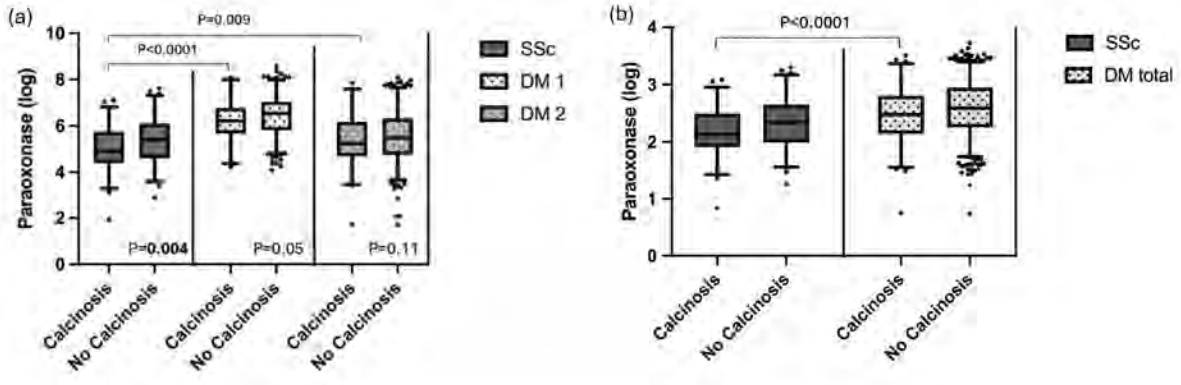
Background/Purpose: Calcinosis is a feature seen in systemic sclerosis (SSc) and dermatomyositis (DM) that leads to significant morbidity and poor quality of life. Inflammatory vasculopathy is hypothesized to play a role in dystrophic mineral deposition. Paraoxonase1 (PON1) is a high-density lipoprotein (HDL) associated protein that protects the vascular endothelium from oxidative injury and damage. The current study aims to assess the association of calcinosis PON1 activity in SSc and DM patients.

Methods: Calcinosis is a feature seen in systemic sclerosis (SSc) and dermatomyositis (DM) that leads to significant morbidity and poor quality of life. Inflammatory vasculopathy is hypothesized to play a role in dystrophic mineral deposition. Paraoxonase1 (PON1) is a high-density lipoprotein (HDL) associated protein that protects the vascular endothelium from oxidative injury and damage. The current study aims to assess the association of calcinosis PON1 activity in SSc and DM patients.

Results: Among 258 SSc patients and 652 DM patients, we identified a total of 186(20%) patients who ever had calcinosis. Calcinosis was more common in SSc (39.6%) compared to DM (13%, p< 0.0001). Calcinosis was associated with longer disease duration in both SSc and DM (Table 1). In SSc, patients with calcinosis were more often white and had higher skin scores, while DM patients with calcinosis were significantly younger, had higher sedimentation rate and had higher incidence of anti SAE and NXP2 antibodies compared to DM without calcinosis (Table 1). Clinical manifestations associated with calcinosis in SSc were digital ulcerations, telangiectasias, and acro-osteolysis, while in DM associated factors were skin ulcers and inflammatory arthritis.

PON1 paraoxonase activity was significantly lower in SSc patients with calcinosis compared to SSc without calcinosis, and a similar trend was seen within each DM cohort (Figure 1-a). Association between calcinosis and low PON1 was significant when the two DM cohorts were combined (Figure 1-b). Multivariate models adjusting for age, sex and disease duration demonstrated that the association between low paraoxonase and calcinosis was significant in SSc, in DM total (DM1+DM2) and in all 3 cohorts combined (SSc+DM1+DM2) (Table 2). SSc patients overall had a significantly lower paraoxonase activity compared to DM (p=0.0002), and SSc patients with calcinosis had the lowest paraoxonase activity.

Figure 1. Paraoxonase in SSc and DM patients with and without calcinosis



Paraoxonase levels compared between patients with and without calcinosis. Box plots for median[IQR]. Paraoxonase is log transformed for normal distribution. (a) comparison within each cohort, (b) comparison within disease subgroup with DM1+DM2 as DM total group. P value by student's t-test

Model 3	0.68[0.57-0.80]	<0.0001	0.67[0.51-0.87	0.003	0.78[0.65-0.93]	0.005

Multivariate logistic regression for calcinosis ever. Paraoxonase is log transformed for normal distribution. All models adjusted for repeated measures.

Model 1: adjusted for age
Mode 2: adjusted for age and sex
Model 3: adjusted for age, sex and disease duration

Conclusion: In our current work, calcinosis was observed in 40% of SSc and 13% of DM patients. Calcinosis was associated with longer disease duration and ulcerations in both SSc and DM. Impairment in the activity of the PON1 enzyme, which normally protects the vascular endothelium from oxidative injury, was associated with the presence of calcinosis in both DM and SSc patients, suggesting potential involvement in the disease pathogenesis.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1191–1220) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: With therapeutic advances in idiopathic inflammatory myopathy (IIM), achieving remission has become an important goal. However, comprehensive data on remission, particularly across IIM subtypes, remain limited. **This stu**dy assessed remission rates and identified predictors of remission in a prospective IIM registry.

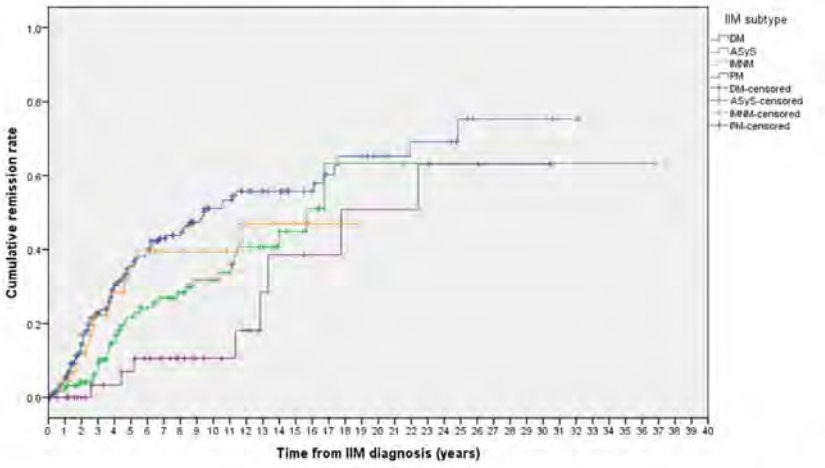
Figure 1. Cumulative first remission rate according to IIM subtype



Abbreviations: ASyS, antisynthetase syndrome; DM, dermatomyositis; IIM, idiopathic inflammatory myopathy; IMNM, immune-mediated necrotizing myopathy; PM, polymyositis

Methods: We analyzed data from adult IIM patients enrolled at the University of Pittsburgh Myositis Center between January 2000 and March 2019. The "remission cohort" included 430 patients with a disease duration of ≥1 year or those who died within the first year (categorized as non-remission). We focused on four IIM subtypes: dermatomyositis (DM), antisynthetase syndrome (ASyS), immune-mediated necrotizing myopathy (IMNM), and polymyositis (PM), according to the physician's judgement based on the 2017 EULAR/ACR classification criteria. ASyS was further defined by clinical symptoms and ASyS antibodies, while IMNM was further defined by clinical symptoms and either anti-HMGCR antibody, anti-SRP antibody, or consistent muscle biopsy. Overlap syndromes and inclusion body myositis were excluded. Remission was defined as the absence of disease activity based on expert clinical assessment, either while receiving stable/de-escalating therapy or off medication. Predictive factors for remission were analyzed using a Cox proportional hazard model in a subcohort of 346 patients with ≥1 year of follow-up post-enrollment.

Results: Among 430 patients (67.4% female, 88.5% white, mean age at diagnosis 50.2 ± 14.3 years), the median follow-up time was 5.1 (IQR 1.2 – 10.1) years, and the median disease duration at last visit was 7.5 (IQR 3.1 – 12.4) years. The remission rate at 12 months post-diagnosis was 3.5%, while the overall remission rate was 35.3%. IIM subtype-specific 12-month and overall remission rates were: DM (5.0%, 42.5%), ASyS (1.6%, 28.0%), IMNM (4.4%, 33.3%), and PM (0.0%, 20.5%) (Table 1 and Figure 1). The median time from diagnosis to first remission was 3.8 (IQR 2.0 – 6.3) years. Flares after remission occurred in 27.0% of patients after median 3.5 (IQR 1.6 – 7.0) years. The overall drug-free remission was achieved in 18.6% of patients, with rates by subtype: DM 23.1%, ASyS 15.2%, IMNM 17.8%, and PM 7.7%. In univariate analysis, predictors of higher remission included non-white/black race (i.e., other), DM subtype, and anti-Mi2 antibody, while predictors of lower remission included PM subtype, interstitial lung disease, pulmonary hypertension, and anti-SSA antibody. In multivariate analysis, non-white/black race (HR 9.79, $P<0.001$) and anti-Mi2 antibody (HR 1.92, $P=0.023$) were independently associated with increased remission likelihood, whereas PM subtype (HR 0.37, $P=0.033$) and pulmonary hypertension (HR 0.37, $P=0.004$) were independently associated with decreased remission likelihood (Table 2).

Conclusion: Remission rates vary across IIM subtypes, with the highest rate in DM and the lowest rate in PM. Race, IIM subtype, autoantibody profile, and comorbid pulmonary hypertension significantly influence remission outcomes. These insights can inform individualized management and prognostication of IIM.

Measurement Properties of a Shorter Health Assessment Questionnaire (HAQ-II) in Patients with Inflammatory Myopathies

Sung-Ki Lee[1], Kristin Wipfler[2], Ethan Ritz[3], Burcu Aydemir[4], Kaleb Michaud[5] and Didem Saygin[6], [1]Rush Medical College, Chicago, IL, [2]FORWARD, The National Databank for Rheumatic Diseases, Omaha, NE, [3]Rush Research Informatics Core, Rush University Medical Center, Chicago, IL, [4]Northwestern University Feinberg School of Medicine, Chicago, IL, [5]University of Nebraska Medical Center, Omaha, NE, [6]Rush University Medical Center, Chicago, IL

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1191–1220) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are a group of autoimmune disorders characterized by chronic skeletal muscle inflammation leading to muscle weakness and limitations in physical function. Despite the clinical significance of functional impairments in IIM, there are few validated tools of physical function in this population. Even though the Health Assessment Questionnaire (HAQ) is widely accepted, data on its validity are limited. Further, its length and complex scoring system make it cumbersome in clinic, requiring development of a more efficient and validated measure of physical function in these patients. The HAQ-II is a shortened version of the HAQ with 10 items validated in RA. In this study, we aim to assess measurement properties of HAQ-II in evaluation of physical function in individuals with IIM.

Methods: Data were from adults enrolled in FORWARD -The National Databank for Rheumatic Disease- between 1999-2023. Participants had a physician diagnosis of IIM and completed the HAQ-II along with other items related to their disease, comorbidities, pain, fatigue, and quality of life. Internal consistency of HAQ-II was assessed using Cronbach's α. Floor and ceiling effects were calculated by identifying the proportion of minimum and maximum possible HAQ-II scores. Discriminant validity was assessed by comparing differences in baseline HAQ-II scores between relevant subgroups. Construct validity was evaluated by comparing HAQ-II scores and measures of physical health, including SF-36 physical functioning, patient global disease activity, fatigue, and pain using Pearson correlations based on a priori hypotheses derived from the literature. Responsiveness of HAQ-II was assessed using linear mixed models.

Results: A total of 192 participants with IIM (mean age 54.8 [±13.7]; 79.3% female) who completed the HAQ-II (mean 1.1 [±0.7]) were included in the study. Cronbach's α of HAQ-II was 0.93. Floor and ceiling effects were negligible with 7.8% and 0%, respectively. All a priori hypotheses for discriminant validity were met with significant differences in HAQ-II scores between participants with low vs high physical functioning, patient global disease activity, fatigue, and pain levels ($p < 0.0001$) (Table 1). Fifteen out of 17 a priori hypotheses (88.2%) were met for the construct validity of HAQ-II. HAQ-II had weak correlations with symptom duration, age, BMI, Rheumatic Disease Comorbidity Index, SF-36 mental component score, role limitations due to emotional problems and emotional well-being, moderate correlations with pain levels, fatigue levels, health satisfaction, SF-36 general health, and social functioning, and strong correlations with SF-36 physical

Table 1. Discriminant validity assessment of HAQ-II comparing scores between subgroups of individuals with IIM with low vs high physical functioning, patient global disease activity, fatigue, and pain.

Groups	HAQ-II	
	Mean (SD)	p value
SF-36 physical functioning <45	1.60 (0.53)	<0.0001
SF-36 physical functioning ≥45	0.59 (0.48)	
Patient global disease activity <4	0.60 (0.52)	<0.0001
Patient global disease activity ≥4	1.50 (0.55)	
Fatigue <4.5	0.68 (0.58)	<0.0001
Fatigue ≥4.5	1.42 (0.61)	
Pain <3	0.71 (0.66)	<0.0001
Pain ≥3	1.38 (0.57)	

*Groups stratified by median scores.

Table 2. Construct validity assessment showing a priori hypotheses and observed correlations between HAQ-II and other relevant variables.

Variables	HAQ-II		
	A priori hypotheses	Observed correlations (Rho)	Met?
Age	Weak	-0.005	Yes
Symptom duration	Weak	-0.005	Yes
Body mass index	Weak	0.27	Yes
Rheumatic disease comorbidity index	Weak	0.33	Yes
Pain level	Moderate	0.56	Yes
Fatigue level	Moderate	0.58	Yes
Patient global disease activity	Moderate	0.71	No
Health satisfaction	Moderate	-0.55	Yes
SF-36 PCS	Strong	-0.79	Yes
SF-36 MCS	Weak	-0.29	Yes
SF-36 Health Concepts:			
SF-36 Physical functioning	Strong	-0.87	Yes
SF-36 Role limit due to physical health	Strong	-0.67	No
SF-36 Pain	Moderate	-0.56	Yes
SF-36 General health	Moderate	-0.50	Yes
SF-36 Vitality	Moderate	-0.59	Yes
SF-36 Social functioning	Moderate	-0.60	Yes
SF-36 Role limit due to emotional problems	Weak	-0.36	Yes
SF-36 Emotional well being	Weak	-0.34	Yes

Table 3. Linear mixed models examining the relationship between longitudinal change* in HAQ-II and other outcome variables over time after controlling for age, sex, and obesity.

Variables	HAQ-II	
	Beta [CI]	P value
Pain level	0.08 [0.06 – 0.09]	<0.0001
Fatigue level	0.08 [0.06 – 0.09]	<0.0001
Patient global disease activity	0.07 [0.06 – 0.08]	<0.0001
SF36 Physical Component Score	-0.03 [(-0.04) - (-0.03)]	<0.0001

component score and physical functioning (Table 2). After controlling for age, sex, and obesity, change in HAQ-II was significantly associated with change in pain, fatigue, patient global disease activity, and SF-36 PCS (Table 3).

Conclusion: HAQ-II demonstrated good internal consistency, validity, and responsiveness in assessing physical function in individuals with IIM. Our findings support the HAQ-II as a valid and practical instrument and support its application in both clinical and research settings.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1191–1220) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II

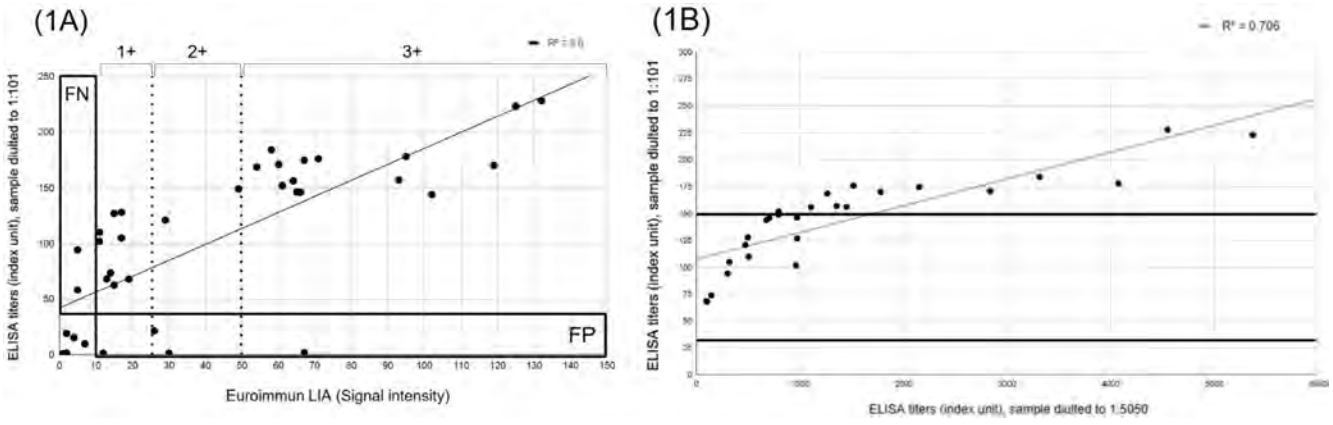
Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Although immunoprecipitation (IP) remains the gold standard for detecting myositis autoantibodies, it is technically demanding and not widely available. Line immunoassay (LIA) has become a primary diagnostic tool in many centers but is prone to false positives and negatives, which may lead to inappropriate treatment—particularly in anti-MDA5 patients at risk of rapidly progressive interstitial lung disease (RPILD). Commercial anti-MDA5 ELISA tests have shown comparable performance to IP and may offer prognostic value, especially with additional sample dilution. We aim to validate the performance of LIA for detecting anti-MDA5 using commercial ELISA as reference and explore the clinical utility of ELISA in a Taiwanese medical center.

Methods: Our center uses the Euroimmun 16-antigen LIA panel for myositis antibodies. Samples with anti-MDA5 positivity on LIA and those with clinical features suggestive of anti-MDA5 disease (e.g., RPILD, cutaneous findings) but LIA-negative were further tested using a commercial anti-MDA5 ELISA (MBL, Japan). ELISA was performed at 1:101 dilution per the manufacturer's protocol and at 1:5050 per Gono et al. Two rheumatologists confirmed the final diagnosis based on clinical course.

Results: We analyzed 40 samples from 33 patients. LIA had 4 false positives and 2 false negatives, yielding a sensitivity of 0.93 and specificity of 0.64. Three of four false positives showed moderate or strong LIA signals. Restricting interpretation to moderate/strong positives improved specificity (0.73) but reduced sensitivity (0.62). Both false negatives occurred in RPILD cases: one patient survived after early immunotherapy guided by timely ELISA, while the other died before ELISA results were available. Among the four false positives, two had mechanic's hands but lacked typical anti-MDA5 features, and the other two had ILD due to other causes.



(A) The correlation between LIA signal intensity and ELISA (standard dilution 1:101). (B) The correlation ELISA with standard dilution (1:101) and dilution of 1:5050. Abbreviations: LIA: Line blotting assay, FN: false negative, FP: false positive

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2: Association of antibody signal intensity (LIA)/ELISA titers and prognosis of patients (morality vs alive).

Among ELISA-positive samples, 45% (13/29) exceeded the 150 IU upper limit at 1:101 dilution, masking antibody titer differences. Dilution to 1:5050 revealed clearer stratification (Figure 1B), with higher titers more strongly associated with poor outcomes (median 1515 vs. 882, p=0.059). In comparison, neither the 1:101 dilution (164 vs. 145 IU, p=0.27) nor LIA signal (64 vs. 57.5, p=0.59) significantly predicted outcome (Figure 2).

Conclusion: Commercial ELISA is a valuable confirmatory tool for anti-MDA5 diagnosis, especially where IP is unavailable and LIA is the standard. ELISA reduces misclassification by LIA and improves treatment guidance. High antibody titers often exceed the ELISA kit's standard detection range, and additional dilution (1:5050) enhances outcome prediction and better identifies high-risk patients.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1191–1220) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: The impact of social determinants of health (SDoH)—including socioeconomic status, social support, and geographic context—on disease outcomes in idiopathic inflammatory myopathies (IIM) remains underexplored. We aimed to assess the association between SDoH and disease-related patient-reported outcomes (PROs) in patients with IIMs.

Methods: Data were derived from the third phase of the Collating the Voice of Autoimmune Diseases (COVAD) global e-survey, conducted in 111 countries across multiple languages [**Fig.1A**]. Descriptive (median, IQR), comparative, regression, and cluster analyses were used to explore associations between SDoH indicators and key patient-reported outcomes [**Fig.1B**].

Results: From a total of 14902 respondents, 1252 patients with IIM (including DM, PM, IBM, NAM, ASyS, OM, JDM, and CAM), diagnosed by a physician (either a rheumatologist, neurologist, dermatologist or internist), were included [**Fig.1C**]. The median age was 59 (47-70) years, with 69% females, 70% Caucasian/White, 24% holding postgraduate degrees, 32% smokers, and 61% alcohol consumers, with a median disease duration of 8 (3-16) years [**Tab.1**].

Half of IIM patients reported high trust in healthcare, 47.2% had little or some trust, and 3.4% reported none [**Fig.2A**]. In comparison, 74% had insurance, 32.2% trusted in their insurer, 52% live comfortably with the household income, and the median household size was 2 people. Adaptation, partnership, growth, affection, and resolve (APGAR) family score was estimated as 13 (10-15) [**Fig.2B**]. Among the 62% of participants not providing care for others, the majority were men (80%, $p< 0.001$), unlike the women caring for older adults (7.3%, $p=0.001$) and disabled relatives (3.9%, $p=0.016$). The age of retirement was 60 (53-65), with 52% reporting this was because of the IIM diagnosis.

Higher income was associated with better physical function (PROMIS PF 4a, $\beta=3$, $p< 0.001$), less fatigue ($\beta = -1.12$, $p< 0.001$), and reduced pain ($\beta = -1.8$, $p< 0.001$), along with greater resilience (Brief Resilience Score, BRS score ranged 6-30) ($\beta = 1.52$, $p=0.02$). Better family function was positively associated with better overall health perception (PROMIS global, $\beta = 0.3$, $P< 0.001$) and resilience ($\beta = 0.45$, $p< 0.001$), and modestly linked to lower pain levels ($\beta = -0.15$, $p< 0.001$) [**Fig.2C**]. Trust in the insurer and type of insurance coverage were largely unrelated to PROs. Cluster analysis revealed three IIM clusters: (1) characterized by the best PROMIS scores and family function, (2) reflects the most severely affected group, with the lowest PROMIS scores, highest fatigue and pain levels, and the highest disease activity, while the least employed and report low family function, and (3) a younger, high-functioning group but lower HDI and family function.

Conclusion: SDoH play a significant role in influencing the outcomes in IIM. Factors, such as trust in healthcare, financial stability, and social support are associated with improved PROs, while socioeconomic disadvantage increases disease burden. These findings underscore critical priorities for healthcare providers and policymakers.

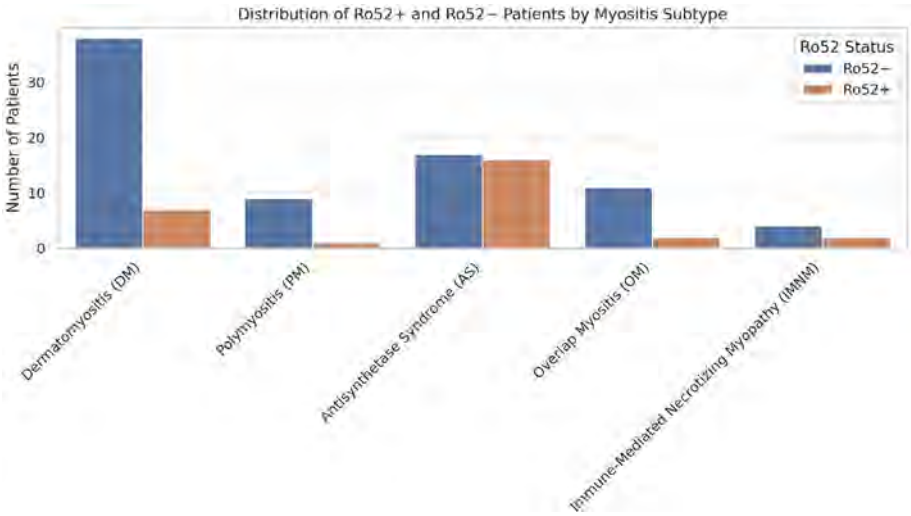
Venn diagramms depicting coexistence of anti-Ro-52 with with most common MAA (anti-Jo1, anti-PL7, anti-PL12)on the left and most common MSA (anti-TIF1γ, anti-Mi2, anti-MDA5) on the right in our cohort.



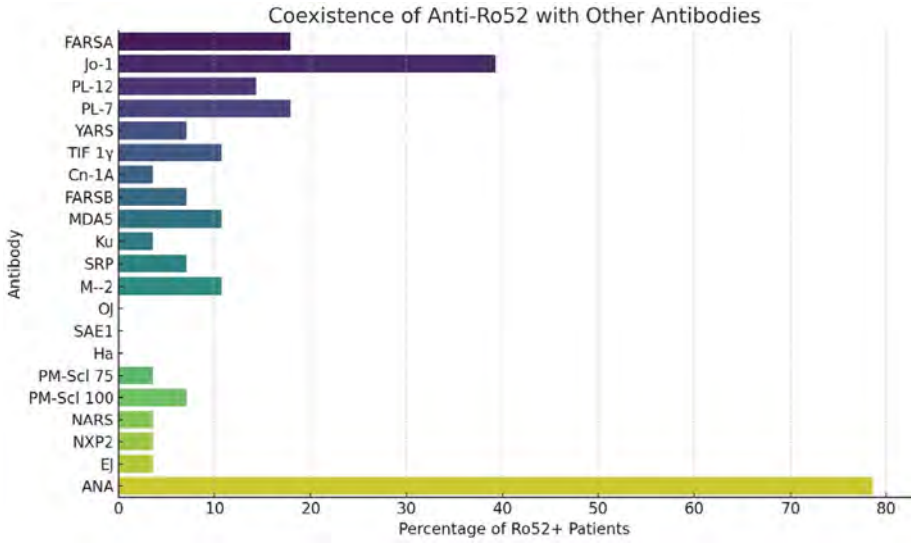
Disease subtypes distribution across our cohort. Blue box represents anti-Ro52(-) while orange box anti-Ro52(+) cases

Background/Purpose: Anti-Ro52 antibodies are commonly detected in idiopathic inflammatory myopathies (IIMs), yet their clinical significance remains incompletely defined. There is evidence that it coexists with anti-synthetase antibodies (ARS). We aimed to investigate the phenotype, survival and antibody coexistence of anti-Ro52 patients within a IIM cohort.

Methods: Retrospective analysis with clinical information regarding skin (CDASI score, typical signs), muscle (MMT-8 score, CPK levels), lung involvement (CT thorax pattern and % predicted Forced Vital Capacity), dysphagia and survival in months, laboratory test (ferritin, LDH, WBC, Hb) and autoantibody profile was performed. Antibody test for Myositis Specific Autoantibodies (MSA) and Myositis Associated Autoantibodies (MAA) was done with myo blot and ANA with indirect immunofluorescence.

Results: A total of 107 patients were analyzed, including 28 (26.2%) positives for anti-Ro52. Anti-Ro52 positivity was significantly associated with antisynthetase syndrome (AS) ($p = 0.009$), with post hoc analysis revealing that AS patients were disproportionately represented among Ro52-positive individuals (standardized residual +2.5). Antibody coexistence was significant for anti-Jo1 ($p=0.001$) and anti-FARS ($p< 0.001$).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Bar chart with coexistence of percentage of anti-Ro52 (+) with other autoantibodies

Patients with anti-Ro52 antibodies were diagnosed at a younger age (mean= 55.6 SD ± 12.36 vs. 61.4 years SD ±12.52, p = 0.039) and exhibited significantly lower FVC% at diagnosis (mean=72.1% SD ± 22.21 vs. 88.3% SD ±14.56, p = 0.001). Lung involvement was significantly more frequent in Ro52-positive patients (64.3% vs. 35.4%, p = 0.015), and CT thorax patterns differed by antibody status (p = 0.015), with non-specific interstitial pneumonia (NSIP) more prevalent among Ro52-positive patients (standardized residual +2.1). While overall survival was lower in the Ro52-positive group, the difference was not statistically significant (p=0.39).

No significant differences were observed in malignancy rates, skin involvement (CDASI score and main typical skin signs), muscle involvement (MMT-8 score, CPK levels) . No difference was seen in main commorbidities including Hypertension, diabetes, coronary artery disease, hypothyroidism and osteoporosis (p=ns). Anti-Ro52-(+) patients did not differ in performance status. Although there was a trend towards more severe scores (PS3 or 4)p=0.09.

Conclusion: These findings highlight a potential role of anti-Ro52 as a marker of severe, lung-predominant IIM phenotype but they do not support any other distinct clinical and radiographic profile associated with anti-Ro52 antibodies.

Figure PPF-associated features across IIM-ILD subtypes classified by MSA

Background/Purpose: Interstitial lung disease (ILD) in idiopathic inflammatory myopathies (IIM) causes worse prognosis. Some patients develop progressive pulmonary fibrosis (PPF) despite appropriate treatment. Identifying predictors of PPF in IIM patients is crucial for clinical management.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Patients with IIM hospitalization from 2015 to 2024 were retrospectively collected to identify factors associated with PPF using the American Thoracic Society, European Respiratory Society, Japanese Respiratory Society and Asociación Latinoamericana de Thórax guidelines PPF criteria published in 2022.

Results: ILD presented in 68.5% of IIM patients (344 /502). During follow up, 28.5% (82/288) developed PPF. The median interval from ILD diagnosis to PPF onset was 10 months. The median daily glucocorticoid dose methylprednisolone equivalents at PPF development was 10 mg, among anti-MDA5+ patients it was 40 mg (Figure). In IIM-ILD patients, the top three positive myositis-specific antibodies (MSAs) were anti-Jo-1 (24.1%), anti-MDA5 (21.5%) and anti-EJ (10.8%), and in IIM-PPF patients were anti-MDA5 (30.5%), anti-Jo-1 (29.3%) and anti-EJ (18.3%). Compared to non-ILD patients, those with ILD were older, more frequently anti-Ro52+ (73.3% vs. 39.2%, P< 0.001), and had higher Krebs von den Lungen-6 (KL-6), carcinoembryonic antigen (CEA) at baseline. Among IIM-ILD patients, PPF patients exhibited older age at onset, higher fever (56.1% vs. 34.5%, P=0.001) and oral ulcer prevalence (11% vs. 2.9%, P=0.014), higher CEA [2.83(1.92, 5.46) vs. 1.95(1.3, 3.27) ng/ml, P< 0.001], more frequent anti-MDA5+ (30.5% vs. 12.9%, P< 0.001), and ground-glass opacity on chest high-resolution CT (89% vs. 78%, P=0.032) (Table). In contrast, patients without PPF had higher anti-PL-7 positivity (11.4% vs. 2.4%, P=0.015), better diffusing capacity for carbon monoxide (58.78%±16.53% vs. 52.29% ±15.66%, P=0.007), and more frequent MMF use (21.4% vs. 9.8%, P=0.021) (Table). KL-6 levels remained statistically comparable between baseline and time of PPF (P=0.23). CEA levels were higher in PPF group [2.83 (1.92-5.46) vs. 1.95 (1.30-3.27) ng/ml, P< 0.001] and longitudinal analysis revealed a marked increase from baseline to PPF [2.79(1.59-5.56) vs. 2.84(1.63-4.91) ng/ml, P=0.03]. Multivariate COX analysis identified fever [HR=2.21, 95%CI (1.39, 3.53), P=0.001], oral ulcer [HR=2.44, 95%CI (1.08, 5.50), P=0.031] and CEA [HR=1.11, 95%CI (1,05, 1.17), P< 0.001] as independently risk factors for PPF, while anti-PL7+ [HR=0.075, 95%CI (0.02, 0.36), P=0.001] and proximal upper limb weakness [HR=0.40, 95% CI (0.19, 0.85), P=0.017] as protective factors.

Conclusion: Manifestations of fever, oral ulcer and higher level of CEA at baseline were independently risk factors for PPF, especially among patients with specific autoantibodies. Close monitor of patients' symptom progression and timely scheduling of chest HRCT and PFTs are necessary, when daily glucocorticoid dose tapering to about 10 mg methylprednisolone equivalent. CEA level at baseline may represent a more promising biomarker candidate for identification of PPF.

Background/Purpose: Oxytocin, also known as love hormone, is important in contextual memory. Oxytocin secreting parvocellular neurons suppress pain through projections to brain and spinal cord besides endocrine action. Optogenetic activation of Oxytocin neurons relieved pain in a rodent model of Fibromyalgia. We had previously shown association of rs6754031 (GG) promoter polymorphism in SCN9A with Fibromyalgia. This hypothalamic expressed voltage sodium channel Nav1.7 is upregulated in stress and its activity is linked to Oxytocin secretion. Hence, we studied SNPs rs4273468, rs3796863 and rs1556314 in genes BST1 (CD157), CD38 and TRPM2 genes involved in hypothalamic Oxytocin secretion. BST1 and CD38 catalyze the formation of cyclic ADP Ribose from NAD+ while TRPM2 is involved in Calcium secretion triggered by cyclic ADP Ribose. The minor alleles of the chosen SNPs are sufficiently common in our population and previously found to be associated with diseases such as Post Traumatic Stress Disorder and Restless Leg Syndrome that are themselves associated with Fibromyalgia

Methods: Patients diagnosed as Fibromyalgia using ACR1990 and/or ACR2016 criteria and consenting to genetic study were included. Healthy subjects with no widespread pain or connective tissue disease or medical comorbidity were taken as controls. Subjects were the same as our prior SCN9A study. DNA was extracted by phenol-chloroform method.

Table 1. Clinical features of FMS cohort

Clinical feature	FMS (n-118)	1990 ACR (n-11)	1990 + 2016 ACR (n-74)	2016 ACR (n-33)	p-value

BST1 polymorphism rs4273468 genotype homozygous GG protects from Fibromyalgia

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Genotyping was done by TaqMan real time PCR. All continuous variables among baseline characteristics are expressed in mean (SD) and comparison by one way ANOVA while Fisher's exact test was used for frequency tables. Odds Ratios and confidence intervals were estimated using Logistic Regression using a recessive minor allele (G) model using STATA14

Results: A total of 118 FMS patients (88% female) of mean age of onset 35 (±9.6) years and 118 healthy controls (78% female) of age 34.7 (±10.9) years were included. Clinical features and comorbidities of patients are given in Table 1. Of the 118 patients, 74 were classified Fibromyalgia by both ACR2016 and ACR1990 criteria while 33 and 11 subjects were classified by ACR2016 and ACR1990 alone respectively. All three SNPs were in Hardy Weinberg equilibrium. Homozygous GG allele of BST1 rs4273468 polymorphism was protective with an **Odds Ratio of 0.058 (0.0075-0.44, P< 0.001**). The rs3796863 polymorphism of CD38 and rs1556314 of TRPM2 did not show any association with Fibromyalgia.

Conclusion: This is the first study showing association of BST1/CD157 with Fibromyalgia. This SNP rs4273468 in BST1 has previously been associated with Idiopathic Restless Leg Syndrome. Genes in the Oxytocin secretion pathway names BST1, CD38, TRPM2 and Oxytocin Receptor gene require further study.

Efficacy of Fasinumab, An Anti-Nerve Growth Factor Monoclonal Antibody, in Managing Chronic Musculoskeletal Pain: A Systematic Review and Meta-Analysis

Ahmed Abouelella[1], Mohammad Alhasan[2], Ahmed Hamoudah[3], Ayman Ibrahim[4], Ola O.A. Abuzied[5], Mansoor Al-Tamimi[6] and Muhammed Elhadi[7], [1]Faculty of Medicine, Benha University, Benha, Al Qalyubiyah, Egypt, [2]Health Education England Internal Medicine Training (Cambridge), Cambridge, United Kingdom, [3]Libyan International University, Sarasota, FL, [4]University of Gezira, Medina, Saudi Arabia, [5]University of Khartoum, Khartoum, Sudan, [6]Faculty of Medicine, Cairo University, Cairo, Egypt, [7]University of Tripoli, Huston, TX

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1221–1247) Pain in Rheumatic Disease Including Fibromyalgia Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Chronic musculoskeletal pain can be a significant source of disability and poor quality of life in adults. Many patients do not achieve adequate relief with standard treatments, highlighting the need for novel therapies. Nerve growth factor (NGF), released by pro-inflammatory cells, is crucial in pain signalling, with elevated levels found in chronic pain patients. Fasinumab is a selective nerve-growth factor inhibitor that has shown efficacy in managing musculoskeletal disorders such as osteoarthritis (OA) and chronic low back pain (CLBP).

Methods: We conducted a systematic search in PubMed, Scopus, Embase, Web of Science, ClinicalTrials.gov, and Cochrane through April 25, 2025. Eligible studies were randomized clinical trials (RCTs) comparing the efficacy of Fasinumab against placebo or other analgesics in treating chronic musculoskeletal pain. Two independent reviewers completed screening and data extraction for each study. Primary efficacy outcomes were pooled mean difference from baseline to endpoint for pain levels, represented either as Western Ontario and McMaster Universities Arthritis (WOMAC) index or low back pain intensity (LBPI) numeric rating score, and physical function represented as either WOMAC index or Roland Morris Disability Questionnaire (RMDQ) score. The secondary outcome was pooled change from baseline for Patient Global

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Assessment (PGA). We used a random-effect model for all the analyses conducted. Outcomes were reported as standardized mean difference (SMD) with a 95% confidence interval (CI).

Results: A total of eight RCTs (12118 patients) met the inclusion criteria, comprising seven OA and one CLBP trial. Two trials included NSAIDs as a comparator. The pooled analysis for Fasinumab against placebo indicated statistically significant pain reduction and physical function improvement; SMD (95%CI) = -0.38 (-0.45: -0.3), p< 0.001, and -0.41 (-0.48: -0.33), p< 0.001, respectively. The pooled mean difference against NSAIDs regarding pain level and physical function was statistically significant; SMD (95%) = -0.19 (-0.29: -0.09), p< 0.001, and -0.21 (-0.3: -0.12), p< 0.001, respectively. Additionally, PGA improvement was statistically significant against placebo and NSAIDs; SMD = -0.25 (-0.33: -0.17), p< 0.001, and -0.11 (-0.2: -0.02), p=0.02, respectively.

Conclusion: This meta-analysis shows that Fasinumab has promising results in managing chronic musculoskeletal pain and suggests it may be superior to placebo or conventional analgesics. Further studies involving more intervention arms are needed to come up with a more definitive answer.

Abstract Number: 1223

Pain and Fibromyalgia Across Autoimmune and Inflammatory Diseases in the AMP AIM Cohort

Alexis Ogdie[1], Astrid Rasmussen[2], Dana Orange[3], Michelle Petri[4], Caroline Shiboski[5], Rebecca Haberman[6], Mala Masson[7], Daniel Goldman[4], Peter Izmirly[8], Brooke Cohen[9], Jennifer Seifert[10], Jennifer Anolik[11], Wade DeJager[12], Alan Baer[13], Jill Buyon[14], Yvonne Lee[15] and Accelerating Medicines Partnership: Autoimmune and Immune-Mediated Diseases Network (AMP AIM), [1]Department of Medicine, Perelman School of Medicine at the University of Pennsylvania, Wilmington, DE, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]The Rockefeller University, New York, NY, [4]Johns Hopkins University School of Medicine, Timonium, MD, [5]University of California San Francisco, San Francisco, CA, [6]NYU Langone Health, New York, NY, [7]NYU Langone Medical Center- Division of Rheumatology, New York, NY, [8]New York University Grossman School of Medicine, New York, NY, [9]Yale Physician Associate Program, New Haven, CT, [10]University of Colorado and Oklahoma Medical Research Foundation, Aurora, CO, [11]University of Rochester Medical Center, Rochester, NY, [12]Oklahoma Medical Research Foundation, Oklahoma City, [13]Johns Hopkins University School of Medicine, Baltimore, MD, [14]NYU Grossman School of Medicine, New York, NY, [15]Northwestern University, Chicago, IL

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1221–1247) Pain in Rheumatic Disease Including Fibromyalgia Poster

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: The Accelerating Medicines Partnership Autoimmune and Immune-Mediated Diseases (AMP AIM) network seeks to understand the cellular and molecular interactions that lead to inflammation and autoimmune diseases. Pain is among the most common symptoms in patients with these diseases, and up to one third have concomitant fibromyalgia. Little is known about how the experience of chronic pain differs across rheumatic diseases and whether it impacts patients with these conditions similarly or differently. The objective of this study was to examine differences in pain intensity, pain interference, pain distribution, pain catastrophizing, and the prevalence of fibromyalgia (FM) among patients with RA, SLE, PsA, Psoriasis (PsO), Sjögren's disease (SjD), and sicca symptoms without SjD (sicca).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. 	Medicaid	1 (5%)	2 (7%)	1 (3%)	9 (23%)	2 (5%)	2 (3%)	1 (2%)
	Medicare	2 (9%)	4 (15%)	4 (13%)	13 (33%)	7 (18%)	19 (29%)	24 (44%)
Chronic pain	3+ months	4 (18%)	22 (81%)	8 (26%)	32 (82%)	18 (47%)	50 (76%)	27 (49%)
	FMS Criteria	1 (5%)	6 (22%)	0 (0%)	12 (31%)	4 (11%)	20 (30%)	12 (22%)

RA = rheumatoid arthritis; SLE = systemic lupus erythematosus (predominantly those with kidney disease in this cohort); PsA = psoriatic arthritis; PsO = psoriasis without PsA; SjD = Sjogren's Disease; Sicca = sicca symptoms without SjD; FM = fibromyalgia

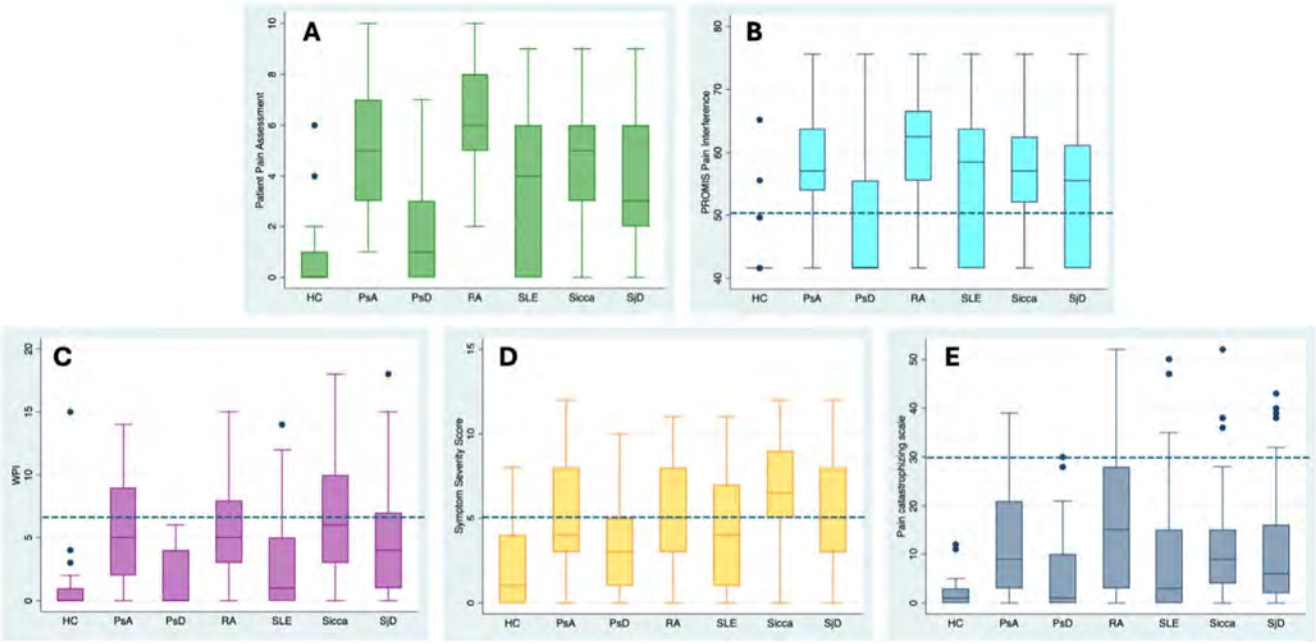

Figure 1. Pain measures across conditions Five pain measures across the enrolled diseases. (A) Pain intensity (0-10); (B) PROMIS Pain Interference scale; (C) WPI; (D) SSS; (E) PCS. Dotted line represents the general population norm (T-score 50) for PROMIS Pain Interference, the cut offs for the 2016 Fibromyalgia criteria for WPI and SSS, and the cut-off for catastrophizing for PCS. Abbreviations: RA = rheumatoid arthritis; SLE = systemic lupus erythematosus (predominantly those with kidney disease in this cohort); PsA = psoriatic arthritis; PsD = psoriasis without PsA; SjD = Sjogren's Disease; Sicca = sicca symptoms without SjD; HC = healthy control

Methods: A common set of patient-reported outcomes was administered to participants in 6 AMP AIM cohorts: RA, SLE (most with nephritis), PsA, PsO, SjD, and Sicca symptoms without SjD. We report demographics and differences among the disease states in the following measures: Pain intensity (0-10) and pain interference (T-score range 41.1-76.3) from the PROMIS-29; Widespread pain index (WPI) as a continuous measure (range 0-19); Symptom Severity Score (SSS) as a continuous measure (range 0-12); FM survey score (sum of WPI and SSS, range 0-31); Pain catastrophizing scale (PCS) (0-52 total score); Presence of FM defined using the 2016 criteria: chronic pain for 3 months or more, pain in 4/5 regions, (WPI ≥

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

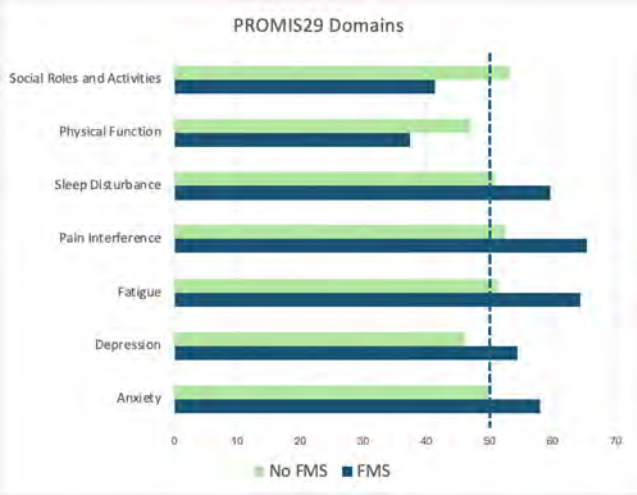

Figure 2. PROMIS29 by 2016 Fibromyalgia criteria The dotted line represents the population norm (50). For social roles and activities and physical function, lower number represent worse outcomes whereas for sleep disturbance, pain interference, fatigue, depression and anxiety, higher numbers represent worse outcomes. Abbreviation: FMS = fibromyalgia syndrome

7 and SSS ≥ 5) or (4 ≤ WPI ≤ 6 and SSS ≥ 9). We examined the differences in each of these PROs by disease and the presence or absence of FM.

Results: Among individuals enrolled in the AMP AIM study (Table 1), 39 participants with RA, 38 with SLE, 27 with PsA, 31 with PsO (without PsA), 55 with SjD, 66 with sicca symptoms but no SjD and 22 healthy controls completed the pain questionnaires. Mean age among the 6 groups varied by disease and ranged from 45 years old in SLE to 60 years in SjD. Sex was predominantly female (80% overall though 49% and 35% in PsA and PsO, respectively). 72% of participants were white, and 61% had a college education or higher. The prevalence of FM was 20% across the various cohorts, highest in participants with RA (31%) and participants with sicca symptoms but no SjD (30%), 22% in SjD, 11% in SLE, 22% in PsA, 5% in healthy controls and not observed in PsO. WPI and SSS scores varied among the groups but were also highest in participants with sicca symptoms but no SjD (Figure 1). PCS was lowest in healthy controls and PsO and similar among the other groups. Across all disease groups, PROMIS 29 scores were worse for participants with FM compared to those without FM (Figure2).

Conclusion: FM prevalence differed among these conditions and was associated with reduced quality of life and greater disease impact. Those with FM had worse PROMIS 29 scores. Patients with RA and those with sicca without SjD had the worst PROs and highest prevalence of FM. This trans-disease study emphasizes the importance of capturing chronic pain and leveraging AMP-AIM to address molecular and cellular mechanisms underlying this health burden.

Comparative Effectiveness of Duloxetine versus Pregabalin in Fibromyalgia: A Large-Scale, Real-World Study Across 300,000 Patients

Chukwuemelie Okeke[1], Queeneth Edwards[2], Ufuoma Mamoh[3], Justin Riley Lam[4] and Chekwubejah Uwakwe[5], [1]Maimonides Medical Center, Brooklyn, NY, [2]Department of Epidemiology and Biostatistics, Jiann-Ping Hsu College of Public Health, Georgia Southern University, Statesboro, GA, [3]Medstar Health Georgetown University Internal Medicine Residency Program, Baltimore, MD, [4]Jefferson Einstein Hospital, Philadelphia, PA, [5]Nnamdi Azikiwe University Teaching Hospital, Nigeria, Nnewi, Anambra, Nigeria

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1221–1247) Pain in Rheumatic Disease Including Fibromyalgia Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Fibromyalgia (FM) is a chronic, debilitating condition characterized by widespread pain, fatigue, and cognitive disturbances. Despite the availability of FDA-approved treatments, real-world comparative effectiveness data between duloxetine and pregabalin remain limited, particularly in diverse patient populations. Understanding which agent offers greater clinical durability and fewer adverse outcomes can inform personalized care in rheumatologic practice.

This study aims to compare the real-world effectiveness, tolerability, and healthcare utilization associated with duloxetine and pregabalin among patients diagnosed with fibromyalgia using a large multicenter electronic health record database.

Methods: This is a retrospective cohort study utilizing data from the TriNetX Global Collaborative Network, encompassing over 144 healthcare organizations worldwide. Adult patients (≥18 years) with a diagnosis of fibromyalgia (ICD-10-CM: M79.7) who received either duloxetine (Cohort A: n = 194,834) or pregabalin (Cohort B: n = 114,556) were identified. Patients receiving both drugs were excluded. Propensity score matching (1:1 greedy nearest-neighbor) adjusted for age, sex, comorbidities, and baseline medication use. Primary outcome was treatment durability (time to discontinuation or switch) over 3 years. Secondary outcomes included pain-related ED visits, new-onset psychiatric diagnoses, and adverse event profiles.

Results: Post-matching, each cohort comprised 113,402 patients. Duloxetine demonstrated a significantly longer median time to treatment discontinuation (HR: 0.82; 95% CI: 0.79–0.85; $p < 0.001$) and fewer discontinuation/switch events within 12 months (24.3% vs. 30.9%). Duloxetine users also had reduced pain-related ED visits (RR: 0.76; 95% CI: 0.71–0.81), and lower incidence of new-onset anxiety/depression ($p < 0.01$). In contrast, pregabalin users reported fewer GI side effects but had higher risks of sedation and weight gain (OR: 1.34; 95% CI: 1.29–1.39). Subgroup analyses revealed that patients with pre-existing mood disorders benefited more from duloxetine, whereas pregabalin performed better in elderly populations and those with neuropathic comorbidities.

Conclusion: In one of the largest real-world analyses of fibromyalgia treatment to date, duloxetine was associated with superior treatment persistence, fewer acute care needs, and improved psychiatric outcomes compared to pregabalin. These results support a precision medicine approach in selecting pharmacologic therapy for FM and call for prospective trials targeting specific patient phenotypes to optimize treatment efficacy and tolerability.

Association Between Anxiety and Tender Swollen Joint Difference in Patients with Rheumatoid Arthritis

Clarice Lin[1], Burcu Aydemir[2], Jing Song[3], Lutfiyya muhammad[2], Clifton Bingham[4], Tuhina Neogi[5], Wendy Marder[6], Marcy Bolster[7], Daniel Clauw[8], Dorothy Dunlop[9] and Yvonne Lee[1], [1]Northwestern University, Chicago, IL, [2]Northwestern University Feinberg School of Medicine, Chicago, IL, [3]Northwestern University Feinberg School of Medicine, Worthington, MN, [4]Johns Hopkins University, Baltimore, MD, [5]Boston University School of Medicine, Boston, MA, [6]University of Michigan, Ann Arbor, MI, [7]Massachusetts General Hospital, Concord, MA, [8]Chronic Pain and Fatigue Research Center, University of Michigan, Ann Arbor, MI, [9]Northwestern University Feinberg School of Medicine, Chicago

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1221–1247) Pain in Rheumatic Disease Including Fibromyalgia Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Some patients with rheumatoid arthritis (RA) have pain, despite normalization of inflammatory markers and reduced swollen joint counts. Among these patients, the number of tender joints often exceeds the number of swollen joints. Pollard et al. reported that a tender swollen joint difference (TSJD) ≥ 7 can identify patients with RA and comorbid fibromyalgia, the prototypical nociplastic pain condition.[1] Fibromyalgia and anxiety often co-occur, and previous studies suggest that psychological factors, such as anxiety, may heighten pain sensitivity. The objective of this study is to assess the relationship between anxiety and TSJD, as an indicator of dysregulated CNS pain processing, in patients with RA.

Methods: This analysis used baseline data from the Central Pain in RA (CPIRA) study, which enrolled 295 participants from four academic medical centers between January 2014 to April 2017. Patients met 2010 ACR/EULAR criteria for RA and were either starting DMARDs or switching DMARDs due to lack of efficacy. TSJD was calculated as the number of tender joints minus the number of swollen joints on a 28-joint exam. A higher TSJD indicates greater discrepancy between tender and swollen joint counts. A dichotomous outcome of high vs. low TSJD was defined using a cut-off of ≥ 7 vs. < 7. We

Table 1. Characteristics of Study Participants.

Characteristic	Overall (n = 276)	TSJD < 7 (n = 172)	TSJD ≥ 7 (n = 104)
Age, years	54.7 ± 13.9	54.8 ± 14.9	54.6 ± 12.0
Female (*n*, %)	226 (82%)	137 (80%)	89 (86%)
White (*n*, %)	207 (75%)	131 (76%)	76 (73%)
Body mass index, kg/m^2	28.6 ± 6.7	27.6 ± 6.6	30.2 ± 6.7
RA Symptom Duration, years	12.5 ± 12.7	11.9 ± 12.4	13.5 ± 13.2
Seropositive (*n*, %)	201 (72.8%)	130 (75.6%)	71 (68.3%)
PROMIS Anxiety, t-score	53.8 ± 8.9	52.5 ± 8.4	55.9 ± 9.3
CRP, mg/L	8.0 ± 12.4	8.7 ± 14.1	6.8 ± 8.6

Table 2. Results of Multivariable Logistic Regression Model, Adjusted Association between Anxiety and Presence of Higher Tender Swollen Joint Difference (TSJD ≥ 7) (n = 276)

Variables	Adjusted OR [95% CI]	p-value
Anxiety, t-score [a]	**1.05 [1.01, 1.08]**	**0.01**
Age, years	1.00 [0.995, 1.003]	0.68
Female	1.12 [0.97, 1.30]	0.12
White	1.01 [0.88, 1.15]	0.92
Seropositivity	0.93 [0.82, 1.06]	0.30
CRP, mg/L	1.00 [0.99, 1.001]	0.17
Body mass index, kg/m^2	**1.01 [1.01, 1.02]**	**<0.001**
RA Symptom Duration, years	1.00 [0.999,1.008]	0.16

a Per 5-unit increase in PROMIS Anxiety T-Score

evaluated associations between PROMIS anxiety t-scores and TSJD using logistic regression. Multivariable logistic regression models were adjusted for age, sex, race, body mass index (BMI), RA symptom duration, seropositivity, and C-reactive protein (CRP).

Results: Among 276 patients with RA (mean age (± SD) 54.7 ± 13.9 years, 82% female), 73% were seropositive for rheumatoid factor and/or anti-cyclic citrullinated peptide, and the mean RA symptom duration was 12.5 ± 12.7 years. The median TSJD was 4.0, (interquartile range of 0-10.3), with 38% having a TSJD of ≥ 7. The mean PROMIS anxiety score was 53.8 ± 8.9. In unadjusted analyses, higher anxiety was significantly associated with presence of higher TSJD (odds ratio [OR] for 5-unit change = 1.05, 95% confidence interval [CI]: 1.02, 1.09). In the multivariable regression model, anxiety remained significantly associated with higher TSJD (OR for 5-unit change = 1.05, 95% CI: 1.01, 1.08) (Table 2). Higher BMI was also significantly associated with higher TSJD.

Conclusion: Greater anxiety was associated with higher TSJD. RA patients with greater TSJD may benefit from a multimodal pain management approach that includes strategies for managing and monitoring symptoms of anxiety.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1221–1247) Pain in Rheumatic Disease Including Fibromyalgia Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Diagnosing juvenile fibromyalgia (JFM) in youth with chronic musculoskeletal (MSK) pain is challenging in the absence of a validated diagnostic tool. The Pain and Symptom Assessment Tool (PSAT) was developed from modifications to the ACR criteria for adult FM (2010) to aid in JFM diagnosis. This ongoing study aims to validate the PSAT as a diagnostic tool by demonstrating how measured differences in pain distribution and accompanying symptoms distinguish JFM from other causes of chronic MSK pain such as JIA or more localized painful disorders.

Methods: This multicenter, cross-sectional observational study enrolled English- and Spanish-speaking adolescents (age range: 11 – 17) with MSK pain of ≥3 months' duration and a clinical diagnosis of JFM, JIA, or localized MSK pain. All participants completed the PSAT, which included both assessment of pain location using the Michigan Body Map© (MBM) and a Symptom Severity Index (SSI) comprised of an inventory of associated symptoms with severity indices for fatigue, nonrestorative sleep, and impaired memory or concentration. One-way ANOVA was performed to look for differences in MBM totals and SSI between diagnostic groups, and post hoc analysis was carried out with Tukey's HSD test to determine the significance of between-group differences. Yunus and Masi's criteria for primary JFM (1985), which include ≥5 tender points on physical exam, were used by study staff as a diagnostic standard with which to evaluate all participants for clinical features consistent with JFM.

Results: A total of 158 participants were enrolled across 5 clinical sites. Participant diagnoses and characteristics are detailed in Figure 1. The average pain intensity rating among study participants was 5.7/10 (sd = 2.2), and 77/158 (49%) participants had ≥5 tender points on physical exam. Yunus and Masi's criteria were fulfilled by 47/60 (78%) participants with a clinical diagnosis of JFM and one participant with JIA. No participants with localized pain met these criteria. MBM totals and SSI both differed between diagnostic groups with $F(2, 155) = 43.43$ ($p < 0.001$, 95% CI [0.26, 1.00]) and $F(2, 155) = 25.79$

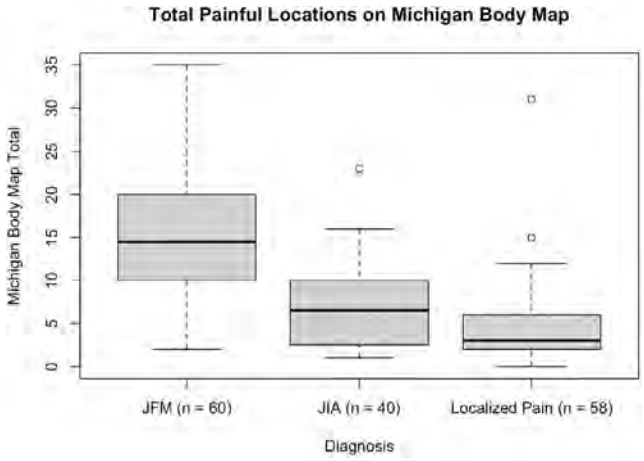

Figure 2: A box plot of total painful locations on Michigan Body Map (MBM) broken down by participant diagnosis. Center bars represent the median. Upper and lower limits of boxes are interquartile ranges. The limits of the whiskers are the full range with significant outliers excluded and plotted separately.

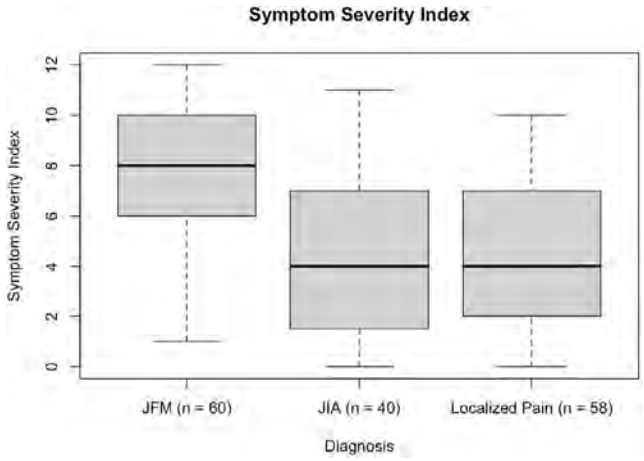

Figure 3: A box plot of participants' Symptom Severity Index (SSI) broken down by diagnosis. Center bars represent the median. Upper and lower limits of boxes are interquartile ranges. The limits of the whiskers are the full range.

($p < 0.001$, 95% CI [0.15, 1.00]), respectively. Post hoc analysis revealed significantly higher MBM totals and SSI among participants with JFM when compared to those with either localized MSK pain or JIA ($p < 0.001$). Figures 2 and 3 illustrate the distribution of MBM totals and SSI across participant diagnoses.

Conclusion: Analysis of these results from PSAT administration to adolescents with chronic MSK pain shows clear differences in measured pain distribution and symptom severity between those participants diagnosed clinically with JFM and those with other chronically painful MSK conditions. As recruitment for this study is ongoing, sensitivity and specificity of the PSAT in comparison with Yunus and Masi's criteria for the diagnosis of JFM will be determined following completion of further data collection and analysis. However, these preliminary results support the utility of the PSAT in distinguishing JFM from other causes of chronic MSK pain in pediatric patients, highlighting a valuable tool to improve the consistency of case definitions in research and ease diagnostic uncertainty in clinical care.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1221–1247) Pain in Rheumatic Disease Including Fibromyalgia Poster

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Over half of patients with RA report clinically meaningful pain, despite treatment with disease-modifying antirheumatic drugs (DMARDs). While joint inflammation is a known cause of pain in patients with rheumatic diseases, emerging data indicate that many patients also suffer from centralized or nociplastic pain. In our prior studies, we have used quantitative sensory testing (QST) to demonstrate that patients with RA have altered CNS pain processing compared to healthy controls and these alterations are associated with clinically meaningful outcomes. However, QST is time-consuming, requires significant assessor training, and is prone to measurement error. There is a critical unmet need to develop quantifiable measurements of the altered cellular state that distinguish patients with centralized pain.

Methods: In this study, we aimed to recruit 50 RA patients with minimal joint inflammation but varying levels of systemic inflammation and pain. All patients consented under the IRB protocol underwent QST to assess centralized pain and provided blood samples for immune profiling using state-of-the-art multi-parameter flow cytometry with a custom panel designed to identify key immune cell types and activation states. Frozen peripheral blood mononuclear cells (PBMCs) from patients in the study with the highest and lowest levels of nociplastic pain were additionally used to generate single-cell RNA-sequencing (scRNA-seq) libraries. These samples were individually labelled using hash tag oligomers (HTO) and pooled for library prep using 10X Genomics technology to reduce batch effect. The resulting sequencing data was processed with cellranger pipeline and analyzed using the Seurat package in R.

Results: We were able to collect 44 usable samples from patients who successfully consented and completed all study requirements. Of these, ~43% reported mild or moderate pain at the time of sample collection as measured by the numeric rating scale. Based on preliminary analyses of scRNA-seq from 6 patients among the highest and lowest pain levels, we annotated 3 subpopulations of T cells (Naïve CD4, Memory CD4, and CD8), NK cells, B cells, Plasma cells, Dendritic cells (DCs), and 2 subpopulations of Monocytes (CD14+ and CD16+/FCGR3A+). The high pain group exhibited decreased proportions of T cells and increased monocytes and DCs compared to the low pain group.

Conclusion: Our preliminary results indicate that the composition of circulating immune cells is associated with nociplastic pain in RA patients. With further analysis, we aim to validate these results in the larger dataset and determine whether there are robust transcriptional changes in specific cell types. Moreover, we are currently in the process of analyzing immunophenotyping data to assess composition and activation across pain levels. These studies provide novel insights into the role of circulating immune cells in altered CNS pain regulation in RA patients.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1221–1247) Pain in Rheumatic Disease Including Fibromyalgia Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Evidence-based behavioral treatments for chronic pain are largely inaccessible, particularly to rural patients. This decentralized randomized controlled trial compared the effectiveness of two digital, evidence-based chronic pain management programs—3D immersive Skills-Based Virtual Reality (EaseVRx+) and interactive pain coping skills training (painTRAINER)—in a rheumatic and musculoskeletal disease (RMD) and chronic pain population.

Methods: Patients were recruited from 3 large health centers and practice networks (Cedars-Sinai Medical Center; the University of Alabama and its affiliated Excellence Network in RheumatoloGY to Innovate Care and High-impact research; Ochsner Health System). Patients meeting study inclusion criteria (qualifying diagnostic code in medical record, primary residence ZIP code defined as rural, aged ≥13, ≥4 pain on 0-10 scale, without history of seizure, etc.) were identified within each participating network. Study coordinators screened individuals by phone; eligible and interested individuals were consented electronically. Participants were required to complete 7 daily baseline surveys which recorded demographics, daily pain intensity as measured by an 11-point pain numeric rating scale (NRS), and daily medication use prior to 1:1 randomization. Participants completed 16 REDCap surveys collecting pain intensity, medication use, and other PROs over 12 weeks. We measured the improvement in pain intensity between baseline and week 8, defined by a minimal clinically important difference (MCID) of 2 points on the standard 11-point numeric rating scale. Secondary outcomes included PROMIS anxiety and pain interference, pain catastrophizing, and pain self-efficacy.

Results: We randomized 330 participants: 169 to EaseVRx+ and 161 to painTRAINER, of which 46.7% were RMD patients. At Week 8, 278 (84.2%) participants completed the primary endpoint, demonstrating a high rate of treatment completion (Table 1). Average pain NRS improved in both arms (mean[SD] 1.22[1.48] units), however the intent-to-treat (ITT) analysis of the primary endpoint found no statistically significant difference in clinically meaningful pain reduction between the EaseVRx+ (22.9% achieving MCID >=2) and painTRAINER arms (32.0%) ($p = 0.088$) (Figure 1).

Between baseline and week 8, the mean (SD) changes in PROMIS pain interference, pain catastrophizing, PROMIS anxiety, and pain self-efficacy for Ease VRx+ and painTRAINER were -3.2 (6.0) vs. -4.5 (6.3), -1.7 (3.2) vs. -1.8 (3.5), -0.6 (7.6) vs. -0.3 (7.6), and 0.6 (2.8) vs. 1.5 (2.7), respectively. The group analyses were not statistically significant, except for pain self-efficacy (greater in the painTRAINER arm at weeks 6, 7 and 8) (Figure 2).

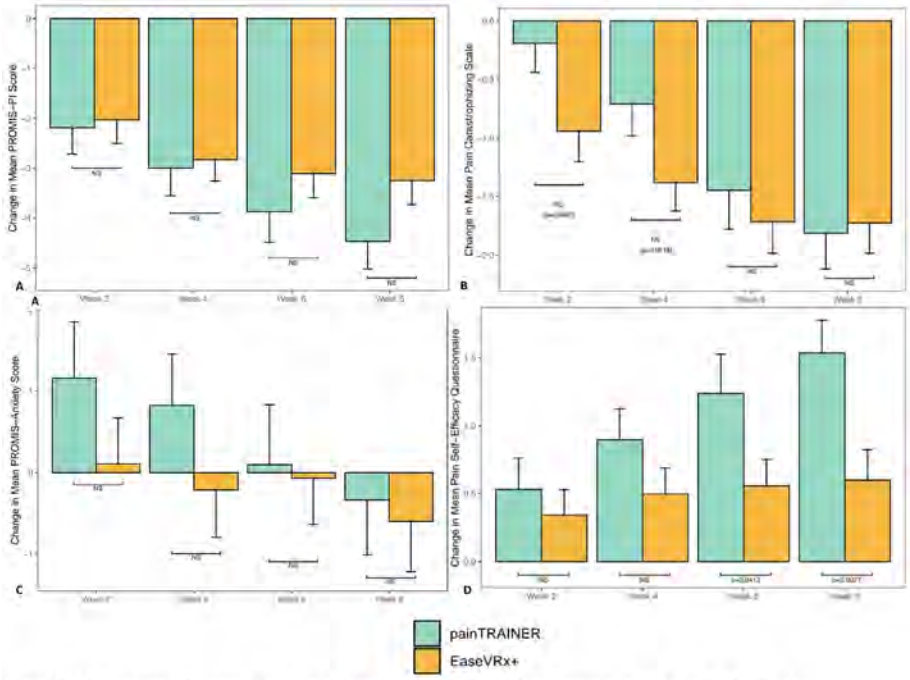
Figure 2: Mean Weekly Changes in PROMIS Anxiety and Pain Interference, Pain Catastrophizing, and Pain Self-Efficacy in painTRAINER and EaseVRx+



a. PROMIS Pain Interference, b. Pain Catastrophizing, c. PROMIS Anxiety, d. Pain Self-Efficacy

Conclusion: This trial displays the viability of implementing autonomous (self-paced) digital behavioral treatments for RMDs and chronic pain in rural areas, especially for patients without access to in-person behavioral treatment. EaseVRx+ and painTRAINER are effective and provide accessible behavioral pain treatment for chronic pain and could play a significant role in improving health equity in underserved populations.

Session Title: (1221–1247) Pain in Rheumatic Disease Including Fibromyalgia Poster

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background/Purpose: Over one third of older Americans experience chronic pain, accompanied by age-related increases in pain-related activity interference (i.e., pain burden). While pain extent (i.e., the number of reported pain sites) is often used as an indicator of this burden, extent tends to plateau or decline after midlife. Thus, it is unclear whether the same pain extent represents the same level of burden in oldest-old adults as it does in younger-old counterparts. Furthermore, there are different ways of assessing pain extent, some of which may better capture the impact of the chronic pain experience. We therefore estimated the prevalence and burden of several chronic pain definitions among older adults by age and sex.

Methods: We used data from a community-based sample of older adults from an ancillary study of the Framingham Heart Study/Omni1. We collected data on number and distribution of pain sites (articular, non-articular, and axial), pain duration, frequency, intensity, and interference with daily activities. We categorized participants with chronic pain (i.e., pain lasting ≥3 months) into 3 extent-based groups: 1) **chronic widespread pain (WSP)** as pain present above and below the waist, on the right and left sides of the body, and in the spine. 2) **chronic multisite pain** as pain occupying ≥3 body sites (and not meeting the WSP definition), and 3) chronic pain in 1-2 pain sites. We additionally characterized participants with bothersome or high-impact chronic pain (**B-HICP**) based upon high pain frequency, intensity, and interference from the Brief Pain Inventory. For each of the 4 pain categorizations, we compared their frequencies across age groups (52-70, 71-80, 81+ years) in a sex-stratified manner and assessed for linear trends. We also assessed mean pain interference from the Brief Pain

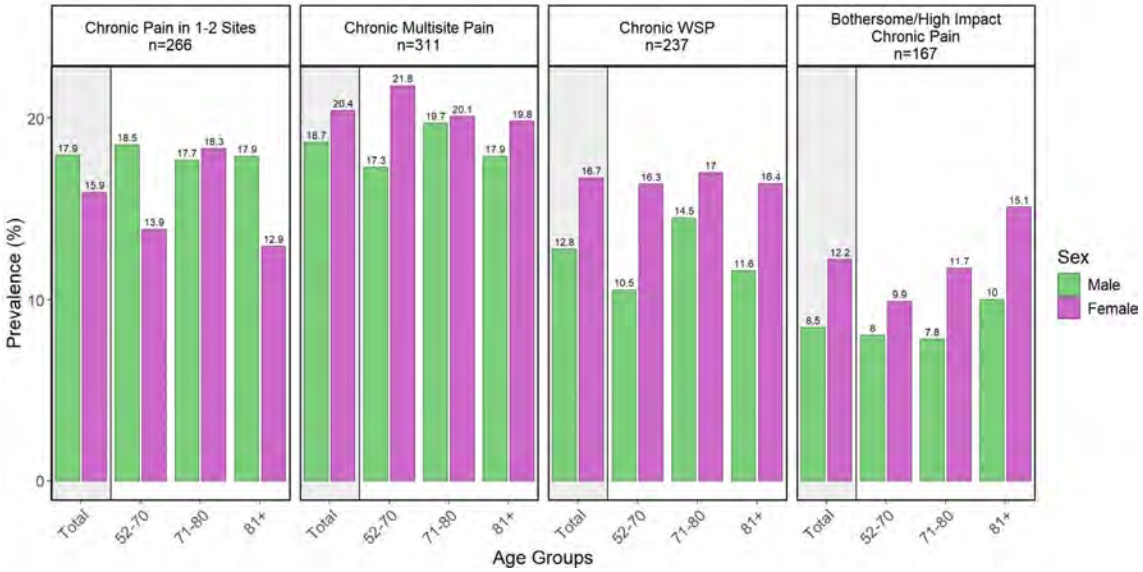

Figure 1: Pain prevalence by classification, stratified by age and sex.

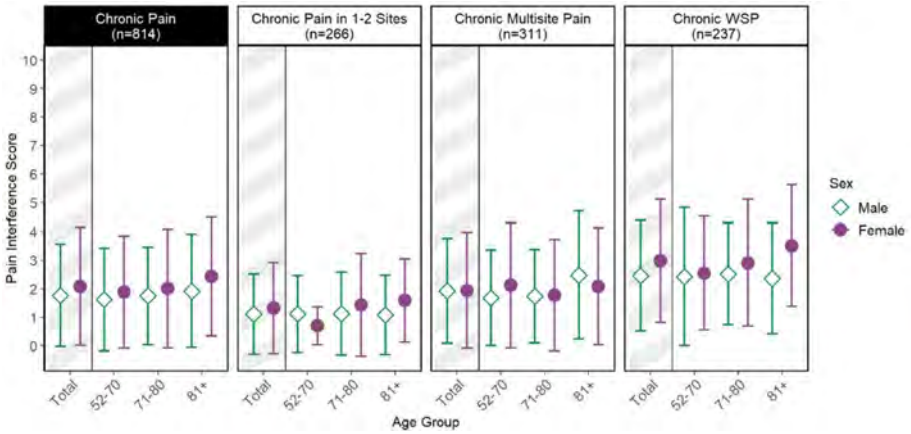

Figure 2: Pain interference score by pain classification, stratified by age and sex.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Inventory for each of the extent-based categorizations across age groups in a sex-specific manner using linear regression. We did not do so for B-HICP because pain interference is included in its definition.

Results: We included 1,584 participants (mean age, 76.1 ± 7.5; range 52-102 years; 56% female), of whom 52% had chronic pain, 36% had chronic multisite pain, 15.6% had chronic WSP, and 10.4% B-HICP (Figure 1). Prevalence of either chronic multisite or WSP did not increase with age ($p>0.05$; Figure 1). However, pain impact—as measured by pain interference and percent whose pain classified as B-HICP—did increase with age for women (both $p< 0.05$; Figures 1 & 2).

Conclusion: Our findings suggest that although pain does not become more widespread with advancing age in either men or women, pain burden does increase with age in women. Thus, similar numbers of pain sites contribute to a greater level of pain burden in oldest-old women than it does in younger-old counterparts. Pain impact measures that incorporate pain frequency, intensity, and pain interference, may better reflect burden than number of pain sites, especially among older women.

Chronic pain phenotypes in older adults: Identifying patterns of musculoskeletal pain and associated burden

Gillian Fennell[1], Sarah Tilley[2], Sayali Dhamne[3], Robert Edwards[4], Mary Gheller[3], Angelo Demalia[3], Margaret Clancy[3], Michael LaValley[5], Emelia J Benjamin[3] and Tuhina Neogi[6], [1]Boston University Medical, Boston, MA, [2]Boston University School of Medicine, Somerville, MA, [3]Boston University Chobanian & Avedisian School of Medicine, Boston, MA, [4]Brigham and Women's Hospital & Harvard Medical School, Boston, MA, [5]Boston University School of Public Health, Arlington, MA, [6]Boston University School of Medicine, Boston, MA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1221–1247) Pain in Rheumatic Disease Including Fibromyalgia Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Over a third of older Americans experience chronic pain, typically occupying multiple musculoskeletal body sites. While number of pain sites (NPS) is often touted as a stronger predictor of quality of life and physical functioning than pain location, studies identifying commonly co-occurring pain locations included younger individuals, whose pain location patterns likely vary from older adults with comorbid pain conditions and activity limitations. This study seeks to identify pain location patterns in older adults to elucidate the role of pain location on age-related pain burden.

Methods: We used data from a community-based sample of older adults from an ancillary study of the Framingham Heart Study/Omni1. We collected data on number and distribution of pain sites (articular, non-articular, and axial) on validated body and joint homunculi. We used an agnostic approach to identify patterns of pain locations. Specifically, we conducted a latent class analysis and used traditional model fit statistics (e.g., BIC, AIC, G2) to select the optimal number of classes. After identifying the optimal model, we examined mental and physical health-related quality of life (HRQoL), physical functioning, and pain interference by pain location pattern (i.e., class). For function, we assessed the Nagi functional impairment scale, Rosow-Breslau mobility scale, and Katz activities of daily living (ADLs) index; for pain interference, we used the Brief Pain Inventory, and for HRQOL, we used the mental and physical component scores from the Short Form-12.

MIN = minimal pain sites; Hand = predominantly hand/wrist pain; JT/AX = multisite joint and axial pain; Predom LE = predominantly lower extremity pain; Extensive = extensive articular and non-articular multisite pain.

Class	Label	# of sites	≥ 1 Nagi limitation	≥ 1 Rosow-Breslau limitation	≥ 1 ADL limitation	Pain interference	PCS	MCS
1	MIN	0.9	37.1%	19.8%	1.5%	0.77	51.0	55.7
2	Hand	4.4	54.0%	24.9%	0.6%	1.65	46.9	54.9
3	JT/AX	4.4	59.7%	31.6%	3.4%	1.75	45.3	55.8
4	Predom LE	5.8	63.3%	29.1%	6.0%	2.47	44.6	54.7
5	Extensive	11.9	82.0%	48.3%	3.4%	3.66	38.4	53.5

MIN = minimal pain sites; Hand = predominantly hand/wrist pain; JT/AX = multisite joint and axial pain; Predom LE = predominantly lower extremity pain; Extensive = extensive articular and non-articular multisite pain

PCS = physical health-related quality of life; MCS = mental health-related quality of life; ADL = activities of daily living

PCS and **MCS** are T-scores centered on a mean of 50 and an SD of 10. Scores higher than 50 indicate better HRQoL.

Percentages under Nagi, ADL, and Rosow-Breslau are the % of people reporting 1 or more limitation. Participants were coded as having an ADL or Rosow-Breslau limitation if they were unable to do one or more of the below tasks without help from another person. Individuals were coded as having a Nagi limitation is they had "some difficulty," "a lot of difficulty," or were "unable to do" one or more of the tasks listed below.

ADLs include dressing, bathing, toileting, transferring, and eating

Rosow-Breslau: Heavy work around the house, walk 1/2 mile without help (if no, walk 1/4 without help), walk up and down 1 flight of stairs without help.

Nagi: pulling / pushing, stooping / crouching / kneeling, reaching / extending arms below shoulder, reaching / extending arms above shoulder, writing / handling small objects, standing for long periods, lifting / carrying under 10 lbs, lifting / carrying over 10 lbs

Pain interference is an averaged score of seven items on a 0 (no interference) to 10 (completely interferes) scale. Participants were asked how much their pain had interfered with their general activity, mood, walking ability, normal work, social relationships, sleep, and enjoyment of life in the past week. Higher scores indicate greater interference.

Results: We included 1610 participants (mean age, 76.1 ± 7.5 years; 56% Female). The model with 5 classes offered the best model fit. The 5 pain patterns identified in this model included: 1) minimal pain sites (MIN; 53.2%); 2. predominantly hand/wrist pain (Hand; 21.2%); 3. multisite joint and axial pain (JT/AX; 12.8%); 4. predominantly lower extremity pain (Predom LE; 7.3%); and 5. extensive articular and non-articular multisite pain (Extensive; 5.5%). All 5 classes reported some frequency of low back pain, ranging from 21% in the MIN class to 77% in the Extensive class with the Hand and Predom LE class reporting the same frequency (38%). The Extensive class reported the lowest (i.e., worst) HRQoL and physical functioning (Table 1), while the Predom LE class reported both the second-highest average NPS and the second-lowest scores on measures of function. Despite the Hand and JT/AX classes having similar NPS and pain interference scores, the JT/AX class reported worse physical HRQoL and functioning.

Conclusion: We identified pain location patterns with differential patterns of physical functioning, pain, and HRQoL. Overall, higher average NPS was associated with lower (worse) scores on measures of function and HRQoL, but JT/AX reported worse outcomes than the Hand class despite reporting the same mean NPS. Our data suggest that pain location contributes to pain burden beyond NPS. More specifically, lower extremity and/or lower back pain appears to contribute to poor physical HRQoL and functioning outcomes more so than predominantly hand pain.

TNX-102 SL, Cyclobenzaprine HCl Sublingual Tablets, Demonstrates Pain Reduction and Favorable Tolerability in Patients with Fibromyalgia

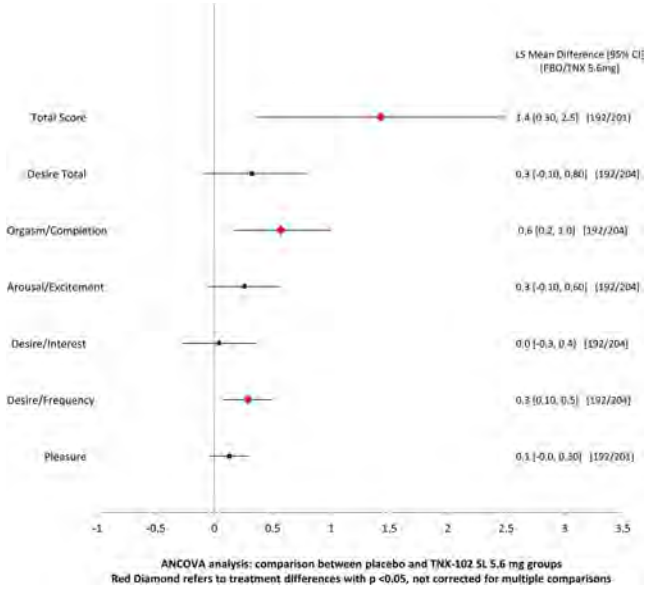
Gregory Sullivan[1], Errol Gould[2], Mary Kelley[1], Jean Engels[1] and Seth Lederman[3], [1]Tonix Pharmaceuticals, Inc., Chatham, NJ, [2]Tonix Pharmaceutical, Inc., Henderson, NV, [3]Tonix Pharmaceuticals, Inc., Austin, TX

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1221–1247) Pain in Rheumatic Disease Including Fibromyalgia Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: FDA-approved treatments for fibromyalgia (FM) have historically been limited by intolerable side effects that often lead to poor adherence. TNX-102 SL, a sublingual formulation of cyclobenzaprine, is under evaluation by the FDA as a treatment for FM. TNX-102 SL treatment has shown statistically significant reduction in pain in two Phase 3 studies, including the RESILIENT study reported below. In these studies, TNX-102 SL was generally well tolerated. The tolerability of TNX-102 SL may provide an appealing alternative to existing therapies.

Methods: The RESILIENT study was a 14-week, randomized, double-blind, placebo-controlled trial designed to evaluate the efficacy and safety of TNX-102 SL in patients with FM. The pre-specified primary endpoint was the change from baseline to Week 14 in the weekly average of daily pain numeric rating scale (NRS) scores, analyzed using a mixed model for repeated measures with multiple imputation for missing data. Exploratory secondary endpoints included assessments of tolerability, such as changes in sexual function (measured by CSFQ-14) and weight gain. Safety evaluations included changes in blood pressure and the incidence of adverse events (AEs).



Changes in Sexual Functioning Questionnaire Change from Baseline to Week 14 in Females

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: TNX-102 SL demonstrated significant improvement in the primary pain endpoint compared to placebo ($p < 0.0001$) at Week 14. Females treated with TNX-102 SL had significantly greater improvements in desire/frequency ($p = 0.010$), orgasm/completion ($p = 0.007$), and total sexual function scores ($p = 0.010$). No significant differences were observed between TNX-102 SL and placebo in weight, systolic, or diastolic blood pressure at Week 14. The most commonly reported AEs were mild to moderate, self-limited events such as transient tongue or mouth numbness and bitter aftertaste, which rarely led to study discontinuation. Systemic AE rates, excluding COVID-19, remained below 4.0%.

Conclusion: TNX-102 SL significantly reduced pain and showed a favorable tolerability profile, including minimal impact on weight and blood pressure, along with its unique mechanism targeting sleep disturbances, supports its potential as a new treatment option for FM. The availability of a well-tolerated treatment may also encourage clinicians to make the diagnosis of fibromyalgia earlier, thereby improving patient outcomes through timely intervention.

Does Social Support Reduce Bodily Pain among African American Women with SLE?: Findings from a Randomized Controlled Trial

Jerik Leung[1], Tomika Caldwell[2], Paul Nietert[3], Clara Dismuke[4], Hetlena Johnson[5], Edith Williams[6] and Everette Keller[3], [1]Emory University, Rollins School of Public Health, Atlanta, GA, [2]Medical University of Souty Carolina, Charleston, [3]Medical University of South Carolina, Charleston, SC, [4]VA Palo Alto Health Care System, Menlo Park, [5]Lupus Community Advocate/Researcher, Columbia, SC, [6]University of Rochester Medical Center, Rochester, NY

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1221–1247) Pain in Rheumatic Disease Including Fibromyalgia Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Peer mentoring has been shown to be an effective intervention for chronic conditions with evidence to suggest that it might improve health related bodily pain among African American women living with systemic lupus erythematosus (SLE). However, there is a lack of evidence to describe the intervention impact when adjusting for self-management of SLE. The present work aims to determine whether greater patient activation is associated with greater reductions in pain overall and within interventions groups.

Methods: We used a randomized controlled trial (RCT) design with experimental and social support control arms to test the peer approaches to lupus support (PALS) intervention (ClinicalTrials.gov # NCT03734055). Participants were recruited through the Medical University South Carolina (MUSC) P30 Core Center for Clinical Research and have validated diagnosis of SLE according to ACR classification criteria. Mentees (n=274) were randomized to either experimental arm or control arms. Participants in the experimental arm were paired with a peer mentor and received the full intervention condition (twelve 60-minute sessions across 24 weeks) covering self-management topics including: goal setting, effective communication, body image, and sexuality/sexual health. Those randomized into the control arm participated in a support group following the same bi-weekly session schedule but did not receive the tailored materials through a peer mentor. We measured pain and patient activation using the Lupus Quality of Life Questionnaire and Patient Activation Measure (PAM) respectively. Linear mixed models and multivariable models were fit to assess the intervention and impact of PAM on each predictor over time, respectively.

Results: The demographic characteristics of participants between experimental and social support control arms were generally comparable across age, education, marriage status, and insurance status. Our analysis includes 274 participants, evenly split between experimental and social support control arms. We did not observe statistically significant differences in pain over the study period between experimental and control groups (Table 1). However, across both groups, greater PAM score was associated with decreased pain (b=-0.13, p=0.019) (Table 2).

Conclusion: Those with higher PAM have reduced bodily pain. Additional work is needed to further typologize the varieties of pain experienced by people living with SLE, in addition to understanding the role of social relations and support. Specifically, additional mechanistic work is needed to understand the role of patient activation and to identify potential mediators and moderators of social support and pain among people living with SLE.

Abstract Number: 1233

Synovial Joint Transcriptomic Differences in Individuals with Knee Osteoarthritis and Neuropathic Pain Symptomology

Joseph Lesnak[1], Michael Zuscik[2], Michael Dayton[2], Craig Hogan[2], Prabil Kaini[2], Andrew Clauw[3], Jennifer Seifert[4], Michael Clay[5], Theodore Price[1] and Larry Moreland[6], [1]University of Texas at Dallas, Dallas, [2]University of Colorado School of Medicine, Aurora, [3]Univ of Colorado, Aurora, CO, [4]University of Colorado and Oklahoma Medical Research Foundation, Aurora, CO, [5]University of Colorado, Aurora, CO, [6]University of Colorado, Denver, CO

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1221–1247) Pain in Rheumatic Disease Including Fibromyalgia Poster

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Osteoarthritis (OA) is a painful disease of the synovial joint and is the most common form of arthritis with a large global burden. A subset of individuals with knee OA complain of neuropathic type pain with symptomology of burning, paresthesia, and spontaneous pain in the affected joint. Since nociceptive and neuropathic pain components may require different treatment strategies, it is imperative to understand mechanisms underlying each symptomology. However, it is unknown how changes in the joint may be driving neuropathic like symptoms. Thus, we set out to compare transcriptomic data of synovial joint samples between individuals with and without neuropathic type pain undergoing joint replacement for knee OA.

Methods: A total of 35 individuals (10 males, 25 females) were enrolled who were diagnosed with knee OA by an orthopedic surgeon and undergoing total knee arthroplasty surgery. All individuals completed the painDETECT questionnaire prior to surgery to determine level of neuropathic pain symptomology. Synovial joint samples from the surgical knee were collected and frozen in pulverized dry ice. A painDETECT cutoff score of ≤12 was used to group individuals into low or moderate/high probability of neuropathic pain. RNA was extracted from tissues and bulk RNA sequencing was performed to compare transcriptomic differences between individuals with low (n=25, 8 males, 17 females) and moderate/high painDETECT scores (n=10, 2 males, 8 females). To determine differentially expressed genes (DEGs), the R package DESeq was used to compare differences between low and moderate/high painDETECT score, with sex run as a covariate (DEG: log2fc >0.585, adjusted p-value < 0.1). To make predictions surrounding synovial joint to nociceptor signaling, a ligand receptor interactome was used to intersect upregulated DEG's encoding for ligands with their known receptors on human nociceptive neurons.

Results: A total of 121 DEGs were identified with 115 upregulated and 6 downregulated. Gene pathway assessment of the upregulated genes revealed enrichment of genes responsible for neutrophil degranulation and extracellular matrix organization. The ligand receptor interactome revealed potential interactions between 5 ligands and 24 receptors on human nociceptive neurons. This included interactions with neurotrophic factors such as L1CAM, CBLN4, and NRXN3. These neurotrophic factors bind to several receptors on neurons which have been shown to drive increased nerve growth including DCC, EGFR, and NEO1.

Conclusion: We found a set of upregulated genes specific to individuals with knee OA who complain of neuropathic like pain. These genes revealed potential enhancement of neutrophil degranulation and increased neurite growth in individuals with neuropathic symptoms. Future work will look to validate these targets using cultured human dorsal root ganglion neurons.

Serum Antibodies Against Glial Fibrillary Acidic Protein in Fibromyalgia: A Proof-of-Concept Study

Felipe Massó[1], **Laura Aline Martinez-Martinez**[2], Luis M Amezcua-Guerra[3], Francisco Mercado[4], Angélica Almanza[5] and Manuel Martínez-Lavín[1], [1]Instituto Nacional de Cardiologia Ignacio Chavez, Mexico city, Mexico, [2]Rheumatology Department at National Institute of Cardiology Ignacio Chávez, Mexico City, Federal District, Mexico, [3]Instituto Nacional de Cardiología Ignacio Chávez, Mexico City, Mexico, Mexico city, [4]Instituto Nacional de Psiquiatría Ramón del la Fuente Muñiz, Mexico city, Mexico, [5]Instituto Nacional de Psiquiatría Ramón de la Fuente Muñiz, Mexico city, Mexico

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1221–1247) Pain in Rheumatic Disease Including Fibromyalgia Poster

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Fibromyalgia (FM) is a stress-related disorder in which dorsal root ganglia (DRG) may play a pivotal pathogenetic role. DRG exhibit unique stress-induced, pro-algesic physio-anatomy, where each pain-sensing nerve fiber soma is tightly encased by metabolically active, immune-competent satellite glial cells (SGCs). Mice receiving IgG from patients with FM display mechanical and cold hypersensitivity and small nerve fiber pathology, in these instances patients IgG is exclusively deposited in mouse DRG SGCs. A subgroup of patients suffering from severe FM harbors anti-SGCs antibodies, although the specific antibody target(s) remain unidentified.

Glial fibrillary acidic protein (GFAP) is an intermediate filament protein serving as an early SGCs activation marker. Different environmental stressors induce GFAP cell-surface expression that could conceivably serve as novel antigen. GFAP antibodies have been implicated in autoimmune encephalomyelitis.

This proof-of-concept study aimed to determine whether the serum of patients suffering from FM contains antibodies against GFAP.

Methods: We included 47 women with "primary" FM (meeting ACR 2010 and Wolfe et al 2016 criteria) without concurrent autoimmune rheumatic disease and 31 age-, sex-, and BMI-matched healthy controls. All participants completed the following standardized clinimetric questionnaires: 2016 Wolfe et al criteria, FIQ-R, COMPASS-31, Small Fiber Symptom Survey, S-LANSS, PHQ-9, GAD-7, IPAQ, and EuroQol-5D.

A sensitive ELISA was developed using recombinant human GFAP (Abcam, Waltham, MA, USA) coated on 96-well plates. Serum samples were incubated overnight, followed by detection with HRP-conjugated anti-human IgG. Each plate included a positive control (commercial anti-GFAP antibody).

Results: Patients with FM exhibited higher GFAP antibody optical densities (OD) compared to controls (median 0.04, 0.02–0.10 vs. 0.02, 0.01–0.05; p = 0.025). Using the controls 99th percentile value (0.127 OD) as cut-off point, 9/47 (19%) of patients suffering from FM tested positive for anti-GFAP antibodies (figure 1). This antibody positivity ratio yields a sensitivity of 19%, specificity of 97%, positive predictive value of 90%, and negative predictive value of 44%. No significant differences in clinimetric scores were observed between GFAP-positive versus GFAP-negative patients.

ELISA detection of GFAP antibodies in patients suffering from fibromyalgia (FM) and controls (C) using the controls 99th percentile as threshold for antibody positivity.

Conclusion: A subset of patients suffering from FM harbors serum antibodies against GFAP. Whether these antibodies are more prevalent in cerebrospinal fluid of individuals with FM, as seen in GFAP-associated autoimmune encephalomyelitis, remains to be determined. These early findings suggest that abnormal GFAP expression may play a role in the pathogenesis of FM, warranting further investigation of FM as satellite gliopathy.

Abstract Number: 1235

Demystifying Pain in patients with Lupus: How much is it Lupus and How much is it Other Stuff?

Meenakshi Jolly, Rush University, Chicago

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1221–1247) Pain in Rheumatic Disease Including Fibromyalgia Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Pain in patients with Systemic Lupus Erythematosus (SLE) is not well understood. There is role of active disease in pain (e.g. arthritis, serositis) also referred as Type I symptoms. Other factors e.g. coexistent fibromyalgia (FM), Stress, Fatigue, Sleep and Depression (Type 2 symptoms) may contribute towards pain.

We undertook analyses of data on patients with SLE to better understand Pain using three different measures of Pain. We focused specifically on contribution/s of disease activity, FM, Sleep, Stress, Depression and Fatigue.

Methods: Cross-sectional Data from 122 SLE patients meeting the 1997 ACR classification criteria were analyzed. Pain was measured using Brief Pain Inventory (BPI), SF-36 Bodily Pain (BP) and LupusPRO Pain domain. Disease activity and Flare were measured using SELENA-SLEDAI and SFI. Tools to measure Sleep, Fatigue, Stress, Depression were the Insomnia Severity Index, FACIT-FT, Perceived Stress Scale-PSS and Patient Health Questionnaire-9/PHQ9. FM status was

			Depression (Patient Health Questionnaire-9) 0.43, 0.36 to 1.37, 0.003		

determined by chart review and patient reported tender point count. We conducted univariate regression analyses with Pain as the dependent variable and others as independent variables. We next undertook multivariate analyses of significant variables from the univariate analysis (Model 1), with FM (Model 2), and stepwise regression analysis (Model 3). We show chart-based FM results below. Results were similar for tender point counts.

Results: 90% were women; 51% Black, 23% White, 12% Hispanic and 9% Asian. Mean age was 40.7 (13.5) yrs, with Mean (SD) SLEDAI 5.03 (4.0) and SDI 0.61 (0.96). Mean Disease duration was 8.6 (7.2) years. 33% had SFI flare, and 63% were on steroids. 16% had FM. There was a good correlation between the three pain measures (r >0.65). Mean (SD) BPI, BP and PRO-Pain were 11.98 (12.29), 58.71 (24.7) and 69.80 (28.16).

Disease activity (including SLEDAI-arthritis and SFI), Sleep, Stress, Fatigue, Depression and Fibromyalgia were associated with Pain (Table 1) on univariate analysis. On multivariate analysis (Table 2) disease activity, sleep, fatigue and depression were associated with Pain after adjusting for all other variables (R^2 60-70%) %, and the associations were not changed significantly by adding FM to the model. On Stepwise Regression, 3-4 variables explained 56-68% of variance in Pain (Table 2), with disease activity being associated in all the three measures of Pain. In addition, sleep, depression and fatigue were associated with Pain, but not FM or stress.

Conclusion: Pain in SLE is associated with active disease. Latter, along with sleep, fatigue and depression explains more than half of the pain in SLE, indicating that besides controlling disease activity, there may be a role for Biopsychosocial model of care in improving pain in SLE. These models report association and not causation. Longitudinal study models will be tested next.

Vestibulocortical Stimulation via Caloric Irrigation in Nociplastic Disease: Therapeutic Effects on Pain, Autonomic Functioning & Quality of Life Measures

Michael Kaplan[1], Alexandra Canori[2], Rebecca Howard[2], Talia Torkian[3], Rebecca Pietro[1], Gabriela Santiago-Pichardo[1], Daniel Clauw[4], David Putrino[2], Yousaf Ali[1], Laura Tabacof[2] and Trung Ngo[5], [1]Division of Rheumatology, Mount Sinai Hospital, New York, [2]Department of Rehabilitation and Human Performance, Icahn School of Medicine at Mount Sinai, New York, [3]Division of Rheumatology, Icahn School of Medicine at Mount sinai, New York, [4]Chronic Pain and Fatigue Research Center, University of Michigan, Ann Arbor, MI, [5]RECOVER Injury Research Centre, The University of Queensland and Surgical, Treatment & Rehabilitation Service (STARS), Queensland, Australia

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1221–1247) Pain in Rheumatic Disease Including Fibromyalgia Poster

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Fibromyalgia (FM) and myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) are prototypical nociplastic disorders marked by centralized pain & fatigue, respectively. Nociplastic symptoms — such as fatigue, psychological distress & dysautonomia — commonly complicate rheumatologic diseases and remain difficult to treat, thus highlighting the need for safe, effective & affordable therapies. Vestibulocortical stimulation (VCS) via caloric irrigation is a

FIGURE 1

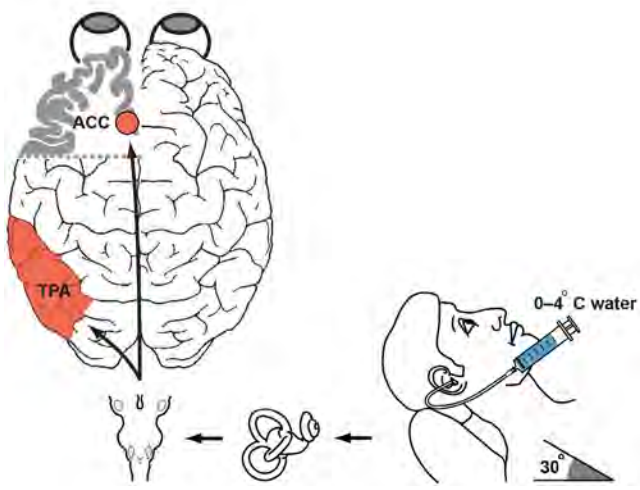

Figure 1: VCS with Caloric Irrigation — From Neurodiagnostic Technique to Therapeutic Neuromodulation Modality. The caloric test — via the vestibulo-ocular reflex — is a simple, low-cost, low-risk, non-invasive and widely used mainstream neurodiagnostic technique for balance problems & brain death, with a long-standing record of safety since its development over a century ago. The technique is routinely performed for example in primary care clinics by family doctors & nurses (for cerumen removal), audiologists, neurologists & ENT physicians. VCS involves irrigation of the external ear canal with warm/cold water (e.g., 1–4° C) while the head is reclined at 30° to the horizontal until nystagmus is observed and vertigo is reported — typically within a few seconds — via stimulation of semicircular canals & brainstem circuits (indicated by the black horizontal arrows). Over recent decades, several brain-imaging studies have shown that cold-water VCS also consistently activates an endogenous highly conserved (>230 million years old) restorative-function network (Ngo & Kaplan, 2023) of predominantly contralateral structures including the anterior cingulate cortex (ACC), temporo-parietal areas (TPA; e.g., temporoparietal junction, superior temporal gyrus, inferior parietal lobe), middle frontal gyrus, insular cortex, thalamus & putamen (in basal ganglia). Correspondingly, the technique's wide-ranging multimodal effects across mood, pain, cognition, attention, perception, beliefs/insight & mobility have been highlighted by remarkable therapeutic benefits shown in adults with often disabling refractory conditions such as nociplastic pain syndromes (e.g., phantom limb & post-stroke thalamic pain, migraine, CRPS/allodynia, spinal cord injury pain, refractory FM — Kaplan et al., 2024); other neurological disorders (e.g., Parkinson's disease, minimally conscious state); and psychiatric illness (e.g., bipolar & schizophrenia spectrum disorders).

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

non-invasive neuromodulation technique that has demonstrated rapid analgesic effects in treatment-resistant nociplastic pain (Figure 1).[1] This study aimed to replicate recent findings of VCS-induced analgesia in FM[2] and assess its broader impact on quality of life to inform the design of randomized placebo-controlled trials.

Methods: We conducted a non-randomized open-label effectiveness trial in 39 patients with nociplastic pain & fatigue (mean age = 40.2; 87% female). Twenty-three patients met criteria for ME/CFS (2015 IOM criteria) and 16 met criteria for FM (2011 ACR criteria) +/- ME/CFS. Each participant completed validated electronic patient-reported outcomes at baseline, prior to receiving a single treatment of unilateral right-ear cold-water (4°C) irrigation at 1-2 cc/second. Pain & quality of life measures were reassessed at post-intervention 30 minutes, 1 day, 1 week, 2 weeks & 4 weeks.

Figure 2

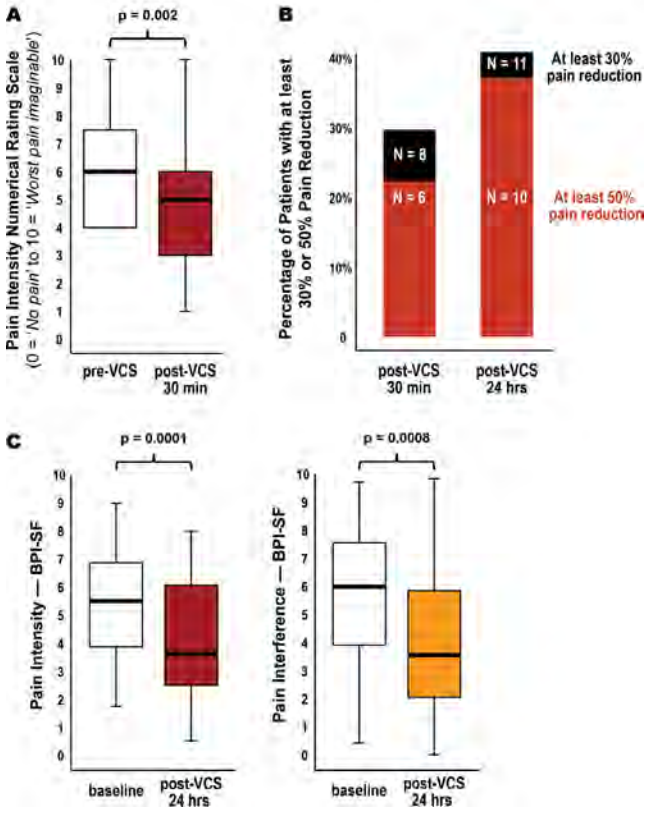

Figure 2. VCS Effects on Pain Measures & Percentage of Participants. (A) Immediate Reduction in Pain Intensity after VCS. The box plot shows the distribution of pain intensity NRS ratings before (pre) and 30 minutes after (post) VCS where 0 = No pain and 10 = Worst pain imaginable. This analysis included participants who experienced at least a 4/10 pre-intervention NRS pain score (N=27). A baseline level of at least 4/10 pain is the standard pain threshold used for inclusion in FM clinical trials. Pain scores were significantly reduced at 30 minutes following the procedure (t = -3.46, p = 0.002). P value is from a paired t-test of pre- and post-VCS pain scores. The bold horizontal bar in each box plot indicates the group's mean pain intensity rating. (B) Percentage of Participants with at least a 30% or 50% Improvement at 30 minutes and 24 hours after VCS. At 30min post-treatment, pain scores decreased by at least 30% in 8 (30%) participants and by at least 50% in 6 (22%) participants. Twenty-four hours after VCS, 11 participants (41%) experienced at least 30% decrease in pain and 10 participants (37%) experienced at least 50% decrease in pain. This analysis included participants who experienced at least a 4/10 pre-intervention NRS pain score (n = 27). The decision to exclude participants with less than 4/10 pain from this analysis was made post-hoc to avoid skewing percentages from participants with baseline scores of 2/10 pain, in which a one-point reduction on the pain scale represented a 50% decrease in pain. (C) Reduction in pain intensity & pain interference (BPI-SF) 24 hours after VCS treatment. The box plots show distribution of BPI-SF pain intensity and pain interference scores for all study participants (n = 39). Paired t tests showed a significant reduction in pain intensity (t = -4.36, p = 0.0008) and pain interference scores (t = -3.67, p = 0.0001). The bold horizontal bar in each box plot indicates the respective group's mean pain intensity & mean pain interference ratings.

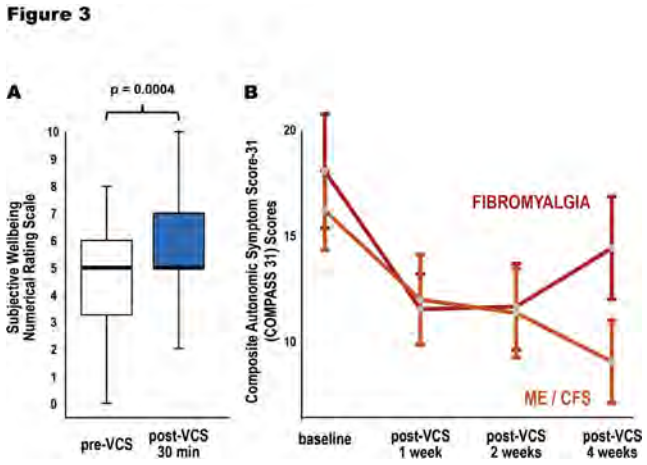

Figure 3. VCS Effects on Subjective Well-being & Autonomic Functioning (A) Immediate Improvement in Subjective Well-Being after VCS. The box plots show the distribution of subjective well-being NRS ratings (0 = lowest quality of life; 10 = best quality of life imaginable) of all study participants (n = 39) before (pre) and 30 minutes after (post) VCS. Overall well-being ratings significantly improved post-procedure (t = 3.89, p <0.001). P value is from paired t-test of pre- & post-VCS ratings. (B) Autonomic Distress Improves for 1 to 4 weeks after VCS. The Composite Autonomic Symptom Score-31 (COMPASS-31) is a validated self-assessment tool used to evaluate the extent of distress secondary to autonomic symptoms. A repeated-measures ANOVA showed COMPASS 31 scores significantly improved over time (p <0.001). Post-hoc comparisons using paired t-tests with Bonferroni correction revealed significant changes in the ME/CFS group (orange line) between baseline and all follow-up timepoints (1 week — t = -3.39, p.adj = 0.016; 2 weeks — t = -3.33, p.adj = 0.019; 4 weeks — t = -3.61, p.adj = 0.019). In the FM group (red line), significant effects were found between baseline and 1 week (t = -3.29, p.adj = 0.049). Beyond one-week post-intervention in the FM group, incomplete data limited our ability to assess the durability of these effects. Nevertheless, the current trial is the first study to demonstrate preliminary findings of VCS therapeutic effects on these autonomic functioning outcome measures in any clinical cohort. All study participants (N=39) were included in analysis.

Results: Regarding pain, 27 of 39 participants reported significant baseline pain intensity (≥4/10). At 30 minutes post-VCS, it significantly decreased (t(26) = -3.46, p = 0.002; Figure 2A) with 30% reporting ≥30% relief and 22% reporting ≥50% relief. At 24 hours post-VCS, 41% achieved ≥30% pain reduction and 37% reported ≥50% improvement (Figure 2B), with significant reductions also found in pain intensity (t(35) = -4.36, p < 0.001) and pain interference (t(35) = -3.67, p < 0.001; Figure 2C). Beyond 24 hours, no significant changes were observed as the study was underpowered to detect effects beyond that timeframe.

Subjective well-being scores increased significantly post-VCS (t(37) = 3.89, p < 0.001; Figure 3A) and autonomic symptom burden (COMPASS-31) decreased over time (F(3,60) = 7.998, p < 0.001; Figure 3B). PROMIS-29 domains showed sustained improvements in anxiety & social role participation at 1, 2, and 4 weeks post-intervention. Fatigue levels remained unchanged and no major adverse events occurred. VCS was safe & well tolerated, with 86.1% of participants reporting a willingness to have the procedure repeated if it reduced pain by half for one week.

Conclusion: These findings provide further open-label trial evidence that VCS offers meaningful relief in nociplastic pain. This study is also the first to show proof-of-concept improvements in autonomic symptoms & quality of life following VCS in nociplastic disease. Large randomized placebo-controlled trials are needed to validate & further advance this simple, bedside procedure into therapeutic standard of care for millions of patients globally suffering with refractory rheumatologic & nociplastic disease.

Six Month Clinical Outcomes of a Digital Therapeutic Augmented Virtual Care Clinic for Fibromyalgia Management

Michael Rosenbluth[1], Yifei Dai[1], Dianne Shumay[1] and Andrea Chadwick[2], [1]Swing Therapeutics, San Francisco, CA, [2]University of Kansas School of Medicine, Kansas City, KS

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1221–1247) Pain in Rheumatic Disease Including Fibromyalgia Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Guidelines for fibromyalgia treatment recommend non-pharmacologic treatment, including cognitive behavioral therapy, alongside medications [1-3]. However, patient access to multi-modal treatment is frequently limited due to a lack of clinics offering integrated care. Early results from a virtual specialty clinic (Swing Care), augmented by an FDA-cleared digital behavioral therapy (Stanza™), have demonstrated significant improvements at 90 days [4]. The purpose of this analysis is to evaluate six-month outcomes of a digital therapeutic augmented virtual specialty clinic for FM.

Methods: A chart review was conducted with IRB approval and consent waiver (Allendale IRB, Old Lyme, CT). FM patients assessed using the 2016 diagnostic criteria received multimodal treatment, combining non-opioid drug and non-drug therapies, including the option of the digital behavioral therapy. Endpoints collected included Patient Global Impression of Change (PGIC), Fibromyalgia Impact Questionnaire-Revised (FIQ-R), Pain Intensity, and Pain Interference (0-10 Likert Scales). Data were collected at baseline, 2, 4, and 6 months. All patients with at least six-month follow-up data were included in analysis.

Table 1. Cohort characteristics, clinical baseline, and outcomes at 6 months.

Cohort			
Female, n (%)	225 (96.6%)		
Age, median (range)	50.0 (22 – 80)		
Clinical Measures	**Baseline**	**Month 6**	***P***
N	233	233	-
FIQ-R, mean (SE)			
Total Score	63.6 (1.2)	48.7 (1.3)	*<.0001*
Function Domain	17.3 (0.4)	13.8 (0.5)	*<.0001*
Impact Domain	13.5 (0.3)	8.6 (0.4)	*<.0001*
Symptoms Domain	32.7 (0.5)	26.3 (0.6)	*<.0001*
Pain (0-best to 10-worst outcome), mean (SE)			
Intensity	6.9 (0.1)	5.4 (0.2)	*<.0001*
Interference	7.3 (0.1)	5.3 (0.2)	*<.0001*

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. PGIC response rate over time (% participants).

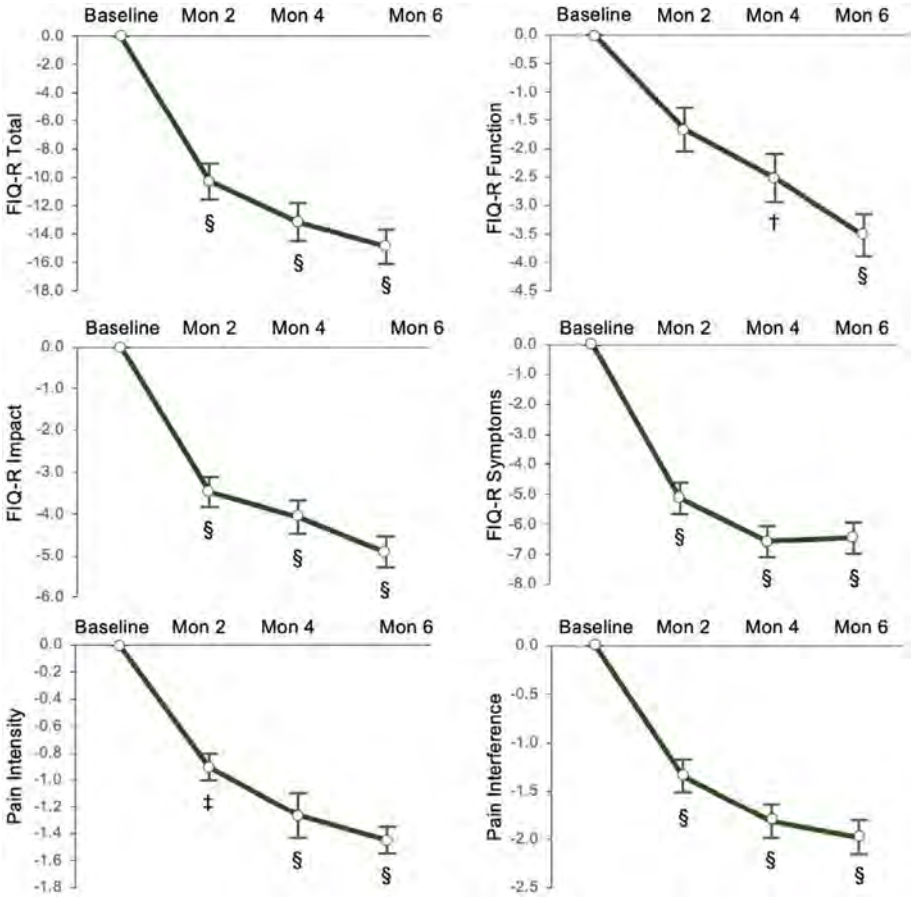

Figure 2. Changes from baseline on the clinical measures. Error bars = one SE. † $p < 0.0100$, ‡ $p < 0.0010$, § $p < 0.0001$.

Results: Outcomes data were available for 233 patients (Table 1). Baseline FIQ-R total score was 63.6 ± 1.2 [mean ± SE] while baseline pain intensity and pain interference scores were 6.9 ± 0.1 and 7.3 ± 0.1 [mean ± SE], respectively (Table 1). At 2 months, 75.5% of patients reported improvement, with 35.4% much improved or better. At 6 months, 88.0% of patients reported improvement, with 55.4% much improved or better (Figure 1). Average FIQ-R total score was significantly reduced at 6 months (by 14.9 ± 1.1 [mean ± SE] points, $p< 0.0001$), with significant improvements starting at 2 months (Figure 2). Significant improvements were also observed in FIQ-R Function, Impact, and Symptom domains ($p< 0.0001$). By six months, pain intensity and pain interference scores were significantly reduced by 1.5 ± 0.1 and 2.0 ± 0.2 [mean ± SE] points, respectively, p values < 0.0001.

Conclusion: Sustained improvements in well-being and reductions in FM severity, pain intensity, and pain interference were demonstrated at the virtual care clinic. These findings highlight the effectiveness of the multidisciplinary approach and the potential of the virtual care clinic as a patient-centered and accessible solution for managing FM.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1221–1247) Pain in Rheumatic Disease Including Fibromyalgia Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Frailty, an increased vulnerability to stressors, is commonly associated with aging and functional decline. Pain, prevalent among older adults, contributes to frailty in the general population. Specifically, it has been shown that pain contributes to frailty by increasing exhaustion and decreasing physical activity. Individuals with RA are more likely to experience both higher levels of pain and frailty. However, research evaluating the relationship within the RA population is limited. We examined the relationship between pain and the risk of frailty in RA.

Methods: Data were from the Veterans Affairs Rheumatoid Arthritis (VARA) registry, a multicenter prospective cohort of US Veterans with RA. Pain was assessed by self-report (range 0-10). Frailty was evaluated using the Veterans Affairs Frailty Index (VA-FI), a validated tool derived from ICD-9/10 and CPT codes, with frailty defined as a score >0.2. Characteristics were described at enrollment, stratified by frailty status. We excluded frail participants at baseline and modeled the incidence of a composite outcome of frailty or death. Censoring occurred when people were lost to follow-up and at the end of the study period. Multivariable Cox regression assessed the association between baseline pain and incident frailty, adjusting

Table 2. Multivariable Cox Regression Analyses Assessing the Impact of Pain on Frailty Among Veterans with Rheumatoid Arthritis*

	HR**	95% CI	p-value
Unadjusted	**1.05**	**1.03-1.08**	**<0.0001**
Adjusted	**1.04**	**1.02-1.07**	**0.001**

*Models were adjusted for age, sex, race, disease duration, DAS28CRP, prednisone use, csDMARD use, bDMARD use, RDCI.
**per 1-point increase in pain intensity on a 0 to 10 rating scale

for baseline age, sex, race, BMI, disease duration (years), DAS28-CRP, csDMARD use, bDMARD use, prednisone use, and Rheumatic Disease Comorbidity Index (RDCI).

Results: 3,276 participants, of whom 86% were male, 70% were White, with a mean age of 72.8 ± 10.3 years, were described at baseline (Table 1). 71% were classified as non-frail, and 29% as frail. Frail individuals were older and had longer disease duration and higher pain than non-frail individuals. Individuals included in the incident analysis (N=2,315) were followed for an average of 5.9 years, during which 1,404 individuals (61%) developed frailty or died. Each 1-point increase in baseline self-reported pain was associated with a 4% increased risk in incident frailty (adjusted HR 1.04, 95% CI 1.02–1.07; p = 0.01) (Table 2).

Conclusion: Higher self-reported pain at baseline is associated with a greater risk of incident frailty among people with RA, independent of important patient and disease-related factors, including disease activity. These findings suggest that pain might be a modifiable risk factor for frailty in RA and underscore the need for targeted pain management strategies to mitigate frailty in this vulnerable population.

JAK inhibition appears to alter clinical and neurobiological markers of nociplastic pain in rheumatoid arthritis: a 7T MRI Brain study

Kristian Stefanov[1], Andrew McGucken[1], Maxine Arnott[1], Tyrone Lau[1], Norah Aldehmi[1], Vinod Kumar[2], Neil McKay[3], James Dale[4], Lindsay Robertson[5], James Brock[1], Flavia Sunzini[6] and **Neil Basu**[7], [1]University of Glasgow, Glasgow, United Kingdom, [2]NHS Tayside, Dundee, United Kingdom, [3]NHS Lothian, Edinburgh, United Kingdom, [4]NHS Lanarkshire, Wishaw, United Kingdom, [5]NHS Grampian, Aberdeen, United Kingdom, [6]Glasgow University, Glasgow, United Kingdom, [7]Institute of Infection, Immunity & Inflammation, University of Glasgow, Glasgow, United Kingdom

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1221–1247) Pain in Rheumatic Disease Including Fibromyalgia Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Pain remains a prevalent and highly impactful issue for people with rheumatoid arthritis (RA). Among modern day targeted therapies, the janus kinase (JAK) inhibitors are especially effective in reducing RA pain, however the mechanisms of their analgesic action are not fully known, and do not appear to be entirely explained by classical nociceptive pain mediators.

In this study of RA, we hypothesised that filgotinib, a selective JAK-1 inhibitor, additionally modifies nociplastic pain mechanisms, as typified in fibromyalgia (FM). Specifically, we predicted that peripherally driven dimensions of nociplastic pain would be altered as demonstrated by modification of functional brain connectivity between the posterior insula and inferior parietal lobe (IPL), an established neurobiological marker of 'bottom up' nociplastic pain which is most powerfully measured by 7 Tesla (7T) functional MR brain imaging (fMRI).

Methods: A single centre, observational test re-test study of people with moderate to severe RA who have been newly prescribed filogotinib as per standard care. Immediately prior to drug initiation, recruits underwent a clinical evaluation which included the ACR FM 2011 survey criteria (a validated subjective score of nociplastic pain, range 0-31). They then undertook an ultra-high resolution (7T) MRI brain scan, incorporating a 10-minute simultaneous-multi-slice (SMS) echo-planar imaging (EPI) sequence to capture resting state fMRI. During the resting state, subjects were instructed not to undertake any task and to stay awake with their eyes open on a fixation cross. To enable structural co-localisation, a whole-brain T1-weighted structural image was collected using a twice magnetization-prepared rapid gradient echo (MP2RAGE) sequence. Subjects then were invited to return to repeat these measures 12 (±1) weeks later. FMRI data was pre-processed and analysed using statistical parametric mapping (SPM) version 12 and the CONN functional connectivity toolbox, both running on MATLAB 2017a. Seed-based connectivity analyses were applied to determine the connectivity maps informed by our *a priori* determined regions of interest (IPL-Posterior insula). Simple descriptive statistics were employed to derive baseline characterisation and evaluation of longitudinal differences.

Results: Of the n=20 recruited, n=16 (75% female; mean age 56.9 [SD 9.6] years, baseline DAS28 4.6 [SD 1.4]) completed study follow-up. Clinically, this group reported a large and statistically significant change (p= 0.001) in their mean ACR FM

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. scores from 14.4 [SD 5.6] to 7.9 [SD 5.4] at follow up. A statistically significant change in functional connectivity between the left IPL and left posterior insula was also observed (p=0.021).

Conclusion: Filgotinib significantly reduced patient reported nociplastic pain, possibly through the attenuation of aberrant posterior insula-IPL brain functional connectivity – a marker of peripherally driven nociplastic pain in RA.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1221–1247) Pain in Rheumatic Disease Including Fibromyalgia Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: For patients with lupus nephritis, active disease can be solely renal or include a range of extrarenal signs, such as arthritis or serositis, that can cause pain and decreased quality of life. However, the etiology of pain in the absence of extrarenal clinical activity remains in question, and no clinical trials have evaluated therapies for this potentially debilitating aspect of SLE. The Accelerating Medicines Partnership (AMP) provides an unprecedented opportunity to evaluate molecular mediators of disease in a well-phenotyped multi-ethnic multi-racial cohort of lupus patients enrolled at centers across the US. Accordingly, this study leveraged the AMP and AMP AIM lupus cohorts to evaluate serum proteins associated with patient reported pain specifically in patients without extrarenal clinical activity.

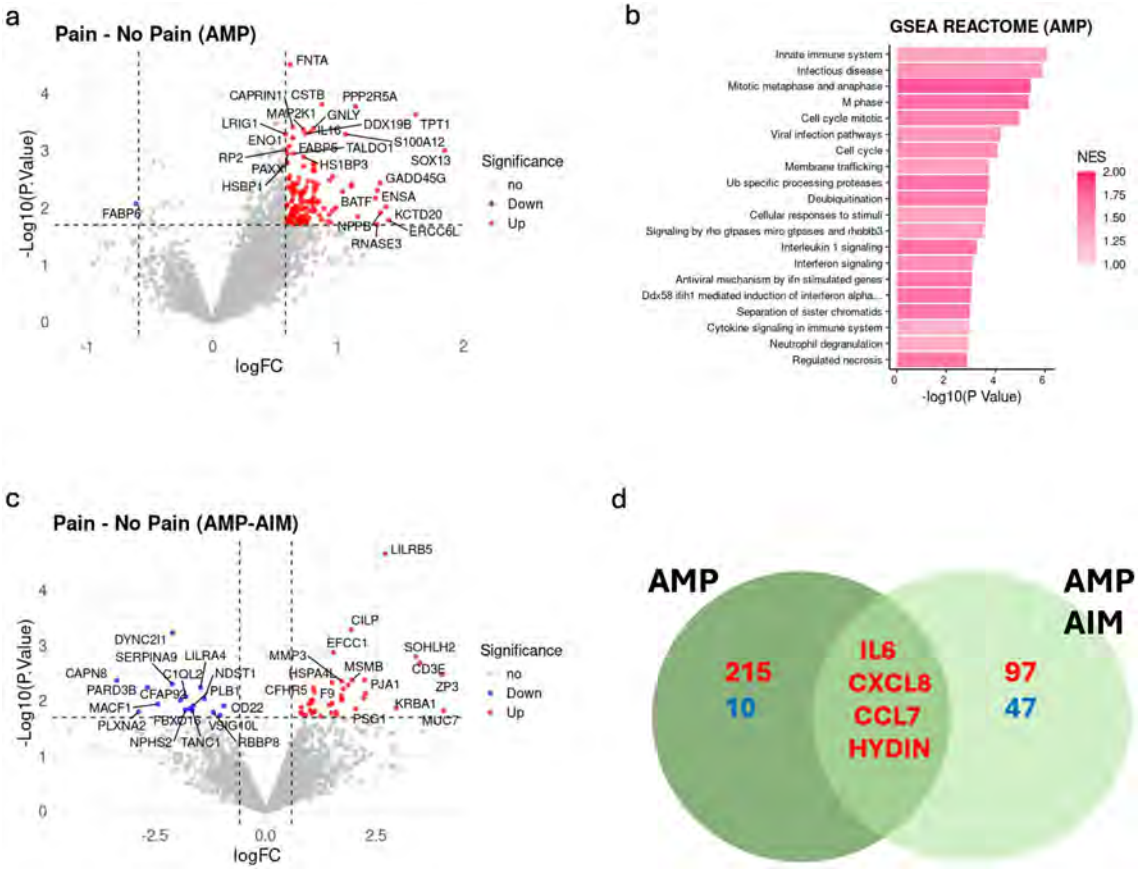

Figure 1 (A) Volcano plot of AMP cohort comparison for Pain vs. No Pain (|logFC| > 1.5, p-value < 0.02). (B) GSEA results for the Reactome pathway database for AMP cohort comparison. (C) Volcano plot of AMP-AIM cohort comparison for Pain vs. No Pain (|logFC| > 1.5, p-value < 0.02). (D) Venn Diagram showing overlap between AMP and AMP AIM differential analysis results (|logFC| > 1.5, p-value < 0.05).

Figure 2 (A) Box plots of NPX (normalized protein expression) values for the in common differential proteins between AMP and AMP AIM cohorts when comparing Pain vs. No Pain. (B) Box plots of the Interferon Signaling Singscore for the AMP cohort. (C) Citations showing each of the four protein candidates has been previously associated with pain.

Methods: Pain was assessed using the PROMIS-29 pain interference questionnaire. To limit variability and focus on clinically meaningful outcomes, only patients without clinical extrarenal disease and PROMIS pain interference T scores < 50 (no reported pain interference) or > 55 (abnormal pain interference) were included. The AMP lupus nephritis cohort was used for the discovery analysis (n=28 without pain, n=50 with pain). The AMP AIM lupus cohort, most with renal disease but all chosen without any extrarenal clinical activity, was used for early validation (n=3 without pain, n=8 with pain). Serum proteins were measured using the Olink Explore HT platform. Assays with less than 5 values (AMP) and 1 value (AMP AIM) above limit of detection in either comparison group were excluded. Differential protein expression was evaluated using unadjusted linear models (limma) with candidate proteins considered at log2FC |1.5| and nominal p< 0.05. Pathways were assessed by gene set enrichment analysis (GSEA). An interferon signaling score was calculated by the Singscore method using the proteins in the Reactome "Interferon Signaling" pathway included in the Olink Assay.

Results: The clinical characteristics of the cohorts are described in Table 1. Differential expression analysis revealed 229 (219 up and 10 down) proteins significantly different between patients with vs. without pain and no extrarenal disease in the AMP cohort (Fig 1A). GSEA identified pathways related to innate immune signaling, including interferon, to be associated with pain (Fig 1B). In the validation AMP AIM cohort, there were 148 (101 up and 47 down) proteins significantly associated with pain in the absence of extrarenal activity (Fig 1C). Four proteins—CCL7, IL6, CXCL8, and HYDIN—were significantly elevated in the pain group across both cohorts (Fig 1D and Fig 2A), and all four have been previously linked to

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. the expression of pain in the literature (Fig 2C). An interferon signaling score significantly associated with pain in AMP but not AMP AIM (Fig 2B).

Conclusion: These data suggest that circulating proteins may be key mediators of pain even in SLE patients without overt extrarenal clinical activity. Experimental evidence from mouse models supports the involvement of the identified candidates: CCL7 in neuropathic pain, IL6 in both neuropathic and nociceptive pain, CXCL8 in nociceptive pain, and HYDIN in nociceptive pain.

Beyond Pain Severity in Psoriatic Arthritis: Pain Catastrophizing Independently Impacts Disease Burden and Quality of Life

Kyra Chen[1], Uma Scher[2] and **Rebecca Haberman**[3], [1]NYU Grossman School of Medicine and NYU Langone Health Psoriatic Arthritis Center, New York, [2]NYU School of Medicine, Scarsdale, NY, [3]NYU Langone Health, New York, NY

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1221–1247) Pain in Rheumatic Disease Including Fibromyalgia Poster

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Pain remains a major burden in psoriatic arthritis (PsA), often persisting despite effective control of synovial inflammation. This persistent pain may prevent patients from achieving remission or meaningful improvements in quality of life (QoL). Although pain severity is typically emphasized in clinical evaluation, emerging evidence suggests that

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

psychological contributors—particularly maladaptive cognitive-emotional processes such as pain catastrophizing—may play a critical, underrecognized role. Pain catastrophizing, defined by magnification of symptoms, ruminative thoughts, and a sense of helplessness, is well documented in other chronic pain conditions but remains poorly characterized in PsA. In this study, we assess the prevalence and impact of pain catastrophizing in a real-world PsA population at the NYU Psoriatic Arthritis Center (PAC).

Methods: Consecutive patients meeting CASPAR criteria were enrolled at the NYU PAC into a cross-sectional study of pain and psychosocial features. Participants completed the Pain Catastrophizing Scale (PCS), which includes three subscores (helplessness, magnification, rumination); a total score >30 was considered clinically significant. Depression was defined by PHQ-9 ≥10. Pain severity was rated on a 0–10 scale. Outcomes included Minimal Disease Activity (MDA), low disease activity per cDAPSA (≤13), and multiple QoL indices (EQ-5D, PROMIS-29). Associations between PCS and disease outcomes were assessed via logistic and linear regression, adjusting for pain intensity, depression, and sex.

Results: Among 91 PsA patients, 5 (5.5%) patients met criteria for clinically significant (PCS >30), all of whom were women. Subscale symptom prevalence included helplessness (6), magnification (12), and rumination (3). Higher PCS scores were associated with reduced odds of achieving cDAPSA low disease activity (OR 0.95, 95%CI 0.90–0.99, p=0.022), and a trend toward lower MDA rates (OR 0.95, CI 0.91–1.00, p=0.060). Catastrophizing was associated with poorer QoL (EQ-5D index b=-0.009 95%CI -0.013, -0.006, p < 0.001), with helplessness driving the strongest effect (β = –0.023, 95%CI –0.03 to –0.02, p< 0.001). After adjusting for current pain level, sex, and the presence of active depression, PCS remained independently associated with QoL (b= -0.004, 95%CI -0.01, -0.004, p =0.03), greater pain interference (β = 0.230, 95%CI 0.090–0.370, p=0.002), and reduced participation in social roles (β = –0.338, 95%CI –0.52 to –0.156, p< 0.001). No association was found with physical function (b= -0.91, 95%CI -0.256, -0.074, p =0.276).

Conclusion: Our findings highlight the critical role of psychological pain processing in PsA. Pain catastrophizing—often undetected by standard clinical assessments—exerts a substantial and independent effect on patient-reported outcomes, even after accounting for actual pain intensity and depression. Addressing this process through interventions such as cognitive behavioral therapy or integrative psychosocial support may be necessary to improve holistic disease management and help patients achieve true remission and restoration of function.

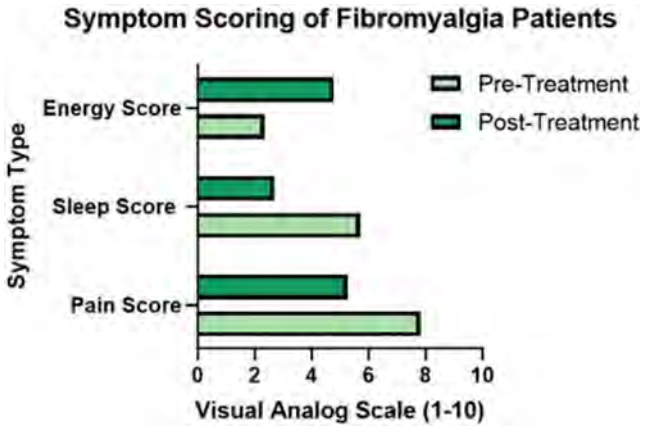

Figure 1. Fibromyalgia Symptom Severity Pre- and Post-Treatment

Background/Purpose: Fibromyalgia (FM) is a multifaceted disorder defined by chronic widespread pain, sleep disruption, fatigue, and cognitive difficulties. Although the predominant theory behind FM pathogenesis involves central sensitization and altered neurotransmitter signaling (e.g., serotonin, norepinephrine, glutamate), emerging evidence suggests peripheral contributors such as increased intramuscular pressure may also play a role. Elevated muscle tension has been correlated with poor sleep quality and higher pain levels, suggesting a cyclical relationship between sleep disturbance and muscular abnormalities. While tricyclic antidepressants (TCAs) have demonstrated some success in relieving FM-related symptoms - particularly sleep and mood disturbances - their use as monotherapy remains insufficient. Furthermore, despite literature on multimodal pharmacologic approaches, no studies to date have examined a combination of TCAs in a dose high enough to achieve uninterrupted sleep and muscle relaxants (MRs) as a targeted therapy for FM. This study explores whether this combination can effectively alleviate symptoms in a clinical population of FM patients.

Methods: We conducted a prospective study of 31 patients (25 females and 6 males) diagnosed with FM using the American College of Rheumatology (ACR) diagnostic criteria. All participants were prescribed a low dose TCA (amitriptyline, doxepin, or trazodone) in the early evening, titrated as needed to induce deep sleep. Once patients reported improved sleep, a nightly muscle relaxant - either cyclobenzaprine or tizanidine - was introduced and gradually increased based on tolerability, up to 30 mg or 24 mg respectively. Visual Analog Scales (VAS) were used to assess changes in pain (0–10), sleep quality (1 = excellent sleep, 10 = no sleep), and energy levels (1 = no energy, 10 = abundant energy) before and after the treatment regimen.

Results: Following treatment, 23 of 31 patients (74%) reported symptomatic improvement. Pain scores on

VAS decreased from a pre-treatment mean of 7.81 to 5.25 post-treatment. Sleep quality improved significantly, with average sleep disruption scores declining from 5.7 to 2.69. Patient-reported energy levels increased from a mean of 2.34 to 4.77. See Figure 1. Eight patients (26%) reported no improvement, and an equal number experienced sedation as a side effect, though no other adverse events were reported. All results were statistically significant with a p-value < 0.01.

Conclusion: This study introduces a novel multimodal pharmacologic regimen combining tricyclic antidepressants and muscle relaxants to target both central and peripheral mechanisms contributing to FM symptomatology. Results suggest that such a combination can improve pain, sleep, and energy in a substantial portion of FM patients, with minimal side effects. Given the limitations of existing monotherapies and the heterogeneity of FM symptoms, this approach warrants further exploration in larger randomized controlled trials. Future studies should also evaluate long-term outcomes and compare this regimen directly with currently approved FM treatments such as duloxetine and pregabalin.

Abstract Number: 1243

Broad Cytokine Dysregulation in Fibromyalgia Patients: A Pilot Immune Profiling Study

Robert Katz[1] and Alexandra Katz Small[2], [1]Rush University Medical Center, Chicago, IL, [2]Rheumatology Associates, CHICAGO, IL

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1221–1247) Pain in Rheumatic Disease Including Fibromyalgia Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

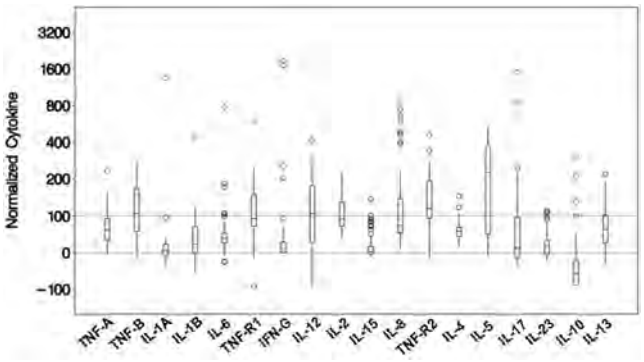
Background/Purpose: Fibromyalgia is a chronic pain syndrome characterized by widespread musculoskeletal pain, fatigue, cognitive disturbances, and poor sleep. Despite accumulating evidence of immune involvement, a clear immunophenotype remains elusive. Previous studies have focused on a limited set of cytokines with inconclusive results. This study aims to explore a broader panel of proinflammatory, anti-inflammatory, and adaptive cytokines to identify immune abnormalities that may contribute to fibromyalgia pathology.

Methods: 46 patients diagnosed with fibromyalgia per the 2016 ACR criteria underwent peripheral blood sampling. Serum levels of 22 cytokines were analyzed at the University of Miami Immunology Lab and compared to age-matched normal controls using a percentile-based cutoff.

Cytokines were categorized as pro-inflammatory (TNF-α, IL-6, IL-8, IL-1α, IL-1β, IFN-γ, IL-17), anti-inflammatory (IL-10, IL-4, IL-13), or adaptive (IL-12, IL-15, IL-23). Levels of soluble cytokine receptors (TNFR1 and TNFR2) were also measured. Levels were deemed abnormal if ≥50% of patients had values greater than the 90th percentile or less than the 10th percentile of the normal range. Flow cytometry was conducted in 25 patients to assess immune cell populations (CD8+, CD26+, CD11a+, CD56+, etc.).

Results: Fibromyalgia patients exhibited elevated levels of TNF-β, IL-5, IL-12, IL-15, IL-23, TNFR1, and TNFR2, suggesting heightened activation of both proinflammatory and adaptive pathways. IL-10, a key anti-inflammatory cytokine, was notably lower than average in most individuals. IL-1β, IL-6, and IL-17 levels exceeded the 90th percentile in a significant subset of patients, indicating innate immune activation. IL-8 elevations correlated with previously reported links to symptom duration.

Flow cytometry revealed reduced frequencies of CD8+, CD26+, and CD11a+ cells, with values below normal in over half of the tested patients



23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Fibromyalgia patients demonstrate a coherent dysregulation in immune signaling, characterized by elevations in several proinflammatory and adaptive cytokines alongside suppression of anti-inflammatory mediators such as IL-10. These findings support hypotheses of central sensitization being partially driven by aberrant immune signaling, even in the absence of classical inflammation. IL-10 deficiency and elevated TNF/IL-23 axis components may represent mechanistic targets for therapeutic intervention.

Further research is needed to validate these biomarkers and explore causal mechanisms.

PACFiND: Co-Designing Principles To Inform Reconfiguration Of Fibromyalgia Care Across Health Systems

Rosemary Hollick[1], Marcus Beasley[1], Ernest Choy[2], Caroline Cupit[3], Debra Dulake[1], Teresa Finlay[3], Louise Locock[1], Paul McNamee[1], Catherine Pope[3], Elaine Wainwright[1], David Williams[4], Gary Macfarlane[1] and PACFIND study team, [1]University of Aberdeen, Aberdeen, United Kingdom, [2]Division of Infection and Immunity, CREATE Centre, Cardiff University, Cardiff, United Kingdom, [3]University of Oxford, Oxford, United Kingdom, [4]University of Michigan, Michigan

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1221–1247) Pain in Rheumatic Disease Including Fibromyalgia Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Fibromyalgia is a contested and poorly supported condition, characterised by widespread pain, fatigue, and cognitive symptoms, often compounded by stigma and delayed diagnosis. Existing services are fragmented and inconsistent, with high patient and system burden. The PACFiND study (PAtient-centred Care for Fibromyalgia: New pathway Design) aimed to inform new models of care for fibromyalgia.

Methods: A mixed method design integrated systematic literature reviews, surveys of, and interviews with, people with fibromyalgia symptoms/diagnosis and healthcare professionals, analysis of routine healthcare data and service case studies, to explore care pathways for fibromyalgia in the UK. Data collection included over 2,700 survey responses from patients and professionals, 31 in-depth interviews, 12 UK-wide service case studies, and national healthcare data on nearly 100,000

The bus infographic represents a patient-led journey through fibromyalgia care, reflecting the uneven pathway of ups and downs, or flare-ups and remissions of symptoms that people living with fibromyalgia experience. The patient, as driver, reflects autonomy and control, with the bus components symbolising flexible, multidisciplinary support grounded in holistic care principles.

Figure 1. Evidence-based principles of care to guide fibromyalgia service redesign.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

individuals. Findings were synthesised through investigator meetings and structured workshops, involving patients, public representatives, clinicians, commissioners, and policymakers to co-design principles of care to inform new care models.

Results: Findings highlighted delayed and inconsistent approaches to diagnosis, especially in men, and limited post-diagnosis support. Many health professionals questioned the validity of a fibromyalgia diagnosis. Patients often faced a revolving door of referrals across specialties, particularly pain management, gastroenterology, and general surgery, and invasive investigations. They reported substantial out-of-pocket costs, difficulty navigating services, and poor work outcomes. Healthcare professionals expressed uncertainty in making a diagnosis and management, with variable understanding of fibromyalgia as a central sensitisation condition. While medication remains a default, patients voiced strong preferences for personalised, holistic, and non-pharmacological interventions, delivered with empathy and continuity. Community resources, such as support groups, play a key role but lack formal recognition. Insights informed evidence based care principles (Figure 1) and potential delivery across different settings. For example: (1) primary care e.g., family physicians for early recognition, supported by training; (2) specialist input for complex diagnosis and management; and (3) wraparound support, integrating physical, psychological, and peer-led services. These aim to reduce inappropriate referrals, improve experience and outcomes, and enable tailored, appropriate place-based care.

Conclusion: The PACFiND study has co-designed multilevel principles for fibromyalgia care aligned with patient needs and system priorities. While conducted in the UK, the challenges identified—delayed diagnosis, fragmented care, and unmet patient needs—are common across healthcare systems globally, including the US. Although the logistics of implementation may differ, the core principles of integrated, person-centred, and evidence-informed care are widely applicable. This model offers a flexible framework to guide service redesign internationally. Next steps include testing in implementation settings and using economic data to support scale-up.

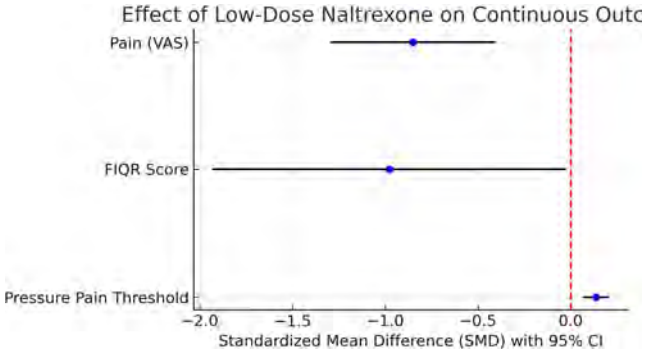
Efficacy And Safety of Low-dose Naltrexone In Fibromyalgia: An Updated Systematic Review And Meta-Analysis of Randomized Controlled Trials (RCTs)

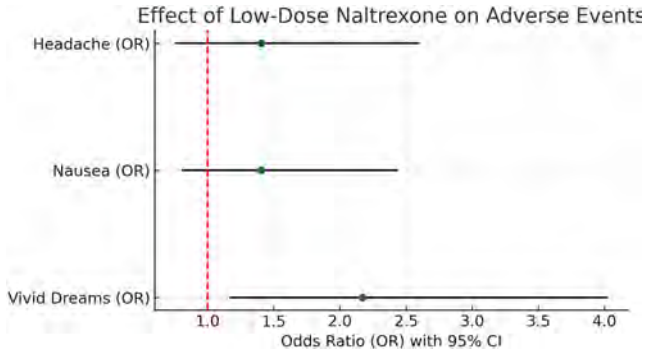
Rubab Rizwan, Sehneet Grewal, Sri Varsha Banda and Mohammad Hazique, Nuvance Health, poughkeepsie, NY

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1221–1247) Pain in Rheumatic Disease Including Fibromyalgia Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Fibromyalgia is a chronic condition marked by widespread pain that can significantly reduce a patient's quality of life. While low-dose naltrexone (LDN) has emerged as a potential treatment option, its use is not yet well supported by robust evidence, particularly from randomized controlled trials. (RCTs). This study evaluates the effectiveness and safety of LDN in managing symptoms of fibromyalgia.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License





Methods: This meta-analysis evaluated the safety and efficacy of LDN in fibromyalgia by systematically reviewing RCTs published through December 2024. Study selection followed PRISMA guideline. Data was analyzed using randome-effect model to calculate the pooled odds ratios (ORs) and Standardized mean difference (SMDs) for the measured outcomes.

Results: A total of five RCTs were included. LDN significantly reduced pain scores compared to placebo, with a pooled SMD of –0.851 (95% CI: –1.290 to –0.412). LDN also improved functional status as measured by the Fibromyalgia Impact Questionnaire Revised (FIQR), with SMD of –0.978 (95% CI: –1.926 to –0.030). Pressure pain threshold showed a small but statistically significant increase in the LDN group (SMD: 0.136; 95% CI: 0.071 to 0.202). Regarding safety, LDN was associated with a higher odds of vivid dreams (OR: 2.17; 95% CI: 1.17 to 4.02), but no significant increase in the risk of headaches (OR: 1.41; 95% CI: 0.76 to 2.60) or nausea (OR: 1.40; 95% CI: 0.81 to 2.43). Heterogeneity ranged from low to moderate across outcomes, and no major safety concerns were identified.

Conclusion: The findings of our analysis indicate that LDN may effectively reduce pain symptoms in patient with fibromyalgia while maintaining the favorable safety profile.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1221–1247) Pain in Rheumatic Disease Including Fibromyalgia Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Experimental and clinical studies suggest that fascial structures play a critical role in the pathogenesis and pain mechanisms of myofascial pain syndrome (MTrP). It is proposed that incorporating fascial structures into treatment may enhance therapeutic outcomes. However, no high-quality randomized controlled trials have been conducted to evaluate this hypothesis. This study aims to assess whether including fascial structures in treatment provides additional benefits compared to conventional intramuscular MTrP injections.

Methods: This triple-blind, randomized, parallel-group, single-center prospective study included seventy-six patients aged 18–65 years diagnosed with active MTrP. In the myo-fascial injection group, injections targeted intermuscular fascia, deep fascia, and superficial fascia in addition to MTrP. In the myo-injection group, only intramuscular injections were performed. Pain intensity, pressure pain threshold, and functional status were assessed before treatment and at 30 minutes, 3 days, and 1 week after treatment.

Results: A significant reduction in pain intensity was observed in both groups at all post-treatment time points compared to baseline. The pressure pain threshold increased after treatment but decreased after the third day. Functional status improved in both groups by the third day, and this improvement continued through the first week. However, no significant differences were found between the groups at any time point regarding any measured outcome.

Conclusion: The injection method targeting fascial structures did not provide a significant advantage over the conventional intramuscular trigger point injection method. Further studies are needed to evaluate the long-term effects of including fascial structures in treatment.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1221–1247) Pain in Rheumatic Disease Including Fibromyalgia Poster

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Widespread pain (WSP) is thought to be related to alterations in nociceptive signaling such as pain sensitization. Whether pain sensitization predisposes to an increase in number of pain sites, including the development of WSP, is not known.

Methods: We included participants from the Multicenter Osteoarthritis Study (MOST), a NIH-funded longitudinal cohort, who reported pain sites on a homunculus at baseline and two years later to determine WSP status (defined as pain above and below the waist, on the right and left sides of the body, and axially), and underwent quantitative sensory testing (QST). We assessed baseline pain sensitization (i.e., alterations in ascending nociceptive signaling) using three QST measures: temporal summation (TS) at the wrist, and pressure pain threshold (PPT) at the patella (average of both knees), and PPT at the wrist. Higher TS indicates more pain sensitization, while higher PPT indicates less pain sensitization.

We analyzed the relations of QST to: 1) the presence of WSP at baseline; 2) an increase of at least two painful sites after two years of follow-up; and 3) incident WSP after two years among those who were free of WSP at baseline. We used logistic regression to estimate presence of WSP at baseline, and modified Poisson regression for the longitudinal analyses. We

Table. Associations between quantitative sensory testing measurements and widespread pain § TS Wrist additionally adjusted for study visit due to protocol change. # Adjusted for the following potential confounders: age, sex (for whole sample), BMI, race, site, presence of symptomatic knee OA in at least one knee, depressive symptoms, NSAID use, Opioid use, and Charlson comorbidity index. * Increase in at least two painful sites over 2 years additionally adjusted for baseline number of painful sites. TS: higher values indicate more pain sensitization; PPT: lower values indicate more pain sensitization. Abbreviations: TS, temporal summation; PPT, pressure pain threshold; SD, standard deviation; WSP, widespread pain; CI, confidence interval; OR, odds ratio; RR, risk ratio.

secondarily performed sex-stratified analyses given known sex differences in QST. All analyses were adjusted for potential confounders, including age, sex (for analyses of the whole sample), BMI, race, site, presence of symptomatic knee osteoarthritis in at least one knee, depressive symptoms, NSAID use, Opioid use, and Charlson comorbidity index.

Results: We included 3078 participants (mean age 62.7, 57.7% female), of whom 32.2% had WSP at baseline (67.8% female), and 23.5% had an increase in two or more painful sites (59.8% female) at two years of follow-up. Among the 2088 participants free of WSP at baseline (mean age 62.1, 52.9% female), 14.9% had incident WSP (55.9% female) over two years. Cross-sectionally, TS was significantly associated with baseline WSP in the whole sample and in females but not in males (**Table**). PPT at the wrist was inversely associated with baseline WSP in the whole sample and in both sexes, while PPT at the patella was inversely associated in the whole sample and female participants, but not in males (**Table**). There were no significant associations between QST measures and either an increase in at least two painful sites or incidence of WSP after two years of follow-up (**Table**).

Conclusion: Although QST measures were associated with WSP cross-sectionally, they were not associated with incident WSP or increase in number of pain sites over two years. However, the null longitudinal findings may have been limited by the phenomenon of depletion of susceptibles (i.e., those most susceptible had already developed WSP in relation to pain sensitization at an earlier age).

Patient and Clinician Perception and Use of Complementary and Alternative (CAM) Medicine for Rheumatic Disease

Ailia Ali[1], Sarah Sun[1], Faryal Shaikh[1], Tamiko Katsumoto[2], Neha Shah[3], Kimberly Trotter[1] and Pankti Reid[4], [1]University of Chicago, Chicago, IL, [2]Division of Immunology and Rheumatology, Stanford University, Millbrae, CA, [3]Stanford University, Palo Alto, CA, [4]University of Chicago Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1248–1271) Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Complementary and alternative medicine (CAM) use is increasingly prevalent among patients with rheumatic diseases, yet alignment between patient practices and clinician perspectives remains poorly defined. This study assesses CAM attitudes, usage patterns, and familiarity amongst both rheumatology clinicians and patients.

Methods: An online patient-facing survey and a separate clinician-facing survey evaluated use and perception of CAM in rheumatic diseases. Eligible patients were ≥ 18 years old and actively going to rheumatology clinic. Clinicians included rheumatology MDs, DOs and advanced practice providers. Dissemination of the survey was done virtually through patient advocacy groups, provider organizations, social media, and messaging via electronic medical records. Results were analyzed using descriptive statistics (Chi-square).

Results: 1221 patients with rheumatic disease across the United States completed the patient survey. For patients, if no familiarity with CAM (163 patients or 13% of respondents) was endorsed, the survey was ended. Patient participants were primarily female (88%), and predominantly Caucasian non-Hispanic (64%). The most common rheumatic disease

reported was rheumatoid arthritis (58%) followed by Sjogren's disease (19%). A high proportion of patients reported CAM usage but many were not familiar with CAM and 76% of patients did not find CAM very accessible. Most patients used the internet or social media as their primary source of information on CAM (40%). Half of the patients had Medicare insurance; of these patients, 26% reported daily CAM usage. There was no difference in CAM usage when comparing Medicare vs. non-Medicare patients ($p > 0.05$). Asian respondents reported high daily usage of CAM while Black

23652205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

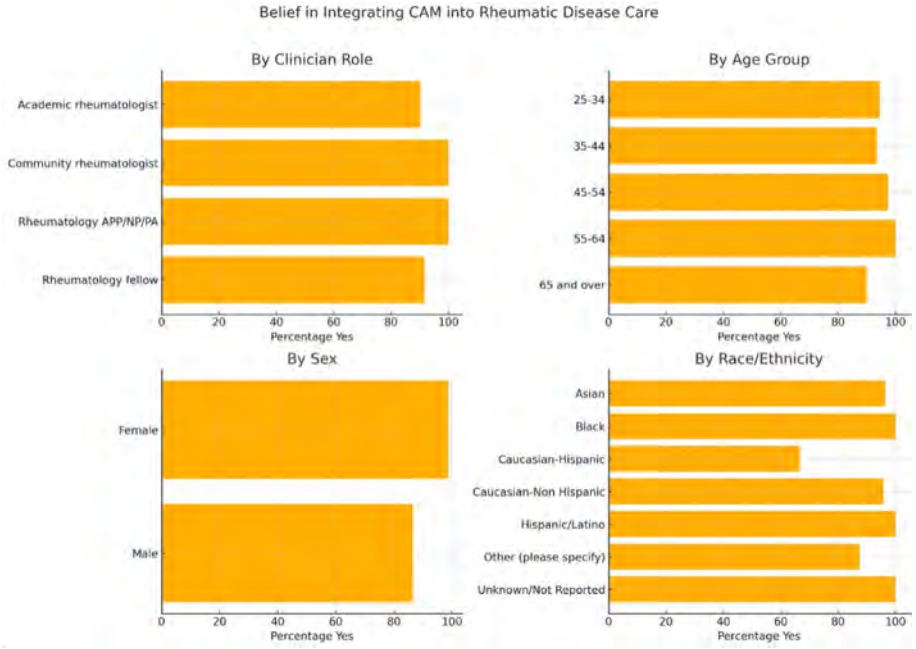

Figure 1: Clinician Belief in Integrating CAM into Rheumatic Disease Care

respondents had a lower daily usage compared to other groups (p=0.02). While patients with higher level education were more likely to use CAM (doctorate or higher with daily: 37.5% and monthly: 12.5% CAM use, master's and college degrees: 35% daily and 7% monthly use), individuals with high school or less education were more likely to never use CAM (35%).

A total of 128 rheumatologists across the United States completed the clinician survey. The majority of respondents were community rheumatologists (47%) and academic rheumatologists (40%). Most were female (66%) and the most common racial background was Asian (42%) and Caucasian-Non Hispanic (38%). Notably, 95.2% of respondents expressed support for integrating CAM therapies into standard rheumatology practice, indicating strong professional interest across practice settings.

Conclusion: CAM usage is prevalent amongst the rheumatic patient population but many patients do not find CAM very accessible and usage varies with different races/ethnicities and education levels. Future implementation needs to focus on more accessible CAM programs. As these patients follow regularly with their rheumatologists, the strong clinician interest for CAM integration into standard rheumatologic care is an opportunity to develop structured education and provide evidence-based resources for patients.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease that can significantly impair physical function and quality of life. While physical symptoms such as joint pain and swelling are primary drivers of disability, psychosocial factors, including emotional well-being, may also influence functional outcomes. Positive affect—defined as the experience of pleasurable emotions and mood—has been associated with better health outcomes in various chronic conditions, but its relationship with physical function in RA, especially in the early stages of the disease, is not well understood. Gaining insight into this relationship early in the disease course is critical, as it may inform more integrated approaches to treatment and improve long-term functional outcomes. This study aimed to evaluate the association between positive affect and physical function in individuals with early, active RA.

Methods: Cross-sectional baseline data were analyzed from adults with early RA enrolled in the on-going Central Pain in RA 2 (CPIRA-2) study. Eligible participants met the ACR/EULAR 1987 or 2010 criteria for RA, had persistent joint symptoms for ≤ 24 months, and active disease. Physical function was assessed by the PROMIS physical function questionnaire, which evaluates the functional capabilities of various body regions and performance of activities of daily living; higher scores indicate better physical functioning. Positive affect was measured with the positive affect subscale of the PANAS self-report questionnaire, a 10-item scale assessing positive emotions such as joy, enthusiasm, and alertness; higher scores reflect greater positive affect. PROMIS instruments were also used to assess symptoms of pain and depression. Descriptive statistics summarized demographic and clinical characteristics. Linear regression models were conducted to estimate unadjusted and adjusted associations between positive affect and physical function. Adjusted models controlled for age, sex, body mass index, swollen joint count, symptom duration, pain, and depression.

Results: Our sample included 106 patients (80% female, 76% white) with mean (SD) age of 51.5 (16.5) years, BMI of 28.8 (7.3) kg/m^2, and RA symptom duration of 10.8 (4.8) months (Table 1). Approximately 61% had mild to severe functional limitations (*t-score* ≤ 45). In unadjusted analysis, greater positive affect (β = 2.4 [95% CI 1.6 to 3.3]) was associated with better physical function. In an adjusted linear regression model, greater positive affect remained associated with physical function; younger age, and lower pain intensity were also significantly associated with better physical function (Table 2).

Conclusion: Greater positive affect was associated with better physical function in patients with early RA, even after adjusting for clinical and demographic factors. Longitudinal investigations are needed to better assess the true directionality of these relationships. Our findings suggest that interventions integrating strategies to enhance emotional well-being alongside effective pain management may help to improve and maintain physical function during the early stages of RA.

Table 1: Tele-Medicine Satisfaction Questionnaire Scores for random sample of Veterans participating in the NTRP (N=160)

	Score (Mean (SD))	Score Range (Low-High)
Overall Satisfaction	57.5 (9.6)	14-70
Subdomains		
Quality of Care	32.3 (5.9)	8-40
Similarity to Face to Face	20.8 (3.4)	5-25
Perception of Interaction	4.4 (0.8)	1-5

Table 2: Generated themes with exemplary quotes according to the Healthcare Quality Model (n=102)

Healthcare Quality Model Construct	Themes	Quotes
Safety	Safety from exposures and infections	*"Everything moves so swiftly with this program. It also provides some safety from covid exposure."*
Effectiveness	Effective treatment	*"Everything seems to be going well. I've only seen them one time but the medicine seems to be helping. I like my Dr."*
	Satisfaction with visit outcomes	*"I'm hopeful it'll help. It was good on the teleconference. He did a great job getting it done."*
	Thorough assessment/evaluation	*"I really like this. I thought this was the best evaluation I've ever received. I really liked this Dr. He's amazing! He was very thorough."*
	Experienced/skilled physician	*"Dr. [name] is absolutely the best Dr. at the VA. Very knowledgeable, very approachable, very involved, and very caring."*
	Dissatisfaction with visit outcomes	*"To be honest it was a waste of time. I didn't feel like a lot got solved and it didn't seem like he understood my condition."*
	Dissatisfaction with treatment	*"I feel like we're not making any progress. I don't think I'm improving, and I think it's better to see a Dr. in person."*
	Limited visit time	*"I didn't get to ask all of the questions I wanted to."*
Efficiency	Collaboration between staff members	*"Having the nurse there was great too, you won't find a better nurse. The way they interacted, you would've thought they've been working together for years. It was top notch. I just want this program to keep going... continuity is my drum beat."*
	Organized process	*"It was pretty straight forward. The transition from medical person to Dr. was very smooth"*
	Convenience	*"It was very convenient. I wish more Dr.'s were like [physician name], you have to jump through so many hoops with other Rheumatologists.?*
	Time saving	*"I live 150 miles from the VA so it definitely saved me time."*
	Ease of use	*"It's easy enough to get on and I'm electronically challenged."*
	Lack of clarity on the visit process	*"I would like a better explanation of how it works before the visit starts."*
	Technical difficulties	*"I wish I could see him in person and sometimes it's kind of hard to get on the telehealth call. Sometimes it's hard to hear as well."*
Timeliness	Fast referral/scheduling	*"I'm glad I got an appointment so quickly. it was good."*
	Prescription delays	*"I still haven't received my new medication so it's a little slow moving."*
Patient Centeredness	Supportive team	*"The program has been Johnny on the spot. You're all proactive and I appreciate everything you guys do. It doesn't feel like I'm fighting an uphill battle anymore."*
	Focused on patient needs	*"It fits my needs. I don't have a lot of issues managing my disease, so it works. My Dr. schedules my appointments regularly and I'm overall happy with it."*
	Attentiveness to patient	*"Dr. [name] is amazing. He listens and really takes his time with me. The whole program has been great so far. I'm happy."*
	Comfortable discussion	*"It was better than I thought. Dr. [name] is great and made me feel very at ease."*
	Empathetic and supportive Physician	*"I want to marry him. Does that answer your question?... He's a great Dr... He makes an extra effort."*
	Preference for in-person visits	*"Those are things a Dr. would notice if we were in person so it's hard to not have that face-to-face care."*
	Discomfort with virtual care	*"I'll never do it again. I was really upset when I heard it was a video visit. I want a person; I can't stand this digital useless stuff."*
	Lack of physical examination	*"I really needed a physical exam, and I just can't get that over telehealth."*
	Lack of face-to-face interaction	*"I like the face-to-face interaction better. It's nice to shake your Dr.'s hand."*
Access and equity	Accessible rheumatology care	*"It's been hard to be seen and having that option is incredible. Community care isn't even an option so it's huge for us here. The way this program's set up is wonderful"*
	Difficulty contacting physicians	*"It's a little challenging to reach my Dr. if I have any follow-up questions about my meds."*

*Positives

Table 3: Joint display analysis according to the Healthcare Quality framework

Healthcare Quality Construct	TSQ statements
Safety	–
Effectiveness	1. My healthcare provider is able to understand my healthcare condition. 2. Overall, I am satisfied with the quality of service being. 3. I find telemedicine an acceptable way to receive healthcare services. 4. I think the healthcare provided via telemedicine is consistent. 5. I will use telemedicine services again.
Efficiency	1. I can hear my healthcare provider clearly. 2. I can easily talk to my healthcare provider. 3. I can see my healthcare provider as if we met in person. 4. Telemedicine saves me time travelling to hospital or a specialist clinic.
Timeliness	–
Patient centeredness	1. I do receive adequate attention 2. I feel comfortable communicating with my healthcare provider. 3. Telemedicine provides for my healthcare need.
Access and equity	1. I obtain better access to healthcare services by use of telemedicine. 2. I do not need assistance while using the system

Background/Purpose: The national shortage of rheumatology clinicians disproportionately affects over 2.7 million rural Veterans with already limited access to healthcare. To address this gap, the National Tele-Rheumatology Program (NTRP) was developed to connect Veterans with rheumatologists via telehealth. This study aimed to evaluate veteran patient satisfaction with the NTRP using a convergent mixed method analysis.

Methods: We invited a random sample of Veterans who had at least 1 rheumatology encounter via the NTRP to participate in telephone surveys. The first group completed the Telemedicine Satisfaction Questionnaire (TSQ), a validated 14-item instrument assessing quality of care, interaction, and satisfaction. The second group provided qualitative feedback through brief open-ended questions about the NTRP ("*What are things that you liked about the program?*" and "*What are things that you did not like about the program?*"). Quantitative data were analyzed using descriptive statistics and qualitative data were analyzed using a multi-stage thematic approach. Data were integrated through joint display analysis framed by the Healthcare Quality Framework (HQF), including domains of safety, patient-centeredness, effectiveness, efficiency, timeliness, and access and equity.

Results: A total of 160 patients responded to the TSQ (86.9% male, mean (SD) age 63.3 (14.7)). Responses reflected moderate to high satisfaction across all survey items (**Table 1**). 102 patients responded to the open-ended questions (79.4% male, mean (SD) age 63.8 (14.6)). Major themes and corresponding quotes are shown in **Table 2**: Veterans expressed high overall satisfaction with the NTRP, highlighting effective treatments, strong coordination, and the convenience of remote care. Many valued the program's efficiency, safety, and time-saving benefits. However, concerns emerged around technical difficulties, limited visit duration, and the absence of physical examinations. A subset of patients also preferred in-person care, underscoring the need for a tailored approach. The joint display analysis, framed by the HQF (**Table 3**), revealed concordant findings from the survey and open-ended questions, though the TSQ was limited in capturing negative perceptions towards the program around safety and timeliness.

Conclusion: Overall, Veterans reported high satisfaction with the NTRP, especially in domains of quality, effectiveness, and efficiency. Moving forward, efforts should aim to streamline logistics and refine patient selection to ensure telehealth is matched to clinical need and individual preferences. These findings can help inform future telehealth program design and implementation across other specialties serving rural populations.

Abstract Number: 1251

Steroids and Me (Sam): engaging and educating steroid-treated patients via patient advocacy partnerships and internet search channels.

Michelle Petri[1], **Martha Stone**[2], John Stone[3], meredith Marinaro[4], Matt Wilkinson[5], Walter Lentfert[6], Camille Kotton[7], Jeffrey Gelfand[8], Jane McDowell[9] and Tricha Shivas[10], [1]Johns Hopkins University School of Medicine, Timonium, MD, [2]Steritas, LLC, Concord, MA, [3]Massachusetts General Hospital , Harvard Medical School, Concord, MA, [4]Novartis, Hartford, CT, [5]UpThereEverywhere, London, United Kingdom, [6]UpThereEverywhere, Charlotte, NC, [7]Harvard Medical School, Boston, MA, [8]UCSF Department of Neurology, Mill Valley, CA, [9]Queens University Belfast, Belfast, United Kingdom, [10]Foundation for Sarcoidosis Research, Chicago, IL

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1248–1271) Patient Outcomes, Preferences, & Attitudes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: We report on two years of engagement with Sam, a patient-facing program to optimize the use of glucocorticoids and discontinue them when possible. We present aggregated data describing steroid-treated who seek, find, and engage with Sam from two channels: 1) Patient Advocacy Partnerships; and 2) Organic search.

Methods: The design and development of Sam included four steps:

1. Resource Review. A survey of the medical literature and internet for current, scientifically rigorous, patient-focused content on steroid use.
2. Needs Assessment. Workshops with patient advocacy groups and industry leaders; meetings with patient advocates; focus groups with patients; and meetings with industry experts.
3. Construction of portal. Optimized for mobile devices, Sam is co-created with patients and physicians across multiple diseases. User testing and journey validation for learning and tracking are at the core of the platform.
4. Development of learning modules, video snippets, behavioral nudges, and adverse event (AE) tracking capabilities.

Engagement (sample). Patient Advocacy and Google Search results to be updated

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Disease specific (sample) Patient Advocacy and Google Search results to be updated

Sam is a companion that provides video and written educational materials and patient reported side effect tracking. The educational content and AE monitoring align with clinical outcome assessments that measure steroid toxicity: Glucocorticoid Toxicity Index (GTI), the GTI-Metabolic Domains (GTI-MD), and the GT-SNAPSHOT, a baseline score of steroid burden.

Results: The engagement of patients with Sam is reported through two channels.

First, the 2025 Patient Advocacy Partnerships include those with the Vasculitis Foundation, the Sarcoidosis Research, the Lupus Research Alliance, IgG4ward! Foundation, Global Asthma & Airways Patient Platform, and the Crohn's and Colitis Foundation. These alliances with advocacy groups have yielded the following insights:

- Strong engagement in learning about steroid-toxicity
- Major interest in tapering, how to talk with doctors, neuropsychiatric side effects
- Multiple articles read
- Multiple side effects tracked
- Substantial engagement and elevated session time

Second, we evaluated 2025 data from individual visitors to Sam who use organic internet searches to learn about a specific steroid induced condition. For example, the query "steroids and brain fog" yielded lessons that patients are:

- Actively seeking knowledge about a steroids in conjunction with one specific side effect
- Successfully finding knowledge on Sam because on high search positions in Google
- Fully engaging in education based - extensive "time spent" on each topic

Conclusion: Steroids and Me (Sam) fills an unmet need for patients who grapple with steroid treatment. Sam engages and informs lay users in plain language, resulting in deeper understanding of the value and pitfalls of steroids. Sam includes steroid side effect mitigation and methods for doctor/patient discussions about safe steroid tapers. Patients from two essential channels (patient advocacy groups and organic search) engage with this unique, highly-curated resource provides education about steroids that leads to patient activation for healthy engagement around steroid use.

Session Title: (1248–1271) Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Identifying informational needs of individuals with inflammatory arthritis is critical to enhancing communication and supporting shared decision making between patients, caregivers, and providers. However, qualitative methods require significant human effort, time, and specialized software. Our goal was to determine how effectively a large language model (LLM) could classify thematic categorization with human-labeled data from 2 nominal group technique (NGT) studies of individuals with inflammatory arthritis.

Table 1: Human and large language model (LLM) – assigned themes by participant group in 2 nominal group studies of patient informational needs

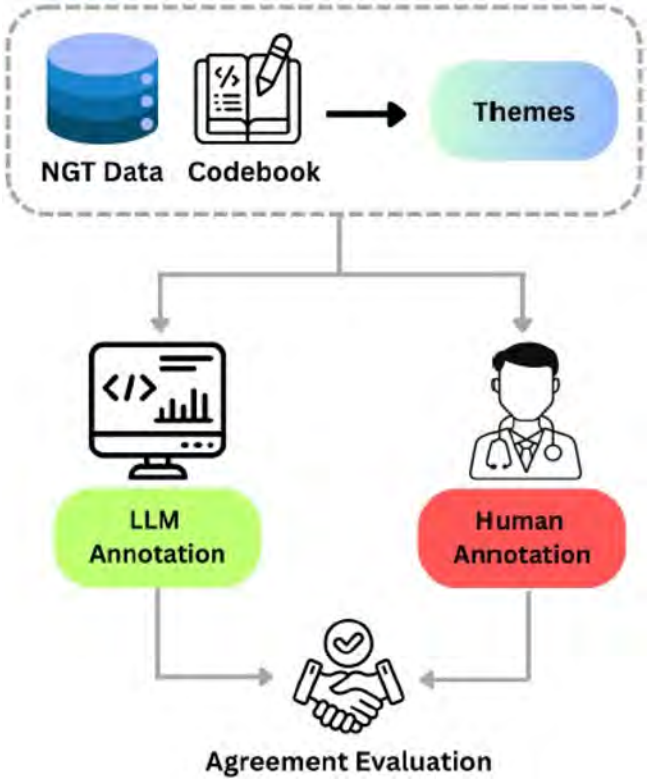

Figure 1: Workflow for Theme Assignment and Agreement Evaluation Between Human Coders and LLMs.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We utilized results from 2 separate NGT studies on the informational needs of individuals with inflammatory arthritis. The first identified information patients want prior to medication changes for juvenile idiopathic arthritis (JIA), including 2 virtual parent groups, 1 virtual adolescent group, and 1 asynchronous adolescent group. The second explored information priorities for adults living with inflammatory arthritis, collected over 6 virtual groups. Qualitative responses to the discussion questions were collected and ranked by participants. Responses were manually assigned themes by at least 2 members of the research team (gold standard). Six LLMs, including advanced proprietary models and open-source alternatives, were zero-shot prompted to assign a single best-fit theme from the human-generated codebook to each participant-generated statement. Model-assigned themes were compared to those assigned independently by 2 human coders. A match was defined as exact agreement between the model's theme and the human-coded themes. Performance was evaluated using accuracy, macro F1 score, Cohen's kappa, and Krippendorff alpha relative to each coder.

Results: The adolescent groups had 12 human-labeled and 12 LLM-assigned primary themes; the parent groups had 10 human-labeled and 11 LLM-assigned themes; the adult groups had 8 of each (Table 1). Model accuracy of theme assignment ranged from 65–82% for adolescent statements, 54–95% for parent statements, and 70–100% for adult statements (Table 2). Model agreement with human coders, measured by Cohen's kappa, ranged from 0.70–0.80 for adolescent statements, 0.47–0.94 for parent statements, and 0.64–1.00 for adult statements. Human interrater Cohen's kappa was 0.57 for adolescents, 0.59 for parents, and 0.74 for adults (Table 2).

Conclusion: LLMs can reliably approximate human coding of qualitative themes in NGT data, and in some cases showed stronger agreement with individual coders than the coders had with each other. Human- and model-assigned themes were often similar, with strong agreement across datasets. Models performed best when statements expressed clear, explicit themes but faced challenges with ambiguity or overlapping concepts. Performance was strongest for advanced reasoning models but remained robust across open-source and earlier-generation models. These findings support LLMs as scalable tools for thematic analysis in qualitative research. Future directions include refining prompts to assess statement salience and exploring LLM-guided theme discovery without predefined codebooks for flexible, data-driven identification of emerging concepts.

Session Title: (1248–1271) Patient Outcomes, Preferences, & Attitudes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background/Purpose: When treating patients with rheumatological conditions, building a strong physician-patient relationship plays an important role in determining disease outcomes. The Routine Assessment of Patient Index Data 3 (RAPID3) is a patient reported outcome measure which is administered to patients in rheumatology clinics. We initiated use of the RAPID3 assessment in our clinic with the hypothesis that in addition to assessing patient reported outcomes, this tool would help residents better understand the disabling effects of rheumatological diseases and that it would also enhance physician-patient relationships by giving the patient a voice to express themselves and explain the impact of their diseases on their daily lives. This study analyzes the impact of RAPID3 on resident education, doctor-patient relationships, and patient care using a 360-degree assessment of both the resident physician and patient perspectives.

Methods: RAPID3 surveys were administered to all patients (regardless of diagnosis) during their clinic visit, with assistance as needed by the resident physician, and responses were discussed with the patient during the clinic visit, in two resident-staffed outpatient Rheumatology teaching clinics at our institution over a 6-month period. After the clinic visit, patient surveys were administered to patients by research volunteers (CB, HL) who were not part of the medical team. Anonymous surveys were also sent to all resident physicians after each clinic session. The surveys included both yes/no questions as well as 5-point Likert scale questions. The mean plus standard deviation was then calculated for each answer.

Table 1. Resident's responses to the questionnaire used to assess the educational and patient care value of RAPID3 survey. (n=37 resident sample size)

Questions:	Mean ± SD
1. The RAPID3 survey helps me understand my patient better.	4.081 ± 0.759*
2. The RAPID3 survey helps me understand the degree of disability associated with musculoskeletal disease in day to day living of my patient.	4.21 ±0.821*
3. The RAPID3 is a waste of clinic time; it does not help me better understand my patient.	1.94 ±0.941*
4. The RAPID3 slows down patient visits and makes me less efficient.	2.08 ±0.682*
5. From your perspective, are your patients more comfortable with you after the RAPID3 is administered?	0.864 ±0.346**
6. Is there any area which you feel that the RAPID3 does not adequately address?	0.054 ±0.226**
7. Does the RAPID3 enhance the doctor-patient relationship?	0.890 ±0.312**
8. Does the RAPID3 improve your communication with your patient?	0.946 ±0.226**
9. Would you want to see the RAPID3 as regular practice in the Rheumatology clinic moving forward?	0.972 ±0.165**

*Questions 1-4 used a five-point Likert scale, *strongly agree=5, agree=4, neither agree nor disagree=3, disagree=2, strongly disagree=1, Questions 5-9 used no=0 and yes =1.*
**Questions 5-9 used yes/no questions

Table 2. Patient responses to the questionnaire used to assess patients' opinions on the RAPID3 survey (n=148 patient sample size)

Questions:	Mean ± SD
1. The RAPID3 form makes me feel like my disease is better understood by my doctor	4.28 ± 0.738*
2. The RAPID3 helps me explain my disease to the treating doctor	4.24 ± 0.777*
3. The questions on the RAPID3 are too intrusive	1.67 ± 0.832*
4. The RAPID3 helps me explain my pain and level of ability in dealing with problems in my daily activity	4.42 ± 0.738*
5. The RAPID3 asks appropriate questions to help me describe how I am doing	4.33 ± 0.759*
6. The RAPID3 helps me feel more comfortable with the treating doctor	4.29 ±0 .730*
7. I want to see the RAPID3 used at every Rheumatology clinic visit from now on	4.19 ± 0.899*

*Questions used a five-point Likert scale, *strongly agree=5, agree=4, neither agree nor disagree=3, disagree=2, strongly disagree=1*

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Resident Belief of Impact of RAPID3 on physician-patient relationships: 89.2% residents agreed/strongly agreed that RAPID3 helped them understand their patient better. 89.2% agreed that RAPID3 helped them get a deeper understanding of the degree of disability patients experience. 86.5% of residents felt that patients were more comfortable with them after completing the survey (Table1).

Resident Acceptance of RAPID3: 91.9% disagreed/strongly disagreed that RAPID3 is a waste of clinic time. 97.3% agreed that the RAPID3 should be a regular part of all future clinics (Table 1).

Patient Acceptance of RAPID3: 86.5% of patients agreed/strongly agreed that the RAPID3 should be used at every visit (Table 2).

Patient Belief of Impact of RAPID3 on physician-patient relationships: 89.9% of patients felt more comfortable with their physician after the survey. 93.3% of patients felt the survey helped the physician better understand the daily impact of disease (Table 2).

Conclusion: RAPID3 was well accepted among patients and residents. It serves as a helpful tool for residents (normally young and healthy) to realize the barriers that patients with rheumatologic and musculoskeletal diseases face. It helped improve patient-physician communication and helped patients feel more comfortable with their physician. Future research may include how to shorten the RAPID3 (i.e., which questions are superfluous) and try to administer RAPID3 regularly prior to visits to always prioritize patient reported outcomes.

Symptom Burden and Treatment Experience in Fibromyalgia: Results From a National Patient Survey

Lesley Arnold[1], Zhao Yang[2], **Parul Houston**[2], Todd Grinnell[2] and Daniel Clauw[3], [1]University of Cincinnati College of Medicine, Cincinnati, OH, [2]Axsome Therapeutics, Inc, New York, NY, [3]Chronic Pain and Fatigue Research Center, University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1248–1271) Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Fibromyalgia (FM) is a chronic, widespread pain disorder driven by dysregulated central pain processing which substantially impairs daily function and quality of life. Approved pharmacotherapies are limited, with no new options introduced in over a decade, and many patients continue to experience burdensome symptoms and impaired daily function despite treatment. A survey of US patients was conducted to understand the current lived experience of people with FM, including their diagnostic journey, impact of disease, and treatment experience.

Methods: The survey was conducted from August-September 2024 among adult patients (≥18 years old) in the US with self-reported FM diagnoses. Respondents, recruited by a third party across a wide range of demographic and care settings, completed a 30-minute online survey assessing diagnosis experience, symptom burden, treatment history, and symptom control.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: The survey comprised 500 respondents (94% female). Mean age at diagnosis was 37 years. The average self-reported time of symptom onset was 17 years prior to the survey. On average, nearly 3 years passed between symptom onset and seeing a healthcare provider. Respondents were most often diagnosed by rheumatologists (42%), primary care providers (PCPs; 25%) and pain specialists (9%). Half reported their FM was currently managed by a PCP, 33% by a rheumatologist, and 13% by a pain specialist.

On average, respondents reported experiencing 6 symptoms in the past week; the most prevalent were pain (96%), fatigue (95%), and muscle stiffness/tenderness (88%). Although pain was most common, it was rated less burdensome than waking very tired and lacking energy. The most common comorbidities were anxiety (51%), migraine (48%), and depression (40%); patients reported 5 comorbid medical conditions on average. Most (93%) reported that FM interfered with their ability to accomplish weekly goals.

Among respondents, 46% were taking multiple medications for their FM, 36% were taking a single medication, and 19% had discontinued pharmacotherapy. Among current medications, off-label therapies were most common; most frequently SSRIs/SNRIs or gabapentin (30% each), cyclobenzaprine (20%), and trazodone or tramadol (13% each). Mean duration of use was ≥5 years for all medications, yet 57% of patients described their FM as not well- controlled. Among those who discontinued medication, 68% cited intolerable side effects and 51% lack of efficacy as reasons; cognitive impairment was the most common side effect leading to discontinuation. Nearly two-thirds of all respondents expected medication to offer only partial relief from their symptoms, and 77% expressed concern they would never be pain-free.

Conclusion: This survey found patients with FM frequently experience persistent, burdensome and impactful symptoms, even after years of treatment. Symptom relief and treatment satisfaction were limited, and expectations for future improvement were low. Use of off-label and combination therapies was high, and rates of discontinuation due to side effects or lack of efficacy were common. These findings highlight the continued substantial burden of FM and the need for more effective and better-tolerated treatment options.

Abstract Number: 1255

Lung Transplantation Outcomes for Pulmonary Sarcoidosis Compared to Idiopathic Pulmonary Fibrosis: A Single Institution Multisite Experience

Reena Yaman[1], Lisa Balistreri[2], Maximiliano Diaz Menindez[3], Sehreen Mumtaz[1], Megan Sullivan[3], Alexander Hochwald[1] and Florentina Berianu[1], [1]Mayo Clinic Florida, Jacksonville, FL, [2]Lee Health, Cape Coral, FL, [3]Mayo Clinic Arizona, Scottsdale, AZ

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1248–1271) Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Pulmonary disease is present in most sarcoidosis cases with up to 10% of patients progressing to advanced lung disease.[1] Pulmonary sarcoidosis accounted for 2.5% of lung transplants in 2015. Idiopathic pulmonary fibrosis (IPF) is a much more common indication for lung transplantation.[2] Post-transplant outcomes for both indications are

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1. Baseline (pre-transplant) characteristics of idiopathic pulmonary fibrosis and sarcoidosis groups. Statistically significant differences are designated by an asterisk (*).

	Idiopathic pulmonary fibrosis (n=26)	Sarcoidosis (n=13)	p-value
Age, years	65 (51-87)	65 (51-80)	0.66
Male sex	23 (88.5%)	11 (84.6%)	1.00
Smoking history	10 (38.5%)	6 (50.0%)	0.72
Pre-transplant radiographic pattern			
Usual interstitial pneumonia	16 (61.5%)	2 (15.4%)	0.008*
Nonspecific interstitial pneumonia	5 (19.2%)	2 (15.4%)	1.00
Hypersensitivity pneumonitis	1 (3.8%)	1 (7.7%)	1.00
Undefined interstitial disease	2 (7.7%)	5 (38.5%)	0.030*

presumed to be comparable.[1,2] The current study evaluates the experience and outcomes across multiple sites at a single institution.

Methods: All lung transplants occurring at any site between July 2017 and March 2023 were reviewed. Descriptive statistics were performed and compared between pulmonary sarcoidosis and IPF indications via Kruskal-Wallis and Fischer's Exact tests. Survival and pulmonary function test results were compared between groups. Kaplan-Meier curves and hazard ratios were used for survival comparison.

Results: Lung transplantation outcomes for 13 cases of sarcoidosis were compared to 26 age- and gender-matched IPF cases. The most common computed tomography pattern was usual interstitial pneumonia (61.5%) in the IPF group compared to undefined pattern (38.5%) in the sarcoidosis group. Baseline characteristics were otherwise comparable (Table 1). A higher proportion of sarcoidosis patients had improved post-transplant forced vital capacity compared to IPF patients although this difference was not statistically significant (Figure 1). Survival plateaued at 75% in both groups after 5 years with hazard ratio 0.56 (p=0.49) (Figure 2).

Conclusion: Lung transplantation is a feasible treatment strategy for pulmonary sarcoidosis and demonstrated comparable outcomes to IPF in this cohort. Rheumatologists treating sarcoidosis can therefore benefit from familiarity with current lung transplantation referral guidelines, disease-specific indications and contraindications, and multidisciplinary collaboration.

Quantitative Analysis of a Pilot Study: Integrating Behavioral Health Services for Patients with Rheumatic Diseases

Shannon Teaw[1], Jessica Link-Malcolm[2], Michelle Ghebranious Farag[3], Dorothy Patterson[2], Jenny Foster[4], Sofia Bereket[2], Urooj Wahid[2], Puneet Bajaj[2], Elizabeth Solow[2], Jennifer Barton[5] and Una Makris[6], [1]UT Southwestern Medical School, Dallas, TX, [2]UT Southwestern Medical Center, Dallas, TX, [3]McGovern Medical School at UT Houston, Houston, TX, [4]UT Southwestern Medical Center, Dallas, [5]VA Portland Health Care System/OHSU, Portland, OR, [6]UT Southwestern Medical Center and Dallas VA, Dallas, TX

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1248–1271) Patient Outcomes, Preferences, & Attitudes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with rheumatic diseases (RD) often experience chronic pain, along with comorbid depression and anxiety, which can be addressed using behavioral health (BH) interventions for motivating behavior change and increasing self-management skills. Despite potential benefits, efforts to integrate BH services into rheumatology clinics have been limited. We developed and piloted a single-arm BH program integrated within a rheumatology clinic to evaluate feasibility and trends towards improved patient-reported outcomes (PRO).

Methods: During their clinic visit, adult patients with RD were invited to participate in a pilot BH program. Interested patients were asked to select up to 3 BH goals of interest from a goal elicitation tool (Figure 1). Those who selected at least 1 of the 3 target goals that the BH specialist would focus on were eligible to participate in the telephone-based intervention, which consisted of up to 8, brief, patient-centered sessions, utilizing techniques such as motivational interviewing and mindfulness

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Goals Wheel. Stars indicate BH services offered.

meditation combined with psychoeducation and supplemental apps/videos. PROs for pain interference (PEG-3), pain catastrophizing, depression/anxiety (PHQ-4) and PROMIS measures of fatigue, quality of life (QoL), physical function, sleep and social satisfaction were collected at baseline and during the final BH session. Depending on the normality of distribution, Wilcoxon signed-rank or student T-tests were used to compare baseline and post-intervention scores.

Results: We enrolled 54 participants, 45 completed the baseline assessment, and 39 engaged in at least 1 BH session beyond baseline. Of these, 28 completed the program (i.e., completed a final assessment session). Among the completers, 79% were women and white. Osteoarthritis (32%), rheumatoid arthritis (21%) and psoriatic arthritis (18%) were the most frequent rheumatologic diagnoses. Fifty percent of the sample had a mental health diagnosis code. Most participants (52%) focused on the goal "Improve My Mood/ Manage Stress & Anxiety" and completed the program in 8 sessions (IQR 6, 8). At baseline (n=28), average PEG-3 score was 3.69/10 and PHQ-4 score was 3.32/12. There was improvement in pre-post mean change scores for PEG-3, pain catastrophizing, PHQ-4, fatigue, sleep and QoL; however, no improvement was noted in social satisfaction or physical function (Table 1).

Conclusion: In this pilot study, recruitment and delivery of an integrated BH program was feasible in a busy rheumatology clinic. We found promising trends toward improvement in PROs for several domains, including pain, pain catastrophizing and depression/anxiety. These results warrant future evaluation with a fully powered randomized controlled trial.

Patient Reported Outcomes (PRO)	Median baseline scores	Pre-Post change score	P-value
PEG-3 Pain interference	3.3	-1.14	*p = 0.002
Pain catastrophizing	9.0	-5.39	*p < 0.001
PHQ-4	3.0	-1.50	*p < 0.001
PROMIS Fatigue	14.5	-2.36	*p = 0.003
PROMIS Sleep	13.5	-2.64	*p < 0.001
PROMIS Quality of Life	3.0	0.39	*p = 0.04
PROMIS Social Satisfaction	16.0	1.29	p = 0.057
PROMIS Physical Function	17.5	0.50	p = 0.12

Integrated Behavioral Health Services for Patients with Rheumatic Diseases: Qualitative Analysis of a Pilot Study

Shannon Teaw[1], Jessica Link-Malcolm[2], Michelle Ghebranious Farag[3], Dorothy Patterson[2], Jenny Foster[4], Sofia Bereket[2], Puneet Bajaj[2], Urooj Wahid[2], Elizabeth Solow[2], Jennifer Barton[5] and Una Makris[6], [1]UT Southwestern Medical School, Dallas, TX, [2]UT Southwestern Medical Center, Dallas, TX, [3]McGovern Medical School at UT Houston, Houston, TX, [4]UT Southwestern Medical Center, Dallas, [5]VA Portland Health Care System/OHSU, Portland, OR, [6]UT Southwestern Medical Center and Dallas VA, Dallas, TX

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1248–1271) Patient Outcomes, Preferences, & Attitudes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatic diseases (RD) often cause pain, fatigue and disability. Depression and anxiety are prevalent comorbidities in RD and ideally managed with behavioral health (BH) strategies. Programs that integrate BH services into rheumatology remain underexplored. Our group conducted a single-arm pilot BH program integrated within rheumatology clinic. This qualitative study explores stakeholder perspectives on barriers and facilitators of integrating BH in rheumatology.

Perspectives on Behavioral Health (BH) Prior to Participating in pilot	Modality of BH Service Delivery and Procedures	Experiences / Perceived Benefits of BH Program	Sustainability and Value
•Participants mostly understood that **health behaviors** were important, but understanding the impact of **mood and anxiety** on health was less common. •Although some participants were well-versed in the connection between stress and RD flare-ups, they did not have the specific skills to change behavior.	•Several participants reported that having their rheumatologist provide a brief introduction about the BH program was helpful and convenient.	•Most participants identified the individualized, patient-centered and goal-focused approach by the BH specialist to be very beneficial.	•Participants reported continuing to use skills and techniques after the BH intervention was completed, as well as intent to use in the future. •Participants appreciated the ability to reference apps, websites, etc., as well as notes some took during sessions
•Participants understood that physical activity benefitted physical health, but they needed help implementing behavioral change to be more active.	•The majority of participants reported it was convenient to meet with the BH specialist in clinic immediately following their rheumatology appointment. •Many felt that meeting the BH specialist in person facilitated participation and rapport-building	•Specific BH skills/ techniques that participants reported were beneficial include mindfulness techniques and breathing exercises (both app-guided and self-guided).	•Some participants reported having shared what they've learned through the pilot program with family members and others, to pay-it-forward.
•Many participants voiced a general understanding that BH could be helpful but lacked specific knowledge and skills to apply it. •Some had never considered the role of BH in RD	•All but one of the participants (who preferred an in-person option) reported that the **telehealth option and short, 20 to 30-minute sessions** were convenient, as they removed transportation barriers and time/scheduling constraints	•Many participants appreciated the accountability associated with regular BH visits, which helped them to experience the benefits of regular practice (i.e., mindfulness, exercise, etc.) and to establish routine habits before managing on their own.	•Given the option, most participants report that they would find it helpful to have booster sessions to reinforce BH skills (q1-3months).
•A few participants expressed initial skepticism about the possibility of BH interventions to improve pain. •Participants, even those voicing skepticism, were open to learning non-medical approaches to managing pain/ flares.	•Two areas several participants identified as needing improvement in this pilot study were **survey burden** (these were required at each session) and **communication challenges** (i.e. contacting the BH specialist)	•Most participants reported improvement in how they viewed their ability to manage their rheumatic disease (i.e., increased confidence, motivation, hope, feelings of control) •The majority of participants also felt more cared for by the institution	•Participants generally agreed that they would pay their usual specialty co-pay if there were costs associated with continuing to receive the BHS. •In most cases this co-pay ranged from $20 to $75.

Figure 1. Rapid Qualitative Analysis (RQA) Matrix of Patient Interviews (N=27)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Perspectives on BH Prior to Participating in BH Program	• "I knew that being active as much as I can is very important to managing my disease. I had never thought before about... emotional triggers" • "Anytime I'm super stressed with work or something personal going on, that's when I'm more inclined to have a flare up." • "Prior to the study, I believed that they could be helpful but kind of lacked the understanding or guidance of how to implement such practices and behaviors."
Modality of BH Service Delivery and Procedures	• "I think that [rheumatologist] knew it would be good for me and that I would be open to it, too." •"If someone would have called me on the phone and told me about the program and I wasn't looking at them and talking to them, then I probably would have said no. Because she approached me in the office and had the demeanor that she did, then I was interested." • "We met in the office, so that was a good thing, and it was really helpful because she saw what I was going through, you know, physically saw."
Experiences / Perceived Benefits of BH Program	• "I felt like that kind of accountability was really helpful in forcing habits that I knew I could develop but never was very diligent about taking the time." • "I went in with no hope and no expectations because I had been told that a lot of my pain was not autoimmune and that it was fibromyalgia...for the breathing to make a difference from the go gave me hope. It never worked before, and she made it so easy to understand from the beginning and it affected my pain levels." • "Overall, I feel like it's really helped my interpretation of pain and how the pain makes me feel. I'm able to deal with it for longer periods of time. It's not as high or I guess as obvious as it used to be."
Sustainability and Value	• "I'm still using the meditation every day, the breathing every day... I think this is something that I'll use forever." • "When in pain or under stress, I will go into a breathing session without even thinking about it." • "I can do this on my own from what she taught me."

Figure 2. Illustrative quotes from Patient Interviews

Methods: Adult patients with any RD were invited to participate in a novel BH program during their rheumatology clinic visit. Participants completed a goal elicitation tool and met with the BH specialist after their visit to discuss the study and determine which of 3 eligible BH goals to focus on. Participants engaged in up to 8 weekly telephone sessions with the BH specialist. After the final session, participants completed a satisfaction survey and semi-structured interview to elicit feedback. Referring rheumatologists and the BH specialist were also interviewed. We used Rapid Qualitative Analysis to identify thematic domains and illustrative quotes.

Introduction and referral to BH	• All agreed that nursing and ancillary staff were an integral part of the introduction to the BH program and helped integrate the BHS in the clinic workflow. •All generally perceived patients as curious about the BH program and open to learning more. Perceived barriers included time, as well as patients not identifying as "sick enough" to require a BH program. •Rheumatologists' introductory pitch to patients is important for framing the program. "I think the way I couched it ...abated some of [the stigma] because I would talk about how [the patient] and I make a plan, but implementing that plan takes a different set of skills and that's where this person [the BH specialist] would come into play...so it wasn't so left field." Per the BH specialist, the rheumatologists' enthusiasm about the program helped minimize stigma.
Who are the most appropriate referrals for the BH program?	•All agreed that referral should not be restricted to certain rheumatic disease diagnoses. •There were slightly contrasting views between rheumatologists regarding the ideal candidate for BH intervention, with one stating a preference for patients with low-to-moderate disease activity. The other rheumatologist, who prior to the BH pilot would have focused on patients with inflammatory conditions, was surprised by the BH outcomes, "It was sort of surprising...it had a broader benefit than I would have expected." This rheumatologist, along with the BH specialist felt all-comers could benefit, "If a patient is in survival mode, it is hard to be in learning mode, but not impossible." •Referrals ultimately should be based on rheumatologist's discretion and patient motivation.
Perceived value of an integrated BH program	•The rheumatologists found value in having a trusted resource they could refer patients to who could assist them in implementing the BH aspects of their treatment plan and provide follow-up care to help the patients reach their goals. "Making small changes is very hard and often times we're asking patients to make major life changes. And it's hard... for patients to... even know where to begin." •Per the BH specialist, the most useful modalities were mindfulness meditation techniques, along with apps patients could utilize on their own time. The BH specialist tailored their approach to each patient and focused on building immediately actionable skills and consistent practice.
Suggestions on future integrated BH programs in rheumatology	•The BH specialist could provide actionable items addressing how the rheumatologist can take the progress a patient has made and apply to their treatment plan. •Establishing an automated referral process utilizing the electronic medical record (EMR). •Extending intervention duration and impact by providing booster sessions or check-ins q 1-3 months.

Figure 3. Rheumatologists and BH Specialist Interview Highlights

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Of 54 patients enrolled, 39 engaged in BH intervention sessions beyond baseline, and 27 completed post-intervention interviews. Interviewees were primarily female (77.8%) and White (81.5%), with an average age of 56 years. Participants (n=27) selected the following goals: managing mood or stress/anxiety (52%), managing pain (26%), and increasing physical activity (22%). We identified 4 thematic domains: pre-existing perspectives on BH, recruitment/delivery procedures, experiences/perceived benefits, and sustainability/value (Figure 1). While some understood the connection between BH and RD prior to the study, participants expressed a lack of specific skills/motivation to change behavior. Key benefits included the patient-centered, goal-oriented approach and accountability provided by regular sessions (Figure 2 lists illustrative quotes). When asked if BH services added value to their rheumatologic care, all interviewees responded positively, "Yes, definitely" (81%) or "Yes, I think so" (19%). The two rheumatologists and BH specialist provided unique perspectives on barriers and facilitators that could enhance future feasibility and success of a BH program (Figure 3).

Conclusion: The integration of an individualized, goal-focused BH intervention into rheumatology clinics is feasible and perceived as beneficial by patients, rheumatologists and the BH specialist. Results from this pilot program will inform the development of an RCT to evaluate clinical and behavioral outcomes in this population.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1248–1271) Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Interstitial lung disease (ILD) is a severe extra-articular manifestation of rheumatoid arthritis (RA). Abatacept and rituximab are usually the recommended drugs. JAK inhibitors (JAKi) have demonstrated efficacy in RA,

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table. Baseline characteristics of RA-ILD patients treated with UPA.

	UPA (n=25)
Age, years mean±SD	61±9
Women, n (%)	16 (64)
Smoker ever, n (%)	20 (80)
Time since ILD diagnosis, months, median [IQR]	34 [17-47]
RF; ACPA, n (%)	23 (92); 22 (88)
FVC (% of the predicted), mean±SD	88±16
DLCO (% of the predicted), mean±SD	68±23
UIP-like fibrotic pattern on HRCT, n (%)	11 (44)
Joint activity n (%)	23 (96)
Previous immunosuppressive therapy, n (%)	
Conventional*	23 (92)
AntiTNF drugs / Tocilizumab	12 (48); 7 (28)
ABA; RTX	11 (44); 4 (18)
Concomitant immunosuppresive therapy, n (%)	12 (48)
Concomitant antifibrotic therapy, n (%)	0 (0)

ACPA, anti-citrullinated protein antibodies; DLCO, diffusing capacity of the lung for carbon monoxide; DMARD, disease-modifying antirheumatic drug; FVC, forced vital capacity; HRCT, high-resolution computed tomography; ILD, interstitial lung disease; JAKi, JAK inhibitor; RA, rheumatoid arthritis; RF, rheumatoid factor; UIP, usual interstitial pneumonia. *23 methotrexate, 5 sulfasalazine, 16 leflunomide, 7 hydroxychloroquine

especially tofacitinib and baricitinib. Nonetheless, evidence on eficacy efficacy of other JAKi like Upadacitinib (UPA) in RA-ILD is scarce. Our objective was to assess **a)** the effectiveness and **b)** the safety of UPA in RA-ILD patients.

Methods: National multicenter study of RA-ILD patients on treatment with UPA. We analyzed from baseline the following outcomes: **a)** forced vital capacity (FVC), **b)** diffusing capacity of the lungs for carbon monoxide (DLCO), **c)** high resolution computed tomography (HRCT), **d)** dyspnea (modified Medical Research Council scale), **e)** arthritis activity (DAS28-ESR), and **f**) sparing effect of glucocorticosteroids.

Results: We studied 25 patients (16 women/9 men; mean age 61±9 years) from clinical practice on treatment with UPA. Baseline demographic and clinical characteristics are shown in **Table**. All patients had received disease-modifying antirheumatic drugs (DMARDs) before UPA [conventional DMARDs (n=23; 92%), anti-TNF (12; 48%), Tocilizumab (7;28%), Abatacept (11; 44%) and Rituximab (4;18%)]. Mean baseline values of FVC and DLCO (% predicted) were 88±16, and 68±23, respectively. Patients were followed-up for a median [IQR] of 12 [6-18] months. The evolution of FVC and DLCO remained stable during the first 12 months **(Figure)**. At the end of the follow-up, available chest HRCT images improved/stabilized in all the patients. Stabilization or improvement of dyspnea was found in all the patients. Most patients [12 (67%)] showed articular remission or low activity. UPA was withdrawn in 5 (20%) patients due to ischemic heart disease (n=2), recurrent respiratory infections (n=1), zoster virus infection (n=1) and joint activity (n=1).

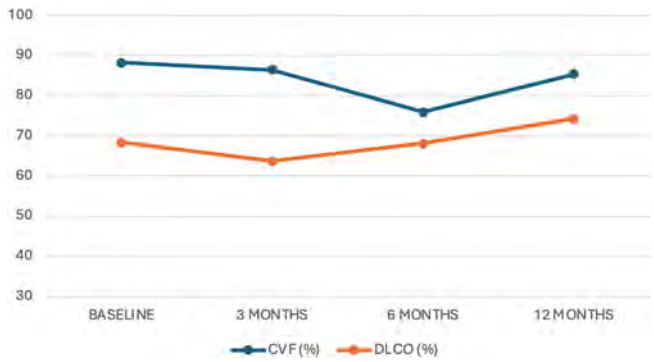

Figure. Evolution of pulmonary function tests (mean % of the predicted FVC and DLCO) in RA-ILD patients with UPA therapy at baseline and 12 months.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: UPA may be useful and safe in controlling the course of both pulmonary and joint disease in RA-ILD patients, even in cases refractory to ABA and/or RTX.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1248–1271) Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Many patients with uncontrolled gout (UG) experience symptoms despite being on urate-lowering therapy (ULT), often requiring support from informal caregivers. UG impacts patients and caregivers, yet research remains limited. This real-world study assessed the impact of UG on health-related quality of life (HRQOL) and activities of daily living (ADL) from the perspectives of patients, caregivers, and healthcare professionals in the United States (US). Results presented here focus on patients and caregivers.

Methods: A cross-sectional web-based survey was conducted among patients with UG and caregivers of such patients. Patients included adults (≥18 years) diagnosed with UG (a history of severe gout, defined as ≥2 gout flares within the last 12 months or presence of ≥1 gout tophus; and either currently taking a ULT or previously treated with uricase therapy in the past 18 months). Caregivers were unpaid adults currently caring for an adult with UG. Data collected included demographics, clinical characteristics, treatment information, and patient-reported outcomes (Work Productivity and Activity Impairment [WPAI] and 12-item Short Form Survey version 2 [SF-12v2]). Data were summarized descriptively.

Results: A total of 100 patients (63% male, mean [SD] age 54.3 [13.2] years) and 40 caregivers (73% female, mean [SD] age 55.1 [10.6] years) completed the survey (**Table 1**). Patients were currently using the following ULT treatments: allopurinol (49%), pegloticase (26%), febuxostat (20%), and probenecid (4%). Despite ULT treatment, 35% experienced tophi and 78% reported gout flares. 72% of patients reported a recent serum urate level of ≥6 mg/dL. HRQOL as measured by the SF-12v2 is reported in **Table 2**. Patients had a mean physical component summary (PCS) score of 37.3 (SD: 6.3) and mental component summary (MCS) score of 42.7 (SD: 10.3), which were "well below"[§] and "below" those of the general US population mean of 50 (SD: 10), respectively. The mean caregiver PCS score was 43.3 (SD: 11.7), which was "below" that of the

*Of those employed (n=61)

**Of those who experienced tophi (n=35)

†Of those who experienced gout flares (n=76)

‡Months since the last gout flare presented for patients assisted by caregivers (n=29)

N/A: Question not asked

general US population, and the MCS score was 45.2 (SD: 11.8). Common issues associated with caring for a patient with UG were stress (40%), inability to carry out a daily routine (35%) and/or work a job (35%), and feelings of being overwhelmed (35%). Over 90% of caregivers reported feeling some level of exhaustion. Overall activity impairment was 60% for patients and 41% for caregivers, measured by the WPAI. Employed patients and caregivers reported 53% and 36% overall work impairment, respectively. Employed patients missed an average of 6.8 (SD: 9.8) hours of work in the past 7 days due to UG, while employed caregivers missed an average of 2.7 (SD: 3.6) hours caring for a patient (**Table 3**).

Conclusion: This is the first study to present data on caregiver burden associated with UG, highlighting significant challenges and reduced HRQOL for caregivers and patients with UG. Both reported HRQOL below the general US population with the largest impact in physical health-related domains, likely due to clinical manifestations of UG for patients, and for caregivers, the physical demands of caring for a patient. Employed individuals also experienced notable work impairment demonstrating the multifaceted impacts of UG.

Table 2. Patient and Caregiver SF-12v2 Scores

SF-12v2 Domain	Patients (N=100) Mean (SD)	Caregivers (N=40) Mean (SD)
Physical component summary (PCS) score	**37.3 (6.3)**	**43.3 (11.7)**
Physical functioning	35.3 (7.8)	41.7 (12.7)
Role - physical	38.5 (7.7)	43.5 (11.5)
Bodily pain	38.2 (9.0)	42.6 (13.5)
General health	38.2 (10.2)	45.0 (12.9)
Mental component summary (MCS) score	**42.7 (10.3)**	**45.2 (11.8)**
Vitality	45.4 (9.4)	49.1 (12.0)
Social functioning	40.5 (9.4)	41.8 (11.3)
Role – emotional	35.9 (10.3)	41.1 (13.9)
Mental health	42.5 (10.8)	45.9 (13.1)

[a]The SF-12v2 scores range from 0 to 100, with higher scores indicating better physical or mental health functioning. The scoring system uses a norm-based approach, where Physical Component Summary (PCS) and Mental Component Summary (MCS) combine the 12 domains in such a way that they compare to a national norm with a mean score of 50.0 and a standard deviation of 10. If the norm-based SF score is 10+ points below the mean, the disease exhibits physical or mental functioning "Well Below" the general population. If it is 5 points to <10 points below, functioning is "Below" average. And scores <5 points below are the "Same or Better" than average.

Abstract Number: 1260

Increasing Zoster Vaccination Rates in Immunosuppressed Veterans at the North Texas VA Medical Center Rheumatology Clinic

Benjamin Gardner[1], Ankitha Lingamaneni[2], Isabel Penabad[3], Jiby Mathew[4], Una Makris[5], Rashmi Arora[6], Swathi Reddy[7] and Nagendra Pokala[8], [1]UTSW, Dallas, TX, [2]University of Texas Southwestern Medical Center, Dallas, TX, [3]UT Southwestern, Dallas, TX, [4]Veteran's Affairs, Rowlett, TX, [5]UT Southwestern Medical Center and Dallas VA, Dallas, TX, [6]VA north texas health centre Dallas, Dallas, TX, [7]UT Southwestern Medical Center / Dallas VA Medical Center, Colleyville, TX, [8]Veterans Affairs North Texas Healthcare System, Dallas, TX

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1248–1271) Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

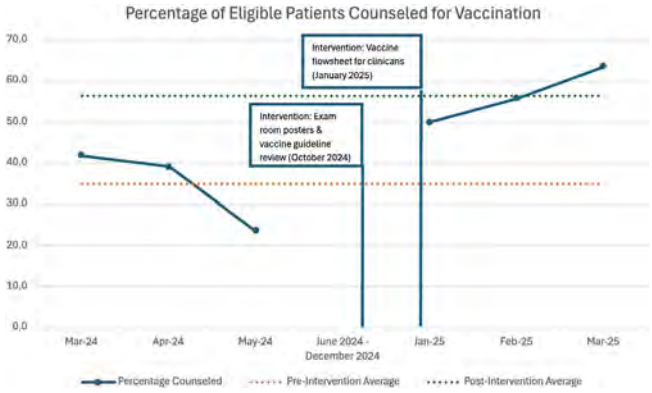
Background/Purpose: Shingles is a painful cutaneous eruption due to the reactivation of latent Varicella zoster virus. Immunocompromised adults, due to a medical condition or immunosuppressive therapies, have a higher risk of shingles. In 2021, recombinant zoster vaccination was formally recommended by the ACIP for adults ages 18-50 who are immunocompromised. Despite this recommendation, zoster vaccination rates in the United States remain low. Our goal is to implement Plan, Do, Study, Act cycles to increase zoster vaccination rates in immunosuppressed patients aged > 18 years at the North Texas VA Medical Center Rheumatology clinic.

Methods: We identified Veterans > 18 years old with rheumatic disease on any immunosuppressive disease-modifying antirheumatic drug and their zoster vaccination status by reviewing charts of patients seen in the VA Rheumatology clinic from March 4, 2024 to May 30, 2024. To obtain baseline vaccination rates, we calculated the proportion of patients who were unvaccinated, partially vaccinated (received 1 of 2 vaccine doses) and fully vaccinated. We developed a process map and identified two areas for intervention (patient and provider education). We created posters for display in exam rooms to increase patient awareness, reviewed vaccination guidelines with rheumatology clinicians, and posted vaccination flowsheets in resident training/ onboarding documents and precepting rooms to improve provider awareness. We then reassessed the data from Jan 2, 2025 to March 31, 2025.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Patient Characteristics	Baseline (n=390)	Post Intervention (n=398)
Average Age (years)	60.1	59.7
Race		
White	212 (54.4%)	190 (47.7%)
Black	125 (32.1%)	132 (33.2%)
Hispanic	23 (5.9%)	35 (8.8%)
Gender		
Male	309 (79.2%)	324 (81.4%)
Female	81 (20.8%)	74 (18.6%)
Diagnosis		
Seronegative Spondyloarthropathy	152 (39.0%)	149 (37.4%)
Rheumatoid Arthritis	146 (37.4%)	150 (37.7%)
Systemic Lupus Erythematosus	18 (4.6%)	24 (6.0%)

Patient Characteristics



Change in Percentage Counseled for Vaccination

Results: We reviewed 752 charts and identified 390 eligible patients for baseline data. The average age was 60 and 79% were men. The most common diagnoses were spondyloarthropathy (39%) and rheumatoid arthritis (37%). At the time of the visit, 34% of patients were not vaccinated, 10% were partially vaccinated and 56% were fully vaccinated. Among those not fully vaccinated and eligible for vaccination 9% were counseled and immunized within one week, 26% were counseled but not immunized within one week, and 65% were not counseled. Post-intervention we reviewed 798 charts and identified 398 eligible patients. The average age was 60 and 81% were men, with similar rheumatologic diagnoses as baseline sample. At the time of visit, 36% were not vaccinated for zoster, 8% were partially vaccinated, and 56% were fully vaccinated. Among those not fully vaccinated and eligible for zoster vaccination 11% were counseled and immunized within one week of the visit, 46% were counseled but not immunized within one week, and 43% were not counseled.

Conclusion: Among patients eligible for zoster vaccination, our results show an increase in both the percentage of patients who were counseled at their visit and vaccinated within with one week. The percentage of fully vaccinated patients did not increase substantially. Following the above-mentioned interventions, zoster vaccination rates and counseling rates among immunosuppressed individuals improved in our outpatient rheumatology clinic.

Abstract Number: 1261

Use of telemedicine to address 'off target' symptoms in psoriatic arthritis (PsA): implementation of PsOWell™ in PsA

Carter Pason[1], Sarah Hopkins Gillespie[1], Joelle Koplin[2], Rachael Hewitt[3], Christine Bundy[3], Ethan Craig[4], Laura Coates[5], Jessica A. Walsh[6] and Alexis Ogdie[7], [1]University of Pennsylvania, Philadelphia, PA, [2]Penn Medicine, Philadelphia, PA, [3]University of Cardiff, Cardiff, United Kingdom, [4]University of Pennsylvania, Wallingford, PA, [5]Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, England, United Kingdom, [6]Division of Rheumatology, Salt Lake City Veterans Affairs Health and University of Utah Health, Salt Lake City, UT, [7]Department of Medicine, Perelman School of Medicine at the University of Pennsylvania, Wilmington, DE

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1248–1271) Patient Outcomes, Preferences, & Attitudes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Approximately 60-70% of patients with PsA do not reach minimal disease activity (MDA) on therapy. However, in many cases, this may not be related to active disease as defined by clinical assessments such as joint count. We hypothesized that "off target" symptoms like fatigue, sleep disturbance, and mood could be addressed by lifestyle behaviors in parallel to standard medical therapy to improve outcomes. The objective of this study was to understand the participant experience in the PsOWell trial through a qualitative process evaluation.

Methods: We conducted the PsOWell pilot? trial among patients with PsA not currently in MDA and with active disease as defined by patient-reported outcomes (PSAID >4 or patient global assessment >4). Patients were required to plan to stay stable on therapy for at least the next 3 months. Patients completed the PSAID and Eq5D at baseline and follow-up within 4-6 months; MDA was recorded at both visits (Figure 1). Between the two primary visits, patients completed two telemedicine visits with a nurse practitioner or clinical research nurse. During these visits, patients chose a target health domain from the Informatree.com site. The provider, trained in motivational interviewing, conducted a first visit using the Action Plan for the corresponding health domain to set goals. A second visit was conducted to check in and modify the plan. The provider took notes for the participant to access through their chart.

The primary outcome was achievement of MDA at the follow up visit. We conducted a qualitative interview at the final visit among the first 25 study completers (target recruitment for the pilot trial is 80 participants). Themes were derived from interviews using content analysis.

Results: We identified recurrent themes about the participants' experiences and the program's impact. The main strengths identified were the ease and convenience of participating via telemedicine and the positive impact of accountability on behavior change. Participants recalled that the nurse practitioners were supportive and provided useful advice to help them execute lifestyle changes. Many participants reported improvements in their chosen health domains.

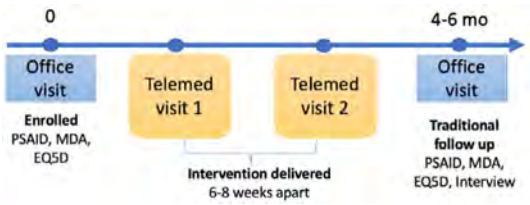

Figure 1. Study Design

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1. Informatree Health Domains

Primary Topic Selected from Informatree	# of Participants (n=25)
Food and weight	7
Sleep	6
Keeping active	3
Fatigue	4
Mood	2
Pain	3
Tobacco	0
Travel	0
Work	0
Social Support	0
Using treatments	0
Different treatments	0
Intimacy	0
Healthcare appointments	0
Alcohol	0

Opportunities for improvement were also identified. Some participants expressed that their lifestyle changes could be solidified by more frequent follow-up calls, nudging messages, more written resources, and a longer program duration. Some noted that the advice from the NPs could be more specific. Some participants wished that physical symptoms of PsA, such as skin issues, could also be addressed during the telemedicine visit. However, this was beyond the scope of the intervention.

Table 2. Example Quotes

STRENGTHS	**Ease and convenience of telemedicine**	"It was very smooth." "There was no burden." "It saves me close to three to four hours or something like that, which is also a good benefit." "I didn't really rearrange my schedule or anything."
	Accountability	"If what you're trying to do is instill changes in behavior, it's good to be held accountable, but she did it in a very gentle way." "Once you put a responsibility to check in with someone, it makes you more apt to follow through."
	Support	"The care and concern that the person showed, was really good." "It helped to have a support system and helped keep him positive."
	Helpful advice	"She did have some good advice." "She was nice, helpful, and informative." "Open, positive, good feedback."
LIMITATIONS	**More follow-ups**	"… if you want to implement behavioral change […] then I think you might have to touch base a little bit more frequently." "…we could have benefited from an additional follow-up meeting."
	Longer duration	"If the program was to be implemented, having a longer period of time just because it is hard to start a habit." "He wished the support could be constant."
	More documentation or messaging	"…maybe more communication or documentation, just because it kind of fell off my awareness."
	More specific	"[The advice was] not particularly specific."

Conclusion: The PsOWell program was received well by participants. Many expressed that they achieved positive changes in health behaviors by participating. The program's main strengths are its convenience and being supported and held accountable by the NPs. However, increasing the frequency of check-ins and extending the program duration could strengthen its impact on sustainable behavior change.

Abstract Number: 1262

Perspectives of Lupus Patients on Quality of Life Measures: A Qualitative Study

Cristina Arriens[1], Fredonna Carthen[2], Alexandre Cammarata-Mouchtouris[1], Judith James[1], Joan Merrill[3] and Motolani Ogunsanya[4], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma, OK, [3]Oklahoma Medical Research Foundation, Oklahoma City 73104, OK, [4]University of Oklahoma Health Sciences Center, Edmond, OK

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1248–1271) Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Lupus has profound impact on physical, social, and emotional well-being. Health-related quality of life (HRQOL) measures are increasingly incorporated into lupus research and the US Food and Drug Administration has called for patient-reported outcomes (PROs) to be key endpoints in trials. This study sought to explore which HRQOL instruments are viewed by lupus patients as most relevant and reflective of their lived experience.

Methods: Five 90-minute focus groups were conducted, each with 4-6 participants with SLE. Participants were asked to independently complete six commonly used PRO instruments before the session: The Functional Assessment of Chronic Illness Therapy – Fatigue Scale (FACIT-Fatigue), the Lupus Foundation of America Rapid Evaluation of Activity in Lupus (LFA-REAL™), RAND 36-Item Short Form Instrument (SF-36), the Lupus-Quality of Life (Lupus-QoL) Questionnaire, Patients Global Impression of Severity (PGIS-Lupus), and Patients Global Impression of Change (PGIC-Lupus). Time to completion was recorded and written comments were encouraged. A trained moderator guided participants through open-ended discussions exploring instrument ease of use, clarity, relevance, comprehensiveness, and acceptability. Sessions were audio-recorded, transcribed verbatim, and thematically analyzed using an inductive approach.

Results: There were 24 participants aged 29-65 years (33% African American, 13% American Indian, 8% Latinx, and 46% European descent). Demographics are summarized in Table 1. Interrater reliability for qualitative coding was high. Table 2 summarizes the instrument characteristics, completion times, and scores. Most instruments utilized a 4 week recall period; FACIT-Fatigue used 7 days. About 1/3 of participants had difficulty recalling and averaging symptoms over the timespan due to disease variability; others valued the structured reflection. Participants suggested adding items on cognitive dysfunction,

Table 1. Patient Characteristics. Demographic and SLE disease specific information. All patients met the American College of Rheumatology (ACR)-1997 classification criteria, the Systemic Lupus International Collaborating Clinics (SLICC)-2012 classification criteria, and the 2019 EULAR/ACR Classification Criteria.

Characteristics of Focus Group Participants (n=24)	
Demographics	
Female (n, %)	22 (91.7)
Race/Ethnicity (n, %)	
African American/Black	8 (33.3)
American Indian/Native American	3 (12.5)
Hispanic/Latinx	2 (8.3)
White/Caucasian	11 (45.8)
Age in Yrs (mean ± SD)	45 ± 9.7
Age in Yrs, Range	29-65
SLE Disease Specific	
Duration of SLE in Yrs (mean ± SD)	15.6 ± 6.3
Duration of SLE in Yrs, Range	6.7-30.7
ACR Classification Criteria Total (mean ± SD)	7.0 ± 2.0
SLICC Classification Criteria Total (mean ± SD)	9.0 ± 2.5
EULAR/ACR Classification Criteria Total (mean ± SD)	24.9 ± 10.0
ANA	24 (100.0)
Arthritis	24 (100.0)
Hemolytic Anemia	2 (8.3)
Leukopenia	8 (33.3)
Lymphopenia <1.5K	20 (83.3)
Lymphopenia <1K	17 (70.8)
Thrombocytopenia	4 (16.7)
Malar	12 (50.0)
Discoid	5 (20.8)
Photosensitve Rash	20 (83.3)
Maculopapular Rash	1 (4.2)
Ulcers	19 (79.2)
Alopecia	17 (70.8)
Anti-dsDNA	13 (54.2)
Anti-Sm	8 (33.3)
Anti-cardiolipin Positive	15 (62.5)
Anti-cardiolipin (medium or high)	8 (33.3)
Anti-Beta 2 Glycoprotein	1 (4.2)
Lupus Anticoagulant	1 (4.2)
Complement	17 (70.8)
Pleurisy	14 (58.3)
Pericarditis	5 (20.8)
Renal (Proteinuria, Biopsy Proven LN)	6 (25.0)
Neurologic	5 (20.8)
Fever	12 (50.0)

Table 2. Health Related Quality of Life Instruments. Details the characteristics of each quality of life questionnaire used and presents our participants' data (completion times, overall and comparable subscale scores) organized to facilitate cross-instrument comparison. Notably, while each individual item on the LFA-REAL™ has a maximum score of 100 millimeters, the total possible score for the entire instrument is 700 millimeters. For the purpose of comparing Pain and Appearance domains with other questionnaires, we combined the LFA-REAL™ scores for Joint Pain and Muscle Pain/Aches into a composite "Pain" score, and similarly combined Rash and Hair Loss scores into a composite "Appearance" score.

Health Related Quality of Life Instruments						
	FACIT-Fatigue	**LFA-REAL™**	**RAND SF-36**	**LupusQoL**	**PGIS-Lupus**	**PGIC-Lupus**

headaches, and depression, which they felt were underrepresented and impactful. Difficulty distinguishing lupus-related from comorbid symptoms was a concern, especially with the Lupus QoL, LFA-REAL™, PGIS, and PGIC. The lupus-specific tools and the FACIT-Fatigue were viewed as more relevant. Lupus QoL was preferred by 78% of the participants, alone or combined with the LFA-REAL™ or FACIT-Fatigue, citing its lupus-specific focus, clarity, and coverage of daily function.

Conclusion: This qualitative study provides insights from SLE patients into how well commonly used PRO measures capture their lived experience and symptom burden. The findings may help to determine whether outcome assessments align with priorities and challenges important to patients living with lupus.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1248–1271) Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Health literacy is a potential social determinant of health, fundamental to patient engagement, clinical communication, and long-term outcomes of disease. Understanding health literacy at the individual and population levels are essential to drive equitable, person-centered healthcare.

We aimed to identify and describe health literacy profiles in people with rheumatic and musculoskeletal diseases (RMDs) attending a tertiary rheumatology service.

Methods: Patients attending the rheumatology clinic at King's College Hospital, UK, were invited to complete a survey including the nine-domain Health Literacy Questionnaire (HLQ), socio-demographic and clinical characteristics. Hierarchical cluster analysis, following the Ophelia (Optimising Health Literacy and Access) process (1) was conducted to identify patient subgroups based on the nine HLQ domains and other characteristics.

Results: In total, 263 people with RMDs were included in this study. Eleven distinct clinically relevant clusters were identified (Table 1).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1: Cluster analysis of Health Literacy Questionnaire (HLQ) data from 263 patients attending the rheumatology clinic at King's College Hospital. HLQ1 (Feeling understood and supported by health care providers), HLQ2 (Having sufficient information to manage my health), HLQ3 (Actively managing my health), HLQ4 (Social support for health), HLQ5 (Appraisal of health information), HLQ6 (Ability to actively engage with healthcare providers), HLQ7 (Navigating the healthcare system), HLQ8 (Ability to find good health information), HLQ9 (Understand health information well enough to know what to do).

Cluster ID*	% in sample	HLQ1	HLQ2	HLQ3	HLQ4	HLQ5	HLQ6	HLQ7	HLQ8	HLQ9
1	9.5	3.77	3.48	3.43	3.63	3.35	4.59	4.37	4.36	4.68
2	9.1	3.49	3.64	3.77	3.48	3.52	4.42	4.25	4.60	4.76
3	6.1	3.13	3.25	3.00	3.25	3.18	4.63	4.26	4.56	4.73
4	8.0	3.50	3.00	3.15	3.41	3.06	3.88	3.56	3.59	3.69
5	9.9	2.88	3.03	3.12	3.07	3.11	3.96	3.80	4.12	4.19
6	15.2	3.01	2.81	2.91	2.80	2.98	3.74	3.46	3.87	4.13
7	17.1	2.78	2.96	2.95	2.91	2.76	3.66	3.34	3.67	3.91
8	8.0	2.21	2.27	3.10	2.60	2.85	2.91	2.75	3.59	4.17
9	12.2	2.73	2.59	2.51	2.46	2.51	3.28	2.90	3.40	3.50
10	1.5	2.00	1.38	3.90	2.23	3.05	1.30	1.53	2.05	2.80
11	3.4	2.08	1.83	2.22	1.92	1.89	1.93	1.83	2.07	2.78

Clusters 1 (10%) and 2 (9%) exhibited high scores across all HLQ domains, with strong engagement, navigation, and comprehension capabilities. These clusters comprised mainly professionally employed women, with Cluster 1 younger patients (mean 32.8 years) with connective tissue diseases (CTD) and cluster 2 including older patients (mean 55.5 years) with inflammatory arthritis (IA).

Cluster 3 (6%) showed high engagement with limited emotional support. Most were men working in technical or professional roles. Clusters 5 (10%), 6 (15%), 8 (8%), and 9 (12%) showed mixed profiles. For instance, Cluster 5, predominantly women, demonstrated strong information-processing skills but only moderate social support. Cluster 8 had adequate comprehension despite poor support.

Figure 1: Infographic summarising characteristics of individuals within each of the described clústers, including health literacy strengths and needs.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Cluster 6 (15%) represented a younger, ethnically diverse group with moderate comprehension, limited support, and high unemployment. Cluster 7 (17%) consisted mainly of older, predominantly white, retired individuals with average literacy levels and low provider engagement.

Clusters 10 (2%) and 11 (3%) reflected the most complex challenges. Cluster 10 revealed a distinct profile of strong self-management despite extremely low support and engagement; members were mostly female, technically trained, and unemployed. Cluster 11, with the lowest scores across all domains, included older, professionally inactive women.

Conclusion: Health literacy among patients at King's College Hospital Rheumatology Clinic is highly variable, with some groups facing substantial barriers to engagement and support. Notable patterns emerged, such as higher health literacy amongst older patients with IA and younger patients with CTD, while lower health literacy in certain domains was associated with unemployment and non-Caucasian ethnicity. Identifying health literacy profiles can support more targeted and equitable approaches to patient communication, care planning, and service design.

Background/Purpose: Approximately 1.3 million Americans have rheumatoid arthritis (RA)[1]. Up to 83% of people with chronic pain, the hallmark symptom of RA also experience anxiety and/or depression[2-5]. Peer coaches, lay individuals who themselves live with the same chronic condition, can be particularly effective at addressing these challenges in people with diabetes and post-partum depression. The purpose of this study was to involve people with RA (PWRA) to inform the adaptation of a proven, effective peer coaching intervention to the context of RA, considering the needs of diverse populations and soliciting input about mental health and physical activity.

How long do you work out for? (Average in minutes)	65

Image 1: Demographic Characteristics and Exercise Habits of 22 Participants with RA

Methods: We conducted semi-structured interviews via teleconference using a topic guide that was informed by Social Cognitive Theory, to elicit the mental and physical experiences of PWRA. Inclusion criteria were: 1) PWRA 18 > years of age, 2) Severe pain interfering significantly with performing activities of daily living over the last 2 weeks, 3) Access to the internet and/or phone, 4) Living in the US including Puerto Rico, and 5) English or Spanish speakers. The topic guide focused on barriers and facilitators related to disease management, mental health, physical activity, and opinions about working with a peer coach (another PWRA trained to coach another PWRA in specific evidence-based health behaviors). Data were analyzed thematically with NVivo software by two independent analysts, highlighting Puerto Rican and Mainland voices.

Results: Of 22 participants, 20 were women, most were >50 years of age, and 5 were residents of Puerto Rico (Image 1). Images 2 and 3 shows the six themes that emerged: (1) Ableism and isolationism: Participants felt a strong sense of separation from their peers without RA; (2) Grief of former self: Many grieved the loss of abilities they had prior to their RA diagnosis, feeling inadequate in tasks they were once self-sufficient at; (3) Resilience: Participants exhibited resilience, adapting their physical and social environments to better support their needs and improve their quality of life; (4) Adaptation of physical activities: Participants emphasized adapting physical activities without causing further injury; (5) Sleep: Participants described challenges with sleep quality that impacted their physical and emotional well-being; and (6) Perception of working with a peer coach: participants valued the guidance of someone with shared experience, who could provide insights into managing pain and mental health.

Theme	Mainland Quotes	Puerto Rican Quotes
Theme 1: Ableism and Isolationism	ID#6 (F,59y/o): "Even my family, to this day, I don't think that they truly understand what I go through. My husband is always shocked when, somehow, they let it be known that they don't understand what I go through on a daily basis. So even the people that I grew up with don't really know how isolating the disease is, how it can make you feel really lonely, how painful it is."	ID#13 (F, 34y/o): "Well, it has been enough from family, friends, my core has decreased considerably but too much, that is, maybe 5 people who were always in my environment, save only 2, because for the same reason, they do not understand the condition, there are people who believe that you are exaggerating, they judge you, and more, and at least save yourself, One of the things that is most important to me is my peace of mind. So, I want to know all those people that I already understood that they had a kind of conflict with the understanding of my condition and moreover, well, I leave them aside."
Theme 2: Grief for former self	ID#1(F, 54y/o): "The mourning, and I think that's probably the better word. I was in mourning for my former abilities and grappling with needing a lot more help than I was used to needing, so it was difficult."	ID#28(F,63y/o): "I don't like to be sitting or lying on a piece of furniture and for me it's even more frustrating because when you lie in bed or whatever and you like to be lying down, it's fine, but when you're a person who is very independent and I help my daughters, I help my mom, I help my granddaughters and then I look like I am in pain, how do I do this? You know, it's very frustrating"
Theme 3: Resilience and tools to cope with diagnosis	*ID#9, (F, 63 y/o) "Well, the benefits of exercise, definitely it helps. Number 1, my emotional state. Whenever I exercise and I'm feeling stronger, feeling like I'm moving better, it immediately just affects my mood. I am always, let's say, more upbeat when there are times that I've noticed in the past that I haven't been able to exercise. I noticed that my mood also changes. Definitely the exercise helps with one's positive state of mind."*	ID#13 (F, 34 y/o): "I just eat and I disconnect, I practice my exercise, and in addition, I talk to myself, I give myself support and everything goes back to normal. But sometimes they don't. Sometimes I do need a little more push"
Theme 4: Adaptation of physical activities	*ID#2, (F,55y/o): "I was playing competitive state league tennis in the state, I played soccer, I played softball, I played all these things, and now all of a sudden, I can't play tennis anymore because my hands swell like sausages every time I try. Realizing I can't do that, but here's what I can do. I can play pickleball because we're playing with a whiffle ball and it's not stressing out my joints the way a tennis ball would, or a tennis racket would."*	ID#20 (F,54 y/o): "At first I couldn't exercise because my feet were swollen and I couldn't move, but then I walked little by little until now I can do a 30-minute exercise routine, at least three times a day, three times a week and yes, on a treadmill, not walking on the road, on the sidewalk, because of the sun, but I do it in a gym, on an electric walker and I can walk, at least I walk my 20 minutes or 30 minutes, it depends on how my body is that day that tells me you can resist a little more and have more courage, and I combine it because as I told you, with music. Relaxing music."

Image 2: Themes and corresponding quotes from Mainland and Puerto Rican participants

Theme	Mainland Quotes	Puerto Rican Quotes
Theme 5: Sleep	ID#18, (F, 61 y/o): "I would get in a position where I could get comfortable, but after laying still for a while, things would freeze up. I wouldn't get to a sound enough sleep to not feel it. Rolling over would hurt, and sometimes it felt like my legs were going to snap off. It took a lot of work to find the right things to sleep with to get the strain off body parts so I could get into a deep sleep. Now, once I'm in a deep sleep, I sleep well. When I wake up, I'm less stiff and feel better."	ID#20, (F, 54 y/o): "The quality of my sleep when without medication is zero" "When I can rest better, these days I wake up better. If I get up...when I don't, I don't have the mood for anything in reality"
Theme 6: Perceptions of working with a peer coach	ID#1, (F, 54y/o): "I think peer coaches are extremely underutilized by the healthcare system and could be very beneficial for people who are newly diagnosed as well as people who've been diagnosed but are experiencing new challenges."	ID#26, (F, 59 y/o): "I would like to] exchange ideas [with a peer coach] to see what makes it different. To get an idea that I'm not doing, maybe he does something that I don't do and can help me in that part, it's the only thing"

Image 3: Themes and corresponding quotes from Mainland and Puerto Rican participants

Conclusion: PWRA identified several barriers (isolationism, ableism, grief, sleep difficulty) and facilitators (resilience, adaptation) that hold potential for improving mental health and physical activity in this population. This could potentially be achieved by having peer coaches assist in behavioral changes and "breaking the veil" of silence and invisibility through role-modeling behaviors and assisting PWRA to cope with challenges related to living with RA. Further interventions should continue to explore similarities and differences between Puerto Rican and Mainland participants to better tailor RA services to diverse populations.

Patient Portal Awareness and Utilization Across Diverse Rheumatology Populations

Emily Gutowski[1], Joshua Novack[2], Allyson Covello[2], Philip Carlucci[3], Scott Goldberg[1], Mary Guan[4], Marcus Hines[2], Elliot Philips[2], Michael Pillinger[5] and Sara Stream[6], [1]New York University Grossman School of Medicine, Brooklyn, NY, [2]New York University Grossman School of Medicine, New York, NY, [3]New York University School of Medicine, New York, NY, [4]NYU Grossman SOM, Brooklyn, NY, [5]New York University Grossman School of Medicine, New York, NY, [6]New York University Grossman School of Medicine, Great Neck, NY

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1248–1271) Patient Outcomes, Preferences, & Attitudes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with rheumatic diseases face complex and chronic diagnoses that require close monitoring and frequent communication with their providers. Given increasing challenges to in-person medical care, including decreased time for clinic visits, physician shortages, and scheduling difficulties, online patient portals serve as important tools to engage patients in their care, allowing them to review test results, schedule appointments, and communicate with physicians. To identify barriers to portal use, we evaluated rheumatology patients' awareness, use, and perceptions of patient portals across three clinical sites: a public safety net hospital, private academic teaching hospital and Veterans Affairs (VA) Hospital.

Methods: We conducted a cross-sectional, survey-based study in outpatient adult rheumatology clinics in three hospitals. During routine visits, surveys were distributed to patients in English or Spanish. Surveys assessed demographics, educational background, familiarity with each hospital system's portal, frequency and reason for portal use, and interest in learning more. Informational handouts on portal capabilities and sign-up instructions were provided.

Table 1. Demographic characteristics of survey respondents.

Table 1

	Public	Private	VA	Total
Number of participants	74	15	50	139
Age, average (st dev)	47 (14.2)	51 (17.6)	62.6 (16.7)	53.1 (17.1)
Female, n (%)	57 (77)	12 (80)	3 (6)	72 (51.8)
Ethnicity, n (%)				
Hispanic	50 (67.6)	5 (33.3)	10 (20)	65 (46.8)
African American	7 (9.5)	6 (40)	18 (36)	31 (22.3)
White	5 (6.8)	2 (13.3)	16 (32)	23 (16.6)
Asian	7 (9.5)	0 (0)	3 (6)	10 (7.2)
Other	4 (5.4)	2 (13.3)	1 (2)	7 (5)
Primary Language, n (%)				
English	44 (59.5)	13 (86.7)	50 (100)	107 (77)
Spanish	30 (40.5)	0 (0)	0 (0)	30 (21.6)
Other	0 (0)	2 (13)	0 (0)	2 (1.4)
Educational Achievement				
Elementary	14 (18.9)	1 (6.7)	0 (0)	15 (10.8)
Middle School	7 (9.5)	3 (20)	13 (26)	23 (16.6)
High School	26 (35.1)	3 (20)	32 (64)	61 (43.9)
College	24 (32.4)	3 (20)	5 (10)	32 (23)
Advanced	2 (2.7)	0 (0)	0 (0)	2 (1.4)
Unknown	1 (1.4)	5 (33.3)	0 (0)	6 (4.3)

Results: 139 patients completed the survey: 50 from the VA, 15 from the private hospital and 74 from the public hospital. The average age was 53.1; 48.2% of respondents were male. Hispanic identity (46.8%) was most common. English was the primary language for 77%. The most reported highest education level was high school (Table 1).

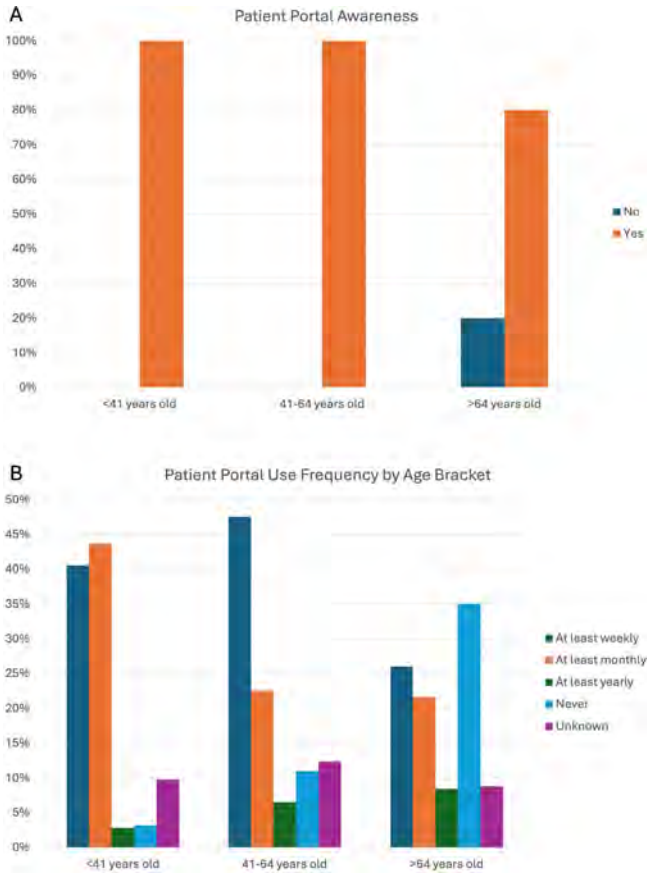

Figure 1. Awareness (A) and use frequency (B) of patient portal by age. Answers for panel A refer to "I am aware of my patient portal."

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

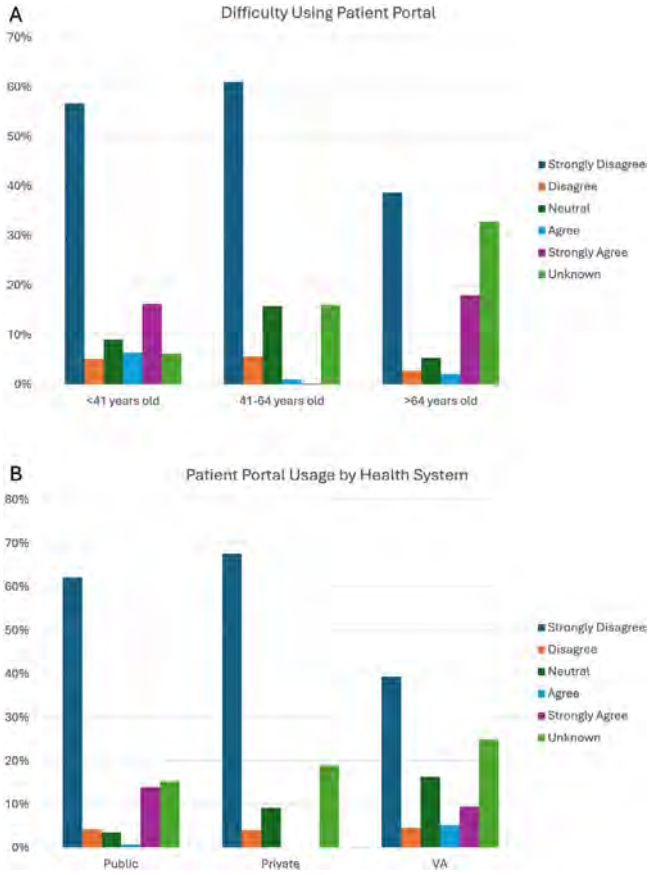

Figure 2. Difficulty using patient portal by age (A) and portal usage by health system (B). Answers refer to "I have trouble using my patient portal" and "I find my patient portal useful for my needs."

93.5% of all patients surveyed were aware of their patient portal, and 71.9% reported using their portal at least once a month. Portal awareness and use declined with age: patients 65 and over were less likely to have internet access or use portals, including a plurality who never used them (Figure 1). Older patients also reported more difficulty navigating portals (Figure 2A). Use varied by hospital, with highest use at the public hospital and lowest at the VA (Figure 2B). At the public hospital, higher educational attainment was associated with increased computer and internet access, whereas computer and internet access were nearly universal at the private hospital, regardless of education.

Conclusion: While awareness of patient portals was high across all sites, actual use was far lower and varied by age and hospital site. Patients 65 and over had the lowest frequency of use, which may be related to reduced access to technology and less favorable attitudes towards portals. Internet and computer access was not universal and varied with educational level, suggesting that access may be a limiting factor. Our findings highlight the need for targeted interventions, such as educational and technical support, as well as alternative communication strategies in those who are unable to utilize patient portals. These efforts would help to increase patient engagement in their medical care, ultimately improving outcomes in rheumatology.

Abstract Number: 1266

Shared Decision Making in Rheumatoid Arthritis: Is RA disease activity associated with patient reported measures of shared decision making pre-SDM intervention?

Jennifer Barton[1], Joshua Baker[2], gabriela Schmajuk[3], Madhavi Valiveti[4], Alexandra Bennett[5], Benjamin Morasco[6], Allison O'Neill[7] and Meike Niederhausen[8], [1]VA Portland Health Care System/OHSU, Portland, OR, [2]University of Pennsylvania, Philadelphia, PA, [3]University of California, San Francisco, and San Francisco Veterans Affairs Medical Center, San Francisco, CA, [4]VAMC Wilmington, Wilmington, DE, [5]Center to Improve Veteran Involvement in Care (CIVIC) and VA Portland Health Care System, Portland, OR, [6]Center to Improve Veteran Involvement in Care, VA Portland Health Care System, Portland, OR, [7]Center to Improve Veteran Involvement in Care, VA Portland Health Care System, Portland, OR, [8]Oregon Health & Science University/VA Portland Health Care System, Portland, OR

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1248–1271) Patient Outcomes, Preferences, & Attitudes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Shared decision making (SDM) is outlined as the first overarching principle of the treat to target guidelines for rheumatoid arthritis (RA). The quality of SDM varies across patient populations with many patients reporting poor communication around SDM. We sought to measure baseline patient-reported SDM in the usual care phase of an RCT designed to measure the impact of a multicomponent intervention to improve SDM among U.S. Veterans with RA and their clinicians. We also evaluated whether SDM correlated with baseline disease activity during this study phase.

Table 1: Baseline characteristics of Veterans with RA enrolled during the usual care phase of an RCT of a multicomponent intervention to implement shared decision making (SDM)

	Overall	Site			
Measure	N = 213 N (%)	Philadelphia N = 66	Portland N = 89	San Francisco N = 33	Wilmington N = 25

Table 2. SDM and disease activity outcomes among US Veterans with RA across 4 sites

	Overall	Site			
Measure	N = 213 N (%)	Philadelphia N = 66	Portland N = 89	San Francisco N = 33	Wilmington N = 25
CollaboRATE Top Score					
No	54 (25%)	17 (26%)	21 (24%)	9 (27%)	7 (29%)
Yes	158 (75%)	49 (74%)	68 (76%)	24 (73%)	17 (71%)
SURE					
No Decisional Conflict	200 (95%)	61 (92%)	87 (98%)	31 (100%)	21 (88%)
Decisional Conflict	10 (4.8%)	5 (7.6%)	2 (2.2%)	0 (0%)	3 (13%)
Rapid3					
Mean (SD)	13.9 (5.2)	14.2 (4.1)	13.9 (6.0)	13.5 (5.9)	13.4 (4.7)

Key: Missing data was <10% for all key variables; CollaboRATE is 3-item measure of SDM (explanation about health issues, elicitation of patient preferences, integration of patient preference into decisions) each scored 0-9 with 9 being highest, if all three questions scored a "9" this is a Top Score; SURE is a 4-item measure of decisional conflict, yes/no response; score of 4 indicates no decisional conflict.

Table 3. RA Disease Activity by level of shared decision making and decisional conflict

		CollaboRATE Top Score			
Measure	Overall N=212	No N=54	Yes N=158	Difference[1]	95% CI[1]
RAPID3					
Mean (SD)	13.8 (5.2)	13.7 (5.0)	13.9 (5.3)	-0.17	-1.9, 1.5
		SURE			
	Overall	No Decisional Conflict	Decisional Conflict	Difference[1]	95% CI[1]
	N=210	N=200	N=10		
RAPID3					
Mean (SD)	13.8 (5.2)	13.7 (5.2)	16.8 (5.3)	-3.1	-7.2, 1.0

[1]Welch Two Sample t-test
Abbreviation: CI = Confidence Interval

Methods: Eligible Veterans with RA and moderate or high disease activity were invited to participate in this stepped-wedge, cluster-randomized trial at 4 U.S. Veterans Health Administration (VA) rheumatology clinics. SDM was assessed during a usual care phase of the trial using two brief, validated patient-reported measures (3-item CollaboRATE; 4-item SURE, yes/no response to: "feeling uncertain," "feeling informed," "feeling clear about values," and "feeling supported in decision-making"). Questionnaires were completed in person on the day of a routine visit along with patient-reported disease activity scores (RAPID3). Participants were also queried on demographics and health literacy. Medications were collected from the medical record. Summary statistics with mean (standard deviation, SD), median, or percentages used for demographics, health literacy, medications, SDM measures, and disease activity. T-tests were used to compare disease activity between SURE scores dichotomized as ≥ 4 vs. < 4 (no decisional conflict v presence of decisional conflict).

Results: 213 adults with RA across 4 sites contributed data during the usual care phases of the study (October 2022-September 2024). Nearly 80% were receiving a conventional synthetic DMARD, 57% a biologic DMARD, and 5% a targeted synthetic DMARD. 75% were male, mean (SD) age 69 (10), 64% white, 23% Black or African American, and 21% had limited health literacy (Table 1). 75% of participants ranked SDM highly on the 3-item CollaboRATE measure (9 out of 9) reflecting top scores. 95% overall reported no decisional conflict by SURE (Table 2). RAPID3 scores did not vary by SDM, however participants with decisional conflict by the SURE measure had slightly higher RAPID3 scores [mean (SD) 16.8 (5.3)] compared with those without decisional conflict [mean (SD) 13.7 (5.2)] though these were not statistically different (Table 3).

Conclusion: One quarter of Veterans with RA and moderate to high disease activity reported suboptimal SDM, which is similar to prior studies among non-Veterans with RA reporting up to 30%, and 5% reported decisional conflict. Ceiling effects of SDM measures present challenges to efficiently and thoroughly measure SDM across many chronic conditions, as identified in this RA population. Future work will use mixed methods to evaluate the effect of a multicomponent intervention on improving SDM and RA disease activity, and whether effects vary by literacy level or other patient- or facility-level characteristics.

Abstract Number: 1267

Patient Reported Outcomes Predict Subsequent Treatment Intensification Among Rheumatoid Arthritis Patients: Longitudinal PRO Measurement Using a Mobile Health App

Leah Santacroce[1], Misti Paudel[2] and Daniel Solomon[3], [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Division of Rheumatology, Inflammation, and Immunity, Boston, MA, [3]Brigham and Women's Hospital, Newton, MA

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1248–1271) Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Patient Reported Outcomes (PROs) collected via a mobile health application (App) can provide valuable insight into the health of patients with Rheumatoid Arthritis (RA). When collected at frequent intervals, providers can use them to assist in making decisions involving treatment intensification. We conducted a study to determine whether a single PRO score and/or sustained worsening in PROs were associated with future treatment intensification.

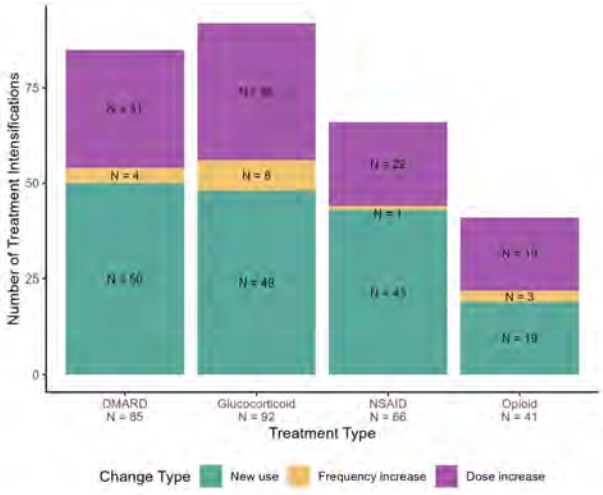
Methods: 150 patients with RA at one academic medical center were prompted to answer 1 of 4 validated PROs every other day through a mobile App ("mPRO") for 1 year; thus, each of the PROs were answered in an 8-day cycle. The PROs included the RA Disease Activity Index 5 (RADAI-5) and PROMIS short forms of pain interference, fatigue, and physical function. Lower function scores are better, where higher scores are worse for the other PROs.

The outcome of interest was RA treatment intensification - an increase in dose, frequency, or new use of any DMARD, NSAID, opioid, or oral glucocorticoid - during the App use period compared to the year prior. We examined 2 aspects of the PRO scores as potential predictors: the short-term PRO score during a given cycle and sustained PRO worsening defined as a clinically significant change compared to the previous measurement that was sustained for 3+ PRO cycles. Treatment intensification at the cycle immediately on or following each PRO score and sustained worsening was assessed. We used latent class mixed models to visualize trajectories of each PRO. Then, we examined mixed-effect logistic regression models to estimate the association between the time-varying PROs and treatment intensification. We conducted sensitivity analysis on a secondary outcome that excluded NSAIDs and opioids.

Results: Of the 150 patients who used the App, 83% were female, 91% were white, 7% had RA for less than 2 years, and the median age was 62 yrs. Over the study period, 284 treatment intensifications occurred among 63 patients, with a mean 1.9 (SD 3.2) changes per participant **(Figure 1)**. **Figure 2** depicts the trajectories of each PRO. The percentage with each trajectory differed by PRO: worsening -- 23% for pain, 18% for fatigue, 26% for function, 10% for RADAI; improvement -- 14% for pain, 12% for fatigue, 8% for function, 9% for RADAI; and stable --63% for pain, 70% for fatigue, 66% for function, 80% for RADAI.

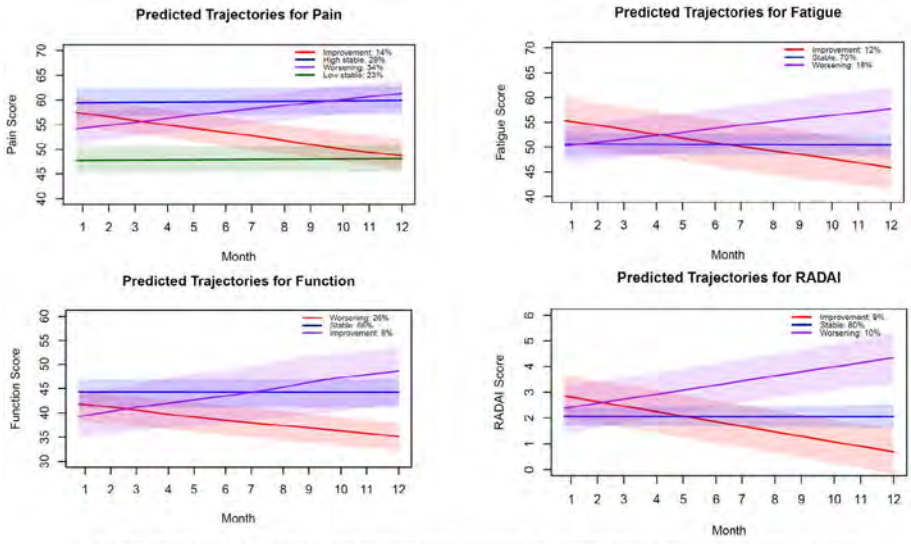
Regression models showed an association with treatment intensification and both short-term PROs and sustained worsening of the PROs. The intensifications were more likely to occur after a sustained worsening of pain interference (OR 2.04, 95% CI 1.10-3.78) or fatigue (OR 2.01, 95% CI 1.13-3.57). All four multivariable models (one for each PRO) had AUCs >

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



*This figure shows 284 treatment intensifications among 63 patients with at least one intensification

Figure 1. Types of treatment intensifications that occurred during a one-year study period among RA patients with at least one intensification.



For Pain, Fatigue, and RADAI higher scores represent worse outcomes, for Function higher scores represent better outcomes

Figure 2. Predicted trajectories of pain interference, fatigue, physical function, and RADAI over one year among patients with RA.

Table 1. The Impact of PRO changes on treatment intensification among patients with RA

PRO:	Pain Model	Fatigue Model	Function Model[1]	RADAI Model
	Odds ratio (95% confidence interval)			
Primary Outcome: All medications				
PRO Score[2]	1.37 (1.15, 1.64)	1.15 (1.01, 1.31)	0.63 (0.51, 0.77)	1.34 (1.17, 1.54)
Sustained PRO worsening[3]	2.04 (1.10, 3.78)	2.01 (1.13, 3.57)	1.09 (0.52, 2.32)	1.66 (0.35, 7.81)
AUC[4]	0.79 (0.74-0.84)	0.76 (0.71-0.81)	0.82 (0.76-0.87)	0.73 (0.67-0.79)
Secondary Outcome: DMARDs and oral glucocorticoids only				
PRO Score	1.43 (1.15, 1.78)	1.18 (1.00, 1.39)	0.55 (0.41, 0.73)	1.32 (1.09, 1.61)
Sustained PRO worsening	2.45 (1.24, 4.84)	2.30 (1.15, 4.61)	1.25 (0.50, 3.13)	1.56 (0.18, 13.2)
AUC	0.70 (0.64-0.75)	0.77 (0.71-0.82)	0.77 (0.71-0.82)	0.75 (0.69-0.81)

All models were adjusted for time, age, sex, and comorbidity index; none of the variables were significant in any model.

[1]Lower function scores are worse, thus odds ratios < 1.0 suggest that worse function is associated with treatment intensification

[2]The Odds Ratios for the PRO score for pain, fatigue, and function are interpreted as a 5-point increase, RADAI is interpreted as a 1-point increase. Higher function is better

[3]The sustained worsening is defined as an increase in 5+ points that remains elevated for 3 or more 8-day cycles for pain and fatigue. Function is defined as a sustained decrease in 5+ points, and RADAI a sustained increase in 1+ points.

[4]Confidence intervals for AUC calculated using bootstrapping

23265205, 2025, 59, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

0.73, indicating moderate to strong discrimination. Models with the secondary outcome (not NSAIDs or opioids) showed similar results, with some stronger odds ratios but larger confidence intervals **(Table 1)**.

Conclusion: Our results show that longitudinally measured PROs can identify periods of worsening pain and fatigue, which are correlated with subsequent treatment intensification. Frequently assessed PROs can help augment clinical decision-making by providing symptom information between visits.

Development of the LupusCoach Chatbot: Results of a Focus Group

Leila Khalili[1], Pooja Desai[2], Maya Souvignier[2], Adrienne Pichon[2], Stephen Suh[3], Alberto Nordmann-Gomes[2], Lena Mamykina[2] and Anca Askanase[1], [1]Columbia University Medical Center, New York, NY, [2]Columbia University Irving Medical Center, New York, NY, [3]Columbia University Irving Medical Center, New York City, NY

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1248–1271) Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Self-management education and coaching are successful interventions for managing chronic health conditions. However, accessibility of in-person coaching is limited; digital coaching is available and has been tested in patients with multiple chronic health conditions, but not in systemic lupus erythematosus (SLE). Building on previous work in collaboration with the biomedical informatics team, the CUIMC Lupus Center team developed a lupus chatbot, *LupusCoach*. The fully scripted chatbot focuses on two areas: 1) weekly educational goal setting for lupus patients that includes lupus specific, lupus clinical trials, and general health information and 2) weekly health management goal setting related to lupus. Here we describe the qualitative feedback of two focus groups evaluating the content and goals for *LupusCoach*.

Methods: Ten diverse lupus patients (all patients met the 2019 ACR/EULAR criteria for SLE) were selected via convenience sampling to give feedback on the chatbot educational content and goals. We conducted two focus groups remotely using video-conferencing software. The focus groups were audio recorded and transcribed verbatim. Reflective thematic analysis was conducted using the NVIVO software.

Results: Thematic analysis across patients from both focus groups identified several main themes relating to participant background and chatbot feedback. Participant background themes included connection between patients and providers, participants' individual experiences with lupus, and strategies for lupus management (Table 1). Themes relating to chatbot feedback included desired features and capabilities, experiences with technology, input on goals and action plans, discussion about informational messages, and user expectations of technology (Table 2). Based on these themes, we made adjustments to *LupusCoach*, specifically by tailoring action plans to different levels of effort. An on-line support community forum was requested, and therefore additional resources for lupus patients were listed on the accompanying FAQ/further information website for *LupusCoach*.

Table 1. Description of Themes Relating to Participant Background and Experience

Theme	Description	Demonstrative Quote
Connection between patients and providers	Participants expressed the importance of a personal connection with their providers, seeking out the best providers and care, importance of direct communication, importance of goal alignment between patients and providers, and long-term relationship with the right provider.	"I've always had severe joint problems, and [the doctor] discovered that it was because [of] the lupus, but none of the [other] doctors made that connection, so I've been with her since..."
Participants individual experience with lupus	Experiences that participants noted living with lupus included: challenging diagnosis processes/delayed diagnosis, unpredictability of symptoms and flares, invisible symptoms, experiencing balancing lupus and life, the peaks and valleys of living with lupus, and the stigma of living with lupus.	"The most annoying thing about this disease is unpredictability. One day you could be fine and the next moment you're sick with a flare."
Strategies for lupus management	Topics discussed relating to lupus management included social structures for support, identifying triggers for flares, medication management, trial and error in lupus management, and self-management strategies.	"Eventually, you find what works for you or helps along the way. But it's trial and error. It takes time. And also, like being able to read your body and sense for what doesn't work for you and what is working." "But I think there's something to [say for] mental self -care, and the very practical, like take your medicine on time, don't skip your medicine, put the sunscreen, don't go in the sun, drink water, go for a walk, do some movement, do some weight -bearing activity, like all that kind of stuff" "I really kind of had to almost build like a, like a personal code for survival, how to kind of get through it."

Conclusion: Overall, patients gave positive feedback both on the contents and goals of *LupusCoach*. The next step is to beta-test the chatbot and survey a larger group of 10-20 patients, using pre/posttest method, questionnaires, and surveying for satisfaction.

Table 2. Description of Themes Relating to Chatbot Feedback

Theme	Description	Demonstrative Quote
Desired features and capabilities	Participants most commonly expressed the desire for incorporation of AI, sharing ideas with other patients/a community board feature, and a user-friendly interface.	"There should be somewhere on the site if anybody has questions and they want to reach out to others ... [who are] having a problem with this"
Experience with technology	Participants noted that they had they had interacted with other apps that encourage behaviors and engagement in a positive manner and had a high awareness of technology.	"I think that there's something around how the psychological framework of the user is... understood so that there isn't like a sense of shame or failure."
Feedback on goals and action plans	Participants expressed an importance that there is a range of action plans tailored to different levels of effort, that patient expertise impacts goal usefulness, sun protection goals are useful, and the desire for specific action plans.	"But sometimes, if you're bedridden, you can't walk on your own. There needs to be simpler options, accommodations."
Feedback on informational messages	Participants stated that they wanted more information about clinical trials, that messages should be concise and meaningful. Focus group participants gave generally positive feedback on informational messages.	"Maybe I would ask for more [specifics about clinical trials]? What kind of trials are there? ...where can I go?"
User expectations of technology	The participants expected that the chatbot would be tailored to person and personal data, the chatbot content is specific for lupus, and AI will be incorporated.	"I think in some ways the challenge becomes... building enough kind of depth and uniqueness for that lupus patient and that unique profile in terms of what's going to be great for them."

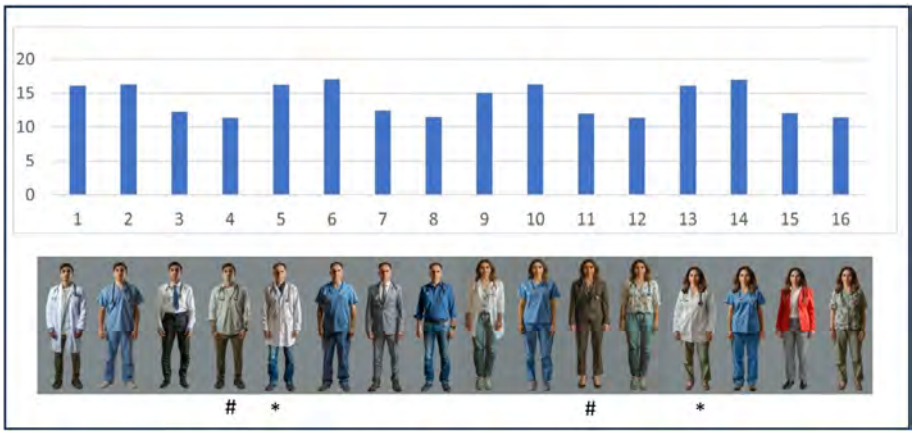
SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1248–1271) Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Physician sociodemographic factors and attire has been shown to influence patients' trust. This study aimed to determine differences on patient perceptions of rheumatologist professionalism, empathy, reliability and medical safety.

Methods: A multicentre study was conducted from 1 December 2024 to 30 May 2025. Patients with chronic inflammatory arthritis (CIA) receiving biologic or targeted synthetic disease-modifying antirheumatic drugs (b/tsDMARDs) were recruited. Demographic and clinical information was collected. Patients completed a questionnaire evaluating 16 standardized photographs, each depicting a fictional rheumatologist with controlled features (race, posture, arm position, facial expression, and use of stethoscope) to minimize nonverbal communication bias. Each physician appeared four times, varying only in attire: formal office wear, scrubs, white coat, and casual clothing. Patients rated the physicians on four criteria—professionalism, empathy, reliability, and medical safety—using a 5-point Likert scale. Additionally, they were asked to select their most and least preferred physicians. A histogram of scores was generated. Statistical differences in sociodemographic preferences were tested with multivariate regression analyses.



Total scores for each physician. *Most preferred physicians; # Least preferred physicians.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: A total of 67 patients participated (median age 53 years; 68.6% women). Diagnoses included rheumatoid arthritis (43.3%), spondyloarthritis (34.3%), and psoriatic arthritis (22.4%). In the multivariate analysis of perception criteria, older physicians were rated significantly better than younger physicians across all dimensions assessed ($p < 0.05$). Among these, professionalism was the most highly rated attribute associated with older physicians. No significant differences were found in patient perceptions based on the physician's gender for any of the evaluated criteria. Regarding attire, scrubs received the highest overall ratings [66.71 (SD 10.84)], followed by the white coat [63.59 (SD 11.88)], formal attire [48.80 (SD 18.04)], and casual clothing [45.76 (SD 20.70)]. Patients showed a clear preference for older physicians—both male and female—wearing white coats. Young male physician with casual attire and young female physician with formal office attire were least preferred physicians.

Conclusion: Patients with CIA perceived rheumatologists in scrubs or white coats as more professional, empathetic, reliable, and medically trustworthy than those in formal or casual attire. In addition, older physicians were preferred by patients. Rheumatologists may consider these contextual cues to enhance patient trust and engagement.

Increasing Participation in the FT819 Cell Therapy Trial Amongst People Living with Lupus: A Focus Group Study

Joy Buie[1], Safoah Agyemang[1], Andrew Henry[2], Andrew BitMansour[3], Vaneet Sandhu[4], Debra Zack[5] and **Michael Fisher**[1], [1]Lupus Foundation of America, Washington, DC, [2]Fate Therapeutics, Inc., San Diego, CA, [3]Fate Therapeutics, Inc., San Carlos, CA, [4]Fate Therapeutics, Inc., San Diego, [5]Fate Therapeutics, San Diego

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1248–1271) Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Clinical trials exploring the safety and efficacy of chimeric antigen receptor (CAR) T-cell therapy for lupus are growing. Challenges linked to recruitment for CAR T-cell clinical trials are likely multifactorial and may include barriers at the healthcare system, provider, and patient level. The aim of this study was to elicit qualitative feedback from people living with systemic lupus erythematosus (SLE) who have the greatest burden of disease to understand attitudes, perceptions, and behaviors related to CAR T-cell therapy clinical trials, specifically the Fate Therapeutics FT819 product.

Methods: A focus group was conducted among people with SLE recruited via the Lupus Foundation of America's Research Accelerated by You (RAY) Registry. Researchers queried RAY for individuals thought to meet inclusion criteria and provided an online screener. Of 205 respondents, 23 were shortlisted based on response timing (5 business days) and alignment with *a priori* inclusion/exclusion criteria. Upon follow-up contact, 6 expressed interest and consented. Five attended a 2-hour virtual focus group in December 2025 via Zoom. Following a slide presentation describing FT819 therapy as an off-the-shelf (uniquely available on-demand) cell therapy with reduced patient burden such as hospitalization requirements, semi-structured questions covered: (1) background and journey to diagnosis and care, (2) general awareness and perceptions of cell therapy, (3) perceptions of FT819 therapy administration, (4) potential benefits and risks of receiving FT819 therapy

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Participant Demographics

Characteristics	Category	N	%
Age (years)	Mean (SD) / Range	40 (5.2) / 30 – 45	–
Duration of Disease (years)	Mean (SD) / Range	20 (8.1) / 15 – 38	–
Sex	Female	5	100%
Race	Black/African-American	5	100%
Ethnicity*	Hispanic Non-Hispanic	1 4	20% 80%
Region	Northeast Midwest South West	1 1 3 0	20% 20% 60% 0%
*Ethnicity and race questions were asked separate from one another.			

Table 2. Perceived Benefits of FT819 Therapy

Key Themes	Illustrative Quotes
Improved Quality of Life	• *Just a better quality of life, it seems it would give.* - Participant 3 • *Less pain or no pain, I think that's the biggest benefit of all for me.* - Participant 1 • *Just waking up, feeling good in the morning. Going about my day. Living my life as normal.* - Participant 5
Potential for Remission	• *With the CAR T cell therapy, it sounds like it's more in that direction of, like, you could achieve remission and not just have consistent disease activity or symptoms.* - Participant 2 • *I have seen from some meetings that I've been in that the side effects are low. And the people are in remission and living great lives at this point.* -Participant 1 • *Remission. The potential for remission.* - Participant 4
Relatively Short Hospital Stay (3-day hospitalization after receiving FT819)	• *I would say it's reasonable to me. Three days is nothing compared to the 30 that other stem cell replacement therapies are requiring.* - Participant 1 • *I've done a lot worse with just lupus, so I could do 3 days.* - Participant 4 • *I wouldn't have a problem with that timeline of being in hospital.* - Participant 5

within a clinical trial, and (5) perceptions and acceptability of follow-up and monitoring. The focus group was audio-video recorded, transcribed, and analyzed in Dedoose using content analysis methodology.

Results: Participants included 5 Black/African American female adults, one of whom also identified as Hispanic. All had active SLE affecting one or more major organ systems (Table 1). Results emerged across 3 categories: (1) Initial perceptions of cell therapy, (2) perceptions of FT819 therapy including benefits and concerns (Tables 2 and 3), and (3) willingness to participate in an FT819 trial and expected outcomes. Initial perceptions indicated participants were familiar with and optimistic about cell therapy but also had concerns. Regarding FT819 therapy, participants perceived benefits such as improved quality of life, potential for remission, and a relatively short hospital stay. Participants also expressed concerns about potential adverse reactions or side effects, chemotherapy or mycophenolate requirements, long-term effectiveness, time and travel, hospital care and quality, caregiver needs, and medication cost and coverage (upon FDA approval). Participants also commented on willingness to participate in an FT819 trial, definition of successful treatment, and required duration of clinical effect.

Conclusion: Clinical trials in the U.S. have often failed to include representative samples, leading to a lack of generalizability. This study identified barriers and facilitators to cell therapy trial participation among a purposive sample. The findings can guide activities such as patient engagement, recruitment, and site selection.

Table 3. Concerns about FT819 Therapy

Key Themes	Illustrative Quotes
Adverse Reactions or Side Effects	• One of the scariest things with taking new medication [is] all the side effects… I just saw a commercial, and it's like 'May cause increased risk for cancer. May affect, you know.' Then, I'm like, what the ****? - Participant 4 • It's just that fear of stopping my medication that I would struggle with, because I had such a life threatening experience… That would be the only thing that would make me hesitate. - Participant 5 • For Benlysta and Saphnelo and other infusion drugs, there can be a higher rate of allergic reactions… So that would be my concern that just the method of delivery… might trigger some sort of allergic reaction. - Participant 2
Chemotherapy/ Mycophenolate Requirement	• I go back to the chemo part. That like terrifies me. So just understanding the side effects from the chemo. How long I would have to do the chemo? - Participant 4 • So, how high of a dosage of [mycophenolate] would you have to be on? Because I've tried that a couple times, I'm actually back on it again, and I'm having bad side effects yet again. - Participant 3 • You know, side effects from chemotherapy or radiation. It's a matter of… Do I stay with this lupus and deal with that or potentially get something else like cancer and have to deal with that as a side effect? - Participant 2
Long-Term Effectiveness	• I would say the you know the long term. What happens after you have that cell therapy replacement? And the years to come, that that is where I have the doubts and the questions, you know, will it return after some? … How long is it? It is it a guarantee? - Participant 1 • I think I would also want to try it. I'm hesitant about it… I think it would just depend on how much more information comes out about this treatment, especially long term studies about how long it might last? … I would be hesitant to stop any and all treatments. - Participant 2 • But my thing would just be kind of like what some of the others are saying. Is this going to work for the long term? - Participant 3
Time and Travel Required for Follow-Up	• The follow up, like the weekly follow up. So like if you had to travel say to New York to get this, and you live in DC or whatever, it is that kind of thing. Where are you gonna have to follow up? - Participant 3 • I think that would help make it easier. To fit it within my life instead of the study itself being the main thing, and I have to fit life around it. - Participant 2 • A lot of the time, like in the clinical trials, they want to reimburse you. But for those that are in my current situation, where I have no income, you would need that travel, the lodging. You would need all of that taken care of ahead of time versus being reimbursed. - Participant 1
Hospital Care and Quality	• I'm always just afraid of additional infection and things like that. You know, the setting itself would have to be obviously highly controlled. That there wouldn't be any kind of infections and things like that. - Participant 3 • [Having] a specific center or a specific rheumatology office that is versed in this, medication, and treatment, that would be a concern. Because I used to work in a hospital, and it's not like they have lupus specialists all over the place. - Participant 4 • I was being evaluated by oncology, and I was one of the only people wearing a mask in the waiting room… Like, cancer patients who are actively taking chemotherapy, [and] doctors and patients weren't even wearing masks. -Participant 2
Caregiver Needs	• If I had to travel outside of where I reside, I wouldn't have a problem with it. But I would have to know ahead of time so that I can prepare, because I don't drive. I need my husband with me. All the time we have children, so. I would definitely need a lot of time to plan ahead. And I would like to make sure he has the resources he needs while I'm going through this. - Participant 5 • So if it's [in my city], sure, I could easily get some family member or something to take me where I need to be. But if I have to go up to Boston or something like that, that's a different story. That would be, having to, again, get my husband to take off work and all that kind of stuff. - Participant 3 • I'm thinking in terms of logistics for caregivers, especially because this is a medication that's going to be impacting our immune system or treatment that's going to impact our immune system, like what changes would they need to make if we're getting this chemotherapy infusion… Do they have to stay out of work or school for a period of? For our own protection? - Participant 2
Medication Cost and Insurance Coverage	• Does my insurance even cover it? … Hopefully, my insurance covers it. And hopefully there's not some huge out of pocket costs. So that's just where my mind goes. - Participant 4 • If I go through this, will I have issues getting back on the medication I was on initially? The concerns I have, I just don't want to recreate a situation for myself when I don't know what's going to happen. - Participant 5 • My thing is like just managing insurance and like work. It just takes so much time. Like a full time job. - Participant 4

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1248–1271) Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are heterogenous autoimmune diseases requiring coordinated, patient-centered care. Understanding patient perspectives on diagnosis, treatment, health screening, and barriers to care is essential for optimizing outcomes and improving patient-centered care. We conducted a survey to assess IIM patient attitudes towards treatment, screening, and barriers to care at the University of North Carolina at Chapel Hill Rheumatology clinic.

Methods: A single anonymous survey with two open-ended and 16 discrete questions was developed to elicit perceptions of multimorbidity, a specific focus on screening, and obstacles to care. Patients with IIM were screened for eligibility from chart review prior to their rheumatology clinic appointment and provided with survey access information at the time of the appointment. Participant responses to open ended questions were analyzed with inductive thematic coding by two reviewers.

Table 1. Descriptive Characteristics of Participants

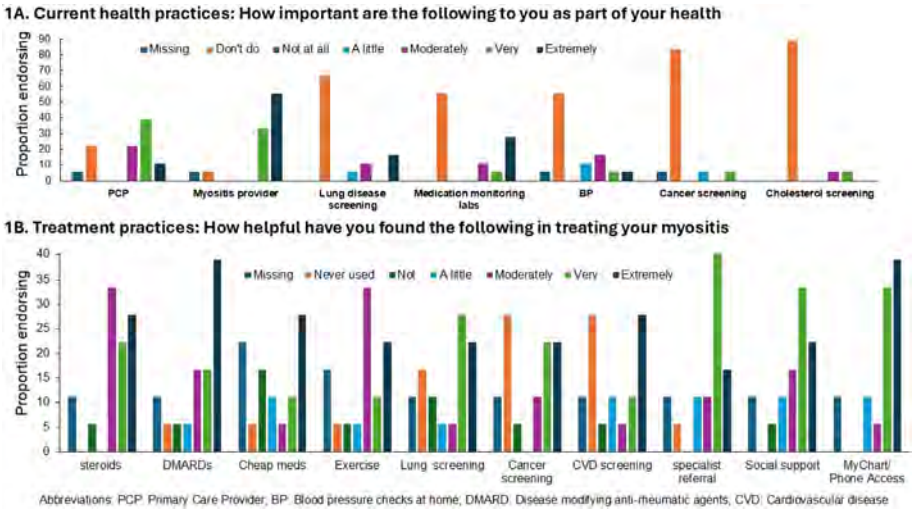
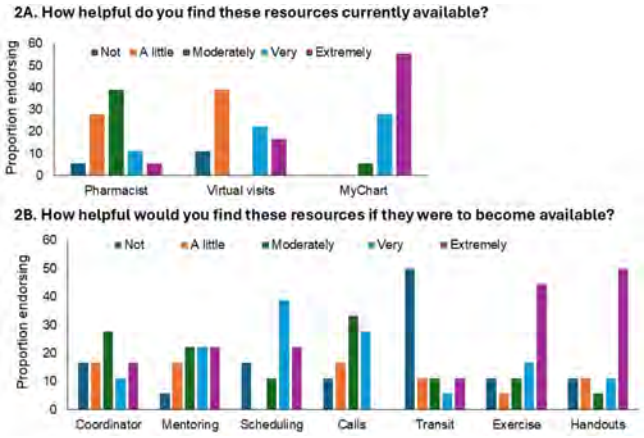
23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License





Results: Of 62 patients seen during routine ambulatory rheumatology care, 16 completed the survey. Most respondents were female (56%) and working (61%, Table 1). Most participants obtained health information from their IIM provider (94%) followed by their primary care provider (61%). Half of participants did not understand the purpose of one or more of their medications, and a third reported high cost or co-pay of one or more of their medications. Most respondents did not endorse participating in screening practices (Figure 1A). Participants endorsed electronic/phone access to care team, disease modifying anti-rheumatic agents and exercise as components they found helpful in managing their myositis (Figure 1B). For current and future resources, participants noted the electronic patient portal (56%), an exercise program (44%), and educational handouts on IIM (50%) as extremely helpful (Figure 2). Regarding what participants wished their myositis provider understood about their condition, participants discussed uncertainty, "*it comes and goes;*" "[it] *creates feelings of inaptitude and unreliability*" and "*…it seems my muscle pains are dismissed since my bloodwork doesn't show increases in certain levels.*" Regarding what participants would improve about their myositis, many responses focused on a cure, while others expressed a desire to understand "*understanding what I was feeling and facing would help me understand more clearly*" and apply disease understanding to decrease flares: "*what preventative actions I can take to prevent a flare other than medicinal.*"

Conclusion: In this single center survey, we found patients with IIM did not participate in screening (e.g. cancer, cardiovascular). Participants expressed uncertainty/unpredictability as obstacles to care and cited MyChart as helpful alongside a

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Abstract Number: 1273

Effectiveness of IV Cyclophosphamide and Mycophenolate Mofetil in the Treatment of Pediatric Systemic Lupus Erythematosus with Lupus Nephritis

Adrienne Katrin Guiang-Valerio, University of Santo Tomas Hospital, Mandaluyong, National Capital Region, Philippines

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Lupus nephritis (LN) is more common in children (occurs in 50-82%) compared to adults. Cyclophosphamide (CYC) and mycophenolate mofetil (MMF) are both treatment options for childhood-onset SLE with LN. Both options are included in the recommendations for the management of LN. However, in children, the optimal treatment of LN is still unknown.

Methods: Single center retrospective cohort study included patients ≤18 years old with SLE with nephritis diagnosed between 2008 and 2024.

Results: A total of 231 patients were included in the study. The proportion of participants who were shifted to another treatment due to poor response was significantly higher among those in the MMF group (81.82% vs. 50.00%, p=0.001), while

Comparisons of Renal Response and Outcomes

Table 4.
Between-Group Comparisons of the Renal Response Rates and Outcomes Between the Two Groups among Childhood Systemic Lupus Erythematosus (cSLE) with Lupus Nephritis in the University of Santo Tomas Hospital from January 2008 to September 2024 (N = 231)

Outcomes	Group Allocation (N = 231)		p-value (Two-Tailed)
	Cyclophosphamide Group (CYC; n = 174)	Mycophenolate Mofetil Group (MMF; n = 57)	
Incidence of Complete Renal Response (Per 100 Person-Months; 95% CI)	4.91 (4.12 to 5.82)	4.71 (3.48 to 6.25)	0.818
Renal Response (f, %)			
No Renal Response	10 (5.75%)	4 (7.02%)	0.727
Partial Renal Response	30 (17.24%)	5 (8.77%)	0.122
Complete Renal Response	134 (77.01%)	48 (84.21%)	0.249
Number of Flares (Md, IQR)			
One-Year Post-Treatment	0.00 (0.00 – 1.00)	1.00 (0.00 – 2.00)	0.007*
Two-Year Post-Treatment	0.00 (0.00 – 2.00)	0.00 (0.00 – 4.00)	0.389
Low C3 Levels (f, %)	34 (19.54%)	17 (29.82%)	0.104
Receipt of Hydroxychloroquine (f, %)	172 (98.85%)	56 (98.25%)	0.574
Receipt of ACEI/ARB (f, %)	170 (97.70%)	57 (100.00%)	0.574
Prednisone Daily Dose (mg; Md, IQR)	5.00 (5.00 – 15.00)	5.00 (5.00 – 30.00)	0.190

Comparisons of Reasons for Shifting to Another Treatment

Table 3.
Comparative Analyses of the Reasons for Shifting to Another Treatment among Childhood Systemic Lupus Erythematosus (cSLE) with Lupus Nephritis in the University of Santo Tomas Hospital from January 2008 to September 2024 (N = 231)

Outcomes	Group Allocation (N = 231)		p-value (Two-Tailed)
	Cyclophosphamide Group (CYC; n = 174)	Mycophenolate Mofetil Group (MMF; n = 57)	
Completed Induction Phase (f, %)	92 (52.87%)	34 (59.65%)	0.372
Patients Shifted to Another Treatment (f, %)	82 (47.13%)	23 (40.35%)	0.372
Reasons for Shifting Treatment (f, %)			
Poor Response	40 (50.00%)	18 (81.82%)	0.001*
Persistence or Recurrence of Hematuria/Proteinuria	25 (31.25%)	4 (18.18%)	0.057
Transitioned	2 (2.50%)	0 (0.00%)	0.226
Pandemic	2 (2.50%)	0 (0.00%)	0.226
Preference or Request	6 (7.50%)	0 (0.00%)	0.033*
Adverse Events (e.g., Infection, Chest Pain, etc.)	5 (6.25%)	0 (0.00%)	0.053

*Significant at 0.05

Comparative Analyses of the Reasons for Shifting to Another Treatment among Childhood Systemic Lupus Erythematosus (cSLE) with Lupus Nephritis in the University of Santo Tomas Hospital from January 2008 to September 2024 (N = 231)

the proportion of those who were shifted due to preference was higher in CYC group. The overall incidence rate of complete renal response was 4.86 per 100 person-months, 4.91 per person-months in the CYC group and 4.71 per person-months in the MMF group. 77.01% of the CYC group had complete renal response, while the MMF group had a rate of 84.21%. During the first-year post-treatment, the median number of flares was significantly higher in the MMF group compared to CYC. Females were 6.85-times more likely to be shifted to another treatment, while those who received MPPT were 2.86-times less likely to be shifted to another treatment. The odds of being shifted to another treatment decreases by 25% for every 1-milligram increase in the daily dosage of prednisone. Females and having tuberculosis increased the odds of shifting to another treatment by 6.14-times and 4.87-times, respectively. In the CYC group who received RTX were 6.67-times less likely to be shifted to another treatment. The likelihood of shifting from MMF to another treatment decreased by 19.00% for every 1-milligram increase in the daily prednisone dosage.

Conclusion: Both CYC and MMF are effective treatments for cSLE with LN, with CYC showing a faster response time compared to MMF (13 months vs 24 months). The probability of complete renal response at 6 months for those in the CYC group was approximately 80%, while those in the MMF group was about 70%. However, patients who were shifted between treatments had a significantly better renal outcome. Early adjustments in therapy may improve long-term results. A personalized approach considering the patient's clinical characteristics, risk factors, and response to therapy is crucial in managing cSLE with LN.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Juvenile idiopathic arthritis is the most common group of inflammatory rheumatic diseases in childhood. Its early onset and the immunosuppressive treatments used to control it may interfere with adherence to the established immunisation schedule and increase the risk of infections in adulthood. Little information is available on the magnitude of this problem in clinical practice.

The aim of this study is to assess the degree of compliance with the Spanish vaccination calendar prior to the rheumatology transitional consultation and to analyse different factors that may influence its implementation.

Methods: A single-centre observational retrospective study of patients with JIA (ILAR 2001) included in the rheumatology transitional consultation register (2012-2024) has been performed. Clinical, therapeutic and vaccination data were collected. Given the variability of the vaccination schedule throughout the follow-up period, it was agreed to include vaccines for HBV, Polyomavirus, Haemophilus influenzae B, Diphtheria-Tetanus-Polio (DTaP), Pneumococcal (13-valent), Men. C, Papilloma, Varicella and MMR. The main variables included were: treatment with biological DMARDs or classical DMARDs, years of exposure to biological DMARDs, age at diagnosis and date at the time of transition consultation.

JIA SUBTYPES	N (%)
OLIGOARTICULAR	24 (24.49%)
POLYARTICULAR RF -	24 (24.49%)
POLYARTICULAR RF +	6 (6.12%)
SYSTEMIC	9 (9.18%)
PSORIATIC	5 (5.1%)
ARTHRITIS-ENTHESITIS	24 (24.49%)
UNDIFFERENTIATED	6 (6.12%)

JIA Subtypes

VACCINE	FULL VACCINATION N (%)	VACCINATION EXPOSURE (at least 1 received dose) N (%)
Diphtheria-tetanus-pertussis (DTaP)	60 (61.86%)	87 (89.69%)
Polyomavirus	51 (52.58%)	72 (74.23%)
Haemophilus influenzae B	41 (42.27%)	56 (57.73%)
Hepatitis B Virus	53 (54.64%)	72 (74.23%)
Pneumococcal (13-valent)	22 (22.68%)	56 (57.73%)
Meningococcal C	38 (39.17%)	80 (82.47%)
MMR (Measles, Rubella and Mumps)	49 (50.52%)	78 (80.41%)
Varicella	12 (12.37%)	20 (20.62%)
Papilloma	45 (46.39%)	47 (48.45%)

Vaccination compliance in JIA patients

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Exposure to the vaccine was considered as having received at least one dose of the vaccine and full vaccination with receiving the doses established in the vaccination schedule of the Valencian Community (Spain)

Logistic regression models were used to study the relationship between the different variables and vaccination compliance.

Results: 98 patients (64.29% female) with a mean age (SD) of 8.65 (4.73) years old at diagnosis and 20.41 (2.54) years old at the rheumatology transition consultation visit, were included. The distribution by JIA subtypes are described in table 1. 53.61% of patients had been treated with biological DMARDs with an average duration of treatment of 18.47 years and 52.04% had been treated with classical DMARDs.

Only 2 patients received the full dose of all the established vaccines and 5 received at least one dose. Table 2 shows the percentage of compliance for each vaccine. Multivariate analysis showed that biological DMARD treatment was associated with lower complete vaccination for MMR (p=0.004), Polyomavuris (p=0.01), H.influenzae B (p=0.02), Men. C (p=0.017), Papilloma (p=0.01) and DTaP (p=0.004). On the other hand, treatment with classical DMARDs was associated with higher exposure to pneumococcal (p=0.004) and HBV (p=0.03) vaccination.

A more recent date at the transition consultation was related to higher percentage of complete vaccination for DtaP (p=0.003), Polyomavuris (p=0.03), Haemophilus Influenzae B (p< 0.001), pneumococcal (p=0.001), Men. C (p=0.034) and Varicella (p=0.001) vaccines.

Conclusion: A low percentage of vaccination exposure and especially a low percentage of complete vaccination was observed for both live and inactivated virus vaccines, mainly related to the biological DMARD prescription. In contrast, treatment with classical DMARDs was associated with higher exposure to pneumococcal and HBV vaccines. Compliance was higher in recent years.

Level of connection (percent of total)	• Improved: 13 (62) • Same: 5 (24) • Decreased: 3 (14)
Anxiety level (percent of total)	• Improved: 7 (33) • Same: 13 (62) • Worsened: 1 (5)

Legend: JIA = Juvenile Idiopathic Arthritis, SLE = Systemic Lupus Erythematosus, ANCA = Anti neutrophilic cytoplasmic antibody, JDM = Juvenile Dermatomyositis, CAPS = Cryopyrin associated periodic fever syndrome

Patient and caregiver characteristics

Background/Purpose: Patients with chronic diseases often report poor health-related quality of life (QOL) and impaired psychosocial functioning. The current model of healthcare in rheumatology emphasizes evidence-based medicine but does not always address broader dimensions of patient well-being, psychological needs, and QOL. Narrative medicine (NM) is a valuable tool that can be used in healthcare by patients, caregivers, and health care professionals to further explore and understand experiences with illness and caregiving. Allowing patients and caregivers to reconstruct their experiences through self-reflection can be cathartic and has been shown to improve patient reported outcomes and QOL

Methods: The Childhood Arthritis and Rheumatology Research Alliance (CARRA) NM workgroup conducted two 60-minute workshops at its 2025 annual meeting. The first workshop was designed for patients and caregivers affected by rheumatic diseases, while the second targeted pediatric rheumatology healthcare professionals (HCPs). Each workshop was led by

Table 2: Healthcare professionals characteristics

Total participants in attendance	17
Number of complete responses	14
Age distribution (Percent of Total)	• 18–30: 3 (21) • 31–40: 8 (57) • 41–50: 1 (7) • 51–60: 2 (14)

Figure 1: Experiences of all participants. Image created with wordclouds.com.

Experiences of all participants

facilitators trained in NM. Participants completed a pre-workshop survey to assess their baseline knowledge and prior experience with NM interventions. A post-workshop survey was administered to evaluate feasibility, to understand participant perceptions of intervention, and to assess immediate changes in their feelings of connectedness and anxiety.

Results: Twenty-five participants attended the patient-caregiver workshop, and 17 participants attended the HCP workshop.

Patient-Caregiver Workshop (Table 1): Twenty-four of 25 participants completed the survey. One participant who was under the age of 18 did not take the survey and three surveys were incomplete. Of the 21 valid responses, seven were completed by patients and the remainder by caregivers. Four of the 21 participants had prior NM experience. All respondents reported being satisfied (n=7) or very satisfied (n=14) with the workshop. Free-text responses reflecting participants' experiences and feelings are depicted in Figure 1.

HCP Workshop (Table 2): Participants included pediatric rheumatologists, advanced practice providers, fellows, and research coordinators. Fourteen of 17 participants completed the survey. Thirteen out of 14 participants reported being satisfied (N=X) or very satisfied (N=X) with the workshop. Free-text responses depicting participant experiences and feelings are depicted in Figure 1.

Conclusion: The NM workshops were well received by patients, caregivers, and HCPs with high satisfaction rates. While most participants had no prior NM experience, many respondents found value in the workshop. Further NM interventions with larger samples are required to adequately explore contributing factors impacting participant degree of connection and impact on anxiety. These findings support the feasibility and acceptability of NM interventions in pediatric rheumatology settings.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Pediatric patients living with chronic rheumatic diseases have high rates of anxiety and depression, which can lead to adverse health outcomes. In 2018, The American Board of Pediatrics launched The RoadMap Project to support the emotional needs of patients with chronic diseases. This project provides clinicians with a toolkit and framework for implementing surveillance and assessment of emotional health in pediatric subspecialty practices. Our local pediatric rheumatology clinic utilized the The RoadMap Project framework to develop a workflow for implementing mental health screening questionnaires into routine clinical practices. This quality improvement initiative aimed to assess the prevalence of anxiety and depression within our patient population and ensure timely allocation of resources to help address mental health concerns identified.

Methods: Beginning October 1, 2024, the Patient Health Questionnaire-9 (PHQ-9) and the Generalized Anxiety Disorder Scale-7 (GAD-7) were piloted in two rheumatology provider clinics for all return visits with patients aged 12 years and older. The nursing staff integrated these questionnaires into the clinical workflow as part of the intake process. Once patients completed the questionnaires, the nursing staff entered scores in a flowsheet within the electronic medical record. A structured response protocol was developed to guide screening responses in real-time. Depending on the severity of symptoms identified, patients were provided a comprehensive mental health educational handout, referred to a licensed counselor within our institution, and/or had a real-time social work consult with safety planning and administration of the Ask Suicide Screening Questions (ASQ) if necessitated. On March 1, 2025 we expanded the screening process to two additional rheumatology provider clinics.

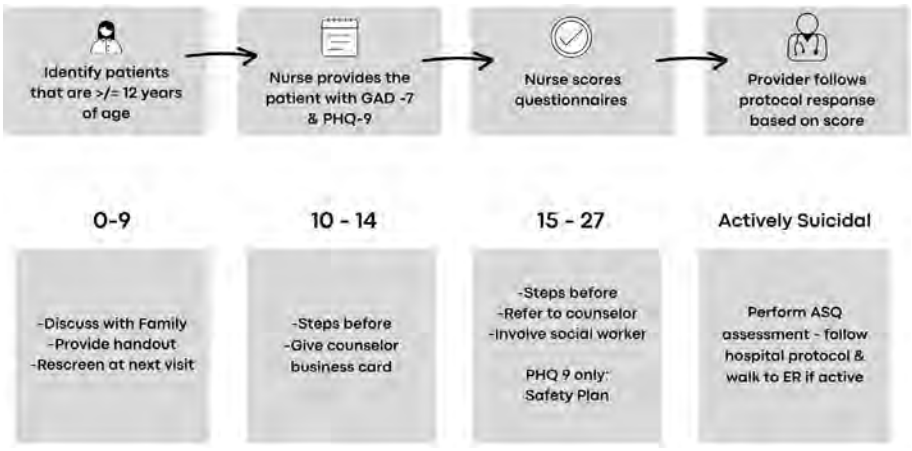

Figure 1. Structured screening and response protocol for PHQ-9 and GAD-7 questionnaires.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: From October 2024 through April 2025, mental health screenings have been completed for a total of 125 patients. Based on PHQ-9 results, 14% of patients reported no depression symptoms, 67% had minimal to mild symptoms (1-9), 9% had moderate symptoms (10-14), and 10% had moderately severe to severe symptoms (15-27). Suicidal ideation was endorsed by six patients, all of whom completed further evaluation using the ASQ tool and none were determined to be actively suicidal at the time of screening. GAD-7 results indicated 21% of patients reported no anxiety symptoms, 53% had minimal to mild symptoms (1-9), 19% had moderate symptoms (10-14), and 7% had severe symptoms (15-21).

Conclusion: We have successfully piloted routine mental health screenings in our pediatric rheumatology clinic, with a plan for complete adoption. In screenings completed to date, we have identified that a majority of pediatric rheumatology patients report mild to moderate symptoms of depression and anxiety, supporting the need for dissemination of mental health screenings as part of standard care. Future efforts will focus on automating the screening process within the electronic medical record to enhance efficiency and sustainability.

Abstract Number: 1277

Combination Therapy with Rituximab and Cyclophosphamide for Treating Pediatric Patients with Severe Manifestations of Rheumatic Disease

Eileen Rife[1], Daniel Reiff[2], John Bridges[3], Emily Smitherman[1], randy Cron[1], Matthew Stoll[1], Melissa Mannion[1], Peter Weiser[4] and Livie Timmerman[5], [1]University of Alabama at Birmingham, birmingham, AL, [2]Boys Town Hospital, Omaha, [3]University of Alabama at Birmingham/Children's of Alabama, Birmingham, AL, [4]University of Alabama at Birmingham, Birmingham, [5]University of Alabama at Birmingham, Gardendale, AL

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Current practice guidelines recommend either rituximab (RTX) or cyclophosphamide (CYC) for treatment of organ-threatening manifestations of systemic vasculitis or connective tissue disease (e.g., diffuse alveolar hemorrhage, active class III, IV, or V lupus nephritis). These diseases are associated with high mortality and are often refractory to standard therapies. Few studies have evaluated the safety and efficacy of combination therapy with RTX and CYC. We conducted this study to evaluate outcomes in the first 12 months following RTX-CYC combination therapy in pediatric patients with rheumatic diseases.

Methods: Patients who received combination RTX-CYC therapy for a rheumatic disease between January 2020 and February 2023 at a single center were included. The primary outcomes of interest were death and infection requiring hospitalization within 12 months of combination therapy. Secondary outcomes included change in serologic lupus disease activity markers and corticosteroid (CS) dose, flare in disease activity, infusion reactions, and incident hypogammaglobulinemia. Patient demographic information, outpatient medications, laboratory data, and admission data were collected for 12 months post-treatment.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

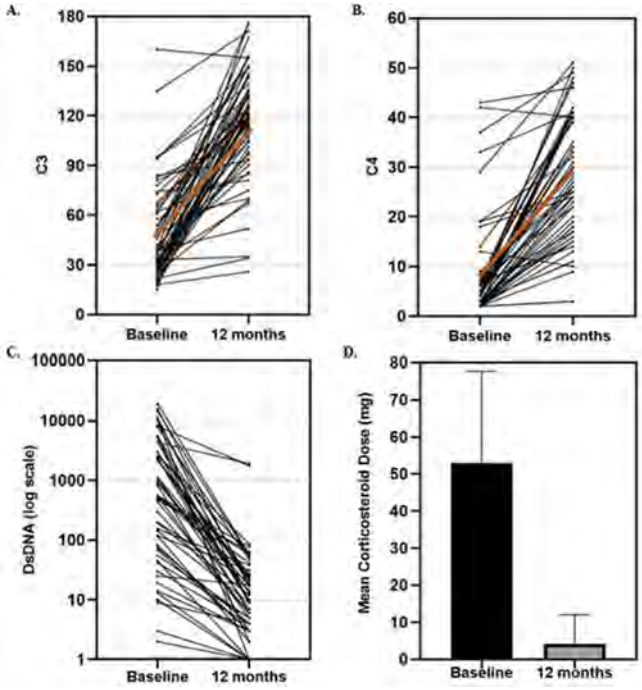

Figure 1. (A) Change in C3 levels in mg/dL – mean 47 ± 29 mg/dL prior to RTX-CYC and 115 ± 34 mg/dL at 12 months. (B) Change in C4 levels in mg/dL – mean 8 ± 10 mg/dL prior to RTX-CYC and 29 ± 13 mg/dL at 12 months. (C) Change in DsDNA levels in IU/mL – mean 2645 ± 4345 IU/mL prior to RTX-CYC and 85 ± 347 IU/mL at 12 months. The brown line represents the regression line. Improvements were significant at $p < 0.0001$. The mean daily prednisone-equivalent dose decreased from 54 mg ± 23.6 to 11 mg ± 9.3, $p<0.0001$ by 12 months (D).

Results: Eighty-nine pediatric patients received combination RTX-CYC therapy for a rheumatic disease during the study period. There were no reported deaths; eight patients (8.9%) were hospitalized with probable or definite infection. Patients with SLE demonstrated significant improvements across all serologic disease activity markers (anti-double stranded DNA antibodies, C3, C4) with $p < 0.0001$. The mean daily prednisone-equivalent dose significantly decreased by the end of the follow-up period from 54 mg ± 23.6 to 11 mg ± 9.3 ($p< 0.0001$), and 54 patients (62%) were able to discontinue CS. Six patients (6.7%) experienced flare of disease and eleven patients (12%) experienced infusion reactions – with 1 patient having a severe reaction to RTX necessitating discontinuation. Twenty-six patients (31%) experienced incident hypogammaglobinemia, with (69%) of cases recovering counts by 24 months.

Table 1: Demographics and Rheumatic Diseases, n=89

Age at start of dual therapy, years

Conclusion: Combination therapy with RTX and CYC can be safely administered to children with rheumatic diseases. Risk of serious adverse events, disease flare, and infusion reactions requiring cessation of therapy is uncommon, allowing for effective treatment with decreased CS burden. Prospective controlled trials comparing combination therapy to standard therapy are needed.

Abstract Number: 1278

Differences in Patient and Provider Perception of Functional Status in Adolescents with Lupus

Emily Masi[1], Kimberly Rapoza[2], Tamar Rubinstein[3], Kathy Kenney-Riley[4] and Joyce Hui-Yuen[5], [1]Cohen Children's Medical Center, North New Hyde Park, NY, [2]Mercy College, Dobbs Ferry, NY, [3]Albert Einstein College of Medicine, White Plains, NY, [4]Mercy University, Dobbs Ferry, NY, [5]North Shore LIJ Health System, Great Neck, NY

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Patient and provider discordance can negatively impact medication adherence and disease outcomes in pediatric lupus. Functional status is known to greatly affect perception of disease activity and outcomes. We aim to investigate discordance in providers' and patients' assessment of functional status in adolescents with lupus, and relation to disease activity.

Methods: This cross-sectional study enrolled adolescent lupus patients between 2019 and 2022. Functional status was assessed by providers using the American College of Rheumatology classification of global functional status (ACR), and patients using subscales of the KIDSCREEN, PedsQL and PROMIS surveys. Clinical data including disease activity score

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(SLEDAI) and provider global assessment (PGA) were also collected. All analyses were corrected with Benjamini-Hochberg tests. Pearson and Spearman correlations were run among study variables. Mann-Whitney U tests examined differences in ACR groups on functional status variables. Kruskal Wallis analyses were conducted on SLEDAI, functional status ratings and patient and provider global ratings.

Results: 96 participants were enrolled, 77% female, with mean age of 17 (range 12-21) years and mean duration of diagnosis 3.36 (range < 1-12) years. Mean SLEDAI was 5.61 (range 0-38), indicating at least moderate disease activity. Eighty-seven subjects were categorized by providers as ACR Class I (able to perform all daily activities), and 7 as ACR Class II or III (at least some limitation to perform usual daily activities). Norm comparisons with one-sample T-tests found patients reported more fatigue but better physical function on PROMIS subscales, scored worse in all subscales of KIDSCREEN except bullying, and better in physical, emotional, social and school function subscales of the PedsQL compared to population means ($p < .001$). Once adjusted, the ACR categories did not significantly differentiate patients based on any of the patient reported functional subscales. SLEDAIs significantly correlated (Benjamini-Hochberg adjusted to $p < .002$) with PGA and the PedsQL social function subscale, but no other variables. There was no significant differentiation (Class II/ Class III ACR vs. Class I) on patient-rated functional status with the KIDScreen, PROMIS or PedsQL., except for pain intensity ($p=.001$). There were no differences for the SLEDAI, absolute discordance, or the patient global disease rating but there was a significant difference in the provider global disease rating ($p \leq .001$).

Conclusion: Adolescent lupus patients' assessment of function as captured on KIDSCREEN, PedsQL, and PROMIS subscales were more varied than providers' assessments using the ACR. SLEDAI correlated with PGA, but not with patient assessments. These findings suggest that provider-based assessments, may not adequately reflect the functional status of adolescents with lupus as experienced by the patients themselves. While disease activity measures like SLEDAI correlate with provider assessments, they do not align with patient-reported functional outcomes. This discrepancy highlights the need for more comprehensive and patient-centered tools to assess functional status in this population.

Whole Blood Gene Expression Defined Subgroups of Treatment Naïve Children and Adolescents with Childhood-onset Systemic Lupus Erythematosus.

Reagan Reid[1], Huayun Hou[2], Isha Datar[2], Daniela Dominguez[3], Andrea Knight[4], Deborah Levy[5], Lawrence Ng[6], Zhaoyu Ding[2], Michael Wilson[2], Lauren Erdman[7], Eleanor Pullenayegum[2] and Linda Hiraki[5], [1]The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada, [2]SickKids Research Institute, Toronto, ON, Canada, [3]The Hospital for Sick Children, Toronto, Canada, [4]Hospital for Sick Children, Toronto, ON, Canada, [5]The Hospital for Sick Children, Toronto, ON, Canada, [6]The Hospital for Sick Children, Toronto, Canada, Toronto, ON, Canada, [7]University of Cincinnati, Cincinnati, OH

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Childhood-onset systemic lupus erythematosus (cSLE) is a clinically and genetically heterogeneous disease. We aimed to define subgroups of new diagnosis patients based on treatment naive gene expression profiles. We then examined how subgroup membership related to gene pathways, demographic and clinical features.

South Asian	3 (13)	4 (10)	1 (10)	
Lupus Nephritis, n (%)	6 (25)	24 (59)	4 (40)	0.03

Methods: Participants were diagnosed and followed in a tertiary care Lupus clinic and met SLE classification criteria. Clinical and laboratory data including disease activity and damage indices were prospectively collected and stored in a dedicated database. Participants were genotyped on a multi-ethnic array and ancestry was genetically inferred. Whole blood was collected prior to treatment initiation with glucocorticoids or other potent immunosuppressants, and whole blood transcriptome wide RNA-sequencing was completed. We identified distinct participant clusters based on gene expression profiles using K-means clustering. Clinical and demographic feature differences between clusters were assessed using ANOVA and Fishers exact test. We generated ranked genes lists based on expression profile for each cluster, by comparing each cluster relative to the others using gene set enrichment analysis (gseGO, clusterProfiler). To gain an understanding of the underlying activated/

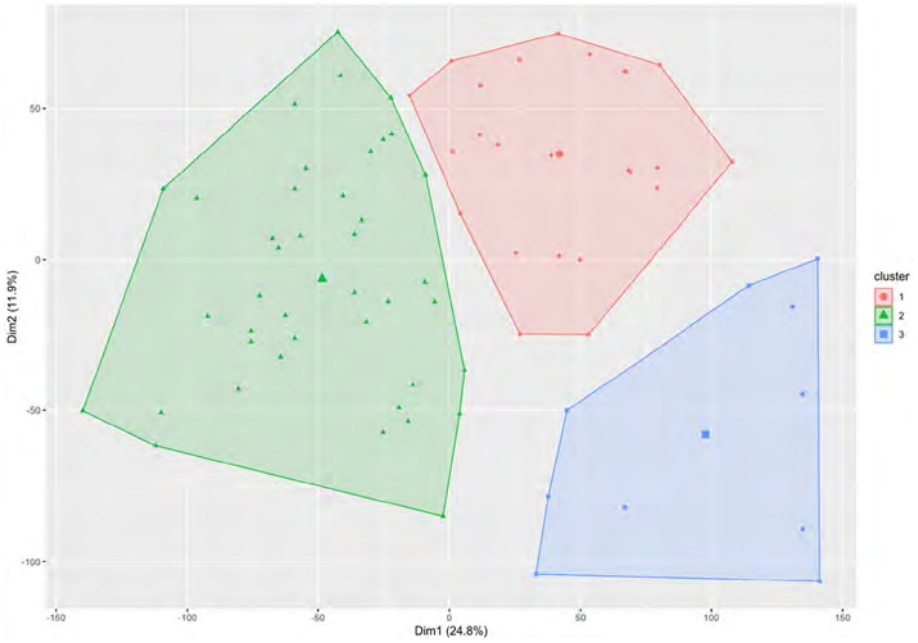

Figure 1 K-means Clusters.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

suppressed processes within each cluster we assessed Gene Ontology (GO) biological processes within each cluster.

Results: The cohort included 75 children and adolescents with cSLE with RNA-sequencing on treatment naïve whole blood samples. Initial K-means plots identified three clusters and one outlier which was excluded resulting in the final cohort. The group was 81% female with a median age at SLE diagnosis of 13.8 years (IQR: 12.1, 15.4).; full participant characteristics are presented in Table 1. We identified three clusters (Figure 1). Clusters differed significantly in proportion of individuals with lupus nephritis (LN) (Cluster 1= 25%, Cluster 2= 59%, Cluster 3= 40%, P= 0.03); the clinical and demographic composition of each cluster is summarized in Table 2. Cluster 1 was characterized by activation of protein synthesis (*RPL10, RPL13, RPS14*) and signaling pathways (*GPR162, FCER1A, CSF1R*), whereas cell cycle processes (CDC16, BCL6, RMI1) were supressed. Cluster 2 showed enrichment of ribosomal related pathways (*UTP20, UTO4, MAK16*) and chromosomal processes (BUB1, NCAPG, MYBL2) while suppressed pathways related to secretory granules (*ATP8B4, ATP11A, CST3*) and innate immune responses (*P2RY1, PIK3CB, MAP1B*). Cluster 3 showed up-regulation of secretory granules and vesicles (*CD177, MMP8, LTF*) while down-regulated pathways were related to ribosomal (*MRPL20, RPS9, RPS3A*) and RNA pathways (*ABT1, RPP38, KARS1*) and the adaptive immune response (*TRAV41, TRAV27, TRGV8)*.

Conclusion: In a clinically heterogeneous, multiethnic cohort of patients with cSLE, treatment naïve whole blood RNAseq genome wide expression generated three discrete clusters of patients. LN was most prevalent in cluster 2 which was characterized by increased activation of ribosomal and chromosomal pathways. Next steps include examining cell specific gene expression pathways.

Abstract Number: 1280

Investigating the Association Between SARS-CoV-2 Infection, COVID-19 Vaccination, and Autoimmune Diseases in a Pediatric Population: A comprehensive analysis

Yonatan Butbul Aviel[1], Arad Dotan[2], Dana Arnheim[2] and Cynthia Freiberg[3], [1]Rambam Health Care Campus, Haifa, Israel, [2]Faculty of Medicine, Tel Aviv University, Ramat Aviv, Israel, Tel Aviv, Israel, [3]Maccabi Healthcare Services, Tel Aviv, Israel, Tel Aviv

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: During the COVID-19 pandemic there were reports of an increased association between COVID 19 and various autoimmune diseases (AID) in adults. This study aims to investigate the incidence of AIDs in children before and during the pandemic and explores potential links to SARS-CoV-2 vaccination.

Methods: We analyzed 493,705 anonymized medical records from Maccabi Healthcare Services, Israel's second-largest healthcare provider, to study AID incidence during 2014-2022. The study period was divided into three phases: two pre-pandemic phases of equal duration (A and B) and a pandemic phase (C).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1.A

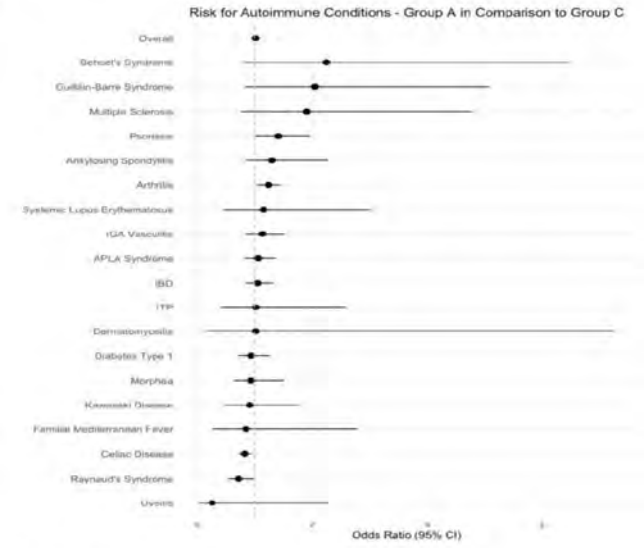

Figure 1.B

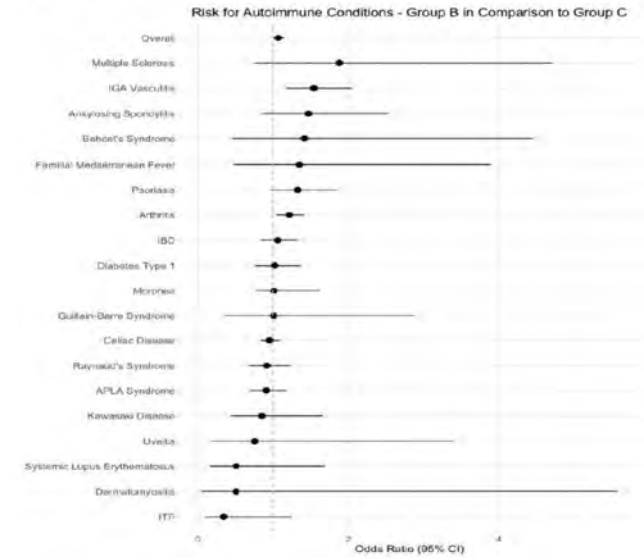

Figure 1.A and B. Multivariable logistic regression analysis comparing the incidence of autoimmune diseases between Group C (pandemic period) and Groups A and B (pre-pandemic periods

Results: Of 4,596 (0.9%) patients diagnosed with an AID in the cohort, incidence rates were 0.9% for Group A (2014-2016), 1.0% for Group B (2017-2019), and 0.9% for Group C (2020-2022) (p = 0.13). Logistic regression showed no significant differences in overall autoimmune disease incidence between the pre-COVID and COVID periods. Notably, specific conditions like celiac disease showed reduced incidence in Group A (OR 0.8309, p = 0.0071) while arthritis was significantly more common in Groups A and B. Additionally, COVID-19 diagnosis was not significantly associated with increased autoimmune disease risk (HR 1.092, p = 0.491); however, receiving at least one COVID vaccine was linked to higher risk (HR 1.2323, p = 0.0033).

Conclusion: Our findings suggest that the overall incidence of new-onset autoimmune diseases in children remained relatively stable during the COVID-19 pandemic. The study indicates a potential association between COVID-19 vaccination and an increased risk of developing autoimmune diseases, necessitating further research to elucidate long-term effects in the pediatric population

Ethnic Disparities in Mental Health Screening, Diagnoses, and Outcomes in Patients with Childhood-Onset Systemic Lupus Erythematosus

Alicia Tran[1], Indrani Das[2], Zhaoyu Ding[3], Daniela Dominguez[4], Sefi Kronenberg[5], Lawrence Ng[6], Alene Toulany[1], Gwyneth Zai[7], Deborah Levy[1], Andrea Knight[8] and Linda Hiraki[1], [1]The Hospital for Sick Children, Toronto, ON, Canada, [2]University of Toronto, Toronto, ON, Canada, [3]SickKids Research Institute, Toronto, ON, Canada, [4]The Hospital for Sick Children, Toronto, Canada, [5]Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, [6]The Hospital for Sick Children, Toronto, Canada, Toronto, ON, Canada, [7]Centre for Addiction & Mental Health, Toronto, ON, Canada, [8]Hospital for Sick Children, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with childhood-onset systemic lupus erythematosus (cSLE) face higher risks of depression and anxiety compared to healthy peers. In 2022, standardized mental health (MH) screening for depression and anxiety was introduced in the cSLE clinic to improve early intervention. While ethnic disparities in accessing MH care have been reported, they remain understudied in cSLE populations. This study examined ethnic differences in the prevalence of elevated symptoms and diagnoses of depression and anxiety among youth with cSLE pre- and post-implementation of standardized MH screening.

Methods: We completed a retrospective study of youth aged ≤ 18 years followed for SLE between January 1, 2000, to December 1, 2024. The cohort was stratified into two periods: pre-implementation (2000-2021) and post-implementation (2022-2024) of standardized MH screening. Ethnicity of patients was grouped into the following categories: European, East Asian, South Asian, African, Latin American, Indigenous American, Admixed (≥2 ethnicities), and Other. Elevated symptoms of depression and anxiety were identified by ever screening positive on any of the following questionnaires: Children's Depressive Inventory (CDI score >13; CDI-2 score ≥20), Patient Health Questionnaire 9-item (PHQ-9 score ≥10), Multidimensional Anxiety Scale for Children (MASC score ≥48; MASC-2 score ≥88), and Generalized Anxiety Disorder 7-item (GAD-7 score ≥10). Diagnoses of depression and anxiety were identified by medical chart review. Univariate and

Note: **Bold** indicates significant difference based on $p < 0.05$.

multivariable logistic regression, adjusted for sociodemographic and clinical variables (age, sex, duration of follow-up, disease damage, neuropsychiatric SLE [NPSLE], lupus nephritis), assessed the association of ethnicity with screening outcomes and diagnoses of depression and anxiety.

Results: Among 610 charts reviewed, 560 patients had self-reported ethnicity data and were included in the study. This analysis focuses on 123 patients actively followed post-implementation of standardized screening, during which 109 patients completed both the PHQ-9 and GAD-7. The cohort was predominantly female (87%) with a median age at SLE diagnosis of 13 years (IQR 9-15). Majority of patients were East Asian (28%), European (22%), and Admixed (20%). NPSLE was present in 15% of patients and 25% had lupus nephritis. Ethnicity was not significantly associated with screening completion, screening positivity, or diagnoses of depression or anxiety. In adjusted models, NPSLE was significantly associated with screening positive on the PHQ-9 (OR = 15.45, CI: 3.07-77.82, p = < 0.001) and receiving a depression diagnosis (OR = 13.76, CI: 2.55-74.22, p = 0.003). No significant associations were found between demographic and clinical variables and anxiety-related outcomes.

Conclusion: In a large multiethnic cohort of youth with cSLE, we did not observe an association between ethnicity and MH screening or a diagnosis of depression and anxiety. NPSLE was significantly associated with screening positive on the PHQ-9 and receiving a depression diagnosis. Further analyses will assess psychotropic medication use by ethnicity and extend findings to the pre-implementation period.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: SLE is a multisystemic autoimmune disease with several manifestations. Childhood-onset SLE (cSLE) has a more severe disease course than adult-onset SLE, with a higher frequency and severity of major-organ involvement and damage accrual. Low disease activity is an important goal. Belimumab (BEL) is the first biological drug approved for cSLE.

The aim of this study is to identify whether low lupus disease activity status on BEL is an achievable goal in cSLE and to describe the characteristics of cSLE patients treated with BEL in real world practice included in the JULES registry, a Spanish multicenter, hospital-based, cSLE registry.

Methods: We analyzed cross-sectional data from 67 patients treated with BEL for cSLE from a total of 250 included in the JULES registry. For the description of the cohort, summary statistics of central tendency and dispersion and percentage statistics were used for numerical and categorical variables respectively.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: 67 patients (26.8%) of the 250 patients included in the JULES registry were treated with BEL. The mean age to diagnosis was 12.9 (3.2) years, with a mean age at inclusion in the registry of 20.4 (8.3). 86.6% were female. Lupus nephritis (LN) prevalence was 56.1%, arthritis was seen in 74.6% and the most common laboratory abnormalities were leucopenia 68.2%, lymphopenia 62.5%, anti-DNA (89.6%) and hypocomplementemia (94%). The most frequent LN class was IV (23.9%), followed by class III (10.4%) and class II (10.4%). The main reasons for BEL initiation were arthritis (44.8%), muco-cutaneous manifestations (40.3%), systemic manifestations (37.3%), LN (26.9%) and hematological involvement (22.4%). 20.9% of patients initiated BEL in the first 6 months of the disease. The mean duration of BEL treatment was 27.78 months (31.65). The mean SLEDAI and SLICC scores were 3.11 (2.12) and 0.46 (1.25) points respectively. 19.4% of BEL-treated patients have inactive disease (SLEDAI 0-1), 70.1% low disease activity (SLEDAI 2-5), and 10.4% moderate activity. In patients with LN, 32.8% achieved complete remission and 10,4% partial remission, 4.5% experienced an improvement and ESRD was observed only in 3% of patients. 74.6% had managed to completely withdraw prednisone and 77.6% were still on BEL treatment. The reasons for suspension were inefficacy (14.9%), adverse events (4.5%) and complete remission of the symptoms (3%).

Conclusion: In the Spanish cSLE registry (JULES), 26.8% of patients were treated with BEL. In this complex and severe population, BEL is an effective and safe treatment for cSLE, allowing to achieve low disease activity state and corticosteroid withdrawal.

***Funding:** The Spanish registry of juvenile SLE (JULES) is funded by GSK. The author din not recive any grant from GSK

Abstract Number: 1283

Impact of Guideline Concordant Care of Renal Outcomes in Childhood-Onset Lupus Nephritis

Alisha Akinsete[1], Orysya Soroka[2], Mangala Rajan[2], Karen Onel[3], Monika Safford[2] and Iris Navarro-Millan[4], [1]Weill Cornell Medical Center, New York, NY, [2]Weill Cornell Medicine, New York, [3]HSS, New York, NY, [4]Weill Cornell Medicine, Hospital for Special Surgery, Poughkeepsie, NY

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: End-stage renal disease (ESRD) is a serious complication of lupus nephritis (LN), yet the effect of guideline-concordant care on this outcome is unclear. Despite the availability of treatment guidelines, adherence remains inconsistent. This study examines the association between guideline-concordant care and adverse renal outcomes in pediatric Medicaid patients with childhood-onset LN.

Table 1: Description of Quality Indicators for Childhood-Onset Systemic Lupus Erythematosus (cSLE) with Lupus Nephritis (LN)

Quality Indicator	Definition	Numerator	Denominator
SLE Medical Management			
Q1 Hydroxychloroquine use (HCQ)	All patients to be prescribed HCQ annually	Prescription of HCQ at any time in the calendar year	All patients
Q2 Medication Toxicity Surveillance with Complete Blood Count (CBC or LFT) tests	Annual surveillance for toxicity with CBC or LFT tests	CBC or LFT done once per calendar year.	All patients
Q3 Renal Disease Activity	At least 4 Renal Function or Urine test (UA, Up/Ucr, 24hr protein, Cr, cystatin C)	Number of patients with at least 4 tests in the calendar year	All patients
Q4 Lupus Disease Activity Surveillance	At least 4 LUPUS activity tests (C3, C4, dsDNA, ESR)	Number of patients with at least 4 tests in the calendar year	All patients
Nephritis Management			
Q5 Adequate Follow-up	Adequate follow-up while undergoing treatment	At least 4 Evaluation and Management (E & M) visits per calendar year	All patients
Q6 Use of steroid-sparing agents	Use of steroid-sparing agents such as DMARDs and/or Biologics	Prescription of DMARDs and/or Biologics at any time in the calendar year	All patients on glucocorticoids
Q7 Use of ACEi/ARBS for Hypertension or Proteinuria	Patients with hypertension or Proteinuria to be prescribed ACE/ARBS	Prescription of ACEi/ARBS at any time in the calendar year	All patients with HTN or Proteinuria

ACE/ARBS - Angiotensin-Converting Enzyme inhibitors/Angiotensin receptor blockers; DMARDs - Disease-Modifying Antirheumatic Drugs; HTN – Hypertension; UA – Urinalysis; Up/Ucr – Urine protein/Urine creatinine ratio; Cr -Creatinine; C3 – Complement 3; C4 – Complement 4; dsDNA - Double-stranded DNA; ESR - Erythrocyte Sedimentation Rate

Table 2: Childhood-Onset Lupus Nephritis Cohort Baseline Characteristics

	Total	No Adverse Renal Outcome	Adverse Renal Outcome	P value
All n, (%)	420 (100)	361 (86)	59 (14)	
Age, mean, (SD)	15.43 (3.7)	15.3 (3.7)	16.3 (3.3)	0.06
Age Category n, (%)				0.14
5-11	79 (18.8)	71 (19.7)	8 (13.6)	
12-17	227 (54.1)	198 (54.9)	29 (49.2)	
18-21	114 (27.14)	92 (25.5)	22 (37.3)	
Sex				0.27
Female n, (%)	361 (86.0)	313 (86.7)	48 (81.4)	
Male n, (%)	59 (14.1)	48 (13.3)	11 (18.6)	
Race and Ethnicity				0.04
Hispanic n, (%)	53 (12.6)	46 (12.7)	7 (11.9)	
Non-Hispanic Black n, (%)	225 (53.6)	192 (53.2)	33 (55.9)	
Non-Hispanic White n, (%)	60 (14.3)	57 (15.8)	3 (5.1)	
Other n, (%)	36 (8.6)	32 (8.9)	4 (6.8)	
Unknown n, (%)	46 (11.0)	34 (9.4)	12 (20.3)	
Medication severity at baseline*				0.12
No Medication n, (%)	18 (4.3)	15 (3.7)	3 (17.7)	
Steroids only n, (%)	37 (8.8)	34 (8.4)	3 (17.7)	
Mild n, (%)	26 (6.2)	25 (6.2)	1 (5.9)	
Moderate n, (%)	53 (12.6)	52 (12.9)	1 (5.9)	
Severe n, (%)	286 (68.1)	277 (68.7)	9 (52.9)

Table 3: Performance on each Quality Indicator (QI) for Childhood-Onset Lupus Nephritis (LN) by Adverse Renal Outcomes

Quality Indicator	All	No Adverse Renal Outcome	Adverse Renal Outcome	P value
Q1 Hydroxychloroquine use (HCQ)	70.3	70.7	61.0	0.11
Q2 Medication Toxicity Surveillance with Complete Blood Count and Liver Function (CBC/LFT) tests	88.6	88.5	91.5	0.47
Q3 Renal Disease Activity	82.7	82.7	83.1	0.95
Q4 Disease Activity Surveillance	63.5	63.4	64.4	0.88
Q5 Adequate Follow up	81.2	81.2	81.4	0.97
Q6 Use of steroid-sparing agents	85.6	85.5	87.8	0.68
Q7 Use of ACE/ARBS for Hypertension or Proteinuria	68.5	69.4	51.9	0.007

Data is presented as percentage of number X person years with QI among number of person X exposure years

ACE/ARBS - Angiotensin-Converting Enzyme inhibitors/Angiotensin receptor blockers

Data is presented as percentage of number X person years with QI among number of person X exposure years

Methods: Using Medicaid via Marketscan data from 2011-2022, we identified individuals with LN between the ages of 5 and 21. Patients are required ≥ 3 or more SLE ICD-9 or ICD-10 codes in outpatient visit claims or hospital discharge diagnosis codes at least 30 days apart and have ≥3 ICD-9/ICD-10 for nephritis and a procedure code for renal biopsy. The exposure was the 7 quality indicators (Table 1), and the outcome was the adverse renal outcome (end-stage renal disease, dialysis, or kidney transplant). Descriptive statistics were used to characterized baseline data (Table 2). We compared quality indicator adherence between patients with and without adverse renal outcomes (Table 3). Hazard Ratio was obtained for adverse renal outcomes with quality indicators exposures that reached statistical significance ($p< 0.05$). Annual adjusted rates of adverse renal outcomes were calculated using Poisson regression with robust standard errors. For patients who had multiple years of exposure, we modeled the impact of cumulative quality indicator exposures on renal outcomes with Poisson regression.

Results: We identified 420 children with prevalent childhood-onset LN. The only statically significant difference noted was race and ethnicity where 12.6% were Hispanic, 53.6% Black, 14.3% White, 11.6% Unknown, 8.6% Other (p=0.04) . Adherence to quality indicators was moderate to high (HCQ use: 77.6%, medication toxicity: 88.6 %, renal disease activity monitoring: 87.7%, lupus disease activity monitoring: 63.5%, adequate follow-up: 81.2%, use of steroid-sparing agent: 85.6%, use of ACEi or ARB 68.5%. (Table 3). Use of ACEi/ARBs for HTN or Proteinuria was lower for those with adverse renal outcomes (69.39% vs 51.85%, p=0.007). The risk of adverse renal outcomes is 45% lower for patients with LN with HTN or proteinuria on an ACEi/ARB than those without (age, sex, race adjusted HR 0.55 [95% CI 0.32-0.96). When looking at the cumulative effect of having the ACEi/ARB quality indicator present 2 and 3+ years was statistically significant. Annual Rates of adverse renal outcome at 0 years was statistical higher compared to year 2 and 3+ year respectively (age, sex, race adjusted rates 11.0 [95% CI 6.5-18.6) vs 4.7 [95% CI 2.3-9.6] and 5.6 [95% CI 3.1-10.0]).

Conclusion: Use of ACE inhibitors or ARBs was associated with a lower risk of adverse renal outcomes in children with lupus nephritis, with greater cumulative exposure linked to further risk reduction. Additionally, hydroxychloroquine use showed a trend toward improved renal outcomes, suggesting potential benefit. These findings support the importance of consistent, guideline-based medication use in improving long-term renal health in this population.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Antiphospholipid antibodies (aPL) have been associated with organ damage and certain features in juvenile-onset systemic lupus erythematosus (jSLE) patients. We aimed to assess the clinical manifestations of jSLE patients according to the presence of aPL and/or clinical antiphospholipid syndrome (APS).

Methods: Patients from the JULES registry were included. JULES is a Spanish multicenter, hospital-based, retrospective, jSLE registry. Three groups were established: a) SLE without antiphospholipid antibodies (jSLE); b) SLE with antiphospholipid antibodies (jSLE-aPL); c) SLE with secondary antiphospholipid syndrome (jSLE-APS). Clinical manifestations were compared between the 3 groups.

Results: We included 249 patients. 177 patients were classified as jSLE, 50 as jSLE-aPL, and 22 as jSLE-APS. The age of the cases ranged from 5 months to 18 years (mean age 12.65, SD 3.31); 207 patients (83.8%) were female. Regarding cardiovascular risk factors, jSLE-APS patients and jSLE-aPL had higher rates of hypertension and dyslipidemia than those with jSLE ($p< 0.001$). jSLE-APS patients showed higher rates of neurological manifestations ($p< 0.05$) and thrombopenia (63% in jSLE-APS, 30% in jSLE-aPL and 21% in jSLE, $p< 0.01$). The presence of livedo reticularis and Raynaud's syndrome was more frequent in the jSL-aPL group ($p< 0.05$). There were no differences in pulmonary or cardiac manifestations.

Regarding pharmacological treatment, in addition to antiplatelet and anticoagulant therapy, rituximab was used more frequently at the beginning in the jSLE-APS group ($p< 0,05$) and intravenous immunoglobulins in both jSLE-aPL y jSLE-APS groups ($p< 0,01$).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: jSLE-APS patients exhibited more severe clinical profiles with higher frequencies of major organ involvement than jSLE-aPL and jSLE patients. Further studies are needed to determine the risk and long-term outcomes of aPL-related events.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with childhood-onset systemic lupus erythematosus (cSLE) are at high risk for neuropsychiatric involvement as disease onset typically occurs during the critical period of adolescent brain development. Previous work has linked serum brain injury markers to systemic inflammation and cSLE disease features. However, the connection between these markers and brain volumetric changes is understudied. We aimed to i) compare serum brain injury markers and brain volumes between cSLE and controls; ii) evaluate the associations between brain injury markers and brain volume parameters; and iii) determine the associations within sub-analysis of the cSLE group.

Methods: This cross-sectional study included cSLE participants (ages 12–17) recruited from the Lupus Clinic at a Canadian tertiary children's hospital (Jan 2020–Dec 2023) and age/sex-matched healthy controls. Serum brain injury markers (serum neurofilament light (sNFL), glial fibrillary acidic protein (GFAP), Tau) were quantified using Simoa Human Neurology 4–Plex B assay (Quanterix, Billerica, MA, USA). T1-weighted MRIs acquired at 3T from cSLE patients and controls were preprocessed with FreeSurfer to automatically segment grey matter, white matter, lateral ventricle, and total brain volumes. Wilcoxon rank-sum tests compared serum brain injury marker levels between both groups and ANCOVA assessed brain volume differences adjusted for age and estimated total intracranial volume (eTIV). Semi-partial Pearson correlations

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

evaluated associations between brain injury markers (adjusted for age) and brain volumes (adjusted for eTIV) in the combined group (cSLE and controls), and in a sub-analysis of the cSLE group.

Results: 56 cSLE participants (mean age=15.1±1.8 years, 86% female) and 43 controls (mean age=15.1±1.7 years, 81% female) were included. GFAP (114.0 vs 74.3 pg/mL) and Tau (3.57 vs 2.58 pg/mL) serum levels were significantly higher in cSLE compared to controls (Figure 1). Adjusted total brain volume [F(1,95)=4.871, p=0.03] and grey matter volume [F(1,95)=5.571, p=0.020] were significantly lower in cSLE compared to controls; there were no differences for white matter and lateral ventricle volume. In the combined group, GFAP had a significant negative correlation with grey matter volume, while both sNFL and GFAP were positively associated with lateral ventricle volume (Table 1). No associations were found

Figure 1: Brain Injury Markers are Higher in cSLE vs. Controls

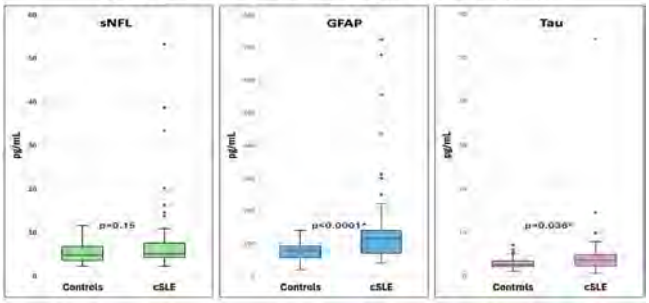

Figure 1: Boxplots showing group differences in serum brain injury marker levels between cSLE and controls. GFAP and Tau were significantly elevated in cSLE group (Wilcoxon rank sum test, $p < 0.05$), with outliers also observed across all brain injury markers for cSLE.

Table 1: Relationship between Brain Injury Markers and Brain Volumes in Combined Cohort of cSLE Patients and Controls (n=99)

	Total Brain Volume	Grey Matter Volume	White Matter Volume	Lateral Ventricle Volume
sNFL	r = -0.136, p = 0.18	r = -0.154, p = 0.13	r = -0.091, p = 0.37	r = 0.228, **p = 0.02**
GFAP	r = -0.155, p = 0.13	r = -0.237, **p = 0.02**	r = -0.041, p = 0.69	r = 0.240, **p = 0.02**
Tau	r = 0.153, p =0.13	r = 0.132, p = 0.19	r = 0.105, p = 0.30	r = 0.024, p = 0.81

Shown are semi-partial Pearson correlations analyzing relationships between serum brain injury markers (adjusted for age) and different brain volumes (adjusted for eTIV). Statistically significant correlations are bolded (p<0.05).

Table 2: Sub-Analysis of Relationship between Brain Injury Markers and Brain Volumes in cSLE only (n=56)

	Total Brain Volume	Grey Matter Volume	White Matter Volume	Lateral Ventricle Volume
sNFL	r = -0.103, p = 0.45	r = -0.125, p = 0.36	r = -0.060, p = 0.66	r = 0.246, p = 0.07
GFAP	r = -0.169, p = 0.21	r = -0.244, p = 0.07	r = -0.024, p = 0.86	r = 0.242, p = 0.07
Tau	r = 0.262, p = 0.05	r = 0.195, p = 0.15	r = 0.173, p = 0.20	r = 0.016, p = 0.91

Shown are semi-partial Pearson correlations analyzing relationships between serum brain injury markers (adjusted for age) and different brain volumes (adjusted for eTIV) in cSLE only. None of the correlations were statistically significant, but the coefficients and directionality of relationships still parallelled that within the combined cohort.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. between Tau and brain volumes. In the cSLE sub-analysis correlations between brain injury markers and brain volumes paralleled the whole group analysis, although not statistically significant (Table 2).

Conclusion: We found elevated serum brain injury markers and reduced total brain and grey matter volumes in patients with cSLE compared to controls. The significant relationships between sNFL/GFAP and grey matter/lateral ventricle volumes in the cohort suggest that these markers are associated with cerebral atrophy. Future studies of larger and longitudinal cohorts will help further explore the relationship between brain inflammation, injury, structure and function.

Response to Hydroxychloroquine in Immune Thrombocytopenia in Childhood-Onset Systemic Lupus Erythematosus

Hamada Natour[1], Y. Ingrid Goh[1], Daniela Dominguez[2], Nicholas Gold[1], Lawrence Ng[3], Andrea Knight[4], Earl Silverman[1], Brian Feldman[1], Linda Hiraki[1] and Deborah Levy[1], [1]The Hospital for Sick Children, Toronto, ON, Canada, [2]The Hospital for Sick Children, Toronto, Canada, [3]The Hospital for Sick Children, Toronto, Canada, Toronto, ON, Canada, [4]Hospital for Sick Children, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: The management of immune thrombocytopenia in childhood-onset systemic lupus erythematosus (cSLE) is not standardized. We examined the efficacy and safety of hydroxychloroquine (HCQ) as monotherapy for thrombocytopenia in cSLE.

Methods: We retrospectively reviewed the medical records of patients who developed thrombocytopenia (platelet count < 100 $\times 10^9$/L) and were diagnosed with cSLE and followed in the rheumatology clinic at The Hospital for Sick Children (SickKids) between January 2005 and December 2023. In this clinic, structured data, including disease activity (assessed by the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI)), are prospectively collected at every visit. Definite cSLE was defined by the 2019 EULAR/ACR classification criteria, while patients with incipient cSLE had clinical features of evolving SLE but achieved a EULAR/ACR score below 10. A complete response was defined as a platelet count >100 $\times 10^9$/L with no bleeding. Partial response was defined as a platelet count >30 $\times 10^9$/L with at least a 2-fold increase from the lowest count and no bleeding. Descriptive statistics were used to characterize the study groups and outcomes.

Results: Of the 729 patient records reviewed (68 with incipient lupus and 661 with definite lupus), 153 (21%) patients had thrombocytopenia (Figure 1). Thirty-three patients with thrombocytopenia, secondary to other causes such as medications or infections, were excluded. One hundred twenty patients (79% female) with a median age of 13 years (IQR 10.3 -14.7) and median platelet count of 23 $\times 10^9$/L (IQR 8.0 - 63.0) at the time of thrombocytopenia diagnosis were included. The median lowest platelet count was 10 $\times 10^9$/L (IQR 2 - 40). Disease characteristics are detailed in Table 1. Ninety-five (79%) patients

**Treated with either one or a combination of azathioprine, mycophenolate mofetil (MMF), eltrombopag, romiplostim, rituximab, cyclophosphamide
***Hyperpigmentation and headaches

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

had definite, and 25 (21%) had incipient cSLE. The median SLEDAI score at cSLE diagnosis (for definite SLE) was 8 (IQR 5.5 - 16). Eighty-three (69%) of patients were treated with corticosteroids and/or IVIG prior to commencing HCQ, and 45 of them (38%) also required one or more additional treatments for thrombocytopenia (those were azathioprine, mycophenolate mofetil (MMF), eltrombopag, romiplostim, rituximab, or cyclophosphamide). Sixty-six (55%) patients achieved complete or partial responses before initiating HCQ. 111 (93%) patients were treated with HCQ, initiated at a median of 6 months (IQR 2.7 - 12.2) after thrombocytopenia diagnosis at a median platelet count of 77 $\times 10^9$/L (IQR 32.5 - 198.0). Of those, twenty-nine (24%) patients were treated with HCQ monotherapy (Table 2). All 29 responded; 26 had complete responses after a median follow-up of 52 months (IQR 33 - 75). Of the 111 patients who received HCQ during their disease course, eight experienced side effects, and 6 of them had to discontinue the treatment due to these effects.

Conclusion: While most patients initially needed additional treatments, HCQ monotherapy effectively maintained a partial or complete response in thrombocytopenia for over four years in approximately one-quarter of cSLE patients. Further analysis will identify characteristics that predict a positive response to HCQ monotherapy.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Juvenile systemic sclerosis(jSSc) is an orphan disease with a prevalence of 3 in 1 000 000 children. In adult systemic sclerosis is interstitial lung disease (ILD) one of the main leading causes of mortality. High resolution computer tomography (HRCT) is the gold standard to assess ILD. To find risk factors or predictive factors for ILD in jSSc has a significant clinical importance.

Methods: We extracted data from patients till March 2025, who had an HRCT evaluation at the time of inclusion into the juvenile scleroderma inception cohort(jSSclC)(1). We compared the clinical presentation of patients with positive (HRCT+) and negative (HRCT-) findings for ILD.

Results: 216 patients had an HRCT result at time of the inclusion in the cohort. 76 of them were HRCT+. In both groups around 70% of the patients had diffuse subset. Median age at the time of the first non-Raynaud´s presentation was 10.8 and 11.3 in the HRCT+ versus HRCT- group. Median disease duration was around 2 years. Significantly more patients had decreased FVC< 80% (44% versus 25%, p=0.011) and DLCO< 80% (62% versus 36%, p=0.004) in the HRCT + then HRCT- group. Median MRSS was lower in the HRCT+ then HRCT- group (8.5 versus 12.5, p=0.031). Lower number of patients had sclerodactyly in the HRCT+ then HRCT- group (68% versus 81%, p=0.039). Nailfold capillary changes occurred more often in the HRCT+ then in HRCT- group (88% versus 73%, p=0.042). In the HRCT+ group pulmonary hypertension occurred more frequently (14% versus 2%, p=0.001). Oesophageal involvement was more frequent in the HRCT+ group (58% versus 34%, p=0.001). We could not find any significant difference regarding antibody profile, cardiac, renal and musculoskeletal involvement.

Table1. Clinical findings of patients with positive and negative ILD

Patients with and without ILD at time of inclusion	Patients without ILD assessed by HRCT N=140	Patients with ILD assessed by HRCT N=76	p-value
FVC < 80% in assessed group	25% (25/101)	44% (28/64)	0.011
DLCO < 80% in assessed group	36% (26/73)	62% 32/52)	0.004
MRSS, median (IQR)	12 (4.5 – 20) n=136	8.5 (4 – 25) n=74	0.031
Sclerodactyly	81% (108/133)	68% (50/73)	0.039
Nailfold capillary changes	73% (97/132)	86% (61/71)	0.042
Pulmonary Hypertension assessed by US	2% (3/140)	14% (11/76)	0.001
Oesophageal Involvement	34% (48/140)	58% (44/76)	0.001

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Conclusion: We found a remarkable clinical pattern associated with HRCT+, with increased capillary changes, more frequent oesophageal involvement and pulmonary hypertension and lower MRSS. This pattern may help to predict ILD. We must remark that we had no central reading of the HRCT imaging. We need more patients and more long term observation period to prove our findings.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Gastroesophageal involvement, particularly reflux, has been identified as a risk factor for development and progression of interstitial lung disease (ILD) in adult systemic sclerosis However, this association has not yet been extensively studied in juvenile systemic sclerosis (jSSc)(1) (2, 3). To further address this gap, the juvenile systemic scleroderma inception cohort(jSScIC) (4) including 279 patients provides an opportunity to investigate the potential link between these two manifestations in the paediatric population.

Methods: We analysed baseline clinical data from all patients enrolled in jSScIC till April 15th, 2025 ~~a~~nd compared the clinical characteristics of patients with and without GR.

Results: We reviewed data of 279 patients: 93 (33%) had reported to have gastroesophageal reflux (GR+). Patients with GR + were more frequently evaluated by barium swallow (32% versus 18%, p=0.006) and endoscopy (22% versus 5%, p=0.041). Approximately 70% of the patients had diffuse cutaneous subset. The Median age at onset of first non-Raynaud presentation was around 11 years. Patients with GR+ had more nailfold capillary changes (91% versus 71%, p=0.001) and telangiectasia (49% versus 30%, p=0.002) compared to GR negative (GR-) patients. GR+ patients were more likely to have lung involvement than GR- patients with higher frequency had FVC< 80% (p=0.05), DLCO< 80% (p=0.001) and ILD as identified by high-resolution CT (p=0.004). The pulmonary function findings GR+ patients had more positive findings for ILD on high resolution CT of the lung as GR- patients (56% versus 37%, p=0.004). No significant differences were observed regarding autoantibody profile, cardiac, renal and musculoskeletal involvement between the groups.

Conclusion: GR+ had a significantly higher prevalence of ILD. Patients reported GR ~~is~~ correlating with an increased frequency of microvascular changes. This findings highlight the importance of assessing all patients for GR to enable timely management of reflux and potentially reduce occurrence/progression for ILD in jSSc. Further long-term studies are needed to prove our hypothesis and support targeted intervention strategies.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Pain is a common symptom in childhood-onset systemic lupus erythematosus (cSLE) which impacts health-related quality of life. Its relationship to disease measures over time is not fully understood. We aimed to i) examine the course of patient-reported pain behavior (outward expressions of pain, e.g., grimacing) and pain interference (extent to which pain disrupts daily life, e.g., sleep, activities, mood) in patients with cSLE versus controls, and ii) explore relationships between these pain measures and disease characteristics in cSLE.

Methods: We conducted a secondary analysis of data collected from a prospective cohort study of patients with cSLE (meeting SLICC or ACR/EULAR SLE classification criteria) and age/sex-matched healthy controls. Patient-Reported Outcomes Measurement Information System (PROMIS) pain behavior and pain interference T-scores, and disease characteristics (disease duration, glucocorticoid use (current prednisone-equivalent dose, cumulative dose from time of SLE diagnosis), and Physician Global Assessment (PGA)) were collected at two time points: baseline (time of study enrollment) and 1-year follow up. Descriptive statistics summarized group characteristics. Within- and between-group differences in PROMIS scores were analyzed using Mann-Whitney and Wilcoxon signed-rank tests. Associations between PROMIS measures and disease characteristics were examined using Spearman's rank correlation test.

Results: We included 51 youth with cSLE (mean age=15y (SD 1.7), 88% female) and 38 controls (mean age =15y (SD 1.7), 84% female). cSLE disease duration at baseline was median 24 months (IQR 12-45) (Table 1). Compared to controls, cSLE participants pain behavior (baseline: 37 vs 25, p < .001; one-year: 37 vs 29: p = .008) and pain interference (baseline: 46 vs

Table 1: Demographic and Disease Characteristics of cSLE and Controls at Baseline and 1-Year Follow-Up

	cSLE n = 51		Controls n = 38	
	Baseline	**At 1-Year**	**Baseline**	**At 1-Year**
Demographic Characteristics				
Age (years), mean (SD)	15.1 (1.7)	16.0 (1.6)	15.2 (1.7)	16.2 (1.7)

Table 2: PROMIS T-Scores at Baseline and 1-Year Follow Up for cSLE and Control Participants, and Within- and Between-Group Comparisons

	cSLE (n=51**)			Controls (n=38)			
PROMIS Measure	Baseline T-Score Mean (SD)	1 Year T-Score Mean (SD)	Within-Group Comparisons	Baseline T-Score Mean (SD)	1 Year T-Score Mean (SD)	Within-Group Comparisons	Between-Group Comparisons
Pain Behavior	38.9 (15.5)	37.2 (14.7)	W= 366, p= 0.954	25.0 (11.3)	29.2 (12.8)	W= 41, p= 0.098	V1: U= 573, **p< 0.001*** V2: U= 655, **p= 0.008***
Pain Interference	45.6 (11.0)	45.7 (10.7)	W= 363, p= 0.868	39.4 (7.7)	40.6 (8.2)	W= 89, p= 0.549	V1: U= 674, **p= 0.007*** V2: U= 704, **p= 0.027***

*Significant at p<0.05
**One patient result missing for Pain Interference at Year1
PROMIS measures reported as standardized T scores with a normative mean of 50 and standard deviation of 10. Higher scores indicate more of the measured trait. Wilcoxon signed-rank tests were used for within-group comparisons, Mann-Whitney U –tests were used for between-group comparisons

Table 3: Exploratory Spearman Correlation Table between PROMIS Pain measures and Disease Characteristics across Baseline and 1-Year Follow-Up for cSLE Participants

	Baseline		1-Year	
	Pain Behavior	Pain Interference	Pain Behavior	Pain Interference
Disease Duration	-0.372* p = 0.007	-0.382* p = 0.005	-0.179 p = 0.218	-0.148 p = 0.310
Physician Global Assessment	0.394* p = 0.004	0.459* p < 0.001	0.389* p = 0.005	0.415* p = 0.003
Current glucocorticoid dose (mg)	0.219 p = 0.123	0.273 p = 0.052	0.078 p = 0.600	0.101 p = 0.499
Cumulative glucocorticoid use (g)	-0.256 p = 0.070	-0.181 p = 0.204	0.108 p = 0.218	0.248 p = 0.105

Spearman Rho and p- value depicted for each correlation
*Significant at p<0.05

39, p = .007; one-year: 46 vs 41, p = .027) were significantly higher (Table 2). Scores remained stable over time within both groups, with no significant mean change at follow-up. For the cSLE group, disease duration negatively correlated with both pain measures at baseline (pain behavior: rho = -.372, p = .007; pain interference: rho = -.382, p = .005), but not at one year follow-up (Table 3). PGA significantly associated with both pain measures for all time points (pain behavior: baseline rho = .394, one-year rho = .389; pain interference: baseline rho = .459, one-year rho = .415, p < .005 for all). Current glucocorticoid dose at visit and cumulative glucocorticoid use did not correlate with pain.

Conclusion: Youth with cSLE report persistently elevated pain interference and pain behavior, underscoring the lasting impact of pain. The association of disease duration with pain weakened over time, initially a negative correlation at baseline and no correlation at one year. This may suggest that early disease manifestations causing pain are controlled (e.g. inflammation), however long-term pain manifestations of SLE may not be. Interestingly, PGA consistently positively correlated with pain indicating that clinicians are sensing and reporting on patient pain in their global assessment, beyond the early manifestations. These findings highlight the importance of furthering our understanding of pain and its causes in youth with SLE

Abstract Number: 1290

Adverse Childhood Experiences: Prevalence and Relationship to Disease and Mental Health Outcomes in Childhood-onset Systemic Lupus Erythematosus (cSLE)

Jin Xuan Zhou[1], Stephanie Fevrier[2], Paris Moaf[2], Lawrence Ng[3], Asha Jeyanathan[4], Louise Boulard[2], Deborah Levy[1], Linda Hiraki[1], Ashley Danguecan[5] and Andrea Knight[5], [1]The Hospital for Sick Children, Toronto, ON, Canada, [2]Hospital for Sick Children, Toronto, Canada, [3]The Hospital for Sick Children, Toronto, Canada, Toronto, ON, Canada, [4]The Hospital for Sick Children, Toronto, Canada, [5]Hospital for Sick Children, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Childhood-onset systemic lupus erythematosus (cSLE) is an autoimmune disease characterized by multi-organ inflammation, alongside high frequencies of mood disorders and cognitive impairment. Adverse Childhood Experiences (ACEs) quantify traumatic childhood events, which have been linked to altered immune response and increased chronic disease risk. Prior studies indicate those with ≥ 4 ACEs, including adults with SLE, face higher risk of worse health outcomes. Limited research exists on ACEs in cSLE. We aimed to describe the prevalence of ACEs among cSLE patients and investigate associations with i) disease activity, ii) patient-reported outcome measures, and iii) self-reported executive function.

Methods: This cross-sectional study analyzed prospective data from cSLE patients aged 13-19 years at the time of assessment. The Pediatric ACEs and Related Life Events Screener (PEARLS) measured 19 self-reported ACEs. Disease activity over the time since diagnosis was measured by the adjusted mean Systemic Lupus Erythematosus Disease Activity Index (SLEDAI-2K). The Patient Reported Outcomes Information System (PROMIS) Pediatric-37 Profile assessed patient-reported anxiety, depression, and fatigue. The Behavior Rating Inventory of Executive Function (BRIEF-2) Global Executive Composite score measured executive function. The frequency of ACEs types was tabulated, and patients were classified into high-risk (≥ 4 ACEs) and low-risk (≤ 3 ACEs) groups. Associations between ACEs risk group and the outcomes were examined using regression analyses with generalized linear models, adjusted for age.

Results: Of 50 cSLE patients (mean age 15.20 ± 1.86 years, 84% female), 72% reported at least 1 ACE, and 30% reported ≥ 4 ACEs (Table 1). The most common ACEs were caregiver verbal abuse, emotional neglect, and separation, as well as community violence (Figure 1). Being in the high-risk ACEs group compared to low risk, was significantly associated with worse scores for PROMIS anxiety ($p< 0.001$), depression ($p< 0.001$), and fatigue ($p< 0.001$), alongside poorer executive function scores ($p< 0.001$) (Figure 2). No significant associations were observed for disease activity ($p=0.263$).

Conclusion: Within our cSLE cohort, ACEs were substantially prevalent, with almost a third of patients having experienced ≥ 4 ACEs. The high risk group had significantly worse patient-reported outcomes and executive function. These results underscore the impact of ACEs on patient well-being, emphasizing the need for integrated medical and mental health care approaches. Future research should examine these associations in larger cohorts.

Note.
[a] Other categories include Latin American (n=3) and multiethnic (n=2) race and ethnicities
[b] Measures are negatively-worded standardized t-scores with a normative mean of 50 and standard deviation of 10. A t-score of 60 indicates outcomes 1 SD worse than average.

Figure 1. Self-Reported Adverse Childhood Experiences (ACEs) in Patients with cSLE: Frequency and Types

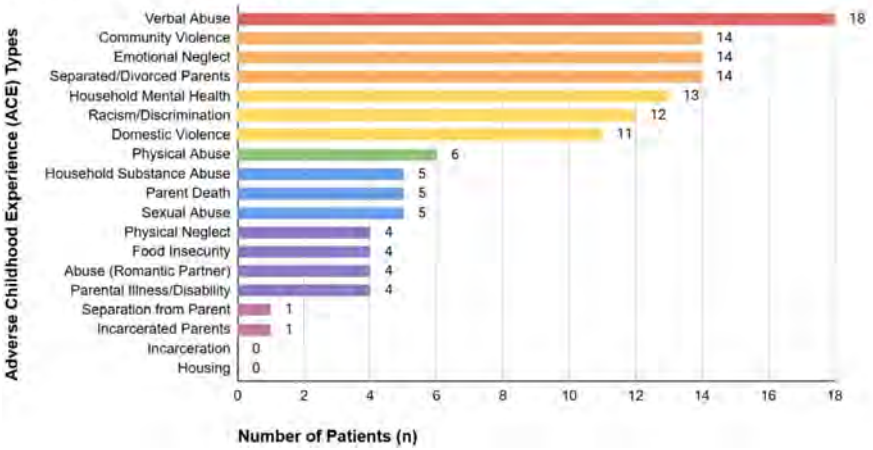

Figure 1 illustrates the distribution of nineteen self-reported adverse childhood experiences (ACEs) types within our cSLE cohort (n=50). Among the total ACEs (n=135) self-reported on the patient PEARLS questionnaire, the most commonly reported ACEs were caregiver verbal abuse (n=18), community violence (n=14), emotional neglect (n=14), and caregiver separation/divorce (n=14).

Figure 2. Relationship between ACEs and Self-Reported cSLE Outcomes

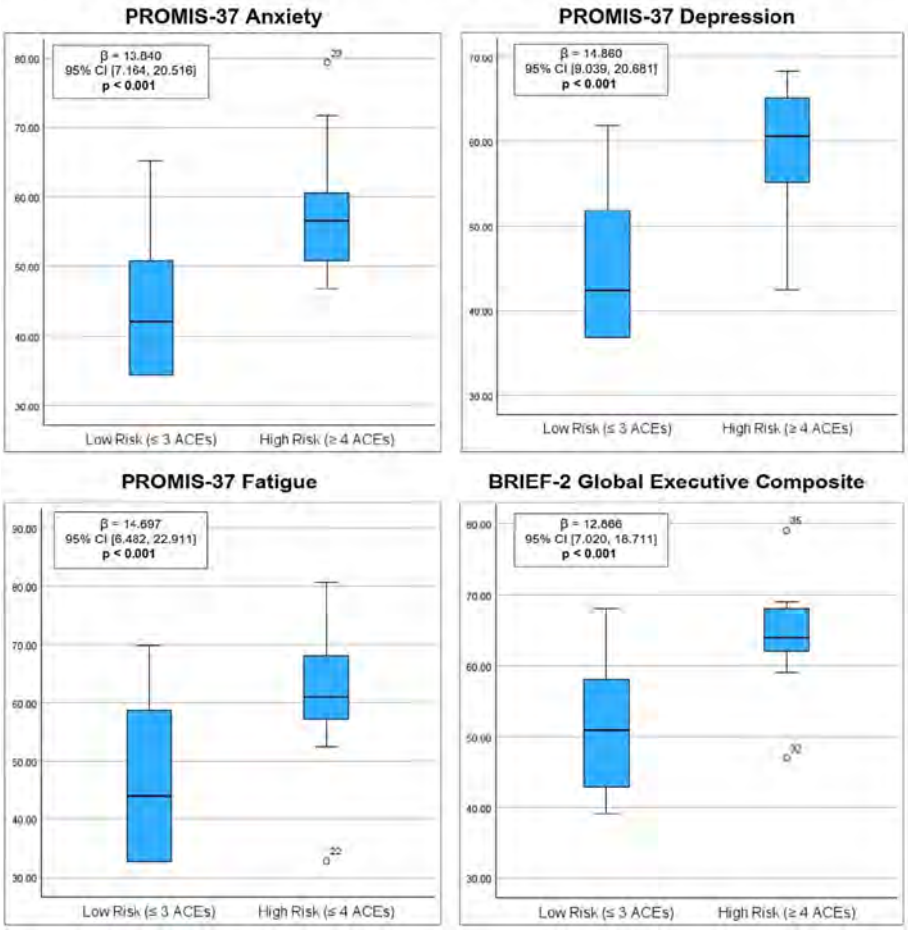

Figure 2 contains four sets of boxplots depicting differences in mean outcome scores between the high-risk and low-risk ACEs groups. Associations show beta coefficients, confidence intervals, and p-values from regression analyses. Regression analyses showed significant associations for worse PROMIS anxiety ($p<0.001$), depression ($p<0.001$), and fatigue ($p<0.001$) scores alongside poorer executive function ($p<0.001$) within the high-risk group. The p-value threshold used for significance was $p<0.05$.

Abstract Number: 1291

Gastrointestinal Tract Involvement in Juvenile Systemic Sclerosis: Results from an International Scoping Review of Outcome Measures

Lauren Robinson[1], Lusine Ambartsumyan[2], Emily Willis[3], Aybuke Gunalp[4], Simone Appenzeller[5], Ozgur Kasapcopur[6], Sarah Ishaq[7], Natalia Vasquez Canizares[8] and Suzanne Li[9], [1]Hospital for Special Surgery, New York, NY, [2]Seattle Children's Hospital, Seattle, WA, [3]Royal Manchester Children's Hospital, Manchester, United Kingdom, [4]Cerrahpasa Medicine School, Cerrahpasa, Istanbul, Turkey, [5]Unicamp, Campinas, São Paulo, Brazil, [6]Istanbul University-Cerrahpasa, Cerrahpasa Medical School, istanbul, Turkey, [7]Osteopathic Medicine , Touro College of Osteopathic Medicine, New York, NY, [8]Children's Hospital at Montefiore, New York, NY, [9]Joseph M. SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Gastrointestinal (GI) tract involvement is nearly universal in patients with systemic sclerosis (SSc) leading to significant morbidity and mortality. In a North American juvenile SSc (jSSc) registry, GI involvement had the strongest correlation with poorer quality of life (QoL) of any organ system. Esophageal dysmotility is the most common GI manifestation and can lead to moderate to severe malnutrition (identified in 14% of jSSc patients, Stevens et al, 2018). Despite the known prevalence and impact of GI tract pathology in SSc, validated outcomes measures are lacking. The International Juvenile Systemic Sclerosis Outcome Group is working to generate consensus organ-specific outcome measures for use in future jSSc studies. We report findings from our GI scoping literature review with a focus on esophageal measures.

Methods: From 4 databases, 24,849 studies were screened, yielding 277 studies identified by title and abstract of which 134 full text articles were extracted (Figure 1). Each level of screening and extraction required two reviewers. A pediatric gastroenterologist experienced in jSSc care helped guide extractions. Twenty-six GI measures were identified and sorted by GI

Table 1: Characteristics of SSc Studies on GI Outcome Measures from Scoping Review

Study Type	Number of Studies (%)
Randomized Controlled Trials	5 (3.7%)
Non-randomized/controlled interventional studies	3 (2.2%)
Observational	122 (91.0%)
- Case series	3
- Cohort	83
- Case-control	27
- Cross-sectional	9
Diagnostic test accuracy	4 (3.0%)
GI Region/Topic Studied	**N (%*)**
Oropharynx	10 (7.5%)
Esophagus	87 (64.9%)
Stomach	28 (20.9%)
Small Intestine	21 (15.7%)
Colorectum	27 (20.1%)
Nutrition	16 (11.9%)
GIT/QoL**	42 (31.3%)
Inclusion of juvenile SSc Subjects	**N (%)**
Yes	3 (2.2%)
No	131 (97.8%)

*many studies included more than one GI region/topic, percentages will total >100%
**GIT= UCLA Scleroderma Clinical Trials Consortium Gastrointestinal Tract instrument; QoL= Quality of Life

Table 2: Use and Performance of Esophageal Outcome Measures in SSc

Esophageal Measure		No. Studies using measure (No. included pediatric patients)	No. studies with intervention (No. with significant response to intervention)	No. longitudinal studies (No. with significant change over time)	No. studies with HC group (No. with significant difference SSc vs HC)	No. studies that compared measure to symptoms* (No. with significant symptom correlation)
anatomical	Chest CT (esophageal diameter)	9 (1)	0	1 (1)	0	1 (0)
	EndoFLIP	3 (0)	0	0	1 (1)	0
	Endoscopy	25 (0)	2 (0)	1 (0)	3 (2)	7 (3)
	Esophagram (UGI) / Barium Swallow	7 (1)	0	0	0	4 (1)
functional	Esophageal Manometry	50 (0)	3 (2)	0	12 (12)	13 (7)
	Esophageal Scintigraphy	14 (0)	2 (0)	2 (2)	7 (6)	6 (2)
	pH and/or pH/Impedance	13 (1)	1 (0)	0	3 (3)	1 (1)

No. = number, SSc = systemic sclerosis, HC = healthy control, CT = computerized tomography, EndoFLIP = Endoscopic functional lumen imaging probe, UGI = upper gastrointestinal series
*Including UCLA Scleroderma Clinical Trials Consortium Gastrointestinal Tract 2.0 Instrument (SSc specific GI symptom scale)

region studied. Extracted data included the presence of jSSc patients, significant change in the outcome measure over time or following intervention, ability of the measure to differentiate SSc from healthy controls (HC), and correlation of the measure with symptoms and QoL measures.

Results: Of 134 studies, only 3.7% were randomized control trials (total of 4 GI measures evaluated). Only 2.2% of the studies included pediatric patients. The most commonly studied GI region was the esophagus (64.9%) followed by stomach (20.9%), colorectum (20.1%), small intestine (15.7%), and oropharynx (7.5%). Nutritional outcomes were reported in 11.9% while QoL measures were included in 31.3% of studies (Table 1). Table 2 shows the characteristics of esophageal measures in SSc. 50/87 (57%) esophageal studies reported on esophageal manometry, with endoscopy the next most commonly reported esophageal measure (25/87, 29%). Esophageal manometry was accurately able to differentiate SSc from HC. Very few studies assessed change over time or in response to intervention. Only 4 of the 26 measures (15%) have been studied in jSSc (esophageal manometry, pH probe, chest CT and esophagram/Upper GI). In studies that evaluated the correlation between GI measures and GI symptoms, correlation was inconsistent.

Conclusion: Esophageal manometry is the most widely studied GI outcome measure in SSc. Despite its established use in children with other GI motility disorders (e.g., achalasia), there were no studies that evaluated esophageal manometry in patients with jSSc. Overall, only 2% of the studies included pediatric patients, and < 10% of studies evaluated the ability of

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. GI outcome measures to assess response to intervention or change over time. Nearly all measures studied demonstrated inconsistent correlation with GI symptoms. Given the morbidity and impact on QoL associated with GI involvement, our study highlights the need for more studies that evaluate GI involvement in SSc, especially for jSSc.

Childhood-onset Behçet's disease: HLA alleles role on diagnosis and treatment in a Latin American tertiary center

Matheus França[1], Thales Souza[2], Ricardo Machado[3], Vinicius Matias[4], Sylvia Farhat[3], Lia Steuer[3], Luisa Forero[3], Verena Balbi[3], Nadia Emi Aikawa[5], Katia Kozu[3], Clovis Artur Silva[6], Adriana Elias[7] and **Lucia Maria Campos**[8], [1]Instituto da Criança e do Adolescente, Hospital das Clinicas, University of Sao Paulo Medical School, Sao Paulo, Sao Paulo, Brazil, [2]Faculdade de Medicina da Universidade de Brasilia, Brasilia, Distrito Federal, Brazil, [3]Instituto da Criança e do Adolescente, Hospital das Clinicas, Sao Paulo, Sao Paulo, Brazil, [4]Faculdade de Ciências Medicas da Santa Casa de Sao Paulo, Sao Paulo, Sao Paulo, Brazil, [5]Rheumatology Division and Pediatric Rheumatology Unit, Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, Sao Paulo, SP, Brazil, Sao Paulo, São Paulo, Brazil, [6]University of São Paulo, São Paulo, São Paulo, Brazil, [7]Pediatric Rheumatology Unit, Instituto da Criança e do Adolescente, Hospital das Clinicas, University of Sao Paulo Medical School, São Paulo, São Paulo, Brazil, [8]Instituto da Criança e do Adolescente, São Paulo, São Paulo, Brazil

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Behçet's disease (BD) is a rare pediatric vasculitis with limited epidemiological data in Latin America centers, especially in children where initial symptoms can be non-specific and disease progression may be protracted. The frequency of HLA-B51, which is associated with increased disease risk, is also lower compared with countries along the Silk-Road. It is possible that in Brazil, a country characterized by mixed population, other HLA alleles might contribute to BD susceptibility. The objective of the study was to identify the HLA alleles in childhood-onset BD patients and characterize clinical manifestations and therapies associated with them.

Methods: The study included 32 childhood-onset BD patients followed at a tertiary and university Pediatric Rheumatology Center in Brazil, diagnosed ≤ 18 years-old, based on expert pediatric rheumatologists' opinion and/or according to the international criteria for BD (ICBD) or the pediatric BD classification criteria (PEDBD). Medical records were reviewed to assess HLA alleles, clinical and therapeutic characteristics of these patients. For further analyses patients were classified according to the presence or absence of HLA-B51 and the groups were compared regarding demographic data, clinical characteristics and treatment.

Results: Demographic data of 32 childhood-onset BD patients were: median age of 4.5(0.5-12) years at diagnosis, female sex in 16(50%) and white ethnicity in 25(78%) of cases. HLA-B51 allele was identified in 16 of 32 patients (50%). Other HLA alleles were found as following: HLA-B15 (n=8), HLA-B35 (n=6), HLA-B42 (n=3), HLA-B53 (n=3), HLA-B39 (n=2), HLA-B58 (n=1), HLA-B57 (n=1), HLA-B52 (n=1) and HLA-B14 (n=1). The presence of other HLA alleles was significantly higher in patients with negative HLA-B51 compared to patients with positive HLA-B51 (75% vs. 38%, p=0.04). HLA-B51 negative

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

patients were significantly older than HLA-B51 positive patients [7.5 (0.5–12) vs. 3 (0.5–11) years; p=0.02] at diagnosis, in contrast to female sex that was less frequent in the former group (31% vs. 69%, p=0.04). The frequency of patients that fulfilled at least one confirmation criteria (PEDBD and/or ICBD) was similar between groups (57% vs. 44%, p=0.72). Likewise, no differences were observed between the groups regarding clinical manifestations, including fever, oral/genital ulcers, articular, cutaneous, ocular, neurological and gastrointestinal involvement. Further analysis of treatment showed that colchicine use was also similar in both groups (94% vs. 98%, p=0.5). However, HLA-B51 negative patients significantly required the use of additional immunosuppressants agents (60% vs. 23%, p=0.05), especially corticosteroids (56% vs. 19%, p=0.03) and azathioprine (69% vs. 19%, p=0.006).

Conclusion: Patients who were negative for HLA-B51 but positive for other HLA alleles were diagnosed at a later stage and required multiple immunosuppressive therapy. These results indicate that in patients outside the Silk Road, other HLA alleles may be associated with BD and could lead to a delayed diagnosis.

Abstract Number: 1293

Synovitis and periarticular soft tissues abnormalities in childhood-onset systemic lupus erythematosus: an ultrasonography study

Marianna Freire[1], Jean Paulo Veronese de Souza[1], Ana Renata Oliveira[1], Renata Kobayasi[2], Vitor Paula[3], Clovis Artur Silva[4] and **Lucia Maria Campos**[5], [1]Pediatric Rheumatology Unit, Instituto da Criança e do Adolescente, Hospital das Clínicas HCFMUSP, São Paulo, Sao Paulo, Sao Paulo, Brazil, [2]Centro de Desenvolvimento de Educação Médica do Hospital das Clínicas HCFMUSP, São Paulo, Sao Paulo, Sao Paulo, Brazil, [3]Pediatric Radiology Unit, Instituto da Criança e do Adolescente, Hospital das Clínicas HCFMUSP, São Paulo, Sao Paulo, Sao Paulo, Brazil, [4]University of São Paulo, São Paulo, São Paulo, Brazil, [5]Instituto da Criança e do Adolescente, São Paulo, São Paulo, Brazil

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Musculoskeletal (MSK) involvement occurs in up to 70% of childhood-onset systemic lupus erythematosus (cSLE). MSK ultrasound (US) has emerged as a tool with greater sensitivity than clinical examination for detecting MSK abnormalities in adult SLE. To date, rare case reports and case series have assessed MSK US in cSLE populations, including small sample sizes, limited anatomical scope or restricted to nondominant side evaluations. Therefore, the objectives of this study were to assess MSK US findings in cSLE patients and healthy controls, focusing on joints, tendons, and entheses sites. We also evaluate demographic, clinical, laboratory and treatment parameters in MKS clinically symptomatic compared to asymptomatic cSLE patients.

Methods: A cross-sectional study was performed in a tertiary and university center, evaluating 63 consecutive cSLE patients(ACR1997 and SLICC 2012 criteria) and 20 healthy controls. US evaluations were performed by two experienced sonographers, assessing 36 MSK structures/participant, including 20 joints, 8 tendons, and 8 entheses (Logic 7-GE-

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Milwaukee, Wisconsin, USA). ML6-15 MHz and hockey stick L8-18i-D MHz linear array probes were used for images on dominant and nondominant subject sides. MSK US abnormalities were defined according to OMERACT criteria. Patients' records were reviewed for demographic, clinical, laboratory, and therapeutic data.

Results: Median age[14.6(13-16) *vs*. 13(11-16)years, p=0.099] and female sex(73% *vs*. 55%, p=0.902) were similar in cSLE patients and heathy controls. MKS US abnormalities were significantly higher in cSLE compared to controls(79.4% *vs*. 5%, p< 0.001), likewise synovitis(34.9% *vs*. 5%, p=0.009), tenosynovitis(66.7% *vs*. 0%, p< 0.001) and enthesitis(28.6% *vs*. 0%, p=0.004). The most frequent MKS US findings in cSLE patients were knee synovitis(14.3%), wrist extensor tenosynovitis(17.4%), fibular tenosynovitis (20.6%) and quadriceps enthesitis(18.2%). Further analyses of MSK US findings showed significantly higher frequency of enthesitis(50% *vs*. 15.4%, p=0.003) in clinically symptomatic compared to asymptomatic cSLE. The frequencies of any MSK US abnormalities(87.5% *vs*. 74.4%, p=0.337), synovitis(41.7% *vs*. 30.8%, p=0.378), and tenosynovitis(75% *vs*. 61.5%, p=0.271) were alike in clinically symptomatic compared to asymptomatic cSLE patients. No differences were observed between the groups regarding demographic data, SLEDAI-2K, antiphospholipid antibodies, cumulative dose of glucocorticoid and immunosuppressive use (p >0.05).

Conclusion: Our findings demonstrate a high frequency of MSK US abnormalities in cSLE, particularly involving periarticular soft tissues. Subclinical involvement highlights the utility of ultrasound in the early detection of silent abnormalities, which may be important for the diagnosis of both inflammation and structural damage, monitoring and management of cSLE. Further longitudinal studies are necessary to assess the potential of MSK US in predicting disease progression and its impact on treatment decisions.

Abstract Number: 1294

Implementation of Pneumococcal Vaccination in Patients with Childhood-Onset Systemic Lupus Erythematous

Kristina Ciaglia[1] and **Magan Fosso**[2], [1]UT Southwestern, Children's Medical Center, and Scottish Rite for Children, Dallas, TX, [2]UT Southwestern, Dallas, TX

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Pneumococcal vaccination is critical in patients with childhood-onset systemic lupus erythematosus (cSLE) due to their immunocompromised status and increased susceptibility to serious infections. Despite this, our institution's baseline vaccination rate was 0%. Inadequate documentation compromises patient safety, continuity of care, and may reflect missed vaccination opportunities. A limited on-site vaccine supply further challenged timely administration and follow-up. Our goal was to increase pneumococcal vaccination documentation rates in cSLE patients from 0% to 70% over a 12-month period.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We conducted a retrospective chart review of cSLE patients seen between February and June 2024. To improve documentation and vaccine delivery, we initiated a Plan-Do-Study-Act (PDSA) cycle. Interventions included the development of a standardized documentation template within the electronic health record (EHR), collaboration with key stakeholders (including clinicians, analysts, and nursing staff), and integration of a consistent vaccination process within our rheumatology clinic.

Results: Fifty pediatric patients with cSLE were included in the initial chart review. Of these, 16 had previously received pneumococcal vaccination, but only 2 had appropriate documentation in the EHR. Following implementation of a standardized documentation process, 59 additional patients were identified with non-protective pneumococcal antibody titers. Among these, 8 patients received appropriate vaccination at Scottish Rite: 6 were vaccinated during their clinic visit, and 2 had received the vaccine within 12 months prior. Our clinic vaccination rate went from a baseline of 0% to 13.5% improvement.

Conclusion: Establishing a clear and structured documentation process significantly enhanced the rate of pneumococcal vaccination and documentation in cSLE patients. Accessible, standardized records improved coordination of care and reduced missed opportunities for immunization. On-site vaccine availability also contributed to improved patient follow-through. Continued PDSA cycles, staff feedback, and outcome monitoring will be essential to sustain and expand these improvements.

Abstract Number: 1295

Neuropsychiatric Lupus in Children and Adolescents: Understanding Current Practices and Barriers to Care Perceived by Pediatric Rheumatology Clinicians in North America

Martha Rodriguez[1], Ekemini Ogbu[2], Ashley Danguecan[3], Marietta De Guzman[4], Alexandra Theisen[5], Lawrence Ng[6], Andrea Knight[3], Ryann Kammeyer[7] and CARRA NPSLE Workgroup, [1]Riley Hospital For Children at Indiana University, Indianapolis, IN, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]Hospital for Sick Children, Toronto, ON, Canada, [4]Baylor College of Medicine, Houston, TX, [5]University of Arkansas, Little Rock, AR, [6]The Hospital for Sick Children, Toronto, Canada, Toronto, ON, Canada, [7]University of Colorado, Denver, CO

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Neuropsychiatric involvement in Systemic Lupus Erythematosus (NPSLE) is a major cause of morbidity and mortality, particularly among children who are still developing neurologically. Despite this high burden of NPSLE in children it is arguably the least understood manifestation of SLE. Additionally, the care needs of children with NPSLE are complex, requiring multidisciplinary services with varying levels of accessibility. We aimed to understand the current practice of care for evaluation of NPSLE in children, and barriers in accessing multidisciplinary care.

Methods: An electronic survey was conducted among members of the Childhood Arthritis and Rheumatology Research Alliance (CARRA) from July to November 2024. It was designed by the CARRA Neuropsychiatric SLE Workgroup, which includes pediatric rheumatologists, neurologists, psychiatrists, psychologists, patients, and caregivers. Eligible participants included physicians, nurse practitioners, and physician assistants who actively care for children with SLE. We collected information on demographics, serum biomarkers, neuroimaging, availability of multidisciplinary support services and barriers to care for patients with NPSLE (15 barriers rated on 5-point Likert scale)

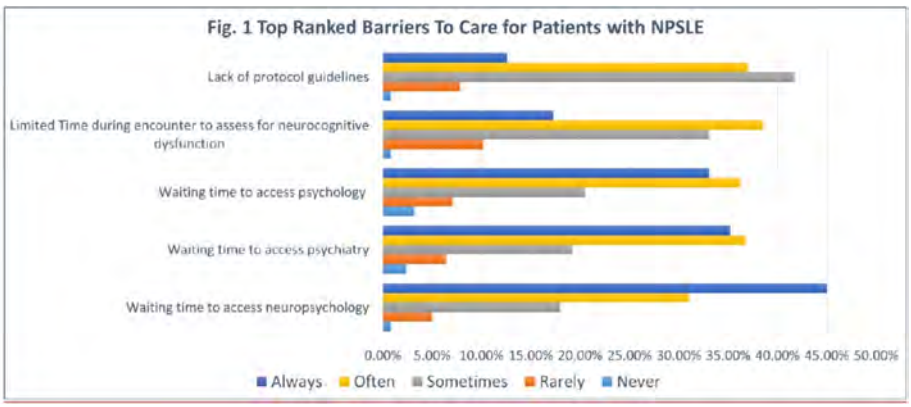
23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table I. Current Practice of care for evaluation of NPSLE in children by CARRA Members: Neuroimaging, Neurocognitive Assessment and Mood Screening.

Diagnostic test	N (%)
Neuroimaging	**55 (41%)**
Brain MRI, MRA, MRV w/ and w/o contrast	60 (46%)
Brain MRI w/ and w/o contrast	56 (43%)
Brain MRI w/ and w/o contrast and MRA w/ and w/o contrast	38 (29%)
Brain MRI w/o contrast	4 (3%)
Advanced Neuroimaging	**29 (22%)**
Brain Single-photon emission computer tomography (SPECT)	14 (47%)
Brain Magnetic resonance spectroscopy(MRS)	11(37%)
Brain Positron emission topography (PET)	7 (23%)
Brain Function MRI (fMRI)	5 (17%)
Neurocognitive Assessment	**29 (22%)**
Tests selected by neuropsychologist performing the assessment	95 (73%)
Unsure what is used at their institution	26 (20%)
Mini Mental Status Exam (MMSE)	18 (14%)
Montreal Cognitive Assessment (MOCA)	12 (9%)
Pediatric Automated Neuropsychological Assessment Metrics (Ped-ANAM)	12 (9%)
No access to neurocognitive test	6 (5%)
Mood Disorder Screening	**75 (57%)**
Depression screening	
Patient Health Questionnaire-9 for Depression	66 (50%)
Informal depression screening (screening symptoms of depression)	49 (37%)
I do not formally screen for depression in my practice	24 (18%)
PROMIS Depression Short Form	8 (6%)

Magnetic Resonance Imaging (MRI), Patient-Reported Outcomes Measurement Information System (PROMIS)

Results: Of the 512 eligible respondents, 149 (29%) completed the survey. The findings revealed that only 5% of respondents felt completely confident in evaluating NPSLE on a 5-point Likert scale. The majority (90%) routinely test for antiphospholipid antibodies during the initial evaluation, while fewer test for anti-ribosomal P (46%), anti-neuronal antibodies (18%), aquaporin-4 antibodies (10%), and antiganglioside antibodies (4%). Among those who responded, 19% obtain cerebrospinal fluid (CSF) analysis for all patients with suspected NPSLE, and 41% use neuroimaging. The most common neuroimaging modality was brain MRI, MRV, and MRA with or without contrast (46%), followed by brain MRI with or without contrast (43%). Only 22% of responders use advanced neuroimaging, 31% lack access to advanced imaging at their institution, and 52% were not familiar with the appropriate indications or interpretation of these imaging modalities. Furthermore, 57% screen for mood disorders in all NPSLE patients (Table I). Only 7% of providers have easy access to neuropsychology, and 10% to psychiatry. Waiting time to access neuropsychology, psychiatry and lack of protocol or guidelines were the most common perceived barriers for the evaluation of NPSLE.



23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: This study highlights significant variability in current practices for evaluating NPSLE in children, underscoring the need for consensus guidelines to standardize NPSLE evaluation and management Improving timely access to neuropsychology and psychiatry services is essential for proper diagnosis and treatment of NPSLE. Given that these services are often very limited, providing training to rheumatology clinicians on less resource-intensive alternatives (e.g Ped-ANAM validated computerized screening neurocognitive battery or questionnaires) may assist in triaging priority patients for multidisciplinary assessment.

Liver Biopsy Findings in Pediatric SLE: A Large Tertiary Center Experience

Meredith Rae[1], Dawn Gist[2], Kaylani Patel[3], Krupa Mysore[3], Andrea Ramirez[2], Marietta De Guzman[2] and Eyal Muscal[2], [1]Baylor College of Medicine/Texas Children's Hospital, Houston, TX, [2]Baylor College of Medicine, Houston, TX, [3]Baylor College of Medicine/Texas Children's Hospital, Houston

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Distinguishing lupus hepatitis (LH) from autoimmune hepatitis (AIH) in SLE is clinically challenging but critical for guiding treatment duration. The mechanisms differ; AIH results from a T-cell-mediated immune response to liver autoantigens, while LH likely results from hepatic vasculitis, complement activation, and rarely, microvascular occlusive disease.

On biopsy, AIH is characterized by lymphoplasmacytic interface hepatitis and hepatocyte rosettes; LH presents with nonspecific mild lobular or periportal inflammation. Systematic histopathologic studies differentiating AIH and LH in pediatric SLE are lacking.

Methods: With IRB approval, we queried our EMR (1/1/12–3/1/25) for pediatric SLE patients who underwent liver biopsy. Clinical, laboratory and histopathology data were abstracted. Disease activity at biopsy was assessed using the SLEDAI-2K.

Results: During the study period, of the 452 patients with SLE, 12 (2.7%) underwent liver biopsy. In three, liver disease predated SLE diagnosis; biopsies (median six months prior to diagnosis; range 6–32) revealed two AIH and one Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) later diagnosed as possible AIH on repeat biopsy. In the other nine patients, biopsies occurred at a median of one month post diagnosis with SLE (range 0-37). All were performed at least in part to exclude AIH.

One patient diagnosed with AIH before SLE was F-actin IgG positive; the other tested negative for F-actin and anti-LKM. Six out of the nine patients who had negative biopsy findings for AIH were positive for either F-actin, anti-Smooth muscle IgG, or anti-LKM Ab. These patients with positive AIH-associated antibodies but negative biopsy had been pre-treated for a median of one week (range three days-seven months). One patient had three serial liver biopsies, one prior to diagnosis and two after to evaluate for AIH. Peak AST was 211 U/L (range 50-1138) and ALT was 206 U/L (107-1111). Of the nine patients with liver biopsies after diagnosis of SLE, one had AIH, one had MASLD, three had possible drug-related injury (secondary to

Arthritis	8 (67%)
Mucocutaneous involvement	7 (58%)
Renal involvement	6 (50%)
Antiphospholipid antibody syndrome	5 (42%)
MAS/HLH	2 (17%)
CNS disease	1 (8%)
	Median (range)
SLEDAI score at biopsy (n=9 patients diagnosed with SLE prior to biopsy)	12 (2–20)
Age (years)	13 (9-18)

antibiotics, sertraline, and acetaminophen), and four had nonspecific findings postulated to be SLE-related. Among the four patients with nonspecific findings, all showed mild portal inflammation with infiltrates including plasma cells, lymphocytes, and/or neutrophils. One had mild focal venulitis, one had grade 1 fibrosis, and one had mild hepatocyte ballooning. All had preserved synthetic function.

Of the patients with AIH, two were already on azathioprine and prednisone (15–30 mg) at the time of biopsy and remained on the same regimen; one was initiated on azathioprine and prednisone (2 mg/kg), and another with concurrent lupus nephritis and AIH was started on mycophenolate. Nonspecific biopsy findings did not alter management. At median follow-up of six years (range 0.2–9), none had persistent clinically evident liver disease.

Conclusion: Despite a cohort with active SLE with multi-organ involvement, lupus-related liver manifestations were transient and self-limited. Liver biopsy remains crucial in diagnosis of comorbid AIH since AIH-related autoantibodies were variably detected and may be unreliable in active SLE.

Background/Purpose: Scleroderma is autoimmune disease that may result in changes to the skin, blood vessels, muscles, and internal organs. It can be either Localized Scleroderma (LS) or Systemic Sclerosis (SSc). Early diagnosis, proper assessment and effective treatment are crucial to improve the long-term outcome.

Tocilizumab, an IL-6 receptor antagonist, and tofacitinib, a JAK inhibitor, have shown promising results in small series and case reports, but pediatric data remain limited.

Table 2: Main outcome measures at the time point of 0, 6th and 12th months of juvenile systemic sclerosis patients treated with tocilizumab.

Table 4: Main outcome measures at the time point of 0, 6th and 12th months of juvenile localized scleroderma patients treated with Tofacitinib

Patient no.	TFC treatment duration (months)	PGA-A 0/6/12th Months of TFC treatment	PGA-D 0/6/12th Months of TFC treatment	LoSSI 0/6/12th Months of TFC treatment	LoSDI 0/6/12th Months of TFC treatment
6	12	6/3/1	5/3/3	7/3/1	7/5/4

The current analysis was conducted from a single center in Saudi Arabia to investigate the long-term efficacy and safety of tocilizumab (TCZ) and tofacitinib (TFC) in patients with SSc and LS.

Methods: We conducted a retrospective chart review of pediatric patients diagnosed with LS or SSc who received TCZ or TFC in a single center at Prince Sultan Military Medical City in Saudi Arabia. Overall, seven patients were included in the study (3 Females and 4 Males with a mean age of 9 years (range 6-12 years).

The modified Rodnan skin score (mRSS), carbon-monoxide diffusion capacity (DLCO), thorax high-resolution tomography (HRCT), patient global assessment (PGA), and Juvenile Systemic Sclerosis Severity (J4S) score were used in patients with SSc as endpoints.

The Localized Scleroderma Cutaneous Assessment Tool (LoSCAT) and physician global assessment of activity and damage (PGA-A and PGA-D) were used in patients with localized scleroderma as endpoints to evaluate TCZ and TFC treatment response at 12 months post-treatment.

Results: Seven children with scleroderma were treated with TCZ, in addition to conventional treatment. The median age at the disease onset is 8.5 years (5–11.5) and at the diagnosis is 9 years (6-12).

Three JSS patients with interstitial lung disease were treated with TCZ with a median treatment duration of 19 (14-24) months. All three patients had radiologically confirmed improvement in thorax HRCT at 12 months post-treatment. They had decreased PGA (mean pre-treatment PGA 5 vs. 2.6 post-treatment PGA at 12 months). They had increased DLCO (mean pre-treatment DLCO 47% vs.12 months post-treatment DLCO 72.6% after the TCZ treatment). In all patients, mRSS and the J4S decreased: 33.3 vs. 14.3 and 10 vs. 4.3, respectively.

Three LS patients were treated with TCZ with a median treatment duration of 22 (6 -48) months. They had decreased PGA-A and PGA-D, with mean pre-treatment PGA-A 7 vs 1.7 in 12 months post-treatment, while the mean pre-treatment PGA-D 6.5 vs 4 in 12 months post-treatment. They had also decreased in LoSSI and LoSDI: 25 vs 2.5 and 21.5 vs 14.7, respectively.

One patient with refractory LS was escalated to TFC (5 mg BID) after a partial response to TCZ. She had decreased PGA-A and PGA-D:
pre-treatment 6 vs 1 and 5 vs 3 in 6 months post-treatment, respectively. She had also reduced LoSSI and LoSDI: 7 vs 1 and 7 vs 4, respectively.

TCZ and TFC treatment are tolerated without side effects.

Conclusion: This case series highlights the promising role of Tocilizumab as a therapeutic option in managing refractory pediatric scleroderma in both LS and SSc. Tofacitinib demonstrated also additional benefit in controlling refractory Localized Scleroderma . Long-term studies with a larger number of patients are needed to provide more relevant data.

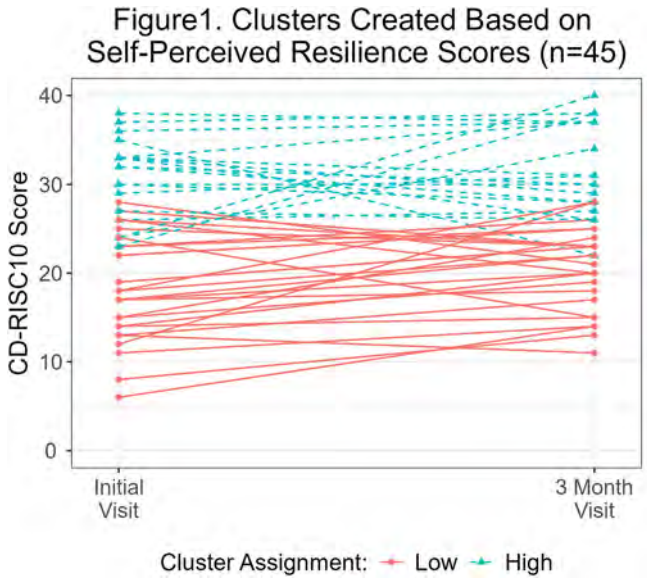
Identifying Psychosocial Profiles in Youth with Chronic Musculoskeletal Pain: A K-Means Clustering Analysis of Resilience Subgroups

Sabrina Gmuca[1], Jan Leonard[2], Alexis Z. Tomlinson[2], Mackenzie McGill[2], **Nellie Butler**[2], Rui Xiao[3], Peter F. Cronholm[3], Tonya M. Palermo[4], Jami F. Young[5], Abby R. Rosenberg[6] and Pamela Weiss[7], [1]Children's Hospital of Philadelphia; University of Pennsylvania, Philadelphia, PA, [2]Children's Hospital of Philadelphia, Philadelphia, [3]University of Pennsylvania, Philadelphia, PA, [4]University of Washington School of Medicine; Seattle Children's Research Institute, Seattle, [5]Children's Hospital of Philadelphia; University of Pennsylvania, Philadelphia, [6]Dana-Farber Cancer Institute; Boston Children's Hospital; Harvard Medical School, Boston, [7]Childrens Hospital of Philadelphia, Philadelphia, PA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Psychological resilience is low among youth with chronic musculoskeletal pain (CMP) at baseline. We aimed to explore resilience profiles among youth with CMP during the first 3-months after the initial clinic visit and their associations with baseline demographics and clinical characteristics as well as changes in psychosocial outcomes over this interval.

Methods: This was a prospective survey study for youth 12-17 years with CMP. Psychological counseling, and physical and occupational therapy were recommended to all youths. Youth completed electronic surveys, including demographics and self-reported psychosocial factors (resilience, benefit finding, hope, mindfulness, pain catastrophizing, self-efficacy, and pain acceptance) at baseline and 3-months. Abstracted baseline data included clinical characteristics and Patient-Reported Outcomes Measurement Information System (PROMIS) measures (fatigue, peer-relationships, and pain interference). Resilience was measured via the Connor-Davidson Resilience Scale 10-item (CD-RISC-10); scores range 0-40 with higher scores



CD-RISC-10= Connor-Davidson Resilience Scale 10-item (range 0-40) with higher scores indicating greater self-perceived psychological resilience.

indicating greater resilience. The primary outcome was the longitudinal resilience profiles based on CD-RISC-10 scores at baseline and 3-months identified by K-means clustering, an unsupervised machine learning method and a non-hierarchical cluster analysis technique. We examined differences in baseline demographics, clinical characteristics, and PROMIS measures between clusters using Fisher's exact, Pearson's Chi-squared and Wilcoxon rank sum tests, as appropriate. We also

Table 2. Average Within Person Change for Psychosocial Factors at 3-month Follow-up by Resilience Cluster (n=45)

Variable	Overall N = 45[1]	Cluster: Low Resilience n = 27[1]	Cluster: High Resilience n = 18[1]	P-value[2]
Change in CD-RISC10 Score	1.8 (6.1)	2.4 (5.4)	0.8 (7.1)	0.41
Change in Benefit Finding	-0.8 (11.5)	-2.0 (10.7)	1.1 (12.7)	0.40
Change in Hope Scale	1.9 (5.7)	2.1 (5.0)	1.6 (6.7)	0.77
Change in CAMM	1.0 (-1.0, 5.0)	2.0 (-1.0, 4.5)	0.0 (-0.8, 4.3)	0.90
Change in PSES-C	-2.0 (-5.0, 0.0)	-1.0 (-4.0, 1.5)	-3.5 (-8.5, -1.3)	**0.018**
Change in PCS Total Score	-4.2 (10.1)	-3.6 (11.1)	-5.2 (8.8)	0.59
Change in Pain Acceptance	-0.3 (4.5)	0.9 (4.1)	-2.1 (4.5)	**0.031**

Widespread pain index and symptom severity scale score according to the 2010 American College of Rheumatology criteria for fibromyalgia syndrome (Ting VT et al, 2016). Connor-Davidson Resilience Scale 10-item (CD-RISC-10) range 0-40, with higher scores indicating greater resilience. BFSC= Benefit Finding Scale for Children. PCS-C= Pain Catastrophizing Scale, Child report. CHS=Children's Hope Scale. CAMM= The Children and Adolescent Mindfulness Measure. CPAQ-A8= The Chronic Pain Acceptance Questionnaire Adolescent Short Form 8 item. PSES-C=The Pain Self-Efficacy Scale Child. K6= Kessler-6 Psychological Distress Scale.
[1]Median (IQR); Mean (SD)
[2]Wilcoxon rank sum test; Welch Two Sample t-test
*Differences were calculated as the 3-month score minus the initial score. A positive difference indicates the score increased between the initial and 3-month visit, whereas a negative score means the initial score was a higher number than the 3-month score. For all measures, other than PSES-C, higher scores indicate more of the construct.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

explored average within-person changes in psychosocial factors from baseline to follow-up (3-month score minus the initial score) based on cluster.

Results: 45 youths completed the surveys. Median age was 15 (IQR: 14-16) and 87% were female. The number of clusters ranged from 1:5. Based on a within-cluster-sum-of-squares scree plot, the optimal number of clusters was k-2: high (n=18) and low (n=27) resilience clusters (Fig.1). Age, race, ethnicity, and sex were not significantly different between clusters, but those in the low resilience cluster were more likely to have prior and current receipt of counseling (both $p< 0.01$; Table 1). The low resilience cluster had greater self-reported depression and obsessive-compulsive disorder (both $p< 0.05$). The low resilience cluster had worse fatigue, peer relationships, pain interference, and pain intensity at baseline (all $p< 0.05$; Table 1). Within person changes in psychosocial factors from baseline to 3-month follow-up differed by cluster. The high resilience cluster had increased pain self-efficacy but decreased pain acceptance (both $p< 0.05$; Table 2).

Conclusion: We identified 2 resilience clusters among youth with CMP. Those with lower resilience demonstrated greater symptom severity at baseline. Youth with higher resilience demonstrated greater improvements in self-efficacy within 3 months of initiating treatment but decreased pain acceptance. Further characterization of resilience profiles may provide insight into tailored treatment strategies focusing on self-efficacy and pain acceptance in this patient population.

Abstract Number: 1299

Pediatric Antiphospholipid Syndrome in a Large Tertiary Center

Rasha Elrefai, Marietta De Guzman, Jun Teruya, Vadim Kostousov, Amir Navaei and Olivia Kwan, Baylor College of Medicine, Houston, TX

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Antiphospholipid syndrome (APS) is an autoimmune condition defined as the presence of thrombotic events and/or pregnancy morbidity, accompanied by persistent antiphospholipid antibodies (aPLs). Pediatric APS is rare, often severe, and usually occurs in conjunction with systemic lupus erythematosus (SLE). There currently are no pediatric specific diagnostic or classification criteria for APS. This study aims to describe the characteristics of children with APS in a large tertiary care center.

Methods: With approval from our Institutional Review Board, retrospective descriptive study of patients diagnosed with APS from 2012 to 2025 was performed. The cohort was further stratified into primary APS and secondary APS. Demographic, clinical manifestations, serologies, and treatments were compared between groups. Threshold criteria were defined utilizing the 2023 ACR/EULAR Antiphospholipid Syndrome Classification Criteria threshold of >40 units for moderate/high titer. Statistical analysis for significance was calculated utilizing Fischer exact test.

SLEDAI at diagnosis	-	-	17 (IQR 17)	-

*Catastrophic antiphospholipid syndrome, **Lupus anticoagulant hypoprothrombinemia syndrome

Results: Thirty-nine patients were included in the study, 16 (41%) with primary APS and 23 (59%) with secondary APS. Most patients with secondary APS had a diagnosis of SLE and 3 patients with primary APS later developed SLE. Hematologic manifestations were more common in secondary APS. Arterial thrombosis most commonly presented as a stroke. Catastrophic antiphospholipid syndrome (CAPS) was identified in 18% of all patients, all of whom survived. Ten patients with LA hypoprothrombinemia syndrome (LAHPS) were identified, only 1 of whom had APS.

Four (10%) patients had aPL below criteria threshold with negative LA, while 5 (13%) had low titer aPL with positive LA. Persistent positivity was observed in 62% of all APS but only 26% were persistent above threshold. Persistence was statistically more common in the primary APS group; however, above threshold persistence only approached statistical significance. Triple positivity was mostly seen at criteria levels, with only 3 patients having triple positivity at low titers.

Table 2 Laboratory manifestations

aPL positivity	All APS n=39	Primary APS n=16	Secondary APS n=23	p value
Anti B2 glycoprotein IgM	16 (41%)	6 (38%)	10 (44%)	0.8
Anti B2 glycoprotein IgG	12 (31%)	7 (44%)	5 (22%)	0.2
Anticardiolipin IgM	29 (74%)	12 (75%)	17 (74%)	1
Anticardiolipin IgG	26 (67%)	8 (50%)	18 (78%)	0.09
Lupus anticoagulant	33 (85%)	15 (94%)	18 (78%)	0.4
Triple positive	16 (41%)	8 (50%)	8 (35%)	0.5
Persistent positive	24 (62%)	13 (81%)	11 (48%)	0.049
Criteria threshold aPL positivity	**All APS**	**Primary**	**Secondary**	**p value**
Anti B2 glycoprotein IgM	10 (26%)	4 (25%)	6 (26%)	1
Anti B2 glycoprotein IgG	11 (28%)	6 (38%)	5 (22%)	0.3

IVIG	11 (28%)	1 (6%)	10 (43%)	0.01
Methotrexate	3 (8%)	1 (6%)	2 (9%)	1
Mycophenolate	18 (46%)	2 (13%)	16 (70%)	0.0008
Plasmapheresis	9 (23%)	2 (13%)	7 (30%)	0.3
Rituximab	26 (67%)	6 (38%)	20 (87%)	0.002
Other	3 (8%)	0	3 (13%)	0.3
None	0	2 (13%)	0	0.2

*Low molecular weight heparin

Anticoagulant treatment was overall similar between the two groups, with heparin-based being most common. While patients with secondary APS received more immunomodulatory therapies, many primary APS patients did receive immunosuppressants, particularly rituximab. Two of the 6 who received rituximab were at the time of progression from primary APS to SLE.

Conclusion: Pediatric APS presents heterogeneously and with severe manifestations. Neurologic manifestations, a non-criteria manifestation, were common in this cohort, as was CAPS. Statistically significant differences between clinical and laboratory manifestations in primary and secondary APS were limited, possibly due to small sample size. Despite the small sample size, this high frequency of severe manifestations suggests APS may be underrecognized in milder cases. About a third of our patients fulfilled the threshold of aPL positive as defined by the most recent classification criteria for APS. This highlights the need for large-scale retrospective and prospective studies to address this definition in pediatric patients.

Table 1. Description of the variations of cCR.

T2T goal	Description of modified criterion associated with variations
Current cCR definition	(1) Clinical SLEDAI score equal to 0, (2) PGA score of < 0.5, (3) prednisolone dose of 0.10 mg/kg/day or a maximum of 5.0 mg/day and no intravenous methylprednisolone, and (4) tolerated standard maintenance immunosuppressive drugs/biological agents.
Variation 1	Removal of 'PGA score' criterion.
Variation 2	Removal of 'tolerated standard immunosuppressive drugs/biological agents' criterion.
Variation 3	Transformation of 'clinical SLEDAI=0' criterion to full SLEDAI-2K=0.
Variation 4	Transformation of 'PGA < 0.5' to equal to 0.
Variation 5	Transformation of 'PGA < 0.5' to ≤ 0.25.
Variation 6	Transformation of 'PGA < 0.5' criterion to ≤ 1.
Variation 7	Transformation of 'prednisolone dose of 0.10 mg/kg/day or maximum of 5 mg/day' to prednisolone dose of 0.10 mg/kg/day or maximum of 2.5 mg/day.
Variation 8	Transformation of 'prednisolone dose of 0.10 mg/kg/day or maximum of 5 mg/day' to prednisolone dose of 0.10 mg/kg/day or maximum of 7.5 mg/day.
Variation 9	Transformation of 'prednisolone dose of 0.10 mg/kg/day or maximum of 5 mg/day' to prednisolone dose of 0.10 mg/kg/day or maximum of 10 mg/day.
cCR, clinical remission on low steroids; PGA, physician global assessment; SLEDAI-2K, systemic lupus erythematosus disease activity index 2000.	

Background/Purpose: Consensus-derived treat-to-target (T2T) goals for childhood-onset SLE (cSLE), including clinical remission on low dose steroids (cCR), have been endorsed by the Paediatric Rheumatology European Society (PReS). This study evaluated whether components of cCR could either be removed or transformed to create modified definitions that provide better protection against high disease activity, as compared to the original consensus-derived cCR.

Methods: Patients from UK JSLE Cohort Study and the CARRA Registry who were < 18 years at diagnosis and met $^{3}4$ ACR/SLICC criteria were included. The components of cCR were either eliminated or transformed as described in Table 1, with 9 variations explored. Prentice-Williams-Peterson (PWP) gap-time models assessed the impact of the new cCR target definitions on high disease activity (SLEDAI-2K ≥10), with the resulting hazard ratios (HRs) compared between original and varied cCR definitions using Student's t-tests. Target attainability was compared between the original cCR and its corresponding variations using Wilcoxon tests.

Results: Data were available from 1,566 cSLE patients (11,965 visits; UK JSLE: n=492, 5,923 visits; CARRA: n=1,074, 6,042 visits). Achieving the original cCR (HR 0.24 [CI 0.18, 0.33]) reduced the hazards of subsequent high disease activity by 76% (p< 0.001, Table 2). Removing the physician global assessment (PGA) criterion (HR 0.31 [CI 0.25, 0.39]) or the criterion for stable immunosuppression (HR 0.27 [CI 0.21, 0.36]) statistically significantly worsened the risk of high disease activity, compared to the original definition (all p< 0.001, Table 2). Transformation of the *clinical* SLEDAI=0 criterion to incorporate *full* SLEDAI-2K=0 (Transformation 3) significantly improved the hazard of high disease activity compared to original

Table 2. Multivariable models showing impact of target attainment on high disease activity.

Description of original and varied cCR targets	Target definitions	Target state attainment at any time point	Significant difference from original cCR
(1) Clinical SLEDAI score equal to 0, (2) PGA score of < 0.5, (3) prednisolone dose of 0.10 mg/kg/day or a maximum of 5.0 mg/day and no intravenous methylprednisolone, and (4) tolerated standard maintenance immunosuppressive drugs/biological agents.	Original cCR	**0.24 (0.18, 0.33); P<0.001**	NA
Removal of 'PGA' criterion.	Variation 1	**0.31 (0.25, 0.39); P<0.001**	**Increased hazards of high disease activity**
Removal of 'stable immunosuppression' criterion.	Variation 2	**0.27 (0.21, 0.36); P<0.001**	**Increased hazards of high disease activity**
Transformation of 'clinical SLEDAI=0' criterion to full SLEDAI-2K=0.	Variation 3	**0.20 (0.13, 0.31); P<0.001**	**Decreased hazards of high disease activity**
Transformation of 'PGA < 0.5' to PGA equal to 0.	Variation 4	**0.26 (0.18, 0.38); P<0.001**	NA
Transformation of 'PGA < 0.5' to PGA ≤ 0.25.	Variation 5	**0.22 (0.16, 0.32); P<0.001**	NA
Transformation of 'PGA < 0.5' to PGA ≤ 1.	Variation 6	**0.29 (0.22, 0.37); P<0.001**	**Increased hazards of high disease activity**
Transformation of 'prednisolone dose of 0.10 mg/kg/day or maximum of 5 mg/day' to 'prednisolone dose of 0.10 mg/kg/day or maximum of 2.5 mg/day.'	Variation 7	**0.24 (0.18, 0.34); P<0.001**	NA
Transformation of 'prednisolone dose of 0.10 mg/kg/day or maximum of 5 mg/day' to 'prednisolone dose of 0.10 mg/kg/day or maximum of 7.5 mg/day.'	Variation 8	**0.24 (0.17, 0.32); P<0.001**	NA
Transformation of 'prednisolone dose of 0.10 mg/kg/day or maximum of 5 mg/day' to 'prednisolone dose of 0.10 mg/kg/day or maximum of 10 mg/day.	Variation 9	**0.24 (0.17, 0.32); P<0.001**	NA
Multivariable Prentice-Williams-Peterson (PWP) gap-time models adjusted for target attainment and significant factors from univariable analyses including history of lupus nephritis within first 6 months, ethnicity, and disease duration. Student's t-test was implemented to compare the hazard ratios (HRs) between original and varied cCR target definitions where a p-value < 0.008 denoted statistical significance. cCR, clinical remission on low steroids; PGA, physician global assessment; SLEDAI-2K, systemic lupus erythematosus disease activity index 2000.			

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

cCR ($p < 0.001$, Table 2). However, this transformation significantly increased time-to-target attainment (Original cCR: 18 months vs. Transformation 3: 20 months) and significantly reduced the time spent in target (Original cCR: 11.3 months vs. Transformation 3: 7.4 months).

Conclusion: These analyses demonstrate that PGA and stable immunosuppression are both essential to defining clinical remission. Although transformation of the *clinical* SLEDAI criterion to incorporate the *full* SLEDAI-2K reduced the hazards of high disease activity, this made the definition of remission significantly less attainable, suggesting that the original definition, derived from the adult definition, is optimal for use in cSLE. Further research should evaluate the consensus and varied cCR definitions in their ability to predict and prevent lupus-related damage.

Prevalence, Clinical and Genetic Risk Factors, and Time to Cataract Development in Childhood-onset Systemic Lupus Erythematosus

Sirikarn Tangcheewinsirikul[1], Zhaoyu Ding[2], Nicholas Chan[3], Daniela Dominguez[3], Andrea Knight[4], Deborah Levy[1], Lawrence Ng[5], Earl Silverman[1], Ruud Verstegen[1] and Linda Hiraki[1], [1]The Hospital for Sick Children, Toronto, ON, Canada, [2]SickKids Research Institute, Toronto, ON, Canada, [3]The Hospital for Sick Children, Toronto, Canada, [4]Hospital for Sick Children, Toronto, ON, Canada, [5]The Hospital for Sick Children, Toronto, Canada, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Cataracts are a significant ocular complication in childhood-onset systemic lupus erythematosus (cSLE). This study aimed to assess the prevalence, time to cataract development, and clinical and genetic risk factors associated with cataracts in cSLE.

Methods: We conducted a cohort study of children and adolescents diagnosed and followed for cSLE until age 18 years at a tertiary lupus clinic from 1992 to 2023. Genotyping was performed using a multiethnic array, ancestry was genetically inferred and individual polygenic risk scores (PRS) for cataracts were calculated using PRSice. Demographic and clinical variables, including sex, age at SLE diagnosis, disease duration, SLE manifestations, and high-dose glucocorticoid (GC) exposure (defined as ≥2 mg/kg/day or ≥40 mg/day if >30 kg, for at least 30 days). Cataract was diagnosed by an ophthalmologist or optometrist and recorded as part of the Systemic Lupus International Collaborating Clinics Damage Index (SLICC-DI). Summary statistics compared demographic and clinical features between patients with and without cataracts.

Table 1. Association of cataracts PRS and cataracts in univariate and multivariable adjusted models.

	OR (95%CI)	P	Adjusted OR (95%CI)	P
Polygenic risk score	1.4 (0.2-8.8)	0.73	1.0 (0.1-8.3)	0.98
Male (referent: Female)	1.9 (0.9-3.9)	0.06	1.6 (0.7-3.4)	0.24
Ethnicity (referent: European)				
East Asian	2.2 (0.9-6.1)	0.10	1.8 (0.7-5.3)	0.26
South Asian	2.5 (0.9-7.0)	0.08	1.8 (0.6-5.5)	0.32
Admixed American	**2.8 (1.1-7.9)**	**0.04**	2.6 (0.9-8.0)	0.08
African	0.7 (0.1-2.9)	0.64	0.6 (0.1-2.7)	0.54
High-dose glucocorticoid exposure	**4.4 (1.8-13.0)**	**0.003**	**4.1 (1.7-12.2)**	**0.005**

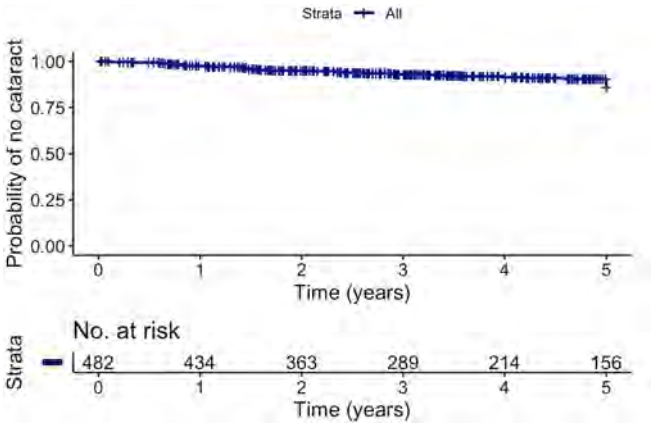

Figure 1. Time to first cataract event in cSLE (n=482).

We completed time to cataract development analyses and estimated the association between clinical features and PRSs with cataract risk in logistic regression models ($P < 0.05$).

Results: Of 482 cSLE patients, 83% were female. The mean age at diagnosis was 13.1±3.1 years, and mean disease duration was 4.5±3.0 years. The cohort was primarily of European (28%) and East Asian (25%) ancestry, followed by South Asian (18%), Admixed American (17%), and African (12%). Lupus nephritis occurred in 42%, and 49% received high-dose GC.

Cataracts were documented in 9% of patients after a mean follow-up of 4.2 years. Cataract prevalence was highest among East Asian (30%), Admixed American (26%), and South Asian (23%) patients but was not statistically significant. High dose GC exposure was associated with cataracts in both univariate and multivariable adjusted models (Table 1).

Cataracts PRS was not associated with odds of cataracts in the univariate or models adjusted for sex, ethnicity and high-dose GC exposure.

Conclusion: In this multiethnic cSLE cohort, 9% developed cataracts within 4.2 years of follow-up. High-dose GC exposure significantly increased cataract risk. We did not observe a significant association between a cataracts-PRS and the odds of developing cataracts in children and adolescents with cSLE. Future studies will include participants with adult-onset SLE.

Abstract Number: 1302

Dose Adjustment was Necessary in Patients with Cryopyrin-Associated Periodic Syndrome Switching from Anakinra to Canakinumab

Soyoung Lee and Hyun Kyung Lee, Chung-Ang University Hospital, Seoul, Republic of Korea

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Cryopyrin-associated periodic syndrome (CAPS) is a spectrum of rare autoinflammatory disorders caused by mutations in the *NLRP3* gene, leading to excessive interleukin-1β (IL-1 β) activity. IL-1 inhibitors, such as anakinra and canakinumab, are primarily used to treat these patients. In South Korea, anakinra has been the initial treatment of choice for CAPS patients, as canakinumab was only recently reimbursed by the National Health Insurance. Despite varying symptoms and different doses of anakinra, most CAPS patients transitioned from anakinra to canakinumab around the same time following a standardized protocol. The aim of this study is to report the efficacy and potential issues associated with switching from anakinra to canakinumab.

Methods: This study included CAPS patients with confirmed molecular diagnoses who switched from anakinra to canakinumab following its reimbursement approval in August 2024. Canakinumab was injected subcutaneously at a dose of 2mg/kg for patients under 40kg and 150mg for those over 40kg. If clinical response was satisfactory, the same dose was injected every 8 weeks. If not, additional dose was given within one week, up to twice. We prospectively analyzed clinical efficacy, adverse events, and quality of life.

Results: Five patients, including a pair of identical twins, were enrolled in this study (3 NOMID/CINCA, 1 MWS, 1 FCAS). The mean age at the time of the study and at diagnosis was 12.6 years (range: 4-23 years) and 15.8 months (range:1-24 months) respectively. All patients experienced recurrent fever and skin rash. Four patients had sensorineural hearing loss, three patients had hydrocephalus, and one patient had severe bone destruction. The mean dose and duration of anakinra were 3.9 mg/kg (range: 2-5.17 mg/kg) and 8.15 years (range: 1.25-14 years), respectively. Canakinumab was initiated at 2 mg/kg in three patients and 150mg in two patients. An additional dose of canakinumab was required twice in four patients, except for the FCAS patient. One patient, the most severe case, discontinued canakinumab and returned to anakinra at week 26 due to an incomplete response despite the use of the maximum dose. The mean final dose of canakinumab was 5.6 mg/kg (range: 2.8-6.6 mg/kg). Reported adverse events included headache, skin rash, infection, dysaesthesia, dizziness, and hypothermia. These adverse events improved with supportive care and diminished over time. Despite several adverse events, both patients and their families reported high satisfaction, with improvements in physical and emotional functioning.

Conclusion: Canakinumab was effective in CAPS patients, particularly in improving quality of life. However, adjustments in both dosage and dosing interval were necessary from the time of switching from anakinra to canakinumab, depending on the severity of clinical symptoms from the initiation.

Impact of Fruits and Vegetables Intake on Immune-mediated Inflammatory Diseases:a Two-sample Mendelian Randomization Study

Xuemei Tang, Yuting Zhou, Yuxiao Chen, Xinglin Wu and Qiang Luo, Department of Rheumatology and Immunology, Children's Hospital of Chongqing Medical University, National Clinical Research Center for Child Health and Disorders, Ministry of Education Key Laboratory of Child Development and Disorders, Chongqing Key Laboratory of Child Rare Diseases in Infection and Immunity, Chongqing, China, Chongqing, China (People's Republic)

SESSION INFORMATION

Session Date: Monday, October 27, 2025

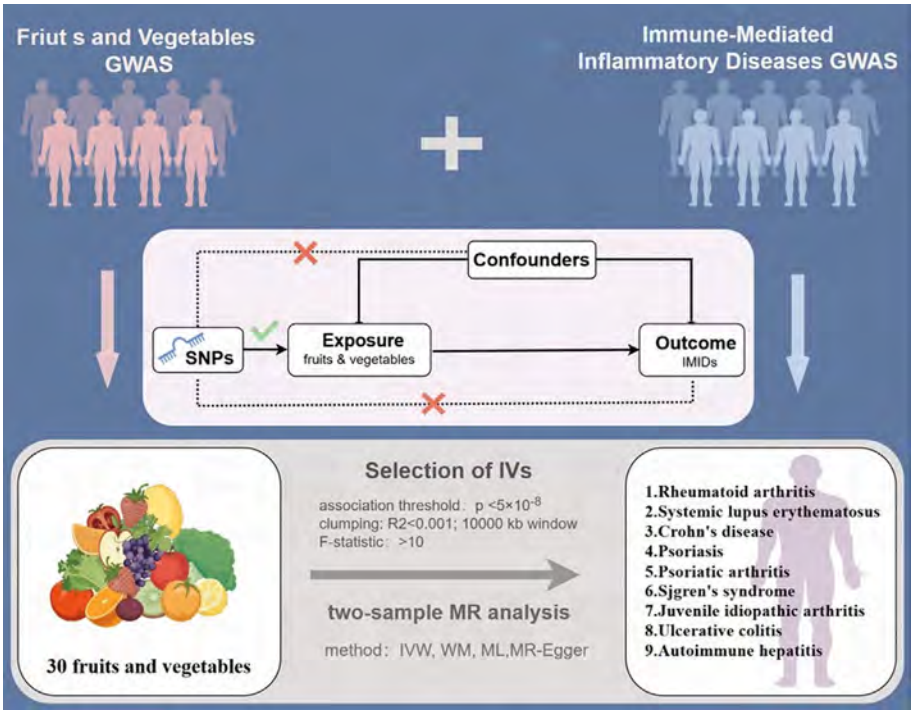
Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: A balanced diet can prevent diseases and promote physical and mental health. Accumulating evidence shows that fruits and vegetables (F&Vs) intake is associated with immune-mediated inflammatory diseases (IMIDs). However, it remains uncertain whether there is causality between the two.

Methods: We comprehensively investigated the association between 30 types of F&Vs and IMIDs, using Dietary habits-Target Mendelian Randomization method. GWAS data on exposure and outcome factors were extracted from the IEU database. Ultimately, Steiger test was used to determine the direction of each SNP.



Graphical abstract A graph illustrates the hypothetical impact of fruits & vegetables on IMIDs. The presence of a dotted line indicates a potential direct causal relationship or pleiotropic effect between fruits & vegetables on IMIDs.The two-sample MR study was analyzed using inverse variance weighted (IVW), weighted median (WM), maximum likelihood (ML), and MR-Egger. IMIDs, immune-mediated inflammatory diseases; MR, Mendelian randomization.

Results: A negative correlation was identified between cauliflower intake and the incidence of psoriasis (OR = 0.993, 95%CI 0.987-0.999, p = 0.016). Inversely, apple intake and onion intake promoted incidence of psoriatic arthritis (OR = 1.864, 95% CI, 1.237-2.809, p = 0.003) and Crohn's disease (OR = 1.850, 95%CI 1.177-2.910, p = 0.008), respectively. Additionally, the findings were consistent across a range of alternative MR methods. Sensitivity analyses did not detect any heterogeneity or pleiotropy in the estimated impact of F&Vs on the risk of developing IMIDs (all p >0.05). Steiger proved that the causal relationship between them was true.

Conclusion: This is the first Dietary habits-Target Mendelian Randomization study to systemically examine the correlation between commonly consumed F&Vs and IMIDs. In conclusion, our findings showed that the intake of cauliflower alleviated psoriasis progression, whereas apple and onion intake promoted psoriatic arthritis and Crohn's disease, respectively.

The role of PET/CT in evaluating rheumatologic conditions in children with fever of unknown origin - a multicenter study

Neta Berlak[1], Lydia Christodoulou[2], Gil Amarilyo[3], Oded Scheuerman[4], Irit Tirosh[5], Eyal Kristal[6], Ester Forer[7], Amit Carmi[8], Alon Kalter[9] and **Yoel Levinsky**[10], [1]Schneider children's medical center of Israel, Tel Aviv, Israel, [2]Tel Hashomer, Periatric rheumatology unit, Tel Aviv, Israel, [3]Schneider Children's Medical Center of Israel, Kibbutz Maggal, Israel, [4]schneider children's meidcal center of Israel, Petah tikva, Israel, [5]Tel Aviv universty, Ramat Gan, Israel, [6]Soroka medical center Beer Sheva, Beer Sheva, Israel, [7]Soroka medical center, Beer Sheva, Israel, [8]Schneider children's meidcal center of Israel, Tel Aviv, Israel, [9]Schneider children's medical center of ISrael, Petah Tikva, Israel, [10]Schneider Children's Medical Cenetr of Israel, Tel Aviv University, JERUSALEM, Israel

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Fever of Unknown Origin (FUO) is a relatively common clinical challenge that is frequently referred for evaluation by pediatric rheumatologists. In many cases, it is necessary to rule out other medical conditions before establishing a rheumatologic diagnosis. 18F-FDG PET/CT is a valuable diagnostic tool that may help identify the fever's source. However, its use in children involves risks, including radiation exposure and the need for sedation. Our aims were To assess the contribution of PET/CT to FUO diagnosis in hospitalized children, and to identify rheumatologic conditions that are either detected through the evaluation or excluded by it. In addition, to identify predictive factors for its diagnostic utility.

Methods: A retrospective cohort study reviewing medical records of children (0-18 years) diagnosed with FUO who underwent PET/CT between 2010 and 2024 in three Israeli medical centers. Clinical and laboratory data were collected, and cases where PET/CT led to a diagnosis were compared to those where it did not.

Results: Among 113 cases, PET/CT contributed to diagnosis in 52 (46%). The majority of diagnoses identified by PET/CT were infectious (53.8%), whereas in cases where PET/CT did not aid in diagnosis, rheumatologic diseases were predominant (66.6%). Of all cases, 21% were ultimately diagnoses with a rheumatologic condition, the most frequent was systemic JIA. Immunodeficiency, low hemoglobin, and low albumin were more frequent in cases where PET/CT was diagnostic, while rash and arthritis were more common in cases where PET/CT did not contribute.

Conclusion: PET/CT is an effective diagnostic tool for FUO in children, aiding diagnosis in 46% of cases. Of all cases, 21% were ultimately diagnoses with a rheumatologic condition. However, most were diagnosed without direct findings on the PET/CT, which primarily served to rule out other conditions. Predictive factors for its utility are reported. In appropriate clinical scenarios, PET/CT should be considered as part of the FUO workup in pediatric patients.

Clinical outcomes of low-to-moderate–dose glucocorticoids in multisystem inflammatory syndrome in children (MIS-C) - a multicenter study

Nina Shirman[1], Liora Harel[2], Gil Amarilyo[3], Kfir Kaidar[4], Yonatan Butbul Aviel[5], Merav Heshin Bekenstein[6], Mohamad Hamad Saied[7], Ofra Goldzweig[8], Adi Miler[9] and **Yoel Levinsky**[10], [1]Schneider children's medical center of Israe, Tel Aviv, Israel, [2]Schneider Children's Medical center, Nettnja, Israel, [3]Schneider Children's Medical Center of Israel, Kibbutz Maggal, Israel, [4]Pediatric rheumatology, Schneider children's medical center of Israel, Petah Tikva, Israel, [5]Pediatric rheumatology, Technion Faculty of Medicine, Haifa, Israel, [6]Tel Aviv Medical Center Israel, Binyamina, Tel Aviv, Israel, [7]Carmel Medical Centre, Technion Faculty of Medicine, Haifa, Israel, [8]Pediatric rheumatology unit, Kaplan medical canter, Rehovot, Israel, [9]Pediatric rheumatology unit, Technion Faculty of Medicine, Haifa, Israel, [10]Schneider Children's Medical Cenetr of Israel, Tel Aviv University, JERUSALEM, Israel

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1272–1305) Pediatric Rheumatology – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Multisystem Inflammatory Syndrome in Children (MIS-C) is an autoinflammatory disease following SARS-CoV-2 exposure. The optimal treatment strategy remains under investigation, though intravenous immunoglobulin (IVIG) and glucocorticoids are commonly used. While some authors suggest induction with pulse steroids, ACR guidelines recommend initiating low-to-moderate dose glucocorticoids (1-2 mg/kg). This study aimed to assess the response of patients treated with low-to-moderate dose corticosteroids and compare outcomes to a historical cohort treated with pulse steroids.

Methods: A multi-center, retrospective study collected data on patients initially treated with low-to-moderate dose corticosteroids. Clinical and laboratory data were compared to a historical cohort to assess disease severity and outcomes. The primary outcome was treatment escalation after 24 hours. Other outcomes included cardiovascular function, need for adjunctive therapies, and length of hospital stay.

Results: Among 41 patients receiving low-to-moderate dose corticosteroids, 7 (17.1%) required escalation. Overall, 13 (34.2%) needed vasopressors, and 2 (5.3%) required mechanical ventilation. Compared to 26 patients treated with pulse steroids, no differences were found in age, sex, fever characteristics, Kawasaki-like symptoms, or hemodynamic instability. Inflammatory markers (CRP, ESR) were similar, though ferritin was lower in the study group. Hospitalization was longer in the pulse steroid group. An echocardiogram performed post-recovery revealed that 87.5% of the study group had normal cardiac function.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1

Table 1. A comparison between the group of patients treated with a low/moderate dose of steroids and a historical group treated with high dose (pulse) steroids

	Low/medium steroids dose (n = 41)	Pulse steroids (n=26)	P-value
Gender (M)	29 (70.7%)	16 (61.5%)	0.5941
Age (y)	9.16 ± 4.17	9.11 ± 4.53	0.9633
Medical history, normal	31 (75.6%)	25 (96.2%)	**0.0403**
Fever length (days)	4.45 ± 1.77	4.6 ± 1.58	0.7259
Fever level DC	38.3 ± 1.08	38.6 ± 0.82	0.2303
Cardiac involvement – abnormal echocardiography	15 (51.7%)	15 (57.7%)	0.7876
Cardiac involvement – abnormal echocardiography OR cardiac enzymes	34 (82.9%)	24 (96%)	0.4646
GI involvement	36 (87.8%)	22 (84.6%)	0.7266
Coagulation disorder	26 (63.4%)	17 (65.4%)	1.000
Hemodynamic instability	22 (53.7%)	15 (53.6%)	0.8046
Elevated troponin	27 (81.8%)	17 (73.9%)	0.7866
Kawasaki criteria	4 (9.8%)	2 (7.7%)	1.0000
CRP at presentation	15.85 ± 10.08	20.6 ± 9.2	0.0563
ESR at presentation	52.55 ± 27.73	59.8 ± 21.1	0.2552
Lymphopenia at presentation	27 (65.9%)	21 (87.5%)	0.0798
Thrombocytopenia at presentation	16 (39.0%)	7 (26.9%)	0.4294
Ferritin at presentation	563.91 ± 630.45	975.9 ± 832	**0.0247**
D-dimer at presentation	2,897 ± 3355.2	7368 ± 7085	**0.0009**
Mechanical ventilation (invasive)	2 (5.3%)	4 (15.4%)	0.1972
Vasopressors treatment	13 (34.2%)	10 (38.5%)	0.6058
Total time of hospitalization (hours)	160.4 ± 81.44	211.4 ± 66.2	**0.0093**

Conclusion: Low-to-moderate dose glucocorticoids are effective for most MIS-C patients, with only 17% requiring escalation. No differences were seen in vasopressor or ventilation needs. Given shorter hospital stays and favorable cardiac outcomes, this approach seems appropriate, although pulse steroids may be considered in severe cases. Further research is needed to optimize dosing and duration of therapy.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Sleep disturbances are prevalent among patients with rheumatoid arthritis (RA), posing a substantial burden to patients and are intricately linked to disease activity and progression. This systematic literature review aimed to 1) identify and evaluate objective digital measures of sleep quality and quantity used in RA research and 2) aggregate present knowledge to inform endpoint selection for future clinical trials.

Methods: A comprehensive search was conducted in Embase, PubMed, and Google Scholar using broad search terms such as "rheumatoid arthritis," "sleep stage," "sleep parameters," "actigraphy," "polysomnography," and "wearable technology." After screening 769 titles and abstracts, 27 articles met inclusion criteria. Data extraction focused on technology used, sleep parameters measured, and correlation between objective and subjective measures.

Results: Three sleep assessment technologies were identified: Polysomnography (PSG;10 studies), wrist/leg actigraphy (16), and novel devices such as armbands and headbands (1). Of these, 8 studies had comparator control patient arms, and 5 studied improvements in sleep in the context of an intervention (e.g. initiation of a biologic therapy such as TNF inhibitors). The most commonly reported sleep parameters were sleep efficiency (SE), sleep latency, total sleep time, wake after sleep onset (WASO), fragmentation index, and number of awakenings. Multiple studies found RA patients experience poor SE (< 85%) and short sleep duration (≤6 hours) (Lee S, etal. 2020, McKenna S, etal. 2018, Katz P, etal. 2021), with 22% of patients experiencing WASO ≥90 minutes nightly (Lee S, etal. 2020). PSG studies confirmed these findings, revealing altered sleep architecture with less stage 2 sleep compared to controls (Bjurström MF, etal. 2017). Sleep disturbance was responsive to advanced therapies, with treatment trials demonstrated improved sleep quality parameters, such as reduced sleep latency and WASO, increase sleep efficiency and deep sleep, as well as sleep quantity with increased total sleep time on anti-TNF therapy (Bjurström MF, etal. 2017, Detert J, etal. 2016, Taylor-Gjevre RM, etal. 2011, Zamarrón C, etal. 2004).

Conclusion: Multiple objective sleep endpoints relevant to RA can be measured with digital technologies to enable sleep assessment. Importantly, patients with RA commonly suffer from sleep disturbance, with the potential for improvement observed in small treatment trials. Further work is needed to better quantify and qualify sleep in patients with RA receiving advanced therapies and explore mechanistic relationships.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) patients have higher body fat percentages, particularly in the abdominal region, which is associated with increased systemic inflammation. Obesity is associated with changes in plasma fatty acid composition, which can affect inflammatory responses. Omega-3 polyunsaturated fatty acids (n3-PUFA) are precursors for anti-inflammatory oxylipins while the roles of n6 PUFAs and monounsaturated fatty acids (MUFAs) remain less well understood. The goal of this study was to investigate FFA composition of plasma of patients with RA and its associations with RA disease activity.

Methods: Cross-sectional study involving 52 RA patients and 30 age-, sex-, and BMI-matched non-RA controls. Participants were evaluated for body mass index (BMI), healthy eating index (HEI), and lipid plasma fatty acid composition after an overnight fast. RA disease activity was assessed using the Clinical Disease Activity Index (CDAI). The correlation between plasma FFAs and CDAI was examined using univariate, Spearman correlation and multivariate linear regression analyses.

Results: Among RA subjects, plasma levels of MUFAs [palmitoleic acid (p=0.022), oleic acid (p=0.001), and gondoic acid (p=0.048)] were higher compared to controls. In contrast, plasma levels of n6 PUFAs [linoleic acid (p=0.031) and arachidonic acid (0.004)] were higher in controls compared to RA patients. Oleic acid ($r = 0.349$, $p = 0.013$) and gondoic acid ($r = 0.435$, $p = 0.002$) showed significant correlations with CDAI. Correlation analyses showed oleic acid ($r = 0.349$, $p = 0.013$) and gondoic acid ($r = 0.435$, $p = 0.002$) significantly correlated with CDAI. Multivariate linear regression analyses revealed CDAI was independently associated with oleic acid ($\beta = 0.09$, 95% CI = 0.02-0.16, $p = 0.014$) and gondoic acid ($\beta = 0.0012$, 95% CI = 0.0005-0.0020, $p = 0.002$), after adjusting for age, sex, BMI, and HEI.

Conclusion: The findings suggest a potential association between elevated plasma MUFAs and disease activity in patients with RA.

Abbreviations: Anti-CCP, anti-cyclic citrullinated peptide antibody, BMI, body mass index; CDAI, clinical disease activity index; FVC, forced vital capacity; ILD, interstitial lung disease; RA, rheumatoid arthritis; RF, rheumatoid factor; UIP, usual interstitial pneumonia.

Background/Purpose: Interstitial lung disease (ILD) is a frequent extra-articular manifestation of RA predisposing to poor health outcomes. The disease course in RA-ILD is variable, with some patients having stable courses while others experience a more progressive disease course. This variation complicates management decisions, particularly since few predictors of RA-ILD progression have been consistently identified. For example, in some, but not all, prior studies, usual interstitial pneumonia (UIP) ILD pattern has been associated with a more severe disease course. In this study, we aimed to evaluate predictors of RA-ILD progression among participants with ILD in a multicenter, prospective RA cohort.

Methods: We studied RA-ILD patients within the Veterans Affairs Rheumatoid Arthritis registry, a multicenter, prospective cohort of U.S. veterans with RA. RA-ILD was systematically identified, and all cases validated via standardized medical

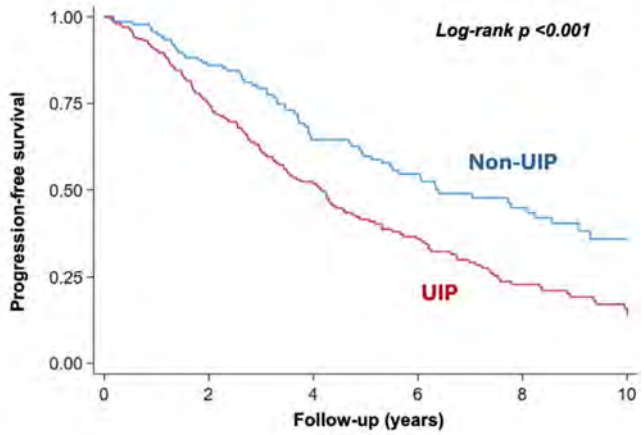
Figure 1. Kaplan-Meier plot of progression-free survival by ILD pattern.



Abbreviations: ILD, interstitial lung disease; UIP, usual interstitial pneumonia.

record review, requiring a clinical diagnosis and supportive imaging or biopsy findings. The index date was the later of registry enrollment or ILD diagnosis, to avoid immortal time bias. ILD progression was defined by change in forced vital capacity (FVC; >5% decline over < 3 years follow-up, >10% decline over >3 years of follow-up) or death up to10 years of follow-up. FVC values were obtained from the electronic health record (EHR) manually or with a validated natural language processing (NLP) tool. Candidate predictors included demographics, RA disease characteristics (e.g., autoantibodies, disease activity), and ILD characteristics (e.g., ILD pattern, baseline FVC % predicted). Predictors were obtained from registry and/or EHR data, with ILD pattern determined per treating pulmonologists and/or radiologists. Multivariable Cox regression models were used to identify determinants of progression.

Results: We studied 347 RA-ILD participants (92% male, mean age 69 years, mean ILD duration 1.7 years) (**Table 1**). Over 1,487 patient-years of follow-up, 205 (59%) RA-ILD patients experienced progression. In unadjusted comparisons, those who experienced ILD progression were more likely male, reported White race, initiated follow-up in earlier calendar years, and were more frequently current smokers, RF positive, used prednisone, and had an UIP ILD pattern (**Table 1**). Upon multivariable modeling, factors independently associated with RA-ILD progression included older age (per year aHR 1.03 [1.01, 1.05], smoking status (former vs. never aHR 1.60 [1.00, 2.56]; current vs. never aHR 1.98 [1.15, 3.40], calendar year period (2016-2024 vs. 2003-2015 aHR 0.55 [0.38, 0.79), and UIP ILD pattern (vs. non-UIP aHR 1.46 [1.06, 2.02]) (**Table 2; Figure 1**).

Conclusion: Older age, cigarette smoking history, and UIP ILD pattern were independently associated with RA-ILD progression in this multicenter RA-ILD cohort. These findings may aid in identifying patient subsets most likely to experience ILD progression and who may warrant closer disease monitoring and more aggressive RA-ILD targeted treatment strategies. Additionally, these findings reinforce the importance of smoking cessation in RA-ILD patients.

Abstract Number: 1309

Transcriptomic biomarkers of progression from undifferentiated arthritis to rheumatoid arthritis

Christina Printzis[1], Keerthana Nagesh Prabhu[2], Regina Sakalyte[3], Sigita Stropuviene[3] and **Damini Jawaheer**[1], [1]Northwestern University, Chicago, IL, [2]Washington University in St. Louis, St Louis, MO, [3]Vilnius University, Faculty of Medicine, Institute of Clinical Medicine, Clinic of Rheumatology, Orthopedics Traumatology and Reconstructive Surgery, Vilnius, Lithuania

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: A broad range (6-55%) of patients classified as having undifferentiated arthritis (UA) tend to progress to rheumatoid arthritis (RA), suggesting that UA in these patients may represent the early stages of RA. Our goal was to identify transcriptional biomarkers predictive of progression from UA to RA so that these patients can be differentiated from other UA patients and targeted for early aggressive treatment. We also examined biological changes that accompanied disease progression from UA to RA and spontaneous remission.

Methods: Patients (n=54) with inflammatory arthritis of one or more joints for >4 weeks, but < 12 months, were enrolled in the Vilnius University Hospital Santaros Klinikos Rheumatology Centre early UA cohort and followed prospectively for 12 months. Blood samples were collected at study entry (T0, n=52) and at 12 months (T1, n=35). We examined the transcriptomes at each timepoint using bulk RNA-sequencing. We performed Differential Expression Analysis (a) between UA groups (pre-RA vs pre-remission) at the T0 baseline to identify biomarkers predictive of progression to RA, and (b) within groups (paired samples: T1 vs T0) to assess transcriptional changes associated with progression to RA or spontaneous remission. Genes were considered differentially expressed (DE) using FDR< 0.05 and fold-change >=2. Functional enrichment analysis was also performed.

Results: Of the 54 UA patients, 33 progressed to RA by 12 months, while 21 went into remission. At the T0 baseline, 43 genes were DE between the two UA (pre-RA and pre-remission) groups. These included several genes previously implicated in RA that were over-expressed in the pre-RA group at T0 (e.g. MAOA, DAAM2 and IFI27) and some that were under-expressed (e.g. SOX5, IGLV3-1 and S100B). Functional enrichment analysis identified myeloid cell homeostatis and differentiation pathways significantly enriched among the DE genes. Analysis of samples available at T1 from UA patients who progressed to RA (n=25) or went into remission (n=10), revealed 229 DE genes between the RA and remission groups. These included genes previously associated with RA such as CD177, S100A12, and MMP9 being over-expressed in the RA group, consistent with previous studies, and many immunoglobulin genes being under-expressed. Inflammatory and immune response pathways were significantly enriched among the DE genes. Surprisingly, as UA progressed to RA over time, no significant DE genes were detected between T0 and T1. In contrast, as UA went into remission, 13 genes were DE between T0 and T1, including some genes previously implicated in RA (e.g. CASP5 and OLFM4) which significantly decreased in expression from T0 to T1.

Conclusion: In our cohort, at the pre-RA stage, UA patients exhibited gene expression signatures that may represent predictive biomarkers of progression to RA. The absence of longitudinal transcriptomic changes when UA progressed to RA suggest that molecular mechanisms that drive the disease process in RA were perhaps already under way at the UA (pre-RA) stage, at our study baseline. Remission, on the other hand, was accompanied by decreasing expression of some genes known to have a pro-inflammatory role in RA.

Naturalized Language Processing Based Extraction of Rheumatoid Arthritis Disease Activity Measures from the Electronic Health Record

Elizabeth Park[1], Iram Kamdar[2], Reid Weisberg[1], Andy Nguyen[1], Joan Bathon[3], Jon Giles[4], Chunhua Weng[5] and Elana Bernstein[1], [1]Columbia University Irving Medical Center, New York, NY, [2]Columbia University Data Science Institute, New York, NY, [3]Columbia University, NEW YORK, NY, [4]Cedars-Sinai Medical Center, New York, NY, [5]Columbia University Department of Biomedical Informatics, New York, NY

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: A treat-to-target approach in rheumatoid arthritis (RA) requires intense monitoring of RA disease activity with measures such as the clinical disease activity index (CDAI). Outside of clinical studies, CDAI may be sparsely recorded by clinicians in real world settings due to their local electronic health record (EHR) systems lacking systematic integration of structured entry forms for CDAI (e.g., homunculus) and variability in documentation practice among clinicians. We hypothesize that most clinicians document CDAI in unstructured free text. Two previous publications developed successful natural language processing (NLP) pipelines extracting CDAI, but the practices were limited to community settings and the Veterans Administration. We explored extracting CDAIs from a large, tertiary academic center EHR with a heterogeneous RA patient population utilizing novel NLP techniques.

Methods: The New York Presbyterian/Columbia University Medical Center Clinical Data Warehouse (NYP/CUMC CDW) contains over 4.5 million patients' data stored in structured and unstructured formats. From a pre-selected group of RA patients in the CDW, a random sample (20%) of free text notes recorded in rheumatology outpatient practices across one EHR system (EPIC) between 2020-2024 were produced. A list of CDAI, its key components, as well as plausible variations in phrasing was generated with expert curation (EP) (Table 1). These keywords, along with serostatus (seropositivity) were extracted using an automated information extraction pipeline, engineered through large language model (LLM) prompts input through Chat GPT-4 Education, a HIPAA compliant, CUMC approved resource (Figure 1).

Table 1. CDAI/Serostatus Terminology Extraction

CDAI Components	CDAI Score Phrasing	Serostatus Terms
Swollen Joint Count: Swollen; SJC; S Tender Joint Count: Tender; TJC; T	"CDAI is..." "CDAI was..." "CDAI was ... today is.." "CDAI went from ... to.."	**Seropositive; Sero+** Rheumatoid Factor (RF) positive; RF+; +RF; RF++; ++RF RF "Number"

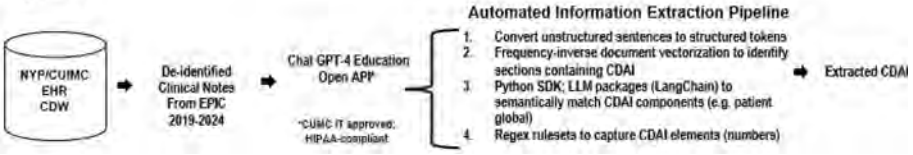
Table 2. Summarized CDAI Extraction

Total RA cohort (n=1,983)*	Prevalence %
CDAI recorded	8.72% (173/1983)
Remission (0-2.8)	34.1% (59/173)
Low Disease Activity (2.9-10.0)	29.4% (51/173)
Moderate disease Activity (10.1-22.0)	17.9% (31/173)
High Disease Activity (22.1-76.0)	17.9% (31/173)
Serologic Status	
Seropositive in total cohort	38.7% (768/1983)
Seropositive in CDAI subset	79.1% (137/173)
Seronegative in total cohort	28.3% (562/1983)
Seronegative in CDAI subset	20.2% (35/173)
Sero status not recorded in total cohort	32.7% (649/1983)
Accuracy	
Precision	0.97
Recall	0.97
F1	0.97

*RA cohort sampled from EHR using International Classification of Disease (ICD) 9 and 10 codes; positive predictive value of 82% when validated against chart review

Summarized CDAI Extraction

Figure 1.



Automated Extraction Pipeline

Results: A total of 1,983 unique RA patients (one note per patient closest to July 1, 2024) were analyzed; 768 (38.7%) were seropositive, 562 (28.3%) were seronegative, and 649 (32.7%) did not have serostatus recorded. The term "CDAI" and its variations were extracted from 173 (8.72%) patients with a median value of 7 (range 0-43). Of the 173 with CDAI recorded, 59 (34.1%) were in remission, 51 (29.4%) had low activity, 31 (17.9%) had moderate activity, and 31 (17.9%) had high activity. Of those with CDAI recorded, 137 (79.1%) were seropositive and 35 (20.2%) were seronegative (Table 2). An expert (EP) performed a chart review of a random 20% sample of the extracted CDAI scores, resulting in a precision of 0.97, recall of 0.97, and F1 score of 0.97.

Conclusion: We demonstrated feasibility and accuracy of a Chat GPT-4 supported NLP/LLM pipeline to extract CDAI scores from a large, academic EHR. At our institution, CDAI appears to be sparsely documented (< 10%) in the sampled portion of notes. Our next steps include: 1) Refining the RA cohort by chart validating those without serostatus (i.e., confirming if they are actual RA cases); 2) Integrating analysis of historical EHRs used prior to EPIC (before 2020) to perform longitudinal extraction of CDAI scores; and 3) Exploring portability of this pipeline to other academic institutions, with the goal of external validation.

Abstract Number: 1311

Decade-Based Trends in First Remission Among Rheumatoid Arthritis Patients: A Population-Based Study

Georges El Hasbani[1], Roslin George[2], Anne Shurtz[1], Cynthia Crowson[3] and Elena myasoedova[2], [1]Mayo Clinic, Rochester, [2]Mayo Clinic, Rochester, MN, [3]Mayo Clinic, Stewartvillle, MN

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II

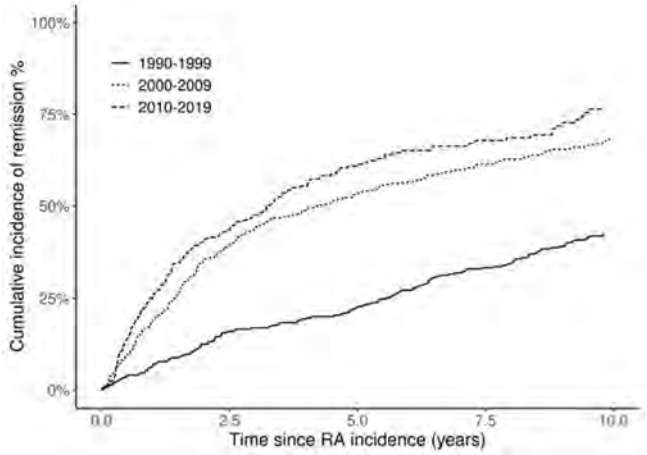
Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Early and aggressive treatment of rheumatoid arthritis (RA) has been linked to improved remission rates, but achieving early and sustained remission remains a challenging task. Temporal trends and risk factors for early remission have not been comprehensively studied in longitudinal population-based RA cohorts. We aimed to investigate the likelihood of achieving first remission in RA by decade of RA incidence, serostatus, and by disease modifying drug (DMARD) use.

Methods: Adult residents of a geographically defined area aged ≥18 years who met ≥4 of the 1987 ACR criteria for RA in 1980-2019 were included. All participants were followed until death, last medical contact, or 12/31/2022. Data on RA characteristics, DMARD use (i.e. conventional DMARDs, biologics, targeted synthetic DMARDs), cardiovascular risk factors and comorbidities was manually collected from the medical records. The cumulative incidence of first remission, adjusted for competing risk of death, was evaluated by decade, age, and sex. Cox models were used to examine factors associated with first remission.

Results: The study included 1,098 patients with RA (mean age 55.7, 68.4% female, 62.8% positive for rheumatoid factor (RF) and/or cyclic citrullinated peptide (CCP) antibodies). The cumulative incidence of first remission was higher in persons with RA onset in 2000-2009 and 2010–2019 vs 1990-1999, with 18.9% (95%CI 15.5-23.1%), 25.2% (95% CI 21.3-29.9%) and 6.8% (95% CI 4.4-10.3%) of patients achieving remission in the first year, respectively (**Figure 1**). The likelihood of first remission was higher in patients with RA onset in 2000-2009 (HR 1.75, 95%CI 1.46-2.09) and 2010-2019 (HR 1.79, 95%CI 1.48-2.17) vs 1990-1999.



Cumulative incidence of remission by decade of RA incidence

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Factor	Hazard Ratio (95% Confidence Interval)
Age	1.10 per 10-year increase, (1.05-1.16)
Men vs. women	1.2 (1.04-1.40)
Seropositive vs. seronegative RA	1.23 (1.06-1.43)
Baseline ESR	1.03 per 5 mm/hr increase (1.01-1.04)
Use of methotrexate in the 1st year of RA	1.23 (1.06-1.43)
Use of glucocorticoids in the 1st year of RA	1.21 (1.04-1.42)
Current smoking	0.81 (0.67-0.98)
Non-white race	0.63 (0.48-0.82)

Factors associated with remission

Risk factors associated with the likelihood of first remission included age, sex, seropositivity, baseline ESR, use of methotrexate in first year of RA, use of glucocorticoids in first year of RA, smoking status and race (Table 2). The association between BMI and remission approached statistical significance (HR per 5 unit increase 0.95, 95%CI 0.90-1.01).

The risk of flare after remission was higher in 2000-2009 (HR 1.30, 95%CI 1.07-1.59) and 2010-2019 (HR 1.34, 95%CI 1.08-1.66) vs 1990-1999, and in seropositive vs seronegative patients (HR 1.41, 95%CI 1.18-1.67).

Early exposure to any 2 or more DMARDs (vs 1 DMARD) increased the likelihood of first remission (HR 1.18, 95%CI 1.01-1.38).

Conclusion: The likelihood of achieving first remission in RA has improved across decades. Despite this improvement in remission rates, patients with RA in recent decades were also more likely to flare after remission. DMARD exposure and particularly early use of methotrexate enhances the likelihood of remission. Persons with seropositive and more active RA, men and older patients had higher likelihood of remission, while smoking, higher BMI and non-white race tended to decrease the likelihood of first remission.

Evolution of patients with active rheumatoid arthritis: analysis of disease activity trajectories in a tertiary-care rheumatology department

Elodie Portier[1], Olivier Fogel[2], Terkia Medkour[3], Sophie Hecquet[3] and **Jérôme AVOUAC**[3], [1]Rheumatology department, Bicetre hospital, Le Kremlin Bicetre, France, [2]AP-HP, Paris, France, [3]Rheumatology department, Cochin hospital, Paris, France

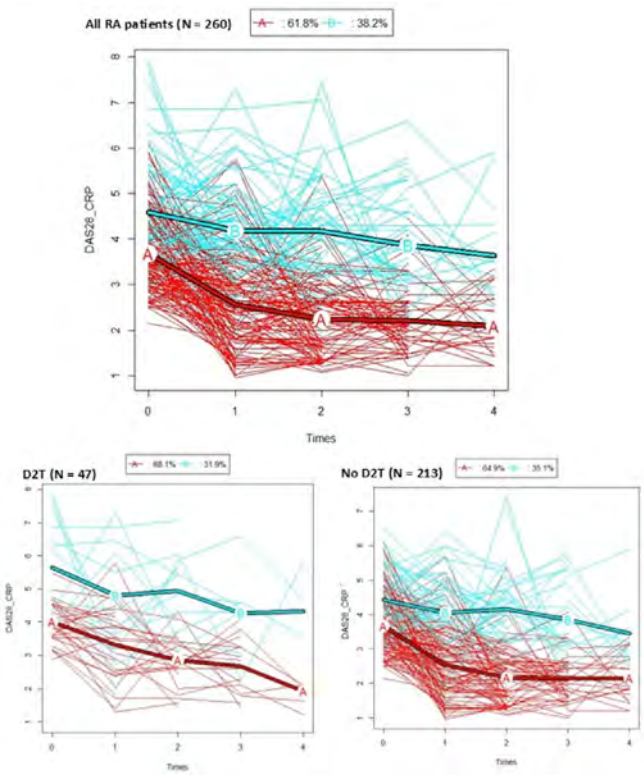
SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: The objective of this study was to identify clusters of patients with rheumatoid arthritis (RA) in clinical practice, according to evolution of disease activity over time (“trajectories”), when focusing on active RA at inclusion.

Methods: Monocentric study including all RA patients seen from January 2021 to December 2022 in day hospitalization in Cochin Hospital, with active disease at screening (DAS28CRP or ESR ≥ 3.2), and with at least one follow-up visit. DAS28CRP trajectories were identified using k-means clustering. Characteristics at baseline and last-follow up visit

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Trajectories of DAS28CRP during follow-up in all RA population, then according to D2T status.

according to trajectory were described, then analyzed with logistic regression to estimate associations between baseline characteristics and trajectories. Secondary analyses evaluated impact of difficult-to-treat (D2T) status at baseline, and was defined as failure of at least 2 biological (b) or targeted synthetic (ts) DMARDs with different mechanisms of action according to EULAR definition of D2T RA.

Results: Among the 362 patients screened, 260 had at least 2 visits with DAS28CRP values and were included, with a mean follow-up of 24 months (standard deviation, SD 9). Patients were mostly women (87%) of 59 yo, 16 years of disease duration, 81% positive ACPA and 60% erosive status. At baseline, patients had active disease with mean DAS28CRP of 4.1 (SD 1), 4 swollen joints, 6 tender joints, and mean level of CRP of 8 mg/L. They had received a mean of 2 different b/tsDMARDs and 47 (18%) were D2T RA. Two trajectories of DAS28CRP were identified: trajectory A (tA, n=158) with improvement in disease activity over the follow-up period, and trajectory B (tB, n=102) with little change in disease activity (**Figure 1**). At baseline, patients in tB had higher DAS28CRP (4.6 vs 3.7 in tA), more current smokers (23 vs 12%), more D2T status (27 vs 12%), and more treatment with corticosteroids (61 vs 46%) and Janus Kinase inhibitors (JAKi) (9.8 vs 3.2%). Multivariate analysis showed association of trajectories with Body Mass Index (BMI), smoking status, DAS28CRP at baseline and JAKi treatment. At the last visit, patients in tB remained more active than tA with DAS28CRP of 3.9 (vs 2.07) and had received more b/tsDMARDs (3.1 vs 2.3). Finally, 174/260 (67%) had DAS28CRP < 3.2 at the end of follow-up, 149 (94%) in tA and 25 (25%) in tB. There was no difference in trajectories when comparing D2T patients and no-D2T patients (**Figure 1**).

Conclusion: This study revealed two trajectories of RA patients with active disease after a 2-year follow-up, one with achieved remission (tA) and the other with persistent high disease activity (tB). Current smoking and high BMI were the main drivers of tB, these comorbidities are known to be associated with poorer outcomes. Level of DAS28CRP at baseline and use of JAKi were also factors independently associated with trajectories, suggesting higher severity of the disease in these patients. Finally, D2T status had no impact on trajectories. Despite the implementation of a treat-to-target strategy, 75%

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Retrospective Analysis of Factors Associated With Fracture in 2855 Patients With Rheumatoid Arthritis, Stratified by Steroid Use

Jonathan Barnes[1], Hamzah Amin[2] and marwan Bukhari[3], [1]Morecambe Bay NHS Trust, Lancaster, United Kingdom, [2]Lancaster University, Lancaster, United Kingdom, [3]University Hospitals of Morecambe bay NHS foundation trust, Lancaster, United Kingdom

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Steroids are used in a proportion of patients with rheumatoid arthritis (RA). Steroids are known to cause a decrease in bone mineral density (BMD), although our recent study suggests a potential for a paradoxically protective effect. We set out to determine if traditional fracture risk factors for fracture are appropriate in those with RA who have been treated with steroids.

The objective of this study was to determine what factors influence fracture in those with rheumatoid arthritis (RA) having received steroid therapy and those who have not, as well as comparing to see if the patterns of fractures are different among those treated with steroids compared to those who have not.

Methods: patients with rheumatoid arthritis (RA) who underwent a DEXA scan at a regional scanner in the North West of England between 2004 and 2021. Demographic data of these patients were collected, including steroid use, alcohol consumption, smoking, secondary osteoporosis, etc., along with the classic FRAX™ risk factors. Bone mineral density (BMD), Z scores and T scores were collected. Group comparisons were performed using t-tests for continuous variables and Chi squared tests for categorical variables, comparing those treated with steroids (past or current) and those not.

Results: 2855 patients were included in the study. Of these patients, 2313 (81.0%) were female, the mean age at scanning was 66.1 (SD ±12.5). Corticosteroid use, either current or prior was reported in 947 patients (33.2%). Fractures were observed in 309 (32.6%) of steroid users and 693 (36.3%) of non-users. Steroid use was not associated with an increase in fractures, rather a reduction - although not statistically significant ($p = 0.057$). Interestingly, among 758 patients currently being treated with steroids, 228 (30.0%) had fractures, compared to those not currently on steroids there were 2097 patients with 774 (36.9%) of those having a fracture. This is suggestive of a protective effect of current steroid use against fracture ($p < 0.01$), although causality cannot be inferred.

The patterns of fractures similar between those having steroid therapy and not, other than forearm fractures which were more common in those without steroid treatment ($p = 0.032$).Traditional FRAX™ factors were not found to be good predictors of fracture in this cohort of patients using steroids, other than femoral neck BMD ($p < 0.01$) and family history of fracture ($p < 0.01$), which both significantly increased fracture risk. Higher total body fat percentage was found to increase fracture risk in both groups of patients ($p < 0.01$), weight was not statistically significant in either group.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Classical FRAX™ risk fractures were not significant predictors of fracture in those on steroids with RA, other than family history and femoral neck BMD. The best predictors of fractures in this cohort were bone mineral density analysis, family history, height loss and total fat percentage.

Fracture patterns were similar between those with and without prior or current steroids, other than fractures of the forearm, which were less likely in those steroids on steroids. Further modelling is needed to determine odds ratios of risk factors at specific sites .

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Cardiovascular disease (CVD) remains the leading cause of death in rheumatoid arthritis (RA), driven primarily by atherosclerotic CVD (ASCVD) and heart failure (HF). Malondialdehyde-acetaldehyde (MAA) adducts are highly immunogenic post-translational modifications (PTM) that result from oxidative stress. MAA adducts are enriched in serum and synovial fluid from patients with RA, as well as the serum and atheromatous lesions in non-RA patients with coronary artery disease. Given the ongoing need to improve CVD risk stratification and management in RA, our objective was to evaluate the associations of protein-specific anti-MAA antibodies with incident ASCVD and HF outcomes in RA.

Methods: We conducted a cohort study among participants in the multicenter Veterans Affairs RA registry. Antibodies to MAA-modified-albumin, -collagen, -fibrinogen, and -vimentin (IgA, IgG, IgM isotypes) were measured by ELISA on banked serum from registry enrollment. Antibody concentrations were log transformed and standardized (per 1 S.D.), categorized into quartiles, and dichotomized at the highest quartile (high vs. low). Incident ASCVD (fatal or non-fatal myocardial infarction or stroke) and HF (HF hospitalization or HF-related death) were identified using validated administrative algorithms in linked VA, Medicare, and National Death Index data. Patients were followed from enrollment to incident CVD, death, or end of study period (12/2022). The associations of anti-MAA antibodies with incident ASCVD and HF were tested separately in multivariable Cox regression models adjusted for age, sex, race, smoking status, body mass index, comorbidities (hypertension, hyperlipidemia, diabetes, chronic lung disease), seropositivity (for RF and/or anti-CCP), and DAS28.

* Values are hazard ratios (95% confidence intervals) estimated in multivariable Cox regression adjusted for age, sex, race, body mass index, smoking status, CVD risk factors, seropositivity, and DAS28.

High vs. low based on highest quartile (Q4) vs. lower quartiles (Q1-Q3).

Abbreviations: ASCVD, atherosclerotic cardiovascular disease; HF, heart failure; MAA, malondialdehyde acetaldehyde; S.D., standard deviation.

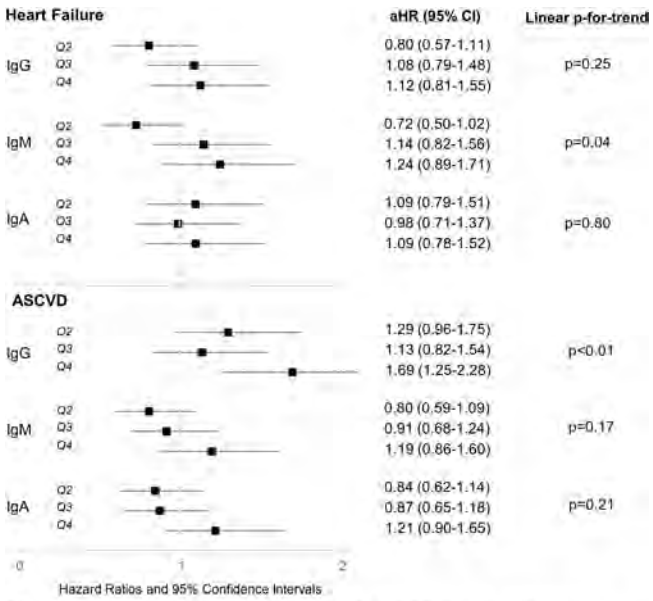

Figure 1. Forest plot illustrating the association of anti-MAA-vimentin isotypes with incident heart failure and ASCVD outcomes. Estimates are hazard ratios adjusted (aHR) for age, sex, race, smoking status, BMI, traditional CVD risk factors, seropositivity, and DAS28. Quartile1 (Q1) is the lowest quartile and serves as the reference (dashed line). A

Figure 1. Association of anti-MAA vimentin quartiles with ASCVD and HF in RA

Results: There were 3,572 participants included in this study (87% male, mean age 64 years, mean DAS28 3.5). Among those without prior ASCVD and HF, we observed 398 incident ASCVD (20.9 events per 1000 person years [PY] over 23,056 PY follow-up) and 327 incident HF events (14.2 per 1000 PY over 19,049 PY follow-up). High values (top vs. lower quartiles) of anti-MAA-vimentin were significantly associated with incident ASCVD for IgG (aHR 1.42, 95% CI 1.13-1.79), IgM (1.27, 1.01-1.60), and IgA isotypes (1.30, 1.03-1.64; **Table 1**). A dose-dependent relationship was observed between IgG anti-MAA-vimentin and incident ASCVD (p< 0.01 for trend across all 4 quartiles; **Figure 1)**. In analyses of all 4 quartiles, higher IgM anti-MAA-vimentin tended to be associated with incident HF (p for trend 0.04; **Figure 1**); findings were not significant for analyses categorized as high vs. low (aHR 1.25, 0.97-1.61; **Table 1**). Other protein-specific anti-MAA antibodies were not associated with ASCVD or HF.

23265205, 2025, 59, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Antibodies against MAA-modified vimentin were independently associated with incident ASCVD in a large, prospective RA cohort. Vimentin, an extracellular matrix protein, commonly undergoes PTM during RA development and MAA is over-expressed in myocardial tissues in animal models of RA. These data support the hypothesis that vimentin modification may serve as a unique driver of ASCVD in RA, and anti-MAA-vimentin antibodies may facilitate CVD risk stratification in RA.

High-resolution thermography and Artificial Intelligence to evaluate and classify Rheumatoid Arthritis

Kale Mayor[1], Joey Mercier[1], Yuxi Long[2], David Robinson[1], Pingzhao Hu[2], Hani El-Gabalawy[1] and Liam O'Neil[1], [1]University of Manitoba, Winnipeg, MB, Canada, [2]Western University, London, ON, Canada

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune polyarthritis that typically affects the small joints of the hands and feet. While imaging modalities such as ultrasound and MRI are valuable for detecting synovitis, their use can be limited by technical requirements and cost. Thermography is a non-invasive imaging technique that captures pixel-level temperature data and has seen growing interest in the assessment of inflammatory arthritis. We aimed to determine if thermal imaging of the hands and feet can effectively distinguish RA patients from healthy controls (HC).

Methods: RA patients were recruited from an academic rheumatology clinic (Winnipeg, Canada). Healthy controls (HC) were recruited through advertising. Thermal images of the dorsal aspects of the hands and feet were captured with a Flir A700 camera. Regions of interest (ROI) were pre-identified as joints commonly affected in RA (Fig1A). ROIs were manually gated, and the max/min/average temperatures were extracted. Data analysis was performed in R to identify temperature differences between groups, followed by machine learning classification. Thermograms were also analyzed using a deep learning model which deployed unsupervised feature extraction (DINOV2) and classification (ElasticNet) in Python.

Results: We recruited 100 RA patients and 137 HC (Fig1B). Principle components analysis using ROI thermogram data revealed clear separation between RA and HC (Fig2A). Differential analysis identified 56 of 114 temperature parameters that were significantly higher in RA patients, for example the maximum temperatures of the right 5th PIP joint (adjusted $p=1.3\times10^{-8}$) and right 4th PIP joint (adjusted $p=7.6\times10^{-8}$). All thermogram parameters (min, max, avg) were increased in joints that were tender or swollen on clinical examination in RA (Fig2C, all p-value < 0.0001). Using thermogram ROI data, XGboost achieved an AUC of .869 to classify RA from control (test set, Fig3A). Rankings of variable importance by SHAP index included average temperatures of L ankle, L Wrist and L 3rd PIP (Fig3B). A computer vision model achieved high performance in classifying RA from controls using entire thermograms (without ROI information), with an AUC of 0.977 and

recall of 0.909 (Fig. 3C). Principal components from this model were mapped to red, green, and blue channels to visualize thermographic differences between RA and control subjects (Fig. 3D).

Conclusion: Thermal imaging is an inexpensive and readily accessible method for detecting synovitis in the small joints of the hands and can readily discriminate the hand joint of a spectrum of RA patients from those of unaffected healthy controls. As such, this modality may be a cost-effective approach to detecting subtle joint inflammation at the earliest stages of RA onset, for example in individuals with clinically suspect arthralgia.

Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disease associated with increased mortality, primarily due to systemic inflammation and comorbidities. While previous studies have identified some prognostic factors in RA, there remains a lack of robust, clinically applicable tools adapted to the Chinese population. This study aims to develop a predictive model for all-cause mortality in Chinese RA patients using routinely available clinical data.

Methods: The clinical data utilized in this study were obtained from the database of the Chinese Registry of Rheumatoid Arthritis (CREDIT), while the survival outcome data were from the Chinese Center for Disease Control and Prevention (CDC) from October 2003 to December 2021. Variable selection was performed using the least absolute shrinkage and selection operator (LASSO) and univariate Cox regression.A multivariate Cox proportional hazards model was constructed and calibrated. Model performance was assessed using Harrell's C-index and Brier score. External validation was conducted using an independent data as validation set from central China provinces (Henan, Hubei, and Hunan) in China, and data from other provinces was randomly split into training and internal test set. A nomogram was developed based on the final multivariate model to facilitate clinical application.

Results: A total of 62,321 patients with complete clinical data (Mean age: 53.13 years, SD: 12.85 years; female: 49,790, 79.9%) from 450 medical centers across the country were included in this study. Among them, 1,901 deaths (3.0%) were recorded during follow-up. 45,126, 12,058, and 5,137 patients were included in training, validation, and test set,

respectively. Assisted with LASSO method, a multivariate Cox model with sex, age, coronary artery disease (CAD), stroke, fragility fracture, interstitial lung disease (ILD), DAS28CRP was built and calibration curve showed great agreement between predicted and observed 3-year survival probabilities. The model demonstrated consistent discrimination across datasets, with Harrell's C-indices of 0.841 (95% CI: 0.816–0.863) in the training set, 0.857 (0.779–0.911) in the test set, and 0.834 (0.784–0.874) in the validation set. Decision curve analysis indicated that the derived nomogram offers meaningful clinical benefit.

Conclusion: This study developed a robust prediction model for all-cause mortality in patients with RA using routinely collected baseline data. The model offers a practical tool for stratifying patients by prognostic risk, particularly through assessment of comorbidity burden.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Insomnia and rheumatoid arthritis (RA) are caught in a snowball effect, where chronic pain disrupts sleep and causes poor sleep quality, which in turn increases pain sensitivity. This growing cycle intensifies RA-related symptoms, further impairing patients physical function and psychological well-being. Despite this significant impact, the association between RA and insomnia remains underexplored. This study aims to explore the association between RA, high disease activity, and insomnia to provide deeper insights into its implications.

Methods: We systematically searched PubMed, Web of Science, and Scopus from inception until March 18, 2025, following PRISMA guidelines (Fig. 1). Studies were included if they had a case-control, cohort, or cross-sectional design and confirmed RA diagnosis by a rheumatologist, classification criteria, ICD codes, or self-reported physician diagnosis. Meta-analysis, applying both random- and fixed-effects models, estimated the pooled association between insomnia and RA, comparing RA patients with controls, those with low/remission disease activity versus moderate/high disease activity, and rheumatoid factor (RF) +ve versus RF -ve patients. Data were extracted and analyzed using Review Manager (RevMan), with heterogeneity assessed using I^2.

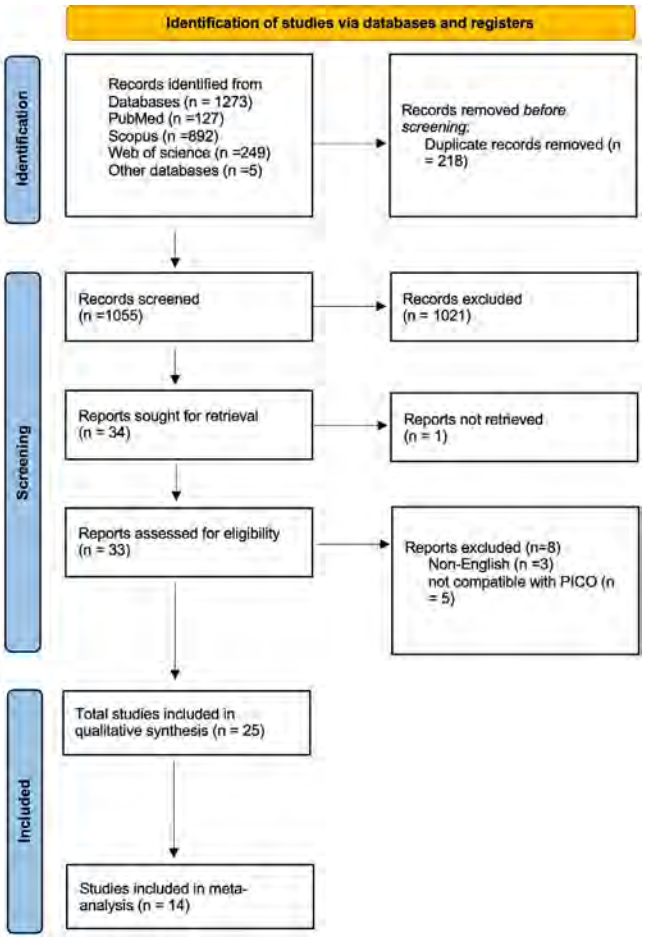

Figure (1) PRISMA Flow Chart Illustrating Search Strategy and Selection of Included Studies

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

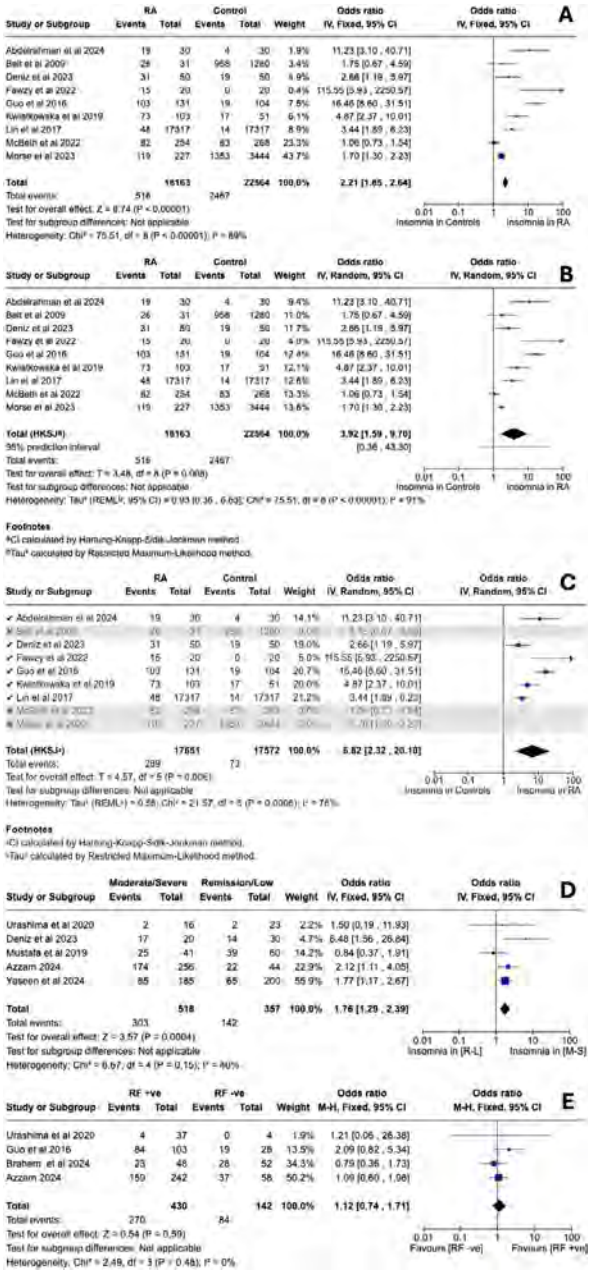

Figure (2) Forest Plots of the Association Between Insomnia, RA, Disease Activity, and RF Status. (A) Fixed-Effects Model: Studies included: Abdelrahman et al. 2024, Belt et al. 2009, Deniz et al. 2023, Fawzy et al. 2022, Guo et al. 2016, Kwiatkowska et al. 2019, Lin et al. 2017, McBeth et al. 2022, Morse et al. 2023. Overall: Significant association between insomnia and RA (OR = 2.21; 95% CI: 1.85–2.64), with considerable heterogeneity (I2=89%). Test for overall effect: Z=8.74 (P<0.00001). Heterogeneity: $\chi2=75.51$, df=8 (P<0.00001). (B) Random-Effects Model: Studies included: Same as fixed-effects model. Overall: Significant association (OR = 3.92; 95% CI: 1.59–9.70), with considerable heterogeneity (I2=91%; $\tau2=0.93$). Test for overall effect: T=3.48 (P=0.008). Heterogeneity: $\chi2=75.51$, df=8 (P<0.00001). (C) Sensitivity Analysis (Excluding Outliers): Studies included: Abdelrahman et al. 2024, Deniz et al. 2023, Fawzy et al. 2022, Guo et al. 2016, Kwiatkowska et al. 2019, Lin et al. 2017. Excluded studies: Belt et al. 2009, McBeth et al. 2022, Morse et al. 2023. Overall: Stronger association (OR = 6.82; 95% CI: 2.32–20.10), with reduced but substantial heterogeneity (I2=76%; $\tau2=0.58$). Test for overall effect: T=4.57 (P=0.006). Heterogeneity: $\chi2=21.57$, df=5 (P=0.0006). Insomnia was consistently associated with RA across models, with the strongest effect observed after excluding outliers (OR = 6.82). (D) Insomnia in Moderate/Severe RA vs. Remission/Low RA: Studies included: Urashima 2020, Deniz 2023, Azzam 2024, Mustafa 2019, Yassen 2024. Overall: Significant association between moderate/severe insomnia and RA (OR = 1.76; 95% CI: 1.29–2.39), with moderate heterogeneity (I2=40%). Test for overall effect: Z=3.57 (P=0.0004). Heterogeneity: $\chi2=6.67$, df=4 (P=0.15). (E) RF-Positive vs. RF-Negative Status in RA: Studies included: Urashima 2020, Guo 2016, Brahem 2024, Azzam 2024. Overall: Non-significant association between Insomnia and RF positivity in RA (OR = 1.12; 95% CI: 0.74–1.71), with no heterogeneity (I2=0%). Test for overall effect: Z=0.54 (P=0.59). Heterogeneity: $\chi2=2.49$, df=3 (P=0.48). Heterogeneity was high in all analyses, likely due to variability in study designs and populations. CI, confidence interval; df, degrees of freedom; OR, odds ratio; I2, heterogeneity index; $\tau2$, Tau-squared; RF, Rheumatoid Factor; RA, Rheumatoid Arthritis.

Country	OR for Insomnia	95% CI	study
Egypt	115.55	5.93-2250.57	Fawzy 2022
	11.23	3.10-40.71	Abdelrahman 2024
Turkey	2.66	1.19–5.97	Deniz 2023
Poland	4.87	2.37–10.01	Kwiakowska 2019
China	16.48	8.68–31.51	Guo 2016
Taiwan	3.44	1.89–6.23	Lin 2017
United Kingdom	1.06	0.73–1.54	McBeth 2022
United States	1.7	1.30–2.23	Morse 2023
Finland	1.75	0.67-4.59	Belt 2009

Figure (3) Map of Insomnia Odds Ratios (ORs) for RA by Country Countries included: Egypt, Turkey, Poland, China, Taiwan, United Kingdom, United States, Finland. Accompanying table: Provides country-specific odds ratios (ORs), 95% confidence intervals (CIs), and associated studies. Map powered by Bing.

Results: The literature search yielded 1,273 articles. We included 25 in the qualitative synthesis and 14 studies in the meta-analysis, encompassing 546,822 and 41,565 patients, respectively. Nine studies explored the association between insomnia and RA. Both fixed- and random-effects models showed significantly higher odds of insomnia in RA patients compared to controls (OR: 2.21; 95% CI 1.85 – 2.64, $p < 0.00001$) and (OR: 3.92; 95% CI 1.59 – 9.7, $p = 0.008$), respectively, with considerable heterogeneity. Sensitivity analysis revealed that RA patients had nearly seven times higher odds of experiencing insomnia (OR: 6.82; 95% CI: 2.32–20.1, $p = 0.006$). Five studies compared insomnia in RA patients based on disease activity. Patients with moderate/high disease activity had higher odds of insomnia (OR: 1.76; 95% CI 1.29–2.39, $p = 0.0004$). RF +ve RA patients had higher but not statistically significant odds of insomnia (OR 1.12; 95% CI 0.74–1.71, $p = 0.59$) (Fig. 2). Among the countries with insomnia in both the RA and control groups, China had the highest odds of insomnia (OR: 16.48; 95% CI 8.68 – 31.51) and UK had the lowest odds (OR: 1.06; 95% CI 0.73 – 1.54) (Fig. 3).

Conclusion: This meta-analysis is the first to assess the association between RA, high disease activity, and insomnia, revealing that RA patients had almost 4 times higher the odds of insomnia than controls and patients with moderate/high disease activity had nearly double the odds of insomnia than those with low/remission disease activity. These findings underscore the need for greater awareness among patients and healthcare providers, as well as the importance of developing targeted interventions to improve both sleep and disease management in RA. Further large-scale studies are needed to better understand the relationship between RF and insomnia in RA patients.

Abstract Number: 1318

Diagnostic Delay in Rheumatoid Arthritis and its Impact on Radiographic Outcomes: A Systematic Review and Meta-analysis of 100,066 Patients

Mohamed Abdelsalam[1], Menat Alla Ayman Ali Mahdy[2], Bassant Elaraby Elsayed Badwy[2], Maryam Lasheen[3], Omar Sameh Nabil El Sedafy[1], Hadeer Hafez[4] and Mohamed Reda Awad[5], [1]Misr University For Science and Technology, 6 october, Al Jizah, Egypt, [2]Misr University For Science and Technology, Nasr City, Al Qahirah, Egypt, [3]Misr University For Science and Technology, Helwan, Al Qahirah, Egypt, [4]6th October University, 6 october, Al Jizah, Egypt, [5]Al Azhar University, Cairo, Egypt, Giza, Al Jizah, Egypt

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Timely diagnosis is the cornerstone of effective rheumatoid arthritis (RA) management, with early treatment shown to significantly improve outcomes through a treat-to-target strategy. While diagnostic delay has been well-characterized in axial spondyloarthritis (axSpA), there remains a significant research gap in understanding diagnostic delays specific to RA, causing many patients to miss the critical "window of opportunity" to prevent irreversible joint damage. This study aims to evaluate the extent of diagnostic delay in RA across multiple countries and examine its impact on radiographic joint damage, with emphasis on erosive outcomes.

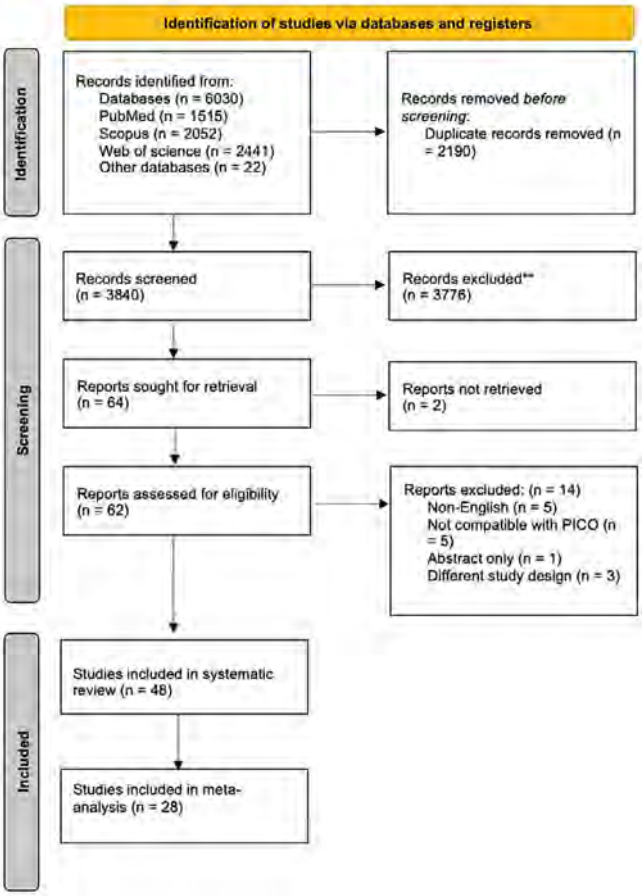

Figure (1) PRISMA Flow Chart Illustrating Search Strategy and Selection of Included Studies

Figure (2) Forest Plots of Diagnostic Delay and Radiographic Damage Prevalence in Rheumatoid Arthritis (RA). (A) Mean Diagnostic Delay (Months): Studies included: Albuquerque 2023, Badsha 2008, Barnabe 2014, Chan 1994, Cho 2019, da Rocha Castelar-Pinheiro 2018, de Albuquerque 2023, Fazaa 2022, Hussain 2016, Iacovantuono 2024, Ibn Yacoub 2012, Jain 2023, Khan 2025, Kim 2017, Naeem 2021, Ndongo 2009, Rodríguez-Polanco 2011, Rosa 2020, Sakr 2023, Sørensen 2015, Teh 2008, Tillmann 2013, Turkcapar 2006, Xiang 2021, Zafar 2012. Overall: Pooled mean diagnostic delay = 31.92 months (95% CI: 27.48–36.37), with considerable heterogeneity (I2 =100% I2 =100%, Tau2=122.2). Test for overall effect: Z= 14.09 (P < 0.00001) Z=14.09(P<0.00001). (C) and (B) Prevalence of Radiographic Damage (Random- and Fixed-Effects Models): Random-effects model: Pooled prevalence = 0.51 (95% CI: 0.43–0.59), with considerable heterogeneity (I2 = 96.16%) I2 =96.16%, Tau2= 0.132). Fixed-effects model: Pooled prevalence = 0.55 (95% CI: 0.54–0.56). Studies included: Badsha 2008, Chitins 2013, Cho 2019, Da Rocha Castelar-Pinheiro 2018, Fazaa 2022, Gomes 2018, Kim 2017, Ndongo 2009, Riad 2020,Rosa 2020, Sakr 2023. CI, confidence interval; RA, rheumatoid arthritis; Tau2 , between-study variance; I2 , heterogeneity index.

Methods: We systematically searched PubMed, Web of Science, and Scopus from inception until April 5th, 2025 following PRISMA guidelines (Fig.1) for observational studies reporting diagnostic delay and radiographic outcomes in RA. Studies were included if RA diagnosis was confirmed by a rheumatologist according to a classification criteria. Diagnostic delays were extracted if reported as mean (SD) or median (IQR). Meta-analyses were conducted for the pooled mean diagnostic delay and prevalence of radiographic damage in delayed diagnosis patients. Heterogeneity was assessed using I^2 statistics following Cochrane guidelines.

Results: A total of 48 studies were identified encompassing 100,066 participants of which 28 were included in the meta-analysis encompassing 15,226 participants. The pooled mean diagnostic delay was 31.92 months (95% CI: 27.48, 36.37) with considerable heterogeneity (I^2 = 100%, τ^2 = 122.29) (Fig. 2). Radiographic outcomes, primarily bone erosions, were reported in a subset of studies. The pooled proportion of patients with radiographic joint damage was 51.4% (95% CI:

Singapore	75	5.47	3.70-7.23

Figure (3) Map of Mean Diagnostic Delay in Months for RA by Country Countries included: United Arab Emirates (UAE), Canada, United States, South Korea, Italy, Morocco, India, Pakistan, Venezuela, Argentina, Denmark, Malaysia, Brazil, Turkey, Tunisia, Saudi Arabia, Senegal, Egypt, UK , and Singapore. The accompanying table provides sample size, mean delay, and 95% CI for each country. Map powered by Bing.

43.3%, 59.5%), with considerable heterogeneity (I^2 = 96.16%) (Fig. 2). There was marked geographic variation in diagnostic delay, with reported mean delays ranging from 5.47 months in Singapore to 120.5 months in Brazil (Fig. 3).

Conclusion: This is the first systematic review and meta-analysis to evaluate diagnostic delay in RA. It revealed a significant mean diagnostic delay, with over half of the patients exhibiting radiographic erosions. These findings highlight critical gaps in early disease recognition, which hinder the implementation of the treat-to-target approach and contribute to irreversible structural damage. The development of clear diagnostic criteria and expansion in the use of diagnostic technologies such as ultrasonography are vital to facilitate earlier detection.

Forest plot of the meta-analysis of rheumatoid arthritis in patients with vitiligo

Background/Purpose: Vitiligo is associated with many autoimmune diseases, but its association with rheumatic disease has not been well-defined. Therefore, we conducted a systematic review and meta-analysis to study the association of vitiligo and occurrence of rheumatoid arthritis.

Methods: A comprehensive literature review was conducted by searching for published

articles indexed in Pubmed, Embase, Google Scholar, and MEDLINE databases from inception through

January 2025. Identify all observational studies that compared the incidence or risk of developing rheumatoid arthritis (RA) in vitiligo patients compared to non-vitiligo. Pooled risk ratio (RR) and 95% confidence interval (CI) were calculated using a random-effect model, DerSimonian and Laird. Publication bias was analyzed with the Egger test.

Results: A total of 262 articles were identified. Following PRISMA for study selection, 6 studies fulfilled the inclusion criteria and were included in the meta-analysis. The risk of developing rheumatoid arthritis among vitiligo patients was significantly higher than in non-vitiligo patients with the pooled RR of 1.47, 95% CI 1.13-1.91: I^2 92.42%. Publication bias analyzed by the Egger test showed no small-study effects with p value of 0.83.

Conclusion: This analysis found that vitiligo is associated with a higher risk of developing rheumatoid arthritis. Further investigation is required to determine the causal relationship.

Table 1. Risk factors for DVT in patients with RA

Parameter	HR (CI)
Age (years) per 10-year increase	1.52 (1.31-1.76)
Obesity (BMI≥30 kg/m²)	1.86 (1.26-2.75)
Charlson comorbidity index	1.17 (1.06-1.28)
Rheumatoid Nodules*	2.88 (1.86-4.47)
Severe extra-articular manifestations of RA*	2.67 (1.42-5.03)
Biologic use*	2.36 (1.22-4.55)

* w/in the first year of meeting RA criteria

Background/Purpose: Venous thromboembolism (VTE) is more common in patients with rheumatoid arthritis (RA) and can present as deep vein thrombosis (DVT) or pulmonary embolism (PE). The changing risks of VTE in patients with RA over time and in relation to RA disease characteristics and treatments have not been comprehensively studied in longitudinal population-based cohorts. We aimed to estimate the risk of incident VTE (PE and DVT) in patients with RA vs the general population, to identify risk factors for VTE, mortality after VTE and time trends of VTE in RA.

Methods: This retrospective population-based cohort study included residents of a geographically defined area, meeting the 1987 ACR RA criteria in 1980-2019 and comparators from the same population with similar demographics. DVT/PE were identified by >2 ICD 9/10 codes >30 days apart and confirmed by manual record review. Cox proportional hazards models were used to compare incident VTE in RA vs. non-RA cohort, adjusting for demographics, smoking and obesity. Cumulative incidence of DVT, PE and total VTE was estimated, adjusting for competing risk of death. Cox models were used to examine risk factors for VTE in RA and to compare mortality in RA vs non-RA.

Results: 2818 individuals were included: 1409 with RA (62% RF/CCP-positive) and 1409 without RA, mean age 55.9 years, 68% women in both groups. Mean follow-up: 14.0 and 14.9 years in the RA and non-RA cohort respectively. DVT developed in 105 and 52 people with and without RA respectively. PE developed in 84 and 55 people with and without RA respectively. Persons with RA had a significantly increased risk of incident DVT (HR 2.26, 95%CI 1.62-3.17) and PE (HR 1.61, 95%CI 1.14-2.27). There was a significant difference in RA as a risk factor for VTE in two of the decades: 1980-1989 (HR 1.57; 95%CI 0.86-2.89), 1990-1999 (HR 2.68, 95%CI 1.55-4.63), 2000-2009 (HR1.80, 95%CI 1.13-2.86), 2010-2019 (HR 1.74, 95%CI 0.95-3.17). There was a significant increase in PE risk in both persons with RA onset after 2000s vs before 2000s (HR 2.00, 95%CI 1.21-3.32) and in the non-RA cohort (HR 2.70, 95%CI 1.38-5.28). Adjusted for age, sex, and calendar year, risk factors for DVT in RA included age, BMI >30 kg/m2, Charlson comorbidity index, rheumatoid nodules, severe extra-articular manifestations, and treatment with biologic in first year (Table 1). Risk factors for PE in RA included age, current and former smoking, BMI >30 kg/m2, rheumatoid nodules, large joint swelling, and

Table 2. Risk factors for PE in patients with RA

Parameter	HR (CI)
Age (years) per 10-year increase	1.53 (1.29-1.81)
Smoking status	
Current	2.16 (1.17-3.99)
Former	2.24 (1.36-3.71)
Obesity (BMI≥30 kg/m²)	2.29 (1.48-3.53)
Rheumatoid Nodules*	2.14 (1.26-3.63)
Large joint swelling*	1.66 (1.04-2.66)
Any remission visit*	0.47 (0.23-0.94)
Biologic use*	2.87 (1.46-5.62)

treatment with biologic in first year. Remission in the first year was associated with lower PE risk (Table 2). Patients with RA were more likely to die following VTE (HR 1.52, 95%CI 1.04-2.21), adjusting for age, sex and year of VTE.

Conclusion: The risk of DVT and PE, and mortality following any VTE event were significantly increased in patients with RA vs non-RA. Several RA disease characteristics were associated with increased risk of DVT and PE. Remission was associated with reduced PE risk, underscoring benefits of tight control of RA disease activity. Despite recent RA treatment advancements, the risk of VTE in RA did not decline after 2000s, like the non-RA population trends. Better understanding of these indicators presents future research areas to improve care of patients with RA at risk of VTE.

Abstract Number: 1321

Efficacy and safety of janus kinase inhibitors in diffuse interstitial lung disease in rheumatoid arthritis. Systematic review

Olga Compán[1], Marta Ibañez[2], Olga Martínez[3], Carolina Cristina Chacón[4], Ricardo López Pérez[3], Borja Felices López[3], Belén Miguel Ibáñez[3], Laura Blanco[4], Sergio Cimadevila Santiago[3], Ana Isabel Turrión Nieves[3], Manuel Cipriano Martin Martinez[3], Cristina Hidalgo Calleja[4], Carlos Montilla[4] and Susana Gómez[4], [1]Rheumatology Service, University Hospital of Salamanca, Carbajosa de la Sagrada, 37191, Spain, [2]Hospital Universitario de la Santa Creu i Sant Pau, Barcelona, Catalonia, Spain, [3]Hospital Universitario de Salamanca, Salamanca, Castilla y Leon, Spain, [4]Rheumatology Service, University Hospital of Salamanca, Salamanca, Castilla y Leon, Spain

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Interstitial lung disease (ILD) is a relatively common serious extra-articular complication in rheumatoid arthritis (RA). Although there have been great advances, we do not have strong evidence of the efficacy of the different drugs in the treatment of this complication, which is even scarcer compared to janus kinase inhibitors (JAKi).

To systematically evaluate the evidence published in the literature on the efficacy and safety of JAKi in the treatment of RA-associated ILD.

Methods: Literature searches were carried out in the Pubmed, Cochrane Library, Embase and Scopus databases between 01/01/2019 and 01/07/24, according to the Cochrane Manual and the PRISMA guidelines. A combination of the terms and their synonyms "janus kinase inhibitors", "interstitial lung disease" and "rheumatoid arthritis" were used. Two independent reviewers participated, using a third if there was no agreement.

Results: Of a total of 387 references obtained in the initial search, a total of 10 original, 8 retrospective and 2 prospective studies were finally included, including 4 communications. We found no randomised trials, meta-analyses or systematic reviews. Tables 1 and 2 show the characteristics of the included studies, demographic data and clinical characteristics of the patients. The mean age range of the patients oscillated from 59 to 74 years, with a variable percentage of women, generally close to 60%. The follow-up range was from 6 to 36 months. The time of evolution of RA in the included patients varied between 7 and 16 years, with positivity for rheumatoid factor (RF) and anti-citrullinated peptide antibody (ACPA) greater than

80% in most cases. The patterns of ILD reported are highly variable, with the first in frequency being usual interstitial pneumonia (UIP) in most studies (up to 58%), followed by non-specific interstitial pneumonia (NSIP). The most frequently used JAKi were tofacitinib and barititinib, which were prescribed as monotherapy in more than half of the patients (60-100%). The methods of assessment of the ILD were highly variable, pulmonary function tests are included (PFT) and high-resolution computed tomography (HRCT). Improved or stabilized HRCT images in more than 80% of patients. Regarding PFT, stabilization was achieved in more than 70% of patients, with a worsening of carbon monoxide difussion capacity test (DLCO) in only 1 study. Only 2 cases of acute exacerbation of ILD were reported in one study, with 1; the rest of the adverse events

Table 2. Characteristics of the included studies

Author, Year	Study design/ follow up; N	Pulmonary function test results	HRCT results	Overall result	Security	Conclusions
Tsuji, A., 2024	Retrospective case-control study at 1 centre. 21 months. (2015–2020) N=21 total.	NS	Significant improvement of the GGO with TAKi (p=0.03), not in fibrosis or in the two parameters with ABT	IMPROVEMENT	ABT and TAKi N=7 No acute exacerbations of ILD.	JAKi is as safe and effective as ABT. There are no differences in persistence (p=0.716), pulmonary complications (p= 0.465) or reasons for discontinuation.
Tanikella, M., 2022	Retrospective multi-at 1 centre. 18 months. N= 51 (TJAKi: 44/ABA)	FVC, ABT pre: 81.38 ± 4.40; post: 82.25 ± 21.07/ JAKi pre: 81.18–5.07; post: 79.10 9– 14.02. DLCO ABT: pre: 60.89 ± 8.2; post: 61.26 ± 11.23. JAKi pre: 59.72 ± 8.36; post: 60.25 ± 12.04.	No statistically significant changes in fibrosis on HRCT. Just in ABA, showed stability or improvement of RA-ILD in 83.9% and 88.6% of patients	STABILITY / IMPROVEMENT	NS	JAKi or ABA were related to the stability or improvement of RA-ILD in 83.9% and 88.6%. The duration of RA is the only variable associated with worsening of RA-ILD on linear mixed with JAKi.
Valero-Juliano, J. A., 2022	Retrospective study at 1 centre. 24 months, until 2020. N= 17	FVC pre: 80% ± 19.03; 1111; post 94% (87–107), DLCO pre: 80% (70-87.5); post: 85% (74-87)	10 patients HRCT available. N= 9 stable (53%), improvement 2 (9%)	STABILITY / IMPROVEMENT	5%	Good performance of JAK (81–10%), the most frequent cause of discontinuation was Non Failure. It was found kept lung function stable
Serrano-Cumplido, A., 2023	Retrospective study. Multicenter study., 37 months N= 37 (33 BAR)	FVC pre: 87±22, DLCO pre: 71 ± 23. Stabilization in the first 12 months	HRCT available (improvement/stabilized 82%	STABILITY / IMPROVEMENT	N= 1 Interventions= due to pneumonia. No acute exacerbation of ILD	JAKi, especially BAR may be useful and safe to control loss, and relax disease in RA-ILD .
Umeda A. 2023	Retrospective study at 1 centre. 2.8 years (2014– 2022) N= 50	NS	Increase in FC reticular opacities more in 8 (16%) in TJAKi(20) 5 vs 0 (0%) JAKi (p= 0.01)	STABILITY	NS	Worsening on HRCT , particularly reticular opacities, less in the period with JAKi=5, (16%) vs DMARDs (8 –40%) JAKi did not stabilize GGO worse, rather it could stabilize it.
Kobayasi T., 2022	Prospective study. Multicenter study. 12 months. N= 41 RA-ILD /87 RA no ILD	RA-ILD: increase FEV1 y FVC statistically significant of FEV1 pre0 and post: 82.11 ± 82.44, FVC pre0 and post: 83.6% ± 82.8. Deterioration FVC>10% in 7 (11.7%) *Clinical deterioration due to no significant clinical improvement (dyspnea in 44.6% patients)	NS	STABILITY	Infections 6.3/100 patients year RA-ILD, 2.4/100 patients year RA no ILD. Infections: same group: exacerbations RA-ILD 23%, in RA no ILD 6.4%.	Statistically significant increase in both FEV1 and FVC in the RA-ILD group; however, not considered clinically significant.
Mochizuki T. 2020	Retrospective study at 1 centre. 1 year (2017 – 2020). Study RA-ILD subgroup. ABT19/ JAKi 21	NS	1) ILD improved, defined by HRCT ABT 2 (10.5%) VS JAKi 3 (14.2%) p= 0.011)	STABILITY		No significant difference was observed in the deterioration of known ILD between the ABT and JAKi groups (p = 0.011)
Navarro F., 2021	Retrospective study. Multicenter study. 19.1 months (2018– 2022). N= 43	FVC: stable 22/28 (78.57%); improvement 3/28 (10.71%); worsening 3/28 (10.71%); Not significant. DLCO stable 18/25 (72%) improvement 2/25 (8%); worsening 5/25 (20%). Slight decrease in DLCO if significant.	Stability 37/43 (86.05%), deterioration 4/43 (9.30%) and improvement 2 (4.65%).	STABILITY	Adverse events with BAR: 1 (4.76%) severe urinary infection, and 2 (9.52%) severe exacerbations of ILD, 1 of them death.	JAKi can stabilize more than 2/3 of patients (about 80%) on DLCO as FVC. In HRCT stability or improvement in 80%, with no differences between JAKi.
Bejarano, M. F., 2019	Retrospective study. Multicenter study 12 months. N= 15	FVC: start <80% 3 patients and >80% in 2. At 12 months, 4 FVC >80%, 10= 4 (27%) grade 3-4 dyspnea at onset. Improvement in dyspnea scale in 8 patients, rest stable.	No progression was observed on HRCT at 12 months in any of the patients evaluated.	STABILITY / IMPROVEMENT	NS	No patient had worsening of dyspnea, with improvement in some. The pulmonary function test were stable, and in 4 patients there was improvement. No progression was observed on HRCT in any patient.
Wang, S., 2023	Prospective study at 1 centre. At least 6 months (2020– 2022). N= 78. TOF+IGU: 24 IGU+ DMARDs: 26; DMARDs 28	DLCO decreased in all groups although without statistically significant differences. FVC does increase significantly (P = 0.013) in the TOF+IGU group compared to DMARDs.	TOF+IGU slight progress GGO in HRCT, without significant differences Vs DMARDs (P = 0.359). Fibrosis on HRCT significant improvement, compared to DMARDs (P = 0.031). IGU+ DMARDs as DMARDs alone, worsening fibrosis	IMPROVEMENT	1 herpes zoster in group TOF+IGU	The TOF+IGU group shows a statistically significant improvement with respect to the UIP pattern at HRCT (P = 0.031), and although the ground glass score slightly increases, this is not significant. There is also a significant increase in FVC compared to DMARDs (P = 0.013).

JAKi= janus kinase inhibitors, DMARDs= conventional synthetic disease-modifying drugs, No sample size, HRCT= thoracic high-resolution computed tomography, ABA: Abatacept, (who not specified, RA= Rheumatoid arthritis , ILD= interstitial lung disease, TOF= tofacitinib, BAR= baricitinib, %FVC= predicted forced vital capacity, %DLCO= predicted diffusing capacity for carbon monoxide, FEV1= Maximum expiration volume in the first second of forced expiration, DMARDs= biological disease-modifying drugs, MTX= methotrexate, UIP= Usual Interstitial Neumonia, IGU= ignatinod, GGO= ground glass opacities, pre=pre-treatment, post= post-treatment. This table has been done by myself.

(AEs) are comparable to what is expected with the safety profile of JAKi, although a higher incidence of such AEs is reported in patients with AR-ILD compared to those with RA without ILD.

Conclusion: JAK inhibitors could be a useful treatment strategy in maintaining stability in RA-associated ILD, including improvement.

The low prevalence of ILD during treatment with JAKi suggests that perhaps we should rethink the treatment algorithm in rheumatoid arthritis, even more so in young patients, without contraindications and at risk of developing ILD.

Prospective, randomized, controlled studies are needed to confirm this hypothesis.

High Rheumatoid Factor Titers and Biologic Persistence in RA: Beyond TNF Inhibitors

Sara Salas Santamaría[1], Marta Chao Moreira[2], Manuel Juárez[3], Marta Novella-Navarro[2], Pilar Nozal[2], Ana Martínez[2], Carolina Tornero[4], Cristina Bohorquez[5], Ana Sánchez[2], Carmen Cámara[2], Eduardo López[2], Eugenio de Miguel[2] and Chamaida Plasencia-Rodríguez[2], [1]Hospital Universitario La Paz, Miranda de Ebro, Castilla y Leon, Spain, [2]Hospital Universitario La Paz, Madrid, Spain, [3]Rheumatology Unit, Hospital Universitario La Paz, IdiPAZ, Madrid, Spain, [4]Hospital La Paz, Madrid, Spain, [5]La Paz University Hospital, Alcalá De Henares, Spain

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid factor (RF), an autoantibody targeting the Fc portion of IgG, is one of the most studied biomarkers in rheumatoid arthritis (RA). High RF titers have been associated with a more aggressive disease course and reduced efficacy of certain biologic DMARDs (bDMARDs), particularly monoclonal anti-TNF agents. RF levels ≥203 IU/mL have been linked to lower serum drug levels and reduced treatment persistence in these therapies. However, this association has not been observed with pegylated TNFi, and its impact on non-TNFi monoclonal antibodies remains unclear.

Methods: We conducted a retrospective longitudinal study of RA patients from our hospital treated with Certolizumab (CZP), Rituximab (RTX), and/or Tocilizumab (TCZ) as up to third-line therapy. Sociodemographic data, use of csDMARDs, bDMARDs, corticosteroids, RF levels at bDMARD initiation, and baseline and 6-month clinical and analytical inflammatory markers were collected (ET approval PI 6366). Drug discontinuation dates and reasons, up to December 31, 2024, were recorded. Patients were grouped by bDMARD received, and comparisons were made using Chi-square or Fisher's exact test for categorical variables, and ANOVA or Kruskal-Wallis for continuous variables. Kaplan-Meier analysis was used to assess drug survival, overall and stratified by RF levels (High; HL ≥203 IU/mL vs. Low; LL < 203 IU/mL).

BMI: Body mass index; CRP: C-reactive protein; RF: Rheumatoid factor; ACPA: Anti-citrullinated peptide antibodies; DAS28: 28-joint Disease Activity Score 28; TJC: Tender joint count; SJC: Swollen joint count; SDAI: Simplified Disease Activity Index; HAQ: Health Assessment Questionnaire; DMARD: Disease- modifying drug; MTX: Methotrexate; bDMARDs: Biologic disease- modifying drugs; TNFi: Tumor Necrosis Factor inhibitors.

Results: A total of 186 patients with RA were included: 43 (23%) received CZP, 46 (25%) RTX, and 97 (52%) TCZ, with no significant sociodemographic differences between groups (Table 1). Baseline DAS28 and SDAI scores were comparable across treatments. In addition, näive patients to b/tsDMARDs were more frequent in CZP group (81% in CZP vs. 19% in RTX vs. 45% in TCZ, p< 0.001). At 6 months after the initiation of bDMARD, patients with high RF levels treated with TCZ showed higher disease activity (DAS28, SDAI) than those with lower RF levels (Table 2), whereas no statistically significant differences in activity were observed in the other treatment groups based on RF levels. Overall, 66% discontinued treatment (22 CZP, 30 RTX and 71 TCZ); 36% due to inefficacy (10 CZP, 5 RTX and 29 TCZ). In survival analysis, RF levels did not

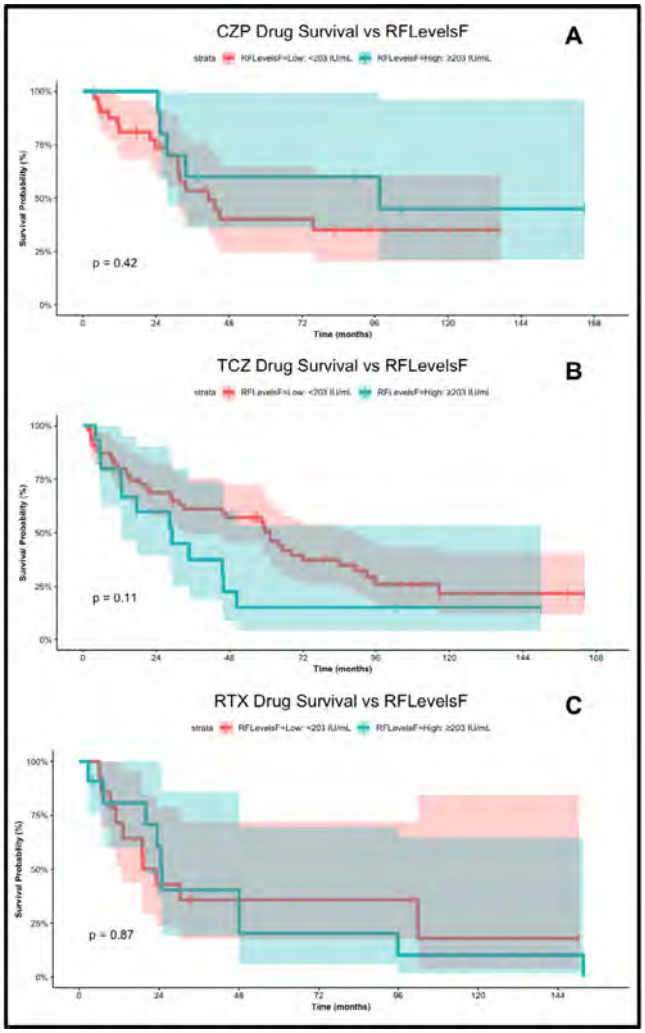

Figure 1. Survival drugs analysis (global) vs RF levels. A: Certolizumab Drug Survival vs RFLevels; B: Tocilizumab Drug Survival vs RFLevels; C: Rituximab Drug Survival vs RFLevels

influence drug persistence in CZP, with a similar curve in both subgroups regardless of RF levels (99.9 in HL vs. 76.9 in LL months, p=0.42) (Figure 1A). The same occurs in the RTX group (Figure 1C), even showing a slightly higher median in the group with higher RF titres (45.1 in HL vs. 55.1 in LL months, p=0.87), consistent with the molecule's mechanism of action. However, when looking at the patients treated with TCZ (Figure 1B), the drug survival mean tended to be lower in patients in the group with RF ≥203 although no statistically significant (46.1 in HL vs 70.8 in LL months, p=0.11).

Conclusion: Patients with RF levels above 203 IU/mL did not show significant differences in drug survival for CZP or RTX. Nevertheless, TCZ showed a poorer short-term clinical response and a trend toward shorter drug survival and in patients with high RF levels. These findings suggest that RF levels might influence the persistence and effectiveness of certain bDMARDs, particularly TCZ, and warrant further investigation in studies with larger sample sizes.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Interleukin (IL)-6 plays an important role in the pathogenesis of depression in rheumatoid arthritis (RA) patients. IL-6 inhibitors used to treat patients with RA may also have an antidepressant effect.

The objective of this study is to evaluate the effectiveness of 24-week IL-6 inhibitor therapy with olokizumab (OKZ) in combination with or without psychopharmacotherapy (PPT) in patients with moderate to high RA activity.

Methods: According to ICD-10, a psychiatrist diagnosed varying severity of depression (chronic or recurrent) in all patients during a semi-structured interview. At week 0, all patients were randomized using sequential numbers in a 2:2:1 ratio into one of three groups: in the group 1, patients received conventional synthetic disease modifying antirheumatic drugs

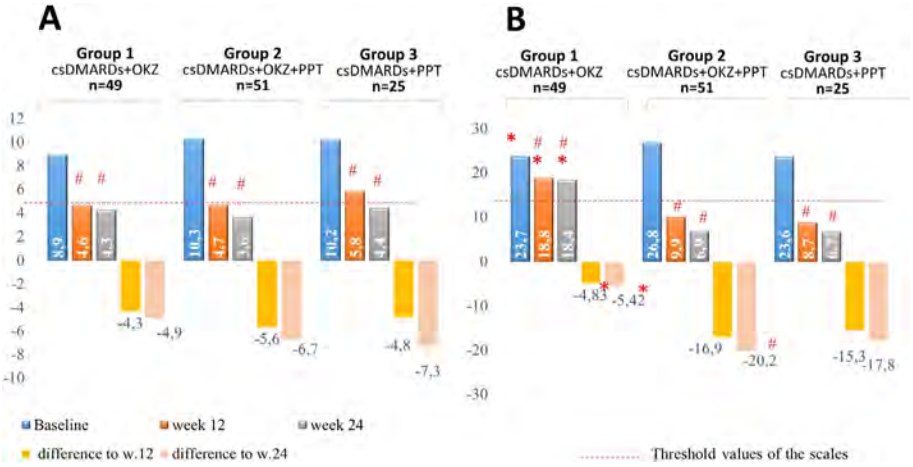

Figure 1. The dynamics of depression severity depending on therapy Note: A, The dynamics of depression severity according to the PHQ-9 self-questionnaire, score B, The dynamics of depression severity according to the MADRS scale, score; * p<0,05 comparison between groups; # p<0,05 comparison between baseline and weeks 12/24 in the group; csDMARDs - conventional synthetic disease modifying antirheumatic drugs; OKZ – olokizumab: PPT - psychopharmacotherapy

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. The dynamics of anxiety severity and the proportion of patients without anxiety according to the HAM-A scale by week 24 Note: A, The dynamics of anxiety severity on the Hamilton scale, score; B, The proportion of patients with clinically significant anxiety on the Hamilton scale; * p<0,05 comparison between groups; # p<0,05 comparison between baseline and weeks 12/24 in the group; csDMARDs - conventional synthetic disease modifying antirheumatic drugs; OKZ – olokizumab: PPT - psychopharmacotherapy

(csDMARDs)+OKZ 64 mg subcutaneously once every 4 weeks (q4w) (n=49); in the group 2, patients received csDMARDs +OKZ 64 mg subcutaneously q4w along with PPT (n=51); in the group 3, patients received csDMARDs + PPT (n=25). The study duration was 24 weeks. The severity of depression was assessed using the PHQ-9 and MADRS scales; while anxiety was assessed using the HAM–A scale. Projective experimental psychological techniques were also used.

Results: A total of 125 patients with RA were included, 102 (81,6%) of them being women. The average age of the patients was 48,5±12,6 years; the majority of the patients (86.4%) had high RA activity and stable 12-week therapy with csDMARDs was ineffective . Additionally, 34 (27,2%) patients had shown inefficacy of one or more biological DMARDs. After 12 and 24 weeks of therapy, a significant decrease in the severity of depression and anxiety was observed in all patients' groups. However, the differences between the final and initial values of the scales filled in by a psychiatrist were statistically significantly greater ($p< 0.001$) in the groups of patients receiving PPT: in group 2 ($\Delta MADRS_{24-0}$=-20.2±6.57; $\Delta HAM\text{-}A_{24-0}$ =-13.2±5.68) and group 3 ($\Delta MADRS_{24-0}$=-17.8±4.73; $\Delta HAM\text{-}A_{24-0}$=-13.4±4.41), compared with group 1 ($\Delta MADRS_{24-0}$=-5.42±7.14; $\Delta HAM\text{-}A_{24-0}$=-4.58±6.80). There were no significant differences between the groups according to the PHQ-9 depression questionnaire (respectively, in group 1, $\Delta PHQ\text{-}9_{24-0}$=-4.89±4.87; in group 2, $\Delta PHQ\text{-}9_{24-0}$ =-6.73±4.97; in group 3, $\Delta PHQ\text{-}9_{24-0}$=-7.26±5.58), despite a greater decrease in the severity of depression in groups with

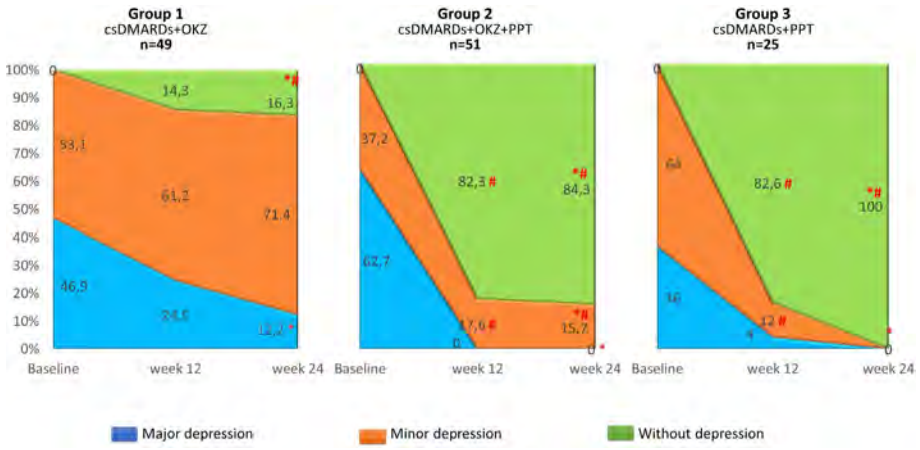

Figure 3. The dynamics of the incidence of major/ minor depression according to DSM-5 criteria depending on therapy Note: csDMARDs - conventional synthetic disease modifying antirheumatic drugs; OKZ – olokizumab: PPT – psychopharmacotherapy; * p<0,05 (comparison between baseline and week.24 in Groups); # p<0,001 (comparison between Group 1 and Groups 2-3)

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

PPT. According to a semi-structured interview with a psychiatrist and projective experimental psychological techniques, the proportion of patients without depression 24 weeks after the start of therapy was significantly higher in the groups receiving PPT: 84.3% in group 2, 100% in group 3, and 16.3% in group 1.

Conclusion: In patients with moderate/high RA activity and comorbid depression, OKZ without PPT can lead to a decrease in severity of depression in 51% of patients with RA, with complete regression of depressive symptoms observed in 16.3% of patients, mainly those with minor depression. OKZ therapy without PPT also reduces the severity of anxiety, but does not eliminate it completely. The combination of OKZ and PPT is optimal for achieving complete regression of depression and anxiety in this category of RA patients.

Similar Negative Effects of Fatigue on Physical Activity in Persons with Rheumatoid Arthritis and Healthy Controls: A Patient-Control Study

Maartje Cox[1], Kyra Theunissen[2], Kenneth Meijer[2], Annick Timmermans[3], **Sofia Ramiro**[4], Annelies Boonen[5] and Guy Plasqui[2], [1]Australian National Phenome Centre - Murdoch University, Booragoon, Western Australia, Australia, [2]Maastricht University, Maastricht, Netherlands, [3]Universiteit Hasselt, Hasselt, [4]Leiden University Medical Center, Bunde, Netherlands, [5]Maastricht University Medical Centre+ & Maastricht University, Maastricht, Limburg, Netherlands

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: People with rheumatoid arthritis (pwRA) are prone to fall short of the World Health Organization's physical activity (PA) recommendations due to perceived fatigue and pain. Given the high prevalence of fatigue and its impact on health-related quality of life and social participation, this study investigated objectively measured PA patterns and the association between PA and self-reported fatigue in pwRA compared to healthy controls (HC).

Methods: In this observational cross-sectional study, pwRA (DAS28 > 2.6) and HC wore a tri-axial accelerometer (ActiGraph wGT3X-BT, ActiGraph LLC) on one ankle for ≥4 days. Accelerometer-based outcomes included vector magnitude counts/min (square root of summed sagittal, frontal, and vertical axes' counts/min squared – primary outcome), step count, and time spent in moderate-to-vigorous intensity PA. Data were separated by day and time (weekday/weekend; daytime/evening) to investigate PA patterns. Fatigue severity was assessed using the Fatigue Severity Scale (FSS, 0–7). Associations between fatigue, RA status, and PA were examined using multilevel generalized estimating equations models (patient and day-timing as levels). Interactions between RA and fatigue were tested. Manual forward selection identified multivariable associations adjusted for confounders.

Results: Participants included 23 pwRA (20 females, age 52 (SD 13), FSS 4.7 (1.4)) and 18 HC (14 females, age 52 (11), FSS 2.1 (1.0)). Vector magnitude counts/min were lower in pwRA than HC at any time, with non-significant differences on weekday daytime (1534.3 (691.3) in pwRA vs 1802.6 (610.6) in HC), and larger differences on weekday evenings (880.7 (491.4) vs 1457.3 (572.7)) (Figure 1). Step count was also lower in pwRA (587 (226) vs 724 (224) steps/h), as was time spent in moderate-to-vigorous PA (1.6 (1.4) vs 2.7 (1.5) min/h). No interaction was found between fatigue and RA, indicating that

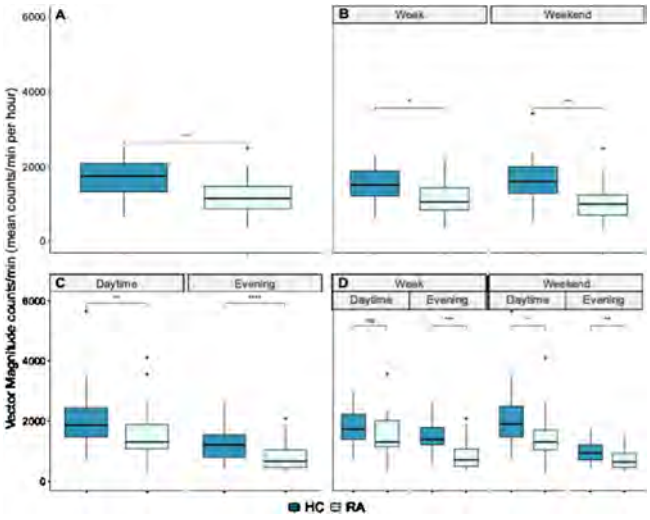

Figure 1: Vector Magnitude counts per minute (mean counts/min per hour) measured in rheumatoid arthritis patients (RA) and healthy controls (HC) overall (A), on weekdays as compared to the weekend (B), during the day and during the evening (C), and separated by day as well as timing of the day (D). ns p > .05, * p < .05, ** p < .01, *** p < .001, **** p < .0001

Table 1: Effect of RA vs HC on the Vector Magnitude Counts per Minute in univariable and multivariable Generalized Estimating Equations analyses

	Univariable model	Multivariable model
Variables	**Coefficient (95% CI)**	**Coefficient (95% CI)**
Age (years)	2.48 (-9.53; 14.50)	ns
Male vs Female	136.46 (-315.00; 587.91)	ns
BMI (kg/m²)	-47.14 (-78.60; -15.67)	-27.18 (-50.73; -3.62)
FFM (kg)	-6.20 (-24.68; 12.28)	ns
RA vs HC	-467.72 (-768.40; -167.05)	-330.63 (-650.45; -10.81)
FSS (0-7)	-117.06 (-216.04; -18.09)	-43.89 (-135.26; 47.48)
Weekend vs Week	-24.48 (-301.03; 252.07)	§
Evening vs Daytime	-724.93 (-945.42; -504.44)	§
Day-Timing:		
Weekend-Daytime	Reference	Reference
Weekday-Daytime	-123.89 (-509.31; 261.54)	-129.66 (-527.19; 267.87)
Weekday-Evening	-687.07 (-1059.60; -314.54)	-723.68 (-1091.19; -356.16)
Weekend-Evening	-942.19 (-1287.31; -597.07)	-970.77 (-1322.72; -618.82)

§Variables Weekend vs Week and Evening vs Daytime were not considered for the multivariable model, since the variable Day-Timing combines the information from both these variables

ns: variable not significant in the univariable model and not a confounder for RA vs HC and therefore not included in the multivariable model

BMI, Body Mass Index; FFM, Fat Free Mass; FSS, Fatigue Severity Scale

fatigue affected PA similarly in both groups. Likewise, no interaction between group and day-timing was observed, suggesting comparable daily PA patterns in pwRA and HC. RA was significantly and negatively associated with vector magnitude counts/min after adjusting for confounders (β = -330.63; 95% CI = -650.45 to -10.81; Table 1). In the multivariable model, lower vector magnitude counts/min was seen in pwRA, persons with higher fatigue severity (β = -43.89; 95% CI = -135.26 to 47.48), and in persons with higher BMI (β = -27.18; 95% CI = -50.73 to -3.62). BMI, RA presence, and fatigue were similarly negatively associated with step count and time spent in moderate-to-vigorous PA.

Conclusion: pwRA performed less objectively measured PA than HC. Fatigue was inversely associated with PA, with no differential impact between groups. Future research should examine the role of transient vs persistent fatigue, employability, inflammation, and medication use in PA participation. This may identify which patients are most at risk of falling short of PA guidelines and help design effective interventions.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: The mechanisms of heart failure (HF) risk in RA remain incompletely understood. HF with preserved ejection fraction (HFpEF) is over-represented in RA, which may be a result of chronic inflammation leading to cardiac remodeling and fibrosis. Matrix metalloproteinases (MMPs) are involved in extracellular matrix remodeling, upregulated in RA circulation and synovium, and associate with RA-interstitial lung disease, another fibrotic extra-articular manifestation in RA. We aimed to evaluate the association of plasma MMP concentrations with HF and HF subtype risk in RA.

Methods: In a multicenter, prospective cohort of US Veterans with RA, MMP-1, -3, -7, and -9 were measured from banked plasma at enrollment, using R-PLEX immunoassays (MesoScale Diagnostics). Analyte concentrations were log-transformed and standardized, categorized into quartiles, and dichotomized as high (quartile 4) vs. low (quartiles 1-3). Incident HF was defined as an outpatient HF diagnosis (2+ diagnostic codes at least 30 days apart), HF hospitalization or HF-related death in linked VA, Medicare, and National Death Index data. HF subtypes (HF with reduced EF [HFrEF] < 40%, HFpEF ≥50%) were defined using the most proximate left ventricular EF prior to or < 30 days after HF event (if prior EF was missing), extracted from clinical notes using a validated natural language processing tool. Participants without HF at baseline were

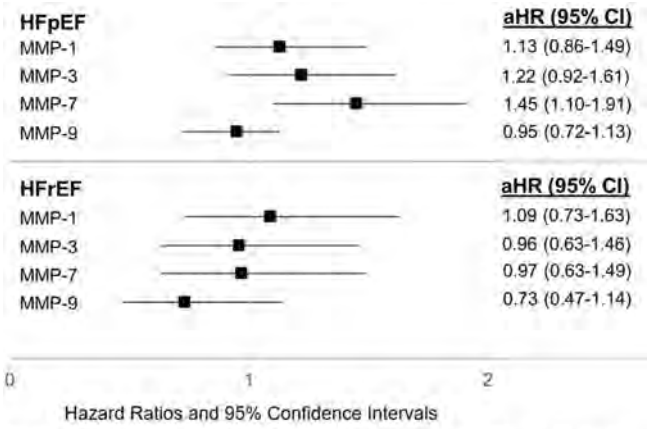

Figure 1. Association of high (quartile 4) vs. low (quartiles 1-3) matrix metalloproteinase (MMP) concentrations with HF subtypes in RA. Forest plot illustrating the association of plasma MMP concentrations with incident heart failure with preserved (HFpEF) and reduced (HFrEF) ejection fraction in RA. Estimates are hazard ratios adjusted (aHR) for age, sex, race, smoking status, body mass index, ischemic heart disease, hypertension, diabetes, and DAS28.

Table 2. Matrix metalloproteinase concentrations and risk of HF-related hospitalization or death in RA patients with prevalent HF

	Per 1 S.D.	High vs. low**
MMP-1	1.11 (0.88-1.41)	1.53 (0.98-2.38)
MMP-3	1.14 (0.88-1.47)	1.53 (0.94-2.48)
MMP-7	**1.40 (1.11-1.76)**	**1.91 (1.23-2.97)**
MMP-9	0.91 (0.73-1.15)	1.07 (0.66-1.72)

* Estimates are hazard ratios (95% CI) adjusted for age, sex, race, smoking status, BMI, ischemic heart disease, hypertension, diabetes, and DAS28 in Cox regression models restricted to RA patients with prevalent HF (N=349)
** High = quartile 4, low = quartiles 1-3
Bold denotes p value < 0.05

followed to incident HF, death, or end of study period (4/2022). The association of MMPs with incident HF and HF subtypes was estimated in multivariable Cox regression models adjusted for age, sex, race, smoking status, BMI, ischemic heart disease, hypertension, diabetes, and DAS28 at baseline. Among patients with prevalent HF, the association of MMPs with risk of future HF hospitalization and HF-related death was tested using similar multivariable Cox regression models.

Results: Among 2,855 participants without HF at baseline (mean age 63 years, 86% male, mean DAS28 3.5) 488 HF diagnoses (N=115 HFrEF, 246 HFpEF) were identified over a median follow up of 7 years. In fully adjusted models, MMP-7 was associated with incident HF risk (per 1 SD aHR 1.21 [1.09-1.35]; **Table 1**) in a dose-dependent manner (quartile (Q)4 vs. Q1 aHR 1.68 [1.27-2.22], p-for-trend < 0.01). This was driven by a stronger association with HFpEF (high vs. low aHR 1.45 [1.10-1.91]; **Figure 1**) compared with HFrEF (high vs. low aHR 0.97 [0.63-1.49]). While a trend toward higher HF risk was observed with higher MMP-1 (Q4 vs. Q1 aHR 1.26 [0.96-1.67], p-for-trend = 0.08) and MMP-3 quartiles (Q4 vs. Q1 aHR 1.24 [0.94-1.64], p-for-trend = 0.07), these were not significant (**Table 1**). Among patients with prevalent HF (N=349), MMP-7 was associated with future HF hospitalization and HF-related death (high vs. low aHR 1.91 [1.23-2.97]; **Table 2**).

Conclusion: MMP-7 was associated with incident HFpEF and a higher risk of HF hospitalization or HF-related death in RA patients with prevalent HF, independent of traditional risk factors and RA disease activity. These findings support MMPs may play a role in cardiac remodeling and dysfunction in RA. Continued research is needed to incorporate these findings into clinical risk stratification and HF prevention strategies in RA.

Abstract Number: 1326

Association Between Physical Function and Nutritional Status in Rheumatoid Arthritis Patients

Yasumori Sobue[1], Mochihito Suzuki[2], Yoshifumi Ohashi[3], Shuji Asai[2] and Shiro Imagama[2], [1]Sobue Orthopedic Clinic Yatomi, Aichi, Japan, [2]Nagoya University Graduate School of Medicine, Nagoya, Japan, [3]Aichi Medical University, Graduate School of Medicine, Aichi, Japan

SESSION INFORMATION

Session Date: Monday, October 27, 2025

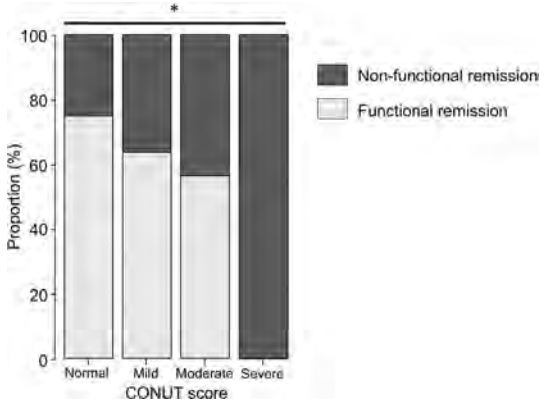
Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is a systemic inflammatory disease that primarily affects the joints but also has substantial implications for physical function. Persistent inflammation may contribute to malnutrition, which in turn can lead to muscle weakness and impaired physical function. While the association between inflammation and nutrition has been reported (1), few studies have examined how nutritional status relates specifically to physical function in RA. This study aimed to investigate the association between nutritional status and physical function in patients with RA.

Methods: Among the 686 patients seen between June and August 2024, this cross-sectional study included 613 RA patients with available background data, including Controlling Nutritional Status (CONUT) scores and Health Assessment Questionnaire-Disability Index (HAQ-DI). The CONUT score, calculated based on serum albumin, total cholesterol, and total lymphocyte count, is a simple and objective tool for assessing the nutritional status of RA patients (2). Nutritional status was classified as normal (0–1 points), mild (2–4 points), moderate (5–8 points), or severe (9–12 points), with a score of ≥2 indicating nutritional risk. Physical function was assessed using the HAQ-DI, with a score of ≤0.5 defined as functional remission. Multivariable logistic regression analysis was conducted to examine the association between nutritional risk and functional



Proportions of Patients with Functional Remission Across CONUT Score Categories. Functional remission was defined as a HAQ-DI score of ≤0.5. Nutritional status based on the CONUT score was classified as normal (0–1), mild (2–4), moderate (5–8), and severe (9–12). A P-value of <0.001 was determined using the Cochran–Armitage trend test.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

remission, adjusting for relevant background factors including age, disease duration, and the Clinical Disease Activity Index (CDAI).

Results: Among the 613 patients (74.2% female), 431 (70.3%) achieved functional remission. The prevalence of non-remission increased with the severity of nutritional risk: 25.2% in the normal, 36.3% in the mild, 43.8% in the moderate, and 100% in the severe CONUT categories (Figure). The mean age (functional remission/non-remission) was 67.1 ±13.2/72.1±13.7 years, disease duration was 12.1±9.2/16.9±11.4 years, CDAI was 3.7±5.2/11.8±9.6, and CONUT score was 1.21±1.23/1.62±1.55, all of which showed significant differences between the groups. Nutritional risk (CONUT score ≥2) was more prevalent in patients without functional remission than in those with remission (47.3% vs. 33.9%, $p < 0.001$). In multivariable logistic regression analysis adjusted for age, disease duration, and CDAI, nutritional risk was significantly associated with non-remission (odds ratio: 1.86, 95% CI: 1.19–2.91).

Conclusion: Nutritional risk was significantly associated with poor physical function in RA patients. Since physical function is a key determinant of quality of life in RA, early identification and management of nutritional risk may contribute to maintaining better function and improving overall outcomes. Nutritional interventions should be considered as part of comprehensive care in RA, especially for those not achieving functional remission.

Systematic Review of Mobility in Rheumatoid Arthritis with Digitally Measured Objective Assessment

Anna fishbein[1], Rachel Lawson[2], Veleka Allen[1], Xiaozhong Zhang[3], Laura Chambre[4], Stephen Ruhmel[1], Sophie Wilhelm[1], Fredric Marrache[5], Maria Wiekowski[1], Markus Kohlmann[6] and Jeffrey Curtis[7], [1]Sanofi, Morristown, NJ, [2]Sanofi, Earley, United Kingdom, [3]Sanofi, Chengdu, China (People's Republic), [4]Sanofi, Cambridge, MA, [5]Sanofi, Gentilly, France, [6]Sanofi, Frankfurt, Germany, [7]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with rheumatoid arthritis (RA) are less physically active than the general population, and these activity differences can be measured through digital devices. This systematic review examined various mechanisms by which mobility has been objectively measured in RA patients and highlighted findings on common digital endpoints related to mobility.

Methods: We performed a literature search using PubMed and Embase databases through August 2024 with search terms including mobility, physical activity, physical function, sedentary behavior, walking, and digital measurement technologies. After removing duplicates, 715 titles were screened, with 105 meeting inclusion criteria (Figure 1). Studies were categorized by primary aim: validation of digital technology, descriptive observational studies, assessment of interventions (e.g. initiation of RA treatment), and digital technology as a monitoring intervention itself. Technology used was assessed based on manuscript categorization.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

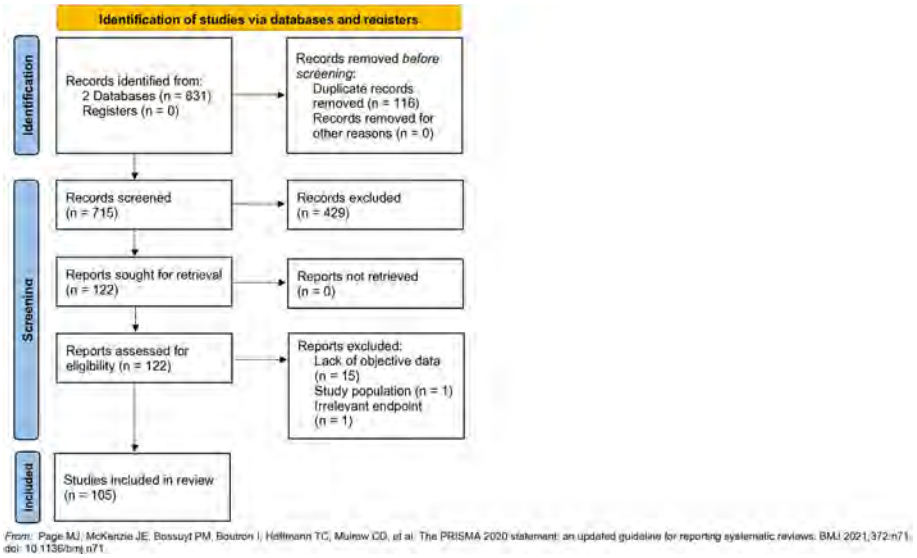

Figure 1: PRISMA 2020 flow diagram for new systematic reviews which included searches of databases, registers and other sources

Results: Among the 105 studies, 28 (26.7%) validated digital technology, 41 (39.0%) were descriptive observational studies, 30 (28.6%) assessed interventions, and 6 (5.7%) used digital technology as intervention. Accelerometers were the most commonly used digital device (n=54, 51.4%), followed by activity monitors (n=19, 18.1%), pedometers (n=6, 5.7%), and smartwatches (n=3, 2.9%). Commonly measured digital endpoints included daily step counts, sedentary time/behavior, and time spent in different physical activity intensities. RA patients showed greater sedentary behavior (9-10 h/day), and significantly less moderate-to-vigorous physical activity ($p < 0.001$) compared to matched controls (Belau MH, et al. 2024). Only 5-17% of RA patients met recommended physical activity guidelines (Bell K, et al. 2022, Khoja SS, et al. 2016). Patients with controlled disease showed greater physical activity than those with active disease (Barami T, et al. 2017). Physical activity was inversely related to fatigue (Rongen-van Dartel SA, et al. 2014) and positively associated with improved mood (Hegarty RSM, et al. 2015) and quality of life (Bell K, et al. 2022). Diurnal patterns revealed reduced activity in afternoons/evenings, with morning stiffness affecting early day mobility (Keogh A, et al. 2020, Prioreschi A, et al. 2013).

Conclusion: We identified numerous ways in which mobility is objectively measured in patients with RA by digital tools, with accelerometers as the predominant technology and step counts, sedentary time, and activity intensity as the key endpoints. Findings suggest that patients with RA are more sedentary and less active than healthy controls, with disease activity significantly influencing mobility patterns. Future work is planned to conduct a meta-analysis of findings described in this abstract.

Abstract Number: 1328

Mortality Trends of Hypertension in Patients with Rheumatoid Arthritis in the United States (1999–2020)

Rameez Qasim[1], Khadija Mohib[2], Muhammad Ali[3], Umm E Aimen Minhas[4], Abu-bakr Ahmed[5] and **Areeba Minhaj**[6], [1]Allama Iqbal Medical College Lahore, Lahore, Pakistan, [2]Kirk Kerkorian School of Medicine at UNLV, Las Vegas, NV, [3]Dow International Medical College, Karachi, Sindh, Pakistan, [4]Allama Iqbal Medical College, Lahore, Pakistan, [5]Kirk Kerkorian School of Medicine, Las Vegas, NV, [6]University of South Dakota, sioux falls, SD

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Hypertension is highly prevalent among patients with rheumatoid arthritis (RA) and significantly increases the risk of cardiovascular disease (CVD). Despite this established relationship, there is limited data on long-term mortality trends related to hypertension in patients with RA in the United States.

Methods: We used the CDC WONDER database to analyze mortality data from 1999 to 2020. Individuals aged 25 years and older who died with both hypertension and RA were identified using ICD codes I10–I15 (hypertension) and M06, M08.0 (rheumatoid arthritis). Age-adjusted mortality rates (AAMR) per 100,000 population were calculated. Joinpoint regression analysis was used to determine Average Annual Percent Change (AAPC), with statistical significance assessed via p-values. Mortality trends were stratified by gender, race/ethnicity, U.S. Census region, and urbanization level.

Results: Between 1999 and 2020, the age-adjusted mortality rate for individuals with both hypertension and RA increased from 3.9 to 14.0 per 100,000 population, with total deaths reaching 3,793 in 2020. Female mortality rates rose more sharply than male rates (AAMR 5.2 to 18.2 vs. 3.7 to 8.3), with AAPCs of -6.9 (95% CI: -7.3 to -6.6) and -6.3 (95% CI: -6.7 to -5.8), respectively. Nonmetropolitan areas had consistently higher mortality rates compared to metropolitan areas, increasing from an AAMR of 5.0 to 17.4 versus 3.7 to 13.4 (AAPC -6.3 vs. -7.0). Regionally, the South had the highest mortality rate in 2020 (AAMR 12.4), while the Northeast had the lowest (AAMR 8.9). Among racial and ethnic groups, Black or African American individuals had the highest mortality (AAMR 15.6; AAPC -6.7), followed by Hispanics or Latinos (AAMR 16.4; AAPC -8.2) and Whites (AAMR 10.4; AAPC -6.5). Mortality increased notably in adults aged 75 and older in 2020, likely influenced by the COVID-19 pandemic.

Conclusion: Hypertension-related mortality in patients with rheumatoid arthritis has risen significantly over the past two decades, with notable disparities across gender, geographic regions, racial and ethnic groups, and urbanization status. These findings underscore the need for targeted interventions and improved cardiovascular risk management strategies in this high-risk population.

Abstract Number: 1329

Relationship Between Circulating Bacterial Small RNAs, Methotrexate Response, and Microbiome in New Onset Rheumatoid Arthritis

Carolina Ramirez-Becerra[1], Tulsi Joishy[2], Sheau-Chiann Chen[2], Marisol Ramirez-Solano[2], Quanhu Sheng[2], Peter Turnbaugh[3], Carles Ubeda[4], Renuka Nayak[5], Rebecca Blank[6], Jose Scher[7] and Michelle Ormseth[2], [1]Vanderbilt University Medical Center, Nashville, TN, [2]Vanderbilt University Medical Center, Nashville, [3]University of California, San Francisco, San Francisco, CA, [4]Fisabio, Madrid, [5]University of California, San Francisco (UCSF), San Francisco, CA, [6]NYU Langone Health, New York, NY, [7]New York University School of Medicine, New York, NY

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Microbiome and microbial products are possible contributors and predictors to methotrexate (MTX) response variability. Bacterial small RNAs (sRNAs) are found in human plasma and can alter host gene expression and immune function. The purpose of this study was to determine 1) if circulating bacterial sRNAs are associated with response to MTX in patients with new onset RA (NORA), 2) whether sRNAs aligning to stool microbiome taxa that are associated with MTX response also are associated with MTX response, and 3) the overall relationship between circulating bacterial sRNAs and stool microbiome.

Methods: The study included a training cohort of 26 NORA and validation cohort of 20 NORA patients who were studied previously for relationship between microbiome and MTX response. Participants met ACR/EULAR 2010 classification criteria for RA, were treatment naïve at the time of plasma collection, and were followed for treatment response to MTX at 4 months. Plasma sRNAs from both cohorts (n=46) were sequenced and aligned to bacterial genomes using the TIGER pipeline. Individual bacterial sRNA sequences and taxa counts were compared in methotrexate responders (MTX-R) versus non-responders (MTX-NR) by DESeq2. Spearman's rank correlation test was used to measure the association between plasma small RNAs and the stool microbiome.

Results: Demographic data are included in **Table 1**. Twelve bacterial sRNAs were enriched in the plasma of MTX-R versus MTX-NR in both the training and validation cohorts and included tRNA derived RNAs (tDRs) and ribosomal derived RNAs (rDRs) mapping to genera such as *Prevotella, Bacteroides, Porphyromonas, Ruminococcus, Blautia*, and *Clostridium*. Stool OTUs corresponding to *Bacteroides and Prevotella*, were abundant and significantly enriched in MTX-R versus MTX-NR in the training cohort as previously reported, and plasma sRNAs aligning to these taxa were also enriched in MTX-R versus MTX-NR in the same participants (p=0.04 and p=0.01, respectively). However, Clostridiales family and Ruminococcus genus that were decreased in MTX-R versus MTX-NR in the prior report were altered in plasma bacterial sRNAs of the same taxa but in the opposite direction (**Figure 1**). Combining training and validation cohorts, the overall correlation between the stool microbiome and respective plasma bacterial sRNA taxa counts was poor; however, several stool taxa were associated with the total abundance of bacterial sRNAs in plasma (**Figure 2**).

Conclusion: Consistent with findings that stool *Prevotella* and *Bacteroides* were increased in MTX-R, plasma sRNAs aligning to these taxa were similarly enriched in MTX-R versus MTX-NR. Moreover, increased abundance of specific plasma sRNAs aligning to *Prevotella* and *Bacteroides* were reproducibly enriched in MTX-R in two cohorts, positioning them as potential predictors of clinical response to MTX. Future studies will be needed to replicate these findings and determine the role of these specific bacterial sRNAs on MTX response and how they may gain entry to human circulation.

Sex and reproductive stage modify the role of endogenous estrogens on coronary atherosclerosis in rheumatoid arthritis and differences reflect effects on inflammation and cholesterol metabolism

George Karpouzas[1], Bianca Papotti[2], Sarah Ormseth[3], Marcella Palumbo[2], Matthew Budoff[1] and Nicoletta Ronda[2], [1]Harbor-UCLA Medical Center, Torrance, CA, [2]University of Parma, Parma, Italy, [3]The Lundquist Institute for Biomedical Innovation, Torrance, CA

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Endogenous estrogens associate with cardioprotective benefits in the general population. Yet, dual pro- and anti-inflammatory effects were described in autoimmune states depending on concentration, disease entity and stage, cell-type involved, target organ environment, and intracellular metabolism. We here explore associations between endogenous estrogens, coronary atherosclerosis and cardiovascular risk in patients with rheumatoid arthritis (RA). Since RA activity is higher in females, especially after menopause, and inflammation is linked to cardiovascular risk, we interrogated whether these relationships varied by sex and menopause and whether they reflected differences in inflammation and lipoprotein functions influencing cell cholesterol homeostasis.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1 (A) Influence of sex on the association of estrone and estradiol with various plaque types. All models adjusted for age, hypertension, diabetes, HDLc, waist circumference, and menopause. (B) Influence of reproductive stage on the association of estrone and estradiol with various plaque types. All models adjusted for age, hypertension, diabetes, HDLc, and waist circumference.

Methods: Computed tomography angiography evaluated coronary atherosclerosis in 140 patients without known cardiovascular disease from a single-center. Serum estrone and 17-b-estradiol were measured with Elisa. Serum cholesterol loading capacity (CLC) on macrophages, which enhances atherosclerosis, was measured in THP-1 monocyte-derived macrophages. High-density lipoprotein cholesterol efflux capacity from macrophages via ATP-binding-cassette-A1 (ABCA1-CEC) and G1 transporters (ABCG1-CEC), which attenuates atherogenesis, was assessed in J774 macrophages and Chinese hamster ovary cells.

Results: Estrone and estradiol associated with higher coronary artery calcium score (p for interaction 0.023) and estradiol with more coronary plaques (p-for-interaction 0.048) in males but not females. Estrone was linked to fewer plaques in premenopausal women (p for interaction 0.043), while both estrone and estradiol associated with more plaques in

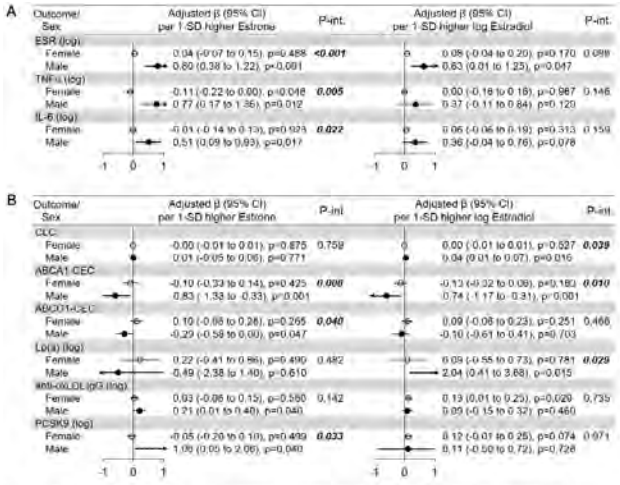

Figure 2 (A) Influence of sex on the association of estrone and estradiol with measures of inflammation. All models adjusted for age, hypertension, diabetes, HDLc, waist circumference, and menopause. **(B)** Influence of sex on the association of estrone and estradiol with lipoprotein parameters, anti-oxLDL IgG and PCSK9. All models adjusted for age, hypertension, diabetes, HDLc, CRP and waist circumference.

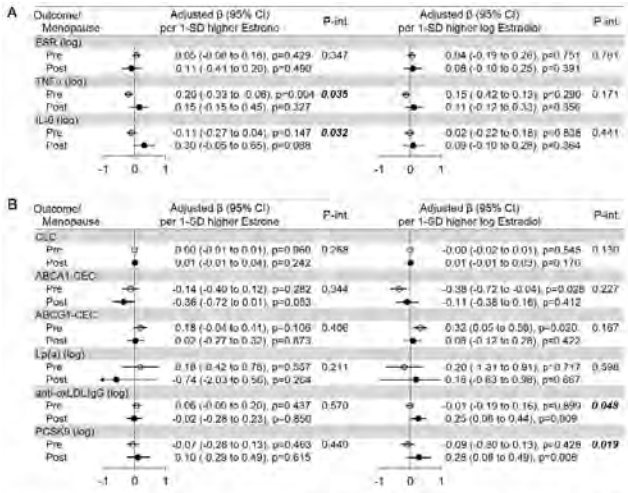

Figure 3 (A) Influence of reproductive status on the association of estrone and estradiol with measures of inflammation. All models adjusted for age, hypertension, diabetes, HDLc, waist circumference, and menopause. **(B)** Influence of reproductive stage on the association of estrone and estradiol with parameters of lipoprotein parameters, anti-oxLDL IgG and PCSK9. All models adjusted for age, hypertension, diabetes, HDLc, CRP and waist circumference. ESR, erythrocyte sedimentation rate; TNFa: tumor necrosis factor a; IL-6, interleukin-6; CLC, serum cholesterol loading capacity; ABCA1-CEC, cholesterol efflux through the ABCA1 transporter; ABCG1-CEC, cholesterol efflux through the ABCG1 transporter; Lp(a), lipoprotein(a); anti-oxLDL IgG, IgG antibodies against oxidized LDL; PCSK9, proprotein convertase subtilisin Kexin type-9; 95% CI, 95% confidence interval; SD, standard deviation

postmenopausal women (Figure 1A and B). Estrone associated with higher proatherogenic cytokine levels in males (Figure 2A) and in postmenopausal women, but lower levels in premenopausal women (Figure 3A). Likewise, estrone inversely associated with ABCA1-CEC (p-for-interaction 0.008) and ABCG1-CEC (p for interaction 0.040) in males (Figure 2B and 3B), while estradiol positively associated with CLC (p for interaction 0.044) and inversely with ABCA1-CEC (p-for-interaction 0.010) in males. Estrone, but not estradiol, inversely associated with cardiovascular risk (adjusted hazards ratio 0.43 [95% confidence interval 0.21-0.86] per standard deviation increase), particularly among premenopausal women (p for interaction=0.015).

Conclusion: Sex and reproductive status modified the effect of endogenous estrogens on coronary atherosclerosis in RA and their associations with inflammation and lipoprotein functions impacting on cholesterol homeostasis. Importantly, estrone levels inversely associated with cardiovascular risk independently of ASCVD score and coronary plaque burden, and further optimized risk estimates.

anti-beta-2-glycoprotein-1 Iga Antibodies Facilitate Macrophage Cholesterol Loading and Influence Coronary Atherosclerosis Progression in a Dose-dependent Manner in Rheumatoid Arthritis

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Changes in serum cholesterol loading capacity (CLC) on macrophages were linked to coronary plaque progression in rheumatoid arthritis (RA). Inflammation, LDL oxidation and autoantibodies influenced macrophage cholesterol loading and plaque burden directly and indirectly. Oxidized LDL formed complexes with beta-2-glycoprotein-1 (b2GPI)—an antiatherogenic protein in serum and plaque—in both RA and controls. Complexes can be then bound by anti-b2GPI antibodies. Anti-b2GPI Ab, particularly of the IgA isotype, independently promoted coronary plaque progression in RA; yet the precise mechanisms remain speculative. We hypothesized that anti-b2GPI IgA may promote atherosclerosis progression by influencing oxidized LDL-mediated cholesterol loading on arterial macrophages.

Methods: Coronary CT angiography evaluated atherosclerosis (noncalcified, mixed, or calcified plaques) in 100 patients without cardiovascular disease at baseline and follow-up 6.9±0.4 years later. Presence of 5 plaques and lesions rendering greater than 50% stenosis were deemed extensive and obstructive disease respectively. CLC was measured as intracellular cholesterol content in serum treated human THP-1 monocyte-derived macrophages with a fluorimetric assay. Serum anti-b2GPI IgA were measured with ELISA at baseline and positivity was confirmed 12 weeks later. Negative binomial regression and logistic regression evaluated the influence of anti-b2GPI IgA on the relationship between CLC change and number of new plaques and likelihood of noncalcified plaque formation and new extensive or obstructive disease respectively.

Results: A significant interaction between CLC change and anti-b2GPI IgA titers on plaque progression was observed. Specifically, increasing anti-b2GPI IgA titers associated with more new plaques overall (p for interaction=0.005), higher likelihood of new noncalcified plaque formation (p for interaction=0.023) and new extensive or obstructive disease (p for interaction=0.043) only at the highest tertile of CLC change (Figure 1). This suggested that anti-b2GPI IgA may be involved in macrophage cholesterol loading by oxidized LDL in a dose-dependent manner. Anti-b2GPI IgA may also determine the composition of newly formed plaques in the context of increasing CLC change (Figure 2). CLC change associated with a greater likelihood of higher-risk noncalcified plaque progression in the presence (odds ratio 2.82, 95% confidence interval 1.40-5.67) but not absence of anti-b2GPI IgA (p for interaction=0.005). In contrast, CLC change associated with a greater likelihood of lower-risk calcified plaque progression in the absence (odds ratio 1.48, 95% confidence interval 1.19-1.84) but not presence of anti-b2GPI IgA (p for interaction=0.046).

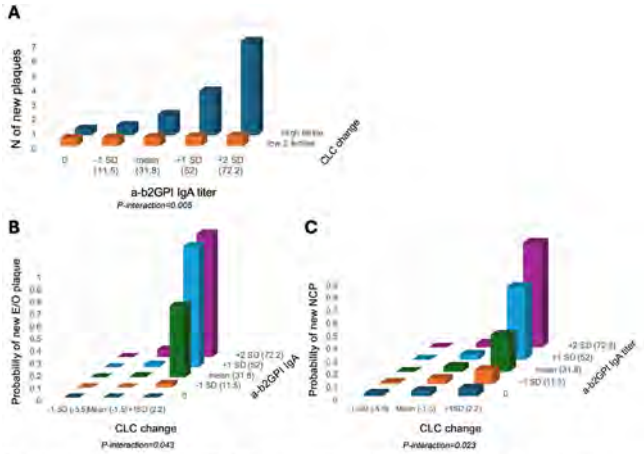

Figure 1. Increasing anti-b2GPI IgA titers associate with **A.** greater number of new plaques overall, **B.** greater likelihood of new extensive or obstructive disease and **C.** greater likelihood of new noncalcified plaques at the highest tertile of CLC change, but not the lower ones.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Effect of CLC on per-segment plaque progression stratified by anti-b2GPI-IgA positivity. All models adjust for 10-year atherosclerotic cardiovascular disease risk score, low-density lipoprotein cholesterol, body mass index, statin exposure during follow-up, and baseline plaque.

Conclusion: Anti-b2GPI IgA may facilitate macrophage cholesterol loading and influence coronary plaque progression and composition in a dose dependent manner, specifically at high levels of CLC change. Anti-b2GPI IgA may bind oxidized LDL/b2GP1 complexes to FcA receptors on arterial macrophages, promote cholesterol loading and atherosclerosis progression.

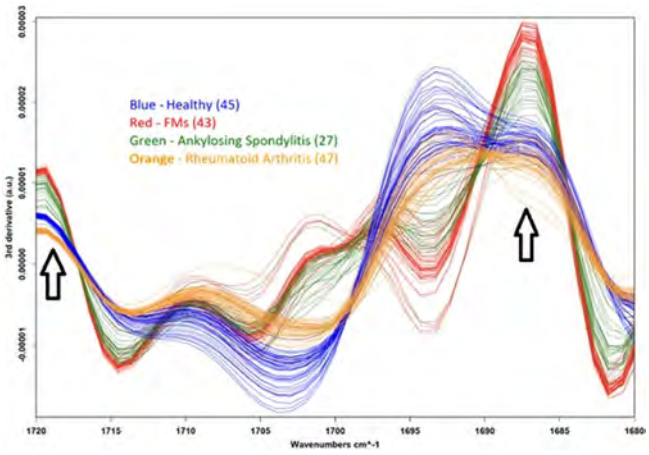
SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Spectral analysis of liquid biopsies has recently emerged as a promising, non-invasive approach to improve the diagnosis of various pathologies. Our objective was to develop a rapid and precise strategy to differentiate among clinically challenging rheumatic inflammatory and autoimmune diseases, as well as to assess their severity, by analyzing the spectral properties of peripheral blood.

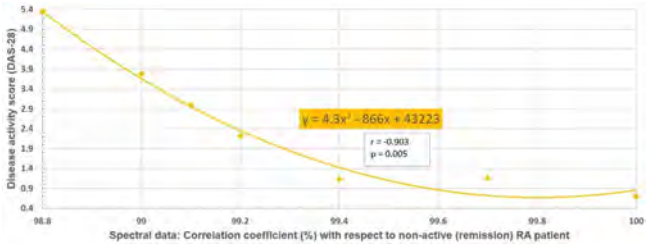
Methods: We recruited patients with rheumatoid arthritis (RA, n=47), ankylosing spondylitis (AS, n=27), fibromyalgia syndrome (FMs, n=43), along with healthy controls (n=45). Disease activity was assessed using the Disease Activity Score-28 (DAS-28) for RA, the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) for AS, and the Fibromyalgia Impact Questionnaire (FIQ) for FMs. Plasma concentrations of inflammatory cytokines (TNF-α, IL-1β, IL-6, IL-17A and IFN-γ) were quantified via U-Plex ELISA (Meso Scale Diagnostics, USA). Peripheral blood mononuclear cells (PBMC) were isolated by standard density-gradient centrifugation (Lymphoprep™). Mid-infrared (Mid-IR) spectra were acquired from plasma and PBMC's supernatants using a Bruker V80 Fourier-transform infrared (FTIR) spectrometer. Correlation coefficient analysis was performed to relate specific spectral features to clinical scores and cytokine levels.

Results: Spectral analysis of plasma samples generated distinct spectral "fingerprints" that reliably distinguished FMs patients from those with RA, AS and healthy controls (Fig. 1). Notably, several infrared spectral features showed strong correlations with RA disease activity (e.g., DAS28) (Fig.2) and inflammatory cytokine levels (e.g. IL-6, IL-17A), indicating that

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

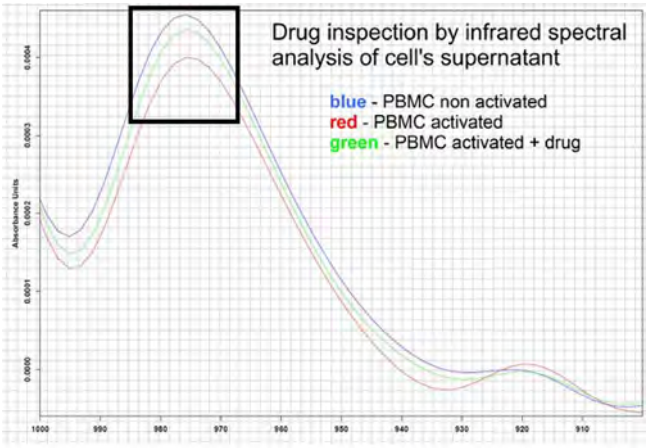


Mid-IR spectral analysis of plasma samples distinguishes fibromyalgia syndrome (FMs) patients (n=43) from other rheumatic inflammatory/autoimmune diseases: rheumatoid arthritis (n=47), ankylosing spondylitis (n=27), and healthy controls (n=45). Black arrows indicate specific optical windows where clear differentiation between the groups is observed, even to the naked eye of a rheumatologist or immunologist. The analysis considers the third derivative of the absorption data with respect to the wavenumbers (cm^{-1}).



A significant correlation between disease activity score of RA patients and spectral data of their plasma. A parabolic relationship between the disease activity score (DAS-28, y-axis) and the spectral data (correlation coefficient in percentage, x-axis). The absorption spectra of plasma derived from RA patients were measured. The correlation coefficient between the spectra and a reference spectrum was calculated (y-axis). The reference can be the average of a healthy control group or an RA patient in remission. The results align with expectations: the closer the spectrum is to the reference (higher correlation coefficient), the healthier the patient (lower DAS28 score). r = -0.903, p value = 0.005.

spectral markers reflect underlying inflammatory burden. Furthermore, spectral analysis of PBMC-derived supernatants from rheumatic patients, following activation (LPS/PHA) and treatment with anti-inflammatory drugs, corelated with biological data reflecting the inflammatory status of the cells (Fig. 3).



Spectral analysis, at a specific optical window, of PBMC-derived supernatants from rheumatic patients revealed spectral peaks (black square) that correlate with the in vitro status of the cells: non-activated cells (blue curve), inflammatory activation (red curve, shifted downward compared to the blue curve), or activation plus anti-inflammatory drug (green curve, shifted back toward the blue curve). The spectral results are consistent with biological findings.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Integrating Mid-IR spectral profiling of liquid biopsies (such as patients-derived plasma or -immune cells' supernatants) with established clinical and biological parameters provides a powerful, non-invasive modality for differential diagnosis and severity stratification of rheumatic diseases. This approach has the potential to improve diagnostic accuracy and guide personalized treatment strategies in rheumatology.

Assessment of Lipid Abnormalities After Initiation of a JAK Inhibitor in Rheumatoid Arthritis in Clinical Practice

Salomé Abdellaoui[1], Omar Al Tabaa[1], Sophie Hecquet[1], Alice Combier[1], Sandrine Carves[1], Olivier Fogel[2], Yannick Allanore[3] and **Jérôme Avouac**[4], [1]Rheumatology department, Cochin Hospital, Paris, France, [2]AP-HP, Paris, France, [3]Université Paris Cité, Paris, France, [4]Hôpital Cochin, AP-HP Centre - Université Paris Cité, Paris, France

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: rheumatoid arthritis (RA) is characterized by a lipid paradox induced by systemic inflammation. JAK inhibitors (JAKi) have been associated with a short-term increase in total cholesterol (TC), LDL and HDL fractions, which could be a direct effect of the drug, or indirectly related to drug-induced systemic inflammation reduction. The aim of this study was to investigate the course of TC levels and fractions following the introduction of a JAKi.

Methods: Retrospective study conducted at a single center, encompassing all RA patients who initiated JAKi therapy between 2019 and 2023. The study population included patients who had at least two follow-up visits and had a lipid panel available at the time of enrollment. Patients who had received statin therapy at the time of enrollment were excluded.

The primary endpoint was defined as changes in TC and fractions at 6 months from the initiation of JAKi treatment. Secondary endpoints included the study of factors associated with changes in TC and fraction at 6 months, and changes in TC and fractions between the first and last available visits.

Results: 85 RA patients (68 women, 80%) met the inclusion criteria, with a mean age of 59± 13 years and a mean disease duration of 19.5± 12.4 years; 73 (86%) and 76 (89%) patients were rheumatoid factor and ACPA positive respectively, and 66 (78%) had bone erosions. 22 patients received baricitinib, 7 tofacitinib, 38 upadacitinib and 18 filgotinib. The DAS28-CRP at inclusion was 4.09± 1.26 with a mean CRP of 10±14 mg/L. Comorbidities, concomitant treatments and lipid profile at inclusion are presented in **Tables 1** and **2**. At inclusion, TC and HDL cholesterol (HDL-C) levels correlated negatively with CRP (respectively r=-0.23, p=0.042 and r=-0.25, p=0.040), but not with DAS28 or DAS28-CRP. This correlation was not observed for LDL and triglycerides.

At 6 months, there was a significant increase in TC (+0.17±0.37 g/L, p=0.016) and HDL-C (+0.09±0.19g/L, p=0.017), but not LDL-C (+0.02±0.31, p=0.68) (**Table 2**). This increase was inversely correlated with the reduction in CRP concentrations (-6±10 mg/L) upon JAKi (TC: r=-0.31, p=0.033 and HDL-C: r=-0.32, p=0.042). This increase was not associated with the

Table 2: Changes in total cholesterol and fractions

	Inclusion	Visit M6	Delta M6-inclusion	p-value	Final visit	Delta Final - M6	p-value
Total cholesterol (g/L)	1.98±0.43	2.15±0.40	+0.17±0.37	0.016	1.96±0.39	-0.11±0.21	0.042
LDL cholesterol (g/L)	1.15±0.36	1.17±0.34	+0.02±0.31	0.68	1.16±0.67	-0.01±0.61	0.74
HDL cholesterol (g/L)	0.65±0.23	0.74±0.27	+0.09±0.19	0.017	0.63±0.17	-0.11±0.16	0.031
Triglycerides (g/L)	1.36±0.88	1.19±0.59	-0.16±0.61	0.16	1.07±0.54	-0.12±0.33	0.17

use of corticosteroids or methotrexate, nor with the course of the number of tender and swollen joints. At the last available visit (20±15 months after the onset of JAKi), there was a drop in TC and particularly in its HDL fraction compared with the first visit, with values close to those at the inclusion visit (**Table 2**). Statins were prescribed for 9 patients during the follow-up period, all of whom had known dyslipidemia at inclusion (10.6%).

Conclusion: This study confirms a transient increase in TC and TC fractions under JAKi, linked to the drug-induced reduction in systemic inflammation. These lipid abnormalities were regressive in the majority of patients. The clinical consequences of this elevation remain to be determined in the context of the cardiovascular tolerance of JAKi.

Cardiac Biomarkers and Prediction of Major Cardiovascular Events in Rheumatoid Arthritis: Results from the ESPOIR Cohort

manon lesturgie[1], Fiona Oudart[1], Anne Cauvet[2], Virginie Gonzalez[2], Bruno Fautrel[3], Arnaud Constantin[4], Nathalie Rincheval[5], Yannick Allanore[6] and **Jérôme Avouac**[7], [1]INSERM U1016, Paris, France, [2]INSERMU1016, Paris, France, [3]Sorbonne Université - APHP, Department of Rheumatology, Hôpital Pitié-Salpêtrière, Inserm UMRS 1136-5, PARIS, France, Paris, France, [4]Hôpital Pierre-Paul Riquet, CHU Purpan, Toulouse, France, [5]Institut de Recherche Clinique EA2415, Université de Montpellier, Département de Statistiques, Montpellier, France, [6]Université Paris Cité, Paris, France, [7]Hôpital Cochin, AP-HP Centre - Université Paris Cité, Paris, France

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with rheumatoid arthritis (RA) experience premature mortality, largely due to cardiovascular (CV) disease. The increased CV risk is due to both the underlying systemic inflammation and the interaction between RA and traditional CV risk factors. Individual CV risk assessment in RA patients is complex because tools validated for the general population have not been adapted to account for disease activity. The use of biomarkers may help to refine risk stratification.

The aim of this study was to evaluate the predictive value of two cardiac biomarkers for major CV events in RA patients.

Methods: This prospective cohort study included patients from the ESPOIR cohort who met the 2010 ACR/EULAR classification criteria for RA and had no prior history of CV events at baseline. Serum levels of high-sensitivity cardiac troponin T (Hs-cTnT, a marker of myocardial injury) and soluble ST2 (a marker of inflammation and myocardial fibrosis) were measured at baseline using electrochemiluminescence and ELISA, respectively. The primary outcome was the occurrence of major CV events (myocardial infarction, ischemic stroke, and CV death) during the observation period.

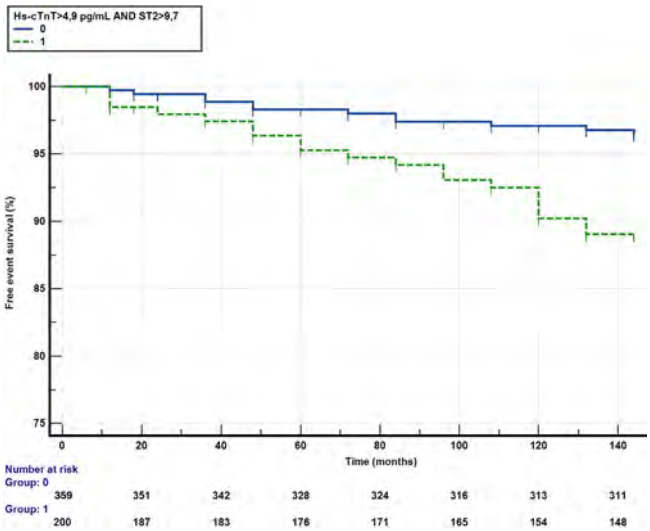

Figure 1: Kaplan-Meier curve illustrating CV event-free survival based on Hs-cTnT and ST2 concentrations.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: We analyzed 559 patients (425 women, 76%) with available data and biomarker measurements. The mean (SD) age was 49 (12) years, and the mean (SD) disease duration was 104 (211) days. Among these patients, 228 (41%) and 253 (45%) were positive for rheumatoid factors and anti-CCP antibodies, respectively, and 218 (39%) had bone erosions. The mean (SD) DAS28 was 5.26 (1.27).

Thirty-three major CV events were identified over a mean (SD) follow-up of 130 (34) months. Baseline mean (SD) Hs-cTnT and ST2 levels were 6.5 (13.8) pg/mL and 5.2 (1.3) ng/mL, respectively, and both correlated with age (r=0.53, p< 0.001 and r=0.22, p< 0.001) and the Framingham risk score (r=0.63, p< 0.001 and r=0.18, p=0.003). Mean ST2 levels were significantly higher in patients with at least two CV risk factors (22.3 (18.8) vs. 15.8 (11.5) ng/mL, p< 0.001).

The area under the curve (AUC) for Hs-cTnT in predicting major CV events was 0.71 (p=0.002), with a sensitivity of 72% and specificity of 60% at a threshold of 4.9 pg/mL. The AUC for ST2 was 0.69 (p=0.019), with a sensitivity of 97% and specificity of 32% at a threshold of 9.7 ng/mL. Elevated levels of Hs-cTnT (>4.9 pg/mL) and ST2 (>9.7 ng/mL) were predictive of major CV events (hazard ratios [HR]: 2.59, 95% confidence interval [CI] 1.31–5.13 and 3.23, 95% CI 1.43–7.27, respectively). The predictive value was higher when both biomarkers were elevated (HR 3.49, 95% CI 1.68–7.24). This combination remained predictive after adjusting for DAS28, CRP, methotrexate exposure, and traditional CV risk factors (adjusted HR 2.22, 95% CI 1.01–4.92).

Conclusion: These two cardiac biomarkers were identified as predictors of major CV events in this prospective RA cohort. The combination of Hs-cTnT and ST2 may improve CV risk stratification in RA patients. Adding these biomarkers to non-specific CV risk scores could better identify patients requiring advanced CV evaluation.

Background/Purpose: Interstitial lung disease (ILD) is a frequent and severe complication of rheumatoid arthritis (RA). Although early diagnosis and screening of ILD in RA patients with risk factors is recommended, there is no current consensus on how to perform screening of ILD in these patients. Spanish guidelines (SER-SEPAR screening criteria) recommend

Abnormal CXR	17 (14.2%)	19 (47.5%)	**<0.001**

Table 1. Characteristic of RA patients with and without ILD.
RA=rheumatoid arthritis, ILD=interstitial lung disease, RF=rheumatoid factor, ACPA= Anti-citrullinated protein antibodies, CXR: chest-Xray FVC=forced vital capacity, DLCO= diffusing capacity of lung for carbon monoxide

chest x-ray (CXR) and pulmonary function test (PFT) to patients with dyspnoea or cough > 3 months and asymptomatic patients with an intermediate risk for ILD. Portuguese guidelines recommend CXR and PFT as screening in patients without symptoms or risk factors for ILD. ACR/CHEST guidelines conditionally recommend against screening with CXR but considers screening with PFT.

The aim of this study is to assess the diagnostic yield of CXR and PFT for diagnosing ILD in patients with RA.

Methods: This is a retrospective study that included patients with RA fulfilling ACR/EULAR 2010 classification criteria that had a thoracic computerized tomography (CT) between 01/01/2020 and 31/12/2024. ILD was diagnosed according to the CT results. CXR and PFT (spirometry and diffusing capacity of lung for carbon monoxide [DLCO]) performed a maximum of 12 months previous to the CT were reviewed. CXR were interpreted blindly to the patient clinical data and classified as normal or abnormal (which included findings suggestive of ILD or another lung pathology that would require a CT). Sensitivity and specificity were calculated for each item individually and combined for diagnosing ILD, using CT as the gold standard.

	CXR	FVC<80%	DLCO<80%	Combined
All patients (n=270)				
- Sensitivity	45.9%	32.4%	62.2%	70.3%
- Specificity	87.5%	75%	61.3%	50%
Asymptomatic patients (screening situation)* (n=201)				
- Sensitivity	28.6%	14.3%	42.9%	57.1%
- Specificity	86.7%	78.3%	65%	56.7%
Symptomatic patients (n=69)**				
- Sensitivity	56.5%	43.5%	73.9%	78.3%
- Specificity	90%	65%	50%	30%
SER-SEPAR criteria* (n=93)**				
- Sensitivity	50%	12.5%	62.5%	75%
- Specificity	89.9%	71.1%	66.7%	48.9%

Table 2. Sensitivity and specificity of CXR and PFT
CXR: chest-Xray, FVC=forced vital capacity, DLCO= diffusing capacity of lung for carbon monoxide
*Asymptomatic patients: patients without lung crackles and without respiratory symptoms (cough or dyspnoea > 3 months)
**Symptomatic patients: patients with lung crackles or respiratory symptoms (cough or dyspnoea > 3 months)
***Indication for a chest-Xray and PFT for ILD screening according to SER-SEPAR criteria

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. We compared patients with ILD and without ILD using χ2 (with Fisher correction as appropriate) for categorical variables and t test/Mann-Whitney test for quantitative variables.

Results: A total of 270 patients with RA and a CT were included, and 58 patients (21.5%) had ILD. The patient's characteristics are represented in table 1. A total of 204 (75.6%) patients had PFT and 160 (59.3%) had CXR performed. In the bivariate analysis, we observed a significant difference between patients without ILD and patients with ILD for abnormal CXR (14.2% vs 47.5%, p< 0.001) and DLCO< 80% (35.3% vs 52.9%, p=0.037). No significant differences were observed for FVC.

The sensitivity and specificity for CXR, FVC< 80%, DLCO < 80% and the combined (abnormal CXR and/or abnormal PFT) results are represented in table 2. The best results were obtained for CXR due to high specificity, but sensitivity was low in all groups.

Conclusion: The diagnostic yield of CXR and PFT is low for ILD diagnosis, especially in patients without respiratory symptoms or lung crackles. Other strategies should be adopted for screening of ILD in patients with RA.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Though the efficacy and safety profile of tofacitinib in RA has been established in prior trials, the effectiveness of tofacitinib in routine care settings compared to biologic DMARDs (bDMARDs) is limited.

This observational cohort study of RA patients (pts) evaluated the real-world effectiveness of tofacitinib compared to select bDMARDs overall and within relevant subgroups of demographic and clinical characteristics using data from OM1 PremiOM™ RA (OM1, Boston, MA), a multisource dataset with linked claims and EHR data on RA pts in the US.

Methods: Pts with RA aged ≥18 years initiating tofacitinib or select bDMARDs (tumor necrosis factor inhibitors (TNFi); abatacept; interleukin 6 inhibitors (IL-6i)) from 01 January 2013 – 13 March 2024 and with ≥1 Clinical Disease Activity Index (CDAI) score in 45 days prior to and including the index date were included. Stabilized inverse probability treatment weights (sIPTW) were calculated to adjust for demographics, treatment history, and comorbidities). Crude incidence rates (IRs) per 1000 pt-years (PYs) were calculated to estimate the first record of CDAI remission (≤ 2.8) measured at 6- and 12-months.

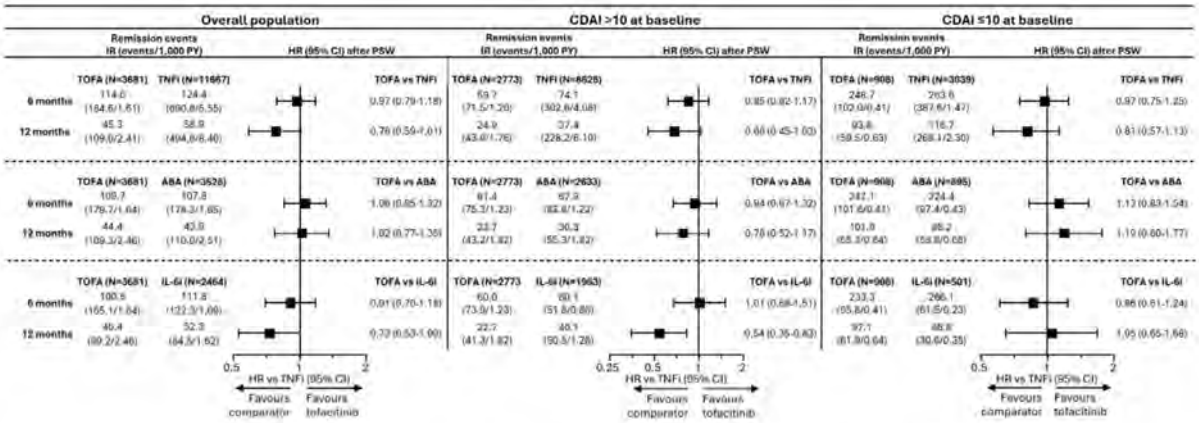
[a]Assessed during the baseline period, defined as all available data prior to and including the index date (date of treatment initiation), unless otherwise stated. For obesity and lab measures, the most recent value over the baseline period was used. Patients diagnosed with concomitant indications for tofacitinib (PsA, UC, pcJIA) anytime prior to cohort entry date were excluded (required at least 2 diagnosis codes at least 30 days apart)
[b]Most recent value in the 45 days prior to and including the index date.

Cox regression with robust standard errors were used to calculate weighted hazard ratios (HRs) and 95% confidence intervals (CIs) overall and stratified by baseline CDAI >/≤ 10. Subgroup analyses by pre-specified variables of interest were conducted to assess heterogeneity of treatment effect (HTE) among pts with baseline CDAI >10.

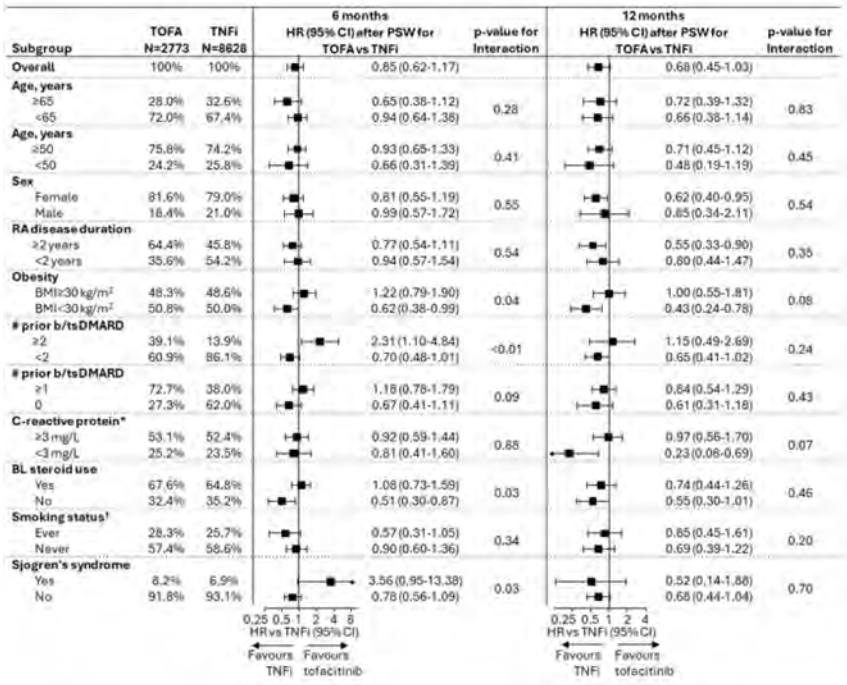


Baseline covariates used to estimate IPTW included: age, sex, race (black, white, other, unknown/not documented), ethnicity (Hispanic, non-Hispanic, unknown/ not documented), insurance status (commercial, Medicare, Medicaid, multiple, other, unknown/ not documented), geographic census region (Northeast, Midwest, West, South, unknown), BMI (<18.5, 18.5-<25, 25-<30, ≥30 kg/m2, unknown), year of index, RA disease duration (<2, ≥2 years), RA disease activity (CDAI score 0-2.8, 2.9-10, 10.1-22.0, 22.1-76.0), Charlson Comorbidity Index (continuous and categorical: 0-1, 2-3, 4-5, ≥6), comorbidities (cardiovascular disease, COPD, fibromyalgia, malignancies, osteoporosis, type 1 diabetes, type 2 diabetes, Sjögren's syndrome), smoking status (ever, never, unknown), hospitalization, laboratory results (RF positive, negative, unknown), anti-CCP (positive, negative, unknown), CRP (<3, ≥3 mg/L, unknown), prior use of medications (csDMARD, bDMARD, tsDMARD), count of prior b/tsDMARD (0, 1, 2, 3, ≥4), and corticosteroid use.

ABA, abatacept; BMI, body mass index; CCP, cyclic citrullinated peptide; CDAI, clinical disease activity index; CI, confidence interval; COPD, chronic obstructive pulmonary disease; CRP, C-reactive protein; HR, hazard ratio; IL-6i; interleukin-6 inhibitor; IR, incidence rate; N, number of evaluable patients; PSW, propensity score weighting; PY, patient years; RA, rheumatoid arthritis; RF, rheumatoid factor; TNFi, tumor necrosis factor; TOFA, tofacitinib.

Figure 1. Effectiveness of tofacitinib vs bDMARDs in achieving remission (CDAI ≤ 2.8) at 6 and 12 months

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



*CRP was unknown in 21.7% (tofacitinib) and 24.2% (TNFi) of patients. †Smoking status was unknown in 14.3% (tofacitinib) and 15.8% (TNFi) of patients.

BMI, body mass index; CCP, cyclic citrullinated peptide; CDAI, clinical disease activity index; CI, confidence interval; COPD, chronic obstructive pulmonary disease; CRP, C-reactive protein; HR, hazard ratio; IL-6i; interleukin-6 inhibitor; IR, incidence rate; N, number of evaluable patients; PSW, propensity score weighting; PY, patient years; RA, rheumatoid arthritis; RF, rheumatoid factor; TNFi, tumor necrosis factor; TOFA, tofacitinib.

Figure 2. Effectiveness of tofacitinib vs TNFi in achieving remission (CDAI ≤ 2.8) at 6 and 12 months, by subgroup.

Results: In total, 21,340 pts were included (tofacitinib, N=3,681; TNFi, N=11,667; abatacept, N=3,528; IL-6i, N=2,464) (Table). Mean age at index date ranged from 58-62 years, and proportion with disease duration ≥ 2 years ranged from 48.7%-70.0%. At baseline, 36.6% of pts initiating tofacitinib had used ≥ 2 prior biologic or targeted synthetic DMARDs (b/tsDMARDs) vs TNFi (13.5%), abatacept (31.2%) and IL-6i (49.6%). Comorbidities and CDAI scores at baseline were similar between cohorts. Treatment switch rates were higher among tofacitinib (5.7-12.9%) vs. comparator (1.7-3.5%) pts at 6- and 12-months, while treatment discontinuation rates were slightly lower (33.8-51.6% vs. 36.6-63.0%).

In the main sIPTW analysis, there were no statistically significant differences in the rate of achieving remission between treatments at 6- and 12-months (Fig 1). Results were consistent when stratifying pts by baseline CDAI >/≤ 10, apart from a lower rate of remission for tofacitinib compared to IL-6i at 12 months among those with baseline CDAI >10 (HR = 0.54, 95% CI 0.35-0.83). Subgroup analyses suggested HTE among pts with obesity (BMI ≥30kg/m2), ≥2 prior biologic or targeted synthetic DMARDs, prior corticosteroid use, and Sjogren's syndrome for tofacitinib compared to TNFi among pts with baseline CDAI >10 at 6 months (p-interaction < 0.05), but not 12 months (Fig 2).

Conclusion: In this large cohort study using real-world data, no significant differences were found in achieving remission between treatments among the overall RA population. Subgroup analyses suggest some potential HTE; however, interpretation is limited by low event rates, missing data, and potential residual confounding.

The Association Between Glucagon-Like Peptide-1 Receptor Agonist and Rheumatoid Arthritis: A Population-Based Case Control Study

Ariel Israel[1], Fadi Hassan[2], Jalal Kurtam[2], Jamal Awad[2], Eugene Merzon[1] and **Mohammad Naffaa**[3], [1]Leumit Health Services, Tel-Aviv, Israel, [2]Galilee Medical Center, Nahariya, Israel, [3]The Azriel's Faculty of Medicine, Bar-Ilan University, Safed, Israel; The Rheumatology Unity, Galilee Medical Center, Naharyia, Israel

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: The increasing use of glucagon-like peptide-1 receptor agonists (GLP1-RAs) for diabetes mellitus (DM) and weight loss has the potential modify the risk for rheumatoid arthritis (RA) development. In this study we aimed to explore the association between GLP1-RA use and RA development.

Methods: This case-control study utilized the Leumit Health Services (LHS) computerized database. Cases were defined as adult RA patients (≥18 years) registered in the database up to December 31, 2023, using ICD-9 code 714.0, who also were prescribed conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs) or diagnosed with RA by a rheumatologist. Each case was matched with five controls based on age, gender, and socioeconomic status from the same database. The primary exposure was the use of either liraglutide, dulaglutide, or semaglutide within the 5 years preceding the

Table 1 - Baseline Characteristics of Study and the Control Groups

Table 3 –Adjusted multivariate analysis for factors associated with RA

Variable	Odds Ratio (CI)	p-value
Liraglutide	1.25 (0.90 to 1.73)	0.18
Dulaglutide	1.26 (0.74 to 2.15)	0.40
Semaglutide	1.13 (0.76 to 1.67)	0.56
Age	1.11 (1.00 to 1.23)	0.06
Past smoking	1.24 (0.99 to 1.54)	0.06
Active smoking	1.08 (0.99 to 1.18)	0.08
DM	1.18 (1.07 to 1.31)	**0.001**

GLP1-RA - Glucagon-like peptide-1 receptor agonists; RA – Rheumatoid arthritis; CI – Confidence interval; DM – Diabetes mellitus.
Bold styling indicates clinical significance.

RA diagnosis (index date). Demographic variables, smoking status, comorbidities, and malignancy history were collected at the index date. Univariate and multivariable logistic regression analyses were performed to evaluate the association between GLP1-RA usage and RA, with the multivariable model adjusting for potential confounders. A p-value of less than 0.05 was considered statistically significant. Ethical approval for the study was obtained from the LHS Institutional Review Board.

Results: The study included 4,405 RA patients and 22,025 matched controls. Baseline characteristics revealed that RA patients had a significantly higher BMI and a greater prevalence of several comorbidities including DM, chronic obstructive pulmonary disease, osteoporosis, hypothyroidism, inflammatory bowel disease, and fibromyalgia (Table 1). GLP1-RA use was non-significantly associated with RA: liraglutide (OR 1.38, p=0.051), dulaglutide (OR 1.54, p=0.101), and semaglutide (OR 1.38, p=0.075) (Table 2). After adjusting for age, smoking status, and DM in a multivariate model, these associations remained non-significant (Table 3). Notably, DM was identified as an independent risk factor for RA (adjusted OR 1.18, p=0.001) (Table 3).

Conclusion: Our findings demonstrated that GLP1-RAs exposure was not associated with a decreased incidence of RA, but rather the exposure trended towards increased incidence. DM was the only variable that was significantly associated with incident RA, pointing to the potential role of metabolic dysregulation in the development of autoimmune disease. Further prospective, interventional studies are warranted to understand the effect of GLP1-RA on the risk of developing RA.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Although genetic factors have been identified in the pathogenesis of RA, the concordance rate in monozygotic (MZ) twins is low, suggesting that other factors contribute to disease development. Further, the relative contribution of such non-genetic elements in identical twins has not been characterized. Here, we aimed to measure host and microbial biomarkers of RA by studying MZ twin pairs discordant for disease using a multi-omics approach.

Methods: Eight pairs of MZ twins discordant for RA (n=16; Table 1) were enrolled in the United States (US). Gut microbiome was assessed using shotgun metagenomic sequencing. Autoantibodies, cytokines, and other plasma proteins were measured in both plasma and feces. Levels of short-chain fatty acids (SCFA) from serum and feces were quantified using gas chromatography mass spectrometry (GC-MS). A metagenomic dataset from a geographically distinct cohort of MZ twins discordant for RA (n=14, Table 2) from TwinsUK was used to validate the findings.

Results: While overall microbiome diversity and composition did not significantly differ between twin pairs in either cohort, we observed a decrease in *Blautia faecis*, a SCFA producer, in RA affected US twins (Fig. 1 A). Affected US twins had higher concentrations of both fecal and plasma citrullinated and non-citrullinated autoantibodies, as well as significantly lower concentrations of fecal butyrate and propionate (Fig. 1 B,C). TwinsUK RA discordant pairs showed comparable differences

Table 1: US Cohort demographics and clinical information.

Characteristic	Unaffected (n = 8)	RA (n = 8)	p-value
Age- years, mean (median)	56.3 (58.0)	56.3 (58.0)	1
Female- n (%)	7 (87.5)	7 (87.5)	1
White/Caucasian- n (%)	8 (100)	8 (100)	1
Disease duration, years, mean (median)	–	7.0 (4.0)	–
Disease activity parameters			
TJC-28, mean (median)	–	10.4 (9.5)	–
SJC-28, mean (median)	–	6.25 (4.0)	–
DAS 28-CRP, mean (median)	–	4.02 (4.0)	–
Serum CCP antibody, units, mean (SD)	13314 (36841)	27203 (33538)	0.117
Medication use ever			
Prednisone, n (%)	–	4 (50.0)	–
Methotrexate, n (%)	–	6 (75.0)	–
Biologic agent, n (%)	–	5 (62.5)	–

TJC = tender joint count; SJC = swollen joint count; DAS28-CRP = Disease activity score-C reactive protein; CCP = cyclic citrullinated peptide

Table 2. TwinsUK sample demographics and clinical information.

Characteristic	Unaffected (n = 7)	RA (n = 7)	p-value
Age- years, mean (median)	63.4 (68)	63.4 (68)	1
Female- n (%)	7 (100)	7 (100)	1
White/Caucasian- n (%)	7 (100)	7 (100)	1
Serum CCP antibody, U/ml, mean (SD)	1.17 (0.41)	95 (116)	0.0047
Medication use ever

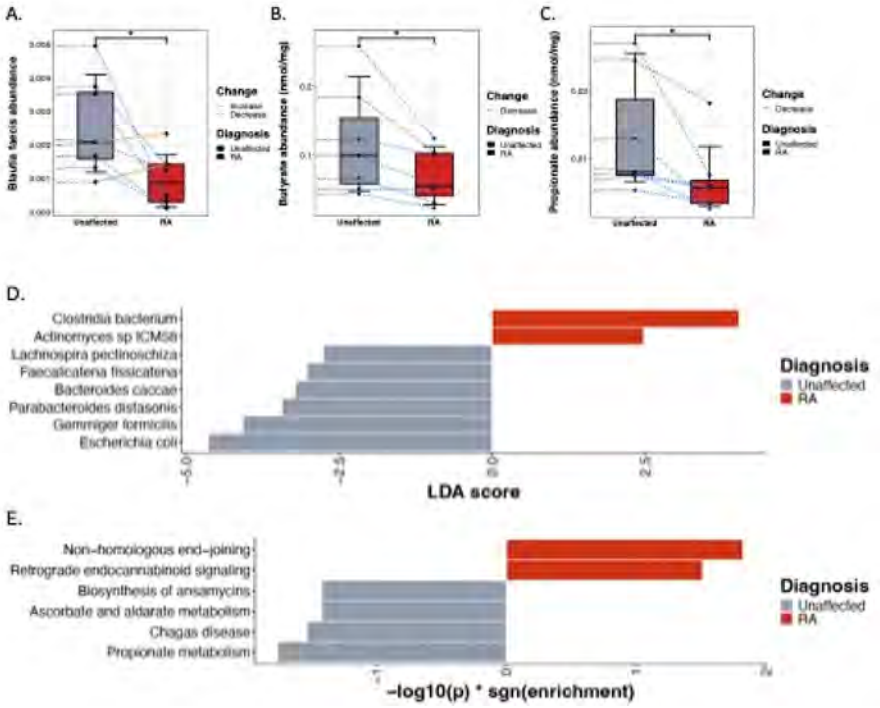
Figure 1. Gut bacterial composition, predicted functional pathways, and fecal SCFA concentration in affected and unaffected twins in US and UK cohorts. (A-C are US cohort; D-E are UK cohort.) (A) Boxplot showing distribution of *B. faecis* abundance in unaffected and affected US twins. Fecal concentration of butyrate (B) and propionate (C) in unaffected and affected US twins. (D) Linear discriminant analysis Effect Size (LEfSe) showing differential species in unaffected twins compared to affected twins in UK cohort. *Gemmiger* and *Faecalicatena* are SCFA producers. (E) Barplot of Wilcoxon effect sizes for differential pathways in UK cohort. *p<0.05, **p<0.01.



using metagenomic-based taxa- and pathways-features. SCFA producing bacteria and pathways were depleted in TwinsUK RA affected twins (Fig 1 D,E).

Conclusion: Multi-omic biomarkers differentiate MZ twins discordant for RA. *Blautia faecis*, which is associated with SCFA production and reduced inflammatory cytokine expression, was decreased in US affected twins. Similarly, SCFA, which are known to have immune modulatory effects, were decreased in affected twins, suggesting further bi-directional interactions between inflammation at the gut barrier and disease state. We observed similar changes in SCFA producing taxa between unaffected and affected twins in a geographically distinct twin cohort. If confirmed in larger cohorts, exhaustive multi-omic approaches may improve our understanding of RA pathogenesis. Future work should focus on the potential for SCFA in diagnostics and therapeutics.

SESSION INFORMATION

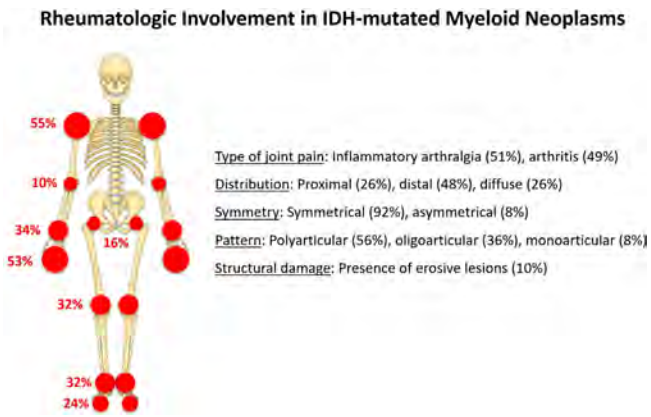
Session Date: Monday, October 27, 2025

Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Clonal hematopoiesis has emerged as a key contributor to systemic inflammation, bridging hematologic and immune-mediated inflammatory disorders (IMIDs). Isocitrate dehydrogenase 1 and 2 (IDH1/2) somatic mutations, typically found in myeloid neoplasms (MN), may be overrepresented in patients with both MN and IMIDs. This study aimed to characterize the clinical, immunological, and molecular features of IDH-mutated MN associated with IMIDs, and to assess outcomes and treatment responses, particularly to IDH inhibitors.



23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

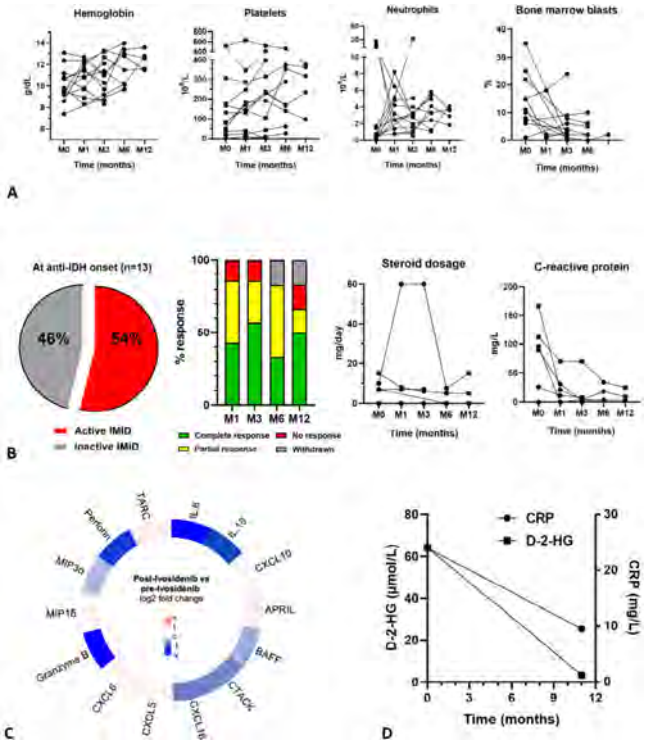


Figure 2: Efficacy of anti-IDH inhibitors on IMID patients with IDH-mutated myeloid neoplasm Legend: (A) Hematological parameters (hemoglobin, platelets, neutrophils, and bone marrow blasts) during follow-up (M0, M1, M3, M6 and M12). Each dot represents an individual patient; (B) Proportion of patients with active versus inactive IMID at anti-IDH onset (left), evolution of inflammatory response rates over time (middle), and longitudinal changes in steroid dosage (mg/day) and C-reactive protein (mg/L) in 7 patients with active IMID (right); (C) Cytokine profile pre- and post-ivosidenib (anti-IDH1) in one patient showing log2 fold changes in circulating cytokines and chemokines, with upregulated (red) and down-regulated (blue) markers; (D) D-2-HG and CRP levels evolution under anti-IDH1 inhibitor in one patient. CRP: C-reactive protein; IMID: immune-mediated inflammatory disorder; VAF: variant allele frequency

Methods: We conducted a multicenter retrospective cohort study of 50 patients with IDH-mutated MN and IMIDs (IDH^{mut} group), compared to 61 patients with MN and IMIDs without IDH mutations (IDH^{wt} group). Clinical and biological characteristics, survival outcomes, therapeutic responses, cytokine profiles, and circulating immune cell populations were assessed.

Results: Fifty patients (25 (50%) male, median age 73 (54-85) years) with IDH-mutated MN and IMID (MN-IMID-IDH^{mut} group) were included. Twenty-seven (54%), 22 (44%) and 1 (2%) patients respectively displayed IDH1, IDH2, both mutations. Thirty-six (72%) had MDS and 14 (28%) patients had CMML. The most common inflammatory manifestations were musculoskeletal in 39 (78%) patients, cutaneous in 22 (44%) and vascular in 12 (24%). Musculoskeletal involvement was inflammatory arthralgia without synovitis in 20 (51%) patients and arthritis in 19 (49%). These symptoms were predominantly symmetrical (92%) and polyarticular (56%), with common involvement of both proximal and distal joints such as the shoulders (55%), hands (53%), and wrists (34%). Erosive lesions were infrequent (10%). The most frequent underlying IMIDs diagnosis were seronegative arthritis in 17 (34%) patients, polymyalgia rheumatica in 13 (26%) and giant cell arteritis in 8 (16%).

Compared to the IDH^{wt} group, patients in the IDH^{mut} group were more frequently female (50% vs 25%, p = 0.006) and older (73 (54-85) vs 69 (20-86) years, p=0.038). Musculoskeletal manifestations were significantly more common in the IDH-mutated group (78% vs 54%, p=0.009), whereas cutaneous, digestive, and renal manifestations were significantly less frequent. Polymyalgia rheumatica was significantly more common in the IDH^{mut} group (26% vs 8%, p=0.011). A specific cytokine signature with significant higher expression of several chemokines implicated in monocyte and dendritic cells recruitment to inflamed tissues was identified.

Follow-up			
Median follow up (months)	31 (1-166)	38 (1-123)	0.645
Alive at last follow-up	36 (72%)	46 (59%)	0.134
Progression to acute myeloid leukemia	10 (20%)	7 (11%)	0.215

Inflammatory efficacy of biologics targeting inflammation and azacitidine were limited with an overall response rate below 25% at 3 months and below 10% at 12 months. Seven patients with active inflammatory disease received IDH inhibitors. The iORR was 86% at 3 months, 83% at 6 months and 66% at 12 months. All of the 7 patients displayed a hematological response.

Conclusion: This study suggests that *IDH* mutations may contribute to a distinct disease phenotype, marked by a predominance of inflammatory rheumatologic manifestations, particularly polymyalgia rheumatica. These findings highlight new therapeutic opportunities, including the use of targeted anti-IDH therapies.

Abstract Number: 1340

Does Moderate Alcohol Use Lower Disease Activity Among Patients with Rheumatoid Arthritis?

Sarah Crisci[1], Joshua Baker[2], Kevin Kane[3], George Reed[4], Dimitrios Pappas[5] and Joel Kremer[6], [1]New York University, New York, NY, [2]University of Pennsylvania, Philadelphia, PA, [3]University of Massachusetts Lowell, Lowell, MA, [4]University of Massachusetts Chan Medical School, Worcester, MA, [5]CorEvitas, New York, NY, [6]The Corrona Research Foundation, Delray Beach, FL

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: The relationship between alcohol use and disease activity among patients with rheumatoid arthritis (RA) remains controversial. Several studies have concluded that moderate drinking may be beneficial for individuals with RA. However, recent concerns about residual confounding have arisen within studies aimed at understanding causal risks of alcohol. This is because non-drinkers may have stopped consuming alcohol because of adverse health. Recent efforts in epidemiologic studies to define occasional use of alcohol as the reference may help reduce this bias. This study aimed to explore associations between alcohol use and clinical disease activity index (CDAI) among RA patients in a large sample, comparing the estimates of association when using non-drinkers or, alternatively, occasional drinkers as the comparison group.

Methods: This cross-sectional study assessed the association between disease activity and frequency of alcohol use, using data from the CorEvitas Rheumatoid Arthritis Registry, a prospective, observational, multi-site study of adults with RA. All patients in the Registry were provided-diagnosed. One visit per patient was randomly chosen, excluding the enrollment visit or last visit. Drinking is patient reported and divided into 6 categories. The association of mean CDAI with drinking categories was estimated using linear regression. A series of nested models adjusted for demographics and drug use, +comorbidities, and +pain and psychosocial factors. Estimates used "Not at All" or "Occasionally" as the reference category in the models.

Results: A total of 30,995 adults with non-missing confounding variables were included in this study. Non-drinkers had higher rates of disability, comorbidities (including diabetes, CAD, CHF, hypertension, obesity, and fibromyalgia), opioid use, depression, and anxiety; as well as higher scores for physician and patient global assessments, tender and swollen joints, pain, and fatigue compared to other categories (Table 1).

Compared to non-drinkers, any amount of drinking was associated with a lower CDAI with the greatest apparent benefit observed for moderate drinkers. [Unadjusted β: -3.65 (95 % CI: -4.16, -3.14)]. This was somewhat attenuated with adjustment for confounders [Fully adjusted β: -2.42 (95% CI: -2.91, -1.93)] (Table 2). The unadjusted estimate for moderate drinkers was reduced substantially when using occasional drinkers as the reference group. [Unadjusted β: -1.85 (95% CI -2.43, -1.17)] and was further attenuated with adjustment [β: -1.11 (95% CI: -1.66, -0.56)]. Figure 1 shows the mean difference in CDAI for the fully adjusted models.

Note: using test pearson across levels of drink6 for sex, smoking status, disabled, previous biologic use, Prednisone dose group, MTX dose group, Morning stiffness, History of diabetes, History of CAD, History of CHF, History of cancer, History of lung disease, History of chronic kidney disease, History of fibromyalgia, Hypertension, History of liver disease, Depression, Anxiety, NSAID use, Opioid use, CDAI cat4, and CCI group.
Note: using test kwallis across levels of drink6 for Age, Pain, Patient global assessment, Fatigue, Tender joints, Swollen joints, Physician global assessment, HAQ, BMI, Duration, CDAI, and CCI.
Note: Marital status, Site US region, Work status, Education, Weight (lbs), and BMI categories not shown for space considerations.

Conclusion: Light to moderate alcohol use was associated with lower disease activity in patients with RA, with moderate users seeing the biggest reduction in CDAI. However, the amount of observed benefit was far less when comparing moderate use to occasional use and after adjustment for confounding factors. These data raise questions regarding the accuracy of the estimated benefit of alcohol from prior studies where non-drinkers were used as the reference group and suggests that residual confounding is likely. A biologic mechanism for a benefit of alcohol effect is not known.

Abstract Number: 1341

Physical Function Across Age in Patients With Rheumatoid Arthritis and Population Controls: A Cross-Sectional Study of Four Performance Measures

Saskia Truijen[1], Annelies Boonen[1], Sofia Ramiro[2] and Marloes van Onna[1], [1]Maastricht University Medical Centre+ & Maastricht University, Maastricht, Limburg, Netherlands, [2]Leiden University Medical Center, Bunde, Netherlands

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) may accelerate age-related functional decline compared to the general population. This study aimed to examine whether four performance measures of physical function differ between older patients with RA and population controls, and whether this decline is stronger with increasing age in patients with RA.

Methods: Cross-sectional data of patients with RA and population controls without inflammatory rheumatic disease aged 55–85 years from the STudying Aging in Rheumatoid arthritis (STAR) study was used. Physical function was assessed using four measures. All participants completed the self-reported Cochin hand functional disability questionnaire (18 items; 0=no

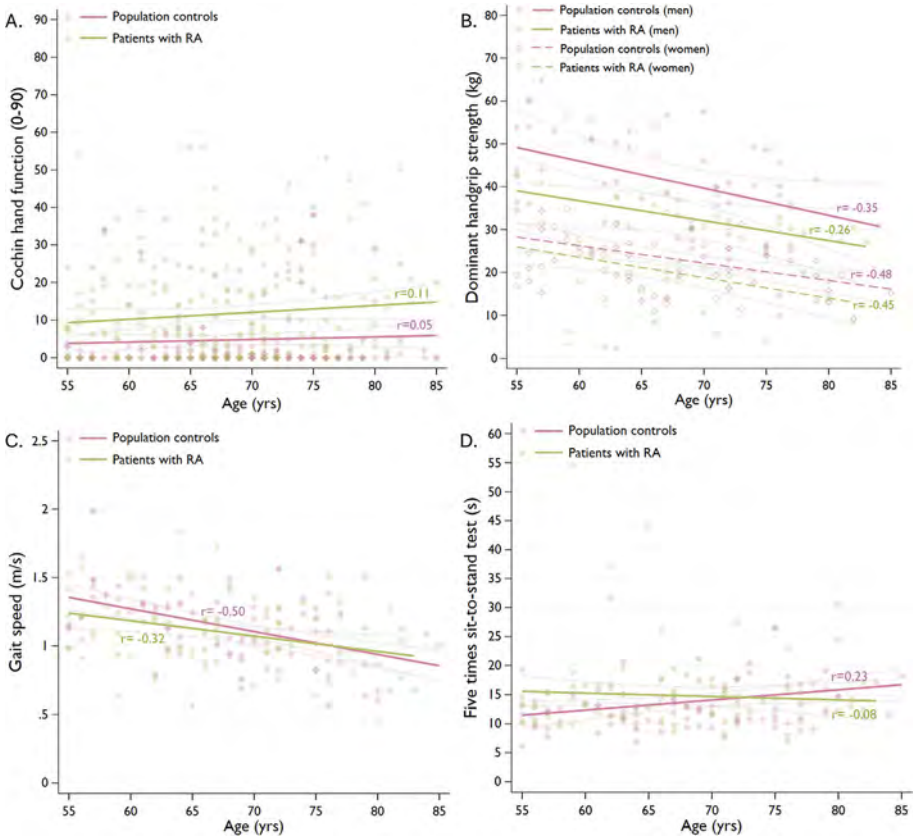

Figure 1. A) The Cochin hand function scale by age, stratified for population controls (n=209; r=0.05) and patients with RA (n=197; r=0.11) B) Observed dominant handgrip strength (kg) by age, stratified for population controls (men: n=38; r=-0.35, women: n=52; r=-0.48) and patients with RA (men: n=39; r=-0.26, women: n=38; r=-0.45) C) Gait speed (m/s) by age, stratified for population controls (n=90; r=-0.50) and patients with RA (n=78; r=-0.32) D) Five times sit-to-stand test (s) by age, stratified for population controls (n=90; r=0.23) and patients with RA (n=78; r=-0.08)

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Associations between group (RA vs control), adjusted for age and sex, and (thresholds of) functional ability assessed by the Cochin hand function scale (n=406), dominant handgrip strength, gait speed and five-times sit-to-stand test (n=168)

Linear regression		Dominant handgrip strength (kg) β (95% CI)	Gait speed (m/s) β (95% CI)	Five times sit-to-stand test (s) β (95% CI)
Age, *years*	-	-0.36 (-0.56 to -0.15)	-0.01 (-0.02 to -0.01)	0.06 (-0.07–0.18)
Sex, *women*	-	-11.34 (-15.39 to -7.30)	-0.10 (-0.18 to -0.03)	0.35 (-1.51–2.21)
Group, *patient with RA*	-	-4.70 (-7.68 to -1.72)	-0.04 (-0.12–0.03)	1.21 (-0.66–3.08)
Height, *cm* [1]	-	0.33 (0.12–0.53)	-	-
Logistic regression	**Cochin hand function scale score ≥1 vs. 0** [2] OR (95% CI)	**Diminished dominant handgrip strength (kg) according to Fried criteria** [3] OR (95% CI)	**Gait speed <0.8 m/s** [4] OR (95% CI)	**Five-times sit-to-stand test >15.0 s** [4] OR (95% CI)
Age, *years*	1.03 (1.00–1.06)	1.10 (1.05–1.15)	1.12 (1.05–1.20)	1.04 (1.00–1.09)
Sex, *women*	2.31 (1.48–3.61)	1.47 (0.72–2.98)	1.57 (0.57–4.34)	0.91 (0.47–1.77)
Group, *patient with RA*	4.90 (3.15–7.62)	2.51 (1.23–5.12)	2.45 (0.88–6.79)	1.81 (0.93–3.54)

[1] Handgrip strength was adjusted for height to account for body size differences
[2] Interaction $p<0.05$, however, not considered clinically relevant after stratification
[3] Based on the threshold for dominant hand grip strength of the Fried frailty criteria, stratified for gender and BMI quartiles:
Men: BMI ≤24 HGS ≤29 kg, BMI 24.1–26.0 HGS ≤30 kg, BMI 26.1–28.0 HGS ≤30 kg, BMI >28.0 HGS ≤32 kg
Women: BMI ≤23 HGS ≤17 kg, BMI 23.1–26.0 HGS ≤17.3 kg, BMI 26.1–29.0 HGS ≤18 kg, BMI >29.0 HGS ≤21 kg
[4] Based on the threshold for low performance (slow walking speed <0.8 m/s) and low strength (chair stand >15.0 s for five rises) according to the European Working Group on Sarcopenia in Older People.

functional hand disability, 90=maximal disability; score ≥1 = impaired). In a subpopulation, additional physical measurements were conducted: grip strength of the dominant hand measured with a dynamometer (kg; fulfilling sex- and BMI-specific Fried frailty criteria = impaired), gait speed using the four-meter walk test (< 0.8 m/s = impaired), and the Five Times Sit-to-Stand Test (FTSST) (>15.0s = impaired). Correlations between age and outcomes of physical function were explored separately for RA patients and controls and visualized using scatter plots. Linear and logistic regressions assessed age and sex adjusted associations between group (RA vs. control) and outcome, and the interaction age*group. Due to a left-skewed distribution, Cochin scores were only analyzed using logistic regression (≥1 vs. 0).

Results: A total of 416 persons were included: 197 patients with RA (mean age 68 ± 7, 62% women) and 209 population controls (mean age 68 ± 7, 60% women). The subpopulation consisted of 168 persons: 78 patients with RA (mean age 67 ± 8, 51% women) and 90 controls (mean age 68 ± 7, 58% women). Age correlated moderately with gait speed in controls and handgrip strength in female controls, but correlated weakly for all other comparisons (Figure 1A-D). For self-reported handfunction, RA patients were more likely to report a functional disability (score ≥1) (OR=4.9, 95%CI: 3.2–7.6) (Table 1). For hand grip strength, patients with RA had lower handgrip strength (β=-4.7, 95%CI: -7.7 to -1.7) and were more likely to meet the Fried criteria for low grip strength (OR=2.5, 95%CI: 1.2–5.1), as compared to controls. For gait speed and FTSST, no associations with RA were observed. A significant interaction between age and group was only observed for the Cochin scale, however, after stratification this was not considered clinically relevant.

Conclusion: These findings suggest that while RA leads to lower physical functioning compared to controls, this effect does not differ across age. Functional decline in RA may be more disease-specific than age-driven, highlighting the importance of early management of RA. The results may also indicate that current RA treatment may be effective in limiting excessive functional decline later in life, by reducing cumulative joint damage over time.

Abstract Number: 1342

The Impact of Age on Health-Related Quality of Life in Patients With Rheumatoid Arthritis Compared to Population Controls: A Cross-Sectional Analysis

Saskia Truijen[1], Annelies Boonen[1], Sofia Ramiro[2] and Marloes van Onna[1], [1]Maastricht University Medical Centre+ & Maastricht University, Maastricht, Limburg, Netherlands, [2]Leiden University Medical Center, Bunde, Netherlands

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: As the population ages, rheumatologists will increasingly care for older persons with rheumatoid arthritis (RA). Aging comes with specific challenges of which rheumatologists are currently insufficiently aware. Among others, there is limited understanding of how older age affects aspects of Health-Related Quality of Life (HRQoL) and whether the impact of age is different compared to controls.

Methods: Cross-sectional data of patients with RA and population controls without inflammatory rheumatic disease aged 55–85 years from the STudying Aging in Rheumatoid arthritis (STAR) study was used. HRQoL was assessed by the eight domains of the self-reported 36-item Short Form (SF-36) Health Survey Questionnaire (score 0–100: 0=worst, 100=best). Linear regression was used to test potential interactions between five age categories (ref 55–59 years) and group (RA/control), while adjusting for sex, with $p_{interaction}<0.10$ considered statistically significant. In subsequent multivariable linear regressions, body mass index (BMI), the no. of self-reported painful joints (Rheumatoid Arthritis Disease Activity Index (RADAI); score 0–48), physical function (Health Assessment Questionnaire (HAQ); score 0–3) and comorbidities (Charlson Comorbidity Index (CCI); score 0, 1, ≥2) were added to explore potential confounding of age category and group.

Results: A total of 406 participants were included: 197 patients with RA (mean age 68±7, 62% women) and 209 population controls (mean age 68±7, 60% women). Across all eight HRQoL domains, patients with RA reported lower scores than controls (∼10–20 points lower on average). For bodily pain (BP), general health (GH), role emotional (RE) and mental health (MH), no differential effect of age category between patients and controls were observed ($p_{interaction}\geq0.10$) (Table 1). For physical functioning (PF), role physical (RP), social functioning (SF) and vitality (VT), interactions between RA/control and age categories were significant. Scores for PF and SF tended to be worse in patients with RA aged 75–85 years compared to the

PF Physical Functioning; RP Role Physical; SF Social Functioning; VT Vitality; RA Rheumatoid Arthritis

youngest group, but remained unchanged (PF) or even improved (SF) in controls aged 70–74 years (Table 2). No effect of age on scores for RP and VT were observed in patients, while better scores with increasing age were observed in controls, specifically in those 70–74 years. After adjusting for health-related confounders, the impact of RA on RE, MH, BP and GH reduced or disappeared, and a positive age effect emerged in those aged 75–85 years for MH and 70–74 for BP (data not shown). For domains that had to be stratified, the effect of age was (i) attenuated for PF among RA patients, (ii) unchanged for VT and SF in patients and controls and (iii) stronger for RP in controls aged 75–85 years.

Conclusion: These findings suggest that age-related changes in HRQoL differ between patients with RA and controls, by age category, and SF-36 domain. Older RA patients begin at a lower baseline, experience a decline in physical functioning, and miss the age-related improvements seen in controls in role physical, vitality and social functioning. Clinicians should more aware of these differences and gain more attention on supporting psychosocial well-being in older patients with RA.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: The six-minute walk distance (6MWD) measures functional capacity in cardiopulmonary diseases, predicts mortality in interstitial lung disease (ILD), and is used as an endpoint in trials. In RA, 6MWD correlates with patient-reported outcomes and adverse cardiovascular events, yet few studies investigate 6MWD in RA-ILD.

Methods: We performed a cross-sectional analysis using baseline data from the Korean RA-ILD (KORAIL) cohort, a multicenter prospective study. RA was diagnosed based on the 2010 ACR/EULAR criteria, and ILD was confirmed by chest CT imaging. Participants were assessed for RA disease activity using the DAS28 and laboratory tests, including ESR and CRP. ILD status was evaluated by chest CT and pulmonary function tests, including forced expiratory volume in one second (FEV_1), forced vital capacity (FVC), and diffusing capacity of the lung for carbon monoxide (DLCO). The expected lower limit of the six-minute walk distance (eLL-6MWD) was calculated based on age, sex, height, and weight. Associations of 6MWD or having a 6MWD below the expected lower limit (eLL-6MWD) with predictors were analyzed using linear or logistic regression, while their associations with progression or mortality were analyzed using Cox regression, adjusting for age, sex, height, and weight.

Results: We analyzed 141 patients with RA-ILD (mean age 66.7 years, 32.6% male, 61.7% with the usual interstitial pneumonia [UIP] pattern). The median RA duration was 6.0 years (interquartile range [IQR] 1.2 to 10.7), and the median ILD duration was 1.5 years (IQR 0.2 to 4.6). The mean DAS28-ESR score was 4.1 (standard deviation [SD] 1.4), with 70.7% of patients having moderate/high disease activity. ILD extent >10% on chest CT was present in 40.4%. The mean FVC% was 84.2 (SD 17.3), DLCO% was 71.3 (SD 19.4), and 6MWD was 339 meters (SD 113). Overall, 49.6% had a 6MWD below the eLL-6MWD. Participants with moderate or high disease activity demonstrated shorter six-minute walk distances (6MWD) compared to those in remission or low disease activity (β -50.3) (Table 1). Higher HAQ scores were also associated with shorter 6MWD (β -50.1) and higher ESR and CRP levels (ESR: -30.5 per SD; CRP: β -23.1 per SD). Higher FEV_1%, FVC

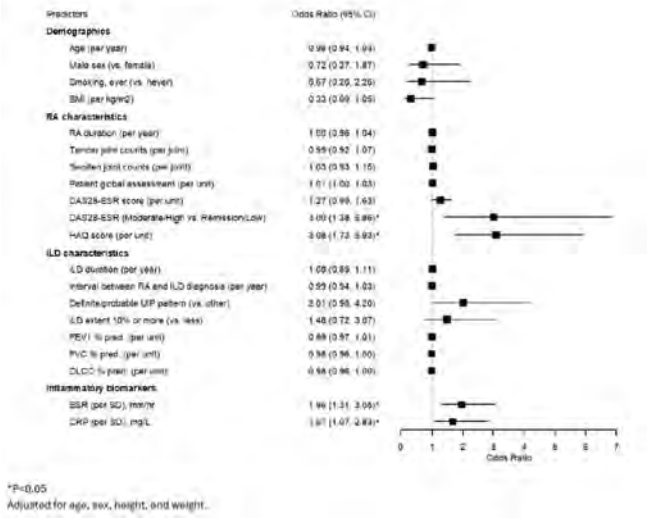
Figure 1. Factors associated with a 6-minute walk distance of less than expected lower limit (adjusted for age, sex, height, and weight) among patients with RA-ILD.



*P<0.05
Adjusted for age, sex, height, and weight.

%, and DLCO% were associated with longer 6MWD (FEV_1%: β 1.1, FVC%: β 1.5, DLCO%: β 1.2). The odds of having a 6MWD below eLL-6MWD were higher among participants with moderate or high disease activity (odds ratio [OR] 3.00), higher HAQ score (OR 3.08 per unit), higher ESR (OR 1.96 per SD), and higher CRP (OR 1.67 per SD) (Figure 1).

No significant associations were observed between 6MWD and ILD progression (hazard ratio [HR] 1.00 per meter, 95%CI 1.00 to 1.00) or all-cause mortality (HR 1.00 per meter, 95%CI 0.99 to 1.00), nor between 6MWD below eLL-6MWD and ILD progression (HR 1.23, 95%CI 0.68 to 2.22) or all-cause mortality (OR 1.85, 95%CI 0.71 to 4.81).

Conclusion: In RA-ILD, older age, moderate/high RA disease activity, worse HAQ, and increased ESR and CRP were associated with shorter 6MWD, while high FEV1%, FVC%, and DLCO% were associated with longer 6MWD. Collectively, these results suggest that the 6MWD test may provide a simple functional assessment that encompasses pulmonary function as well as RA-related disease activity and function.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Tofacitinib is the first oral targeted synthetic disease-modify anti-rheumatic drug for patients with moderate to severe rheumatoid arthritis [1]. This study aimed to identify the factors associated with the discontinuation of tofacitinib in patients with RA in clinical practice.

Methods: RA patients who received tofacitinib between 2015 and 2020 were included in this observational cohort study. The patients were followed for at least one year, ending on December 31, 2022. A tofacitinib non-responder was defined as a patient who required discontinuation or switch to another bDMARD. Conversely, tofacitinib responders were defined as those who could continue to receive tofacitinib without experiencing a loss of efficacy or severe adverse events. Univariate and multivariate Cox regression analyses and Kaplan–Meier survival curve analysis were used to investigate the factors associated with the discontinuation of tofacitinib.

Results: A total of 266 patients were enrolled. The average age of the patients was 57.07 ± 12.07 years, and 99 (37.2%) were tofacitinib non-responders. Univariate analysis revealed that the non-responders had a lower rate of concomitant hydroxychloroquine treatment, and higher rates of leflunomide, biological disease-modifying antirheumatic drug (bDMARD), and tumor necrosis factor inhibitor (TNFi) treatment compared to the responders. Cox regression adjusted analysis indicated that prior bDMARD treatment (hazard ratio (HR) = 1.423, 95% confidence interval (CI) = 1.024, 1.976, p = 0.036), prior TNFi treatment (HR = 1.605, 95% CI = 1.165, 2.212, p = 0.004), and prior non-TNFi treatment (HR = 1.326, 95% CI = 1.012, 2.075, p = 0.048) were associated with a higher non-response rate. Moreover, Kaplan–Meier survival curve analysis revealed that the patients with prior bDMARD treatment had a higher non-response rate.

Conclusion: The RA patients who received tofacitinib in this study had a good response rate, and the average non-response rate was around 37% after two years of treatment. The main factor associated with an inadequate response to tofacitinib was prior bDMARD treatment. Prior TNFi treatment was the strongest factor associated with a non-response to tofacitinib. Patients with a non-response to tofacitinib may consider bDMARDs with other mechanisms if previous treatment with TNFis was unsuccessful.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1306–1346) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Difficult-to-treat rheumatoid arthritis (D2T-RA) represents a clinically challenging RA subset defined by failure to achieve disease control despite multiple conventional and advanced therapies. The immunopathogenesis of D2T-RA remains poorly understood. Prior studies suggest that elevated pretreatment type I interferon (IFN) signatures are associated with poor responses to tumor necrosis factor inhibitors (TNFi). Although Janus kinase (JAK) inhibitors, which modulate multiple cytokine pathways, are widely used, D2T-RA persists in a subset of patients. This study aimed to elucidate the immunological basis of D2T-RA through transcriptomic comparisons between propensity score–matched D2T and non-D2T patients.

Methods: Peripheral blood samples were obtained from 473 RA patients enrolled at the Department of Rheumatology, Japanese Red Cross Okayama Hospital, between March 2012 and September 2023, prior to initiation of new treatments. Based on EULAR criteria, 14 patients were identified as D2T, and 459 as non-D2T, the latter confirmed by at least two years of follow-up. Propensity score matching (1:1) was performed using age, DAS28-ESR, and the number of prior medications, yielding 13 matched pairs. RNA sequencing was conducted, and differentially expressed genes (DEGs) were identified using the LRM Paired-edgeR approach. Subsequent analyses included hierarchical clustering, Gene Ontology (GO) and pathway enrichment analyses, and weighted gene co-expression network analysis (WGCNA).

Results: At least 11 of 14 D2T patients demonstrated inadequate responses to JAK inhibitors. A total of 2,875 DEGs ($P < 0.05$) were identified, among which 288 genes with transcripts per million (TPM) ≥ 1 in either group were subjected to further analysis. Hierarchical clustering did not distinctly segregate D2T from non-D2T patients. Of these 288 genes, 114 were upregulated (positive DEGs) and 174 downregulated (negative DEGs) in the D2T group. GO analysis of the positive DEGs revealed enrichment of genes associated with immunity, particularly those involved in T cell function, innate immunity, and Toll-like receptor (TLR) signaling—most notably, the TLR7 pathway. Pathway analysis confirmed significant upregulation of TLR-related pathways. WGCNA identified five modules, one of which was enriched for TLR-associated genes.

Conclusion: This transcriptomic study identified marked upregulation of TLR signaling, especially TLR7-associated pathways, in patients with D2T-RA. These findings suggest that dysregulated TLR signaling may play a central role in the pathogenesis of treatment-refractory RA and offer potential insights for targeted therapeutic strategies.

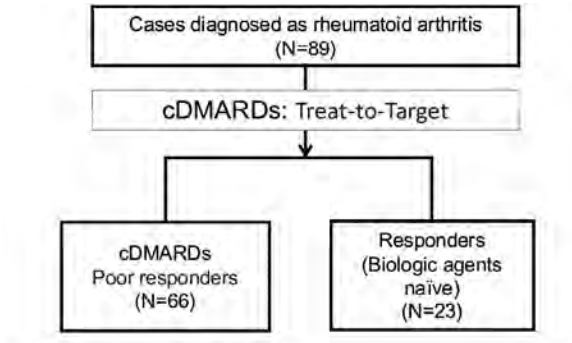
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

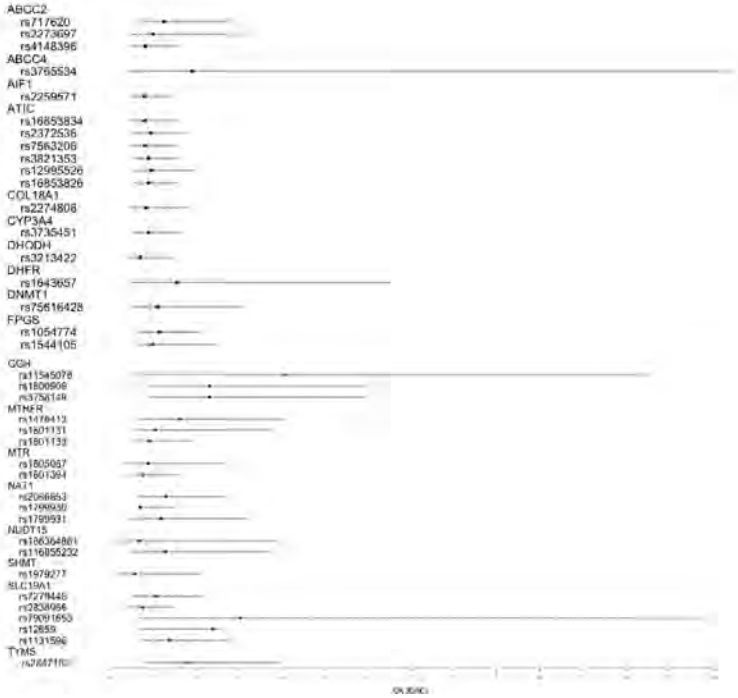
Background/Purpose: Multiple Single-Nucleotide Polymorphisms (SNPs), including those in the methotrexate and azathioprine metabolic pathways, are associated with poor response to conventional disease-modifying anti-rheumatic drugs (cDMARDs) in Caucasians with rheumatoid arthritis. This retrospective cohort study aimed to investigate the association between SNPs and cDMARDs in responders and poor responders.

Methods: cDMARDs responders were defined as patients who had received standard treatment for at least 6 months and had not yet used biological agents. Poor responders were defined as patients who had received cDMARD therapy for at least 6 months and subsequently required treatment with biological agents. Genotype analysis was performed using *Axiom Genome-Wide TPM 2.0 Array Plate*, specifically designed for our population and contained 752,922 probes per array plat. A total of 38 SNPs were selected in *AMPD*, *ATIC*, *DHFR*, *FPGS, GGH, ITPA*, *MTHFR*, *SLC19A1* and *TYMS* genes, which affect the methotrexate and azathioprine metabolic pathways. The distribution of allele frequency, odds ratio (OR), and 95% confidence intervals (CI) were calculated to evaluate the association between the categorical variables. A p-value of < 0.05 was considered to be statistically significant.



Clinical characteristics

cDMARDs	Poor responders	Responders	P vaule
Age	58.8 ± 11.3	57.4 ± 10.6	0.5951
Female (%)	48 (73%)	15 (68%)	0.6707
RF	315.52 ± 578.46	333.74 ± 554	0.8825
anti-CCP	189.21 ± 165	103.7 ± 135.3	0.01137*
1st CRP	1.76 ± 2.68	1.44 ± 2.63	0.5215
1st ESR	34.5 ± 22.7	32.64 ± 25.6	0.6758
ΔCRP 6M	-0.70± 2.72	-1.34 ± 2.84	0.2342
ΔESR 6M	-8.21 ± 22.71	-13.02 ± 26.17	0.3153



Flow chart and Result of OR CI95% illustrated by forest plot

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Approximately 724,985.3 ± 416.1 (mean ± standard deviation) of SNP per sample met quality control requirements. SNPs affecting the methotrexate and azathioprine metabolic pathways were then selected. A total of 89 study participants including 66 DMARDs poor responders and 23 DMARDs responders were included in this study. There were no significant differences in age and sex between the two groups. Serum anti-CCP levels were significantly higher in the cDMARDs poor responder group (189.2 versus 103.7 U/mL, p = 0.011*). The distribution of allele frequency of the selected 38 SNPs and 2 in *GHH* (rs1800909 and rs3758149) were statistically different between the two groups (p =0.04062*, OR = 2.31, 95% CI: 0.91–5.31), and were associated with lower methotrexate efficacy.

Conclusion: The pharmacogenetics effects of cDMARDs poor responders could not be demonstrated in this study due to the small sample size. However, two SNPs (rs1800909 and rs3758149) in *GHH* which affect the methotrexate metabolic pathway were significantly different between the two groups. These SNPs exhibited a tendency towards an increasing OR. These genotypes can be presented as cDMARDs poor responders in our cohort.

Abstract Number: 1347

The Better Disease-modifying antirheumatic drug (DMARD)? Efficacy and Safety of Methotrexate Versus Leflunomide Monotherapy in Rheumatoid Arthritis: A Systematic Review and Meta-Analysis

Aakanksha Pitliya[1], Srivatsa Surya Vasudevan[2], Sarthak Sharma[3], Bijay Mukesh Jeswani[4], Tanya Ratnani[5] and Rajesh Thirumaran[6], [1]Mercy Catholic Medical Center, Darby, PA, Clifton Heights, PA, [2]Louisiana State University Health Sciences Center, Shreveport, LA, [3]Government Medical College, Jammu, Jammu, Jammu and Kashmir, India, [4]GCS Medical College, Hospital and Research Center, Ahmedabad, Gujarat, India, [5]Chhattisgarh Institute of Medical Sciences, Bilaspur, Chhattisgarh, India, [6]Mercy Catholic Medical Center, Darby, PA

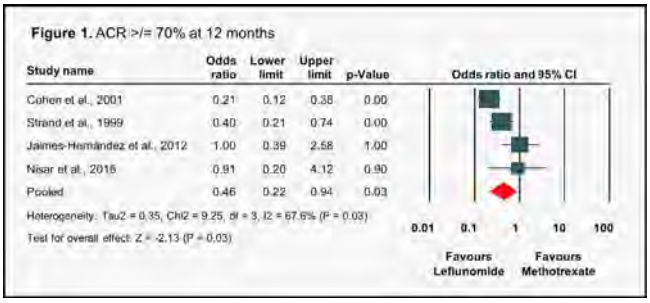
SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1347–1375) Rheumatoid Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Methotrexate (MTX) and leflunomide (LEF) are commonly used disease-modifying antirheumatic drugs (DMARDs) in the treatment of rheumatoid arthritis (RA). While both are widely prescribed, their comparative efficacy and safety remain a subject of clinical debate. This systematic review and meta-analysis aimed to evaluate and compare the efficacy and safety outcomes of MTX and LEF monotherapies in RA patients.

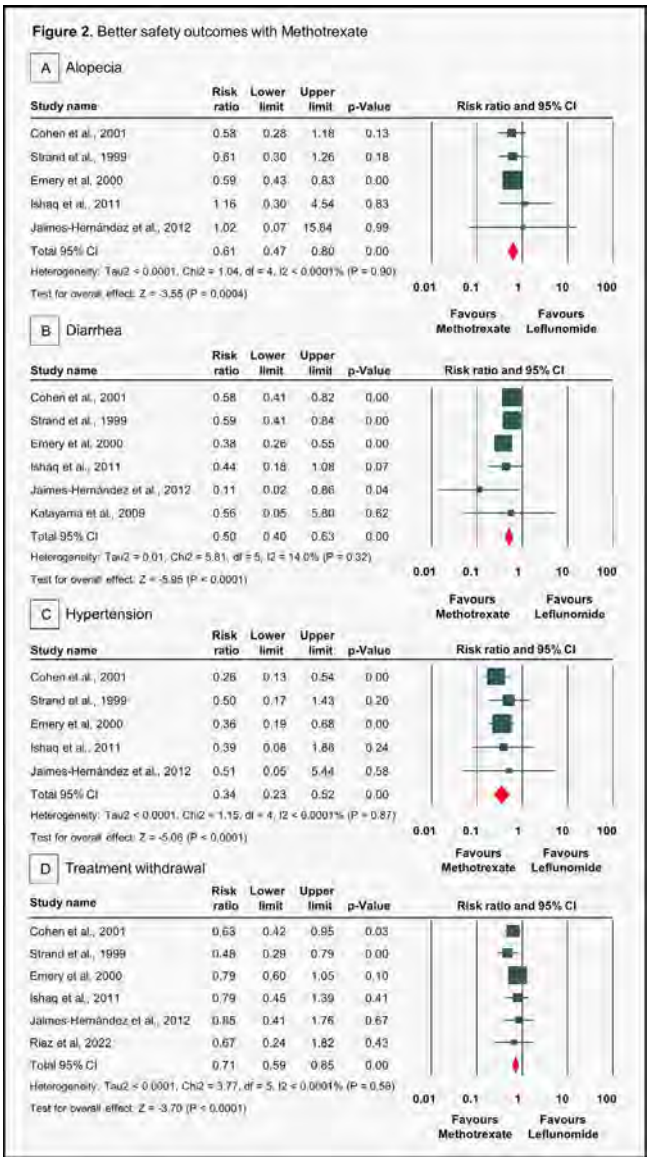
Methods: We conducted a systematic review and Meta-analysis using PRISMA guidelines. A comprehensive literature search was conducted in Medline, Embase, and the Cochrane Library from inception to 2025 to identify clinical trials and observational studies comparing MTX and LEF. A total of 7920 articles were initially identified. After removing duplicates and screening titles and abstracts, 39 full-text articles were reviewed, and 10 studies met the inclusion criteria. The quality analysis was conducted by two independent reviewers using the Cochrane RoB 2 for RCTs and the Newcastle Ottawa tool for observational studies. Primary outcomes were comparative efficacy and safety of both drugs. A random-effects model was used to perform meta-analyses, with odds ratios (ORs) calculated for efficacy outcomes and risk ratios (RRs) for safety outcomes to compare the two treatment groups. Heterogeneity among studies may affect the comparability of outcomes.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Ten studies were included for comparative analysis, comprising 6 RCTs and 4 observational studies, with a total of 5514 participants (2059 in the LEF group and 3455 in the MTX group). The study population had a mean age of approximately 51.5 ± 0.21 years and a female predominance of 78.39%. Efficacy analysis revealed that methotrexate was significantly less effective than leflunomide in achieving a 70% improvement in ACR response (ACR ≥70) at

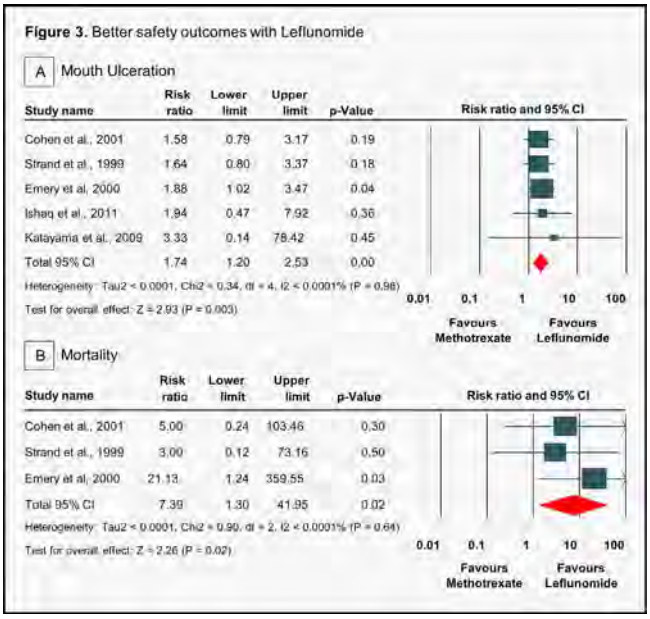


Comparison of the statistically significant efficacy of Methotrexate and Leflunomide



Comparison of safety outcomes: Methotrexate and Leflunomide with Methotrexate showing superior outcomes

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Comparison of safety outcomes: Methotrexate and Leflunomide, with Leflunomide showing superior outcomes

12 months (OR 0.46, 95% CI 0.22–0.94, p = 0.03) (Figure 1). No other ACR response comparisons at 12 or 24 months showed statistically significant differences between the two treatments. Regarding safety outcomes, methotrexate was associated with a lower risk of diarrhea (RR 0.50, 95% CI 0.40–0.63, p < 0.001), alopecia (RR 0.61, 95% CI 0.47–0.80, p = 0.0004), withdrawal due to adverse events (RR 0.71, 95% CI 0.59–0.85, p = 0.0002), and hypertension (RR 0.34, 95% CI 0.23–0.52, p < 0.001) compared to leflunomide (Figure 2). However, it was associated with a higher risk of mouth ulceration (RR 1.74, 95% CI 1.20–2.53, p = 0.003) and mortality (RR 7.39, 95% CI 1.30–41.95, p = 0.02) (Figure 3).

Conclusion: This meta-analysis demonstrates significant differences in both efficacy and safety outcomes between the two treatment groups. Leflunomide showed superior efficacy compared to methotrexate in achieving a high-level ACR response at 12 months, while methotrexate was associated with a more favorable safety profile, including lower risks of diarrhea, alopecia, hypertension, and treatment withdrawal.

Session Title: (1347–1375) Rheumatoid Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Here, we provide descriptive baseline characteristics and effectiveness outcomes of Baricitinib (BARI) and other ts/bDMARDs at 24-month (24M) in both European (EU) and non-European regions (OEU) regions, in addition to the effectiveness of BARI in EU countries at 36M, from the RA-BE-REAL study.

Methods: Patients (N=1322) with rheumatoid arthritis (RA) from five EU countries (France, Germany, Italy, Spain, and UK) and three OEU countries (Australia, Canada, and Saudi Arabia) initiated BARI 2 mg or 4 mg (Cohort A) or any other targeted synthetic (ts) or biologic (b) disease-modifying antirheumatic drugs (DMARDs)(Cohort B) as per label requirements for the first time. Response rates for remission (REM) and low disease activity (LDA) were determined by the Clinical Disease Activity Index (CDAI), and patient's assessment of pain using the 100 mm pain visual analog scale (VAS).

Results: A summary of patient characteristics identified higher baseline disease activity in OEU countries however, improvements in disease activity and pain were observed in both regions at 24M, **Table 1**.

Table 1: Baseline data and effectiveness of treatment at 24M

Baseline Data	EU Region N=1071		OEU Region N=251		Overall EU & OEU Regions N=1322
	Baricitinib Cohort A N=511	Other ts/bDMARDs Cohort B N=560	Baricitinib Cohort A N=115	Other ts/bDMARDs Cohort B N=136	
Age, years	59.2 *(13.24)*	57.1 *(13.86)*	59.9 *(12.41)*	57.0 *(12.95)*	58.1 (13.44)

Table 2: Effectiveness of BARI at 24M and 36M in the EU subgroup

	Baseline n/N=469/511	CFB at 24M n/N=275/339	CFB at 36M n/N=255/315
CDAI, mean (SD)	23.7 (11.66)	-15.3 (12.43)	-14.2 (13.14)
Pain VAS, mean (SD)	58.9 (22.94)	-24.4 (30.10)	-23.6 (31.34)
CDAI REM, n (%)	1 (0.2)	65 (23.6)	69 (27.1)
CDAI LDA, n (%)	42 (9.0)	123 (44.7)	120 (47.1)

Abbreviations: Bari, baricitinib; M, months; EU, European; CFB, Change from Baseline; CDAI, Clinical Disease Activity Index; VAS, visual analog scale (mm); REM, Remission; LDA, low disease activity.

Effectiveness results at 24M within the EU and OEU subgroups mirrored the overall effectiveness data. The overall CDAI mean CFB at 24M was -13.3 (12.63) in the EU and -21.2 (17.19) in the OEU regions. The mean CFB in pain VAS was -20.6 (30.36) and -21.9 (28.97) in EU and OEU regions, respectively. Most patients within the EU and OEU subgroups achieved CDAI REM or LDA by 24M (EU: 68.3% Cohort A [23.6% REM, 44.7% LDA], 61.4% Cohort B [23.1% REM, 38.3% LDA]; OEU: 70.8% Cohort A [27.7% REM, 43.1% LDA], 65.4% Cohort B [24.4% REM, 41.0% LDA]), with results numerically favoring BARI.

Patients treated with BARI in the EU subgroup were followed up for 36M, and improvements in disease activity and pain were maintained from baseline, **Table 2**.

Conclusion: Baseline clinical characteristics indicated that OEU patients exhibited higher disease activity, with similar improvements observed in EU and OEU patients treated with BARI. Effectiveness outcomes within EU and OEU subgroups reflected overall results, with results numerically favoring BARI. Effectiveness outcomes in the EU population of patients treated with BARI demonstrated a sustained response over 36M.

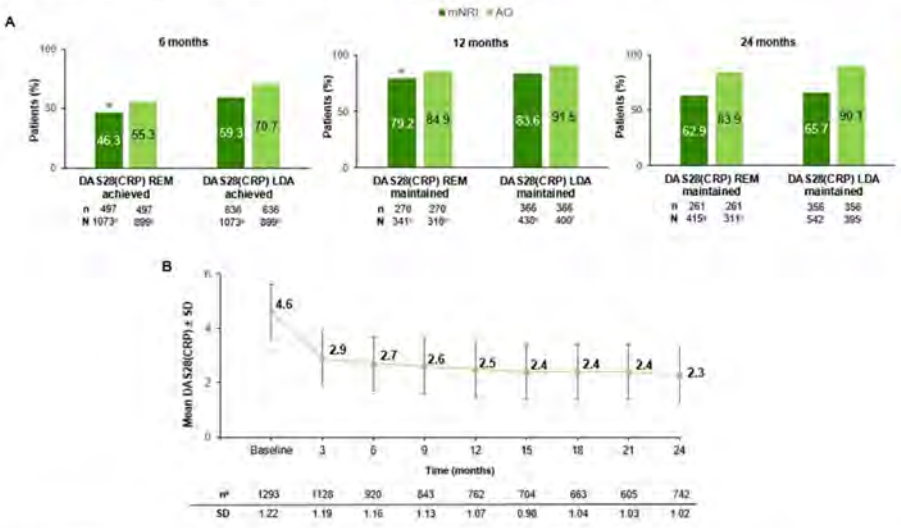
Background/Purpose: We evaluated long-term achievement of treatment targets, sustained clinical response, and safety of upadacitinib (UPA) over 2 years in patients with moderate-to-severe rheumatoid arthritis (RA).

Methods: UPHOLD (NCT04497597) is an observational cohort study of UPA-naïve adults with RA (data collected: 16 October 2020-15 May 2024). Co-primary endpoints were achievement of DAS28(CRP) remission < 2.6 (6 months) and maintenance of DAS28(CRP) remission (or ≤0.6-point increase) at 12 months (analyzed by modified non-responder imputation (NRI) or as observed [AO]). mFAS1 included patients in FAS (receiving ≥1 UPA dose) who completed 6 months and those who discontinued before 6 months; mFAS2 included patients achieving DAS28(CRP) remission within mFAS1 who completed 12 months and those discontinuing between 6 and 12 months. Key endpoints were proportion achieving/maintaining DAS28(CRP) low disease activity (LDA≤3.2); maintaining DAS28(CRP) remission/LDA by treatment strategy (UPA monotherapy or csDMARD combined) and prior therapy exposure (ts/bDMARD-naïve, ts/bDMARD-experienced, tsDMARD-experienced or TNF inhibitor only-experienced); mean DAS28(CRP) values; proportion in each DAS28(CRP)/CDAI/SDAI disease category; PROs change from baseline.

Results: 1699 of 1715 total participants received ≥1 UPA dose (FAS; UPA monotherapy [48.3%], +/- csDMARDs [51.7%]). 1029 (60.0%) completed 24 months and 686 (40.0%) prematurely discontinued (lack of efficacy [15.2%], adverse events [9.5%] and loss to follow-up [5.5%]). 1524 participants received prior therapy (≥1 bDMARD [64.3%] and ≥1 tsDMARD [18.3%]). In mFAS1 (n=1073, 6 months), 46.3% (mNRI) and 55.3% (AO) achieved DAS28(CRP) remission. In mFAS2 (n=341, 12 months), 79.2% (mNRI) and 84.9% (AO) maintained DAS28(CRP) remission. Similar trends for 6 and 12 months were observed with higher rates for DAS28(CRP) LDA (Figure 1A). Of 6-month responders, most maintained response until the end of the study at 24 months (DAS28(CRP) remission: 62.9% [mNRI]; 83.9% [AO]; DAS28(CRP) LDA: 65.7% [mNRI]; 90.1% [AO]) (Figure 1A). DAS28(CRP), CDAI(≤2.8) and SDAI(≤3.3) remission was achieved at 24 months in 66.8%, 36.1%

Figure 1. Effectiveness: (**A**) Achievement of DAS28(CRP) remission (<2.6) and LDA (≤3.2) and maintenance of response through 24 months; and (**B**) decrease in mean DAS28(CRP) per analysis visit in patients with moderate-to-severe RA treated with UPA through 24 months



*Co-primary endpoints.

[a]mFAS1: FAS patients who completed 6 months of treatment and had DAS28(CRP) data available or discontinued the study for any reason before month 6. [b]mFAS1 patients with non-missing DAS28(CRP) data. [c]mFAS2: mFAS1 patients who achieved REM at 6 months, completed 12 months of treatment and had DAS28(CRP) data available, or discontinued the study for any reason between 6 and 12 months. [d]mFAS2 patients with non-missing DAS28(CRP) data. [e]mFAS1 patients who achieved LDA at 6 months, completed 12 months of treatment and had DAS28(CRP) data available, or discontinued the study between 6 and 12 months. [f]mFAS1 patients who achieved LDA at 6 months, completed 12 months of treatment and had DAS28(CRP) data available. [g]FAS patients who achieved REM at 6 months, completed 24 months of treatment and had DAS28(CRP) data available at 6 and 24 months, or discontinued the study between 6 and 24 months. [h]FAS patients who achieved REM at 6 months, completed 24 months of treatment and had DAS28(CRP) data available at 6 and 24 months. [i]FAS patients who achieved LDA at 6 months, had DAS28(CRP) data available at 6 and 24 months, and continued to receive UPA at 24 months or discontinued the study between 6 and 24 months. [j]FAS patients who achieved LDA at 6 months, had DAS28(CRP) data available at 6 and 24 months, and continued to receive UPA at 24 months. [k]Patients with non-missing data.

AO, as observed; DAS28(CRP), disease activity score in 28 joints using C-reactive protein; FAS, full analysis set; LDA, low disease activity; mFAS, modified FAS; mNRI, modified non-responder imputation; RA, rheumatoid arthritis; REM, remission; SD, standard deviation; UPA, upadacitinib.

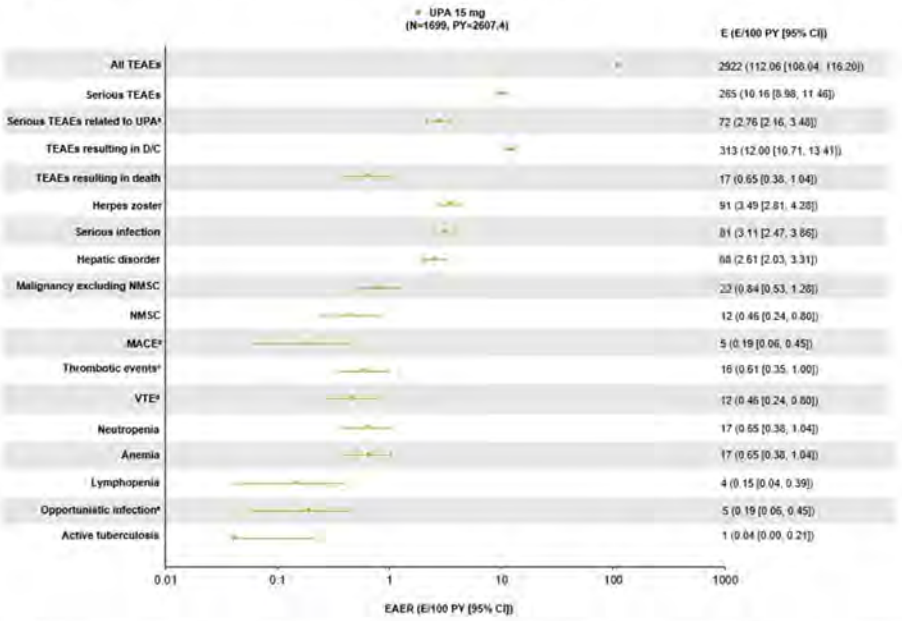
Figure 2. Safety: EAERs of TEAEs in patients with moderate-to-severe RA treated with UPA



Safety was evaluated by assessing all TEAEs (AEs occurring after the first dose of study drug and up to 30 days after the last dose of study drug) occurring in the FAS up to the data cutoff date of 15 May 2024. There were no reported events of gastrointestinal perforation. [a]Reasonable possibility. [b]Includes cardiovascular death, non-fatal myocardial infarction, and non-fatal stroke. [c]Includes VTE, other venous thrombosis, and arterial thromboembolic events. [d]Includes deep vein thrombosis, venous thromboembolism, and pulmonary embolism. [e]Excluding herpes zoster and active tuberculosis.

AE, adverse event; CI, confidence interval; D/C, discontinuation; E, event; EAER, exposure-adjusted event rate; FAS, full analysis set; MACE, major adverse cardiovascular events; NMSC, non-melanoma skin cancer; PY, patient-years; RA, rheumatoid arthritis; TEAE, treatment-emergent adverse event; UPA, upadacitinib; VTE, venous thromboembolic events.

and 36.7% participants, respectively (FAS; AO). Mean DAS28(CRP) decreased from 4.6 at baseline to 2.9 (3 months) and 2.3 (24 months) (Figure 1B). Improvements were observed regardless of UPA monotherapy/csDMARD combined treatment or prior therapy exposure in all assessed PROs at 3 months and maintained or improved through 24 months. 2922 TEAEs and 265 serious TEAEs were reported. Rates of herpes zoster, serious infection, hepatic disorder, malignancy excluding non-melanoma skin cancer (NMSC), NMSC, VTE and MACE were consistent with previous UPA safety data (Figure 2).[2]

Conclusion: UPA was effective in treating RA in RW practice. About half of patients treated with UPA achieved DAS28(CRP) remission at 6 months; almost 80% maintained remission at 12 months and >60% at 2 years (mNRI). The benefit–risk profile remains consistent with phase 3 clinical trials.[1,2]

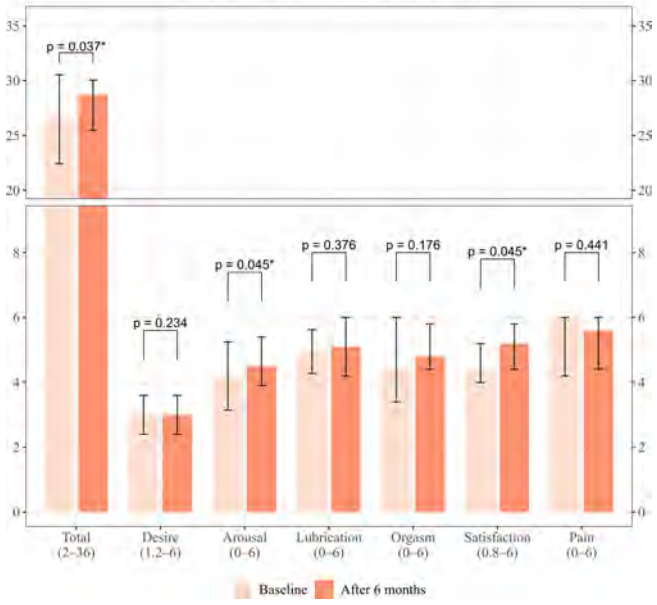
SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1347–1375) Rheumatoid Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) significantly impacts quality of life in multiple domains. This study aimed to evaluate the impact of initial biologic/targeted synthetic disease-modifying anti-rheumatic drug (b/tsDMARD) therapy on sexual function in women with RA and sought to assess changes in sexual function over six months of treatment and identify clinical and laboratory predictors of these changes.

Figure 1. Female Sexual Function Index
Before and after b/tsDMARD therapy (n = 23)



23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1. Baseline Characteristics

Characteristic (score range: worst - best)	Total n = 23
Age [years]	49.19 (39.39, 54.93)
Seropositivity	16 (73%)
DAS-28-CRP	5.52 (4.74, 6.40)
DAS-28-ESR	5.63 (5.38, 6.40)
CRP [mg/L]	7.17 (5.56, 17.75)
ESR [m/hours]	13.00 (9.00, 20.00)
Biological Therapy - Agent	
adalimumab	11 (48%)
baricitinib	1 (4.3%)
certolizumab pegol	3 (13%)
etanercept	8 (35%)
Biological Therapy - MoA	
TNFa inhibitor	22 (96%)
JAK inhibitor	1 (4.3%)
HAQ (3-0)	1.38 (1.00, 1.63)
MDHAQ-RAPID3 (30-0)	15.70 (12.00, 18.20)
EuroQol (0-1)	0.62 (0.09, 0.69)
SF-36 Mental Component Score (5.5–63.6)	38.78 (34.42, 46.70)
SF-36 Physical Component Score (16.6–57.9)	26.56 (21.93, 31.12)

Table 1 shows the baseline characteristics of our patient cohort. Data are presented as median (IQR) for continuous and n (%) for categorical variables. Acronyms: CRP, Creactive protein; DAS-28, Disease Activity Score 28; ED; ESR, Erythrocyte sedimentation rate; HAQ, Health Assessment Questionnaire; MDHAQ – RAPID3, Multidimensional Health Assessment Questionnaire; SF-36, Short Form Health Survey Questionnaire.

Methods: Women with RA indicated for b/tsDMARD therapy within the Czech ATTRA registry were recruited. Participants completed the Female Sexual Function Index (FSFI; higher scores indicate better sexual function) at baseline (M0) and after six months (M6). Routine clinical and laboratory data were collected, with patient-reported outcomes regarding function and quality of life (Health Assessment Questionnaire (HAQ), 36-Item Short Form Health Survey (SF-36), EuroQoL 5-Dimension Questionnaire (EuroQoL), and Multidimensional Health Assessment Questionnaire (MDHAQ)). Comparisons were performed using the Wilcoxon test, p-values adjusted for multiple comparisons using the Benjamini-Hochberg method. Selection of baseline predictors with improvement in IIEF domains was performed using LASSO regression. Associations with FSFI improvement were assessed using bivariate screening.

Results: Out of 36 screened patients, 23 sexually active women completed the questionnaires at both time intervals (Table 1). The baseline prevalence of sexual dysfunction was 47% (defined as the published cutoff of FSFI Total < 26.55).

At the 6-month follow-up, b/tsDMARD therapy had a significant positive effect on inflammation (ESR, CRP), disease activity (DAS28-ESR, DAS28–CRP), function, and quality of life (HAQ, MDHAQ, SF-36, and EuroQoL) ($p < 0.05$ for all).

Table 2. Predictors of Sexual Function Improvement

IIEF Domain (follow-up – baseline)	Coefficients
FSFI Total	FSFI Satisfaction (-0.91), HAQ (0.77), Cardiovascular Disease (-0.7), FSFI Total (-0.4)
FSFI Desire	FSFI Desire (-0.19), FSFI Total (-0.09), HAQ (0.05)
FSFI Arousal	FSFI Arousal (-0.18), HAQ (0.01)
FSFI Lubrication	-
FSFI Orgasm	FSFI Orgasm (-0.56), HAQ (0.27), Weight (0.21), Importance of Sexual Activity (0.19), Swollen Joint Count (-0.18), Cardiovascular Disease (-0.15), Tender Joint Count (-0.13), FSFI Satisfaction (-0.08), NSAID use (0.07), FSFI Lubrication (0.07), Disease activity reported by the patient (0.06), Metabolic disease (-0.05), Age (-0.02)
FSFI Satisfaction	FSFI Satisfaction (-0.21), NSAID use (0.03)
FSFI Pain	-

Table 2 shows the baseline predictors associated with improvements in FSFI domains. These variables were selected using the LASSO regression method – we are reporting the standardized coefficients to better report the effect of the variables. Acronyms: FSFI, Female Sexual Function Index; HAQ, Health Assessment Questionnaire.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Regarding sexual function, we observed small but significant benefits in the FSFI Total Score (from 26.65 to 28.7, p=0.037), as well as in the domain of Arousal (from 4.2 to 4.5, p=0.0453) and Satisfaction (from 4.4 to 5.2, p=0.0453) (Figure 1). The 6M follow-up prevalence of sexual dysfunction was 30%

In bivariate analysis, improvements in sexual function correlated with reduced inflammation (CRP), lower disease activity (DAS28-CRP, DAS28-ESR, SDAI), and improved function/quality of life (HAQ, EuroQoL, SF-36).

LASSO regression identified baseline FSFI domain scores as the strongest predictors of improvements in sexual function. However, weaker but relevant predictors were also observed (Table 2).

Conclusion: Women with RA experienced modest but significant improvements in sexual function (particularly in the domain of Arousal and Satisfaction) after six months of initial b/tsDMARD therapy. These changes were associated with reduced inflammation, better physical function, and improved quality of life. Further research is needed to confirm these associations and elucidate underlying mechanisms.

Abstract Number: 1351

Are Glucocorticoids Associated with Worse Overall Survival Among Rheumatoid Arthritis Patients Treated with Immune Checkpoint Inhibitors? The Confounding Effect of Dexamethasone

Deanna Jannat-Khah[1], Jeffrey Curtis[2], Fenglong Xie[3], Ashish Saxena[4] and Anne R. Bass[1], [1]Hospital For Special Surgery, New York, NY, [2]Foundation for Advancing Science, Technology, Education and Research, Birmingham, AL, [3]The University of Alabama at Birmingham, Birmingham, AL, [4]Weill Cornell Medicine, New York

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1347–1375) Rheumatoid Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Previous studies suggest that glucocorticoids are associated with worse survival in patients receiving immune checkpoint inhibitors (ICI). This is an important issue for Rheumatoid Arthritis (RA) patients initiating ICI since they may require glucocorticoids for RA disease control or management of immune related adverse events. Glucocorticoids are also used for cancer palliation, and for this indication dexamethasone is the preferred formulation. We investigated the association between glucocorticoid use and type and overall survival (OS) among patients with pre-existing RA treated with ICI for non-small cell lung cancer (NSCLC).

Methods: We used a curated Medicare claims dataset (2010-2019) that consists of a 100% sample of patients with RA. Inclusion criteria: Age ≥ 66 years; RA preceding NSCLC diagnosis initiating nivolumab, pembrolizumab or atezolizumab (during dates approved only for metastatic/ stage 4 cancer, to homogenize cancer stage).

Table 1 Demographic and Clinical Characteristics Rheumatoid Arthritis Patients with Non-Small Cell Lung Cancer Treated with Immune Checkpoint Inhibitors from Medicare Fee for Service Claims Data.

		All Patients		
Factor	Total N (%)	No Glucocorticoids	Glucocorticoids	p-value
N	779	300 (39)	479 (61)	
Age, mean (SD)	74.69 (7.21)	75.3 (6.9)	74.3 (7.4)	0.067
White race	684 (87.8)	225 (85)	429 (89.6)	0.22
Female	507 (65.1)	207 (69)	300 (62.6)	0.07
Chronic lung disease*	352 (45.2)	134 (44.7)	218 (45.5)	0.82
DMARDs in the 91 days after ICI initiation	34 (4.4)	<11	Redacted	0.14
Modified Elixhauser score median (IQR)	1.8 (1.26, 2.6)	2 (1.2, 2.6)	1.8 (1.2, 2.6)	0.13
Radiation ever	511 (65.6)	200 (66.7)	311 (64.9)	0.62
Second line ICI or ICI plus chemotherapy	458 (58.8)	173 (57.7)	285 (59.5)	0.61
ICI plus chemotherapy	119 (15.3)	48 (16)	71 (14.8)	0.66
ICI Duration, median (IQR)	84 (21, 244)	92.5 (0, 262)	84 (28, 233)	0.43
Death	610 (85.8)	240 (80)	370 (77.2)	0.36
Time from ICI initiation to death, median (IQR)	207 (78.5, 431.5)	175 (48, 386)	228 (101, 467)	<0.001
Any Glucocorticoid use	479 (61.5)	N/A	479 (100)	N/A
Average glucocorticoid dose, median (IQR)	7.91 (4.07, 13.19)	N/A	7.91 (4.07, 13.19)	N/A
Non-dexamethasone glucocorticoid use	363 (54.8)	N/A	363 (75.78)	N/A
Non-dexamethasone glucocorticoid dose, median (IQR)	7.69 (3.35, 13.02)	N/A	7.69 (3.51, 13.02)	N/A
Dexamethasone use	116 (15)	N/A	116 (24)	N/A
Average daily dexamethasone dose, median (IQR)	7.91 (5.27, 15.82)	N/A	7.91 (5.27, 15.82)	N/A

* Chronic lung disease is defined as Interstitial Lung Disease or Chronic Obstructive Pulmonary Disease
Per the data use agreement with the Centers for Medicare and Medicaid, values less than 11 are not reported
Unknown or missing values: Race: N=36 (4.7%); Hispanic ethnicity N=70 (9%)

Kaplan Meier (KM) curves and 90-day landmark Cox proportional hazard (PH) models were created to measure OS from first ICI initiation, stratified by glucocorticoid (GC) use in the first 90 days. Adjusted models controlled for age, sex, race, ethnicity, interstitial lung disease, chronic obstructive pulmonary disease, prior radiation, year of ICI initiation, modified Elixhauser score, first- or second-line ICI, concomitant chemotherapy. Steroid use was modeled both as binary (KM curves) and as a continuous variable. Schoenfeld residuals were used to assess the PH assumption. Patients were followed through 12/31/2019, or time of death.

Results: We identified 779 eligible RA patients with mean age 74.7 (SD 7.2) years, 87.8% White, 65% female. Among these, 479 (61%) were treated with GCs in the first 90 day. GC users had similar demographics to the overall cohort (table 1). Among GC users, median dose was 7.9 mg prednisone equivalents/day [IQR 4.1,13.2]. In KM analyses, glucocorticoid

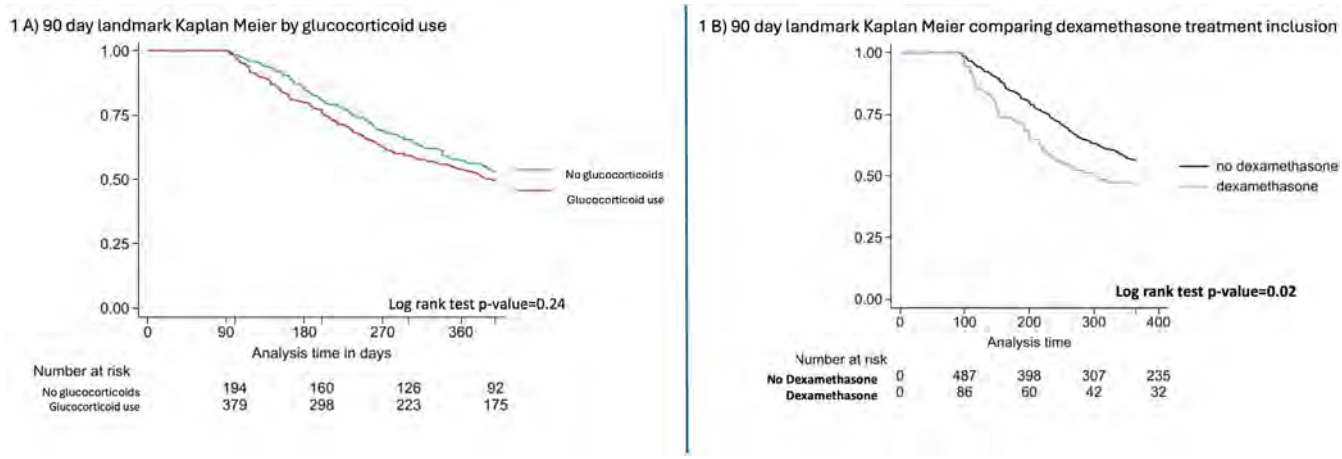

Figure 1 A) 90 day landmark Kaplan Meier by glucocorticoid use; B) 90 day landmark Kaplan Meier comparing dexamethasone treatment inclusion

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

use (yes/no) was associated a non-significant trend towards worse overall survival (Figure 1a). In a separate KM curve, dexamethasone use was associated with worse OS compared to non-users (Figure 1b).

In adjusted models, higher mean glucocorticoid dose was associated with worse overall survival (aHR 1.08 [95%CI 1.01, 1.16]), but in a sensitivity analysis that excluded dexamethasone-treated patients, the association of glucocorticoid dose with overall survival disappeared [HR 0.91 95%CI [0.83, 1.01].

Conclusion: Glucocorticoids used to treat RA and irAE were not associated with worse survival in NSCLC patients with RA after exclusion of dexamethasone-treatment. Dexamethasone, often given palliatively at high doses to alleviate work of breathing, nausea and/or brain edema in cancer patients, should be excluded (or reason for censoring) from studies assessing the association between glucocorticoid use and survival in patients with RA.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1347–1375) Rheumatoid Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Autoimmune arthritis, including Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PA), are among the most common forms of inflammatory joint diseases. These conditions affect joints and surrounding structures, often leading to systemic skeletal complications and an increased risk of fragility fractures. Treatment typically involves steroids-based therapy, mostly glucocorticoids, which are known to enhance bone resorption and reduce bone strength. Radiofrequency Echographic Multi-Spectrometry (REMS) is a non-ionizing technology that represents the alternative to the current standard Dual X-Ray Absorptiometry (DXA) and allows to predict the imminent (within 5 years) fracture risk (FR). Therefore, the aim of the present study is to assess the REMS-based 5-years FR in a cohort of patients with RA and PA.

Methods: REMS automatically analyses the raw, unprocessed backscattered radiofrequency signals by comparing them to a proprietary reference database, extracting both quantitative (BMD, T- and Z-score) and qualitative (bone microarchitecture via Fragility Score, FS) data. Furthermore, the REMS-measured parameters are integrated into a progressive fracture risk classification system consisting of 7 risk levels, R1 to R7, each corresponding to a defined probability of imminent FR. To assess the potential impact of steroid therapy on risk classification, a logistic regression analysis was carried out.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: A cohort of RA and PA patients (n = 56, Caucasian, both genders), who either received (n = 28, median age: 65.5 years old, 50% women under 65) or did not receive (n = 28, median age: 45 years old, 92.8% women under 65) steroids-based therapy underwent REMS scans at femoral neck. The FR analysis on hips revealed that 5.4% of the patients were classified in R1, 44.6% in R3, 48.2% in R5 and 1.8% in R7. Notably, 78.6% of the patients classified in the high-risk classes (R5-R7) were undergoing a steroid-based therapy, whereas 78.6% of those in the low-risk classes (R1-R4) were not receiving steroid treatment. The results from logistic regression showed an OR = 12,83 (95% CI = 3.57-46.15; $p <$ 0.0001), indicating a strong and statistically significant association between steroid use and high fracture risk. Since the steroids-based patients showed a high FS (36.25 ± 8.44), it means that information of bone quality plays a greater impact on the FR probability, aligning with current literature stating that steroids-induced bone loss is more trabecular than cortical.

Conclusion: The analysis confirmed the detrimental impact that a steroid-based therapy can exert on the skeletal system, especially on the trabecular architecture, thus highlighting the potentiality of REMS to directly measure FR through the integration of data from both bone quality and quantity analysis. Furthermore, considering that the annual cost of providing care for osteoporotic fractures in USA is estimated to increase to $95 Bln in 2040, the presented approach will allow potential cost savings through effective prevention strategies, such as reducing the incidence of subsequent fractures in patients facing challenges to access bone test like women < 65.

Session Time: 10:30AM–12:30PM

Background/Purpose: RGB-19 is a proposed biosimilar to tocilizumab, a monoclonal antibody that competitively inhibits the binding of interleukin-6 (IL-6) to its receptor. Results of a Phase 3 study (jRCT2031220512) assessing the clinical equivalence in efficacy between RGB-19 and reference tocilizumab at Week 12, and comparing secondary efficacy, safety and immunogenicity outcomes up to Week 24, have been previously reported.[1] Here, secondary outcomes up to Week 52 (safety to Week 54) are reported.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. [a]Imputation method: observed case. [b]ANCOVA model: included the treatment group and the administration history of biological DMARDs as factors, and DAS28-ESR score at baseline as the covariate, if data were missing due to the occurrence of an intercurrent event, DAS28-ESR at each time point was imputed using the multiple imputation method under the assumption of missing at random. Cases analyzed: RGB-19 N=162; tocilizumab N=161; [c]RGB-19 group − tocilizumab group. [d]Remission defined as SDAI ≤3.3 or CDAI ≤2.8; [e]N=163; [f]EULAR response rate consists of participants with a "good response" (improvement in DAS28-ESR >1.2 for those with low disease activity [DAS28-ESR ≤3.2]) or "moderate response" (improvement of >0.6 to ≤1.2 for those with low or moderate disease activity [DAS28-ESR ≤5.1]) or improvement in of >1.2 for those with moderate or high disease activity (DAS28-ESR >3.2)

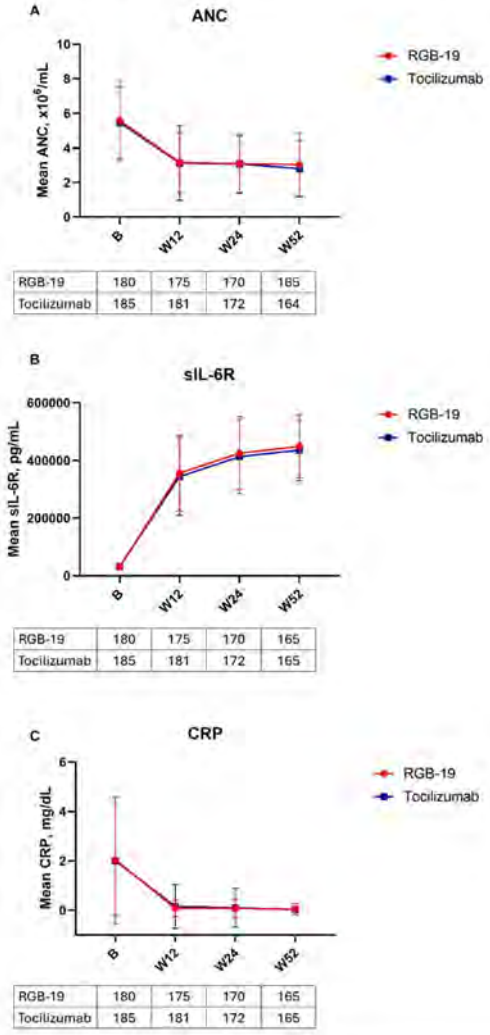
Figure. Mean (SD) pharmacodynamic outcomes at Week 52 (PD analysis set)



ANC, absolute neutrophil count; B, baseline; CRP, C-reactive protein; PD, pharmacodynamic; SD, standard deviation; sIL-6R, soluble interleukin-6 receptor; W, week.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 2. Safety outcomes at end of follow-up period, Week 54 (safety analysis set)

	RGB-19 N=182	Tocilizumab N=186
TEAEs, n	695	773
Participants with ≥1 TEAE, n (%)	164 (90.1)	173 (93.0)
Participants with AEs leading to treatment discontinuation, n (%)	5 (2.7)	14 (7.5)
Participants with AEs leading to death, n (%)	0	1 (0.5)*
Severe AEs, n	7	19
Participants with ≥1 severe AE, n (%)	6 (3.3)	17 (9.1)
Serious AEs, n	7	21
Participants with ≥1 serious AE, n (%)	6 (3.3)	18 (9.7)
ADRs, n	235	253
Participants with ≥1 ADR, n (%)	100 (54.9)	109 (58.6)
Participants with ADRs leading to treatment discontinuation, n (%)	5 (2.7)	9 (4.8)
Participants with ADRs leading to death, n (%)	0	0
Severe ADRs, n	2	11
Participants with ≥1 severe ADRs, n (%)	2 (1.1)	9 (4.8)
Serious ADRs, n	3	12
Participants with ≥1 serious ADRs, n (%)	3 (1.6)	9 (4.8)

ADR were defined as treatment-related TEAEs.
ADR, adverse drug reaction; AE, adverse event; N, number of participants analyzed; TEAE, treatment-emergent adverse event.
*Severe renal injury, which considered not to be correlated to tocilizumab administration.

Methods: This Phase 3, randomized, double-blind study enrolled Japanese adults with active rheumatoid arthritis and an inadequate response to methotrexate, a baseline Disease Activity Score based on 28 joints with erythrocyte sedimentation rate (DAS28-ESR) of ≥3.2, and swollen/tender joints (≥6 from 66/68). Participants were randomized 1:1 to intravenous infusions of either RGB-19 8 mg/kg or tocilizumab 8 mg/kg, administered every 4 weeks to Week 52, and participants were followed to Week 54. The primary endpoint was the mean change from baseline (CfB) in DAS28-ESR at Week 12 (previously reported).[1] Key secondary outcomes included efficacy, serum concentration, pharmacodynamics (PD; absolute neutrophil count [ANC], C-reactive protein [CRP], and soluble IL-6 receptor [sIL-6R]), and immunogenicity up to Week 52, and safety up to Week 54.

Results: Overall, 368 participants were randomized. A total of 335 participants completed the secondary evaluation period from Week 12 to Week 52 (RGB-19 n=169; tocilizumab n=166). The most common reason for withdrawal from the secondary evaluation period was adverse events (AEs; RGB-19 n=3; tocilizumab n=8). Baseline demographics were balanced between groups, as previously reported.[1]

The CfB in DAS28-ESR at Week 52 was similar between groups (confidence intervals within the primary endpoint equivalence margin of ±0.6; **Table 1**). Achievement/disease remission rates (American College of Rheumatology [ACR] 20/50/70, Simplified Disease Activity Index [SDAI], Clinical Disease Activity Index [CDAI], and European League Against Rheumatism [EULAR]) were also similar up to Week 52 (**Table 1**). Mean serum concentration time profiles and ANC, CRP, and sIL-6R PD outcomes were all similar between groups up to Week 52 (**Figure**).

Safety profiles were similar between groups, with comparable incidences of treatment-emergent AEs, and adverse drug reactions up to Week 54 (**Table 2**). The incidence of treatment-emergent antidrug antibodies (RGB-19 2.7%, tocilizumab 5.4%) and neutralizing antibodies (RGB-19 2.7%, tocilizumab 4.3%) was similarly low in both groups.

Conclusion: Similar efficacy, serum drug concentration, PD, safety and immunogenicity outcomes were shown for RGB-19 and tocilizumab up to the end of this Phase 3 study. These results support previously reported data that demonstrated the clinical equivalence in efficacy at Week 12 and similarity in secondary outcomes between treatments at Week 24.[1]

Effect of Ivarmacitinib on Joint Swelling and Tenderness in Patients with Moderate-to-severe Rheumatoid Arthritis: A Post-hoc Study of a Phase III Clinical Trial

Hongtao Jin, Huifang Guo, Yuxiang Han and Meng Ding, The Second Hospital of Hebei Medical University, Shijiazhuang, China (People's Republic)

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1347–1375) Rheumatoid Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Joint swelling and tenderness are major symptoms of rheumatoid arthritis (RA). This post-hoc analysis evaluated the effect of ivarmacitinib (SHR0302), a selective Janus kinase 1 inhibitor, on joint swelling and tenderness in patients with moderate-to-severe RA, using data from a phase III clinical trial (NCT04333771, Liu J, Jiang Y, Zhang S, et al. Ivarmacitinib, a selective Janus kinase 1 inhibitor, in patients with moderate-to-severe active rheumatoid arthritis and inadequate response to conventional synthetic DMARDs: results from a phase III randomised clinical trial. Ann Rheum Dis. Published online November 27, 2024. doi:10.1136/ard-2024-226385).

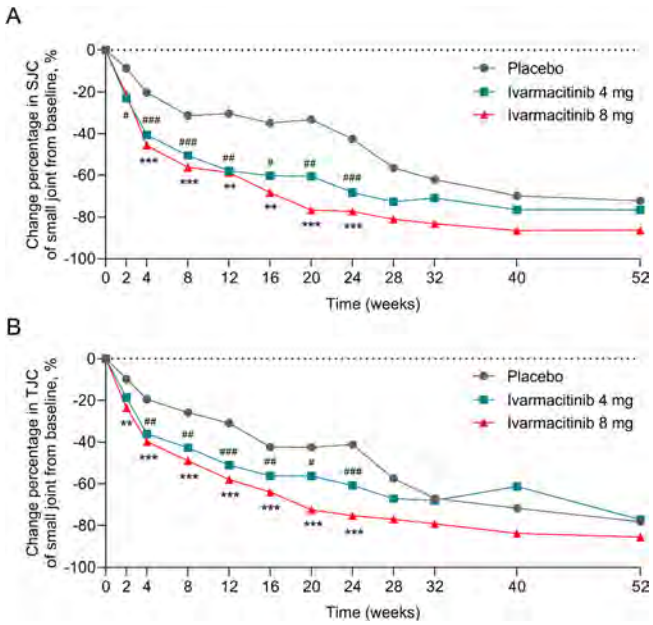

Figure 1. Comparison of the change in SJC and TJC of small joints from baseline between groups. **, P <0.01 between placebo vs. Ivarmacitinib 8 mg; ***, P <0.001 between placebo vs. Ivarmacitinib 8 mg. #, P <0.05 between placebo vs. Ivarmacitinib 4 mg; ##, P <0.01 between placebo vs. Ivarmacitinib 4 mg; ###, P <0.001 between placebo vs. Ivarmacitinib 4 mg.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Comparison of the change in SJC and TJC of large joints from baseline between groups. *, P <0.05 between placebo vs. Ivarmacitinib 8 mg; **, P <0.01 between placebo vs. Ivarmacitinib 8 mg; ***, P <0.001 between placebo vs. Ivarmacitinib 8 mg. #, P <0.05 between placebo vs. Ivarmacitinib 4 mg; ##, P <0.01 between placebo vs. Ivarmacitinib 4 mg; ###, P <0.001 between placebo vs. Ivarmacitinib 4 mg.

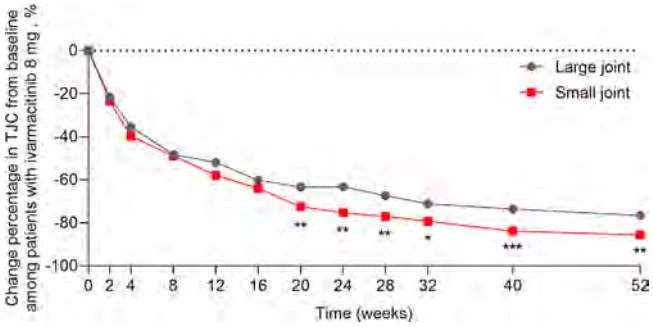

Figure 3. Comparison of the change in TJC from baseline between small joints and large joints in ivarmacitinib 8 mg group. *, P <0.05; **, P <0.01; ***, P <0.001 between small joints and large joints.

Methods: Patients were randomized to receive ivarmacitinib 4 mg (n=189), ivarmacitinib 8 mg (n=189) or placebo (n=188) for 24 weeks. At week 24, patients in the placebo group switched to ivarmacitinib 4 mg, while others continued the initial regimen until 52 weeks. Changes in swollen joint count (SJC) and tender joint count (TJC) from baseline were compared between groups and between small (metacarpophalangeal joints, proximal interphalangeal joints, second through fifth metatarsophalangeal joints, thumb interphalangeal joints, and wrists) and large joints (shoulders, elbows, hips, knees, and ankles).

Results: During the initial 24 weeks, both ivarmacitinib groups demonstrated greater reductions in SJC and TJC of both small and large joints compared to placebo. From week 24 to 52, both ivarmacitinib 4 mg and 8 mg groups showed sustained benefits in improving SJC and TJC of small and large joints. (**Figure 1** and **Figure 2**). In addition, ivarmacitinib 4 mg and placebo/placebo-ivarmacitinib 4 mg groups presented no difference in SJC or TJC reduction between small joints and large joints at most timepoints. However, ivarmacitinib 8 mg group demonstrated greater reduction of TJC in small joints compared with large joints from week 20 to week 52 (**Figure 3**).

Conclusion: Ivarmacitinib significantly improves joint swelling and tenderness in patients with moderate-to-severe RA. Moreover, ivarmacitinib 8 mg provides superior long-term benefits in improving tenderness of small joints than large joints.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

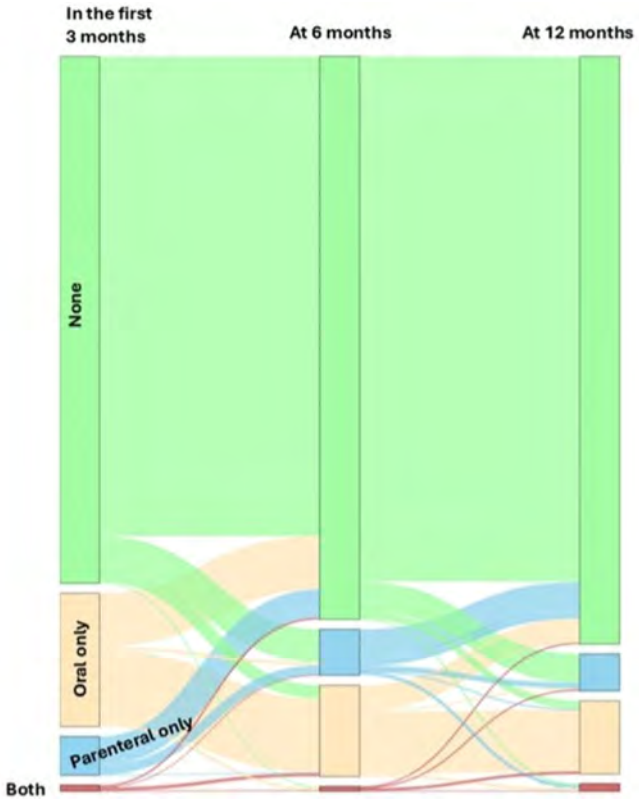
Session Title: (1347–1375) Rheumatoid Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: The 2023 EULAR recommendations for the management of Rheumatoid Arthritis (RA) emphasizes the importance of limiting the dose and duration of glucocorticoids (GC) used in early disease. However, no recommendation about the preferred route of GC administration is available, nor is it known if GC route is associated with total

Table 1. Multivariate logistic regression estimating the odds for GC and advanced therapy use over time



23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

GC exposure. In this study we describe the route of GC administration in patients with early RA (ERA), and determine if GC route is associated with the likelihood of being GC-free and/or requiring advanced therapy at 12 months.

Methods: Participants included newly diagnosed RA patients (symptoms < 1 year) enrolled in the Canadian Early Arthritis Cohort (CATCH) between (dates) and excluded if they reported GC use 90 days prior to baseline, were on advanced therapy by 3 months, or had < 12 months. Patients were stratified by use of GC during the first 3 months of follow-up: none; oral only; parenteral only (intramuscular or intraarticular); or both (oral +parenteral). Multivariate logistic regression adjusted by confounders was used to calculate the OR of GC use at 6 and 12 months and/or progression to advanced therapies (biologics or JAKi).

Results: The sample included 2,222 ERA patients. Mean (SD) age was 55 (15), disease duration 5.5 (3) months, 73% were female, and 86% were white, 69% were initially on methotrexate (MTX) at a mean dose of 20.1 (4.2) mg/week. Mean CDAI at baseline and 12-month scores were 26 (14) and 7.5 (8.6). The majority (1,661; 75%) received no GC; oral-only GC was 421 (19%); parenteral-only GC was 121 (5%), and both oral and parenteral was 19 (1%). Mean CDAI at baseline was lowest in the no GC and highest in those receiving both (24.1 vs 31.6, vs 30.2, vs 32.8, p< 0.0001), but no differences were observed among groups at 12 months. GC and advanced therapeutics at 12 months were: 8% and 7% (no GC); 47% and 14% (oral); 26% and 14% (parenteral); 63% and 16% (both). Table 1 shows that any GC use, particularly oral-only, increases odds of chronic GC use at 6 and 12 months, as well as advanced therapy utilization. Figure 1 features a Sankey diagram illustrating changes in GC use over 12 months.

Conclusion: Initial use of GC is low despite EULAR recommendations suggesting their use for patients with higher baseline disease activity. Among patients with active early RA, those receiving parenteral GC were half as likely to remain on GC at 12 months, compared to those using oral GC. Both GC groups had similar rates of use of advanced treatment use, which were higher compared to the no GC group. Parenteral GC use may support earlier discontinuation of steroids.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1347–1375) Rheumatoid Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Although most healthcare professionals are convinced of the quality, safety, and favorable economic impact of biosimilars, their routine use is not yet widespread. MSB11456 is the first tocilizumab biosimilar approved for both IV and subcutaneous administration. Its biosimilarity to the originator has been demonstrated in an extensive non-clinical and clinical program in patients with moderate-to-severe rheumatoid arthritis (RA).

The aim of RUBY, a multinational, prospective non-interventional study, is to evaluate the use of MSB11456 (either in initiation or switch) in RA patients over 12 months, assess persistence rate at 6 months after treatment initiation, and identify factors associated with treatment persistence for at least 12 months.

Methods: Adult RA patients were included; those participating in any interventional clinical trial were excluded. The primary endpoint was the persistence on MSB11456 by 6 months after treatment initiation. Data collected included basic clinical characteristics, inflammatory disease history, current clinical status including disease activity score (DAS28-CRP), and adverse events at each follow-up visit up to 12 months. Data are presented using descriptive statistics. A logistic regression model will be employed to identify potential predictive factors of persistence at 12 months. We present here patient baseline characteristics, and 6-months intermediate results.

Results: 241 RA patients in Germany (219), UK (17) and Spain (5) completed the 6-month follow-up visit. At MSB11456 initiation, the median duration of RA was 10.5 years. 59.3% patients were naïve to tocilizumab, whereas 40.7 % switched from the originator. Patient characteristics at baseline, are summarized in **Table 1**. The most frequent comorbidity was hypertension (48.5%) and most frequent extra-articular manifestations were rheumatoid nodules (9.1%), Raynaud's phenomenon (2.1%) and pulmonary fibrosis (2.1%). MSB11456 was administered as monotherapy in 52.3% patients, mainly by subcutaneous route (78%) using often the autoinjector. DAS28-CRP disease activity improved at 6 months, with high rates of low-disease activity and remission (**Table 2**). Corticosteroids (CS) dose decreased in 28/82 (34.2%) tocilizumab-naïve patients (in which 13 patients < 5 mg/day or discontinuing CS). By 6 months, 127 patients (53%) experienced at least one adverse event (AE), of which 66 (27%) had AE(s) possibly attributable to MSB11456 that led to permanent discontinuation in 22 (9%) patients **At 6 months, 86% of patients remained on MSB11456**. Among patients with comorbidities, no worsening in existing conditions was observed, with high persistence rates (86.5% to 100%) **(Table 3)**.

Table 1: Patient characteristics at baseline

		Baseline (N=241)
Age	Median [Min, Max]	60.0 [53.0 - 69.0]
Gender	Male	61/241 (25.3%)
	Female	180/241 (74.7%)
BMI	Median [Min, Max]	26.85 [23.42 - 31.14]
Comorbidities	Hypertension n (%)	117 (48.5)
	Cardiac Disease n (%)	37 (15.4)
	Diabetes n (%)	32 (13.3)
	Stroke n (%)	8 (2.3)

BMI, body mass index.

Table 2: Patients with DAS28-CRP at baseline and at 6 months of FK-tocilizumab treatment

		Baseline (N=176)	6 months (N=139)
	Median [Min, Max]	3.3 [1.6 - 4.1]	1.9 [1.3 - 2.7]
DAS28-CRP categorical	Remission (< 2.6)	70 (39.8%)	96 (69.1%)
	Low disease activity (2.6- <3.2)	15 (8.5%)	17 (12.2%)
	Moderate disease activity (3.2- <5.1)	72 (40.9%)	24 (17.3%)
	High disease activity (>=5.1)	19 (10.8%)	2 (1.4%)

Sites chose between ESR or CRP to calculate DAS28 scores. As of the abstract, 139 of 176 patients had completed Month 6 or discontinued. All patients will complete Month 6 or discontinue before ACR 2025.

Table 3: Patients with comorbidities at baseline and at 6 months of FK-tocilizumab treatment

Comorbidity	Baseline			6 Months				
	N valid	Severity		N valid	Severity	Evolution	Persistence rate	Main discontinuation cause
Hypertension	117	Mild	61 (52%)	105	Mild	55 (52%)	100% stable	89.7%	AE
		Moderate	56 (48%)		Moderate	50 (48%)			
		Severe	0%		Severe	0%			
Cardiac disease	37	Mild	11 (30%)	31	Mild	10 (32%)	100% stable	88.5%	Patient withdraw consent
		Moderate	22 (60%)		Moderate	17 (55%)			
		Severe	4 (10%)		Severe	4 (13%)			
Diabetes	32	Mild	18 (56%)	32	Mild	18 (56%)	100% stable	87.5%	Patient withdraw consent
		Moderate	12 (38%)		Moderate	12 (38%)			
		Severe	2 (6%)		Severe	2 (6%)			
Stroke	8	Mild	5 (63%)	8	Mild	5 (63%)	100% stable	100%	NA
		Moderate	3 (38%)		Moderate	3 (38%)			
		Severe	0%		Severe	0%			

Conclusion: The RUBY study evaluates the real-world use of the first tocilizumab biosimilar to treat RA. Results at 6-months demonstrate high persistence on treatment with improvement in RA disease activity and no worsening of cardiovascular comorbidities. Further study will examine factors influencing treatment persistence at 12 months in clinical practice.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1347–1375) Rheumatoid Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Validated rheumatoid arthritis (RA) disease activity measures such as the Disease Activity Score-28 (DAS28) are used in clinical trials but not universally recorded in routine clinical care. Lack of readily available disease activity measures limits the use of electronic health records (EHRs) for generating real-world evidence (RWE) on RA treatment effectiveness. However, the key components of RA disease activity measures such as DAS28, including physical examination findings and laboratory assessments, are often documented in the EHRs, presenting an opportunity to determine disease activity using computational algorithms. The objective of this study was to produce scalable EHR RA disease activity metrics and conduct a test case comparing outcomes among RA patients switching from one tumor necrosis factor inhibitor (TNFi) to another vs changing mechanism of action (MOA).

Methods: We used data from a large EHR-based RA cohort (n=35,235) from a large multihospital healthcare system in the United States with natural language processing of clinical notes, coded EHR data, and laboratory results. A subset of these patients (n=1,579) was co-enrolled in an established RA disease registry and had planned assessment of RA disease activity by formal DAS28-CRP every 6 months. We developed a scalable **m**achine learning **i**mputed **d**isease **a**ctivity **s**core (miDAS) using EHRs, computed aggregating semi-supervised and supervised learning approaches that combine DAS28-CPR measurements from the registry subset and large RA EHR cohort without DAS28-CRP. Using miDAS, we defined longitudinal moderate to severe RA disease activity (DAS28-CRP >3.2 or miDAS >0.365) over the full EHR cohort. We identified the patients who initiated TNFi and either 1) cycled to a second TNFi or 2) switched to a biologic DMARD or targeted-synthetic DMARD with another MOA. We then conducted the RWE study comparing the disease activity following the two treatment strategies. The primary outcome was the rate of medium to high disease activity 1 year after treatment switching adjusted for potential confounding using doubly robust causal modeling.

	Corresponding patients in BRASS Registry, N (%)	Patients in EHR Cohort Included in Clinical Use Case, N (%)	p-value‡
Cohort size	71	2,119

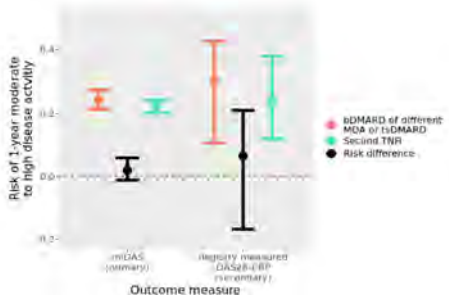
	miDAS*	LATTE	Adaptive Lasso	xgBoost	Random Forest
All registry visits (N=9414)	0.829	0.812	0.780	0.807	0.821
1-year disease activity (N=238)	0.813	0.779	0.765	0.776	0.833

* The final miDAS was created by combining LATTE, adaptive Lasso, xgBoost and random forest through a linear ensemble

Accuracy of miDAS and its machine learning components for classifying moderate to high disease activity as measured by area under curve

Estimated treatment effects on 1-year RA disease activity with 95% confidence intervals (vertical bars). After adjustment, we observed no statistically significant difference in RA disease activity at 1-year when comparing treatment with a second TNF inhibitor vs bDMARD with a different mechanism of action or tsDMARD using either miDAS or registry DAS28-CRP values, though confidence intervals were more narrow using miDAS as the outcome measure.



Treatment outcomes in clinical use case

Results: A total of 2,119 RA patients were included with baseline characteristics listed in **Table 1**. Cross-validated against registry outcomes, miDAS achieved area-under-reception-operator-curve (AUC) for classifying moderate to high disease activity 0.829 (**Table 2**). There was no significant difference in risk of moderate to high disease activity at 1 year between TNFi cycling vs. MOA switching (average risk difference 1.9% [95% CI, -1.2% to 5.8%]) (**Figure 1**).

Conclusion: We used longitudinal electronic health records data and computational algorithms to derive and validate a disease activity measure (miDAS) with strong agreement with DAS28-CRP scores recorded in registry. This technique will allow for future real-world studies assessing RA treatments with imputed disease activity as an outcome. We also performed a proof-of-concept study demonstrating that switching mechanism of action after discontinuation of first TNFi did not result in significant difference in 1-year disease activity compared to cycling to a second TNFi.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1347–1375) Rheumatoid Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Methotrexate (MTX) is a foundational agent in the management of rheumatoid arthritis (RA). While oral MTX is widely prescribed, its subcutaneous (SC) formulation may enhance bioavailability and reduce gastrointestinal intolerance. Despite these theoretical advantages, real-world comparative data—particularly incorporating musculoskeletal ultrasound (MSUS)—remain sparse. This study aimed to compare clinical efficacy, sonographic synovial response, and safety between SC and oral MTX, adjusting for potential confounders such as MTX dosage and baseline disease activity.

Methods: In this retrospective observational study, we analyzed 96 RA patients from two Japanese centers who initiated either SC MTX (n = 75) or oral MTX (n = 21) between April 2022 and March 2025. All patients fulfilled the 2010 ACR/EULAR criteria. Disease activity indices—including TJC28, SJC28, DAS28-CRP, SDAI, and CDAI—were assessed at baseline and at 1, 3, and 6 months. Serial MSUS assessments were performed in the SC group to evaluate synovitis using power Doppler (PD) and gray scale (GS) imaging (semi-quantitative scale 0–3). Multivariable linear regression models were applied to adjust for baseline scores and MTX starting doses.

Results: At 6 months, SC MTX was associated with significantly greater reductions in TJC28 (–4.0 vs. –1.0; p = 0.0229), DAS28-CRP (–1.28 vs. –0.57; p = 0.0117), SDAI (–6.8 vs. –2.0; p = 0.0005), and CDAI (–7.3 vs. –2.8; p = 0.0414). SJC28 changes did not differ significantly (p = 0.8711). Multivariable analysis adjusting for baseline MTX dose confirmed the superiority of SC MTX in improving DAS28-CRP (β = –0.74, p = 0.005), CDAI (β = –7.15, p < 0.001), SDAI (β = –7.15, p < 0.001), and TJC28 (β = –2.34, p = 0.036), while no significant difference was observed for SJC28 (β = –0.61, p = 0.438). PD and GS scores declined steadily in the SC group, although PD signals recurred in some patients at month 6. No serious adverse events were observed. Mild hepatic and renal function changes occurred more frequently in the oral MTX group, though not significantly.

Table 1. Baseline Demographic and Clinical Characteristics

Table 1. Baseline Demographic and Clinical Characteristics

Variable	Metoject (n=75)	Oral MTX (n=21)	P-value
Mean age ± SD (years)	60.8 ± 13.1	59.4 ± 11.4	0.57
Female, %	85.5	90.1	0.74
Disease duration, mean ± SD (years)	15.9 ± 11.5	5.8 ± 3.5	<0.001
ACPA positive, %	88.2	70.0	0.08
RF positive, %	89.3	80.9	0.33
Smoking history, %	6.6	11.1	0.61
Concomitant steroid use, %	53.3	66.6	0.31
Steinbrocker class (I / II / III / IV), %	34.6 / 24 / 20 / 21.3	95.2 / 4.7 / 0 / 0	<0.001
Metoject dosage (7.5 / 10 / 12 / 15 mg), %	36.8 / 24 / 29.3 / 9.3	N/A	N/A
Oral MTX dosage (2 / 4 / 6 / 8 / 10 / 12 mg), %	N/A	4.7 / 4.7 / 19 / 19 / 23.8 / 28.6	N/A

N/A: not applicable

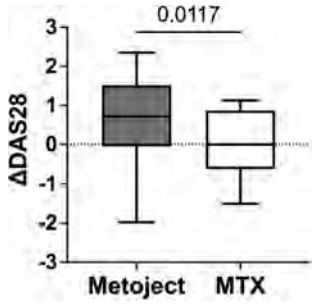

Figure 2. Longitudinal changes in disease activity indices DAS28-CRP scores at baseline, 1, 3, and 6 months in the subcutaneous and oral MTX groups.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

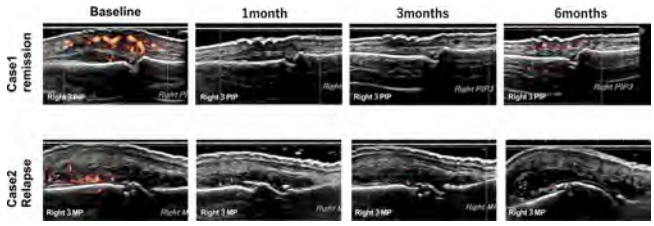

Figure 3. Ultrasound findings in the subcutaneous MTX group Representative musculoskeletal ultrasound (MSUS) images demonstrating resolution (upper panel) and recurrence (lower panel) of power Doppler (PD) signal at baseline, 3 months, and 6 months.

Conclusion: Subcutaneous MTX demonstrated enhanced clinical and ultrasonographic outcomes compared to oral MTX, independent of baseline disease activity or starting dose. These findings support broader adoption of SC MTX as a practical and effective strategy for RA management prior to escalation to biologic agents. The inclusion of imaging and dose-adjusted outcomes strengthens the generalizability and clinical relevance of this study.

Comparative Safety Outcomes of Tofacitinib Versus Upadacitinib in Patients with Rheumatoid Arthritis: A Retrospective Cohort Study

Maya Khasho[1], Ahmad Alomari[2], Reem Elmusa[3] and Rafal Ali[4], [1]University of central florida, Gainesville, FL, [2]UCF- North Florida hospital, Gainesville, FL, [3]UCF/ HCA - North florida hospital, Gainesville, FL, [4]Jefferson Einstein Philadelphia, Lansdale, PA

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1347–1375) Rheumatoid Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid Arthritis (RA) is a chronic autoimmune disease affecting synovial joints, often leading to joint destruction if untreated. Disease-modifying antirheumatic drugs (DMARDs), including Janus kinase (JAK) inhibitors like tofacitinib and upadacitinib, are essential for managing RA to achieve remission or low disease activity. However, JAK inhibitors are associated with adverse effects such as venous thromboembolism, malignancy, cerebrovascular and cardiovascular events, infections, and hyperlipidemia. Here is a comparative safety data between tofacitinib and upadacitinib.

Methods: We included RA patients aged ≥18 years, identified by ICD-10 codes, who initiated tofacitinib (n=20,305) or upadacitinib (n=6,281). The index event was the first RA diagnosis with corresponding medication. Propensity score matching (1:1) was performed based on demographics, comorbidities (e.g., diabetes, hyperlipidemia, hypertension), and concurrent medications (e.g., methotrexate, TNF inhibitors). Post-matching, 6,276 patients per cohort were analyzed. Outcomes within five years post-treatment initiation included acute myocardial infarction, cerebral infarction, venous thrombosis/embolism, diverticular disease, pneumonia, herpes zoster, depression, hyperlipidemia, suicidal ideation, lymphoma/leukemia, basal cell carcinoma (BCC), squamous cell carcinoma (SCC), transaminitis, and neutropenia. Patients with prior occurrences were excluded. Risk ratios (RR) with 95% confidence intervals (CI) were calculated.

Obesity	15.39	18.89	<0.0001	0.0930	18.24	18.86	0.3705	0.0160
Diabetes mellitus	15.27	16.14	0.0950	0.0240	15.60	16.14	0.4062	0.0148
Chronic kidney disease	5.97	6.53	0.1060	0.0231	6.07	6.53	0.2868	0.0190
Inflammatory bowel disease	6.2	5.56	0.0613	0.0274	4.87	5.56	0.0844	0.0308
Tobacco use	3.49	3.92	0.1095	0.0228	3.76	3.90	0.6756	0.0075

Results: After matching, each cohort included 6,276 RA patients. Tofacitinib was associated with higher risks of cerebral infarction (RR=1.694, 95% CI 1.29–2.24, P< 0.0001), acute myocardial infarction (RR=2.43, 95% CI 1.858–3.17, P< 0.0001), venous thrombosis/embolism (RR=1.465, 95% CI 1.182–1.818, P=0.0005), diverticular disease (RR=1.373, 95% CI 1.176–1.604, P< 0.0001), pneumonia (RR=1.73, 95% CI 1.472–2.034, P< 0.0001), herpes zoster (RR=1.413, 95% CI 1.157–1.725, P=0.0006), hyperlipidemia (RR=1.24, 95% CI 1.126–1.366, P< 0.0001), and depression (RR=1.453, 95% CI 1.287–1.640, P< 0.0001) compared to upadacitinib. No significant differences were found for suicidal ideation, lymphoid/hematopoietic malignancies, BCC, SCC, transaminitis, or neutropenia as shown in the table below

Conclusion: RA patients treated with tofacitinib have increased risks of cardiovascular events, venous thrombosis/embolism, diverticular disease, pneumonia, herpes zoster, hyperlipidemia, and depression compared to those on upadacitinib. Prospective studies are needed to confirm these findings and investigate underlying mechanisms. Continuous monitoring of patient safety profiles is essential in RA management

Evaluating Causal Effects of Biologic and Targeted Synthetic Disease-modifying Anti-rheumatic Drugs Targets in Rheumatoid Arthritis Using Mendelian Randomisation

Mihye Kwon[1], Chung-il Joung[1] and Young Soo Song[2], [1]Konyang University Hospital, Daejeon, Republic of Korea, [2]Konyang University Hospital, Daejeon, Taejon-jikhalsi, Republic of Korea

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1347–1375) Rheumatoid Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disease in which biologic and targeted synthetic DMARDs (bDMARDs, tsDMARDs) have substantially improved clinical outcomes. While randomized controlled trials (RCTs) support their clinical use, RCTs have limitations in cost, generalizability, and long-term risk assessment. Mendelian randomization (MR), using genetic variants as proxies for drug target modulation, provides an alternative approach for inferring causality. This study aimed to assess whether genetically proxied modulation of known therapeutic targets is causally associated with RA risk, thereby validating drug efficacy from a genetic perspective.

Methods: We applied a two-sample drug-target MR framework using cis-eQTLs from the eQTLGen Consortium for 18 gene targets corresponding to approved RA therapies. Outcome datasets included three large RA GWASs: a pan-European cohort (ieu-a-834), and two Finnish FinnGen cohorts stratified by seropositivity. Three MR methods (inverse variance weighted, MR-Egger, weighted median) were applied. Sensitivity analyses included MR-PRESSO, Steiger directionality, heterogeneity testing, and Bayesian colocalization. Results were interpreted based on convergence across methods, consistency in directionality, and robustness to pleiotropy.

Results: Across three independent datasets, TNF, FCGR2B, IL1R1, and JAK1 consistently demonstrated statistically significant and directionally concordant associations with RA risk, affirming their causal relevance. TNF and JAK1 were negatively associated with RA, consistent with their known therapeutic effects. FCGR2B and IL1R1 also showed strong associations, supporting their roles as immune regulators. Colocalization analysis identified a shared causal variant for CTLA4 in the

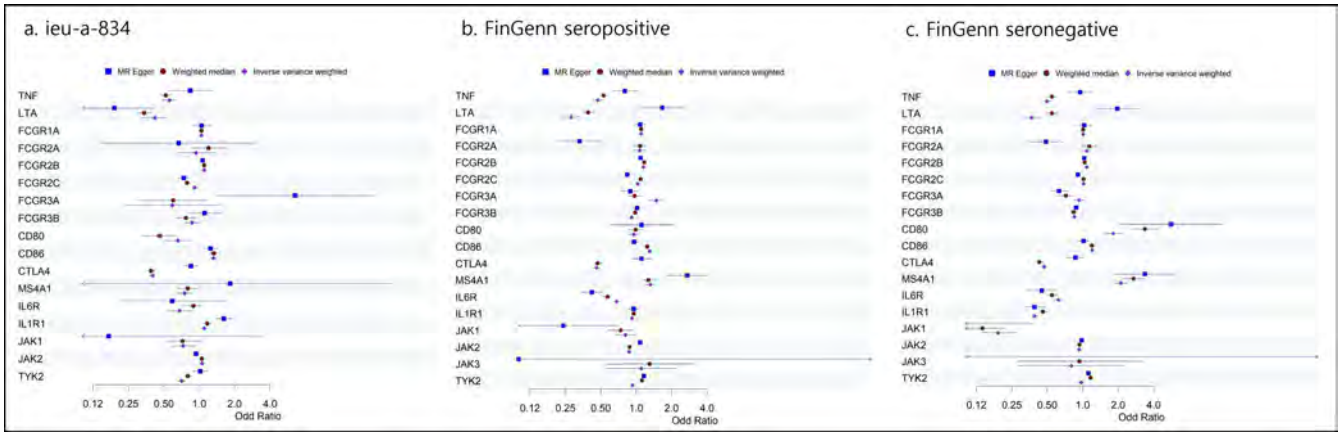

Figure 1. Forest plots of Mendelian randomization estimates for 18 candidate genes across three rheumatoid arthritis GWAS datasets

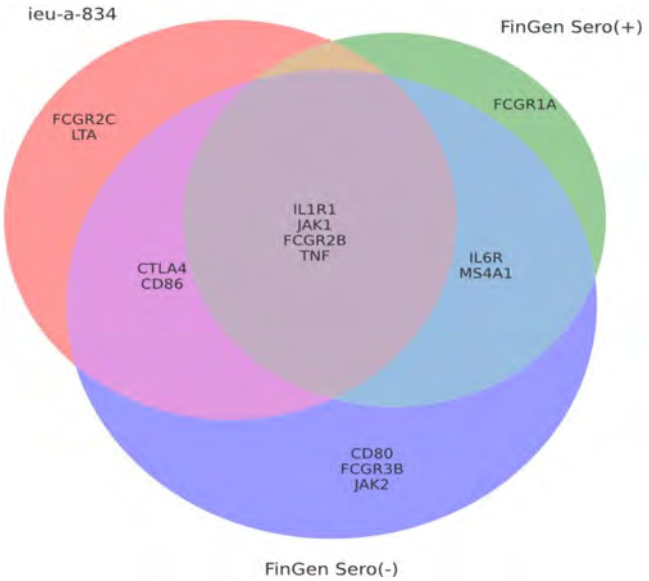

Figure 2. Venn diagram showing genes significantly associated with RA in each dataset

pan-European cohort (PP.H4 = 1.0), while TNF and LTA showed distinct variants. Other genes such as MS4A1 (CD20), IL6R, and CTLA4 demonstrated inconsistent or dataset-specific effects, indicating population-dependent signals or context-specific relevance. A multitarget MR of abatacept-related genes (CD80, CD86, CTLA4) also showed a significant protective effect. Discrepancy analysis revealed that beta estimates and standard errors varied by cohort, underscoring the importance of dataset selection.

Conclusion: This study is the first to apply a systematic drug-target MR framework to validate approved RA therapies. MR reliably recapitulated the effects of known therapeutic targets such as TNF, JAK1, and FCGR2B. Integration with colocalization analysis enhanced causal interpretation, particularly for CTLA4. However, inconsistent findings for MS4A1 and IL1R1 across cohorts highlight the need for population-specific and tissue-specific validation. Our findings demonstrate the utility of MR in therapeutic target evaluation and support its use alongside RCT data in future drug development and repurposing strategies.

Background/Purpose: Connective tissue disease-associated interstitial lung disease(CTD-ILD) represents a significant cause of mortality among patients. Presently, research on treatment options for CTD-ILD is limited, with most evidence derived from studies involving patients with systemic sclerosis-associated ILD (SSc-ILD). Each type of CTD possesses unique clinical characteristics, and the concurrent ILD manifestations vary, necessitating tailored treatment strategies. Furthermore, there is a lack of consensus regarding the timing, dosage, duration, and tapering of various medications.

Methods: Patients with severe ILD, characterized by pronounced shortness of breath and an oxygenation index below 300, were treated with a combination of glucocorticoids (GCs), Rituximab (RTX) at a dosage of 375 mg/m^2 per week for four weeks, and Telitacicept at a dosage of 160 mg per week.

Figure 1:Chest CT scans at baseline and after 6 months of treament（pSS-ILD）

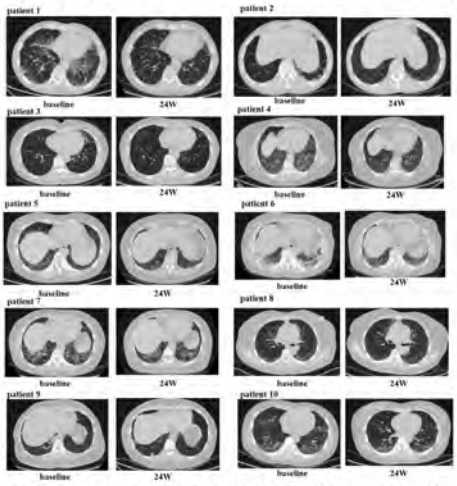

Figure 2:Chest CT scans at baseline and after 6 months of treament（ASS-ILD）

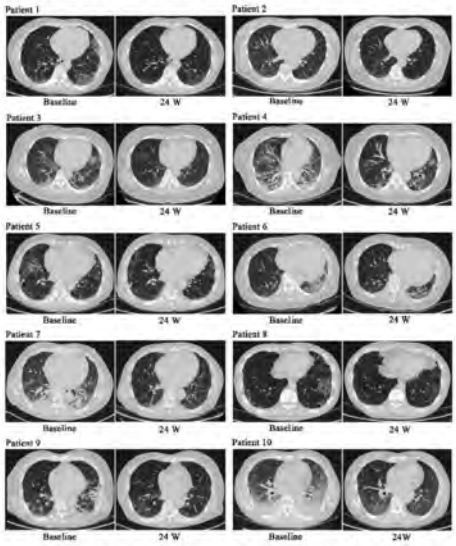

Figure 3:Chest CT scans at baseline and after 6 months of treament（RA-ILD）

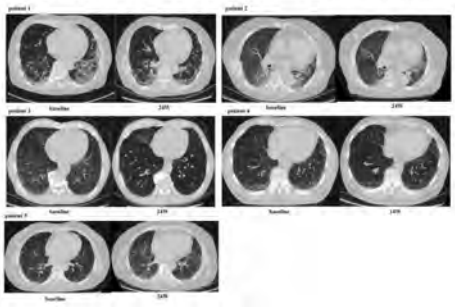

Patients with refractory CTD-ILD who do not respond adequately to glucocorticoids (GCs) combined with conventional immunosuppressants, those who struggle to reduce GC dosage, those at high risk of infection, those who refuse high-dose GCs or traditional therapies, and those with additional connective tissue diseases or other systemic damage were treated with Telitacicept 160 mg, administered subcutaneously once a week. Follow up observation for 24 weeks, gradually reducing hormones and immunosuppressant, observing the improvement of CTD and ILD conditions in patients, as well as whether there are adverse reactions such as infection, allergies, organ damage.

Results: A total of twenty-five patients were included in the study, ten patients with pSS-associated ILD, ten patients with ASS-associated ILD and five patients with RA-ILD. During the treatment process, no adverse reactions were found in all 25 patients. All patients gradually reduced prednisone to 5-7.5 mg/day, while Telitacicept was extended to 160 mg/two weeks. The disease activity has decreased. Chest CT scans revealed varying degrees of reduction in bilateral lung lesions, and lung function demonstrated significant improvement, with FVC% and DLCO% increased, along with the 6MWT elevated.

Conclusion: This is the first clinical trial of the use of Telitacicept for the treatment of CTD-ILD. Our work indicates that the treatment of PSS-ILD, ASS-ILD, RA-ILD by using Telitacicept has achieved good therapeutic effects. Currently, there is insufficient evidence regarding the efficacy of Telitacicept for treating CTD-ILD. This clinical trial suggests that Telitacicept could be a potential option for CTD-ILD.

Multimodal Spatial and Single-Cell Profiling of Synovial Tissue Reveals Macrophage Programs Associated with Biologic TherapyTreatment Response in Rheumatoid Arthritis

Mohammad Daud Khan[1], Matthew Dapas[2], Salina T Dominguez[1], Tyler Therron[3], Kathleen Aren[4], Mary Carns[5], Hadijat Makinde[5], Arthur M Mandelin[1], Eric M Ruderman[1], John F Seagrist[5], Ruth Misha[1], Carla Marie Cuda[5], Harris R Perlman[5] and Deborah Rachelle Winter[6], [1]Northwestern University, Chicago, [2]Northwestern University Feinberg School of Medicine, Chicago, IL, [3]Northwestern Feinberg School of Medicine, Chicago, IL, [4]Northwestern University Division of Rheumatology, Chicago, IL, [5]Northwestern University, Chicago, IL, [6]Northwestern University, Skokie, IL

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1347–1375) Rheumatoid Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disease driven by persistent synovial inflammation and progressive joint damage. Selecting an effective biologic therapy remains a costly, time-consuming trial-and-error process, as blood-based biomarkers poorly predict therapeutic response. In this study, we analyzed synovial tissue from RA patients by integrating single-cell and spatial transcriptomics to identify tissue-resident immune populations, particularly macrophage subsets, associated with response or resistance to therapy

Methods: Samples from minimally invasive, ultrasound-guided synovial biopsies were collected at baseline (n=15) and 12-week follow-up (n=6) from RA patients prior to start of a new DMARD (responders n=8; non-responders n=6; dropped out n=1) under IRB-approved protocols with informed consent. Samples were dissociated, enriched for $CD45^+$ or $CD45^+CD11b^+$ cells, and processed on the 10X Genomics Chromium platform to generate libraries for single-cell RNA sequencing with cell-surface protein detection (CITE-seq). Adjacent sections were analyzed with 10X Xenium (n=3, 196-gene panel) and NanoString CosMx (n=1, 1,000-gene panel) platforms to profile spatially resolved gene expression of synovial tissue at single-cell resolution.

Results: From the synovial CITE-seq analysis, five major immune populations were identified: myeloid cells, T cells, B cells, plasma cells, and mast cells. Clinical response stratification of patients revealed that baseline samples from non-responders exhibited increased T cells proportions compared to responders. However, the T cell to myeloid ratio tended to decrease in

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

these patients following therapy. In the myeloid compartment, the FCN1+S100A12 macrophage subpopulation was enriched in non-responders, but decreased after treatment. On the other hand, the MERTK^{+}LYVE1^{+} and TIMD4 subpopulations were depleted in responders but both increased after treatment. Spatial molecular imaging by CosMx revealed layered tissue organization, with transcriptionally distinct macrophages (including MERTK+LYVE1+) and fibroblasts at the synovial lining, and sub-lining macrophages, stromal, vascular, and immune cells occupying interstitial and perivascular zones. Xenium spatial profiling confirmed a compartmentalized immune–stromal landscape with lymphocytes forming discrete follicle-like clusters, supporting spatially organized immune–stromal niches in RA.

Conclusion: Our results demonstrating that TIMD4^{+} and SPP1^{+} macrophages in non-responders reflects persistent synovial inflammation despite therapy, whilesynovial lining MERTK^{+}LYVE1^{+} and TIMD4+ expansion indicates a broader tissue-adaptive programmacrophages are enriched in responders support prior observations that these cells are necessary for synovial health. The opposing trends in the myeloid compartment suggest that deciphering the interactions between cells is critical to understanding treatment response. Our integrated single-cell and spatial analysis highlights macrophage subset dynamics and immune–stromal organization linked to treatment outcomes, offering new insights into RA pathogenesis and therapeutic resistance.

Abstract Number: 1363

Evaluation of the Clinical Outcome of Baricitinib in Patients with Rheumatoid Arthritis from Multi-center Collaborative Study in Japan: Sub-analysis for Difficult-to-treat RA.

Naoki Kondo and Nariaki Hao, Division of Orthopedic Surgery, Niigata University Medical and Dental General Hospital, Niigata, Japan

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1347–1375) Rheumatoid Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: The aim is to examine the efficacy and safety of baricitinib (BARI) in Japanese rheumatoid arthritis (RA) patients in real clinical practice and is to perform a subgroup analysis dividing cases into difficult-to-treat RA (D2TRA) and non-D2TRA.

Methods: This study involved 192 patients with RA (39 men, 153 women) who were administered with BARI. We examined patient background, treatment response at 52 weeks after initiation, continuation rate, and adverse events. We analyzed cases categorized as meeting the definition of D2TRA and those that did not in a similar manner.

Results: The mean age of enrolled patients was 66.0±13 years, and the mean disease duration was 13.4±11.4 years. Rheumatoid factor and anti-CCP antibody were positive in 77% and 76% of patients, respectively, with 9.9% of patients being negative for both antibodies. Prednisolone (PSL) and methotrexate (MTX) were co-administered in 74 cases (5.5 ±3.3 mg/day) and 85 cases (7.9±2.7 mg/week), respectively. There were 56 naive cases of biological agents/JAK inhibitors,

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table1. The demographic data of difficult-to-treat RA (D2TRA) and non D2TRA groups. Rheumatoid factor value at the baseline in D2TRA shows significantly higher than that in nonD2TRA.

Table 1

	D2TRA	Non D2TRA	
Cases	62	130	
Men: Women	11: 51	28:102	
Age (years old)	63 [26-83]	68 [35-91]	
RA duration (years)	14 [1.7-31]	13.1 [0.1-54.9]	
2mg: 4mg of baricitinib dose/day	22:40	66:64	
% of 4mg of baricitinib	63	49	
Anti-CCP antibody :Positivity rate (%)	86	82	
Anti-CCP Ab Titer (IU/l)	269 [0.5-1200]	263 [0.5-1958	
RF; Positivity rate (%)	88 %	89 %	
RF Titer (IU/l)	262 [5-2261]	138 [5- 1720]	p<0.05

58 cases who received a second agent, and 78 cases who were introduced to agents after the third. The continuation rate at 52 weeks after starting BARI was 76%, and CDAI and DAS28-ESR(4) significantly decreased from 17.3±11.2, 4.0±1.5 to 5.2±4.5 ($p< 0.05$), 2.6±0.9 ($p< 0.05$), respectively. The number of PSL co-administered cases at 52 weeks decreased to 38 cases (3.7±2.1 mg). The occurrence of herpes zoster during the observation period was 4 cases (2.1%). Events leading to the discontinuation of BARI included 32 cases of primary ineffectiveness, 3 cases of secondary ineffectiveness, 10 cases of adverse events (disseminated herpes zoster, pericarditis, dizziness, onset of dermatomyositis, diverticulitis, death due to pneumonia, urticaria, anemia, ileus, mood discomfort), and 1 unknown case. There were 62 cases of D2TRA and 130 of non-D2TRA. No significant differences were found in the ratio of females, age at initiation, disease duration of RA, proportion of the initial BARI dose of 4 mg/day, positive rate or titer of anti-CCP antibodies. While there was no difference in the positive rate of rheumatoid factor, the RF levels were significantly higher in D2TRA (262 vs 138 IU/l, $p< 0.05$). The continuation rate at 52 weeks after starting BARI was 62% for D2TRA and 81% for non-D2TRA, but no significant difference was observed. CDAI significantly decreased from initiation to 52 weeks, with no significant difference between the two groups. The DAS28-ESR(4) before initiation was 4.27 for D2TRA and 4.00 for non-D2TRA, showing no significant difference, but it was significantly higher for D2TRA at 52 weeks after initiation (2.94 vs 2.47, $p< 0.05$). The DAS remission rate was 40% for D2TRA and 65% for non-D2TRA. The ineffectiveness discontinuation cases were 26% for D2TRA and 15% for non-D2TRA. The discontinuation cases due to adverse events were 8% for D2TRA and 4.6% for non-D2TRA, with no significant differences observed.

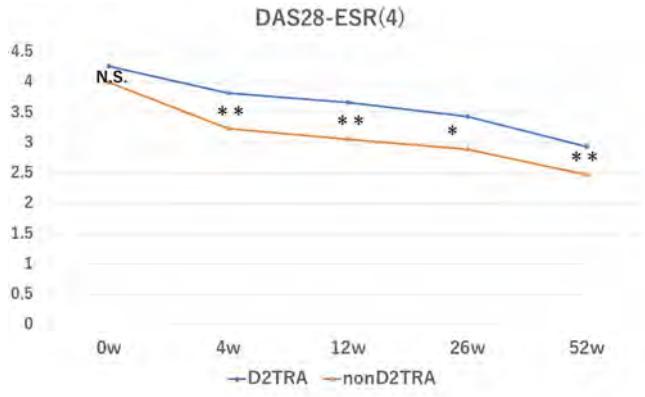

Figure 1

Figure 1. The time course of DAS28-ESR(4) after the baricitinib. In the administration of baricitinib, no significant difference between the difficult-to-treat RA (D2TRA) and non D2TRA. However, 4, 12, 26, and 52 weeks after the administration, DAS28-ESR(4) in D2TRA is significantly higher than that in nonD2TRA. N.S.; not significant difference, *; $p<0.05$, **; $p<0.01$.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: BARI significantly reduced disease activity and showed a high continuation rate. Serious adverse events were infrequent, confirming efficacy and safety in real clinical practice. BARI did not demonstrate the comparable efficacy in D2TRA cases compared to non-D2TRA.

Efficacy Of Ayurvedic Treatment Versus Placebo, Each In Combination With Methotrexate In Early RA Over 20 Weeks: An Exploratory Randomized Control Trial

Prativa Priyadarshani Sethi[1], Venkatesh Srinivasa Pai[2], Rajat Ranka[2], Avneet Kumar Gupta[3], Ashish Baweja[4], ritu sangwan[5], Abhishek Rai[6], Sryla Punjadath[1] and Nithya Maskani[2], [1]All India Institute of Medical Sciences, Rishikesh, Rishikesh, Uttarakhand, India, [2]AIIMS RISHIKESH, Rishikesh, Uttarakhand, India, [3]AIIMS RISHIKESH, Lucknow, Uttar Pradesh, India, [4]Medanta, The Medicity, Gurugram, New Delhi, Delhi, India, [5]AIIMS ,Rishikesh, Rishikesh, Uttarakhand, India, [6]AIIMS ,RISHIKESH, Bhilai, Chhattisgarh, India

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1347–1375) Rheumatoid Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Early rheumatoid arthritis (RA) is a critical therapeutic window where prompt treatment targeting remission or low disease activity can significantly reduce long-term disability and systemic complications. Methotrexate (MTX) remains the standard of care, but interest in complementary approaches, particularly Ayurveda—a WHO-recognized traditional Indian medical system with anti-inflammatory and immunomodulatory properties—is increasing. A prior pilot RCT suggested potential benefit of Ayurvedic formulations when combined with MTX, without added toxicity. We conducted a double-blind, randomized controlled trial to evaluate the efficacy and safety of combining Ayurvedic treatment with methotrexate versus methotrexate with placebo in early RA, hypothesizing greater benefit with combination therapy in early disease.

Methods: This exploratory, double-blind RCT was conducted over 15 months (Aug 2023–Dec 2024) in patients fulfilling 2010 ACR/EULAR RA criteria with ≤1 year disease duration. Patients (n=140) were randomized into two groups: MTX + Ayurveda (n=70) or MTX + Placebo (n=70). Ayurvedic treatment included Panchkol churna, Erand oil, Rasna Saptak Kwath, and Singhnad guggul administered sequentially alongside stable MTX dosing (15–25 mg/week). Blinding was maintained for participants and outcome assessors. Data were represented in mean (SD) and analysed as treated. Fisher's exact test and Chi-Square tests were used for categorical variables. Group comparisons were done at baseline and 20 weeks using t-tests and Wilcoxon-Mann Whitney U Test for parametric and nonparametric data respectively (figure 1).

Results: Of 140 enrolled, 130 patients completed 20 weeks. There was no statistical significant difference among two groups in terms of baseline disease activity including age, rheumatoid factor and anti-CCP positivity. At 20 weeks, numerically more patients in the Ayurveda + MTX (49.2%) arm achieved remission as compared to placebo+ MTX (33.8%) by DAS28CRP, though between-group differences were not statistically significant (Figure 2). However, mean reduction in DAS28-CRP, DAS28-ESR, CDAI, and SDAI scores from baseline to 20 weeks was significantly greater in the combination arm ($p< 0.05$ for all). ACR20 and ACR50 response rates were also significantly higher in the Ayurveda + MTX group (ACR20: 90.8% vs 70.8%, p=0.007; ACR50: 81.5% vs 60.0%, p=0.012) (Figure 3). Adverse events, mostly gastrointestinal, were comparable between groups and mild.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1347–1375) Rheumatoid Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic, progressive, potentially disabling autoimmune disease, with substantial economic burden, particularly related to its high-cost pharmacological treatment. Early treatment, goal-oriented management (treat to target, T2T), and strict disease control have been shown to modify the course of the disease, and might influence its economic impact.This cost-minimization study aimed to estimate the financial impact associated with biological disease-modifying antirheumatic drugs (bDMARDs) use in patients with RA treated with a strict control strategy versus conventional management under real-life conditions.

Methods: 256 participants meeting the ACR/EULAR 2010 classification criteria for RA, diagnosed within one year of symptoms onset, distributed into one strict control and three conventional management groups (64 patients per group) were assessed. Cost data for a comprehensive range of bDMARDs available in clinical practice during the study period (2018–2022) were sourced from public procurement records, based on annual maintenance doses in adults with RA. Potential cost reduction was estimated by multiplying the difference in bDMARD usage proportions by the weighted cost (based on market share) over one- and five-year horizons. Deterministic (Tornado diagram) and probabilistic (Monte Carlo) sensitivity analyses were performed using minimum and maximum parameter values to address uncertainty. A 95% confidence interval (CI) was applied to the proportional differences in bDMARD use between groups. Beta distributions were used for proportions (bDMARD use and market share), and gamma distributions for costs and patient counts. All costs are presented in U.S. dollars, adjusted for inflation to reflect May 2024 price levels.

Results: Table 1 summarizes the background characteristics and clinical outcomes of the study groups. Average annual spending on bDMARDs during the study period amounted to approximately USD 151 million. National projections based on the strict control scenario suggested potential annual savings of USD 83.94 (95% CI: USD 40.13–113.97) million in 2024, representing a 55.6% (95% CI: 26.6%-75.5%) reduction in bDMARD expenditures compared to conventional management. Assuming stable population size, therapeutic strategies, and drug prices, cumulative savings over five years could reach up to USD 419.73 (95%CI: USD 200,65 - USD 569,85) million (Figures 1 and 2).

Table 1 – Comparison of Early Rheumatoid Arthritis Treatment: Strict Control vs. Conventional Management

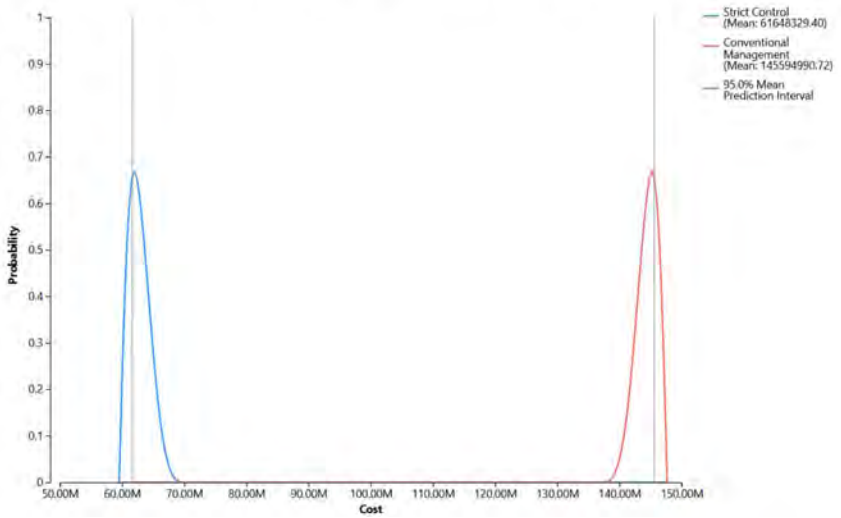
DAS28-ESR Score, Mean (SD)	2,9 (1,3)	3,61 (0,74)	3,4 (1,3)	3,2 (1,4)	0,018§

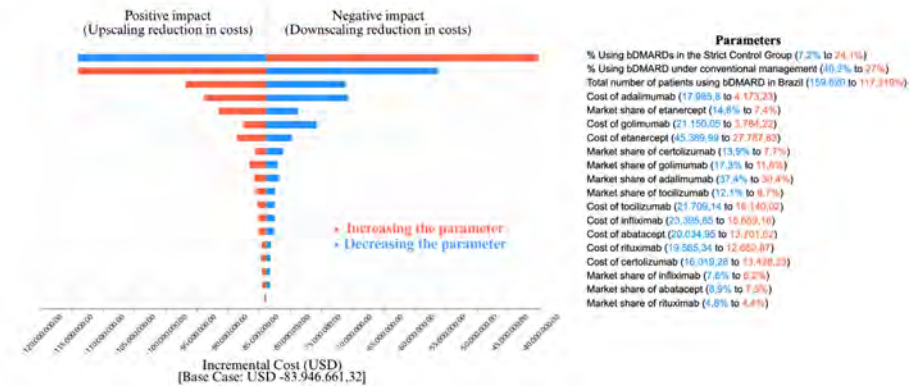
Legend: * Strict disease control group. ** Groups under conventional management of Rheumatoid Arthritis. † For categorical variables, Pearson's chi-square test was used for comparisons; for continuous variables, analysis of variance (ANOVA) with Welch's correction was applied when appropriate. § Characteristics for which at least one group significantly differed from the others ($p < 0.05$).

Figure 1. Distribution of bDMARD-Related Costs Across the Analyzed Rheumatoid Arthritis Treatment Strategies (Strict Control vs. Conventional Management), Considering the Population Eligible for bDMARD Therapy Within the Public Healthcare System



Legend: biological disease-modifying antirheumatic drugs (bDMARD)

Figure 2. Deterministic Sensitive Analysis (Tornado Diagram) of the projected incremental cost of strict disease control vs. conventional management, concerning bDMARD utilization for the treatment of rheumatoid arthritis, at current prices in 2024, expressed in American Dollars (USD).



Conclusion: A strict control strategy compared to conventional management in early RA showed substantial expenditure reductions concerning the usage of bDMARD, along with improved clinical outcomes. These findings support that, under real-life conditions of healthcare systems, the implementation of strict disease control in early RA is a feasible and potentially cost-saving approach.

Cost Per Responder Analysis of Certolizumab Pegol Versus Adalimumab in Patients with Moderate to Severe Active Rheumatoid Arthritis and High Rheumatoid Factor Levels: A Payer Perspective from Canada and Brazil

Rémi Marty[1], Baran Ufuktepe[2], Nicola Tilt[3], Flore Decuypere[4], Angela Blake[3], Sandeep Kiri[3] and Mohammed Soomro[3], [1]UCB Pharma, Brussels, Belgium, Anderlecht, Belgium, [2]UCB Pharma Istanbul, Turkey, istanbul, Turkey, [3]UCB Pharma, Slough, United Kingdom, Slough, United Kingdom, [4]UCB Pharma Brussels, Belgium, Brussels, Belgium

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1347–1375) Rheumatoid Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: According to the 2022 EULAR recommendations for the management of rheumatoid arthritis (RA), the presence of rheumatoid factor (RF), particularly at high levels, is recognised as a poor prognostic factor.[1] In patients with poor prognosis who fail to achieve treatment targets with initial conventional synthetic DMARD (csDMARD) therapy, the addition of a biological DMARD (bDMARD) is recommended.[2,3] Despite this recommendation, patients with high RF levels are associated with reduced response to monoclonal anti-TNF therapies.[4] Certolizumab pegol (CZP), a TNF inhibitor without a fragment crystallizable (Fc) region, may offer improved efficacy for these patients.[5,6] Given the unmet need in patients with RA and high RF levels, who are less likely to respond to Fc-containing TNF inhibitors and are considered at poor prognostic risk, we evaluated the cost per responder (CPR) for CZP versus adalimumab (ADA) to support value-based treatment decisions from the perspective of Canada and Brazil over a 104 week time horizon.

Methods: A 104-week (Wk) CPR model was developed using data from EXXELERATE,[7] a phase IV, randomised, head-to-head trial comparing CZP plus methotrexate (MTX) with ADA plus MTX, in patients with moderate to severe RA. Response rates were defined by achievement of low disease activity (LDA), measured as a Disease Activity Score 28 joints-C-reactive protein (DAS28-CRP) ≤2.7. CPR at Wk104 was calculated by multiplying the total number of doses administered over 104 weeks by the drug acquisition cost divided by the corresponding response rate. Treatment regimens followed the approved product labels: CZP 400 mg at Weeks 0, 2, and 4, followed by 200 mg every 2 weeks; ADA 40 mg every other week. Average prices were considered to derive ADA biosimilar costs.

Results: At Wk104, the LDA achievement rates were higher with CZP compared to ADA (42.5% vs 25.5%). The cost per LDA achievement for CZP vs ADA respectively, was CAD 94,348 vs CAD 97,828 in Canada, and BRL 156,203 vs BRL 793,888 in Brazil (Table 1 and 2).

A sensitivity analysis was performed to test the robustness of these findings under varying list-to-net pricing assumptions. Across multiple scenarios, CZP consistently maintained a more favourable cost profile compared to ADA, highlighting its potential value under a range of pricing conditions.

Conclusion: At Wk104, CZP at list price demonstrated a lower CPR compared to ADA biosimilar price in both Canada and Brazil. These findings suggest that, for patients with moderate to severe active rheumatoid arthritis and high rheumatoid factor levels, CZP may offer a more personalised and cost-effective treatment strategy, supporting more efficient allocation of healthcare resources and potentially reducing the budgetary burden for payers in Canadian and Brazilian healthcare settings.

Molecular Signature Response Classifier Identifies Contribution of GLP-1 Therapy to TNF Inhibitor Response in Rheumatoid Arthritis Patients

Lixia Zhang[1], Angus Wong[2], Alex Jones[2], Sherry Guardiano[2], Reginald Seeto[2] and **Ryan T, Phan**[3], [1]Scipher Medicine, Plainsboro, NJ, [2]Scipher Medicine, Waltham, [3]Scipher Medicine, Los Gatos

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1347–1375) Rheumatoid Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Tumor necrosis factor-α inhibitors (TNFi) are extensively utilized in the management of rheumatoid arthritis (RA). Therapeutic responses remain highly heterogeneous. Emerging evidence suggests glucagon-like peptide-1 (GLP-1) plays a role in the regulation of inflammatory processes relevant to RA pathophysiology and may influence TNFi efficacy in RA patients[1,2]. This study reports evidence of GLP-1 therapy contributing to TNFi response, documented by a validated molecular signature response classifier (MSRC) that predicts TNFi treatment outcomes[3].

Methods: Data obtained from two independent RA patient cohorts: NETWORK-004, an observational clinical study of 259 samples from 152 unique eligible patients designed to evaluate and validate MSRC[3] performance and real-world evidence (RWE) from 34,795 RA patients treated by 1623 physicians across 962 rheumatology clinics in 48 states in the US. GLP-1 treatment records obtained from open claims databases.

Table 1. Baseline Characteristics for NETWORK-004 study and Real-world cohort

	Category	NETWORK-004	Real World Cohort
Number of Unique Patient		152	34795
Number of Unique Practices		73	962
Number of Unique Physicians		N/A	1623
Gender (%)	Female	119 (78.3)	27266 (78.4)
	Male	33 (21.7)	7481 (21.5)
	Unknown	0 (0)	48 (0.1)
Ethnicity (%)	Not Hispanic or Latino	113 (74.3)	N/A
	Hispanic or Latino	35 (23.0)	N/A
	Not Reported	4 (2.6)	N/A
Age (mean (SD))		57.18 (14.18)	59.30 (16.09)
BMI (mean (SD))		30.76 (7.65)	30.08 (6.74)
BMI Category	Less than 30	73 (48.0)	18896 (54.3)
	Greater or equal to 30	79 (52.0)	15899 (45.7)
Patient Global Assessment (mean (SD))		52.74 (23.77)	53.04 (26.45)
Anti-CCP result (%)	Negative	77 (50.7)	20957 (60.2)
	Positive	75 (49.3)	13176 (37.9)
	Unknown	0 (0)	662 (1.9)

MSRC scores, ranging from 1 to 25, were evaluated for each patient. A higher MSRC score predicts greater likelihood of inadequate TNFi response. MSRC ≥18.5 is classified as having a very high likelihood of inadequate response.

Results: Study participants demographic information reported in table 1. The analysis of NETWORK-004 demonstrated although no direct linear correlation of body mass index (BMI) and MSRC was observed, a larger proportion of patients with BMI ≥30 (40.9%) compared to BMI < 30 (4.7%) exhibited MSRC score ≥18.5. The difference statistically constitutes a 9-fold increase (Fig 1a). Remarkedly, modeling BMI reduction of 10% to 20% would result in a reduction of MSRC median 8.4% to 17.6%, respectively, indicating that decreasing BMI may lead to decreasing the likelihood of inadequate TNFi response (Fig 1b).

Consistent with these findings, examination of the RWE cohort revealed that a larger proportion of patients with BMI ≥30 (24.1%) exhibited very high likelihood of inadequate TNFi response compared to BMI <30 (4.7%), documented by MSRC score ≥18.5 (Fig 2a). The impact of GLP-1 exposure in the RWE cohort was evaluated. Analysis showed GLP-1 patients

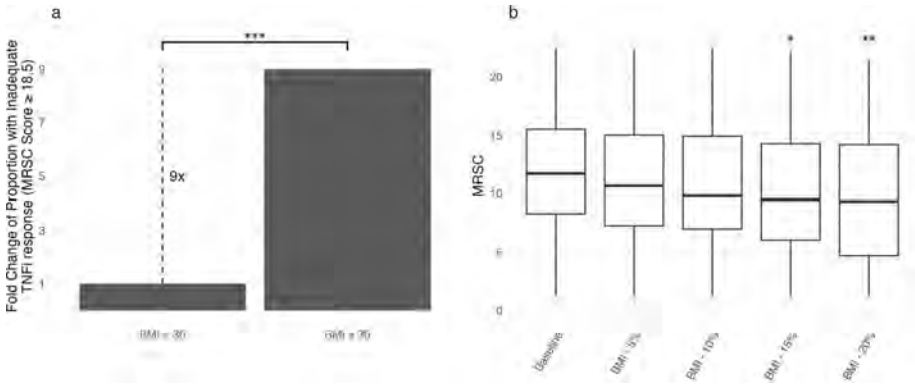

Figure 1. BMI Association between inadequate TNFi response predicted by MSRC in NETWORK-004 study. Figure 1a illustrates a 9-fold increase in the proportion of patients with MSRC scores ≥18.5 (<5% chance of TNFi response) among those with BMI ≥30 comparing to those with BMI < 30 in the NETWORK-004 cohort, as shown in bar charts with fold change on the y-axis. Figure 1b demonstrates the modeled downward shift in MSRC scores corresponding to hypothetical BMI reductions ranging from 5% to 20% relative to baseline.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

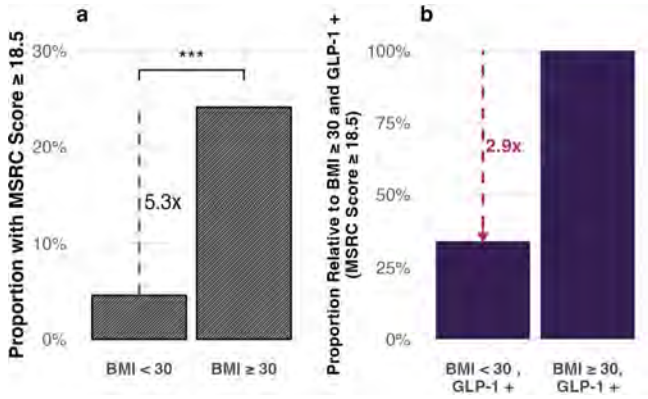

Figure 2. Real-world evidence from MSRC tested cohort. Figure 1a displays shaded bar charts presenting the proportion of patients with MSRC scores ≥18.5 (<5% chance of TNFi response), stratified by BMI group (BMI <30 vs. BMI ≥30) in the overall cohort, demonstrating a 5.3-fold increase in the higher BMI group. P-values were calculated using chi-square tests. Figure 1b depicts the proportion relative to BMI ≥30 among patients with concurrent or prior GLP-1 treatment, where a reduced 2.9-fold difference is presented.

achieving BMI < 30 demonstrated a significant reduction in TNFi inadequate response (9.0%) compared to patients with BMI ≥30 (26.5%). The reduction is approximately 194% and equivalent to 2.9-fold decreased likelihood of inadequate TNFi response for GLP-1 patients achieving BMI < 30 (Fig 2b).

Conclusion: In this study, GLP-1-based interventions, traditionally employed in the treatment of metabolic diseases, enhanced TNFi therapeutic efficacy in specific RA patient subgroups. Future randomized clinical trials are warranted to validate the efficacy of GLP-1 receptor agonists and TNF inhibition combined therapies for RA and potentially other autoimmune diseases. In precision medicine, MSRC can serve as a biomarker to identify patients who may benefit from these combinatorial therapeutic regimens.

Thrombocytosis Predicts Response to Biologic and Targeted Synthetic DMARDs in Rheumatoid Arthritis: Data from the Korean KOBIO Registry

Se Hee Kim[1] and kyung-Ann Lee[2], [1]Kyung Hee University College of Medicine, Seoul, Republic of Korea, [2]Soonchunhyang University Hospital Seoul: Soonchunhyang University Hospital, Seoul, Republic of Korea

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1347–1375) Rheumatoid Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: This study aimed to evaluate the clinical characteristics of thrombocytosis, its relationship with disease activity and joint involvement, and its influence on the effectiveness of biologic and targeted synthetic disease-modifying antirheumatic drugs (b/tsDMARDs) in patients with rheumatoid arthritis (RA).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. RAPID	1.005(0.952-1.061)	0.862	-	-
DM	0.567(0.308-1.044)	0.069**	-	-
BOOP	0.743(0.011-51.827)	0.891	-	-
PGA	1.100(0.910-1.331)	0.325	-	-
PhGA	0.935(0.784-1.115)	0.455	-	-

Methods: Data from 2,104 patients with RA from the Korean College of Rheumatology Biologics and Targeted Therapy registry were analyzed. Thrombocytosis was defined as a platelet count >450 × 10^9/L. Baseline demographics, comorbidities, laboratory results, joint involvement, and disease activity indices (DAS28, SDAI, CDAI, RAPID3, ESR, CRP) were compared between patients with and without thrombocytosis. Responses to b/tsDMARDs over 1 year were assessed using ACR and EULAR criteria. Logistic regression identified independent predictors of thrombocytosis.

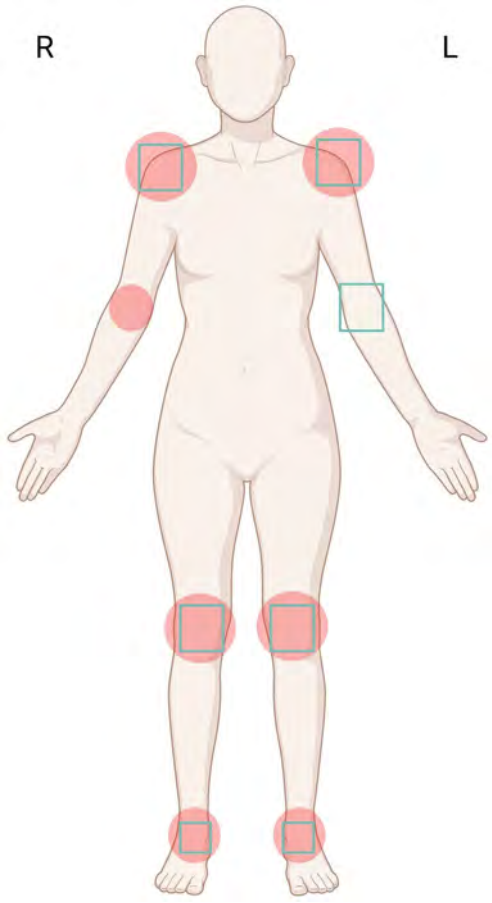

Figure. Involvement of swollen and tender joints in the thrombocytosis group. Swollen and tender joint involvement was more frequent in the thrombocytosis group. Transparent red circles indicate greater involvement of swollen joints, while green squares represent joints with increased tenderness in the thrombocytosis group.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

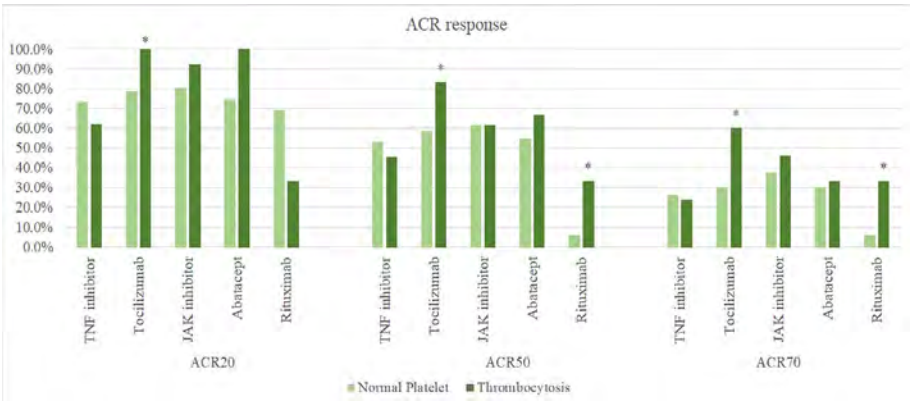

Figure. ACR response according to b/tsDMARDs. ACR, American College of Rheumatology; b/tsDMARDs, biologic and targeted synthetic disease-modifying antirheumatic drugs; TNF, tumor necrosis factor; JAK, Janus kinase. *statistically significant (p<0.005).

Results: Thrombocytosis was found in 97 patients (4.6%). Compared to those with normal platelet counts, these patients had significantly higher ESR, CRP, and WBC counts, lower hemoglobin, higher disease activity scores, and more frequent large joint involvement. Anemia, diabetes, obesity, and bronchiolitis obliterans organizing pneumonia were also more common. At 1 year, ACR70 response rate was significantly higher in the thrombocytosis group (39.2% vs. 29.0%, p=0.041), while ACR20 and ACR50 responses were similar. IL-6 inhibitors, particularly tocilizumab, were more effective in patients with thrombocytosis, achieving higher ACR20/50/70 responses and greater reductions in platelet count and inflammatory markers. Other b/tsDMARDs, such as TNF and JAK inhibitors displayed favorable but non-significant trends. Multivariate logistic regression identified higher WBC count, lower hemoglobin, and elevated ESR as independent predictors of thrombocytosis in RA.

Conclusion: Thrombocytosis in RA indicates increased disease activity and greater joint involvement. Monitoring platelet counts helps assess disease severity and tailor treatments, particularly IL-6 targeting therapies.

No	11,370 (93.1%)	305 (92.7%)	203 (89.8%)
Yes	844 (6.9%)	24 (7.3%)	23 (10.2%)
DMARDs Escalation			
No escalation	9,911 (81.1%)	268 (81.5%)	187 (82.7%)
Yes escalation	2,303 (18.9)	61 (18.5)	39 (17.3)

This table shows the number of patients in each group who experienced flare-related events. The RA Flare Composite Score was calculated per patient to reflect total flare burden: 1 point each for oral prednisone use, elevated CRP (≥10 mg/L), elevated ESR (≥20 mm/h), and DMARD escalation; IV steroids and joint injections counted as 1 point per three counts. Higher scores reflect more flare activity.

Table 3. RA Flare Status Pre- and Post-Initiation of GLP1 or SGLT2i

	Pre- initiation of medication, n (%)	Post-initiation of medication, n (%)	p-value
DMARDs + GLP-1 (n=329)	135 (41.0%)	68 (20.7%)	0.1525
DMARDs + SGLT2i (n=226)	77 (34.1%)	27 (12.0%)	0.0407

This table shows the number and percentage of patients who experienced a flare before and after starting GLP-1 receptor agonists or SGLT2 inhibitors.

effect in RA is limited. This study examines the association between SGLT2 or GLP-1 use and RA flare outcomes in DMARD-treated patients using real-world retrospective data.

Methods: A retrospective cohort study was conducted using TriNetX data between 2019 and 2024. Adults with RA and >12 months follow-up after DMARD initiation were included and categorized into: (1) DMARDs only, (2) DMARDs + SGLT2 inhibitor, and (3) DMARDs + GLP-1 receptor agonist. Patients with other inflammatory arthritides, malignancy, transplant, pregnancy, combined SGLT2/GLP-1 use, or prolonged prednisone use (>3 months) were excluded. Data included demographics, comorbidities, treatment timing, short-term oral prednisone, IV methylprednisolone, joint injections, ESR/CRP, and DMARD changes. RA flares were defined using a composite of: IV methylprednisolone, intra-articular injection, oral prednisone use less than 3 months, number of DMARD escalation, or increased CRP (≥10 mg/L) or ESR (≥20 mm/h).

Results: In Table 1, the GLP-1 group had the highest baseline DMARD count (mean 2.51), lowest end count (mean 1.31). ESR and CRP were most elevated in the SGLT2i group. Table 2 reports significantly different flare burden scores ($p = 0.00006$): DMARDs-only (1.12 ± 2.44), DMARDs+GLP-1 (1.71 ± 3.79), and DMARDs+SGLT2i (1.30 ± 1.78). Flare proxies such as IV steroids, joint injections, and inflammatory marker elevations were more common in the GLP-1 group. The composite flare burden score included oral prednisone use (1 point if present), IV methylprednisolone and joint injections (1 point per three administrations), frequency of CRP ≥10 mg/L, frequency of ESR ≥20 mm/hr, and if DMARD escalation was present. Flare proxies like IV steroids, injections, and inflammatory marker elevations were more frequent in the GLP-1 group. These findings suggest a possible association between GLP-1 use and higher flare burden, though further adjustment for baseline differences is needed. Table 3 shows patients with post-initiation flare declined significantly in the SGLT2i group (34.1% to 12.0%, $p = 0.0407$) and non-significantly in the GLP-1 group (41.0% to 20.7%, $p = 0.1525$). Limitations include lack of standardized disease activity measures (e.g., DAS28), potential confounding factors, and the inability to include DMARD escalation in pre-treatment and post-treatment analysis.

Conclusion: The use of SGLT2i was associated with a significant reduction in RA flares. GLP-1 showed a non-significant trend toward flare reduction, though this may reflect higher baseline RA severity which may influence the trend. These findings support the need for further prospective studies to validate the anti-inflammatory potential of SGLT2 inhibitors in RA and further explore the effect of GLP-1 on RA flare.

Abstract Number: 1370

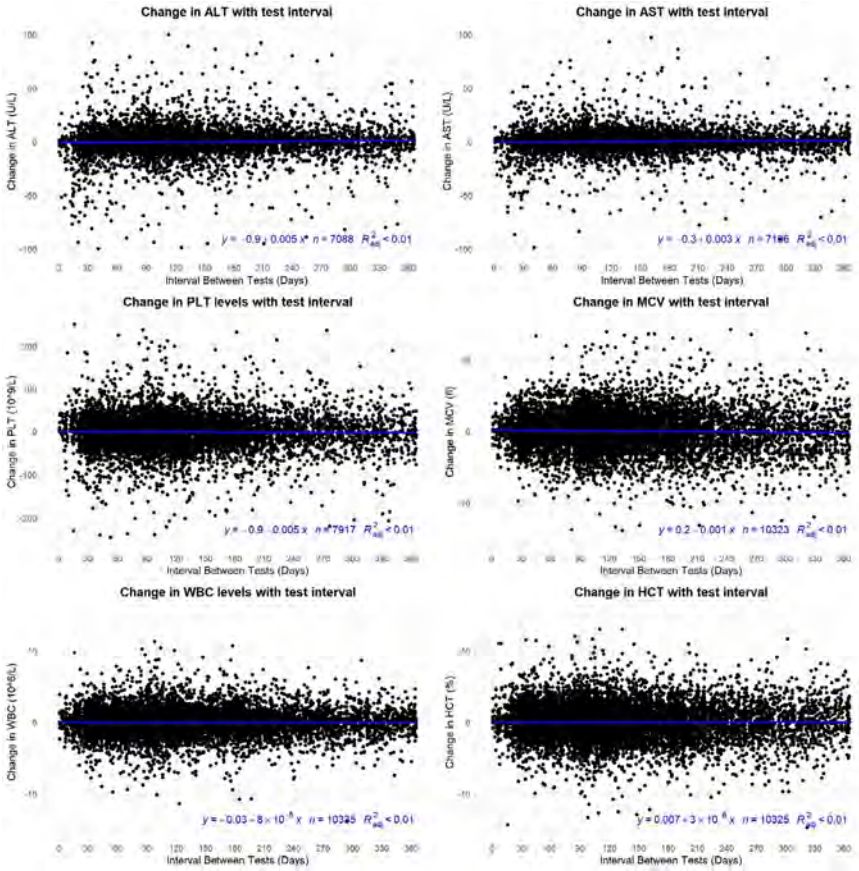
Impact of Six-Month Monitoring Compared to Three-Month Monitoring of Labs for Methotrexate Toxicity

Spencer Simko[1], Sohini Mukherjee[2], Ray Zhang[2], Puneet Bajaj[3] and Bonnie Bermas[4], [1]University of Texas Southwestern, Dallas, TX, [2]University of Texas Southwestern, Dallas, [3]UT Southwestern Medical Center, Dallas, TX, [4]UTSouthwestern.edu, Dallas, TX

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1347–1375) Rheumatoid Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

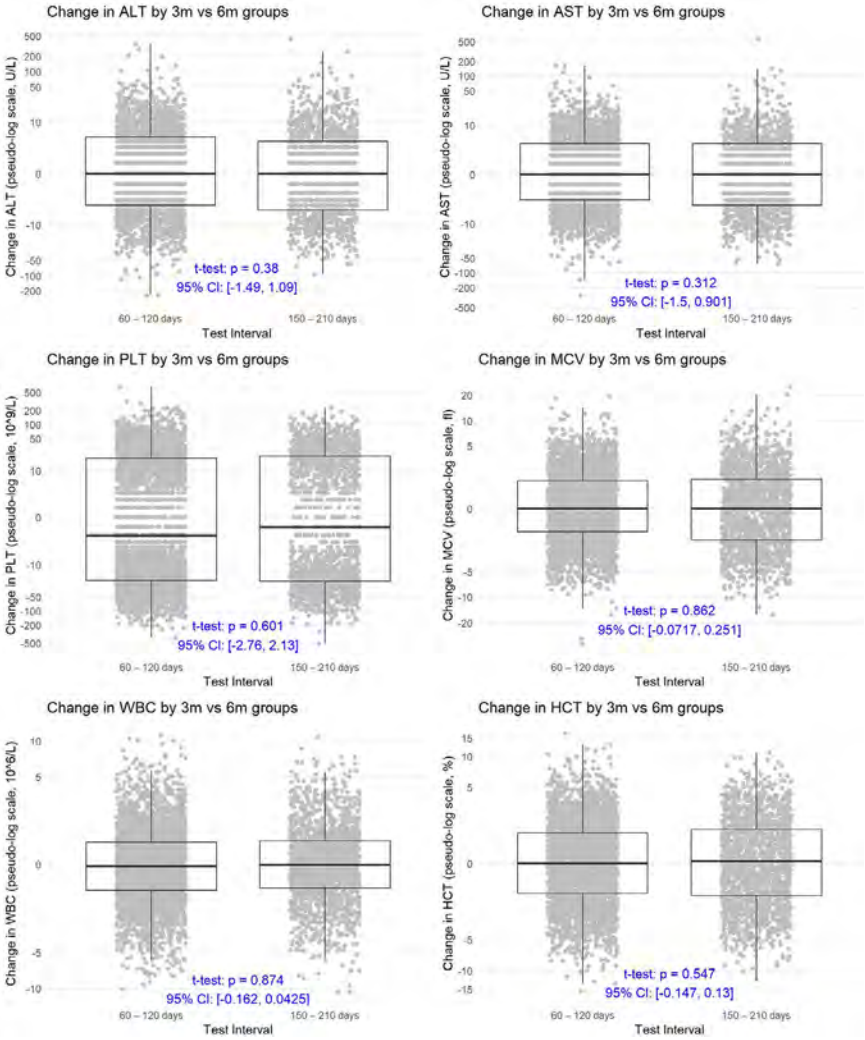
Background/Purpose: Current rheumatology treatment guidelines recommend lab monitoring for methotrexate toxicity at three-month intervals for established patients. We sought to evaluate whether monitoring labs at six-month intervals instead of recommended intervals was associated with more frequent reporting of lab test abnormalities.

Methods: We performed a retrospective analysis on patients at a large academic medical center who were taking methotrexate and who had at least two laboratory measurements of ALT, AST, PLT, WBC, MCV or HCT. Data for 3,821 patients spanning 2017–2024 were extracted from the electronic health record. Query parameters included patient MRN, sex, BMI, birth date, encounter date, methotrexate prescriptions, HCT, MCV, PLT, WBC, ALT, and AST. Only encounters in which the



Linear regression of test level changes vs. time interval between tests in patients taking MTX longer than 90 days

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Comparing changes in LFT and CBC across 2 different testing intervals: 60 – 120 days and 150 – 210 days for patients taking MTX longer than 90 days. A one-tailed t-test was performed with the p-value reported on the figure and a two-tailed 95% confidence interval for the difference in means was calculated.

patient was prescribed MTX more than 90 days prior were analyzed in order to exclude patients new to methotrexate. We plotted the changes in lab values from one encounter to the next against their respective test intervals and conducted linear regression analysis. We defined two different testing intervals: 3 months (2-4 months) and 6 months (5-7 months) and tested whether there was a difference in the mean change in lab value between the two testing intervals. We tested whether

Table 1. Percent of lab values starting in a clinically normal range that crossed a clinically concerning threshold in the subsequent test for two different testing intervals representing 3 months and 6 months in patients taking MTX longer than 90 days. Odds-ratio that the longer interval was associated with abnormal lab values adjusted by age, sex and BMI is also reported. The upper limit of normal (ULN) was established as 35 U/L (females) or 50 U/L (males) for ALT, as 50 U/L for AST. The lower limit of normal (LLN) was established as than 35% (female) or 37% (male) for HCT.

	Clinically Relevant Value	60 – 120 days	150 – 210 days	Δ% P-value	Adj-OR	Adj-OR P-value
ALT	>2x ULN	1.2%	1.7%	0.28	1.38	0.26
AST	>2x ULN	0.4%	0.9%	0.08	2.38	0.05
WBC	<4x10^6/L	3.8%	3.8%	1	0.99	0.93
HCT	<LLN	4.7%	5.8%	0.11	1.27	0.08
MCV	>100 fl	2.9%	2.6%	0.58	0.94	0.72
PLT	<100x10^9/L	0.1%	0.0%	0.42	-	-

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

patients were more likely to transition from a clinically normal lab value to a lab value exceeding a clinically relevant threshold in either testing interval group.

Results: There was no correlation between test frequency and ALT, AST, WBC, HCT, MCV or PLT count (R-squared < 0.01, Figure 1). Additionally, the average change between tests in these lab values was not different when measured every six months compared to every three months (Table 2). Patients tested at six months were not more likely to develop an abnormal lab result after a previously normal result compared to patients tested at three months (Figure 2).

Conclusion: Monitoring routine labs for methotrexate therapy using a six-month interval was not worse than monitoring at three months for detecting impactful lab abnormalities. The current ACR guideline to perform the measurements at three months may not be necessary and should be re-evaluated for cost-effectiveness and unnecessary patient burden.

Abstract Number: 1371

Effect of bDMARDs and tsDMARDS on diffuse interstitial lung disease associated with rheumatoid arthritis: systematic review and meta-analysis

Stéphane HILLIQUIN[1], Enrico VISMARA[1], Virginia BERLENGIERO[2] and Jérôme AVOUAC[3], [1]Département de Rhumatologie, Hôpital Cochin, Assistance publique des Hôpitaux de Paris, Université Paris-Cité, Paris, France, PARIS, France, [2]Rheumatoloy Department, Cochin Hospital, PARIS, France, [3]Rheumatology department, Cochin hospital, Paris, France

SESSION INFORMATION

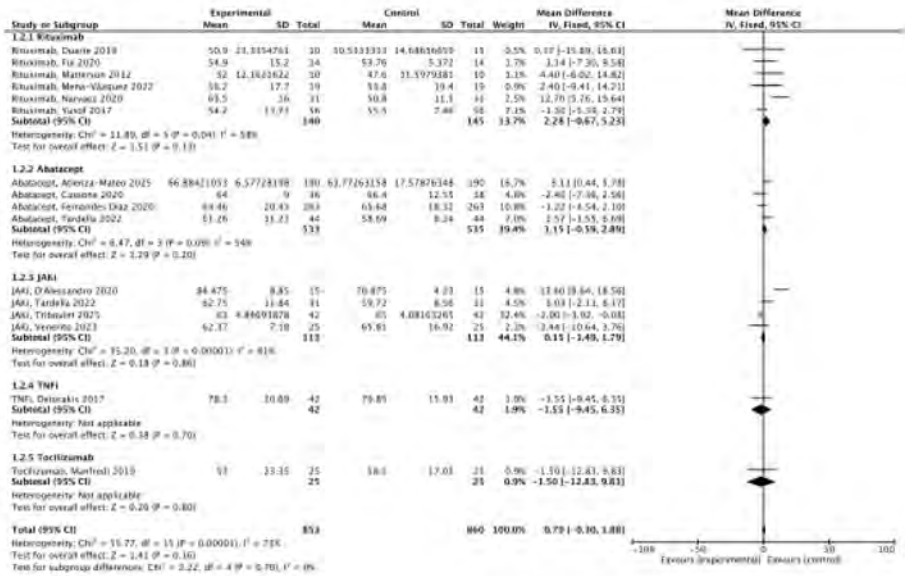
Session Date: Monday, October 27, 2025
Session Title: (1347–1375) Rheumatoid Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Interstitial lung disease (ILD) is a severe complication of rheumatoid arthritis (RA), associated with increased morbidity and mortality. The pulmonary safety of biologic (bDMARDs) and targeted synthetic DMARDs (tsDMARDs) in RA-ILD remains unclear due to limited and heterogeneous data. **The aim** is to assess the impact of bDMARDs and tsDMARDs on interstitial lung disease in rheumatoid arthritis.

Methods: The SLR aimed to include all reports of controlled trials and observational studies of biological and targeted synthetic disease-modifying antirheumatic drugs (DMARDs) used in patients with a diagnosis of RA, defined as fulfilment of the 1987 ACR criteria or 2010 ACR/EULAR criteria. We searched PubMed and Cochrane databases for English articles published until 2025 using the keywords « interstitial lung disease AND "Arthritis, Rheumatoid"[Mesh]) AND "Arthritis, Rheumatoid/therapy"[Mesh] ». The MA was performed with Review Manager (RevMan v.5.4.1) software with the inverse variance method on FVC and DLCO parameters.

Results: Out of 861 abstracts screened, 15 observational studies were included, evaluating the effects of abatacept, rituximab, tocilizumab, TNF inhibitors (TNFi), and Janus kinase inhibitors (JAKi) on RA-ILD. These studies collectively involved 958 patients (mean age: 65 years; 57% female) with a mean disease duration of 115 months. Among the ILD patterns, usual

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



interstitial pneumonia (UIP) accounted for 48% and non-specific interstitial pneumonia (NSIP) for 40%. Data on changes in DLCO and FVC were available from 6 studies on rituximab, 4 on abatacept, 4 on JAK inhibitors, 1 on TNFi, and 1 on tocilizumab.

Analysis of FVC (%) variation before and after treatment revealed no significant overall change across all therapies (mean difference: -0.85%, 95% CI [-2.40, 0.71]; p=0.29). Rituximab was the only agent associated with a potential increase in mean FVC (+3.39%, 95% CI [-2.75, 9.53]), although this difference did not reach statistical significance (p=0.28). Similarly, DLCO values remained stable following treatment (mean difference: +0.79, 95% CI [-0.30, 1.88]; p=0.16). No statistically significant differences were observed between the individual treatment groups.

Conclusion: In conclusion, while bDMARDs and tsDMARDs show potential in stabilizing pulmonary function in RA-ILD, no significant differences were observed between treatments, highlighting the need for further research to clarify their impact on interstitial lung disease progression.

Treatment Patterns and Outcomes After Janus Kinase Inhibitor Discontinuation in Rheumatoid Arthritis: A Real-World Cohort Study

Sungwon Ko[1], Young-Eun Kim[1], Soo Min Ahn[1], Ji Seon Oh[1], Yong-Gil Kim[1], Chang-Keun Lee[2], Bin Yoo[1] and Seokchan Hong[1], [1]Division of Rheumatology, Department of Internal Medicine, University of Ulsan College of Medicine, Asan Medical Center, Seoul, South Korea, Seoul, Republic of Korea, [2]Department of Rheumatology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Seoul, Republic of Korea

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1347–1375) Rheumatoid Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Janus kinase (JAK) inhibitors are recommended for patients with rheumatoid arthritis (RA) who have an inadequate response to conventional synthetic or biologic disease-modifying antirheumatic drugs (csDMARDs or bDMARDs). However, evidence is limited regarding optimal treatment strategies following JAK inhibitor failure. This study aimed to evaluate real-world treatment patterns after JAK inhibitor discontinuation and to compare the efficacy and drug retention rates among different bDMARD classes in this context.

Methods: This retrospective study included patients with RA who discontinued JAK inhibitors due to inefficacy or intolerance between August 2015 and March 2025 and subsequently switched to an alternative bDMARDs. Changes in disease activity, as measured by the Disease Activity Score in 28 joints using ESR (DAS28-ESR), were assessed at 6 months post-switch, and drug retention rates were compared across three bDMARD groups: TNF inhibitors, IL-6R inhibitors, and other bDMARDs. Low disease activity (LDA) was defined as DAS28-ESR score < 3.2.

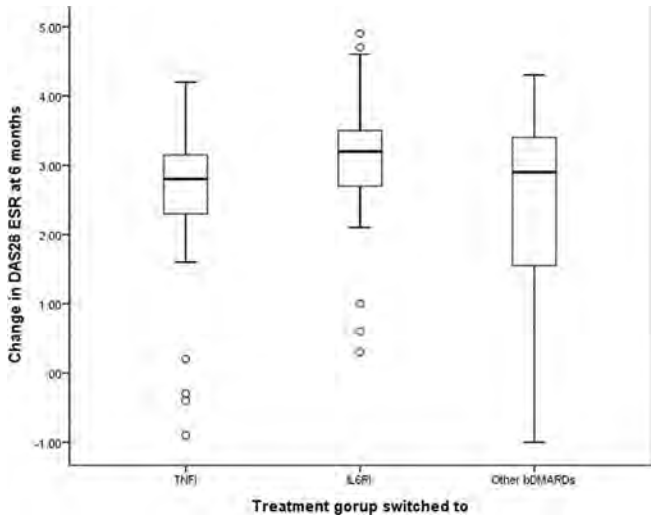

Figure 1. Change in DAS28-ESR over 6months following bDMARD switch after JAK inhibitor discontinuation. Statistical comparisons between groups were performed using the Mann–Whitney U test with Bonferroni correction. Adjusted p-values: 0.027 (TNF inhibitor vs. IL-6R inhibitor), 0.378 (IL-6R inhibitor vs. other bDMARDs), and 1.000 (other bDMARDs vs. TNF inhibitor).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Of 151 patients who discontinued JAK inhibitors, 59 (39.1%) switched to TNF inhibitors (adalimumab N=33, etanercept N=16, golimumab N=9, infliximab N=1), 69 (45.7%) to IL-6R inhibitors, and 23 (15.2%) to other bDMARDs (abatacept N=19, rituximab N=4). Among them, 113 patients (40 TNF inhibitor group, 53 IL-6R inhibitor group, and 20 other bDMARD group) remained on therapy for at least 6 months and were included in the efficacy and drug retention analyses. Baseline characteristics were generally comparable across the groups, although patients in other bDMARDs group were older and had a higher number of prior bDMARDs. Baseline DAS28-ESR was also significantly higher in the other bDMARD group than in the IL-6R inhibitor group ($p = 0.012$).

At 6 months, patients who switched to IL-6R inhibitors showed significantly greater improvement in DAS28-ESR compared to those who switched to TNF inhibitors (adjusted $p = 0.027$). No significant differences were observed between IL-6R inhibitors and other bDMARDs (adjusted $p = 0.378$), or between TNF inhibitors and other bDMARDs (adjusted $p = 1.000$). LDA was achieved in 83.0% (44/53) of the IL-6R inhibitor group, compared to 62.5% (25/40) in the TNF inhibitor group and 60.0% (12/20) in the other bDMARD group. The overall group difference was statistically significant ($p = 0.042$), but pairwise comparisons did not remain significant after Bonferroni correction (TNF vs. IL-6R: adjusted $p = 0.075$; TNF vs. other bDMARDs: adjusted $p = 1.000$; IL-6R vs. other bDMARDs: adjusted $p = 0.114$). Drug retention rates did not differ significantly among the three groups ($p = 0.249$).

Conclusion: In this real-world cohort of RA patients who discontinued JAK inhibitors, IL-6R inhibitors were the most frequently selected subsequent therapy and were associated with greater clinical improvement at 6 months compared to TNF inhibitors. However, drug retention rates were comparable across all bDMARD classes. These findings provide insight into treatment decisions and outcomes following JAK inhibitor failure in RA management.

Abstract Number: 1373

Effect of JAK Inhibitors on Bone Mineral Density in Rheumatoid Arthritis Patients with Osteoporosis: A Comparative Study with Biologics

Sungwon Ko[1], Young-Eun Kim[1], Soo Min Ahn[1], Ji Seon Oh[1], Yong-Gil Kim[1], Chang-Keun Lee[2], Bin Yoo[1] and Seokchan Hong[1], [1]Division of Rheumatology, Department of Internal Medicine, University of Ulsan College of Medicine, Asan Medical Center, Seoul, South Korea, Seoul, Republic of Korea, [2]Department of Rheumatology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Seoul, Republic of Korea

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1347–1375) Rheumatoid Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Osteoporosis is more prevalent in patients with rheumatoid arthritis (RA) than in the general population. Janus kinase (JAK) inhibitors and tumor necrosis factor (TNF) inhibitors are widely used in RA treatment; these drugs effectively reduce disease activity and prevent joint destruction by suppressing inflammation. However, their effects on bone mineral density (BMD) remain unclear. Thus, this study aims to compare BMD changes in RA patients with osteoporosis treated with JAK inhibitors versus TNF inhibitors, thereby providing insights into their impact on bone metabolism and informing optimal treatment strategies for osteoporosis management in RA

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Clinical characteristics of RA patients undergoing osteoporosis treatment: Comparison between JAK inhibitor users and TNF inhibitor users.

	JAK inhibitor (n = 23)	TNF inhibitor (n = 13)	P
Age, years	66.0 (62.5 – 71.0)	59.0 (54.0 – 65.0)	0.14
Female	23 (100)	12 (92.3)	0.99
Body mass index, kg/m²	22.4 (20.7–23.9)	24.7 (23.5–24.7)	0.21
Duration of RA, years	17.0 (3.3–38.8)	22.8 (5.9–40.2)	0.51
Treatment of osteoporosis			0.82
Bisphosphonate	13 (56.5)	7 (53.8)	
Denosumzb	8 (34.8)	5 (38.5)	
Teriparatide	1 (4.3)	0	
Zoledroic acid	1 (4.3)	0	
Romosozumab	0	1 (7.7)	
Initial BMD, T-score			
Lumbar spine	-2.9 (0.5)	-2.8 (0.5)	0.36
Femur neck	-2.2 (0.6)	-1.7 (0.6)	0.71
Follow-up BMD, T-score			
Lumbar spine	-2.9 (0.7)	-2.7 (0.4)	0.23
Femur neck	-2.2 (0.6)	-1.9 (0.7)	0.35
% change in BMD			
Lumbar spine	3.9 (1.9–5.8)	3.3 (2.2–8.2)	0.50
Femur neck	2.3 (0.7–2.7)	1.8 (1.1–2.2)	0.61

BMD, bone mineral density; JAK, Janus kinase; TNF, tumor necrosis factor; RA, rheumatoid arthritis

Methods: This retrospective study included RA patients diagnosed with osteoporosis who were treated with either TNF inhibitors or JAK inhibitors at a tertiary referral center between January 2005 and December 2024. Areal BMD (g/cm^2) was measured at the lumbar spine, femoral neck, trochanter, and total femur using dual-energy X-ray absorptiometry. The rate of BMD change was expressed as the annualized percentage change between the initial and follow-up measurements

Results: Among RA patients who received biologics (n = 23) and JAK inhibitors (n = 13), 23 (100.0%) and 12 (92.3%) were women, respectively. The mean ages at initial BMD measurement for these patients were 66.0 years (IQR, 62.5–71.0 years) and 59.0 years (IQR, 54.0–65.0 years), respectively (P = 0.14). There was no significant difference in baseline clinical characteristics, including laboratory data and baseline BMD, between the two groups. With osteoporosis treatment, follow-up areal BMD was significantly increased compared with the initial value at the lumbar spine and femur neck in RA patients, regardless of concomitant use of JAK inhibitors or TNF inhibitors. Further, no statistically significant differences were observed in annualized BMD changes between RA patients receiving TNF inhibitors and JAK inhibitors (P = 0.83).

Conclusion: In RA patients receiving osteoporosis treatment, JAK inhibitors did not provide a significant additional effect on bone formation compared with TNF inhibitors.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1347–1375) Rheumatoid Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: AZD1163 is a novel bispecific antibody that inhibits the activity of extracellular Peptidyl Arginine Deiminases (PADs) 2 and 4, enzymes responsible for protein citrullination in patients with Rheumatoid Arthritis (RA). In susceptible individuals, citrullinated proteins activate a cascade of T cell driven events, promoting B cell maturation and activation, leading to the production of pathogenic anti-citrullinated protein antibodies (ACPA). ACPAs are associated with a worse prognosis, often translating to more severe joint damage and a rapidly progressing disease course. In vitro, AZD1163 inhibits protein citrullination and increased PAD activity present in serum and synovial fluid from patients with RA. The aim is to present the first clinical findings on AZD1163 safety and tolerability, pharmacokinetic properties, and pharmacodynamic effect of AZD1163 on systemic PAD enzyme activity in healthy volunteers.

Methods: This randomized, double-blind, placebo-controlled Phase I study (NCT06103877) in healthy participants comprised of two parts: Part A consisted of nine single-ascending dose (SAD) cohorts, each receiving AZD1163 mg intravenous infusion or placebo, where one dose level was administered subcutaneously (SC). In the first two cohorts, 2 participants received AZD1163 and 1 received placebo. Subsequent cohorts had 6 (or 8 for the SC cohort) participants on AZD1163 and 2 (or 3 for the SC cohort) on placebo. Part B included two multiple-ascending dose (MAD) cohorts dosed twice, two weeks apart (Q2W), with either AZD1163 SC or placebo. In each cohort, 6 participants received AZD1163 and 3 received placebo. Safety and tolerability were assessed through the evaluation of adverse events, clinical chemistry/hematology, ECG, and vital signs. PK characteristics and immunogenic profile of AZD1163 were evaluated through repeated sampling in serum. Inhibition of solid phase bound histone H3 citrullination (% change from baseline) was used to demonstrate *ex vivo* AZD1163 target engagement.

Results: Sixty-five participants were included in the SAD and eighteen in the MAD. A dose proportional exposure increase was observed for AZD1163, with maximum concentration occurring 10 days post-SC dose. The bioavailability following SC dosing was estimated at 65 %. Mean systemic clearance was 0.15 L/day and the mean elimination half-life was 38 days. A significant, dose dependent inhibition of PAD2/4 activity was observed, with maximum inhibition exceeding 95%, confirming target engagement. Anti-drug antibodies (ADA) incidence was low at 6.7% among AZD1163 recipients. Adverse events were few and escalating doses were well-tolerated. No trends were evident in vital assessments, lab values, or ECGs.

Conclusion: This first-in-human study of a novel bispecific antibody inhibiting PAD 2 and 4 enzymes, demonstrated that Q2W dosing of AZD1163 was well tolerated in healthy volunteers, with favorable PK characteristics in the dose range studied. Target engagement was demonstrated by inhibition of PAD2/4 activity *ex vivo* in plasma. Results generated from this Phase I study, supports the further evaluation of AZD1163 in patients with RA.

Abstract Number: 1375

86-96% of Rheumatoid Arthritis (RA) Patients with RA Who Have 0 or 1 Swollen Joint or Tender Joint but Are Classified as Moderate/high on RA Indices Have 1-9 Comorbidities Recognized on a Multidimensional Health Assessment Questionnaire (MDHAQ)

Theodore Pincus[1], Juan Schmukler[1] and Tengfei Li[2], [1]Rush University Medical Center, Chicago, IL, [2]Rush, chicago, IL

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1347–1375) Rheumatoid Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) guidelines suggest management according to "treat-to-target," with escalation of treatment in patients with moderate/high (M/H) DAS28 (disease activity score 28) or CDAI (clinical disease activity index) according to shared decisions toward low activity/remission (R/L). It is recognized that elevated RA clinical core data set measures and indices may be seen in the absence of inflammatory activity in RA patients with comorbid joint damage and/or fibromyalgia. A multidimensional health assessment questionnaire (MDHAQ) includes queries to screen for fatigue, back pain, neck pain, headache, problems with sleep or thinking, and indices to screen for anxiety, depression and fibromyalgia. Analyses were performed of RA patients with 0 or 1 swollen and tender joint counts (SJC & TJC), who met criteria for remission according to these measures, but who were classified as M/H on DAS28-ESR (disease activity score 28–erythrocyte sedimentation rate) , CDAI (clinical disease activity index), or RAPID3 (routine assessment of patient index data) and would be regarded as candidates for escalation of therapy, to identify comorbidities found on the MDHAQ which may explain the elevated index scores.

Methods: Unselected patients with RA seen in routine care completed an MDHAQ prior to seeing the rheumatologist, who performed a standard 28 joint count. DAS28–ESR, CDAI, and RAPID3 were computed, and patients were classified as L/R or M/H. The proportion of patients who were identified as having each of 9 generally non-inflammatory comorbidities on the MDHAQ and any of 9 was computed for each index, recognizing that these comorbidities may reflect inflammation in certain patients.

Results: In 173 patients with RA seen in 2021, SJC and TJC 0 or 1 was found in 73 (42%), of whom 7%, 34%, and 58% were classified as M/H according to DAS28-ESR, CDAI, and RAPID3, respectively. Among these patients, positive MDHAQ screening was seen in 29-33% for anxiety , 26-33% for depression, 17-38% for fibromyalgia, 67-81% for fatigue >3/10,

SJC0,1 TJC0,1	n (%)	a.Anxiety	b. Depression	c. Fibromyalgia	d.Fatigue >3/10	e.Back pain	f.Neck pain	g.Headache	h. Sleep prblms	i.Think prblms	j. Any a-i
DAS28-ESR R/L	60 (90%)	1 0 (17%)	7 (12%)	4 (8%)	23 (40%)	23 (38%)	24 (40%)	8 (13%)	19 (32%)	7 (12%)	41 (68%)
M/H	7 (10%)	2 (33%)	2 (33%)	1 (17%)	4 (67%)	4 (57%)	4 (57%)	0 (0%)	3 (43%)	0 (0%)	6 (86%)
CDAI R/L	47 (66%)	6 (13%)	3 (7%)	0 (0%)	12 (26%)	12 (26%)	17 (36%)	2 (4%)	10 (21%)	1 (2%)	27 (57%)
M/H	24 (34%)	8 (33%)	8 (33%)	6 (38%)	17 (81%)	16 (67%)	13 (54%)	7 (29%)	15 (63%)	8 (33%)	23 (96%)
RAPID3 R/L	30 (42%)	2 (7%)	0 (0%)	0 (0%)	3 (10%)	9 (30%)	10 (33%)	0 (0%)	3 (10%)	0 (0%)	14 (47%)
M/H	42 (58%)	12 (29%)	11 (26%)	6 (19%)	26 (67%)	20 (48%)	21 (50%)	9 (21%)	22 (52%)	9 (21%)	37 (88%)

Proportion of Rheumatoid arthritis patients with 0 and 1 swollen (SJC) and tender (TJC) joints on a 28 joint count who reported positive responses for 9 comorbidities within the MDHAQ vs classification as DAS28–ESR, CDAI, or RAPID3 remission/low (R/L) or moderate/high (M/H)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

48-67% for back pain, 50-57% for neck pain, 0-21% for headache, 43-63% for problems with sleep and 0-33% for problems with thinking. One of the 9 comorbidities was seen in 86-96% of patients with SJC and TJC 0 or 1, who were classified as M/H (Table). In patients with SJC and TJC 0 or 1 who were classified as R/L, 47%-68% reported one of the 9 symptoms. The proportion reporting each symptom was higher in the M/H group for all 3 indices other than two symptoms reported by none of 7 patients with 0 or 1 SJC and TJC who were classified as DAS28–ESR M/H (Table).

Conclusion: In 173 patients with RA seen in 2021 who met SJC and TJC criteria for remission but were classified as DAS28-ESR, CDAI, or RAPID3, 86-96% reported one of 9 non-inflammatory comorbidities on the MDHAQ found on the MDHAQ. One limitation is that it is possible that one or more comorbidities identified as "non-inflammatory" may result from inflammation in certain patients. Nonetheless, the MDHAQ, which is completed by most patients in 5-10 minutes and is available in the February 2025 release of the Epic electronic medical record (EMR), can be helpful to interpret RA index scores for treat-to-target, description of outcomes, and general patient management.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1376–1404) Sjögren's Disease – Basic & Clinical Science Poster II: Clinical Manifestations and Health Outcomes

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Sjögren's disease (SjD) is a chronic systemic autoantibody driven disorder characterized by glandular dysfunction that typically presents with oral and ocular dryness, fatigue, and pain. Ninety percent of affected individuals are female, and the condition imposes significant clinical, humanistic, and economic burden. Limited information is known regarding the total economic burden associated with SjD including direct, indirect, or societal costs and the implications for patients living with SjD. We conducted a systematic literature review (SLR) to identify, evaluate, and summarize the economic burden on patients with SjD. The SLR was supplemented by a roundtable discussion of patients living with SjD to add additional insight and context regarding the burden of disease.

Methods: The SLR was developed using the PRISMA reporting guidelines for systematic reviews and conducted using the MEDLINE and Embase databases (via OvidSP), covering the period from January 1, 2014 to April 12, 2024. Additional searches were performed in the bibliographies of relevant studies, Google Scholar, disease-specific websites, and conference proceedings. Data were extracted to report on healthcare resource utilization (HCRU), direct medical costs, as well as indirect and societal costs. A focus group discussion of patients living with SjD generated qualitative insights to identify themes across diagnosis, treatment, and burden of disease.

Table 1: Studies measuring total direct health care resource utilization

Study	Country	Study population	Metric	Costs
McCormick 2015	Canada	SjD vs non-SjD	Total cost (CAD) PPPY, mean (IQR); times increase	11,748 (9,640–13,856) vs 4,213 (3,762–4,665); 2.8x
Perera 2018	USA	SjD vs non-SjD	1. Total all-cause cost (USD) PPPY, mean; times increase 2. SjD-related cost (USD) PPPY, mean; times increase	1. 10,729 vs 6,534; 1.6x 2. 2,214 vs 1,503; 1.5x
Yao 2018	China	SjD (with DED) vs non-SjD	Total cost (CNY) PPPY, mean, times increase	7,637 vs 1,179; 6.5x
Chan 2021	Canada	SjD (with DED) vs non-SjD	Total cost (CAD) PPPY, mean; times increase	2,689 vs 2,203; 1.2x
Westerlund 2021	Sweden	SjD vs non-SjD	Total cost (SEK) per patient, median (IQR); times increase	23,735 (9,907–58,180) vs 8,128 (2,822–24,540); 2.9x
Cafaro 2024	Italy	SjD vs non-SjD	Total cost (Euro) PPPY, mean; times increase	1,171 vs 372; 3.1x
Birt 2017	USA	Post- vs pre-diagnosis of SjD	1. Total cost (USD) PPPY, mean; times increase 2. SjD-related cost (USD) PPPY, mean	20,417 vs 14,612; 1.4x 1,742 vs NA
Kim 2020	Korea	SjD	Total cost (USD) PPPY, mean	503 in 2012 and 643 in 2016
McCoy 2022	USA	SjD	Total cost (USD) PPPY, mean	5,748
Bowman 2017	UK	SjD subgroups (rituximab vs PBO)	Total cost (GBP) per patient over 48 weeks, mean; times increase	10,752 vs 2,672; 4.0x
Perera 2018	USA	SjD subgroups (extra-glandular vs glandular disease only)	Total cost (USD) PPPY, mean; times increase	14,387 vs 4,878; 2.9x
Alemao 2019	USA	SjD subgroups with RA (abatacept vs anti-TNFs)	Total adjusted* cost (USD) per patient per 180-days, mean; times increase	17,050 vs 27,469; 0.6x
Lee 2022	USA	SjD subgroups (with vs without interstitial lung disease)	Total cost (USD) per patient per 180-days, mean; times increase	23,192 vs 8,648; 2.7x
Ndife 2022	USA	SjD subgroups (ESSDAI ≥5 vs ESSDAI <5)	Total cost (USD) PPPY, mean; times increase	15,656 vs 11,165; 1.4x
Seror 2024	France	SjD subgroups (with other autoimmune disease vs SjD only)	Total cost (Euro) PPPY, mean; times increase	8,819 vs 5,780 in 2011; 1.5x 13,273 vs 9,710 in 2018; 1.4x

DED, dry eye disease; ESSDAI, EULAR Sjögren Syndrome Patient Reported Index; ILD, IQR, NA, not available; PBO, placebo; PPPY, per patient per year; pSS, primary Sjögren's syndrome; RA, rheumatoid arthritis; SjD, Sjögren's disease; TNF, tumor necrosis factor.

Results: A total of 53 publications (43 unique studies) reported outcomes related to economic burden of SjD. The studies were performed across many countries, predominately in North America (23) and Europe (13). The publications reflected 23 studies reporting on HCRU, with 18 assessing direct and/or indirect costs. Direct health care costs for patients with SjD were, on average, 2.8 times higher than for patients without SjD (**Table 1**). Direct patient out-of-pockets costs were not measured in any study. The studies underscore that patients with SjD require more frequent hospitalizations, outpatient visits, emergency room care, and dental visits compared to the patients without SjD. Productivity loss was reported in 15 studies. On average, patients with SjD had two times higher total indirect costs (**Table 2**). The studies also highlighted significant societal costs associated with SjD, including a higher likelihood of early retirement, reduced work hours, and

Table 2. Studies measuring indirect costs for patients with SjD

Study	Country	Study population	Metric	Costs
Chan 2021	Canada	1. SjD (with dry eye disease) vs non-SjD 2. SjD with dry eye disease by severity (overall vs mild vs moderate vs severe)	Indirect cost (CAD) PPPY, mean; times increase	1. 41,094 vs 17,694; 2.3x 2. 24,331 (presenteeism: 19,304; absenteeism: 2,702) vs 5,961 vs 16,525 vs 25,485
Yao 2018	China	SjD (with dry eye disease) vs non-SjD	Indirect cost (CNY) PPPY, mean; times increase	828 vs 487; 1.7x
McCormick 2019	Canada	SjD	Indirect cost (CAD) per patient, mean	Weekly cost: 377 (presenteeism: 320; absenteeism: 191) Annual cost: 14,092

PPPY, per patient per year; SjD, Sjögren's disease.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. part-time work due to health. The patients interviewed confirmed they were unable to work due to disease impact and fatigue as well as an inability to afford living alone and experiences of financial insecurity.

Conclusion: Current published studies demonstrate that SjD results in considerable healthcare costs, loss of productivity, and a profound financial burden on both individuals and healthcare systems, highlighting an increased need for inpatient care and extended stays. Indirect costs, primarily arising from lost productivity, further amplify the economic burden of SjD. In total, these costs highlight a significant economic and societal burden of SjD, reflecting both direct healthcare costs and significant indirect costs.

Session Date: Monday, October 27, 2025
Session Title: (1376–1404) Sjögren's Disease – Basic & Clinical Science Poster II: Clinical Manifestations and Health Outcomes
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Sjögren's disease (SjD) is a chronic systemic autoimmune disorder that imposes significant clinical, humanistic, and economic burdens on patients. It is associated with multiple comorbidities and significant heterogeneity in disease manifestation, including an increased risk of lymphoma, which further exacerbate its impact. Despite numerous drugs (such as rituximab and abatacept) having been tested, there are currently no approved treatments for the disease. While some drugs are prescribed to help relieve symptoms, many patients report inadequate relief, which exacerbates the emotional and social impact of the disease. We conducted a systematic literature review (SLR) to identify, summarize, and evaluate the existing evidence on the impact of treatments on the humanistic burden of SjD, with a particular focus on their impact on patients' health-related quality of life (HRQoL).

Methods: The SLR was conducted using the MEDLINE and Embase databases (via OvidSP), covering the period from January 1, 2014 to April 12, 2024 for publications in the English language. Additional searches were performed in the bibliographies of relevant studies, Google Scholar, disease-specific websites, and conference proceedings. Articles were screened, and data were extracted to report on HRQoL outcomes, including disease-specific instruments (EULAR Sjögren's Syndrome Patient-Reported Index [ESSPRI]), generic tools (European Quality of Life 5 Dimensions [EQ-5D], Short

form–36 Health Survey [SF-36], Visual Analogue Scale [VAS]), and specific HRQoL domains such as pain, fatigue, activity participation, anxiety, depression, ocular health, oral health, and sexual health.

Results: Twenty-nine publications reporting the effect of treatment on humanistic burden outcomes of SjD were identified (19 related to systemic treatments and 10 to non-systematic/non-pharmacological interventions; **Table 1**). In randomized controlled trials (RCTs) involving rituximab, leniolisib, and abatacept, no significant differences in ESSPRI scores were found between treatment and placebo groups, indicating similar levels of symptom burden reduction (**Table 2**). In contrast, iguratimod and dazodalibep demonstrated significant improvements in overall ESSPRI scores compared to placebo in small or local trials. An RCT of tocilizumab failed to show significant improvements in anxiety or depression outcomes compared to the control group (**Table 3**). Use of systemic treatments was found to result in non-significant improvements in fatigue, oral dryness, and ocular dryness compared to placebo. Non-pharmacological interventions, including exercise-based therapies and traditional Chinese medicine, also showed inconsistent effects on HRQoL.

Table 2. Impact of systemic treatments on ESSPRI score

Conclusion: Both systemic treatments and non-pharmacological interventions have generally shown limited efficacy in reducing the HRQoL burden in SjD. Although some treatments have demonstrated potential, these findings are primarily derived from clinical studies with small sample sizes and require validation. There remains a significant unmet need for therapies that can effectively alleviate the quality-of-life burden in patients with SjD.

Background/Purpose: Sjögren's disease is a systemic autoimmune disorder with diverse clinical manifestations affecting multiple organ systems. While dry mouth, dry eyes, fatigue and pain are the most common features, involvement of the central nervous system (CNS) is increasingly reported among Sjögren's patients. CNS manifestations may precede Sjögren's diagnosis and can occur in the absence of classic sicca symptoms, potentially leading to delayed or missed diagnoses. To better understand the neurological aspects, we conducted a scoping review and meta-analysis to characterize the prevalence of CNS manifestations in Sjögren's disease.

Methods: The Sjögren's Foundation convened an expert panel to conduct this scoping review as part of a broader CNS guideline project. We searched PubMed, Embase, and ECRI for articles containing prevalence data on CNS manifestations in Sjögren's from 1980 to September 16, 2024. All articles were screened in duplicate by members of the panel using predefined inclusion criteria (>17 years of age; any sex, gender, ethnicity, or location; any study design; published in English). Studies that were not conducted in a general Sjögren's population were excluded. One author (JFH) extracted data on event counts and total sample size, and a second author (AV) conducted an audit of the extracted data. We used the meta package in R to conduct random-effects meta-analyses of proportions. To stabilize the variance of proportions, we used the Freeman-Tukey double arcsine transformation. We estimated between-study heterogeneity using the restricted maximum likelihood (REML) method.

Results: Our literature search resulted in 20,549 citations. After duplicates were removed, we screened 17,305. 110 articles met the inclusion criteria. Prevalence data for the following CNS manifestations were identified: anxiety, aseptic meningitis, bipolar, brain stem-related symptoms, central sensitization, cerebellar syndrome, cerebral vasculitis, cerebral vascular disease, chronic fatigue syndrome, cognitive dysfunction/impairment, dementia, demyelinating diseases, depression, encephalopathy/delirium, fibromyalgia, headache, insomnia, long-COVID-CNS manifestations, migraine, movement disorders, multiple sclerosis, myelopathy, neuromyelitis optica spectrum disorder, optic neuritis, Parkinson's disease, psychosis, restless leg syndrome, schizophrenia, seizure disorder, stroke, transverse myelitis. Meta-analysis of proportions for each of these CNS manifestations will be presented.

Conclusion: This scoping review and meta-analysis of proportions highlights the prevalence of CNS manifestations in individuals with Sjögren's. By systematically identifying and quantifying these neurological features, this study provides critical insights to inform earlier recognition, prompt referral, and improved multidisciplinary management of Sjögren's disease. These results also support the need for future guidelines and research focused specifically on CNS manifestations to enhance care for this complex patient population.

Abstract Number: 1379

Renal tubular acidosis in Sjögren's disease and non-Sjögren's sicca in an Oklahoma cohort

Biji T Kurien[1], Martha Tsaliki[2] and R Hal Scofield[1], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]OMRF, Oklahoma City, OK

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1376–1404) Sjögren's Disease – Basic & Clinical Science Poster II: Clinical Manifestations and Health Outcomes
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Renal involvement in primary Sjögren's disease (pSjD) is a well-known extraglandular manifestation with a prevalence of 5-14% in several studies. Mostly, it affects the renal tubules through tubulointerstitial nephritis, resembling lymphocytic infiltration in the exocrine glands. Distal renal tubular acidosis (RTA), rather than proximal RTA, is the most frequent tubular dysfunction in SjD. We hypothesized that RTA occurs in SjD and non-SjD sicca and will be found in those with high urinary pH, and that it will correlate with serum hypokalemia and bicarbonate.

Methods: We screened urinary and serum metabolic data from primary SjD, incomplete SjD, and healthy controls from the database maintained by Oklahoma Sjögren's Syndrome Center of Research Translation at the Oklahoma Medical Research Foundation (OMRF). This work was part of a study approved by the Institutional Review Board of OMRF and the University of Oklahoma Health Sciences Center.

Results: We found data for urinary pH and metabolic profile in 504 pSjD, 725 incomplete Sjögren's, and 13 healthy controls. Sixty pSjD, 115 non-Sjögren's sicca subjects, and 2 healthy controls had a urinary pH greater than 7.5. Of these 23 SjD, 46 incomplete SjD and 1 healthy control had a pH greater than 8. Seven SjD subjects had a urinary pH of 8.5, while 2 had a pH of 9. Two each of incomplete Sjögren's had a pH of 8.5 and 9. The 23 SjD subjects had a significantly higher alkaline pH compared to incomplete Sjögren's (pH 8.24 ±0.275 Vs 8.06 ±0.224 respectively, p= 0.01). All the 60 pSjD or 115 non-Sjögren's sicca subjects had a highly significant alkaline pH compared to healthy controls (p< 0.0001). However, very interestingly, there was no significant difference in bicarbonate, potassium, or chloride levels between the SjD, incomplete SjD, or the controls in subjects. Anion gap was within normal range in the SjD, non-Sjögren's sicca, and healthy controls. While the SjD and non-Sjögren's sicca subjects with highly alkaline urinary pH may have specific tubular defects that hinder urine acidification, the defects may not be severe enough to bring about RTA in our cohort.

Conclusion: Higher urinary pH is found in SjD compared to non-Sjögren's sicca, and healthy controls. However, the defect in urine acidification does not appear to be related to RTA in our cohort.

Abstract Number: 1380

Phenotyping Neuropathic Pain in Sjögren's Disease: A Cluster-Based Approach

Beatrice Dei[1], Stefano Donati[1], Gaetano La Rocca[2], Giovanni Fulvio[1], Federico Fattorini[1], Antonello Sulis[1], Michele Moretti[1], Elena Elefante[1], Francesco Ferro[3], Giulia Ricci[4], Marta Mosca[5] and **Chiara Baldini**[5], [1]Rheumatology Unit, University of Pisa, Pisa, Toscana, Italy, [2]University of Pisa, Rheumatology Unit, Pisa, Pisa, Italy, [3]Clinical and Experimental Medicine Department, Azienda Ospedaliero-Universitaria Pisana, Pisa, Pisa, Italy, [4]Neurology Unit, University of Pisa, Pisa, Toscana, Italy, [5]University of Pisa, Pisa, Pisa, Italy

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1376–1404) Sjögren's Disease – Basic & Clinical Science Poster II: Clinical Manifestations and Health Outcomes

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Neuropathic pain (NeP) is increasingly recognized as a relevant symptom domain in primary Sjögren's disease (SjD), contributing to the disease burden beyond glandular involvement. Despite its potential impact on quality of life, the clinical and patient-reported (PROs) outcomes associated with NeP in SjD remain incompletely understood.

Aim of this study is to investigate the prevalence of NeP in patients with SjD, and identify its associations with clinical features, immunological markers, and PROs including fatigue, pain severity, small fiber symptoms, and emotional distress.

Methods: We conducted a cross-sectional analysis of 112 (105 F:7 M) patients diagnosed with SjD according to ACR/EULAR criteria. NeP was assessed using the DN4 questionnaire (cut-off ≥4). Extra glandular manifestations were prospectively assessed following the ESSDAI. PROs included the ESSPRI, FACIT-Fatigue, VAS items, and the Hospital Anxiety and Depression Scale (HADS). Fibromyalgia was diagnosed according to ACR 2016 criteria. Immunological data included SSA/SSB status, gammaglobulin fractions, complement levels, and histological findings. The SFNSL was administered to assess symptoms related to small fiber neuropathy. Logistic regression models were used to identify independent predictors of neuropathic pain and K-means clustering was applied to DN4 scores to explore phenotypic subgroups.

Results: NeP (DN4 ≥4) was identified in 25% (28/112) of SjD patients. Coexisting fibromyalgia was present in 31.5% (35/112) of the cohort. Patients with NeP had significantly higher fibromyalgia severity scores, ESSPRI, HADSA, HADSD and lower FACIT scores (Fig 1). In multivariate logistic regression, fibromyalgia severity (OR = 1.13, p = 0.017), ESSPRI

Table 1: DN4-based Clusters: Clinical features and Patient-Reported Outcomes

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

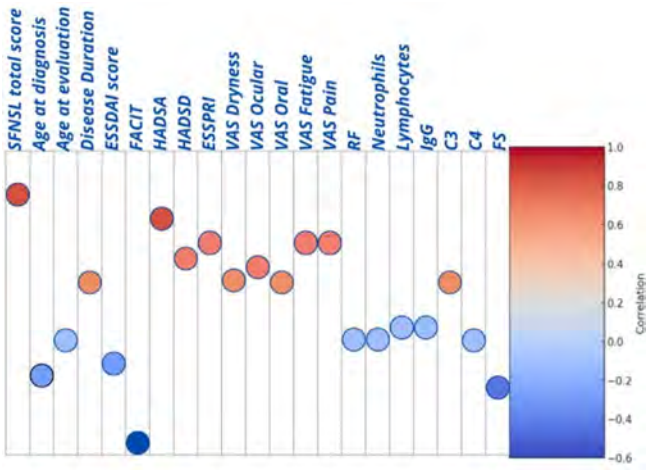

Figure 1: Correlations between DN4 and clinical, histological and laboratory features in SjD

(OR = 1.99, p = 0.024), and FACIT (OR = 0.91, p = 0.032) emerged as independent predictors of NeP. ESSDAI scores did not differ between groups.

Cluster analysis identified three distinct DN4-based phenotypes: high NeP (n=10, DN4≈8), moderate NeP (n=34, DN4≈5), and low/negligible NeP (n=68, DN4≈1) (Table1). These clusters differed significantly in total fibromyalgia score ($p < 0.001$), fatigue ($p < 0.001$), VAS pain, dryness, and SFNSL scores (all $p < 0.001$) (Fig 2). Disease duration was shorter in the high NeP cluster ($p = 0.003$). No significant differences were observed in systemic disease activity (ESSDAI), complement levels, or focus score. A significant association was found between DN4 clusters and SSA status ($p = 0.002$), with SSA-negative patients more frequently classified in higher DN4 clusters. Notably, a strong convergence was observed between DN4 and SFNSL scores ($r=0.754$, $p< 0.001$), supporting the reliability of NeP identification through both tools in this population.

Conclusion: Neuropathic pain defines a distinct symptomatic phenotype in SjD, associated with greater symptom burden, fibromyalgia, and SSA-negativity. Unsupervised clustering highlights the existence of clinically meaningful subgroups based on NeP severity, which are not mirrored by systemic inflammation. These findings underscore the need for comprehensive symptom profiling in SjD beyond conventional immunological and systemic markers.

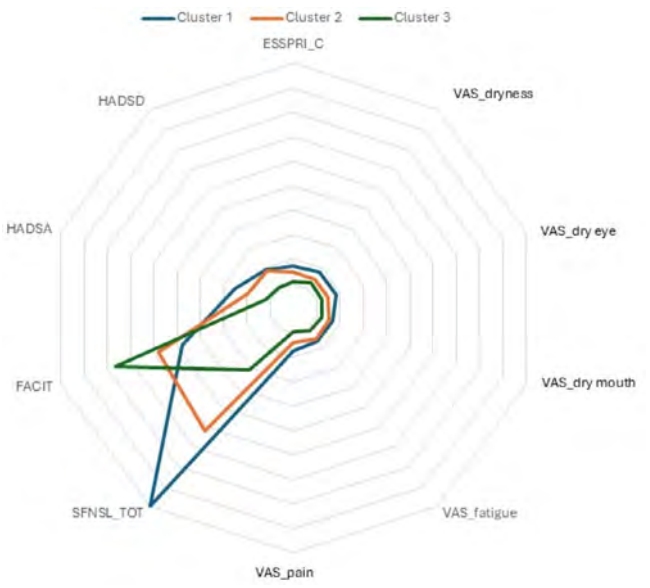

Figure 2: Radar Chart Depicting Differences in Patient-Reported Outcomes Across DN4-Based Clusters"

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1376–1404) Sjögren's Disease – Basic & Clinical Science Poster II: Clinical Manifestations and Health Outcomes

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with Sjögren's Disease (SjD) frequently report debilitating symptoms such as pain, fatigue, and dryness, significantly impacting health-related quality of life. Although sleep disturbances in SjD are well documented, only a few studies have objectively assessed sleep using wrist actigraphy, and none have explored circadian rhythm alterations or their clinical correlates. This study aimed to: (1) evaluate differences in self-reported and actigraphic sleep and circadian parameters between SjD patients and healthy controls (HCs); and (2) examine associations between these disruptions and clinical indices, including disease activity and patient-reported outcomes.

Table 1: Self-reported and Actigraphic Sleep and Circadian Rhythm Parameters in SjD and HCs

Variable	HCs N = 40	SjD N = 46	p-value
Age, mean (SD)	54 (9)	56 (13)	0.4

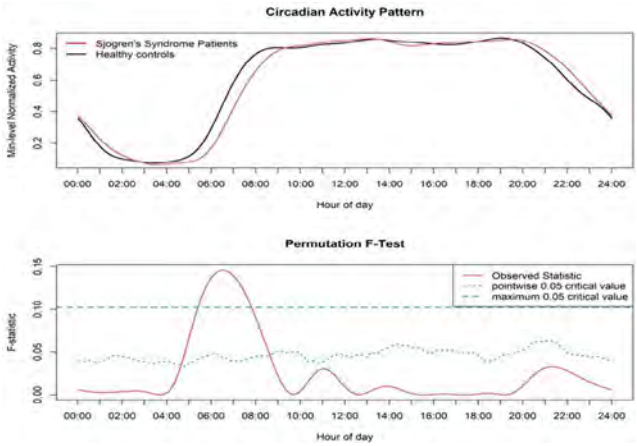

Fig.1 F-Test for 24h-circadian activity

Methods: In this cross-sectional study, we enrolled female SjD patients meeting the 2016 ACR/EULAR criteria, along with age-, sex-, and BMI-matched HCs. Participants underwent 7-day wrist actigraphy. Subjective measures included the Pittsburgh Sleep Quality Index (PSQI), Epworth Sleepiness Scale (ESS), and reduced Morningness-Eveningness Questionnaire (rMEQ). Circadian rhythm parameters were estimated using both parametric and non-parametric methods. Patient-reported outcomes included the EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI), Functional Assessment of Chronic Illness Therapy (FACIT), and Hospital Anxiety and Depression Scale (HADS). Disease activity was assessed using the EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI).

Results: Forty-six SjD patients and forty HCs were included. Compared to controls, SjD patients reported poorer sleep quality (higher PSQI scores) and greater daytime sleepiness (higher ESS). Actigraphy revealed lower sleep efficiency (SE), increased wake after sleep onset (WASO), an earlier sleep midpoint, and a significantly advanced sleep midpoint and acrophase, indicating an objective shift towards eveningness (Table 1, Fig 1).

Higher ESSPRI and HADS scores were associated with worse subjective sleep quality, greater sleepiness, lower total sleep time, reduced sleep efficiency, and increased WASO. Higher ESSDAI scores correlated with reduced daytime activity levels (lower MESOR) and fewer daily steps. Sensitivity analyses suggested that greater disease activity was linked to longer total sleep time and reduced sleep regularity (Table 2).

Conclusion: Conclusions: SjD is associated with both subjective and objective disruptions in sleep and circadian rhythms. These alterations correlate with disease activity and patient-reported outcomes, especially fatigue, mood disturbances, and physical inactivity. Circadian rhythm dysregulation may represent an underrecognized aspect of SjD, with potential implications for future therapeutic approaches.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1376–1404) Sjögren's Disease – Basic & Clinical Science Poster II: Clinical Manifestations and Health Outcomes
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Sjögren's disease (SjD) is a chronic autoimmune disorder primarily targeting exocrine glands. A significant extraglandular manifestation is interstitial lung disease (ILD), which contributes to considerable morbidity and can adversely affect patient outcomes. Our aim is to describe the clinical characteristics and disease course of a primary Sjögren's syndrome-associated ILD (pSS-ILD) cohort, with a specific focus on the proportion progressing to progressive pulmonary fibrosis (PPF).

Methods: This multicenter, retrospective, observational study included patients with pSS-ILD confirmed by high-resolution chest CT (HRCT). Diagnosis of pSS was based on anti-SSA/Ro positivity, salivary gland biopsy, or salivary gland ultrasound (grade 2 or 3 according to OMERACT SG US definitions).

Results: A total of 45 patients (91% women) were included, with a mean age at ILD diagnosis of 67 years (SD: 11). ILD preceded pSS diagnosis in 78% (35/45), with a median lead time of 8 months (IQR: 4–17). In 22% (10/45), ILD developed after pSS, with a median interval of 48 months (IQR: 21–64.5). Anti-SSA/Ro antibodies were present in 38% (16/42), anti-SSB/La in 24.5% (11/45), and 38% (17/45) were seronegative.

TABLE 1: Basal and follow-up general, immunological, clinical, radiological and treatment characteristics of our cohort of patients with Sjogren Disease (SjD) and interstitial lung disease (ILD), n=45.

General Characteristics:	
Sex, W:M (% women)	10:1 (91)
Age at ILD diagnosis, mean (SD)	67.0 (11)
ILD first;SS after, n (%)	35 (78)
Total follow-up, months, median [Q1-Q3]	56 [30-84]
Months between ILD and SjD, median [Q1-Q3]	8 [4-17]
Immunological characteristics:	
ANA positive, n (%)	36 (73%)
Anti-SSA/Ro, n=42 (%)	16 (38%)
RF, n (%)	15 (33%)
Anti-SSB/La, n (%)	11 (24.5%)
Hypergammaglobulinemia, n (%)	23 (47%)
Cryoglobulins, n (%)	1 (6%)(n=16)
Sjögren's disease characteristics:	
Raynaud's phenomenon, n (%)	8 (17)
Parotidomegalia, n(%)	7 (15)
Vasculitis, n(%)	0
Skin involvement, n(%)	0
Arthritis, n (%)	11 (23.4)
Renal disease, n (%)	4 (8.5)
Peripheral neuropathy, n(%)	2 (4.3)
Lymphoma, n (%)	2 (4.3)
Liver involvement, n (%)	2 (4.3)
ILD basal characteristics:	
NSIP, n (%)	26 (58)
OP, n (%)	9 (20)
LIP, n (%)	4 (9)
UIP, n (%)	6 (13)
ILD treatment, n=43	
GC, any dose, n (%)	33 (77)
GC initial dose, mg/day, mean (SD)	32 (14)
Conventional immunosuppressive, n, (%)	33 (77)
Rituximab, n (%)	11 (25.6)
Abatacept, n (%)	1 (2.3)
Antifibrotic, n (%)	10 (26)
ILD follow-up characteristics:	
Follow-up FVC, %, mean (SD)	83 (30)
Follow-up DLCO, %, mean (SD)	55 (26)
6 min walking distance, mts.; mean (SD)	341 (120)
CT follow-up, months, median [Q1-Q3]	31 [15-70]
Oxygen requirement	11 (24)

Radiologically, 58% (26/45) had nonspecific interstitial pneumonia (NSIP), including 14 with fibrotic NSIP; 13% (6/45) had usual interstitial pneumonia (UIP); 20% (9/45) had organizing pneumonia (OP) or NSIP with OP; and 9% (4/45) had lymphocytic interstitial pneumonia (LIP). Follicular bronchiolitis was found in 38% (17/45).

At ILD diagnosis, mean %pFVC was 84.4 ± 21.5 (IQR: 70.8–101.7), %pDLCO was 62.2 ± 17.3 (IQR: 48–76), and 6MWT distance was 371 ± 114 m (IQR: 306–422). Mean ESSDAI was 12 (SD: 5; IQR: 7–16).

Treatment included glucocorticoids in 77% (33/43; mean prednisone dose: 32 ± 14 mg/day), immunosuppressants in 77% (mycophenolate in 31, azathioprine in 2), and biologics in 28% (rituximab in 11, abatacept in 1). Antifibrotic therapy (nintedanib or pirfenidone) was initiated in 26% (10/43) due to progression to PPF.

After a median follow-up of 56 months (IQR: 30–84), 24% (11/45) required oxygen therapy due to chronic respiratory failure, 4% (2/45) were referred for lung transplantation, and 18% (8/45) died due to ILD progression or infections.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: ILD was the initial or predominant manifestation leading to pSS diagnosis in 78% of cases. Seronegative status was common (38%), highlighting the need to consider pSS in ILD patients with sicca symptoms. At least 26% progressed to PPF and required antifibrotic therapy.

Obesity in Primary Sjogren's Disease

Gabriela Hernandez-Molina[1], Donaji Gómez-Velasco[2], Ariel Garcia-Torralba[2], Carlos Aguilar-Salinas[2] and Ivette Cruz-Bautista[2], [1]Instituto Nacional de Ciencias Medicas y Nutricion, Mexico City, Federal District, Mexico, [2]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1376–1404) Sjögren's Disease – Basic & Clinical Science Poster II: Clinical Manifestations and Health Outcomes
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Obesity is an excessive fat accumulation that presents a risk to health. Little is known about the relationship between obesity and Sjögren's disease (SjD). We evaluated the prevalence of obesity in a cohort of patients with primary SjD, as measured by anthropometric indices such as body mass index (BMI), waist circumference (WC), waist-to-hip ratio (WHR), as well as with a body composition variable, the fat mass index (FMI). We also assessed the association of obesity with clinical and serologic features, disease activity, damage, and symptoms (sicca/fatigue/pain).

Methods: We included 91 patients with SjD. We registered demographics, comorbidities, glandular/ extraglandular and serologic variables. We assessed the Schirmer-I test and non-stimulated salivary flow, and scored the cumulative ESSDAI, SSDDI and ESSPRI scores. We measured the body mass index (BMI), waist circumference (WC) and waist-to-hip ratio (WHR). We defined obesity as a BMI ≥30 kg/m^2. Central obesity was defined as WC >90 cm and >80 cm; or by a WHR >0.90 and >0.85, for men and women, respectively. All patients underwent bioimpedance analysis (BIA) to measure body fat mass index (FMI). An elevated/high FMI according to BIA definitions was classified as obese (≥9.3 kg/m^2 for women and ≥6.2 kg/m^2 for men).

Results: 97.8% were women with a mean age of 54.4±12.8 years, and a median disease duration of 10 years. The prevalence of obesity was 19.7%, 52.7%, 52.7% and 40.6%, according to the BMI, WC, WH, and FMI, respectively. When we compared obese vs non-obese patients according to BMI, the first group had a higher prevalence of anti-Ro/SSA antibodies (90.4% vs 66.7%), and were more likely to have hypertension (25% vs 6.7%).

When we compared obese vs non-obese patients according to their WC, the obese group had a longer disease duration (13 vs 9 years) and a higher cumulative ESSDAI score (12 vs 6.5 points). They were also more likely to have parotid gland enlargement (58.1% vs 34.5%), and higher globulin levels (3.9 vs 3.5 g/dL). In logistic regression analysis, the variables that remained associated with obesity were disease duration (OR 1.06 95% CI 0.99-1.1, p=0.05) and the SSDDI score (OR 1.36, 95% CI 1.04-1.7, p=0.02). A similar finding was observed when we compared obese patients according to the WHR with their counterpart (SSDDI score OR 1.31, 95% CI 1.01-1.69, p=0.03)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Patients with obesity according to the FMI were more likely to have parotid gland enlargement (54.1% vs. 31.4%), neurologic involvement (35.1 vs 13.5%), higher cumulative ESSDAI scores (11 vs 7 points) , higher SSDDI scores (3 vs 2 points), and higher globulin levels (3.8 vs 3.6 g/dL). These patients were also more likely to have hypertension (24.3% vs 9.3%). In the logistic regression analysis, the variable that was again associated with obesity was the SSDDI score (OR 1.50, 95% CI 1.1-1.9, p=0.005).

Conclusion: According to BMI, at least 20% of patients were obese, this prevalence increased to 40% when BIA was used, with a higher prevalence found in central obesity. Obesity was associated with accrual damage. Our results may have implications for weight reduction in this patient group.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1376–1404) Sjögren's Disease – Basic & Clinical Science Poster II: Clinical Manifestations and Health Outcomes
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Sjögren's disease is recognized as a multifaceted autoimmune disease impacting almost any organ or body system. Of particular importance is the central nervous system (CNS) involvement, which may manifest before classic sicca symptoms. The Sjögren's Foundation is conducting a systematic review on the treatment of CNS manifestations, the conclusions of which will inform the development of clinical practice guidelines and advance patient outcomes in an often underrecognized aspect of Sjögren's.

Methods: The Sjögren's Foundation convened an expert panel to conduct a systematic review as part of a broader CNS guideline project. Our PICO question was: *What are effective treatments for Sjögren's patients >17 years of age with or without an accompanying rheumatic or non-rheumatic autoimmune disorder who are diagnosed with any central nervous system manifestation?* Outcomes of interest include mortality, disability, health-related quality of life, any qualitative or quantitative measures of clinically relevant improvement, symptom stabilization, serious adverse events specific to Sjögren's, activities of daily living, effects on family or caregivers, healthcare resource utilization, and cost-effectiveness. In

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

anticipation of very limited direct evidence in a Sjögren's population, evidence on treating CNS manifestations in lupus was included as an indirect source of evidence. We searched PubMed, Embase, and ECRI for articles containing prevalence data on 53 CNS manifestations in Sjögren's disease from 1980 to September 16, 2024. All articles were screened in duplicate by members of the panel using predefined inclusion criteria (>17 years of age; any sex, gender, ethnicity or location; any treatment, published in English). Exclusions were narrative reviews, editorials, case reports, and case series with < 4 cases.

Results: Our initial literature search resulted in 20,549 citations. After duplicates were removed, we screened 17,305. 16,222 articles were excluded based on title and abstract review, and 1083 articles are undergoing full-text review. Due to insufficient data for conducting a meta-analysis, summative narrative results will be presented.

Conclusion: Our preliminary findings underscore both the complexity and the critical importance of accurately identifying and managing CNS manifestations in Sjögren's disease. Although the initial literature search yielded a high volume of citations, a substantial number did not meet the inclusion criteria, underscoring the relative scarcity of robust data on this topic. Given the limited available evidence specific to Sjögren's disease, the decision to include parallel data from lupus research provides a necessary indirect comparison to inform clinical decision-making. The results of this systematic review will be essential for developing rigorous, evidence-based recommendations on the evaluation and management of CNS manifestations in Sjögren's disease.

Session Time: 10:30AM–12:30PM

Background/Purpose: Ocular and oral dryness, occurring in isolation, represent distinct phenotypic subsets within Sjögren's disease (SjD). However, potential differences in glandular imaging findings and pathophysiological mechanisms have not yet been adequately investigated. This study investigates how isolated ocular, isolated oral, and combined dryness

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1 - Comparative Analysis of Patient-Reported Outcomes Across Dryness Phenotypes in Sjögren's Syndrome This radar chart illustrates the differences in various patient-reported outcomes including quality of life (QoL), Oral Health Impact Profile (OHIP), EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI), and Visual Analogue Scale (VAS) assessments for ocular and oral dryness, total dryness, pain, and fatigue. Each colour represents a different group: no dryness (blue), isolated ocular dryness (red), isolated oral dryness (orange), and double dryness (green), highlighting their respective impacts on the dimensions assessed.

phenotypes in SjD differ with respect to ultrasonographic patterns, histological findings, functional test outcomes, and patient-reported metrics

Methods: We retrospectively reviewed patients diagnosed with SjD based on the 2016 EULAR/ACR criteria from January 2017 to December 2024. All participants underwent labial gland biopsies and comprehensive imaging using high-frequency ultrasonography: 18 MHz for major salivary glands (SGUS), 48 MHz for lacrimal glands (LGUHFUS), and 70 MHz for labial salivary glands (LSGUHFUS). A semiquantitative OMERACT score (0–3) was used to define abnormal imaging (score ≥2).

Table 1 - Demographic and Clinical Characteristics of Sjögren's Syndrome Patients by Dryness Phenotype This table presents a comprehensive comparison of demographic and clinical parameters among Sjögren's syndrome patients categorized into no dryness, isolated ocular dryness, isolated oral dryness, double dryness, and combined isolated ocular or oral dryness groups. Key parameters include age, gender distribution, Ocular Surface Disease Index (OSDI), unstimulated salivary flow rate (USWR), Schirmer's test scores, Focus Score, Ectopic Lymphoid Structures (ELS), Major Salivary Gland Ultrasonography (SGUS), Lacrimal Gland Ultrasonography (LGUHFUS), labial salivary glands (LSGUHFUS) and EULAR Sjögren's syndrome disease activity index (ESSDAI).

	No Dryness	Isolated Ocular Dryness	Isolated Oral Dryness	Double Dryness	p-value
Age	51.4±6.2	52.3±3.8	56.8±3.5	56.6±2.2	0.147
Gender	1/22 (4.5%)	4/32 (12.5%)	2/24 (8.3%)	9/113 (8.0%)	0.764
OSDI	5,1±2.4	15,8±3.6	7,9±3.5	18,2±2.1	**0,001**
USWR	3,5±1.7	3,7±1.1	2,9±1.5	1,8±0.4	**0.002**
Schirmer	12,2±3.5	5,6±2.0	6,2±2.4	5,0±0.8	**0**
Focus Score	2,0±0.8	1,3±0.32	1,4±0.36	1,9±0.4	0.24
ELS	2,1±1.1	1,3±0.5	2,3±1.3	2,1±0.5	0.362
SGUS	4,1±2.1	3,3±1.6	5,6±2.2	4,9±1.0	0.333

ESSDAI	4,7±1.2	3.3±0.9	5,6±1.1	**0.023**

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Patient-reported outcome (PRO) included the ESSPRI, OSDI, OHIP, and VAS scores for oral and ocular dryness. Dryness was categorized into four groups based on VAS scores: no dryness (VAS ocular< 5, VAS oral < 5), isolated ocular dryness (VAS ocular ≥5, VAS oral < 5), isolated oral dryness, (VAS ocular< 5, VAS oral ≥5) and double dryness (VAS ocular≥5, VAS oral≥5). In addition, patients presenting with either ocular dryness or oral dryness were analyzed separately. Systemic disease activity was evaluated using the ESSDAI score while functional assessment included unstimulated salivary flow rate (USWR) and the Schirmer's test

Results: Among 191 SjD patients (mean age 55.3 ± 1.9 years; 8.4% male), 22 had no dryness, 32 isolated ocular, 24 isolated oral, and 113 both symptoms. PROs scores followed a gradient, with the double dryness group reporting the highest symptom burden, the no dryness group the lowest, and the isolated dryness groups falling in between (see Fig.1). Quality of Life (QoL) scores were higher in the no dryness group. Patients with isolated ocular dryness exhibited lower Schirmer's test values compared to those with no dryness and isolated oral dryness (5.6±2.0 vs 12.2±3.5 and 6.2±2.4 respectively), but higher than double dryness (5.0±0.8, p< 0.001). Similarly, patients with isolated oral dryness had lower USWR than those with no dryness or isolated ocular dryness (2.9±1.5 vs 3.5±1.7 and 3.7±1.1 respectively), but higher than patients with double dryness (1.8±0.4) (Tab.1). No significant differences were observed in labial salivary gland histology or in the ultrasonographic findings of the lacrimal, labial, and major salivary glands. Finally, ESSDAI scores were lower in isolated ocular (2.8 ±1.1) and oral dryness (3.9±1.4) compared to no dryness (4.7±1.2) or double dryness (5.6±1.1)

Conclusion: In SjD isolated ocular and oral dryness are linked to specific functional deficits in the lacrimal and salivary glands, respectively. However, these isolated forms do not exhibit significant differences in histological features or glandular ultrasonographic findings. Clinically, isolated dryness appears to define a milder and distinct phenotype of SjD, marked by limited systemic involvement and a moderate burden on patient-reported outcomes

Characterization and Progression of Localized Amyloidosis in Sjogren's Syndrome: Evidence Long-Term (1995-2025) Follow-Up of a Cohort compared to Literature Review.

Hoang Nguyen[1], Philip Moresco[2], Antoine Chiu[2], Asha Patnaik[3] and Peter Gorevic[4], [1]Stony Brook University-Renaissance School of Medicine- Department of Rheumatology, Jamaica, NY, [2]Stony Brook University -Renaissance School of Medicine, Stony Brook, NY, [3]Stony Brook University Hospital, Stony Brook, NY, [4]Stony Brook University, Stony Brook, NY

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1376–1404) Sjögren's Disease – Basic & Clinical Science Poster II: Clinical Manifestations and Health Outcomes
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: -Sjogren's syndrome (SS) is a chronic autoimmune disorder, defined by keratoconjunctivitis sicca (KCS), specific serologies, and a significant risk of extra-exocrine disease manifestations and B-cell lymphoma[1].

- Amyloidosis is the local or systemic accumulation of abnormal protein aggregates[2].

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Patient Number	Age of SS Diagnosis	Age of Amyloidosis Diagnosis	Length of F/U (Years)	Location(s) of Amyloid	Amyloid Typing	Serum IFE and/or Urine IFE	Kappa/Lambda Ratio	Systemic Progression
1	38	38	9	Pulmonary	AL(λ)	(-)	0.49	None
2	26	41	2	Pulmonary	AL(λ) & AL(κ)	(-)	1.48	None
3	60	68	15	Cutaneous	AL(λ)	(-)	N/A	None
4	51	73	11	Pulmonary	AL(κ)	(-)	0.97	Yes
5	49	56	3	Pulmonary	AL(λ)	(-)	1.36	None
6	54	59	21	Cutaneous	AL(λ)	(-)	N/A	None
7	17	37	1	Cutaneous	AL(λ)	(-)	1.73	None
8	32	41	7	Breast → Pulmonary	AL(λ)	(-)	1.02	None

Cohort Characteristics

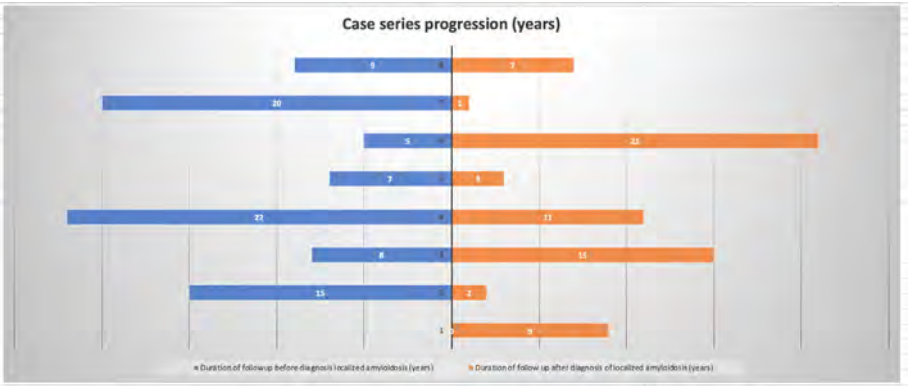
-Localized amyloidosis is a known, but rare, complication of SS[3], and is poorly characterized as to long-term course and treatment options.

-We report a case series of eight individuals with SS and localized amyloidosis, followed for an average of 8.65 years (range 1-21 years). Our results were compared to literature review to compile a description of localized amyloidosis in the setting of SS.

Methods: Our eight-patient cohort was seen and followed by PG over a 30-year period as part of an amyloidosis referral practice. PubMed was searched through January 2025 for the terms: amyloidosis, amyloid, Sjogren's syndrome, and their combinations.

Results: -In our cohort, the average age of SS at diagnosis was 40.9 (range 17-54). The average age at the time of amyloidosis diagnosis was 51.6 (range 37-73). 7/8 patients developed amyloid after being diagnosed with KCS/SS 12.3 years prior (range 5-22). In the remaining patient, SS and amyloidosis were diagnosed concurrently. The diagnosis of amyloidosis was made by immunohistochemistry and amyloid typing by sequence analysis, including mass spectrometry (7/8 patients). All samples stained positive for Congo red, and 8/8 were the AL subtype. Six patients had AL (λ), one had AL (κ), and in one patient both light chain types were present. All eight patients initially presented with localized amyloidosis, with no indication of systemic disease on detailed work-up. Of these patients, 4 had pulmonary amyloidosis, 3 had cutaneous amyloidosis, and 1 had intraparenchymal breast amyloidosis (**Figure 1A**). During the averaged 8.6 year follow-up (range 1-21), only the patient with intraparenchymal breast amyloid progressed to have systemic disease. In this patient, a pulmonary amyloid lesion presented six years after the original amyloid diagnosis. The remaining seven patients have had stable disease (**Figure 1B**; **Table 1**).

-We performed a literature search for articles published on SS and amyloidosis and found 55 publications comprising 74 total patients. The mean age of diagnosis of SS was 52, while amyloidosis was diagnosed at 59. The predominant subtype was AL (κ) (39.7%), followed by AL (λ) (19.05%). Most patients presented with local amyloidosis (92.68%) with the most



Case series progression follow-up

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1: Location of amyloid in case series (**A**) or literature search (**C**) and disease progression in case series (**B**) or literature search (**D**).

Location of localized amyloid and disease progression in case series versus literature review.

common location being pulmonary (43.42%), cutaneous (30.26%), and breast (6.58%) (**Figure 1C**). Of those reported, 86.54% with localized disease did not have disease progression, 11.54% did have progression, and one patient had terminal disease (**Figure 1D**).

Conclusion: -In our long-term follow-up of amyloidosis in SS, we monitored for local and systemic progression for an average duration 8.6 years (range 1-21 years).

-Between our cohort and our literature search, we find the most common location for amyloidosis in SS is pulmonary, then cutaneous, and finally breast.

-While the majority of cases are stable and do not progress, a subset of patients do, requiring close monitoring.

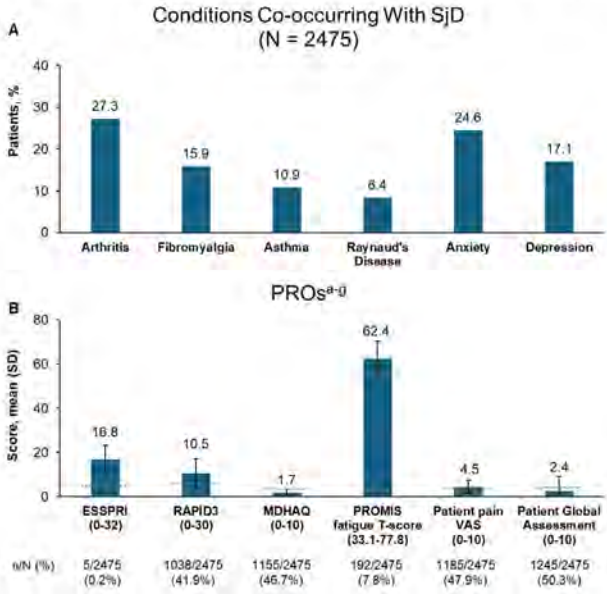
NA, not applicable; SS-A, Sjogren's syndrome-related antigen A. a n/M is the number of patients with positive test/number of evaluable patients.

Background/Purpose: Sjögren's disease (SjD) is a chronic autoimmune disease characterized by systemic symptoms such as dryness, fatigue, musculoskeletal pain, and extraglandular manifestations. SjD may overlap with other autoimmune diseases like systemic lupus erythematosus (SLE) or rheumatoid arthritis (RA). This analysis characterized the demographics, clinical characteristics, and patient-reported outcomes (PROs) of patients with SjD treated in a rheumatology setting and evaluated comorbidities 12 months post-diagnosis.

Figure 1. (**A**) Proportion of Patients With Conditions Co-Occurring With SjD at 12 Months Post-Index and (**B**) Mean PRO Scores Collected Closest to Index Up to 12 Months Post Diagnosis



ESSPRI, EULAR Sjogren's Syndrome Patient Reported Index; MDHAQ, Multidimensional Health Assessment Questionnaire; n/N, number of patients evaluated/total patient population; PRO, patient-reported outcome; PROMIS, Patient-Reported Outcomes Measurement Information System; RAPID3, Routine Assessment of Patient Index Data 3; SjD, Sjögren disease; VAS, visual analog scale. a Gray dotted lines represent cutoff points for moderate disease for each PRO. b ESSPRI score of ≥5 indicates unsatisfactory symptom status. c RAPID3 disease severity states are defined as remission (≤3), low (3.1-6), moderate (6.1-12), and high (≥12). d MDHAQ physical function score of 3.3 to 6.6 indicates moderate limitation of physical function. e PROMIS fatigue T-score is defined as normal (≤50), mild (50-55), moderate (55-65), and severe (≥65). f Patient pain VAS is defined as mild (≤3.4), moderate (3.5-7.4), and severe (≥7.5). g Patient Global Assessment is defined as mild disease (≤3), moderate (4.1 to <7), and severe (≥7).

Methods: Adult patients in the Excellence Network in RheumatoloGY (ENRGY) rheumatology network with ≥2 ICD-9 and ICD-10-CM codes for SjD diagnoses ≥28 to ≤365 days apart from January 2017 through February 2023 were included in this retrospective analysis of electronic health record (EHR) data. Prior to diagnosis by a rheumatologist, patients were required to have ≥12 months without an SjD diagnosis. Patient EHR data were linked to administrative claims from the Komodo Health database. The index date was defined as the date of the first SjD diagnosis. Demographic and clinical data were captured at index. Clinical manifestations and PRO outcomes collected closest to and within 12 months before or after index were reported

Results: Among 2475 patients, 91.8% were female and the mean (SD) age was 52.9 (12.9) years. Dryness symptoms were common (55.8%) prior to diagnosis, including dry eyes (22.4%) and mouth (10.8%). Asthenia-polyalgia was the most commonly occurring symptom in the pre-index period (87.9%), including arthralgia (71.0%), fatigue (52.6%), or myalgia (23.0%) (**Table 1**). Many patients had ≥1 extraglandular symptom (70.7%) (**Table 1**). Among the 58.5% of patients who underwent SS-A antibody testing, 34.0% tested positive. Diagnostic procedures including salivary gland ultrasound (15.4%) were infrequent, and magnetic resonance sialography, ocular surface staining test, and unstimulated whole saliva flow test were rare (< 0.1%). Anxiety (35.9%) and depression (27.1%) were common, and 42.3% had overlapping autoimmune diseases pre- and post-index, such as RA (29.1%), SLE (15.6%), and systemic sclerosis (2.2%). Patient characteristics were similar irrespective of overlapping autoimmune disease (**Table 1**). Frequent comorbidities 12 months post-diagnosis included arthritis, anxiety, Raynaud's disease, depression, and fibromyalgia (**Figure 1**). Mean (SD) PRO scores included EULAR Sjögren's Syndrome Patient Reported Index (16.8 [6.5]; n=5), Routine Assessment of Patient Index Data 3 (10.5 [6.6]; n=1038), Pain 0-10 (4.5 [2.9]; n=1185), and Patient Global Assessment (2.4 [6.6]; n=1245).

Conclusion: This analysis of EHR data revealed a range of extraglandular symptoms and comorbidities with SjD. Diagnostic procedures were infrequent, and common symptoms like dryness were under-reported. PRO scores indicated high disease burden, with high rates of anxiety, depression, and arthritis—the latter most commonly co-occurring 1 year post-diagnosis. These findings reveal the complex clinical challenges faced by patients with SjD.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1376–1404) Sjögren's Disease – Basic & Clinical Science Poster II: Clinical Manifestations and Health Outcomes

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Table 1: Definitive, probable, possible, or unlikely classification of primary Sjögren's syndrome using the 2016 ACR-EULAR classification criteria

Classification Designation	Criteria
Definitive	Meets ACR-EULAR classification criteria
Probable	Positive serology (SSA) with other supporting characteristics* or being treated for Sjögren's by a rheumatologist
Possible	Positive serology (SSA)
Unlikely	Does not meet any diagnostic criteria and alternate diagnosis is suspected.

*Supporting characteristics include presence of renal tubular acidosis, polyclonal hypergammaglobulinemia, autonomic neuropathy, elevated inflammatory markers, lymphoma, fevers, weight loss, lymphadenopathy, glandular swelling, unexplained rashes, lung involvement, joint pain, in the absence of alternative explanation.

Background/Purpose: Primary Sjögren's syndrome is a multisystem autoimmune disorder characterized by progressive dysfunction of exocrine glands leading to symptoms of keratoconjunctivitis and xerostomia.

There is no cure for Sjögren's syndrome, however a multidisciplinary approach with care from a rheumatologist, dentist, and ophthalmologist can be adopted to help manage symptoms. Diagnosis of the condition can be difficult due to the overlap between Sjögren's syndrome and other diseases. In 2016 the ACR-EULAR classification criteria for primary Sjögren's syndrome were established. Application of these classification criteria, especially for enrollment in clinical trials, can help differentiate between primary Sjögren's syndrome and patients that need further evaluation. Accurate classification of patients is crucial for their treatment and prognosis.

Methods: We analyzed a quaternary medical center-based biobank cohort identifying patients with 2+ ICD codes associated with Sjögren's syndrome. This was done as a subset of a study investigating patients with interstitial lung disease (ILD) within the biobank, Patients also had 2+ codes associated with ILD as well as 1+ codes for computed tomography scan of the chest. Patient records were manually reviewed for information leading to a definitive, probable, possible, or unlikely classification of primary Sjögren's syndrome using the 2016 ACR-EULAR classification criteria (Table 1). Patient characteristics were compared using Kruskal-Wallis and chi-square tests. We calculated positive predictive value (PPV) for each of the ICD codes associated with Sjögren's syndrome to assess whether code-based algorithms could be used to predict definitive Sjögren's syndrome.

Table 2: Characteristics of patients with 2+ diagnostic codes for Sjögren's syndrome

Characteristic	Definitive n=14 (17) n(%)	Probable n=23 (28) n(%)	Possible n=20 (24) n(%)	Unlikely n=26 (31) n(%)	Total n=83 (100) n(%)	p-value

Table 3: PPV of various ICD codes in predicting definitive Sjögren's syndrome classification subtypes

ICD-10 Code*	Definitive (n=14) n (PPV)	Probable (n=23) n (PPV)	Possible (n=20) n (PPV)	Unlikely (n=26) n (PPV)
M35.00 (Unspecified Sjögren / SICCA)	11 (0.26)	13 (0.30)	13 (0.30)	6 (0.14)
M35.01 (Keratoconjunctivitis Sjögren/SICCA)	2 (0.33)	0 (0)	3 (0.50)	1 (0.17)
M35.02 (Sjögren/SICCA with lung involvement)	2 (1)	0 (0)	0 (0)	0 (0)
M35.05 (Sjögren/SICCA with inflammatory arthritis)	0 (0)	0 (0)	0 (0)	1 (1)
M35.09 (Sjögren/SICCA with other organ involvement)	1 (1)	0 (0)	0 (0)	0 (0)
ICD-9 710.2 (SICCA syndrome)	12 (0.21)	18 (0.32)	9 (0.16)	17 (0.30)

PPV – positive predictive value, ICD – International Classification of Disease

*2+ codes 30+ days apart at any point in time

Results: Eighty-three patients with codes of interest were identified within the biobank cohort (Table 2). Of these 83 patients, 14 (17%) fit classification criteria for definitive Sjögren's syndrome, 23 (28%) - for probable Sjögren's syndrome, 20 (24%) -for possible Sjögren's syndrome, and 26 (31%) were unlikely to be classified with primary Sjögren's syndrome. Positive anti-SSA (Ro) was the most common classification criteria seen among the 71 (86%) patients who underwent serological testing in the cohort. Diagnosis of Sjögren's syndrome by a rheumatologist was noted in 55% of the total cohort but in 100% of the definitive subgroup. None of the ICD codes had a high PPV for definitive Sjögren's syndrome category by chart review (Table 3).

Conclusion: This work highlights the difficulty with the classification of Sjögren's syndrome even within a group of patients that have multiple diagnostic codes for the condition. A large proportion of patients had missing data, many did not have serological or clinical testing available for review. Continued education for providers who are likely to evaluate patients for Sjögren's syndrome in their clinic, such as primary care or ophthalmology, is crucial to improve diagnosis and patient care. Future directions include development of an algorithm to help accurately classify patients with definitive Sjögren's syndrome without extensive chart review.

Session Title: (1376–1404) Sjögren's Disease – Basic & Clinical Science Poster II: Clinical Manifestations and Health Outcomes

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background/Purpose: Sjögren's Syndrome (SS) is a multisystemic autoimmune disease that causes hypofunction of salivary and lacrimal glands, manifesting in xerostomia and xerophthalmia among other systemic manifestations. Unstimulated whole salivary flow rate (UWSF) is a test used to quantify saliva production, a decrease in USWF rate impacts the quality of life in patients with SS. Similarly, dry eye tests are useful tools in everyday clinical practice to identify inflammatory damage to the ocular surface. An abnormal UWSF, along with positive serology, a reduced Schirmer's test, and a positive minor salivary gland biopsy is included in the 2016 ACR/EULAR SS classification criteria. However, the association between UWSF and dry eye tests is poorly known. We aimed to explore if there is an association between UWSF and dry eye severity.

Methods: A cohort of rheumatic patients with dry eye disease (DED) (2015-2024) was analyzed. Patients aged 18-years or older, with DED symptoms and primary SS diagnosis (according to ACR-EULAR 2016 criteria) were included. Patients were divided into two groups according to UWSF in 5 minutes (group 1: UWSF ≤0.5 ml/5min, group 2: UWSF >0.5 ml/5min). MSG biopsy, tear film osmolarity (OSM), matrix metalloproteinase 9 (MMP-9), Ocular Surface Disease Index (OSDI), Tear break-up time (TBUT), SICCA Ocular Surface Staining (SICCA OSS), and Schirmer tear test with and without anesthesia (STT) were evaluated. Only the worst eye was included, which was selected as the eye with the higher SICCA OSS score. Associations and results were presented using (frequencies [%], mean ± SD, median [IQR]), and we used Chi^2, Mann-Whitney U, or Student's tests as appropriate. Institutional ethics committee approval was received; all participants provided written informed consent.

Results: Eighty-nine patients with primary SS were included, the mean age was 52.6 ± 12.8 years, and 97.7% (87/89) were women. Forty-three (48.3%) patients had a UWSF ≤0.5 ml/5 min, and 46 (51.7%) patients had a UWSF >0.5 ml/5 min. We observed a higher proportion of patients with positive MMP-9 in the UWSF ≤0.5 ml/5 min group (15/43,34.9%) than those with a UWSF >0.5 ml/5 min (7/46,15.2%; p=0.041). Patients with UWSF ≤0.5 ml/5 min also showed higher OSDI scores (48.85 ± 27.83) than patients with UWSF >0.5 ml/5 min (34.76 ± 21.58; p=0.010). There was no difference in SICCA OSS scores, Schirmer's tear test with or without anesthesia, tear film osmolarity, and tear break-up time.

Conclusion: Patients with low salivary flow had greater ocular surface damage and more dry eye disease symptoms.

Table 1. Dry eye severity according to unstimulated whole salivary flow rate (UWSF) among patients with Sjögren's Syndrome.

	All N= 89	Low salivary flow (≤0.5 ml/5 min) N=43	Normal Salivary flow (>0.5 ml/5 min) N=46	p-value*

Cystic Lung Disease and Autoantibodies in Lymphocytic Interstitial Pneumonia: Exploring the Impact of Sjögren's Syndrome

KARLA CHACON[1], ALBERTO ALEJANDRO MARQUEZ-SANCHEZ[1], Jorge Rojas-Serrano[2] and MAYRA MEJÍA[1], [1]Instituto Nacional de Enfermedades Respiratorias, CIUDAD DE MEXICO, Distrito Federal, Mexico, [2]Instituto Nacional de Enfermedades Respiratorias, Mexico City, Mexico

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1376–1404) Sjögren's Disease – Basic & Clinical Science Poster II: Clinical Manifestations and Health Outcomes

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Lymphocytic interstitial pneumonia (LIP) is a rare interstitial lung disease, most commonly associated with Sjögren's syndrome, but it may also occur in the context of other autoimmune diseases. Despite its low prevalence, LIP can significantly impact patients' quality of life, particularly in cases progressing to severe pulmonary restriction. Accurate characterization of LIP is essential, as early diagnosis can guide timely interventions, including consideration for lung transplantation in advanced cases.

Methods: We conducted a cross-sectional study of patients with lymphocytic interstitial pneumonia (LIP) diagnosed by multidisciplinary consensus between rheumatology and pulmonology. Clinical, serological, and functional variables were systematically collected. Pulmonary function tests included forced vital capacity (FVC); a restrictive pattern was defined as FVC < 80% of predicted. Chest CT scans were evaluated for the number and size of pulmonary cysts. Cystic disease was considered diffuse when more than 10 cysts were identified. The largest cyst in each patient was measured along its longest axis and reported in millimeters.

Table 1. Comparison of Clinical, Serological, and Radiological Characteristics in Patients With Lymphocytic Interstitial Pneumonia According to Sjögren's Status

Variables	Total n=46	Sjögren's n = 27	Non Sjögren's n=19	p

Chest CT of a Patient With Sjögren's Syndrome and Lymphocytic Interstitial Pneumonia Showing Cysts >10 mm in Diameter; A–B: Inspiratory Phase, C–D: Expiratory Phase

Results: A total of 46 patients with LIP were included; 58.7% had associated Sjögren's syndrome. Other autoimmune diagnoses included rheumatoid arthritis (10.9%), rheumatoid arthritis with Sjögren's overlap (6.5%), systemic sclerosis (8.7%), lupus (2.2%), antisynthetase syndrome (2.2%), and interstitial pneumonia with autoimmune features (IPAF) (2.2%). Four patients (8.7%) had no identifiable autoimmune disease.There were no significant differences in age, sex, smoking history, or pulmonary function between groups. Sjögren's patients had a higher prevalence of ANA positivity (100% vs 78.6%, p=0.01), anti-Ro (71.4% vs 25%, p< 0.01), and anti-La antibodies (65% vs 20%, p< 0.05). High-titer anti-Ro was significantly more frequent in the Sjögren's group (61.9% vs 18.8%, p< 0.05). Serum immunoglobulin levels, complement levels, and the proportion of patients with IgG >2000 mg/dL did not differ significantly. Although diffuse cystic disease (defined as >10 cysts) was common in both groups (88.9% vs 73.7%, p=0.18), the largest cyst size was significantly greater in patients with Sjögren's (33.8 ± 26.0 mm vs 19.8 ± 10.6 mm, p=0.03).

Conclusion: In this cohort of patients with LIP, those with Sjögren's syndrome exhibited a more pronounced autoimmune profile and significantly larger cysts, despite similar lung function. These findings support the hypothesis that LIP in Sjögren's may represent a distinct immunopathologic phenotype, potentially driven by exaggerated bronchus-associated lymphoid tissue (BALT) hyperplasia. Early recognition of this phenotype may inform prognosis and guide decisions regarding close monitoring or early referral for lung transplantation.

Session Title: (1376–1404) Sjögren's Disease – Basic & Clinical Science Poster II: Clinical Manifestations and Health Outcomes

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: For women with Sjögren's disease, the risk of Fetal Atrioventricular Block (fAVB) is a critical aspect in pregnancy counseling. To date, the most reliable predictor of fAVB is a previously affected child, followed by high titer Anti-SSA/Ro52 and 60 antibody titers. In advising on risk for women without an affected child, physicians face the challenge of interpreting different reporting units and upper limits of commercial assay values. Accordingly, this current study leveraged a prospective, anti-SSA/Ro positive pregnancy cohort to compare results obtained from commercial laboratories across the U.S. to those measured in a central research laboratory. The goal was to identify commercial values that would associate with a low risk of fAVB and reduce the need for standard of care surveillance.

Table 1: Anti-SSA/Ro Testing Across Eight Laboratories.

Commercial Laboratory	Negative	Positive Range	Total Patients	Positive below upper limit and < 1000 EU for both anti-Ro52 + 60	Positive below upper limit and > 1000 EU for either anti-Ro52 or 60	Positive above upper limit but < 1000 EU for both anti-Ro52 + 60	Positive above upper limit and > 1000 EU for either anti-Ro52 or Ro 60
ARUP	< 40	Linear, no limit	74	N/A- See Table 2	N/A- See Table 2	N/A- See Table 2	N/A- See Table 2
Bioplex	< 1.0	1 - >8 no specificity	354	66/81	15/81	49/273	224/273
Mayo Labs	≤ 19.9	Anti Ro52 20 - >1374.8 Anti Ro60 20 - >1885.3	21	8/10	2/10	0/11	11 /11
Minnesota Healthpartners	< 6.9	7 - >240 no specificity	21	10/12	2/12	0/9	9/9
UCSF China Basin Labs	< 20	Anti-Ro52 20 - >1300 Anti-Ro60 20 - >1300	17	6/6	0/6	0/11	11/11
SHC Lab	< 20	20 - >100 no specificity	15	4/7	3/7	0/8	8/8
UCLA Lab	< 20	20 - >80 no specificity	13	6/6	0/6	0/7	7/7
Yale New Haven Lab	< 7.0	7 - >240 no specificity	11	2/3	1/3	1/8	7/8

Table 2: Spearman's Rank Correlation Coefficient Between ARUP Laboratory and NYU Research Laboratory.

	Anti-52kd	Anti-60kd
Spearman's Rank Correlation Coefficient	0.7788	0.7497
r^2	0.6065	0.5621
P-value	2.22E-16	1.53E-14
Covariance	360.0137	346.661
Sample size (n)	74	74

Methods: Seven hundred and sixty-six pregnant subjects from 24 centers who tested positive for anti-SSA/Ro (either anti-Ro52 or anti-Ro60 or both) in their local commercial assay were referred to STOP BLOQ for prospective evaluation by home fetal Doppler to rapidly identify emergent fAVB. Eight laboratories were included in this analysis, each testing at least 10 subjects (capturing 526 study participants). The values and descriptors of ranges are provided in Table 1. Each sample was tested for anti-Ro52kD (recombinant antigen) and Ro60kD (native antigen) in the central NYU research lab at serial dilutions ranging from 1:100 to 1:100,000. A threshold titer for risk of fAVB was set at 1,000 ELISA units (EU) for either anti-Ro52kD or Ro60kD based on the evaluation of 50 subjects with a child affected by fAVB (Buyon, A&R, 2023). None of the 10 cases of fAVB in STOP BLOQ were < 1000 EU for either anti Ro52kd or 60kD.

Results: Only one of the commercial laboratories, ARUP (tested in 74), provided a linear range of positivity for both anti Ro52kD and Ro60kD. Previous studies identified a risk threshold at 110 arbitrary units (AU) for each specificity (Kaizer, AJOG, 2022). For anti-Ro52, 29 were > 110 AU and all but one was > 1000 EU. For anti-Ro60 44 were > 110 AU and all but 6 were > 1000 EU. Overall, the values for ARUP and NYU were strongly correlated (Table 2). Seven of the 8 commercial laboratories provided a negative cutoff and an upper threshold for positivity. Three hundred and fifty-four patients were tested using the BioPlex assay. Of 81 below the upper limit > 8, 66 did not meet the research risk threshold and none had an affected child. Of 273 above the upper limit, 224 exceeded the threshold risk of 1000 EU for either anti-Ro52kD or 60kD (PPV: 82%; NPV: 81%), 5 of which developed fAVB. Twenty-one pregnant subjects were tested in the Mayo labs. Of 10 below the commercial lab upper limit, 8 did not meet the research risk threshold. Of the 11 that exceed the commercial lab upper limit, all exceed the research risk threshold. Values for the 6 other commercial labs are detailed in Table 1.

Conclusion: These data provide a framework for evaluating commercial values to guide fetal surveillance of anti-SSA/Ro pregnancies. However, there are inconsistencies in the ability of a test result to associate with risk, with most labs demonstrating that anti-SSA/Ro below the positive upper limit are not at risk, but for a few, predictions are less reliable.

Abstract Number: 1392

Cancer Mortality in Sjogren's Disease: Disproportionate Increase in Mortality from Cancers in Sjogren's Disease Relative to All-Cancers

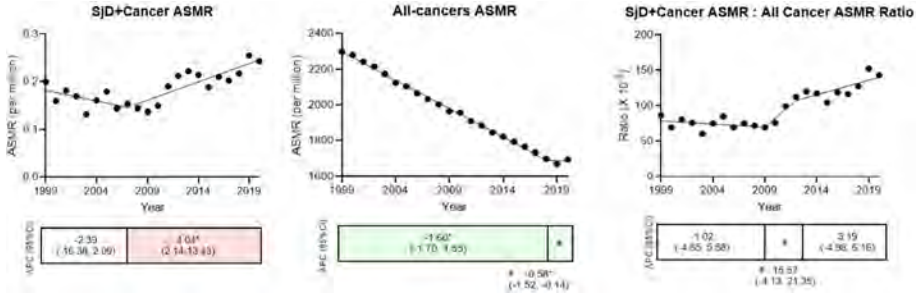
Margaret Essien and Ram Singh, UCLA David Geffen School of Medicine, Los Angeles, CA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1376–1404) Sjögren's Disease – Basic & Clinical Science Poster II: Clinical Manifestations and Health Outcomes
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Sjögren's disease (SjD), an autoimmune condition with chronic inflammation in exocrine glands, is associated with increased risks of cancers. The impact of cancer on mortality from SjD is not well documented. Here, we assessed trends associated with mortality from cancer in SjD across the US over a 22-year period.

Methods: This is a population-based study using a national mortality database and census data covering all U.S. residents. We calculated age-standardized mortality rates (ASMR) for cancer in SjD (SjD-C) and all-cancers, overall and by demographic variables. For comparison, we calculated ASMRs for SjD, non-Hodgkin's lymphoma that is the commonest malignancy in SjD, and another autoimmune disease dermatopolymyositis. We performed joinpoint trend analysis to estimate annual percent change (APC) in ASMRs, and Chi-square statistics with Yates's correction to compare changes in different cancer deaths over time.

Results: SjD was recorded as a cause of death in 7,817 decedents from 1999 through 2020. Of these, 1,395 (17.8%) had both SjD AND cancer recorded as multiple causes of death. During the same time-period, the number of all-cancer deaths was 8,096,904. The ASMRs for SjD-C initially showed a decreasing trend (p=NS), but significantly increased in the last decade at an APC of 4.04% (95% CI, 2.14-13.43; 2007-2020). In contrast, the all-cancers ASMRs decreased throughout the 22-year period. The average APC for the entire 1999-2020 was 1.54% (95% CI, 0.43-3.19) for SjD-C ASMR and -1.50% (95% CI, -1.58% to -1.46%) for all-cancer ASMRs. Mortality from dermatopolymyositis-associated cancers and non-Hodgkin's lymphoma decreased during the study period. The SjD-C mortality rates were higher in females than males, non-Hispanic whites than other race/ethnic groups, ≥65-years old than in 0-64-years, and decedents in the West than in other census regions. Proportions of hematological cancer deaths decreased, whereas lung cancer deaths increased in SjD during the last decade.



Trends in ASMR for SjD+cancer and all-cancers, and Ratio of SjD+cancer to all cancer Mortality Rates, 1999-2020. Green bars indicate a statistically significant decreasing trend, Red bars indicate a statistically significant increasing trend, and White bars indicate that the trend is not statistically significant. *p<0.05.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: In this nationwide, population-based study, cancer mortality in SjD exhibited an increasing trend in the last decade, while all-cancer mortality continually decreased. Prospective, population-based studies are needed to identify causes underlying this increase.

Prevalence of Sjögren's Disease in the United States - A Retrospective Cohort Study Among a Commercially Insured Population (2019-2023)

Minoti Ganguli, Annie Kilby, Ahva Shahabi and Tsu-Chieh Jay Lin, Amgen Inc., Thousand Oaks, CA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1376–1404) Sjögren's Disease – Basic & Clinical Science Poster II: Clinical Manifestations and Health Outcomes
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Sjögren's disease (SjD) is a systemic autoimmune condition characterized by diverse clinical manifestations, which often complicates diagnosis and disease management[1]. Previous epidemiological estimates of SjD prevalence in the US have varied significantly due to differences in methodologies and data sources[2]. Consequently, SjD is frequently underdiagnosed or misclassified, affecting accurate prevalence estimates and complicating clinical decision-making[1].

This retrospective cohort study aims to characterize temporal trends in the annual prevalence of overall diagnosed SjD, including SjD without overlapping autoimmune conditions and SjD with overlapping autoimmune conditions (systemic lupus erythematosus, rheumatoid arthritis and ankylosing spondylitis) among commercially insured adult patients in the US (2019–2023).

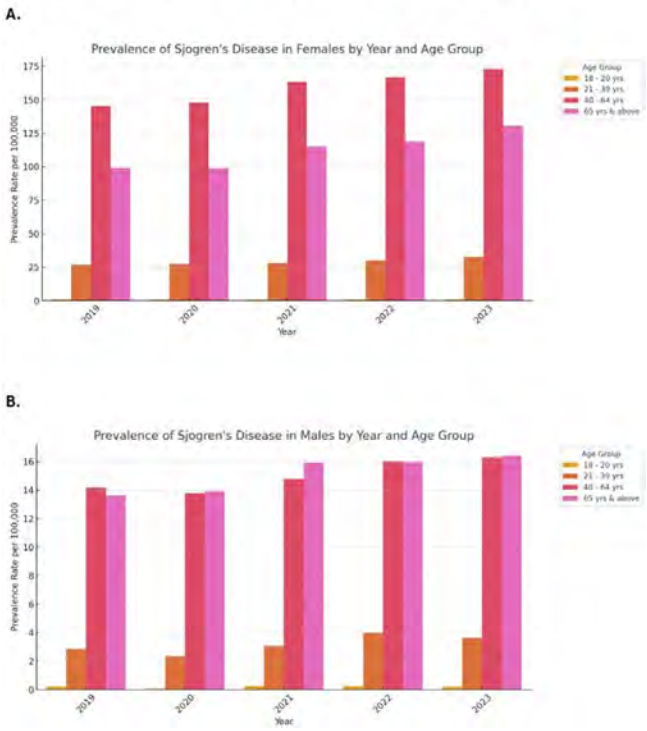
Methods: This retrospective cohort study utilized data from the Optum Clinformatics® Data Mart database, encompassing US adults (≥18 years) with Commercial or Medicare Advantage insurance. Patients with ≥1 inpatient or ≥2 outpatient claims for SjD (ICD-10: M35.x) during the period of interest (POI) from 2019–2023 were considered as prevalent cases. Annual prevalence was calculated by dividing the number of identified SjD patients by the total number of eligible enrollees during each annual POI prevalence was age and sex standardized to the US population using the US Census and reported as a rate (per 100,000 persons). A one-year lookback period prior to each POI was used to ascertain disease status. Generalized linear regression was employed to assess temporal trends.

Table 1 – Prevalence of overall diagnosed Sjögren Disease and Sjögren Disease without and with overlapping autoimmune conditions

Year	Overall diagnosed Sjögren Disease	Sjögren without autoimmune conditions	Sjögren Disease with overlapping autoimmune conditions
2019	195.95	144.48	51.48
2020	197.93	145.81	52.12
2021	223.99	165.37	58.62
2022	239.20	177.57	61.64
2023	259.20	192.76	66.44

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Fig 1: Age- and sex-adjusted prevalence of overall diagnosed Sjögren's Disease



Results: Between 2019 and 2023, the prevalence proportion per 100,000 persons steadily increased from 195.95 to 259.20 in overall diagnosed SjD, from 144.48 to 192.76 in SjD without overlapping autoimmune conditions, and from 51.48 to 66.44 in SjD with overlapping autoimmune conditions. The prevalence of overall diagnosed SjD and those without any overlapping autoimmune conditions was higher in women (vs men) and in the age groups 45–64 and ≥65 years (Fig 1a and 1b). Generalized linear regression showed statistically significant increasing trend in prevalence over time ($p< 0.01$) for overall diagnosed SjD in the US.

Conclusion: Findings from this large, claims-based analysis indicate a rising trend in diagnosed SjD, including SjD without and with overlapping autoimmune conditions, among adults from 2019–2023. The increasing prevalence in the US indicates an unmet need and disease burden, especially among women aged ≥40 years. This highlights the need for improved

Fig 2: Age- and sex-adjusted prevalence of Sjögren's Disease without any overlapping autoimmune conditions

Abstract Number: 1394

Burden of Comorbidities Across EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI) Domains: Treatment Prevalence Among Commercially Insured Sjögren's Patients in the United States

Minoti Ganguli, Annie Kilby, Ahva Shahabi and Tsu-Chieh Jay Lin, Amgen Inc., Thousand Oaks, CA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1376–1404) Sjögren's Disease – Basic & Clinical Science Poster II: Clinical Manifestations and Health Outcomes
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Sjögren's disease (SjD) is a systemic disorder characterized by exocrine gland inflammation, leading to dry eyes/mouth, and multiple organ systems involvement[1]. The European League Against Rheumatism (EULAR) developed the Sjögren's Syndrome Disease Activity Index (ESSDAI) to capture systemic disease activity across clinical domains, to monitor disease progression and guide treatment[2].

Patients with SjD often have comorbidities across multiple ESSDAI domains – musculoskeletal, central nervous system (CNS), hematological, pulmonary, renal, and others – significantly affecting morbidity, quality of life, and clinical management strategy [3].

This study evaluates the prevalence of ESSDAI domain-specific comorbidities and treatment in patients diagnosed with SjD as well as those without any overlapping autoimmune conditions (2019–2023).

Methods: A retrospective cohort study using Optum Clinformatics® Data Mart (2019–2023) included adults (≥18 years) with ≥1 inpatient or ≥2 outpatient SjD claims. All relevant domain-specific comorbidities were identified using ≥2 ICD-10-CM diagnosis codes/year. Treatments assessed included biologics, immunosuppressants, NSAIDs, opioids, and neuropathic agents. Descriptive analyses were conducted for overall SjD patients and SjD patients without overlapping autoimmune disease, by calendar year.

Results: In the overall SjD patients (n=38,456) and SjD patients without overlapping autoimmune conditions (n=24,657), majority were female (90.6%, 89.3%), most were aged ≥65 years (62.8%, 66.2%), and predominantly identified as non-Hispanic (77.6%, 78.9%) and White (68.1%, 69.6%), followed by Black (10.3%, 9.3%) and Asian (2.6%, 2.7%).

In the overall SjD cohort, musculoskeletal comorbidities were the most prevalent (15.66-16.42%) while CNS involvement was highest in those without overlapping autoimmune conditions (8.88-9.20%). Both cohorts showed consistently high rates of hematological, pulmonary, and neurological domains. In both cohorts, fibromyalgia was the most prevalent CNS

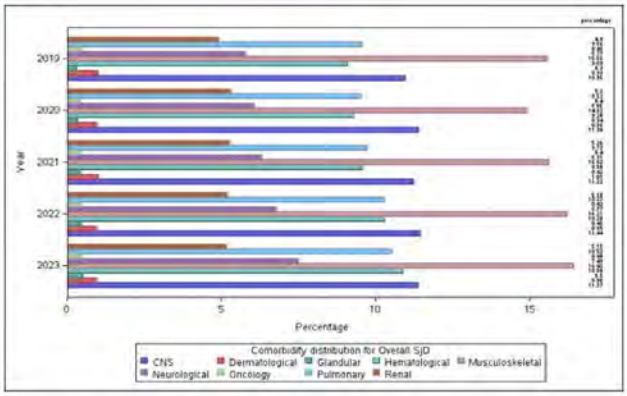
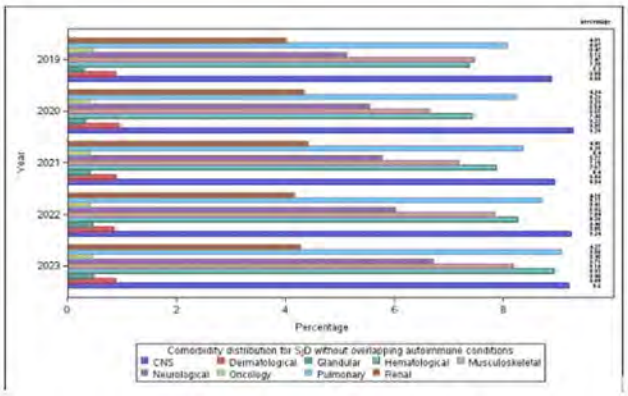
Fig 1: Annual Prevalence Trends of ESSDAI Domain Comorbidities in patients with overall SjD and SjD without overlapping autoimmune disease (2019–2023)

A.



B.



condition (~8–10%), hypokalemia was the leading renal comorbidity (up to 4.34%), and anemia was highest among hematological conditions (7.80–9.28%).

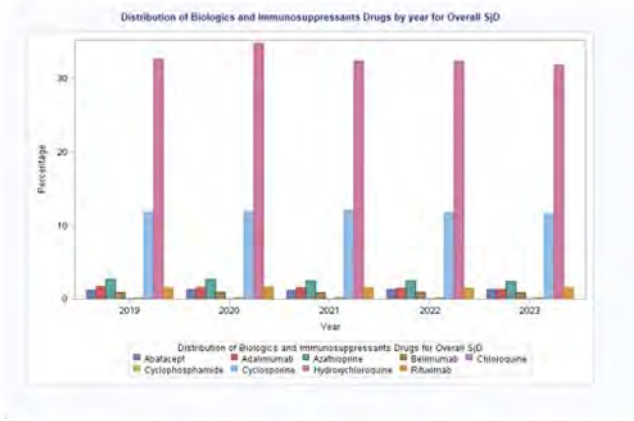
SjD patients without overlapping autoimmune conditions had lower comorbidity prevalence versus overall SjD cohort (Table 1). Top treatments for both cohorts included hydroxychloroquine (32.8% vs. 28%), cyclosporine (~12%), azathioprine, rituximab, and adalimumab (Figure 2). The overall SjD patient cohort had consistently higher treatment rates.

Table 1. Most Prevalent ESSDAI domains in both Overall Sjögren's Disease and Sjögren's Disease without overlapping autoimmune conditions, 2019-2023

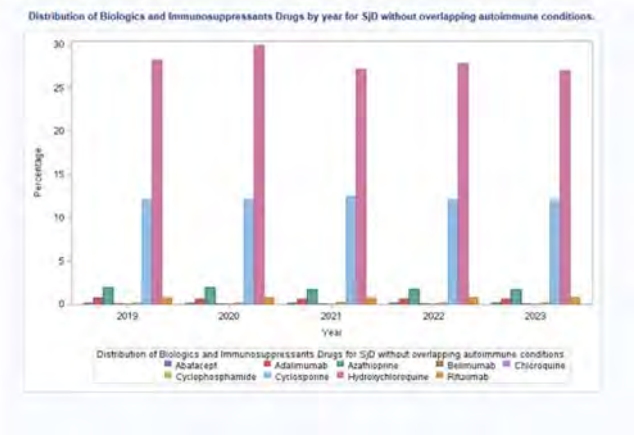
	2019	2019	2020	2020	2021	2021	2022	2022	2023	2023
Comorbidity	Prevalence (%) among Overall Sjögren	Prevalence (%) among Sjögren's without overlapping autoimmune disease	Prevalence (%) among Overall Sjögren	Prevalence (%) among Sjögren's without overlapping autoimmune disease	Prevalence (%) among Overall Sjögren	Prevalence (%) among Sjögren's without overlapping autoimmune disease	Prevalence (%) among Overall Sjögren	Prevalence (%) among Sjögren's without overlapping autoimmune disease	Prevalence (%) among Overall Sjögren	Prevalence (%) among Sjögren's without overlapping autoimmune disease
Musculoskeletal	15.56	7.47	14.92	6.65	15.62	7.18	16.21	7.84	16.42	8.18
Central nervous system (CNS)	10.95	8.88	11.39	9.20	11.22	9.04	11.44	9.24	11.37	9.20
Hematological	9.09	7.38	9.28	7.43	8.58	7.87	10.28	8.26	10.88	8.93
Pulmonary	9.56	8.07	9.53	8.23	9.72	8.36	10.27	8.71	10.52	9.06
Neurological	5.77	5.12	6.05	5.54	6.31	5.77	6.77	6.02	7.49	6.71

Fig 2 - Top 5 Pharmacological Treatments in A) overall SjD and B) SjD without overlapping autoimmune conditions, (2019-2023)

A.



B.



Conclusion: Musculoskeletal, CNS, hematologic, pulmonary and neurological domains contribute substantially to high comorbidity burden in overall SjD patients and those without overlapping autoimmune conditions. High comorbidity and treatment rates were seen in both overall SjD and SjD without overlapping autoimmune conditions suggest a more complex disease phenotype, underscoring the need for targeted treatment strategies.

Abstract Number: 1395

A Comparative Study of Yao Syndrome and Primary Sjögren's Syndrome

Nayaab Bakshi[1], Christopher Loh[2], Song Wu[3] and Qingping Yao[3], [1]Stony Brook University, Dix Hills, NY, [2]Stony Brook University, Lake Grove, NY, [3]Stony Brook University, Stony Brook, NY

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1376–1404) Sjögren's Disease – Basic & Clinical Science Poster II: Clinical Manifestations and Health Outcomes
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Yao syndrome (YAOS, OMIM 617321) is formerly named Nucleotide-binding oligomerization domain containing protein 2 (NOD2)-associated autoinflammatory disease affecting multiorgan systems characterized by recurrent fever, dermatitis, arthralgias, gastrointestinal, sicca symptoms, eyelid swelling, and distal leg swelling. Sicca symptoms are common in YAOS, which can be confused with Sjögren's syndrome. This study aimed to compare the clinical and laboratory characteristics between YAOS and primary Sjögren's Syndrome (pSS).

Methods: A retrospective study of 27 adult patients with YAOS seen in the Center of Autoinflammatory Disease at Stony Brook University Hospital between 2015 and 2025 was conducted. YAOS was diagnosed based on our prior published criteria in the American Journal of Medicine in 2017. Since the presence of certain NOD2 gene mutations is required for the diagnosis of YAOS, a periodic fever syndrome gene panel was performed for all these patients. To compare patients with pSS, we also performed a chart review of 29 adult patients with pSS diagnosed in the same Institution during the same period. Patients with pSS were diagnosed based on the 2016 ACR/EULAR diagnostic criteria. Categorical variables were compared between the YAOS and pSS groups using either Fisher's exact test or the Chi-squared test. Continuous variables were compared using two-sample t-tests.

Results: In both YAOS and pSS groups, females were predominant, and an overwhelming majority of patients were Caucasian. Disease onset occurred at an earlier age in YAOS than pSS (27.7 ± 13.9 vs. 42.7 ± 15.2 years, p = 0.002). Although Sicca symptoms were common in both diseases, compared with pSS, several presentations were significantly more frequent in YAOS, including fever (66.7% vs. 10.3%, P=0.00002), rash (100% vs. 24.1%, $p < 0.000001$), eyelid swelling (52% vs. 0%, $p = 4.1 \times 10^{-5}$), abdominal pain (70.4% vs. 20.7%, p = 5.2 × 10-4), and non-bloody diarrhea (51.9% vs. 14.3%, p = 0.007) (Table to be presented). In addition, oral ulcers, chest pain, arthralgia, and asthma were more common in YAOS. All patients with pSS had positive autoantibodies, SSA in particular, whereas patients with YAOS did not have elevated autoantibodies in general.

Conclusion: While both YAOS and pSS share sicca symptoms, YAOS possesses a characteristic manifestation and distinctive clinical constellation from pSS. Since therapeutic approaches and outcomes differ between these two conditions, this study will further increase awareness of YAOS, an underdiagnosed disease, to avoid diagnostic confusion.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1376–1404) Sjögren's Disease – Basic & Clinical Science Poster II: Clinical Manifestations and Health Outcomes

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Patient-centred care and improvement of daily life are the main components in chronic disease management. The aim of the study was to determine associations among age, Patient Empowerment, Engagement, and Activation status and Daily impairment in patients with Sjögren disease (SjD).

Methods: In this cross-sectional study, 164 patients with SjD (F/M: 157/7; mean age: 54.4±12.4 years, disease duration: 9.02±7.14 years) were included. Data were collected by clinical examinations and a questionnaire.

The Patient Empowerment (n=7 items), Engagement (n=7 items), and Activation (n=7 items) Survey (PEEAS) scale, the 5-Level EQ-5D scale (EQ-5D-5L) for quality-of-life status (high score: good QoL status) as well as the EULAR SS Patient Reported Index (ESSPRI) score were used in the study. High scores reflected Empowered, Engaged and Active patients (7-35 points in each group) in PEEAS and good self-reported health status (0-100 mm: the best health status) whereas high score of Work Productivity and Activity Impairment (WPAI)-Daily impairment and ESSPRI score were associated with poor conditions.

After preliminary analysis, moderation analysis was used to test the influence of age as a third variable (Z), on the relationship between dependent (Y; WPAI, PEEAS) and independent (X; self-reported health status) variables.

Results: Increase in age was correlated with decreases in scores of EQ-5D-5L (0.62±0.21), self-reported general health status (61.92 ±11.59), Empowerment, Engagement and Activation subgroups (26,65±4.33; 26.68±4.20; 25.10±6.20)($p< 0.05$). Moreover, an elevated WPAI-Daily impairment score (43.59±22.20) was correlated with poorer self-reported general health status and younger age ($p< 0.05$). According to Moderator analysis, the negative impacts of self-reported health status (X) on WPAI-Daily impairment were stronger in young (Z) patients ($p< 0.05$). Similar relation was not seen for PEEAS subgroups for young patients ($p >0.05$).

Low EQ-5D-5L score as well as elevated ESSPRI score (6.48±1.64) and long duration for ocular dryness were also associated with poor scores of Empowerment, Engagement and Activation in PEEAS scale (25.10±6.20)($p< 0.05$).

Conclusion: This study highlights the relationships between age, self-reported health status, patient empowerment, engagement, and those actively patient in their management. In addition, younger individuals who have poorer health perception may experience greater impairment on a daily basis. Prolonged ocular dryness emphasizes the importance of tailored interventions to enhance patient-centred care.

Session Date: Monday, October 27, 2025

Session Title: (1376–1404) Sjögren's Disease – Basic & Clinical Science Poster II: Clinical Manifestations and Health Outcomes

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: To evaluate the incidence of cardiovascular and cerebrovascular events (CVEs) in patients with Sjögren's Disease (SjD), focusing on major adverse cardiovascular events (MACE), defined as non-fatal myocardial infarction, non-fatal stroke, or cardiovascular death. Additional objectives were to identify both traditional and disease-specific risk factors associated with CVEs; to assess CV risk using the SCORE2 algorithm and compare predicted versus observed event rates; to examine the impact of CVEs on all-cause mortality; and to determine the prevalence of conventional cardiovascular risk factors (CVRFs) within this population.

Methods: We conducted a prospective, multicenter observational study including 314 patients with SjD who met the 2002 AECG classification criteria. Median follow-up was 9.5 years. Clinical, serological, demographic variables, CVRFs, and CVEs were recorded. Independent predictors of MACE and overall CVEs were identified using multivariate Cox proportional hazards regression models. Cardiovascular risk was estimated using the SCORE2 algorithm. Expected event rates were calculated by summing individual predicted probabilities. CV mortality was compared to the general population using

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Baseline Cardiovascular Risk Factors in the SjögrenSER-PROS Cohort.

Variable	Men	Women	Total
Age, median [IQR], years	65.4 [59.2 - 74.6]	58.4 [50.7 - 66.8]	58.7 [50.7 - 67.1]
Disease duration, median [IQR], years	3.9 [1.9 - 5.6]	7.0 [3.2 - 12.2]	6.8 [3.0 - 12.0]
Smoking			
Former smoker, n (%)	10 (58.8)	45 (15.2)	55 (17.6)
Current smoker, n (%)	2 (11.8)	24 (8.1)	26 (8.3)
Alcohol			
0-5 UBE, n (%)	8 (53.3)	23 (11.3)	31 (14.2)
BMI			
BMI 25-29.9 kg/m², n (%)	4 (36.4)	71 (33.3)	75 (33.5)
BMI ≥30 kg/m², n (%)	4 (36.4)	39 (18.3)	43 (19.2)
Diabetes Mellitus, n (%)	1 (5.9)	18 (6.1)	19 (6.1)
Hypertension, n (%)	5 (29.4)	78 (26.3)	83 (26.4)
Dyslipidemia, n (%)	7 (41.2)	97 (32.7)	104 (33.1)
Cholesterol >200 mg/dL, n (%)	1 (6.7)	130 (48.2)	131 (46.0)
Cholesterol >240 mg/dL, n (%)	0 (0.0)	39 (14.4)	39 (13.7)
LDL Cholesterol ≥ 130 mg/dL, n (%)	2 (18.2)	74 (40.7)	76 (39.4)
HDL Cholesterol: Men < 40 mg/dL, Women < 50 mg/dL, n (%)	6 (54.6)	141 (75.8)	147 (74.6)
Triglycerides ≥ 150 mg/dL, n (%)	3 (23.1)	29 (12.1)	32 (12.7)

standardized mortality rate (SMR), based on official data from the Spanish National Institute of Statistics. Relative risk (RR) of all-cause mortality was assessed according to the presence of prior or incident CVEs.

Results: Among 314 patients (94.6% women; median age 58.7 [IQR 50.7–67.1]), 29 CV events occurred: pericarditis (1.27%), conduction abnormalities (1.27%), ischemic heart disease (1.59%), heart failure (1.59%), peripheral artery disease (0.95%), and cerebrovascular events (2.55%). Seventeen patients (5.41%) experienced MACE: 7 non-fatal strokes (2.23%), 5 non-fatal myocardial infarctions (1.59%), and 5 cardiovascular deaths (1.59%). Among the 130 patients with complete SCORE2 data, the expected number of events was 5.74 (4.41%), while 11 events (8.46%) were observed, including 6 MACE (4.62%) and 5 non-MACE events (3.85%).

Independent predictors of CV events were age (OR 1.06; 95% CI 1.01–1.14), cryoglobulinemia (OR 10.13; 95% CI 1.63–62.88), glucocorticoid use (OR 3.44; 95% CI 1.29–9.19), and antiphospholipid antibodies (OR 5.33; 95% CI 1.15–24.79). Predictors of MACE included age (OR 1.07; 95% CI 1.01–1.14), cryoglobulinemia (OR 10.41; 95% CI 1.37–79.26), and glucocorticoid use (OR 3.53; 95% CI 1.00–12.51). See the prevalence of traditional CVRFs in Table 1. CV mortality accounted for 11.9% of all deaths. The SMR for CV mortality was 5.09 (95% CI 5.08–5.11). Previous CVEs were significantly associated with increased all-cause mortality (RR 3.27; 95% CI 1.90–5.63).

Conclusion: Sjögren's Disease is associated with a significantly increased incidence of cardiovascular events, exceeding predicted risk estimates. Disease-specific factors—including cryoglobulinemia, glucocorticoid exposure, and the presence of antiphospholipid antibodies—emerge as independent contributors to this elevated burden. Cardiovascular mortality was fivefold higher than expected, and prior CV events were strong predictors of all-cause mortality.

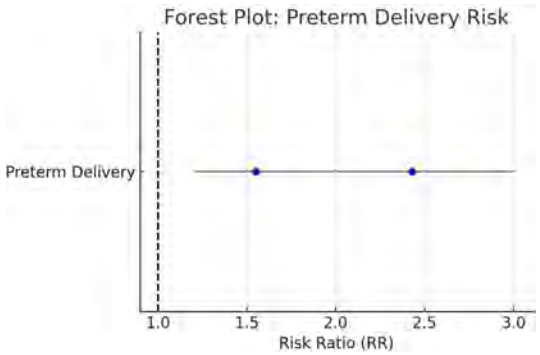
Forest Plot: Reproductive Outcome in SS and Systemic Sclerosis



Forest Plot: Preterm Delivery Risk

Background/Purpose: Autoimmune rheumatic diseases such as Sjögren's Syndrome (SS) and Systemic Sclerosis (SSc) can significantly impact reproductive health and increase maternal cardiovascular risk. These conditions are associated with fertility challenges, obstetric complications, and cardiac events during pregnancy, necessitating a thorough understanding for optimal maternal care. Evaluate reproductive outcomes and cardiac complications in women of reproductive age diagnosed with SS or SSc, including fertility status, pregnancy loss, preterm birth, cesarean delivery, and maternal cardiac morbidity.

Methods: A systematic search of PubMed, Embase, and Cochrane Library databases was conducted up to 2020. Eligible studies reported fertility and/or pregnancy outcomes in women with SS or SSc, with or without comparison to healthy controls. Data were pooled using a random-effects model, and heterogeneity was assessed using the I^2 statistic.

Results: A total of 32 studies comprising 4,820 women (SS: 2,140; SSc: 2,680) were included. Compared to controls, women with SS had a 1.8-fold increased risk of miscarriage (RR: 1.81, 95% CI: 1.42–2.30), while those with SSc showed a 2.4-fold increase in preterm delivery (RR: 2.43, 95% CI: 1.95–3.01). Fertility rates were modestly decreased in both groups (SS: –15%, SSc: –22%). Cardiac complications were significantly higher in SSc pregnancies, with elevated rates of arrhythmias (RR: 3.10, 95% CI: 2.05–4.70), preeclampsia (RR: 2.75), and heart failure events (RR: 2.12). Cesarean delivery was more common in both groups (SS: RR 1.48; SSc: RR 1.67).

Conclusion: Women with Sjögren's Syndrome and Systemic Sclerosis are at increased risk of adverse reproductive and cardiac outcomes. These findings highlight the need for preconception risk assessment, specialized obstetric care, and interdisciplinary collaboration to improve maternal and fetal outcomes in this high-risk population.

Significance of Antiphospholipid Antibodies in Patients with Sjogren's Disease

Rashmi Thimmapuram[1], Ahmad Alkhatib[2], Joshua Baker[3], Mehrdad Maz[4] and Ghaith Noaiseh[2], [1]University of Kansas Medical Center, Westwood, KS, [2]University of Kansas Medical Center, Kansas City, KS, [3]University of Pennsylvania, Philadelphia, PA, [4]The University of Kansas Medical Center, Kansas City, KS

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1376–1404) Sjögren's Disease – Basic & Clinical Science Poster II: Clinical Manifestations and Health Outcomes

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: A few reports have evaluated the frequency of antiphospholipid antibodies (aPL) in Sjogren's disease (SjD) and their association with SjD or Antiphospholipid Antibody Syndrome (APS) manifestations. Some authors have suggested an association between presence of aPL and peripheral neuropathy, hypergammaglobulinemia, stroke, and venous thrombosis. Our aim was to assess the frequency of aPL detected in a cohort of well-characterized SjD patients and determine their correlation with key phenotypic features of SjD and clinical manifestations of APS.

Methods: We performed a retrospective chart review of 117 consecutive patients seen at SjD specialty clinic at the University of Kansas Medical Center meeting the 2016 ACR/EULAR classification criteria for SjD who were tested for aPL. All patients underwent testing for anti-cardiolipin antibodies (ACL) IgG/IgM, anti-beta-2-glycoprotein-1 antibodies (B2GP-1) IgG/IgM, and lupus anticoagulants, including Dilute Russell's Viper Venom Time (DRVVT) and hexagonal phase phospholipid neutralization assay (HPPNA). Clinical, laboratory, and histological manifestations of both SjD and APS were collected. Statistical analyses included Chi-squared, Fisher's exact test, and Student t-tests, as appropriate.

Table 1. 16 SjD patients with positive aPL. F = female, M = male, WP = weakly positive (25-39.9 GPL), MHP = moderate-high positive (> 40 GPL), NA = not available, N = No, Y = Yes, VTE = venous thromboembolism, ART = arterial thrombosis, MI = myocardial infarction, CVA = cerebrovascular accident, CAPS = catastrophic antiphospholipid syndrome, TCP = thrombocytopenia, (+) = positive test, (-) = negative test.

Patient	Age (y)	Gender	ACL IgG	ACL IgM	B2GP-1 IgG	B2GP-1 IgM	Hexagonal assay	DRVVT	Twice	VTE	ART	MI	CVA	Obstetric APS	CAPS	TCP

Unprovked VTE	1	6%	6	6%	1.00
ART	2	13%	0	0%	0.02
MI	1	6%	0	0%	0.14
CVA	2	2%	0	0%	1.00

Results: 103 patients (88%) were females, mean age was 54.6 +/- 13.9 years, 100 patients (85%) were white, and mean disease duration was 2.9 years. Of the 117 SjD patients, 16 (13.7%) had at least one positive testing for antiphospholipid antibodies (Table 1). Only 3 patients (2.5%) met criteria for APS. Detection of aPL was associated with monoclonal gammopathy (56.25% of aPL-positive vs 22.77% of aPL-negative, p = 0.012) and arterial thrombosis (12.5% vs 0%, p = 0.02). We did not observe any other association with clinical, laboratory, or histological parameters (Table 2). Of the 16 patients with positive aPL, 5 patients (31%) had aPL positivity confirmed at least 12 weeks apart whereas 11 patients (69%) had aPL checked only once. There was no association between the number of occurrences of aPL positivity and monoclonal gammopathy (46% of one-time aPL positive vs 80% of two time-aPL positive, p = 0.31) or arterial thrombosis (1% of one-time aPL positive vs 20% of two-time aPL positive, p = 1).

Conclusion: A minority of patients with SjD had aPL and an even smaller group met the criteria for APS. Detection of aPL was associated with the presence of monoclonal gammopathy and arterial thrombosis. Larger studies are necessary to determine the clinical significance and utility of screening for antiphospholipid antibodies in SjD, particularly in those with monoclonal gammopathy.

Beyond the Glands: Hypogammaglobulinemia as a Clue to Peripheral Neuropathy in Sjogren's Disease

Renata Fróes Ramos de Lima[1], Regis Sewa Marques[2], Zoraida Sachetto[3] and Alisson Pugliesi[4], [1]Universidade Estadual de Campinas (UNICAMP), Campinas, Sao Paulo, Brazil, [2]Universidade Estadual de Campinas, Campinas, Sao Paulo, Brazil, [3]UNIVERSIDADE ESTADUAL DE CAMPINAS, UNICAMP, Campinas, Sao Paulo, Brazil, [4]Unicamp, Campinas, Brazil

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1376–1404) Sjögren's Disease – Basic & Clinical Science Poster II: Clinical Manifestations and Health Outcomes

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Sjogren's disease (SjD) is a systemic autoimmune disorder characterized by inflammatory involvement of the exocrine glands and extra-glandular manifestations. Among the latter, there is a growing interest in the study of neurological involvement, as the prevalence and association factors are still divergent in the literature. Thus, the objective was to evaluate the frequency of neurological manifestations in SjD, as well as the laboratory factors associated with the disease.

Methods: This retrospective observational study reviewed the electronic medical records of patients diagnosed with SjD, according to the 2002 or 2016 ACR criteria, at a tertiary outpatient clinic. Only patients over 18 years of age with the primary form of the disease were included. Patients with neurological manifestations were assessed and reviewed to determine whether the manifestations could be attributed to SjD. When attributable, their types and frequencies in the study population and their association factors were described. Inferential analysis was performed by comparing patients with neurological manifestations and those without neurological manifestations with regard to the presence of anti-Ro, anti-La, ANA, rheumatoid factor, C3, C4, cryoglobulins, hypergammaglobulinemia or hypogammaglobulinemia using Fischer and Chi Square statistical methods and, if necessary, multivariate analysis with logistic regression.

Results: 92 patients with SjD were evaluated. A prevalence of 17,39% neurological manifestations was found in the context of SjD in the peripheral nervous system (PNS). The main types of PNS found were ganglionopathy, sensitive neuropathy, multiple mononeuritis, fine fiber neuropathy and sensitive-motor neuropathy and are illustrated in figure 1. The two patients with CNS manifestations were attributed to concomitant Neuromyelitis Optica Spectrum Disease. Thus, a comparative inferential analysis was carried out between laboratory markers and the presence of PNS manifestations. In the univariate analysis, only hypogammaglobulinemia showed a significant statical association (p = 0.008). This association also occurred in the multivariate analysis, using rituximab as a covariate (p = 0,010). Table 1 shows the results obtained after statistical analysis.

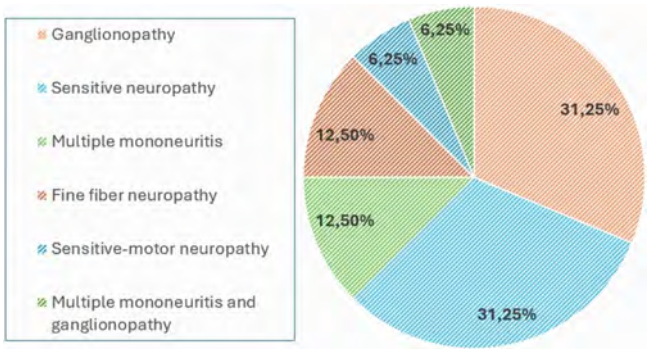

Figure 1: Types of neurological manifestations of PNS attributable to Sjögren's disease

Table 1: Statistical analysis comparing patients with Sjögren's Disease with and without associated peripheral neuropathy

Clinical/ Laboratory markers	PNS absent	PNS present	P-value
Extraglandular manifestation	49/76 (64,5%)	11/16 (68%)	p = 0,97
C3	6/76 (7,9%)	2/16 (12%)	p = 0,9276
C4	16/76 (21%)	3/16 (18%)	p = 1
C3 or C4	19/76 (25%)	3/16 (18%)	p = 1
ANA	74/76 (97,4%)	15/16 (93%)	p = 1
Anti-Ro	74/76 (97,4%)	15/16 (93%)	p = 1
Anti-LA	38/76 (50%)	11/16 (68%)	p = 0,3288
Cryoglobulins	7/76 (9,2%)	5/16 (31%)	p = 0,1104
Rheumatoide factor	45/76 (59,2%)	11/16 (68%)	p = 0,9623
Hypergammaglobulinemia	37/76 (48,7%)	6/16 (37,5%)	p = 0,2771
Hypogammaglobulinemia	9/76 (11,8%)	7/16 (43%)	p = 0,008* p = 0,010**

NOTE: * Univariate analysis / ** Multivariate analysis

Conclusion: In our sample, we found a prevalence of approximately 17,39% of neurological manifestations, with only PNS involvement attributable to SjD. The two CNS manifestations found to be immune in nature were attributed to the Neuromyelitis Optica spectrum disorder. Hypogammaglobulinemia, independent of rituximab use, was the only variable associated with PNS manifestations.

Real World Treatment Patterns and Health Care Resource Use in Patients With Newly Diagnosed Sjögren's Disease (SjD) in the United States

Sara McCoy[1], Anjana Lalla[2], Nilesh Choudhary[3], Shraddha Chatterjee[3], Shiwani Prasad[3] and Antton Egana[2], [1]University of Wisconsin–Madison, Madison, WI, [2]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [3]Novartis India, Hyderabad, India

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1376–1404) Sjögren's Disease – Basic & Clinical Science Poster II: Clinical Manifestations and Health Outcomes
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: SjD is a chronic, systemic, progressive autoimmune disease characterized by dry mouth and eyes, but it is often accompanied by extraglandular symptoms and signs that affect the entire body. About two-thirds of SjD occurs alone; the remaining one-third is associated with other autoimmune connective tissue diseases such as RA, SLE, or systemic sclerosis. This analysis describes treatment patterns and health care resource use (HCRU) over 12 months in US patients newly diagnosed with SjD.

Methods: This retrospective cohort analysis included adult patients with a first diagnosis (index date) of sicca syndrome or SjD (*ICD-9-CM*: 710.2; *ICD-10-CM*: M35.0-9, M35A-C; together termed SjD here) from October 2015 through March 2023 (identification period) and a second diagnosis within 28 to 365 days of first diagnosis in the Optum EHR database. Patients had ≥12 months pre-index documented clinical history with no record of a SjD diagnosis (baseline period), as well as ≥12 months follow-up post index (follow-up period). Treatment patterns and HCRU were assessed during the follow-up period. Patients' HCRU and medication use in the baseline and follow-up periods were reported descriptively.

Results: Of the 35,035 patients with SjD who met the inclusion criteria, 67.2% had SjD only whereas 32.8% had SjD occurring with other autoimmune conditions such as RA, SLE, and systemic sclerosis (SjD+other). HCRU for all patients with SjD increased from the baseline to follow-up period, irrespective of whether patients had SjD only or SjD+other (**Table 1**). An

ED, emergency department; IP, inpatient; IQR, interquartile range; OP, outpatient; PPPY, per patient per year; SjD, Sjögren disease; SSA, Sjögren's-syndrome-related antigen A; SSB, Sjögren's-syndrome-related antigen B. a Associated autoimmune conditions were looked in all available pre-index and 1 year post-index period. b Lab tests include the following: parotidectomy, punctal occlusion, antinuclear antibodies, rheumatoid factor, Anti-double stranded DNA (dsDNA%) test (for associated lupus), beta 2 microglobulin, complement C3, complement C4, complete blood count with differential, comprehensive metabolic panel, cryoglobulins, cyclic citrullinated peptide (associated rheumatoid arthritis), free light chain, lactate dehydrogenase, myositis antibodies, pulmonary function test, scleroderma antibodies, serum protein electrophoresis, uric acid, urine protein electrophoresis. c Imaging includes chest x-rays, computed tomography scans, magnetic resonance imaging, and ultrasound.

increase in patients with HCRU from baseline to follow-up was observed across all HCRU categories (all-cause outpatient visits [OP, 89.9% vs 99.6%], inpatient admissions [IP, 5.0% vs 11.8%], emergency department visits [ED, 16.5% vs 20.8%], SjD-specific diagnostic procedures [28.5% vs 41.2%], lab tests [55.2% vs 74.6%], and imaging [26.6% vs 36.8%]). A higher proportion of SjD+other patients had an IP visit in the follow-up period compared with SjD only patients. In addition to the increase in the proportion of patients with any HCRU during the follow-up period, the mean (SD) number of IP, ED, and lab visits per patient per year (PPPY) increased slightly in the follow-period vs baseline, with a substantial increase in OP visits (**Table 1**). Mean OP visits PPPY increased to a greater extent in the SjD+other group (41% increase) vs the SjD only group (32% increase). The 3 most commonly prescribed treatment classes in the overall cohort were systemic corticosteroids (42.8%), antidepressants (32.2%), and hydroxychloroquine and antimalarials (29.0%) (**Table 2**). This trend was similar for the SjD+other cohort; however, in the SjD only cohort, NSAIDs were among the top 3 classes along with systemic corticosteroids and antidepressants. Conventional DMARDs and biologic DMARDs were used by 14.2% and 5.6% of patients, respectively, in the follow-up period.

Table 2. Treatment Classes During Baseline and Follow-Up Periods for the Overall Cohort, Patients With SjD Only, and Patients With SjD and Overlapping Autoimmune Disease.

SjD-specific drugs prescribed, n (%)	Overall Cohort (N=35,035)		SjD+Other[a] (n=11,503)		SjD Only (n=23,532)	
	Baseline	Follow-Up	Baseline	Follow-Up	Baseline	Follow-Up

Saliva substitute	59 (0.2)	298 (0.9)	17 (0.1)	117 (1.0)	42 (0.2)	181 (0.8)
Systemic corticosteroids	10,490 (29.9)	14,993 (42.8)	4410 (38.3)	6349 (55.2)	6080 (25.8)	8644 (36.7)
Topical corticosteroids	3303 (9.4)	4111 (11.7)	1101 (9.6)	1398 (12.2)	202 (9.4)	2713 (11.5)
Systemic NSAIDs	7052 (20.1)	9472 (27.0)	2721 (23.7)	3680 (32.0)	4331 (18.4)	5792 (24.6)
Topical NSAIDs	1308 (3.7)	2079 (5.9)	518 (4.5)	829 (7.2)	790 (3.4)	1250 (5.3)

bDMARDs, biologic disease-modifying antirheumatic drugs; csDMARDs, conventional synthetic disease-modifying antirheumatic drugs; NSAIDs, nonsteroidal anti-inflammatory drugs; SjD, Sjögren's disease; TNFi, tumor necrosis factor inhibitor. a Associated autoimmune conditions were looked in all available pre-index and 1 year post-index period.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: This real-world analysis confirmed that patients with newly diagnosed SjD alone or with other autoimmune diseases have high disease burden within 12 months of diagnosis as demonstrated by increases in HCRU, largely driven by greater use of OP, IP, and ED services. Although treatment use increased during follow-up, biologic use was limited.

Understanding Fatigue Through Patients' Eyes: Development of a Novel Questionnaire Capturing the Complexity of Real-Life Fatigue in Sjögren's Disease

Saviana Gandolfo[1], Flavia Riccio[2], Mariachiara Visconti[3], Corrado Parlati[3], Nicola Della Rossa[4], Enrico Tirri[5] and Francesco Ciccia[3], [1]Rheumatology Unit, Ospedale del mare, Naples, Naples, Naples, Italy, [2]Rheumatology Section, University of Campania L. Vanvitelli, Naples, Italy, Naples, [5]Rheumatology Unit, Ospedale del mare, Naples, Italy, Naples, Italy

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1376–1404) Sjögren's Disease – Basic & Clinical Science Poster II: Clinical Manifestations and Health Outcomes
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Fatigue is one of the most frequent, debilitating and impactful symptoms for patients with Sjögren's Disease (SjD), and one of the most challenging to measure. To date, there are no PROs fully capturing fatigue as experienced by patients in their daily lives.

The purpose of this study was to define a new PRO for assessing fatigue and its impact on the quality of life of patients with SjD, based on lived experiences and their own definitions of fatigue.

Methods: Inspired by an essay written by a patient with SjD on the Sjögren's Foundation website (1), a new fatigue questionnaire, including 15 distinct types of fatigue (basic, rebound, sudden, weather-related, molten lead phenomenon, tired-wired, flare-related, fatigue related to other physical causes, fatigue-related concentration impairment, stress/distress/anxiety/depression SDAD-related fatigue, not sleeping well fatigue, normal aging fatigue, chronic illness fatigue, fatigue from trying to keep up with family and friends without a chronic illness, and doctor fatigue) was created and administered to SjD patients. Correlations with ESSPRI, ESSDAI, clinical and laboratory parameters were analyzed.

Results: 90 consecutive patients (female 93.4%) fulfilling SjD ACR/EULAR 2016 criteria, mean age 57.1 years (range 21–82), completed the questionnaire. The most frequently reported types of fatigue were SDAD(88.9%), basic (86.7%), and rebound (86.7%), while the least reported was weather-related (60%). Among all types, the SDAD had the highest impact on quality of life (mean impact score 82.8%). Males more frequently reported SDAD (100%), doctor fatigue (100%), and not sleeping well (83.4%), while females reported rebound (89.3%), basic (88.1%), and SDAD (88.1%). Younger and older patients reported basic fatigue more frequently (85.7% and 100%, respectively), compared to middle-aged groups, reporting SDAD(36–59 years: 92.1%; 60–70 years: 87.5%). Rebound was the only type correlating with disease duration (r=0.22, p0.03). Although SDAD was the most frequently reported and impacting type, it did not significantly correlate with ESSPRI,

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

whereas strong correlations were observed between ESSPRI and other types, particularly basic (r=0.54, p< 0.0001) and rebound (r=0.50, p< 0.0001). Certain types of fatigue strongly correlated with each other, such as basic and rebound (r=0.90, p< 0.0001), or specifically with other symptoms, such as flare-related and VASglobal pain (r=0.41, p< 0.0001). No correlations were observed with ESSDAI or lab parameters, except for the molten lead phenomenon with CRP (r=0.55, p0.007).

Conclusion: This novel SjD fatigue questionnaire captures aspects of real-life fatigue previously underrepresented in existing PROs, and reveals heterogeneity in patient experiences. These differences, along with the clustering of fatigue types and symptoms, underscore the importance of a fatigue-based patient profiling, with potential implications for pathophysiological understanding and personalized treatment. Ongoing efforts focus on validating the questionnaire, stratifying patients based on fatigue, and establishing its role as an outcome measure.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1376–1404) Sjögren's Disease – Basic & Clinical Science Poster II: Clinical Manifestations and Health Outcomes

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: About 70% of patients with primary Sjögren's disease (pSjD) suffer from fatigue. Fatigue is associated with functional deficits(1), leading to anxiety, depression and reduced quality of life. Recent studies showed that sleep apnea syndrome (SAS) is common in patients with pSjD(2,3).

We aimed to determine the prevalence of SAS in pSjD patients and to examine to what extent SAS treatment could improve fatigue and disease activity in pSjD.

Methods: We report the 4-week (W4), 3-month (V2) and 6-month (V3) data of patients included between 2019-2024. Three different cohorts (pSjD, psoriatic arthritis (PsA) and patients with SAS without underlying rheumatologic disease (SAS+)) were screened for SAS and compared. All patients with pSjD and PsA fulfilled the respective ACR/EULAR criteria for their diseases. An apnoea-hypopnoea index >5/h triggered treatment with CPAP or positional therapy.

SAS+: non-rheumatological patients with sleep apnea syndrome; pSjD+: patients with primary Sjögren's disease with initiation of therapy after sleep apnea syndrome diagnosis; pSjD-: patients with primary Sjögren's disease without sleep apnea syndrome or without initiation of therapy after sleep apnea syndrome diagnosis; PsA+: patients with psoriatic arthritis with initiation of therapy after sleep apnea syndrome diagnosis; PsA-: patients with Psoriatic arthritis without sleep apnea syndrome or without initiation of therapy after sleep apnea syndrome diagnosis; ESSDAI: EULAR Sjögren's syndrome disease activity index; FACIT: Functional Assessment of Chronic Illness Therapy; ESSPRI: EULAR Sjögren's Syndrome Patient Reported Index; PHQ-9: Patient Health Questionnaire-9; EPS: Epworth Sleepiness Scale; WHOQOL-BREF: World Health Organization Quality of Life Questionnaire, short form (soc: social, env: environmental). Values in bold are statistically significant, values in italics trended towards significance.

Assessments after W4 comprised fatigue (FACIT), visual analogue scale for pain and quality of life, depression (PHQ-9), quality of life (WHOQOL-BREF), daytime sleepiness (EPS) and ESSPRI. Assessments at inclusion (V1), V2 and V3: CRP and ESSDAI. Level of significance was set at a p-value < 0.05.

Results: The Departments of Rheumatology and Clinical Immunology, University Medical Center in Freiburg and Strasbourg examined 41 patients with pSjD (age 54.98 ± 12.36) and 21 patients with PsA (age 56.00 ± 9.12) for SAS. The SAS+ control group (age 58.46 ± 9.90) comprised of 13 individuals. The pSjD+ patients were significantly older than the pSjD- patients (p=0.00076). In pSjD, 15/41 (36.6%) of patients were diagnosed with SAS; 13/15 were treated with CPAP or positional therapy (pSjD+). In PsA, 11/ 21 patients had SAS; 8/11 received CPAP or positional therapy (PsA+). In SAS, 13/13 received CPAP treatment.

Between V1 and V2, and V1 and V3, the FACIT score improved significantly in SAS+ and PsA+ patients (p=0.008, p=0.012; p=0.017, p=0.034). Furthermore, in patients with pSjD+, the ESSDAI and ESSPRI (improved domains: fatigue and limb pain) scores improved significantly between V1 and V3 (p=0.003; p=0.043), while the Soc WHOQOL-BREF score significantly decreased between V1 and V2 (p=0.017). In PsA+ patients the PHQ-9 score improved significantly between V1 and V2 (p=0.020), and V1 and V3 (p=0.035), the Health WHOQOL-BREF and the Env WHOQOL-BREF scores improved significantly between V1 and V2 (p=0.042; p=0.044), the EPS between V1 and V3 (p=0.014). Table 1 gives further details.

Interestingly in PsA- patients, the following significant improvements were noted: joint tenderness between V1 and V2 (p=0.036), PHQ-9 between V1 and W4 (p=0.017), and FACIT between V1 and V2 (p=0.036).

Conclusion: SAS affected 36.6% of pSjD patients, which is within the range of analyses published in literature. In individuals with pSjD, adequate SAS treatment markedly reduced disease activity and symptoms; this implies that SAS screening in pSjD is in general appropriate.

Successful immunosuppressive treatment might positively influence PHQ-9 and FACIT in PsA- patients.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1376–1404) Sjögren's Disease – Basic & Clinical Science Poster II: Clinical Manifestations and Health Outcomes

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Primary Sjögren's syndrome (pSS) can have a systemic involvement with extraglandular manifestations, which are associated with more severe disease and with higher risk of complications, such as lymphoma. pSS has also been associated with an increased prevalence of cardiovascular risk (CV) factors and cardiovascular disease. The aim of the study was to describe the clinical characteristics of a cohort of Spanish patients with pSS from a tertiary hospital and to analyze the rates of CV factors and lymphoma between groups.

Methods: A retrospective descriptive study of patients with a diagnosis of pSS between January 1990 and December 2024 who met the ACR/EULAR 2016 classification criteria for pSS, in follow-up in a tertiary hospital in Madrid, Spain.

Patients diagnosed with other systemic connective tissue diseases were excluded. Patients with glandular involvement were compared to patients with systemic involvement (extraglandular). Categorical variables were presented as proportions or percentages, whereas continuous variables were reported as means with standard deviations (SD). Group comparisons were conducted using the Student's t-test or the χ^2test, as appropriate.

Results: A total of 110 patients were included, 39 (35.5%) had extraglandular involvement. Main characteristics are reported in Table 1. There were no differences regarding age, sex, time in follow up and smoking status. Cardiovascular risk (CV) factors were similarly distributed between groups, but a higher proportion of patients with extraglandular involvement had more than 1 CV risk factor. No cardiovascular events were reported after pSS diagnosis. Articular involvement was the most frequent followed by Raynaud, peripheral nervous system and interstitial lung disease.

Regarding neoplasia, 14.5% of patients developed malignancies, rates were higher in extraglandular patients. The reported incidence rate of lymphoma was 4.54 per 100 patients with pSS, being 2.82 per 100 patients in the glandular group and 7.69 per 100 patients in the extraglandular group.

Hydroxychloroquine was the main treatment in both groups, with higher rates of corticosteroids, rituximab and immunosuppressive treatments in patients with extraglandular involvement, as expected.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1405–1433) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: The computed tomography (CT) syndesmophyte score (CTSS) has shown to be more sensitive in capturing spinal structural damage progression in axial SpA (axSpA), compared to the current gold standard, the modified Stoke Ankylosis Spondylitis Spine Score (mSASSS) (de Koning A *et al*, Ann Rheum Dis 2018). Additionally, assessing facet joint ankylosis (FJA) on CT seems promising in further detecting progression (Stal R *et al*, Rheumatology 2020). We investigated whether a score combining syndesmophytes and FJA is more sensitive than CTSS for assessing spinal damage progression in axSpA.

Methods: Data from the Sensitive Imaging in Ankylosing Spondylitis cohort were used, including axSpA patients fulfilling the modified New York criteria and with ≥1 syndesmophyte. Conventional radiography (CR) and low-dose computed tomography (ldCT) of the spine were performed at baseline and 2 years (2Y) and scored by 3 (CR) or 2 (ldCT) central readers, blinded for time order. Syndesmophytes were assessed on CR and ldCT by the mSASSS and CTSS, respectively (Figure 1). The presence of FJA was evaluated on ldCT with the facet ankylosis score (FAS) on 19 facet joints (levels C5-T2 excluded due to poor visibility). The total mSASSS, CTSS and FAS were calculated per reader at each timepoint. Three versions of a combined score of syndesmophytes and FJA were proposed and computed by adding the CTSS and FAS while giving equal weight to both components (CT facet ankylosis syndesmophyte spine score A [CTFASSS-A]), 50% (CTFASSS-B) or 100% more weight to FAS (CTFASSS-C). Change scores were calculated per reader by subtracting the baseline from the 2Y score and then averaged across readers. The number of patients with positive and negative change as well as net change >0 and >0.5 were calculated for each score and compared. The total number of new or growing syndesmophytes and new FJA were calculated per reader and then averaged across readers.

Results: Forty-eight patients were included: mean (SD) age of 49 (9.7) years, 85% male, 81% HLA-B27+. Between baseline and 2Y, progression of spinal damage was observed as assessed by all scores: mean (SD) mSASSS 18.3 (14.3) vs 20.4 (15.1), CTSS 161.6 (127.1) vs 179.5 (132.3), FAS 8.2 (9.8) vs 9.4 (10.2). CTFASSS changed from 169.8 (134.5)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. CTFASSS: Computed Tomography Facet Ankylosis Syndesmophyte Spine Score; **CTSS:** Computed Tomography Syndesmophyte Score; **FJ:** facet joint; **FAS:** Facet Ankylosis Score; **IDS:** intervertebral disc space; **mSASSS:** modified Stoke Ankylosing Spondylitis Spine Score; **VC:** vertebral corner; **VU:** vertebral unit.

Figure 1. Schematic representation to guide the calculation of the mSASSS (A), CTSS (B), FAS (C) and CTFASSS (D)

(CTFASSS-A), 174.0 (138.4) (CTFASSS-B) and 178.1 (142.3) (CTFASSS-C) at baseline to 188.9 (140.0), 193.6 (143.9) and 198.3 (147.9) at 2Y, respectively.

After 2Y, CTFASSS-A, CTFASSS-B and CTFASSS-C detected any net change in a higher percentage of patients compared to CTSS (96% vs 83%) and, most notably, to mSASSS (96% vs 46%) and FAS (96% vs 48%) (Table 1A). Moreover,

Table 1. Number of axSpA patients with spinal structural damage progression on low-dose computed tomography (n=48)

A. According to change in spinal structural damage scores

	mSASSS*	CTSS	FAS	CTFASSS-A (CTSS + FAS)	CTFASSS-B (CTSS + 1.5 x FAS)	CTFASSS-C (CTSS + 2 x FAS)
Change >0, n (%)						
Positive	24 (65)	43 (90)	27 (56)	47 (98)	47 (98)	47 (98)
Negative	7 (20)	3 (6.3)	4 (8.3)	1 (2.1)	1 (2.1)	1 (2.1)
Net progression$	17 (46)	40 (83)	23 (48)	46 (96)	46 (96)	46 (96)
Change >0.5, n (%)						
Positive	22 (59)	43 (90)	23 (48)	45 (94)	47 (98)	47 (98)
Negative	6 (16)	3 (6.3)	2 (4.2)	1 (2.1)	1 (2.1)	1 (2.1)
Net progression$	16 (43)	40 (83)	21 (44)	44 (92)	46 (96)	46 (96)

B. According to syndesmophyte and facet joint ankylosis development

	Total number of new lesions&	Mean (SD)	Range	≥1, n(%)#	≥2, n(%)#	≥3, n(%)#
New syndesmophytes	327	6.8 (7.0)	0-33	35 (73)	31 (65)	22 (46)
Growing syndesmophytes	145	3.0 (2.5)	0-8	25 (52)	19 (40)	14 (29)
New or growing syndesmophytes	472	9.8 (8.3)	0-37	41 (85)	36 (75)	28 (58)
New facet joint ankylosis	73	1.5 (2.0)	0-8	11 (23)	10 (21)	6 (13)
New/growing syndesmophytes and FJA	545	11.3 (9.0)	0-42	41 (85)	38 (79)	33 (69)

* Retrieved from: de Koning A *et al. Ann Rheum Dis* 2018;77:293-299 (n=37).
$ Net progression: number of patients with positive progression minus number of patients with negative progression.
& Total number of new lesions (out of 48 patients) is the average across both readers.
# Agreement between both readers was required on the presence of ≥1, ≥2 and ≥3 lesions.
axSpA: axial spondyloarthritis; **CTFASSS:** Computed Tomography Facet Ankylosis Syndesmophyte Spine Score; **CTSS:** Computed Tomography Syndesmophyte Score; **FAS:** Facet Ankylosis Score; **mSASSS:** modified Stoke Ankylosis Spondylitis Spine Score.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

considering all 48 patients, 472 new or growing syndesmophytes and 73 new FJA were detected on ldCT, denoting that the combined score captured 1.15 times more new bone formation than CTSS (545 vs 472 new lesions) (Table 1B).

Conclusion: A combined score assessing syndesmophytes and FJA captures more spinal structural damage progression in axSpA than assessing syndesmophytes alone. With respect to sensitivity to change, all CTFASSS proposals performed similarly, with the simple addition of CTSS and FAS (CTFASSS-A) being the most straightforward approach. However, further validation will define which is the best combination.

Table 1. Spearman's correlation between spinal structural damage scores and spinal mobility (at baseline, n=46)*

	mSASSS	CTSS	FAS	CTFASSS-A (CTSS + FAS)	CTFASSS-B (CTSS + 1.5 x FAS)	CTFASSS-C (CTSS + 2 x FAS)
	r_s	r_s	r_s	r_s	r_s	r_s
Spinal mobility						
Occiput-to-wall distance	0.50	0.64	0.64	0.65	0.66	0.66
Lateral spinal flexion	-0.61	-0.72	-0.53	-0.72	-0.72	-0.73
Modified Schober test	-0.41	-0.50	-0.40	-0.50	-0.50	-0.50
Cervical rotation	-0.49	-0.58	-0.62	-0.58	-0.59	-0.59
Chest expansion	-0.32	-0.49	-0.31	-0.49	-0.49	-0.48
Composite measure						
BASMI	0.60	0.71	0.65	0.71	0.72	0.72

* Aggregate scores (average across readers) were used. Higher r_s values mean higher strength of the association; the following cutoffs were applied (Castro MP *et al*, *Clin Rheumatol* 2016;35(7):1777-87):
Low: 0.00-0.20; Fair: 0.21-0.40; Moderate: 0.41-0.60; Substantial: 0.61-0.80; Excellent: 0.81-1.00
BASMI: Bath Ankylosing Spondylitis Metrology Index; **CTFASSS:** Computed Tomography Facet Ankylosis Syndesmophyte Spine Score; **CTSS:** Computed Tomography Syndesmophyte Score; **FAS:** Facet Ankylosis Score; **mSASSS:** modified Stoke Ankylosis Spondylitis Spine Score; r_s: Spearman's rho.

Background/Purpose: In axial SpA (axSpA), the computed tomography (CT) syndesmophyte score (CTSS) has shown to capture more spinal structural damage progression and to better correlate with spinal mobility than the modified Stoke Ankylosis Spondylitis Spine Score (mSASSS, the current gold standard) (Stal R *et al*, *RMD Open* 2023). Recently, a combined score of syndesmophyte and facet joint ankylosis (FJA) development has been proposed as a more sensitive instrument in capturing damage progression. We aimed to assess whether this combined score retains good correlation with spinal mobility compared to current measurement instruments.

Methods: Data from the Sensitive Imaging in Ankylosing Spondylitis cohort were used, including axSpA patients fulfilling the modified New York criteria and with ≥1 syndesmophyte. Conventional radiography (CR) and low-dose computed tomography (ldCT) of the spine were performed at baseline (BL) and scored by 3 (CR) or 2 (ldCT) central readers, blinded for time order. Syndesmophytes were assessed on CR and ldCT by the mSASSS and CTSS, respectively. FJA was evaluated on ldCT with the facet ankylosis score (FAS) on 19 facet joints (levels C5-T2 excluded due to poor visibility, range: 0-38). Three different versions of a combined score of FJA and syndesmophyte development (the CT facet ankylosis syndesmophyte spine score, CTFASSS) were proposed and computed by adding the CTSS and FAS while giving equal weight to both components (CTFASSS-A = CTSS + FAS), 50% more weight to FAS (CTFASSS-B = CTSS + 1.5xFAS) or 100% more weight to FAS (CTFASSS-C = CTSS + 2xFAS). At BL, the following spinal mobility measures were evaluated: occiput-to-wall distance (OWD), lateral spinal flexion (LSF), modified Schober test (mSchober), cervical rotation and chest expansion. The composite score BASMI was calculated. Correlations between each spinal structural damage score and spinal mobility were assessed at BL with Spearman's rank correlation coefficients and compared. A cumulative probability plot was created to better illustrate correlations between CTFASSS and BASMI.

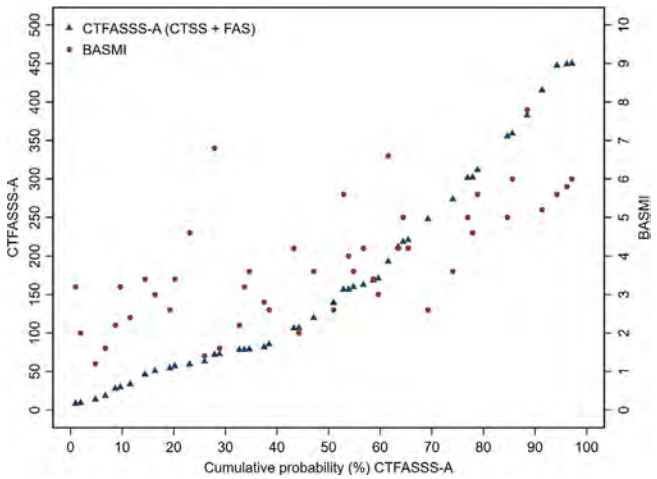

Figure 1. Cumulative probability plot representing the relationship between BASMI and CTFASSS-A (BASMI: Bath Ankylosing Spondylitis Metrology Index; CTFASSS-A: Computed Tomography Facet Ankylosis Syndesmophyte Spine Score version A; CTSS: Computed Tomography Syndesmophyte Score; FAS: Facet Ankylosis Score)

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Forty-six patients had data available for all structural damage scores and spinal mobility measures at BL: mean (SD) age of 47 (9.6) years, 87% male, 83% HLA-B27+. All versions of the CTFASSS showed substantial correlations with OWD (CTFASSS-A: r_s 0.65; CTFASSS-B and CTFASSS-C: r_s 0.66) and LSF (CTFASSS-A and CTFASSS-B: r_s -0.72; CTFASSS-C: r_s -0.73) and moderate correlations with the other measures, to a similar degree to that observed for CTSS, but better than mSASSS (Table 1). Notably, compared to mSASSS, FAS alone correlated better with OWD (r_s 0.64 vs 0.50) and cervical rotation (r_s -0.62 vs -0.49). However, no additional benefit was obtained with a CTFASSS score attributing more weight to FAS compared to the simple sum of the components (i.e. CTFASSS-A). Although substantial correlations were observed between all imaging scores and BASMI, better results were seen with CTSS and CTFASSS (Figure 1).

Conclusion: A composite score assessing syndesmophytes and FJA correlates with spinal mobility similarly well as CTSS but better than mSASSS, supporting the validity of the combined score in assessing spinal damage progression in axSpA.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1405–1433) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Axial Spondyloarthritis (axSpA) frequently eludes early recognition, particularly before structural sacroiliitis becomes visible. We analyzed decade-specific diagnosis delay, clinical subtype distribution, and first-symptom profiles in men and women within a nationwide cohort to assess the impact of updating classification criteria on presentation patterns.

Methods: This was a cross-sectional data analysis from the Brazilian Spondyloarthritis Registry (RBE), including 19 centers nationwide. All patients included were diagnosed with axSpA by a rheumatologist and met the ASAS classification criteria for axSpA. Patients were grouped by the decade in which their first SpA-related symptom.

Results: A total of 791 patients were included, whose disease onset (initial symptoms) occurred between 1961 and 2024. A male predominance was observed (n = 547, 69.2%). Notably, all patients with disease onset before 1970 were male, but female representation increased progressively according to the decade of disease onset (30% in the 1970s to 50% in the 2020s). The mean diagnosis delay interval dropped from 41.7 ± 4.2 years in the 1960s (n=3) to 1.9 ± 1.5 years in 2020–2024 (n=18) (Figure 1). Diagnostic delay decreased similarly in both sexes across decades (p for interaction = 0.971). In each decade of initial symptom, delay was comparable between men and women, with no significant differences observed (all p > 0.05) (Figure 2). Radiographic axSpA (r-axSpA) accounted for all cases before 2009 and declined to 83.3 % by 2020–2024 as non-radiographic axSpA (nr-axSpA) reached 16.7 %. Diagnosis delay improved markedly for both subtypes (p< 0,001). Low back pain was the dominant initial symptom over the decades varying from 90.0% to 81.1%. Regarding symptoms, men reported more hip pain than women (23.2% vs. 8,6%, p< 0.001). Initial symptoms with upper-limb arthritis, dactylitis,

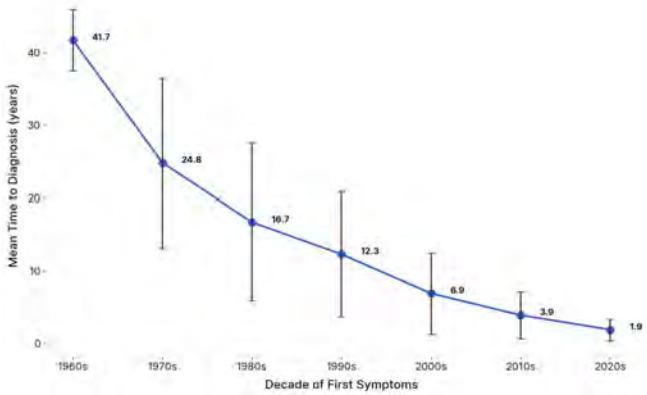

Figure 1. Overall Diagnostic Delay by Initial Symptom Decade

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

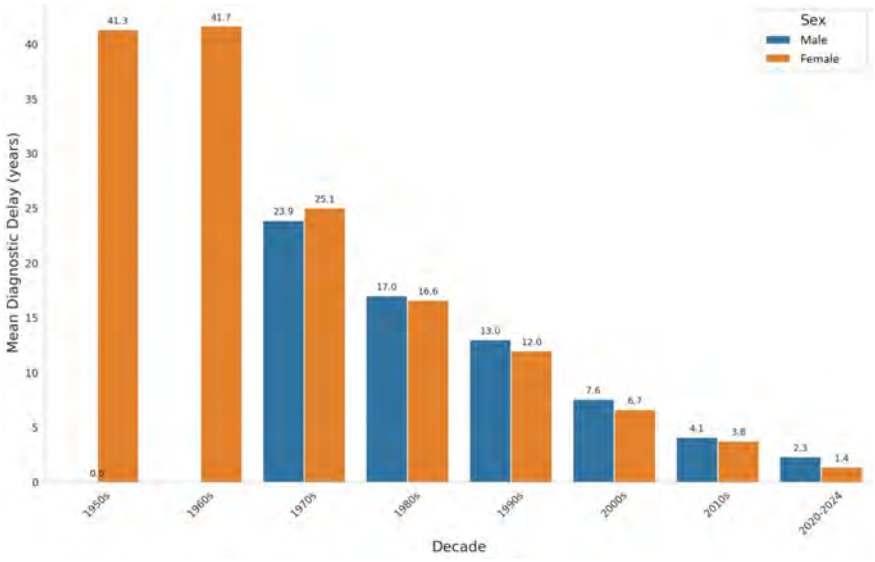

Figure 2. Comparison of Mean Diagnostic Delay by Sex and Initial Symptom Decade

cervical pain, buttock pain was similar between men and women (p >0.05). **Compared to radiographic disease, non-radiographic axSpA showed more hip pain as initial symptom (23.2% vs. 8.2%, p=0.024), while frequencies of upper-limb arthritis, lower-limb arthritis, and back pain were similar (**p >0.05).

Conclusion: These findings suggest a significant improvement in the recognition of axSpA in recent decades, possibly related to the adoption of new axSpA biomarkers, such as the use of magnetic resonance imaging, as well as increased awareness of the disease. This progress has led to greater recognition of previously underdiagnosed female patients. The growing proportion of non-radiographic axSpA highlights the need for early imaging-based referral protocols and management strategies.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1405–1433) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Sex differences in axial spondyloarthritis (axSpA) are well recognized, but their clinical consequences remain understudied in real-world settings. This study aimed to assess sex-based differences in demographic, clinical, functional, and treatment-related characteristics among patients with axSpA, and to explore sex-specific predictors of disease burden

Methods: Cross-sectional analysis of patients with axSpA enrolled in the Brazilian Registry of Spondyloarthritis (RBE), a multicenter, observational cohort involving 46 referral centers across Brazil. Eligible participants were adults diagnosed with SpA and classified according to ASAS criteria. Disease activity and impact were assessed using validated indices: BASDAI, ASDAS-CRP, BASFI, BASMI, ASQoL, and mSASSS. Sex-stratified multivariable linear regression models were developed to identify independent predictors of disease activity, function, mobility, and quality of life. Model assumptions and multicollinearity were evaluated, and results were expressed as unstandardized beta coefficients with 95% confidence intervals.

Results: A total of 828 patients were included: 568 (68.6%) males and 260 (31.4%) females, with a similar median age between groups (p = 0.351). Although HLA-B27 positivity has been more frequent in males (71.0% vs. 29.0%; p = 0.009), the family history of SpA was more frequently reported by females (26.2% vs. 17.2%; p = 0.002), as well as anxiety (18.6% vs. 9.6%; p< 0.001; OR 2.14), depression (18.2% vs. 5.8%; p< 0.001; OR 3.58), and fibromyalgia (23.0% vs. 5.8%; p< 0.001; OR 4.80). Figure 1 illustrates significantly higher scores of BASDAI, ASDAS-CRP, BASFI, and ASQoL in women, while men had worse BASMI. Correlation matrices showed stronger associations between patient-reported outcomes in women and a stronger mSASSS–BASMI correlation in men. Multivariable models revealed distinct sex-specific patterns. In women, functional limitation (BASFI) and patient global assessment were consistent predictors across outcomes. In men, disease burden was associated with root joint pain, enthesitis, comorbidities (fibromyalgia, depression), and work status. Complementary logistic regression identified fibromyalgia, depression, family history, and higher BASDAI as independent correlates of female sex, while HLA-B27 positivity, hip limitation, and higher BASMI were associated with male sex.

Conclusion: These findings highlight contrasting profiles of axSpA by sex: a predominantly functional and subjective burden in women, and a more structural axial damage and inflammatory phenotype in men. Tailored assessment strategies may improve disease evaluation and management in both groups.

Table 1. Baseline demographics and clinical characteristics

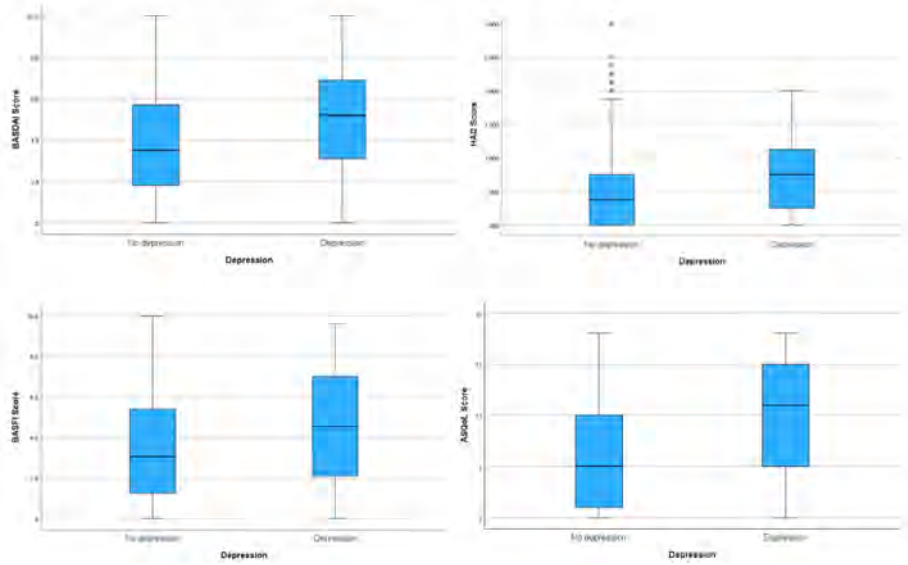
Demographics	
Total Participants	914
Age, Mean (SD)	45.85 (12.63)
Year born, n (%)	
• 1930-1949	63 (6.9)
• 1950-1959	130 (14.2)
• 1960-1969	219 (24)
• 1970-1979	257 (28.1)
• 1980-1989	196 (21.4)
• 1990-	49 (5.4)
Caucasian, n (%)	885 (96.8)
Male, n (%)	687 (75.2)
Ever Smoker, n (%)	527 (57.5)
HLA B27 positive, n (%)	631 (68.8)
Psoriasis, n (%)	150 (16.4)
Inflammatory Bowel Disease, n (%)	96 (10.5)
Uveitis, n (%)	308 (33.7%)
Dactylitis, n (%)	60 (6.6%)
Peripheral arthritis, n (%)	276 (30.2)
Enthesitis, n (%)	162 (17.7)
Disease Characteristics	
Disease Duration, median (25^{th},75^{th})	20.89 (10.25, 25)
Delay to diagnosis (25^{th},75^{th})	5.0 (2.0, 11.0)
Patient Reported Outcomes	
BASDAI, mean (SD)	4.0 (2.4)
BASFI, mean (SD)	3.6 (2.6)
HAQ, median (25^{th}, 75^{th})	0.4 (0.0,0.8)
ASQoL, mean (SD)	6.1 (5.0)

Background/Purpose: The burden of comorbidities in Axial Spondyloarthritis (axSpA) is increasingly recognised and contributes to the concept of difficult-to-treat axSpA (D2T-axSpA). The need to assess for non-inflammatory causes of uncontrolled disease is vital. We aim to characterise the prevalence and impact of depression in an Irish axSpA cohort.

Methods: The Ankylosing Spondylitis Registry of Ireland is a well-established observational multi-centre study of clinically diagnosed axSpA patients in Ireland. This study was conducted within the framework of ASRI. Depression was identified using a participant-reported physician-confirmed diagnosis.

Comorbidities and medication history were compiled using structured interviews. Validated outcome measures including Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Health Assessment Questionnaire (HAQ), Bath Ankylosing Spondylitis Functional Index (BASFI) and Ankylosing Spondylitis Quality of Life (ASQoL) scale were recorded.

Figure 1. Association between depression and disease activity



23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: At analysis, 914 participants were enrolled in the registry (75.3% male, mean age 45.85). Basic demographics are available at Table 1. In total, depression was reported in 94 (10.3%) participants. A significant association between age group and depression (p=0.049) was observed, with higher prevalence in older cohorts.

Participants with comorbid depression had a higher prevalence of peripheral manifestations of axSpA compared to their peers without depression: peripheral arthritis was more common in those with depression (42.9% vs 29.6% without depression; p< 0.01); 27.5% of patients with depression had enthesitis vs 16.8% of those without depression (p< 0.01); psoriasis was present in 25.3% of cases with depression vs 15.7% of those without depression (p=0.02). No differences were found in dactylitis (6.6% in both groups; p=0.60) or inflammatory bowel disease (13.3% vs 10.4%; p=0.24). No statistical difference between genders was seen when assessing depression in this cohort (11.1% male vs 13% female, p=0.59).

Participants with depression had significantly (p< 0.001) higher disease activity scores compared to those without, including BASDAI (5.04 vs 3.81), HAQ (0.76 vs 0.49), BASFI (4.56 vs 3.46) and ASQoL (9.93 vs 6.07) (Figure 1). Unemployment status also differed significantly (p< 0.01) between those with (28.7%) and without depression (16.6%). Depression was also more prevalent in homemakers (13.8% vs 4.9%; p< 0.01).

Conclusion: In an Irish axSpA cohort, depression is a prominent factor affecting approximately 1 in 10 participants. Depression is significantly associated with higher disease activity, poorer functional status, and increased peripheral manifestations indicating a greater burden of disease in these patients.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1405–1433) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: In axial spondyloarthritis cohorts, patient reported outcomes are vital for tracking disease progression and response to therapy. However, many cohorts enrolled prior to the development and validation of the ASDAS-CRP as a generally accepted standard measurement of disease activity. Our goal is to formally assess if patient global assessment (PGA) activity prior to ASDAS can be used when the modern questionnaire is unavailable.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

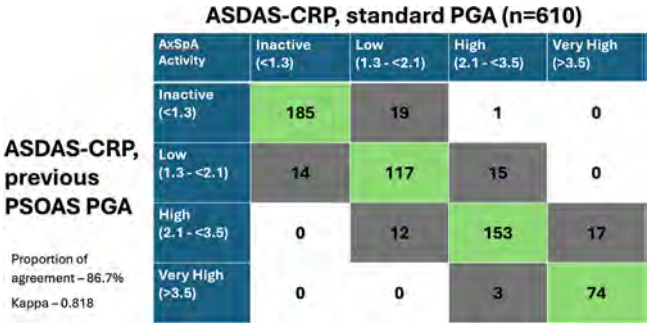

Figure 1. Agreement table comparing ASDAS-CRP calculated with the previous PSOAS PGA measure and the ASDAS-CRP with standard PGA, including weighted Cohen's kappa coefficient.

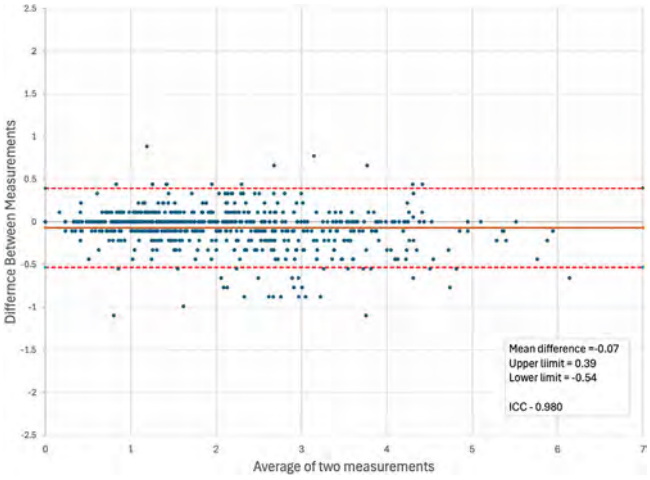

Figure 2. Bland-Altman Plot assessing agreement between ASDAS-CRP calculated with the previous PSOAS PGA measure and the ASDAS-CRP with standard PGA.

Methods: Data from the Prospective Study of Outcomes in Ankylosing Spondylitis (PSOAS) observational cohort were analyzed. Patients met Modified New York (mNY) criteria for AS and assessed their global disease activity during study visits. Before the development of ASDAS-CRP, global disease activity was rated on a numeric rating scale with the prompt: "Considering all the ways that your ankylosing spondylitis affects you, rate how you are doing." The currently used ASDAS global prompt instead asks: "How active was your spondylitis on average during the last week?"

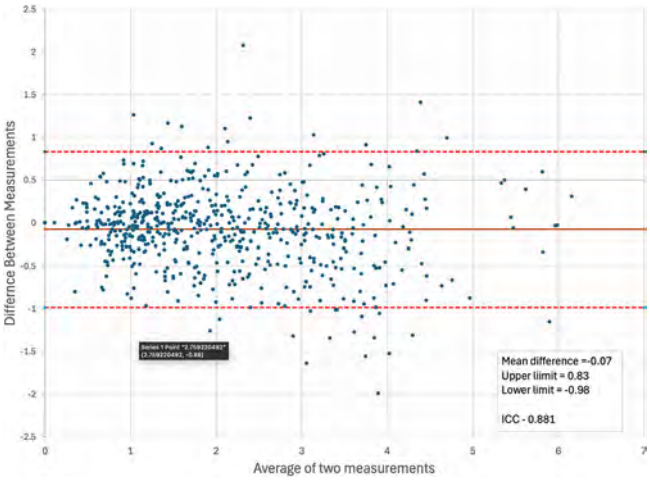

Figure 3. Bland-Altman plot assessing agreement between ASDAS-ESR and ASDAS-CRP

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

We analyzed patients with visits that included both the older global score and the ASDAS global score to assess agreement between the two measures; ASDAS-CRP was calculated using both the older global assessment compared to the standard ASDAS global assessment. We also compared the standard ASDAS-CRP and ASDAS-ESR. We compared ASDAS disease activity categories between the comparisons and calculated weighted Cohen's Kappa coefficients. We also compared the older vs. newer global single-item scores with intraclass correlation coefficients (ICC) to evaluate agreement.

Results: 610 unique patient visits were analyzed. The proportion of agreement of ASDAS-CRP calculated with the old PGA compared to the newer PGA was 86.7% based on disease activity categories with Cohen's Kappa Coefficient of 0.818 (values of 0.81 – 1.00 are considered perfect agreement). The ICC was calculated using a two-way random effects model and was 0.980, consistent with excellent agreement. In other studies, the proportion of agreement of ASDAS-CRP to ASDAS-ESR has been calculated based on disease severity categories. In our study, this proportion was 72.6% with Kappa Coefficient of 0.62, which is similar to other studies.

Conclusion: Prior measures of PGA utilized before the validation of ASDAS-CRP are a valid substitution for the PGA in the ASDAS-CRP based on calculation of a Kappa Coefficient showing perfect agreement. This is important in scenarios where investigators are calculating the ASDAS-CRP in patients who were a part of observational cohorts prior to its development.

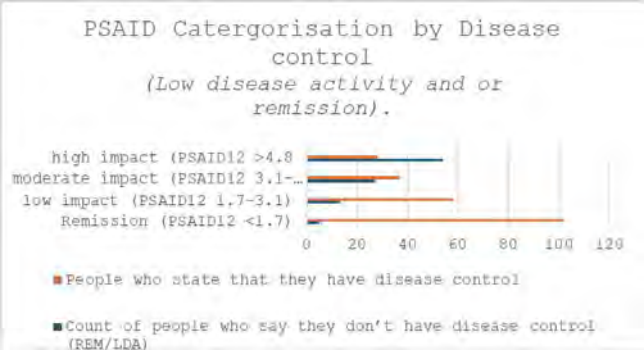

Figure 1: Patient REM/LDA compared to PsAID categories

Table 1: Sensitivity, specificity, PPV and NPV for each MDA definition using Patient REM/LDA as a gold standard

	Patient REM/LDA n=308	Standard MDA-HAQ	MDA-PsAIDrem	MDA-PsAIDlow
All patients n=308	Sensitivity	67.1	58.1	66.2
	Specificity	79.7	86.5	82.4
	Positive predictive value	91.3	93.2	92.3
	Negative predictive value	43.4	39.5	43.6
Patients over 65 years n=51	Sensitivity	63.4	56.1	68.3
	Specificity	80.0	90.0	80.0
	Positive predictive value	92.9	95.8	93.3
	Negative predictive value	34.8	33.3	38.1

Background/Purpose: Treat to target management is recommended in psoriatic arthritis (PsA) to improve disease control and patient quality of life. Minimal disease activity (MDA) criteria for PsA are a recommended target for treatment. However, the criteria include the health assessment questionnaire (HAQ) which may not always align or be responsive to changes in disease activity or accurately represent disease activity in older patients.

We aimed to test if the new PsA impact of disease (PsAID) score categories of remission and low impact can be used as an alternative item within the MDA criteria and whether this may better reflect patient opinion of disease remission/ Low disease activity (REM/LDA) than the HAQ.

Methods: A post-hoc analysis of data from the Remission/Flare in PsA (ReFlaP) study utilised real world data from adults with PsA for >2 years (NCT03119805). Data included HAQ, PSAID, and patient self-assessment of REM/LDA at clinic visits in 14 countries between 2017-2019. Patients with missing MDA/PsAID/REM data were excluded.

Patients were classified as meeting MDA (5/7 items) and very low disease activity (VLDA; 7/7 items) using either HAQ< 0.5 or PsAID thresholds. PsAID12 was categorised as REM < 1.7; Low impact 1.7-3.1; Moderate impact >3.1-4.8; high impact >4.8. Analysis included summary statistics and chi-squared analysis for categorical variables (p for significance < 0.01) and was performed in SPSS v 30.0.

Results: A total of 308 (164 M, 144 F) patients were included in the analysis (median age 53, IQR 43, 61). 171 were receiving biologic medication and 186 conventional DMARDs. At the baseline visit 234 (131M, 103F) patients reported that they felt that they were in REM/LDA. At baseline, using PSAID12 cut-offs, 126 were in remission and 65 in low impact. 94.4% of those in PsAID remission and 80.0% of those in low impact self-reported that they identified that they were in REM/LDA (figure 1).

There was a significant correlation at both visits between PSAID12 and HAQ scores and good agreement between MDA using HAQ as an item and MDA using PsAID as an item (89.0% for PsAID-rem and 91.0 for PsAID-low). Using the standard MDA-HAQ as a reference, MDA-PsAIDrem and MDA-PsAIDlow had sensitivity 82.6% and 90.7% and specificity was 97.1% and 91.2%.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Using patient reported REM/LDA as a gold standard, sensitivity, specificity, positive and negative predictive values were calculated for all the patients and separately for those over 65 years of age (table 1).

Conclusion: Patient perspective on disease severity is an important variable which is challenging to quantify. Using PsAID remission/low impact (≤3.1) instead of HAQ≤0.5 within the MDA showed very good agreement with a standard MDA assessment. The different MDA definitions showed similar agreement with patient opinion of REM/LDA in the full population.

We propose that PSAID12 category of remission/LDA (< 3.1) could be used as an alternative to HAQ< 0.5 in the MDA criteria and may correlate slightly better with patient opinion in those over 65 years old.

Classification of sacroiliits using an artificial intelligence model

Esther Fernández Guill[1], Yazmina Bautista Mártir[2], Eduardo Fernández Jover[3] and Irene Cases Susarte[4], [1]Sociedad Española de Reumatologia, Murcia, Spain, [2]Sociedad Española de Medicina de Familia, Murcia, Spain, [3]Universidad Miguel Hernandez, Alicante, Spain, [4]Sociedad Española de Radiologia, Murcia, Spain

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1405–1433) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Axial Spondyloarthritis (axSpA) is a chronic inflammatory disease that mainly involvessacroiliac joints and spine. It is caused by ankylosing spondylitis and other rheumatic diseases and affects mostly young adults, leading to a decreased quality of life and complications if not diagnosed promptly. Conventional radiographs of sacroiliac joints are the first imaging technique in patients with suspected axSpA. However, the diagnosis of sacroiliitis remains subject to significant intrapersonal and interpersonal variation, especially in the early stages. The ability to identify meaningful patterns in large data sets makes machine learning very attractive for screening of diseases such as axSpA.

The objective is to To develop and validate a new approach based on artificial intelligence techniques for the automatic classification of the grade of sacroiliitis on conventional radiographs.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We included 267 X-ray images of patients with clinical suggestion of axSpA. Images were reviewed by 3 rheumatologists and 1 radiologist who graded the severity of sacroiliitis according to the New York criteria (Figure 1 and 2). We performed some pre processing steps using Fiji, median filter, manual adjustment and data augmentation. For model training we used 10-fold stratified cross-validation. Grayscales images were expanded to 3 identical channels and images were resized for the ResNet50, EfficientNetV2S and Xception Backbones. At first we used transfer learning technique by combining a base CNN model as feature extractor, with a top dense stack customized. For the base model, several flavors of Resnet, EfficienNet and Inception architectures were used, besides a custom designed CNN core for basic comparison. We also used XGBoost.

Results: First results were disappointing (Figure 3). To improve performance, we used the XGBoost ensemble learning combined with CNN based onResNet50 architecture. We kept the convolutional kernel, and eliminated the top classifier. A tensor of shape was used as the input for the XGBoost model. After grid search for optimizing XGBoost, we obtained an accuracy of 57% (Figure 3) Therefore, we found that the sensitivity (recall) for all classes was over 60%, except for Class 1 which was misclassified.

Conclusion: -Our trained model successfully detected the grade of sacroiliitis with an accuracy over 60 %.-With further improvement and validation this approach could be helpful to aid the detection and classification of radiographic sacroiliitis

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1405–1433) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Restless legs syndrome (RLS) is a chronic neurological disorder associated with brain iron metabolism. Although RLS has been linked to various immune-mediated inflammatory diseases, such as psoriatic arthritis (PsA), little is known about the influence of inflammation on this association or the impact of RLS on disease activity, disease burden, and other comorbidities. The objective is to evaluate the prevalence of restless legs syndrome (RLS) in patients with psoriatic arthritis (PsA) and its association with clinical, inflammatory, functional characteristics, and comorbidities.

Methods: This is a cross-sectional observational study including 230 PsA patients. RLS screening was performed using the International Restless Legs Syndrome Study Group questionnaire, with diagnostic confirmation by a neurologist. Demographic data, disease activity (measured by DAPSA), functionality (measured by HAQ), disease impact (measured by PsAID), and comorbidities (anxiety, depression, sleep quality, obesity, and fibromyalgia) were collected.

Abbreviations: bDMARD: Biologic Disease-Modifying Antirheumatic Drug; csDMARD: Conventional Synthetic Disease-Modifying Antirheumatic Drug; FACIT-F: *Functional Assessment of Chronic Illness Therapy*; mMASES: Modified Maastricht Ankylosing Spondylitis Enthesitis Score; n: Number; PASI: *Psoriasis Area Severity Index*; SD: Standard Deviation; PSAID: *Psoriatic Arthritis Impact of Disease*; TNFi: Tumor Necrosis Factor Inhibitor; tsDMARD: Targeted Synthetic Disease-Modifying Antirheumatic Drug.

Results: RLS was confirmed in 46 patients (20%). Patients with RLS showed a higher frequency of polyarthritis (27% vs. 6%; p< 0.001), a greater number of swollen joints (2.0 vs. 1.4; p=0.04), increased fatigue (p< 0.001), higher disease activity (p< 0.001), greater disease impact (p< 0.001), and poorer functionality (p=0.01). RLS was associated with higher rates of anxiety, depression, and poor sleep quality (all p< 0.001).

In the regression analysis, polyarthritis (OR: 1.03; 95% CI: 1.00–1.9; p=0.04) and skin problems (OR: 1.4; 95% CI: 1.03–2.0; p=0.03) were significantly associated with the presence of RLS.

Conclusion: RLS is common in patients with PsA and is associated with poorer functionality, higher disease burden, increased fatigue, anxiety, depression, and worse sleep quality. Inflammation and psoriasis-related symptoms could be related to the presence of RLS in these patients.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1405–1433) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Psoriatic arthritis (PsA) develops in ∼20-30% of psoriasis patients. However, early PsA diagnosis is challenging due to heterogeneous, subtle symptoms and overlap with psoriasis without arthritis (PsO). Even a brief diagnostic delay (∼6 months) can lead to joint erosions and functional decline. We aimed to address this unmet need by identifying early clinical/imaging markers and developing a composite index for timely PsA detection.

Methods: We analyzed a retrospective case-control dataset (2014-2022) of 100 early PsA patients (≤2-year duration) and 100 psoriasis-only controls. All subjects underwent standardized clinical evaluation of tender/swollen joint counts (TJC, SJC), morning stiffness, enthesitis, and dactylitis, non-specific inflammatory biomarkers (ESR and CRP) along with musculoskeletal ultrasound and MRI imaging. A composite index (φAPs) was derived using multivariate logistic regression to integrate significant clinical and imaging predictors. Model performance (sensitivity, specificity, ROC area) was assessed and internally validated via bootstrap resampling.

Results: Early PsA patients demonstrated significantly elevated inflammatory activity compared to PsO controls. The mean TJC was 7.5±0.5 in early PsA vs 2.2±0.5 in PsO (p=0.0032), and the SJC was 4.5±0.3 vs 2.9±0.7 (p=0.0057), respectively. Morning stiffness duration was markedly longer in early PsA (37.7±5.5 minutes vs 10.2±4.5 minutes, $p< 0.001$). Enthesitis was present in 78% of PsA cases vs 31% in PsO (p=0.00023). Dactylitis affected 65.6% of early PsA patients, compared to 9% in PsO ($p< 0.001$), predominantly involving toes II–IV and fingers IV–V.

Non-specific inflammatory biomarkers (ESR and CRP) were significantly elevated in early PsA: mean ESR was 37.8 ±2.4 mm/h vs 15.2±2.1 mm/h (p=0.0071); CRP was 36.25±2.23 mg/L vs 8.12±3.14 mg/L (p=0.0056). MRI detected tenosynovitis in 89.3% and early bone erosions in 40.4% of cases. Power Doppler ultrasonography identified active synovial proliferation in 91.7% and entheseal changes in key anatomical locations.

The composite predictive model (φAPs), which integrates clinical and laboratory variables, demonstrated a sensitivity of 89% and specificity of 84% for early PsA identification. ROC curve analysis yielded an AUC of 0.91. Internal validation by 1,000 bootstrap replicates confirmed model robustness. In subgroup PsA analyses, φPsA values ≥2.3 correlated with confirmed early PsA in 92% of cases, while values < 1.8 excluded PsA in 95%. The most informative variables contributing to the model were dactylitis, enthesitis, and CRP elevation.

Conclusion: This composite clinical-imaging model greatly enhances early PsA recognition in psoriasis patients, enabling earlier intervention to prevent irreversible joint damage. By incorporating hallmark features like enthesitis and dactylitis, it helps clinicians distinguish incipient PsA from psoriasis alone at the earliest stages. External validation is underway to establish the φAPs index as a practical tool that improves clinical decision-making and patient outcomes.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1405–1433) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Mechanical stress is known to trigger and exacerbate psoriatic arthritis (PsA). Based on the hypothesis that biomechanical stress is greater in the dominant extremity, we aimed to investigate the association between handedness and radiographic damage in PsA.

Table 1. Baseline characteristics (clinic entry).

Variable	Overall (n=359)	Right-handed (n=324)	Left-handed (n=35)	p-value
Demographic features				
Age in years, mean (SD)	43.7 (12.9)	43.2 (12.7)	48.1 (13.8)	**0.03**
Sex (male), n (%)	204 (57.0)	185 (57.3)	19 (54.3)	0.87
Ethnicity White, n (%)	299 (84.7)	270 (84.6)	29 (85.3)	1.00
Duration of PsA in years, mean (SD)	4.8 (6.7)	4.6 (6.6)	6.4 (7.6)	0.15
Duration of PsC in years, mean (SD)	15.8 (14.0)	14.9 (13.2)	24.6 (17.7)	**<0.01**
BMI in kg/m², mean (SD)	28.3 (6.2)	28.0 (6.0)	30.8 (6.8)	**0.01**
Disease-related features

Table 2. Linear mixed models analyzing the association between handedness and peripheral damage.

Variable*	Estimate	95% CI		p-value
Outcome: Total (four-limb) mSS				
Left-handedness	7.59	-0.88	16.07	0.08
Outcome: Total mSS in the hands				
Left handedness	6.34	0.24	12.44	**0.04**
Outcome: Total mSS in the feet				
Left handedness	1.30	-1.77	4.38	0.41
Outcome: Total right-sided mSS				
Left-handedness	3.82	-0.54	8.17	0.09
Outcome: Total left-sided mSS				
Left-handedness	3.79	-0.52	8.09	0.09
Outcome: Right-hand mSS				
Left-handedness	2.98	-0.17	6.13	0.07
Outcome: Left-hand mSS				
Left-handedness	3.37	0.25	6.48	**0.04**
Outcome: Right-foot mSS				
Left-handedness	0.87	-0.74	2.49	0.29
Outcome: Left-foot mSS				
Left-handedness	0.44	-1.12	2.00	0.58

CI, confidence interval; mSS, modified Steinbrocker score
*Models are adjusted for baseline age, psoriasis duration, and BMI

Methods: We included PsA patients from a prospective observational cohort. Handedness was determined by self-report of the writing hand. To assess the relationship between handedness and peripheral joint damage, we used linear mixed models (LMMs) with the modified Steinbrocker score (mSS) as the outcome. We studied the association of handedness with total mSS, total hand or foot mSS, single-sided mSS, and single-sided hand or foot mSS. As no known confounders exist between the exposure (handedness) and the outcome (radiographic damage), models were adjusted only for variables that were imbalanced between groups and are known to be associated with peripheral damage.

Results: Among 359 patients, 324 (90.3%) were right-handed and 35 (9.7%) were left-handed **(Table 1)**. At baseline (clinic entry), the mean (SD) age was 43.7 (12.9) years. Compared to right-handed individuals, left-handed patients were older, had longer psoriasis duration, and higher BMI. In LMMs adjusted for these variables **(Figure 1 and Table 2)**, left-handedness was associated with a trend toward higher total mSS (β = 7.59, 95% CI -0.88 to 16.07). A significant association was observed with higher total hand mSS (β = 6.34, 95% CI 0.24 to 12.22). Similar trends were seen in side-specific analyses: left-handedness was associated with higher mSS on both right and left sides (β = 3.82, 95% CI -0.54 to 8.17; β = 3.79, 95% CI -0.52 to 8.09, respectively). Notably, left-handedness was linked to significantly higher left-hand mSS (β = 3.37, 95% CI 0.25 to 6.48), whereas the association with right-hand mSS was weaker (β = 2.98, 95% CI -0.17 to 6.13). Associations with foot mSS—both unilateral and bilateral—were less pronounced.

Conclusion: In PsA, where right-handedness predominates, left-handed individuals appear to experience greater peripheral joint damage, particularly in the hands, with a stronger effect observed in the left hand. Mechanical stress from daily activities—shaped by tools and environments predominantly designed for right-handed individuals—may contribute to this pattern. Potential cross-laterality (e.g., left-handedness with right-foot dominance) may attenuate observed patterns of foot involvement.

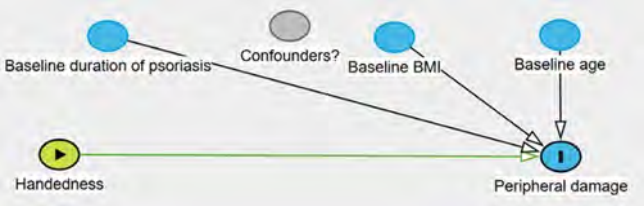

Figure 1. DAG showing the relationship between the exposure (handedness) and outcome (peripheral damage) in our model.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1405–1433) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Axial involvement is one of the key features of psoriatic arthritis (PsA) and is associated with increased disease burden. However, rates and predictors of structural damage progression in the spine in PsA are not well defined. This study aimed to explore associations between factors reflecting activity and severity across PsA domains and the development and progression of structural damage in the spine in a large longitudinal cohort.

Methods: We analyzed patients from a prospective longitudinal PsA cohort. Axial damage was assessed using two outcomes: (1) syndesmophyte development (binary), and (2) modified Stoke Ankylosing Spondylitis Spine Score (mSASSS, continuous). Cox proportional hazards models were used for syndesmophyte development, and generalized estimating equation (GEE) models were used for mSASSS progression. Variables reflecting activity/severity included cDAPSA, swollen joint count (SJC), SPARCC enthesitis score, dactylitis, nail involvement, PASI, modified Steinbrocker score, radiographic sacroiliitis score (sum of grades on two sides; range 0-8), BASDAI, ESR, and CRP. Multivariable models were adjusted for potential confounders, including age, sex, PsA duration, BMI, smoking status, decade of observation, HLA-B*27, HLA-A*29 (known to be associated with a reduced risk of axial disease), radiographic sacroiliitis score (where appropriate), NSAID use, and biologic or targeted synthetic (b/ts) DMARD use.

Lastly, we conducted sensitivity analyses stratified by observation period (pre-2000 vs. 2000 and beyond).

Results: The study included 1584 patients with PsA, with a median age of 45 years [IQR: 34.3–54.7]. At baseline (clinic entry), 218 patients (13.8%) had syndesmophytes. The median mSASSS was 0 [IQR: 0–0], while the mean (SD) was 1.6 (6.2). Over the study follow-up period, 166 of the 922 individuals (18.0%) without syndesmophytes at baseline who had repeat spine X-rays developed syndesmophytes, with a median time to development of 5.8 years [IQR: 2.4, 9.9].

Abbreviations: HR: Hazard Ratio, CI: Confidence Interval, PsA: Psoriatic Arthritis, BMI: Body Mass Index, SJC: Swollen Joint Count, cDAPSA: Composite Disease Activity Index for Psoriatic Arthritis, SPARCC: Spondyloarthritis Research Consortium of Canada, PASI: Psoriasis Area and Severity Index, BASDAI: Bath Ankylosing Spondylitis Disease Activity Index, ESR: Erythrocyte Sedimentation Rate, CRP: C-Reactive Protein, HLA: Human Leukocyte Antigen, NSAIDs: Non-Steroidal Anti-Inflammatory Drugs, DMARDs: Disease-Modifying Anti-Rheumatic Drugs. *Sum of the two sides (0-8)

Figure 1 shows a Kaplan-Meier curve of syndesmophyte-free survival, with the results of the univariable models shown in **Table 1**. In multivariable Cox models **(Figure 2A)**, higher ESR (HR 1.02, 95% CI 1.01–1.03) and radiographic sacroiliitis score (HR 1.19, 95% CI 1.07–1.32) were significantly associated with syndesmophyte development. In multivariable GEE

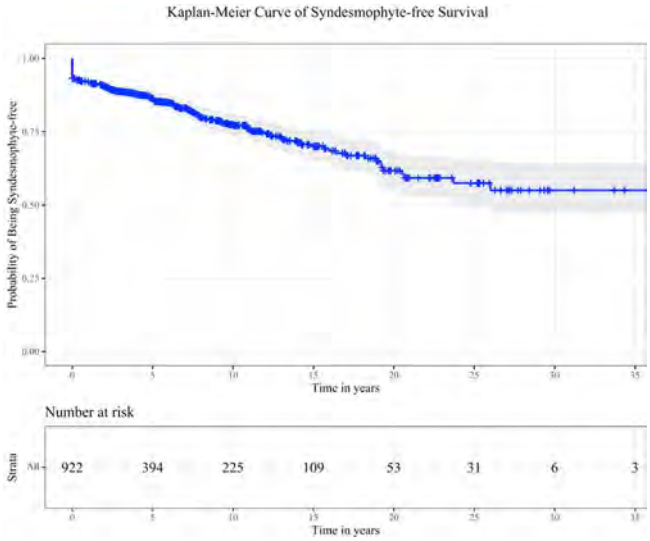

Figure 1. Kaplan–Meier survival analysis depicting the probability of remaining syndesmophyte-free over time.

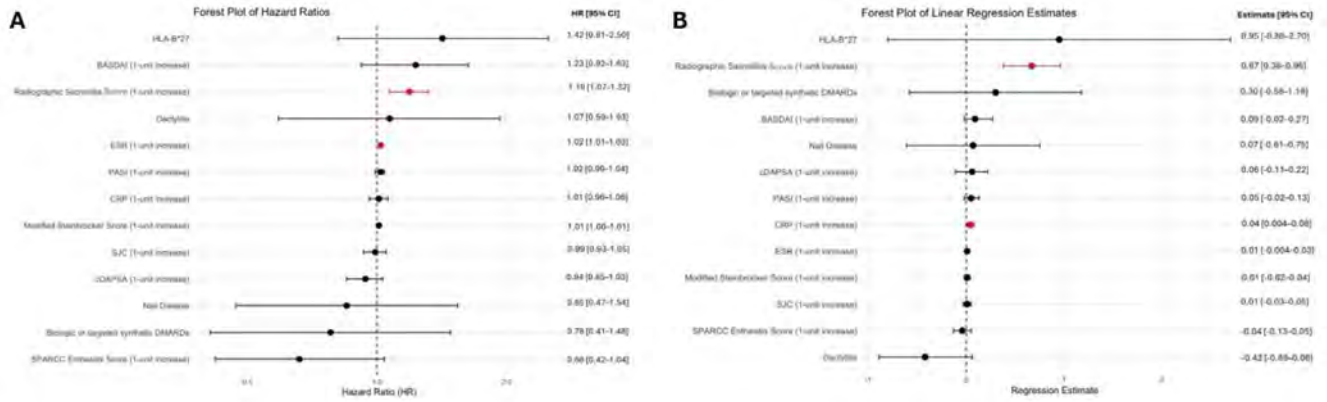

Figure 2. A: Multivariable Cox proportional hazards models identifying factors associated with syndesmophyte development in patients with psoriatic arthritis (PsA). B: Multivariable generalized estimating equation (GEE) models identifying factors associated with mSASSS progression among PsA patients. Abbreviations: HLA-B*27: Human Leukocyte Antigen B*27; BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; ESR: Erythrocyte Sedimentation Rate; PASI: Psoriasis Area and Severity Index; CRP: C-Reactive Protein; SJC: Swollen Joint Count; cDAPSA: Clinical Disease Activity Index for Psoriatic Arthritis; DMARDs: Disease-Modifying Antirheumatic Drugs; SPARCC: Spondyloarthritis Research Consortium of Canada.

models **(Figure 2B)**, higher CRP (estimate 0.04, 95% CI 0.004–0.08) and sacroiliitis score (estimate 0.70, 95% CI 0.40–1.00) were associated with mSASSS progression. Sensitivity analyses confirmed consistent findings across observation periods.

Conclusion: Systemic inflammation, reflected by elevated ESR and CRP levels, was the strongest predictor of radiographic spinal progression in axial PsA. Radiographic sacroiliitis also showed an association with structural damage in the spine in PsA.

Skin	1.8	5.3	2.4
Obstetric	2.0	1.4	1.4
Eye/Ear	0.2	0.3	0.2

Abbreviations: *AxSpA: axial spondylarthritis; PsA: Psoriatic Arthritis; IBD-A: Inflammatory Bowel Disease.*

Background/Purpose: Axial spondylarthritis (AxSpA), psoriatic arthritis (PsA), and inflammatory bowel disease-associated arthritis (IBD-A) are chronic inflammatory conditions with systemic involvement, leading to substantial morbidity and health-care utilization. There is a paucity of national-level data on reasons for hospitalizations in patients with these conditions. We aimed to identify major diagnostic categories for hospitalizations and top reasons for hospitalization among patients with AxSpA, PsA, and IBD-A, using a large United States population-based database.

Methods: We conducted a retrospective cohort study using the National Inpatient Sample (NIS) from 2016 to 2020. The NIS is the largest inpatient hospitalization database in the U.S., representing 20% of hospitalizations from all non-federal acute care hospitals. We identified patients with a primary or secondary diagnosis of AxSpA, PsA, or IBD-A using ICD-10 codes. Principal diagnoses for hospitalization were analyzed and categorized into major diagnostic categories. Weighted analyses were performed to calculate national estimates of hospitalization reasons and determine the top principal diagnoses for each disease group.

Table 3: Most Common Principal Diagnoses among Spondylarthritis Hospitalizations in NIS 2016-2020

Disease Group	Five Most Prevalent Principal Diagnosis (% hospitalizations)				
AxSpA n= 139130	Sacroiliitis, not elsewhere classified 7.6%	Sepsis, unspecific 5.3%	Acute kidney failure 1.3%	Pneumonia 1.2%	Primary OA of hip, unilateral 1.0%
PsA n=223745	Sepsis, unspecified 6.5%	Primary OA of knees 3.5%	NSTEMI 1.7%	Pneumonia 1.6%	Acute kidney failure 1.5%
IBD-associated arthritis N=1880	Ulcerative Colitis 12.2 %	Sepsis 10.6%	Crohn's Disease with and without complications 6.0%	Enterocolitis due to Clostridium difficile with and without toxic megacolon 4.4%	Primary Osteoarthritis of Right Shoulder 1.9%

Abbreviations: *AxSpA: axial spondylarthritis; PsA: Psoriatic Arthritis; IBD-A: Inflammatory Bowel Disease.*

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: A total of 139,130 AxSpA, 223,745 PsA, and 1,880 IBD-A hospitalizations were analyzed. Demographics for the study cohort appear in Table 1. The top five most frequent major diagnostic categories for each group are summarized below [Table 2]:

- **AxSpA:** 1) Rheumatological disorder, 2) Injury/Poisoning, 3) Gastrointestinal disorders, 4) Cardiovascular disease, 5) Infections.
- **PsA:** 1) Cardiovascular disease, 2) Rheumatological, 3) Gastrointestinal disorders, 4) Infections, 5) Injury/Poisoning.
- **IBD-A:** 1) Gastrointestinal disorders, 2) Rheumatological disorder, 3) Infection, 4) Respiratory conditions, 5) Injury/Poisoning.

The leading principal diagnoses [Table 3] for AxSpA included sacroiliitis (7.6%), sepsis (5.3%), and acute renal injury (1.3%). For PsA, the top principal diagnoses included sepsis (6.5 %), primary osteoarthritis of the knee (3.5%), and non-ST-elevated myocardial injury (1.7 %). IBD-A population was most frequently admitted for ulcerative colitis (12.2%), followed by sepsis (10.6%), and then Crohn's disease with and without complications (6.0%)

Conclusion: Hospitalization patterns in AxSpA, PsA, and IBD-A differ by disease type but share common themes of rheumatological, cardiovascular disease, infectious, injury/poisoning, and gastrointestinal involvement. These findings may highlight key areas for targeted management and preventive efforts to optimize healthcare resource utilization and improve quality care for patients

Impact of Type 2 Diabetes Mellitus on Cardiovascular Outcomes in Patients with Ankylosing Spondylitis on NSAID Therapy

Godbless Ajenaghughrure[1], Sila Mateo Faxas[2], **Gurjot Singh**[3], Nirys Mateo Faxas[4], Kim Nguyen[3], Nicole Tejeda[5] and Kimberly Ramirez Bonetti[6], [1]Trihealth Good Samaritan Hospital, Cincinnati, OH, [2]Good Samaritan Hospital, Cincinnati, OH, [3]Trihealth Good Samaritan Hospital, Cincinnati, [4]Independent Author, Santo Domingo, Dominican Republic, [5]Independent Author, Cincinnati, [6]Independent Author, cincinnati, OH

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1405–1433) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with ankylosing spondylitis (AS) have increased cardiovascular risk, potentially exacerbated by NSAID therapy. However, the additional impact of Type 2 diabetes mellitus (T2DM) in this population remains poorly characterized.

Methods: We conducted a retrospective cohort study using the TriNetX global federated health research network across 100 healthcare organizations. Two cohorts of adult patients (18-99 years) with AS on non-salicylate NSAIDs were analyzed: Cohort 1 with T2DM (n=9,499) and Cohort 2 without T2DM (n=9,499), propensity-score matched for demographic and clinical characteristics. Cardiovascular outcomes were assessed over a 5-year follow-up period (1825 days) after index date.

Results: Patients with AS on NSAID therapy and comorbid T2DM demonstrated significantly higher rates of major adverse cardiovascular events compared to matched patients without T2DM. Specifically, risk ratios (RR) and hazard ratios (HR) were significantly elevated for: mortality (RR 2.03, 95% CI 1.79-2.29; HR 1.95, 95% CI 1.72-2.21), cardiac arrest (RR 3.51, 95% CI 2.44-5.06; HR 3.37, 95% CI 2.34-4.86), atrial fibrillation (RR 2.97, 95% CI 2.60-3.39; HR 2.92, 95% CI

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

2.55-3.35), heart failure (RR 2.73, 95% CI 2.48-2.99; HR 2.76, 95% CI 2.50-3.04), cerebral infarction (RR 2.29, 95% CI 1.93-2.73; HR 2.59, 95% CI 2.02-3.32), and ventricular arrhythmias (RR 2.16, 95% CI 1.73-2.73; HR 2.09, 95% CI 1.66-2.64). Additionally, patients with T2DM had significantly higher rates of requiring pacemaker implantation (RR 2.44, 95% CI 2.09-2.84) and experiencing pulmonary complications including pulmonary hypertension (RR 2.26, 95% CI 1.93-2.64) and pulmonary embolism (RR 3.55, 95% CI 2.36-5.36).

Conclusion: T2DM significantly amplifies cardiovascular risk in patients with ankylosing spondylitis on NSAID therapy. This represents the largest analysis to date quantifying this increased risk across multiple cardiac outcomes. These findings highlight the need for enhanced cardiovascular monitoring and risk mitigation strategies in this high-risk population

Abstract Number: 1419

Effectivenss of an educational program on non-radiographic axial spondyloarthritis

Hideto Kameda[1], Toshihide Shuto[2], Akimichi Morita[3], Yasuharu Nakashima[4], Kiyoshi Matsui[5], Masaaki Mori[6] and Masahiro Yamamura[7], [1]Department of Internal Medicine, Toho University, Tokyo, Japan, [2]Chiyoda Hospital, Hyuga, Japan, [3]Department of Geriatric and Environmental Dermatology, Graduate School of Medical Sciences, Nagoya City University, Nagoya, Japan, [4]Kyushu University, Fukuoka, Japan, [5]Amagasaki Chuo Hospital, Amagasaki, Japan, [6]Institute of Science Tokyo, Tokyo, Japan, [7]Okayama Saiseikai General Hospital, Okayama, Japan

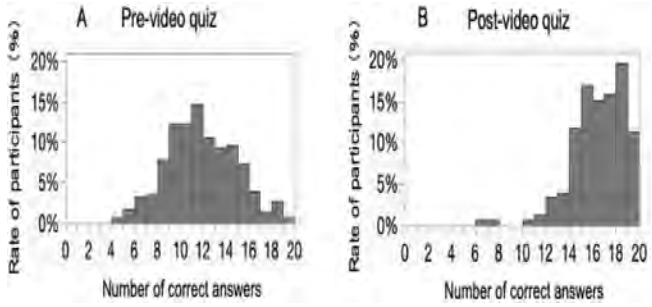
SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1405–1433) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Non-radiographic axial spondyloarthritis (nr-axSpA) is a relatively new disease concept. We developed an educational program to promote early and appropriate referral to specialists based on a correct understanding of nr-axSpA. The objective of this study was to analyze the outcomes and challenges identified through the educational program.

Methods: The program targeted physicians in internal medicine, orthopedics, and dermatology, as well as other healthcare professionals. A 30-minute educational video on nr-axSpA was uploaded to the official website of the society. A 30-question quiz was created to assess knowledge before and after watching the video. Upon accessing the website, participants first answered 20 questions. After completing this initial quiz, they were allowed to watch the video. Following the viewing, they answered another set of 20 questions—10 of which were identical to those from the pre-video quiz, and the remaining 10 were new. Anonymous response data were analyzed to assess changes in correct answer rates before and after the video, and to explore pre-video correct answer rates by participant background.

Results: From April 2023 to September 2024, 420 healthcare professionals registered for the program. Membership distribution was as follows: 88% were members of the Japan College of Rheumatology, 25% of the Japanese Orthopaedic Association, 11% of the Japan Spondyloarthritis Society, and 4% of the Japanese Society for Psoriasis Research. A total of 316 participants completed the pre-video quiz, with a median correct answer rate of 55% (range: 20–100%; Figure 1A). After viewing the video, 180 participants completed the post-video quiz, achieving a median correct answer rate of 80% (range: 30–100%; Figure 1B). A paired test revealed a significant improvement in the correct answer rate from 57% to

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



The distribution of the correct answer rates of the pre- and post-video quiz.

80% ($p < 0.0001$). For the identical 10 questions, the correct response rate significantly increased from 55% before viewing to 86% after viewing ($p = 0.0033$). Even for different questions, there was a trend toward improvement, with correct responses increasing from 61% before viewing to 75% after viewing ($p = 0.20$). No correlation was observed between years of professional experience in spondyloarthritis and pre-video correct answer rates (correlation coefficient $r^2 = 0.0042$).

Conclusion: The educational program demonstrated clear benefits, indicating that when nr-axSpA is suspected, referral to specialists or clinicians with relevant training–rather than relying primarily on years of clinical experience in spondyloarthritis–may be both appropriate and advantageous.

Background/Purpose: Ankylosing spondylitis (AS) is a chronic inflammatory disease with systemic complications that may contribute to increased mortality risk. This study examines the characteristics and causes of in-hospital death among adult AS patients in the United States using a claims-based database.

Methods: A retrospective analysis of all adult hospitalizations with a diagnosis of AS (ICD-10: M45) in the National Inpatient Sample (NIS) database (2017 - 2021) was conducted. Descriptive statistics were used to analyze demographics, hospital length of stay (LOS), insurance status, total hospital charges, and causes of death categorized by ICD-10 codes.

Results: Of the 96,330 adult AS hospitalizations in the 2017 - 2021 NIS database, 2,390 (2.5%) died in the hospital (Table 1). AS patients who died compared to those discharged alive were more likely to be male (79.7% vs. 62.9%; $p < 0.001$), were older (median age 73 vs. 62 years; $p < 0.001$), had longer median hospital LOS (7 vs. 4 days; $p < 0.001$), had higher median total hospital charges ($104,275 vs. $44,345; $p < 0.001$), more Medicare (73.6% vs. 54.6%; $p < 0.001$), less Medicaid (4.8% vs. 10.3%; $p < 0.001$), less private insurance (16.3% vs. 30.1%; $p < 0.001$), and a lower percentage of the top household income quartile (18.6% vs. 24.9%; $p = 0.002$). Racial distribution did not significantly differ between groups.

The causes of in-hospital death of AS patients as determined by their "principal ICD-10 billing diagnosis category" were as follows: injury/poisoning (29.1%), infections (22.0%), cardiovascular (CV) diseases (11.3%), respiratory diseases (11.1%), hematologic/oncologic conditions (7.5%), gastrointestinal diseases (5.0%), genitourinary diseases (3.1%), factors influencing health status (1.5%), rheumatologic diseases (1.3%), neurologic diseases (0.8%), endocrine diseases (0.6%), and other causes (0.6%) (Table 2).

The most common specific injury diagnosis was traumatic subdural hemorrhage (ICD-10: S06.5X0A) (table 3), followed by fractures of the thoracic (ICD-10: S22.089A, S22.088A, S22.078A, S22.069A, S22.079A), cervical (ICD-10: S12.300A, S12.400A, S12.490A, S12.200A), and lumbar vertebrae (ICD-10: S32.019A). Severe spinal cord injuries (ICD-10: S14.115A, S24.102A, S24.103A, S14.106A), traumatic subarachnoid hemorrhage (ICD-10: S06.6X0A), and thoracic trauma, including hemothorax and hemopneumothorax (ICD-10: S27.1XXA, S27.2XXA), were also frequent (Table 3).

Table 1. Descriptive Characteristics of Adult Ankylosing Spondylitis Patients from 2017 - 2021 National Inpatient Sample Database (n = 96,330). Abbreviations: AS = ankylosing spondylitis; n = number; IQR = interquartile range

Characteristic	Discharged Alive (n= 93,940)	In-Hospital Deaths (n=2,390)	P value
Male, n (%)	59,085 (62.9%)	1,905 (79.7%)	<0.001
Age, median (IQR) years	62 (49-73)	73 (64-81)	<0.001
Age Distribution, n (%)			
18-40 years	11,860 (12.6%)	35 (1.5%)	<0.001
40-60 years	29,445 (31.3%)	350 (14.6%)	<0.001
60-80 years	41,325 (44.0%)	1,330 (55.6%)	<0.001

Conclusion: Our analysis represents the only report to date to comprehensively study AS inpatients on a U.S. national level. Over 1 of 50 AS hospitalizations ended in death, and they were predominantly older males, most of whom had Medicare insurance. Injury-related conditions were the most frequent cause of death. The leading injury diagnoses were brain bleeds, vertebral fractures, and spinal cord injuries. Further research is needed to explore the factors contributing to injuries and falls in AS patients.

Impact of Psoriatic Arthritis Disease Activity and Fatigue on Subjective Cognitive Decline ("Brainfog")

Lily Mikolajczak[1], Helena Kuhn[1], Leslie Harrold[2] and George Reed[3], [1]Kuchnir Dermatology and Dermatologic Surgery, Milford, MA, [2]CorEvitas, Northborough, MA, [3]University of Massachusetts Chan Medical School, Worcester, MA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1405–1433) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with psoriatic arthritis often report having brain fog, describing symptoms such as forgetfulness, difficulty thinking and memory issues. It has been hypothesized that these symptoms, consistent with subjective cognitive decline, may be the result of fatigue, depression, associated chronic pain and inflammation. We proposed to explore the association between disease activity and subjective cognitive decline when taking into account patient factors, comorbidities and PsA characteristics.

Methods: We identified patients with a diagnosis of PsA from the CorEvitas PsA/SpA registry with a visit between 7/22/2013-10/20/2024 that included information on Minimal Disease Activity (MDA) and confounding covariates of interest. MDA assesses joint pain, swelling, skin involvement, physical function and pain, making it a comprehensive assessment of disease activity. Subjective Cognitive Decline (SCD) or "Brainfog", was defined as the patient indicating problems thinking/confusion or problems with memory/forgetfulness. The association of MDA (achievement of ≥5 of the 7 criteria) with SCD was estimated using logistic regression models controlling for demographic (age, sex, education), behavior (smoking, drinking), BMI, disease duration, modified Charlson Comorbidity Index, fibromyalgia, medication use (narcotics, analgesics, NSAIDs, biologic/targeted synthetic DMARDs), patient reported fatigue, depression, and anxiety. Odds Ratios (ORs) with 95% confidence intervals are presented to estimate risk of SCD in those not in MDA vs those in MDA. The proportion with SCD is estimated based on the number of MDA criteria met.

Results: There were 4077 eligible PsA patients. Of those, 315 (7.7%) were missing at least one covariate of interest. Of the remaining 3762 patients, 385 or 10.2%, indicated SCD (3% for those in MDA and 16% in those not in MDA). Table 1 breaks out selected covariates by SCD or not. Those reporting SCD were more often female, had more comorbidities including fibromyalgia, as well as fatigue, anxiety and depression. Figure 1 illustrates ORs comparing risk of SCD in those not in MDA vs those in MDA for a series of tiered models that illustrate the adjusted ORs for nested inclusion of key covariates. Unadjusted OR= 5.33 [95% CI: 4.0, 7.10] and after adjustment for demographics, behavior, BMI, comorbidities, and medications OR=4.34 [3.21, 5.87]. Adding "Fatigue" reduces the OR=2.15 [1.54, 3.01]. Patient depression and anxiety had less

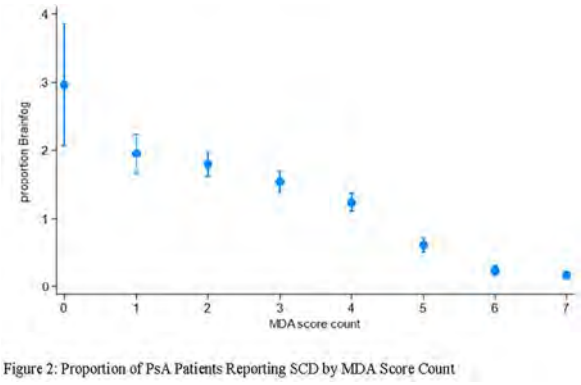

Figure 2: Proportion of PsA Patients Reporting SCD by MDA Score Count

Figure 2.

of an impact (OR= 3.53 and 3.72, respectively). Figure 2 illustrates the proportion of SCD by the number of criteria met for achieving MDA showing decreasing SCD with additional indicators of MDA.

Conclusion: Not achieving MDA shows a high risk of SCD (OR >4) adjusting for differences in patient characteristics. Adjusting for fatigue reduces the associated risk of SCD with not being in MDA, suggesting a potential mechanism for the impact of disease activity. However, it does not completely explain the association. The monotonic association of SCD with MDA markers illustrates this is not a threshold effect. Additional longitudinal analyses are planned to elucidate the impact of PsA disease activity on a patient's cognitive well-being.

Work-productivity loss (WPAI)	0.64	**0.001**	0.70	**0.001**

Abbreviations: VAS = visual analogue scale; BASDAI = Bath Ankylosing Spondylitis Disease Activity Index; BASFI = Bath Ankylosing Spondylitis Functional Index; ASDAS = Ankylosing Spondylitis Disease Activity Score; ESR = erythrocyte sedimentation rate; CRP = C-reactive protein; ASAS-HI = Assessment of SpondyloArthritis International Society-Health Index; WPAI = Work Productivity and Activity Impairment Questionnaire.

Background/Purpose: DificuLtAR and ModAL, two spanish-language questionnaires that assess work difficulties and workplace adaptations, were originally developed and validated for rheumatoid arthritis (RA). Their performance in axial spondyloarthritis (axSpA) remains unknown.

Objective: (1) to validate DificuLtAR and ModAL in axSpA (2) Identify factors associated with work difficulties and the use of workplace modifications and adaptations reported by employed patients with axSpA.

Methods: An adaptation of the DificuLtAR for EspAax (DificuLtAx) questionnaire was made, Both questionnaires were applied to patients ≥18 years old, both genders, with a diagnosis of axSpA (ASAS-2009) and actively working. Cronbach's alpha (DifficuLtAx=0.92 and ModAL=0.83) and construct validity were explored through factor analysis. The Eigenvalue values for a single factor (DificuLtAx=0.89 and ModAL=0.81) and correlation coefficients greater than 0.40 for all questions of both questionnaires after varimax rotation were aceptable. Spearman correlation coefficients, Mann-Whitney or Kruskal-Wallis tests, were calculated. ($p < 0.05$).

Results: 72 patients were included, 72% men, median age 42 years (IQR 37-53), disease duration 97 months (IQR 40-156), 54% B27positive, and 67% radiographic. The median ASDAS-PCR 2 (IQR 1-3) and BASFI 3.5 (IQR 2-5). 58% were in formal salaried employment and the median WPAI (labor productivity) was 0 (IQR 0-44). The greatest difficulties were sitting or standing for prolonged periods of time (75%) and working crouched (84%) and the most frequent modifications were taking breaks (78%) and furniture changes (45%). The median DificuLtAx 5 (IQR 2-9) and ModAL 3.5 (IQR 2-6), with a correlation between both of rho: 0.67 (p 0.001). See correlations Table 1. Female gender 5.5 vs 3.5 (p 0.001) and boss's knowledge of the disease 4 vs 3 (p 0.05), were associated with greater modifications.

Conclusion: DificuLtAx and ModAL showed good reliability and construct validity. The main work difficulties were to remain seated or standing and to work crouching/kneeling, and the most frequent modifications were to take breaks and modify the furniture; these were more common in women and in those in whom the boss was aware of the disease.

Genetic and Cytokine Correlates in Ankylosing Spondylitis: rs27038 polymorphism of ERAP1 gene and IL-17 Interactions : A Case-Control Study

Meghna Gavali[1], Husna Fatima[2], Bhavya Sirivelu[3], Nishanth S[3] and Noorjahan M[3], [1]nizam's institute of medical sciences ,Hyderabad, Hyderabad, Telangana, India, [2]Nizami Institute of Medical Sciences, Hyderabad, Telangana, India, [3]Nizam's Institute of Medical Sciences, Hyderabad, Telangana, India

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1405–1433) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Ankylosing Spondylitis (AS) is a chronic inflammatory disorder primarily affecting the axial skeleton and associated with HLA-B27. Non-HLA genes, including ERAP1 (Endoplasmic Reticulum Aminopeptidase 1), also play a role in pathogenesis by influencing peptide trimming and cytokine regulation. The rs27038 SNP in ERAP1 may affect antigen processing and inflammatory responses. IL-17, a key proinflammatory cytokine, is central to AS immunopathology. This study investigates the association of ERAP1 rs27038 SNP with AS susceptibility, IL-17 levels, and disease severity.There is limited data on ERAP1 gene polymorphisms and IL-17 levels in Indian patients with Ankylosing Spondylitis, despite genetic and immunological differences across populations. This study addresses the gap by exploring the association of ERAP1 rs27038 and IL-17 in South Indian AS patients, aiming to improve early diagnosis and guide population-specific therapeutic approaches.

Methods: A case-control study included 75 AS patients (modified New York criteria) and 25 age- and sex-matched healthy controls from a tertiary care centre in South India . Clinical parameters (BASDAI, ESR, hsCRP) were recorded. Genomic DNA was extracted, amplified using qPCR and rs27038 SNP genotyping was done via Sanger's sequencing. Serum IL-17 was quantified by ELISA. Genotypic and allelic frequencies were compared using Chi-square test. IL-17 levels were compared using the ManWhithey U test. Correlations with disease activity were analyzed using Spearman's rank correlation.

Results: Serum IL-17 levels were significantly elevated in AS patients (median 48.39 pg/mL) compared to controls (median 8.78 pg/mL, p=0.0002). The ERAP1 rs27038 polymorphism showed significant association with AS susceptibility, with the A allele being more frequent in cases than controls (22% vs. 8%, p=0.03, OR=3.15, 95% CI: 1.05-9.24). Serum IL-17 demonstrated good diagnostic performance (AUC=0.848, 95% CI: 0.755-0.917), comparable to hsCRP (AUC=0.843). Il-17 showed a significant correlation with hsCRP levels (rho=0.353, p=0.0009), but did not show association with BASDAI/ASDAS (rho=0.120, p=0.34; rho=0.13, p=0.31 respectively). Logistic regression identified HLA-B27 positivity (OR=38.25), elevated ESR (OR=1.095), and Patient Global Assessment (OR=1.94) as independent predictors of AS. However, no significant associations were found between rs27038 genotypes and IL-17 levels.

BIOLOGICAL AGENTS: Adalimumab	33 (44)

Conclusion: Our findings support the role of both IL-17-mediated inflammation and ERAP1 genetic variants in AS pathogenesis. Serum IL-17 could serve as a valuable biomarker for AS diagnosis, potentially enabling earlier detection and intervention. The ERAP1 rs27038 polymorphism contributes to AS susceptibility but appears to act through pathways independent of IL-17 regulation. These results provide insights into AS pathogenesis and suggest potential applications in diagnosis, risk assessment, and targeted therapies.

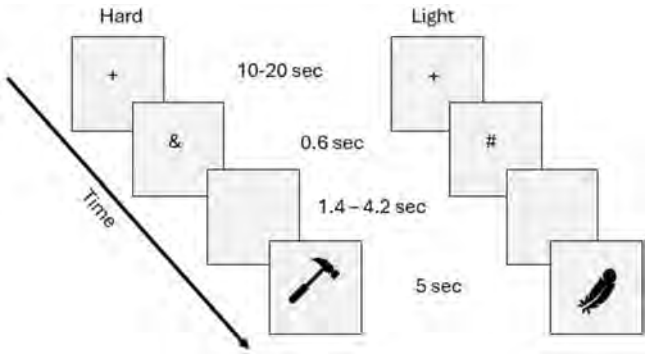

Fig. 1. Illustration of the fMRI tactile pressure task. The painful and light trials differ only in the stimulus cues (&,#) and the stimulus pressure. The crosshair is present during the variable inter-trial interval. The post-cue interval (1.4 – 4.2s) is jittered to permit deconvolution of the cue and stimulus hemodynamic responses.

Background/Purpose: Chronic pain is one of the common causes of disability in axial spondyloarthritis (axSpA). The mechanism behind this pain is not well understood, hindering the development of safe and efficacious treatments. The aim of this exploratory study is to examine differences in brain responses to painful stimuli between axSpA patients and healthy controls (HC).

Methods: Six axSpA patients and 6 age-and-sex matched HC underwent functional brain magnetic resonance imaging (fMRI) while tactile pressure to the thumbnail was applied: a light pressure (LSTIM) that is perceived but not painful, and a hard pressure (HSTIM) rated as a 1 pain, on a scale of 0-10 (Fig 1). A visual cue appeared 1.4 – 4.2 seconds prior to the stimulus, indicating a light or hard level of the subsequent stimulus. Analysis of fMRI data was exploratory due to small sample size. AxSpA and HC groups were combined to maximize power to detect signal changes associated with the pressure task. Areas with increased signal were used to create regions of interest (ROIs), which were then analyzed for group effects, using repeated measures mixed effects models.

Results: AxSpA patients were 50% females, had a mean age of 40 and mean ASDAS-CRP score of 2.7. The visual cue conditions produced increased signal throughout the brain, including areas in the occipitotemporal pathway, anterior insula, frontal operculum, medial superior frontal gyrus, and parietofrontal (PF) complex. Signal decreases were seen in areas typically associated with the default mode network (DMN). The tactile stimulation produced increased signal throughout the

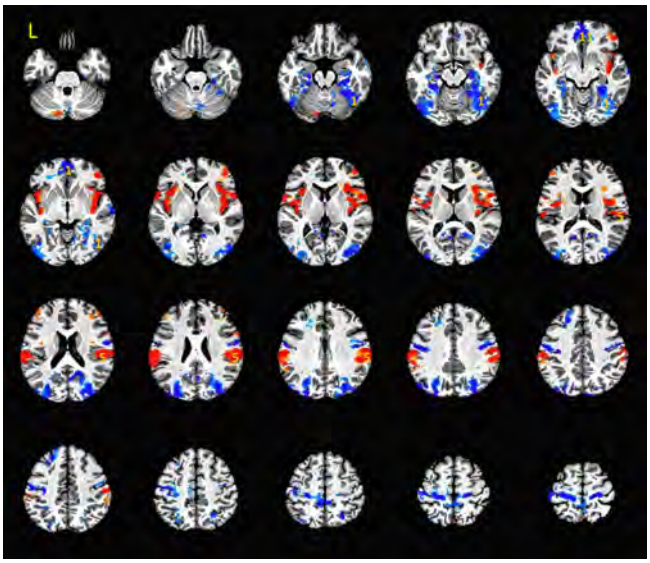

Fig. 2: Combined whole-brain analysis showing hyperactive (red) and hypoactive (blue) regions of interest (ROIs) following pressure stimulus. Numbers indicate ROIs with significant effects shown in Fig. 3.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Fig. 3. Signal response achieving statistical significance ($p<0.05$) of ROIs to LSTIM (blue) and HSTIM (yellow) in axSpA and HC. ROI: region of interest. LSTIM: light pressure. HSTIM: hard painful pressure. axSpA: axial spondyloarthritis. HC: healthy control.

insula bilaterally, somatomotor areas along the central sulcus, fusiform gyrus, middle frontal gyrus, and the area at the PF junction (Fig 2). Decreased activity was seen in occipitotemporal areas, occipitoparietal areas, frontal pole, and precentral sulcus, bilaterally.

When comparing axSpA vs HC responses to LSTIM and HSTIM (within and between groups), there were statistically significant differences in 3 ROIs: the fusiform gyrus, the PF junction, and the frontal pole (Fig 3). At the level of the fusiform gyrus (involved in visual processing and pain anticipation), axSpA patients had a decreased signal over time in response to HSTIM compared to LSTIM, while the opposite was seen in HC. The PF junction, which is part of the salience network (SN), is involved in cognitive functions and pain processing. AxSpA patients had more pronounced response with HSTIM compared to LSTIM at the level of the PF complex compared with no difference in stimulus response in HC. The frontal pole, including the anterior cingulate cortex and medial prefrontal cortex, and part of the DMN, is involved in cognitive functions and modulating chronic pain. In the axSpA group, there was an increased signal over time in response to HSTIM compared to LSTIM; this signal was decreased in HC.

Conclusion: In this proof-of-concept exploratory study, patients with active axSpA had altered brain response to painful stimuli at regions encompassing SN and DMN, which have been previously implicated in chronic pain conditions. Further studies are planned to characterize central nervous system dysregulation and its role in chronic pain in larger cohorts of axSpA patients.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1405–1433) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Psoriatic arthritis (PsA) significantly affects physical function (PF), which is influenced by both disease activity and structural damage. Despite its clinical importance, there is limited quantitative data on how radiographic damage impacts PF in PsA. This study aimed to assess the relationship between radiographic damage and PF in PsA patients.

Methods: We analyzed data from a large, prospectively enrolled cohort of PsA patients followed since 1978. Assessments were performed every six months, including evaluations of disease activity, patient-reported outcomes, and treatment details. Radiographs were obtained every two years. Disease activity was measured by swollen joint count (SJC), and PF was assessed using the Health Assessment Questionnaire (HAQ; 0-3) and the Short Form 36 (SF-36) PF domain score (0-100). Radiographic damage was scored using the modified Steinbrocker scoring system (mSS, 0-168). Only patients with PF data collected within three months of their radiographs were included in the analysis.

Baseline characteristics at enrollment were summarized. Cumulative probability plots were created to illustrate visit-to-visit changes in both mSS scores and PF scores. Multivariable linear mixed models (LMM) were used to examine the association between PF measures (HAQ and SF-36 PF) and mSS, adjusting for covariates including age at PsA diagnosis, disease activity (SJC at the time of radiographs), sex, and disease duration. Further, we assessed the severity of joint damage (any joint graded 2, 3, or 4) and the number of severely damaged joints (graded 2, 3, or 4) per patient for their association with SF-36 PF using LMM, adjusting for SJC, age at PsA diagnosis, sex, and disease duration.

Results: Among 1,177 patients, the mean age at enrollment was 44.61 ± 12.76 years, and 657 (55.8%) were male. The median mSS was 2 (IQR 0, 8.5), HAQ was 0.62 (IQR 0.12, 1.12), and SF-36 PF score was 60 (IQR 35, 85) at enrollment. The mSS change scores in relation to the corresponding HAQ and SF-36 PF change scores are presented in Figure 1.

The mSS showed significant associations with both HAQ (b = 0.003, 95% CI 0.002 to 0.004) and SF-36 PF (-0.10; 95% CI -0.15 to -0.05), after adjusting for disease activity (SJC), age at PsA diagnosis, sex, and disease duration (Table 1). While the presence of a damaged joint was not significantly associated with PF, the number of severely damaged joints (graded 2, 3,

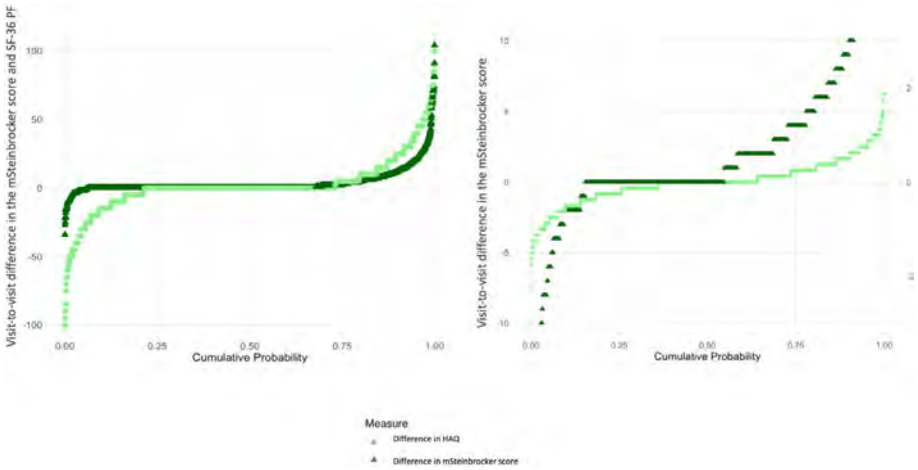

Figure 1: Cumulative probability plots reflecting visit-to-visit change scores of the modified Steinbrocker score with SF-36 PF (A) and HAQ (B)

Table 1: Association between mSteinbrocker score and physical function using multivariable linear mixed models

	HAQ, 0-3				SF-36 PF, 0-100			
	Estimate	95% CI		p-value	Estimate	95% CI	p-value	
Modified Steinbrocker's score, 0-168	0.003	0.002	0.004	<0.001	-0.10	-0.15	-0.05	<0.001
SJC, 0-68	0.039	0.034	0.044	<0.001	-1.54	-1.77	-1.30	<0.001
Age at PsA diagnosis, years	0.005	0.003	0.008	<0.001	-0.19	-0.30	-0.07	0.002
Sex, male	-0.298	-0.365	-0.231	<0.001	12.30	9.35	15.26	<0.001
Duration of PsA, years	0.006	0.004	0.009	<0.001	-0.20	-0.31	-0.08	<0.001

Abbreviations: SF: Short Form, HAQ: Health Assessment Questionnaire, SJC: Swollen Joint Count, PsA: Psoriatic Arthritis

or 4) per patient was significantly associated with both HAQ (b = 0.01, 95% CI 0.001 to 0.01) and SF-36 PF (-0.22, 95% CI -0.37 to -0.07).

Conclusion: Structural damage, as quantified by the mSS , is significantly associated with physical function in PsA, independent of disease activity and other factors. Specifically, a one-unit increase in the mSS corresponds to a 0.003 increase in HAQ and 0.10 decrease in SF-36 PF. While the presence of a single damaged joint does not notably affect PF, the cumulative number of severely damaged joints is significantly associated with a decline in PF. These findings underscore the importance of early diagnosis and effective management of PsA to preserve physical function and prevent structural damage.

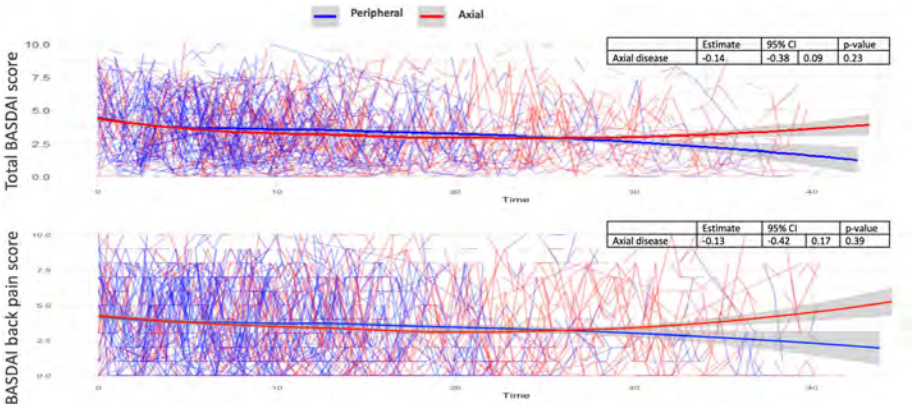

Figure 1: Smooth trajectories of BASDAI and BASDAI back pain over follow-up

Background/Purpose: The Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) is the most commonly used tool to assess axial disease in psoriatic arthritis (PsA). However, five of its six questions focus on general disease activity rather than being specific to axial involvement. Furthermore, back pain itself is a non-specific symptom and is potentially affected by many factors. This raises concerns regarding the utility of the BASDAI back pain question for monitoring axial disease in a multidomain disease like PsA. We aimed to evaluate the utility of the BASDAI and its back pain subscore in assessing axial disease in patients with PsA.

Methods: Patients with available BASDAI scores (done every 6 months after 1999) were selected from a large longitudinally assessed PsA cohort initiated in 1978. These patients are followed every six months with comprehensive documentation of demographic data, clinical and patient-reported outcomes, and treatment details. Axial disease was defined as sacroiliitis (modified New York criteria) and/or syndesmophytes. The trend of BASDAI and back pain was studied across axial and peripheral subgroups over the follow-up duration. The association of axial disease with total BASDAI and BASDAI back pain scores was studied using multivariable linear mixed models (LMM) for the whole cohort, adjusting for swollen joint count (SJC), tender joint count (TJC), enthesitis, dactylitis, Psoriasis Area and Severity Index (PASI), modified Steinbrocker score, and drug use. Drivers of BASDAI and BASDAI back pain scores were studied in the peripheral and axial subgroups using multivariable GEE models.

Results: Of 1,059 patients, 610 (57.6%) had peripheral disease, 449 (42.39%) had axial involvement at any time over their follow-up. The mean age was 44.4 years (SD 12.8), with 55.9% being males.

The BASDAI and back pain scores were similar between the axial and peripheral subgroups (Figure 1).

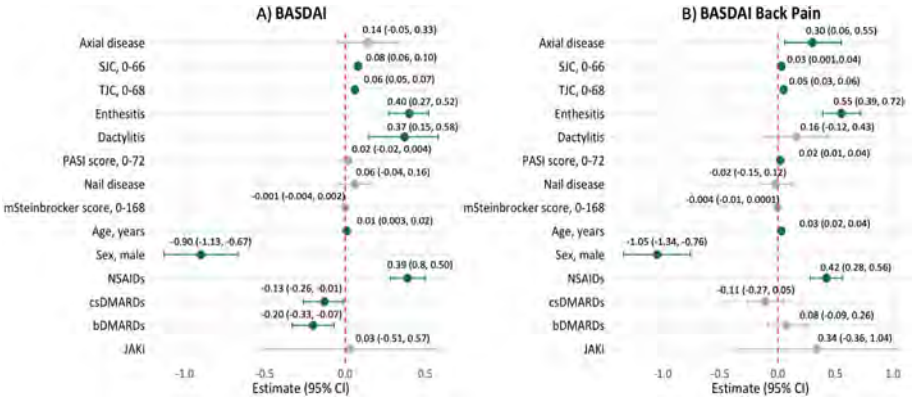

Figure 2: Multivariable linear mixed models for association of axial disease with BASDAI and BASDAI back pain

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

When compared to patients with peripheral disease, the presence of axial involvement did not show an association with BASDAI [β -0.14 (-0.05 to 0.33)] after adjustment for confounders. However, the presence of axial disease was associated with a small but significant effect on the BASDAI back pain subscore [β 0.3 (0.06 to 0.55)] as compared to peripheral disease. (Figure 2)

Among patients with axial disease, higher BASDAI back pain scores were positively associated with TJC [β 0.06 (95% CI: 0.074–0.08)], enthesitis [0.49 (0.25-0.74)], PASI score [0.03 (90.02–0.05)], along with age and sex. In patients with peripheral disease only, BASDAI back pain was significantly driven by SJC [0.05 (0.01-0.08], TJC [0.05 (0.03-0.07)], enthesitis [0.62 (0.40-0.84)] and PASI score [0.04 (0.02-0.07)] along with age and sex.

Conclusion: BASDAI and BASDAI back pain scores are influenced by age, sex, peripheral joint (arthritis, enthesitis), and skin involvement in PsA, regardless of axial involvement. Similar factors drive this association in patients with axial and peripheral disease. These findings highlight that the BASDAI back pain question is not a reliable outcome measure for assessing axial disease in PsA

Background/Purpose: Patients with psoriatic arthritis (PsA) have an increased cardiovascular (CV) risk due to a higher prevalence of comorbidities and chronic systemic inflammation. In those with an inadequate response to conventional synthetic disease-modifying antirheumatic drugs, biologic therapy is recommended. Previous studies have shown that inhibition of proinflammatory cytokines, such as tumor necrosis factor (TNF)-α, interleukin (IL)-1, and IL-6, exerts beneficial effects on cardiac function and could prevent the development of atherosclerosis. However, current evidence remains limited. For this reason, we aim to associate the use of biologic therapy with the presence of subclinical atherosclerosis and left ventricular (LV) function in patients with PsA.

Methods: A Cross-sectional, descriptive, comparative study was conducted. Patients aged 30 to 75 with PsA who met the 2006 CASPAR Classification criteria were included. Those with CV disease history were excluded. Patients were divided into two groups: those without biologic therapy and those receiving biologic treatment for at least one month. Patients receiving biologic therapy were matched 1:1 based on age, sex, and the presence of at least two cardiovascular risk comorbidities.

Carotid ultrasound was performed on 98 participants, carotid plaque (CP) was defined as a diffuse carotid intima-media thickness (IMT) ≥1.2 mm or focal thickness ≥0.8 mm. The transthoracic echocardiogram was performed on 60 patients, which included left ventricular mass index (LVMI), relative wall thickness (RWT), and left ventricular ejection fraction (LVEF). Subclinical systolic dysfunction (SSD) of the left ventricle (LV) was defined as a global longitudinal strain (GLS) >-18%. Group distribution was evaluated using the Kolmogorov-Smirnov test. Comparisons were made using the Chi-square, T-student, or Mann-Whitney U tests. A p-value ≤0.05 was considered statistically significant.

Results: In both populations, most patients were women with anti-TNF therapy. Among the 98 patients who underwent carotid ultrasound (Table 1), the median duration of biologic treatment was 26 months (IQR 12–60). Dyslipidemia was significantly more prevalent in the biologic therapy group (p=0.041), while no significant differences were found for other comorbidities. The prevalence of CP was lower in patients not receiving biologic therapy (40.8%, p=0.54).

In the group of 60 patients who underwent echocardiography (Table 2), 30 were receiving biologic therapy, with a mean treatment duration of 44.0 ± 50.7 months. No significant differences in CV risk comorbidities were observed between groups. The LVMI was higher in patients without biologic therapy, but other echocardiographic parameters showed no statistically significant differences.

Conclusion: According to our data, biological therapy is not associated with the prevalence of carotid plaque or left ventricular function. However, this may be due to the short duration of biological therapy use among patients. While biologics are essential for managing disease activity, larger prospective studies are needed to determine their impact on CV risk assessment.

Ankylosing Spondylitis Related Mortality Trends in USA from 1999-2020: Analysis of CDC Wonder Database

Sanjana Thimmannagari[1], Shiamak Cooper[2], Asim Khanfar[1] and Candrika Dini Khairani[1], [1]Rochester General Hospital, Rochester, NY, [2]Rochester General Hospital, Irondequoit, NY

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1405–1433) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Ankylosing spondylitis is a significant cause of mortality and morbidity in the United States (US), with a prevalence of 0.2%–0.5%. However, trends in mortality among patients with ankylosing spondylitis in the US remain unclear. Therefore, we aim to analyze mortality trends in patients with ankylosing spondylitis in the US from 1999 to 2020, stratified by year, sex, and rural-urban status.

Methods: Age-adjusted mortality rates (AAMR) per 100,000 individuals were obtained from the Centers of Disease Control and Prevention WONDER database from the years of 1999-2020. Joinpoint regression was applied to calculate the annual percentage change (APC) to evaluate significant differences in the change of AAMR over time.

Results: A total of 4405 deaths occurred in patients with Ankylosing Spondylitis from 1999 to 2020. The AAMR declined from 1999 to 2004 (APC -7.96 [-23.02, -1.43]) and remained stable from 2004 to 2020 (APC 0.44 [-0.95, 8.57]). Among females, AAMRs were stable from 2002 to 2020 (APC 2.51 [-0.99, 6.68]). Among males, the AAMR declined from 1999 to 2004 (APC -7.56 [-18.71, -2.31]) and remained stable from 2004 to 2020 (APC -0.73 [-1.76, 4.68]). The AAMR in urban

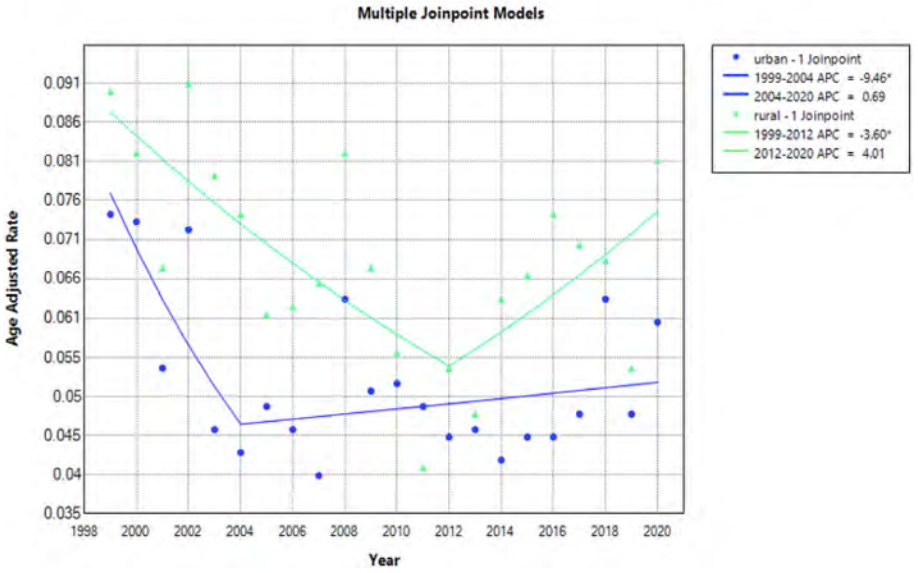
Annual Percentage Change in Ankylosing Spondylitis-Related Mortality by Year and Gender



Annual Percentage Change in Ankylosing Spondylitis-Related Mortality by Urban Status

areas declined from 1999 to 2004 (APC -9.46 [-25.62, -1.70]) and remained stable from 2004 to 2020 (APC 0.69 [-0.99, 9.63]). In rural areas, the AAMR declined from 1999 to 2012 (APC -3.60 [-11.60, -1.57]) and then increased from 2012 to 2020 (APC 4.01 [-0.001, 18.745]).

Conclusion: From 1999 to 2020, ankylosing spondylitis mortality initially declined but later plateau. Mortality rates remained constant in females and urban areas, while rural areas had increased mortality after 2012. These potential disparities warrant further research into quality of care delivered and phenotype of disease based on sex and rural status.

Survival Outcomes in Elderly Patients with Axial Spondyloarthritis and Concomitant Cancer

Savannah Bowman[1], Mei Li[2], Xiudong Lei[3], Hui Zhao[3], Juan Ruiz[4], Sharon H. Giordano[3], Alexis Ogdie[5] and Maria Suarez-Almazor[6], [1]Baylor College of Medicine, Houston, [2]The University of Texas Health Science Center at Houston, Houston, [3]The University of Texas MD Anderson Cancer Center, Houston, [4]Hospital Alemán, Buenos Aires, Argentina, [5]University of Pennsylvania, Philadelphia, PA, [6]MD Anderson Cancer Center, Houston, TX

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1405–1433) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Axial spondyloarthritis (axSpA) is associated with several comorbidities, including cancer. Prior studies have shown that elderly patients with rheumatoid arthritis and concomitant breast or prostate cancer have worse survival outcomes than patients with cancer alone. Our objective was to examine survival outcomes in elderly patients with recently diagnosed cancer, with or without axSpA, as there are currently no studies investigating survival outcomes in this population.

Methods: We conducted a population-based study using Medicare claims linked to the Surveillance, Epidemiology, and End Results (SEER) to examine overall survival (OS) and cancer-specific survival (CSS) in patients aged ≥ 66 with 1 of the 4 most common types of cancer (breast, prostate, lung, colorectal) diagnosed between 2006-2019 with or without axSpA. Patients in the axSpA cohorts were required to have ≥2 claims with an ICD 9/10 diagnosis of axSpA. For the non-axSpA cancer controls, we excluded patients with claims for connective tissue diseases. Patients with axSpA were matched to 2-5 controls using cancer type, age at cancer diagnosis, sex, stage, and year of cancer diagnosis. We investigated OS and CSS (censored at 5 years). Kaplan-Meier (KM) analysis and log-rank tests assessed survival time in patients with or without axSpA. Cox proportional hazard regression models were performed for each cancer, with analysis adjusted for competing risks for CSS.

Results: There were a total of 6103 patients (2061 breast, 1988 prostate, 1234 lung, 820 colorectal) with axSpA matched with 29,004 controls in this study (Table 1). Mean ages ranged from 74 (breast, prostate, lung) to 77 (colorectal) (Table 1). Table 2 shows the results of 5-year OS and CSS estimates and Cox regressions within each type of cancer. No statistically significant differences were observed in OS or CSS between patients with or without axSpA, for breast, prostate or lung cancer. For colorectal cancer, patients with axSpA had a decreased risk of death compared to patients without axSpA: 5-year

Table 1: Distribution of baseline demographics for matched axSpA and non-axSpA patients by cancer types.

	Breast		Prostate		Lung		Colorectal

Table 2. Survival outcomes and hazard ratios (HR) for patients with or without axSpA.

	Breast	Prostate	Lung	Colorectal
OVERALL SURVIVAL				
5-year probability (95% CI)				
axSpA	0.83 (0.81-0.85)	0.81 (0.79-0.83)	0.41 (0.37-0.44)	0.67 (0.63-0.71)
Non-axSpA	0.83 (0.82-0.83)	0.82 (0.81-0.83)	0.41 (0.40-0.43)	0.63 (0.61-0.65)
Log-rank p value	0.81	0.17	0.85	**0.03**
HR (95% CI)*	0.87 (0.76-1.00)	0.95 (0.84-1.08)	0.94 (0.86-1.03)	**0.72 (0.62-0.83)**
p value	0.051	0.44	0.18	**<0.0001**
CANCER-SPECIFIC SURVIVAL				
5-year probability (95% CI)				
axSpA 5-year	0.95 (0.94-0.96)	0.96 (0.95-0.97)	0.68 (0.65-0.71)	0.91 (0.88-0.93)
Non-axSpA 5 year	0.96 (0.95-0.96)	0.96 (0.95-0.96)	0.71 (0.70-0.73)	0.87 (0.86-0.89)
Log-rank p value	0.47	0.82	0.34	**0.02**
HR (95% CI)*	1.07 (0.80-1.43)	1.00 (0.75-1.35)	1.10 (0.96-1.25)	**0.73 (0.55-0.97)**
p value	0.64	0.99	0.16	**0.03**

*Cox regression with non-axSpA group as reference value, adjusted for covariates. Covariates included cancer stage, cancer subtype (for breast cancer: hormone receptor positive, HER2-positive, and triple negative; for lung cancer: small cell, adenocarcinoma, and squamous cell carcinoma), age at diagnosis, frailty index, marital status, cancer treatment (surgery, radiation, chemotherapy, and hormonal therapy where applicable), Charlson comorbidity index, Yost socioeconomic quintile, and poverty quartile.
Abbreviations: axSpA= axial spondyloarthritis, HR= hazard ratio, CI= confidence interval.

OS hazard ratio (HR): 0.72 (95% CI: 0.62-0.83, p=< 0.0001) and CSS HR: 0.73 (95% CI: 0.55-0.97, p=0.03) (Table 2).

Conclusion: Elderly patients with axSpA and concomitant breast, prostate, and lung cancer had similar OS and CSS compared to patients with cancer alone. Elderly patients with axSpA and concomitant colorectal cancer were associated with increased OS and CSS compared to patients without axSpA. Further research is needed to explore the potential reasons for longer survival in elderly patients with colorectal cancer and axSpA compared to those without axSpA.
