Methods: Since program inception, 716 navigator-patient encounters were documented (mean 5.44 per patient; median 4.00), primarily addressing appointment scheduling (40.3%). To assess social risk, 64 of 169 patients (37.9%) completed PRAPARE screening via standardized telephone interviews conducted by navigators in December 2024.

Results: Among 64 individuals enrolled in a rheumatology patient navigator program, the mean PRAPARE social risk score was 5.9 (SD 3.32; range 1–18). The most frequently reported social needs were elevated stress levels (28%), housing instability (18%), limited social integration (16%), safety concerns at home (11%), and material insecurity (8%). Among the 9 patients with scores >8 (defined as a high social risk), 100% reported transportation barriers, 67% reported stress, and 56% reported housing instability. Subgroup analysis revealed that individuals identifying as Hispanic/Latino ($p = 0.0204$) and those with limited English proficiency ($p = 0.0012$) were more likely to have high PRAPARE scores. Spearman correlation analysis demonstrated a strong positive correlation between household size and total PRAPARE score ($\rho = 0.72$), suggesting that larger households may be associated with increased social risk burden.

Conclusion: The program identified a significant burden of unmet social needs among patients. These findings support the integration of routine SDoH screening in rheumatology clinics to better identify at-risk individuals and guide tailored interventions. Further research is needed to evaluate the long-term impact of targeted support measures on health outcomes.

Abstract Number: 1709

Association Between Social Risk Factors and Major Adverse Cardiovascular Events Among Individuals with Rheumatic Conditions

Leah Santacroce[1], Jeong Yee[2], Jing Cui[3], Emily Oakes[1], Hongshu Guan[4] and Karen H. Costenbader[5], [1]Brigham and Women's Hospital, Boston, MA, [2]Sungkyunkwan University, Suwon, MA, South Korea, [3]Brigham Women's Hospital, Boston, MA, [4]Brigham and Women's Hospital/ Harvard Medical School, Boston, [5]Harvard Medical School and Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Healthcare Disparities in Rheumatology (1704–1709)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Individuals with rheumatic conditions are at an increased risk of experiencing cardiovascular events. Social risk factors contribute to disparities in comorbidities and adverse outcomes and may confer higher risk of Major Adverse Cardiovascular Events (MACE) in patients with rheumatic conditions. We aimed to understand whether MACE risk differed by exposure to specific social risk factors including poverty, discrimination and food insecurity.

Methods: We used data from the nationwide NIH All of Us Research Program (V8) and included adults age ≥18 years with ≥ 2 diagnosis codes ≥30 days apart for lupus (SLE), rheumatoid arthritis (RA), and osteoarthritis (OA) 2 years pre-enrollment. We required participants to have completed Social Determinants of Health-related questionnaires at enrollment. We examined individual answers to social risk factor questions about economic instability, healthcare access challenges, and neighborhood factors, as well as scores on the previously validated Everyday Discrimination Scale and Ross-Mirowsky Neighborhood Disorder Scale. The primary outcome was MACE (myocardial infarction, stroke, intervention for coronary artery disease). Patients were followed from enrollment until their first MACE-related event or end of study period. We used multivariable Cox proportional hazard models to evaluate associations between each social risk factor and MACE, adjusting for age, sex, race, ethnicity, rheumatic disease and Deyo-Charlson Comorbidity index.

Results: We identified 17,121 individuals in All of Us who met our criteria. The mean (SD) age was 65 (11) years, 69% were female, and 75% were white. There were 1,336 outcome events, and the mean (SD) follow up time was 2.6 (1.8) years. After adjusting for covariates, presence vs. absence of several social risk factors was associated with a higher risk of MACE (Figure 1). Specifically, food insecurity (HR 1.35, 95% CI 1.16 – 1.56), delaying medical care due to cost (HR 1.17, 95% CI

Table 1. New definition of inflammatory enthesitis at the single-enthesis level.

Inflammatory Enthesitis Definition
"The presence of a power Doppler signal grade ≥2 near the bone cortex, in the presence of hypoechogenicity and/or thickening of the entheseal structure, and within the appropriate clinical context*." **This excludes cases where findings are better explained by mechanical stress or trauma.*

Background/Purpose: Enthesitis affects 30–40% of PsA patients but remains difficult to diagnose due to overlap with non-specific entheseal pain. While OMERACT has standardized ultrasound (US) elementary lesions, no validated definition of inflammatory enthesitis (IE) exists at the single-enthesis level. This limits diagnostic specificity and contributes to misclassification and overtreatment. We aimed to develop an expert- and data-driven definition of sonographic IE at the single-enthesis level in PsA, with the goal of improving diagnostic accuracy and patient selection for clinical research.

Methods: Ten expert sonographers from the DUET (Diagnostic Ultrasound Enthesitis Tool)[1] study independently reviewed 90 US video scans of PsA patients at six entheseal sites. Each scan was score from –10 ("Definite not IE") to +10 ("Definite IE"), and those with ≥70% agreement and scores of +7 were labeled "Definite IE." Experts annotated key sonographic features influencing their assessments. Quantitative analysis included group comparison of elementary lesion distribution using the DUET consensus scoring for descriptive statistics and chi-square tests. Thematic analysis was performed on free-text annotations. This data was used to inform a proposed definition of IE, which was subsequently approved through a Delphi vote.

Results: Of 90 scans, 29 (32.2%) were "Definite IE", 21 (23.3%) "Definite not IE", and 40 (44.5%) "Uncertain". Most "Definite IE" had ≥4 elementary lesions, while "Uncertain" scans commonly had 2 to 4 lesions (**Figure 1A**). The absence of elementary lesions or presence of isolated findings characterized the "Definite not IE" group.

Power Doppler (PD) grade ≥ 2 near the bone cortex was present in 97% of the "Definite IE" group and in 55% of "Uncertain" scans (**Figure 1B, Figure 2F**). Importantly, grades 2-3 PD were almost exclusively found in these two groups, with grade 3 almost only found in the "Definite IE" group. Thematic analysis revealed that lesion combinations, cortical location of PD, and contextual interpretation were critical for classification. Isolated findings (e.g., small enthesophytes) lacked diagnostic

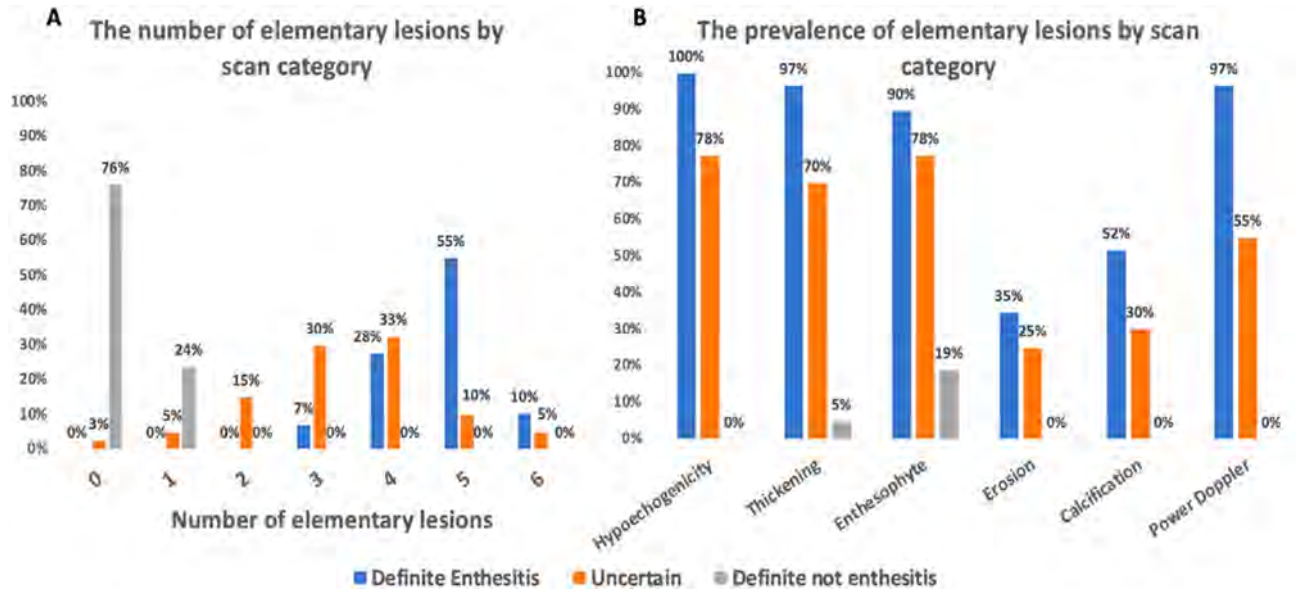

Figure 1A . Number of elementary lesions identified in each category; 1B. Distribution of sonographic elementary lesions by category.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

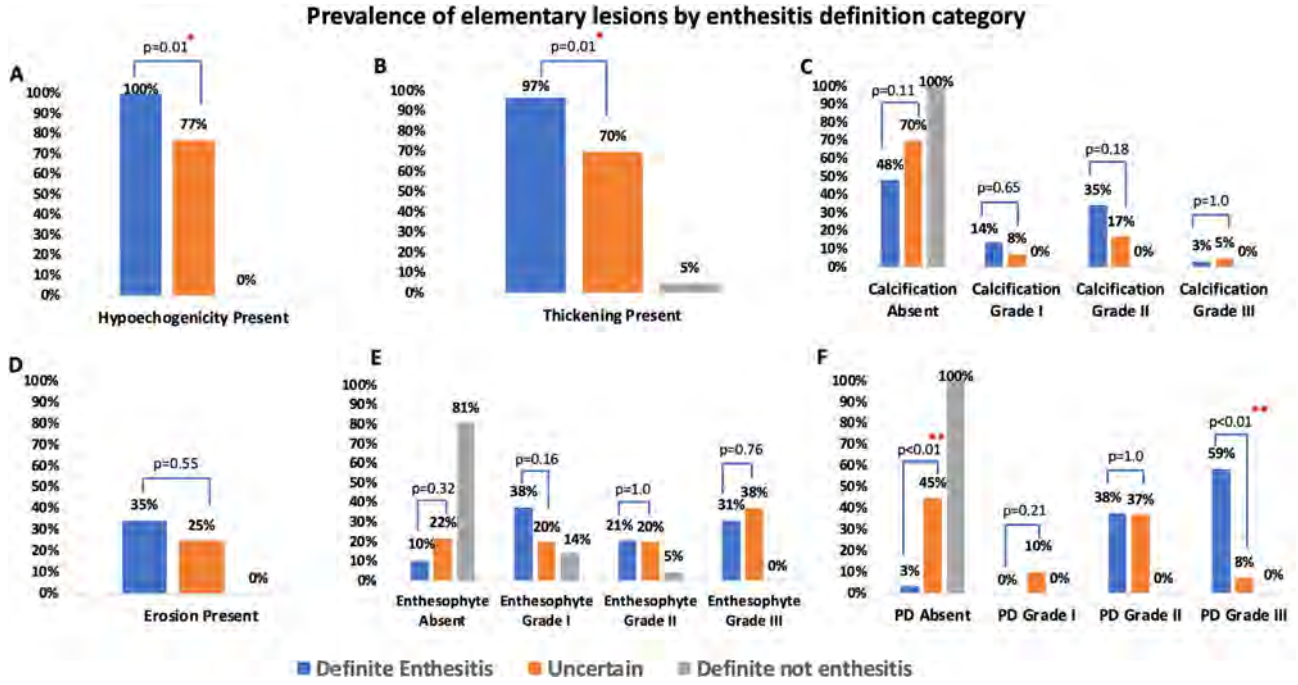

Figure 2. The prevalence of elementary lesions by enthesitis definition category. 1A. Hypoechogenicity (score 0-1); 1B. Enthesophyte (score 0-3); 1C. Thickening (score 0-1); 1D Calcification (Score 0-3); 1E. Erosion (score 0-1); 1F. Power Doppler (score 0-3). Chi-square test was performed to compare the "definite enthesitis" and "uncertain" groups, with p-value < 0.05 marked with an asterisk (*) and a p-value < 0.01 marked with two asterisks.

value unless part of a broader inflammatory pattern. Structural lesions (e.g., cortical irregularities, erosions) were interpreted as signs of prior inflammatory process.

Based on these findings the proposed definition for IE is "**"The presence of a power Doppler signal grade ≥2 near the bone cortex, in the presence of hypoechogenicity and/or thickening of the entheseal structure, and within the appropriate clinical context*."** This excludes cases where findings are better explained by mechanical stress or trauma." (**Table 1**). This definition achieved consensus in the Delphi exercise (10 out of 10 voted to approve).

Conclusion: The new proposed definition for sonographic IE in the context of PsA should facilitate the development of standardized diagnostic criteria for IE in PsA, and improve patient enrollment specificity in clinical research.

Dysfunctional Neurobiology Of The Insula Characterizes Fatigue In Psoriatic Arthritis

Andrew McGucken[1], Flavia Sunzini[2], Kristian Stefanov[1], Joel Parkinson[1], Salim Al-Wasity[1], John McLean[1], Gordon Waiter[3], Stefan Siebert[1] and Neil Basu[4], [1]University of Glasgow, Glasgow, United Kingdom, [2]Glasgow University, Glasgow, United Kingdom, [3]University of Aberdeen, Aberdeen, United Kingdom, [4]Institute of Infection, Immunity & Inflammation, University of Glasgow, Glasgow, United Kingdom

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes I: Advances in Psoriatic Disease (1710–1715)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Fatigue is a pervasive and burdensome symptom for people with psoriatic arthritis (PsA). The mechanisms underlying PsA related fatigue are unknown. In other clinical populations, the brain's insula region, a key integration hub between peripheral signals of pain/inflammation and central signals such as mood, has emerged as a key component of the fatigue network[1]. Moreover, excess levels of brain glutamate has been implicated with this symptom[2]. To date, no studies have specifically examined the potential role of brain connectivity and glutamate in PsA fatigue.

Methods: Patients with active PsA who fulfilled the CASPAR criteria were evaluated. Fatigue was measured using a fatigue numeric rating scale averaged over the prior week (7-day fatigue NRS). Subjects then undertook functional MRI and single voxel MRI spectroscopy brain scans. Images were acquired using 3 Tesla Siemens PRISMA with 32-channel phased array head coil using a T2*-weighted gradient-echo echo-planar imaging pulse sequence. Functional MRI data was analyzed using functional connectivity CONN toolbox employing a right posterior insula seed. The functional connectivity of this region of interest to the whole brain was estimated, followed by group level multiple linear regression to 7-day fatigue NRS corrected for age, sex and multiple comparisons (FDR< 0.05). Right posterior insula spectroscopy data was analyzed using LCModel. Individual glutamate/glutamine concentrations were calculated and corrected for levels of brain creatine (Glx/Cr). Glx/Cr correlation with fatigue scores and insula seed functional connectivity was assessed.

Results: 38 enrolled patients completed both functional MRI and MRI spectroscopy (mean age 46.7 ± 9.9; 47% female; mean BMI 29.2 ± 4.6; mean 7-day fatigue NRS 6.4 ± 2.8; mean DAPSA 38 ± 15.8). Higher fatigue scores correlated with higher functional connectivity from the right posterior insula to cerebellum (R=0.694, p< 0.022FDR) and anti-correlated with functional connectivity to the superior frontal gyrus, which covers the medial prefrontal cortex (R=-0.7029, p=0.0008FDR) (Figure A). PsA patients with higher fatigue scores also trended towards increased Glx/Cr (R=0.3, p=0.07) in the right posterior insula and these levels significantly correlated with fatigue associated functional connectivity of this region (cerebellum: R=0.49, p=0.003 and superior frontal gyrus: R=-0.4, p=0.016) (Figure B).

Conclusion: We demonstrate for the first time that the brain may have a role in PsA fatigue. Specifically, the multifaceted role of the insula is highlighted. Altered functional connectivity between the posterior insula to brain regions involved in movement, motivation, and peripheral sensations (cerebellum); and executive decision making/emotions (superior frontal gyrus) appears to characterize fatigue severity in PsA. Excess of the excitatory neurotransmitter glutamate within the posterior insula may mediate this neural dysfunction but further research is warranted to understand it's functional role and clarify its potential as a future therapeutic target for PsA fatigue.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

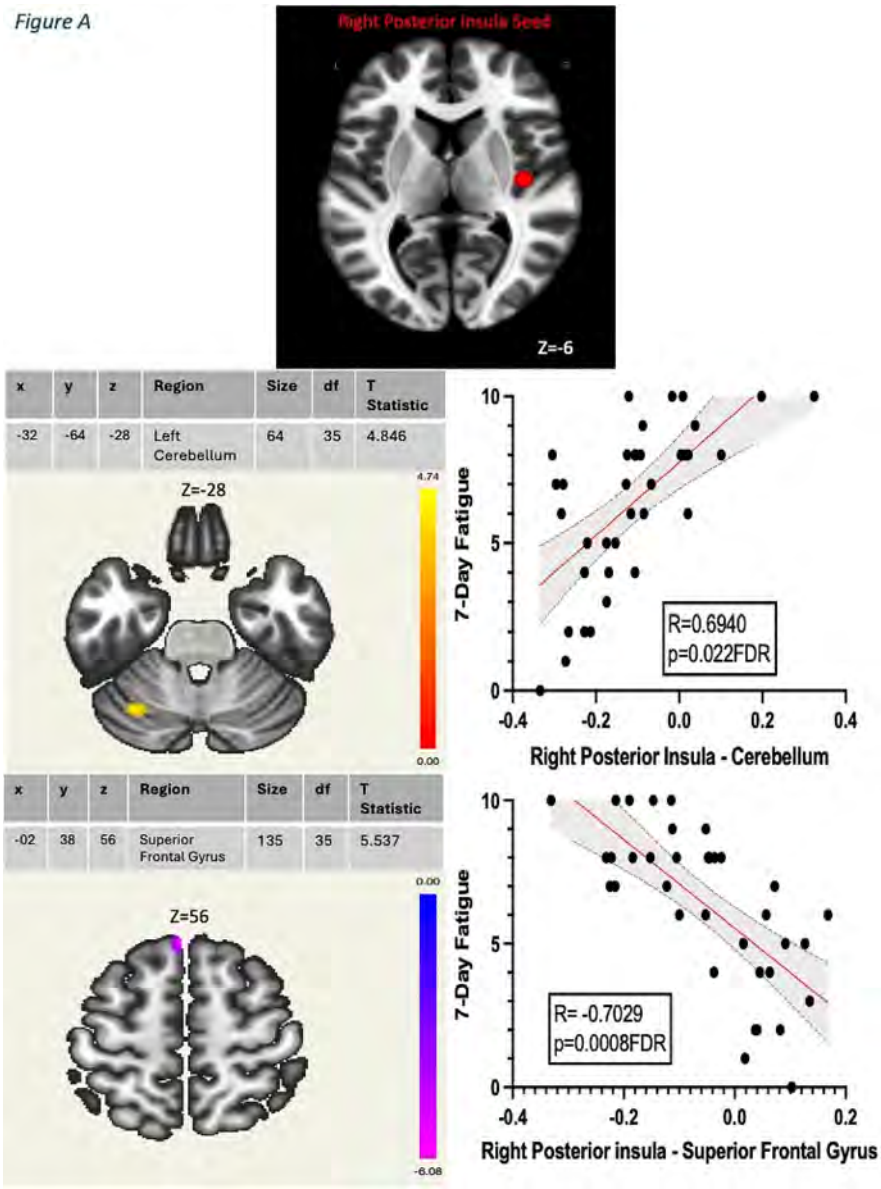

Figure A shows significant altered functional connectivity that correlates with fatigue scores. The top panel demonstrates the insula seed used for the seed-to-voxel analysis. The images show the voxel positions (colored area on brain slice) with slice number (Z) at the top of each image. The scatterplots visualize the correlation of functional connectivity (Fischer z-transformed r values) between two brain regions and fatigue scores, Pearsons R, and p values after false discovery rate for multiple comparisons (FDR). The tables demonstrate results from multi-linear modelling (correcting for age and sex), degrees of freedom (df), peak voxel co-ordinates in MNI space (x,y,z), and cluster size.

Reduced Cardiometabolic Burden and Inflammation in Patients with Psoriatic Arthritis Cared for in a Multi-Disciplinary, Combined Psoriasis-Psoriatic Arthritis Center

Rebecca Haberman[1], Nicolas Coudray[2], Xu Han[2], Morgan Grams[2], Eric Oermann[2], Aristotelis Tsirigos[2] and Jose Scher[3], [1]NYU Langone Health, New York, NY, [2]NYU Grossman School of Medicine, New York, [3]New York University School of Medicine, New York, NY

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes I: Advances in Psoriatic Disease (1710–1715)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Psoriatic arthritis (PsA) is a chronic, systemic inflammatory disease that affects both the skin and musculoskeletal system and is frequently associated with a heightened burden of cardiometabolic comorbidities, including hypertension (HTN), obesity, and type 2 diabetes (DM2). These conditions contribute to elevated morbidity and mortality.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Comorbidities in patients with psoriasis, psoriatic arthritis (PsA), and PsA seen in the Psoriatic Arthritis Center (PAC). All p-values adjusted for false discovery rate (FDR) given multiple comparisons.

Despite growing awareness, management of systemic inflammation and comorbid risk factors remains suboptimal in routine care. Multi-disciplinary, integrated centers that co-locate rheumatology, dermatology, cardiology and allied specialties offer a promising approach to comprehensive, disease-targeted care. However, real-world data supporting their effectiveness in mitigating systemic burden remain limited. We aimed to evaluate whether patients with PsA seen under optimized care—the NYU Psoriatic Arthritis Center (PAC)—demonstrate improved health profiles compared to those receiving standard specialty care at the same institution.

Methods: Using the electronic medical record (EMR) system at NYU Langone Health (Epic), we identified patients with ICD-10 codes for psoriasis or PsA from 2012 to 2024. Patients with both diagnoses were classified as PsA. PsA patients were further categorized into those seen at the NYU PAC (PAC group) versus those seen exclusively outside the PAC (non-PAC group). For all groups, comorbidities were extracted using ICD-10 codes, and laboratory markers of systemic inflammation (CRP, ESR) were obtained. Comparisons of comorbidity prevalence and laboratory values were performed using Mann-Whitney U tests and mixed linear regression, adjusting for age. False discovery rate (FDR) correction was applied using the Benjamini-Hochberg method.

Results: 890 PAC patients, 12,079 non-PAC PsA patients, and 28,393 patients with only skin psoriasis were identified. PAC and non-PAC patients had similar rates of comorbidities prior to the age of 55 (**Figure 1**). Among those ≥55 years old, PAC patients had significantly lower rates of key cardiometabolic conditions compared to non-PAC PsA patients, including DM2, obesity, HTN, ischemic heart disease, atrial fibrillation, and chronic kidney disease (all FDR-adjusted p<

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

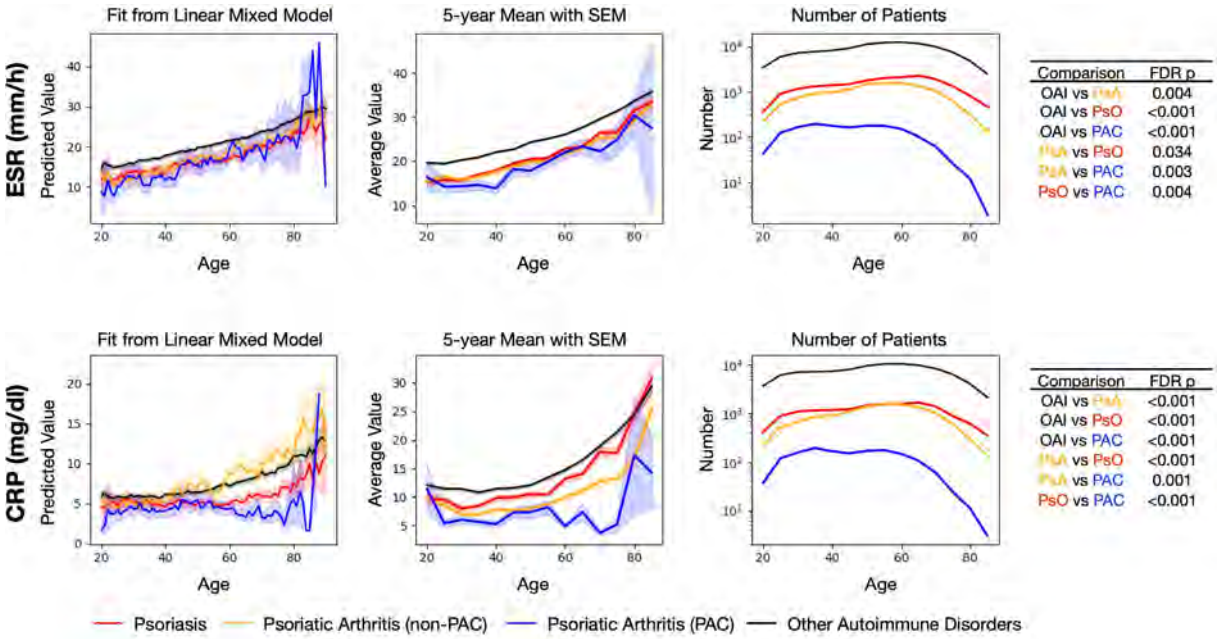

Figure 2. Systemic markers of inflammation in patients with psoriasis, psoriatic arthritis (PsA), PsA seen in the Psoriatic Arthritis Center (PAC), and other autoimmune disorders. ESR denotes erythrocyte sedimentation rate, CRP denotes C-reactive protein, FDR false discovery rate, SEM standard error of the mean. Other autoimmune disorders include celiac disease, Sjogrens Syndrome, Hashimoto's thyroiditis, ulcerative colitis, Crohn's disease, type 1 diabetes, multiple sclerosis, systemic lupus erythematosus, and rheumatoid arthritis.

0.05). Inflammatory markers were also significantly lower in PAC patients (ESR p< 0.001; CRP p=0.026, **Figure 2**). Rates of osteoarthritis were higher in PAC patients (p=0.005), possibly reflecting more active musculoskeletal screening. Of interest, both PAC and non-PAC PsA patients had lower anxiety and systemic inflammation compared to patients with psoriasis alone or other autoimmune diseases.

Conclusion: In this large EMR-based study, patients with PsA receiving care at a dedicated, multi-disciplinary, specialized center had a significantly reduced burden of cardiometabolic comorbidities and inflammation, particularly in older adults. While validation of these observations is warranted in other combined clinics (i.e., PPACMAN dual-care facilities), our findings highlight the potential of integrated psoriatic disease care models to modify systemic disease expression, decrease the deleterious effects of metabolic and cardiovascular comorbidities and improve overall long-term outcomes in PsA.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes I: Advances in Psoriatic Disease (1710–1715)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Psoriatic arthritis (PsA) remains widely underdiagnosed and misdiagnosed worldwide, leading to delays in appropriate management and increased disease burden. While diagnostic delay has been extensively studied in axial spondyloarthritis (axSpA), there remains a significant research gap in understanding delays specific to PsA. This study aims to examine the extent and consequences of diagnostic and referral delays in PsA and their impact on radiographic outcomes.

Methods: We systematically searched PubMed, Web of Science, and Scopus from inception until March 16, 2025, following PRISMA guidelines (Fig.1) to identify observational studies reporting diagnostic delay in PsA. Studies were included if they diagnosed PsA patients based on the CASPAR classification criteria, confirmed diagnosis by a rheumatologist or self-reported physician diagnosis. Diagnostic and referral delays were extracted if reported as mean (SD) or median (IQR).

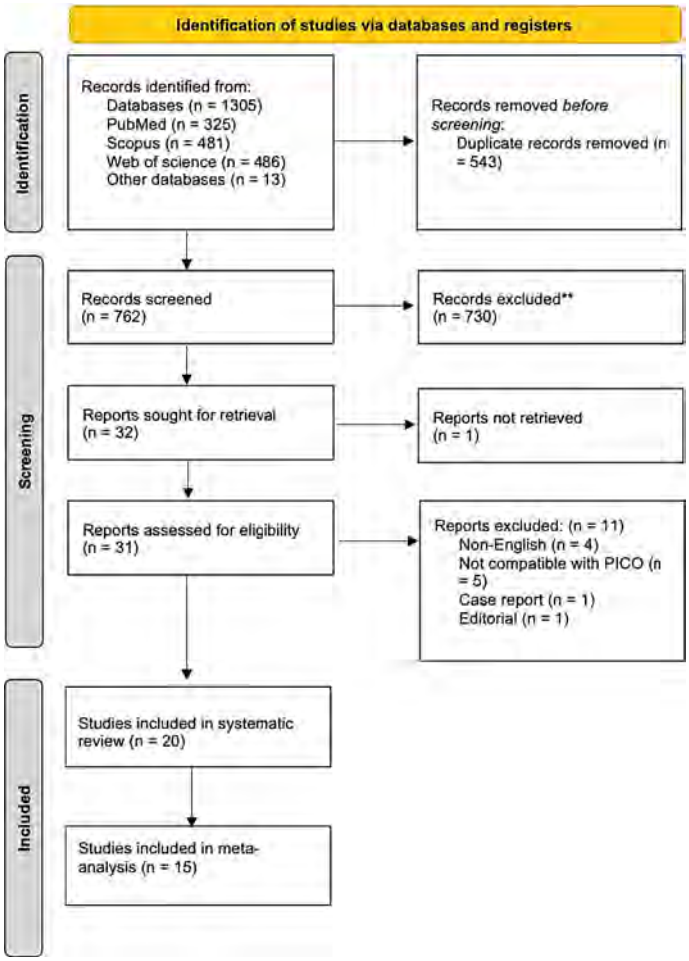

Fig (1) PRISMA Flow Chart Illustrating Search Strategy and Selection of Included Studies

Meta-analysis was conducted using Review Manager software 5.4 (RevMan), employing random- and fixed-effects models using the inverse variance method. Heterogeneity was assessed using I^2 statistics following Cochrane guidelines.

Results: A total of 20 observational studies were included encompassing 23,894 participants, with 15 contributing to the meta-analysis encompassing 22,749 participants. The pooled mean diagnostic delay was 31.24 months (95% CI: 22.48, 40.00) using a random-effects model, with considerable heterogeneity (I^2 = 100%) (Fig. 2). The mean referral delay was analyzed using both fixed- and random-effects models, with the random-effects model yielding a pooled mean referral delay of 21.69 months (95% CI: 15.02, 28.35) and the fixed-effects model yielding 15.32 months (95% CI: 13.98, 16.67), with considerable heterogeneity (I^2 = 92%) (Fig. 2). Patients with prolonged diagnostic delay had significantly increased odds of radiographic damage. The fixed-effects model yielded a pooled OR of 2.80 (95% CI: 2.31, 3.39), while the random-effects model showed an OR of 2.54 (95% CI: 1.58, 4.09). Heterogeneity for both was moderate (I^2 = 49%) (Fig. 2). Studies indicated substantial geographic variation in diagnostic delay, with reports ranging from 6.55 months in India to over 62.4 months in Italy (Fig. 3).

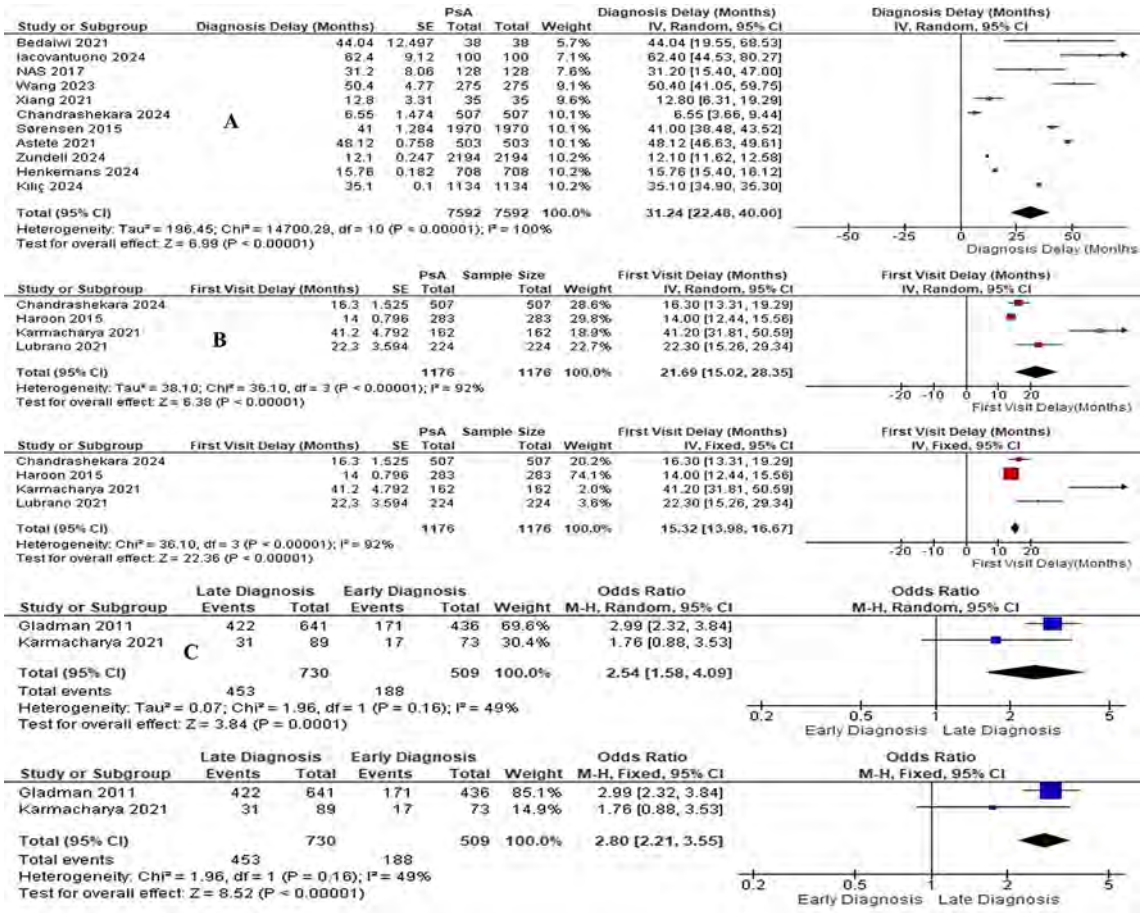

Fig 2. (A) Forest Plot of PsA Diagnosis Delay (Months): Forest plot of PsA diagnosis delay (months). Studies included: Bedaiwi 2021, Iacovantuno 2024, NAS 2017, Wang 2023, Xiang 2021, Chandrashekara 2024, Sørensen 2015, Astete 2021, Zundell 2024, Henkemans 2024, Kilic 2024. The plot shows the mean diagnosis delay for each study and the overall pooled mean delay of 31.24 months (95% CI: 22.48 to 40.00), with considerable heterogeneity (I^2=100%). (B) Forest plot of PsA first visit delay (months) (Random and Fixed effects model). Studies included: Chandrashekara 2024, Haroon 2015, Karmacharya 2021, Lubrano 2021. The plot shows the mean first visit delay for each study and the overall pooled mean delay of 15.32 months (95% CI: 13.98 to 16.67), with considerable heterogeneity (I^2=92%). (C) Forest Plot of Odds Ratio Comparing Late Diagnosis to Early Diagnosis in PsA Patients (Random and Fixed effects model). Forest plot of odds ratio comparing late diagnosis to early diagnosis in PsA patients. Studies included: Gladman 2011, Karmacharya 2021. The overall pooled odds ratio was 2.80 (95% CI: 2.21 to 3.55), indicating a significant association (P<0.00001), with moderate heterogeneity (I^2=49%). CI, confidence interval; df, degrees of freedom; IV, inverse variance; SD, standard deviation.

Fig 3. Map of Mean Diagnostic Delay in Years for PsA by Country. Countries included: United States, Netherlands, Turkey, Italy, India, China, Singapore, Spain, Saudi Arabia, Denmark. The accompanying table provides classification criteria, sample size, mean delay, and 95% CI for each country. Map powered by Bing.

Conclusion: This is the first systematic review and meta-analysis that explores diagnostic and referral delays in PsA, and their relationship to radiographic joint damage. This meta-analysis confirmed that both diagnostic and referral delays in psoriatic arthritis are statistically and clinically significant, with longer delays linked to an increased risk of radiographic joint damage. These delays reflect gaps in disease recognition and care coordination. Improving early detection, particularly in primary care and dermatology settings, and streamlining referral pathways to rheumatology are essential in reducing structural damage and improving patient outcomes.

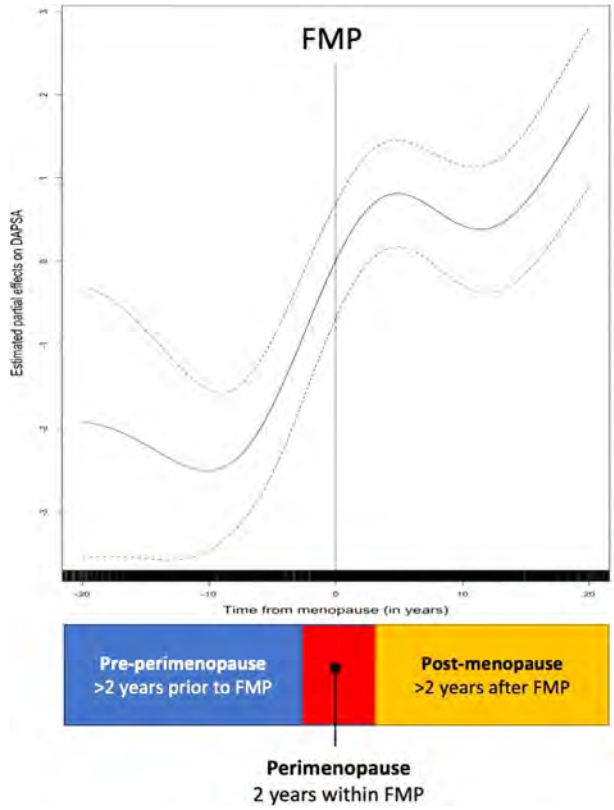

Figure 1: Time from final menstrual period (FMP) estimated partial effect on the individual mean DAPSA score by Generalized Additive Model adjusted for age, disease duration and medication use

Background/Purpose: Perimenopause is associated with a wide spectrum of symptoms, including mood changes, sleep disturbances, and joint pains. Limited information exists on the effect of perimenopause on psoriatic arthritis (PsA). We assessed whether PsA disease activity worsens during perimenopause compared to the pre- and post-menopause stages.

Methods: We analyzed data on female patients with PsA followed in a prospective cohort from 1978 to 2024. Data on PsA disease activity, medications, co-morbidities, and age at menopause were collected using standard protocols. Pre-perimenopausal and post-menopausal stages were defined as >2 years before and after the final menstrual period (FMP), respectively, while the perimenopause stage was within two years (before or after) of the FMP. PsA disease activity was assessed at each visit using Disease Activity in PsA (DAPSA), tender and swollen joint counts, PASI, CRP, and FACIT-

Table 1 - Estimated fixed effects on change in PsA disease activity measures for perimenopause stage using linear mixed effects models

Table 1 - Estimated fixed effects on change in PsA disease activity measures for perimenopause stage using linear mixed effects models (N=477 patients, 8381 visits)

Model 1: Mediator ~ Menopause stage + age + disease duration + medications
Model 2: DAPSA ~ Mediator + Menopause stage + age + disease duration + medications
Model 3: DAPSA ~ Menopause stage + age + disease duration + medications

Effect of menopause stage on the potential mediator (Model 1)*					Model estimates for menopause stage effect on DAPSA with the mediator (Model 2) and without it (Model 3)*			
Menopause stage	BMI		FACIT-Fatigue		BMI		FACIT-Fatigue	
	Adjusted β coefficient	P value	Adjusted β coefficient	P value	Without BMI in model	With BMI in model	Without FACIT in model	With FACIT in model
Peri- vs. Pre-perimenopause	0.33	0.30	-1.41	0.05	1.92	1.88	1.92	1.57
Peri- vs. Post-menopause	0.18	0.53	-0.58	0.29	1.56	1.53	1.56	1.37

*All models reports the β coefficient for menopause stage adjusted for age, PsA duration, csDMARD, ts/bDMARD and corticosteroid use

Figure 2: Assessment of the mediating effect of BMI and fatigue on DAPSA change during peri-menopause.
First we assessed the overall effect of perimenopause on the potential mediator (**Model 1**). No significant effect of peri-menopause on BMI while an increase in fatigue levels (reduction in FACIT) was seen vs. pre-perimenopause. We then assessed the effect perimenopause on DAPSA with and without including the potential mediator in the regression model (**Model 2** and **3**). FACIT-fatigue is a partial mediator of the DAPSA increase during peri-menopause, as its inclusion in the model resulted in a 18.2% attenuation in the β coefficient (1.92 to 1.57) for peri- vs. pre-perimenopause and in a 12% reduction in the β coefficient (1.88 to 1.53) for peri- vs. post-menopause.

Figure 2: Assessment of the mediating effect of BMI and fatigue on DAPSA change during peri-menopause.

fatigue. Disease activity during the perimenopause stage was compared to the pre-perimenopause and post-menopause visits.

The association between menopausal stages and PsA disease activity measures was assessed with a Generalized Additive Model with splines (considering time from FMP as continuous variable) and with linear mixed-effects models (considering menopausal stages as categorical variables). Each model was adjusted for age, disease duration, and medication use, and accounted for repeated observations via a subject-specific random effect.

We assessed the mediating effects of BMI and fatigue on the increase in DAPSA during perimenopause.

Results: A total of 477 female patients provided data for 8,381 visits over a mean follow-up of 12.1 years. Mean age at first visit was 44.9±13.9 years, and mean age at menopause was 48.7 years. Hormone replacement therapy had been used by only 1.5% of patients at any time point. A rise in DAPSA scores was found during perimenopause years, followed by a slight drop post-menopause (Figure 1).

Linear mixed models found an association between being in perimenopause and higher DAPSA compared to the pre-perimenopause ($\beta = 1.92$, $p < 0.001$) and post-menopause stages ($\beta = 1.56$, $p=0.001$, Table 1). Significantly higher tender and swollen joint counts were found in perimenopause compared to both pre- and post-menopause. Higher PASI scores were found in perimenopause compared to the post-menopause stage (Table 1).

An increase in fatigue levels during perimenopause only partially mediated the increase in DAPSA during perimenopause, explaining 12% to 18% of this change (Figure 2). BMI did not have a mediating effect on DAPSA change during perimenopause.

Conclusion: Perimenopause is associated with an increase in PsA disease activity, which includes both patient-reported outcomes and objective measures of activity. These findings highlight the need to study the effect of hormone replacement therapy in perimenopausal PsA patients.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes I: Advances in Psoriatic Disease (1710–1715)

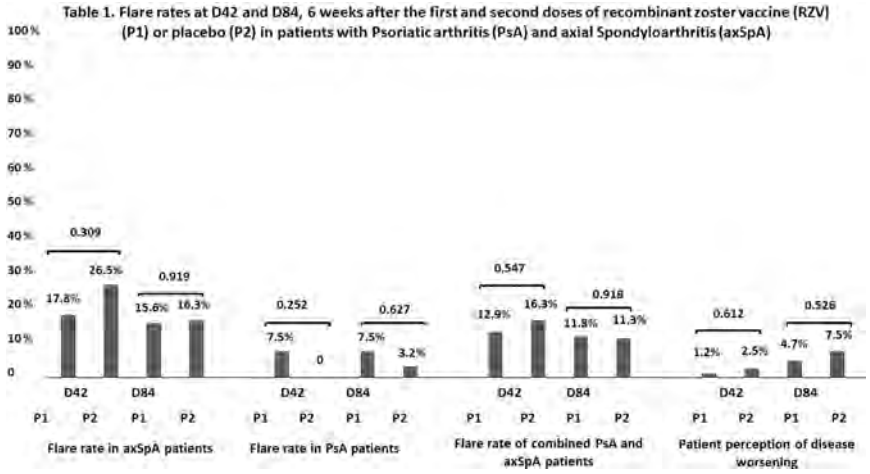
Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Psoriatic arthritis (PsA) and axial spondyloarthritis (axSpA) patients are at increased risk for herpes zoster(HZ) due to impaired cell-mediated immunity associated with the underlying disease and therapies. Although the adjuvanted recombinant zoster vaccine (RZV, Shingrix®) has shown high efficacy and a favorable safety profile in immunocompetent individuals, its performance in PsA and axSpA patients under immunosuppressive treatment has not been evaluated and may hamper vaccination recommendations for these patients. The present study evaluates the humoral immunogenicity and safety of RZV in immunosuppressed PsA and axSpA patients compared to healthy controls (CG) and to investigate the possible impact of immunosuppressive conventional and/or biologic disease-modifying antirheumatic drugs (DMARDs) and disease activity on vaccine response.

Methods: This was a prospective, randomized, placebo-controlled clinical trial enrolled adult PsA and axSpA. Patients were randomized 1:1 to receive RZV (P1) and placebo(P2). A CG was included at a 2:1 (ARD:CG) ratio. Both CG and P1 groups received two intramuscular dose of the recombinant zoster vaccine (RZV) administered 6 weeks apart (Day 0 and Day 42) while P2 received placebo. After unblinding at Day 84, P2 participants received two doses of the vaccine. A positive humoral response was defined as an anti-gE antibody concentrations at least four times above the assay's lower detection at baseline and 6 weeks after second dose. Geometric mean titres (GMTs) and factor increase (FI) were calculated. Safety was evaluated using standardized one-week diary and disease flares was assessed by the rheumatologist in each visit using validated disease indices/scores: BASDAI, ASDAS, PASI, DAPSA and MDA.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



For safety analyses, all patients who adhered to protocol were included (n=165): 71 axSpA patients (40 in P1 and 31 in P2) and 94 PsA patients (45 in P1 and 49 in P2). Results are expressed in n (%) and compared with the chi-square or Fisher's exact test, as appropriate, as two-sided analyses; Flare rate in axSpA patients was defined as an increase > 0.9 in ASDAS-CRP. Flare rate in PsA patients was defined as worsening in DAPSA category. ASDAS-CRP, DAPSA classification and patient perception of disease worsening at D42 and D84 were compared to baseline status (D0)

Results: A total of 185 SpA patients and 92 controls with similar sex distribution (37.8% vs. 38.0% female, p=0.974) and age (54.7±13.0 vs. 58.3±8.6 years, p=0.071) were enrolled. At D84 after vaccination, seroconversion (93.9% vs. 98.9%,p=0.037) and GMT [(8.9(7.6-10.4) vs. 13.5(11.6-15.7), p=0.001)] were significantly reduced in patients compared to CG. FI-GMT was similar between groups [(43.3(33.9-55.3) vs. 59.0(44.1-78.8), p=0.083)]. No factor was identified to contribute to decreased seroconversion in SpA patients (p >0.05). Disease safety evaluation revealed no increase in disease flares among patients who received P1 in comparison to patients who received P2 at D84 (11.8% vs. 11.3%,p=0.918) in the whole group or among patients with axSpA according to ASDAS-CRP (7.5% vs. 3.2%,p=0.627) or PsA according to the DAPSA (15.6% vs 16.3%,p=0.919) (Figure 1). RZV was well-tolerated, with adverse events being mild and self-limited.

Conclusion: In this first prospective controlled study, RZV demonstrated favorable safety and high rates of immunogenicity in PsA and axSpA patients under immunosuppressive treatment. However, the lower frequency of seroconversion and reduced antibody titers compared to CG raise concerns about vaccine-induced protection. These findings support the use of RZV in high-risk patients and highlights the need for long-term monitoring of vaccine efficacy. (ClinicalTrials NCT05879419).

Abstract Number: 1716

The frequency and impact of cardiovascular disease in systemic lupus erythematosus: a Nationwide, matched case-control study.

Jessica Fairley[1], **Laura Ross**[1], Elizabeth Paratz[2], Penelope McKelvie[3], Simin Daneshvar[3], Shereen Oon[4], Dylan Hansen[3], Wendy Stevens[1], Andre La Gerche[2] and Mandana Nikpour[5], [1]The University of Melbourne, Melbourne, Victoria, Australia, [2]St Vincent's Institute of Medical Research, Melbourne, Victoria, Australia, [3]St Vincent's Hospital Melbourne, Melbourne, Victoria, Australia, [4]St Vincent's Hospital Melbourne, Melbourne, Victoria, Australia, [5]University of Sydney School of Public Health and Department of Rheumatology, Royal Prince Alfred Hospital, Sydney, Victoria, Australia

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes II: Morbidity & Mortality (1716–1721)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Cardiovascular disease is the leading cause of death in systemic lupus erythematosus (SLE).[1] Whilst histopathology remains the gold standard for establishing the pathogenesis of cardiac disease, endomyocardial biopsy is invasive and subject to sampling error. We aimed to examine the frequency of cardiovascular disease in SLE compared with the general population, and associations of specific findings with patient outcomes.

Methods: A case-control study was performed using data from the Australian National Coronial Information System, a database of deaths referred for forensic investigation. SLE cases were identified via keyword/ICD-10 code search. Age- and sex-matched controls were selected from victims of motor vehicle accidents. Demographic data and autopsy findings (macroscopic and histopathological) were extracted. Cardiomegaly was defined as heart weight >95th centile for body weight/sex. Odds ratios (OR) were calculated with 95% confidence intervals (CI).

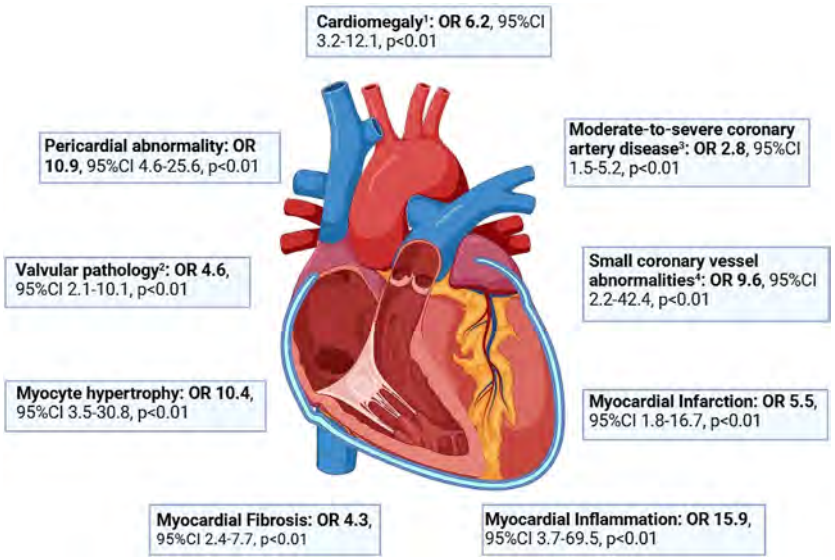

Figure 1: Odds of cardiovascular disease in SLE compared to controls using logistic regression, adjusted for age and sex. Abbreviations: CI (confidence interval), OR (odds ratio), SLE (systemic lupus erythematosus). 1Cardiomegaly defined as heart weight >95th centile for body weight. 2Valvular pathology defined as at least moderate aortic stenosis, aortic regurgitation, mitral stenosis or mitral regurgitation. 3Coronary artery disease defined as moderate to severe when stenosis >50% vessel occlusion, or qualitative description of "moderate", "severe" or "critical". 4Small vessel coronary abnormalities defined as thickening, vasculitis or other abnormality within the small intramural coronary arteries.

Association with sudden cardiac death				
Cardiomegaly[1]	113	3.4	1.5-7.5	<0.01
Myocardial fibrosis	110	1.4	0.7-3.2	0.36
Myocardial Inflammation	108	0.8	0.3-2.0	0.65
Pericardial abnormalities	115	1.0	0.4-2.1	0.90
Moderate to severe coronary artery disease[2]	116	2.5	1.1-5.7	0.03
Myocyte hypertrophy	110	0.6	0.3-1.5	0.27
Valvular vegetations	118	2.9	0.5-16.0	0.22
Valvular pathology[3]	118	1.1	0.5-2.6	0.80

Results: 123 SLE cases and 123 controls were included. Both groups were predominantly female (85%) and of similar age (median SLE 53 (IQR 40-65) years vs. control 54 (41-65) years, p=0.90).

After adjusting for age and sex, myocardial fibrosis (OR 3.4, 95%CI 1.8-6.5, p< 0.01), myocardial inflammatory infiltrates (OR 15.5, 95%CI 3.5-68.5, p< 0.01) and pericardial abnormalities (OR 8.9, 95%CI 3.7-21.3, p< 0.01) were significantly more common in SLE (Figure 1). SLE cases were 6.2-times more likely to have cardiomegaly (95% CI 3.2-12.1, p< 0.01). Moderate-to-severe epicardial coronary artery disease (CAD; OR 2.8, 95% CI 1.5-5.2, p< 0.01), myocardial infarction (OR 5.5, 95% CI 1.8-16.7, p< 0.01) and abnormalities of the small intramural coronary vessels (OR 9.6, 95% CI 2.2-42.4, p< 0.01) were more common in SLE after age and sex adjustment. These associations persisted after adjustment for age, sex and moderate to severe CAD (cardiomegaly OR 4.9, 95% CI 2.5-9.7, p< 0.01; myocardial fibrosis OR 3.4, 95%CI 1.8-6.5, p< 0.01; myocyte hypertrophy OR 8.2, 95%CI 2.7-24.8, p< 0.01; small intramural coronary vessel abnormalities OR 9.9, 95%CI 2.2-45.0, p< 0.01). Coronary vasculitis was exclusively identified in 8% of SLE cases. Valvular pathology was more common in SLE (OR 4.9, 95% CI 2.2-10.8, p< 0.01), with vegetations observed in 6% of cases.

Cardiovascular death was more common in SLE cases with myocardial fibrosis (OR 2.6, 95% CI 1.1-5.9, p=0.02), moderate-to-severe CAD (OR 4.0, 95% CI 1.8-9.2, p< 0.01) and cardiomegaly (OR 3.6, 95% CI 1.6-7.9, p< 0.01), after adjusting for age and sex (Table 1). Sudden cardiac death was more common in those with cardiomegaly (OR 3.4, 95% CI 1.5-7.5, p< 0.01) and moderate-to-severe CAD (OR 2.5, 95%CI 1.1-5.7, p=0.03), after age and sex adjustment.

Conclusion: SLE is associated with a significant excess of atherosclerotic vascular, inflammatory and fibrotic cardiac lesions. These data highlight the scope of cardiovascular abnormalities occurring in SLE, and their association with cardiovascular causes of death.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes II: Morbidity & Mortality (1716–1721)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Frailty has been shown to predict damage accrual in patients with SLE, including those from Latin America. However, the impact of frailty on mortality has been scarcely evaluated, particularly in the Latin American population. The aim of this study was to evaluate frailty as a predictor of mortality in Latin American SLE patients.

Methods: The Almenara Lupus Cohort is a longitudinal study which was started in January 2012. The present study includes all patients in this cohort from its inception until the end of follow-up in March 2025. All patients met the ACR 1997 or the SLICC 2012 criteria set and were older than 18 years of age at baseline. Patients who had a diagnosis of other autoimmune disease except for Sjögren's and the antiphospholipid syndromes were excluded. Mortality was defined as the vital status according to the official information from the Peruvian Department of Health. Frailty was ascertained using the SLICC-FI as a continuous variable. Univariable and multivariable Cox regression models were done to estimate the impact of the SLICC-FI on mortality. Multivariable model was adjusted for possible confounders (age at diagnosis, gender, socioeconomic status, years of education, ethnic group, tobacco use, disease duration, SLEDAI-2K, SLICC/ACR damage index,

Table 1. Association between SLICC-FI and mortality risk. Unadjusted and adjusted analyses* * Cox regression multivariable model was adjusted for age at diagnosis, gender, socioeconomic status, ethnic group, tobacco use, disease duration, SLEDAI-2K, SLICC/ACR damage index, prednisone daily dose, antimalarial and immunosuppressive drugs use. SLICC-FI: Systemic Lupus International Collaborating Clinics Frailty Index; HR: Hazard ratio

	Unadjusted			Adjusted		
Variable	HR	(95% IC)	*p* value	HR	(95% IC)	*p* value
SLICC-FI per 0.05 increase	1.888	(1.466-2.432)	<0.001	1.540	(1.108-2.138)	0.010

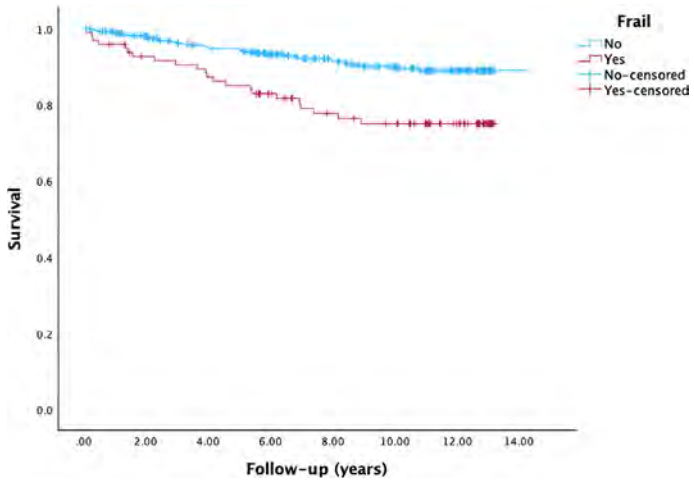

Image 1. Survival by frail status

prednisone daily dose, antimalarial and immunosuppressive drugs use). Additionally, a Kaplan-Meier curve was calculated by frail status (frail: SLICC-FI > 0.21 and non-frail: SLICC-FI ≤ 0.21).

Results: Five-hundred and nine patients were included, 470 (92.3%) were women and 96 (18.9%) were frail. Their mean (SD) age at diagnosis was 35.0 (14.0) years, their disease duration at baseline was 6.7 (6.1) years and their mean follow-up time was 8.5 (4.1) years. Fifty-seven (11.2%) patients died during the follow-up. The SLICC-FI predicted mortality in the unadjusted and adjusted models, which are depicted in Table 1. The corresponding Kaplan-Meier curve is depicted in Figure 1 (log-rank: $p < 0.001$).

Conclusion: Frailty, as ascertained with the SLICC-FI, predicted mortality, even after adjustment by possible confounders, in a Latin American cohort of SLE patients. Additional research is needed to evaluate this association and its impact as a clinical outcome in SLE in different settings. Further strategies to improve frailty should be developed.

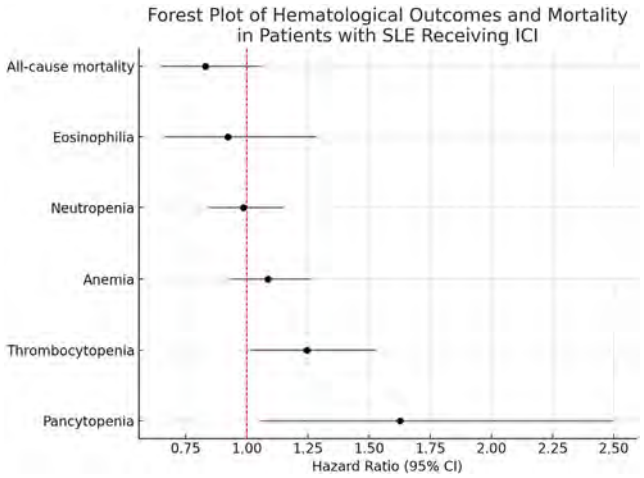

Figure 1: Forest plot of adjusted hazard ratios and 95% confidence intervals for hematological outcomes and all-cause mortality in cancer patients with pre-existing SLE treated with ICIs.

Background/Purpose: Immune checkpoint inhibitors (ICIs) have revolutionized cancer treatment, but their safety profile in patients with pre-existing autoimmune diseases, such as systemic lupus erythematosus (SLE), is not well characterized. Hematologic abnormalities are common in patients with SLE. Given the potential for ICIs to exacerbate immune-mediated adverse events, this study evaluated the risk of mortality and hematological adverse events in patients with cancer and pre-existing SLE treated with ICIs compared to matched patients without SLE.

Methods: We conducted a propensity score-matched cohort study using electronic health records from 101 U.S. healthcare organizations. Patients diagnosed with SLE (identified using International Classification of Diseases 10 codes) prior to cancer treatment and subsequently treated with ICIs (anti-PD-1/PD-L1 or CTLA-4) were matched 1:1 with non-SLE comparators based on demographics, comorbidities, cancer types, metastatic status, and prior cancer treatments. Outcomes of interest were a) hematologic abnormalities that were determined using laboratory measurements (i.e., defined by the presence of an abnormal lab value recorded after ICI initiation) and included pancytopenia, thrombocytopenia, anemia, neutropenia, and eosinophilia; and b) all-cause mortality. Cox proportional hazards models estimated the risk of hematological adverse events and all-cause mortality adjusting for above confounders.

Results: The analysis included 403 SLE patients and 403 matched non-SLE patients receiving ICIs. Mean age was 63.1 years; 77.8% were female and 68.7% White. Patients with pre-existing SLE demonstrated a significantly higher risk of developing pancytopenia (13.2% vs. 8.4%; HR=1.63, 95% CI: 1.06–2.5) and thrombocytopenia (50.9% vs. 42.4%; HR=1.25, 95% CI: 1.02–1.53). Risks of anemia, neutropenia, and eosinophilia did not differ significantly between groups. All-cause mortality was not significantly increased in patients with SLE compared to non-SLE controls (29.8% vs. 35.5%; HR=0.83, 95% CI: 0.65–1.06).

Conclusion: Cancer patients with pre-existing SLE receiving ICIs exhibit an increased risk of hematological adverse events, notably pancytopenia and thrombocytopenia, compared to matched controls without SLE. However, overall survival was comparable between both groups. These findings highlight the importance of vigilant hematological monitoring in this patient population and suggest the need for tailored management strategies when initiating ICI therapy in patients with SLE.

Abstract Number: 1719

Impact of SGLT2 Inhibitors on Cardiovascular Events, Mortality, and Lupus Nephritis in Patients with Systemic Lupus Erythematosus and Diabetes: Retrospective Cohort Study

Rusudan Tskitishvili[1], Abdallah Hussein[2], Nanuka Tsibadze[3], Shatha Shahwan[4] and Priju Varghese[2], [1]Virtua Health, Camden, NJ, [2]Virtua Health, Camden, [3]Jefferson Health - Einstein, Philadelphia, PA, [4]Jordan University of Science and Technology, Jordan

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes II: Morbidity & Mortality (1716–1721)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is associated with increased risks of cardiovascular events, renal complications, and premature mortality. Sodium-glucose co-transporter-2 (SGLT2) inhibitors have shown cardiorenal benefits in diabetic populations, but their impact among patients with both SLE and diabetes remains unclear.

Methods: This retrospective cohort study utilized data from the global TriNetX Collaborative Network and included adult patients (aged ≥18 years) diagnosed with systemic lupus erythematosus (SLE) and diabetes, with or without exposure to sodium-glucose co-transporter-2 (SGLT2) inhibitors, between January 1, 2015, and December 31, 2023. Patients were grouped based on receipt of SGLT2 inhibitors. The primary outcome was all-cause mortality, while secondary outcomes included major adverse cardiovascular events (MACE) and incidence of lupus nephritis over one year. Propensity score matching was employed to balance baseline characteristics between the SGLT2 and non-SGLT2 groups. Risk ratios and 95% confidence intervals (CIs) were calculated for univariable comparisons of outcomes after matching.

Results: After propensity score matching, 1,024 patients were included in each group. The overall cohort's mean ± SD age was 58.4 ± 12.4 years, with 80% female and the majority identifying as White (approximately 36%). Matching achieved balance across cohorts (standardized differences < 0.1 for key demographics). The incidence of major adverse cardiovascular events (MACE) was lower in the SGLT2 group compared to the non-SGLT2 group (4.3% vs. 6.1%; risk ratio [RR], 0.71; 95% CI, 0.487–1.034; p = 0.0726), though not statistically significant. All-cause mortality was significantly lower in the SGLT2 group (4.7% vs. 7.8%; RR, 0.60; 95% CI, 0.424–0.849; p = 0.0035). However, the incidence of lupus nephritis was significantly higher in the SGLT2 group compared to the non-SGLT2 group (11.3% vs. 5.0%; RR, 2.28; 95% CI, 1.655–3.125; p < 0.0001).

Conclusion: Among patients with SLE and diabetes, treatment with SGLT2 inhibitors was associated with a significant reduction in all-cause mortality but an increased risk of lupus nephritis. Although a trend toward fewer cardiovascular events was observed, it did not reach statistical significance. These findings highlight the need for careful benefit-risk assessment when prescribing SGLT2 inhibitors in this population and underscore the importance of further prospective studies.

Abstract Number: 1720

Comparison of Mortality Trends in Adults with Systemic Lupus Erythematosus and Cutaneous Lupus Erythematosus: A 21-Year Analysis Using CDC WONDER DATABASE.

Khadija Mohib[1], Rameez Qasim[2], Zaiya Waseem[3], Shaheer Ahmad[4] and Ahmad Ali Hussain[5], [1]Kirk Kerkorian School of Medicine at UNLV, Las Vegas, NV, [2]Allama Iqbal Medical College Lahore, Lahore, Pakistan, [3]AtlantiCare Regional Medical Center, New Jersey, [4]Allama Iqbal Medical College, Lahore, Pakistan, [5]Allama Iqbal Medical College Lahore, Lahore

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes II: Morbidity & Mortality (1716–1721)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Systemic Lupus Erythematosus (SLE) and Cutaneous Lupus Erythematosus (CLE) are chronic autoimmune diseases with significant morbidity and mortality, collectively accounting for approximately 5,000 deaths annually in the United States. Understanding long-term mortality trends can inform clinical management strategies and public health policies aimed at reducing mortality and addressing disparities across populations. This study analyzes national mortality data from 1999 to 2020 to compare demographic and geographic disparities in deaths associated with SLE and CLE. The goal is to identify at-risk populations and inform future interventions to improve outcomes and reduce preventable deaths.

Methods: Age-adjusted mortality rates (AAMRs) per 1,000,000 adults were calculated using CDC WONDER data. Deaths attributed to SLE were identified using ICD-10 code M32, while CLE-related deaths included codes L93.0 (discoid lupus), L93.1 (subacute cutaneous lupus), and L93.2 (other local lupus). Age-stratified trends were examined in 10-year intervals. Joinpoint regression analysis was used to estimate annual percent change (APC) and average annual percent change (AAPC) in mortality from 1999 to 2020.

Results: From 1999 to 2020, mortality rates for both systemic lupus erythematosus (SLE) and cutaneous lupus erythematosus (CLE) declined overall. However, deaths from SLE remained consistently higher than those from CLE. During this period, there were 47,337 recorded deaths due to SLE and 24,563 due to CLE. The average age-adjusted mortality rate (AAMR) for SLE was 6.6 per million, compared to 3.4 per million for CLE. Mortality rates were higher in females for both conditions, with a particularly large gap in SLE—10.7 in females versus 2.2 in males. Racial disparities were evident as well: non-Hispanic Black individuals had the highest mortality for both SLE (17.4) and CLE (7.4), followed by Native Americans. Urban areas saw slightly higher SLE mortality (6.6) than rural areas (6.4), while the opposite was true for CLE, with rural areas showing a higher rate (4.1 vs. 3.3). Regionally, SLE mortality was highest in the West and lowest in the Northeast, whereas CLE mortality peaked in the South and was lowest in the Northeast. Among states, Oklahoma reported the highest SLE mortality (10.8), while Arkansas had the highest for CLE (6.9).

Conclusion: Although overall mortality rates for SLE and CLE have declined over the past two decades, marked disparities persist by sex, race, and geography. SLE disproportionately affects females, NH Black individuals, urban populations, and those residing in the Western U.S. Conversely, CLE mortality is highest among females, NH Blacks, rural populations, and those in the Southern U.S.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. These findings underscore the need for state-specific interventions, improved access to rheumatologic care, and targeted public health strategies. Enhanced screening, early diagnosis, and equitable healthcare access are essential for reducing disease burden and closing existing mortality gaps. Future research should explore the underlying causes of these disparities and evaluate the impact of proposed interventions.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes II: Morbidity & Mortality (1716–1721)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Five-year survival in SLE has plateaued since the 1990s. Most epidemiologic studies pool all SLE phenotypes; It is possible that the excess mortality observed in SLE occurs and is driven predominantly in subgroups of patients. We examined whether excess mortality is confined to LN and/or antiphospholipid-antibody (aPL)–positive subsets.

Methods: We identified incident SLE cases diagnosed between 1976 and 2018 in a 27-county region of the US Midwest. Each case was matched 1:2 to non-SLE comparators on age, sex, race/ethnicity, and county of residence. SLE onset was defined by the first date fulfilling the 2019 EULAR/ACR criteria. A time-dependent lupus state exposure model was applied. All SLE patients initially contributed person-time to a non-renal, aPL-negative state (**SLE state**). Transition to an **aPL-positive state** occurred upon detection of lupus anticoagulant or IgG anticardiolipin/β2-glycoprotein I antibodies (≥40 GPL); transition to the **LN state** occurred at the first biopsy-confirmed nephritis or proteinuria ≥500 mg/24h. Patients fulfilling both criteria were classified in the LN state. Follow-up continued until death, emigration, or June 30, 2023. All-cause mortality was assessed using time-updated Cox proportional hazards models adjusted for age, sex, race/ethnicity, smoking status, and index date. Restricted mean survival time was used to estimate years of life lost compared to comparators.

Table 1. Baseline Characteristics of Systemic Lupus Erythematosus (SLE) Cases and Matched comparators*

Table 2. Association of Systemic Lupus Erythematosus (SLE), aPL (Antiphospholipid Antibodies positive), and lupus nephritis (LN) with mortality risk.

Mortality Risk		
States	**HR (95% CI)**	**p value**
SLE	1.72 (1.24 – 2.39)	0.001
aPL+	3.51 (1.80 – 6.84)	<.001
LN	4.65 (2.98 – 7.26)	<.001

Abbreviations: HR, Hazard ratios; CI, Confidence intervals.

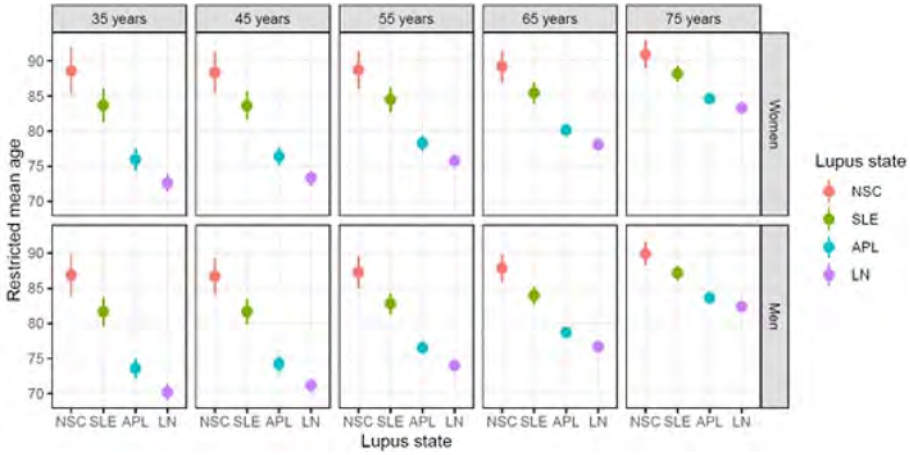

Figure. Restricted Mean Survival Age by Lupus Status, Sex, and Baseline Age. Each panel represents the restricted mean survival age for individuals categorized by baseline age (35, 45, 55, 65, and 75 years) and stratified by sex (women: top row, men: bottom row). Groups include non-SLE comparators (NSC), systemic lupus erythematosus (SLE), positive aPL (aPL), and lupus nephritis (LN). Error bars indicate confidence intervals.

Results: Among 1,128 participants (376 SLE, 752 comparators; median age 45 y; 80.6 % women), median follow-up was 9 years (IQR 7-14). There were 97 deaths among SLE patients and 100 among comparators, corresponding to crude mortality rates of 22 and 10 per 1,000 person-years, respectively. Among SLE patients, 105 developed LN, 69 became aPL-positive, and 227 remained free of both conditions. Twenty-five fulfilled criteria for both LN and aPL and were analyzed within the LN state (**Table 1**).

While patients remained in the SLE state, mortality was 72 % higher than in matched controls (HR 1.72, 95 % CI 1.24–2.39; $p = 0.001$). Risk rose sharply after transition to high-risk phenotypes—365 % higher with LN (HR 4.65, 95 % CI 2.98–7.26; $p < 0.001$) and 251 % higher after aPL seroconversion (HR 3.51, 95 % CI 1.80–6.84; $p < 0.001$) (**Table 2**). Restricted-mean survival showed life-expectancy deficits of 5 years for the SLE state, 16 years with LN and 13 years with aPL positivity (**Figure**).

Conclusion: Excess mortality in SLE was largely attributable to renal and aPL-positive disease. These findings support phenotype-based risk stratification and targeted interventions for high-risk subgroups, while offering a more reassuring prognosis for patients who remain free of nephritis and aPL seroconversion.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: Plenary III (1722–1727)
Session Type: Plenary Session
Session Time: 8:00AM–9:30AM

Background/Purpose: Current guidelines recommend using hydroxychloroquine (HCQ) dose ≤5.0 mg/kg for managing SLE. However, 6-fold higher SLE flares, including those requiring hospitalizations, are noted with HCQ dose of ≤5mg/kg vs. >5mg/kg (Jorge, 2022). Moreover, clear guidance on adjusting HCQ dose in chronic kidney disease (CKD) is lacking. HCQ blood level monitoring could better guide precise HCQ dosing based on patient risk factors. Leveraging data from diverse SLE cohorts, we aimed to study the upper threshold to define a therapeutic range for HCQ blood levels to support clinical use and inform dose adjustments.

Methods: Data were pooled from the SLICC Inception Cohort (n=660, 33 centers in 11 countries in North America, Europe, Asia), one longitudinal prevalent SLE registry (n=269, Wisconsin, USA), and three previously published studies of HCQ levels in SLE (n=1081, centralized in Paris, France). HCQ levels (T0) at first visit for the registry/cohort were measured in whole blood or serum; HCQ serum levels were converted to HCQ whole blood equivalent using the validated conversion factor of dividing by 0.53. The primary outcome was HCQ-related systemic toxicity (cardiac, retinal, muscle) at the last follow-up

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Fig. 1. Adjusted restricted cubic splines to show associations between: HCQ blood levels and toxicity (panel A), and HCQ blood levels and active lupus (SLEDAI ≥6) (panel B) using data from 1842 patients

(T last visit), identified from clinical reports. SLE Disease Activity Index (SLEDAI-2K) at T0 was abstracted to identify active SLE defined as SLEDAI-2K ≥6 (Secondary outcome). Using mixed regression analysis, we first identified a HCQ blood level (T0) predictive of higher HCQ toxicity (T last visit). Next, we tested if this upper threshold was supratherapeutic (no further risk reduction for active SLE). Finally, we examined associations between CKD stage ≥3 and supratherapeutic/toxic HCQ blood levels at T0.

Results: Among 1842 patients, 4.4% had toxicity (85% retinopathy, 9% cardiomyopathy, 6% myopathy). Odds of toxicity were 1.9-fold higher with blood levels >1150 ng/mL (Fig. 1A, Table 1A), and 1.04-fold higher with cumulative HCQ dose per 100g increase (Table 1A).

Using 750-1150 ng/ml as a reference range, levels < 750 ng/mL were associated with 1.4 fold higher odds of active SLE (Table 1B), while levels >1150 ng/mL were associated with a saturation in therapeutic effect, indicating supratherapeutic levels (Fig. 1B, Table 1B).

Patients on HCQ dose < 5mg/kg had 1.9-fold higher odds of active SLE (Table 1B); 52% of patients on ≤5mg/kg dose had subtherapeutic levels (< 750 ng/ml), and 18% supratherapeutic levels (>1150 ng/mL).

Statistically significant p-values (<0.05) shown in bold font.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Patients with CKD stage ≥3 had 2.3-fold higher odds of having supratherapeutic/toxic levels (>1150 ng/mL) (Table 2A). These associations remained significant even in patients on HCQ dose ≤5mg/kg (OR=1.94; Table 2B).

Conclusion: HCQ whole blood levels >1150 ng/mL predicted 2-fold higher risk of HCQ-related toxicity (confirming findings in Petri et al 2020), while levels < 750 ng/mL were associated with 1.4-fold higher active SLE risk. Even with HCQ dose ≤5mg/kg, 52% had subtherapeutic vs. 18% had supratherapeutic levels risking active SLE vs. toxicity, while those with CKD stage ≥3 had supratherapeutic/toxic levels (>1150 ng/mL). These findings establish the clinical significance of HCQ blood level monitoring to guide precise and optimal HCQ use to balance safety and efficacy in SLE.

Abstract Number: 1723

Impaired Maintenance of X-Chromosome Inactivation in B Cells, But Not T Cells, Exacerbates Interferon-Driven Systemic Autoimmunity

Nikhil Jiwrajka[1], Claudia Lovell[1], Zowie Searcy[1], Katherine Forsyth[1], Emma Welter[1], Natalie Toothacre[2], Nuriban Valero-Pacheco[1], Katherine Premo[1] and Montserrat Anguera[1], [1]University of Pennsylvania, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Plenary III (1722–1727)
Session Type: Plenary Session
Session Time: 8:00AM–9:30AM

Background/Purpose: Many systemic autoimmune diseases associated with chronic type 1 interferon (IFN) signaling, including SLE, SjD, and SSc, preferentially afflict females. The biological basis of this female sex bias and its role in chronic IFN signaling are not well understood. Emerging data have implicated the X chromosome as a key contributor to female-biased autoimmunity. In XX individuals, X chromosome dosage is balanced with that of XY individuals via X-Chromosome Inactivation (XCI), an epigenetic mechanism that transcriptionally silences supernumerary X chromosomes via the long non-coding RNA, XIST. Strikingly, T and B cells from females with SLE exhibit epigenetic features of impaired XCI maintenance (XCIm). However, it is unclear from these data whether impaired XCIm in T or B cells directly contributes to IFN-mediated disease. Given the many immunomodulatory X-linked genes with roles in lymphocyte function and IFN signaling, we investigated whether impaired XCIm in female lymphocytes modifies the development of IFN-driven systemic autoimmunity.

Methods: We generated female C57BL/6 mice with either a B-cell-specific deletion of *Xist* (Mb1cre$^{+/-}$Xist$^{fl/fl}$, "Xist BcKO") or a T cell-specific deletion of *Xist* (Cd4cre^{+}Xist$^{fl/fl}$, "Xist TcKO"). Female Xist BcKO mice and littermate controls ("WT") or female Xist TcKO mice and littermate controls ("WT") were treated thrice weekly with topical imiquimod (IMQ), a Tlr7 agonist, for 12 weeks (**Fig. 1A**). Serum, spleens, cervical lymph nodes, kidneys, and other tissues were harvested upon euthanasia and processed for autoantibody quantification, flow cytometry, and histology.

Results: IMQ-treated Xist BcKO mice exhibited markedly increased spleen mass, increased anti-dsDNA and anti-U1RNP/Smith autoantibody production, and more severe glomerular disease compared to WT mice (**Fig. 1B-C**). In contrast, IMQ-treated Xist TcKO mice did not exhibit significant differences in spleen mass, autoantibody levels, or glomerular pathology compared to IMQ-treated WT mice (**Fig. 1D**). Unlike IMQ-treated Xist TcKO mice, IMQ-treated Xist BcKO mice exhibited greater proportions of antibody-secreting and activated T and B cell subsets, including germinal center (GC) and age-associated B cells (ABCs), across the spleen, lymph nodes, and peripheral blood. Anti-U1RNP/Smith autoantibody levels were strongly correlated with the proportion of ABCs across all tissues; both rely on Tlr7 signaling (**Fig. 2A-B**). Activated B cell subsets from IMQ-treated Xist BcKO mice exhibited higher median fluorescence intensities of X-linked proteins, including Tlr7 and Cxcr3, suggesting their aberrant overexpression in the setting of *Xist* deletion (**Fig. 2C**).

Conclusion: These data demonstrate that impaired XCIm via *Xist* deletion has cell-type-specific effects on IFN-driven autoimmunity. They also demonstrate that impaired XCIm in B cells, but not T cells, amplifies humoral, cellular, and histopathological features of IFN-driven disease, and results in the overexpression of X-linked proteins likely derived from the inactive X chromosome. These findings support a novel mechanism of female-biased autoimmunity wherein impaired XCIm in B cells enhances susceptibility to IFN-mediated autoimmunity.

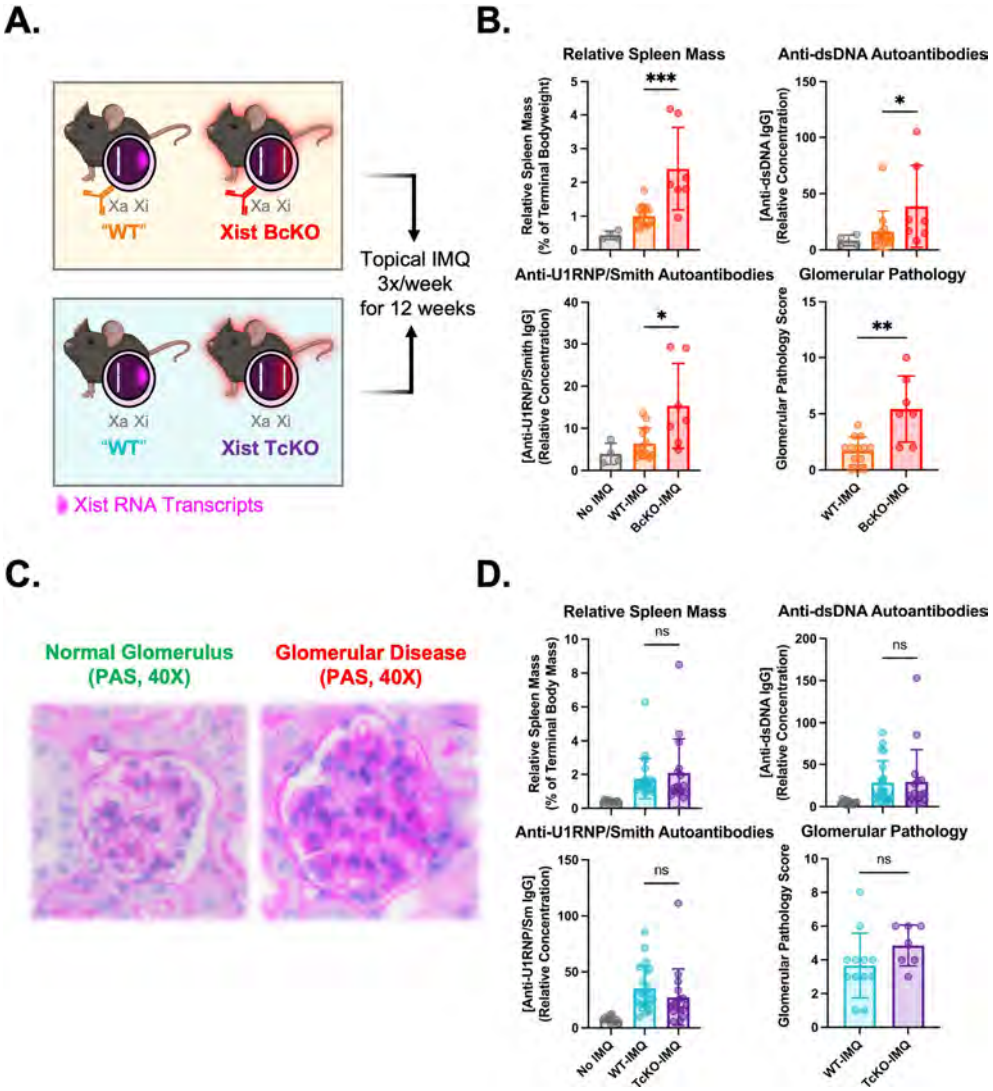

Figure 1. Xist Deletion in B Cells, But Not T Cells, Exacerbates Humoral and Histopathological Features of IMQ-Induced Disease. A. Schematic of the experimental approach. B. Quantification of relative spleen mass, autoantibody concentration, and glomerular pathology in IMQ-treated Xist BcKO mice (n=7) versus IMQ-treated WT mice (n= 13). The "Glomerular Pathology Score" represents the sum of subscores (0 = none, 1 = minimal, 2 = mild, 3 = moderate, 4 = severe) for key histopathologic features specific to the glomerulus; 10-50% of glomeruli were affected in most mice. C. Images of an unaffected and a diseased glomerulus (40X; same image scale), stained with periodic acid-Schiff (PAS). D. Quantification of relative spleen mass, autoantibody concentration, and glomerular pathology in IMQ-treated Xist TcKO mice (n=16) versus IMQ-treated WT mice (n=21). WT mice that were not treated with IMQ are included for both experiments to serve as a reference (n=4 for Xist BcKO experiments; n=12 for Xist TcKO experiments). Data are depicted as mean +/- SD. *, **, *** = $p < 0.05$, 0.01, 0.001 via pairwise Mann-Whitney U test (IMQ-cKO vs. IMQ-WT). ns = not statistically significant; Xa = active X chromosome; Xi = inactive X chromosome.

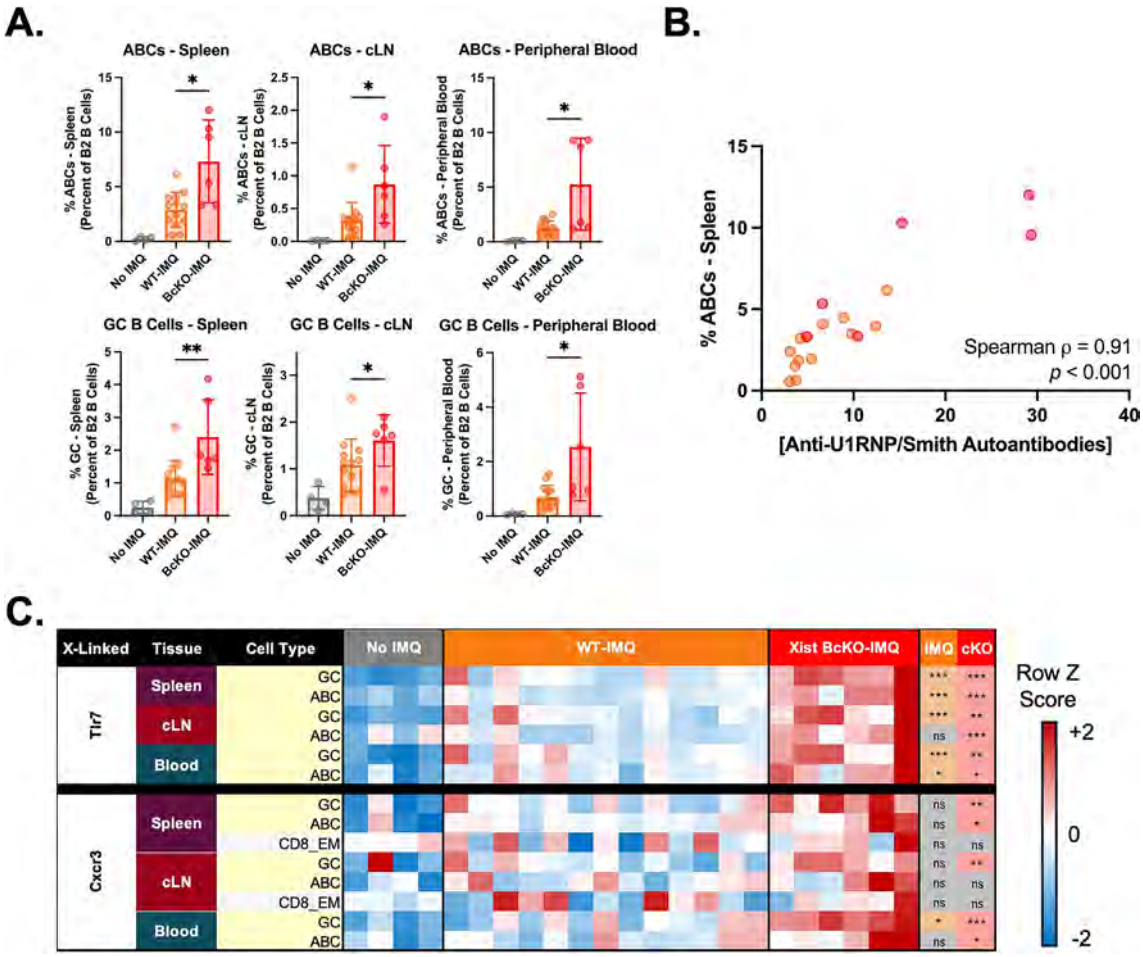

Figure 2. IMQ-treated Xist BcKO Mice Exhibit Increased Proportions of Activated B Cell Subsets in the Setting of Increased Tlr7 Protein Levels. A. Proportions of activated B cell subsets across the spleen, cervical lymph nodes, and peripheral blood in untreated WT, IMQ-treated WT, and IMQ-treated Xist BcKO mice, quantified via flow cytometry‡. Data are depicted as mean +/- SD. *, ** = p < 0.05, and 0.01, respectively, via pairwise Mann-Whitney U test (BcKO-IMQ vs. WT-IMQ). B. Scatterplot and Spearman correlation of anti-U1RNP/Smith antibody concentration versus the percent of splenic age-associated B cells among IMQ-treated mice. Data are colored by experimental group. C. Heatmap depicting the row-normalized median fluorescence intensities of Tlr7 and Cxcr3 across B cell subsets, tissue types, and experimental groups. Each column represents a unique biological sample. The results of the pairwise Mann-Whitney U tests are depicted in the columns "IMQ" and "cKO". "IMQ" refers to the pairwise comparison between "WT-IMQ" and "No IMQ". "CKO" refers to the pairwise comparison between "BcKO-IMQ" and "WT-IMQ". *, **, *** = p < 0.05, 0.01, and 0.001, respectively. ABCs = age-associated B cells (Cd21/35-Cd23-Cd11c+Tlr7+); CD8_EM = CD8+ Effector

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: Plenary III (1722–1727)
Session Type: Plenary Session
Session Time: 8:00AM–9:30AM

Background/Purpose: Mucosal-associated invariant T (MAIT) cells are innate-like lymphocytes that produce cytokines and cytotoxic molecules. Reduced frequencies and altered phenotypes of MAIT cells have been described in autoimmune diseases. Their ability to interact with microbiota and accumulate in inflamed tissues suggests a role in RA pathogenesis.

The objective was to explore the phenotypic, functional, and transcriptomic alterations of MAIT cells in blood and synovial fluid (SF) in RA and assess their impact on inflammation and joint damage using in vitro and in vivo models.

Methods: MAIT cells were analyzed by flow cytometry in peripheral blood from 75 RA patients and 42 healthy donors (HD). SF MAIT cells were studied in 19 RA patients. Single-cell RNA sequencing (scRNA-seq) was performed on paired blood and SF samples from 6 RA patients and 4 HDs. MAIT–fibroblast-like synoviocyte (FLS) interactions were assessed in co-culture. To study their in vivo role, MAIT cells were modulated in two arthritis mouse models—mBSA (methylated bovin serum albumin)-induced and TNF-transgenic—using MR1 knockout mice and Ac-6-FP, a pharmacological inhibitor of MAIT cell activation.

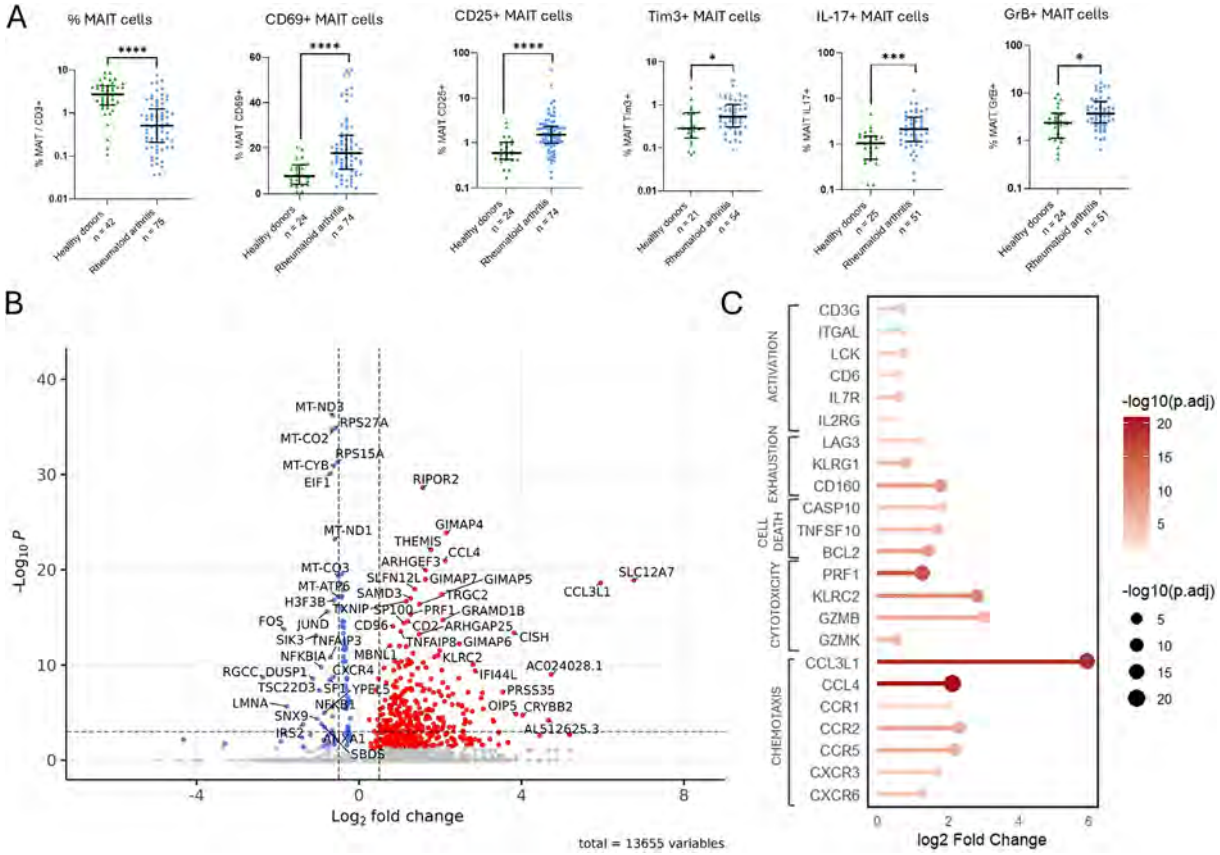

Figure 1. Phenotypic and transcriptomic alterations of circulating MAIT cells in RA. (A) Frequency and functional profile of circulating MAIT cells in RA patients compared to healthy donors (HD), including expression of CD69, CD25, Tim-3, IL-17, and granzyme B after stimulation. (B) Volcano plot showing differentially expressed genes in RA MAIT cells versus HD, based on single-cell RNA sequencing (scRNA-seq). (C) Lollipop plot summarizing selected upregulated genes in RA MAIT cells, categorized into functional groups: activation, exhaustion, apoptosis, cytotoxicity, and chemotaxis. Statistical comparisons were performed using Mann–Whitney test. MAIT: mucosal-associated invariant T cell; RA: rheumatoid arthritis; HD: healthy donor; scRNA-seq: single-cell RNA sequencing.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

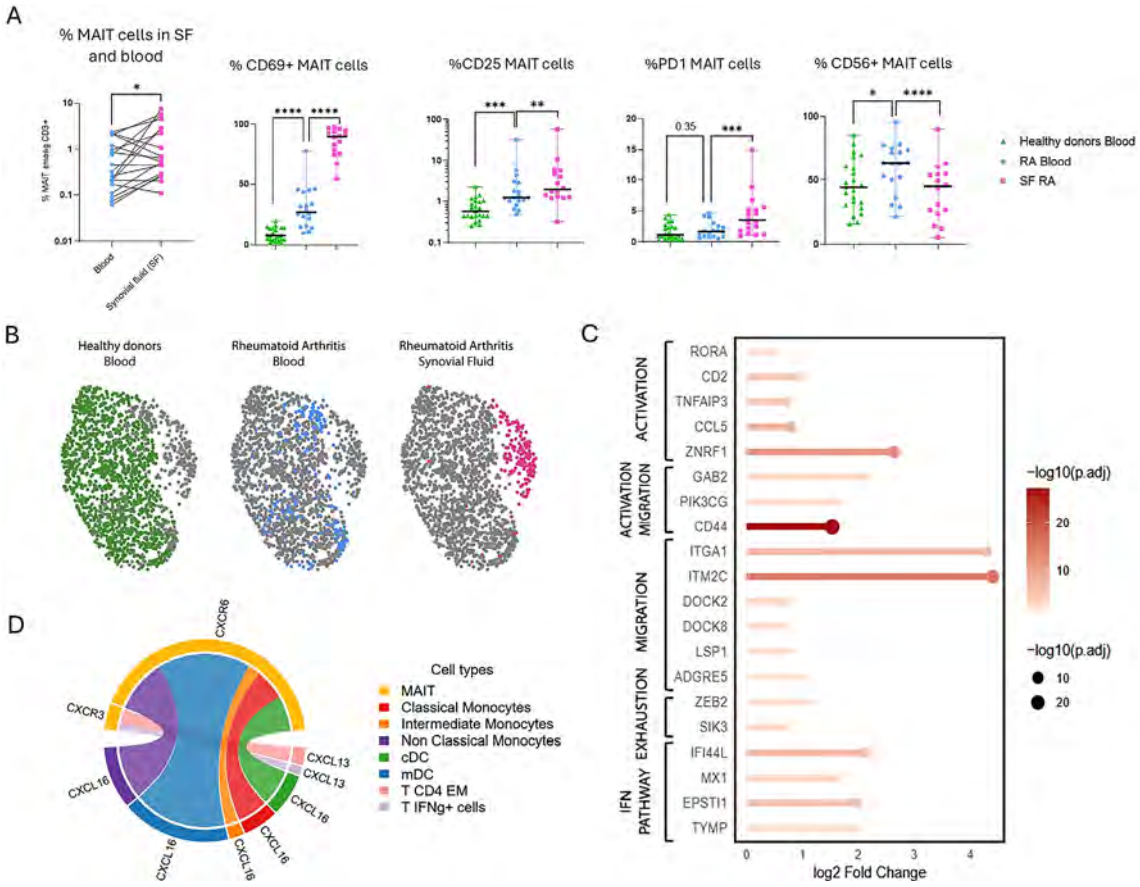

Figure 2. Phenotypic and transcriptomic profile of MAIT cells in synovial fluid. (A) Frequency and surface marker expression of MAIT cells from synovial fluid (SF) of RA patients compared to paired peripheral blood MAIT cells and blood MAIT cells from healthy donors (HD), including CD69, CD25, PD-1, and CD56. (B) UMAP projection of all MAIT cells analyzed by single-cell RNA sequencing (scRNA-seq), colored by sample origin: HD blood, RA blood, and RA SF. (C) Lollipop plot showing selected differentially expressed genes in RA SF MAIT cells compared to RA blood MAIT cells, grouped by function: activation, activation/migration, migration, exhaustion, and interferon (IFN) pathway. (D) Circos plot illustrating CellChat-predicted interactions between chemokine receptors expressed by circulating MAIT cells (e.g., CXCR3, CXCR6) and their ligands expressed by synovial immune cell subsets. Statistical comparisons were performed using Wilcoxon Test. MAIT: mucosal-associated invariant T cell; RA: rheumatoid arthritis; SF: synovial fluid; HD: healthy donor; scRNA-seq: single-cell RNA sequencing; IFN: interferon.

Results: Circulating MAIT cells were reduced in RA compared to HD (0.51% vs 2.7%, p< 0.001), with an activated/exhausted phenotype (↑CD69, CD25, Tim-3) and increase production of IL-17 and granzyme B. scRNA-seq showed upregulation of genes linked to activation, exhaustion, apoptosis, cytotoxicity (GZMB, PRF1), and chemokines receptors (CCR1, CXCR6). Despite their depletion in blood, MAIT cells were enriched in SF (0.65% vs 0.32%, p=0.048), especially in early arthritis. SF MAIT cells were more activated (↑CD69, CD25), exhausted (↑PD-1, ↓CD127), and had lower CCR6 and CD56 expression. scRNA-seq confirmed this profile, and revealed type I IFN pathway engagement, as well as chemokine-driven migration signature. CellChat analysis implicated pDCs and monocytes in generating a chemokine gradient recruiting MAIT cells into joint. SF MAIT cells also showed increased IL-10, suggesting combined inflammatory and regulatory roles.

Activated MAIT cells enhanced FLS activation in co-culture, increasing ICAM1 and PDPN expression, and secretion of IL-1β, IL-6, IL-8, and MCP-1. Bulk RNA-seq of FLS exposed to activated MAIT cells showed upregulation of inflammatory cytokines, chemokines, IFN-stimulated genes, and matrix-degrading enzymes.

In vivo, MR1 KO mice showed reduced arthritis severity and joint damage in both models. Ac-6-FP treatment also improved clinical and histological outcomes in mBSA arthritis.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

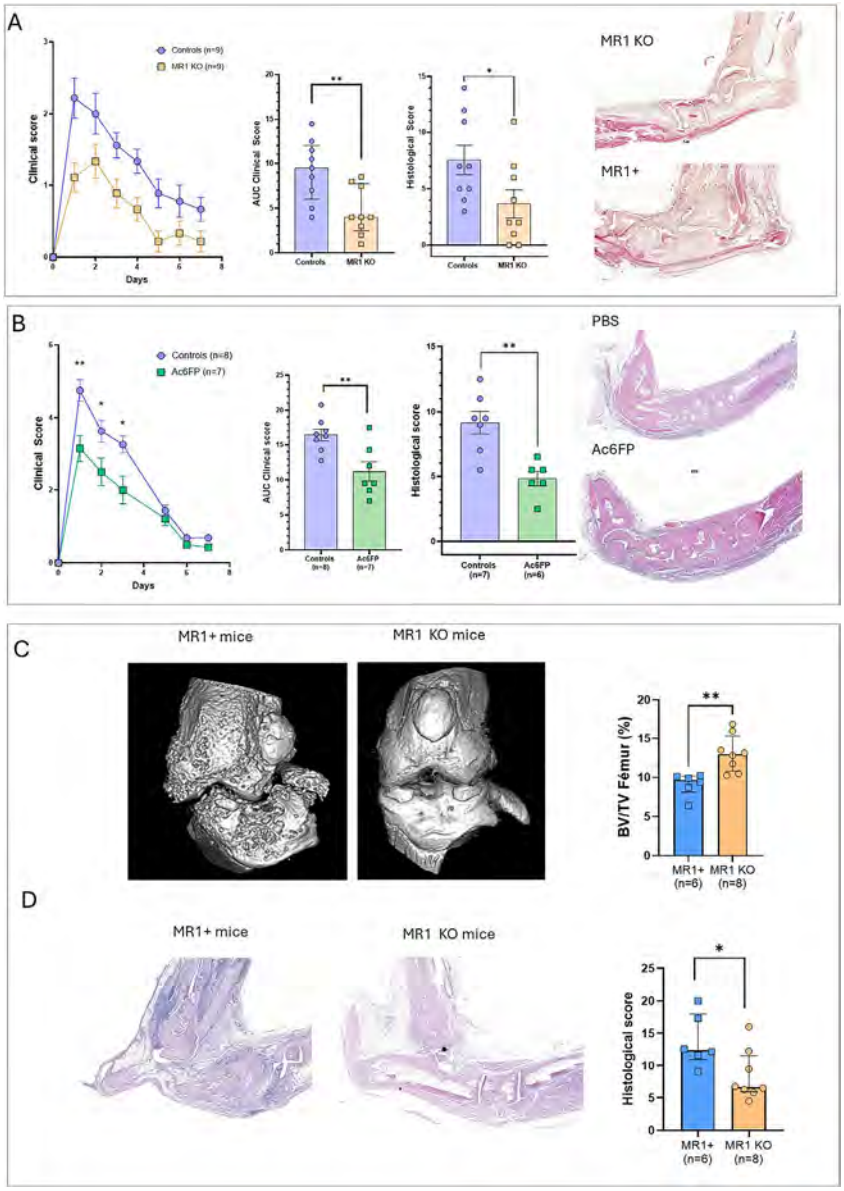

Figure 3. In vivo modulation of MAIT cells in two murine models of arthritis. (A) Clinical arthritis score and histological inflammation score in the mBSA-induced arthritis model, comparing MR1 knockout (KO) mice (MAIT cell-deficient) to wild-type controls. (B) Effect of pharmacological MAIT cell inhibition using Ac-6-FP versus PBS control in the mBSA model: clinical score and histological inflammation score. TNF arthritis in MR1 KO mice compared to controls : (C) Micro-computed tomography (microCT) assessment of bone erosions showing increased bone volume fraction (BV/TV) in MR1 KO mice compared to controls. (D) Histological inflammation score in TNF-transgenic MR1 KO and control mice. Statistical comparisons were performed using Student T test. MAIT: mucosal-associated invariant T cell; MR1 KO: MR1 knockout; mBSA: methylated bovine serum albumin; BV/TV: bone volume/total volume; PBS: phosphate-buffered saline.

Conclusion: MAIT cells are reduced in blood but accumulate in RA synovial fluid, where they are highly activated and exhausted, likely shaped by local inflammation. Their migration from blood to the joint may be driven by a synovial chemokine gradient. In the joint, they promote inflammation through cytotoxicity, cytokine production, and FLS activation. Notably, their IL-10 expression suggests additional immunoregulatory functions. Modulating MAIT cells reduces arthritis in murine models, supporting their therapeutic potential in RA.

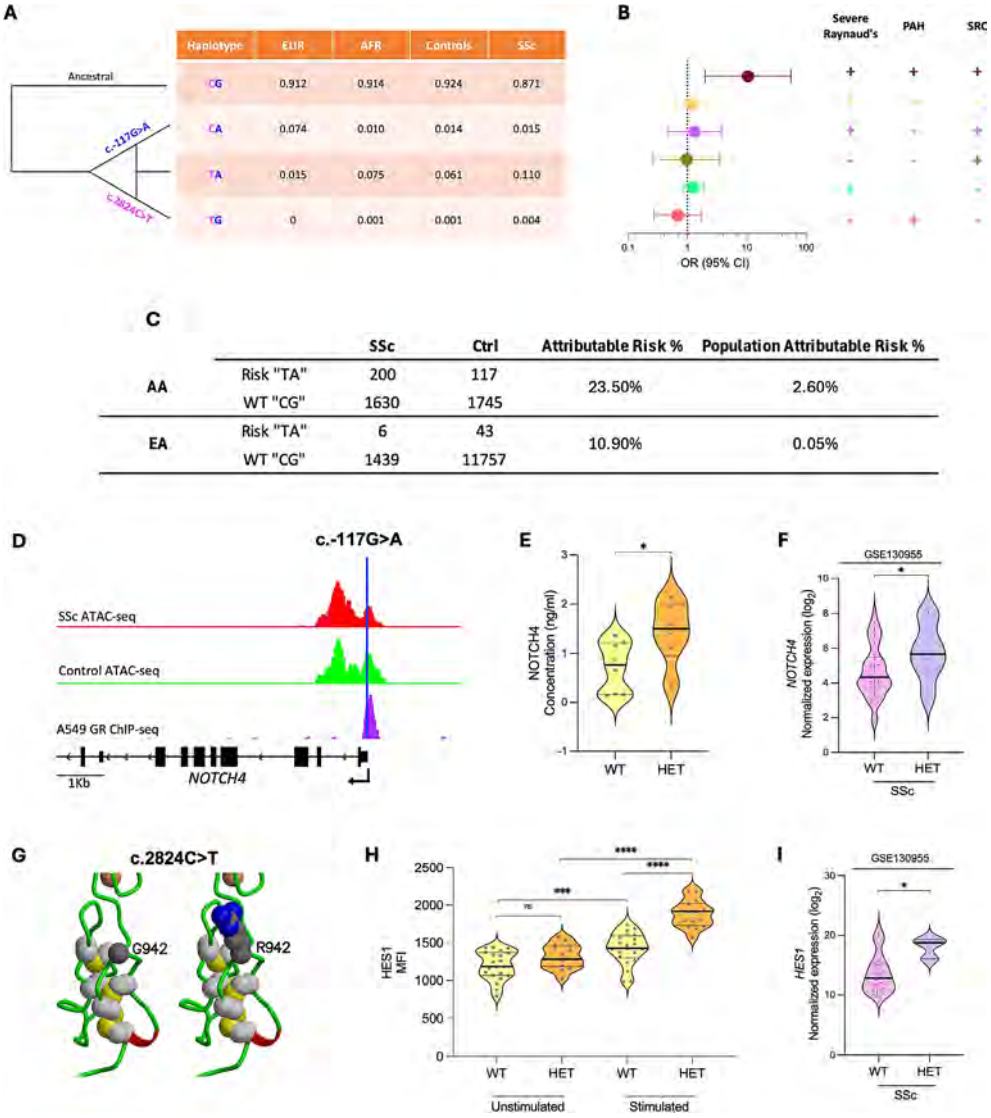

Fig. 1. A. Frequencies of c.2824C>T and c.-117G>A haplotypes in SSc cases, controls and reference European (EUR) (n=136) and African (AFR) (n=471) ancestral populations. B. Odds ratios for the risk "TA" haplotype vs. wildtype "CG" across SSc vascular phenotypes. C. Population Attributable risk for the NOTCH4 haplotype in African Americans (AA) and European Americans (EA). D-F show c.-117G>A data. G-I show c.2824C>T data. D. ATAC-seq signal at the NOTCH4 locus in primary endothelial cells from SSc patients and healthy controls (GSE163199) and the GR-a ChIP-seq in A549 cells with c.-117G>A marked in blue. E. NOTCH4 ELISA data in unstimulated LCLs wild type (WT) or Heterozygous (HET) for c.-117G>A. F. NOTCH4 expression in SSc skin, stratified by the c.-117G>A variant (GSE130955). G. c.2824C>T alters glycine to arginine at position 942. H. Flow cytometry data for HES1 before and after stimulation of NOTCH4 with DLL4 ligand, in LCLs WT or HET for the c.2824C>T variant. I. HES1 expression in SSc skin, stratified by the c.2824C>T variant (GSE130955).

Background/Purpose: Systemic sclerosis (SSc) is characterized by vasculopathy, progressive fibrosis of skin and internal organs, and autoimmunity. Notably, African American (AA) patients with SSc exhibit a more severe vascular phenotype and poorer outcomes than European Americans. We hypothesized that common variants in SSc tag gene regions enriched for rare, functional variants cause increased disease burden in AAs with SSc.

Methods: Exome and targeted sequencing were performed in discovery and replication cohorts comprising 969 AA SSc patients and 771 AA controls, focusing on 32 SSc-associated genes. Two *NOTCH4* variants were examined in lymphoblastoid cell lines (LCL) using RT-PCR, ELISA, and flow cytometry. SSc skin single-cell RNA-Seq and publicly available bulk gene expression datasets were analyzed. Endothelial cell (EC) lines and variant-carrying ECs from SSc patients (pECs) were used

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Fig. 2. A. UMAP plot of subclustered skin cells of SSc and control subjects with colors denoting different subpopulation. B. Density plot for NOTCH4 expression, primarily in endothelial cells, with lighter color indicating higher expression. C. UMAP plot of reclustered endothelial cells in SSc and control subject. D. Density plot for NOTCH4 expression, primarily in arterial, mature capillary and tip endothelial cell cluster, with lighter color indicating higher expression. E. Decreased tube formation upon NOTCH4 activation by its ligand DLL4 in endothelial cell line, unaffected by prior NOTCH4 knockdown. F. Restoration of normal tube formation after inhibition of NOTCH4 signaling using anti-NOTCH4 antibody, DAPT, or Nirogacestat prior to DLL4 stimulation. G-H. Rescued tube formation in SSc primary endothelial cells (WT and HET for c.-117G>A variant) after blocking NOTCH4 signaling with anti-NOTCH4 antibody or Nirogacestat. I. Co-staining of Acta2 (red), CD31 (green) and Erg (white) in thin-walled vessels of constitutively Notch4* expressing brain endothelial cells in Tie2-tTA;TRE-Notch4* mutant mice and Tie2-tTA littermate control mice. J. Quantification of thin-walled vessels co-stained for Acta2 (EndoMT marker) and CD31 in constitutively Notch4* expressing brain endothelial cells in Tie2-tTA;TRE-Notch4* mutant mice and Tie2-tTA littermate control mice. K. Increase in EndoMT markers NOTCH3 and SNAI2 following DLL4-induced NOTCH4 stimulation; restored to baseline levels with Nirogacestat. L. Decrease in ACTA2, COL1A1, and SNAI1 expression in primary endothelial cells from SSc patients (Het for c.-117G>A) after Nirogacestat treatment.

to assess angiogenesis using tube formation assays and to study endothelial-to-mesenchymal transition (EndoMT) following NOTCH4 stimulation or inhibition. A Tie2-tTA;TRE-Notch4* mouse model with inducible, EC-specific expression of active Notch4 was used to study EndoMT.

Results: Gene-based testing identified *NOTCH4* association with SSc (P=1.6x10^{-7}) particularly in AAs with severe vasculopathy (P=3.5x10^{-7}). The risk haplotype "TA", defined by the missense (c.2824C >T) and promoter (c.-117G >A) variants, was enriched in AAs with SSc (11%) and increased the risk of having severe Raynaud's, scleroderma renal crisis (SRC), and pulmonary arterial hypertension (PAH) (OR=10.6, 95% CI 2-56) (Fig. 1A-B). The population attributable risk due to this haplotype in AAs with SSc was 2.6%, 52-fold higher than in European Americans (Fig. 1C). The c.-117A allele bound glucocorticoid receptor and increased NOTCH4 protein expression (Fig. 1D-E). SSc skin samples with c.-117G >A variant had a higher *NOTCH4* expression than those with the G allele (Fig. 1F). The c.2824T allele upregulated NOTCH4 signaling in LCLs (Fig. 1G-H), confirmed in vivo by elevated *HES1* transcripts in c.2824T **vs. c.2824C** SSc samples (Fig. 1I). scRNA-Seq data for SSc skin revealed that *NOTCH4* is predominantly expressed by ECs (Fig. 2 A-B) especially arterial, mature capillary and

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

tip cells (Fig 2 C-D). NOTCH4 stimulation in the EC line and c.-117A allele-carrying pECs led to decreased tube formation (an angiogenesis indicator) (Fig. 2E-H) and increased EndoMT (Fig. 2K-L). NOTCH4 overexpression in *Tie2-tTA;TRE-Notch4** mutant mice also increased Acta2 (EndoMT marker) expression in ECs (Fig. 2I-J). Nailfold capillary abnormalities, decreased angiogenesis, and fibrosis of the vascular lumen are commonly seen in SSc. Inhibition of NOTCH4 using genetic knockdown, blocking antibody, or the FDA-approved drug Nirogacestat restored angiogenesis (Fig. 2 E-H) and normalized EndoMT in ECs (Fig. 2 K-L).

Conclusion: Functional variants in *NOTCH4* gene are associated with SSc pathogenesis and vasculopathy and may explain the higher disease burden of SSc in AAs. Blocking NOTCH4 signaling restored angiogenesis and EndoMT, highlighting its potential as a therapeutic target in restoring angiogenesis in SSc and connective tissue diseases.

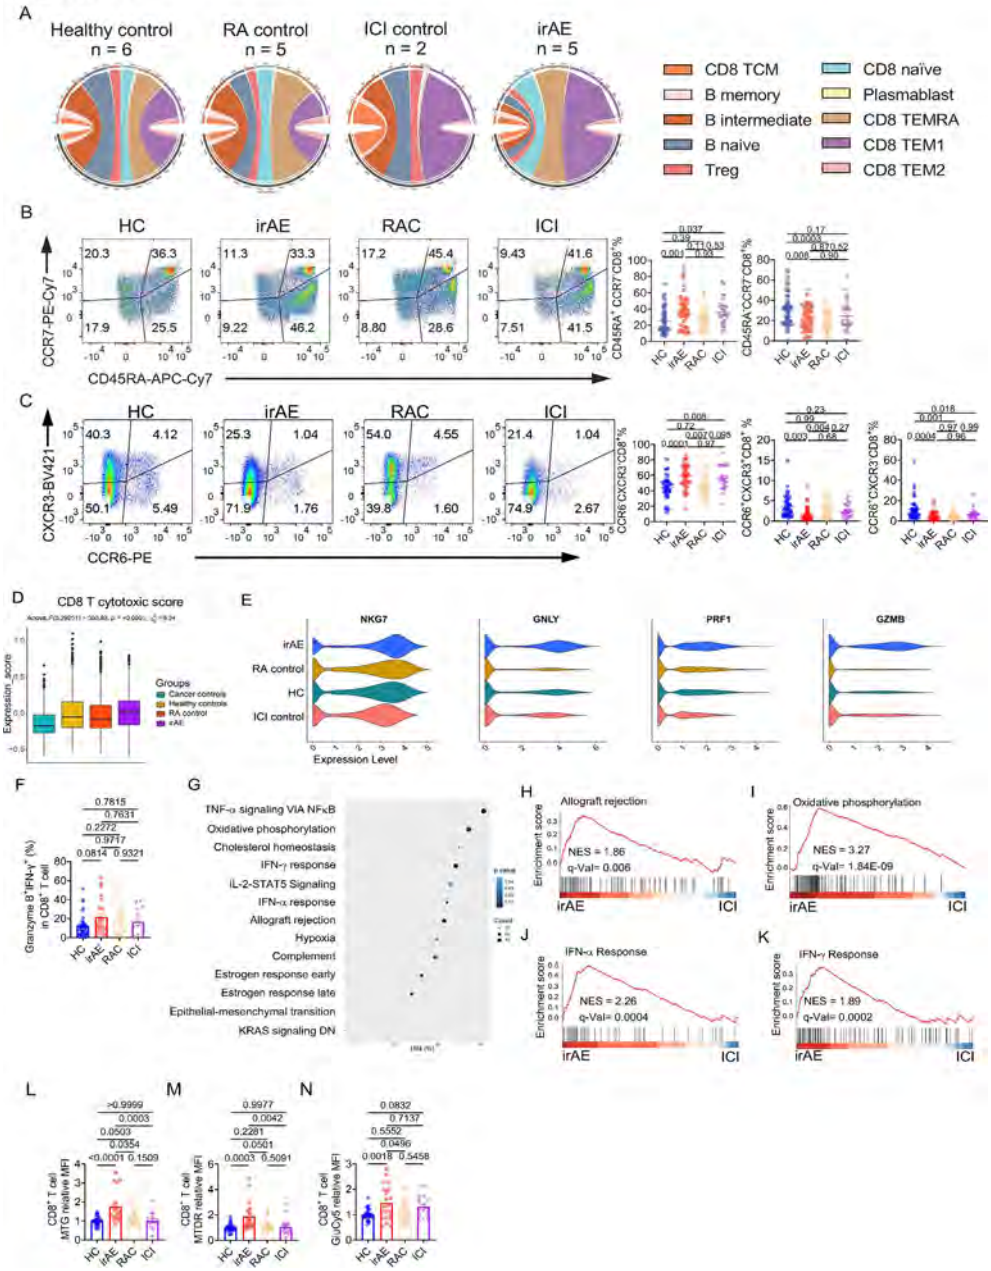
SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: Plenary III (1722–1727)
Session Type: Plenary Session
Session Time: 8:00AM–9:30AM

Figure 1



(A) Circos plots show the percentage of different subsets of CD8+ T cells and B cells. (B) Representative flow cytometry plot of CD45RA and CCR7 expression on CD8+ T cells from HC, ICI, RAC or irAE. Right, summaries of the percentage of CD45RA+CCR7–CD8+ T cells and CD45RA–CCR7–CD8+ T cells. (C) Representative flow cytometry plot of CXCR3 and CCR6 expression on CD8+ T cells. Right, summaries of CXCR3–CCR6–CD8+, CXCR3+CCR6+CD8+, and CCR6+CXCR3–CD8+ T cells. (D) The cytotoxic score was evaluated on CD8+ T cells using the gene list identified in the paper (78) . (E) Specific cytotoxic or effector function–related genes were evaluated on the CD8+ T cells. (F) Fresh PBMCs from different groups were stimulated with PMA/Ionomycin/Monensin for 5 h, Granzyme B+IFN–g+CD8+ T cells were evaluated. (G–K) GSEA was performed on the CD8+ T cells between irAE and ICI. (G) Pathways that were significantly enriched in the comparison. GESA plot of the allograft rejection (H), oxidative phosphorylation (I), IFN–a response (J), and IFN–g response (K). (L–N) PBMCs from different groups were stimulated with 10 μg/mL plate–coated anti–CD3 and anti–CD28 for 5 days, dyes including mitochondria green (MTG) (L), mitochondria deep red (MTDR) (M), or GlucoseCy5 (GluCy5) (N) were examined on CD8+ T cells, and the expression was normalized to the HC in each experiment. Data in graphs represent mean ± SEM, Significance was tested by one-way ANOVA.

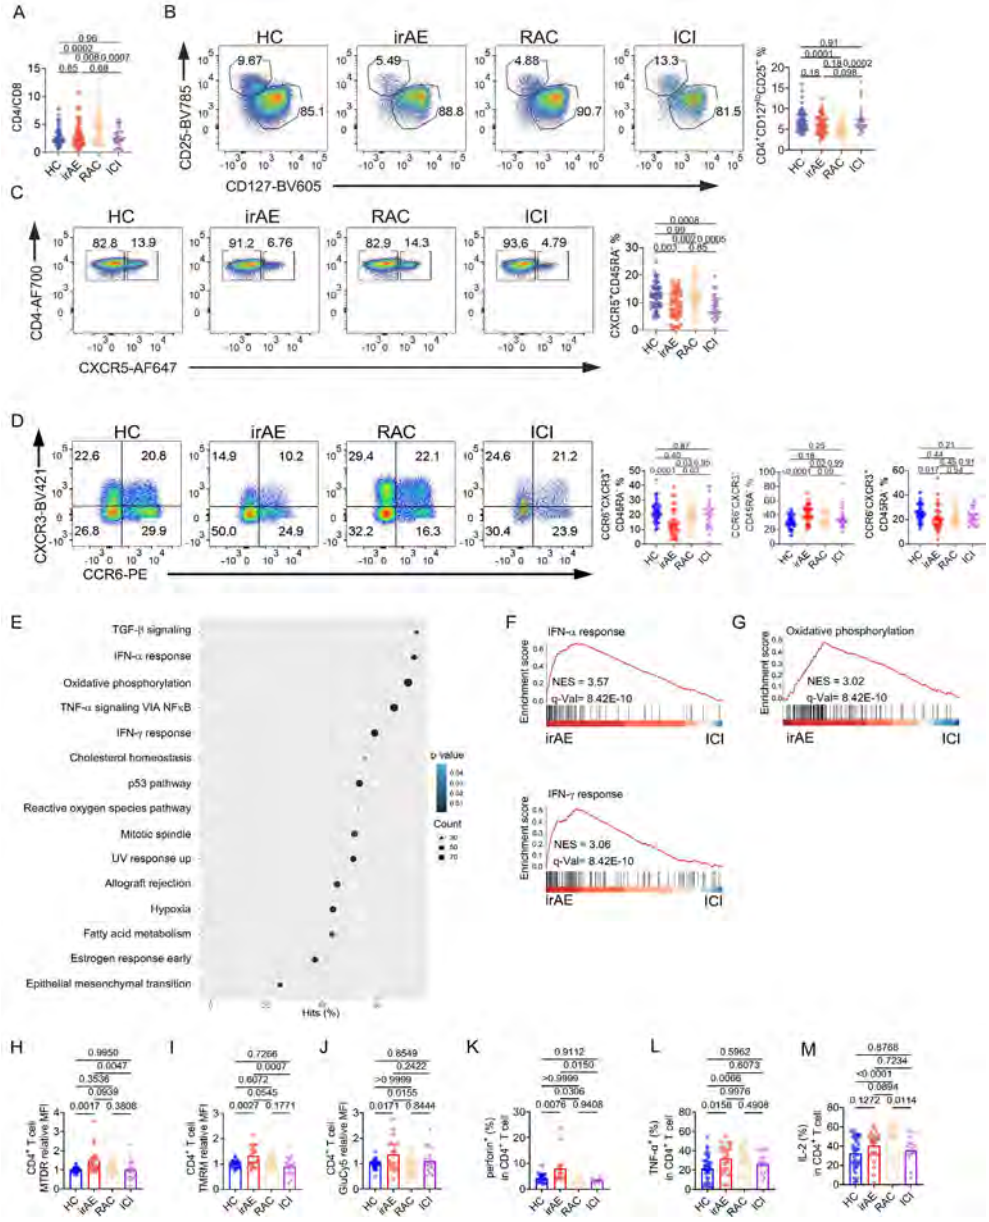
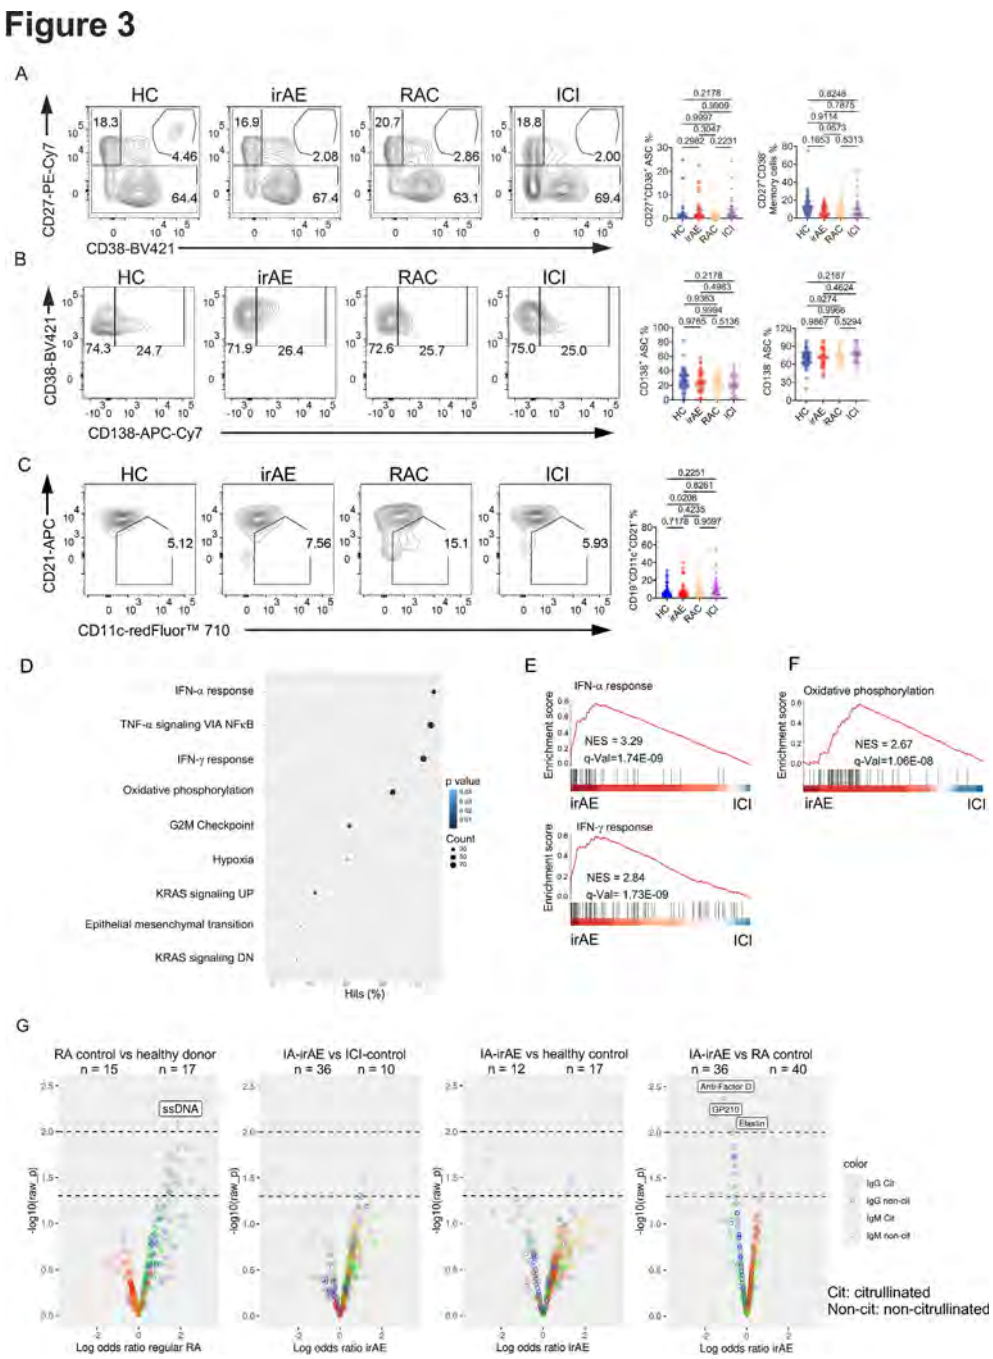
Figure 2



(A) The ratio of CD4 to CD8 in the PBMCs was calculated. (B) Representative flow cytometry plot of CD25 and CD127 expression on CD4+ T cells. Right, a summary of the percentage of CD25+CD127lo regulatory T cells in CD4+ T cells from different groups. (C) Representative flow cytometry plot of CXCR5 and CD4 expression on the CD45RA–CD4+ T cells. Right, a summary of the percentage of CXCR5+CD45RA–CD4+ T cells. (D) Representative flow cytometry plot of CCR6 and CXCR3 expression on CD45RA–CD4+ T cells. Right, summaries of the percentage of CXCR3+CCR6–CD45RA–, CXCR3+CCR6+CD45RA–, CXCR3–CCR6–CD45RA– CD4+ T cells. (E–G) GSEA was performed on the CD4+ T cells between irAE and ICI. (E) Significantly enriched pathways in CD4+ T cells from irAE and ICI. GSEA plots of IFN–a and IFN–g response (F), and oxidative phosphorylation (G). (H–M) PBMCs from different groups were stimulated with 10 μg/mL plate–coated anti–CD3 and anti–CD28 for 5 days, dyes including MTDR (H), TMRM (I), or GluCy5 (J) were measured on CD4+ T cells, and the expression was normalized to the HC in each experiment. (K-M) Fresh PBMCs from different groups were stimulated with PMA/Ionomycin/Monensin for 5 h, and perforin+ (K), TNF–a+ (L) and IL–2+ CD4+ T cells were examined. Data in graphs represent mean ± SEM, Significance was tested by one-way ANOVA.

Background/Purpose: The immunological basis of inflammatory arthritis (IA) immune related adverse event (irAE) following anti-PD-1/PD-L1 immune checkpoint inhibition (ICI) therapy is incompletely understood. The relationship between IA irAE and rheumatoid arthritis (RA) remain unclear. Furthermore, while both autoreactive T and B cells critically contribute to



(A) Representative flow cytometry plot of CD27 and CD38 expression on the PBMCs. Right, summaries of the percentage of CD27hiCD38hi antibody–secreting cells (ASCs) and CD27+CD38– memory B cells. (B) Representative flow cytometry plot of CD138 in CD27hiCD38hi ASCs. Right, summaries of the percentage of CD138+ ASCs and CD138– ASCs. (C) Representative flow cytometry plot of CD11c and CD21 expression on IgD–CD27– B cells and summary of the percentage of CD11c+CD21–IgD–CD27– B cells. (D–F) GSEA was performed on the B cells between irAE and ICI. (D) Significantly enriched pathways in B cells from irAE and ICI. GSEA plots of IFN–a and IFN–g response (E), and Oxidative phosphorylation (F). (G) The volcano plot of the citrullinated or non–citrullinated relative IgG or IgM–isotype autoantigen levels comparing RA and HC, irAE and ICI, irAE and HC, or irAE and RA. The autoantigens were labeled when $p < 0.01$. Data in graphs represent mean ± SEM, Significance was tested by one-way ANOVA.

immunopathology in most RA patients, the existence of antibody independent arthritis has been suggested, but remains contentious. We aim to investigate the distinguishing immunological phenotypes between anti-PD-1/PD-L1 treated patients with IA irAE and those without irAE, and the relationship between IA irAE and serologically matched RA.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We analyzed a cohort of 163 patients, including 34 rheumatic irAE patients (all with inflammatory arthritis), 26 ICI control patients (cancer patients receiving anti-PD-1/PD-L1 treatment without developing irAE), 47 RA control (age, sex and serologically matching rheumatic irAE patients) and 56 healthy controls. Flow cytometry was employed to analyze immune cell subsets, metabolic states, and response to soluble factors. Single cell RNA sequencing was performed on a small group of patients to profile gene expression. Beads based multiplex assay was carried out to measure plasma concentrations of major cytokines and chemokines. Autoantigen array was used to assess plasma autoantibody levels. T and B cells were purified and cultured in vitro to assess their functions in the presence of various cytokines and blocking antibodies.

Results: $CD8^+$ T cells from irAE and ICI control patients exhibited elevated expression of effector molecules, but irAE $CD8^+$ T cells, but not ICI control $CD8^+$ T cells, had the highest level of cytotoxic molecule expression. RA control patients, but not irAE patients, had increased CD4/CD8 ratio and reduced regulatory T cell (Treg) frequency. IrAE $CD4^+$ T cells had significantly increased $CXCR3^-CCR6^-$ subset and reduced $CXCR3^+CCR6^+$subset compared to other control groups. Both $CD4^+$ and $CD8^+$ T cells from irAE patients exhibited increased metabolic activities. RA control patients, but not irAE patients, had increased frequency of $CD11c^+CD21^-$atypical B cells and increased level of autoantibodies. IrAE patients showed increased plasma levels of IL-6, IL-12 and enhanced expression of type I interferon (IFN) signatures. Combination of IL-6, IL-12 and IFNα promotes T cell cytotoxic gene expression, whereas blockade of IL-6 receptor, IL-12 and IFNA receptor reduces cytotoxic and metabolic phenotypes of irAE T cells.

Conclusion: Inflammatory arthritis irAE is immunologically distinct from conventional RA, distinguished by high level of cytotoxic gene expression in $CD8^+$ T cells, reduced CXCR3 and CCR6 expression in $CD4^+$ T cells and increased metabolic activity in both $CD4^+$ and $CD8^+$ T cells. It is likely driven primarily by autoreactive T cells following anti-PD-1/PD-L1 inhibition, but potentially independent of autoantibodies. Some of the immunological abnormalities may be driven by increased IL-6, IL-12 and type I IFN.

Abstract Number: 1727

Distribution of Fracture Risk Status and Osteoporosis Treatment Use Among Postmenopausal Women with Osteoporosis in the United States

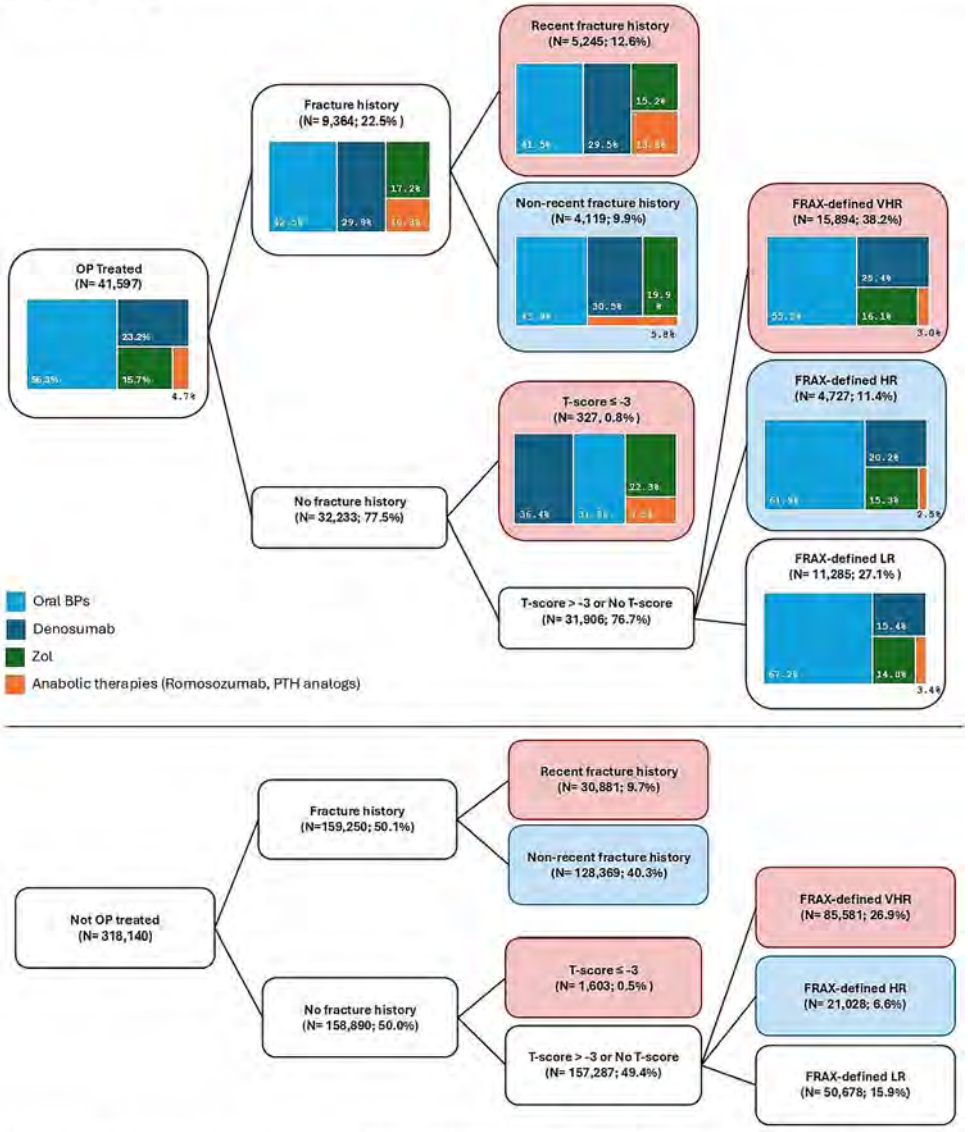
Hsu-Chih Chien, Min Kim, Michele McDermott, Mary Oates, Xiaodong Li and **Lara Yoon**, Amgen Inc, Thousand Oaks, CA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Plenary III (1722–1727)
Session Type: Plenary Session
Session Time: 8:00AM–9:30AM

Background/Purpose: Current guidelines recommend treating women with postmenopausal osteoporosis (PMO) based on fracture risk. Anabolic therapy (AT), the RANKL inhibitor denosumab (Dmab), and intravenous zoledronic acid (ZOL) are recommended as initial therapy for patients at very high risk (VHR) for fracture. This study described the proportion of PMO women at VHR or high risk (HR) of fracture by treatment status in a commercially insured population in the US.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 1. Distribution of Fracture Risk Characteristics and OP Treatments Among Postmenopausal Women with Osteoporosis



Red-shaded boxes refer to very high risk (VHR) of fracture and includes those with fracture in the past 12 months, without fracture history but with a BMD T-score ≤ -3.0, or without fracture history, a BMT T-score > 3.0 or no BMD T-score, or a BMI-based FRAX score for major osteoporotic fracture of > 30% or hip fracture > 4.5%. Blue shaded boxes refer to high risk (HR) of fracture and includes those with no fracture history, a BMD T-score > 3.0 or no BMD T-score, and a major osteoporotic fracture risk of 20-30% or hip fracture of 3-4.5%.
Acronyms: Ats, anabolic therapies; BMD, bone mineral density; BPs, bisphosphonates; HR, high risk; LR, low risk; OP, osteoporosis; PTH, parathyroid; VHR, very high risk; Zol, zotendronic acid.

Methods: This retrospective cohort study used Optum® Market Clarity Bone Data. Women ≥55 years with a diagnosis of osteoporosis (OP), fracture, or OP medication use, ≥455 days of continuous enrollment, a valid BMI and race, and no history of Paget's disease or metastatic cancer were included. Women who newly initiated an OP treatment from April 1, 2016 – September 30, 2023 were included in the treated cohort; date of treatment initiation was the index date. Women with no history of OP treatment in the 15-months prior to January 1, 2023 (index date) were included in the untreated cohort. Cohorts were not mutually exclusive. OP medications included oral bisphosphonates (BPs; alendronate, risedronate, ibandronate), Dmab, ZOL, and AT (romosozumab, parathyroid hormone analogues [teriparatide, abaloparatide]). HR and VHR were defined based on AACE guidelines for the treatment of PMO women and assessed over 15-months before index.

Results: Of the 41,597 treated PMO women identified (mean age=73 y), 51.6% met the VHR criteria, including 5,245 women with recent (≤12 months) fracture (12.6%), 327 with a BMD T-score ≤ -3.0 (0.8%), and 15,894 with a FRAX score indicating VHR (38.2%). Approximately 21.3% were HR; 27.1%, low risk (LR). The most frequent OP treatments overall

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

and among fracture risk subgroups were oral BPs (56.3%) followed by Dmab (23.2%) and ZOL (15.7%). Only 4.7% of treated PMO women overall and 5.7% of treated VHR PMO women were using AT. Among the 318,140 untreated PMO women identified (mean age=74 y), 118,065 (37.1%) met the criteria for VHR; 149,397 (47.0%), HR; 50,678 (15.9%), LR.

Conclusion: More than 1/3 of untreated PMO women are at VHR for fracture and eligible for ATs, Dmab, or ZOL in accordance with treatment guidelines. Among treated VHR PMO women, over half were treated with oral BP in contradiction with current treatment guidelines. Only a small percentage were treated with ATs, which clinical studies have shown are the most effective initial therapy for PMO women at VHR for fracture.

Longitudinal Proteomic Signatures for Prediction of Immune-Related Adverse Events during Immune Checkpoint Inhibitors therapy: A Machine Learning-Guided Prospective Biomarker Discovery Study

Jiana Chen[1], Jiaqi Xu[1], Ziyue Zhou[2], Xu Jiang[1] and **Huaxia Yang**[1], [1]Department of Rheumatology and Clinical Immunology, National Clinical Research Center for Dermatologic and Immunologic Diseases, the Ministry of Education Key Laboratory, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, 100730, Beijing, China, Beijing, China (People's Republic), [2]peiking meidical, beijing

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Immunological Complications of Medical Therapy (1728–1733)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: Immune checkpoint inhibitors (ICIs), while revolutionary in cancer treatment, may induce severe or even fatal immune-related adverse event (irAE). The mechanisms underlying irAE development remain unclear, and early identification of predictive biomarkers for irAE is urgently needed to improve risk stratification and clinical management. However, most current studies on irAE-related potential biomarkers predominantly conduct cross-sectional analyses at a single time point, leaving a critical cap in tracking dynamic changes predicting irAE onset.

Methods: This prospective study enrolled 60 lung cancer patients receiving ICIs therapy at Peking Union Medical College Hospital from January 2022 to September 2024. Additionally, 23 irAE patients with various cancers were included at the time of irAE onset as an observational cohort. Serum samples collected longitudinally at baseline (pre-treatment), 1-3 weeks, 3-6 months post-treatment and the onset of irAE after starting ICIs were analyzed by Olink proximity extension assay technology. Advanced analytical approaches included time-series clustering, linear mixed-effects models, and differential expression analysis across multiple time points. Predictive performance of candidate biomarkers was assessed using receiver operating characteristic (ROC) analysis and support vector machine (SVM) classifiers integrating temporal features.

Results: In the prospective cohort, 26 out of 60 patients (43.3%) developed irAE within 6 months after ICIs initiation. Longitudinal proteomic analysis revealed distinct temporal profiles between irAE and non-irAE groups, with six proteins (IL10, NT-3, CCL23, FGF-19, LIF-R and uPA) exhibiting significantly different trajectories **(Fig.1)**. At baseline, 10 serum proteins (e.g., CXCL1, CXCL6, CXCL11, IL6 and HGF) were significantly depressed in irAE patients, with moderate predictive accuracy for irAE occurrence (AUC > 0.6). Besides, patients with new-onset irAE exhibited significantly elevated CCL25, IL4, IL10

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

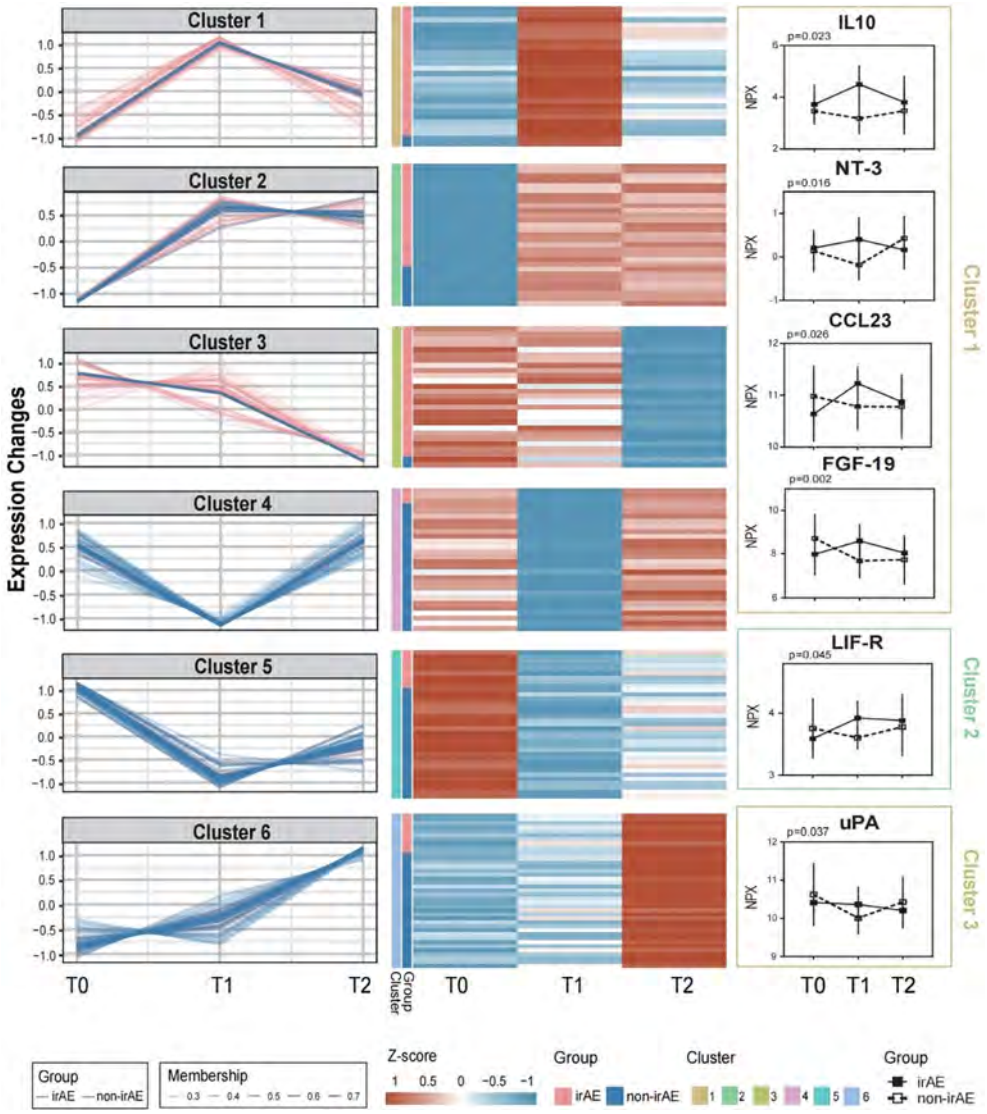

Fig.1. Longitudinal serum proteomic clustering analysis in irAE and non-irAE patients. Mfuzz analysis of differential proteins expression between irAE and non-irAE groups and heatmap of Z-score–normalized expression profiles across three time points (T0, T1, T2) for proteins grouped in each cluster. Linear mixed-effects regression analysis of 6 significant proteins for the three time points in two groups. irAE, immune-related adverse event; NPX, normalized protein expression; T0, before the initiation of ICIs treatment; T1, 1-3 weeks after treatment; T2, 3-6 months after treatment. The y axis represents the Olink assay value (NPX). P-values were calculated using linear mixed-effects models.

and IL20, and decreased IL-15RA and CD8A l compared to non-irAE patients. Longitudinal fold-change analyses from baseline to irAE onset further identified 24 significantly differential proteins, with CXCL9, IL33, IL-18R1, FGF-19 and FGF-23 showing strong predictive power (AUC > 0.8). Furthermore, machine learning models based on SVM integrating temporal features achieved high accuracy in predicting irAE development (AUC > 0.9) **(Fig.2)**, suggesting that these protein-based models provide robust predictive power for irAE occurrence.

Conclusion: Our study provides valuable insights into the dynamic temporal immunological patterns associated with the development of irAE. The identification of temporally regulated biomarkers and the development of predictive models based on machine learning offer promising tools for early risk prediction, diagnostic stratification, and longitudinal monitoring of therapeutic response. These findings advance our understanding of irAE pathogenesis and may inform future biomarker-driven approaches to individualized patient management and targeted therapeutic interventions.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Immunological Complications of Medical Therapy (1728–1733)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: Immune checkpoint inhibitors (ICIs) are a mainstay of cancer immunotherapy. However, their increasing use has led to more immune-related adverse events (irAEs), including rheumatic irAEs (rh-irAEs). These often have delayed onset, may require extended immunomodulatory therapy beyond CS, and were previosly underreported in ICI registration trials due to limited awareness and clinical heterogeneity.

To address this, the ERIN registry (Evaluation of Rheumatologic Immune-related Adverse Events) was launched in May 2024 at LMU University Hospital. As the national, multicenter, first practice-based online registry focused on rh-irAEs, ERIN complements existing initiatives by enabling real-time data collection embedded in routine care. This collaborative effort aims to improve understanding and support evidence-based management of rh-irAEs.

Table 1. Baseline Characteristics of the ERIN Cohort (n = 40)

General	Total patients, n	40
	Male sex, n (%)	23 (57.5%)
	Median age, years (IQR)	65 (58–73)
	Median age of axSpA patients (IQR)	46 (44–49.75)
Cancer types, n (%)	Malignant melanoma	18 (45.0%)
	NSCLC	6 (15.0%)
	Urothelial carcinoma	5 (12.5%)
	Breast cancer	4 (10.0%)
	Squamous cell carcinoma	3 (7.5%)
	Renal cell carcinoma	2 (5.0%)
	Pleural mesothelioma	1 (2.5%)
	Diffuse B-cell lymphoma	1 (2.5%)
ICI therapies, n (%)	Nivolumab	14 (35.0%)
	Pembrolizumab	14 (35.0%)
	Nivolumab/Ipilimumab	6 (15.0%)
	Ipilimumab	2 (5.0%)
	Durvalumab	1 (2.5%)
	Atezolizumab	1 (2.5%)
	Cemiplimab	1 (2.5%)
	Relatlimab	1 (2.5%)
	Avelumab	1 (2.5%)
Most frequent rh-irAEs, n (%)	RA-like polyarthritis	21 (52.5%)
	Peripheral SpA-like syndrome	6 (15.0%)
	PMR-like syndrome	5 (12.5%)
	axSpA-like syndrome	4 (9.1%)
	Monoarthritis	2 (5.0%)
	Myositis	1 (2.5%)
	Sarcoidosis-like syndrome	1 (2.5%)
History / Comorbidities, n (%)	Pre-existing RD flare, n (%)	2 (5.0%)
rh-irAE grading, n (%)	Mild (Grade I)	2 (5.0%)
	Moderatee (Grade II)	22 (55.0%)
	Severe (Grade III)	14 (35.0%)
	Life threating (Grade IV)	2 (5.0%)
Treatment outcome, n (%)	ICI interruption, n (%)	7 (17.5%)
	ICI discontinuation, n (%)	11 (27.5%)
	Complete remission, n (%)	12 (30.0%)
	Improvement only, n (%)	28 (70.0%)

Abbreviations: IQR = interquartile range; NSCLC= Non-small cell lung cancer; ICI = immune checkpoint inhibitor; rh-irAE = rheumatic immune-related adverse event; RA = rheumatoid arthritis; SpA = spondyloarthritis; PMR = polymyalgia rheumatica; axSpA = axial SpA; RD = rheumatic disease; csDMARD = conventional synthetic disease-modifying antirheumatic drug; bDMARD = biologic DMARD;

Methods: ERIN is open to healthcare professionals and includes adult patients (≥18 years) with rh-irAEs under ICI therapy. It supports prospective and retrospective, longitudinal and cross-sectional data collection on comprehensive demographic, rheumatic and oncologic characteristics, diagnosis, treatment and outcomes. Complete remission was defined as symptom absence. Ethics and data protection approvals were obtained. As of early 2025, 9 German centers contribute with increasing numbers. A scientific advisory board was formed in January 2025.

Results: As of May 2025, 40 patients were enrolled (23/40 males, 57.5%; median age 65, IQR: 58–73). The most common malignancy was melanoma (18/40, 45.0%), followed by non-small cell lung cancer (6/40, 15.0%). Nivolumab and pembrolizumab were each used as monotherapy in 14 patients (35.0%). RA-like polyarthritis was the leading rh-irAE (21/40, 52.5%), followed by peripheral spondyloarthritis (SpA)-like rh-irAE (6/40, 15.0%), PMR-like (5/40, 12.5%), and axial SpA (axSpA)-like syndromes (4/40, 9.1%). AxSpA patients were younger (median age 46, IQR: 44–49.75). A flare of pre-existing rheumatic disease occurred in 2/40 (5.0%). rh-irAEs were moderate (grade II) in 22/40 (55.0%) and severe (grade III) in 14/40 (35.0%) per Common Terminology Criteria for Adverse Events. ICIs were interrupted in 7/40 (17.5%) and discontinued in 11/40 (27.5%). Systemic CS was initiated in 32/40 (80.0%). Complete remission occurred in 12/40 (30.0%), improvement in 28/40 (70.0%). Among those in remission, conventional synthetic (cs) DMARDs were used in 6 cases (50.0%); others received biological DMARDs (n=2), intra-articular CS (n=2), or systemic CS (n=2).

Conclusion: ERIN provides real-world insight into rh-irAEs under ICIs. RA-like polyarthritis was the most common rh-irAE, while axSpA-like manifestations occurred more often in younger patients, suggesting age-related immune patterns. Systemic CS were initiated in most cases, underlining their key role in early management. Frequent csDMARD use in patients

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

achieving remission highlights their therapeutic value. These findings emphasize rh-irAE heterogeneity and the need for personalized care. Developing evidence-based guidelines and collaborating with other irAE-focused initiatives like MalheuR and SERIO are key to improving care and understanding of rh-irAEs.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Immunological Complications of Medical Therapy (1728–1733)

Session Type: Abstract Session

Session Time: 10:00AM–11:30AM

Background/Purpose: As immune checkpoint inhibitor (ICI) usage increases for various cancers the prevalence of rheumatologic immune related adverse events (irAEs) also grows. Glucocorticoids are first line treatment, but standardization in dosing, tapering, and duration is lacking. There are mixed results on the effect of oral glucocorticoids on progression-free survival (PFS) among ICI-treated patients. We investigated oral glucocorticoid use and its association with PFS among ICI-treated cancer patients with ICI-inflamatory arthritis (ICI-IA).

Table1. Demographic and Cancer Characteristics of N=206 RADIOS patients

Table 1 Demographic and Cancer Characteristics (N=206)	
Age, mean (SD)	65.41(12.36)
Female*	100 (48.5%)
White Race	177 (85.9%)
Hispanic	10 (4.9%)
Baseline irAE grade 3 or 4*	22 (10.7%)
Melanoma	67 (32.5%)
Non Small Cell Lung Cancer	24 (11.7%)
Renal Cell Cancer	38 (18.4%)
Baseline Cancer Stage 3 or 4*	175 (85%)
ICI combination	76 (36.9%)
Time to glucocorticoid initiation from arthritis onset in days, median (IQR)	24.5 (3, 63)
Time to glucocorticoid initiation from ICI initiation in days, median (IQR)	210 (86.5, 442)
Cancer Progression	46 (22.3%)
Time to cancer progression if progressed from ICI initiation in days, median (IQR)	487 (255, 881)
Time to cancer progression if progressed from steroid initiation in days, median (IQR)	82.5 (-70, 283)
Has ICI been held for rheumatic irAE at any point since ICI start?	71 (34.5%)
ICI duration from ICI initiation in days, median (IQR)	188 (77, 397)
irAE=immune related adverse events ; ICI= immune checkpoint inhibitor ; IQR= interquartile range ; *Missing data : N=1 for female ; N= 40 for baseline irAE grade ; N=17 baseline cancer stage.	

Methods: Data from the RADIOS registry, a prospective U.S. multi-center rheumatic irAE cohort was used. Patients enrolled since February 2023 who were treated with an ICI for cancer and who developed ICI-IA, which we defined as inflammatory arthritis, arthralgia, or PMR, and were treated with glucocorticoids for ICI-IA were included. Patients were excluded if they had pre-existing autoimmune disease or were being treated with glucocorticoids for another irAE. Demographics, cancer and cancer treatment, DMARD and glucocorticoid treatment were collected. Glucocorticoid dosage was converted to prednisone equivalents. Cumulative glucocorticoid exposure and the average daily prednisone dose was calculated at 1-2 weeks, 2-4 weeks, month 2, and months 3,4,5 and displayed in a box plot. Descriptive statistics were calculated. Thirty-day landmark Kaplan Meier plots assessed glucocorticoid exposure and its association with PFS, measured from

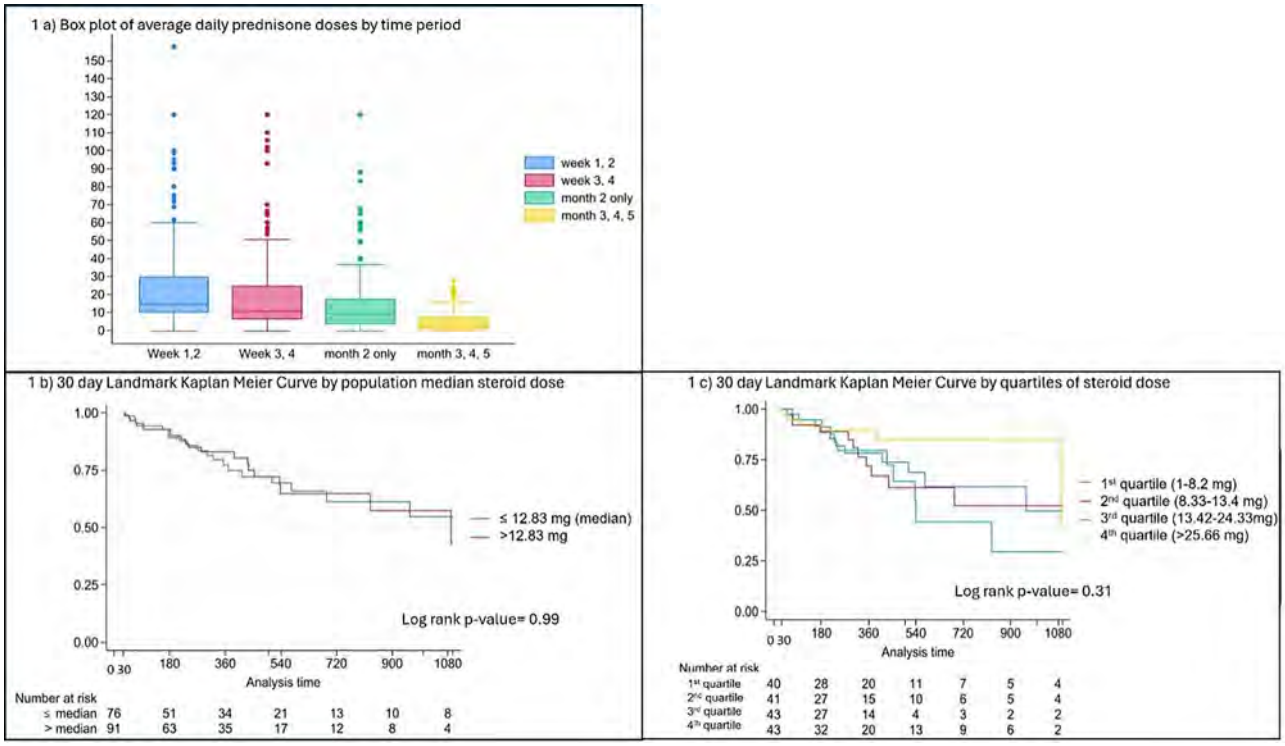

Figure 1. A) Box plot of average daily prednisone doses by time period. B) 30 Day Landmark Kaplan Meier Curve by population median steroid dose C) 30 day Landmark Kaplan Meier Curve by quartiles of steroid dose

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

glucocorticoid initiation to radiographic cancer progression or death. Adjusted cox proportional models with a time varying covariant (time from ICI initiation to glucocorticoid treatment) were performed. Models were adjusted for age, irAE grade at baseline, cancer type (melanoma, non-small cell lung cancer [NSCLC], renal cell cancer [RCC]), cancer stage, ICI combination therapy.

Results: The analytic cohort consisted of 206 patients with a mean age of 65 (SD 12.36), 48.5% were female and 85.9% were White (**Table 1**). Most patients had melanoma (32.5%), RCC (18.4%), or NSCLC (11.7%), and were Stage 3 (26.7%) or 4 (58.3%). The median time from ICI-IA diagnosis to glucocorticoid initiation was 24.5 days (IQR 3, 63). Cancer progression occurred in 46 patients (22.3%), and the median time from glucocorticoid initiation to cancer progression was 82.5 days (IQR -70, 283).

Figure 1a displays the median and interquartile ranges of the average daily prednisone dose, which was highest in the first month of treatment and decreased over time. The first month median glucocorticoid dose was not associated with PFS in a landmark Kaplan Meier curve (log-rank p-value 0.99, Figure 1b). Additionally, there was no difference between quartiles of glucocorticoid dose and PFS (log rank p-value 0.31, Figure 1c). None of the adjusted Cox models were significant for glucocorticoid dose and PFS.

Conclusion: In this cohort, there was not a dose-dependent effect of glucocorticoids on PFS in patients with ICI-IA. Rheumatologists typically use a lower dose than oncology guidelines suggest, and these findings suggest that glucocorticoid treatment of ICI-IA may not have a substantial impact on cancer outcomes.

Characteristics of Patients with Immune-Mediated Adverse Reactions Reported to the FDA Adverse Event Reporting System (FAERS)

(AEs) remain poorly defined. Emerging case reports and small series suggest a potential link between CAR-T and new-onset autoimmune conditions. As the use of CAR-T expands to rheumatologic conditions, understanding the autoimmune safety profile is critical.

Methods: We conducted a pharmacovigilance analysis of autoimmune AEs reported to the FDA Adverse Event Reporting System (FAERS) for each FDA-approved CAR-T product through March 2025. All individual case safety reports listing any of the CAR-T therapies—tisagenlecleucel (tisacel), axicabtagene ciloleucel (axicel), lisocabtagene maraleucel (lisocel), brexucabtagene autoleucel (brexucel), idecabtagene vicleucel (idecel), and ciltacabtagene autoleucel (ciltacel)—as the suspected drug were included. Autoimmune AEs were identified using standardized MedDRA terms. The patient characteristics including malignancy, CAR-T products and AEs were summarized. Disproportionality analysis was performed using Reported Odds Ratio (ROR).

Results: There were 207 immune-mediated AEs with CAR-T reported in the FAERS database (Table 1 and 2). Compared to other products, Idecel was associated with development of sarcoidosis (ROR 17.15, CI 4.28-68.67, $p< 0.0001$). Ciltacel was associated with Guillain-Barre syndrome (ROR 7.31, CI 3.57-14.93, $p< 0.0001$) and immune effector cell associated enterocolitis (IEC-EC) (ROR 58.42, CI 17.90-190.62, $p< 0.0001$). Axicel was associated with dermal autoimmune AEs (Table 2) (ROR 3.65, CI 1.18-11.33, $p=0.024$). Tisacel was associated with myocarditis (ROR 6.20, CI 1.48-25.95,

Thyroiditis	5 (2.4%)
Type 1 Diabetes Mellitus	1 (0.5%)

Immune-Mediated Adverse Events Following CAR-T Therapy

p=0.012) and vasculitis (ROR 4.96, CI 1.11-22.16, p=0.036). Compared to other malignancies with CAR-T approval, indolent B-cell lymphoma was associated with myocarditis (ROR 10.72, CI 2.07-55.40, p=0.004) and musculoskeletal autoimmune AEs (Table 2) (ROR 8.05, CI 2.21-29.37, p=0.001) - in particular, myositis (ROR 10.72, CI 2.07-55.40, p=0.004) and lupus/lupus-like reaction (ROR 13.37, CI 1.21-147.72, p=0.034). Follicular lymphoma in particular was associated with vasculitis (ROR 9.66, CI 1.002-93.06, p=0.049). Higher odd of developing optic neuritis was seen in patients age < 18 years (ROR 7.41, CI 1.35-40.55, p=0.02), acute B-cell lymphoblastic leukemia (ROR 21.78, CI 4.22-112.37, p=0.0002), and Tisacel (ROR 22.33, CI 2.69-185.53, p=0.004). Female sex and age >65 were more likely to develop IEC-EC (ROR 1.90, CI 0.90-4.0, p=0.089; ROR 2.04, CI 1.01-4.14, p=0.047).

Conclusion: This post-marketing pharmacovigilance analysis highlights product- and disease-specific patterns of autoimmune AEs following CAR-T therapy. While limited by FAERS reporting bias, these findings support the need for monitoring strategies and emphasize the importance of prospective studies to validate these associations. Integrating pharmacogenomic and immunologic correlates may further elucidate underlying mechanisms.

Abstract Number: 1732

Incidence of Flares in Pre-existing Rheumatologic Diseases Among Patients with Solid Tumors Undergoing Cancer Immunotherapy: A Systematic Review and Meta-analysis

Takemichi Matsui[1], Kenji Yamada[2], Toshiaki Takahashi[3], Yoshito Nishimura[4] and Yu Fujiwara[5], [1]Department of Medicine, Mount Sinai Morningside/West Hospitals, Icahn School of Medicine at Mount Sinai, New York, NY, [2]Department of Allergy and Rheumatology, Kameda Medical Center, Chiba, Japan, [3]Department of Medicine, John A. Burns School of Medicine, University of Hawaii, Honolulu, HI, [4]Division of Hematology/Oncology, Mayo Clinic, Rochester, MN, [5]Department of Medicine, Roswell Park Comprehensive Cancer Center, Buffalo, NY

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Immunological Complications of Medical Therapy (1728–1733)

Session Type: Abstract Session

Session Time: 10:00AM–11:30AM

Background/Purpose: Immune checkpoint inhibitors (ICIs) have become essential in cancer treatment, offering significant survival benefits across various malignancies. However, ICIs can cause immune-related Adverse Events (irAEs) and potentially exacerbate pre-existing autoimmune diseases. Rheumatologic diseases (RDs) are frequently excluded from clinical trials of ICIs due to these concerns. Understanding flare incidence is crucial for optimizing cancer management and ensuring safety in patients with co-existing autoimmune RDs. Thus, we investigated the incidence and severity of disease flares of pre-existing RDs, with a focus on rheumatoid arthritis (RA), in patients with solid tumors treated with ICIs.

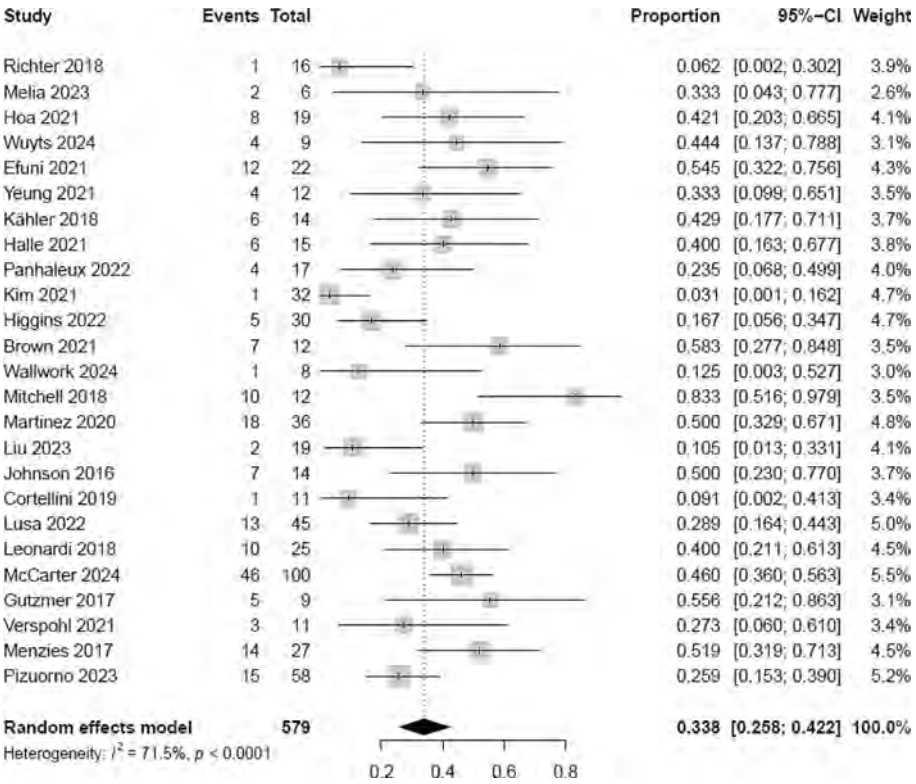

Figure 1: Incidence of flares in patients with pre-existing RDs

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

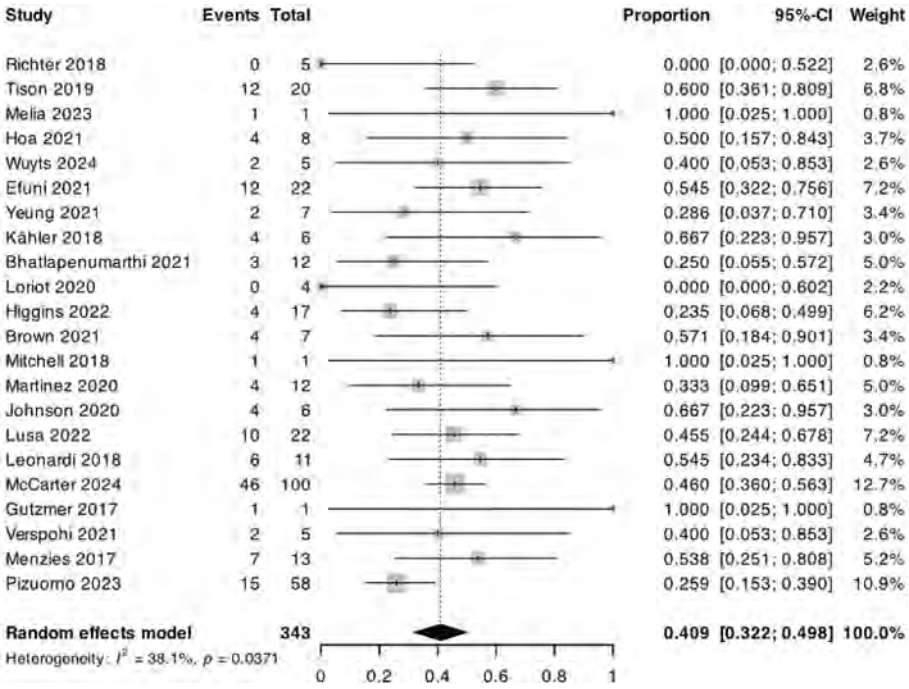

Figure 2: Incidence of flares in patients with pre-existing RA

Methods: A systematic review was conducted in PubMed/MEDLINE and Embase for all peer-reviewed articles from inception to May 16, 2024. Eligible studies were cohort studies and case series (>5 cases) involving patients with solid tumors and concomitant RD treated with ICI therapy. A proportional meta-analysis with a random-effects model was conducted to pool the incidence of grade 1-5 flares and grade 3-5 severe flares in RDs and RA based on Common Terminology Criteria for Adverse Events (CTCAE) across the included studies.

Results: Among 2599 studies, 247 articles were eligible for full-text review, and 31 studies were included in the analysis. In total, 579 patients with RA, systemic lupus erythematosus, Sjögren's syndrome, systemic sclerosis, sarcoidosis, spondyloarthritis, myositis, Behçet's disease, vasculitis, polymyalgia rheumatica were included. Three studies evaluated PD-1/PD-L1 inhibitor monotherapy, two studies evaluated CTLA-4 inhibitor monotherapy, and 12 studies evaluated dual ICIs (ICI subtype unclear in 14 studies). Among all the RDs, the pooled incidence of flares was 33.8% (95% CI, 25.8–42.2; Figure 1). The median time to the first flare after initiating ICIs was 38.5 days (interquartile range: 30.0 – 52.6 days). The incidence of severe flares among overall RDs was 4.2% (95% CI, 0.6-9.6). Patients with RA were included in 22 studies with 343 patients. The pooled incidence of flares in patients with RA was 40.9% (95% CI, 32.2–49.8; Figure 2). Among patients with RA who developed flares, the incidence of severe flares was 8.3% (95% CI, 4.3–15.4).

Conclusion: Our study revealed that more than 30% of cases with RDs and RA develop flare with ICI therapy. These findings would be informative upon risk and benefit discussion before the initiation of ICI therapy for patients with solid tumors and concurrent RDs. Future studies are warranted to explore risk factors of flare and preventative strategies to mitigate the risk of flare development.

Abstract Number: 1733

Risk factors for the development of immune checkpoint inhibitor-related adverse events, including rheumatology-related presentations

Adela Francis-Malave[1], Terri Laufer[2], Joshua Baker[3], Kyra Sacksith[4], Melissa Batson[4] and Sokratis Apostolidis[3], [1]University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA, [2]University of Pennsylvania, Bala Cynwyd, PA, [3]University of Pennsylvania, Philadelphia, PA, [4]University of Pennsylvania, Philadelphia

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Immunological Complications of Medical Therapy (1728–1733)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: While immune-related adverse events (irAEs) are a commonly reported complication of immune checkpoint inhibitor (ICI) therapy, factors associated with their development remain poorly defined. In this unique prospective cohort study, we explored lab data and patient-reported outcomes (PROs) associated with the probability of developing irAEs, focusing on those that could prompt a rheumatology consult. We aimed to identify high-risk patients who would potentially benefit from closer monitoring and early referral.

Methods: We enrolled cancer patients who were initiating ICI therapy. Demographics, PROs, and lab data were collected during routine clinical visits. irAEs were defined by health providers during routine practice. Rheumatologic-related irAEs included arthritis, myositis, myocarditis, rash, and dry mouth/eyes. Analysis was performed using chi-square or t-tests to compare the pre-treatment characteristics of patients who developed at least one irAE vs those who did not. Logistic regression models were used to evaluate if factors such as age, sex, treatment type (monotherapy with PD-1/PD-L1 inhibitors vs. combination therapy including CTLA-4 inhibitors), as well as baseline lab values (e.g., lymphocyte count, neutrophil-to-lymphocyte ratio, liver function tests), and PROs increased the odds of developing any irAE or rheumatologic irAEs. Cox regression models were used to assess whether time-varying assessments of these characteristics could identify those at more immediate risk.

Table 1. Baseline comparison of cancer patients on immune checkpoint inhibitors who developed at least one irAE vs those who did not develop an irAE

Demographics and lab values	No irAE	At least one irAE	p-value
Age, years	64.0 (10.5)	64.7 (11.1)	0.64

Frequency of swelling	0.91 (0.73, 1.15)	0.44	0.90 (0.69, 1.18)	0.46
Swelling interfering with daily life	0.74 (0.57, 0.96)	**0.02**	0.76 (0.57, 1.01)	0.06
Severity of swelling	0.94 (0.69, 1.27)	0.67	0.97 (0.69, 1.36)	0.86
Severity of itching	1.17 (0.83, 1.67)	0.37	1.0 (0.68, 1.47)	0.99

Results: Among 256 patients, 71.1% were male (n=182). Non-small lung cancer was the most common malignancy (23.1%), and the most common ICI was Pembrolizumab (40.9%). The incidence rate for any irAE was 11.3% (events/person-month) while it was 3.6% for rheumatologic irAEs. Notably, 50% of patients on ICIs had developed an irAE within 3.5 months, with 25% experiencing their first adverse event in the first month. At baseline, those who had irAEs had similar age, sex, rates of combination therapy with ICIs and PROs compared to those who did not. Patients who developed at least one irAE had higher lymphocyte counts (p=0.03) and a lower AST (p=0.04) (Table 1). Higher lymphocyte count (OR: 1.03; 95% CI: 1.0, 1.1; p=0.03) and lower AST (OR: 0.99; 95% CI: 0.98, 1.0; p=0.03) were associated with higher odds of developing an irAE, while use of combination immunotherapy (OR: 2.27; 95% CI: 1.11, 4.66; p=0.03) was associated with a higher odds of developing a rheumatologic irAE (Table 2). Most evaluated factors were unrelated to the immediate risk of developing irAEs.

Conclusion: In this large cohort study, PROs assessed at baseline and over time were poor predictors of irAE onset, including irAEs that would likely result in rheumatology referral. Consistent with prior literature, use of combination immune checkpoint inhibitor (ICI) therapy was associated with increased odds of irAEs, including rheumatologic irAEs. Higher baseline lymphocytes and lower AST levels were associated with an increased odds of irAE, and the neutrophil-to-lymphocyte ratio tended to be associated with irAEs, as has been observed in prior studies. Future studies should evaluate whether recent changes in lab values or PROs can predict the onset of irAEs.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Osteoarthritis & Joint Biology – Basic Science (1734–1739)

Session Type: Abstract Session

Session Time: 10:00AM–11:30AM

Background/Purpose: Osteoarthritis (OA) is an age-related joint disease that cause chronic pain and reduced mobility. Current treatments mainly relieve pain and inflammation, often with corticosteroid injections. However, no therapy modifies disease progression, highlighting the need for new strategies. Our team is investigating intra-articular GLP-1 analogs for their anti-inflammatory and protective properties. This study evaluates liraglutide, a GLP-1 analogue, in a rat model of OA, focusing on its effects on synovial membrane and cartilage structure.

Methods: The effects of one, two, or eight intra-articular (IA) injections of liraglutide or vehicle were evaluated in a rat OA model induced by ACLT/pMMx surgery, compared to eight injections of dexamethasone. Sham-operated animals were used as controls. Body weight was monitored. Synovial membrane (Krenn [0–9] and Obeidat scores) and cartilage (OARSI [0–26]) were blindly assessed per joint quadrant (MTP, MFC, LTP, LFC) by two independent investigators. The Krenn score evaluates the inner synovial layer, cell density, and inflammation; the Obeidat score evaluates hyperplasia, cellularity, and fibrosis; the OARSI score quantifies the depth and extension of of cartilage lesions.

Table 1: Krenn, Obeidat and OARSI score in ACLT/pMMx rat model Mean ± SD, Statistical analyses: Mann-Whitney test: * p<0.05, **p<0.01, *** p<0.001 and **** p<0.0001 vs 3M - ACLT/pMMx/vehicle (2IA) group; *p<0.05, vs 5M - ACLT/pMMx/ Liraglutide 60 µg (1IA) group; $ p<0.05, $ $p<0.01, $$$ p<0.001 and $$$$ p<0.0001 vs 4M - ACLT/pMMx/vehicle (8IA) group. $ p<0.05, $$p<0.01, $$$ p<0.001 vs 8M - ACLT/pMMx/ Dexamethasone 120 µg (8IA) group. Figure 1: Representative picture of Hematoxylin eosin and Safranin O/Fast green staining to determine the Krenn, Obeidat and OARSI score

Results: The total synovitis score using Krenn methods showed a significant increase in synovial inflammation in ACLT/pMMx/vehicle groups vs. respective sham controls ($p< 0.001$), while treatment significantly reduced this score by ±48–63% for liraglutide and 38% for dexamethasone ($p< 0.001$ and $p< 0.0001$ for liraglutide groups, $p< 0.0001$ for dexamethasone). Liraglutide 60 μg significantly improved all synovitis parameters compared to vehicle, with superior effects to dexamethasone ($p< 0.05$ for density, $p< 0.01$ for layer, inflammatory, and total synovitis scores). These results suggest that liraglutide reduces the severity of synovitis, with 2 or 8 injections showing the greatest improvement. Obeidat scores showed increased hyperplasia, cellularity, and fibrosis across all quadrants (MTP, MFC, LTP, LFC) in the vehicle versus sham groups. Both treatments significantly reduced these scores compared to vehicle, with liraglutide showing broader effects. In particular, liraglutide 60 μg was more effective than dexamethasone in reducing medial cellularity and fibrosis. OARSI scores showed significantly increased cartilage degradation in the vehicle groups compared to sham ($p< 0.01$). Liraglutide reduced degradation by 34–55%, while dexamethasone had no significant effect (17%). The global severity index confirmed these findings: liraglutide improved cartilage integrity ($p< 0.05$, $p< 0.001$, $p< 0.01$ for 1, 2, 8 injections vs. vehicle), while dexamethasone showed no benefit (Figure 1, Table 1).

Conclusion: These results show that intra-articular liraglutide effectively reduces synovial inflammation and protects joint structure. It outperforms dexamethasone by preserving both synovial tissue and cartilage, highlighting its potential as a superior OA treatment offering symptomatic relief and structural preservation, unlike dexamethasone, which lacks cartilage protection and may be harmful in the long-term.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Osteoarthritis & Joint Biology – Basic Science (1734–1739)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: Osteoarthritis (OA) affects over 590 million individuals globally. Epidemiological data suggest that exposure to environmental pollutants, particularly endocrine-disrupting chemicals (EDCs) such as phthalates, PFAS, and heavy metals, may contribute to increased OA risk and severity (1). Chronic exposure to these compounds begins as early as in utero and continues throughout life via environmental and household sources with at least 14 EDCs ubiquitously present in daily life (2). Several have also been identified in the synovial fluid of OA patients, indicating both systemic and local joint exposure. Yet, their functional role in pain modulation and joint inflammation remains insufficiently understood **This study aimed to determine whether local and/or systemic low-dose exposure to a mixture of 14 EDCs modulates OA severity and pain**, and to explore potential effects on sensory neuron.

Methods: Male and female 12-week-old C57BL/6 mice were exposed either locally by intra-articular (IA) injections of an EDCs mix (e.g., Perfluorooctanoic acid [PFOA]=10^{-7}M) or vehicle, one week before and after OA induction by IA injection of monoiodoacetate. An additional cohort was systemically (via lifelong administration through drinking water) exposed to the EDCs mix from in utero through 15 weeks. Pain-related behaviour, locomotor activity, and body weight were monitored over 21 days. Histological and molecular analyses were performed on knee joints and dorsal root ganglia (DRG). In vitro, primary DRG neurons from male mice were treated with the EDCs mix (e.g., [PFOA]=10^{-8}M or 10^{-9}M), and calcium responses to capsaicin (TRPV1 agonist) were recorded.

Results: In male mice, local IA EDCs exposure significantly increase OA-related pain over the 21-day period ($p< 0.001$) and reduce the physical activity (day 21: mean [SEM] 13.2m [4.7] vs. 17.4m [2.3] in controls, $p< 0.05$). Histological analysis revealed more severe synovitis (Krenn score) (5.1 [1.55] vs. 4.3 [1.5], $p< 0.05$) and OARSI cartilage damage (3 [0.75] vs. 2.5 [2.94], $p=0.03$). Enhanced macrophage infiltration and elevated Bdnf gene expression in the DRG were also observed. In contrast, female mice with IA EDCs exposure did not display significant mechanical hypersensitivity, although they exhibited reduced physical activity (day 21: 13.5m [1.4] vs 19.5m [2.3] in controls, $p< 0.05$) along with upregulation of Bdnf expression in DRGs.

Male mice exposed systemically to EDCs via drinking water developed persistent OA pain-related behaviours ($p=0.001$) and unexpectedly showed increased physical activity (16.9m [181.0] vs. 13.6m [127.8], $p< 0.05$), potentially reflecting EDCs-induced anxiety. No significant effects were observed in female mice. In vitro, EDCs-treated sensory neurons displayed altered calcium dynamics with prolonged depolarization following capsaicin stimulation.

Conclusion: This study reveals that low-dose exposure to EDCs can amplify OA-related pain and inflammatory responses in a sex-specific manner. This study supports the role of EDCs in modulating neuroimmune interactions and sensory neuron excitability in OA pathophysiology.

Multi-Model Evaluation of the Impact of CD14 on Synovial Inflammation and Pain During PTOA.

Kevin Burt[1], Sanique South[2], Natalie Adamczyk[3], Shingo Ishihara[3], Vu Nguyen[4], Robert Mauck[4], Anne-Marie Malfait[5], Timothy Griffin[6], Rachel Miller[7] and Carla Scanzello[1], [1]University of Pennsylvania, Philadelphia, PA, [2]University of Oregon, Eugene, [3]Rush University, Chicago, [4]University of Pennsylvania, Philadelphia, [5]Rush University, Oak Park, IL, [6]Oklahoma Medical Research Foundation, Oklahoma City, [7]Rush University Medical Center, Chicago, IL

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Osteoarthritis & Joint Biology – Basic Science (1734–1739)

Session Type: Abstract Session

Session Time: 10:00AM–11:30AM

Background/Purpose: Soluble CD14, a co-receptor of inflammatory toll-like receptor signaling that is produced primarily by monocytes/macrophages, is present in synovial fluid in patients with OA and positively associates with joint space narrowing and pain. **Utilizing both global genetic deletion of CD14 and intra-articular CD14 blockade across mild to severe models of murine PTOA, we aimed to test the hypothesis that CD14 inhibition can attenuate synovial inflammation and associated pain during disease progression**.

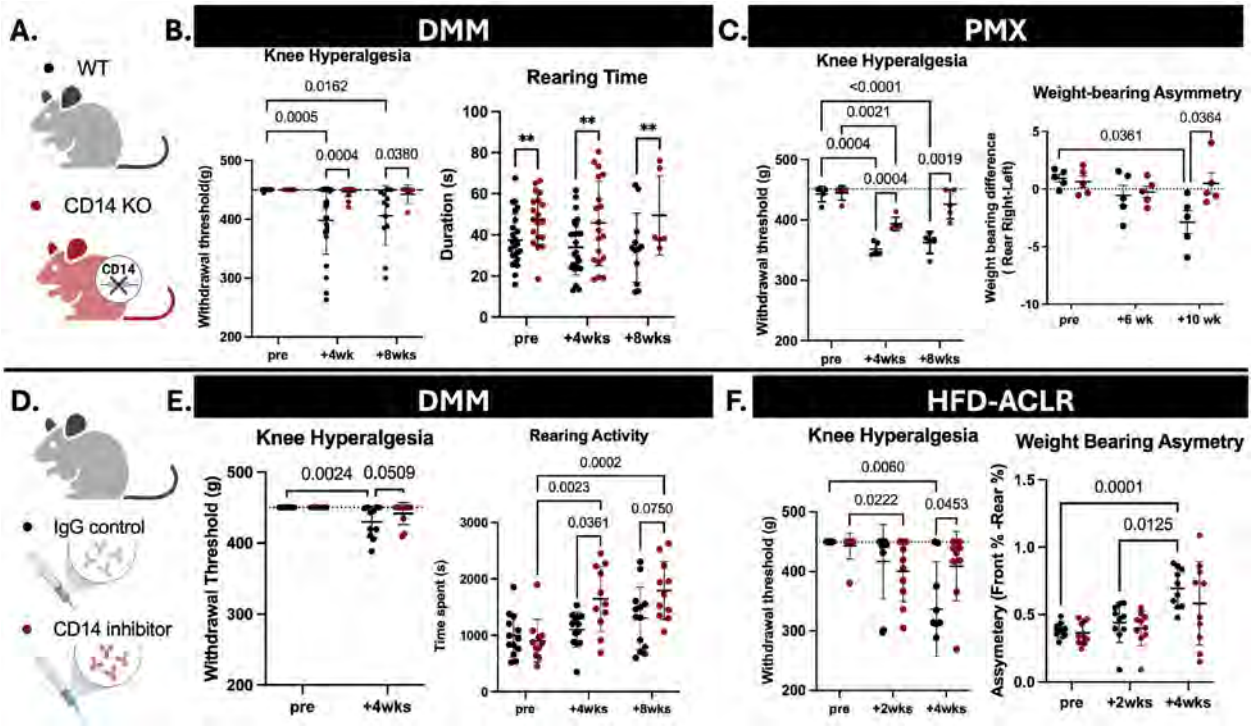

Figure 1: (A,D) Study schematic. (B,C,E,F) Knee hyperalgesia measured via withdrawal threshold (g). (B,E) Time spent rearing (sec). (C) Weight bearing asymmetry measured as (C) the difference between rear right (DMM) to rear left paw (unoperated) weight (g) or (F) as front to rear paw weight bearing ratio (%/%).

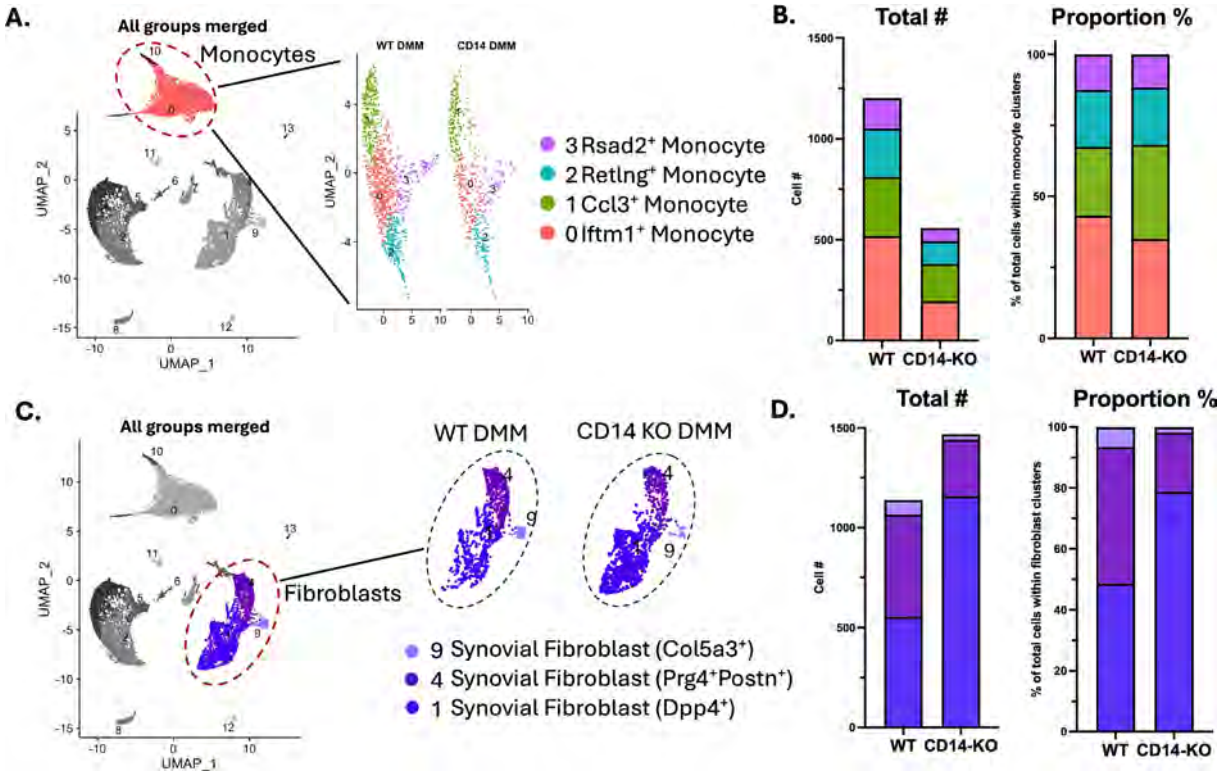

Figure 2: (A) UMAP of cell clusters within WT and CD14 KO synovium harvested 4-wks post injury with re-clustered monocyte populations delineated. (B) Monocyte specific cell cluster breakdown represented as the number and percentage of total cells within monocyte clusters. (C) UMAP of re-clustered monocyte populations. (C) UMAP of cell clusters within WT and CD14 KO synovium harvested 4-wks post injury with fibroblast clusters (Clusters 1, 4, & 9) delineated. (D) Fibroblast cell cluster breakdown represented as the number and percentage of total cells within fibroblast clusters. (pooled n=15/group).

Methods: *DMM:* Destabilization of the medial meniscus (DMM) surgery was performed in 12-wk old male C57BL/6 mice. *2) PMX:* Partial meniscectomy (PMX) surgery was performed in 12-wk old male mice. *3) HFD-ACLR:* Nonsurgical anterior cruciate ligament rupture (ACLR) was performed via overloading in 36-wk old female mice fed a high fat diet (HFD). *CD14 knockout:* A global genetic knockout of CD14 was utilized and evaluated in the DMM and PMX models. *Drug intervention:* WT mice were treated intra-articularly (IA) with either an anti-CD14 monoclonal antibody or an IgG2a control (0.5mg/kg). Mice received 3 weekly injections beginning 48 hours post DMM or ACLR injuries. *Evoked pain:* Knee hyperalgesia was measured using a pressure application measurement (PAM) device. *Spontaneous pain behavioral:* Spontaneous cage behavior was evaluated using the Laboratory Animal Behavior Observation Registration and Analysis System™. Paw weight bearing distribution and rearing behavior was measured using the Advanced Dynamic Weight Bearing system or a static incapacitance meter system. *Single-cell sequencing (scRNA-seq) (n=15):* Synovial cells were isolated from DMM- and sham- operated knee joints 4-wks post-surgery. scRNA-seq data was processed using Seurat.

Results: Global deletion of CD14 mitigated knee hyperalgesia in both DMM and PMX models of PTOA, with a significant increase in withdrawal threshold in CD14-KO mice compared to WT post-injury (**Fig. 1A-C**). Further, delivery of a CD14 blocking antibody mitigated knee hyperalgesia in both DMM and HFD-ACLR models of PTOA (**Fig. 1D-F**). Spontaneous pain behavior analysis revealed that genetic deletion of CD14 increased mobility (rearing time) in the DMM model, comparing to WT. Further, a protection from weight bearing asymmetry was observed following PMX injury in CD14-KO mice compared to WT (**Fig. 1A-C**). IA delivery of anti-CD14 increased rearing activity following DMM and protected from weight bearing asymmetry following ACLR injury, both compared to the IgG control (**Fig. 1D-F**). Mild attenuation of OA histopathology was observed across models. Lastly, synovial scRNA-seq analysis at 4-wks post DMM revealed clear decreases across multiple monocyte populations, as well as a differential modulation of multiple fibroblast populations within the CD14-KO synovium compared to WT (**Fig. 2**).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: The consistent attenuation of pain behavior in both mild and severe models of PTOA strongly supports the potential of targeting CD14 to treat painful OA. Our scRNA-seq results suggest that the protective effects may be mediated in part by decreased inflammatory signaling within the synovium, which influenced both the myeloid and fibroblast populations that emerge after injury.

Abstract Number: 1737

CR10049, the first intra-articular Src family kinase inhibitor as a long-acting symptom- and disease-modifying drug for the inflammatory OA phenotype

Luigino Giancotti, Tiziana Piepoli, Roberto Artusi, Matteo Ghirri, Michela Visintin, Gianfranco Caselli and Lucio Rovati, Rottapharm Biotech, Monza, Italy

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Osteoarthritis & Joint Biology – Basic Science (1734–1739)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: The inflammatory osteoarthritis (OA) phenotype is characterized by the presence of synovial membrane inflammation, pain and pathological changes in joint structure leading to rapid disease progression and debilitating chronic conditions. Efforts to develop effective OA therapies against a single target failed. Therefore, we designed a small molecule, CR10049, which preferentially inhibits the pro-inflammatory Src family kinases members, along with kinases that have a major role in OA development and maintenance such as members of the Ephrin receptor, Trk and the VEGFR family.

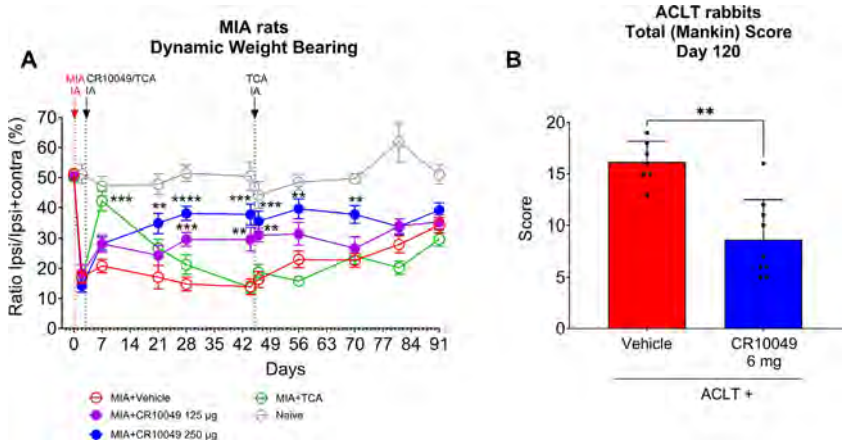

Figure 1. Representative data of the weight-bearing imbalance (A) and Mankin score (B) of CR10049-treated animals. Results are expressed as mean ± SEM (A) or SD (B) for n=11/group-n=6/naïve (A) or n=7/9 (B) animals and analyzed by two-way ANOVA with Dunnett (A) or Mann-Whitney t-test (B) comparisons. ** p<0.01, ***p<0.001, **** p<0.0001 vs Vehicle.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The aim of this study was to characterize the pharmacological activity of CR10049 in vitro and in long-lasting small (rats) and large (rabbits) animal models of OA. Moreover, preliminary acute toxicology studies were employed to support the next development for human clinical trials.

Methods: A panel assay of 159 kinases was used to evaluate the binding affinity of CR10049. In vivo, OA was induced by injecting 2 mg of MIA into the knee of Sprague Dawley rats. On day 3 (D3) after MIA injection, animals received CR10049 (125 and 250 μg) or vehicle intraarticularly (IA, 30 μl). On D3 and D45 an additional control group received IA triamcinolone acetonide (TCA, 60 μg). Pain was blindly evaluated by electronic Von Frey testing and dynamic weight bearing for 91 days, at variance with the 28 days of the conventional MIA OA model. In another experiment, New Zealand rabbits that underwent ACL transection (ACLT), were administered IA with CR10049 (6 mg in 600 μl) or vehicle on D7, D20 and D40. At sacrifice (D120), explanted joints were processed for blinded histology evaluation. For toxicology studies in Wistar rats, CR10049 was injected intravenously (IV) at doses up to 60 mg/kg and IA up to 5 mg.

Results: CR10049 inhibited, in a nanomolar range (IC_{50} < 25 nM), the Src family member cSrc, Lck, Fyn, Fgr, Frk and Yes as well as other kinases including VEGFR1/2, FGFR1, EPHA3, EPHA5, TrkB and TrkC that have a major role in synovial inflammation and fibrosis, cartilage degradation, bone remodeling and pain status.

In the long MIA rat paradigm, CR10049 significantly reduced weight-bearing imbalance for long period (Fig.1A) in a dose-dependent fashion; these effects were confirmed by mechanical allodynia and were significant up to D91. TCA exerted the known acute benefit that was rapidly lost and not replicated with a second injection (Fig.1A). In ACLT rabbits, CR10049 significantly preserved cartilage tidemark integrity and reduced GAG degradation, cartilage and cell damage, osteophytes formation and subchondral bone thickening for 3 months after the last IA injection (as summarized by total score in the fig.1B). In preliminary rat toxicology studies, CR10049 did not induce toxicological effects when injected systemically (IV) up to 60mg/kg and locally (IA) up to 5 mg, i.e. a 20x higher dose than the maximum effective dose.

Conclusion: We identified the first intra-articular drug, CR10049, with a long-acting effect on pain reduction and joint structure improvement in the experimental inflammatory OA setting. Its unique characteristics of selectively targeting kinases with a major role in OA, makes CR10049 a good candidate for the treatment of the OA inflammatory phenotype.

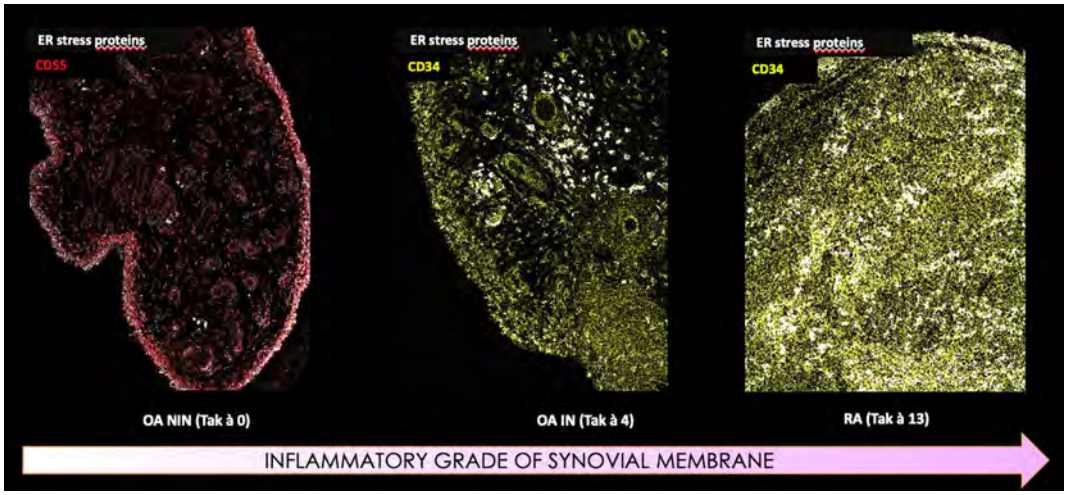
SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Osteoarthritis & Joint Biology – Basic Science (1734–1739)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: A strong crosstalk exists between endoplasmic reticulum (ER) stress and synovitis. Several ER chaperone proteins, besides their function in protein folding, can play a role in cell survival enhancing inflammation and immunogenicity once ER stress occurs in pathological conditions. This research aims at localizing and quantifying ER stress proteins (BiP, HYOU1, MANF, PDIA4, GANAB, HSP90B1, TXNDC5, DNAJB11, LMAN1, ERP29 and CALR) in inflamed and non-inflamed synovial membranes, as well as assessing their cellular localization. It also investigates the modulation of these ER protein expressions in fibroblast-like synoviocytes (FLS) under ER stress, profibrotic and proinflammatory conditions.

Methods: Immunohistochemistry was performed on formalin-fixed paraffin-embedded synovial tissues from patients with osteoarthritis (OA; n=9), chronic pyrophosphate arthropathy (n=7), and rheumatoid arthritis (n=8), exhibiting continuous degree of inflammation. These results were confirmed using the collagenase-induced osteoarthritis (CIOA) mouse models. Protein localization and semi-quantification were done using QuPath. Imaging mass cytometry (IMC) was performed on the biopsies but were conjugated with metal antibodies recognizing synovial cells (FLS, immune cells, ...) and the 11 ER stress proteins, followed by laser desorption and time-of-flight mass spectrometry to detect and quantify the spatial distribution of multiple proteins simultaneously. FLS were isolated from OA patient synovium post-surgery and stimulated in vitro with tunicamycin (0.1–10 µg/mL, 1–7 days) to induce ER stress. TNF-α and TGF-β were used to mimic inflammatory or fibrotic conditions. Protein expression and secretion were assessed by western blot on cell lysates and supernatants. Fibroblasts markers (CD55 and CD34) expression was also evaluated by immunofluorescence.

Results: ER stress proteins were mostly restricted to the lining layer in mildly inflamed synovium and infiltrated the whole sCollynovium when the inflammation was severe. Their differential expression was confirmed in a CIOA mice model. This spatial distribution mirrors the fibroblast phenotype shift, with $CD55^+$ (lining) fibroblasts predominating in non-inflamed OA and declining with inflammation, while $CD34^+$ (sublining) fibroblasts, enriched in inflamed OA and RA, become prominent in the sublining. IMC confirmed the co-expression of ER stress proteins with $CD55^+$ fibroblasts in the lining layer of non-inflamed OA, and with $CD34^+$ fibroblasts in the sublining layer of inflamed OA. ER stress proteins do not co-express with lymphocytes markers. In vitro, these proteins were observed under basal conditions in FLS, which expressed CD55 and CD34. ER stress induction increased their intracellular levels and, for some, their secretion. Inflammatory (TNF-α) and profibrotic (TGF-β) stimuli further enhanced their expression.



23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: These findings suggest that fibroblasts infiltrating the synovial membrane—particularly CD34$^+$ cells—may play a central role in the pathogenesis of synovial inflammation, acting as secretory cells of the chaperone proteins which may exhibit pro-inflammatory and pro-fibrotic properties.

Acute Transcriptomic Response of Synovium and Dorsal Root Ganglia to Joint Injury

Michael Newton[1], Lai Wang[2], Anne-Marie Malfait[3], Rachel Miller[2] and Tristan Maerz[4], [1]University of Michigan, South Lyon, MI, [2]Rush University Medical Center, Chicago, IL, [3]Rush University, Oak Park, IL, [4]University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Osteoarthritis & Joint Biology – Basic Science (1734–1739)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: In arthritic synovium, emerging clinical evidence suggests crosstalk between synovial cells and dorsal root ganglion (DRG) neurons drives nerve sprouting and pain sensitization [Bai+ 2024, Nanus+ 2021]. Similarly, preclinical post-traumatic osteoarthritis (PTOA) models demonstrate progressive knee hyperalgesia and rapid nociceptor sprouting post-injury [Bergman+ 2023, Obeidat+2024]. To elucidate the synovium-nerve signaling underpinning injury-induced nociceptor sprouting, we used bulk RNA sequencing to characterize the acute response of paired synovium and DRG to ACL rupture (ACLR).

Methods: Under IACUC approval, 12-week-old male C57Bl/6 mice underwent ACLR or sham procedure (n=6). At 1, 3, or 7 days post-injury, total RNA was isolated from ipsilateral synovium and L3-L5 DRGs for bulk RNA sequencing. Quality control confirmed high RNA and sequencing quality and high DRG neuronal enrichment (Fig 1A,B). Data were analyzed for differentially-expressed genes (DEGs) via weighted Limma-Voom, and pathway enrichment via gene set enrichment analysis (GSEA). A published DRG interactome database [Wangzhou+ 2021] was utilized to identify putative interactions between ACLR-upregulated synovial ligands and DRG-neuron receptors. Reference single cell RNA sequencing (scRNAseq) data of murine synovium and DRG was used to assess cell-specific ligand/receptor expression.

Results: The synovium exhibited a marked, gradually-evolving response to ACLR (Fig 1C,D). Most injury-induced DEGs (>60%) were conserved across timepoints (Fig 1E), with >10% shared between adjacent timepoints (Fig 1E). Angio- and neurogenic synovial signaling was detectable at 1d and progressive out to 7d (Fig 1D,E). Inflammatory signaling was most enriched at 1d but sustained throughout (Fig 1D). Neuroinflammatory leading edge genes suggested multifaceted neuroimmune signaling (e.g. complement (C5ar1), toll-like receptor (Tlr7), and cytokine (Tnfrsf1b) pathways, Fig 1E). Progressive fibroblast-associated matrix changes denoted initiation of progressive fibrosis, hyperplasia, and ossification known to present at later timepoints in this model (Fig 1D). DRG response to ACLR was comparatively subtler (Fig 2A-C), but GSEA revealed significant enrichment of several neuron sprouting pathways (Fig 2D,E) across timepoints, with different facets preferentially enriched at 1, 3, and 7 days post-ACLR (Fig 2D), suggesting a rapid, evolving post-injury response. Interactome analysis (Fig 3A) implicated pathways including NGF, semaphorin-plexin, FGF and integrin signaling as putative mediators

(G) Expression of leading-edge genes from significant GSEA terms.

of time-dependent (Fig 3C), injury-induced synovium-nerve crosstalk. scRNAseq demonstrated synovial ligand secretion primarily by fibroblasts, Schwann cells, and pericytes (Fig 3B), with receptor expression by various neuronal subsets (Fig 3D).

Conclusion: These data reveal a rapid, injury-induced neuroinflammatory synovial response concomitant with transcriptional programs indicative of neuronal plasticity in the DRG. Putative synovium-DRG interactome analysis implicated pathways such as NGF and sema-plex as potential axes of synovium-DRG crosstalk underlying injury-induced nociceptor sprouting.

Background/Purpose: Adults with dermatomyositis face a well-established 2–3-fold increased risk of major adverse cardiovascular events, driven by systemic inflammation, endothelial dysfunction, and treatment-related metabolic complications. In contrast, cardiovascular risk in juvenile dermatomyositis (**JDM**) remains poorly defined, despite a higher prevalence of clinical vasculopathy in children and emerging evidence that early, severe vasculopathic skin involvement is linked to cardiovascular dysfunction. Our previous work identified circulating calprotectin—a marker of neutrophil activation and NET formation—as a predictor of future cardiovascular disease (**CVD**) and a correlate of impaired HDL function in the general population. Notably, many JDM patients have elevated calprotectin levels. This study aimed to evaluate HDL function and early atherosclerotic risk in JDM and to investigate their potential association with calprotectin.

Methods: We assessed cholesterol efflux capacity (**CEC**, a measure of HDL function) in HDL-rich (apoB-depleted) plasma from 51 JDM patients and 24 pediatric controls without systemic autoimmune disease (**Fig. 1A**). We also measured plasma paraoxonase-1 (**PON1**) activity, an indicator of oxidative stress and HDL dysfunction linked to future CVD risk, and conducted a foam cell formation assay to evaluate plasma-driven fatty acid uptake, where greater uptake reflects a more pro-atherogenic profile.

Results: Compared to pediatric controls, JDM patients exhibited significantly impaired CEC and reduced PON1 activity (**Fig. 1B–C**), consistent with dysfunctional HDL. CEC was inversely correlated with fatty acid uptake in a foam cell assay ($r = -0.39$, $p = 0.0045$), indicating a shift toward a more pro-atherogenic state marked by increased lipid accumulation in macrophages. Among JDM patients, those with elevated circulating calprotectin had significantly lower CEC and PON1 activity (**Fig. 2A–B**), linking neutrophil activation and NET-associated inflammation to HDL dysfunction. Reduced CEC also correlated with clinical markers of disease activity, including elevated muscle enzymes such as creatine phosphokinase (CPK; $r = -0.35$, $p = 0.012$) and aspartate aminotransferase (AST; $r = -0.28$, $p = 0.046$), suggesting an association between active myositis and impaired vascular protection. Notably, JDM patients receiving immunomodulatory therapy

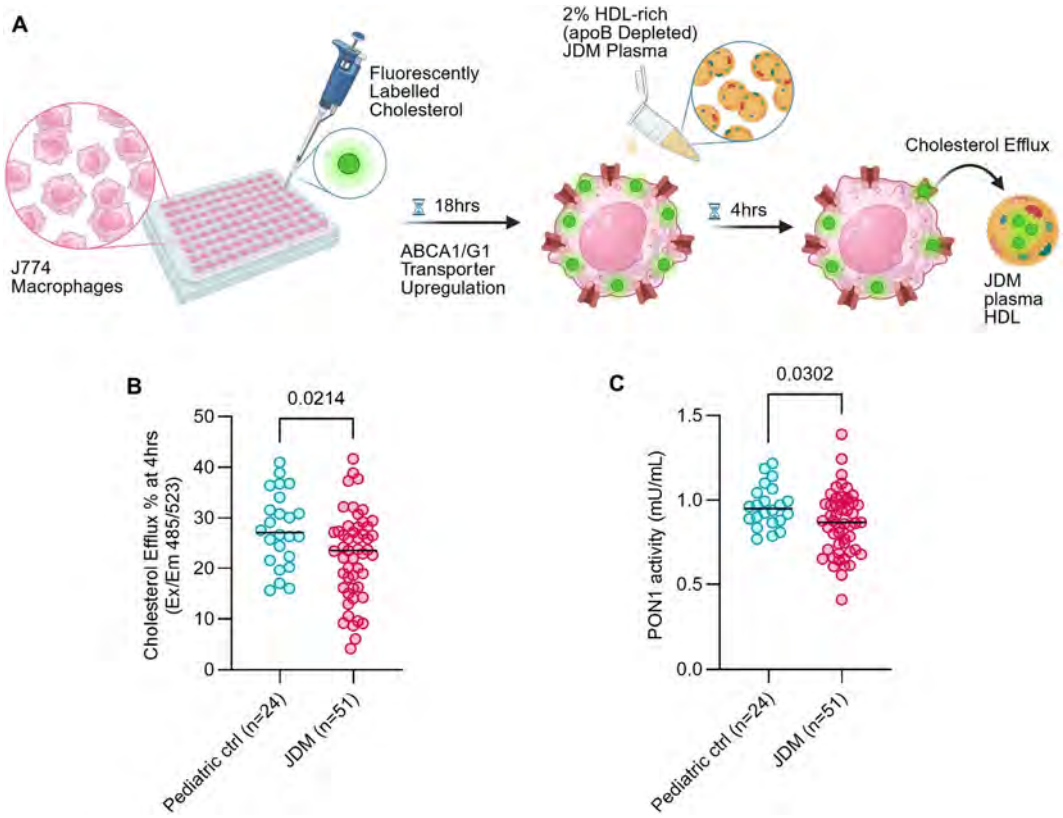

Figure 1: Impaired cholesterol efflux capacity (CEC) and reduced PON1 activity among JDM patients. A, Schematics of CEC assay. B, % CEC in JDM patients versus pediatric controls. C, Plasma PON1 Activity (mU/mL) in JDM patients compared to pediatric controls.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

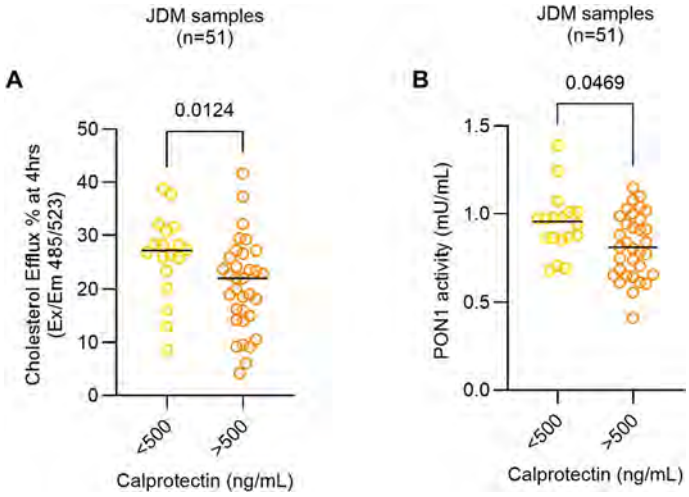

Figure 2: JDM patients with elevated calprotectin levels exhibit impaired cholesterol efflux capacity and decreased PON1 activity. A, % CEC and B, Plasma PON1 Activity (mU/mL) in JDM patients with high calprotectin levels (>500 ng/mL) compared to those with low calprotectin levels (<500 ng/mL).

(e.g., methotrexate) had significantly higher CEC than untreated patients ($p = 0.04$), raising the possibility that such treatments may help preserve or restore HDL function and vascular health beyond their anti-inflammatory effects.

Conclusion: JDM patients demonstrate marked HDL dysfunction that correlates with both heightened calprotectin levels and disease activity, underscoring a link between inflammation and early atherogenic risk. These findings support the importance of early cardiovascular surveillance and proactive management strategies in JDM patients, also highlighting the critical need to develop biomarkers of vascular health in children with JDM.

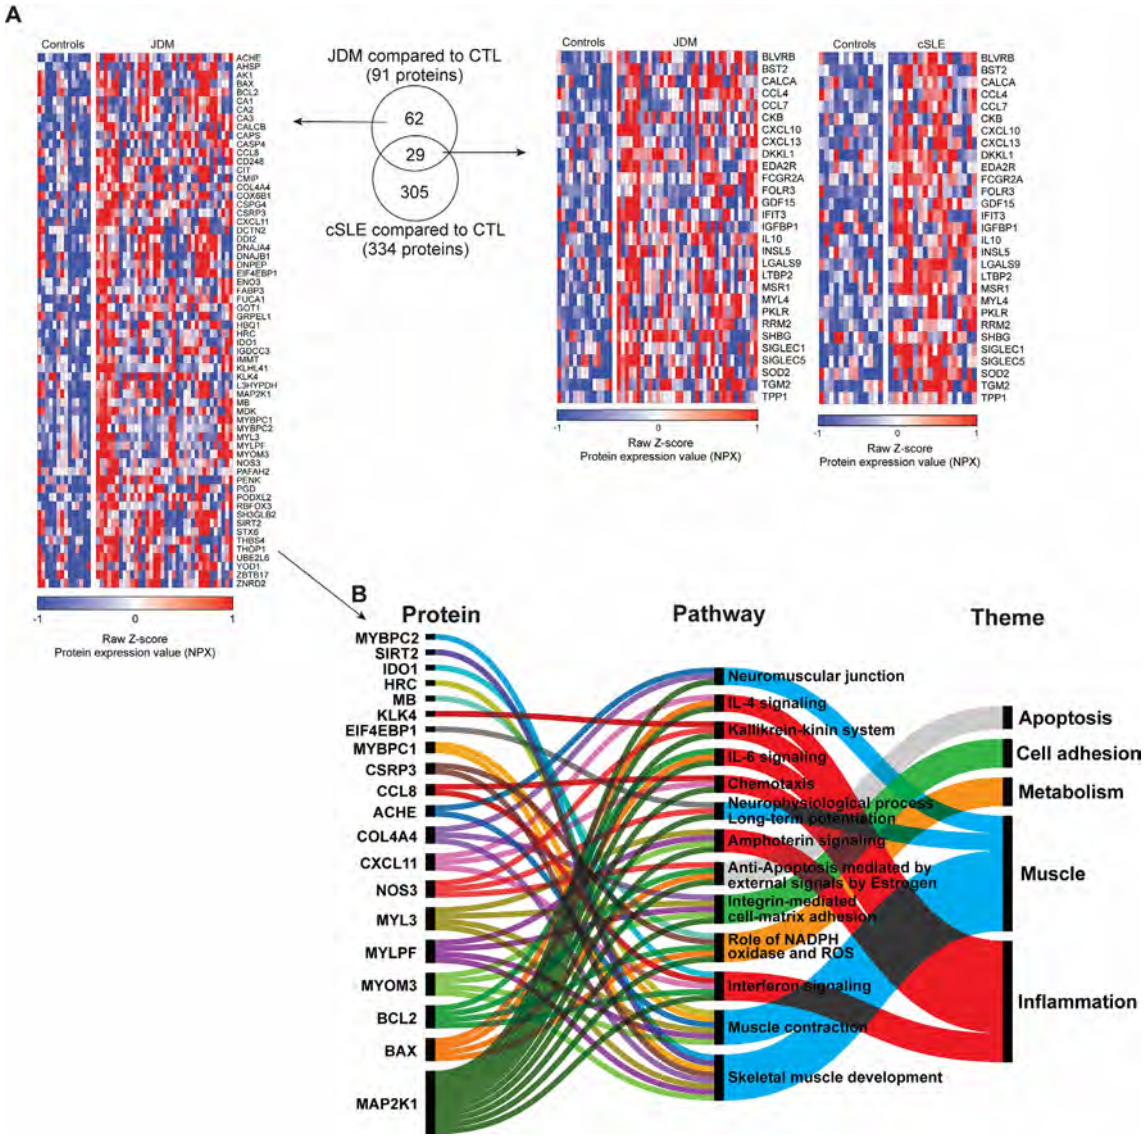

Figure 1. Comparison of plasma proteomic signature in JDM vs. cSLE highlights altered muscle signaling in JDM and shared interferon and innate immune signature with cSLE. A.) Venn Diagram highlighting number of differentially regulated proteins (DRPs) in each JDM (n=36) and cSLE (n=18) relative to CTL (n=14), with heatmap on left demonstrating 62 DRPs unique to JDM vs. CTL comparison and heatmap on right highlighting 29 DRPs in common between each JDM and cSLE relative to CTL. In the heatmaps, each column represents an individual patient sample while each row represents a DRP, with color indicating NPX z-score expression of each protein. B.) Alluvial plot showing biological pathways and associated proteins regulated in JDM.

Methods: Plasma protein levels were measured using the Olink® Explore 3072 panel in 36 JDM, 18 cSLE and 14 controls (CTL). All JDM and cSLE met EULAR/ACR classification criteria. Differential expression analysis identified differentially regulated proteins (DRPs) (false discovery rate (FDR)< 0.10) in (1) all JDM, (2) all cSLE and (3) treatment naïve (TN) JDM (n=6) relative to CTL. Regulated pathways were assessed using MetaCore™ (FDR< 0.10). Pearson correlation evaluated association of DRPs with global and organ-specific JDM disease activity measures (p< 0.05). We further evaluated candidate disease activity-associated DRPs by analyzing cell-type specific RNA expression of genes encoding the DRPs in a JDM single-nucleus transcriptomic dataset from muscle (n=6) and single-cell transcriptomic datasets from skin (n=12) and blood (n=5).

Results: We identified 91 DRPs in JDM and 334 in cSLE, of which 29 DRPs overlapped in JDM and cSLE **(Fig 1A)**. 62 DRPs were unique to JDM, representing five biological pathway themes, including skeletal muscle development and contraction, inflammation, apoptosis, metabolism and cell adhesion **(Fig 1B)**. In TN JDM vs. CTL, 962 DRPs were identified, with

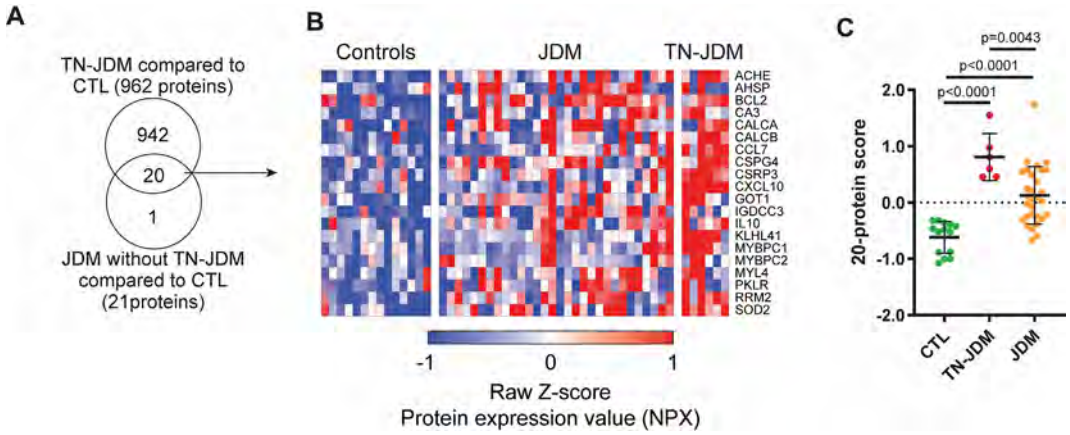

Fig 2. Identification of 20 common differentially regulated proteins (DRPs) in both treatment naïve (TN) and chronic JDM. A.) Venn diagram displaying number of DRPs in each TN JDM (n=6) and chronic JDM (n=30) relative to CTL (n=14). B.) Heat map demonstrating NPX z-score expression of the 20 common DRPs in each TN and chronic JDM samples. C.) Protein expression score of the 20 common DRPs in TN JDM, chronic JDM and CTL samples. Protein expression score is higher in both TN and chronic JDM compared to CTL.

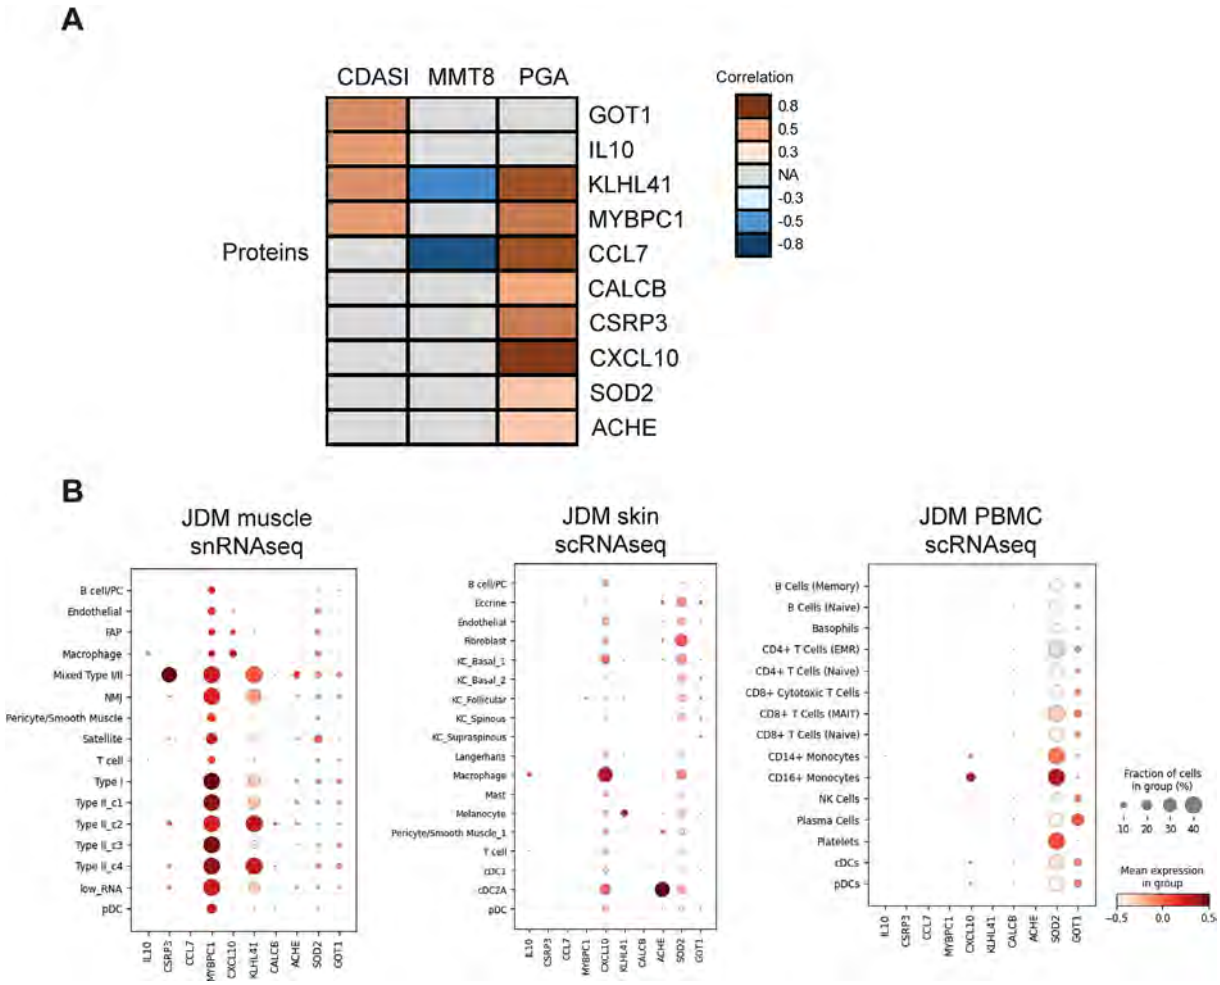

Fig 3. Ten differentially regulated proteins in chronic JDM also display association with JDM disease activity measures. A.) Pearson correlation of ten DRPs from chronic JDM with JDM disease activity measures for skin (Cutaneous Dermatomyositis Disease Area and Severity Index; CDASI activity score), muscle (Manual Muscle Testing; MMT-8 scores) and global (Physician's Global Activity Assessment; PGA scores) disease activity ($p<0.05$). B.) Dot plots displaying normalized and scaled gene expression (indicated by color) and percent of cells (indicated by size of dot) expressing the ten candidate markers in three additional datasets: single-nuclei RNA-sequencing data from muscle (n=6 JDM), single-cell RNA-sequencing data from skin (n=12 JDM) and treatment naïve peripheral blood mononuclear cells (PBMCs) (n=5 JDM).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

neutrophil degranulation, IL-10 and death receptor signaling representing top biological pathways. To identify a chronic JDM signature, we analyzed DRPs in non-TN JDM, which resulted in 21 DRPs **(Fig 2A,B)**, including both immune signaling (IL-10, CCL7, CXCL10) and muscle and metabolism-associated (CSRP3, MYBPC1, KLHL41, CALCB, ACHE, SOD2, GOT1). A protein expression score incorporating the 20 overlapping proteins from chronic and TN JDM was higher in JDM versus CTL ($p< 0.05$) **(Fig 2C)**. Ten of these chronically elevated DRPs correlated with JDM disease activity measures **(Fig 3A)**. Upon evaluation of cell-type specific, single-cell expression of these ten markers, we identified a predominant tissue-based origin, with only CXCL10, SOD2 and GOT1 exhibiting expression in circulating immune cells (**Fig 3B**). Interestingly, IL-10 displayed specific expression only in skin and muscle tissue macrophages, while CXCL10 exhibited widespread expression, including circulating CD14 and CD16+ monocytes and resident muscle and skin populations (FAPS, ECs, basal keratinocytes, fibroblasts) **(Fig 3B)**.

Conclusion: JDM as compared to cSLE demonstrated increased expression of proteins associated with myogenesis and metabolism. We identified a chronic disease signature in JDM, which included DRPs associated with metabolism (GOT1, SOD2), myogenesis/muscle structure (KHL41, CSRP3, MYBPC1), and immune dysregulation (CXCL10, IL10, CCL7). The majority of chronic DRPs in JDM, including DRPs specific to immune cells, exhibited higher gene expression in tissue, highlighting the need for further tissue-based studies in JDM to identify targeted therapies and biomarkers.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Pediatric Rheumatology – Clinical II (1740–1745)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: Cognitive impairment is common in childhood-onset systemic lupus erythematosus (cSLE), particularly in domains like executive function and attention. However, attributing cognitive difficulties to brain inflammation—such as interferon (IFN)-mediated processes in cSLE—remains challenging. Neuroglial proteins are potential biomarkers of brain injury and cognitive impairment in cSLE. S100B is a calcium-binding signaling protein produced by astrocytes that reflects acute brain injury. Elevated levels of S100B and related S100 proteins have been reported in patients with neuropsychiatric lupus (NPSLE) and cognitive impairment but remain understudied in pediatric populations. We compared serum S100B

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1: Boxplot showing group differences in serum S100B level between cSLE and controls. Boxes represent median and IQR; whiskers extend to 1.5×IQR below Q1 and above Q3. Using Wilcoxon Rank Sum Test, no significant differences were observed.

Figure 1: Boxplot showing comparison of serum S100B level between cSLE and controls.

Table 1: Relationship between S100B, Disease Characteristics, and Interferons in cSLE (n=49)

Table 1: Relationship between S100B, Disease Characteristics, and Interferons in cSLE (n=49)

	SLEDAI-2K at Study Visit	SDI	Current GC Dose	Cumulative GC Exposure	IFN-α	IFN-γ
S100B	r = -0.10 p = 0.514	r = 0.22 p = 0.124	r = 0.20 p = 0.168	r = -0.07 p = 0.617	r = -0.30 **p = 0.039**	r = -0.35 **p = 0.014**

Shown are Spearman correlations analyzing relationships between S100B, cSLE disease features, and serum-IFN levels. Statistically significant correlations are bolded ($p<0.05$).

Table 2: Correlations between S100B and Cognitive Measures in cSLE (n=49)

Table 2: Correlations between S100B and Cognitive Measures in cSLE (n=49)

	Inhibition	Inhibition Switching	Digit Span	Omissions	Commissions	Hit Reaction Time
S100B	r = 0.07 p = 0.643	r = 0.02 p = 0.904	r = -0.07 p = 0.639	r = 0.12 p = 0.423	r = 0.13 p = 0.377	r = 0.09 p = 0.545

Shown are Spearman correlations analyzing relationships between S100B and cognitive measures in cSLE. The cognitive domains tested include cognitive inhibition and mental flexibility using Delis-Kaplan Executive Function System Color Word Interference Test (inhibition, inhibition/switching scaled scores), working memory using Wechsler Adult Intelligence Scale IV or Wechsler Intelligence Scale for Children V (digit span scaled score), and attention using Conners Continuous Performance Test 3 (omissions, commissions, hit reaction time t-scores).

levels between children with cSLE and controls, and investigated its relationship with cSLE disease features, serum-IFN levels, and cognitive functioning.

Methods: Cross-sectional data were prospectively collected from cSLE participants (ages 12-17 years) meeting ACR classification criteria for SLE, recruited from the Lupus Clinic at a Canadian tertiary children's hospital from Jan 2020–Dec 2023 and age-, sex-matched healthy controls. S100B, IFN-α and IFN-γ serum levels were quantified using their respective Simoa assays (Quanterix, Billerca, MA, USA). Disease features included disease activity (SLEDAI-2K), damage (SLICC damage index, SDI >0), glucocorticoid (GC) dose at study visit, and cumulative GC exposure (prednisone-equivalent). Assessment of cognitive function domains included: cognitive inhibition and mental flexibility using Delis-Kaplan Executive Function System Color Word Interference Test (inhibition, inhibition/switching), working memory using Digit Span from the Wechsler Adult Intelligence Scale IV/Wechsler Intelligence Scale for Children V, and attention using Conners Continuous Performance Test

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. 3 (omissions, commissions, hit reaction time). Wilcoxon rank sum test compared S100B levels; Spearman correlations tested associations.

Results: 49 cSLE participants (mean age=15.2±1.8 years, 90% female) and 40 controls (mean age=15.3±1.7 years, 80% female) were included. For cSLE, median disease duration was 25.1 months (IQR 13.3-46.2), median SLEDAI-2K was 2.0 (IQR 2.0-4.0), 10% had disease damage, 41% were using glucocorticoids at study visit, and median cumulative GC exposure was 2.3 grams (IQR 0.6-7.0). One patient had a NPSLE diagnosis. There were no group differences in serum S100B levels between cSLE and controls (median 1714.9 vs 2369.4 ng/mL; Figure 1). In cSLE, S100B showed positive but non-significant correlations with SDI and current GC dose (Table 1). Significant inverse associations were observed between S100B and both IFN-α and IFN-γ (Table 1). No correlations were found between S100B and cognitive test performance (Table 2).

Conclusion: In cSLE, serum S100B was not associated with cognitive functioning and did not differ from controls, contrasting prior findings in adult SLE. Inverse associations with type I and II IFNs suggest a potential downregulation of this protein in IFN-driven inflammation, perhaps during the early stages of brain inflammation. Future studies will examine these relationships longitudinally in larger cSLE cohorts.

Abstract Number: 1743

Comparative assessment of cardiovascular risk and its predictors in a large cohort of young adults with juvenile systemic lupus erythematosus and juvenile dermatomyositis

Jiangning Li, Shreya Doddi, Tharuni Mailoo and **Coziana Ciurtin**, University College London, London, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Pediatric Rheumatology – Clinical II (1740–1745)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: Juvenile systemic lupus erythematosus (JSLE) and juvenile dermatomyositis (JDM) are associated with chronic inflammation that can accelerate atherosclerosis. There is no specific guidance regarding the best way to stratify adolescents/young adults (AYA) based on cardiovascular disease (CVD)-risk for personalised management.

Objective: To evaluate the performance of validated CVD-risk scores in JSLE/JDM, comparing risk prediction with long term atherosclerotic burden indicators.

Methods: A retrospective cohort analysis of 155 AYA with JSLE (n=76) and JDM (n=79) using descriptive statistics/regression analysis was conducted. CVD-risk was assessed at last follow-up using validated adult scores: Framingham Risk Score (FRS), Atherosclerotic Cardiovascular Disease (ASCVD) and QRISK3, and the Pathobiological Determinants of Atherosclerosis in Youth (PDAY) score (validated from age 14).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: AYA with JSLE vs. JDM were 84% vs.72% females (P=0.08), 60% vs. 29% Non-White (P < 0.001), with age at last follow-up of 22.3±5.4 vs.18.3±5.5 years (P < 0.001), and median age at disease onset 13.0 (11-16) and 7.5 (5-10) years (P < 0.001). At last assessment, AYA with JSLE had more hypertension (13% vs. 3%, P=0.02), and higher total cholesterol (P=0.01) and LDL-cholesterol (P=0.02) levels compared to JDM, while there were no differences in BMI, smoking or diabetes prevalence. The cumulative dose of steroids was higher in JSLE vs. JDM (P < 0.001).

The PDAY score was the only one with adequate performance, stratifying 43.5% and 32.8% of JSLE patients as 'high' and 'very high' risk, respectively, while only 15% of AYA with JDM were classified as 'high' risk (P < 0.001). PDAY scores remained significantly higher in JSLE vs. JDM after adjusting for age/disease duration (P < 0.001). PDAY did not correlate with FRS, ASCVD or QRISK3 scores in either cohort.

When last visit was dichotomized by any major flare, AYA with active JSLE or damage (PedSDI >1) had higher PDAY score (mean 11 vs. 7, P=0.004, and mean 10 vs. 6, P=0.02, respectively). In a multivariable logistic model, four independent predictors of high CVD-risk were identified in JSLE: older age (OR ∼1.5 per 5-year increase, P=0.03), longer disease duration (OR ∼1.4 per 5-year increase, P=0.04), higher LDL level (OR ∼2.0 per 1 mmol/L increase, P=0.02), and presence of active JSLE (OR ∼3.3 for any BILAG A vs. no BILAG A flare at last visit, P=0.01). Too few AYA with JDM had 'high' CVD-risk based on PDAY score for robust modeling; all were males (N=12), one was an ex-smoker and N=9 had low HDL-cholesterol during active disease. None of the typical JDM features (muscle enzyme levels, MMT8 score or CDASI skin disease score) showed an association with PDAY, supporting that traditional factors drove the high CVD-risk observed in JDM.

Conclusion: Traditional 10-year CVD-risk assessments validated in adults consistently classified all AYA with JSLE and JDM as low risk, while PDAY score was the only one useful for risk stratification in AYA with JSLE/JDM. This study is the first to highlight higher CVD-risk in JSLE vs. JDM in young adulthood, after adjustment for age/disease duration, as well as disease-related factors driving high CVD-risk in JSLE compared to traditional ones in JDM in young adulthood.

Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: Childhood-onset Systemic Lupus Erythematosus (cSLE) affects approximately 1 in 10,000 children in the United States, with the estimated prevalence of childhood neuropsychiatric SLE (NPSLE) at 43 - 95%. Risk factors of NPSLE are poorly understood though NPSLE could severely impact cognitive development and long-term neurologic outcomes. Thus, identification of accurate predictors of increased NPSLE risk are greatly needed. The objective of our study

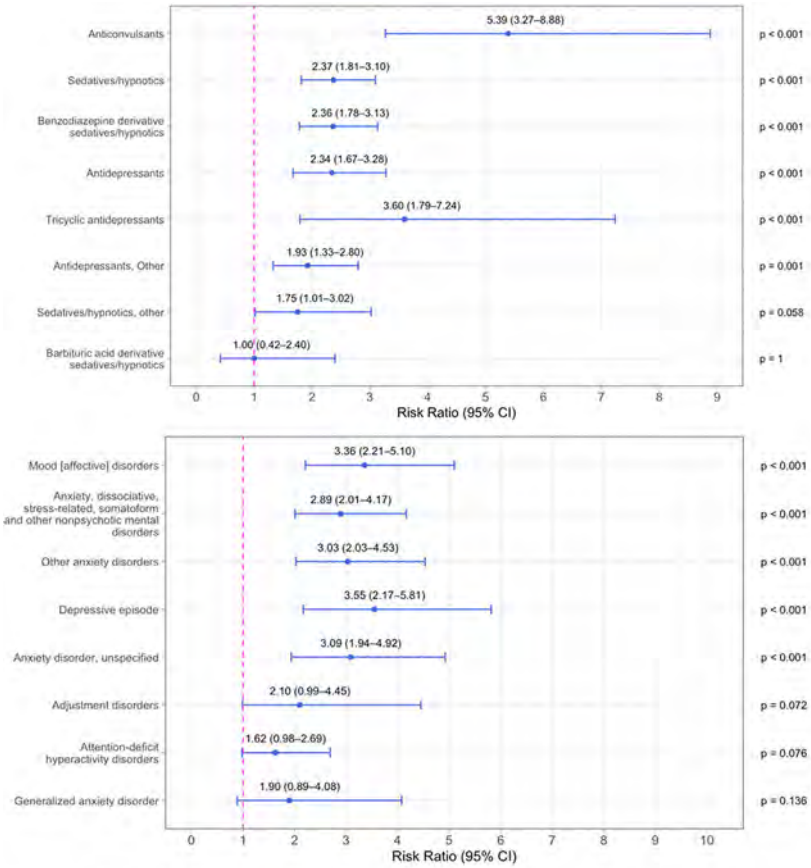

Figure 2: Risk of NPSLE occurrence in relation to premorbid mental health diagnosis or prescription within 18 months prior to cSLE diagnosis.

Figure 2: Risk of NPSLE occurrence in relation to premorbid mental health diagnosis or prescription within 18 months prior to cSLE diagnosis.

was to understand whether premorbid mental health history predicted neuropsychiatric disease in cSLE. We hypothesized that mental health diagnoses and prescriptions occurring before cSLE diagnosis are predictive of future NPSLE.

Methods: Retrospective case-control study using a federated patient database (TriNetX Research network). We included patients aged ≤18 years at first SLE diagnosis between January 2014 and April 2025. We defined NPSLE using the 19 American College of Rheumatology classified neuropsychiatric syndromes with corresponding ICD-10 codes. Premorbid mental health diagnosis was defined as a neuropsychiatric diagnosis any time up to one day before initial SLE diagnosis using specific ICD-10 codes [(i.e. mood disorders (F30 - 39), depression (F32), anxiety disorders (F40 – 48; F41, F41.1, F41.9), adjustment disorders (F43.2) and attention deficit hyperactivity disorder (F90)]; and prescriptions using Veterans Affairs National Drug File (VA NDF) codes (CN300, CN301, CN302, CN309, CN400, CN600, CN601, CN609). The risk of NPSLE occurrence in relation to premorbid mental health diagnosis or prescription was analyzed over 2 time periods: (a)18-months and (b) total observation period, prior to SLE diagnosis. Propensity score matching was based on patient sex and race, and regression analyses conducted for the risk of NPSLE compared between cases and controls.

Results: The total TriNetX population queried included approximately 140 million patients from 102 healthcare organizations . A total of 8504 cSLE patients (5,880 cSLE patients with NPSLE and 2,624 without NPSLE) were identified. After propensity matching by sex, ethnicity, and race, 2,313 patients were included in each cohort (Table 1). Premorbid diagnosis of mood disorders, depression and anxiety disorders within 18 months prior to cSLE diagnosis were associated with > 2-fold risk of subsequent NPSLE (RR: 3.4, 3.6, 3.0; all $p < 0.05$. Similarly, the risk of developing NPSLE was increased with a diagnosis of mood disorders, depression, anxiety and attention-deficit hyperactivity disorder at

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

any time point prior to cSLE diagnosis (RR: 2.9, 3.0, 3.0,2.1; all $p < 0.05$). History of use of anticonvulsant, antidepressants and sedatives within 18 months or at any time prior to cSLE diagnosis was also associated with increased risk of subsequent NPSLE. (Figures 1 & 2).

Conclusion: Preceding mental health diagnoses predict future neuropsychiatric disease in cSLE. Further research is needed to understand earlier clinical, laboratory and neuroimaging indicators of NPSLE development to delineate surveillance measures and interventions.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Pediatric Rheumatology – Clinical II (1740–1745)

Session Type: Abstract Session

Session Time: 10:00AM–11:30AM

Background/Purpose: Juvenile lupus & dermatomyositis (JSLE/JDM) patients experience high emotional distress and premature loss of cardiovascular health (CVH), defined as protective factors against cardiovascular disease (CVD). Although general pediatric studies show emotional distress is associated with worse CVH, the contribution of emotional distress to suboptimal CVH in JSLE/JDM has not been studied. We present longitudinal analyses from the Lupus Erythematosus & Dermatomyositis Stress & Cardiovascular Health (LEADS-CV) cohort, the first multicenter biopsychosocial study assessing emotional distress and CVH in JSLE/JDM.

Methods: Of 83 LEADS-CV participants (5-22yo), 72 with non-missing data on study measures at ≥1 study visit (baseline, 6 & 12 months) were included for analysis. Emotional distress measures included PROMIS® Pediatric Psychological Stress Experiences, Depressive Symptoms, and Anxiety (self-report in ≥8yo, parent-report in 5-7yo). CVH Behaviors (diet quality screener, self-report ≥12yo, parent-report < 12yo; PROMIS Pediatric Physical Activity self-report ≥8yo, parent-report 5-7yo) and CVH Factors (body mass index, blood pressure, non-HDL cholesterol, HbA1c) were assessed. CVH Summary (CVH-S, all 6 indicators), Behaviors (CVH-B), and Factors (CVH-F) scores were determined using AHA guidelines (0 = very poor, 100 = ideal). Linear mixed-effects models (LMMs) assessed associations of emotional distress and CVH-S/-B/-F,

^Reference groups for binary predictors are as follows: 6 mo vs baseline visit reference group; 12 mo vs baseline visit reference group; Active Disease (PGA ≥ 1.5) vs Minimal/Inactive Disease (PGA < 1.5) reference group; Current Steroid Use vs Off Steroids reference group; Any US Minority Race and/or Ethnicity vs Non-Hispanic White reference group; Female Gender vs Male Gender reference group; Diagnosis JDM vs JSLE reference group

adjusted for gender, race/ethnicity, diagnosis, disease activity, steroid use, and time. Growth mixture models (GMMs) identified latent trajectories of emotional distress and CVH-S/-B/-F. Proportions of patients in CVH-S/-B/-F latent trajectories were compared across emotional distress latent trajectories.

Results: LMM results (Table 2) show JSLE and active disease are associated with lower CVH-S and CVH-F scores across all models. Higher PROMIS Anxiety is associated with lower CVH-S and CVH-F. Increasing age is associated with lower CVH-B . Across models, slightly higher CVH-S was estimated at the 12-month visit compared with baseline. Among patients with maximal (79.8) vs minimal (38.8) PROMIS Anxiety scores, estimated CVH-S and CVH-F scores were lower (-7.79 and -10.25, respectively). GMMs identified latent trajectories of CVH and emotional distress with clinically distinct

score distributions; worse CVH-S/-B/-F was more common in higher emotional distress latent trajectory classes, with 69-78% of patients in higher emotional distress latent trajectory classes having poor CVH-B (Table 3).

Conclusion: Higher emotional distress is associated with worse CVH in JSLE/JDM. Severe anxiety is associated with sufficiently large decreases in CVH-S/-F that higher mid-life risk of CVD events would be expected. Low CVH-B is present in most JSLE/JDM patients following high emotional distress latent trajectories. Interventions are needed to address dual risks of emotional distress and suboptimal CVH in JSLE/JDM. Our ongoing work will identify mediators by which emotional distress worsens CVH and child/parent targets for stress reduction and CVH promotion interventions in JSLE/JDM.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes I: Breathe (ILD/Pulmonary) (1746–1751)

Session Type: Abstract Session

Session Time: 10:00AM–11:30AM

Background/Purpose: There exists a need to identify informative peripheral blood biomarkers for RA-interstitial lung disease (RA-ILD) and elucidate the pathophysiological processes driving RA-ILD onset. Several inflammatory- and fibrosis-related mediators have been identified in diseases characterized by tissue fibrosis such as idiopathic pulmonary fibrosis (IPF) and heart failure, but few have been evaluated specifically in RA-ILD. We investigated the association of inflammatory- and fibrosis-related biomarkers with RA-ILD risk in a large, prospective RA cohort.

Methods: Using a multicenter, prospective cohort of U.S. Veterans with RA, we performed a cross-sectional study of prevalent RA-ILD and cohort study of incident RA-ILD. Inflammatory- and fibrosis-related biomarkers discovered in IPF and heart failure: growth differentiation factor-15 (GDF-15), interleukin-18, interferon-gamma inducible protein-10, interferon-inducible T-cell alpha chemoattractant, monokine induced by gamma interferon, pentraxin-3, and soluble vascular cell adhesion molecule, were measured from serum at enrollment using the MesoScale Discovery platform. Biomarker concentrations were log-transformed and standardized, as well as categorized into quartiles to assess non-linear associations. RA-ILD was identified through informatics-based screening and validation by a board-certified rheumatologist requiring a clinical diagnosis

Table 1. Associations of selected inflammatory- and fibrosis-related mediators with prevalent and incident RA-ILD.

Table 1. Associations of selected inflammatory- and fibrosis-related mediators with prevalent and incident RA-ILD.

Analyte	aOR/aHR (95% CI) per SD
Prevalent RA-ILD (aOR)	
Growth differentiation factor-15 (GDF-15)	1.42 (1.08, 1.87)
Interleukin-18	0.97 (0.80, 1.17)
Interferon-gamma inducible protein-10 / CXCL10	0.93 (0.76, 1.14)
Interferon-inducible T-cell alpha chemoattractant / CXCL11	0.97 (0.80, 1.17)
Monokine Induced by Gamma Interferon / CXCL9	0.81 (0.66, 1.00)
Pentraxin-3	1.30 (1.07, 1.58)
Soluble vascular cell adhesion molecule	0.95 (0.79, 1.16)
Incident RA-ILD (aHR)	
Growth differentiation factor-15 (GDF15)	1.20 (0.99, 1.46)
Interleukin-18	1.15 (0.99, 1.35)
Interferon-gamma inducible protein 10 / CXCL10	1.10 (0.94, 1.28)
Interferon-inducible T-cell alpha chemoattractant / CXCL11	1.10 (0.94, 1.29)
Monokine Induced by Gamma Interferon / CXCL9	1.03 (0.86, 1.23)
Pentraxin-3	1.17 (0.99, 1.38)
Soluble vascular cell adhesion molecule	1.07 (0.91, 1.26)

Models adjusted for age, sex, race, smoking status, BMI category, anti-CCP antibody positivity, DAS28, Rheumatic Disease Comorbidity Index score. Analytes assessed in separate models.

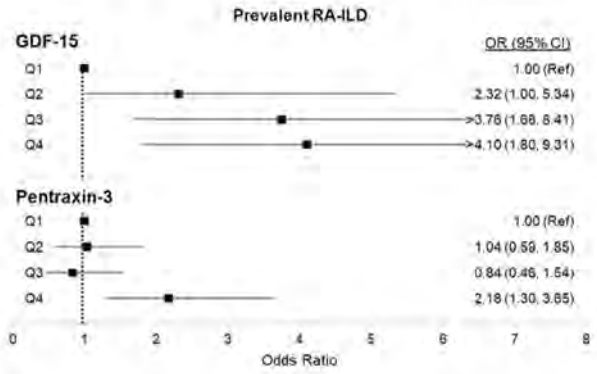
plus imaging or biopsy findings. The associations of candidate biomarkers with RA-ILD were assessed separately in multivariable logistic (prevalent RA-ILD) and Cox (incident RA-ILD) regression models adjusted for age, sex, race, smoking status, body mass index category, anti-CCP antibody positivity, DAS28, and comorbidity burden.

Results: Cross-sectional analyses were conducted among 2,737 RA participants (87% male, mean age 64 years), with 124 having prevalent RA-ILD. Higher concentrations of GDF-15 (per 1 SD aOR 1.42 [1.08, 1.87]) and pentraxin-3 (aOR 1.30 [1.07, 1.58]) were significantly associated with prevalent RA-ILD (**Table 1**). Referent to the lowest quartile, higher

Figure 1. Associations of Growth Differentiation Factor-15 and Pentraxin-3 quartiles with prevalent RA-ILD.



Models adjusted for age, sex, race, smoking status, BMI category, anti-CCP positivity, DAS28, and Rheumatic Disease Comorbidity Index Score. Analytes assessed in separate models.

Q4 = highest quartile
Q1 = lowest quartile (referent)

Abbreviations: OR, odds ratio; CI, confidence interval

Figure 1. Associations of Growth Differentiation Factor-15 and Pentraxin-3 quartiles with prevalent RA-ILD.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Cumulative hazard of incident RA-ILD by Growth Differentiation Factor-15 quartiles.

quartiles of GDF-15 (Q3 aOR 3.76 [1.68, 8.41]; Q4 4.10 [1.80, 9.31]) and the highest quartile of Pentraxin-3 (aOR 2.18 [1.30, 3.65]) were associated with prevalent ILD (**Figure 1**). Concentrations of other biomarkers were not associated with prevalent RA-ILD. After excluding those with prevalent RA-ILD, 174 participants developed incident RA-ILD over 20,957 patient-years of follow-up. None of the analyte concentrations were significantly associated with incident RA-ILD risk (**Table 1**). However, the highest quartile of GDF-15 was associated with a >3-fold higher risk of incident RA-ILD (adjusted HR 3.21 [1.94, 5.32]) (**Figure 2**).

Conclusion: GDF-15, a member of the transforming growth factor-β family, was independently associated with both prevalent and incident RA-ILD in a large RA cohort. Other inflammatory- and fibrosis-related mediators seen in other fibrotic diseases, such as IPF and heart failure, were not associated with RA-ILD risk, suggesting there may be unique disease specific inflammatory and fibrotic pathophysiologic pathways in RA-ILD.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

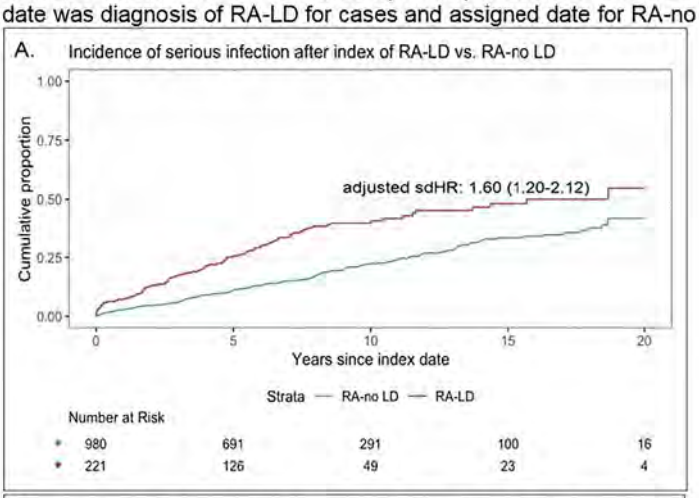
Session Title: Abstracts: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes I: Breathe (ILD/Pulmonary) (1746–1751)

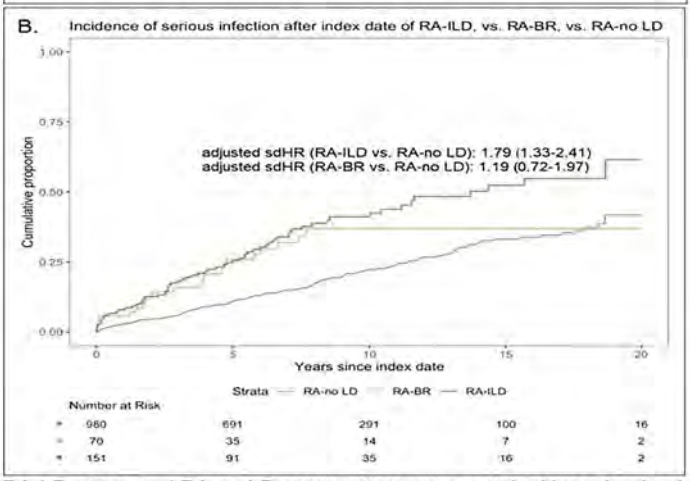
Session Type: Abstract Session

Session Time: 10:00AM–11:30AM

Background/Purpose: RA-associated lung disease (RA-LD), including RA-associated interstitial lung disease (RA-ILD) and RA-associated bronchiectasis (RA-BR), contributes significantly to morbidity and mortality in RA patients. RA is associated with a 2-fold increased risk of serious infection compared to the general population. However, the association of RA-LD and the risk of serious infection is unclear.

Figure 1. A. Cumulative incidence of first serious infection, comparing rheumatoid arthritis-associated lung disease (RA-LD) cases and RA-no LD comparators. B. Cumulative incidence of first serious infection, comparing RA-associated interstitial lung disease (RA-ILD) cases, RA-associated bronchiectasis (RA-BR) cases, and RA-no LD comparators. The index date was diagnosis of RA-LD for cases and assigned date for RA-no LD comparators.





RA-LD cases and RA-no LD comparators were matched by calendar date, age, sex, and RA duration at index date of RA-LD diagnosis.
Additionally adjusted for propensity score that included smoking status, pack-years, Charlson Comorbidity Index score, serostatus, glucocorticoids, csDMARDs, bDMARDs, previous serious infection, and health care utilization.

RA-BR, rheumatoid arthritis-associated bronchiectasis; RA-ILD, rheumatoid arthritis-associated interstitial lung disease; RA-no LD, rheumatoid arthritis without lung disease; SARS-CoV-2, severe acute respiratory syndrome coronavirus 2

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We conducted a retrospective matched cohort study of patients enrolled in the biobank of a large U.S. health care system, comparing RA-LD cases to RA patients without lung disease (RA-no LD), matched by calendar date, age, sex, and RA duration at the index date of RA-LD diagnosis. Patients with RA met the 2010 ACR/EULAR classification criteria. RA-LD cases were verified by medical record review and chest imaging for clinically-apparent RA-ILD and/or RA-BR. The primary outcome was serious infection, defined as infections requiring hospitalization. Secondary outcomes included any infection, infections by anatomic site, pathogen type, and specific pathogens. Incidence rates and propensity score-adjusted subdistribution hazard ratios (sdHR) using Fine and Gray models to account for competing risk of death were calculated for RA-LD vs. RA-no LD as well as RA-ILD or RA-BR vs. RA-no LD.

Results: We analyzed 221 RA-LD cases (151 RA-ILD and 70 RA-BR) and 980 RA-no LD matched comparators. After propensity score adjustment, RA-LD cases had a significantly higher risk of serious infections compared to RA-no LD comparators (55.8 vs. 25.8 per 1,000 person-years, adjusted sdHR 1.60, 95%CI 1.20-2.12, **Figure 1**). The increased risk remained significant for RA-ILD cases (adjusted sdHR 1.79, 95%CI 1.33-2.41), but not for RA-BR cases (adjusted sdHR 1.19, 95%CI 0.72-1.97). Anatomic sites of infection that were more common in RA-LD cases vs. RA-no LD comparators, including pulmonary (31% vs. 10%, p< 0.001), skin and soft tissue (13% vs. 7%, p=0.006), and ear, nose and throat (7% vs. 2%, p=0.002, **Table 1**). RA-LD was associated with pathogen types: viral (16% vs. 8%, p< 0.001), bacterial (19% vs. 9%, p< 0.001), fungal (10% vs. 3%, p< 0.001), and mycobacterial infections (2% vs. 0.1%, p=0.001). Specific pathogens with higher frequency in RA-LD cases vs. RA-no LD comparators, particularly among RA-BR cases, included influenza virus (7% vs. 2%, p=0.008), respiratory syncytial virus (3% vs. 0.3%, p=0.04), *Staphylococcus* (14% vs. 6%, p=0.005), *Pseudomonas* (10% vs. 1%, p< 0.001), and nontuberculous mycobacteria (11% vs. 0.7%, p< 0.001, **Table 2**).

Conclusion: RA-LD, particularly RA-ILD, was associated with higher risk of serious infection across anatomic sites and diverse pathogen types. While RA-BR was not associated with serious infection, it was associated with higher risk of pulmonary infection and nontuberculous mycobacterial infection. Findings may be explained by lung damage and/or more intense immunosuppression, so tailored infection prevention strategies, including vaccination, are essential for this vulnerable population.

Background/Purpose: While air pollution has been implicated in the pathogenesis of rheumatoid arthritis (RA), its association with RA disease activity remains insufficiently investigated (1, 2). We aimed to evaluate the effect of air pollution on disease activity and flare occurrence in patients with RA.

Methods: This prospective study included patients with RA who visited a tertiary medical center in South Korea between January 2021 and October 2024, with at least 6 months of follow-up. Air pollution levels were assessed using monthly mean concentrations of six air pollutants (SO_2, NO_2, O_3, CO, PM_{10}, and $PM_{2.5}$) obtained from the Korean National Institute of Environmental. RA disease activity was evaluated using the tender joint count, swollen joint count based on 28 joints (TJC28, SJC28), clinical disease activity Index (CDAI), and disease activity score based on 28 joints (DAS28). Flare events were defined based increases in DAS28 scores. Associations between air pollution and RA disease activity or flare occurrence were analyzed using linear and logistic generalized estimating equations (GEE), accounting for repeated measures within the study population and adjusting for prespecified covariates including age, sex, smoking status, serologic status, dose of concomitant glucocorticoids, type of disease-modifying anti-rheumatic drugs (DMARDs), and climate variables (temperature and humidity).

Results: A total of 1,056 RA patients were included, with a mean (SD) age of 61.2 (12.7) years, and 907 (85.9%) were female. Patients contributed data for a median (IQR) of 11.0 (8.0, 13.0) visits. There were 1,724 flare events during the observation period, with an incidence rate of 56.3 per 100 person-years (95% CI: 53.7 to 59.1). Air pollution concentrations were high in winter and spring and low in summer (Figure 1). Increases in PM_{10}, and $PM_{2.5}$ levels were associated with flare occurrence (Table 1). Among individual pollutants, O_3 was associated with SJC28 and CDAI, and PM_{10} was associated with both DAS28 CRP and DAS28 ESR. In particular, higher $PM_{2.5}$ levels showed the strongest association with increased RA disease activity, with β coefficients (95% CIs) of 0.078 (0.020 to 0.136) for TJC28, 0.068 (0.023 to 0.112) for SJC28, 0.211 (0.069 to 0.353) for CDAI, 0.040 (0.017 to 0.064) for DAS28 CRP, 0.037 (0.013 to 0.061) for DAS28 ESR when six air pollutants were standardized to a mean of 0 and standard deviation of 1 (Table 2).

Conclusion: Elevated air pollution levels, especially PM 2.5, are associated with increased RA disease activity and flare occurrence in patients of RA.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes I: Breathe (ILD/Pulmonary) (1746–1751)

Session Type: Abstract Session

Session Time: 10:00AM–11:30AM

Background/Purpose: RA-associated interstitial lung disease (RA-ILD) causes substantial morbidity and mortality in RA. Despite this, a limited number of clinical and genetic risk factors have been identified. Recently, a combined clinical-genetic risk score (VARA-ILD Combined Risk Score) has been shown to enhance identification of ILD among RA patients (Wheeler et al., *Rheumatology* 2024). We performed external validation of that combined risk score in a cohort of early RA patients from northern Sweden.

Methods: Participants were enrolled in an inception RA cohort from northern Sweden who were diagnosed with RA between 1996-2016. Clinical data including age, sex, smoking history, and disease activity score with 28-joint count (DAS28) were collected routinely by treating rheumatologists. RF and anti-CCP were assessed at baseline using standard lab methods. ILD screening was performed per clinical indication, with ILD diagnosis based on consistent chest x-ray and/or high-resolution chest CT findings. Genotyping was performed on DNA collected at baseline using the Illumina Global Screening Array, and single nucleotide polymorphisms (SNPs) included in the VARA-ILD Genetic Risk Score (GRS) were extracted. The VARA-ILD Combined Risk score was calculated for each participant and evaluated via multivariable regression. Overall model performance was assessed using the area under the receiver operating characteristic curve (AUC). Sensitivity and specificity were calculated at the recommended cut-point value (0.05) and at the cut-point that optimized Youden's index in this cohort.

Results: We studied 1,118 RA participants (70% female), with ILD present in 60 (5.4% prevalence). RA-ILD participants were older, had more RF positivity, and had higher disease activity (**Table 1**). Among SNPs included in the VARA-ILD GRS, *MUC5B* rs35705950 (OR 3.70, 95% CI 2.18-6.32) and *FAM13A* rs2609255 (OR 1.91, 95% CI 1.13-3.25) were individually associated with RA-ILD (**Table 2**). Within the VARA-ILD combined risk score regression model, the largest effects were seen with the VARA-ILD GRS (OR 2.36, 95% CI 1.24-4.48) and RF positivity (OR 2.96, 95% CI 1.14-7.70). The VARA-ILD Combined Risk Score enhanced discrimination of ILD (AUC 0.75, 95% CI 0.69-0.81) over the GRS alone (AUC 0.62, 95% CI 0.54-0.69; **Figure 1**). At the recommended cut-point of 0.05, the VARA-ILD Combined Risk Score yielded 93% sensitivity and would eliminate 36% of the cohort from undergoing additional testing for ILD. We also calculated an optimal cut-point of 0.08 within this cohort which would yield a sensitivity of 79% and specificity of 95%.

Conclusion: The VARA-ILD GRS and VARA-ILD Combined Risk Score were externally validated in a cohort of early RA patients in northern Sweden. Given the differences in study population between this cohort and the VARA-ILD derivation cohort, our findings demonstrate the generalizability and potential clinical utility of these risk stratification tools for RA-ILD.

Table 1. Characteristics of participants in the northern Sweden early RA cohort. Values shown as mean (standard deviation) unless specified. *DAS28 averaged from prior 24 months. SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes I: Breathe (ILD/Pulmonary) (1746–1751)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: Interstitial lung disease (ILD) is a serious pulmonary complication of rheumatoid arthritis (RA), contributing significantly to morbidity and mortality. Non-invasive tools for identifying ILD risk in RA patients remain limited. As a stable and accessible biofluid, urine represents a promising source of biomarkers. We aimed to identify ILD-associated urinary proteomic signatures and evaluate their potential utility for risk stratification and clinical assessment.

Methods: We analyzed the urine proteome of 78 RA patients (14 with ILD and 64 without ILD) using data-independent acquisition (DIA) liquid chromatography-tandem mass spectrometry (LC-MS). ILD-associated proteins were identified through differential expression analysis and LASSO regression, supported by 1000 bootstrap iterations. Candidate markers were evaluated using logistic regression, ROC analysis, and correlation with pulmonary function.

Results: A total of 2,482 urinary proteins were quantified. Differential expression analysis, LASSO regression, and 1,000 bootstrap iterations (Figure 1) jointly identified two robust ILD-associated proteins: SPOCK1 and PGRMC1, both significantly upregulated in RA-ILD patients ($p < 0.001$). A composite Urine_ILD_Score was constructed based on their expression levels. The score was significantly elevated in ILD patients ($p < 0.001$; Figure 2A) and associated with pulmonary impairment.

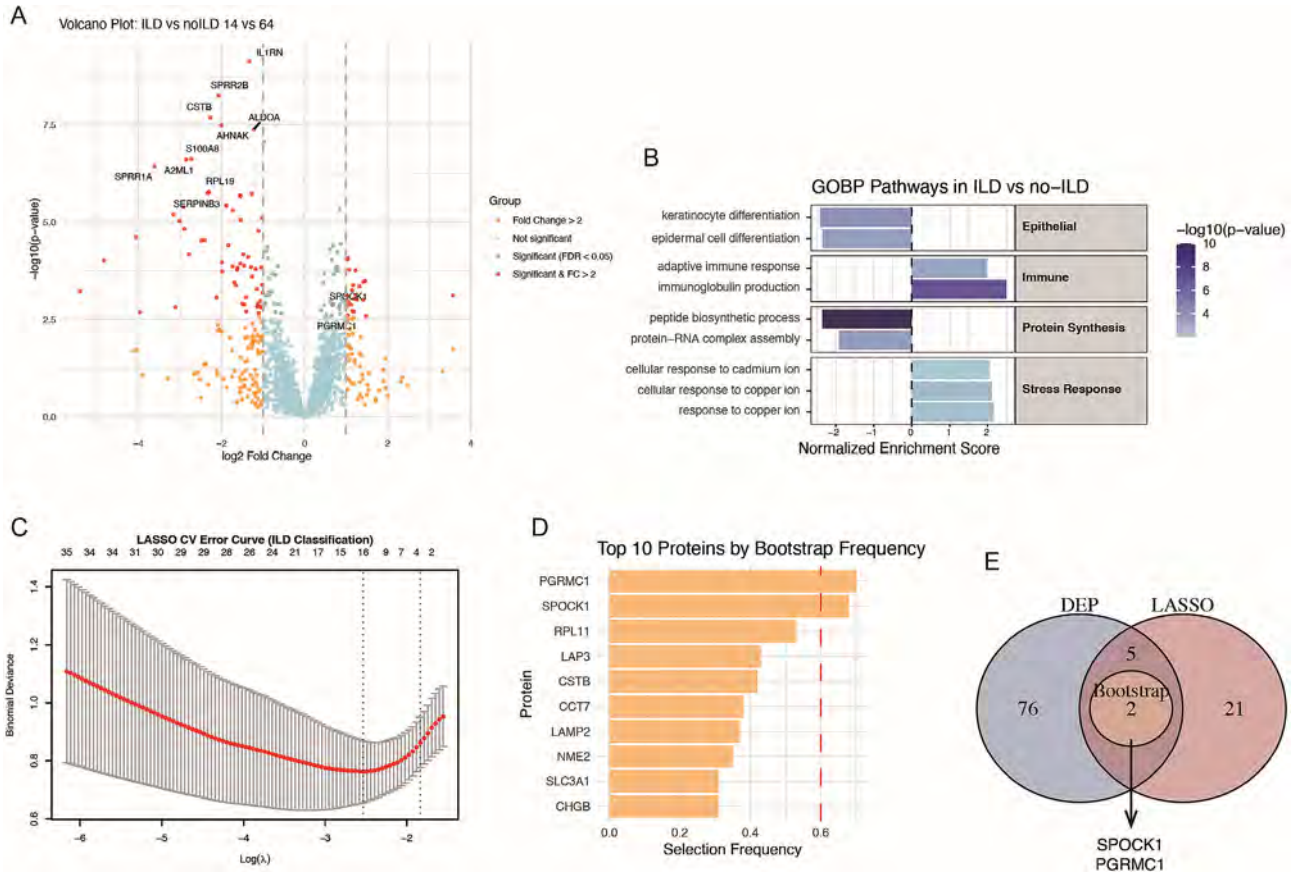

Figure 1. Identification of ILD-associated urinary proteins in RA patients. (A)Volcano plot of differentially expressed urinary proteins between RA patients with ILD (n = 14) and without ILD (n = 64). (B) Gene set enrichment analysis (GSEA) of Gene Ontology Biological Processes based on ranked protein expression between ILD and no-ILD RA patients. (C) LASSO regression with 10-fold cross-validation for ILD classification. (D) Top 10 proteins ranked by bootstrap selection frequency across 1,000 iterations. (E) Venn diagram showing overlap of differentially expressed proteins, LASSO-selected features, and proteins consistently selected by bootstrap.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

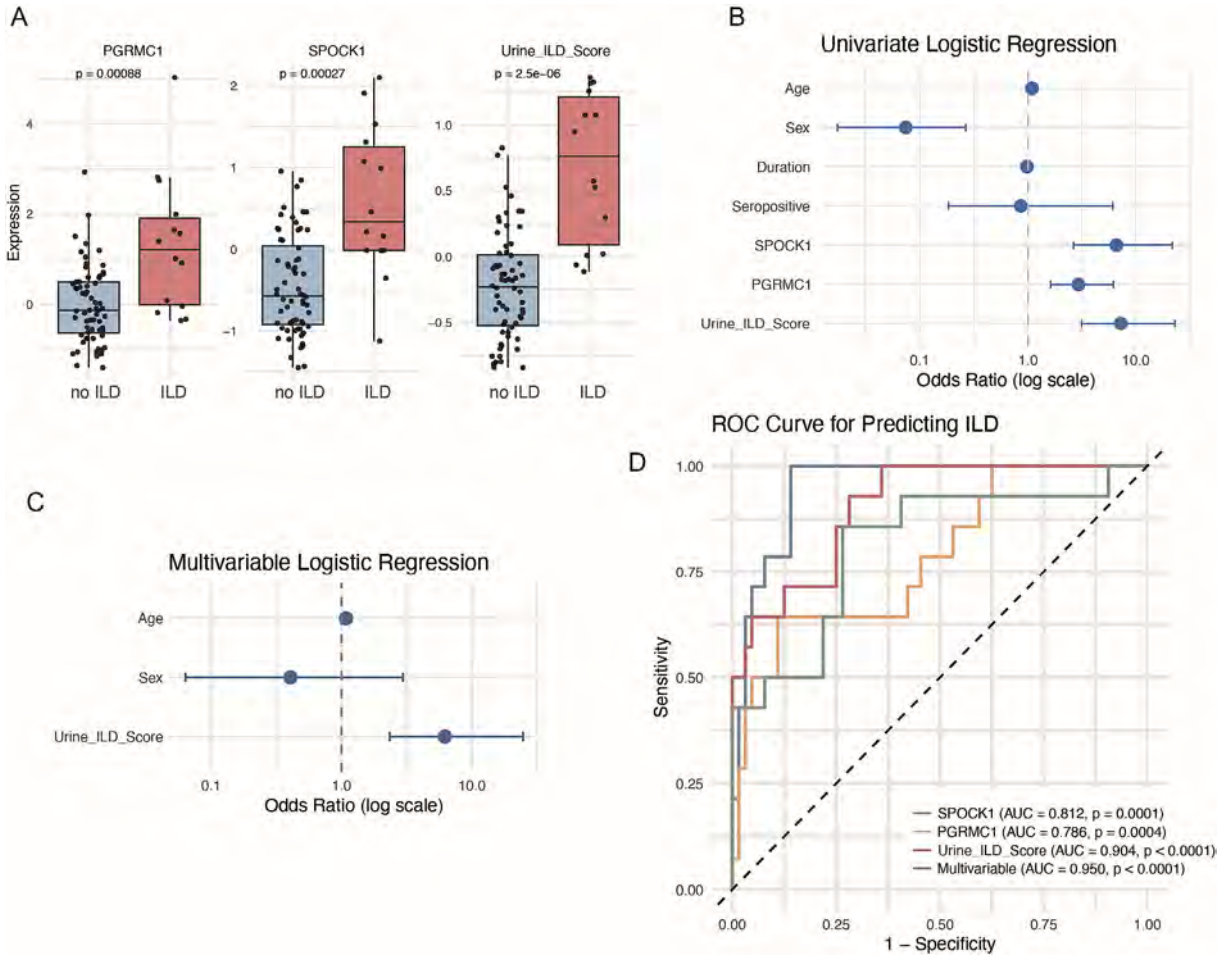

Figure 2. Urine-based protein biomarkers and composite score predict ILD in RA patients. (A)Expression levels of SPOCK1, PGRMC1, and the composite Urine_ILD_Score in RA patients with and without ILD. (B) Forest plot of univariable logistic regression assessing the association of clinical and proteomic variables with ILD status. (C) Forest plot of multivariable logistic regression including age and sex as covariates. (D) ROC analysis comparing the discriminatory performance of SPOCK1, PGRMC1, the composite score, and a full multivariable model (including clinical covariates).

In ROC analysis, the score demonstrated high discriminatory ability (AUC = 0.904, $p < 0.0001$), outperforming either protein alone (SPOCK1: AUC = 0.812; PGRMC1: AUC = 0.786; Figure 2D). In multivariable logistic regression adjusting for age and sex, the Urine_ILD_Score remained independently associated with ILD (OR = 6.19, 95% CI [2.34–24.64], $p = 0.002$; Figure 2C). A combined multivariable model incorporating clinical covariates further improved classification performance (AUC = 0.950; Figure 2D). Importantly, PGRMC1 levels correlated positively with KL-6 ($r = 0.79$, $p = 0.028$) and negatively with total lung capacity (TLC%) ($r = –0.79$, $p = 0.048$), suggesting potential relevance to ILD pathogenesis and severity.

Conclusion: Urinary proteomic profiling can identify RA patients at increased risk for ILD. A composite score based on SPOCK1 and PGRMC1 provides a promising, non-invasive biomarker for ILD risk stratification in RA and may support clinical decision-making and patient monitoring.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes I: Breathe (ILD/Pulmonary) (1746–1751)

Session Type: Abstract Session

Session Time: 10:00AM–11:30AM

Background/Purpose: Quantitative computed tomography (QCT) methods using machine learning have been developed to automatically quantify parenchymal lung features on chest CT imaging. QCT can detect subtle or early abnormalities, and abnormal QCT findings have been associated with symptoms, progressive lung disease, and mortality in general population studies. Based on prior studies linking RA disease activity to interstitial lung disease (ILD) in patients with established RA, we hypothesized that higher RA disease activity would be associated with increased interstitial changes on QCT in early RA.

Methods: We performed a cross-sectional study of participants in SAIL-RA (Study of Inflammatory Arthritis and ILD in Early RA), an ongoing prospective, multicenter longitudinal study of patients recently diagnosed with RA at five U.S. sites between 2017 and 2025. All participants had early RA (diagnosed < 2 years prior to enrollment) and were assessed with physical examination, chest high-resolution CT imaging, pulmonary function tests (PFTs), and peripheral blood testing. QCT was performed using a *k*-nearest neighbor machine learning classifier that categorizes regions of interest into normal lung, interstitial changes, or emphysema based on the local tissue density and distance from the pleural surface. Interstitial changes on QCT may represent features of ILD or other abnormalities such as scarring after infection. We examined the correlation of QCT interstitial changes with PFTs, RA disease activity, and erythrocyte sedimentation rate (ESR) using Spearman correlation coefficients. We tested the association between baseline age, sex, smoking status, RF, anti-CCP, and RA disease activity with QCT interstitial features using multivariable linear regression.

Results: We performed chest QCT analysis on 200 participants with early RA (median RA duration 0.72 years, mean age 55.7 years, 75% female, 85% seropositive) (**Table 1**). On QCT, early RA patients had mean normal lung percentage of 88.0% (SD 7.8). The mean percentage of interstitial changes and emphysema was 5.6% (SD 6.8) and 1.2% (SD 1.7), respectively. Interstitial changes on QCT were correlated with higher DAS28-ESR (rho=0.26, p=0.0003) and ESR (rho=0.30, p< 0.0001), as well as lower FVC% (rho=-0.23, p=0.002) and DLCO% (rho=0.42, p< 0.0001) (**Figure 1**). In a multivariable linear regression model, older age (b=+0.14 per year, 95%CI 0.07-0.21, p< 0.0001) and DAS28-ESR (b=0.64 per point, 95%CI 0.01-1.26, p=0.046) were independently associated with percentage of interstitial changes (**Table 2**). The b

DLCO% (per unit)	-0.16	(-0.20, -0.11)	**<0.0001**			

* = multivariable linear regression adjusted for age at RA diagnosis, sex, smoking status, RF status, and DAS28-ESR

Anti-CCP = anti-cyclic citrullinated peptide antibody, csDMARD = conventional synthetic disease modifying antirheumatic drug, DAS28-ESR = disease activity score of 28 joints with erythrocyte sedimentation rate, DLCO = diffusion capacity of carbon monoxide, FEV_1 = forced expiratory volume in 1 second, FVC = forced vital capacity, HRCT = high resolution computed tomography, IQR = interquartile range, MRC = modified research council, RF = rheumatoid factor, SD = standard deviation, SJC = swollen joint count, TJC = tender joint count, TNFI = tumor necrosis factor inhibitor

from the linear regression model can be interpreted as a percentage increase in interstitial changes per unit increase in the predictor (increase of 0.70% per point of DAS28-ESR).

Conclusion: In this prospective, multicenter study of 200 patients with early RA analyzed using machine learning QCT methods, older age and higher RA disease activity were associated with more QCT interstitial changes. QCT interstitial changes were correlated with lower FVC and DLCO. These findings emphasize the role of inflammation in RA-ILD pathogenesis early in the RA disease course and demonstrate the potential of QCT for RA-ILD screening and monitoring.

Prg4+ Ligament Cells Are Involved in Ligament Ossification in Ankylosing Spondylitis

Kunhai Tang[1], Lilu Zu[1], Chenyuan Wu[1], Jiucun Wang[1] and Jing Liu[2], [1]Fudan University, shanghai, China (People's Republic), [2]Fudan University, Shanghai, Shanghai, China (People's Republic)

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Basic Science (1752–1757)

Session Type: Abstract Session

Session Time: 10:00AM–11:30AM

Background/Purpose: Ankylosing spondylitis(AS) is a chronic inflammatory disease with clinical symptoms characterized by inflammatory low back pain and spinal ankylosis due to ligament ossification. Enthesitis is considered an important manifestation of ankylosing spondylitis and is involved in ligament ossification in AS. However, the exact mechanism of ligament

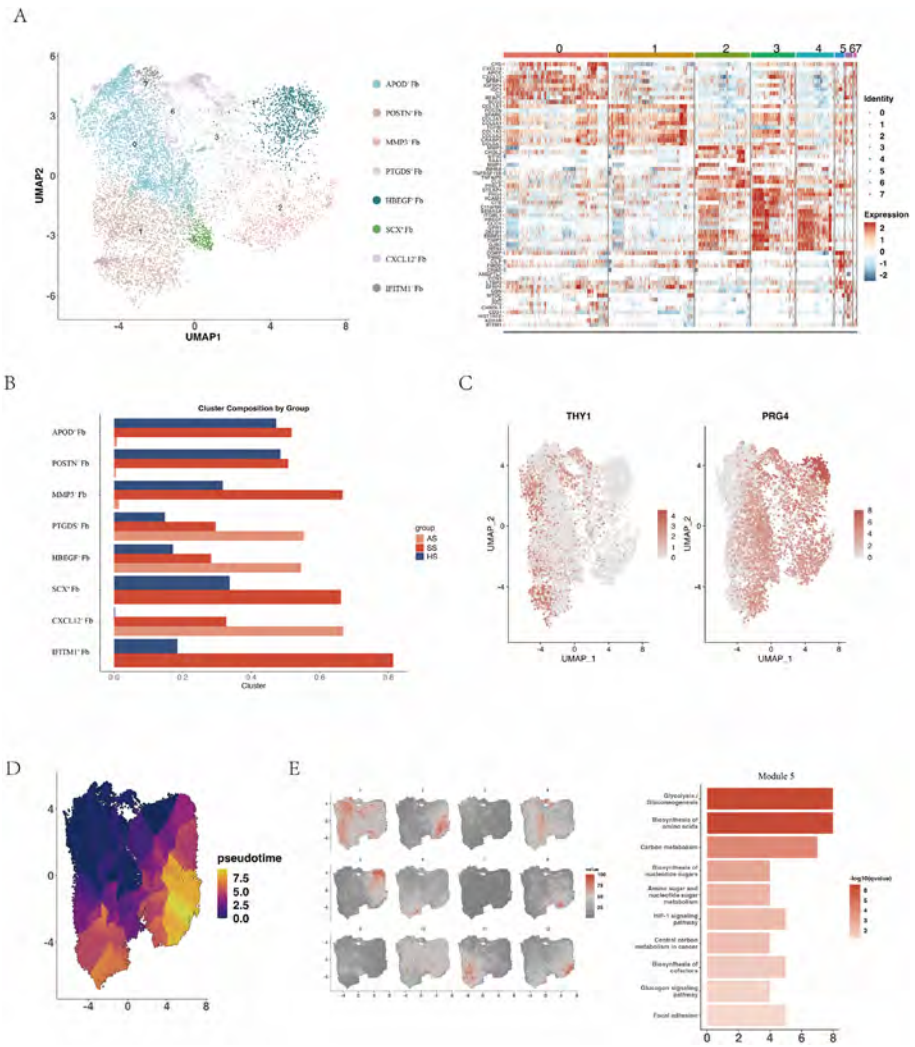

Figure 1 A) Single-cell UMAP plot and cluster marker gene heatmaps of spinal ligament fibroblasts from healthy subjects, AS patients, and patients with degenerative spinal stenosis. B) Cluster composition map between three groups. C) Distribution of PRG4 and THY1 in different clusters. D) Pseudotime analysis of different modules. E) Gene pathway enrichment analysis (KEGG) of module 5 between healthy controls and AS patients.

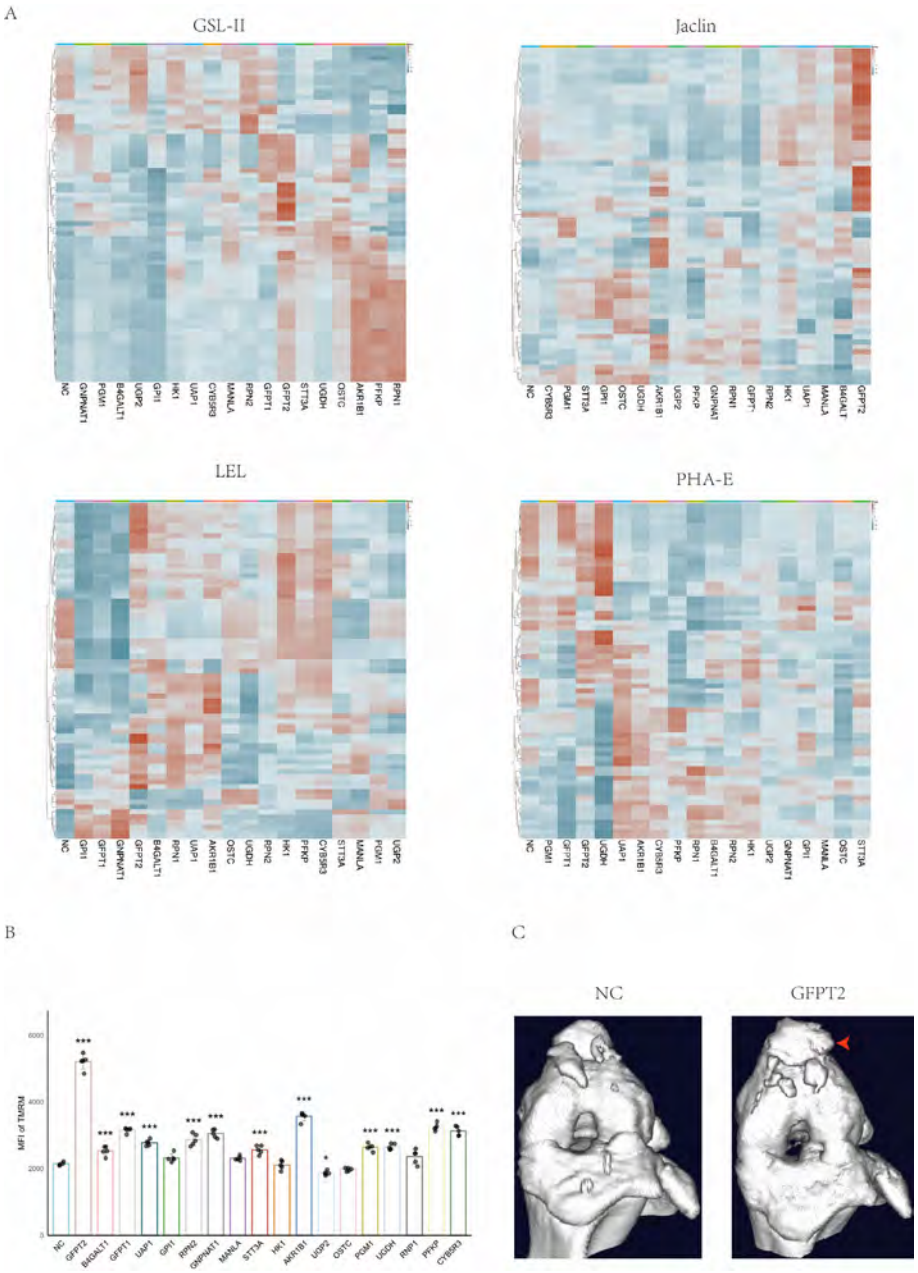

Figure 2 A) Detection of glycosylation levels in cells overexpressing different genes by high content imaging system using four different lectins. Mapping of heatmaps using high content parameters. B) Mitochondrial membrane potential (MPP) was detected by flow cytometry in cells overexpressing different genes. C) MicroCT assay of mice transplanted with different TT-D6 cell sheets after patellar ligament resection modeling. Red arrows indicate abnormal ossification at the enthesis.

ossification is still poorly understood. The aim of this study was to systematically investigate the mechanisms of AS ligament ossification through combination of multiple methods.

Methods: Single-cell sequencing of spinal ligament samples from AS patients (ligament ossification) and healthy controls. Pathway enrichment analysis (KEGG) and gene set enrichment analysis (GSEA) was conducted on the differential cell populations between the two groups. Eighteen-key differential genes (up-regulated in AS) identified by single cell sequencing were separately overexpressed in TT-D6 (mouse tendon cell line) using the CRISPR-Cas9 system. Intracellular glycosylation levels and mitochondrial membrane potential were detected by using a high-content cell imaging system and flow cytometry respectively. Effect of key gene overexpression on ligament ossification in vivo verified by tendon cell sheet transplantation experiments.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Through single-cell transcriptome analysis, we identified a population of fibroblasts (ligament cells) with Prg4 as a marker gene whose proportion was significantly upregulated in ligament ossification AS patients (**Figure 1A-C**). Gene pathway enrichment analysis (KEGG) showed significant activation of glycolysis and nucleotide biosynthesis pathways in this subpopulation of cells in AS patients (**Figure 1D**). GFPT2 (Glutamine-Fructose-6-Phosphate Transaminse 2) as identified as a possible key gene involved in AS ligament ossification by a CRISPR-Cas9 gene screen combined with high content cell imaging system and flow cytometry (**Figure 2A and 2B**). In vivo transplantation experiments show that GFPT2 enhances abnormal ossification at the enthesis after patellar ligament resection modeling in mice (**Figure 2C**).

Conclusion: GFPT2 is a key gene for ligament ossification in AS, and targeting GFPT2 may serve as a novel approach to treating ankylosing spondylitis.

Axial Psoriatic Arthritis is Phenocopied in a Humanized Mouse Model

Christopher Ritchlin[1], Javier Rangel-Moreno[2], Angel Rangel-Garcia[3], Marissa Krantz[4], Madison Brien[2], Thiloginy Sathilaseenlan[2], Jeffrey Fox[5], Ronald Wood[2] and **Maria de la Luz Garcia-Hernandez**[3], [1]University of Rochester Medical Center, Canandaigua, NY, [2]University of Rochester, Rochester, NY, [3]University of Rochester, West Henrietta, NY, [4]University of Rochester, Bethesda, MD, [5]University od Rochester, Rochester, NY

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Basic Science (1752–1757)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: Psoriatic arthritis (PsA) is a complex and heterogeneous inflammatory disorder involving the axial skeleton in approximately 30% of patients. The mechanisms that underlie psoriatic axial inflammation (AxPsA) are not well understood and longitudinal studies to examine the immune mechanisms involved in disease pathogenesis and progression

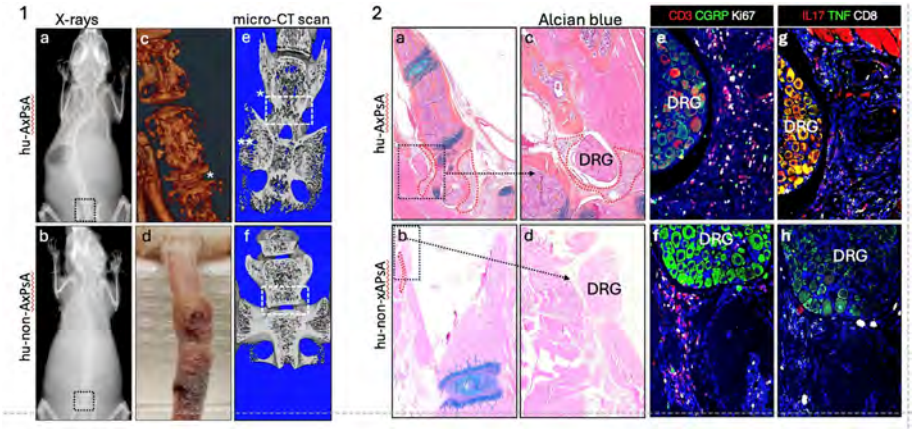

Figure 1. Humanized NSG-SGM3 mice generated with sera and PBMC from AxPsA and non-AxPA patients. 1) Hu-AxPsA mice demonstrated (a), cervical and thoracic kyphosis not seen in controls (b) (c), spinal fusion and erosion in the lumbar spine (c, * fusion and erosion below), (d) tail inflammation and necrosis and (e) L5, S1 fusion * and bone resorption ** not observed in controls (f). Figure 2. Alcian blue staining of the spine shows abundant infiltrating immune cells (dotted red line) around the dorsal root ganglion (DRG) (a,c) and low infiltration in the spine of hu-non-AxPsA mice (b,d). Immunofluorescence staining shows more proliferating CD3 (red and white) and IL-17+ (red) TNF + (green) CD8+ (white) and Il-17+ TNF+ cells in the DRG of hu-AxPsA (e, g) compared to hu-non-AxpSA mice (f,h).

using human cells in an animal model have not been performed. In previous analyses, we demonstrated that human PsA phenotypes in the peripheral skeleton, entheses and skin are recapitulated in the NSG-GM3 humanized mouse model. Herein, we examined if axial disease is phenocopied in this mouse model.

Methods: Two groups of NSG-SGM3 mice were injected with serum and peripheral blood mononuclear cells (PBMC) collected from three biologic naive PsA patients with inflammatory back pain and radiographic or MRI documented sacroiliitis (AxPsA) and controls (PsA patients without axial disease). At day 30, mice were anesthetized, and their spines were dissected for radiographic and micro-CT scan analysis. Tissue sections from decalcified spines were stained with anti CD45, CD14, CD8, Ki67, TNF and Il-17 antibodies.

Results: NSG-SGM3 mice injected with serum and engrafted with PBMC from patients with AxPsA exhibited pronounced spinal deformities. Radiographic imaging revealed marked cervical and thoracic kyphosis, bone erosion and osteoproliferation in the tail and micro-computed tomography (micro-CT) scans identified both bone resorption and pathological bone fusion in the sacroiliac joint and lumbar spine. In contrast, mice injected with PBMC and sera from non-AxPsA controls did not demonstrate significant inflammation or structural alterations. Histological analysis in the spine of mice injected with AxSpA PBMC and sera revealed accumulation of lymphocytes in and around the dorsal root ganglion (DRG) and in the surrounding muscle. Inflammatory cell infiltrates were characterized by proliferating CD3 T and CD8 T cells that expressed both TNF and IL-17. TNF and IL-17 expression were elevated most notably in the DRG.

Conclusion: Injection of PBMC and sera from AxPsA patients recapitulated axial clinical features in hu PsA mice. HuAxPsA mice developed kyphosis in the distal cervical and thoracic spine and structural damage in the lower lumbar and sacroiliac region and tail, including bone loss and new bone formation. Proliferating $CD3^+$ T and $CD8^+$ T cells expressing TNF and IL-17 were noted near the DRG and in surrounding tissues and paravertebral muscles. This model will accelerate investigation of immune mechanisms in AxPsA.

Session Time: 10:00AM–11:30AM

Background/Purpose: The rs6759298 variant near *B3GNT2* is associated with Axial Spondyloarthritis (AS); however, its pathogenic mechanisms remain unknown. In this study, we explored the role of B3GNT2 in glycosylation modifications and their impact on Th17/Treg imbalance, contributing to AS development.

Methods: We conducted SNP genotyping and RNA-seq analysis on blood samples from 39 AS patients. Additionally, we generated *B3gnt2*-deficient mice (*B3gnt2*$^{+/-}$ and *B3gnt2*$^{-/-}$) to investigate the role of B3GNT2 in AS using a proteoglycan-induced arthritis (PGIA) model. The mechanism of B3GNT2 in AS was further explored through flow cytometry, RNA-seq, lectin blotting and mass spectrometry analysis.

Results: The rs6759298 mutant genotype (G/G) significantly downregulated *B3GNT2* expression in AS patients. In the PGIA model, *B3gnt2*-deficient mice exhibited an earlier onset of arthritis, higher arthritis severity scores, and prolonged inflammation. Functionally, we found a disrupted Th17/Treg balance in *B3gnt2*-deficient mice. Lectin blotting analysis revealed a marker reduction in poly-lactosamine expression on T cells from *B3gnt2*-deficient mice. Mass spectrometry identified integrin β3 (ITGB3) as a key glycoprotein differentially modified by B3GNT2. Furthermore, treatment of SKG mice with Cilengitide, an ITGB3 antagonist, effectively delayed disease onset.

Conclusion: This study demonstrates that rs6759298 reduces *B3GNT2* gene expression, thereby altering the glycosylation of ITGB3 and promoting the progression of AS. These findings offer new insights into the immune mechanisms underlying AS.

Multi-Omic Profiling Of CD8+ T Cells In Axial Spondyloarthritis (axSpA) And Reactive Arthritis (ReA) Implicates Common Pathways

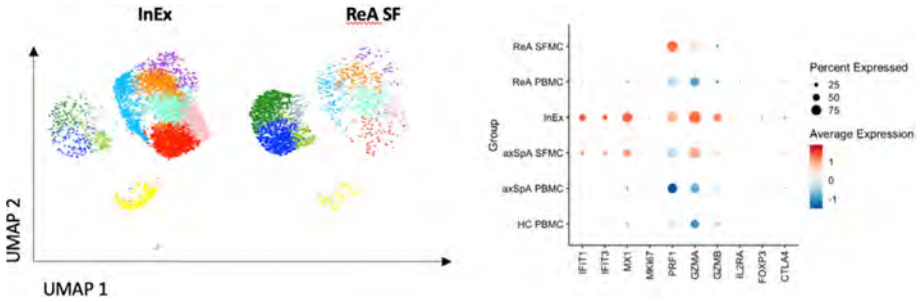
Zoya Qaiyum[1], Michael Tang[2], Shirin Soleimani[3], Addison Pacheco[2], Melissa Lim[4], Fataneh Tavasolian[4], Trevor Pugh[3] and Robert Inman[2], [1]Schroeder Arthritis Institute, University Health Network, Toronto, ON, Canada, [2]University Health Network, Toronto, ON, Canada, [3]Princess Margaret Cancer Centre, University Health Network, Toronto, Canada, [4]University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Basic Science (1752–1757)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

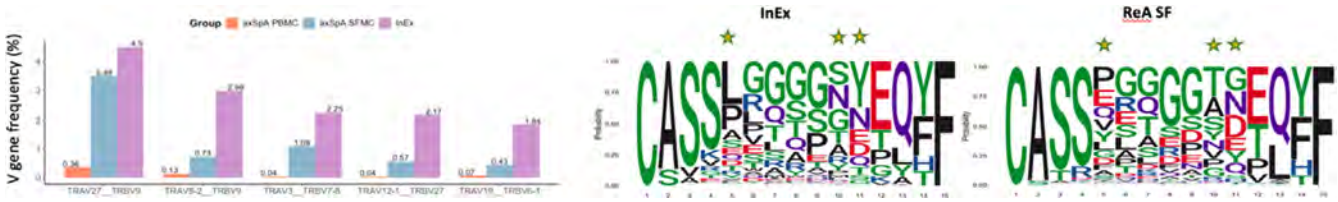
Background/Purpose: The strong clinical and genetic associations between axial spondyloarthritis (axSpA) and inflammatory bowel disease (IBD) underscore the pathogenic role of the gut-joint axis. We previously identified a subpopulation of pathogenic mature CD8+ T cells in the axSpA synovial fluid (SF), expressing CD103+ and CD49a+ integrins (InEx cells). The expression of integrins on InEx cells implicates their role in aberrant migration between the gut-joint axis. Whether InEx cells recognize an arthritogenic peptide remains unclear. We hypothesize that InEx cells may incite and perpetuate chronic inflammation in axSpA. To this end, we characterized their T-cell receptor (TCR) repertoire and gene expression profile.

Methods: Patients fulfilling the ASAS classification for axSpA were recruited (n=4). Active joint effusion from these patients is reflective of active joint inflammation which coincided with high disease activity (BASDAI >4). We isolated peripheral blood mononuclear cells (PBMCs) and synovial fluid mononuclear cells (SFMCs), followed by FACS-sorting of mature CD8+ T cells and InEx cells. Subsequently, single-cell TCR (paired ab chains) and RNA sequencing were performed on these cell types. An HLA-B27+ reactive arthritis (ReA) sample were used as a comparison. These were all compared to HLA-B27+ healthy controls (n=4). Additionally, we used the GLIPH2 computational tool to assess TCR sequence convergence based on shared motifs to infer antigen-specific TCR groups.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Left panel displaying transcriptome profile of InEx vs mature CD8+ ReA SFMCs on UMAP plots. Genetic profile of InEx cells cluster differently to ReA SF. Right panel displaying notable gene expression across all groups, particularly in InEx and ReA SFMC. UMAP = Uniform Manifold Approximation and Projection, SF = synovial fluid, HC = healthy controls.



Left panel displaying the V gene frequency (% total cells in the group) of paired TRAV_TRBV genes expanded in InEx cells vs axSpA PBMC. Right panel displaying the CDR3b sequence logo plots between InEx and ReA SF mature CD8 T cells. Yellow stars highlight the amino acids that differ between the two groups.

Results: 12 distinct clusters of mature CD8+ T cells from all samples were observed, exhibiting gene expression consistent with TRM-like, cytotoxic and interferon-stimulated gene (ISG) potential. axSpA InEx cells showed a preferential expression of clusters associated with ISG expression and proliferation vs ReA mature CD8+ T cells, as judged by high *IFIT1*, *IFIT3*, *MX1*, and *MKI67* transcripts. Increased cytotoxic potential, based on elevated *GZMA* and *GZMB*, with some suppressive capacity, based on elevated *IL2RA*, *FOXP3*, and *CTLA4*, was also observed in axSpA InEx cells. The axSpA InEx TCR repertoire was less diverse, clonally expanded, and demonstrated specific TRBV9_TRAV27, TRBV9_TRAV8-2, and TRBV7-8_TRAV3 gene usage vs mature CD8+ T cells from either axSpA PB or SF. However, axSpA InEx cells demonstrated similarities with ReA mature CD8+ T cells, based on TCR gene usage (TRBV20-1_TRAV1-2, TRBV6-1_TRAV1-2, and TRBV6-2_TRAV1-2) and CDR3b motifs.

Conclusion: These observations suggest that InEx cells may incite inflammation similarly to ReA due to potential recognition of similar peptides, ultimately driving the selection of specific T cell clones. However, InEx cells represent a hybrid tissue resident memory-like population, likely primed by chronic type I interferon exposure. This may underlie the functional capacity of their clonal expansion and their ability to perpetuate inflammation which is distinct from ReA. This has important implications for therapeutic designs attempting to target integrin blockade in axSpA.

Exosomal Cargo and Surface Markers: Informative Signals in Axial Spondyloarthritis

Fataneh Tavasolian[1], star lively[2], chiara Pastrello[3], Melissa Lim[1], Addison Pacheco[4], Zoya Qaiyum[5], Michael Tang[4], Zeynep Baskurt[3], Igor Jurisica[6], Mohit Kapoor[5] and Robert Inman[4], [1]University of Toronto, Toronto, ON, Canada, [2]University Healklth Network, Toronto, [3]University Health Network, Toronto, [4]University Health Network, Toronto, ON, Canada, [5]Schroeder Arthritis Institute, University Health Network, Toronto, ON, Canada, [6]University Health Network, Toronto, Canada

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Basic Science (1752–1757)

Session Type: Abstract Session

Session Time: 10:00AM–11:30AM

Background/Purpose: Exosomes are small extracellular vesicles carrying surface molecules and molecular cargo, including microRNAs (miRNAs), that mediate intercellular communication. Both the exosomal cargo and surface markers are increasingly recognized as key players in immune modulation and potential biomarkers in autoimmune diseases. In ankylosing spondylitis (AS), their role remains underexplored. We conducted an integrated investigation of exosomal surface markers, miRNA profiles, and their functional impact on regulatory T cells (Tregs) and purinergic signaling, aiming to identify new diagnostic and therapeutic avenues.

Methods: Plasma-derived exosomes were isolated from AS patients and healthy controls (HC). Exosomal surface markers were analyzed using flow cytometry, and miRNA sequencing was performed to profile cargo signatures. Functional effects were assessed in CD4+ T cells and Tregs by evaluating FOXP3+IRF4+ and FOXP3+IRF4+CTLA4+ subsets, proliferation assays, and CD39/CD73 enzymatic activity. DNA methylation of FOXP3, IL2R, and IRF4 was analyzed in four groups: HC Tregs, AS Tregs, HC Tregs exposed to AS exosomes, and CD4+CD25– controls. Gene expression profiling in sorted Tregs was used to assess key immune regulatory and apoptotic genes.

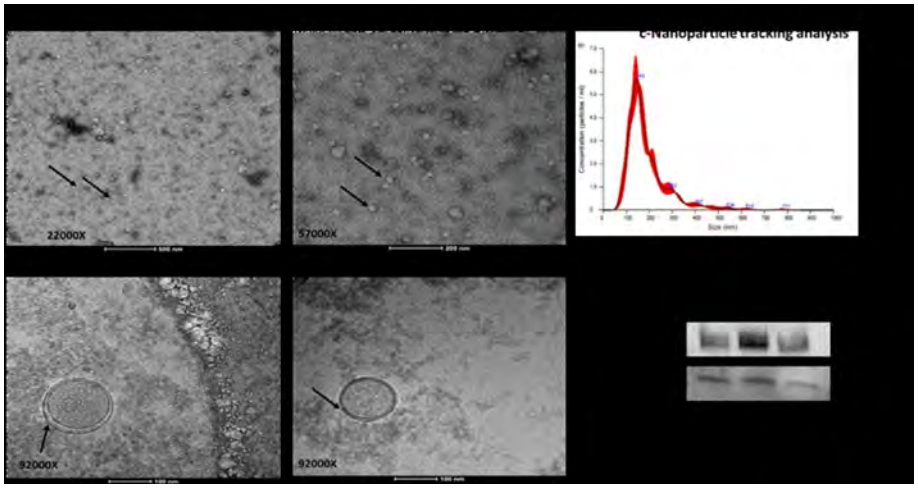

Figure 1- Exosome Isolation and Validation : (a) Exosome characteristics with morphology, size and markers. Exosomes display a round-shaped morphology in negative transmission electron microscopy (TEM). It is at 22 000× magnification, demonstrating the density of isolated exosomes in plasma (b) and are bilayer and spherical by cryo-TEM imaging. (c) Exosome sizes can be determined using nanoparticle tracking. Nanoparticle tracking analysis was used to examine the exosome size and concentration, and the results showed that the exosomes had an average size of 147 nm. (d) Expression of the exosomal markers CD63 and CD9 was confirmed with western blot.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2: Immune Dysregulation and Exosome-Mediated Adenosine Modulation in axial spondyloarthritis (AS) (A) Immune Dysregulation in AS: The enthesitis microenvironment (EME) in AS is characterized by cellular interactions that drive inflammation and pathological bone remodeling. Panel A depicts cellular interactions where IL-23 stimulates Th17 cells to produce IL-17 and TNF-α, recruiting macrophages and neutrophils to the entheses. The cytokine release amplifies inflammation, leading to tissue damage and fibrosis. Panel B illustrates the roles of fibroblasts, macrophages, and T cells in the dysregulated cytokine signaling cascade. IL-17 and TNF-α receptor activation stimulate fibroblasts to release RANKL and MMP, driving osteoclast activity and disrupting bone homeostasis. Concurrently, osteoblast activation leads to pathological bone formation (syndesmophytes), highlighting the imbalance in bone remodeling. Panel C demonstrates genetic dysregulation in AS, with HLA-B27 misfolding inducing ER stress, promoting IL-23 production, and driving Th17-mediated inflammation. Panel D emphasizes cytokine-driven bone remodeling, showing osteoclast-mediated bone resorption and osteoblast-driven syndesmophyte formation under persistent inflammation. (B) Exosome-Mediated Adenosine Modulation of Inflammation and Bone Dynamics in AS: Exosomes released from immune and stromal cells deliver enzymes (CD39/CD73) and miRNAs (e.g., miR-146a, miR-29b) to modulate immune responses and bone remodeling in AS. CD39/CD73-mediated adenosine production suppresses osteoclast activity and enhances osteoblast activity via A2A receptor signaling. While adenosine reduces RANKL and MMP expression in fibroblasts and promotes M2 macrophage polarization, the reduced CD39/CD73 expression observed in AS limits adenosine availability, impairing its anti-inflammatory and bone-regulating effects. The balance between osteoclast-mediated bone erosion and osteoblast-mediated syndesmophyte formation is critical to AS pathology. Arrows indicate cellular interactions and regulatory pathways modulated by adenosine and exosomal components.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Results: Gene expression profiling of sorted Tregs from AS patients revealed downregulation of IKZF2/Helios, TNFα, CD95/FAS, BCLXL, and CD45RO, alongside upregulation of IGF1R, indicating disrupted transcriptional networks important for Treg survival and stability. DNA methylation analysis demonstrated hypermethylation of FOXP3, IL2R, and IRF4 in AS Tregs, with similar patterns observed in HC Tregs exposed to AS exosomes, highlighting the epigenetic reprogramming potential of exosomes. miRNA sequencing of AS plasma-derived exosomes identified upregulation of miR-30c-5p, a regulator targeting IRF4, directly linking exosomal cargo to impaired Treg function. Functionally, AS exosomes carrying miR-30c-5p led to decreased proliferation of CD4+ T cells and a marked reduction in FOXP3+IRF4+ and FOXP3+IRF4+CTLA4+ Treg subsets. In parallel, AS exosomes induced reduced CD39/CD73 surface expression and impaired ATPase activity, indicating defective extracellular adenosine production and weakened immunosuppressive signaling. Collectively, these results demonstrate that AS exosomes orchestrate immune dysregulation through parallel effects on Treg stability and purinergic signaling.

Conclusion: Our integrated study demonstrates that AS plasma-derived exosomes drive immune dysregulation through miRNA-mediated gene regulation, epigenetic remodeling, and impaired purinergic signaling, culminating in Treg instability and loss of immune tolerance. These findings highlight exosomal signatures as promising biomarkers and therapeutic targets to restore immune balance in AS.

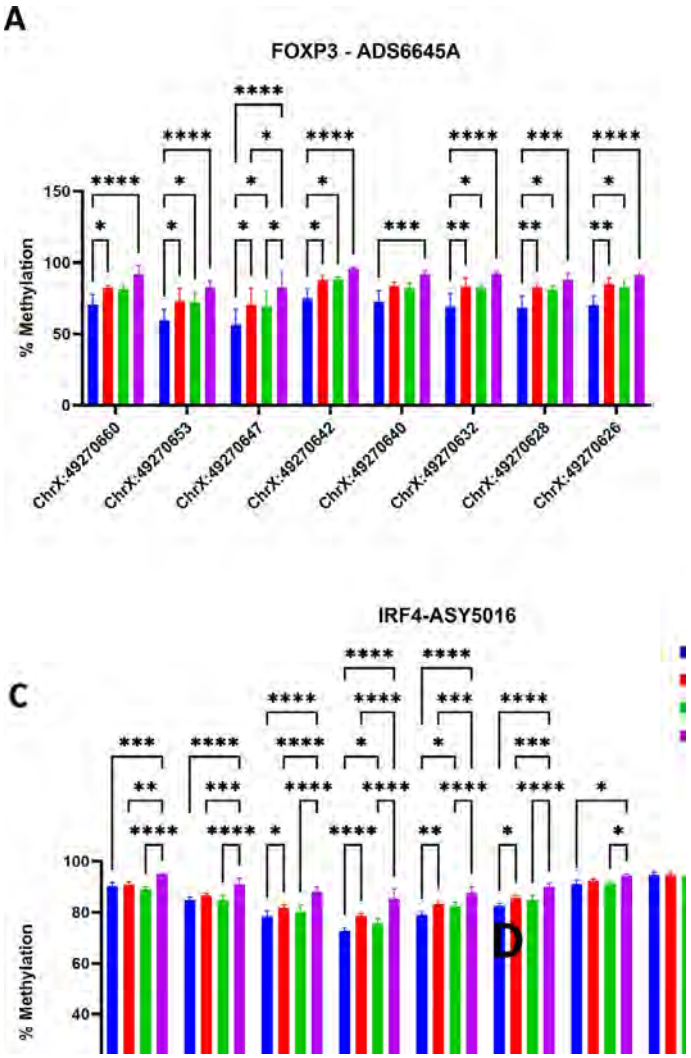

Figure 3. DNA Methylation Analysis. A: Hypermethylation of FOXP3 in AS Treg cells compared to HC. B: Hypermethylation of IL2R in AS Treg cells, contrasting with the typical demethylation observed in Tregs. C & D: Hypermethylation of IRF4 in Treg cells may impair their function in AS. This alteration may impact Treg function. HC Treg cells exposed to AS exosomes exhibited similar methylation patterns to AS Treg cells in all figures, highlighting the role of AS exosomes in Treg dysfunction.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Basic Science (1752–1757)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: Psoriatic arthritis (PsA) develops in about 30% of individuals with psoriasis (PsO), highlighting a critical connection between skin and joint inflammation. However, the mechanisms driving the transition from skin-limited disease to joint involvement remain unclear. This study investigates the skin-joint axis in PsA pathogenesis using a preclinical model, with translational validation in human samples.

Methods: We employed the IL-23 overexpression (IL-23OE) mouse model in KAEDE mice, which facilitate the tracking of skin-derived immune cell migration via photo-conversion. Psoriatic skin lesions were converted to KAEDE-RED through UV irradiation, allowing for detailed analysis using light sheet fluorescence microscopy (LSFM) and flow cytometry. Immune cell populations were characterized through imaging flow cytometry, while single-cell RNA sequencing (scRNA-seq) offered insights into their phenotypic profiles. To corroborate these findings, we analyzed human samples from individuals with established PsO and early PsA, utilizing scRNA-seq and imaging mass cytometry. Cell trafficking in human was further examined by sequencing mitochondrial DNA (mtDNA-seq) from paired skin and synovial tissue samples of early PsA patients to identify shared lineages between skin- and joint-derived myeloid cells.

Results: The IL-23OE model successfully induced psoriatic skin lesions and enabled the migration of immune cells from inflamed skin to the synovial compartments. However, the presence of these skin-derived immune cells did not consistently correlate with the development of arthritis. Notably, although $CD2^{+}MHCII^{+}$ myeloid progenitors trafficked into the synovial membrane, some mice remained resistant to inflammation. Comparative analysis revealed no intrinsic differences in the myeloid progenitors between resistant and susceptible animals; rather, once within the synovium, these cells differentiated

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. into pro-inflammatory macrophages in PsA-susceptible mice, whereas in resistant mice, they adopted an M2-like anti-inflammatory phenotype. $CD200^{+}$ synovial fibroblasts emerged as key modulators of macrophage fate, promoting protective immune responses that mitigated arthritis development. In parallel, human scRNA-seq confirmed the presence of the corresponding myeloid precursors in psoriatic skin and in synovial tissue of both PsO and earla PsA patients, with flow cytometry detecting them in circulation. Imaging mass cytometry localized these precursors within synovial niches, showing an increase of CD200+ fibroblasts in the non-arthritic tissues. Finally, mtDNA sequencing further validated the skin origin of these myeloid precursors within the synovial tissue of early PsA patients.

Conclusion: This study identifies a key role for synovial fibroblasts in shaping macrophage differentiation and joint inflammation outcomes. Crucially, it provides the first direct evidence of a functional skin-joint axis in humans, showing that immune cells originating in the skin can contribute to joint pathology. These insights may inform early PsA diagnosis, risk stratification, and precision therapeutic strategies in PsO patients.

Treg need a MAIT: Investigating the contribution of MAIT cells to impaired UV-induced Treg expansion in lupus photosensitive reactions

Grace Crossland[1], Lindsay Mendyka[1], Vianey Chavez[1], Kaitlyn Dowling[1], Michael Constantinides[2] and Sladjana Skopelja-Gardner[1], [1]Dartmouth College, Lebanon, NH, [2]Scripps, La Jolla

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Systemic Lupus Erythematosus – Animal Models (1758–1763)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: Most systemic lupus erythematosus (SLE) patients experience sensitivity to ultraviolet (UV) light, which can trigger disfiguring skin lesions or systemic flares. In healthy skin, UV light promotes a robust immunosuppressive response, driven in part by the expansion of regulatory T cells (Treg). In contrast, UV light instead elicits an inflammatory response in SLE skin. The cellular mediators that drive Treg response in healthy skin and the mechanisms by which this

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

response fails in SLE remain incompletely understood. Here, we present new findings that implicate mucosal-associated invariant T cells (MAITs) in the (dys)regulation of skin response to UV light in healthy and lupus skin.

Methods: 8-week-old female B6, MAIT-deficient (*Mr1-/-*), and SLE (MRL/lpr or imiquimod, TLR7/8 agonist) mice were exposed to chronic low-dose UVB (50mJ/cm^2 daily, 2 or 6 doses). Skin MAITs were expanded by topical application of MAIT antigen, 5-OP-RU (1mM, every 48hr x 4). Skin inflammatory responses, including MAIT detection by 5-OP-RU-loaded MR1 tetramer, were quantified by scRNAseq and flow cytometry.

Results: In healthy (B6) skin, UV light stimulated ~5-fold expansion of both MAIT cells and Treg. MAITs were required for UV-induced T_{reg} expansion, as no increase in skin Treg proportion or number was seen in MAIT-deficient (*Mr1-/-*) mice following UVB. Moreover, Treg in MAIT-deficient skin did not proliferate (no change in %Ki67+ vs. >10% increase in Ki67+ in B6 skin) and exhibited a fragile phenotype early after UVB (only 2 doses): Neuropilin-1^{low}GITR^{low}ICOS^{low} but PD1^{high}CD69-^{high}. Consistent with a potential tolerogenic role of myeloid cells in the skin, Langerhans cells (LCs), monocyte-derived dendritic cells (moDCs), and type 2 dendritic cells (cDC2s) expanded only in B6 but not *Mr1-/-* skin after two doses of UV light. Like in *Mr1-/-* skin, Treg did not proliferate or expand in response to UV in SLE-prone (MRL/lpr) skin, which is low in MAITs (~2% of TCRb+ T cells vs. ~12% in B6 skin). In the absence of Treg expansion, CD8+ T cells increased ~10-20-fold in MRL/lpr skin, leading to a marked reduction in the Treg:CD8 ratio. The same reduction in the Treg:CD8 ratio following UV was observed in the TLR7/8 model of SLE in *Mr1-/-* but not B6 skin. The CD8s that expanded in SLE-like skin expressed high Ki67, CD69, PD1, and CXCR6. Exposing SLE-like skin to UV after first topically expanding MAITs restored the Treg:CD8 ratio, and the CD8 T cells in MAIT-expanded UV-exposed skin expressed lower levels of Ki67, CD69, PD1, and CXCR6, compared to UV-exposed skin without prior MAIT expansion.

Conclusion: In healthy skin, UV-induced proliferation and immunosuppressive phenotype of Treg are dependent on MAIT cells and may require the contribution of a subset of myeloid cells, such as LCs, moDCs, or cDC2s. SLE-like skin fails to mount the Treg response to UV light, which enables proliferation and activation of CD8 T cells, known contributors to SLE skin pathology. The failure of the UV-induced MAIT-Treg axis in SLE skin can be reversed by topically expanding MAIT cells prior to UV exposure, revealing a novel therapeutic strategy to mitigate photosensitive skin reactions in lupus.

Background/Purpose: SLE is an autoimmune disease that causes progressive multi-organ damage, leading to renal injury, or lupus nephritis (LN), in half of patients. Despite treatment, 20% progress to renal failure within 15 years (1). Recent studies show that about 40% of LN flares are linked to intestinal expansions of the human pathobiont *Ruminococcus gnavus* (RG), which produces an immunogenic pro-inflammatory cell wall lipoglycan (LG) (2). LN patients with gut dysbiosis may represent a distinct endotype, where increased gut permeability and microbial factors contribute to pathogenesis. In murine studies, we have demonstrated gut colonization of mice with human RG strains (3,4). Notably, in Sle1.Sle2.Sle3 B6 congenic lupus-prone mice, colonization with an LG+ strain accelerated disease progression (4). To investigate pathogenic mechanisms, we here used a different lupus-prone murine model to elucidate the pathways connecting RG-driven platelet activation to worsening renal disease progression.

Methods: Using whole-blood transcriptomics, we recently demonstrated that RG intestinal colonization induced platelet and myeloid cell activation (manuscript submitted). Here, lupus-prone FcgRIIb$^{-/-}$ B6 congenic mice were either sham-treated or colonized with RG strains, including isogenic paired strains that differ only in LG production. Colonization was confirmed by fecal qPCR. Splenic megakaryocytes were quantified by CD41+ immunofluorescence. Renal histology was evaluated by H&E.

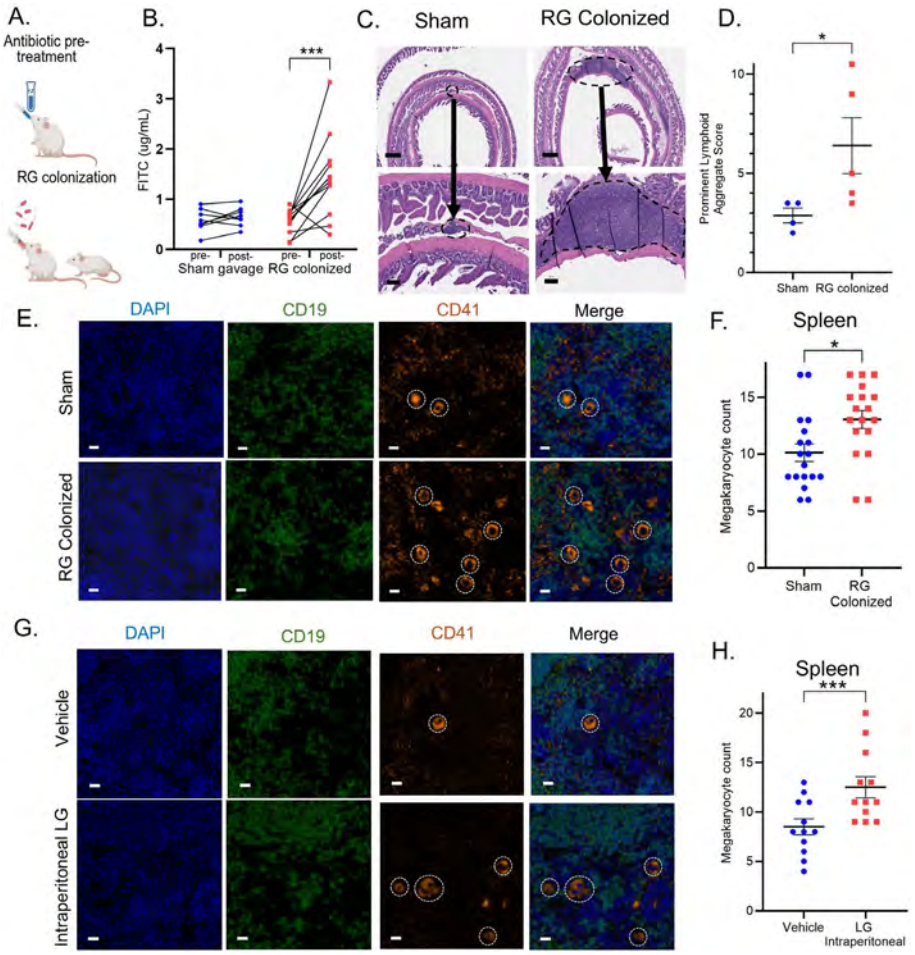

Figure 1. Effect of R. gnavus gavage and RG-immunodominant lipoglycan on the intestine and spleen. (A) Mice were orally treated with antibiotics, then subsequently orally gavaged with RG culture or sham (B). Serum FITC-dextran levels were determined pre- and post-oral gavage of sham vs. RG-treated (RG colonized B6) mice. (C) Lymphoid aggregates were observed in sham (left) vs. RG-colonized (right) B6 mice at the terminal ileum. (D) Quantification of total prominent lymphoid aggregates, which were scored in the equivalent total length of the distal small intestine in Swiss rolls. Scoring was based on the number of lymphoid cells per aggregate; +0.5 represents 25-55 lymphocytes/aggregate, +1: 56-149/ aggregate, +2: 150–299/ aggregate, +3:300+ /aggregate, and +1:GC identified. (E,F) Immunofluorescence of splenic megakaryocyte in B6 mice after RG gavage as identified by CD41+. In 3-4 months old, female. (G,H) IF megakaryocyte quantification in the spleens of 5-8 month old lupus-prone, female FcgRIIb-/- mice at six days after a single LG intraperitoneal injection (2ug/g). (E-H) Cell count per high-powered field, in at least three mice per group. *p<0.05. ***p<0.01.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Pathogenic R. gnavus strains that produce lipoglycan, but not strains without lipoglycan, drive increases in splenic megakaryocytes. (A) Immunofluorescence of splenic megakaryocyte in FCGRIIb-/- mice as defined by CD41+ after RG gavage with lipoglycan-positive strains (nb92, RG2) versus strains without lipoglycan (nb90). 12 months old, female. (B) Cell count per high-powered field, at least three mice per group.**p<0.02, ***p<0.01 (C, D) Platelet activation induced by a single intraperitoneal injection of lipoglycan in FCGRIIb-/- mice was evaluated by flow cytometric monitoring of the percentage of surface P-selectin expressing cells after thrombin stimulation at 8 hours, 2 days (48 hours), and 6 days (144 hours) after administering 1.5 μg/g of lipoglycan. *p<0.05. (C) shows mean with range.

Results: Colonization with LG+ RG resulted in increased intestinal permeability, as quantified by serum detection of orally administered fluorochrome-labeled dextran (FITC-dextran, Fig. 1B). Increased gut leakiness correlated with prominent lymphoid follicles in the small intestine (Fig. 1C,D). RG colonization with LG-producing strains induced persistent platelet activation (Fig 2C), as well as extramedullary expansions of platelet progenitors (megakaryocytes), in the spleen (Fig 1E & 2A). Renal injury was induced as documented by increased tubulointerstitial lymphoid infiltrates (Fig. 3). To assess the direct pathogenic effects of purified LG, mice were given an intraperitoneal LG injection, which also induced persistent splenic megakaryocytosis that was detected after 6 days (Fig. 1G).

Conclusion: To understand how the RG pathobiont induces systemic platelet activation and neutrophil death extracellular trap release (i.e. NETosis) in a subset of active LN patients, we have here elucidated distinct pathogenic pathways of this newly identified endotype of proliferative LN. In murine models, we have documented that RG strains that produce an immunostimulatory lipoglycan cause the expansion of splenic megakaryocytes and renal disease exacerbation.

Session Time: 10:00AM–11:30AM

Background/Purpose: Approximately 90% of patients with systemic lupus erythematosus are women, and skin is one of the most frequently affected organs. We previously found that the transcription coregulator VGLL3 is enriched in the keratinocytes of healthy women, where it promotes expression of inflammatory genes. We subsequently showed that mice with

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. epidermal overexpression of VGLL3 develop cutaneous and systemic lupus-like autoimmune disease. However, the value of VGLL3 as a therapeutic target in lupus remains unknown.

Methods: We have combined mouse modeling and investigations in human skin to explore VGLL3 as a potential therapeutic target in lupus. To gain insight into VGLL3-related disease mechanisms, we developed several novel transgenic mouse models that enable us to reverse epidermal VGLL3 overexpression, test VGLL3 necessity for cofactor binding, and robustly induce VGLL3 in adulthood. Furthermore, we used in vitro IP-mass spectrometry (IP-MS) as well as proximity ligation assay to identify VGLL3 binding partners in human keratinocytes and skin from discoid lupus erythematosus (DLE) patients, respectively.

Results: We determined that normalization of epidermal VGLL3 activity ameliorates skin and select systemic manifestations of VGLL3-induced murine lupus. Through *in vitro* IP-MS, we identified TEAD1 and TEAD3 as major binding partners of VGLL3 in human keratinocytes, while our proximity ligation assay data showed nuclear colocalization of VGLL3 and TEAD transcription factors in the epidermis of healthy human individuals and in patients with DLE, with increased detection in the latter. Exploiting our novel transgenic mouse models, we determined that TEAD binding capacity is required for epidermal VGLL3 to cause murine lupus-like disease. Mutations in the binding site where VGLL3 interacts with TEADs abrogated disease development in mice that overexpress VGLL3 in the epidermis. Furthermore, induction of epidermal VGLL3 overexpression in adulthood resulted in rapid onset of murine lupus that was attenuated by simultaneous epidermal deletion of *Tead1*, resulting in significantly improved survival. Similarly, pharmacologic inhibition of VGLL3-TEAD binding improved survival of mice with epidermal VGLL3 overexpression. Currently, we are testing additional drugs that are predicted to target TEAD interaction with transcription coregulators for therapeutic effect utilizing both our innovative lupus mouse models and human patient skin explants.

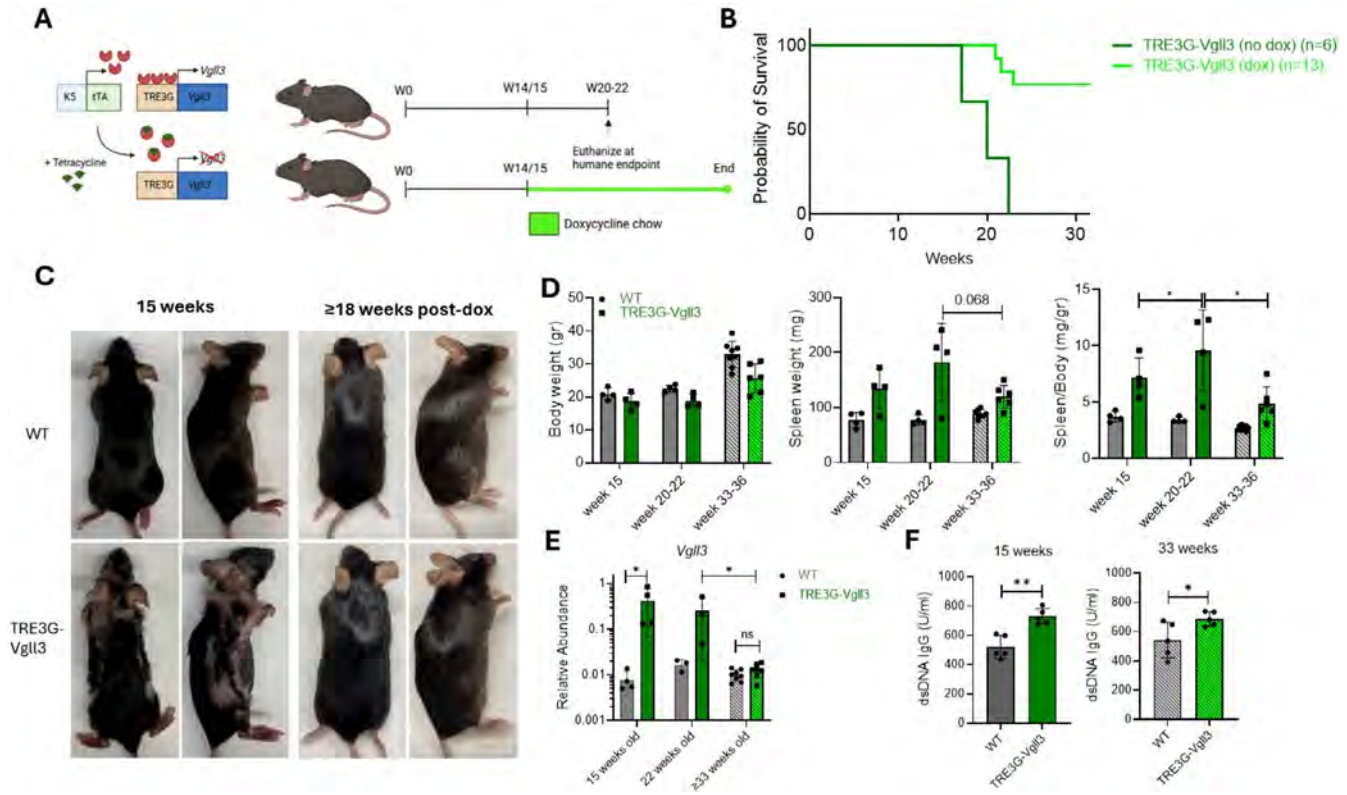

Figure 1: Normalization of epidermal VGLL3 activity ameliorates skin disease and select systemic manifestations. A. Schematic overview of K5-tTAxTRE3G-Vgll3 mouse model and experimental approach. B. Conclusion: The results of this work show the relevance of VGLL3-TEAD interaction in murine lupus-like disease development and are anticipated to provide vital preclinical data supporting the approach of VGLL3-TEAD inhibition in lupus patients with skin involvement.

The Application of SLE Patient-derived PBMC-induced Mouse Model in Preclinical Pharmacological Studies

Juan Liang[1], Yinlian Zhang[2], Feng Li[2], Yingfeng Huang[3], Ruixia Zhang[3] and Ruixue Dai[3], [1]Gempharmatech, Nanjing, Jiangsu, China, [2]GemPharmatech, Nanjing, China (People's Republic), [3]CytoCares, Shanghai, China (People's Republic)

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Systemic Lupus Erythematosus – Animal Models (1758–1763)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a multisystem autoimmune disorder characterized by the production of autoantibodies targeting nuclear antigens, immune complex deposition, and chronic inflammation of organs such as the skin, joints, and kidneys. Despite advancements in diagnosis and therapeutic strategies, SLE continues to impose a significant clinical challenge, underscoring the urgent need for novel therapies. While indispensable for elucidating disease mechanisms and evaluating treatments, conventional animal models are limited by interspecies differences in immune systems that hinder translational relevance. To overcome this, we developed a humanized SLE model by engrafting immunodeficient mice with peripheral blood mononuclear cells (PBMCs) derived from SLE patients. This model successfully mimics key pathological features, including elevated autoantibody levels (e.g., anti-dsDNA) and renal immune complex deposition, making it a valuable platform for evaluating B cell-targeted antibody therapies and cell-based interventions.

Methods: SLE model was generated by intraperitoneal injection of SLE patient-derived PBMC. Three therapeutic evaluation cases were conducted:

Case 1: Three T cell engagers (TCEs) were administered intraperitoneally once weekly for four weeks, starting on day of PBMC engraftment. Peripheral blood was collected on days 7, 14, 21, and 28 days for flow cytometry analysis of hCD20+ B cells. Plasma was analyzed for human anti-dsDNA antibodies and total IgG.

Case 2: T cell engager and Blincyto were administered intravenously 7 days post-PBMC engraftment, twice a week for three consecutive weeks. Peripheral blood was collected 14 and 28 days for flow cytometry analysis of plasma B cells. Plasma was analyzed human anti-dsDNA antibodies and total IgG. Kidneys was collected and freshly embedded for Immunofluorescence staining of human IgG.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Case 3: CAR-T cells were administered intravenously on day 6 post- engraftment. Plasma was collected 3 weeks after PBMC inoculation for ELISA test of human total IgG.

Results: Following PBMC engraftment, SLE-PBMC-NCG humanized mice demonstrated elevated levels of total human IgG and anti-dsDNA antibodies.

Case 1: Treatment with TCEs reduces auto-antibody levels and the number of peripheral hCD20+B cells in SLE PBMC-NCG mice.

Case 2: T cell engager and Blincyto treatment both led to reduction in plasma B cell and anti-dsDNA antibody levels. IgG deposition in the kidneys was also considerably reduced 3 weeks post-treatment.

Case 3: CAR-T treatment led to a decrease in total human IgG levels two weeks post-infusion.

Conclusion: The SLE patient-derived PBMC-NCG model effectively reproduces key pathogenic features of SLE and responds to multiple therapeutic modalities, including TCEs and CAR-T. This model offers a translationally relevant platform for preclinical evaluation of B-cell targeted therapies, supporting biomarker identification, dosing optimization, and acceleration of SLE drug development.

Spatial Organization and Function of Disease-Associated Macrophages in Lupus Nephritis: Insights from Cross-Species Analyses

Paul Hoover[1], Chirag Raparia[2], Rollin Leavitt[3], Nir Hacohen[4], Arnon Arazi[5] and Anne Davidson[2], [1]Brigham and Women's Hospital, Boston, MA, [2]Feinstein Institutes for Medical Research, Manhasset, NY, [3]Broad Institute, Boston, MA, [4]Broad Institute, Cambridge, MA, [5]The Feinstein Institutes for Medical Research, Manhasset

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Systemic Lupus Erythematosus – Animal Models (1758–1763)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: Myeloid cells are linked to kidney injury in lupus nephritis (LN) but lack targeted therapies, underscoring the need to better understand myeloid biology in LN. While LN mouse models provide biological systems to develop new therapies, identifying shared molecular features relevant to human disease is essential to fully optimize the effectiveness of these models. We recently compared kidney myeloid single-cell datasets from four LN mouse strains with different pathogenic backgrounds and 155 patients across various disease stages and histologic subtypes (Fig. 1). This revealed similar intrarenal myeloid subsets, including Disease-Associated Macrophages (D-Macs), which correlated with clinical disease in both species (Fig. 1C, F). In this follow-up study, we examined two aspects of myeloid biology in mouse and human LN: 1) the in situ distribution of D-Macs and myeloid subsets to evaluate whether analogous cells could interact similarly with their tissue microenvironment, and 2) functional characteristics of murine D-Macs relevant to LN pathogenesis.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Fig. 1. Integrated landscape of myeloid cells in kidneys from mice and patients with lupus nephritis. (A) Kidney myeloid cells from 155 LN patients and 30 control biopsies were collected and processed for single-cell RNA seq with the AMP RA/SLE Network. (B) UMAP of human myeloid cells and cluster names. (C) Frequency of D-Mac (vs. all myeloid cells) is associated with activity index. A dot=1 pt. (D) Kidney myeloid cells from 4 lupus mouse strains were processed similarly and integrated with human data set. (E) UMAP of lupus murine myeloid cells and cluster names. (F) Frequency of D-Mac (vs. all myeloid cells) is associated with nephritis in all mouse models. A dot=1 mouse. Results in mice were confirmed by flow cytometry (not shown).

Methods: To map myeloid localization, we used Xenium spatial transcriptomics on FFPE kidney sections from 2 mouse strains and human patients (n=6 LN pts. with proliferative or mixed histologic classes; mean ISN/RPS activity = 13.5; S.D = 5.8) and 2 controls, employing custom probes based on scRNA-seq and the multi-tissue panel. For functional assays, we performed ex vivo phagocytosis and metabolic tests on single-cell suspensions from myeloid cells isolated by flow from dissociated murine kidneys (pre- and post-nephritis), using fluorescent immune complexes (ICs) and ATP substrates to evaluate phagocytic capacity and metabolism—particularly of D-Macs—via flow cytometry.

Results: In situ mapping findings (Fig. 2): (1) In nephritic mice, D-Macs resided within glomeruli and periglomerular infiltrates, with strain-specific differences. In humans, D-Macs were most abundant within nephritic glomeruli. (2) Resident macrophages in both species localized mainly in the tubulointerstitium, with murine RMs forming rings around glomeruli. (3) Non-classical myeloid subsets were primarily restricted to glomeruli, with minimal presence in the interstitium. (4) Murine dendritic cells localized to parenchymal areas and aggregates, while human dendritic cells were mainly in the tubulointerstitium.

Murine D-Mac functions (Fig. 3): Compared to other monocyte subsets enriched in nephritic glomeruli (C1, NC1, NC2), D-Macs showed increased uptake of immune complexes and higher membrane potential and ATP levels, suggesting an alternatively activated state.

Conclusion: Across species, D-Macs, along with classical and non-classical monocytes, were positioned near injured glomeruli—within glomeruli in humans—while resident macrophages and dendritic cells mainly localize to the tubulointerstitium and periglomerular zones. Mouse studies further indicate D-Macs adopt an alternatively activated phenotype, potentially contributing to immune complex uptake that emerges in nephritic glomeruli that may modulate inflammation. These studies advance our understanding of D-Macs in LN and support the use of mouse models to study human-derived hypotheses.

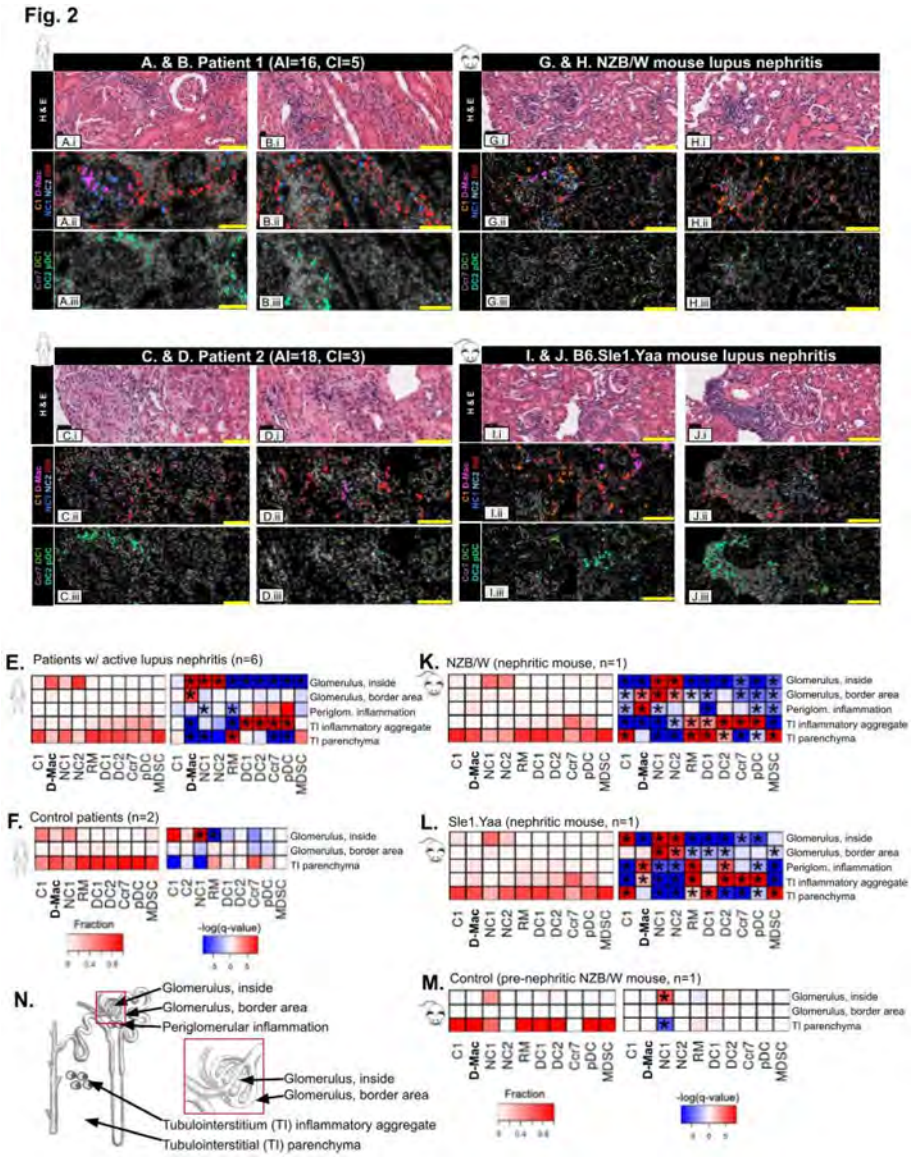

Fig. 2. In situ localization of analogous myeloid states in human and mouse kidney sections. (A-J) This series presents images of kidney sections and myeloid states within renal compartments from patients (A-D) and mice (G-J) with lupus nephritis. All panels are stained with hematoxylin and eosin (H&E), highlighting various subsets of monocytes and macrophages (D-Mac, C1, NC1, NC2, RM) as well as dendritic cells (Ccr7, DC1, DC2, pDC). The Activity Index (AI) and Chronicity Index (CI) are noted. Scale bars indicate measurements of 100 microns. (E-M) These panels quantify myeloid subsets by compartment in humans with lupus nephritis (E) and human control kidneys (F), as well as in lupus nephritis mouse models (K. NZB/W; L. Sle1.Yaa) and pre-nephritic mice (M. NZB/W). The left side of each panel displays the proportion of each indicated cell type within renal compartments across all samples. The right side presents the -log of the q-value, which indicates either depletion (blue) or enrichment (red) of the respective cell type for each renal compartment. Asterisks mark q-value <0.05. (N) Areas of renal compartments that were analyzed in the spatial assessment. Abbreviations: TI = tubulointerstitial; Periglom. = Periglomerular. Definitions: Glomerulus, inside = area within annotated glomerular border. Glomerulus, border = area that includes -/+ 20 microns from annotated border; Periglomerular inflammation = area adjacent to at least 25% of annotated glomerular border containing >50% immune cells. Tubulointerstitial inflammatory aggregate = non-adjacent area outside of glomerular border with >10 contiguous immune cells.

Choi[6], Zachary Wallace[3] and Emily Hyle[2], [1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital, Boston, [3]Massachusetts General Hospital, Newton, MA, [4]University of Pennsylvania, Philadelphia, PA, [5]Massachusetts General Hospital , Harvard Medical School, Concord, MA, [6]MASSACHUSETTS GENERAL HOSPITAL, Lexington, MA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Vasculitis – ANCA-Associated (1764–1769)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: Evaluating the effectiveness and safety profile of treatment strategies for the induction of remission of individuals with newly diagnosed AAV is important for guiding care. We expanded AAV-Sim, a previously developed and validated microsimulation model of ANCA-Associated Vasculitis (AAV). Thus far, the model has simulated strategies to maintain remission in AAV. We expanded the model to project clinical outcomes in the setting of induction of remission in individuals with newly-diagnosed AAV receiving rituximab along with a reduced-dose glucocorticoid (GC) taper.

Methods: We expanded AAV-Sim, a C++-based microsimulation model with a monthly timestep that simulates clinical events among individuals with AAV undergoing treatment, to incorporate outcomes during induction of remission among those with newly-diagnosed disease (**Figure**). At model start, all simulated individuals are newly-diagnosed with active disease and are at risk of severe infection, end-stage renal disease (ESRD), diabetes mellitus, and death. The model assumes all individuals receive rituximab as remission induction therapy. Remission within 6 months is based on a probability of entering remission during each month. Once an individual enters remission, there is a monthly probability of minor or major relapse. Inputs were derived from outcomes observed in clinical trials (RAVE or LoVAS, depending on outcome of interest) (**Table 1**) or from an observational cohort of individuals with AAV seen in a large academic center. We also included

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

multipliers for certain parameters (e.g., risk of ESRD among those with vs. without baseline renal involvement from AAV) from observational data. We performed validation by using the mean average percent error (MAPE), a measure of the accuracy of predictions in forecasting methods, to compare the predicted outcomes in AAV-Sim with observed outcomes. MAPE results less than 10% are considered to be highly accurate and 11-20% are considered very good. We projected model outcomes over 6 months for: time to remission, minor and major relapse, severe infection, incident diabetes mellitus, ESRD, and death.

Results: Using the expanded AAV-Sim model, we projected outcomes similar to observed outcomes in clinical trials and observational data, including: *time to remission* (2.44 months in AAV-Sim vs. mean of 2.37 months in RAVE, MAPE 3.0%), *minor relapse* (2.39% in AAV-Sim vs. 2.90% in LoVAS, MAPE 17.6%), *major relapse* (1.32% in AAV-Sim vs. 1.45% in LoVAS, MAPE 9.0%), *≥1 severe infection* (6.66% in AAV-Sim vs. 7.24% in LoVAS, MAPE 8.0%), *incident diabetes* (11.54% in AAV-Sim vs. 13.04% in LoVAS, MAPE 11.5%), *incident ESRD* (0.40% in AAV-Sim vs. 0.51% in MGB AAV cohort, MAPE 21.6%), and *death* (2.71% in AAV-Sim vs. 2.90% in LoVAS, MAPE 6.6%) (**Table 2**).

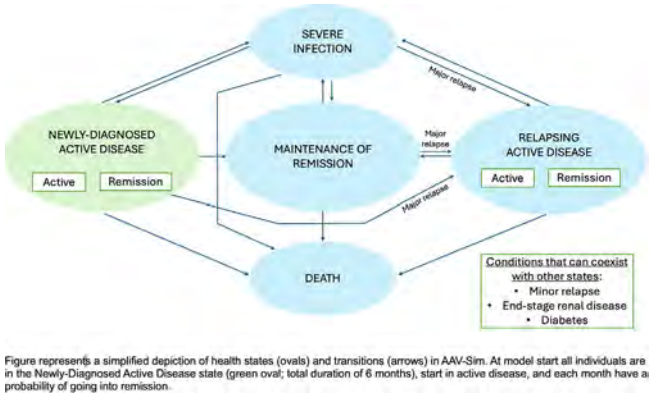

Figure represents a simplified depiction of health states (ovals) and transitions (arrows) in AAV-Sim. At model start all individuals are in the Newly-Diagnosed Active Disease state (green oval; total duration of 6 months), start in active disease, and each month have a probability of going into remission.

Figure. Schematic of Health States and Transitions in the Expanded AAV-Sim Model that Incorporates Induction of Remission in People with Newly-Diagnosed Active ANCA-Associated Vasculitis

Table 1. Selected Input Parameters for the Expanded AAV-Sim Model that Includes Induction of Remission in People with Newly-Diagnosed ANCA-Associated Vasculitis

Input Parameter	Base Case Value		Source
Demographics			
Age, years, mean (SD)	73.0 (9.1)		LoVAS
Male, %	42		LoVAS
MPO-ANCA(+), %	87		LoVAS
Renal involvement, %	69		LoVAS
Time from newly-diagnosed active disease to remission, months, mean (SD)	2.4 (1.7)		RAVE
	Base Case Monthly Transition Probability		
Remission to minor relapse	PR3(+)/MPO(+)	0.01476/0.00741	LoVAS
Remission to major relapse	PR3(+)/MPO(+)	0.00735/0.00368	LoVAS
Severe infection among people with:			
No diabetes or ESRD	0.01493		LoVAS
Diabetes	0.02964		LoVAS and observational data*
ESRD	0.02217		LoVAS and observational data*
Incident diabetes	0.02301		LoVAS
Incident ESRD[#]	0.00085		Real-world AAV cohort and observational data*
Death[§]	0.00243		LoVAS

ANCA, anti-neutrophil cytoplasmic antibody; AAV, ANCA-associated vasculitis; PR3, proteinase 3; MPO, myeloperoxidase; ESRD, end-stage renal disease; LoVAS, reduced-dose vs. high-dose glucocorticoids in AAV trial (*JAMA* 2021;325(21):2178); RAVE, rituximab in AAV trial (*NEJM* 2010;363:221)

*Data for multiplier for severe infection with diabetes from *Clin Infect Dis* 2016;63(4):501: data for multiplier for severe infection with ESRD from 2021 USRDS Annual Data Report, National Institutes of Health. Data for multiplier for ESRD risk with active renal disease from *Rheumatol* 2019;58(1):103

[#]Based on a 73-year-old with renal involvement from AAV at baseline

[§]Based on a 73-year-old male with active disease and no end-stage renal disease

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 2. Model-Projected Outcomes versus Observed Outcomes over 6 months during Induction of Remission in Newly Diagnosed Disease Using the Expanded AAV-Sim Model

Outcome	AAV-Sim Projections	Observed Data Estimates	MAPE, %
Time to remission, months, mean	2.44	2.37	3.0
Minor relapse, %	2.39	2.90	17.6
Major relapse, %	1.32	1.45	9.0
1 or more severe infection, %	6.66	7.24	8.0
Incident diabetes, %	11.54	13.04	11.5
Incident ESRD, %	0.40	0.51	21.6
Death, %	2.71	2.90	6.6

ESRD, end-stage renal disease; MAPE, mean average percent error

Conclusion: We expanded and validated a model to simulate induction of remission in AAV. The expanded AAV-Sim model can be used to project clinical outcomes after induction of remission. These results can be used and further expanded upon to address important clinical questions in AAV in research studies and in clinical trial design. Further expansion of the model will evaluate outcomes between those receiving different GC regimens.

Background/Purpose: The eosinophilic granulomatosis with polyangiitis (EGPA) guidelines recommend considering maintenance therapy after remission to reduce the risk of relapse and toxicity, but data on maintenance therapy is limited. The primary objective of this randomized, double-blind trial was to compare rituximab (RTX) and azathioprine (AZA) maintenance therapy on the duration of remission in EPGA patients who had recently achieved vasculitis remission after standard therapy, including tapering/withdrawal of glucocorticoids (GCs).

Methods: Patients with newly diagnosed or relapsing EGPA within 30-360 days of achieving vasculitis remission were randomized to receive maintenance AZA (2 mg/kg/d, 24 months) plus placebo RTX infusions or 500 mg RTX every 6 months for 18 months (4 infusions) plus placebo AZA for 24 months. The primary endpoint was total remission duration over the 28-month study period, defined as the accrued number of weeks a patient remained in remission (BVAS=0) and prednisone ≤7.5 mg/d. Secondary endpoints included the proportion of participants who remained in remission (i) with prednisone ≤7.5 mg/d during the 28-month study period; (ii) regardless of GC dose; (iii) with prednisone ≤4 mg/d at month 18 and month 28; percentage of patients with ≥1 vasculitis flare; of those with ≥1 clinically significant asthma/rhinosinusitis exacerbations; cumulative GC dose; adverse events; damage, disability and quality of life.

Results: 98 patients were enrolled from 36 centers between March 2018 and June 2022, 49 per arm: newly diagnosed (75%), MPO-ANCA+ (49%), five-factor score (FFS) ≥1 (46%), remission achieved with GCs only (29%). The mean number of weeks in remission with prednisone ≤7.5 mg/d was 96.0 vs 91.1 in the AZA and RTX arms, respectively (mean difference 5.0; 95% CI [-6.2 to 16.1]). The percentage of patients who remained in remission during the 28-month study period (i) with prednisone ≤7.5 mg/d was 11/49 (22.5%) vs 17/49 (34.7%) (RR 0.66 [0.37 to 1.20]) and (ii) regardless of GC dose was 31/49 (63.3%) vs 41/49 (83.7%) (RR 0.76 [0.60 to 0.94]) in the AZA and RTX arms, respectively. The percentage of patients in remission with prednisone ≤4 mg/d was (i) 25/49 (51.0%) vs 34/49 (69.4%) at month 18 (RR 0.79 [0.60 to 1.02]) and (ii) 23/49 (46.9%) vs 37/49 (75.5%) at month 28 (RR 0.62 [0.48 to 0.80]) in the AZA and RTX arms, respectively. The relapse rate for vasculitis was 22.2% vs 14.4%, and the rate of clinically significant exacerbations of asthma and/or rhinosinusitis was 40.5% vs 32.7% in the AZA vs RTX arms, respectively. No differences were found in the cumulative GC, damage, disability, or quality of life. One patient in the AZA group died of SARS-CoV2 infection before the vaccine was developed. No difference in serious adverse events was observed.

Conclusion: Following remission within the previous year after a new EGPA diagnosis or vasculitis relapse, RTX did not show overall superiority to AZA in maintaining vasculitis remission, reducing asthma/rhinosinusitis exacerbations or sparing GC. However, RTX was superior to AZA in maintaining remission with prednisone ≤4 mg/d at month 28. It remains to be determined whether RTX can reduce vasculitis relapse rates in ANCA-positive patients, who are at a higher risk of relapse.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Vasculitis – ANCA-Associated (1764–1769)

Session Type: Abstract Session

Session Time: 10:00AM–11:30AM

Background/Purpose: Rituximab (RTX) is the standard of care for both induction and maintenance in ANCA-associated vasculitides (AAVs). While CD19 B-cell monitoring is used to evaluate the duration and magnitude of the biological effect of RTX, its prognostic value in predicting relapse remains controversial. We aimed to determine the significance of incomplete B-cell depletion during maintenance therapy in AAV patients and its subsequent risk of relapse.

Methods: This is a retrospective, single-center cohort study on AAV patients including patients with the following inclusion criteria: i) newly diagnosed or relapsing granulomatosis with polyangiitis or microscopic polyangiitis, ii) induction therapy with either cyclophosphamide (CYC) or RTX, iii) standard maintenance therapy with RTX 500 mg fixed dose every 6 months. Follow-up started from the first maintenance treatment (month 0) until the earliest occurrence of flare, last follow-up, or death. CD19 levels were measured at each RTX infusion and analyzed as a time-dependent variable. We analyzed the risk of relapse separately in 2 phases: during RTX maintenance treatment (from the first RTX infusion until 6 months after the last infusion), and after RTX discontinuation (from 6 months after the last RTX infusion until last follow-up).

Results: 199 patients were included. The median duration of RTX maintenance was 19 (IQR 18-40) months. A total of 21 relapses were observed during maintenance, and 30 after discontinuation of RTX. At month 0, incomplete B-cell depletion, either defined for CD19 >1/mm3 or >5/mm3 were observed in 29% and 18.1% of patients, respectively, and remained stable during maintenance treatment.

Variables that were associated with the magnitude of B-cell depletion during RTX maintenance therapy, evaluated by the area under the curve (AUC) of CD19+ B cells, were the age at diagnosis (β = -0.05; 95% CI: -0.11 to 0.00) and serum creatinine level (β = 0.01; 95% CI: 0.00 to 0.02).

During maintenance therapy, age was the only variable associated with the risk of relapse (OR 0.97, 95%CI 0.94-1.00, p=0.019), while B cell count, whatever the definition used, was not associated with relapse during maintenance. In multivariate analysis, age remained associated with the risk of relapse (HR 0.97, 95%CI 0.94-1.00, p=0.019).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

After RTX discontinuation, variables that was associated with the risk of relapse were absolute CD19+ B cell count (HR 1.01, 95%CI 1.00-1.01, p=0.024), CD19+ B cell ≤5/mm3 (HR 0.44, 95%CI 0.21-0.95, p=0.036) at last RTX infusion, and the AUC of CD19+ B cells during maintenance (HR 1.01, 95%CI 1.00-1.03, p=0.040). In multivariate analysis, all these variables related to B-cell depletion remained associated with the subsequent risk of relapse.

Conclusion: Incomplete B-cell depletion during RTX maintenance, which occurs in one third of patients, is not associated with an increased risk of relapse while RTX is continued. In contrast, after discontinuation of RTX, the B-cell count at the last RTX infusion or the AUC of CD19+ B cells during maintenance were associated with subsequent relapse risk, suggesting that achieving complete B-cell depletion may be a goal to reduce the risk of subsequent relapse.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Vasculitis – ANCA-Associated (1764–1769)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: One proposed mechanism of tissue damage in ANCA-associated vasculitis (AAV) is the formation of neutrophil extracellular traps (NETs) during extravasation of neutrophils into and through blood vessel walls. NETs carry antimicrobial peptides, myeloperoxidase, proteinase 3, and alternative pathway (AP) complement protein split products. AAV is typically described as pauci-immune, with renal and other tissues often reported as C3 negative.

This study aimed to characterize complement activation in affected tissue in AAV using novel techniques to identify active complement as compared to C3d deposition. C3d is a covalently membrane-bound biomarker generated by C3 cleavage that demonstrates extended tissue half-life.

Methods: Immunofluorescence (IF) staining was performed using an anti-C3c polyclonal antibody (Dako) and a novel anti-C3d monoclonal antibody (mAb, 3d8b mouse IgG1). IF was conducted on renal biopsy samples from patients with AAV (n=32), IgA nephropathy (IgAN, n=29), C3 glomerulonephritis (C3G, n=9), and class III lupus nephritis (LN, n=30), and skin biopsy samples from patients with leukocytoclastic vasculitis (LCV, n=37), and skin lesions in AAV (n=4). Immunohistochemistry (IHC) staining of C3d was performed on biopsy samples of kidney (n=8), skin (n=3), lung (n=5), and sinus (n=2) from patients with AAV. Immunostainings (IF and IHC) were semi-quantitatively scored. Renal biopsy IF intensity was further evaluated for digital quantification using image analysis software.

Results: IF staining detected active complement (anti-C3c) and C3d deposition (anti-C3d) in the glomeruli of AAV, IgAN, C3G, and LN) (Figure 1). Both semi-quantitative scoring and digital quantification revealed a moderate glomerular IF intensity in AAV and IgAN, and a higher intensity in C3G and LN. A distinct glomerular staining pattern with C3c/C3d was seen in AAV and IgAN with deposition more in mesangium than capillaries, as compared to C3G and LN in which C3c/C3d deposited equally in mesangium and capillaries. IHC staining of AAV renal tissue confirmed C3d deposition in glomeruli and revealed extra-glomerular small vessels (Figure 2); 3/6 of these same biopsies tested negative for C3 by routine diagnostic immunostaining.

IF staining detected active complement and C3d deposition on superficial dermal vasculature in LCV. Semi-quantitative scoring demonstrated higher anti-C3c staining than anti-C3d IF intensity in four AAV-LCV samples, as compared to non AAV-LCV samples (Figure 3). IHC staining of FFPE tissue also detected C3d deposition in skin, lung, and sinus biopsies from AAV patients.

Conclusion: Immunostaining for complement AP fragments, particularly C3d, reveals evidence of complement activation in AAV in kidney, skin, lung, and sinus, including biopsies deemed negative by routine C3 staining. These data demonstrate that glomerulonephritis in AAV is less "pauci-immune" than previously considered. These findings also suggest that the complement AP contributes to the pathogenesis of AAV and that treatment using an anti-C3d tissue targeted AP inhibitor approach could mitigate inflammation-related damage in AAV.

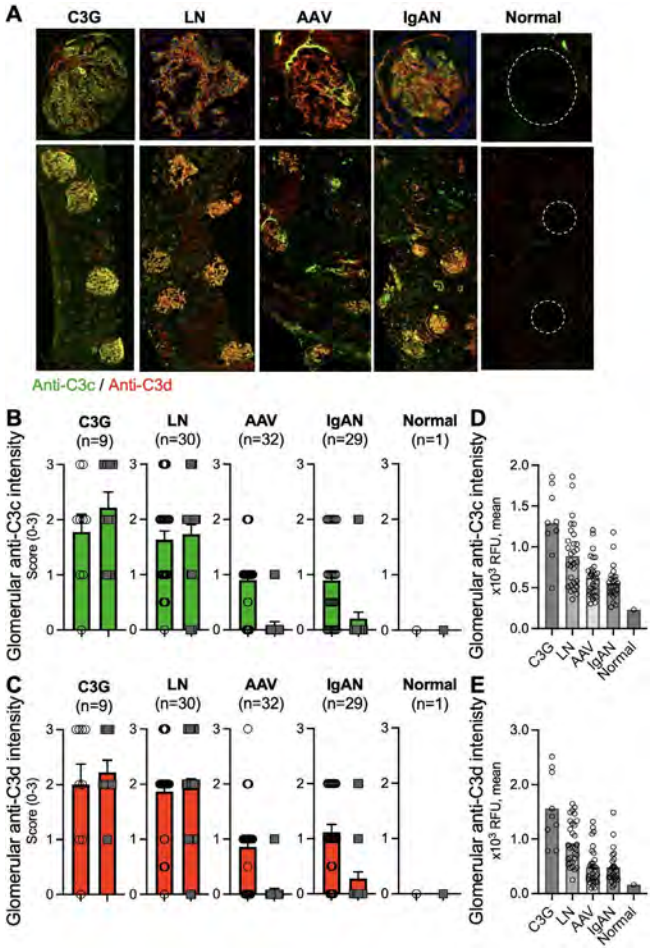

Figure 1. Immunofluorescent staining developed to capture complement fragments demonstrates glomerular complement activation in frozen kidney biopsies from patients with ANCA-associated vasculitis, in comparison to other glomerulonephritides and normal tissue. Anti-C3c and anti-C3d stainings (A, representative images) were semi-quantitatively scored (B-C) and evaluated for digital quantification (D-E).

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Vasculitis – ANCA-Associated (1764–1769)

Session Type: Abstract Session

Session Time: 10:00AM–11:30AM

Background/Purpose: ANCA-associated vasculitis (AAV) is a small-vessel vasculitis that can lead to life-threatening renal injury. Neutrophils, monocytes and macrophages play a pivotal role not only in sustaining inflammation and promoting fibrosis, but also in mediating tissue repair. In this study, we investigated the role of TREM-1 and TREM-2, two key receptors expressed on myeloid cells, in regulating myeloid cells activation and their contribution to AAV-induced kidney injury.

Methods: We analyzed blood and renal biopsy samples from patients with AAV and controls, as well as publicly available transcriptomic datasets. Surface expression of TREM-1 and TREM-2 on circulating leukocytes was assessed by flow cytometry, while serum concentrations of soluble TREM-1 (sTREM-1) and sTREM-2 were measured by ELISA. To investigate the role of TREM-1 and TREM-2 *in vivo*, we used a murine model of MPO-ANCA-induced glomerulonephritis. Disease was induced in wild-type, *Trem1-/-* or *Trem2-/-* mice, *via* passive transfer of anti-MPO antibodies. Renal inflammation and tissue injury were assessed by histological scoring.

Results: Publicly available transcriptomic datasets from microdissected renal biopsies of AAV patients revealed significant upregulation of *TREM1* and *TREM2* in glomerular compartments, whereas only *TREM2* was upregulated in the tubulointerstitial region. Single-cell RNA sequencing of renal $CD45^+$ immune cells showed a strong enrichment of $TREM1^+$ neutrophils in AAV samples, while *TREM2* was restricted to two macrophage subsets distinguished by *FOLR2* expression.

In peripheral blood, surface expression of TREM-1 and TREM-2 on circulating neutrophils and monocytes was similar between AAV patients and controls, except for higher mean TREM-1 fluorescence intensity on neutrophils in AAV. Serum levels of sTREM-1 and sTREM-2 were significantly elevated in AAV patients (both GPA and MPA) compared to controls (sTREM-1: 608.9 ± 386.2 vs. 209.2 ± 87.2 pg/mL, $p< 0.0001$; sTREM-2: 996.7 ± 788.7 vs. 253.8 ± 105.0 pg/mL, $p< 0.0001$), and both were significantly higher in AAV patients with renal involvement compared to those without. Furthermore, sTREM-1 positively correlated with CRP ($r=0.30$, $p=0.045$), serum creatinine ($r=0.61$, $p< 0.0001$) and BVAS ($r=0.48$, $p< 0.001$), and sTREM-2 correlated with serum creatinine ($r=0.61$, $p=0.009$) and BVAS ($r=0.39$, $p=0.01$).

To investigate the role of TREM-1 and TREM-2 *in vivo*, we induced MPO-ANCA glomerulonephritis in wild-type, *Trem1-/-*, and *Trem2-/-* mice. *Trem1-/-* mice showed milder kidney injury, with fewer crescentic and necrotic glomeruli and increased normal glomeruli. Neutrophil infiltration was significantly reduced in the kidneys of *Trem1-/-* mice. In contrast, *Trem2-/-* mice developed more severe disease and showed reduced survival compared to wild-type mice.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: TREM-1 and TREM-2 are differentially involved in AAV-associated glomerulonephritis. Their circulating levels correlate with disease activity, and mouse models show opposing roles in renal injury: TREM-1 promotes inflammation, whereas TREM-2 is protective. These findings identify TREM pathways as promising therapeutic targets in AAV.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Vasculitis – ANCA-Associated (1764–1769)

Session Type: Abstract Session

Session Time: 10:00AM–11:30AM

Background/Purpose: Results from the ongoing open-label extension (OLE) of the MANDARA trial (NCT04157348) have demonstrated the efficacy of two years of anti-interleukin-5/receptor (anti-IL-5/R) therapies in inducing and maintaining remission in more than half of patients with eosinophilic granulomatosis with polyangiitis (EGPA). This analysis describes the types of relapses occurring in patients during the combined double-blind (DB) period and first year of the OLE.

Methods: 140 patients were randomized to receive either benralizumab (n=70) or mepolizumab (n=70) in the DB period of the MANDARA trial. After completing the 52-week DB period, 128 patients entered an OLE where they continued benralizumab (benra/benra; n=66) or switched from mepolizumab to benralizumab (mepo/benra; n=62) along with oral glucocorticoid (OGC) therapy, which could be tapered based on disease status. Relapse was defined as the presence of 1) active vasculitis (Birmingham Vasculitis Activity Score [BVAS] >0); OR asthma; OR sinonasal disease, leading to 2) an increase in OGC dose to >4 mg/day; OR initiation or increase in other immunosuppressive therapy; OR hospitalization for worsening EGPA. In this analysis, relapses were classified as asthma-related, sinonasal-related, 'other' (i.e., not asthma or sinonasal-related), or a combination of these three types for a total of seven types of relapses.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: During the DB period, 21 (30%) in each treatment group experienced a relapse. Among the 128 patients who entered the OLE, 15 (22.7%) patients in the benra/benra group and 20 (32.3%) patients in the mepo/benra group experienced a relapse. During the study, there were 127 relapse events reported during the DB (n=64) and first year of the OLE (n=63). Of these, 60 relapses occurred in the benralizumab (during the DB) or benra/benra group, and 67 in the mepolizumab (during the DB) or mepo/benra group (**Figure 1**). Over the two-year period, 103 (81.1%) of relapses involved asthma and/or sinonasal disease: 40 (31.5%) asthma, 27 (21.3%) sinonasal, 16 (12.6%) asthma-sinonasal, and 8 (6.3%) asthma-sinonasal-other. There were 24 (18.9%) exclusively 'other' types of relapses. The most common disease manifestations associated with the 'other' category of relapse were arthralgia/arthritis, myalgia, and sensory peripheral neuropathy (**Figure 2**).

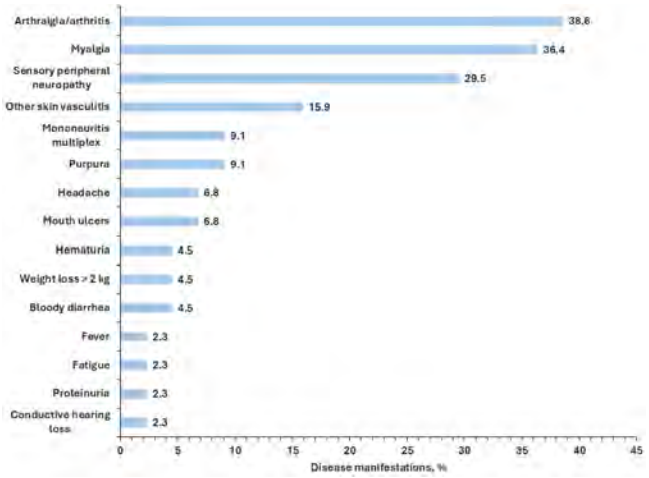

Figure 1. Subtypes of relapses in patients with eosinophilic granulomatosis with polyangiitis treated with anti-IL-5/R therapies

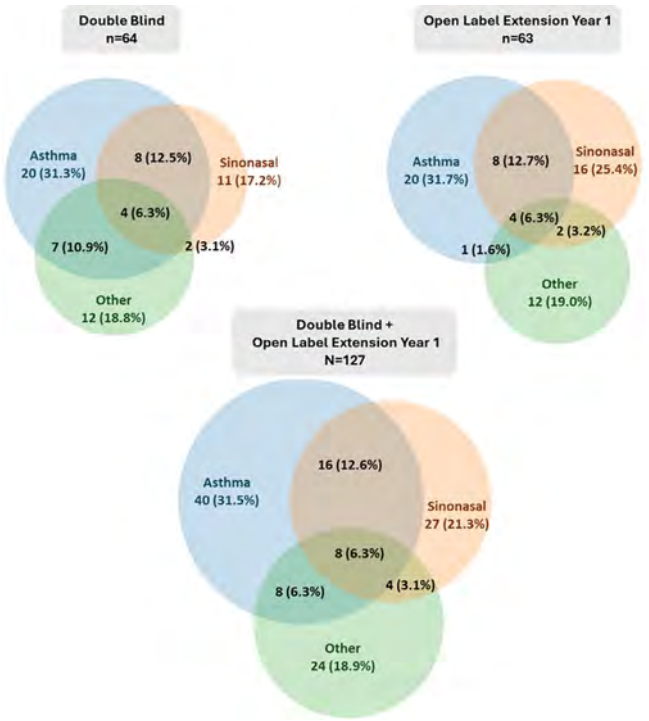

Figure 2. Disease manifestations of relapses of eosinophilic granulomatosis with polyangiitis involving non-airway manifestations among patients treated with anti-IL-5/R therapies during the one-year double-blind period and the first year of the open-label extension periods in MANDARA. Relapses may be associated with more than one disease manifestation.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Among patients with EGPA treated with anti-IL-5/R therapies, the majority of relapses are airway-related, including asthma and/or sinonasal relapses. Arthralgia/arthritis, myalgia, and sensory peripheral neuropathy are the most common manifestations of non-airway relapses.

Background/Purpose: Dermatomyositis (DM) is a rare autoimmune disease of the skin and muscles with significant unmet need and limited treatment options. Brepocitinib is an oral, selective inhibitor of TYK2/JAK1 that suppresses signaling of multiple pathogenic cytokines that have been implicated in the pathogenesis of DM disease activity including Type I and II interferons (IFN) and IL-6. Previous data has suggested that brepocitinib 30 mg may demonstrate superior inhibition of DM-relevant cytokine signaling *in vitro* compared to tofacitinib, a JAK1/JAK3 inhibitor.[1] The purpose of this study was to evaluate the ability of brepocitinib to inhibit pathogenic cytokine signaling *ex vivo* in peripheral blood mononuclear cells (PBMCs) from patients with DM and healthy donors.

Methods: PBMCs were isolated from whole blood from six participants with a diagnosis of DM according to the 2017 EULAR/ACR Classification Criteria for Idiopathic Inflammatory Myopathies and screened for baseline responsiveness to cytokine stimulation. PBMCs from responsive DM patients (n=5) and healthy donors (n=3) were separately pooled, pretreated with brepocitinib [0.0192 to 1500 nM] for 2 hours, and then stimulated with IFNα, IFNβ, or IL-6. IC_{50} curves for both groups were generated for inhibition of downstream STAT1 and STAT3 phosphorylation from each cytokine using flow cytometry.

Results: Brepocitinib potently inhibited STAT1 and STAT3 phosphorylation following IFNα, IFNβ, or IL-6 stimulation. All IC_{50}s were ≤ 30 nM in pooled PBMCs from 5 DM patients, with IC_{50} values of 4 nM and 2 nM for IFNα- and IFNβ-induced STAT1 and STAT3 phosphorylation, respectively. Brepocitinib demonstrated greater potency in inhibiting signaling in

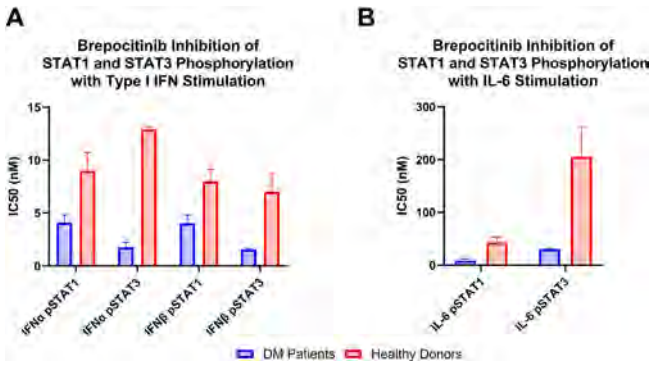

Figure 1: IC50 Values for Brepocitinib Inhibition of (A) Type I IFN Signaling and (B) IL-6 Signaling. N = 5 donors, 2 replicates for DM patients. N = 3 donors, 3 replicates for healthy donors. Error bars represent SEM

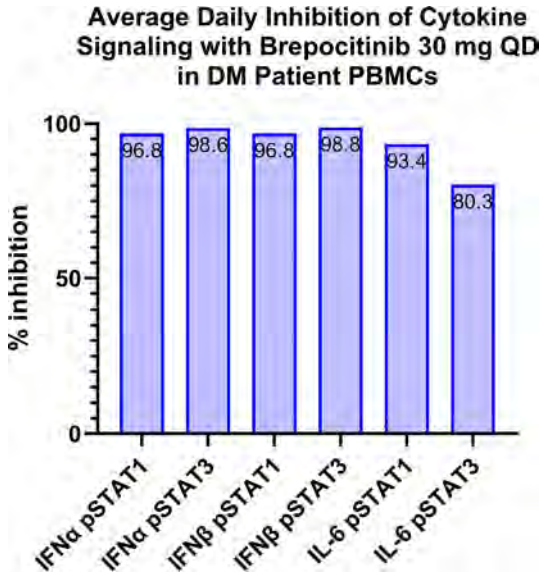

Figure 2: Percent Inhibition of Cytokine Signaling in DM Patient PBMCs. The average daily percent inhibition was calculated using: (free Cavg × 100) / (free Cavg + IC50).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

PBMCs from DM patients compared to healthy donors (Figure 1). Daily average unbound plasma concentrations (free C_{avg}, 123 nM) after administration of 30 mg once daily exceed these IC_{50}s by ≥ 4-fold, resulting in > 96% inhibition of IFNα and IFNβ signaling and > 80% inhibition of IL-6 signaling over a 24-hour dosing interval in the pooled DM patient PBMCs (Figure 2).

Conclusion: Brepocitinib demonstrated potent inhibition of proinflammatory cytokine signaling in PBMCs at exposures achieved with brepocitinib 30 mg QD. This inhibition was more potent in samples from patients with DM than healthy donors, which may reflect pathologic overactivation of JAK-STAT signaling in DM. These results confirm findings from previous work and strongly support the therapeutic rationale for TYK2/JAK1 inhibition with brepocitinib in DM. Results of a global, Phase 3, randomized, placebo-controlled trial are expected in late 2025 (VALOR; NCT05437263).

Interferon- α, Anti-Interferon-Alpha Antibodies and Disease Activity in Systemic Lupus Erythematosus

Gollakota Nandita[1], Kambhampati Sreelekha[2], Kaushik Puranam[3], Phani Kumar D[4], Meghna Gavali[5] and Liza rajasekhar[6], [1]NIMS, Hyderabad, Hyderabad, Telangana, India, [2]Nizams institute of medical sciences, hyderabad, Andhra Pradesh, India, [3]Nizams Institute Of Medical Sciences , Hyderabad, hyderabad, Telangana, India, [4]NIMS, Hyderabad, Telangana, India, [5]nizam's institute of medical sciences ,Hyderabad, Hyderabad, Telangana, India, [6]Nizam's Institute of Medical Sciences, Hyderabad, Telangana, India

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1770–1779) Cytokines & Cell Trafficking Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a complex autoimmune disease, partly driven by Interferon-alpha (IFN-α). Studies suggest that anti-IFN-α antibodies (AIAA) may neutralize IFN-α, potentially reducing disease activity, promoting clinical quiescence despite serologic activity, and increasing the risk of infections.

Methods: SLE patients meeting the revised 1997 ACR/EULAR criteria who attended rheumatology services at a tertiary care center in India between July 2024 and February 2025, along with healthy controls, were enrolled. Exclusion criteria included active infections, juvenile SLE, pregnancy, and lactation. Data collected included baseline demographics, disease characteristics and activity, steroid dose at the time of sampling, and history of infections.

Disease activity was assessed using SLEDAI (with HDA defined as ≥10 and LDA as ≤4) and numerical BILAG scores, with BILAG scores prioritized in case of conflict. LDA patients were further classified as either serologically active (SACQ) or serologically and clinically quiescent (SQCQ).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Serum IFN-α and AIAA levels were measured using ELISA (GENLISA kits, Krishgen Biosystems); detection ranges were 7.82–500 pg/mL for IFN-α and 16–256 pg/mL for AIAA. Levels were compared between patients and controls and correlated with disease duration, clinical features, anti-dsDNA, complement levels, ESR, steroid dose, and disease activity.ROC curve analysis was performed to evaluate and compare the sensitivity and specificity of various markers in predicting disease activity. A p-value < 0.05 was considered statistically significant. Written informed consent was obtained from all participants.

Results: A total of 117 lupus patients (112 females) and 30 healthy controls (24 females) were included. Baseline characteristics are shown in Table 1. IFN-α levels were significantly higher in patients [median(IQR): 15.989(8.18-22.370)]compared to healthy controls (median: 0). They were undetectable in 29 cases and all controls with a p-value < 0.0001. Surprisingly, AIAA levels were significantly higher in healthy controls [median(IQR): 146.74(21.29-45.4)) than in patients [median(IQR): 31.34 (32.06-303.31)], p-value < 0.0001.

IFN-α positively correlated with ESR, c-SLEDAI, and BILAG scores. AIAA showed no correlation with any parameter. No significant differences in IFN-α or AIAA levels were seen between disease activity groups (LDA, HDA, SACQ, SQCQ) or clinical features or prior infections. Steroid dose showed no correlation with either IFN-α or AIAA (Table 2).

Upon comparison of IFN-α and AIAA with traditional markers such as ESR, dsDNA, C3, and C4, the conventional markers demonstrated superior performance in predicting disease activity.

Conclusion: IFN-α levels correlated with higher disease activity, as measured by BILAG scores. Established markers anti-dsDNA, C3, C4, and ESR performed better than interferon as a biomarker of disease activity.AIAA levels were not predictive of disease status or clinical phenotype. AIAA presence was not associated with infections or disease flares. If reproducible , the higher AIAA levels in healthy controls may suggest a protective role against autoimmunity.

Table 1- Baseline Demographics and Clinical Manifestations

Demographics & Laboratory Parameters

Variable	Median (IQR)
Age (years)	27 (23.0 – 33.2)
BILAG Score at Sampling	12 (1 – 25)
C3 (mg/dL)	75 (45.75 – 106)
C4 (mg/dL)	10 (5 – 19)
Steroid Dose (mg)	20 (5 – 40)
Anti-dsDNA (IU/mL)	80 (20 – 234.5)
ESR (mm/hr)	37 (17.5 – 52.5)
AIAA (pgm/l)	31.34 (21.29 – 45.5)
IFN-α (pg/mL)	15.98 (0.33 – 52.6)
SLEDAI	7 (2 – 14)

Clinical Manifestations

Manifestation	n (%)
Mucocutaneous	34 (29.1%)
Musculoskeletal	32 (27.4%)
Cardiovascular	20 (17.1%)
Gastrointestinal	12 (10.3%)
Haematological	53 (45.3%)
Constitutional	19 (16.2%)
Nephritis	49 (41.9%)
Neuropsychiatric Lupus	9 (7.7%)
Ophthalmological	1 (0.9%)

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1770–1779) Cytokines & Cell Trafficking Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Soluble checkpoint molecules (sCM) may be involved in the pathophysiology of autoimmune diseases by inhibiting the suppressive signals of immune cell activation through binding to membrane-bound checkpoint molecules. The serum levels of soluble programmed death-1 (sPD-1) and soluble programmed death ligand 1 (sPD-L1) have been reported to correlate with disease activity in systemic lupus erythematosus (SLE) , but their dynamics in other autoimmune diseases remain unclear.

Methods: Plasma from healthy controls (HC) and patients was used. The plasma concentrations of sPD-1, sPD-L1, and soluble cytotoxic T-lymphocyte-associated protein 4 (sCTLA-4) were measured (pg/ml) by a fully automated immunoassay (HISCL system). If possible, samples at multiple timepoint were collected from the same patient with different disease states. Disease activity was assessed using Simplified Disease Activity Index (SDAI) for RA, SLE Disease Activity Index (SLEDAI) for SLE, Birmingham Vasculitis Activity Score (BVAS) for AAV and Myositis Intention To Treat Activity Index (MITAX) for Idiopathic inflammatory myopathies (IIM). Other clinical evaluation items, such as C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR), were also compared.A patent application has been filed related to the methodology described in this study.

Results: There were 29 HC (44% female, median age 35 years), 30 RA patients (59 samples, 81% female, median age 66 years), 42 SLE patients (84 samples, 94% female, median age 43 years), 20 AAV patients (41 samples, 70% female, median age 75 years), and 21 IIM patients (49 samples, 59% female, median age 58 years). In the present patient cohort,

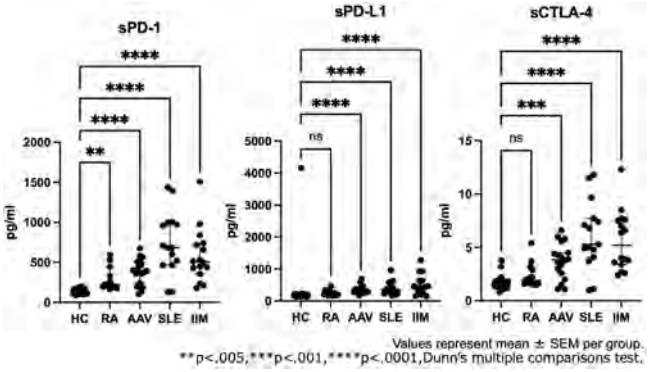

Figure1. Plasma sCM in healthy individuals and autoimmune disease patients before treatment.

All IIM samples (n=49)		
valuables	Spearman rho	p value
sCTLA-4	0.81	<.0001
sPD-1	0.76	<.0001
sPD-L1	0.75	<.0001
CK†	0.48	0.0009
ESR	0.47	0.0015
CRP	0.36	0.0092

† Analysis was performed using only the 43 samples from patients who presented with muscle symptoms at their initial visit.

Anti-ARS antibody positive (n=17)		
valuables	Spearman rho	p value
sCTLA-4	0.87	<.0001
sPD-L1	0.82	<.0001
sPD-1	0.80	<.0001

Anti-MDA5 antibody positive (n=16)		
valuables	Spearman rho	p value
sCTLA-4	0.89	<.0001
sPD-1	0.87	<.0001
sPD-L1	0.82	<.0001
Anti-MDA5 Ab	0.64	0.0098
Ferritin	0.36	0.163

Figure 2. The correlation of each assessment parameter with MITAX.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

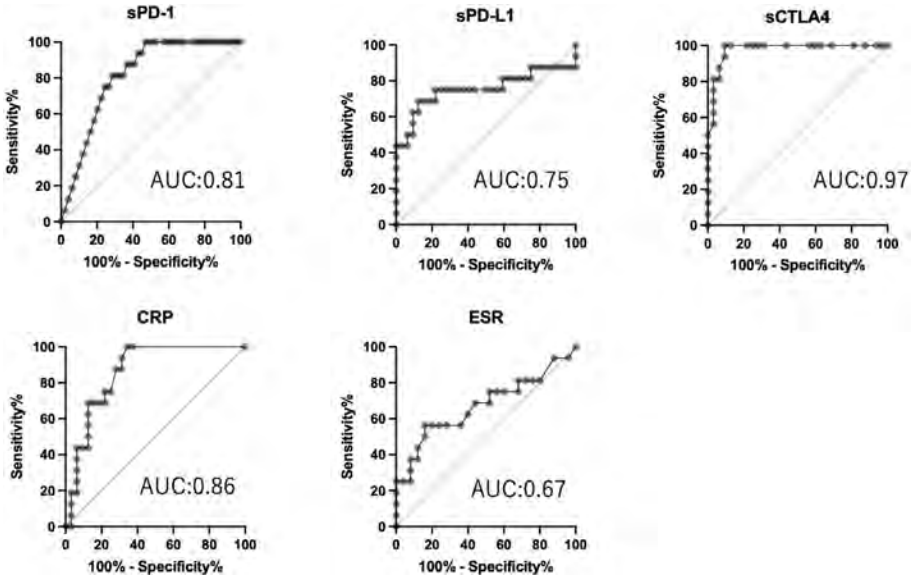

Figure 3. Receiver Operating Characteristic Curve (ROC) of plasma sCM in IIM patients before and after treatment.

untreated patients generally showed higher levels of sCM compared to HC. The SDAI had no correlation with sCM. SLEDAI and BVAS showed mild correlations with sCM (rs=0.48-0.55; p< 0.001). MITAX showed high correlations with sCM (sPD-1, sPD-L1, sCTLA-4; rs=0.76, 0.75, 0.81; p< 0.0001), In particular, sCM showed a stronger correlation with MITAX (rs > 0.8) in cases of anti-ARS antibody or anti-MDA5 antibody positive. And when calculating the AUC using ROC curves, sCTLA-4 (0.97) were able to distinguish between pre- and post-treatment more effectively than CRP (0.86) and ESR (0.67) in IIM patients. Even after performing multivariate analysis with age, sex, sPD-L1, and sCTLA4, sCTLA-4 and sPD-L1 remained independent factors associated with MITAX, regardless of age and sex.

Conclusion: The correlation between disease activity and sCM varied among autoimmune diseases. sCM may be useful as evaluation parameters, especially in IIM patients.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1770–1779) Cytokines & Cell Trafficking Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: IgG4-related disease (IgG4-RD) is a systemic fibroinflammatory disorder characterized by elevated serum IgG4 levels and tissue infiltration by IgG4-positive plasma cells. Despite advances in understanding this entity, there is a lack of reliable biomarkers for assessing disease activity and improving follow-up.

The aim is to evaluate the role of novel biomarkers, including plasmablasts and the cytokines IL-1β, IL-4, IL-5, IL-10, IL-13, IL-21, and IFN-gamma as well as their respective ratios, in monitoring disease activity. Additionally, to compare them with classical biomarkers used to date.

Methods: An ambispective cohort of patients with IgG4-RD was recruited at a single tertiary care hospital. Inclusion required fulfilling at least one of the established diagnostic criteria: Umehara, Okazaki, or the 2019 ACR/EULAR classification criteria. Clinical variables were collected, including demographic data and initial disease manifestations. Disease activity was assessed using the IgG4-RD Responder Index, blood tests, and physician-determined activity, all evaluated at the same time point upon study inclusion. In patients with an available PET-CT at that time, this was also included as an additional variable.

Table 1. Baseline demographic characteristics

	N=35	p-value
Gender (men)	27 (77,14%)	0,6855
Okazaki criteria	23 (65,71%)	1

Biomarkers used to assess activity included classical parameters: CRP, ESR, serum IgG4 and total IgG levels (and their ratio), C3, C4, hemoglobin, and eosinophil count. Novel biomarkers included plasmablasts and the cytokines IL-1β (proinflammatory), IL-10 (anti-inflammatory), IL-13 (profibrotic), IFN-gamma (Th1 phenotype), IL-5 (Th2), IL-4 and IL-21 (follicular Th phenotype), as well as their respective ratios.

Results: The study included 35 patients with IgG4-RD, predominantly male (77.14%), with a mean Responder Index of 6.09 (CI 4.63–7.55) (Tabla 1). PET-CT evaluation showed statistically significant correlations with eosinophil count (p=0.03) and the ratios IL-13/IFN-γ (p=0.04), IL-21/IFN-γ (p=0.02), and IFN-γ/IL-4 (p=0.00), highlighting the role of these interleukins in inflammatory processes. Physician-based activity assessment showed a statistically significant correlation only with IgG levels (p=0.01).

The Responder Index correlated significantly with IgG (p=0.02), IgG4 (p=0.01), and IL-5 levels (p=0.03), as well as with the IL-10/IL-5 (p=0.05) and IL-21/IL-5 (p=0.05) ratios. Neither CRP nor ESR showed statistically significant associations (Table 2)

Conclusion: This study demonstrates the utility of novel biomarkers in monitoring IgG4-RD activity. The correlation between PET-CT findings and cytokine ratios (IL-13/IFN-γ, IL-21/IFN-γ, IFN-γ/IL-4) supports their role in inflammatory assessment. IgG and IgG4 remain relevant markers correlated with the Responder Index, whereas CRP and ESR showed limited utility. IL-5 stands out as key, especially through its ratios with IL-10 and IL-21, showing significant correlations with disease activity. These findings support an integrative approach combining classical and novel biomarkers (particularly cytokine ratios) to improve disease activity monitoring in IgG4-RD.

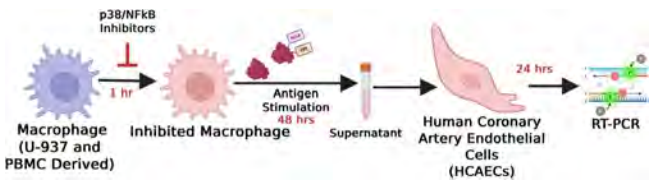
Citrullinated and Malondialdehyde-Acetaldehyde Co-Modified Fibrinogen Activates Macrophages and Induces Pro-Fibrotic shift in Coronary Endothelium Phenotype

Nozima Aripova[1], Wenxian Zhou[2], Hannah Johnson[1], Michael Duryee[1], Kimberley Sinanan[1], Carlos Hunter[1], Tate Johnson[1], Mabruka Alfaidi[1], Daniel Anderson[3], Kishore Bidasee[1], Geoffrey Thiele[1] and Ted Mikuls[1], [1]University of Nebraska Medical Center, Omaha, NE, [2]University of Nebraska Medical Center, Bellevue, NE, [3]0587964, Durham, NC

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1770–1779) Cytokines & Cell Trafficking Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) patients are at increased risk for developing heart failure with preserved ejection fraction (HFpEF), which is characterized by impaired left ventricular relaxation. The mechanisms underlying RA-associated HFpEF remain unclear, but pro-fibrotic pathways are well-characterized. Citrulline (CIT) and malondialdehyde-acetaldehyde (MAA) are post-translational modifications (PTMs) that serve as autoantigens in RA. These mediators synergistically activate macrophages via NFkB and p38 signaling, leading to pro-inflammatory and pro-fibrotic responses *in vitro*. Our laboratory recently demonstrated that PTMs are over-expressed and co-localized in the cardiac tissues of RA-HF compared to non-RA HF patients. The objective of this study is to investigate whether cardiac fibrosis is also increased in RA-HF patients and to identify whether PTMs induce a pro-fibrotic responses in human coronary artery endothelial cells (HCAECs).

Methods: Left ventricular (LV) apex tissues from RA-HF patients (n=3) and age- and sex-matched non-RA HF controls (n=3) were stained with Masson's trichrome. Cardiac fibrosis was measured by quantifying collagen deposition using ImageJ and analyzed using Student's t test. In separate experiments, human U-937 monocytes (source) were differentiated into macrophages (**Fig. 1**). Macrophages were pre-incubated for 1 hr with either 1 μM BIRB-796 (p38 inhibitor), 50 μM BAY-11-7085 (NF-κB inhibitor), or media control. After that, macrophages were stimulated with 25 μg/mL of either unmodified fibrinogen (FIB) or PTM co-modified fibrinogen (FIB-MAA-CIT) for 48 hours. After stimulation, supernatants were collected and applied to HCAECs for 24 hours. HCAEC mRNA was isolated, and expression of fibrotic mediators (SMAD3, ACTA2, PDGF) was quantified by qRT-PCR. Fibrotic mediator expression was then compared using one-way ANOVA followed by Tukey's post hoc test.



Methods set up.

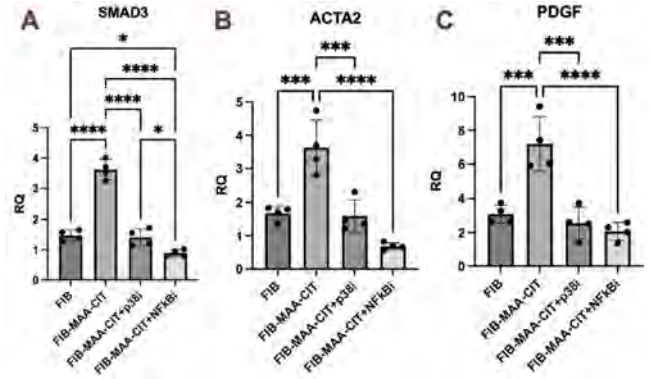
Trichrome stain measuring collagen deposition in human heart tissues. Cardiac tissues from non-RA controls (non-RA HF controls) and RA patients (RA-HF) with Heart Failure (n=3/group). Collagen deposition (blue) were quantified using with Fiji plug-in and mean values from 3 images/patient calculated. Images were taken around blood vessels (perivascular fibrosis) and between cardiomyocytes (interstitial fibrosis). Representative image of 20X frame at left ventricle apex was shown. Data shown on graphs are mean ± standard deviation. Student's t test was performed, and statistical differences were shown in *: * p<0.05.



PCR measuring pro-fibrotic markers in HCAEC cells following stimulation with macrophage supernatants. Macrophage supernatants were collected post antigen stimulation (FIB or FIB-MAA-CIT) in the presence or absence of inhibitors (p38i or NFkBi). HCAEC gene expression was measured post 24-hour incubation for A) SMAD3, B) ACTA2, and C) PDGF. One-way ANOVA was performed and the statistical differences were shown in *: * p<0.05; *** p<0.001; **** p<0.0001.

Results: Patients with RA-HF exhibited significantly increased perivascular fibrosis (p< 0.05) and a non-significant trend toward increased interstitial fibrosis (p=0.18) compared to non-RA HF controls (**Fig. 2**). Supernatants from FIB-MAA-CIT–stimulated macrophages significantly upregulated mRNA expressions of *SMAD3*, *ACTA2*, and *PDGFB* in HCAECs compared to FIB (p< 0.001). Pre-treatment with p38 or NF-κB inhibitors brought pro-fibrotic gene expression back to baseline levels (**Fig. 3**).

Conclusion: Our findings suggest that PTM–activated macrophages secrete soluble factors that induce marked pro-fibrotic responses in HCAECs. Those soluble factors are potentially contributing to increased collagen deposition, suggested by perivascular fibrosis observed in RA-HF cardiac tissues. Macrophage activation via p38 and NF-κB pathways appears critical in this process. Targeting PTMs or their downstream signaling pathways may represent a novel therapeutic strategy to attenuate HF burden in RA.

Abstract Number: 1775

Study Of Type -1 Interferon Gene Signature Markers In Muscle Biopsy Samples Of Patients With IIM

pradeep sosigowda[1], Phani Kumar D[1], Megha Uppin[1] and Liza rajasekhar[2], [1]NIMS, Hyderabad, Telangana, India, [2]Nizam's Institute of Medical Sciences, Hyderabad, Telangana, India

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1770–1779) Cytokines & Cell Trafficking Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Idiopathic inflammatory myopathies (IIMs) are a heterogeneous group of autoimmune diseases primarily affecting skeletal muscle, with potential involvement of other organs. They are classified into five distinct subsets: dermatomyositis (DM), polymyositis (PM), inclusion body myositis (IBM), immune-mediated necrotizing myopathy (IMNM), and anti-synthetase syndrome (ASyS). Diagnosing IIMs remains challenging due to overlapping clinical features and limitations in current diagnostic modalities. Emerging evidence implicates Type 1 interferons (IFNs), particularly in the pathogenesis of DM. Identifying IFN-related markers in muscle biopsies may enhance diagnostic precision and guide targeted therapy.

Methods: A cross-sectional observational study was conducted involving patients who met the 2017 EULAR/ACR classification criteria or the Bohan and Peter criteria for IIMs. Muscle biopsy samples were analyzed via immunohistochemistry for the expression of Type 1 IFN-inducible genes—Myxovirus resistance protein A (MxA), Interferon-stimulated gene 15 (ISG15), and Retinoic acid-inducible gene I (RIG-I). The expression patterns of these markers were compared between DM and non-DM IIM subgroups.

Results: The study included 50 patients: 25 with DM and 25 with non-DM IIMs (18 IMNM, 4 ASyS, 2 IBM, and 1 PM). A distinct differential expression of all three Type 1 IFN markers was observed, with significantly higher expression in the DM group.

- In DM patients, MxA expression was predominantly perifascicular, while ISG15 and RIG-I showed focal or scattered sarcoplasmic distribution.
- Thirteen DM patients were myositis-specific antibody (MSA) negative; a majority of these exhibited significant expression of Type 1 IFN markers.
- MHC Class I upregulation was observed in all DM cases and in 84% of non-DM cases.
- Among seven DM patients negative for perifascicular atrophy (PFA), six showed positive expression of at least one Type 1 IFN marker.
- Of the four ASyS patients, all were PFA-positive, but only one exhibited Type 1 IFN expression.

These findings highlight the pathological relevance of Type 1 IFN markers, suggesting they may offer superior specificity for DM diagnosis compared to traditional histopathological features like PFA.

Table 1- IFN -1 Expression in muscle biopsy specimens of DM versus non DM

	DM	Non DM	P value
MxA	19/25(76%)	3/25(12%)	0.001
RIG-I	15/25(60%)	6/25(24%)	0.03
ISG-15	12/25(48%)	4/25(16%)	0.015

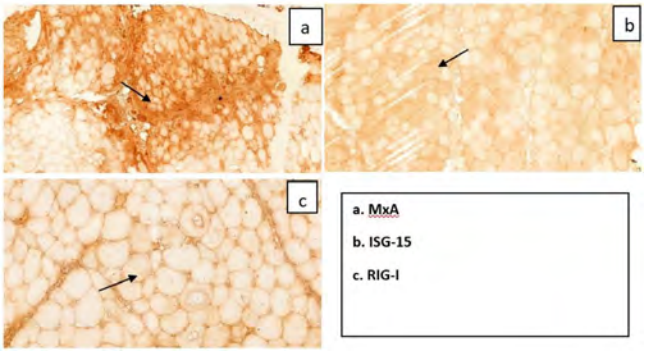
Expression in muscle biopsy specimens of DM and Non DM

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 2- INF -1 Expression in MSA negative subset of DM

MSA Negative	DM(n=13)	NON-DM(n=15)	P value
MxA Positive	9	2	0.0029
ISG 15 positive	6	2	0.057
RIG Positive	6	3	0.149

IFN-1 expression in MSA negative subset of DM



Histopathological images showing all 3 IFN-1 markers

Conclusion: This study underscores the diagnostic utility of Type 1 IFN markers—MxA, ISG15, and RIG-I—in distinguishing DM from other IIMs. Among these, MxA showed the most pronounced differential expression and demonstrated sensitivity and specificity comparable to PFA. Notably, MxA was positive in 72% of MSA-negative DM cases. While PFA remains a hallmark of DM, our findings suggest that IFN markers, particularly MxA, may serve as valuable adjuncts or alternatives in diagnostic evaluation. These insights support the incorporation of IFN markers into routine histopathological assessment and highlight their potential role in advancing precision medicine for DM.

Preclinical Development of a Novel TL1A-Targeting Antibody with Extended Half-life and Low Immunogenicity Risk for the Treatment of Inflammatory Diseases

Yali Zhou[1], Huilin Li[1], Hang Su[1], Mingjun Zhao[1], Haiying Wang[1], Qiong Wang[1], Xiaojin Zhang[2], Yanliu Fan[1], Lulu Li[1], Miaomiao Wang[1], Jinglu Xia[1], Wenyue Zong[1], Jingjing Li[1], Simin Yi[1], Bing Zou[1], Zhen Lu[1], Yali Wang[1], Yupeng Zhu[1], Lingjian Yang[1], Zenglin Pei[1], Barry Duplantis[3], Yuhao Wang[3], Yi Li[1] and **Quan Yu**[1], [1]Ailux, Shanghai, China (People's Republic), [2]XtalPi, Shanghai, China (People's Republic), [3]Ailux, Boston, MA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1770–1779) Cytokines & Cell Trafficking Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Autoimmune and inflammatory diseases such as inflammatory bowel disease (IBD) and psoriasis are driven by dysregulated cytokine networks. TL1A, a member of the TNF superfamily, plays a key role in modulating inflammation and fibrosis through interaction with its cognate receptor, DR3. While anti-TL1A antibodies have shown promising efficacy in clinical trials, there remains a significant need for next-generation therapeutics with improved efficacy and safety,

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

and more convenient dosing. Here, we describe the development and characterization of a humanized anti-TL1A antibody engineered for extended serum half-life and reduced immunogenicity risk. On this basis, a bispecific antibody targeting both TL1A and an orthogonal pathway such as IL-23 may offer synergistic benefits in alleviating IBD pathogenesis.

Methods: Humanized anti-human TL1A antibodies were derived from immune repertoire mining and optimized for pH-sensitive TL1A binding and FcRn-mediated IgG recycling. Binding to TL1A or related TNF superfamily members was assessed using surface plasmon resonance and ELISA, respectively. The formation of antibody-TL1A immune complexes was analyzed by negative-stain electron microscopy. Functional inhibition of TL1A signaling was evaluated using TF-1 cell apoptosis assay and human whole blood-based IFN-γ secretion assay. In vivo efficacy was assessed in a 2,4,6-trinitrobenzene sulfonic acid (TNBS)-induced colitis model using human TL1A transgenic mice. Immunogenicity was evaluated by monitoring anti-drug antibody (ADA) responses in animal models. Serum half-life was examined in non-human primates following single-dose administration.

Results: The anti-TL1A antibody demonstrated epitope-specific pH-sensitive binding with human TL1A and cross-reactivity with cynomolgus TL1A, with no detectable binding to TNF-α or TRAIL. The antibody did not form large immune complexes when incubated with TL1A trimers in vitro, nor did it elicit ADA responses in animal models. It selectively inhibited TL1A/DR3 interaction while sparing TL1A/DcR3 binding, and effectively suppressed TL1A-induced TF-1 cell apoptosis and IFN-γ secretion in vitro. In the TNBS-induced mouse colitis model, the antibody exhibited a strong anti-inflammatory effect and alleviated disease symptoms. In non-human primates, the antibody showed an extended serum half-life compared to clinical-stage antibodies.

Conclusion: The humanized anti-TL1A antibody demonstrates high binding specificity and potent anti-inflammatory activity both in vitro and in vivo. The multi-objective antibody engineering confers extended half-life and low immunogenicity risk, supporting the potential for infrequent subcutaneous administration and improved safety. Further preclinical studies and development of a novel bispecific antibody targeting TL1A and an orthogonal inflammatory pathway are warranted.

Background/Purpose: Recent studies have shown that monocytes, macrophages, and conventional DCs, but not plasmacytoid dendritic cells (pDC), are major sources of IFNα in cutaneous lupus erythematosus (CLE). However, novel medications targeting pDCs reduce IFNα levels and improve CLE. Granzyme B is a proteolytic enzyme that induces apoptosis, and large concentrations are produced by pDCs in CLE, yet its role in modulating signaling pathways, including IFNα release, has not been elucidated.

Methods: Peripheral blood mononuclear cells (PBMCs) were obtained from 25 CLE patients. PBMCs were co-incubated for 20 hours with 500U of recombinant human granzyme B alone or with either 100ug/mL C307 (TLR7 agonist), 10ug/mL TL8-506 (TLR8 agonist), 1.5uM CpG (TLR9 agonist) or 60ug/mL cGAMP (STING agonist). Positive controls were PBMCs stimulated separately with only C307, TL8-506, CpG or cGAMP. Supernatants were then analyzed for IFNα production via ELISA.

Results: PBMCs incubated with granzyme B alone did not produce any IFNα (n=5). PBMCs co-incubated with granzyme B and C307 (n=5) did not result in any significant change in IFNα production compared to PBMCs incubated with C307 alone (mean IFNα 20.0±13.3 vs. 22.7±15.3 pg/mL respectively, p=0.11). PBMCs co-incubated with granzyme B and CpG (n=5) significantly reduced IFNα production compared to PBMCs incubated with CpG alone (mean IFNα 20.6±9.1 vs. 95.2 ±21.5 pg/mL respectively, p< 0.01). However, PBMCs co-incubated with granzyme B with either TL8-506 (n=5) or cGAMP (n=5) produced significantly increased IFNα compared to PBMCs incubated with either TL8-506 or cGAMP alone (for TL8-506, mean IFNα 18.9±2.4 vs. 2.2±0.7 pg/mL respectively, p< 0.01; for cGAMP, mean IFNα 14.1±2.2 vs 6.1±2.0 pg/mL respectively, p< 0.01).

Conclusion: CpG stimulates the TLR9 pathway primarily on pDCs and granzyme B may have a negative feedback effect in suppressing TLR9-induced IFNα release from pDCs, as suggested by recent studies. Granzyme B may not affect the TLR7 pathway which is also highly expressed on pDCs. However, monocytes and macrophages primarily use the TLR8 and STING pathways for IFNα production. Granzyme B which is produced in large numbers by pDCs may potentiate IFNα release by enhancing the TLR8 or STING pathways on macrophages and monocytes in CLE. Outside of its role in inducing apoptosis, granzyme B may be a bridge between pDCs and other immune cells by modulating signaling pathways, in particular that of type-1 IFN in CLE.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1770–1779) Cytokines & Cell Trafficking Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Interstitial lung disease (ILD) is one of the leading cause of mortality in patients with connective tissue diseases (CTDs) [1]. The onset of CTD-ILD is insidious, and the clinical symptoms are atypical and not obvious, therefore ILD is often diagnosed in later stages with severe consequences [1]. Moreover, a confident diagnosis of CTD-ILD can be difficult due to certain similarities with idiopathic pulmonary fibrosis (IPF), the most severe ILD with different prognosis and therapies [2]. Early and accurate diagnosis is crucial to delay fibrosis progression in CTD-ILD, but the limitations of current clinical

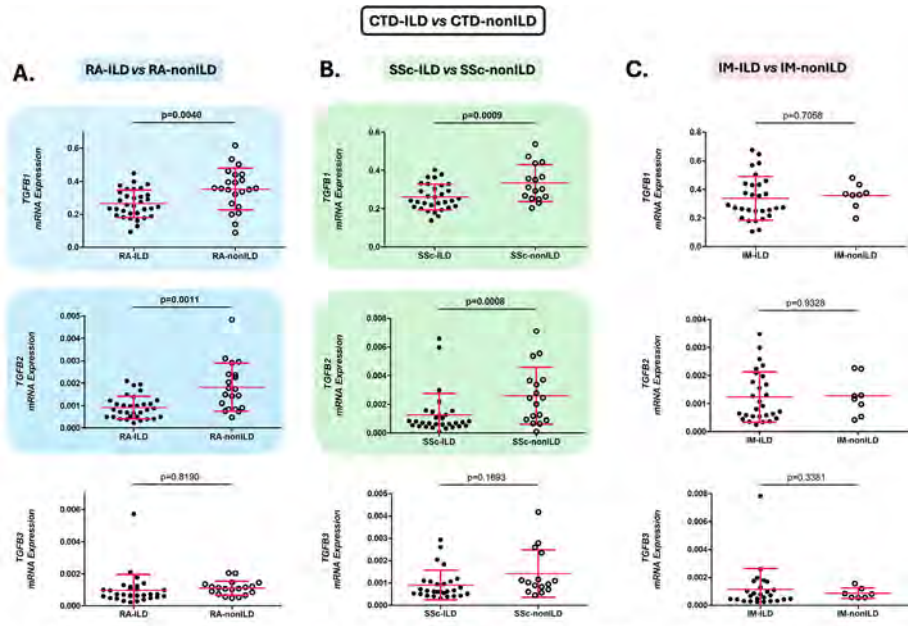

Figure 1. Role of TGFB isoforms mRNA expression as biomarkers for the early diagnosis of CTD-ILD. A. Differences in TGFB1, TGFB2, and TGFB3 mRNA expression between patients with RA-ILD and those with RA-nonILD; B. Differences in TGFB1, TGFB2 and TGFB3 mRNA expression between patients with SSc-ILD and those with SSc-nonILD; C. Differences in TGFB1, TGFB2 and TGFB3 mRNA expression between patients with IM-ILD and those with RA-nonILD. CTD: connective tissue disease; ILD: interstitial lung disease; RA: rheumatoid arthritis; SSc: systemic sclerosis; IM: inflammatory myopathies. Significant results are highlighted in ***bold****.*

tools highlight the need to complement them with accessible and non-invasive methods. Transforming growth factor-β (TGF-β) is the main profibrogenic agent involved in different lung pathologic conditions [3]. Therefore, it is plausible to think that the *TGFB* expression is differentially altered in CTD-ILD patients. Accordingly, we focused on evaluating the role of *TGFB* isoforms as new biomarkers with clinical value for the early and accurate diagnosis of ILD in the most affected CTDs for this devastating disease, systemic sclerosis (SSc), rheumatoid arthritis (RA), and inflammatory myopathies (IM).

Methods: Peripheral blood was collected from 93 CTD-ILD patients: 33 RA-ILD, 31 SSc-ILD, and 29 IM-ILD; 48 CTD-nonILD patients: 22 RA-nonILD, 18 SSc-nonILD, and 8 IM-nonILD; and 148 IPF patients. The relative *TGFB1*, *TGFB2*, and *TGFB3* mRNA expression was quantified by qPCR.

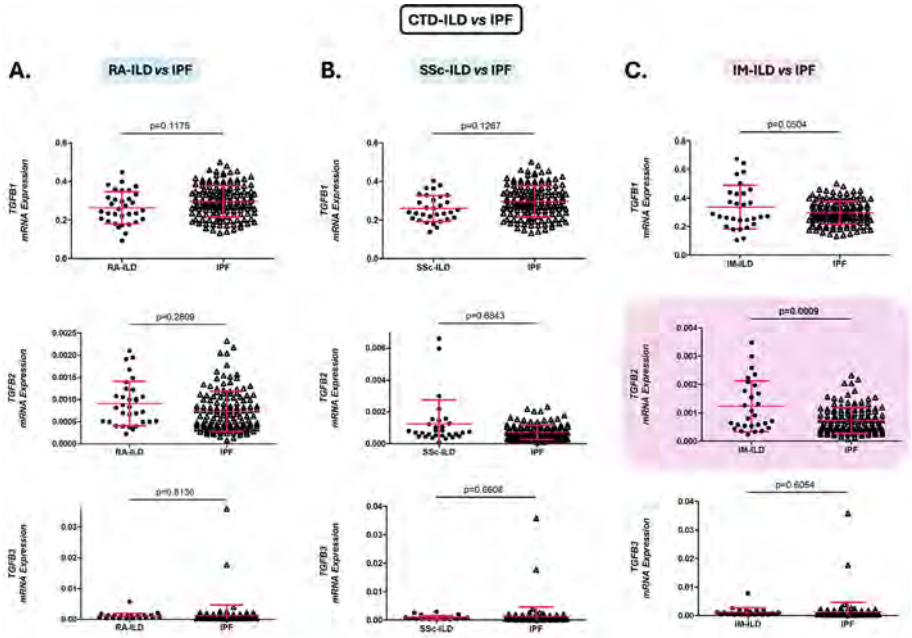

Figure 2. Role of TGFB isoforms mRNA expression as biomarkers for the accurate diagnosis of CTD-ILD. A. *Differences in TGFB1, TGFB2, and TGFB3 mRNA expression between patients with RA-ILD and IPF;* ***B.*** *Differences in TGFB1, TGFB2 and TGFB3 mRNA expression between patients with SSc-ILD and IPF;* ***C.*** *Differences in TGFB1, TGFB2 and TGFB3 mRNA expression between patients with IM-ILD and IPF. CTD: connective tissue disease; ILD: interstitial lung disease; RA: rheumatoid arthritis; SSc: systemic sclerosis; IM: inflammatory myopathies; IPF: idiopathic pulmonary fibrosis. Significant results are highlighted in* ***bold****.*

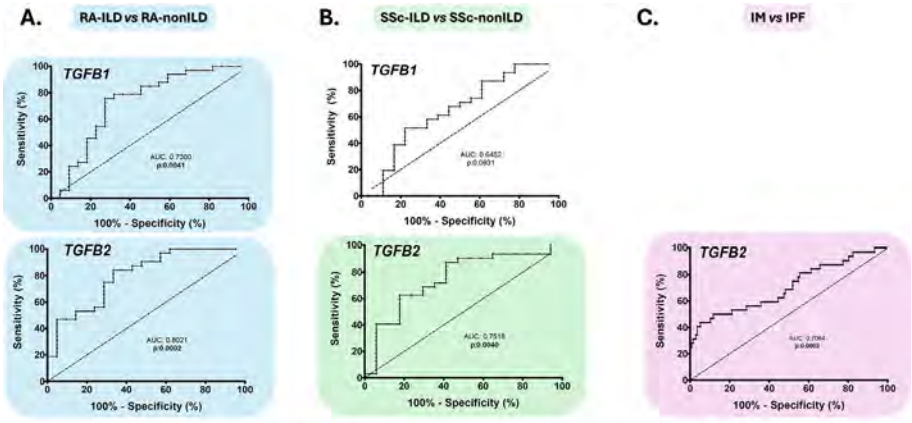

Figure 3. Utility of TGFB isoforms as biomarkers for the early and accurate diagnosis of CTD-ILD. A. ROC curve analysis to evaluate the ability of TGFB1 and TGFB2 to discriminate RA-ILD from RA-nonILD (A), SSc-ILD from SSc-nonILD (B) and IM-ILD from IPF (C). *CTD: connective tissue disease; ILD: interstitial lung disease; RA: rheumatoid arthritis; SSc: systemic sclerosis; IM: inflammatory myopathies; IPF: idiopathic pulmonary fibrosis. Significant results are highlighted in* ***bold****.*

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: A significant decrease in *TGFB1* and *TGFB2* expression was observed in RA-ILD and SSc-ILD patients compared to those with RA-nonILD and SSc-nonILD, respectively (*TGFB1*: p=0.0040, **Figure 1A** and p=0.0009, **Figure 1B**, respectively; and *TGFB2:* p=0.0011, **Figure 1A** and p=0.0008, **Figure 1B**, respectively). Interestingly, IM-ILD patients showed an increased *TGFB2* expression compared to IPF patients (p=0.0009, respectively, **Figure 2C**),

In a further step, ROC curve analysis confirmed the capacity of *TGFB1* and *TGFB2* expression to differentiate RA-ILD from RA-nonILD, acting as biomarkers for the early detection of RA-ILD (p=0.0041 and p=0.0002, respectively, **Figure 3A**) with < 0.3185 for *TGFB1* and < 0.001410 for *TGFB2* as optimal cut-off values. Furthermore, *TGFB2* expression levels also revealed an ability to discriminate SSc-ILD and SSc-nonILD patients, representing an early diagnostic biomarker of SSc-ILD (p=0.0040, **Figure 3B**) with < 0.001795 as optimal cut-off value. Meanwhile, differences in *TGFB2* gene expression were sufficient to differentiate between patients with IM-ILD and those with IPF, acting as a biomarker for the accurate diagnosis of IM-ILD (p=0.0003, **Figure 3C**) with >0.001547 as optimal cut-off value.

Conclusion: *TGFB1* and *TGFB2* constitute biomarkers with clinical value for the early detection of ILD in RA and SSc, and the accurate diagnosis of IM-ILD versus IPF, representing promising screening tools for CTD-ILD in clinical practice.

Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Endothelial cell (EC) dysfunction is a key driver of cardiovascular (CV) complications in rheumatoid arthritis (RA), yet mechanisms underlying EC dysfunction in RA are not fully understood. Citrulline (CIT) and malondialdehyde-acetaldehyde (MAA) are post-translational modifications (PTMs) that are increasingly expressed and co-localized in RA tissues. These PTMs synergistically activate macrophages, leading to pro-inflammatory and pro-fibrotic responses *in vitro*. Our lab recently demonstrated increased expression and co-localization of CIT and MAA in heart tissues

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. of mice with collagen-induced arthritis (CIA) that precedes fibrosis, suggesting a role of these PTMs in promoting local CV inflammation. However, their effects on EC function has not been examined. This study aims to examine whether CIT and MAA induce inflammatory responses in human coronary artery endothelial cells (HCAECs).

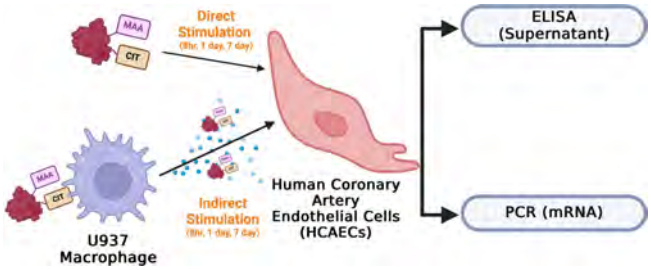

Fig 1. Study schema. HCAECs were either directly stimulated with CIT- and/or MAA-modified FIB or indirectly stimulated with supernatants from antigen-stimulated U-937 macrophages for 8 hours, 1 day, and 7 days. After stimulation, HCAEC supernatants were collected for ELISA, and mRNA was extracted for PCR.

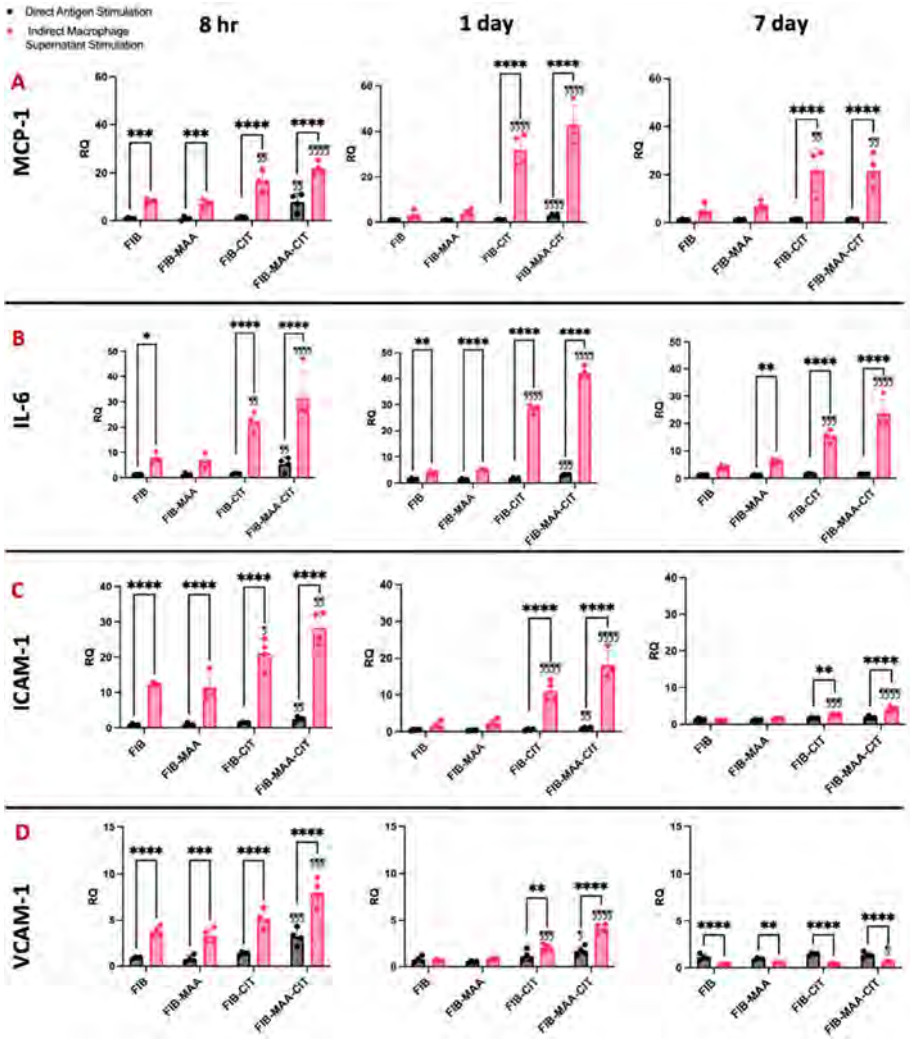

Fig. 2. PCR Demonstrating Changes in HCAEC Gene Expression Following Direct Antigen Stimulation and Indirect Stimulation with Macrophage Supernatants. 8hr, 1 day, and 7 day mRNA expression was measured for A) MCP-1, B) IL-6, C) ICAM-1, and D) VCAM-1. Relative quotient (RQ) compared to media-cultured negative control cells were calculated and shown in y-axis. Two-way ANOVA was performed and the statistical differences between direct and indirect stimulation were shown in *: * p<0.05; ** p<0.01; *** p<0.001; **** p<0.0001. Statistical differences between CIT- and/or MAA-modified FIB compared with unmodified FIB were shown in ¶: ¶ p<0.05; ¶¶ p<0.01; ¶¶¶ p<0.001; ¶¶¶¶ p<0.0001.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Methods: Human U-937 monocytes were differentiated into macrophages (M0 cells) and stimulated for 48 hrs with 25 ng/mL of fibrinogen that was unmodified (FIB) or modified with MAA (FIB-MAA), CIT (FIB-CIT), or MAA and CIT (FIB-MAA-CIT) (**Fig. 1**). To assess crosstalk, macrophage supernatants were collected, and HCAECs were **indirectly** stimulated with these supernatants using 25% of total well volume for 8 hrs, 1 day, or 7 days. Concurrently, HCAECs were **directly** stimulated with FIB, FIB-MAA, FIB-CIT, or FIB-MAA-CIT. After stimulation, HCAEC supernatants were analyzed by ELISA and mRNA measured by qRT-PCR. Statistical analyses were performed using GraphPad Prism and statistical significance was achieved when $p < 0.05$ and data comparision was conducted by a two-way ANOVA and Tukey's post hoc test.

Results: Direct EC stimulation with FIB-MAA-CIT resulted in significantly higher levels of mRNA expressions of proinflammatory mediators, including MCP-1, IL-6, ICAM-1, VCAM1 (**Fig. 2**) and protein secretion (**Fig. 3**) vs. direct stimulation with FIB-MAA, FIB-CIT, or FIB alone. Interestingly, indirect stimulation of HCAECs with macrophage supernatants showed a similar pattern of inflammatory responses as direct stimulation, but the magnitude of the response was remarkably higher with indirect stimulation compared to direct antigen stimulation, suggesting an additional souble mediator secreted by macrophages

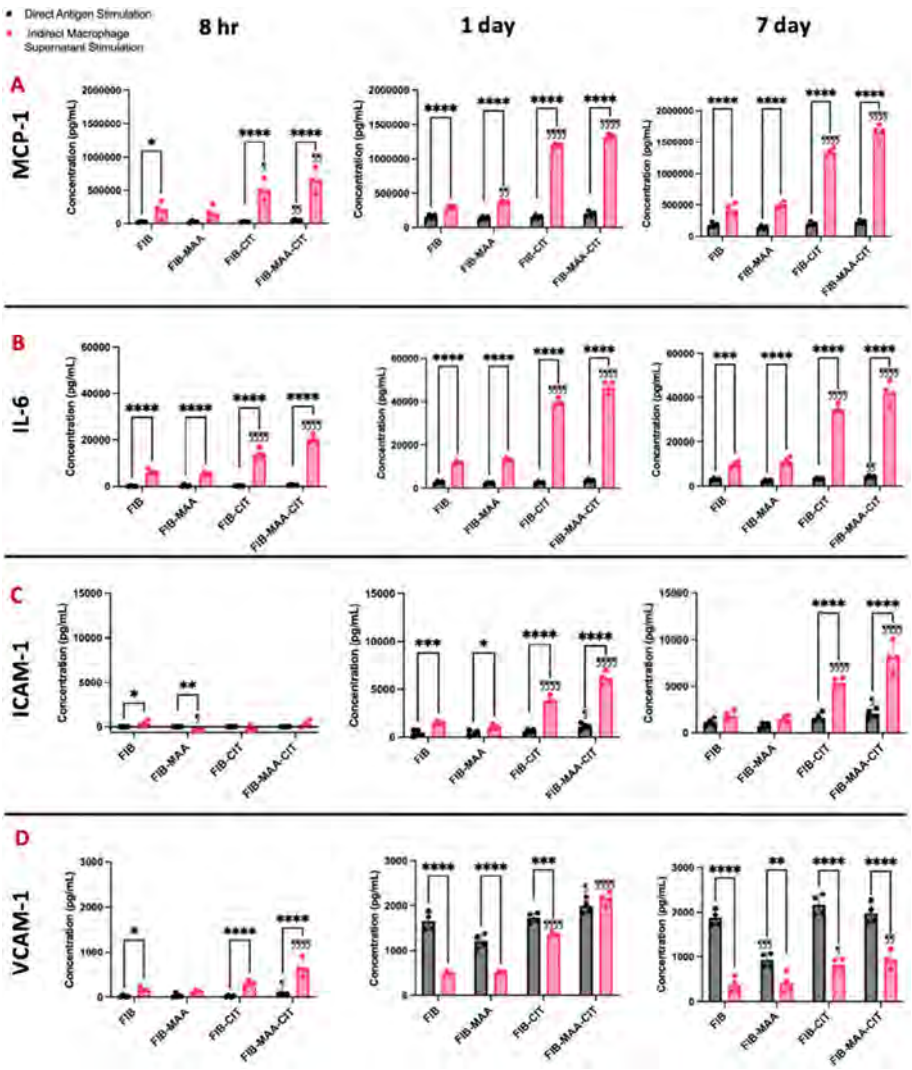

Fig. 3. ELISA Demonstrating Changes in HCAEC Protein Secretion Following Direct Antigen Stimulation and Indirect Stimulation with Macrophage Supernatants. 8hr, 1 day, and 7 day protein concentrations in supernatants were measured for A) MCP-1, B) IL-6, C) ICAM-1, and D) VCAM-1. Two-way ANOVA was performed and the statistical differences between direct and indirect stimulation were shown in *: * $p<0.05$; ** $p<0.01$; *** $p<0.001$; **** $p<0.0001$. Statistical differences between CIT- and/or MAA-modified FIB compared with unmodified FIB were shown in ¶: ¶ $p<0.05$; ¶¶ $p<0.01$; ¶¶¶ $p<0.001$; ¶¶¶¶ $p<0.0001$.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. contributing to EC activation. Additionally, we observed an earlier activation at mRNA and protein levels for adhesion molecules than peaks for cytokines, confirming cellular cross communications in response to MAA and CIT.

Conclusion: This research provides novel insights into the mechanistic crosstalk between inflammatory cells and coronary EC activation in RA. The data suggest that proteins co-modified with MAA and CIT (enriched in RA tissues) act synergistically to induce inflammatory responses in HCAECs. These inflammatory responses in HCAECs are amplified through macrophage activation and secretion of soluble mediators. In addition to identifying these mediators, further research is needed to examine whether inhibition of MAA, CIT, or downstream signaling pathways attenuates HCAEC activation and reduces CV complications in RA.

Modeling Osteoarthritis Knee Joint in a Compartmentalized Microfluidic System using IPSC-derived Sensory Neurons and human Synovial Fibroblasts

Abdelhak Belmadani[1], Dongjun Ren[1], Daniel Hoffman[2], Nirupa Jayraj[1], Paola Pacifico[1], Vince Truong[3], Patrick Walsh[3], Daniela Menichella[1], Anna Rapp[4], Carla Scanzello[5], Rachel Miller[6], Richard Miller[7] and Anne-Marie Malfait[8], [1]Northwestern University Chicago, Chicago, IL, [2]Rush University, Chicago, IL, [3]Anatomic Inc, Minneapolis, MN, [4]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, [5]University of Pennsylvania, Philadelphia, [6]Rush University Medical Center, Chicago, IL, [7]Northwestern University, Chicago, [8]Rush University Medical Center, Chicago

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1780–1808) Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Joint pain is one of the most significant clinical hallmarks of knee osteoarthritis (OA). Knee OA is a chronic degenerative disease of the joints characterized by the breakdown of articular cartilage, changes in the subchondral bone (sclerosis) and synovium (synovitis). Uncovering the mechanisms and circuits underlying pain in knee OA remains a major challenge to finding effective and disease-modifying therapy. The synovium is heavily innervated by sensory nerve terminals potentially enabling communication between synovial fibroblasts (sFBs), the predominant cells of the synovium and knee afferents. The aim of this study is to explore mechanisms by which sFBs communicate with knee afferents and how this communication impacts sensory neuron sensitivity in OA knee joints using a microfluidic coculture system.

Methods: In a pilot and feasibility studies, we pioneered a compartmentalized microfluidic system, in which we integrated human iPSCs-derived sensory neurons (SNs) and human sFBs and tested the effects of various stimuli, known to be released by FBs on neurite outgrowth, activity and pain signaling pathways.

Results: Using a two-compartment microfluidic device, we found that hiPSCs–SNs were able to grow neurites towards sFBs within 7 days, where they form extensive connections with cocultured hsFBs. Real time monitoring of the changes in intracellular calcium levels in hiPSC-SNs cocultured with sFBs revealed a dynamic interplay between neuronal activity and

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

sFBs. For example, we have used this system for targeting specific signaling pathways or receptors such as NGF and MRGPRD and study the effects on neurite growth and sensitivity. Similarly, calcium imaging studies in hsFBs from OA patients revealed that the number of FBs with higher baseline signal was significantly increased compared to sFBs from heathy individuals, indicating altered calcium homeostasis, which can impact various cellular processes, including the release of various factors that can activate nociceptors.

Conclusion: This human relevant platform with hiPSCs and hsFBs can be used to explore mechanisms and accelerate the identification of targets for analgesic therapy in joint pain in various health conditions such as in OA.

Specific gut microbiome remodeling occurs after induction of OA via DMM surgery compared to sham surgery

Aleksander Szymczak[1], Cindy Miranda Brawner[2], Nicholas Hanebutt[2], Gabriella Dyson[2], Montana Barrett[2], Anna Rapp[3], Carla Scanzello[4] and Matlock Jeffries[1], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma City, [3]University of Pennsylavnia, Philadelphia, [4]University of Pennsylvania, Philadelphia

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1780–1808) Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The destabilization of the medial meniscus (DMM) model is widely used in murine OA research due to its reproducibility and ability to recapitulate key features of human disease, particularly in the central weight-bearing regions of the medial tibial plateau and femoral condyle. While the role of the gut microbiome in OA pathogenesis is increasingly recognized, with mounting evidence linking gut dysbiosis to musculoskeletal outcomes, the impact of DMM-induced OA on the gut microbiota-and whether similar shifts occur following sham surgery-remains insufficiently characterized. This study addresses this gap by systematically evaluating gut microbiome changes following DMM and sham interventions in mice.

Methods: Male (N = 59) and female (N = 14) B6 mice underwent either DMM or sham surgery (skin, fascia, and joint capsule opened but no meniscus transection) at 12 weeks of age. Biological samples in the form of cecal contents were collected at 4 weeks, 8 weeks, and 12 weeks after surgical intervention. Bacterial DNA was isolated from these samples and subjected to 16S rRNA gene sequencing using an Illumina MiSeq sequencer. The obtained data were analyzed using the Qiime2 workflow. Group comparisons were determined using LEfSe analysis, with a 95% confidence interval after taxonomic assignment by alignment to the Greengenes2 dataset. Differences among bacterial groups were assessed using the Mann-Whitney U test.

Results: In a comparison between DMM and Sham samples, data reveals shift in microbiota composition. Specifically, the Sham group exhibited significant enrichments ($p < 0.005$) in Clostridia_258483 (Christensenellales, CAG_552), Oscillospirales ($p < 0.002$) including Acutalibacteraceae, Oscillospiraceae_88309, and Ruminococcaceae, as well as TANB77

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1: Differential microbiome clades between DMM and sham surgery

(CAG_508) and Bacilli (RF39, Turicibacter). Conversely, the DMM group showed significant enrichments in Oscillospirales ($p< 0.002$) including Oscillospiraceae_88309 and Ruminococcaceae, TANB77 ($p< 0.05$) including CAG_508, and Bacilli ($p< 0.05$) including RF39 and UBA660. Additional comparisons revealed that DMM vs Control groups showed significant increases in Bacteroidota ($p< 0.002$) including Bacteroidia, Rikenellaceae, and Muribaculaceae, Oscillospirales ($p< 0.002$) including Acutalibacteraceae, and Bacilli ($p< 0.05$) (Erysipelotrichales and Coprobacillaceae), while no significant differences were observed between Sham and Control mice.

Conclusion: Our data underscore a modulatory role for the gut microbiota in OA progression while confirming that brief surgical trauma alone does not perturb the intestinal microbial community. Mapping these gut–joint interactions may unveil novel microbiome-targeted strategies for OA treatment. Ongoing and future work to dissect the mechanistic links and long-term effects of dysbiosis will be critical to advancing our understanding of OA pathogenesis and guiding precision therapies.

Background/Purpose: Knee joints are densely innervated by sensory neurons, predominantly nociceptors. Knowledge about innervation of healthy human synovium and the changes that accompany osteoarthritis (OA) is limited. Very few studies described innervation changes in select areas of synovium collected at total knee arthroplasty (1-3). Here, we sought to perform a comprehensive analysis of the sensory innervation of the synovium of healthy human knees.

Methods: Leveraging the availability of non-OA *postmortem* knee samples from human donors of different ages, we collected synovia from 4 males, ages 23, 42, 52 and 81, all from knees where cartilage was scored as grade 1-1.5 on the Modified Outerbridge classification. For each donor, a total of 18 tissue blocks were collected from 18 distinct synovial locations in the knee **Fig. 1**. These areas are medial (area 1,2) and lateral (area 5,6) femoral gutters, medial and lateral perimeniscal synovium (MMS M, MMS L) and anterior synovium (areas 3,4,7,8), the synovium covering the anterior cruciate ligament (ACL) and posterior cruciate ligament (PCL), medial and lateral suprapatellar compartments (SPC M, SPC L), medial and lateral parapatellar recess (PPR M, PPR L), posterior synovium (Post syn), and suprapatellar fat pad (SPFP). Tissues were formalin fixed, paraffin embedded and shipped from Scripps to Rush. Five-mm sections were stained with hematoxylin and eosin (H&E) and sent to the Hospital for Special Surgery for synovial scoring. Adjacent sections were used for immunohistochemical staining with the pan-neuronal marker, PGP9.5 (Abcam ab27053, 1:200), endothelial cell markers (CD31, Abcam Ab28364, 1:50), calcitonin gene related peptide (CGRP, immunostar 24112,1:500) or isotype control (Rabbit IgG, Abcam Ab172730, 1μg/ml). Proteinase K was used for antigen retrieval. Sections were incubated with primary antibody at 4°C overnight, stained with biotin-streptavidin/HRP and DAB chromogen, and counterstained with methyl green. PGP9.5+ and CGRP+ signal was quantified in adipose and fibrous areas of synovium using Qupath by 2 blinded observers.

Results: In all 18 regions, PGP9.5+ innervation was denser in the adipose rich areas compared to the fibrous areas. PGP9.5+ nerve signal was abundant in the synovium of medial and lateral femoral gutters, medial and lateral suprapatellar compartment, anterior synovium and synovium of the suprapatellar fat pad. PGP9.5+ nerves were more abundant in the medial synovium of the 81yr-old compared to younger donors **Fig. 2**. PGP9.5 innervation of SPFP and anterior and lateral perimeniscal synovium declined with age but increased in the lateral femoral gutters. Further characterization of the synovial samples, including CD31 staining for blood vessels is ongoing.

Conclusion: PGP9.5+ nerve fibers were abundant in medial, lateral and anterior synovium of non-OA male donors aged 23 to 81, but a marked heterogeneity was observed across the 18 regions. Adipose rich synovium showed more innervation compared to fibrous synovium. These findings are the foundation for future studies on describing the innervation changes in the OA synovium.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1780–1808) Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The neurotrophin, nerve growth factor (NGF), a key mediator of pain and inflammation, is increased in joints with osteoarthritis (OA). Neutralizing NGF with monoclonal antibodies has shown promising analgesic effects in painful knee OA, but clinical development was stopped owing to ill-understood side effects in the joints[1]. Knowledge about the biological effects of long-term exposure of healthy joint tissues to NGF is limited. Therefore, we aimed to explore the effects of repeated intra-articular (IA) injections of NGF into the knee joints of healthy mice on sensitization and pain, as well as joint innervation and structure.

Methods: All animal experiments were IACUC approved. Five experiments were conducted, all using 12-week old naïve male mice. In Experiment 1, NGF (50 ng or 500 ng in 5 uL, n=5 mice/group) or vehicle control (0.1% BSA in PBS, n=5 mice) was injected IA into the right knee joint of wildtype (WT) C57BL/6 mice, twice a week for 4 weeks. We assessed knee

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

swelling and knee hyperalgesia as described[2], as well as joint histopathology. Synovial changes including hyperplasia, cellularity and fibrosis were assessed by four different scorers blinded to treatment groups[3]. In Experiment 2, mice were injected with NGF (500ng) or vehicle, twice a week for 4 weeks and microCT of the knee was performed. In Experiment 3, $Na_V1.8$-tdTomato reporter mice were injected with NGF (500ng) or vehicle, twice a week for 4 weeks, and joint innervation was assessed[4]. In Experiment 4, WT mice received 500ng NGF or vehicle twice a week for 4 weeks and were used for single cell RNA sequencing (scRNAseq) of the synovium. In Experiment 5, L3-L5 DRGs were collected from mice that received 3 IA injections of 500ng NGF or vehicle twice a week for 10 days and processed for bulk RNA sequencing.

Results: Repeated bi-weekly IA injections of both doses of NGF caused knee hyperalgesia in naïve mice **(Fig. 1A)**. NGF caused dose-dependent knee swelling **(Fig. 1B)**, synovial pathology **(Fig. 1C)**, increased bone mineral density and trabecular bone thickness in the medial subchondral bone. NGF also caused osteophyte growth in the medial compartment, but no cartilage degeneration **(Fig. 1D)**. NGF injection caused sprouting of $Na_V1.8$+ neurons in the medial but not the lateral synovium **(Fig. 1E)**. ScRNAseq of the synovium revealed upregulated genes related to neuronal sprouting, synovial fibrosis and ossification, confirming histopathological findings **(Fig. 2)**. Bulk RNA seq of DRG showed upregulated pathways related to axonal growth **(Fig. 3)**.

Conclusion: In healthy mouse knees, NGF induced mechanical sensitization, synovitis, neoinnervation in the medial synovium, and subchondral bone changes and osteophyte growth in the medial compartment, thus capturing many pathological changes observed in OA, except cartilage damage. It will be critical to describe in great depth the distribution of NGF and its receptors in all joint tissues, and how they change with age and disease. Such insights are

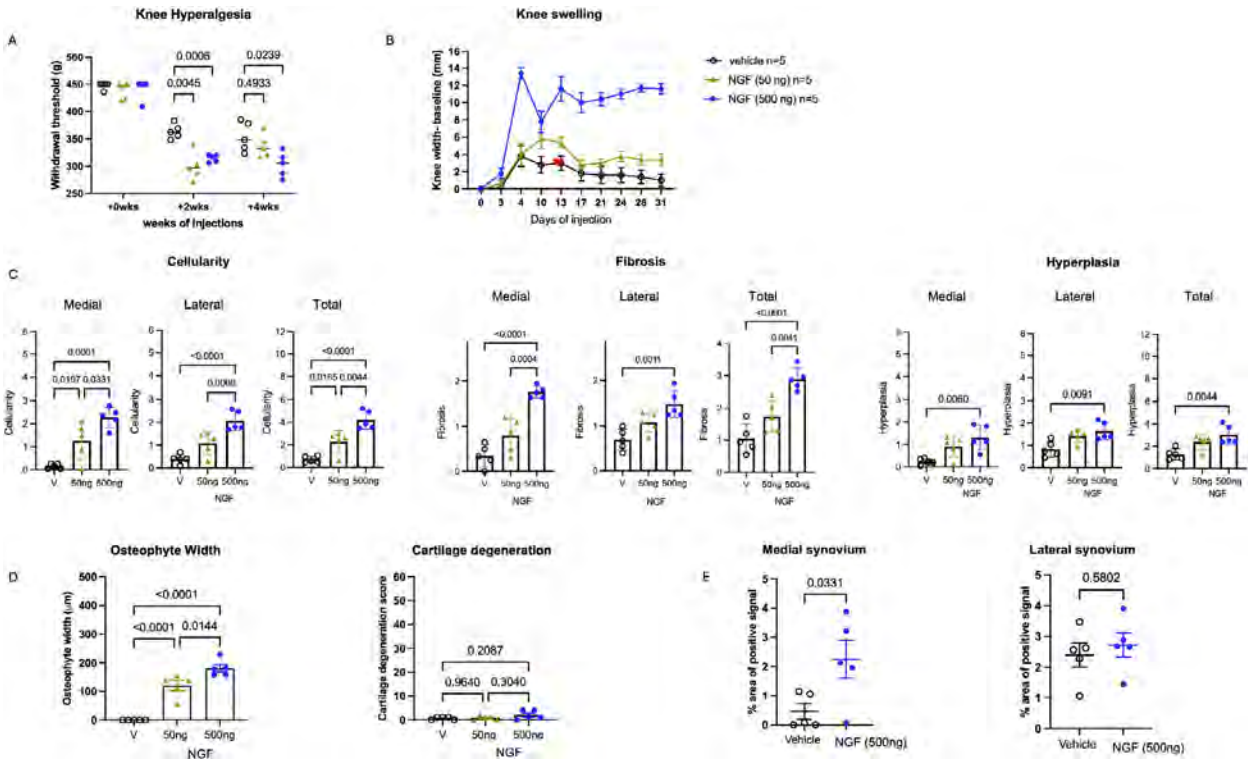

Figure 1: (A) Knee hyperalgesia was assessed for mice given repeated intra-articular injections of recombinant murine NGF (i.a. 50 ng or 500 ng, 5 µL, 2x/week) or vehicle (5 µL, 2x/week) for 4 weeks at 0-, 2, and 4-week (B) Knee swelling was assessed in wild-type mice given NGF (50 ng or 500 ng) or vehicle. Red arrowhead indicates the first injection. (C) Synovial cellularity, fibrosis and hyperplasia were evaluated in wild-type mice that received NGF at 50 ng or 500 ng or vehicle. (D) Osteophyte width measured in µm and cartilage degeneration scores. (E) Quantification of neuronal signal in the medial and lateral synovium of NaV1.8-tdTomato mice injected with vehicle or NGF. (A) Two-way ANOVA with Dunnett's post-test. (C-D) Two-way ANOVA with Sidak's post-test. (E) Unpaired two-tailed t test.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1780–1808) Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Bone toxicity during drug development can arise from intended pharmacologic mechanisms or off-target effects. Standard histopathological evaluation often fails to detect early skeletal alterations, especially in short-term studies. Early detection is crucial for mitigating risks in compounds affecting skeletal remodeling, growth, or maintenance.

Methods: Data was compiled from naïve Sprague-Dawley rats typically used in early exploratory and chronic toxicity studies. Naïve male Sprague-Dawley rats were treated with prednisolone (7.5 mg/kg/day) for 14 or 28 days. Bone mineral density (BMD) was measured using dual-energy X-ray absorptiometry (DXA), and microCT analysis assessed trabecular microarchitecture. Serum biomarkers related to bone turnover were also evaluated.

Results: Prednisolone treatment significantly reduced femoral BMD in the 28-day group, with a decreasing trend in the 14-day group. MicroCT showed compromised trabecular microarchitecture with decreased thickness and increased separation. Histology revealed thinning of the physis, indicating impaired growth. Serum biomarkers such as P1NP, osteocalcin, and CTX-1 showed reduced bone formation and resorption.

Conclusion: Integrating serum biomarkers and imaging assays with routine histopathology improves detection and characterization of skeletal toxicity. This multimodal approach enhances nonclinical safety assessments' sensitivity and supports including bone-specific endpoints in early toxicology studies.

Soluble CD14 Amplifies Chondrocyte Inflammatory Responses to Lipopolysaccharide and Is Targetable by Anti-CD14 Therapy

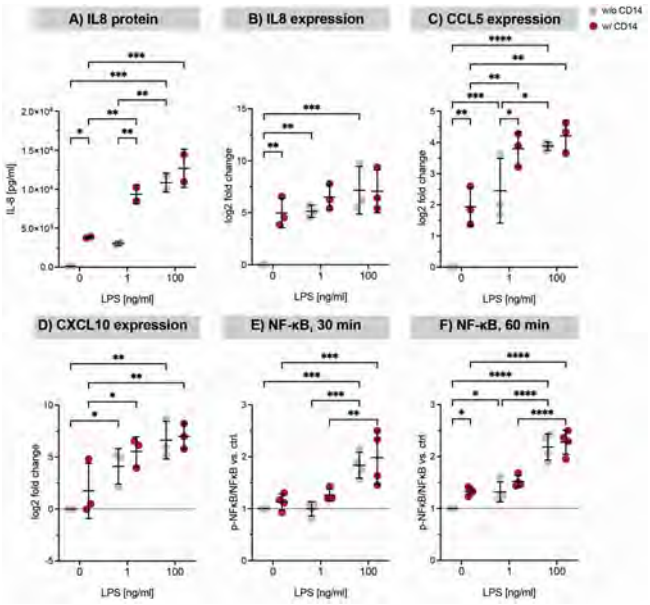
Anna Rapp[1], Kate Sharp[1], Baofeng Hu[2] and Carla Scanzello[1], [1]University of Pennsylvania, Philadelphia, PA, [2]University of Pennsylvania, Wynnewood, PA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1780–1808) Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

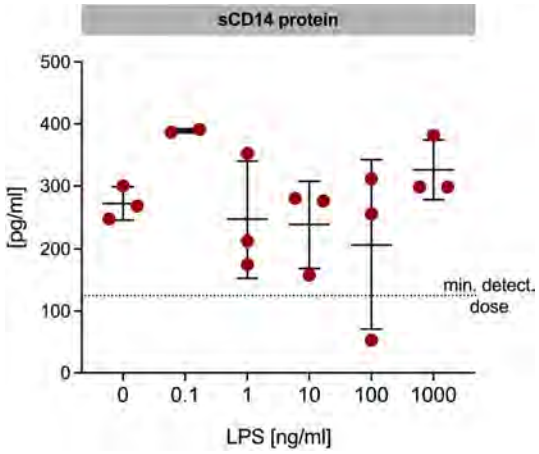
Background/Purpose: Osteoarthritis (OA) is characterized by a pro-inflammatory joint microenvironment, including elevated levels of endogenous pattern recognition receptor ligands in synovial fluid. Notably, both lipopolysaccharide (LPS) and its soluble co-receptor, soluble CD14 (sCD14), are increased in OA synovial fluid, and sCD14 levels correlate with disease severity. sCD14 facilitates LPS transfer to Toll-like receptor 4 (TLR4), potentiating immune responses to otherwise sub-threshold ligand levels. Although this mechanism has been demonstrated in myeloid cells and synovial fibroblasts, whether sCD14 can enhance LPS-driven inflammatory activation of human chondrocytes, at the low levels found in OA joints, remains unclear.

Methods: Primary human articular chondrocytes (hACs) were isolated from non-arthritic knee cartilage (obtained through the National Disease Research Interchange) and treated with LPS at OA-relevant (1 ng/mL) or supraphysiologic (100 ng/mL) concentrations, with or without sCD14 (2 μg/mL). NF-κB activation was assessed via Western blot, inflammatory gene expression by qPCR, and IL-8 and sCD14 secretion by ELISA (n=2–4). To assess CD14 dependency of the responses, C28/I2 chondrocytes (Merck) were treated with anti-CD14 antibody in parallel experiments.

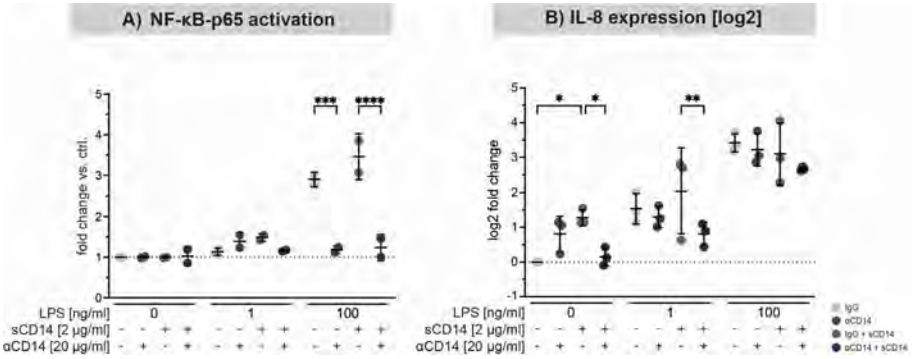


hAC were stimulated with 1 and 100 ng/ml LPS with and without 2 μg/ml sCD14. A) IL-8 secretion was determined by ELISA. Expression of B) IL-8, D) CCL5, and E) CXCL10 were determined by qPCR. Activation of NFkB-p65 was measured by western blot after E) 30 and F) 60 min. n= 2-4 donors, mean±SD. 2-way ANOVA and Tukey's post hoc.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



sCD14 was determined in supernatants form hAC stimulated with increasing LPS concentrations. n = 2-3 donors, mean±SD.



C28/I2 cells were stimulated with 1 and 100 ng/ml LPS±sCD14, with and without anti-CD14 (αCD14, clone 18D11). Anti-CD14 prevented A) NFκB activation by high-dose LPS independent of sCD14 (1h) and reduced the sCD14-dependent increase in B) IL-8 expression after low-dose LPS+sCD14 (24h). n= 2-3, mean±SD. 2-way ANOVA and Dunnett's multiple comparisons test.

Results: Disease-relevant concentrations of LPS (1 ng/mL) alone did not increase IL-8 secretion by hAC; however, co-treatment with sCD14 significantly elevated IL-8 protein levels compared to either condition alone (Fig. 1A). Expression of IL-8, CCL5, and CXCL10 was moderately increased with 1 ng/ml LPS, with trends toward enhancement by sCD14. In contrast, supraphysiologic LPS (100 ng/mL) induced robust inflammatory gene expression that was not further enhanced by sCD14, indicating a threshold effect (Fig. 1B-D). NF-κB activation was modestly affected by sCD14, suggesting involvement of additional signaling pathways (Fig. 1E, F). We further observed that chondrocytes did not secrete sCD14 under basal or LPS-stimulated conditions, supporting an exogenous origin of sCD14 (Fig. 2). Notably, sCD14 alone induced low-level inflammatory gene expression, suggesting it may function as a damage-associated molecular pattern in chondrocytes.

In a therapeutic approach, CD14 blockade abrogated NF-κB activation induced by high-dose LPS, regardless of sCD14 presence, but had no effect on IL-8 expression. Importantly, at the OA-relevant concentration of 1 ng/mL LPS, CD14 inhibition reversed the sCD14-mediated increase in IL-8, effectively dampening inflammation (Fig. 3A, B).

Conclusion: sCD14 enhances chondrocyte sensitivity to disease-relevant concentrations of LPS, promoting inflammatory activation in a CD14-dependent manner. These findings identify sCD14 as a potential amplifier of chondrocyte-inflammatory responses in OA and support the potential of CD14 blockade to mitigate low-grade inflammation in cartilage.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1780–1808) Osteoarthritis & Joint Biology – Basic Science Poster

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Osteoarthritis (OA) is a chronic, debilitating joint disease affecting 595 million people worldwide, including over 32 million in the United States. It is characterized by progressive degeneration of articular cartilage, most commonly in the knees, hips, and hands. Risk increases with age, joint overuse, and obesity. Despite an annual economic burden of $550 billion in the US, no FDA approved disease-modifying osteoarthritis drugs (DMOADs) are currently available. In this study, we evaluate the therapeutic potential of SEV-101, a novel exosome-based treatment, to promote hyaline cartilage regeneration in weight-bearing regions of the knee in a rat model of OA.

Methods: SEV-101 is a novel exosome therapeutic isolated from induced pluripotent stem cell (iPSC)-derived cartilage tissue. To evaluate the efficacy of SEV-101 in regenerating hyaline cartilage, the rat monosodium iodoacetate (MIA) model of OA was utilized. On Day 1, animals received a unilateral intra-articular injection of MIA in the knee (femorotibial) joint.

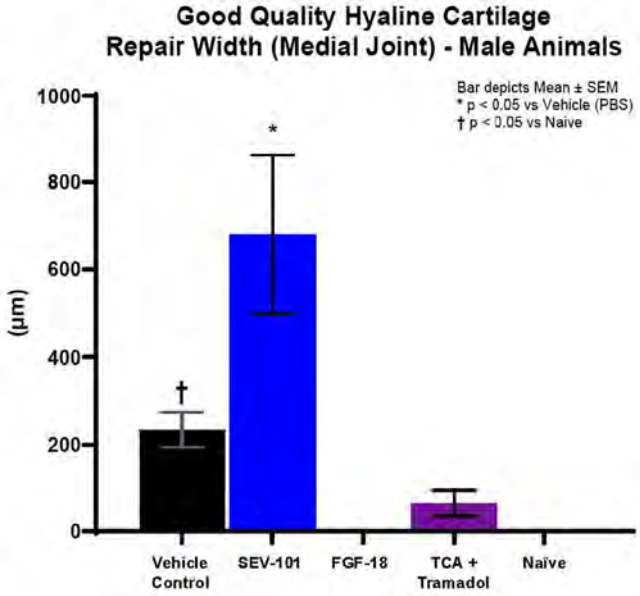

Figure 1. Good Quality Hyaline Cartilage Repair Width in the Medial (weight bearing) Knee Joint. Toluidine Blue Stained Histological sections of knee joints in male animals were assessed using the following criteria to ensure that regeneration, and not preservation was being measured: 1) the tidemark and corresponding bone/calcified cartilage had evidence of resorption, 2) the presence of proteoglycan (any degree of blue pigment) and/or chondrocytes within the intact pre-existing cartilage matrix, 3) had evidence of normal chondrocyte arrangement/maturation (does not have obvious features of fibrocartilage, such as elongate cellular morphology or streaming).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

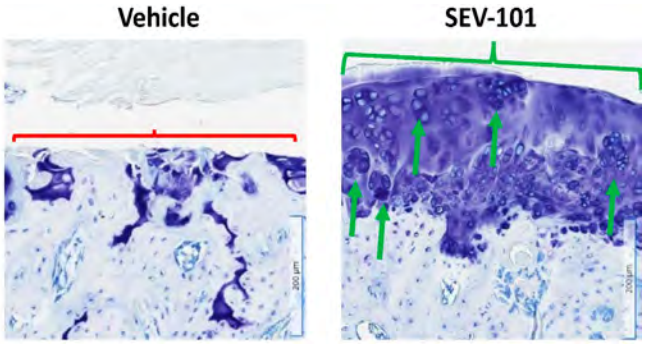

Figure 2. Histopathology of the medial compartment of male right stifle (knee) joints stained with toluidine blue. Vehicle control animals showed extensive loss of articular cartilage (red bracket delineates affected areas) with minimal regeneration of articular cartilage evident. SEV-101 treated animals showed prominent regions of articular hyaline cartilage regeneration (green bracket delineates this region and green arrows indicate chondrogenic clusters forming hyaline cartilage).

Treatment began on Day 4 and was administered once per week for 10 weeks. Animals were randomized into four treatment groups (7 males, 7 females per group) and one naïve control group (5 males, 5 females). SEV-101 was dosed at 2.2 × 10^{11} exosomes. Phosphate-buffered saline served as a vehicle control. FGF-18 was used as a positive control as it has been shown to promote cartilage regeneration. A standard-of-care positive control for pain included intra-articular triamcinolone and oral tramadol. In-life assessments included safety monitoring and Dynamic Weight Bearing (DWB) analysis. Animals were sacrificed on Day 72, and joints underwent histological evaluation, including quantitative analysis of hyaline cartilage regeneration in the medial joint compartment. Rigorous criteria included presence of tidemark and bone resorption, in addition to other measurements that ensured that the cartilage being measured was new, good quality hyaline cartilage.

Results: No safety signals were observed in SEV-101 treated rats. SEV-101 treated male rats showed a statistically significant increase in regeneration of hyaline articular cartilage in weight-bearing regions of the knee joint (designated as "good quality hyaline cartilage") compared to all other treatment groups. In addition, SEV-101 treated male rats showed more intact meniscus structure and more Type 2 Collagen immunohistochemical staining compared to vehicle controls. There was no significant difference in DWB vehicle controls and SEV-101 treated animals.

Conclusion: SEV-101 promoted the regeneration of new hyaline cartilage rather than merely preserving existing cartilage. Additionally, SEV-101-treated animals exhibited improved meniscal integrity and increased Type II Collagen staining relative to vehicle controls. These findings support SEV-101's capacity to regenerate cartilage in weight-bearing regions of the joint and to confer structural protection, reducing the risk of further degeneration. Collectively, these data strongly support the continued development of SEV-101 as a DMOAD.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1780–1808) Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Although not part of the formal ACR criteria for RA, PsA, or OA, synovial pathology can be a helpful tool in clinical practice. Histopathologic evaluation in RA has led to the development of a synovitis score and a joint pathology algorithm. Three synovial pathotypes—lympho-myeloid, diffuse-myeloid, and pauci-immune—have been described, but are based on a limited number of markers and currently provide limited clinical information. Recent advances allow for minimally invasive synovial biopsies and multiplex microscopy to provide mechanistic insights into tissue pathology. This is especially relevant as targeted therapies for OA are still lacking. Artificial intelligence (AI) enables detailed image analysis, preserving spatial context, allowing for single-cell quantification and identification of cellular interactions that may inform therapy and predict response. Our objective was to apply a novel high-plex IF platform coupled with a semi-automated image analysis approach using machine learning algorithms to characterize synovial inflammatory infiltrates in patients with PsA, RA, and OA

Methods: FFPE synovial tissue biopsies from nine patients from patients with RA (n=5), OA (n=2), and PsA (n=2) were stained with a 17-marker IF panel targeting nuclei, CD31, CD68, CD163, CD20, CD4, CD8a, CD45RO, PD-L1, CD3e, Ki-67, PD-1, FOXP3, CD45, Pan-CK, vimentin, and SMA. Some RA and PsA samples had prior classification (lymphoid or lympho-myeloid) based on conventional IF/IHC staining. Whole sections were scanned at 20x using the Orion platform.A semi-automated AI pipeline originally developed for pancreatic tissue was adapted to synovial tissue. Regions of interest (ROIs, lining and sublining) were selected. Cell classification was based on fluorescence intensity and morphology. Spatial context and cellular neighborhoods were also analyzed using unsupervised clustering algorithms

Results: Nine synovial biopsies from five male and five female (mean age 59.1 years, SD10.1) with a total of 105,364 cells across 130 ROIs were analyzed over 23.7 mm^2 of tissue. Cellular density was higher in the lining (mean 10,461 cells/mm^2) than in the sublining (mean 5,017 cells/mm^2). As expected, OA showed fewer immune cells, fibroblasts, and vessels than RA and PsA. Macrophage and fibroblast predominance was observed across all samples, especially in immune-mediated arthritis. In RA, T cell infiltration was more abundant in the sublining, and proportions of T cell subsets were similar across knees and wrists. Distinct cellular clusters were identified in the unsupervised analysis, differentiating between diseases

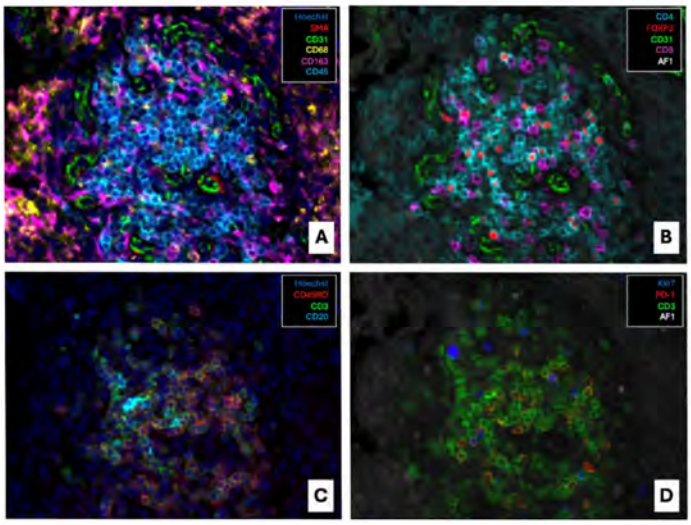

Figure 1: Synovial tissue biopsy from knee of a patient with PsA. A, B, C, D show different combinations of markers to visualize different immune infiltrates within the same tissue region. A high level of definition for different immune cell types is displayed in the images acquired at 20x with Orion slide scanner. **A.** Macrophages (magenta & yellow) surround a lymphocyte cluster (cyan), CD31 highlights endothelium (green) surrounded by SMA (red). **B.** Nuclear FOXP3 (Treg, red) is expressed by a subset of CD4+ T cells. **C.** A subset of T cells display memory phenotype (CD45RO (red) is visualized in yellow/orange after combining with CD3 (green)), B cells (cyan) present in lymphoid cluster. **D.** A subset of T cells co-express PD-1 (red), proliferating cells (Ki67+, blue nuclei)

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: These preliminary findings support the suitability of this new high-plex microscopy technology and AI-driven image analysis in assessing synovial inflammation. Despite limited tissue, we achieved robust, high-resolution profiling of thousands of cells. We envision that this type of data may help create algorithms in joint pathology to further aid in patient management. Novel platforms currently restricted to research can be incorporated into the clinical arena to serve as a diagnostic tool as well as a personalized treatment tool based on a patient's specific histological characteristics

Abstract Number: 1788

Manganese-associated Single-nucleotide Polymorphisms are Associated with Radiographic Knee Osteoarthritis: The Johnston County Osteoarthritis Project

Griffin Sonaty[1], Carolina Alvarez[2], Liubov Arbeeva[3], Joanne Jordan[1], Brian Diekman[4], Doug Phanstiel[1], Richard Loeser[5] and Amanda Nelson[1], [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]University of North Carolina at Chapel Hill, Miami, FL, [3]University of North Carolina, Chapel Hill, Carrboro, NC, [4]Univesity of North Carolina at Chapel Hill, Chapel Hill, NC, [5]University of North Carolina, Chapel Hill, NC

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1780–1808) Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Trace elements may be differentially associated with osteoarthritis (OA) risk. Single-nucleotide polymorphisms (SNPs) have been found to correlate to cumulative exposure level, free of temporal effects. The purpose of this study was to identify whether SNPs known to be associated with the body concentration of certain trace elements were associated with OA development in a prospective cohort and then explore functional consequences (Figure 1).

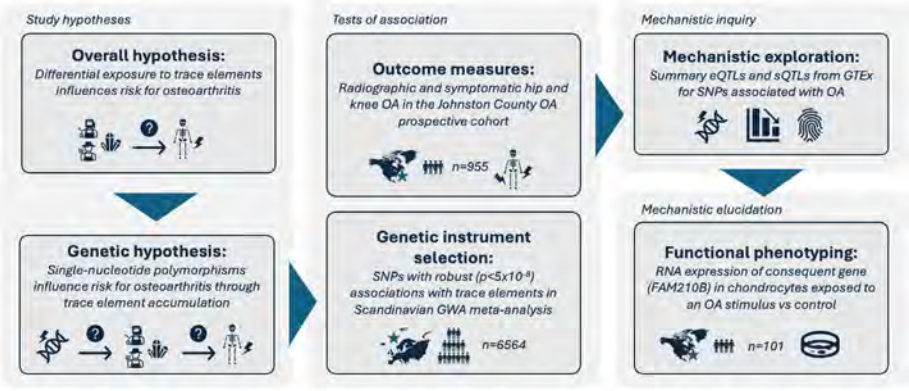

Figure 1. Study overview from conception to mechanistic elucidation in four stages: hypothesis generation, tests of association with primary outcome and genetic instruments, exploration of genetic consequences (expression and splicing quantitative trait loci, eQTL and sQTL, respectively) from a large database (Adult Genotype Tissue Expression Project, GTEx), and functional outcomes on consequent genes in an OA chondrocyte model. GWA, genome-wide association; OA, osteoarthritis; SNP, single-nucleotide polymorphism.

Methods: This was a cross-sectional analysis from the second follow-up visit (2006-11) of the Johnston County Osteoarthritis Project, a prospective population-based cohort designed to evaluate risk factors for development of OA. This analysis was limited to White participants with toenail metals data, as exposure SNPs were selected from those with robust ($p < 5x10^{-8}$) associations with trace element body concentration in a Scandinavian population (PMID: 38594418). Radiographic knee (rKOA) and hip (rHOA) OA were defined by Kellgren-Lawrence (K/L) grade ≥ 2 on bilateral posteroanterior knee or hip radiograph, respectively, at any point throughout follow-up. Symptomatic OA (sOA) consisted of radiographic OA with pain in the same joint. Linear regression of each SNP variant with natural log-transformed toenail metal concentrations was assessed before performing logistic regression for OA outcomes and each SNP, metal, and their interaction as predictors, providing odds ratio [OR]; 95% confidence interval [CI]) if interaction p-value< 0.1. Each model was adjusted for age, sex, body mass index (BMI), smoking, and alcohol use. A functional study was then conducted for a novel impacted gene (FAM210B) in a previously described chondrocyte OA model (PMID: 33248223).

Results: Among 955 White adults (mean age 66 ± 11, mean BMI 30 ± 6 kg/m^2, 38% male), 42% had rKOA and 30% had rHOA. There were no associations between toenail metal concentrations of selenium, mercury, chromium, scandium, zinc, iron, or cadmium with selected SNPs. However, SNPs previously linked to decreased manganese concentration including *rs6099115* and *rs855791* were associated with rOA, but not sOA. In multivariable regression, both heterozygous and

Table 1. Adjusted associations, odds ratio (95% CI), between SNPs and OA outcomes.

	Outcome			
SNPs	*Knee rOA*	*Hip rOA*	*Knee SOA*	*Hip SOA*
rs6099115				
homozygous unaffected	1 (reference)	1 (reference)	1 (reference)	1 (reference)
heterozygous	**2.66 (1.01, 7.05)**	0.96 (0.40, 2.29)	1.28 (0.43, 3.77)	1.04 (0.29, 3.77)
homozygous affected	**3.05 (1.18, 7.90)**	0.95 (0.41, 2.20)	1.61 (0.63, 5.18)	1.11 (0.32, 3.87)
rs855791				
homozygous unaffected	1 (reference)	1 (reference)	1 (reference)	1 (reference)
heterozygous	0.72 (0.49, 1.05)	1.01 (0.69, 1.49)	0.71 (0.47, 1.07)	0.70 (0.40, 1.22)
homozygous affected	0.73 (0.48, 1.10)	1.27 (0.83, 1.92)	0.87 (0.56, 1.35)	1.21 (0.68, 2.13)

Logistic regression modeling log odds of OA outcome and its association with each SNP variant and toenail metal. Shown **BOLD** when significant at 0.05 level. Each model includes covariables for age, sex, BMI, past/current smoking, alcohol use, and SNP variant. rOA, radiographic osteoarthritis; SOA, symptomatic osteoarthritis; SNP, single-nucleotide polymorphism.

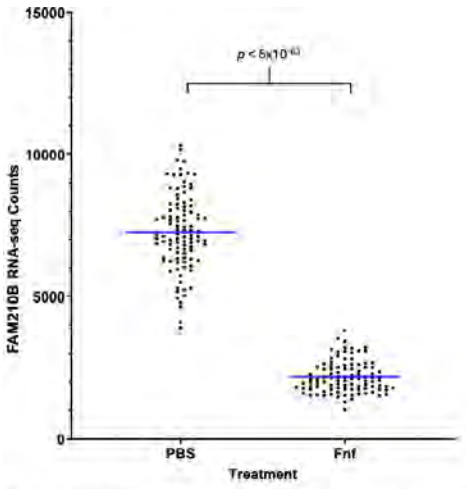

Figure 2. FAM210B expression is significantly decreased in chondrocytes responding to an OA stimulus. RNA-sequence counts of FAM210B in paired donor chondrocytes treated with fibronectin fragments (Fnf) [OA model] vs phosphate-buffered saline (PBS) [control].

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

homozygous variants of *rs6099115* were associated with increased odds of rKOA (OR 2.66; 95% CI 1.01, 7.05 and 3.05; 1.18, 7.90, respectively, Table 1). Homozygous affected variant *rs855791* was associated with increased odds of rKOA only when toenail levels of chromium or iron were increased (OR 1.62; 1.13, 2.31, and 1.53; 1.07, 2.18, respectively). Variants in *rs855791* result in missense mutations in transmembrane protease serine 6 (TMPRSS6), involved in extracellular matrix degradation and hepcidin regulation. Variants in *rs6099115* result in missense mutations of FAM210B, a mitochondrial membrane transporter involved in cellular response to iron, estradiol, and cell differentiation. In a chondrocyte OA model, FAM210B expression was decreased by 69.2%, $p < 5x10^{-63}$ (Figure 2).

Conclusion: Two novel associations were identified, linking risk of rOA with SNPs known to be associated with decreased manganese concentrations, with functional consequences in FAM210B. Further investigation in the roles of FAM210B and TMPRSS6 in the pathogenesis of OA is needed.

Spatial Analysis of Advanced Osteoarthritis Synovial Tissue

jacob Dickman[1], Stephanie Ruzicka[1], Holub Meaghan[2], Jutras Brandon[3], Adam Edelstein[3] and Robert Lochhead[4], [1]Medical College of Wisconsin, Milwaukee, WI, [2]Central Michigan University College of Medicine, Mount Pleasant, MI, [3]Northwestern University, Chicago, IL, [4]Medical College of Wisconsin, GERMANTOWN, WI

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1780–1808) Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Osteoarthritis (OA) is a joint pathology involving joint cartilage destruction and synovial inflammation. Severe knee OA is often surgically treated with total knee arthroplasty (TKA) joint replacement. Approximately 20% of patients experience continued pain and dysfunction postoperatively, but no predictors of outcome are known. We previously reported that bacterial peptidoglycan (PG) is associated with increased synovitis and elevated IL-6. However, PG did not correlate with patient reported outcomes (PRO) post-TKA, indicating other immune mediators may be contributing to surgical outcome. We therefore used highly multiplexed cell imaging to identify cell-cell interactions associated with incomplete responses to surgery and other disease features.

Table 1: Patient Data.

Patient Diagnosis (sample n)	Median Age (min – max)	Median BMI	KOOS JR Pre-operative Average (St. Dev)	KOOS JR 12 months post-TKA Average (St. Dev)
Osteoarthritis (OA) (20)	67 (52-85)	31.8	39.9 (15.6)	79.5 (13.0)
Inflammatory Arthritis (2)	29 (29-48)	22.9	41.9 (15.0)	75.0 (35.3)
Revision due to Infection (1)	NA	NA	NA	NA
All Patients (23)	66 (29-85)	31.6	40.1 (15.2)	79.0 (15.1)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Discarded synovial tissue (ST) were collected from 23 patients undergoing primary TKA, 20 (87%) of which met ACR criteria for knee OA (Table 1). Knee Osteoarthritis Outcome Score – Joint Replacement (KOOS JR) PRO were collected at pre-operative and 3-, 6-, and 12-month post-operative time points. Multiplexed immunofluorescence microscopy (Akoya Biosciences) was used to identify T cells (CD3, CD4, CD8), antigen presenting cells (HLA-DR, CD11c), endothelial cells (CD31), plasma cells (CD138), and stromal cells (CD90, CD34) in synovial tissue. Cell-cell distance was calculated to infer cell interaction using the Scimap Python package. For the patients with advanced knee OA, associations between spatial

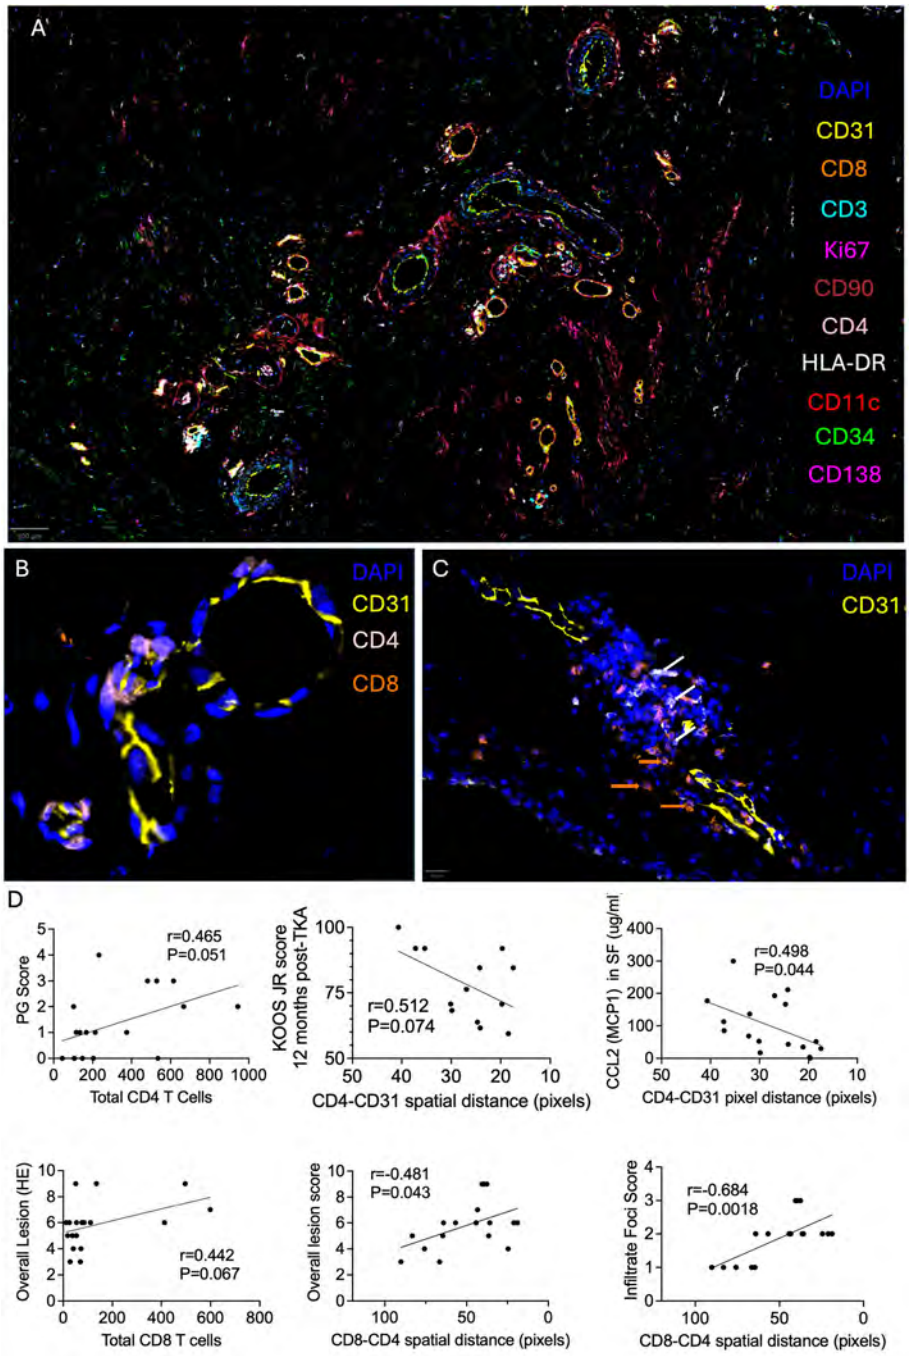

Figure 1. Spatial imaging analysis of advanced OA synovial tissue. (A) Representative images are shown of OA synovial tissue is shown using cell markers indicated in figure; (B) a representative image of CD4 T cells in close proximity to CD31+ endothelial cells; (C) and a representative image of typical inflammatory foci containing CD4 and CD8 T cells. (D) Associations between total T cell numbers and cell-cell spatial distances with disease features. Pearson's R and P values are indicated in figure. For spatial distance analyses, only OA synovial tissue were included, and spatial distance is shown in pixels (1 pixel≅2 μm).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. imaging data and disease features, including PRO scores, were determined by calculating Pearson's r correlation coefficients using Prism software (v.10).

Results: Patient synovitis was highly variable, consisting of infiltrate-rich inflammatory foci and/or regions of vascular inflammation and fibrosis (Fig 1A). Vascular lesions typically contained CD4+ T cells near CD31+ endothelial cells (Fig 1B). Inflammatory foci were enriched in both CD4+ T cells and CD8+ T cells (Fig 1C). Total CD4+ T cells correlated with PG in tissue, whereas total CD8+ T cells correlated with overall synovial lesion score (Fig 1D). CD4-CD31 spatial distance tended to be shortest in patients with low/variable PRO score 12 months post-TKA (Pearson's r=0.512, P=0.074), whereas CD8-CD4 spatial distance was associated with inflammatory synovitis.

Conclusion: Spatial imaging of advanced OA ST revealed an important role in T cells in contributing to synovitis. In our cohort, average distances between CD4+ T-helper cells and CD31+ endothelial cells in ST at time of surgery correlated with low 12-month PRO score, suggesting that vascular inflammation in OA synovitis may contribute to poor or variable long-term outcome post-TKA.

Targeted Ablation of Knee-innervating Nociceptors Attenuates Pain and Cartilage Degeneration in Experimental Osteoarthritis

Lai Wang[1], alia obeidat[2], Shingo Ishihara[3], Jun Li[2], Frank Ko[2], Terese Geraghty[2], Natalie Adamczyk[3], Sarah Soorya[2], Richard Miller[4], Rachel Miller[1] and Anne-Marie Malfait[2], [1]Rush University Medical Center, Chicago, IL, [2]Rush University Medical Center, Chicago, [3]Rush University, Chicago, [4]Northwestern University, Chicago

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1780–1808) Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Nociceptors abundantly innervate the knee joint. In experimental osteoarthritis (OA), nociceptors sprout in the medial synovium and in subchondral bone channels. We aimed to determine the effect of selective ablation of knee-innervating nociceptors in murine OA.

Methods: Adeno-associated virus AAV.PHP.S carrying diphtheria toxin A (dtA) (AAV-dtA) or control AAV (AAV-Ctrl) was injected intra-articularly (i.a.) into the knee cavity of 7-week old male $Na_V1.8$-Cre mice. Destabilization of the medial meniscus (DMM) or sham surgery were performed 3 weeks later. Pain-related behaviors (weight bearing and knee hyperalgesia) were assessed up to 16 weeks after surgery. Knee joints were collected for histology, microCT, innervation analysis, and protein antibody array. Lumbar dorsal root ganglia (DRG) were collected for immunofluorescence staining or qPCR analysis.

Results: Injection of AAV-dtA effectively ablated joint nociceptors. This had no effect on knee hyperalgesia but attenuated weight bearing deficits (Fig. 1A-B), with decreased *Ccl2* in DRG (Fig. 1C). AAV-dtA administration suppressed nociceptor sprouting in subchondral bone channels (Fig. 1D), but not in the medial synovium (Fig. 1E). Marked cartilage damage observed in AAV-Ctrl injected joints was attenuated in AAV-dtA injected mice (Fig. 2A), while synovitis, osteophytes, and microCT of the subchondral bone were similar in both groups. Knee joint lysates showed lower levels of calcitonin gene-

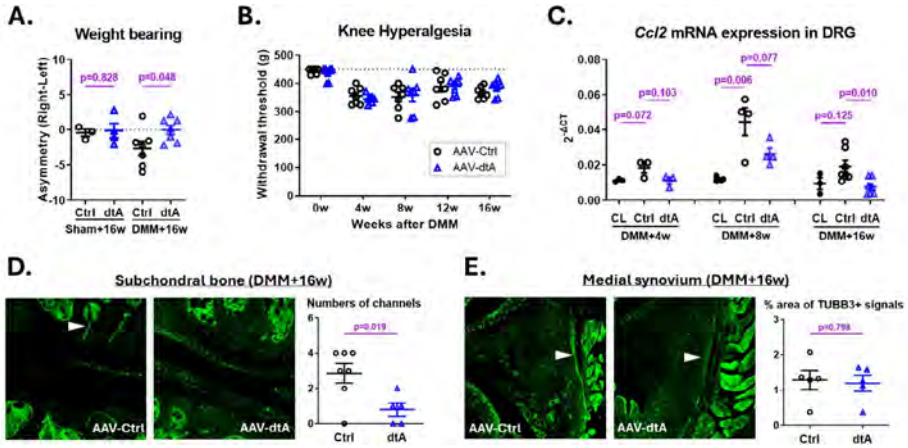

Fig. 1. Pain behavioral tests and knee joint innervation analysis in DMM mice with IA NaV1.8+ neuron ablation. (A) Weight bearing tests. (B) Knee hyperalgesia tests. (C) Expression of pro-algesic Ccl2 mRNA in ipsilateral L3-L5 DRG. (D, E) Nerve sprouting in subchondral bone (D) and medial synovium (E) was analyzed with IF staining of a pan-neuronal marker TUBB3.

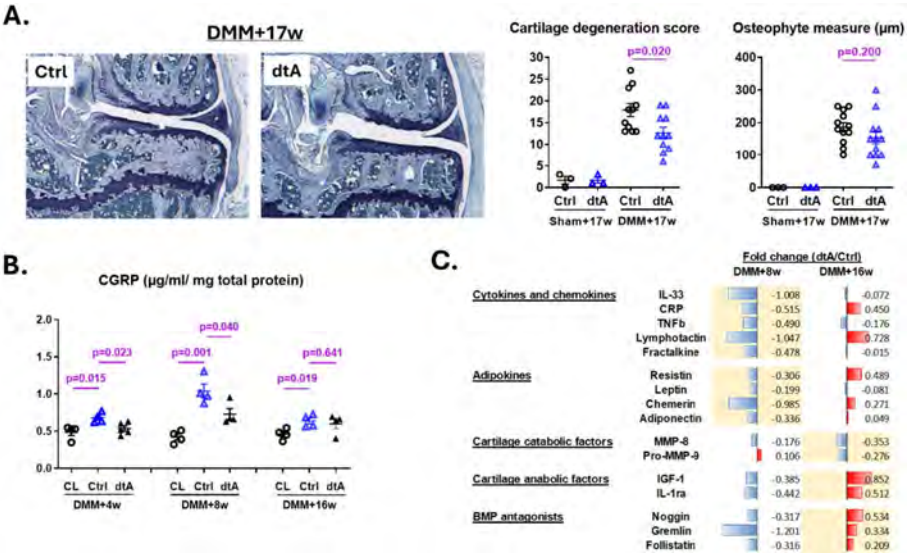

Fig. 2. Knee joint histopathological analysis and joint lysate protein analysis of DMM mice with intra-articular NaV1.8+ neuron ablation. (A) Representative images of medial compartments of mouse knee sections stained with toluidine blue. Cartilage degeneration and osteophyte formation were evaluated using a modified OARSI scoring system. (B) ELISA assay of CGRP protein in DMM knee joint lysates. (C) Antibody arrays of DMM knee joint lysates (Quantibody® Mouse Cytokine Antibody Array, RayBiotech).

related peptide (CGRP) 4 and 8 weeks after DMM in AAV-dtA injected mice (Fig. 2B), as well as decreased pro-inflammatory factors 8 weeks after DMM and increased levels of cartilage-anabolic markers 16 weeks after DMM (Fig. 2C). CGRP+ neurons were also decreased in ipsilateral lumbar DRGs, along with reduced $Na_V1.8$+ neurons after ablation.

Conclusion: Knee-innervating nociceptor ablation before DMM attenuated weight bearing asymmetry, subchondral bone nerve sprouting, and cartilage degeneration. Cartilage anabolic factors were increased in the joints, while CGRP levels were decreased. The neurogenic contribution to OA may result from the neuropeptides released from nerve endings in early stages of OA.

Session Date: Tuesday, October 28, 2025

Session Title: (1780–1808) Osteoarthritis & Joint Biology – Basic Science Poster

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Osteoarthritis (OA) is a debilitating disease affecting ~54% of US adults 75 and older. Toll-like receptor 4 (TLR4), and its co-receptor CD14, have been implicated in disease severity and progression. CD14 sensitizes TLR4 to low concentrations of its ligands, including ligand lipopolysaccharide (LPS). Osteoblasts (OB) from the mesenchymal cell (MSC) lineage are not known to express significant levels of CD14 but do express TLR4. As a result, the role of CD14 on OB differentiation has not been fully elucidated. However, the response of OB to LPS has been reported to be multi-faceted and dependent on LPS concentration; the effect may be stimulatory at low concentrations and inhibitory at high concentrations. **With this, we aimed to identify the effect of CD14 deficiency on bone remodeling in a murine model of OA in vivo and characterize the effect of low-level, OA-relevant LPS stimulation in vitro**.

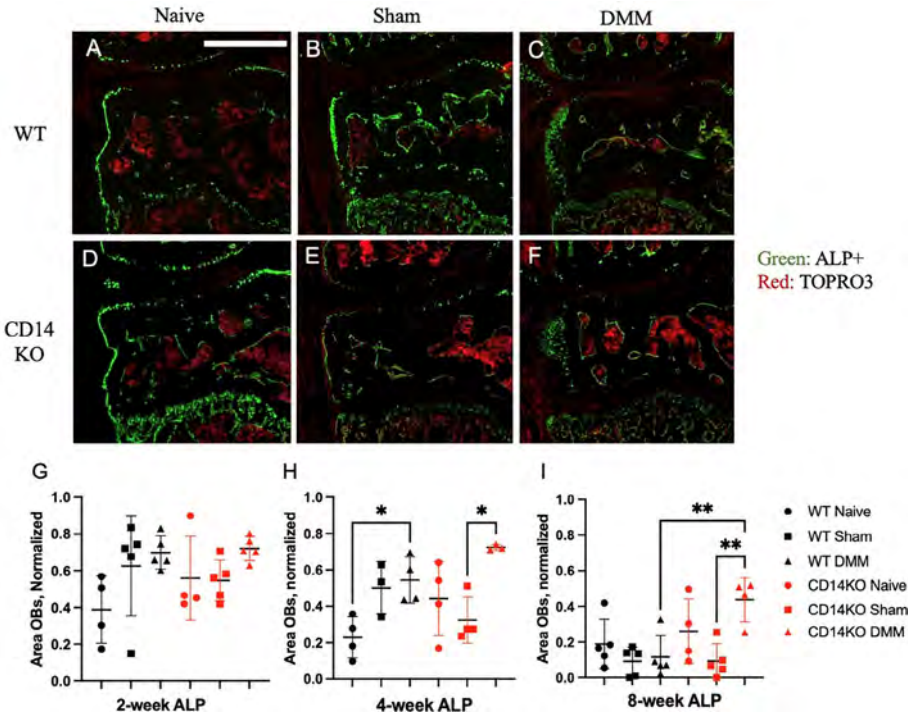

Figure 1: (A-F) Representative images of in vivo ALP activity 4-wks post-surgery. (A) WT Naïve, (B) WT Sham, (C) WT DMM, (D) CD14KO Naïve, (E) CD14KO Sham, (F) CD14KO DMM. (G, H, I) 2, 4, and 8-wk quantification of OB area in the medial subchondral bone region normalized to trabecular area. *p<0.05, scale bar = 500 μm.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

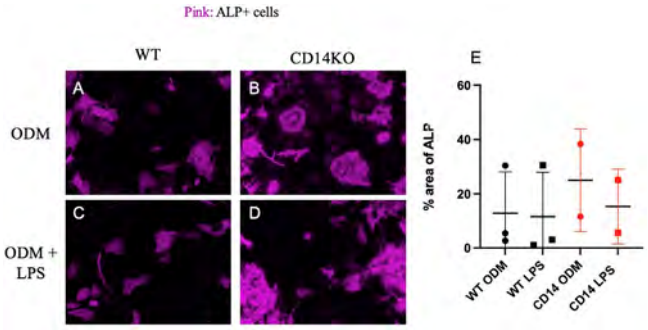

Figure 2: (A-D) Representative images of in vitro ALP activity after 14 days in cell culture imaged in the Cy5 fluorescent channel at 10x. (A) WT MSCs cultured with ODM. (B) CD14KO MSCs cultured with ODM. (C) WT MSCs treated with ODM + 1 ng/mL of LPS. (D) CD14KO MSCs treated with ODM + LPS. (E) Quantification of % area of ALP normalized by total area.

Methods: We first performed destabilization of the medial meniscus (DMM) or sham surgery on 4-5 C57BL/6 (WT) and CD14KO male mice at 12 wks of age. After 2-, 4-, and 8-wks post-surgery, the knees were processed and stained for alkaline phosphatase (ALP) using ELF 97 fluorescent substrate followed by TOPRO3 nuclear counterstaining. Area of ALP+ staining in the medial tibial subchondral area was quantified and normalized to overall trabecular area. *In vitro*, MSCs were harvested from 5-7 WT and CD14KO male mice at 12 wks of age. Upon confluency, cells were passaged and cultured for 14d with osteogenic differentiation media (ODM □ MEM + 10% FBS + ascorbic acid + □-glycerophosphate) with or without 1 ng/mL of LPS. After 14d, the cells were stained for ALP and imaged at 10x. Percent area of ALP (+) staining was quantified via Cell Profiler.

Results: Fig. 1A-F depicts representative sections from naïve, sham, and DMM-operated WT and CD14KO mice stained for ALP. At 2wks ALP activity seemed to be increased in the surgical groups of both strains,but no significance differences were observed (**Fig. 1G**) At 4wks, the area of ALP was increased in both the WT and CD14KO DMM groups compared to either naïve (WT) or sham (CD14KO) controls (**Fig 1H**). By 8 wks, there was no difference between WT DMM and WT control groups (**Fig 1I**). However, ALP+ area remained elevated in the CD14KO DMM group compared to both sham controls, and the WT DMM group (**Fig 1I**). *In vitro* staining for ALP revealed no significant difference between strains, with or without LPS both qualitatively (**Fig. 2A-D**) and quantitatively (**Fig 2E**).

Conclusion: In conclusion, our findings suggest OB density is increased in the remodeling subchondral bone post-DMM injury, and the response of WT and CD14KO mice is similar up to 4 wks. However, by 8 wks, ALP activity in WT DMM mice decreased back to baseline, but remained elevated in the DMM-injured CD14KO mice, suggesting prolonged or delayed OB-genesis in response to DMM in CD14KO mice. Thus far, our *in vitro* experiments did not reveal an inherent defect in osteoblast differentiation evaluated by ALP staining between strains, either in the presence or absence of low concentrations of LPS. Future experiments will more fully characterize the effects of LPS dosage and of related gene expression to determine whether OB differentiation or activity is altered on WT and CD14KO mice.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1780–1808) Osteoarthritis & Joint Biology – Basic Science Poster

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Mounting evidence suggests that gut microbiome shifts may be associated with knee osteoarthritis (OA) development. We have previously shown that gut microbiome transplantation from OA-resistant MRL/MpJ mice into OA-susceptible B6 mice results in robust protection against OA development. In the present study, we evaluated genus *Acomys* (African spiny mice), also previously shown to be resistant to OA.

Methods: Fresh frozen cecal content from 7 adult male spiny mice was obtained from the University of Kentucky colony (Dr. Seifert). Under sterile conditions, cecal content was diluted in 200uL of 50:50 sterile glycerol and PBS then transplanted via oral gavage into n=8 11-week-old B6 non-Germ-free (SPF) male mice and n=4 11-week-old C57BL6 (B6) Germ-free (GF) male mice in the OMRF gnotobiotic facility. One week later, unilateral destabilization of the medial meniscus (DMM) surgery was performed. Control groups included n=7 B6-SPF-microbiota-into-male GF mice, n=10 male B6-SPF mice, and n=6 male B6-GF mice. Mice were euthanized 8 weeks after DMM and submitted for OARSI histopathologic scoring. For microbiome analysis, cecal DNA was extracted, 16S rRNA gene amplification done, initial analysis performed via QIIME2 amplicon v.2024-10, aligned to the GreenGenes2 reference tree, and differential microbiome analysis performed using Maaslin2 (v.1.16.0). We also analyzed similarities to our previous histologic and microbiome studies of the OA-protected MRL/MpJ mouse strain (n=5 SPF MRL-into-B6 GF, n=12 SPF MRL-into-B6).

Results: Gut microbiome transplantation from spiny mice to SPF B6 mice prior to DMM surgery resulted in substantial protection from histologic OA development (spiny-into-B6 2.9±0.8 vs. B6 control 7.8±0.5, mean summed OARSI score±SEM, P=0.0003, **Figure 1A, 1B**). We then confirmed this finding by transplanting gut microbial content from spiny mice to GF B6 mice (ordinarily OA protected), where spiny transplantation induced mild OA susceptibility, whereas wild-type B6 cecal transplant did induce OA susceptibility (spiny-into-GF 2.3±0.3, GF control 1.5±0.3, B6-into-GF 11.2±0.9, P=0.053 spiny-into-GF vs. GF control, P=0.003 spiny-into-GF vs. B6-into-GF). In microbiome analysis, substantial differences were present between spiny mice and B6 mice (n=75 differences, q≤0.05). These differences were substantially similar to our previously published MRL-into-B6 transplantation experiments (n=29 in current reanalysis), **Figure 2**. Indeed, 13 of these microbiome clades were shared in both comparisons, and 11 were similar in direction and magnitude of change (increased in MRL were all increased in spiny and vice-versa).

Conclusion: The gut microbiome of OA-protected spiny mice confers OA protection in wild-type mice following microbiome transplantation. Microbiome differences in spiny mice are largely similar to previous studies of another OA protected strain, MRL/MpJ. Future work should evaluate whether spiny mouse microbiome transplantation also confers OA pain/behavioral protection and the degree to which individual microbiome species contribute to these findings.

Session Title: (1780–1808) Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Macrophages are found in nearly every tissue of the body where they maintain homeostasis and drive healthy immune response. However, macrophages are dysregulated with age and have been found to play a role in many age-associated diseases, such as arthritis. We hypothesized that macrophage dysregulation in aging stems from an increased contribution of infiltrating monocytes that have been reprogrammed by the aging environment of the bone marrow in a manner that prevents them from fully recapitulating the tissue-resident macrophage phenotype. To test this hypothesis, we are investigating aging macrophages in the murine joint synovium using functional genomic approaches.

Methods: We compared synovial macrophage composition and transcriptional profiles in young vs. aged joints from male and female mice using single-cell RNA sequencing with cell-surface protein detection (CITE-seq).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: We identified both conserved age-related changes and those that differed between sexes. Among synovial macrophages, we observed significant ($p < 0.0001$) expansion of infiltrating Ly6C+ monocytes/macrophages in both males and females (8.0% vs. 2.1%, and 9.5% vs. 2.3%, respectively) and significant reductions in the proportion of CXCR1+ lining macrophages (35.6% vs. 29.8%, and 32.4% vs. 24.9%, respectively). In females, there were significantly more MHCII+ macrophages in aged mice (17.3% vs. 12.9%) and no statistical difference in osteoclast precursors (5.8% vs. 5.3%), but in males there were significantly fewer MHCII+ macrophages in aged mice (11.3% vs. 14.7%) and significantly more osteoclast precursors (7.6% vs. 4.6%). Pseudotime analysis revealed four diverging trajectories of differentiation from infiltrating Ly6C+ monocytes/macrophages to CXCR1+ lining macrophages, AQP1+ interstitial macrophages, RELM-α+ interstitial macrophages, and osteoclast precursors, respectively, with fewer early-stage interstitial cells observed in aged mice. Total inter-macrophage heterogeneity was significantly greater in aged vs. young mice in females ($p < 0.0001$), but not statistically different in males. Overall, age-associated gene expression changes were not highly correlated between sexes, with mean fold-change correlations ranging from r=-0.065 in MHCII+ macrophages to r=0.23 in interstitial macrophages. Significantly enriched pathways included upregulated electron transport chain signaling in interstitial macrophages in both sexes and downregulated EGFR signaling in osteoclast precursors in females.

Conclusion: We find that monocyte-derived synovial macrophages are increased in the aging joint and synovial macrophages exhibit decreased expression of homeostatic genes. Our results provide insights on how macrophage programming changes with age and the impact on tissue health. This study will inform efforts to boost immune system function in aging.

OA-associated pain sensitivity is reduced in OA-protected MRL/MpJ mice, partially mediated by the gut microbiome, and transferable via microbiome transplantation

Gabriella Dyson[1], **Montana Barrett**[1], Nicholas Hanebutt[1], Aleksander Szymczak[2], Cindy Miranda Brawner[1], Pratibha Dube[3], Ausitn Lopez[1], Padmaja Mehta-d'Souza[1] and Matlock Jeffries[2], [1]Oklahoma Medical Research Foundation, Oklahoma City, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]Oklahoma Medical Research Foundation, Edmond, OK

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1780–1808) Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: MRL/MpJ (MRL) mice are protected from developing post-traumatic osteoarthritis (OA) histologic changes. We have previously shown the gut microbiome to play a key role in mediating this OA protection, wherein microbiome transplantation from MRL mice to B6 mice can prevent OA. The goal of the present study was to examine the effects of microbiome manipulation on OA-associated pain in MRL and wild-type C57BL/6 (B6) mice.

Methods: Young adult male B6 or MRL mice (11 weeks of age) underwent one-time microbiome transplantation via oral gavage of 200uL of diluted cecal contents from adult reciprocal-strain animals (n=6 MRL-into-B6, n=6 B6-into-MRL), or 200uL control solution (n=6 MRL, n=6 B6). One week later, unilateral destabilization of the medial meniscus (DMM) surgery

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1: Pain sensitivity (withdrawal) thresholds by microbiome transpl. group

was used to induce OA. Pain sensitivity thresholds were measured via small animal algometry of the operated and contralateral knees prior to intervention (10 weeks of age). Algometry data were collected every 4 weeks until euthanasia 12 weeks after DMM.

Results: There were no differences at baseline in pain sensitivity, although there was a trend towards lower pain sensitivity in MRL animals at all timepoints (P=0.073 at baseline, P=0.069 at 4 weeks, P=0.033 at 8 weeks, P=0.16 at 12 weeks). At 4 weeks after DMM, MRL-into-B6 transplanted mice had substantially reduced pain sensitivity compared to B6 controls (P=0.0090), which was lost at later timepoints (P=0.17 at 8 weeks, P=0.23 at 12 weeks, **Figure 1**). B6-into-MRL transplantation did not alter pain sensitivity in MRL recipient mice at any timepoint. In the contralateral (unoperated) knee, we found MRL mice to have reduced pain sensitivity at all timepoints. MRL-into-B6 transplantation reduced pain sensitivity at 4 weeks (P=0.015) and 12 weeks (P=0.032). B6-into-MRL transplantation increased pain sensitivity at 4 weeks (P=0.012). Correlation of gut microbiome changes with pain sensitivity is ongoing.

Conclusion: Knee pain sensitivity is reduced in OA-protected MRL mice compared to wild-type B6 mice and is partially mediated by the gut microbiome, although the effects of a single timepoint microbiome manipulation are lost at timepoints beyond 4 weeks post-DMM. Future studies should investigate whether sustained changes in pain sensitivity could be seen with repeated microbiome manipulation, and whether OA-associated behavioral changes are similarly mitigated with microbiome manipulation.

Trends and Disparities in Osteoarthritis-Related Mortality in the United States: A 21-Year Analysis (1999-2020)

muzamil Khan[1], Swetha Balaji[2], Ayesha Cheema[3], Wajdan Ahmad[3], Dhruv gandhi[4] and Steven Golombek[5], [1]George Washington University School of Medicine and Health Sciences, Washington D.C, [2]New York Medical College at St. Mary's General Hospital and St. Clare's Health, Parsippany-Troy Hills, NJ, [3]Al Tibri Medical College, Karachi, Pakistan, [4]St. Francis Medical Center, Monroe, [5]NYMC at St. Mary's General Hospital and St. Clare's Health, Dover

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1780–1808) Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Osteoarthritis/arthrosis is an aging-related disease which is associated with significant morbidity in the United States. However, epidemiological data regarding osteoarthritis-associated mortality in the United States (US) remains scarce. The aim of this study is to determine trends and disparities in osteoarthritis-related mortality in the US between 1999 and 2020.

Methods: A retrospective analysis was conducted using the Centers for Disease Control and Prevention Wide-Ranging Online Data for Epidemiologic Research database. The age-adjusted mortality rates (AAMR) and crude death rates per 100,000 persons were determined. The average annual percentage change (AAPC) was calculated through Joinpoint regression analysis. The results were compared to determine temporal trends in sex, race, geographical distribution and patient age-related mortality in osteoarthritis patients.

Results: Between 1999 and 2020, 277,211 deaths occurred in osteoarthritis patients aged 45 years and above. Majority of the patients had died within nursing homes/long-term care facilities (47.38%). The AAMR reduced from 15.5 in 1999 to 6.52 in 2020 with an AAPC of -4.52% (p< 0.0001). Females were disproportionately affected with higher AAMR (12.04) compared to males (8.27), although their AAPCs were nearly similar (-4.36% vs. -4.39%, respectively). Racial differences persisted with non-Hispanic (NH) White having the highest AAMR (11.43) followed by NH Black/African American (9.52), NH American Indian/Alaskan Native (7.53), Hispanic/Latino (5.73) and NH Asian/Pacific Islander (4.24). Between 1999-2020, Hispanic/Latino showed the greater overall decline in osteoarthritis-related mortality (AAPC of -5.16%; p< 0.0001) while

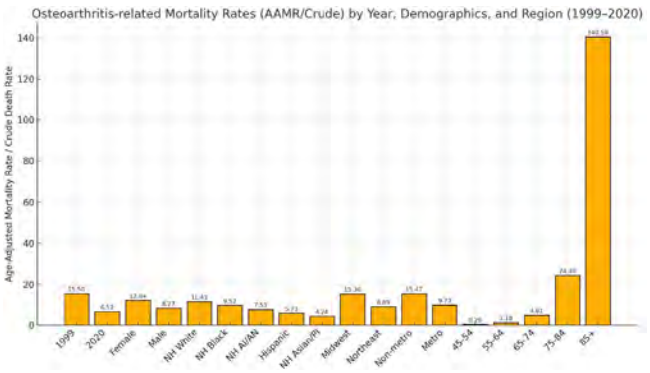

Image 1: Osteoarthritis related Age-Adjusted Mortality Rate (AAMR)

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

American Indian/Alaskan Natives showed the least decline (AAPC of -3.88%; p< 0.0001). Geographically, the Midwest had the highest AAMR (15.36) while the Northeast had the lowest (8.89). The decline in osteoarthritis-related mortality was nearly similar between the various census regions (AAPC: -4.25% to -4.34%). States with the highest AAMRs included Nebraska, Ohio, West Virginia, Vermont, and South Dakota. Residents of non-metropolitan areas showed a higher AAMR (15.47) compared to metropolitan areas (9.73). Age-stratification into 10-year age groups showed a consistent increase in the crude death rate with age (from 0.29 in 45-54 years to 140.58 in those older than 85 years). The decline in osteoarthritis-related mortality between 1999-2020 was seen in all age-groups with the greatest overall decline seen in the 75-84 years age group (AAPC:-4.56%; p< 0.0001) followed closely by the 85+ age group (AAPC:-4.45%; p< 0.0001).

Conclusion: Over the past two decades, osteoarthritis-related mortality in the US has significantly declined, with notable disparities across sex, race, geographic location, and age. Females, non-Hispanic Whites, residents of the Midwest, and those in non-metropolitan areas had higher mortality rates. These findings emphasize the need for targeted interventions to address disparities and further reduce mortality.

Multi-Tissue Molecular and Histopathological Profiling of Facet Joints and Intervertebral Discs

Nashrah Ahmad[1], Lisa Janssen[1], Hannah Swahn[2], Rachel Miller[3], Anne-Marie Malfait[4], Merissa Olmer[5] and Martin Lotz[6], [1]Scripps Research, San Diego, CA, [2]Scripps Research Institute, Carlsbad, CA, [3]Rush University Medical Center, Chicago, IL, [4]Rush University, Oak Park, IL, [5]Scripps Research Institute, La Jolla, CA, [6]Scripps Research, La Jolla, CA

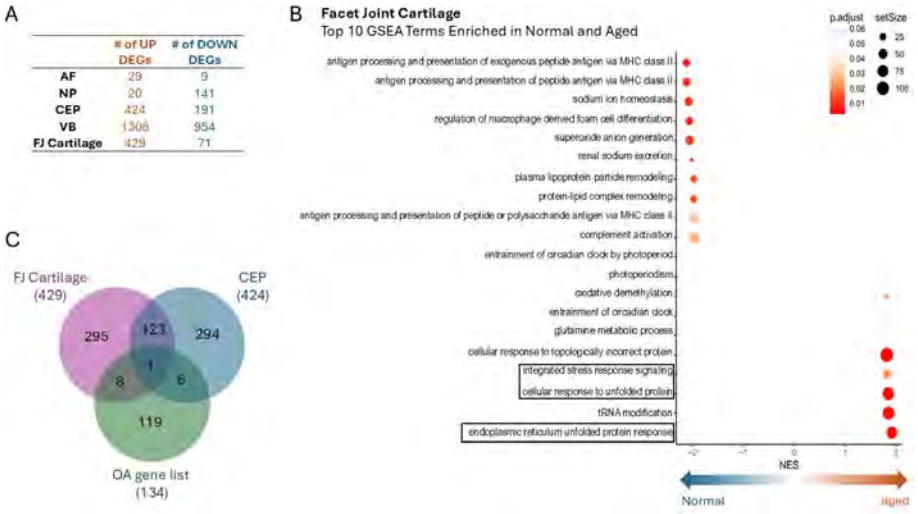
SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1780–1808) Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Intervertebral disc (IVD) degeneration and facet joint (FJ) osteoarthritis (OA) often co-exist, and both are major contributors to lower back pain (LBP). Despite their clinical relevance, the shared mechanisms of tissue damage in these anatomically and functionally linked tissues remain poorly understood. The objective of this study was to perform histological analyses and omics profiling of FJs and IVDs from the same young and aged human donors. Data were analyzed for molecular and cellular alterations linked to tissue damage and LBP.

Methods: IVDs and FJs were harvested from the L3/L4 of 5 young, healthy (aged 23-37) and 10 aged (aged 67–81) donors. IVD and FJ sections were stained with Safranin O and histologically graded using the Thompson system for nucleus pulposus (NP), annulus fibrosus (AF), vertebral body (VB), and cartilaginous end plate (CEP) and OARSI systems for FJ sections. Bulk RNA sequencing was performed on all tissues using SMARTseq.

Results: Histological grading revealed significantly higher overall scores in IVDs from aged donors as compared to normal donors. Sub-compartment scores of VB, NP, AF, and CEP were also elevated in the aged group. Similarly, OARSI scores were significantly higher in FJ cartilage from aged donors compared to young healthy. Transcriptomic analysis identified 38, 161, 615, 2262, and 500 differentially expressed genes (DEGs) in AF, NP, CEP, VB, and FJ, respectively **(A)**. Gene Set Enrichment Analysis (GSEA) revealed upregulation of cartilage and bone development pathways, along with extracellular

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



(A) Differentially expressed genes (DEGs) identified as upregulated or downregulated in nucleus pulposus (NP), annulus fibrosus (AF), vertebral body (VB), cartilage endplate (CEP), and facet joint (FJ) cartilage. (B) Gene set enrichment analysis (GSEA) highlighting the top 10 enriched pathways in normal versus aged FJ cartilage. (C) Venn diagram illustrating the overlap of DEGs among CEP, FJ cartilage, and a curated osteoarthritis (OA) gene set.

matrix (ECM) remodeling in aged AF. In aged NP, ER-associated degradation (ERAD) and unfolded protein response (UPR) pathways were prominently enriched. GSEA in degenerated CEP highlighted enrichment of stress responses and hypoxia-related pathways. In VB, pathways related to oxygen transport, adipogenesis, and neurovascular regulation were enriched. In FJ cartilage, GSEA revealed upregulation of UPR, integrated stress response, and circadian rhythm pathways **(B)**. Notably, stress responses and UPR pathways were consistently upregulated across degenerated NP, CEP, and FJ (highlighted in **B**). Additionally, we investigated the molecular overlap between knee OA pathways and spine degeneration by assessing whether OA-associated genes identified in knee articular cartilage were upregulated in the cartilaginous components of the spine specifically, the CEP and FJ cartilage **(C)**. While transcriptomic profiles of CEP and FJ cartilage showed considerable similarity to each other, overlap with the knee OA gene set was limited, with only 6–8 of the 134 OA-associated genes commonly upregulated. KCNN4, upregulated across CEP, FJ, and OA gene sets, is linked to cartilage homeostasis and mechanotransduction.

Conclusion: The strong correlation between IVD and FJ degeneration, along with shared upregulation of stress-related pathways particularly the UPR and integrated stress response suggests common molecular mechanisms driving IVD and FJ degeneration. These findings highlight the importance of targeting cellular stress response and UPR pathways to develop more effective, system-level therapeutic strategies to address structural damage to IVD and FJ and associated LBP.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1780–1808) Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: SEV-101 are exosomes that are isolated from cultures of Induced Pluripotent Stem Cell (iPSC)-derived hyaline cartilage tissue. Gene expression profiles of the tissue are consistent with early hyaline cartilage development. Given that the biological effects of exosomes tend to parallel those of the cells from which they were derived, we hypothesize that SEV-101 which is secreted from iPSC-derived hyaline cartilage tissue, could deliver effective regenerative cues for cartilage regeneration in addition to factors that promote anti-inflammatory activities.

Methods: Exosomes in iPSC-derived hyaline cartilage tissue culture medium were isolated through a series of centrifugation steps followed by ultracentrifugation. Particle concentration and size distribution was characterized utilizing Nanosight. Mixed Lymphocyte Reaction (MLR) cultures of human Peripheral Blood Mononuclear Cells (PBMCs) were performed in the presence of SEV-101 from multiple batches, and the results were analyzed using multiparametric flow cytometry to asses regulatory T cell populations, including Tregs and Tr1cells. Additionally, activation markers such as CD69 were evaluated to quantify activated Tregs and Tr1 cells. Proliferation of chondrocytes in the presence of SEV-101 were detected via Ki-67 based assays and colony formation assays. Preliminary proteomics was performed by mass spectrometry.

Results: SEV-101 contained high levels of anti-inflammatory molecules such as CD9 and CD81 compared to the exosomes isolated from undifferentiated iPSC culture medium. SEV-101 effectively reversed TNFa-induced inflammation in PBMCs. Treatment with SEV-101 increased the frequency of $CD4^+FoxP3^+$ regulatory T cells (Tregs) by 1.3- to 2.03-fold and $CD49b^+LAG\text{-}3^+$ Tr1 cells by 1.33- to 3.34-fold. Furthermore, the proportion of $CD69^+$ T cells, including $CD69^+$ Tregs and $CD69^+$ Tr1 cells-was significantly elevated in human MLR cultures treated with SEV-101. CD69+ T cells can induce indoleamine 2,3-dioxygenase in OA models and down-regulate inflammatory immune responses. Ki-67-based proliferation and colony formation assays demonstrated that SEV-101 induces chondrocyte proliferation by 82.18 to 96.29 fold. Preliminary proteomics showed the presence of pro-regenerative and anti-inflammatory proteins.

Conclusion: SEV-101 exhibits potent anti-inflammatory and chondro-regenerative properties in vitro, indicating its potential as a disease-modifying agent for the treatment of osteoarthritis.

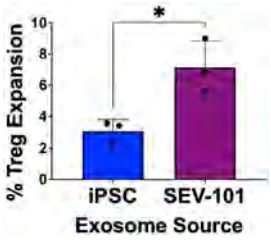

Figure 1. SEV-101 increase proliferation of Treg cells. Flow cytometric analysis of peripheral blood mononuclear cells treated with 100 μg of SEV-101 exosomes showed a significant ($P<0.0196$) increase in the expansion of CD4+ CD25+ FoxP3+ Tregs compared to iPSC exosome treated controls. Each data point represents the mean ± SD of three independent experiments and were analyzed with a student's t-test (*$P<0.05$).

Session Title: (1780–1808) Osteoarthritis & Joint Biology – Basic Science Poster

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatic diseases are characterized by pain and a progressive loss of joint function. Classical treatments alleviate pain symptoms but fail to fully repair sites of articular cartilage damage. Gene therapy for rheumatic diseases aims to deliver gene-based treatments into the joint space, resulting in a localized, controlled, and long-term

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. therapeutic effect to protect and regenerate damaged cartilage. Recombinant adeno-associated viral (rAAV) vectors are the only class of vectors currently available that allow for both an effective, direct, and prolonged gene transfer to articular cartilage *in vivo*. This study aims to characterize the proteomic changes induced by gene therapy on human mesenchymal stromal cells (MSCs) derived from patients with osteoarthritis (OA). The goal is to gain insights into the underlying pathways and mechanisms involved, and to explore their potential roles in cartilage regeneration

Methods: Different chondrogenic factors (IGF-I, FGF-2, TGF-β, SOX9, and reporter *lacZ* as the control) were delivered using rAAV vectors for hMSC-based gene therapy. hMSC cultures were transduced with the rAAV and maintained for 21 days in a defined chondrogenic medium. Proteomic profiling of the micromasses was performed using high resolution mass spectrometry (TimsTOF-Pro, Bruker). Differential expression analysis was conducted using protein-wise linear models combined with empirical Bayes statistics (adjusted p-value < 0.05 and log2 fold change ≥0.5)

Results: Proteomic analysis was performed on 25 micromass samples (five samples for each chondrogenic factor and control). A total of 3,565 proteins (with >1 unique peptides) were identified in the micromass proteome (Fig. 1). Subsequent data analysis revealed 139, 100, 150, and 230 proteins that were significantly differentially expressed under IGF-I, FGF-2, TGF-β, and SOX9 conditions, respectively. The growth factors IGF-I, FGF-2, and TGF-β shared 16 significant proteins related to metabolic processes and intracellular protein transport (Fig. 2). IGF-I and TGF-β shared 25 proteins related to RHO GTPase effectors and asparagine N-linked glycosylation. IGF-I and FGF-2 shared 22 proteins related to carbohydrate catabolism and translation, while FGF-2 and TGF-β shared 12 proteins involved in membrane trafficking. SOX9 exhibited minimal overlap with the other factors and had 219 uniquely significant proteins associated with ossification, neutrophil degranulation, and extracellular matrix (ECM) components such as glycoproteins, collagens, and proteoglycans. TGF-β modulated

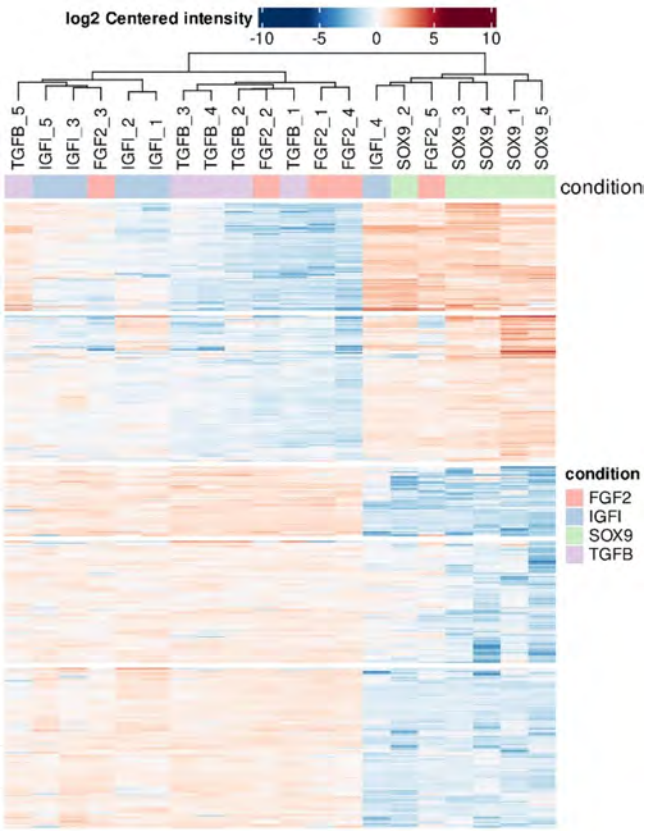

Figure 1. Heatmap showing the differential proteomic profiles induced in hMSCs following gene therapy treatment with various chondrogenic factors. Five independent experiments are displayed, with lacZ used as the control.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

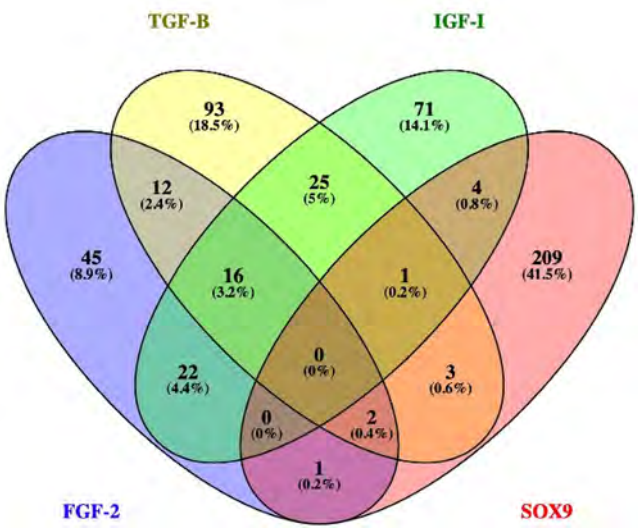

Figure 2. Venn diagram of significant proteins, illustrating the number of unique and shared proteins altered in response to each chondrogenic factor.

93 exclusive proteins linked to VEGFA-VEGFR2 signalling and proteolysis. IGF-I uniquely affected 71 proteins involved in intracellular EGF-EGFR signalling and metabolism. Finally, FGF-2 was characterized by 45 unique proteins associated with ECM glycoproteins and lipid metabolism

Conclusion: This study provides valuable data supporting the use of gene therapy with chondrogenic factors as a promising strategy for cartilage regeneration. The identification of key proteins involved in cartilage repair and regeneration pathways highlights the therapeutic potential of this approach for the treatment of articular cartilage diseases

Background/Purpose: Zhuling has traditionally been utilized in the treatment of gouty arthritis (GA). Although its therapeutic benefits are recognized, the molecular mechanisms underlying Zhuling's action and those of its principal component are still largely uncharted. The purpose of this study was to clarify the molecular mechanisms responsible for the therapeutic benefits of Cerevisterol, a principal component of Zhuling, in the treatment of gout. This was achieved through an integrated approach that combined network pharmacology with in vitro and ex vivo experimental methods.

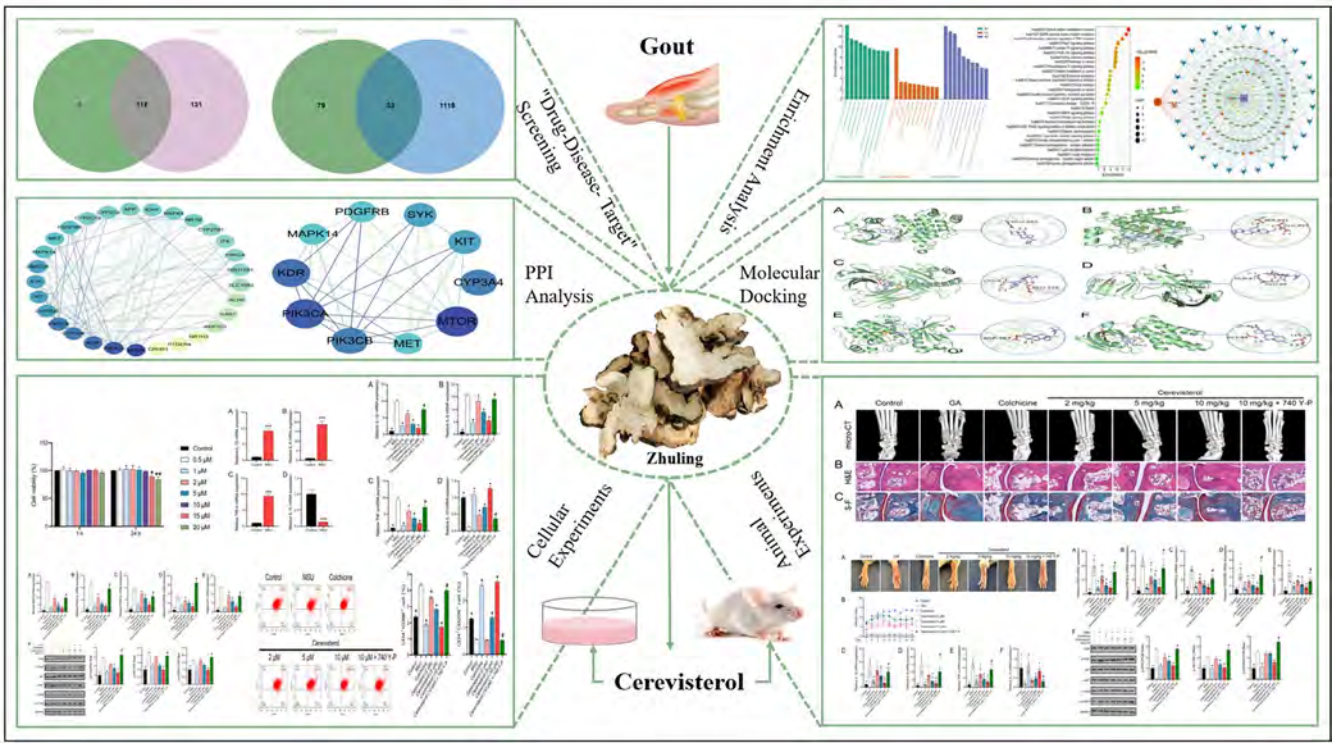

Graphical Abstract

Methods: We employed the TCMSP database, the Uniprot platform, and SwissTargetPrediction to identify the targets of Zhuling and Cerevisterol. Gout-associated targets were sourced from DrugBank, GeneCards, OMIM, and DisGeNET. Utilizing Cytoscape, we constructed a protein-protein interaction (PPI) network to pinpoint core targets. Pathway enrichment analysis was conducted using Metascape and the Microbiotics platform. Subsequently, we focused on the potential targets and related pathways of Cerevisterol, followed by molecular docking simulations using AutoDockTools and PyMOL. To validate our in silico findings, we established an monosodium urate (MSU)-induced GA cell model using mouse bone marrow-derived macrophages (BMDMs) and evaluated the expression of inflammatory factors, pivotal pathway proteins, and macrophage polarization via RT-qPCR, Western blot, and flow cytometry. We also developed GA mouse models to assess ankle swelling and joint dysfunction indices, and quantified serum inflammatory factors using RT-qPCR. Pathological changes in mouse joints were examined using Micro-CT, H&E staining, and S-F staining, while the impact of Cerevisterol on key pathway proteins was investigated using Western blot.

Results: Network pharmacology and bioinformatics analyses revealed 243 potential targets for Zhuling in gout treatment, among which 112 were potential targets for the treatment of gout by its principal active component, Cerevisterol. Cerevisterol was found to modulate the expression of pro-inflammatory factors such as IL-1β, IL-6, and TNF-α, while upregulating the anti-inflammatory factor IL-10 in MSU-induced GA cells and mouse models. Additionally, Cerevisterol facilitated macrophage polarization towards the M2 phenotype by targeting key molecules like KDR, PIK3CA, PRKCA, PDGFRB, and KIT, Cerevisterol exerted its therapeutic effects by regulating the PI3K/AKT/mTOR signaling pathway and the expression of critical proteins, thereby ameliorating the inflammatory response and pathological changes in GA models.

Conclusion: Our findings suggest that Cerevisterol, a pivotal active ingredient in Zhuling, may exert its therapeutic effects on gout through a multi-target and multi-pathway mechanism. In vitro and in vivo studies corroborate that Cerevisterol can mitigate joint inflammation and pathological alterations in gout by influencing macrophage polarization and the expression of inflammatory mediators through the PI3K/AKT/mTOR pathway. These insights offer a promising avenue for the clinical management of gout.

The Role of Nociceptor-Expressed Piezo2 in Nervous System Immune Cell Infiltration in a Mouse Model of Osteoarthritis

Natalie Adamczyk[1], Terese Geraghty[2], Shingo Ishihara[3], alia obeidat[2], Jun Li[2], Anne-Marie Malfait[2] and **Rachel Miller**[1], [1]Rush University Medical Center, Chicago, IL, [2]Rush University Medical Center, Chicago, [3]Rush University, Chicago

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1780–1808) Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Osteoarthritis is one of the leading causes of chronic pain and disability worldwide with 500 million people affected. We have previously reported that nociceptor-conditional Piezo2 knock-out mice ($Na_V1.8$cre-Piezo2fl/fl; Piezo2cko), were protected from pain-related behaviors associated with a surgical model of OA along with spontaneous OA with aging, while joint damage was not affected. Persistent pain development is associated with molecular and cellular changes in the dorsal root ganglia (DRG), which contain the cell bodies of nociceptors as well as various types of non-neuronal cells. Previously, in wild-type mice, we have reported elevated levels of immune cells such as macrophages in the knee-innervating DRG in mouse models of OA, but the link between stimuli sensed by nociceptors in the knee joint and the recruitment of these cells in the DRG is not yet fully elucidated. The objective of the present study was to investigate whether the ion channel Piezo2, expressed by nociceptors, plays a role in these changes within the dorsal root ganglia in a mouse model of osteoarthritis (OA).

Methods: Twelve-week-old WT and Piezo2cko mice of both sexes underwent PMX or sham surgery (n=9-10). Mice were behaviorally assessed pre-operatively and every 4 weeks thereafter for knee hyperalgesia and weight bearing asymmetry. At 13 weeks *post* operatively knees were used for OA scoring by H&E and Safranin-O. Spinal cords were used for immunofluorescent staining for IBA1+ microglia and GFAP+ astrocytes. Separate cohorts of mice were used to perform flow cytometry or bulk RNAseq on L3-L5 DRG.

Results: Piezo2cko mice of both sexes were protected throughout the time course from knee hyperalgesia and from weight bearing asymmetry development, however Piezo2cko mice developed OA pathology at the same level as WT PMX mice. Piezo2cko PMX mice were protected from innate immune cell influx of NK1.1+ and F4/80+ cells compared to WT PMX mice, which was supported by DRG bulk RNAseq findings. Neuroimmune protection seen at the DRG extends to the CNS as Piezo2cko PMX mice had less activated IBA1+ microglia. In addition, male WT PMX mice displayed an increase in the number of GFAP+ astrocytes compared to Piezo2cko PMX mice. No differences in GFAP+ astrocytes were observed in female mice across the conditions.

Conclusion: Piezo2cko from nociceptors was protective against pain-related behaviors and neuroimmune changes associated with OA in the PMX model in both sexes. However, conditional knockout did not protect from OA joint pathology. Targeting Piezo2 could prove to be a valuable target for inhibiting chronic pain in patients.

Matrikine Activation of Synovial Fibroblasts Promotes Monocyte Migration and Stimulates an OA Chondrocyte Phenotype

Richard Loeser[1], Jorge Fernandez Davila[1], Philip Coryell[2], Susan Chubinskaya[3] and Doug Phanstiel[4], [1]University of North Carolina, Chapel Hill, NC, [2]University of North Carolina-Chapel Hill, Chapel Hill, NC, [3]University of Texas Medical Branch, Galveston, TX, [4]University of North Carolina at Chapel Hill, Chapel Hill, NC

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1780–1808) Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Protease cleavage of matrix proteins generates matrix fragments including fibronectin fragments (FN-f) found in OA cartilage and synovial fluid. Matrix fragments or "matrikines" activate signaling to increase production of OA mediators promoting a feed-forward loop of matrix destruction. Stimulation of chondrocytes with an Fn-f (FN7-10) that binds the α5β1 integrin has been shown to model the OA chondrocyte phenotype. Synovial fibroblasts contribute to OA by producing factors that promote synovitis and cartilage destruction. The **purpose of this study** was to determine if FN7-10 activates synovial fibroblasts to produce factors that promote monocyte migration, differentiation, and an OA chondrocyte phenotype.

Methods: OA synovial fibroblasts (SFs) were isolated from tissue obtained during knee replacement and chondrocytes from normal cartilage were from tissue donors. RNA and serum-free conditioned media were collected after 18 hours of stimulation of SFs with FN7-10 or PBS as control and used for RNAseq, cytokine/chemokine protein arrays for 80 proteins and Luminex assays designed to measure 18 OA mediators. To evaluate the effects of activated SFs on the OA microenvironment, a 4-hour FN7-10 stimulation was performed, followed by a transition to serum-free medium and overnight incubation. The conditioned media was harvested and assessed for its chemotactic effects on THP1 monocytes, and its impact on the expression of inflammatory mediators in THP1 monocytes and chondrocytes.

Results: SF RNAseq revealed 1487 differentially expressed (DE) genes (772 up and 715 down) in response to FN7-10 vs PBS control (DESeq2, adjusted p value < 0.05, absolute differences of log2 fold-change >1). Upregulated genes were enriched for KEGG pathways including TNF and IL-17 signaling, cytokine-cytokine receptor interaction, and NOD-like,Toll-like receptor, and NFκB signaling. There were 22 upregulated chemokine genes (**Fig.1**) many of which also exhibited increased protein levels (greater than 2-fold) as detected by cytokine/chemokine protein arrays and/or Luminex including IL-6, CXCL5, CCL5, MCP1-3, CXCL10, CXCL20, LIF, FGF-2, MMP-3, MMP-13 and TNFα. Conditioned media from SFs stimulated by FN7-10 induced monocyte migration, which was blocked by CCR2 and CXCR2 chemokine receptor inhibitors (**Fig. 2**), and induced macrophage differentiation. Chondrocytes incubated with SF FN7-10 conditioned media demonstrated significant increases in expression of OA mediators and a downregulation of aggrecan (*ACAN*) and *COL2A1* (**Table 1**).

Conclusion: OA SFs produce proinflammatory cytokines, chemokines, and MMPs when exposed to a matrikine (FN7-10) produced by cartilage degradation. Chemokines released from activated SFs induce monocyte migration and promotion of a macrophage phenotype which could contribute to synovitis. SF factors also stimulated chondrocytes to produce key OA mediators, down regulate anabolic genes and increase expression of the OA biomarker CRTAC1. These findings demonstrate a mechanism for cross-talk between the synovium and cartilage mediated by cartilage matrix damage that could promote OA progression.

Abstract Number: 1802

Clearance Kinetics and Cartilage Retention of MM-II, a Dispersion of Large Empty Liposomes, in Rat Knees

Roni Wechsler and Rany Rotem, Moebius Medical, Tel Aviv, Israel

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1780–1808) Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: MM-II is a dispersion of large, empty multilamellar liposomes for intraarticular (IA) injection that reduced knee pain in osteoarthritic patients for up to 26 weeks in a global clinical study (NCT04506463). Previous studies showed these liposomes coat cartilage and menisci under compression, providing lubrication and reducing wear. After injection, most liposomes are absorbed and metabolized by joint tissues, while some adhere to knee

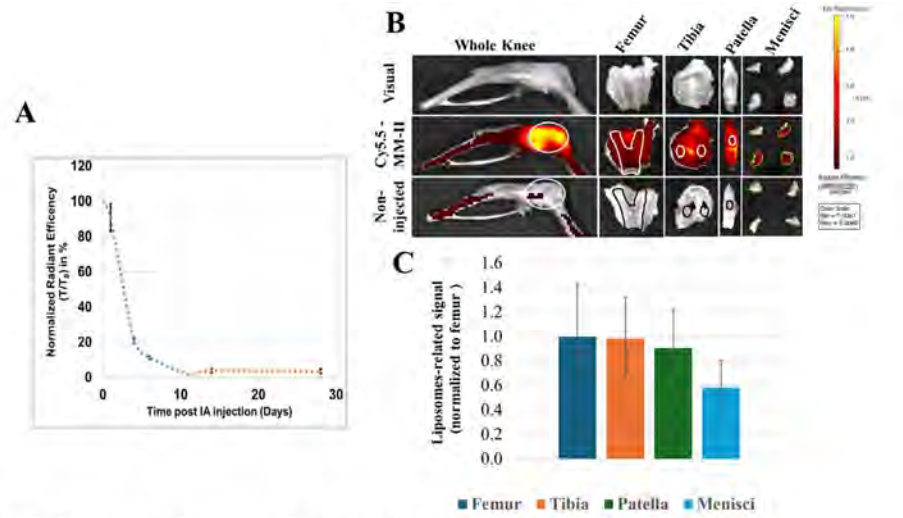

Figure 1. Clearance profile of intraarticularly injected MM-II and its retention in articular cartilage and menisci .
A = In vivo clearance profile of IA-injected sulfo-Cy5.5-MM-II (N=8 rats for days 0-14 and N=4 rats for day 28). Background in each time point was determined each day using average of both knees from one non-injected rat and subtracted from the corresponding values. Blue dotted line indicates initial exponential phase and orange dotted line indicates the second phase; **B** = Representative images of whole knees and knee components that were scanned on day 28 to quantitate cartilage-retained MM-II. The ROIs in cartilaginous areas were selected while being blinded to fluorescence signal to avoid bias; **C** = Relative MM-II associated signal at day 28 in cartilage of femur, tibia and patella as well as in menisci. Data is normalized to average signal found in femurs. Background in each time point was subtracted for each knee region using non-injected corresponding region. The presented data are mean values with standard error of the means.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. surfaces to maintain lubrication. This study aimed to characterize MM-II clearance and its association with knee components in healthy rats.

Methods: Sulfo-Cyanin 5.5–labelled MM-II (Cy5.5-MM-II) liposomes were produced from dipalmitoylphosphatidylcholine (DPPC), dimyristoylphosphatidylcholine (DMPC), and Sulfo-Cy5.5-phosphatidylethanolamine at a molar ratio of 0.5445:0.4550:0.0005. Male Wistar rats (N=8) received bilateral IA injections of Cy5.5-MM-II (3.2 mg per knee) on day 0 and were imaged with an IVIS Lumina LT on days 0, 1, 4, 6, 14, and 28 to measure radiant efficiency, with a non-injected rat as a background control. On day 28, knees from N=3 Cy5.5-MM-II injected rats were excised, soft tissues removed, and components (femur head, tibia plateau, patella, menisci) isolated for scanning. Regions of interest (ROIs) were defined in cartilage areas to normalize fluorescence signals. Additional knees were decalcified, stained with DAPI, cryosectioned, and analyzed via fluorescent microscopy.

Results: MM-II clearance showed an initial exponential phase (half-life ~3 days) for 11 days, followed by a terminal phase where approximately 3% of the dose remained through day 28 (Figure 1A). Ex vivo imaging and histology at day 28 (Figure 1B, C) confirmed similar liposome distribution in femur, tibia, and patella cartilage, with retention also observed in the menisci.

Conclusion: IA injection in rat knees led to most MM-II liposomes clearing within 1–2 weeks, while a fraction persisted on cartilage and menisci for at least 28 days, supporting clinical findings of prolonged knee pain relief.

Abstract Number: 1803

Patching of Damaged Meniscus and Cartilage of Osteoarthritic Animals by MM-II, a Dispersion of Empty Large Multilamellar Liposomes

Roni Wechsler and Rany Rotem, Moebius Medical, Tel Aviv, Israel

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1780–1808) Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Cartilage wear in knee osteoarthritis (KOA) is linked to reduced boundary lubrication. Occasionally, the meniscus also wears out in KOA, potentially accelerating the disease. MM-II is a dispersion of empty, large multilamellar liposomes for intraarticular (IA) injection. A single injection of MM-II has reduced knee pain for up to 26 weeks in a global clinical study (NCT04506463). MM-II was shown to coat cartilage and menisci and to reduce cartilage degeneration in surgically induced KOA models. The current study aimed to assess interaction of MM-II with cartilage and menisci in monosodium-iodoacetate KOA rat model in which cartilage pathology is reminiscent of human KOA.

Methods: Osteoarthritis was induced by 0.6mg monoiodoacetate (MIA) IA injection in rats. At 14 days post MIA injection, fluorescently labelled MM-II liposomes were bilaterally IA injected. Knees were harvested at 1-week post-injection, fixed, decalcified in EDTA, frozen, cryosectioned, stained with DAPI and visualized by fluorescent microscopy. Animal procedures were approved by the local ethics committee and relevant authorities.

Results: In MIA-treated knees, accumulation of MM-II was seen one week post administration specifically in regions with extensive cell death in both cartilage and meniscus. In contrast, in flanking regions with live cells or in healthy knees, MM-II was shown to coat cartilage and meniscus with fine layer as seen previously in surgically induced KOA models.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Pending on the KOA model, MM-II liposomes coat or patch OA cartilage and menisci. These observations, together with previous ones showing lubrication by MM-II, suggest a novel mechanism that may underlies MM-II clinical benefit in KOA.

Abstract Number: 1804

Pharmacology of LEVI-04, a novel treatment for OA

Simon Westbrook[1] and Kerry af Forselles[2], [1]Levicept Ltd, Sandwich, United Kingdom, [2]Levicept, Sandwich, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1780–1808) Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: LEVI-04 is a novel fusion protein comprising the extracellular domain of p75 neurotrophin receptor (p75NTR) coupled to IgG1 Fc, being developed for the treatment of osteoarthritis (OA) symptoms and disease progression. Results from a phase II study showed a significant reduction of WOMAC pain, function and stiffness vs placebo, supporting its clinical potential[1]

Methods: Binding affinities of LEVI-04 to neurotrophins (NTs) were determined using surface plasmon resonance assays. Functional potency was assessed in cell-based assays measuring inhibition of NT-induced activation of Trk and p75NTR/Trk receptors. Analgesia (weight-bearing) and disease modification (histopathology) were assessed in a monosodium iodoacetate (MIA) induced OA model in the rat.

Results: LEVI-04 bound to all NTs, with highest affinity for NT-3 (Table 1). However, while dissociation from NT-3, BDNF, and NT-4 was slow, such that rate measurement was challenging, dissociation from NGF was rapid. LEVI-04 inhibited the activation of Trk receptors by all NTs. However, while LEVI-04 completely inhibited NT-3-induced activity, inhibition of NGF, BDNF, and NT-4 was not complete (Figure 1), especially when Trk receptors were co-expressed with p75NTR. LEVI-04 had highest potency for inhibition of NT-3 at TrkC receptors and TrkC receptors co-expressed with p75NTR (Table 1).

In the MIA model of OA, analgesia was seen with therapeutic LEVI-04 treatment (0.03–3 mg/kg SC) initiated following establishment of pain (determined by imbalance of weight distribution). LEVI-04 returned the MIA-induced imbalance in weight distribution to normal. MIA injection caused chondrocyte death, reduced cartilage thickness and reactive joint and bone

	NT-3	BDNF	NT-4	NGF

Inhibition of NT-induced activity by LEVI-04 in U20S cells expressing (A) TrkA and p75NTR, (B) TrkB and (C) TrkC receptors

pathology. LEVI-04 treatment resulted in chondroprotection, with reduced bone pathology and osteolysis-mediated bone erosion compared with IgG control. In MIA-injected joints in the LEVI-04-treated groups there was reduction in osteolysis, thus limiting myeloid cell activation, and osteoblast pool expansion thereby augmenting the mesenchyme cell pool, leading to repair and reduction in MIA-induced histopathology.

Conclusion: LEVI-04 supplements endogenous soluble p75NTR. Like soluble p75NTR, LEVI-04 interacts with all NTs but inhibits NT-3. Of note, NGF-, BDNF- and NT-4-induced Trk receptor activity cannot be fully inhibited by LEVI-04. In the MIA model of OA, LEVI-04 provided analgesia and reduced histopathology. Phase 3 trials to assess the effect of chronic LEVI-04 treatment on OA symptoms and disease progression are planned.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1780–1808) Osteoarthritis & Joint Biology – Basic Science Poster

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: The knee menisci are essential in joint biomechanics while meniscus damage is a driver of knee osteoarthritis (OA) and an important source of knee pain. As early molecular and cellular changes mediating the onset of tissue damage and mechanisms of progression are poorly understood, there are no approaches to prevent, delay or stop progression of meniscus destruction. The goal of this study is to discover genes and mechanisms of meniscus aging and OA at early and late stages.

Methods: This study used human knees from organ donors, including young healthy donors and aged donors with macroscopically normal knee cartilage and menisci, aged donors with cartilage damage indicative of mild OA and patients with

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

severe OA undergoing total knee arthroplasty (TKA) (**A**). The menisci were scored for histopathological changes (**B**). Bulk RNA-sequencing (RNA-seq) and single nuclei multiome were performed.

Results: Meniscus histopathology scores were normal in the young donor group (5.18±3.6) but also in the aged group (6.00 ±3.3) (**B**). The meniscus scores of the aged mild OA group were (9.14±2.7) and of the TKA group were 13.0±2.7 (**B**). RNA-seq detected only three DEGs in the menisci from aged normal donors as compared to the young normal. The aged OA group showed some separation from the young normal group on a principal component analysis (PCA) plot (**C**) and had 84 downregulated genes (DRGs) and 413 upregulated genes (URGs) (**D**). Metascape analysis revealed biological processes (BPs) regulated by the DRGs including macroautophagy, Endoplasmic-reticulum-associated protein degradation (ERAD), protein folding and NABA core matrisome (**E, F**). The URGs were also enriched for BPs related to extracellular matrix (ECM) and sensory system remodeling (**E**). The TKA group showed clear separation from the young normal group on PCA plot (**G**) and had 577 DRGs and 2680 URGs (**H**). The DRGs were enriched for metabolic pathways and protective BPs related to response to amino acid deficiency and antimicrobial defense (**I**). The URGs were strongly enriched for matrisome and ECM and for neuronal system, synaptic transmission and sensory organ development (**I**). Among the URGs were genes related to pain, including *NGF* and *ANK3* (**J**), and genes encoding voltage-gated sodium channels and transient receptor potential cation channels (**K**). In multiome analysis, several cell populations were significantly enriched in TKA compared to normal (clusters 0, 10 and 16). Cluster 10 had 1554 differentially expressed genes with enrichment for the OA-promoting genes, pathways related to calcium signaling, ECM, chondrocyte/bone differentiation and mitochondrial dysfunction. NFATC2 and NFATC1 were differentially expressed in cluster 10 in TKA compared to normal and had enhanced regulon activity.

Conclusion: Early or mild stages of OA are primarily characterized by disruption of cellular homeostasis and defense mechanisms and a relatively low level of ECM process activation. These processes are more enriched in late-stage OA which also has a marked enhancement of processes related to neuronal remodeling and pain. A pathogenic cell population that is expanded in OA and is a promising new therapeutic target.

Abstract Number: 1806

Sex differences in knee joint microbial DNA of C57BL/6 mice and the effect of cross-sex microbiome transplantation

Veera Durga Vaishnavi Kurra[1], Ausitn Lopez[2], Aleksander Szymczak[3], Gabriella Dyson[3], Pratibha Dube[4], Padmaja Mehta-d'Souza[2] and Matlock Jeffries[3], [1]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma City, [3]Oklahoma Medical Research Foundation, Oklahoma City, OK, [4]Oklahoma Medical Research Foundation, Edmond, OK

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1780–1808) Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Recent studies have suggested an association between the gut microbiome and osteoarthritis. We have previously shown that the joint microbiome is derived at least in part from the gut microbiome. However, there is little information on the role of the joint microbiome in OA development or progression, or on the differences in the joint microbiome based on biological sex. The goal of the present study was to examine sex differences in knee joint microbial DNA and the impact of opposite sex transplantation on the joint microbiome with and without PTOA using paraffin-embedded tissue sections of the knee joint.

Methods: Diluted cecal microbiome samples (200uL or vehicle control) was transplanted via single-timepoint oral gavage at 11 weeks of age. One week later, OA was induced in the right knee via destabilization of the medial meniscus (DMM) surgery. Mice were euthanized 8 weeks after DMM and knee joints were processed into formalin-fixed paraffin-embedded (FFPE) blocks. Eight 6μm sections per knee were then subjected to DNA extraction from both knees in each animal (DMM'd and unoperated) in four groups of mice (male and female controls and transplanted F- >M, transplanted M- >F).

Staphylococcus	-0.23	0.16	0.15

Table 3

Table 3: DMM-induced OA differences in knee joint microbial DNA pattern

Clade	Enriched Group	LDA coefficient	*P* value
Clostridiaceae	Non-DMM	1.3	0.043
Alistipes	Non-DMM	1.3	0.057
Duncaniella	Non-DMM	0.470.47	0.11
Clostridium_T	Non-DMM	0.66	0.14
Geobacillus	Non-DMM	0.89	0.14

DNA was extracted using a QIAamp FFPE Tissue Kit, quantified using Qubit dsDNA HS Assay, and 16S libraries were generated by real-time quantitative PCR, using unique primer indexes. The pooled library was sequenced on an iSeq sequencer and the taxonomic profiles determined. 16S data were analyzed using a custom QIIME2-based pipeline, Maaslin2 was used for group and correlation analyses.

Results: When considering both DMM and control mice, 5 microbiome clades were discordant or trended towards discordance according to sex (cutoff $P \leq 0.15$), 5 were discordant when only OA knees were tested, and 3 when only non-OA knees were tested (**Table 1**). Next, we included specimens from cross-sex microbiome transplants and performed linear correlation analysis across the sex spectrum (male, female-into-male, male-into-female, female). Eight clades were correlated in this analysis (**Table 2**). We also evaluated the effect of OA by comparing DMM to non-DMM knees and found 5 clades discordant (**Table 3**). All of these were seen in our sex analysis and were enriched in female mice.

Conclusion: Although our study was underpowered, we nonetheless detected several statistically significant or suggestive differences in the mouse joint microbial DNA pattern according to sex, and these differences can be transferred to the other sex via gut microbiome transplantation. Intriguingly, all 5 of the DMM-associated microbial differences were concordant (all were reduced with DMM and enriched in female animals, which have a lower histologic severity following DMM). Although a larger confirmation study is indicated, our findings nonetheless suggest that sex-associated microbiome differences may be present in joint tissues and may correlate with OA propensity, underscoring the role of non-genetic factors in sex-specific OA susceptibility.

Abstract Number: 1808

Lightsheet imaging with 3D analysis for wholistic assessment of synovial lymphatic vasculature within joints of murine models of arthritis

Xi Lin[1], Edward Schwarz[2] and Lianping Xing[3], [1]University of Rochester, Rochester, NY, [2]University of Rochester, Rochester, NY, USA, Rochester, NY, [3]University of Rochester, Webster, NY

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1780–1808) Osteoarthritis & Joint Biology – Basic Science Poster

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: The synovial lymphatic system (SLS) maintains joint homeostasis. Post-traumatic osteoarthritis (PTOA) has increased lymphatic vessels (LVs), but decreased SLS drainage. LVs are routinely studied by immunostaining of Lymphatic Vessel Endothelial Hyaluronan Receptor 1 (LYVE1) on tissue sections, but it cannot address the discrepancy between increased LV #s and decreased SLS function in PTOA joints. Lightsheet microscopy allows observation of the full depth of a 600-700mm mouse joint, compared to 4-10mm in 2D imaging. Here we describe the first lightsheet microscopy study of healthy vs. PTOA mouse knees for distribution and alteration of synovial LVs. We hypothesize that lightsheet 3D imaging is superior to traditional immunohistochemistry for comprehensive LV network analyses of mouse knee joints in full depth, which provides new information of SLS.

Methods: Knee joints of 5-m-old C57 male mice receiving sham or PTOA surgery (n=3/group) were stained for synovial LVs with anti-LYVE1. Samples were subjected to lightsheet microscopy and a total of 550-650 consecutive 1mm slices were collected for volumetric/branching analysis in Imaris 10.2 software.

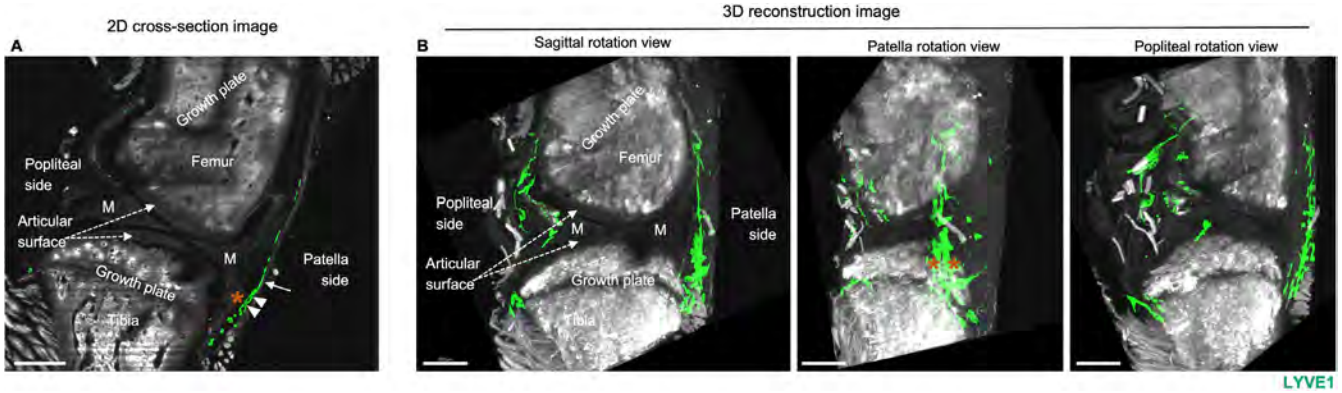

Fig 1. 3D reconstruction of the synovial lymphatic vessels from light sheet images reveals much more extensive lymphatic network than those from a 2D image. Knee joints of 5-m-old C57Bl/6 male mice were processed for the lightsheet microscopy. The synovial LVs were labeled with anti-LYVE1/AlexaFluor647 antibody. Joints were mounted in a sagittal position, and a series of 550-650 consecutive images (=slices) were collected from the medial side of the joint with a step size of 1mm. Fluorescence signal were collected in the AlexaFluor647 channel to visualize the LYVE1+ LVs (green) and GPF channel to visualize the anatomic structure of the joint using the GPF autofluorescence of the bone. (A) A 2D cross-section of 1 mm from the series of 622 slices collected for this joint. The autofluorescence signal shows the histology landmarks, including the distal end of femur and the proximal end of tibia with articular cartilage, subchondral bone, growth plates, and menisci (M). Arrow: most LYVE1+ signals are located on the anterior (patellar) side as unbranched vessel-like structures. Arrowheads: a possible lymphatic vessel branch point. Star: two circular LYVE1+ structures near the tibial growth plate. Note that since this is a 2D cross-section, whether they are two branching vessels perpendicular to the observation plane or two vessels parallel to the tibia axis is unclear. (B) 3D reconstruction of the synovial LVs of the joint (622mm), including sagittal, patella, and popliteal views. Anatomical structures of the joint can be observed. Note that in contrast to the 2D image, both the patella side and popliteal side have initial LVs with extensive branching. *Note in the patella rotation view, at the level of the tibial growth plates, two LVs are parallel to the tibial axis, which as represented as the two circular structures in the 2D cross-section image. Scale bar= 500mm

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Fig 2. Synovial lymphatic vessels in PTOA joints have increased branches, but shorter length, thinner diameter and smaller volume. 3D reconstruction showing LYVE1+ LVs (green) in the sham and PTOA joints. Branch analysis was performed using the "filament" module in Imaris10.2 (Oxford), which identifies branches (grey) and branch points (red). (A&B) Initial LVs in the PTOA joint visibly differs from sham. (C) Branch number/joint. (D) The mean length of all individual branches recognized by Amira in one joint. (E) The mean diameter of all individual branches recognized by Amira in one joint. (F) The total volume of LYVE1+signal of one joint. (G) LYVE1+LV volume/the volume of the synovial tissues. Student t-test were used to assess the statistical difference between sham and PTOA group.

Results: 1. 3D reconstruction of LVs reveals extensive LV network compared to a 2D image in the normal joint (Fig.1). One 1μm thick image of lightsheet 2D data resembled a typical LYVE1 immunohistochemistry of the knee, where the LYVE1+ signals were located in the synovium on the patella side, forming long unbranched vessel-like structures. Few LYVE1+ signals were on the popliteal side (1A). 3D reconstruction of 622μm in depth revealed LYVE1+ signals on both side of the joint, forming extensive LV structure with complex branching (1B). To visualize the LV branching structure, the 3D reconstructed image was rotated towards the patella (1B middle) and popliteal side (1B right). Notably, the star shows 2 circular LYVE1+ structures at the tibial growth plate level in the 2D (1A) were 2 LVs along the tibial axis in 3D (1B middle).

2. Synovial LVs in PTOA joints have increased branches with shorter length, thinner diameter, and smaller volume (Fig.2). We performed quantitative branching analysis, recognizing LV structures in grey lines, and branching points in red balls. PTOA joints had increased branching that were smaller and shorter (2A-B): increased branch # (197±22 vs. 74±9 in sham, p=0.0008) (2C), decreased mean branch length (59±7 vs. 146±3μm in sham, p< 0.0001) (2D), diameter (15±5 vs. 29 ±5μm in sham, p=0.03) (2E), and smaller LVYE1+ volume (0.36±0.11 vs. 12±4% in sham, p=0.03) (2G).

Conclusion: PTOA induces local lymphangiogenesis with impaired function. We found decreased LV volume (3D) despite increased LV branching #s (2D) in PTOA joints. Possible explanations for the difference between 2D and 3D analysis are: 1) 2D area underestimates the diameter changes; and 2) histology sections (4-10μm) underrepresents the fewer LV branches with ~30μm-diameter. Thus, impaired SLS draining function in PTOA joints are likely due to decreased LV volume. In conclusion, lightsheet imaging/3D analysis is an advantaged tool for studying SLS than the conventional immunostaining, allowing the observation of LV network in full depth of joints.

Abstract Number: 1809

Mass Spectrometry-Based N-Terminomics Uncovers Proteolytic Signatures and Pathways in Juvenile Idiopathic Arthritis Synovial Fluid

Andrew Zeft[1], Sirada Panupattanapong[2], Laura Nedorezov[3], Sumit Bhutada[3] and Suneel Apte[3], [1]Cleveland Clinic, Cleveland, OH, [2]Cleveland Clinic Foundation, Cleveland, OH, [3]Cleveland Clinic, Cleveland

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1809–1829) Pediatric Rheumatology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Juvenile idiopathic arthritis (JIA) is a chronic disease marked by persistent synovial inflammation, often leading to structural joint damage. While numerous proteases produced by synovial cells, chondrocytes, macrophages, and polymorphonuclear cells were implicated in joint damage in rheumatoid arthritis, few studies explored similar mechanisms in JIA. Targeting proteolysis represents a promising disease-modifying strategy and may yield novel biomarkers for JIA, but this approach requires a comprehensive understanding of proteolytic activity. The study objective was to utilize N-terminomics to define the proteolytic landscape of JIA joints.

Methods: Synovial fluid samples (n=5) were collected from JIA patients under an approved IRB protocol. Proteins were labeled at their N-termini using reductive dimethylation. Samples underwent trypsin digestion, followed by enrichment of N-terminally labeled or modified peptides using HPG-ALD polymer. Peptides were further separated by high-pH off-line fractionation and analyzed on a Bruker TimsTOF Pro mass spectrometer. High-confidence peptides were identified using a stringent false discovery rate and mapped to full-length protein sequences to determine cleavage sites. Proteases present in the samples were also identified.

Results: This analysis of JIA synovial fluid identified 13,268 proteolytically cleaved peptides from 854 proteins. Of these, 5,805 peptides (44%) originated from secreted proteins, reflecting the prevalence of circulating proteins in synovial fluid. Notably, 2,732 peptides (19.2%) were detected in all five samples. Comparison with the previously characterized osteoarthritis (OA) synovial fluid degradome showed 6,978 cleavage sites (32.9%) from 325 proteins to be unique in JIA synovial fluid. Ingenuity Pathway Analysis of peptides unique to JIA identified neutrophil degranulation as the most significant pathway. In total, 95 proteases were detected in JIA synovial fluid, including neutrophil-derived proteases and others distinct from OA synovial fluid.

Conclusion: Our findings demonstrate a vast proteolytic landscape of JIA synovial fluid, providing an unprecedented expansion of proteolytic events and identifying potentially causative proteases. Implication of neutrophil activity in protein and joint breakdown highlights the relatively neglected role of innate immunity in JIA and identifies numerous potential biomarkers of their impact. Continued degradome analysis of larger JIA cohorts and stratification by clinical variables will be crucial for elucidating affected pathways and advancing both diagnostic and therapeutic strategies for JIA.

Background/Purpose: T peripheral helper (Tph) cells stimulate excessive B cell responses in the joints of patients with autoantibody-positive arthritis, including seropositive RA in adults and ANA-positive oligoarticular (oligo) JIA in children. Despite this potentially shared disease pathogenesis, a substantial proportion of children with oligo JIA enter long-term remission while this is rare in seropositive arthritis. To better understand these divergent outcomes, we studied the ability of regulatory T (Treg) cells to restrain Tph-B cell interactions in oligo and seropositive polyarticular (poly) JIA.

Table 1. Clinical Characteristics of Study Participants.

	JIA (N=22)	Adult Controls (N=10)
Age at disease onset (median years, IQR)	6.5 (8.7)	-
Age at sampling (median years, IQR)	16.0 (9.0)	24.0 (6.0)

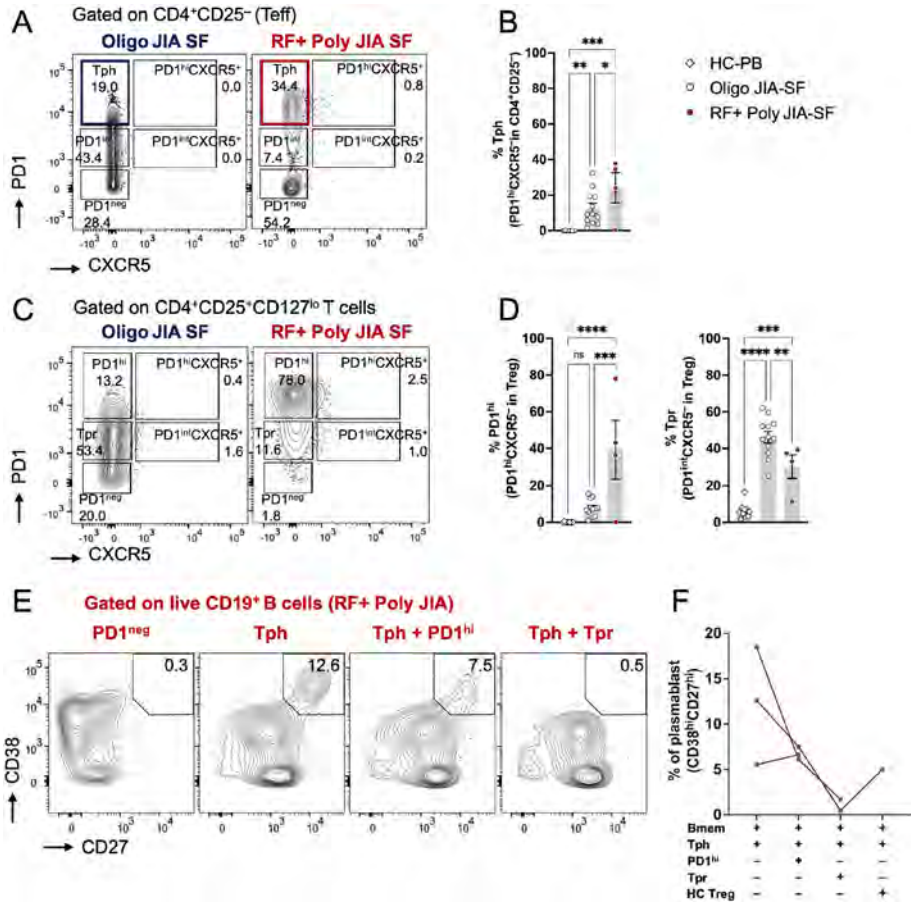

Figure 2. Synovial fluid Treg compartment of RF+ poly JIA patients display features of destabilized Treg cells. A) Representative flow staining showing Tph cells (CD4+CD25–PD1hiCXCR5–) from the oligo JIA-SF and RF+ poly JIA-SF. B) Bar chart showing the % of Tph cells from oligo JIA-SF (n=12) and RF+ poly JIA-SF (n=4) compared to HC-PB (n=10). C) Representative flow staining showing Tpr (PD1intCXCR5–) and PD1hi T cells (PD1intCXCR5–) from the oligo JIA-SF and RF+ poly JIA-SF. D) Bar charts showing % of PD1hi and Tpr cells in SF from oligo JIA-SF (n=12) and RF+ poly JIA-SF (n=4) compared to HC-PB (n=10). E) Representative flow staining showing % of plasmablast (CD38hiCD27+) of alive CD19+ B cells after co-culture of the given T cell populations from a RF+ poly JIA patient with Bmem cells from the PB of a third party. F) Scatter plot showing the % of plasmablast after co-culture SF Tph cells and an indicated Treg cell population from RF+ poly JIA-SF (n=3) with Bmem from PB of a third party. Mean ± SEM is shown. Statistical analysis: One-way ANOVA with Holm-Šidák 's correction for multiple comparisons. P-value: ns, >0.05; *, ≤0.05; **, ≤0.01; ***, ≤ 0.001; ****, ≤ 0.0001. HC, healthy control; oligo JIA, oligoarticular juvenile idiopathic arthritis; poly, polyarticular; RF, rheumatoid factor; PB, peripheral blood; SF, synovial fluid; Bmem, memory B cells; Tph, T peripheral helper cells; Tpr, T peripheral regulatory cells; Teff, effector T cells; Treg, regulatory T cells.

Methods: Synovial fluid (SF) from children with oligo and RF+ poly JIA (ILAR criteria) and peripheral blood (PB) from healthy controls were studied. Mononuclear cells were stained for surface markers, fixed/permeabilized for FOXP3 staining, and evaluated by flow cytometry. Bisulfite conversion pyrosequencing was done for methylation analysis of cytosine guanine dinucleotide (CpG) sites in the conserved noncoding sequence 2 (CNS2) region of *FOXP3* (EpigenDx). SF Tph cells were co-cultured in the presence of SEB for 5 days with memory B cells (Bmem) obtained from controls with/without a given Treg population at a ratio of 1:10:1. The percentage of plasmablasts measured by flow cytometry and total IgG level measured by ELISA served as co-culture readouts.

Results: Table 1 summarizes the study participants. FOXP3, the lineage defining transcription factor for Treg cells, was measured in Treg and T effector (Teff) cells oligo JIA SF. We identified a population of SF Tregs that co-expressed Treg ($CD4^+CD25^+CD127^{lo}FOXP3^+$) and B cell help ($PD1^{int}$) markers, which we termed T peripheral regulatory (Tpr) cells (Fig 1A-B). By contrast, T cells in the Treg gate that were $PD1^{hi}$ expressed low levels of FOXP3. Similar to PB Tregs, Tpr cells maintained a Treg-specific methylation pattern while $PD1^{hi}$ T cells did not (Fig 1C-D). Confirming their suppressive capacity, the addition of Tpr cells to Tph-Bmem co-cultures reduced plasmablast differentiation and IgG production (Fig 1E-G). Next,

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. we compared RF+ poly vs. oligo JIA and found that SF Tph cells were significantly more frequent in seropositive patients (Fig 2A-B). In the SF Treg compartment, PD1^{hi} T cells predominated in RF+ poly JIA patients while PD1^{int} Tpr cells were more plentiful in oligo JIA patients (Fig 2C-D). While not statistically significant, there was a trend towards reduced plasmablast differentiation in Tph-B cell co-cultures with PD1^{int}Tpr cells compared to PD1^{hi} T cells from RF+ poly JIA patients (Fig 2E-F).

Conclusion: Tpr cells expressing intermediate levels of PD1 were enriched in the joints of oligo vs. RF+ poly JIA patients and displayed features of stable Treg cells, including robust FOXP3 expression, Treg-specific methylation patterns, and intact suppressive capacity. By contrast, the Treg compartment of seropositive JIA patients was characterized by PD1^{hi} cells that had low FOXP3 expression, lack the Treg epigenic signature, and may be less suppressive. These findings suggest that Treg fitness and ability to suppress Tph-B cell interactions may play a role in disease course.

Session Title: (1809–1829) Pediatric Rheumatology – Basic Science Poster

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Interleukin (IL)-1 inhibitors are now regarded as the first line treatment option for systemic juvenile idiopathic arthritis (sJIA), however in up to half of cases there may be an incomplete response. Our objective was to evaluate the use of candidate biomarkers to predict responsiveness to IL-1 inhibition in a real-world cohort of new-onset sJIA patients who were enrolled in the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry FROST study.

Methods: FROST patients who received IL-1 inhibitors and had available DNA, RNA or plasma were included. Response was defined as cJADAS10 inactive disease (≤ 2.5, without fever or steroids) at 6 months while on IL-1 monotherapy. Whole

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

genome sequencing was used to determine class II HLA alleles and *IL1RN* single nucleotide polymorphisms (SNPs) associated with poor response to IL-1 therapy (PMID: 29609200). Expression of candidate genes associated with response and non-response (PMID: 33452871) and 28 interferon stimulated gene panel (ISG-28) were measured with custom NanoString assays. IL1RA autoantibodies were measured using Luciferase Immunoprecipitation System.

Results: 17/31 (54%) patients responded to IL-1 inhibition. We found no significant differences in expression of IL-1 response genes or in ISG-28 scores; however, *STAB1*, *CD163* and *VCAN* expression were significantly higher at baseline in non-responders compared to responders. A composite geomean score of these three genes >545 yielded 78% sensitivity and 93% specificity for non-response to IL-1 inhibitors. Non-responders trended toward lower neutrophil counts at baseline (p=0.0944). 6/29 (20%) patients were positive for HLA-DRB*15. There was no difference in response rate based on homozygosity for high-expressing IL1RN SNPs, presence of HLA-DRB1*15 or HLA-DRB1*11. No patients presented with autoantibodies to IL1RA at disease onset, but 2 patients developed them at 6 months. Both patients had been exposed to anakinra and achieved clinical response, which was maintained through 18 months. 3 patients had adverse events reported which may be suggestive of a possible drug hypersensitivity reaction (2 severe injection site reactions, one hepatitis). None of these patients were positive for HLA-DRB1*15 and 2 were positive for HLA-DRB1*11. There was no significant difference in the median ISG-28 scores between baseline and follow up of patients with paired samples (329.5 vs 509.0, p = 0.42), suggesting stability of the signature.

Conclusion: In this real-world cohort of new onset sJIA patients, we confirmed that *STAB1*, *CD163* and *VCAN* expression at baseline correlated with poor response to IL1 inhibition, suggesting a different immunologic phenotype that might benefit from alternative therapy. 2 patients who responded to IL-1 inhibitors developed anti-IL1RA antibodies at follow up. We identified that IL-1 inhibitors do not significantly increase type I interferon signatures in sJIA patients. *IL1RN* SNPs and HLA-DRB1*15 were not different between responders and non-responders in this cohort. It is possible that biomarkers have less predictive effect on treatment response in new onset patients, which might include monophasic patients who will improve independently of therapy.

Inflammasome and UPR activation in monocytes of HLA B27 positive children with Enthesitis related arthritis category of JIA

Shivika Guleria[1] and Amita Aggarwal[2], [1]SGPGIMS, Lucknow, Lucknow, Uttar Pradesh, India, [2]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India, Lucknow, Uttar Pradesh, India

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1809–1829) Pediatric Rheumatology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Enthesitis related arthritis (ERA) is a chronic immune-inflammatory disease with unknown etiology. HLA-B27 is the strongest risk factor predisposing to ERA like Spondyloarthritis (SpA). In adult SpA, HLA-B27 has been associated with unfolded protein response (UPR) and inflammasome activation in monocytes. However, no data is available in ERA.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table1. Clinical Characteristics and demographic details of the JIA-ERA patients

Parameter	HLA B27 Positive ERA	HLA B27 Negative ERA	p-value
Number	12	6	
Male/ Female	12/0	6/0	
Median age (years)	15 (12.25-17.5)	20.5(14.5-22.75)	**0.0497**
Median duration of illness (months)	25 (10-54)	72 (21-102)	
Arthritis	10 (83%)	3 (50%)	**<0.0001**
Enthesitis	8(66%)	0 (0%)	**<0.0001**
Sacroiliitis	8 (66%)	2 (33%)	**<0.0001**
Uveitis	0 (0%)	0 (0%)	
IBP	6 (50%)	3 (50%)	
ESR (mm/h)	48 (40-110)	23 (15.5-64)	
Family History	3 (25%)	1 (16%)	
Disease activity (JSpADa score)	4.75 (2.25-5)	1.75 (0.75-3.375)	**0.0196**

Methods: Patients with ERA and healthy controls (HC) were enrolled after informed consent. Monocytes from ERA patients and HC were separated from PBMCs/SFMCs using MACS columns. Purity and viability were checked by flow cytometry. Monocytes were stimulated with LPS (100ng/ml) and mRNA levels of TLR4, NLRP3, IL-1β, IL-18, BiP, sXBP1, CHOP, IRE1α and IL-23R were measured by qPCR. Protein levels of IL-1β and IL-18 in the culture supernatant were measured by ELISA. The caspase-1 activity was measured by flow cytometry using the Caspase 1 Kit.

Results: 12 HLA B27 positive, 6 HLA B27 negative ERA patients and 6 HLA B27 negative HC were included. Clinical features such as arthritis, enthesitis and sacroiliitis were more common in HLA-B27 positive ERA patients than in B27 negative patients (**Table1**). HLA B27 positive patients had higher disease activity compared with HLA B27 negative patients.

Monocytes of HLA-B27 positive ERA patients had more than 1.5-fold increase in mRNA expression of IL-1β, NLRP3, and TLR4 than HC. On the other hand, monocytes from HLA-B27 positive ERA patients also had more than 1.5-fold increase in mRNA expression of IL-18, NLRP3, and TLR4 as compared to monocytes from HLA-B27 negative patients. Monocytes from HLA B27 positive ERA patients produce more IL-1β than HLA B27 negative HC ($p< 0.01$). After LPS stimulation, there was further increase in mRNA expression of all the 4 genes and IL-1β production ($p< 0.001$). In comparison to HLA-B27 negative HC ($p< 0.05$) and HLA -B27 negative ERA patients ($p< 0.05$), the caspase expression was greater in HLA B27 positive ERA patients (**Figure1**). Expression of mRNA related to UPR activation (BiP and sXBP1, IRE1α) were similar in all 3 groups.

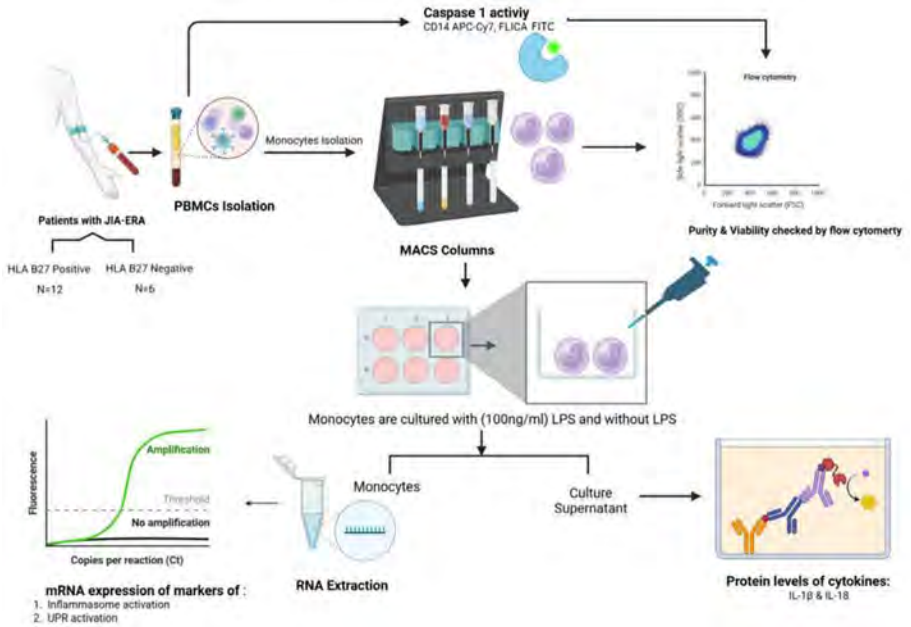

Figure1. Workflow of experiments

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

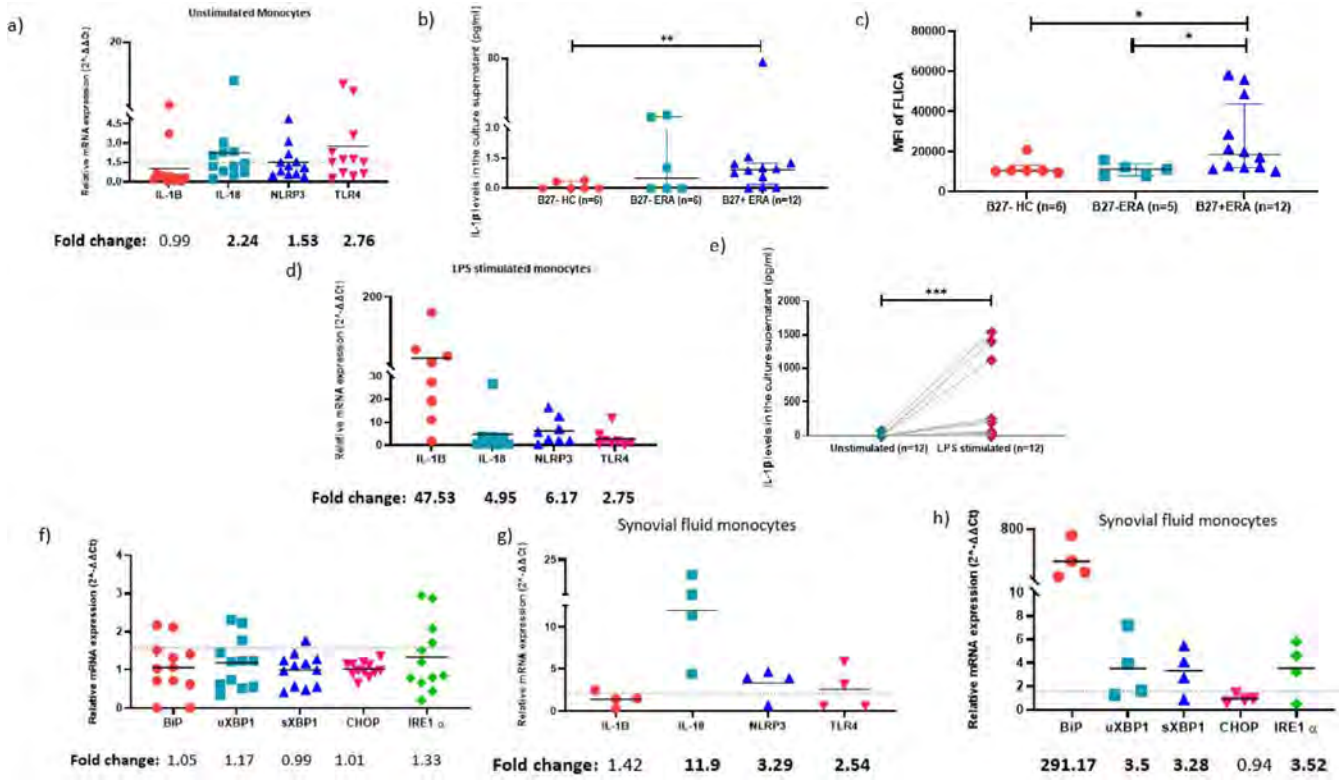

Figure2. a) Relative mRNA expression of inflammasome markers in the monocytes isolated from HLA B27 positive ERA patients compared to HLA B27 negative patients at baseline b) IL-1β levels in the culture supernatant of unstimulated monocytes of HLA B27 negative HC, HLA B27 negative patients, and HLA B27 positive ERA patients c) Mean Fluorescence Intensity (MFI) of FLICA FITC in HLA B27 negative HC, HLA B27 negative patients, and HLA B27 positive ERA patients d) Relative mRNA expression of inflammasome markers in the monocytes isolated from HLA B27 positive ERA patients after LPS stimulation e) IL-1β levels in the culture supernatant of LPS stimulated monocytes of HLA B27 positive ERA patients f) Relative mRNA expression of UPR activation markers in the monocytes isolated from HLA B27 positive ERA patients compared to HLA B27 negative patients g) Relative mRNA expression of inflammasome markers in monocytes from SFMCs compared to monocytes from PBMCs of HLA B27 positive ERA patients h) Relative mRNA expression of UPR activation markers in monocytes from SFMCs compared to monocytes from PBMCs of HLA B27 positive ERA patients

Paired analysis of monocytes from SFMCs of HLA B27 positive patients revealed 1.5-fold higher expression of IL-18, NLRP3, TLR4, BiP, sXBP 1, and IRE1α as compared to PBMCs. IL23R mRNA expression was only present in the monocytes isolated from SFMCs.

Conclusion: Activation of inflammasome pathway in the circulating monocytes and activation of both ER stress and inflammasome pathway at local site may contribute to higher inflammation burden and more severe disease in HLA-B27 positive ERA patients.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1809–1829) Pediatric Rheumatology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Juvenile Idiopathic Arthritis (JIA) is characterized by joint pain and inflammation. Persistent oligoarticular JIA(oligoJIA) is defined by the involvement of up to 4 joints throughout disease course. OligoJIA can progress to an extended form of arthritis (extended-oligoJIA), involving 5 or more joints after the first 6 months of disease. Polyarticular JIA is defined as affecting 5 or more joints in the first 6 months of disease. Over 30% of children with extended-oligoJIA experience uncontrolled disease requiring the use of several immunosuppressive medications even after 8-year follow-up. Moreover, even with current treatment options, 50-60% of children with extended-oligoJIA continue to experience pain, functional disability, disease activity, and impaired quality of life extending into adulthood. There is limited understanding of the cellular composition of inflammatory tissues in JIA, particularly in the affected synovium, which is a major barrier for the identification of disease biomarkers, diagnosis, and therapeutic targeting. The purpose of this study was to identify cell subsets associated with disease progression and severity in the synovium of children with JIA.

Methods: Fourteen synovial tissue biopsies of children with oligoJIA or polyarticular JIA, were collected by ultrasound guided biopsy. Cryopreserved synovial tissue was thawed and enzymatically digested in Liberase and DNAse I, prior to staining with a comprehensive antibody panel encompassing all major immune and non-immune cell types. Matching PBMC samples were also stained for flow analysis from 5 of the individuals. Synovial fluid biomarkers were measured by Luminex.

Results: Flow cytometry analysis revealed significant differences in the cellular composition of B cells, fibroblasts, and T-cell subtypes between PBMC and synovium samples from patients with JIA. Interestingly, we note a significant difference in tissue-specific HLA-DR+ CD8+ activated T cells in polyarticular JIA when compared to oligoJIA. Extending this analysis, we discovered significant correlations of activated and regulatory CD8+ T cell states with Juvenile Arthritis Disease Activity Scores (JADAS). Synovial fluid biomarkers such as IL-18, CD25, IL-6, and IL-23 were similarly correlated to disease activity and the frequency of tissue-specific activated T cells (PD-1+ CD-8+), T peripheral helper cells (HLA-DR+ CD4+), and HLA-DR+ fibroblasts.

Conclusion: With comprehensive flow cytometry analysis, we characterized the heterogenous cellular composition of JIA in both PBMC and disaggregated synovium. We observed increased frequencies of activated T cells specifically within the synovium correlated to disease severity and synovial fluid biomarkers.

Trapped in the NET: Impaired DNase function and targeted antibodies in the pathogenesis of pediatric lupus nephritis

Sohei Makita[1], Joyce Hui-Yuen[2], **Bharati Matta**[3], Betsy Barnes[4], Jenna Battaglia[5], Tatiana Borja[6], Boris Reizis[7], Lydia Thomas[8] and Kim Simpfendorfer[9], [1]NYU, New York, [2]North Shore LIJ Health System, Great Neck, NY, [3]The Feinstein Institutes for Medical Research, Manhasset, NY, [4]Northwell Health, Manhasset, NY, [5]Northwell Health, Manhasset, [6]Northwell Health- Cohen Children's Medical Center, Elmhurst, NY, [7]New York University Grossman School of Medicine, New York, NY, [8]Northwell Health - Cohen Children's Medical Center, Lake Success, NY, [9]Feinstein Institutes for Medical Research, Manhasset, NY

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1809–1829) Pediatric Rheumatology – Basic Science Poster

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Up to 80% of patients with pediatric systemic lupus erythematosus (pSLE) can present with renal abnormalities. Treatment of pSLE is often difficult and includes broad immunosuppression, which can lead to further damage, necessitating the discovery of new targets for therapy. In adult SLE (aSLE), neutrophil extracellular traps (NETs) have been shown to play a role in the development of lupus nephritis (LN). Further, loss-of-function mutations in the genes encoding for *DNASE1* and *DNASE1L3* are associated with aSLE and *DNASE1L3* mutations have been implicated in early onset monogenic lupus. Anti-NET protective antibodies have been also shown to be present in aSLE serum, thus protecting the NETs from DNASE digestion. In a cohort of treatment naïve pSLE patients with and without LN, we detected a significant increase in both blood and urinary NETs. The purpose of this study was to determine the mechanisms driving spontaneous NETosis in these patients, pre- and post-treatment, and evaluate whether NET levels may be used as an indicator of treatment response.

Methods: Plasma was obtained from 21 pSLE treatment-naïve patients, 13 post-treatment patients and 12 age- and sex-matched healthy children (pHC). Lupus disease activity was measured using SELENA-SLEDAI scoring, dsDNA antibody levels, and urine protein/creatine ratios. ELISA and smear assay were used to detect NETs in plasma and urine samples. DNase1L3 concentration was measured by ELISA, DNase enzymatic activity was determined via targeted assay (Dnase1 versus DNase1L3), NET degradation was determined with patient plasma, and blocking assays were used to assess autoantibody functionality. Targeted and whole exome sequencing was performed to identify genetic mutations. Immunofluorescence in renal biopsies was performed to evaluate NETs at end organ.

Results: Accumulation of NETs was observed with significant inhibition of DNase1 and DNase1L3 activities pre-treatment. Notably, NET levels remained high post-treatment. No known loss-of-function variants in *DNASE1L3* or *DNASE1* were found. Finally, we found higher anti-DNASE1 and anti-DNASE1L3 antibodies selectively playing role in inhibition of DNASE1L3 activity. Moreover, higher anti-NET protective antibodies were found in pLN plasma pre- and post-treatment.

Conclusion: Our data show that defective functional DNase1/1L3 activity and increased anti-NET protective antibodies drive delayed clearance and accumulation of NETs in pLN. Taken together, our results suggest NETs and the mechanisms driving spontaneous NETosis as novel non-invasive biomarkers of pLN and potential novel targets for therapy.

Abstract Number: 1815

New-Onset Juvenile Spondyloarthritis is Characterized by Bone Metabolism Disturbances with Biomarker Potential

Brittney Newby[1], Timothy Brandon[1], Pamela Weiss[2] and E. John Wherry[3], [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]Childrens Hospital of Philadelphia, Philadelphia, PA, [3]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1809–1829) Pediatric Rheumatology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Juvenile spondyloarthritis (JSpA) management is hindered by the lack of reliable biomarkers to predict which patients will develop progressive structural changes, such as erosions and ankylosis. Chronic inflammation, driven by cytokines like IL-17 and TNFα, disrupts bone homeostasis by enhancing osteoclast-mediated resorption and compensatory osteoblast-driven deposition, ultimately resulting in bone damage. Bone turnover proteins may serve as potential biomarkers for disease activity and progression in JSpA. In this study, plasma levels of key regulators of bone resorption-including osteopontin (OPN), acid phosphatase 5 (ACP5), and dickkopf-1 (DKK-1)-as well as bone formation markers, such as platelet-derived growth factor-BB (PDGF-BB), and alkaline phosphatase (ALPL), were compared between JSpA patients and healthy controls.

Methods: This cross-sectional, single-center study analyzed plasma samples from 30 systemic medication-naïve JSpA patients who met at least one of the following criteria: (1) International League of Associations for Rheumatology (ILAR) enthesitis-related arthritis (ERA) criteria, or (2) inflammatory sacroiliitis on MRI. Plasma concentrations of 13 bone metabolism–related proteins, along with IL-17, IFN-γ, and TNFα, were measured using the LEGENDPlex multiplex bead-based immunoassay. These levels were compared to previously published reference ranges from healthy controls using the Mann-Whitney test. Plasma concentrations were correlated with other analytes and clinical metadata using Spearman's Rank Correlation.

Results: Table 1 summarizes the demographic data and plasma protein concentrations. Compared to healthy controls, subjects with JSpA had significantly higher levels of OPN ($P < 0.0001$), ACP5 ($P < 0.0001$), and ALPL ($P < 0.0001$). In contrast, DKK-1 ($P < 0.001$) and PDGF-BB ($P = 0.004$) levels were significantly lower in JSpA patients. TNFα was significantly

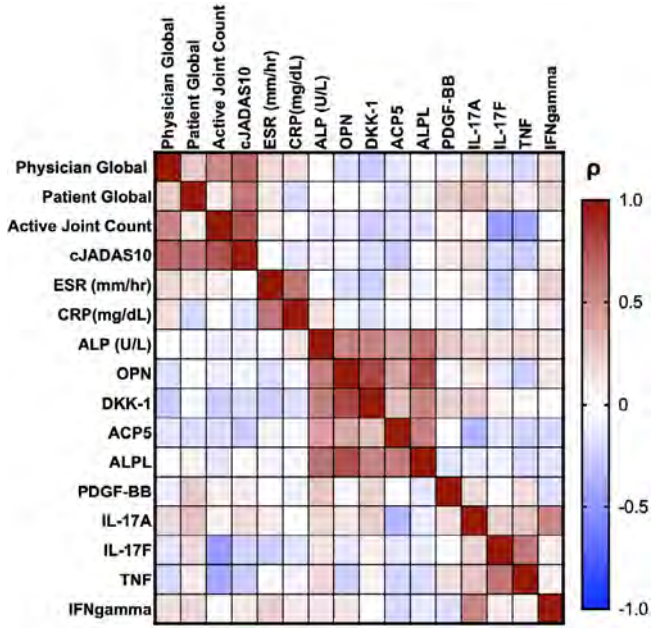
Juvenile Spondyloarthritis Patients reveal an altered bone metabolism profile



Spearman Rank Correlation Analysis of Bone Metabolism Proteins with Clinical Metadata

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

elevated in patients, whereas no significant differences were observed in IL-17 or IFN-γ. Sub analysis reveals no difference between HLA B27 positive and negative subjects. These findings are graphically represented in Figure 1. These proteins had low correlation with clinical Juvenile Arthritis Disease Activity Score (cJADAS10) and inflammatory markers (ESR and CRP), with all r between -0.25 and < 0.25 (Figure 2). OPN, ACP5, ALPL, and DKK-1 had strong, positive correlations with alkaline phosphatase activity

Conclusion: Significant differences in bone metabolism proteins were observed between JSpA patients and healthy controls, suggesting a shift toward bone resorption driven by increased osteoclast activity and disrupted bone homeostasis. Further, the low correlations observed between disease activity measures and inflammatory markers highlight the need for a multimodal approach to assessing activity in axJSpA. Further validation is needed to determine whether bone metabolism proteins could serve as biomarkers of disease progression and potential therapeutic targets.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1809–1829) Pediatric Rheumatology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Juvenile dermatomyositis (JDM) is the most common idiopathic inflammatory myopathy in children. JDM often presents with rash, and skin inflammation is more refractory to treatment compared to muscle inflammation. Treatments are limited due to incomplete understanding of disease pathogenesis, including under-explored analysis of the cellular composition of lesional skin, exacerbated by a lack of access to pediatric tissue. Therefore, we assembled a cohort of archival JDM skin biopsies and performed single-nuclei RNA-sequencing for an unbiased analysis of skin-specific cellular and transcriptomic drivers of JDM.

Methods: Single nuclei RNA was isolated from formalin-fixed paraffin-embedded (FFPE) skin biopsies using the 10X Genomics Flex platform; the cohort included patients with JDM (n=12) and controls (CTL, n=4). All JDM patients met 2017 EULAR/ACR classification criteria, and 11/12 were treatment-naïve at sampling. We used SoupX to remove ambient RNA, and DoubletFinder to remove doublets. We performed UMAP dimensionality reduction and Louvain clustering with Seurat. Cell clusters were annotated using published cell type-specific marker genes. Analysis of differentially expressed genes (DEG) was performed using Model-based Analysis of Single-cell Transcriptomics. Cell type abundance between JDM and CTL was analyzed with Milo and the Wilcoxon rank sum test. Gene set scores were calculated using the Seurat AddModuleScore() function. Given clinical differences between skin and muscle inflammation in JDM, we compared our skin data to a single-nuclear RNA-sequencing dataset from JDM (n=6) and control (n=7) muscle biopsy samples.

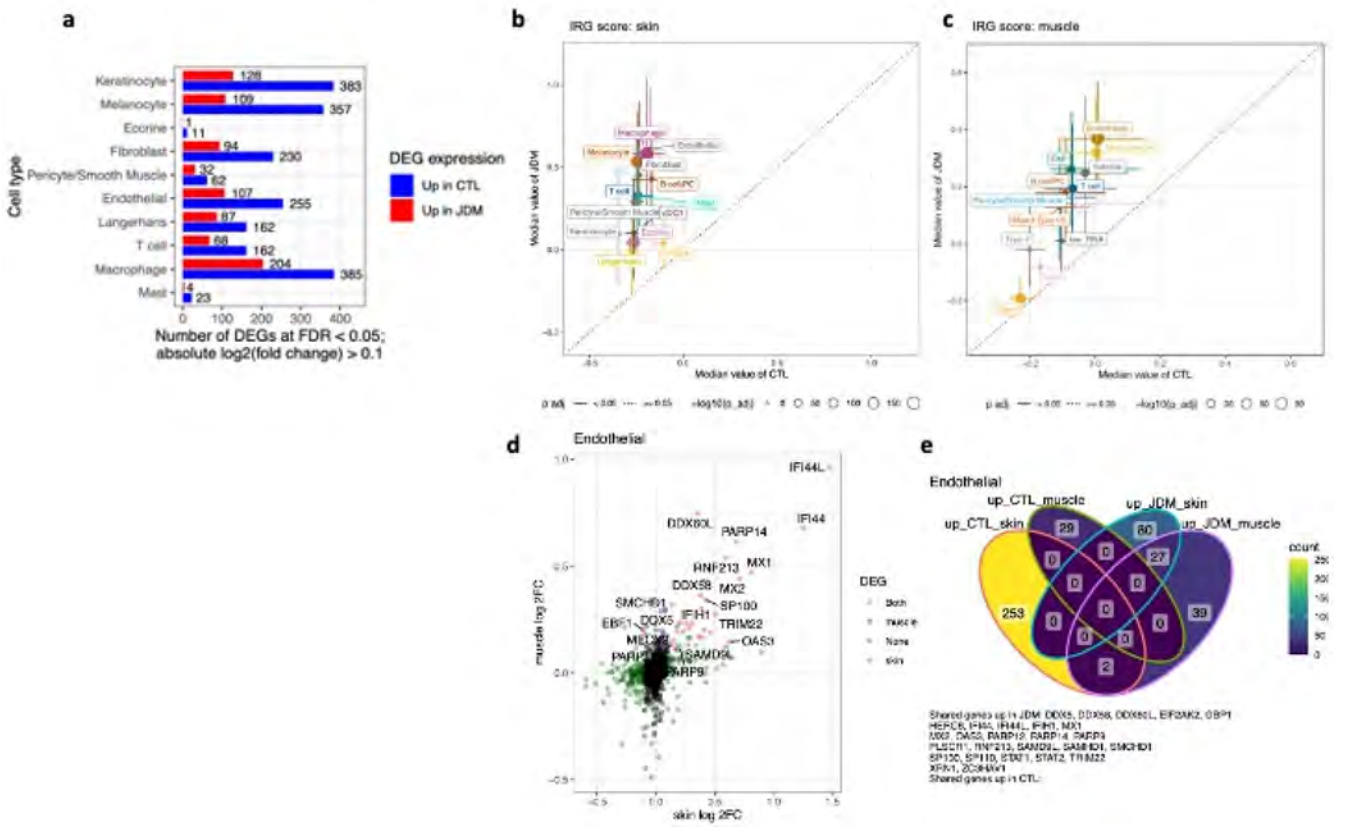

Fig 3. Endothelial cells exhibit high differential expression of IFN-response genes in both muscle and skin JDM samples. a) Number of differentially expressed genes (DEG) in each cell type that show increased expression in JDM or CTL. b,c) IRG score for b) skin samples and c) an outside muscle biopsy single-nuclei RNA-seq dataset. Scores are calculated using 28 IRG from Kim et al 2018. Dots indicate the median IRG score across all cells in a cell type from CTL samples (X-axis) and JDM samples (Y-axis); lines indicate interquartile range. d) Scatterplot comparing the log2(fold change) values of DEG analysis in muscle (X-axis) and skin (Y-axis); DEG criteria is FDR < 0.05, absolute(log2(fold change)) >0.1. e) Venn diagram comparing DEG in outside muscle data set and skin JDM atlas.

Results: From the 91,216 cells analyzed, we identified 14 major cell types (Fig 1a,b) and 20 unique cell clusters (Fig 1c). JDM samples showed increased abundance of immune cells compared to CTL (Fig 2a,b). Analysis of cellular neighborhoods also identified subsets of neighborhoods with consistently higher abundance of JDM in immune cell types (Fig 2c,d). Keratinocytes, melanocytes, endothelial cells, and macrophages showed the highest number of differentially expressed genes (Fig 3a). In all skin cell types, JDM samples had higher average expression of Interferon (IFN)-response genes (IRG) compared to CTL (Fig 3b). Endothelial cells showed the highest median IRG set expression in both JDM skin (Fib 3b) and muscle (Fig 3c), with many IRG demonstrating differential expression in both skin and muscle endothelial cells (Fig 3d,e).

Conclusion: Single cell skin transcriptomics in JDM highlights dysregulated immune and endothelial cell populations contributing to disease pathogenesis. Altered IFN is a hallmark of JDM skin tissue, with macrophages, melanocytes, and endothelial cells exhibiting the highest levels of IRG expression. While all cell types show high IRG expression in JDM, endothelial cells exhibit the highest median IRG expression in both muscle and skin. This unique single-cell atlas of JDM skin will generate critical hypotheses for investigating cellular mechanisms of JDM rash and vasculopathy and for identifying targeted therapies.

Abstract Number: 1817

Sex-specific mechanisms associated with female childhood-onset systemic lupus erythematosus revealed by transcriptomic analysis of transgender adolescents undergoing gender-affirming sex hormone therapy.

Heather Cross[1], Hannah Peckham[1], Gary Butler[2], Elizabeth Rosser[3], Elizabeth C Jury[1], George Robinson[1] and **Coziana Ciurtin**[1], [1]University College London, London, United Kingdom, [2]University College London Hospital NHS Trust, London, England, United Kingdom, [3]University College London, London, England, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1809–1829) Pediatric Rheumatology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Sex determinants may play a role in the immunological sexual dimorphism of childhood-onset systemic lupus erythematosus (cSLE). This study aimed to investigate the impact of sex determinants on immune transcriptomic changes and their association with cSLE.

Methods: We performed PBMC RNAseq analysis on post-pubertal cis-female adolescents with cSLE (n=74) and healthy controls (HCs, n=20), as well as transgender adolescents (trans-male, XX TM; trans-female, XY TF, n=32 samples) undergoing gender-affirming hormone therapy (GAHT) across 3 timepoints; pre-treatment, on gonadotrophin-releasing hormone agonist (GnRHa, puberty blocker) and on GAHT, TM on testosterone (T) and TF on oestradiol (E). Rstudio was used to

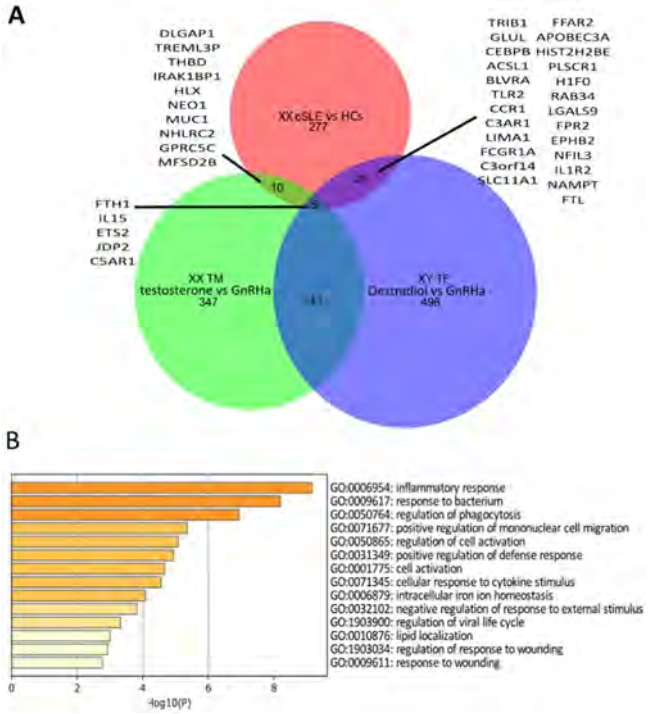

Figure 1. A. Venn diagram showing DEGs shared between cSLE cohort vs. age matched healthy controls (HCs) and transgender cohort for each distinct sex chromosomal background, comparing the effect of GAHT (XX TM receiving testosterone vs. VY TF receiving estrogen) vs. GnRHa ($P<0.05$). B. Pathway enriching analysis of the overlapping 40 DEGs between the cSLE cohort vs. HCs vs. transgender cohort, indicating the inflammatory response as being the most enriched.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

identify the significantly differentially expressed genes (DEGs, DEseq2). Pathway enrichment analysis (PEA), clustering and normalised gene count analysis were conducted with compatible software.

Results: We identified 40 DEGs (fold change >1.5, P< 0.05) in the cis-female cSLE cohort vs. HCs (defining a post-pubertal cSLE signature) that overlapped with the transgender cohort (on GAHT) **(Figure 1A**). Specifically, in the XY TF group (on E vs. GnRHa), there were 24 upregulated/1 downregulated DEGs, including TLR2 (upregulated, p= 0.0077), and IL1R2 (upregulated, p=0.018), which overlapped with the cSLE signature. Similarly, in the XX TM group (on T vs. GnRHa), there were 6 upregulated/4 downregulated overlapping DEGs, including IL15 (upregulated, p= 0.019). PEA revealed DEGs linked to the inflammatory response processes, cell migration/activation and lipid regulation (**Figure 1B**). Additionally, we discovered 63 X-linked DEGs (P < 0.05) in the GAHT vs. GnRHa groups across both XX and XY backgrounds, however, these did not overlap with the cSLE signature, suggesting a lesser impact of sex hormones on X-linked transcripts related to cSLE susceptibility. However, the X-linked non-coding RNA X-inactive specific transcript (XIST) and the XIST antisense non-coding RNA TSIX, were both significantly increased in cSLE vs. HCs (p=0.018 and 0.0007). XIST correlated negatively with cSLE interferon scores (P=0.0010, r=-0.38) and X-linked TLR7 expression (P=0.0004, r=-0.40), but TSIX did not, supporting a role for X chromosome inactivation in controlling the pathogenic mechanisms associated with cSLE in females.

Conclusion: This analysis demonstrated unique inflammatory transcriptomic changes (DEGs) induced by GAHT in transgender adolescents, which overlapped with cis-female cSLE adolescents, as well as sex hormone-independent associations between XIST expression and inflammatory cSLE pathogenic mechanisms. To our knowledge, this is the first exploration of the impact of sex hormones disaggregated from their corresponding sex chromosomal background in driving transcriptomic changes potentially relevant for understanding female cSLE pathogenesis.

Session Title: (1809–1829) Pediatric Rheumatology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Childhood-onset lupus is generally associated with a more severe disease course than adult-onset lupus. DNA methylation alterations are known to play a key role in lupus pathogenesis. While we previously showed that childhood-onset lupus is linked to a higher genetic risk burden compared to adult-onset disease, the epigenetic landscape of childhood-onset lupus remains largely unexplored. This study aimed to characterize DNA methylation changes in childhood-onset lupus.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. K-means clustering of patients with childhood-onset lupus based on DNA methylation profiles. Hypomethylated CpG sites characteristic of each cluster were analyzed for functional enrichment, revealing significant overrepresentation in Gene Ontology (GO) biological processes and KEGG pathways.

Methods: A total of 64 patients with childhood-onset lupus and 47 healthy controls were included in this study, along with an independent validation cohort of 38 additional patients. DNA was isolated from PBMCs in the study cohort and from whole blood in the validation cohort to assess DNA methylation using the Infinium MethylationEPIC v2.0 array (Illumina). Quality controls and statistical analyses were performed using *minfi* and *limma* R packages. Methylation differences among groups were tested through linear regression, adjusting for age, sex, medication use, and cell subset compositions. Differences in clinical manifestations were assessed using Fisher's exact tests. Gene ontology enrichment analyses were performed with Metascape and GREAT.

Results: Case-control differential DNA methylation analysis revealed significant hypomethylation in interferon-regulated genes in lupus, such as *DTX3L*, *PARP9*, *IFI44L*, and *MX1*. The enrichment analysis confirmed the presence of type I interferon signature-related biological processes, consistent with adult-onset lupus. Hypomethylation in genes related to B cell activation and cellular senescence was correlated with more active disease, as measured by SLEDAI scores. K-means clustering analysis of patients based on DNA methylation patterns identified 3 distinct lupus clusters. Cluster 1 was characterized by the enrichment of hypomethylated genes involved in cell adhesion and response to growth factor pathways; Cluster 2 exhibited hypomethylation in genes related to regulation of cell differentiation and cell fate determination; and Cluster 3 was enriched in response to oxidative stress and Rap1 signaling pathway in hypomethylated genes. Sex-based analysis revealed hypomethylation in males at sites enriched in immune response pathways, with over 80% of differentially methylated positions in male individuals with childhood-onset lupus validated in the replication cohort.

Conclusion: Childhood-onset lupus is marked by significant hypomethylation in interferon-regulated genes, with DNA methylation changes correlating with disease activity and revealing distinct epigenetic molecular subgroups. Sex-specific patterns further suggest epigenetic contributions to sex-based disease heterogeneity in lupus.

Abstract Number: 1819

Spatial Transcriptomic Profiling Reveals Interferon Activation and CD8$^+$ T Cell Dominance in Systemic Juvenile Idiopathic Arthritis-Macrophage Activation Syndrome Liver Inflammation

Esraa Eloseily[1], Taskin Sabit[2], Lara Berklite[3], Grant Schulert[4] and Alexei Grom[4], [1]UT Southwestern Children's Medical Center, Dallas, TX, [2]Cincinnati Children's Hospital Medical Center, Division of Rheumatology, Cincinnati, OH, [3]Cincinnati Children's Hospital, Cincinnati, OH, [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1809–1829) Pediatric Rheumatology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic juvenile idiopathic arthritis (SJIA) with macrophage activation syndrome (MAS) involves severe systemic inflammation and hepatocellular injury. Our prior histopathology studies showed increased CD8$^+$ T cell and CD163$^+$ macrophages in SJIA-MAS compared to SJIA without MAS (1). However, distinguishing SJIA-MAS liver involvement from autoimmune hepatitis (AIH), familial hemophagocytic lymphohistiocytosis (FHLH), and steatohepatitis (SH) remains challenging. We aimed to define spatial immune signatures across SJIA-MAS, AIH, FHLH, SH, and healthy controls (HC) using spatial transcriptomics with the ultimate goal to develop diagnostic biomarkers for clinical practice.

Methods: Formalin-fixed, paraffin-embedded liver tissues from SJIA-MAS (n=6), SJIA without MAS (n=1), AIH (n=7), FHLH (n=6), SH (n=5), and HC (n=6) were analyzed using the NanoString GeoMx DSP® platform. Immunofluorescent staining for CD18, CD68, CDE, and nuclear DNA was used to select regions of interest (ROIs) enriched for (1) hepatocytes; (2) macrophages, and (3) lymphocytes. Spatially resolved gene expression was Q3 normalized. In the initial analysis, levels of expression of the IFN-induced signature genes (ISG) as well as markers specific for CD4+ T cells, cytotoxic T cells (CD8, GZMb, PRF) and macrophages (CD163) were compared between the clinical groups in macrophage- and T cell-enriched compartments.

Results: SJIA-MAS samples showed strong interferon-stimulated gene (ISG) activation (STAT1, EPSTI1, CXCL9) in both macrophage and T lymphocyte enriched ROIs and higher expression of cytotoxic markers (GZMB), particularly in T cell–enriched areas, compared to mild ISG activation in SJIA without MAS (figure 1). AIH samples exhibited heterogeneous

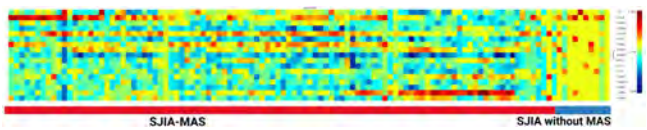

Figure 1 Heatmap showing differential expression of interferon-stimulated genes and genes and T cell markers between SJIA-MAS and SJIA without MAS

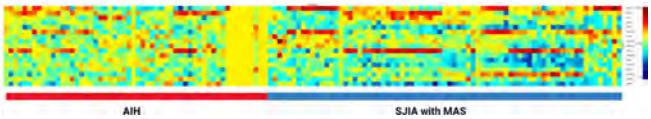

Figure 2 Heatmap showing differential expression of interferon-stimulated genes and genes and T cell markers between autoimmune hepatitis and SJIA-MAS

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1. Spatial expression of immune markers across SJIA-MAS, SJIA without MAS, AIH, and FHLH. SJIA-MAS shows high ISG and cytotoxic signatures; other groups display lower or variable expression

Feature / Marker	SJIA-MAS	SJIA without MAS	AIH	FHLH
STAT1 / CXCL9 / EPSTI1	High (consistent across cell types)	Moderate	mild to moderate	Low to moderate
GZMB (cytotoxic markers)	High	Mild	Low	Low
CD8A (CD8+ T cell infiltration)	High	Mild	Low	Low
CD4 (CD4+ T cells)	Low	Moderate	Moderate	Low to moderate
LY6E	Low to moderate	Mild	Low to mild	Moderate to High (in macrophages)
Overall ISG intensity	Strong and widespread	Mild to moderate	Weak and inconsistent	Low to moderate, Patchy

immune profiles with variable but modest $CD4^+$ T cell expression with less prominent ISG (figure 2). FHLH shared partial interferon signatures but had lower overall ISG expression. LY6E was selectively elevated in FHLH macrophages (table 1).

Conclusion: SJIA-MAS is defined by activation and expansion of $CD8^+$ T cells in addition to strong type I/II interferon responses, distinct from SJIA without MAS, AIH, and FHLH. Particularly high expression of CXCL9 distinguished SJIA-MAS. This suggests that serum CXCL9 may help distinguish MAS-related liver injury from other SJIA-associated pathologies. Global gene expression analysis in the same samples is ongoing.

Abstract Number: 1820

Cytokine profiling in refractory systemic juvenile idiopathic arthritis reveals distinct signatures for macrophage activation syndrome and lung disease.

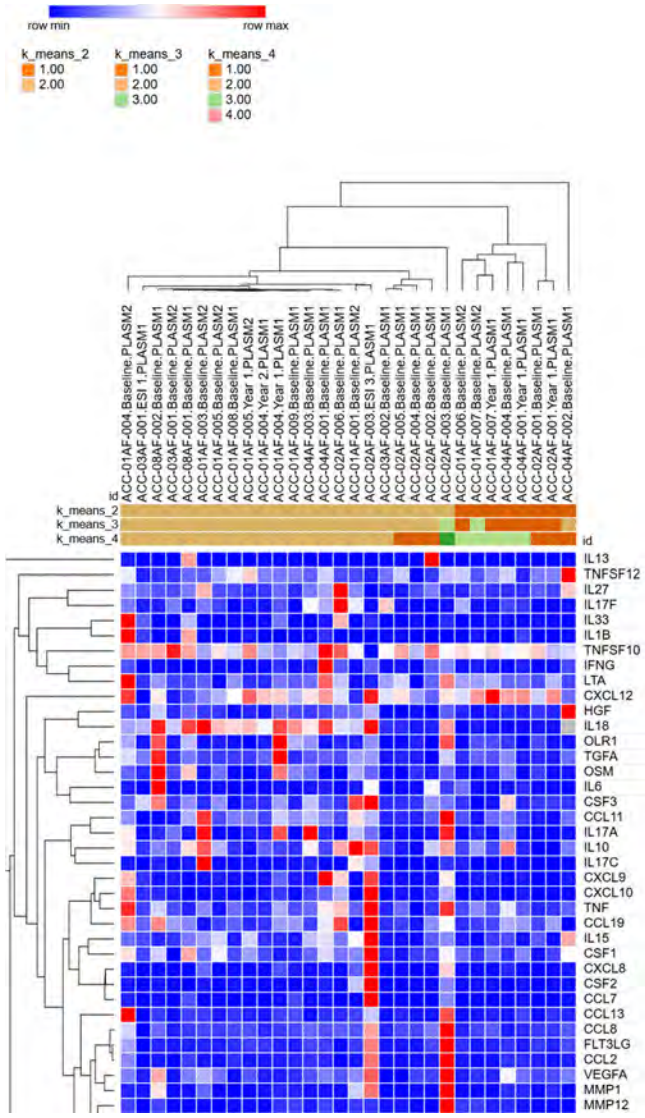
Taskin Sabit[1], Minyi Yu[2], Joy Baker[1], Sanjeev Dhakal[3], Sam Chiang[4], Scott Canna[5], Randy Cron[6], Lauren Henderson[7], Karen Onel[8], Mona Riskalla[9], Tiphanie Vogel[10], Pui Lee[11], **Grant Schulert**[2] and Alexei Grom[2], [1]Cincinnati Children's Hospital Medical Center, Division of Rheumatology, Cincinnati, OH, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]Cincinnati Children hospital, Cincinnati, OH, [4]Cincinnati Children's Hospital Medical Center, Cincinnnati, OH, [5]Children's Hospital of Philadelphia, Philadelphia, PA, [6]University of Alabama at Birmingham, Birmingham, AL, [7]Boston Children's Hospital, Watertown, MA, [8]HSS, New York, NY, [9]University of Minnesota Masonic Children's Hospital, Minneapolis, MN, [10]Baylor College of Medicine, Houston, TX, [11]Boston Children's Hospital, Newton, MA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1809–1829) Pediatric Rheumatology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic Juvenile Idiopathic Arthritis (SJIA) is a severe inflammatory disorder that affects the joints as well as other organ systems, with complications including Macrophage Activation Syndrome (MAS) and Lung Disease (LD). Identification of biomarkers and cytokines remains crucial for prognosis and for defining therapeutic targets for SJIA with and without MAS and LD. In this study, we investigated plasma cytokine profiles in a large, multicenter cohort of refractory SJIA cases.

Methods: 22 SJIA patients were enrolled from 5 centers along with 6 healthy sibling controls. 11 had MAS at the onset of SJIA diagnosis, 8 had been diagnosed with LD, 4 have 1-year follow-up, 1 has 2-year follow-up. Based on clinical history, the samples were subdivided into groups as SJIA with/without MAS or LD. Plasma cytokine profiling of 37 cytokines,

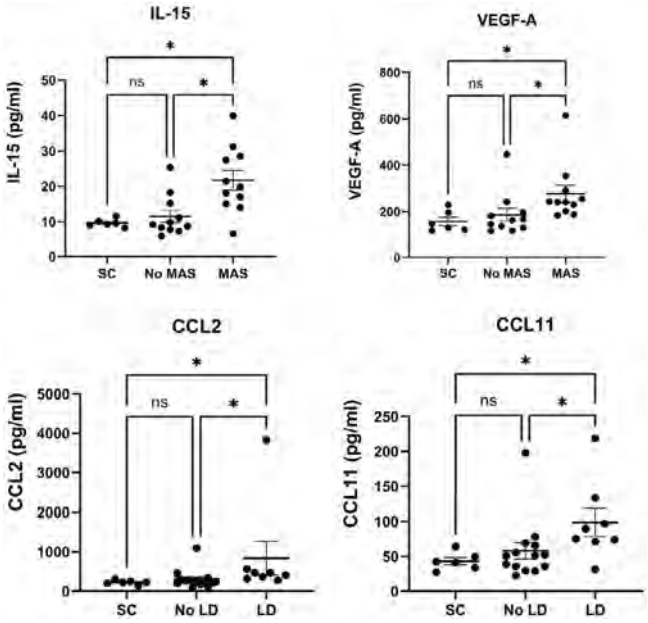
23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



chemokines and immune-related signaling proteins were measured using the Target 48 Olink cytokine panel. Interferon transcriptional scores were determined using a custom Nanostring panel.

Results: Plasma levels of several cytokines—including IL-2, IL-1β, HGF, IL-7, IL-18, IFN-γ, CXCL8, CSF3, CCL7 and IL-17A—were significantly elevated in SJIA patients compared with sibling controls. Hierarchical clustering of the cytokine profiles showed that healthy controls clustered with a subset of patients samples, but were segregated from patients with SJIA and elevated IL-18. K-means clustering of patients revealed 3 distinct groups (Figure). SJIA with MAS (n=11) at onset showed an upregulation in IL-15 and Vascular Endothelial Growth Factor-A (VEGF-A) compared to the SJIA without MAS group (n=11). While CCL2 and CCL11 showed similar levels in SJIA patients without lung disease (no LD group, n=14) and sibling controls (SC group, n=6), these chemokines were significantly elevated in SJIA patients with lung disease (LD group, n=8). Of the 13 SJIA patients who underwent Interferon transcriptional score test, only one was newly diagnosed and treatment-naive, while the remaining patients had previously been diagnosed with SJIA and had already received treatment. Interferon transcriptional scores were normal in most patients, but were elevated at 3 patient visits and in one control. One patient had an elevated type I IFN score (120.5, normal range < 57) with various scratched bug bites and dry skin on shins and salves at time of sample collection. Another patient with a highly elevated type I IFN score (563.2) had a history

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



of acute illnesses at the time of sample collection (cough and congestion). Another patient, triggered by disease flare and had MAS at the time of sample collection exhibited an elevated type I IFN score of 238.5.

Conclusion: This represents a multisite, longitudinal cohort of refractory SJIA patients. Our analysis reveals a distinct biomarker signature for SJIA complications, suggesting differential immunopathogenic mechanisms. Interestingly, most patients did not have an elevated interferon score at visit 1 for the study cohort. Further work will examine how inflammatory signatures change during treatment of refractory SJIA.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1809–1829) Pediatric Rheumatology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Chronic anterior uveitis (CAU) is a potentially sight-limiting complication of pediatric rheumatic diseases, including juvenile idiopathic arthritis. However, the underlying inflammatory biology of CAU in the eye is poorly understood, and there is a critical need for improved biomarkers for CAU development, progression, and damage. Here, we developed methods for RNA collection and transcriptional profiling from tear fluid of children with CAU.

Methods: Tear fluid was collected using Schirmer strips. CAU was graded as active (anterior chamber [AC] cell ≥0.5+) or inactive (AC=0) by Standardization of Uveitis Nomenclature (SUN) criteria. RNA was extracted from fresh or frozen absorbed Schirmer strips using three methods. MagMAX-96 Total RNA Isolation Kit was used after incubating with either 140uL of Lysis/Binding, or with 500uL Phosphate Buffered Saline (PBS). Alternatively, 500uL of TRIzol Reagent (ThermoFisher) was added to each tear strip, followed by RNA extraction. Samples with RNA Integrity Number (RIN) > 4 were selected for transcriptional profiling using the Ampliseq Transcriptome Panel on the Ion Torrent sequencing system. Sequencing data was processed and aligned using Ion Torrent, and differential gene expression for genes with mean reads per million > 5 was determined using AltAnalyze ($p < 0.05$, fold change >2). Pathway analysis was performed using GO-Elite.

Results: For both RNA extraction methods using the MagMAX-96 Total RNA Isolation kit, the concentration of RNA was low and of poor quality. In contrast, for 32 samples that were extracted via TRIzol, RNA concentrations ranged from 6.9ng/uL – 69.8ng/uL with RIN numbers 1.0 – 7.8. We then performed Ampliseq Transcriptome profiling on 6 tear RNA samples from 4 patients with active CAU and 7 samples from 5 patients with inactive CAU (Table 1). One patient with active CAU was excluded after sequencing for low read quality. The remaining samples were sequenced to a mean depth of 6.4 million reads (range 4.0-9.9 million) and we identified 11,595 genes with mean expression >5 RPM. Comparing active to inactive CAU, we found 113 significantly upregulated and 35 significantly downregulated genes (Figure 1). Among the most enriched gene pathways of upregulated genes in active CAU were laminin complex (z-score 13.3, adjusted p=0.026), extracellular matrix (z-score 7.6, adjusted p=0.003), and regulation of cell migration (z-score 5.1, adjusted p=0.09). The most significantly enriched gene pathway of downregulated genes in active CAU was immune system processes (z-score 6.2, adjusted p=0.0001), including *IL7R*, *IRF5*, *NAIP*, and *NCF1*. Among the marker genes for patients with inactive CAU was MAPILC3A, which encodes LCA3, expressed in the retinal pigment epithelium, which has a key role in blood-retinal barrier and retinal immune regulation.

Table 1: Clinical and demographic features of uveitis patients in the study, as well as RNA concentration, quality, and sequencing depth.

Sample ID	Sex	Age	Diagnosis	OD/OS?	Uveitis Activity	SUN Grade	RNA concentration (ng/uL)	RIN	Sequence depth

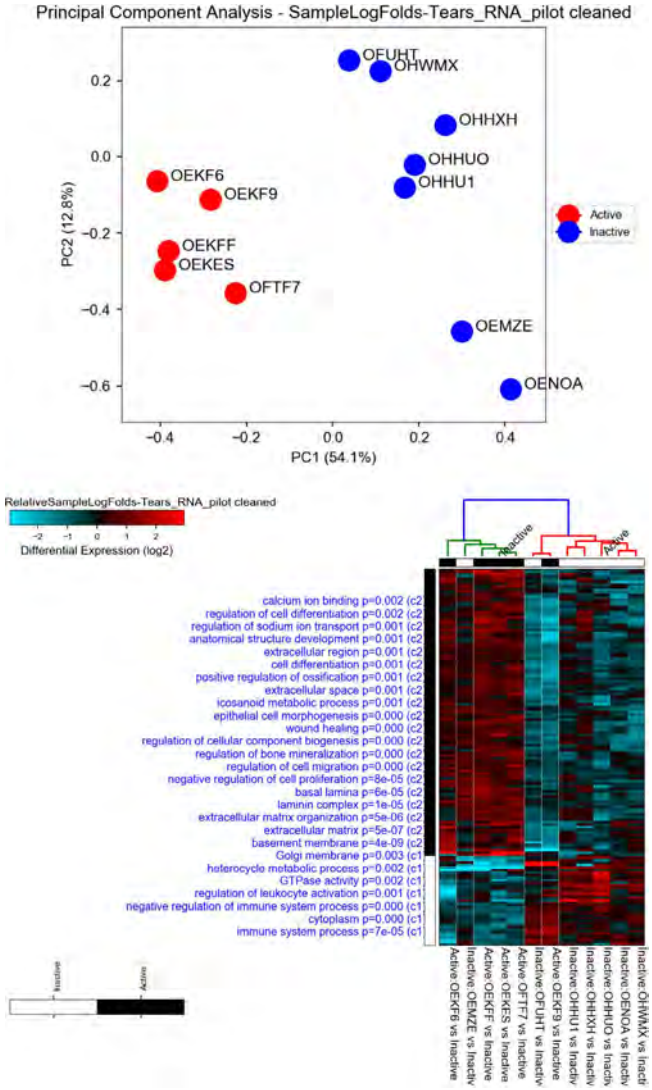

Figure 1: Transcriptomic profiling of tear RNA from chronic anterior uveitis. Top: principal component analysis of differentially expressed genes. Red= active uveitis, blue= inactive uveitis. Bottom: hierarchical clustering of differentially expressed genes between active and inactive uveitis.

Conclusion: This pilot work demonstrates our ability to obtain high-quality RNA suitable for transcriptomics from tear fluid of children with CAU. We also find that active CAU is associated with transcriptional activation in pathways associated with eye injury and blood-retinal barrier, including laminin complex, extracellular matrix, and cellular migration, as well as downregulation of inflammatory response genes.

Abstract Number: 1822

The Circulating Immune Profile of Systemic JIA Patients with HLA-DRB1*15 alleles, Eosinophilia, and Lung Disease

Jennifer Cheng[1], Alexandra Pommier[2], Ki Pui Lam[3], Evan Hsu[4], Courtney Leson[5], Kyle McBrearty[1], Itohan Aigbekaen[1], Maryam Ashoor[6], Ahmad Bakhsh[1], Carrie Bryant[1], Siobhan Case[7], Mia Chandler[1], Margaret Chang[1], Ezra Cohen[8], Fatma Dedeoglu[1], Olha Halyabar[9], Jonathan Hausmann[10], Melissa Hazen[1], Sonia Iosim[1], Liyoung Kim[6], Jeffrey Lo[1], Mindy Lo[1], Emma Materne[1], Esra Meidan[11], Megan Perron[12], Helene Powers[13], Mary Beth Son[1], Holly Wobma[1], Peter Nigrovic[6], Alicia Casey[1], Joyce Chang[1], Pui Lee[4] and Lauren Henderson[14], [1]Boston Children's Hospital, Boston, MA, [2]Harvard Medical School, Boston, MA, [3]Division of Immunology, Boston Childrens Hospital, Harvard Medical School, Boston, MA, [4]Boston Children's Hospital, Newton, MA, [5]Boston Children's Hospital, Boston, [6]Boston Children's Hospital, Brookline, MA, [7]UpToDate, Brigham and Women's Hospital, Boston Children's Hospital, Boston, MA, [8]Bmc, NEEDHAM, MA, [9]Children's Hospital/Boston Medical Center, Newton, MA, [10]Boston Children's Hospital / Massachusetts General Hospital, Cambridge, MA, [11]Boston Children's Hospital, Somerville, MA, [12]Boston Children's Hospital, Natick, MA, [13]Division of Immunology, Boston Children's Hospital, Harvard Medical School, Boston, MA, [14]Boston Children's Hospital, Watertown, MA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1809–1829) Pediatric Rheumatology – Basic Science Poster

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: We aimed to explore the association between HLA-DRB1*15 alleles, eosinophilia, and lung disease (LD) in patients with systemic juvenile idiopathic arthritis (sJIA) through proteomic profiling of circulating immune proteins.

Table 1. Clinical Characteristics of the Study Participants

	sJIA (N=26)	Healthy Controls (N=51)*
Age at sampling (median years, IQR)	4, 8.4	5, 10
Sex (% female)	50%	55%
Self-Reported Race (n, %)		
-American Indian/Alaska Native	0, 0%	-
-Asian	2, 8%	-
-Black	3, 12%	-
-Native Hawaiian/Pacific Islander	0, 0%	-
-Other	2, 8%	-
-Undisclosed	5, 19%	-
-White	14, 53%	-
Ethnicity (n, %)		
Hispanic	4, 15%	-
Non-Hispanic	19, 73%	-
Undisclosed	3, 12%	-
HLA-DRB1*15:01 (n, %)		
Yes	8, 31%	-
No	10, 38%	-
Unknown	8, 31%	-
History of MAS (n, %)Δ		
Yes	13, 50%	-
No	13, 50%	-
Unknown	0, 0%	-
Eosinophilia @ sampling (n, %)◊		
Yes	9, 35%	-
No	17, 65%	-
Diagnosis of sJIA-LD (n, %)		
Yes	4, 15%	-
No	22, 85%	-

*Healthy controls were deidentified and only information on sex and age were available. No demographic information was available for 2/51 controls.

ΔMAS defined by the 2016 Classification Criteria for MAS in sJIA

◊Eosinophilia defined as AEC >500/μL by clinical CBC on the day the research sample was collected.

sJIA, systemic juvenile idiopathic arthritis; MAS, macrophage activation syndrome; LD, lung disease

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

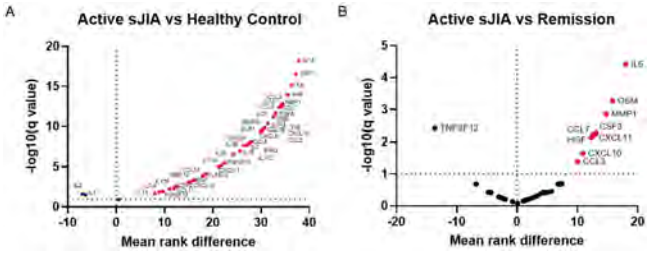

Figure 1. Differential expression of circulating immune proteins in study participants. Volcano plot of immune proteins from plasma in patients with A) active sJIA (n=25) vs. healthy controls (n=51), and B) active sJIA vs. sJIA patients in remission (n=21). Dots in red are significantly higher in patients with active sJIA than the comparison group, with dots in blue representing significantly lower levels. Statistics: Mann-Whitney U tests corrected for an FDR of 0.1. sJIA, systemic juvenile idiopathic arthritis; CCL, C-C motif chemokine; CSF, colony stimulating factor; CXCL, C-X-C motif chemokine; EGF, pro-epidermal growth factor; FLT3LG, fms-related tyrosine kinase 3 ligand; HGF, hepatocyte growth factor; IFNG, interferon gamma; IL, interleukin; LTA, lymphotoxin-alpha; MMP, matrix metallopeptidase; OLR, oxidized low-density lipoprotein receptor; OSM, oncostatin-M; TGFA, transforming growth factor alpha; TNF, tumor necrosis factor; TNFSF, tumor necrosis factor ligand superfamily; TSLP, thymic stromal lymphopoietin; VEGFA, vascular endothelial growth factor A.

Methods: Peripheral blood (PB) was obtained from children with sJIA (PRINTO criteria) and healthy controls evaluated at our center. Disease status (active/remission) was defined by the treating clinician and confirmed through chart review based on the presence/absence of fever, rash, arthritis, serositis, hepatosplenomegaly, and/or elevated inflammatory markers. Eosinophilia was defined as an absolute eosinophil count (AEC) > 500/μl. A pulmonologist adjudicated the diagnosis of sJIA-LD. HLA typing was done on a clinical basis or through research testing of samples in our institutional biorepository. A proximity extension assay (PEA, Olink Proteomics) was used to profile 45 immune proteins in plasma. Mann-Whitney U tests corrected for an FDR of 0.1 for our discovery analysis were used to compare groups. Volcano plots were generated with GraphPad Prism while PCA plots were created with Clustvis Web Tool.

Results: Table 1 summarizes study participants. Most sJIA patients treated with IL-1 inhibitors at the time of sampling. As expected, broad differences in protein expression were found between active sJIA patients and controls (Fig1A). Previously reported sJIA biomarkers, CCL7, CXCL10, CXCL11, HGF, IL-6, MMP1, and OSM, were confirmed to be significantly elevated in patients with active disease compared to those in remission (Fig1B). We also identified novel proteins differentially expressed in this comparison, including CCL3, CSF3, and TNFSF12/TWEAK (Fig1B). Next, we evaluated sJIA patients with or without eosinophilia at the time of sampling, stratified by disease activity. By univariate testing, IL-33 was elevated in sJIA

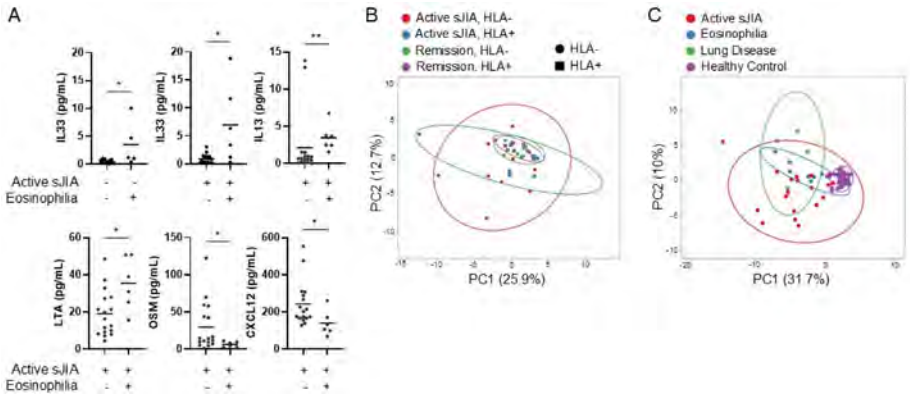

Figure 2. Immune profile of patients with sJIA and eosinophilia. A) Expression level of the given immune protein found in the plasma of patients with sJIA in remission with (n=5) and without eosinophilia (n=12) or during active disease with (n=6) and without eosinophilia (n=17). Eosinophilia was defined as AEC >500/μL by clinical CBC on the day the research sample was collected. Only the immune proteins that were significantly different based on Mann-Whitney U tests are reported. P value, ns, >0.05; *, ≤ 0.05; **, ≤ 0.01. No significance was found after correction for multiple comparison. B-C) PCA plots using z-scores for all 45 proteins in the PEA were included. 95% confidence level was used for ellipses. B) Groupings of patients during active sJIA with (n=8) and without HLA-DRB1*15:01 alleles (n=11), and patients in remission with (n=7) and without HLA-DRB1*15:01 alleles (n=9) are shown in their respective colors. C) Groupings of patients with active sJIA (n=19), healthy controls (n=51), patients with eosinophilia (n=8), and patients with sJIA-LD (n=4) are shown in their respective colors. sJIA, systemic juvenile idiopathic arthritis; AEC, absolute eosinophil count; PEA, proximity extension assay; CXCL, C-X-C motif chemokine; IL, interleukin; LTA, lymphotoxin-alpha; OSM, oncostatin-M

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

patients with vs. without eosinophilia, regardless of disease status (Fig2A). In patients with active sJIA, IL-13 and LTA were increased while CXCL12 and OSM were decreased in those with vs. without eosinophilia (univariate testing) (Fig 2A). Levels of circulating immune proteins were not significantly different in patients with and without HLA-DRB1*15:01 alleles when stratified by disease activity and PCA confirmed this finding (Fig2B). Finally, PCA showed that samples obtained from sJIA patients during an episode of eosinophilia closely associated with samples from patients with sJIA-LD who did not have eosinophilia at the time of testing (Fig 2C).

Conclusion: We identified a network of immune proteins in sJIA linked with eosinophilia and type 2-related cytokines. This includes OSM, an IL-6 family member that induces eotaxin-1 release, in sJIA patients with active disease. The IL-1 cytokine family member IL-33, which induces innate lymphoid 2 cells (ILC2s) to produce IL-4, -5, and -13, was associated with eosinophilia in sJIA patients. HLA status did not significantly impact the profile of circulating immune proteins in this cohort. Our studies suggest that the sJIA cytokine milieu may promote type-2 immunity and these responses are likely important in patients who develop eosinophilia and lung disease.

Genome-Wide DNA Methylation Analysis in Familial Mediterranean Fever

Kader Cetin Gedik[1], Desire Casares Marfil[2], Busra Baser Taskin[3], Elif Kilic Konte[4], Sezgin Sahin[4], Mckenna Bowes[2], Ferhat Guzel[5], Micol Romano[6], Ozgur Kasapcopur[7], Nuray Aktay Ayaz[3], Erkan Demirkaya[6] and Amr Sawalha[2], [1]UPMC Children's Hospital of Pittsburgh/University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, [3]Istanbul University Medical School, Istanbul, Turkey, [4]Istanbul University Cerrahpasa Medical School, Istanbul, Turkey, [5]Department of Research and Development, Ant Biotechnology, Istanbul, Turkey, [6]University of Western Ontario, London, ON, Canada, [7]Istanbul University-Cerrahpasa, Cerrahpasa Medical School, istanbul, Turkey

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1809–1829) Pediatric Rheumatology – Basic Science Poster

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Familial Mediterranean fever (FMF) is an autoinflammatory disease most commonly associated with biallelic mutations in the *MEFV* gene. Patients carrying the same pathogenic variant in *MEFV* can exhibit a broad spectrum of clinical phenotypes. Identifying factors contributing to this clinical variability is essential for understanding disease mechanisms. DNA methylation has been proposed as a potential modifier of *MEFV* mutations and clinical presentation. However, prior studies exploring this hypothesis included heterogeneous cohorts, lacked genome-wide methylation analyses, and yielded inconsistent findings. We aimed to investigate the role of DNA methylation in FMF using a genome-wide DNA methylation approach.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We conducted a cross-sectional, genome-wide DNA methylation analysis using whole blood samples from pediatric FMF patients and age- and ethnicity-matched healthy controls (2:1 ratio), all recruited from Istanbul University Medical School. To minimize confounding, we included only patients homozygous for the M694V mutation and from the same geographical region. DNA methylation profiling was performed using the Illumina Infinium MethylationEPIC v2.0 BeadChip array, covering over 930,000 CpG sites. Data analysis was conducted in R (v4.4.0), adjusting for age, sex, and cell composition.

Results: We identified 22 differentially methylated CpG sites in 32 FMF patients compared with 16 healthy controls. Of these, 18 were hypomethylated—including a CpG site within the *MEFV* gene—and four were hypermethylated. Notably, several differentially methylated CpGs were located in genes encoding zinc finger proteins, a family of transcriptional regulators. Of the 22 CpGs, 13 were found on chromosome 16, where *MEFV* is located. Three hypomethylated CpGs were within 1.1 kb of the *MEFV* transcription start site, two of which overlapped with enhancer regions, suggesting a potential regulatory role. Cell-type–specific analysis revealed significant differential methylation in NK cells, $CD8^+$ T cells, and $CD4^+$ T cells in FMF patients compared with controls.

Conclusion: Our findings suggest that DNA methylation changes may contribute to the pathogenesis of FMF. The enrichment of differentially methylated sites near *MEFV* on chromosome 16 and in immune cell subsets supports a role for epigenetic regulation in disease expression. These results highlight DNA methylation as a potential modifier of FMF and a promising target for future biomarker development and personalized therapeutic strategies.

Abstract Number: 1824

Tissue-Resident Natural Killer Cells May Drive Monocyte Differentiation And Macrophage Accumulation In The Inflamed Joints Of Pediatric Juvenile Idiopathic Arthritis Patients

Roselyn Fierkens[1], Jun Inamo[2], Clara Lin[3], Nathan Rogers[4], Kari Hayes[1], Heather Leach[3] and Kentaro Yomogida[1], [1]University of Colorado, Aurora, CO, [2]University of Colorado School of Medicine, Aurora, CO, [3]Children's Hospital Colorado, Aurora, [4]Children's Hospital Colorado, Aurora, CO

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1809–1829) Pediatric Rheumatology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Natural Killer (NK) cells are the most abundant innate lymphoid cells, accounting for 10–40% of total lymphocytes in peripheral blood. They adapt to diverse tissue microenvironments and exert tissue-specific functions. Juvenile idiopathic arthritis (JIA) is the most common chronic arthritis of childhood, with oligoarticular/polyarticular (oligo/poly JIA) subtypes comprising about 80% of cases. Although JIA research has primarily focused on T cells, the role of NK cells remains underexplored despite their abundance and potent immunomodulatory functions.

Methods: Peripheral blood, synovial fluid, and synovial tissue biopsies were obtained from children diagnosed with oligoarticular JIA or RF-negative polyarticular JIA, meeting the ACR criteria for JIA. Lymphocytes were isolated using density

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

gradient centrifugation. Cells were analyzed for comprehensive profiling and stimulated to evaluate cytokine production. Synovial tissue biopsy was fixed and assayed for spatial transcriptomics using 10x genomics protocol. Cell types were evaluated for colocalization within the inflamed tissue.

Results: NK cells were classified into two subsets based on CD56 expression: cytotoxic $CD56^{dim}$ and immunomodulatory $CD56^{bright}$. We discovered that the immunomodulatory $CD56^{bright}$ subset was predominant in JIA synovial fluid, whereas the cytotoxic $CD56^{dim}$ subset made up the majority of peripheral NK cells. These synovial NK cells expressed tissue-residency markers such as CD49a, CD103, and CD69. Functionally, synovial NK cells produced abundant cytokines, including IFN-γ and TNF-α. Although previous reports have identified T cells as the primary producers of GM-CSF in inflammatory arthritis, our data showed that synovial NK cells were one of the main producers of GM-CSF alongside T cells. With GM-CSF being an established stimulant of monocyte differentiation, we analyzed spatial transcriptomic data obtained from synovial tissue biopsy. Here, NK cells were found to be consistently in close proximity with macrophages.

Conclusion: Our data suggests that tissue-resident synovial NK cells may drive monocyte differentiation and macrophage accumulation through elevated GM-CSF secretion, acting as a mechanism to exacerbate inflammation in juvenile arthritis. Our findings reveal novel immunoregulatory functions of synovial NK cells, highlighting their significance in understanding JIA disease pathogenesis and treatment.

Session Title: (1809–1829) Pediatric Rheumatology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Dengue virus (DENV) is a global public health threat that is increasing in incidence and endogenous DENV infections are expected to dramatically rise in the US. DENV has four serotypes (DENV1-4) and infection with any serotype can cause two main syndromes: 1) mild disease characterized by non-specific symptoms including fever, rash, and musculoskeletal pain, and 2) severe disease/hemorrhagic fever that can rapidly lead to multi-organ failure and death. However, the immunologic drivers of severe disease remain poorly understood. Using serum proteomics and peripheral

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1 – Serum proteomic analysis reveals upregulation of MAS biomarkers and complement dysregulation are features of severe dengue. (A) Principal component analysis of serum proteomic data from pediatric control (CTRL, N=9), mild dengue infection (DENV, N=12), and severe dengue/dengue hemorrhagic fever (DHF, N=9). (B) Box and whisker plots showing expression of the MAS associated proteins IFNG, IL10, CXCL9, IL2RA (sIL2R), IL18BP. (C) Reactome pathway analysis of significantly differentially expressed proteins comparing DHF to DENV. (D) Box and whisker plots of expression of the individual proteins that make up the Reactome Complement Cascade pathway. NPX = O-link's Normalized Protein Expression.

blood mononuclear cell (PBMC) single cell RNA sequencing (scRNAseq) from pediatric patients with mild and severe dengue infection we interrogated immunologic factors associated with severe disease.

Methods: In this cross-sectional study, sera and PBMCs were collected from pediatric patients with mild dengue (DENV) (N=12) and severe dengue/hemorrhagic fever (DHF) (N=9) at the Robert Reid Cabral Children's and Antonio Musa District Hospitals, Dominican Republic and from age-matched healthy controls (N=9) at the Children's Hospital of Philadelphia. Serum proteomics was performed using the O-link Explore HT platform. 5' scRNAseq was performed using the 10X Genomics platform. Data analysis was performed in R.

Results: Principal component analysis of ~5000 serum proteins revealed 3 distinct clusters that separate DHF, DENV, and healthy controls (Figure 1A). DHF patients showed upregulation of multiple biomarkers consistent with Macrophage Activation Syndrome (MAS) physiology (Figure 1B). Additionally, pathway analysis performed on the significantly differentially expressed proteins (DEPs) comparing DHF to DENV demonstrated complement activation was the most significantly altered pathway (Figure 1C). Examination of the specific proteins that drive this difference showed widespread consumption of complement proteins across the complement cascade (Figure 1D). scRNAseq analysis showed increased *IFNG* transcription in *IFNG*-positive cells in DHF compared to DENV, consistent with the serum protein MAS markers (Figure 2A,B). Furthermore, the monocyte cluster is altered in DHF compared to DENV and healthy controls (Figure 2B). Re-clustering of the monocytes showed an increase in 4 monocyte subclusters in DHF (Figure 2C). Differential expression analysis to identify

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2 – scRNAseq of PBMCs from patients with dengue infection shows increased IFNG expression and an altered monocyte compartment with overrepresentation of a subpopulation expressing early complement genes in severe dengue. (A) UMAP projection overlayed with IFNG transcription in mild dengue infection (DENV, N=9) and severe dengue/dengue hemorrhagic fever (DHF, N=6). (B) Violin plot of IFNG expression among all IFNG positive cells in DENV (N=9) and DHF (N=6). P value determined by unpaired T-test. (C) UMAP projection showing Azimuth l1 annotated cell types stratified by disease state; pediatric control (control, N=5), DENV (N=9), DHF (N=6). (D) UMAP projection showing Seurat clusters following re-clustering of the Monocyte population, stratified by disease state; control (N=5), DENV (N=9), DHF (N=6). (E) Heatmap of top differentially expressed genes that define each of the Monocyte Seurat Clusters. Clusters 1,3,4,5 are overrepresented in DHF (marked by red arrows). The red box highlights the genes that are uniquely upregulated in Cluster 1, which are composed of the genes for the C1q complement complex.

the top genes that define each cluster revealed that one of these clusters was characterized by early complement gene expression (*C1QA, C1QB, C1QC*) (Figure 2D).

Conclusion: We have identified MAS and complement dysregulation as unique features of severe dengue. Serum proteomics showed elevated IFNg and CXCL9 as well as consumption of complement proteins and loss of complement regulatory proteins that typically constrain complement activation. *IFNG* was also increased at the transcriptional level. Moreover, monocytes expressing early complement components are overrepresented in severe dengue patients. These findings may unveil factors that predispose to risk of developing severe dengue and support precision immunomodulation with either MAS directed or complement inhibiting therapies in severe dengue.

Abstract Number: 1826

Single Nuclei Multiome of JDM Muscle Biopsies Reveals Novel Upregulation of Inflammatory and Vascular Pathways

Shannon O'Connor, Casey Swoboda, Matthew Weirauch, Alexander Zygmunt, Douglas Millay and Leah Kottyan, Cincinnati Children's Hospital Medical Center, Cincinnati, OH

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1809–1829) Pediatric Rheumatology – Basic Science Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Juvenile dermatomyositis (JDM) is a multisystem vasculopathy and inflammatory myopathy characterized by proximal muscle weakness, distinct rash, and risk of long-term complications such as calcinosis, skin ulceration, and chronic disease. Although Type I and Type II Interferon signatures are well established, this alone does not explain the full pattern of disease; the basic biology of JDM remains poorly defined. Heterogeneity in outcomes necessitates a more fundamental understanding of disease mechanisms.

Our objective is to understand genome-scale gene dysregulation in JDM through a multiomic study of single nuclei from treatment naïve muscle biopsies. We hypothesize that JDM etiology is mediated by molecular and cellular changes in the muscle and associated small blood vessels.

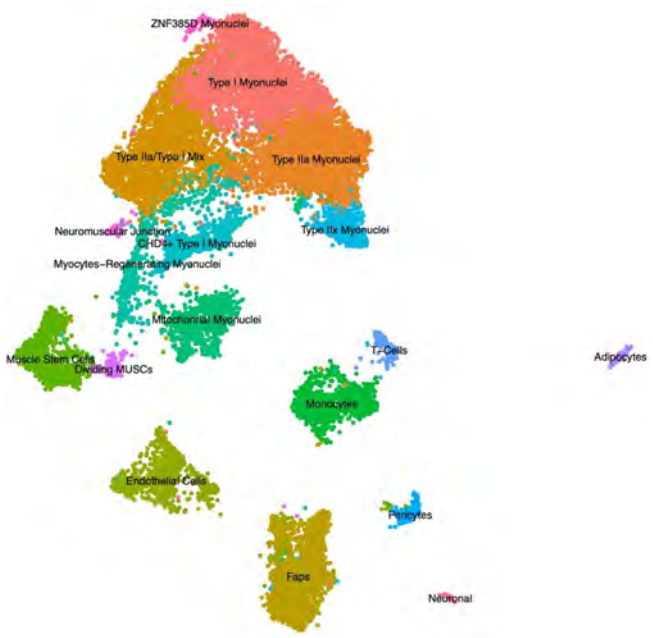

Figure 1. Uniform Manifold Approximation and Projection (UMAP) visualization represents sixteen color-coded nuclei clusters identified by tandem single nuclei RNA-sequencing and ATAC-sequencing. Data were generated from treatment naïve muscle biopsies from patients with juvenile dermatomyositis and congenital myopathy. FAPs = fibro-adipogenic precursors. MT = mitochondrial. NK = natural killer.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Heatmap of differentially expressed genes by cell type (columns) highlighting significant changes in expression profiles across specific pathways (left side). Data generated by tandem single nuclei RNA-sequencing and ATAC-sequencing from treatment naïve muscle biopsies from patients with juvenile dermatomyositis and congenital myopathy. FAPs = fibro-adipogenic precursors.

Methods: Muscle biopsies were collected from treatment naïve patients with JDM and congenital myopathy (CM). Biopsies were flash-frozen in liquid nitrogen and stored at -80°C (Cincinnati Children's Hospital Medical Center (CCHMC) Pathology Core). Single nuclei isolation was performed (10x Genomics protocol with optimization performed on murine samples), followed by Chromium Next GEM Single Cell Multiome ATAC+ Gene Expression processing (CCHMC Single Cell Genomics Core).

Sequencing data were analyzed through DNA and RNA read alignment and quantification using CellRanger. Ambient mRNA was removed, doublets identified, and low-quality nuclei removed using CellBender. Data were visualized in a two-dimensional space using dimensionality reduction and cluster identification using Seurat. Additional discovery of molecular pathway signatures was performed using CellHarmony.

Results: Single nuclei clustering revealed typical cell types consistent with previously demonstrated normal muscle tissue (Figure 1). Differentially expressed genes within individual cell types highlighted the known interferon signatures in multiple cell types. We also identified molecular signals consistent with dysfunction of vascular signaling pathways, especially between muscle and endothelial cells. There was marked upregulation of several inflammatory pathways that have not previously been described in JDM but have been identified in other inflammatory conditions (Figure 2).

Conclusion: We conducted a multiome study of single nuclei from treatment naïve muscle biopsies in JDM patients with a comparator group of congenital myopathy patients. While typical cell types of muscle are maintained, several pathways, in addition to a known interferon signature, demonstrate dysregulation, opening doors for further studies into the molecular dysfunction driving JDM pathology.

Session Date: Tuesday, October 28, 2025

Session Title: (1809–1829) Pediatric Rheumatology – Basic Science Poster

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Periodic Fever, Aphthous Stomatitis, Pharyngitis, and Adenitis (PFAPA) is the most common periodic fever presenting with frequent episodes of pain and impaired function. While its etiology remains unknown, evidence suggests a genetic component and dysregulation of innate immunity. Our objective is to develop transcriptomic insights into the molecular pathways predicting PFAPA flares.

Methods: Ten PFAPA patients, fulfilling consensus patient characteristics, had blood samples collected during flare and non-flare times. Differences between groups were analyzed with the paired t-test. Differentially Expressed Genes (DEGs) were analyzed with standard RNA sequencing pipelines, including quality control, alignment to the reference genome (hg39), and quantification of transcript levels (STAR). Genes with significant differential expression were identified (DESeq2) and analyzed for pathway enrichment (gseapy). We trained a random forest (RF) classifier on gene expression counts to distinguish between flare and non-flare states, obtaining a final model with area under the ROC curve of 1. Top-ranked features' biological relevance to understand key pathways driving disease flares were evaluated.

Results: The PFAPA cohort's age of onset was 32 (IQR; 12-78) months, maximum temperature of 104.9 (IQR 103.4-105.2) degrees Fahrenheit, fever duration of ~4 (IQR:3-4.25) days and an 8 out of 10 in severity (IQR: 6-8,9) with how an episode feels and affects function. During flares, 100% of patients had pharyngitis, 80% cervical lymphadenopathy, and 50% oral

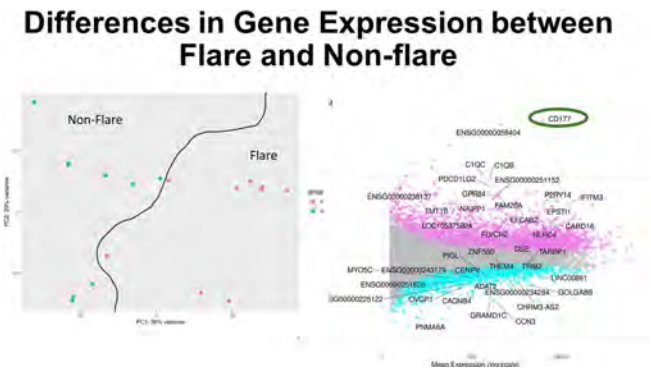

Figure 1: (Left) Principal Component Analysis Showing a Clear Separation and (Right) MA Plot of Log Fold Change Between PFAPA Flare and Non-Flare Plotted Against Mean Gene Expression. Significantly altered genes at p value < 0.05 are marked in color .

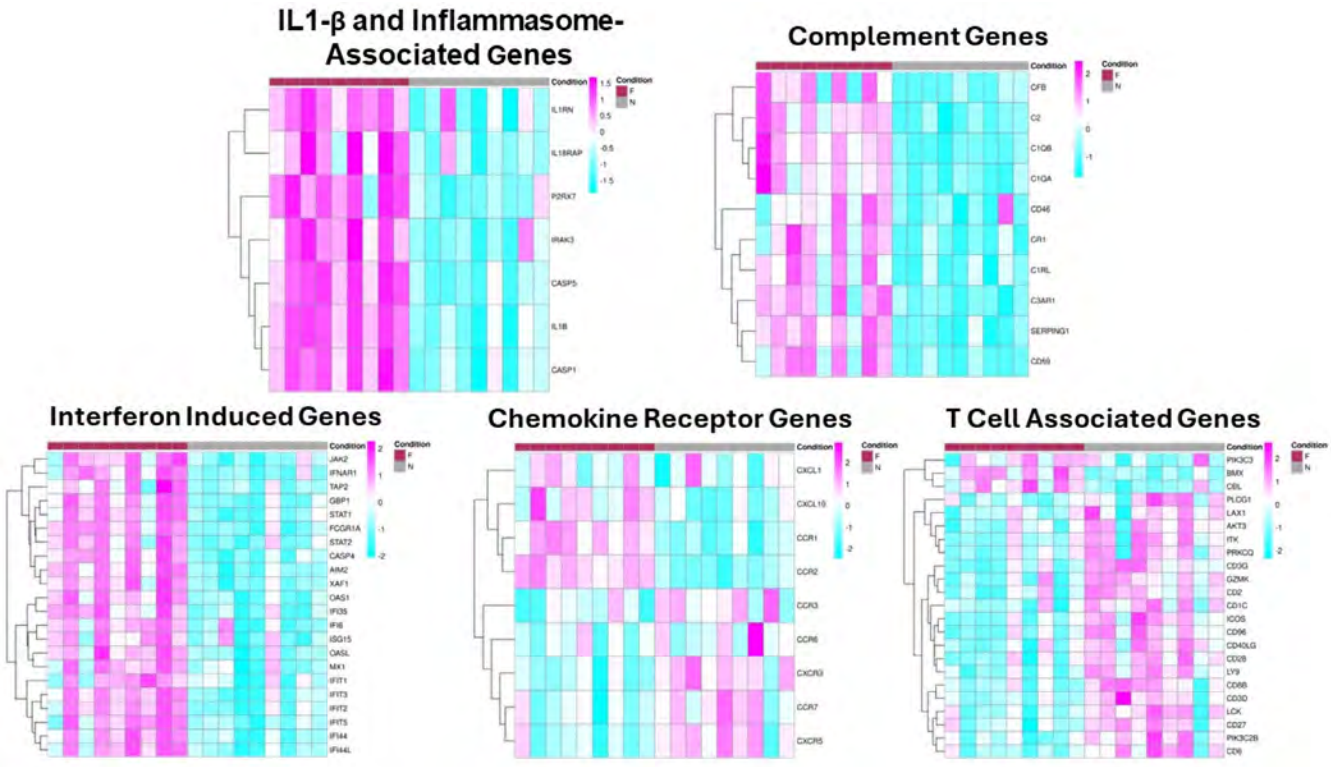

Figure 2: Gene Expression Signatures between PFAPA Flare and Non-Flare for Gene Ontologies Associated with Inflammation

aphthae. Lab abnormalities with flare included leukocytosis, neutrophilia, monocytosis, lymphopenia, and increased CRP ($P < 0.01$). A clear distinction between flare and non-flare gene expression was identified by RNA-sequencing Principal Component Analysis with multiple DEGs (Fig. 1). The top 50 DEGs by adjusted p-value included upstream regulators of immune pathways (*CD177*, *GPR84, C1QC*, and *CARD17P*). Gene Set Enrichment Analysis identified neutrophilic, interferon, response to organism and protein processing as key inflammatory pathways. Differentially regulated pathway signatures are depicted in Fig. 2. The top 20 features from the RF of flare versus non-flare were related to cell cycle arrest and microtubule polymerization. The highest-ranking feature was microRNA 5195 (downstream effectors Fig. 3), which at low levels was most predictive of flare.

Conclusion: We identified distinct gene expression profiles between PFAPA states demonstrating a transcriptomic signature of immune dysregulation associated with flares. The flare state reflects neutrophilic activation (modulated by corticosteroids aborting fever), interferon signaling, innate immune dysregulation and heightened cellular activity manifesting as cell cycle arrest as well as microtubule polymerization (modulated by colchicine). The MicroRNA 5195 gene was identified as the highest-

Session Title: (1809–1829) Pediatric Rheumatology – Basic Science Poster

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic juvenile idiopathic arthritis (sJIA) is an autoinflammatory disorder characterized by systemic immune dysregulation. However, reliable biomarkers to predict its unpredictable disease course are still lacking. Identifying immune cell subsets and molecular drivers of disease progression is crucial for improving prognosis and developing targeted therapies.

Methods: We performed comprehensive immunophenotypic profiling of PBMCs from sJIA patients across five clinical centers. Deconvolution analysis combined with clinical follow-up in the Chongqing cohort was used to assess the prognostic value of key subpopulations. In vivo validation was performed using UBE2D1 knockout mice. A cross-disease single-cell reference was developed to compare sJIA-associated immune subsets with those found in other inflammatory diseases.

Results: We identified a novel CD14+CXCL10+monocyte subset distinguished by a unique transcriptomic signature enriched in immune regulatory genes. Notably, flow cytometry revealed that this subset was significantly elevated during the active phase of sJIA and decreased during remission, demonstrating a strong correlation with disease activity. In vitro inflammatory stimulation promoted the differentiation of monocytes into the CXCL10+phenotype. But, this process was

(B) Violin plot showing CD14+CXCL10+monocyte levels across pJIA, ERA, oJIA, controls, and sJIA. (C) ROC curve illustrating the diagnostic performance of CD14+CXCL10+monocyte for distinguishing sJIA. (D) Differential expression of monocyte subpopulations in sJIA patients with and without remission. (E) Dot plot showing the Spearman's correlations of CD14+CXCL10+monocyte and clinical features across the Chongqing Clinical Dataset (*p<0.05, **p<0.01, ***p<0.001, and ****p<0.0001). (F) Flow cytometry analysis of CD14+CXCL10+monocyte in peripheral blood of sJIA patients and controls. Left: Representative flow cytometry plots showing the percentage of CD14+CXCL10+monocyte in PBMCs from sJIA patients (top row) and controls (bottom row). Top right: Quantification shows that the proportion between sJIA and controls. Bottom right: Longitudinal analysis in the progression of sJIA disease.

markedly impaired in UBE2D1-deficient mice, which exhibited lower expression of CXCL10 mediators, underscoring the pivotal role of UBE2D1 as a central driver of this inflammatory program. Finally, by comparing this subset with other JIA subtypes and inflammation-related diseases, we found that it exhibits a distinct expression pattern in sJIA.

Conclusion: Our findings suggest that UBE2D1-driven CD14+CXCL10+monocyte play a key role in sJIA pathogenesis and may serve as both a biomarker and therapeutic target for disease monitoring and intervention.

Background/Purpose: Juvenile idiopathic arthritis (JIA) is the most common chronic inflammatory rheumatic disease of childhood, affecting 1:1,000 children worldwide. The hallmark of JIA is immune-mediated chronic inflammation in the synovium – clinically reflected by the presence of arthritis or a combination of joint pain, swelling, or limitation of joint movement. If inadequately treated, JIA can lead to profound lifelong joint deformity and disability. Thus, early diagnosis and treatment initiation is essential in the management of patients with JIA. Histological examination of synovium, although limited in scope, has identified immune cell infiltration of lymphocytes, plasma cells, macrophages as well as proliferation of fibroblast- and macrophage-like synoviocytes. To date, no comprehensive studies of JIA synovium have been performed as current best-practices do not routinely collect tissue biopsies for diagnosis or analysis. Recent single cell methodologies that assay open chromatin and transcriptome have made great strides in bridging this gap in adult rheumatic conditions by directly examining the synovium. The objective of this study is to leverage novel multiomic single cell strategies to characterize cell heterogeneity in the synovium of children with JIA.

Methods: Ultrasound guided synovial biopsies were performed in two children to isolate synovium. Tissue was enzymatically digested, sorted for viability, nuclei isolated, and single cell libraries generated with the 10X multiome (RNA + ATAC) pipeline. A PBMC sample from a JIA patient was also included to define tissue enrichment. Data was aligned with cellranger and processed with custom analysis pipelines.

Results: We obtain high quality data from three samples for single cell RNA and ATAC sequencing with a median of 1350 genes and 6233 ATAC peaks from 5771 cells. Integration of gene expression and open chromatin data, harmonization by donor, and clustering identifies 11 broad populations including T, B and fibroblasts cells. Comparison between tissue and blood sample identifies an enrichment of activated/memory CD4 and CD8 T cells and a decrease in monocytes populations specific to the synovium. Pathogenic HLA-DR+ fibroblasts are exclusively identified in synovium. Fine-grained analysis of T cells with our recently developed T cell annotation program (TCAT) identifies evidence of proliferation in Tfh/Tph and T regulatory cells.

Conclusion: To our knowledge, this is the first multiomic single cell study of JIA synovium that simultaneously captures gene expression and open chromatin. We implement a high-quality processing pipeline and identify cell heterogeneity specific to the synovium. In particular, we find evidence of immune cell activation and proliferation in Tfh/Tph and T regulatory cells from synovium.

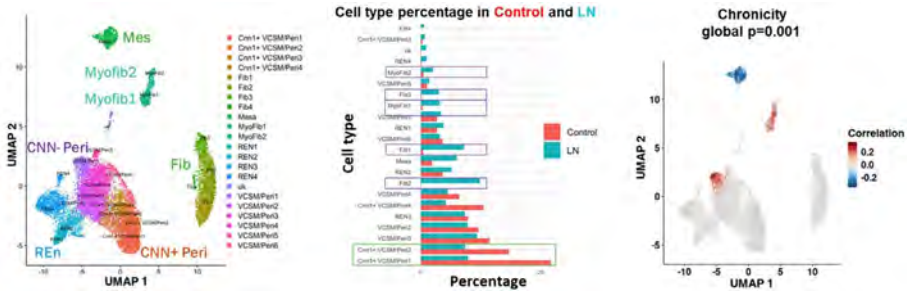

Figure 1: Fibroblast-like PDGFRB+ cell landscape in Lupus Nephritis. A. UMAP of 6 PDGFRB+ subsets, each containing unique subclusters from single-cell RNA-sequencing of stromal cells from 156 LN patients and 30 live donor controls. B. A bar graph of each subcluster as a percentage of total PDGRB+ stromal cells in LN patients (Blue) and controls (red), highlighting subclusters that increased in frequency during LN (Purple box; Fib1-3, Myofib 1-2) and subclusters that decreased (Green box; CNN1+ VSCM/Per1-2). C. Covarying Neighborhood Analysis (CNA) on LN patients projecting onto the PDGFRB+ stromal cells showing association with chronicity. Red indicates a significant positive clinical correlation with the cell subset, while blue indicates a significant negative correlation. The false detection rate is less than 0.1.

Background/Purpose: Lupus nephritis (LN) is a severe complication of SLE that can progress to chronic kidney disease, renal fibrosis, and eventual renal failure. Fibroblasts activated by pro-inflammatory cytokines and damage signals adopt a heterogeneous pro-inflammatory or profibrotic phenotype, which contribute to pathological fibrosis; however, the fibroblast landscape in autoimmune kidney disease remains poorly understood. Here, using renal biopsies collected through the AMP-SLE, we define and localize fibroblast heterogeneity in LN through single-cell and spatial transcriptomics.

Methods: Single-cell RNA-sequencing was used to profile dissociated kidney biopsies collected from 156 LN patients and 30 controls. High-resolution clustering was performed to identify both tissue and immune cell subsets. 16,187 PDGFRB+ stromal cells were used for further subclustering. Covarying Neighborhood Analysis (CNA) was performed to identify statistically significant Pearson's correlations between the frequencies of cell subsets and the ISN chronicity and activity indices. Spatial transcriptomics was performed using the 10x Genomics Xenium platform, with a gene panel customized to allow the identification of high-resolution myeloid populations.

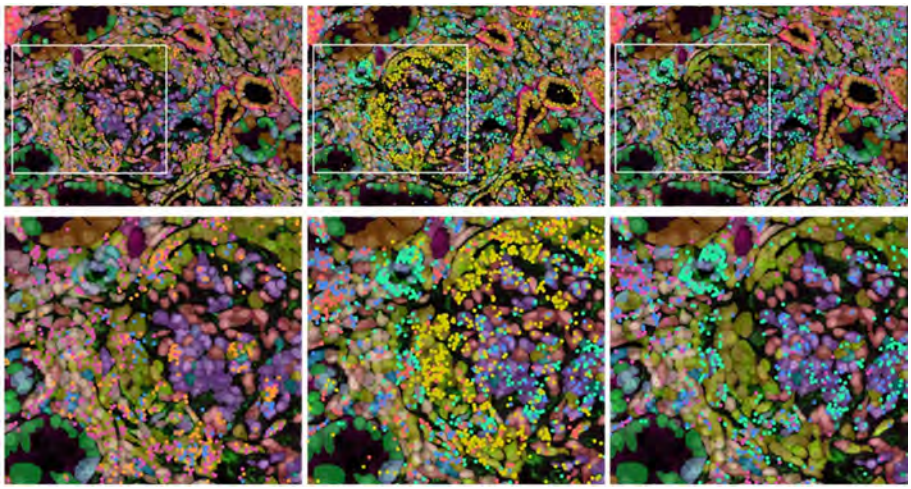

Figure 2: Spatial transcriptomic representation of a glomerulus from a LN patient renal biopsy. A. An overview of the area of interest (Top) with damage-associated macrophage transcripts GPNMP, FABP5, and CSF1R are highlighted. Magnification of the boxed area (bottom) shows GPNMP+ and FABP5+ macrophages localizing in the glomeruli and peri-glomeruli areas (white arrows) compared to macrophages expressing CSF1R alone in the interstitium B. Image of the same area (Top) with Myofib2 transcripts ACTA2, ITGA3, and VCAN highlighted. Magnification of the boxed area (bottom) shows Myofib2, located in the glomerulus and in the crescent (C) (white arrows). V indicates an Acta2+ blood vessel. C. Image of the same area (Top) with Myofib1 transcripts PDFGRA and C7 highlighted. Magnification of the boxed area (bottom) details Myofib1, which are predominantly located in the interstitium (white arrows), separate from Myofib2.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: We identified fibroblasts, myofibroblasts, CNN1+ vascular smooth muscle cells/pericytes (VSMC/peri), mesangial cells and renal endothelial cells, with relative expansion of fibroblasts, myofibroblasts, and mesangial cells occurring during LN together with relative contraction of CNN1- VSMC/peri (Fig.1A, B). Fine clustering of myofibroblasts revealed two transcriptionally distinct myofibroblast-like populations with increased collagen scores compared to other fibroblast-like subsets: proinflammatory myofibroblasts (Myofib1) and profibrotic myofibroblasts (Myofib2). CNA revealed that both clusters of myofibroblasts and the VCSM/Peri1 subset were positively correlated with chronicity (Fig. 1C), but not with the activity index. Gene expression and pathway enrichment analyses highlighted MyoFib2 as a matrix-producing, contractile population, while MyoFib1 was enriched for immune signaling and complement pathways. PDGFRA+, ACTA2+ C7+ ITGA3- Myofib1 myofibroblasts were located preferentially in the interstitium adjacent to CSF1R+ resident macrophages, whereas PDGFRA, ACTA2+, ITGA3+ VCAN+ Myofib2 myofibroblasts were located in sclerotic areas of the glomeruli and fibrous crescents adjacent to GPNMB+ FABP5+ damage-associated infiltrating macrophages (Fig. 2A-C). Vascular mural cells also showed heterogeneity: VCSM/Peri1 was enriched for immune-related genes and expressed a detachment profile, whereas VCSM/Peri2–6 retained a contractile phenotype.

Conclusion: Our findings reveal the diversity of PDGFRB+ populations in LN kidneys and the presence of both proinflammatory and profibrotic myofibroblasts in various renal compartments associated with LN chronicity. Previously described LN associated resident and infiltrating macrophages co-localize with proinflammatory and profibrotic fibroblasts respectively creating unique renal niches that promote tissue damage.

Session Title: (1830–1854) Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: : Systemic Lupus Erythematosus (SLE) follows a characteristic relapsing-remitting course with unpredictable flares interspersed with periods of relative quiescence. Mycophenolate mofetil (MMF) has emerged as a cornerstone immunosuppressive therapy in SLE management, the challenges of balancing effective disease control against medication-associated toxicities remain significant. Our recent clinical trial (Chakravarty, et al. Lancet Rheum 2024) suggests that MMF discontinuation in clinically quiescent patients may allow remission rates similar to continuous therapy in select patients. However, an integrated set of clinically and biologically relevant biomarkers capable of identifying patients at the highest risk of disease flare following MMF withdrawal is needed to optimize clinical outcomes and guide clinical care.

Methods: Safety of Estrogens in Lupus Erythematosus National Assessment - Systemic Lupus Erythematosus Disease Activity Index (SELENA-SLEDAI) flares were tracked for 60 weeks post-MMF withdrawal. Serum (baseline) samples from SLE patients (n=50) with clinically quiescent disease (physician defined and SLEDAI< 4) on long-term MMF from the "Randomized MMF Withdrawal in Systemic Lupus Erythematosus (SLE) (ALE06)" trial (Chakravarty, et al. Lancet Rheum. 2024) with available samples and appropriate follow-up were collected prior to and after MMF taper. Soluble serum proteins were profiled using Olink Explore HT and an iterative machine learning approach (ML) used to elucidate soluble protein signatures that predict disease flare post-MMF withdrawal.

Results: In total, 31 SLE patients experienced a SELENA-SLEDAI flare within 60 weeks of MMF withdrawal, compared to 19 who did not. Using 283 known secreted protein levels predictive ML modeling was able to identify disease flares post-MMF withdrawal with 70.3% accuracy and an AUC of 88.4 ± 9 using 34 proteins (**Fig 1A**). Among the top predictors, TGF-β2, a less recognized immune modulatory isoform of TGF-B that can directly regulate T cell functions, was lower in patients who flared (**Fig 1B**). Of note, T cells are one of the cell lineages directly affected by MMF usage. Protein set enrichment analysis of ML model proteins show elevations of ERK1/2 signaling proteins, B cell proteins such as FcγR2b a moderator of B Cell activity with known deficiencies in lupus, and phagocytosis-associated proteins in patients who flared post MMF withdrawal (**Fig 1C**). Together, these findings suggest that immunologic pathway dysregulation is present in clinically quiescent patients at the highest risk of disease flares after MMF withdrawal.

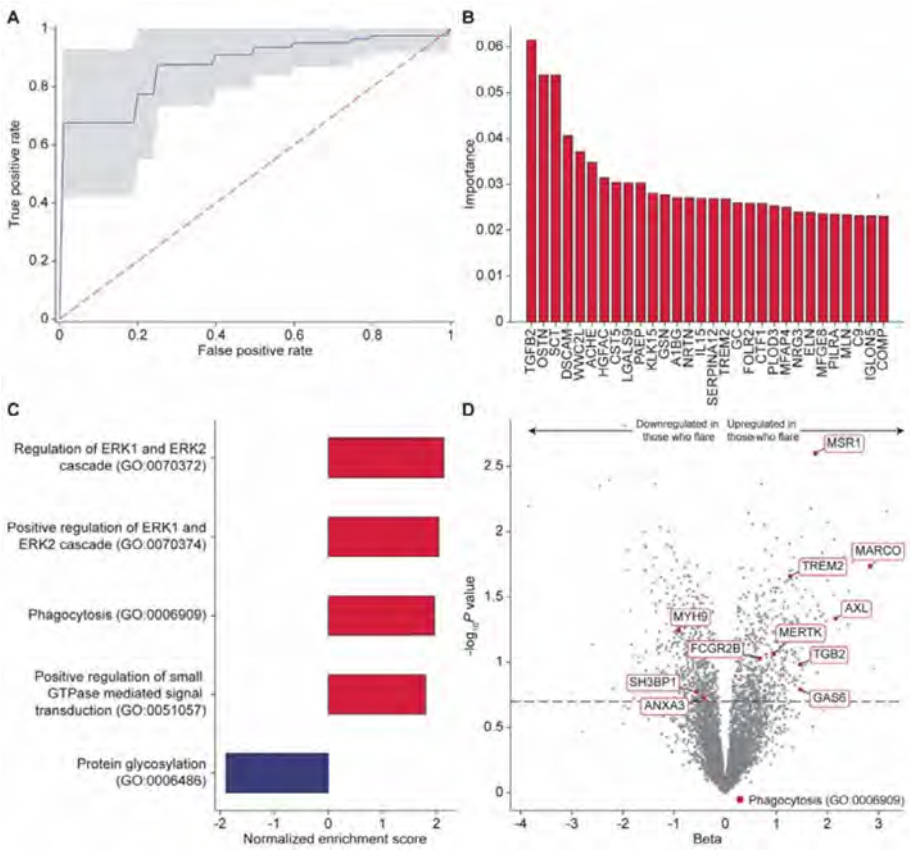

Fig. 1: Proteomic biomarkers are associated with subsequent disease flare following MMF withdrawal in SLE patients. (A) Random forest model using baseline serum levels of secreted proteins (identified via the Human Protein Atlas) predicts SELENA-SLEDAI flare within 60 weeks of MMF discontinuation. (B) Ranked importance of the top secreted protein predictors for disease flare following MMF withdrawal, as determined by the random forest model. (C) Pathways with significant enrichment in patients with disease flare following MMF withdrawal. (D) Volcano plot of phagocytosis-related proteins showing differential abundance between patients who experienced a disease flare compared to those who did not following MMF withdrawal.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Conclusion: Our findings demonstrate that a secreted protein-based proteomic signature can robustly predict imminent SLE flares following MMF withdrawal, with TGF-β2 and FcγR2b emerging as key biomarkers associated with flare risk. These results also highlight the value of proteomic profiling for risk stratification and provide new insights into the mechanisms underlying disease reactivation after immunosuppressant withdrawal.

Time-to-Event Analysis of Statin Use and Thrombotic Risk in Patients with Systemic Lupus Erythematosus: A Single-Center Retrospective Study

Christine Lenchur[1], Niurka Liranzo Tejera[1], Adal Abonamah[1], Takemichi Matsui[1], Emily Cosentino[1], Priscilla Abate Namnum[2], Olga Marushchak[1], Melissa Akselrad[1], Martin John[3], Sophia Lutgen[4], Celestine He[5], Boluwatito Oladeinde[3], Harleen Sidhu[6], Emilia Bagiella[5], Ian Wright[5] and Chrisanna Dobrowolski[5], [1]Mount Sinai Morningside/West Hospitals, Icahn School of Medicine at Mount Sinai, New York, NY, [2]Mount Sinai Morningside/West Hospitals, Icahn School of Medicine at Mount Sinai, New York, [3]Icahn School of Medicine at Mount Sinai, New York, [4]Mount Sinai Morningside/West Hospitals, Icahn School of Medicine at Mount Sinai, New York City, NY, [5]Icahn School of Medicine at Mount Sinai, New York, NY, [6]Icahn School of Medicine at Mount Sinai/NYC H+H- Elmhurst, Queens, NY, Rego Park, NY

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1830–1854) Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) face elevated risk of thrombotic events (TEs) due to traditional cardiovascular factors and chronic inflammation. Statins may offer anti-inflammatory effects beyond lipid lowering, making them potentially valuable in this population. This retrospective cohort study examines the association between statin use and TEs in SLE patients, aiming to clarify inconsistent findings in prior research and optimize further management strategies.

Methods: We conducted a retrospective cohort study using the Mount Sinai Health System's Epic-linked electronic medical record to identify patients >18 years old diagnosed with SLE via ICD-10 codes between January 2000 and March 2024. Patients not meeting the 2019 ACR/EULAR classification criteria for SLE were excluded. The primary outcome of the study was the occurrence of a TE (arterial or venous), assessed using time to event analysis from the time of SLE diagnosis to the TE event or last follow-up. Patients free of a TE by the time of the last follow-up were censored. Statin use was the primary predictor variable. Univariate extended Cox models were utilized to explore the role of seven independent variables, including the primary exposure of interest as a time-dependent variable, on the risk of thrombotic events. P-values < 0.05 were considered statistically significant.

Results: A total of 376 patients with SLE were included in the study. Patient demographics, hydroxychloroquine use, as well as concomitant comorbidities of smoking, hypertension, diabetes mellitus, secondary antiphospholipid syndrome (APS) and lupus nephritis are detailed in Table 1. Of the 376 patients, 6.4% experienced thrombotic events during follow-up; 35.6% of

Table 1. Patient clinical characteristics and co-morbidities.

Characteristic	Number (%)
Female	348 (92.6%)
Mean Age of Diagnosis (SD)	40.4 (±17.4) years
Race	
White	153 (40.7%)
African American	116 (30.9%)
Other/Unknown	88 (23.4%)
Asian	19 (5.1%)
Ethnicity	
Non-Hispanic	203 (53.9%)
Hispanic	93 (24.7%)
Other/Unknown	80 (21.2%)
Antiphospholipid Syndrome	36 (9.6%)
Lupus Nephritis	52 (13.8%)
Use of Hydroxychloroquine	258 (68.6%)
Hypertension	152 (40.4%)
Diabetes Mellitus	36 (9.6%)
Smoker	94 (25.0%)
Thrombotic Event	24 (6.4%)
Statin Use	65 (17.3%)

Table 2. Univariate extended Cox models of thrombotic risk by demographics, comorbidities, and treatment variables.

Parameter	Comparison	Estimate	Std Error	Chi Sq	P-value	Hazard Ratio	95% CI
Statin Use	Yes vs No	1.89	0.51	13.80	**< 0.01**	6.62	[2.44, 17.93]
Sex	Male vs Female	0.43	1.04	0.17	0.677	1.54	[0.20, 11.90]
APS Diagnosis	Yes vs No	3.86	0.78	24.65	**<0.01**	47.34	[10.33, 217.00]
APS Diagnosis	Unconfirmed vs No	4.17	0.85	24.29	**<0.01**	64.52	[12.30, 338.40]
Hydroxychloroquine	Yes vs No	-0.13	0.51	0.07	0.79	0.88	[0.32, 2.37]
Hypertension	Yes vs No	0.11	0.49	0.05	0.83	1.11	[0.43, 2.91]
Diabetes mellitus	Yes vs No	-15.31	1169	0.00	0.99	0.00	[0.00, 0.00]
Smoking	Yes vs No	-0.51	0.64	0.64	0.42	0.60	[0.17, 2.10]

Table 3. Final extended Cox model assessing the association between time-dependent statin use and thrombotic events.

Parameter	DF	Parameter Estimate	Standard Error	Chi Square	P-value	Hazard Ratio	95% CI
Statin Use	1	1.89	0.51	13.80	**< 0.01**	6.62	[2.44, 17.93]

these patients had a diagnosis of secondary APS. In univariate analyses, statin use, and secondary antiphospholipid syndrome (APS) showed significant associations with TEs. However, due to sparse data and wide confidence intervals, particularly among patients without APS, APS variable was excluded from the final model. Statin exposure was unexpectedly associated with an increased hazard of thrombotic events (HR 6.62; 95% CI: 2.44–17.93; $p < 0.001$; Table 2, Table 3).

Conclusion: While these results were statistically significant, the wide confidence interval suggests variability in the estimate, likely reflecting the limited number of events among non-statin users and heterogeneous exposure timing. These findings should be interpreted in the context of an exploratory analysis and warrant further investigation in a larger study. Results likely also reflect residual confounding, such as the preferential use of statins in higher-risk patients. Similar findings have been reported in other chronic inflammatory conditions, suggesting that statins alone do not sufficiently address thrombotic risk in people living with SLE.

DM618: A Novel Anti-IL12p35 Antibody Specifically Inhibiting IL-12 with Therapeutic Potential in a Set of Autoimmune Diseases

Dong ZHANG, Guangan Hu, Xiaodong Jiang, Quanju Zhao, Tainfei Hou, Zhengwang Sun, Mousheng Xu and Nan Bing, D2M Biotherapeutic, Inc, NATICK, MA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1830–1854) Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: IL-12, via its p35 subunit, drives Th1-mediated pathology in autoimmune diseases. Genome-wide association studies (GWAS) suggested that *IL12A* encoding IL12p35 is associated with systemic lupus erythematosus (SLE), systemic sclerosis (SSc), primary biliary cholangitis (PBC), and Sjögren's syndrome (SS), but *IL12B* and *IL23R* are not. Antibodies targeting *IL12B* and *IL23A* have been developed in the clinic but no proven effects were shown for the above-mentioned immune diseases. DM618, a monoclonal antibody selectively targeting IL12p35, was designed to inhibit IL-12 signaling without affecting IL-23. Preclinical efficacy was evaluated using a surrogate anti-mouse IL12p35 antibody.

Methods: Colocalization analyses of gene expression/protein quantitative trait loci (eQTLs/pQTLs) with autoimmune disease GWAS data were performed. Anti-IL12p35 antibody was generated in RenMab mice. Affinity was measured using Biacore, and IL-12 neutralization was assessed in reporter and primary cells. *In vivo* evaluation employed murine models: DNFB-induced skin inflammation, streptozotocin-induced SS, and IMQ-NZBWF1 lupus nephritis. Pharmacokinetics were evaluated in human FcRn transgenic mice.

Results: The eQTLs/pQTLs of IL-12 pathway genes *IL12A* and *IL12RB2* colocalized with SLE, SSc, PBC, and SS, but not with other autoimmune diseases such as psoriasis (Pso), ankylosing spondylitis (AS), Crohn's disease (CD), ulcerative colitis (UC), or inflammatory bowel disease (IBD). In contrast, *IL12B* and *IL23R* eQTLs colocalized with Pso, AS, CD, UC, and IBD, but not SLE, SSc, PBC, or SS. DM618, the lead candidate, exhibited high Biacore affinity (KD = 6.49×10^{-11} M) and superior IL-12 neutralization (EC_{50}: 0.0059 μg/mL) compared to ustekinumab (anti-IL12p40; EC_{50}: 1.3 μg/mL) in IL-12 reporter cells. DM618 suppressed both exogenous and endogenous IL-12-induced IFN-γ secretion in primary cell-based assays, outperforming ustekinumab. Critically, DM618 did not inhibit IL-23 signaling. Due to its lack of cross-reactivity with mouse IL-12, preclinical validation was conducted using a surrogate anti-mouse IL12p35 antibody in murine models. The surrogate antibody significantly reduced ear thickness ($P = 0.0026$) in a subchronic DNFB-induced skin inflammation model, alleviated salivary gland inflammation in an SS model, and decreased albuminuria in a lupus nephritis model (10-fold reduction vs. controls). Importantly, the human genetic association data have informed the clinical development pathway for DM618.

Conclusion: DM618, a first-in-class anti-IL12p35 antibody, selectively inhibits IL-12 and demonstrates potential to address Th1-driven autoimmune pathology. Supported by human genetic evidence and preclinical validation using a surrogate antibody, DM618's specificity preserves IL-23-mediated immunity, aligning with the distinct roles of IL-12 and IL-23 in their

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Integrative Bioinformatics Analysis Reveals Key Genes and Immune Profiles Associated with Preeclampsia in Lupus Pregnancy

Rodolfo Martinez-Canales[1], **Eva Abigaid Galindo-Calvillo**[2], Andres M. Ortiz-Rios[2], Braulio R. Avalos-Garcia[2], Lorena Perez-Barbosa[2], Dionicio A. Galarza-Delgado[3], Cassandra Michele Skinner-Taylor[2], Mario Cesar Salinas-Carmona[1] and Noe Macias-Segura[1], [1]Immunology Service, Hospital Universitario Dr. José Eleuterio González, Universidad Autónoma de Nuevo León, Monterrey, Nuevo Leon, Mexico, [2]Rheumatology Service, Hospital Universitario Dr. José Eleuterio González, Universidad Autónoma de Nuevo León, Monterrey, Nuevo Leon, Mexico, [3]Rheumatology Service, Hospital Universitario Dr. José Eleuterio González, Universidad Autónoma de Nuevo León, Monterrey, Mexico

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1830–1854) Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Preeclampsia (PE) is a serious complication of pregnancy associated with significant maternal and fetal outcomes. Systemic lupus erythematosus (SLE) significantly increases the risk of PE, which is not explained by traditional risk factors. A dysregulated immune response, with altered gene expression and aberrant immune cell activation play a critical role in the development of PE in patients with SLE. We conducted an integrative bioinformatics analysis to identify candidate genes and pathways implicated in PE among patients with SLE. By leveraging publicly available transcriptomic datasets, we aimed to uncover potential early biomarkers and explore their association with immune cell populations in peripheral blood, providing insights into the immunopathogenesis of PE in SLE.

Methods: We selected the next datasets from the Gene Expression Omnibus database: GSE177029, GSE185047, and GSE48424 (Table 1). We filtered differentially expressed genes (DEGs) using the R-based tool GEO2R, with a false-discovery rate (FDR) value of < 0.05 and a log2foldchange >1 for upregulated genes. A Venn diagram was drawn to visualize shared DEGs across datasets. Enrichment analysis was performed to retrieve gene ontology (GO) biologic processes (BP) and KEGG pathways using ShinyGO. Protein-protein interactions (PPIs) were analyzed with the Cytoscape software, and key hub genes (HGs) were identified with the Cytohubba plugin using the maximal clique centrality algorithm. The Cibersort online tool was utilized to characterize the immune cell population from peripheral blood in dataset GSE48424. A two-way ANOVA test was done to compare immune cell proportions. The two-stage step up method was applied as a post-hoc test to control the FDR. Mean fluorescence intensity (MFIs) values were retrieved, and a Spearman correlation test was performed to assess the relationship between the HG expression and immune cell populations.

Results: 40 DEGs were shared in at least two different datasets (Figure 1A), and whose functional enrichment was notable for BPs related to regulation of viral genome replication and response to type I interferon (Figure 1C). Such terms were then supported by KEGG pathways related to viral infections such as pertussis, measles and influenza A (Figure 1D). PPI analysis

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Correlation heatmap between candidate hub genes and immune cell populations in peripheral blood of pregnant women with systemic lupus erythematosus (SLE). Spearman correlation coefficients are represented by color scale, with red indicating positive and blue indicating negative correlations. Significant correlations are marked with asterisks (*p < 0.05, **p < 0.01). Genes along the x-axis correspond to top hub genes identified through PPI analysis (e.g., THBS1, COL4A3, THBD), and immune cell subsets along the y-axis were estimated using CIBERSORT. Notable associations include negative correlations between THBD and neutrophils, and positive correlations between THBD and regulatory T cells (Tregs), suggesting immune regulatory involvement in preeclampsia pathogenesis in SLE.

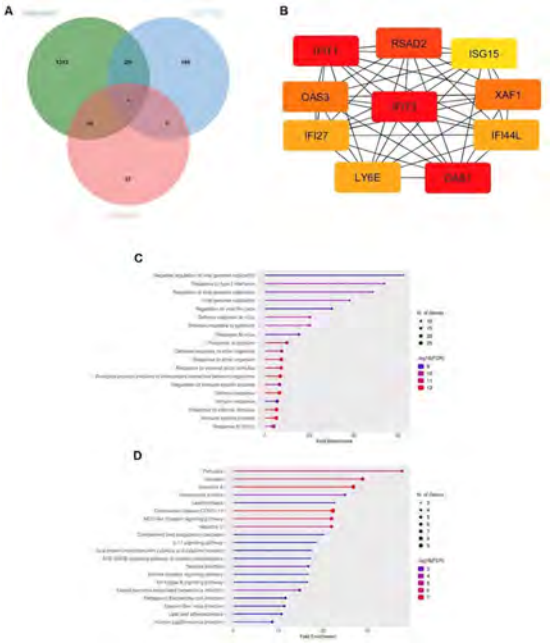

Figure 2. Transcriptomic analysis of shared differentially expressed genes (DEGs) in preeclampsia among pregnant women with systemic lupus erythematosus (SLE). (A) Venn diagram showing overlapping DEGs among three GEO datasets: GSE177029, GSE185047, and GSE48424. A total of 40 genes were shared by at least two datasets. (B) Protein-protein interaction (PPI) network of the top hub genes identified via CytoHubba's MCC algorithm in Cytoscape. Key interferon-stimulated genes such as IFIT1, OAS3, ISG15, and IFI44L were prominent. (C) Gene ontology (GO) enrichment analysis (biological processes) revealed significant overrepresentation of terms related to type I interferon signaling, viral genome replication, and immune response regulation. (D) KEGG pathway enrichment analysis identified key pathways involving infectious and inflammatory responses, including pertussis, measles, COVID-19, complement and coagulation cascades, and IL-17 signaling, highlighting immune activation as a central mechanism in SLE-associated preeclampsia.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Characteristics of GEO datasets

Dataset ID	Platform	Disease	Sample	Subjects
GSE185047	GPL570	SLE	Peripheral Blood	10 HC, 87 SLE
GSE177029	GPL24676	SLE	Placenta	8 HC, 8 SLE
GSE48424	GPL6480	PE	Peripheral Blood	18 HC, 18 PE

Abbreviations: SLE = systemic lupus erythematosus; PE = preeclampsia; HC = healthy controls.

successfully depicted 40 nodes and 172 edges. The MCC algorithm identified the top 10 HGs (Figure 1B) Regarding immune cell populations in peripheral blood, significant differences were observed in CD8+ T cells and neutrophils proportions. Finally, IFIT1, OAS3, IFI27, LY6E, OAS1, IFI44L, XAF1, and ISG15 were observed to have significant correlations with different immune cells (Figure 2).

Conclusion: This study aimed to identify candidate early biomarkers for preeclampsia in pregnant patients with SLE with novel approach. Ten candidate genes were identified and showed to be significantly correlated with immune cell populations in peripheral blood in patients with preeclampsia. These results provide a molecular framework for the study of preeclampsia in pregnant patients with SLE, which warrant further validation in a longitudinal cohort of patients.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1830–1854) Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a heterogeneous autoimmune disease in which lupus nephritis (LN) remains a major cause of morbidity and mortality. Zonulin, a modulator of intestinal permeability via tight junction regulation, has been implicated in the pathogenesis of several inflammatory diseases. Elevated zonulin levels are associated with systemic inflammation and have been linked to gut-organ axes, such as the gut-joint axis in spondyloarthritis and the gut-brain axis in neuropsychiatric disorders. However, its role in SLE and renal involvement remains largely unexplored.

This study aimed to investigate the potential role of zonulin in SLE pathogenesis, with a specific focus on its association with LN.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

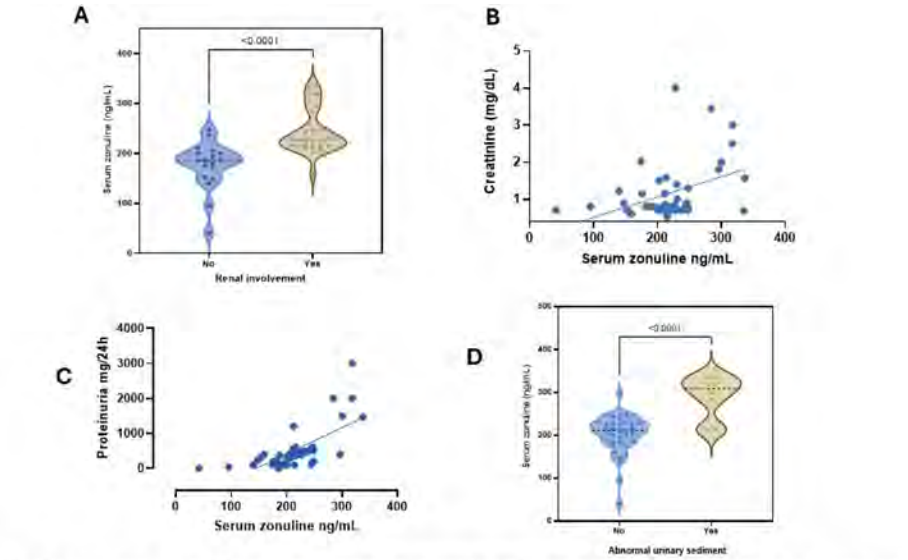

Fig.1 **A:** Correlation ($p < 0.0001$) observed between serum zonulin levels and renal involvement, suggesting a potential link between zonulin and kidney dysfunction.**B:** Correlation ($p < 0.005$; $r = 0.16$) is found between serum zonulin and plasma creatinine in SLE patients (n=46), indicating a limited association with kidney function.**C:** Correlation ($p < 0.0001$; $r = 0.349$) observed between serum zonulin and proteinuria in SLE patients (n=46), suggesting zonulin could be a useful marker for proteinuria.**D:** Correlation ($p < 0.0001$) observed between serum zonulin and abnormal urinary sediment, reflecting potential kidney damage.

Methods: Serum zonulin levels were measured in 46 patients with SLE (2019 ACR/EULAR criteria) and 41 healthy controls using an enzyme-linked immunosorbent assay (ELISA) in a cross-sectional study. Comprehensive demographic, clinical, laboratory, and clinimetric data were collected. Associations between zonulin levels and renal involvement, urinary sediment, serum creatinine, and urinary protein were analyzed. Zonulin expression in LN kidney biopsies was assessed by immunohistochemistry and immunofluorescence.

Results: Analysis of serum zonulin levels revealed a significant increase in SLE patients compared to healthy controls (mean 217.37 ± 56.96 vs. 120.63 ± 83.37; $p < 0.0001$). To determine whether zonulin levels differ between SLE patients with and without lupus nephritis (LN), we analyzed serum zonulin levels according to renal involvement. Interestingly, a substantial increase in zonulin levels was observed in patients with LN compared to those without LN (mean 244.19 ± 44.61 vs. 175.6 ± 48.67; $p < 0.0001$). To investigate whether serum zonulin levels might be associated with renal disease activity or damage, we analyzed zonulin levels in relation to urinary sediment abnormalities, serum creatinine levels, and urinary protein levels. Zonulin levels were significantly higher in patients with abnormal urinary sediment compared to those with normal sediment (mean 289.8 ± 50.25 vs. 202.1 ± 45.6; $p < 0.0001$). Additionally, serum zonulin levels showed a positive correlation with serum creatinine levels ($p < 0.005$; $r = 0.16$) and urinary protein levels ($p < 0.0001$; $r = 0.349$) (Fig. 1).

IHC staining revealed local presence of zonulin in glomeruli and tubules, with higher expression in the latter, suggesting either local production or binding of circulating zonulin, and supporting a direct role in modulating glomerular and tubular function.

Conclusion: Elevated circulating zonulin is associated with renal involvement in SLE, suggesting a previously unexplored gut-kidney axis and a novel biological function of zonulin in regulating glomerular permeability.

Session Title: (1830–1854) Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: B cells play an essential role in lupus nephritis (LN) pathogenesis. However, abnormalities in specific subtypes like age-associated B cells (ABCs) and double negative (DN) cells have been associated with this clinical manifestation. These cell populations share an increased response to intracytoplasmic TLR (iTLR) stimulation, leading to increased autoantibody production. Besides, diverse cytokines/chemokines have shown to play a role in LN. Nonetheless, the association between B cell subtype-specific expression of iTLRs and the serum levels of diverse cytokines/chemokines with lupus nephritis has not been fully addressed, which is the aim of the present study.

Methods: We carried a cross-sectional study including 54 lupus patients that fulfilled the 2019 EULAR/ACR classification criteria for SLE. 28 with LN according to laboratory and/or histopathological findings and 26 with extrarenal activity (NLN) with SLEDAI-2K ≥6. From each subject we collected clinical, and laboratory data related to disease activity and isolated

Table 1. Demographic, activity and treatment data by study group. LN, lupus nephritis group ; NNL, active non-lupus nephritis ; IQR, interquartile range.

PBMCs for flow cytometry analysis of TLR7 and TLR9 expression (percentage and absolute number of positive cells and median fluorescence intensity (MFI)) in these B cells subtypes ($CD19^+$): transitional ($CD27^-$ $CD24^{hi}$ $CD38^{hi}$), naïve ($CD27^-$ $CD24^-$ IgD^+), classical ($CD27^+$) and non-classical memory ($CD27^-$ $CD24^+$ $CD38^{-/lo}$), ABCs ($CD21^-$ $CD11c^+$ T-bet^+), DN ($CD24^+$ $CD27^-$ IgD^-) and plasmablasts ($CD27^{hi}$ $CD38^{hi}$). Additionally, serum cytokines were measured by luminometry in a multiplexed assay , including: IL-1α, IL-1β, IL-1ra, IL-2, IL-3, IL-4, IL-5, IL-6, IL-7, IL-8, IL-10, IL-12, IL-12 (p70), IL-13, IL-15, IL-17ª, IP-10, MCP-1, MIP-1α, MIP-1β, TNF-α, TNF-β, VEGF and eotaxin. Demographic variables were compared with the Mann-Whitney U test, potential confounder variables were assessed with the G test and associations with mixed logistic regression.

Results: Demographic, laboratory and treatment data are shown in Table 1. Mycophenolate and azathioprine were the only confounding variables. Therefore, we analysed the association of immunological variables adjusted by treatment. As shown in Table 2, a higher expression of MyD88 was constantly associated with LN, from early stages like transitional and naïve B cells to late ones like memory and DN cells. We found that TLR7 associates with LN when expressed in naïve and DN1 cells, and only through transitional cells, TLR9 is associated with LN. All significant variables competed to create a multivariate predictive model. One was selected according to Akaike information criteria, which resulted from the mixed effect of TLR9 MFI in transitional cells (OR 1.006, CI 95% 1.001-1.01, p 0.013) and serum eotaxin (OR 1.018, CI 95% 1.003-1.03, p 0.017), Figure 1.

Conclusion: Our data shows that TLR7/9 and MyD88 expression in B cells and their relation with LN are subtype-specific. However, further studies are needed to delimitate the functional effects of TLRs signaling by cell subset and their relationship to renal affection. As for eotaxin, its potential as a LN biomarker in serum and urine has been previously reported. Nonetheless, the source and specific cell effect induced by this chemokine in LN context remains to be explored.

Table 2. TLR7, 9 and MyD88 expression by B cell subtype associated with LN. Results obtained by mixed logistic regression adjusted by treatment. OR, Odd ratio; CI, confidence interval; MFI, median fluorescence intensity; AU, arbitrary units.

B cell subtype	OR (CI 95%)	p

Enhanced Mitochondrial Activity in B cells from Females Is Required to Drive Increased T-bet Induction by TLR7 in Lupus

John D. Mountz[1], Kathryn Sullivan[2], Shanrun Liu[2], Cynthia Liu[2], Min Gao[2], Walter Winn Chatham[3], Tanecia Mitchell[2] and Hui-Chen Hsu[2], [1]University Alabama Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]University of Nevada, Las Vegas, Las Vegas, NV

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1830–1854) Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a predominantly female autoimmune disease, with a 9:1 female-to-male ratio. Our previous studies indicated that increased T-bet$^+$ age-related B cells (ABCs) was associated with elevated circulating type I interferon (IFN) and autoantibody development in female, but not male, lupus prone BXD2 mice. While dysregulated type I IFN signaling and Toll-like receptor 7 (TLR7) activation are established contributors to SLE, the molecular mechanisms underlying sex-specific immune responses in mice and humans are not fully understood.

Methods: The transcriptomic profiles of naïve B cells (*IGHM+IGHD+IGHG-*) from 11 female (5 SLE patients and 6 healthy) and 11 male donors (4 autoimmune inflammatory disease patients [AID] and 7 healthy) were analyzed by single cell-RNA sequencing analysis. B-cell response induced by R848 (TLR7 agonist) plus IFNβ *in vitro* was analyzed for early activation of CD69 at 4h and T-bet at 24h, respectively, using B cells derived from female and male BXD2 mice. Real-time PCR was used to determine if R848 plus IFNβ impacts the expression of mitochondrial electron transport chain (ETC) complex I genes, *Ndufa1* and *Ndufa3*. Mitochondrial oxidative phosphorylation (OxPhos) was measured using the Mitochondrial Stress Test and Seahorse Analyzer at 48 and 72h. Flow cytometry was used to evaluate the impact of the complex I inhibitor IM-156 on R848 plus IFNβ-induced T-bet and GL7 upregulation at 72h.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Increased IFN-stimulated genes was the primary transcriptomic signature in female SLE patient B cells. B cells from females, regardless of health status and ethnicity, exhibited elevated expression of mitochondrial ETC genes, including complex I genes compared to males. Regarding mice, there was similar early activation of CD69 at 4h and T-bet expression at 24h in B cells from both sexes. However, B cells from female mice exhibited significantly higher expression of *Ndufa1* and *Ndufa3* at 24h and 72h. There was a significant increase in basal and maximal respiration, ATP production, and reserve capacity in B cells from female mice at 48h and 72h. This was associated with significantly increased development of T-bet^{+}GL7^{+} B cells in female mice at 72h. *In vitro* pharmacologic inhibition of complex I with IM-156 significantly attenuated T-bet upregulation in B cells of female mice.

Conclusion: These findings suggest that the development of T-bet^{+} B cells in female BXD2 mice is strongly dependent on increased mitochondrial OxPhos. Sex-biased differences in OxPhos may therefore act as an intrinsic factor, making it more likely for precursor B cells to reach the energy thresholds needed for differentiation into ABCs under TLR7 and type I IFN stimulation in females with lupus.

Abstract Number: 1838

Differential Expression Of Activation Markers On dsDNA-reactive B-cells Between Healthy Subjects And SLE Patients Reveals Unconventional Extrafollicular Activation In SLE

Lars Van Vliet, Annemarie Dorjée, René Toes and **Jolien Suurmond**, Leiden University Medical Center, Leiden, Netherlands

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1830–1854) Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Anti-dsDNA IgG antibodies are a hallmark of systemic lupus erythematosus (SLE), an autoimmune disease characterized by chronic inflammation and multi-organ damage. Evidence suggests that anti-dsDNA antibodies contribute to a range of end-organ injuries, particularly lupus nephritis. Although the overall expansion of plasma cells is well established in SLE, surprisingly little is known about the phenotype of antigen-specific, dsDNA-reactive B cells and the mechanisms underlying tolerance break towards dsDNA. As insights into these mechanisms are important to understand the emergence of autoantibody responses hallmarking SLE, we aimed to disentangle the cellular phenotype and B cell differentiation pathways involved in the production of anti-dsDNA antibodies.

Methods: PBMCs were isolated from healthy subjects and SLE patients. A novel flow cytometry staining for dsDNA was developed using fluorescent dsDNA tetramers and validated using supernatants of single-cell sorted dsDNA-reactive B cells. Phenotyping of dsDNA-reactive B cells was performed using spectral flow cytometry on PBMCs from healthy subjects (n=10), and anti-dsDNA+ (n=10) and anti-dsDNA- (n=11) SLE patients. Anti-dsDNA positivity in serum and culture supernatants was determined using ELISA.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: By index sorting and single cell culture we show that naïve dsDNA-reactive B cells are present in both healthy donors and SLE patients. Spectral flow cytometry revealed that dsDNA-reactive B cells are expanded and activated in anti-dsDNA+ SLE patients only, as compared to negative patients and healthy subjects. The largest expansion was observed in the activated CD21-CXCR5- B cell subsets, pointing to activation through the extrafollicular pathway. While comprising only 2.3% ± 0.2% of the dsDNA-reactive B cells in healthy controls, class-switched CD21-CXCR5- B cells accounted for 21% ± 1.5% of the dsDNA-reactive cells in anti-dsDNA+ SLE patients. These findings indicate a direct relationship between immunological activity of dsDNA-reactive B cells and serological anti-dsDNA positivity, which was further confirmed by the observation that dsDNA-reactive B cells in anti-dsDNA+ versus anti-dsDNA- subjects exhibit increased expression of CD11c, CD95, CD69, Ki67, and BST2, and decreased expression of CXCR5, CD23, and CD72. Interestingly, whereas most CD11c+ cells in the total B cell compartment co-expressed T-bet, CD11c+ dsDNA-reactive B cells largely lacked T-bet expression.

Conclusion: We conclude that dsDNA-reactive B-cells are present within resting naïve B cells in healthy subjects and anti-dsDNA IgG-negative SLE, pointing to defective elimination of dsDNA-reactivity in the human naïve B cell repertoire. In anti-dsDNA+ SLE patients, these cells display markers typifying an extrafollicular pathway maturation and are hallmarked by CD11c expression in the absence of T-bet. These findings identify a novel, unconventional, pathway of CD11c+ B cell differentiation, indicate that human dsDNA-IgG responses in SLE have been licensed to differentiate through an extrafollicular pathway, and offer potential targets for selectively inhibiting these cells in SLE.

Transcriptional Profiling of Whole Blood and Kidney Biopsy Samples from Lupus Nephritis and IgA Nephropathy Patients Suggests Different Disease Pathways

Christopher Sisk[1], **Loqmane Seridi**[2], Alan Perlman[3], Matthew Loza[2], Sheng Gao[2], Thomas Parker[4], Daniel Levine[4], Thangamani Muthukumar[5], Yonatan Bardash[6], Benjamin Horowitz[7], Surya Seshan[5] and James Chevalier[3], [1]Johnson & Johnson, San Diego, CA, USA, San Diego, CA, CA, [2]Johnson & Johnson, Spring House, PA, [3]The Rogosin Institute, New York, NY, [4]The Rogosin Institute, Weill Cornell Medical College, New York, NY, [5]Weill Cornell Medical College, New York, NY, [6]Hackensack Meridian Health, Hackensack, NJ, [7]Columbia University Medical Center, New York, NY

SESSION INFORMATION

Session Title: (1830–1854) Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Lupus nephritis (LN) is a severe complication of systemic lupus erythematosus (SLE), associated with significant morbidity and mortality. IgA nephropathy (IgAN) is the most common form of primary glomerulonephritis worldwide, characterized by IgA deposition in the glomeruli and subsequent renal damage. Although LN and IgAN share some clinical and immunological similarities, their underlying pathogenic pathways are likely distinct, necessitating further research into their molecular profiles. While the transcriptomic profiles of whole blood samples from SLE patients have been investigated in different cohorts and pointed to the dysregulations of key immune pathways, the differences have not been closely examined in the kidney for LN and IgAN. This study evaluated and compared the transcriptomic profiles of whole blood and kidney biopsy samples from the LN and IgAN patients, as well as the matching healthy controls.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Samples from 52 patients (34 with LN and 18 with IgAN) were included in this study. Whole blood samples (33 LN and 18 IgAN) were collected in PAXGene tubes. Kidney biopsy samples (24 LN and 16 IgAN) were collected following standard clinical practice, with residual samples preserved for transcriptomic analysis. Healthy control samples including whole blood (n=30) and kidney tissue (n=7) were obtained independently. RNA was extracted from whole blood and kidney samples and used for standard RNA sequencing analysis. In this analysis, statistical significance for differentially expressed genes (DEGs) was defined as a fold change > 2 and FDR < 0.05. Interferon (IFN) gene signature enrichment was quantified using gene set variation analysis (GSVA).

Results: In comparison to healthy controls, there were 2151 differentially expressed genes (DEGs) identified in whole blood of LN patients and 200 DEGs in IgAN patients, respectively. The LN vs IgAN comparison revealed 1054 DEGs. LN DEGs were enriched in Reactome pathways related to "innate immune" and "neutrophil activation", while IgAN DEGs were enriched in "B cell" and "Fc receptor signaling" pathways. Both LN and IgAN kidney samples exhibited over 3000 DEGs compared to controls and shared similar enriched pathways, with IFN pathway further enriched in LN. The kidney IFN gene signature score correlated with serum creatinine levels and eGFR in both diseases.

Conclusion: Transcriptomic analysis highlighted similar and distinct dysregulated pathways in LN and IgAN whole blood and kidney. Greater differences were observed in whole blood transcriptomics, indicating a greater extent of systemic immunological dysregulation between LN and IgAN. Renal IFN pathway activation was prominent in LN and correlated with the severity of kidney dysfunction in both diseases.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1830–1854) Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: 3TR (taxonomy, treatment, targets and remission) aims to provide insights into the mechanisms of response and non-response to treatment in systemic autoimmune diseases, including SLE. The lupus arm of 3TR focuses on identifying biomarkers of disease activity. Volatile organic compounds (VOCs) can be generated by metabolic processes in the body. VOCs can diffuse from their point of origin into the blood and be emitted through breath, providing a potential non-invasive method to assess whole-body metabolism and pathophysiological associations.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Thirty SLE patients and 29 age- and sex-matched healthy controls were recruited to a single-site, case-control observational study. Breath VOC sampling was performed using the ReCIVA® breath sampler, linked to a clean air supply (CASPER®). Samples were collected on sorbent tubes and analyzed by thermal desorption gas chromatography-mass spectrometry (TD-GC-MS) by Owlstone Medical. VOCs were chemically identified in alignment with the Metabolomics Standards Initiative (MSI) criteria, with blank air samples analyzed to discern VOCs genuinely present in patients' breath. Associations with disease activity (SLEDAI-2K, BILAG-2004, PGA, PhGA), LLDAS, DORIS remission, and fatigue measures were assessed using robust covariate-adjusted models.

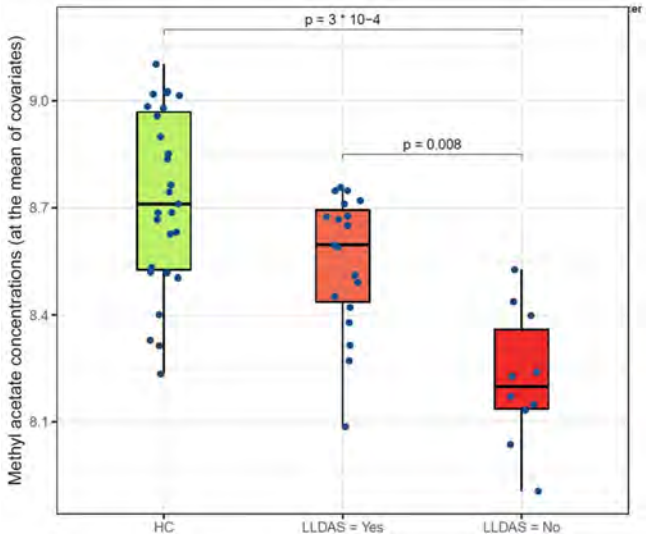

Figure 2 – Concentrations of methyl acetate in HC and in relation to LLDAS status

Results: Demographic and clinical characteristics of patients and controls are summarized in the Table. Among 1,433 detected VOCs, 539 exceeded background levels. Focusing on high-confidence annotations (MSI tier 1 or 2), several significant correlations emerged with clinical parameters, as depicted in Figure 2. Based on compound correlations, five distinct VOC clusters were identified: 1) The anti-inflammatory compound methyl acetate stood apart as the only compound negatively associated with disease activity indices and failure to achieve LLDAS or DORIS remission; consistently, its levels in healthy controls were higher and comparable to those in non-active SLE patients (figure 3); 2) A cluster of four VOCs containing by-products of lipid peroxidation showed a coherent pattern of association with disease activity, lack of remission, and fatigue; 3) A cluster, composed of nitrogen-containing heterocycles of exogenous origin and suggestive of gut barrier disruption, showed moderate associations with disease activity; 4) A cluster, whose main representative a member of the Cyclopentenediones family with pro-inflammatory prostaglandin properties, related with disease activity and fatigue measures; 5) A small heterogeneous group with weak associations with SLEDAI-2K and LLDAS.

Conclusion: These data demonstrate the potential of breath-based VOC analysis in detecting non-invasively pathophysiological changes in SLE. Our findings highlight the intricate role of unresolved inflammation, oxidative stress, and gut barrier dysfunction in driving disease activity, as well as in influencing the patient's perception of fatigue and overall disease severity. Future work should focus on validating these markers and exploring their associations with additional inflammatory indicators as well as assessing their potential for monitoring changes, therapy response, and prognostication.

Differential metabolomic signatures along lupus nephritis spectrum

Mariana Jiménez Tirado[1], karina santana[2], Jiram Torres Ruiz[3], Jennifer Tiaré Balderas Miranda[4], Diana Gómez-Martín[5], José Carlos Páez Franco[6], Nancy R Mejía Domínguez[7], Hilda Sánchez Vidal[6] and Imelda Cecilia Zarzoza Mendoza[8], [1]Instituto Nacional de Nutrición Salvador Zubirán, Mexico City, Distrito Federal, Mexico, [2]INCMNSZ, Ciudad de México, Federal District, Mexico, [3]INCMNSZ, Mexico, Federal District, Mexico, [4]Universidad Nacional Autónoma de México, Coyoacán, Federal District, Mexico, [5]INCMNSZ, Mexico city, Federal District, Mexico, [6]Red de Apoyo a la Investigación, Instituto Nacional de Ciencias Médicas y Nutrición, Mexico City, Distrito Federal, Mexico, [7]Universidad Nacional Autónoma de México, Mexico City, Distrito Federal, Mexico, [8]Red de Apoyo a la Investigación, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán and Universidad Nacional Autónoma de México, Mexico City, Distrito Federal, Mexico

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1830–1854) Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Lupus nephritis (LN) is a common feature in systemic lupus erythematosus (SLE) affecting up to 50% of the individuals with this disease. The gold standard for diagnosis is renal biopsy, nonetheless this procedure can entail complications due to its invasive nature. Metabolomic profile seems to be a promising alternative as a noninvasive diagnostic tool, as it has demonstrated to be useful distinguishing between active LN, SLE without renal involvement and healthy controls. However, scarce information exists about metabolomic profile differences in LN active patients, patients achieving renal response and patients with sustained response. The aim of this study is to characterize the metabolomic profile of three distinct groups of patients representing a broad spectrum of LN, from activity to sustained response.

Methods: Adult patients that met the 2019 ACR/EULAR criteria for SLE were eligible for inclusion and assigned into groups according to LN activity and treatment response. Group 1 included patients with active LN diagnosed by renal biopsy and/or 24-hour urinary protein-creatinine ratio greater than 0.5, active urinary sediment and creatinine increase of 0.3 mg/dl from baseline. Group 2 encompassed patients with either complete or partial renal response after 6 months of starting induction therapy. Group 3 encompassed patients with sustained response defined as a period greater than 2 years since achieving complete response to induction therapy without relapse. Urine metabolomic analysis was performed using a non-targeted method based on liquid chromatography tandem mass spectrometry.

Results: Urine metabolomic profile was obtained from 21, 21 and 20 patients in groups 1, 2 and 3 respectively. The population included adults with a median age of 36 years out of which 90% were female. Among 37 identified metabolites, 10 differential metabolites were detected, of which 7 were increased in group 1. Most of these correspond to sugar acids such as threonic acid (median concentration of 125 in group 1 vs. 89 and 82 in group 2 and 3 respectively, $p < 0.001$), as reported in previous literature reports, has been shown to differentiate between SLE with renal involvement from non-renal involvement. Amino acids were also increased in group 1, such as vanillylmandelic acid (median concentration 5.4 vs 4.6 and 4.1 group 2 and 3 respectively, $p= 0.010$) and norvaline (5.5 vs 4.8 and 4.4, group 2 and 3 respectively, $p= 0.025$), which differs from previous data. Citrate was diminished in active LN, but increased in group 2 and 3 patients (9 vs. 27 and 53 respectively, $p=0.008$). This observation has been related to a dampened oxidative phosphorylation in activated immune cells which normalize after treatment.

Conclusion: Urine metabolomic profile differentiates active LN patients from individuals that have achieved and maintained response to treatment and may serve as a noninvasive diagnostic tool for LN. Active LN is characterized by increased sugar acids and lower citrate levels. These findings give insight into the metabolomic shifts underlying renal activity in SLE and may resolve once response to therapy has been achieved.

Social Vulnerability Index, Type 2 Lupus Symptoms, and Select Dysregulated Immune Features Identify Stage 2 (Pre-classification) SLE in the Lupus Autoimmunity in Relatives (LAUREL) Follow-up Cohort

Melissa Munroe[1], Zoe Reed[2], Joel Guthridge[2], Diane Kamen[3], Timothy Niewold[4], Kendra Young[5], Angel Weng[5], Emma Wu[5], Gary Gilkeson[6], Michael Weisman[7], Mariko Ishimori[7], Daniel Wallace[8], John Harley[9], David Karp[10], Jill Norris[11] and Judith James[2], [1]Oklahoma Medical Research Foundation; Progentec Diagnostics, Inc., Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]Medical University of South Carolina, Johns Island, SC, [4]Hospital for Special Surgery, New York, New York, [5]Colorado School of Public Health, Aurora, CO, [6]Medical University of South Carolina, Charleston, SC, [7]Cedars-Sinai Medical Center, LOS ANGELES, CA, [8]Cedars Sinai Medical Center, Studio City, CA, [9]US Department of Veterans Affairs Medical Center, Cincinnati, OH, [10]UT Southwestern Medical Center, Dallas, TX, [11]Colorado School of Public Health, Denver, CO

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1830–1854) Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Socioeconomic environmental factors are associated with SLE disease activity and early mortality and may contribute to disease progression in at-risk populations. Blood relatives (BRs) of lupus patients have an increased risk of SLE; identification of those at greatest risk of disease transition is essential for early intervention strategies and prevention trial enrollment. The goal of this study is to determine factors associated with the Social Vulnerability Index (SVI; Flanagan et al. 2011. JHSEM. 8[1]: Article 3) that distinguish previously healthy BRs who progress to SLE compared to those who remain stable.

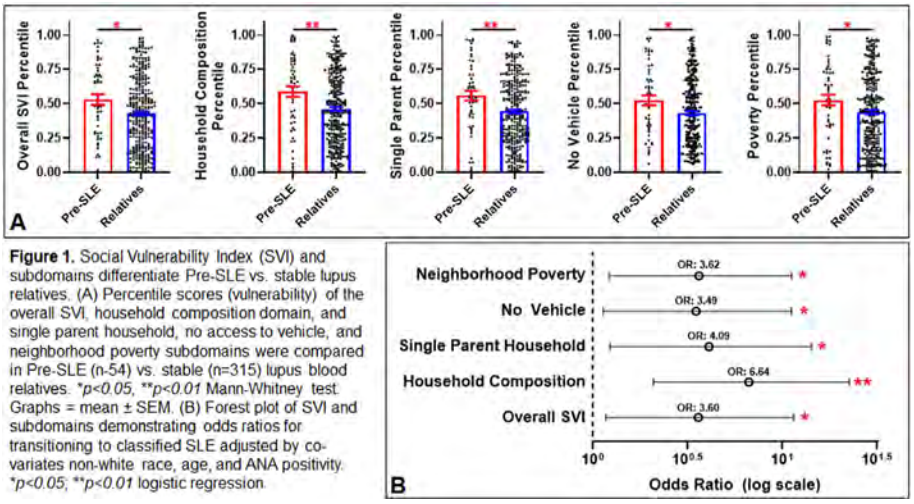

Figure 1. Social Vulnerability Index (SVI) and subdomains differentiate Pre-SLE vs. stable lupus relatives. (A) Percentile scores (vulnerability) of the overall SVI, household composition domain, and single parent household, no access to vehicle, and neighborhood poverty subdomains were compared in Pre-SLE (n-54) vs. stable (n=315) lupus blood relatives. *$p<0.05$, **$p<0.01$ Mann-Whitney test. Graphs = mean ± SEM. (B) Forest plot of SVI and subdomains demonstrating odds ratios for transitioning to classified SLE adjusted by covariates non-white race, age, and ANA positivity. *$p<0.05$; **$p<0.01$ logistic regression.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We evaluated domains/sub-domains of the census-tract informed SVI in follow-up Pre-SLE (n=54) vs. stable (n=315) BRs of SLE patients with available geographical location data who previously enrolled in a genetics study (mean time to follow-up = 6.3 yrs) and did not meet SLE classification (≥4 ACR criteria) at baseline (BL). ACR classification criteria were determined by medical record review. BRs completed the connective tissue disease questionnaire (CSQ), type 2 symptom questions, and provided demographic and geographic information. Census-tract based percentile rankings of the overall SVI and its domains/subdomains were calculated. BL sample data included serum ANA and SLE-associated autoantibody specificities, as well as 52 plasma immune mediators (xMAP and ELISA assay available for 54 Pre-SLE vs.137 matched stable BRs).

Results: The overall SVI, as well as household composition domain and single parent household, no vehicle, and neighborhood poverty subdomains differentiated Pre-SLE from stable relatives ($p< 0.05$, **Fig. 1A**) with increased vulnerability (percentile) in Pre-SLE BRs, even after adjusting for race, age, and ANA positivity (**Fig. 1B**). Type 2 symptoms, including anxiety, depression, and chronic fatigue, as well as < 7 hours of sleep/night were consistently associated with SVI/domains ($p< 0.05$; representative features shown in **Fig. 2**) and specifically affected Pre-SLE vs. stable BRs to varying degree (**Fig. 2**).

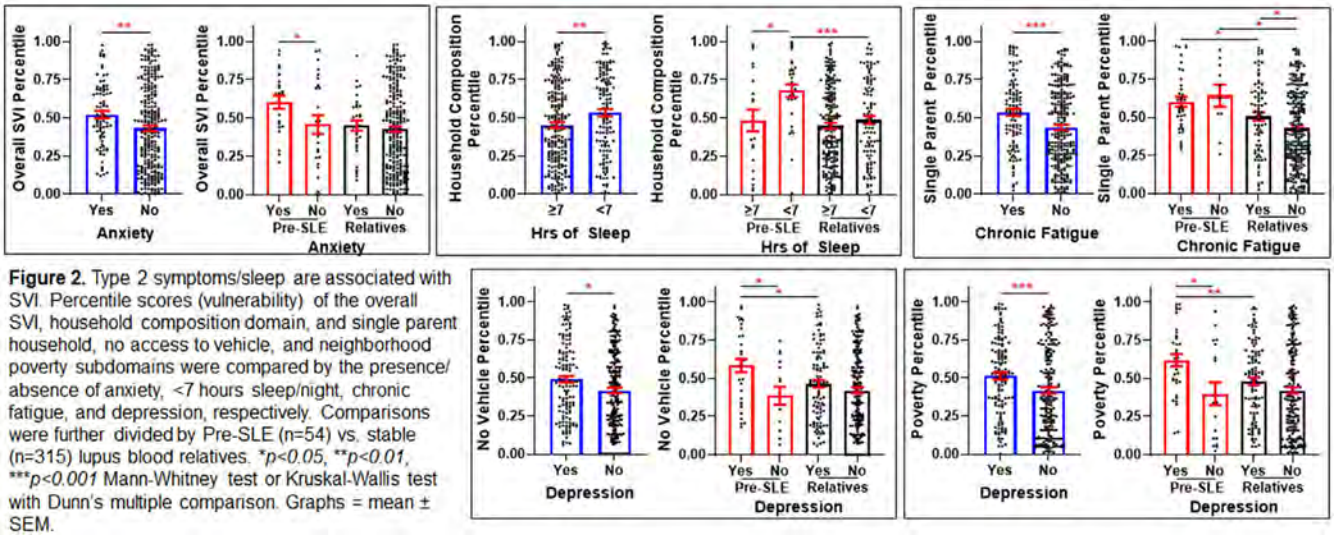

Figure 2. Type 2 symptoms/sleep are associated with SVI. Percentile scores (vulnerability) of the overall SVI, household composition domain, and single parent household, no access to vehicle, and neighborhood poverty subdomains were compared by the presence/absence of anxiety, <7 hours sleep/night, chronic fatigue, and depression, respectively. Comparisons were further divided by Pre-SLE (n=54) vs. stable (n=315) lupus blood relatives. *$p<0.05$, **$p<0.01$, ***$p<0.001$ Mann-Whitney test or Kruskal-Wallis test with Dunn's multiple comparison. Graphs = mean ± SEM.

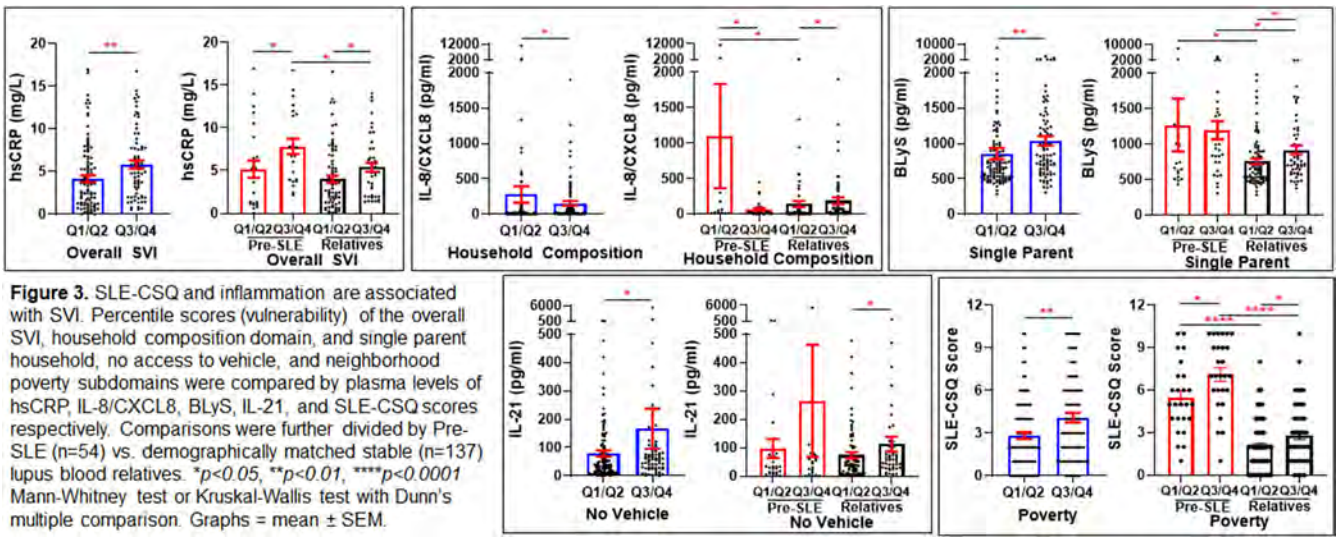

Figure 3. SLE-CSQ and inflammation are associated with SVI. Percentile scores (vulnerability) of the overall SVI, household composition domain, and single parent household, no access to vehicle, and neighborhood poverty subdomains were compared by plasma levels of hsCRP, IL-8/CXCL8, BLyS, IL-21, and SLE-CSQ scores respectively. Comparisons were further divided by Pre-SLE (n=54) vs. demographically matched stable (n=137) lupus blood relatives. *$p<0.05$, **$p<0.01$, ****$p<0.0001$ Mann-Whitney test or Kruskal-Wallis test with Dunn's multiple comparison. Graphs = mean ± SEM.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

In addition to BMI and its associated immune mediator leptin (Spearman r >0.2, $p< 0.01$), the SLE-CSQ and associated inflammatory factors CRP, BLyS, IL-8/CXCL8, and IL-21 consistently correlated (Spearman r >0.2, $p< 0.01$) and associated with SVI/domain percentiles/quartiles and specifically affected Pre-SLE vs. stable BRs to varying degree, with IL-8/CXL8 increased with less vulnerability, while other inflammatory and symptomatic factors, including CRP, BLyS, IL-21 and SLE-CSQ scores being increased with greater vulnerability ($p< 0.05$, representative characteristics shown in **Fig. 3**).

Conclusion: The SVI was associated with type 2 and inflammatory features, distinguishing BRs at risk of SLE disease transition vs. BRs who remained stable. Addressing aspects of socioeconomic vulnerability, including poverty, single parent households, and access to vehicle transportation, may be required to advance early intervention strategies and prevention trial participation to decrease chronic inflammation and type 2 symptoms associated with SLE in at-risk populations.

Tissue Neutrophils in The Pathogenesis of Lupus Nephritis

Norio Hanata[1], Carmelo Carmona-Rivera[1], Victoria Hoffman[2], Kan Jiang[3], davide Randazzo[4], Meryl Waldman[5], Sarfaraz Hasni[6] and Mariana Kaplan[1], [1]Systemic Autoimmunity Branch, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, Bethesda, MD, [2]Diagnostic and Research Services Branch, Division of Veterinary Resources, Office of Research Services, National Institutes of Health, Bethesda, MD, Bethesda, [3]Biodata Mining and Discovery Section, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, Bethesda, [4]Light Imaging Section, Office of Science and Technology, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, Bethesda, [5]Kidney Disease Section, Kidney Diseases Branch, National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, Bethesda, MD, Bethesda, PA, [6]National Institutes of Health, Bethesda, MD

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1830–1854) Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a multiorgan autoimmune disease that frequently affects the kidneys, with lupus nephritis (LN) being a major contributor to morbidity and mortality. A neutrophil gene signature in peripheral blood has been associated with LN, and neutrophil infiltration has been detected in the lupus kidney parenchyma. A putative pathogenic contribution of neutrophils to SLE is the externalization of modified autoantigens and proteins that are detrimental to the host, through dysregulated neutrophil death by the formation of neutrophil extracellular traps (NETs). However, the specific pathogenic impact of neutrophils/NETs in LN has not been systematically studied.

Methods: Lupus-prone NZB/W F_1 and control C57BL/6 (B6) mice were analyzed. The number and maturity of neutrophils were assessed in PBS-perfused kidneys by flow cytometry. The morphology and localization of neutrophils were evaluated by different light microscopy approaches such as, brightfield, namely, hematoxylin-eosin and immunohistochemical (IHC) staining, as well as by immunofluorescence (IF) staining. Kidney biopsies from patients with LN were also analyzed by IHC and IF to corroborate findings obtained from mice. Furthermore, human mesangial cells were stimulated with NETs, and their interactions were assessed by IF and RNA sequencing.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: NZB/W F_1 mice exhibited increased renal neutrophil infiltration in comparison to the control B6 mice, particularly following the onset of proteinuria, which correlated with its severity. Kidney-infiltrating neutrophils exhibited a predominantly mature phenotype and localized primarily in the glomerular region. Fragmented neutrophil remnants, suggesting cell death and enhanced debris deposition, accumulated in mesangial areas post-proteinuria onset and in association with mesangial matrix damage score. IF analysis confirmed that NETs deposited in the mesangial regions. Similar findings were observed in biopsies from SLE patients with a diagnosis of LN. *In vitro*, human mesangial cells internalized NETs via endocytosis and phagocytosis, leading to phenotypic changes detectable by RNA sequencing and functional studies.

Conclusion: These results suggest that neutrophils contribute to the pathogenesis of LN through infiltration, NET formation, and interaction with mesangial cells. These observations further implicate aberrant neutrophils in the pathogenesis of lupus-associated organ damage.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1830–1854) Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: In collaboration with the AMP-RA/SLE network, we identified disease-associated macrophages (D-Macs) in kidney biopsies from 155 patients with active lupus nephritis (LN) and 30 controls, using single-cell RNA sequencing of ~25,000 myeloid cells (Fig. 1A, B). D-Macs comprised several macrophage subsets and expressed an injury-associated gene program, including TREM2, CD63, CTSD, APOE, SPP1, GPNMB, CD9, and FABP5 (Fig. 1C), which are conserved across monocytes and macrophages in other injured tissues. D-Macs showed positive correlation with the ISN/RPS activity index and were more prevalent in proliferative and mixed histological classes (III/IV±V) compared to the pure membranous class (V) or healthy individuals (not shown). In this follow-up study, we explored the origins and significance of D-Macs in proliferative/mixed LN.

Methods: We analyzed kidney biopsies from LN patients and controls using single-cell RNA sequencing to identify distinct cell populations. Spatial transcriptomics was performed with a custom gene panel to map myeloid subtypes in FFPE kidney samples. We also examined transcriptomic responses to putative nephritic glomerular factors plus M-CSF in healthy CD14 monocytes using flow cytometry and RNA sequencing.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Bioinformatic analysis suggested that D-Macs likely differentiate in situ from infiltrating monocytes or resident macrophages, indicating a process of "convergent differentiation" where blood and tissue myeloid cells adopt similar transcriptional profiles in response to factors from diseased kidneys (Fig. 1D-G). To gain further insight into D-Mac differentiation and function, we mapped each D-Mac subset alongside other myeloid populations across renal compartments and in relation to lesions in FFPE sections from 6 LN patients with proliferative or mixed histologic classes (mean ISN/RPS activity = 13.5; S.D = 5.8) and 2 controls. Certain D-Mac subsets were statistically enriched in glomeruli with proliferative lesions (Glomerular D-Macs), while others were mainly found in the tubulointerstitium (Tubulointerstitial D-Macs) (Fig. 2), suggesting that distinct D-Mac subsets may differentiate from different precursors in a compartment-specific manner.

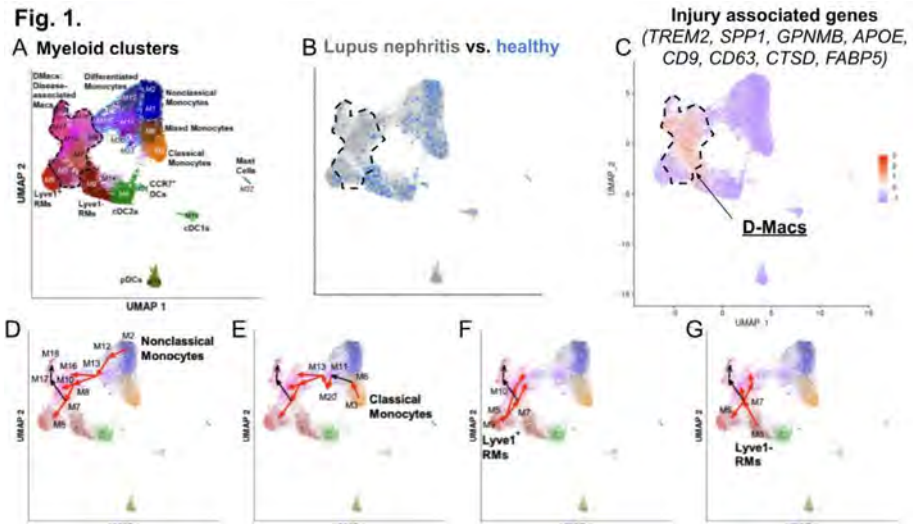

Fig. 1. (A-C) UMAP of single-cell analysis of myeloid cells labeled by clusters (A), case vs. controls (B), or average expression of injury associated genes. Black dotted line outlines the D-Mac clusters. (D-G) Assessing the feasibility of differentiation of monocytes and RMs into DMac clusters. The shortest paths from each putative origin into each DMac cluster is shown based on the results of trajectory analysis using partition based graph abstraction (PAGA) (PMID 30890159). Edges colored in red area also supported by the colocalization analysis presented below in Fig. 3. Paths originating from (D) CD16+ nonclassical monocytes (cluster M2); (E) CD14+ classical monocytes (cluster M3); (F) Lyve1+ RMs (cluster M9); (G) Lyve1- RMs (cluster M0).

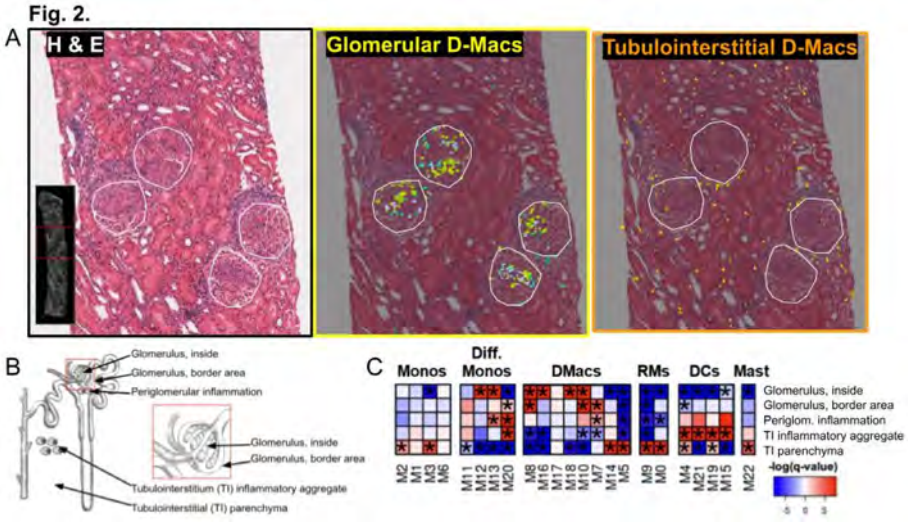

Fig. 2. Specific D-Mac subsets localize to glomeruli or tubulointerstitial regions of tissue. (A) Top panel shows example biopsy from patient with cass IV+V, activity 16/24 and chronicity 5/12. Bottom panel shows (B) areas of kidney in our analysis and (C) quantification of enrichment (red), depletion (blue), and statistical significance (asteriks) across indicated areas from 6 patients and 2 controls.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

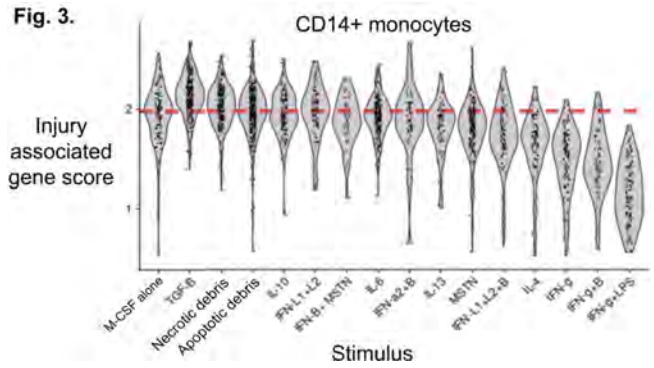

Fig. 3. CD14 monocytes were stimulated with M-CSF alone or with the indicated factors and subject to single cell RNA-seq to measure the average expression of the injury associated score (genes in Fig. 1C).

To determine whether factors from nephritic glomeruli drive D-Mac differentiation from infiltrating CD14+ or CD16+ monocytes, we screened 40 inflammatory mediators identified through single-cell data, spatial transcriptomics, histology, and literature review. Results showed that several glomerular factors—such as immune complexes with resiquimod, cell debris, and TGF-β—promoted the induction of D-Mac-like states, including an injury-associated gene program similar to that observed in patients, from both CD14+ (Fig. 3) and CD16+ (not shown) monocyte precursors.

Conclusion: Our findings highlight key glomerular mediators in proliferative lupus nephritis that may promote D-Mac differentiation from infiltrating monocytes. They support the idea that distinct monocyte states respond similarly to nephritic factors, converging on a shared cellular phenotype. Ongoing studies are focused on elucidating the functional roles of these cells.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1830–1854) Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) significantly increases the risk of premature atherosclerosis, contributing to long-term morbidity and mortality. Traditional cardiovascular risk factors do not fully explain this phenomenon. Immunologically driven endothelial injury is proposed as a key mechanism. This study integrates transcriptomic and immune cell profiling data to identify molecular and cellular signatures associated with subclinical atherosclerosis in SLE.

Methods: Transcriptomic datasets GSE154851 and GSE110174 were obtained from the Gene Expression Omnibus. GSE154851 includes patients with increased carotid intima-media thickness (CIMT), while GSE110174 includes SLE patients without CIMT and healthy controls. Gene set enrichment analysis (GSEA) was conducted to identify genes linked to coronary atherosclerosis. Protein-protein interaction (PPI) networks were analyzed using Cytoscape, with hub genes (HGs) identified through five centrality algorithms. Immune cell fractions (22 types) were estimated via CIBERSORTx. A two-way ANOVA with FDR correction was used to compare cell populations across groups, and logistic regression assessed associations with CIMT status.

Results: Nineteen genes were significantly enriched in the atherosclerosis phenotype, including ACTA2, ABCA1, MYH11, APOB, PCSK9, PPARG, TGFBR1, and SMAD3. Immune cell profiling revealed significant differences in CD8+ T cells, CD4+ naïve and memory subsets, NK cells, monocytes, M0 macrophages, and neutrophils. CD8+ T cells, CD4+ naïve T cells, and resting NK cells were negatively associated with CIMT, whereas CD4+ memory resting T cells, monocytes, and

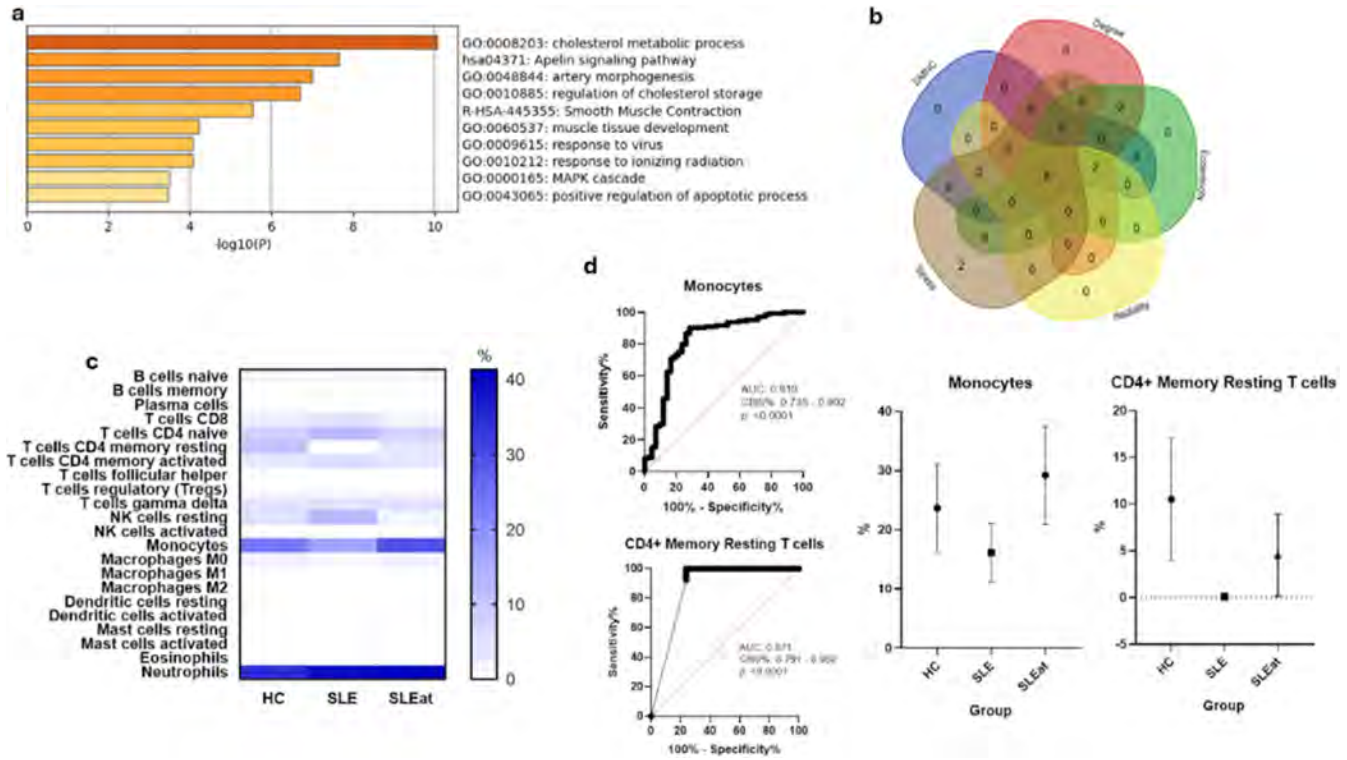

Figure 1. Immune profiling and diagnostic relevance of hub genes in SLE-related atherosclerosis. (a) Gene set enrichment analysis of transcripts linked to coronary atherosclerosis in individuals with systemic lupus erythematosus (SLE). (b) Common hub genes determined by the intersection of five centrality-based algorithms. (c) Relative abundance of 22 immune cell subsets in healthy controls (HC), SLE patients without carotid intima-media thickening (CIMT), and SLE patients with increased CIMT (SLEat). (d) Receiver operating characteristic (ROC) curves showing the predictive performance of monocyte counts and resting CD4+ memory T cells for identifying subclinical atherosclerosis in the SLE cohort.

Table 1. Logistic Regression Analysis of Immune Cell Types Associated with SLE-Related Atherosclerosis

Cell Type	OR	CI 95%	p
CD8+ T cells	0.72	0.62 – 0.85	<0.001
CD4+ Naïve T cells	0.81	0.74 – 0.89	<0.001
CD4+ Memory Resting T cells	4.81	2.48 – 9.35	<0.001
CD4+ Memory Activated T cells	0.36	0.25 – 0.51	<0.001
Resting Natural Killer cells	0.27	0.14 – 0.50	<0.001
Monocytes	1.41	1.26 – 1.58	<0.001
Macrophages M0	2.71	1.87 – 3.91	<0.001

Note: Odds ratios (OR), confidence intervals (CI95%), and p-values indicate the strength of association between immune cell subsets and the presence of increased carotid intima-media thickness (CIMT) in SLE patients, relative to those without CIMT.

M0 macrophages showed positive associations (all $p < 0.001$). Diagnostic accuracy was supported by ROC curve analysis, highlighting monocytes and CD4+ memory T cells as potential biomarkers.

Conclusion: This study uncovers specific immune cell subsets and gene networks linked to atherosclerosis in SLE. The findings emphasize the contribution of innate and adaptive immune dysregulation in vascular pathology and support further exploration of immune-based biomarkers to stratify cardiovascular risk in lupus.

Background/Purpose: Lupus nephritis (LN) is characterized by kidney inflammation and leads to loss of kidney function. Depending on race/ethnicity, up to 60% of Systemic Lupus Erythematosus (SLE) patients develop LN early in their disease. However, the cellular pathways driving disease onset and progression remain poorly defined. Because these pathways involve cell interactions at different spatial scales, spatial mapping of kidney biopsies can provide critical insights. This study aimed to spatially profile kidney biopsies from early LN patients to identify key cellular states, interactions, and regions associated with disease progression and to construct a spatial atlas of early LN pathology.

Methods: We analyzed Formalin-Fixed Paraffin-Embedded (FFPE) kidney biopsies from patients with LN and UPCR between .250 and .499 (n = 8), non-LN SLE (no LN; n = 3), and healthy controls (n = 4). Serial sections were profiled using Xenium (5 μm; 5101 genes) and single-cell FFPE RNA seq (23 μm; whole transcriptome). Xenium transcripts were quality filtered and segmented into cells using a transcript density-based segmentation method (Baysor). Custom pipelines were used to process and integrate Xenium and scFFPE data. After QC, we obtained ∼400,000 cells from Xenium and ∼100,000 cells from scFFPE.

Results: Integration of scFFPE and Xenium data revealed 8 major cell lineages based on marker expression (Fig. 1A, B). LN and non-LN samples showed enrichment of lymphocytes compared to controls (Fig. 1C). Cell projections (Xenium)

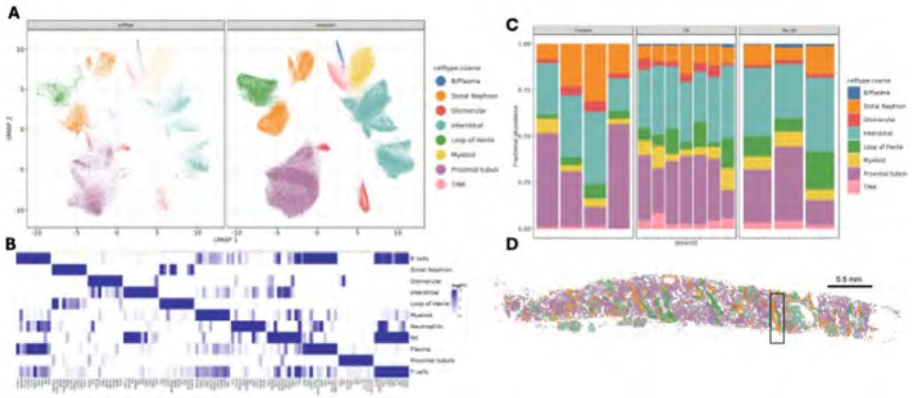

Figure1: (A) UMAP projection of cells from scFFPE RNA sequencing and Xenium datasets. Cells are colored by their major cell types. (B) Heat map of logFC of top 15 marker genes for every cell type. (C) Relative abundance of cell type populations in each sample. Relative abundance is the ratio of number of cells of each type to the total number of cells in the sample. (D) Spatial projection of the cell types in (A) onto tissue space. Insert highlights the distal tubule.

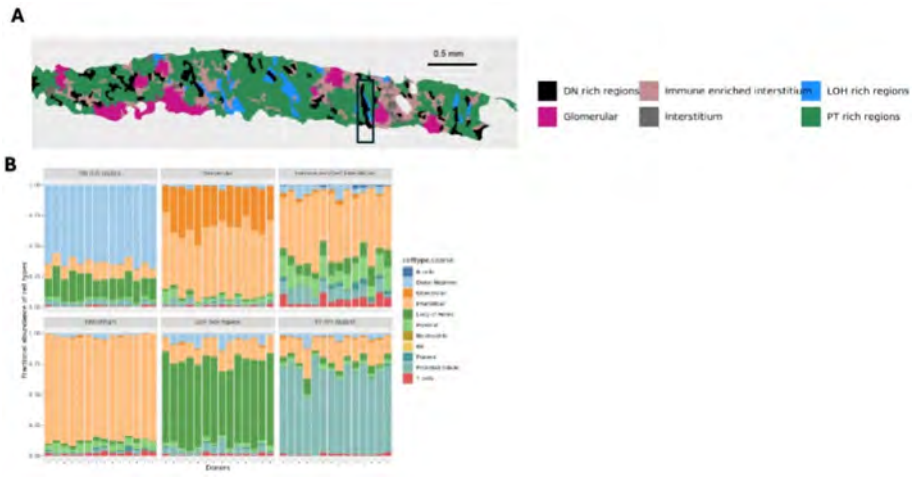

Figure2: (A) Spatial segmentation of the tissue shown in 1D. Regions are colored by their type. Insert highlights the distal tubule in 1D, which is now detected and annotated as a DT rich region. (B) Relative abundance of cell types in each region in each sample in the dataset. Regions are annotated based on their cell composition.

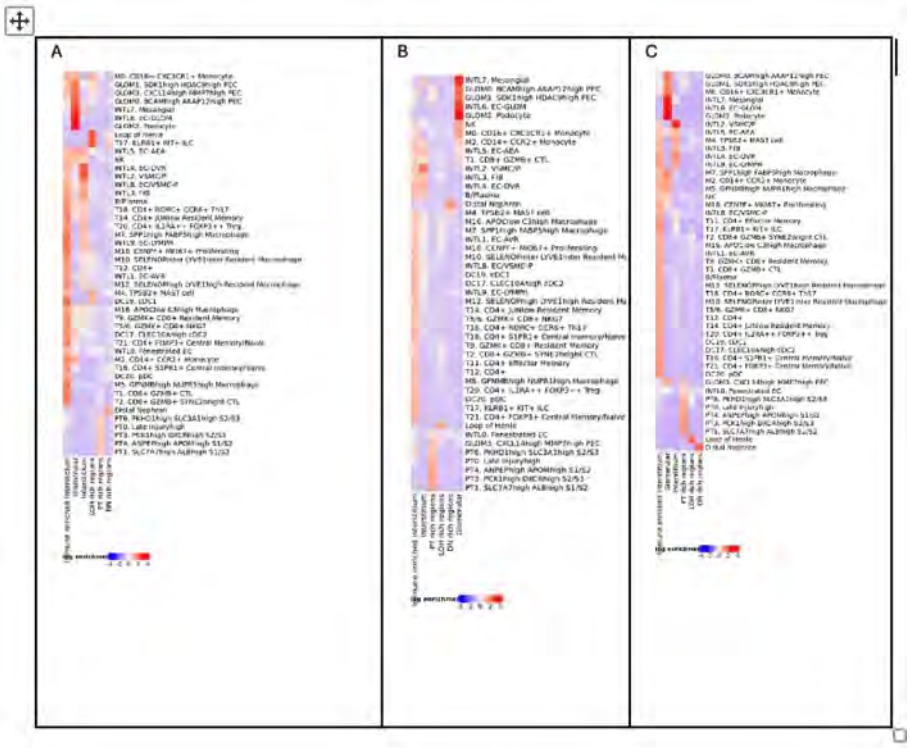

Figure3: (A-C): Log enrichment of cell states within each spatial region: (A) in control samples, (B) No LN samples, (C) LN samples.

confirmed that profiled cells localized to expected anatomical regions (Fig. 1D). Using the public AMP SLE reference and in house pipelines, we annotated 43 cell states across the 8 cell lineages and mapped in tissue space. Transcript-based tissue segmentation with Tessera identified six regions: 3 tubular, 1 glomerular, and two interstitial (Fig. 2A, B).

We next quantified cell state enrichment in each region across groups (Fig. 3). In controls, cell states localized to expected regions. In LN, macrophage subsets M5 (GPNMB high NUPR high) and M7 (SPP1 high FABP5 high) were enriched in glomerular regions, compared to interstitial enrichment in controls and non-LN SLE. Colocalization analyses revealed that M5 and M7 colocalized in the glomerular regions in LN samples, suggesting recruitment to inflamed regions during early disease.

Conclusion: We generated a comprehensive kidney spatial atlas of early LN, non-LN SLE, and healthy controls, integrating scFFPE RNA sequencing and Xenium spatial transcriptomics. In this initial study of patients with early-stage LN, we have started to characterize distinct cell states that may be involved in the development of LN in patients with SLE. We found that patients with SLE and no LN accumulated lymphocytes, suggesting that even in the absence of frank LN, the kidneys of lupus patients may be affected. We also found that resident macrophages tend to move from the interstitium to the glomerular region in patients with early LN. These macrophages may be involved in initiating glomerular injury in LN.

Abstract Number: 1847

Spatial transcriptomics reveals a complex microanatomic patterning of complement mediated inflammation and fibrosis in Class III pediatric lupus nephritis associated with local histologic injury

Sarah McCuaig[1], Julia Rood[1], Em Elliott[1], Portia Kreiger[1] and Edward Behrens[2], [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]CHOP, West Chester, PA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1830–1854) Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Lupus nephritis (LN) occurs in over 50% of patients with pediatric systemic lupus erythematosus (pSLE) and results in significant morbidity due to suboptimal kidney remission rates and the sequelae of prolonged intensive immunosuppressive therapy. LN is often patchy, with some glomeruli severely damaged while others remain histologically unaffected in the same kidney. However, the local factors that drive this patchy tissue injury remain unclear. Using novel spatial transcriptomic technology, we interrogated microanatomic transcriptional differences between histologically damaged and unaffected glomeruli and adjacent tubules in pSLE LN to understand local drivers of renal injury.

Methods: Archived pre-treatment FFPE pediatric renal biopsies were stained with H&E. Using the Visium 10x platform, spatially barcoded gene expression libraries mapped to 55μM diameter spots were sequenced. A pediatric pathologist identified histologically damaged and unaffected glomeruli based on H&E staining. Loupe Browser (10X Genomics) was used to annotate damaged versus unaffected glomeruli (Figure 1A) and adjacent tubules (Figure 2A) and their associated barcoded spots. Differential gene expression analysis of spots was performed in R. 3 cases of pSLE Class III LN, 3 cases of pSLE Class V LN, and 3 "healthy control" kidneys resected for non-immune pathology were assessed. Immunofluorescence staining was used to assess cellular localization of specific transcriptional changes at the protein level.

Results: Differential gene expression analysis revealed a unique transcriptional signature in histologically damaged compared to unaffected Class III LN glomeruli (Figure 1B). While interferon-stimulated genes were unchanged (Figure 1C), damaged Class

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1 – Damaged Class III LN glomeruli show upregulation of C5AR1 and genes linked to fibrosis. Spatial transcriptomics using the Visium 10x platform was performed on FFPE renal biopsies from pediatric patients with Class III LN (N=3), Class V LN (N=3), and "healthy" controls (N=3). (A) Representative H&E section from Class III LN biopsy with overlay of 55uM spots showing pathologist annotation of histologically damaged (pink) and unaffected (black) glomeruli. (B) Enhanced volcano plot showing differentially expressed genes comparing histologically damaged to unaffected glomeruli Class III LN glomeruli. Positive log2 fold changes are genes with increased expression in damaged compared to unaffected glomeruli. (C) ISG score computed as the average of the expression of IFI44, IFI44L, MX1, IFIT1, HERC6. Each dot is expression from a 55uM spot. X axis numbers represent individual patients in each disease subset. **** p< 0.0001 unpaired T-test for comparison between damaged and unaffected Class III LN glomeruli. (D) C5AR1, ITGA11, FN1 expression. Each dot is expression from a 55uM spot. N=3 healthy control. N=3 Class III LN. N=3 Class V LN. ****p<0.0001, ***p<0.001, **p<0.01, one way ANOVA with Tukey's post-test for multiple comparisons. (E) Publicly available single cell sequencing data from LN biopsies from the Accelerating Medicines Partnership (AMP) showing C5AR1 expression is highest in the macrophage clusters. (F) Immunofluorescence staining of C5AR1, CD68 (marks myeloid cells), PODXL (marks podocytes) in a representative Class III LN biopsy.

III LN glomeruli showed increased expression of *C5AR1* and both *ITGA11* and *FN1* compared to unaffected Class III LN glomeruli (Figure 1D) implicating complement component 5a activity and fibrosis respectively. *C5AR1* expression is likely driven by myeloid cells based on analysis of single cell RNA sequencing data from the Accelerating Medicines Partnership (Figure 1E) and immunofluorescence staining (Figure 1F). Periglomerular tubules next to damaged Class III LN glomeruli show increased early complement gene expression and expression of the fibrosis inducing gene *POSTN* compared to those next to unaffected Class III LN glomeruli and those far from glomeruli (Figure 2B,C). All changes remain significant even after correcting for patient level differences. *POSTN* expression correlates with other fibrosis-related genes including *LGALS1* (Figure 2D).

Conclusion: LN is characterized by a specific microanatomic patterning of inflammation and fibrosis. Damaged glomeruli and adjacent tubules in Class III LN are marked by local complement gene and *C5AR1* expression and fibrosis-related

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1830–1854) Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Toll-like receptor (TLR) 7 is a pattern recognition receptor that recognizes nucleic acids and is implicated in the pathogenesis of systemic lupus erythematosus (SLE). We have previously shown that DS-7011a, an anti-TLR7 monoclonal antibody, inhibits IFNα and IL-6 release from TLR7 agonist-stimulated human peripheral blood mononuclear cells (PBMCs). As TLR7 is expressed in human plasmacytoid dendritic cells (pDCs), B cells and monocytes, in this study, we aim to investigate the inhibitory effects of DS-7011a on TLR7-mediated activation of pDCs, B cells and monocytes related to the pathogenesis of SLE. Additionally, we also aim to evaluate the inhibitory effects of DS-7011a on the production of multiple cytokines/chemokines implicated in the pathogenesis of SLE in human PBMCs.

Methods: Human PBMCs were isolated from fresh whole blood of healthy donors and frozen purified human pDCs, B cells and monocytes were purchased. These cells were stimulated with TLR7 agonists in the presence of DS-7011a to evaluate its inhibitory effects on TLR7-mediated activation *in vitro*. The production of cytokines/chemokines after stimulation was measured by Multiplex assay or AlphaLISA. The production of IgG from B cells was measured by cell-based ELISA,

Results: The production of IFNα, IL-6 and IgG stimulated with TLR7 agonists in human pDCs, monocytes and B cells respectively, was suppressed by DS-7011a dose dependently. Additionally, stimulation with a TLR7 agonist led to the production of several cytokines/chemokines implicated in the pathogenesis of SLE, including IL-6, monocyte chemoattractant protein (MCP) -1, MCP-3, monocyte inflammatory protein (MIP) -1α, MIP-1β, IL-12 (p40), and TNF-α in human PBMCs. All of these cytokine productions were also inhibited by DS-7011a in a dose-dependent manner.

Conclusion: DS-7011a demonstrated inhibitory effects on TLR7-mediated activation of immune cells and suppressed the production of IgG and pro-inflammatory cytokines/chemokines implicated in the pathogenesis of SLE. Since autoantibodies and pro-inflammatory cytokines/chemokines are known as therapeutic targets individually, DS-7011a has shown potential as a novel therapeutic agent for SLE by inhibiting these multiple mechanisms.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1830–1854) Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) encompasses a subset of patients who exhibit resistance to standard treatments, posing a significant challenge to achieving remission. Our study aimed to elucidate the molecular mechanisms underlying treatment resistance in clinical practice. To address this, we conducted RNA sequencing analysis using longitudinal peripheral blood samples.

Methods: 42 peripheral blood samples from naïve or flare 14 SLE patients were collected before treatment and 4 and 12 weeks after treatment who received standard induction therapy except for belimumab, anifrolumab, and rituximab. Patients were divided into two groups based on their response to treatment. 1) Treatment responder group; those who achieved a SLEDAI-2K score of less than 4 after 12 weeks, and 2) Treatment-resistant group; those who did not achieve less than 4.

RNA sequencing was performed using NovaSeq 6000 (Illumina) with a paired-end read of 100 base pairs. FASTQ format data were mapped to the UCSC human genome 38 as the reference sequence. Sequence read count data was analyzed using R (4.3.2). Basic analysis were performed using edgeR. Time-course expression analysis was performed using maSigPro. We identified differentially expressed genes (DEGs) by comparing samples obtained before treatment and at 12 weeks post-treatment.

Results: Patients with a SLEDAI score of 4 or less at 12 weeks were classified as responders (n=8), and those with a score of more than 4 were classified as the resistant group (n=6). In PCA plot of RNA-seq of peripheral blood, there was no clear distinction between responders and resistant. No clear group discrimination was found after treatment.

In DEG analysis, 19 DEGs were detected in responder comparing 0w and 12 weeks after treatment, and 85 in resistant. Enrichment analysis showed that adequately suppressed immune response in resistant group. We thought that information of the time series sample of the same person was not utilized, and planned to take advantage of the sequential sampling information.

We performed time-course analysis using samples before treatment and 4 and 12 weeks after treatment to identify critical factors that are involved in treatment resistance over time. maSigPro is a software to identify genes that show different gene expression profiles across analytical groups in time-course experiments. maSigPro can also perform time-series clustering to identify genes with significant intergroup differential expression.

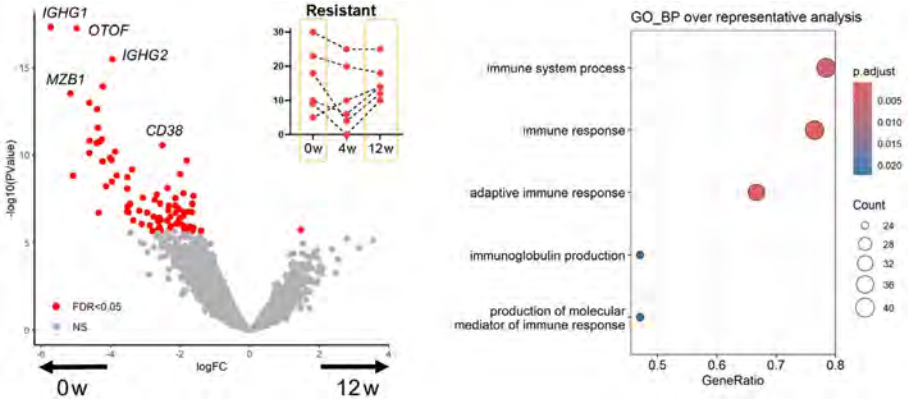

Figure 1. DEG-based analysis; 85 DEGs were detected in treatment-resistant group comparing 0w and 12 weeks after treatment (left, volcano plot). Enrichment analysis (right) showed that immune response process is suppressed in treatment-resistant group.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Time course expression of TNFRSF17 and MZB1; The time course expression patterns of TNFRSF17 and MZB1, being sufficiently suppressed from the week 4 and further decreasing at week 12. ***: p <0.001, ****: p <0.0001.

The responder and resistant group were compared, and the differentially expressed genes in the time series were extracted. *TNFRSF17* ($P = 1.144 \times 10^{-21}$) and *MZB1* ($P = 3.547 \times 10^{-16}$) were identified in addition to immunoglobulin-related genes. *TNFRSF17* (BCMA), a receptor for BAFF/BLyS, has been investigated as a therapeutic target for SLE. MZB1 is a B-cell-specific endoplasmic reticulum chaperone complex that plays a key role in antibody secretion and is increased in SLE lymph nodes. These molecules are supposed to be critical for treatment resistance.

Conclusion: Time-course analysis using longitudinal peripheral blood samples of SLE suggested that the expression levels and trends of *TNFRSF17* and *MZB1* are important for treatment resistance in SLE.

First American SLE patients demonstrate enhanced lipid metabolism and B cell activation by high-content proteomic analyses

Rufei Lu[1], **Tayte Stephens**[2], Carla Guthridge[1], Miles Smith[1], Joseph Kheir[1], Cristina Arriens[1], Joan Merrill[3], Marci Beel[4], Susan Macwana[1], Wade DeJager[5], Nicholas Domingez[1], Teresa Aberle[1], Joel Guthridge[1] and Judith James[1], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]University of Oklahoma Health Science Center, Oklahoma City, OK, [3]Oklahoma Medical Research Foundation, Oklahoma City 73104, OK, [4]Oklahoma Medical Research Foun, Oklahoma City, OK, [5]Oklahoma Medical Research Foundation, Oklahoma City

SESSION INFORMATION

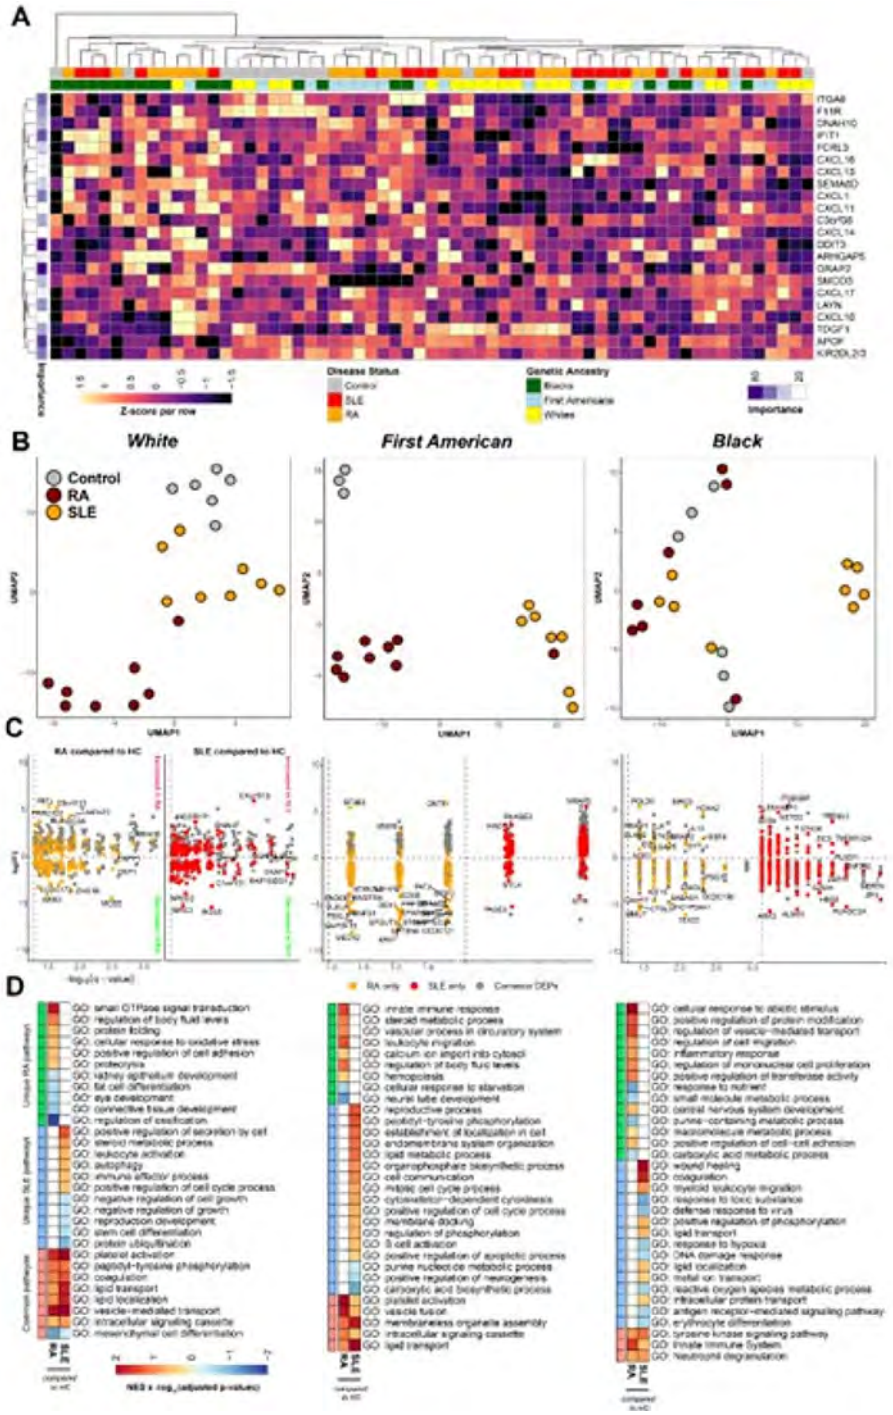
Session Date: Tuesday, October 28, 2025
Session Title: (1830–1854) Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) are autoimmune diseases with overlapping yet distinct immunopathologies. Proteomic profiling of soluble plasma factors can reveal disease- and ancestry-specific immune dysregulation. Using RA as a disease control, we investigated ancestry-specific plasma proteomic signatures in SLE to elucidate unique pathways contributing to disease pathogenesis.

Methods: Serum samples from 90 female participants (SLE=30, RA=30, healthy controls=30) stratified by ancestry-Black, First American, and White were analyzed using the Olink Explore HT assay, quantifying over 5,000 proteins. Differential expression and pathway enrichment analyses were performed with false discovery rate correction (FDR< 0.05) to identify ancestry- and disease-specific proteomic alterations.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Proteomic profiles distinctly separated SLE, RA, and healthy controls, with notable ancestry-associated differences (Figure). In SLE, all ancestries demonstrated increased lipid and vesicle-mediated transport pathways; however, First American patients uniquely exhibited lipid metabolic dysfunction. Black patients showed increased myeloid activity, including neutrophil degranulation and migration pathways. White patients displayed dysregulated protein degradation and nucleotide modification pathways, particularly involving nuclear proteins and SUMOylation. Notably, First American SLE patients had



A, Heatmap of top predictors revealing distinct soluble proteomic profiles among different ancestries between rheumatic disease and healthy controls. B, UMAPs based on Olink Explore HT Assay highlighting distinct soluble proteomics between two rheumatic diseases (RA and SLE) and healthy controls. C, Volcano plots showing the differentially detected proteins (DEP) between RA and SLE and healthy controls in different ancestries. D, Heatmaps of gene set enrichment analyses based on DEPs.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

significantly elevated B-cell activation pathways, consistent with heightened interferon hypersensitivity and cellular frequency data. Using RA as a disease control, we observed that Black RA patients had pronounced upregulation of vesicle-mediated transport pathways compared to SLE. Additionally, White RA patients showed downregulation of connective tissue-related pathways and First American RA patients exhibited neuronal and vascular system pathway alterations. Across diseases, Black patients demonstrated predominant dysregulation of innate immune pathways, whereas White and First American patients showed more adaptive immune system involvement.

Conclusion: Ancestry shapes plasma proteomic landscapes in SLE and RA, with distinct immune and metabolic pathways differences. The use of RA as a disease control underscores unique SLE-specific proteomic signatures, particularly in lipid metabolism and B-cell activation among First American patients and myeloid-driven inflammation in Black patients. These results emphasize the importance of integrating ancestry and disease context in proteomic analyses to inform personalized therapeutic strategies in autoimmune diseases.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1830–1854) Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a multifaceted autoimmune disorder characterized by marked clinical variability, which complicates both diagnosis and treatment. Among its most severe manifestations are cardiovascular (CV) complications and lupus nephritis (LN), both of which are associated with increased morbidity and mortality. Conventional biomarkers often fall short in capturing the molecular intricacies of these conditions, highlighting the need for integrative multi-omic strategies.

Methods: In this study, proteomic and metabolomic analyses were combined to uncover molecular signatures linked to CV risk and LN. Serum samples from 199 SLE patients were examined using proximity extension assays for proteomic profiling and nuclear magnetic resonance (NMR) spectroscopy for metabolomic analysis. In vitro assays were performed by treating HUVECs and HK2 cells with serum from SLE patients to assess endothelial and renal proteomic responses. Ex vivo experiments involved culturing rat kidney slices with the same sera to evaluate inflammatory signalling through p65 immunofluorescence.

Results: Unsupervised clustering based on proteomic data identified two patient subgroups: one with high disease severity (HDS) and another with low disease severity (LDS). The HDS group showed increased levels of inflammatory proteins (e.g., IL6, CD40, CXCL9) and metabolites (e.g., creatinine, citrate), which were associated with CV risk and renal involvement. Using machine learning, patients were accurately classified into HDS and LDS groups (AUC = 0.77), with biomarkers such as citrate and LDL subclasses playing a key role.

These results were validated in an independent patient cohort, confirming the robustness of the identified molecular patterns. In vitro assays revealed that serum from HDS patients induced endothelial dysfunction in HUVECs and triggered inflammatory responses in HK2 kidney cells, including the upregulation of proteins involved in tissue damage and immune activation. Furthermore, ex vivo experiments using rat kidney slices demonstrated NF-κB pathway activation in tissues exposed to HDS serum.

Conclusion: Overall, this study provides compelling evidence that CVS risk and LN in SLE are associated with distinct proteomic-metabolomic signatures that reflect underlying disease mechanisms. The integration of omics data with functional assays offers valuable insights into the molecular drivers of organ-specific damage in SLE. These findings might pave the way for biomarker-driven diagnostic tools and personalized therapeutic strategies based on patient stratification, aiming to mitigate disease-related complications.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1830–1854) Systemic Lupus Erythematosus – Etiology and Pathogenesis Poster

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Cutaneous lupus erythematosus (CLE) is a chronic inflammatory skin disease associated with systemic lupus erythematosus (SLE) and characterized by a prominent type I interferon response. Although the mechanisms that trigger cutaneous lupus lesions remain unclear, recent therapeutic developments have highlighted a pivotal role for plasmacytoid dendritic cells (pDCs) in its disease pathogenesis.

Methods: As part of the NIH AMP-AIM-supported Lupus Omics Cutaneous Kidney Investigation Team (LOCKIT), we performed advanced multi-omics profiling using single-cell and spatial transcriptomics on paired lesional and non-lesional skin samples from 12 patients with CLE, including 11 with discoid lupus erythematosus (DLE) and 1 with subacute CLE (SCLE). CLE patients were treatment-naïve or on treatment with hydroxychloroquine only.

Results: Biopsies were obtained from scalp (n=10) and back (n=2) from 12 patients (5 Black, 7 White, 80% female). For scRNA-seq, we generated 537 million reads from over 130,000 cells. Our analysis identified two distinct pDC populations, pDC1 and pDC2 (pDC-like cells), based on expression of *LILRA4* (ILT7), *CLEC4C* (BDC2A), *LTK*, GZMB, *SIGLEC6*, and *IRF7*. Both pDCs predominantly enriched in lesional skin (>74%), with pDC1 comprised 0.06% to 4.66% of total cells and pDC2 ranged from 0% to 0.31%, while both were markedly reduced (∼0.16%) in non-lesional skin. pDC1 (891 cells) expressed classical pDC markers such as *GZMB*, *C12orf75*, *IRF7*, *SOX4*, and *LDLRAD4*. In contrast, pDC2 (68 cells) showed lower *GZMB* and higher expression of *PPP1R14A*, *LTK*, and *KCNK17*, and clustered with the rest of the myeloid cells, suggesting a transitional myeloid state (**Figure 1**). Among the differentially expressed genes, *CLEC4C* (BDCA2) was significantly higher in pDC1 (adjusted $p = 7.09 \times 10^{-19}$, $\log_2$FC = 2.48) compared to pDC2. While both *LILRA4* (ILT7) and CLEC4C (BDCA2) were found prominently on pDCs and pDC-like cells, lower intensity of *CLEC4C* was seen on a larger percentage of cDC1 cells, while *ILT7* was present on a small number of cDC1 cells. Macrophages and other cell types did not express these genes (**Figure 2**). Using the Xenium platform with a 5,000-gene core and 100 custom genes, we spatially profiled 28 skin samples. Cell type annotations derived from scRNA-seq confirmed the presence and distribution of both pDC subsets. Neighborhood analysis revealed that pDC1s were proximity to B and T cells, whereas, conversely, pDC2s were localized near pDC1s and conventional dendritic cells (cDCs) (**Figure 3**).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

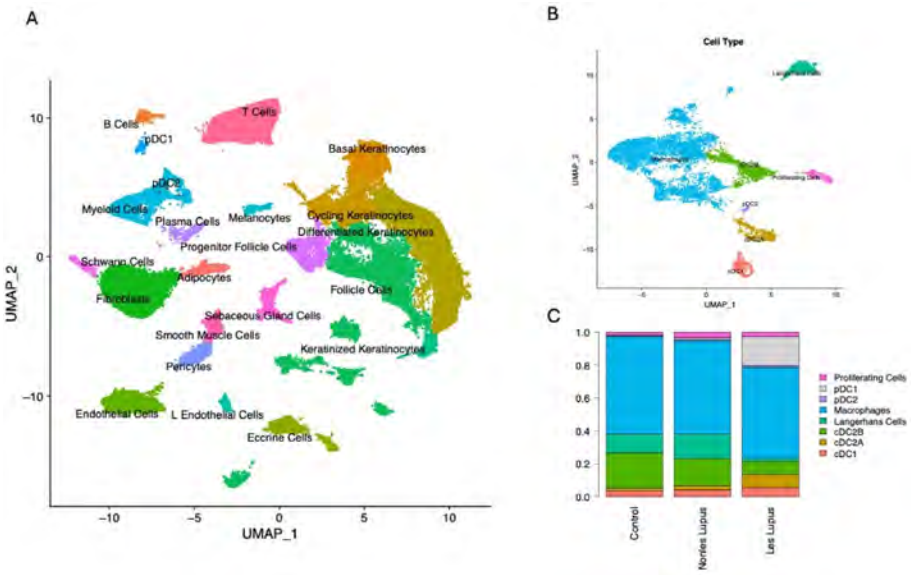

Figure 1: UMAP visualization of single-cell RNA-seq data in major- (A) and sub- (B) types. The distribution highlights transcriptionally distinct myeloid subsets and a pDC-like (pDC2) population relevant to autoimmune pathogenesis. Histogram illustrates proportions of each cell populations in different skin types (C).

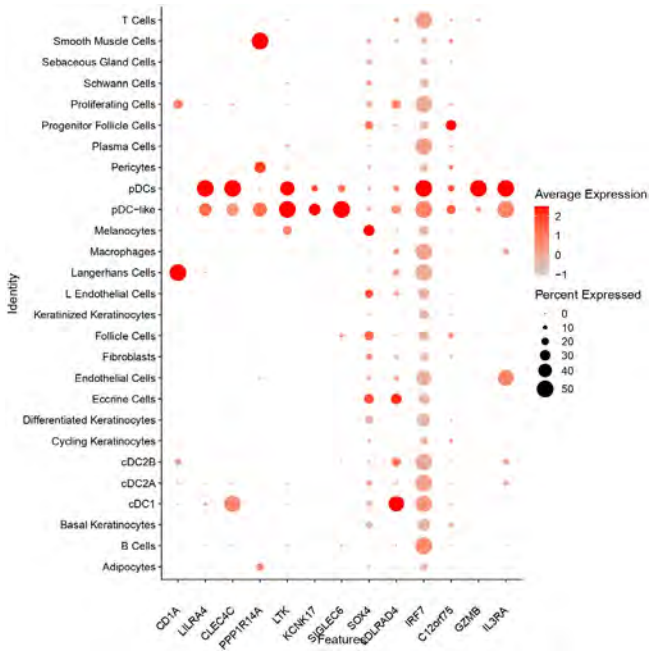

Figure 2: Dot plot showing expression of selected genes across annotated skin and immune cell types. Dot size represents the percentage of cells expressing each gene, while color intensity reflects average expression. pDC and pDC-like populations show enriched expression of LILRA4, CLEC4C, IRF7, and GZMB, consistent with their transcriptional identity.

Conclusion: This study provides new insights into early disease mechanisms in cutaneous lupus and identifies two transcriptionally distinct pDC populations associated with specific cellular niches and immune interactions in the skin, suggesting complex cellular hierarchy in driving inflammation and type I interferon responsesD in CLE.

GATA-3 and IL4 production, absence of mature germinal centers and loss of T cell-dependent B cell maturation. mature germinal centers, and loss of T cell-dependent B cell maturation. Our earlier research revealed elevated SAP levels in lupus and established a link between the proliferation of SAP-expressing T helper cells and lupus nephritis (LN). In this abstract, we reveal the mechanistic role of these SAP+ T cells in driving the inflammatory response associated with LN.

Methods: We enrolled lupus patients who had not previously been analyzed for SAP expression. We performed extra- and intra-cellular immunophenotyping of PBMCs using a CYTEK Aurora 35-color flow cytometry panel. PBMCs were isolated and stored in liquid nitrogen. All samples were analyzed at the same time to minimize batch effect bias. Data was analyzed in GraphPad Prism 8.4.3.

Results: 13 patients with SLE (mean age 36±13, 85% female, median SLEDAI-2K score 6 [IQR 2-7]) and 4 age and gender matched controls (age 35±7, 75% female) were included. Figure 1A shows a higher frequency of SAP+ T cells in SLE patients with a SLEDAI of ≥6 compared to controls (44% vs 27%, Mann-Whitney U test, p=0.042). SAP expression differentiates T cell maturation subsets, especially in CD4+ T cells, where SAP+ cells were more likely to be central and effector memory subsets and less likely to be naïve (Fig. 1C, 2-way ANOVA p< 0.001). Figure 2A (top panel) shows that in CD4 T cells, SAP expression is associated with polarization away from T regulatory (Treg) (CD127^{low}CD25^{hi}) and T follicular helper (TFH) (CXCR5+) lineages and instead associates with increased TH2 differentiation (*CCR4*+CCR6-CD161-CXCR3-). A smaller but still significant increase in TH1 (CCR4-CCR6-CD161-*CXCR3*+) and TH17 (CD161+) subsets was also seen among the SAP+ vs. SAP- CD4 T cells. Figure 2A (bottom panel) shows increased GATA3 transcription factor expression in SAP+ CD4 T cells, further supporting predisposition to TH2 differentiation in these cells. On the other hand, Figure 2B shows that in CD8 T cells, SAP expression is associated with an increase in CCR4-CXCR+ subset and T-Bet transcription factor expression, consistent with a Th1-like CD8 T cell (TC1). Increased HLADR and granzyme B expression in SAP+ CD8 T cells suggests an activated, cytotoxic effector phenotype.

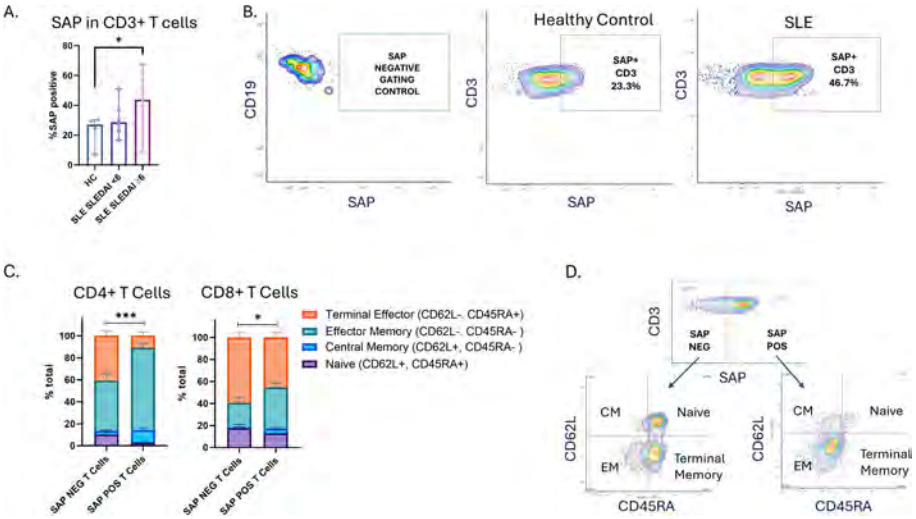

Figure 1. SAP expression is increased in effector T cells isolated from SLE patients. A. PBMCs from 13 patients with SLE (SLEDAI-2K <6 in N=6, SLEDAI-2K≥6 in N=7) and healthy controls (HC, N=4), were analyzed by flow cytometry. The frequency of SAP positive T cells is shown. B) An example of differential SAP expression between a healthy control and a patient with SLE. Gate selection was based on B cells, which do not express SAP. C) T cell maturation subsets were defined by cell surface expression of CD62L and CD45RA. In CD4 T cells (left) and CD8 T cells (right) the association of SAP expression with the distribution of maturation subsets was assessed. The stacked bars represent total population of SAP negative (SAP NEG) vs. SAP positive (SAP POS) cells from 13 patients with SLE, with the proportion of maturation subsets shown as purple (naïve cells), blue (central memory, CM), turquoise (effector memory, EM) and orange (terminal effectors). A 2-way ANOVA was used to compare subset distributions between SAP negative vs. SAP positive cells. (D) An example of T cell subset distribution comparing SAP negative to SAP positive T cells isolated from the same patient.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

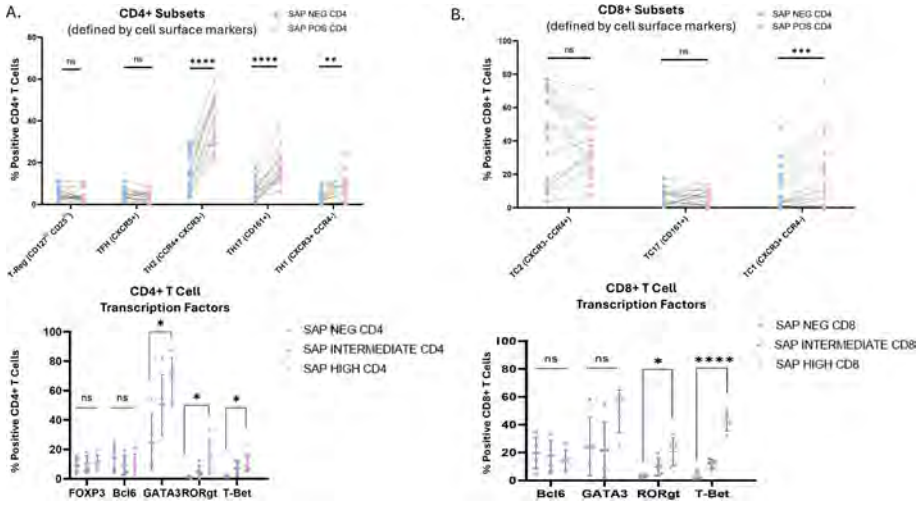

Figure 2. SAP Positive T Cells are polarized towards differentiated TH2, TH1 and TH17 subsets. A. (Top Panel) CD4+ T cell subsets were defined based on cell surface expression markers and further stratified by SAP expression (POS vs. NEG). Every paired line is a unique patient sample. (Bottom Panel) Expression of transcription factors was quantified using intracellular flow cytometry and stratified by SAP expression (negative, intermediate, high). Mean ± S.D is shown. B. (Top and Bottom Panels) CD8+ T cells subsets were defined using the same method as in 2A. A t-test with p-value adjusted using the Benjamini and Hochberg correction for multiple comparisons was used. * p<0.05, ** p<0.01, **** p<0.0001.

Conclusion: T cell SAP levels are elevated in SLE and are linked to disease severity. Mechanistically, we demonstrate that SAP expression correlates with T cell maturation and differentiation into pro-inflammatory effector subsets. This is significant because a better understanding of signaling downstream of SAP activation can reveal novel targetable pathways in SLE pathogenesis.

Background/Purpose: Fatigue is one of the most frequent constitutional symptoms in systemic lupus erythematosus (SLE), usually accompanied with impaired quality of life. Resting-state functional magnetic resonance imaging (rs-fMRI) has emerged as a powerful technique for mapping extensive neural networks in the human brain through blood-oxygen-level-dependent (BOLD) signal. The temporal synchronization between separate brain regions of interest (ROI) can be termed as functional connectivity (FC). Although several altered FCs have been confirmed to be associated with fatigue severity in diseases such as multiple sclerosis and chronic fatigue syndrome, specific FCs associated with fatigue in SLE remain unclear. In this study, we aim to identify the specific FCs linked to fatigue in patients with SLE.

Methods: Totally 16 patients with SLE and 16 healthy controls (HCs) were enrolled in this study. Rs-fMRI data from 32 subjects were acquired. The patients' fatigue severity and psychiatric status were estimated by 11-item Chalder Fatigue Scale and Hospital Anxiety and Depression (HAD) Scale respectively, in addition to Visual Analogue Scale to rate pain (pain-VAS). The scores were collected at the same date of conducting fMRI. Demographic and clinical data were collected from medical records. We used functional connectivity multivariate pattern analysis (fc-MVPA) to identify the clusters distinguishing SLE patients from HCs, adjusted for age and sex. And seed-based connectivity (SBC) analysis was conducted to identify the FCs associated with fatigue severity. Finally, we used simple linear regression to calculate the correlations.

Results: A total of 16 SLE patients (93.75% female; median age: 46.5 years, IQR: 31.75–56.75) and 16 HCs (56.25% female; median age: 41 years, IQR: 33–45.75) were enrolled. In patients with SLE, the median Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) score was 4 (IQR: 2–8), the median prednisolone (PSL) dose was 6.0 mg/day (IQR: 2.875–13.75), and the median Chalder fatigue scale score was 18.5 (IQR:11.25–24). The fatigue severity showed no significant correlation with age (p=0.81), SLEDAI (p=0.3) or PSL dose (p=0.89), while it was positively correlated with HAD scores (p< 0.0001). We identified an alteration of FCs between the MVPA-identifying ROI centering on left superior frontal gyrus and SBC-identifying ROI containing atlas ROIs of left inferior lateral occipital cortex and left temporooccipital middle temporal gyrus. In patients of SLE, the FCs were significantly correlated with fatigue severity (p< 0.0001, R^2=0.80), and separately, correlated with physical symptom scores (p< 0.0001, R^2=0.70) and mental symptom scores (p< 0.0001, R^2=0.75). Besides, these FCs were also significantly correlated with HAD scores (p=0.0006, R^2=0.58). There was no significant correlation between FCs and SLEDAI or pain-VAS scores.

Conclusion: Altered connectivity involving the left inferior lateral occipital cortex and left temporooccipital middle temporal gyrus were associated with fatigue severity, reflecting the influence of anxiety and depression.

Background/Purpose: Systemic sclerosis (SSc) is characterized by peripheral vasculopathy and widespread fibrosis of skin and internal organs. Up to 90% of SSc patients report gastrointestinal (GI) symptoms of varying severity. Small intestinal bacterial overgrowth by quantitative cultures and breath testing have been well described in SSc. However, no studies to date have assessed small intestinal microbial composition in SSc. We aimed to characterize the small bowel microbiome composition and *in vivo* intestinal absorption in SSc patients with and without GI symptom burden.

Methods: SSc patients meeting ACR/EULAR 2013 criteria were prospectively recruited. The UCLA GIT 2.0 questionnaire was used to evaluate GI symptom severity. Non-SSc healthy volunteers (HV) without any GI symptoms matched for age, sex and BMI were used as controls. Upper endoscopies were performed on SSc and healthy volunteers to collect duodenal aspirates, from which DNA was extracted and underwent 16S sequencing. Reads were processed via nf-core AmpliSeq pipeline (v.2.12) and Silva (v138) database for taxonomy assignment. Alpha diversity was calculated using R phyloseq package with beta diversity measured using the R GUniFrac and tested via PERMANOVA. Lactulose and ^{13}C mannitol tracer-based testing was used to evaluate small intestinal (SI) permeability and absorptive capacity, respectively.

Results: 94 SSc participants (79 females; mean age ± SD: 58.0 ± 12.2 years) were enrolled, and a subset of these underwent SI microbiome analysis (n=28) and permeability testing (n=26). The average UCLA GIT 2.0 score for SSc participants was 0.6±0.4, indicating moderate GI disease severity. Compared to healthy volunteers (n=38), there is decrease in α-diversity in SSc (Observed, FDR< 0.001) suggesting decreased species richness and evenness as well as compositional changes in the microbiota structure as described by β-diversity measures (UniFrac FDR< 0.001). On taxonomic analysis, these differences were observed at all phylogenetic levels. Twelve differentially abundant bacterial species were identified (FDR< 0.01), with 9 in greater abundance in SSc patients. Of note, two species of *Fusobacterium* were in greater abundance in SSc, a genus previously identified to correlate with severity of GI symptoms in SSc. Firmicutes, which constitute a major phylum of the duodenal microbiome of healthy populations by providing a homeostatic role and aiding in absorption, were decreased in SSc individuals. SSc participants, compared to HV (n=29), had a lower cumulative 0–2-hour ^{13}C mannitol excretion (6.7±4.6 vs 11.4±3.3 mg, P < 0.001), suggestive of decreased SI absorptive function.

Conclusion: This is the first and only study to our knowledge that has explored the SI microbiome composition in SSc. Impaired SI absorptive capacity coupled with a loss of microbiota diversity was observed in SSc patients. Expansion of pathobionts like *Fusobacterium* and depletion of *Firmicutes* colonizing the SI may contribute to fibrosis and worse GI function. Future work investigating the mechanisms of SI absorptive properties and the specific role of intestinal microbiota will be critical in addressing GI dysfunction in SSc.

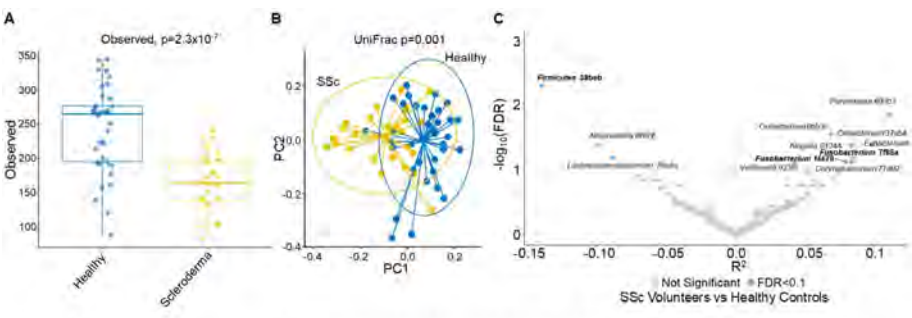

Figure1. Systemic sclerosis patients are characterized by reduced microbial diversity and compositional changes in small intestinal microbiota. A. Observed alpha diversity between healthy and scleroderma (SSc) volunteers (p=2x10^{-7}, Observed, n= 38 healthy, 28 SSc). Observed alpha diversity refers to average species diversity within a single sample, considering the number of different species observed. **B.** PCoA plot of UniFrac β-diversity metric with describes differences in SI microbiota composition between healthy and SSc volunteers. Compositionally, SSc volunteers are distinctly different from healthy participants (p=0.001, UniFrac, PERMANOVA, n= 38 healthy, 28 SSc). **C.** Volcano plot highlighting species level differences between healthy and SSc (n= 38 healthy, 28 SSc). 12 species were differentially abundant between the groups, with 9 in greater abundance in SSc. PC= Principal Coordinate, FDR= False Detection Rate.

Session Title: (1855–1876) Systemic Sclerosis & Related Disorders – Basic Science Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Primary heart involvement (pHI) is one of the leading causes of death in systemic sclerosis (SSc). However, the cellular and molecular pathomechanisms of SSc-pHI are largely unknown (1, 2). Compared with other forms of autoimmune or non-immune-related myocarditis associated with fibrotic remodeling, SSc-myocarditis presents a higher degree of myocardial fibrosis, which is associated with increased mortality (3). Imaging mass cytometry (IMC) is a spatial proteomic technique with cellular resolution. We aimed to characterize the fibroblast populations and their microenvironment in SSc-pHI and compare it to other forms of virus-negative, autoimmune-related myocarditis (aVNM) and isolated VNM (iVNM)) using IMC.

Methods: Endomyocardial biopsies (EMB) were obtained from the right ventricle of ten SSc-pHI-, nine iVNM, and seven aVNM patients. We designed and validated a panel of 40 metal-labeled antibodies for the identification of fibroblast populations and other types of stromal cells, as well as immune cell subsets. Data analysis was performed as described previously (4-7).

Results: We detected a total of 17985 fibroblasts and 6444 immune cells. We identified seven distinct fibroblast populations: PI16^{-}/POSTN^{high}, PI16^{high}/POSTN^{high}, FAP^{high}/POSTN^{+}, TCF21^{+}, CD90^{+}/ADAM12^{+}/FSP1^{+}, and SOX9^{+} fibroblasts,

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

and myofibroblasts. We observed a significant upregulation of SOX9^{+} and CD90^{+}/ADAM12^{+}/FSP1^{+} fibroblasts in SSc-pHI compared with the other forms of myocarditis. PI16^{-}/POSTN^{high} and PI16^{high}/POSTN^{high} fibroblasts were associated with both SSc-pHI and aVNM. The expression of FAP^{high}/POSTN^{+} fibroblasts was increased in aVNM and iVNM, compared with SSc-pHI. CD163^{high}/HLA-DR^{+} macrophages and HLA-DR^{high} monocytes were significantly upregulated in SSc-pHI compared with aVNM and iVNM. Activated helper and cytotoxic T cells and CD20^{+} B cells were less frequent in SSc-pHI than in aVNM. The microenvironment of PI16^{-}/POSTN^{high} fibroblasts was enriched in helper T cells and FAP^{high}/POSTN^{+} fibroblasts, while the PI16^{high}/POSTN^{high} fibroblast niche was enriched in TCF21^{+} fibroblasts, CD163^{+}/HLA-DR^{-} macrophages, HLA-DR^{high} monocytes, and CD20^{+} B cells. The microenvironment of SOX9^{+} fibroblasts was enriched in several subsets of immune cells and FAP^{high}/POSTN^{+} fibroblasts. The SOX9^{+} fibroblast, CD34^{+} stromal cell, and pericyte niches were upregulated in SSc-pHI compared to aVNM and iVNM. We detected two myofibroblast niches, which were enriched in CD163^{high}/HLA-DR^{+} macrophages, or CD90^{+}/ADAM12^{+}/FSP1^{+} fibroblasts and CD68^{+} mast cells, respectively. These cellular changes were associated with profound differences in the cellular interaction network of the fibroblast subsets in SSc-pHI compared to aVNM and iVNM.

Conclusion: We identify seven distinct fibroblast populations in SSc-pHI, as well as profound changes in their frequencies, their microenvironment and cellular interactions compared with other forms of myocarditis. Our findings provide new insights into the pathophysiology of SSc-pHI and may offer a rationale for specific targeting of individual fibroblast populations in cardiac fibrosis.

Background/Purpose: Anti-Melanoma differentiation-associated gene 5-positive dermatomyositis (MDA5-DM) is often complicated by rapidly progressive interstitial lung disease (RP-ILD) and has a poor prognosis. Although there has been one report on this disease mouse model, the role of autoantigen-specific reactivity, especially anti-MDA5 antibody itself, on the pathogenesis of the disease has never been elucidated. In this study, we established a new mouse model of MDA5-DM-ILD and investigated the meanings of autoreactivity to MDA5 in the pathogenesis of the disease.

Methods: C57BL/6J wild-type mice were immunized with complete Freund's adjuvant (CFA) and recombinant human MDA5 protein purified from baculovirus-insect cell system 6 times once a week, and polyinosinic-polycytidylic acid (poly I:C) was administered intratracheally 16 times over a 4-week period, starting from the 3rd week. The production of anti-mouse MDA5 antibodies was confirmed by immunoprecipitation. The area of cell infiltration in lung was quantitatively evaluated using an all-in-one fluorescence microscope (BZ-X810), the cell ratio was evaluated by flow cytometry, and interferon-stimulated gene (ISG) was evaluated by RT-PCR. In addition, we observed whether the lung infiltrating cells were reacted with MDA5 protein and releasing cytokines and granzyme B. After then, CD4(+) T cells and B cells were sorted and co-cultured, and IFN-γ production was confirmed by adding MDA5 protein. Furthermore, anti-human MDA5 monoclonal mouse antibodies were transferred intraperitoneally to C57BL/6J wild-type mice 5 times once a week, and poly I:C was administered intratracheally 16 times over a 4-week period, and the area of cell infiltration in lung tissue was quantitatively evaluated.

Results: We confirmed the production of anti-mouse MDA5 antibodies in immunized mice. The MDA5-immunized/poly I:C mice showed larger cellular infiltration area of the lungs ($p< 0.01$, Figure1) and lower survival ($p< 0.05$) compared to CFA only immunized/poly I:C mice. ISG15 expression in lung tissue was increased. In vitro cytokine releasing assay using MDA5 protein revealed that lung-infiltrating cells of MDA5-immunized/poly I:C mice produced significantly more IFN-γ, IL-15, and granzyme B than control mice ($p< 0.05$, Figure2), which can be observed even after purification of infiltrating B cells and CD4(+) Tcells.

The area of pneumonia in the mice injected with the monoclonal antibody was different from that in the mice injected with normal IgG, with dominant cellular infiltration just below the pleura, which was similar to the initial development of ILD in MDA5-DM patients (Figure3).

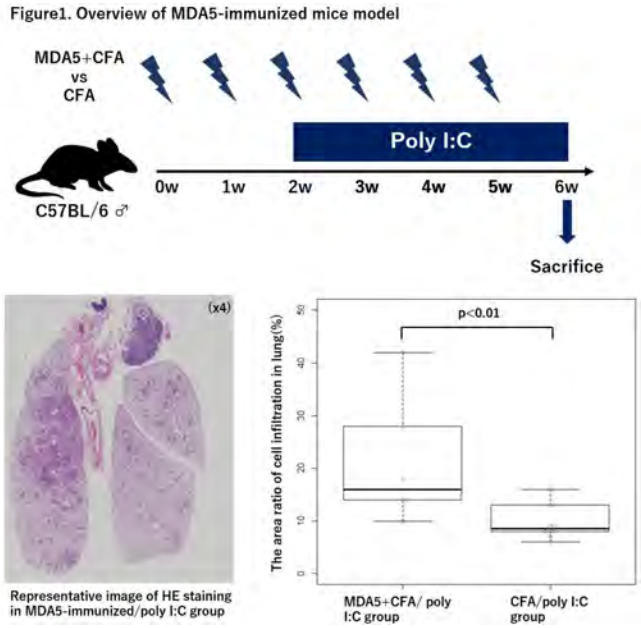

Figure 1. Overview of MDA5-immunized mice model

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. The release of IFN-γ, IL-15, and Granzyme B by lung-infiltrating cells

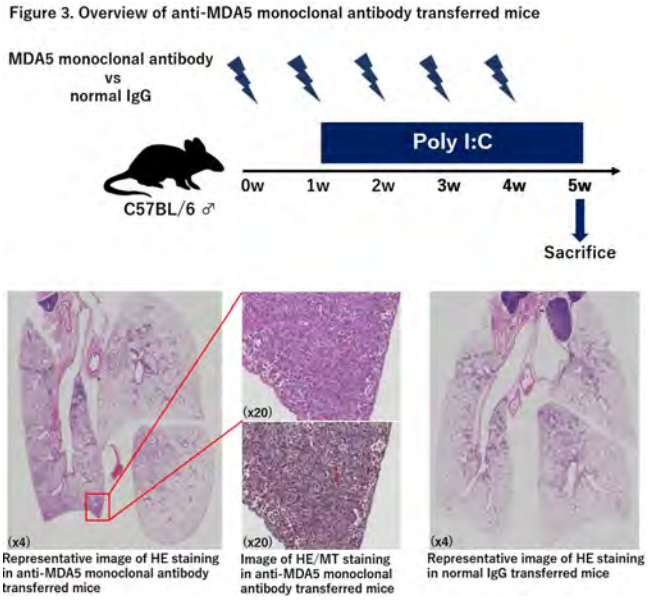

Figure 3. Overview of anti-MDA5 monoclonal antibody transferred mice

Conclusion: Infiltration of MDA5-specific T/B cells in the lungs as well as anti-MDA5 antibody itself may play a pivotal role for lung injury in MDA5-DM.

Session Title: (1855–1876) Systemic Sclerosis & Related Disorders – Basic Science Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Antinuclear autoantibodies (ANA) are robust biomarkers for the diagnosis and prognosis of systemic sclerosis (SSc), but their role in pathogenesis is still uncertain. Recent evidence showed that purified IgG from SSc patients alter the molecular signatures of key effector cells (fibroblasts [FB] and endothelial cells [EC]) in a serotype-dependent manner, and that ANA might interact with intracellular antigens. This study aims to evaluate ANA's ability to penetrate cells, understand the internalization mechanisms and determine intracellular interactions.

Methods: We employed a panel of antibodies (Ab) comprising total purified IgG from anti-topoisomerase I positive (IgG-ATA$^+$) and anti-centromere positive (IgG-ACA$^+$) patients, alongside IgG from healthy controls (IgG-HC). In addition, we utilized polyclonal SSc ATA (poly-ATA, TopoGEN®) and fluorochrome-conjugated poly-ATA antibodies (fluo-poly-ATA). Following a 72-hour culture and 24-hour serum deprivation, FB and EC were incubated with the aforementioned antibodies

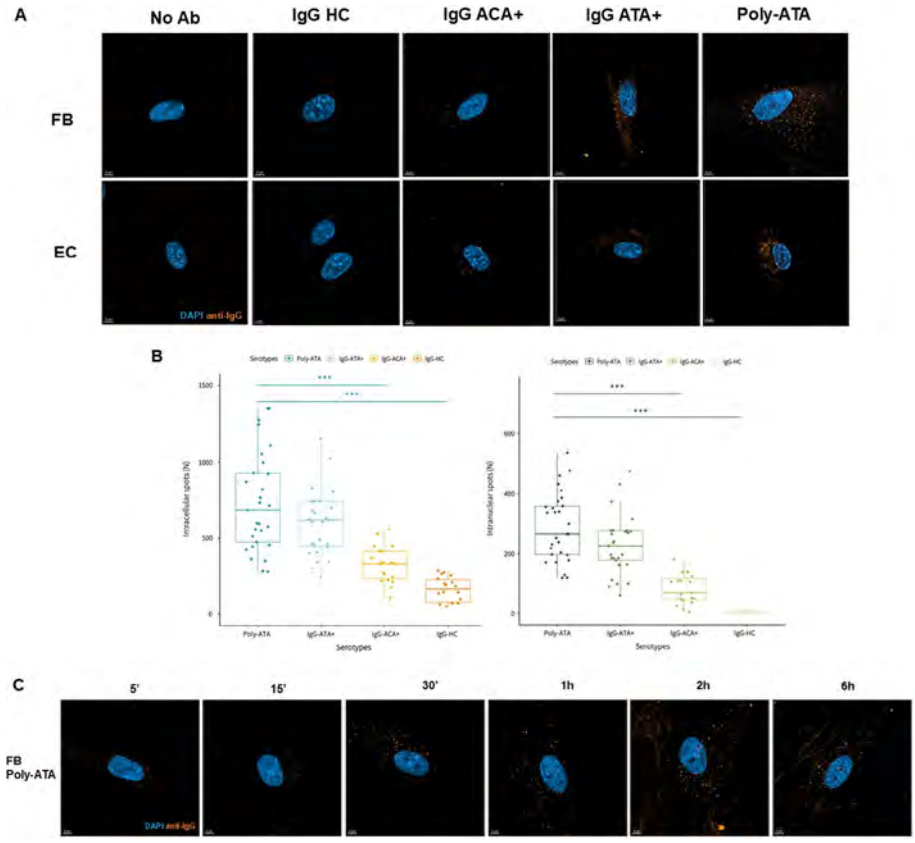

Figure 1. A. Representative image of FB and EC following 1-hour incubation with IgG-HC, IgG-ACA+, IgG-ATA+ and poly-ATA (number of patients for each total IgG condition=5). B. Quantification of fluorescently labeled antibodies in FB and EC following 1-hour incubation with distinct IgG serotypes. Ab spot counts were quantified using Imaris in both cytoplasmic and nuclear compartments. A total of 30 cells per condition were analyzed across two to three independent experiments, depending on the serotype. Data are presented as median ± interquartile range (IQR). Statistical significance was assessed using the Kruskal–Wallis test followed by Dunn's post hoc test; ***$p < 0.001$. C. Kinetic of fluorescence patterns in FB incubated with poly-ATA for durations ranging from 5 minutes to 6 hours.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

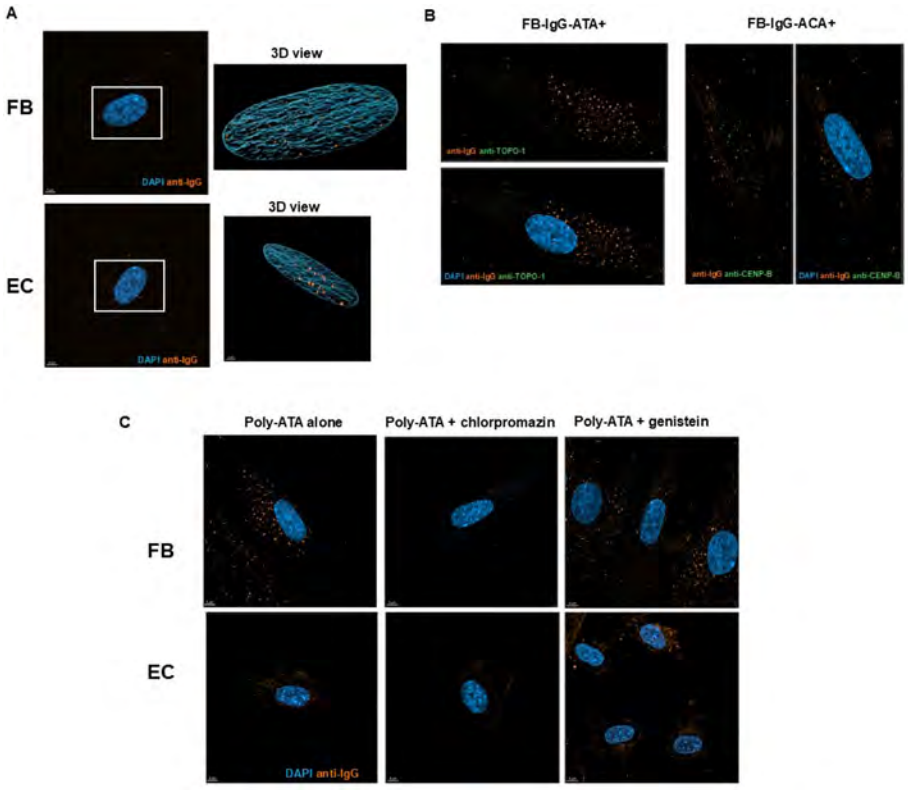

Figure 2. A. Three-dimensional FB and EC incubated 1 hour with poly-ATA generated from Z-stack confocal imaging (0.2 μm optical sections). B. FB topoisomerase-I protein co-staining after 1-hour incubation of IgG-ATA+ and FB CENP-B protein co-staining after 1-hour incubation of IgG-ACA+. C. FB and EC after 1 hour with poly-ATA alone, poly-ATA + clathrin endocytosis pathway blockage pretreatment (chlorpromazine) and poly-ATA + caveolin endocytosis pathway blockage pretreatment (genistein).

for 5 minutes to 6 hours. For fixed-cell imaging, cells were washed post-incubation, fixed, permeabilized, and stained using anti-human IgG antibodies. For live-cell imaging, fluo-poly-ATA was added to the cultures, and time-lapse experiments were performed using confocal microscope. Confocal images were obtained using a LSM 980 Airyscan 2 confocal microscope (Zeiss) and analyzed with Imaris 10.2 software (Oxford Instruments).

Results: Following 1-hour of Ab incubation, intracellular fluorescent spots were detected in cytoplasmic and nuclear compartments of FB and EC exposed to total IgG from SSc patients and poly-ATA. These spots were more numerous in cells treated with IgG-ATA$^+$ and poly-ATA compared to IgG-ACA$^+$. In contrast, while some fluorescence was detected in cells incubated with IgG-HC, nuclear localization was minimal to absent under this condition (**Figure 1A and B**). Using poly-ATA, fluorescent signal appeared as early as 5 minutes post-incubation and increased progressively up to 6h (**Figure 1C**). Live-cell microscopy confirmed the rapid cellular uptake and nuclear penetration of fluo-poly-ATA. To verify nuclear localization of ANA, Z-stack confocal imaging was performed with 0.2 μm optical sections to generate three-dimensional cell reconstructions. These analyses confirmed nuclear localization of poly-ATA and fluo-poly-ATA both in FB and EC (**-Figure 2A**). Co-immunostaining with topoisomerase-1 revealed 28% and 31% colocalization with IgG-ATA$^+$ and poly-ATA, respectively, while CENP-B protein exhibited 22% colocalization with IgG-ACA$^+$ (**Figure 2B**). To investigate the mechanism of internalization, endocytic pathway inhibition assays were conducted. Pretreatment of FB with a clathrin-mediated endocytosis inhibitor significantly reduced intracellular fluorescence, whereas caveolin pathway inhibitor had no observable effect (**Figure 2C**).

Conclusion: SSc ANA can penetrate cells and reach their target antigen *in vitro*. A clathrin-mediated endocytosis mechanism for ANA internalization is suggested. Further mechanistic and *in vivo* studies are needed to assess ANA pathogenicity in SSc.

Unraveling Disparities in Systemic Lupus Erythematosus-Related Mortality Among U.S. Adults (≥25 Years) with Malignancy: A Longitudinal Analysis of Gender, Race, and Geographic Inequities Using CDC WONDER (1999–2020)"

Asma Chaudhary[1], Aizaz Anwar Khalid[2] and **Ayesha Khan**[3], [1]Fazaia Medical College, Islamabad, Pakistan, [2]peshawar medical college, Pesahwar, North-West Frontier, Pakistan, [3]Dow medical college, Karachi, Pakistan

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1855–1876) Systemic Sclerosis & Related Disorders – Basic Science Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease that increases vulnerability to malignancy and premature mortality. Understanding long-term trends and disparities in SLE-related cancer deaths is essential for guiding equitable public health strategies.

Methods: A retrospective population-based analysis was performed utilizing the Centers for Disease Control and Prevention Wide-Ranging Online Data for Epidemiologic Research (CDC WONDER) database. Age-adjusted mortality rates (AAMR) per 1,000,000 individuals were extracted and calculated the annual percentage change (APC) through Joinpoint regression The data were stratified to evaluate temporal trends and disparities based on sex, race, and geographic region in systemic lupus erythematosus (SLE)-related cancer mortality among adults.

Results: From 1999 to 2020, a total of 2,642 cancer-related deaths among adults aged ≥25 years with SLE were recorded in the United States. The overall AAMR for SLE-associated cancer mortality rose from 0.58 [95% CI: 0.46–0.69] in 1999 to 0.69 [95% CI: 0.59–0.79] in 2020. A period of stability was observed between 1999 and 2016 (APC: -1.00; 95% CI: -2.09–0.09; p=0.07), followed by a significant increase from 2016 to 2020 (APC: 10.71; 95% CI: 1.91–20.27; p=0.02). Sex-based disparities were evident, with females exhibiting a markedly higher AAMR [0.83; 95% CI: 0.79–0.87] compared to males [0.22; 95% CI: 0.20–0.24]. Racial disparities were also pronounced, with non-Hispanic (NH) Black or African American individuals experiencing double the AAMR [1.03] of NH White individuals [0.49]. Regionally, the Western United States reported the highest AAMR [0.59; 95% CI: 0.54–0.64], while the Northeast had the lowest [0.43; 95% CI: 0.39–0.47]. Additionally, nonmetropolitan areas demonstrated higher mortality rates [0.59; 95% CI: 0.53–0.64] compared to large metropolitan areas [0.54; 95% CI: 0.52–0.56].

Conclusion: Emerging data highlight a rising trend in SLE-associated cancer mortality, particularly in recent years, alongside marked disparities by sex, race, and geography. These findings underscore the urgent need for tailored, population-level interventions to mitigate inequities and improve outcomes in vulnerable populations.

Abstract Number: 1860

GLUT and FAPα as molecular imaging markers for interstitial lung disease in systemic sclerosis

Bo Broens[1], Conny van der Laken[1], Teodora Radonic[1], Douwe Mulder[2], esther Nossent[1], Yehya Al-Adwi[2], Tji Gan[2], Wim Timens[2], Alexandre Voskuijl[3] and Jan Willem Duitman[1], [1]Amsterdam UMC, Amsterdam, Netherlands, [2]UMCG Groningen, Groningen, Netherlands, [3]Amsterdam University Medical Center, Amsterdam, Netherlands

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1855–1876) Systemic Sclerosis & Related Disorders – Basic Science Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: The clinical management of systemic sclerosis-associated interstitial lung disease (SSc-ILD) is challenging due to its heterogeneous progression. While recent studies have shown that pulmonary uptake of ^{18}F-FDG and ^{68}Ga-FAPI on positron emission tomography (PET) may indicate ILD activity, the spatial distribution of their molecular targets—GLUT1, GLUT3, and FAPα—in SSc-ILD lung tissue is largely unexplored. Here, we investigate the expression patterns of these markers across varying fibrosis stages in lung tissue of SSc-ILD patients and controls to improve PET interpretation.

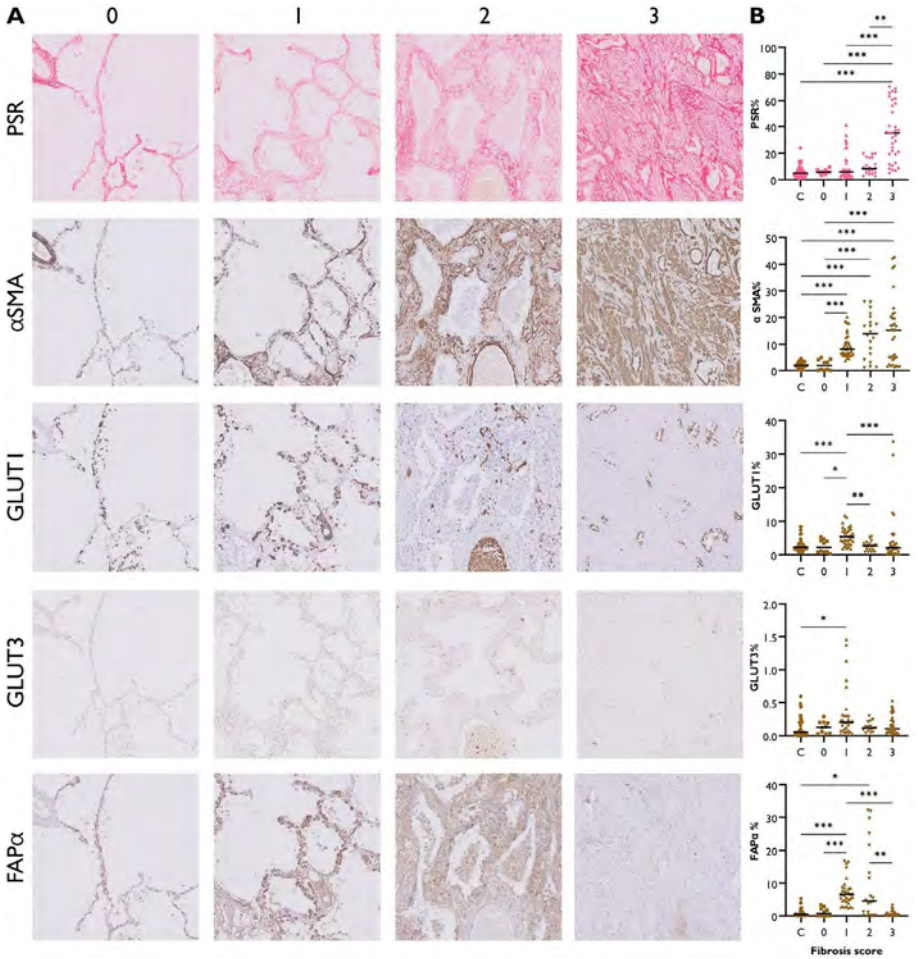

Figure 1. Expression of GLUT1, GLUT3 and FAPα varies between areas with different stages of fibrosis (0-3) in systemic sclerosis-associated interstitial lung disease.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Immunohistochemistry for GLUT1, GLUT3, and FAPα was performed on lung tissue from SSc-ILD patients (n=9) and controls (n=8). Fibrosis stage and cell-type-specific expression of these markers were analyzed by 2 experienced ILD pathologists, and quantitative staining was assessed using QuPath software. Marker expression was analyzed in and compared between areas with varying fibrosis stages.

Results: GLUT1 positive cells were primarily erythrocytes, GLUT3 positive cells were mainly myeloid cells and FAPα positive cells were predominantly fibroblasts, endothelial cells, epithelial cells, and macrophages. All cells positive for these markers were significantly more present in SSc-ILD compared to controls, with GLUT1 and FAPα positive cells showing highest prevalence in areas with early signs of fibrosis (Figure 1).

Conclusion: The prevalence of cells expressing GLUT1 and FAPα is increased in areas with early signs of fibrosis and the expression of GLUT1, GLUT3 and FAPα is observed in different cell types suggesting that ^{18}F-FDG and ^{68}Ga-FAPI PET each may be useful to visualize different aspects of ILD activity.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1855–1876) Systemic Sclerosis & Related Disorders – Basic Science Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune disease characterized by widespread fibrosis, vasculopathy, autoantibody presence, and high mortality in its diffuse subtype with limited effective therapies. Genome-wide association studies (GWAS) have identified candidate genes that contribute to SSc development, but do not fully explain the drivers of heterogeneity between subtypes. Preliminary evidence suggests somatic (acquired) mutations contribute to SSc, and that there is elevated age-related clonal hematopoiesis (ARCH) variant burden in SSc versus healthy individuals. We hypothesized that immune dysregulation of ARCH contributes to the pathogenesis of the increased inflammatory phenotype of diffuse SSc.

Methods: Our cohort consists of limited cutaneous SSc (lcSSc) (n = 1611, mean = 55.9 ± 13 years, non-White = 6.82%, Female = 90.2%), diffuse cutaneous SSc (dcSSc) (n = 1240, mean = 50.47±13 years, non-White = 18.1%, Female =

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

82.3%), and healthy control (HC) (n= 984, mean = 46.7 ± 15.4 years, non-White = 5.7%, Female = 54.9%) whole blood exome sequences (WES) (median depth = 39X). We performed somatic variant calling with Mutect2 and a panel of normals generated from a subset of our HC sequences. We filtered germline and technical artifacts and annotated variants with ANNOVAR. We adhered to best practices of sequence-based filtering (DP >20, minAD ≥ 3, F2R1 ≥ 1, variant allele fraction (VAF) > 2%) and curated ARCH variants for all samples against a list of 74 CH driver genes. Logistic regression and Fisher's exact test were used to compare CH between sample groups and clinical features when suitable and linear regression was used for inspection of CH rate increases.

Results: We observe a significantly higher likelihood of ARCH in dcSSc compared to lcSSc after adjusting for age and sex, with confirmation in the UK Biobank (n=454,787). Additionally, the rate of CH with age rises faster in dcSSc than lcSSc or HC (R^2 values = 0.86, 0.65, 0.85 respectively). The most frequently mutated genes are *DNMT3A*, *TET2*, and *ASXL1* and the median VAF of all ARCH variants is 12.3%. *PPM1D* variants are elevated in dcSSc and occur in younger patients (n= 7, mean = 55.3 years) compared to lcSSc (n= 2, mean = 76.0 years). *PPM1D* variants are also associated with shorter disease duration in dcSSc patients (mean = 4.12 years, total mean of dcSSc ARCH variants = 9.17 years). We observe modest odds of anti-RNA polymerase III autoantibody presence and ARCH in dcSSc (OR = 1.20), and moderate association between ARCH and an impaired lung function threshold of % predicted diffusing capacity of the lung for carbon monoxide (DLCO) < 40 (p = 0.1, OR = 2.02 adjusted for disease duration). However, larger clone ARCH variants with VAF > 10% confer significant likelihood of having % predicted DLCO < 40 within dcSSc subtype (p = 0.0495, OR = 1.53 adjusted for disease duration).

Conclusion: Higher prevalence of ARCH in dcSSc versus lcSSc and gene-specific patterns of ARCH variant occurrence in dcSSc suggest a biological mechanism driving clonal selection between subtypes and possibly influencing fibrotic progression patterns. Understanding the timing and gene-specific nature of these mutations provides insight into selective pressures underlying SSc subtype heterogeneity.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1855–1876) Systemic Sclerosis & Related Disorders – Basic Science Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: The main causes of death in systemic sclerosis (SSc) are pulmonary complications such as SSc-associated interstitial lung disease (SSc-ILD). SSc-ILD is highly heterogeneous and difficult to manage. Although several studies have proven the crucial role of genetics in SSc susceptibility, especially in the major histocompatibility complex (MHC) region, genetic research focusing on SSc-ILD patients is scarce, with limited sample size and statistical power. Considering this, we aimed to conduct a comprehensive MHC genetic scan in the largest cohort of SSc-ILD to date, encompassing a total of 2,363 SSc-ILD patients, 3,526 SSc patients without ILD, and 15,026 controls from 10 international cohorts of European ancestry.

Methods: After genotypic quality controls, the MHC region was imputed using the human leukocyte antigen (HLA) imputation tool from the Michigan Imputation Server. Variants with imputation quality > 0.3 and minor allele frequency > 0.01 were considered for association analyses. Logistic regressions were performed adjusting for the first five principal components and sex, considering two comparisons: SSc-ILD vs SSc patients without ILD, and SSc-ILD vs controls. Finally, inverse variance weighted meta-analyses were performed. To identify jointly significant variants, conditional stepwise analyses were carried out separately for HLA classical alleles, polymorphic amino acid positions (AAs), and single nucleotide polymorphisms (SNPs).

Results: Results from the meta-analyses identified 2,966 significant variants associated with SSc-ILD when compared to SSc patients without ILD, and 5,610 variants when compared to controls. After conditional analysis, the most significant associations mapped in class II HLA genes, such as *HLA-DQA1*01:01:01:01* (odds ratio [OR] = 0.54 and 95% confidence interval [95%CI] [0.48 – 0.61] p-value = 3.41×10^{-21}) and, interestingly, we also found novel associated variants implicating class I HLA genes as *HLA-B*35:02:01:01* (OR = 2.44 [1.81 – 3.29], p-value = 5.64×10^{-9}), *HLA-C*07:01:01:01* (OR = 1.30 [1.19 – 1.42], p-value = 1.54×10^{-9}), and the serine substitution in position 24 of *HLA-B* (OR = 1.28 [1.18 – 1.39], p-value = 4.44×10^{-9}).

Conclusion: In this study, we identify for the first time class I HLA associated with SSc-ILD. These results emphasize the potential role for $CD8^+$ T cell mediated cytotoxicity in the pathogenesis of this clinical manifestation. Risk variants in class I HLA region may contribute to the unpaired immune response and tissue injury in the lungs, leading to inflammation and fibrosis. These findings could have significant clinical implications, with potential role as progression biomarkers in SSc patients with lung involvement.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1855–1876) Systemic Sclerosis & Related Disorders – Basic Science Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: BAG3 (Bcl2-associated athanogene 3) regulates cellular pathways including apoptosis and autophagy, and induces fibroblast-to-myofibroblast transformation. In systemic sclerosis (SSc), myofibroblasts drive fibrosis of skin and internal organs, with interstitial lung disease (ILD) affecting ~50% of patients and being the leading cause of mortality. Recent evidence shows BAG3 serum levels correlate with nintedanib treatment response in SSc-ILD. This study aimed to investigate the role of BAG3 in SSc pathophysiology using complementary in vitro, ex vivo, and in vivo approaches

Methods: Immunohistochemistry of BAG3 expression was performed on lung tissue from SSc patients (N=3) and healthy controls (N=5). For in vivo studies, pulmonary fibrosis was induced in mice (N=23) using bleomycin, followed by treatment with either vehicle (N=11) or anti-BAG3 mAb (20mg/kg twice weekly, N=12) after 7 days until day 28. Lungs were collected for proteomic analysis using label-free shotgun proteomics following the SP3 protocol, with protein expression analyzed using Proteome Discoverer 2.4 software. Skin-derived fibroblasts of 10 SSc patients and 7 healthy controls (HC) were evaluated for BAG3 expression and its receptor. We tested nintedanib's (50nM) influence on BAG3 release in HC fibroblasts before and after TGFβ stimulation.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Our study revealed a clear pattern of BAG3 dysregulation in SSc. Western blotting demonstrated significantly higher BAG3 expression in SSc skin fibroblasts versus HC, both in whole cell lysates and supernatants (Fig 1A), while flow cytometry showed corresponding upregulation of the BAG3 receptor IFITM-2 in SSc fibroblasts (70% positive cells vs 40% in HC, p=0.0016), with increased mean fluorescence intensity (p=0.007) indicating higher receptor density (Fig 1B). To understand the regulation of this pathway, we assesed that TGF-β1, a key profibrotic cytokine, significantly induced BAG3 expression in HC fibroblasts in a dose-dependent manner (75 pg/ml at 10 ng/ml and 40 pg/ml at 5 ng/ml TGFβ, $p < 0.01$). Importantly, nintedanib treatment effectively suppressed this TGF-β-induced BAG3 expression to near-baseline levels (Fig 2), suggesting a mechanism for its antifibrotic effects. Extending these findings to tissue level, immunohistochemistry confirmed significant BAG3 overexpression in SSc lung specimens compared to controls, particularly in areas with inflammatory infiltrates and fibrotic changes. To establish causality, we employed a bleomycin-induced pulmonary fibrosis model where anti-BAG3 mAb treatment (N=12) markedly reduced fibrotic areas compared to PBS-treated controls (N=11). Proteomic analysis of lung tissue from both experimental groups revealed that BAG3 inhibition downregulated key pathological processes including apoptosis, fibrosis, and inflammation while activating cell survival pathways, providing mechanistic insights into BAG3's role in fibrosis pathogenesis.

Conclusion: This study establishes BAG3 as a central player in SSc-associated fibrosis. These findings identify BAG3 as both a potential therapeutic target and biomarker for monitoring treatment response in SSc-ILD, warranting further investigation in larger cohorts.

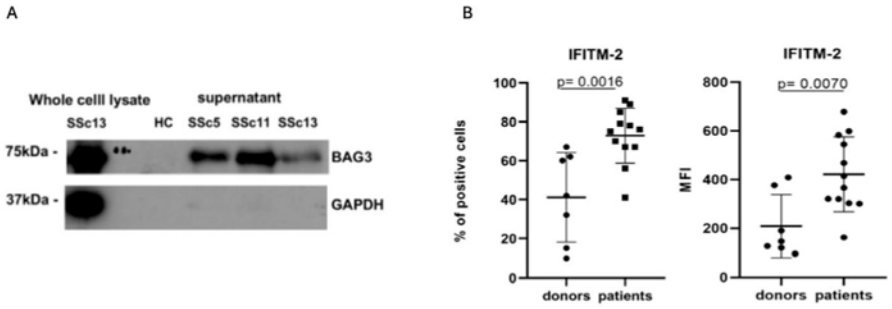

Figure 1. Expression of BAG3 and its receptor IFITM-2 in SSc and healthy control fibroblasts. (A) Western blot analysis showing BAG3 protein expression in whole cell lysates and supernatants from SSc patients (SSc5, SSc11, SSc13) and healthy control (HC) fibroblasts. GAPDH was used as loading control. (B) Flow cytometric analysis of IFITM-2 (BAG3 receptor) expression in SSc patients and healthy donors (HD) fibroblasts. Left panel shows the percentage of IFITM-2-positive cells ; right panel shows mean fluorescence intensity (MFI) of IFITM-2 expression. Data are presented as mean ± SD.

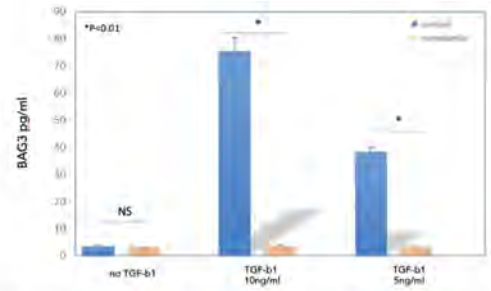

Figure 2. Effect of nintedanib on TGF-β1-induced BAG3 secretion in healthy control fibroblasts. BAG3 levels were measured in supernatants of healthy control fibroblasts treated with TGF-β1 (5 ng/ml and 10 ng/ml) in the presence or absence of nintedanib. Data are presented as mean ± SEM of three independent experiments.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1855–1876) Systemic Sclerosis & Related Disorders – Basic Science Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune disease characterized by type I interferon (IFN-I) production and mitochondrial dysfunction. Emerging evidence suggests that activation of the stimulator of interferon genes (STING) pathway in SSc is triggered by cytosolic mitochondrial DNA (mtDNA) released during mitochondrial stress. This link is further supported by the similarities between SSc and SAVI (STING-associated vasculopathy with onset in infancy) syndrome, a condition caused by a gain-of-function mutation in TMEM173 (which encodes STING) that phenocopies many key features of SSc. Nevertheless, the role of mitochondrial damage in activating cGAS-STING and driving IFN-I production in SSc remains poorly understood.

This study aims to investigate whether mitochondrial dysfunction activates the cGAS-STING pathway and drives IFN-I production and fibrosis in SSc.

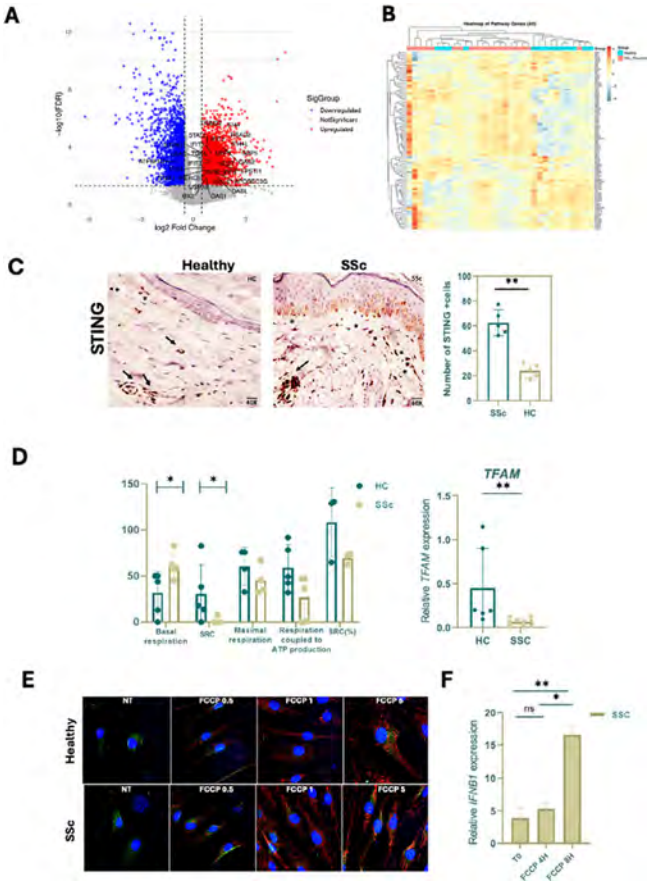
Methods: Transcriptomic analysis was performed on RNA-seq data (GSE231692, FaSScinate trial) to assess mitochondrial, cGAS-STING, and interferon-related gene expression. Skin biopsies from SSc patients and healthy controls (n=10 per group) were analyzed by RT-PCR and immunohistochemistry (IHC) for cGAS, STING, IRF3, and IFN-I. Mitochondrial dysfunction was evaluated through TFAM and MTND1 expression, Seahorse metabolic profiling, and ATP quantification in fibroblasts. To examine STING activation, fibroblasts were treated with the mitochondrial uncoupler FCCP, followed by confocal microscopy and IFNB1 quantification. In vivo relevance was tested in bleomycin-induced fibrosis (BIF) mice, with or without treatment with the selective STING inhibitor H-151.

Results: SSc skin exhibited upregulation of STING1, cGAS, TBK1, IFI16, and STAT1 compared to controls, with overexpression of STING, cGAS, and IFNB1 confirmed by RT-PCR ($p < 0.01$) and IHC. Mitochondrial dysfunction was evident in SSc fibroblasts, with significantly reduced TFAM expression ($p < 0.01$), impaired oxidative phosphorylation, decreased ATP levels, and increased glycolytic activity. FCCP-induced mitochondrial stress promoted STING nuclear translocation and IFNB1 induction, more pronounced in SSc than in control fibroblasts supporting the idea of a direct link between

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

mitochondrial dysfunction, STING activation, and IFNβ production. Bleomycin-treated mouse models mirrored these findings, with STING-related genes (Irf3, Tmem173) being upregulated, and antioxidant defenses (Sod1, Prdx3) diminished. Treatment with H-151 significantly reduced dermal thickness and collagen deposition, underscoring the role of STING in fibrosis and the possible therapeutic potential of targeting the STING pathway in SSc.

Conclusion: Mitochondrial dysfunction in SSc promotes activation of the cGAS-STING pathway and IFN-I production, contributing to fibrotic remodeling. Pharmacologic inhibition of STING attenuates skin fibrosis in vivo, supporting STING as a novel therapeutic target in systemic sclerosis.



A. Volcano plot illustrating upregulated and downregulated gene in RNAseq of SSc skin vs HCs. B. Heatmap of the expression of mitochondrial, cGAS-STING and Interferon-associated genes across SSc vs HCs skin. C. Representative immunohistochemistry image of skin tissue showing overexpression of Sting in SSc compared to HC. D. On the left, mitostress analysis showing increased mean basal respiration and reduced spare respiratory capacity (SRC) of five control and five paired lesional SSc fibroblast cultures; on the right, rtPCR result showing TFAM downregulation in SSc skin compared to HC. E. Representative immunofluorescence image showing nuclear Sting translocation at 1 and 5 umol FCCP concentration compared to HC. F. The graph shows significant upregulation of Interferon Beta 1 gene in scleroderma fibroblasts 4 and 8 hours after FCCP stimulation, linking mitochondrial damage to interferon induction."Error bars indicate standard deviation. Asterisks denote statistically significant differences (*P<0.05; **P<0.005).

Background/Purpose: Antinuclear antibodies (ANA) are detected in over 95% of systemic sclerosis (SSc) patients. Compared to cutaneous subtype classification, autoantibody-based stratification more accurately predicts survival, disease progression, and organ involvement. The distinct clinical features associated with each SSc-specific autoantibody suggest underlying molecular phenotypic differences. Recent studies have revealed distinct

molecular signatures between SSc patients with anti-centromere (ACA) and anti-topoisomerase antibodies (ATA). However, the molecular features of those less frequent autoantibody groups have not been studied.

Methods: This study aims to investigate the shared and unique molecular signatures among SSc patients with different SSc-associated autoantibody group (ACA, ATA, anti-RNA polymerase III antibodies (ARA), anti-U3RNP, anti-U1RNP, anti-Th/To, and anti-Ku antibodies) through a multi-omics analysis including plasma proteomics, PBMC transcriptomics, and immune cell phenotyping.

Results: 166 Asian SSc patients were included in this study and grouped by different SSc-associated antibody status: 55 patients with ACA, 58 with ATA, 24 with ARA, 12 with anti-U1RNP, 8 with anti-U3RNP, 4 with anti-Ku, and 5 with anti-Th/To antibodies. Plasma proteomic profiling identified 1,159 proteins, with 846 remaining after stringent filtering. Differential expression analysis revealed 86 consistently upregulated proteins across all antibody subgroups compared to healthy controls (HCs). These proteins were closely associated with endothelial injury, cell-cell adhesion, extracellular matrix deposition, and growth factor binding, reflecting shared pathogenic mechanisms in SSc. Gene Set Enrichment Analysis (GSEA) further identified antibody-specific pathway activation patterns, correlating with distinct clinical manifestations, including calcinosis, renal involvement, cancer, myopathy, and cardiomyopathy. PBMC RNA-seq analysis demonstrated that common upregulated pathways across autoantibody groups (vs. HCs) were associated with immune activation, the ubiquitin-proteasome system, and cytoskeletal regulation. Additionally, GSEA highlighted unique metabolic and immune activation pathways that varied among autoantibody subgroups. Immune cell phenotyping revealed broadly consistent alterations across SSc subgroups, including increased neutrophils and monocytes, decreased lymphocytes and regulatory B (Breg) cells, and elevated activated T cells. However, the magnitude of these changes differed significantly among autoantibody-defined subgroups, indicating heterogeneous immune dysregulation in SSc.

Conclusion: This study provides the first multi-omics characterization of both common and rare SSc-associated autoantibody groups, revealing shared and distinct molecular signatures that correlate with clinical features. Our findings highlight the potential for autoantibody-based stratification to guide precision management of SSc. Future studies should validate these molecular profiles in larger cohorts and explore their therapeutic implications, paving the way for biomarker-driven approaches in SSc care.

Background/Purpose: Gastrointestinal (GI) involvement in systemic sclerosis (SSc) affects over 90% of patients and represents a large clinical burden and unmet need. Unlike the skin and lung, GI disease does not respond to immunosuppression and generally worsens with time despite treatment. Postmortem studies describe smooth muscle atrophy, fibrosis, and increased immune cells within the wall of the GI tract, but the cellular pathogenesis remains poorly understood. Here we investigate the single-cell composition of biopsies taken from SSc patients, particularly fibroblast subsets which may contribute to disease pathogenesis.

Methods: Gastric biopsies were obtained from four SSc patients, and four healthy controls (HC). Single-cell RNA sequencing (scRNAseq) was performed on whole biopsies using 10X Genomics Chromium workflow. Data were analysed using scanpy, scvi-tools, pertpy and pydeseq2.

Results: After filtering we analyzed 30,872 cells. There was a significant expansion of T cells proportions in SSc compared to HC, and a significant reduction in fibroblast, plasma cell, and epithelial cell cluster frequencies (FDR < 0.2) (Figure 1).

Within the stomal cell compartment, we identified several fibroblast clusters with similar gene expression to skin fibroblast subsets. Myofibroblasts and pericytes showed a trend to increased abundance in SSc compared to HC. Fibroblasts with similar gene expression to mesenchymal fibroblasts were most abundant across all samples, with no difference between SSc and HC. There was a significant reduction of *SFRP1*+ *CXCL12*+ and *EGR1*+ *POSTN*+ fibroblasts (FDR< 0.05) in SSc compared to HC. These have similar gene expression to secretory/papillary fibroblasts and proinflammatory skin fibroblasts. Pseudobulk differential gene expression analysis (Figure 2) across all fibroblasts revealed downregulation of *KLF2*, *TNFSF10*, and *C3*, whilst *AREG, STC1*, and *FAM155A* were upregulated in SSc compared to HC.

Gene Set Enrichment analysis between SSc and HC of each fibroblast cluster (using Reactome and Hallmark pathways) revealed upregulation of the mTOR pathway in the mesenchymal-like fibroblasts in SSc. Within the EGR1+POSTN+ fibroblasts there was significant downregulation of interferon signalling and complement cascade pathways in SSc compared to HC (FDR < 0.05).

There was significant expansion of CD8 T cells in SSc compared to HC (FDR< 0.05), with reduction in IgA plasma cells, SELL + CD4 cells, and memory B cells (FDR< 0.2) (Figure 3).

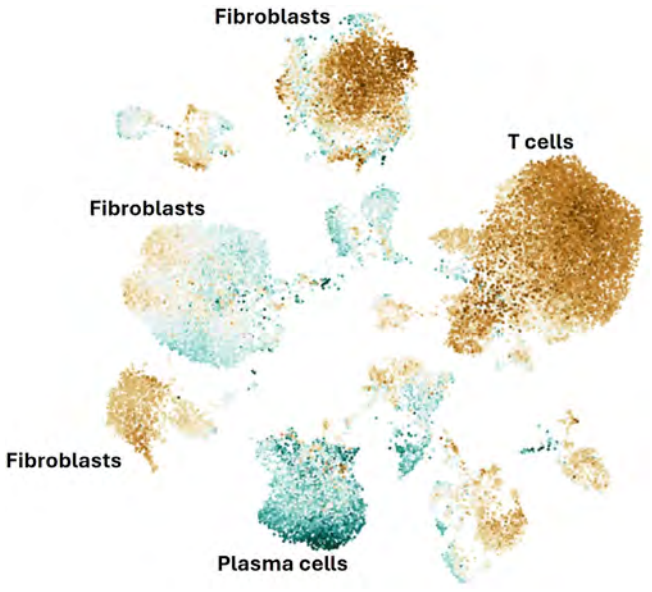

Figure 1: UMAP displaying differential abundance of all cells in the stomach, highlighting increased T cells, reduced plasma cells and perturbed fibroblast populations (Brown = increased, blue = reduced)

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

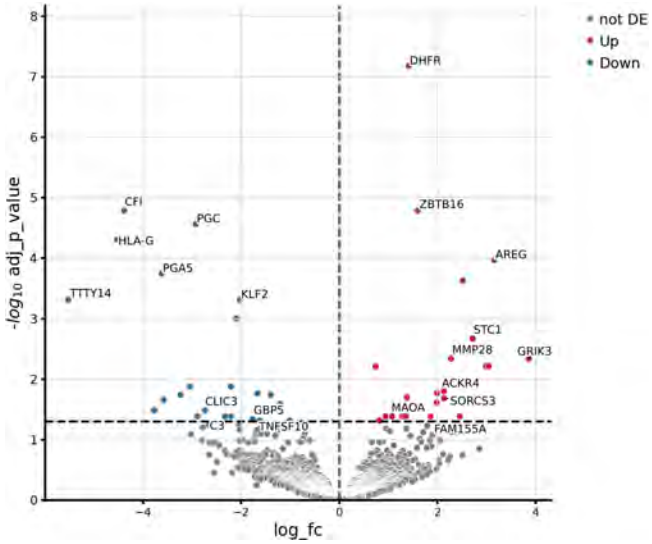

Figure 2: Pseudobulk analysis of differential gene expression across the whole fibroblast compartment, comparing differentially expressed genes between SSc and HC

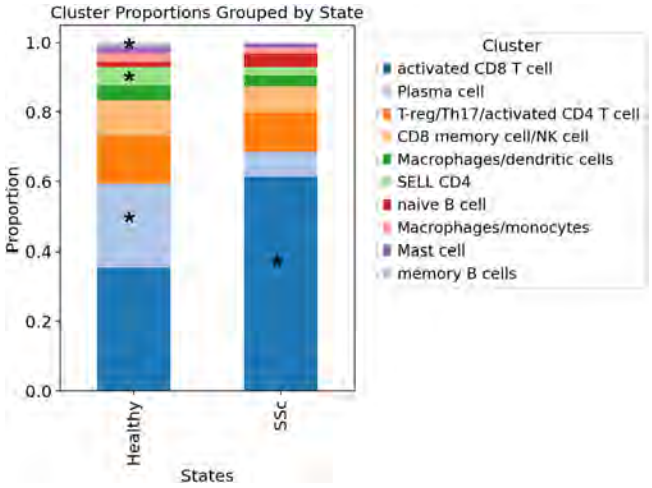

Figure 3: differential abundance within the immune cell compartment comparing SSc and HC. Activated CD8 T cells, plasma cells, SELL+CD4 T Cells and memory B cells all showed significant difference between SSc and HC (indicated by *).

Conclusion: Utilising scRNAseq on gastric tissue biopsies, we have identifed marked differences in immune cells, including increased abundance of cytotoxic CD8 T cells, and reduction in plasma cells in SSc compared to HC. Within the stromal compartment, there was a proportional increase in pericytes and myofibroblasts. Fibroblast gene expression analysis confirmed similarities to SSc skin (e.g. downregulation of KLF2), but also some notable differences including reduction in PTGDS, TNFSF10 and C3, and Interferon signaling. These represent a distinct population of gastric fibroblasts not present in SSc skin. Our findings may help to explain differences in natural history and treatment response between gut and other organs in SSc.

Session Title: (1855–1876) Systemic Sclerosis & Related Disorders – Basic Science Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: SSc frequently results in serious gastrointestinal (GI) complications that contribute to increased morbidity and mortality. Understanding the molecular changes across different disease stages is crucial for elucidating the pathophysiology. Our study employs high-definition spatial transcriptomics to decipher the molecular and cellular landscape of the GI, assessing distinct alterations in the lamina propria associated with early and late disease stages.

Methods: We studied gastroduodenal biopsies from SSc patients enrolled in the ReSScue trial (n=10, 2013 ACR/EULAR classification criteria). Patients presented moderate to severe lower GI symptoms assessed by the UCLA GIT score. Formalin-fixed paraffin-embedded (FFPE) samples were processed for spatial transcriptomics using the Visium HD Spatial Gene Expression Reagent kit v1. Libraries were sequenced on the Illumina NovaSeq X platform and alignment was performed with Space Ranger 3.1.3. The data was analyzed using the packages *Seurat* v5 and *Banksy* for cell typing. *Speckle* was used for compositional analysis between SSc patients with early (symptom onset < 3.5 years) and late stage disease (symptom onset > 13.5 years). Differentially expressed genes (DEG) were identified between early and late patients using *MAST* (adjusted p-value < 0.05, |log2 FC| ≥ 0.2) and the *clusterProfiler* package was used for pathway over-representation analysis (ORA) and gene set enrichment analysis (GSEA) with the Gene Ontology (GO) database.

	All	Early SSc	Late SSc	p-value
	n = 10	*n* = 5 (50%)	*n* = 5 (50%)	
Age, mean years (SD)	59.4 (9.3)	56 (5.3)	63 (2.4)	0.3

Fig. 1: Characteristics and clinical data for SSc patients with early and late disease. mRSS = modified Rodnan skin score, ILD = Interstitial lung disease. * symptoms assessed by the UCLA GIT score.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: We included 5 SSc patients with early and 5 with late stage, with mean disease durations of 1.9 years and 18.6 years, respectively. The two groups did not differ in other clinical parameters (Fig. 1). Six tissue domains were annotated: Epithelium (villi), crypts, lamina propria, Brunner's glands, muscularis mucosae and isolated lymphoid follicles (ILF; Fig. 2A-B). Compositional analysis between early and late disease showed no significant differences in the tissue regions (Fig. 2C). DEG of the lamina propria revealed 61 significantly upregulated genes and 2,355 significantly downregulated genes in early compared to late disease (Fig. 3A). ORA showed upregulated pathways related to pathogen defense (*GBP3*, *GBP5*, *LYZ*, *CHGA*) in early compared to late disease (Fig. 3B). In contrast, several pathways associated with extracellular matrix (ECM) organization, including *ADAM19* and various collagen types, were significantly downregulated in early compared to late disease (Fig. 3C). Also, both ORA and GSEA showed downregulation in early SSc of immune response pathways, including JAK-STAT signaling and interferon responses (e.g., *JAK1*, *STAT2*, *IRF8*, *IRF4*), and pathways related to actin cytoskeleton organization and angiogenesis (e.g. *CAPZA2*, *GSN*, *VEGFA*, *VEGFB*; Fig. 3C).

Conclusion: This is a first report investigating the molecular landscape in GI tissue of SSc patients using high-definition spatial transcriptomics across different disease stages. Our findings could allude to the importance of exogenous agents in early disease stages, with an upregulation of pathogen defense pathways in early SSc. In addition, our results show an upregulation of fibrosis pathways and ongoing inflammatory processes in late SSc.

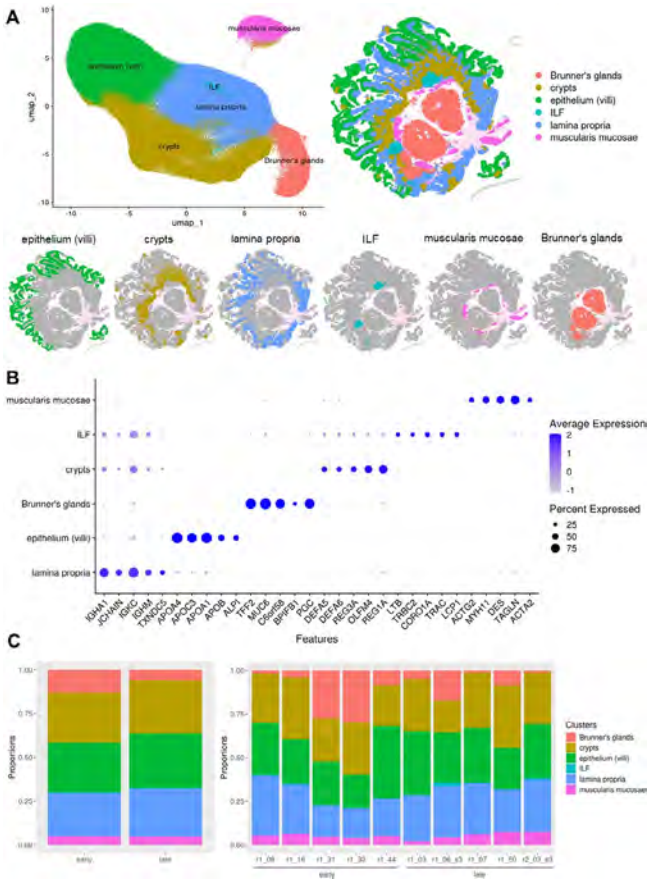

Fig. 2: Spatial transcriptomic analysis reveals 6 distinct tissue regions in the duodenum of SSc patients. A) UMAP of all 10 samples (908,423 8x8µm bins) and representative spatial plots of 1 sample show 6 distinct tissue regions. B) A dotplot of the 6 identified tissue regions shows the top 5 expressed marker genes in each cluster, which were used for manual annotation. C) Compositional analysis shows no significant differences in the proportions of the tissue regions between early and late SSc patients.

Abstract Number: 1868

Global Downregulation of Fli1 in Mice Induces Cardiac Dysfunction via Enhanced β-fatty acid Oxidation and Collagen Deposition

Knowledge Mudhibadhi Moyo[1], Fatima-Ezzahrae El Adili[2], Maria Trojanowska[1] and Andreea Bujor[1], [1]Boston University, Boston, MA, [2]Boston University School of Medicine, Revere, MA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1855–1876) Systemic Sclerosis & Related Disorders – Basic Science Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Primary cardiac involvement is a common complication of Systemic sclerosis (SSc), characterized by fibrosis and diastolic dysfunction, presumably due to microvascular dysfunction and repeated ischemia reperfusion injury. Downregulation of transcription factor Fli1 in SSc contributes to vasculopathy and skin fibrosis, but its potential role in cardiac disease is unclear. Using mice with heterozygous deletion of Fli1 (*Fli1*$^{+/-}$), we aim to uncover the effects of Fli1 downregulation on cardiac dysfunction in SSc through cardiac phenotypic studies and single-cell analyses.

Methods: Cardiac function was evaluated at 10-12 weeks in wild type and *Fli1*$^{+/-}$ mice using echocardiography. Sirius red staining followed by Image J analysis was used to assess cardiac collagen content. Cardiac apex tissue underwent mechanical and enzymatic dissociation for single-nuclei isolation using the 10X Genomics Nuclei Isolation Kit. The nuclei were barcoded using the 10X Chromium Single-Cell Platform, followed by cDNA library preparation. FASTQ files were generated and analyzed using BioTuring Single-Cell Analysis Software to identify distinct cellular clusters and transcriptional changes.

Results: *Fli1*$^{+/-}$ mice exhibited diastolic dysfunction, with elevated *E/e'* and prolonged isovolumic relaxation time, as well as reduced systolic function indicated by decreased ejection fraction and fractional shortening (Fig. 1A). Sirius red staining confirmed increased collagen deposition in *Fli1*$^{+/-}$ hearts (Fig. 1B). Single-cell transcriptomic analysis identified 13 major cell types (Figure 2A). Cardiomyocyte cluster analysis revealed a transcriptional shift, with appearance of a novel, mutant specific cluster, and loss of a wild type cluster (Figure 2B). Differential gene expression analysis between these two

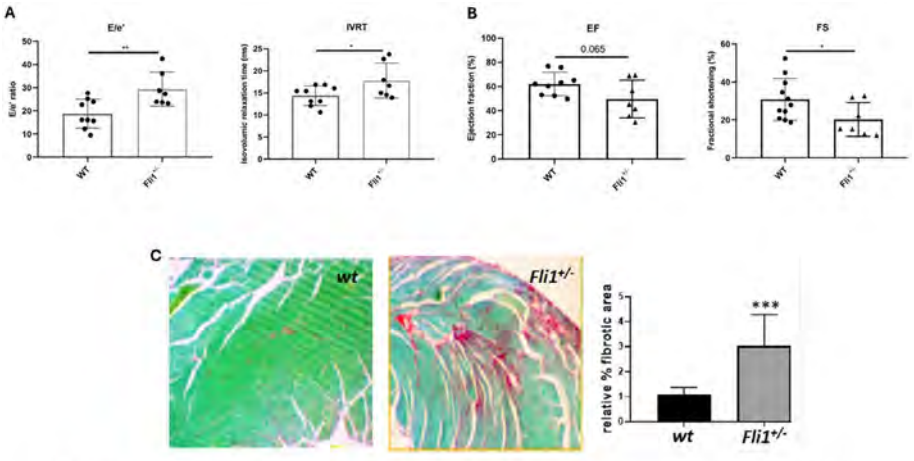

Figure 1. Fli1 downregulation resulted in diastolic and systolic dysfunction, and increased collagen accumulation in cardiac tissue

Fli1 downregulation resulted in diastolic and systolic dysfunction, and increased collagen accumulation in cardiac tissue

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. UMAP of cardiac tissue cells, upregulated pathways and differentially expressed genes in cardiomyocytes, fibroblasts and macrophages.

UMAP of cardiac tissue cells, upregulated pathways and differentially expressed genes in cardiomyocytes, fibroblasts and macrophages

clusters revealed several upregulated genes including *PDK4 (log2FC=3.3 FDR=1.36e-23)*, and *ANGPTL (log2FC=2.18 FDR=7.54 e-64)*. Analysis of the enriched pathways revealed upregulation of β-fatty acid oxidation in Fli1$^{+/-}$ cardiomyocytes (2.78e-15), a metabolic shift previously linked to impaired cardiomyocyte proliferation following ischemia-reperfusion injury. Additionally, macrophages from *Fli1*$^{+/-}$ mice showed increased expression of *PLA2G7*, a gene linked to inflammatory remodeling and fatty acid metabolism in cardiac macrophages. Supporting a role in cardiac fibrosis, *Fli1+/-* fibroblasts displayed elevated expression of fibrosis related genes including *LOX, COL20A1, TGFBR3L, CCN2, SERPINE1, LOXL2, NOX4*, and *IL6RA*.

Conclusion: Fli1 haploinsufficiency drives cardiac dysfunction and fibrosis via metabolic reprogramming in cardiomyocytes and macrophages with enhanced fatty acid oxidation and profibrotic activation of fibroblasts through TGF-β/LOX pathways. This suggest that Fli1 deficiency may be a contributor to primary cardiac involvement in SSc.

Abstract Number: 1869

A Mirna Signature Consisting of High let7i-5p, High mir-483-5p, Low mir-223- 3p Characterizes Connective Tissue Diseases with Interstitial Lung Disease

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1855–1876) Systemic Sclerosis & Related Disorders – Basic Science Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with interstitial lung disease associated to a connective tissue disease (CTD-ILD) are a heterogeneous population both concerning mechanisms and trajectories. In an RNA Seq approach we have previously identified differentially expressed miRNA in patients with CTD-ILD. The current study was conducted to confirm the association of 7 miRNA with CTD-ILD and with disease subgroups.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: The selected miRNA were analysed with qPCR techniques. The study population comprised 110 patients (89% women) and 10 healthy controls (90% women) from the NEREA register of CTD-ILD. Demographics and process-related data were extracted from RedCap files where the register is hosted. Results are shown as mean (SEM) or n (%). Associations were assessed with cross-sectional variables and with 18 month follow-up outcomes. Functional deterioration was defined by a 10% fall in forced vital capacity (FVC). Statistics were done with t test and Spearman's correlation. Target prediction analysis was carried out with miRPath v4.0 tools.

Results: Age was 64.9 (1.1) in the CTD-ILD group and 62.1 (1.2) yrs in healthy controls (ns). Process related variables are shown at the **Table**. At baseline, disease duration was 4.1 (0.5) yrs. Survival at endpoints was 91%, while functional decline was observed in 24%.

As compared to healthy controls, patients with CTD-ILD were identified by higher **Let7i-5p** (p 0.001) and **miR-483-5p** (p 0.018), accompanied by lower **miR-223-3p** (p 0.025).

Within the patient cohort, the presence of SSc-related antibodies associated with higher **miR-142-5p** (p 0.013) and lower **miR185-5p** (p 0.039). An increase in miR-142-5p levels was also shown in relationship with NVC alterations (p 0.04). Patients with RA had lower levels of **miR-320d** (p 0.03), while patients with SS had higher **Let7i-5p** (p 0.043), lower **miR-142-5p** (p 0.016) and higher **miR-185-5p** (p 0.025). No specific miRNA profiles differentiated between radiographic patterns, whereas fibrotic disease associated with lower **miR-142-5p** (p 0.004) and this miRNA levels also dropped in correlation with disease duration (p 0.047).

Patients requiring oxygen therapy had lower levels of **miR-483-5p** (p 0.016), while functional deterioration over time was associated with lower **Let7i-5p** (p 0.019). Fatal outcomes were marginally associated to lower baseline levels of miR-320d (p 0.065) and of miR-483-5p (p 0.095). Principal differentially regulated molecules in each subgroup and pathways involved are shown in the **Figure**.

Conclusion: A 3 miRNA signature consisting of high Let7i-5p, high miR-483-5p, low miR-223- 3p defined the CTD-ILD population. According to our data, the up-regulation of Let7i-5p and miR-483-5p might drive an adaptive response to lung injury, whose loss parallels functional deterioration. On the other hand, patients with vasculopathy showed a distinc profile characterized by an increase in miR-142-5p. The latter miRNA could also have a regulatory role, since its levels descended in fibrotic disease and in advanced stages.

TABLE

CTD-ILD cohort: process related variables

Clinical diagnoses		Radiographic patterns		Autoantibodies		Nailfold capillaroscopy		Functional status	
SSc/related conditions	24p (21.8%)	NSIP	48p 843.6%)	RF	36p (35%)	Major alterations	41p (54.6%)	FVC (% predicted values)	78.6 (3.4)

Paracrine WNT Signaling Modulates Profibrotic Macrophage Metabolic Activation in Systemic Sclerosis

emily Morris[1], Helen Jarnagin[1], Chen-Yu Wang[1], Michael Whitfield[2] and **Patricia Pioli**[3], [1]Dartmouth College, Lebanon, NH, [2]Geisel School of Medicine, Lebanon, NH, [3]Geisel School of Medicine at Dartmouth, Lebanon, NH

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1855–1876) Systemic Sclerosis & Related Disorders – Basic Science Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: An immune fibrotic axis consisting of activated macrophages (MØs) and fibroblasts has been identified in autoimmune systemic sclerosis (SSc) that drives disease across affected tissue types. In prior work, we have shown that SSc fibroblasts and MØs, which co-localize in lesional SSc skin, participate in reciprocal paracrine signaling mediated by SSc fibroblast-derived exosomes. The goal of this study was to identify the specific cargo carried by SSc fibroblast exosomes that mediates profibrotic MØ activation, and to elucidate the molecular mechanism responsible for this activation. Because MØ activation is intrinsically dependent on ATP availability, we hypothesized that SSc fibroblast-derived paracrine signals may induce profibrotic MØ activation in part by driving functional changes in MØ bioenergetics.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: To identify candidate regulators responsible for inducing dermal SSc MØ activation, publicly available single cell RNAseq (scRNA-seq) data from SSc patient and non-SSc control skin were interrogated. Because MØ activation is driven by metabolic utilization, exosome-mediated effects on MØ bioenergetics were ability investigated using Single Cell ENergetIc metabolism by profilng Translation inhibition (SCENITH). Protein content of exosomes was analyzed by immunoblot. Inhibitor studies were performed to assess the contribution of noncanonical WNT signaling to exosome-mediated profibrotic MØ activation, and co-cultures were employed to determine the requirement for WNT signaling in the ability of SSc fibroblast exosome-stimulated MØs to induce reciprocal fibroblast activation.

Results: scRNA-seq analyses of SSc and control skin demonstrated that pathways related to lipid metabolism, nutrient sensing, and oxidative phosphorylation (OXPHOS) were significantly enriched in SSc dermal MØs. Using SCENITH, we demonstrated that stimulation of MØs with SSc fibroblast-derived exosomes resulted in enhanced OXPHOS reliance, consistent with scRNA-seq results, while healthy fibroblast-derived exosomes failed to increase OXPHOS utilization. Furthermore, intact OXPHOS was required for profibrotic activation of human MØs by SSc fibroblast-derived exosomes. WNT5A, a known regulator of myeloid metabolism, was overexpressed in SS fibroblast exosomes, and studies with the WNT5A inhibitor Box5 demonstrated that blockade of WNT5A signaling abrogates OXPHOS upregulation and significantly attenuates the ability of SSc fibroblast exosome-stimulated MØs to elicit SSc fibroblast activation.

Conclusion: Collectively, our data indicate that SSc fibroblast-derived paracrine signals promote profibrotic MØ activation by altering MØ bioenergetics through noncanonical WNT-mediated signaling. These findings suggest that MØs meet the increased energy demand of the SSc dermal fibrotic niche by upregulating both mitochondrial dependency and mitochondrial content, and that blocking either OXPHOS or the WNT5A receptor, FZD5, is sufficient to inhibit profibrotic SSc MØ activation. Thus, MØ-specific metabolism and/or WNT5A signaling may represent novel therapeutic targets in SSc.

Session Title: (1855–1876) Systemic Sclerosis & Related Disorders – Basic Science Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Our prior research demonstrated that epigenetic modifications are central to the pathogenesis of scleroderma (SSc)[1]. Using ATAC-seq, we found that chromatin accessibility was significantly reduced in diffuse cutaneous (dc) SSc dermal endothelial cells (ECs) compared to those from healthy individuals. We also observed an increase in the chromatin binding of ETV2, a key transcription factor in the ETS family, within dcSSc ECs. ETV2 is crucial for both

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

hematopoietic and EC function and has been implicated in reprogramming non-ECs to an endothelial phenotype. Its deficiency results in developmental failure of blood vessels in embryos. Here, we explore the impact of ETV2 dysregulation on EC dysfunction in SSc.

Methods: ECs were isolated from skin biopsies of healthy subjects and dcSSc patients. We evaluated ETV2 expression using qPCR, Western blot, and immunofluorescence. ETV2 was overexpressed in ECs via viral transduction, and its expression was also profiled in scRNA-seq data from 18 healthy individuals and 23 dcSSc patients. We assessed functional outcomes like proliferation and angiogenesis. To pinpoint genes influenced by ETV2 in dcSSc ECs, CUT&RUN-seq and bulk RNA-seq were utilized. Statistical significance was set at $P< 0.05$.

Results: Despite low baseline levels, ETV2 was markedly upregulated in dcSSc ECs compared to controls. scRNA-seq analysis showed increased ETV2 expression in capillary and venular ECs in SSc skin. ETV2 overexpression in dcSSc ECs significantly boosted EC proliferation (n=4 patient lines, $p< 0.01$) and angiogenic activity, evidenced by increased tube and node formation on Matrigel (n=4 patient lines, $p< 0.05$). Relative to healthy ECs, dcSSc ECs showed decreased *CDH5* and increased *COL1A1* and *CDKN1A* expression, indicative of an endothelial-to-mesenchymal transition phenotype and elevated cellular senescence. ETV2 overexpression elevated EC marker *CDH5* (1.385 ± 0.17, $p< 0.05$ vs. control, fold change) and diminished fibrotic marker *COL1A1* (0.680 ± 0.147, $p< 0.05$ vs. control, fold change) and senescence marker *CDKN1A* (0.719 ± 0.175, $p< 0.05$ vs. control, fold change). Through CUT&RUN-seq and bulk RNA-seq, we identified specific genes and pathways significantly regulated by ETV2 in dcSSc ECs.

Conclusion: This study highlights the significant impact of ETV2 in modifying EC function in dcSSc. Upregulation of ETV2 is associated with increased cell proliferation and angiogenesis, which may contribute to disease progression. Changes in gene expression following ETV2 overexpression suggest its potential to reverse endothelial-to-mesenchymal transition and reduce senescence. Further investigation into ETV2-regulated pathways could provide valuable insights into SSc vasculopathy.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1855–1876) Systemic Sclerosis & Related Disorders – Basic Science Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: High-Resolution Computed Tomography (HRCT) is crucial for diagnosing and managing interstitial lung disease associated with systemic autoimmune rheumatic diseases (SARD-ILD), as it reveals characteristic patterns that inform treatment and prognosis in clinical practice. However, molecular expression patterns linked to HRCT findings remain underexplored. Since lung sampling is invasive and rare clinically, identifying alternative biological materials that reflect lung processes is essential. The united airway disease hypothesis posits that similar molecular pathways exist between the upper and lower respiratory tracts. Therefore, the objective of this study was to investigate the association between HRCT patterns and molecular expression profiles in SARD-ILD using transcriptomics.

Figure 1: Underlying SARD segregated by the HRCT pattern groups.

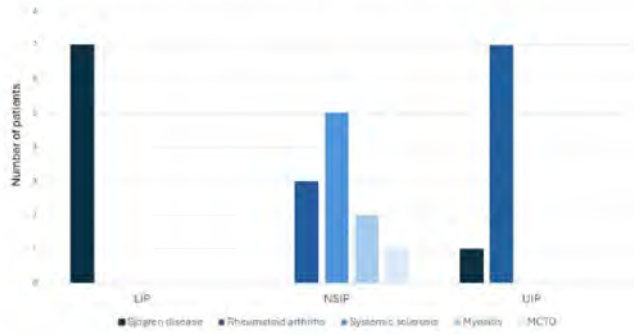

Figure 2: Volcano plots of LIP, NSIP, and UIP differentially expressed genes (DEG) compared to healthy control (|log2FC| ≥ 0.58 (up-regulated) or ≤ -0.58 (down-regulated), corresponding to fold change of 1.5, and adjusted p-value < 0.05).

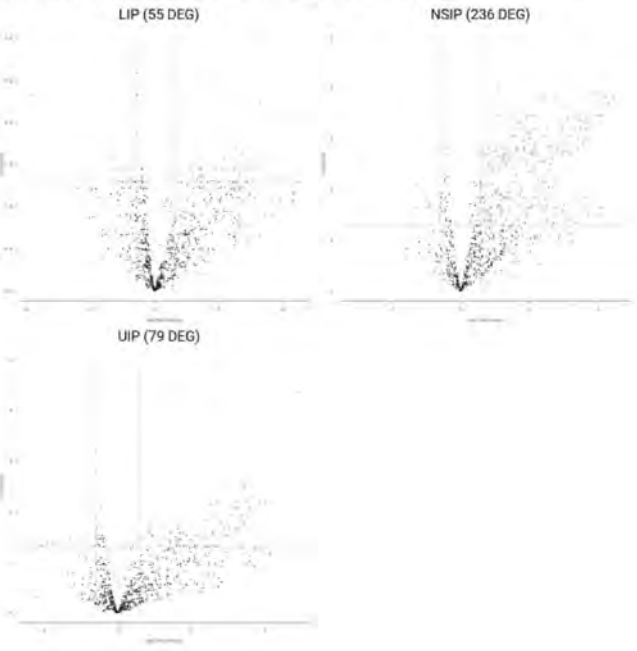

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Methods: Nasal mucosa samples were collected via Copan Flocked Swab (Copan Diagnostics 56380CS01) from SARD-ILD patients at Oslo University Hospital and healthy controls from UCLA and Oslo. HRCT patterns and clinical data were collected simultaneously. We assessed nasal mucosa transcriptomes to identify molecular expression profiles of SARD-ILD with lymphocytic interstitial pneumonia (LIP), nonspecific interstitial pneumonitis (NSIP) and usual interstitial pneumonia (UIP) compared to healthy controls. Transcriptomes were determined by NanoString technology, using the Autoimmune Profiling panel. Gene expression and pathway analyses were conducted using ROSALIND software (https://www.rosalind.bio/). To confirm lung-level findings, lung tissue samples were collected at the University Hospital Zurich from eight SARD-ILD and two healthy controls. Gene expression patterns were assayed using the 10x VisiumHD spatial transcriptomics platform.

Results: We included nasal mucosa samples from 7 LIP, 11 NSIP, 8 UIP patients, and 10 healthy controls (Fig. 1). We identified 55, 236, and 79 significant differentially expressed genes for LIP, NSIP, and UIP, respectively, compared to controls (Fig. 2). LIP was enriched mainly for IFN-type I, MHC class I antigen presentation, epigenetic and transcriptional regulation, and IFN-type II; NSIP for IFN-type I, Treg and TH2 differentiation, and IFN-type II; UIP for TH2 differentiation, complement system, IL activation, inflammasomes, Treg, and TH17 differentiation (Fig. 3). Visium HD data from lung biopsies are being processed to spatially resolve whole transcriptomes and further examine these pathways in the lung.

Conclusion: The molecular fingerprints of LIP, NSIP, and UIP provide critical insights into their distinct pathophysiological mechanisms. While LIP is characterized by significant inflammation driven by lymphocytes, NSIP shows a mixed inflammatory response with some regulatory T cell involvement. In contrast, UIP is associated with a complex interplay of immune pathways that drive chronic inflammation and tissue remodeling. Understanding these molecular profiles is essential for

Session Title: (1855–1876) Systemic Sclerosis & Related Disorders – Basic Science Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Emerging evidence implicates mitochondrial dysfunction as a contributor to tissue fibrosis in systemic sclerosis (SSc) (1). Endothelial cells, which are a key player in vascular injury and immune activation, are increasingly recognized as one of the main drivers of both fibrotic and type I interferon responses in SSc tissues (2). Since increased TGF-β stimulation is a hallmark of SSc pathogenesis, we hypothesized that it drives mitochondrial stress and impairs mitophagy in SSc endothelial cells, leading to cytosolic mitochondrial DNA (mtDNA) accumulation and subsequent activation of the cGAS-STING pathway that ultimately promote disease progression.

Methods: Primary dermal microvascular endothelial cells (MVECs) and fibroblasts from healthy donors (HD) and SSc patients were treated with TGF-β (10 ng/mL), IL-4 (5 ng/mL, negative control) or CCCP (positive control for mitophagy). Mitochondrial fission and stress-related transcripts were assessed by RT-qPCR. Oxygen Consumption Rate (OCR) was measured via Seahorse assays. Mitochondrial morphology and content were analysed via Immunofluorescence using MitoTracker Deep Red. Immunoblots were used to evaluate cGAS-STING pathway activation (P-STING, P-IRF3). The presence of mtDNA release in the supernatant was assessed by qPCR. Conditioned media from stimulated cells were tested in THP-1 dual luciferase reporter cells for ISRE/IRF3-driven transcription.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: At steady-state, MVECs from SSc patients exhibited an elevated expression of mitochondrial fission genes and a reduction in mitochondrial content compared to HD MVEC, suggesting defective mitochondrial quality control in SSc MVECS. Fibroblasts and MVECs from HD exposed to TGF-β upregulated multiple mitochondrial fission and mitophagy-related genes (DRP1, RALA, SPIRE1, HDN1) after 24 hours.

Long-term TGF-β exposure (7 days) in HD MVECs led to a 2.5-fold reduction in baseline and maximal OCR as assessed by Seahorse analysis. Concordantly, Seahorse assays revealed a marked decrease in basal and maximal respiration in SSc MVECs compared to HD MVECs at baseline.

Short-term TGF-β treatment (6h) of MVECs induced cGAS-STING activation, as evidenced by increased P-STING and P-IRF3. Conditioned media from TGF-β-treated MVECs triggered time-dependent IRF3-driven luciferase activity in THP-1 reporter cells, correlating with duration of TGF-β exposure, suggesting the hypothesis of a paracrine transmission of mtDNA or other interferon stimulating mediators.

Conclusion: Long-term TGF-β exposure induces mitochondrial fragmentation, stress, and dysfunctional mitophagy in HD MVECs. This leads to cytosolic accumulation and extracellular release of mtDNA and induces a *low-respiration* phenotype similar to SSc primary MVECs. This process triggers intracellular and paracrine activation of the cGAS-STING axis. Our findings uncover a novel mechanistic link between TGF-β signalling, mitochondrial dysfunction, and innate immune activation in SSc endothelium, identifying mitochondrial quality control as a potential therapeutic target

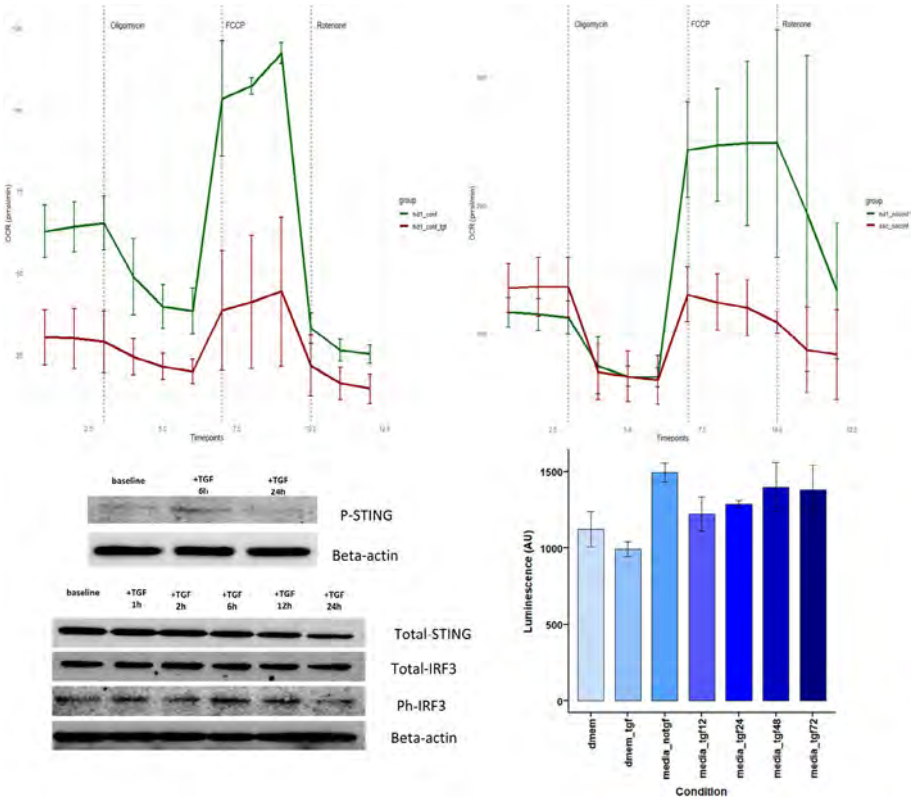

Figure 1. Mitochondrial dysfunction and STING pathway activation in endothelial cells treated with TGF-β. Top: Seahorse OCR traces showing reduced mitochondrial respiration in TGF-β treated endothelial cells (left: healthy untreated vs healthy treated with TGF; right: healthy untreated vs Systemic Sclerosis untreated). Dotted lines indicate the addition of oligomycin, FCCP, and rotenone. Data are presented as mean ± SEM. Bottom left: Western blot showing P-STING, total STING, total IRF3, and phosphorylated IRF3 (Ph-IRF3) in endothelial cells at baseline and after TGF-β stimulation. Beta-actin was used as a loading control. Bottom right: Luminescence assay quantifying cGAS-STING pathway activation at different time points following TGF-β treatment, confirming sustained activation at 12-72h.

Neutrophil Extracellular Trap-Rich Systemic Sclerosis Plasma Promotes Microvascular Endothelial Cell Proliferation and Migration: Implications for Aberrant Angiogenesis

Wenying Liang[1], James St. Clair[1], Pei-Suen Tsou[2], John Varga[2], Jason S. Knight[2], Dinesh Khanna[2] and Ramadan Ali[3], [1]University of Michigan, Ann arbor, [2]University of Michigan, Ann Arbor, MI, [3]University of Michigan, Ann Arobr, MI

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1855–1876) Systemic Sclerosis & Related Disorders – Basic Science Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic sclerosis (**SSc**, also known as scleroderma) is a systemic disease characterized by fibrosis, autoimmunity, and vasculopathy. Neutrophil extracellular traps (**NETs**) are web-like chromatin structures released by activated neutrophils. They contribute to the vascular pathology in multiple diseases, but their role in SSc remains poorly understood. We recently demonstrated elevated plasma NET levels in SSc patients with vascular complications compared to those without vascular complications. Here, we sought to determine the direct effects of NET-rich SSc plasma on microvascular endothelial cells (**MVECs**).

Methods: Human dermal MVECs were cultured in the presence of 2% pooled plasma from SSc patients with vascular complications exhibiting high circulating NET remnants (n=5), 2% pooled plasma from matched SSc patients without vascular complication exhibiting low circulating NET remnants (n=5), 2% pooled plasma from matched healthy controls (n=5), or purified NETs (0.1-0.5 μg/ml). Proliferation was quantified over 24 hours and calculated as the relative confluence change. Migration was evaluated via a scratch-wound assay over 24 hours and quantified by wound confluence (%).

Results: We first stimulated MVECs with different concentrations of purified NETs (0.1 μg/ml versus 0.5 μg/ml) for 24 hours. Compared with vehicle control, NETs (0.5 μg/ml) increased MVEC proliferation (1.4-fold change, P=0.0001) and migration (mean 52% vs. 23% wound confluence, P=0.0001) at 24 hours in a concentration-dependent manner (**Figure 1**). Next, we stimulated MVECs with 2% NET-rich SSc plasma compared with 2% NET-poor SSc plasma or 2% healthy control plasma. We found that NET-rich SSc plasma promoted MVECs proliferation (P=0.0003) and migration (P=0.0001) over 24 hours. In contrast, the effects of NET-poor SSc plasma on proliferation (P=0.986) and migration (P=0.729) were comparable to healthy control plasma (**Figure 2**). Notably, NET-targeting agents, such as anti-histone 4 and a neutrophil elastase inhibitor, significantly reduced MVEC proliferation and migration induced by NET-rich SSc plasma.

Conclusion: Our study demonstrates that SSc plasma containing high levels of NETs robustly stimulates MVEC proliferation and migration in vitro, and that NET-targeting agents can reverse these effects significantly. These data preliminarily identify NETs as mediators of abnormal angiogenesis contributing to the aberrant and dysfunctional characteristics of the SSc

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. SESSION INFORMATION

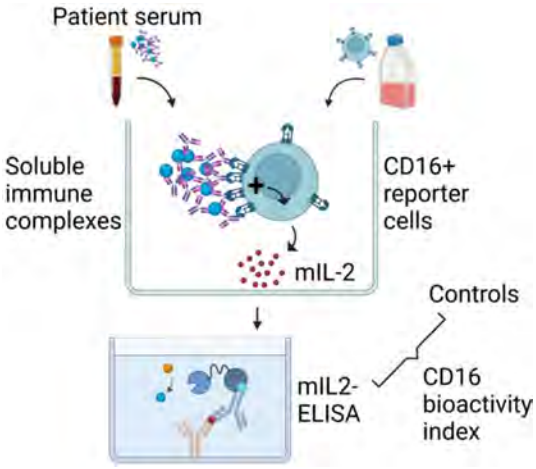
Session Date: Tuesday, October 28, 2025
Session Title: (1855–1876) Systemic Sclerosis & Related Disorders – Basic Science Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The role of autoantibodies in systemic autoimmunity, such as connective tissue diseases (CTD), has been recently highlighted by the successful treatment with CD19-targeting CAR-T cells. Although many downstream effects of autoantibodies require immune complex formation as to activate low-affinity IgG/Fcγ-receptors (FcγRs), circulating immune complexes (cICs) have experienced far less attention in the last decade. In fact, clinical testing of cICs, and thus thorough investigation of this potential chain link between adaptive and innate immune mechanisms, was impeded by lacking reliable detection methods. We have recently overcome methodological limitations by introducing a novel reporter cell assay that directly measures the presence of cICs in untreated serum with high sensitivity via their functional engagement to single FcγRs.

Methods: Here, we used a comprehensive reporter cell panel to assess the presence of cICs in autoantibody-positive CTD patients (cross-section analysis) and in eight patients treated with CD19.CAR-T cells (longitudinal analysis).

Results: The bioactivity of cICs in the CTD cohort was highly significantly elevated compared to healthy individuals and patients with autoantibody-negative psoriatic arthritis. Analyses of individual diseases indicated that cICs were present in sera from all CTD, including systemic sclerosis (SSc) and primary Sjögren's syndrome (SjS). FcγR-activation of cICs was heterogeneous within disease entities and correlated with the extent of cutaneous and lung manifestations in SSc, indicating pronounced cIC-bioactivity in the more systemic disease forms. In patients treated with CD19.CAR-T cells, the bioactivity of cICs was significantly reduced.

Conclusion: In summary, our study closes a knowledge gap by proving the presence of FcγR-engaging cICs that can be associated with clinical parameters and treatment in systemic autoimmune diseases.



Graphical overview of the reporter cell model used to determine the bioactivity of circulating immune complexes in patient sera at Fc-receptors such as CD16. Sera are diluted in assay medium without other processing steps.

Session Title: (1855–1876) Systemic Sclerosis & Related Disorders – Basic Science Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: A key event driving pulmonary fibrosis in interstitial lung disease (ILD) is the accumulation of pathologic senescent myofibroblasts, thought to be promoted by insufficient clearance by exhausted NK cells. The aim of this study was to identify mechanisms of NK cell inhibition in pulmonary fibrosis with a focus on checkpoint receptors, which may represent novel targets for the treatment of age-related fibrotic disorders.

Methods: Transcriptomic datasets and spectral flow cytometry were applied to characterize pulmonary NK cells. The bleomycin-induced lung fibrosis model and in vitro cultures were used to investigate the effect of NKG2A-inhibition on lung fibrosis and the elimination of senescent primary human lung fibroblasts.

Results: Proteomics and transcriptomics analyses revealed that NKG2A exhibits the highest and most selective expression among NK checkpoints in human ILD. In preclinical models, blockade of NKG2A promoted resolution of established pulmonary fibrosis, as demonstrated by reduced collagen content and decreased number of senescent myofibroblasts. Importantly, we showed translational potential of this therapeutic approach to human disease by showing that NKG2A blockade with the checkpoint inhibitor monalizumab unleashed patient-derived NK cell activity and significantly increased lysis of

human senescent myofibroblasts in vitro. Of note, monalizumab did not activate NK cells in absence of senescent myofibroblasts, ensuring selective killing and lowering the risk of unwanted generalized NK cell activation.

Conclusion: In summary, NKG2A checkpoint blockade selectively enhances elimination of senescent myofibroblasts by NK cells and promotes the resolution of fibrosis in preclinical models.

Demographics and trends of Inflammatory Arthritis-Related Mortality in the United States, 1999–2019

Aishwarya Sudheer[1], Ishan Jani[2], Sarath Lal Mannumbeth Renjithlal[2] and Qi Wang[3], [1]Saint Vincent Hospital, Worcester, MA, [2]Rochester General Hospital, Rochester, NY, [3]Metrohealth System/Case Western Reserve University, Cleveland, OH

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1877–1913) Epidemiology & Public Health Poster III

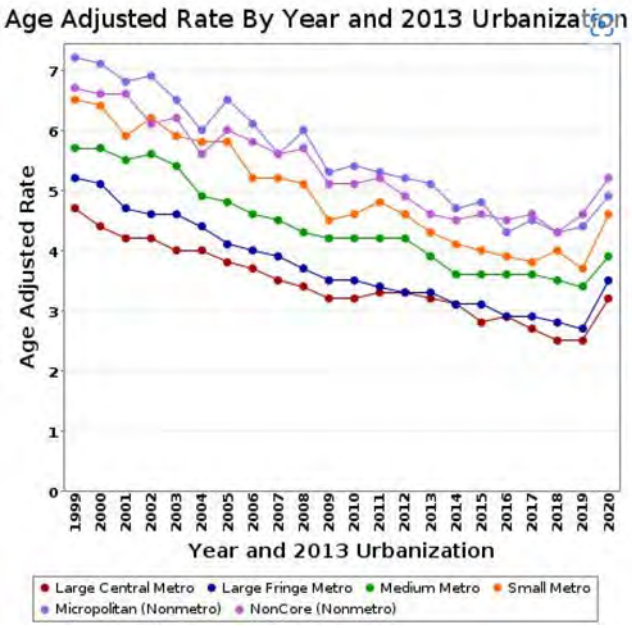
Session Type: Poster Session C

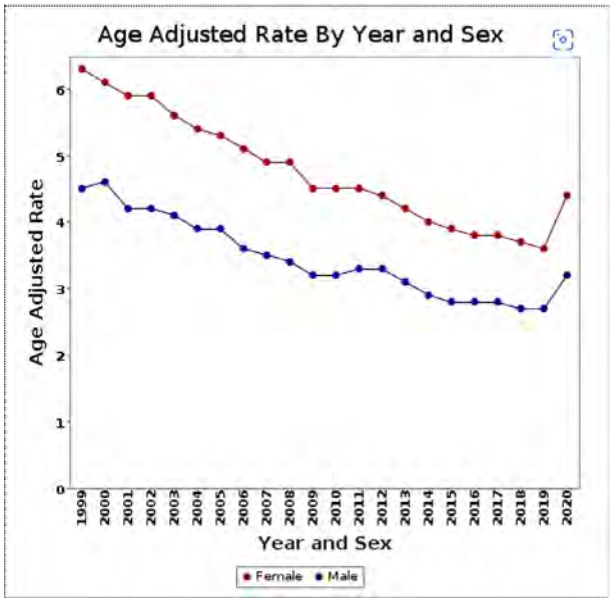
Session Time: 10:30AM–12:30PM

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

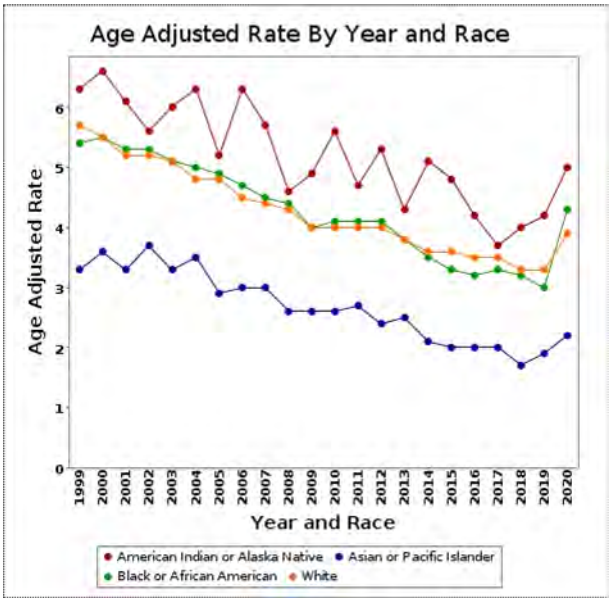
Background/Purpose: The study aims to evaluate the racial, sex-related and urbanization-related trends of deaths in patients with inflammatory polyarthropathies in the United States between 1999 and 2019

Methods: A retrospective analysis was conducted using the Centers for Disease Control and Prevention Wide-Ranging Online Data for Epidemiologic Research (CDC-WONDER) database. Deaths attributed to inflammatory polyarthritis were identified using ICD-10 codes M05–M13. Age-adjusted mortality rates (AAMRs) per 1,000,000 individuals were calculated, and temporal trends were analyzed using Joinpoint regression to estimate annual percentage changes (APCs) and 95% confidence intervals (CIs). Mortality trends were stratified by sex, race/ethnicity, and urbanization level.





23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Results: Between 1999 and 2019, a total of 288,661 deaths were associated with inflammatory polyarthropathies. The overall AAMR declined from 5.6 (95% CI: 5.4–5.6) in 1999 to 3.2 (95% CI: 3.2–3.3) in 2019. Women had consistently higher AAMRs than men throughout the study period. Among females, the AAMR decreased from 6.3 (95% CI: 6.2–6.4) to 3.6 (95% CI: 3.5–3.7), with an overall rate of 4.7 (95% CI: 4.7–4.7). In comparison, the AAMR in males declined from 4.5 (95% CI: 4.4–4.7) to 2.7 (95% CI: 2.6–2.8), with an overall rate of 3.3 (95% CI: 3.3–3.4).

Racial disparities were evident, with the highest AAMR observed among American Indian/Alaska Native populations at 5.0 (95% CI: 4.7–5.2), followed by White individuals at 4.2 (95% CI: 4.2–4.2), and Black individuals at 4.1 (95% CI: 4.1–4.2).

Stratification by urbanization revealed higher mortality rates in rural non-metro areas (AAMR 5.3, 95% CI: 5.3–5.4) compared to large metropolitan areas (AAMR 3.4, 95% CI: 3.4–3.4).

Conclusion: In the United States, there has been a general reduction in mortality associated with inflammatory polyarthritis over the last two decades. Early diagnosis and improvement in treatment modalities could be the reason for this trend. Further studies to evaluate role of access to rheumatology care needs to be investigated as a cause for worse mortality rates in rural areas and specific ethnicities.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The management of SLE varies worldwide. Current SLE treatment goals focus on preventing flares, controlling disease activity, and preventing organ damage accrual. LupusNet is the largest federated data network in SLE that combines and harmonizes data from 5 existing registries to enable greater data consistency and enhance understanding of global clinical presentations and outcomes of SLE. This study assessed treatment patterns for patients with SLE, categorized by disease severity, from LupusNet and a US claims database.

Methods: Data from 3 of 5 SLE registries in LupusNet, APLC (Asia Pacific), RELESSER (Europe), and Almenara (South America), were analyzed from 2012 to 2024, using a privacy-preserving federated data network approach where only aggregated results were shared. Additionally, data from the US Merative MarketScan® Commercial Claims and Encounters (CCAE) Database from 2019 to 2024 were included in the analysis. In LupusNet, data from patients with ≥3 years of follow-up and ≥3 follow-up visits were collected and stratified into mild, moderate, or severe disease based on a SLEDAI score at year 3 follow-up visit (**Table 1**). In the US claims database, data from patients who were diagnosed with SLE were stratified by mild, moderate, or severe disease based on documented symptoms and clinical features (**Table 1**). Treatment exposures (ie, glucocorticoids, antimalarials, immunosuppressants, biologic therapies, and other immunosuppressants/immunomodulators) were assessed over follow-up.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: LupusNet included 3857 eligible patients: 3070 with mild disease, 637 with moderate disease, and 150 with severe disease. US claims data included 49,350 eligible patients: 23,461 with mild disease, 16,172 with moderate disease, and 9717 with severe disease. Glucocorticoid use was widespread across all disease severity levels: 63%-65% of patients with mild disease, 76%-84% with moderate disease, and 89%-95% with severe disease received glucocorticoids in both

Table 1. Classification of disease severity in patients with SLE from LupusNet and the Merative MarketScan® CCAE Database

Definition	LupusNet Classification	Merative MarketScan® CCAE Database Classification[1]
Mild disease	SLEDAI score <6 at year 3 follow-up visit	Absence of moderate and severe SLE symptoms, and no record of rituximab or cyclophosphamide treatment
Moderate disease	SLEDAI score from 6 to <11 at year 3 follow-up visit	Record of scleritis, hemolytic anemia, myelopathy, avascular necrosis, demyelinating disease, pancreatitis, polyradiculoneuropathy, chorioretinitis, myocarditis, pleural effusion, pleurisy, retinal vasculitis, seizure, uveitis, mononeuropathy, episcleritis, and/or nephritis
Severe disease	SLEDAI score ≥11 at year 3 follow-up visit	Record of psychosis, aortitis, end-stage renal disease, stroke, optic neuritis, pulmonary hemorrhage, intestinal obstruction, delirium, thrombosis, and/or cranial neuropathy

CCAE, Commercial Claims and Encounters; LupusNet, Lupus federated data Network.

LupusNet and US claims data (**Figure 1**). Antimalarials were also frequently prescribed in 58%-66% of patients, regardless of disease severity. In contrast, use of immunosuppressants varied with disease severity: 25%-50% of patients with mild disease, 43%-67% with moderate disease, and 69%-81% with severe disease received immunosuppressants. Biologic therapies and other immunosuppressants/immunomodulators were utilized less frequently across all disease severity levels in LupusNet (4% and 2%-4%, respectively), while the use of these therapies increased with disease severity in US claims data (8%-44% and 4%-13%, respectively).

Conclusion: This analysis of patient data from LupusNet registries and the US claims database revealed that a considerable number of patients with active, severe SLE across geographic locations were not receiving immunosuppressants or biologic therapies. This suggests a heavy dependence on glucocorticoids to control disease activity and a potential underutilization of steroid-sparing therapies. Additional research is needed to explore long-term treatment trends and barriers to accessing treatments in patients with SLE.

Abstract Number: 1879

Infections in Hospitalized Patients With and Without Psoriatic Arthritis (2016–2021): A National Inpatient Sample Study

Ayema Haque, Ana Salas, Bruna Diniz, Harshank Patel and Philip Kroth, Western Michigan University School of Medicine, Kalamazoo, MI

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Psoriatic arthritis (PsA) is a chronic, immune-mediated inflammatory disorder affecting up to 30% of psoriasis patients and is associated with increased infection risk. This study evaluates the incidence, trends, and outcomes of common infections during PsA hospitalizations, including healthcare utilization and inpatient mortality.

Methods: Discharge data from the 2016–2021 National Inpatient Sample (NIS), an all-payer database representing a 20% stratified sample of U.S. hospitalizations, were analyzed. Hospitalizations with predefined clinical infections were identified and categorized by the presence (cohort 1) or absence of PsA (cohort 2). Descriptive statistics included counts and percentages for categorical variables, and medians with interquartile ranges for numerical variables. Trends were assessed using Cochran-Armitage tests. Rao-Scott chi-square tests evaluated associations, with odds ratios (95% confidence intervals) reported. Statistical significance was set at $p< 0.05$, with Bonferroni correction applied when appropriate. Analyses followed NIS guidelines and were conducted using SAS version 9.4.

Results: From 2016 to 2021, there were 8,598,744 (99.8%) hospitalizations with infections identified without PsA (cohort 1) and 14,683 (0.17%) with PsA (cohort 2). Cohort 2 was younger (median age 63.9 vs 67.6 years) and more likely to be female (OR 1.28; 95% CI 1.24-1.33; $p < 0.0001$), and Caucasian (OR 5.96; 95% CI 5.39-6.58; $p < 0.0001$). From 2016 to 2021, opportunistic infections (OIs) and urinary tract infections (UTIs) decreased significantly in cohort 1 ($p < 0.0001$), while skin and soft tissue infections (SSTIs), pneumonia, and sepsis increased significantly ($p < 0.0001$) (see figure 1). In cohort 2, OIs decreased significantly ($p < 0.0001$), pneumonia and sepsis increased significantly ($p < 0.0001$), and no significant changes were observed for SSTIs ($p = 0.7$) or UTIs ($p = 0.07$) (see figure 2). Cohort 2 had significantly increased odds of developing OI (OR 1.60; 95% CI, 1.50–1.70; $p < 0.0001$), SSTI (OR 1.4; 95% CI, 1.3–1.4; $p < 0.0001$), and sepsis (OR 1.1; 95% CI, 1.1–1.2; $p < 0.0001$), while having significantly lower odds of UTI (OR 0.8; 95% CI, 0.7–0.8; $p < 0.0001$)

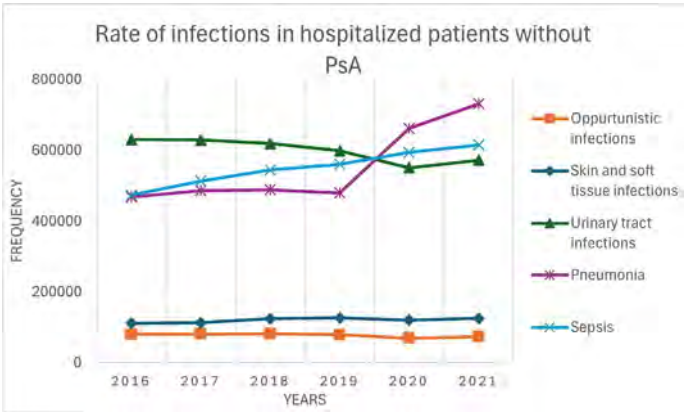

Figure 1: Rate of infections in hospitalized patients without PsA

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

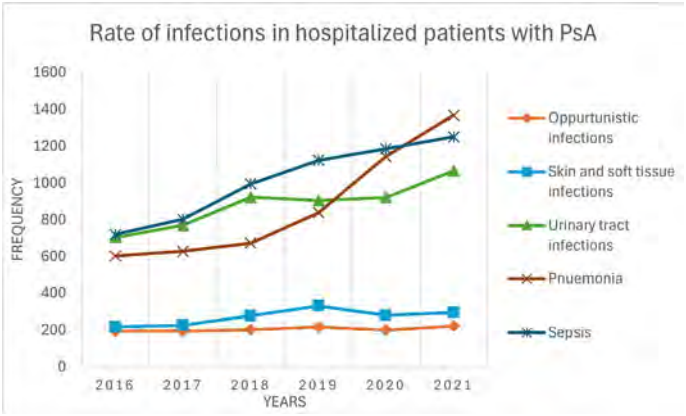

Figure 2: Rate of infections in hospitalized patients with PsA

and pneumonia (OR 0.8; 95% CI, 0.8–0.9; $p < 0.0001$). No significant associations were found between cohort 2 and alcohol abuse, drug abuse, and diabetes ($p > 0.05$). In cohort 2, severe renal failure was less common (OR 0.58; 95% CI, 0.54–0.63; $p < 0.0001$), while both mild (OR 1.60; 95% CI, 1.51–1.68) and severe liver disease (OR 1.38; 95% CI, 1.25–1.51) were more prevalent ($p < 0.0001$). Inpatient mortality was lower in cohort 2 (OR 0.66; 95% CI, 0.60–0.70; $p < 0.0001$). There was no significant difference in hospital charges (median charges $42407 vs $42410) and length of stay (median 4.25 vs 4.27) between the cohorts ($p > 0.05$).

Conclusion: Hospitalized PsA patients had higher odds of opportunistic infections, SSTIs, and sepsis, but lower odds of pneumonia and UTIs compared to those without PsA. Despite these differences, length of stay and hospital charges were similar, while inpatient mortality was lower in the PsA group. These findings highlight a distinct infection profile in PsA and emphasize the need for targeted infection management.

Rheumatoid Arthritis Mortality in the U.S. (1999–2020): A Decline in Rates, But Not in Disparities

Aziz-ur-Rahman Khalid[1], Ghassan Makhoul[2], Hasan Munshi[2], Islam Rajab[2], Emmanuel Olumuyide[3], MD Walid Akram Hussain[2], Aqsa Sorathia[2], Elvira Assaf[2], Amer Al Badawy[2], John Salama[2] and Robert Lahita[4], [1]St. Joseph's University Medical Center, wayne, [2]St. Josephs University Medical Center, Paterson, [3]Advocate Illinois Masonic Medical Center, Chicago, [4]St. Josephs University Medical Center, Wayne, NJ

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is a systemic autoimmune disease associated with increased morbidity and mortality. While treatments have evolved, national trends and sociodemographic disparities in RA-related mortality are poorly characterized. This study evaluates patterns in RA mortality over two decades, focusing on age, sex, race, geography, and place of death.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Graphs showing state, demographic, gender, race, age groups, place of death, and yearly mortality from Rheumatoid Arthritis

Methods: Mortality data for RA (ICD-10 code M06.9) from 1999–2020 were obtained from the CDC WONDER database. Age-adjusted mortality rates (AAMRs) per 100,000 population were calculated using census-adjusted estimates. Data were stratified by year, state, age group (10-year intervals), sex, race/ethnicity, Hispanic origin, urbanization level (2013 classification), and place of death.

Results: Between 1999 and 2020, there were 47,075 deaths related to rheumatoid arthritis (RA) in the United States. The age-adjusted mortality rate (AAMR) declined significantly from 0.87 per 100,000 in 1999 to 0.42 in 2020, representing a 51.7% decrease. Women experienced 2.4 times higher mortality than men, with an AAMR of 0.84 compared to 0.35. Mortality increased steeply with age, peaking at 10.1 per 100,000 among those aged 85 and older. By race and ethnicity, American Indian/Alaska Native individuals had the highest AAMR (1.07), followed by White (0.66), Black (0.49), and Asian/Pacific Islander (0.31); Hispanic individuals had an AAMR of 0.52. Urbanization patterns revealed the lowest AAMR in large central metro areas (0.52) and the highest in noncore rural areas (0.81). Geographic variation showed state AAMRs ranging from 0.52 in California to 1.27 in Montana, with elevated rates in older, less urbanized states. In terms of place of death, most occurred in inpatient settings (40.4%) or nursing homes (26.6%), followed by the decedent's home (23.2%), hospice facilities (2.6%), outpatient/ER (3.6%), and other locations.

Conclusion: RA-related mortality in the U.S. declined significantly from 1999 to 2020. However, persistent disparities by age, sex, race, urbanization, and place of death underscore the need for targeted public health and clinical strategies to improve equity in RA outcomes and end-of-life care.

Abstract Number: 1881

Silent Impact: Two Decades of Sjögren's Syndrome Mortality in the United States

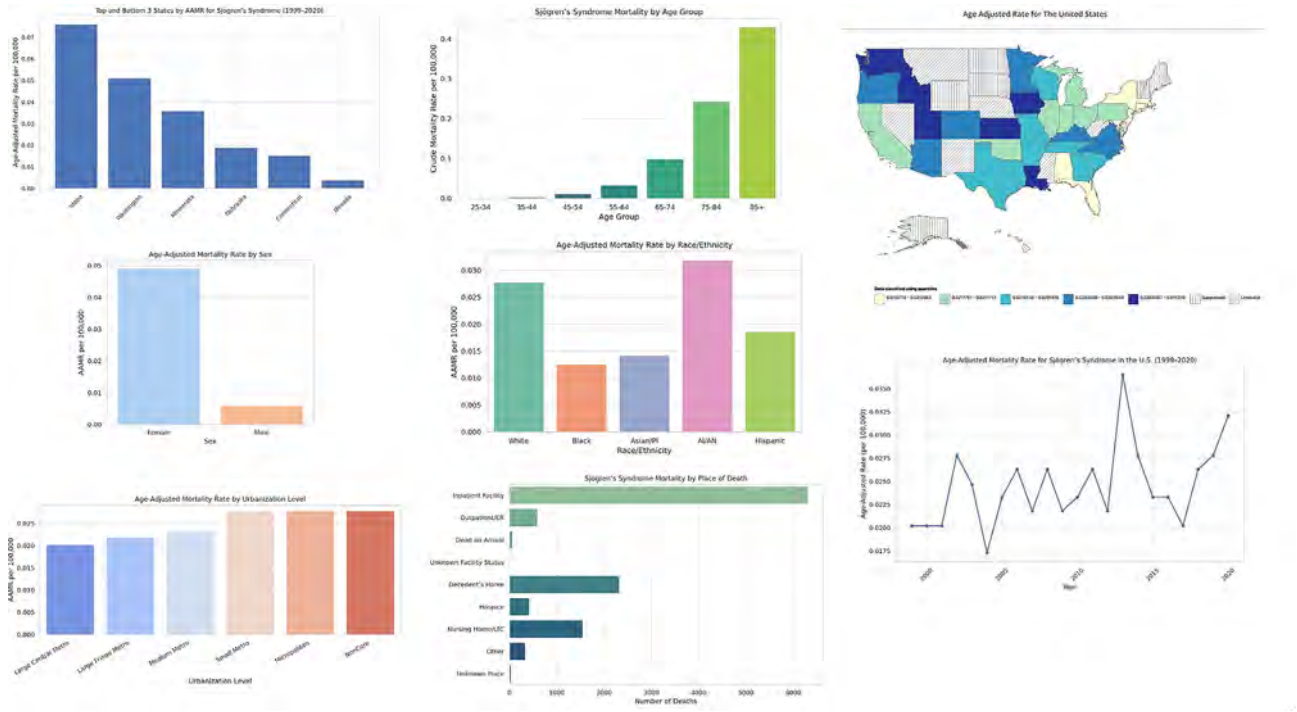
Aziz-ur-Rahman Khalid[1], Ghassan Makhoul[2], Hasan Munshi[2], Islam Rajab[2], MD Walid Akram Hussain[2], Reshma John[2], Elvira Assaf[2], Amer Al Badawy[2], Barbare Khatiashvili[2], Rouba Isshak[2], John Salama[2], Ibrahim Sabah[2] and Robert Lahita[3], [1]St. Joseph's University Medical Center, wayne, [2]St. Josephs University Medical Center, Paterson, [3]St. Josephs University Medical Center, Wayne, NJ

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Sjögren's syndrome is a chronic autoimmune disease characterized by lymphocytic infiltration of exocrine glands with potential systemic involvement. Despite its known complications, population-level mortality trends in Sjögren's syndrome remain poorly characterized. This study evaluates national mortality trends and sociodemographic disparities in Sjögren's syndrome-related deaths in the United States from 1999 to 2020.

Methods: We used the CDC WONDER Multiple Cause of Death database to identify decedents with ICD-10 code M35.0 (Sjögren's syndrome) listed as a cause of death from 1999 to 2020. Age-adjusted mortality rates (AAMRs) were calculated per 100,000 population using the direct method and the 2000 U.S. standard population. Mortality trends were analyzed over time and stratified by sex, age, race/ethnicity, urbanization, place of death, and U.S. state of residence.



Graphs showing state, urbanization, gender, race, place of death, age and year.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: A total of 2,149 Sjögren's syndrome-related deaths occurred during the study period. The AAMR increased by 57.5%, from 0.0202 in 1999 to 0.0321 in 2020. Females accounted for 88.2% of deaths and had an AAMR over eight times higher than males (0.049 vs. 0.006). Mortality increased markedly with age, from 0.01 per 100,000 in adults aged 45–54 to 0.43 in those aged ≥85 years. By race/ethnicity, White individuals had the highest AAMR (0.028), followed by American Indian/Alaska Native (0.032), Black (0.013), Asian/Pacific Islander (0.014), and Hispanic individuals (0.019). AAMRs rose with increasing rurality, ranging from 0.0202 in large central metro areas to 0.0278 in noncore rural regions. State-level AAMRs varied widely, from 0.015 in Connecticut to 0.051 in Washington. The majority of deaths occurred in inpatient hospital settings (42.3%) and nursing homes or long-term care facilities (26.6%), followed by the decedent's home (23.9%), hospice facilities (1.9%), and emergency/outpatient departments (2.6%).

Conclusion: Mortality from Sjögren's syndrome in the United States has increased over the past two decades, with a disproportionate burden among elderly women, rural populations, and White individuals. These findings underscore the need for improved disease recognition, timely systemic management, and targeted interventions to address healthcare disparities in Sjögren's syndrome.

Vessels Under Fire: National Mortality Trends in Systemic Vasculitides in the United States, 1999–2020

Aziz-ur-Rahman Khalid[1], Ghassan Makhoul[2], Hasan Munshi[2], Islam Rajab[2], Emmanuel Olumuyide[3], MD Walid Akram Hussain[2], Ahmed Huzien[2] and Robert Lahita[4], [1]St. Joseph's University Medical Center, wayne, [2]St. Josephs University Medical Center, Paterson, [3]Advocate Illinois Masonic Medical Center, Chicago, [4]St. Josephs University Medical Center, Wayne, NJ

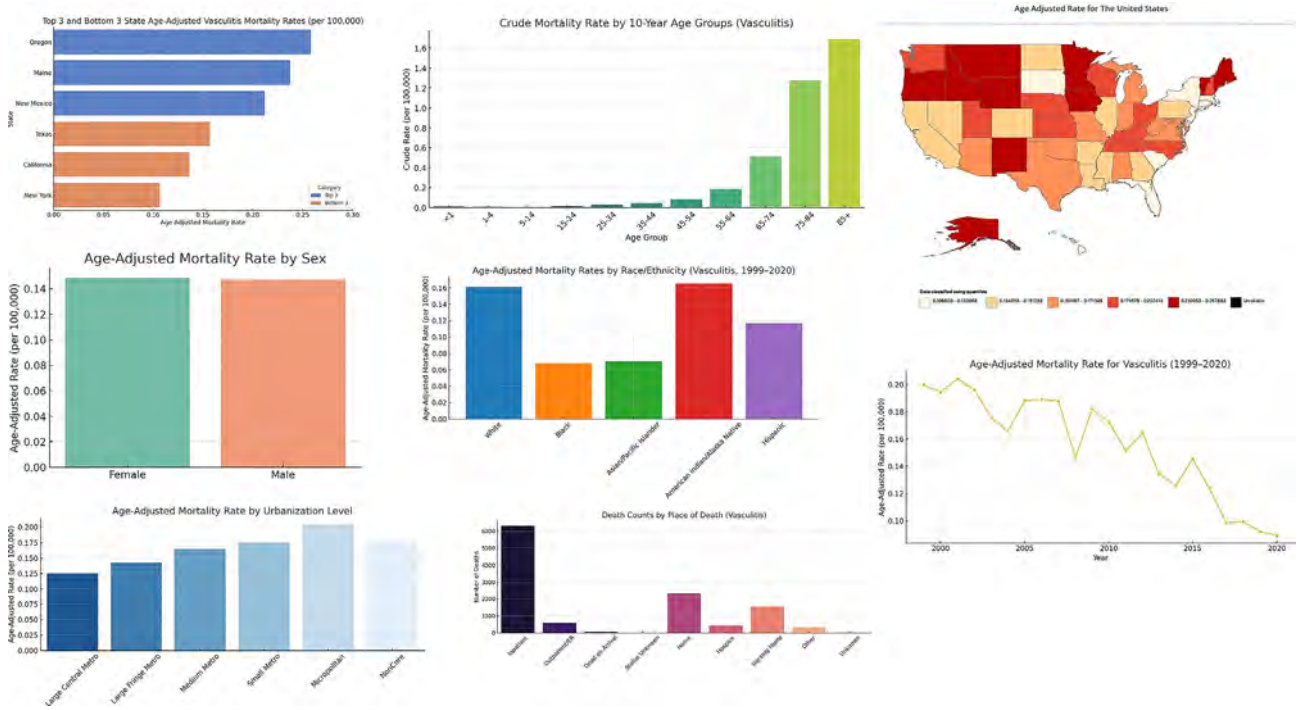
SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic vasculitides are rare but potentially life-threatening inflammatory disorders affecting blood vessels. Despite therapeutic advances, national mortality trends across vasculitis subtypes remain poorly defined. We analyzed U.S. mortality trends from 1999–2020 using CDC WONDER, focusing on 10 vasculitis-related ICD-10 codes.

Methods: CDC WONDER Multiple Cause of Death data (1999–2020) were queried using ICD-10 codes: D69.0 (Allergic purpura), M30.0 (Polyarteritis nodosa), M30.1 (Churg-Strauss), M30.3 (Kawasaki disease), M31.3 (Wegener granulomatosis), M31.4 (Takayasu arteritis), M31.5 (Giant cell arteritis with polymyalgia rheumatica), M31.6 (Other giant cell arteritis), M31.7 (Microscopic polyangiitis), and M35.2 (Behçet disease). Age-adjusted mortality rates (AAMRs) were calculated using the 2000 U.S. standard population. Analyses were stratified by age, sex, race/ethnicity, urbanization, state, and place of death.

Results: A total of **11,602 vasculitis-related deaths** occurred from 1999–2020. The **overall AAMR was 0.15 per 100,000**, declining from **0.20 in 1999 to 0.09 in 2020**. The **highest age-specific mortality** occurred in adults ≥85 years (**AAMR: 1.69**), with the **lowest** in children 5–14 years (**AAMR: 0.004**). Females accounted for **56% of deaths**, with AAMRs

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Graphs showing state, urbanization, gender, race, age, and year mortality from Vasculitis

nearly equal between sexes (**0.149 vs. 0.147**). By race, **American Indian/Alaska Native (0.165)** and **White (0.161)** individuals had the highest AAMRs, while **Black (0.068)** and **Asian/Pacific Islander (0.070)** individuals had the lowest. **Hispanic individuals** had an AAMR of **0.117**. The highest mortality occurred in **micropolitan** (0.205) and **noncore rural areas** (0.178). Regarding place of death, **54.3% occurred in inpatient medical facilities**, followed by **20.0% at home** and **13.3% in nursing homes**.

Conclusion: Vasculitis-related mortality in the U.S. has declined substantially since 1999. However, disparities persist among older adults, rural populations, and American Indian/Alaska Native individuals. These findings highlight the need for improved access to rheumatologic care and early detection strategies in high-risk populations.

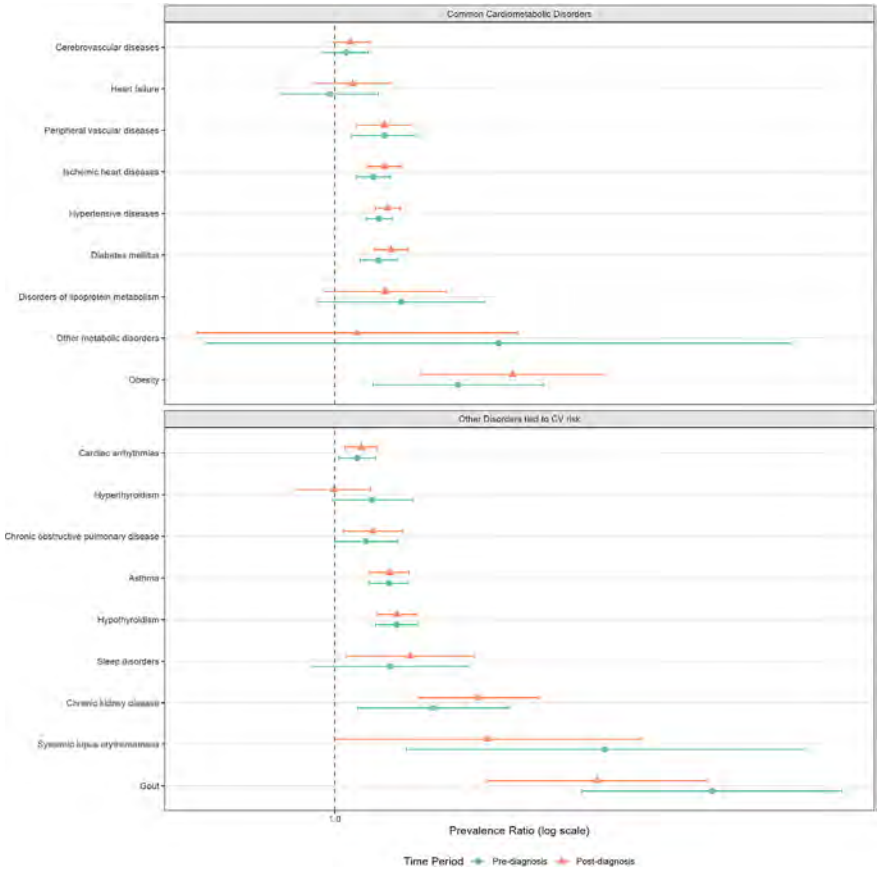
SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: While the association between psoriatic arthritis (PsA) and cardiometabolic disorders is established, the temporal sequence and progression of these comorbidities remain poorly characterized. To examine the temporal relationship between psoriatic arthritis (PsA) and cardiometabolic disorders by comparing their prevalence patterns before and after PsA diagnosis.

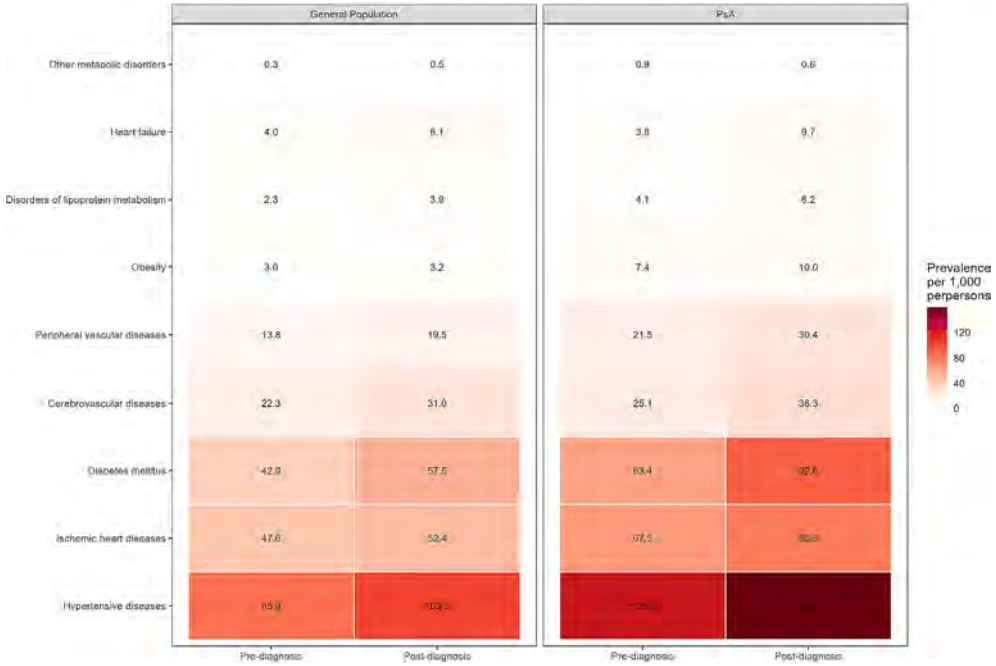
Methods: This nationwide retrospective case-control study analyzed Polish National Health Fund claims data (2011–2021). We identified 3,391 incident PsA patients diagnosed in 2016 using a definition requiring either: ICD-10 codes (M07.0-M07.3, L40.5) plus DMARD prescriptions, or ≥3 encounters with these codes in rheumatology settings. Cases were matched 1:10 to population controls by age, sex, and region. Cardiometabolic conditions (including hypertension, diabetes, ischemic heart disease, and metabolic disorders) were assessed based on ≥2 recorded diagnoses during five-year periods before and after PsA diagnosis.



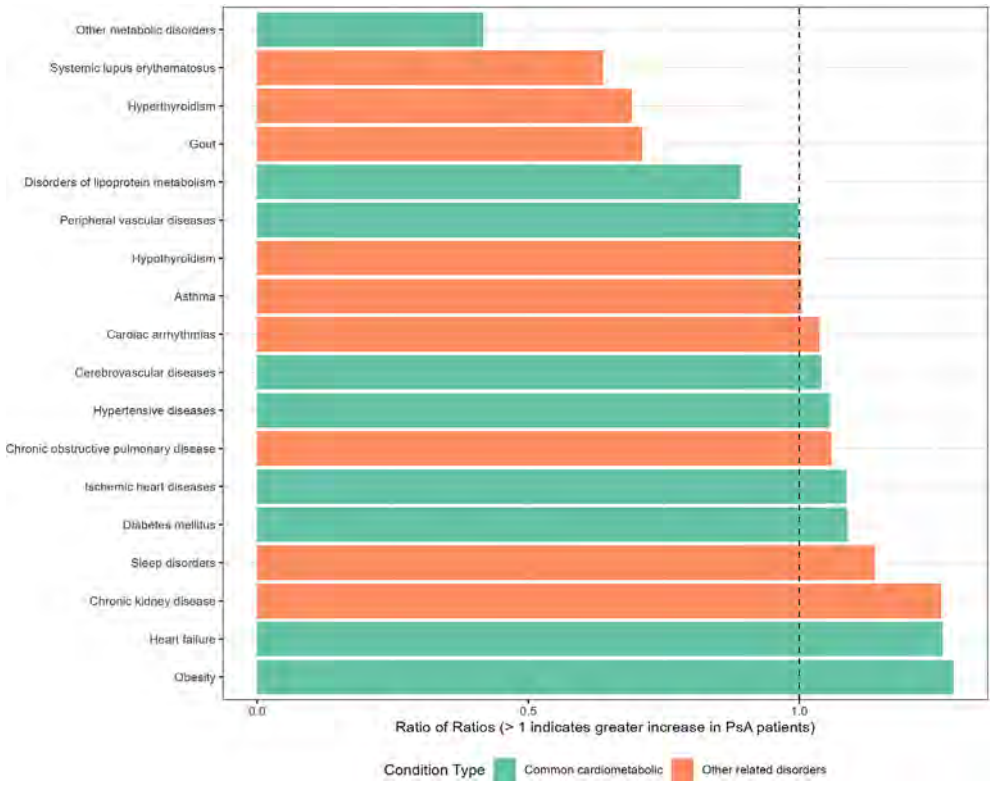
Temporal risk of various cardiometabolic disorders in patients with incident psoriatic arthritis as compared to the general population

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: PsA patients demonstrated significantly elevated cardiometabolic risk both before and after diagnosis. Prevalence ratios (PR) were consistently higher across multiple conditions, with slight increases observed following diagnosis: hypertensive diseases (pre-PR 1.05 [95% CI 1.03–1.06] to post-PR 1.06 [1.04–1.07]), diabetes mellitus (pre-PR 1.05 [1.03–1.07] to



Heatmap for the overall burden of common cardiometabolic disorders in incident psoriatic arthritis patients and the general population



Temporal change in the burden of various cardiometabolic disorders in the five years after psoriatic arthritis diagnosis, as compared to the general population.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

post-PR 1.06 [1.04–1.08]), and ischemic heart diseases (pre-PR 1.04 [1.02–1.06] to post-PR 1.05 [1.03–1.07]). Notably, obesity showed the highest relative risk (pre-PR 1.13 [1.04–1.24] to post-PR 1.20 [1.09–1.32]). The mean cardiometabolic burden per patient increased by 34% following PsA diagnosis (from 0.32 to 0.43 conditions), with marked increases in heart failure (154%), lipoprotein disorders (50%), and diabetes (46%).

Conclusion: Temporal patterns in comorbidity of cardiovascular significance support the concept of shared inflammatory and metabolic pathways underlying these associations, highlighting the need for early cardiometabolic risk assessment and intervention in PsA management.

Abstract Number: 1884

The Importance of Adherence to Dietary Recommendations for Rheumatoid Arthritis Risk May Be Greater in Younger Individuals – Results from a Nested Case-Control Study

Rebecka Bäcklund[1], Ulf Bergström[1], Michele Compagno[1], Linnea arvidsson[2], Emil Rydell[3], Emily Sonestedt[1] and **Carl Turesson**[3], [1]Lund University, Malmö, Sweden, [2]Lund University, Malmö, [3]Lund University, Malmö, Sweden

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Healthy eating habits might prevent the development of rheumatoid arthritis (RA). The impact of such lifestyle factors on the risk of RA may differ across age groups. We previously reported a reduced risk of RA among individuals who adhere to dietary recommendations, particularly regarding higher intake of vegetables and fruit and reduced consumption of red/processed meat. In a post hoc analysis, we investigated the relation between adherence to dietary recommendations and the risk of RA in models stratified by age.

Methods: A nested case-control study was conducted within a population-based survey performed in 1991-1996. Incident cases of RA were identified through linkage with patient registers up to December 2016, and the diagnoses were validated according to established criteria. Four controls for each case, matched for sex, year of birth, and year of inclusion, were included. The controls were alive and free of RA when the index person was diagnosed with RA. Diet was assessed using a modified diet history method comprising of a seven-day menu book, a diet history questionnaire, and a complementary diet history interview. The cutoff values for the recommendations in the Swedish Dietary Guidelines (SDG) from 2015 are based on the Nordic Nutrition Recommendations from 2012 and the WHO guidelines from 2015. Logistic regression analysis, taking into account the matched design of the study, was applied to investigate the relation with future RA for fibers, vegetables and fruit, fish, added sugar and red/processed meat as dichotomous (compliant with recommendation or not) and continuous variables per standard deviation. Furthermore, we assessed the impact of the SDG score (SDGS; 1 point

Odds ratio (OR), Swedish Dietary Guidelines Score (SDGS), Rheumatoid arthritis (RA), Standard deviation [SD], Percent of total energy intake (E%), Confidence interval (CI), Reference (Ref)
* All potential energy misreporters excluded
** SD for fiber 0.64; vegetables and fruits 185.60; fish and shellfish 229.58; added sugar 4.28; Red and processed meat 406.01

for adherence to each recommendation, total 0-5) on the risk of RA. Analyses were adjusted for factors that have been associated with both diet and RA (smoking, alcohol and leisure time physical activity). All models were adjusted for reported total energy intake, and stratified by age at inclusion in the health survey (above vs below the median). Misreporters of total energy intake were excluded.

Results: A total of 305 incident cases of RA were identified (76% women, mean time from screening to diagnosis 12 years). A high adherence (SDGS 4-5 vs 0-1) was associated with a reduced risk of future development of RA (odds ratio 0.26; 95% confidence interval 0.09-0.78) among survey participants aged ≤55.8 years, whereas there was no such association among older individuals (Table 1). Younger individuals who were adherent to recommendations on fiber, vegetables and fruit, and red/processed meat, had a lower risk of RA. There were corresponding associations with quantified intakes of each of these diet components in the younger group, but not in the older age group (Table 1).

Conclusion: Adherence to dietary recommendations, including high intakes of fiber and vegetables and fruit, and limited consumption of red/processed meat, may reduce the risk of RA in younger individuals. These findings suggest that the impact of lifestyle factors such as diet on future RA development may vary by age, potentially reflecting distinct early disease mechanisms.

Abstract Number: 1885

Sex-specific Associations of Anthropometrics, Smoking and Eduction with the Risk of Rheumatoid Athritis: A Nested Case-Control Study

Carl Turesson[1], Linnea arvidsson[2], Emil Rydell[1] and Ulf Bergström[3], [1]Lund University, Malmö, Sweden, [2]Lund University, Malmö, [3]Lund University, Malmö, Sweden

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Smoking is an established risk factor for rheumatoid arthritis (RA), and there is also evidence for an association with socioeconomic factors. As RA is more common in women compared to men, most studies of disease predictors have mainly included women, and data on risk factors in men are limited. Some studies indicate an increased risk of RA in women with high body mass index (BMI), whereas a negative association between BMI and future RA development in men has been reported. The purpose of this study was to investigate BMI, other anthropometric factors, smoking and level of formal education as potential predictors of RA in middle-aged men and women.

Methods: A nested case-control study was performed including participants in a population-based survey performed in 1991-1996. Cases diagnosed with RA from inclusion until December 2016 were identified through register linkage and validated in a structured process. Four controls for each case, matched for sex, year of birth, and year of inclusion, were included. Height and weight were measured as part of the health survey, and BMI was calculated as weight (in kg)/height (in m)^2. Waist was measured as the circumference (cm) between the lowest rib and the iliac crest. Hip circumference (cm) was measured as the largest circumference between waist and thighs. Waist/hip ratio (WHR) was defined as the waist circumference divided by the hip circumference. Information on lifestyle habits and socioeconomics was collected using a self-administered questionnaire. Logistic regression analysis, taking into account the matched design of the study, was applied to investigate the relation between these exposures and risk of RA diagnosis during the follow-up.

Results: There were 305 incident cases of RA (232 women, 73 men), with a mean time from screening to diagnosis of 12 years. The mean age at inclusion in the survey for those diagnosed with RA during the follow-up was 56.8 years, and similar in women and men (Table 1). These cases were compared to 1220 matched controls (Table 1).

Table 1.

Table 1. Baseline characteristics at inclusion in the health survey of pre-RA cases and controls; by sex

	Women		Men	
	Pre-RA cases	Controls	Pre-RA cases	Controls

Table 2.

Table 2. Relation between baseline factors and subsequent development of rheumatoid arthritis, by sex. Logistic regression. Odds ratios with 95% confidence intervals

	Women	Men
BMI (per SD)	1.03 (0.88-1.22)	**0.63 (0.46-0.87)**
Waist (per SD)	1.09 (0.93-1.28)	0.75 (0.55-1.01)
Hip (per SD)	1.13 (0.96-1.33)	0.92 (0.68-1.22)
Waist/hip ratio (per SD)	0.97 (0.82-1.14)	**0.68 (0.51-0.93)**
Current smoking	**1.99 (1.34-2.95)**	1.11 (0.52-2.37)
Low level of formal education*	**3.08 (1.69-5.63)**	1.09 (0.42-2.84)

*<8 years of school compared to university degree
SD, Standard deviation: BMI men 3.5 kg/m^2, women 4.4 kg/m^2; Waist men 10.3 cm, women 11.1 cm; Hip men 6.8 cm, women 10.0 cm; Waist/hip ratio men 0.06, women 0.05.

In men, higher BMI was associated with a reduced risk of RA (odds ratio [OR] 0.63 per standard deviation [SD]; 95% confidence interval [CI] 0.46-0.87). There was also a trend towards a lower waist circumference among men who subsequently developed RA (Table 2), and a significant negative association with the WHR (OR 0.68 per SD; 95% CI 0.51-0.93). No associations between anthropometric measures and RA risk were found in women (Table 2). However, smoking and a low level of formal education were predictive of RA in women, but not in men (Table 2).

Conclusion: Anthropometric measures seem to have differential effects on the risk of RA in women and men. The inverse association between BMI and RA risk in men is supported by a similar relation with WHR. This suggests distinct underlying mechanisms related to abdominal obesity in men and women. Female smokers and women with limited education had an increased risk of RA, whereas no similar associations were observed in the smaller subset of men in this study.

Abstract Number: 1886

Thirty Percent of Older Adults with Rheumatic Disease Receive High-Risk Medication

Christine Anastasiou[1], Eric Roberts[2], gabriela Schmajuk[3] and Jinoos Yazdany[4], [1]Stanford University, Pleasanton, CA, [2]University of California, San Francisco, SF, CA, [3]University of California, San Francisco, and San Francisco Veterans Affairs Medical Center, San Francisco, CA, [4]UCSF, San Francisco, CA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: High-risk medications (HRMs) may increase the risk of adverse events such as falls and fractures, hospitalizations, hospital length of stay, and death in older adults. We hypothesized that older adults with rheumatic disease, especially those with multiple comorbidities, had significant use of HRMs. We aimed to characterize HRM use, sources of prescription, and predictors of HRM exposure in older adults in a large national registry of older adults with rheumatic conditions.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Methods: We analyzed 2021 data from practices enrolled in the Rheumatology Informatics System for Effectiveness (RISE) registry linked to Medicare parts A, B, D. Patients ≥65 years old with ≥2 RISE visits, continuous Medicare enrollment, and a qualifying rheumatic diagnosis were included (SLE, RA, PsA, axSpA, SS, SSc, Gout, OA). HRM exposure was defined according to the Merit-Based Incentive Payment System Clinical Quality Measure #238 "Use of High-Risk Medications in Older Adults". We determined prescriber specialty using National Provider Identifiers (NPI) and a list of provider specialties

Table 1

10 Most Commonly Prescribed HRM

		Full Sample (N=49210)	Among patients with any HRM (N=15035)
Drug	N	%	%

from the Centers for Medicare & Medicaid Services to categorize prescribers as rheumatologist, non-rheumatologist MD, a rheumatology affiliated NP or PA, or a NP or PA not affiliated with a rheumatology practice. We reported the frequency and percent of patients exposed to the top 10 most common high-risk medications by primary rheumatic diagnosis. We constructed a series of logit linear models predicting exposure to any high-risk medication using generalized estimating equations to adjust for patients nested within practices.

Results: Out of the 49,210 patients (mean age 76±6.5, 75.4% women, 87.7% non-Hispanic white) meeting inclusion criteria, 30.6% received ≥1 HRM in 2021; 7.6% received ≥2 HRMs. The top most-used high-risk medications included cyclobenzaprine (6.6% of full sample; 21.7% among patients with any HRMs) and zolpidem (4.0% of full sample; 13.2% among patients with any HRMs), among others (Table 1). Four of the ten most common prescriptions were for psychotropic medications. Prescriptions primarily originated from non-rheumatology physicians (67.1%) or non-rheumatology affiliated NP or PA (9.9%). In adjusted models, patients with SS and axSpA had the highest odds of receiving a HRM when compared with RA (OR 1.48, 95% CI 1.2 – 1.4 and OR 1.42, 95% CI 1.24 – 1.62); (Table 2). Patients with fibromyalgia, mood disorder or anxiety disorder, and patients with higher Charlson Comorbidity Index (3-4+) also had higher odds of receiving a HRM (Table 2).

Conclusion: Thirty percent of older adults with rheumatic diseases received at least one high-risk medication. The most common medications prescribed were cyclobenzaprine and zolpidem, suggesting that this population has significant pain and sleep dysfunction prompting use of HRMs. Further research is warranted to identify optimal strategies and medications to balance symptom relief with patient safety, ensuring that pain, mood, and insomnia in older adults with rheumatic disease are effectively managed without incurring undue harm in this vulnerable population.

Incidence, Prevalence and Mortality of Systemic Lupus Erythematosus – A 20-year territory-wide analysis of electronic health records in Hong Kong

Danting zhang[1], jiaxin S. Wu[1] and Desmond Yat-Hin Yap[2], [1]The University of Hong Kong, Hong Kong, Hong Kong, [2]Department of Medicine, The University of Hong Kong, Hong Kong SAR, Hong Kong

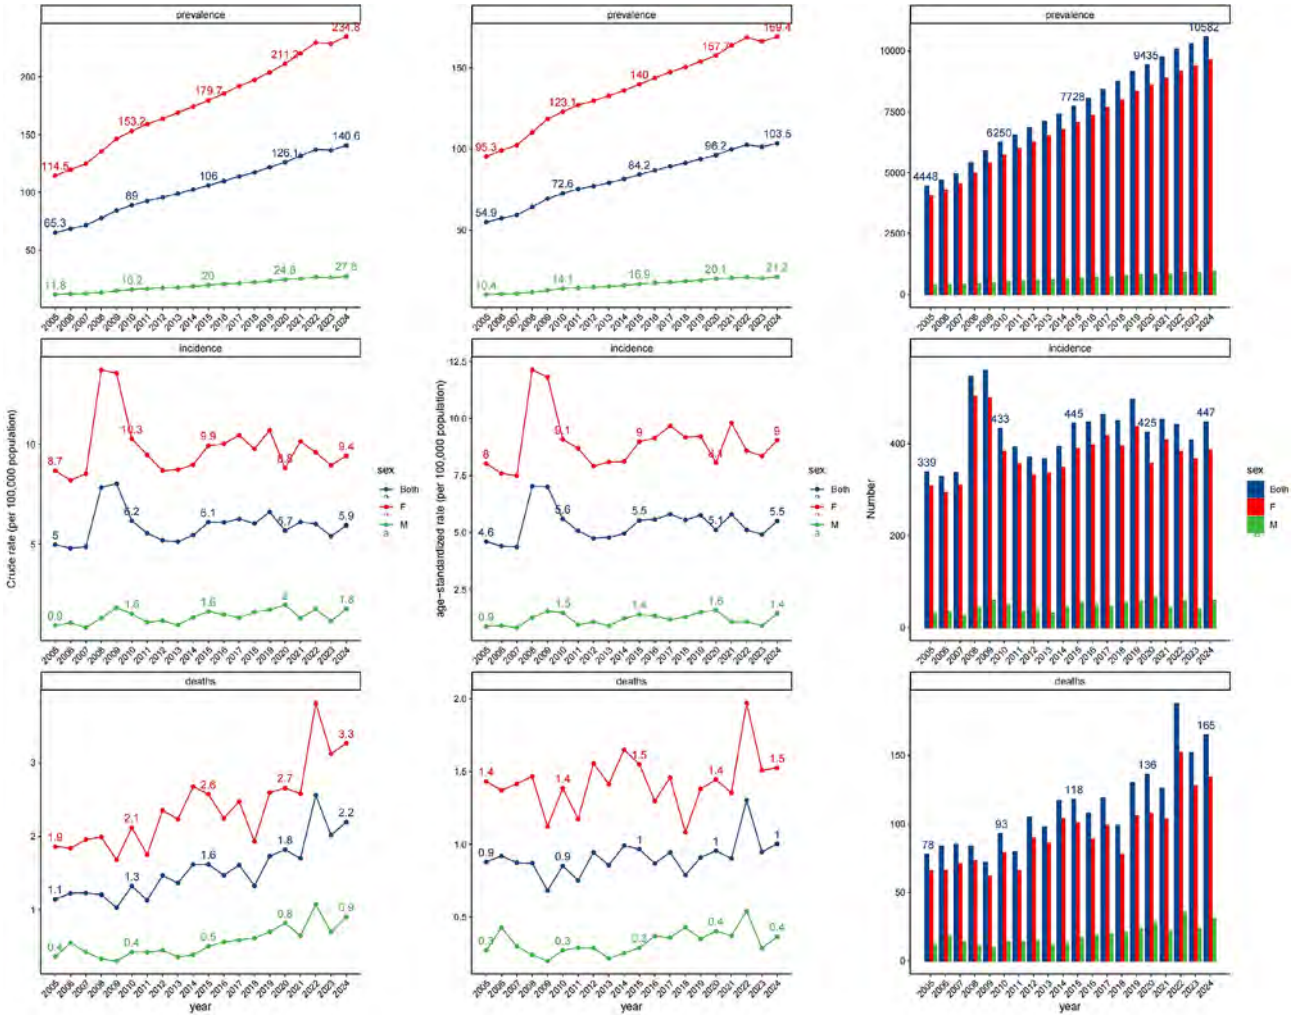
SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

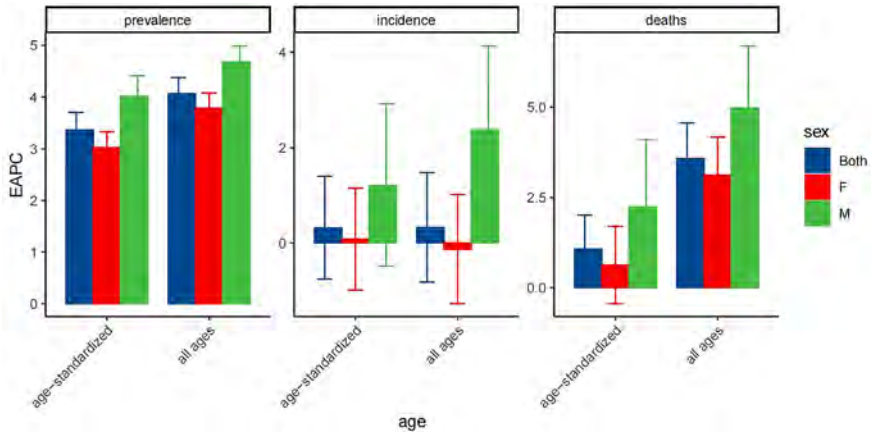
Background/Purpose: Advancements in immunosuppressive treatments and general medical care in the past two decades have influenced the disease burden and outcomes of patients with systemic lupus erythematosus (SLE). This study aimed to provide an up-to-date analysis on the prevalence, incidence, and mortality in the present era of SLE management.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We established a large retrospective cohort of SLE patients using the Clinical Data Analysis and Reporting System (CDARS, an territory-wide electronic health records system managed by the Hospital Authority of Hong Kong) between 1995 to 2024. The incidence, prevalence and all-cause mortality were evaluated between 2005 and 2024, and age-



The trends in crude and age-standardized rates of prevalence, incidence and death in SLE between 2005 and 2024



Estimated annual percentage change (EAPC) for crude and age-standardized rates of prevalence, incidence and death in SLE between 2005 and 2024

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

standardization was based on the WHO 2000–2025 standard population (SEER datasets). The change of trends was assessed by the estimated annual percentage change (EAPC).

Results: 8,545 incident cases were observed between 2005 and 2024, with a prevalence of 10,582 in 2024. Crude prevalence (per 100,000 persons) of SLE increased from 65.3 to 140.6 [EAPC: 4.1 (3.8 to 4.4)], and prevalence rates for female and male were 234.8 and 27.6 respectively by the end of 2024. Crude incidence (per 100,000 persons) remained largely unchanged over the years [5.0 vs. 5.9 (EAPC: 0.3 (-0.8 to 1.5)], but the crude mortality (per 100,000 persons) increased from 1.1 to 2.2 [EAPC: 3.1 (2.1 to 4.2)]. The life-expentacy for female and male SLE patients were 77 and 73.8 years, respectively. While the age-standardized death rate for male showed a significant increase [EAPC 2.2 (0.4 to 4.1)], the rate for female has remained unchanged [EAPC 0.6 (-0.4 to 1.7)]. The female to male rate ratio for age-standardised prevalence, incidence and death rate were 8, 6 and 4, respectively, in 2024. Disparity in trends was also observed among different age groups.

Conclusion: The evolution of SLE management has led to increased disease prevalence. Such change in disease burden may be related to better immunosuppressive therapies and general medical care that has led to reduced early mortality.

Abstract Number: 1888

Developing Machine Learning Algorithm in Electronic Health Record to Accurately Identify Psoriasis Patients

Dilli Poudel[1], Leslie Crofford[2], Avery Fortier[3], Lee Wheless[4], Georgina Sellyn[4], Gyaljin Sherpa[5], Alexis Ogdie[6] and Paras Karmacharya[7], [1]Vanderbilt University Medical Center, Nashville, TN, [2]Vanderbilt University Medical Center, Melbourne, AR, [3]Vanderbilt University, Lexington, MA, [4]Vanderbilt University, Nashville, TN, [5]Mercy Health - St. Elizabeth Youngstown Hospital, Newyork, NY, [6]Department of Medicine, Perelman School of Medicine at the University of Pennsylvania, Wilmington, DE, [7]Vanderbilt University, Nashville, TN, Hermitage, TN

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Accurate identification of patients with psoriasis from large electronic health record (EHR) databases is crucial for conducting robust real-world research. While EHRs offer an efficient resource, traditional identification methods are often laborious. Machine learning (ML) can present a promising high throughput approach with accuracy. The objective of this study was to develop and validate machine learning algorithms using EHR data to identify patients with psoriasis.

Methods: We used data from Vanderbilt University Medical Center's de-identified EHR database, the Synthetic Derivative (SD), which contains longitudinal clinical data from approximately 3.5 million subjects. Adult patients (≥18 years) were initially screened based on potential psoriasis indicators like International Classification of Diseases (ICD) codes or keywords. Non-overlapping random samples formed the training (N=200) and validation (N=300) sets. A true psoriasis case was defined through manual chart review as documented confirmatory or probable diagnosis by a dermatologist or rheumatologist, or a positive skin biopsy. Potential machine learning features included ICD-9/10 codes for psoriasis and related conditions, provider specialty associated with codes (dermatology, rheumatology), problem list keywords, and use of relevant medications (e.g., topical treatments, systemic therapies, biologics). Three ML models (logistic regression, random forest, XGBoost)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

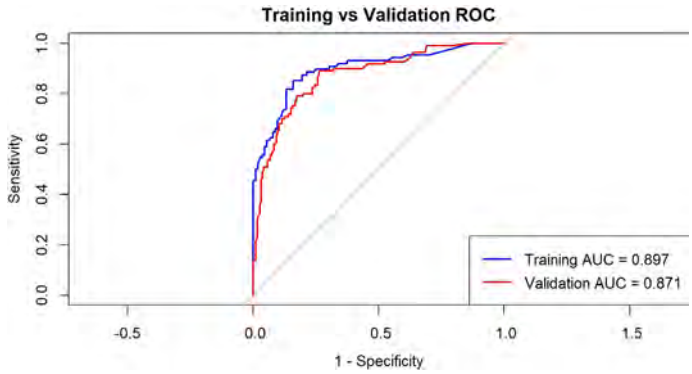
were developed on the training set, with the random forest model undergoing hyperparameter tuning via repeated 10-fold cross-validation. Models were tested on the independent validation set, assessing performance using F1-score, sensitivity, positive predictive value (PPV), area under the receiver operating characteristic curve (AUC), and accuracy.

Results: All three ML models demonstrated strong performance identifying psoriasis patients in the validation set. Tuned random forest model achieved the highest F1-score (0.757), with an AUC of 0.871, sensitivity of 0.791, and PPV of 0.725 (**Table 1, Figure 1**). Feature importance analysis confirmed that ICD codes related to psoriasis diagnoses documented by dermatologists and rheumatologists, overall psoriasis visit codes, and specific medication usage patterns were among the most significant predictors of a true psoriasis diagnosis (**Figure 2**).

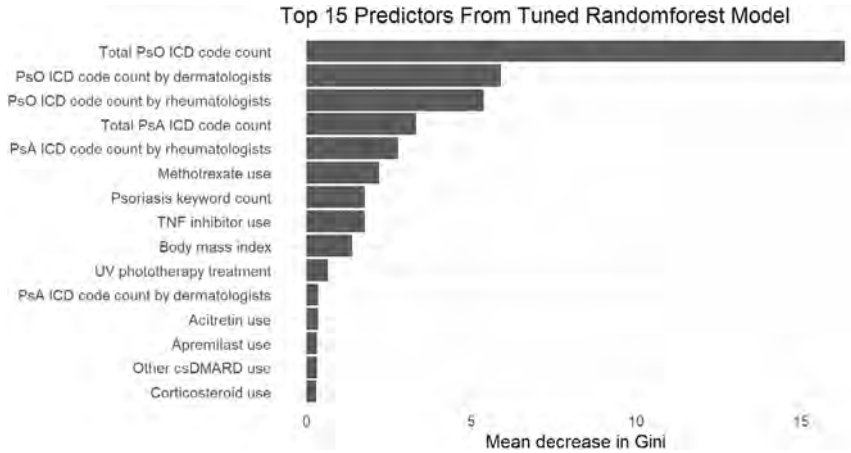
Conclusion: Machine learning algorithms, particularly tuned random forest models, leveraging readily available EHR data could provide an accurate and efficient method for identifying psoriasis patients comparable to true diagnosis made by dermatologist or rheumatologist or with skin biopsy. Such validated algorithms represent valuable tools for researchers seeking to assemble large, real-world cohorts of patients with psoriasis enabling studies on disease epidemiology, treatment effectiveness, and patient outcomes.

Model	F1-score	Sensitivity	PPV	AUC	Accuracy
Logistic Regression	0.726	0.739	0.713	0.856	0.7867
Random Forest	**0.757**	0.791	0.725	0.873	0.8133
XGBoost	0.75	0.736	0.764	0.88	0.8233

Comparison of Performances Among Three Different Machine Learning Models



Receiver Operating Curves with Area Under Curve for Random Forest Model in Training and Validation Sets



Top 15 Predictors of a True Psoriasis Diagnosis

Navigating Diagnostic Challenges: Insights into the Patient Journey and Delays in Diagnosing Dermatomyositis from a Real-world Survey in the United States and Europe

Esther Yi[1], Jason Xenakis[1], Chris Blazos[2], Jade Garratt-Wheeldon[2], James Piercy[2], Peter Anderson[2] and Rohit Aggarwal[3], [1]Pfizer Inc., New York, United States of America, New York, [2]Adelphi Real World, Bollington, United Kingdom, Bollington, United Kingdom, [3]University of Pittsburgh, Rheumatology and Clinical Immunology, Pittsburgh, United States of America, Pittsburgh, PA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Idiopathic inflammatory myopathies (IIMs) are a heterogenous group of rare autoimmune inflammatory rheumatic diseases, including dermatomyositis (DM).

Methods: Data were drawn from the Adelphi Real World IIMs Disease Specific Programme™, a cross-sectional survey, including retrospective data collection, of rheumatologists, dermatologists, neurologists, and internists in Europe (France, Germany, the United Kingdom) and the United States (US) from September 2023–July 2024. Physicians reported demographics, consultation history, tests, and diagnoses, for up to 10 consecutively consulting adult patients with a physician-confirmed diagnosis of DM. Analyses were descriptive, and missing data were not imputed.

Results: Overall, 222 physicians provided data on 513 DM patients (n=381 Europe, n=132 US). Physician reported patient demographics at survey are reported in **Table 1**. Mean (standard deviation [SD]) patient age was 49.5 (12.8) years, 73% were female, and 87% were White. Mean [SD] time since DM diagnosis was 2.7 (2.9) years. Family history of an autoimmune disease was confirmed for 38% of patients and 67% had a confirmed comorbidity.

Signs/symptoms present at onset included fatigue (63%; Europe 66%, US 53%), heliotrope rash (45%; Europe 46%, US 41%), Gottron's papules (46%; Europe 48%, US 41%), erythematous rashes (without secondary changes) (40%; Europe 39%, US 42%), and myalgia 29%; Europe 29%, US 29%).

Diagnostic characteristics are reported in **Table 2**. Mean (SD) time from symptom onset to diagnosis was 24.3 (32.4) weeks, and 13.1 (27.2) weeks from first consultation to diagnosis. Following DM symptom onset, 47% of patients initially consulted a general practitioner (GP)/ primary care physician (PCP), 22% consulted a dermatologist, and 14% consulted a rheumatologist. For patients who initially consulted a GP/PCP, dermatologist, or rheumatologist, the mean (SD) durations from first consultation to DM diagnosis were 12.4 (21.1), 8.1 (11.6), and 16.7 (33.4) weeks, respectively.

Creatine kinase (CK) testing was conducted to aid diagnosis for 84% of patients and myositis specific/associated antibody testing for 74%.

Table 1: Physician reported patient demographics at time of survey, across Europe and the United States

	All patients	Europe	US
Patient age, years	***n=513***	***n=381***	***n=132***
Mean (SD)	49.5 (12.7)	48.3 (12.5)	52.8 (12.9)
Patient ethnicity, n (%)	***n=375***	***n=243***	***n=132***
White	325 (87%)	216 (89%)	109 (83%)
Black	27 (7%)	11 (5%)	16 (12%)
South Asian (Indian subcontinent)	15 (4%)	11 (5%)	4 (3%)
East or Southeast Asian	4 (1%)	3 (1%)	1 (1%)
Middle Eastern or North African	4 (1%)	3 (1%)	1 (1%)
Other	2 (1%)	0 (0%)	2 (2%)
Patient sex, n (%)	***n=513***	***n=381***	***n=132***
Male	139 (27%)	107 (28%)	32 (24%)
Female	374 (73%)	274 (72%)	100 (76%)
Time since Dermatomyositis diagnosis, days	***n=484***	***n=359***	***n=125***
Mean (SD)	979.8 (1044.9)	953.1 (1062.8)	1056.6 (991.9)
Top 5 most frequently reported autoimmune conditions with confirmed family history, n (%)	***n=181***	***n=146***	***n=35***
Thyroid-related disease (e.g., Grave's disease, Hashimoto's thyroiditis)	52 (29%)	41 (28%)	11 (31%)
Rheumatologic disease	49 (27%)	42 (29%)	7 (20%)
Inflammatory bowel disease	31 (17%)	25 (17%)	6 (17%)
Multiple sclerosis	20 (11%)	15 (10%)	5 (14%)
Sjogren's syndrome	19 (10%)	15 (10%)	4 (11%)
Top 10 most frequently reported comorbidities, n (%)	***n=344***	***n=245***	***n=99***
Hypertension	128 (37%)	77 (31%)	51 (52%)
Anxiety	104 (30%)	69 (28%)	35 (35%)
Dyslipidemia	95 (28%)	66 (27%)	29 (29%)
Depression	81 (24%)	58 (24%)	23 (23%)
Thyroid-related disease (e.g., Grave's disease, Hashimoto's thyroiditis)	45 (13%)	29 (12%)	16 (16%)
Diabetes without chronic complications	40 (12%)	21 (9%)	19 (19%)
Any malignancy, including and lymphoma	26 (8%)	16 (7%)	10 (10%)
Rheumatologic disease	22 (6%)	17 (7%)	5 (5%)
Arrythmia	19 (6%)	14 (6%)	5 (5%)
Mild liver disease	19 (6%)	16 (7%)	3 (3%)

Overall, 34% of patients were initially diagnosed with a different condition, which was later identified as DM. Among these patients, initial diagnoses included 21% fibromyalgia, 20% systematic lupus erythematosus, and 16% rheumatoid arthritis (**Table 2**). Figure 3 shows the rate of initial diagnoses by physician types that conducted the first consultation. For patients that had been given an initial diagnosis, mean (SD) duration from first consultation to DM diagnosis was 18.2 (34.8) weeks (Europe 17.3 [27.4], US 19.7 [44.8]).

Conclusion: While almost half of patients first consulted a PCP, DM diagnosis was invariably made by a specialist. Despite significant levels of testing to aid diagnosis, other than CK, testing practice varies between patients but more generally between the US and Europe. Further research is needed to confirm the consequences of delay in terms of clinical and patient-reported outcomes.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1877–1913) Epidemiology & Public Health Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA), a chronic systemic inflammatory disorder, imposes a significant global health burden. Smoking is a well-established modifiable risk factor implicated in both the onset and progression of RA. However, comprehensive estimates of the global burden of RA attributable to smoking over time remain limited. This study aims to quantify the burden of RA attributable to smoking across 204 countries and territories over a 32-year period, disaggregated by age, sex, and location.

Methods: We estimated deaths, DALYs, and YLDs attributable to smoking-related RA from 1990 to 2021 across 204 countries and territories using a standardized global burden of disease study 2021 risk attribution framework. Burden estimates were stratified by age, sex, year, and geography. Counterfactual analysis assuming zero smoking exposure was applied to

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

compute attributable fractions, and temporal trends were assessed using annual percentage change in age-standardized rates and absolute counts.

Results: Between 1990 and 2021, the total number of deaths due to RA attributable to smoking increased from 1,791 (95% UI: 1,323–2,227) to 2,263 (1,509–2,911). During the same period, DALYs rose from 145,727 (102,543–200,899) to 215,779 (147,152–300,761), and YLDs increased from 102,310 (65,671–151,392) to 166,709 (107,433–247,042). From 1990 to 2021, smoking-attributable deaths due to RA declined in High SDI regions (APC: –1.04%) and High-income settings (–0.99%), while increasing in High-middle SDI regions (APC: +1.91%). In contrast, DALYs rose substantially in High-middle SDI regions (APC: +2.48%) and to a lesser extent in Central and Eastern Europe (+0.79%) and High-income regions (+0.18%), reflecting a shifting burden from mortality to chronic disability. By 2021, individuals aged 50–54 years recorded the highest burden with 21,342 DALYs and 16,213 YLDs, showing consistent increases since 1990 (APC: +0.84% and +0.96%, respectively). In 2021, females accounted for 57% of total DALYs and 61% of YLDs, with a slower decline in mortality rates compared to males (APC: –0.88% vs –1.15%).

Conclusion: In the last 3 decades, the global burden of RA attributable to smoking revealed a complex epidemiological shift—mortality declined in several high-income regions, while DALYs and YLDs rose markedly in Eastern Europe, Central Asia, and Southern Latin America. The disproportionate rise among midlife adults and females highlights a growing chronic

Geographic Trends in the Burden of Gout in the United States from 1990 to 2021: A State-Level Analysis of Prevalence, Incidence, and Disability

Eva Kalra[1], Drumadala Gajbhiye[2], Chandana Tummala[3] and Hardik Dineshbhai Desai[4], [1]Trident Medical Center, North Charleston, SC, [2]Government medical college Akola Maharashtra India 444001, Akola, India, [3]Internal Medicine, Vydehi Institute Of Medical Sciences and Research Centre, Whitefield-560066, Bangalore, Karnataka, India, Banglore, India, [4]Ahmedabad, Gujarat, India, 382350, Ahmedabad, India

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1877–1913) Epidemiology & Public Health Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Gout, a chronic inflammatory arthritis driven by hyperuricemia, has become an increasingly significant cause of disability in the United States. Despite therapeutic advances, its rising burden and geographic disparities remain poorly understood. This study quantifies the long-term trends in gout-related prevalence, incidence, and years lived with disability (YLDs) across all 50 U.S. states from 1990 to 2021.

Methods: We utilized the Global Burden of Disease (GBD) 2021 study framework to estimate gout-related prevalence, incidence, and years lived with disability (YLDs) across all U.S. states from 1990 to 2021. Data were stratified by sex and analyzed at the state level. To assess temporal trends, we calculated the annualized percentage change (APC).

Results: Nationally, from 1990 to 2021, the age-standardized prevalence rate of gout increased from 1,036 to 1,723 per 100,000, incidence rose from 140 to 230 per 100,000, and YLDs grew from 31.8 to 56.4 per 100,000. The corresponding national APCs were 1.61% for prevalence, 1.45% for incidence, and 1.87% for YLDs. State-level analysis revealed the highest APC in YLDs occurred in Mississippi (2.12%), Georgia (2.10%), and Hawaii (2.09%), while the lowest was observed in Minnesota (1.50%). For prevalence, Mississippi (2.17%) and Georgia (2.12%) again led, whereas Minnesota (1.55%) and Maine (1.58%) showed the slowest rise. Incidence rates saw the steepest increase in Wyoming (1.40%) and Mississippi (1.38%), with the smallest change in Minnesota (0.89%). Sex-specific analysis showed consistently higher rates and steeper increases in males compared to females across all measures.

Conclusion: The burden of gout has risen substantially across the U.S. over the past three decades, with marked geographic heterogeneity. Southern states like Mississippi and Georgia experienced the fastest growth across all indicators. These findings underscore the urgent need for targeted public health interventions and equitable access to preventive and therapeutic gout care in high-burden regions.

Impact of Systemic Lupus Erythematosus on In-Hospital Outcomes Following Percutaneous Coronary Intervention: Insights from a 7 year Nationwide Analysis

siddharth Agrawal[1], **Freya Shah**[1], Ritu Tated[2], Radhe Shah[3] and Mahir Modi[4], [1]landmark medical center, cumberland, RI, [2]New York Medical College, Vallaha, [3]Beth Israel Deaconess Medical Center, Boston, [4]GCS Medical College, hospital and Research Centre, Ahmedabad, India

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1877–1913) Epidemiology & Public Health Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background/Purpose: Systemic lupus erythematosus (SLE) is associated with systemic inflammation and heightened cardiovascular risk. However, the impact of SLE on outcomes following percutaneous coronary intervention (PCI) remains understudied. We aimed to evaluate in-hospital outcomes in SLE patients undergoing PCI.

Methods: We performed a retrospective analysis of the National Inpatient Sample from 2016 to 2022, identifying adult patients who underwent PCI. Patients were stratified based on the presence or absence of SLE. Multivariate logistic regression models adjusted for demographics, comorbidities, and hospital characteristics were used to assess outcomes. The primary outcome was in-hospital mortality; secondary outcomes included stroke, atrial fibrillation, heart failure, and bleeding complications.

Results: Of 3,132,560 PCI hospitalizations, 12,765 (0.4%) involved patients with SLE. Compared with non-SLE patients, SLE patients were younger, more likely to be female (78.7% vs 32.5%), and more often Black (23.5% vs 9.6%) (all p< 0.001). SLE patients had a higher prevalence of hypertension, anemia, chronic kidney disease, peripheral arterial disease,

Table 1. Baseline Characteristics of Patients Undergoing PCI, Stratified by SLE Status

Variable	No SLE (n=3,119,795)	SLE (n=12,765)	P-value
Age			<0.001
18–34 years	0.60%	2.32%	
35–49 years	9.57%	15.54%	
50–64 years	35.60%	41.90%

Table 2. Adjusted In-Hospital Outcomes for SLE vs Non-SLE Patients Undergoing PCI

Outcome	Adjusted Odds Ratio (OR)	95% Confidence Interval (CI)	P-value
Death	0.954	0.856–1.063	0.3905
Stroke	1.407	1.348–1.474	<0.001
Atrial Fibrillation	1.078	1.022–1.136	0.005
Heart Failure	1.023	0.983–1.066	0.281
Bleeding Complication	1.147	1.051–1.253	0.002

and coagulation disorders. There was no significant difference in adjusted in-hospital mortality between groups (OR 0.954, 95% CI 0.856–1.063, p=0.391). However, SLE was associated with higher odds of stroke (OR 1.407, 95% CI 1.348–1.474, p< 0.001), atrial fibrillation (OR 1.078, 95% CI 1.022–1.136, p=0.005), and bleeding complications (OR 1.147, 95% CI 1.051–1.253, p=0.002). No significant difference was observed in the incidence of heart failure.

Conclusion: Among patients undergoing PCI, SLE is associated with increased risks of stroke, atrial fibrillation, and bleeding, but similar in-hospital mortality compared to non-SLE patients. Focused risk mitigation strategies may improve outcomes in this high-risk population.

Abstract Number: 1893

Increased Atrial Fibrillation Risk in Rheumatoid Arthritis: Greater in Seropositive Than Seronegative Patients

Hyungjin Kim[1], Seonyoung Kang[2], Kyungdo Han[3], Jinhyung Jung[4], Seulkee Lee[5], Hoon-Suk Cha[5], Jaejoon Lee[6], Seonghye Kim[5] and Se Yun Kim[7], [1]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea, [2]Samsung Medical Center, Sungkyunkwan University School of Medicine, Gangnam-gu, Seoul, Republic of Korea, [3]Soongsil University, Seoul, Republic of Korea, [4]Sungkyunkwan University School of Medicine, Suwon, Republic of Korea, [5]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [6]Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [7]Sungkyunkwan University, Seoul, Republic of Korea

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The association between rheumatoid arthritis (RA) and cardiovascular disease (CVD) is well-established, with systemic inflammation as a potential mechanism. Although atrial fibrillation (AF) is the most common arrhythmia, the link between RA and AF has received less attention compared to other CVD traits like myocardial infarction and stroke.

This study aimed to examine the association between RA and incident AF in Republic of Korea, considering serostatus (seropositive RA [SPRA], seronegative RA [SNRA]) and the use of biologic or targeted synthetic DMARDs (b/tsDMARDs).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: This retrospective cohort study used the National Health Insurance Service database to include participants (aged ≥40 years) who were first diagnosed with RA between 2010 and 2017, had no previous AF, and who had a health checkup within 2 years before the index date (to collect covariate information). Matched non-RA controls were selected at a 1:3 ratio by age, sex, and index date. Participants were followed from 1 year after the index date until December 31, 2020, to mitigate surveillance bias.

Results: Totals of 48,885 RA patients (34,699 SPRA, 14,186 SNRA) and 146,655 matched controls were included. Patients with RA had a significantly higher risk of AF than did controls (adjusted hazard ratio [aHR] 1.55, 95% confidence interval [95% CI] 1.46-1.65). Both patients with SPRA (aHR 1.63, 95% CI 1.52-1.74) and SNRA (aHR 1.37, 95% CI 1.23-1.53) had a higher AF risk than did those without RA. Patients with SPRA had a higher risk compared to those with SNRA (aHR 1.19, 95% CI 1.02-6.34). The use of bDMARDs was associated with a slightly higher risk of AF, while tsDMARD use led to risk reduction but, non-statistical significant.

Conclusion: This study shows that both patients with SPRA and SNRA are at a significantly greater risk for AF compared to those without RA, with SPRA patients at the highest risk. The use of b/tsDMARDs might be associated with RA-related AF, but further studies are warranted to confirm this association and understand the underlying mechanisms.

Abstract Number: 1894

Opioid Use Disorder Among Patients with Rheumatic Conditions in the *All of Us* Research Program: A Descriptive Analysis

Jacob Riegler[1], Leah Santacroce[2], Karen H. Costenbader[3] and Candace Feldman[4], [1]Cambridge Health Alliance, Harvard Medical School, Somerville, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Harvard Medical School and Brigham and Women's Hospital, Boston, MA, [4]Brigham and Women's Hospital/ Harvard Medical School, Boston

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Opioid use disorder (OUD) is associated with high morbidity and mortality and in the U.S. in 2022, resulted in over 81,000 overdose deaths.[1] However, little is known about the prevalence of OUD in patients with rheumatic disease (RMD). Medications for OUD (MOUD; buprenorphine, methadone, naltrexone) are known to reduce mortality in OUD, yet no study has examined the use of MOUD in patients with RMD. This study had two primary objectives: to describe the population of patients with RMD with and without OUD and to assess use of MOUD in this population.

Methods: The data source used in this study was the All of Us Research Program (version 8), a national cohort consisting of electronic medical records for > 393,000 enrolled U.S. adults. We identified those with ≥2 ICD-9/10 or SNOMED codes for RA, SLE, spondyloarthritis (SpA), or osteoarthritis ≤ 2 years pre-enrollment. Patients with OUD were identified with ≥1 ICD 9/10 or SNOMED code for opioid dependence or abuse that occurred after the first code for RMD. Demographic characteristics (race, age at enrollment, sex at birth, insurance type), prevalent psychiatric disorders (bipolar disorder, schizophrenia, schizoaffective disorder, borderline personality disorder, depression, anxiety, and post-traumatic stress disorder),

Rheumatoid Arthritis	4,136 (11.6)	216 (14.4)	
Systemic lupus erythematosus	2,023 (5.7)	137 (9.1)	
Spondyloarthritis	588 (1.6)	30 (2.0)	
Psychiatric diagnoses [a,b], N (%)			<0.001
Bipolar disorder	2,007 (5.6)	285 (19.0)	
Schizophrenia	232 (0.6)	33 (2.2)	
Schizoaffective disorder	213 (0.6)	29 (1.9)	
Borderline personality disorder	138 (0.4)	28 (1.9)	
Depression	3,460 (9.7)	297 (19.8)	
Anxiety	7,875 (22.0)	739 (49.2)	
PTSD	1,544 (4.3)	165 (11.)	
Charlson comorbidity index [b], mean (SD)	1.9 (2.4)	3.1 (2.9)	<0.001
ER visits and inpatient admissions [b], mean (SD)	3.6 (9.3)	7.3 (14.5)	<0.001

*Chi square tests calculated for categorical variables and t tests calculated for continuous variables
[a] Cell sizes <20 suppressed per All of Us reporting requirements. Asian race was collapsed into the other category and obsessive-compulsive disorder was not shown here due to reporting guidelines.
[b] Catalogued ≤ 1 year prior to first opioid use disorder code

Charleson comorbidity index (CCI), and acute care utilization (emergency department [ED] visits, hospitalizations) ≤ 1 year prior to first OUD code were compared between patients with RMD with and without OUD. We identified a subset of patients with OUD codes and no prior MOUD use at any point prior to the first OUD code and examined differences in patient characteristics between those who received MOUD vs. did not in the subsequent period.

Results: Among 37,282 patients with RMD, we identified 1,502 (4%) with OUD billing codes (Table 1). Patients with vs. without OUD were younger, had more comorbidities, had higher acute care utilization, were more likely to have Medicaid insurance, and had a higher prevalence of psychiatric diagnoses, including psychotic and mood disorders. Patients with vs. without OUD were more likely to have RA, SLE, and SpA diagnoses. MOUD was initiated in 163/1121 (14.5%) patients. Patients who received vs did not receive MOUD were younger (mean (SD) age 55.6 (12.3) $p = 0.003$), had fewer comorbidities (CCI (SD) 2.6 (2.6) vs 3.3 (3.1) $p = 0.001$) more likely to be male (42.9% vs 27.7% $p < 0.001$), and were more likely to have PTSD (14.1% vs 8.7% $p = 0.04$).

Conclusion: In this nationwide population with RMD, we found demographic, clinical and psychiatric differences among patients with RMD with vs. without OUD. General population estimates of MOUD are around 25%, which is higher than in this RMD population.[1] Future research is needed to understand the barriers that exist for patients with RMD and OUD to receiving MOUD, the influence of social risk factors on development and treatment of OUD, and the role of increased screening for psychiatric disorders with comorbid OUD and RMD.

Abstract Number: 1895

Assessing the Validity of Self-reported Medication Data Through Metabolite Analysis: Data from the Osteoarthritis Initiative

Kate Lapane[1], Anne Hume[2], **Jeffrey Driban**[3], Shao-Hsien Liu[1], Timothy McAlington[4], Charles Eaton[5], Shike Xu[6] and Bing Lu[7], [1]UMass Chan Medical School, Worcester, MA, [2]College of Pharmacy, University of Rhode Island, Kingston, RI, [3]University of Massachusetts Chan Medical School, Marlborough, NH, [4]UMass Chan School of Medicine, Arlington, MA, [5]Brown University, Pawtucket, RI, [6]University of Connecticut Health Center, Farmington, CT, [7]UConn Health Center, Newton, MA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Pharmacotherapy, including non-steroidal anti-inflammatory agents (NSAIDs), is commonly used to alleviate symptoms of osteoarthritis (OA); however, these medications may increase the risk of adverse effects and drug interactions, especially in older adults taking multiple medications for other comorbid conditions. Accurate documentation of medication use in OA research is important and is often based on self-report. While self-reported medication use provides insights into real-world patterns of medication use, its validity in research studies remains largely unknown. In this study, we evaluated the validity of the Osteoarthritis Initiative's (OAI) medication inventory form by comparing self-reported use with metabolites or active ingredients measured in plasma.

Methods: The OAI had a structured protocol to collect detailed information on prescription medications. Participants were told to bring all medications used in the 30 days before each study visit. The study staff then recorded all the prescription medications. If a participant forgot to bring their medications, the interviewer relied on a medication list or conducted a follow-up call to complete the medication inventory form. Although drug metabolites and active ingredients were not routinely measured in the OAI, a case-cohort sub-study that included 465 participants had plasma assayed using liquid chromatography-tandem mass spectrometry. We calculated sensitivity, specificity, and kappa statistics for the most commonly reported medications with metabolite or active ingredient plasma levels.

Results: Among the 465 participants, 301 (65%) were females, 197 (42%) had frequent knee pain, and the mean age was 60 years (SD=9) with a mean body mass index of 27.8 kg/m^2 (SD=4.6). Table 1 shows strong agreement between self-report and presence of metabolites for antihypertensive medications (e.g., hydrochlorothiazide κ=0.71) and anti-diabetic medications (e.g., metformin κ=0.97), with sensitivity exceeding 85% and specificity exceeding 90%. For NSAIDs, we found strong agreement for celecoxib (κ=0.94), but not naproxen (κ=0.42) or ibuprofen (κ=0.23). While specificity was high for celecoxib, naproxen, and ibuprofen (>97%), sensitivity was high only for celecoxib.

Table. Sensitivity, Specificity, and Kappa Agreement of Self-reported Medication Use and Detectable Presence of Metabolite/Active Ingredients

Table. Sensitivity, Specificity, and Kappa Agreement of Self-reported Medication Use and Detectable Presence of Metabolite/Active Ingredients

	Self-reported	Detectable Presence of Metabolite/Active Ingredient Yes	No	Prevalence of self-reported use	Sensitivity	Specificity	Kappa (95% CI)
					Percentages		
Hydrochlorothiazide	Yes	62	31	20.0	87.3	92.1	0.71 (0.62-0.79)
	No	9	363				
Atenolol	Yes	30	2	6.9	100.0	99.5	0.97 (0.92-1.00)
	No	0	433				
Metformin	Yes	20	0	4.3	95.2	100	0.97 (0.92-1.00)
	No	1	444				
Celecoxib	Yes	24	3	5.8	100.0	99.3	0.94 (0.87-1.00)
	No	0	438				
Naproxen	Yes	17	2	4.1	30.9	99.5	0.42 (0.28-0.57)
	No	38	408				
Ibuprofen	Yes	6	11	3.7	19.4	97.5	0.23 (0.11-0.36)
	No	25	423				
Omeprazole	Yes	12	5	3.7	40.0	98.9	0.49 (0.31-0.67)
	No	18	430				

Note. 95% CI = 95% confidence interval

Conclusion: The validity of self-reported medication use in the OAI varied by medication. Sensitivity and agreement were high for some medications but lower for others. The three medications with low sensitivity were the only ones we examined that were available over the counter at the baseline visit (2004-2006). Specificity was high across all medications. These findings highlight the need to consider potential misclassification for specific drug classes when using the data from the OAI medication inventory, as some classes offer more reliable and higher accuracy of self-reported medication use than others.

Abstract Number: 1896

Electronic Cigarette Use in Association with Risks of Developing Rheumatoid Arthritis or Systemic Lupus Erythematosus in the All of Us Research Program

Jeong Yee[1], Emily Oakes[2], Candace Feldman[3] and Karen H. Costenbader[4], [1]Sungkyunkwan University, Suwon, MA, South Korea, [2]Brigham and Women's Hospital, Boston, MA, [3]Brigham and Women's Hospital/ Harvard Medical School, Boston, [4]Harvard Medical School and Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Electronic cigarettes, or e-cigarettes, are inhalable aerosol nicotine-delivery devices increasingly used in addition or in place of cigarettes. Cigarette smoking is strongly associated with an at least ~1.5-fold increased risk of both rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). The association of e-cigarettes with RA and SLE risk has not been well studied, however. We investigated e-cigarette use and risks of developing RA or SLE in a nationwide US cohort.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We used data from the All of Us Research Program (version 8), comprised of >393,000 U.S. adults with linked electronic health records. Using a matched cohort design, we identified participants with baseline self-reported ever use of e-cigarettes, including electronic nicotine products such as vape pens and hookah pens. We created a cohort matched on age, sex at birth, race/ethnicity, enrollment year, and cigarette smoking status, without any e-cigarette use. The primary outcome was RA or SLE, identified by ≥ 2 ICD9, ICD10, or SNOMED codes. After excluding those with RA or SLE pre-enrollment, individuals were followed from enrollment until 1st occurrence of RA or SLE, death, end of study period (October 1, 2023), or up to 5 years, whichever occurred first. We estimated incidence rates (IRs) and an incidence rate ratio (IRR) and plotted the cumulative incidence curves. Stratified and interaction analyses by cigarette smoking status were performed.

Results: We identified 60,285 e-cigarette users and 60,285 matched non-users (**Table 1**). The mean age was 40 (SD 14) years and 40% were male; 65% were ever smokers. A total of 271 cases developed among e-cigarette users in 182,978 person-years (IR 1.48 [95% CI 1.31-1.67]) vs 239 incident cases among matched non-users in 186,127 person-years (IR 1.28, 95% CI 1.13-1.46; IRR 1.15 [95% CI: 0.97-1.37]). E-cigarette users had a not statistically significant higher risk of RA or SLE (p 0.1, **Figure 1**). In analyses stratified by smoking status, a similar trend was observed among smokers, while

Table 1. Baseline Characteristics of Study Population in the All of Us Research Program (version 8) by Baseline Self-Report of E-Cigarette Use

	E-Cigarette User Cohort (n=60,285)	Matched E-Cigarette Non-user Cohort (n=60,285)
***Age**, mean years (SD)	39.9 (14.5)	40.9 (14.4)
***Male at birth**, N (%)	24,347 (40.4)	23,687 (39.3)
***Self-reported Race/Ethnicity**, N (%)		
Black	8,853 (14.7)	10,708 (17.8)
Hispanic	11,561 (19.2)	12,037 (20.0)

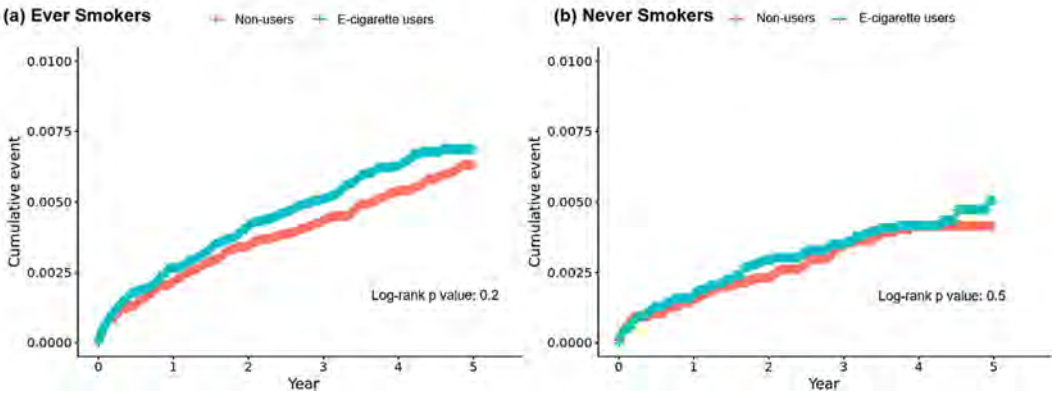
Figure 2. Cumulative incidence curves for the time to rheumatoid arthritis or systemic lupus erythematosus between e-cigarette users and non-users within the All of Us Research Program (version 8), stratified by smoking status. (a) Smokers. (b) Non-smokers.



the risk of RA or SLE was comparable between e-cigarette users and non-users among non-smokers (**Figure 2**). No statistically significant interaction according to smoking status was observed on either the additive or multiplicative scale.

Conclusion: Our findings suggest that e-cigarette users may have a slightly higher risk of developing RA or SLE vs. non-users, especially in smokers. Key considerations in interpreting these results include that a substantial proportion of e-cigarette users were smokers, a known risk factors for RA and SLE itself and the intensity of smoking and e-cigarette use were not well captured by the survey. E-cigarette users were also younger, although we matched by age to limit age-related bias. Further studies are warranted, particularly those assessing the amount, frequency, or duration of e-cigarette use.

Abstract Number: 1897

Changes in SLE Mortality During and After the COVID-19 Pandemic

Laura Hernandez[1] and Ram Singh[2], [1]University of California, Los Angeles, Murrieta, CA, [2]UCLA David Geffen School of Medicine, Los Angeles, CA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) are vulnerable to infections due to both underlying immune dysfunction and the use of immunosuppressive therapies. Hence, it was assumed that patients with SLE would experience disproportionately poor outcomes during the COVID-19 pandemic. We aimed to evaluate changes in SLE mortality in relation to the COVID-19 pandemic: before (2018–2019), during (2020–2022), and after (2023); and to assess whether these trends differed from all-cause mortality.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Age standardized mortality rates for SLE before (2018-2019), during (2020-2022), and after (2023) the COVID-19 pandemic.

Methods: We retrieved mortality data for SLE from the CDC national mortality database, and calculated age-standardized mortality rates (ASMRs) per million population with 95% confidence intervals (CI), overall and by race/ethnicity, age group (≤44, 45–64, ≥65 years), sex, and U.S. census region (Northeast, Midwest, South, West) across three time periods: pre-pandemic (2018–2019), during the pandemic (2020–2022), and post-pandemic (2023). We repeated these analyses for all-cause deaths other than SLE (non-SLE). We then computed ratios of SLE ASMR to non-SLE ASMR to contextualize lupus mortality within overall general population mortality trends. We performed percent change calculations between the three periods.

Results: SLE-ASMR increased from 6.1 per million (95% CI, 5.9–6.3) pre-pandemic to 7.1 (95% CI: 6.9–7.2) during the pandemic, before declining to 5.8 (95% CI: 5.5–6.0) post-pandemic. Non-SLE ASMR followed a similar trend, however, non-SLE ASMR remained significantly elevated post-pandemic compared to pre-pandemic levels. Consequently, the ratio of SLE-ASMR to non-SLE-ASMR continued to decline from the pre-pandemic to pandemic years (by 0.83%) and from the pandemic to post-pandemic years (by 8.71%). This trend was seen in all subpopulations by race/ethnicity, age, sex, and geographic region, except in individuals aged ≥65 years and those living in the South census region of the U.S. that experienced increases in the ratio.

Conclusion: This nationwide analysis shows that SLE mortality did not increase disproportionately during the COVID-19 pandemic, and that it declined more than the all-cause mortality after the pandemic. However, certain subgroups including older individuals and people in the South, experienced relatively higher SLE mortality during the pandemic. Further analyses of reasons underlying these trends, including the precise identification of subpopulations in the South that had the highest SLE mortality during the pandemic, would have implications for managing these at-risk subpopulations during future viral outbreaks and medical emergencies.

Abstract Number: 1898

Assessing Representation in a Nation-wide Psoriasis Registry: A Single-institution Comparison

Evelyn Fagan[1], Joseph McGrath[1], Calla Sullivan[1], **Mackenzie Kilton**[1], Kaeli Samson[2], Kaleb Michaud[3] and Sarah Lonowski[1], [1]University of Nebraska Medical Center Department of Dermatology, Omaha, NE, [2]University of Nebraska Medical Center Department of Biostatistics, Omaha, NE, [3]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Ensuring that data registries include a representative sample is crucial for obtaining findings that can be generalized to the larger population. This comparative observational study sought to determine whether participants with psoriasis and psoriatic arthritis, enrolled in the FORWARD Psoriasis Registry, reflect the broader invited population at a single institution.

Table 1. Demographic Characteristics and Comorbidities in Enrolled and Invited Psoriasis FORWARD Registry Groups

	Enrolled (n=113)	Invited (n=804)	P-value
Age			0.004[1]
Mean (SD)	48.8 (15.7)	53.5 (16.3)	
Median (IQR)	48.0 (36.0, 61.0)	54.0 (41.0, 67.0)	
Sex, n (%)			0.400[2]
Male	41/113 (36.3%)	325/804 (40.4%)	
Female	72/113 (63.7%)	479/804 (59.6%)	
Race, n (%)			0.801[2]
White	103/112 (92.0%)	722/791 (91.3%)	
Non-white	9/112 (8.0%%)	69/791 (8.7%)	
Ethnicity, n (%)			0.413[2]
Non-Hispanic	105/112 (93.8%)	764/800 (95.5%)	
Hispanic	7/112 (6.3%)	36/800 (4.5%)	
Rurality, n (%)			0.589[2]
Urban	104/113 (92.9%)	750/803 (93.4%)	
Rural	9/113 (8.0%)	53/803 (6.6%)	
Insurance			0.013[2]
Medicare	23/113 (20.4%)	262/781 (33.5%)	
Medicaid	9/113 (8.0%)	39/781 (5.0%)	
Private	81/113 (71.7%)	480/781 (61.5%)	
Smoking status, n (%)			0.168[2]
Non-Smoker	64/113 (56.6%)	423/800 (52.9%)	
Current	7/113 (6.2%)	98/800 (12.3%)	
Former	42/113 (37.2%)	279/800 (34.9%)	
Comorbidities			
Obesity, n (%)	59/113 (52.2%)	398/798 (49.9%)	0.642[2]
Hypertension, n (%)	51/113 (45.1%)	374/804 (46.5%)	0.782[2]
Hyperlipidemia, n (%)	43/113 (38.1)	358/804 (44.5%)	0.194[2]
Thromboembolic event, n (%)	9/113 (8.0%)	82/804 (10.2%)	0.457[2]
Diabetes, n (%)	18/113 (15.9%)	167/804 (20.8%)	0.230[2]
Psoriatic arthritis, n (%)	30/113 (26.5%)	136/804 (16.9%)	0.013[2]

[1]Equal variance two sample t-test p-value; [2]Chi-Square p-value

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Methods: The FORWARD Psoriasis Registry is a multi-institutional, prospective U.S. study collecting patient-reported outcomes via online questionnaires.1 Patients with "psoriasis" documented in their medical record were invited to the registry via email. Enrollment status was tracked, and medical records were reviewed for demographics, comorbidities, dermatology visits, and current and past psoriasis therapies. Patients without a confirmed psoriasis diagnosis were excluded. Chi-squared, Fisher's Exact, Wilcoxon rank sum, and equal variance t-tests were used to compare enrolled and non-enrolled groups.

Results: Of 917 patients invited, 113 enrolled (12%) and 804 (88%) did not. Enrollees were younger than non-enrollees (mean age 48.8 vs. 53.5; p=0.004), and insurance type varied significantly between groups (p=0.013). Enrollees had a higher proportion of private insurance while non-enrollees were more likely to have Medicare. Enrollees and non-enrollees did not differ across other demographic variables. Rates of obesity, hypertension, hyperlipidemia, thromboembolic events, and diabetes were not significantly different between groups. However, psoriatic arthritis was more common among enrollees (26.5% vs. 16.9%; p=0.013) (Table 1). Plaque psoriasis was the most common psoriasis phenotype among both enrollees and non-enrollees, and the proportion of those with plaque psoriasis did not vary between groups (p=0.455). The use of topical and biologic therapy did not differ between groups, though there was a significantly greater proportion of enrollees who utilized non-biologic systemic therapy in the past (34.5% vs. 24.9%; p=0.029) (Table 2).

Table 2. Psoriasis Phenotype and Therapy Usage in Enrolled vs. Invited Psoriasis FORWARD Registry Groups

	Enrolled (n=113)	Invited (n=804)	P-value
Phenotype			0.455[1]
Plaque psoriasis	88/107 (82.2%)	622/786 (79.1%)	
All other types	19/107 (17.8%)	164/786 (20.9%)	
Guttate	3/107 (2.8%)	26/786 (3.3%)	
Pustular	6/107 (5.6%)	14/786 (1.8%)	
Inverse	1/107 (0.9%)	31/786 (3.9%)	
Sebopsoriasis	2/107 (1.9%)	60/786 (7.6%)	
Erythrodermic	0/107 (0.0%)	1/786 (0.1%)	
Isolated nail psoriasis	0/107 (0.0%)	4/786 (0.5%)	
Multiple	7/107 (6.5%)	28/786 (3.6%)	
Therapy			
Current use of topicals	101/113 (89.4%)	684/796 (85.9%)	0.317[1]
Previous use of topicals	2/111 (1.8%)	756/793 (95.3%)	0.215[2]
Current use of biologics	38/113 (33.6%)	202/797 (25.3%)	0.061[1]
Previous use of biologics	43/112 (38.4%)	250/795 (31.4%)	0.141[1]
Current use of non-biologic systemics	19/113 (16.8%)	89/796 (11.2%)	0.082[1]
Previous use of non-biologic systemics	39/113 (34.5%)	200/796 (25.1%)	0.029[1]
Total # of biologics			0.081[3]
Mean (SD)	2.2 (1.48)	1.9 (1.29)	
Median (IQR)	2.0 (1.0, 3.0)	1.0 (1.0, 2.0)	
Total # of non-biologic systemics			0.029[3]
Mean (SD)	1.7 (0.98)	1.3 (0.63)	
Median (IQR)	1.0 (1.0, 2.0)	1.0 (1.0, 2.0)	
Number of UNMC/NM dermatology visits			0.638[3]
Mean (SD)	4.5 (3.68)	4.5 (3.61)	
Median (IQR)	4.0 (2.0, 6.0)	4.0 (2.0, 6.0)	
Days since last dermatology visit			0.039[3]
Mean (SD)	266.3 (233.26)	309.8 (240.62)	
Median (IQR)	205.0 (108.0, 341.5)	226.0 (125.0, 423.5)	

[1]Chi-Square p-value; [2]Fisher Exact p-value; [3]Wilcoxon rank sum p-value

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Conclusion: Enrollees were broadly representative of those who were invited across demographic and cardiometabolic variables, though they were younger, had a higher prevalence of psoriatic arthritis, and were more likely to have tried non-biologic systemic therapy previously. This bias may reflect higher levels of participation among patients who are more comfortable with the registry's online format and may indicate that patients with multisystem (i.e. skin and joint) disease are more motivated to participate in research registries. Overall, the study suggests findings from this institution's FORWARD psoriasis registry can be generalized to the broader psoriasis population if these important differences are taken into account in future research.

SESSION INFORMATION

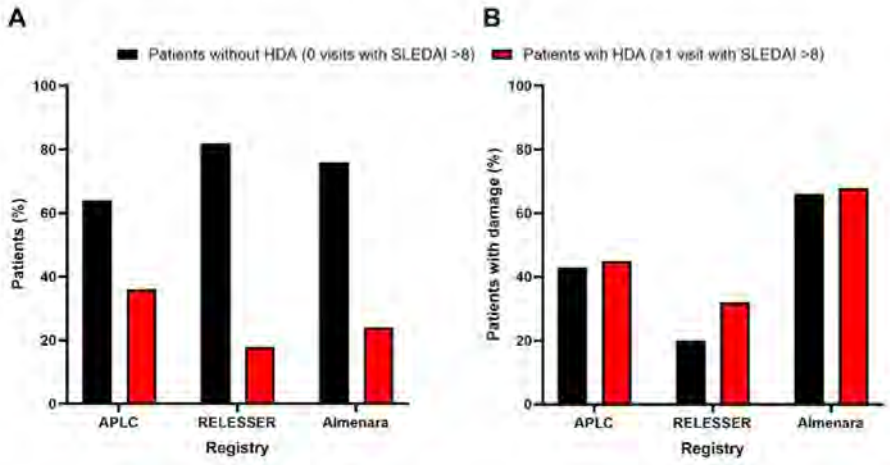
Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: SLE is characterized by heterogeneous clinical presentation and periods of flare and remission, with variation in management globally. A goal for SLE management is to achieve and maintain remission or low disease activity to minimize long-term accrual of organ damage. This goal of this study is to assess the frequency, severity, and accrual of damage in patients with SLE as a function of disease activity using LupusNet, the largest existing federated data network in SLE. LupusNet combines and harmonizes data from 5 existing SLE registries, which enables data consistency and enhances understanding of global clinical presentations and outcomes of SLE.

Methods: Data from patients with ≥3 years of follow-up and ≥3 follow-up visits in 3 of 5 LupusNet registries, APLC (Asia Pacific), RELESSER (Europe), and Almenara (South America), were analyzed using a privacy-preserving federated data network approach where only aggregated results were shared. Disease activity was assessed using SLEDAI (recorded at least once a year) and organ damage was measured using SLICC Damage Index (SDI score >0). High disease activity (HDA) was defined as a SLEDAI score >8 at ≥1 visit. The proportion of patients experiencing HDA over the 3-year observation period and the presence of organ damage were reported.

Results: A total of 5019 patients from LupusNet were included. At baseline, 34%, 41%, and 48% of patients had damage in APLC, RELESSER, and Almenara, respectively. At any time over the 3-year follow up, 36% of patients in APLC, 18% in RELESSER, and 24% in Almenara experienced HDA; after 3 years, damage occurred in 44% of patients in APLC, 23% in RELESSER, and 66% in Almenara, and was similar between patients with HDA (32%-68%) and without HDA (20%-66%) across cohorts (**Figure 1**). However, renal, ocular, and skin damage were more prevalent in patients who experienced HDA compared to those without HDA (**Figure 2**). Regional variations were evident in the types of organ damage observed, with renal and musculoskeletal damage being consistently prominent across regions. Notably, ocular damage was more prevalent in RELESSER, while gastrointestinal damage was more prevalent in Almenara. The prevalence of most types of

Figure 1. Proportion of Patients (A) with HDA and without HDA and (B) Presence of Damage (SDI score >0) by HDA over 3 Years of Follow-up.



Almenara, Almenara Lupus Cohort; APLC, Asia Pacific Lupus Collaboration; HDA, high disease activity; RELESSER, Lupus Register of the Spanish Society of Rheumatology; SDI, SLICC Damage Index.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Proportion of Patients with SDI Organ Damage by Disease Activity Over Follow Up.

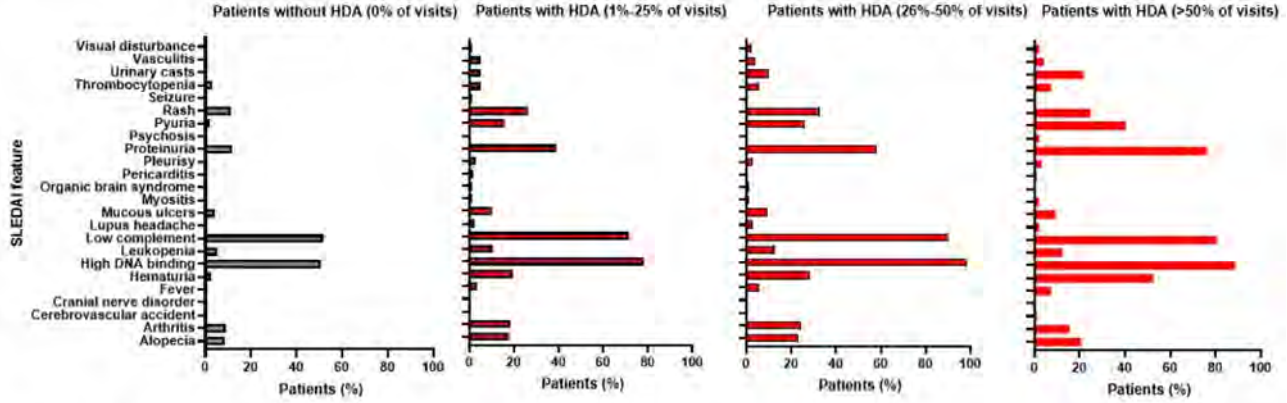
Almenara, Almenara Lupus Cohort; APLC, Asia Pacific Lupus Collaboration; HDA, high disease activity; RELESSER, Lupus Register of the Spanish Society of Rheumatology; SDI, SLICC Damage Index.

Figure 3. Proportion of Patients with SLEDAI Features by Disease Activity Over Follow-up.



HDA, high disease activity.

organ damage was lower in APLC compared to Almenara and RELESSER. When analyzed by the proportion of visits with HDA, patients who had SLEDAI >8 at more visits exhibited higher rates of proteinuria, haematuria, urinary casts, and pyuria compared to patients without visits with SLEDAI >8. Low complement and high DNA binding were commonly observed irrespective of disease activity (**Figure 3**).

Conclusion: Despite the well-known link between disease activity and damage accrual, this analysis revealed similar overall rates of damage between patients with and without HDA. However, renal, ocular, and skin damage were more prevalent in patients with HDA. Moreover, regional variations in damage types underscore the complexity of SLE. These findings provide further insights into damage accrual as a function of disease activity in patients with SLE, highlighting the impact of disease activity on certain types of damage and the need for further research to identify factors driving these disparities.

Abstract Number: 1900

Capturing Patient Cohorts: A Temporal Arteritis Classifier

Megan Sullivan[1], Joseph Rosen[1], Christopher Grilli[1], Kenneth Warrington[2] and Victor E Ortega[1], [1]Mayo Clinic Arizona, Scottsdale, AZ, [2]Mayo Clinic, ROCHESTER, MN

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Giant cell arteritis (GCA) is a granulomatous vasculitis affecting cranial and large arteries in individuals over 50 years of age. Its relative rarity poses challenges for large-scale study. Institutional electronic medical record (EMR) datasets offer opportunities to examine GCA at scale but are often hindered by unstructured data formats. To address this, we developed a natural language processing (NLP) pipeline to classify temporal artery biopsy reports as positive or negative for arteritis.

Methods: Patients seen within our tri-site single-center institution with an ICD code consistent with GCA or polymyalgia rheumatica were identified. Temporal artery biopsy impression statements authored by pathologists were extracted and preprocessed using a custom regular expression script to remove Rich Text Formatting, standardize punctuation, and convert text to lowercase. These statements were then tokenized and input into a fine-tuned ClinicalBERT model[1] (MedicalAI, Hugging Face). The dataset was split 80:20 into training and testing sets, with further subdivision of the training set for validation. The dataset used to train the model consisted of 349 negative and 137 positive samples. "Healed arteritis" in the report was considered a negative biopsy result. Data augmentation was implemented following initial training with

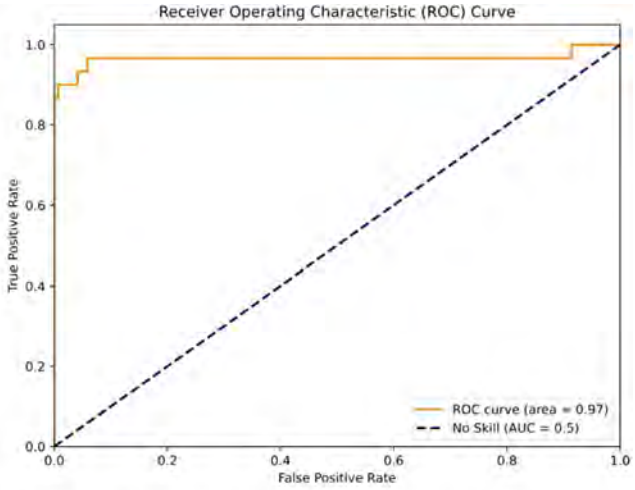

Figure 1 - Discrimination performance of the model in a receiver operating characteristic curve

Table 1 - Model Prediction Metrics

Metrics	Estimate
Total Validation Cohort	320
Total Correct Predictions	315
True Positives	26
False Positives	1
True Negatives	289
False Negatives	4
Performance	
Accuracy	0.98
Precision	0.96
Recall	0.87
F1	0.91

5 augmented impression reports added to the training dataset to enhance model performance. Discrimination performance was assessed using the area under the receiver operating characteristic curve (AUC).

Results: The validation cohort, consisting of 320 patient records (30 positive entries and 290 negatives), was able to provide significant discrimination of positive temporal artery biopsies with an area under the curve of 0.97 **(Figure 1)**, accuracy of 98%, precision of 96%, and recall of 87%. Of the predictions, 315/320 (98.4%) were correct. This amounted to 5 misclassifications within the dataset, which included 1 false positive and 4 false negatives (**Table 1)**.

Conclusion: Fine-tuned language models trained on clinical text can accurately classify pathology reports, offering a scalable approach to identifying specific diagnoses within large EMR datasets. This method improves the accuracy and utility of cohort identification for rare conditions such as GCA, supporting future research efforts.

Abstract Number: 1901

Epidemiology of Adult-Onset Still's Disease in South Korea: A Nationwide Study Using Health Insurance Claims Data

Mihye Kwon[1], Younghee Jung[2], Chung-il Joung[1] and Jeeyoung Hong[1], [1]Konyang University Hospital, Daejeon, Republic of Korea, [2]Chungnam National University Hospital, Daejeon, Republic of Korea

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1877–1913) Epidemiology & Public Health Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Adult-onset Still's disease (AOSD) is a rare systemic autoinflammatory disorder characterised by heterogeneity in clinical course and long-term outcomes. Despite its rarity being recognised globally, population-based epidemiologic studies estimating the incidence, prevalence, and mortality of AOSD remain extremely limited. This study aimed to estimate the national incidence, prevalence, and mortality of AOSD and to describe the demographic and clinical characteristics of affected individuals in South Korea.

Methods: We identified AOSD patients using the Korean National Health Insurance Service (NHIS) database from 2002 to 2022, applying the ICD-10 diagnostic code in conjunction with characteristic patterns of hospital utilisation and medication prescription. To improve diagnostic specificity, individuals with coexisting autoimmune diseases or malignancies diagnosed within three months before or after the first AOSD claim were excluded. Age- and sex-adjusted incidence and prevalence rates per 100,000 population were calculated annually, and temporal trends were assessed. Using operational definitions, disease courses were categorised into monocyclic, polycyclic, and chronic patterns.

Table 1. Baseline demographic and clinical characteristics of South Korean AOSD patients (2003-2020) using 3 year-incidence

Characteristics	Total	2003-2005	2006-2008	2009-2011	2012-2014	2015-2017	2018-2020

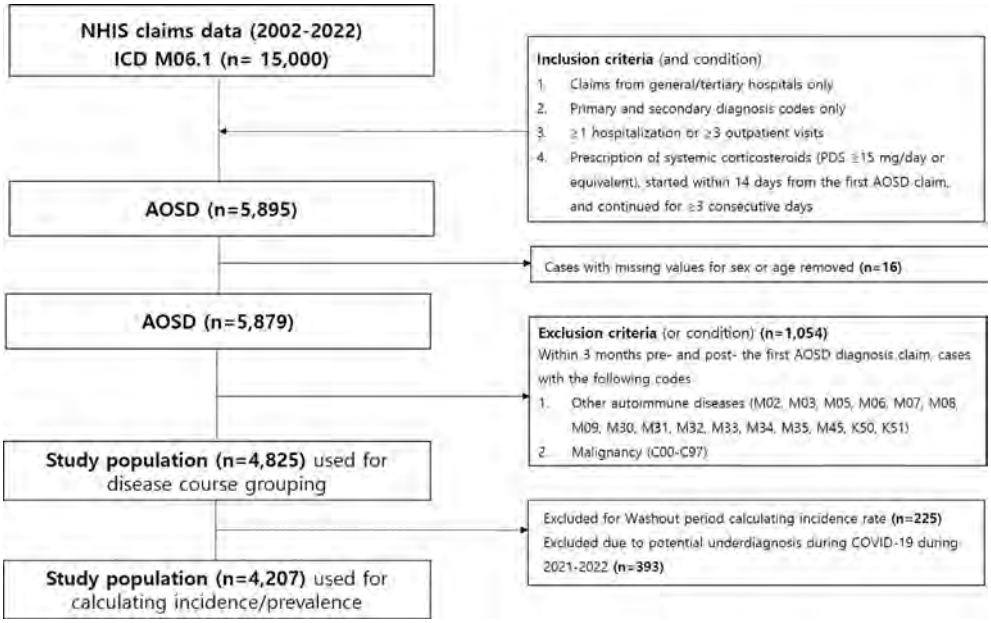

Figure 1. A flow chart for defining study population.

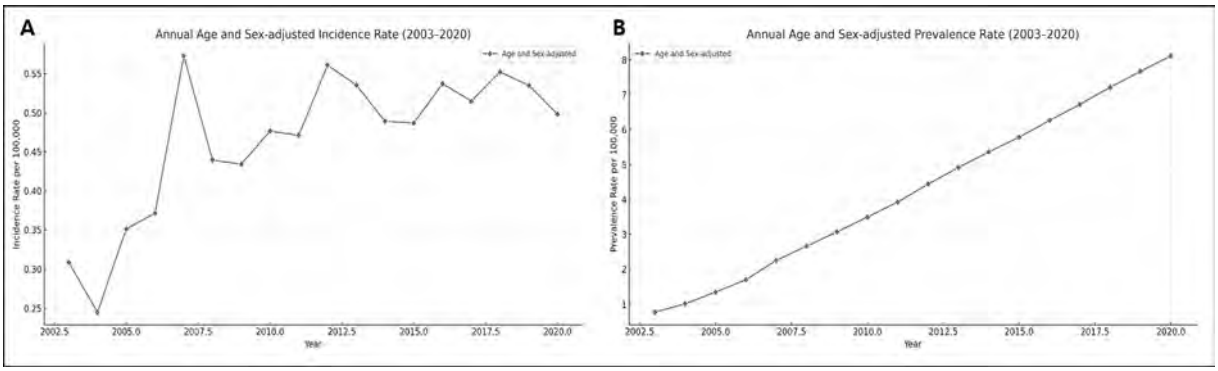

Figure 2. Annual age-, sex- adjusted incidence and prevalence of AOSD in South Korea 2003-2020

Results: A total of 4,825 patients met the criteria for AOSD, and 4,207 patients diagnosed between 2003 and 2020 were included in the final analysis. The overall age- and sex-adjusted incidence and prevalence rates across the study period were 0.49 and 4.25 per 100,000 population, respectively. Annual incidence rates showed a gradually increasing trend from 0.32 in 2003 to 0.50 in 2020, with slight fluctuations across years. The female-to-male ratio was 2.56, and the mean age at diagnosis was 45.5 ± 16.7 years. Based on disease course classification, 1,867 patients (38.7%) had a monocyclic course, 1,197 (24.8%) polycyclic, and 1,761 (36.5%) chronic. During the observation period, 376 patients died, among whom 8 deaths were attributed to macrophage activation syndrome (MAS), the most severe complication of AOSD.

Conclusion: Leveraging 21 years of longitudinal, nationwide claims data, this study provides the first comprehensive national estimates of the incidence, prevalence, and mortality of AOSD in South Korea. Our findings confirm that AOSD remains a rare disease with persistently low incidence and increasing prevalence, mirroring international observations. These data underscore the value of long-term epidemiologic surveillance and may inform future research and health policy planning related to rare systemic autoinflammatory disorders.

Abstract Number: 1902

Investigating Factors Associated With Respiratory Syncytial Virus Vaccination and Breakthrough Infection Among Patients With Systemic Autoimmune Rheumatic Diseases

Natalie Davis[1], Jiaqi Wang[2], Xiaosong Wang[3], Liya Sisay Getachew[4], Lauren O'Keeffe[5], Grace Qian[5], Kevin Mueller[5], Madison Negron[6], Alene Saavedra[5], Naomi Patel[7] and Jeffrey Sparks[4], [1]Brigham and Women's Hospital, Brookline, MA, [2]Massachusetts General Hospital, BOston, [3]Brigham and Women's Hospital, Natick, MA, [4]Brigham and Women's Hospital, Boston, MA, [5]Brigham and Women's Hospital, Boston, [6]Harvard Extension School, Medford, MA, [7]Massachusetts General Hospital, Boston, MA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1877–1913) Epidemiology & Public Health Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Respiratory syncytial virus (RSV) vaccines were approved starting in May 2023 and are recommended by the US CDC to adults aged 60 years or older at increased risk for poor outcomes, including immunocompromising conditions or medications. We previously showed that RSV is associated with poor outcomes and high rates of hospitalization in people with systemic autoimmune rheumatic diseases (SARDs), but less is known about RSV vaccine uptake among individuals with SARDs. Therefore, we described the prevalence, associations, and breakthrough infection of RSV vaccination among people with SARDs.

Methods: We performed a retrospective, cross-sectional study in a US tertiary healthcare system. We identified patients with 2 or more SARD codes and who were prescribed a DMARD or oral glucocorticoid as of February 2025 (positive predictive value 95%). We excluded patients who had died or whose last encounter was on or before May 2023 and those less than 60 years of age on the last day of observation or at time of RSV vaccination. The primary outcome was RSV vaccination documented in the electronic health record. We evaluated factors associated with RSV vaccination and used multivariable logistic regression to assess for associations. We then described breakthrough infections with positive testing after RSV vaccination.

Results: We analyzed 10,587 SARD patients aged 60 years or older at the time of RSV vaccination or the date of last observation (median age 71.7 years, 72.4% female, and 88.0% White; **Table 1**). The most common SARD type was RA (56.8%), and the most common medications were conventional synthetic DMARDs (40.8%). We identified 1,075 people with SARDs (10.2%) who received the RSV vaccine. There was no association of any SARD type with RSV vaccination after adjusting for general population factors that included demographics, comorbidities, area-level income, serious infection, and other vaccine receipt (**Table 2**). Influenza vaccine receipt in the previous year had the strongest association with RSV vaccination (no vs. yes OR 0.021, 95%CI 0.018 to 0.026). No DMARD class was significantly associated with RSV vaccination. CD20 inhibitor use had an OR for RSV vaccination of 0.78 (95%CI 0.45 to 1.36) compared to antimalarial monotherapy. Glucocorticoid users were less likely (OR 0.33, 95%CI 0.23 to 0.49) and interstitial lung disease was more likely (OR 1.53, 95%CI 1.14 to 2.04) to receive RSV vaccination. We identified 9 cases of breakthrough RSV infections, occurring a median of 301 days after vaccination (**Table 3**).

Conclusion: Among patients with SARDs aged 60 years or older, 10.2% were documented to receive RSV vaccination. After accounting for general population factors, glucocorticoid users were less likely to receive RSV vaccination. Neither SARD type nor DMARD class, including CD20 inhibitors, were associated with RSV vaccination. Only 2 of 9 documented

Abstract Number: 1903

Seasonal and Racial/Ethnic Variation in Achieving Target Uric Acid Levels in Gout Patients on Urate Lowering Therapy in US Veterans in Central California

Nidaa Rasheed[1] and Candice Reyes[2], [1]UCSF Fresno, Fresno, CA, [2]VACCHCS, Fresno, CA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Gout is a chronic, inflammatory arthritis driven by monosodium urate (MSU) crystal deposition and elevated serum uric acid (SUA) levels, increasing the risk for cardiometabolic comorbidities and premature mortality. While gout and hyperuricemia result from complex gene-environment interactions, emerging evidence suggests that disparities in gout outcomes across racial/ethnic groups are more strongly influenced by social determinants of health than genetic factors. While prior studies have largely focused on differences in gout diagnosis and initiation of urate-lowering therapy (ULT), there is limited data on factors influencing long-term disease control. This project examined racial/ethnic and seasonal differences in maintaining target SUA (< 6 mg/dL) among patients on ULT to better understand non-genetic drivers of disease progression.

Methods: We analyzed data from the San Francisco Quality Enrichment Research Initiative, comprising 747 U.S. veterans in Central California with physician-diagnosed gout on ULT from 1999 to 2023. We excluded patients who declined to report race/ethnicity, were of mixed origin, or lacked recent SUA testing. Seasonal variation was assessed using the subset of patients with ULT and SUA measurements in 2023.

Results: Of the 386 self-identified Caucasian patients, 103 (27%) achieved target SUA, compared to 348 patients identifying as persons of color (POC) (African American, Hispanic/Latinx, Asian, American Indian, Native Hawaiian), of whom only 76 (22%) were at target SUA. African American patients were particularly affected, with just 30% achieving target levels. Overall, POC patients were significantly less likely to reach target SUA despite appropriate ULT [Odds ratio 0.61, 95% CI 0.412-0.899, P = 0.0063].

Figure 1. Weekly average proportion (%) of patients on ULT with uric acid labs at target (UCL = upper collection limit and LCL = lower collection limit) in the 2023 year

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Seasonal analysis revealed a notable decline in target SUA achievement in the spring and early summer, with only 38% of patients reaching goal, compared to other times of the year [Figure 2]. This seasonal effect highlights the potential impact of environmental factors like heat, dehydration, and air pollution, particularly in regions like the Central Valley, known for severe particulate and ozone pollution.

Conclusion: Our findings emphasize the need to move beyond one-size-fits-all gout management and consider the complex interplay of racial/ethnic and environmental factors that influence disease control. Providers should account for the broader social and environmental contexts, including housing location, humidity, seasonal changes, and air quality, as they may contribute to elevated SUA and increased flare risk. Addressing these factors could improve outcomes for historically marginalized groups and reduce the overall burden of gout.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Interstitial lung disease (ILD) is a prevalent feature among patients suffering from connective tissue diseases (CTD), associated with considerable morbi-mortality. Nonetheless, this complication is still poorly defined in our field.

The purpose of this work is to assess the main characteristics of CTD-ILD in our area.

Methods: An ambispective regional registry (NIRRVANA Registry: Neumopatía Intersticial en Reumatología Registro VAsco-NAvarro) of CTD-ILD was conducted in the Basque Country and Navarre, Spain. Adult patients with ILD associated with aPLS, IIM, MCTD, RA, sarcoidosis, SjS, SLE, SSc, UCTD and vasculitis (classification criteria or clinician's judgment) were included, as well as patients meeting criteria for IPAF.

Data on demographics, clinical, radiological and anatomo-pathological features, laboratory results, and outcomes were collected.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Statistical analyses were conducted using standardized tests.

Results: One hundred and thirty-one patients were indentified (87 female, 44 male), with a median disease duration of 6.66 (2.72-13.49) years for CTDs.

RA (26.7%), followed by IIM (16.8%) and SSc (16.8) were the most frequent CTDs, while NSIP and IUP, for ILDs, were evident in equal proportion (29.8%) in this sample. Patients with NSIP were more frequent in the SSc and UCTD groups. UIP and OP were more common in the RA and IIM (specifically, ASS) groups, respectively. LIP was identified in only one case of SjS.

Table 2: Treatments used among CTD-ILD patients in the NIRRVANA Registry.

Treatments, %			
GC	84.1	ABA	14.2
MMF	35.9	Nintedanib	13.7
MTX	29.6	TAC	11.9
RTX	20.5	antiTNF	10.3
LEF	18.4	iJAK	7.1
HCQ	16	iIL6	6.2
AZA	15.1	CsA	5
CFM	14.2	IVIg	4

ABA: abatacept; AZA: azatyoprine; CFM: cyclophosphamide; CsA: ciclosporine;
HCQ: Hydroxicloroquine; IL6: interleucine 6 inhibitors; iJAK: JAK kinase inhibitors; IVIg: intravenous immunoglobuline; LEF: leflunomide; RTX: rituximab; TAC: tacrolimus

Fifty-six (42.7%) patients were diagnosed with CTD prior to ILD, 44 (33.6%) patients had CTD and ILD diagnoses concurrently, and 31 (23.7%) patients were diagnosed with ILD prior to CTD.

Details on both CTD and ILD identified, as well as demographic and clinical features, and main complementary studies performed, are collected in "*Table 1*".

Glucocorticoids (GC) were used in 84.1% of the patients (mean initial oral dose 21.3mg per day, mean actual oral dose 2.3mg per day; 38.9% reached complete withdrawal of GC). Mycophenolate (MMF) and methotrexate (MTX) were the most commonly used immunosuppressants (IS). 48.4% of the patients needed ≥2 IS. Antifibrotics were needed in 13.7% of the patients. Regarding other treatments used in the NIRRVANA Registry, these are summarized in "*Table 2*".

After 4.48 (2.2-9) years of median ILD duration, 16.8% patients showed improvement, with total resolution of ILD in 2 cases; stabilization was observed in 50.6% and progression in the remaining 32.6% cases. Of this latter group, 3 patients underwent pulmonary transplant, after a mean follow-up of 5.3 years, and 1 of them died in the context of acute respiratory failure and anasarca.

Conclusion: ILD is a common but yet misunderstood complication of CTDs. The NIRRVANA Registry aims to deepen our understanding of the primary characteristics of these complications within a specific Spanish region, which will hopefully lead to improved management in the future. Ending of cross-sectional phase, a longitudinal follow-up of this registry, which is currently in progress, will provide with additional and relevant data towards achieving such goal.

Abstract Number: 1905

Exploring the Association Between Environmental Quality Index and Rheumatoid Arthritis Mortality in the United States

Rohan Sharma[1], Eric Yen[2] and Ram Singh[3], [1]UCLA, Bakersfield, CA, [2]UCLA, Los Angeles, CA, [3]UCLA David Geffen School of Medicine, Los Angeles, CA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Environmental factors such as smoking, pollutants, diet, and geography as well as sex, race/ethnicity, and genetics have been linked with rheumatoid arthritis (RA) pathogenesis and outcomes. However, most studies assess individual exposures. The U.S. Environmental Protection Agency's Environmental Quality Index (EQI) provides a multi-domain composite county-level measure of environmental quality by combining 219 variables across five domains: air, water, land, built, and socio-demographic. This offers a unique opportunity to evaluate these cumulative environmental risks on RA mortality. Using this tool, we aimed to investigate the association between EQI domains and the odds of RA-related death versus all-cause mortality, adjusting for urbanization, race/ethnicity, sex, and age.

Methods: We analyzed the individual U.S. death certificate data from 2011 to 2015 using the CDC Multiple Cause of Death dataset. RA deaths were identified using ICD-10 codes for seropositive and seronegative RA. EQI scores for 2006-2010 were linked to decedents' counties using FIPS (Federal Information Processing Standard) codes. Two multivariable logistic regression models were constructed: one assessing total EQI, and another examining individual EQI domains. Both models adjusted for Rural-Urban Continuum Codes (RUCC), race/ethnicity, sex, and age. Interaction terms evaluated effect modification, and stratified analyses were conducted by race/ethnicity and RUCC.

Results: Among 12,970,917 total deaths, 43,757 were attributed to RA. Total EQI was not significantly associated with RA mortality. However, individual domains showed significant associations with RA death odds: increased odds: poorer water (OR 1.13; 95% CI, 1.12–1.14), land (1.05; 95% CI, 1.04–1.06), and socio-demographic (1.05; 95% CI, 1.04–1.06) quality; decreased odds: poorer air (0.95; 95% CI, 0.94–0.96) and built environment (0.91; 95% CI, 0.90–0.92) quality (all $p < 0.001$). Additionally, RA mortality was higher in nonmetro-urbanized areas (OR 1.09; 95% CI, 1.05–1.13) compared to metro areas. Significant interactions were found between the five EQI domains and race/ethnicity and RUCC. Stratified analyses

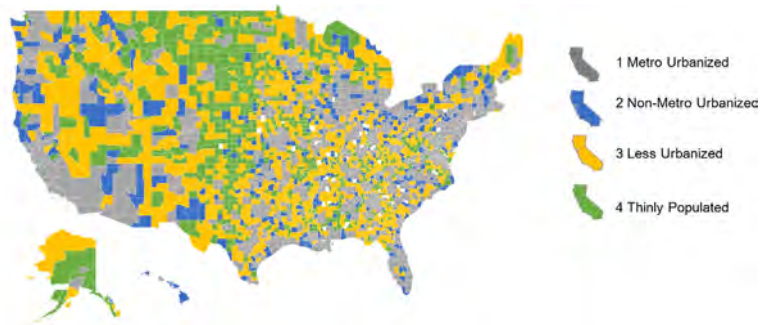

Figure 1. Rural-Urban Continuum Codes (RUCC) by County Counties were grouped into four urbanization categories following EPA methodology. This map illustrates the spatial distribution of RUCC designations across the U.S., providing geographic context for environmental quality and RA mortality patterns.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

revealed differential associations across racial/ethnic groups and urbanization levels. For example, poor water quality was significantly associated with RA death in Hispanic individuals in metro and less-urbanized areas but not in others.

Conclusion: Environmental quality domains independently associate with RA mortality, with variable effects across urbanization and racial/ethnic groups. These findings highlight the importance of addressing environmental and healthcare access disparities to reduce RA-related mortality in vulnerable populations.

Abstract Number: 1906

The incidence and mortality of connective tissue diseases in England: a population-level cohort study from 2012 to 2023

Samir Patel[1], Mark Russell[1], Katie Bechman[1], Maryam Adas[1], Zijing Yang[1], Edward Alveyn[1], Chris Wincup[2], Alexandru Dregan[1], Kate Bramham[1], Sam Norton[1], James Galloway[1] and Patrick Gordon[1], [1]King's College London, London, United Kingdom, [2]King's College Hospital, London, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The reported incidence and mortality of connective tissue diseases (CTDs) in England has been inconsistent in the literature. Our objective was to describe current trends in the incidence and mortality of systemic lupus erythematous (SLE), Sjogren's syndrome (SjS), systemic sclerosis (SSc), idiopathic inflammatory myopathies (IIM) and mixed connective tissue disease (MCTD).

Methods: We conducted a retrospective population-level study using primary care records in England via the Clinical Practice Research Datalink (CPRD). We included individuals ≥18 years old with new CTD diagnoses between 2012 and 2023. Our outcomes were incidence and all-cause mortality, which included age-standardized mortality rates (ASMRs), standardized mortality ratios and risk of death over time using flexible parametric models.

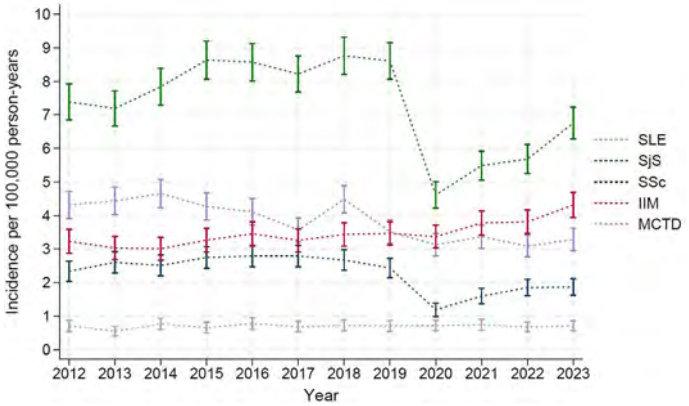

Figure 1. Age and sex standardized incidence rates (ASIRs) by year, 2012-2023, with 95% confidence intervals (95% CI).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1. Number and characteristics of deaths associated within each incident CTD cohort. Crude and age and sex-standardised mortality rates (AMSRs) are given with 95% confidence intervals (95% CI). Individuals with more than one CTD diagnosis contributed to each relevant group. Counts less than eight were redacted (*).

	SLE	SjS	SSc	IIM	MCTD
	N=385	N=730	N=531	N=755	N=67
Age at death in years: Median (IQR)	72.0 (63.0-80.0)	77.0 (69.0-84.0)	75.0 (66.0-82.0)	74.0 (65.0-81.0)	72.0 (60.0-78.0)
Gender: N (%)					
Male	94 (24.4%)	128 (17.5%)	113 (21.3%)	395 (52.3%)	16 (23.9%)
Female	291 (75.6%)	602 (82.5%)	418 (78.7%)	360 (47.7%)	51 (76.1%)
Ethnicity: N (%)					
White	204 (53.0%)	361 (49.5%)	250 (47.1%)	360 (47.7%)	31 (46.3%)
Black	24 (6.2%)	13 (1.8%)	17 (3.2%)	36 (4.8%)	9 (13.4%)
Asian	18 (4.7%)	45 (6.2%)	26 (4.9%)	48 (6.4%)	10 (14.9%)
Mixed and Other	89 (23.1%)	203 (27.8%)	142 (26.7%)	179 (23.7%)	*
Missing	50 (13.0%)	108 (14.8%)	96 (18.1%)	132 (17.5%)	*
Crude mortality rate per 1,000 person-years	15.46 (13.92 - 17.01)	14.82 (13.74 - 15.89)	37.30 (34.13 - 40.48)	40.89 (37.97 - 43.80)	15.38 (11.70 - 19.06)
ASMR per 1,000 person-years	16.74 (15.03 - 18.46)	9.70 (8.75 - 10.65)	24.43 (22.13 - 26.72)	27.83 (25.63 - 30.03)	16.27 (12.11 - 20.42)

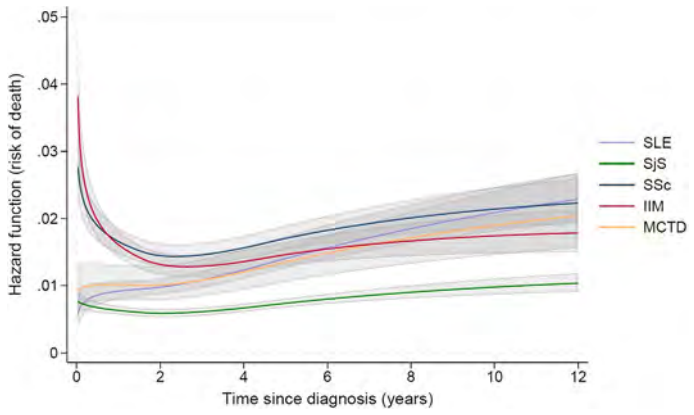

Figure 2. Risk of death in relation to time from each CTD diagnosis with 95% confidence intervals (shaded area).

Results: There were a total of 22,829 incident CTD diagnoses (81.1% female, median age 57). The age and sex-standardised incidence of SLE and SSc fell over the study period 2012 to 2023 (SLE: 4.32 to 3.29 per 100,000 person years (py) and SSc: 2.33 to 1.86 per 100,000 py), whereas SjS and MCTD incidence remained relatively stable (Figure 1). In contrast, IIM diagnoses rose from 3.23 to 4.31 per 100,000 py. ASMRs across the study period were highest for IIM (27.83 per 1,000 py), followed by SSc (24.43), SLE (16.74), MCTD (16.27) and lowest for SjS (9.70) (Table 1). Compared to the general population, mortality was higher in incident SSc, IIM, MCTD and SLE groups (SMRs of 1.74, 1.56, 1.50, and 1.30 respectively). Among all CTDs, the risk of death from time of diagnosis was highest in those diagnosed with IIM or SSc (Figure 2).

Conclusion: Our findings revealed a falling incidence of SLE, a simultaneous rise in IIM incidence and overall high all-cause mortality within IIM and SSc cohorts. Our findings acknowledge the changing landscape of CTDs in England and will aid healthcare resource planning for this vulnerable population.

Abstract Number: 1907

Twenty-Year Trends in the U.S. Burden of Gout: A State-Level Analysis of Disability and Prevalence from 2001 to 2021

Shiza sarfraz, Hassam Ali and debargha basuli, East Carolina University Brody School of Medicine, Greenville, NC

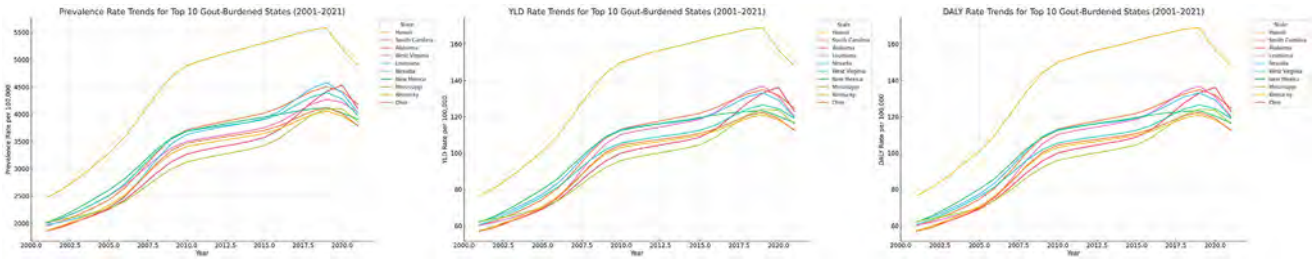
SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Gout is the most common inflammatory arthritis and an important driver of chronic disability. However, long-term trends in gout burden across U.S. states are not well-characterized. Using nationally representative data, we aimed to quantify changes in age-standardized gout-related disability-adjusted life years (DALYs), years lived with disability (YLDs), and prevalence rates between 2001 and 2021, with a focus on regional disparities.

Methods: We extracted age-standardized DALY, YLD, and prevalence rates for gout from the Global Burden of Disease 2021 dataset for adult patients. Annual rates per 100,000 population were obtained for all 50 U.S. states and the national average from 2001 to 2021. We calculated national trends with 95% confidence intervals (CIs) and computed percent change in burden over time for each state. The ten states with the highest burden in 2021 were identified.

Results: Between 2001 and 2021, the national average DALY rate for gout increased from 53.1 (95% CI: 51.4–54.8) to 102.9 (95% CI: 99.4–106.4) per 100,000—a 93.7% increase. The YLD rate mirrored this trend, rising from 53.1 (95% CI: 51.4–54.8) to 102.9 (95% CI: 99.4–106.4). The prevalence rate more than doubled, from 1,677.2 to 3,408.9 per 100,000 (+103.2%). In 2021, the states with the highest DALY and YLD rates included Hawaii (147.7, +93.3%), South Carolina (124.7, +107.4%), Alabama (123.0, +114.0%), and Louisiana (120.4, +99.6%). Prevalence rates followed a similar pattern, with Hawaii (4,902.4, +98.6%), South Carolina (4,185.0, +114.0%), and Alabama (4,104.9, +118.2%) ranking among the highest. All ten highest-burden states demonstrated steep upward trajectories over the two-decade period (Figure 1). Regional clustering was evident, with the Southeast disproportionately represented (Figure 2).

Conclusion: The prevalence and disability burden of gout in the United States have more than doubled over the past 20 years. DALY and YLD rates show that the impact of gout extends beyond symptoms, contributing significantly to long-term health loss. Southern and Western states carry the highest burden, emphasizing the need for targeted public health strategies.



Trends in gout burden among the top 10 most affected U.S. states, 2001–2021.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Haemochromatosis arthropathy (HA) has been little researched to date. Arthropathy frequently is amongst the

first clinical manifestations of haemochromatosis, but might be overlooked or misdiagnosed as being of different origin, which impacts significantly on the patient's joint function and health due to delayed diagnose and therapy initiation. This SLR aimed to summarise the imaging and clinical features of haemochromatosis arthropathy to inform the development of EULAR classification criteria for HA.

Methods: We performed a systematic literature review by searching Medline (PubMed, Ovid), the Cochrane Library and

Embase, as well as conference abstract databases. Only original articles describing clinical and/or imaging features of HA (without language restriction or year of publication) were eligible for inclusion. After article and abstract screening, we assessed articles in detail for eligibility based on study quality and adequate reporting of outcomes. Random intercept logistic regression was utilised (using R, version 4.2.1) to calculate individual probabilities of outcomes assessed.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Of 595 articles initially screened, 52 were analysed in detail and 36 studies were found appropriate for final analysis (Figure 1). The most common ineligibility reasons during detailed article review were poor study quality and insufficient reporting of outcomes. The most prevalent clinical characteristics were focussed on the MCP2 and MCP3 joints, with limited range of motion (pooled proportion: 62%, Figure 2 A+B), bony enlargement (48%) and pain (41%). With regards to imaging characteristics, MCP joints 2/3 showed the highest frequency of subchondral cysts (MCP2 and MCP3 52%, respectively), joint space narrowing (MCP2: 62% and MCP3 62%, respectively, Figure 2 C+D), and osteophytes (MCP2: 49%; MCP3:

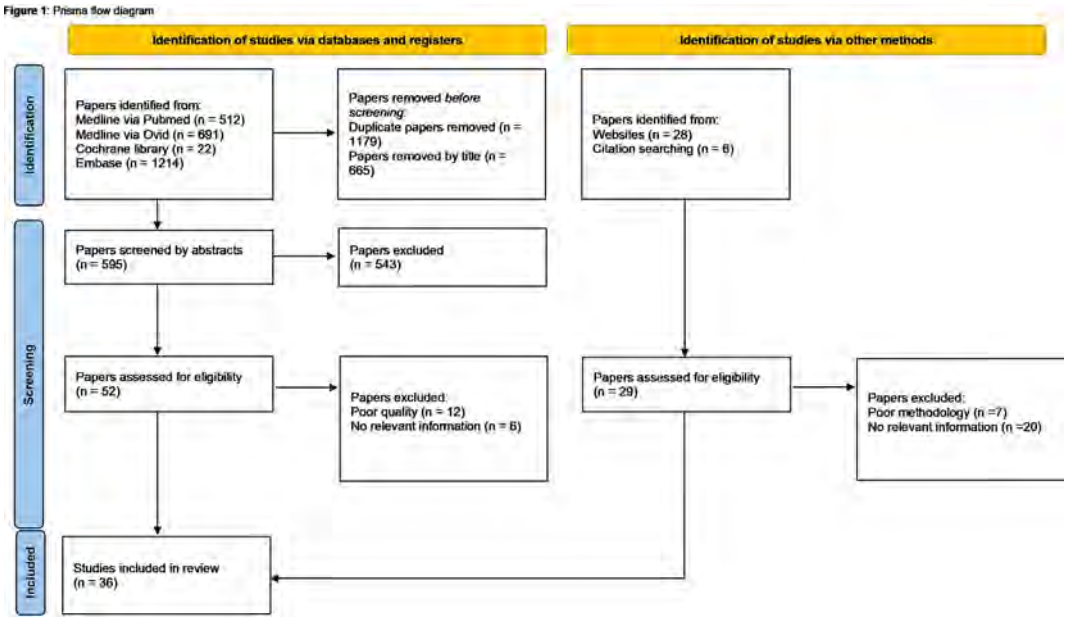

Figure 1: Prisma flow diagram

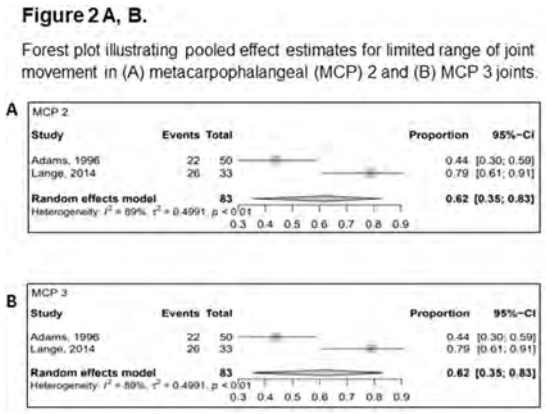

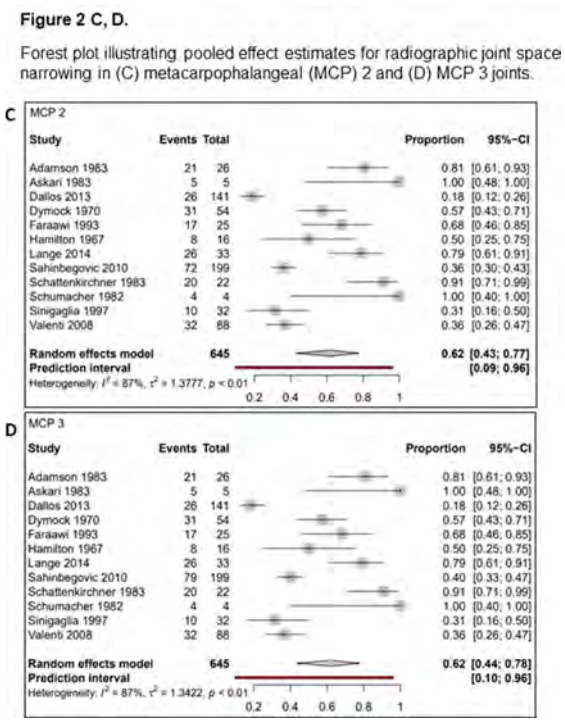

Figure 2 A, B: Forest plot illustrating pooled effect estimates for limited rang of joint movement in (A) metacarpophalangeal (MCP) 2 and (B) MCP 3 joints. Figure 2 C, D: Forest plot illustrating pooled effect estimates for radiographic joint space narrowing in (A) metacarpophalangeal (MCP) 2 and (B) MCP 3 joints.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1: Detailed results of clinical and imaging findings showing the pooled proportions derived from random intercept logistic regression analyses on reported outcomes.

Table 1: Detailed results of clinical and imaging findings showing the pooled proportions derived from random intercept logistic regression analyses on reported outcomes.

Characteristic	Joint(s)	Pooled proportion	95 % CI	I^2 (%)
Clinical findings				
Limited range of motion	MCP 2/3 (pooled)	0.62	0.35 – 0.83	89
Bony enlargement		0.48	0.09 – 0.90	24
Pain		0.41	0.22 – 0.63	90
Imaging findings				
Subchondral cysts	MCP 2	0.52	0.37 – 0.66	84
	MCP 3	0.52	0.37 – 0.66	84
Joint-space narrowing	MCP 2	0.62	0.43 – 0.77	87
	MCP 3	0.62	0.44 – 0.78	87
Osteophytes	MCP 2	0.49	0.30 – 0.68	85
	MCP 3	0.52	0.33 – 0.71	86
Chondrocalcinosis	Knee	0.29	0.17 – 0.45	87
Subchondral sclerosis	Hip	0.61	0.03 – 0.99	65

52%). Chondrocalcinosis prevailed in the knee (29%), and subchondral sclerosis in the hip in 61%. Considerable heterogeneity (I^2) across most meta-regressions was identified ($p< 0.01$ for all analyses except for bony enlargement in MCP2/3 and subchondral sclerosis of the hip). Table 1 summarizes the detailed results and estimates of the meta-regression analyses.

Conclusion: Our SLR identified the most commonly reported clinical characteristics and imaging patterns of HA joint involvement. As expected for this rare disease, only a limited number of articles were identified and most studies described small numbers of patients, with significant variability of outcomes, also leading to high heterogeneity in our analyses. This SLR summarizes the current evidence on clinical and imaging features important in HA, demonstrating the unmet need of developing classification criteria in patients with HA.

SESSION INFORMATION

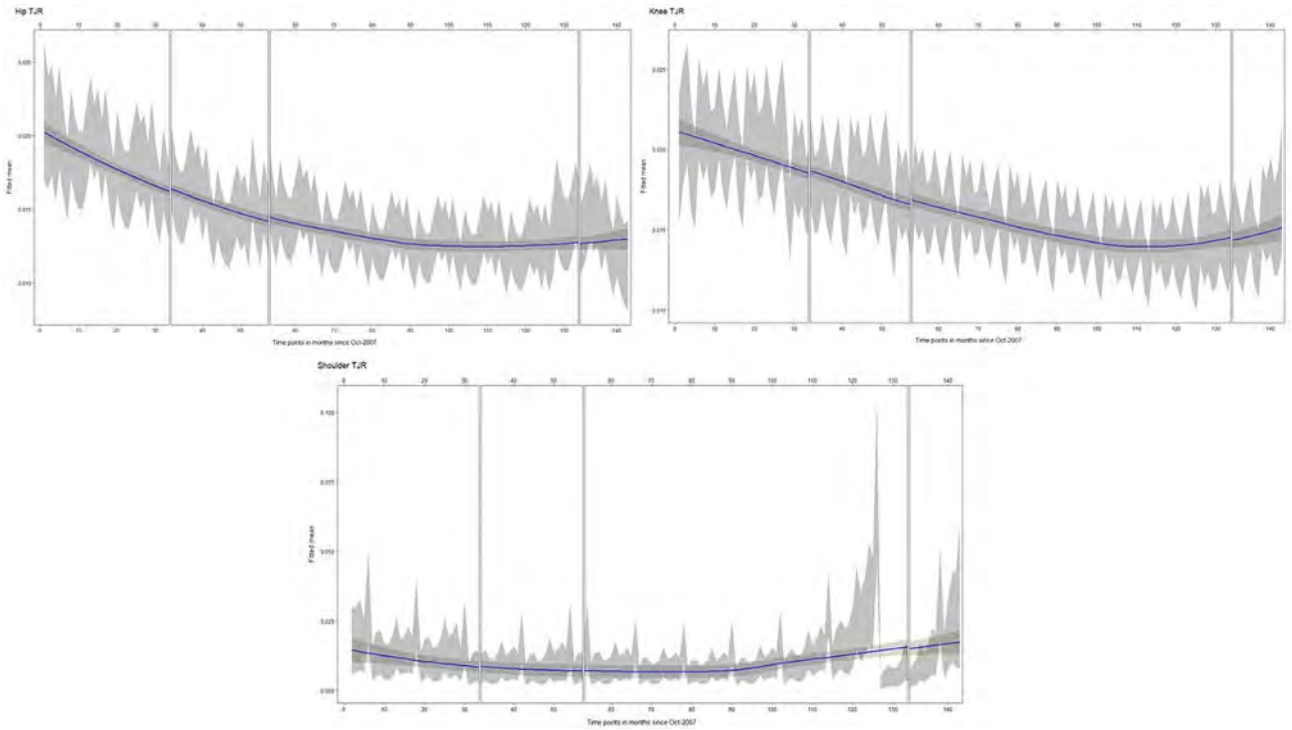
Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Joint replacement (JR) surgery is one of the preferred management for end-stage arthritis. Venous Thromboembolism (VTE) is one of the major post-surgical complications after JR. However, trends of the VTE after JR in the UK and whether the guideline updates resulted in a shift in VTE rates has not been studied yet.

The aim of the study was to explore if and how rates of VTE after JR have changed in the UK over the last 12 years since the year 2007.

Methods: We used routinely collected primary care data Clinical Practice Research Datalink (CPRD AURUM) and linked hospital episode statistics (HES) and Office of National Statistics (ONS) for the study(1). We included all adult patients who had primary knee, hip or shoulder replacement surgery between October 2007 and September 2019. The outcome for the study was the recording of VTE within 6 months of JR date (index date). The outcome was reported as overall and separately for hip, knee, and shoulder joints. VTE rate estimated during the study period was compared with respect to different intervention introduced by National Health Services (NHS) in the year 2010(2), 2012(3), and 2018(4). Trends of the VTE rates for all the joints and examined using the Cox-Stuart trend test, and the seasonality and impact of the interventions (NHS guidelines) was examined using logistic regression with a polynomial function.

Results: A total of 476,620 joint replacement records were found to be eligible for the study during the study period 1st Oct 2007 and 30th Sep 2019 (both dates inclusive). Nearly 1.5% of total population had recording of VTE within 6 months from



Fugre 1 Polynomial regression plots with fitted mean for the trends of VTE incidence in the UK. Blue line represents the fitted mean trends and the shadow represents the confidence interval. Grey shadow in the background shows the actual distribution with confidence interval against time (in months). Vertical splits represents the three months after the NICE guideline for VTE prevention was introduced (March 2010, March 2012, and June 2018).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

the date of the procedure. The prevalence was higher for knee joints (1.6%) followed by hip (1.4%) and shoulder (1%). The incidence rate of VTE after 6 months was 16.85 per 1000 person-6months for knee, 14.81 per 1000 person-6months, and 10.35 per 1000 person-6months. A decline in overall VTE incidence rate was seen until end of the year 2016, followed by a rise in the trend (p trend = 0.02). A significant decline in VTE was reported within 6 months for hip (p = 0.04) and knee joints (p trend = 0.008). The trend test of VTE for shoulder joint was not statistically significant. (Figure 1)

Adjusted logistic regression with a fifth degree orthogonal polynomial showed the seasonal pattern for the VTE in three joints separately. The three months after effect of three interventions (CG92 in January 2010; TA245 in January 2012; NG89 in March 2018) was examined in the polynomial model after adjusting for the seasonality and regions. No significant step change was seen because of the intervention in the trends of VTE for any joints other than Shoulder joint.

Conclusion: here was no significant change in the rate of VTE after the NICE guidelines introduced. Further study is needed to explore the economic benefits of the change in NICE guidelines.

Clinical profile and healthcare resource utilization of patients diagnosed with giant cell arteritis or polymyalgia rheumatica in the US: a real-world cohort study using a large database of administrative health claims

Julie Mouchet[1], Tim Nguyen[2], **Valeria Jordan M.**[3], G S Ramakrishna[4], Linda Grinnell-Merrick[2], Andrew Heaney[5], Anushka Mitra Das[5], Pooja Shah[6] and Evi Zhuleku[7], [1]Novartis Pharma AG, Basel, Switzerland, [2]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [3]Novartis Pharmaceuticals Corporation, Tenafly, NJ, [4]Novartis Healthcare Private Limited, Hyderabad, India, [5]Novartis Ireland Ltd, Dublin, Ireland, [6]Cytel Inc, Cambridge, ON, Canada, [7]Cytel Inc, Berlin, Germany

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Polymyalgia rheumatica (PMR) and giant cell arteritis (GCA) are systemic inflammatory conditions which predominantly affect individuals over the age of 50 years. The conditions share overlapping clinical features[1,2] and can significantly impact patients' quality of life. The main symptoms of PMR include pain and stiffness in the shoulder, neck, and hips[1]; whereas patients with GCA present with headache, scalp tenderness, fever, jaw claudication, as well as aortic aneurysm, aortitis and visual disturbances[2,3]. Both conditions are associated with significant disease burden, including cardiovascular, cerebrovascular and malignancies for PMR and detrimental effects on vision for GCA[1,2]. This real-world cohort study aims to understand the clinical profile and healthcare resource utilization (HCRU) of patients with PMR and GCA in the US.

Methods: Adult patients with a first diagnosis (index date) of PMR or GCA aged ≥50 years during Jan 2017- May 2023 and with at least 1 year of database continuous enrolment pre- and post-index were identified from Optum® Clinformatics Data Mart (CDM) claims. To increase the specificity of the diagnosis, at least two ICD-10 CM codes (PMR: M35.3 - GCA: M31.6) recorded 7-30 days apart were required. Patients were also required to have ≥2 outpatient prescriptions of oral glucocorticoids within six months post-index. The total number of patients, and the distribution by age, sex, comorbidities, as well as

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

HCRU during follow-up were reported. Patients were followed from index to earliest of death, end of insurance or study period (5/31/2024).

Results: A total of 13,786 patients newly diagnosed with PMR and 1,520 patients with GCA were included in the study population (Table 1). Mean age (SD) was 74.8 (7.8) years for PMR and 75.0 (8.0) years for GCA. Women represented 57.7% and 68.5% of the PMR and GCA patients, respectively. The mean Charlson Comorbidity Index was slightly higher for GCA (1.7) vs. PMR (1.3). Prevalence of the top 10 comorbidities at baseline ranged from 22 to 68% (Figure 1). On average, patients with PMR and GCA were followed 3.5 (1.7) and 3.3 (1.7) years, respectively. Inpatient and ER visits were reported for 44.0% and 64.3% of patients with PMR. Higher proportions were observed for GCA patients with 66.3% and 80.1% for inpatient and ER visits, respectively.

Conclusion: In the US, both PMR and GCA predominantly affect elderly female patients. The clinical profile of these patients indicates a considerable burden related to highly prevalent comorbidities including cardiovascular, endocrine and musculoskeletal disorders. This impacts HRCU substantially, highlighting the need for better management strategies to reduce clinical and economic burden among patients with GCA and PMR.

Characterizing Psoriasis Patients at Risk for Transition to Psoriatic Arthritis: Early Insights from the STOP PsA At-Risk Cohort

Victoria Konzett[1], Eva Manger[2], Simon Reider[2], Johannes Griss[3], Constanze Jonak[3], Kastriot Kastrati[4], Peter Mandl[4], Gudrun Ratzinger[5], Christina Duftner[2], Thomas Karonitsch[4], Daniel Aletaha[6] and the STOP PsA study group, [1]Department of Medicine III, Division of Rheumatology, Medical University of Vienna, Vienna, Austria, [2]Department of Internal Medicine, Clinical Division of Internal Medicine II, Medical University of Innsbruck, Innsbruck, Austria, [3]Department of Dermatology, Medical University of Vienna, Austria, Vienna, Austria, [4]Department of Medicine III, Division of Rheumatology, Medical University Vienna, Vienna, Austria, [5]Department of Dermatology, Venereology and Allergology, Medical University of Innsbruck, Austria, Innsbruck, Austria, [6]Medical University Vienna, Wien, Austria

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Psoriatic arthritis (PsA) develops predominantly in patients with psoriasis (Pso). Although key drivers and predictors of disease progression have been identified in recent years, prospective studies and a detailed understanding of the pathogenetic mechanisms underlying disease transition remain limited.

Methods: The Susceptibility of Transition from Psoriasis to Psoriatic arthritis (STOP PsA) study is a prospective, longitudinal, multicenter cohort study of Pso patients at risk of developing PsA. Comprehensive clinical assessments, including detailed joint counts, patient-reported outcomes (PROs), cardiovascular risk evaluation, and joint sonography, together with transcriptomic and epigenetic analyses of peripheral blood mononuclear cells (PBMC) and skin biopsies, as well as microbiome

Table 1. Baseline characteristics; data are given as N (%) or mean (standard deviation)

	228 patients
Female (%)	108 (47.4%)
Age (years)	44.6 (13.6)
Body Mass Index (kg/m²)	27.8 (6.1)
Caucasian (%)	206 (90.4%)
Psoriasis Duration (years)	17.1 (13.4)
Psoriasis Area and Severity Index (PASI)	4.1 (5.0)
C-reactive protein (mg/dl)	0.3 (0.4)
Tender Joint Count (68 joints)	2.0 (4.5)
Patient Pain Assessment (0-10)	2.0 (2.6)
Patient Global Disease Assessment (0-10)	2.6 (2.6)
Maastricht Ankylosing Spondylitis Enthesitis Score (MASES; 0-13)	0.6 (1.4)
Leeds Enthesitis Index (LEI; 0-6)	0.5 (1.0)
Bath Ankylosing Spondylitis Metrology Index (BASMI; 0-10)	2.0 (1.0)
Dermatological Life Quality Index (DLQI; 0-30)	5.8 (6.2)
Psoriatic Arthritis Impact of Disease (PSAID; 0-10)	2.3 (2.2)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

profiling of skin and gut samples, will generate a broad, multi-dimensional dataset to enable in-depth investigation of disease transition and risk stratification. We included patients with Pso but without clinical arthritis, synovitis or enthesitis. This abstract provides first insights into the baseline characteristics of this patient population in the ongoing study.

Results: After prescreening, a total of 253 patients were assessed in a baseline visit, of whom 228 were finally included. At baseline, ten patients were diagnosed with PsA, and two patients with axial spondyloarthritis (SpA), indicating a 4.7% prevalence of incipient PsA/SpA in this at-risk population. Other reasons for exclusion were patients' decline to participate (n=6), revision of dermatological diagnosis (n=2), and previous diagnosis of arthritis missed at pre-screening (n=5). Included patients had a mean age of 44.6 ± 13.6 years, and a mean Pso duration of 17.1 ± 13.4 years. 108 (47.4%) were female, and 195 (85.5%) had a psoriasis vulgaris subtype. 91 patients (39.9%) had at least one tender joint at screening, and the mean tender joint count of 68 joints was 1.96 ± 4.54. A detailed list of baseline characteristics is shown in Table 1.

106 (46.5%) of patients were DMARD naïve, and 107 (46.9%) received DMARD therapy at screening. Figure 1 displays the distribution of compounds (Panel A) and mechanisms of action (Panel B) among treated patients.

Conclusion: Approximately 40% of Pso patients in this study reported arthralgia, and several early PsA/SpA cases were identified during the screening period. Future analyses from this ongoing study aim to deepen our understanding of disease transition, identify early biomarkers and explore potential therapeutic targets for arthritis prevention.

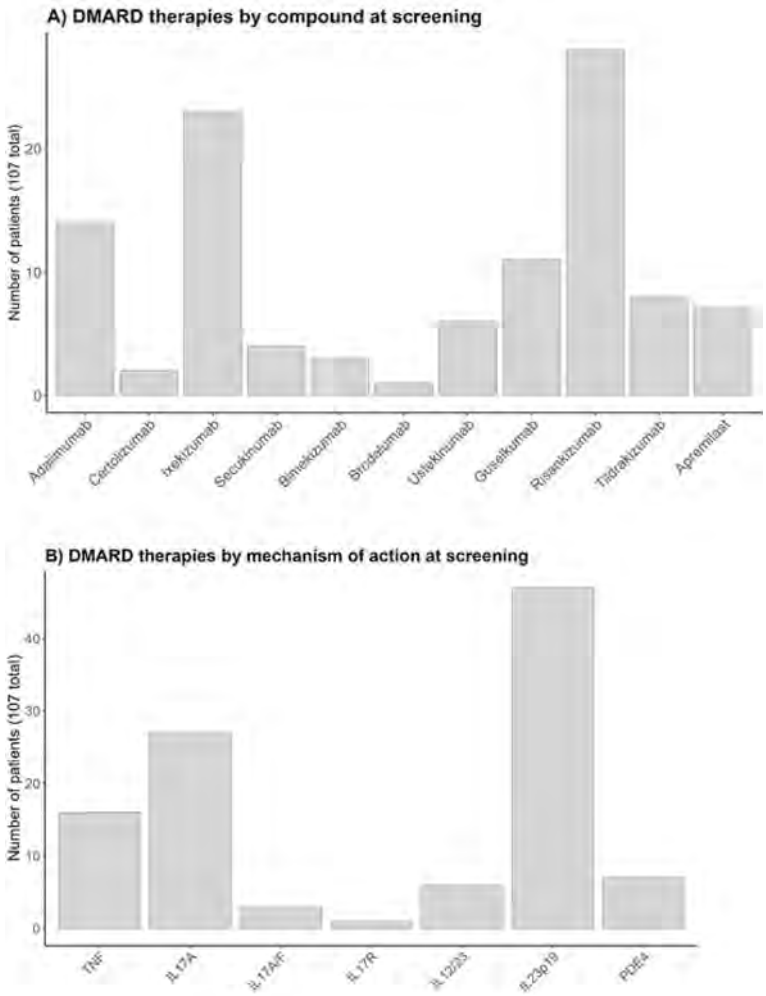

Figure 1. Distribution of disease-modifying anti-rheumatic drug (DMARD) therapies by compound (Panel A) and mechanism of action (Panel B) among the 107 patients receiving therapy at screening.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Vasculitis is a group of rare, multisystem diseases which may involve the skin. Characterization of the frequency, type, and significance of cutaneous manifestations in various vasculitides is incomplete.

Methods: This study analyzed cross-sectional data collected through the Diagnostic and Classification Criteria in Vasculitis (DCVAS) (NCT01066208) study, a large, multinational, collaborative effort involving 136 clinical sites in 32 countries from 2011 to 2017, collecting comprehensive clinical data on patients with several forms of vasculitis from disease onset to 6 months after initial presentation. Summary statistics were used to describe cutaneous manifestations of each included type of vasculitis, and logistic regression analysis was used to calculate the odds ratio for severe systemic manifestations of vasculitis based on presence of skin findings.

Results: Data from 4,468 adults diagnosed with vasculitis were analyzed, including 270 with IgA vasculitis (IgAV), 201 with Behçet's disease (BD), 57 with cryoglobulinemic vasculitis (CV), 1,023 with granulomatosis with polyangiitis (GPA), 505 with microscopic polyangiitis (MPA), 382 with eosinophilic granulomatosis with polyangiitis (EGPA), 194 with polyarteritis nodosa (PAN), 1,206 with giant cell arteritis (GCA), and 630 with Takayasu arteritis (TAK). Participants in the DCVAS study were from Europe (59%), North America (21%), Asia (17%), Oceania (2%), and Africa (1%).

Cutaneous manifestations were common at the time of presentation for all types of vasculitis except large-vessel vasculitis (GCA and TAK), ranging from 20% of patients with MPA to 97% of patients with IgAV (Table 1). The frequency of specific cutaneous manifestations encountered in each type of vasculitis varied considerably, although petechiae/purpura was the most common skin finding in all types of small-vessel vasculitis (IgAV, CV, GPA, MPA, and EGPA).

Skin biopsy was utilized to varying degrees, performed in 22-82% of those with small- or medium-vessel vasculitis. When performed, skin biopsy was diagnostic in the majority of cases, including 95% (205/216) of IgAV, 73% (16/22) of CV, 73% (67/92) of GPA, 73% (16/22) of MPA, 67% (49/73) of EGPA, and 70% (52/74) of PAN. Skin biopsy was less often useful for diagnosis of BD (35%; 7/20), GCA (0%; 0/1), and TAK (33%; 2/6).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Univariable logistic regression demonstrated that patients with cutaneous manifestations had significantly greater odds of severe systemic manifestations of GPA (OR 1.8, 95% CI 1.3, 2.6) and EGPA (OR 1.8, 95% CI 1.1, 2.9); those with cutaneous manifestations had lower odds of severe systemic manifestations of PAN (OR 0.5, 95% CI 0.3, 0.99) (Table 2).

Conclusion: These findings characterize the cutaneous manifestations of vasculitis at the time of diagnosis and highlight the potential diagnostic and prognostic importance of the skin in these multisystem diseases. For patients presenting with small-

Microscopic polyangiitis	0.9 (0.4, 1.7)	0.666
Eosinophilic granulomatosis with polyangiitis	1.8 (1.1, 2.9)	0.019
Polyarteritis nodosa	0.5 (0.3, 0.99)	0.046

* Severe systemic manifestations of vasculitis were defined based on components of the Birmingham Vasculitis Activity Score (BVAS) and include: scleritis, sensorineural deafness, mesenteric ischemia, alveolar hemorrhage, respiratory failure, red blood cell casts in urine, rise in serum creatinine >30% or fall in creatinine clearance >25%, meningitis, spinal cord lesion, stroke, cranial nerve palsy, sensory peripheral neuropathy, or mononeuritis multiplex. Analysis was limited to vasculitis types with >10% prevalence of cutaneous manifestations.

Severe systemic manifestations of vasculitis were defined based on components of the Birmingham Vasculitis Activity Score (BVAS) and include: scleritis, sensorineural deafness, mesenteric ischemia, alveolar hemorrhage, respiratory failure, red blood cell casts in urine, rise in serum creatinine >30% or fall in creatinine clearance >25%, meningitis, spinal cord lesion, stroke, cranial nerve palsy, sensory peripheral neuropathy, or mononeuritis multiplex. Analysis was limited to vasculitis types with >10% prevalence of cutaneous manifestations.

Do We Screen For and Do We Miss Antimalarial-Induced Cardiomyopathy (AMIC)? Risk Profiles according to Hydroxychloroquine Exposure Duration

Youngmin Kim[1], Robert Padera[2], Brittany Weber[3] and Karen H. Costenbader[4], [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston, [3]Brigham and Women's Hospital, DEDHAM, MA, [4]Harvard Medical School and Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1877–1913) Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Hydroxychloroquine (HCQ) is widely used for autoimmune diseases but carries a risk of antimalarial-induced cardiomyopathy (AMIC) that increases with long-term use and is often diagnosed after irreversible heart damage. Endomyocardial biopsy with electron microscopy is the gold standard for diagnosis but is rarely conducted as it is invasive. Screening guidelines, including cardiac biomarkers, ECGs, and imaging, have been proposed to detect early AMIC, but it is not known if they are followed (Tselios et al., 2018; Desmarais et al., 2021; DiGregorio et al., 2025). We aimed to evaluate demographic and clinical features, cardiac biomarkers and cardiac test utilization for patients taking HCQ, according to cumulative HCQ duration, to inform potential risk-based screening approaches.

Methods: We identified patients with ≥10 HCQ prescriptions in the electronic health records (EHR) of our large academic medical center. We extracted patient demographics, rheumatologic diagnoses, HCQ prescription dates, cardiac biomarker testing and results (troponin-I, troponin-T, hsCRP, CK-MB, NT-proBNP), and cardiac testing (ECG, echocardiography [ECHO], cardiac MRI, endomyocardial biopsy). Patients were stratified into 3 groups by HCQ exposure duration: ≤5 years, 5–10 years, and >10 years. Group comparisons were conducted using ANOVA for continuous and Chi-square tests for categorical variables. Cardiac biopsy reports were reviewed to identify AMIC.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Among 13,266 patients (mean age 62.1 [SD 16.9]; 82.9% female), 56.9% had ≤5 years, 22.4% had 5–10 years, and 20.7% had >10 years of HCQ use. While cardiac testing was more common in longer-duration groups, only 70% had ECGs, 41% echocardiograms, and 4.6% cardiac MRI. Importantly, biomarker testing was performed in only a fraction of the total cohort (e.g., troponin-I in 13.3%, CK-MB in 21.6%). Troponin-I abnormalities did increase in prevalence with longer exposure (8.1% in ≤5 years vs 12.4% in >10 years, p=0.02) among those tested. Of 35 patients who underwent biopsy (0.3%), 11 (31.4%) had biopsy-confirmed AMIC.

Conclusion: Despite known risks, cardiac biomarker and imaging tests are underutilized in long-term HCQ users, and biopsy remains rare. Many patients with potential AMIC risk never had testing, limiting recognition of the true disease burden. Our findings highlight a need to develop and implement standardized, non-invasive screening protocols for AMIC to improve early detection and quantify incidence more accurately in high-risk populations.

Table 1. Demographics and Clinical Characteristics of Patients with ≥10 Prescriptions of Hydroxychloroquine in a Large Academic Hospital Electronic Health Record Database (n=13,266)

Demographics	
Age (mean, SD)	62.1 (16.9)

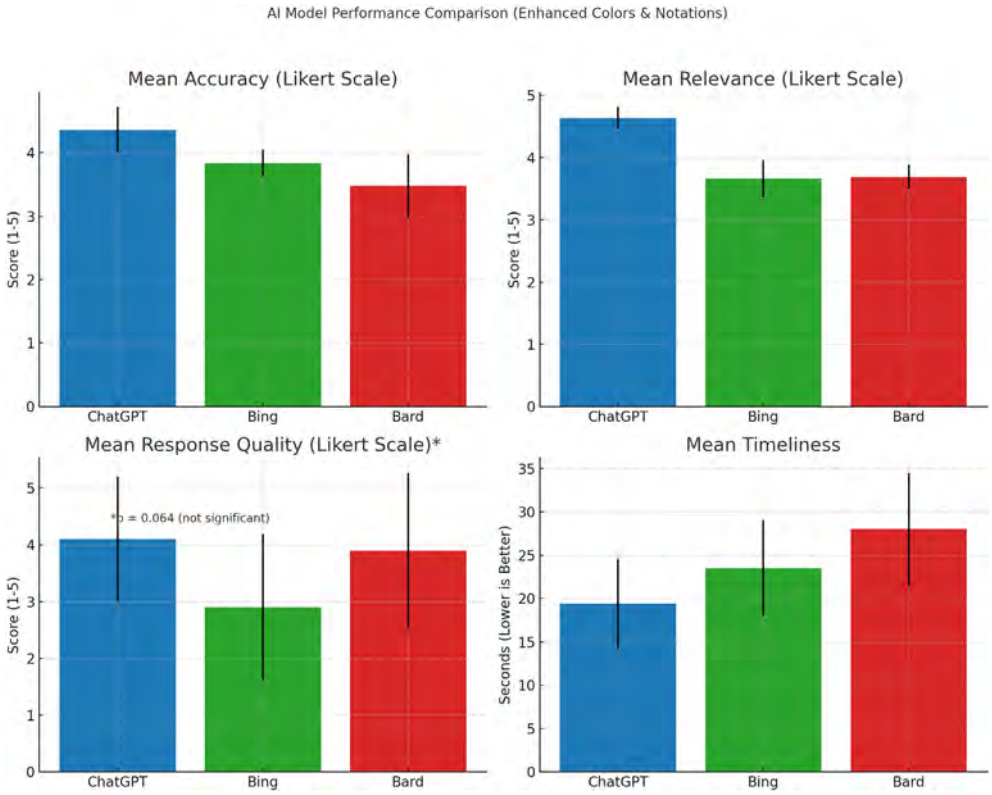
Performance Comparison of Artificial Intelligence tools ChatGPT, Bing AI, and Google Bard for Clinical Rheumatology Decision Support: When AI Talks Rheumatology

Aakanksha Pitliya[1], Hema Latha Anam[2], Richard Oletsky[2], Alexandra Georgiana Boc[2], Dipabali Chaudhuri[2] and Rajesh Thirumaran[2], [1]Mercy Catholic Medical Center, Darby, PA, Clifton Heights, PA, [2]Mercy Catholic Medical Center, Darby, PA

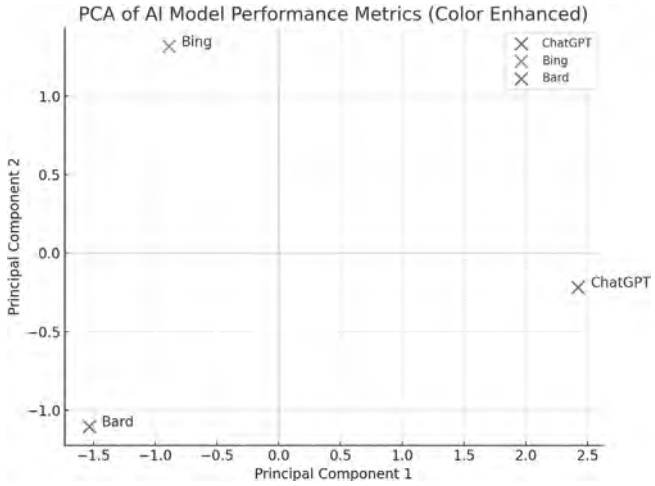
SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1914–1935) Health Services Research Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Artificial intelligence (AI) has shown promise as a tool to assist in clinical decision-making. Given the complex nature of autoimmune pathologies and the critical need for guideline-based precision in management, the relative efficiency of AI tools in answering specific rheumatology questions remains undetermined. This study aimed to evaluate the performance of three leading AI language models: ChatGPT (OpenAI), Bing AI (Microsoft), and Google Bard in responding to clinical questions in rheumatology, focusing on key domains of accuracy, relevance, response quality, and timeliness.



Comparison of AI Model Performance on Clinical Rheumatology Questions Using Likert Scale Metrics.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Principal Component Analysis visualization of the AI models based on their multidimensional performance across accuracy, relevance, response quality, and timeliness.

Metric	ChatGPT (Mean ± SD)	Bing (Mean ± SD)	Bard (Mean ± SD)	ANOVA *p*-value
Accuracy	4.36 ± 0.36	3.84 ± 0.21	3.48 ± 0.50	0.000076
Relevance	4.64 ± 0.17	3.66 ± 0.30	3.69 ± 0.20	1.32×10^{-7}
Response Quality	4.10 ± 1.10	2.90 ± 1.29	3.90 ± 1.37	0.064
Timeliness (s)	19.4 ± 5.19	23.5 ± 5.54	28.0 ± 6.50	1.09×10^{-11}

Likert scale metrics are scored on a 1–5 scale.

Methods: Physician reviewers structured a panel of 50 clinical questions with a rheumatology focus. Each question was submitted independently in plain text to Google Bard, Bing AI, and ChatGPT. Responses were anonymized and rated on a 5-point Likert scale for quality (clarity, completeness, and educational value), accuracy (clinical correctness and factual precision), and relevance (appropriateness and applicability to the question asked) by blinded Internal Medicine Residents to avoid bias. Response latency (in seconds) was recorded for each model via stopwatch timing from prompt submission to completion of response. Descriptive statistics were calculated, and one-way ANOVA was performed to detect significant differences across the models. Principal Component Analysis (PCA) was used for multivariate clustering to explore underlying patterns and potential clustering of model responses. All statistical analyses were conducted using R (v4.3.2). A p-value < 0.05 was considered statistically significant.

Results: ChatGPT scored highest in accuracy (mean ± SD: 4.36 ± 0.36) and relevance (4.64 ± 0.17), with statistically significant differences compared to Bing and Bard (ANOVA $p < 0.001$ for both). While ChatGPT also led in response quality (4.10 ± 1.10), the difference was not statistically significant($p = 0.064$)*. Timeliness varied significantly among models, with ChatGPT responding fastest (19.4 ± 5.19s), followed by Bing (23.5 ± 5.54s) and Bard (28.0 ± 6.50s). PCA demonstrated that ChatGPT exhibited unique multidimensional performance by clustering independently.

Conclusion: Among the three AI systems evaluated, ChatGPT performed most proficiently in answering clinical rheumatology questions, with considerable improvements in accuracy, relevance, and timeliness. According to our research, generative AI models may be used as a supplement to clinical judgment in rheumatology, particularly in instances when quick and accurate synthesis of complicated data is essential.

Session Title: (1914–1935) Health Services Research Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Women with Systemic Lupus Erythematosus (SLE) are at a higher risk of persistent HPV infection and developing premalignant cervical lesions and cervical cancer. High-risk oncogenic HPV genotypes, particularly types 16 and 18, are the primary causal agents in most cases. Cervical cancer screening using HPV testing and cytology enables early detection of precursive lesions, preventing their progression to invasive cancer. The study aimed to evaluate adherence to the cervical cancer screening program in women with Systemic Lupus Erythematosus of reproductive age. Additionally, it sought to identify the most prevalent high-risk HPV genotypes within this population.

Table 1. Epidemiological characteristics and results of women with SLE (n=128)

Variable	Mean ± SD	n (%)	Adherence CQR≥80 (n, %)	p - value
Age (years)	53,35 ± 14,27

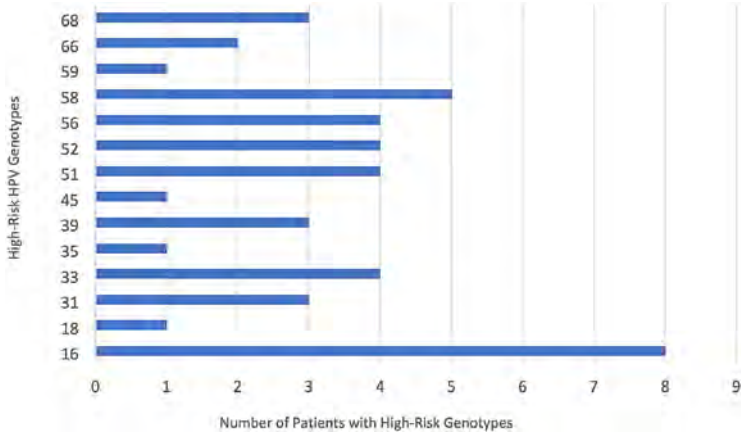

Figure 1. Identified high-risk (HR) HPV genotypes. N= 22 patients

Methods: A retrospective observational study was carried out in a cohort of 128 women with SLE aged 20-50 years, followed in the outpatient rheumatology clinic of a tertiary care hospital in northern Spain.

Results: A total of 128 women were included, with a mean age of 39.11 ± 7.91 years and a mean disease duration of 11.16 ± 7.53 years (Table 1). Among them, 19.53% had never undergone cytology or HPV testing. Among the 80.46% who participated in screening, only 34.37% adhered to the recommended intervals (every three years or less), while the remainder were screened sporadically or outside the established periodicity. A total of 22.65% underwent screening at least once, and 23.43% were screened two or more times without following the recommended intervals. Regarding HPV infections, 18.75% tested positive, predominantly for high-risk genotypes (17.18%), with 8.59% showing coinfection with low-risk genotypes. Genotype 16 was the most frequently identified among high-risk infections (Figure 1). Cervical lesions related to HPV were detected in 14.06% of the women, with 9.37% presenting high-grade lesions (HSIL) and 4.68% presenting low-grade lesions (LSIL). Cervical cancer was diagnosed in 7.03% of the cases, with two patients presenting associated intraepithelial neoplasia of the vagina and vulva. Regarding smoking habits, 21.09% of the women were active smokers, 26.56% were former smokers, and 52.34% had never smoked. No statistically significant association was found between tobacco use and cervical cancer in this cohort ($p = 0.0735$).

Conclusion: The findings reveal a high prevalence of high-risk HPV infections in women with SLE, associated with a considerable risk of progression to premalignant lesions and cervical cancer. However, low adherence to the screening program was observed, highlighting the need for strategies to promote greater participation in such programs.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1914–1935) Health Services Research Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Social risk factors (SRFs) are associated with health outcomes, and patients with chronic conditions often report disproportionately higher rates of SRFs, complicating their disease management.[1,2] Although SRFs change over time, the period over which these changes occur is not well-understood.[3] Further, while routine screenings for SRFs are being incorporated in clinical settings, there are no data-driven guidelines for how often screenings should be conducted. Thus, this study aimed to evaluate the timing of SRF changes in a rheumatology outpatient population.

1. Walker et al. *Endocrine*, 2014. doi: 10.1007/s12020-014-0195-0
2. Heller et al. *Prev Med*, 2021. doi: 10.1016/j.ypmed.2021.106752
3. Xu et al. *Med Care*, 2021. doi: 10.1097/MLR.0000000000001441

Methods: Patients seen in Washington University School of Medicine's Division of Rheumatology outpatient clinics were screened for SRFs between 1/1/2023 and 1/31/2025. Patients completed a standardized SRF screening questionnaire via mobile phones before their visit or iPads upon checking in, with responses automatically uploaded to the Epic electronic health record. Four core (financial resource strain, food insecurity, housing instability, and transportation instability) and four supplemental (physical activity risk, social isolation, stress, and depression) SRF domains were assessed and scored as "at risk" or "not at risk" based on existing Epic criteria. For patients with multiple visits during the study period, SRF data from all

Table 1. Descriptive characteristics of the rheumatology outpatient population, stratified by number of total screenings, 2023-2025.x

Table 2. Prevalence of SRFs over time, proportion with any changes over time, and median time to event for change in SRF status

	Prevalence			% with Any Changes over Time	Median Time to Change (days)
	Visit 1	Visit 2	Visit 3		
Core Domains					
Financial Strain	32% (298/921)	32% (99/305)	36% (40/111)	16% (47/290)	200
Housing Instability	21% (170/803)	15% (43/288)	21% (22/109)	13% (32/253)	201.5
Transportation Needs	10% (97/966)	12% (38/319)	16% (18/114)	12% (37/310)	231
Food Insecurity	24% (218/904)	23% (68/298)	29% (32/111)	10% (28/269)	192
Supplemental Domains					
Stress	51% (489/960)	47% (147/316)	51% (58/114)	31% (95/310)	183
Physical Inactivity	73% (711/977)	74% (231/314)	75% (86/114)	21% (64/310)	170.5
Social Isolation	56% (470/833)	56% (157/279)	61% (60/98)	19% (47/251)	182
Depression	17% (159/937)	16% (50/315)	19% (22/116)	16% (48/300)	186

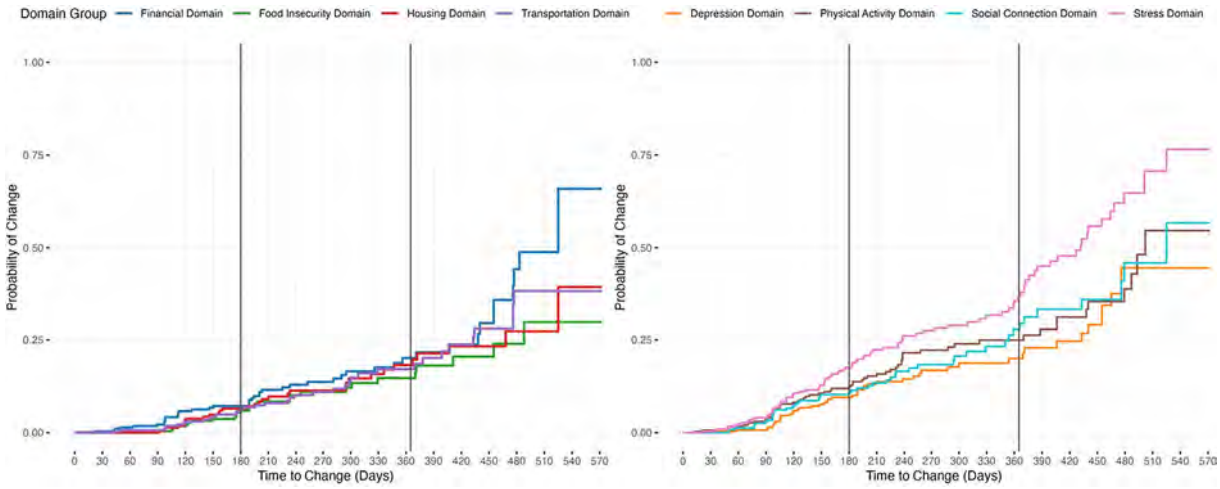

Figure 1. Change curves for all social risk factor domains

relevant visits were used. Descriptive statistics were used to summarize patient characteristics and SRF prevalence. Kaplan-Meier time-to-event analyses and change curves assessed time to changes in risk status for individuals with 2 or more screenings. Events were defined as any change in SRF status from "at risk" to "not at risk," or vice versa. If no change was reported, patients were censored on their last SRF screening date during the study period.

Results: 992 patients (50% 40-64 years, 81% female, 31% Black) were screened for SRFs, with 322 (33%) screened more than once. Characteristics of patients with 2+ screenings were similar to those with only one, except for race (36% vs. 29% Black, respectively; Table 1). The prevalence of SRFs across visits remained fairly stable, with physical inactivity most prevalent (73%-75%) and transportation needs least prevalent (10%-16%) at all visits (Table 2). Only 10% of patients changed risk status for food insecurity compared to 31% for stress, and the median time to change ranged from 170.5 days for physical inactivity to 231.0 days for transportation needs (Table 2). Change curves (Figure 1) showed that stress was most likely to change over time, while the core SRF domains showed low probability of changes.

Conclusion: SRFs among rheumatology outpatients remained stable over time, with most patients reporting consistent SRF status for 6 months or more. Stress exhibits greater variability over time, while less than 25% of patients report changes in core SRF domains over 1 year. This work provides insight into how frequently SRFs should be screened and highlights the importance of incorporating interventions to address SRFs as part of clinical care.

Abstract Number: 1918

Vigorous Physical Activity in Patients with SLE Was Not Associated with Disease Activity or Socioeconomic and Social Factors

Heather Gold[1], Yi Li[1], Isabella Giunta[1], Jill Buyon[1], Peter Izmirly[2], Mala Masson[3], Amit Saxena[1], H Michael Belmont[4], Chung-E Tseng[5] and Rebecca Anthopolos[1], [1]NYU Grossman School of Medicine, New York, NY, [2]New York University Grossman School of Medicine, New York, NY, [3]NYU Langone Health, New York, [4]NYU School of Medicine, New York, NY, [5]New York University Grossman School of Medicine, Flushing, NY

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1914–1935) Health Services Research Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Physical activity can mitigate cardiovascular disease and depression risk and improve fatigue, physical function, and quality of life in patients with SLE. To facilitate physical activity in a diverse patient population with SLE, it is critical to understand whether and how it is associated with socioeconomic, social, demographic, or clinical factors.

Methods: Cross-sectional analysis of patients with SLE from a large, urban city (n=189) who completed the International Physical Activity Questionnaire (IPAQ) based on the past 7-days recall of vigorous physical activity, moderate activity, or walking. Examples of vigorous physical activity include heavy lifting, digging, aerobics, or fast bicycling; moderate activity would include carrying light loads, bicycling at a regular pace, or doubles tennis, but not walking. Variables considered were financial insecurity, Everyday Discrimination Scale, education, age, sex, race, ethnicity, lupus-specific disease activity (any of cutaneous, nephritis, or arthritis), immunosuppressive medication, and Area Deprivation Index. Statistical tests of associations were 2-sided: chi-squared for categorical and Spearman rank correlation for continuous variables. Multivariable analyses applied a quasi-Poisson model due to overdispersion.

Results: The majority of patients (n=120/189, 64%) reported zero days of vigorous physical activity, whereas 42% reported no moderate activity (n=79) and only 4% reported no walking (n=7). Bivariate analyses showed that vigorous physical activity was associated only with lower disease activity (median=0, IQR=0-2 for no vigorous activity vs. median=0, IQR=0-1 for any vigorous activity; p=0.047). Multivariable analysis indicated that the count of vigorous activity days was modestly and negatively associated with disease activity, where a 1-unit increase in disease activity was associated with a 46% decrease in

Table. Multivariable analysis of days of vigorous physical activity in the past week.

	Coefficient	Standard Error	Percentage change*	p-value
Any financial insecurity	0.17	0.27	0.19	0.5
Everyday Discrimination Scale	-0.07	0.09	-0.07	0.5
Disease activity	-0.62	0.34	-0.46	0.068
College degree or more	0.42	0.47	0.51	0.4
Age	-0.01	0.01	-0.01	0.3
Male sex	-0.06	0.39	-0.05	0.9
Asian	-0.74	0.41	-0.52	0.07
Black	-0.38	0.33	-0.32	0.3
Other race	-0.23	0.36	-0.21	0.5

physical activity (p=0.068). Results suggest there is insufficient evidence of significant associations with most covariates in our sample.(Table) Outcomes of total physical activity, moderate activity, and walking in multivariable models showed no significant associations with covariates, leaving only vigorous activity reported here.

Conclusion: The null findings are illuminating and suggest that disease activity and socioeconomic and social factors did not keep patients from engaging in vigorous activity. Future longitudinal analysis will aid in understanding patterns of physical activity related to clinical factors and patient-reported outcome measures of pain, fatigue, depression, and more.

Abstract Number: 1919

Financial insecurity and discrimination are associated with patient-reported quality of life in patients with SLE

Heather Gold[1], Yi Li[1], Peter Izmirly[2], Jill Buyon[1], Mala Masson[3], Amit Saxena[1], H Michael Belmont[4], Chung-E Tseng[5] and Rebecca Anthopolos[1], [1]NYU Grossman School of Medicine, New York, NY, [2]New York University Grossman School of Medicine, New York, NY, [3]NYU Langone Health, New York, [4]NYU School of Medicine, New York, NY, [5]New York University Grossman School of Medicine, Flushing, NY

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1914–1935) Health Services Research Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Manifestations of SLE are known to affect patient-reported outcome measures (PROs) such as physical function, fatigue, and pain. Other work has suggested economic insecurity is associated with worse PRO scores, and discrimination can have a chronic effect on health status. This study focused on the association of PROs with individual and structural socioeconomic factors and SLE-related clinical variables.

Methods: A cohort of patients (n=272) diagnosed with SLE according to standard classification criteria (ACR revised classification, European Alliance of Association for Rheumatology/ACR classification, or SLICC classification) were surveyed using measures from the NIH Patient-Reported Outcomes Measurement Information System (PROMIS) for physical function, cognitive function, pain interference, fatigue, anxiety, sleep disturbance, and depression. Analyses included demographics, financial/material insecurity such as in housing, finances, healthcare, or job status, and clinical data on disease activity (any of cutaneous, nephritis or arthritis) and immunosuppressive medication use. Everyday Discrimination Scale was captured to quantify the potential impact of discrimination and its associated chronic stress on health (coded as never vs ever experienced 9 discrimination types and summed across types). Multivariable linear regression models of PROs included clinical and socioeconomic factors.

Results: The cohort was 90% female, 28% African American/Black, 17% Asian, 39% white, and 16% other/unknown, with an average age of 40 years. Average SLEDAI was 3.17 (SD=3.52) and SLICC damage score 1.12 (SD=1.53). Multivariable models showed that experiencing financial insecurity was associated with significantly worse scores on all PROs, from 4-7

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table. Multivariable linear regression analysis of patient-reported outcome measures (coefficient & significance level), n=272

PROMIS measure	financial insecurity		Disease activity (any of cutaneous, arthritis, nephritis)		Immunosuppressive medications		Everyday Discrimination Scale	
Physical Function	-5.17	***	-4.24	*	-0.50		-1.33	**
Cognitive Function	-6.10	**	-1.10		-1.35		-1.22	*
Pain Interference	7.39	***	2.71		0.97		1.59	**
Fatigue	5.76	***	2.69		0.17		2.02	**
Sleep Disturbance	3.80	*	3.37	*	-2.87	*	1.38	*
Depression	4.82	***	4.14	***	-0.26		1.43	**
Anxiety	3.53	*	2.25	*	-0.48		1.53	**

***p<0.0001; **p<0.001; *p<=0.04
Models adjusted for age, sex, race, ethnicity, Area Deprivation Index.
Note: PROs for function are better when higher, whereas PROs for symptoms are better when lower.

points worse (p< 0.01). Each additional point on the Everyday Discrimination Scale was associated significantly with 1 point worse on physical and cognitive function score, 1 point higher sleep disturbance, depression, and anxiety, and 2 points higher on fatigue on average (p< 0.05). Finally, experiencing disease activity was significantly associated with lower physical function and higher sleep disturbance, depression, and anxiety (p< 0.05). (Table)

Conclusion: Experiencing financial insecurity was associated with clinically important negative impacts in function and symptom PROs; everyday discrimination consistently significantly negatively affected PRO scores; and disease activity was negatively associated with 4 of the 7 measures. Understanding the full experience of patients with SLE, beyond their clinical manifestations, may help identify approaches to support patients for improved function and reduced symtpoms.

Abstract Number: 1921

Re-escalation of Treatment in Older Adults with Rheumatoid Arthritis After Anti-TNF Therapy De-escalation

Jiha Lee[1], Jonathan Martindale[2], Una Makris[3] and Julie Bynum[2], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, [3]UT Southwestern Medical Center and Dallas VA, Dallas, TX

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1914–1935) Health Services Research Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Older adults with rheumatoid arthritis (RA) treated with biologic disease-modifying antirheumatic drugs (bDMARDs), including anti-TNFs, are at an increased risk of adverse effects. Current guidelines recommend de-escalating DMARDs for patients with low disease activity or remission to optimize the benefit-harm ratio of treatment. We previously found that 20% of older adults with RA de-escalated anti-TNFs. In this follow-up study, we investigated the frequency and factors associated with re-escalation of treatment after de-escalation of anti-TNFs.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We used 20% Medicare data from 2009-2022 to identify RA patients ≥66 years of age on Part D self-injectable anti-TNF therapy (i.e. Adalimumab, Etanercept, Certolizumab, and Golimumab) with de-escalation by cessation (> 90-day gap) or by taper (>50% effective dose reduction), and at least one rheumatologist visit pre- post-de-escalation (i.e. index date). The outcome of interest was re-escalation, defined as restarting the same anti-TNF or another bDMARD after at least a 90-day gap or increasing the effective dose of anti-TNF by >50% after the index date. Information on baseline patient characteristics, concomitant use of conventional synthetic DMARDs (csDMARDs), and changes in average glucocorticoids (GC) dose were collected. The Cox proportional hazard model was used to identify factors associated with re-escalation.

Results: We identified 949 Medicare beneficiaries who met the inclusion criteria. Three in five (61.6%) re-escalated treatment with a median time of 164 (IQR 113-301) days since the index date (Figure 1). Older adults who re-escalate treatment, compared to those with sustained de-escalation, were less frequently non-Hispanic white (72.6% vs 81.3%, p=0.002) and had fewer comorbidities (mean Elixhauser index 2.9 [2.1] vs 3.3 [2.4], p=0.003) (Table 1). The two groups, re-escalators vs. sustained de-escalators, were similar in their age distribution (mean age 74.9 [5.8] vs 75.4 [SD 5.9], p=0.172), female predominance (83.2% vs 81.3%, p=0.447), low-income subsidy (LIS) status (43.9% vs 38.7%, p=0.115), and concomitant use of csDMARDs at index (62.7% vs 61.0%, p=0.590). The change in average daily dose of glucocorticoids pre- and post-index was not significantly different between the two groups (mean 0.6mg/day [4.0] vs 0.5 [SD 3.7], p=0.334). In Cox analyses, re-escalation was more likely in blacks, Hispanics/others, and those with lower comorbidity burdens (Table 2).

Table 1: Baseline characteristics of older adults with RA who had de-escalation of primary anti-TNF use and in fee-for-service Medicare, between 2009-2022

Variables	All RA patients N=949	Pattern of Primary Anti-TNF use after de-escalation		P*value

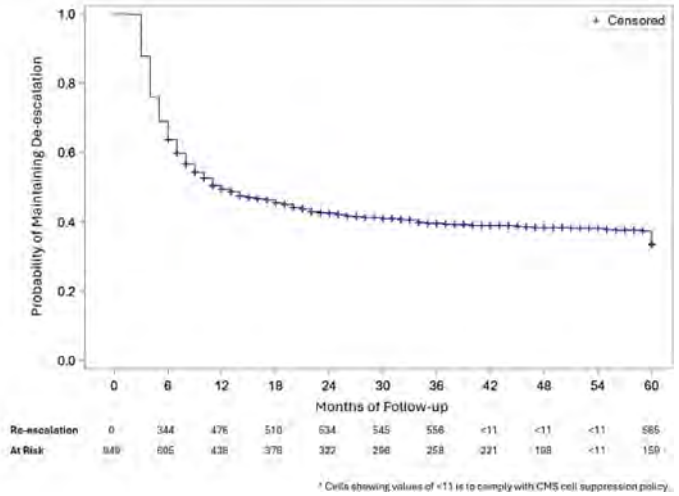
Concomitant csDMARD use	1.05 (0.89, 1.25)	1.08 (0.91, 1.28)
Increase in average dose steroids pre- to post-index, (mg/day)	1.01 (0.98, 1.03)	1.01 (0.99, 1.03)
Index Year	Not significant	Not significant

Figure 1: Kaplan-Meier curve for time to re-escalation of treatment in older adults with RA after de-escalation of anti-TNFs



[1] Cells showing values of <11 is to comply with CMS cell suppression policy.

Conclusion: Nearly two-thirds of older adults re-escalate treatment within a year of de-escalating anti-TNF therapy, displaying a frequency comparable to that observed in the younger population. These findings suggest that continued exposure to anti-TNF for most older RA patients. In our prior study, de-escalation was associated with a greater comorbidity burden. In this follow-up study, re-escalators had fewer comorbidities, possibly due to concerns for more adverse effects with anti-TNF or other bDMARD therapy. Additional research is needed to identify and understand the subset of older RA patients able to maintain drug-free RA control.

Abstract Number: 1923

A Real-World Survey on Physicians Perspectives of Uncontrolled Gout and Gout Management Practices

John Botson[1], Menaka Bhor[2], Nathan Meyer[2], Molly Edwards[3], Emily Goddard[3], Victoria Barton[4] and Jeff Peterson[5], [1]Orthopedic Physicians of Alaska, Anchorage, AK, [2]Sobi Inc, Waltham, MA, [3]Adelphi Real World, Bollington, United Kingdom, [4]Adelphi Real World, Macclesfield, United Kingdom, [5]Western Washington Arthritis Clinic, Bothell, WA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1914–1935) Health Services Research Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

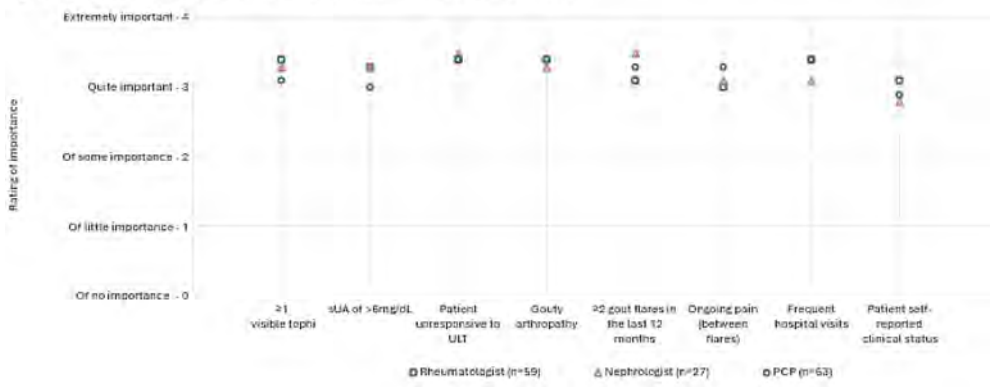
Background/Purpose: Managing uncontrolled gout (UG) can involve a multi-disciplinary approach involving physicians of different specialities, all of whom may have differing perspectives or approaches for management of the condition due to the complex clinical manifestations and comorbidities. An understanding of physician perspectives of gout management across different physician specialties may help to improve education and patient care. This study evaluated physicians' perspectives of UG and gout management practices.

Methods: Data was extracted from the Adelphi Real World Gout Disease Specific Programme (DSP)™, a cross-sectional survey (with retrospective data collection) from rheumatologists, nephrologists and PCPs in the United States from August 2023 - March 2024. Physicians who participated in this study managed ≥ 8 patients with gout in a month with urate lowering therapy (ULT). Physicians' perspectives obtained on UG included importance of different attributes in defining UG (where 0 was of no importance and 4 was extremely important); factors contributing to UG development; management of gout (including UG): use of treat to target (T2T), diagnostic and monitoring tests; and remission. Analyses were descriptive.

Results: Overall, 59 rheumatologists, 27 nephrologists and 63 PCPs participated in the study.

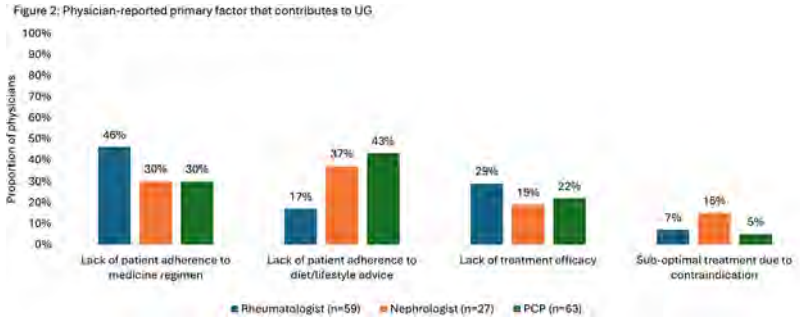
Physicians across specialities rated most attributes associated with UG with an importance of 3-3.5 out of 4 (Figure 1). Overall, non-response to ULT and presence of gouty arthropathy were rated the most important (with an overall mean score of 3.4 across all physicians).

Figure 1. Physician-rated Importance Of Attributes Associated With Uncontrolled Gout



Frequent hospital visits: >2 annually. Gouty arthropathy: defined clinically or radiographically as joint damage due to gout. sUA: serum uric acid, PCP: primary care physician, UG: uncontrolled gout, ULT: urate lowering therapy.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



PCP: primary care physician, UG: uncontrolled gout

The top factor contributing to UG reported by rheumatologists was lack of patient adherence to medicine regimen (46%), whereas adherence to diet/lifestyle advice was the top reason reported by nephrologists (37%) and PCPs (43%) (Figure 2).

To monitor clinical manifestations of their UG patients, test use varied across physician types. Tophi size measurement was used by 56% of rheumatologists, 37% of nephrologists and 48% of PCPs. C-reactive protein tests were used by 53%, 37%, 35% and synovial fluid aspiration by 15%, 11% and 5% respectively, whilst sUA levels were monitored by >80% physicians regardless of speciality.

When looking at treatment response, T2T was reported to be used in all patients with gout by 59% of rheumatologists, 41% of nephrologists and 40% of PCPs.

With regard to possibility of remission of gout and UG, 42% of rheumatologists reported that remission was possible in all patients with gout, as opposed to 26% of nephrologists and 35% of PCPs.

Conclusion: There was variation in perceptions of UG and gout management practices amongst physician specialties, which may come from differences in training and experience with managing patients with uncontrolled gout. Future research initiatives which focus on education, adherence to guidelines, intensive management (T2T), monitoring, and remission as a goal may standardize care among specialties and may improve patient outcomes.

Background/Purpose: Systemic autoimmune rheumatic diseases (SARDs) are a group of autoimmune diseases that affect multiple organ systems, including the lungs. The development of interstitial lung disease (ILD) in the context of SARD (SARD-ILD) is a significant clinical concern due to its high prevalence, progressive nature, and its associated morbidity and mortality. There is limited published evidence describing how SARD-ILD patients with disease progression are being managed in the United States. This study aims to bridge the knowledge gap by describing the treatment patterns of patients with SARD-ILD following ILD progression.

Methods: This retrospective cohort study used Optum Clinformatics® administrative claims database from 01 January 2017 to 31 March 2024. The study cohort included adult patients diagnosed with SARD-ILD on or after 01 Jan 2018 and with evidence of ILD progression. Disease progression was identified using previously published claims-based proxies, which included health care utilization related to the management of ILD progression The earliest date of ILD progression was defined as the index date, with a requirement for a minimum of 12-month continuous enrollment before (baseline period) and after the index date (follow-up period). The proportion of patients receiving pharmacologic and non-pharmacologic treatments related to SARD-ILD following ILD progression was descriptively assessed for the overall SARD-ILD cohort. Pharmacologic treatments include antifibrotics, biologic and non-biologic disease modifying antirheumatic drugs (DMARDs), immunomodulators, oral corticosteroids, and other ILD-related treatments. Non-pharmacologic treatments included lung transplant, pulmonary rehabilitation and supplemental oxygen therapy.

Results: The study included a total of 6,431 patients. The mean (standard deviation [SD]) age of the overall cohort was 71.2 (11.1) years and 75.3% were female (Table 1). Rheumatoid arthritis was the most prevalent underlying SARD type (52.6%). The mean (SD) follow-up duration was 936 (467) days. While 83% of patients received any pharmacologic treatment group during the follow-up, only 55% have received disease modifying treatments (i.e., biologic and non-biologic DMARDs, immunomodulators, and antifibrotics). Oral corticosteroids and non-biologic DMARDs were the most frequently prescribed pharmacologic treatment groups (Figure 1). Among immunomodulators, mycophenolate (10.6%), azathioprine (5.5%), and

Abbreviations: DMARD – disease modifying antirheumatic drugs
Notes: Treatment groups are not mutually exclusive.
Medications included in each treatment group: *Antifibrotics* (nintedanib and pirfenidone); *Biologic DMARD* (Abatacept, adalimumab, etanercept, infliximab, rituximab, tocilizumab); *Immunomodulators* (azathioprine, cyclosporine, cyclophosphamide, mycophenolate mofetil/mycophenolic acid, tacrolimus); *Other* (N-acetylcysteine, azithromycin, Inhaled treprostinil, sildenafil, epoprostenol, bosentan, macitentan, ambrisentan, riociguat, tadalafil); *Non-biologic DMARDs* (chloroquine phosphate, hydroxychloroquine, leflunomide, methotrexate, penicillamine, sulfasalazine); *Oral corticosteroids* (betamethasone, dexamethasone, methylprednisolone, prednisone, prednisolone, cortisone acetate).

Figure 1. Proportion of patients receiving ILD-related treatments after ILD progression during follow-up, among all patients with SARD-ILD

tacrolimus (0.8%) were the most commonly prescribed medications. While only 3.5% of patients received antifibrotics after progression, we observed increasing trend in the use of antifibrotics across the study period. Supplemental oxygen therapy was the most commonly used non-pharmacologic treatment (Figure 1).

Conclusion: The study provides real-world insights into the treatment patterns of patients with SARD-ILD after ILD progression. The study findings suggest unmet needs and gaps in current treatment strategies remain. The limited use of disease modifying pharmacotherapies post-progression underscores a gap between real-world practice and evidence-based recommendations, potentially leading to suboptimal disease management.

Abstract Number: 1925

Associations Between representation And quality in Clinical Trials for Systemic Lupus Erythematosus

Joshua Skydel[1], Anna Leland[2], Reshma Ramachandran[3], Fotios Koumpouras[3] and Joshua Wallach[2], [1]Yale-New Haven Hospital, New Haven, CT, [2]Rollins School of Public Health, Atlanta, GA, [3]Yale School of Medicine, New Haven, CT

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1914–1935) Health Services Research Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Drug development in SLE is informed by US Food and Drug Administration recommendations for study design, enrollment, and efficacy endpoints. However, persistent challenges to conducting high-quality randomized clinical trials (RCTs) have been noted, including variation in endpoint assessment, predominantly urban enrollment, and underrepresentation of minoritized populations. RCT quality contributes to the perceived strength of research findings, yet little is known about heterogeneity in trial design, including potential associations between representation and the quality of RCTs in SLE.

[a] Includes trial evaluating anifrolumab, belimumab, or voclosporin for use in SLE or LN.

[b] Based on National Center for Health Statistics Urban-Rural Classification, updated 2023.

[c] Based on Health Resources and Services Administration designation of US counties lacking access to primary care services, updated December 2024.

[d] Based on US Census Bureau nomenclature. Enrollment data was not available for all trials (see Table 2 footnotes).

[e] Includes 5 trials for which "Hispanic" was reported as a race, and 38 trials for which "Hispanic" was reported as an ethnicity (i.e., independent of race).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We identified RCTs of small molecules and biologics for SLE registered on ClinicalTrials.gov and published in peer-reviewed journals as of January 2025. Eligible RCTs evaluated a primary efficacy endpoint and included 1+ US enrollment site. US enrollment sites for RCTs were classified using the National Center for Health Statistics Urban-Rural Classification Scheme; medically underserved areas were identified. For each RCT, enrollment by sex, race, and ethnicity was identified from publications and compared to the demographics of US Centers for Disease Control and Prevention SLE registries using participation-to-prevalence ratios (PPRs). PPRs greater than 0.8 indicated adequate representation. RCT quality was assessed using the Cochrane Risk of Bias 2 tool. Associations between RCT enrollment and quality were evaluated using Fisher's exact tests, with significance set at .05.

Results: There were publications for 54 RCTs and 1 pooled analysis of 2 RCTs. Median enrollment among 55 unique RCT reports was 298 (interquartile range, 130-449) (**Table 1**). Half of RCTs enrolled in at least one small metropolitan or non-metropolitan area in the US; however, most US sites (1392/1845, 75%) were in large metropolitan areas. Representation across RCTs was adequate for female (median PPR 1.0), Hispanic (median PPR 1.3), Asian (median PPR 2.1) and White (median PPR 1.0) participants, while American Indian/Alaska Native (AIAN, median PPR 0.7) and Black (median PPR 0.4) participants were underrepresented. Enrollment was similar regardless of whether therapeutics are approved for use in SLE. Among 55 RCTs, there were similar numbers with low risk (19, 34%), some concerns (19, 34%), or high risk (17, 30%) of bias (**Table 2)**. There were no significant differences in RCT quality by geographic enrollment features. A significantly higher proportion of RCTs at high risk of bias was observed among those inadequately enrolling AIAN (*P*=.04) or White (*P*=.02) participants.

Conclusion: This study suggests that although numerous therapies have been investigated for use in SLE, US enrollment remains limited outside of large metropolitan areas, and enrollment overall underrepresents minoritized populations at risk of severe disease. Although RCT quality was not associated with geographic enrollment features, high risk of bias was less

Table 2: Cochrane Risk of Bias 2 analyses for SLE clinical trials

Table 2: Cochrane Risk of Bias 2 analyses for SLE clinical trials

		Clinical trials, No. (%)[c]	Overall risk of bias assessment, No. (%)			*p*-value
			Low risk	Some concerns	High risk

frequently observed among RCTs with adequate enrollment of AIAN and White participants. Variation in RCT quality is notable and may limit the generalizability of findings to real-world patients, contributing to uneven update and lack of clarity over the optimal use of promising therapies.

Abstract Number: 1926

Real World Rate of Efficacy of Adalimumab Biosimilars Following a Mandated Switch in an Academic Medical Center

Katharine McCarthy, viktoriya avlasevich and Darren Tabechian, URMC, Rochester, NY

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1914–1935) Health Services Research Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The proliferation of similar biotherapeutic products (biosimilars) has helped to reduce the cost burden of biologic therapies for health care systems[1]. Multiple studies have demonstrated biosimilars to be equally effective based on head-to-head trials of various adalimumab biosimilars in inflammatory autoimmune diseases[2]. Switching from adalimumab to a biosimilar in patients with stable and controlled diseases generally results in 1-year retention rates of 90% from real world experience outside the U.S.[3]. Due to the dynamic changes of insurance plans and formularies within the United States healthcare system, there is minimal data on retention rates and persistence of efficacy in real-world U.S. patients. It was our intention to survey the rate of continuation of adalimumab biosimilars in patients switched from adalimumab for inflammatory indications in a single academic medical center.

Methods: All patients 2 years of age and older who had received adalimumab or a biosimilar dispensed by the University of Rochester Specialty Pharmacy between 7/1/2023 and 12/31/2024 were included in the study. Patients were categorized into two cohorts, including those continuing adalimumab exclusively compared to patients who switched to a biosimilar agent(s). Patients were followed until 3/31/2025. The URMC IRB approved the study as exempt with data collected from Epic electronic medical record and Willow Ambulatory Pharmacy dispensing databases.

Results: 1,006 patients were identified and included in the study with an average age of 44 years old (range 2 – 88) and majority (60.2%) female. Rheumatoid arthritis was the most common diagnosis (32.1%) Across the 18-month time period, 97 patients (9.6%) were switched to a biosimilar with adalimumab-adaz and adalimumab-bwwd most common. 15 of 97 (15.5%) did not continue the biosimilar

Conclusion: Real world experience following mandated switch from adalimumab to a biosimilar showed a marginally higher rate of discontinuation than comparable cohorts from outside the United States. The cost of medication saved by switching to biosimilar medications may justify this rate of unanticipated mediation interruption.

Oral Health in Patients with Rheumatic Diseases: A Pilot Quality Improvement Program

Margarita Isabel Alarcon-Jarquin[1], Fernanda M. Garcia-Garcia[2], Vanessa L. Lopez-Flores[1], Aleydis Gonzalez-Melendez[3], Gabriel Figueroa-Parra[3], Dionicio A. Galarza-Delgado[2] and Janett C. Riega-Torres[4], [1]Rheumatology Service, University Hospital "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Monterrey, Nuevo Leon, Mexico, [2]Rheumatology Service, Hospital Universitario Dr. José Eleuterio González, Universidad Autónoma de Nuevo León, Monterrey, Mexico, [3]Rheumatology Service, Hospital Universitario "Dr. Jose Eleuterio Gonzalez", Universidad Autonoma de Nuevo Leon, Monterrey, Mexico, [4]Rheumatology Service, Hospital Universitario "Dr. Jose Eleuterio Gonzalez", Universidad Autonoma de Nuevo Leon, Monterrey, Nuevo Leon, Mexico

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1914–1935) Health Services Research Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with rheumatic diseases commonly experience oral health issues such as dental caries, xerostomia, and periodontal disease. These complications are linked to both the disease itself and immunosuppressive treatments, often leading to reduced quality of life and poor systemic inflammatory control. Despite this, oral health remains insufficiently addressed in rheumatologic care.

This study presents the experience of an interdisciplinary rheumatology-dentistry clinic. It evaluates the impact of collaborative care on early oral risk detection, health promotion, and oral health-related quality of life in patients with rheumatic diseases.

Methods: A structured interdisciplinary care model was established in 2017 to link rheumatologists with dental professionals. Its aim was to prevent oral health deterioration in patients with rheumatic diseases. During routine evaluations, rheumatologists screened for oral risk factors and referred patients to dentists trained in rheumatologic oral conditions.

Dentists conducted comprehensive evaluations including physical exams, salivary tests, ICDAS (International Caries Detection and Assessment System), and GOHAI (Geriatric Oral Health Assessment Index) scoring. Individualized prevention plans were developed addressing hygiene, diet, salivary stimulation, and fluoride use. Referrals to dental specialists were made as necessary. The model ensured continuous monitoring of clinical and patient-reported outcomes, creating a feedback loop to promote adherence and sustained care integration (Figure 1).

Results: A total of 415 patients with rheumatic diseases were included. The mean age was 52.27 ± 14.17 years; 91.1% were female, and 6.3% were pregnant. Diagnoses included rheumatoid arthritis (57.1%), systemic lupus erythematosus (17.1%), primary Sjögren's syndrome (14.2%), and other conditions (11.6%).

All patients attended the initial dental consultation; 90% were referred to other dental specialties. Prevalence of oral conditions included dental caries in 60.7%, reduced unstimulated salivary flow in 46.7%, and missing teeth in 10.3%. All received personalized oral health recommendations from trained dental professionals.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 1. Integrated Oral Health Workflow in Rheumatology Care

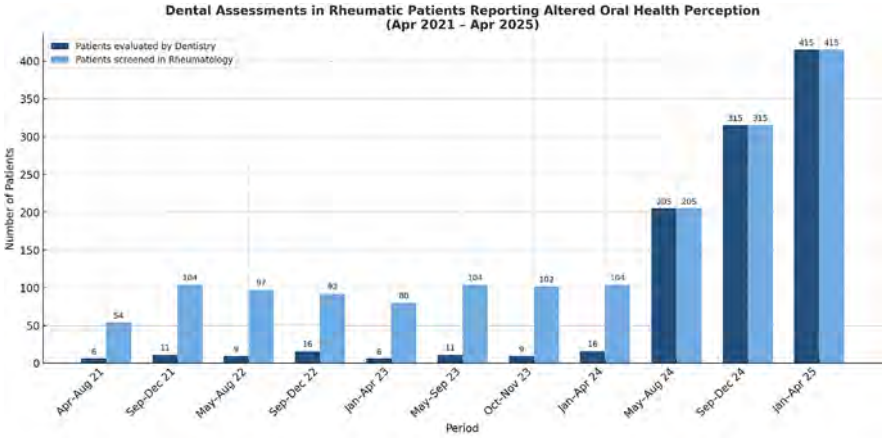

Figure 2. Rheumatologic and *dental assessments over time in patients with rheumatic diseases reporting altered oral health perception (April 2021 – April 2025).*

Initially launched in collaboration with the dentistry department, the program expanded in 2024 due to increasing demand. That year, dental services were fully integrated within the rheumatology clinic's physical space, significantly increasing dental consultations and improving referral pathways and specialized care access (Figure 2).

Conclusion: Integrating dental evaluations into rheumatology care improved detection and management of oral health issues in patients with rheumatic diseases. The increase in referrals and enhanced interdisciplinary collaboration demonstrates the feasibility and value of coordinated care. Immediate referrals and universal oral health guidance highlight the success of this patient-centered, integrated model.

Abstract Number: 1929

Economic Burden of Macrophage Activation Syndrome (MAS) in Patients with Still's Disease (Systemic Juvenile Idiopathic Arthritis (sJIA) and Adult-onset Still's Disease (AOSD)): Analysis of a US National Administrative Claims Database

Michael Marrone[1], Christopher McPherson[2] and Abiola Oladapo[3], [1]Sobi Inc., Mt Pleasant, SC, [2]Sobi, University City, MO, [3]Sobi INC, Waltham, MA

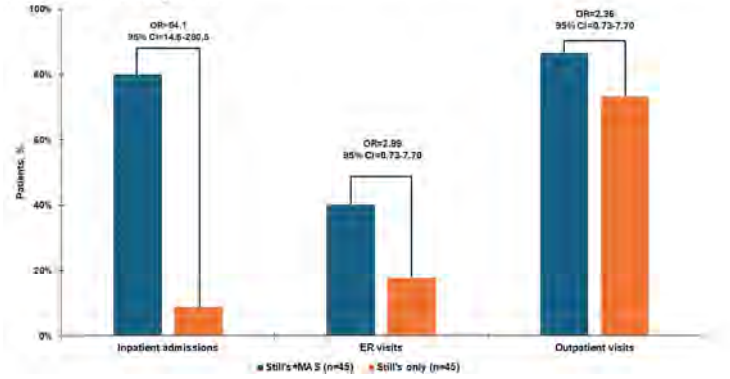
SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1914–1935) Health Services Research Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Macrophage activation syndrome (MAS) is a severe, life-threatening complication of rheumatologic disease. MAS is a form of secondary hemophagocytic lymphohistiocytosis which occurs most frequently in patients with Still's disease (i.e., systemic juvenile idiopathic arthritis (sJIA) or adult-onset Still's disease (AOSD)). MAS, if not properly treated, may progress to multiple organ failure and mortality. Treatment is aimed at achieving clinical stability and symptom resolution. However, there is currently no FDA approved therapy for MAS and corticosteroids remain the mainstay of treatment. Further, limited information exists regarding the economic burden (i.e., healthcare resource utilization (HCRU) and costs) of MAS in patients with Still's disease in the United States.

Methods: A retrospective analysis of administrative claims (IQVIA PharMetrics Plus) from 2019 to 2024 was used to identify: Patients diagnosed with Still's disease [(ICD-10:M082) including AOSD (ICD-10:M061) and sJIA (ICD-10:M08)] with ≥6 months of continuous enrolment prior to Still's diagnosis (index date) and ≥12 months of continuous enrolment post-index without a MAS diagnosis (ICD-10:D76.1); and patients with Still's disease with ≥6 months of continuous enrolment prior to earliest MAS diagnosis observed in the study period and ≥12 months of continuous enrolment post-MAS diagnosis. A propensity score was used to match patients (1:1) with Still's disease with and without MAS. All-cause HCRU (inpatient [IP] admission, emergency room [ER] visits, and outpatient [OP] visits) and costs (all-cause and rheumatologic; adjusted to

Figure 1. All-cause HCRU (i.e. proportion of patients by visit type) during the post-index period



HCRU was measured during the observation period, defined as the 12-month post-index period. ORs were evaluated for binary variables (ie, at least one visit) using logistic regression. Models were controlled for age at Still's diagnosis, underlying Still's diagnosis (AOSD, sJIA), sex, and ECI during the baseline period. ORs >1 indicate higher odds for patients with Still's and MAS compared with propensity score matched patients with Still's without MAS. ECI= Elixhauser Comorbidity Index; CI=Confidence interval; ER= Emergency room; HCRU=Healthcare resource utilization; MAS=Macrophage Activation Syndrome; OR= Odds ratio.

Outpatient cost				
Mean (SD)	3,627 (5,200)	910 (2,186)	3,455.76 (824 – 6,097)	0.01
Pharmacy cost				
Mean (SD)	30,857 (58,592)	9,533 (26,624.45)	21,224.10 (-1210 – 43,658)	0.06
Rheumatologic-related cost (Medical and Pharmacy)				
Mean (SD)	163,099 (575,457)	1,930 (4,063)	161,169 (22,714 – 299,623)	0.02

* Results remained robust when adjusted for age at Still's diagnosis, underlying Still's diagnosis (i.e., AOSD, sJIA), sex, and ECI †Limited to patients with at least 1 in-patient admission AOSD= Adult-onset Still's disease (AOSD); CI=Confidence interval; ECI= Elixhauser Comorbidity Index; ER=Emergency room; MAS= macrophage activation syndrome; sJIA= Systemic juvenile idiopathic arthritis

2024 US dollars using the medical component of the Consumer Price Index) were ascertained in the post-index period. Differences in HCRU and costs were estimated using both unadjusted and adjusted analysis.

Results: After propensity score matching, 45 patients with Still's and 45 patients with Still's and MAS were included (mean [SD] age, 26.8 [15.1] and 26.8 [16.0] years at Still's diagnosis, respectively; female, 55.6% and 60.0%, respectively). Mean (SD) Elixhauser Comorbidity Index was 1.6 (1.5) and 2.1 (2.8), respectively. The most common comorbidities were rheumatoid arthritis (48.9% and 42.2%) and cardiac arrythmia (13.3% and 22.2%) in patients with Still's with and without MAS, respectively.

Patients with MAS were significantly more likely to have an ER visit (P=0.04) and/or IP admission (P< 0.001) than patients without MAS in the 12-month post-index period (Figure 1). They also had significantly more frequent IP admissions (P< 0.001), ER visits (P< 0.001), OP visits (P=< 0.001), and longer IP stays (P< 0.001) than patients without MAS (Table 1). In addition, patients with MAS incurred significantly (P=0.008) higher total all-cause ($318,828 vs $19,233) and rheumatologic-related ($163,099 vs $1,930) healthcare costs (P=0.02) than patients without MAS (Table 2).

Conclusion: Patients with Still's and MAS incurred significantly higher HCRU and associated costs compared with similar patients without MAS. Availability of novel therapies targeted to treat MAS may reduce the overall burden of disease to patients and the healthcare system.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1914–1935) Health Services Research Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Delayed diagnosis and treatment in chronic inflammatory rheumatic diseases (CIRDs), including rheumatoid arthritis (RA), axial spondyloarthritis (axSpA), and psoriatic arthritis (PsA), is associated with poorer clinical outcomes. Although referral algorithms exist, there is limited evidence on the real-world effectiveness of awareness campaigns in improving referral practices to rheumatology.

The objective of this study was to assess the impact of a multinational awareness campaign on referral trends and diagnostic delays for CIRDs across Arab countries.

Methods: This prospective pre-post interventional study was conducted in eight Arab countries between November 2023 and November 2024. Baseline data on referral patterns and diagnostic delays were collected in November 2023. Diagnostic delay was defined as the interval from symptom onset to confirmed diagnosis in newly diagnosed CIRD patients. From December 2023 to October 2024, a structured awareness campaign targeted primary care physicians and non-rheumatology specialists.

Table 1. Change in the proportion of new patients referred to 14 high-volume rheumatology clinics in 8 countries, before and after the multinational awareness campaign

	2023 (pre-campaign)	2024 (post-campaign)	Absolute difference in %	p-value
N	2490	3616		
New patients, N (%*)	746 (29.96%)	1031 (28.51%)	-1.45%	
New patients with CIRDs, N (%**)	234 (31.37%)	383 (37.15%)	**+5.78%**	<0.001
New patients with RA, N (%**)	124 (16.62%)	184 (17.85%)	+1.23%	<0.001
New patients with axSpA, N (%**)	94 (12.60%)	136 (13.19%)	+0.59%	<0.001
New patients with PsA, N (%**)	16 (2.14%)	63 (6.11%)	+3.97%	<0.001

*Percentages from all patients (in columns)

**Percentages from new patients (in columns)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Key timelines in the referral of new patients with CIRDs to rheumatology, before and after the multinational awareness campaign

The campaign featured live webinars (n=9), social media dissemination via the Arab League of Associations for Rheumatology (ArLAR) channels, and in-person workshops held in September–October 2024 (n=22), using a previously validated referral algorithm. The primary outcome was the change in the proportion of newly referred RA, axSpA, and PsA patients (collectively referred to as CIRDs) across 14 high-volume rheumatology centers. Secondary outcomes included time intervals from symptom onset to first physician contact and to rheumatologic diagnosis. Descriptive statistics were presented using medians and interquartile ranges (IQRs). Multivariable linear regression was used to identify factors associated with diagnostic delays.

Results: In November 2024, 3616 patients were seen across the 14 clinics, including 1031 (28.5%) new patients, of whom 383 (37.1%) were newly diagnosed with CIRDs (RA: n=184; axSpA: n=136; PsA: n=63). Compared to baseline, the proportion of newly referred CIRD cases increased by 5.8% (from 31.4% to 37.1%, $p< 0.001$). Subgroup increases were observed in RA (from 16.6% to 17.8%), axSpA (12.6% to 13.2%), and PsA (2.1% to 6.1%) (Table 1). Among 365 newly diagnosed CIRD patients (mean age 42.6±15.2 years; 62.7% female), the median time from symptom onset to diagnosis decreased from 18.4 months (IQR 5.8–48.7) to 12.0 months (IQR 4.0–36.0). Reductions were also observed by disease subtype: RA (12.2 to 9.0 months), axSpA (36.5 to 27.5 months), and PsA (24.3 to 12.0 months) (Figure 1). Multivariable analysis identified longer disease duration (B=4.969, $p< 0.001$), lower educational attainment (B=10.589, $p=0.015$), and longer time to rheumatologist consultation (B=0.727, $p< 0.001$) as independent predictors of diagnostic delay.

Conclusion: This multinational intervention was associated with increased rheumatology referrals and significantly reduced diagnostic delays for patients with CIRDs. While causality cannot be definitively established, the findings support the value of targeted awareness strategies in improving early access to rheumatologic care. Further longitudinal studies are recommended to evaluate sustained impact.

Abstract Number: 1931

COSMOS Prevalence of aTTP in SLE

Nisha Sapkota[1], Yevheniia Andriushchenko[2], Saadia Malik[2], Sarang Choi[2] and Sima Terebelo[2], [1]Interfaith Medical Center, One Broolyn Health, Brooklyn, NY, [2]Brookdale Hospital Medical Center, One Brooklyn Health, Brooklyn

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1914–1935) Health Services Research Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex autoimmune disease with diverse manifestations, including thrombotic thrombocytopenic purpura (TTP), a life-threatening hematologic disorder. The pathogenesis of acquired TTP (aTTP) in SLE is believed to involve formation of autoantibodies against ADAMTS13, which inhibit this matrix metalloproteinase activity, thus inhibiting the cleavage of von Willebrand factor multimers and ultimately promoting platelet aggregation and leading to microvascular thrombosis. The clinical overlap between SLE flares and aTTP poses significant diagnostic and therapeutic challenges. This study aims to assess the prevalence, clinical characteristics, and management of aTTP in SLE patients.

Methods: We conducted a retrospective cohort study using the Cosmos Cohort, an integrated database with nearly 296 million patient encounters from multiple US healthcare systems. We searched all encounters from March 31, 2015 to March 5, 2025 for aTTP cases using the grouper name "thrombotic microangiopathy" and included all subsets. We then identified SLE patients using the grouper name "systemic lupus erythematosus" and included all subsets. We then combined both datasets to analyze population characteristics. To compare with local data, we extracted SLE and aTTP cases from our institutional dataset using Epic SlicerDicer and performed a comparative analysis of prevalence, demographics, and treatment patterns.

Results: Among 751,633 SLE patients in the Cosmos Cohort, 1,610 (0.21%) were diagnosed with aTTP, with a female predominance (1,346 females, 264 males; 83.6% female). In our institutional dataset of 1,397 SLE patients, the prevalence was

Table 1 compares number of SLE and aTTP cases from COSMOS and our institutional dataset by age, sex, treatment, and complications.

	OBH Epic	Cosmos
SLE cases	1397	751633
TTP cases	95	15903
TTP in SLE	4	1610
Age (years)	Age: 50 to 84 Average = 60 Median =54	Age: 5 to 101 Average 47y Median 46 y
Sex	Female: 2 Male: 2	Female: 1346 Male: 264

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

slightly higher at 0.29% (4 patients: 2 females, 2 males). The mean age was 46 years in the Cosmos Cohort and 60 years in our dataset. SLE activity showed Kidney involvement in 60.6% (976 patients, lung involvement in 9% (143 patients), pericarditis in 7.9% (127 cases) and other organ or system involvement in 41% (653 patients). There was a history of renal biopsy in 525 patients. Treatments in the Cosmos Cohort included rituximab (28.6%, 460 patients), mycophenolate mofetil (47.5%, 764 patients), and cyclophosphamide (14%, 225 patients).12 patients received plasma exchange (PLEX) therapy. In our dataset, 3 of 4 patients (75%) received rituximab, while the treatment for the remaining patient was unknown. A total of 397 patients in the Cosmos cohort are currently deceased, however the cause of death and relationship to aTTP and SLE are unknown.

Conclusion: SLE-associated aTTP is a rare yet severe complication requiring early detection and aggressive treatment. Our study describes its prevalence in the modern era of immunosuppression, highlights differences in prevalence and treatment approaches across datasets, and emphasizes the need for standardized guidelines. Further research, including multi-center prospective studies, would be beneficial to establish a more comprehensive understanding of aTTP prevalence in SLE patients across different populations and settings and investigate effectiveness of treatment approaches.

Evaluating a Potential Cause of Excess Lung Cancer Mortality in RA: An Analysis of Chest CT Imaging Frequency in RA

Rebecca Brooks[1], Sara Achenbach[2], Vanessa Kronzer[1], Bryant England[3], Emily Leasure[1], Elena myasoedova[1], John Davis[1] and Cynthia Crowson[4], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Rochester, [3]University of Nebraska Medical Center, Omaha, NE, [4]Mayo Clinic, Stewartvillle, MN

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1914–1935) Health Services Research Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Recent studies have demonstrated that patients with RA are at an increased risk for the development of lung cancer and lung cancer related death. However, the cause for the increased risks has not been established. Although previous studies have investigated the delay of other age recommended cancer screenings, few studies have investigated lung cancer screening in RA patients with a smoking history. Therefore, we evaluated the cumulative incidence of chest CT imaging in RA patients with either a current or former smoking history between 50-80 years old.

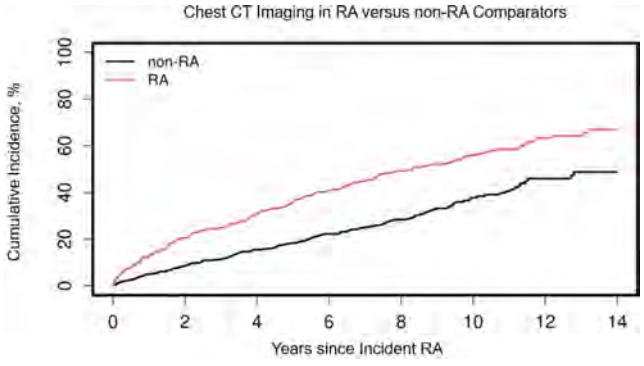

Figure 1. Cumulative Incidence of Chest CT Imaging in RA versus non-RA comparators

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We performed a retrospective cohort study of patients with incident RA in a geographically defined area who fulfilled either the 1987 ACR or 2010 ACR/EULAR classification criteria between 2010 and 2019. Non-RA comparators of similar age, sex and county were randomly selected. The analyses included RA and non-RA patients who were between the ages of 50 and 80 years old and were either former or current smokers. Patients with a prior history of lung cancer were excluded from analyses. Chest CT imaging was defined as completed if it was performed by the end of the study period, emigration out of the geographical area, or death. Aalen-Johansen methods determined the cumulative incidence of chest CT imaging in both cohorts, accounting for the competing risk of death. Cox proportional hazard models adjusted for age, sex, index year, and education were utilized to compare the rates of chest CT imaging.

Results: This study included 407 patients with RA and 360 non-RA comparators. The patients with RA had a mean age of 63 years, 57% being female, and 52% having education beyond high school. During follow-up, >50% of the RA patients had chest CT imaging (55.8% [50.7-61.5]) compared to the non-RA cohort with < 40% (37.8% [32.3-44.2]) (Figure 1). After adjusting for age, sex, index year, and education, the patients with RA were 90% more likely to have chest CT imaging compared to the non-RA cohort (aHR 1.90 [1.51-2.39]. The increased likelihood of chest CT imaging persisted when examining former (aHR 1.95 [1.48-2.57]) and current (aHR 1.88 [1.23-2.89]) smokers separately.

Conclusion: RA was associated with an >85% increase in chest CT imaging after adjusting for potential confounders in this analysis of former and current smokers. These findings suggest that the increased risk of lung cancer related death in RA patients is not due to a decrease in chest CT imaging leading to a delay in the diagnosis of lung cancer. The increased incidence of chest CT imaging in the RA cohort could partially be explained by the increased risk of interstitial lung disease in those with RA, prompting more frequent evaluation of respiratory symptoms with chest CT imaging. Therefore, further studies investigating adherence to lung cancer screening guidelines, the effect of changes in lung cancer screening guidelines, and the impact of pack years are necessary to fully understand the impact of lung cancer screening on the RA population.

Background/Purpose: Adequate immunization is essential for patients with inflammatory rheumatic and musculoskeletal diseases (iRMD). Autoimmunity itself and immunotherapy increase the risk of infection independent of each other. In Germany, the Standing Committee on Vaccination recommends influenza and pneumococcal vaccine for all patients above the age of 60 and for all iRMD patients above the age of 50. However, many data suggest that this vulnerable group is not sufficiently vaccinated. To explore barriers and facilitators to influenza and pneumococcal vaccine uptake in immunosuppressed adults with iRMDs.

Methods: Using claims data of a German statutory health insurance, the "VAC-MAC" - VACcination of MS/Arthritis/Colitis Patients´ project analysed vaccine uptake in patients with rheumatoid arthritis (RA), axial spondyloarthritis (axSpA) and systemic lupus erythematous (SLE). Quantitative analyses were based on approximately 9 million individuals in Germany insured from 2013-2021. Determinants of vaccine uptake were analyzed based on insurance data of 2019 with univariate and multivariate logistic regression analysis. The analysis includes both the overall patient cohort and a subset of newly vaccinated iRMD patients, defined as those who were unvaccinated for three or more consecutive seasons and received the influenza vaccine between Q3 2019 and Q2 2020. Additionally, semi-structured interviews with trained qualitative researcher were performed in 2023 with in total 30 patients, rheumatologist, and primary care physicians.

Results: We identified 229.913 patients (73% female, mean age 66±15 years) in 2019. The rate of influenza vaccination with 31% was moderate for the total iRMD group but higher with 41,.6% in the group ≥ 50 years of age and substantially higher with 47% in the group ≥ 60 years of age. The rate of pneumococcal vaccine was low with 6.0% in the total iRMD group with an insignificant increase to 6.8% in the group ≥ 50 years of age and to 8.2% in the group ≥ 60 years of age. Older age, more frequent physicians´ visits, higher number of comorbidities, health care provided by vaccination-oriented physicians and residence in the former East German states, were associated with a higher vaccination rate (figure 1).

The following barriers to vaccination were identified in the qualitative survey: 1) concerns about side effects including experience of flares, 2) negative vaccination experiences, 3) insufficient medical information and proactive discussion about the need for vaccination, 4) too little or complicated information material, 5) gaps in knowledge about immunomodulation and vaccination recommendations for patients with autoimmune diseases, and 6) unclear roles and too little communication between treating rheumatologist and general practitioners.

Conclusion: Although influenza vaccination is recommended of all iRMD patients, a German health insurance dataset shows an influenza vaccination rate of only 37% of all iRMD patients in 2019. There is a substantial gap in quality of care in vaccination against pneumococci. Physicians and patient factors as well as fears and concerns about side effect of patients and physicians can serve as modifiable factors to improve quality of care for iRMD patients.

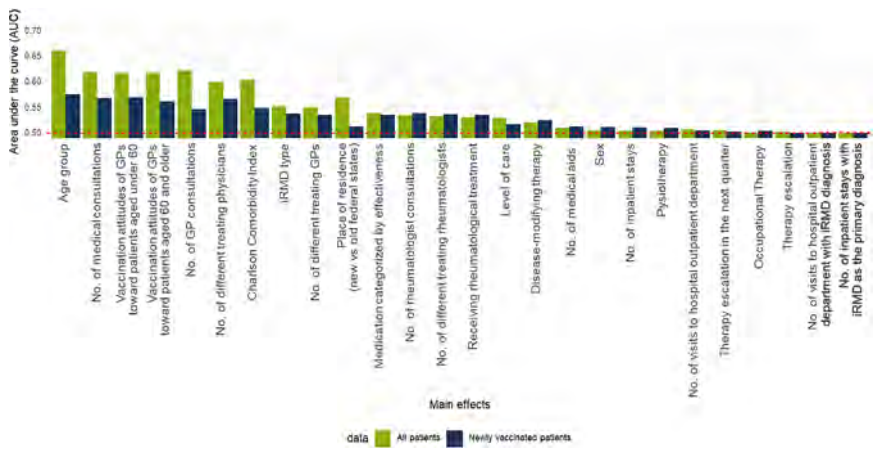

Figure 1: Area under the curve (AUC) of univariate models assessing factors influencing influenza vaccination coverage in patients with iRMD

Sex-associated disparities in industry payments to US authors in high-impact rheumatology journals correlate with author impact

William Stohl[1], Krishan Parikh[1], Anuj Parikh[2] and Sheldon Stohl[3], [1]University of Southern California, Los Angeles, CA, [2]Cerritos High School, Cerritos, CA, [3]Hadassah Medical Center, Jerusalem, Israel

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1914–1935) Health Services Research Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: To assess sex-associated disparities in industry payments to US physician-authors in high-impact rheumatology journals and their correlation with author impact.

Methods: US authors of publications in four high-impact rheumatology journals (January-June 2023 issues of *Lancet Rheumatol*, *Nat Rev Rheum*, *Ann Rheum Dis*, *Arthritis Rheumatol*) were vetted on Open Payments Database (OPD) for industry payments (2017-2021). The *h*-index (an accepted metric of author impact) and dollar amounts were recorded. Differences in the percentages of male vs female US authors with or without OPD entries, in research-associated and non-research-associated payments, and in *h*-indexes were determined. Two hematology, two surgery, and two obstetrics/gynecology (ob/gyn) high-impact journals were similarly vetted.

Results: We vetted 296 publications in the rheumatology journals. Of the 712 (356M + 356F) discrete US physician-authors, 150 (42.1%) men and 112 (31.5%) women received ≥1 industry payment ($p = 0.003$). Total, non-research-associated, and research-associated industry payments to the 150 men than to the 112 women ($p \leq 0.022$). Male US physician-authors of publications in hematology, surgery, and ob/gyn journals also received greater payments than did corresponding female US physician-authors (Table I), with the disparities being numerically greater for rheumatology than for the other disciplines (Fig 1A).

The *h*-indexes of the men in each journal-discipline were also greater than those of the corresponding women ($p < 0.001$; Fig 1B). Plots of industry payments vs *h*-index revealed the regression lines for the women to be lower than those for the men at low *h*-indexes but to catch up and overtake at higher *h*-indexes (Fig 2A). Of note, at the female *h*-index 90th percentiles for the individual journal-disciplines, total, non-research-associated, and research-associated payments were all numerically greater to the women than to the men only in rheumatology. In contrast, the respective payments in hematology and surgery remained numerically greater to the men than to the women, with the payments to the men and women being similar in ob/gyn (Fig 2B). This suggests that, especially in rheumatology, author impact is an important contributory factor to the magnitude of industry payments.

Table I

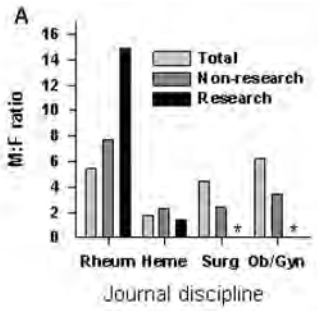
Table I. Industry payments to US physician-authors of publications in the vetted journals.

Journal discipline	Category	Sex/Gender	Median	25% percentile	75% percentile	Maximum	P value
Rheumatology (150M + 112F)	Total	Male	$107,853	$4,284	$948,192	$20,407,159	<0.001
		Female	$19,774	$646	$324,972	$5,473,919	
	Non-research	Male	$15,702	$868	$104,280	$1,825,932	<0.001
		Female	$2,038	$178	$24,068	$873,069	
	Research	Male	$55,740	$0	$616,148	$20,329,307	0.022
		Female	$3,756	$0	$262,102	$4,600,851	
Hematology (432M + 214F)	Total	Male	$209,445	$6,522	$1,379,625	$99,003,346	0.091
		Female	$117,081	$1,421	$1,096,739	$149,476,816	
	Non-research	Male	$11,056	$566	$66,959	$1,466,214	0.002
		Female	$4,732	$241	$31,684	$671,046	
	Research	Male	$149,837	$0	$1,213,598	$98,136,786	0.311
		Female	$104,252	$0	$992,111	$149,452,759	
Surgery (369M + 200F)	Total	Male	$5,282	$312	$69,588	$10,862,686	<0.001
		Female	$1,195	$144	$18,186	$30,003,962	
	Non-research	Male	$2,002	$204	$15,475	$6,344,435	<0.001
		Female	$837	$123	$5,658	$680,228	
	Research	Male	$0	$0	$8,358	$10,786,531	0.008
		Female	$0	$0	$0	29,941,815	
Ob/Gyn (181M + 257F)	Total	Male	$5,350	$251	$104,098	$9,803,592	<0.001
		Female	$852	$116	$14,838	$17,914,107	
	Non-research	Male	$1,077	$100	$12,632	$527,233	0.004
		Female	$311	$91	$3,098	$226,802	
	Research	Male	$0	$0	$51,804	$9,781,100	0.001
		Female	$0	$0	$2,650	$17,914,107	

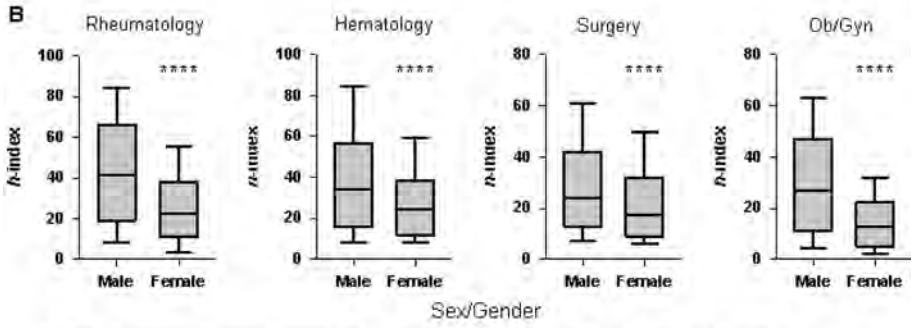
Results are presented as industry payments rounded to the nearest dollar.
"Ob/Gyn" denotes obstetrics/gynecology.

Conclusion: Significant differences exist in industry payments and *h*-indexes between male and female US physician-authors of publications in high-impact journals, especially high-impact rheumatology journals. The correlation between industry payments and *h*-index suggests that the greater payments to men than to women are not a conscious preference by the pharmaceutical industry for men *per se* but rather reflects industry's preference for physicians, male or female, with "stature" (high author impact). Nonetheless, differential industry payments to male vs female authors may have unknown ramifications for the types of studies executed and the experimental approaches taken. Additional studies are warranted to elucidate the root causes for the differences in author impact between men and women and how they lead to differential industry payments to men vs women.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

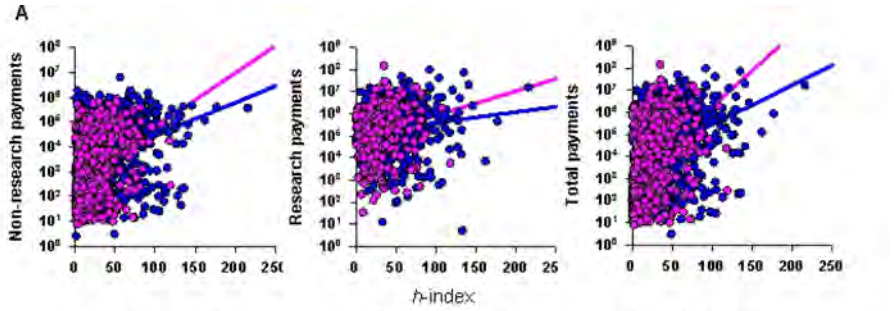


The ratios of the median dollar payments to males to the median dollar payments to females (M:F) are plotted as bars for total payments (light gray), non-research-associated payments (dark gray), and research-associated payments (black) for the indicated journal-disciplines for all US physician-authors who received ≥1 industry payment.

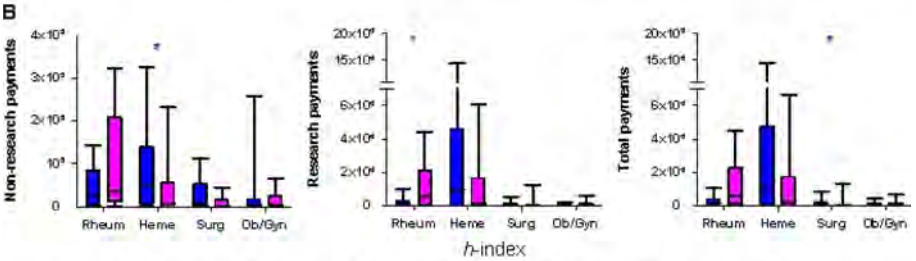


The *h*-indexes of the vetted male and female US physician-authors of publications in the indicated journal-disciplines are plotted as box plots. In each panel, the lines inside the boxes indicate the medians, the outer borders of the boxes indicate the 25th and 75th percentiles, and the bars extending from the boxes indicate the 10th and 90th percentiles. "****" denotes $p \leq 0.001$.

Figure 1



The scatter plots indicate non-research-associated industry payments, research-associated industry payments, and total industry payments vs *h*-index. The blue circles represent the individual male authors, and the pink circles represent the female authors. The blue and pink solid lines indicate the respective linear regression lines.



Results are presented as box plots for non-research-associated (left), research-associated (middle), and total (right) industry payments to the male (blue bars) and female (pink bars) US physician-authors at the female *h*-index 90th percentiles for the individual journal-disciplines. Blue asterisk indicates male value significantly greater than female value, and pink asterisk indicates female value significantly greater than male value ($p < 0.05$).

A Fully Automated Method for Measuring Minimum Tibiofemoral Joint Space Width in Knee Osteoarthritis Assessment: Data from the FNIH Cohort

Ahmad Almhdie-Imjabbar[1], Yousra TOUZANI[2], Hechmi Toumi[2] and Eric Lespessailles[3], [1]University Hospital Center of Orleans, Orleans, France, [2]PRIMMO- University Hospital Center of Orleans, Orleans, France, [3]CHU Orléans, Orléans, France

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1936–1971) Imaging of Rheumatic Diseases Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Osteoarthritis is one of the most prevalent chronic diseases worldwide, with knee osteoarthritis (KOA) being a particularly painful and debilitating form. The minimum tibiofemoral joint space width (mJSW) is a key criterion for assessing KOA progression. This study aims to evaluate a fully automated method for measuring mJSW in a reproducible and reliable manner, accounting for structural changes in knee anatomy.

Methods: This study included 599 patients from the Foundation for the National Institutes of Health (FNIH) cohort, in which measurements of the Medial Compartment mJSW were reported. Our method consists of two main steps. First, we use a machine learning-based tool to automatically detect the tibiofemoral contour of the knee. Second, we compute mJSW as perpendicular distance from each point on the femoral side to the line connecting the two closest points on the tibial side, Figure 1. Statistical analyses were performed to compare our measurements with those obtained by the FNIH team. Reliability was assessed using the Intraclass Correlation Coefficient (ICC) and the Bland–Altman analysis.

Results: The ICC demonstrated excellent agreement (0.906, 95% CI: 0.891 – 0.919) across all patients. The Bland–Altman analysis revealed a bias of -0.202 mm (limits of agreement: -1.095 mm to +0.691 mm), Figure 2. The observed bias is systematic and does not depend on the width of the joint space.

Conclusion: The proposed method enables fully automated, reliable, and reproducible measurement of mJSW. While our method slightly underestimates mJSW compared to the reference measurements from the FNIH team, it remains a robust and consistent approach for assessing KOA progression.

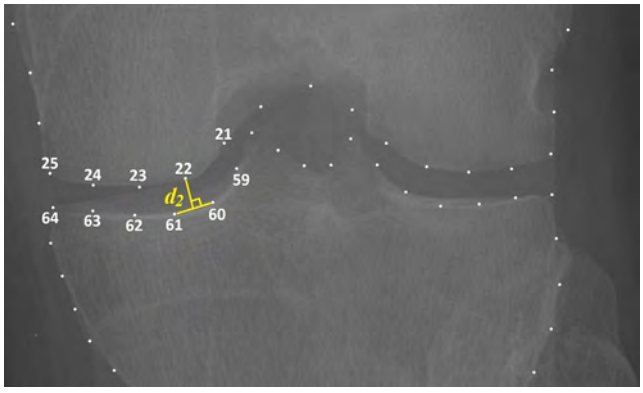

Figure 1: Calculating the minimum tibiofemoral joint space

Does Combining Standard MRI-Based Scores with Radiographic Trabecular Bone Texture Biomarkers Improve Predictive Performance for Radiographic Knee Osteoarthritis Progression?

Ahmad Almhdie-Imjabbar[1], Saida Daroussi[2], Daniela Herrera[3], Hechmi Toumi[2] and Eric Lespessailles[4], [1]University Hospital Center of Orleans, Orleans, France, [2]PRIMMO- University Hospital Center of Orleans, Orleans, France, [3]PRIMMO- University Hospital Center of Orleans, Olreans, France, [4]CHU Orléans, Orléans, France

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1936–1971) Imaging of Rheumatic Diseases Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Knee osteoarthritis (KOA) is a major cause of disability worldwide, particularly impacting the elderly and obese population. Radiographic trabecular bone texture (TBT) is demonstrated as a promising biomarker for predicting KOA progression. However, integrating MRI biomarkers with TBT from the Osteoarthritis Initiative (OAI) cohort remains underexplored. Our study aimed to assess whether associating MRI biomarkers with TBT biomarkers could enhance the predictive performance of models for KOA progression

Methods: From the OAI database, 1812 patients were selected, meeting predefined criteria (outlined in Figure 1), including knees with Kellgren-Lawrence (KL) scores of 2 or 3, availability of baseline and 48-month follow-up medial joint space narrowing (JSNM) scores, and availability of baseline clinical and MRI parameters. Clinical parameters included sex, age, body mass index, pain, and race. MRI parameters investigated included quantitative measures such as cartilage thickness (CartTh) and area (CartA), as well as semi-quantitative assessments such as meniscal tears (MTs), bone marrow lesions (BMLs) and anterior cruciate ligament (ACL) damage. Cases were defined as those with increased JSNM within 48 months. A prediction model using TBT biomarkers associated with the aforementioned clinical covariates and other radiological scores (KL and JSNM) served as a reference model. Other prediction models were created by incorporating combinations of the aforementioned MRI biomarkers. Performance analyses employed logistic regression with 10-fold cross-validation

* Alternative knees refer to the knees opposite to the targeted knees for patients with two knees available at this corresponding stage, in order to keep one knee per patient in our study.

Figure 1: Diagram of the data selection process followed in the study.

Table 1: Characteristics of the dataset included in the study.

Dataset	Biomarkers		Size	Females	Age	BMI	KL=2	KL=3
1	Cartilage thickness and area	Progressors	279	145	62.6±8.7	30.4±4.7	114	165
		Non progressors	702	440	61.7±9.0	29.8±4.8	468	234
		All	981	585	62.0±8.9	30.0±4.8	582	399
2	Bone marrow lesions	Progressors	250	1235	63.1±8.6	30.5±4.8	114	136
		Non progressors	513	326	62.4±8.9	29.8±4.8	347	166
		All	763	461	62.5±4.8	30.1±4.8	461	302
3	Meniscal tears	Progressors	250	135	63.1±8.6	30.5±4.8	114	136
		Non progressors	512	325	62.4±8.9	29.8±4.8	346	166
		All	762	460	62.6±8.8	30.1±4.8	460	302
4	Anterior cruciate ligament	Progressors	211	112	63.3±8.7	30.7±4.8	89	122
		Non progressors	342	218	61.5±8.8	30.5±4.7	222	120
		All	553	330	62.2±8.8	30.6±4.8	311	242

Values of age and Body Mass Index (BMI) are represented as mean ± standard deviation

Table 2: Performance results of the prediction models evaluated in the study.

Data size	Model	BACC	PPV	NPV	AUC (95%CI)	p-value
981	TBT← CLIN+KL+JSNM*	0.60	0.53	0.77	0.74 (0.71 - 0.77)	-
	TBT	0.55	0.52	0.74	0.66 (0.63 - 0.70)	0.000
	CartTh	0.54	0.58	0.73	0.57 (0.53 - 0.62)	0.000
	TBT ← CLIN+KL+JSNM+ CartTh	0.62	0.54	0.77	0.75 (0.72 - 0.78)	0.280
	CartArea	0.53	0.61	0.73	0.70 (0.66 - 0.75)	0.221
	TBT ← CLIN+KL+JSNM+ CartA	0.60	0.53	0.76	0.73 (0.69 - 0.76)	0.115
763	TBT← CLIN+KL+JSNM*	0.62	0.56	0.74	0.72 (0.68 - 0.76)	-
	TBT	0.56	0.50	0.71	0.65 (0.61 - 0.69)	0.000
	BMLs	0.60	0.66	0.73	0.66 (0.62 - 0.70)	0.011
	TBT ← CLIN+KL+JSNM+ BMLs	0.64	0.58	0.75	0.73 (0.69 - 0.77)	0.156
762	TBT← CLIN+KL+JSNM*	0.62	0.55	0.74	0.72 (0.68 - 0.75)	-
	TBT	0.56	0.50	0.71	0.65 (0.62 - 0.69)	0.000
	MTs	0.52	0.45	0.68	0.61 (0.57 - 0.65)	0.000
	TBT ← CLIN+KL+JSNM+MTs	0.62	0.56	0.74	0.72 (0.68 - 0.75)	0.911
553	TBT← CLIN+KL+JSNM*	0.64	0.59	0.71	0.70 (0.66 - 0.75)	-
	TBT	0.58	0.56	0.67	0.65 (0.60 - 0.69)	0.001
	ACL	0.52	0.58	0.63	0.74 (0.69 - 0.78)	0.319
	TBT ← CLIN+KL+JSNM+ACL	0.63	0.58	0.71	0.70 (0.66 - 0.74)	0.421
	TBT← 5MRIs	0.62	0.59	0.69	0.66 (0.62 - 0.71)	0.150
	TBT ← CLIN+KL+JSNM+5MRIs	0.64	0.57	0.72	0.71 (0.67 - 0.75)	0.745

TBT refers to trabecular bone texture; CLIN refers to clinical covariates (sex, age, BMI, race); KL refers to Kellgren-Lawrance grades; JSNM refers to medical joint space narrowing scores; CartTh refers to cartilage thickness; CartA refers to cartilage area; BMLs refers to bone marrow lesions; MTs refers to meniscal tears; ACL refers to anterior cruciate ligament; 5MRIs refers to the five MRI parameters evaluated (CartTh, CartA, BMLs, MTs and ACL).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

repeated 300 times. The area under the ROC curve (AUC) served as the primary metric, and balanced accuracy (BACC), positive predictive value (PPV) and negative predictive value (NPV) as secondary metrics.

Results: Among the analyzed knees, 981, 763, 762 and 553 had CartTh and CartArea, BMLs, MTs, and ACL data, respectively. The characteristics of these datasets are presented in Table 1. Performance results, as shown in Table 2, demonstrated slightly higher AUC scores, but not statistically significant, when adding one or a combination of MRI parameters to the reference model. For example, when adding all 5 MRI biomarkers, the model slightly improved (AUC=0.71, p-value=0.7), compared to the reference model (AUC=0.70). Comparable results were observed for secondary metrics.

Conclusion: Integrating certain MRI-based biomarkers (CartTh, CartA, MTs, BMLs and ACL data) into a reference XR-based model using TBT biomarkers associated with clinical and radiographic biomarkers did not show evidence of improving the performance in predicting radiographic KOA progression.

Abstract Number: 1938

Optimizing Patient Outcomes: The Experience of a Multidisciplinary Rheumatology and Hand Surgery Clinic with Point-of-Care Musculoskeletal Ultrasound Integration

Aidan pye[1], Samuel Chan[2], Gary Xu[3] and Mohammad Bardi[4], [1]University of British Columbia, VANCOUVER, BC, Canada, [2]UBC, Vancouver, [3]UBC, Vancouver, Canada, [4]UBC, Vancouver, BC, Canada

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1936–1971) Imaging of Rheumatic Diseases Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: In the last decade, rheumatologists have employed musculoskeletal Ultrasound (MSUS) as a highly sensitive and accurate clinical assessment tool at the bedside. By integrating complementary specialties, interdisciplinary clinics aim to enhance patient outcomes. Here, we introduce a novel Rheumatology and Hand Surgery interdisciplinary clinic and examine the patient outcomes when MSUS is used for assessment of active joint disease.

Methods: We conducted a retrospective chart review of 218 patients seen at a Rheumatology-Plastic Surgery interdisciplinary hand clinic from January 2018 to May 2024. Demographics data, use of MSUS diagnostically, frequency of modifying disease-modifying antirheumatic drugs (DMARDSs) escalation/surgery, and out data were compared and analysed.

Results: With MSUS implementation, subclinical synovitis was detected in 31% of patients (whereas clinical synovitis was only detected in 12% of patients on physical exam only). As patients with active synovitis are recommended escalation of DMARDs rather than surgical management, there was a 25.8% absolute reduction in surgery recommendation (from 60% to 34%), and a 26.2% absolute increase in DMARD escalation recommendation (from 5% to 31%).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

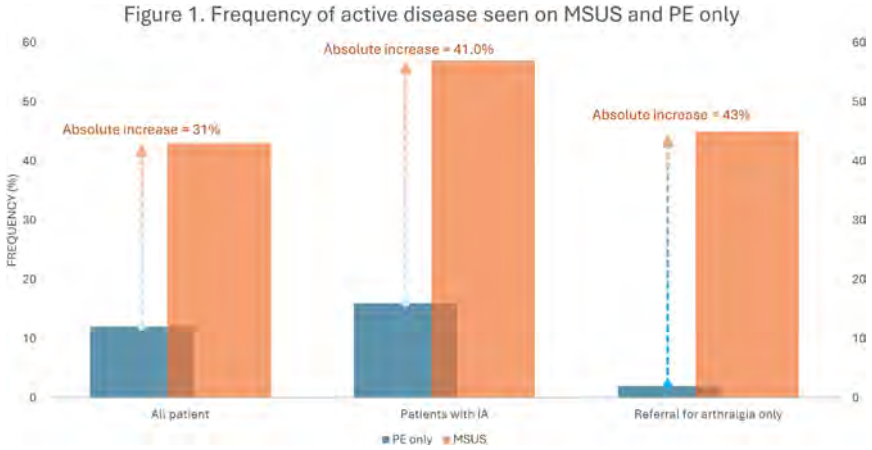

Figure 1 shows how commonly active inflammatory hand disease was found on assessment with physical exam alone as compared to with MSUS. It shows the comparison for all patients who attended the clinic, as well as two subgroups: patients referred with confirmed inflammatory arthritis and patients referred for pain as their main concern.

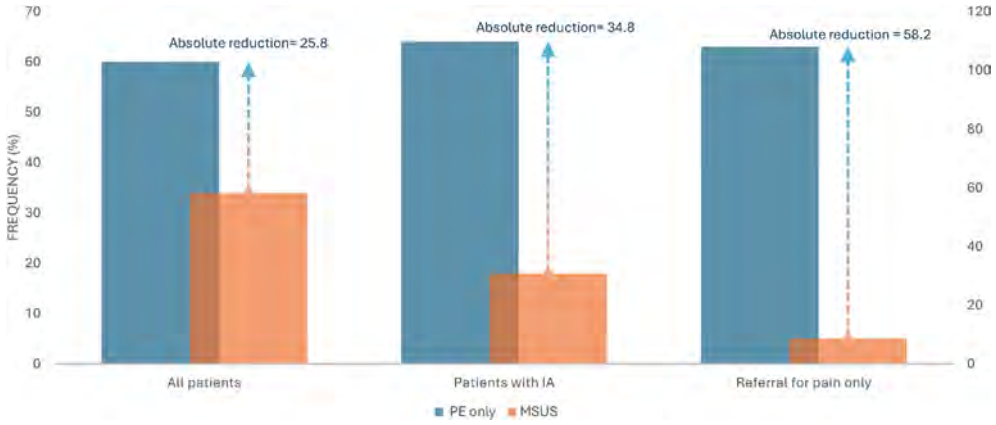

Figure 2 shows how commonly surgery was recommended with physical exam alone as compared to with MSUS. It shows the comparison for all patients who attended the clinic, as well as two subgroups: patients referred with confirmed inflammatory arthritis and patients referred for pain as their main concern.

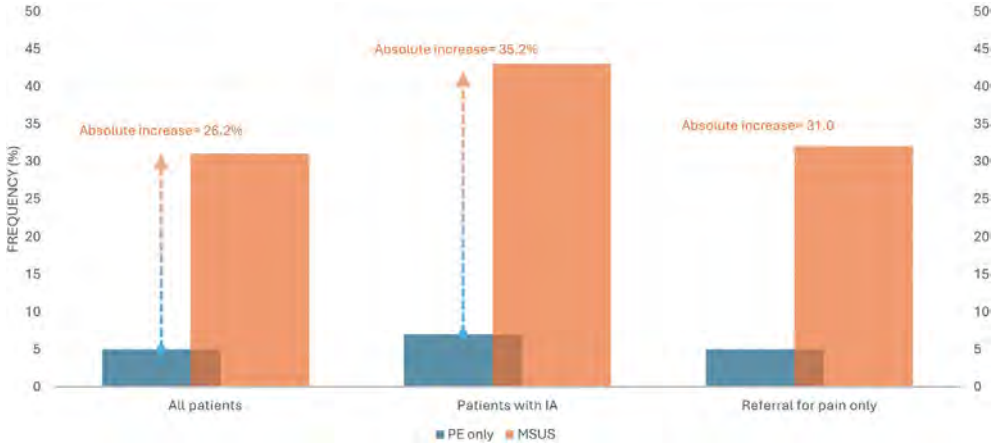

Figure 3 shows how commonly DMARD escalation was recommended with physical exam alone as compared to with MSUS. It shows the comparison for all patients who attended the clinic, as well as two subgroups: patients referred with confirmed inflammatory arthritis and patients referred for pain as their main concern.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: The use of MSUS significantly improves the detection of active inflammatory arthritis in referred patients, resulting in increased DMARD escalation and decreased surgery recommendations. These data suggest that it may be beneficial to incorporate MSUS into standard care. The use of MSUS may aid in identifying patients with active disease, such that these patients may be medically optimized with DMARDSs and potentially avoid surgical intervention.

Abstract Number: 1939

Salivary Gland Ultrasounds Can Be Read by General Radiologists: A Review Of 4 Years of Reports from an Urban Academic Radiology Department

Ali Dhanaliwala and Dana DiRenzo, University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1936–1971) Imaging of Rheumatic Diseases Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Salivary gland ultrasound (SGUS) has the potential to inform diagnosis and progression of Sjogren's disease, a systemic autoimmune disease which results in progressive inflammation and loss of exocrine gland function. SGUS has primarily been performed and read by rheumatologists in Europe. Despite its potential benefit, SGUS is not widely performed in the United States. Radiology departments have the resources to perform SGUS, however there remains little referral. To assess the feasibility of radiology performed SGUS in the United States, we sought to review the implementation and outcomes of a standardized SGUS protocol at a large urban academic radiology department in the United States which includes a large number of radiologists with diverse experience.

Methods: A standardized SGUS protocol was developed by the radiology department in consultation with rheumatology. SGUS were performed and read by two groups, a general radiology practice, and an academic practice. A retrospective analysis of these studies was performed. SGUS between August 2021, when the protocol was instituted, and February 2025 were identified within the radiology information system stored within a web-based data lake. Meta data within the image DICOM header was used to calculate study metrics such as time to complete study, number of images within study, and storage size of study. A large language model (LLM) was used to evaluate the consistency of the reports with the standardized template and to extract OMERACT score and gland size from the reports. Outcomes for patients with suspected lymphoma were reviewed.

Results: A total of 811 SGUS were performed over the 41-month period. The mean age of the patients was 54 ± 15 years with 89% (721/811) female. The study was ordered by 58 different departments with 78% (632/811) of the orders coming from a Rheumatology practice. Studies were read by 53 different radiologists, 55% of which were in the academic group. The academic group read 56% (458/811) of the studies. Exams took a median of 15 minutes (IQR = 12 min) to complete. Each exam contained an average of 11.8 cines and 84 still images and a median size of 274 MB (IQR = 223 MB).

Analysis of the report text by the LLM demonstrated 64% (519/811) to be consistent with the template. Of the inconsistent reports, 35% (99/292) were from the academic group. Incomplete scoring of all the glands (at least one gland not given an OMERACT score) was found in 13% (103/811) of the reports of which 71% (73/103) were from the academic group.

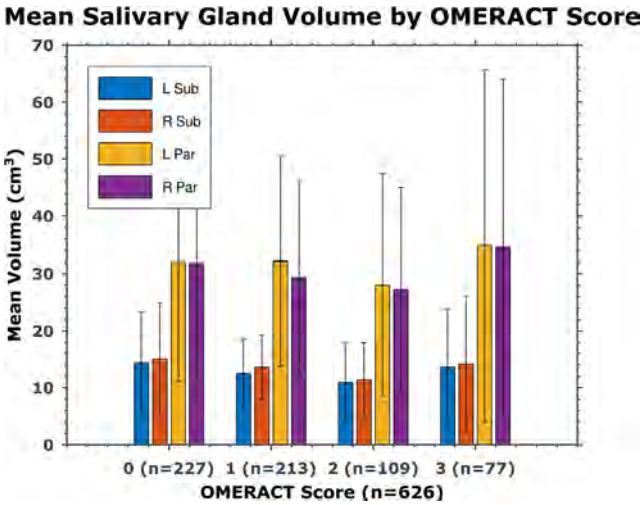
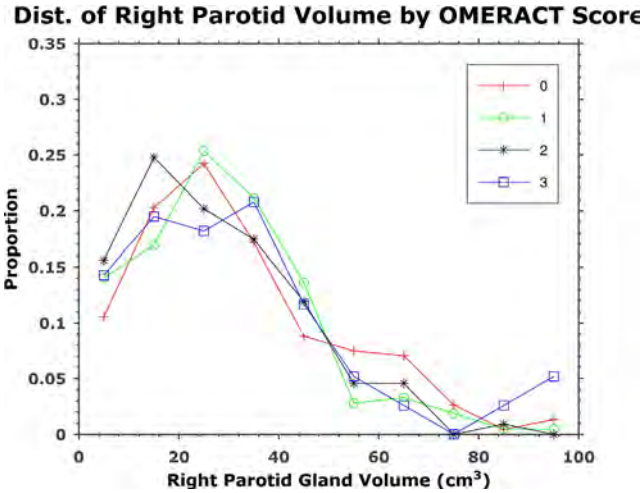
Salivary gland ultrasound study characteristics. Differences in mean right parotid volume according to maximum OMERACT score calculated via ANOVA. SGUS: salivary gland ultrasound.



Mean salivary gland volume by OMERACT score. No significant difference identified.



Distribution of right parotid volume by OMERACT score. No significant difference identified.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Incomplete measurements of the glands (at least one dimension not reported) were found in 23% (188/811) of which 79% (149/188) were from the academic group.

No association was found between salivary gland volume and OMERACT score. Only 0.5% (4/811) of studies had a recommendation for a gland biopsy due to concern for lymphoma. Of these four, only one was positive for lymphoma, and was likely a recurrence as the patient had a prior history of lymphoma.

Conclusion: SGUS can be reasonably implemented by both general and academic radiologists with minimal time and storage burden. Radiologists create consistent reports which can be used for subsequent cohort analysis.

Correlation of Hand and Lymphatic Function Post Exercise Intervention in Rheumatoid Arthritis

Allen Anandarajah[1], Ronald Wood[2], Edward Schwarz[3], Ram Haddas[2] and Homaira Rahimi[2], [1]University of Rochester Medical Center, Rochester, NY, [2]University of Rochester, ROCHESTER, NY, [3]University of Rochester, Rochester, NY, USA, Rochester, NY

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1936–1971) Imaging of Rheumatic Diseases Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory joint disease which often leads to deformities and loss of function of hands. Despite the availability of new treatments for RA, patients can have persistent and refractory disease. Thus, optimal management requires a holistic personalized medicine approach and exercise programs are now broadly acknowledged to be a high priority in rheumatology. We have previously demonstrated that lymphatic drainage is dysfunctional in the hands of RA patients with active disease (Bell RD, et al. 2020 Arthritis Rheumatol 72:1447). In this pilot study, we aim to determine the correlation between hand strength as assessed by Manugraphy and lymphatic flow and study the effects of standardized hand exercises on these outcome measures.

Methods: Five subjects with RA of less than 6 years disease duration were recruited with four completing Manugraphy studies. Three subjects completed both hand strength assessments and lymphatic studies. Hand grip and strength measures were completed using a Jamar Dynamometer and Manugraphy device followed a day later by lymphatic flow measurements. Lymphatic function was assessed using a novel near-infrared indocyanine green (NIR-ICG) method as previously published. Briefly, 0.1mL ICG dye was injected into the webspaces of each hand and ICG flow was recorded for 10 minutes to calculate lymphatic contraction rate. One week later, hands were again measured to quantify clearance. Patients were educated on standardized hand exercises by an occupational therapist. Subjects were provided calendars to document compliance of exercises over the next 6 weeks. Hand strength and lymphatic function assessments were then repeated.

Results: Preliminary baseline results of the right hand of a subject are shown in Figure 1. Lymphatic function at baseline confirms the presence of contracting lymphatic vessels from each webspace and clearance was measured at 5373 fluorescence units. Parameters were quantified for each digit per hand to be correlated with lymphatic data. Peak pressure was measured for the 1st digit and found to be 120.6 +/- 8.2 kPa. Additional Manugraphy parameters measured include

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

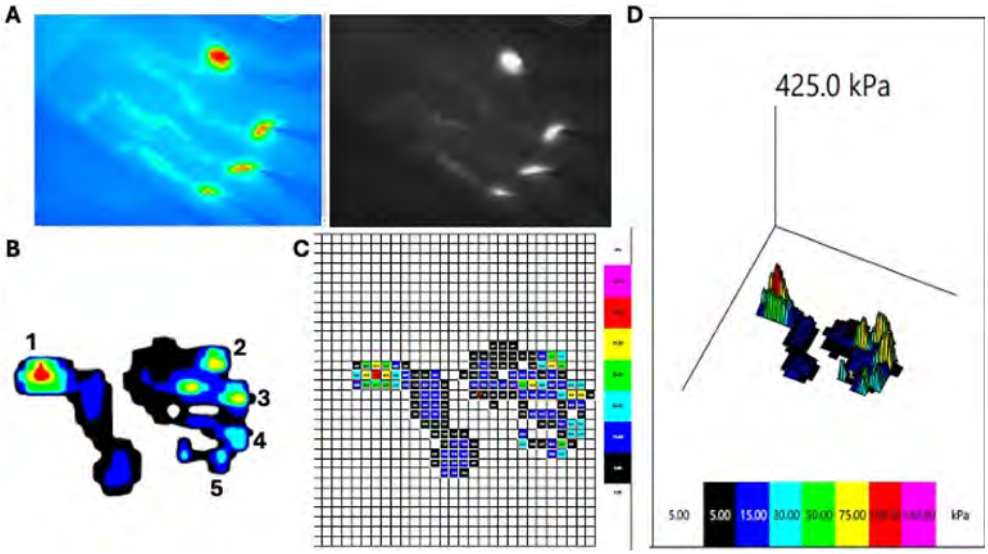

Fig 1: (A) Representative NIR-ICG images of active lymphatic flow after webspace injections and 1 week later. (B) Hand measurements via Manugraphy captures pictorial representation of digits (labeled 1-5) and further quantified via (C) "heat map". (D) Pressure measurements analysis delineates specific pressures at each area of the hand with peak pressure (in red) of 120.6+/-8.2 kPa identified at 1st digit.

maximum force (49.3 N), force-time integral 125.4 (N*s), force for the mean value picture (MVP) (41.7N), contact area for MVP (11.17 cm2), and contact area for the maximum pressure picture (12.17 cm2).

Conclusion: We initiated a novel study to correlate lymphatic function with hand function measures in patients with RA. Preliminary baseline measures show altered lymphatic function consistent with prior data and confirm ability to measure hand function using Manugraphy. Post-exercise intervention studies will be completed to determine if active hand mobility and lymphatic function can be altered in subjects with RA.

Background/Purpose: In research, imaging findings are often assessed by multiple readers and individual readers' scores are combined into aggregate scores to determine the presence of lesions. In longitudinal studies, the focus shifts to change in lesions. Diverse strategies for aggregating change scores are at hand, but may yield different results. We aimed to establish a methodological framework for aggregating change scores, using the example of syndesmophyte progression in axial spondyloarthritis (axSpA).

Methods: Data from the Sensitive Imaging in Ankylosing Spondylitis cohort were used, including patients with axSpA and established spinal damage. Syndesmophytes were assessed on vertebral corners (hereafter 'level') on conventional radiography (CR) and low-dose computed tomography (ldCT) of the spine at baseline and 2 years. CR were scored by 3 central readers and ldCT by 2, blinded for time order. Consensus was determined by majority reader agreement. New syndesmophytes (change score) were assessed by 2 strategies. Strategy 1 calculates change score per reader, then determines consensus on the change per level. Strategy 2 derives consensus change scores from consensus status scores (syndesmophyte present/absent) (Box 1). The means and standard deviations (SD) of the different aggregate change scores were compared. For analyses at the patient level, the total number of new syndesmophytes was averaged across readers, only if patients had ≤25% scores missing per spinal segment at both timepoints.

Results: Complete data from 52 patients were used. In example 3 (Figure 1a), the two strategies yielded different results. When consensus change scores are derived from change scores of individual readers (strategy 1), because only reader C detected a new syndesmophyte, there is no new syndesmophyte in the aggregated score. In contrast, when consensus status scores are determined first (strategy 2), indicating no syndesmophyte at baseline but one at 2 years, the consensus change score suggests a new syndesmophyte.

Strategy	Description	Key steps
1	Consensus change score is based on the agreement of individual readers' change scores	1. Assess delta (progression) of a lesion per level for each reader 2. Calculate consensus change score by assessing the majority reader agreement on change score per level
2	Consensus change score is based on the change of consensus status scores	1. Calculate consensus status scores by assessing the majority reader agreement on lesion presence at each timepoint per level 2. Calculate change scores based on delta from consensus status scores per level

Box 1. Explanation of two strategies for defining a consensus change score in multi-reader imaging assessments

1a. Examples of calculating new syndesmophytes based on scores per level of three readers according to two strategies

	Reader A	Reader B	Reader C	Consensus status score	Strategy 1: Consensus change score based on individual readers' change scores	Strategy 2: Consensus change score based on change of consensus status scores	Average of total new syndesmophytes across readers (patient level)
Example 1							
Syndesmophyte at baseline	0	0	0	0			
Syndesmophyte at 2 years	0	1	0	0			
New syndesmophyte	0	1	0		0	0	
Example 2							
Syndesmophyte at baseline	0	0	0	0			
Syndesmophyte at 2 years	1	1	0	1			
New syndesmophyte	1	1	0		1	1	
Example 3							
Syndesmophyte at baseline	0	1	0	0			
Syndesmophyte at 2 years	0	1	1	1			
New syndesmophyte	0	0	1		0	1	
Total new syndesmophytes	**1**	**2**	**1**		**1**	**2**	**1.33**

1b. Total number of new syndesmophytes at the level and at the patient level in the SIAS cohort calculated according to two strategies

Strategy	Imaging modality	Number of patients	Number of vertebral corners	Total new syndesmophytes: agreement at the level Mean (SD)	Range	Total new syndesmophytes: average across readers at the patient level Mean (SD), n*
1	CR	51	1035	0.69 (0.95)	0 – 4	0.66 (1.10), n=36
2				0.86 (1.00)	0 – 4	
1	ldCT	52	9035	2.35 (4.44)	0 – 18	5.55 (6.65), n=48
2				7.23 (7.46)	0 – 41	

* To calculate the total number of new syndesmophytes at the patient level, only patients with ≤25% scores missing per spinal segment (on ldCT, the cervical and thoracic spine were considered together) at both timepoints were included (with the remaining missing scores considered 'no (new) syndesmophyte').
0: absence of a (new) syndesmophyte; **1:** presence of a (new) syndesmophyte; **CR:** conventional radiography; **ldCT:** low-dose computed tomography; **SIAS:** Sensitive Imaging in Ankylosing Spondylitis cohort.

Figure 1. Comparison of strategies for assessing new syndesmophytes in patients with axial spondyloarthritis after 2 years, illustrating a broad imaging framework for consensus change scores

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Strategy 2 is more sensitive, identifying 1.2 times more new syndesmophytes on CR (mean [SD]: 0.86 [1.00] *vs* 0.69 [0.95]) and 3.1 times more on ldCT (7.23 [7.46] *vs* 2.35 [4.44]). However, this is accompanied with higher variability (Figure 1b). Only strategy 1 represents "true consensus" among readers, but requires site-level agreement, which compromises sensitivity to change at the patient level. At the patient level, the total number of new syndesmophytes should be calculated as the average of the total number across all readers (CR: 0.66 [1.10]; ldCT: 5.55 [6.65]).

Conclusion: Consensus change scores should be derived from individual readers' change scores. Strategy 1 approaches true change best, while strategy 2 artificially inflates change. At the patient level, the average total number of new syndesmophytes across readers should be reported. While we focus on syndesmophyte progression in axSpA, this framework is broadly applicable to imaging findings across multiple diseases. Advanced statistical analyses beyond descriptive purposes should preferably be performed on individual readers' scores, using multilevel models that properly account for variability in reader assessment.

Background/Purpose: Inflammatory arthritis occurs in up to 90% of patients and is a main cause of SLE work-related disability. SLE arthritis is difficult to evaluate because of the evanescent nature of the symptoms and limitations of physical exams and imaging. Although advanced imaging modalities have been used to characterize SLE arthritis insights into the pathophysiology and predictive biomarkers to address optimal surveillance, and clinical trial design are lacking. We leveraged serum collected at the time of arthritis evaluations to agnostically survey potential soluble mediators of arthritis in SLE patients using the Olink platform.

Methods: Sera from 15 subjects with clinical lupus arthritis were evaluated. All samples were collected in proximity to clinical and imaging evaluations. Swollen and tender joint counts were performed, MSK US used multiplanar grey-scale (GS) to evaluate synovitis/effusion and power Doppler (PD) for synovial hypertrophy/inflammation, and was scored by OMERACT definitions to generate a composite PDGS score on a scale of 0-3 (2-3 representing moderate/severe arthritis) at bilateral PIP joints. Serum proteins were assessed by the Olink Explore HT assay to evaluate >5400 proteins. All included samples passed standard Olink quality control metrics. K-means clustering agnostically defined groups of interest. Principal component analysis (PCA) was used for data visualization and a t-test was employed to compare clusters with candidate proteins considered at adjusted p-value by Benjamin-Hochberg method < 0.01 and log2fc |1.5|.

Results: Clinical and imaging variables for the 15 patients are described in Table 1. Olink data identified 2 clusters of interest, cluster A (5 subjects) and cluster B (10 subjects) (Fig 1A). Differential protein expression revealed 238 proteins significantly higher in cluster A vs cluster B (Fig 1B). Gene ontology (GO) analysis showed significant enrichment of pathways related to innate immune signaling in cluster A (Figure 1C). The top 10 proteins higher in cluster A compared to cluster B are shown in Figure 2. Clinically, patients in cluster A had significantly higher levels of active synovitis measured by GS compared to those in cluster B (PDGS >/=2) (p=0.05) (Table 1) despite having similar tender/swollen joint counts on physical exam (Table 1).

Conclusion: In this serum proteomic evaluation, an unsupervised machine learning algorithm was able to agnostically identify patients with more severe arthritis as measured by MSK US but not physical exam. These data suggest significant aberrations in the serum proteome likely contribute to arthritis severity in SLE.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1936–1971) Imaging of Rheumatic Diseases Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Palindromic rheumatism (PR) is characterized by intermittent episodes of arthritis or periarthritis, and it can progress to rheumatoid arthritis (RA), particularly in patients with positive autoantibodies (RF and/or ACPA). Few studies have used ultrasonography (US) to assess joints during symptom-free periods, and most have found no evidence of subclinical synovitis. [1,2]. However, none of these studies have included the feet, specifically the metatarsophalangeal (MTP) joints, which are commonly affected in RA.

To assess the presence of subclinical synovitis and erosions by ultrasound (US) during the intercritical phase of seropositive PR and to evaluate the added value of including the feet in the assessment.

Methods: 39 seropositive PR patients (76% female, mean age 54.4 years), 67% received csDMARDs (mainly hydroxychloroquine). Table1.

Ultrasound assessment of 1,404 joints revealed synovial hypertrophy (SH ≥2) in 1.7% of joints and 28% of patients; power Doppler signal (PD ≥1) in 1.28% of joints and 23% of patients. US-active synovitis (SH ≥2 plus PD ≥1) was found in 23% of patients. Subchondral bone erosions were detected by US in 0.85% of joints (18% of patients), mostly grade 1. Only two erosions were visible on X-rays.

When comparing patients with and without US-active subclinical synovitis, a significantly higher frequency of US-detected bone erosions and use of hydroxychloroquine was observed in the former group (Table 2).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: A total of 39 patients (76% female) with seropositive PR were included. The mean age was 54.4 years (±12.6), and the mean disease duration was 9.2 years (±8.5). RF was positive in 23 patients (59%), and ACPA in 32 patients (82%). A total of 26 patients (67%) were treated with csDMARDs, mainly hydroxychloroquine (51%).

A total of 1,404 joints (858 in the hands and 546 in the feet) were assessed by US in the 39 patients. Synovial hypertrophy (SH) ≥2 (gray scale) was observed in 24 joints (1.7%)-9 in the hands and 15 in the feet-and in 28% of patients. Power Doppler (PD) ≥1 was observed in 18 joints (1.28%)-9 in the hands and 9 in the feet-and in 9 patients (23%). US-active synovitis, as previously defined (SH ≥2 plus PD ≥1), was observed in 15 joints (8 in the hands and 7 in the feet) and in 9 patients (23.1%).

Subchondral bone erosions detected by US were observed in 12 joints (0.85%)-5 in the hands and 7 in the feet (MTP)-corresponding to 7 patients (18%). All US-detected erosions were grade 1 (< 2 mm), except for one case of grade 2 (>2 mm). Erosions were also observed on X-rays in only two of these cases.

When comparing patients with and without US-active subclinical synovitis, a significantly higher frequency of US-detected bone erosions and use of hydroxychloroquine was observed in the former group (Table 2).

	US Subclinical Active Synovitis (n=9)	No US Subclinical Active Synovitis (n=30)	p-value

Prevalence of US findings in RP patients

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: In patients with longstanding seropositive PR, significant subclinical active synovitis in at least one joint was observed in 23% of patients during the intercritical period, and US-detected bone erosions were found in 18% of patients, especially in the feet (metatarsophalangeal joints). These findings support that subclinical synovitis and even erosions may be present in patients with PR in the absence of a history of persistent clinical arthritis.

Musculoskeletal Ultrasound Clinic Referral Patterns and Joint Findings in a Tertiary Care Center amongst Patients with Elevated BMI and Inflammatory Arthritis

Anna Lichtiger[1], Ying Jin[2], Caroline Rourke[1], Kiera Brennan[3], Hillary Weisleder[4], Melissa Fazzari[5] and Melissa Band[6], [1]Montefiore Medical Center, The Bronx, NY, [2]Albert Einstein College of Medicine, Bronx, NY, [3]Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY, [4]Montefiore Einstein, New York, NY, [5]Department of Epidemiology & Population Health, Albert Einstein College of Medicine,, Bronx, NY, [6]Montefiore Medical Center, New York, NY

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1936–1971) Imaging of Rheumatic Diseases Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Musculoskeletal ultrasound (MSUS) has been well known to aid in both early diagnosis and monitoring of inflammatory arthritis. Patients with an elevated BMI have an increased prevalence of inflammatory joint disease, pose a more challenging clinical exam, and traditional disease activity scores may overestimate tender joint counts[1]. This study aims to assess differences in reasons for referral to the rheumatology MSUS Clinic and in joint findings among patients with elevated BMI compared to those with a normal BMI.

Methods: A retrospective analysis of 203 patients that attended the MSUS Clinic at Montefiore Medical Center, a tertiary academic center, was performed from March 2022 to September 2023. Electronic health record data was extracted to assess demographics, referral questions, joint findings, and underlying rheumatologic diseases. Differences in these domains between patients with normal BMI, overweight, and obese BMI were assessed with bivariate analyses using Pearson's Chi-squared tests and Fischer's exact test as appropriate. Patients were divided into three groups: normal weight (BMI 18.5-24.99), overweight (BMI 25-29.99), and obese (BMI ≥30).

Results: There were no significant differences seen in the reason for referral to the MSUS clinic between the three groups. Normal weight patients were referred more frequently for monitoring and evaluation of inflammatory joint disease, while patients with obesity were more frequently referred for procedures, however this was not statistically significant (figure 2). Patients with a normal BMI were significantly more likely to have active inflammatory arthritis on ultrasound (38% vs. 22% in overweight patients and 13% in obese patients $p < 0.01$) (figure 3). Joint findings between the groups were otherwise not statistically significant, however, there was a trend towards increased chronic inflammatory arthritis in patients with obesity (figure 3).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: MSUS has an important role in identifying inflammatory arthritis. Among our patient population, overweight and obese patients were less likely to have active inflammatory arthritis, which is concordant with previous research demonstrating patients with elevated BMI have less hyperemia on ultrasound[1]. However, in our cohort, there was a non-significant trend

Table 1. Patient Characteristics by BMI Category

Table 3. MSUS Joint Findings by BMI Category

	Overall (N=203)[1]	BMI Category			p-value[2,3]
		Normal (N=29)[1]	Overweight (N=60)[1]	Obese (N=114)[1]	
Active inflammatory arthritis	39 (19%)	11 (38%)	13 (22%)	15 (13%)	0.009**
Chronic inflammatory arthritis	20 (9.9%)	2 (6.9%)	4 (6.7%)	14 (12%)	0.51
Noninflammatory conditions	90 (44%)	12 (41%)	28 (47%)	50 (44%)	0.88
Procedures	62 (31%)	7 (24%)	17 (28%)	38 (33%)	0.57
Other	51 (25%)	5 (17%)	13 (22%)	33 (29%)	0.33

1. Frequency (%) is reported for all categorical variables.
2. *p<0.05; **p<0.01; ***p<0.001
3. Fisher's exact test was used for chronic inflammation, while Pearson's Chi-squared tests were used for all other conditions.

toward more chronic inflammatory arthritis. This differs from previous ultrasound studies showing less radiographic joint damage in patients with obesity based on the proposed theories of decreased bone remodeling in obesity and protective effects of adipocytes on the synovium[1]. These results highlight the need for more consistent MSUS in elevated BMI patients with inflammatory arthritis as the length to the initial diagnosis of inflammatory arthritis in this cohort may be contributing to this trend. Patients with elevated BMI were referred more often for procedural accuracy rather than evaluation and monitoring of inflammatory arthritis, which also highlights the need for more referrals for evaluation and monitoring in this cohort.

Significance of Finger Joint Tenderness With or Without Swelling in Relation to MRI, Ultrasound, and X-Ray Findings in Psoriatic Arthritis_Final results

Victoria Furer[1], iris Eshed[2], Moshe Iluz[1], Ori Elkayam[3] and **Ari Polachek**[4], [1]Tel-Aviv Medical Center, Tel-Aviv, Israel, [2]Department of Diagnostic Imaging, Sheba Medical Center, Tel Hashomer affiliated with School of Medicine, Tel Aviv University, Tel Aviv, Israel, [3]Tel Aviv medical center, Tel Aviv, Israel, [4]Rheumatology Institute of Beilinson Hospital, Petah Tikva, Israel

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1936–1971) Imaging of Rheumatic Diseases Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Musculoskeletal involvement in psoriatic arthritis (PsA) affects both articular and extra-articular structures, presenting as inflammatory and structural lesions. The relationship between tender and/or swollen joints and these lesions on imaging is not fully defined.

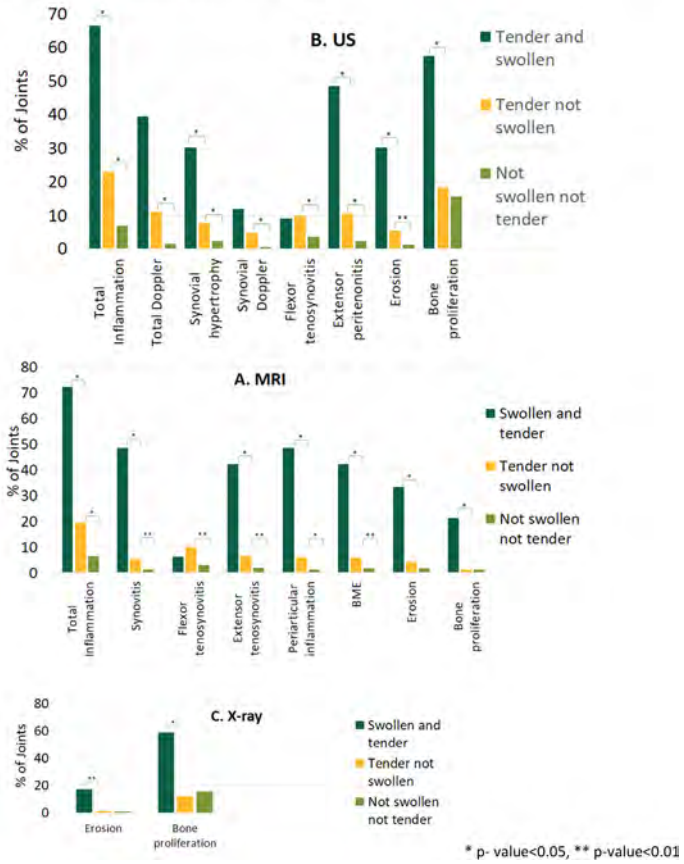
23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Purpose: To assess the clinical significance of tender-only (TJ+/SJ–) finger joints in PsA, compared to tender and swollen joints (TJ+/SJ+), in relation to inflammatory and structural lesions on MRI, ultrasound (US), and X-ray, and to evaluate the added diagnostic value of imaging.

Methods: This prospective study included 100 consecutive PsA patients (CASPAR criteria) with finger joint involvement. Physical exam categories were: tender and swollen joints (TJ+/SJ+), tender only (TJ+/SJ–), and normal joints (TJ–/SJ–). Swollen-only joints (TJ–/SJ+) were excluded due to small numbers (n=3). On the day of clinical evaluation, all patients underwent US (gray scale and Doppler) of 14 finger joints on the symptomatic hand (MCP I–V, IP, PIP II–V, DIP I–V), assessing synovitis, flexor tenosynovitis, extensor peritenonitis, erosions, and bone proliferation per EULAR-OMERACT. Within 3 days, MRI of the hand was performed, assessing the same lesions plus bone marrow edema (BME) and periarticular inflammation using PsAMRIS. Seventy patients completed hand X-rays within 1 month, scored by PsA Ratingen Score. Imaging assessors were blinded to clinical findings.

Results: Mean age was 51.2±12.6 years, 59% were female, and mean PsA duration was 10.3±11.2 years. TJ+/SJ+ joints had the highest prevalence of inflammatory and structural lesions across all modalities. However, 28% (MRI) and 33% (US) of joints in this category showed no inflammatory lesions. TJ+/SJ– joints had a lower prevalence of findings but were more involved than TJ–/SJ– joints. Subclinical inflammation (in TJ–/SJ–) was rare. Agreement between TJ+/SJ+ and imaging findings ranged from slight to moderate (kappa 0.42–0.01), with highest values for synovitis. TJ+/SJ– showed lower

Figure 1: Prevalence of inflammatory and structural lesions (dichotomized) in MRI, US and X-ray according to Tender and/or swelling joints



A) MRI, (B) Ultrasound (US), and (C) X-ray findings showing the percentage of joints with dichotomized inflammatory and structural lesions, stratified by physical examination: tender and swollen (TJ+/SJ+), tender only (TJ+/SJ–), and non-tender/non-swollen (TJ–/SJ–). TJ+/SJ+ joints had the highest prevalence of imaging-detected abnormalities across modalities. TJ+/SJ– joints showed intermediate frequencies, while TJ–/SJ– joints had low prevalence, indicating minimal subclinical inflammation. Asterisks indicate statistically significant differences between groups (*p<0.05, **p<0.01).

Tot Inf	0.26	0.73	0.92	0.12	0.19	0.92	0.26	0.28	0.94
US									
Synovitis	0.27	0.63	0.89	0.08	0.19	0.90	0.17	0.26	0.91
Syn. Hyp	0.22	0.30	0.97	0.07	0.08	0.97	0.13	0.11	0.98
Syn. Dopp	0.15	0.36	0.98	0.07	0.06	0.98	0.09	0.11	0.99
Flex. Teno	0.03	0.00	0.98	0.09	0.04	0.96	0.08	0.03	0.99
Ext. Teno	0.13	0.09	0.99	0.05	0.04	0.99	0.08	0.04	0.99
Tot. Dopp	0.3	0.40	0.97	0.13	0.11	0.97	0.21	0.16	0.99
Tot. Inf	0.26	0.66	0.91	0.15	0.23	0.91	0.26	0.30	0.93

Agreement (κ), sensitivity, and specificity of physical examination categories—tender and swollen (TJ+/SJ+), tender only (TJ+/SJ–), and either tender or swollen (TJ or SJ)—for detecting inflammatory lesions on MRI and ultrasound (US). TJ+/SJ+ joints demonstrated higher sensitivity but only slight to moderate agreement, while TJ+/SJ– joints showed low sensitivity and agreement. Specificity was consistently high across all categories. Tot. Inf = Total inflammation; Syn. Hyp = Synovial hypertrophy; Syn. Dopp = Synovial Doppler; Flex./Ext. Teno = Flexor/Extensor tenosynovitis; BME = Bone marrow edema; Periartic = Periarticular inflammation.

agreement. Sensitivity and positive predictive value (PPV) of TJ+/SJ+ ranged from low (tenosynovitis) to moderate (synovitis), while specificity and negative predictive value (NPV) were high. TJ+/SJ– had low sensitivity and PPV but high specificity and NPV. MCP, PIP, and DIP joint-level analyses showed similar trends.

Conclusion: Tender and swollen joints (TJ+/SJ+) were associated with the highest prevalence of imaging-detected inflammatory lesions. However, a considerable proportion of these joints did not show active inflammation on MRI or US, highlighting the limited positive predictive value of physical examination. Tender-only joints (TJ+/SJ–) demonstrated fewer imaging abnormalities but still had a higher prevalence of lesions than clinically inactive joints (TJ–/SJ–), indicating their intermediate diagnostic relevance. Importantly, subclinical inflammation in non-tender, non-swollen joints (TJ–/SJ–) was rare, reinforcing the utility of physical examination in ruling out active disease. These findings underscore the limitations of physical examination alone and support the integration of imaging into routine PsA assessment.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1936–1971) Imaging of Rheumatic Diseases Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Interstitial lung disease (ILD) frequently complicates the disease course in RA. While forced vital capacity (FVC) from pulmonary function tests (PFTs) is the most common measure used to monitor RA-ILD, quantitative imaging analysis of chest computed tomography (qCT) represents an alternative, and increasingly feasible, approach. We evaluated the role of qCT in RA-ILD by comparing to PFTs, respiratory patient-reported outcomes (PROs), and evaluating its prognostic value for survival.

Methods: We performed cross-sectional and cohort analyses using a multicenter, prospective cohort of patients with RA-ILD. Patients fulfilling ACR criteria for RA who were diagnosed with ILD by their treating clinician and had supporting imaging findings were enrolled between 1/2021 and 2/2025. qCT analysis was performed on baseline non-contrast chest CT as part of routine clinical care using the 3D SLICER Chest Imaging Platform. High attenuation areas between -600 and -250 Hounsfield units were quantified by the percentage of lung voxels in six lung regions to assess ILD (%HAA), with higher values indicating a greater degree of lung involvement. Additional assessments completed among participants included PFTs (FVC, diffusion capacity [DLCO]) and respiratory PROs (University of California San Diego Shortness of Breath Questionnaire [UCSD SOBQ] and Leicester Cough Questionnaire [LCQ]). Participants' vital status was reported by site investigators. We assessed the correlations of chest CT %HAA with PFTs and respiratory PROs using Pearson correlations, as well as associations with survival using Cox regression adjusting for age and sex.

Results: We studied 113 participants with RA-ILD from 9 sites in this prospective cohort. The cohort had a mean (SD) age of 70.4 (8.0) years, was primarily male (78.8%), had frequent smoking history (69.9%), a mean RA duration of 20.5 (14.2) years, and a mean ILD duration of 6.7 (8.0) years. Mean (SD) FVC % predicted was 87.7 (22.1), and DLCO % predicted was 58.3 (19.9). Mean total lung %HAA was 6.2, with higher values in the lower lung regions (9.2 and 9.9) compared with the upper

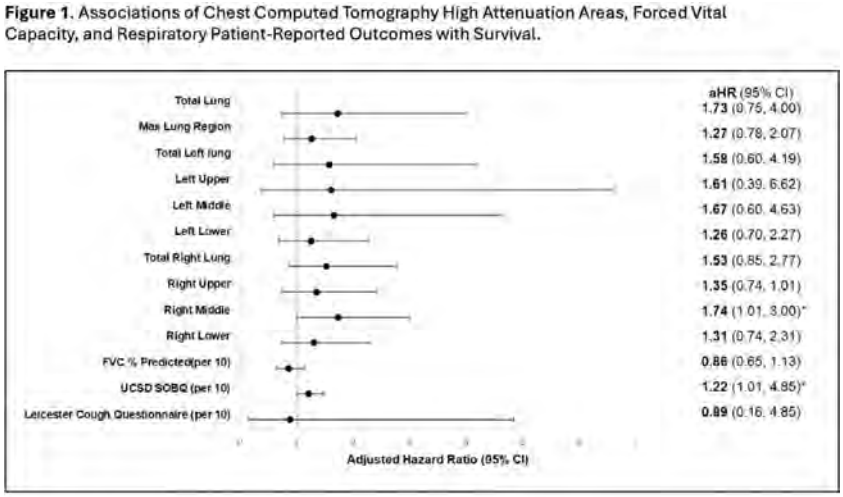

Figure 1. Associations of Chest Computed Tomography High Attenuation Areas, Forced Vital Capacity, and Respiratory Patient-Reported Outcomes with Survival.

regions (4.3 and 3.5). qCT %HAA parameters were weakly to moderately negatively correlated with FVC (range *r* -0.22 to -0.37; p< 0.05) and DLCO (range *r* -0.22 to -0.35; p< 0.05) (**Table 1**). Lung %HAA was not associated with respiratory PROs. Over 169 patient-years of follow-up, 17 deaths occurred. Patients with higher %HAA tended to have poorer survival (range aHR 1.26 to 1.74 per 10 %HAA; **Figure 1**), though findings did not reach statistical significance. While FVC was similarly not significantly associated with survival, higher UCSD SOBQ scores, but not LCQ scores, were associated with poorer survival (per 10 units, aHR 1.22 [1.01, 1.48]).

Conclusion: In this study, qCT %HAA was weakly to moderately correlated with FVC and DLCO percent predicted in a multicenter, prospective RA-ILD cohort. Over an initial follow-up period with a limited number of deaths, qCT %HAA appeared to provide similar prognostic information on survival as FVC % predicted. These findings highlight a potential role for chest CT quantitative analysis to characterize and monitor RA-ILD.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1936–1971) Imaging of Rheumatic Diseases Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with rheumatoid arthritis (RA) have a greater cardiovascular risk than does the general population. The coronary calcium score is a measure used to determine subclinical coronary disease in patients with low or intermediate cardiovascular risk. (Pearson GJ, et al. Can J Cardiol. 2021;37:1129–50). Incidental findings in cardiac computer tomography scans (CT) in the general population have been described in up to 28% of patients, and 3–39% are of clinical relevance (Bendix K, et al. Eur J Radiol. 2011;80:109–114). However, although there is information about cardiovascular risk measured by coronary calcium scores in patients with RA, incidental findings have not been systematically described. The objective of this subanalysis is to describe the incidental CT findings of coronary calcium studies in patients with RA.

Methods: CT studies of patients with RA who attended the rheumatology outpatient clinic of a national reference center for cardiovascular diseases were included. The patients included were of indistinct sex, seropositive for RA, and 18 years of age or older. Cardiovascular risk was classified according to the Canadian Society of Cardiology. Incidental CT findings were classified according to the anatomy of their location, system, and clinical significance. The records of all the participants were reviewed, and they provided their informed consent for the CT procedure. Informed consent was signed for this protocol.

Descriptive statistics were performed, and the data are expressed according to the distribution of the data based on normality analysis. A value of $p< 0.05$ was considered statistically significant.

Results: Fifty-four patients were analyzed, 87% of whom were women. The mean age was 57 years (+/-10), with a median RA evolution of 11.5 years (IQR 5-16), 67% were in remission and the rest (33%) had some degree of activity measured by the DAS-28PCR at the time of the study. A total of 74% of the patients were under treatment with methotrexate, 31% with sulfasalazine, 21% with leflunomide, 34% with hydroxychloroquine, and 5% with biological DMARDs. Fifty-four CT scans were analyzed, revealing a minimum coronary calcium score of 0 in 61% of the patients and a maximum of 4,530 in the group with increased cardiovascular risk.

The frequency of incidental findings was 96%, of which 30% were clinically significant; 18% required some type of medical follow-up. The most prominent findings were pulmonary nodules (41%) and atelectasis (31%), cardiovascular findings, atherosclerosis (11%), pericardial effusion (9%), and osteodegenerative changes (60%).

Conclusion: The percentage of incidental findings found in the measurement of coronary calcium in patients with RA in a reference center for cardiovascular diseases is high, with the most frequent findings being osteodegenerative, pulmonary, and cardiovascular findings. Interestingly, more than 10% of cases are clinically relevant and require some type of follow-up. To date, this is the first study to report incidental findings in patients with RA in whom coronary calcium was measured. However, larger studies are needed to confirm these results.

Abstract Number: 1948

Enhanced Prediction of Knee Osteoarthritis Progression through Deep Learning-Based Multimodal Data Fusion

Daniela Herrera[1], Ahmad Almhdie-Imjabbar[2], Hechmi Toumi[3] and **Eric Lespessailles**[4], [1]PRIMMO- University Hospital Center of Orleans, Olreans, France, [2]University Hospital Center of Orleans, Orleans, France, [3]PRIMMO- University Hospital Center of Orleans, Orleans, France, [4]CHU Orléans, Orléans, France

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1936–1971) Imaging of Rheumatic Diseases Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Effective diagnosis and management of knee osteoarthritis (KOA) increasingly rely on integrating diverse data sources, including imaging and clinical information. The practice of combining data from several modalities to extract more comprehensive and complementary information for machine learning models that perform better than those that only use one data modality is known as data fusion. Data fusion in machine learning is expected to enhance predictive power for decision-making in health, leading to more reliable outcomes in poor validity conditions. This study aimed to evaluate the use of multimodal deep learning models assisted by transfer learning (TL) to enhance the prediction of KOA progression. The Development and application of a two-step transfer learning strategy utilizing the OAI and MOST datasets were also evaluated

Methods: From the Osteoarthritis Initiative (OAI) and the Multicenter Osteoarthritis Study (MOST) cohorts, the MRI and X-ray images of 973 and 741 knees were selected, respectively as shown in Figure 1. Two primary encoders were used as the backbone for the fusion of features extracted from MRI and X-ray images: Resnet 34 and DenseNet 201. TL strategies included one-step transfer using ImageNet pretrained weights and two-step transfer initially pretraining on one KOA cohort and then fine-tuning and validating on an external KOA cohort.

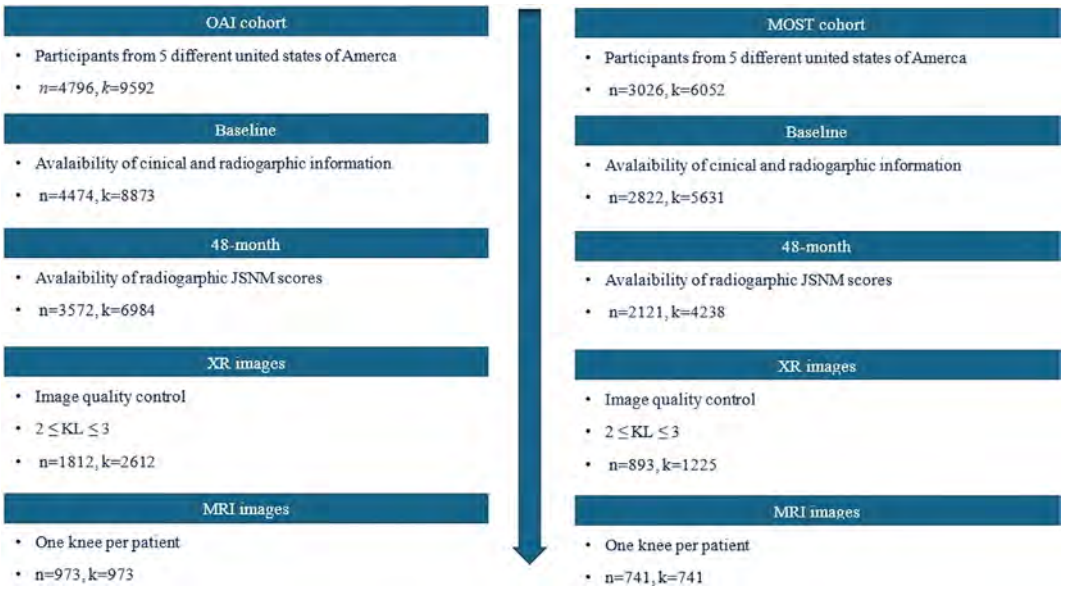

Figure 1: The CONSORT diagram of the subject selection process showing the number of patients (n) and number of knees (k) at each selection stage.

Table 1. AUC results for testing different fusion combinations without transfer learning in a) OAI and b) MOST cohorts. Results presented as mean AUC (± standard deviation)

	a) OAI		b) MOST	
	Resnet 34	**DenseNet 201**	**Resnet 34**	**DenseNet 201**
Single modality: *X-ray*	0.643 (± 0.035)	0.694 (±0.010)	0.653 (±0.023)	**0.719 (±0.036)**
Single modality: *MRI*	0.629 (± 0.038)	**0.708 (±0.051)**	0.630 (±0.039)	0.659 (±0.036)
Dual modality: *X-ray + Radio-Clinical data*	0.598 (± 0.023)	0.683 (± 0.036)	0.650 (± 0.029)	**0.735 (±0.018)**
Dual modality: *MRI + Radio-clinical Clinical data*	0.671 (± 0.041)	0.674 (±0.041)	0.680 (±0.05)	0.670 (±0.06)
Dual modality: *X-ray + MRI*	0.652 (± 0.035)	0.686 (± 0.03)	0.589 (± 0.010)	**0.719 (±0.024)**
Multimodality: *X-ray + MRI + Radio-clinical Clinical data*	0.646 (± 0.031)	0.678 (± 0.027)	0.662 (±0.020)	**0.713 (±0.04)**

AUC values greater than 0.7 are highlighted in bold, indicating models that met the threshold for acceptable predictive performance

Table 2. AUC results for testing different fusion combinations with transfer learning in a) OAI and b) MOST cohorts. Results presented as mean AUC (± standard deviation)

	a) OAI		b) MOST	
	Resnet34	**DenseNet 201**	**Resnet34**	**DenseNet 201**
Single modality: *X-ray*	0.721 (± 0.019)	0.733 (±0.043)	0.769 (±0.031)	0.786 (±0.035)
Dual modality: *X-ray + Radio-Clinical data*	0.739 (± 0.015)	0.662 (±0.034)	0.776 (±0.021)	0.786 (±0.028)
Dual modality: *X-ray + MRI*	0.739 (± 0.017)	**0.741 (±0.032)**	**0.783* (±0.031)**	0.776 (±0.03)
Multimodality: *X-ray + MRI + Radio-clinical Clinical data*	**0.749* (± 0.012)**	0.739 (±0.032)	0.774 (±0.033)	**0.787 (±0.038)**

The best AUC values in each category are highlighted in bold, representing the top-performing models across cohorts. An asterisk (*) denotes statistically significant differences compared to the values achieved by the single-modality X-ray model.

Results: Results demonstrated that ImageNet-based TL significantly improved the predictive performance of X-ray models, with AUC scores exceeding 0.7 in both the OAI and MOST cohorts (Tables 1 and 2). For MRI-based models, the lack of large-scale pretrained weights limited the performance benefit of TL. Multimodal configurations offered no clear advantage over unimodal or dual-modality models (Table 2). Without TL, DenseNet almost outperformed ResNet (Table 1). However, with TL, neither encoder demonstrated a clear advantage. The two-step TL did not show a significant benefit over one-step TL, highlighting the need for pretrained weights derived from larger KOA datasets.

Conclusion: These findings underscore the potential of transfer learning in predicting KOA progression and help fill an important gap in the focus on progression prediction

Abstract Number: 1949

Relapsing Polychondritis: Mimicking Asthma while Airways get Damaged

Eric Robbins[1] and Marcela ferrada[2], [1]University of Maryland, baltimore, [2]University of Maryland, Bethesda, MD

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1936–1971) Imaging of Rheumatic Diseases Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Relapsing polychondritis (RP) is an autoimmune disorder that can present with airway inflammation, leading to dyspnea, cough, and fatigue. These respiratory symptoms are frequently misattributed to difficult-to-control asthma, often resulting in delayed or missed RP diagnoses. In our single-center prospective cohort, we aimed to evaluate the prevalence of prior asthma diagnoses and characterize airway findings on imaging among patients ultimately diagnosed with RP.

Methods: All patients had with confirmed diagnosis of RP based were enrolled in a prospective cohort study. A presumptive diagnosis of asthma was defined as either a chart-documented asthma diagnosis or a prescription for a rescue or maintenance inhaler prior to the RP diagnosis. All patients were evaluated for disease activity and organ damage at the time of clinical assessment. Patients with respiratory symptoms underwent dynamic expiratory CT imaging to evaluate for airway involvement. Statistical analysis was performed using t-tests for categorical variables to assess associations

Results: A total of 40 patients with confirmed relapsing polychondritis (RP) underwent dynamic expiratory CT imaging at our institution. Of these, 15 (38%) had a prior diagnosis of asthma, and 7 (18%) were diagnosed with tracheomalacia (TM). Overall, 6 patients were male; of those, 4 had TM. Males were more likely to have TM in this cohort. All patients were tested for VEXAS, and none of the male patients tested positive.

Air trapping, indicative of small airway involvement, was identified in 13 patients (33%). TM strongly correlated with air trapping: all 7 patients with TM had air trapping, while none of the patients without TM did (100% vs. 19%, $p < 0.001$). Of the 13 patients with air trapping, 7 (54%) had TM.

Despite frequent respiratory symptoms, only 5 patients underwent pulmonary function testing (PFTs), and none demonstrated improvement with bronchodilators. Only 3 patients had been evaluated by a pulmonologist. Most were treated empirically with short-acting beta agonists, without objective testing or confirmation of the underlying cause.

There were no significant differences between patients with and without TM in inflammatory markers, including C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), or Factor VIII. Muscle weakness was also not significantly different between groups

Conclusion: This study demonstrates that patients with relapsing polychondritis often have airway involvement, which is frequently misdiagnosed as asthma. The overlap in symptoms can lead to delayed recognition of RP-related airway disease and inappropriate treatment. These findings highlight an urgent need for better diagnostic tools to identify early airway involvement and prevent long-term damage. Future research should focus on characterizing the full spectrum of RP-related airway disease and developing reliable, noninvasive tests to support early diagnosis and targeted intervention.

Abstract Number: 1950

Pericoronary fat enhancement in rheumatoid arthritis differs from controls and associates with coronary atherosclerosis independently of epicardial fat volume

Frederik Enevoldsen[1], Sarah Ormseth[2], Dzenan Masic[1], Matthew Budoff[3], Ellen-Margrethe Hauge[1] and George Karpouzas[3], [1]Aarhus University, Aarhus, Denmark, [2]The Lundquist Institute for Biomedical Innovation, Torrance, CA, [3]Harbor-UCLA Medical Center, Torrance, CA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1936–1971) Imaging of Rheumatic Diseases Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Pericoronary adipose tissue attenuation (PCATa) reflects the composition of the fat directly surrounding the coronary arteries and is associated with coronary wall inflammation. In general patients with coronary atherosclerosis, PCATa, particularly around the right coronary artery (RCA), predicted plaque burden, plaque vulnerability, and optimized cardiovascular risk estimates. The volume of epicardial adipose tissue (EATv) contained between the free cardiac surface and the visceral pericardium, which includes PCAT, was linked to coronary atherosclerosis burden and progression in rheumatoid arthritis (RA). We here explore differences in PCATa and PCATa-atherosclerosis associations between RA and controls and whether PCATa relates to coronary plaque burden and composition independently of EATv in RA.

Methods: PCATa around the proximal left anterior descending (LAD), left circumflex (LCx) and RCA, total EATv, and atherosclerosis burden and composition (noncalcified, mixed and calcified) were evaluated with coronary computed tomography angiography (CCTA) in 150 RA patients and 120 age and gender-matched controls without known coronary artery disease. Linear regression evaluated the association between RA and PCATa. Negative binomial regression explored the association of collective (3-artery) and artery-specific PCATa on numbers of plaques (total and plaque subtypes). RA x PCATa interactions evaluated the moderating effect of disease state on plaque outcomes.

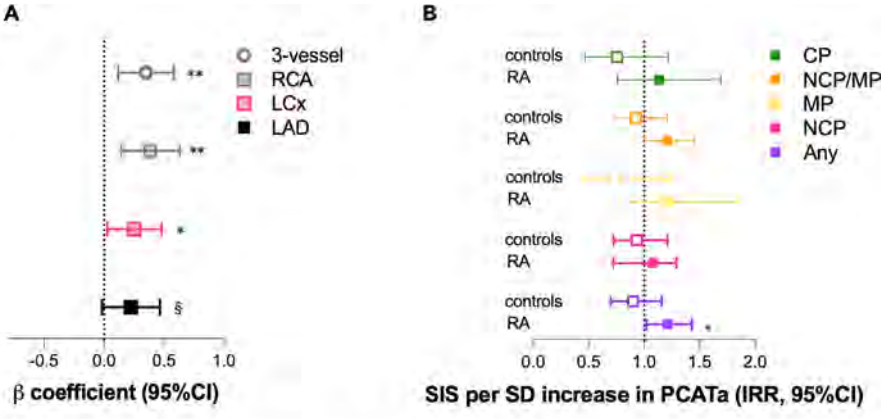

Figure 1 Differences in PCATa and their links to atherosclerotic burden between RA and controls **A.** Collective and artery-specific PCATa is higher in RA compared to controls. **B.** PCATa associates with coronary atherosclerosis burden in RA but not controls (p-for-interaction=0.037). Models adjusted for age, sex, HTN, DM, dyslipidemia, EATv LAD: left anterior descending, LCx: left circumflex, RCA: right coronary artery, NCP: noncalcified, MP: mixed, CP: calcified plaque, β: standardized coefficient, SIS: segment involvement score representing number of plaques per patient, SD: standard deviation, CI: confidence interval, PCATa: pericoronary adipose tissue attenuation. §p=0.070, *p<0.05, **p<0.01

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

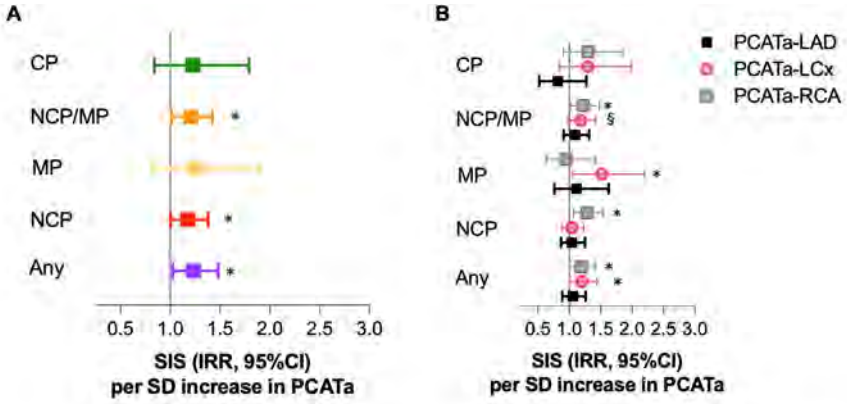

Figure 2 Collective **(A)** and artery-specific **(B)** PCATa associates with atherosclerosis burden and plaque composition in RA. Models adjusted for atherosclerotic cardiovascular risk score (ASCVD), EATv, erythrocyte sedimentation rate (ESR), prednisone and statin use. NCP: noncalcified, MP: mixed, CP: calcified plaque, SIS: segment involvement score representing number of plaques per patient, IRR: incidence rate ratio, SD: standard deviation, CI: confidence interval, PCATa: pericoronary adipose tissue attenuation.
§p=0.077, *p<0.05

Results: Collective PCATa (standardized b-coefficient 0.35, 95% confidence interval 0.12-0.58) and artery-specific PCATa around LCx (b 0.25, 95%CI 0.03-0.48) and RCA (b 0.39, 95%CI 0.14-0.63) was higher in RA compared to controls (Figure 1A) after adjustments for age, sex, hypertension, diabetes, dyslipidemia and EATv. Collective PCATa (per standard deviation increase) associated with 21% more total plaques in RA (incidence rate ratio-IRR 1.21, 95%CI 1.02-1.43) but not in controls (p for interaction=0.037, Figure 1B) after similar adjustments. In patients with RA, collective PCATa (IRR 1.23, 95%CI 1.03-1.48) and artery-specific PCATa around LCx (IRR 1.20, 95%CI 1.01-1.44) and RCA (IRR 1.19, 95%CI 1.00-1.41) associated with more plaques, especially those with soft components (noncalcified or mixed, Figure 2A and B) after adjustment for atherosclerotic cardiovascular risk score, EATv, erythrocyte sedimentation rate, prednisone, and statin use. There was no difference in artery-specific PCATa among matched normal arteries in RA patients with and without atherosclerosis (all p >0.05). In contrast, upon comparing matched arteries with vs. without plaque, PCATa was higher only around atherosclerotic LCx vessels.

Conclusion: Cumulative PCATa is higher and is linked to coronary atherosclerosis burden in RA but not controls. Cumulative and artery-specific PCATa in RA is linked to more total, soft, and vulnerable plaques, and provides additional information over EATv on atherosclerosis burden. The nature of compositional changes in PCAT may vary regionally and reflect the presence of explicit structural changes, such as plaque, in the underlying vessel wall.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1936–1971) Imaging of Rheumatic Diseases Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Interstitial Lung Disease (ILD) is a frequent manifestation of Sjögren's Disease (SjD), associated with significant morbidity and mortality. However, data on the prevalence of progressive ILD in SjD remain scarce, and biomarkers for predicting progression are lacking. Computer-Aided Lung Informatics for Pathology Evaluation and Rating (CALIPER) is a validated CT-based software that quantifies ILD patterns such as ground-glass opacities, reticulation, honeycombing, and low attenuation areas. CALIPER-derived parameters correlate with pulmonary function tests (PFT) and outcomes in IPF and other autoimmune ILDs, but their role in SjD-ILD is unexplored.

The aim of this study was to assess the prognostic value of CALIPER-derived parameters in SjD-ILD patients

Methods: SjD patients (2016 ACR/EULAR criteria) with HRCT-confirmed ILD followed from Jan 2018 to Sep 2023 were retrospectively included if ≥1 HRCT was suitable for CALIPER analysis. Clinical, lab, respiratory, and PFT data were collected at baseline and follow-up. Progressive fibrosing ILD (PF-ILD) was defined (ATS criteria) by ≥2 of: worsening symptoms, FVC decline ≥5% or DLCO ≥10%, or radiological progression within 1 year. CALIPER-derived ILD% (sum of ground-glass, reticular, honeycombing) and VRS% (vascular-related structures) were calculated. Visual ILD extent (Warrick score) and ILD pattern were assessed by a thoracic radiologist

Results: Twenty-three patients (F:M=18:5, mean age 66.2±9.5 yrs, mean follow-up 6.1±5 yrs) were enrolled. ILD patterns included NSIP (n=14), UIP (n=6), and NSIP+OP (n=3). Dyspnea and cough occurred in 21 and 19 patients, respectively. Median baseline FVC and DLCO were 83% and 64%. Seventeen patients received immunosuppressants; none received antifibrotics. Seven required long-term oxygen (LTO2) and 7 developed PF-ILD.

Both baseline ILD% and VRS% demonstrated a moderate to strong correlation with FCV% and DLCO%, visual ILD quantification with Warrick score and between them (table 1). VRS%, Reticulation%, and Honeycombing% were significantly higher in UIP (p=.021, .038, and .047, respectively). On univariate regression analysis, VRS% (OR 3.2, 95%CI 1.1-9.1, p=.03) and ILD% (OR 1.13, 95%CI 1.01-1.3, p=.05) were associated with LTO2 necessity. According to ROC analysis, VRS% had an AUC of 0.813 (p=.019) with an optimal cut-off of 3.8%, yielding a sensitivity of 71.4% and a specificity of 87.5% in predicting LTO2 necessity. ILD% had an AUC of 0.777 (p=.038) with a cut-off of 11.6% resulting in a sensitivity of 71.4% and a specificity of 75% in predicting LTO2 necessity.

On univariate regression analysis VRS% (OR 2.8, 95%CI 1-8, p=.05) was associated with a PF-ILD behavior in the next year, with an AUC of 0.85 (p=.023) and an optimal cut-off of 3.8% resulting in a sensitivity of 83.3% and specificity of 80%.

Conclusion: CALIPER-derived parameters correlate strongly with lung function and predict adverse outcomes in SjD-ILD. Automated HRCT analysis offers promising digital biomarkers for disease assessment and risk stratification. Integrating these metrics with clinical and functional data could support early identification of progressive ILD and guide therapy. Further validation in larger cohorts is warranted

Dermatoscopy Limitation and the Critical Role of Capillaroscopy in Systemic Sclerosis and Raynaud's Phenomenon among African American Veterans

Genessis Maldonado[1], Maurizio Cutolo[2], Tracy Frech[1], Mislav Radic[3], Marcus Snow[4] and Vanessa Smith[5], [1]Vanderbilt University Medical Center, Nashville, TN, [2]University of Genova, Genova, Italy, [3]University Hospital Split, Division of Rheumatology and Clinical Immunology, Split, Croatia, Split, Croatia, [4]University of Nebraska Medical Center, Omaha, NE, [5]Ghent University Hospital, Gent, Belgium

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1936–1971) Imaging of Rheumatic Diseases Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Nailfold capillaroscopy (NFC) is an essential tool for evaluating microvascular abnormalities in patients with Raynaud's phenomenon (RP) in United States (U.S.) Veterans (1). While dermatoscopy is an acceptable and cost-effective screening method for nailfold assessment in systemic sclerosis (SSc), published guidelines highlight the importance of clear image acquisition for appropriate interpretation (2). The objective of this project was assessment of NFC in patients with concern for connective tissue disease (CTD)-related RP to determine whether different intensities of skin pigmentation impacts the interpretability of dermatoscopy screening.

Methods: Patients undergoing evaluation for CTD-related RP were consented for participation in Institutional Review Board approved research at the time of care at the Veterans Affairs (VA) Hospital (No. 1618579-17). Patients were prepared for NFC per published protocols (3). Images were obtained with two devices available at the VA Hospital, a dermatoscope attached to a smart phone (200X magnification, smart phone focus) and Smart G-Scope (250X magnification, USB

Early SD-pattern	9.09% [1]	75% [3]
Active SD-pattern	9.09% [1]	80% [4]
Late SD-pattern	27.27 [3]	57.1% [4]
Non-specific	36.36% [4]	55.6% [5]

Table 3: Capillaroscopy findings in the uninterpretable group.

Table 3

Capillaroscopy in Uninterpretable Dermatoscopy	[n =5]
Capillary Density (No. per mm)	4.56 ± 1.91 [2.5-6.8]
Giant capillaries %	0.82%
Apical Diameter (um)	20.18 ± 3.25 [16.7-24.2]
Dilated Capillaries	19.65%
Tortuous Capillaries (%)	3.90%
Abnormal shapes (%)	1.97%
Hemorrhages (%)	80%
Pattern	
Normal	20% [1]
SD-Pattern	60% [3]
Early SD-pattern	20% [1]
Active SD-pattern	20% [1]
Late SD-pattern	20% [1]
Non-specific	20% [1]

automatic focus). Each image was classified for the clarity of image by two capillaroscopy experts. Microvascular findings for capillary density, apical enlargement, hemorrhages, and abnormal shapes were determined by the capillarscopy.io software application.

Results: A total of 38 U.S. Veterans were assessed for RP by NFC using clinically available two devices. Among these, 28% (n=11) of subjects were classified as African American. As shown in Table 1, dermatoscopy produced blurry images in 63.6% (7/11) of patients with Fitzpatrick skin type IV and V and 37% (10/31) in Fitzpatrick skin type I, II, and III. In 45.5% (5/11) of dermatoscopy exams in Fitzpatrick skin type IV and V skin were deemed uninterpretable compared to 37% (10/31) of Fitzpatrick skin type I, II, and III (kappa statistic >0.9). Smart G-Scope improved interpretability across the cohort of patients (Table 2), especially in Fitzpatrick Skin Types IV and V. A scleroderma (SD)-pattern characteristic of scleroderma microangiopathy was detected by the Smart-G-scope in 3 of those 5 uninterpretable dermatoscope acquired images (Table 3).

Conclusion: In patients with CTD-related RP, particularly among African American Veterans, a dermatoscopy device led to a high rate of uninterpretable examinations. The Smart-G USB device improved diagnosis of abnormal NFC. These results highlight that reliance on dermatoscopy alone as a screening tool may risk underdiagnosing microvascular involvement in SSc.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1936–1971) Imaging of Rheumatic Diseases Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Artificial intelligence (AI) has increasingly been integrated into the analysis of nailfold capillaroscopy (NFC), offering new opportunities to automate image interpretation and enhance diagnostic accuracy in rheumatologic conditions. NFC is a key non-invasive tool for the evaluation of Raynaud's phenomenon (RP), which may be primary (PRP) or secondary to a connective tissue disease (CTD). Differentiating PRP from early or overlapping autoimmune conditions remains a clinical challenge, especially when NFC findings fall within a non-specific pattern -characterized by tortuosity, abnormal shapes, dilated capillaries, and microhemorrhages. The ability to detect subtle morphological differences using machine learning may support early diagnosis, risk stratification, and clinical decision-making. The aim of this study was to differentiate PRP from various autoimmune conditions that may present with secondary Raynaud's or overlapping CTD features.

Methods: We developed a machine learning classifier using quantitative image-based features extracted via the Capillary.io platform[1-2], Images were uploaded by multiple rheumatology centers across Europe. A 50-fold stratified cross-validation approach was employed to ensure robust performance estimation, with 20% of the cases (n=153) serving as the validation set in each fold.

Results: A total of 761 NFC cases were analyzed. All cases were automatically classified as having a non-specific capillaroscopic pattern by the Capi-Detect algorith. Clinical diagnoses were made independently, based on established criteria and without reference to the capillaroscopic findings. Among the cohort, 473 patients were diagnosed with PRP, while others were diagnosed with: inflammatory myopathies (n=49; including dermatomyositis n=38, polymyositis n=4, antisynthetase syndrome n=4, necrotizing myopathy n=2, overlap syndrome n=1), systemic lupus erythematosus (SLE; n=61), limited

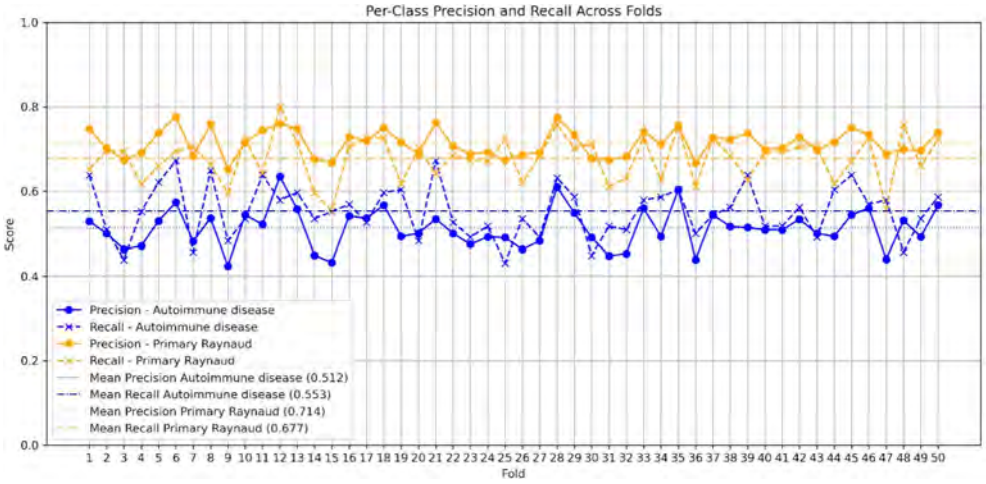

Figure 1: Precision and Recall Across Folds

systemic sclerosis (lSSc; n=54), Sjögren's syndrome (n=34), diffuse systemic sclerosis (dSSc; n=26), very early diagnosis of systemic sclerosis (VEDOSS; n=23), antiphospholipid syndrome (APS; n=9), and ANCA-associated vasculitis (n=3).

The classifier achieved a mean weighted precision of 0.637, recall of 0.630, and F1-score of 0.632 across all folds. Weighted F1-scores ranged from 0.56 to 0.71, indicating performance variability across different data splits. The majority of misclassifications involved autoimmune cases being labeled as PRP (Figure 1), underscoring the morphological overlap that exists within the non-specific capillaroscopic pattern category.

Conclusion: These findings suggest that subtle but quantifiable differences exist between PRP and autoimmune diseases presenting with non-specific capillaroscopic patterns. Machine learning models may aid in identifying these distinctions and improving diagnostic interpretation. Further studies involving larger, more balanced cohorts are warranted to enhance model sensitivity, generalizability, and overall diagnostic performance.

Lowered Density	150
Blurry	882

*multi-label: one image may have no label, one label or multiple labels

Background/Purpose: Nailfold capillaroscopy plays a critical role in the diagnosis and management of systemic sclerosis (SSc) and related connective tissue diseases. However, access to capillaroscopy remains limited outside specialized rheumatology centers. Dermatoscopy is a more accessible alternative, but its use for nailfold evaluation lacks standardization. In 2024, we demonstrated preliminary evidence that artificial intelligence (AI) could support dermatoscopic nailfold analysis in rheumatology clinics (Maldonado et al., Arthritis Rheumatol. 2024). Building on that work, we now present a refined and more efficient AI model designed for possible real-world implementation.

Methods: We developed a multi-label image classification model using 1,405 dermatoscopic nailfold images labeled for five key features: abnormal shapes, giant capillaries (replacing the broader "enlarged" category for better dermatoscopic specificity), hemorrhages, low capillary density, and image blurriness. Unlike our 2024 approach, which used separate binary models per feature, this year's model employs a unified architecture to predict all labels simultaneously—enhancing computational efficiency and deployment feasibility. The model was based on ConvNeXt V2 and trained on an 80/20 stratified split, with performance evaluated using standard machine learning metrics. Images were retrieved using a 200x magnification lens adapted for smartphones (value $30).

Results: The model achieved strong performance across all target features (table 1), with F1-scores as follows: abnormal shapes (0.643), giant capillaries (0.647), hemorrhages (0.649), low density (0.667), and image too blurry (0.874), yielding a mean F1-score of 0.696. The multi-label framework significantly reduced inference time and memory usage while maintaining consistent accuracy across folds (table 2). The model also demonstrated robustness despite the lower resolution typical of dermatoscopic images compared to nailfold capillaroscopy.

Conclusion: This AI-driven model shows promising accuracy in detecting microvascular abnormalities from dermatoscopic images and represents a meaningful step toward accessible, point-of-care screening for SSc and related diseases. By leveraging the lightweight ConvNeXt V2 architecture in a multi-label framework, we pave the way for integration into mobile applications using a smartphone camera and dermatoscopy lens. Such a tool could support early detection of microvascular abnormalities in patients with Raynaud's phenomenon, especially in non-specialist or resource-limited settings. However, given the high proportion of low-quality (blurry) images in dermatoscopy and in alignment with current recommendations (Mislav R. et al. Clin Exp Rheumatol. 2020;38 Suppl 125:132–136), nailfold video capillaroscopy should be pursued for comprehensive evaluation when clinically indicated. Prospective validation and clinical integration studies are ongoing.

Regional variations in the relationship between pericoronary fat enhancement and atherosclerosis may reflect differences in local vascular inflammation in rheumatoid arthritis

George Karpouzas[1], Frederik Enevoldsen[2], Dzenan Masic[2], Matthew Budoff[1], Ellen-Margrethe Hauge[2] and Sarah Ormseth[3], [1]Harbor-UCLA Medical Center, Torrance, CA, [2]Aarhus University, Aarhus, Denmark, [3]The Lundquist Institute for Biomedical Innovation, Torrance, CA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1936–1971) Imaging of Rheumatic Diseases Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The composition of fat around the coronary arteries is evaluated as pericoronary adipose tissue attenuation (PCATa) on coronary CT-angiogram (CCTA). In general patients PCATa was linked to plaque burden and cardiovascular risk independently of epicardial adipose tissue volume (EATv) and is considered to reflect arterial inflammation. In the presence of plaque and an inflamed vessel wall, higher EATv offset inflammation in PCAT and inversely associated with PCATa. Rheumatoid arthritis (RA) therapies attenuated EATv, arterial inflammation, plaque progression and promoted plaque stabilization via fibrosis and calcification. We here explore the relationships between artery-specific PCATa and atherosclerosis burden in the respective arteries, the influence of methotrexate, prednisone and statin use on those relationships and the link between artery-specific PCATa and inflammation in RA.

Methods: PCATa around proximal left anterior descending (LAD), left circumflex (LCx) and right coronary artery (RCA), total EATv, atherosclerosis burden and composition (noncalcified, mixed and calcified) were evaluated with CCTA in 150 RA

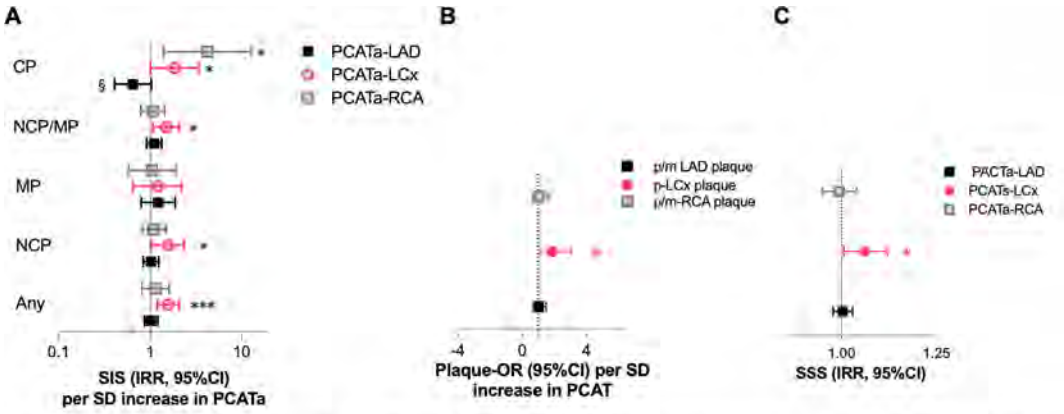

Figure 1 Associations of artery-specific PCATa with **A.** Artery-specific plaque burden and composition, **B.** likelihood of plaque presence in directly underlying segments and **C.** stenotic plaque severity in directly underlying segments. Models in panel A adjusted for adjusted for ASCVD, EATv, ESR and prednisone. LCx models for any plaque and models for CP additionally adjusted for statins. Models in panel B adjusted for ASCVD, bDMARD use, EATv, DAS28-CRP. Models in panel C adjusted for ASCVD and EATv. LAD: left anterior descending, LCx: left circumflex, RCA: right coronary artery, NCP: noncalcified, MP: mixed, CP: calcified plaque, SIS: segment involvement score representing number of plaques per patient, SSS: segment stenosis score, IRR: incidence rate ratio, SD: standard deviation, CI: confidence interval, PCATa: pericoronary adipose tissue attenuation.

§p=0.082, *p<0.05, **p<0.01, ***p<0.001

patients without known coronary artery disease. Serum cytokines were measured with microparticle immunoassay. Negative binomial regression explored associations of artery-specific PCATa and its interactions with methotrexate, prednisone and statin use on plaque numbers (total and subtypes) and stenotic severity in underlying coronary segments. Robust linear regression assessed associations of cytokines with artery-specific PCATa.

Results: Artery-specific PCATa was linked to artery-specific plaque burden and composition exclusively for LCx (all p< 0.05, Figure 1A). Each standard deviation increase in PCATa only around LCx associated with 85% greater likelihood of plaque presence in directly underlying segments (odds ratio-OR 1.85, 95% confidence interval 1.12-3.06) and greater stenotic severity (Figure 1B,C). Plaque presence only in LCx, but not other arteries, influenced the relationship between PCATa and EATv: PCATa around LCx inversely associated with EATv only in the presence of plaque (p for interaction< 0.05, Figure 2A). PCATa around LCx associated with interleukin-17F (figure 2B), and plaque presence exclusively in LCx influenced the relationship between PCATa and IL-17A (p for interaction < 0.01). Likewise, in the presence of mixed plaque exclusively in LCx, PCATa around LCx associated with serum vascular endothelial growth factor (VEGF, p for interaction=0.002). Lastly, PCATa associated with more noncalcified plaques in the absence of methotrexate, prednisone, or statin use (all p-for-interactions< 0.05) exclusively in LCx.

Conclusion: The association of increased PCATa with atherosclerosis burden and composition specifically around LCx may coincide with regional inflammation-dependent compositional changes in PCAT including IL-17A,F-induced adipocyte remodeling and VEGF-induced neovascularization and edema. In contrast, post-inflammatory fibrosis or adaptive remodeling may account for increased PCATa and the lack of association with plaque in LAD and RCA.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1936–1971) Imaging of Rheumatic Diseases Poster

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Interstitial lung disease (ILD) is the leading cause of death in MDA5 dermatomyositis (MDA5-DM). Fibrosis and inflammation are pivotal drivers in the pathogenesis of DM-ILD. This study aims to investigate the imaging characteristics of ^{68}Ga-FAPI-04 and ^{18}F-FDG PET/CT in MDA5 DM ILD, and to evaluate the association between pulmonary metabolic parameters of fibrosis and inflammation and mortality in MDA5 DM-ILD.

Methods: Between August 2022 and November 2024, 20 patients with newly diagnosed (duration ≤6 months) MDA5 DM were enrolled in the study, followed by a 6-month longitudinal observation period.All participants underwent baseline ^{68}Ga-FAPI-04 PET/CT and ^{18}F-FDG PET/CT scanning. Parameters including total lesion volume (TLV), total target-to-background ratio (TBR_total), mean TBR (TBR_mean), and maximum TBR (TBR_max) based on standardized uptake values (SUV) were quantified.Non-parametric Mann-Whitney U tests compared group differences.Spearman's rank correlation analyes parameter associations, and point-biserial correlation coefficients quantified associations with mortality.

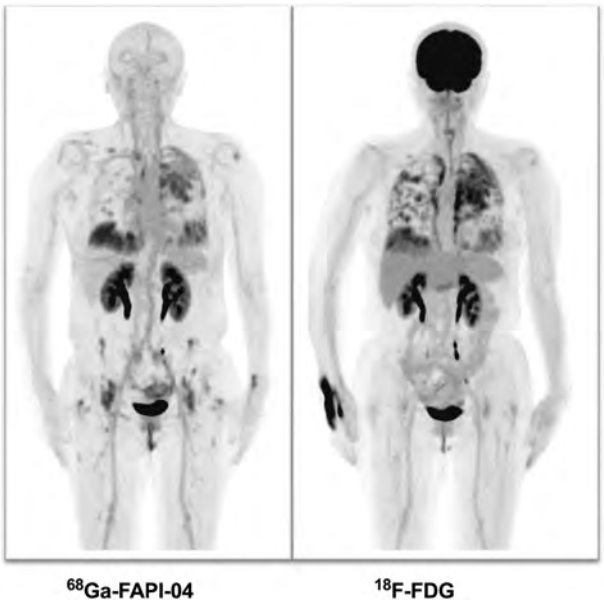

Figure 1 68Ga-FAPI-04 and 18F-FDG PET/CT imaging in a representative patient

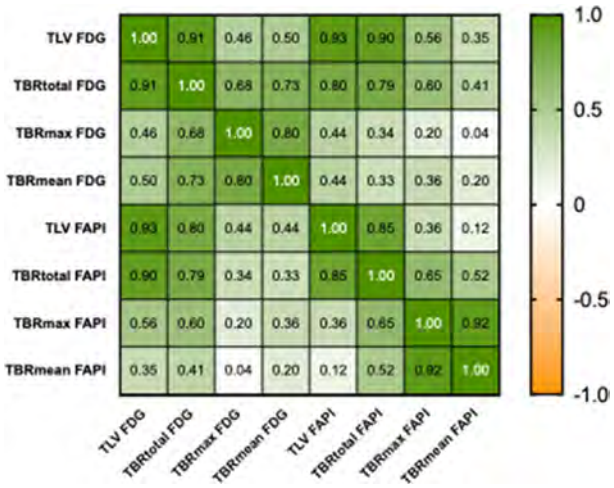

Figure 2 The association between pulmonary metabolic parameters of FAPI and FDG in MDA5 DM-ILD.

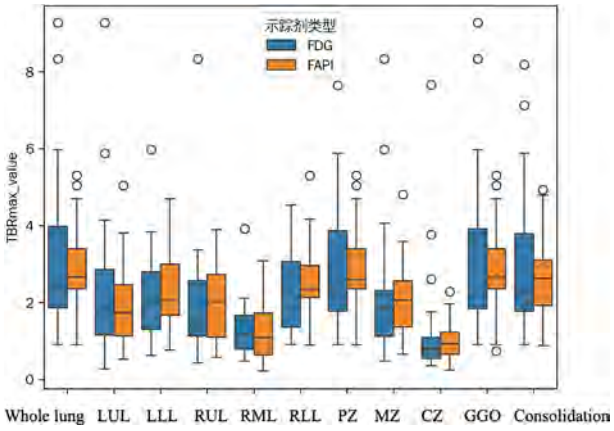

Figure 3 Boxplot of TBRmax for FDG and FAPI Tracers in Different Regions

Results: The study included 20 patients with a mean age of 50.2 ± 13.8 years ,and 60% were male. The median disease duration was 2.0 months (interquartile range [IQR], 1.0–3.0 months). During follow-up , mortality was observed in 3 of the 20 enrolled patients. Lesion volumes quantified by ^{68}Ga-FAPI-04 and ^{18}F-FDG PET/CT exhibited high concordance, with a robust positive correlation (Spearman's ρ = 0.93), indicating spatial colocalization of inflammation and fibroblast activation in the affected regions. TBRmax FAPI and TBRmean also showed a strong positive correlation (Spearman's ρ=0.92). Deceased patients demonstrated significantly elevated ^{18}F-FDG TBRmax values compared to survivors (median: 5.97 vs. 2.04, *P*=0.04), suggesting that inflammatory activity within lung lesions may contribute to the mortality risk of individuals with MDA5 DM.

Conclusion: In MDA5 DM patients, pulmonary lesions were characterized by hypermetabolism and active fibrosis. The ^{18}F-FDG TBRmax emerged as a potential prognostic marker for mortality, reflecting localized hypermetabolism in lung tissue that may indicate aggressive disease progression and correlate with poor clinical outcomes. These findings highlight the complementary roles of inflammation (FDG) and fibrosis (FAPI) imaging in characterizing disease severity. Further studies are warranted to validate the prognostic utility of TBRmax FDG and explore integrated imaging strategies for risk stratification in MDA5 DM-associated interstitial lung disease.

Abstract Number: 1957

Correlates Between Cardiovascular Risk Scores with Coronary Microvascular Function and Plaque Burden in Rheumatoid Arthritis

Katherine Zhong[1], Lauren rusnak[2], Ying Qi[3], Ilana Usiskin[4], Gregory McDermott[5], Brittany Weber[6], Marcelo DiCarli[5] and **Katherine Liao**[2], [1]Brigham and Women's Hospital, Short Hills, NJ, [2]Brigham and Women's Hospital, Boston, MA, [3]Brigham and Women's Hospital, Boston, [4]Division of Rheumatology, Inflammation, and Immunity, Department of Medicine, Brigham and Women's Hospital, Boston, [5]Brigham and Women's Hospital, Boston, [6]Brigham and Women's Hospital, DEDHAM, MA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1936–1971) Imaging of Rheumatic Diseases Poster

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: A combination of traditional risk factors and chronic inflammation account for the excess cardiovascular risk (CV) observed in rheumatoid arthritis (RA), including atherosclerotic cardiovascular disease (ASCVD) and heart failure (HF). Advanced cardiac imaging methods enable quantitative measurements of CV risk while informing mechanisms for risk such as coronary microvascular disease and plaque burden. The recently published PREVENT equations enable estimates for 10-year risk for ASCVD and HF. The objective of this study was to determine the correlation between the PREVENT estimated ASCVD and HF risk with imaging measurements corresponding to mechanisms of CV risk, specifically coronary microvascular function and plaque volume in patients with RA.

Methods: We studied subjects from the Lipids, Inflammation and Cardiovascular Risk in RA (LiiRA) study (1), which enrolled RA patients, age >35, without a history of CVD, not on a statin and about to initiate a TNFi. All subjects underwent a stress myocardial perfusion PET (cardiac PET) enabling calculation of myocardial flow reserve (MFR) and assessment for coronary microvascular disease (CMD) defined as MFR< 2.5. In a long-term extension study 2+ years post-baseline, a subset of LiiRA subjects with and without MFR< 2.5 had a follow-up cardiac PET and a coronary CT angiogram to quantify plaque volume. ASCVD and HF risk was assessed for all subjects using the PREVENT equations. We tested the baseline cross-sectional correlation between the PREVENT-ASCVD and HF risk with MFR using the Spearman rank correlation test. In the subset of patients with long-term follow-up, we tested the correlation between baseline ASCVD and HF risk with MFR and plaque volume at 2+ years (Figure 1).

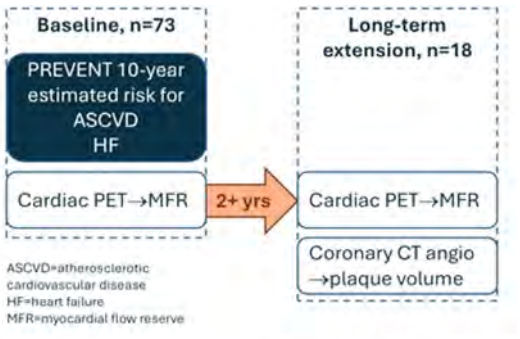

Figure 1. Overview of study design depicting available baseline and follow-up data for analyses.

Figure 1. Overview of study design depicting available baseline and follow-up data for analyses.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Baseline clinical characteristics of the LiiRA cohort n= 73.

Clinical Characteristics	
Age, years mean (SD)	55 (11)
Female, %	82
RA duration, years mean (SD)	7.4 (8.4)
RF or anti-CCP positive, %	68
CV risk factors, %	
Hypertension	24
Known coronary artery disease	0
Diabetes	4
Ever smoker	50
BMI, mean (SD)	30 (7.2)
eGFR, median [IQR]	97 [84 – 107]
PREVENT 10-year estimated CV risk %, median [IQR]	
ASCVD	2.2 [0.95 – 5.3]
HF	2.1 [0.67 – 4.4]

Table 2. Correlation between baseline PREVENT ASCVD and HF risk with (a) MFR and (b) plaque volume at 2+ years (n=18).

(a) Outcome: MFR measured by cardiac PET

PREVENT	r_s	P-value
ASCVD	-0.35	0.152
HF	**-0.54**	**0.022**

(b) Outcome: Plaque burden measured by coronary CT angiogram

PREVENT	Total plaque volume		Total calcified plaque		Total non-calcified plaque	
	r_s	P-value	r_s	P-value	r_s	P-value
ASCVD	0.32	0.191	0.18	0.472	0.32	0.194
HF	**0.61**	**0.008**	0.38	0.124	**0.57**	**0.014**

Results: We studied n=73 subjects, 82% female, 68% seropositive; the overall cohort had low estimated ASCVD and HF risk (Table 1). At baseline a higher HF risk was cross-sectionally correlated with lower MFR (r_s=-0.31, p=0.008); no correlation was observed for the PREVENT ASCVD with MFR. In the long-term extension study, a higher HF risk remained correlated with lower MFR (r= -0.54, p=0.022) as well as higher total and non-calcified plaque volume (Table 2).

Conclusion: RA patients with a higher estimated HF risk at baseline had worse coronary microvascular function, in line with prior studies implicating coronary microvascular disease as a mechanism for HF. After 2+ years, a higher estimated HF risk at baseline correlated with worse coronary microvascular function and a higher plaque burden. These findings suggest that the PREVENT HF equations are a promising approach to identify RA patients should be considered for additional CV screening.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1936–1971) Imaging of Rheumatic Diseases Poster

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Imaging outcomes are often evaluated using longitudinal analysis based on scores from multiple readers. However, the input into the analysis can vary from the scores of multiple individual readers to using a consensus or average across multiple readers. We assessed if this choice at the analysis stage can result in different estimates of change, we performed longitudinal analyses on different imaging outcomes in patients with early axial SpA (axSpA), using both individual reader scores and consensus scores/averages of readers.

Methods: Patients with chronic back pain (^{3}3 months; ≤2 years; onset < 45 years) from the SPondyloArthritis Caught Early cohort with a rheumatologist's diagnosis of axSpA at the 2-year follow-up were included. MRIs and radiographs of the sacroiliac joints and spine were obtained at baseline, 3 months, 1 and 2 years of follow-up and afterwards scored for inflammatory and structural lesions by 3 central readers, except for the MRI spine (2 readers). Patients included in this analysis had ≥1 score from ≥1 reader at 2-year follow-up. Each outcome was analyzed per reader and also according to the consensus (^{3}2 readers) or average across readers. Change over time was analyzed with generalized estimating equations, with 'time' as explanatory variable. For the analysis per individual reader, a multilevel analysis was performed, taking each individual reader into account. For the analysis of the consensus/average scores, each outcome was modelled according to its consensus/average score across readers.

Results: In total we analyzed 279 patients with axSpA (mean age 31 (SD 8) years; 53% males). As shown in Table 1, change estimates for continuous scores were very similar based on individual reader scores and using average scores across readers. However, larger discrepancies were found when comparing change estimates for dichotomous variables, expressed as yearly percentage change (Table 2).

Overall, the difference between the analytical choices could go in both directions. Spinal change was underestimated using the consensus scores of dichotomous variables, while change scores of the dichotomous variables in SIJ were mostly overestimated, especially of variables including erosions. In dichotomous variables, percentual differences between change scores calculated according to both analytical methods ranged from -35.4 to 37.5%.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: The seemingly simple decision of how to incorporate imaging outcomes from multiple readers into a model of change over time can significantly influence the final estimates, especially when dealing with dichotomous outcomes. To minimize the risk of introducing bias at the analytical stage, multilevel analyses that account for individual reader scores are recommended, rather than relying on pre-calculated consensus scores. This analysis also shows the vulnerability of dichotomous outcomes, reinforcing the disposition to use continuous measures as outcomes in analyses.

Table 1. Mean change per year for continuous imaging outcomes over 2-years of follow-up, according to the two different analytical methods, in early axSpA patients (n = 273-278)

	Imaging outcomes	Longitudinal analysis of individual reader scores (multilevel analysis)	Longitudinal analysis of average scores across readers
		Unit change per year (95% CI)	Unit change per year (95% CI)
Sacroiliac joints	**Inflammatory lesions (MRI)**		
	SPARCC SIJ score (0-72)	-1.68 (-2.19; -1.16)	-1.69 (-2.20; -1.17)
	Structural lesions (MRI)		
	No. of fat lesions and/or erosions (0-80)	0.58 (0.38; 0.77)	0.57 (0.38; 0.77)
	No. of erosions (0-40)	0.22 (0.12; 0.31)	0.22 (0.12; 0.31)
	No. of fat lesions (0-40)	0.36 (0.20; 0.52)	0.36 (0.20; 0.52)
	No. of (partial) ankylosis (0-24)	0.04 (0.01; 0,07)	0.04 (0.01; 0.07)
	Total structural lesions (0-144)	0.61 (0.41; 0.82)	0.61 (0.40; 0.81)
	Total structural lesions without sclerosis (0-104)	0.62 (0.42; 0.82)	0.61 (0.41; 0.81)
	Structural lesions (radiograph)		
	mNY continuous grade (0-8)	0.06 (0.03; 0.10)	0.06 (0.03; 0.10)
Spine	**Inflammatory lesions (MRI)**		
	SPARCC spine score (0-414)	-0.45 (-0.76; -0.15)	-0.44 (-0.74; -0.13)
	Structural lesions (MRI)		
	No. of erosions (0-92)	0.02 (-0.01; 0.04)	0.02 (-0.01; 0.04)
	No. of fat lesions (0-92)	0.35 (0.19; 0.50)	0.35 (0.20; 0.50)
	No. of bone spurs (0-92)	0.04 (-0.00; 0.08)	0.04 (0.00; 0.08)
	No. of ankylosis (0-46)	0.00 (0.00; 0.00)	0.00 (0.00; 0.00)
	Total structural lesions (0-322)	0.41 (0.23; 0.59)	0.42 (0.24; 0.59)
	No. of fat and/or erosions and/or bone spurs (0-276)	0.41 (0.23; 0.59)	0.41 (0.24; 0.59)
	Structural lesions (radiograph)		
	mSASSS (0-72)	0.08 (0.01; 0.16)	0.08 (0.0.; 0.15)

The longitudinal multilevel analysis of individual readers included scores from the individual readers, while the readers were included in the model as a level. The longitudinal analysis of average scores included average scores across readers directly into the analysis, i.e. as the outcome and therefore no further corrections for reader in the model would be possible. The total of structural lesions in the MRI of the sacroiliac joints is a sum of erosions, fat lesions, (partial) ankylosis, and sclerosis. The total of structural lesions in the MRI of the spine is a sum of erosions, fat lesions, bone spurs and ankylosis. AxSpA, axial spondyloarthritis; CI, confidence intervals; mNY, modified New York criteria; MRI, Magnetic resonance imaging; No., number; SIJ, sacroiliac joints; SPARCC, Spondyloarthritis Research Consortium of Canada.

Table 2. Mean percentual change per year for dichotomous imaging outcomes over 2 years of follow-up, according to the two different analytical methods, in early axSpA patients (n = 273-279)

	Imaging outcomes	Longitudinal analysis of individual reader scores (multilevel analysis)	Longitudinal analysis of consensus scores across readers	% difference between change estimates (consensus scores minus individual reader scores)
		% change per year (95% CI)	% change per year (95% CI)	
Sacroiliac joints	**Inflammatory lesions (MRI)**			
	Sacroiliitis (ASAS criteria), no. %	-5.78 (-8.57; -2.99)	-5.57 (-8.78; -2.36)	-3.8
	Structural lesions (radiograph)			
	mNY dichotomous, no. %	0.84 (0.05; 1.63)	1.34 (0.17; 2.52)	37.3
Spine	**Inflammatory lesions (MRI)**			
	MRI-spine positive (ASAS criteria)	-1.29 (-2.85; 0.27)	-0.71 (-2.14; 0.73)	-21.4
	Structural lesions (radiograph)			
	≥1 syndesmophyte, no. %	1.34 (0.07; 2.60)	0.99 (-0.44; 2.42)	-35.4

The longitudinal multilevel analysis of individual readers included scores from the individual readers, while the readers were included in the model as a level. The longitudinal analysis of consensus scores included consensus scores across readers directly into the analysis, i.e. as the outcome and therefore no further corrections for reader in the model would be possible. ASAS, Assessment of SpondyloArthritis international Society; axSpA, axial spondyloarthritis; BME, bone marrow edema; CI, confidence intervals; mNY, modified New York criteria; MRI, Magnetic resonance imaging; No., number; SPARCC, Spondyloarthritis Research Consortium of Canada.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1936–1971) Imaging of Rheumatic Diseases Poster

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Enthesitis is a key lesion in psoriatic arthritis (PsA). The Diagnostic Ultrasound Enthesitis Tool (DUET) study aimed to develop and validate a novel sonographic scoring system for enthesitis to aid PsA diagnosis.

Methods: We prospectively enrolled patients with early PsA, psoriasis alone, and people with non-inflammatory musculoskeletal symptoms as controls, across 17 centers. Participants underwent ultrasound assessment of 16 entheseal sites in the upper and lower extremities, performed by local sonographers. Images were centrally reviewed by 3 readers to derive a consensus score for inflammatory lesions (hypoechogenicity [0–1], thickening [0–1], power Doppler [PD, 0–3]) and structural lesions (calcification [0–3], enthesophyte [0–3], erosion [0–1]).

Using a stepwise approach with logistic regression models stratified by age, we identified optimal combinations of lesions and their weighting, and entheseal sites that maximized the ability to distinguish PsA from controls. Data from the discovery cohort, supplemented by an existing validation dataset, were used to determine cut-off points that optimize sensitivity while

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

maintaining specificity above 70%. We further evaluated the association between the DUET score and PsA disease activity measures.

Results: We analyzed 213 patients with PsA (mean duration 1.9±3.4 yrs), 100 with psoriasis and 106 controls. The mean age was 49.9±14.6 and 53.7% were females. Tenderness at ≥1 entheseal site was observed in 70% of PsA patients, 49% of controls and 33% of psoriasis (SPARCC score: PsA: 3.2, control: 2.5, psoriasis: 1.2). Initial evaluation of 4 inflammatory and 5 structural sub-scores across 16 entheseal sites yielded 48 candidate scores. Stratification by age improved discriminative performance. The best performing score (DUET score), comprising inflammatory (hypoechogenicity + thickening + 2×PD) and structural (enthesophyte + 3×erosion, **Fig. 1**) sub-scores at the Achilles, patellar tendon (patellar insertion), and triceps tendon, achieved an overall AUC of 0.65.

Age-specific cut-offs (age cut off 55) yielded specificity of 73–74% and sensitivity of 47–49% (**Fig. 2**). In the validation cohort (101 PsA, 69 controls), specificity improved to 74–100% with comparable sensitivity (49–52%). Sensitivity increased up to 63% in patients with tender entheseal sites (**Fig. 3**). The mean DUET score was significantly higher in PsA compared with controls and psoriasis (9.07 vs. 5.48 and 6.38, respectively; $p < 0.01$ for both, **Fig. 3**). Scores were elevated among obese patients, those with tender entheses, and those about to escalate PsA therapy.

Conclusion: DUET is a newly developed sonographic tool that may assist in the diagnosis of PsA, particularly among individuals with tender entheseal sites. The findings suggests that large joint enthesitis is not a universal feature of early PsA.

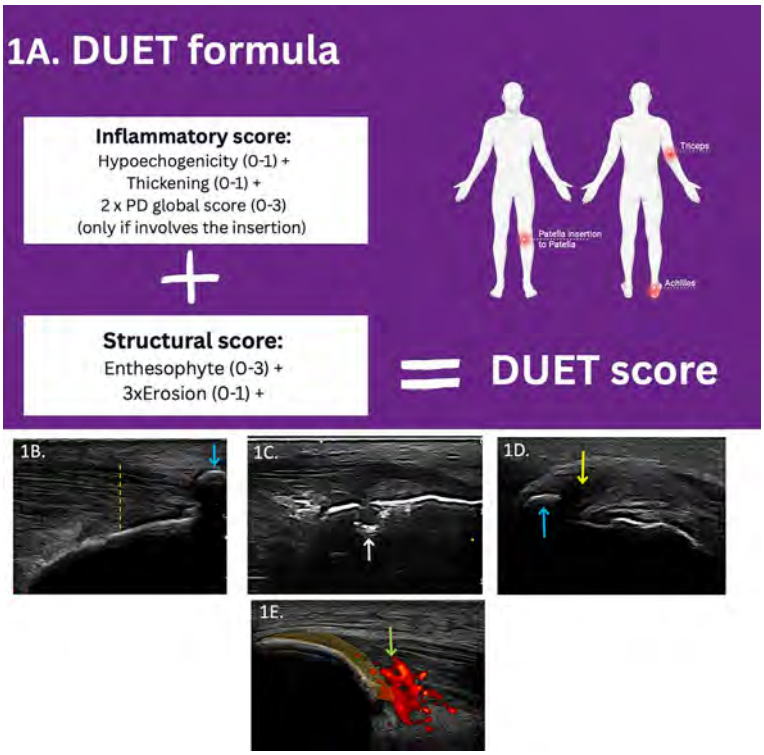

Figure 1: A summary of the DUET score. 1A. The DUET score formula is calculated based on a total of 6 entheseal sites: the Achilles and triceps insertions, and the patellar insertion to the patella. 1B–E. Depiction of selected elementary lesions and their corresponding DUET scores: 1B. Achilles tendon insertion showing thickening (1 point, vertical orange line) and enthesophyte (3 points, blue arrow); 1C. Achilles tendon insertion with erosion (1 point × 3, white arrow); 1D. Triceps tendon insertion with hypoechogenicity (1 point, yellow arrow) and enthesophyte (3 points, blue arrow); 1E. Patellar ligament insertion to the patella showing Doppler signal. The Doppler signal involves the area close to the bone (depicted by the orange marking), but the grading also considers Doppler intensity beyond this marking (3 points × 2).

Abstract Number: 1960

Item Response Theory to Develop an Ultrasound Composite Score for Knee Osteoarthritis Assessment

Liubov Arbeeva[1], Carolina Alvarez[2], Jonathan Samuels[3], Janice Lin[4], Minna Kohler[5], Catherine Bakewell[6], Todd Schwartz[7] and Amanda Nelson[8], [1]University of North Carolina, Chapel Hill, Carrboro, NC, [2]University of North Carolina at Chapel Hill, Miami, FL, [3]NYU Langone, Rye Brook, NY, [4]Stanford University, Palo Alto, CA, [5]Massachusetts General Hospital, Harvard Medical School, Boston, MA, [6]Intermountain Healthcare, Salt Lake City, UT, [7]University of North Carolina-Chapel Hill, Chapel Hill, NC, [8]University of North Carolina at Chapel Hill, Chapel Hill, NC

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1936–1971) Imaging of Rheumatic Diseases Poster

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Semi-quantitative scoring systems have long been used for radiographic findings in osteoarthritis (OA), but limited work has utilized ultrasound (US). The aim of this study was to utilize a rigorous approach based on factor analysis and nonparametric item response theory (IRT) to determine whether a single US summary score is appropriate for knee OA assessment.

Methods: Data were from Johnston County Health Study (JoCoHS) participants who underwent standardized radiography and ultrasonography of bilateral knees (PMID39989271). Symptomatic knee OA (sxKOA) was defined as a Kellgren-Lawrence grade of 2 or more in a knee with self-reported symptoms. A series of iterative procedures, i.e., Principal Components Analysis (PCA), Parallel Analysis (PA), Item Cluster Analysis (ICA), Very Simple Structure analysis (VSS), Confirmatory Factor Analysis (CFA), Mokken Scaling Analysis (MSA), and Classical Test Theory, were used to derive final items and subscales from US features (**Table 1**). In CFA, we considered the comparative fit index (CFI), the Tucker–Lewis index (TLI), and the root mean square error of approximation (RMSEA). MSA examines coefficients of homogeneity for items (H_i) and scale (H) and explores possible dimensionality solutions. Monotonicity, scalability, and invariant ordering of any determined subscales were also assessed.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Complete data for 13 US features were available for 824 of 902 JoCoHS participants (91%); 33% were male, 39% had sxKOA, mean age 55 ± 10 years and mean BMI 33 ± 8 kg/m^2. After exclusions based on test diagnostics and outliers, 791 participants and 12 items (all but double contour) remained for analyses. Items with the lowest H_i were removed one by one, and the analyses were repeated until H_i and H were above 0.3. H was 0.356 when all 5 problematic items were excluded (7 items remained, **Table 1**).

Table 1. US features, item inclusion/exclusion and subscale assignment

Subscale	US feature	Reason for item exclusion*
1	Grayscale effusion/synovitis	--
1	Grayscale synovitis	--
1	Grayscale effusion	--
Excl*	Power Doppler for synovitis	Coefficient of homogeneity < 0.3
2	Osteophytes, medial	--
2	Osteophytes, lateral	--
Excl*	Meniscal extrusion, medial	Automatic item selection algorithm
Excl*	Meniscal extrusion, lateral	Coefficient of homogeneity < 0.3
2	Cartilage damage, medial	--
2	Cartilage damage, lateral	--
Excl*	Popliteal cyst	Coefficient of homogeneity < 0.3
Excl*	Calcium crystal deposition	Coefficient of homogeneity < 0.3
Excl*	Double contour sign	>95% responses in a single category (i.e., rare finding)

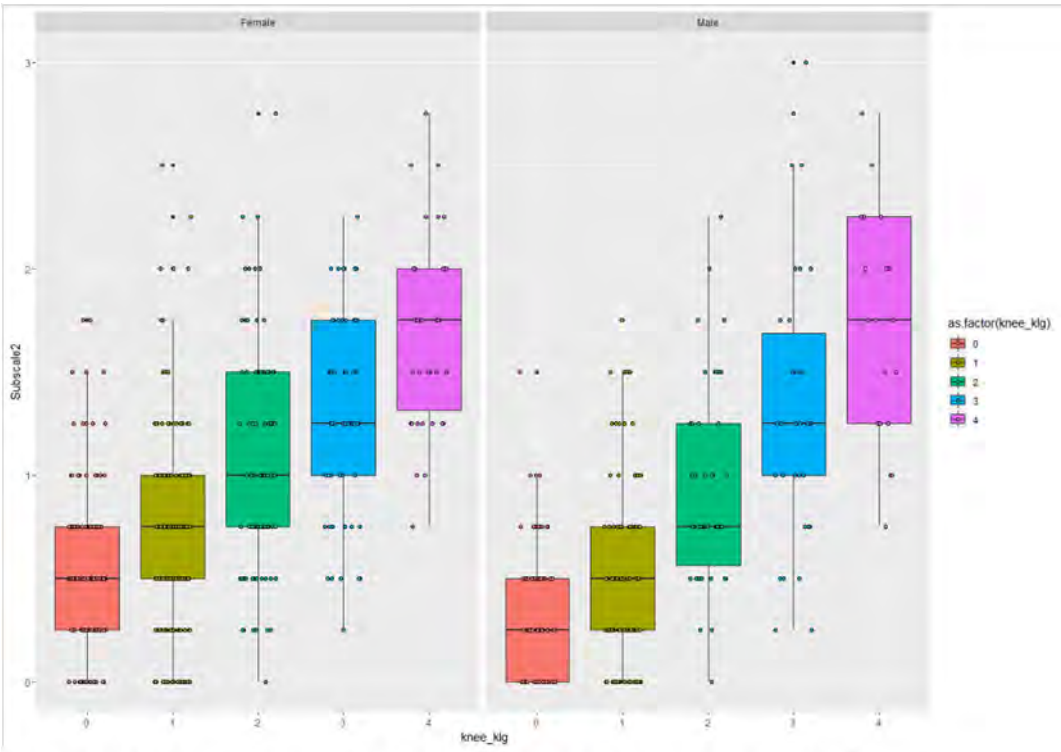

Figure 1. Subscale 2 score by KL score (0-4) at the knee, separately for female (left) and male (right) participants

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The PA, ICA, and VSS analysis on 8 and 7 items suggested 2 factors, but were inconsistent regarding the inclusion of medial meniscal extrusion. As the PCA loadings for this item were low, and its inclusion reduced reliability, we determined that the optimal number of items was 7, and the number of subscales was two (**Table 1**). The 2-factor CFAs of the 7-item model produced CFI and TLI = 0.99; RMSEA = 1.16. The coefficients of homogeneity were 0.747 for Subscale 1 (3 items) and 0.452 for Subscale 2 (4 items).

Since only Subscale 2 met all criteria, a composite score was derived for the second subscale only, demonstrating a linear relationship with KL grade for both females and males (**Figure 1**).

Conclusion: A robust composite score could be applied in clinical and research settings where only US is available or is preferred. The 4 US features in Subscale 2 form a moderate to strong Mokken scale, enabling persons to be ordered using a summary score. Future work will investigate Subscale 1 and the reason for MSA assumptions violation given that the three grayscale US features form a strong Mokken scale (H >=0.5). These results demonstrate that US summary score development and validation can benefit from both CFA and nonparametric IRT. Parametric IRT will be used to diagnose fit further and for scoring algorithm development.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1936–1971) Imaging of Rheumatic Diseases Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Diagnosing arthritis remains challenging in a subset of patients despite advances in imaging, serological markers, and clinical scoring systems. Ultrasound-guided synovial biopsy (USG-SB) stands as a potentially valuable tool in clarifying diagnoses and guiding treatment in atypical or refractory joint presentations.

The objective is to evaluate the clinical utility and patient-reported outcomes (PROMs) of USG-SB in patients with refractory arthritis in a real-world, secondary care setting.

Case No.	Age	Sex	Clinical history	Main diagnosis	Pattern	Krenn score	Final diagnosis
1	50	M	Psoriasis, IBD	Undifferentiated arthritis	Oligoarticular	3	Degenerative arthritis
2	45	M	AR (FR 85, ACPAs>320)	RA	Polyarticular	1	Non-active RA
3	45	F	AR (FR 58, ACPAs 7)	RA	Polyarticular	8	Active RA
4	45	F	Psoriasis, PsA	PsA	Oligoarticular	5	Active PsA
5	25	F	None	Undifferentiated arthritis	Oligoarticular	0	Mechanical arthritis
6	55	F	RA (FR-, ACPAs-)	Seronegative RA	Polyarticular	5	Active RA (CD20-)
7	34	M	Psoriasis, PsA	PsA	Polyarticular	5	Active PsA

Figure 1. Clinical and histological features of patients undergoing ultrasound-guided synovial biopsy (SGB). RA: Rheumatoid arthritis; PsA: Psoriatic arthritis; RF: Rheumatoid factor; ACPA: Anti-cyclic citrullinated peptide antibodies

Methods: We conducted a case series of seven patients who underwent knee USG-SB based on clinical indication by the treating rheumatologist. Histological samples were evaluated using the Krenn synovitis score, with scores < 5 indicating non-inflammatory or degenerative pathology, and scores ≥5 suggestive of active rheumatic disease. PROMs were assessed 7–10 days post-procedure via structured questionnaire.

Results: USG-SB provided diagnostic clarification or therapeutic guidance in 5 of 7 cases (71%). Inflammatory histological features (Krenn ≥5) were found in 4 patients and led to treatment adjustments in 3 cases. In one case, CD marker analysis guided selection of a biologic agent. Two patients were reclassified as having non-inflammatory arthritis, avoiding unnecessary immunosuppressive treatment.

PROMs showed that 6 out of 7 patients (86%) reported clear and sufficient pre-procedure information, and 6 out of 7 experienced minimal or no pain during the biopsy, with a median visual analogic score (VAS) of 0. Median VAS in the first 24 hours was 1. No patients reported functional limitations or infection at the puncture site. Most patients (86%) resumed normal activities within 3 days. All patients rated healthcare staff attention as "excellent," and 6 out of 7 (86%) indicated they would repeat the procedure if needed.

Conclusion: USG-SB is a safe, well-tolerated, and clinically useful procedure in patients with refractory arthritis. It contributed to diagnostic clarification and therapeutic decision-making in most cases, with minimal discomfort reported by patients. Its implementation in secondary care centers may help expand access to precision rheumatologic care.

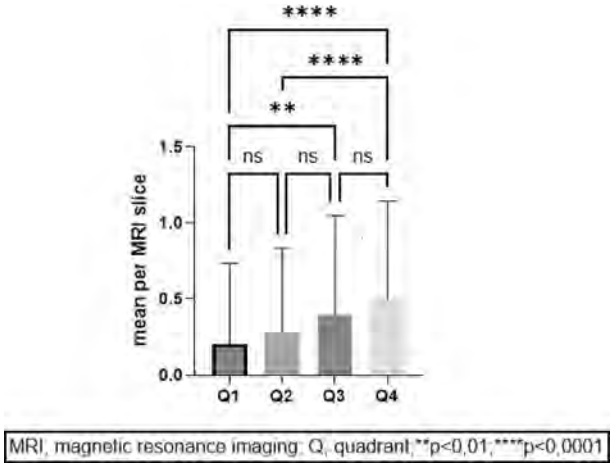
SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1936–1971) Imaging of Rheumatic Diseases Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Enteropathic spondyloarthritis (eSpA) is a subtype of SpA associated with inflammatory bowel disease (IBD). Sacroiliac joints (SIJs) involvement is common in eSpA but often clinically silent, contributing to diagnostic delay. Magnetic resonance imaging (MRI) enables detection of early inflammatory and structural changes, yet lesion patterns specific to eSpA insufficiently characterized. This study aimed to assess active and chronic inflammatory lesions on SIJ MRI.

Methods: We included 107 patients: 46 with IBD and 51 with axSpA with suspected eSpA, plus 10 with previously established eSpA. All underwent SIJ MRI; patients with MRI-confirmed sacroiliitis also underwent SIJs radiographs, scored using Bennett's criteria (stage ≥2 sacroiliitis defined as positive for uni/bilateral involvement). MRI was assessed using the SPARCC scoring system for both active and structural lesions. The distribution of defined lesions were examined in four quadrants (scores ranging from 0-2 per quadrant on each sides of SIJ, expressed as mean (±SD)) and across slices. Two experienced readers, blinded to clinical data, independently scored all images; averaged scores were used. Cohen's kappa showed high inter-reader reliability (BME: 0.8; fat metaplasia: 0.83; erosions: 0.88; backfill: 0.65; ankylosis: 0.84).



Difference in bone marrow edema distribution

Figure 2A: Difference in fat metaplasia distribution

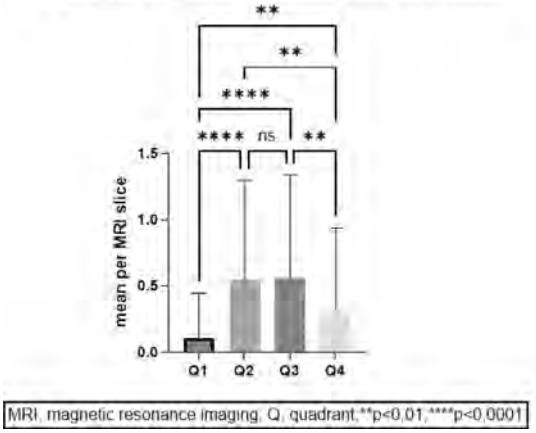


Figure 2B: Difference in distribution of erosions

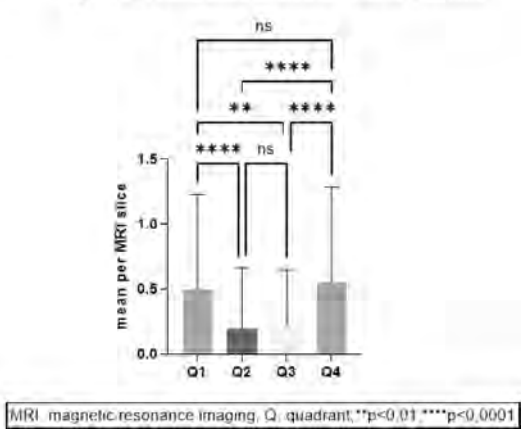
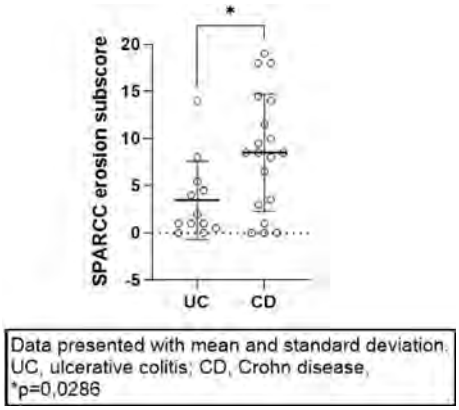


Difference in fat metaplasia distribution, Difference in distribution of erosions

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Presence of erosions in patients with SpA/IBD: ulcerative colitis vs. Crohn disease

Results: Among 97 evaluated patients, 26 (27%) met classification criteria for eSpA. Including the 10 pre-diagnosed patients, 36 were analyzed: 20 (56%) had radiographic axSpA, 11 (31%) had non-radiographic axSpA, and 5 (14%) had unknown status due to missing x-ray data. Radiographic sacroiliitis was bilateral in 18 (58%), unilateral in 8 (26%), and absent (stage < 2) in 5 (16%). MRI revealed distinct quadrant-level lesion patterns. Bone marrow edema (BME) was significantly more prevalent in Q4 compared to Q1 and Q2 (0.5 (± 0.6) vs. 0.2 (±0.5) and 0.3 (±0.6), p< 0.0001 and < 0.0001, respectively) and in Q3 compared to Q1 (0.4 (±0.7) vs. 0.2 (±0.5), p=0.0023), with no significant difference between Q4 and Q3 (Figure 1). Fat metaplasia was significantly more frequent in Q2 and Q3 compared to Q1 and Q4 (0.5 (±0.8) and 0.6 (±0.8) vs. 0.1 (±0.3) and 0.3 (±0.6) SPARCC SIJ structural score, p< 0.0001, p=0.0051, p< 0.0001, p=0.0033, respectively) and between Q1 and Q4 (0.1 (±0.3) and 0.3 (±0.6), p=0.0043) (Figure 2). Erosions were significantly more frequent in Q1 and Q4 compared to Q2 and Q3 (0.5 (±0.7) and 0.6 (±0.7) vs. 0.2 (±0.5) and 0.2 (±0.4), p< 0.0001, p=0.0030, p< 0.0001, p< 0.0001, respectively) (Figure 2). No significant differences were observed in lesion distribution across MRI slices. Patients with Crohn's disease exhibited significantly more erosions than those with ulcerative colitis (8.5 (±6.2) vs. 3.5 (±4.1), p=0.0286) (Figure 3).

Conclusion: Most patients with eSpA demonstrate bilateral SIJ involvement on radiographs. MRI revealed distinct patterns of inflammatory and structural lesions, with quadrant-specific predilections for BME, fat metaplasia, and erosions. Crohn's disease was associated with a higher burden of erosive changes compared to ulcerative colitis, suggesting phenotypic heterogeneity in musculoskeletal manifestations of eSpA.

Session Title: (1936–1971) Imaging of Rheumatic Diseases Poster

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Primary results from the phase 4 MOSAIC trial demonstrated that apremilast (APR) improved inflammation in patients (pts) with PsA based on PsA MRI scoring of the hand. Pts also underwent optional dynamic contrast-enhanced MRI (DCE-MRI), which evaluated perfusion within soft tissues and bone marrow of the hand to estimate the degree of joint and soft tissue inflammation in dactylitis, a hallmark of PsA characterized by swelling and inflammation of digits. We report the efficacy of APR in pts from the MOSAIC trial with pre-existing dactylitis.

Methods: MOSAIC (NCT03783026) was a multicenter, single-arm, open-label study that evaluated pts with PsA (duration: 3 mo to 5 y; met CASPAR criteria) who received oral APR 30 mg twice daily for up to 48 weeks. Conventional MRIs of pts with clinically reported dactylitis at baseline (BL; digit not specified) were read by an independent radiologist to determine the most affected dactylitic finger. Another 2 independent readers, blinded to time point and clinical information, reviewed DCE-MRI using the Dynamic Contrast-Enhanced MRI Quantification (DEMRIQ) method; the volume of contrast-enhanced voxels in dactylitic fingers and joints were calculated: volume of enhancement (DEMRIQ-Vol), volume of enhancement × mean maximum enhancement (DEMRIQ-ME), and volume of enhancement × mean initial rate of enhancement (DEMRIQ-IRE) within each region of interest around each digit and joint. We report changes in these 3 DCE-MRI outcomes

Figure 1 DCE-MRI outcomes of the MRI-determined most-affected dactylitic finger joint in patients with dactylitis at W24 (n=32) and W48 (n=23)

		DEMRIQ-Vol (mL)	DEMRIQ-ME (mL)	DEMRIQ-IRE (mL/s)
Mean	BL	0.35	0.58	0.035
% Change from BL	W24	20.0	18.7	56.2
	W48	17.1	24.1	11.4

Asterisks indicate statistical significance based on *P* values <0.05. Most-affected joints included distal interphalangeal joints (n=12), proximal interphalangeal joints (n=15), and metacarpophalangeal joints (n=5).
BL, baseline; CI, confidence interval; DCE-MRI, dynamic contrast–enhanced magnetic resonance imaging; DEMRIQ-IRE, DEMRIQ–initial rate of enhancement; DEMRIQ-ME, DEMRIQ–maximum enhancement; DEMRIQ-Vol, DEMRIQ-volume; W, week.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

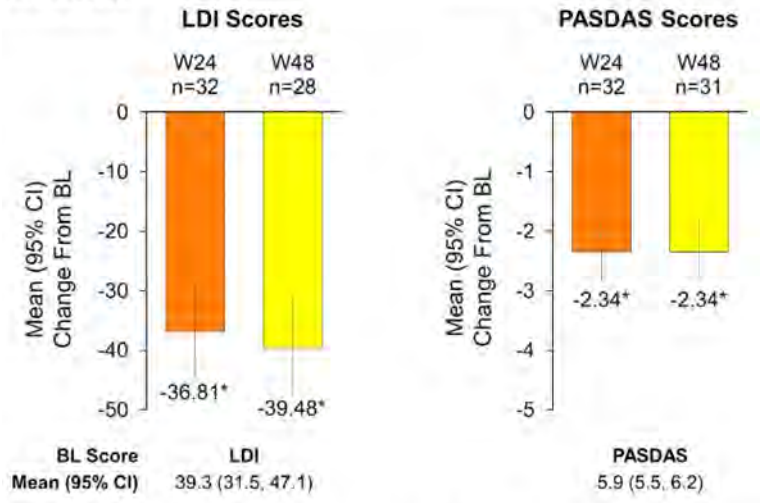
in the MRI-determined most-affected joint of the dactylitic finger, as well as in clinical disease activity measured by the Leeds Dactylitis Index (LDI) and the PsA Disease Activity Score (PASDAS) at Week (W) 24 and W48 (clinical assessments not blinded to time point).

Results: Thirty-two pts in MOSAIC had both BL dactylitis and W24 imaging (mean age: 41.6 y; mean PsA duration: 1.9 y; moderate Clinical Disease Activity Index for PsA [cDAPSA] score [>13 to ≤27]: 46.9%; high cDAPSA score [>27]: 50.0%); 23 had W48 imaging. Statistically significant decreases in DEMRIQ-Vol (W24 and W48) and DEMRIQ-ME (W48) were observed for the MRI-determined most-affected joint ($P< 0.05$; **Figures 1, 2**). DEMRIQ-IRE showed no significant change. Statistically significant decreases in the mean (95% CI) change from BL were observed for clinical outcomes at W24 (LDI: -36.8 [-44.4, -29.2]; PASDAS: -2.3 [-2.8, -1.8]) and W48 (LDI: -39.5 [-47.8, -31.1]; PASDAS: -2.3 [-2.9, -1.8]; **Figure 3**). At W48, 26/28 pts (92.9%) had an LDI of 0, and 13/31 pts (41.9%) had PASDAS < 3.2 (indicating minimal disease activity). Subgroup analyses by BL disease activity will be presented.

Figure 2. Representative images of DCE-MRI of the hand and wrist of a patient with dactylitis at baseline, W24, and W48

This series of images shows MRI scans with superimposed maps of maximum enhancement. The colors indicate the degree of perfusion or inflammation within individual tissues. Those tissues with the highest degree of perfusion as well as blood vessels present in white-yellow colors; tissues with lower degree of perfusion are shown in redder colors, as per the color scale on the left of the image. All colors and measurements are normalized between the 3 exams showing significant reduction in the volume and degree of inflammation.
DCE-MRI, Dynamic Contrast-Enhanced Magnetic Resonance Imaging; W, week.

Figure 3. Mean change from baseline in LDI and PASDAS in patients with dactylitis at W24 and W48



Asterisks indicate statistical significance based on 95% CI. BL, baseline; CI, confidence interval; LDI, Leeds Dactylitis Index; PASDAS, Psoriatic Arthritis Disease Activity Score; W, week.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: There were significant reductions in DEMRIQ-ME and DEMRIQ-Vol with APR at W24 and/or W48; DEMRIQ-IRE did not show significant changes. Clinical outcomes significantly improved. DCE-MRI outcomes suggest increased capillary permeability, synovial and joint capsule volume, engorged microvasculature, and delayed contrast washout within dactylitic finger joints in PsA that improve at different rates after APR treatment and highlight the potential of using different DCE-MRI parameters to understand, quantify, and monitor the complex inflammatory load and response to treatment in pts with PsA and dactylitis.

Background/Purpose: To develop a deep learning model for classifying ultrasound images of salivary glands (SG) [parotid (PG) and submandibular (SMG)] based on the Outcome Measures in Rheumatology (OMERACT) 0-3 semiquantitative scoring system for B-mode ultrasound-assessed parenchymal abnormalities in SG in Sjögren syndrome (SjS) (Figure 1)

Methods: For training, we used 3 datasets of SG (PG and SMG) ultrasound images representative of the OMERACT scores: 1) 225 images from 150 suspected or confirmed SjS patients acquired with different ultrasound systems across 4 European centers (https://www.frontiersin.org/articles/10.3389/fmed.2020.581248/full); 2) 80 images from 20 SjS patients provided by a European center; 3) Of 39 SjS patients and 10 controls, 6 images of each acquired by 2 experts with 2 systems (a high-end and a wireless handheld device) in a European center (1176 images). We used a ResNet18 architecture, which was pre-trained on ImageNet and then fine-tuned for this task. The model was trained hierarchically: initially classifying broad categories (scores 0/1 vs. 2/3) and subsequently refining the classification for the specific stages of the disease. 70% of the images were used for training, 15% for validation, and 15% for test. For training, we used a dataset of ultrasound images along with labels indicating the grade of SG involvement. We employed standard deep learning techniques such as data

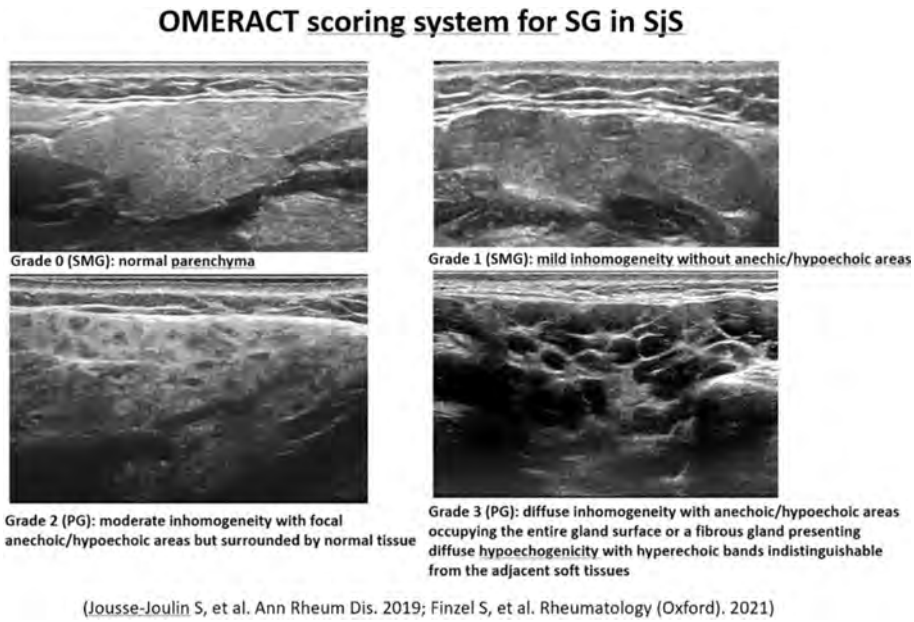

Figure 1

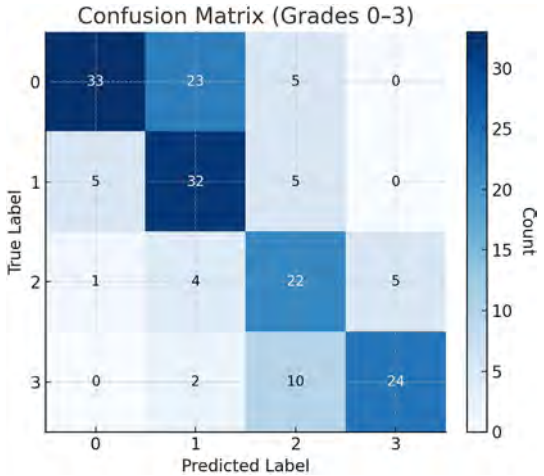

Figure 2

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1

Table 1.

	Precision	Recall	F1-score
Grade 0	0.85	0.54	0.66
Grade 1	0.52	0.76	0.62
Grade 2	0.52	0.69	0.59
Grade 3	0.83	0.67	0.74

augmentation (e.g., random flipping and brightness adjustments) to increase the model's robustness and generalization capabilities and a step learning rate scheduler to optimize the training process. Precision (correct classifications per predicted class), recall (correct classifications per actual class), and F1-score (harmonic mean of precision and recall) were calculated for each grading class.

Results: The overall performance of the model for grading classes is shown in Table 1. The broad model achieved an accuracy of 90% in distinguishing between 0/1 and 2/3 grades. However, the more specific models, fine-tuned for the 0/1 and 2/3 categories, had lower accuracy (approximately 65% for each). This reflects the increased difficulty of fine-grained classification. The confusion matrix (Figure 2) showed that the model performed well in classifying SG with grade 3 but faced challenges with intermediate categories (class 1 and class 2). The network showed difficulty discriminating between grade 0 and 1; on retrospective review of the ultrasound labels, we noted that this boundary is visually subtle and prone to greater interobserver variability, which likely contributes to the model's confusion between these two lowest scores.

Conclusion: Our results showed the potential of deep learning models, specifically convolutional neural networks, to classify SG ultrasound images based on parenchymal involvement, offering a promising tool for SjS diagnosis. While the broad classification model performed very well, the fine-tuned models, which differentiate between more specific disease stages, still faced challenges. Future work should refine the fine-tuned models with additional data, allowing more complex architecture or domain-specific adjustments.

Background/Purpose: Recurrent monoarthritis (RM) is a significant therapeutic challenge in rheumatology, often persisting despite NSAIDs, corticosteroids (CS), DMARDs, and biologic therapies. Local interventions like intra-articular aspiration (IAA) and CS injections offer transient relief and are limited by high recurrence rates. Surgical and chemical synovectomy have largely been abandoned due to poor efficacy and high complication rates. Microwave ablation (MWA) is a well-known technique in the treatment of benign or malign lesions of different etiologies. Building upon our initial findings using MWA in RM sucessfully, we present long-term outcomes from a larger cohort of medical treatment-resistant RM, providing real-world data on the efficacy and safety of MWA.

Methods: Patients with RM associated with various inflammatory diseases were included. MWA was performed after measuring the size of synovial hypertrophy (SH) with 15 or 20-watt power and different durations until microbubbles were shown indicating necrosis (Figure 1). Both clinical and radiologic data were recorded baseline and prospectively.

Results: We applied MWA to a total of 43 knee joints in 37 patients (18 female and 19 male) aged between 22 and 71 years. The median number of IAA required in the 6 months prior to MWA was 5 (0–15). Three patients had previously undergone surgical synovectomy. In 3 knees of 2 patients, the number of IAAs in the last 6 months was 0; these patients had persistent synovial effusion and abundant synovial hypertrophy but declined IAA. A 2nd MWA session was required in 5 patients, and 1 patient underwent a 3rd. The median follow-up period was 15 months (5–25). The IAA frequency dropped dramatically from 207 over 258 patient-months (0.81/month) before MWA to just 21 over 624 patient-months post-MWA (0.03/month; $p < 0.001$). Short-term, Lowe dose CS therapy was administered in 14 patients (16 knees) with all anti-inflammatory treatments maintained unchanged during the first 6 months post-procedure.

CS reduction or cessation was achieved in 16 patients. Functional disability and pain scores showed significant improvement, with the median score decreasing from 9 to 1 ($p < 0.0001$ for both, Figure 2). No complications were observed during the procedure or follow-up. While both SH and effusion persisted to varying degrees at the 1st and 3rd months on USG and

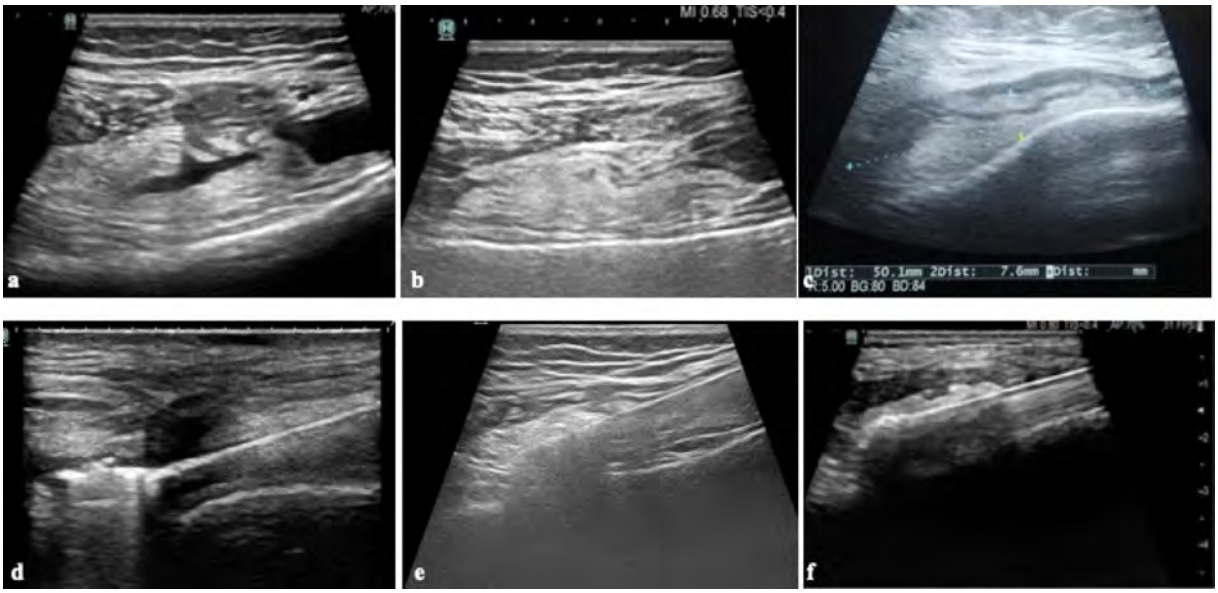

Figure 1. Microwave Ablation Technique. Synovial hypertrophy was assessed using ultrasound (USG), and significant joint effusion, if present, was aspirated. The targeted hypertrophic area is demonstrated in panels 1a and 1b, and the measurement of horizontal and longitudinal dimensions is shown in panel 1c. Following surgical asepsis and local anesthesia, antimicrobial prophylaxis with ampicillin/sulbactam and sedation with midazolam and fentanyl were administered. A monopolar internally cooled MWA probe was inserted through a 2 mm skin incision under USG guidance. Examples of probe placement into hypertrophic synovium are illustrated in panels 1d, 1e, and 1f. Ablation was performed using 15–20 W of energy with the moving-shot technique until microbubbles, indicating effective necrosis, were observed (panels 1d and 1f). For larger hypertrophic areas, multiple ablation zones were treated sequentially. Energy output and ablation duration were recorded.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2: Functional disability and pain scores of patients before MWA procedure and at 1st, 3rd, 6th, and 12th month visits. The figure 2a shows the functional disability score and 2b shows the pain score rated between 0 an 10. 0 means no funcitonal disability or pain, and 10 is the worst possible funcitonal disability or pain, in both.

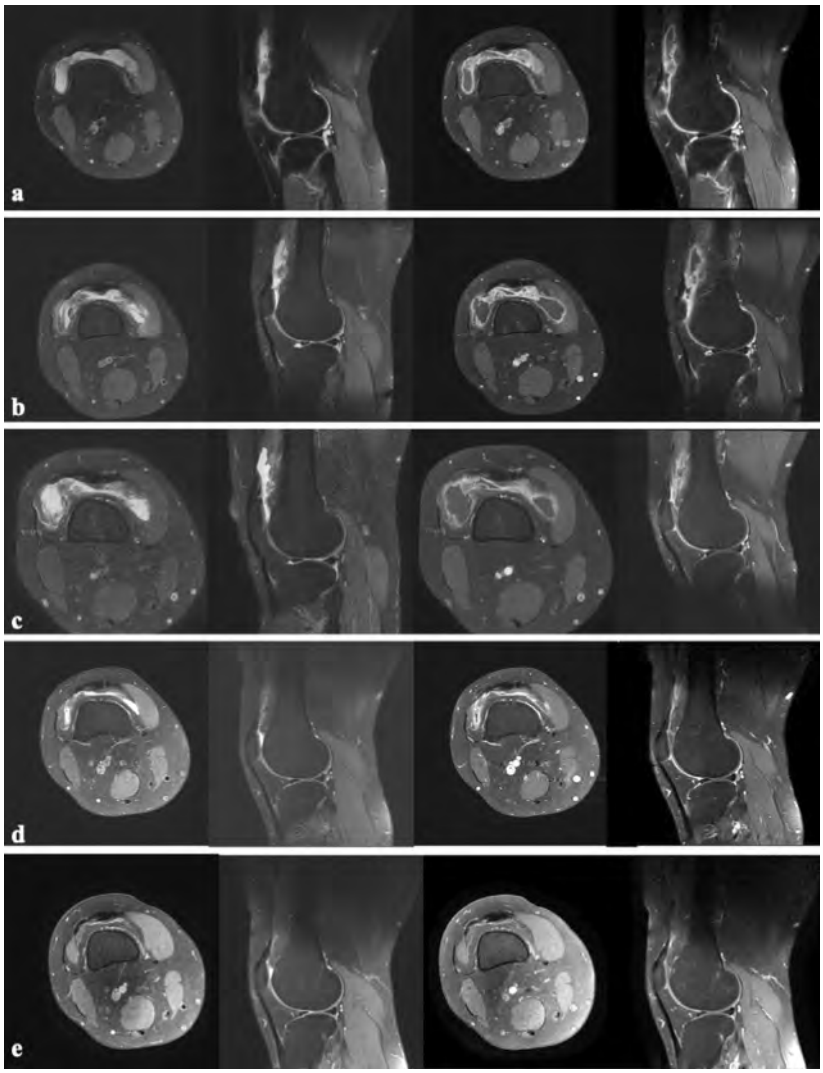

Figure 3: An example of a patient with pre-procedure, and post-procedure 1st, 3rd, 6th, and 12th month MRI images indicating consistent improvement in MRI findings with time. The figure 3a shows pre-procedure, 3b shows post-procedure 1st month, 3c shows post-procedure 3rd month, 3d shows post-procedure 6th month, and 3e shows post-procedure 12th month MR images of the patients. In all rows, the order of images are positron density weighted (PDW) in the axial plane, PDW in the sagittal plane, T1-weighted contrast enhanced in the axial plane, and T1-weighted contrast enhanced in the sagittial plane, from left to right. Synovial hypertrophy and effusion did not show any significant change in the 1st and 3rd months after the procedure, whereas a significant regression was observed starting from the 6th month.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

MRI, IAA was deferred unless symptoms developed. Significant regression in SH was demonstrated on MRI at the 6th month (Figure 3). A discordance between clinical improvement and radiological findings was observed in a small subset of the cohort.

Conclusion: MWA is a safe, effective, and minimally invasive adjunctive option for managing RM with SH. It significantly reduces arthritis flares frequency, CS dependecy, and the need for IAAs while improving functional outcomes and pain. Although early imaging may show persistent effusion and SH, significant regression by six months correlates with sustained clinical improvements. These long-term results support MWA as a promising alternative to surgical interventions in RM resistant to conventional medical therapies.

Assessing the Impact of Cutaneous Melanin on Microvascular Oxygenation Measurement in Systemic Sclerosis Using Multispectral Imaging

Rosie Barnes[1], Joanne Manning[2], Graham Dinsdale[3], Ariane Herrick[4], Mark Dickinson[5] and Andrea Murray[6], [1]University of Manchester, Manchester, England, United Kingdom, [2]Northern Care Alliance NHS Foundation Trust, Salford, United Kingdom, [3]Northern Care Alliance, Salford, United Kingdom, [4]The University of Manchester, UK, Aberdeen, United Kingdom, [5]The University of Manchester, Manchester, [6]University of Manchester, Salford, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1936–1971) Imaging of Rheumatic Diseases Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Microvascular abnormalities, leading to hypoxia, drive the SSc disease process. Accurate measurement of skin oxygenation, both baseline and during 'stress'/reperfusion (which can be mimicked in the laboratory by occlusion), would not only facilitate studies of pathogenesis but also provide a surrogate outcome measure for clinical trials of vasoactive therapies. But measuring skin oxygen is challenging, especially in darker skin tones. Our aim was to (a) explore the effect of skin tone on skin oxygenation measurements using multispectral imaging (MSI) (which measures oxygen by imaging the skin under white light) and (b) compare skin oxygenation between patients with SSc and healthy controls (HC).

Methods: Fifty patients with SSc (49 fulfilled ACR criteria or were VEDOSS; median age 55.0 (IQR 45.50-63.75) years; F:M 45:5) and 50 healthy controls (55.5, (44.75-64.00) years; F:M 45:5) were recruited. Objective measurements of participants' 'individual typology angle' (ITA) were taken using a colorimeter, to record skin tone. ITA data from recruited participants are given in Table 1. Participants underwent an occlusion of the middle finger on their non-dominant hand to reduce oxygenation and their hands were imaged with MSI before, during, and after occlusion release. From the MSI data an index of oxygenation (Oxy) was calculated. The Oxy index was averaged over a region of interest on the occluded finger. A multiple linear regression model was used to estimate the impact of skin tone and cohort on the change in Oxy (ΔOxy) upon occlusion release.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1: The number of participants (healthy controls, patients, and total) recruited in each skin tone group by individual typology angle (ITA).

SKIN TONE GROUP	HEALTHY CONTROLS	PATIENTS	TOTAL
VERY LIGHT (ITA ≥ 55°)	3	1	4
LIGHT (55° > ITA ≥ 41°)	25	15	40
INTERMEDIATE (41° > ITA ≥ °28)	14	20	34
TAN (28° > ITA ≥ 10°)	4	9	13
BROWN (10° > ITA ≥ −30°)	2	4	6
DARK (−30° > ITA)	2	1	3

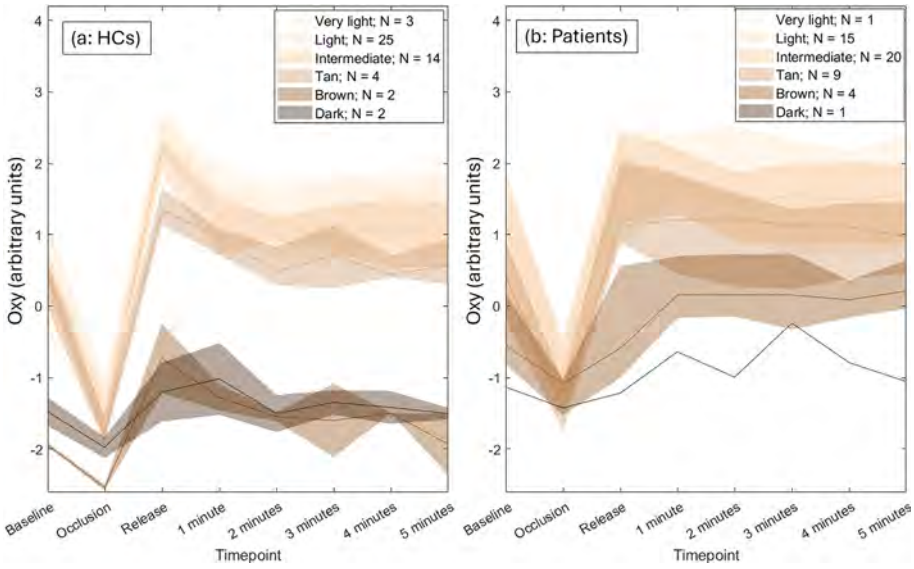

Figure 1: Oxy over time (before, during, and for 5 minutes after occlusion) colour-coded by skin tone group as given in Table 1, showing the median and IQR of each group for (a) healthy controls (HC) and (b) patients. ΔOxy is calculated as the difference in Oxy between release and occlusion.

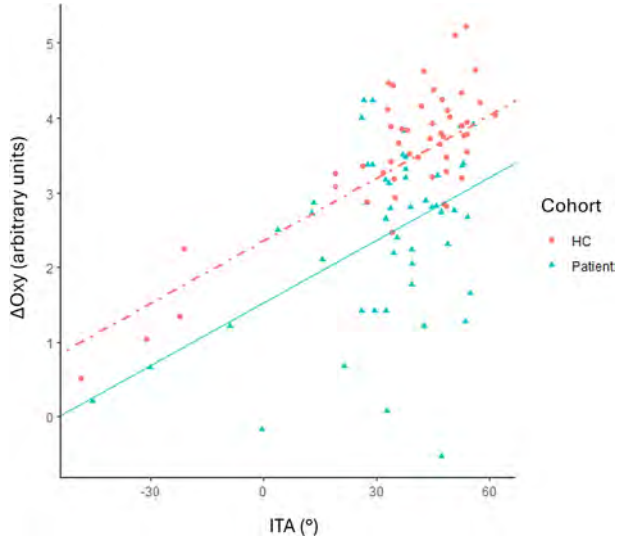

Figure 2: The fitted multiple linear regression model showing the linear effect of individual typology angle (ITA), aka skin tone, on ΔOxy and the difference between cohorts. The red dashed line is the healthy control (HC) fit, while the blue solid line is the patient fit. The model accounts for 47% of variance in the data, with an R^2 of 0.47.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Median and IQR of Oxy over time is shown in Figure 1. The fitted model of ΔOxy, shown in Figure 2, was significant, $F(2,97) = 45.66$, $p < 0.001$, and showed that both cohort, $t(97) = -5.596$, $p < 0.001$, and ITA, $t(97) = 7.041$, $p < 0.001$, had a significant effect on ΔOxy. ΔOxy was reduced for lower ITA, i.e. darker skin tone, and for patients compared with HCs.

Conclusion: (a) Skin tone had a significant effect on Oxy measurements, with lower ΔOxy in darker skin tones. We believe this is due to a lack of sensitivity of the Oxy index to oxygenation in dark skin caused by strong absorption of light by eumelanin (which sits above the vascular network in the skin). This is a problem that is inherent to visible light imaging of the skin and needs to be addressed in MSI and similar optical techniques. This work represents a first step in understanding the effect melanin has on oxygenation measurements; future work is required to further understand and account for this effect and thus ensure equitable techniques for all patients.

(b) ΔOxy was lower in patients, suggesting that patients display a muted response to the occlusion, with less pronounced reactive hyperaemia compared to HCs of a similar age and sex. This clear difference demonstrates the vascular dysfunction in patients, and Oxy could be a promising marker for disease measurement.

Developing an Algorithm to Quantify Dermatomyositis-associated Calcinosis Using Infrared Imaging

Saahil Sachdeva[1], Briana Cervantes[2], Lisa Rider[3] and Adam Schiffenbauer[4], [1]NIEHS/NIBIB/NIH, Danville, CA, [2]Department of Emergency Medicine, Norfolk, VA, [3]National Institute of Environmental Health Sciences/National Institutes of Health, Environmental Autoimmunity Group, Bethesda, MD, [4]National Institute of Health/National Institute of Dental and Craniofacial Research, Bethesda, MD

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1936–1971) Imaging of Rheumatic Diseases Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Dermatomyositis (DM) is a rare autoimmune disease characterized by chronic muscle and skin inflammation. One potential complication of DM is calcinosis, the heterotopic calcification of soft tissue. The differences in depth and densities of these calcifications make early detection difficult by physical exam.

Infrared imaging (IR) is a light-based modality that measures an object's surface temperature. It has been used for other medical applications; however, IR imaging has not previously been employed for assessing DM-associated calcinosis. We proposed an IR algorithm to detect calcinosis in patients with juvenile and adult DM (J/DM) by measuring the value and variability of skin surface temperature. We believe its use will provide clinicians with a supplementary non-ionizing, inexpensive, and easy-to-use imaging modality to quantify DM-associated calcinosis at an early onset.

Methods: Study subjects were recruited from a myositis natural history study conducted at the National Institutes of Health in Bethesda, MD, and enrolled from August 2020 to July 2022. Inclusion criteria for the present study were probable or definite J/DM by Bohan and Peter criteria. Each patient also had suspicion of calcinosis, either self-reported or by documented assessment from a medical professional.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Patient scans were conducted by an IR camera (ImageIR® 8300, InfraTec, Germany) at the NIH Clinical Center in Bethesda, MD. All scans were done in a temperature-controlled and humidity-monitored room (18-22 °C, 50-60 % humidity). Target scan locations were selected beforehand based on common calcinosis areas in J/DM, including the abdomen, back, arms, and legs. All images were taken as close to perpendicular to the patient as possible.

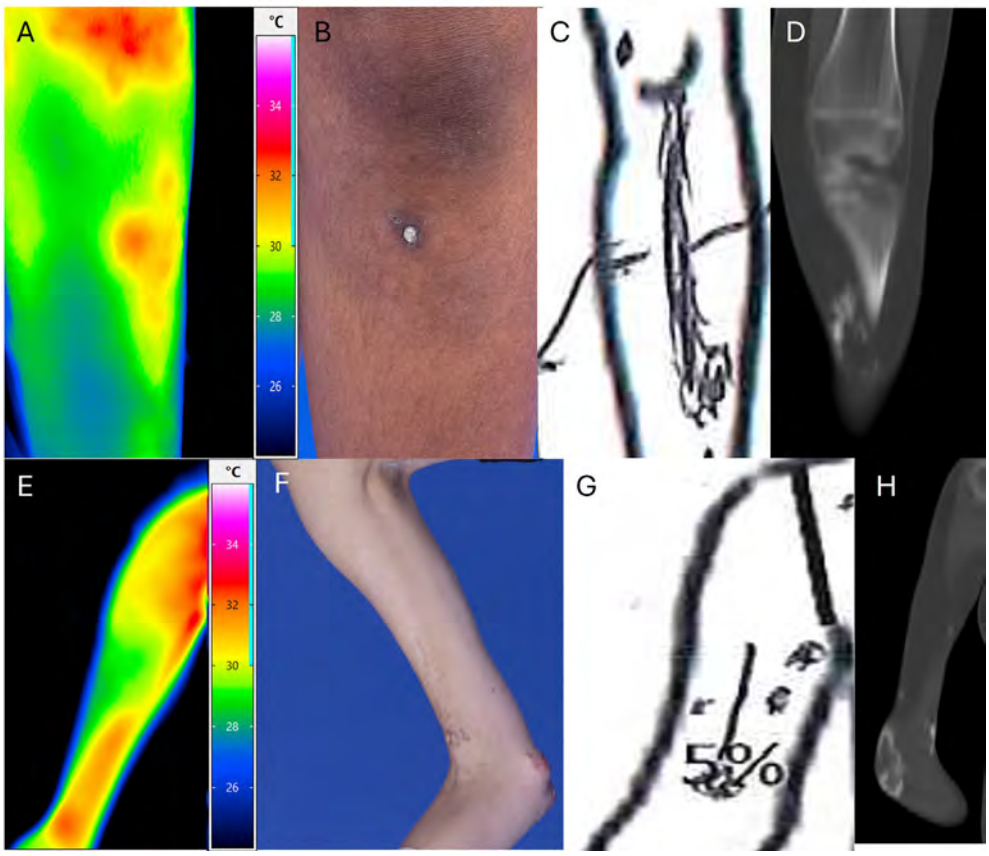
Results: Two hundred fifty-seven IR images from 3 DM and 12 JDM patients (age 9-60) were obtained from 6 body regions consisting of the right/left upper/lower extremities, abdomen, and back. For the population, the mean and range for CDASI activity, damage, and total calcinosis were (10, 2-41; 13, 2-25; 6, 2-11) respectively.

Table: Calcinosis distribution in 15 patients with adult and juvenile dermatomyositis, as determined by an infrared imaging algorithm

Body Region	Average PCA (%)	Standard Deviation of PCA (%)	Minimum PCA (%)	Maximum PCA (%)	Calcinosis Frequency of Each Region
Upper Right Extremities	12.7	4.8	0.1	22.4	12/43 (27.9%)
Upper Left Extremities	12.1	4.3	0.2	24.1	8/43 (18.6%)
Abdomen	11.4	8	0.3	29.8	11/43 (25.6%)
Back	6.4	6.6	0	31.7	3/42 (7.1%)
Lower Right Extremities	11.3	4.4	4.9	24	8/43 (18.6%)
Lower Left Extremities	11.6	5	1.4	24.4	8/43 (18.6%)

Abbreviations: PCA, Percent Calcinosis Area

Figure: Infrared and comparative imaging of calcinosis areas



Patient 1 had calcinosis in their left lower extremity distal to the knee. Image A is the IR image of this area and image B is the traditional photo of the same area. Image C is the physician drawing of the calcinosis from physical exam. Image D is the CT scan of the same area. Patient 2 had calcinosis in their right upper extremity proximal to the elbow. Image E is the IR image of this area and Image F is the traditional photo of the same area. Image G is the physician drawing of the calcinosis from physical exam. Image H is the CT scan of the same area.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The percent calcinosis area (PCA) was calculated as the pixels determined to contain calcinosis by the algorithm divided by the pixels determined to contain body area, multiplied by 100 to express the result as a percent. When PCA exceeded 15% to account for edge effect, the region was defined as positive for calcinosis. The calcinosis frequency of each region was calculated as the number of positive images of the region by its total number of images. The areas most and least frequently identified as positive for calcinosis by IR imaging were the upper right extremities and back, respectively.

The IR algorithm's suspected calcinosis areas ranged from 0.2% to 31.7%, with averages of each region ranging from 6.4 – 12.7% PCA (Table). Left and right extremities were within 0.6% of each other's averages.

Example IR image comparisons with traditional photography, physician exam, and CT are provided in Figure 1 and 2 from patients with calcinosis.

Conclusion: IR detected calcinosis in all body regions examined and demonstrated relative symmetry between left and right extremities. Further evaluation against other standards is required to validate the utility of IR in detecting calcinosis.

Session Title: (1936–1971) Imaging of Rheumatic Diseases Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune joint disease with systemic involvement which can affect the nerves through either compressive pathology due to intra-articular synovitis and tenosynovitis or vasculitis of the vasa vasorum. Carpal tunnel syndrome (CTS) is a compression neuropathy caused by entrapment of the median nerve within the carpal tunnel. This study aimed to evaluate morphological and elasticity-related changes of the median nerve using B-mode ultrasonography (US) and shear wave elastography (SWE) in RA patients without signs of median nerve involvement and to examine the relationship between these changes, disease activity, and hand functions.

Methods: This cross-sectional study included 55 RA patients without CTS symptoms fulfilling the 2010 ACR/EULAR Classification criteria and 55 age- and sex-matched healthy controls. Exclusion criteria were having diagnosis of CTS, pregnancy, endocrine disorders such as diabetes and hypothyroidism, and trauma or surgery history of the upper limbs. Demographic characteristics, disease activity score (DAS28-CRP), medications, hand grip strength (Jamar dynamometer), lateral pinch strength (pinch meter), and hand function (Duruöz Hand Index) were recorded. An experienced physician blinded to patients' data performed bilateral US evaluations to assess median nerve cross-sectional area (CSA, mm^2) and

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. presence of flexor digitorum tenosynovitis by B-mode, inflammatory activity via Power Doppler US, and nerve stiffness using SWE (median and mean velocity values, m/s) using a high frequency linear probe (Siemens S2000 Acuson, Mountain View, CA). The Outcome Measures in Rheumatology (OMERACT) US grading system was used for US evaluations. IBM SPSS Statistics 26 and Python were used for statistical analyses.

Results: The mean age of the RA patients was 58.6 ± 9.1 years and the mean disease duration was 14.3±8.9 years. Sixty nine percent of the cohort was RF positive. RA patients had significantly lower grip strength and worse hand function compared to controls ($p< 0.001$). The mean median nerve CSA (13.79±4.41 mm^2) and the presence of flexor digitorum tenosynovitis and Power Doppler signal were significantly higher in the RA group compared to controls ($p< 0.001$) (Table 1). The mean SWE velocity of the meadian nerve was significantly higher in the RA group (2.58±0.38 m/s vs 1.76±0.45 m/s; $p< 0.001$) and RA patients with flexor tenosynovitis ($p=0.012$). While the median nerve CSA did not show significant relationship with clinical parameters, median nerve SWE velocity showed significant positive correlations with height ($p=0.012$, $r=0.346$) and grip strength ($p=0.018$, r=0,326) and significant negative correlations with CRP and ESR ($p=0.046$, $r=-0.278$; $p=0.001$, $r=-0.460$ respectively).

Conclusion: The median nerve CSA and SWE-measured stiffness were significantly higher in RA patients without CTS symptoms compared to healthy individuals. The association between tenosynovitis and increased SWE values suggests that local subclinical inflammation may affect biomechanical properties of the median nerve. Therefore, SWE appears to be a promising tool for the early detection of subclinical nerve changes in RA.

Background/Purpose: Raynaud's phenomenon (RP) is a painful and disabling feature of systemic sclerosis (SSc) that significantly impairs quality of life. Tools that integrate subjective symptom assessment with objective microvascular evaluation—ideally collected at the point of care—are essential to evaluate therapeutic response. Among U.S. Veterans, RP is highly prevalent, highlighting the importance of early diagnosis and intervention. Nailfold capillaroscopy (NFC) is the gold standard for direct visualization of microvascular changes. The Associated Raynaud Phenomenon (ASRAP) questionnaire is a patient-reported outcome (PRO) that captures the lived experience of RP. This study assessed the combined use of ASRAP and NFC to evaluate short-term therapeutic responses in Veterans with SSc and hand pain.

Methods: This prospective study enrolled Veterans from the SSc Registry (IRB No. 1618579-17) with SSc and RP initiating a single therapeutic intervention for hand pain. Follow-up was conducted 4–8 weeks after baseline. Participants completed the 10-item ASRAP questionnaire[1] and underwent same-day NFC at both visits, using the G-Scope device per standardized protocols. Interventions included the initiation or dosage adjustment of a vasodilator or immunosuppressive agent. Changes in ASRAP scores and NFC parameters—including capillary density, apical diameter, and microhemorrhages—were compared pre- and post-intervention.

Results: Of the total 22 enrolled SSc Registry Veterans, 8 met inclusion criteria between January–April 2025. The majority were male (62%, n=5), with a mean age of 61±12.1 years. Most (75%, n=6) reported military-attributable exposures associated with RP onset. At baseline, all were on a vasodilator; 50% (n=4) were also on immunomodulators (Table 1). The most

Active SD-pattern	25 [2]	12.5 [1]
Late SD-pattern	12.5 [1]	25 [2]

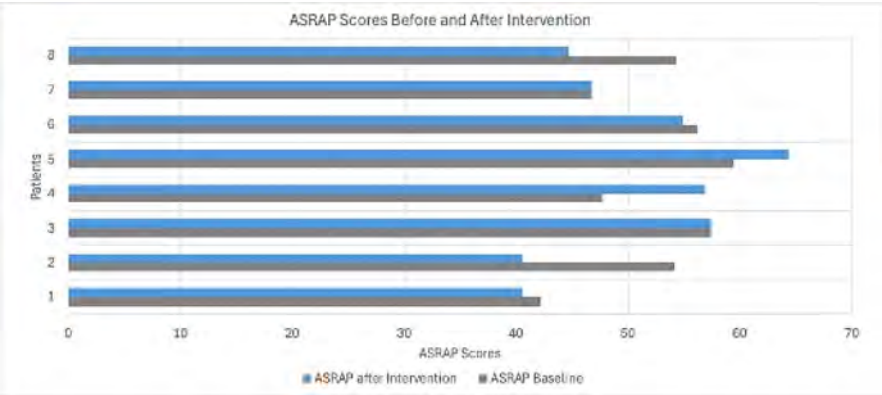

Figure 1: ASRAP scores

frequent intervention was initiation or dose increase of phosphodiesterase-5 inhibitors (PDE5-Is) in five subjects (63%). Three participants (38%) discontinued treatment due to gastrointestinal side effects (two vasodilators, one immunosuppressant). Mean ASRAP scores decreased from 52.25±6.02 to 50.76±8.79 (Figure 1). Capillary density slightly decreased (6.01 ±1.37 μm to 5.85±1.66 μm), apical diameter remained stable (22.08±6.28 μm to 22.27±6.19 μm), and the prevalence of giant capillaries declined (7.33% to 3.20%), while microhemorrhages increased (62.5% to 75%). Two patients had normal NFC throughout (Table 2). One patient who discontinued a vasodilator developed a late scleroderma pattern despite symptom improvement.

Conclusion: Combining ASRAP and NFC provides a multidimensional assessment of RP in Veterans with SSc, particularly in those with military exposure history. Despite short-term improvements in PRO scores, capillaroscopic findings often revealed ongoing or progressive microvascular damage. These findings underscore the need for continued vascular monitoring, early detection of drug intolerance, and proactive strategies for microvascular protection. Larger, longer-term studies are needed to validate these results and optimize RP management in this high-risk population.

Session Title: (1936–1971) Imaging of Rheumatic Diseases Poster

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Lupus arthritis has heterogeneous phenotypes and severity, complicating clinical management and trial endpoints. Advances in musculoskeletal ultrasound (MSK US) and optical imaging have been proposed as objective assessment tools. In a prior study of 20 systemic lupus erythematosus (SLE) patients, we demonstrated that frequency-domain optical imaging (FDOI) and a glove-like optical imaging system (GLOIS) can differentiate inflamed from normal joints by measuring transmitted and reflected lights to assess changes in tissue properties. Here we present extended data comparing FDOI with MSK US in evaluating lupus arthritis, and exploratory findings using GLOIS to monitor arthritis resolution.

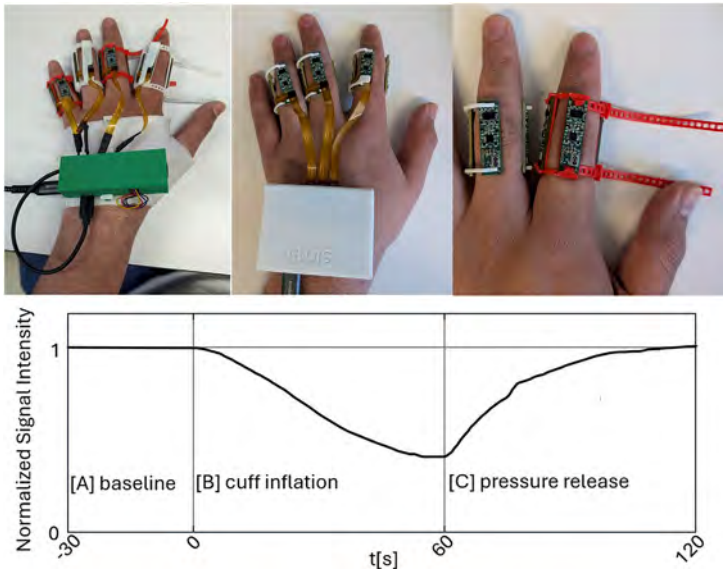

Figure 1. Glove-like optical imaging system (GLOIS) in the Evaluation of Lupus Arthritis The top part of the figure exhibits the glove-like optical imaging system (GLOIS), which comprises a control module, four optical imaging patches, a flexible printed circuit (FPC) connecting band, and an adjustable flexible fixation band. The optical imaging patches deliver light into the affected joint and measure the resulting reflected and transmitted light. Each patch comprises two source-detector modules spaced 10 mm apart, each with three light-emitting diodes (LEDs) (wavelength λ = 880 nm, 660 nm, and 530 nm) and a photodiode. The patches are connected to each other and the control module via the flexible connecting band at 15 mm spacings, allowing the patches to be wrapped around the proximal inter-phalangeal (PIP) joint. The band and patches are fixed to the finger using a 3D-printed flexible fixation band. The bottom part of the figure shows a typical signal trace measured by GLOIS for one source detector, showing significant events, including the baseline measurement (A), the sphygmomanometer cuff inflation (B) to the subject's diastolic blood pressure causing a complete venous occlusion and partial arterial occlusion , and the release of pressure (C) accompanied by 60 more seconds of measurement.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Evaluation of lupus arthritis by frequency domain optical imaging (FDOI) in comparison to musculoskeletal ultrasound (MSK US) ROC curve (A) and discriminant linear analyses (B) of frequency domain optical imaging (FDOI) in comparison to musculoskeletal ultrasound (MSK US) evaluation of lupus arthritis. The three parameters of choice for the discriminant analysis include the mean of the scattering coefficient, variation of the absorption coefficient, and percentage of total finger volume interested. Joints with no/minimal arthritis (PDGS 0 or 1) and moderate/severe arthritis (PDGS 2 or 3) show significantly different mean and standard error of scattering (C) and absorption (D) in reconstructed optical data.

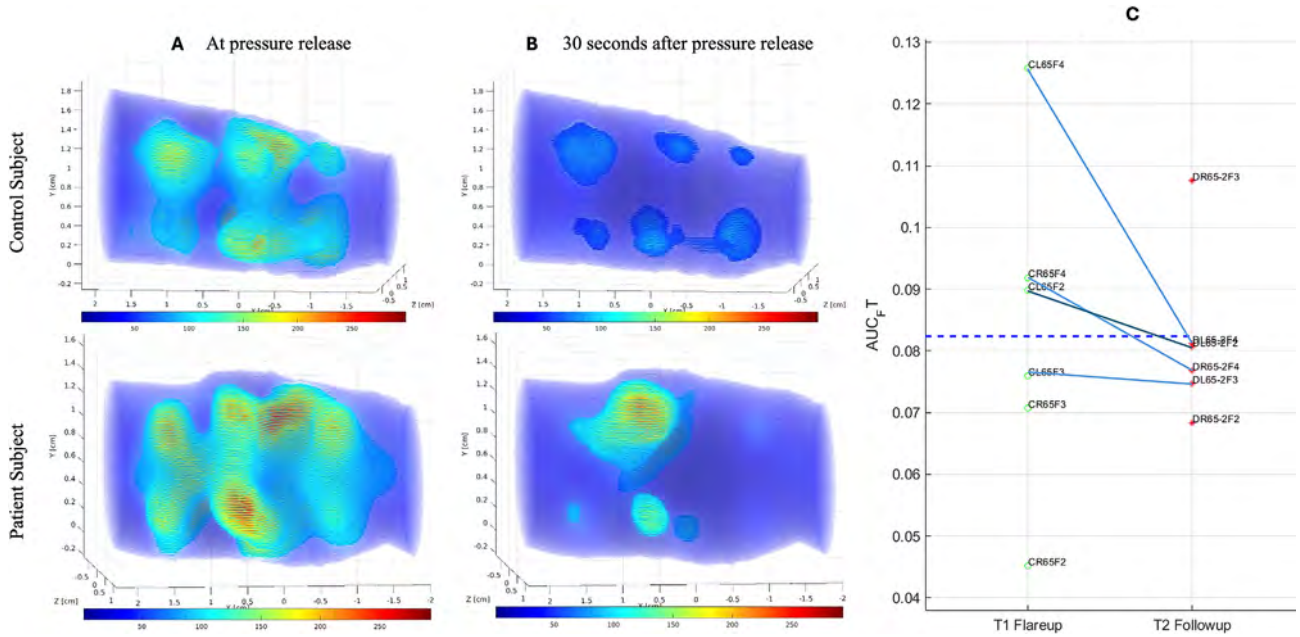

Figure 3. Glove-like optical imaging system (GLOIS) evaluation of joints in patients with lupus and healthy controls 3D Reconstructions of the total hemoglobin (HbT) concentrations in a healthy subject and control subjects at the time of pressure release (A) and 30 seconds after pressure release (B). AUC of Fall Time decreases for 4 of the 6 fingers (C) during and after a lupus arthritis flare.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We evaluated 31 SLE patients and 22 healthy controls via convenience sampling. For each subject, 8 proximal interphalangeal (PIP) joints (bilateral PIPs 2–5) were evaluated by FDOI and MSK US within two hours. MSK US used multiplanar grey-scale (GS) and power Doppler (PD) imaging, scored by OMERACT definitions to generate a composite PDGS score. FDOI employed a 670 nm, 8 mW laser modulated at 300 MHz, and scanned across each PIP to reconstruct three-dimensional (3D) maps of light absorption and scattering. Additionally, 2 SLE patients and 2 healthy controls underwent GLOIS evaluation (Fig 1), and 1 SLE patient was evaluated by GLOIS before and after therapy for an arthritis flare. GLOIS (Fig 1) used flexible bands with 8 optical modules (each with a photodiode and 3 LEDs at 530, 660, and 880 nm). LEDs were sequentially activated; photodiodes captured the transmitted signals. A sphygmomanometer was inflated to the subject's diastolic blood pressure, inducing a complete venous occlusion and partial arterial occlusion, then released after 60 seconds accompanied by 60 more seconds of measurement. Subsequently, the measurements from all the source/detector pairs around the finger joint were used to tomographically reconstruct the distributions of total hemoglobin (HbT) concentrations in the joint.

Results: FDOI data (Fig 2) from 235 PIPs (SLE) and 136 PIPs (controls) produced an AUC of 0.87, with 89% sensitivity and 66% specificity (Fig 2A, 2B). Among 120 joints assessed by MSK US, PDGS scores were 0 (n=47), 1 (n=73), 2 (n=61), and 3 (n=54). Joints with moderate/severe arthritis (PDGS 2–3) had significantly higher scattering (8.8±1.4 vs. 8.3±0.6/cm, $p< 0.01$, Fig 2C) and absorption coefficients (0.25±0.18 vs. 0.18±0.1/cm, $p< 0.01$, Fig 2D) than those with minimal/no inflammation (PDGS 0–1).

3D tomographically reconstructed GLOIS imaging showed higher HbT concentration at pressure release (Fig 3A) and 30 seconds post-release (Fig 3B) in SLE joints (42 μM at both timepoints) with PDGS of 2 compared to controls (29 and 30 μM). In the SLE patient examined at the time of flare (T1) and after symptom resolution (T2), Fall Time AUC decreased in 4 of 6 fingers (Fig 3C), suggesting improvement.

Conclusion: These data support the use of FDOI and GLOIS to reliably detect MSK US-confirmed arthritis in SLE joints and to monitor disease activity. Optical imaging shows promise as a non-invasive, objective tool for lupus arthritis assessment in clinical care and trials. Further development is warranted and ongoing.

Background/Purpose: Antiphospholipid syndrome (APS) is a systemic autoimmune disorder characterized by thrombotic events and obstetric complications. While macrovascular and microvascular manifestations have been increasingly acknowledged—particularly with the inclusion of microvascular lesions in the 2023 ACR/EULAR classification criteria—arterial stenosis within the central nervous system (CNS) remains insufficiently recognized. This study aimed to systematically evaluate the prevalence, imaging features, and possible pathophysiological mechanisms of intracranial arterial stenosis in patients with APS.

Methods: We prospectively enrolled 123 APS patients meeting the 2023 ACR/EULAR classification criteria. All participants underwent cerebrovascular screening using magnetic resonance angiography (MRA) to detect potential abnormalities. Patients with suspected arterial stenosis on MRA subsequently underwent computed tomography angiography (CTA) for definitive anatomical confirmation. In those with CTA-confirmed intracranial stenosis, high-resolution magnetic resonance vessel wall imaging (HR-VWI) was performed to assess wall morphology, contrast enhancement, and features suggestive of inflammatory vasculopathy (**Fig.1**).

Results: Among the 123 APS patients screened, MRA revealed cerebrovascular abnormalities in 76 patients (61.79%), including 32 patients (26.0%) with confirmed intracranial arterial stenosis with CTA. Other observed MRA findings included suspected stenosis (2.44%), arterial slenderness (18.70%), protrusion shadows potentially indicating aneurysms (7.32%), conical narrowing (1.63%), focal bulging (1.63%), and wall irregularities (4.07%). Among 32 patients with arterial stenosis, the most frequent sites of stenosis were the posterior cerebral artery (PCA) and internal carotid artery (ICA), each observed in 12 patients (37.5%). This was followed by the anterior cerebral artery (ACA) in 9 patients (28.33%), middle cerebral artery (MCA) in 7 patients (21.88%), and vertebral artery (VA) in 5 patients (15.62%) (**Table.1**).HR-VWI in stenosis-confirmed cases

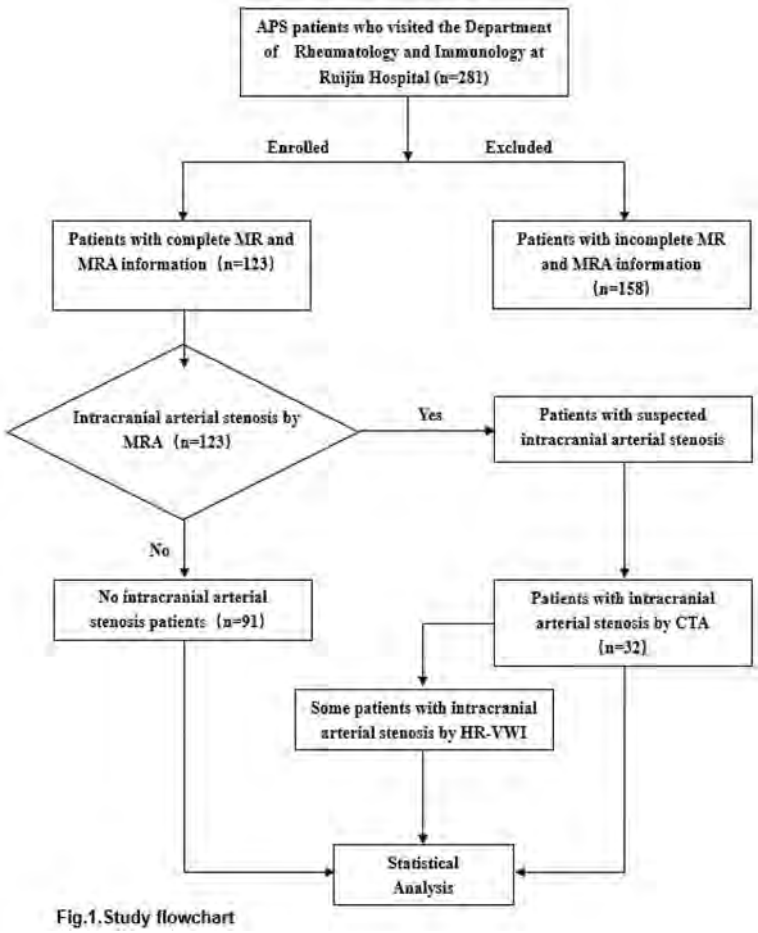

Fig.1.Study flowchart

Table.1. Prevalence and Distribution of Intracranial Vascular Abnormalities in a Cohort of 123 Patients

Table.1. Prevalence and Distribution of Intracranial Vascular Abnormalities in a Cohort of 123 Patients

Intracranial vascular condition	Number(n=123)
cerebrovascular abnormalities	76(61.79%)
Intracranial vascular stenosis	32(26.0%)
ACA	9(28.33%)*
MCA	7(21.88%)*
PCA	12(37.5%)*
ICA	12(37.5%)*
VA	5(15.62%)*
suspected stenosis	3(2.44%)
arterial stenderness	23(18.70%)
protrusion shadows potentially indicating aneurysms	9(7.32%)
conical narrowing	2(1.63%)
focal bulging	2(1.63%)
wall irregularities	5(4.07%)
normal	47(38.2%)

*Percentages for specific arteries are calculated based on total cases with intracranial vascular stenosis (n=32)

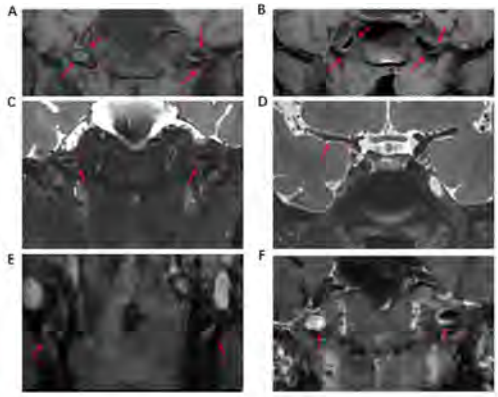

Fig.2. High-Resolution Vessel Wall Imaging (HR-VWI) in a Patient with Intracranial Vascular Stenosis Associated with Antiphospholipid Syndrome (APS). A, B, T1-weighted (T1W) images demonstrate bilateral internal carotid artery (ICA) wall thickening, more pronounced on the right side, with multisegment moderate to severe stenosis in the right ICA. **C, D,** Bilateral ICA wall thickening (predominantly on the right) showing slightly hyperintense signal on T2-weighted (T2W) images. **E, F,** Marked enhancement of the thickened vessel walls (right > left), indicating inflammatory activity and neovascularization within the arterial wall, suggestive of vulnerable plaque formation.

Fig.2. High-Resolution Vessel Wall Imaging (HR-VWI) in a Patient with Intracranial Vascular Stenosis Associated with Antiphospholipid Syndrome (APS).

demonstrated focal vessel wall thickening, contrast enhancement, and vasculitis-like features, suggesting possible immune-mediated endothelial injury (**Fig.2**). Further analysis revealed that stenosis severity was positively correlated with elevated antiphospholipid antibody titers, comorbid valvular heart disease, and cognitive impairment.

Conclusion: This study provides the first systematic evaluation of intracranial arterial stenosis in APS, revealing it to be a relatively common and potentially underrecognized manifestation. Multimodal imaging combining MRA, CTA, and HR-VWI offers a comprehensive strategy for early detection and characterization of CNS vascular involvement. These findings expand the vascular phenotype of APS and underscore the importance of early cerebrovascular surveillance in patients with high-risk clinical or serologic features.

Enhancing Patient Safety: Improving Contraceptive Counseling for Patients on Teratogenic Medications in the Rheumatology Clinic

Abimbola Fadairo-Azinge[1], jobelle Romulo[2], Daniella Flores[3], jose Giron[2], Joshua Ng[4], Sarah Patterson[5], Jinoos Yazdany[6] and Andrew Gross[6], [1]UCSF, San Francisco, [2]University of California San Francisco, San Francisco, [3]University of California San Francisco, San Francisco, CA, [4]University of California San Francisco, SAN-FRANCISCO, CA, [5]University of California, San Francisco, Pacifica, CA, [6]UCSF, San Francisco, CA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1972–1989) Measures & Measurement of Healthcare Quality Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The American College of Rheumatology (ACR) recommends contraceptive counseling for reproductive-age women with rheumatic and musculoskeletal diseases (RMDs), especially those on teratogenic medications. These medications are associated with major birth defects, making it critical to ensure effective contraception counseling for these patients

At the time of the pre-intervention assessment, among 109 patients with rheumatologist diagnoses seen in the UCSF rheumatology clinic who were treated with leflunomide, mycophenolate, or methotrexate, only 41% had contraception use documented and only 35% had documentation of contraception counseling. This project aimed to increase contraceptive counseling documentation to over 70% for all rheumatologic patients on teratogenic medications within the next nine months.

Methods: Eligibility criteria for counseling included patients with any rheumatologic condition who were maintained on methotrexate, mycophenolate, or leflunomide and were being followed at the UCSF Rheumatology Clinic at the Parnassus location, either through in-person or telehealth visits.

The team used the Lean Improvement Methodology to identify the gaps in contraceptive screening and counseling (Figure 1). Most identified gaps led to targeted Interventions which include

- Development of a standardized documentation SmartPhrase in the electronic health record (EHR)
- Collaboration with the complex contraception clinic withing the OB/GYN department to create patient-facing educational materials
- Training of nursing staff to conduct contraceptive counseling
- Workflow redesign to include counseling across visit types (telemedicine and in-person)
- Monthly audits tracked counseling documentation rates among patients prescribed the three targeted teratogenic medications.

Results: Over the course of the project, we reviewed our findings every six weeks by monitoring the in-process metric, which was the percentage of eligible patients missed during each intervention cycle. This was measured to evaluate progress and determine if further changes were necessary. In the first two months, despite implementing targeted interventions, approximately 60% of eligible patients were still missed for contraceptive counseling. This gap was primarily due to challenges in capturing patients seen via telehealth, a limitation of the existing clinic workflow. After identifying this issue, we revised the workflow, enabling nurses with training in contraceptive counseling to proactively identify our target patient

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

sample whether they were receiving care via telehealth and in-person. These changes significantly improved outcomes: documented contraceptive counseling rates rose from 35% (N=109) at baseline to 82% (N=331) (Figure 2), and the proportion of missed eligible patients dropped from 64% in November 2024 to 1.82% in April 2024 (Figure 3). Whenever counseling occurred, contraceptive use was documented in 100% of cases, indicating whether or not the patient was using contraception.

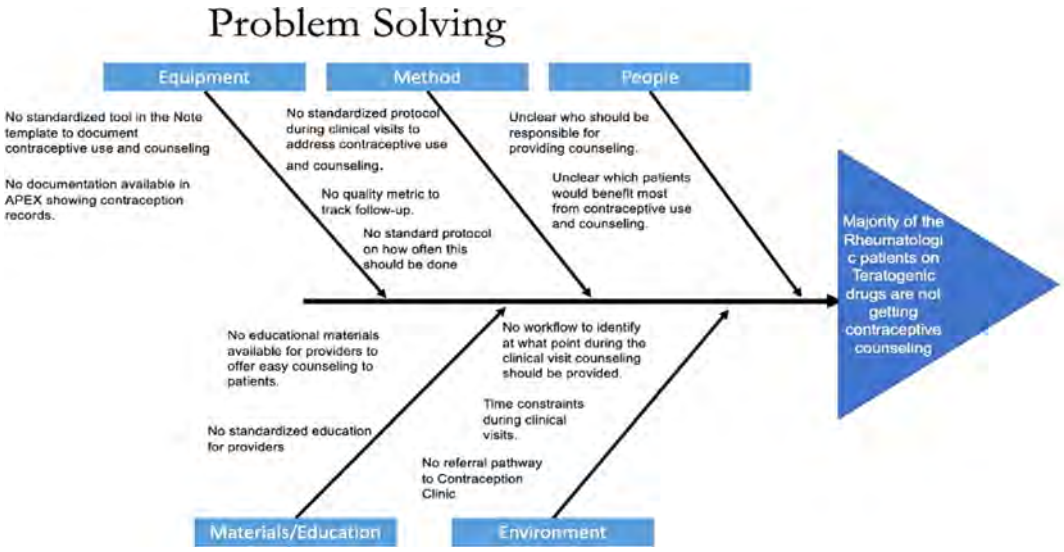

Figure 1. Fishbone Diagram Identifying Barriers to Contraceptive Counseling for Patients on Teratogenic Medications. This diagram outlines the root causes contributing to missed contraceptive counseling opportunities.

Figure 2. A line graph showing the percentage of eligible patients with documented counseling, increasing from 35% at baseline to 82% after the intervention period.

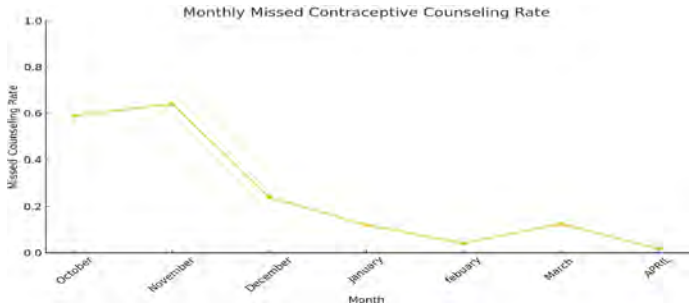

Figure 3. In-process metric showing Reduction in Missed Eligible Patients for Contraceptive Counseling. This is a line graph displaying the decline in missed counseling opportunities, from 64% in November 2024 to 1.82% in April 2025, following workflow revisions and nurse-led interventions.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: A multidisciplinary, systems-based approach led to a substantial improvement in contraceptive counseling rates for patients on teratogenic medications.

Abstract Number: 1973

Evaluating the Impact of Clinical Pharmacist Integration on Patient Care Outcomes in a Private Rheumatology Clinic

Madana Kamineni[1], Janelle Vircks[1], Jessica Lynton[1], Clarisse Purvis[1] and **Brittany Panico**[2], [1]Optum, Gilbert, AZ, [2]Summit Rheumatology, Gilbert, AZ

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1972–1989) Measures & Measurement of Healthcare Quality Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Existing data demonstrate that clinical pharmacist integration in rheumatology clinics improves provider satisfaction, patient outcomes, medication adherence, and RAPID-3 (Routine Assessment of Patient Index Data 3) scores, yet studies have largely focused on tertiary care settings. This study addresses the gap by evaluating pharmacist integration within a private rheumatology clinic and its impact on patient outcomes, provider satisfaction, and pharmacist-led interventions.

Methods: The study received IRB exemption and was conducted from August 1, 2024, to January 31, 2025. Data were collected manually from the clinic's electronic medical record and analyzed using descriptive statistics. All rheumatology patients referred to the clinical pharmacist during this period were included.

Primary outcomes included changes in RAPID-3 scores at baseline, day 28, 3 months, and 6 months, and documentation of pharmacist interventions such as medication reviews, education, access support, and provider decision-making assistance. These interventions occurred during collaborative visits, phone follow-ups, and real-time consults. Secondary outcomes measured provider satisfaction via a post-study survey.

Results: A total of 302 pharmacist-led consults were conducted. Of these, 224 (74%) involved prior authorization (PA) support, 167 (55%) included patient education, and 120 (40%) addressed side effect management. RAPID-3 assessments were completed for 150 patients (50%). Results showed a statistically significant median RAPID-3 score reduction of 2.65 points ($p<0.0001$), although this did not meet the 3.5-point threshold for minimal clinically important improvement (MCII). Notably, 68 patients (45.3%) achieved clinically meaningful improvement, indicating that nearly half experienced significant benefit from pharmacist involvement.

Provider satisfaction (n=7) was overwhelmingly positive. All respondents agreed or strongly agreed that the pharmacist improved care quality, reduced administrative burden, and supported prior authorization processes. Most strongly agreed that the pharmacist improved medication understanding and was readily accessible. All rated the impact on workflow and prescribing positively, with 71.4% describing it as "very positive." Open-ended comments highlighted enhanced efficiency, decreased workload, and improved patient care.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Integration of a clinical pharmacist into a private rheumatology clinic had a meaningful clinical and operational impact. The pharmacist contributed significantly to disease monitoring, medication access, patient education, and treatment side effect management. While the average RAPID-3 improvement did not meet the MCII threshold, nearly half of the patients achieved clinically significant benefit. The high provider satisfaction further supports pharmacist integration as a valuable model for improving quality of care and clinic operations in private practice settings. Further research is warranted to explore long-term outcomes and scalability.

Serial ferritin as a diagnostic surrogate marker in Hemophagocytic Lymphohistiocytosis (HLH), a retrospective single-center study

Chen Chao[1], Anna Lichtiger[2], Xianhong Xie[3], Melissa Fazzari[4] and Ayesha Bibi[5], [1]Rheumatology Division, Department of Medicine, Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY, NY, [2]Internal Medicine, Albert Einstein College of Medicine/Montefiore Medical Center, The Bronx, NY, [3]Department of Epidemiology & Population Health, Albert Einstein College of Medicine, Bronx, NY, [4]Department of Epidemiology & Population Health, Albert Einstein College of Medicine,, Bronx, NY, [5]Rheumatology Division, Department of Medicine, Albert Einstein College of Medicine/Montefiore Medical Center, Woodbridge Township, NJ

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1972–1989) Measures & Measurement of Healthcare Quality Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Hemophagocytic lymphohistiocytosis (HLH) is an immune-mediated disorder characterized by cytokine dysregulation, resulting in multi-organ involvement and high mortality. (1-2) There is a time lag in the consideration of HLH diagnosis and initiation of treatment using HLH-2004 criteria. (1) There is a paucity of current literature to predict the ongoing cytokine storm in these patients, as it necessitates the analysis of soluble interleukin-2 receptor (sIL2r) and bone marrow biopsy, which has a delayed reporting time. Ferritin is a cost-effective and rapidly available biomarker. Our study in a tertiary center highlights the importance of periodic trending of ferritin levels in critically ill patients, which could be used as a surrogate for predicting patients who progress towards HLH and guiding the timely initiation of therapy.

Methods: After Institutional Review Board (IRB) approval, the electronic medical record (EMR) database was queried from 2016 to 2024 to identify patients ≥ 18 years, who were considered to have HLH during their hospital course. Patients were stratified into three groups based on the fulfillment of HLH-2004 criteria: those without HLH (≤ 3/8 criteria), probable HLH (4/8 criteria), and definitive HLH (≥ 5/8 criteria). A Retrospective EMR chart review was conducted. SAS software version 9.4 and R version 4.2.2 were used for the statistical analyses. Two-sample t-tests and Wilcoxon's rank sum tests were used to compare continuous variables depending on whether the variable is normally distributed. Chi-square tests and Fisher's exact tests were used for comparing categorical variables as appropriate. Receiver Operating Characteristic (ROC) curves were drawn, the Youden index was used to choose the best thresholds, and the DeLong method was used to calculate the confidence intervals on the area under the curve (AUC).

Non-Hispanic	41 (47%)	26 (44%)	11 (69%)	4 (31%)
Unknown	9 (10%)	7 (12%)	0 (0%)	2 (15%)
Race				
Black	23 (26%)	13 (22%)	7 (44%)	3 (23%)
Caucasian	9 (10%)	6 (10%)	3 (19%)	0 (0%)
Asian	6 (7%)	5 (9%)	0 (0%)	1 (8%)
Other	50 (57%)	35 (59%)	6 (38%)	9 (69%)
HLH-2004 criteria				
Fever (> 101°F > 48 hours)	73 (83%)	53 (90%)	10 (63%)	10 (77%)
Splenomegaly	56 (64%)	51 (86%)	5 (31%)	0 (0%)
More than 2 Cytopenias (Hb < 9; PLT < 100; Neutrophils < 1000)	43 (48%)	38 (64%)	5 (31%)	0 (0%)
Hypertriglyceridemia	61 (70%)	41 (70%)	10 (63%)	10 (77%)
Hypofibrinogenemia	4 (5%)	3 (5%)	1 (6%)	0 (0%)
Both	15 (17%)	12 (20%)	3 (19%)	0 (0%)
Hyperferritinemia	87 (99%)	59 (100%)	15 (94%)	13 (100%)
Bone marrow biopsy with hemophagocytosis	20 (23%)	18 (31%)	2 (13%)	0 (0%)
Low/absent NK-cell activity	5 (6%)	4 (7%)	1 (6%)	0 (0%)
High soluble IL-2r	70 (80%)	54 (92%)	12 (75%)	4 (31%)

23265203, 2025, 59, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: We identified a total of 88 patients, with a mean age of 49 years, of whom 56 (63%) were males and 38 (43%) were Hispanics. (Table 1) This cohort was critically ill, 53 (60%) requiring intensive care unit, 22 (25%) new replacement kidney therapy and 37 (42%) mechanical ventilation.

Of these 88 patients, 59 were definitive HLH, 16 probable HLH and 13 without HLH. sIL2r is a highly specific marker with a high turnaround time, making its utility low in treatment initiation. Logistic regression analysis of sIL2r showed an odds ratio of 2.09 for in-hospital mortality (1.32-3.30 CI 95%; p-value 0.002). ROC analysis of ferritin levels (Figure 1) achieved a sensitivity of 89% at the time of considering the diagnosis, while a cut-off of 5000 ng/mL was associated with a high specificity of 91% in the first week of suspicion for HLH.

Conclusion: HLH-2004 criteria are not time-sensitive in managing these critically ill patients due to delays in reporting of sIL2r and bone marrow biopsy results. Our study emphasizes that periodically monitoring serial ferritin levels could serve as a valuable, cost-effective surrogate marker to sIL2r for the timely initiation of immunomodulator therapy and avoiding untoward patient outcomes.

Baseline QTc Screening and Monitoring Among SARD Patients with High Cardiovascular Risks on Hydroxychloroquine Based on 2021 ACR Consensus: A Quality Improvement Project

Cristine Kuzhuppilly Arcilla[1], Gabriel Kirsch[2], Gurjit Kaeley[3] and Myint Thway[4], [1]University of Florida Jacksonville, Jacksonville, FL, [2]University of Florida - Jacksonville, Jacksonville, FL, [3]UF COM-J, Ponte Vedra Beach, FL, [4]UF Jacksonville, ponte vedra, FL

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1972–1989) Measures & Measurement of Healthcare Quality Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: In 2017, FDA approved warnings regarding fatal cardiac effects such as cardiomyopathy, torsades de pointes, and QTc prolongation related to both acute and chronic Hydroxychloroquine (HCQ) use. QTc >470 ms during HCQ treatment was associated with increased mortality risk[1]. COVID-19 pandemic in 2020 reemerged discussions regarding HCQ's cardiotoxicity as it was experimentally used in the acute setting. In 2021, a white paper on consensus between rheumatologists and cardiologists was released by ACR[2]. While it acknowledged that the foundational benefits of HCQ outweigh the associated cardiac risks in SARD patients, it mentioned utilizing ECG for patients with high-risk cardiovascular (CV) factors. These factors include female, older age (>68 years), recent heart disease, prolonged duration of HCQ use, and >1 QTc-prolonging medications, such as concurrent fibromyalgia and depression/anxiety, prevalent in the SARD population. Hence, this study aims to increase cardiac screening/monitoring through routine ECG, particularly in SARD patients with high CV risks on HCQ.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: This quality improvement (QI) project retrospectively analyzed medical records of patients at least 18 years old on HCQ seen at University of Florida rheumatology clinic sites from 06/2023 to 12/2023 and had ECG done within the past year as initial data (pre-intervention phase). Coordination with cardiology and scheduling team allowed same-day walk-in ECG, especially for high-risk patients based on cardiac risk stratification, increasing ECG accessibility. Interventions also included creating flyers and educating medical staff periodically. Documentation of ECG results was facilitated by generating smart phrases into patient's visit note under the specific cardiac risk stratification and diagnosis. Subsequent retrospective chart review of 50 patients was performed after 12 months to analyze impact of interventions.

Results: Initial data showed the need for increasing ECG testing in our high-risk SARD patients (Table 1). All patients were on adequate HCQ dosing. Only 12% had baseline ECG within past year. Post-intervention, this percentage increased to 55%, with more than 2/3 done on same-day rheumatology visits along with electronic documentation of ECG and cardiac risk stratification. Eight percent had QTc 470–500 ms; 3 patients with QTc >500 ms were associated with more acute settings (ESRD, acute admission, and pacemaker) (Figures 1 and 2). Risks vs benefits discussions and decisions on adjusting HCQ dose based on weight and HCQ levels, closer monitoring, and even switching to another DMARD were done accordingly.

Conclusion: This QI project demonstrates routine ECG as simple and inexpensive cardiac screening/monitoring tool for SARD patients with high CV risks on HCQ. We developed interventions (interdepartment collaboration, etc) that facilitated ECG accessibility, identification of cardiac risk stratification, improved documentation and modification, and

Table 1. Patient demographics and clinical characteristics of our SARD patients with high cardiovascular risks on HCQ based on the 2021 ACR Consensus.

Risk factor	% of our SARD patients
Female sex	80
Older age (especially >68 years)	20
Heart disease (including recent history of admissions for cardiac arrhythmias, myocardial infarction, and heart failure) and diabetes mellitus	40
CKD	18
>1 concurrent QTc prolonging drugs	42
More than 5 years HCQ use	42
>1 comorbidities	28
>3 comorbidities	6

Implementing a Change Package for Depression Screening and Appropriate Response for Children with Rheumatic Disease

Emily Vara[1], Mileka Gilbert[1], Kelly Rouster-Stevens[2], Talia Buitrago-Mogollon[3], Sarah Mabus[3], Justin Moore[4] and Sheetal Vora[5], [1]Medical University of South Carolina, Charleston, SC, [2]Emory University/Children's Healthcare of Atlanta, Peachtree Corners, GA, [3]Atrium Health Levine Children's Center for Advancing Pediatric Excellence, Charlotte, NC, [4]Wake Forest School of Medicine, Winston Salem, NC, [5]Atrium Health Levine Children's Hospital, Charlotte, NC

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1972–1989) Measures & Measurement of Healthcare Quality Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Children with rheumatic diseases (RD) are at increased risk for developing mental health (MH) issues, including depression, which can negatively impact disease outcomes. MH disorders are underrecognized in pediatric RD. The ACR recently published MH screening guidelines in pediatric RD (Cunningham et al.). The American Board of Pediatrics' "The Roadmap Project" has a readiness checklist to prepare for outpatient MH screening, which was used to create a depression screening change package with appropriate response documented. An implementation science (IS) framework was applied to gauge the effectiveness of our change package.

Goal: To ensure that our change package can be used across diverse pediatric rheumatology clinics. Aims: 1) Assess IS outcomes of change package feasibility and acceptability to aid depression screening with appropriate response. 2) Determine the impact of implementing the change package on contextual factors of relative advantage and adoptability of depression screening.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Meetings to design the implementation strategy included physicians, psychologists, social workers, parents/patients and an IS scientist. A mixed methods approach using the Health Equity Implementation Framework was designed to implement the change package at 3 pediatric rheumatology clinics to screen patients with RD ≥8 (PROMIS) or ≥12 years old (PHQ-9), using a validated depression tool. Each center revised specific quality improvement tools to address unique barriers to screening and responding to screening results. A health equity fishbone diagram captured root cause delinquencies in depression screening. IS outcome and clinical quality measures, along with effectiveness of each change package component, are currently being assessed by the clinical team/parents/patients via REDCap survey at a regular cadence.

Results: We are 5 months into the 12-month implementation strategy. Survey results are reviewed at local and multi-site team meetings. Identified modifications are implemented. At baseline, the 5 parents/patients team members surveyed all agreed with the importance of screening, approved of routine screening, and MH resource pamphlet value. Table 1 is the first staff survey after change package introduction with all 3 teams' agreement of process feasibility, acceptability and package components' helpfulness. Initially weekly and then monthly random sampling of patients eligible for screening was done to assess clinical quality measures (Figure 1). This sample of patients were 77% female, 60% White, 29% Black, 15% Hispanic, 93% English primary language, 50% with private insurance, and 41% with Medicaid. The most common RD were JIA and SLE, as expected. Appropriate response to screening employed the change package tools and community/clinic resources (Figure 2). No patient required emergent care.

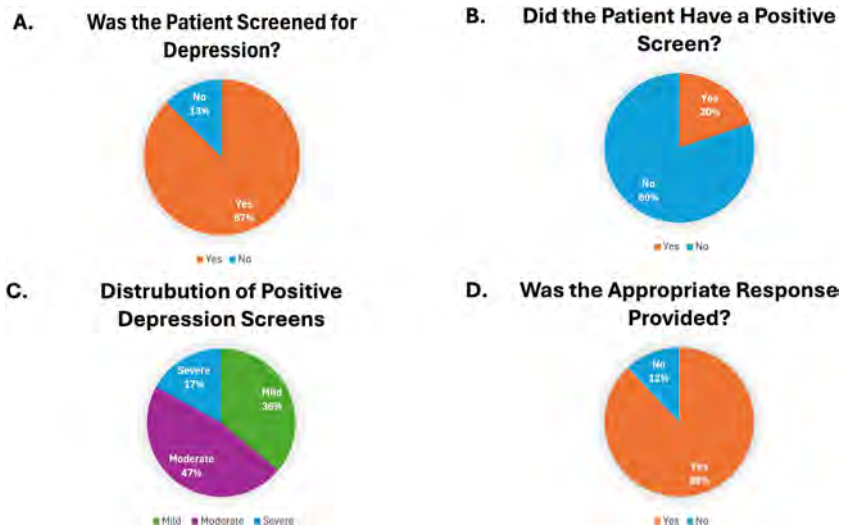

Figure 1. A: 87% of patients were screened for depression. B: 20% of those screened had a positive result. C: for those with a positive depression screen, 36% were mild, 47% moderate, and 17% severe. D: of those with a positive screen, 88% received an appropriate response.

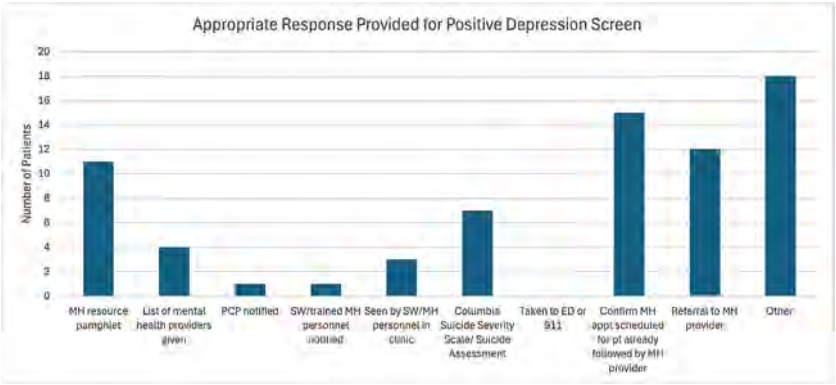

Figure 2. In those with a positive depression screen, 88% received one of the responses noted above. Other included situational stressors reviewed with patient and patient to return to office if symptoms persist or worsen (13 of 18), PCP arranging local therapy referral (1 of 18), and corresponded in EMR with Behavioral/Mental Health provider (1 of 18). Primary Care Provider=PCP, SW=Social Worker, MH=Mental Health

Abstract Number: 1977

The Westergren Sedimentation Rate: To Be or Not to Be! The Westergren Sedimentation Rate is being "Killed" but has not "Died".

John Goldman[1], Michael Goldman[2], Glenn R. Parris[3] and Parris and Associates, [1]Emory University St Josephs Hospital, Atlanta, GA, [2]SENTA Southeastern Ear, Nose, Throat and Allergy, Atlanta, GA, [3]PARRIS & ASSOCIATES, Lilburn, GA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1972–1989) Measures & Measurement of Healthcare Quality Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The Westergren Sedimentation Rate (WSR) is a simple, cost-effective laboratory test commonly used by rheumatologists to assess systemic inflammation. This study was initiated to evaluate the current status and availability of the erythrocyte sedimentation rate (ESR) for practicing physicians. Specifically, we aim to compare the accuracy and concordance of the manually performed STAT WSR, processed within two hours of sample collection, with the ESR performed at the central laboratory (CRL), which uses automated capillary photometry. We are particularly interested in

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

whether delays in specimen transport to the CRL impact the reliability of ESR results compared to the more immediate manual WSR.

Methods: We reviewed WSR reports for 106 de-identified patients (Table 1) tested in the POL, and for whom a specimen was also sent the same day to a CRL for erythrocyte sedimentation rate (ESR) testing. This dual testing was initiated after observing that ESR results from the CRL were frequently lower than the POL WSR. Notably, no charges for the in-office WSR.

The POL used manual WSR testing. In contrast, the CRL utilized the iSED® system by Alcor, an automated method that directly measures red blood cell aggregation using capillary photometry during rouleaux formation. We also investigated whether the time interval between specimen collection and analysis at the CRL had an impact on ESR comparability.

Results: The ESR measured in the POL was significantly higher than that in the CRL, as demonstrated by both statistical analysis and Passing-Bablok regression (Table 2 and Figure 1). Additionally, we assessed the coefficient of variation (CV) for manual sedimentation rates using three tube comparisons.

Conclusion: This study was conducted to assess the rationale behind requiring WSR specimens to be sent to a CRL and to evaluate how effectively the CRL performs ESR testing. Although the CRL claims its methodology is equivalent to WSR, its ESR testing process is not performed while the specimen is fresh.

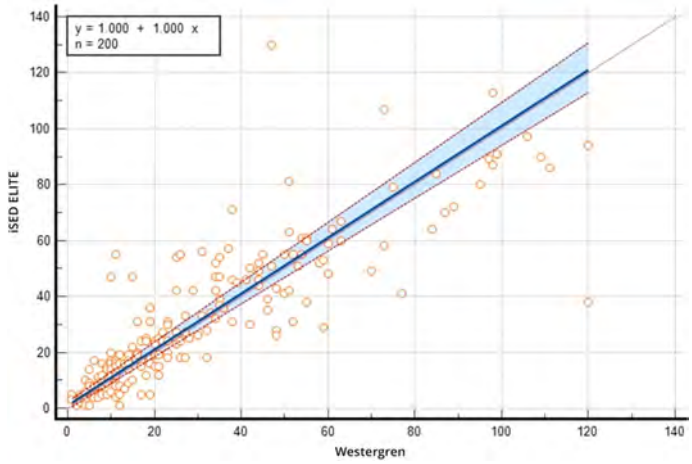

Figure 1. Passing Bablok of the Westergren Sedimentation Rate Compared to the iSED Sedimentation Rate

A WSR must be performed rapidly—ideally within 2 hours of specimen collection—while the blood is still fresh. In the POL it is ordered as a STAT test. Many American patients are covered under insurance plans that either require testing through a CRL or permit POL testing. However, POL testing requires full CLIA certification, which entails substantial administrative overhead, including paperwork, inspections, and associated costs. In-office WSR, by contrast, is a CLIA-waived test, making it a practical option.

The CRL uses automated photocytometry for large-scale ESR testing. However, it remains uncertain whether this automated method provides equivalent clinical value when compared to manual WSR. The core concern is the total turnaround time, from the moment the blood is drawn to when the ESR is actually performed. Some CRLs are located far from the physician's office, in some cases even out of state, necessitating courier or air transport. Often, specimens drawn throughout the day are not shipped until evening. Both resulted in processing delays up to 24 hours or more. This delay could significantly affect clinical decision-making, especially when monitoring conditions such as rheumatoid arthritis using metrics like the DAS28ESR.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1972–1989) Measures & Measurement of Healthcare Quality Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background/Purpose: The Pediatric Rheumatology Care and Outcomes Improvement Network (PR-COIN) is a multi-site learning health network organized to improve outcomes of juvenile idiopathic arthritis (JIA). PR-COIN has a centralized registry that tracks 10 outcome measures, 6 process measures, 3 data quality measures, and 1 balancing measure. A 'gap to target' feature was implemented in the registry for each categorical quality measure (QM). This feature enumerates the count of individual patients (or visits) that would need to meet qualification to pass the QM in order for the performance to reach the established network QM target value. Reporting the performance deficit in individual terms sharpens improvement focus, conveys the order of magnitude to reach the goal, and facilitates interventions to close quality of care gaps for individual patients at the site level.

Methods: The PR-COIN registry captures data from 21 sites with more than 14,500 JIA patients and 96,000 visits since 2011. In 2022, our collaborative switched to a new registry vendor, Hive Solutions, LLC., and developed a new measure dashboard and population management tool. Network performance goals were updated in 2024 based on current network-wide performance, balanced with performance data of specific sites selected based on data completeness for each given measure and representativeness (over 75% of clinic patients enrolled in registry), input of parent/patient partners, and published JIA outcomes. Additional registry functionality was added to include a 'gap to target' feature both at a network and site level.

Results: The 'gap to target' was added to our main measure dashboard page (Figure 1). When viewing network data, the 'gap to target' column identifies the specific number of patients (or visits) needed to be added to a measure numerator (based off the previous month's data) for the network goal to be achieved. Specific sites can also review this data in relation to their own JIA population and the network targets with a separate feature to identify specific patients not yet meeting the measure definition. An additional 'gap to target' page can look at each QM by month (starting in May 2024) to identify the gap to network target by percentage with a quick visual to denote whether that month's performance was better than the target (green check) or lower than the target (orange box), if the desired direction of improvement is up (Figure 2).

Conclusion: Identifying specific gaps to target for QMs will help quantify the scope of effort needed to achieve network goals. This gap analysis can help the PR-COIN sites and the collaborative prioritize efforts to optimize care and outcomes for children with JIA. This registry feature also helps sites stay engaged and encouraged as they can closely track the

Measure Category	Measure Sub-Category	Measure	Network Target	Network Performance Prior Reporting Period	Gap to Target (Prior Month)

Utility of ALT/AST and Fibrosis-4 Index (FIB-4) Score in Monitoring Methotrexate Hepatotoxicity in Rheumatologic Disease: A Retrospective Analysis

Julia Wajsberg[1], Dana Nachawati[2], Lenche Kostadinova[3], Donald Anthony[4] and Maya Mattar[3], [1]University Hospitals Cleveland Medical Center/Case Western Reserve University, Cleveland, OH, [2]University Hospitals, Cleveland, [3]Louis Stokes Cleveland VA, Cleveland, [4]The MetroHealth System at Case Western Reserve University School of Medicine, Cleveland, OH

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1972–1989) Measures & Measurement of Healthcare Quality Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Methotrexate (MTX) is widely used in rheumatologic disease but carries hepatotoxic risk. Standard monitoring relies on measurement of alanine and aspartate aminotransferase (ALT and AST), though their variability limits specificity. The FIB-4, a composite fibrosis index that combines biochemical values (platelet count, ALT, and AST) and age, may offer a more stable marker of hepatic injury. Our objective was to evaluate the utility of ALT, AST, and FIB-4 in monitoring MTX-related hepatotoxicity and to characterize provider management of transaminitis.

Methods: We retrospectively analyzed 43 patients followed at the Louis Stokes Cleveland Veterans Affairs Medical Center Rheumatology Clinic, treated with MTX for rheumatologic disease, and with AST/ALT >2× upper limit of normal (ULN) during this treatment. Interventions and clinical data—including FIB-4 scores, cumulative MTX exposure, and risk factors (non-alcoholic fatty liver disease (NAFLD), body mass index (BMI) statin use, diabetes, hyperlipidemia, hypertension)—were analyzed. Discriminative performance for MTX dose changes in relation to AST/ALT/Fib4 change was assessed using area under the ROC curve (AUC).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: MTX was held or reduced in 60% of cases (with the median delay between first AST/ALT elevation and MTX dose change: 4.2 months). Responses included early (less than 3 months) repeat of LFTs (37%), liver imaging (12%), and no action (19%). FIB-4 showed modest discrimination for MTX associated change in laboratory parameters (AUC 0.64), slightly outperforming ALT (0.62) and AST (0.57); a composite score incorporating all three yielded a higher AUC of 0.66. None reached statistical significance. Cumulative MTX dose did not differ significantly between patients with persistent vs. non-persistent transaminitis (mean 48,650 mg vs. 55,307 mg; p=0.34). No demographic or clinical variable—including NAFLD, BMI, or statin use—was independently associated with AST, ALT or FIB-4 change.

Conclusion: Provider responses to MTX-induced transaminitis were inconsistent and often delayed beyond 3 months. A composite of FIB-4, ALT, and AST showed the highest discriminative value for guiding MTX modification. Neither traditional metabolic risk factors nor cumulative methotrexate dose were predictive of hepatotoxicity in this cohort. FIB-4 may offer a more consistent signal for MTX hepatotoxicity monitoring compared to AST/ALT, though this requires additional analysis in a larger cohort.

Abstract Number: 1980

Improving Vaccination Rates in the Rheumatology Clinic

Kajal Patel[1], Sunita Paudyal[1] and Deborah Hurley[2], [1]Prisma Health, Columbia, [2]Prisma Health Midlands, Columbia

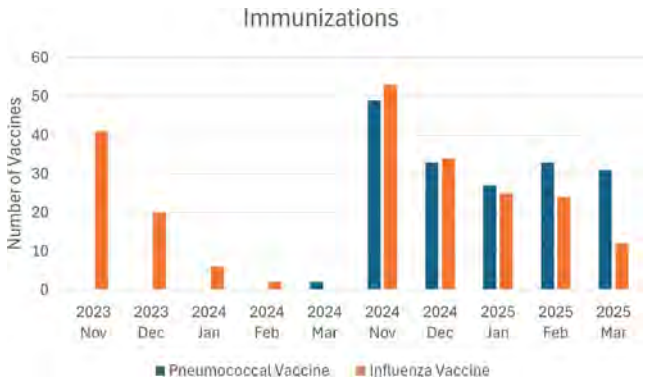
SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1972–1989) Measures & Measurement of Healthcare Quality Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Influenza and pneumococcal infection can cause mild to severe illness and potentially lead to serious complications or death. Patients with rheumatic diseases have weakened immune defenses due to the disease and immunosuppressive therapy, increasing their risk of infections and complications. The American College of Rheumatology recommends the high-dose or adjuvanted influenza vaccine and the pneumococcal vaccine for patients with rheumatic or musculoskeletal diseases on immunosuppressive therapy. Despite these guidelines, vaccination rates in this population remains suboptimal. Barriers include lack of provider prompts, inconsistent vaccination documentation, and lack of or vaccine misinformation for patients. Our goal is to improve vaccination rates in Rheumatology clinic to protect this vulnerable population.

Methods: Baseline data on influenza and pneumococcal vaccination rates were collected from November 1, 2023 to March 31, 2024 (Period 1). During each visit, patients received a questionnaire to assess vaccine status and interest. Providers and clinic staff attended an educational session outlining the importance of vaccination in immunosuppressed patients, project objectives, and strategies for identifying eligible patients using the questionnaire and electronic medical record care gap alerts. Post-intervention vaccination rates were assessed from November 1, 2024, to March 31, 2025 (Period 2).

Results: Baseline data collected from period 1 revealed administration of 69 influenza vaccines and 2 Pneumococcal (Prevnar 20) vaccines. Following implementation of our intervention, period 2 data demonstrated a marked rise in vaccination rates, with 144 influenza vaccines administered – an 108.9% increase - and 170 Prevnar 20 vaccines administered, reflecting an 8,400% increase. The mean number of influenza vaccines each month was 13.8 and 29.6 in period 1 and 2 respectively with a p-value of 0.144. The mean number of pneumococcal vaccines each month was 0.4 and 34.6 in period 1 and 2 respectively with a p-value of 0.010.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Pneumococcal and Influenza Vaccination Rates from November 1, 2023 to March 31, 2024 and from November 1, 2024 to March 31, 2024.

Conclusion: Vaccinations are crucial in patients with rheumatic and musculoskeletal diseases and receiving immunosuppressive therapy. Baseline data revealed low influenza and pneumococcal vaccine rates, highlighting a critical gap in preventative care. After implementing patient questionnaires and staff education, we observed a marked increase in vaccine uptake—suggesting that targeted interventions with a multidisciplinary team of physicians and ancillary medical staff can effectively improve vaccination rates in high-risk populations. Challenges included inconsistent use of the questionnaire after a few months which was partially mitigated through staff reminders. Furthermore, an area for improvement was ensuring patients receive the high-dose or adjuvanted influenza vaccine when indicated. Limitations included inconsistent access to up-to-date vaccination records and therefore not having denominators for statistical analysis. Moving forward, ongoing education, tracking, and extended outreach are necessary to sustain improvements, ensure administration of indicated vaccines, and further reduce the risk of preventable infections.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1972–1989) Measures & Measurement of Healthcare Quality Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Patient education is critical for managing rheumatic diseases. Rheumatology clinic pharmacists are well-positioned to assess and address gaps in patients' understanding of their medications. The objective of this study was to determine patient satisfaction and assess patient understanding of rheumatology medications after a pharmacist-led education (PURPLE) in patients starting new treatment for a rheumatic disease.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Patients attending a rheumatology clinic at the University of Utah (UoU) or Salt Lake City Veterans Affairs Health (VA) who were initiating or switching a disease-modifying antirheumatic drug (i.e., conventional synthetic-, biologic-, and targeted synthetic- DMARDs) received initial medication education by the rheumatologist and/or the clinic pharmacist, per standard-of-care practice. Patients were offered a virtual or phone appointment with a rheumatology clinical pharmacist, approximately 2-4 weeks later. The appointments included 1) a structured assessment of the patients' knowledge about their medication and 2) education tailored to each patients' education needs and questions. After the appointment, patients were invited to complete an anonymous survey assessing their satisfaction and knowledge learned during the education appointment.

Results: Among the 62 participants who completed the survey, 49 were from the UoU and 13 from the VA. Patients agreed or strongly agreed the PURPLE education visit was worthwhile (94%), increased their comfort with medication safety (92%), improved their confidence in the medication effectiveness (89%), and provided useful information (95%) (Figure 1). Satisfaction rates were similar between the patient subsets from the UoU and VA (Figure 2). The most frequent categories of information learned during the visit included potential medication related adverse events, what to do if an adverse event occurs, how to administer the medication, and anticipated time to maximum effectiveness (time to onset) (Figure 3).

Conclusion: Patients reported high satisfaction with the PURPLE program. The similarity in outcomes between the clinic sites suggests the program is applicable across different health care systems. These findings underscore the value of personalized, pharmacist-led education for patients receiving treatment for rheumatic diseases.

Bridging the Gap in Underserved Care: A Quality Improvement Initiative to Increase Pneumococcal Vaccination Rates in Immunocompromised Rheumatology Patients

Kuan-Tung Lin[1], Yue Hao[2], Mai Abdelnabi[2] and Wai-Hang Jackie Lam[2], [1]North East Medical Services, San Mateo, CA, [2]North East Medical Services, San Francisco, CA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1972–1989) Measures & Measurement of Healthcare Quality Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with rheumatologic conditions who are on immunosuppressive therapy face an elevated risk of pneumococcal infections, particularly those in medically underserved populations. Per ACR and recent CDC guidelines, pneumococcal vaccination is recommended for immunocompromised adults under age 65 and, more recently, for those aged 19–49. However, in busy outpatient settings, vaccination is frequently overlooked. Our goal is to increase pneumococcal vaccination rates among immunocompromised rheumatology patients from a baseline of 33% to 50% in 3 months at North East Medical Services (NEMS), a federally qualified health center (FQHC).

Methods: We focused on patients under 65 years of age diagnosed with RA, PsA, AS, or SLE who were receiving immunosuppressive therapy (excluding hydroxychloroquine and sulfasalazine monotherapy). We used the prior age cutoff (< 65) as the updated CDC guideline for adults under 50 was only released in October 2024 and likely has had limited impact so far. From September 2024 to January 2025, the baseline vaccination rate was identified as 33%. We

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

considered a variety of pneumococcal vaccination sequences valid, including PCV20 or PCV21 alone, PPSV23 followed by PCV20 or PCV21, and PCV13 followed by PCV20 or PCV21.

A root cause analysis (Figure 1) revealed key barriers: patient, physician and other departments (eg, pharmacy, dental). To address these, we introduced a bilingual patient education flyer (English and Mandarin, Figure 2) distributed across all NEMS clinics, simplified the vaccine protocol to PCV20 only, and implemented EMR-based care gap alerts. Additionally, a blast email was sent to all NEMS providers, including PCPs, specialists, and dental staff. The initiative was highlighted during our monthly Medical Quality meeting. At the 2-month mark, we also engaged the pharmacy department to review patients' medication and problem lists during dispensing and offer vaccination if not offered already during clinic visits..

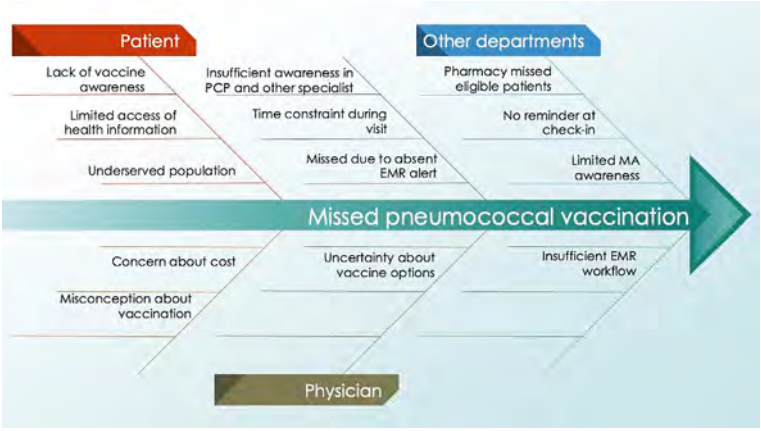

Figure 1: Root cause analysis identified key barriers across three main areas—patients, physicians, and other departments

Figure 2: Patient education flyer (in English and Mandarin) on pneumococcal vaccination for immunocompromised individuals with rheumatologic conditions

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1: Comparison of vaccination rates and patient demographics at baseline and after intervention

	Baseline (Sep/2024-Jan/2025)	Post-QI (Feb-May/2025)
Vaccination rate	33% (36/109)	50% (50/100)
Vaccinated patient	36	50
Gender		
Male	12 (33%)	18 (36%)
Female	24 (67%)	32 (64%)
Race		
Asian	30 (83%)	38 (76%)
African American	0 (0%)	1 (2%)
Caucasian	1 (2.7%)	3 (6%)
Others	5 (13.8%)	8 (16%)
Diseases		
RA	19 (52.7%)	28 (56%)
SLE	11 (30.5%)	10 (20%)
PsA	4 (11.1%)	7 (14%)
AS	2 (5.5%)	5 (10%)
Primary Payer		
Medicare/Medi-Cal	29 (80.5%)	42 (84%)
Private Insurance	7 (19.4%)	8 (16%)

Results: Between September 2024 and January 2025, 109 patients under 65 with RA, PsA, AS, or SLE were seen in the NEMS rheumatology clinic. At baseline, 36 patients (33%) had received a pneumococcal vaccine. By the two-month checkpoint, the rate had increased to 42%, still short of our 50% target. In response, we strengthened collaboration with the pharmacy department, emphasizing their role in reviewing patient records and administering missed vaccinations. This effort led to a continued rise in coverage, and after three months of intervention (February to May 2025), the vaccination rate increased from 33% to 50%, successfully reaching our goal.

Conclusion: Patients with rheumatologic diseases are at increased risk of pneumococcal infection, particularly those in underserved communities. By implementing targeted interventions such as patient education, provider reminders, streamlined EMR alerts, and pharmacy engagement, we successfully reached our vaccination rate goal. With a longer intervention period, we believe coverage could improve even further. This quality improvement model can also be adapted for other types of vaccines and high-risk populations, offering a sustainable strategy to reduce disparities in preventive care.

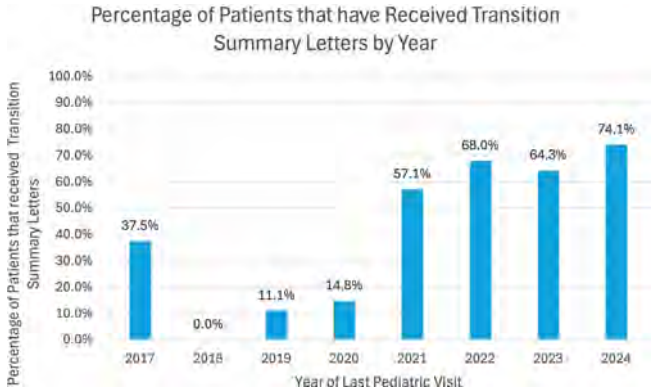
Session Date: Tuesday, October 28, 2025
Session Title: (1972–1989) Measures & Measurement of Healthcare Quality Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The transition from pediatric to adult care poses unique challenges for patients with childhood-onset disease, many of whom were young at presentation and do not recall key events surrounding their diagnosis and treatment. This may contribute to knowledge gaps and reduced self-efficacy, increasing the risk for lapses in care and

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Bar Chart displaying the percentage of patients that received transition summary letters each year (based on the date of their last pediatric visit). The intervention began in February of 2023.

disease flares during transition. We have developed a pediatric rheumatology transition program and implemented a comprehensive initiative, including a formal transition policy, systematic tracking of patients, use of a structured planning tool, and self-assessment of transition readiness. We have also introduced a formal acknowledgment at the final pediatric visit, including a personalized transition summary letter to support continuity of care and minimize information loss.

Methods: We conducted a retrospective review to assess delivery of transition summary letters to patients with childhood-onset rheumatic disease transitioning to adult care since the start of our program in 2017. We reviewed the electronic medical record of transitioned patients, identified through provider notification or chart review, to determine whether a transition summary letter was provided. In February 2023, we initiated reminder emails to providers—initially biweekly, then weekly—listing all transition-age patients with upcoming visits and reminding providers to discuss transition. Patients aged 17 and older were highlighted due to their impending transfer. Our aim was to increase distribution of summary letters compared to prior years and ensure at least 90% of transitioning patients received a letter post-intervention.

Results: From 2017-2024, 278 patients transitioned to adult rheumatology and had data accessible for analysis. Overall, 149/278 (53.5%) received a transition summary letter. By year, the percentage of patients that received a transition summary letter ranged from 0% in 2018 to a peak of 74% in 2024. Prior to the implementation of our reminder emails in 2023, 66/153 patients received transition summary letters (43%). After implementation of our initiative, 83/125 patients received transition summary letters (66%). Overall, the distribution of transition summary letters trended upward (Figure 1).

Conclusion: Many patients experience information loss as well as lapses in access to care during the transfer from pediatric to adult providers. For this project, we built upon the transition pathway created within pediatric rheumatology to consolidate information for adult providers through a transition summary letter written by the pediatric rheumatology provider. Overall, 53.5% of patients received a transition summary letter, and the distribution to patients has trended upwards over time. Following the institution of a weekly reminder email, 23% more patients received transition summary letters compared to years prior. Our next steps include developing interventions to increase the frequency of transition summary letters toward our goal (>90%) and to longitudinally follow these patients to evaluate the impact of this intervention on successful transfer and continuity of care.

Abstract Number: 1984

Improving Lipid Screening Rates in Rheumatic Disease Patients: An Academic Fellowship Quality Improvement Project

Mahnoor Javed[1], Deepak Jagannath[2], Lilly Morgan[1], Rishi Patel[1], Eleonora Avenatti[1], Kanika Monga[1] and Kenneth Williams[1], [1]Houston Methodist, Houston, [2]Houston Methodist Hospital, Sugar Land, TX

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1972–1989) Measures & Measurement of Healthcare Quality Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Autoimmune diseases, including rheumatoid arthritis (RA) and spondyloarthritis (SpA)—which encompasses ankylosing spondylitis (AS) and psoriatic arthritis (PsA)—are associated with chronic inflammation and increased cardiovascular morbidity and mortality. Despite guidelines recommending routine lipid testing for these patients, many fail to receive appropriate screening. Obtaining lipid panels helps calculate the Atherosclerotic Cardiovascular Disease (ASCVD) risk score to guide preventive treatment for patients that are deemed high risk. This quality improvement (QI) project at Houston Methodist Hospital (HMH) aimed to increase lipid screening rates among patients with RA and SpA (including AS and PsA) in the rheumatology fellows' continuity clinic.

Methods: Patients seen at HMH in the rheumatology fellows' clinic from July 2024 to February 2025 with ICD codes for RA, AS, or PsA (diagnosed by a rheumatologist) were analyzed for lipid panel screening in the year prior to their visit. This percentage served as a baseline. Two Plan-Do-Study-Act (PDSA) cycles were implemented from March to May 2025. PDSA 1 focused on a house staff education session on lipid screening protocols, creation of an Epic dot phrase and workstation reminder stickers. Lipid panel orders were collected via retrospective chart review. PDSA 2 involved pre-screening patients and pending a lipid panel order in Epic prior to arrival. Upon chart completion of the visit, these orders were signed by the fellows and data was again collected via retrospective chart view.

Results: At baseline, 0% of fellows were ordering lipid panels in their continuity clinics. After PDSA 1, 49 patients with seropositive RA, AS, or PsA were identified over 4 weeks. Of these, 26 (53.1%) had a lipid panel within the prior 12 months. These were ordered by PCPs predominantly. The remaining 23 patients had no recent lipid panel, and 2 new orders were placed by rheumatology fellows, resulting in a post-intervention rate increase of 8.6%. In PDSA 2, 14 patients were identified

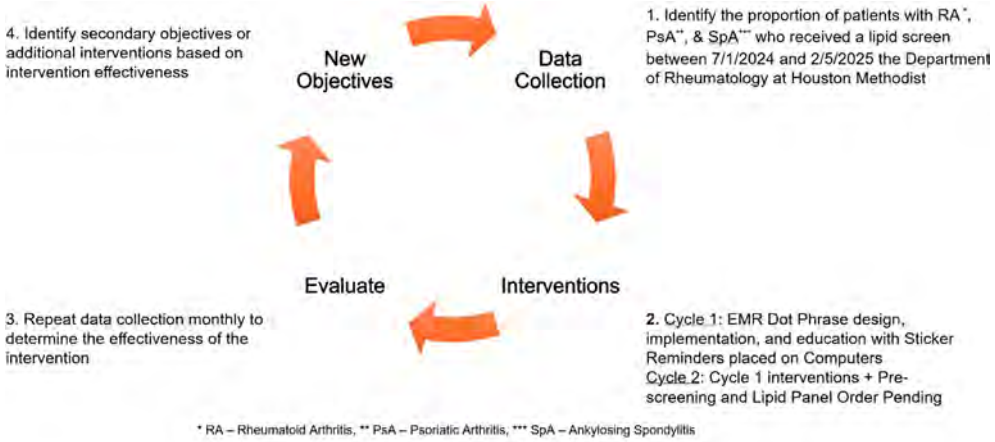

Figure 1. PDSA Cycle 1 and 2

PDSA Cycle 1 and 2

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

as lacking appropriate lipid panels within the prior year. After intervention, 13/14 (92.8%) patients received appropriate screening over 4 weeks.

Conclusion: Pre-charting to identify high risk patients and then pre-pending lipid panel orders prior to clinic visits in the fellows' clinic were more effective than educational interventions alone. This agrees with current research that suggests education alone is a low-value improvement intervention. This workflow modification reduced the burden on fellows during busy clinic sessions and led to a higher and more consistent screening rate, suggesting that system-level changes can improve lipid screening. Ongoing data collection and refinement of this QI strategy will help sustain and expand improvements. Future steps will include treatment of patients with elevated ASCVD scores.

Abstract Number: 1985

Identifying Gaps in Documented Contraception Counseling and Gynecology Referrals for Women on Teratogenic DMARDs: A Foundation for EMR-Based Quality Improvement

Rachel Galvao, Anokhi Saklecha, Julia Stevenson, Ritche Hao, Eugenia Chock and Abhijeet Danve, Yale University, New Haven, CT

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1972–1989) Measures & Measurement of Healthcare Quality Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Teratogenic medications are commonly prescribed to women of reproductive age who have rheumatic conditions. Counseling on teratogenicity and contraception is critical to reducing patients' risk of miscarriage and fetal congenital anomalies. This study assessed the frequency of rheumatologist-documented teratogenic risk counseling, gynecology referrals, and contraceptive methods among women of reproductive age on teratogenic DMARDs in an academic rheumatology clinic. Findings informed the development of a Best Practice Advisory (BPA) in the electronic medical record (EMR) with the goal of improving family planning counseling and documentation.

Methods: Medical records were reviewed for women aged 18–49 who attended at least one rheumatology clinic visit and were prescribed a teratogenic DMARD (methotrexate, mycophenolate, leflunomide, or cyclophosphamide). Descriptive statistics were used to analyze documentation dated between April 1, 2022, and July 31, 2024, including demographic data, clinical notes, referrals, and medication lists.

Results: We reviewed 157 patient charts. Patients had mean age 37 years (SD 8) with lupus as the most common diagnosis (Table 1). Methotrexate was the most frequently prescribed teratogenic DMARD. Over one-quarter of patients (N=41) were not using any contraception, though 45% (N=71) used a highly effective method (sterilization, intra-uterine device, progestin implant) (Figure 1). Documentation of teratogenic risk or contraceptive counseling in rheumatology notes was found in 34% (N=54) and 33% (N=52) of charts, respectively. Contraceptive counseling by Obstetrics/Gynecology (Ob/Gyn) was documented in 41% of cases (N=65). 18% of patients (N=28) had been referred to Ob/Gyn within the study timeframe, of whom 64% (N=18) attended a visit and 14% (N=4) initiated contraception. These findings informed the development of a BPA

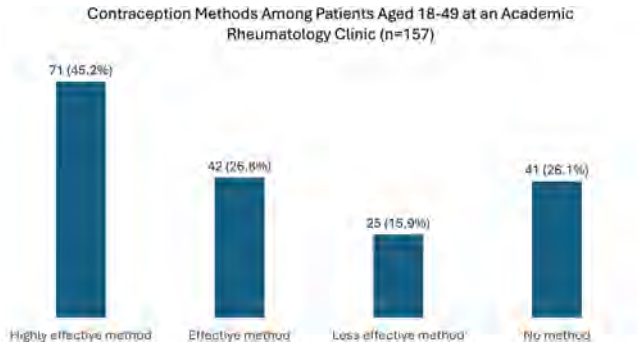

Figure 1. Contraception Methods Among Patients Aged 18-49 at an Academic Rheumatology Clinic. Highly effective method = sterilization (hysterectomy or tubal ligation), intra-uterine device, or progestin implant. Effective method = oral contraceptive pills, depot medroxyprogesterone acetate, transdermal patch, or vaginal ring. Less effective method = condoms. Note: some patients had multiple methods documented.

which will notify rheumatologists of patients' teratogenic medication use, encourage appropriate documentation of counseling, and provide a one-click Ob/Gyn referral pathway with the aim of strengthening quality of care and patient safety (Figure 2).

Conclusion: This study demonstrates substantial gaps in counseling documentation, Ob/Gyn referrals, and contraception for women with rheumatic diseases on teratogenic medications. A BPA was developed in the EMR to improve patient safety and quality of care. We plan to prospectively study the impact of this intervention.

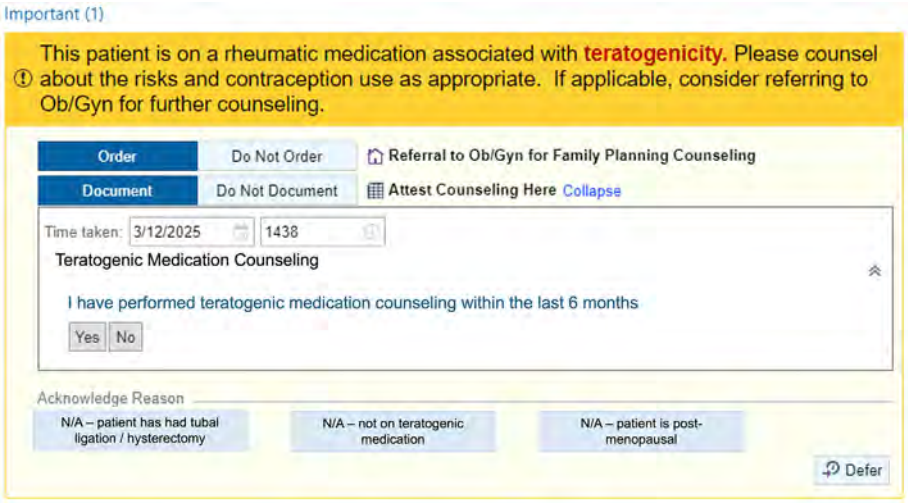

Figure 2. EMR Best Practice Advisory for Teratogenic Medication Counseling. The advisory appears when rheumatologists open an encounter for female patients aged 18-49 with a teratogenic medication on their list or when they prescribe teratogenic medications for patients in this demographic. The advisory provides a one-click order for referral to the academic center's family planning clinic. Documentation is performed directly in the alert and can be viewed in the "Flowsheets" section of the EMR. The alert will not appear if a patient's chart contains history of tubal ligation, hysterectomy, or other surgical sterilization. Once teratogenic medication counseling is documented, the alert will stop appearing for six months, or if the rheumatologist clicks "N/A," the alert will no longer appear.

Evaluating User Engagement and Real-World Impact of a PMR-Specific Digital Symptom Assessment Tool: A 12-Month Analysis of PainSpot™

Shilpa Venkatachalam[1], Erik Stone[2], Ian Carroll[3], angela Degrassi[3], Shelley Fritz[4] and David Curtis[5], [1]Global Healthy Living Foundation, New York, NY, [2]Global Healthy Living Foundation, Nyack, NY, [3]Global Healthy Living Foundation, Upper Nyack, NY, [4]Global Healthy Living Foundation, Kalaheo, HI, [5]Global Healthy Living Foundation, Meriden

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1972–1989) Measures & Measurement of Healthcare Quality Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Polymyalgia rheumatica (PMR) is a systemic inflammatory condition affecting individuals over 50, marked by bilateral shoulder and hip stiffness and pain. Its nonspecific symptoms and overlap with other musculoskeletal disorders often lead to diagnostic delays and misclassification, contributing to avoidable morbidity. Awareness of PMR remains limited, especially outside of rheumatology. Digital tools, such as algorithm-based symptom checkers, offer a scalable approach to identifying PMR-consistent symptom patterns and prompting medical evaluation. To address this gap, the PainSpot™ platform was enhanced with a PMR-specific pathway co-developed by clinicians and patients. This study assessed real-world tool engagement, diagnostic likelihood distribution, and user-reported outcomes.

Methods: PainSpot™ was modified to include a PMR-specific algorithm co-developed by a multi-stakeholder working group including rheumatologists, outcomes researchers, and patients with confirmed PMR diagnoses. Thirteen condition-specific questions were generated and refined through a literature review, clinical input, and patient interviews focusing on

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1: PainSpot (TM) PMR Pathway User Engagement Overview

METRIC	VALUE
Total users who completed the PMR assessment	94,454
Users routed to PMR likelihood result	10,545
Average time spent per user	2 minutes and 19 seconds
Total number of follow-up survey respondents	193 (symptom confirmation)

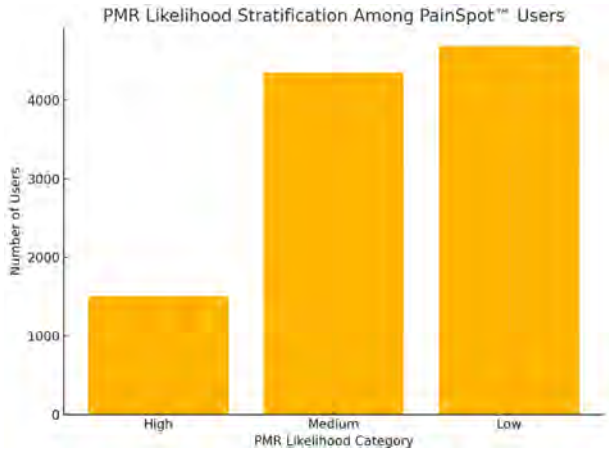

Figure 1: PMR Likelihood Stratification Among PainSpot Users

pre-diagnosis symptom recall. Between March 1, 2024, and February 28, 2025, user-level engagement data were collected and analyzed to evaluate assessment completion rates, PMR likelihood results, and follow-up survey responses.

Results: Of 94,454 users who completed the PainSpot™ assessment between March 2024 and February 2025, a subset were routed to a potential PMR result based on algorithmic analysis of symptom patterns. Among these, 1,509 users (21.0%) were classified as high likelihood of PMR, 4,353 (60.6%) as medium likelihood, and 4,683 (65.2%) as low likelihood. These stratifications were derived from a weighted question algorithm developed through clinician and patient input. Average engagement time across users was 2 minutes and 19 seconds, indicating sustained interaction with the digital interface. Follow-up surveys were administered to users who completed the assessment. Among 111 respondents, 89.2% (n=99) reported discussing their results with a healthcare provider, suggesting potential influence on care-seeking behavior. Additionally, 193 assessment completers (across all diagnostic pathways, not limited to PMR) responded to a separate follow-up question regarding the accuracy of the tool's output; 82.4% (n=159) indicated that the result they received aligned with their symptom experience or was subsequently confirmed.

Conclusion: The PMR-specific pathway within PainSpot™ demonstrated high engagement meaningful stratification of diagnostic likelihood, and strong perceived utility based on user-reported outcomes.. While only a subset of users confirmed seeking medical follow-up, a larger proportion—over 80% of survey respondents—indicated that the tool's output aligned with their symptom experience. These findings support the utility of patient-informed, algorithm-based tools in recognizing symptom patterns consistent with PMR. This work aligns with a four-year CDC-funded initiative aimed at improving national awareness, education, and diagnostic strategies for PMR.

Abstract Number: 1988

Advancing Vascular Assessment: Combining NIRS-VOT and Ultrasound-based Brachial Artery Diameter for Improved Diagnostics in Healthy Controls and APS

Soongho Park[1], Julie Mathew[1], Sharon Osgood[2], Claudia Gomez[1], Eric Leifer[1], Ecem Sevim[1] and Yogendra Kanthi[3], [1]NIH, Bethesda, [2]NHLBI/NIH, Bethesda, [3]National Heart, Lung and Blood Institute, National Institutes of Health, Bethesda, MD

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1972–1989) Measures & Measurement of Healthcare Quality Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Near-Infrared Spectroscopy combined with Vascular Occlusion Test (NIRS-VOT) is a non-invasive diagnostic method for assessing microvascular function. However, its diagnostic accuracy is often limited by inter-individual variability, particularly anatomical differences in vascular structure, such as brachial artery diameter (BAD). Since BAD significantly influences blood flow and may affect NIRS-VOT readings, we propose incorporating BAD as a reference parameter to standardize NIRS-VOT results and improve diagnostic reliability. This approach is particularly relevant in diseases like Antiphospholipid Syndrome (APS), a rare autoimmune disorder characterized by vascular dysfunction.

Methods: We applied this combined method to a cohort of 10 healthy controls (HCs) and 9 patients with APS. Brachial artery diameter was measured using ultrasound imaging, and NIRS-VOT was performed to assess tissue oxygen saturation (StO_2) parameters during vascular occlusion and reperfusion. We conducted correlation analyses to evaluate the relationship between BAD and NIRS-VOT parameters and performed logistic regression to examine whether including BAD improved classification between HCs and APS patients. Multiple statistical analyses were used to identify independent predictors of key NIRS-VOT outcomes.

Results: Our results indicate that incorporating BAD into NIRS-VOT significantly improves interpretation of hemodynamic parameters. In HCs, strong correlations were observed between BAD and NIRS-derived parameters (e.g., $r = 0.95$, $p < 0.01$), while correlations in APS patients were notably weaker, suggesting greater variability in vascular response. Both

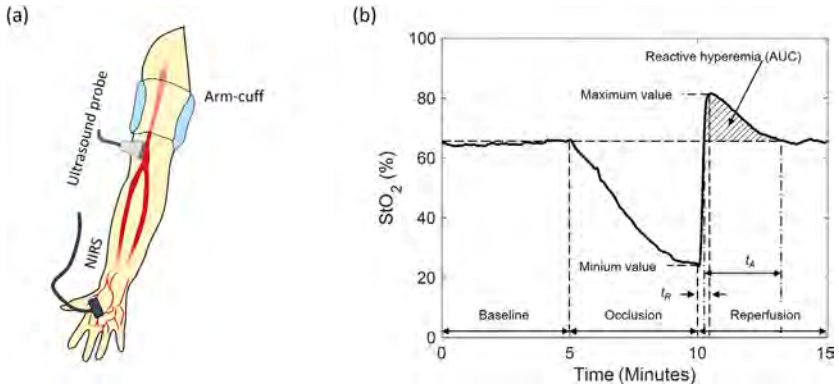

Figure 1. (a) Experimental setup combining a linear ultrasound probe on the upper arm to measure brachial artery diameter and a NIRS probe on the thenar for vascular occlusion testing (VOT). (b) Schematic of NIRS-derived tissue oxygen saturation (StO2) during VOT, including Baseline, Occlusion, and Reperfusion phases. Key parameters analyzed: baseline, minimum, maximum, resaturation time (tR), area under the curve (AUC), and hyperemic recovery time (tA).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

BAD and APS status emerged as significant independent predictors of key NIRS-VOT metrics. Logistic regression analysis showed that the inclusion of BAD improved classification accuracy—by at least 7.14% for baseline and minimum StO_2, and by up to 28.57% for maximum StO_2. Without BAD, the highest classification accuracy for maximum StO_2 was 78.57%, whereas including BAD increased it to 92.86%.

Conclusion: This study demonstrates the feasibility and utility of combining NIRS-VOT with ultrasound-derived BAD measurements for assessing microvascular function. To our knowledge, this is the first study to explore the interplay between conduit artery structure and NIRS-based functional assessments in this way. The integration of BAD into NIRS-VOT significantly enhances diagnostic accuracy, reduces inter-individual variability, and offers a more robust framework for evaluating vascular health. This approach shows promise not only for identifying vascular dysfunction in rare conditions such as APS but may also be applicable to other conduit arteries like the femoral artery, broadening the method's potential clinical applications.

Moving Out of the Kid's Rheum: Transitioning Young Adult Patients from Pediatric to Adult Rheumatology Practices

Victoria Koenigsberger[1], Madeleine Ward[2], Meghan Geary[3] and Ali Yalcindag[4], [1]The Warren Alpert Medical School of Brown University, Providence, RI, [2]The Warren Alpert Medical School of Brown University, Division of Medicine-Pediatrics, Providence, [3]The Warren Alpert Medical School of Brown University, Division of General Internal Medicine, Providence, [4]The Warren Alpert Medical School of Brown University, Division of Rheumatology, Department of Pediatrics, Milton, MA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1972–1989) Measures & Measurement of Healthcare Quality Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Young adults with childhood-onset rheumatic conditions encounter challenges and barriers to care when transitioning to an adult rheumatologist. At this Pediatric Rheumatology Clinic, patients aged 18 and older were provided with a list of adult providers to call and set up follow-up, however no formal transition process existed. This study aimed to pilot the practice's first program to systematically transition pediatric patients using aspects of the Six Core Elements of Health Care Transition (HCT) from Got Transition.

Methods: One research assistant, two primary care physicians, one pediatric and ten adult rheumatology providers facilitated the program. Patients were eligible if they were 18 years of age or older with confirmed rheumatic disease, and deemed stable to transition by the pediatric rheumatologist. The program structure consisted of four visits, ~three months apart: two appointments with pediatric rheumatology, with ~50% of the time devoted to transition readiness education; a final in-person appointment with pediatric rheumatology, with their chosen adult rheumatologist on video for a warm handoff; and a first appointment with adult rheumatology. Patient-reported transition readiness was assessed at each visit using the Transition Readiness Assessment (TRA) from Got Transition. Patient demographics were assessed via chart review.

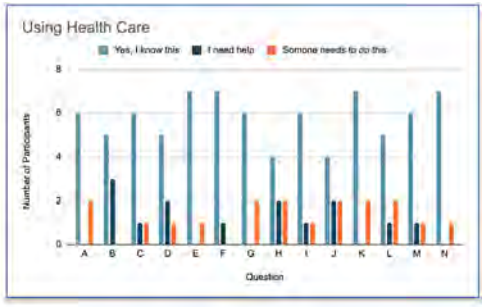
TRA responses from initial survey for knowing health (A: I know my medical needs; B: I can explain my medical needs to others; C: I know my symptoms including ones that I quickly need to see a doctor for; D: I know what to do in case I have a medical emergency; E: I know my medicines, what they are for, and when I need to take them; F: I know my allergies to medicines and medicines I should not take; G: I carry my important health information with me every day; H: I understand how health care privacy changes at age 18 when legally an adult; I: I can explain to others how my customs and beliefs affect my health care decisions and medical treatment)



TRA responses from initial survey for using health care (A: I know or I can find my doctor's phone number; B: I make my own doctor appointments; C: Before a visit, I think about questions to ask; D: I have a way to get to my doctor's office; E: I know to show up 15 minutes before the visit to check in; F: I know where to go to get medical care when the doctor's office is closed; G: I have a file at home for my medical information; H: I have a copy of my current plan of care; I: I know how to fill out medical forms; J: I know how to get referrals to other providers; K: I know where my pharmacy is and how to refill my medicines; L: I know where to get blood work or x-rays if my doctor orders them; M: I have a plan so I can keep my health insurance after 18 or older; N: My family and I have discussed my ability to make my own health care decisions at age 18)

Figure 2: Baseline Transition Readiness (TRA) Responses

Results: 64 patients aged 18 and older had scheduled appointments with the Pediatric Rheumatology Clinic from 5/1/24 to 1/31/25. Of these patients, 13 were eligible, determined by diagnosis and disease stability, of which eight (62.5%) chose to enter the pilot (Figure 1). Patient demographics are shown in Table 1.

All participants (100%) completed a baseline TRA. The mean age at enrollment was 19.5 years (range: 18-23). Mean TRA scores for patients' initial self-perceived importance of transition to an adult doctor and confidence in transitioning were 8.13 and 7.13, respectively (out of 0 [not] to 10 [very]). The majority of participants reported knowing their health needs and being able to explain them to others. Knowledge regarding navigating health care, such as getting referrals to other providers, was more mixed (Figure 2). Seven participants (87.5%) have completed at least two transition appointments, and two (25%) have successfully transitioned to adult rheumatology.

Conclusion: Appropriate HCT is crucial to support the health of young adults with childhood-onset chronic illnesses. Initial stages of this transition process have proven acceptable with the majority of patients approached agreeing to participate. It appears that self-perceived importance of transitioning to an adult rheumatologist was greater than confidence in doing so at the initial appointment. It has also proven feasible to complete successful warm video handoff visits with the adult rheumatologists at their final pediatric appointment. Challenges to implementation include time and clinical infrastructure. Next steps involve finalizing remaining adult appointments and assessing the impact of this program on patients with multi-modal data - qualitative and quantitative surveys.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1990–2014) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatology guidelines endorse a treat-to-target (TTT) approach targeting serum urate (SU) < 6 mg/dL among patients with gout who qualify for urate-lowering therapy (ULT). However, implementation of TTT remains suboptimal, in part due to frequent laboratory visits required to serially check SU for ULT titration. Prior studies (Kehasse et al., ACR abstract 2023, PMID: 29720236, PMID: 31072349) have investigated the role of capillary point-of-care (POC) SU measuring devices to reduce barriers associated with TTT. However, the results have been inconsistent, with intraclass correlation coefficients (ICC) ranging from 0.75 to 0.90 and Pearson correlation coefficient of 0.96. We sought to investigate the accuracy of a POC device, the BeneCheck Supreme (the same device brand used in a randomized trial of supported self-management in gout (PMID: 38294032) and approved in Europe for home testing), in measuring SU as compared to traditional venous laboratory analysis (TVA) among patients with gout.

Methods: We identified patients with gout who presented in-person to the rheumatology clinic at our academic hospital. Among patients who had a clinical indication to measure SU, we measured SU using both the capillary POC device and TVA on the same day. Written informed consent was required to participate in this Institutional Review Board-approved study. Demographic and clinical information was obtained through retrospective review of the electronic health record. We assessed the correlation between POC and TVA SU values using intraclass correlation coefficients (ICC). A Bland-Altman analysis assessed variability in the difference and limits of agreement between POC with TVA. The performance of POC SU measurements in identifying those with SU >6 mg/dL was analyzed using ROC curve analysis with area under curve (AUC), and was additionally adjusted for the presence of hypertension (HTN), chronic kidney disease (CKD) Stage 3 or greater, and type 2 diabetes mellitus (T2DM).

Table 1. Baseline characteristics of the study population.

	N=27
Mean age (SD)	59.1 (15.3)
Male, n (%)	25 (92.6)
Race, n (%)	
White	20 (74.1)
Asian	4 (14.8)
Black	3 (11.1)
T2DM, n (%)	4 (14.8)
CKD stage 3 or greater, n (%)	5 (18.5)
HTN, n (%)	17 (63.0)
ULT use, n (%)	19 (70.4)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

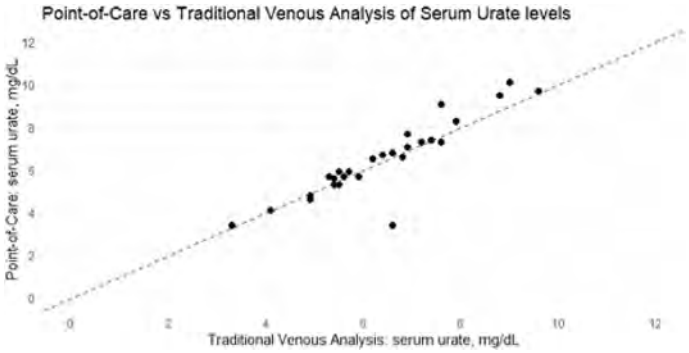

Figure 1. Scatterplot of POC serum urate measurement as compared to TVA measurements, showing ICC of 0.89 (95% CI, 0.77 to 0.95).

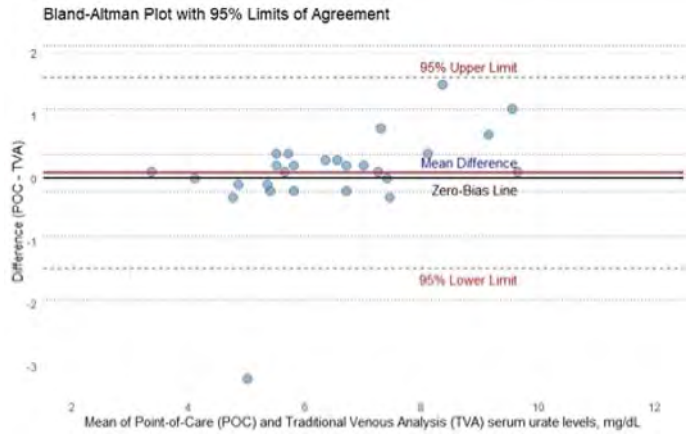

Figure 2. Bland-Altman plot comparing POC to TVA serum urate measurements. Mean difference was 0.09 mg/dL, with limits of agreement of -1.4 to 1.6 mg/dL.

Results: Our study included 27 patients, of whom 25 (92.6%) were male and 20 (74.1%) were White (**Table 1**). Most patients (70.4%) were on ULT. The POC SU measurements ranged from 3.4 to 10.1 mg/dL, with a mean of 6.5 mg/dL. TVA measurements ranged from 3.3 to 9.6 mg/dL, with a mean of 6.4 mg/dL. The ICC between POC and TVA measurements was 0.89 (95% CI, 0.77 to 0.95) (**Figure 1**). In the Bland-Altman analysis, the bias, or mean difference (POC-TVA), was 0.09 mg/dL, with limits of agreement of -1.4 to 1.6 mg/dL (**Figure 2**). For POC detection of SU >6 mg/dL, the unadjusted AUC was 0.94. The results did not differ significantly with inclusion of ULT in the model, but improved nominally to 0.95 with inclusion of HTN, CKD, and T2DM. The sensitivity and specificity of the POC device for detecting SU >6 mg/dL was 0.93 and 1.00, respectively.

Conclusion: In this small pilot study, the POC device and TVA for SU were strongly correlated, with a mean difference of 0.09 mg/dL between the POC and TVA measurements. The POC correctly identified 93% of individuals with SU >6 mg/dL, a clinically meaningful threshold for ULT dose titration. Such POC devices may facilitate real-time implementation of the TTT approach in gout management.

Co-Use of Mycophenolate Mofetil with Pegloticase Yielded Similar Clinical Outcomes as the Co-Use of Methotrexate

Tingting Zhang[1], Kenneth Saag[2], Yasir Qazi[3], **Bradley Marder**[4] and Brian Lamoreaux[5], [1]Amgen, Inc., Thousand Oaks, [2]The University of Alabama at Birmingham, Birmingham, AL, [3]Keck School of Medicine Renal Transplant Program, University of Southern California, Los Angeles, CA, [4]AMGEN, Inc, Denver, CO, [5]Amgen, Inc., Deerfield, IL

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1990–2014) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Pegloticase significantly reduces serum uric acid (sUA) values in patients with refractory gout. Co-use of methotrexate (MTX) improves efficacy and safety of pegloticase by reducing the development of anti-drug antibodies[1]. Because MTX is primary excreted through the kidney, there has been concern that MTX use may increase adverse effects in patients with renal impairment. The present study was designed to examine effects of co-using pegloticase with mycophenolate mofetil (MMF), another immunomodulatory (IMM) proven to extend pegloticase efficacy[2].

Methods: This is a longitudinal analysis using the Optum Clinformatics® DataMart®, 2016-2024. The study participants included new users of pegloticase; the first pegloticase infusion defined the index date. Based on the presence of IMM treatment ±90 days from the index date, we defined three exposure groups: MTX co-therapy group, MMF group and pegloticase monotherapy (IMM nonusers). We described pegloticase duration of use, patterns of sUA values and estimated Glomerular Filtration Rate (eGFR). Analyses were stratified by baseline eGFR (60+ vs. < 60 ml/min/1.73m^2).

Results: We identified 903 pegloticase new users who met the inclusion criteria (297 in the MTX co-therapy group, 144 in the MMF group and 462 monotherapy group). The MMF co-therapy group was older, had a high prevalence of comorbid CKD stages 3+ (60%), as well as higher proportions of all-cause hospitalizations and comorbidities than the other two groups (Table 1). By comparison, the MTX group had 23% and the monotherapy group had 37% with advanced CKD. The median number of pegloticase infusions was 11 for the MMF group (IQR: 4-18), 8 for the MTX group (IQR: 3-15) and 6 for the immunomodulator nonusers (IQR: 2-14). The mean sUA levels changed from over 7 mg/dL at baseline, to ~2 mg/dL between 1-6th infusions and ~1mg/dL between 7th infusion and follow-up end (Figure 1). The mean eGFRs were

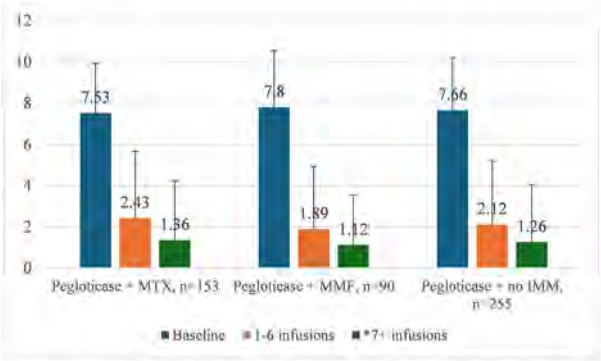
Figure 1. Mean and standard deviation of serum uric acid levels at baseline, between 1-6 infusions and 7th infusions onwards



Note: Approximately half of the study participants in each group had sUA values available at baseline and between 1-6 infusions. A total of 103 patients in the MTX group, 62 patients in the MMF group and 173 patients in the immunomodulator nonuser group had sUA value available from 7th infusion to the end of follow-up.

stable [MTX group: 111 (SD: 62) ml/min/1.73m^2 at baseline to 105 (SD: 53) during the follow-up; MMF group: 62 (39) to 60 (34); monotherapy: 108 (69) to 108 (71)]. Stratified analyses produced consistent findings.

Conclusion: 49% of pegloticase patients were treated with immunomodulating co-therapy, among which MMF was 33% of IMM use, with most patients going on MMF having advanced CKD. Pegloticase duration, effectiveness in terms of sUA reduction and eGFR stability in the MMF group were similar to the MTX group. The co-therapy of MMF and pegloticase may be an option for patients with pre-existing renal impairment.

Background/Purpose: Methotrexate (MTX) coadministered with pegloticase attenuates anti-drug antibody formation, leading to higher response rates and markedly reduced infusion reaction risk compared with pegloticase + placebo (PBO).[1] Here, we evaluate overall MTX safety data in pts enrolled in the MIRROR RCT.

Methods: Patients (pts; N=152) with uncontrolled gout (SU ≥7 mg/dL, oral ULT failure/intolerance, and tophi, ≥2 flares/yr, and/or gouty arthritis) received up to 52 wks of pegloticase (8 mg infusion Q2W) with either 15 mg oral MTX/wk or PBO and 1 mg folic acid daily; pts with eGFR < 40 ml/min/1.73 m^2 were excluded. First infusion (Day 1) occurred after a 2-wk MTX tolerance period (Wk -6 to Wk -4) and a 4-wk MTX/PBO run-in (Wk -4 to Day 1). Baseline (BL) was prior to MTX exposure (Wk -6). Safety data from on-treatment pts (N=96 MTX and N=49 PBO; ≥1 pegloticase dose) were examined in aggregate (Figure 1).

Results: During the 52-wk tx period, the most common on treatment-emergent adverse event (TEAE) was gout flares (MTX: 66.7%; PBO: 71.4%).[1] MTX-associated AEs (gastrointestinal disorders, skin disorders, infections) were similar between both groups.[1] Pulmonary disorders (9.4% vs 4.1%) occurred more often in the MTX group, but with similar incidence rates **(Table 1)**. More pts in the MTX vs PBO group had transient ALT levels >ULN (13.6% vs 6.3%; no >2 x ULN or above in either group). Pt proportion with AST levels >ULN was similar (6.9% MTX vs 6.3% PBO; >2 x ULN [n=2 vs 0] and >3 x ULN [n=1 vs 0]). However, ALT (+0.6 ± 23.3 vs. +2.5 ± 14.4 U/l), AST (+1.5 ± 22.1 vs. +1.5 ± 11.0 U/l), as well as Fib-4 index, a predictor of hepatic fibrosis progression, did not meaningfully change from BL at Wk 52.[1,2] Occurrence of infections was similar (MTX: 18.8% vs PBO: 18.4%), with COVID-19 being most common (9.4% vs 6.1%; nominal p=0.35). Leukopenia and anemia each occurred in 1 pt in the MTX group (none in the PBO group; **Table 1)**. Permanent MTX and PBO withdrawal due to TEAEs occurred in 11.5% and 16.3% of pts; 2 deaths occurred in the MTX group during the 52-wk tx (cardiac arrest and COVID-19 with multiple comorbidities), deemed unrelated to study tx. Renal function remained stable during tx in both groups.[1] The change in creatinine from BL was -0.08 ± 0.15 and 0.01 ± 0.32 mg/dL. Stomatitis was uncommon (1 event during MTX run-in [1%], with no recurrence). MCV increased by ~4 fL from BL in the MTX group (3.8 ± 3.47]), with no change in the PBO group (0.0 ± 3.51), which is indicative of RBC macrocytosis, a surrogate marker for MTX compliance. Alcohol users (≥3 servings/wk) comprised 3.2% (4/126) of total screening failures. Among alcohol users enrolled (97/159; 61%), liver function did not worsen in the MTX vs PBO groups (ALT increase: 1 pt each [1.7% vs 3.4%]; AST increase: 1 pt [1.7%] vs 0).

Conclusion: MTX safety data from MIRROR RCT demonstrates that MTX in uncontrolled gout pts does not lead to an increased number/frequency of TEAEs vs PBO, including no increase in durable liver function changes and no increase in infections. These findings further underscore the safety of MTX coadministration with pegloticase during the 12 month MIRROR RCT.

Abstract Number: 1993

Risk of Cardiovascular Conditions, Bone Fractures and Mortality in Patients with Uncontrolled Gout in Comparison to Those with Controlled Gout

Tingting Zhang[1], Christian W. Mende[2], Ashraf El-Meanawy[3], Michael Pillinger[4], Kaiding Zhu[5], Bradley Marder[6] and **Brian Lamoreaux**[7], [1]Amgen, Inc., Thousand Oaks, [2]University of California San Diego, San Diego, CA, [3]Medical College of Wisconsin, Milwaukee, WI, [4]New York University Grossman School of Medicine, New York,, NY, [5]Amgen, Inc., San Francisco, CA, [6]AMGEN, Inc, Denver, CO, [7]Amgen, Inc., Deerfield, IL

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1990–2014) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Gout may increase the risk of cardiovascular events (CVEs) and bone fractures through urate deposition and chronic inflammation[1,2]. However, the additional effects of uncontrolled gout on these outcomes relative to controlled gout is still unclear. This study was designed to examine the risk of CVEs, fractures and mortality in people with uncontrolled versus controlled gout.

Methods: This retrospective cohort study used Optum Clinformatics DataMart® (2016-2024). Controlled gout was defined by no flares, no visible tophi during the baseline year plus normal baseline serum urate (SU) levels (i.e., pre-index SU < 6 mg/dL for three months). An uncontrolled gout group was defined using a new flare, tophi or gout-related emergency department visit or hospitalization following the use of urate-lowering therapies at baseline, along with pre-index SUs ≥6 mg/dL for three months. Outcomes included 1) a composite outcome of incident stroke/acute myocardial infarction; 2) a composite outcome of incident osteoporosis fractures identified using validated algorithms, and 3) all-cause mortality. Each outcome was analyzed in a separate analysis. We estimated inverse-probability of treatment weights (IPTW) for each comparison group using propensity scores. Poisson regressions were used to estimate incidence rates (IRs) and Cox proportional hazard models were used to generate hazard ratios (HRs). Sensitivity analysis was conducted with exact matching of all covariates.

Results: Study participants included 19,645 patients with uncontrolled (72% males; 63% aged 65+) vs. 13,126 patients with controlled (60% males; 71% aged 65+) gout for the CVE analyses, 21,237 uncontrolled vs. 13,569 controlled gout patients for the fracture analysis, and 21,292 uncontrolled vs. 13,615 controlled patients for the

Weighted HR and 95%CIs	2.3 (2.2 – 2.5)	1
Bone fracture		
Cohort size, n	21,237	13,569
Fracture events, n (%)	929 (4.4)	564 (4.2)
Total person-years of follow-up	75,951	90,742
IR of fracture per 1,000 person years	12.2 (11.5 – 13.1)	6.2 (5.7 – 6.7)
Weighted HR and 95%CIs	2.1 (1.9 – 2.4)	1
Mortality		
Cohort size, n	21,292	13,615
Events, n (%)	3,876 (18.2)	1,821 (13.4)
Total person-years of follow-up	79,982	94,960
Mortality per 1,000 person years	59.9 (58.2 – 61.6)	42.2 (40.9 – 43.6)
Weighted HR and 95%CIs	1.5 (1.4 – 1.6)	1

mortality analysis. (Table 1 shows an example of the mortality analysis). All baseline covariates were balanced after IPTW. Following IPTW, uncontrolled gout compared to controlled gout was associated with a higher rate of developing incident stroke/AMI (adjHR 2.3; 95%CI 2.2-2.5; 51 versus 23 events per 1,000 person-years), a higher rate of an incident fracture (adjHR 2.1; 95%CI 1.9-2.4; 12 versus 6 events per 1,000 person-years) and a higher mortality (adjHR 1.5; 95%CI 1.4-1.6; 60 versus 42 events per 1,000 person years, Table 2). Sensitivity analysis yielded consistent findings (Table 2).

Conclusion: Patients with uncontrolled gout experienced increased risk of CVEs, bone fractures and mortality compared to controlled gout. These findings highlight the need for clinician awareness and further research to clarify how better control of gout may improve health outcomes.

Background/Purpose: Pegloticase is approved for uncontrolled gout as 8-mg infusions admixed in 250 cc of normal saline over 120 minutes or more administered every 2 wks with methotrexate (MTX) coadministration. Given the logistical burden of 2-hr infusions every 2 wks and normal saline supply disruptions, the AGILE study evaluated faster 60-minute infusions every two wks with pre-mixed 8 mg pegloticase, in 50 cc ready-to-use (RTU) vials, with MTX co-administration. The overall results of the AGILE study demonstrated a comparable efficacy and safety profile to that of the standard infusion formulation,[1] but the pharmacokinetic (PK) results have not been reported.

Methods: The AGILE study was a phase 4, multicenter, open-label study including patients with uncontrolled gout (oral ULT failure or intolerance, SU ≥6 mg/dL, more than one tophus, more than one flare/yr, or gouty arthritis). Key exclusion criteria were contraindication to MTX, G6PD deficiency, serious bacterial infection, eGFR < 40 mL/min/1.73m^2, or elevated liver function tests. Eligible patients underwent a 4-wk oral MTX run-in of 15 mg weekly with 1 mg daily of folic acid then 24 wks of pegloticase with MTX co-administration. Three cohorts were enrolled receiving 60-, 45-, and 30-minute infusions. Ultimately the 60-minute group was deemed optimal and fully enrolled based on safety reviews. The PK analysis set included all patients who received ≥1 dose of pegloticase and had a post-pegloticase sample evaluable for PK analysis. PK parameters (C_{min}, C_{max}) were analyzed at week 12, including pre- and post-infusion concentrations.

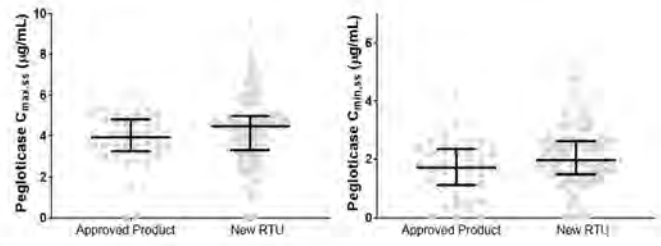
Results: Efficacy and safety of AGILE have been reported among the 60-minute cohort (n = *116)*, showing an infusion reaction rate of 6% (95% CI, 2.5%-12.0%, 7/116) and SU efficacy response rate at month 6 of 67.2% (95% CI, 57.9%-75.7%, 78/116), which were comparable to standard pegloticase with MTX treatment.[1,2] PK analyses included all 3 infusion cohorts and occurred at study week 12, showing a median C_{max} of 4.46 (Q1 of 3.29, Q3 of 4.96, n = 90) for RTU vs 3.92 (Q1 3.24, Q3 4.80, n = 41) for standard pegloticase. The C_{min} followed the same trend, with median C_{min} of 1.96 (Q1 of 1.49, Q3 of

Table 1. Median Peak (Cmax,ss) and Trough (Cmin,ss) Pegloticase Concentrations at Week 12 in Uncontrolled Gout Patients Treated With Approved (Standard) Pegloticase Formulation and New RTU Vial Formulation

Median (Q1, Q3)	Standard Formulation	New RTU Formulation
Observed $C_{max,ss}$ (μg/mL)	3.92 [3.24, 4.80] (n = 41)	4.46 [3.29, 4.96] (n = 90)
Observed $C_{min,ss}$ (μg/mL)	1.70 [1.13, 1.96] (n = 41)	1.96 [1.49, 2.61] (n = 89)

RTU, ready-to-use; Q, quartile; ss, steady-state.
Median concentration is shown with upper and lower error bars representing the first (Q1) and third (Q3) quartiles.

Figure 1. Comparison of Peak (Cmax,ss) and Trough (Cmin,ss) Pegloticase Concentrations at Week 12 in Uncontrolled Gout Patients Treated With Approved (Standard) Pegloticase Formulation and New RTU Vial Formulation



RTU, ready-to-use; Q, quartile; ss, steady-state.

Cmax and Cmin were calculated using pegloticase concentrations observed at Week 12 after reaching steady state. Median concentration is shown with upper and lower error bars representing the first (Q1) and third (Q3) quartiles. 1/41 and 1/91 data point of Cmax were not included in the plot in the approved product and new RTU, respectively, due to abnormally high values. 1 of 89 patients in new RTU group was not included in the plot of Cmin due to abnormally high values.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. 2.61, n = 89) vs 1.70 (Q1 of 1.13, Q3 of 1.96, n = 41) for standard pegloticase. (**Table 1, Fig. 1)**. These differences were small relative to overall exposure variability and not considered clinically significant. Overall, the RTU formulation showed an 11.7% higher geometric mean simulated exposure compared to standard pegloticase (clinically insignificant). Of note, 5 patients (60-minute cohort [n=1]; 30-minute cohort [n=4]) received standard admixed pegloticase and RTU formulation during the study; the PK parameters and response rates in these patients were comparable to the pegloticase RTU and standard formulations.

Conclusion: Pegloticase given in RTU form of premixed 50 cc with 8 mg of pegloticase coadministered with MTX over 60 minutes showed comparable safety, efficacy, and PK results to standard pegloticase. Among a small number of patients that switched from standard pegloticase to RTU formulation, no change in PK was seen.

Choi[5], [1]Massachusetts General Hospital, Waltham, MA, [2]Massachusetts General Hospital, Boston, [3]Massachusetts General Hospital/Harvard Medical School, Boston, MA, [4]Arthritis Research Canada, Vancouver, BC, Canada, [5]MASSACHUSETTS GENERAL HOSPITAL, Lexington, MA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1990–2014) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Gout is an inflammatory-metabolic condition that is associated with a heavy burden of cardiovascular-kidney-metabolic (CKM) comorbidities. Accordingly, multimorbidity and polypharmacy are important considerations which could impact gout management yet have been understudied in this population. We sought to determine the prevalence of multimorbidity and polypharmacy among individuals with gout in the United States.

Methods: We used data from the National Health and Nutrition Examination Survey (NHANES) 2017-18 in which self-reported data on history of gout were ascertained. We examined the national prevalence and population estimates of eight CKM comorbidities, which were defined using a combination of self-reported history, laboratory values, anthropometric measurements, medications, and physical examination data (**Table 1**). Multimorbidity was defined as having two or more CKM conditions. Polypharmacy was defined as having five or more prescription medications. We conducted logistic regression analyses to quantify the magnitude of association between the presence of gout and the presence of comorbidities,

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

including sub-group analyses based on sex and age ≥65. All statistical analyses were performed using survey commands of SAS to adjust for clusters and strata of the complex sample design and to incorporate sample weights to generate estimates for the total civilian, non-institutionalized US population.

Results: In the NHANES 2017-18, 5.1% (12.1 million) of the US population reported a history of gout. Multimorbidity was present in 76.7% (9.4 million) of individuals with gout compared to 47.1% of individuals without gout, yielding an age- and sex-adjusted odds ratio (OR) of 1.9 (95% CI, 1.1 to 3.2), which was significantly higher among women with gout compared to men with gout (OR 2.7 versus 1.6, p for interaction 0.006) (**Table 2**). Among those age 65 or greater, individuals with gout were 2.7-fold (1.2 to 6.2) more likely to have multimorbidity compared to those without gout. Individuals with gout were also more likely to experience polypharmacy compared to those without gout, with an age- and sex-adjusted OR of 1.9 (1.1 to 3.4) (**Table 2**). Examining the different CKM conditions, the most prevalent among individuals with gout were hypertension (64.7%; 7.9 million), dyslipidemia (60.9%; 7.4 million), and obesity (57.3%; 6.8 million) (**Table 3**). The prevalences were significantly higher among individuals with gout than those without gout for all conditions except dyslipidemia and MASLD, with highest age- and sex-adjusted OR of 2.7 (1.6 to 4.7) for CKD, followed by 2.3 (1.1 to 4.7) for heart failure (**Table 3**). In our sex-stratified analyses, comorbidities tended to be more frequent among women with gout than men with gout, most notably for hypertension and CHD (**Table 3**).

Conclusion: A significant proportion of US adults with gout experience multimorbidity and polypharmacy. With the emergence of medications with multiple CKM benefits, such as sodium-glucose cotransporter type 2 inhibitors and glucagon-like peptide-1 receptor agonists, additional studies are warranted to determine best practices to streamline gout and CKM comorbidity care.

Table 1. CKM Comorbidities and Their Definitions

Comorbidity	Definition
Obesity	Body mass index ≥30
Hypertension	Self-reported history of hypertension
Type 2 diabetes (T2DM)	Treatment with diabetes medication or self-reported history of diabetes
Dyslipidemia	Hypercholesterolemia (cholesterol >2g/L or treatment with lipid-lowering medications) and/or hypertriglyceridemia (triglycerides >2.5g/L)
Coronary heart disease (CHD)	Self-reported history of angina and/or myocardial infarction
Heart failure	Self-reported history of heart failure
Chronic kidney disease (CKD)	Estimated glomerular filtration rate <60 mL/min/1.73m² using CKD-EPI
Metabolic dysfunction-associated steatotic liver disease (MASLD)	Hepatic steatosis (CAP ≥ 274 dB/m or ≥ 248/302 dB/m) plus one or more cardiometabolic risk factors: overweight/obesity, impaired glucose metabolism, elevated blood pressure, elevated triglycerides, low HDL; excluded individuals with excessive alcohol consumption or other identifiable causes of hepatic steatosis

CAP: controlled attenuation parameter on vibration-controlled transient elastography

Table 2. Prevalence of Multimorbidity and Polypharmacy Among Individuals with and without Gout in the US in 2017-18

	Gout (n =338)		No Gout (n =5222)		OR (95% CI)	P value for Interaction

Abstract Number: 1996

Hospital Burden of Crystal-related Arthritis in Spain: a nationwide dataset of 183,001 inpatients.

Cristina Rodríguez-Alvear[1], Fernando Borrás[2] and Mariano Andrés[3], [1]Virgen de la Peña General Hospital, Fuerteventura, Spain, [2]Miguel Hernández University of Elche, Alicante, Spain, [3]Dr Balmis Alicante General University Hospital-ISABIAL, Alicante, Spain

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1990–2014) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Gout and calcium pyrophosphate crystal deposition disease (CPPD) are frequent in hospital settings. In Spain, last available data (2005-2015) indicated that 0.48% of hospital discharges had a gout diagnosis, with rising prevalence and mortality (PMID 34168227). Conversely, no population-based studies exist for CPPD. We aimed to analyze prevalence, hospital stays, mortality, and costs of hospitalized patients with gout or CPPD between 2016 and 2022 in Spain.

Methods: We used the Minimum Basic Data Set (MBDS) from the National Health Service to study adult patients with any primary or secondary diagnosis of gout (ICD-10-ES codes M10.X or M1A.X) or CPPD (M11.X) admitted to public or private hospitals between 2016 and 2022.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Prevalence with 95% confidence intervals (CIs) and temporal trends were calculated over annual hospitalization discharges. Differences in age, sex, mean hospital stay, mortality, and costs (measured based on All Patient Refined Diagnosis-Related Groups) were analyzed between patients with gout and CPPD, stratified by being primary or secondary diagnoses. Kruskal-Wallis and chi-square tests were used for comparisons.

Results: After excluding 13,987 for errors in coding, we studied 183,001 patients in the 2016–2022 period. The prevalence of gout was 0.58% (n=167,693/28,861,486; 95%CI 0.58-0.58%), coded as primary diagnosis in 5,314 (3.2%) and secondary in 162,379 (96.8%). Meanwhile, the prevalence of CPPD was 0.05% (n=14,473/28,861,486; 95%CI 0.05-0.05%), mostly as secondary diagnoses (95%, n=13,752). 835 patients had both crystal diagnoses.

Compared to gout, patients with primary or secondary CPPD were older (74.4±14.2 vs 70.8±14.3 years, $p< 0.001$; 79.7 ±10.9 vs 74.8±12.1 years, $p< 0.001$) with a female predominance (52.6% vs 15.8%, $p< 0.001$; 61.4% vs 16.5%, $p< 0.001$). The average age steadily increased up to +2.4 years in gout and +4.8 in CPPD in the study period.

Mean hospital stay was significantly longer in gout than in CPPD (6.5±7 vs 5.6±5.3 days, $p< 0.001$). It decreased only for patients with secondary diagnoses of gout or CPPD (Gout: -0.7 days, $p< 0.001$; CPPD: -0.1 days, $p=0.047$).

Mortality of inpatients with primary diagnosis was 0.7% in gout and 0.1% in CPPD ($p< 0.001$). In secondary diagnoses, respective mortalities were 6.1% and 4.7% ($p< 0.001$). Mortality showed a significant increase in gout (Primary Gout: +0.5%, $p=0.02$; Secondary Gout: +1%, $p< 0.001$), while only in secondary diagnoses of CPPD (+1.1%, $p< 0.001$).

Costs were similar in gout and CPPD-related hospitalizations (3624.6±1794.66 € and 3645.40±1644.52 €), but higher for gout in secondary diagnoses (5318.5±5257.6 € vs 4933.9±4316.3 €, $p< 0.001$). In all cases, mean costs increase progressively.

Conclusion: The updated prevalence of gout in hospitalizations surpasses previous reports. Novel national CPPD data shows it occurs more frequently in older patients and women. Gout results in longer hospital stays and higher mortality. Hospitalizations, age, costs, and mortality rates rose during the study period, indicating a significant burden of crystal-related arthritis in hospitals.

Background/Purpose: Patients with gout may be at high risk for developing osteoporosis and fractures, but osteoporosis may be under-recognized and inadequately managed for gout patients. We evaluated fracture rates and features associated with bone health management in patients with gout and comparator groups using data from the American College of Rheumatology's (ACR) Rheumatology Informatics System for Effectiveness (RISE) registry linked to Medicare claims data.

Methods: We performed a retrospective analysis of the RISE registry linked to claims data, 2015-2021. Inclusion criteria: age ≥18 at index (later of qualifying cohort diagnosis date, enrollment start+365 days), ≥1 provider visit after index, and no baseline immunomodulators. Gout and two comparator cohorts (osteoarthritis [OA], soft tissue rheumatism [STR]) were identified using ICD-10-CM codes and medications, and patients were selected via this hierarchy. Gout required ≥2 ICD-9/10 codes and urate-lowering therapy or colchicine. Comparator groups required ≥2 ICD-9/10 codes for OA or STR and no ULT or colchicine. Patients in the gout cohort were matched 1:1 by age (±2 years), sex, race, and Medicare enrollment quarter to patients in the OA cohort and (separately) to the STR cohort. We examined medications, comorbidities,

OA: osteoarthritis. STR: soft tissue rheumatism. SMD: standardized mean difference. SD: standard deviation. IQR: Interquartile range. BMI: body mass index. ADI: area deprivation index. GC: glucocorticoid. IMM: immunomodulatory therapy. NSAID: nonsteroidal anti-inflammatory drug. ULT: urate lowering therapy. BP: bisphosphonate. IV: intravenous. COPD: chronic obstructive pulmonary disease. CPD: chronic pulmonary disease.
Note: All baseline characteristics utilized the most recent measurements prior to the index, unless otherwise specified. IMM includes cyclosporine, leflunomide, methotrexate, and sulfasalazine. ULT includes allopurinol, febuxostat, probenecid, lesinurad, pegloticase. Bone protective therapy includes oral/IV bisphosphonate, raloxifene, denosumab, romosozumab, teriparatide, and abaloparatide.
SMDs > 0.10 is a common threshold used to identify factors that may be clinically relevant.
* n(%) or median (IQR)
** on or before index date

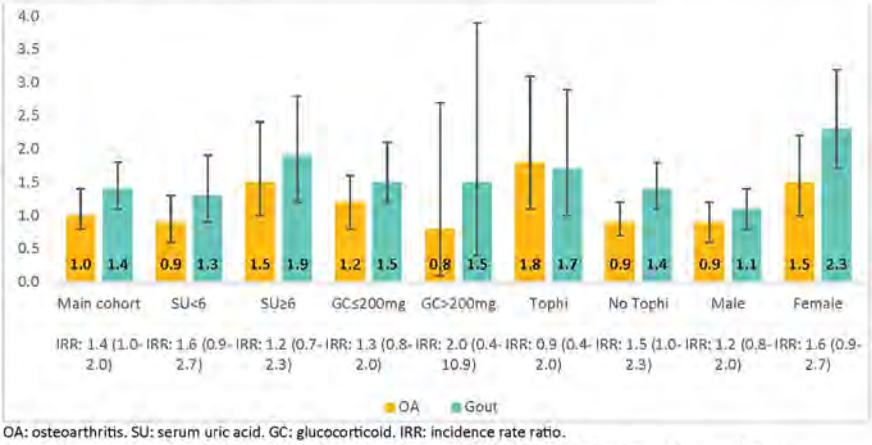
demographics, and bone protective therapy use and computed crude and adjusted incidence rates (IRs) and incidence rate ratios (IRRs) for fracture (allowing for multiple events) in the gout vs. comparator cohorts.

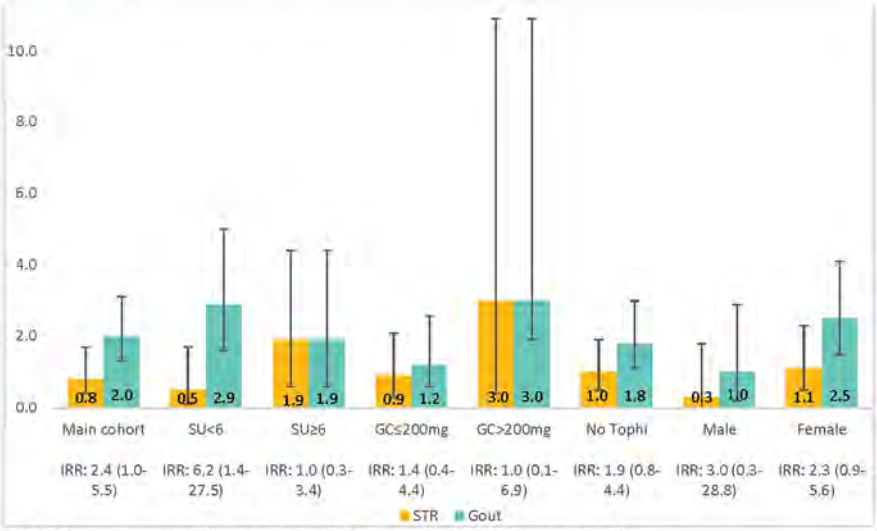
Results: We identified 6700 gout patients and matched them to 6700 OA patients. Most were white (85.5%) and male (64.2%), with median age of 72.0 years (Table 1). Approximately 5% of patients with gout used bone protective therapy at baseline, compared to 11.8% in OA. Baseline fracture and osteoporosis diagnosis prevalence was 1.4% and 7.1% in gout vs. 2.6% and 15.4% in OA patients. The gout and STR cohorts were smaller (n=1544 each) and mostly female (73.3%) with

Figure 1 : Follow-Up Nonvertebral Fracture Incidence Rates per 100 patient-years in Patients with Gout vs. Osteoarthritis*



OA: osteoarthritis. SU: serum uric acid. GC: glucocorticoid. IRR: incidence rate ratio.
*among individuals not using bone protective therapies at baseline. Crude IRs and IRRs for the matched populations.
For the GC ≤200mg subgroup, the patients are in matched pairs, and both patients have GC ≤200mg at baseline. The same applies to the GC >200mg subgroup. For the SU <6 subgroup, the patients are in matched pairs, but the SU condition is restricted only to patients with gout. The same applies to the SU ≥6 subgroup, tophi, and no tophi subgroups.

Figure 2: Nonvertebral Fracture Incidence Rates per 100 patient-years in Patients with Gout vs. Osteoarthritis*



STR: Soft tissue rheumatism. SU: serum uric acid. GC: glucocorticoid. IRR: incidence rate ratio.
*among individuals not using bone protective therapies at baseline. Crude IRs and IRRs for the matched populations.
For the GC ≤200mg subgroup, the patients are in matched pairs, and both patients have GC ≤200mg at baseline. The same applies to the GC >200mg subgroup. For the SU <6 subgroup, the patients are in matched pairs, but the SU condition is restricted only to patients with gout. The same applies to the SU ≥6 subgroup and no tophi subgroups.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

demographics otherwise similar to the gout/OA cohorts. Approximately 9.0% of patients with gout used bone protective therapy at baseline, compared to 23.2% in STR. Baseline fracture and osteoporosis diagnosis prevalence was 1.9% vs. 10.9% in gout and 3.4% vs. 30.7% in STR.

Excluding the small number of patients using baseline bone protective medications, higher fracture rates were observed in gout patients compared to OA (IRR: 1.4, 95% CI: 1.0,2.0) and STR (IRR: 2.4, 95% CI: 1.0,5.4) (Figures 1 and 2). The IRRs comparing gout to OA patients were minimally different after adjustment for BMI, NSAIDs, diabetes, and comorbidity, but were higher compared to the STR cohort (aIRR 4.1; 95% CI: 1.4,12.4). New bone protective therapies were infrequently used in all cohorts during follow-up (gout: 2.0% vs. OA: 4.5%; gout: 3.4% vs. STR: 10.3%).

Conclusion: Patients with gout experience greater rates of fracture and more commonly have fracture risk factors (e.g. chronic kidney disease, greater glucocorticoid use) compared to OA and STR patients yet are less likely to receive bone protective therapies. Improved awareness of the risk of fracture and osteoporosis in gout appears warranted, as are strategies to protect bone health in gout patients.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1990–2014) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Patients (pts) with uncontrolled gout (UG) and tophi experience joint pain, impaired function and poor quality of life (Schlesinger *et al. Semin Arthritis Rheum* 2020; Dalbeth *et al. Nat Rev Dis Primers* 2019; Dalbeth *et al. Lancet* 2021). With oral urate-lowering therapies, tophus resolution may take several years despite optimal dosing (Laurent *et al. RMD Open* 2023). NASP (formerly SEL-212) is a novel, every 4-week, sequential infusion therapy consisting of targeted immunomodulating, nanoencapsulated sirolimus (NAS; formerly SEL-110) co-administered with a pegylated uricase (formerly SEL-037) designed to reduce serum uric acid (sUA) levels in pts with UG. Here, we report pooled tophus outcomes from the DISSOLVE studies.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

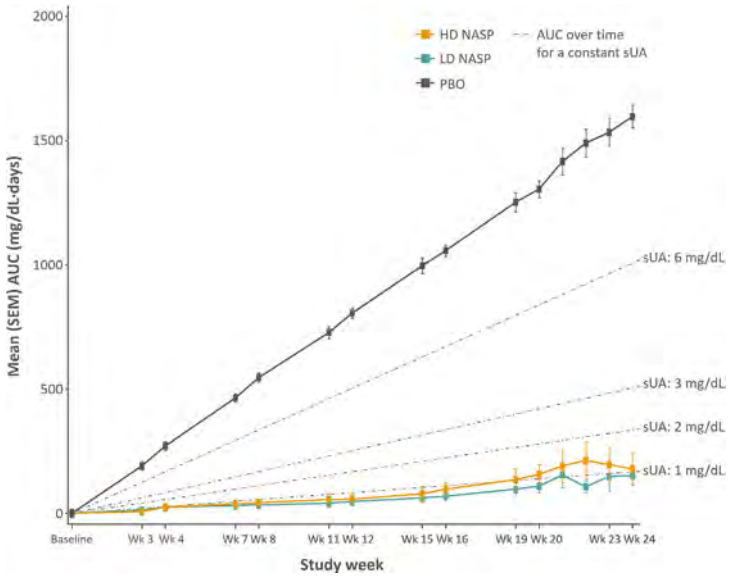

Figure 1. Mean cumulative sUA AUC through week 24 in patients who completed 6 doses of NASP or PBO with tophi at baseline. Cumulative sUA is a measure of the duration and intensity of sUA exposure over time, defined in this study as AUC at each time point (average of the current and previous sUA values multiplied by the time between the current and previous sUA values). The cumulative sUA AUC at each study week in the figure is the total AUC from day 1 up to that week. SUA assessments were performed at the end of each week. Mean (±SEM) is shown for pts with tophi at baseline who completed 6 doses of HD NASP (yellow), LD NASP (teal) or placebo (dark gray). Dashed lines show what the cumulative area under the curve would be at each point in time for a subject that had constant sUA level. AUC, area under the curve; HD NASP, sequential infusions of 0.15 mg/kg nanoencapsulated sirolimus and 0.2 mg/kg pegadricase, LD NASP, sequential infusions of 0.10 mg/kg nanoencapsulated sirolimus and 0.2 mg/kg pegadricase; PBO, placebo; SEM, standard error of mean; sUA, serum uric acid; Wk, week.

Methods: This *post hoc* analysis pooled data from DISSOLVE I II ((NCT04513366, NCT04596540) in the intent-to-treat (ITT) population and in pts who received 6 doses of NASP (high-dose [HD]: sequential infusions of 0.15 mg/kg NAS and 0.2 mg/kg pegadricase; low-dose [LD]: sequential infusions of 0.10 mg/kg NAS and 0.2 mg/kg pegadricase) or placebo (PBO). Tophi response was a predefined secondary endpoint. Percent tophus response included partial response (PR), defined as ≥50% and < 100% reduction in the area of a tophus without enlargement of any existing tophus and no new tophus, and complete response (CR), defined as 100% reduction in area of or complete disappearance of a tophus without enlargement of any existing tophus and no new tophus. A triple read model of tophus evaluation was established after unblinding to improve the quality of measuring tophus size and improve data handling in instances of images with quality issues.

Results: In the ITT population (among pts with tophi at baseline (BL): n=55 [HD]; n=55 [LD]; n=57 [PBO]), tophus response of PR or better was observed in 82% in HD (p=0.0077), 88% in LD (p=0.0016), vs 51% in PBO by week 24. NASP treatment resulted in a clinically relevant response of CR in significantly more patients receiving NASP compared with PBO by week 24: HD, 31% (p=0.0044); LD, 48% (p=0.0001), vs PBO, 5%. In the subset of pts with tophi at BL who received 6 doses of treatment (n=23 [HD]; n=22 [LD]; n=42 [PBO]), a significantly greater proportion of patients on NASP experienced CR by week 24: HD, 49% (p=0.0002); LD, 70% (p< 0.0001), vs PBO, 5%. Consistent with the correlation between tophus reduction and sUA reduction, patients who received 6 doses of HD NASP had 89% lower sUA than PBO-treated patients at Day 168 (end of study) with a similar response for LD NASP (**Figure 1**).

Conclusion: Treatment with NASP resulted in a greater tophus response compared to PBO. In addition, a robust sUA reduction, a key factor in tophus resolution, was observed in NASP-treated pts. These results highlight the effectiveness of NASP in lowering sUA and promoting tophus resolution.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1990–2014) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Uricase-based therapies may profoundly lower serum uric acid (sUA) in patients (pts) with uncontrolled gout (UG) but often lead to anti-drug antibody (ADA) formation, which can predispose pts to infusion reactions (IRs). NASP (formerly SEL-212) is an investigational, novel, every 4-wk (Q4W), sequential 2-component infusion therapy consisting of tolerogenic nanoencapsulated sirolimus (NAS, formerly SEL-110), which mitigates formation of antipegadricase antibodies, and a uricase (pegadricase [P]; formerly SEL-037), which reduces sUA. NASP has shown efficacy and safety in UG (Baraf *et al*. *Rheumatology* 2024). To characterize events that met Rheumatology Common Toxicity Criteria for allergic reaction/hypersensitivity and anaphylaxis (Woodworth *et al*. *J Rheumatol* 2001), we show pt-specific IR details within 1 h of NASP completion from the phase 3 DISSOLVE I and II (NCT04513366, NCT04596540) studies.

Methods: DISSOLVE I and II were replicate, double-blind, placebo (PBO)-controlled trials evaluating 2 NAS doses (0.15 [high-dose; HD] or 0.1 mg/kg [low-dose; LD]) prior to 0.2 mg/kg P in adults with a UG diagnosis per ACR guidelines (Neogi *et al*. *Arthritis Rheumatol* 2015). Eligible pts had a history of symptomatic gout (≥3 gout flares within 18 mo of screening, ≥1 tophus, or current gouty arthritis), lack of sUA normalization and symptom control despite urate-lowering therapies, and sUA ≥7 mg/dL. Pts were randomized 1:1:1 to receive NASP (HD or LD) or PBO Q4W with preinfusion IR prophylaxis (up to six 4-wk treatment periods). Twenty-four–wk safety outcomes included IRs (eg, anaphylaxis, hypersensitivity) within 1 h per NIAID/FAAN criteria (Sampson *et al*. *Ann Emerg Med* 2006).

Results: Overall, 175 pts received HD (n=87) or LD (n=88) NASP; 90 received PBO. Of these, 7 pts (overall: n=7/175, 4.0%; HD NASP: n=3/87, 3.4%; LD NASP: n=4/88, 4.5%; PBO: n=0) had an IR within 1 h of NASP completion (all male; aged 36–63 y). Six IRs occurred shortly after exposure to both NASP components; 1 was during NAS only (pt did not receive P). All IRs were early in the study (first 12 wk). Of the 7 pts with IRs within 1 h, 4 had anaphylactic reactions (2.3% of NASP-treated

pts overall; 2 in each NASP arm). Common signs/symptoms included rash and shortness of breath. Three of these IRs were grade (G) 3 (2 HD NASP; 1 LD NASP); 1 LD NASP-treated pt had a G4 IR. All pts fully recovered with appropriate medical intervention (mainly steroids and antihistamines) provided at the infusion center; 1 pt received epinephrine for anaphylaxis. One pt each in the HD/LD NASP arms (G3/G4 IRs, respectively) was sent to the emergency room, received observation only, and was discharged the same day. No pts required in-pt hospitalization or intubation. Three pts had hypersensitivity reactions (2 G1; 1 G2); signs/symptoms included flushing (most common) and shortness of breath (G2 only). No pts with hypersensitivity reactions were hospitalized; 1 pt was able to resume NASP after a pause.

Conclusion: The low incidence (4.0%) of pts experiencing IRs, including hypersensitivity reactions, within 1 h of NASP suggests that NAS mitigates ADA formation. No pts required in-patient hospitalization or intubation, and all IRs resolved with standard measures (mainly at the infusion center).

Disclosure: H. Baraf: Arthrosi, 2, Olatec, 2, Otsuka, 3, Pacira, 2, Selecta Biosciences, 2, Sobi, 2; **A. Sulich**: AbbVie, 6, AM, 6, Amgen, 6, AstraZeneca, 6, GlaxoSmithKlein(GSK), 6, UCB, 6; **G. Can Uric Acid Protect Joints? Lower Incidence of Large Joint Replacements Among Individuals with Higher SUA

Janis Timsans[1], Raine Tiihonen[2], Jenni Kauppi[3], Vappu Rantalaiho[4], Anne Kerola[1], Kia Hakkarainen[5], Tiina Lehto[6], Hannu Kautiainen[7] and Markku Kauppi[1], [1]Päijät-Häme Central Hospital, Department of Rheumatology, Lahti, Finland, [2]Päijät-Häme Central Hospital, Department of Orthopedics and Traumatology, Lahti, Finland, [3]Päijät-Häme Central Hospital, Unit of Physiatry and rehabilitation medicine, Lahti, Finland, [4]Tampere University, Faculty of Medicine and Health Technology; Tampere University Hospital, Centre for Rheumatic Diseases, Tampere, Finland, [5]Päijät-Häme Central Hospital, Department of Nephrology, Lahti, Finland, [6]Fimlab Laboratoriot Oy, Department of Clinical Chemistry, Lahti, Finland, [7]Folkhälsan Research Center, Helsinki, Finland

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1990–2014) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Serum uric acid (SUA) has been linked to various health conditions, including osteoarthritis (OA), though findings have been inconsistent. Data on the relationship between SUA and OA in large joints are particularly limited, and its potential association with the need for large joint replacements (LJRs) has not been previously investigated. This study aimed to examine the association between SUA levels and the incidence of LJRs.

Methods: Data were drawn from the GOAL (**GO**od **A**geing in **L**ahti region) study, a prospective cohort study of individuals aged 52–76 years in Finland's Lahti region. Baseline data included SUA levels, other laboratory parameters, comorbidities, medication use, lifestyle factors, and socioeconomic variables. Information on LJRs was obtained from the National Care Register for Social Welfare and Health Care. After excluding participants with prior LJRs or cancer diagnoses, 2,403

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

individuals (1,115 women and 1,288 men) were included. The incidence of large joint arthroplasty over a 12.7-year follow-up was analyzed in relation to SUA levels, adjusting for age, sex, body mass index (BMI), and Charlson Comorbidity Index (CCI). Hyperuricemia was classified as renal when SUA was ≥420 μmol/L (≈7 mg/dL) and estimated glomerular filtration rate (eGFR) ≤67 ml/min/1.73 m^2 (25^{th} percentile), and as metabolic when SUA was ≥420 μmol/L with eGFR >67 ml/min/1.73 m^2.

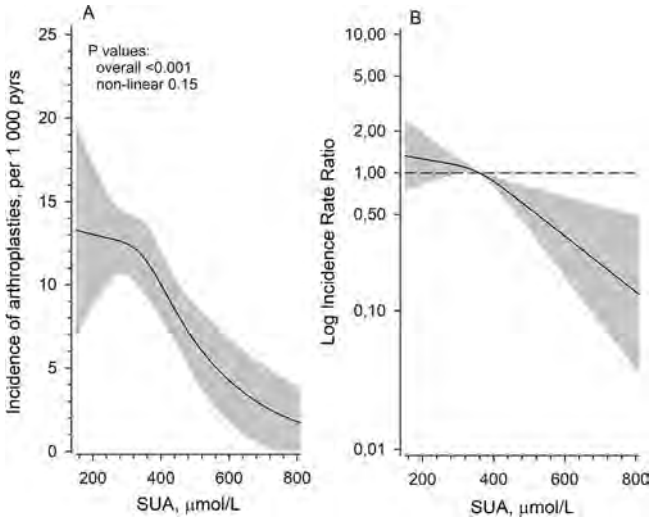

Figure 1. Panel A: Association of serum uric acid (SUA) level and incidence of arthroplasties. Panel B: Log incidence rate ratio of arthroplasties by SUA level. Denominator of IRR is SUA 420 μmol/L. The results are adjusted for age, sex, body mass index and Charlson Comorbidity Index.

Table 1. Incidence and incidence rate ratio (IRR) for incident large joint replacements across different SUA groups. SUA, serum uric acid; LJRs, large joint replacements; pyrs, person-years; IRR, incidence rate ratio

SUA	[Total number of LJRs] Incidence* (95% CI) per 1000 pyrs	IRR (95% CI)*
<300, μmol/L	[88] 13.4 (10.4 to 16.4)	1.00 (Reference)**
300-359, μmol/L	[96] 11,7 (9.4 to 14.1)	0.88 (0.65 to 1.18)
≥360, μmol/L	[69] 11,0 (8.4 to 13.6)	0.82 (0.59 to 1.14)
≥420, μmol/L	[50] 7.1 (5.0 to 9.2)	0.53 (0.36 to 0.78)
		p for linearity 0.006*
Total	[303] 11.2 (10.1 to 12.3)	

*Adjusted for age, sex, body mass index and Charlson Comorbidity Index.
** Denominator of incidence rate ratios

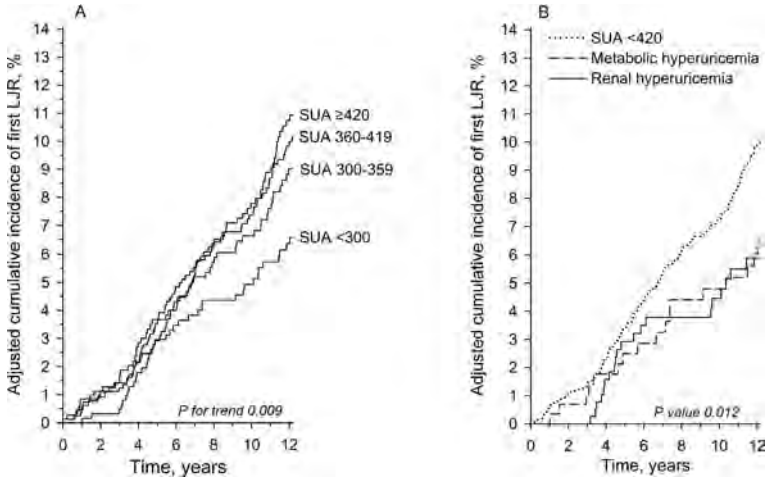

Figure 3. Adjusted cumulative incidence of first LJR. SUA, serum uric acid; LJR, large joint replacement

23265203, 2025, 59, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Over the 12.7-year follow-up period, a total of 303 LJRs were performed in the study population, including 133 hip replacements, 161 knee replacements, 8 shoulder replacements, and 1 elbow replacement; no ankle replacements were reported. In models adjusted for age, sex, BMI, and CCI, higher SUA levels were associated with a lower incidence of LJRs (Figure 1). When analyzing the incidence rate ratio across SUA categories (< 300 μmol/L, 300–359 μmol/L, 360–419 μmol/L, ≥420 μmol/L), a statistically significant decreasing trend in LJRs with increasing SUA was observed ($p = 0.006$; Table 1). While the adjusted cumulative incidence of first LJR increased with higher SUA, there was no substantial difference between individuals with metabolic versus renal hyperuricemia (Figure 2).

Conclusion: In our study population, individuals with higher SUA levels were less likely to undergo LJR during the 12.7-year follow-up period. This finding has not been previously demonstrated. Future studies are needed to determine whether uric acid has a protective effect on cartilage in large joints, potentially reducing cartilage degradation. Replicating our findings in other studies and further investigating the impact of uric acid on cartilage health are essential.

Session Title: (1990–2014) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Gout flares are an important treatment outcome in gout. Although flares are typically assessed by occurrence (yes/no) or a simple count in trials of urate-lowering therapy (ULT), it is possible that certain flare characteristics could also serve as a measure of ULT efficacy. We evaluated gout flare characteristics among trial participants who were started on treat-to-target ULT and assessed the extent to which achievement of serum urate (SU) goal impacted flare characteristics.

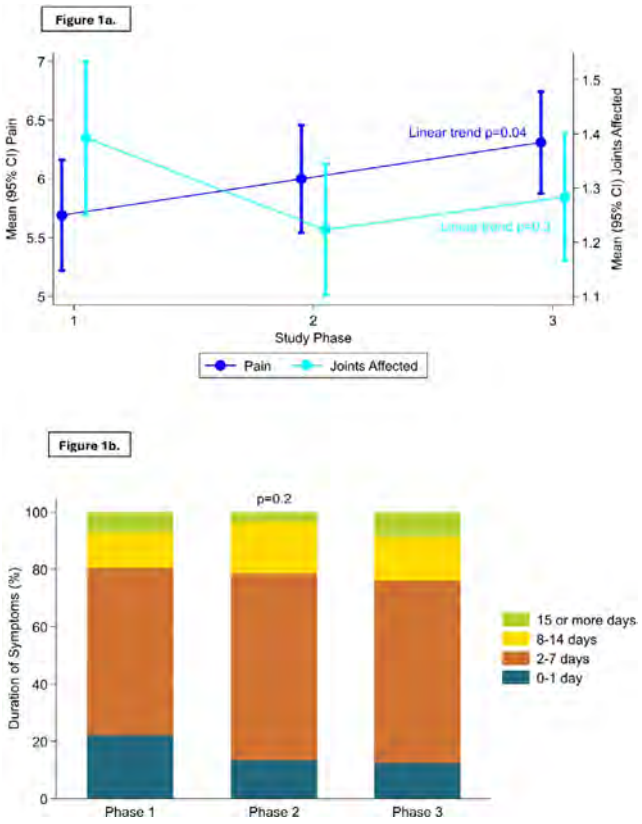

Figure 1a. Mean Pain Intensity and Mean # of Joints Involved for the 1st Flare Within Each Phase in Those who Experienced at least 1 Flare in All Three Phases (n=113). Figure 1b. Duration of Flare Symptoms for the 1st Flare Within Each Phase in Those who Experienced at least 1 Flare in All Three Phases (n=113).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Methods: We performed a post-hoc analysis of the STOP Gout trial, a non-inferiority, randomized, double-blind, placebo-controlled trial of allopurinol vs. febuxostat (PMID 35294114). In Phase 1 (0-24 weeks), ULT dose was adjusted to achieve SU goal (i.e., < 6mg/dL or < 5mg/dL with tophi) and prophylaxis was provided (NSAIDs, colchicine, glucocorticoids). In Phase 2 (25-48 weeks), a single ULT dose adjustment was allowed to achieve SU goal. Prophylaxis was discontinued prior to Phase 3 (49-72 weeks). Flares were identified throughout the trial using a modification of validated criteria. Flare characteristics were assessed as pain intensity, number of joints involved, and duration. For those experiencing a flare during all 3 study Phases, characteristics of the first flare in each Phase were compared via generalized linear mixed models with random effects for participants. We next compared characteristics of the first flare in Phase 3 (when participants were off prophylaxis) based upon SU goal achievement at the end of Phase 2. We repeated these analyses limited to those without baseline tophi because the flare criteria may be less sensitive in those with tophi.

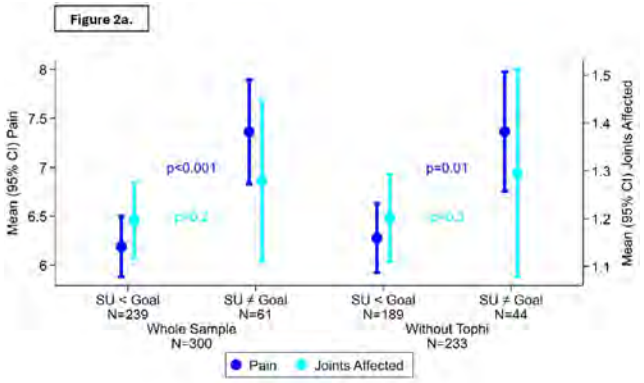
Results: Of the 940 STOP Gout participants, 602 (64%) (99% male, mean baseline SU 8.6mg/dL, 19% with tophi) had ≥1 flare during the 72-week study. Flare characteristics were similar across the 3 Phases among the 113 participants with ≥1 flare in each of Phase 1-3 (**Figure 1**); these results did not change after excluding those with tophi (not shown). Of 835 participants with SU measured at the end of Phase 2, 239/648 (37%) who achieved SU goal and 61/187 (33%) who didn't achieve SU goal had ≥1 flare in Phase 3. Flares in those who achieved SU goal had significantly lower mean pain intensity, but similar durations and number of joints involved than in those who did not (**Figure 2**). Among those without baseline tophi, both flare pain intensity and symptom duration were significantly lower with SU goal achievement (vs. not) (**Figure 2**).

Conclusion: In those who experienced ≥1 flare in all three study phases, the flare characteristics did not change meaningfully over time. However, achievement of SU goal was associated with significantly lower pain intensity and shorter symptom duration among those without tophi. With prior reports suggesting that ≥2 years of oral ULT may be required to meaningfully



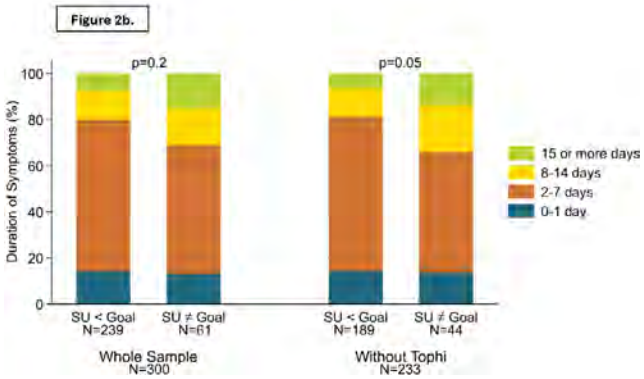


Figure 2a. Comparison of Mean Pain Intensity and Mean # of Joints Affected for the 1st Flare in Phase 3 Based on SU Goal Achievement in the Whole Sample (n=300) and in Those Without Baseline Tophi (n=233). Figure 2b. Comparison of Duration of Flare Symptoms for the 1st Flare in Phase 3 Based on SU Goal Achievement in the Whole Sample (n=300) and in Those Without Baseline Tophi (n=233).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. reduce flares counts, these results suggest that the inclusion of flare characteristics such as pain intensity and symptom duration into trial outcomes could potentially provide insights into efficacy of ULT in a shorter amount of time than conventional studies utilizing flare counts as the outcome.

Background/Purpose: Informative censoring in epidemiologic research studies (the loss of data from the risk set that is related to the exposure and/or outcome) can cause bias in the estimation of causal risks. An example of this bias occurs when there is a competing risk of death for an outcome that occurs in older individuals, such as dementia. Gout and hyperuricemia have been associated with a lower risk of dementia in observational studies, leading to questions about the potential neuroprotective role of hyperuricemia. However, these prior findings may result of this type of bias. In this situation, *gout may appear to lower the risk of dementia because many patients with gout do not live long enough to develop it*. The purpose of this study was to evaluate distinct methods to estimate causal risks of gout on the risk of dementia using data from the Veterans Affairs (VA) health system.

Methods: We studied patients with gout and age- and sex- matched controls from national VA health record data. We defined incident cases of gout based on the presence of an ICD-9 or ICD-10 code from at least two separate encounters at least 30 days apart and matched to controls of similar age, sex, and calendar year. The outcome of dementia was defined using previously validated administrative algorithms. An extensive list of comorbidities, medications, and other covariates were extracted from the medical record and defined using validated algorithms. We tested three approaches to estimating the causal risks of gout: 1) a traditional Cox model, 2) a commonly used competing risks model (Fine & Gray) and 3) a joint frailty model that accounts for informative censoring by considering the propensity for dementia among those that died (Figure 1). Due to large sample sizes and computational requirements, we meta-analyzed up to 30 models for each method run on the same randomly selected samples of 0.1% of the population adjusting for potential confounders identified in the descriptive analysis.

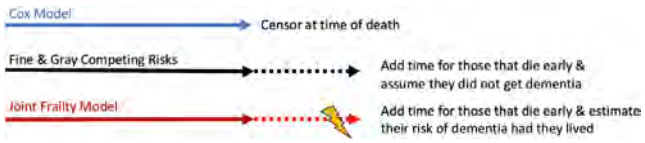

Figure 1: Illustration of modeling approaches to consider the competing risk of death.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

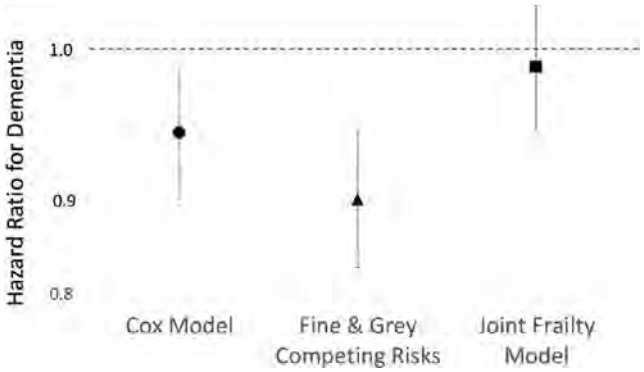

Figure 2: Hazard Ratios for the risk of dementia for patients with gout based on 3 distinct modeling approaches: 1) Cox proportional hazards model (circle), 2) Fine and Gray competing risks model (triangle), and 3) the joint frailty model (square).

Results: There were significant and expected differences in patient characteristics between the 533,465 patients with gout and 4,935,717 matched controls including higher body mass index (BMI) and higher rates of cardiovascular comorbidity (not shown). In the traditional adjusted Cox model that assumes that censoring is uninformative, the risk of dementia among patients with gout was significantly lower than controls [HR: 0.93 (95% CI: 0.87, 0.98)]. The protective effect was larger in Fine & Gray competing risks models [HR 0.90 (95% CI: 0.85, 0.96)]. In contrast, the joint frailty model accounting for informative censoring suggested no significant reduction in dementia risk in gout compared to controls [HR: 0.97 (95% CI: 0.91, 1.03)] (Figure 2).

Conclusion: Estimates of the risk of dementia in patients with gout varied according to the method used to address the competing risk of death. Analyses performed using a method that more comprehensively accounts for informative censoring suggested no reduction in the risk of dementia among patients with gout. These findings call into question the results of multiple prior studies and should help to reassure clinical providers that urate-lowering to manage gout is not likely to increase the long-term risk of dementia.

Includes pegloticase new users with 12 months of baseline and follow-up data and receiving label recommended 12 infusions within 180 days. Patient socio-demographics characteristics were measured on index date, while clinical characteristics were measured at baseline.

treatment, remains limited. This study assessed gout flare outcomes pre and post treatment amongst pts with uncontrolled gout treated with pegloticase.

Methods: The study included adults diagnosed with gout who were newly treated with pegloticase between January 1, 2018, and December 31, 2021 in the MORE2 registry or Medicare Fee-For-Service (FFS) databases. Pts were required to have at least 360 days of baseline and follow-up enrollment from the index date (date of first pegloticase dose) and at least 12 infusions of pegloticase within 180 days from the index date. The primary outcome, gout flare, was identified as follows: 1) having an inpatient visit with a primary diagnosis of gout or 2) having an outpatient or emergency department claim with a diagnosis of gout accompanied by treatment or follow-up visit within a 7-day period, or 3) an outpatient or ED claim with a diagnosis for unspecified joint pain accompanied by a claim for oral/injectable colchicine within 7 days. Gout flare rates as well as secondary outcomes of any glucocorticoid prescription and any opioid prescription were assessed during the following time periods: from 360 days prior to index date to the day prior to the index date (baseline), from end of the first 180 days after index date until the earliest event of death, disenrollment or end of study (12/31/2022) (Follow-up 1), and from date of pegloticase treatment discontinuation to the earliest of death, disenrollment or end of study (12/31/2022): (Post completion). The outcomes were

Table 2. Pegloticase treatment characteristics during the follow-up period

Pegloticase treatment pattern	
Methotrexate combination therapy (n, %)	70 (34.5%)
Number of pegloticase claims (mean [SD])	26.7 (17.9)
Time on pegloticase in days (mean [SD])	376.5 (247.5)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 3. Flare and treatment outcomes pre-post pegloticase

	Baseline[&]	Follow-up 1[#]	Post completion[^]
Gout flare rate per person per years	1.3	0.2*	0.1*
Glucocorticoid prescription (n, %)	171 (84.2%)	111 (54.7%)*	80 (39.4%)*
Opioid prescription (n, %)	169 (83.3%)	127 (62.6%)*	92 (45.3%)*

*p-value<0.001 compared with baseline using generalized estimating equations.
Gout flares were identified as follows: having an inpatient visit with a primary diagnosis of gout or OR having an outpatient or emergency department (ED) claim with a diagnosis of gout accompanied by treatment or follow-up visit within a 7-day period, OR an outpatient or ED claim with a diagnosis for unspecified joint pain accompanied by a claim for oral/injectable colchicine within 7 days.
[&]Baseline period was defined as 360 days prior to index date to the day prior to the index date.
[#]Follow-up 1 was defined as period from the end of the first 180 days after index date till the earliest of death, disenrollment or end of study (12/31/2022).
[^]Post completion was defined as period from the date of pegloticase treatment discontinuation to the earliest of death, disenrollment or end of study.

compared between baseline and Follow-up 1 and between baseline and post completion using generalized estimating equations.

Results: The final cohort included 203 pts initiating pegloticase (mean [SD] age: 67.1[13.1] years; 76.4% male; 67.5% White) with a mean [SD] Elixhauser comorbidity score of 9.0 [9.12] (Table 1). The most prevalent baseline comorbidities were hypertension (85.2%), osteoarthritis (50.2%), chronic kidney disease (57.6%), and type 2 diabetes mellitus (41.87%). The average treatment duration was 376.5 days (SD=247.5), and 70 (34.5%) of the pts had a co-prescription for methotrexate (Table 2). At baseline the cohort experienced a flare rate of 1.3 flares per person years (ppy), which was significantly reduced at Follow-up 1 (0.2 flares ppy) and at post completion period (0.1 flares ppy); (Table 3). Similarly, both proportion of pts with a prescription for glucocorticoids and with a prescription for opioids were lower by at least 20 percentage points during Follow-up 1 compared to baseline and by at least 35 percentage points at post completion compared to baseline.

Conclusion: Pts with CRG, treated with pegloticase in the MORE[2] and Medicare FFS, showed a substantial reduction in the rate of gout flares during the follow-up periods. These data further support the use of pegloticase, as a uric acid debulker, for CRG management, thus decreasing the risk of flareup.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1990–2014) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The burden of gout is rising in low-income and middle-income countries in the Asia-Pacific region. However, individuals with gout in this region remain underrepresented in research, resulting in a limited understanding of the unique challenges and pain points shaped by their geographic and cultural context. The Asia Pacific League of Associations for Rheumatology (APLAR) Gout Registry was established to gain a deeper understanding of the characteristics and management of gout among patients in this region.

Methods: This is a longitudinal, multinational, rheumatologist-reported registry that began in August 2023. It includes adults (aged 18 years or older) diagnosed with gout who are under the care of, and being followed by, participating rheumatologists. Gout was defined as having experienced at least one gout flare and receiving a diagnosis of gout by the reporting physician. Data on demographics, comorbidities, gout symptoms, gout treatments, serum urate levels, and flares were collected over a 12-month period from the time of recruitment.

Results: A total of 549 participants from eight countries were recruited, and data from 903 visits were collected by December 2024 (Figure 1). The cohort was predominantly male (512/549, 93%) with a mean age of 53 years. The most common

Figure 1. Participating Asia-Pacific countries

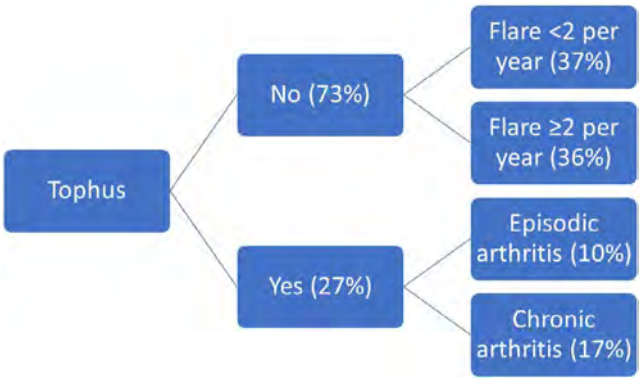

Figure 2. Clinical manifestations at baseline categorized by the presence of tophi and pattern of articular symptoms

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

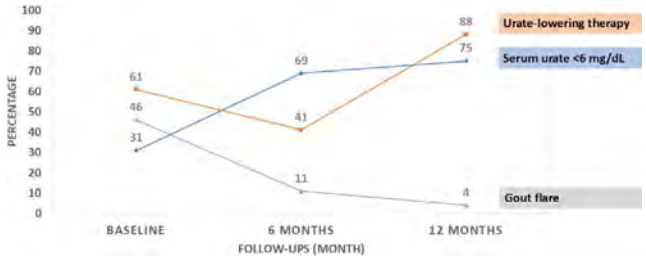

Figure 3. Prevalence of ULT prescription, gout flare and serum urate at target during 12-month period

comorbidities were hypertension (196/549, 36%), followed by hyperlipidemia (123/549, 22%) and chronic kidney disease (103/549, 19%). The mean duration of gout since the first flare was 8.2 years. The first metatarsophalangeal joint was the most commonly affected site (311/549, 57%). Tophaceous gout was present in 144 individuals (27%), and chronic symptoms were reported in 90 individuals (17%) (Figure 2). At baseline, 314 participants (57%) were receiving at least one urate-lowering therapy (ULT); however, only 128 of 498 individuals (30%) had a serum urate level below 6 mg/dL (0.36 mmol/L). Among those not taking ULT at baseline, 17% (40/235) were using colchicine for gout flare prophylaxis. At the 12-month follow-up, 75% (37/49) of individuals had achieved serum urate levels below 6 mg/dL, and 88% (43/49) were prescribed at least one ULT. Gout flares were reported in 46% (152/326) of participants at baseline, decreasing to 4% (2/49) at the 12-month follow-up (Figure 3).

Conclusion: Gout patients in the Asia-Pacific region face multiple challenges, including severe disease manifestations, low rates of ULT prescription, and poor attainment of serum urate targets. These suboptimal outcomes persist even under specialist care, highlighting the urgent need for improved gout management strategies in this population.

Abstract Number: 2005

Elevated Serum Uric Acid as an Independent Risk Factor for Multiple Stent Placement in Non-Hypertensive, Non-Diabetic Patients with Coronary Artery Disease: A Retrospective Cohort Analysis

qingyan li[1], Jianguo Li[1], Mengwen Niu[1], Tianshu chu[1] and **lemei an**[2], [1]Henan Provincial People's Hospital, zhengzhou, China (People's Republic), [2]Henan Provincial People's Hospital, zhengzhou

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1990–2014) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: While the relationship between serum uric acid (SUA) and coronary artery disease (CAD) remains controversial, emerging evidence suggests a particularly significant association in patients lacking traditional cardiovascular risk factors. The specific role of hyperuricemia in determining CAD severity in non-hypertensive, non-diabetic populations warrants further investigation.

Methods: In this retrospective cohort study, we analyzed 716 consecutive CAD patients undergoing percutaneous coronary intervention (PCI), with a focus on 279 individuals without hypertension or diabetes. We employed multivariable logistic

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

regression and stratified analyses to assess the independent association between SUA levels and multiple stent implantation (≥2 stents), a robust indicator of CAD complexity and prognosis. Hyperuricemia was defined using gender-specific thresholds (>420 μmol/L for males and postmenopausal females; >360 μmol/L for premenopausal females).

Results: In the overall cohort, multivessel disease (OR=2.27, 95% CI:1.94–3.96, p< 0.001) and diabetes (OR=1.47, 95% CI:1.05–2.07, p=0.027) independently predicted multiple stent placement. Notably, in the non-hypertensive, non-diabetic subgroup, hyperuricemia emerged as a strong independent predictor (OR=4.62, 95% CI:1.93–11.07, p=0.001), exceeding the predictive value of multivessel disease (OR=3.16, 95% CI:1.78–5.55, p< 0.001). No significant association was observed between SUA levels and stent number in the broader cohort.

Conclusion: Elevated serum uric acid independently predicts complex coronary lesions requiring multiple stent placements in non-hypertensive, non-diabetic CAD patients. These findings suggest that uric acid assessment may enhance risk stratification in this specific patient population, warranting further investigation into its clinical implications.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1990–2014) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with gout are frequently treated in the emergency department (ED) for flares but may not receive consistent outpatient care. Approaches to mitigate this care pattern are understudied. We tested whether a direct-to-patient multimodal behavioral intervention could improve outpatient follow-up for gout after an ED visit.

Methods: We conducted a multicenter parallel group randomized clinical trial at 4 geographically diverse sites in the U.S. Participants were randomized 2:1 to the intervention or usual care (control) groups. The intervention included: 1) a storytelling video with gout patient testimonials, and 2) patient navigation whereby patients were contacted by phone after their ED visit by lay navigators to encourage outpatient follow up for gout. We assessed outcomes by phone surveys at 3-months. The primary outcome was the proportion of participants with an outpatient visit addressing gout in the 3-months post-ED visit, assessed by self-report and electronic health record (EHR) review. Secondary outcomes included rates of gout medication use, opioid use, and acute care utilization in the 3 months post-ED visit (documented in EHR, and as binary composite outcome including self-report). We performed intent-to-treat (ITT) and per-protocol (PP) analyses (i.e., intervention participants that viewed the storytelling video and 1+ navigator interaction). Differences in proportions were compared using Chi square tests and means using t-tests.

P<0.05 represented in bold. *Not Married includes: divorced, widowed, separated, never married, a member of an unmarried couple. **not seeking work includes student, retired, disabled, unpaid primary care giver. Health status was assessed with the question "In general, how would you rate your health?" and 'good' defined by grouping the following answers: "extremely" or "very good". Health literacy was assessed with the question "How confident are you filling out medical forms by yourself?" and "inadequate" defined by grouping the following answers: "Somewhat", "A little bit", and "Not at all". PROMIS, Patient-Reported Outcomes Measurement Information System, SD, standard deviation. Marital Status missing for 3 individuals; health status missing for 3 individuals; health literacy missing for 2 individuals; education level missing for 3 individuals; employment status missing for 4 individuals; income missing for 13 individuals; smoking status missing for 5 individuals; alcohol use missing for 4 individuals.

Results: From June 2021 to June 2024, 200 individuals (mean age 58 years; 76% men, 69% Black), were enrolled, with 135 randomized to intervention and 65 to control groups. Baseline characteristics are reported in Table 1. In ITT analyses, we found no significant differences between intervention vs control groups in rates of outpatient gout follow-up (47% vs 54%, p=0.4) (**Table 2**). Of gout follow-up visits captured in the EHR, a majority occurred with primary care (60%) followed by internal medicine subspecialties (29%). In the intervention group compared to control, there were no statistically significant differences in self-reported new allopurinol use post-ED (17% vs 11%, p=0.2). Among those who reported past or present allopurinol use, new initiation post-ED visit was more common in the intervention group (23/55 [42%] vs 7/32 [22%], p=0.05). Intervention group participants were less likely to have subsequent ED visits (intervention vs control 32% vs 49%, p=0.02) and there was a non-significant trend for fewer subsequent ED visits documented in the EHR at each site (intervention vs control 0.3 vs 0.6 visits, p=0.09). There were no differences in opioid prescription use or incident

Table 2: Results for primary and secondary outcomes by randomization group, intent-to-treat and per protocol analyses; number (%) represented unless otherwise stated. P<0.05 represented in bold.

hospitalizations between groups. In PP analyses, trends were similar to ITT analysis with no significant differences between groups.

Conclusion: While our intervention did not lead to a significant improvement in outpatient gout follow-up, we did observe trends in improved uptake of allopurinol initiation and reduction in repeat ED visits. The findings suggest that while patient activation strategies may play a role, achieving improvements in routine gout follow-up care likely requires multifaceted approaches beyond behavioral interventions targeted to patients alone.

Abstract Number: 2007

Machine Learning-Based Prediction of Gout Onset in Individuals with Asymptomatic Hyperuricemia Using a Common Data Model

Min Jung Kim[1], Sang Min Lee[2], Jun Seok Kim[2], Borim Ryu[2] and Kichul Shin[3], [1]Seoul Metropolitan Government Boramae Medical center, Dongjak-gu, Seoul, South Korea, [2]Center for Data Science, Biomedical Research Institute, Seoul Metropolitan Government–Seoul National University Hospital Boramae Medical Center, Seoul, Republic of Korea, [3]Seoul National University, Seoul, South Korea

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1990–2014) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Long-term hyperuricemia is essential for the development of gout. However, only 9.9% of individuals with asymptomatic hyperuricemia (AHU) develop gout within 10 years. Identifying high-risk individuals with AHU is crucial for implementing timely and targeted interventions to prevent or delay the onset of gout. We aimed to create a machine learning-based risk stratification model to predict the onset of gout in individuals with AHU.

Methods: We conducted a retrospective cohort study utilizing a Common Data Model (CDM) database from a single academic medical center. Subjects (age ≥ 18 years) were identified if they had at least one serum urate level ≥ 7 mg/dL or a diagnosis of AHU (concept ID 4147761) between 2010 and 2022. The index date was defined as the earliest report of a high serum urate level or the first diagnosis of AHU. Subjects were excluded if they had a prior diagnosis of gout or received a prescription for colchicine, allopurinol, febuxostat, or benzbromarone within 365 days before the index date. The outcome measured was the development of gout between 90 and 3650 days after the index date. Machine learning models, including LightGBM, XGBoost, Random Forest, AdaBoost, Decision Tree, and Logistic Regression, were employed to predict the development of gout. Model performance was assessed using the area under the receiver operating characteristic curve (ROC-AUC) and the precision-recall AUC (PR-AUC). We evaluated the contribution of each variable to the model's predictions using feature importance and SHAP values. The Cox proportional hazard model was applied to construct a risk-scoring model with key predictors.

≥8, <9	-0.124	0.884 (0.635-1.229)	0.462	-
≥9, <10	0.090	1.094 (0.729-1.642)	0.664	1
≥10	0.452	1.572 (1.063-2.326)	0.024	5

tCO2, total carbon dioxide; ESR, erythrocyte sedimentation rate; LDL, low-density lipoprotein; HR, hazard ratio.

Results: Among 8,139 subjects with AHU, 223 (2.7%) developed gout during the 10-year follow-up period. Eighty-three percent of the patients were male, most between 30 and 40 years of age. LightGBM demonstrated the best performance among the models, achieving an ROC-AUC of 0.812 and a PR-AUC of 0.112. Among the top 15 features identified by feature importance and SHAP values (figure), serum urate level, LDL cholesterol, total carbon dioxide (tCO2), ESR, age, chronic kidney disease, and hypertension were identified as key predictors. In the final risk-scoring model, chronic kidney disease was assigned 24 points, hypertension 4, age 4 to 5, low tCO2 7, high LDL cholesterol 5, high ESR 3, and serum urate level 1 to 5 points (table). The C-index of the model was 0.730.

Conclusion: We developed a machine learning-based risk-scoring model using real-world data to predict the onset of gout in individuals with AHU. This model showed promising results based on routinely collected clinical parameters that may help identify high-risk individuals who would benefit from rigorous lifestyle monitoring or early intervention.

absence in humans. This enables homeostatic control over urate levels, particularly in those with chronic kidney disease (CKD) where the role of extrarenal urate elimination increases. Indeed, in severe CKD the gut becomes predominant site of urate disposition.

Since treatment with anaerobe-targeted antibiotics rapidly elevates serum and cecal urate in mice,[1] and has been linked to increased incidence of gout diagnosis in a Stanford University cohort,[1] we hypothesized such treatment in humans with CKD is linked to more frequent gout flares.

We conducted target trial emulations to compare rate of gout flares among patients (stratified by CKD) treated with clindamycin, an antibiotic targeting both aerobic and anaerobic microbes, versus trimethoprim/sulfamethoxazole (T/S), antibiotic with limited anaerobic coverage.

Methods: We included adults aged ≥18 years with dispensed prescriptions for ≥ 5 days of oral clindamycin or T/S, and no diagnosis of gout or receipt of antibiotics in prior 12 months. Randomization was emulated based on pre-exposure prognostic factors including sociodemographics, infections, comorbidities, medications, and healthcare use.

Primary outcome was gout flare counts over 3 months after index date, ascertained by emergency department, hospital, outpatient, and prescription records;[3] We assessed *C. difficile* infection as positive control outcome and osteoarthritis (OA) encounter as negative control outcome. Poisson and Cox models were used to calculate adjusted rate ratios (RR) and hazard ratios (HR) with 95% confidence intervals (95% CI).

Results: After 1:1 matching, we included 306,058 adults initiating clindamycin and 306,058 initiating T/S (43% male, mean age 47). Baseline characteristics were well-balanced between treatment arms (standardized differences < 0.1 for all factors).

Among the 13,550 propensity-matched individuals with CKD, rate of gout flares was higher among those initiating clindamycin vs T/S (37.2 vs 10.3 per 1000 person-years, respectively), with adjusted RR 3.71 (95% CI: 2.17, 6.34) (**Table 1**). Associations were smaller but remained significant among non-CKD, with adjusted RR 1.61 (1.37, 1.89) (**Table 1**) (p-interaction 0.003).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Associations persisted when assessing gout flares for 12 months after index date (**Table 1**) and comparing rates of all gout-primary encounters, regardless of medication dispensing (**Table 2**). Clindamycin initiators showed higher risk of *C. diff*. infection vs T/S (HR 3.14 [2.02, 4.90]), but no altered risk of OA encounter, both as expected.

Conclusion: In this general population study, exposure to an anaerobe-targeted antibiotic was associated with >3-fold higher rate of gout flares versus the non-anaerobe-targeted antibiotic T/S, among those with CKD. These findings support a substantial role of gut purine-degrading bacteria (PDB) in urate disposition, as well as suppression by gut PDB of gouty inflammation, particularly in those with CKD.

Abstract Number: 2009

Value of New PREVENT Calculator in Detecting Cardiovascular Disease in Patients with Gout

Patrick Williamson[1], Rouhin Sen[2] and Angelo Gaffo[3], [1]Tinsley Harrison Internal Medicine Residency, Department of Medicine, University of Alabama at Birmingham, Birmingham, [2]University of Alabama at Birmingham, Department of Medicine, Division of Clinical Immunology & Rheumatology, Birmingham, [3]Division of Rheumatology and Clinical Immunology, University of Alabama, Birmingham, AL, USA; Birmingham VA Medical Center, Birmingham, AL, USA, Birmingham, AL

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1990–2014) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Gout is associated with a 50% increased risk of cardiovascular disease (CVD).[1] The current recommendation for evaluating CVD risk in gout is to use prediction tools developed in the general population.[2] Studies have shown that CVD risk assessment tools underestimate CVD in people with gout.[3] The Predicting Risk of cardiovascular disease EVENTs (PREVENT) calculator is a newly developed CVD risk predictor that is the first to combine multiple organ systems and social determinants of health.[4] Whether the PREVENT calculator improves prediction of atherosclerotic CVD in patients with gout is unknown. Our aim is to assess the performance of the PREVENT calculator in detecting coronary plaque in patients with gout, against gold standard coronary artery calcium (CAC) testing, a CT-based technique to detect subclinical coronary atherosclerosis.[5]

Methods: We identified adult patients with gout seen in the University of Alabama at Birmingham clinics from 2016-2024. Patients were excluded if they were missing variables needed to calculate PREVENT or missing CAC score. High CVD risk was defined as having a PREVENT score of $\geq 7.5\%$ 10-year total CVD risk or a CAC score > 0.[4,5] Baseline variables were collected at time of CAC score. To assess the discriminative value of PREVENT in detecting coronary plaque, a 2x2 table was created to match high risk PREVENT scores vs high risk CAC scores. Sensitivity, specificity, positive and negative predictive values, and positive and negative likelihood ratios were calculated with their 95% confidence intervals (CI).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1: Baseline Demographics at the Time of the CT Scan

Baseline Demographics	Value
Mean age, years (SD)	61.4 (8.4)
Sex, females (n, %)	18 (26.1%)
Race/Ethnicity (n, %)	
Black or African American	6 (8.7%)
White	59 (85.5%)
Other*	4 (5.8%)
Mean BMI (SD)	29.8 (4.0)
Diabetes, n (%)	10 (14.5%)
Smoker (Former or Current), n (%)	23 (33.3%)
Use of anti-HTN, n (%)	53 (76.8%)
Use of lipid lowering medications, n (%)	34 (49.3%)
Mean LDL, mg/dL (SD)	113.4 (32.0)
Mean HgbA1c, % (SD)	5.8 (0.9)
Average serum uric acid, mg/dL (SD)	6.0 (1.9)

*Declined, Multiple, Hispanic or Latino, American Indian or Alaska Native, Asian, Native Hawaiian or Other Pacific Islander

Table 2: Statistical Measures Comparing CAC to PREVENT Scores

Statistic	Value	95% CI
Sensitivity	40.0%	25.7% to 55.7%
Specificity	83.3%	62.6% to 95.3%
Positive Predictive Value	81.8%	63.2% to 92.2%
Negative Predictive Value	42.6%	35.5% to 50.0%
Positive Likelihood Ratio	2.4	0.9 to 6.3
Negative Likelihood Ratio	0.7	0.5 to 1.0

Results: 69 patients with gout were eligible for the study. The mean age was 61.4 years, 18 patients were female, 59 patients were White (see Table 1 for other demographics). 65.2% of patients had a high CAC score; 31.9% of patients had a high PREVENT score. The results (95% CI) for sensitivity, specificity, positive, and negative predictive values were 40.0% (25.7–55.7%), 83.3% (62.6–95.3%), 81.8% (63.2–92.2%), and 42.6% (35.5–50.0%), respectively.

Conclusion: The PREVENT score is an inaccurate tool to predict presence of coronary atherosclerosis in patients with gout, being insensitive at identifying individuals with coronary plaque. Like prior calculators, the absence of inflammatory and disease-specific markers in risk tools may limit their discriminative value. Future studies should continue searching for better predictive tools for CVD risk in patients with gout.

Session Title: (1990–2014) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: *CSF1* and *CSF1R* encode a secreted and membrane-bound cytokine and its receptor controlling differentiation of monocytes into macrophages and inflammatory activity of macrophages. There are genetic associations

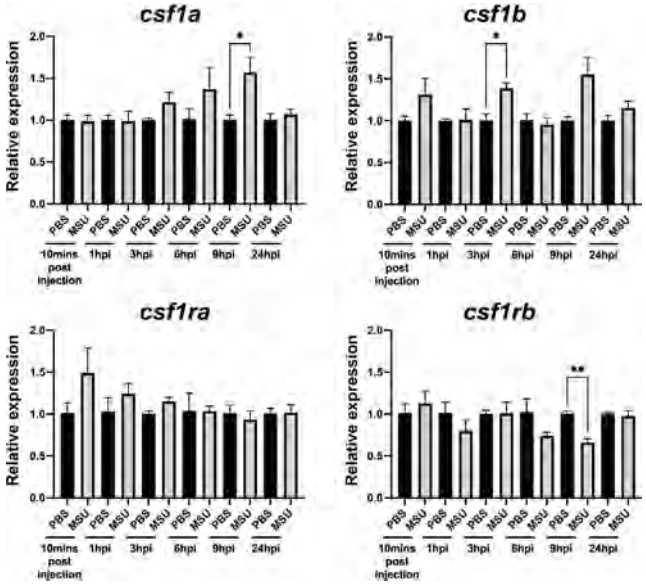

Figure 1. Expression of csf1a, csf1b, csf1ra, csf1rb after injection of MSUc into the hindbrain of 2-day zebrafish larva.

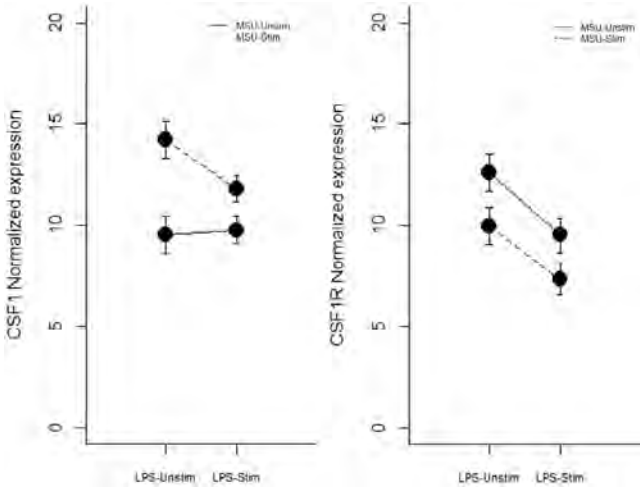

Figure 2. Expression of CSF1 and CSF1R in PBMCs in response to MSU crystal, LPS and their combination at 8-hrs.

with gout in regulatory regions at each locus which connect with the promoter of each gene in stimulated innate immune cells. The *CSF1* locus contains a long noncoding RNA (*LINC01768*) that is more expressed in stimulated innate immune cells and also a putative enhancer RNA. The *CSF1* genetic signal associates with gout but not urate, and CSF1 protein expression is increased in flaring gout patients. We hypothesized that CSF1 has a causal role in gouty inflammation. Our Aim was to gain insights into the molecular control of *CSF1* and *CSF1R* expression.

Methods: MSU crystal (MSUc) was injected into the hindbrain of 2-day larval zebrafish and expression analysis was done by qRT-PCR. For *in vitro* PBMC studies from 20 gout patients, LPS (1ng/mL), MSUc (300ug/mL), and their combination were used to stimulate cells. Total RNA at 8 hrs was sequenced and reads counted and normalized (to cells-only control). A linear mixed model was fit for *CSF1* and *CSF1R* expression (log2 transformed). Fixed effects were tested for main and two-way interactions of MSUc and LPS. THP-1 cells were stimulated with 30 ng/ml PMA up to 96 hrs to upregulate *CSF1* and *CSF1R* expression. For expression analysis of the putative enhancer RNA and *LINC01768*, random hexamers were used for reverse transcription and digital PCR was done. *CSF1* and *CSF1R* mRNA levels were quantified using qPCR.

Results: Zebrafish have two orthologs of each of *CSF1* and *CSF1R* (*csf1a, csf1b, csf1ra, csf1rb*). Injection of MSUc into the hindbrain of zebrafish increased expression of both *csf1a* and *csf1b* up to 1.5-fold within 3-9 hrs (**Fig 1**). However, expression of *CSF1R* orthologs did not change or decreased. In PBMCs, stimulation with MSUc increased expression of *CSF1* with the presence of LPS subduing the increase (**Fig 2**). In contrast, maximal expression of *CSF1R* happened under no stimulation, with LPS and MSUc repressing expression. In THP-1 cells PMA treatment induced expression of *CSF1*, the *LINC01768* IPL and the putative enhancer RNA. Maximal expression of the enhancer RNA and *LINC01768* preceded that of *CSF1*. Maximal expression of *CSF1R* was observed after 48-hours. These *CSF1* and *CSF1R* expression data are

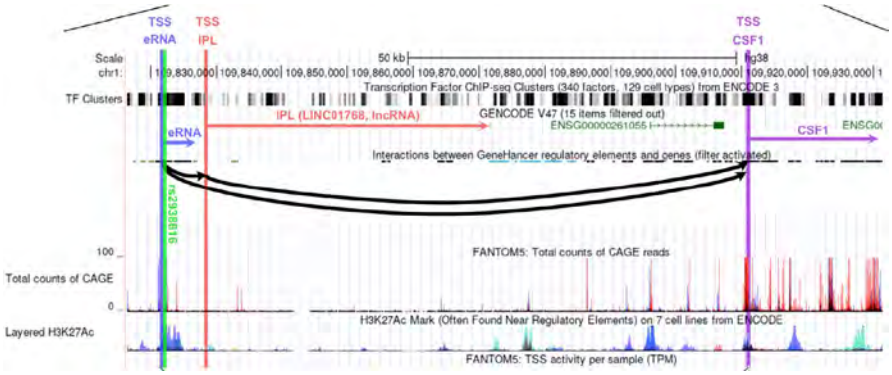

Figure 3. Genomic organization of the CSF1 locus (from the UCSC and Zenbu browsers).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

consistent with previous research. At *CSF1* there were multiple FANTOM5-CAGE multiple transcription start site peaks in monocytes but not in T-cells near the lead SNP (**Fig 3**). Rs2938616 maps within an H3K27Ac transcriptionally active peak, and there are interactions with both *CSF1* and *LINC01768*. FANTOM6-CAGE data provides evidence for selective expression of the transcription start sites upon PMA stimulation of monocytes. Our data are consistent with a model of genomic control where, in response to stimulation, the gout causal genetic variant mediates induction of the enhancer and *LINC01768* RNAs which in turn mediate *CSF1* expression.

Conclusion: In diverse experimental systems MSUc induces *CSF1* expression, and suppresses *CSF1R* expression. With the previous genetic association data our findings directly implicate *CSF1* in the pathogenesis of gout.

A Phase 1 Placebo Controlled, Single (SAD) and Multiple Dose Escalation (MAD) Safety and Pharmacokinetic (PK) Study of a Novel Colchicine Analogue ABP-745 in Healthy Volunteers (HV)

ullrich schwertschlag[1], Roy Wu[2], yan yang[3] and William Shi[4], [1]Atom Therapeutics, PALO ALTO, CA, [2]Atom Bioscience, San Francisco, CA, [3]Atom Therapeutics, Suzhou, China (People's Republic), [4]Atom Therapeutics, Newark, CA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (1990–2014) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: ABP-745 is a novel colchicine analogue in development as an anti-inflammatory agent for the treatment of acute gout and other chronic inflammatory conditions. In preclinical models, ABP-745 demonstrated comparable biological activity to colchicine with an improved safety profile including no significant drug-drug interactions.

Methods: Subjects were randomized to active drug or placebo in a 6/2 ratio. Subjects were dosed qd or bid in an ascending order (SAD). SAD Cohorts qd or bid of ABP-745 0.5 mg qd, 1.5 mg qd, 4 mg qd , 5 mg qd and 2.0 mg bid, 2.5 mg bid and placebo (N=32). Multiple ascending dose (MAD, 8 days) cohorts were ABP-745 0.5 mg qd; 1.5 mg qd; 4 mg qd; 2.5 mg bid; 2 mg bid (N=41). Single-dose food effect (ABP-745, 4 mg) was also studied (N=8). Safety was monitored until 3 days post last dose by clinical and laboratory methods. PK was followed over 36 hours (single dose) and on Day 1 (24 h) and Day 8 (36 h) of the MAD regimens.

Results: ABP-745 concentrations were detected 10 minutes post dose across all SAD levels. Maximum ABP-745 mean concentrations peaked between 1.50 h and 2.00 h with biphasic decline across all dose levels. Mean ABP-745 concentrations and exposure parameters (Cmax, AUClast, and AUC0-inf) increased over the 0.5 mg to 5 mg dose range. Mean Cmax ranged from 37.7 ng/mL to 216 ng/mL; mean AUClast ranged from 226 h*ng/mL to 1520 h*ng/mL. Mean ABP-745 Cmax, AUClast, and AUC0-inf increased in a less than proportional manner with increases in single ascending ABP-745 doses. MAD: mean ABP-745 concentrations and exposure parameters (Cmax and AUCτ on Day 1; Cmax,ss and AUCs on Day 8) increased with ascending multiple doses of ABP-745 across study days. On Day 8, mean Cmax,ss ranged from 34.0

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

ng/mL to 175 ng/mL, mean AUCτ ranged from 181 h*ng/mL to 1230 h*ng/mL. Accumulation ratios for Cmax,ss (RCmax) and AUCτ (RAUCτ) indicated no accumulation in ABP-745 exposure occurred during qd and bid 8-day dose regimens. RCmax values ranged from 0.944 to 1.13 for qd treatments and from 1.15 to 1.24 for bid treatments. On Day 8 approximately 20% of the administered oral dose was recovered in the urine. On Day 1 of MAD, maximum and total ABP-745 exposure (Cmax and AUCτ) generally increased in a less than proportional manner with an increase in multiple ascending QD doses. ABP-745 trough concentrations were higher for bid treatments compared to the qd treatment. Steady-state: Day 2 of dosing for both qd and bid dosing regimens. Food effect (fed/fasted) was studied (N=8). Mean ABP-745 Cmax and AUC0-inf were similar after administration of 4 mg ABP-745 under fed and fasted conditions. Median Tmax was delayed by @ 30 minutes under fed conditions (1.50 h vs. 0.988 h, respectively). Four treatment emergent AEs (TEAE) were reported in the SAD in the 5 mg single dose cohort as gastrointestinal symptoms (single events of diarrhea, nausea, abdominal pain, vomiting). In the MAD cohort 11 TEAE were reported in the 2 highest bid dose groups, such as single cases of nausea, constipation, headache, elevated blood lipase and amylase levels.

Conclusion: Safety and pharmacokinetics (PK) of ABP-745 following single, and multiple qd and bid oral doses in healthy volunteers under fasted and fed conditions further supports development of ABP-745 in an acute gout indication.

Table 2. Response rate (N/%) at selected categories 24 h post dose

24 h post dose	1 mg (n=7)	2 mg (n=7)	4 mg (n=7)	6 mg (n=7)	12 mg (n=7)	Placebo (n=10)
sUA < 6.0 mg/dL	6 (85.7)	7 (100)	7 (100)	7 (100)	7 (100)	0
sUA < 5.0 mg/dL	4 (57.1)	6 (85.7)	6 (85.7)	7 (100)	7 (100)	0
sUA < 4.0 mg/dL	1 (14.3)	1 (14.3)	1 (14.3)	4 (57.1)	7 (100)	0

7/2 ratio. All subjects underwent a dose escalation dosing period starting from 0.2 mg to 1 mg over a 9-day or 10-day period to mitigate any renal uUA overload. A 7-day dosing period of ABP-671 or placebo followed. The groups were enrolled separately and conducted sequentially (Table 1).

TEAEs were reported in 24 (53.3%), including 5 (71.4%), 4 (57.1%), 6 (85.7%), 4 (57.1%), 1 (14.3%), and 4 (40%) in the 1, 2, 4, 6, and 12 mg and placebo groups, respectively. There were no SAEs, grade $\geq$3 TEAEs, or deaths. The incidence of AEs was not found dose dependent.

Results: Serum UA (sUA) levels decreased in a dose dependent manner. The max median decrease of sUA occurred at 3.00-9.00 h post dose. For placebo, 1, 2, 4, 6 and 12mg dose groups, the maximum mean sUA decrease in gout subjects was 17.7%, 56.4%, 58.1%, 69.4%, 77.0%, and 79.2% from baseline, and in hyperuricemia subjects, they were 19.9%, 50.1%, 64.1%, 73.2%, 81.2%, and 82.1%. Subjects (%) with sUA levels lower than 6.0, 5.0, and 4.0 mg/dL 24 h post dose were 85.7%, 57.1%, and 14.3% for 1 mg, 100%, 85.7%, and 14.3% for 2 mg, 100%, 85.7%, and 14.3% for 4 mg, 100%, 100%, and 57.1% for 6 mg, and 100%, 100%, and 100% for 12 mg.

Conclusion: ABP-671 has acceptable safety and tolerability in Chinese subjects with hyperuricemia or gout. ABP-671 reduced the sUA in a dose-dependent manner.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (1990–2014) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Acute gouty arthritis(GA) is a common and debilitating condition, especially for patients unsuitable for standard therapy. Firsekibart, previously called Genakumab, is a first-in-class fully IgG4/λ anti-human-IL-1β monoclonal antibody, making it a significant option for gout treatment.

Methods: This phase III clinical trial was a multicenter, randomized, double-blind, double-dummy, active-controlled study conducted from Jan. 2023 to Jun. 2024 across 51 centers in China (NCT05983445). Patients aged 18–75 years with GA, contraindicated of, intolerance of, or unresponsiveness to NSAIDs and/or colchicine, with ≥2 episodes during the last 12 months were screened for eligibility.Patients were randomized 1:1 to receive a single subcutaneous dose of Firsekibart (200 mg) or an intramuscular dose of CB 7 mg.The co-primary endpoints were change in pain intensity from baseline to 72 hours in the most affected joint measured on VAS (0–100 mm) and the time to first new episode over 12 weeks. Secondary endpoints included: change in VAS scores at other time points(6h, 24h, 48h, 7 days post-dose), time to reduce 50% pain,proportion of patients experiencing ≥ 1 new flare, the mean flare rate per patient over 12 and 24 weeks, proportion of patients requiring rescue therapy,the dosage of rescue medicine and safety assessments.

Results: The full analysis included 311 patients, with 156 receiving Firsekibart and 155 receiving CB. The median age was 42, 89.4% patients had ≥ 3 flares in the last 12 months. Firsekibart significantly delayed median time to first new flare (Not estimable vs. 45 days) and reduced risk of new flare by 90% (HR0.10; 95% CI: 0.06, 0.17; $p< 0.0001$) over 12 weeks, by 87% (HR 0.13; 95% CI: 0.08, 0.21; $p< 0.0001$) over 24 weeks. Although the reduction of pain intensity and the median time to reduce ≥50% pain were similar Firsekibart showed better pain relief in GA patients from 48 hours to 7 days. Significantly fewer patients treated with Firsekibart experienced ≥ 1 new flare over 12 weeks and 24 weeks (10.9% vs. 65.2%, 14.7% vs. 66.5%, $p < 0.0001$), and the mean number of new flares per patient was lower in Firsekibart group over 12 and 24 weeks (0.2 (0.52) vs. 1.2 (1.27), 0.2 (0.79) vs. 1.6 (1.79)) (mean(SD)). A smaller proportion of patients in the Firsekibart group required rescue therapy (10.9% vs 48.4%). Less mean dosage of rescue medicine was uesd in Firsekibart group (corticosteroid was 69.33 mg vs 202.03 mg).

The overall incidence of treatment-emergent adverse event (TEAE) was comparable, occurring in 111 patients (71.2%; grade ≥3: 12.2%) in the Firsekibart group and 109 patients (69.9%; grade ≥3: 10.9%) in the CB group. The most common TEAE in Firsekibart group was hypertriglyceridaemia(27.6%; grade ≥3: 10.3%), and it may own to the high proportion of patients with dyslipidemia at baseline. Neither extra safety risk for patients with abnormal liver or kidney function nor treatment-related serious adverse events(TRSAE) were reported in Firsekibart group. All 3 TRSAE were reported in CB group.

Conclusion: Firsekibart is effective and well-tolerated for acute gout flares in patients with limited treatment options, demonstrating rapid pain relief and significant superiority in preventing flare compared with CB.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (1990–2014) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Approximately 70% of adults with gout have CKD (Chronic Kidney Disease) ≥Stage 3 (i.e estimated glomerular filtration rate (eGFR) < 60ml/min/1.73m^2), significantly restricts treatment options such as colchicine or NSAIDs due to the potential renal toxicity. Firsekibart, previously known as Genakumab, is a novel IgG4/λ anti-human-IL-1β monoclonal antibody eliminated by degradation through intracellular enzymes rather than excretion through the kidney making it a significant option for gout with CKD. Here, we report the efficacy and safety of Firsekibart vs compound betamethasone(CB) in a subgroup of patients with eGFR < 60ml/min/1.73m^2.

Methods: This multicenter, randomized, double-blind, double-dummy, active-controlled phase III clinical trial was conducted across 51 centers in China. (NCT05983445). Patients (aged 18-75) who had acute arthritis of primary gout (GA) and contraindicated of, intolerance of, or unresponsiveness to NSAIDs and/or colchicine, with ≥2 episodes during the previous 12 months were screened for eligibility. Patients were randomized in a 1:1 ratio to either a single subcutaneous dose of Firsekibart (200 mg) or an intramuscular dose of CB 7 mg treatment. The co-primary endpoints were change in pain intensity from baseline to 72 hours in the most affected joint measured on VAS (0–100 mm) with non-inferiority testing and the time to first new episode over 12 weeks with superiority testing. Secondary endpoints included percentage of patients with at least one new flare (12weeks, 24weeks) and the safety evaluation.

Results: Of 313 patients, 42 patients had eGFR< 60ml/min/1.73m^2 at baseline (21 in Firsekibart group and 21 in CB group). 95.24%patients had more than 3 episodes in the preceding 12 months and 50% patients had gouty tophi. Firsekibart demonstrated a competing effect in reducing VAS pain score (58.22 (-67.516, -48.927) mm vs. -58.33 (-67.635, -49.022) mm) (Least Squares Mean(95CI%)). Compared to CB, Firsekibart significantly delayed median time to first new episode (Not estimable vs 21 days) reduced the risk of a new flare by 98% over the 12-week period (HR 0.02; p=0.0002), by 96% over the 24-week period (HR 0.04, p<0.0001). A significantly lower proportion of patients treated with Firsekibart experienced at least one new flare over 12 weeks (4.76% vs. 95.24%) and 24 weeks (9.52% vs. 95.00%).

The treatment emergent adverse events and treatment-related adverse events were 10 (47.6%) and 7 (33.3%) in the Firsekibart-treated group, versus 11 (52.4%) and 6 (28.6%) in the CB-treated group. No serious adverse events were

reported in Firsekibart-treated group. Besides, neitiher Firsekibart nor CB showed significant damage to kidney function, only one patient in Firsekibart-treated group experienced renal function deterioration over 24 weeks after treatment. (eGFR decreased from 30∼60 to < 30ml/min/1.73m^2).

Conclusion: Compared with a potent long-acting corticosteroid (Compound betamethasone), Firsekibart showed a comparable effect in pain relief and offering significantly better prevention of new flares in GA patients with eGFR < 60ml/min/1.73m^2. The safety profile in this sub population was consistent with that of the overall study population.

Background/Purpose: IgG4-related diseases (IgG4-RD) is rare and unique fibroinflammatory disorder. The aim of our study was to study the characteristics of IgG4-RD cohort diagnosed and followed at our secondary/tertiary medical centre.

Methods: This retrospective study covered a period from January 2012 to December 2024. A review of medical records of adult patients diagnosed with IgG4-RD was performed and patient's demographics, comorbidities and IgG4-RD features at presentation were extracted. Data were analysed with descriptive statistical methods.

Results: During a 13-year observation period, 58 patients with IgG4-RD were identified (46 (79.3%) males, median (IQR) age at diagnosis 63.0 (51.3; 68.9) years). Ten patients had a history of diabetes mellitus, 10 of asthma and 5 of atopy. Median (IQR) duration of symptoms attributed to IgG4RD before the diagnosis was 6 (3; 18) months.

Table 1 shows characteristics of our IgG4-RD cohort at diagnosis. The average number of organs and/or regions affected was 2 (ranging from 1 to 7). Thirty-seven (63.8%) patients had predominantly proliferative and 21 (36.2%) predominantly

Table1. Clinical characteristics of IgG4 related disease

Characteristic	No. (%)	Characteristic	No. (%)
Meninges	1 (1.7%)	Aorta	13 (22.4%)
Orbital tissue	8 (13.8%)	Lymph nodes	10 (17.2%)
Lacrimal glands	9 (15.5%)	Joints	1 (1.7%)
Nasal cavity & sinuses	4 (6.9%)		
Salivary glands	13 (22.4%)	Elevated serum IgG4	41/49 (83.7%)
Lungs	6 (10.3%)	Hypergammaglobulinemia	16/40 (40.0%)
Pleura	4 (6.9%)	Hypocomplementemia	2/28 (7.1%)
Hepatobiliary tract	7 (12.1%)	Peripheral eosinophilia	6/43 (14.0%)
Pancreas	12 (20.7%)		
Kidneys	7 (12.1%)	**Biopsy findings**	47 (81.0%)
Omentum, mesenterium	4 (6.9%)	Consistent with IgG4RD	36/47 (76.6%)
Retroperitoneal tissue	16 (27.6%)	Possible IgG4RD	4/47 (8.5%)
		Negative/Non-representative	7/47 (14.9%)
		Fulfilment of 2019 ACR/EULAR IgG4-RD Classification Criteria	40/58 (69.0%)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. fibrotic phenotypes. We classified 10 (17.2%) patients as pancreato-hepato-biliary disease, 25 (43.1%) as retroperitoneal fibrosis and/or aortitis, 6 (10.3%) as head and neck limited disease and 15 (25.9%) as Mikulicz syndrome with systemic involvement. In 2 patients the disease could not be classified. Forty-seven patients had an organ biopsy, and histopathological features were consistent with IgG4-RD in 36 (76.6%), and suspicious of IgG4-RD in 4 (8.5%) patients. 2019 ACR-EULAR IgG4RD classification criteria were fulfilled in 40 (69.0%) patients.

A total of 44 patients (75.9%) received systemic therapy: 41 patients were treated with systemic glucocorticoid, 25 with an immunomodulatory medication (3 of them as therapy and 22 concomitantly with glucocorticoids). Nine patients received surgical therapy. Five patients were observed only.

Conclusion: Our IgG4-RD cohort was dominated by middle-aged men with retroperitoneal fibrosis and/or aortitis phenotype.

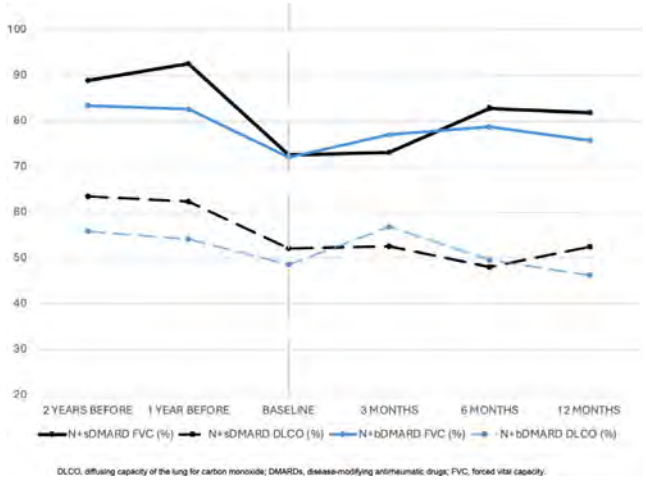
ACPA, anti-citrullinated protein antibodies; CRP, C-reactive protein; DLCO, diffusing capacity of the lung for carbon monoxide; ESR, erythrocyte sedimentation rate; FVC, forced vital capacity; HRCT, high-resolution computed tomography; ILD, interstitial lung disease; mMRC, modified Medical Research Council; NSIP, non-specific interstitial pneumonia; RA, rheumatoid arthritis; RF, rheumatoid factor; UIP, usual interstitial pneumonia.



DLCO, diffusing capacity of the lung for carbon monoxide; DMARDs, disease-modifying antirheumatic drugs; FVC, forced vital capacity.

Figure. Evolution of pulmonary function in 74 patients with RA-ILD according to the combination of nintedanib with only biologic or only synthetic DMARDs.

nintedanib (NINTE) in RA-ILD patients with pulmonary progressive fibrosis (PPF) in pulmonary function had been reported. However, data on articular response is limited, although NINTE seems to have no efficacy on the articular domain. Therefore, NINTE should be administered combined with DMARDs. Our objective was to assess the evolution of joint and pulmonary outcomes in RA-ILD patients with PPF treated of NINTE and DMARDs in clinical practice.

Methods: National Spanish multicenter study of RA-ILD patients treated with NINTE due to PPF. the main outcome measures were joint activity and forced vital capacity (FVC) evolution of different groups of treatment according to DMARDs category (biological [bDMARDs] or synthetic [sDMARDs]) were the main outcome measures.

Results: A total of 74 patients (43 men/31 women) were collected, mean age of 69±9 years. Median [IQR] ILD duration up to antifibrotic initiation was 51 [22-78] months.

NINTE was used **a)** combined with bDMARDs (n=47, 33 abatacept, 10 rituximab); **b)** combined with sDMARDs (n=29, 7 leflunomide, 6 methotrexate, 4 JAK inhibitor, 8 mycophenolate, 2 hydroxychloroquine, 1 azathioprine and 1 cyclophosphamide); **c)** combined with both bDMARDs and sDMARDs (n=9); and **d)** monotherapy (only glucocorticoids) (n=13).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

To avoid interference, we select only those who are on either biological or synthetic DMARDs. Main baseline characteristics of patients are shown in **Table**. After 12 months of follow-up, joint activity was controlled in 81% of patients (87% in the group of NINTE+ only bDMARDs and 83% in the group of NINTE+ only sDMARDs, p=0.82). In addition, no significant decline in mean FVC or DLCO values was observed, with no statistically significant differences between the 2 groups of treatment (**Figure**).

Conclusion: In our series of RA-ILD patients with PPF treated with NINTE, articular inflammation could be managed either with bDMARDs or sDMARDs, with similar pulmonary function evolution.

Abstract Number: 2017

Baseline and 2-year Follow-up of Pulmonary Function Among CTD-ILD Subtypes

Ivana Ilic, **Anchal Sabharwal**, Galina Marder and Sonali Narain, Northwell, Great Neck

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Interstitial lung disease is a major cause of morbidity and mortality in patients with connective tissue disease (CTD-ILD). Evaluation of ILD severity and progression relies on symptoms along with pulmonary function tests (PFT) and high-resolution computed tomography (HRCT). It has been previously reported that Ro52 antibodies are associated with more severe ILD phenotype. The goal of this study is to evaluate PFT characteristics across CTD-ILDs and whether anti-Ro52 presence determines more severe ILD in scleroderma, Sjogren's, idiopathic inflammatory myopathy (IIM), and Mixed Connective Tissue Disease (MCTD) subgroups.

Methods: This is a retrospective analysis of the Northwell CTD-ILD cohort, meeting classification criteria for scleroderma, IIM, Sjogren's, or MCTD. Cases with rheumatoid arthritis ILD and post-transplant were excluded. We combined 22 previously reported cases of IIM-ILD with 101 CTD-ILD patients followed between 2012 – 2024. Longitudinal analysis of PFTs was performed over a 2-year period. HRCT chest were recorded as improved, stable or worsened by radiologist read. Descriptive statistics, Anova (with Geisser-Greenhouse correction, Welch's ANOVA and repeated measures ANOVA) and Mann-Whitney (non-parametric) tests were used.

Results: 123 patients were included in the analysis. Our cohort comprised of 45 IIM, 30 scleroderma, 21 Sjogren's, and 27 MCTD patients. The median age was 58 (22-83) years with a predominantly females (80.5%) with ~5 years follow-up (1-12 years), Table 1. A quarter of patients (26.8%) were Ro-52+ with most distributed between Sjogren's (47.6%) and

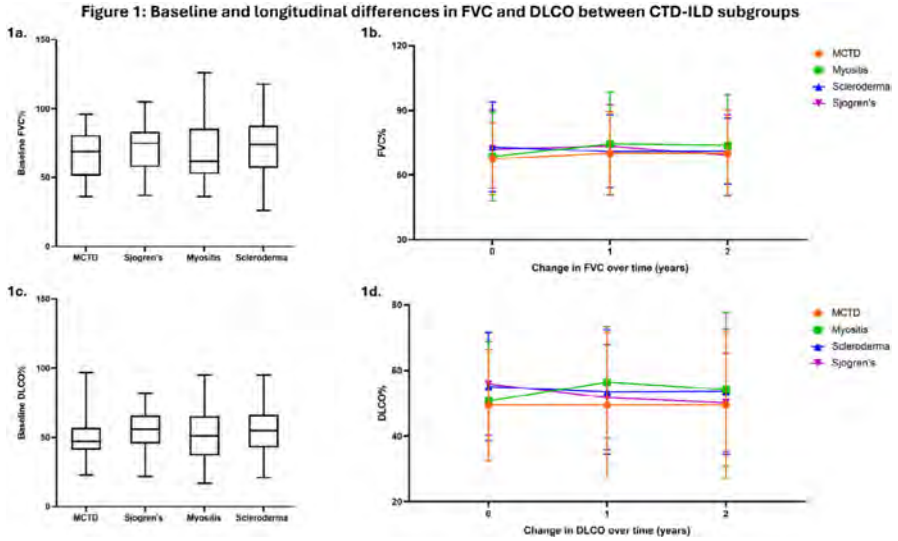
Rituximab	8 (17.8%)	0	4 (19%)	2 (7.4%)	14 (11.4%)
Plaquenil	4 (8.9%)	6 (20%)	5 (23.8%)	10 (37%)	25 (20.3%)
Ro-52 + (n, %)	19 (42.2%)	1 (3.3%)	10 (47.6%)	3 (11.1%)	33 (26.8%)
Baseline PFT parameters (mean, SD)					
FVC % (SD)	68.7 (20.7)	72.6 (21.1)	72.1 (18.3)	69.4 (15.5)	70.1 (19.4)
DLCO % (SD)	50.8 (18.1)	55.1 (16.9)	55.9 (16.1)	52.2 (17.8)	52.4 (17.1)
Baseline HRCT ILD Pattern (n, %)					
NSIP	39 (86.7%)	26 (86.7%)	16 (76.2%)	20 (74.1%)	101 (82.1%)
UIP	2 (4.4%)	0	1 (4.8%)	6 (22.2%)	9 (7.3%)
OP	1 (2.2%)	0	1 (4.8%)	0	2 (1.6%)
OP/NSIP	0	1 (3.3%)	0	0	1 (0.8%)
No ILD	3 (6.7%)	4 (13.3%)	3 (14.3%)	1 (3.7%)	11 (8.9%)

Patient Demographics and Characteristics



Baseline and Longitudinal Differences in FVC and DLCO Between CTD-ILD Subgroups

IIM (42.2%) subgroups. NSIP was the most common ILD pattern. Most patients in our cohort were on at least 1 immunosuppressive agent, led by mycophenolate mofetil (Cohort: 58.5%; Scleroderma 76.7%, IIM 53.3%, Sjogren's 38.1%, and MCTD 63%).

At baseline, mean FVC % (p=0.67) and DLCO% (p=0.42) were similar across subgroups, Fig1a,c and Ro-52+ patients (all cohort and IIM subgroup) had significantly lower DLCO% compared to Ro52- patients (Cohort: 46.3 vs. 54.8, p=0.02; IIM 43.1 vs. 56.4, p=0.01), while this was not observed for any other subgroups of ILD, Fig 2a,b.

Baseline and Longitudinal Differences in FVC and DLCO Between Ro52+ and Ro52- Subgroups

When we looked at change in disease over time in individual CTD-ILD subgroups, a trend for improvement in both FVC% and DLCO% was noted only in the IIM subgroup (FVC% p=0.05 with baseline to year 1 p=0.02 and to year 2 p=0.04; DLCO% p=0.14 with baseline to year 1 p=0.09 and to year 2 p=0.4, data not shown). When the ILD subgroups were compared to each other, there was no significant change in FVC% or DLCO% over the 2-year period, Fig1b,d.

Similarly, there was no significant change in FVC% or DLCO% between Ro-52+ and negative groups over 2 years (p=0.889). However, Ro52 negative patients consistently maintained higher DLCO% over time (p=0.003) Fig 2c,d. Most patients had stable HRCT over 2-year period in all subgroups.

Conclusion: While all CTD-ILD share similar evolution when compared to each other, myositis-ILD has a higher chance of improvement by PFT parameters. Anti-Ro52 positivity is associated with consistently lower DLCO% over time and may serve as harbinger of more severe ILD across all CTD-ILD subgroups.

Abstract Number: 2018

Investigating Epidemiology, Clinical associations, and Outcomes of Uveitis: A Retrospective Cohort Study

Archit Srivastava[1], Jayesh Valecha[2], Sehreen Mumtaz[1], Caroyln Harvey[3], Florentina Berianu[1] and Vikas Majithia[4], [1]Mayo Clinic Florida, Jacksonville, FL, [2]Saint Vincent Hospital, Worchester, FL, [3]Mayo Clinic, Phoenix, AZ, [4]Mayo Clinic Hospital, Jacksonville, FL

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Uveitis is a significant cause of visual impairment in the U.S., with a prevalence of 438 per 100,000 persons [1]. It is anatomically classified into anterior, intermediate, posterior, and panuveitis, and is frequently associated

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Combined baseline characteristics, laboratory findings, autoantibody profiles, and HLA typing across uveitis subtypes. Anterior uveitis was the most prevalent (84.5%). Significant differences were observed in age distribution and HLA-B27 positivity (p=0.062, 0.349 respectively). Autoantibodies such as ANA (36.2%) and HLA-B27 (35.0%) were commonly present. Bilateral eye involvement was dominant across all subtypes (75.5%). These findings highlight the clinical heterogeneity and immunological associations in non-infectious uveitis.

Table 1. Combined Patient Characteristics, Labs, Serologies, and HLA

Patient Characteristics

with systemic autoimmune conditions. Management strategies include corticosteroids, immunomodulatory agents, and biologics, tailored to disease severity and underlying etiology [2].

Methods: This retrospective cohort study includes patients ≥18 years diagnosed with uveitis seen at Mayo Clinic Florida Rheumatology Clinic between 10/12/2021 and 10/12/2023. Patients were identified using ICD-10 and location codes. Data include demographics, diagnostic testing, ocular features, serologies, imaging, comorbidities, treatments, morbidity, and mortality. Categorical and continuous variables are analyzed using Fisher's exact and Kruskal-Wallis tests, respectively. Time to remission was assessed using Kaplan-Meier analysis. The primary objective was to investigate the epidemiology,

Table 2. Diagnosis, treatment, complications, and outcomes of uveitis by anatomical subtype. Anterior uveitis was the most common (84.5%), with iritis and iridocyclitis predominating. Cataract and glaucoma were the most frequent complications. Corticosteroids were widely used, but mycophenolate, adalimumab, and methotrexate showed greater association with remission in posterior and panuveitis. Overall remission was achieved in 92.6% of patients, with relapse rates highest in intermediate and panuveitis.

Table 2. Diagnosis, Complications, Treatment, Relapses, and Remission

Uveitis Diagnosis by Intraocular Compartment						
Diagnosis	Anterior Uveitis (N=125)	Intermediate Uveitis (N=6)	Posterior Uveitis (N=8)	Panuveitis (N=9)	Total (N=148)	P-value
Iritis	95 (76.0%)	1 (16.7%)	0 (0.0%)	1 (11.1%)	97 (65.5%)	<.001[1]
Iridocyclitis	31 (24.8%)	2 (33.3%)	0 (0.0%)	1 (11.1%)	34 (23.0%)	0.318[1]

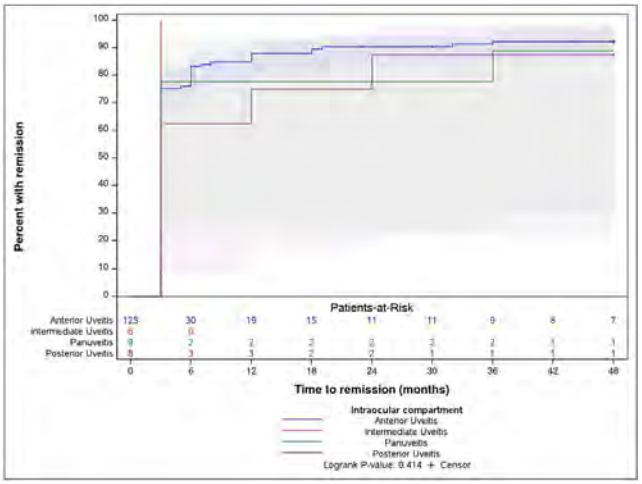

Figure 1: Kaplan-Meier survival analysis showing time to remission among patients with anterior, intermediate, posterior, and panuveitis over a 48-month period. Most patients with anterior uveitis achieved early remission, while posterior and panuveitis cases showed slower remission trends. Shaded areas represent 95% confidence intervals. No statistically significant difference in time to remission was observed between uveitis types (Log-rank test, p = 0.414).

clinical associations, and outcomes of uveitis. Secondary objectives included identifying risk factors, evaluating diagnostic strategies, and determining the most effective treatment regimens. A p-value < 0.05 was considered significant.

Results: A total of 148 adult patients with uveitis were analyzed: anterior (n=125), intermediate (n=6), posterior (n=8), and panuveitis (n=9). The mean age was 51.7 years, and 114 (77%) were female. Most patients were White (76.4%) and non-Hispanic (88.5%). Bilateral involvement was observed in 75.5% of cases (Table 1). Anterior uveitis was most prevalent (84.5%), with iritis being the most common subtype (65.5%). Sarcoidosis was significantly associated with intermediate/posterior uveitis (p=0.029). Visual acuity was preserved in most patients, but those with panuveitis had higher rates of visual impairment. Glaucoma (21.6%) and cataract (41.9%) were notable complications, especially in posterior and panuveitis (p=0.035). Corticosteroids were administered in 98% of cases; topical use predominated, though intraocular delivery was more frequent in posterior/panuveitis (p=0.006). Methotrexate (35.1%) and adalimumab (45.9%) were the most used immunosuppressants. Mycophenolate use varied significantly across types (p< 0.001). Remission was achieved in 92.6% of patients (Figure 1). Adalimumab was associated with higher remission in posterior/panuveitis (p=0.037), and mycophenolate and methotrexate were also linked to remission (Table 2).

Conclusion: This retrospective study demonstrates high remission rates in adult uveitis patients, with 137 (92.6%) achieving remission. Anterior uveitis was the most common subtype, accounting for 115 cases (92.0%). Corticosteroids were widely used, but adalimumab and mycophenolate were significantly effective in posterior/panuveitis. Early diagnosis and targeted therapy are key to improving uveitis outcomes.
