SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

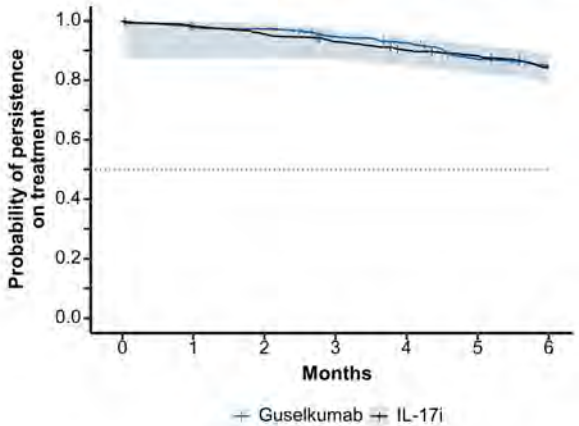
Session Time: 10:30AM–12:30PM

Background/Purpose: Randomized controlled trials have demonstrated the efficacy of IL-23 inhibitors (i) and IL-17i in PsA; however, real-world data on their effectiveness in heterogeneous patient (pt) subgroups in routine care are limited. Some subgroups, such as older, obese, or biologic-experienced pts, are of particular interest as pts in these groups report worse treatment outcomes.[1] The objective of the current analysis was to assess the 6-month persistence and effectiveness of guselkumab (GUS) and IL-17i across these subgroups of interest.

Methods: PsABIOnd (NCT05049798) is a global (20 countries) observational study in pts with PsA starting GUS or IL-17i as 1st-to-4th line of biologic therapy per their standard of care.[2] Here, the full population of the PsABIOnd study over 6 months

Fig 1. Persistence on treatment over 6 months with GUS and IL-17i

Kaplan-Meier curve of treatment persistence by initial treatment line through month 6.



Number of Patients at Risk

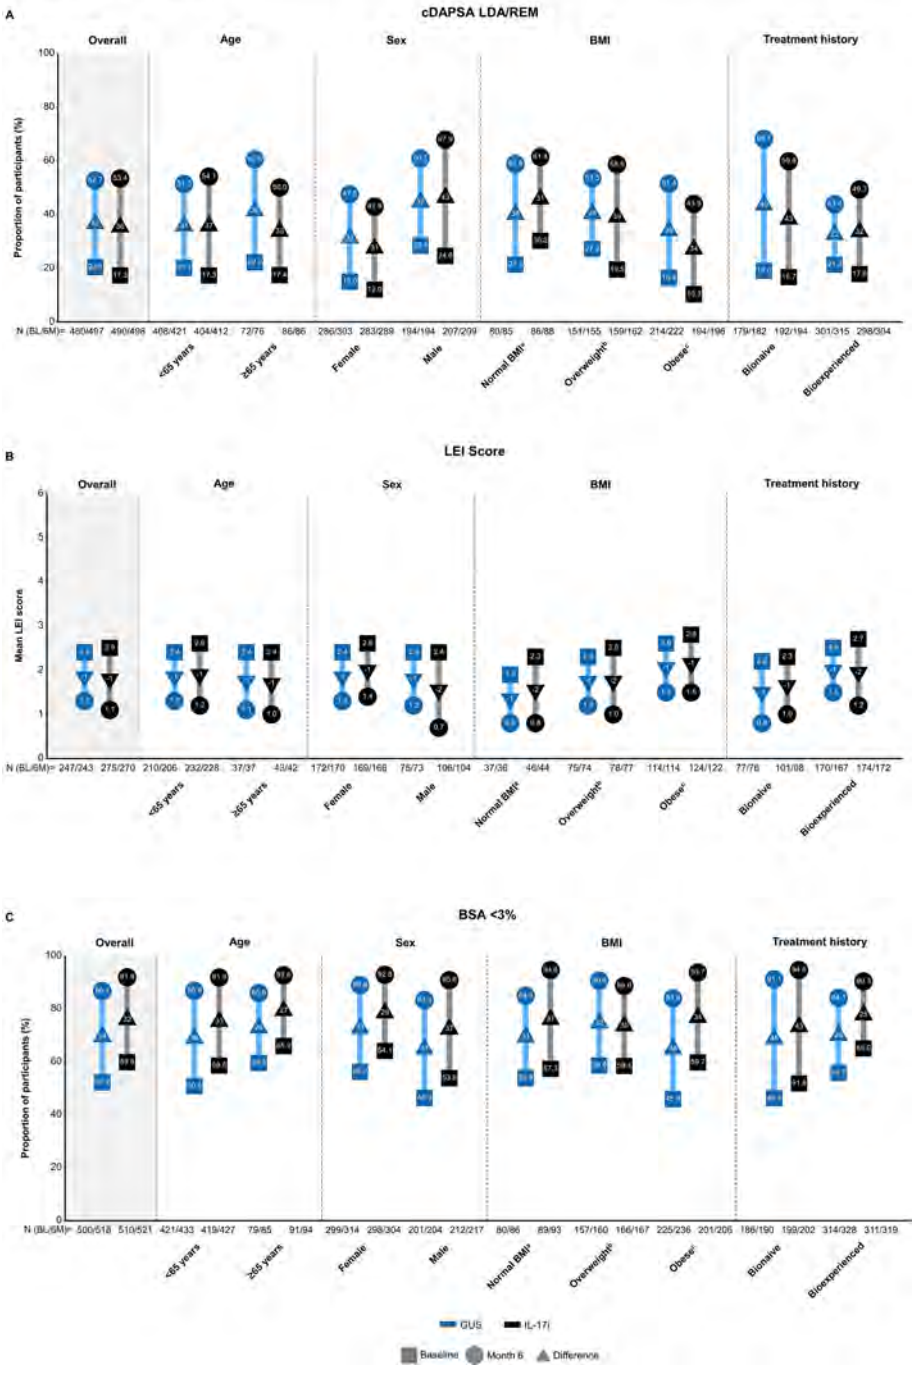
Guselkumab	555	545	540	521	509	477	461
IL-17i	579	567	552	535	516	506	480

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

of follow up was analyzed. Analyses were performed according to initial treatment group allocation in the overall population and in specific subgroups defined by baseline (BL) age, sex, BMI categories, and prior biologic use. Persistence on treatment (i.e., no stop/switch) over 6 months was assessed via the Kaplan-Meier estimator function. Propensity score (PS) analysis was used to evaluate hazard ratio (HR) of GUS vs IL-17i stop/switch prior to the 6-month visit, adjusting for BL variable imbalances across cohorts. Effectiveness was descriptively assessed using rates and means at BL and 6 months of the following measures: swollen (SJC66) and tender (TJC68) joint counts, clinical Disease Activity Index for PsA (cDAPSA)-based low disease activity (LDA)/remission (REM; ≤13), the Leeds Enthesitis Index (LEI; 0-6), psoriasis body

Fig 2. PsA clinical outcomes at baseline and the 6-month visit with GUS and IL-17i across distinct participant subgroups: (A) cDAPSA LDA/REM, (B) LEI score, and (C) BSA<3%

Absolute difference between baseline and month 6 presented in triangles. Last observation carried forward was imputed for participants with no 6-month visit. [a]BMI: ≥18.5 to <25 kg/m². [b]BMI: ≥25 to <30 kg/m². [c]BMI: ≥30 kg/m².



23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. surface area (BSA)< 3%, Dermatology Life Quality Index (DLQI), and number of nails affected by psoriatic disease (0-20). Dactylitis was not assessed due to the low prevalence of dactylitis at BL

Results: Of the 1134 pts analyzed, 555 and 579 pts received GUS or IL-17i, respectively, as their initial treatment. At BL, the GUS/IL-17i cohorts were generally well balanced across subgroups of interest: 83.4%/81.3% were < 65 years of age; 60.4%/59.2% were female; 48.0%/43.4% had BMI≥30 kg/m^2; and 63.4%/62.3% had previously received ≥1 targeted therapy.

Persistence on treatment up to 6 months was high in both cohorts, with 526/555 (94.8%) GUS and 539/579 (93.1%) IL-17i pts remaining on their initial treatment line at the 6-month visit (PS-adjusted HR of GUS vs IL-17i stop/switch [95% confidence interval]: 0.93 [0.75-1.16]; **Fig 1**). Persistence on GUS and IL-17i was also comparable in the different pt subgroups (data not shown). Across pt subgroups of interest, similar improvements in joint symptoms (SJC66; TJC68; cDAPSA LDA/REM; **Fig 2A**), enthesitis (LEI; **Fig 2B**), skin involvement (BSA< 3%; **Fig 2C;** DLQI), and psoriatic nail disease were observed with GUS and IL-17i at the 6-month visit.

Conclusion: Treatment with GUS or IL-17i resulted in comparable treatment persistence and effectiveness, regardless of age, sex, BMI, or treatment history, through 6 months. These results support the real-world effectiveness of GUS and IL-17i across PsA subpopulations

Abstract Number: 0578

Real-world Effectiveness of Upadacitinib on Group for Research and Assessment of Psoriasis and Psoriatic Arthritis Core Domains for Patients with Psoriatic Arthritis: Data from the CorEvitas Psoriatic Arthritis/ Spondyloarthritis Registry

Philip J. Mease[1], Xiaolan Ye[2], Christopher Saffore[3], Thomas Iyile[4], Nicole Middaugh[5], Taylor Blachley[5], Melissa Eliot[5] and Alexis Ogdie[6], [1]Department of Rheumatology, Providence-Swedish Medical Center and University of Washington, Seattle, WA, [2]AbbVie Inc., Mettawa, IL, [3]AbbVie Inc., waukegan, IL, [4]AbbVie Inc, North Chicago, IL, [5]CorEvitas, LLC, Waltham, MA, [6]Department of Medicine, Perelman School of Medicine at the University of Pennsylvania, Wilmington, DE

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

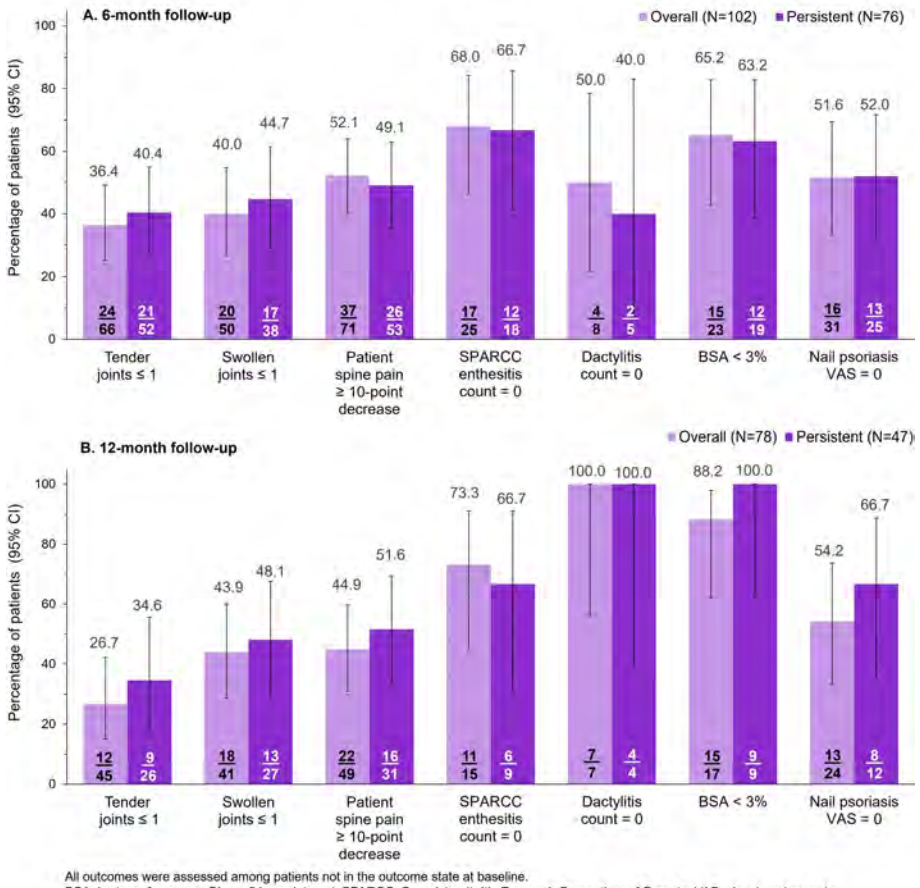
Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Psoriatic arthritis (PsA) is a heterogenous inflammatory disease that can cause substantial impairment in quality of life in affected patients. The Group for Research and Assessment of Psoriasis and PsA (GRAPPA) domain-based treatment recommendations for PsA highlight 6 key domains: peripheral arthritis, axial disease, enthesitis,

Figure 1. Response rates of clinical outcomes among patients with PsA initiating upadacitinib overall and among those persisting on therapy



All outcomes were assessed among patients not in the outcome state at baseline.
BSA, body surface area; CI, confidence interval; SPARCC, Spondyloarthritis Research Consortium of Canada; VAS, visual analog scale.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. dactylitis, skin psoriasis, and nail disease. Upadacitinib (UPA) has demonstrated efficacy versus placebo across key domains in clinical trials in patients with PsA, but real-world data are limited. In this study, we evaluated changes in disease activity measures and patient-reported outcomes (PROs) in patients with PsA who initiated UPA and persisted on therapy for 6 and 12 months overall in a real-world setting.

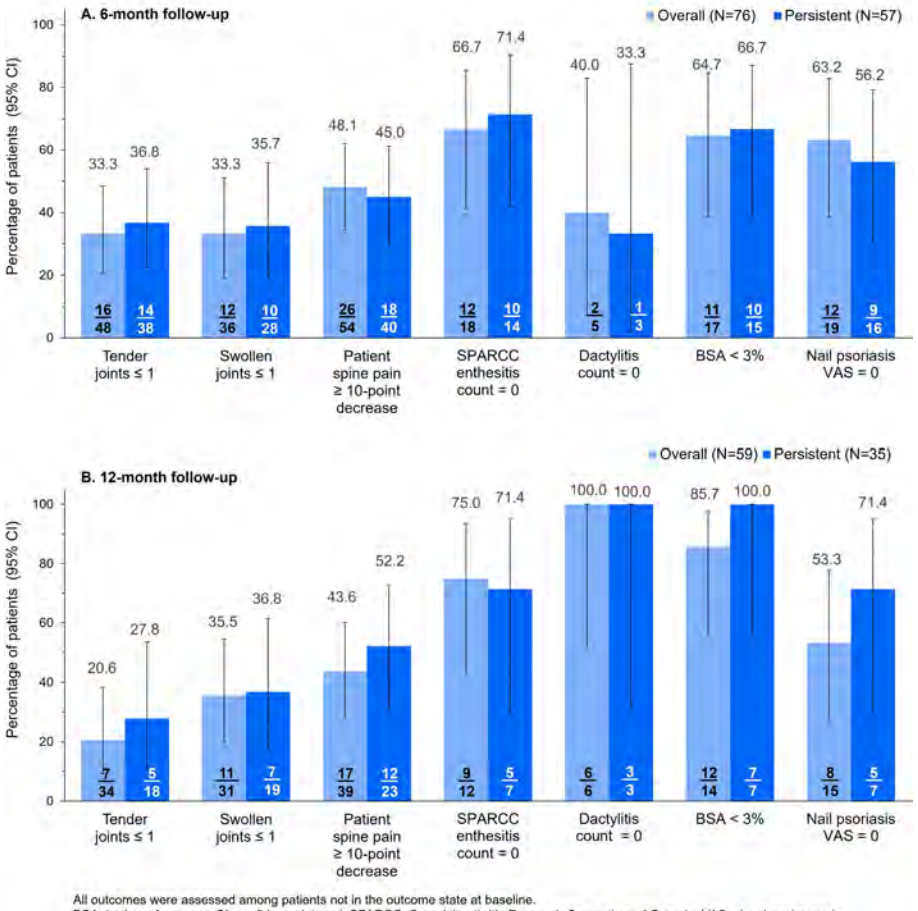
Methods: Patients with PsA in the CorEvitas PsA/Spondyloarthritis Registry who initiated UPA during or after December 2021 and had a baseline visit associated with UPA initiation were included. Disease activity and PROs were summarized at baseline; response rates (n [%]; 95% [confidence intervals] CI) for patients who were not in the outcomes state at baseline were calculated at 6 and 12 months. Outcomes included achievement of tender joint count ≤ 1, swollen joint count ≤ 1, patient spine pain (0–100 visual analog scale [VAS]) ≥ 10-point decrease, enthesitis count = 0, dactylitis count = 0, < 3% body surface area (BSA) affected by psoriasis, and nail psoriasis (0–100 VAS) = 0. Results are reported for all initiators, for those persisting on UPA treatment at 6 or 12 months, and for a subset of patients with prior TNFi-experience.

Results: This analysis included 214 patients who initiated UPA. Of these 48% (n/N, 102/214) and 36% (78/214) had 6-month and 12-month follow-up visit data available, respectively. Among all initiators, 65% (140/214) were female, mean age was 54 years, 41% (88/214) were conventional synthetic DMARD-naïve and 61% (130/214) had previously used ≥2 biologic or targeted synthetic DMARDs. Among those with respective follow-up visits, 75% (76/102) and 60% (47/78) were

Figure 2. Response rates of clinical outcomes among TNFi-experienced patients with PsA initiating upadacitinib overall and among those persisting on therapy



All outcomes were assessed among patients not in the outcome state at baseline.
BSA, body surface area; CI, confidence interval; SPARCC, Spondyloarthritis Research Consortium of Canada; VAS, visual analog scale.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. persistent on therapy at 6 and 12 months. At the 6-month follow-up visit, 36% (24/66) of all initiators achieved ≤ 1 tender joint, 40% (20/50) achieved ≤ 1 swollen joint, 52% (37/71) experienced a ≥10-point decrease in spine pain, 68% (17/25) achieved resolution of enthesitis, 50% (4/8) achieved resolution of dactylitis, 65% (15/23) achieved BSA < 3%, and 52% (16/31) achieved nail psoriasis VAS = 0 (**Figure 1**). Similar trends were seen in the subset of patients who were TNF-experienced (**Figure 2**), and in those who persisted on UPA therapy for 6 and 12 months.

Conclusion: This real-world study of patients with PsA showed that those who initiated UPA had improvements in disease activity and PROs consistent with key GRAPPA domains at 6 and 12 months. Similar results were observed in the subset of TNFi-experienced patients.

Abstract Number: 0579

Characteristics and Treatment Patterns among Patients with Psoriatic Arthritis in the CorEvitas Psoriatic Arthritis/Spondyloarthritis Registry Initiating a Third or Higher Line of Biologic or Targeted Disease-Modifying Antirheumatic Drug Therapy

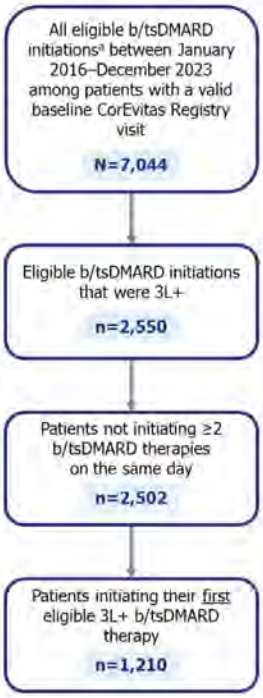
Philip J. Mease[1], Nicole Middaugh[2], Yolanda Muñoz Maldonado[2], Chao Song[3], Melissa Eliot[2], Robert Low[3] and Alexis Ogdie[4], [1]Department of Rheumatology, Providence-Swedish Medical Center and University of Washington, Seattle, WA, [2]CorEvitas, LLC, Waltham, MA, [3]UCB, Smyrna, GA, [4]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Psoriatic arthritis (PsA) is a heterogeneous chronic inflammatory disease affecting the joints, skin, and other regions of the body. It impacts up to 36% of patients with psoriasis in the US, often substantially impairing quality of life.[1,2] Biologic or targeted synthetic (b/ts) DMARDs, including interleukin (IL)-17, IL-12/23, tumor necrosis factor (TNF), and Janus kinase (JAK) inhibitors (i), have been effective in improving symptoms, but patients may experience suboptimal response or loss of response despite undergoing multiple lines of treatment.[2,3] This study analyzed characteristics and treatment patterns of patients with PsA upon initiation of a third-line or higher (3L+) b/tsDMARD therapy. Understanding these patterns may offer insights into the benefits of managing PsA in its early stages with effective treatments.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 1. Selection of eligible 3L+ b/tsDMARD initiations in the CorEvitas PsA/Spondyloarthritis Registry



[a] Initiations included any line of therapy. Eligible bDMARDs included abatacept, adalimumab, bimekizumab, certolizumab pegol, etanercept, golimumab, guselkumab, infliximab, ixekizumab, risankizumab, secukinumab, ustekinumab. Eligible tsDMARDs included tofacitinib and upadacitinib. 3L+: third-line or higher; b/tsDMARD: biologic or targeted synthetic disease-modifying antirheumatic drug; PsA: psoriatic arthritis.

Methods: This retrospective cohort study included patients who were ≥18 years of age, had a PsA diagnosis, and initiated a b/tsDMARD between January 2016–December 2023 as a 3L+ therapy at or after entry into the CorEvitas PsA/Spondyloarthritis Registry (baseline), a prospective, multicenter, observational US registry. Patient characteristics, treatment histories, and treatment patterns were assessed at baseline. Continuous variables were reported as means with standard deviation (SD) or medians with interquartile range (IQR), while categorical variables were described with counts and percentages.

Results: The CorEvitas registry included 7,044 initiations of b/tsDMARDs, with 2,550 (36.2%) being 3L+ initiations. This analysis included 1,210 patients initiating their first eligible 3L+ b/tsDMARD therapy (**Figure 1**). The mean (SD) age was 54.2 (12.3) years, 721 (59.7%) patients were female, and 1,105 (92.9%) patients were white. Two or more comorbidities were observed in 446 (36.9%) patients. The most common comorbidities were obesity, hypertension, and depression, reported in 734 (61.6%), 484 (40.0%), and 262 (21.7%) patients, respectively. Patients had a median (IQR) PsA duration of 7.0 (3.0, 12.0) years and symptom duration of 10.0 (5.0, 18.0) years. The median (IQR) time from first b/tsDMARD therapy to initiation of current therapy was 1.5 (0.7, 2.9) years. Most patients (813 [94.2%]) reported active disease as the reason for initiating a 3L+ therapy. Patients frequently used two prior bDMARDs (700 [57.9%]), while 1,102 (91.1%) were tsDMARDs naïve (**Table 1**). Concomitant conventional synthetic DMARDs were taken by 328 (27.1%) patients. Biologics most often used immediately prior to 3L+ therapy were TNFis (726 [68.5%]) or IL-17is (182 [17.2%]) (**Figure 2**). The most commonly initiated 3L+ b/tsDMARD class was IL-17i, used by 455 (37.6%) patients, followed by TNFis (338 [27.9%]), IL-23is (169 [14.0%]), and JAKis (148 [12.2%]).

Conclusion: These findings highlight the disease burden in this heavily pre-treated population, underscoring the need for early, more effective PsA treatments that provide a sustained response.

Table 1. Baseline characteristics and disease activity measures of patients with PsA in the CorEvitas PsA/Spondyloarthritis Registry

Characteristic	Total Patients Included (N=1,210)
Demographics	
Age (years), mean (SD)	54.2 (12.3)
Sex (female; N=1,207), n (%)	721 (59.7)
Race (white; N=1,190), n (%)	1,105 (92.9)
Comorbidities, n (%)	
Obesity (BMI ≥30)	734 (61.6)
Hypertension	484 (40.0)
Depression	262 (21.7)
Fibromyalgia	226 (18.7)
Diabetes	199 (16.4)
Cardiovascular Disease	139 (11.5)
Anxiety	82 (6.8)
Malignancies	79 (6.5)
IBD	30 (2.5)
Uveitis	19 (1.6)
PsA Disease Characteristics, median (IQR)	
Duration of Disease[a] (years; N=1,202)	7.0 (3.0, 12.0)
Duration of Symptoms (years; N=1,194)	10.0 (5.0, 18.0)
PsA Disease Activity Measures	
cDAPSA: moderate (>13–≤27; N=1,149), n (%)	489 (42.6)
MDA[b] (N=1,199), n (%)	215 (17.9)
VLDA[c] (N=1,209), n (%)	51 (4.2)
SJC66 (N=1,175), mean (SD)	2.7 (4.4)
TJC68 (N=1,175), mean (SD)	7.7 (10.3)
Dactylitis Count, mean (SD)	0.4 (1.6)
LEI (N=1,007), mean (SD)	0.5 (1.1)
PGA of Arthritis (VAS-100; N=1,196), mean (SD)	31.7 (23.4)
PGA of PsA and Psoriasis (VAS-100; N=1,193), mean (SD)	36.7 (23.9)
BSA (% Involvement; N=1,178), mean (SD)	5.5 (10.5)
Patient-Reported Outcomes, mean (SD)	
PtGA of Arthritis (VAS-100; N=1,187)	47.2 (26.3)
PtGA of Arthritis and Psoriasis (VAS-100; N=1,185)	47.4 (26.6)
HAQ-DI (score: 0–3; N=1,192)	0.9 (0.7)
Pain (VAS-100; N=1,201)	54.0 (27.7)
Fatigue (VAS-100, N=1,203)	53.8 (28.0)
Time from First b/tsDMARD to Initiation of Current Therapy[d] (years; N=649), median (IQR)	1.5 (0.7, 2.9)
Prior csDMARDs, n (%)	
0	308 (25.5)
1	614 (50.7)
2+	288 (23.8)
Prior bDMARDs, n (%)	
0	5 (0.4)
1	104 (8.6)
2	700 (57.9)
3	246 (20.3)

Mease[1], Nicole Middaugh[2], Yolanda Muñoz Maldonado[2], Chao Song[3], Melissa Eliot[2], Robert Low[3] and Alexis Ogdie[4], [1]Department of Rheumatology, Providence-Swedish Medical Center and University of Washington, Seattle, WA, [2]CorEvitas, LLC, Waltham, MA, [3]UCB, Smyrna, GA, [4]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Psoriatic arthritis (PsA) is a chronic disease that causes inflammation of the joints, entheses, spine, skin, and nails.[1] While available advanced treatments (txs) for PsA have expanded, many patients (pts) have suboptimal responses despite undergoing multiple lines of biologic or targeted synthetic DMARDs (b/tsDMARDs).[2] This study evaluated tx persistence (time to discontinuation) and change from baseline (CfB) in disease activity and pt-reported outcomes (PROs) among pts with PsA following initiation of a third-line or higher (3L+) b/tsDMARD.

Methods: This retrospective cohort study included pts who were ≥18 years old, had a PsA diagnosis, and initiated a 3L+ b/tsDMARD between January 2016–December 2023, at or after entry into the CorEvitas PsA/ Spondyloarthritis Registry (baseline), a prospective, multicenter, observational US registry. Persistence was defined as time from therapy initiation to

[a] N=1,210 pts initiating a 3L+ b/tsDMARD, of which n=637 had a 6-month follow-up. For all measurements except EQ-5D-3L, higher values indicated worse health state; thus, a negative change indicated improvement; **[b]** CfB=$\text{outcome}_{\text{6-month}} - \text{outcome}_{\text{baseline}}$; **[c]** Categorical variables were assessed by evaluating response achievement in outcomes among patients who had not achieved response at baseline; **[d]** Results are considered statistically significant if the 95% CI does not include zero for CfB or achievement response rate; **[e]** BSA <3% at follow-up among pts with BSA ≥3% at baseline; **[f]** IGA=0 or 1 at follow-up among pts with IGA >1 at baseline; **[g]** If cDAPSA ≤13 among pts with cDAPSA >13 at baseline; **[h]** If cDAPSA ≤4 among pts with cDAPSA >4 at baseline; **[i]** MDA was achieved if 5 out of the following 7 conditions were met: TJC68 ≤1, SJC66 ≤1, BSA ≤3%, pain (VAS-100) ≤15, PtGA of PsA and Psoriasis (VAS-100) ≤20, LEI ≤1, and HAQ-DI (score: 0–3) ≤0.5; **[j]** VLDA was achieved if all of the following conditions were met: TJC68 ≤1, SJC66 ≤1, BSA ≤3%, pain (VAS-100) ≤15, PtGA of PsA and Psoriasis ≤20, LEI ≤1; **[k]** For EQ-5D-3L, lower values indicated more severe disease; thus, a positive change indicated improvement. 3L+: third-line or higher; BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; BSA: body surface area; b/tsDMARD: biologic/targeted synthetic disease-modifying antirheumatic drug; cDAPSA: Clinical Disease Activity Index for PsA; CfB: change from baseline; CI: confidence interval; EQ-5D-3L: EuroQoL 5-dimensional, 3-level; FSS: Fibromyalgia Severity Scale; HAQ-DI: Health Assessment Questionnaire Disability Index; IGA: Investigator Global Assessment; LDA: low disease activity; MDA: minimal disease activity; mPASDAS: modified PsA Disease Activity Score; PGA: Physician Global Assessment; PRO: patient-reported outcome; PtGA: Patient Global Assessment; PsA: psoriatic arthritis; SJC66: swollen joint count in 66 joints; TJC68: tender joint count in 68 joints; VAS: Visual Analog Scale; VLDA: very low disease activity; WPAI: Work Productivity and Activity Impairment.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

discontinuation (with or without switch); pts were censored at the last available registry visit within 24 months after initiation or end of the study period, whichever occurred first. CfB in PsA disease activity and PRO measures were assessed after the 6-month follow-up period. Continuous variables were reported as mean (standard deviation [SD]) and median (interquartile range [IQR] or 95% confidence intervals [CIs]). Categorical variables were described with counts and percentages.

Results: The registry included 7,044 b/tsDMARD initiations, with 2,550 (36.2%) being 3L+. This study included 1,210 pts initiating their first 3L+ b/tsDMARD; of these, 637 had a 6-month follow-up. Of the 1,210 pts included in this analysis, mean (SD) age was 54.2 (12.3) years and median (IQR) PsA duration was 7.0 (3.0, 12.0) years (**Table 1**). At b/tsDMARD initiation, mean (SD) swollen joint count (SJC) and tender joint count (TJC) were 2.7 (4.4) and 7.7 (10.3), respectively. Baseline PROs demonstrated moderate-to-high disease severity. Mean (SD) Health Assessment Questionnaire Disability Index (HAQ-DI) score was 0.9 (0.7). Mean (SD) pain and fatigue Visual Analog Scale (VAS)-100 scores were 54.0 (27.7) and 53.8 (28.0), respectively (**Table 1**).

Median (95% CI) tx persistence was 13.4 (12.4, 15.2) months (**Figure 1**); 76.0% (95% CI: 73.0, 78.0), 54.0% (95% CI: 51.0, 57.0), and 42.0% (95% CI: 39.0, 45.0) of pts remained on therapy at 6, 12, and 18 months, respectively. Among pts with 6-month follow-up (n=637), statistically significant improvements from baseline occurred in most disease activity and PRO measures except for dactylitis count, HAQ-DI, EuroQoL 5-dimensional, 3-level (EQ-5D-3L), and Work Productivity and Activity Impairment (WPAI) absenteeism (**Table 2**).

Conclusion: While median tx persistence greater than 1 year was observed, suboptimal improvements were reflected across disease activity measures and quality of life-related PROs, suggesting that pts may experience insufficient disease control even after multiple lines of tx. Therefore, earlier, more effective tx options are needed to mitigate the development of persistent symptoms and achieve disease control.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

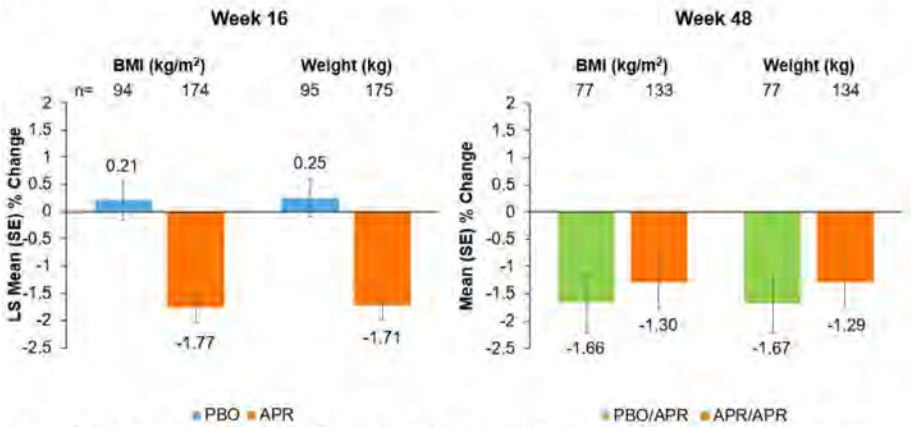
Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: The prevalence of cardiometabolic diseases, including obesity and diabetes, is higher in patients with psoriatic arthritis (PsA) than those without PsA.[1,2] Metabolic syndrome is a common comorbidity of PsA that can impact treatment choice.[3] Weight loss and improvements in other cardiometabolic biomarkers have been observed with apremilast (APR) treatment in randomized controlled trials and real-world studies.[4-6] The aim of this post hoc analysis was to evaluate the effects of APR on body mass index (BMI), weight, and HbA1c over 48 weeks in patients with early oligoarticular (oligo) PsA from the FOREMOST trial (NCT03747939).

Methods: FOREMOST was a phase 4, multicenter, randomized, double-blind, placebo (PBO)-controlled trial that enrolled patients with early (duration ≤5 years) oligo PsA (>1 to ≤4 swollen joints and >1 to ≤4 tender joints; 66–68 joints assessed). Patients were randomized 2:1 to APR (n=203) or PBO (n=105) for 24 weeks (early escape at Week 16), followed by an extension phase in which all patients received APR through Week 48. Percent changes from baseline to Weeks 16 and 48 in BMI and weight were assessed. The percent change in weight from baseline to Week 48 was assessed overall and by baseline BMI category (normal: < 25 kg/m^2, overweight: ≥25 to < 30 kg/m^2, class I–II obesity: ≥30 to < 40 kg/m^2, class III obesity: ≥40 kg/m^2). Additionally, changes in BMI and HbA1c category (normal: < 5.7%, pre-diabetic: ≥5.7% to < 6.5%, and diabetic: ≥6.5%) were evaluated from baseline to Week 48.

Figure 1. Percent Change From Baseline in BMI and Weight at Weeks 16 and 48



Week 16: Full analysis set (N=308). Based on an MMRM model which includes treatment group, time, treatment group by time interaction, prior/concomitant use of csDMARD (naive, prior use only, both prior and concomitant use) and baseline glucocorticosteroids use (yes/no) as factors, and baseline value as a covariate.
Week 48: APR patients as randomized (n=203) or transitioned from PBO at Week 16 or 24 (n=88). Data as observed.
APR, apremilast; csDMARD, conventional synthetic disease-modifying antirheumatic drugs; LS, least squares; MMRM, mixed-effects model for repeated measures; PBO, placebo; SE, standard error.

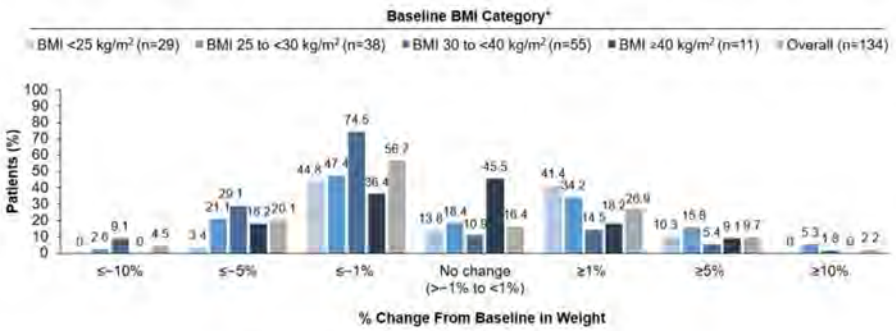
Figure 2. Cumulative Weight Percent Change From Baseline at Week 48 Overall and by Baseline BMI



APR patients as randomized. Data as observed.
*Normal: <25 kg/m²; overweight: 25 to <30 kg/m²; class I-II obesity: ≥30 to <40 kg/m²; class III obesity: ≥40 kg/m².
APR, apremilast; BMI, body mass index.

Figure 3. Shift in BMI and HbA1c Category From Baseline at Week 48

BMI Categories at Baseline*	BMI Categories at Week 48*			
	Class III Obesity	Class I-II Obesity	Overweight	Normal
Normal (n=28)	0%	0%	3.6%	96.4%
Overweight (n=38)	0%	18.4%	65.8%	15.8%
Class I-II Obesity (n=56)	3.6%	87.5%	8.9%	0%
Class III Obesity (n=11)	81.8%	18.2%	0%	0%

Patients with ≥1 BMI category improvement
Patients with no change in BMI category
Patients with ≥1 BMI category worsening

HbA1c Categories at Baseline†	HbA1c Categories at Week 48†		
	Diabetic	Pre-diabetic	Normal
Normal (n=82)	0%	9.8%	90.2%
Pre-diabetic (n=42)	14.3%	61.9%	23.8%
Diabetic (n=16)	87.5%	12.5%	0%

Patients with ≥1 HbA1c category improvement
Patients with no change in HbA1c category
Patients with ≥1 HbA1c category worsening

APR patients as randomized. Data as observed.
*Normal: <25 kg/m²; overweight: 25 to <30 kg/m²; class I-II obesity: ≥30 to <40 kg/m²; class III obesity: ≥40 kg/m².
†Normal: <5.7%; pre-diabetic: ≥5.7% to <6.5%; diabetic: ≥6.5%.
APR, apremilast; BMI, body mass index.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Baseline BMI, weight, and HbA1c were similar between APR and PBO patients (30.2 vs 31.4 kg/m^2, 87.3 vs 91.5 kg, and 5.8 vs 5.7%, respectively). Greater percent reductions in BMI (-1.77 vs 0.21%) and weight (-1.71 vs 0.25%) were seen with APR vs PBO at Week 16 (**Figure 1**). Decreases in BMI and weight were maintained through Week 48 with continued APR treatment (APR/APR; **Figure 1**); similar improvements were seen in patients who transitioned to APR at Week 24 (PBO/APR). Over the 48-week period, a greater proportion of patients randomized to APR experienced weight loss than weight gain. More than 50% of patients had a weight reduction of ≥1% and approximately 20% achieved a reduction of ≥5% (**Figure 2**). Among patients randomized to APR, there was a general shift in BMI and HbA1c categories from baseline toward lower-risk categories after 48 weeks of treatment (**Figure 3**).

Conclusion: APR treatment through Week 48 was associated with improvements in BMI and weight in the FOREMOST study of early oligo PsA. Consistent with prior studies of APR in polyarticular PsA and psoriasis, greater changes in cardiometabolic markers were observed in patients in the highest risk categories (ie, obesity and diabetic subgroups).

Long-Term Efficacy and Safety of Tofacitinib in Active Axial Spondyloarthritis: Experience from a Tertiary Care Center in South India

Prabhu Vasantha Kumar[1], John Mathew[2], Ashish Jacob Mathew[3] and Ruchika Goel[2], [1]Christian Medical College, Vellore, Tamil Nadu, India, Vellore, Tamil Nadu, India, [2]Christian Medical College, Vellore, Tamil Nadu, India, [3]Christian Medical College, Vellore, India

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Despite the good efficacy of bDMARDs in nearly 60% of patients with axial spondyloarthritis (AxSpA), high costs limit their use in resource-limited settings. Few studies suggest JAK inhibitors to be more accessible and cost-effective alternative

Methods: Objective: This study aimed to evaluate the long-term effectiveness and safety of generic tofacitinib in Indian patients with active axial SpA.

Table-1: Baseline characteristics of study population

Characters	Total (N=290)
Age in Years, Mean ± SD	27 (± 5.6)
Male Patients, n (%)	247 (85.1%)
Active Smokers, n (%)	124 (42.7%)
Disease Duration since symptom onset (Median, IQR, Years)	4 (4-12)
Disease Duration since diagnosis (Median, IQR, Years)	2 (2-6)
History of Uveitis, n (%)	46 (15.9%)
Current Uveitis, n (%)	7 (2.4%)
History of IBD, n (%)	4 (1.3%)
Current IBD, n (%)	1 (0.3%)
History of Peripheral Arthritis, n (%)	147 (50.7%)
Current Peripheral Arthritis, n (%)	88 (30.3%)
HLA B27	
Positive, n (%)	141 (48.6%)
Negative, n (%)	24 (8.2%)
Not Available, n (%)	125 (43.1%)
CRP– mg/L, Mean ± SD	27.1 (±7.8)
Swollen Joint Count (SJC), Mean ± SD	5 (±2)
Tender Joint Count (TJC), Mean ± SD	7 (±3)
Presence of enthesitis based on MASES > 1, n (%)	1 (±1.4)

Figure-1: Sankey diagram depicting the efficacy of tofacitinib in patients with active axial SpA

Materials and Methods: This retrospective single-center study included 290 patients aged ≥18 years with active axial spondyloarthritis (axSpA), defined by BASDAI ≥4 or ASDAS ≥2.1, who were initiated on generic tofacitinib between January 2021 and March 2023, despite prior treatment with csDMARDs and/or bDMARDs. Only patients with a minimum follow-up of one year were included. Baseline data—including age, sex, disease duration, comorbidities, smoking status, HLA-B27 status, inflammatory markers (ESR, CRP), presence of uveitis, inflammatory bowel disease, enthesitis, disease activity indices (BASDAI, ASDAS), and concomitant medications—were recorded. Follow-up data on disease activity was systematically extracted from prospectively maintained electronic medical records. The primary endpoint was the proportion of patients achieving inactive disease or low disease activity (ASDAS < 2.1). Failure to meet this target within 12–24 weeks, or later in the event of disease flares, was classified as treatment failure. The details of adverse events at follow up visits were also noted

Results: Baseline characteristics of 290 patients included in the study are summarized in Table 1. After a median follow-up of 25 months (IQR 15-33), 258 of 290 patients (89%) achieved either inactive disease with ASDAS < 1.3 (n=112, 39%) or Low disease activity defined by ASDAS 1.3–2.1(n=146,50%) [Figure 1]. Tofacitinib failed in 32 patients (11%) of whom 10 (3.4%) patients had initial response but flared later. No significant predictors of non-response were identified.

Adverse events were reported in 52 patients (17.9%), most commonly transaminitis (42, 14.5%), followed by dyslipidemia (5, 1.7%), herpes zoster (3, 1%), and tuberculosis (2, 0.7%). Ten (3.4%) patients discontinued tofacitinib due to adverse effects. Transaminitis occurred at a median of 8 months and was associated with fatty liver in 29 patients (10%). Most cases of transaminitis (37, 12.7%) were mild and resolved with dose reduction. No serious infections, major adverse cardiovascular events (MACE), thromboembolic events, or deaths were observed.

Conclusion: Tofacitinib was effective and well-tolerated for controlling disease activity in active axial SpA in real life settings

Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Previous studies have identified subgroups of patients with psoriatic arthritis (PsA) based on the severity of the disease [1,2]. However, no analysis to date has evaluated hidden pattern of PsA according to the peripheral manifestations and their influence on the response to TNF inhibitors (TNFi). The objectives of this study were: a) to identify

Table 1. Baseline characteristics of patients with Psoriatic Arthritis prior to initiation of biologic therapy, stratified by clusters.

Characteristics	Baseline characteristics. N = 68	Cluster 1 N = 37	Cluster 2 N = 31	p-value
Sex, male	38 (55.8)	20 (54.1%)	18 (58.1%)	0.931
Age in years, mean (SD)	49.0 (10.8)	51.1 (10.8)	46.4 (10.8)	0.075

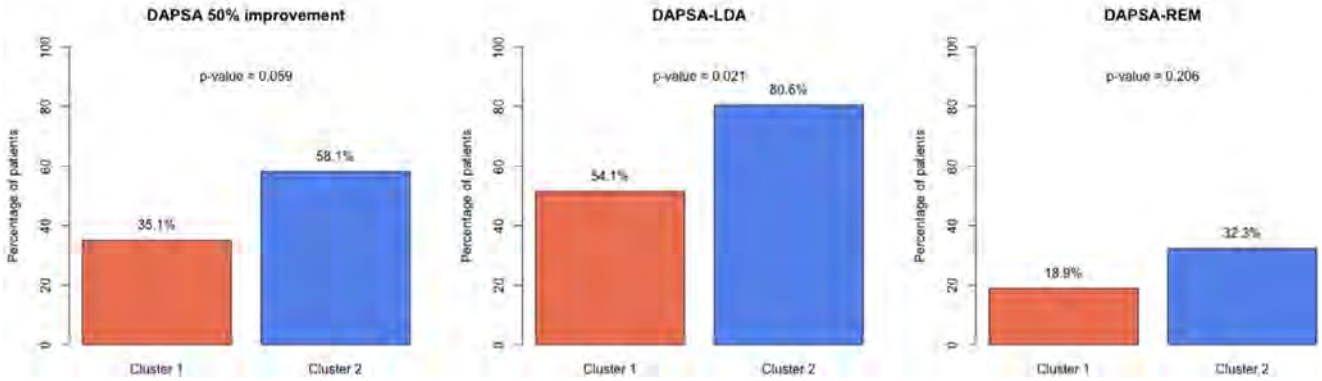
Figure 1. Comparison of treatment response to TNF inhibitors between clusters after 6 months.



clusters of PsA patients based on the presence of peripheral manifestations and psoriasis at the time of TNFi initiation, and b) to compare the effectiveness of the first TNFi across these clusters after 6 months of follow-up.

Methods: An observational, retrospective study was conducted in PsA patients naïve to TNFi. An unsupervised cluster analysis using the k-means technique was performed based on key peripheral features of PsA (arthritis, enthesitis, and dactylitis) and the presence of psoriasis. The response to TNFi treatment at 6 months (defined as ≥50% improvement in DAPSA) as well as achievement of DAPSA-LDA (DAPSA ≤ 14) and DAPSA-REM (DAPSA ≤ 4), were compared between clusters using the chi-square test.

Results: A total of 68 patients were included, 55.8% of whom were male, with a mean age of 50 years (SD 16.7) and a mean disease duration of 7.2 years. Two clusters were identified after the k-means analysis. Phenotypically, Cluster 1 (n=37) had a significantly lower prevalence of dactylitis (0% vs. 100%, p< 0.001) and psoriasis (64.9% vs. 90.3%, p=0.029) compared to cluster 2 (n=31) (Table 1). Other clinical variables at baseline, including mean swollen joint count (3.0 vs. 3.7, p=0.497) and tender joint count (6.0 vs. 5.4, p=0.628), were similar between clusters. However, CRP levels were significantly higher in Cluster 2 (21.4 vs. 8.5, p=0.049). No significant differences were found on the prevalence of concomitant csDMARDS (86.5% vs. 83.9%).

After 6 months of TNFi treatment (Figure 1), the percentage of responders (defined as a ≥50% improvement in DAPSA) was numerically higher in Cluster 2 compared to Cluster 1, approaching statistical significance (35.1% vs. 58.1%, p=0.059). The proportion of patients achieving DAPSA-LDA was significantly greater in Cluster 2 (54.1% vs. 80.6%, p=0.021), while no significant difference was observed in DAPSA-REM rates between clusters.

Conclusion: Our findings suggest the presence of two distinct clinical phenotypes, primarily defined by the presence of dactylitis and psoriasis. Patients belonging to this phenotype had a higher likelihood of achieving low disease activity after 6 months of TNFi treatment. These results suggest that baseline phenotypic features may help predict treatment response.

Abstract Number: 0584

Difficult-to-Manage Axial Spondyloarthritis According to ASAS Criteria in Reuma-Check Cohort: Frequency, Predictive Factors, and Treatment Patterns.

Rodrigo García Salinas[1], Nataly Mejia[2], Santiago Ruta[3] and Sebastian Magri[4], [1]Hospital Italiano La Plata, La Plata, Argentina, [2]Hospital Italiano de La Plata, La Plata, Argentina, [3]Hospital San Martin de La Plata, La Plata, Argentina, [4]Hospital Italiano La Plata, Melchor Romero, Argentina

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose:

The concept of difficult-to-Manage axial spondyloarthritis (axSpA D2M), recently introduced by ASAS, describes patients who fail ≥2 lines of b-tsDMARDs treatment and remain active (amog others). Refractory patients are defined as those with D2M and objective signs of inflammation. This study aimed to estimate the frequency of D2M in the Argentinian Reuma-Check axSpA cohort, describe treatment trends, and analyze baseline characteristics associated with D2M during follow-up.

Methods: This prospective observational study (2017–2024) included axSpA patients aged ≥18 years. The Reuma-Check program conducted structured assessments, including blood tests (HLA-B27), sacroiliac X-rays, MRI (ASAS protocol), and enthesis ultrasound. Data collected included demographics, educational levels, back pain characteristics, diagnostic delay, NSAID response, VAS pain scores, morning stiffness, BASDAI, BASFI, MASES, and HAQ (figure 1). D2M was defined as the lack of response to ≥2 biological therapies with active disease. Descriptive statistics, comparative analyses, and logistic regression were performed to identify associated factors.

Results: A total of 129 axSpA patients were included, with a follow-up of 12 months (IQR: 3–36). The frequency of D2M was 8.53% (n=11; 95% CI: 4.83%-14.62%). The average time on the first biologic was 19 months (SD: 16) and the prevalence of use was 50%, 21 months (SD: 19) on the second before D2M definition. Among first-line therapies 30% failure: 8% failed TNFi, and 20% IL17, regardin second-line faiuler: 85% failed TNFi, 10% IL17, and 5% JAKi (figure1). Only four patients met criteria for refractory disease, two showing elevated CRP and two active MRI findings. Baseline variables associated with D2M included BASFI (4.16 ± 2.54 vs. 2.87 ± 2.15; p=0.04; 95% CI: 0.03–2.54), BASDAI (5.11 ± 2.87 vs. 3.54 ± 2.42; p=0.01; 95% CI: 0.32–2.82), and ASDAS (3.72 ± 1.45 vs. 2.84 ± 1.16; p=0.009; 95% CI: 0.23–1.53). Significant categorical variables included smoking (OR=6.347; 95% CI: 1.256–32.084; p=0.012), psoriasis (OR=3.771; 95% CI: 1.069–13.305; p=0.029), sacroiliac joint maneuvers (OR=3.71; 95% CI: 1.030–13.417; p=0.043), peripheral X-rays (OR=5; 95% CI: 1.3–6.487; p=0.01), and articular ultrasound (OR=10.65; 95% CI: 1.42–80.09; p=0.022). Multivariate analysis identified articular ultrasound as the only significant predictor (OR=10.651; 95% CI: 1.416–80.094). Among D2M patients, six received JAKi, three IL17, and two TNFi as third-line therapies.

Conclusion: The Reuma-Check cohort revealed a low prevalence of axSpA D2M. Clinical and imaging features, particularly articular ultrasound and disease activity scores (BASFI, BASDAI, ASDAS), were predictive of D2M. These findings underscore the importance of advanced diagnostic tools and a multidimensional approach to optimizing the management of this complex population

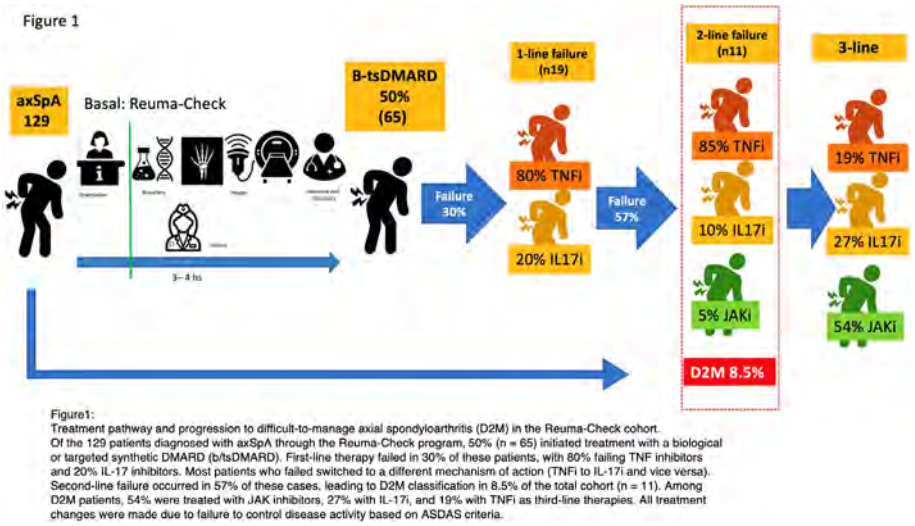

Figure1:
Treatment pathway and progression to difficult-to-manage axial spondyloarthritis (D2M) in the Reuma-Check cohort. Of the 129 patients diagnosed with axSpA through the Reuma-Check program, 50% (n = 65) initiated treatment with a biological or targeted synthetic DMARD (b/tsDMARD). First-line therapy failed in 30% of these patients, with 80% failing TNF inhibitors and 20% IL-17 inhibitors. Most patients who failed switched to a different mechanism of action (TNFi to IL-17i and vice versa). Second-line failure occurred in 57% of these cases, leading to D2M classification in 8.5% of the total cohort (n = 11). Among D2M patients, 54% were treated with JAK inhibitors, 27% with IL-17i, and 19% with TNFi as third-line therapies. All treatment changes were made due to failure to control disease activity based on ASDAS criteria.

Fungal Infections, Including *Candida*, in Patients With Active Axial Spondyloarthritis Treated With Secukinumab: A Pooled Analysis of 10 Phase 3 Trials

Shikha Singla[1], Linda Grinnell-Merrick[2], Weibin Bao[3], Artem Zharkov[4] and Abhijeet Danve[5], [1]Medical College of Wisconsin, Milwaukee, WI, [2]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [3]Novartis Pharmaceuticals Corporation, Hanover, NJ, [4]Novartis Pharma AG, Basel, Switzerland, [5]Section of Rheumatology, Department of Medicine, Yale School of Medicine, New Haven, CT

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Axial spondyloarthritis (axSpA) is a chronic disease characterized by inflammatory low back pain and is often accompanied by inflammation of the peripheral joints and entheses. Patients receiving treatment with an IL-17 inhibitor, such as secukinumab (SEC), reported higher incidence of *Candida* and other fungal infections. The objective of this post hoc analysis is to describe the incidence, severity, seriousness, and type of fungal infections, including *Candida*, among patients with active axSpA treated with SEC.

Methods: This post hoc analysis included patients with active axSpA, including radiographic and non-radiographic disease, from a pooled population of 10 phase 3 clinical trials who received SEC 150 mg or placebo (PBO). Following the PBO-controlled period, patients randomized to PBO were switched to SEC 150 mg, while patients randomized to SEC 150 mg at baseline continued the same dose or were uptitrated to SEC 300 mg through the entire treatment period. Baseline demographic and clinical characteristics are reported in patients with or without ≥1 fungal infection adverse event during the entire treatment period. Incidence of fungal infections, including *Candida*, are reported for the PBO-controlled period and through

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Fungal Infections, Including *Candida*, During the PBO-Controlled Period in Patients With AxSpA Receiving Secukinumab

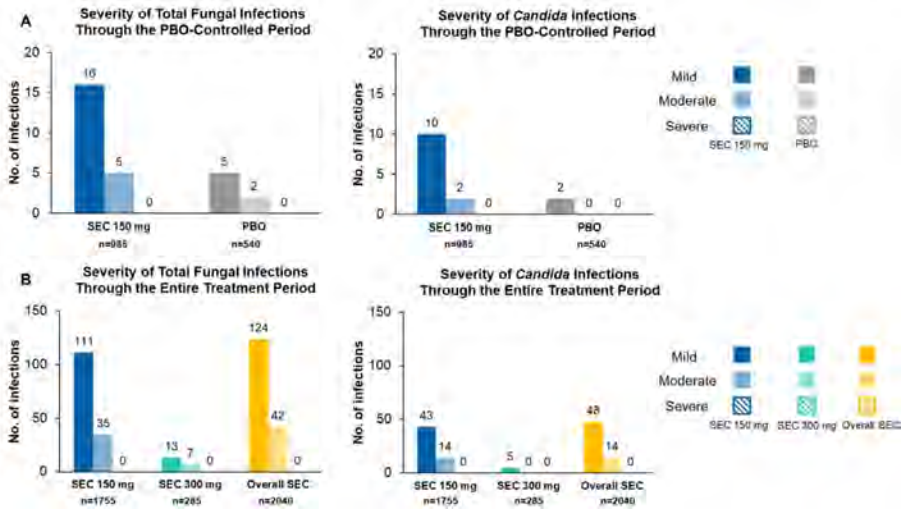
Infection type, EAIR (95% CI)[a,b]	SEC 150 mg (n=985)	PBO (n=540)
Total fungal infections	5.51 (3.26-8.70)	3.39 (1.24-7.38)
Candida infections	3.05 (1.46-5.60)	0.56 (0.01-3.13)
Oral candidiasis	1.52 (0.49-3.54)	0.56 (0.01-3.13)
Vulvovaginal candidiasis	1.22 (0.33-3.11)	0.56 (0.01-3.13)
Oesophageal candidiasis	0.30 (0.01-1.69)	0.00 (0.00-2.07)
Fungal infections (NEC)[c]	1.21 (0.33-3.11)	2.25 (0.61-5.77)
Fungal foot infection	0.61 (0.07-2.19)	0.56 (0.01-3.13)
Onychomycosis	0.30 (0.01-1.69)	1.13 (0.14-4.07)
Vulvovaginal mycotic infection	0.30 (0.01-1.69)	0.56 (0.01-3.13)
Tinea infections	1.22 (0.33-3.11)	0.56 (0.01-3.13
Tinea pedis	1.22 (0.33-3.11)	0.00 (0.00-2.07)
Tinea versicolour	0.00 (0.00-1.12)	0.56 (0.01-3.13

EAIR, exposure adjusted incidence rate per 100 patient-years; MedDRA, Medical Dictionary of Regulatory Activities; NEC, not elsewhere classifiable; PBO, placebo; SEC, secukinumab. a MedDRA preferred term. b A patient with multiple occurrences of an infection while receiving 1 treatment was counted only once in the infection category for that treatment. c NEC denotes infections that were not specifically classified into any of the MedDRA preferred terms.

the entire treatment period. Characteristics of infections including the specific types (defined by MedDRA preferred term), severity grades, resolution, and infections resulting in treatment discontinuation are reported through the entire treatment period.

Results: Overall, 2040 and 540 patients with active axSpA receiving SEC or PBO, respectively, were included. A total of 124 (6.1%) patients receiving SEC reported ≥1 fungal infection through the entire treatment period, and most (55.6%) were male. Male patients comprised 66.7% of the entire study population and the mean age was 41.3 years. During the PBO-controlled period, the incidence of total fungal infections were infrequent in each treatment group (exposure adjusted incidence rate [EAIR] per 100 patient-years [95% CI], SEC 150 mg: 5.51 [3.26-8.70], PBO: 3.39 [1.24-7.38], **Table 1**). EAIRs of *Candida* infections were also infrequent in patients receiving either SEC 150 mg: 3.05 (1.46-5.60) or PBO: 0.56 (0.01-3.13). Through the entire treatment period, the rates of total fungal infections (SEC 150 mg: 3.70 [3.01-4.50]; SEC 300 mg: 2.9 [1.73-4.76]) and *Candida* infections (SEC 150 mg: 1.30 [0.91-1.79]); SEC 300 mg: 0.68 [0.19-1.74]) did not increase. All fungal infections, including *Candida*, in patients receiving any dose of SEC through the entire treatment period were mild or moderate; no serious infections were reported (**Figure 1**). The vast majority (86.7% of total fungal infections

Figure 1. Severity of Total Fungal and *Candida* Infections Through (**A**) the PBO-Controlled Period and (**B**) the Entire Treatment Period[a]



PBO, placebo; SEC, secukinumab. a Infections are reported as the number of infections per treatment arm.

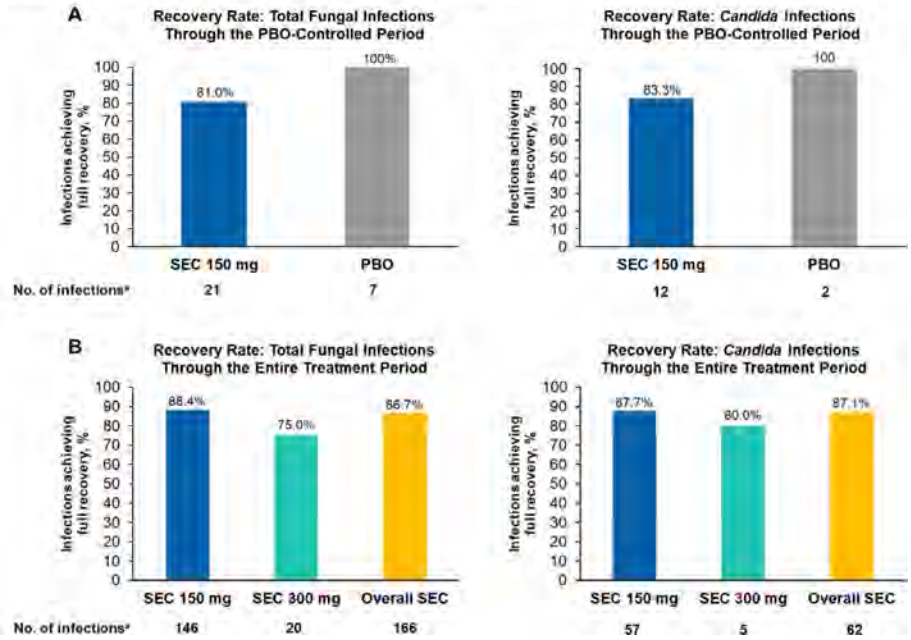
Figure 2. Recovery Rates of Total Fungal and *Candida* Infections Through (**A**) the PBO-Controlled Period and (**B**) the Entire Treatment Period



PBO, placebo; SEC, secukinumab. a Total number of infections through the indicated time.

and 87.1% of *Candida* infections) were fully resolved before the end of the treatment period (**Figure 2**), and 5 (3.0%) of infections resulted in treatment discontinuation.

Conclusion: Fungal infections, including *Candida*, were infrequent with incidence rates not increasing throughout the entire treatment period. Fungal infections during treatment with SEC were mild or moderate and most infections were fully resolved before the end of treatment, allowing almost all patients to continue treatment.

Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Check point inhibitor PD-1 (programmed death protein 1) is upregulated during T lymphocyte activation and is important for limiting the duration of activation. Thus, maintain self-tolerance. Insufficient PD-1 signaling can

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

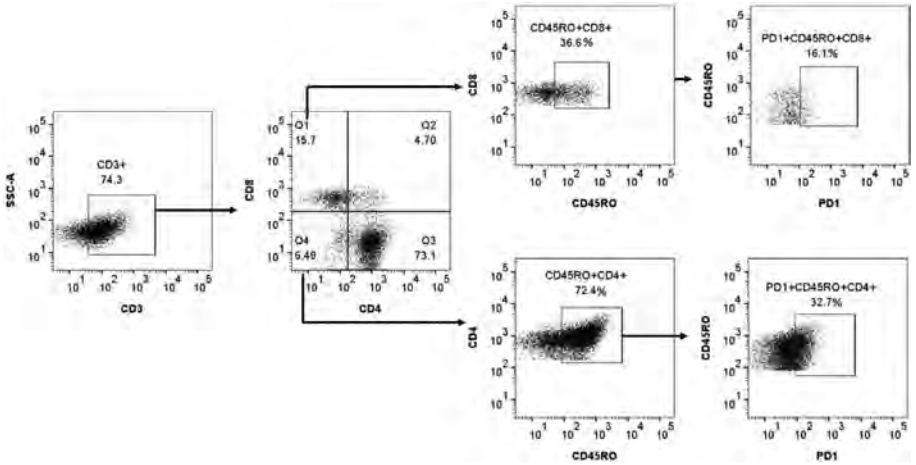

Figure 1. In flow cytometric Hi-D FACS study it was observed that a high number of psoriatic arthritis synovial CD4+/CD8+ Effector Memory T cells expressed Check point inhibitor PD-1 (programmed death protein 1). First activated live lymphomononuclear cells were gated and then effector memory [CD4+/CD8+CD11a+CD45RO+] T (TEM) cells were characterized.

lead to dysregulated T cell response. The functional significance of PD-1 and its ligands PD-L1/L2 is not studied in psoriatic arthritis (PsA). Our objectives were to (i) investigate the expression of PD-1 in PsA synovium (ii) determine its functional significance (iii) explore mechanistic of checkpoint agonists (Recombinant Human PD-L1/B7-H1; R&D system) as a novel therapy for T cells mediated autoimmune diseases.

Methods: Mononuclear cells from peripheral blood (PBMC) and synovial fluid (SFMC) of age/sex matched PsA patients (n=10), and RA patients (positive control, n=10) were isolated. Isolated $CD3^+$ T cells (1x 10^6/ml) were activated with CD3/CD28 antibody (5μg each/ml) for 3 days in the presence/absence of recombinant PD-L1 (1μg/mL).

Hi-D FACS studies were done : (1) to identify PD-1 in activated effector memory [CD4+/CD8+CD11a+CD45RO+] T (TEM) cells in PsA and RA SFMC; (2) to determine the anti-proliferative effect of recombinant PD-L1 on the SFMCs TEM cells by CFSE dilution test; (3) to determine the effect of recombinant PD-L1 agonist on the expression of IL-17A, IL-17F, IL-22 on SFMC TEM cells. Studies were performed using a FACSfusion Aria flow cytometer and data were analyzed using FlowJo software (Treestar, Ashland, OR). Western blot assays were done on lysates of the cultured CD3+T cells with recombinant PD-L1 in PsA and RA PBMC to determine effect on T cell signaling proteins (stat3/p-stat3, RORγt).

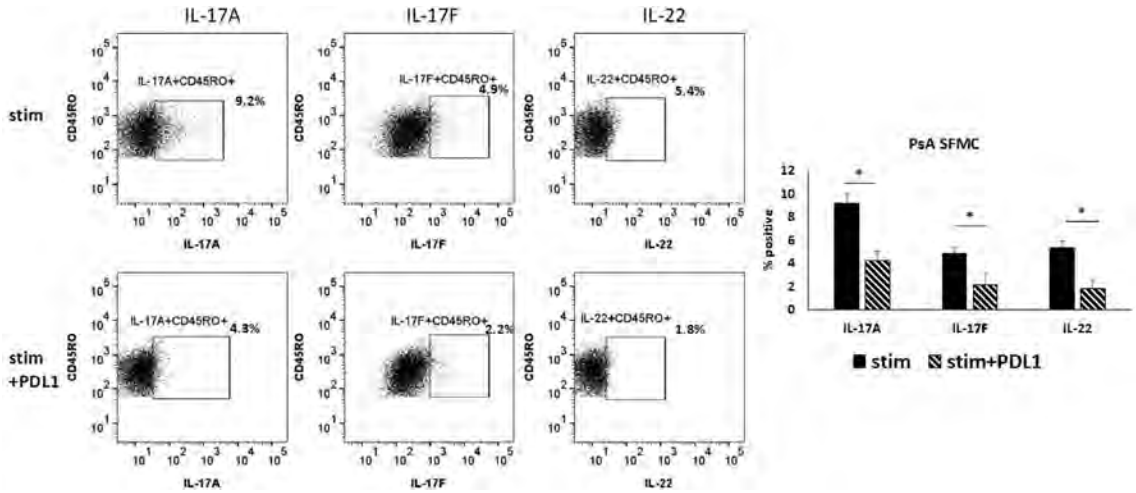

Figure 2. Hi-D FACS study to determine the effect of recombinant PD-L1 agonist on the key pathologic Th17 cytokines (IL-17A, IL-17F, IL-22) which drives the pannus formation in psoriatic arthritis (PsA). Expression of IL-17A, IL-17F, and IL-22 in CD4+CD45RO+ T (TEM) cells were significantly reduced when CD3/CD28 stimulated PsA synovial fluid mononuclear cells were treated with recombinant human PD-L1 (1μg/mL).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

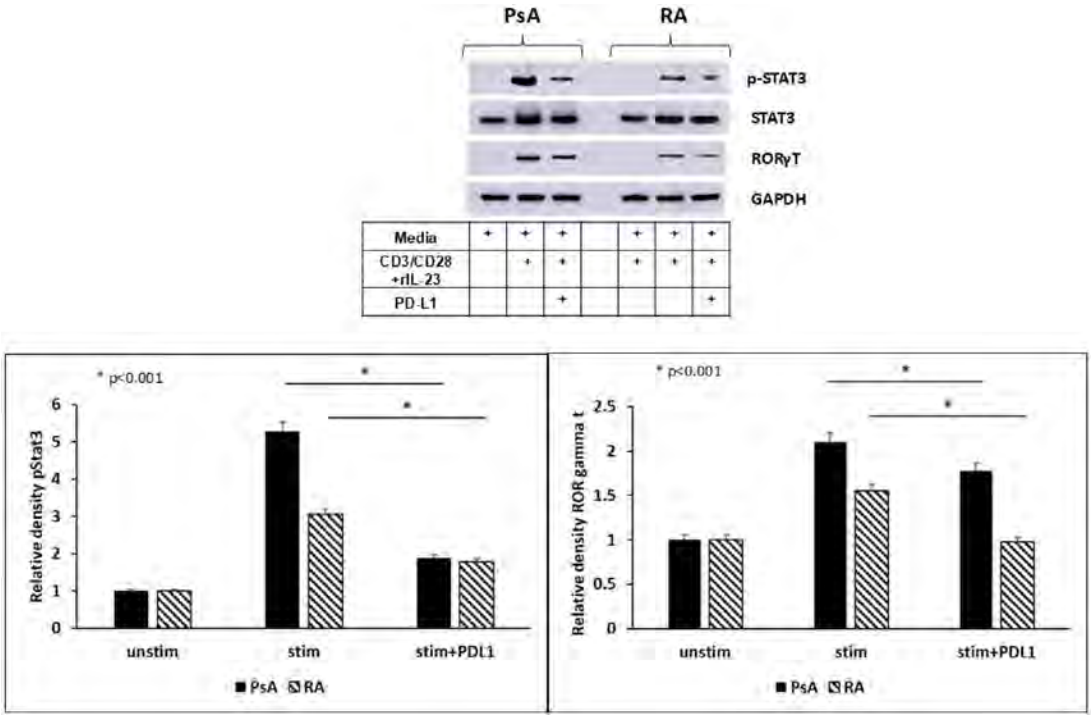

Figure 3. PD-1 activation in T cells regulates Th17 cell function by inhibiting IL-23 induced STAT3/ RORγt activation. Western blot assays were done on lysates of the cultured CD3+T cells. PBMC T cells from psoriatic arthritis (PsA) and rheumatoid arthritis (RA) were stimulated with anti-human CD3 (1μg/mL) and CD28 (1μg/mL) and rIL-23 (40ng/mL) in presence/absence of recombinant human PD-L1 agonist (1μg/mL). AS expected rIL-23 induced phosphorylation of STAT3 and upregulated RORγt expression. PD-L1 agonist treated PsA PBMC and RA PBMC CD3+ T cells had significant decreased expression of phospho-STAT3 compared to untreated CD3+ T cells ($p<0.001$). Similar effect was seen on the expression of RORγt.

Results: High PD-1 expression (Fig 1) was observed in CD4+ (43.3%±12.6) and CD8+ (20.5%±6.5) activated TEM cells of PsA PBMC/SFMC and RA PBMC/SFMC. CFSE dilution assay showed proliferation of CD3/CD28 antibody stimulated memory CD4+ SFMC of PsA reduced significantly from 72.2%±2.2 to 30.1%±3.13 when treated with recombinant PD-L1 ($p< 0.001$). Similarly in RA SFMC with recombinant PD-L1, CD4+ TEM cell proliferation significantly reduced from 53.3% ±2.6 to 26.2%±2.7 ($p< 0.001$).

In CD3/CD28 stimulated PsA SFMC, Hi-D FACS analysis showed expression of IL-17A (9.2+0.8%), IL-17F (4.9+0.5%), and IL-22 (5.3+0.5%) in CD4+CD45RO+ T (TEM) cells were significantly reduced when treated with recombinant PD-L1 (4.3+0.8%, 4.9+0.5%, and 5.3+0.5%, respectively, $p< 0.001$). (Fig 2)

Findings from western blot assays showed PD-L1 agonist treated PsA PBMC and RA PBMC activated CD3+ T cells had decreased expression of phospho-STAT3 compared to PD-L1 agonist untreated CD3+ T cells by 5-fold and 3-fold decrease, respectively ($p< 0.001$, Fig 3). Similar results were also seen in the expression of RORγt, the signaling proteins induced by rIL-23. (Fig 3)

Conclusion: Here we identified significance of PD-1 in PsA: (i) PD-$1^{+}T_{EM}$ cells in SFMC of PsA are functional and regulates Th17 cell function through STAT3/ RORγt; (ii) recombinant human PD-L1 agonist significantly inhibited SFMC TEM cell proliferation and Th17 cell cytokine production (IL-17A, IL-17F, IL-22). Agonistic immune checkpoint-based therapy is likely to offer new avenues for treatment of psoriatic disease.

Abstract Number: 0587

Regulatory Role of IL17 F in the Pannus Formation of Psoriatic Arthritis: A Comparative Study with IL-17A

Siba Raychaudhuri[1], Christine Abria[2] and Smriti K Raychaudhuri[3], [1]UC Davis, School of Medicine/ VA Medical Center, Sacramento, Davis, CA, [2]Sacramento VA Medical Center, Mather, CA, [3]Sacramento VA Medical Center, Davis, CA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: IL-17A and IL-17F are the key inflammatory mediators in the IL-17 cytokine family (IL-17A to IL-17F). IL-17A is the widely recognized inflammatory cytokine in this family. IL-17F has drawn increasing attention for its functional similarity with IL-17A and its clinical efficacy in psoriatic arthritis (PsA). Like IL-17A, IL-17F utilizes IL-17RA/RC receptor. Limited studies are available on IL-17F in human diseases. The objective of this study was to evaluate the significance of IL-17F in the pathognomonic 'pannus' formation in PsA and to compare that with the contributing role of IL-17A.

Methods: Here we determined functional role IL-17F on Synovial fibroblasts (FLS) proliferation and on induction of inflammatory cytokines/endopeptidase (IL-6, IL-8, MMP3) related with pannus formation.

A. FLS isolated from PsA (n=5) were cultured with rIL-17F (100 ng/ml) for 5 days. For proliferation assay MTT/CFSE dilution assays were done. To determine the effect of IL-17F on the production of relevant cytokines/chemokines the PsA-FLS culture supernatants were evaluated for IL-6, IL-8, and MMP3 by specific ELISA kits. Similar experiments were done with rIL-17A (100 ng/ml), rIL-22 (100 ng/ml), TNF-α (20ng/mL). Concentrations of rIL-17 A/F, rIL-22, TNF-α were selected by doing dose curves.

B. As IL-17F and IL-17A shares ~50% homology, we evaluated additive or synergistic effect of these cytokine combinations on FLS proliferation and cytokine/chemokine production in PsA-FLS.

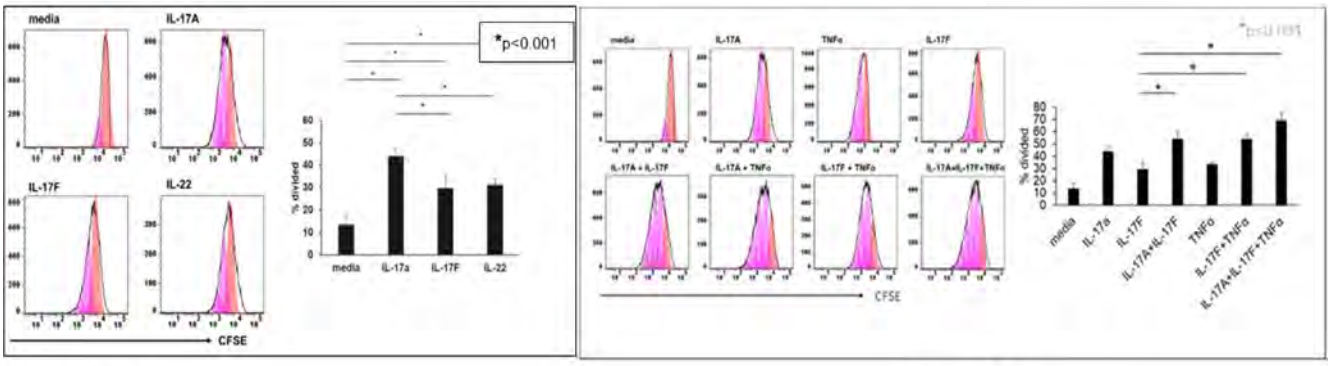

Figure 1 A **Figure 1 B**

Figure 1. Comparative effect of IL-17A and IL-17F and their synergism on proliferation of synovial cells (FLS) of psoriatic arthritis (PsA). All experiments were done in triplicate. Fig 1 A. Effect of IL-17F on Fibroblast proliferation. Representative histograms showing proliferation of PsA FLS cells stimulated with rIL-17A, rIL-17F, and rIL-22 on left. Bar diagram on right shows significant increase of proliferation of PsA FLS with rIL-17A compared to rIL-17F or rIL-22 ($p<0.001$). All experiments were done in triplicate. Fig 1B. Synergistic effect of IL-17F with IL-17A and/or with TNF-α on PSA FLS proliferation. On left side representative histograms showing proliferation of PsA FLS cells stimulated with rIL-17F, rIL-17A and TNF-α. Bar diagram on right showing the significant synergistic effect of IL-17F with IL-17A and with TNF-α on PsA FLS proliferation ($p<0.001$).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

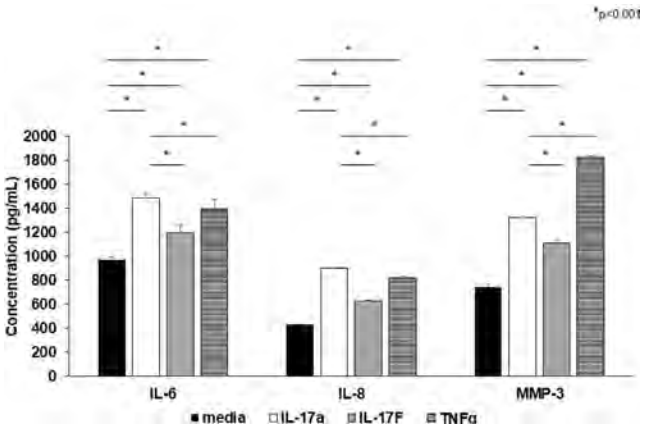

Figure 2. Effect of rIL-17F on IL-6, IL-8, and MMP-3 Expression. Bar diagrams of the average concentration (pg/mL) of cytokines in cell culture supernatant of PsA FLS treated with rIL-17A, rIL-17F or TNF-α. Compared to rIL-17F upregulation of IL-6, IL-8 and MMP3 were significantly higher with rIL-17 A ($p<0.001$) All experiments were done in triplicate.

C. By Flow cytometric studies of T cells derived from PsA synovial fluid (SF) (n=10) we identified the expression of IL-17A and IL-17F in the effector memory T (TEM) cells.

Results: In MTT assay we observed rIL-17F induced significant proliferation in PsA FLS (OD: 1.49±0.05) compared to unstimulated (OD: 0.19±0.04; $p< 0.001$). Treatment with rIL-17A (OD: 1.85±0.07) induced significantly more proliferation than rIL-17F and rIL-22 (1.49±0.05; $p< 0.05$, 1.48±0.02; $p< 0.001$, respectively). However, compared to rIL-17A alone (OD:1.85±0.07) stimulation with rIL-17A+rIL-17F induced significantly more proliferation in PsA FLS (OD: 2.05±0.09; $p< 0.001$). Furthermore, PsA FLS treated with TNF-α+rIL-17A+rIL-17F had highest proliferation (OD 1.85±0.07). In CFSE proliferation assay the results were similar (Fig 1).

PsA FLS stimulated with rIL-17A, rIL-17F and TNF-α produced significantly more IL-6, IL-8 and MMP3 compared to media ($p< 0.001$). However, compared to IL-17F upregulation of IL-6, IL-8 and MMP3 were significantly higher with IL-17 A ($p< 0.001$) as shown in Fig 2.

In the SF of PsA patients the level of IL-17A was higher than IL-17F (Fig 3). In SF derived T cells with Hi-D FACS studies we identified (i) CD4+ TEM cells secreted IL-17A and IL-17F (ii) IL-17A+ TEM cells were more than IL-17F (Fig 3B, $p< 0.001$).

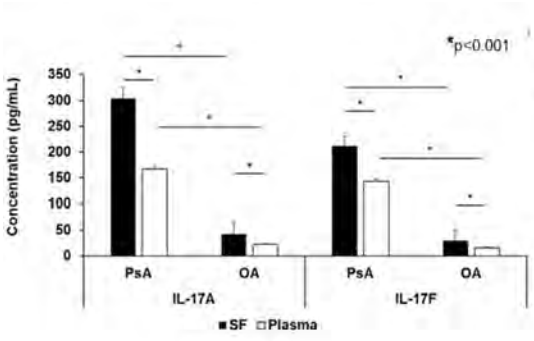

Figure 3 A

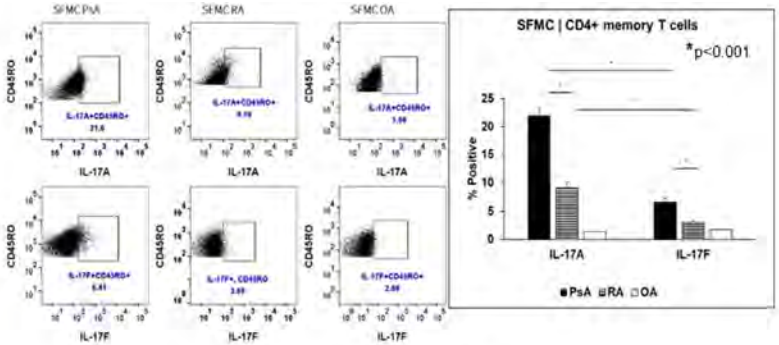

Figure 3 B

Figure 3. Source of IL-17A & IL-17F: Both in the synovial fluid (SF) of psoriatic arthritis (PsA) and at single cell level of effector memory CD4+ T cells IL7A is the predominant cytokine compared to IL-17F. Fig 3A. Bar diagrams demonstrating average concentration (pg/mL) of IL-17A and IL-17F in synovial fluid and plasma of PsA and osteoarthritis (OA) patients. IL-17A levels were significantly higher than IL-17F ($p<0.001$). All experiments were done in triplicate Fig 3B. Expression of IL-17A is significantly higher compared to IL-17F in activated CD4+ T memory T cells in synovial fluid T cells of psoriatic arthritis patients. A representative flow plot showing expression of IL-17A and IL-17F in CD4+ memory T cells. Bar diagram showing significantly higher numbers of IL-17A+ CD4+ memory T cells compared to IL-17F ($p<0.001$) in PsA and RA in synovial fluid derived T cells. All experiments were done in triplicate.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: IL-17A is more in the PsA synovium and functionally more potent than IL-17F in respect to its regulatory role on pannus formation. That explains the success of anti-IL-17A mab therapy in PsA. There is moderate level of synergism with IL-17A and IL-17F in respect to FLS proliferation and upregulations of FLS secreted inflammatory cytokines. This substantiates the combined role of IL-17A/F in the pathogenesis of PsA.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: In axial spondyloarthritis (axSpA), peripheral musculoskeletal manifestations (peripheral arthritis, enthesitis, dactylitis) are common and contribute to the burden of disease. Our objective was to evaluate the evidence on the efficacy of biological and targeted synthetic therapies (bDMARDs/tsDMARDs) on peripheral musculoskeletal manifestations in axSpA.

Methods: Systematic literature review (SLR) of controlled trials that assessed the effect of bDMARDs/tsDMARDs compared to any active treatment or placebo on peripheral arthritis, enthesitis or dactylitis in adult axSpA patients (PROSPERO CRD42024532666). Studies were identified using previous SLRs on bDMARD/tsDMARD efficacy for the 2016/2022 updates of the ASAS-EULAR axSpA management recommendations (≤2021)[1-3] and an updated search (2022 – March 2024). Standardised mean differences (SMDs; < 0.5 small, 0.5-0.8 moderate, >0.8 large effect; negative SMDs favour intervention) were calculated for change from baseline, and complete resolution of each peripheral manifestation was assessed. If SMDs could not be calculated, post-intervention outcome values were considered instead.

Results: In total, 50 studies were included. Most investigated bDMARDs, especially TNF inhibitors (n=24 [48%]) and IL-17 inhibitors (n=13 [26%]), while few focused on tsDMARDs (n=6 [12%]). Studies often compared active treatment to placebo (n=35 [70%]), although several included a head-to-head comparison (n=6 [13%], usually biosimilar versus originator comparison). Some studies (n=4 [8%]) focused on tapering or complete withdrawal of bDMARDs. Risk of bias was often low (n=33 [66%]).

Of the 50 included studies, 37 (74%) reported results on peripheral arthritis, 46 (92%) on enthesitis and only 1 (2%) on dactylitis. Effects on peripheral arthritis were small for both bDMARDs and tsDMARDs (n=16 studies), with most SMDs ranging from -0.5 to 0 (Table). Of note, only few studies reported results in the subgroup with peripheral arthritis at baseline, showing

For studies that investigated multiple dosing schemes, results are shown for the registered dosage (if approved for axSpA, otherwise all investigated doses are shown). *For dactylitis, no SMDs could be calculated due to lack of data. **Negative SMDs favour intervention over comparator. #Study also included other instruments to assess enthesitis or peripheral arthritis, but without sufficient data to calculate SMD. ¥Number of joints considered not reported. †With naproxen. ‡For dose/frequency arms: 18/90/180mg (Baeten 2018), 40/80/120mg (AILAS). §For stopping and tapering arms, respectively. Phys = physician, pt = patient, SJC = swollen joint count, TJC = tender joint count.

slightly higher effects. Complete resolution of peripheral arthritis in those affected at baseline (n=2 studies, both on bimekizumab) occurred in 58-64% for bimekizumab and 36-42% for placebo. Similar to peripheral arthritis, SMDs indicated mainly small to moderate effects on enthesitis for both bDMARDs and tsDMARDs (n=19 studies, Table). Complete resolution of enthesitis (n=5 studies) occurred in 34-52% of patients for various bDMARDs and 14-33% for placebo. Results were similar in studies for which no SMD could be calculated. Finally, for dactylitis, the only available study was a TNF inhibitor tapering study. Dactylitis counts were similar in both study arms (median of 0 in both), although most patients did not have active dactylitis at baseline.

Conclusion: In axSpA, bDMARDs and tsDMARDs have small to moderate effects on peripheral arthritis and enthesitis. For dactylitis, efficacy data for these drugs are very scarce in axSpA. Most studies do not report results in the population of interest (those affected at baseline), possibly resulting in an underestimation of intervention effects.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

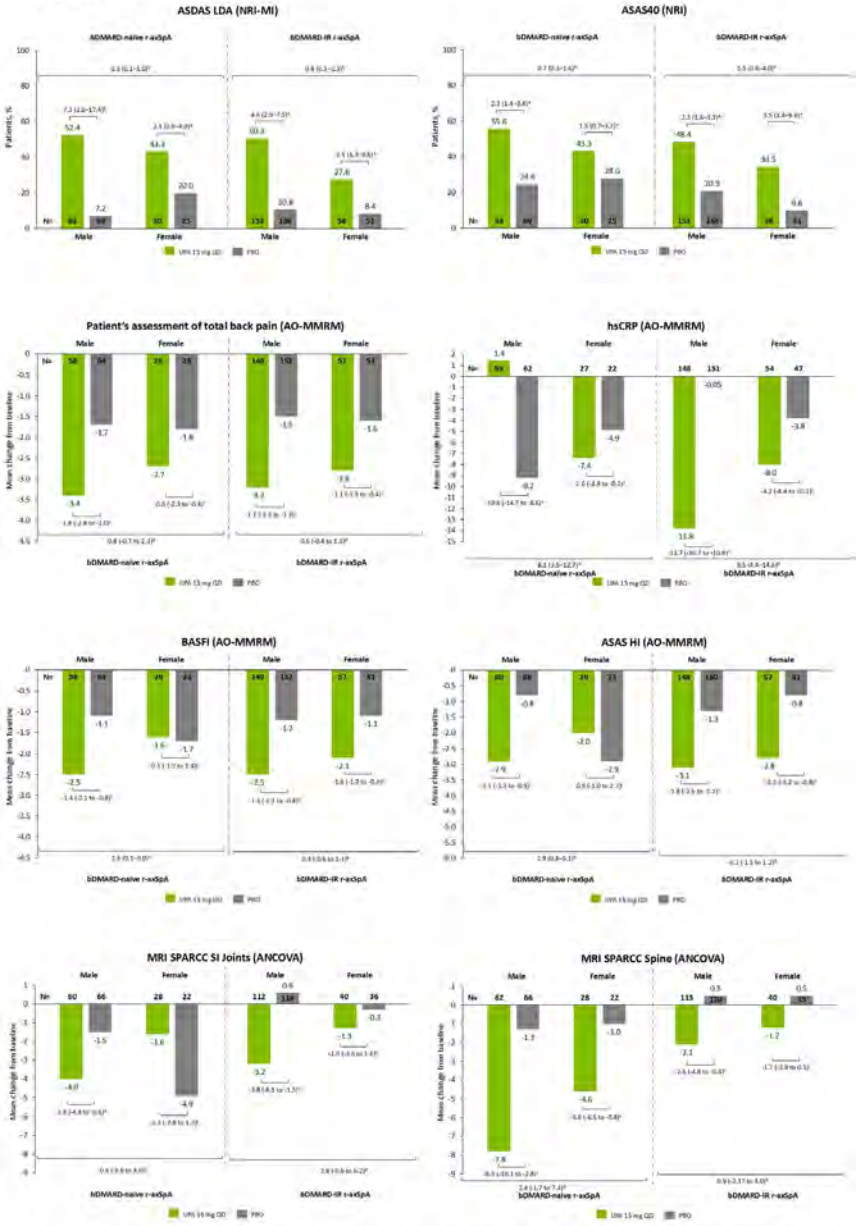
Background/Purpose: Evidence suggests that the treatment effectiveness of TNFis and IL-17is is higher in male (M) vs female (F) patients (pts) with axSpA.[1,2] Data comparing the efficacy of JAKis in M and F pts with axSpA are limited. This post hoc analysis of data from 2 phase 3 clinical trials evaluated differences in efficacy between M and F pts with axSpA who were treated with upadacitinib (UPA), an oral JAKi.

Methods: Data were from SELECT-AXIS 1 (NCT03178487; included pts with r-axSpA [historically referred to as AS] naïve to bDMARDs [bDMARD-naïve]) and SELECT-AXIS 2 (NCT04169373; 2 substudies: [1] pts with r-axSpA with an intolerance or inadequate response to bDMARD therapy [bDMARD-IR], [2] pts with nr-axSpA, which included 33% bDMARD-IR pts).[3–5] Pts were randomized to UPA 15 mg once daily (UPA15) or placebo (PBO) for 14 (bDMARD-naïve and bDMARD-IR) or 52 (nr-axSpA) weeks (W). In this post hoc analysis, efficacy endpoints were assessed through W14 in all pt populations, and through W52 in the nr-axSpA population. Response rates, stratified by sex (M vs F), were calculated using non-responder imputation (NRI) or NRI with multiple imputation for binary endpoints, and as observed with mixed-effect model for repeated measures for continuous endpoints. Analysis of covariance model was used for mean change from baseline in MRI SPARCC score (SI joints and spine). Efficacy of UPA15 vs PBO was assessed by relative risk (RR) (binary outcomes) or mean between-group differences (continuous outcomes) within each sex (M and F), and the effect of UPA vs PBO in M and F was assessed by the RR ratio (RRR) (binary outcomes) or difference between groups in means (continuous outcomes). Information on the interpretation of RRR and difference between groups in means can be found in the figures.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: 920 pts were included, of whom 460 (283/177 M/F) received UPA15 and 460 (290/170 M/F) received PBO. Baseline characteristics were generally similar between sexes, except for greater hsCRP, HLA-B27, and MRI scores in M vs F at baseline. Higher efficacy was seen with UPA vs PBO in both sexes for most endpoints (Figures). At W14, although M generally had numerically better outcomes, results were mostly consistent between M and F, as reflected by RRR or mean difference between differences showing minor differences between both sexes. A trend for higher efficacy outcomes among M vs

Figure 1. Efficacy outcomes stratified by sex in the bDMARD-naïve r-axSpA and bDMARD-IR r-axSpA populations at W14



Response rates for binary endpoints were calculated using non-responder imputation (NRI) or NRI with multiple imputation (SELECT-AXIS 2 study only, where missing data due to COVID-19 was imputed).
For continuous endpoints, an AO-MMRM was applied.
For change from baseline in MRI SPARCC score (SI joints and spine), the analysis of covariance model was used.
For binary endpoints, an RR above 1 indicated better outcomes with UPA vs PBO. For all continuous endpoints a between-group difference lower than 0 indicated better outcomes with UPA vs PBO.
For binary endpoints, an RRR above 1 indicated better outcomes with females vs males, while an RRR below 1 indicated worse outcomes with females vs males. For all continuous endpoints, a between treatment group difference above 0 indicated worse outcomes with females vs males, while a between treatment group difference below 0 indicated better outcomes with females vs males.
[a]RR (95% CI) UPA vs PBO. [b]RRR (95% CI) male vs female. [c]Between-group difference (95% CI) UPA vs PBO. [d]Between treatment group difference (95% CI) male vs female.
AO, as observed; bDMARD, biologic DMARD; bDMARD-IR, intolerance or inadequate response to bDMARD therapy; bDMARD-naive, naive to bDMARDs; CI, confidence interval; Hi, health index; MMRM, mixed-effect model for repeated measures; NRI-MI, non-responder imputation with multiple imputation; PBO, placebo; QD, once daily; r-axSpA, radiographic axSpA; RR, relative risk; RRR, RR ratio; SPARCC, SpondyloArthritis Research Consortium of Canada; UPA, upadacitinib; W, Week.

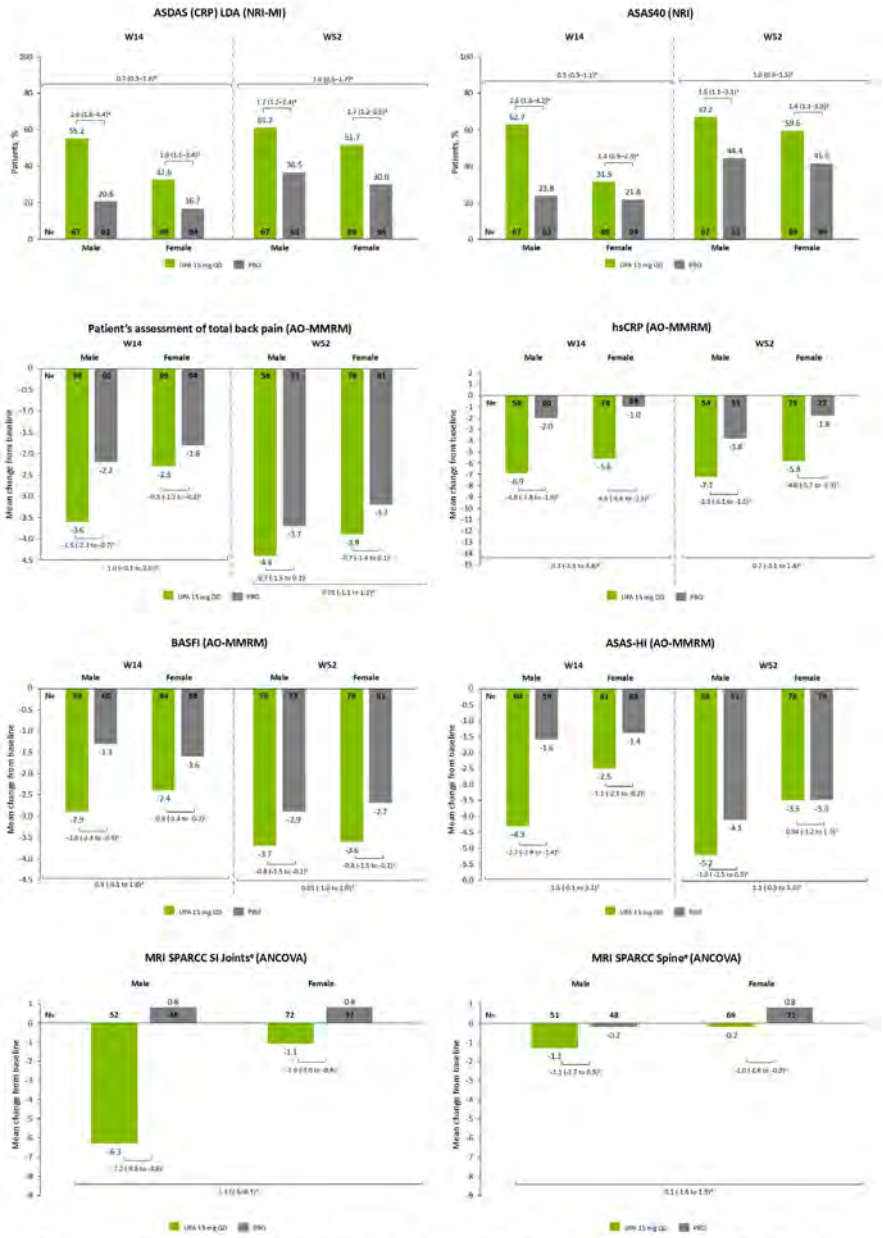
F pts was most apparent among the bDMARD-naïve r-axSpA population, which had the smallest number of F pts (311/109, M/F). In 3 instances (ASAS40 and ASAS HI in bDMARD-IR r-axSpA, and MRI SPARCC SI joints in bDMARD-naïve r-axSpA), F had numerically better outcomes vs M, based on the RRR or mean difference between differences (Figure 1). In nr-axSpA, there was no strong evidence of differences between M vs F pts at W52 (Figure 2).

Figure 2. Efficacy outcomes stratified by sex in the nr-axSpA population at W14 and W52



Response rates for binary endpoints were calculated using non-responder imputation (NRI) or NRI with multiple imputation (SELECT-AXIS 2 study only, where missing data due to COVID-19 was imputed).
For continuous endpoints, an AO-MMRM was applied.
For change from baseline in MRI SPARCC score (SI joints and spine), the ANCOVA model was used.
For binary endpoints, an RR above 1 indicated better outcomes with UPA vs PBO. For all continuous endpoints, a between-group difference lower than 0 indicated better outcomes with UPA vs PBO.
For binary endpoints, an RRR above 1 indicated better outcomes with females vs males, while an RRR below 1 indicated worse outcomes with females vs males. For all continuous endpoints, a between treatment group difference above 0 indicated worse outcomes with females vs males, while a between treatment group difference below 0 indicated better outcomes with females vs males.
[a]RR (95% CI) UPA vs PBO. [b]RRR (95% CI) male vs female. [c]Between-group difference (95% CI) UPA vs PBO. [d]Between treatment group difference (95% CI) male vs female. *Only W14 data available.
ANCOVA, analysis of covariance; AO, as observed; CI, confidence interval; HI, health index; MMRM, mixed-effect model for repeated measures; nr-axSpA, non-radiographic axSpA; NRI, non-responder imputation; NRI-MI, NRI with multiple imputation; PBO, placebo; QD, once daily; RR, relative risk; RRR, RR ratio; SPARCC, SpondyloArthritis Research Consortium of Canada; UPA, upadacitinib; W, Week.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: UPA generally demonstrated better efficacy vs PBO in both sexes and across all axSpA populations. Efficacy in M vs F pts was generally comparable.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Understanding how treatments affect disease-relevant biomarker expression is essential for advancing targeted therapies. Deucravacitinib, an oral, selective, allosteric tyrosine kinase 2 (TYK2) inhibitor, has demonstrated superior efficacy in the placebo (PBO)-controlled phase 3 POETYK PsA-1 (NCT04908202) and PsA-2 (NCT04908189) studies. This pooled post hoc analysis of the POETYK PsA studies aimed to identify biomarkers reflecting clinically relevant factors potentially associated with poor prognosis in PsA and to evaluate associations among these biomarkers, deucravacitinib treatment, and clinical responses.

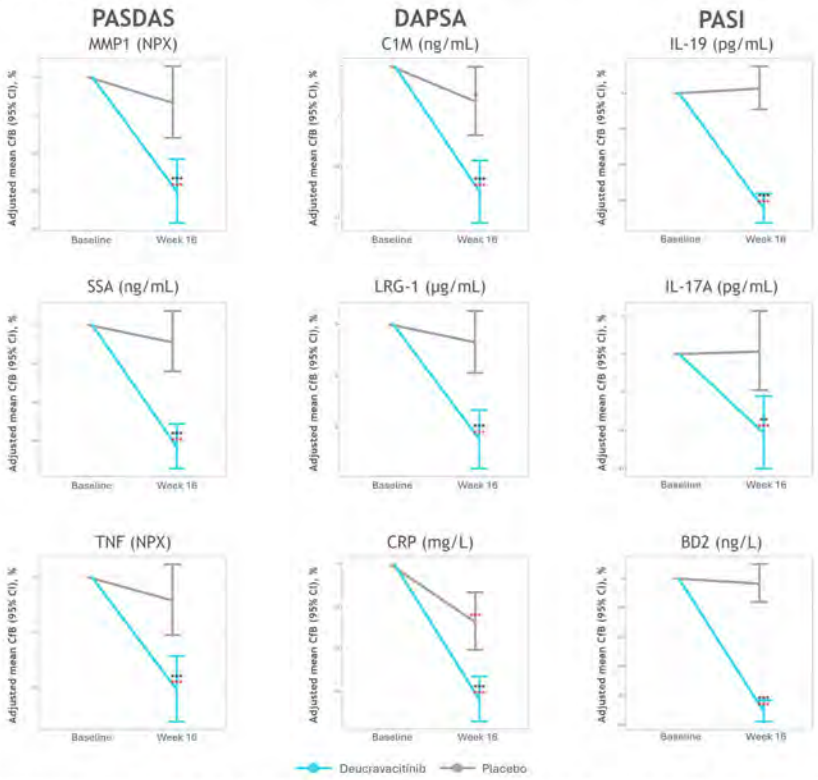
Methods: Spearman correlations between 48 PsA and immune response–related biomarkers and PsA disease activity (PASDAS, DAPSA, PASI) at baseline (BL) and W16 were performed. Pharmacodynamic effects of deucravacitinib on biomarkers were analyzed using a mixed effects model to show covariate-adjusted change from BL for disease activity and Patient Global Assessment of Pain (Pain). Logistic regression was used to assess the relationship between BL biomarkers (eg, CRP, neutrophil-to-lymphocyte ratio [NLR]) and ACR 20 response, minimal disease activity (MDA) response, and modified Sharp-van der Heijde (mSvdH) total score (radiographic progression [defined as change of mSvdH > 0]; evaluated in POETYK PsA-1 only); covariates included BL BMI and prior MTX use. mSvdH nonprogression was evaluated using a stratified Cochran-Mantel-Haenszel test with BL csDMARD use as the stratification factor.

Results: Deucravacitinib significantly reduced disease activity–associated biomarkers, including those impacting skin (eg, IL-19, IL-17A, BD2) and joint (eg, CRP, C1M, LRG-1, MMP1, SAA, TNF) manifestations vs PBO (**Figure 1**). Patients treated with deucravacitinib were more likely to achieve ACR 20 and MDA response vs PBO at W16 in those with high (≥ median) BL NLR, IL-19, IL-17A, CRP, BD2, and SAA (**Figure 2A,C**). Response rates for ACR 20 and MDA were higher with deucravacitinib vs PBO at W16, with significant differences observed in patients with high (≥ median) BL IL-19, IL-17A, and BD2 for ACR 20 (**Figure 2B**) and high BL NLR (≥ 2.81) or high BD2 levels (≥ 7185 ng/L) for MDA (**Figure 2D**). Deucravacitinib reduced pain-associated biomarkers (eg, CRP, C1M, MMP3, TNF, ICAM-1) vs PBO at W16. Given the clinical relevance of CRP, additional analyses in patients with high BL CRP (≥ 3 mg/L) showed that deucravacitinib significantly reduced Pain score vs PBO as early as W4 ($P < 0.01$) with sustained reduction at W16 ($P < 0.001$), provided a greater reduction in mSvdH total score (PBO corrected) vs those with normal BL CRP, and led to reduced radiographic progression vs PBO at W16 (21.1% vs 30.6%; $P < 0.05$).

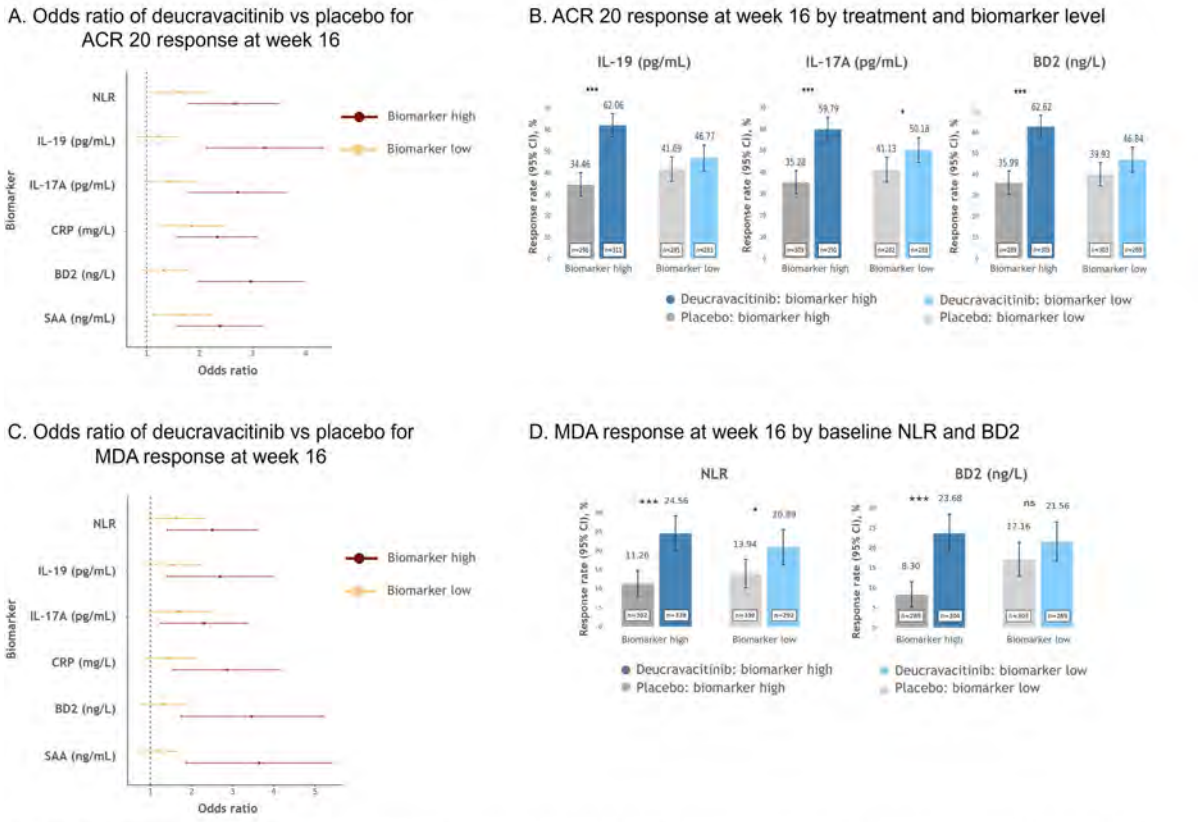
Figure 1. Changes in expression of disease-relevant biomarkers with deucravacitinib vs placebo at W16



Representative biomarkers are shown. *** $P < 0.001$; ** $P < 0.01$; * $P < 0.05$. Red asterisks indicate a significant CfB within a treatment group. Black asterisks indicate a significant difference between deucravacitinib and placebo. Covariates included BL PASI score, BL DAS28-CRP score, and prior MTX use. CfB was used as the repeated measures; fixed effects included BL value, visit, arm, visit-by-arm interaction, and randomization stratification factors. NPX is the Olink unit of protein expression level in a $\log_2$ scale.
BD2, beta-defensin 2; BL, baseline; C1M, MMP-mediated type I collagen degradation; CfB, change from baseline; DAPSA, Disease Activity in Psoriatic Arthritis; LRG-1, leucine rich alpha-2-glycoprotein 1; NPX, Normalized Protein eXpression; PASDAS, Psoriatic Arthritis Disease Activity Score; PASI, Psoriasis Area and Severity Index; SSA, serum amyloid A; W16, week 16.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 2. Biomarkers associated with response to deucravacitinib at W16



*** $P < 0.001$; ** $P < 0.01$; * $P < 0.05$. Logistic regression was used to assess the relationship between treatment response and BL biomarkers; data were dichotomized based on median cutoffs of biomarker expression levels (high vs low).
ACR 20, American College of Rheumatology 20% improvement in response; BD2, beta-defensin 2; BL, baseline; MDA, minimal disease activity; NLR, neutrophil-to-lymphocyte ratio; ns, not significant; SSA, serum amyloid A; W16, week 16.

Conclusion: Deucravacitinib significantly reduced PsA disease–associated biomarkers in patients with elevated BL biomarkers (eg, CRP, NLR), which may be indicative of severe disease and poor prognosis, and improved efficacy outcomes for multiple disease domains, including radiographic progression. These data provide biological evidence for deucravacitinib as a potential new oral PsA therapy that may benefit patients with severe and difficult-to-treat disease.

Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: PsA is a chronic inflammatory disease with a significant burden on patients' (pts) health-related quality of life (HRQoL).[1] Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits interleukin (IL)-17F in addition to IL-17A, has demonstrated sustained efficacy to 2 years in clinical trials of pts with PsA.[2–3] BKZ has been approved for treatment of PsA in Europe since June 2023, and the US since September 2024.[4,5] SPEAK is the first prospective, observational study in routine clinical practice in Europe evaluating HRQoL and clinical outcomes with BKZ in pts with active PsA or axial spondyloarthritis (axSpA). We report interim data from SPEAK, describing characteristics of pts with PsA at BKZ treatment initiation and HRQoL to 24 weeks (wks) in a real-world setting.

Table. Baseline characteristics of PsA patients in the SPEAK study

	Previous b/tsDMARD exposure			
Characteristic, mean (SD) unless otherwise stated	b/tsDMARD naïve N=80	1 b/tsDMARD N=89	≥2 b/tsDMARDs N=207	Total N=376
Age, years	51.6 (12.1)	50.8 (11.8)	53.2 (10.6)	52.3 (11.2)
Sex, male, *n* (%)	39 (48.4)	43 (48.3)	74 (35.7)	156 (41.5)
BMI	29.3 (6.5)	30.9 (6.4)	29.5 (6.2)	29.8 (6.3)
Time since diagnosis, years	4.7 (6.0)	7.2 (8.0)	11.6 (9.2)	9.1 (8.8)
History of IBD, n (%)	0 (0)	1 (1.1)	4 (1.9)	5 (1.3)
TJC	10.5 (8.3)	10.2 (10.1)	13.1 (12.3)	11.9 (11.2)
SJC	5.0 (4.9)	6.7 (8.0)	5.4 (6.6)	5.7 (6.7)
CRP, mg/L, median (min–max)	3.6 (0.0–46.0)	3.3 (0.0–49.8)	3.6 (0.0–112.0)	3.6 (0.0–112.0)
PsAID-12 total score	5.0 (1.9)	5.3 (2.2)	5.5 (2.1)	5.4 (2.1)
HAQ-DI score	1.0 (0.6)	1.2 (0.8)	1.4 (0.7)	1.3 (0.7)
PGADA score	57.0 (19.3)	57.6 (23.3)	61.1 (21.3)	59.4 (21.4)
SF-36 PCS score	37.3 (8.1)	36.4 (9.4)	34.3 (9.3)	35.6 (9.2)

Safety analysis set (includes all patients enrolled into the study). BMI: body mass index; b/tsDMARD: biologic/targeted synthetic disease-modifying antirheumatic drugs; CRP: C-reactive protein; HAQ-DI: Health Assessment Questionnaire Disability Index; PGADA: Patient Global Assessment of Disease Activity; PsA: psoriatic arthritis; PsAID-12: 12-item PsA Impact of Disease; SD: standard deviation; SJC: swollen joint count; SF-36 PCS: Short Form 36-Item Health Survey Physical Component Summary; TJC: tender joint count; VAS: Visual Analog Scale.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Methods: SPEAK is an ongoing 52-wk, multi-country, observational study in Belgium, Czechia, France, Germany, Greece, Spain, and the United Kingdom. This planned interim analysis reports data to April 2, 2025 (~50% enrolment). Adult pts with active PsA or axSpA who initiated BKZ in routine clinical practice could be included if receiving treatment per label (subcutaneous BKZ 160 mg every 4 wks). We report PsA Impact of Disease 12-Item Questionnaire total score (PsAID-12; 0–10), Short Form 36-item Health Survey Physical Component Summary (SF-36 PCS, norm-based T-scores with mean [SD]: 50 [10] in the US general population), and Pt Global Assessment of Disease Activity score (PGADA; 0–100) for pts with PsA to 24 wks. Other clinical outcomes were collected but not available for the data cut. Baseline (BL) characteristics and adverse events are also reported.

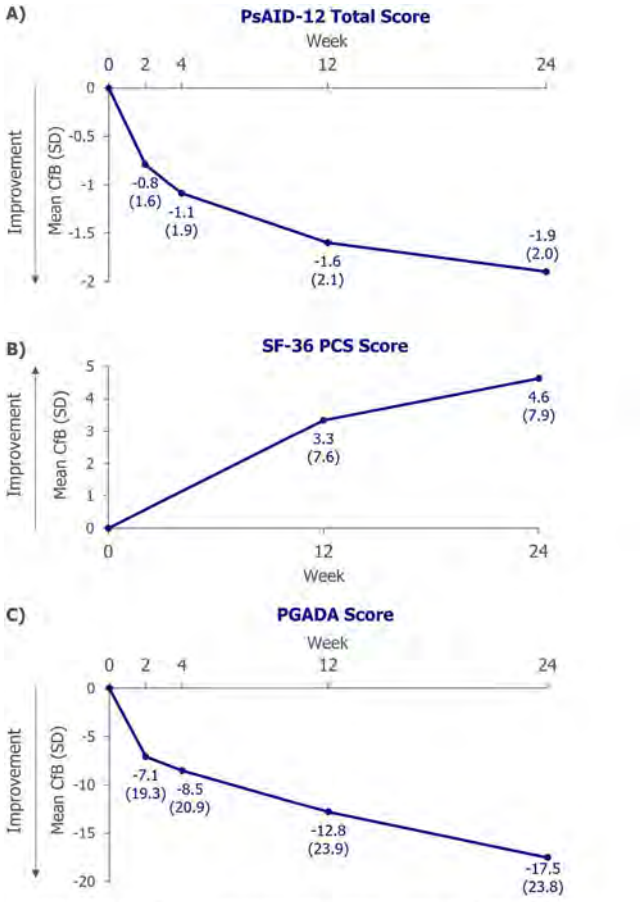
Results: By April 2025, BL characteristics were available for 376 pts with PsA (**Table**). Overall, 80 were biologic/targeted synthetic disease-modifying antirheumatic drug (b/tsDMARD) naïve, 89 had 1 previous b/tsDMARD and 207 had ≥2 previous b/tsDMARDs.

Improvements in PsAID-12 total score were observed to 24 wks, with mean (SD) CfB at Wk 24 of –1.9 (2.0). SF-36 PCS scores improved to Wk 24 (mean [SD] CfB: +4.6 [7.9]), as did PGADA scores (Mean [SD] CfB: –17.5 [23.8]); **Figure**; BL values in **Table**).

TEAEs were reported in 61.4% pts; in 34.8% they were deemed drug-related. One pt reported uveitis (0.3%). 43 pts reported *Candida* infections (11.4%), including 29 with oral candidiasis (7.7%; 3.5% led to BKZ discontinuation). There were no cases of IBD or suicidal ideation/behavior.



Full analysis set. b/tsDMARD: biologic/targeted synthetic disease-modifying antirheumatic drugs; CfB: change from baseline; PGADA: Patient Global Assessment of Disease Activity; PsA: psoriatic arthritis; PsAID-12: 12-item PsA Impact of Disease; SD: standard deviation; SF-36 PCS: Short Form 36-Item Health Survey Physical Component Summary; VAS: Visual Analog Scale.

Figure. CfB in PsAID-12, SF-36 PCS and PGADA scores to week 24 (OC)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: In this first report of HRQoL outcomes in an observational setting of BKZ-treated pts with PsA in routine clinical practice, BKZ treatment led to improvements in pt-reported outcomes at 24 wks, with changes observed as early as Wk 2, demonstrating rapid HRQoL improvements. The real-world findings complement data from phase 3 trials, for both HRQoL and safety.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Axial spondyloarthritis (axSpA) is a chronic inflammatory disease with a significant burden on patients' (pts) health-related quality of life (HRQoL).[1] Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits interleukin (IL)-17F in addition to IL-17A, has demonstrated sustained efficacy to 2 years in clinical trials of pts with non-radiographic [nr-] and radiographic [r-]axSpA.[2] BKZ has been approved for treatment of axSpA in Europe since June 2023, and the US since September 2024.[3,4] SPEAK is the first prospective, observational study in routine clinical practice in Europe evaluating HRQoL and clinical outcomes with BKZ in pts with active axSpA and PsA. We report interim data from SPEAK, describing characteristics of pts with axSpA at BKZ treatment initiation and HRQoL to 24 weeks (wks) in a real-world setting.

Methods: SPEAK is an ongoing 52-wk, multi-country, observational study in Belgium, Czechia, France, Germany, Greece, Spain, and the United Kingdom. Adult pts with active axSpA or PsA who initiated BKZ in routine clinical practice could be included if receiving treatment per label (subcutaneous 160 mg every 4 wks). This planned interim analysis reports data to April 2, 2025 (~50% enrolment). We report Assessment of SpondyloArthritis international Society Health Index (ASAS HI; 0–17), Short Form 36-item Health Survey Physical Component Summary (SF-36 PCS, norm-based T-score with mean

Table. Baseline characteristics of patients with axSpA in the SPEAK study

Full analysis set. PGADA in this study was assessed using a 0–100 Visual Analog Scale (VAS): data presented here is the rescaled score used to derive the ASDAS and which ranges from 0 to 10. ASAS HI: Assessment of SpondyloArthritis international Society Health Index; axSpA: axial spondyloarthritis; b/tsDMARD: biologic/targeted synthetic disease-modifying antirheumatic drugs; CfB: change from baseline; nr-axSpA: non-radiographic axSpA; OC: observed case; PGADA: Patient Global Assessment of Disease Activity; r-axSpA: radiographic axSpA: SD: standard deviation; SF-36 PCS: Short Form 36-Item Health Survey Physical Component Summary; VAS: visual analog scale.

Figure. Change from baseline in ASAS HI, SF-36 PCS and PGADA scores to Week 24 (OC)

[SD]: 50 [10] in the US general population) and Pt Global Assessment of Disease Activity score (PGADA; 0–10) for pts with axSpA to 24 wks. Other clinical outcomes were collected but not available for data cut. Baseline (BL) characteristics and adverse events are also reported.

Results: By April 2025, BL characteristics were available for 197 pts with axSpA (nr-axSpA: 78, r-axSpA: 119; **Table**). Overall, 38 were biologic/targeted synthetic disease-modifying antirheumatic drug (b/tsDMARD) naïve, 56 had 1 previous b/tsDMARD and 103 had ≥2 previous b/tsDMARDs.

Improvements in ASAS HI score were observed to 24 wks, with mean (SD) CfB at Wk 24 of –1.6 (3.0). SF-36 PCS scores improved to Wk 24 (mean [SD] CfB: +5.7 [7.3]), as did PGADA scores (mean [SD] CfB: –1.0 [2.5]; **Figure**; BL values in **Table**).

TEAEs were reported in 62.9% of pts; in 33.0% they were deemed drug-related. Three cases of uveitis were reported by 2 pts (1.5%), 15 Candida infections (7.6%), including 12 oral candidiasis (6.1%, 3.0% led to BKZ discontinuation), 1 case of IBD (0.5%) and no suicidal ideation and behavior.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: In this first report of HRQoL outcomes in an observational setting for BKZ-treated pts with axSpA in routine clinical practice, BKZ treatment led improved pt-reported outcomes at 24 wks, with changes observed as early as Wk 2, demonstrating rapid HRQoL improvements. The real-world findings complement data from phase 3 trials, for both HRQoL and safety.

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease with diverse clinical manifestations. Genetic predisposition contributes significantly to its pathogenesis, and higher genetic load is linked to more severe disease[1]. This study aims to elucidate the role of genetic variation in shaping the clinical heterogeneity observed in SLE.

Methods: Scandinavian SLE patients meeting the 1997 ACR criteria were genotyped using Illumina's Global Screening Array, with clinical data extracted from medical records. Participants were randomly assigned to a discovery (n=884) and a test (n=524) cohort. A weighted SLE polygenic risk score (SLE-PRS) was calculated using 138 established non-HLA SLE risk single nucleotide variants (SNVs) (GWAS-significant in European populations). Subphenotype-specific PRSs were constructed in the discovery cohort, by analysis of 4,088 SNVs previously associated with immune or inflammatory diseases. Validation in the test cohort was conducted using logistic regression comparing the top quartile to the remainder, adjusting for sex and age, with model performance evaluated via ROC curve analysis. Disease and pathway enrichment analyses were conducted using FUMA[2] and Metascape[3].

Results: The SLE-PRS was associated with nephritis (OR=1.4, $p=1.1\times10^{-5}$, AUC=0.60) and photosensitivity (OR=1.1, $p=3.6\times10^{-3}$, AUC=0.57), but not with other ACR-97 manifestations. Excluding SNVs not associated with specific SLE subphenotypes enhanced the predictive accuracy of the SLE-PRS, with improved performance for nephritis (OR=1.6, $p=4.4\times10^{-6}$, AUC=0.61) and serositis (OR=1.3, p=0.02, AUC=0.56).

We next developed subphenotype-specific PRSs, each comprising an average of 34 SNVs. Of the total 307 SNVs, 26 were shared across multiple PRSs, with the largest overlap observed in the immunological disorder-PRS (9 shared SNVs). The nephritis-PRS contained the largest fraction of known SLE loci (23%). Several PRSs demonstrated predictive ability, including the malar rash-PRS (OR=1.3, $p=7.1\times10^{-5}$, AUC 0.66), nephritis-PRS (OR=1.4, $p=4.6\times10^{-12}$, AUC 0.70), and neurological disorder-PRS (OR=1.1, p=0.02, AUC 0.60).

Enrichment analysis of SNV annotated genes showed significant association between multiple sclerosis and all PRSs, with the strongest association for neurological disease ($p=1.17\times10^{-11}$). Functional enrichment analysis showed strong association between photosensitivity and the Nuclear factor of activated T-cells (NFAT) pathway ($p=7.8\times10^{-12}$) and hematological manifestations with interleukine-27 signaling ($p=2.5\times10^{-6}$).

Conclusion: The results demonstrate that subphenotype-specific PRSs are selectively associated with distinct clinical manifestations of SLE, and that inclusion of non-SLE risk SNVs can enhance predictive power. The limited overlap of contributing SNVs across PRSs underscores the genetic heterogeneity of SLE. Functional enrichment analyses further reveal distinct biological pathways underlying different disease features, pointing to potential targets for personalized therapeutic strategies.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: The pathogenesis of SLE involves genetic, environmental and epigenetic factors (1). Increased levels of Bisphenol A (BPA) have been observed in the urine of patients with SLE (2). Since altered immune responses and DNA methylation changes have been observed following BPA treatment in vitro (3, 4), we aimed to investigate if a BPA methylation score associate with SLE and whether it can be linked to SLE risk genes and gene expression changes in immune signalling pathways.

Methods: Potential BPA sensitivity of 198 genes for SLE genetic loci (GWAS catalogue, $p \leq 5x10^{-8}$, reported in ≥2 studies) was tested using gene-chemical interactions data from the Comparative Toxicogenomics Database (CTD).

Swedish patients with SLE fulfilling ≥ 4 ACR-82 criteria (n=548) and healthy controls (n=587) from a discovery and replication cohort were included. DNA methylation levels were investigated by the Illumina HM450k array. CpG sites reported as differentially methylated in blood in ≥2 of 7 BPA exposure studies and verified in DepMap (n=19 loci) were selected for calculation of a BPA_{All} score based on all 19 CpG sites and a BPA_{SLE} score based on three of the sites collocated with GWAS SLE risk loci. Interferon (IFN) regulation status was determined using the database Interferome. Clinical data were collected from patient charts.

BPA treatment effects were checked using GEO2R-recalculated publicly available gene expression data from four BPA-treated cell lines; Ishikawa, HepG2, Y79 and MCF7. Functional enrichment was estimated using PANTHER pathways.

Results: For 152 (77%) of the 198 SLE risk genes, BPA was among the top ten gene-interacting chemicals in CTD. BPA was the top interacting compound for 50 (25%) of the genes.

Patients with SLE had significantly higher BPA_{SLE} score compared with controls in the discovery (OR 1.34, $p=4.6x10^{-13}$), replication (OR 1.28, $p=1.1x10^{-5}$), and meta-analysis (OR 1.32, $p=3.3x10^{-17}$). Higher BPA_{All} score associated with SLE in the discovery (OR 1.05, $p=2.3x10^{-3}$) but not in the replication cohort with a significant difference in the meta-analysis (OR 1.05, $p=7.0x10^{-4}$). In the combined cohort, both scores associated with prednisolone treatment ($p< 0.001$) and the BPA_{SLE} score associated with serositis (p=0.019) and anti-RNP antibodies (p=0.027).

BPA-induced gene expression changes common for ≥2 of four cell lines showed enrichment of B cell activation, MAP kinase cascade and IFN-γ (type II IFN) signaling pathways. Out of the 29 genes annotated to the BPA-sensitive sites, 20 (69%) were reported as type II IFN-regulated in Interferome and 10 (34%) were reported as differentially expressed in at least one of the

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. four cell lines, of which *MAP3K9* exhibited the most significant change (logFC 1.17, p=2.1x10^{-17}). One of the genes annotated to a an SLE-collocated BPA-sensitive CpG site, *MICB*, was differentially expressed.

Conclusion: This is the first study to suggest an association between BPA exposure and epigenetic changes in SLE, possibly altering expression of genes involved in immune response pathways such as IFN-γ and MAPK signalling.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Treat-to-target (T2T) states in SLE, such as the Lupus Low Disease Activity State (LLDAS) and remission (REM) as defined by the Definitions of Remission in SLE (DORIS), are now reflected in treatment guidelines. However, while sustained attainment of these states is reported in response to CD19 CAR-T treatment, limited long-term data exist quantifying the frequency of sustained attainment of these states on standard of care.

Methods: We examined the cumulative and sustained (continuous) attainment of LLDAS, REM, and steroid-free remission (REM-0) utilising the Asia Pacific Lupus Collaboration (APLC) patient cohort. Data were collected from 25 sites across 13 countries between 1st January 2013 and 31st December 2023 using standardised templates. LLDAS was defined as Golder *et al*., 2019 (1) (SLEDAI≤4, no new activity, PGA ≤1, prednisolone (PNL) ≤7.5 mg/d, antimalarials (AM) and immunosuppressants (IS) allowed). REM was defined as Vollenhoven et al, 2021 (2) (clinical SLEDAI=0, PGA < 0.5, PNL≤5 mg/d, AM/ IS allowed), while REM-0 was defined as clinical SLEDAI=0, PGA < 0.5, PNL=0 mg/d, AM/ IS allowed. We examined these outcomes in all patients, and in patients who at enrolment were not at target (i.e. not in LLDAS).

Table 1 — Patient characteristics

	All patients n=5,053	Non-LLDAS at enrolment n=2,517
	Median [IQR] or n (%)	
Study duration (years)	3.1 [2.0, 7.0]	3.2 [2.0, 7.1]
Age at APLC enrolment (years)	40 [30, 50]	37 [29, 48]
SLE duration at enrolment (years)	8.0 [3.0, 15]	7.0 [2.0, 14]
Females	4604 (91.4%)	2290 (91.3%)
Glucocorticoids (GC) at least once (ever)	4352 (86.1%)	2371 (94.2%)
TAM-GC (mg/day)	5.0 [2.0, 8.4]	7.5 [4.7, 10.6]
Cumulative GC (g)	5.4 [1.4, 12.3]	8.5 [3.8, 16.3]
Anti-malarials (AM) -ever	4281 (84.7%)	2098 (83.4%)
Immunosuppressants (IS) -ever	3656 (72.4%)	2069 (82.2%)
TAM-SLEDAI-2K (AMS)	2.7 [1.1, 4.4]	3.9 [2.2, 5.5]
TAM-PGA	0.3 [0.1, 0.6]	0.5 [0.3, 0.9]
Mild/moderate/severe flare ever	3023 (59.8%)	1773 (70.4%)
Annual flare rate	0.3 [0.0, 0.7]	0.5 [0.0, 1.0]
Organ damage present (SDI>0) at enrolment	1846 (42.6%)	968 (43.5%)
Damage accrual (ΔSDI>0)	1111 (25.6%)	643 (28.9%)
Deceased patients	139 (2.8%)	87 (3.5%)
LLDAS-ever	4131 (82.2%)	1655 (65.8%)
%T in LLDAS	48.2 [13.0, 74.1]	22.2 [0, 50]
LLDAS-50	2442 (48.3%)	639 (25.4%)
12m sustained LLDAS	1916 (37.9%)	600 (23.8%)
REM-ever	3507 (69.9%)	1281 (51.1%)
%T in REM	29.2 [0.0, 66.8]	2.8 [0.0, 35.8]
REM-50	1866 (36.9%)	411 (16.3%)
12m sustained REM	1704 (33.7%)	480 (19.1%)
REM-0-ever	1554 (31.0%)	451 (18.0%)
%T in REM-0	0 [0, 12.2]	0 [0, 0]
REM-0-50	684 (13.5%)	106 (4.2%)
12m sustained REM-0	682 (13.5%)	140 (5.6%)

IQR = interquartile range; TAM = time adjusted mean; %T = cumulative percent-time, LLDAS/REM-50 = ≥50% in LLDAS/REM

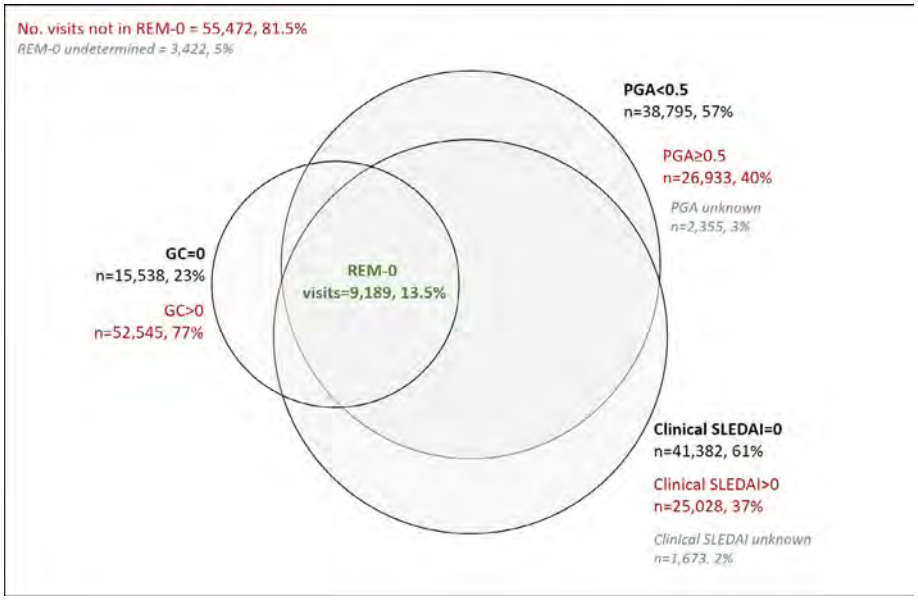

Figure 1: Patient visits fulfilling REM-0

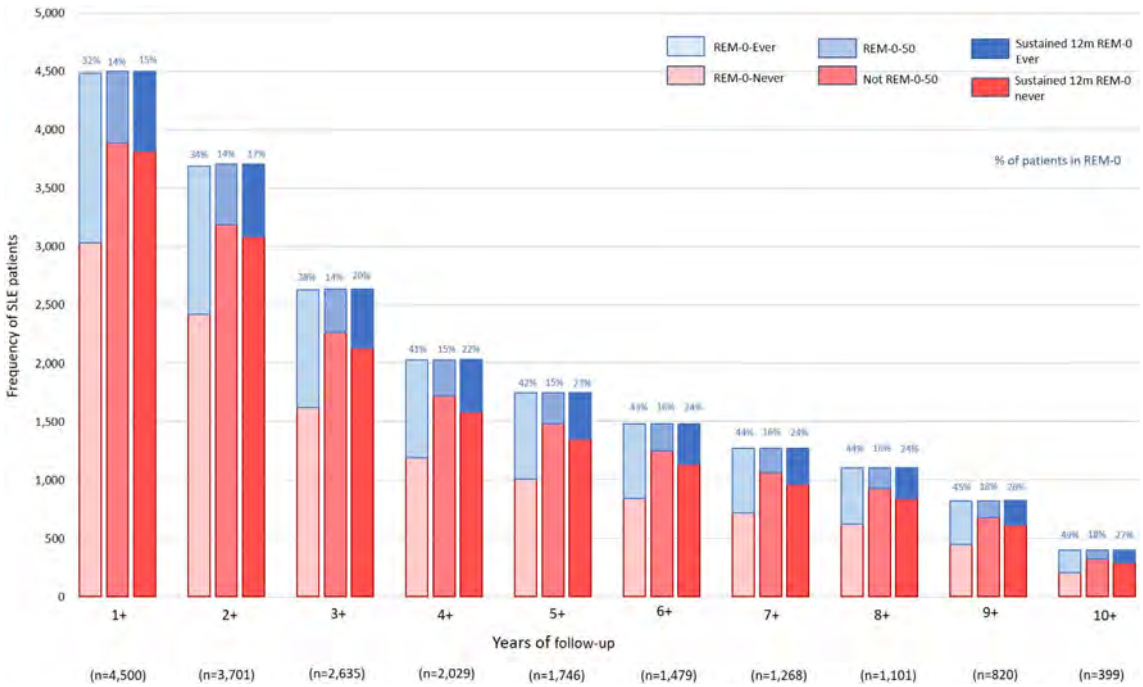

Figure 2 – Attainment of steroid-free remission (REM-0) overtime

Results: A total of 68,083 visits from 5,053 patients with ≥2 visits were evaluated. About 82% of patients attained LLDAS; ~70% attained REM, and 31% attained REM-0 at least once during the observation period. Accordingly, LLDAS was achieved in 48% of visits (n= 31,706); REM in 37% of visits (n= 31,706), and REM-0 in 13.5% of visits (9,189) (Figure 1). Cumulative and sustained attainment of these T2T states were low, especially sustained REM-0 (~14%) (Table 1). Although the proportion of patients attaining sustained REM-0 gradually increased over time, the majority of patients never achieved this state (Figure 2). Overall, patients who attained sustained REM0 were older, had a longer study duration, and had used more AM (88% vs. 84% of sustained REM0-never patients, p=0.015).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

We further examined the attainment of these T2T states in 2,517 patients who were not at target (i.e. not in LLDAS) at enrolment (51% of the cohort). These patients were younger and had shorter SLE disease duration than those in LLDAS at enrolment. Fewer of these patients attained T2T states; only 18% achieved REM-0 at least once, and < 6% achieved 12 months sustained REM-0 (Table 1).

Conclusion: Sustained attainment of steroid-free remission was infrequent in SLE patients receiving standard of care.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Previous studies have shown that male gender is an independent predictor of organ damage in patients with systemic lupus erythematosus (SLE), particularly in the early stages of their disease.[1,2] In the previous GLADEL cohort, male patients had a higher SLICC/ACR Damage Index (SDI) than their female counterparts, although this difference was not statistically significant.[3] This study assessed organ damage, as measured by the SDI, as a function of gender in the GLADEL 2.0 cohort.

Methods: A total of 43 centers from 10 Latin American countries enrolled patients 18 years of age or older who met the 1982/1997 ACR and/or 2012 SLICC classification criteria. Descriptive analyses were conducted. An interaction analysis between gender and time was performed using a mixed-effects model in R. SDI was the dependent variable, while gender (between-subjects) and time (within-subjects) were the independent variables. A random intercept per participant was included to account for within-subject variability.

Logistic regression modeling was used to examine the factors associated with changes in the SDI from baseline to the end of follow-up. A significance level of 5% was applied to all analyses and R version 4.4.0 software was used.

Results: Of the 1081 patients enrolled in the GLADEL 2.0 cohort, 385 patients matched by gender were considered. Of these, 190 completed at least four annual visits and were included in these analyses. Seventy percent of patients were women and 30% were men (Table 1). No statistically significant differences in organ damage, as measured by the SDI, were

Table 1. Sociodemographic and clinical characteristics of patients with SLE by gender

	Male (N=113)	Female (N=272)	*p*-value	Total (N=385)

Use of antimalarial at baseline visit, n (%)	64 (56.6)	162 (59.5)	1.000	226 (58.7)
Type of lupus, n (%)			0.838	
1= Patient with SLE, no history of lupus nephritis.	31 (27.4)	82 (30.1)		113 (29.4)
2= Patient with SLE, with prevalent inactive lupus nephritis.	21 (18.6)	55 (20.2)		76 (19.7)
3= Patient with SLE, with active prevalent lupus nephritis.	28 (24.8)	67 (24.6)		95 (24.7)
4= Patient with SLE, with incident (active) lupus nephritis.	33 (29.2)	68 (25.0)		101 (26.2)

found between male and female patients (p=0.563). This trend remained consistent throughout the follow-up period, with no significant interactions observed (p=0.90). Damage accumulation over time increased significantly in both sexes (Figure 1A). The affected SDI domain frequency was examined both at baseline and during follow-up (Figure 1B). In general, males had a higher occurrence of ocular and cutaneous, and a moderate increase in malignant involvement compared to females, whereas females had a higher frequency of gastrointestinal, gonadal failure, pulmonary, peripheral vascular and musculoskeletal involvement. After adjusting for sociodemographic and clinical/immunologic characteristics, multivariate analysis revealed that disease duration (odds ratio [OR]: 1.05; 95% CI: 1.0-1.1) and disease activity, as measured by the SLEDAI-2K (OR: 1.05; 95% CI: 1.0-1.1), were associated with a higher likelihood of an increase in SDI.

Conclusion: Although male gender was not associated with an increased risk of damage accumulation, the proportion of patients with an increased SDI was higher in males than in females. Organ damage during follow-up increased significantly in both sexes. As patients in this cohort continue to be closely monitored, the impact of gender on damage accumulation may become more evident.

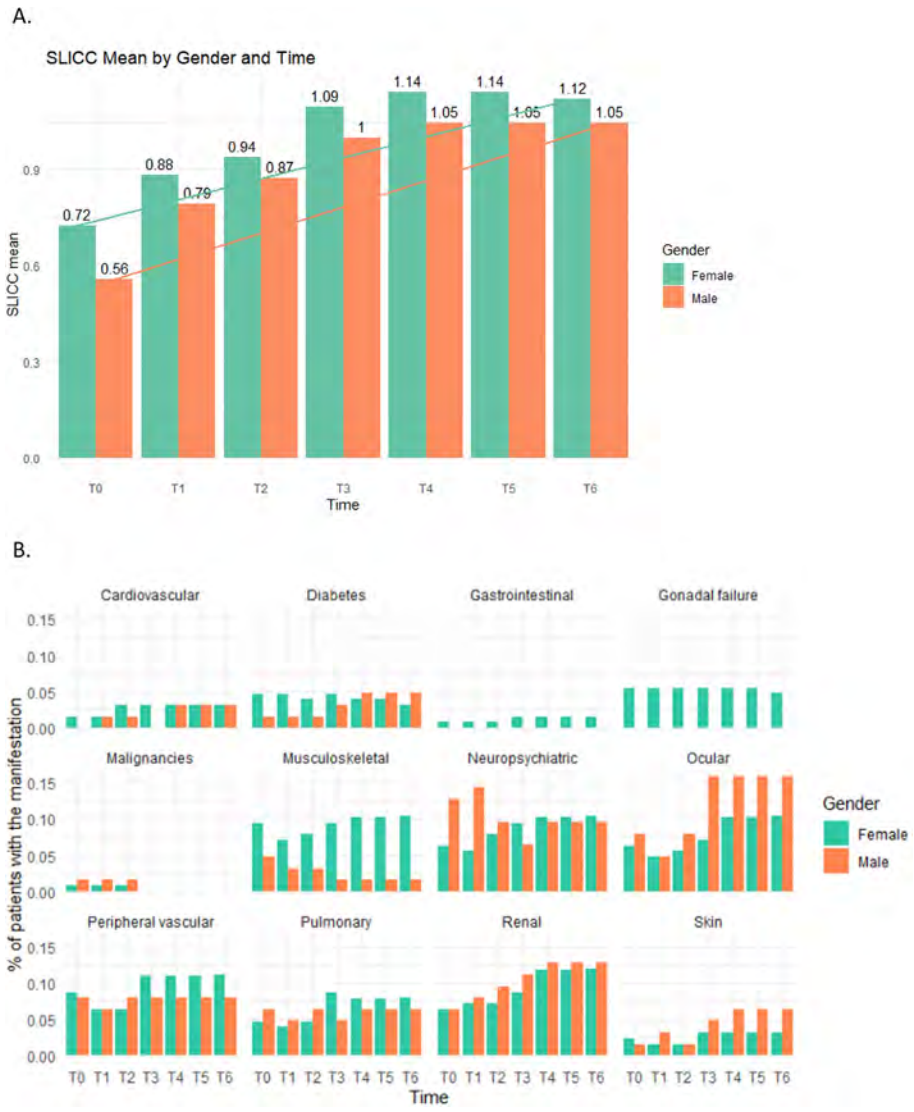

Figure 1. (A) Mean SLICC/ACR score and (B) frequency of manifestations by SDI area by gender and follow-up time

Abstract Number: 0597

Low 25-hydroxyvitamin D Levels are Associated with Higher Mortality and More Cardiovascular Events in Systemic Lupus Erythematosus

Theerada Assawasaksakul[1], Andrea Fava[2], Daniel Goldman[3], Laurence Magder[4] and **Michelle Petri**[3], [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]Johns Hopkins University School of Medicine, Timonium, MD, [4]University of Maryland, Baltimore, Baltimore, MD

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: No studies have directly examined the link between 25-hydroxyvitamin D [25(OH)D] and cardiovascular outcomes in SLE. This study aimed to assess this association, hypothesizing that low 25(OH)D levels correlate with increased mortality and cardiovascular event risk in SLE.

Methods: Our longitudinal cohort measured 25(OH)D levels at quarterly clinic visits from 2009 onwards. Patients were categorized based on their first measured, mean, and most recent 25(OH)D levels (the last two measures reflecting supplementation). The "most recent 25(OH)D" was defined as the 25(OH)D level measured at the most recent past visit. The first prospective analysis examined monthly follow-up data, categorizing by 25(OH)D levels and assessing cardiovascular events (CVE) or mortality using pooled logistic regression. For the analysis using mean 25(OH)D levels, the mean 25(OH) vitamin D in previous visits was the mean 25(OH)D level from all visits prior to that month. The second lifetime

	40-49	2348	12	5.1
	50+	3243	20	6.2

[1]Adjusted for age, sex, race, and body mass index

analysis evaluated the association between initial 25(OH)D levels and a patient's lifetime cardiovascular event history, adjusting for confounders with a Cox Proportional Hazards model. This approach included events that might occur before cohort entry.

Results: The study analyzed a cohort of 1,792 SLE patients, primarily female (92%), White (48%), and African American (40%), with a mean age of 42 years. In the prospective analysis, cardiovascular events (CVE; defined as stroke, myocardial infarction (MI), and angina/bypass) were assessed over 11,302 person-years of follow-up, with 67 events recorded. Patients with 25(OH)D levels below 20 ng/mL had the highest mortality and CVE rates (Table 1). Only initial 25(OH)D levels were significantly associated with mortality and cardiovascular risk, while mean and recent levels were not (Table 2). Compared to patients with levels of 30-39 ng/mL, those with levels below 20 ng/mL had: higher mortality risk (HR: 2.05, 95% CI: 1.19–

20-29	2.10	0.96	4.58	0.062
30-39	1 (ref)			
40-49	1.69	0.73	3.92	0.22
50+	3.41	1.50	7.74	0.0033

[1] Adjusted for age, race, sex, and body mass index

3.54, p = 0.0095); higher risk of CVE (HR: 1.74, 95% CI: 1.20–2.54, p = 0.0038); increased MI risk (HR: 2.42, 95% CI: 1.12–5.24, p = 0.025); but no significant association with stroke (HR: 1.41, 95% CI: 0.90–2.20, p = 0.14).

In the second (lifetime) analysis (Table 3), the analysis included more CVE than the prospective analysis (261 stroke/MI/angina; 229 stroke or MI; 176 stroke; 76 MI). A U-shaped relationship was observed, with both low (< 20 ng/mL) and high (≥50 ng/mL) 25(OH)D levels linked to an increased risk of myocardial infarction. Using mean 25(OH)D levels in the model for mortality (assuming the log-rate of mortality declines in a linear way), the slope was significant (p=0.0002). The odds ratio was 0.72 for each 10 unit increase in mean 25(OH)D level (i.e., a 28% decline in mortality per 10 unit increase in 25(OH)D levels).

Conclusion: An initial 25(OH)D level below 20 ng/mL led to a significantly increased risk of mortality and cardiovascular events (but not stroke) in SLE. The U-shaped association with MI, found in the lifetime analysis, suggests both deficient and high 25(OH)D levels increase the risk of myocardial infarction. Analysis of mean 25(OH)D levels (which represent routine supplementation) found a 28% decline in mortality per 10 unit increase in 25(OH)D levels.

Abstract Number: 0598

Study of Long Term HCQ Safety on Cardiac Muscle Function in Patients with SLE and other Rheumatic Diseases

Jaspreet Bhatti[1], Kyu-In Lee[2], **Nirali Sanghavi**[3], Stephen Zak[4], Julia Ash[5], James Miceli[6], Kirk Sperber[4], Stephen Pan[7] and Amy Wasserman[8], [1]Westchester Medical Center, Hopewell Junction, NY, [2]Westchester Medical Center, Fort Lee, NJ, [3]Westchester Medical Center, White Plains, NY, [4]New York Medical College, Valhalla, [5]Westchester Medical center, Dobbs Ferry, NY, [6]Westchester Medical Center, Hawthorne, NY, [7]Westchester Medical Center, Valhalla, [8]New York Medical College at Westchester Medical Center, Armonk, NY

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: HCQ induced cardiomyopathy leading to heart failure is a rare but serious potential treatment complication. Currently there are no screening guidelines for detecting HCQ related cardiotoxicity. This study aims to identify signs of cardiotoxicity, including cardiomyopathy, in patients on HCQ. Secondary objectives include identifying non-invasive modalities for detection of HCQ induced cardiac toxicity.

Methods: We conducted a cross-sectional observational study from 2023 to 2025 at an academic medical center. We included patients aged 18–75 with a confirmed diagnosis of rheumatic disease and current HCQ therapy. We excluded patients with known history of cardiomyopathy from an alternative etiology. BNP, Troponin, serum HCQ level, ECG and echocardiogram were performed. Interventricular septal thickness at end-diastole (IVSd), an established echocardiogram criterion for LVH and a reported early finding of HCQ cardiac toxicity, was documented (1). Patients with increased IVsd (>1.2cm) and/or other cardiac abnormalities were referred to cardiology for further evaluation and possible biopsy.

ANOVA Analysis				
	<5years (n=22)	5-10 years (n=23)	>10years (n=39)	p-value
QTC	436.27	431.6	442.48	0.37
Troponin	5.58	13.48	4.27	0.36
BNP	37.31	63.65	96.18	0.42
IVSD	0.83	0.91	0.96	0.08
Chi Squared Analysis				
LVEF <40%	0 (0%)	1 (4%)	0 (0%)	0.26

Results: We evaluated 84 patients on HCQ, with baseline characteristics summarized in Table 1. Patients were divided into three groups based on treatment duration and cardiac parameters were compared (Table 2). Cardiac abnormalities of QTc > 440 ms were observed in 25 patients, IVSd > 1.2 cm in 7 patients, BNP > 100 pg/mL in 18 patients, troponin elevation in one patient, and reduced EF (< 40%) in one patient. Two patients underwent cardiac biopsy with findings consistent with HCQ toxicity. Both had MCTD diagnosis (SLE/SSc and positive anti-RNP), were on HCQ for over 10 years, had GFR < 40, QTc >450 ms; one had IVSd > 1.2 cm, and both had normal EF. ANOVA analysis did not show statistically significant differences in QTc, troponin, BNP or IVSd between the treatment duration groups. A chi-squared test assessing EF by HCQ duration also showed no significant difference ($p = 0.24$). A secondary analysis using a one-tailed t-test revealed a statistically significant difference in IVSd between patients receiving HCQ for >10 years compared to those treated for < 10 years ($p = 0.03$).

Conclusion: Our study found no statistically significant difference between the duration of HCQ use and measures of cardiac toxicity. Overall, abnormal cardiac findings were infrequent and did not correlate with HCQ exposure length. Numerically, there is a trend toward increased LVH in patients on long-term HCQ (>10 years), and a secondary analysis shows a statistically significant difference in IVSd between patients on HCQ for >10 years compared to those treated for < 10 years. However, given the small sample size in this cross-sectional study, a definitive association cannot be established. IVSd appears to be superior to EF as a noninvasive marker for potential HCQ cardiac toxicity. Similar to HCQ retinal toxicity, patients with reduced GFR and higher cumulative dose may benefit from enhanced screening.

Abstract Number: 0599

Efficacy of Statin Medications for Secondary Prevention of Atherosclerotic Cardiovascular Disease Among Patients with Systemic Lupus Erythematosus

Aakash V. Patel[1], Lingxiao Zhang[2], Emily S. Lau[3], Baijun Zhou[2], Yuqing Zhang[4], Hyon K. Choi[5] and April Jorge[6], [1]Massachusetts General Hospital, Harvard Medical School, Boston, MA, [2]Massachusetts General Hospital, Boston, [3]Massachusetts General Hospital, Harvard Medical School, Boston, [4]Massachusetts General Hospital, Quincy, MA, [5]MASSACHUSETTS GENERAL HOSPITAL, Lexington, MA, [6]Massachusetts General Hospital, Boston, MA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is associated with up to a three-fold increased risk of myocardial infarction (MI) and stroke. Statins have well-established cardioprotective benefits among non-SLE patients with atherosclerotic cardiovascular disease (ASCVD), but data assessing their efficacy for the secondary prevention of ASCVD in this population are scarce.

Methods: We specified and emulated a pragmatic target trial to compare outcomes among SLE patients initiating versus not initiating a statin following their first clinical ASCVD event. We identified an SLE cohort from TriNetX, a large electronic health record (EHR) database in the United States. We included patients with SLE (≥2 ICD codes ≥30 days and ≤2 years apart) between January 2002 and August 2021 who had a first clinical ASCVD event, including acute MI, coronary artery disease requiring intervention, unstable angina, ischemic stroke, or transient ischemic attack (TIA), identified by ICD codes during an inpatient or emergency room encounter. We excluded patients treated with a statin in the year preceding the index ASCVD event or with a contraindication. We compared the treatment strategies of statin initiation within 30 days after the index event versus no statin initiation. Study follow up commenced at the date of statin initiation or a randomly assigned date within the same 30-day period for non-initiators. We employed propensity score overlap weighting to emulate randomization. Covariates included demographics, type of index ASCVD event, comorbidities, SLE disease manifestations, medications, and healthcare utilization. Efficacy outcomes included all-cause death, major adverse cardiovascular events (MACE),

*Includes myocardial infarction, ischemic stroke, heart failure hospitalization, or cardiovascular death

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

and new-onset end-stage kidney disease (ESKD). We assessed the control outcome of injury/trauma. We utilized Cox regression to compare incidence rates between the two groups and employed a primary per-protocol approach, censoring patients upon deviation from their assigned treatment, and an intention-to-treat (ITT) approach as a secondary analysis.

Results: There were 1736 patients with SLE who met the inclusion/exclusion criteria (**Figure 1**). Of these, 726 patients initiated a statin, compared with 1010 non-initiators **(Table 1)**. Baseline covariates were similar across both groups following propensity sore overlap weighting (standard difference < 0.001). The mean age was 53 years; 85% were female. In the per-protocol and ITT analyses, statin users had a lower risk of all-cause death (HR 0.55 [95% CI 0.34-0.91] and 0.53 [95% CI 0.34-0.82], respectively, **Table 2)**. There was no difference in the risks of MACE (HR 0.96 [0.77-1.21], ESKD (HR 1.26 [95% CI 0.77-2.08]), or the control outcome of injury/trauma (HR 0.97 [95% CI 0.71-1.33]).

Conclusion: In this emulated target trial using a large, EHR-based cohort of patients with SLE and clinical ASCVD, we identified a lower risk of all-cause death associated with initiating a statin, although there were no significant differences in rates of MACE or ESKD. This study is limited by the possibility of residual bias and the use of administrative codes. These findings underscore the role for statin treatment in patients with SLE and ASCVD.

Session Date: Sunday, October 26, 2025
Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Difficult-to-treat systemic lupus erythematosus (D2T-SLE) presents a major challenge due to disease heterogeneity and a lack of unified classification. While the D2T concept has advanced management in other autoimmune diseases, no operational definition exists for SLE. This study aimed to define clinician-endorsed criteria for D2T-SLE across the Middle East and North Africa (MENA) region.

Methods: A cross-sectional online survey was distributed to rheumatologists and nephrologists in 12 MENA countries. Clinicians rated factors relevant to D2T-SLE, including disease persistence, treatment failure, corticosteroid use, patient-

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Summary of Key Findings from the D2T-SLE Clinician Survey

Key Variable	Value
Total Respondents	141
Rheumatologists (%)	125 (88.7%)
Nephrologists (%)	10 (7.1%)
Included PROs in DTT-SLE definition	93%
Supported Organ-Specific Criteria	88%
Supported Corticosteroid Criterion	82%
Supported Overlap Syndromes Inclusion	62%
Mean QOL Importance (1–5)	3.87
Factor 1 Loading (QOL)	-0.85
Factor 2 Loading (Fatigue)	-0.32
Top Cluster Focus	PRO-heavy (Cluster 1)
Logistic: Pain -> QOL (p)	0.042
Cohen's Kappa (Steroid Inclusion)	-0.009

reported outcomes (PROs), overlapping syndromes, and psychosocial factors. Quantitative analysis included descriptive statistics, exploratory factor analysis, k-means clustering, logistic regression, and Cohen's Kappa for agreement.

Results: A total of 141 clinicians responded (89% rheumatologists). Most participants had experience in academic lupus settings, with 68% involved in research or publication and 50% in international SLE workshops. There was broad support for incorporating both clinical and PRO elements (93%), organ-specific involvement (88%), and corticosteroid dependency (82%) into a D2T-SLE definition. Top criteria included persistent moderate-to-high disease activity, failure of multiple therapies, and recurrent flares. Overlapping autoimmune syndromes—particularly APS, MAS, and Sjögren's—were identified as major complicating factors, with 62% supporting their inclusion in D2T-SLE criteria. The agreement on corticosteroid thresholds was low (κ = -0.009).

Factor analysis identified two latent domains: psychosocial burden (fatigue, psychological distress) and functional burden (pain, QOL, and activity limitation). Cluster analysis revealed three clinician phenotypes: one prioritizing PROs, another emphasizing clinical damage, and a balanced group. Logistic regression showed that fatigue ($p = 0.015$), pain ($p < 0.001$), and functional impairment ($p = 0.027$) significantly predicted prioritization of QOL. Clinicians favored including kidney and CNS involvement in the definition, based on persistent SLEDAI-2K ≥6, BILAG A/B scores, and frequent flares.

Commonly cited causes of treatment failure included primary inefficacy, secondary loss of response, toxicity, comorbidities, and non-adherence.

Conclusion: Clinicians across the MENA region strongly supported defining D2T-SLE using a composite of treatment failure, corticosteroid burden, PROs, and organ involvement. These findings align with the broader D2T paradigm seen in other autoimmune diseases and advocate for a multidimensional, consensus-based framework. This study provides the quantitative foundation for future international classification efforts.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Posterior reversible encephalopathy syndrome (PRES) is an underrecognized neuroradiologic complication of SLE, characterized by acute neurological symptoms and vasogenic edema on neuroimaging. Its precipitating factors, clinical spectrum, and long-term outcomes remain poorly defined. We sought to delineate the presentations, triggers, and prognoses of PRES in patients with SLE through a multicenter cohort study and systematic literature review (SLR).

Methods: We conducted a multicenter retrospective cohort study (August 1999–October 2024) and an SLR according to the PRISMA guidelines. Patients were included if they met the 2019 EULAR/ACR SLE classification criteria or were described as having SLE by study authors in the SLR, had confirmed PRES episodes, defined as: 1) first sudden appearance of neurologic symptoms attributed to PRES such as seizures, altered mental status, headache, visual impairment, or focal deficits; 2) radiologic evidence of vasogenic edema on CT or MRI; and 3) not better explained by alternative diagnoses.

We did a comprehensive search in multiple databases from their inception to October 1, 2024, in any language. Two reviewers independently screened and reviewed the articles. We included studies reporting cases that met the inclusion criteria used for the cohort. Extracted data included demographics and clinical characteristics at presentation, laboratory data, radiologic findings, therapeutic strategies, and clinical outcomes. For outcome analyses, we included only cases with sufficient data that met our quality criteria, adapted from the Murad et al. tool for evaluating case reports. Kaplan-Meier methods estimated time-to-event outcomes. Logistic and Cox regressions, adjusted for age and sex, identified associated factors.

Results: We analyzed 550 patients (53 cohort; 497 SLR), mean age 26.7 ± 10.2 years, 504/546 (92%) female. In the cohort, PRES was most often precipitated by hypertension in lupus nephritis 43/53 (81%), followed by hypertension without nephritis 7/53 (13%), sepsis 2/53 (4%), and immunosuppression 1/53 (2%). Also, 42/53 (79%) patients required antiseizure medications (ASMs), and among those who did, median time to ASMs discontinuation was 0.4 years (95% CI 0.1–3.9), with 78.1% off therapy by five years (Figure 1a).

Across all cases (cohort and SLR), presenting symptoms included seizures 389/490 (79%), headache 251/464 (54%), altered mental status 205/466 (44%), and visual disturbances 192/464 (41%). PRES was the initial SLE manifestation in 48/362 (13%) of cases (Table 1). Five-year PRES recurrence was 11.5% (95% CI: 2.3–19.9) (Figure 1b). Thirty- and 180-day survival rates were 96.3% and 93.7%, respectively (Figure 1c). Older age increased odds of persistent neurological deficits (OR 1.63 per 10-year increase in age, 95% CI 1.12–2.39) (Table 2).

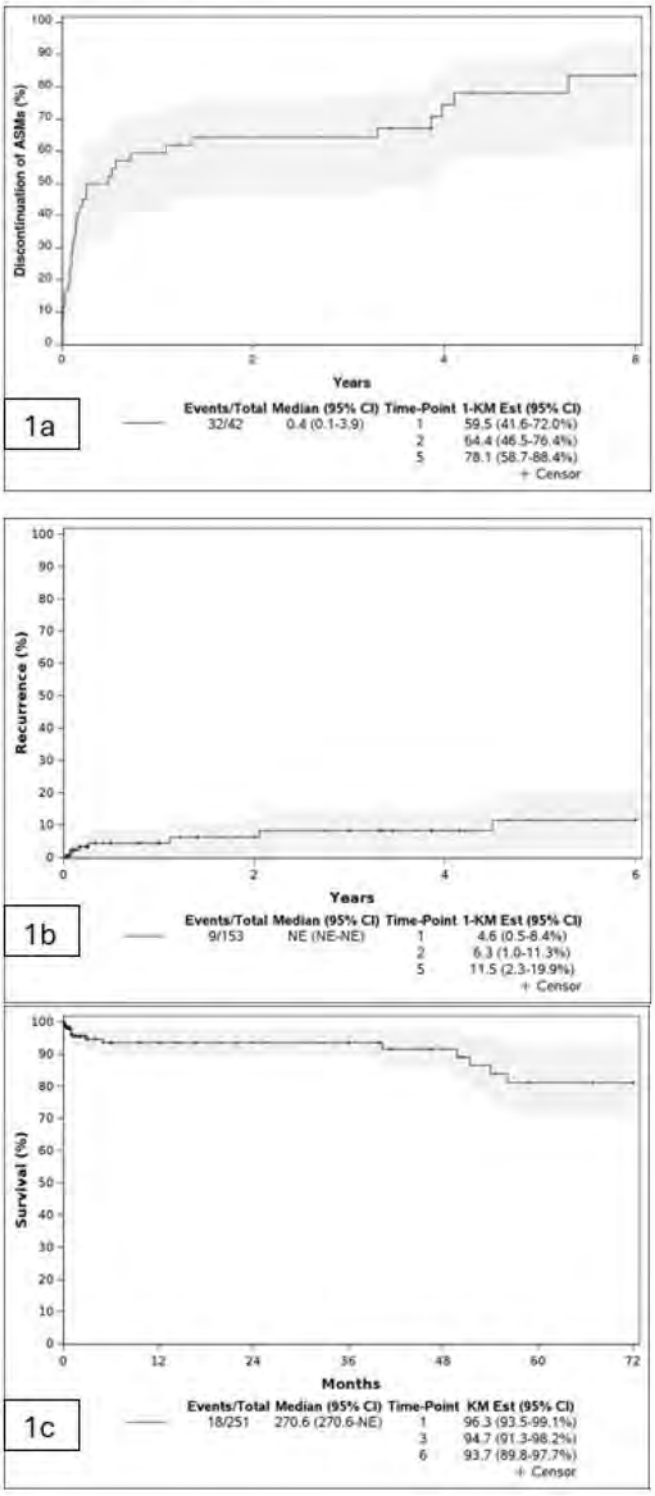
Figure 1a-c. Kaplan-Meier curves for outcomes in SLE patients with PRES: (a) anti-seizure medications discontinuation; (b) recurrence of PRES; (c) overall survival.



Conclusion: In SLE, PRES most commonly follows hypertensive crises in lupus nephritis and presents with seizures and headache. While short-term prognosis is excellent, long-term deficits are influenced by age.

Abstract Number: 0602

Association of Systemic Lupus Erythematosus with Healthcare Resource Utilization and Healthcare Expenditures: Analysis of Nationally Representative Data, 2017-2022

Ami Vyas[1], Steven Cohen[2] and Christine Eisenhower[2], [1]University of Rhode Island, Kingston, RI, [2]University of Rhode Island, Kingston

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Limited information is available about the effect of systemic lupus erythematosus (SLE) on healthcare resource utilization and healthcare expenditures. The associations between SLE and healthcare resource utilization and expenditures were examined using the most recently available data.

Methods: A retrospective US population-based study was conducted using Medical Expenditure Panel Survey data for 2017-2022. Patients with SLE were those who both self-reported SLE diagnosis and who reported SLE-related medication use and/or visit to a rheumatologist in the survey year. Eight patients without SLE were matched to each SLE patient on survey year, age, and sex, to create a reference cohort. Appropriate multivariable generalized linear regression, either negative binomial regression or Poisson regression, with log link, was used to obtain an adjusted annualized event rate ratio (AAERR) for each component of healthcare resource utilization. Multivariable ordinary least square regression was conducted to examine the association between SLE and log expenditures. To avoid retransformation bias of log expenditures, the subgroup-specific smearing factor was used to account for unequal variances between the SLE and non-SLE patients.

Results: Compared to those without SLE, patients with SLE had higher adjusted rates of outpatient visits (AAERR=2.603, $p< 0.05$), office-based provider visits (AAERR=1.447, $p< 0.05$), and emergency room visits (AAERR=1.518, $p< 0.05$). However, there were no significant differences in adjusted rates of inpatient visits between those with and without SLE (AAERR=1.365, p=0.065). With regard to healthcare expenditures, those with SLE had significantly higher average annual healthcare expenditures compared to those without SLE ($18,566 vs. $9,366, $p< 0.0001$), and the findings were consistent for expenditures by each healthcare resource component. In the adjusted analyses, average annual healthcare expenditures for those with SLE were significantly higher than those without SLE ($13,664 vs. $11,781, $p< 0.05$).

Conclusion: Our study findings suggest higher healthcare resource utilization and, hence, higher healthcare expenditures among patients with SLE compared to their non-SLE counterparts.

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease with widespread clinical manifestations. Neuropsychiatric SLE (NPSLE), a complex and poorly understood subset of SLE, comprises of 19 conditions with high rates of morbidity and mortality. Included in the spectrum of NPSLE is transverse myelitis (TM), a neuroinflammatory disorder characterized by rapid-onset motor and sensory deficits. In this study, we aim to investigate the prevalence of TM among the general SLE population and to compare clinical characteristics and outcomes between SLE patients with and without TM.

Methods: A retrospective chart review was conducted utilizing data from the TriNetX global research network platform, a health record electronic database. A total of 135,027 patients with SLE (ICD-10: M32) were identified across 97 health care organizations, of which 1,224 patients had a diagnosis of transverse myelitis (ICD-10: G37.3 or G04.9) and 133,803 patients did not have transverse myelitis. A 1:1 propensity score matching was done using 60 demographic and clinical variables, and yielded two cohorts of 1,219 patients each. The variables studied included baseline patient demographics, clinical manifestations/comorbidities, and autoantibody profile. Outcomes analyzed included mortality, laboratory findings, and medication usage. Kaplan-Meier curve and log-rank test were used for survival analysis. Statistical significance was defined as a p-value of < 0.05.

Results: The prevalence of TM among the general SLE population was 0.91%. Analysis of the demographic data before propensity matching revealed higher rates of TM in male (p=0.019), African-American, and Asian patients (p-values < 0.001).

Clinical manifestations such as glomerular disease, thrombosis, other neurological involvement including seizures, psychosis and neuromyelitis optica (NMO), as well as various hematological lab abnormalities were more frequent in the TM group prior to matching (all p-values < 0.001). The frequencies of Ro/SSA, La/SSB, Ribosomal-P (all p-values < 0.001), RNP

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1A

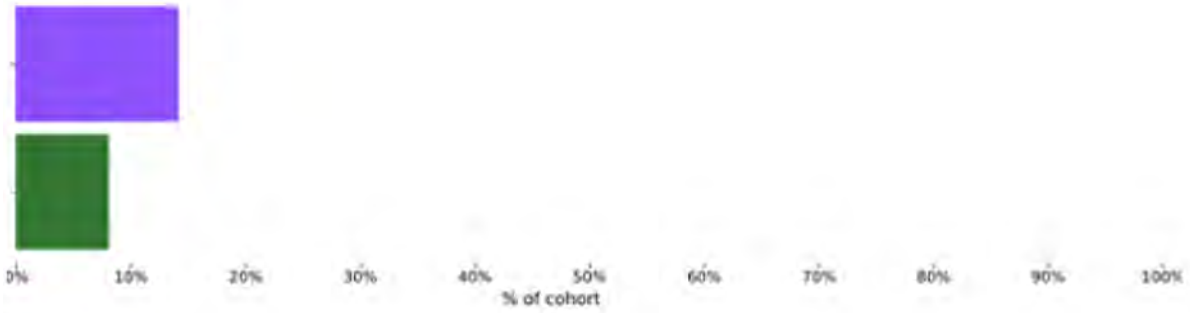

Figure 1B

Figure 1A: Survival Probability in Systemic Lupus Erythematosus With and Without Transverse Myelitis Using Kaplan-Meier Survival Analysis. Figure 1B: Mortality Rate Data in Systemic Lupus Erythematosus With and Without Transverse Myelitis.

(p=0.009), DsDNA antibodies (p=0.020), as well as low C3 and C4 complements (p< 0.001) were significantly higher in TM patients before matching (Table 1 and 2).

After propensity matching, neurological manifestations such as myasthenia (p=0.002) and NMO (p< 0.001) as well as the frequency of La/SSB antibody (p=0.030) were significantly higher in the TM SLE group (Table 1 and 2).

Kaplan-Meier survival analysis revealed that TM is a significantly poor prognostic factor in SLE patients, with lower survival probability compared to patients without TM (HR: 1.423, 95% CI:1.11-1.82). During the study period, 14.2% of patients with TM died and 8.1% of patients without TM died (RR: 1.75, 95% CI: 1.38-2.21) (Figure 1A and 1B).

Conclusion: Transverse myelitis is a rare, but significant complication of SLE and with a poor prognostic factor in SLE patients. TM was also associated with distinct antibody profiles and clinical manifestations/comorbid conditions, especially other NPSLE findings. Given the risk of profound neurological deficits, early diagnosis and treatment is of the utmost importance to help improve long-term outcomes.

González-Gay[4] and Iván Ferraz Amaro[1], [1]Servicio Canario de Salud, La Laguna, Canarias, Spain, [2]Servicio Canario de Salud, La Laguna, Spain, [3]Hospital Doctor Negrín, Las Palmas de Gran Canaria, Canarias, Spain, [4]Department of Rheumatology and Joint and Bone Research Unit, Hospital Universitario Fundación Jiménez Díaz, and Instituto de Investigación Sanitaria-Fundación Jiménez Díaz, Madrid, Spain, and Medicine and Psychiatry Department, University of Cantabria, Santander, Spain

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: The Metabolic Score for Insulin Resistance (METS-IR) is a recently developed index proposed as a predictor of cardiovascular (CV) events. In this study, we calculated the METS-IR in patients with systemic lupus erythematosus (SLE), a condition associated with increased CV risk. We assessed its relationship with disease characteristics and CV comorbidities, including disease activity and damage, lipid profile, carotid atherosclerosis, and insulin resistance (IR) indices.

Methods: A total of 308 patients with SLE were enrolled. METS-IR was calculated as previously described: METS-IR = (Ln [(2 × glucose) + triglycerides] × BMI) / Ln(HDL-cholesterol). Disease activity and damage were assessed using the SLEDAI and SDI scores, respectively. Additional evaluations included a full lipid profile, IR indices via HOMA2 (Homeostatic Model Assessment), and carotid ultrasound to measure intima-media thickness and detect carotid plaques. Multivariable linear regression analysis was performed to examine associations between disease characteristics and METS-IR.

Results: METS-IR value in SLE patients was 39.6 ± 10.2. Both waist and hip circumference were significantly and positively associated with METS-IR. Among classical CV risk factors, hypertension was significantly associated with higher METS-IR values, whereas diabetes and smoking were not. No significant associations were observed between METS-IR and disease duration, SLEDAI score, LLDAS or DORIS remission indices, antinuclear antibody profile, or the use of prednisone or other therapies. The SDI damage index showed a significant association with METS-IR in univariable analysis (β = 1.0, 95% CI 0.3–2.0, p = 0.013), but this was not confirmed after adjustment. In contrast, C-reactive protein levels remained positively associated with METS-IR after adjustment for covariates (β = 0.1, 95% CI 0.05–0.2, p = 0.004). Regarding the lipid profile, METS-IR (which includes HDL and triglycerides in its formula) was not significantly associated with serum total cholesterol or LDL-cholesterol levels but showed significant associations with apolipoprotein A1 (β = -0.08, 95% CI -0.1 to -0.07, p < 0.001) and apolipoprotein B (β = 0.04, 95% CI 0.02–0.06, p < 0.001). Although METS-IR does not include insulin or glucose metabolism parameters, both insulin and C-peptide serum levels showed a significant positive association with METS-IR after adjustment. Similarly, HOMA2-IR and beta-cell function indices were also independently and positively associated with METS-IR. In contrast, the presence of carotid plaque and intima-media thickness were not related to METS-IR values. Notably, the SCORE2 CV risk calculator showed a significant positive association with METS-IR (β = 0.4, 95% CI 0.04–0.7, p = 0.030).

Conclusion: In patients with SLE, the METS-IR index is significantly associated with markers of central adiposity, insulin resistance, classical CV risk factors, inflammatory activity, and CV risk estimation, but not with disease activity, accumulated damage, or subclinical carotid atherosclerosis. These findings suggest that METS-IR reflects the metabolic and cardiovascular risk profile in SLE, independently of specific disease characteristics.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: The Systemic Lupus International Collaborating Clinics Frailty Index (SLICC-FI) was developed to ascertain frailty in systemic lupus erythematosus (SLE) patients. The aim of this study is to evaluate the SLICC-FI as a predictor of self-efficacy in patients from a prevalent Latin American Mestizo lupus cohort.

Methods: Patients from a single-center lupus cohort were included in these analyses. Self-efficacy was ascertained with the Patient-Reported Outcomes Measurement Information System (PROMIS) self-efficacy for managing chronic conditions. Frailty was ascertained using the SLICC-FI. Results are shown as means and standard deviations or numbers and percentages, as appropriate. Generalized estimating equations were performed, using each domain of the PROMIS self-efficacy as an outcome in the subsequent visit and the SLICC-FI (as a continuous variable) in the previous visit. Alternative analyses were also carried out including the SLICC-FI as a categorical variable (frail versus non frail). In both approaches, the multivariable models were adjusted for possible confounders (age at diagnosis, sex, socioeconomic status, ethnicity, Systemic

Table 1: The predictive value of the SLICC-FI (as a continuous variable) on PROMIS self-efficacy for managing chronic conditions in SLE patients *Adjusted for age at diagnosis, sex, ethnicity, socioeconomic status, Systemic Lupus Erythematosus Disease Activity Index-2000 (SLEDAI-2K), Systemic Lupus Erythematosus International Collaborating Clinics/American College of Rheumatology Damage Index (SLICC/ACR DI), disease duration at baseline, prednisone daily dose, antimalarial, immunosuppressive drugs use and the same domain of self-efficacy from the previous visit. **QIC - Quasi-likelihood Information Criterion value to assess model fit

Symptoms	-1.79 (0.67)	0.008	-0.92 (0.48)	0.054	62.254
Emotions	-0.85 (0.71)	0.235	-0.87 (0.53)	0.097	38.809
Daily activities	**-3.86(0.65)**	**<0.001**	**-1.18 (0.41)**	**<0.001**	38.429

Lupus Erythematosus Disease Activity Index-2000 (SLEDAI-2K), SLICC/American College of Rheumatology Damage Index (SLICC/ACR or SDI), disease duration, prednisone daily dose, antimalarial and immunosuppressive drug use, and the same domain of the PROMIS self-efficacy in the previous visit). Statistical significance set at $p < 0.05$.

Results: Three-hundred and seventy SLE patients and 1561 visits were included in this study; these patients were followed for 4.9 (3.7) years; 342 (92.4%) were women and the age of diagnosis was 35.2 (13.4) years. At baseline, the disease duration was 1.01 (7.4) years, while SDI and SLICC-FI scores were 1.3 (1.5) and 0.17 (0.05), respectively. Eighty patients (21.6%) were classified as frail, 270 (73.0%) were classified as least fit, 20 (5.4%) were classified as less fit, and no patient was classified as robust. At baseline, of the PROMIS general self-efficacy was 47.3 (9.8), self-efficacy for managing emotions was 44.8 (7.5), for managing symptoms was 47.4 (7.5), for managing daily activities was 45.5 (7.2), for managing social interactions was 42.4 (7.6) and for managing medications and treatment was 43.8 (7.5). In the main analyses, after adjusting by possible confounders, the SLICC-FI scores predicted worse general self-efficacy and worse self-efficacy for managing daily activities; these data are depicted in Table 1. In the alternative analyses, the frail category, predicted worse general self-efficacy and worse self efficacy for managing daily activities, after adjustment by possible confounders; these data are depicted in Table 2.

Conclusion: The SLICC-FI predicts worse self-efficacy as assessed by the PROMIS self-efficacy for managing chronic conditions in a prevalent Latin American lupus cohort, supporting the relevance of this index in the evaluation of these patients.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Herpes Zoster (shingles) is a common preventable adverse event in SLE. In Quebec, Canada, the Recombinant Zoster Vaccine (RZV) became free of charge for immunocompromised adults in May 2023. We evaluated RZV vaccination rates before and after this date, and examined factors associated with vaccination in SLE.

Methods: We studied participants from 2 prospective SLE cohorts who met ACR/SLICC classification criteria. Annual standardized data collection included demographics, clinical characteristics, medications, and vaccinations. Follow-up started at the first study visit after October 2017 (when RZV first became available), left-censoring person-time prior to the first study visit and excluding participants vaccinated before this date. Follow-up continued until RZV vaccination, death, end of cohort follow-up, or December 31, 2024. We compared vaccination rates before and after May 2023 (start of free vaccination), and evaluated demographic and clinical associations with vaccination using Cox proportional hazards regression.

Results: Among 647 participants, 89% were female, 65% were White, and mean age was 47.4 years (SD 16), with an SLE duration of 15 years (SD 12). Nearly half (46%) were taking an immunosuppressant, primarily mycophenolate (24%). A history of previous shingles was reported in 108/489 (22%; data from one cohort only). Over the study follow-up, 172 (27%) received at least one RZV dose (Table 1). Vaccination rates were higher May 2023-December 2024 (16 per 100 person-years; 95% CI 13-20) compared to October 2017-April 2023 (3 per 100-person years; 95% CI 2-4). In multivariable analyses, age (each year, adjusted HR 1.04; 95% CI 1.02-1.05), White race/ethnicity (aHR 1.7; 95% CI 1.2-2.5), and immunosuppressant use (aHR 2.1, 95% 1.5-3.0) were associated with receiving the RZV, while prednisone use was potentially associated (HR 1.4, 95% CI 0.9-2.2). Among those who received a first RZV dose, 76/170 (45%) received the second dose within 3 months, and 120/139 (86%) received the second within 12 months (median time between doses 84 days, IQR 64-134).

Conclusion: Despite the young age of this cohort, nearly a quarter had previous shingles, highlighting a high burden in SLE. Although a provincial policy providing the 2-dose RZV free of charge to immunocompromised adults was associated with increased vaccination rates, less than a third of patients across both cohorts have been vaccinated. Interventions should target subgroups less likely to receive the vaccine (or complete the vaccination series).

Abstract Number: 0607

Age at Diagnosis of SLE Has Increased in a United States Longitudinal Cohort

Daniel Goldman[1], Andrea Fava[2], Laurence Magder[3] and Michelle Petri[1], [1]Johns Hopkins University School of Medicine, Timonium, MD, [2]Johns Hopkins University, Baltimore, MD, [3]University of Maryland, Baltimore, Baltimore, MD

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: The demographics of our lupus cohort have shifted over the decades towards an older population. While much of the shift can be attributed to advances in patient care leading to longer survival, we have also observed an increase in the age at which patients are being diagnosed with lupus. We examined this increase in the age of diagnosis and the impact on the disease manifestation profile.

Methods: The study was based on 3060 patients from a longitudinal SLE cohort in whom the date of SLE diagnosis was known (extracted from review of medical records), and who had at least 1 cohort visit. Patients were divided into 7 cohorts based on the decade of SLE diagnosis (1960-1969, 1970-79, 1980-89, 1990-99, 2000-09, 2010-2019, ≥2020). The catchment area of the cohort has remained Baltimore city and surrounding counties.

The study incorporated all components of the 1997 ACR classification criteria for SLE (malar rash, discoid rash, photosensitivity, oral ulcers, arthritis, pleuritis or pericarditis, proteinuria, neurologic manifestations, hematologic manifestations, immunologic manifestations) to determine if there were differences in the percent of patients presenting with a given

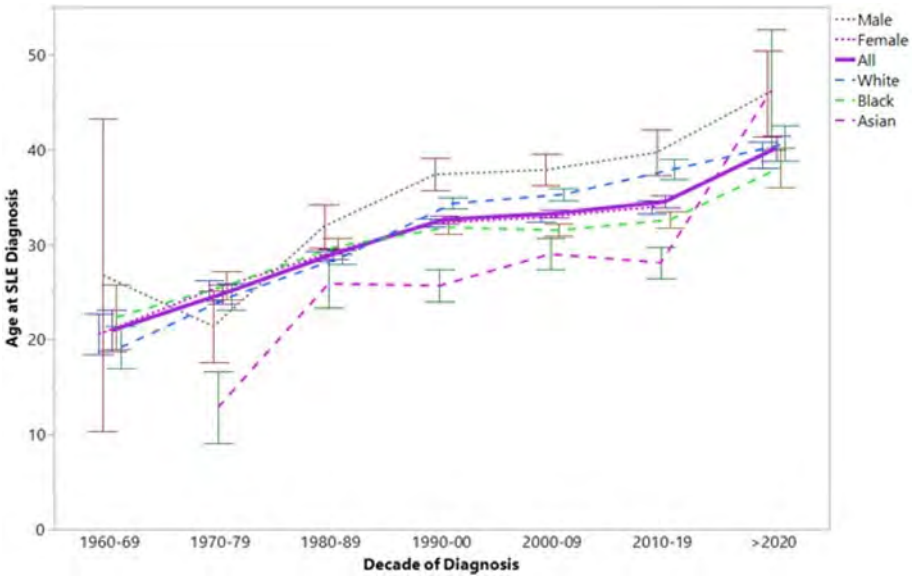

Figure 1 - Average Age of Diagnosis by Decade

manifestation at the time of SLE diagnosis (and up to 1 year after diagnosis). For analysis of lupus manifestations we used Chi-squared tests (Pearson) and exact Cochran Armitage for trend.

Results: The average age of diagnosis steadily increased over time, from 21.0 years in the 1960's to 40.2 years after 2020 (Figure 1). Similar increases were seen for Blacks, Whites and East Asians as well as females and males (Figure 1). For those diagnosed between 1990 to 2019, men were significantly older than women at diagnosis and Whites were significantly older than Blacks and East Asians at diagnosis (Table 1). Those diagnosed after 30 years of age were more likely to have oral ulcers, hematologic manifestations, immunologic manifestations and positive ANA, and less likely to have malar rash and proteinuria compared to those diagnosed before 30 years of age (Table 2). The same patterns for the ACR classification criteria were also observed at 5 years after diagnosis.

Conclusion: SLE has long been characterized as a disease with onset under 30. While diagnosis before the age of 30 years still predominates, diagnosis after the age of 30 has become more and more evident. SLE diagnosed in older adults exhibits a different profile of manifestations with less malar rash and proteinuria, but more hematologic and immunologic manifestations.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I

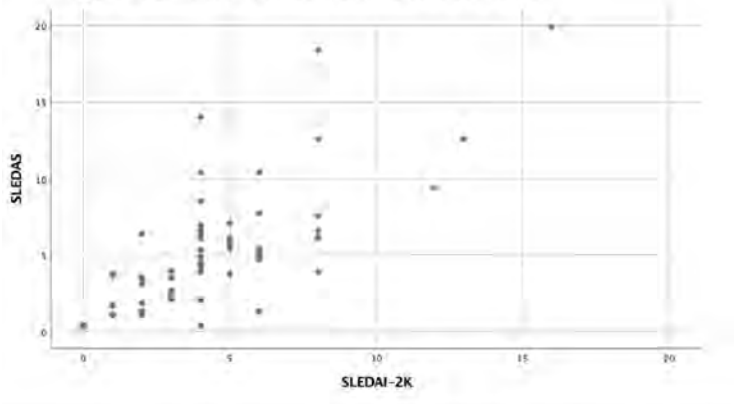
Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Assessing disease activity in systemic lupus erythematosus (SLE) is essential for effective treatment. SLEDAI-2K uses dichotomous items, while SLE-DAS incorporates both dichotomous and continuous variables. We intend to analyze the correlation between SLEDAI-2K and SLE-DAS in patients with systemic lupus erythematosus from central Spain, as well as to identify factors contributing to discordance in disease activity classification.

Methods: Retrospective assessment of 324 SLE patients followed up from 2010 to 2024 at Madrid's Fundación Jiménez Díaz Hospital (Spain). Data were collected from the patients' most recent visits and disease activity was evaluated using SLEDAI-2K and SLE-DAS, and discordant classifications between the tools were analyzed.

Figure 1. Correlation between SLEDAI-2K and SLE-DAS*.



*Strong correlation was observed between both scores (ρ = 0.970, p < 0.001), with high concordance (linearly weighted Kappa index = 0.8004, p < 0.001

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 2. Multivariate analysis to identify predictors of discordant evaluation of disease activity when SLEDAI-2K and SLE-DAS were applied.

	OR CI 95%	p value
Skin (ref. absence)	4.36 (1.09, 17.4)	0.04
Hematologic (ref. absence)	2.94 (1.05, 8.29)	0.04
LLDAS (ref. no use)	0.03 (0.01, 0.14)	<0.001
Lupus anticoagulant (ref. negative)	1.73 (0.62, 4.80)	0.29
Corticosteroids (ref. no)	2.06 (0.80, 5.28)	0.13
Biological therapy (ref. no)	5.98 (0.02, 1.32)	0.09

LLDAS: Lupus Low Disease Activity State; SLEDAI: Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K); SLEDAS: Systemic lupus erythematosus disease activity state.

39 were discordant at only one level of disease activity. Notably, in 37 of the 44 cases, SLE-DAS classified patients as having a higher degree of disease activity compared to SLEDAI-2K. Patients with skin and hematological manifestations were more commonly discordant in terms of disease activity.

Conclusion: SLEDAI-2K and SLE-DAS demonstrate a strong correlation and high reproducibility for assessing disease activity in the Spanish population. However, SLE-DAS offers additional information, particularly in patients with hematologic and skin involvement, enabling a more precise evaluation of disease activity in SLE patient.

Abstract Number: 0609

Neutropenia in SLE: a Retrospective Cohort Study of Etiologies, Severity, Management, and Infection Outcomes

Eleni Papachristodoulou[1] and Vasileios Kyttaris[2], [1]Mount Auburn Hospital, Harvard Medical School, Cambridge, MA, [2]Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Neutropenia is a known hematologic manifestation of SLE, yet its clinical implications remain poorly defined. We conducted a retrospective study to characterize the frequency, severity, causes, management, and infectious outcomes of neutropenia episodes in patients with SLE.

Methods: We analyzed data from patients enrolled in the Beth Israel Deaconess Medical Center Lupus Cohort (2008–2025) who met the 1997 ACR SLE classification criteria. Neutropenia episodes were defined as an absolute neutrophil count (ANC) ≤1,500/μL and categorized by severity: mild (ANC 1,000–1,500/μL), moderate (ANC 500–999/μL), or severe (ANC < 500/μL). For each episode, we collected data on demographics, timing relative to SLE diagnosis, clinical features, laboratory data, treatment, presumed etiology (SLE, medications, infections, other), and infections within 30 days.

Results: Among 150 patients with SLE (93% female, mean age 46.2 years; Table 1), 52 (35%) experienced at least one neutropenia episode, totaling 169 episodes (Table 2); 13 (25%) patients had a single episode, while 39 (75%) had recurrent episodes. Episodes occurred a median of 9 years after SLE diagnosis. Neutropenia was prolonged (>4 weeks) in 45 (27%)

Table 1. Demographic and Clinical Characteristics of Patients with SLE	
Variable	Patients, n/N (%)
Total number of patients	150 (100%)
Female sex	140/150 (93%)
Age, mean (SD)	46.2 (12.5)
Race	
Asian	19/150 (13%)
Black	47/150 (31%)
White	72/150 (48%)
Other	11/150 (7%)
Comorbidities	
Diabetes Mellitus	21/150 (14%)
Chronic Kidney Disease	20/150 (13%)
Dialysis	2/150 (1%)
Solid Organ Transplant	3/150 (2%)
Sjögren's syndrome	6/150 (4%)
Antiphospholipid syndrome	5/150 (3%)
Outcomes	
Developed neutropenia (≥1 episode)	52/150 (35%)
• Single episode of neutropenia	13/52 (25%)
• Recurrent episodes of neutropenia	39/52 (75%)
Developed infection in the setting of neutropenia	15/52 (28.8%)
Abbreviations: standard deviation, SD.	

episodes. Median ANC was 1.26×10^3/μL; severity was mild in 134 (79%), moderate in 27 (16%), and severe in 8 (5%). Lymphopenia and hypocomplementemia were present in 61% and 57% of episodes, respectively.

Neutropenia was attributed to SLE in 138 episodes (82%), medications in 22 (13%), and as a reaction to an infection in 7 (4%); 2 episodes (1%), both in a single patient, were due to hemophagocytic lymphohistiocytosis (Table 2). Azathioprine and mycophenolate were the most commonly implicated medications, associated with 11 (6%) and 5 (3%) episodes,

Table 2. Characteristics of Neutropenia Episodes	
Variable	n/N of available data, (%)
Total neutropenia episodes	169 (100%)
Years between SLE diagnosis and neutropenia episode identification, median (IQR)	9 (4-15)
Patient age during episode (years), mean (SD)	39.08 (12.6)
Recurrent episodes	156/169 (92.3%)
Isolated episodes	13/169 (7.7%)
Episodes lasting >4 weeks	45/169 (26.6%)
ANC (cells/μL), median (IQR)	1.26 (1.03-1.40)

Table 3. Parameters of patients with neutropenia and concomitant infections

Age/Sex, comorbidities	ANC, $10^3/\mu L$	Immunosuppressive regimen at neutropenia identification; changes within last 6 months	Infection and testing	Infection Onset Relative to Neutropenia	Presumed neutropenia cause	Infection Treatment, Neutropenia Management and Outcome
37/F, DM	0.01	Corticosteroids, HCQ, MTX, Belimumab; increased MTX dose, started Belimumab	Gingivostomatitis /mucositis, throat culture negative	3 days after	Medication (MTX)	Inpatient workup for neutropenic fever for 3 days, treated with antibiotics for 8 days, full recovery. Neutropenia resolved with MTX discontinuation
47/F, None	0.42	HCQ, MNa, Belimumab; received 4 weekly doses of MTX (5 months before)	Influenza virus, PCR positive	4 days before#	Infection	Outpatient treatment with oseltamivir. Neutropenia resolved post infection.
25/F, None	0.81	Corticosteroids, HCQ, MNa, Belimumab; no changes	Periorbital cellulitis, wound and blood cultures negative	8 days after	Medication (MNa)	Hospitalized for 34 days, treated with IV antibiotics for 28 days for concern of brain abscess, full recovery. Neutropenia resolved with MNa discontinuation
25/F, None	0.94	HCQ; no changes	Coxsackie B infection, positive serologies	Same day as neutropenia	Infection	Inpatient workup for neutropenic fever for 6 days, full recovery. Neutropenia resolved post infection.
34/F, CKD	1.01	Corticosteroids, HCQ, MNa, Belimumab; missed Belimumab doses	Unclear, increased PET scan uptake in axillary & parotid glands, blood & urine cultures negative, suspected viral	Same day as neutropenia	Infection	Inpatient workup for neutropenic fever for 11 days, treated with antibiotics for 3 days, full recovery. Neutropenia resolved post infection.
55/F, None	1.03	Corticosteroids, LEF, Belimumab; missed Belimumab doses	Cervical lymphadenitis, throat culture & Strep test negative	18 days after	SLE-related	Outpatient oral antibiotics (clindamycin and azithromycin) for 10 days, full recovery. Neutropenia persisted post infection and attributed to SLE. Resumed Belimumab.
52/F, Sjogren	1.04	HCQ, Anifrolumab; restarted HCQ and Anifrolumab after break	Cystitis, *Escherichia coli*	1 day after	SLE-related	Outpatient oral Fosfomycin, full recovery. Neutropenia persisted post infection and attributed to SLE. IS unchanged
27/F, DM, CKD	1.11	Rituximab (1 year ago), HCQ, MMF; no changes	Influenza virus, PCR positive	3 days before*	Infection	Inpatient workup & treatment with oseltamivir for 6 days, full recovery. Neutropenia resolved post infection.
30/F, None	1.26	HCQ, AZA; no changes	Cystitis, *Escherichia coli*	3 days after	SLE-related	Outpatient oral Nitrofurantoin, full recovery. Neutropenia persisted post infection and attributed to SLE. IS unchanged
51/F, DM	1.30	Corticosteroids, HCQ, AZA, Belimumab; missed Belimumab doses	Pyelonephritis, *Klebsiella pneumoniae*	3 days before*	Infection	Hospitalized for 3 days, blood cultures remained negative, treated with IV antibiotics, full recovery. Neutropenia resolved post infection.
26/F, None	1.32	HCQ; no changes	Herpes Zoster, clinical diagnosis	4 days after	Infection	Outpatient valacyclovir, full recovery. Neutropenia resolved post infection.
27/F, CKD s/p kidney transplant rejection on dialysis	1.35	Corticosteroids, MNa; no changes	Cellulitis, wound ex: *Proteus spp., Staphylococcus aureus, Enterococcus faecalis, Corynebacterium spp.*	7 days before*	Infection	Hospitalized for 16 days, treated with IV antibiotics, full recovery. Neutropenia resolved post infection.
25/F, None	1.40	HCQ; no changes	Cystitis, *Proteus mirabilis*	6 days after	SLE-related	Outpatient oral Ciprofloxacin, full recovery. Neutropenia persisted post infection and attributed to SLE. IS unchanged
51/F, None	1.42	HCQ, AZA; missing AZA doses	Cystitis, culture negative	3 days after	Medication (AZA)	Outpatient oral Nitrofurantoin, full recovery. Neutropenia resolved with decreasing AZA dose
37/F, Kidney transplant	1.44	MNa; started MNa and tacrolimus after renal transplant (3 months before neutropenia)	BK Virus viremia, PCR positive	Persistent Viremia, started 3 months before*	Medication (MNa)	Outpatient management, chronic transplant rejection. On filgrastim. Neutropenia resolved with holding MNa for 2 weeks,

Abbreviations: absolute neutrophil count, ANC; Diabetes Mellitus, DM; Hydroxychloroquine, HCQ; Methotrexate, MTX; Mycophenolate sodium, MNa; Chronic Kidney Disease, CKD; Polymerase Chain Reaction, PCR; Positron Emission Tomography, PET; Mycophenolate Mofetil, Immunosuppression, IS; MMF; Leflunomide, LEF; Azathioprine, AZA.
#CBC was obtained after the onset of infection
*Bloodwork obtained at the onset of the infectious episode demonstrated normal or elevated ANC

respectively. Neutropenia was managed by escalating immunosuppression in 44 (32%) SLE-related episodes and agent reduction or discontinuation in 20 (91%) medication-related episodes. Filgrastim was used once.

Infections occurred during 15 episodes (9%), including 5 bacterial, 5 viral, and 5 of unknown etiology, each in a different patient (Table 3). No fungal infections were observed. The most frequent site was the urinary tract (n=5, 33%). Infections occurred during SLE-related (4, 27%) or medication-related (4, 27%) neutropenia in 8 episodes (53%), and preceded neutropenia in 7 (47%). Seven infections required hospitalization: 2 with medication-related neutropenia and 5 with infection-related neutropenia. All infections resolved except one case of chronic BK viremia, which preceded the neutropenia episode; no infection-related deaths occurred.

Conclusion: Neutropenia affected over one-third of patients with SLE and was frequently recurrent or prolonged. Most episodes were attributed to active SLE and a minority to medications or infections. Infections during neutropenia were infrequent, generally mild, and often preceded neutropenia, suggesting a reactive process. These findings highlight the heterogeneity of neutropenia in SLE. Clinical context should guide management, and further studies are needed to clarify the clinical significance of neutropenia in SLE and distinguish it from neutropenia in other immunocompromised states.

Abstract Number: 0610

The Role of Active Nephritis, Compared to Active Non-Renal SLE, in Pregnancy Outcomes

Emma Trachman[1], Amanda Eudy[2] and Megan Clowse[3], [1]Duke University, Durham, NC, [2]Duke University, Raleigh, NC, [3]Duke University, Chapel Hill, NC

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: The ACR recommends against pregnancy in patients with SLE with high disease activity. These recommendations do not distinguish between the various manifestations of active SLE. While existing research highlights the poor outcomes associated with active LN during pregnancy, comparative data on pregnancy outcomes in patients with active non-renal SLE remain limited. This study aimed to evaluate pregnancy outcomes across different SLE disease manifestations. Given the pregnancy-related morbidity and mortality associated with social determinants of health in the U.S., this study also assessed and adjusted for characteristics of social disadvantage.

Table 1. Patient Demographics and SLE Activity During Pregnancy

	Overall	Inactive SLE	Non-renal Active SLE	Active LN	p-value (across all 3 groups)
	N=114	n=71	n=26	n=17	
Patient Demographics

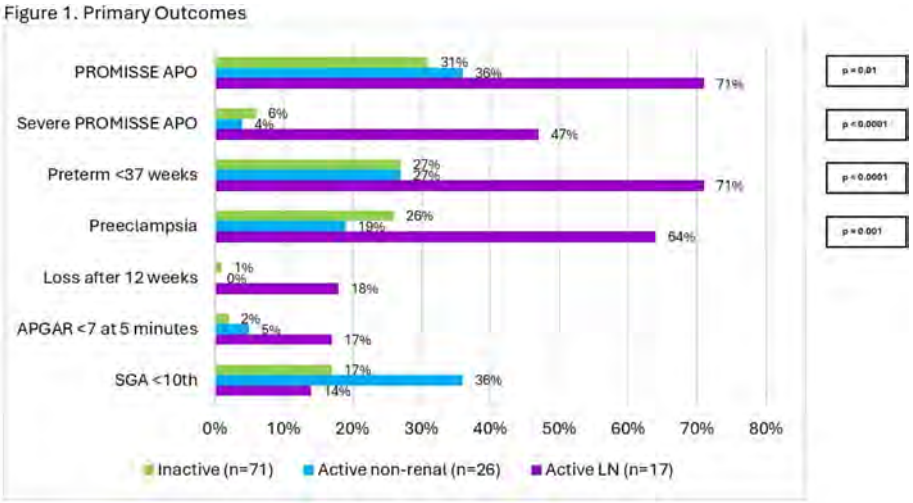
Active LN	-4.37 (-6.08, -2.67)
Black Race	-0.84 (-1.95, 0.26)
Social Disadvantage	1.11 (-0.10, 2.33)

Methods: We analyzed pregnancies from prospective pregnancy registries at a U.S. center. Disease activity was assessed using the Physician's Global Assessment (PGA) and the SLE Pregnancy Disease Activity Index (SLEPDAI). Patients were categorized into 3 groups: inactive SLE (PGA < 1.5 and SLEDAI < 6 throughout pregnancy, no renal activity), active non-renal SLE (PGA ≥1.5 in pregnancy or SLEDAI ≥6, no renal activity), and active LN (active nephritis during pregnancy). Primary outcomes included PROMISSE adverse pregnancy outcomes (APOs), severe APOs, small for gestational age, preterm birth, preeclampsia, loss after 12 weeks gestations, and APGAR score < 7 at 5 minutes. Race, education, marital status, income, and insurance were also studied. Logistic regression models estimated the association between disease activity group with pregnancy outcomes, adjusting for race and social disadvantage.

23265205, 2025, 59, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Results: We included 114 pregnancies, of which 71 patients had inactive SLE, 26 had active non-renal SLE, and 17 had active LN. Patient demographics and pregnancy outcomes are in Table 1. Nearly all patients were on HCQ (92%) and low dose ASA (87%). At least half of patients in both active SLE groups were also on AZA and prednisone. Half of patients in the LN group had active LN at their initial pregnancy visit.

Active LN was associated with higher rates of APOs, including preeclampsia, preterm birth with delivery 3-5 weeks earlier, and fetal loss, compared to inactive and active non-renal SLE (Fig 1). Despite similar rates of positive dsDNA and hypocomplementemia among patients with LN and those with active non-renal SLE, patients with active non-renal SLE did not experience an increase in APOs relative to the inactive SLE group. The rates of APOs, preterm birth < 37 weeks, and preeclampsia were nearly identical between these groups.

Social disadvantage was most prevalent in the active LN group (93%). In multivariate analysis (Table 2), active LN, but not race or social disadvantage, remained an independent predictor of severe APOs.

Conclusion: Active LN, but not active non-renal SLE, is a strong predictor of adverse pregnancy outcomes. While social disadvantage is associated with active LN in pregnancy, it is not an independent risk factor for adverse pregnancy outcomes. Importantly, non-renal SLE activity may not require delaying pregnancy, even in the presence of serologic activity. Our findings emphasize the need for a dual-pronged approach: prevention of pregnancy in patients with active LN and optimized management for those who conceive with active disease.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Venous thromboembolism (VTE) is a known complication of systemic lupus erythematosus (SLE), yet there is a lack of high-quality studies specifically focused on lupus nephritis (LN). This study aimed to assess the frequency of VTE in patients with LN and identify risk factors for its development.

Methods: We included patients with biopsy-proven LN from a prospective observational cohort followed between 1970 and 2024. The primary outcome, VTE occurring after the onset of LN, was monitored longitudinally, and the time to the first event was calculated. Time-dependent univariable and multivariable cause-specific Cox proportional hazards models were used to identify factors associated with the first VTE, with death considered a competing risk.

Results: A total of 324 patients were included in the study, with a mean age of 34.2 years [IQR, 25.9, 43.0] at baseline **(Table 1)**. The cohort was predominantly female (279 patients, 86.1%) and the majority of patients identified as White (184 patients, 57%). Over a long-term follow-up period of 9.9 years [IQR: 5.0–16.4], 30 patients (9.3%) developed at least one VTE, with a median time to the first event from LN onset of 4.3 years [IQR, 0.1, 14.1] **(Figure 1)**. Most events were

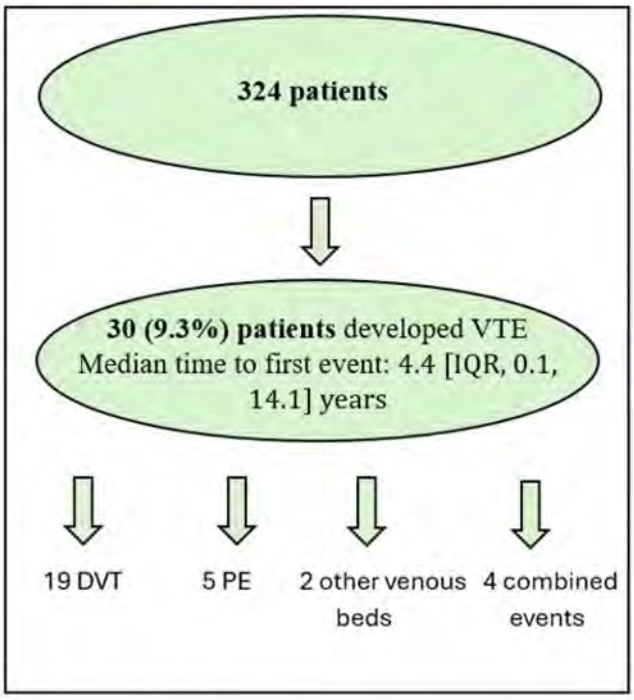

Figure 1. A flowchart depicting the frequency of venous thromboembolic events in our cohort and the involved venous beds.

DVT, deep vein thrombosis; PE, pulmonary embolism

isolated (86.7%), including 19 deep vein thromboses (DVTs, 59.4%), 5 pulmonary embolisms (PEs), and 2 events involving other venous beds.

In the multivariable model, the following factors were independently associated with the development of VTE: the SLEDAI-2K score (HR = 1.05, 95% CI: 1.01–1.10) and proteinuria level (HR = 1.26, 95% CI: 1.08–1.47) **(Table 2)**.

Conclusion: VTE can complicate the course of LN at any stage, mostly manifesting as DVT and PE. Disease activity and proteinuria are the primary risk factors for its development.

Table 2. Time-dependent univariable and multivariable cause-specific Cox proportional hazard models for factors associated with VTE in our cohort[a].

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Antimalarials, particularly hydroxychloroquine, are a cornerstone of systemic lupus erythematosus (SLE) management, with well-established benefits including reduced disease activity, prevention of flares, and mitigation of long-term organ damage. We aimed to assess whether antimalarial use is associated with a decreased risk of developing incident lupus nephritis (LN) among patients with SLE.

Table 1: Baseline Characteristics at Clinic Entry.

Characteristic	Total (n = 674)	Never developed Proteinuria (n = 520)	Developed Proteinuria (n = 154)
Age, years (median [IQR])	33.6 [24.9–45.4]	34.4 [25.3–46.4]	30.8 [23.5–41.3]
Sex, Female (%)	598 (88.7%)	465 (89.4%)	133 (86.4%)
Race (%)			
Black	74 (11.2%)	51 (10.0%)	23 (15.1%)
Chinese	47 (7.1%)	38 (7.5%)	9 (5.9%)

Table 2. Multivariable Cox Regression Analysis of Factors Associated with the Development of Lupus Nephritis in Patients with SLE

Variable	HR (95% CI)*	p-value
Cumulative duration of antimalarial exposure in years (1-unit increase)	0.96 (0.92–1.00)	0.08
Age in years (1-unit increase)	1.00 (0.99–1.02)	0.70
Sex (female sex as a reference)	1.57 (0.91–2.69)	0.10
Race (Black as a reference)	0.85 (0.52–1.39)	0.52
SLE disease duration in years (10-unit increase)	0.64 (0.58–0.71)	**<0.01**
Low C3	1.31 (0.85–2.01)	0.22
Low C4	0.71 (0.47–1.10)	0.12
Anti-dsDNA	1.41 (0.96–2.09)	0.08
SLEDAI-2K score (1-unit increase)	1.23 (1.19–1.26)	**<0.01**
Glucocorticoid use	1.53 (0.99–2.34)	0.053
Immunosuppressive use	1.04 (0.70–1.55)	0.84

HR = Hazard Ratio; CI = Confidence Interval; SLE = Systemic Lupus Erythematosus; C3 = Complement component 3; C4 = Complement component 4; anti-dsDNA = Anti–double-stranded DNA antibody; SLEDAI-2K = Systemic Lupus Erythematosus Disease Activity Index 2000
*Adjusted for calendar time (pre-2005 vs. 2005 and onward), reflecting the introduction of mycophenolate mofetil into routine care within the cohort.

Methods: We included SLE patients from an inception cohort without prior diagnosis of LN, followed prospectively at regular intervals. The association between antimalarial exposure (measured as cumulative duration in years) and the development of LN (defined by new-onset proteinuria as per SLE Disease Activity Index 2000 [SLEDAI-2K]) was evaluated using a time-dependent univariable Cox proportional hazards model to estimate the overall effect. A time-dependent multivariable Cox regression model adjusted for clinically relevant covariates was also employed to estimate the risk of LN in the full cohort and, in a sensitivity analysis, among patients with serologically active disease. Death was treated as a competing risk.

Results: A total of 674 inception SLE patients were included, with a median baseline age of 33.6 years [IQR: 24.9, 45.4] **(Table 1)**. Over 6,961.5 patient-years of follow-up, 154 patients (22.8%) developed new-onset SLE-related proteinuria, indicating LN, yielding an incidence rate of 2.2 cases per 100 person-years. The median time to LN onset was 3.6 years [IQR: 0.9–8.8]. Cumulative antimalarial exposure was not significantly associated with reduced LN risk, in either the univariable analysis (HR: 0.98; 95% CI: 0.94–1.02, p=0.25) or the adjusted multivariable model (HR: 0.96; 95% CI: 0.92–1.00, p=0.08) **(Table 2)**. Similar results were observed in the sensitivity analysis restricted to patients who presented with serologically active disease (HR: 0.95; 95% CI: 0.89–1.01, p=0.12) **(Table 3)**. Notably, shorter SLE duration (HR: 0.64; 95% CI: 0.58–0.71 per 10-year increase) and higher SLEDAI-2K scores (HR: 1.23; 95% CI: 1.19–1.26) were significantly associated with increased risk of LN **(Table 2)**. This association persisted in patients with serologically active disease, along with glucocorticoid use **(Table 3)**, likely reflecting confounding by indication.

Table 3. Multivariable Cox Regression Analysis of Factors Associated with the Development of Lupus Nephritis in Patients presenting with serologically active disease

Variable	HR (95% CI)*	p-value
Cumulative duration of antimalarial exposure in years (1-unit increase)	0.95 (0.89–1.01)	0.12
Age in years (1-unit increase)	1.00 (0.98–1.02)	0.98
Sex (female sex as a reference)	1.43 (0.75–2.73)	0.28
Race (Black as a reference)	1.20 (0.62–2.32)	0.58
SLE disease duration in years (10-unit increase)	0.63 (0.55–0.72)	**<0.01**
Low C3	1.19 (0.69–2.04)	0.54
Low C4	0.64 (0.39–1.07)	0.09
Anti-dsDNA	1.30 (0.70–2.44)	0.41
SLEDAI-2K score (1-unit increase)	1.21 (1.17–1.26)	**<0.01**
Glucocorticoid use	2.71 (1.47–4.99)	**<0.01**
Immunosuppressive use	0.97 (0.60–1.57)	0.92

HR = Hazard Ratio; CI = Confidence Interval; SLE = Systemic Lupus Erythematosus; C3 = Complement component 3; C4 = Complement component 4; anti-dsDNA = Anti–double-stranded DNA antibody; SLEDAI-2K = Systemic Lupus Erythematosus Disease Activity Index 2000
*Adjusted for calendar time (pre-2005 vs. 2005 and onward), reflecting the introduction of mycophenolate mofetil into routine care within the cohort.

Conclusion: In this inception cohort-based study, antimalarial use was not significantly associated with a reduced risk of incident LN. These findings should be interpreted within the context of the study's specific objective and are not intended to challenge the well-established role of antimalarials in the management of SLE or their recognized clinical benefits. Further studies with larger sample sizes are needed to confirm our results.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Baseline kidney biopsy is the gold standard for diagnosing incident lupus nephritis (LN). However, in certain cases, obtaining a biopsy may not be feasible due to medical, technical, or patient-specific factors, resulting in a clinical diagnosis of LN. We aimed to evaluate differences in outcomes between biopsy-confirmed and clinically diagnosed LN cases to provide guidance in scenarios where a biopsy cannot be obtained.

Methods: This retrospective study included inception SLE patients from an observational cohort (2000–2024) who developed incident LN. Patient inclusion began in 2000 to reflect treatment changes associated with the introduction of mycophenolate mofetil. The outcomes assessed were: (1) complete proteinuria recovery (CPR) (< 0.5 g/g) at one year; (2) progression to end-stage kidney disease (ESKD), defined as eGFR < 15 mL/min/1.73 m^2, dialysis, or kidney transplantation, or a sustained ≥30% eGFR decline; and (3) a composite adverse outcome, including infection, hospitalization, or death. Time-to-event outcomes were evaluated using Kaplan-Meier (KM) survival curves. Comparisons between biopsy-confirmed and clinically diagnosed LN groups were assessed using Fine-Gray subdistribution hazard models, treating death as a competing risk for the first two outcomes. The models were adjusted for proteinuria as a potential confounder, as well as for imbalanced variables known to clinically impact the outcomes.

Results: 127 patients were included: 84 (66.1%) with biopsy-confirmed LN and 43 (33.9%) with clinically diagnosed LN). Baseline characteristics are summarized in **Table 1**. Baseline differences were observed in age, proteinuria and albumin levels, SLEDAI-2K, and SLICC/ACR damage index (SDI). Outcomes are summarized in **Table 2**, and KM curves are provided in **Figures 1A-C**.

Antimalarial use, n (%)	97 (76.4)	36 (83.7)	61 (72.6)	0.24
ACEi or ARB use during first year, n (%)	86 (67.7)	28 (65.1)	58 (69.0)	0.80

Abbreviations: LN, lupus nephritis; SLE, systemic lupus erythematosus; IQR, interquartile range; eGFR, estimated glomerular filtration rate; dsDNA, double-stranded DNA; SLEDAI-2K, Systemic Lupus Erythematosus Disease Activity Index 2000; SDI, SLICC/ACR Damage Index; NA, Not Applicable; NIH, National Institutes of Health; ACEi, angiotensin-converting enzyme inhibitor; ARB, angiotensin receptor blocker

Statistically significant p-values are in bold (p < 0.05). Biopsy class and NIH indices only available for patients who underwent kidney biopsy.

*The 5-year cumulative glucocorticoid dose was not significantly different between patients who underwent a kidney biopsy (median 125.1 mg [IQR: 75.8, 212.5]) and those who did not (median 111.0 mg [IQR: 73.0, 148.8]; p = 0.07).

< - **CPR at 1 Year:** Achieved in 58.4% of patients, with no significant differences between groups in rate (p=0.36) and time to event (p=0.81). Adjusted models indicated comparable risk (HR 1.19, 95% CI: 0.76–1.84).

< - **ESKD or ≥30% Decline in eGFR:** Occurred in 22.4% of patients, with no significant differences between groups in rate (p=0.39), time to event (p=0.66), or risk (HR 1.11, 95% CI: 0.46–2.69).

Table 2. Outcomes of patients with clinically diagnosed and biopsy-confirmed lupus nephritis.

	Overall (n=127)	Clinically Diagnosed (n=43)	Biopsy-confirmed (n=84)	p-value
Outcomes				
Complete proteinuria recovery at 1 year, n (%)	73 (58.4)	28 (65.1)	45 (54.9)	0.36
Time to CPR, years, Median [IQR]	0.8 [0.3, 2.2]	0.9 [0.3, 1.7]	0.8 [0.5, 2.3]	0.81
ESKD or sustained[a] ≥30% decline in eGFR, n (%)	28 (22.4)	7 (16.7)	21 (25.3)	0.39
Time to ESKD or ≥30% eGFR decline, years	5.9 [2.2, 9.9]	3.4 [1.4, 7.2]	7.1 [3.9, 10.0]	0.66
Infection, hospitalization, or death, n (%)	70 (55.1)	19 (44.2)	51 (60.7)	0.11
Time to infection, hospitalization, or death, years	2.7 [0.8, 5.8]	1.6 [0.6, 4.0]	3.22 [0.8, 7.2]	0.60

Abbreviations: CPR, complete proteinuria recovery; ESKD, end-stage kidney disease; eGFR, estimated glomerular filtration rate; IQR, interquartile range

[a]Observed over at least two consecutive visits

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

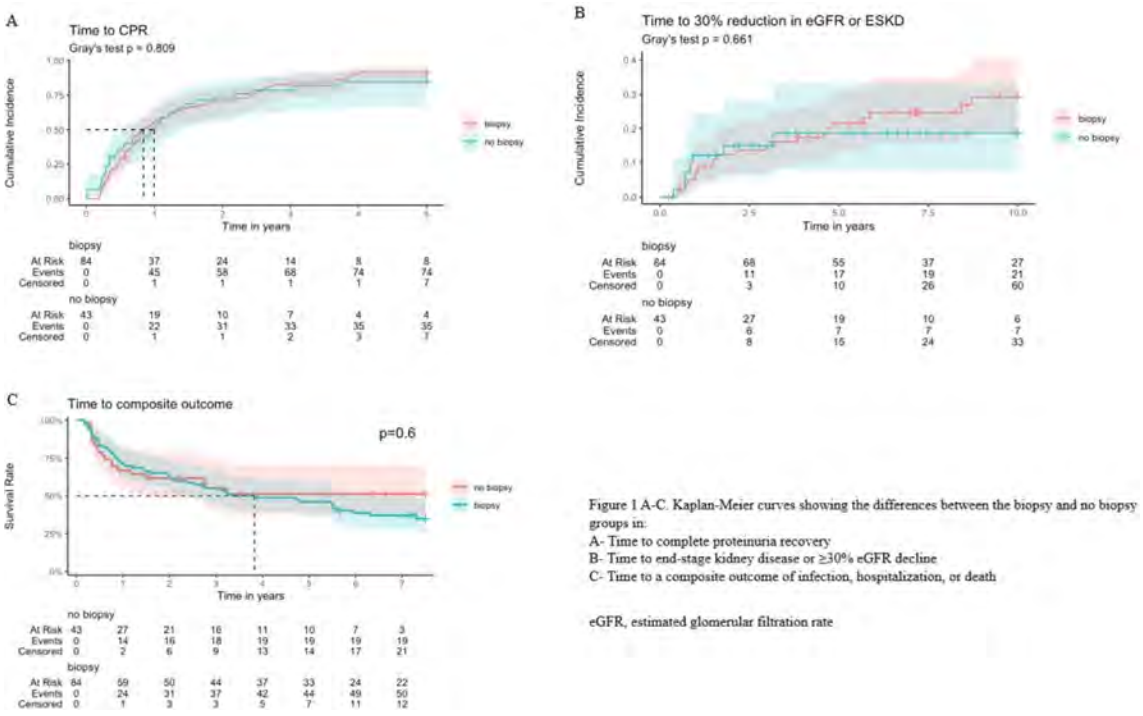

Figure 1 A-C. Kaplan-Meier curves showing the differences between the biopsy and no biopsy groups in:
A- Time to complete proteinuria recovery
B- Time to end-stage kidney disease or ≥30% eGFR decline
C- Time to a composite outcome of infection, hospitalization, or death

eGFR, estimated glomerular filtration rate

< - **Composite Outcome:** Occurred in 55.1% of the cohort, with no significant differences between groups in rate (p = 0.11), time to event (p = 0.60), or risk (HR 0.99, 95% CI: 0.56–1.74).

Conclusion: Clinically diagnosed incident LN, when treated according to standard-of-care protocols, shows comparable outcomes to biopsy-confirmed LN. While these findings may provide some reassurance, they apply specifically to cases where a baseline biopsy is not feasible and should not be interpreted as a challenge to current diagnostic standards.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease associated with an elevated risk of cardiovascular (CV) disease, largely due to chronic inflammation and its contribution to atherogenesis. The Pathobiological Determinants of Atherosclerosis in Youth (PDAY) score estimates the probability of advanced coronary artery atherosclerosis using eight factors: age, sex, cholesterol levels, smoking status, blood pressure, presence of obesity, and hyperglycemia. The PREVENT (Predicting Risk of Cardiovascular Disease Events) calculator estimates 10- and 30-year risks for atherosclerotic cardiovascular disease (ASCVD) and heart failure. Both tools are designed for younger populations, making them potentially applicable to patients with SLE, who are at risk of developing premature ASCVD. However, the utility of these new scores in this population remains underexplored. Therefore, the objective was to evaluate the correlation between carotid intima-media thickness (cIMT) and CV risk as estimated by the PDAY and PREVENT tools in patients with SLE.

Methods: A cross-sectional study was conducted including SLE patients aged ≥15 years who met the 2019 ACR/EULAR classification criteria. Patients with established cardiovascular disease, overlap syndromes, or current pregnancy were excluded. Carotid ultrasound was used to assess cIMT via B-mode ultrasonography. PDAY scores and PREVENT 10- and 30-year ASCVD risk estimates were calculated for all participants. The Kolmogorov–Smirnov test assessed data normality. Spearman's correlation coefficients (rs) were calculated to assess associations between PDAY/PREVENT scores and left/right cIMT values. A p-value ≤0.05 was considered statistically significant.

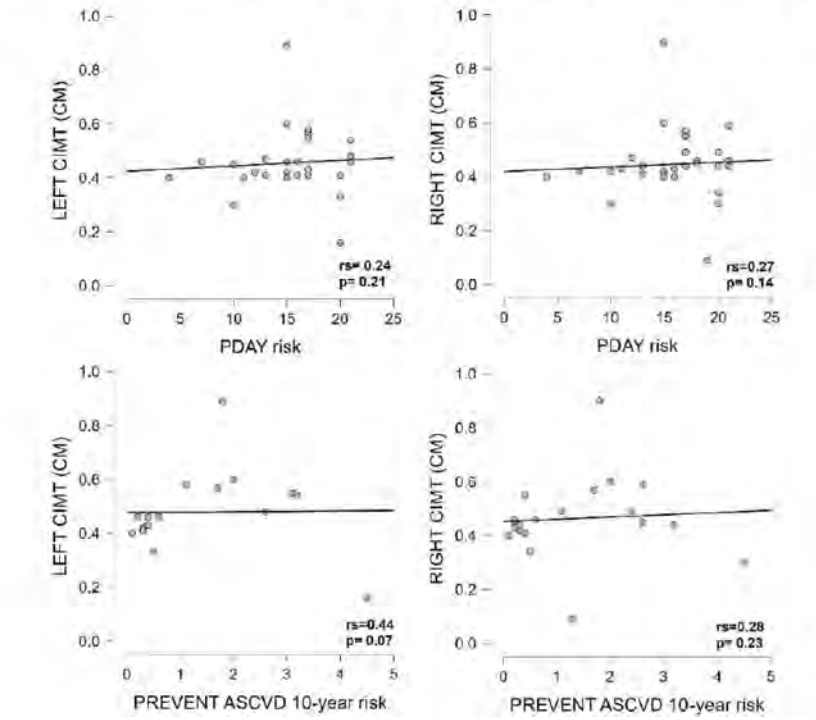
Results: Thirty-five SLE patients were included (mean age 39.6 ± 13.6 years; 94.2% female). Clinical and disease characteristics are detailed in Table 1. The mean SLEDAI score was 10.1, indicating moderate disease activity. The median PDAY score was 15. The mean 10- and 30-year ASCVD risks estimated by PREVENT were 1.4% and 6.9%, respectively. Mean

Table 1. Demographic, clinical, and disease characteristics.

	SLE patients (n=35)
Age (years), mean ± SD	39.6 ± 13.6
Women, n (%)	33 (94.2)
Disease duration (years), mean ± SD	7.6 ± 6.6
Non-HDL cholesterol (mg/dL), mean ± SD	93 ± 46.22
HDL cholesterol, (mg/dL), mean ± SD	50.2 ± 15.2
Smoking, n (%)	2.0 (5.88)
Hypertension, n (%)	12 (35.2)
Obesity, n (%)	8.0 (23.5)
HbA1c, mean ± SD	5.45 ± 0.8
HCQ, n (%)	32 (94.1)
Glucocorticoids, n (%)	25 (73.5)
SLEDAI-2K (points), mean ± SD	10.1 ± 6.8
PDAY risk, median, (IQR)	15 (10-18)
PREVENT ASCDV 10-year risk, mean ± SD	1.4 ± 1.2
PREVENT ASCVD 30-year risk, mean ± SD	6.9 ± 5.5
Left cIMT (cm), mean ± SD	0.45 ± 0.16
Right cIMT (cm), mean ± SD	0.44 ± 0.12

SD, standard deviation; IQR, interquartile range; SLE, systemic lupus erythematosus, HDL, high-density lipoprotein; HbA1c, glycated hemoglobin; HCQ, hydroxychloroquine; SLEDAI-2K, Systemic Lupus Erythematosus Disease Activity Index 2000; PDAY, Pathobiological Determinants of Atherosclerosis in Youth; PREVENT, Predicting Risk of Cardiovascular Disease Events; ASCVD, atherosclerotic cardiovascular disease; cIMT, carotid intima-media thickness.

Figure 1. Correlations between CV risk estimations and cIMT in SLE patients.



cIMT measurements were within normal limits: 0.45 cm (left) and 0.44 cm (right). No significant correlations were found between cIMT and either PDAY or PREVENT risk estimates (Figure 1).

Conclusion: This study found no significant association between subclinical atherosclerosis, as measured by cIMT, and cardiovascular risk predictions using the PDAY or PREVENT tools in patients with SLE. These findings highlight the limitations of conventional risk calculators in this population and support the incorporation of direct vascular imaging—such as carotid ultrasound—into routine cardiovascular risk assessment for SLE patients, given their predisposition to early, subclinical atherosclerotic CV disease.

Background/Purpose: It has been observed that systemic lupus erythematosus (SLE) activity often goes into remission in patients with end-stage kidney disease (ESKD) on dialysis or after a kidney transplant, although the exact mechanism remains elusive. Greater than a quarter of these patients can experience an SLE flare, with patients on dialysis having higher flare rates compared to transplant recipients. This study aims to characterize and identify the clinical phenotypes and risk factors of patients with SLE who continue to flare on dialysis or after transplant. Furthermore, this study analyzes flare manifestations and timing of flares from initial SLE diagnosis, as well as the impact of medications, dialysis modality, and transplant on SLE activity.

Methods: A single-center retrospective chart review was performed using the inclusion criteria of patients 18 years and older diagnosed with SLE who have ESKD on dialysis or after transplant, with records searched between 2015 and 2022. The proportion of patients who met the ACR classification criteria for SLE was 100%. SLE flare was defined as increased disease activity requiring a change in management and flare confirmation by a rheumatologist or nephrologist. For included patients, demographics, clinical phenotypes, and medical characteristics were recorded and analyzed between flare and no-flare groups.

Results: A total of 144 patients with SLE were included; there was a mean age of 48.5 years, 86.8% female, and 60.4% African American (Table 1). Lupus flare occurred in 20.8% of the study population. Flare rates were similar in patients on PD and HD, although this was not statistically significant (Table 1; p = 0.47). Of the patients who experienced a flare, 43.3% occurred within one year of dialysis initiation or after transplant. The most common flare manifestations included hematologic (66.7%), hypocomplementemia (56.7%), and kidney involvement (46.7%) (Figure 1). Mortality rates were similar in the flare group (31.6%) and no-flare group (30.0%). Lastly, patients in the flare group had lower rates of calcineurin inhibitor use (16.7%)

Characteristic	Total n = 144	Flare n = 30	No Flare n = 114	P-value
Demographic variables				
Age, mean, years	48.5	44.5	49.5	0.110[2]
Female sex, %	86.8	96.7	84.2	0.125[2]

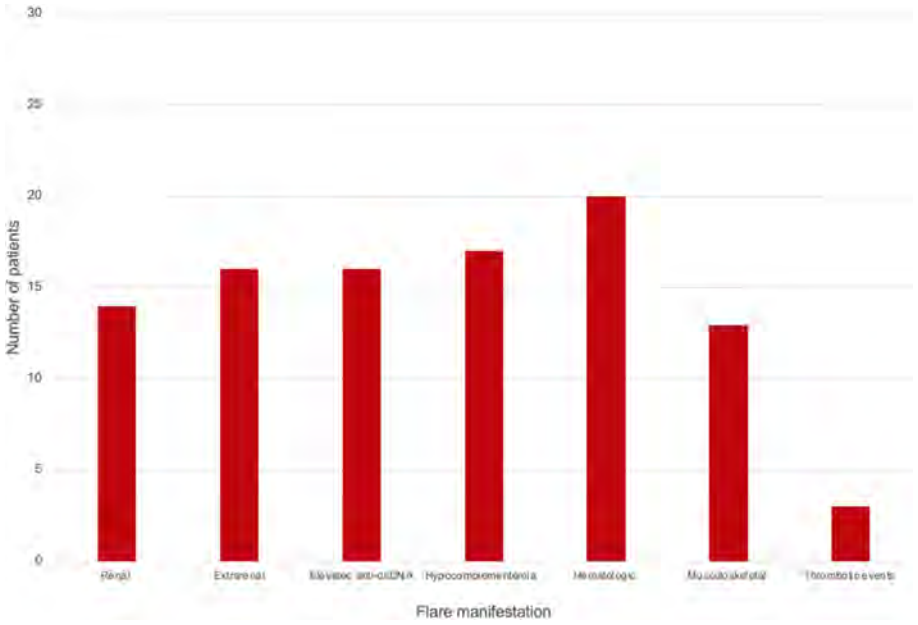
[2] Fisher Exact p-value
Missing data: cDMARD, *n* = 1; dialysis modality, *n* = 2; SLE diagnosis to dialysis or transplant, *n* = 7

Demographic and clinical differences in patients with ESKD secondary to SLE on dialysis or after transplant in flare and no-flare groups



Flare manifestations in patients with ESKD secondary to SLE on dialysis or after transplant

than the no-flare group (29.8%) (Table 1; p = 0.17). The use of immunosuppression agents, including prednisone, cDMARDs, and hydroxychloroquine, was similar between the groups.

Conclusion: Greater than 20% of patients experience an SLE flare while on renal replacement therapy or after transplant. Common manifestations include hematologic abnormalities, hypocomplementemia, and kidney involvement. Only about half of the flare group had elevated anti-dsDNA or hypocomplementemia, and providers must look beyond the numbers during diagnosis. Lastly, flares frequently occur within the first year, therefore, patients should be monitored closely after dialysis initiation or transplantation.

Background/Purpose: Neuropsychiatric manifestations of systemic lupus erythematosus (SLE) are common and frequently represent a diagnostic challenge due to its heterogeneous manifestations. Neurofilament light chain (NfL) is a marker of axonal neuronal damage that has been investigated in neurological conditions such as multiple sclerosis, stroke, and dementia. This study aims to evaluate the serum levels of NfL in SLE patients and their association with neuropsychiatric manifestations. Secondary objectives included assessing the association of NfL levels with cognitive dysfunction (CD), and cumulative damage over a longitudinal follow-up.

Methods: A longitudinal study was conducted including 66 patients that met the SLICC/ACR 2019 criteria for SLE. NPSLE was defined according to the SLICC A and B models. Demographic and clinical data including laboratory tests, SLICC/ACR Damage Index (SDI), treatment, and presence of comorbidities were collected. Baseline serum NfL levels were measured using the Single Molecule Array (SiMoA) technique. Cognitive function was assessed through a comprehensive neuropsychological battery. After a mean follow-up of 7.46 ± 1.34 years, 48 patients were re-evaluated for disease activity, damage, and cognitive status. The best cutoff of NfL levels for the detection of NPSLE and CD was evaluated using ROC curve analysis. Univariate and multivariate analysis was used to identify risk factors associated with NPSLE and CD.

Table 2. Predictors of NPSLE and Cognitive Dysfunction in SLE Patients

	Univariate Analysis Predictors (OR [IC95%])	Multivariate Analysis Predictors (OR [IC95%])
NPSLE SLICC A	Nfl>10.54pg/ml (9.25 [2.82 - 30.29], p<0.001) Age (0.94 [0.89 - 0.99], p= 0.037) Anti-Ncs (5.60 [1.24 - 22.25], p=0.025) Renal Involvement (0.25 [0.08 - 0.75], p= 0.013) IVIG (10.46 [2.95 - 37.09], p<0,001)	Nfl>10.54pg/ml (22.94 [2.91 - 180.45], p=0.003) Age (0.90 [0.82 - 0.99] , p= 0.040) Anti-NCs (3.09 [0.38 - 25.31], p= 0.293) Renal involvement (0.25 [0.05 - 1.27], p= 0.095) IVIG (10.46 [2.95 - 37.09], p<0.001)
NPSLE SLICC B	Nfl>10.54pg/ml (5.95 [1.84 - 19.19], p=0.003) Hypertension (0.27 [0.08 - 0.82], p=0.021) Renal involvement (0.18 [0.06 - 0.53], p= 0.002) IVIG (10.46 [2.95 - 37.09], p<0.001)	Nfl>10.54pg/ml (11.28 [2.52 - 50.48], p=0.002) Hypertension (1.24 [0.23 - 6.78], p=0.805) Renal involvement (0.29 [0.07 - 1.25], p=0.290) IVIG (11.64 [2.42 - 56.11], p=0.005)
Moderate to Severe Cognitive Dysfunction	Nfl>10.54pg/ml (3.75 [1.20 - 11.68], p=0.023) NPSLE (4.40 [1.39 - 13.96], p=0.012) Diabetes Mellitus (4.68 [0.06 - 0.53], p= 0.002) IVIG (3.33 [1.06 - 10.43], p=0.039) Educational level (0.86 [0.72 - 1.03], p=0.102)	Nfl>10.54pg/ml (5.17 [1.06 - 25.10], p=0.041) NPSLE (1.74 [0.34 - 8.98, p=0.508) Diabetes Mellitus (4.80 [1.10 - 20.99], p= 0.037) IVIG (1.55 [0.35 - 6.91], p=0.560) Educational Level (0.77 [0.59 - 0.99], p=0.041)

SLE: Systemic lupus erythematosus, NPSLE: Neuropsychiatric systemic lupus erythematosus, Nfl:Neurofilament light chain, Ncs: Nucleosomo, IVIG :intravenous immunoglobulin

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: The mean age of the 66 SLE patients was 38.10 ± 10.55 years. According to SLICC A model 21 patients had NPSLE and 45 had not; according to SLICC B model 33 patients had NPSLE and 33 had not. Eighteen (27,3%) patients had moderate to severe CD. Patients with NPSLE according to SLICC A had significantly higher NfL levels than non-NPSLE patients (12.90 ± 6.32 vs. 8.08 ± 3.66 pg/mL; p = 0.001). Patients with focal central nervous system (CNS) involvement exhibited higher NfL levels compared to those with diffuse CNS involvement and non-NPSLE patients (Figure 1). NfL showed good accuracy in identifying NPSLE (SLICC A) (AUC = 0.766; 95% CI: 0.631–0.900; p = 0.001) (Table 1). By multivariate analysis, NPSLE per SLICC A and SLICC B were significantly associated with NfL levels >10.54 pg/mL (OR = 22.94, 95% CI: 2.91-180.45; OR = 11.28, 95% CI: 2.52–50.48, respectively) and treatment with immunoglobulin (OR = 10.46, 95% CI: 2.95-37.09; OR = 11.64, 95% CI: 2.42-56.11, respectively). Moreover, NPSLE (SLICC A) was significantly associated with lower age (OR = 0.90, 95% CI 0.82-0.99). CD was independently associated with NfL >10.54 pg/mL (OR = 5.17; 95% CI: 1.06-25,10), diabetes mellitus (OR = 4.80; 95% CI: 1.10-20.99) and lower education level (OR=0.77; IC 95% 0.59-0.99) (Table 2). At follow-up, patients remained cognitively stable and baseline NfL levels were not predictive of worsening of CD and cumulative damage over time. The presence of anti-RNP antibodies was independently associated with mild CD at follow-up (OR = 4.46, 95% CI 1.09–18.30, p = 0.038).

Conclusion: Serum NfL is a promising biomarker for identifying NPSLE and CD in patients with SLE. Although baseline NfL did not predict cognitive decline over time, its association with NPSLE and CD supports its role in disease stratification.

Abstract Number: 0617

Autoantibodies to Extracellular Antigens in Lupus Patients Serum Versus Controls; Predominance of Autoantibodies to Type I Interferons in Lupus Sera

Kathryn Counts[1], Dulaney Wilson[2], Leon Furchtgott[3] and Gary Gilkeson[1], [1]Medical University of South Carolina, Charleston, SC, [2]Medical University of South Carolina, Charleston, [3]SeraNova Bio, Boston, MA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Key features in the pathophysiology of SLE include cytokine dysregulation and autoantibody production. Traditional autoantibody testing in SLE is primarily limited to intracellular antigens best represented by the ANA and ENA. A novel technique, Rapid Extracellular Antigen Profiling (REAP), enables detection of autoantibodies to extracellular antigens in their 3D conformation via expression in a yeast library. This study investigates the presence of autoantibodies (AAbs) to over 1500 extracellular antigens, including 11 Type A IFNs in longitudinal serum samples from SLE patients and controls.

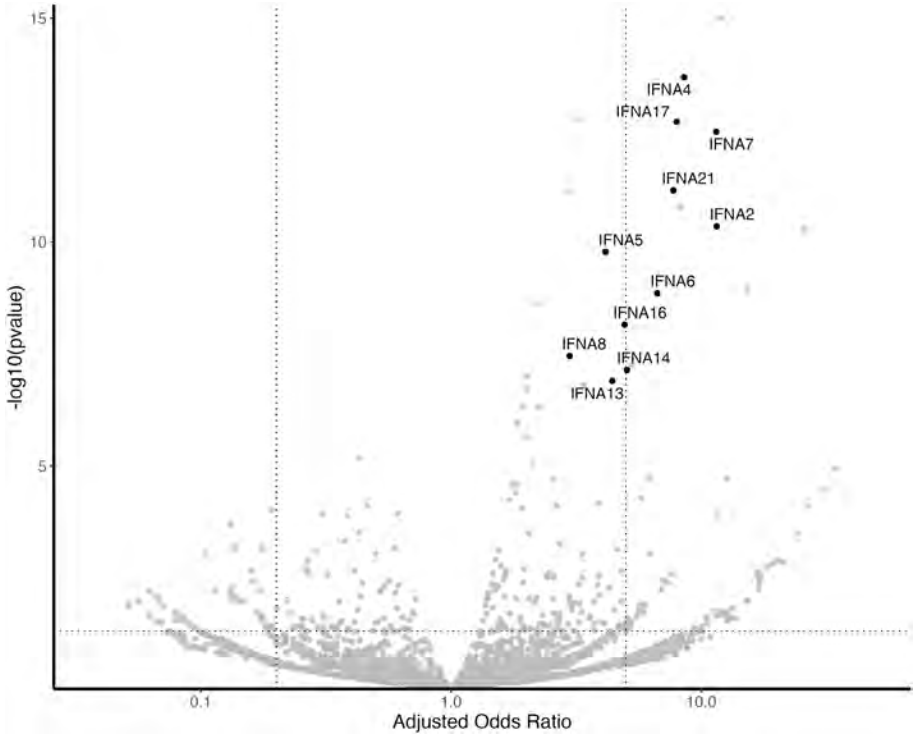
Methods: Serum Abs were quantified through the REAP assay on over 4000 individual samples from 635 SLE patients, 485 healthy controls and 186 unaffected family members. REAP score reproducibility was assessed by running samples in duplicate, with a resulting high REAP score correlation (median correlation 0.87). Results are a readout of increased

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

antibody binding to an antigen on a scale of 0-4, with higher scores indicating increased binding. Reactivity of the REAP assay was confirmed by ELISA for specific antigens.

Results: Lupus patient sera had increased numbers of AAbs to extracellular antigens compared to controls. Black SLE patients had increased extracellular AAbs compared to White patients. AAbs were persistent and the number trended to increase over time in sera from SLE patients. There was correlation of AAbs in SLE patients vs first degree relatives. As shown in the volcano plot in Figure 1, there was a markedly higher prevalence of Type I IFN AAbs in SLE sera vs controls and healthy family member sera (36% vs 13%; p= $4.2x10^{-6}$). The IFN library included 11 distinct Type I IFNs. Among those with SLE who had Type I interferon reactivity, 28% exhibited reactivity to all 11 Type I IFN (Figure 2 and 3). Only 2 controls exhibited reactivity to all 11 Thpe I IFNs Inhibition assays demonstrated no cross-reactivity between the different IFN antigens, indicating that each AAb reactivity is specific to one of the 11 Type I IFN antigens. Surprisingly, presence of Type I IFN AAbs was not found to be associated with the presence of lupus nephritis nor with increased lupus disease activity as measured by SLEDAI. During 2019-2021 there was an increase in Type I IFN AAbs in control sera but not in the lupus cohort, possibly reflecting COVID vaccination or COVID infection. We are currently testing the sera and controls with or without Type I IFN AAbs for inhibitory activity against Type I IFNs and whether there is a correlation between Type I IFN inhibition with disease activity.

Conclusion: Our study demonstrates a significantly higher prevalence of autoantibodies to extracellular antigens in lupus sera compared to controls. There was a highly significant correlation of type I IFN AAbs in serum of patients with SLE compared to healthy controls. The presence of Type I IFN AAbs overall was not associated with LN or overall disease activity. Further characterization of neutralizing AAbs may yield additional insight into their disease pathogenesis. Further analysis of correlations of lupus manifestations, chronic damage and disease activity is in progress.



This analysis identifies AAbs associated with SLE compared to healthy controls and unaffected family members, adjusting for age, sex, race. 635 patients with SLE; 485 controls and unaffected family members. Firth (penalized) logistic regression, adjusted for age, sex, race, using baseline sample for each subject. Note significantly higher prevalence of type-I interferon AAbs in patients with SLE. Control antibodies on the left and Lupus antibodies on the right.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Renal involvement is a major prognostic factor in systemic lupus erythematosus. Pure lupus membranous nephropathy (PLMN, class V) represents 5–20% of lupus nephritis cases, with up to 30% progressing to end-stage kidney disease. Unlike proliferative forms, the benefit-risk profile of immunosuppressive therapy in PLMN remains poorly defined. Accordingly, real-world data from unselected patients treated with contemporary therapeutic regimens are critical to delineate response patterns, identify predictors of treatment failure, and establish clinically meaningful therapeutic targets.

Methods: We conducted a nationwide, population-based observational study between 2000 and 2020, involving 25 centers across France (IRB registration: 00012437). Patients experiencing a first flare of PLMN were classified into four treatment groups: (i) supportive care, receiving no immunosuppressive therapy; (ii) mycophenolate mofetil (MMF), treated with MMF combined with low- or high-dose corticosteroids; (iii) rituximab (RTX), treated with RTX and corticosteroids; and (iv) other treatments, receiving immunosuppressive agents excluding MMF and RTX. Renal responses were defined according to the 2024 KDIGO guidelines. Treatment failure was defined as failure to achieve complete or partial response by month 12, occurrence of a relapse, or need for a change in therapeutic class before month 12—excluding initiation of maintenance therapy.

Follow up duration – months median (IQR)	76.0 (41.1 – 117.1)	62.3 (36.1– 97.6)	0.31	80.9 (35.3– 99.4)	38.3 (27.6 – 68.1)	71.2 (45.8 – 101.6)	**0.03**

Abs: antibodies, CRR: Complete renal response, eGFR: estimated glomerular filtration rate, IQR: Interquartile range, LN: Lupus nephritis, n: Number, ORR: Overall renal response, PRR: Partial renal response, UPCR: urine protein creatinine ratio

Results: A total of 194 patients with a first flare of PLMN were analyzed. At the time of PLMN diagnosis, 53 patients (27.3%) received supportive care only, while 141 (72.7%) were treated with at least one immunosuppressive agent. Among them, 54 (38.3%) received a mycophenolate mofetil (MMF)-based regimen, 26 (18.4%) a rituximab (RTX)-based regimen, and 61 (43.2%) other types of immunosuppressive treatment (**Table 1**). Complete renal response (CRR) at 6 and 12 months was achieved in 1/47 (2.1%) and 18/49 (36.7%) patients in the supportive care group, 11/50 (22%) and 31/51 (60.8%) patients treated with MMF, 5/23 (21.7%) and 16/25 (64.0%) patients treated with RTX, and 14/51 (27.4%) and 25/55 (45.4%) patients treated with other regimens, respectively. Treatment with steroids was not associated with treatment response (p = 0.3). Patients treated by RTX had a shorter duration treatment (p< 0.01) and a lower corticosteroids exposure (p=0.02) than patients treated by other regimens (**Figure 1**). Independent risk-factors for treatment failure were the presence of anti-U1RNP antibodies (OR=2.5 [95% CI: 1.35-4.75]) and the absence of extra-renal involvement (OR=0.34 [95% CI: 0.19 – 0.73]) (**Table 2**).

Conclusion: While 22–27% of patients achieve CRR by 6 months, this proportion increased substantially without treatment modification to 45–64% at 12 months, underscoring that premature modification of therapy may be unwarranted in PLMN

Table 2 – Characteristics at baseline associated with renal outcomes in univariable and multivariable analysis.

UNIVARIABLE ANALYSIS						
Variable		**Number of patients**	**Number of treatment failure at 12 months**	**OR**	**95% CI**	**p**
Age (per 1-year increment)		180	73	0.992	0.966 – 1.019	0.548
Sex	Female	157	63	0.871	0.360 – 2.110	0.760
Origin	Afro-Caribbean ancestry	79	33	1.094	0.601 - 1.992	0.769
Previous renal flare	Yes	36	17	1.406	0.674 – 2.933	0.364
Time between lupus and PLMN diagnoses (per 1-year increment)		173	80	0.987	0.946 – 1.030	0.562
CKD-Epi (per 1 ml/min/1/73m² increment)		180	73	0.999	0.989 - 1.009	0.839
Proteinuria (per 1 g/g increment)		176	72	1.175	0.854 – 1.616	0.322
Nephrotic syndrome	Yes	61	27	1.173	0.622 - 2.211	0.621
Proteinuria < 1 g/g	Yes	35	14	0.903	0.448 – 2.030	0.803
Proteinuria ≥ 1 and ≤ 3 g/g	Yes	72	35	0.645	0.347 – 1.199	0.166

Background/Purpose: SLE patients are at increased risk of infections, including herpes zoster (HZ). Prior studies evaluating the recombinant herpes zoster vaccine (RZV) in SLE have been limited by small sample sizes and the absence of control groups. To address these gaps, we conducted a prospective, randomized controlled trial to evaluate the humoral immunogenicity, safety and impact of immunosuppressive therapies on RZV response in a large SLE cohort compared to healthy controls.

Methods: This prospective, randomized, placebo-controlled study enrolled SLE patients randomized 1:1 to receive the RZV (P1 group) or placebo (P2 group) on Day 0 (D0) and Day 42 (D42). Healthy control group (CG) received the RZV at D0 and D42. At D84, the blinding was lifted, and the placebo group (P2) received the RZV at D84 and D126. Anti-gE antibody concentrations (ELISA) were assessed before the 1st vaccine dose and 6 weeks after the 2nd dose. Disease activity was defined as new exacerbation or worsening based on SLE activity criteria: Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K), Physician Global Assessment (PGA) and Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI). SLE patients (P1 and P2) were blindly analyzed for disease activity, laboratory and treatment data at D0, D42 and D84. Participants were also followed through scheduled visits and telephone contact for the first 3 months to assess adverse events.

Results: A total of 301 SLE patients and 137 controls balanced for age and sex were enrolled with 266 SLE patients completing the 3-month follow-up for this interim analysis. At D84, seroconversion was significantly lower in SLE vs. CG (89.5% vs. 99.3%, p< 0.001). SLE patients also exhibited a lower geometric mean titer (GMT) of anti-gE [7.35 (95%CI 6.35 – 8.51) vs. 11.92 (95%CI 10.66 – 13.34) mUI/mL, p=0.001] and a reduced factor increase in GMT [25.13 (95%CI 20.87 – 30.27) vs. 59.15 (95%CI 47.20 – 74.12), p< 0.001] compared to CG. The overall systemic adverse events were lower in SLE compared to CG: fever (12% vs. 21%, p=0.015) and headache (26% vs. 38, p=0.010) after the 1st dose; fever (12% vs. 22%, p=0.009) and chills (12% vs. 31%, p< 0.001) after the 2nd dose. No serious adverse events were reported. Further analysis of disease activity parameters showed no significant difference in disease flare between SLE patients receiving RZV (P1) and placebo (P2) (1.9% vs. 7.0%, p=0.104), as well as similar median of SLEDAI-2K, PGA and CLASI in both groups. Among SLE patients, male sex, lower prednisone dose, previous HZ and belimumab use were associated with higher anti-gE titers after the 2nd dose (p< 0.05). Patients receiving MMF had a reduced antibody response compared to non-users, as evaluated by GMT [6.18(95%CI 4.89 – 7.70) vs. 8.51 (95%CI 7.08 – 10.23) mUI/mL, p=0.048].

Conclusion: This large, randomized study confirms RZV safety and immunogenicity in SLE, despite a reduced response versus controls. Importantly, MMF impaired vaccine response and may require strategies to enhance protection. Conversely, we provide evidence that lower glucocorticoid doses and belimumab improves vaccination antibody titers. (ClinicalTrials NCT05879419).

Abstract Number: 0620

The usefulness of neutrophil-to-lymphocyte ratio as a biomarker to predict lupus flares in patients under remission

Luis Daniel Fajardo Hermosillo and María Karina Lizbeth López Ramírez, Unidad Médica de Alta Especialidad, Hospital de Especialidades, Centro Médico Nacional de Occidente, Instituto Mexicano del Seguro Social, GUADALAJARA, Jalisco, Mexico

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Remission in Systemic Lupus Erythematosus (SLE) is described by the Definition of Remission in SLE (DORIS), but it is hardly achieved in clinical practice, while Lupus Low Disease Activity State (LLDAS) is easier achieved by a larger proportion of patients. Lupus flares negatively impact patient outcomes and survival. Only 24-hour urine protein (24hUP), anti-double-stranded DNA antibodies (anti-dsDNA) and serum complement components (C3) have been described as predictors of lupus flares [1]. Lately, the neutrophil-to-lymphocyte ratio (NLR) has emerged as potential biomarker of SLE activity and some studies have showed a correlation between NLR and lupus flares [2]. Since the lupus manifestations vary across different populations, can NLR be used as a biomarker to predict flares in the Mexican-Mestizo SLE patients under remission?

To explore the usefulness of NLR as a biomarker to predict lupus flares in patients under remission.

Methods: A retrospective cohort study including patients over 18 years of age with a diagnosis of SLE according to the SLICC 2012 criteria, who achieved LLDAS and DORIS remission for more than two years. The Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K) was used to assess disease activity. NLR, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), SLEDAI-2k, 24hUP, anti-dsDNA, and C3 were compared between patients with and without lupus flares. Correlations between NLR and previous variables were analyzed. Receiver operating characteristic (ROC) analysis was performed to determine the best NLR cutoff value for detecting lupus flares. Test characteristics, including

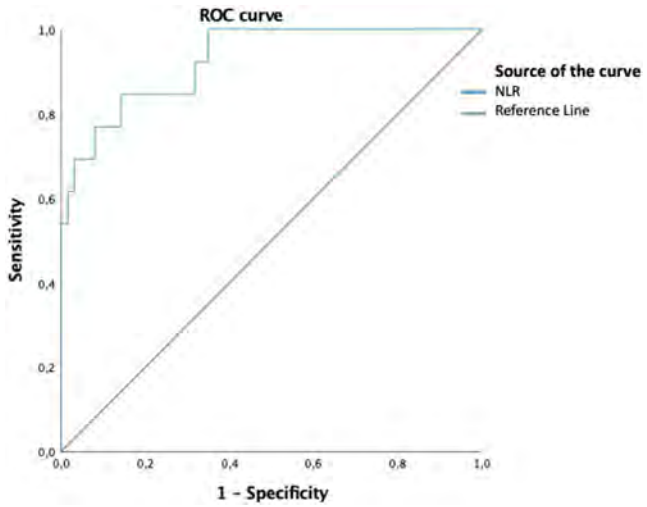

Figure 1. Receiver operating characteristic (ROC) curve analysis of neutrophil-to-lymphocyte ratio (NLR) to predict lupus flares in patients under remission. For NLR, the cut-off value was 2.59, and the area under the curve was 0.928 (95% confidence intervals: 0.856-0.997; p=<0.001), with sensitivity, specificity, and diagnostic accuracy of 84.6%, 85.7%, and 85.5% respectively.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

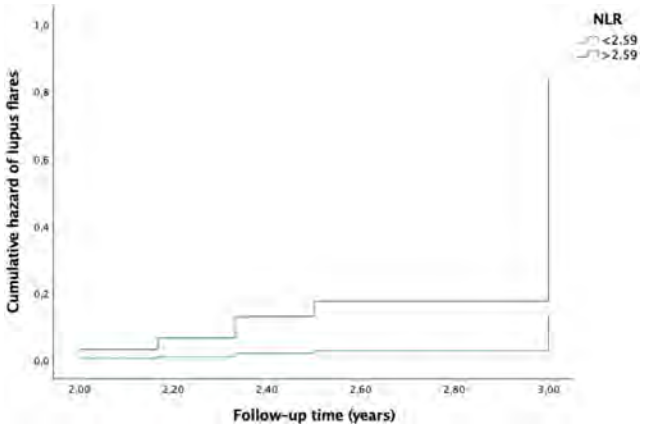

Figure 2. Multivariate Cox regression analysis using the Cox proportional hazards model was conducted to evaluate the risk of lupus flares, establishing NLR as predictive factor.

sensitivity and specificity were calculated. A Cox proportional hazards model (CHM) was conducted to evaluate lupus flares risk with NLR as a predicting factor, reporting hazard ratio (HR) and 95% confidence intervals (95% CI).

Results: Of the 250 patients with SLE, 76 (30.4%) and 40 (16%) achieved LLDAS and DORIS remission, respectively. The most common lupus manifestation was articular (64.5%), followed by cutaneous (53.9%) and renal involvement (46.1%). A total of 13 (17.1%) patients experienced lupus flares, followed for a mean of 2.7 years (SD 0.35), across 912 visits. Of these, 46.2% had renal flares and 38.5% had articular flares. Patients with lupus flares more frequently had hypocomplementemia, and higher levels of anti-dsDNA, 24hUP, and CRP compared to patients without lupus flares (p=0.001). The median (IQR) NLR was higher in lupus flares patients than in those without flares [3.57 (2.74-4.36) vs 1.71 (1.40-2.34); p=< 0.001]. NLR had a moderate correlation with SLEDAI-2K (r=0.411; p=< 0.001). The NLR cut-off value was 2.59, and the area under the curve was 0.928, with 84.6% of sensitivity and 85.7% of specificity (Figure 1). In CHM, NLR > 2.59 (HR 6.45; 95% CI, 1.10-37.1; p= 0.039) was an independent factor associated with lupus flares during the follow-up (Figure 2).

Conclusion: This study suggests that NLR can be a useful and low-cost biomarker to predict lupus flares in patients under remission. However, these observations must be confirmed in larger and prospective studies.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a multisystemic autoimmune disease. Pleuropulmonary (PP) manifestations, including pleural effusion (PE), interstitial lung disease (ILD), pulmonary hypertension (PH), shrinking lung syndrome (SLS), and alveolar hemorrhage (AH) have been described (Medlin JL et al, Semin Arthritis Rheum 2018; Liu Y et al, Lupus 2023); however, data on the frequency and associated risk factors related to occurrence are scarce in the Latin American SLE population. A better understanding of PP manifestations in this population is crucial due to the risk of severe and irreversible damage, the direct impact on morbidity, mortality, and patient quality of life.

Shrinking lung syndrome				
Serositis		2.62 (1.01–6.80)		0.047
SDI		1.46 (1.17–1.82)		<0.001

Methods: Patients from the Latin American GLADEL 2.0 cohort who met the American College of Rheumatology/European Alliance for Rheumatology (ACR/EULAR) 2019 and/or the Systemic Lupus International Cooperating Clinics (SLICC) SLE classification criteria were included. Patients with PP manifestations (PE, ILD, PH, SLS, AH) were identified and compared to those without PP manifestations. Patients with polyautoimmunity, where the disease could have another explanation,

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

were excluded. Univariate (UV) analyses were conducted to determine possible associations for each PP manifestation, using data recorded prior to the report of the PP manifestation. Subsequently, multivariate (MV) logistic regression analyses were performed, adjusting for age, gender, and other variables found to be significant in the UV analyses ($P< 0.05$).

Results: From 1,083 patients included in the GLADEL 2.0 cohort, 242 patients with PE, 38 with ILD, 26 with PH, 20 with SLS, and 9 with AH were identified. The factors associated with each manifestation, except for AH (due to small n), are summarized in Table 1. Age at diagnosis, disease duration, history of renal involvement (including both active and inactive nephritis), and the degree of organ damage, assessed with the SLICC Damage Index (SDI), were frequently associated with PP manifestations. In the MV analysis, the association between SDI and PP remained statistically significant for all complications, with odds ratios ranging from 1.35 to 1.56. Disease activity, measured by the SLE Disease Activity Index (SLEDAI-2K), was only found to be significant for PE (P=0.001). Significant associations between the presence of serositis and PH (P=0.005) and SLS (P=0.001) were found.

Conclusion: Damage, as assessed by the SDI score, was a consistent risk factor associated with PP manifestations among patients in the GLADEL 2.0 cohort; this risk factor has not been previously reported for PP in SLE. These data highlight the importance of close monitoring for PP in patients with SLE who have organ damage. Additionally, serositis significantly increased the risk of developing PH and SLS in this cohort, consistent with data reported in previous studies. Risk factors for AH could not be examined due to small case numbers.

Background/Purpose: Shrinking Lung Syndrome (SLS) is a rare pulmonary complication of systemic lupus erythematosus (SLE), characterized by unexplained dyspnea, pleuritic chest pain, loss of lung volume and a restrictive ventilatory defect without overt parenchymal or pleural disease. The pathogenesis is poorly understood. Due to its rarity and non-specific presentation, the diagnosis is often delayed. Treatment is individualized, as there are no defined guidelines for management. This study aims to identify the clinical and immunological risk factors, and therapeutic interventions impacting outcome in SLS, define prognostic indicators and inform treatment management.

Methods: We compiled a pooled database of all 49 published cases of confirmed SLS associated with SLE from the literature. We then performed a retrospective analysis describing the demographic and clinical characteristics, immunological signatures and therapeutic interventions that influenced outcomes. Fisher's exact test was used to assess the association between prognostic factors and outcomes. Odds ratio (OR) and *p*-values were computed.

Results: The median age of SLS diagnosis was 30 years (range 12-58) and females were predominantly affected (Table 1). Median time from diagnosis of SLE to SLS was 36 months (range: 0 - 240). The most common presenting symptoms were pleuritic chest pain and exertional dyspnea (Table 1). Moderate to severe pulmonary restriction (forced vital capacity % predicted [FVCpp] < 60%) was seen in 71.4% of patients. The median nadir FVCpp was 38.5% (range 14-77). Table 2 describes the therapeutic interventions. Although improvement of symptoms with immunosuppression (corticosteroids, azathioprine, hydroxychloroquine, cyclophosphamide, methotrexate, mycophenolate mofetil [MMF], and Rituximab) was observed in 92% of patients, only 61% showed functional improvement on pulmonary function tests. Relapse or progression of symptoms were noted in 12% of patients (Table 3). Despite high morbidity, mortality was low (2%). High ANA titres (>1:2560) (OR=33.0, *p*=0.027) and anti-SSA antibody positivity (OR=6.75, *p*=0.036) were associated with poor outcomes and these patients additionally required rituximab for management of disease. Anti-dsDNA positivity was associated with favorable outcomes, with patients demonstrating >100% increase in FVCpp after treatment (OR = 12.29, *p*=0.048). Anti-SSB antibody positivity (OR = 9.39, *p*=0.062) and the use of beta-agonists (OR = 10.02, *p*=0.052) were also associated with

Table 1: Baseline Demographics and Clinical Characteristics of Patients with Shrinking Lung Syndrome (SLS) in Systemic Lupus Erythematosus (SLE) (N=49)

Characteristic	Number of Patients (%)	Characteristic	Number of Patients (%)
Age (years)		**Presenting Symptoms of SLS**

Baseline Demographics and Clinical Characteristics of Patients with Shrinking Lung Syndrome (SLS) in Systemic Lupus Erythematosus (SLE) (N=49)

Table 2: Therapeutic Interventions for Systemic Lupus Erythematosus (SLE) and Shrinking Lung Syndrome (SLS) (N=49)	
Intervention	**Number of Patients (%)**
Treatment for SLE	
Corticosteroids	33 (67.3%)
Hydroxychloroquine	23 (46.9%)
Azathioprine	11 (22.4%)
Methotrexate	8 (16.3%)
Mycophenolate Mofetil	6 (12.2%)
Cyclophosphamide	6 (12.2%)
Treatment for SLS	
Corticosteroids	44 (89.8%)
Pulse Steroid Therapy	11 (25%)
Prednisone Dose >30 mg/day	26 (66%)
Prednisone Dose <30 mg/day	4 (9.1%)
Improvement with steroids alone	8 (16.3%)
Hydroxychloroquine	8 (16.3%)
Azathioprine	16 (32.6%)
Cyclophosphamide	18 (36.7%)
Mycophenolate Mofetil	5 (10.2%)
Methotrexate	3 (6.1%)
Rituximab	9 (18.4%)
Theophylline	5 (10.2%)
Beta Agonist	5 (10.2%)
Change to SLE Regimen for Management of SLS	38 (77.5%)
Medications Added to SLE Regimen	31 (63.3%)
Doses of Medications in SLE Regimen Increased	23 (46.9%)
Other Therapeutic Interventions	
BiPAP or Non-Invasive Ventilation	5 (10.2%)
Intubation	2 (4%)

Therapeutic Interventions for Systemic Lupus Erythematosus (SLE) and Shrinking Lung Syndrome (SLS) (N=49)

Table 3: Outcomes of Patients with Shrinking Lung Syndrome in Systemic Lupus Erythematosus with Treatment (N=49)	
Outcome	**Number of Patients (%)**
Symptomatic Improvement	**45 (91.8%)**
<2 weeks	8 (16.3%)
>2 weeks, <3 months	8 (16.3%)
3-6 months	6 (12.2%)
6-12 months	3 (6.1%)
>1 year	3 (6.1%)
No Symptomatic Improvement	2 (4%)
Time to symptomatic improvement not available	17
Symptomatic outcome not available	2
Improvement in Forced Vital Capacity (% of Predicted Value)	**30 (61.2%)**
1-50% increase	11 (22.4%)
51-100% increase	8 (16.3%)
101-200% increase	3 (6.1%)
>200% increase	2 (4%)
No Improvement	9 (18.3%)
% Improvement not available	6
Data not available	10
Time to Improvement of Forced Vital Capacity (months)	
<6	6 (12.2%)
6-12	12 (24.5%)
>12	5 (10.2%)
No Improvement	9 (18.3%)
Not available	17
Radiological Findings After Treatment	
Improvement	10 (20.4%)
No Improvement	5 (10.2%)
Status on Follow-Up	
Median follow up (months)	22 (3-240)
Improved clinically and functionally	27 (55.1%)
Remained stable	14 (28.5%)
Worsened / Relapsed	6 (12.2%)
Died	1 (2%)
Not available	2

Outcomes of Patients with Shrinking Lung Syndrome in Systemic Lupus Erythematosus with Treatment (N=49)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

clinical and functional improvement. In contrast, treatment with azathioprine correlated with delayed symptomatic recovery exceeding 1 year (OR = 33.44, p=0.01), and MMF use was associated with increased need for non-invasive ventilation or intubation due to respiratory compromise (OR = 20.0, p=0.01).

Conclusion: SLS is a rare complication of SLE associated with high rates of morbidity. Specific immunologic profiles and therapeutic interventions were associated with better clinical and functional recovery, and can guide prognostication and treatment selection. These findings highlight the need for greater clinical awareness, and development of standardized treatment protocols to optimize patient outcomes.

Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex autoimmune disease with heterogeneous clinical manifestations. Evidence from high-income countries suggests that socioeconomic status (SES) and environmental factors influence SLE outcomes, yet data from Latin America remain limited. The objective of this research was to evaluate, across three levels (individual, regional, and national), whether socioeconomic and environmental factors impact the clinical presentation of SLE in the GLADEL 2.0 cohort.

Methods: We analyzed data from 1,083 patients with SLE enrolled in the GLADEL 2.0 cohort across 10 Latin American countries. All patients fulfilled the 1982/1997 American College of Rheumatology (ACR) or 2012 Systemic Lupus International Cooperating Clinics (SLICC) classification criteria. Clinical outcomes were disease activity (SLEDAI-2K), organ involvement (renal, hematologic, cutaneous, musculoskeletal), and organ damage (SLICC/ACR damage index; SDI). Variables

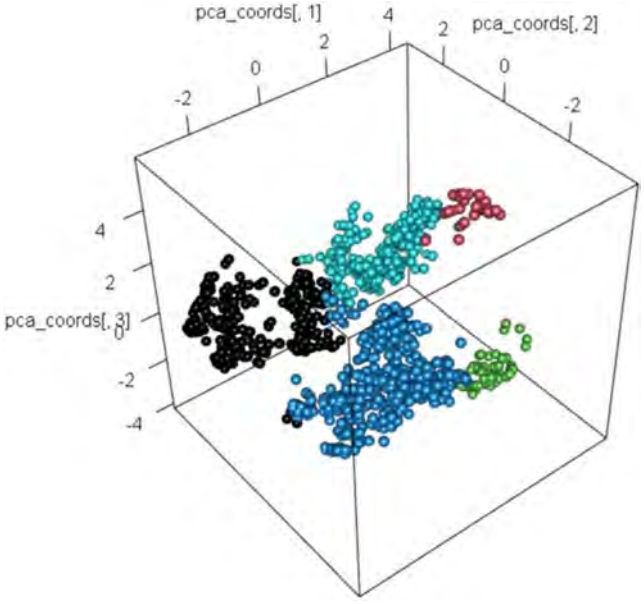

Figure. Three-dimensional representation of the first three principal components, showing the five clusters of SLE patients derived from socioeconomic and environmental variables

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

were structured into three levels: Level 1 (individual), Level 2 (state/province), and Level 3 (national). Multilevel analyses included sociodemographic variables, environmental exposure to air pollutants ($PM_{2.5}$, PM_{10}, NO_2), and contextual indicators (income, unemployment, distribution of income or wealth through the Gini index, CO_2 emissions). Statistical analysis included cluster analysis (Ward's method) and principal component analysis (PCA).

Results: Five clusters emerged based on socioeconomic and environmental determinants. Cluster two (urban, high-income, low inequality) exhibited low damage (SDI [mean ± SD] 0.66 ± 0.9) and high disease activity (SLEDAI [mean ± SD] 13.0 ± 9.2). Conversely, Cluster four (middle-low SES, high inequality, high NO_2 exposure) demonstrated high disease impact (SDI [mean ± SD] 1.06 ± 1.4) and greatest work productivity loss (36.1%). Cluster three (low-income, low pollution) presented the highest accumulated damage (mean SDI [mean ± SD] 1.73 ± 1.95). Environmental exposures varied significantly; Cluster five showed the highest CO_2 emissions and solar irradiance, while Cluster three had the lowest environmental burden. PCA showed that clinical manifestations, disease activity and chronicity were different across clusters. The figure highlights the separation of the characteristics according to the three principal components.

Conclusion: Socioeconomic and environmental factors at individual, regional, and national levels influence the cumulative clinical manifestations and patient-reported outcomes in SLE. Our findings underscore the role of social vulnerability and environmental stressors as potential modifiers of SLE phenotype in Latin America, highlighting the need for context-sensitive interventions and policies to mitigate health inequities.

Polygenic risk of lupus is differentially associated with individual EHR-derived classification criteria

Noah Forrest[1], Sachleen Tuteja[2], Jennifer Pacheco[3], Vesna Mitrovic[3], Rosalind Ramsey-Goldman[1], Theresa Walunas[3] and **Matthew Dapas**[1], [1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Northwestern University, Evanston, [3]Northwestern University Feinberg School of Medicine, Chicago

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a heterogeneous autoimmune disease characterized by diverse clinical presentation, posing significant challenges in diagnosis and management. Reflecting this clinical complexity, multiple sets of classification criteria have been developed for SLE. Genetic factors contribute significantly to SLE susceptibility, with genome-wide association studies (GWAS) identifying over 130 distinct genetic loci linked to increased disease risk. Importantly, polygenic risk scores (PRSs) derived from these loci have been associated with specific clinical manifestations, including cardiovascular and renal involvement, indicating that genetic risk may drive distinct phenotypic expressions within SLE. Here, we developed an SLE PRS and evaluated its associations with electronic health record (EHR)-derived clinical phenotypes and laboratory parameters available in the Electronic Medical Records and Genomics (eMERGE) Network biobank. We further assessed the relationships between the PRS and individual Systemic Lupus International Collaborating Clinics (SLICC) classification criteria.

Methods: We modeled polygenic risk for lupus using PRS-CS on summary statistics from a large genome-wide association study consisting of 6,748 SLE cases and 11,516 controls of European ancestry and derived PRSs in European ancestry eMERGE participants. We performed a phenome-wide association study between the lupus PRS and 1,706 phecodes in Northwestern University eMERGE participants (n=1,061), adjusting for age, sex, number of encounters, and the top 3 principal components of ancestry. We then calculated correlations between the lupus PRS and the prevalences of individual SLICC criteria across all eMERGE sites (n=32,329), adjusting for the number of encounters.

Results: The PRS predicted SLE with a receiver operating characteristic area under the curve of 0.724. Within the Northwestern cohort, the PRS was significantly associated with "Lupus (localized and systemic)" ($P=1.6\times10^{-9}$) and "systemic lupus erythematosus" ($P=3.0\times10^{-9}$). Nominally associated phecodes ($P< 5.0\times10^{-3}$) included "cardiac complications" ($P=2.8\times10^{-3}$) and "impaired renal function" ($P=4.6\times10^{-3}$). PheWAS associations were significantly enriched for circulatory system ($P=9.7\times10^{-5}$) and hematopoietic ($P=3.2\times10^{-2}$) traits. Across eMERGE, the SLE PRS was significantly associated with 5/6 immunological and 3/11 clinical SLICC criteria (Acute cutaneous lupus, thrombocytopenia, and leukopenia). Of the SLICC criteria, the PRS was most strongly associated with low complement levels ($P=7.4\times10^{-31}$), with nearly twice the rate of lupus patients with low complement levels in the highest PRS decile than those in the bottom PRS decile (55% vs. 30%, respectively).

Conclusion: Our findings indicate that different clinical and immunological criteria are more or less associated with genetic SLE risk. Future studies should consider incorporating genetic risk for developing more comprehensive and accurate prediction models of SLE to inform strategies for clinical prevention, intervention, and management.

DNA methylation patterns in systemic lupus erythematosus associated with nephritis status

Meghan Nelson[1], Mary Horton[2], Joanne Nititham[3], Jinoos Yazdany[4], Maria Dall'Era[5], Cristina Lanata[3] and Lindsey Criswell[2], [1]NIH/NIAMS/NHGRI, Bethesda, MD, [2]NIH/NHGRI, Bethesda, MD, [3]NIH/NHGRI, Bethesda, [4]UCSF, San Francisco, CA, [5]Division of Rheumatology, University of California, San Francisco, CA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Individuals with systemic lupus erythematosus (SLE) experience significant variability in clinical outcomes. Our current understanding of the causes of disease heterogeneity are limited, preventing successful risk stratification. To investigate the contribution of epigenetic variation to disease heterogeneity, we generated DNA methylation profiles for a large cohort of SLE patients and examined methylation patterns associated with presence of nephritis, given its importance to morbidity and mortality in SLE.

Methods: We studied 1,882 multi-ancestry SLE patients recruited during routine clinical care. Clinical data were collected at study enrollment and peripheral blood cell collection. Genome-wide methylation profiles were generated using Illumina's EPICv2 BeadChip which includes 937,690 CpG sites. Samples were randomly subset into discovery (n= 1505; ~80%) and validation (n= 377; ~20%) cohorts. Normalization and quality control were performed using *minfi*. Methylation sites (CpGs) with high detection p-values and cross-reactive probes were excluded. Among the discovery cohort, differentially methylated positions (DMPs) associated with nephritis were identified using limma. We used methylation beta values for coefficient interpretation, and methylation M values to determine statistical significance. Models adjusted for genetic principal components, Houseman estimated blood cell proportions, batch, age, disease duration, and sex. DMPs with FDR q< 0.05 were considered significant. Significant DMPs were then tested for their association in the validation cohort using the same models. DMPs with FDR q < 0.05 and the same direction of effect in both cohorts were considered validated.

Results: In the discovery cohort, we identified 5,783 CpGs with FDR q< 0.05. Of these, 12 CpGs had at least a 5% difference in methylation between nephritis cases and non-nephritis SLE controls. 184 CpGs had FDR q < 0.05 and the same direction of effect in the validation cohort. Of these validated CpGs, 13 had at least a 5% difference in methylation between nephritis cases and controls. Validated CpGs included CpGs in *IL1R1* (receptor for Interleukin-1), *STAB1* (a scavenger

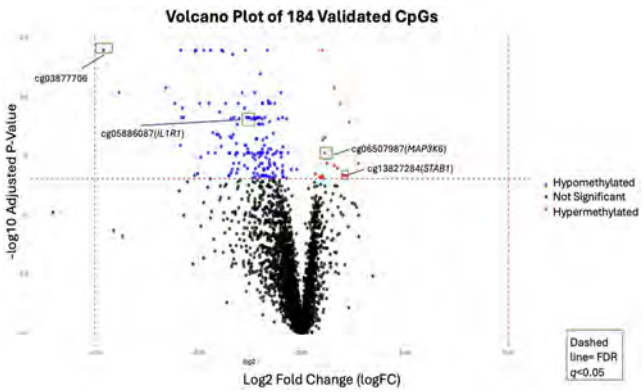

Figure 1. Volcano Plot of validated significant CpG sites.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

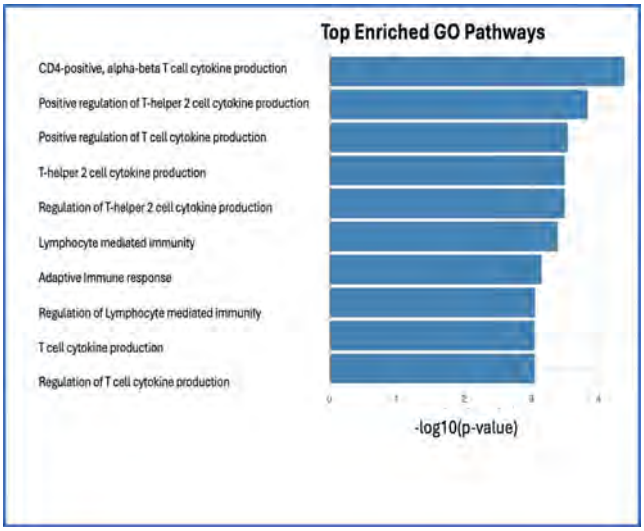

Figure 2. Gene Set Enrichment Analysis (GSEA) with Gene Ontology.

receptor expressed in macrophages and modulator of inflammation), and *TRIM62* (a tripartite motif involved in innate immunity and antiviral response). Of the validated CpG sites, the absolute change in methylation between nephritis cases and controls ranged from 0.2 to 9.5%. A majority of these were hypomethylated; 13 were located within genes, and 23 were in promoter regions. Gene set enrichment analysis revealed enrichment in T-cell production and lymphocyte mediated immunity, although adjusted p-values were not significant (Figure 2).

Conclusion: In the largest SLE multi-ancestry methylation data set to date, we identified 5,783 CpGs that were differentially methylated in SLE patients with nephritis, and we validated approximately 3% of these CpGs in a validation cohort. These results suggest that methylation patterns may provide opportunities to further subtype SLE patients for risk stratification in clinical settings.

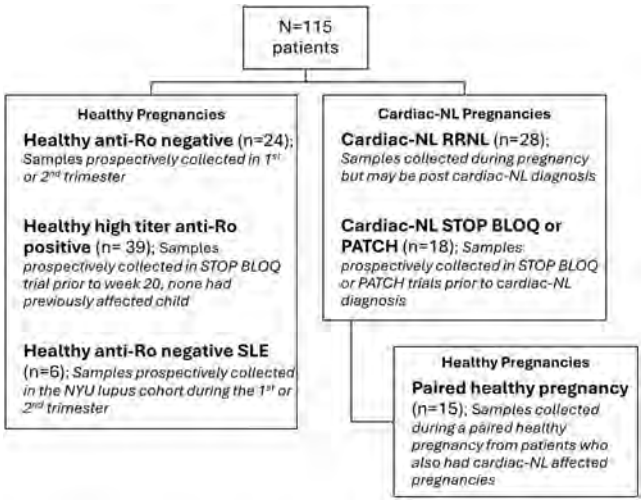

Figure 1: Flow chart describing the sources of the samples used in the study. RRNL: Research Registry for Neonatal Lupus; STOP BLOQ: Surveillance and Treatment to Prevent AV Block Likely to Occur Quickly; PATCH: Preventive Approach To Congenital Heart Block with Hydroxychloroquine

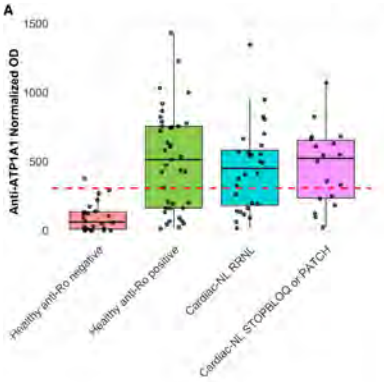
Background/Purpose: For childbearing women with SLE and other autoimmune diseases, the nearly invariant association of cardiac-NL with maternal SSA/Ro52/60kD autoantibodies supports the necessity of these reactivities in the pathogenesis. Although high titer and a history of a previously affected child further increase the risk of fetal disease, the incidence is < 20%, suggesting that another factor, be it protective or permissive, is operative. Addressing the latter, a novel antigenic target Na+/K+ ATPase subunit α1 (ATP1A1), which maintains ion balance across cell membranes, was discovered by western blot screening of fetal hearts and stem-cell derived immature cardiomyocytes, and found to be uniquely targeted only in pregnancies affected by cardiac-NL (Hamilton, ACR, 2022). To facilitate high throughput clinical assessments of this specificity, we leveraged an extensive collection of sera from high titer anti-Ro pregnancies, both affected and unaffected by cardiac-NL, to evaluate the utility of an ELISA based approach to detect anti-ATP1A1 for risk evaluation (Fig 1).

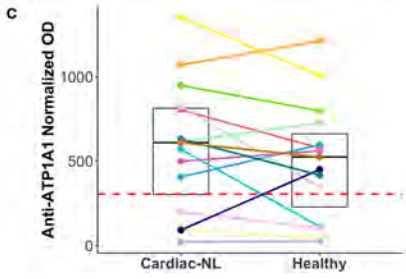
Methods: Commercially available full-length ATP1A1 was coated at a concentration of 0.2 ug/well. All sera were diluted 1:1000. The patient with the highest OD on the first plate was tested on all subsequent plates and all samples were divided

Figure 2: (A) Boxplots showing the normalized optical density (OD) values for the healthy anti-Ro negative, healthy anti-Ro positive, Research Registry for Neonatal Lupus (RRNL) cardiac-NL, and STOP BLOQ or PATCH cardiac-NL samples. The red dashed line at 305 indicates mean + 2 standard deviations above the healthy anti-Ro negative samples. (B) Table showing the percent of patients in each group above the 305 threshold and the median and interquartile range. (C) Boxplots showing the ATP1A1 levels between paired samples collected from a patient during a cardiac-NL (RRNL, PATCH, or STOP BLOQ) and a healthy pregnancy.



B

Group	Total N	Positive anti-ATP1A1 by threshold N (%)	ATP1A1 Normalized OD Median (IQR)
Healthy anti-Ro Positive	39	25 (64%)	514 (162-755)
Cardiac-NL RRNL	28	18 (64%)	450 (183-582)
Cardiac-NL STOPBLOQ or PATCH	18	12 (67%)	522 (234-654)



23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 3: Correlation between Anti-ATP1A1 and Anti-Ro52 (A) or Anti-Ro60 (B). Pearson's correlation coefficient and p-value are listed on the graphs.

by this calibrator to generate a normalized OD. Positive reactivity was defined as 2SD above the mean normalized OD obtained for 24 sera from healthy anti-Ro negative first trimester pregnancies. Sources of all samples are shown in Figure 1.

Results: Of the 46 anti-Ro positive sera tested during pregnancies affected by cardiac-NL (18 in the early second trimester prior to the identification of a fetal arrhythmia), 65% were reactive with full length ATP1A1 (Fig 2A & 2B). Comparable frequencies were observed in 39 anti-Ro positive sera tested during the second trimester of cardiac healthy fetuses, specifically 64%. Similarly, on a continuous scale, ATP1A1 levels did not distinguish cardiac-NL from healthy outcomes (Fig 2A & 2B). To address whether anti-ATP1A1 may be present only during affected pregnancies, unlike anti-Ro antibodies, we evaluated 15 pairs in which one pregnancy was healthy and another affected in the same individual. There were no significant differences between ATP1A1 levels in the affected vs unaffected pregnancy (Fig 2C). One patient became seropositive in the affected pregnancy, while one other lost reactivity in the affected pregnancy (Fig 2C). ATP1A1 levels correlated with anti-Ro52 ($r=0.8$, $p < 0.0001$) and anti-Ro60 ($r=0.5$, $p< 0.0001$) titers. Consistent with this association, reactivity with ATP1A1 was not detected in any of six anti-Ro negative SLE pregnancies.

Conclusion: These data suggest that autoantibodies against full length ATP1A1, measured by ELISA, are present in the majority of anti-Ro+ pregnancies and represent a novel reactivity. However, as tested, this reactivity does not predict the development of cardiac-NL. Binding specific epitopes in the western blot could differ from our approach. The strong correlation with anti-Ro52 implicates cross-reactivity between these targets.

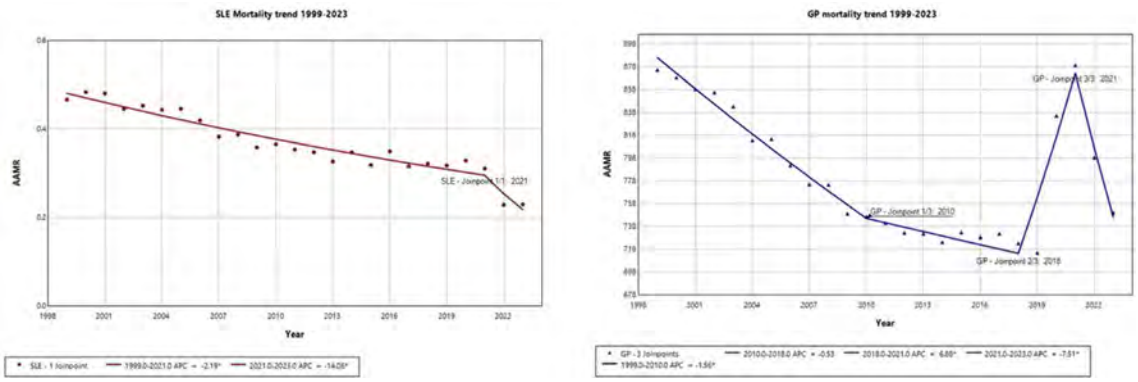

Figure 1 A. Mortality trends in SLE between 1999-2023. Figure 1B. Mortality trends in general population between 1999-2023.

Background/Purpose: Previous studies have shown a decline in systemic lupus erythematosus (SLE)-related mortality rates from 1999 to 2020. This study aimed to evaluate SLE-related mortality trends in the United States during the COVID-19 pandemic.

Methods: We analyzed SLE mortality data from 1999 to 2023 using the CDC WONDER Underlying Cause of Death database and its query system. Age-adjusted mortality rates (AAMRs) were calculated by sex, race, and ethnicity for both SLE and the general population (GP). The first cases and deaths related to COVID-19 in the U.S. were reported in 04/2020. To assess the impact of COVID-19, we focused on mortality rates from 2020 onward. Trends over the study period were assessed using the NCI's Joinpoint Regression Program to identify statistically significant changes in the slope of mortality trends and to calculate annual percentage changes (APCs).

Results: From 1999 to 2023, a total of 30,060 deaths were identified in the US with SLE listed as the underlying cause. Joinpoint trend analysis revealed one inflection point in 2021 within the SLE group. The AAMR for SLE declined between 1999-2021 (APC =–2.19; 95%CI:–2.52 to –1.51; p=0.032), followed by a more pronounced decrease from 2021 to 2023 (APC = –14.1; 95%CI:–22.5 to –3.67; p< 0.00001) (Fig 1A). In the GP, 3 joinpoints were identified (Fig 1B). Pairwise comparison testing indicated a parallel trend in AAMRs between the SLE and general population cohorts over the study period.

Among female SLE patients, trend analysis identified one joinpoint. AAMR declined modestly from 1999 to 2021 (APC =–2.03; 95%CI: –2.39 to –1.6; p=0.0024), followed by a sharp decline after 2021 (APC = –18.93; 95%CI: –25.66 to –8.59; p< 0.00001) (Fig 2A). In females in the GP, 2 joinpoints were identified (Fig 2B). In the male SLE group, no joinpoints were detected, and AAMR declined consistently across the entire study period (APC = –2.32; 95%CI: –3.02 to –1.66; p< 0.00001). In contrast, 3 joinpoints were identified in males in the GP.

Joinpoint analysis identified two inflection points in African American (AA) patients with SLE. The AAMR declined between 1999 and 2013 (APC=–3.14; 95%CI: –7.9 to –2.1; p=0.038), remained stable from 2013 to 2020 (APC= 0.28; 95%CI: –

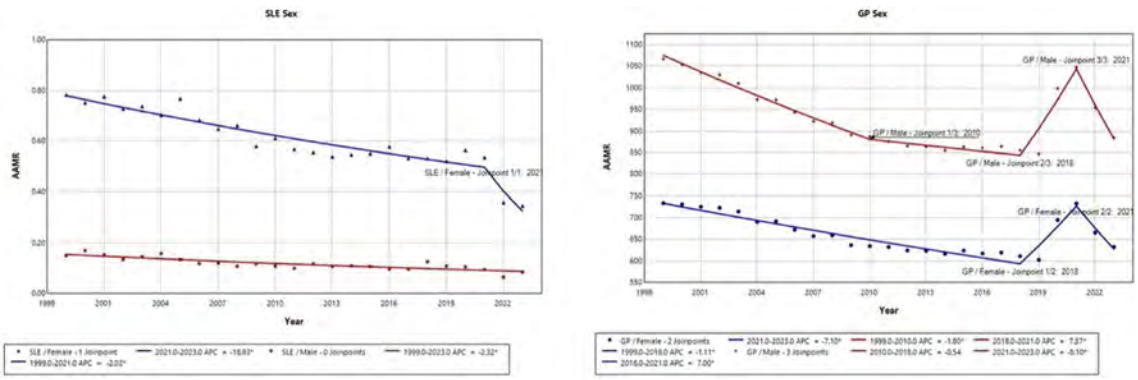

Figure 2A. Mortality trends in SLE by sex. Figure 2B. Mortality trends in general population by sex.

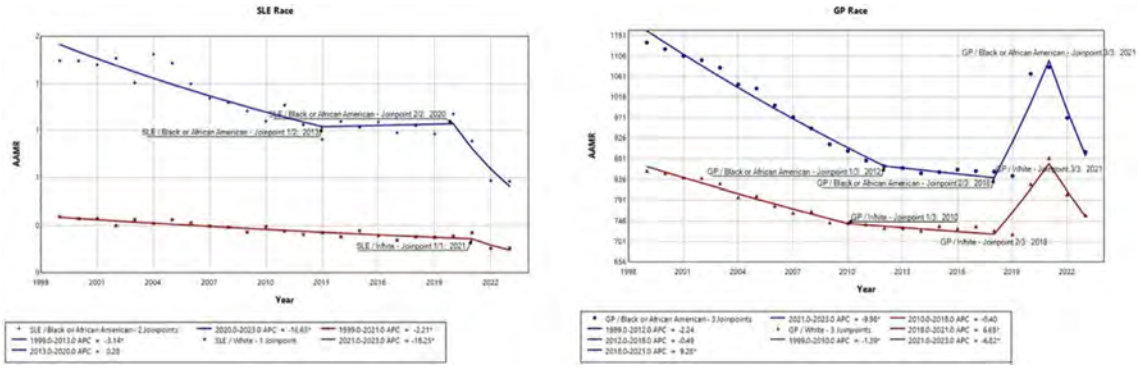

Figure 3A. Mortality trends in SLE by race Figure 3B. Mortality trends in general population by race.

2.1 to 7.3; p=0.76), and then decreased significantly after 2020 (APC=–16.6; 95%CI:–27.1 to –9.9; p< 0.00001). In the White SLE group, 1 joinpoint was identified in 2021. AAMR declined gradually until 2021 (APC = –2.2; 95%CI: –2.7 to –0.6; p=0.045), followed by a more pronounced decrease thereafter (APC=–18.2; 95%CI: –29.9 to –3.0; p=0.0004) (Fig 3A).

In the GP, both White and AA groups showed 3 joinpoints (Fig 3B). Hispanic and non-Hispanic SLE patients displayed similar patterns, with a notable joinpoint observed in 2021.

Conclusion: While overall SLE-related mortality continued to decline through 2023, a marked inflection point was observed during the COVID-19 pandemic across demographic subgroups. Notably, AA patients showed significant post-2021 improvements in mortality trends, suggesting potential impacts of healthcare access, disease management, or pandemic-related factors. Continued monitoring of these trends is essential to understand long-term outcomes and disparities in SLE mortality.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Background/Purpose: Organ damage drives morbidity and mortality in systemic lupus erythematosus (SLE), yet no validated tools exist to predict early damage. We aimed to develop and validate a machine learning model using standard clinical features to forecast organ damage within five years since diagnosis.

Methods: We analyzed a discovery cohort of 914 SLE patients and an independent validation cohort of 50 SLE patients to associate clinical and immunological features with increases in the SLICC/ACR Damage Index within five years of diagnosis (physician-based). The discovery cohort was split into training (70%) and test (30%) sets. Clinically curated panels of classification and non-criteria features were used to build LASSO logistic regression models, with hyper-parameter tuning via 10-fold cross-validation. Performance was assessed by AUC, sensitivity, specificity, and accuracy. Cutoffs were selected by maximizing the F1 score or Youden's index.

Results: A LASSO logistic regression model, integrating both classification criteria and non-criteria clinical features, outperformed

existing classification criteria in predicting early organ damage, with an AUC of 0.86 (95% CI 95% CI 0.76 to 0.97) in the external validation cohort. Key damage predictors were neurologic involvement (SLICC-2012), class III/IV lupus nephritis (EULAR/ACR-2019), and myocarditis. The model achieved a specificity of 0.898 (95% CI: 0.78–0.95) as a binary classifier. When simplified into an 8 variable scoring system, a threshold of > 3 yielded an AUC of 0.86 (95% CI: 0.75–0.96).

Conclusion: We developed and validated an interpretable tool for predicting early organ damage in SLE. Pending further validation, this tool may facilitate individualized risk assessment and damage-preventative strategies including the timely use of biologic treatments.

SDI*, median [IQR]	0.00 [0.00, 1.00]	0.87 [0.00, 1.66]	0.50 [0.00, 1.24]	<0.01

*SDI without the Musculoskeletal component at the last follow-up visit
** univariable analyses comparing non deforming, rhupus, and Jaccoud's arthropathy using chi square/ANOVA.
Abbreviations: IQR: Interquartile range, CI: Confidence Intervals, OR: Odds Ratio, SLEDAI-2K: SLE Disease Activity Index 2000, SDI: SLE damage index, SF: short form, MCS: mental component score, PCS: physical component score, CCP: cyclic citrullinated peptide

Methods: This is a retrospective analysis of a prospective SLE cohort with arthritis defined by the ACR or EULAR/ACR SLE classification criteria at presentation and SLEDAI 2K over follow-up identified from a single-center SLE database (July 1970-Aug 2024) from both inception and prevalent cohorts. Demographic, clinical, laboratory (including interferon signature), radiographic features, and treatment variables were retrieved from the database. Descriptive statistics were used to outline features across three subtypes of arthritis: ND arthritis (determined by clinical examination), arthritis with reducible

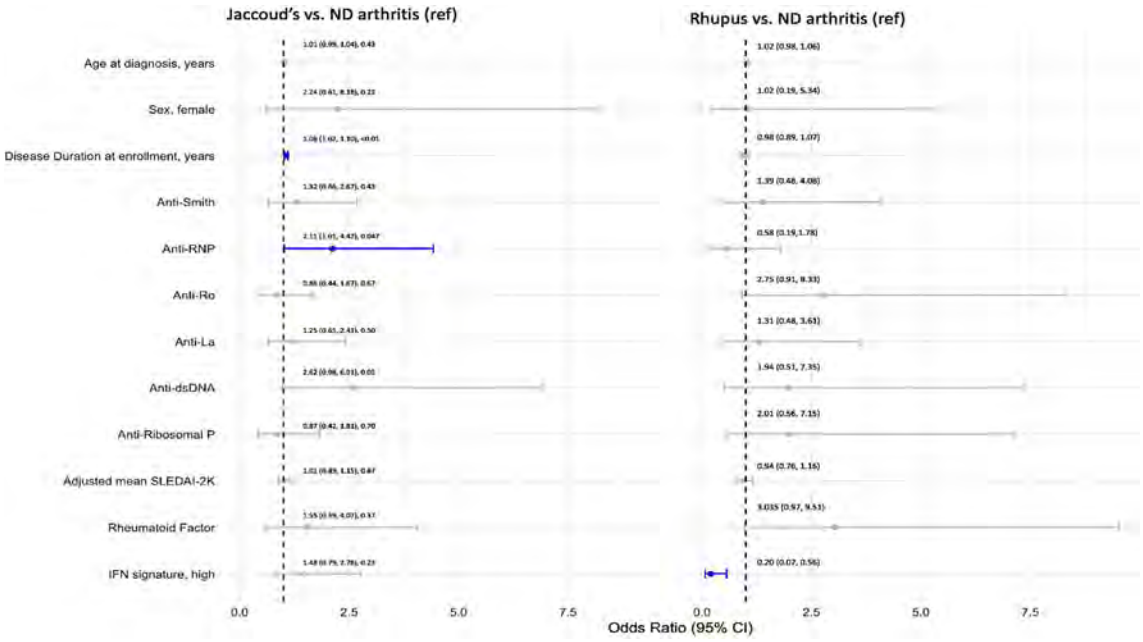

Figure 1: Multivariable logistic regression analyses to identify associations with Jaccoud's and rhupus, non-deforming arthritis being the reference. (n=318)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

deformities or Jaccoud's Arthropathy (JA), and arthritis with non-reducible deformities or rhupus. Factors associated with deforming arthritis were determined using binary logistic regression, including age, sex, disease duration, antibodies, adjusted mean SLEDAI-2K, and Type 1 IFN scores. Time to deformities and predictors were studied in the inception subgroup using fine and gray time-to-event analyses.

Results: Arthritis was observed in 1,248 of 2264 (55.12%) patients, of whom 908 (72.6%) had ND, 239 (19.2%) had JA, 101 (8.1%) had rhupus. The median age at diagnosis of SLE was comparable, though a higher proportion of females was observed in JA (p=0.03).

The distribution of organ involvement and antibodies was similar across the three subtypes, except nervous system involvement (p=0.03) and anti-Ro antibodies (p=0.04) being more frequent in rhupus. Rheumatoid factor and anti-citrullinated protein antibody positivity did not differ significantly. The proportion of patients with high interferon signature was the highest in JA, followed by ND arthritis, and lastly, rhupus (p< 0.01). Radiographs (n, 95) revealed erosive disease in 10 of 43 (23.2%) with JA, 12 of 36 (33.3%) with rhupus, and 2 of 16 (12.5%) with non-deforming arthritis. (Table 1)

In the multivariable analysis, rhupus was associated with a lower odds for a high type I IFN signature (0.20 [0.07, 0.56]) with a direction of positive association towards rheumatoid factor (3.04 [0.97, 9.51] and anti-Ro (2.75 [0.91, 8.33]) positivity when compared with ND arthritis. No associations were observed with JA when compared with ND arthritis. (Figure 1)

The time to development of deformities from enrollment was 2.07 (1.15, 7.6) years for JA and 4.64 (1, 9.78) years for rhupus within the inception cohort. Anti-RNP was predictive of JA on multivariable analysis [4.88 (1.02, 23.5)].

Conclusion: Arthritis was observed in half the cohort, with the majority being non-deforming. Among deforming arthritis, JA was more common than rhupus. JA and ND arthritis were associated with a high IFN signature score while rhupus was characterized by a low IFN signature score. This sheds light on two different mechanisms for deforming arthritis in SLE. Erosions were observed in both types of deforming arthritis blurring the line of radiologic differences historically outlined between them.

b. drug therapy & monitoring c. role of investigations in disease diagnosis and monitoring) was prepared. All questions had an item-level content validity index (I-CVI) of at least 0.9. The scale-level content validity index based on the universal agreement method (S-CVI/UA) was 0.8 for the whole questionnaire as assessed by 6 experts. All questions had an option of 'I don't know' which would prevent patients from guessing the answer from the available options. Each question was given a score of 1 if answered correctly. The questionnaire was applied 3 times: at baseline, immediately after an information course to see the immediate impact and after 6 months to see the retention of the information. Information on demographic features and socio-economic status was also collected. Frequency data were compared using McNemar test for paired nominal data & kappa statistics for ordinal data. Student's paired t-test was used for comparison of mean scores to see the impact. A p-value< 0.5 was considered significant.

Results: At baseline, the questionnaire was applied to 56 patients with SLE (F:M=54:2; median age 29(16-53) years) and the median(range) score was 10(2-19) (Table–1). Among them, 39 patients attended the information course. The option 'I don't know' was exercised 509 times (39.51%) before the information course which reduced to 169 (18.84%) times after the course and 108 (13.04%) times at 6 months.

After the information course, median score increased from 10(2-19) to 17(0-23) (p< 0.001) which was irrespective of the socio-economic classes and education status of the patients (Figure-1). A total of 13 questions recorded a higher number of correct responses as compared to baseline and this increase was significant for all 13 questions (Table–1).

Upon re-administering the questionnaire after 6 months, 36 patients out of 39 responded. The median score 16(0-23) of the questionnaire (n=36) remained significantly higher (p< 0.001) as compared to baseline score. Eight out of 23 questions achieved statistical significance (Table–2).

Conclusion: Indian patients with SLE have a poor knowledge base which can be improved by implementing short information courses. The information course was effective across the socio-economic classes and educational status and the information was retained at 6th month without any reinforcement course.

Background/Purpose: Patients with systemic lupus erythematosus (SLE) are predisposed to infections due to immune dysregulation. Autoantibodies to cytokines can cause serious infections, including severe COVID-19, by mycobacteria or other intracellular microbes. We describe here antibodies to type I, II and III interferons (IFNα, ω, γ & λ) as a cause for infections in an inception cohort of SLE (INSPIRE) from India.

Methods: Newly diagnosed SLE (SLICC 2012 criteria) within 6 months of disease onset were enrolled in the INSPIRE cohort from 2018-2023. We developed an ELISA for antibodies to IFN α, ω, γ and λ. Baseline sera retrieved from the biobank were tested for these antibodies. Antibody titres were expressed as optical density (OD) and the 95th percentile of antibody titres in healthy-control population was used to develop cutoffs for positivity. Outcomes studied were infections in the initial 2 years of follow up. Serious infections were those that led to hospitalisation or mortality.

Results: A total of 313 patients of SLE (294 females) with a mean age 27.7±10.2 years were enrolled from 2 centres in North India. In addition, sera from 59 healthy controls were also tested for anti IFN antibodies. Antibodies to IFN-α, IFN-ω, IFN- γ and IFN-λ were present in 73 (23.3%), 18 (5.5%), 18 (5.5%) and 30 (9.6%) patients respectively. Eight patients (2.72%) had more than 1 anti-interferon antibodies. In contrast, 3 (5.08%) healthy controls had antibodies to IFN-α, IFN-ω, IFN- γ and IFN-λ each.

In the initial 2 years, there were 107 infections, of which 31 were serious infections. Bacterial including mycobacterial infections (79, 25.2%) were most common followed by viral (32, 10.2%) and fungal (15, 4.8%). Herpes zoster (25, 7.9%) was the most common infection followed by tuberculosis (11, 3.5%). No healthy control had history of serious infections.

Antibodies to IFN-α were associated with serious infections (OR 2.79, 1.29-6.04), tuberculosis (OR 3.46, 1.03-11.68), viral infections (OR 2.64, 1.23-5.68) and Herpes zoster (OR 3.1, 1.2-8.02), but not with overall infections (OR 1.3, 0.76-2.35), bacterial (OR 1.27, 0.69-2.36) or fungal (OR 1.23, 0.38-3.99) infections. Antibodies to IFN-λ were associated with serious infections (OR 2.93, 1.1-7.83) but not with any subtype of infection. Antibodies to IFN-ω and IFN-γ were not associated with any higher risk of infections.

Conclusion: Antibodies to IFN-α are the most common anti-interferon antibody in an Indian inception cohort of SLE and predispose to serious infections, especially viral infections, Herpes zoster and tuberculosis in the initial 2 years of follow-up.

Abstract Number: 0632

Comparative Outcomes of GLP-1 Receptor Agonists Versus SGLT2 Inhibitors in Patients with Systemic Lupus Erythematosus and Diabetes: A Propensity-Matched Retrospective Cohort Study

Rusudan Tskitishvili[1], Abdallah Hussein[2], Roman Karagulyan[2], Shatha Shahwan[3] and Priju Varghese[2], [1]Virtua Health, Camden, NJ, [2]Virtua Health, Camden, [3]Jordan University of Science and Technology, Jordan

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is associated with a heightened risk of cardiovascular and renal complications, particularly in patients with comorbid diabetes mellitus. While both GLP-1 receptor agonists and SGLT2 inhibitors have shown cardio-renal benefits in the general diabetic population, comparative outcome data in patients with SLE remain limited.

Methods: This retrospective cohort study utilized data from the global TriNetX Collaborative Network and included adult patients (aged ≥18 years) diagnosed with both SLE and diabetes between January 1, 2015, and December 31, 2023. Patients were grouped based on exposure to either GLP-1 receptor agonists or SGLT2 inhibitors. The primary outcome was all-cause mortality, while secondary outcomes included major adverse cardiovascular events (MACE) and lupus nephritis. Propensity score matching (1:1) was used to balance baseline characteristics between groups. Risk ratios (RRs), 95% confidence intervals (CIs), and p-values were calculated for outcome comparisons after matching.

Results: After matching, 885 patients were included in each group. The mean ± SD age was 57.7 ± 12.1 years, with approximately 82% female and 39% identifying as White. Baseline characteristics were well balanced following propensity score matching. The incidence of MACE was significantly lower in the GLP-1 group (3.2%) compared to the SGLT2 group (6.0%; RR, 0.53; 95% CI, 0.337–0.827; $p = 0.0045$). Similarly, the incidence of lupus nephritis was significantly lower in the GLP-1 group (4.7%) compared to the SGLT2 group (9.8%; RR, 0.48; 95% CI, 0.338–0.689; $p < 0.0001$). All-cause mortality was slightly lower in the GLP-1 group (1.6%) versus the SGLT2 group (2.1%), but this difference did not reach statistical significance (RR, 0.74; 95% CI, 0.372–1.46; $p = 0.737$).

Conclusion: Among patients with systemic lupus erythematosus and diabetes, treatment with GLP-1 receptor agonists was associated with significantly lower rates of major adverse cardiovascular events (MACE) and lupus nephritis compared to SGLT2 inhibitors. While all-cause mortality was numerically lower in the GLP-1 group, the difference was not statistically significant. These findings suggest that GLP-1 receptor agonists may offer greater cardio-renal protection in this high-risk population and warrant further investigation in prospective clinical trials.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Diffuse alveolar hemorrhage (DAH) is a rare but severe complication in Systemic Lupus Erythematosus (SLE), occurring in up to one-third of cases at disease onset. In ANCA-associated vasculitis (AAV), the prevalence of DAH is around 25%, with high morbidity and mortality. DAH in both SLE and AAV requires prompt investigation, presenting challenges in initiating life-saving treatments. The objective of this study is to compare the in-hospital mortality in patients with DAH secondary to AAV versus DAH secondary to SLE, aiming to inform management strategies and improve clinical decision-making.

Methods: We used the National Inpatient Sample database from Jan 2020 to Dec 2022 to compare baseline characteristics and outcomes of patients with DAH due to AAV versus SLE. Both groups were analyzed for demographic factors, comorbidities, hospital-related variables, and clinical outcomes. Key outcomes included length of stay (LOS), total charges, and in-hospital mortality, with logistic regression used to assess factors associated with mortality.

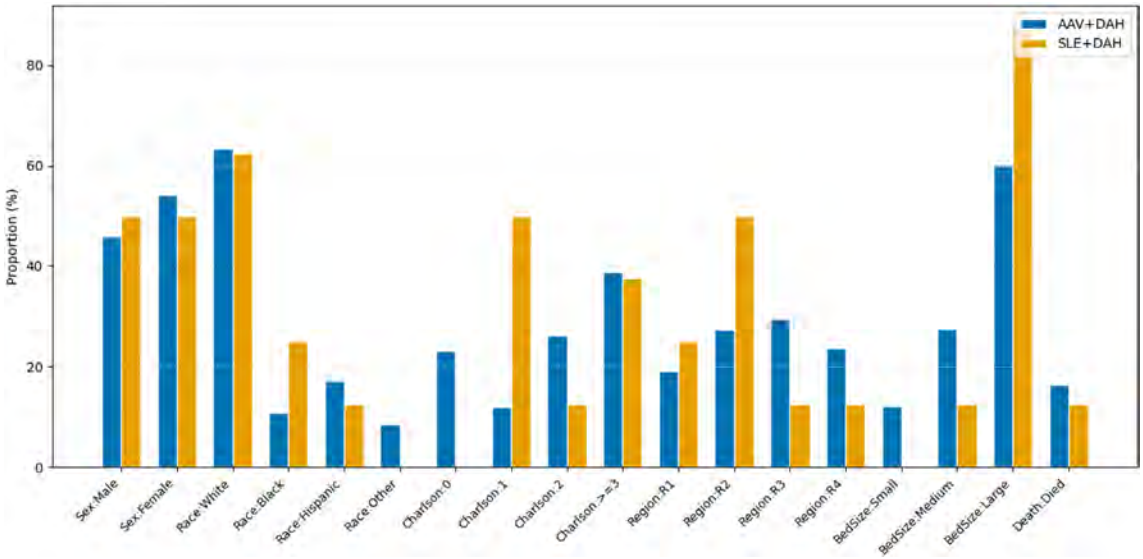

Figure 1: Baseline comparison of Diffuse Alveolar Hemorrhage (DAH) due to Systemic Lupus Erythematosus (SLE) versus ANCA-associated vasculitis (AAV).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: A total of 1,470 patients with AAV + DAH and 915 patients with SLE + DAH were identified. In the AAV + DAH group, 54.2% were female, compared to 50% in the SLE + DAH group. The mean age for AAV + DAH patients was significantly higher at 55.34 years, compared to 43.25 years in the SLE + DAH group. Racial distribution showed 63.4% of AAV + DAH patients were White, compared to 62.5% in the SLE + DAH group. AAV + DAH patients had a higher proportion of severe comorbidities (38.8%) compared to SLE + DAH (37.5%). Hospital region distribution showed SLE + DAH patients were more likely to be admitted to hospitals in the South (50%) compared to AAV + DAH (27.3%). More SLE + DAH patients were admitted to large hospitals (87.5%) compared to AAV + DAH (60.1%) (Fig 1).

The mean LOS was 16.30 days for AAV + DAH and 15.87 days for SLE + DAH, with total charges for AAV + DAH higher at $273,083 compared to $233,180 for SLE + DAH. The mortality rate for AAV + DAH was 16.4%, compared to 12.5% for SLE + DAH ($p = 0.7671$). Logistic regression showed no significant difference in mortality between the two groups. (OR 0.73, $p = 0.7680$).

Conclusion: This study highlights the similarities and differences in the clinical characteristics, comorbidities, and healthcare burden of DAH secondary to AAV versus SLE. While both groups share significant morbidity and mortality, AAV + DAH patients were older, had more severe comorbidities, and incurred higher healthcare costs compared to SLE + DAH patients. Despite these differences, there was no significant difference in in-hospital mortality between the two groups, suggesting that the severity of DAH may not differ substantially based on the underlying disease. The findings underscore the need for further research to better understand the impact of DAH in these distinct patient populations.

Association of Lifestyle and Integrative Health Practices with Health-related Quality of Life in Women with Systemic Lupus Erythematosus and Connective Tissue Disease

Sarah Lieber[1], Yongjay Kim[2], Lucy Masto[3], Amaya Smole[4], Neha Nagpal[1], Ranqing Lan[1], Michael Parides[1], Caroline Siegel[1], Lisa Mandl[1], Michael Lockshin[5], Medha Barbhaiya[1] and Lisa Sammaritano[1], [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, Englewood Cliffs, NJ, [3]Hospital for Special Surgery, San Francisco, CA, [4]Hospital for Special Surgery, Brooklyn, NY, [5]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Although available evidence supports the benefits of lifestyle interventions in SLE, the prevalence of lifestyle and integrative health behaviors and their association with health-related quality of life (HRQoL) in real world practice are not well understood. We describe the association of physical activity (PA), diet, and integrative health behaviors with HRQoL in women with SLE and other connective tissue disease (CTD) at a single tertiary care musculoskeletal center.

Methods: We included women aged 18-65 years evaluated by a Hospital for Special Surgery rheumatologist ≥2 times who enrolled in the Rheumatology Women's Reproductive Health and Wellness Cohort from 12/2022-5/2024. The current cross-sectional analysis includes women with SLE and other CTD (identified by ≥2 ICD-10 codes ≥7 days apart) who shared

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

type and frequency of PA, dietary quality, and integrative health practices and responded to questions on HRQoL reflecting 4 domains (life satisfaction, life worthwhile, happiness, anxiety, each scored on a 0-10 scale, with 0 "not at all" and 10 "completely") from the United Kingdom Office for National Statistics. We performed descriptive analyses to summarize self-reported demographic and clinical characteristics, diet, PA, and integrative health practices. Logistic regression models were built using each of the 4 HRQoL domains (dichotomized) as outcomes, with lifestyle and integrative health behaviors as independent variables. Adjusted models controlled for age, race, ethnicity, and immunosuppressive medication use.

Results: Of 255 women (mean age 46.8 ±12.1 years), 180 (71%) reported exercising ≥1-3 times per week, and 105 (41%) rated their diet as very good or excellent; 166 (65%) participants were pursuing ≥1 integrative health practice at survey completion (Table 1). In unadjusted models, participants who reported never engaging in PA were less likely to report life satisfaction (odds ratio [OR] 0.18, 95% confidence interval [CI] 0.03-0.81] and happiness (OR 0.21, 95% CI 0.04-0.90) compared to those who exercised >3x/week while participants with a poor diet had lower odds of reporting life worthwhile (OR 0.17, 95% 0.03-0.94) and higher odds of reporting anxiety (OR 6.75, 95% 1.42, 39.68) compared to those with an excellent diet

Poor	0.39 (0.07-1.91)	0.15 (0.03-0.85)	0.77 (0.16-3.68)	8.19(1.62-51.18)
≥1 integrative health practice	0.97 (0.47-1.95)	0.95 (0.44-2.00)	1.08 (0.55-2.09)	1.39 (0.75-2.59)

[a]Dichotomized into high/very high (score 7-10) and medium/low (score 0-6) based on Office of National Health Statistics-4
[b]Dichotomized into high (score 4-10) and medium/low/very low (score 0-6) based on Office of National Health Statistics-4
*Adjusted for age, race, ethnicity, and immunosuppressive medication use

(Table 2). In adjusted models, participants who reported never engaging in PA were less likely to report life satisfaction (OR 0.19, 95% CI 0.03-0.90) and happiness (OR 0.20, 95% CI 0.04-0.88) compared to those who exercised >3x/week while participants with a poor diet had lower odds of reporting life worthwhile (OR 0.15, 95% 0.03-0.85) and higher odds of reporting anxiety (OR 8.19, 95% 1.62, 51.18) compared to those with an excellent diet (Table 3); any exercise was potentially associated with life worthwhile (high/very high versus medium/low).

Conclusion: In this sample, engagement in lifestyle and integrative health behaviors was common in SLE and other CTD. Lack of PA and poor diet were generally associated with decreased HRQoL. Interventional strategies promoting PA and healthy diet may improve wellbeing in this population alongside disease-directed therapies.

Background/Purpose: Sarcopenia, i.e., loss of skeletal muscle mass and strength, has been associated with multiple adverse health outcomes, including mortality. We have previously demonstrated associations of the SARC-F, a simple self-report screening tool for sarcopenia, with functional outcomes in adults with systemic lupus erythematosus (SLE). However, to our knowledge, whether the SARC-F is associated with objective measures of sarcopenia in patients with SLE has not been explored [1]. Accordingly, this study sought to assess the association of the SARC-F with dual energy x-ray absorptiometry (DXA)-based definitions of sarcopenia.

Table 3. Cross sectional association of SARC-F with objective sarcopenia definitions

Objective Sarcopenia Definition (N, %)	SARC-F*		p-value
	Sarcopenia (N=16)	No sarcopenia (N=40)

Methods: Women 18-70 years of age with validated SLE were enrolled in a single-center cross-sectional study. Sociodemographic characteristics, clinical features, and the SARC-F (which includes questions on strength, assistance walking, rising from a chair, climbing stairs, and falls) were self-reported or collected from the patient's electronic medical record. Disease activity and damage were provided by treating physicians. Sarcopenia was measured via DXA using 4 consensus definitions. Descriptive statistics were used to compare sociodemographic characteristics, clinical features, SLE disease severity, and objective measures of sarcopenia between participant groups. SARC-F scores were dichotomized as ≥4 (i.e., at risk for sarcopenia) versus < 4 (i.e., not at risk for sarcopenia) based on established cut points. Fisher's exact tests evaluated the relationship between the SARC-F and objective measures of sarcopenia.

Results: Of 57 participants, 16 (29%) were at risk for sarcopenia based on SARC-F score ≥4 (Table 1). Participants with SARC-F ≥4 were older (p=0.02) and had greater organ damage (p< 0.01) and slower gait speed (p< 0.01 to p=0.04) than those with SARC-F < 4 (Tables 1 and 2). Among 56 women who had DXA, there were no significant associations between the SARC-F and any of the 4 standard validated measures of objective sarcopenia (Table 3). The European Working Group on Sarcopenia in Older People definition had the highest specificity (data not shown).

Conclusion: In this exploratory study of adult women with SLE, very few participants had low muscle mass meeting DXA-based definitions of sarcopenia. In non-elderly women with SLE, DXA scores with a lower threshold for sarcopenia, without BMI adjustment (i.e., European Working Group on Sarcopenia in Older People definition), may preferentially identify those at risk for sarcopenia. Ongoing studies in larger cohorts are needed.

Table 1. Demographic and Clinical Characteristics of Study Cohort
Table shows sex, race, age, serum creatinine, and eGFR across five groups: lupus nephritis (LN, n=31), matched apparently healthy volunteers for LN (n=31), diabetic kidney disease (DKD, n=99), matched AHV for DKD (n=99), and the combined cohort (n=260). LN mainly affects younger females, while DKD affects older individuals with a balanced sex ratio. (Introduction)

Background/Purpose: Lupus nephritis (LN) and diabetic kidney disease (DKD) are leading causes of chronic kidney disease (CKD) that differ by age, sex, and underlying mechanisms. Both would benefit from earlier detection, but in both cases conventional markers such as serum creatinine or estimated glomerular filtration rate (eGFR) are insensitive for detection of early renal damage. We hypothesized that a panel of kidney-enriched cell type specific plasma proteins could provide earlier detection of LN and DKD and reflect disease-specific biological pathways.

Methods: Four kidney-specific biomarkers—uromodulin (UMOD), myo-inositol oxygenase (MIOX), heparanase (HPSE), and apoptosis-resistant E3 ubiquitin ligase 1 (AREL1)—were measured in plasma specimens from apparently healthy volunteers (AHV), patients with DKD, and patients with biopsy-confirmed LN. Cohorts included type 1 and type 2 diabetes CKD (combined n=99) and LN (n=31), with age and sex matched AHV controls (total n=130). Biomarker levels were quantified by ELISA. A multi-class logistic regression model was trained to classify AHV, DKD, and LN based on the four biomarkers. Performance was evaluated by area under the ROC curve (AUC) for each class (one-vs-rest), as well as confusion matrix and predicted probability distributions (Figure 1). Pathway enrichment (KEGG and Reactome) as well as protein–protein interaction (STRING) analyses were performed to interpret functional roles of the biomarkers. Data from PERL and FIND were provided by NIDDK CR, a program of the National Institute of Diabetes and Digestive and Kidney Diseases.

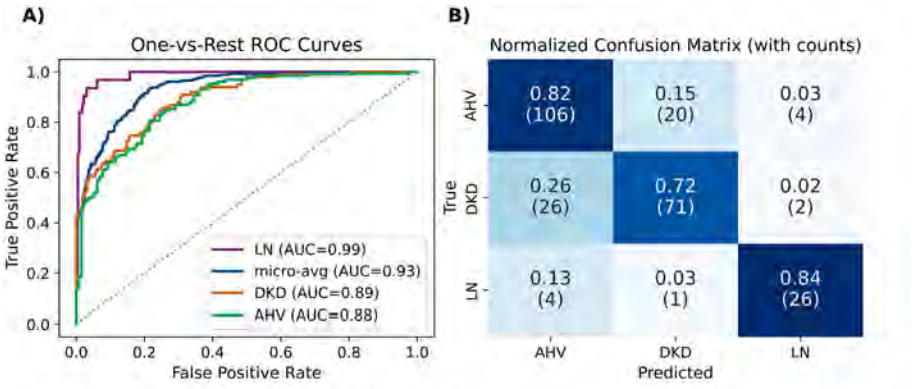

Figure 1. Multi-class Classification Performance of the Four-Biomarker Panel.
(A) One-vs-rest ROC curves illustrate the ability of a logistic regression model trained on UMOD, MIOX, HPSE, and AREL1 to distinguish among AHV, DKD, and LN groups. Class-wise AUCs demonstrate near-perfect discrimination for LN (AUC = 0.99), excellent performance for DKD (AUC = 0.89), and strong accuracy for AHV (AUC = 0.88). The micro-average AUC (AUC = 0.93), which aggregates true positives and false positives across all classes, reflects the overall model performance.
(B) Normalized confusion matrix with raw counts confirms high accuracy across all three classes. LN samples were correctly classified in 84% of cases, with minimal confusion between DKD and AHV. DKD was correctly predicted in 72% of cases, with most misclassifications being AHV. AHV samples were correctly identified 82% of the time.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

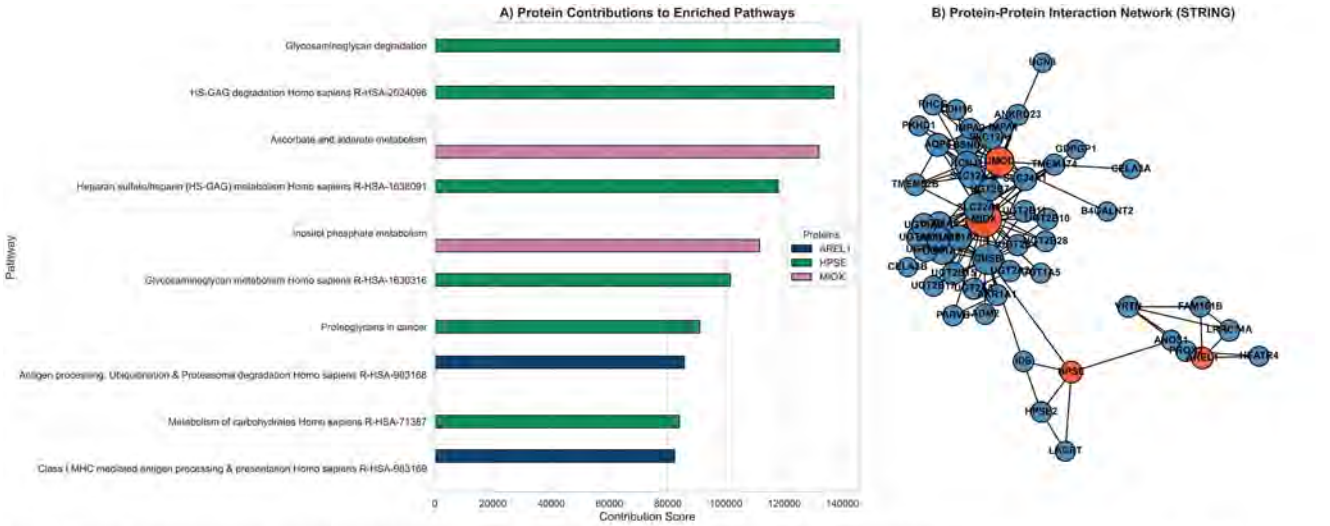

Figure 2. Distinct pathway enrichment and interaction networks for kidney biomarkers. (A) KEGG and Reactome pathway enrichment analysis for three of the biomarkers (HPSE, MIOX, AREL1) revealed unique, non-overlapping pathway associations (UMOD was not included due to absence of significant annotation in KEGG/Reactome databases). HPSE was enriched in glycosaminoglycan degradation and extracellular matrix (ECM) remodeling pathways; MIOX in inositol phosphate and ascorbate metabolism; and AREL1 in antigen processing (MHC class I-mediated) and proteasomal degradation pathways. (B) STRING protein–protein interaction (PPI) analysis showed that the biomarkers primarily clustered within distinct functional modules, with limited shared interactors between groups. UMOD and MIOX clustered with renal tubular transport proteins (including solute carriers, UDP-glucuronosyltransferases [UGTs], and aquaporin-6 [AQP6]); HPSE interacted with ECM components and lysosomal enzymes involved in glycosaminoglycan catabolism (e.g., iduronate 2-sulfatase [IDS], β-glucuronidase [GUSB]); and AREL1 associated with a protein degradation cluster, including ubiquitin pathway components (e.g., UBE2D1, UBC), consistent with its role in ubiquitin-mediated proteostasis. These distinct enrichment profiles and PPI clusters underscore each marker's distinct mechanistic role in kidney pathology, highlighting their complementary contributions to disease mechanisms.

Figure 2. Distinct pathway enrichment and interaction networks for kidney biomarkers

Results: LN patients had markedly lower UMOD and MIOX but higher HPSE and AREL1 compared to AHV and DKD ($p < 0.001$). DKD patients exhibited reduced HPSE and elevated MIOX relative to AHV. The panel yielded AUCs of 0.99 for LN, 0.89 for DKD, and 0.88 for AHV, indicating strong discriminatory performance across all three groups. Confusion matrix and probability plots confirmed minimal misclassification and clear separation between classes, underscoring the model's robustness. Notably, the biomarker panel vastly outperformed creatinine and eGFR in detecting LN. Pathway enrichment analysis linked HPSE to glycosaminoglycan metabolism (extracellular matrix remodeling), MIOX to inositol phosphate metabolism (tubular function), and AREL1 to MHC class I antigen processing and proteasomal degradation pathways (Figure 2, Panel A), consistent with its known role as an E3 ubiquitin ligase. Consistently, STRING network analysis showed UMOD and MIOX clustering in a renal tubular transport network, HPSE in an extracellular matrix network, and AREL1 in a protein degradation network, consistent with its role in ubiquitin-mediated proteostasis (Figure 2, Panel B).

Conclusion: A four-protein biomarker panel reliably detects early LN and DKD and differentiates between them, when compared to healthy states, providing both high diagnostic accuracy and insight into disease-specific mechanisms. Its strong performance—especially the near-perfect discrimination for LN (AUC = 0.99)—suggests this panel can greatly enhance early detection of lupus nephritis and diabetic kidney disease.

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease that disproportionately affects individuals of Amerindian ancestry and those who self-identify as Hispanic. The term "Hispanic" encompasses diverse populations, genetic backgrounds, and environments, making it challenging to understand the drivers of disease disparities. Since DNA methylation (DNAm) is shaped by genetic and environmental factors, it may help disentangle these influences. We aim to assess whether DNAm differs between genetically similar SLE individuals living in Peru and the U.S.

Methods: We utilized whole blood genotype and methylation data from SLE cohorts in the U.S. (n=1,671) and Peru (n=74). We used principal component analysis (PCA), including genetic data from the 1000 Genomes and Peruvian Genome Project, to identify genetically similar individuals.We selected individuals within 1.75 standard deviations of the Peruvian population centroid based on the first three principal components (PCs). DNAm was profiled using the Illumina EPIC v2.0 array. After quality control and normalization, 801,370 CpG sites were retained. We linearly modeled differential methylation by country (U.S. vs. Peru) using *limma*, adjusting for age, disease duration, estimated blood cell proportions, and genetic PCs 1–3. Pathway analyses was performed using missMethyl.

Results: We identified genetically similar Peruvian (n=64) and U.S. individuals (n=86). Results showed 13,736 CpG sites differentially methylated by country at a false discovery rate (q) < 0.05 (Figure 1). Of these, 870 CpGs had an average absolute methylation difference ≥3% between the two groups. The sites with the largest differences in methylation between U.S and

Peru SLE cases were located in genes involved in immune function (Table 1). In particular, a CpG site within *PSCA* had an average of 19% lower methylation in U.S. compared to Peruvian samples. This gene is linked to immune cell infiltration and may reflect cohort-specific differences in inflammatory regulation. Another CpG site within *NMI* had an average of 11% less methylation in U.S. samples. *NMI* enhances STAT-mediated transcription in response to cytokines such as IL-2 and IFN-γ, both critical to SLE pathogenesis. Additionally, a Cpg within *TXNIP* was 7% more methylated in Peruvian samples. *TXNIP* is a vitamin D–responsive gene involved in oxidative stress and immune signaling via JAK-STAT and PI3K/Akt pathways.

Conclusion: As an epigenetic mechanism shaped by genetic and environmental factors, DNAm offers insights into population-level disease variation. Our findings suggest that geographic context is associated with epigenetic variation in SLE when accounting for similar genetic ancestry. The most differentially methylated CpGs were in genes involved in immune regulation, pointing to geographically distinct immune responses potentially shaped by environmental exposures. Although the precise drivers are uncertain, these differences may reflect an interplay of social, cultural, and environmental factors. Understanding how these shape epigenetic patterns may offer new insights into SLE pathogenesis across populations.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease associated with an increased risk of chronic kidney disease (CKD), avascular necrosis (AVN), and mortality. Despite advancements in management, the contemporary prevalence and risk factors for these complications remain incompletely characterized. This study aimed to assess these outcomes within the context of modern SLE management.

Methods: We conducted a retrospective analysis of patients with SLE who received follow-up care at a tertiary referral center between April 2006 and February 2023. The prevalence and risk factors for lupus nephritis, progression to CKD stage 4 or 5, AVN, and all-cause mortality were evaluated using hazard ratios.

Results: Among 484 patients, lupus nephritis was observed in 26.2%, AVN in 4.8%, and CKD stage 4 or 5 in 2.9%, while the overall mortality rate was 2.5%. Lupus nephritis was more prevalent in patients diagnosed before age 20, whereas CKD progression and mortality were significantly higher in those with later-onset SLE. Hydroxychloroquine use was protective against CKD progression (HR 0.19, 95% CI 0.05–0.69, p = 0.012) and mortality (HR 0.14, 95% CI 0.031–0.66, p = 0.013). Methylprednisolone pulse therapy was associated with an increased risk of AVN (HR 6.10, 95% CI 2.42–15.35, p < 0.001).

Conclusion: Compared to historical cohorts, the prevalence of CKD stage 4 or 5, AVN, and mortality has declined in this cohort. Hydroxychloroquine improves outcomes by reducing CKD progression and mortality, while caution is warranted with methylprednisolone pulse therapy due to its association with AVN.

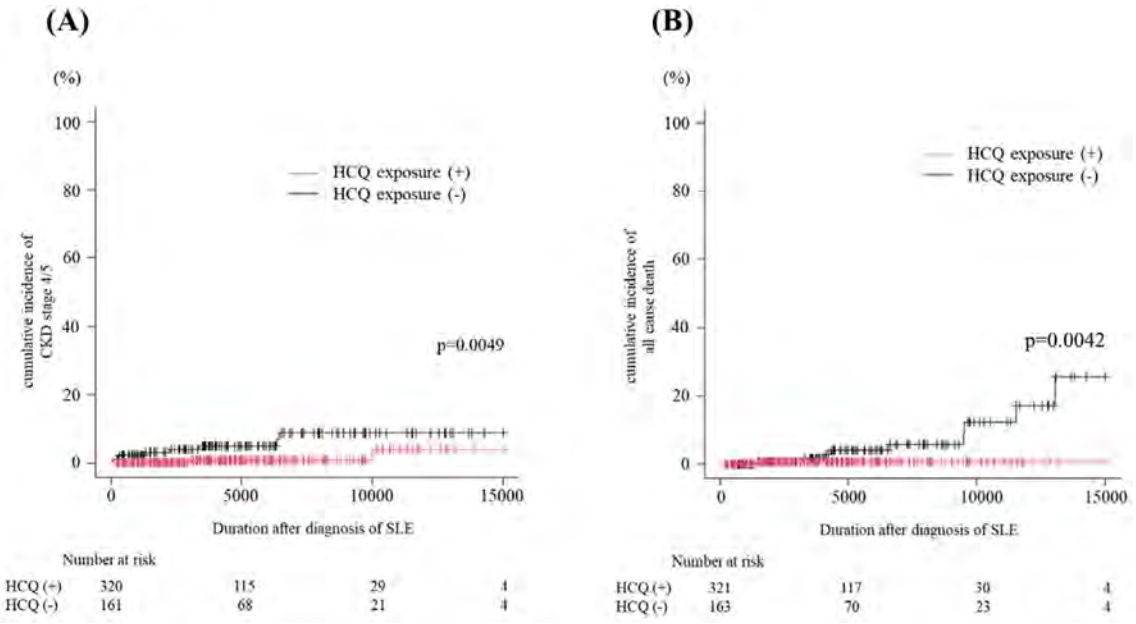

Figure 1 Hydroxychloroquine prescription and its impact on cumulative incidence of CKD stage 4 or 5 and all-cause mortality (A) Hydroxychloroquine prescription and its impact on cumulative incidence of CKD stage 4 or 5 (B) Hydroxychloroquine prescription and its impact on cumulative incidence of all-cause mortality

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Lupus nephritis (LN) is a serious complication of systemic lupus erythematosus (SLE) affecting to 40-60% of SLE. End-stage renal disease (ESRD) occurs in up to 10-20% of LN, occasionally requiring kidney transplantation (KT) **[1]**.

In a series of LN patients who underwent KT, our aim was to assess a) clinical and histological features, b) frequency of renal graft loss, and c) SLE and LN flares.

Methods: Multicenter study of all consecutive patients who underwent KT due to LN in 10 Spanish reference University hospitals between January 1980 and December 2023. Demographic, epidemiological, clinical, analytical and histological data on SLE and LN were collected. In addition, cases of graft loss and their causes, as well as LN flares, were recorded.

Results: We include 103 (80 women, 77.7%), patients; mean age of 38.6±17.1 years. When KT was performed, the main clinical manifestations were joint (n=54; 52.4%) and mucocutaneous involvement (n=44, 42.7%). The predominant histological diagnosis of LN was class IV (n= 47, 45.6%), followed by class III (n=12; 11.6%). The main general features are summarized in **TABLE 1**.

The subtypes of renal replacement therapy (RRT) used prior to KT were: hemodialysis (n=67, 65%), peritoneal dialysis (n=17, 16.5%), combined therapy (n=9, 8.7%) The median [IQR] time from initiation of RRT to KT was 3 years [1-5].

Age (mean± D, years)	38.6±17.1
Sex	
- Male, n (%)	23 (22.3%)
- Female, n (%)	80 (77.7%)
Cardiovascular Risk Factors	
- Arterial hypertension, n (%)	73 (70.3%)
- Dyslipidemia, n (%)	33 (32%)
- Diabetes mellitus, n (%)	9 (8.7%)
Heart disease, n (%)	25 (24.3%)
Histological Diagnosis	
- Class I, n (%)	1 (0.97%)
- Class II, n (%)	9 (8.7%)
- class III, n (%)	12 (11.6%)
- Class IV, n (%)	47 (45.6%)
- Class V, n (%)	4 (3.9%)
- Class IV-V, n (%)	3 (2.9%)
- Unclassifiable LN, n (%)	3 (2.9%)
- Unknown, n (%)	24 (23.3%)
Time from RRT to Kidney Transplantation, median [IQR]	3 years [1–5]

Peritoneal dialysis, n (%)	1 (0.9%)
Deceased, n (%)	14 (13.6%)
Unknown, n (%)	2 (1.9%)

TABLE 2. KIDNEY TRANSPLANT COMPLICATIONS AND EVOLUTION. Abbreviations: LN: Lupus Nephritis

The most frequently reported types of donations were brain death (n=45, 43.7%) and asystole (n=29, 28.2%).

Renal graft loss was observed in 31 (30.1%) patients. The most common causes were: acute rejection (n=11, 35.5%), chronic rejection (n=8, 25.8%), combined acute and chronic rejection (n=5, 16.2%), graft thrombosis (n=4, 12.9%) (**TABLE 2**).

In most patients, the graft remains functional (n= 65; 63%). A SLE flare was observed in 17 (13.1%) patients, with renal involvement in 6 (5.8%) cases. LN flare in the graft was the cause of organ loss in only 3 patients (9.7%).

Conclusion: Despite concerns about the recurrence of LN after KT, our results indicate that graft loss is lower in our cohort compared to other published series, and that LN recurrence in the graft is not a frequent cause of organ loss

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0593–0640) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

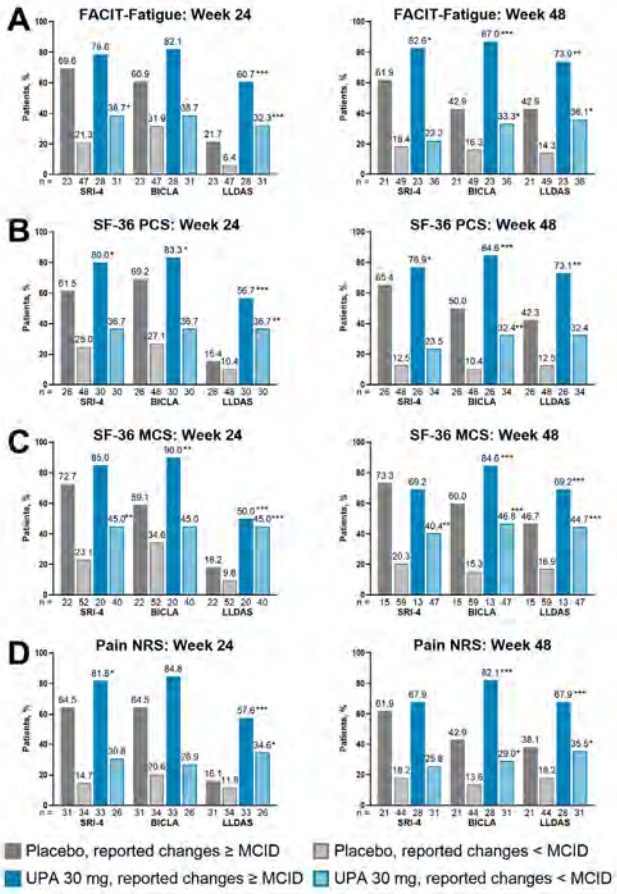
Background/Purpose: This analysis evaluated associations between clinically important improvements in patient-reported outcomes (PROs) and reduced disease activity from the phase 2 SLEek trial evaluating upadacitinib (UPA) vs placebo (PBO) in patients with systemic lupus erythematosus (SLE).

Methods: Data are reported for patients in SLEek who received UPA 30 mg monotherapy or PBO for 48 weeks. Assessments included achievement of British Isles Lupus Assessment Group-Based Composite Lupus Assessment (BICLA), Systemic Lupus Erythematosus Responder Index 4 (SRI-4), and Lupus Low Disease Activity State (LLDAS) responses among patients who reported or did not report minimum clinically important differences (MCID) in PROs at weeks 24 and 48. MCIDs were defined as: ≥ 4-point increase in Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue (in patients with FACIT-Fatigue ≤ 48 at baseline), ≥ 2.5-point increase in 36-Item Short-Form Health Survey Physical and Mental Component Summary scores, (SF-36 PCS and MCS scores; in patients with SF-36 PCS and MCS scores ≤ 97.5 at baseline), and ≥ 1-point reduction from baseline in Patient's Assessment of Pain Numerical Rating Scale (NRS). Between-group differences and P values were estimated using Cochran-Mantel-Haenszel test, adjusted for baseline corticosteroid dose, Systemic Lupus Erythematosus Disease Activity Index 2000 score at screening, baseline interferon score, and baseline immunosuppressant use.

Results: 137 patients were included in the analysis (UPA 30 mg, n = 62; placebo, n = 75); 90% were female and most were White. Mean baseline FACIT-Fatigue, SF-36 PCS, SF-36 MCS, and Pain NRS scores were 29.3, 40.3, 42.4, and 5.3 (PBO); and 27.1, 38.2, 43.7, and 7.1 (UPA). Among patients who reported changes ≥ MCID for fatigue, physical or mental function, or pain at week 48, a higher proportion achieved SRI-4, BICLA, and LLDAS responses with UPA vs PBO ($P < .05$ for most; Figure 1). Similar trends were observed at week 24 (Figure 1). SRI-4, BICLA, and LLDAS responses at weeks 24 and 48 were lower among patients who did not report clinically meaningful improvements in PROs; however, a higher proportion of these patients achieved SRI-4, BICLA, and LLDAS responses with UPA vs PBO. Of patients who received UPA and reported changes ≥ MCID for FACIT-Fatigue at week 48, over 80% achieved SRI-4 and BICLA responses, and approximately

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 1. Proportion of Patients Achieving SRI-4, BICLA, or LLDAS Responses With Upadacitinib vs Placebo Based on Changes in MCID for (A) FACIT-Fatigue, (B) SF-36 PCS Scores, (C) SF-36 MCS Scores, or (D) Pain NRS at Weeks 24 and 48 (NRI).



BICLA, British Isles Lupus Assessment Group-Based Composite Lupus Assessment; FACIT-Fatigue, Functional Assessment of Chronic Illness Therapy-Fatigue; LLDAS, Lupus Low Disease Activity State; MCID, minimal clinically important differences; NRI, nonresponder imputation; Pain NRS, Patient's Assessment of Pain Numerical Rating Scale; PRO, patient-reported outcome; SF-36 MCS, 36-Item Short-Form Health Survey Mental Component Summary; SF-36 PCS, 36-Item Short-Form Health Survey Physical Component Summary; SRI-4, Systemic Lupus Erythematosus Responder Index 4; UPA, upadacitinib.
After a planned interim analysis when 50% of the patients reached week 24 or withdrew from the study, the upadacitinib 15 mg/elsubrutinib 60 mg and elsubrutinib 60 mg monotherapy treatment arms were discontinued due to lack of efficacy with no safety concerns.
*P < .05; **P < .01; ***P < .001 vs placebo.

three-quarters achieved LLDAS (Figure 1A). In patients who received UPA and reported clinically meaningful changes in SF-36 PCS or MCS scores or Pain NRS at week 48, over 80% achieved BICLA, and SRI-4 and LLDAS were achieved by approximately three-quarters of patients who reported changes ≥ MCID for SF-36 PCS scores (Figure 1B) and approximately two-thirds of patients who reported changes ≥ MCID for SF-36 MCS scores (Figure 1C) and Pain NRS (Figure 1D).

Conclusion: Patients who reported changes ≥ MCID in PROs for fatigue, physical and mental function, and pain generally demonstrated higher SRI-4, BICLA, and LLDAS responses than those who did not. These findings demonstrate the strong association of PRO improvements with disease activity improvements in SLE and highlight the potential multifaceted benefits of UPA for patients with SLE.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0641–0670) Systemic Lupus Erythematosus – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Engineered T cells expressing a chimeric antigen receptor (CAR) binding CD19 are powerful tools to deplete B-cells, representing an attractive therapy for severe autoimmune diseases, such as systemic lupus erythematosus (SLE), idiopathic inflammatory myositis (IIM) and systemic sclerosis (SSc). Case reports and case series have supported the feasibility of CAR T-cell therapy in SLE, IIM and SSc showing preliminary safety and efficacy (1-3). Clinical data from phase I/II studies investigating the potential of CAR T-cell therapy in autoimmune disease are underway. Their results will provide further insights in the therapeutic role of CAR T-cells in these diseases.

Methods: CASTLE is a phase I/II basket study (Miltenyi Biomedicine, EudraCT-Nr.2022-001366-35) assessing the safety (primary endpoint) and efficacy (secondary endpoint) of $1x10^6$ autologous CD19 CAR T-cells (MB-CART19.1) /kg BW after lymphodepleting chemotherapy with Fludarabin/Cyclophosphamide in patients with SLE, IIM and SSc. Previous immunosuppressants/immunomodulatory therapies were stopped at the time of lymphodepletion. 8 patients were recruited in a first safety phase, followed by additional 16 patients in the second phase. Dose limiting toxicity (DLT) and consecutive stopping rules were grade 3/4 cytokine release syndrome (CRS), grade 3/4 immune cell-associated neurotoxicity syndrome (ICANS), clinically relevant neutropenia or thrombopenia lasting >4 weeks or grade 3/4 organ toxicity within 4 weeks after IMP-infusion. Efficacy was assessed by B-cell depletion and CAR T-cell expansion. Clinical responses were defined by DORIS

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. remission in SLE, ACR/EULAR Moderate or Major Response in IIM, and no progression of interstitial lung disease in SSc.

Results: In total, 28 patients were screened, 24 patients were enrolled (17 women, 7 men) with a median (IQR) age of 39 [26; 53] years. 10 patients had SLE, 9 SSc and 5 IIM with a median (IQR) number of 4 [3; 6] previous immunosuppressive treatments. 18/24 developed mild CRS (17 grade 1; 1 grade 2). No higher-grade CRS and no ICANS occurred. No clinically relevant neutropenia or thrombopenia >4 weeks were recorded. One grade 3 organ toxicity due to renal thrombotic microangiopathy in conjunction with CMV infection occured. Local immune effector cell-associated toxicity syndrome (LICATS (4)) was reported in 88% of patients with grade 1/2 in the vast majority of patients. Median (IQR) CAR T-cell expansion was 140 [82; 360] cell/microliter, median (IQR) time of CAR T-cell presence was 83 [56; 113] days. B-cells were depleted in all patients. Six-month efficacy data were available in 19/24 patients at data cut-off of May 12, 2025: All 7 SLE patients were in DORIS remission, all 8 SSc showed no disease progression and all 4 IIM patients met ACR/EULAR Moderate or Major Response. In addition, clinical responses were also observed in the residual 5 patients, in whom follow-up time was still less then 6 months. All 24 patients stopped any immunosuppressive medication.

Conclusion: The CASTLE study met its primary safety and secondary efficacy endpoint. The data confirm favorable safety and high efficacy of MB-CART19.1 in the setting of a controlled phase I/II study in patients with autoimmune disease.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0641–0670) Systemic Lupus Erythematosus – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: The newly published ACR guidelines recommend initiating triple therapy for all patients with proliferative lupus nephritis (LN). While belimumab (BEL) has demonstrated efficacy in clinical trials, real-world data on its early use in combination regimens remain limited.

We aimed to evaluate the effectiveness of triple therapy including BEL plus standard of care (SoC) initiated within 6 months of LN onset in achieving renal response and glucocorticoid tapering in a real-world multicenter cohort.

Methods: Retrospective multicenter study in Spain including patients with proliferative LN (ISN/RPS class III, IV, or mixed III/IV+V) treated with BEL-based triple therapy within 6 months of diagnosis.

Results: A total of 38 patients were included (78.9% female, mean age 38±14 years); 68.4% were Caucasian and 21.1% Hispanic. A history of previous LN episodes was present in 38.5% of patients.Histological classification included class III (n=11), class IV (n=20), and mixed III/IV+V (n=7); two had thrombotic microangiopathy. Mean activity and chronicity indices were 9.4±4.0 and 2.3±1.9, respectively. All patients had a minimum follow-up of 6 months, with a median follow-up of 25 months (IQR 14.5–41).

Induction therapy included intravenous methylprednisolone in 63.2%, with a mean initial oral prednisone dose of 35.7±17.9 mg/day. Most patients (76.3%) received MMF, while 23.7% were treated with cyclophosphamide. Maintenance therapy consisted of MMF in 94.7% of cases, with only two patients (5.3%) receiving azathioprine.

CRR was achieved in 60% within 12 months; 65.7% achieved a primary response and 72.2% a partial response (Figure 1). Proteinuria decreased from 3.0±2.9 g/day at baseline to 560±466 mg/day at 12 months; eGFR remained stable, with progressive improvement from 71.3±30.3 to 78.4±23.1 mL/min/1.73m^2 at 12 months and 80.9 at 24 months (Table 1).

Table 1. Evolution of renal parameters over time

Variable	Basal	3 Months	6 Months	12 Months	24 Months
Prednisone (mg/día)	35,7 ± 17,9	12,4 ± 8,4	6,0 ± 3,2	4,0 ± 3,7 (n=30)	3,6 ± 5,0 (n=16)
Creatinine (µmol/L)	126,6 ± 120,7	106,2 ± 108,2	98,7 ± 78,8	101,8 ± 105,8 (n=29)	100,1 ± 107,4 (n=19)
eGFR (ml/min/1.73 m^2)	71,3 ± 30,3	74,6 ± 23,5	75,6 ± 23,0	78,4 ± 23,1 (n=32)	80,9 ± 19,5 (n=21)
Proteinuria (mg/24h)	3 ± 2.9	1.408 ± 1.486	904 ± 1.153	560 ± 466 (n=33)	350 ± 462 (n=19)
Anti-dsDNA (IU)	478,8 ± 526,4	148,7 ± 161,3	148,4 ± 164,2	175,3 ± 227,0 (n=28)	105,1 ± 186,7 (n=18)

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Evolution of Renal Response Rates

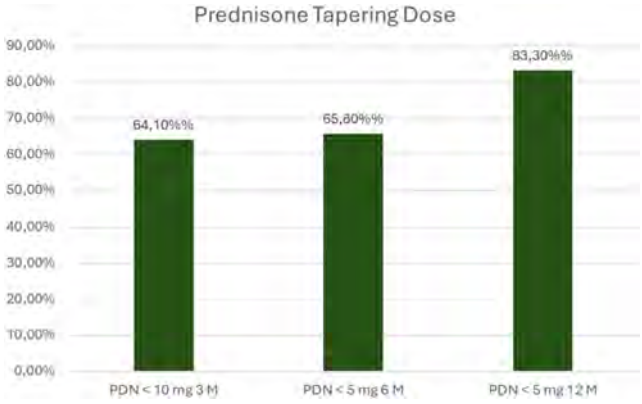

Figure 2. Proportion of Patients Achieving Glucocorticoid Tapering Targets

Regarding glucocorticoid tapering, the 2023 ACR recommendations propose a target of ≤5 mg/day of prednisone by month 6. In our cohort, 65.8% of patients achieved this goal, with a mean dose of 6.0±3.2 mg/day at 6 months. Mean prednisone dose declined from 35.7±17.9 mg/day at baseline to 4.0±3.7 mg/day at 12 months. By month 12, 83.3% of patients were receiving ≤5 mg/day (Figure 2). At 24 months, mean prednisone was 3.6±5.0 mg/day (Table 1).

Renal relapse occurred in 6 patients while on treatment with BEL (15.7%); BEL was discontinued in 2, while 4 continued BEL with intensified immunosuppression. Three patients experienced mild to moderate non-renal flares, managed with therapy adjustments (anifrolumab, methotrexate, or prednisone increase).

When comparing early initiation of BEL (< 3 months) versus delayed initiation (3–6 months post-flare), early use was associated with a significantly shorter time to achieve CRR (HR 4.7, 95% CI 1.6–13.5; p=0.04) and partial renal response (HR 2.47, 95% CI 1.1–5.8; p=0.037).

Conclusion: Initiation of triple therapy with BEL in proliferative LN was associated with robust renal responses and achievement of ACR steroid-sparing targets in most patients. Earlier treatment onset may further enhance renal outcomes

Session Title: (0641–0670) Systemic Lupus Erythematosus – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Table. Baseline demographics, disease characteristics, and PRO scores

	DZP+SOC n=208	PBO+SOC n=107
Age, years, mean (SD)	43.5 (12.3)	41.5 (12.4)
Female, n (%)	193 (92.8)	100 (93.5)
Time since first diagnosis of SLE, years, mean (SD)	10.1 (7.9)	9.8 (8.5)
SLEDAI-2K, mean (SD)	10.7 (3.5)	11.2 (3.4)
SLEDAI-2K ≥10, n (%)	140 (67.3)	79 (73.8)
Concomitant systemic glucocorticoids, n (%)	171 (82.2)	87 (81.3)
Glucocorticoid dose, mg/day, mean (SD)	7.9 (5.9)	9.6 (8.1)
Glucocorticoid dose >7.5 mg/day, n (%)	105 (50.5)	51 (47.7)
FACIT-Fatigue,[a] mean (SD)	28.5 (11.2)	27.7 (10.5)
FATIGUE-PRO,[b] mean (SD)		
Physical Fatigue	49.2 (22.7)	51.4 (23.0)
Mental and Cognitive Fatigue	35.2 (23.8)	38.2 (24.1)
Susceptibility to Fatigue	49.3 (24.1)	49.7 (23.4)
LAMDA,[c] mean (SD)		
Musculoskeletal pain	56.0 (23.1)	54.1 (25.5)
Morning stiffness	54.9 (26.2)	52.7 (26.1)

Full analysis set. Baseline was defined as the last available value before the first dose of the study drug. It was generally the value at Day 1 but if there were no available data at Day 1 then the screening visit data were used. [a] FACIT-Fatigue score range: 0–52, lower scores indicate greater fatigue and an increase in score over time reflects improvement; [b] FATIGUE-PRO score range: 0–100 calculated for each of the three scales, higher scores indicate greater fatigue and a decrease in score over time reflects improvement; [c] LAMDA is a composite musculoskeletal disease activity measure; VAS range: 0–100, higher scores indicate more musculoskeletal pain or morning stiffness and a decrease in score over time reflects improvement.

DZP: dapirolizumab pegol; FACIT: Functional Assessment of Chronic Illness Therapy; LAMDA: Lupus Arthritis and Musculoskeletal Disease Activity; PBO: placebo; PRO: patient-reported outcome; SD: standard deviation; SLE: systemic lupus erythematosus; SOC: standard of care; VAS: visual analogue scale.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Background/Purpose: Fatigue, musculoskeletal pain, and joint stiffness are common manifestations of SLE, presenting considerable treatment challenges, particularly in addressing chronic fatigue. Dapirolizumab pegol (DZP) is a novel CD40L inhibitor with broad modulatory effects on SLE immunopathology;[1,2] it consists of a polyethylene glycol (PEG)-conjugated antigen-binding fragment (Fab'), which lacks an Fc domain. In the phase 3 PHOENYCS GO trial (NCT04294667), the primary endpoint was met; DZP plus standard of care (DZP+SOC) resulted in significantly higher rates of BILAG-based Composite Lupus Assessment (BICLA) response vs placebo (PBO)+SOC at Week (Wk) 48.[3] We report the impact of DZP on patient (pt)-reported fatigue, musculoskeletal pain, and morning stiffness in PHOENYCS GO.

Full analysis set; MMRM. All p-values are nominal and were not controlled for multiplicity. The LS mean, difference between DZP+SOC and PBO+SOC, 95% CIs and p-values were computed using a MMRM.
CI: confidence interval; DZP: dapirolizumab pegol; FACIT: Functional Assessment of Chronic Illness Therapy; LS: least square; MMRM: mixed model for repeated measurements; PBO: placebo; PRO: patient-reported outcome; SOC: standard of care.

Figure 1. LS mean change from baseline in FACIT-Fatigue and FATIGUE-PRO scores by visit

Full analysis set; MMRM. All p-values are nominal and were not controlled for multiplicity. The LS mean, difference between DZP+SOC and PBO+SOC, 95% CIs and p-values were computed using a MMRM.
CI: confidence interval; DZP: dapirolizumab pegol; LAMDA: Lupus Arthritis and Musculoskeletal Disease Activity; LS: least square; MMRM: mixed model for repeated measurements; PBO: placebo; SOC: standard of care.

Figure 2. LS mean change from baseline in LAMDA musculoskeletal pain and morning stiffness scores by visit

Methods: PHOENYCS GO, a 48-wk, randomized, double-blind, PBO-controlled trial, included pts aged ≥16 years with moderate-to-severe, active SLE characterized by persistently active or frequently flaring/relapsing-remitting disease activity despite stable SOC medication (antimalarials, glucocorticoids and/or immunosuppressants). Pts were randomized 2:1 to intravenous DZP 24 mg/kg+SOC or PBO+SOC every 4 wks.

Fatigue was assessed using Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue and FATIGUE-PRO (which consists of three scales: Physical Fatigue, Mental and Cognitive Fatigue, and Susceptibility to Fatigue). Musculoskeletal pain and morning stiffness were evaluated using the visual analogue scales (VAS) from the Lupus Arthritis Musculoskeletal Disease Activity (LAMDA) instrument. The least square (LS) mean change from baseline is reported through Wk 48. For FACIT-Fatigue, the proportion of pts with an improvement ≥4 (minimal clinically important difference [MCID])[4] at Wk 48 is also reported.

Results: The study was completed on treatment through Wk 48 by 85.4% (182/213) of pts randomized to DZP+SOC and 79.6% (86/108) randomized to PBO+SOC. Baseline fatigue, musculoskeletal pain, and morning stiffness scores were comparable between the groups (full analysis set; DZP+SOC: n=208; PBO+SOC: n=107; **Table**).

Pts receiving DZP+SOC vs PBO+SOC demonstrated consistently larger LS mean changes from baseline to Wk 48 in FACIT-Fatigue and all three FATIGUE-PRO scores (nominal p< 0.05; **Figure 1**). A nominally significantly greater proportion of pts receiving DZP+SOC vs PBO+SOC achieved an improvement of ≥4 (MCID) in FACIT-Fatigue at Wk 48 (50.5% vs 35.5%; difference: 14.5 [95% CI: 3.0, 25.9]; nominal p=0.0131).

LS mean changes from baseline to Wk 48 in musculoskeletal pain and morning stiffness were also larger for pts receiving DZP+SOC vs PBO+SOC (nominal p< 0.05; **Figure 2**).

Conclusion: Improvements in fatigue, musculoskeletal pain, and morning stiffness were greater in pts treated with DZP +SOC vs PBO+SOC. Alongside the previously reported improvements in clinical measures of SLE disease activity,[3] these data suggest that DZP improves core pt-reported symptoms in SLE.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0641–0670) Systemic Lupus Erythematosus – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Dapirolizumab pegol (DZP) is a novel CD40L inhibitor with broad modulatory effects on SLE immunopathology;[1,2] it consists of a polyethylene glycol (PEG)-conjugated antigen-binding fragment (Fab'), which lacks an Fc domain. In the phase 3 PHOENYCS GO trial (NCT04294667), the primary endpoint was met; DZP plus standard of care (DZP+SOC) resulted in significantly higher rates of BILAG-based Composite Lupus Assessment (BICLA) response vs placebo (PBO)+SOC at Week (Wk) 48.[3] Remission (based on Definition of Remission in SLE [DORIS]) and low disease activity (based on Lupus Low Disease Activity State [LLDAS]) are recommended treatment targets in SLE,[4] and achievement of both DORIS and LLDAS are associated with reduced organ damage accrual and improved outcomes in patients (pts).[5,6] We report achievement of LLDAS and DORIS in pts with SLE treated with DZP in PHOENYCS GO.

Methods: PHOENYCS GO, a 48-wk, randomized, double-blind, PBO-controlled trial, included pts aged ≥16 years with moderate-to-severe, active SLE characterized by persistently active or frequently flaring/relapsing-remitting disease activity

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

despite stable SOC medication (antimalarials, glucocorticoids and/or immunosuppressants). Pts were randomized 2:1 to intravenous DZP 24 mg/kg+SOC or PBO+SOC every 4 wks.

Achievement of LLDAS in ≥50% of visits through Wk 48, achievement of LLDAS by visit, cumulative number of visits in LLDAS through Wk 48, and achievement of DORIS[7] by visit are reported.

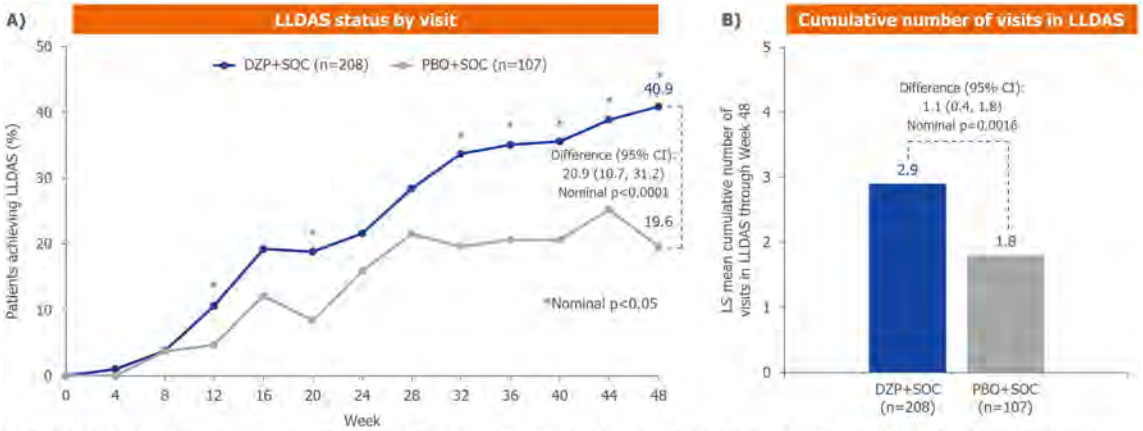
Results: The study was completed on treatment through Wk 48 by 85.4% (182/213) of pts randomized to DZP+SOC and 79.6% (86/108) randomized to PBO+SOC. Baseline characteristics were comparable between the groups (full analysis set; DZP+SOC: n=208; PBO+SOC: n=107; **Table**).

Through 48 wks, 23.6% of pts receiving DZP+SOC achieved LLDAS in ≥50% of visits vs 15.9% receiving PBO+SOC (nominal p=0.1042). At Wk 48, 40.9% of pts receiving DZP+SOC achieved LLDAS vs 19.6% receiving PBO+SOC (nominal p< 0.0001; **Figure 1**). As early as Wk 12, greater proportions of pts receiving DZP+SOC achieved LLDAS vs PBO+SOC (nominal p< 0.05). The proportion of DZP+SOC LLDAS-responders continued to rise to Wk 48, while in PBO+SOC pts, achievement of LLDAS plateaued from Wk 28. The least square mean (SE) cumulative number of visits in LLDAS through Wk 48 was greater in pts receiving DZP+SOC (2.9 [0.2]) vs PBO+SOC (1.8 [0.3]; nominal p=0.0016; **Figure 1**).

Table. Baseline demographics and disease characteristics

	DZP+SOC n=208	PBO+SOC n=107
Age, years, mean (SD)	43.5 (12.3)	41.5 (12.4)
Female, n (%)	193 (92.8)	100 (93.5)
Time since first diagnosis of SLE, years, mean (SD)	10.1 (7.9)	9.8 (8.5)
SLEDAI-2K, mean (SD)	10.7 (3.5)	11.2 (3.4)
SLEDAI-2K ≥10, n (%)	140 (67.3)	79 (73.8)
PGA, mean (SD)	58.9 (14.1)	59.7 (14.1)
Concomitant systemic glucocorticoids, n (%)	171 (82.2)	87 (81.3)
Glucocorticoid dose, mg/day, mean (SD)	7.9 (5.9)	9.6 (8.1)
Glucocorticoid dose >7.5 mg/day, n (%)	105 (50.5)	51 (47.7)

Full analysis set.
DZP: dapirolizumab pegol; PBO: placebo; PGA: Physician's Global Assessment; SD: standard deviation; SLE: systemic lupus erythematosus; SLEDAI-2K: SLE Disease Activity Index-2K; SOC: standard of care.

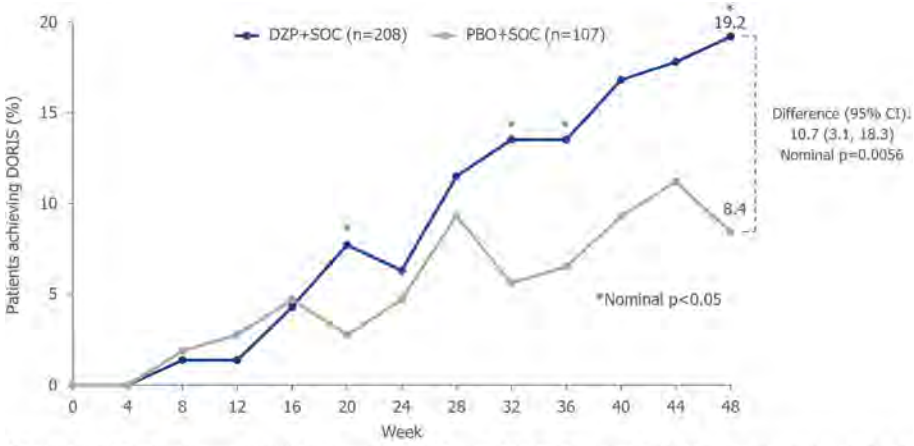


Full analysis set; NRI. All p-values are nominal and were not controlled for multiplicity. LLDAS requires all of the following criteria to be met: SLEDAI-2K score ≤4 with no activity in major organ systems (renal, CNS, cardiopulmonary, vasculitis, fever); no new and/or worsening disease activity defined as no SLEDAI-2K component documented as present that was not documented present at previous visit; PGA ≤33 mm; prednisone equivalent systemic dose ≤7.5 mg/day at >50% of the last 28 days and ≤7.5 mg/day at all days in the 7 days before a visit, at the day of the visit and at the day after the visit; stable standard maintenance doses of immunosuppressive drugs. (A) Differences in proportions between DZP+SOC and PBO+SOC, 95% CIs and p-values were estimated and tested using the CMH risk difference estimate controlling for stratification factors. (B) The LS means, difference between DZP+SOC and PBO+SOC, 95% CIs and p-values were estimated using ANCOVA including stratification factors.

ANCOVA: analysis of covariance; CI: confidence interval; CMH: Cochran-Mantel-Haenszel; CNS: central nervous system; DZP: dapirolizumab pegol; LLDAS: Low Lupus Disease Activity State; LS: least square; NRI: non-responder imputation; PBO: placebo; PGA: Physician Global Assessment; SLE: systemic lupus erythematosus; SLEDAI-2K: Systemic Lupus Erythematosus Disease Activity Index-2K; SOC: standard of care.

Figure 1. (A) Achievement of LLDAS by visit and (B) cumulative number of visits in LLDAS through Week 48

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Full analysis set; NRI. All p-values are nominal and were not controlled for multiplicity. DORIS requires all of the following criteria to be met: clinical SLEDAI-2K score of 0 (SLEDAI-2K without serology: anti-dsDNA and C3/C4 items); PGA ≤16 mm; prednisone equivalent systemic dose ≤5 mg/day at >50% of the last 28 days and ≤5 mg/day at all days in the 7 days before a visit, at the day of the visit and at the day after the visit. Differences in proportions between DZP+SOC and PBO+SOC, 95% CIs and p-values were estimated and tested using the CMH risk difference estimate controlling for stratification factors.

Anti-dsDNA: anti-double stranded DNA; CI: confidence interval; C3: complement C3; C4: complement C4; CMH: Cochran-Mantel-Haenszel; DORIS: Definition of Remission in SLE; DZP: dapirolizumab pegol; NRI: non-responder imputation; PBO: placebo; PGA: Physician Global Assessment; SLE: systemic lupus erythematosus; SLEDAI-2K: Systemic Lupus Erythematosus Disease Activity Index-2K; SOC: standard of care.

Figure 2. Achievement of DORIS by visit

A higher proportion of pts receiving DZP+SOC vs PBO+SOC achieved DORIS at Wk 48 (19.2% vs 8.4%; nominal p=0.0056), as well as at Wks 20, 32, and 36 (nominal p< 0.05; **Figure 2**).

Conclusion: Treatment with DZP+SOC resulted in higher rates of achievement and time in the prognostically important endpoints of LLDAS and DORIS vs PBO+SOC. These findings provide further insights into the potential benefits of treatment with DZP for pts with SLE.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0641–0670) Systemic Lupus Erythematosus – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Immune reset of autoimmune disease has been proposed to be a potential benefit of T cell engagers (TCEs) and CD19 CAR T therapy. A-319, a highly potent TCE, can deplete CD19+ B cells in patients (pts) with hematological malignancies. We evaluated the safety profile of A-319 in systemic lupus erythematosus (SLE) pts and explored if A-319 has the potential to reset autoimmunity in a dose-finding clinical study.

Methods: Twelve pts were enrolled in the study with baseline characteristics shown in Table 1. In week (W) 1, pts received A-319 at 0.05μg/kg/day(D), on D1, 3 and 5 by 24hr IV infusion. In W2-4, pts received A-319 at 0.3 (cohort 1, n=6), or 0.6 (cohort 2, n=3) or 1.2μg/kg/day (cohort 3, n=3), on D1, 3 and 5 by 6hr IV infusion. Safety, pharmacokinetics (PK) and pharmacodynamics (PD) parameters including peripheral blood (PB) B cell counts, autoantibodies, and other disease-related biomarkers and efficacy are evaluated for up to 1 year. The study, approved by the local hospital IRB, was registered as NCT06400537.

Table 1. Baseline characteristics

Characteristic	Total (n=12)	Characteristic	Total (n=12)
Age, years		Autoantibodies present	
Mean (SD)	35.9 (10.2)	ANA (≥ 1: 100), n (%)	12 (100)
Median (Min; Max)	38 (21; 54)	dsDNA, n (%)	7 (58)
Female sex, n (%)	12 (100)	Sm, n (%)	5 (42)

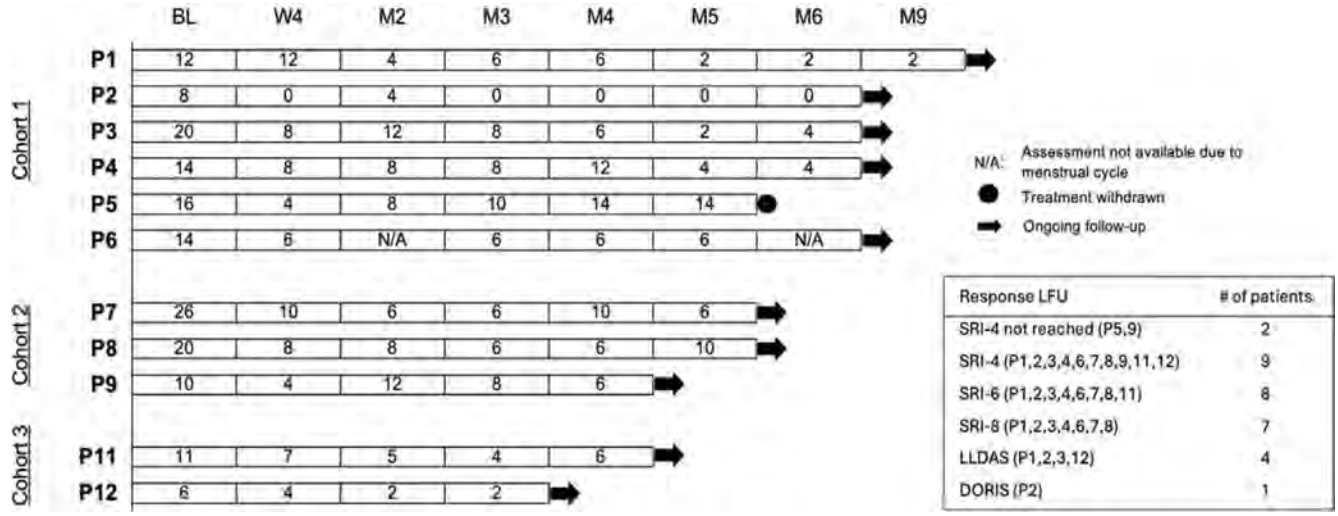
Table 2. Safety summary

Variable	Cohort 1 (n=6), n	Cohort 2 (n=3), n	Cohort 3 (n=3), n	Total (n=12), n (%)
Patients with any AE	6	3	3	12 (100)
Patients with any serious AE	0	0	0	0 (0)
AE leading to withdrawal	0	0	1	1 (8)
AE leading to dose interruption	0	0	1	1 (8)
Deaths	0	0	0	0 (0)
CRS	6	3	3	12 (100)
Grade 1	6	2	3	11 (92)
Grade 2	0	1	0	1 (8)
Grade ≥3	0	0	0	0 (0)
ICANs (any grade)	0	0	0	0 (0)
Infection (any grade)	2	0	1	3 (25)
Lymphopenia (any grade)	6	3	3	12 (100)
Anemia	5	3	2	10 (83)
Grade 1	3	1	0	4 (33)
Grade 2	2	2	0	4 (33)
Grade ≥3	0	0	2	2 (17)
Leukopenia (any grade)	1	0	2	3 (25)
Neutropenia (any grade)	1	1	0	2 (17)
Hypogammaglobulinemia	0	0	0	0 (0)

AE, adverse event; CRS, cytokine release syndrome; ICANS, immune effector cell-associated neurotoxicity syndrome.



Response LFU	# of patients
SRI-4 not reached (P5,9)	2
SRI-4 (P1,2,3,4,6,7,8,9,11,12)	9
SRI-6 (P1,2,3,4,6,7,8,11)	8
SRI-8 (P1,2,3,4,6,7,8)	7
LLDAS (P1,2,3,12)	4
DORIS (P2)	1

Figure 1. Clinical response (SLEDAI-2K score)

Results: Safety summary is listed in Table 2. No Grade ≥3 cytokine release syndrome (CRS), immune effector cell-associated neurotoxicity syndrome (ICANs), or hypogammaglobulinemia were reported. One case of Grade 2 CRS was reported and resolved within 12hr without tocilizumab. One pt (P10) in Cohort 3 withdrew on D10 due to renal complications. One pt (P5) in Cohort 1 withdrew from the study at Month(M) 5 due to disease rebound.

Dose-dependent peripheral blood B cell depletion was demonstrated. Cohort 1 achieved incomplete B cell depletion with 10±9% remaining at W4. However, B cell counts in Cohorts 2 and 3 were at 0.0 cell/uL at W4 and W2-W6, respectively. B cell recovery observed at ~W6 and M2, except for pts 9 and 11. The B cell subtype analysis and single cell sequence results demonstrated significantly different profiles at baseline, end of dosing and follow-up. Disease-related biomarker changes including autoantibody reduction (e.g., anti-ANA, dsDNA, Sm, SS-A, SS-B, ribosomal P protein, chromatin, Scl-70, Ro-52), normalization of complement levels (C3 and C4), and reduction of 24hr proteinuria, were also observed.

The preliminary efficacy (Figure 1) at the last follow-up (LFU, 9 to 3 months) visit showed reduced SLEDAI-2K scores with the achievement of SRI-4 (n=9), SRI-6 (n=8), SRI-8 (n=7), LLDAS (n=4), and DORIS (n=1). Seven pts had reductions in 24hr total urine protein (Utp) levels. Four of 7 pts with baseline Utp ≥0.5 g/24hr achieved levels < 0.5 g/24hr by M6 (3 in Cohort 1, 1 in Cohort 2). All pts reduced glucocorticoid (GC) dose below baseline levels. At the LFU, 8 pts reduced to < =7.5 mg/day,

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. including 6 pts further reduced to < =5 mg/day. Disease rebound in P5 corelated with incomplete B cell depletion and auto-antibody level rebound.

Conclusion: A-319 was well tolerated and demonstrated efficacy even at a (low) dose associated with incomplete B cell depletion. These results suggest that A-319 could potentially reset autoimmunity in refractory SLE patients to achieve remission.

anti-cd19 Chimeric Antigen Receptor T Cell Therapy for Refractory Systemic Lupus Erythematosus: An Open-label Pilot Study

Jinxia Zhao, Xiaoying Zhang, Xinyi Li, Hui Wei, Rui Liu, Lin Sun, Zhaohua Li, Wei Guo and **Rong Mu**, Peking University Third Hospital, Beijing, China (People's Republic)

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0641–0670) Systemic Lupus Erythematosus – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: This pilot study aims to evaluate the preliminary efficacy and safety of autologous anti-CD19 chimeric antigen receptor T cell (CAR T) named IM19 therapy in patients with refractory systemic lupus erythematosus (SLE).

Methods: Six patients with refractory SLE (three women and three men) with a median (range) age of 37 (19 to 43) years, median (range) disease duration of 9.5 (3 to 14) years were enrolled in the study. All met the 2019 EULAR/ACR classification

the patients after lymphodepletion with fludarabine and cyclophosphamide. Preliminary efficacy was assessed by the changes of SLEDAI-2K at 3 months after CAR T cell therapy. Safety was assessed by recording cytokine-release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) during the first 28 days. The study was registered at ClinicalTrials.gov (NCT06513429).

Results: The demographic and clinical characteristics of the patient at baseline are summarized in Table 1. The median (range) follow-up was 5.5 (4 to 7) months. The CAR T cells expanded significantly (median peak CAR+ T cells: 188.1cells/μL at median day 8.5 (range 7-11))(Fig.1 a). Complete circulating B-cell depletion (CD19+ B cells< 5 cells/μL) was achieved in 5/6 patients by day 1 post-infusion and in all patients by day 4 (Fig.1 b). The median SLEDAI-2K score demonstrated a significant reduction from 12 (range, 10 to 24) to 5.5 (range, 4 to 13) at 1 month, with a further decline to 5.0 (range, 2 to 10) by the 3-month follow up (Fig.2 a). During the observation period, complete renal remission was achieved in 2 patients, with partial remission observed in 1 patient. The remaining 3 patients exhibited persistent proteinuria with no significant improvement throughout the follow-up period (Fig.2 b). Anti-dsDNA antibodies converted to negative in 3 patients (Fig.2 c) and the complement returned to normal levels in all the patients within 2 months after CAR T cell administration (Fig.2 d). IM19 CAR T cell therapy was well tolerant with grade 1 CRS in 4 patients. No ICANS occurred in the study.

Conclusion: IM19 CAR T cell therapy demonstrated an acceptable safety profile and induced profound circulating B-cell depletion in refractory SLE, which correlated with accelerated serological normalization and clinically meaningful reductions in disease activity. Notably, the study revealed renal response in 50% of participants with refractory lupus nephritis, indicating a selective rather than universal therapeutic effect. These findings underscore the necessity of future large-scale trials with prolonged follow-up durations to evaluate the durability of therapeutic effects and safety profiles of this innovative cellular therapy.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0641–0670) Systemic Lupus Erythematosus – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by multiorgan organ damage, and early mortality. Anifrolumab (ANI), a human monoclonal antibody targeting the type I interferon receptor, is approved for the treatment of moderate to severe SLE. However, its efficacy and safety profile for cutaneous lupus erythematosus (CLE) is limited. Our aim was to assess the efficacy and safety of ANI in subgroups of SLE and CLE.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Patients with SLE were identified from each hospital's electronic database between April 2015 and April 2025 in five centers after receiving IRB approval. Those aged >18 years who were receiving ANI every 4 weeks were included in the study. These patients were categorized into four subgroups: Total cohort, SLE only, SLE and CLE, and CLE (subacute and chronic) only. Data collected encompassed sociodemographic details, clinical features, SLE organ involvement, laboratory findings, previous and current medications along with their adverse effect profiles, and disease activity indices. Serial

Changes in disease activity scores and levels over a 12-month period on anifrolumab.

measurements of C3, C4, dsDNA, SLEDAI-2k, CLASI-A, and CLASI-D, as well as adverse effects related to ANI, were tracked over a 12-month period. Descriptive statistics were used for data analysis.

Results: The total cohort (n = 63) was predominantly female (88.9%) and of Arab ethnicity (66.7%) with a mean SLE disease duration of 87.3 ± 87.8 months. Mucocutaneous involvement was the most common disease manifestation (74.6%), followed by musculoskeletal (73%) and hematological (61.9%) domains. The mean age at ANI initiation was 37.9 ± 11 years and the mean duration on ANI was 9.7 ± 5.7 months. The most reported adverse event reported was upper respiratory tract infection (URTI) (12.7%), with one patient report of both URTI and gastroenteritis (**Table 1**). The SLE subgroup had the longest disease duration at 100.3 ± 89.9 months and had the highest previous use of prednisolone (87.5%) and the highest prevalence of adverse effects from prior therapy (37.5%). The SLE and CLE subgroup commonly had mucocutaneous (100%) and musculoskeletal involvement (76.2%), with a higher anti-Sm (59.5%) and SSA positivity (61.9%) compared to the SLE only group. They received immunosuppressive agents such as MMF (38.1%) and belimumab (30.9%). Mean duration on anifrolumab was 7.6 ± 5.5 months and 14.3% reported URTI as an adverse event. The CLE subgroup consisted mainly of females (80%). Organ involvement was limited to the skin, with chronic cutaneous lupus being most common (80%), followed by subacute cutaneous lupus (20%). Serologies were less frequently positive. Prior immunosuppressive use was limited. The mean age of ANI initiation was 32 ± 9.8 years and remained on ANI for 9.8 ± 5.5 months with no adverse events reported. Over the 12-month follow up, disease activity scores and laboratory investigations across all subgroups showed numerical improvement (**Figure 1**).

Conclusion: Anifrolumab demonstrated a favorable safety and tolerability profile across both SLE and CLE in a multicenter setting. These findings support the expansion of the role of ANI in CLE and highlight the need for further studies to understand its utility across the lupus spectrum.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0641–0670) Systemic Lupus Erythematosus – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Belimumab, a B-cell modulator monoclonal antibody that selectively inhibits BLyS and reduces autoreactive B-cells that drive lupus disease activity, has consistently demonstrated improved efficacy compared with standard therapy alone, across diverse groups of adults and children with systemic lupus erythematosus (SLE). This 2-year, large, ambi-directional, observational cohort study (RELIABLE; funding: GSK214958) conducted across China aimed to assess the real-world effectiveness of belimumab.

Methods: Eligible patients were adults with SLE who were newly prescribed belimumab within 6 months and had ≥1 available assessment of all components for the Lupus Low Disease Activity State (LLDAS) within 3 months before belimumab initiation (index). Patients were followed up retrospectively (up to 6 months after index) and/or prospectively for a total maximum of 24 months. The primary outcome was proportions of patients achieving LLDAS at 12 and 24 months after index. The results for this interim analysis which was conducted after all patients completed baseline visits are reported here, focusing on LLDAS.

Results: From July 08, 2023, to September 29, 2024, 400 patients were enrolled (female, 366 [91.5%]). Mean (standard deviation [SD]) age was 31.0 (12.7) years at SLE diagnosis and 36.3 (12.5) years at index, with a mean gap of 63.7 (SD, 76.2) months (**Table 1**). At baseline, 273 (68.3%) patients had a SLICC/ACR Damage Index (SDI) of 0, 156 (39.0%) received ≤1 prior immunosuppressant, 274 (68.5%) received oral steroid ≥7.5 mg/d, 6 (1.5%) had a disease duration of < 2 years, and mean SLEDAI-2K score was 10.2 (SD, 5.9). By data cut-off (October 31, 2024), 76 (19.0%) patients completed a 12-month follow-up and 22 (5.5%) withdrew. Thirty-eight (9.5%) patients received belimumab consecutively for ≥12 months

Table 1. Demographics and Baseline Characteristics

Characteristics	Patients (N=400)
Female, n (%)	366 (91.5)
Mean (SD) age at diagnosis, years	31.0 (12.7)
Mean (SD) age at belimumab initiation, years	36.3 (12.5)
Mean (SD) time since first SLE diagnosis, months	63.7 (76.2)
SDI=0, n (%)	273 (68.3)
Disease duration <2 years, n (%)	6 (1.5)
≤1 prior immunosuppressant, n (%)	156 (39.0)
Oral concomitant steroid ≥7.5 mg/d, n (%)	274 (68.5)
Mean (SD) SLEDAI-2K score	10.2 (5.9)
Employed, n (%)	176 (44.0)
Recorded medical history, n (%)	
Lupus nephritis	151 (37.8)
Anemia	73 (18.3)
Leukopenia	22 (5.5)
Thrombocytopenia	21 (5.3)

Abbreviations: SD, standard deviation; SDI, SLICC/ACR Damage Index; SLE, systemic lupus erythematosus; SLEDAI-2K, Systemic Lupus Erythematosus Disease Activity Index 2000; SLICC/ACR, Systemic Lupus International Collaborating Clinics/American College of Rheumatology.

Table 2. Summary of Efficacy Results

Efficacy measure	n (%, [95% CI*])
LLDAS attainment	
Baseline (N=394)	34 (8.6, [6.1, 11.9])
Month 3 (N=269)	50 (18.6, [14.1, 23.8])
Month 6 (N=182)	66 (36.3, [29.3, 43.7])
SLEDAI-2K: a reduction of ≥4 points from baseline	
Month 3 (N=142)	138 (97.2, [92.9, 99.2])
Month 6 (N=109)	105 (96.3, [90.9, 99.0])
FACIT-F: total score >34 (i.e. no significant fatigue)	
Baseline (N=177)	129 (72.9)
Month 3 (N=270)	212 (78.5)
Month 6 (N=213)	183 (85.9)
High† anti-dsDNA antibodies	
Baseline (N=359)	233 (64.9)
Month 3 (N=244)	113 (46.3)
Month 6 (N=160)	71 (44.4)
Low† C3	
Baseline (N=375)	271 (72.3)
Month 3 (N=307)	122 (39.7)
Month 6 (N=200)	66 (33.0)
Low† C4	
Baseline (N=374)	187 (50.0)
Month 3 (N=307)	62 (20.2)
Month 6 (N=201)	24 (11.9)

Note: *95% CIs were estimated using the Clopper-Pearson method. †Based on investigator assessment. **Abbreviations**: CI, confidence interval; FACIT-F, Functional Assessment of Chronic Illness Therapy-Fatigue; LLDAS, Lupus Low Disease Activity State; SD, standard deviation; SLEDAI-2K, Systemic Lupus Erythematosus Disease Activity Index 2000.

and 249 (62.3%) had a proportion of days covered of ≥0.8. The proportion of patients achieving LLDAS progressively increased from 8.6% (34/394) at baseline (treatment initiation) to 18.6% (50/269) at Month 3 and 36.3% (66/182) at Month 6 following belimumab initiation. At Month 3, 97.2% (138/142) of patients achieved a reduction of ≥4 points in SLEDAI-2K from baseline; this trend continued at Month 6 with a proportion of 96.3% (105/109). The proportion of patients without significant fatigue, i.e., scoring >34 on the Functional Assessment of Chronic Illness Therapy-Fatigue scale (FACIT-F), rose from 72.9% (129/177) at baseline to 78.5% (212/270) at Month 3 and 85.9% (183/213) at Month 6. Improvements in biomarkers were observed after belimumab initiation (**Table 2**).

Conclusion: The interim results of RELIABLE demonstrated that belimumab reduces disease activity, evidenced by increased rates of LLDAS attainment, along with improved biomarkers and patient-reported outcomes, within 6 months after belimumab initiation among Chinese SLE patients from real-world settings. These findings are clinically important due to the large and diverse patient population from 14 sites across China. Long-term follow-up is expected to further demonstrate enhanced clinical outcomes and improved quality of life following belimumab initiation and to enrich the clinical, real-world, and long-term evidence for belimumab in China.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0641–0670) Systemic Lupus Erythematosus – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: The Phase III REGENCY study (NCT04221477) demonstrated superiority of obinutuzumab (OBI) over placebo (PBO) in achieving complete renal response (CRR) at Week 76 when added to standard therapy (ST) of mycophenolate mofetil (MMF) plus glucocorticoids in patients with active lupus nephritis (LN).

Improvement or stabilization of kidney function and improvement of proteinuria are commonly included in the definitions of complete response in recent LN clinical studies, but there is no standardized definition of the CRR endpoint.

In these post hoc analyses, we evaluated i) the effect of OBI+ST vs PBO+ST across different renal response definitions used in recent studies, ii) the efficacy of OBI+ST vs PBO+ST on each component included in the REGENCY CRR definition, and iii) the oral prednisone intake over time between the two treatment groups.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: REGENCY, BLISS-LN and AURORA-1 renal response endpoint definitions were used for analysis of the REGENCY dataset at Week 76. Endpoint measure definitions are in **Table 1**. The Cochran–Mantel–Haenszel test statistic stratified by the IxRS stratification factors, region and race, was used for the two treatment comparisons. All patients met ACR criteria for SLE and had biopsy-proven active LN. As part of ST, all patients received oral prednisone (or equivalent) and followed a standardized tapering schedule to achieve a target dose of 5 mg/day (or equivalent) by study Week 24.

Results: In the OBI+ST (n=135) and PBO+ST groups (n=136), respectively, 46.4% and 33.1% of patients achieved CRR at Week 76 (adjusted difference 13.4%, 95% CI, 2.0 to 24.8%; *P*=0.0232). The proportions of patients at Week 76 achieving i) a modified BLISS-LN primary efficacy renal response were 51.8% and 39.7% (adjusted difference: 12.1%, 95% CI, 0.5 to 23.8%; *P*=0.0432); ii) a modified BLISS-LN CRR were 48.7% and 33.1% (adjusted difference: 15.7%, 95% CI, 4.3 to 27.2%; *P*=0.0084); iii) a modified AURORA-1 CRR were 48.7% and 33.8% (adjusted difference: 15.0%, 95% CI, 3.6 to 26.5%; *P*=0.0117) (**Figure 1**).

In REGENCY, the proportions of patients achieving the individual components of CRR at Week 76 were numerically higher in the OBI arm compared with the PBO arm for all three components (UPCR < 0.5 g/g: 47.4% vs 36.0%; eGFR ≥85% of baseline: 83.7% vs 75.7%; no occurrence of intercurrent events: 88.9% vs 75.0% for OBI+ST and PBO+ST, respectively). In both arms, the main reasons for not attaining CRR were a UPCR ≥0.5 or an eGFR < 85% of baseline (54.8% OBI+ST vs 65.4% PBO+ST).

The mean daily prednisone intake was consistently lower in patients in the OBI arm compared with the PBO arm from Week 24-76, although the 95% CI overlapped at some intermediate visits (**Figure 2**). The proportions of patients achieving a daily prednisone (or equivalent) dose of ≤5 mg/day were consistently higher in the OBI vs PBO arm from Week 36. This reached a 10-percentage point absolute difference from Week 64-76 (78.5% vs 68.4% for OBI+ST vs PBO+ST, respectively; adjusted difference (95% CI): 10.1% (–0.5 to 20.4), *P*=0.0589).

Conclusion: In a post hoc analysis of the REGENCY trial outcomes, OBI showed consistent benefit across various patient subgroups, utilizing multiple alternative definitions of CRR, and also exhibited steroid-sparing properties.

Table 1. Renal Response Definitions

Renal Response	Definition
REGENCY CRR	• eGFR ≥85% of baseline eGFR • UPCR <0.5 • No rescue therapy, treatment failure, death or study withdrawal
Modified BLISS-LN PERR[a]	• eGFR ≥80% (no worse than 20%) of baseline eGFR or eGFR ≥60 mL/min/1.73 m² • UPCR ≤0.7 • No rescue therapy, treatment failure, death or study withdrawal
Modified BLISS-LN CRR[b]	• eGFR >90% of baseline eGFR or eGFR ≥90 mL/min/1.73 m² • UPCR <0.5 • No rescue therapy, treatment failure, death or study withdrawal
Modified AURORA-1 CRR[c]	• eGFR ≥60 mL/min/1.73 m² or no decrease from baseline in eGFR of >20% • UPCR ≤0.5 • No rescue therapy, treatment failure, death or study withdrawal • No more than 10 mg prednisone equivalent per day for 3 or more consecutive days or for 7 or more days from Week 64 through Week 76

CRR, complete renal response; eGFR, estimated glomerular filtration rate; LN, lupus nephritis; PERR, primary efficacy renal response; UPCR, urine protein-to-creatinine ratio.

[a]The original primary endpoint at Week 104 was a PERR (a UPCR of ≤0.7, an eGFR ≥20% below the value before the renal flare [preflare value] or ≥60 mL/min/1.73 m² of body surface area, and no use of rescue therapy); [b]The original major secondary endpoint at Week 104 was a CRR (a ratio of UPCR of <0.5, an eGFR that was ≥10% below the preflare value or ≥90 mL/min/1.73 m², and no use of rescue therapy); [c]The original primary endpoint at Week 52 was CRR defined as a composite of UPCR of ≤0.5 mg/mg, stable renal function (defined as eGFR ≥60 mL/min/1.73 m² or no confirmed decrease from baseline in eGFR of >20%), no administration of rescue medication and no more than 10 mg prednisone equivalent per day for 3 or more consecutive days or for 7 or more days during Weeks 44 through 52, just before the primary endpoint assessment.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1: Proportion of Patients Achieving Renal Responses at Week 76 According to Different Endpoints Across the REGENCY, AURORA-1 and BLISS-LN Studies Using REGENCY Dataset

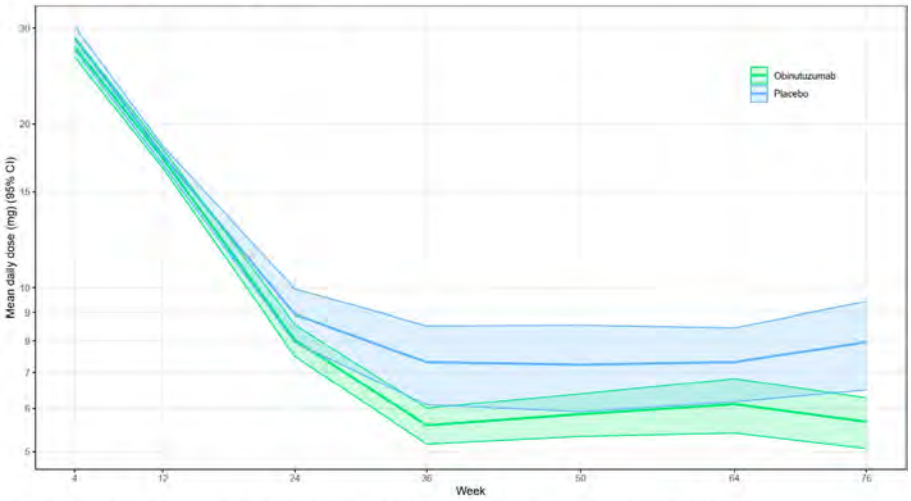
CI, confidence interval; CRR, complete renal response; LN, lupus nephritis; m, modified; MMF, mycophenolate mofetil; PERR, primary efficacy renal response; ST, standard therapy.
[a]ST consisting of MMF plus glucocorticoids.

Figure 2: Mean Daily Dose of Prednisone for Patients Treated With Obinutuzumab or Placebo Plus Standard Therapy



Y axis is on a logarithmic scale. Solid lines represent the mean, shaded areas represent the 95% CI.
Only oral doses were considered. For each patient, the individual corticosteroid prednisone equivalent dose was computed (no dose=0 mg). The individual mean daily dose was then calculated between 2 consecutive visit weeks:
[0-4 Weeks], [4-12 Weeks], [12-14 Weeks], [24-36 Weeks], [36-50 Weeks], [50-64 Weeks], [64-76 Weeks].
Then in each treatment arm, the mean daily dose was calculated between these consecutive visit weeks. Week 4 value corresponds to the mean daily dose between actual Weeks 0 (Day 1) and 4 (Day 28); Week 12 value corresponds to the mean daily dose between actual Weeks 4 (Day 28) and 12 (Day 84) etc.

CI, confidence interval.

Abstract Number: 0651

The ERβ Agonist, OSU-ERβ-012, Suppresses Systemic, Kidney and Heart Inflammation in a Chimeric Mouse Model of Systemic Lupus Erythematosus

Braden Zeno[1], Tim Alexandrov[2], Hongyu Yuan[3], Shane Bruckner[3] and Wael Jarjour[2], [1]Ohio State University, upper arlington, OH, [2]The Ohio State University, Columbus, OH, [3]OSU, Columbus, OH

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0641–0670) Systemic Lupus Erythematosus – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease that causes inflammation in many of the body's tissues, including the skin, joints, lungs, kidneys and heart. This inflammation causes damage to these tissues and produces significant mortality, with most complications of the disease involving direct effects on these organs. SLE affects young women between the ages of 15 and 45 years at a 9:1 rate as compared to men. The etiology is complex and remains elusive, however the susceptibility of women during the years in which estrogen levels are at their highest suggests a significant and critical contribution to the development of SLE. Estrogens are known to have pleiotropic effects on the immune system which is mediated through either estrogen receptor α (ERα), estrogen receptor β (ERβ) or the cell surface G-protein coupled receptor GPER1. ERα has been studied extensively in this context, however ERβ and GPER1 have received much less attention. Previously, our group and others have shown that ERα carrying immune cells are mediators of proinflammatory effects of estrogen more so than cells that lack this receptor. In the pursuit of a drug that is tailored to have a favorable selective estrogenic effect, the OSU Drug Development Institute discovered a novel carborane-based selective estrogen receptor modulator (SERM), OSU-ERβ-012. This ERβ agonist exhibits potent binding of human ERβ (Ki = 2.0 nM) and functional selectivity for ERβ over ERα of at least 200-fold. The work presented herein describes the utility of OSU-ERβ-012 in treating SLE in a humanized mouse model of the disease.

Methods: PBMC isolated from patients with active SLE were adoptively transferred into NSG mice and allowed to expand in vivo for one week. The mice were divided into 3 cohorts receiving either vehicle control, prednisone or OSU-ERβ-012 via daily oral gavage for five weeks. Blood samples were taken at baseline, 3 and 5 weeks. Serum was analyzed for circulating cytokines using the MSD human V-PLEX Proinflammatory Panel. At 5 weeks, mice were euthanized, kidneys and hearts were harvested and processed for H&E, Masson's Trichrome and IHC histology. Lupus patient PBMCs were isolated and stimulated *in vitro* under various conditions and then flow cytometry was used to identify specific cell types affected by OSU-ERβ-012.

Results: OSU-ERβ-012 was as effective as prednisone in suppressing glomerular inflammation and more effective at inhibiting inflammation of the heart. More specifically, the ERβ agonist was superior to prednisone at inhibiting pericarditis, myocarditis and cardiac fibrosis. OSU-ERβ-012 demonstrated effectiveness in suppressing pro-inflammatory cytokines. The in vitro effect of OSU-ERβ-012 confirmed the suppression of IFNγ and TNFα and revealed the cell type specific effects of the drug.

Conclusion: OSU-ERβ-012 is an effective inhibitor of the SLE inflammatory process and warrants additional study as a potential therapeutic in patients with SLE.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0641–0670) Systemic Lupus Erythematosus – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Lupus Therapeutics (LT), the clinical affiliate of the Lupus Research Alliance, oversees the premier North American Lupus Clinical Investigators Network (LuCIN). As cell therapy emerges as a potentially transformative, but operationally demanding modality in lupus trials, understanding site readiness and barriers is essential. To address the

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

anticipated expansion of cell therapy trial activity, an annual network-wide survey was conducted to assess the capability and requirements necessary for sites to engage in cell therapy clinical studies.

Methods: Using an internet-based platform, an annual survey was administered between Dec 17, 2024, and Feb13, 2025; a total of 60 LuCIN sites submitted multiple team responses. The survey asked about institutional infrastructure, interdepartmental collaboration, readiness for various cell therapy modalities, and educational/training priorities.

Results: Of the 124 respondents, enthusiasm for cell therapy was high: 60% expressed a preference to participate in Phase 2 trials while 35% in Phase 1 cell therapy trials. Chimeric antigen receptor T-cell (CAR-T) was the preferred modality (75%) followed by allogenic CAR-Natural Killer cell (44%) or other allogeneic approaches (40%) **Table 1**. Most sites (≥74%) reported the presence of core inpatient infrastructure (e.g., apheresis, drug storage, certified infusion providers, SOPs, toxicity monitoring), 62% had outpatient infusion capabilities, highlighting significant network readiness and evolution to adopt cell therapy for further study in lupus. Interdepartmental collaboration was active, as 66% reported partnerships with oncology/hematology and 59% seeking training to enable further collaboration. The most common operational challenges were logistical hurdles (74%), competing clinical studies (58%), and limited shared staffing capacity (39%). Meanwhile, 48% of respondents noted there are "too many" cell therapy opportunities. Investment in cell therapy capabilities, while increasing, was uneven where 59% reported enhanced multidisciplinary collaboration, 31% on additional staff or expertise and 20% reported new infrastructure, but 31% reported no new investments. Educational gaps were present as 76% requested new patient education materials, including CAR-T, with a priority on safety monitoring (66%), recruitment and patient

Table 1: Trial Preferences and Cell Therapy Readiness Across LuCIN Sites

*Selection of more than 1 response option were allowed		

education (64%), clinical protocol design (61%), among others (**Table 2**). Respondents identified target audiences of research staff (64%), patients (62%), and providers (56%) for cell therapy education opportunities.

Conclusion: Understanding readiness for cell therapy in lupus is critical to build a network of capable cell-therapy trialists for lupus and beyond. Using this knowledge, strategic investment in operational planning, capacity building and tailored education efforts for staff, patients, and providers will provide the research community support for the safe, effective and scalable integration of cell therapy in lupus trials. Careful attention to resource allocation, multidisciplinary partnerships and trial prioritization will be essential to avoid saturation and sustain momentum across LuCIN sites.

In Vitro Pharmacological Profile of GLPG3667 Suggests Differentiation from the TYK2 Inhibitors Deucravacitinib and Zasocitinib at Their Clinical Dose Regimens

May-Linda Lepage[1], Patrick Nolain[1], Céline Cottereaux[1], Emilie Lagoutte[1], Justine Dao[1], Adrien Cosson[1], Laetitia Furio[1], Willem Hettema[2], **Chantal Tasset**[3], Roland Blanqué[1], Isabelle Parent[1] and René Galien[1], [1]Galapagos SASU, Paris, France, [2]Galapagos B.V., Leiden, Netherlands, [3]Galapagos NV, Mechelen, Belgium

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0641–0670) Systemic Lupus Erythematosus – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Tyrosine kinase 2 (TYK2), a Janus kinase (JAK) family member, is attracting a lot of interest as a new target to treat patients with autoimmune and inflammatory diseases, including inflammatory bowel diseases, and several inhibitors are currently in clinical development. *In vitro* pharmacological profiling of TYK2 inhibitors has been employed to evaluate potency and selectivity; however, such data are best viewed in relation to clinical exposure levels. We compared expected levels of inhibition of TYK2-dependent and -independent pathways for deucravacitinib, zasocitinib and GLPG3667 at their respective clinical dose regimens and demonstrate that relevant differences exist between these compounds.

Methods: Potency of the TYK2 inhibitors was compared for TYK2-dependent pathways (IFNα, IL-12, IL-23), TYK2-independent pathways (IL-6, IL-2, GM-CSF) and the anti-inflammatory IL-10 pathway in *in vitro* human whole blood assays using STAT phosphorylation (flow cytometry) and cytokine release (ELISA) measures. Sigmoidal E_{max} models were fitted to the concentration–inhibition data from healthy donors to estimate IC_{50}, E_{max} and Hill slope for each assay and compound. The obtained relationships were subsequently coupled to the clinical pharmacokinetic (PK) profiles of the compounds (such as C_{avg}, C_{max} and C_t from population PK model for GLPG3667 and published PK metrics for deucravacitinib and zasocitinib) to estimate the level of inhibition of the various pathways at clinically relevant dose regimens.

Results: Human whole blood assays performed for various JAK pathways demonstrated that all TYK2 inhibitors display selectivity for TYK2 over the JAK1–3 family members, with zasocitinib being the most selective. At exposure levels associated with its clinical dose of 150 mg once daily, GLPG3667 showed inhibition of the IFNα, and IL-23 pathways, comparable to the expected inhibition for deucravacitinib at its clinical dose regimens, without a measurable impact on TYK2-independent pathways. Inhibition of the IL-12 pathway was more pronounced for GLPG3667 than for deucravacitinib. Zasocitinib showed the most sustained inhibition of TYK2-dependent pathways. GLPG3667 showed no measurable inhibition of IL-10-mediated signalling up to the highest concentration tested (~10-fold above clinical concentrations) in monocytes, $CD4^+$ T cells and $CD19^+$ B cells, while strong inhibition was observed with deucravacitinib and overall zasocitinib at concentrations corresponding to the respective clinical dose regimens.

Conclusion: At concentrations corresponding to its highest anticipated clinical dose, GLPG3667 shows selective inhibition of TYK2-mediated signalling, with a level of inhibition similar to deucravacitinib clinical dose regimens. While GLPG3667 did not show any impact on IL-10-mediated signalling, inhibition of this anti-inflammatory pathway is expected for the allosteric TYK2 inhibitors at their clinical exposure levels.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0641–0670) Systemic Lupus Erythematosus – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Lupus nephritis (LN) is characterized by kidney inflammation. B cells play a central role in LN pathogenesis and type I interferon (IFN-I) pathway activation amplifies inflammation. Obinutuzumab, a glycoengineered, type II CD20 antibody demonstrated efficacy in patients (pts) with LN when added to standard therapy in the Phase II NOBILITY (NCT02550652) and Phase III REGENCY (NCT04221477) trials.

This study explored the efficacy of obinutuzumab vs placebo (plus standard therapy) in various serological biomarker subgroups of pts with LN from the NOBILITY trial.

Methods: Pts received obinutuzumab or placebo at Weeks 0, 2, 24 and 26, plus standard therapy of mycophenolate mofetil (MMF) plus glucocorticoids. All pts met ACR SLE classification criteria and had biopsy-proven proliferative LN. Whole blood from participants (88/126 pts) was used for bulk RNA sequencing. Baseline IFN-I status (high [hi] vs low [lo]) was determined in samples from healthy volunteers, using previously published gene signatures from the ROSE (NCT00962832) and TULIP (NCT02446912) trials. Cut-off for IFN-I status was determined using the median +2x median absolute deviation of age- and sex-matched healthy controls. Anti-dsDNA, anti-nuclear antibodies (ANA; SSA, SSB, RNP and Sm) and complement C3/C4

Table 1. Obinutuzumab's Impact on CRR* at Week 52 in High and Low IFN-I Subgroups

	Placebo, n=43 (CRR over total)	Obinutuzumab, n=45 (CRR over total)	OR (80% CI)	*P* value
All patients	8/43 (18.6)	18/45 (40.0)	3.08 (1.64 to 5.99)	0.02133
High IFN-I gene signature	7/36 (19.4)	16/39 (41.0)	2.94 (1.49 to 6.00)	0.0395
Low IFN-I gene signature	1/7 (14.2)	2/6 (33.3)	4.00 (0.69 to 29.44)	0.3115

There are only a few responders in the serologically active 2 and anti-La SSB-positive subgroups, thus the results from the logistic regression may not be reliable/interpretable.

Anti-dsDNA, anti-double-stranded DNA; CI, confidence interval; CRR, complete renal response; mITT, modified intention to treat; MMF, mycophenolate mofetil; OR, odds ratio.

*Defined as anti-dsDNA+ and hypocomplementemia. †Defined as anti-dsDNA+ or hypocomplementemia.

levels were assessed. Subgroup analyses were performed on baseline biomarker categories using the endpoint of Week 52 complete renal response (CRR). Odds ratios (OR) relative to placebo or MMF were estimated by logistic regression, with a significance level of α=0.2.

Results: Of 88 pts, 75 (85.2%) were categorized as IFNhi and 13 (14.8%) as IFNlo using the ROSE IFN-I gene signature. Baseline IFN-I status did not reliably predict the likelihood of achieving CRR at Week 52. At Week 52, in the IFNhi subgroup, 41% (16/39) of pts receiving obinutuzumab achieved CRR vs 19.4% (7/36) of pts receiving placebo (P< 0.2; OR [80% CI], 2.9 [1.5 to 6], **Table 1**). A statistically significant trend favoring obinutuzumab was observed in the IFNlo subgroup (33.3% [2/6] vs 14.2% (1/7); P >0.2; OR [80% CI], 3.0 [0.9 to 9.6], **Table 1**). Using the REGENCY Week 76 CRR definition and the TULIP IFN-I gene signature yielded similar results. A multivariable logistic regression analysis using treatment and baseline IFN-I status as covariates did not reveal a statistically significant association between IFN-I status and response (P=0.6221; OR [80% CI], 1.4 [0.5 to 3.64]. Across subgroups defined by baseline complement, anti-dsDNA and other autoantibodies, more CRRs were observed with obinutuzumab vs placebo, including in pts with high serological activity (**-Figure 1**). Results were generally consistent using the Week 76 REGENCY CRR definition.

Conclusion: Analyses suggest that obinutuzumab may be an effective therapy in pts with LN regardless of baseline serological biomarker status. A significant CRR benefit was observed in the IFNhi subgroup and a similar trend was seen in the IFNlo subgroup. Obinutuzumab generally demonstrated greater efficacy vs placebo across baseline serological biomarker subgroups. Whilst limited sample size restricted significance, similar ORs across subgroups suggest a consistent trend favoring obinutuzumab regardless of serological status.

Abstract Number: 0655

Blood pressure remains elevated in patients initiating voclosporin with low baseline blood pressure: evidence from patients in routine clinical care

Eric Roberts[1], gabriela Schmajuk[2] and Jinoos Yazdany[3], [1]University of California, San Francisco, SF, CA, [2]University of California, San Francisco, and San Francisco Veterans Affairs Medical Center, San Francisco, CA, [3]UCSF, San Francisco, CA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0641–0670) Systemic Lupus Erythematosus – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Hypertension was a common adverse event in RCTs testing voclosporin, an oral calcineurin inhibitor approved in 2021 to treat lupus nephritis (LN). In these trials, increases in blood pressure (BP) were generally transitory and frequently diminished after the first 4 weeks of use. Here we characterize BP changes in real-world data.

Methods: Data came from RISE, a national registry with electronic health records from over 1100 US rheumatologists. Voclosporin use was abstracted from medication tables. All systolic and diastolic BPs from 60 days before the first order to 90 days after the last order were tabulated. Baseline BP was defined as the lowest BP before the index date (inclusive) and categorized as follows: normal < 130 mmHg AND < 80 mmHg; elevated, 130-164 mmHg OR 80-104 mmHg; and high, ≥165 mmHg OR ≥105 mmHg. Covariates included age, sex, race and ethnicity, insurance coverage, area deprivation index, BMI, smoking status, and time-varying antihypertensive drug use.

We describe patient characteristics overall and stratified by whether the patient experienced an 8 mmHg increase in systolic BP (minimum clinically important difference (MCID)) during the first year of use. We calculated the median time to a MCID within a year for both systolic and diastolic using Kaplan Meier estimates. Finally, we present mean changes in BP between baseline and the lowest BP reading in windows of 0-1, 1-2, 2-3, 3-6, 6-9, and 9-12 months after the index date.

Results: We included 287 patients: 83.6% were female, 32% were black; mean (SD) age was 41.4 (±14.1) years (Table 1). The mean systolic BP at baseline was 125.7 (±16.1)/79.2 (±10.8) (42.2% categorized as normal, 54% elevated, and 3.8% high). At baseline, 67.3% were on an antihypertensive medication.

Overall, 63.8% experienced a systolic MCID, and 49.1% a diastolic MCID. The median time to a recorded increase in systolic was 77 days (95%CI: 62-91) (Figure 1), and 134 days (95%CI: 99-198) for diastolic. The average systolic/diastolic BP change was largest in the first month for patients with normal baseline BP 13.7 (±18.6)/6.0 (±13.8), and less pronounced

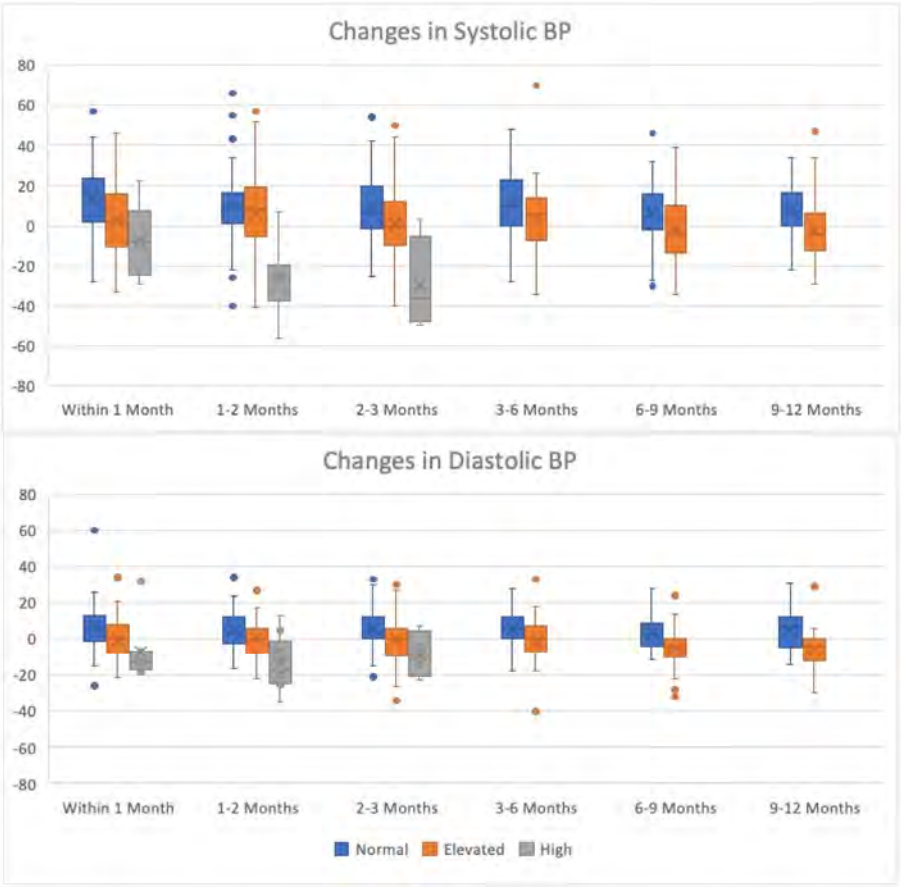

Figure 2. Box and whisker plots of mean change in systolic and diastolic blood pressure between baseline and the specified time stratified by patient's baseline hypertension category.

for those with elevated BP 2.7 (±18.8)/-0.6 (±11.2); BP decreased for those with high baseline BP -7.9 (±17.8)/-7.3 (±16.5) (Figure 2). BPs were stable over time for those with baseline normal BP whereas BPs returned to baseline levels after 6 months for patients with elevated baseline BPs. Although the sample size was small for patients with high baseline BPs we observed large decreases in BP during the first 3 months of use, likely due to the beneficial effects of voclosporin on underlying LN.

Conclusion: >50% of patients using voclosporin had a MCID in the first year of use. Increases tend to occur in the first 3 months of use and on average were larger for patients with normal baseline BPs. In contrast to findings reported from RCTs, BP increases for patients with normal baseline BPs were persistent over 12 months. Although the MCID may seem small, it has been associated with up to 20% increase in the risk of cardiovascular disease (CVD) events. The clinical significance of BP changes related to voclosporin use warrant further investigation, especially since people with LN are already at increased risk for CVD.

Abstract Number: 0656

Low-dose belimumab reduced disease flares in patients with systemic lupus erythematosus at low disease activity: a multicenter, randomized, double-blind, placebo-controlled trial

Fangfang Sun[1], Huijing Wang[1], Danting Zhang[1], Nan Shen[1], Sheng Chen[1], Tiing Li[1], Weiguo Wan[2], Shengming Dai[3] and Shuang Ye[4], [1]Renji Hospital, Shanghai, China (People's Republic), [2]Huashan Hospital, Shanghai, China (People's Republic), [3]Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China (People's Republic), [4]Renji Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China, Shanghai, Shanghai, China (People's Republic)

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0641–0670) Systemic Lupus Erythematosus – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: B-lymphocyte stimulator was involved in the pathogenesis of SLE. The humanized monoclonal antibody belimumab with 10mg/kg was effective for active patients. The efficacy of low-dose belimumab for prevention of disease flares in patients with SLE with low disease activity was evaluated in this randomized trial (NCT04515719).

Methods: This was a 52-week, randomized, placebo-controlled trial. Patients who have Safety of Estrogens in Lupus Erythematosus National Assessment–Systemic Lupus Erythematosus Disease Activity Index (SELENA-SLEDAI) scores≤6; with no A score or no more than one B score on the British Isles Lupus Assessment Group (BILAG) scale; and who are treated with prednisone ≤20mg/day at screening were enrolled and randomly assigned in a 1:1 ratio to intravenous 120mg belimumab or placebo (saline) arm on weeks 0, 2, and 4, and then every 4 weeks until 48 weeks on the basis of standard of care (SOC). The primary outcome was a composite index of severe or mild-to-moderate disease flare (SELENA-SLEDAI Flare

Table 1. Baseline characteristics of participants in two arms.

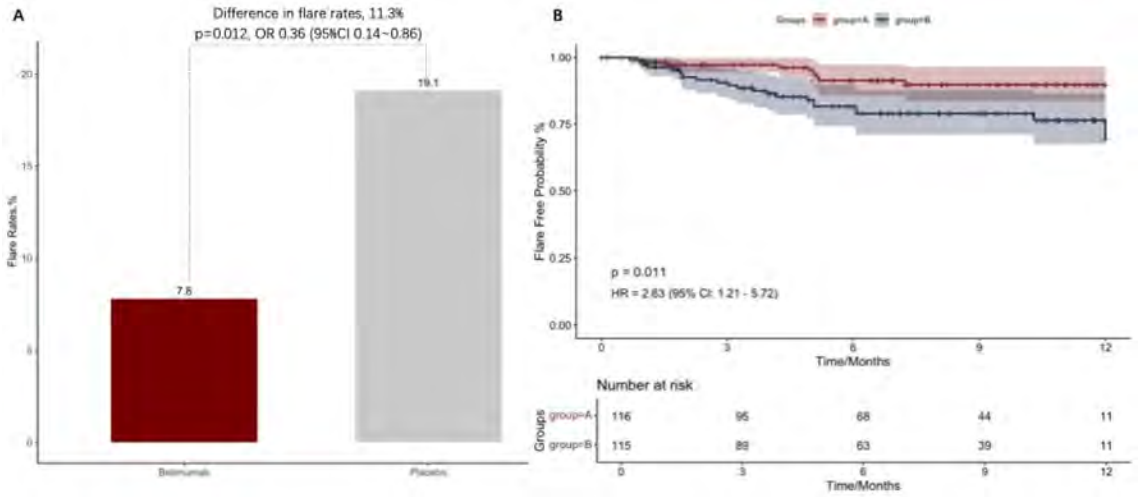

Figure 1. The difference of overall disease flares between low-dose belimumab and placebo on the basis of SOC (A). Kaplan-Meier Curves demonstrated flare-free survival of participants from two arms (B).

Index) within 52 weeks. Secondary outcomes included the percentage of severe flare, the percentage of mild-to-moderate flare, time to the first disease flare, changes in prednisone dose, SELENA-SLEDAI and safety analysis. The locked-down due to COVID-19 pandemic in Shanghai, China from April 2022 to June 2022 has greatly impacted patient recruitment and follow-up. Therefore, the trial was terminated prematurely at April 10th, 2022 when Renji Hospital, South campus was designated as a COVID-19 referral center during Shanghai locked-down.

Results: Overall, 90.5% of 116 patients receiving belimumab and 86.1% of 115 patients receiving placebo completed the study within a mean follow-up of 31.0 ± 16.1 weeks. Baseline characteristics were generally similar between treatment groups (**Table 1**). The primary endpoint was met. 7.8% (9/116) of patients receiving low-dose belimumab + SOC had disease flares within follow-up, which was significantly lower than that in patients receiving placebo + SOC, that is 19.1% (22/115) (p=0.012; difference 11.3%, OR 0.36 (95%CI 0.14∼0.86); **Figure 1A)**. Severe flares in belimumab group was only numerically lower than that in placebo group (1.7% vs 6.1%, p=0.1). Kaplan-Meier curves also demonstrated higher flare-free survival in patients receiving belimumab plus SOC (p=0.011, HR 2.63, 95% CI (1.21-5.72)) (**Figure 1B**). Glucocorticoid-sparing effects were observed in two groups (changes in prednisone from baseline to last visit, 1.64 ± 10.24 vs 0.91 ± 7.48, p=0.055). SELENA-SLEDAI was reduced by 0.62 ± 2.17 in belimumab group, however increased

Table 2. Adverse events.

	Belimumab (n=116)	Placebo (n=115)
Adverse event (n≥1)	71 (61.2%)	53 (64.3%)
Severe adverse event (n≥1)	4 (3.4%)	6 (5.2%)
Discontinuations due to adverse events	3 (2.6%)	6 (5.2%)
Infections	45 (38.8%)	41 (35.7%)
Upper respiratory infections	29 (25.0%)	25 (21.7%)
Skin infections	3 (2.6%)	3 (2.6%)
Gastroenteritis	7 (6.0%)	8 (7.0%)
Urogenital tract infection	6 (5.2%)	7 (6.1%)
Gingivitis	2 (1.7%)	1 (0.9%)
Pneumonia	3 (2.6%)	2 (1.7%)
Admission to hospital due to infections	3 (2.6%)	2 (1.7%)
Headache	3 (2.6%)	1 (0.9%)
Hypertension	2 (1.7%)	2 (1.7%)
Abdominal discomfort	3 (2.6%)	4 (3.5%)
Infusion reactions	3 (2.6%)	4 (3.5%)
Rash	10 (8.6%)	8 (7.0%)
Athralgia	6 (5.2%)	8 (7.0%)
Elevated liver enzyme	3 (2.6%)	4 (3.5%)
Leukopenia	5 (4.3%)	4 (3.5%)
Osteonecrosis	2 (1.7%)	0 (0%)

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

by 0.22 ± 2.82 in placebo group (p=0.004). Any adverse events were comparable between belimumab and placebo groups (61.2% vs 64.3%). Only 4 (3.4%) and 6 (5.2%) severe adverse events occurred in two groups (**Table 2**). There was no death.

Conclusion: Treatment with low-dose belimumab helped reduce disease flare risks in Chinese patients with SLE at low disease activity. Belimumab was generally well tolerated.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0641–0670) Systemic Lupus Erythematosus – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease of unknown etiology with mortality still approaching 10% in 5 years. The major causes of death in SLE include infections due to the toxicity of immunosuppressant medications. Our study design has been formulated on the premise that safe and effective treatment should target key checkpoints of pathogenesis. The depletion of cysteine and reduced glutathione (GSH) underlie mitochondrial oxidative stress, activation of the mechanistic target of rapamycin (mTOR), inflammatory lineage specification and antinuclear autoantibody production in SLE. An earlier completed double-blind, placebo-controlled study provided preliminary evidence that replacement of cysteine and GSH with amino acid precursor, N-acetylcysteine (NAC), can safely reduce mTOR activation, anti-DNA antibody production, and disease activity in SLE (PMID: 22549432; PMID: 23400548).

Methods: The study is a multicenter randomized, double-blind, placebo-controlled clinical trial, using an innovative enriched enrollment randomized withdrawal (EERW) design that allows participants to use an individualized dosage of study medication, which mimics clinical practice in terms of how NAC would be administered. Eligibility criteria required clinically active

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1: Clinical assessment as measured by SLEDAI, BILAG, ASRS Inattention and Hyperactivity, and FAS Physical and Mental Fatigue scores. BILAG organ domain scores were converted to numerical values: A=12, B=8, C=1, D/E=0. Data are presented as mean ± standard deviation (STDEV). P values indicate comparisons between pretreatment (Month 0) and 3-month post-treatment measurements (Month 3) using a two-tailed paired t-test, corrected for multiple comparisons; differences (Δ) between Month 0 and Month 3 are also reported.

Clinical Assessment Scores	Month 0 (M0)		Month 3 (M3)		M0 vs M3	Difference (Δ)	
	Mean	STDEV	Mean	STDEV	P Value	Mean	STDEV
SLEDAI (n=68)	8.73	3.093	4.91	2.92	$1.1x10^{-11}$	3.671	3.201
BILAG (n=68)	23.808	5.099	8.750	6.027	$1.9x10^{-22}$	15.058	8.424
ADHD Inattention (n=54)	19.259	2.960	16.407	7.449	$1.5x10^{-2}$	2.851	6.645
ADHD Hyperactivity (n=54)	14.962	7.530	13.185	7.809	$1.3x10^{-2}$	1.777	4.063
Physical Fatigue (n=54)	19.259	2.960	16.092	3.972	$2.5x10^{-8}$	3.166	3.318
Mental Fatigue (n=54)	14.425	4.574	12.092	4.814	$6.2x10^{-5}$	2.333	3.518

disease with ≥6 SLE Disease Activity Index (SLEDAI) and British Isles Lupus Assessment Group (BILAG) organ domain scores ≥1 BILAG A or ≥2 BILAG B (clinicaltrials.gov NCT00775476). All participants received NAC for 3 months, titrated up to a maximally tolerated dosage between 2.4 g/day and 4.8 g/day. Subjects tolerating ≥2.4 g/day NAC have been randomized to receive either NAC or placebo at the subject's tolerated dosage for the remaining 9 months of treatment. Our preliminary analysis evaluated the BILAG and SLEDAI scores in 68 patients, and validated Fatigue Assessment (FAS) and ADHD Self-Report Scales (ASRS) (PMID: 23400548) in 54 SLE patients, before and after a 3-month open-label dose titration phase. Statistical analysis included two-tailed paired t-tests and correlations corrected for multiple comparisons using the Bonferroni correction in GraphPad software.

Results: We observed a significant reduction of SLE disease activity as measured by the reduction of SLEDAI and BILAG muco-cutaneous and musculoskeletal organ domain scores. ASRS cognition/inattention and fatigue scores also improved (Table 1). Adverse events—including headache, nausea, gastrointestinal upset, constipation, and diarrhea—were all transient and reversible. By month 3, 18 participants had withdrawn: 1 due to adverse events, 1 due to scheduling conflicts, 6 were lost to follow-up, 3 were unwilling to continue, 5 withdrew consent, and 2 experienced serious adverse events unrelated to the study drug.

Conclusion: This preliminary analysis supports the notion that NAC may serve as a safe and effective treatment for patients with SLE, but these observations could be affected by the absence of blinding in the open-label phase and regression-to-the-mean. The double-blind phase of the ongoing multicenter trial will confirm whether NAC is efficacious in treating SLE.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0641–0670) Systemic Lupus Erythematosus – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Human papillomavirus (HPV) is responsible for 99.7% of cervical neoplasms and is the fourth most common cancer among women worldwide. Patients with systemic lupus erythematosus (SLE) have been shown to have a higher prevalence of HPV infection than the general population, with a greater frequency of high-risk serotypes and intraepithelial squamous lesions (SIL), particularly high-grade lesions (H-SIL). While an association has been described between immunosuppressive treatment and cyclophosphamide use, there is limited evidence on HPV progression in patients treated with biologic disease-modifying antirheumatic drugs (bDMARDs).

Our objectives were to assess the relationship between HPV infection and biologic therapy in SLE patients, as well as with factors associated with SLE disease course and HPV progression.

To determine the prevalence of HPV infection in a Spanish cohort of SLE patients receiving biologic therapy.

Methods: We conducted a retrospective, multicenter, cross-sectional study including 232 women with SLE treated with bDMARDs. Clinical, laboratory, and treatment-related variables associated with SLE and HPV infection were reviewed. Logistic regression analysis was performed to evaluate associations between HPV infection, SLE-related disease activity, and HPV progression.

Results: A total of 232 women with SLE were included, with a mean age of 46 years. HPV infection was identified in 9.9% (n=23) of patients. Among infected patients, 65.5% (n=19) had SIL (53.9% L-SIL [n=7]; 46.2% H-SIL [n=6]). Two patients (2.1%) developed cervical cancer. All patients had received at least one bDMARD (100%); 52 patients (22.41%) received two, and 3 patients (1.29%) received three different bDMARDs. Among HPV-infected patients, three had received more than one biologic agent.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

No statistically significant associations were found between HPV infection, biologic therapy, SLE disease-related variables (SLEDAI, SLICC, number of previous flares, disease duration), or risk factors for HPV progression (smoking, leukopenia).

No significant associations were observed between HPV infection and the analyzed potential risk or progression factors. The cohort included a homogeneous group of patients with high SLE activity but lacked a control group, which may limit the interpretation of associations. Additionally, socioeconomic data—potentially relevant to HPV risk—were not available.

The observed HPV prevalence (9.9%) was lower than previously reported in Spain (14.3%), potentially influencing the absence of significant associations. This may be due to low screening adherence among patients, though data were insufficient to confirm this hypothesis.

Table 1. Baseline characteristics of the cohort

	Total (n=232)
Age (years), mean (SD)	46 (13,3)
Smoking status, n (%)	62 (26,7)
Previous conventional DMARD, median (IQR)	218 (93,8)
Previous bDMARd, n (%)	55 (23,7)
SLICC, n (%)	
0	142 (62,0)
1	52 (22,7)
2	13 (5,7)

Conclusion: The prevalence of HPV infection in this cohort was 9.9%, with 65.5% of HPV-positive patients presenting SIL and two cases of cervical cancer (2.1%).

No significant associations were found between HPV infection, biologic therapy, SLE-related disease parameters, or HPV progression.

HPV prevalence in this cohort was lower than the general prevalence reported in Spain.

Effects of Deucravacitinib on Dysregulated Autoimmune Gene Modules That Correlate With Skin Disease Severity and Treatment Response in Patients With Cutaneous Manifestations of Lupus Erythematosus: Biomarker Results From a Global, Randomized, Placebo-Controlled Phase 2 Study

J. Michelle Kahlenberg[1], Victoria Werth[2], Joerg Wenzel[3], John Schwarz[4], Jinqi Liu[4] and Brandon Johnson[4], [1]University of Michigan, Ann Arbor, MI, [2]University of Pennsylvania, Philadelphia, PA, [3]Department of Dermatology and Allergy, University Hospital of Bonn, Bonn, Germany, [4]Bristol Myers Squibb, Princeton, NJ

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0641–0670) Systemic Lupus Erythematosus – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Deucravacitinib, an oral, selective, allosteric tyrosine kinase 2 (TYK2) inhibitor approved in moderate to severe plaque psoriasis, has demonstrated significant improvements in cutaneous manifestations in the phase 2 PAISLEY SLE study (NCT03252587). TYK2, an important mediator of cytokine signaling (eg, types I and III IFNs, IL-23, and IL-12) involved in immune-specific responses, plays a role in cutaneous lupus erythematosus (CLE) pathophysiology. In the phase 2 PAISLEY CLE study (NCT04857034), the primary endpoint of Cutaneous Lupus Erythematosus Disease Area and Severity Index activity (CLASI-A) improvement was met with deucravacitinib in patients with CLE. This post hoc analysis aimed to identify dysregulated gene modules associated with CLE, evaluate the impact of deucravacitinib on these modules, and determine their predictive value for response to deucravacitinib.

Methods: Gene expression in whole blood was evaluated using a targeted PCR array (DxTerity AIP panel) in samples from patients with CLE with or without SLE treated in PAISLEY CLE (deucravacitinib 3 mg [n = 24] or 6 mg twice daily [n = 22] vs placebo [PBO; n = 24]). Selected genes were normalized and clustered into predefined modules, including IFN-5 (5-gene module associated with type I IFN transcription; *MX1, HERC5, IFIT1, RSAD2, EIF2AK2*), IFN-γ (*TRIM38, SP100, LBA1*), and inflammation (*CXCL10, LGALS3BP, APOL6, TNFSF13B*). Gene module expression (GME) in baseline (BL) samples from patients adjusted for

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure. Pharmacodynamic changes in expression of the inflammation gene module with deucravacitinib and placebo

*** $P < 0.001$; ** $P < 0.01$. Black asterisks indicate significant difference between deucravacitinib 3 mg BID or 6 mg BID vs PBO at the given time points. Red asterisks indicate significance of the overall deucravacitinib 3 mg BID or 6 mg BID curve vs the PBO curve. The inflammation gene module includes *CXCL10*, *LGALS3BP*, *APOL6*, and *TNFSF13B*.
BID, twice daily; IQR, interquartile range; NHV, normal healthy volunteer; PBO, placebo.

Table. Correlation of pharmacodynamic changes in gene modules with CLASI-A changes over time

	All patients				SLE absent			
Biomarker	Correlation direction	n	R	*P* value	Correlation direction	n	R	*P* value
Week 4								
IFN-5 module	Positive	66	0.35	0.004	Positive	38	0.40	0.013
Inflammation module	Positive	66	0.32	0.008	Positive	38	0.35	0.031
IFN-γ module	Positive	66	0.30	0.016				
Week 16								
IFN-5 module	Positive	51	0.44	0.001	Positive	29	0.52	0.004
Inflammation module	Positive	51	0.40	0.004	Positive	29	0.50	0.005
IFN-γ module	Positive	51	0.45	0.001	Positive	29	0.48	0.008

The IFN-5 gene module includes *MX1*, *HERC5*, *IFIT1*, *RSAD2*, and *EIF2AK2*. The inflammation gene module includes *CXCL10*, *LGALS3BP*, *APOL6*, and *TNFSF13B*. The IFN-γ gene module includes *TRIM38*, *SP100*, and *LBA1*.
IFN, interferon, R, correlation coefficient; SLE, systemic lupus erythematosus.

covariates and modeled by least-squares mean change was compared to GME in age- and sex-matched normal healthy volunteers (NHVs). Changes in GME with deucravacitinib vs PBO were compared using mixed model for repeat measures. Correlation analyses of clinical response with GME at BL and change from BL were performed using Spearman's rank correlation.

Results: Higher BL CLASI-A was associated with higher BL IFN-5 GME ($P = 0.0005$). There were no significant differences in BL CLASI-A or the ratio of high-to-low IFN-5 GME by SLE subgroup. IFN-5, IFN-γ, and inflammation GME were significantly elevated at BL in patients vs NHVs in both SLE subgroups ($P = 0.0001$ [IFN-γ, SLE absent]; $P < 0.0001$ [all others]). Higher BL IFN-5 and inflammation GME correlated with more severe BL CLASI-A ($P = 0.002–0.007$). Deucravacitinib significantly reduced IFN-5, IFN-γ, and inflammation GME vs PBO, normalizing to NHV levels (**Figure**); changes correlated with improved CLASI-A, and correlations strengthened over time (**Table**). BL IFN-γ GME correlated with response to deucravacitinib at W4 ($P = 0.044$) and W16 ($P = 0.009$); in patients with SLE, BL IFN-5 GME correlated with response to deucravacitinib at W4 ($P = 0.025$). Responders with a ≥ 50% reduction from baseline in CLASI-A had greater decreases in IFN-5 ($P = 0.0051$) and IFN-γ ($P = 0.0505$) GME vs nonresponders.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: IFN and inflammation gene modules were dysregulated in CLE and positively correlated with CLASI-A. Normalization of these signatures with deucravacitinib correlated with CLASI-A improvement. Results warrant further evaluation of deucravacitinib and the utility of these biomarkers in patients with cutaneous manifestations of lupus erythematosus.

Real-world Effectiveness and Usage of Voclosporin: Data from the Enlight-LN Registry

Leanna Wise[1], Laura Geraldino-Pardilla[2], Niloofar Nobakht[3], Mohammad Kamgar[3], Amber Rosales[4], Barbara McIntosh[4] and Ron Flauto[4], [1]LAGMC/Keck Medicine of USC, Los Angeles, [2]Columbia University, New York, NY, [3]University of California Los Angeles, Los Angeles, CA, [4]Aurinia Pharmaceuticals Inc., Edmonton, AB, Canada

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0641–0670) Systemic Lupus Erythematosus – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: The 2024 American College of Rheumatology Lupus Nephritis (LN) Guideline recommends triple immunosuppressive therapy, including the option of a calcineurin inhibitor (CNI)-based regimen, for patients with active lupus nephritis (LN). Voclosporin is a second generation CNI approved for adults with active LN. During clinical trials, voclosporin, in combination with mycophenolate mofetil (MMF) and low-dose glucocorticoids, led to significant reductions in proteinuria with stable estimated glomerular filtration rate (eGFR) with up to 3 years of exposure compared to MMF and glucocorticoids alone. The Enlight-LN registry was designed to characterize the real-world effectiveness and usage patterns of voclosporin in the United States. Here we describe the initial outcomes of patients who participated in this registry.

Methods: The Enlight-LN registry enrolled patients between March 2022 and January 2025 (NCT05337124). Patients were ≥18 years with biopsy-confirmed LN who initiated or had already initiated treatment with commercial voclosporin prior to study consent. Patients received standard of care in accordance with usual clinical practice at each site. Mandatory assessments included renal parameters and blood pressure. Data were extracted from patient records approximately every 3 months. Safety data were collected via spontaneous reporting.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: As of April 4, 2025, data were available on 229 patients. Median (range) patient age was 34.0 (18-78), with 36.2% of patients ≤30 years; 83.4% were female. Most patients self-identified as White (43.2%) or Black/African American (38.0%); 35.4% were Hispanic/Latino. Median (range) time since first LN diagnosis was 1.6 (0, 26.2) years. The majority of patients had Class V disease (31.4%) or Class IV disease (20.1%).

Median (range) UPCR decreased from 2.3 (0.1-16.8) g/g at baseline (n=191) to 0.9 (0.1-18.7) g/g at month 6 (n=89). Median (range) corrected eGFR was 89.3 (6-90) mL/min/1.73 m^2 at baseline (n=222) and 82.0 (3-90) mL/min/1.73 m^2 at month 6 (n=120). Safety data collected during the registry appears to be consistent with the established safety profile of voclosporin.

Conclusion: Patients in the Enlight-LN registry reflect the larger LN population in the US, including high percentages of Black and Hispanic and/or Latino patients. The outcomes data from this initial analysis are consistent with the findings from the voclosporin clinical trials, with substantial reductions in proteinuria observed over the first few months of treatment, with no new safety signals. These real-world data support the recent updates to the ACR guidelines recommending use of triple immunosuppressive therapy first-line in patients with active LN.

Efficacy Across Baseline Characteristic Subgroups in Patients With Systemic Lupus Erythematosus Treated With Upadacitinib: Results From SLEek, a Phase 2 Randomized

Marta Mosca[1], Karen H. Costenbader[2], Amit Saxena[3], Michelle Petri[4], Andrea Rubbert-Roth[5], Karim Masri[6], Christopher Saffore[7], Ling Cheng[8] and Joan Merrill[9], [1]University of Pisa, Pisa, Pisa, Italy, [2]Harvard Medical School and Brigham and Women's Hospital, Boston, MA, [3]Division of Rheumatology, Department of Medicine, NYU Grossman School of Medicine, New York, NY, [4]Johns Hopkins University School of Medicine, Timonium, MD, [5]Division of Rheumatology and Immunology, Cantonal Hospital St Gallen, St Gallen, Switzerland, [6]AbbVie Inc., North Chicago, IL, [7]AbbVie Inc., waukegan, IL, [8]AbbVie, North, IL, [9]Oklahoma Medical Research Foundation, Oklahoma City 73104, OK

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0641–0670) Systemic Lupus Erythematosus – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Clinical and immunological manifestations of systemic lupus erythematosus (SLE) vary widely across patients, complicating diagnosis and treatment (1,2). Upadacitinib (UPA), an oral selective JAK inhibitor, significantly reduced disease activity compared with placebo (PBO) in the phase 2 SLEek trial of adult patients with moderately to severely active SLE (3). In this analysis, we evaluate potential differences in treatment responses to UPA vs PBO associated with baseline patient characteristics.

Methods: SLEek was a phase 2, randomized, double-blind, PBO-controlled trial (NCT03978520) (3). This post hoc analysis included participants who were randomized to receive once-daily UPA 30 mg or PBO for 48 weeks. We report the proportions of trial participants in each group who met the composite measures of disease improvement, Lupus Low Disease Activity State (LLDAS) and/or British Isles Lupus Assessment Group-Based Composite Lupus Assessment (BICLA).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Participants were stratified into subgroups by sex, age, race, region, body mass index, medication use, clinical markers, and medical history. Missing data were handled with nonresponder imputation incorporating multiple imputation to handle missing data due to COVID-19. Between-group differences and 95% CIs were estimated according to the Cochran-Mantel-Haenszel test adjusted for baseline corticosteroid use (≤10 mg or >10 mg), Systemic Lupus Erythematosus Disease Activity Index 2000 score at screening (< 10 or ≥10), baseline interferon score (high, low, or not applicable), and baseline immunosuppressant use (yes or no). Analyses were exploratory, and the reported data are descriptive.

Results: A total of 137 participants (UPA 30 mg, n = 62; PBO, n = 75) were included. Most participants were White (56.2%) and female (96.4%). As previously published, at week 48, 31 participants (50.0%) treated with UPA 30 mg and 18 (24.0%) treated with PBO achieved LLDAS; 33 participants (53.2%) treated with UPA 30 mg and 19 (25.3%) treated with PBO achieved BICLA (3). A numerically higher proportion of participants in most baseline characteristic subgroups treated with UPA 30 mg vs PBO achieved LLDAS and/or BICLA (**Table**), with treatment differences (estimated by the Cochran-Mantel-Haenszel test) consistent with potential benefits of UPA 30 mg across most subgroups (**Figure**).

Conclusion: After 48 weeks of treatment, participants with SLE treated with UPA30 mg were more likely than those receiving PBO to achieve LLDAS and/or BICLA across various baseline demographics and clinical characteristics; however, the interpretation of data in this study is limited by sample size. These findings, if corroborated in further studies, may support the potential benefit of UPA in a broad spectrum of patients with SLE despite the heterogeneity of the disorder.

anti-dsDNA, anti–double-stranded DNA; BICLA, British Isles Lupus Assessment Group-Based Composite Lupus Assessment; BMI, body mass index; LLDAS, Lupus Low Disease Activity State; NA, not applicable; SLEDAI-2K, Systemic Lupus Erythematosus Disease Activity Index 2000. aPercentage of responders with available data on LLDAS or BICLA.

anti-dsDNA, anti–double-stranded DNA; BICLA, British Isles Lupus Assessment Group-Based Composite Lupus Assessment; BMI, body mass index; LLDAS, Lupus Low Disease Activity State; NA, not applicable; SLEDAI-2K, Systemic Lupus Erythematosus Disease Activity Index 2000. Response rate differences and 95% CIs were estimated according to the Cochran-Mantel-Haenszel test adjusted for baseline corticosteroid use (≤10 mg or >10 mg), Systemic Lupus Erythematosus Disease Activity Index 2000 score at screening (<10 or ≥10), baseline interferon score (high, low, or not applicable), and baseline immunosuppressant use (yes or no).

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0641–0670) Systemic Lupus Erythematosus – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Anti-CD19 chimeric antigen receptor (CAR) T cell therapy shows promise in autoimmune disease. However, autologous CAR T-cell therapy is limited by prolonged pre- and post-apheresis timelines, access to authorized treatment centers, T cell product inconsistency, high costs, and production capacity to support a broad patient (pt) base. Derived from a clonal master induced pluripotent stem cell (iPSC) bank for mass production of CAR T cells for on-demand and broad utilization, FT819 is an off-the-shelf CD19-targeting CAR T cell product engineered with features designed to improve safety and efficacy via a 1XX CAR signaling domain that extends T cell effector function without exhaustion; integration of CAR transgene directly into the T cell receptor (TCR) alpha constant locus promotes uniform CAR expression and enhanced potency; and complete bi-allelic disruption of TCR expression for the prevention of graft-versus-host disease (GVHD).

Methods: A Phase 1 dose-escalation study evaluating the safety, pharmacokinetics, and anti-B-cell activity of FT819 in pts with B-cell mediated autoimmune diseases (NCT06308978) is ongoing. All pts enrolled to date have SLE (EULAR/ACR 2019 classification with at least one antibody: ANA 1:160, anti-dsDNA, or anti-smith), whose severity is defined by SLEDAI-2K $\geq$ 8 + 1 BILAG A/2 BILAG B scores. FT819 was administered as a single dose under 2 regimens (Reg): Reg A, fludarabine-free conditioning chemotherapy (CCT) with single-dose cyclophosphamide or bendamustine daily for 2 days prior to FT819; and Reg B, no CCT with continued stable dose of maintenance therapy, including mycophenolate (MMF).

Results: As of the data cutoff date, pts treated in Reg A and Reg B had follow-up ranging from 1-12 months (mo). All pts tolerated FT819 without dose-limiting toxicity. Expected cytopenias after CCT were observed in Reg A. No Grade >2 CRS, ICANS, GvHD, or death was reported.

Pts in Reg A experienced rapid and deep peripheral B cell depletion, with greater depletion observed at dose level 2 (DL; DL1 = 3.6×10^8 viable cells (VC)/dose; DL2 = 9×10^8 VC/dose). Reconstitution of the B cell compartment, predominantly naïve, was noted within 1-3 mo post-FT819. Pts from both Regimens experienced sustained improvements in SLEDAI-2K, PGA, and FACIT-fatigue scores and UPCr improved in pts with lupus nephritis (LN). Pts with LN achieved either a primary efficacy renal response or complete renal response (CRR) by last follow up.

In the first pt in Reg A, steroids were discontinued at 3 mo, Definition of Remission in SLE (DORIS) achieved at 6 and 12 mo, and CRR at 9 mo. In the first pt in Reg B (BILAG A cardiorespiratory), MMF was continued without CCT, and Low Lupus Disease Activity State was achieved at 3 mo. Additional pt outcomes of current and additional pts will be highlighted at the time of presentation.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Preliminary patient data indicates a favorable safety profile, effective B cell depletion, and promising initial efficacy. These findings support the continued evaluation of FT819 in SLE as well as other B-cell mediated autoimmune diseases (ANCA-associated vasculitis, idiopathic inflammatory myositis, and systemic sclerosis) included in the FT819 protocol.

Abstract Number: 0664

Pharmacodynamic Effects of Obinutuzumab on B cells and Serological Markers in Patients With Active Lupus Nephritis: Results From a Phase III Trial

Richard Furie[1], Ioannis Parodis[2], Rachel Jones[3], Liz Lightstone[4], Olivia Hwang[5], Amelia Au-Yeung[5], Imran Hassan[6], Huiyan Mao[6], William Pendergraft[5], Jay Garg[5], Harini Raghu[5] and Brad Rovin[7], [1]Division of Rheumatology, Northwell Health, Great Neck, NY, [2]Karolinska Institutet and Karolinska University Hospital, Department of Medicine Solna, Division of Rheumatology, Stockholm, Sweden, [3]Renal Medicine, Cambridge University Hospitals, Cambridge, England, United Kingdom, [4]Department of Immunology and Inflammation, Faculty of Medicine, Imperial College London, London, England, United Kingdom, [5]Genentech, Inc., South San Francisco, CA, [6]Hoffmann-La Roche Ltd, Mississauga, ON, Canada, [7]The Ohio State University, Columbus, OH

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0641–0670) Systemic Lupus Erythematosus – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Lupus nephritis (LN) is a severe manifestation of systemic lupus erythematosus, marked by kidney inflammation and damage. Obinutuzumab, a glycoengineered, type II CD20 antibody demonstrated effective B-cell depletion, reduced serum anti-double-stranded DNA (anti-dsDNA) antibodies and increased complement C3 and C4 levels in patients (pts) with LN in the Phase II NOBILITY (NCT02550652) trial. The Phase III REGENCY trial (NCT04221477) of obinutuzumab plus standard therapy in pts with active LN demonstrated a statistically significant improvement in Week 76 complete renal response and an acceptable safety profile.

Exploratory analyses of peripheral B-cell populations and serological markers were performed to confirm the pharmacodynamic effects of obinutuzumab in pts enrolled in the REGENCY trial.

Methods: Adults with active LN received placebo or obinutuzumab plus standard therapy (mycophenolate mofetil plus glucocorticoids). All pts met ACR SLE classification criteria and had biopsy-proven proliferative LN. Peripheral B cells and B-cell subsets were assessed using validated high-sensitivity flow cytometry (HSFC) assays minimal residual B-cell panel (MRB) 1.1 and BCP2.2, respectively. The lower limit of quantification (LLOQ) of CD19+ B cells by MRB1.1 is 0.441 cells/μL. Complement and anti-dsDNA antibody levels were measured by nephelometry and enzyme-linked immunosorbent assay,

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Longitudinal Characterization of Total CD19+ B Cells (A), Naive B (B), Memory B (C) and Plasmablasts/Plasma Cells (D) in the Blood REGENCY Study

HSFC, high-sensitivity flow cytometry; MRB, minimal residual B-cell panel.

Table 1: Normalization of C3, C4 and Anti-dsDNA in Patients With Abnormal Baseline Values at Weeks 12 and 76 by Treatment Arm in the Phase III REGENCY Trial

Serological biomarker at baseline	Treatment arm (n = abnormal at baseline)	Normalized at Week 12, n (%)	Normalized at Week 76, n (%)
C3 <0.9g/L	Obinutuzumab (n=77) Placebo (n=76)	38 (49) 25 (33)	48 (62) 22 (29)
C4 <0.1g/L	Obinutuzumab (n=32) Placebo (n=42)	24 (75) 23 (55)	28 (88) 23 (55)
Anti-dsDNA >120 kU/L	Obinutuzumab (n=57) Placebo (n=61)	24 (42) 10 (16)	32 (56) 10 (16)

respectively. Peripheral B-cell and serum biomarker assessments were performed on samples from Weeks 0, 4, 12, 24, 50 and 76.

Results: Baseline biomarker levels were comparable between arms and no pt had B-cell levels below the LLOQ. At Week 4, mean total CD19+ B-cell levels were greatly reduced with obinutuzumab (mean cells/μL [SD]: 4.7 [45.6], –99.8 median % change from baseline) vs placebo (mean cells/μL [SD]: 317.8 [338.5], –4.2 median % change) and remained low relative to placebo at every timepoint tested through Week 76 (**Figure 1A**). Similar decreases in B-cell subsets were observed with obinutuzumab relative to placebo from Week 4-76 (**Figures 1B-D**). Obinutuzumab treatment also resulted in greater reductions in anti-dsDNA antibody levels and increases in complement C3 and C4 vs placebo. In pts with abnormal baseline serologies, higher normalization rates for C3 (43% vs 14%), C4 (70% vs 39%) and anti-dsDNA antibody levels (45% vs 11%) were observed at Week 12 for obinutuzumab vs placebo; these normalization rates were sustained or further improved through Week 76, with normalization rates of 62% vs 29% for C3, 88% vs 55% for C4 and 56% vs 16% for anti-dsDNA antibody levels at Week 76 (**Table 1**).

Conclusion: Obinutuzumab plus standard therapy induced rapid and sustained depletion of total peripheral CD19+ B cells and B-cell subsets in pts with active LN. Obinutuzumab treatment demonstrated improvements in serological markers of disease activity, increases in serum C3 and C4 levels, and reductions in anti-dsDNA antibody levels over placebo in all pts.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Among pts with abnormal baseline marker values, obinutuzumab led to earlier and greater normalization rates vs placebo. These data support the hypothesis that deep B-cell depletion with obinutuzumab contributes to the improved clinical responses observed in pts with LN.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0641–0670) Systemic Lupus Erythematosus – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: The REGENCY (NCT04221477) trial demonstrated superior efficacy of obinutuzumab and standard therapy (OBI+ST) over placebo and ST (PBO+ST) in patients (pts) with active lupus nephritis (LN). Although an acceptable safety profile was observed, insights related to IRRs and hematologic effects of OBI are needed to guide future management. In this study, we further characterize important non-infectious adverse events including the IRR profile of OBI and describe the occurrence of neutropenia in the REGENCY trial.

Methods: Incidence, severity and attribution of IRRs and hematologic abnormalities, including drug-related neutropenia, were determined in the REGENCY trial based on investigator and NCI CTCAE v5.0 adverse event grading. Descriptive analyses were performed comparing pts receiving OBI+ST vs PBO+ST. All pts met ACR SLE classification criteria and had biopsy-proven proliferative LN.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: The proportion of pts who experienced at least one IRR was higher in the OBI+ST arm vs the PBO+ST arm (21 [15.4%] vs 15 [11.4%], respectively) during the 76-week period. In the OBI+ST arm, the majority (19 [14.0%]) experienced IRRs of Grade (Gr) 1-2, which resolved following protocol guidance. Two pts (1.5%) experienced Gr 3-4 IRRs in the OBI+ST arm and both events resolved: one non-serious IRR of Gr 3 and one serious IRR of Gr 4, one leading to treatment discontinuation for this pt. No Gr 5 IRRs were observed. The most frequently reported signs and symptoms of IRRs in the OBI vs PBO arms respectively were nausea (4 [2.9%] vs 4 [3.0%]), headache (4 [2.9%] vs 3 [2.3%]) and vomiting (4 [2.9%] vs 2 [1.5%]). IRR incidence and severity was highest at first infusion, with Gr 3-4 observed only then, and decreased with additional infusions (**Table 1**).

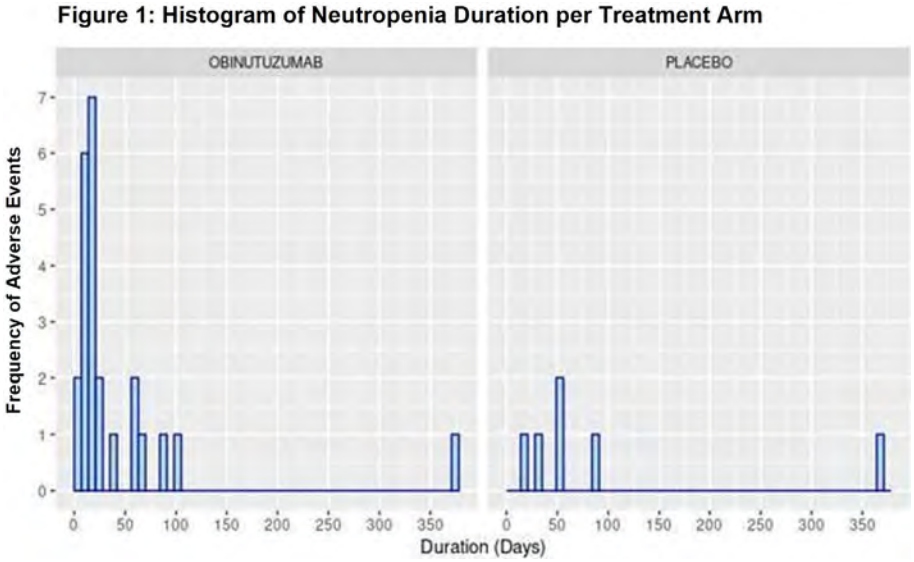
The frequencies of shifts observed from Gr 1-2 at baseline to Gr 3-4 post-baseline were notably different between the treatment arms only for neutrophils and lymphocytes. As lymphopenia is an expected pharmacologic effect of anti-CD20 therapies, this analysis focused on drug-related neutropenia. The proportion of pts who experienced at least one drug-related

Table 1: Incidence and Grade of Infusion-Related Reactions by Infusion Visits and Treatment

	Obinutuzumab (n=136)	Placebo (n=132)
Infusion 1		
Patients who had infusion, n (%)	136 (100)	132 (100)
Total patients with ≥1 IRR, n (%)	14 (10.3)	8 (6.1)
Total patients with ≥1 IRR grade 1-2, n (%)	12 (8.8)	8 (6.1)
Total patients with ≥1 IRR grade 3-5, n (%)	2 (1.5)	0
Infusion 2		
Patients who had infusion, n (%)	133 (97.8)	132 (100)
Total patients with ≥1 IRR, n (%)	5 (3.7)	4 (3)
Total patients with ≥1 IRR grade 1-2, n (%)	5 (3.7)	4 (3)
Total patients with ≥1 IRR grade 3-5, n (%)	0	0
Infusion 3		
Patients who had infusion, n (%)	128 (94.1)	124 (93.9)
Total patients with ≥1 IRR, n (%)	3 (2.2)	3 (2.3)
Total patients with ≥1 IRR grade 1-2, n (%)	3 (2.2)	3 (2.3)
Total patients with ≥1 IRR grade 3-5, n (%)	0 (0)	0 (0)
Infusion 4		
Patients who had infusion, n (%)	127 (93.4)	123 (93.2)
Total patients with ≥1 IRR, n (%)	2 (1.5)	0 (0)
Total patients with ≥1 IRR grade 1-2, n (%)	2 (1.5)	0 (0)
Total patients with ≥1 IRR grade 3-5, n (%)	0 (0)	0 (0)
Infusion 5		
Patients who had infusion, n (%)	120 (88.2)	112 (84.8)
Total patients with ≥1 IRR, n (%)	0 (0)	2 (1.5)
Total patients with ≥1 IRR grade 1-2, n (%)	0 (0)	2 (1.5)
Total patients with ≥1 IRR grade 3-5, n (%)	0 (0)	0 (0)
Infusion 6		
Patients who had infusion, n (%)	117 (86)	108 (81.8)
Total patients with ≥1 IRR, n (%)	1 (0.7)	2 (1.5)
Total patients with ≥1 IRR grade 1-2, n (%)	1 (0.7)	2 (1.5)
Total patients with ≥1 IRR grade 3-5, n (%)	0 (0)	0 (0)

Safety analyses included all patients who received any infusion of obinutuzumab or placebo, grouped according to the infusion that was actually administered. All study participants were premedicated with methylprednisolone (80 mg IV), acetaminophen (650-1000 mg) orally and diphenhydramine (50 mg orally or IV [or equivalent dose of a similar agent]) prior to each infusion of obinutuzumab or placebo.
IRR was defined as any AE occurring during or within 24 hours after IV infusion of obinutuzumab or placebo assessed by study investigators to be related to the infusion. Systemic IRRs were considered AEs of special interest.
AE, adverse event; IRR, infusion-related reaction; IV, intravenous.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



neutropenia was higher in the OBI+ST arm vs the PBO+ST arm (17 [12.5%] vs 5 [3.8%], respectively). Most cases of neutropenia were incidentally detected during routine hematology labs at scheduled study visits. Median time for resolution was 16 days (d) (min-max: 4-378 d) and 50.5 d (min-max: 21-371 d) in the OBI+ST and PBO+ST arm, respectively. Seven pts (4.1%) had Gr 3-4 drug-related neutropenia (including 1 febrile neutropenia) in the OBI+ST arm, whereas none in the PBO +ST arm had Gr 3-4 neutropenia. All drug-related neutropenia resolved with treatment by protocol guidance except for one PBO pt whose neutropenia was recovering/resolving at the clinical cutoff. No Gr 5 neutropenia was observed. Five patients received G-CSF treatment for drug-related neutropenia (4 in the OBI+ST arm vs 1 in the PBO+ST arm).

Conclusion: Although the incidence of IRRs and drug-related neutropenia was higher in pts receiving OBI+ST compared with PBO+ST, these risks remained low overall; many were Gr 1-2, self-limited, easily manageable and without consequence for most pts. These data provide insights into adverse events related to OBI.

Abstract Number: 0666

Reported Adverse Events Associated With Systemic Lupus Erythematosus (SLE) Treatment: Insights From the FDA Adverse Event Reporting System (FAERS) 2023

Sarah Crisci, New York University, New York, NY

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0641–0670) Systemic Lupus Erythematosus – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease with heterogeneous symptoms, complicating diagnosis and treatment. Historically, treatment included broad immunosuppressants, but real-world

Table 1: Characteristics of primary suspect reports associated with Belimumab, Anifrolumab, and all drugs, among SLE patients in 2023

	Belimumab n (%)	Anifrolumab n (%)	Total – all drugs n (%)
Total number of patients	1822	267	4707
Sex			
Male	46 (2.52%)	23 (8.61%)	319 (6.78%)

ROR = Reporting Odds Ratio; CI = Confidence Interval; SOC = System Organ Class; * = positive signal

data now show significant adverse effects associated with traditional treatments. Since 2011, two biologics have been approved for SLE, but clinical trials are not always representative of real-world populations, necessitating post-marketing safety evaluation.

Methods: FDA Adverse Event Reporting System data were analyzed using a disproportionality analysis to detect risk signals for each approved biologic. Reporting odds ratios (ROR) were calculated for each system organ class (SOC) and preferred term (PT), defined by the Medical Dictionary for Regulatory Activities.

Results: In 2023, 125,675 primary suspect adverse events (AEs) were reported among individuals with SLE, including 10,737 belimumab and 661 anifrolumab cases. Belimumab AEs occurred in all 27 SOCs and were significant in five [Social circumstances (ROR 5.27, 95% CI 4.34, 6.39), Reproductive system and breast disorders (ROR: 4.62, 95% CI 2.73, 7.82), Product issues (ROR 3.48, 95% CI 2.96, 4.09), Ear and labyrinth disorders (ROR: 2.26, 95% CI 1.61, 3.17), Respiratory, thoracic and mediastinal disorders (ROR: 2.10, 95% CI 1.90, 2.32)]; and anifrolumab AEs occurred in 25 SOCs and were significant in three [Reproductive system and breast disorders (ROR: 4.36, 95% CI 1.57, 12.06), Renal and urinary disorders (ROR: 2.96, 95% CI 1.93, 4.53), Cardiac disorders (ROR: 2.15, 95% CI 1.35, 3.41)].

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

In total, 169 belimumab PTs and 20 anifrolumab PTs displayed significant disproportionality. The top five belimumab PTs by strength of safety signal were Product complaint (ROR 164.28, 95% CI 22.72, 1187.69), Product storage error (ROR 133.73, 95% CI 18.42, 970.81), Exposure via skin contact (ROR 127.63, 95% CI 17.56, 927.48), Wrong technique in device usage process (ROR 71.09, 95% CI 22.38, 225.82), and Product supply issue (ROR 69.77, 95% CI 9.42, 516.71); for anifrolumab these were Insurance issue (ROR 78.51, 95% CI 17.54, 351.42), Appendicitis (ROR 39.25, 95% CI 11.05, 139.39), Anaphylactic reaction (ROR 31.57, 95% CI 13.34, 74.69), Herpes zoster (ROR 23.15, 95% CI 14.23, 37.65), and Cardiac failure (ROR 19.65, 95% CI 7.12, 54.21).

Conclusion: In belimumab clinical trials, the most common SOC AEs were infections, gastrointestinal, musculoskeletal, nervous system, and skin disorders. Each of these was frequent in this study, but not disproportionately high. However, five other SOCs show significant disproportionality, indicating possible safety concerns not identified in trials.

In anifrolumab clinical trials, the most common SOC AEs were infections, general and administration site conditions, respiratory disorders, and musculoskeletal disorders. None showed disproportionately high safety signals in this study, but three additional SOCs were disproportionately high.

Despite limitations of spontaneous reporting systems, these findings highlight potential safety concerns with biologics in SLE. Further research using real-world data is needed.

Abstract Number: 0667

Retrospective Chart Audit Reveals Gaps in Steroid Tapering and Use of ACR Guideline-Recommended Regimens in LN

Sawyer May[1], Lynn Price[1] and Ryan Rex[2], [1]Spherix Global Insights, Exton, PA, [2]Spherix Global Insights, Chester Springs, PA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0641–0670) Systemic Lupus Erythematosus – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: In May 2025, ACR released updated recommendations for the management of LN[2]. Notably, since the previous guidelines update in 2012, the FDA has approved belimumab and voclosporin for the treatment of LN.

Methods: 1,017 moderate-to-severe (M/S) adult SLE patient records were collected in collaboration with 176 US rheumatologists via an online survey platform from January through March 2025. This analysis focuses on a subset of 226 SLE patients with biopsy-proven ISN Class III, IV, or V LN disease. These patients also had to exhibit active, new-onset, or flaring renal disease, defined as an LN diagnosis within the past five years, a flare within the past six months, or active renal involvement at their most recent rheumatology visit.

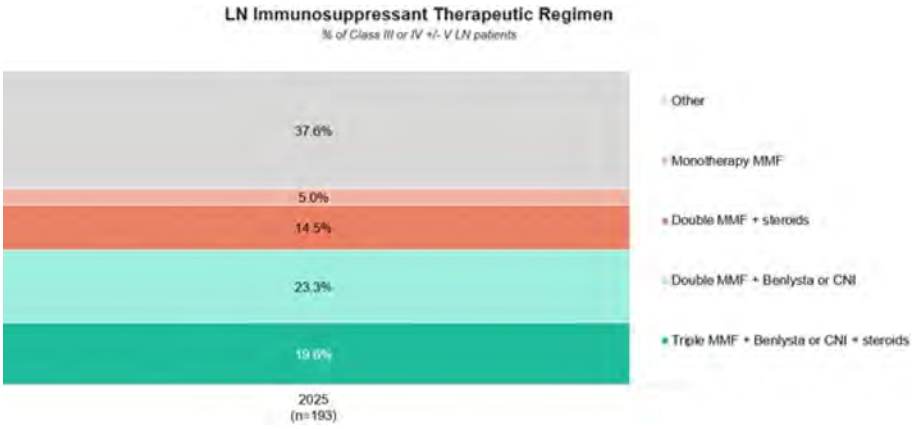
Results: ACR strongly recommends that patients with Class III, IV, or V LN be treated with hydroxychloroquine (HCQ), unless contraindicated. This retroactive chart analysis finds that 88.1% of these patients are currently prescribed HCQ.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

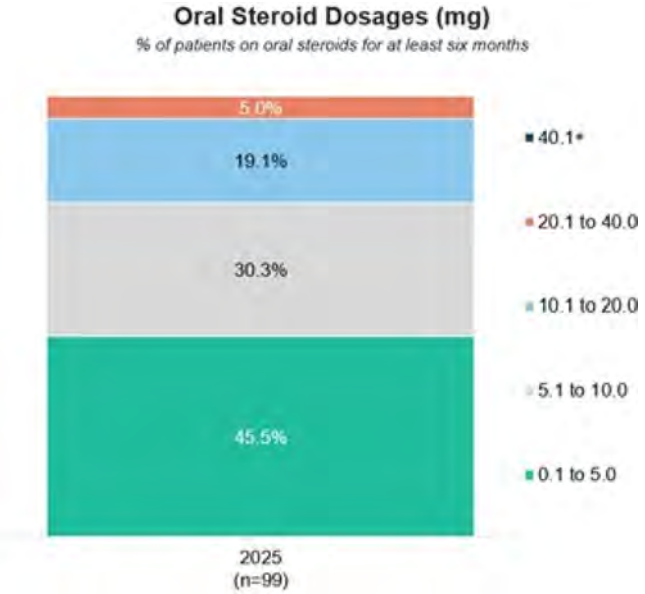
Second, ACR recommends use of RAAS-I therapy for Class III, IV, or V LN patients with any level of proteinuria in their urine. Our analysis shows that 69.3% of these patients are on RAAS-I therapy, most commonly ACE inhibitors such as lisinopril and enalapril.

Third, ACR recommends that oral steroids be tapered to at least 5mg per day within six months of initiating the treatment for Class III, IV, or V LN patients. Furthermore, daily steroid dosages should not exceed 40mg/day. Our analysis shows that 50.4% of patients are currently receiving steroid treatment, with none prescribed more than 40 mg per day. Notably, over half (54.5%) of patients who have been on oral steroids for at least six months are taking doses higher than 5mg daily. Only 51.5% of patients who are on oral steroid dosages exceeding 5mg per day are currently on a regimen consisting of belimumab or a calcineurin inhibitor (CNI), which have been demonstrated to be effective steroid-sparing agents.[3,4]

Fourth, for patients with Class III or IV ± V LN, ACR recommends a triple therapy regimen of steroids, MMF or cyclophosphamide (CYC), and either a CNI or belimumab. Among the 193 patients meeting these criteria, 19.6% are currently prescribed MMF and steroids in combination with a CNI or belimumab. Furthermore, 23.3% of patients are prescribed MMF and belimumab or a CNI without steroids.



LN Immunosuppressant Therapeutic Regimen



Oral Steroid Dosages (mg)

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Currently, rheumatologists frequently prescribe HCQ and RAAS-I therapies to their LN patients, in line with the updated ACR guidelines. However, many patients remain on high-dose steroids after six months of treatment. Nearly half of those on high-dose steroids are not prescribed a CNI or belimumab, suggesting an opportunity to reduce steroid use through broader use of these drugs. Additionally, only a minority of qualified Class III or IV ± V patients are on a double therapy regimen (MMF or CYC + belimumab or a CNI ± steroids), underscoring the potential impact guideline adoption could have on the management of this disease.

Glucocorticoid-Sparing Effects and Flare Suppression: Metformin Versus SGLT2 Inhibitors in Systemic Lupus Erythematosus

Takeshi Suzuki, Yoshiki Ishizaki, Takayasu Ando, Shotaro Suzuki, Keiichi Sakurai, Kumiko Tonooka, Yukiko Takakuwa, Hiroko Nagafuchi, Seido Ooka and Kimito Kawahata, St. Marianna University School of Medicine, Kawasaki, Kanagawa, Japan

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0641–0670) Systemic Lupus Erythematosus – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: While both metformin (MET) and SGLT2 inhibitors (SGLT2i) have potential immunomodulatory effects in Systemic Lupus Erythematosus (SLE), their comparative efficacy in glucocorticoid (GC)-sparing remains unclear. This study aims to compare GC discontinuation and flare suppression between MET and SGLT2i in SLE patients.

Methods: This is a retrospective cohort study using TriNetX's Global collaborative network. We defined a cohort of SLE patients (ICD-10 M32) prescribed hydroxychloroquine and with anti-dsDNA antibody testing. Within this cohort, patients initiating glucocorticoid treatment (prednisolone or prednisone) were then categorized into two distinct groups for analysis: the MET group, comprising those subsequently prescribed metformin, and the SGLT2i group, comprising those subsequently prescribed a SGLT2i after glucocorticoid exposure. The primary endpoint was GC discontinuation (defined as no GC prescriptions) within a 3-12 month period following the index prescription of MET or an SGLT2i. Primary outcome sensitivity analyses focused on GC tablets ≤5 mg, with additional analyses in the glucocorticoid ≤5 mg tablet group when MET or SGLT2 inhibitors were subsequently prescribed. The secondary endpoint, assessed in patients from both groups who had discontinued GC, was GC reinitiation within a 3-month to 3-year period. The primary endpoint was compared between groups using the Chi-squared test. For the secondary endpoint, comparisons were made after propensity score matching (age, sex, race, BMI, anti-dsDNA antibody, complements, MMF, Belimumab, Anifrolumab, Diabetes mellitus, HbA1c, Heart failure, End-stage renal disease, Chronic kidney disease, unspecified) utilizing the TriNetX platform.

Results: MET was initiated in 1228 patients, with 89.5% being women, and the mean age was 56 ± 14 years. SGLT2i was initiated in 718 patients, with 82.4% being women, and the mean age was 55±17 years. The duration of SLE disease before the first prescription of MET and SGLT2i was 1827 ± 1386 and 2593 ± 1608 days, respectively. Mycophenolic acid use was 71% in the SGLT2i group and 53% in the MET group. Baseline HbA1c levels were numerically higher in the MET group (6.3 ± 1.4%) than in the SGLT2i group (5.8 ± 1.13%). Among these patients, GC was discontinued in 445 (36.2%) patients in the MET group and in 488 (68.4%) patients in the SGLT2i group. GC discontinuation was significantly more frequent in the SGLT2i group ($p < 0.001$; Odds Ratio [OR] 3.85, 95% CI 3.23-4.60). The sensitivity analyses corroborated the primary

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

results. After propensity score matching of patients who had discontinued GC, 248 patients remained in each group for the secondary endpoint analysis. In this propensity score-matched cohort, the GC reinitiation rate within 3 months to 3 years after GC discontinuation was significantly lower in the SGLT2i group (10.1%) compared to the MET group (23.0%) ($p < 0.0001$; OR 3.87, 95% CI 1.60-4.43).

Conclusion: In SLE patients treated with GC, SGLT2i use was associated with a significantly higher rate of GC discontinuation and a lower rate of subsequent GC reinitiation compared to MET. These findings suggest that SGLT2 inhibitors may offer a superior GC-sparing effect in SLE patients.

Clinical and Laboratory Factors Associated With Biopsy-Confirmed Antimalarial-Induced Cardiomyopathy

Youngmin Kim[1], Norioscar Cabello[2], Robert Padera[2], Brittany Weber[3] and Karen H. Costenbader[4], [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston, [3]Brigham and Women's Hospital, DEDHAM, MA, [4]Harvard Medical School and Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0641–0670) Systemic Lupus Erythematosus – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Hydroxychloroquine (HCQ) is widely prescribed in rheumatology, particularly for systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA). Though generally safe, HCQ can cause rare but serious antimalarial-induced cardiotoxicity (AMIC). AMIC diagnosis is challenging, as cardiac biopsy with electron microscopy (EM) remains the gold standard but is invasive. This study evaluated screening practices for AMIC among HCQ users, focusing on clinical, imaging, and laboratory assessments performed prior to cardiac biopsy.

Methods: We conducted a retrospective review of patients with HCQ exposure who underwent native heart biopsy at our large academic medical center. Biopsy reports were reviewed for AMIC features (e.g., curvilinear, lamellar, myeloid bodies) or other findings. Structured EHR data were extracted for demographics, diagnoses, HCQ prescription dates, cardiac biomarkers (Troponin-I/T, NT-proBNP, CK-MB, hsCRP), and cardiac testing (EKG, echocardiogram, cardiac MRI) prior to biopsy. HCQ exposure duration was calculated from first prescription to biopsy. Abnormal biomarkers were defined by any elevated result prior to biopsy. Group comparisons used t-tests, Fisher's exact tests, ANOVA, and Tukey's HSD post-hoc tests.

Results: Among 73 HCQ users who underwent biopsy, 15 had biopsy-confirmed AMIC and 58 did not. AMIC patients more frequently had SLE (80% vs. 38%, p=0.007), while other baseline characteristics (age, sex, race, HCQ duration) did not differ significantly (**Table 1**). Mean HCQ duration before biopsy was longer in patients with AMIC on biopsy (283 vs. 205 weeks). Few patients had cardiac biomarker testing prior to biopsy, but abnormalities were more common in AMIC, including elevated troponin-T (63% vs. 35%) and CK-MB (56% vs. 32%), though not statistically significant. Cardiac MRI was also underutilized: 53% in AMIC vs. 35% in non-AMIC. Among non-AMIC patients, only 12 (21%) had EM performed as AMIC was not suspected on toluidine blue staining (**Table 2**). Most biopsies showed non-specific findings such as hypertrophy (74%), fibrosis (45%), and vacuolization (21%).

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1. Demographic, clinical, laboratory, and cardiac imaging characteristics of 73 patients with biopsy-confirmed antimalarial-induced cardiomyopathy (AMIC) and patients without AMIC (non-AMIC)

	AMIC (n = 15)	Non-AMIC (n = 58)	*p*
Demographics			
Age (mean, SD)	65.7 (13.5)	63.3 (12.0)	0.54
Females (*n*, %)	12 (80.0)	40 (69.0)	0.53
Whites (*n*, %)	12 (80.0)	45 (77.6)	1
Hydroxychloroquine Duration Prior to Biopsy (Weeks; mean, SD)	282.6 (362.6)	204.8 (300.7)	0.47
Rheumatologic Diagnosis			
Systemic Lupus Erythematosus (*n*, %)	12 (80.0)	22 (37.9)	0.007
Rheumatoid Arthritis (*n*, %)	2 (13.3)	16 (27.6)	0.33
Sarcoidosis (*n*, %)	0 (0)	6 (10.3)	0.34
Vasculitis (*n*, %)	1 (6.7)	1 (1.7)	0.37
Myositis (*n*, %)	0 (0)	3 (5.2)	1
Cardiac Biomarker Abnormalities			
Troponin-I (n, % of tested)	1/6 (16.7)	3/19 (15.8)	1.00
Troponin-T (n, % of tested)	5/8 (62.5)	7/20 (35.0)	0.23
CKMB (n, % of tested)	5/9 (55.6)	11/34 (32.4)	0.26
NT-BNP (n, % of tested)	7/9 (77.8)	15/20 (75.0)	1.00
hs-CRP (n, % of tested)	3/4 (75.0)	3/9 (33.3)	0.27
Cardiac Tests			
Electrocardiography	15 (100.0)	51 (87.9)	0.33
Echocardiography	13 (86.7)	45 (77.6)	0.72
Cardiac MRI	8 (53.3)	20 (34.5)	0.24

Values are presented as mean (standard deviation) for continuous variables and number (percentage) for categorical variables. p-values were calculated using Fisher's exact test for categorical variables and Student's t-test for continuous variables. AMIC: antimalarial-induced cardiomyopathy; HCQ: hydroxychloroquine; cBx: cardiac biopsy; SLE: systemic lupus erythematosus; CKMB: creatine kinase myocardial band; NT-BNP: N-terminal pro B-type natriuretic peptide; hs-CRP: high-sensitivity C-reactive protein.

Table 2. Features of Cardiac Biopsies in Patients Without Confirmed AMIC (n = 58)

Indications for Biopsy, Suspected Diagnoses	***n* (%)**
Cardiomyopathy	26 (44.8)
Sarcoidosis	6 (10.3)
Amyloidosis	5 (8.6)
Myocarditis	4 (6.9)
Connective Tissue Disease (SLE, EGPA)	9 (15.5)
AMIC	2 (3.4)
Autopsy	2 (3.4)
Heart Failure	4 (6.9)
H&E Biopsy Findings/Final Diagnosis	
Myocyte Vacuolization	12 (20.7)
Myocyte Hypertrophy	43 (74.1)
Interstitial Fibrosis	26 (44.8)
Ischemic Heart Disease	5 (8.6)
Amyloidosis	3 (5.2)
Sarcoidosis	2 (3.4)
Electron Microscopy	
Not performed as low suspicion AMIC	46 (79.3)
Confirmed Absence of AMIC	12 (20.7)

Conclusion: This study provides one of the largest biopsy-confirmed AMIC case series to date, comparing findings to those of patients taking HCQ who had cardiac biopsies in which AMIC was not confirmed. Few patients underwent cardiac biomarker testing or advanced imaging before biopsy, revealing missed opportunities for earlier detection. These findings underscore the need for non-invasive AMIC screening strategies to improve recognition, estimate disease burden, and enable timely intervention.

Abstract Number: 0670

Clinical Significance of Therapeutic Drug Level Monitoring for Mycophenolate in Patients With Extra-renal Systemic Lupus Erythematosus – A Systematic Review & Meta-analysis

Zahraa Qamhieh[1], Dalia Sriwi[1], Callie Saric[2], Tripti Singh[3], Christie Bartels[4] and Shivani Garg[5], [1]University of Wisconsin, Madison, Department of Medicine, Madison, WI, [2]University of Wisconsin, Madison, School of Medicine and Public Health, Madison, WI, [3]University of Wisconsin, Madison, Department of Nephrology, Madison, WI, [4]University of Wisconsin School of Medicine and Public Health, Madison, WI, [5]University of Madison, School of Medicine and Public Health, Madison, WI

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0641–0670) Systemic Lupus Erythematosus – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Clinical response to Mycophenolic acid (MPA) is highly heterogeneous; thus, therapeutic drug monitoring (TDM) of MPA could help improve treatment efficacy. Our objective in this systematic review and meta-analysis was to examine therapeutic ranges for MPA levels that are associated with better outcomes and safety in patients with SLE, particularly those with extra-renal SLE manifestations.

Methods: We performed a comprehensive search of studies measuring an association between MPA levels and clinical SLE response. Using forest plots, we calculated pooled odds of clinical response by MPA levels. Additionally, we measured the weighted mean difference in MPA levels across clinical outcomes. Analysis was performed in all patients with SLE, then separately in patients with extra-renal SLE manifestations.

Results: Among 459 reviewed abstracts, 24 met inclusion. Summarized evidence supported maintaining MPA AUC0-12 levels within 30-60 mg h/L or MPA C12 within 1-2.5 mg/L; these levels were not associated with higher adverse events. Therapeutic MPA levels were associated with 12-fold higher odds (95% CI 5.44-27.35, $P < 0.0001$, $I2 = 41\%$) of overall clinical SLE response, and 15-fold higher odds (95% CI 4.74–46.89); $p < 0.0001$; I2=61%) of clinical response in patients with extra-renal manifestations. Additionally, MPA levels were 32 units higher (95% CIs 17.35 45.67) in overall SLE responders, and 39 units (95% CI 15.05-62.53) higher in patients with extra-renal manifestations.

Conclusion: This study highlights the clinical utility of TDM to guide precise MPA dosing to balance efficacy vs. safety in all patients with SLE, including those with extra-renal manifestations.

Session Date: Sunday, October 26, 2025

Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Cardiac manifestations significantly impact the prognosis of patients with systemic sclerosis (SSc), underscoring the need for early risk stratification. While gastrointestinal (GI) symptoms are common and impair quality of life, their role as predictors of cardiac involvement remains unclear. Emerging data suggest a link between GI and cardiac manifestations, possibly through shared mechanisms like dysautonomia and immune-mediated damage to mesodermally derived neurons. This study explores whether baseline GI symptoms could serve as early indicators of future cardiac events, aiming to identify high-risk phenotypes for personalized management.

Methods: We analyzed data from 459 patients with early SSc enrolled in a prospective cohort. GI and cardiac manifestations were comprehensively evaluated both at baseline and during follow-up. GI involvement was defined as the presence of one or more of the following symptoms: dysphagia, peptic ulcer, bloating, diarrhea, malabsorption, constipation, or pseudo-obstruction. To assess whether any of these early GI symptoms could predict the later development of cardiac complications—specifically conduction abnormalities or cardiomyopathy—we applied multivariable logistic regression and Cox models, adjusting for key confounders such as age, sex, and disease duration.

Results: At baseline, GI involvement was present in 60% of patients with early systemic sclerosis. During follow-up, 26% of these patients developed cardiac complications, mainly conduction defects (24%) and less frequently cardiomyopathy (5%).

Table 1. Associations between GI manifestations and cardiac complications* in SSc patients over time: results from logistic models. Definition of GI manifestations: (a) Dysphagia, defined as pain or difficulty in swallowing or passing food; (b) Peptic ulcer, documented; (c) Bloating; (d) Diarrhea; (e) Malabsorption, confirmed by diarrhea associated with >10% weight loss or by abnormal chemical studies. Symptoms from (c) to (d) were self-reported by patients. *Cardiac complications refers to the following domains: cardiomyopathy and conduction defects. § Refers to the age at the time of the first cardiac complication (if applicable) or the maximum age reached during the study period (if no cardiac complication occurred). # Refers to disease duration from the first non-Raynaud symptom to the time of the first cardiac complication (if applicable), or to the maximum disease duration reached during the study period (if no cardiac complication occurred). Values are Odds Ratio (95% confidence interval). † Statistically significant.

Characteristic	Cox regression	Cox regression adjusted for age§, sex and disease duration#
Any GI	**1.45 (1.02-2.07)**	1.19 (0.79-1.78)
Upper GI	1.19 (0.84- 1.67)	1.11 (0.74-1.669
Dysphagia	1.24 (0.88-1.75)	1.14 (0.76-1.70)
Lower GI	**1.82 (1.3-2.56) †**	1.40 (0.93-2.13)
Bloating	**2.79 (1.91-4.10) †**	**2.72 (1.71 – 4.32) †**
Diarrhea	1.06 (0.69-1.64)	1.21 (0.73-2.10)
Malabsorption	**19.90 (9.89-40.06) †**	**33.56 (15.85-71.06) †**

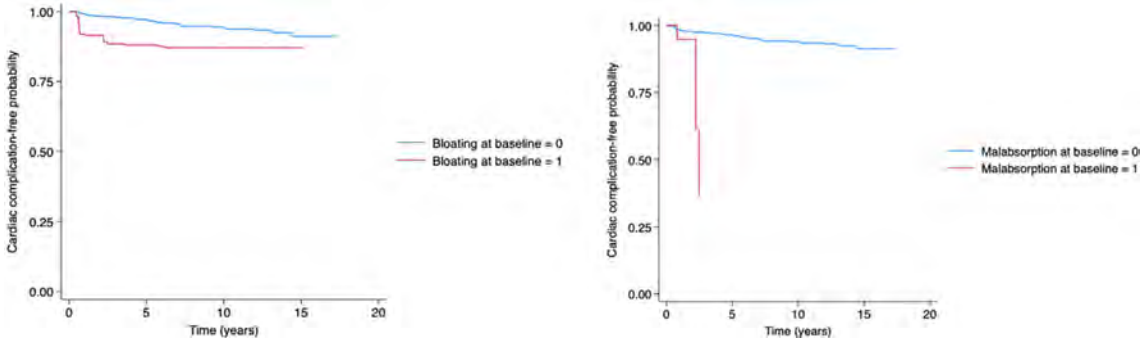

Figure 1. Kaplan-Meier analysis of time to cardiac complications* onset according to baseline bloating and malabsorption. *Cardiac complications refers to cardiomyopathy and/or conduction defects. Log-rank test: Bloating at baseline, $p < 0.001$; Malabsorption at baseline, $p < 0.001$.

A significant association was found between GI manifestations and cardiac involvement, with bloating showing the strongest association (OR 3.3, 95% CI 1.7–6.2), even after adjustment in the multivariable model (Tab.1). We then examined the strength of the association between individual GI symptoms and the two cardiac complications. Notably, upper GI symptoms like dysphagia (OR 3.3; 95% CI: 1.8–6.0) and peptic ulcers (OR 3.2; 95% CI: 1.5–7.2) were specifically associated with conduction defects, while malabsorption was strongly associated with cardiomyopathy (OR 4.6; 95% CI: 1.4–15.0). These associations remained robust even in the multivariable model. Cox regression was then applied to identify baseline GI symptoms in SSc patients that predict cardiac complications. Interestingly, malabsorption and bloating emerged as the strongest predictors of subsequent cardiac complication with malabsorption in particular conferring the highest risk, with a hazard ratio (HR) of 33.6 (95% CI: 15.8–71.1), after adjusting for potential confounders (Fig.1) (Tab.2).

Conclusion: Upper GI symptoms were selectively associated with cardiac conduction defects, suggesting that autonomic nervous system dysfunction may contribute to this relationship. In contrast, lower GI involvement—particularly malabsorption—was linked to cardiomyopathy in early SSc, pointing to a possible shared mechanism. If confirmed in other early SSc cohorts, these findings support the integration of early GI symptoms into cardiac risk stratification and highlight the importance of targeting these patient subgroups in future translational research.

Abstract Number: 0672

Determinants of Progressive Microstomia in Systemic Sclerosis: Insights from the GENISOS Cohort with a Focus on GI Involvement

Francesca Romana Di Ciommo[1], **Ashish Balar**[2], Robert M. Anderton[2], Michael Hughes[3], Brian Skaug[4], Maureen Mayes[5], Shervin Assassi[6], Ali Y Ayla[2] and Zsuzsanna McMahan[7], [1]La Sapienza University of Rome, Rome, Italy, [2]UTHealth Houston, Houston, TX, [3]Division of Musculoskeletal and Dermatological Sciences, The University of Manchester, Manchester Academic Health Science Centre, Manchester, UK, Manchester, England, United Kingdom, [4]UTHealth Houston Division of Rheumatology, Houston, TX, [5]UT Health Houston Division of Rheumatology, Houston, TX, [6]Division of Rheumatology, UTHealth Houston, Houston, Texas, USA, Houston, TX, [7]UT Health Houston, Houston, TX

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic sclerosis (SSc) is a complex autoimmune condition characterized by vascular abnormalities, immune dysregulation, and progressive fibrosis affecting both the skin and internal organs. Among its manifestations, facial and perioral involvement may lead to mouth opening reduction, known as microstomia, which negatively impacts nutrition, oral hygiene, and the tolerance of procedures like endoscopy or intubation. Despite its clinical impact, it remains unknown who will develop microstomia, and whether it is predictive of other SSc complications. This study aims to determine the evolution of microstomia over time, identify predictors of its progression, and explore its potential association with systemic manifestations of SSc.

Methods: We conducted a longitudinal analysis in the GENISOS cohort, including SSc patients with serial measurements of maximal mouth opening (MO), defined as the distance between the upper and lower lips. The percentage reduction in mouth opening was calculated from baseline to the minimum value recorded for each patient. Only patients with at least two observations separated by at least 6 months were included. Based on the distribution of MO percentage reduction values, a cut-off of 12.3% from baseline (top third of patients with the most significant MO change) was used *a priori* to define severe microstomia. Patients with a reduction >12.3% were classified as severe (group 2) and compared to those with a reduction $\leq$ 12.3% (group 1). Clinical variables, including disease duration, skin involvement, and symptoms of internal organ dysfunction (e.g., dysphagia), were compared across groups. Logistic and Cox regression models were used to identify predictors of severely reduced MO.

Table1. Longitudinal Comparison of Demographic and Clinical Characteristics in GENISOS SSc Patients With (Group 2) and Without (Group 1) Severe Reduction in Oral Aperture. MO= mouth opening;SD standard deviation; IQR = interquartile range; FVC = forced vital capacity; DLco =diffusing capacity for carbon monoxide; p p-value; GERD = gastroesophageal reflux disease; mRSS = modified Rodnan Skin Score * Age at the date of minimum oral aperture. § Disease duration from any symptom to the date of minimum oral aperture. ‡ Maximum Medsger general, GI, skin, lung, peripheral vascular, and muscle severity score of >1; Maximum Medsger cardiac and joint severity score of >1. # Value is expressed as a percentage. FVC and DLco are represented by the minimum values ever recorded. † Statistically significant.

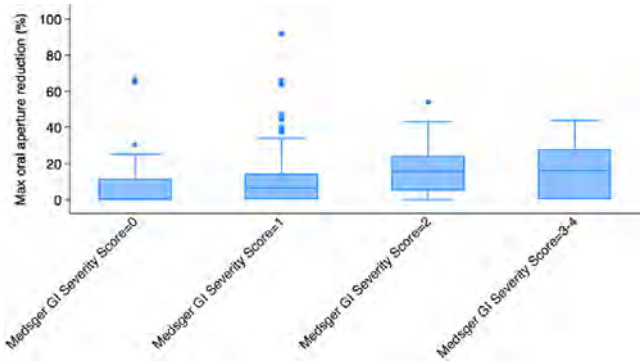

Figure 1. Distribution of maximal percent reduction in oral aperture across worsening Medsger GI Severity Scores. Score 0 (n = 52): median 0%, IQR 0–11.55 Score 1 (n = 241): median 6.25%, IQR 0–14.28 Score 2 (n = 31): median 15.55%, IQR 5–24 Score 3–4 (n = 18): median 16.1%, IQR 0–28 The p-value was calculated using the Kruskal-Wallis test to compare differences between groups. P-value < 0.001

Results: Patients with mild-to-moderate MO reduction (group 1) reached their lowest MO after a median of 0 months from baseline (IQR: 0.0-1.0), while those in the severe group (group 2) reached their lowest point after a median of 1.9 years (IQR: 0.9- 4.15). The severe group had a longer disease duration and a higher prevalence of facial telangiectasia and xerostomia. GI involvement was significantly more prevalent in group 2, with symptoms such as dysphagia, peptic ulcers, diarrhea, bloating, and malabsorption being particularly frequent (Table 1) (Figure 1). Multivariate analysis showed that longer disease duration (OR 1.2 per year; 95% CI 1.1–1.3) and GI Severity Score >1 (OR 2.7; 95% CI 1.1–6.5) were independently associated with severe reduction in MO. Cox regression confirmed that baseline GI involvement (GI Severity Score >1) predicted severe MO reduction (>12.3%) (HR 2.3; 95% CI 1.8–3.0), with baseline dysphagia (HR:1.4; 95% CI 1.2–1.7) and/or diarrhea (HR:1.8; 95% CI 1.5–2.2) being the strongest predictors (Table 2).

Conclusion: Early GI symptoms—particularly dysphagia and diarrhea—were significantly associated with severe microstomia, suggesting that microstomia may serve as an external marker of progressive internal GI involvement. These findings highlight a potential shared pathophysiological mechanism and underscore the need for further studies to validate this association and elucidate the underlying connection.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Vasoactive-vasodilating drugs (VVD) are the cornerstone of the treatment of pulmonary arterial hypertension (PAH), a form of precapillary pulmonary hypertension (pPH) that represents a severe complication of systemic sclerosis (SSc). VVD include the categories of endothelin receptor antagonists (ERAs), phosphodiesterase type 5 inhibitors (PDE5i) and prostanoids, which are commonly used in SSc to treat digital ulcers (DU) and Raynaud's phenomenon. As additional protective effects remain unclear, we investigated the effectiveness of VVD on the primary prevention of pPH and, specifically, of PAH.

Methods: SSc patients from the European Scleroderma Trials and Research (EUSTAR) cohort who underwent right heart catheterization (RHC) were included; postcapillary PH cases (pulmonary wedge pressure – PWP >15 mmHg) were excluded.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Data about demographics, disease features, immunosuppressive and vasoactive treatment exposure and right heart catheterization from the study population, compared between patients with and without precapillary pulmonary hypertension. ACA, anti-centromere antibody; b/csDMARDs, biologic/conventional synthetic anti-rheumatic disease modifying drugs; DLCO, diffusion lung capacity of carbon monoxide; ERA, endothelin receptor antagonists; FVC, forced vital capacity; NYHA, New York Heart Association; PH, pulmonary hypertension; PDE5i, phosphodisterase 5 inhibitors; SSc, systemic sclerosis; sPAP, systolic pulmonary arterial pressure.

	All patients (n=944)	Patients without PH (n=446)	Patients with PH (n=498)	*p-value*
Female sex	761 (81%)	350 (79%)	411 (83%)	0.116
Age (years)	61 ± 12	59 ± 13	64 ± 11	**<0.001**
Diffuse SSc	344 (36%)	185 (42%)	159 (32%)	**0.002**
Disease duration (years)	11 ± 9	10 ± 9	12 ± 9	**<0.001**
ACA positivity	438 (46%)	170 (38%)	268 (54%)	**<0.001**
Current digital ulcers	404 (43%)	206 (46%)	198 (40%)	**0.046**
Telangiectasias	706 (75%)	311 (70%)	395 (79%)	**< 0.001**
Dyspnea (NYHA class >I)	709 (75%)	303 (68%)	406 (82%)	**< 0.001**
ILD on HRCT	526 (56%)	240 (54%)	286 (57%)	0.263
Glucocorticoids ever	50 (5%)	23 (5%)	27 (5%)	0.318

bDMARD ever	41 (4%)	22 (5%)	19 (4%)	0.400
FVC (% predicted)	86 ± 23	89 ± 22	84 ± 23	**< 0.001**
DLCO (% predicted)	54 ± 19	61 ± 18	49 ± 18	**< 0.001**
Diastolic dysfunction	240 (25%)	98 (22%)	142 (29%)	**0.021**
sPAP on Echo (mmHg)	39 ± 16	32 ± 9	46 ± 18	**< 0.001**
ERA, ever	181 (19%)	63 (14%)	118 (24%)	**< 0.001**
PDE5i, ever	111 (12%)	27 (6%)	84 (17%)	**< 0.001**
Prostanoids, ever	128 (14%)	64 (14%)	64 (13%)	0.502

Multivariable logistic regression assessed the association between exposure to VVD and detection of pPH (mPAP >20 mmHg, PVR>2 WU and PWP≤15 mmHg) and of PAH (pPH, ILD extent < 20% and FVC >70%).

Models 1 & 2 tested the exposure at the time of RHC *ever* and *ongoing* to VVD categories (ERAs, PDE5i and prostanoids), *models 3 & 4* tested the same for specific VVD molecules.

The primary outcome was the diagnosis of precapillary PH; PAH was analyzed as sensitivity analyses.

All models were adjusted for known confounders, including DLCO, age, current DU and systolic PAP on echocardiography. Interaction terms between VVDs and current DU were also tested.

Results: Among 944 eligible patients, 498 (53%) were diagnosed with pPH, of whom 367 (74%) had PAH **(Table 1)**.

For VVD classes, a statistically significant association was detected for the interaction of ERAs and current DU with the detection of pPH, in both logistic regression models 1 and 2 (**Figure 1a** and **1b**). However, this finally resulted in a non-significant association between ERAs exposure in patients with current DU and PH detection when calculating marginal effects estimates (ERAs ongoing: OR 0.435, 95% CI 0.193 - 1.064; ERAs ever: OR 0.636, 95% CI 0.349 - 1.158). Additionally, both models showed lack of effectiveness of ERAs in patients without current DU, as well as for PDE5i or prostanoids overall.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Forest Plots of regression Models 1 (a), 2 (b), 3 (c), and 4 (d) evaluating the association between independent variables and the detection of precapillary pulmonary hypertension. ACA, anti-centromere antibody; DLCO, diffusion lung capacity of carbon monoxide; DU, digital ulcers; ERA, endothelin receptor antagonists; PAH, pulmonary arterial hypertension; sPAP, systolic pulmonary arterial pressure; PDE5i, phosphodiesterase 5 inhibitors.

When focusing on specific VVD molecules, exposure "ever" to bosentan showed a significant protective association with precapillary PH diagnosis, independently from the presence or absence of current DU (**Figure 1c**). Finally, we noted again a statistically significant interaction between ongoing bosentan and current DU, which turned into a statistically significant marginal effects estimate (OR 0.230, 95% CI 0.081 – 0.652) indicating protective effects of this medication towards the diagnosis of precapillary PH in patients with current DU (**Figure 1d**).

The protective effects of bosentan were confirmed in all sensitivity analyses targeting PAH detection.

Conclusion: Our data show that bosentan is associated with less frequent diagnosis of PAH and precapillary PH, in particular when employed in patients with current DU at the time of RHC. Our results support further research to optimize the timing and patient selection for VVD therapy in SSc, aiming also at additional preventive effects at pulmonary level.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Calcinosis cutis (CC) is a disabling skin condition associated with systemic sclerosis (SSc). Although many CC treatments including sodium thiosulfate (STS) have been proposed, no clinical trials have been conducted due, in part, to a lack of validated quantitative outcome measures.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Patients with severe SSc-CC, enrolled in an open-label case series were treated with 25% STS was administered topically twice daily for 6-12 months or injected intradermally monthly for six months (0.1ml per injection for total of 1-2.5ml STS injected per session) to a patient-selected region-of-interest (ROI). All patients satisfied the ACR classification criteria of SSc. Three clinical coordinators independently assessed computer-assisted annotation of SSc-CC on computed

tomography (CT) exams for quantitative measurement of volume changes compared to symptomatic and photographic responses during STS treatment using BioImage Suite Web software. Inter-rater agreement and test-retest reliability were determined with intraclass coefficient (ICC).

Results: Five women, with SSc-CC involving the upper arm, bilateral ischial tuberosities, hands (two patients) and bilateral patellae, received topical (n=2) or intralesional (n=3) STS. Variable changes in symptoms, digital camera imaging, and CC volume by CT imaging (28% reduction in upper arm; 75% and 10% reductions in left and right, buttock, respectively; 18% increase in left forefinger; 27% increase in right hand; and 12% reduction in left, and 4% increase in right, patellae) were observed. Inter-rater agreement was excellent with an ICC of 0.93. Volume of CC on repeated measures performed one week apart was within 3%. Annotation time ranged from < 30 minutes for arm and buttock to >four hours per case for other ROI.

Conclusion: Intradermal STS treatment was associated with symptomatic and volumetric improvement in arm and buttocks, but not finger CC. Topical STS was not associated with symptomatic or imaging CC improvement in fingers or patellae. Computer-assisted annotation and volumetric measurement of CC on CT imaging appears to be a reproducible and sensitive quantitative outcome. However, time to annotate CC close to bone was lengthy due to similar radiographic density. Computer-assisted quantification of CC on CT is a useful quantitative outcome for future clinical trials, but additional methods for automating CC annotation need to be developed.

Abstract Number: 0675

Neutrophil-to-Lymphocyte Ratio as a biomarker for disease onset and a predictor for mortality in Systemic Sclerosis – real-world data from a large healthcare provider in Israel.

Shiri Keret[1], Shlomit Yaari[2], gleb Slobodin[3] and **doron Rimar**[3], [1]Bnai Zion Medical Center, Atlit, Israel, [2]Maccabi Healthcare Services, HaMered 27, Tel Aviv, 68125, Israel., Tel Aviv, Israel, [3]Bnai Zion Medical Center Faculty of Medicine, Technion Israel institute of technology, Haifa, Israel

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Elevated neutrophil-to-lymphocyte ratio (NLR) in systemic sclerosis (SSc) has been demonstrated to predict worsening skin and lung involvement, and a cutoff of 2.95 was shown to be related to a decreased 5-year survival in a recent pilot study. The aim of this study was to further define a cutoff of baseline NLR that predicts poor outcome of SSc and to explore longitudinal variations of NLR with respect to disease onset in a large healthcare database.

Methods: Adult SSc patients from the Maccabi healthcare services (MHS) database,a 2.7-million-member, state-mandated, health provider in Israel, between 2003 and 2023 were included. Identification algorithm included an ICD

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. 9 diagnosis of "systemic sclerosis" or "scleroderma" by a rheumatologist or at hospital discharge or a diagnosis in the presence of at least one high titer autoantibody (ANA or SCL-70 or anticentromere or anti RNA POLIII).

Results: Overall, 1752 SSc patients fulfilled the inclusion criteria over the study period. In 2023 the estimated prevalence of SSc in Israel was 735 per million.

241 patients were excluded because of steroid use. Thus, baseline study cohort included 1511 patients of whom 1232 had NLR values at baseline (Table1). The mean NLR at diagnosis was 2.21±1.36, including 110 (9%) with value between 3-4 and 81 (6.5%) above 4. At diagnosis, NLR was significantly higher in men, in patients with pulmonary fibrosis (n=245, 16%), pulmonary hypertension (n=233, 15%), and with MMF treatment (n=139, 9%). In patients with a high baseline NLR >3 (n=191, NLR 4.4±2.21), NLR showed a statistically significant increase at onset when compared to values measured 1, 5, 10, and 15 years prior to diagnosis (Figure 1). Thirty six percent of these patients had specific antibodies up to 15 years before diagnosis. NLR did not change over time or with therapy over 15 years of follow-up after diagnosis (Figure 1). During 20 years of follow-up, 360 patients (20%) died. Each 1-point increase in baseline NLR was linked to higher 5- and 10-year mortality rates, as demonstrated by the Kaplan-Meier curve (figure2). The highest mortality rates were observed in NLR >4, reaching 25% at 5 years and 31% at 10 years ($p < 0.001$), (Figure 2). A Cox regression model that included covariables (age, sex, pulmonary fibrosis, pulmonary hypertension) found in patients with NLR above 4 had a hazard ratio of 2.83 (-2 log-likelihood chi-square = 277.3, $p < 0.001$) for time to death (Figure 3).

Conclusion: This extensive cohort study confirms that a high baseline NLR is predictive of 5- and 10-year mortality, with a refined threshold of NLR greater than 4. Male sex, pulmonary fibrosis and pulmonary hypertension were key risk factors for high baseline NLR and predicted mortality. Notably, elevated NLR was already present at disease onset—even when autoantibodies appeared earlier and remained persistently high for over 15 years, unaffected by treatment. NLR was not

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Hand disability is a major feature of systemic sclerosis (SSc), driven by skin thickening and joint contractures, with significant impact on quality of life. Its assessment remains challenging and calls for more sensitive tools than traditional clinimetric scores. The Hand Test System (HTS) engineered glove has previously provided detailed data on hand dexterity in rheumatoid arthritis [1] through three quantitative parameters: touch duration (TD), inter-tapping interval (ITI), and movement rate (MR). The primary aim was to evaluate the applicability of the HTS glove in assessing hand dexterity in SSc patients by comparing its parameters with healthy controls (HC). Secondary endpoints included the correlations between HTS parameters with patient-reported outcomes (PROMs), nailfold videocapillaroscopy (NVC) findings, and dermal thickness measured by high frequency skin ultrasonography (HFSU) at the sites assessed by the modified Rodnan skin score (mRSS).

Methods: Twenty-five patients with systemic sclerosis (SSc) and 25 healthy controls were enrolled (**Table 1**). All participants underwent assessment using the HTS glove, grip strength measurement, and the following PROMs: the Health Assessment Questionnaire for Systemic Sclerosis (SHAQ), Hand Mobility in Scleroderma (HAMIS) test, and Duruöz Hand Index (DHI).

Table 1. Clinical and demographic features of the included patients Legend. ACA; anti-centromere autoantibodies; dcSSc; diffuse cutaneus SSc, DMARDs; disease modifying anti-rheumatic drugs, lcSSc; limited cutaneous SSc, mRSS; modified Rodnan skin score, Scl-70; anti-topoisomerase I antibodies. * Patients were classified as with dcSSc if the involvement of the skin included also arms, trunk, and thighs. Vasodilating agents: Aminaftone was taken by 17/25 (68%), calcium channel blockers by 6/25 (24%), endothelin receptor antagonists by 12/25 (48%), PDE5-inhibitors by 4/25 and riociguat by 1/25 (4%). DMARDs: Mycophenolate mofetil was taken by 7/25 (28%), methotrexate by 5/25 (20%), rituximab by 2/25 (8%), hydroxychloroquine by 1/25 (4%), cyclophosphamide by 4/25 (16%), and low-dose (< or = 5 mg daily) prednisone by 6/25 (24%). Pulmonary involvement: Defined based on the presence of ILD on high-resolution computed tomography (HRCT). Gastroesophageal involvement: Defined based on manometric evidence of esophageal dysmotility. Kidney involvement: Defined based on increased renal resistive index and/or elevated serum creatinine levels. Significant p-values are reported in bold

SSc patients met the 2013 ACR/EULAR criteria and underwent standard clinical evaluation, nailfold videocapillaroscopy (NVC)[2] and HFSU (22 MHz), used to measure dermal thickness, with a focused analysis on the middle fingers, dorsum of hands, and total dermal thickness.

Results: In SSc patients, HTS parameters significantly correlated with PROMs, worsening in parallel with poorer PROMs (-**Table 2**). Notably, both mean TD and ITI were directly correlated with the mRSS, whereas MR, as expected, was inversely correlated (Table 2). Grip strength showed a significant correlation only with mean ITI ($r = -0.43$, $p = 0.03$).

As expected, significant differences in HTS parameters were observed between SSc patients and HC (**Table 2**). SSc patients performed finger movements more slowly and less efficiently than HC, as shown by prolonged TD and ITI, and reduced MR.

When analyzing subgroups of SSc patients based on clinical features, no significant differences were detected in HTS parameters according to the different organ involvement, autoantibody profiles or NVC findings (**Tables 2-3**).

However, significant correlations were, instead, observed between the mean TD directly correlating with the increase of the HFSU-measured dermal thickness of the dorsum of the hands and with the total dermal thickness (all p-values < 0.05, **Table 2**).

Conclusion: The HTS glove can provide detailed and quantitative data on hand dexterity in SSc patients. Significant correlations with PROMs, mRSS, hand strength and with HFSU-measured dermal thickness might suggest a significant relationship between disease-related skin thickness and hand functionality. Further studies with larger cohorts are in progression to explore the HTS glove's utility in monitoring disease outcomes and therapeutic response in SSc.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: The incidence of sudden cardiac death (SCD) is suspected to be increased in systemic sclerosis (SSc). However, data describing SCD incidence in SSc are sparse and confined to small cohorts. Accordingly, this study aims to estimate SCD incidence in SSc and assess the association with disease characteristics.

Methods: Individuals from the Australian Scleroderma Cohort Study with a definable SSc subtype meeting ACR/EULAR criteria were included. International Classification of Diseases (ICD)-10 code cause of death was sourced from the Australian National Death Index. Two authors adjudicated SCD events, which were considered present when an ICD-10 code cause of death for an acute cardiovascular pathology was listed (sudden cardiac death, cardiac arrest, ventricular fibrillation/flutter, acute myocardial infarction/acute ischaemic heart disease (IHD), ventricular tachycardia, cardiac tamponade, pericardial effusion, aortic or mitral valve lesion) excluding those with major pulmonary, renal or gastrointestinal primary causes of death. Between-group comparisons (SCD vs. overall cohort) were performed using Chi-squared testing or Wilcoxon rank-sum testing as appropriate, and multivariable Cox proportional hazard modelling was used to identify associations of SCD.

Results: Among 1708 SSc patients, 32 SCD events occurred (1.9%) over 10,650 person-years' follow-up (Figure 1), equivalent to an observed incidence rate of 300 per 100,000 person-years. This rate is 3-9 times higher than published general population estimates (35-89/100,000 person-years).[1,2]

Participants who experienced SCD were more likely to have IHD (40.6% vs. 13.8%, p< 0.001) and reduced left ventricular ejection fraction (LVEF< 50%; 18.5% vs. 5.5%, p=0.004). SSc heart involvement (18.8% vs. 9.4%, p=0.074), aortic valve pathology (12.9% vs. 5.7%, p=0.089) and pulmonary hypertension (18.8% vs. 11.3%, p=0.188) were numerically more common in those with SCD, although not meeting statistical significance. While cardiovascular risk factors including

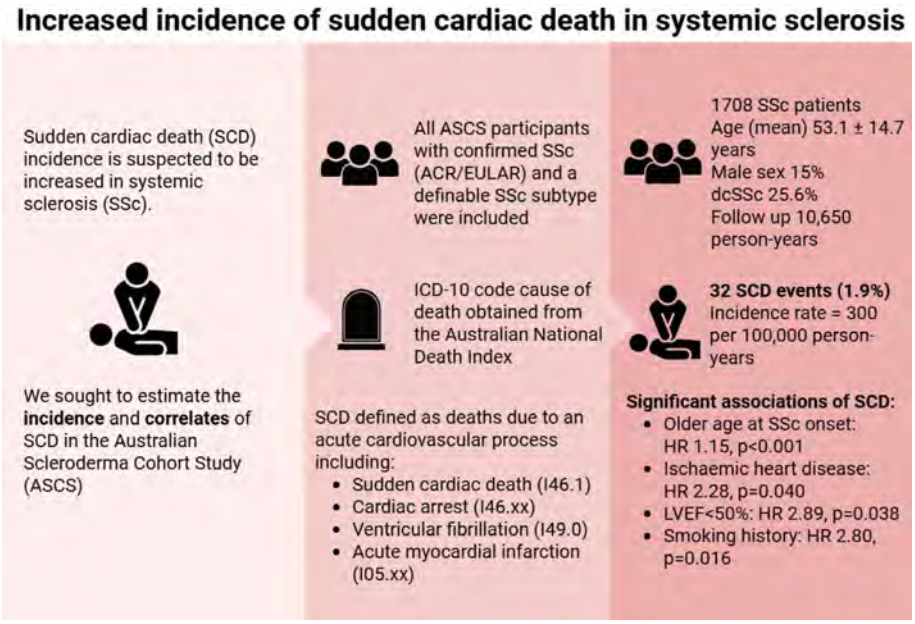

Figure 1: Graphical Abstract

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

hypertension, dyslipidaemia and smoking history were not associated with SCD, these patients were numerically more likely to have two or more of these factors (60.7% vs. 47.5%, p=0.165).

Multivariable Cox hazard modelling identified that older age (hazard ratio (HR) 1.15 (95% confidence interval (CI) 1.10-1.20), p< 0.001), IHD (HR 2.28 (95%CI 1.04-5.00), p=0.040), reduced LVEF (HR 2.89 (95%CI 1.06-7.90), p=0.038) and smoking exposure (HR 2.80 (95%CI 1.21-6.49), p=0.016) were associated with SCD.

Conclusion: SCD occurred in 1.9% of a large SSc cohort, with an incidence rate of 300 per 100,000 person-years. This is significantly higher than the rate of SCD reported in the general population. Older age, IHD, reduced LVEF and smoking were key risk factors for SCD, highlighting important and potentially modifiable risk factors for SCD in SSc.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic sclerosis (SSc) possesses the highest case-related mortality of all rheumatic diseases. B cell-targeting, including CD19-targeting CAR-T cells, has shown efficacy but failed to eliminate the SSc-specific anti-topoisomerase-I autoantibodies. [1-4]

Methods: We treated three high-risk cases of severe treatment-refractory diffuse cutaneous SSc (dcSSc) with the plasma cell-depleting antibody teclistamab (**Table 1**). After six cycles of teclistamab, one cycle of rituximab was administered to block recovery of autoantibody-producing cells. All patients were anti-topoisomerase-I antibody positive and have not responded sufficiently to multiple immunosuppressive therapies. Immunosuppressive and antifibrotic therapies were discontinued prior to baseline (BL). Patients were followed for more than six months.

Results: Treatment with teclistamab depleted all plasma cells in the skin. Anti-topoisomerase-I-autoantibody titers seroconverted in two patients and dropped by 83% in the third patient. This immunological response was associated with a decrease of the modified Rodnan skin score, stabilization of SSc-ILD, resolution of tendon friction rubs and decreases in the EUSTAR-AI. The effect on SSc-associated primary myocardial involvement was heterogeneous.

Table 1. Patient characteristics at baseline. Abbreviations: Scl-70 Ab, anti-topoisomerase-I (Scl70) autoantibodies; mRSS, modified Rodnan Skin Score; TFR, tendon friction rubs; ILD, interstitial lung disease; SSc-pHI, systemic sclerosis primary heart involvement

	1st patient	2nd patient	3rd patient
Age	65 years	52 years	56 years
Sex	Male	Male	Male

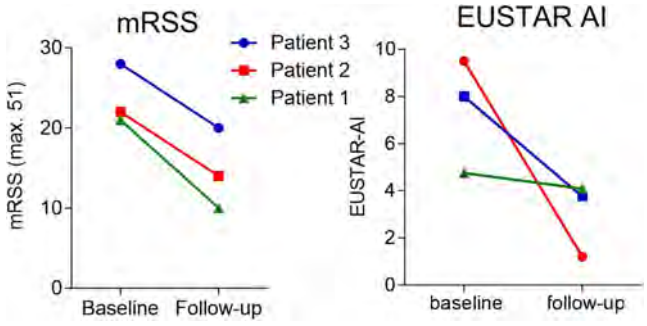

Image 1. Selected clinical outcomes (modified Rodnan skin score, mRSS; EUSTAR activity index, AI).

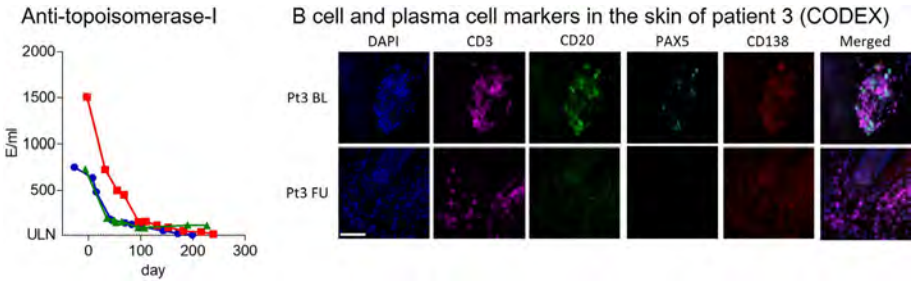

Image 2. Immunological outcomes (serological anti-topoisomerase-I titres and multi-color immunofluorescence stainings of skin biopsies from patient 3 using CODEX; DAPI stains nuclei, CD3 stains T cells and CD20, PAX5 and CD138 stain B cells and plasma cells, respectively)

Treatment with teclistamab was associated with several adverse events including cytokine release syndrome, hypogammaglobulinemia and mild infections (despite regular immunoglobulin replacement).

Conclusion: Teclistamab may offer potential as a rescue therapy for selected patients suffering from severe, treatment-refractory dcSSc, even with advanced disease.

Abstract Number: 0679

Inhibition of TGFb3 in Systemic Sclerosis Patients Does Not Result in TGFb Pathway Modulation in Skin Biopsies or Circulation

Parisa Mazrooei, **Xuting Rebecca Sheng**, Xiaoyun Yang, Lyrialle Han, Samira Jamalian, Daniel Repplinger, Jingxuan He, Evelin Logis, Jeongsup Shim, Angela Hendricks, Lena Wang, Andrew Thorley and Sara Glickstein, Genentech/Roche, South San Francisco

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: There are 3 isoforms of Transforming Growth Factor Beta (TGFb), a cytokine frequently upregulated in fibrosis. Chronic targeting of TGFb1 and TGFb2 for fibrotic conditions has historically been problematic due to toxicity. Monoclonal antibodies that selectively target the TGFb3 isoform offer a potential solution, aiming to reduce fibrosis by inhibiting the TGFb pathway with a more favorable safety profile. Systemic sclerosis (SSc) is a debilitating disease where the TGFb pathway has been implicated as a disease driver. TGFb3 RNA correlated strongly with a 24-gene TGFb-responsive signature in SSc skin and also correlated with modified Rodnan skin score (Sun et al., 2024). Therefore, it was hypothesized that TGFb3 may be the main isoform involved in pathological fibrosis.

Methods: GA43360 is a Ph1b safety, tolerability, and pharmacokinetics study of SSc patients treated with 3 monthly doses of anti-TGFb3 (RO7303509). The study randomized 56 participants across three cohorts: Cohort A (75mg, n=12, and placebo, n=3), Cohort B (225mg, n=2, 360mg, n=15, and placebo, n=4), and Cohort C (1200mg, n=16, and placebo, n=4). To assess TGFb pathway modulation, we performed bulk RNAseq on patient skin biopsies collected pre- and post-anti-TGFb3 treatment and analyzed a 24-gene TGFb-responsive signature. Healthy control vendor-procured skin biopsies were also sequenced and analyzed for comparison. Indirect target engagement was assessed by measuring circulating TGFb3 protein levels in serum using the NULISA inflammation panel, and pathway modulation was evaluated by measuring serum periostin and COMP levels using immunoassays.

Results: Our drug was well tolerated at all doses, and the safety profile was acceptable. Pharmacokinetics for all doses were in agreement with model predictions and within the range of expected variability. We saw evidence of indirect target engagement through the upregulation of total TGFb3 levels in circulation post-dose with dose-dependent effects. We also observed higher levels of TGFb3 and TGFb pathway genes in SSc skin compared to healthy control skin, and elevations of periostin and COMP proteins in circulation. After 3 months of anti-TGFb3 treatment, we did not see modulation of TGFb pathway genes in the skin or circulation.

Conclusion: We demonstrated indirect target engagement but did not observe pathway modulation, suggesting that inhibition of TGFb3 alone is not sufficient for decreasing TGFb-driven pathway activation in SSc patients.

Altered Mirna Patterns of Peripheral Blood Mononuclear Cells Show Correlations with Pulmonary Manifestations of Systemic Sclerosis

Dóra Csige, Szilárd Póliska, János Rózsa, Dóra Tari, Szilvia Szamosi, **Zoltán Szekanecz**, Gabriella Szűcs and Levente Bodoki, University of Debrecen, Debrecen, Hungary

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune rheumatic and musculoskeletal disease (RMD) with a high mortality. Epigenetic factors, such as miRNAs might play an important role in the pathogenesis of SSc. In this cross-sectional study we assessed miRNA in SSc and associated miRNA expression with disease-related organ manifestations.

Methods: We investigated the miRNA profiles of 52 SSc patients (42 women and 10 men; mean age: 59.1 years (range: 33-76 years). Anticoagulated blood samples were taken from SSc patients, as well as age- and gender-matched healthy controls. Peripheral blood mononuclear cells (PBMC) were isolated on a Ficoll gradient, stored in TRIzol at -20°C until use. Total RNA was purified. Sequencing of miRNAs was performed using high-throughput, new generation (Illumina) sequencing, and an established miRNA library.

Results: Altogether 58 miRNAs showed significantly differential expression in SSc patients compared to controls. Among these miRNAs, 34 were significantly upregulated and 24 downregulated. Out of the differentially expressed miRNAs, 9 upregulated (let-7e-3p, miR-16-1-3p, miR-16-2-3p, miR-27a-5p, miR-34c-5p, miR-92a-1-5p, miR-130b-5p, miR-143-5p, miR-183-5p) and 8 downregulated miRNAs (miR-7-1-3p, miR-17-5p, miR-20a-5p, miR-30b-5p, miR-106a-5p, miR-151a-5p, miR-320b és miR-335-5p) had previously been described in the literature. Thus, the differential expression of further 41 (25 upregulated and 16 downregulated) miRNAs is a novel finding. When comparing SSc patients with (n=34) and without (n=18) interstitial lung disease (ILD)/pulmonary fibrosis, 4 miRNAs (miR-210-3p, miR-222-3p, miR-379-5p, miR-3935-5p) showed elevated, while 4 miRNAs (miR-125a-5p, miR-199b-5p, miR-941, miR-1226-3p) showed decreased expression levels in patients with SSc-ILD. Some of the differentially expressed miRNAs are associated with TGFβ signalling pathways.

Conclusion: SSc is associated with differential expression of several miRNAs. The up- or down-regulated expression of some miRNAs might be associated with SSc-ILD. Thus, miRNAs might have an important role in the molecular pathogenesis of SSc, as well as SSc-ILD and some of them might serve as therapeutic targets as well.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic sclerosis (SSc) is a connective tissue disease that can manifest as widespread skin and visceral fibrosis, potentially affecting major organs including the heart. Cardiac involvement is a major complication in SSc, often asymptomatic but associated with increased mortality. Despite recent improvement in survival and therapies, SSc remains the rheumatic disease associated with the highest morbidity and mortality. Cardiovascular magnetic resonance (CMR) is a sensitive, non-invasive tool for detecting cardiac abnormalities. However, the prognostic value of serial CMR monitoring and the effects of immunosuppressive therapy remain unclear. This study aimed to assess the prognostic significance of changes in CMR parameters for long-term cardiovascular outcomes, and to evaluate the impact of immunosuppressive treatments.

Methods: We conducted a monocentric retrospective study including consecutive SSc patients followed in the Internal Medicine department at Cochin University Hospital who underwent two CMR exams due to cardiovascular involvement. All patients met the American College of Rheumatology and European Alliance of Associations for Rheumatology 2013 classification criteria for SSc. Patients with two CMR scans performed on the same equipment between February 2009 and June 2023 were included, and parameter changes were compared using paired t-tests. The impact of treatments and CMR parameter changes on major adverse cardiovascular event (MACE) and all-cause mortality was assessed using Kaplan-Meier curves and log-rank tests.

Results: Forty-four SSc patients were included with a median [interquartile range] follow-up duration of 6.3 [3.1-9.2] years. The median interval between CMR scans was 1.5 [1.0-3.9] years. MACE occurred in 16 (33%) patients. There was no significant difference in the distribution of cardiovascular risk factors – including smoking (p=0.3), diabetes (p >0.9), and hypertension (p=0.7) – between patients who experienced MACE and patients who did not. In contrast, the prevalence of anti-Scl70 antibodies (p=0.023) and pulmonary hypertension (p=0.022) was higher among patients with MACE, although baseline functional, volumetric, and anatomical CMR parameters were not altered (**Table 1**). Right ventricle end-diastolic volume significantly decreased at the time of second CMR scan (p=0.04), contrary to maximal T1 (p=0.2), left ventricle end diastolic volume (p=0.1), left (p=0.5) and right (p=0.7) ventricular ejection fractions. Importantly, rituximab significantly decreased maximal T1 (p=0.029) (**Figure 1**), a marker of diffuse fibrosis also linked to an increased risk of all-cause death (p=0.044). Methotrexate was associated with a significant increase in left ventricular ejection fraction (p=0.032) (**Figure 1**) and a reduced risk of MACE (p=0.024).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. T2 hypersignal	4 (9.3)	3 (11)	1 (6.3)	>0.9
LA dilation	1 (2.3)	1 (3.6)	0 (0)	>0.9
Maximal T1 value (ms)	1,362 (1,287, 1,459)	1,361 (1,287, 1,400)	1,482 (1,335, 1,483)	0.4
LGE	21 (48)	16 (57)	5 (31)	0.10
T2 hypersignal	4 (9.3)	3 (11)	1 (6.3)	>0.9
LA dilation	1 (2.3)	1 (3.6)	0 (0)	>0.9
RA dilation	2 (4.5)	1 (3.6)	1 (6.3)	>0.9
LVDEV mL/m²	73.0 (61.0, 87.0)	75.0 (60.0, 87.0)	70.0 (64.0, 87.0)	0.9
LVEF (%)	57.0 (49.0, 61.0)	56.0 (48.0, 61.0)	57.0 (51.0, 63.0)	0.6
RV dilation	8 (18)	5 (18)	3 (19)	>0.9
RVEF (%)	4.0 (34.0, 44.0)	41.0 (36.0, 44.0)	38.0 (33.0, 43.0)	0.5
Pericardial effusion	25 (57)	18 (64)	7 (44)	0.2
Paradoxical septum	4 (9.3)	3 (11)	1 (6.3)	>0.9

Conclusion: Methotrexate use was associated with a decrease in MACE occurrence, highlighting a possible cardioprotective effect. Rituximab was linked to a decrease in maximal T1 value, a marker of diffuse fibrosis associated with increased mortality. These findings support the prognostic value of CMR monitoring and the potential benefit of immunosuppressive therapy in SSc-related cardiac involvement.

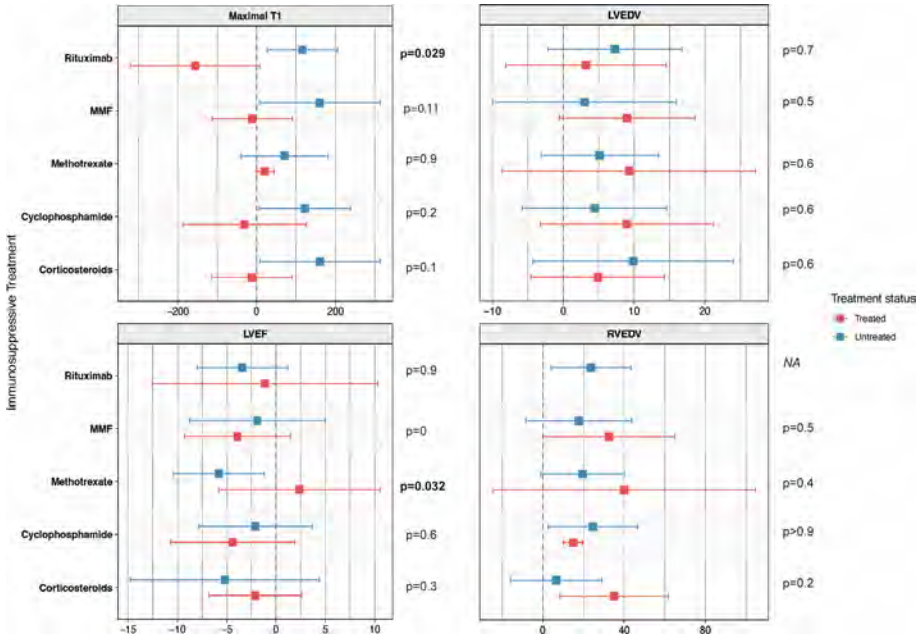

Figure 1. Forest plot representation of changes in CMR parameters stratified by immunosuppressive treatment. Mean differences in CMR measurements were compared between patients who received immunosuppressive therapies (including corticosteroids, mycophenolate mofetil, cyclophosphamide, rituximab, and methotrexate) and those who did not. Comparisons were performed using paired t-tests. Each square represents the mean difference, and the horizontal lines indicate the 95% confidence intervals. Patients treated with rituximab had a significant decrease in Maximal T1 value between 2 CMR scans. Abbreviations: CMR: cardiac magnetic resonance imaging; LVEDV: left ventricle end diastolic volume; LVEF: left ventricle ejection fraction; RVEDV: right ventricle end-diastolic volume; RVEF: right ventricle ejection fraction.

Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Scleroderma Renal Crisis (SRC) is a severe manifestation of Systemic Sclerosis (SSc) associated with elevated morbidity and mortality. We aimed to address the challenges of studying this rare condition by collecting and analyzing data to further our understanding of SRC. This research builds upon our previous work presented at ACR in 2022. We previously found that patients who did not have a diagnosis of SSc before SRC had a statistically significant higher odds of requiring hemodialysis (HD) during SRC compared to patients who had a prior diagnosis of SSc. We also found that patients with a history of hypertension (HTN) had a statistically significant higher odds of 1-year mortality compared to patients without HTN. We did not find any statistically significant increase in the odds of severe outcomes in SRC for African-American patients, patients with RNA Polymerase III antibodies, or patients with late SRC.

Table 1. Selected Characteristics of 44 Scleroderma Renal Crisis Patients Seen at MedStar Georgetown University Hospital from 2008 to 2020

Variables	Number of Patients	Percentage of All Patients
Female	36	82%
African-American	20	45%
Diffuse SSc Disease	37	84%
Anti-RNA Polymerase III (+)	19	43%
Late SRC	7	16%

Legend: SSc = Systemic Sclerosis, also known as Scleroderma, Anti-RNA Polymerase III (+) = Patients who tested positive for the Anti-RNA Polymerase III antibody, SRC = Scleroderma Renal Crisis, Late SRC = Patients with at least 4 years between first SSc symptom and SRC. The mean age of patients was 51.5, and the ages of patients ranged from 27 to 88 years old.

Table 2: Associations of Potential Predictors with Hemodialysis Requirement at the Time of SRC Diagnosis

	HD Need at SRC (N=19)	No HD Need at SRC (N=24)	P-value
Sex	Male: 75%	25%	0.111
	Female: 37%	63%	
Specialist Care	Yes: 18%	82%	0.077
	No: 53%	47%	
Schistocytes at SRC	Yes: 47%	53%	0.115
	No: 0%	100%	
Hgb Nadir at SRC	7.5 (7.0, 8.0)	8.8 (7.8, 10.2)	**0.023**
Platelet Nadir at SRC	111.0 (82.0, 162.5)	219.0 (124.0, 279.0)	**0.044**
Creatinine at SRC Dx	2.60 (1.80, 3.30)	1.24 (0.90, 1.80)	**0.001**

Legend: SRC = Scleroderma Renal Crisis, HD = Hemodialysis, Dx = Diagnosis, Specialist Care = Patients under the care of a rheumatologist with Scleroderma expertise, Schistocytes = Presence of schistocytes on a peripheral blood smear at the time of Scleroderma Renal Crisis diagnosis. For continuous variables, median and interquartile range (Q1 and Q3) are reported. For categorical variables, proportions (%) are reported. Statistically significant P-values are bolded. *One patient had missing data regarding dialysis need at Scleroderma Renal Crisis Presentation.

Methods: We obtained data through chart review of 44 patients at our institution who developed SRC between 2008 and 2020. All patients met ACR/EULAR 2013 classification criteria for SSc. We evaluated predictors of HD at time of SRC and 1-year mortality post-SRC using Fisher's exact tests and Wilcoxon rank-sum tests, and we reported related p-values.

Results: Table 1 includes selected characteristics of our patients with SRC. We found that patients who required HD at time of SRC had a statistically significant elevation in creatinine and decreases in platelet count and hemoglobin, compared to patients who did not require HD (Table 2). While there were no statistically significant differences regarding HD need at time of SRC based on sex, specialist care, or presence of schistocytes on peripheral blood smear (PBS), there were trends toward statistical significance. Furthermore, we found statistically significant differences in 1-year mortality based on patient sex and age (Table 3). Male sex and older age were associated with 1-year mortality, which supports previously reported findings (1). There was not a statistically significant difference in 1-year mortality between patients on HD 6 months-post SRC and those who were not on HD 6 months-post SRC.

Conclusion: We identified statistically and clinically significant differences in SRC lab parameters between patients who required HD at SRC and those who did not. The median creatinine and hemoglobin levels differed by over one unit, and thrombocytopenia was a predictor of HD requirement at SRC. Because there were trends toward statistical significance for sex, specialist care, and presence of schistocytes regarding HD requirement, we hope to reevaluate these potential predictors on larger datasets. We found that older age and male sex were associated with elevated 1-year mortality. Combining these results with our previous findings, we have identified several predictors of severe outcomes in SRC. These findings can assist clinicians with risk-stratification of SRC patients, lay the groundwork for future research, and help mitigate severe outcomes.

Table 3: Associations of Potential Predictors with Mortality One Year after SRC Diagnosis

	Not Alive 1 year Post-SRC (N=7)	Alive 1 year Post-SRC (N=36)	P-value
Sex	Male: 50%	50%	**0.015**
	Female: 9%	91%	
Age	62.0 (56.0, 72.0)	47.5 (34.0, 62.0)	**0.029**
HD 6 Mo. Post-SRC	Yes: 29%	71%	0.197
	No: 11%	89%	

Legend: SRC = Scleroderma Renal Crisis, HD = Hemodialysis. For continuous variables, median and interquartile range (Q1 and Q3) are reported. For categorical variables, proportions (%) are reported. Statistically significant P-values are bolded. *One patient had missing data regarding 1-year mortality after Scleroderma Renal Crisis.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Virtually all patients with systemic sclerosis (SSc) experience gastrointestinal (GI) manifestations over the course of their disease, affecting any region from the mouth to the anorectum. Currently, there are limited risk factors predicting worse GI outcomes in patients with early SSc. In this study, we aimed to use baseline GI symptoms to better characterize the clinical heterogeneity and outcomes in SSc-related GI disease.

Methods: Patients with SSc who were enrolled in our large, well-defined prospective cohort were included in the study. All participants met the 2013 ACR/European League Against Rheumatism classification criteria and had a disease duration of less than five years from the onset of their first non-Raynaud's symptom at the time of enrollment. They were followed every six months for the first three years and annually thereafter. Hierarchical clustering was used to divide the patients according to their baseline GI symptoms and manifestations. These were dysphagia, gastroesophageal reflux disease (GERD), peptic ulcer, bloating, constipation, diarrhea, malabsorption, and pseudo-obstruction. The characteristics and the disease outcomes of the clusters were compared.

Results: A total of 450 patients were included, with a mean follow-up of 5.3 years. Three symptom-based gastrointestinal (GI) clusters were identified: Cluster 1 (upper GI predominant), Cluster 2 (lower GI predominant), and Cluster 3 (diffuse GI involvement). GERD was highly prevalent across all clusters. The majority of patients (n = 406) belonged to Cluster 1, which was characterized by dysphagia (41%) and peptic ulcer disease (5%). Cluster 2 included 30 patients and was marked by bloating, constipation, and diarrhea. Cluster 3, the most severe phenotype, comprised 14 patients, all of whom had malabsorption; 93% had diarrhea, and 86% had dysphagia. Extraintestinal features also varied between clusters. Cluster 3 had the highest proportion of male patients (43%, $P = 0.026$) and diffuse cutaneous disease (91%, $P = 0.037$). Baseline forced vital capacity (FVC%) and modified Rodnan skin score (mRSS) did not differ significantly among the three groups. Although cluster 3 had higher mortality, it did not reach significance ($P = 0.088$).

Table 1. Characteristics of Patients with Systemic Sclerosis Stratified by GI Symptom-Based Clusters

Characteristic	Cluster 1 N = 406	Cluster 2 N = 30	Cluster 3 N = 14	p-value
Age, mean (SD)	48 (14)	47 (11)	47 (11)	0.237
Female sex, n (%)	341 (84%)	23 (77%)	8 (57%)	0.022
Race, n (%)				0.084
Asian	17 (4.2%)	0 (0%)	0 (0%)	
Black	75 (18%)	7 (23%)	3 (21%)	
Indian	1 (0.2%)	1 (3.3%)	1 (7.1%)	
White	313 (77%)	22 (73%)	10 (71%)	
Hispanic ethnicity, n (%)	106 (26%)	10 (33%)	4 (29%)	0.614
Diffuse involvement, n (%)	251 (77%)	16 (57%)	10 (91%)	0.037
Disease duration, yrs, mean (SD)	2.45 (1.51)	2.20 (1.18)	3.61 (1.17)	0.125
mRSS, mean (SD)	17 (12)	15 (10)	18 (12)	0.659
FVC%, mean (SD)	81 (20)	72 (18)	75 (11)	0.056
Anti-centromere antibody positivity, n (%)	55 (14%)	4 (14%)	0 (0%)	0.448
Anti-Scl70 antibody positivity, n (%)	76 (19%)	4 (14%)	2 (14%)	0.897
Anti-RNA polymerase III antibody positivity, n (%)	89 (23%)	4 (14%)	1 (7.1%)	0.275
Dysphagia, n (%)	165 (41%)	7 (23%)	12 (86%)	<0.001
GERD, n (%)	302 (74%)	30 (100%)	12 (86%)	<0.001
Peptic ulcer, n (%)	21 (5.2%)	0 (0%)	0 (0%)	0.559
Bloating, n (%)	21 (5.2%)	29 (97%)	6 (43%)	<0.001
Constipation, n (%)	73 (18%)	12 (40%)	1 (7.1%)	0.011
Diarrhea, n (%)	60 (15%)	11 (37%)	13 (93%)	<0.001
Pseudo-obstruction, n (%)	0 (0%)	3 (10%)	2 (14%)	<0.001
Malabsorption, n (%)	0 (0%)	2 (6.7%)	14 (100%)	<0.001

Conclusion: Patients with systemic sclerosis exhibit distinct patterns of gastrointestinal symptoms at baseline. Recognizing these symptom-based clusters may improve risk stratification, help predict clinical outcomes, and inform clinical trial design for GI disease in patients with SSc.

Translation to Spanish and Linguistic Validation of the Assessment of Systemic Sclerosis-associated Raynaud's Phenomenon (ASRAP)

Antonia Valenzuela[1], Adriana Miguel Alvarez[2], Patricia E. Carreira[3], Alejandra Babini[4], Diana Rocío Gil Calderón[5], John Pauling[6] and Tatiana Rodriguez-Reyna[2], [1]Pontificia Universidad Catolica de Chile, Santiago, Chile, [2]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, [3]Hospital Universitario 12 de Octubre, Madrid, Spain, [4]Hospital Italiano, Córdoba, Argentina, [5]Hospital Universitario Mayor MEDERI, Universidad del Rosario, Artmedica SAS, Bogotá, Colombia, [6]North Bristol NHS Trust, Bristol, United Kingdom

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic sclerosis-associated Raynaud's phenomenon (SSc-RP) significantly impacts patients' quality of life, yet validated tools to assess this condition in Spanish-speaking populations are lacking. The Assessment of Systemic Sclerosis-associated Raynaud's Phenomenon (ASRAP) is a new patient-reported outcome measure originally developed in English. This study aims to adapt the ASRAP into Spanish using a rigorous cross-cultural methodology.

Methods: We designed a prospective, qualitative, observational, and multicenter study to ensure cultural and linguistic equivalence of the ASRAP in Spanish. The adaptation process followed established international guidelines and included the following steps: (1) forward translation by two independent native Spanish-speaking healthcare professionals; (2) reconciliation to create a consensus version; (3) back-translation by a native English speaker unfamiliar with the questionnaire; (4) review of the back-translation to identify discrepancies; (5) harmonization through expert panel input involving bilingual SSc specialists from Spain and Latin America; (6) cognitive debriefing with iterative testing in 11 Spanish-speaking SSc-RP patients using semi-structured interviews and a 5-point rating scale to assess comprehension and relevance; (7) two rounds of professional proofreading; and (8) generation of the final Spanish version of the ASRAP.

Results: The four initial steps of the translation process were completed without complications. During the harmonization phase with the expert panel, some discrepancies emerged, particularly in wording choices. After discussion, the term *"Medianamente"* was replaced with *"Algo"*, and *"Episodios"* was revised to *"Ataques"* to better reflect common usage among Spanish-speaking patients with RP. The pre-final Spanish version of the ASRAP was field-tested in 11 patients with SSc-RP (6 from Chile and 5 from Mexico). The mean age was 58.5 ± 13.0 years, and 10 participants were female. The mean disease duration since RP onset was 11.3 ± 14.4 years, and 10.9 ± 13.7 years since the first non-RP symptom. Six participants (54%) had completed higher education. Overall, patients found the questionnaire clear and easy to understand. A minor revision was suggested during cognitive debriefing, specifically for item 27. Based on patient feedback, the phrase *"Un cambio en mi rutina normal ha hecho que me preocupe sobre un posible empeoramiento de mis síntomas de Raynaud"* was revised to *"Un cambio en mi rutina normal hizo que me preocupara sobre un posible empeoramiento de mis síntomas de*

Raynaud". As an initial validation step, the short-form ASRAP (ASRAP-SF, 10 items) was administered to 37 consecutive patients with SSc-RP (25 from Mexico and 12 from Chile), yielding a broad distribution of scores (mean ± SD: 50.5 ± 9.8; range: 31.32–67.07).

Conclusion: This collaborative cross-cultural adaptation process ensures that the Spanish version of the ASRAP is conceptually and culturally equivalent to the original, linguistically neutral, and relevant, clear, and comprehensible for Spanish-speaking patients with SSc-RP. Ongoing validation will further establish its utility across Spanish-speaking populations.

Abstract Number: 0685

Targeting Refractory Reflux in Systemic Sclerosis: Early Outcomes following a Novel Intervention

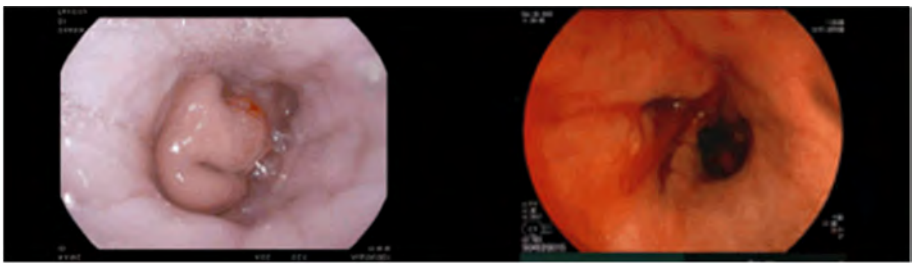
Areeka Memon[1], Monique Hinchcliff[2] and Amir Masoud[3], [1]Yale New Haven Health, New Haven, CT, [2]Yale School of Medicine, Westport, CT, [3]Hartford Healthcare, hartford

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Gastrointestinal tract (GIT) symptoms impact up to 90% of individuals with SSc. Hiatal hernia, decreased esophageal contractility, and lower esophageal sphincter tone contribute to dysphagia and gastroesophageal reflux disease (GERD) reducing quality-of-life.

Nissen fundoplication is often avoided in SSc due to risk of worsening dysphagia. Transoral incisionless fundoplication (TIF) with the EsophyX System (EndoGastric Solutions Redmond, WA, USA), in conjunction with hiatal hernia repair—termed cTIF—was employed to treat SSc patients with refractory GERD. The EsophyX System offers an alternative treatment option by enabling fasteners to be placed endoscopically at the gastroesophageal junction, resulting in partial recreation of the lower esophageal sphincter at less than or equal to 270 degrees. This approach avoids generating high distal esophageal pressures, which is important in SSc, where esophageal hypomotility increases risk of outflow obstructions and dysphagia. We present a case series highlighting effective use of cTIF for patients with SSc.



pre and post cTIF endoscopy photos revealing improvement of the gastric contents intussuscepting through the esophagus

baseline characteristics

Patient #	Esophagram Report	pH Study - Acid Exposure Time (severe >10, normal <4)	High Res Manometry (Chicago Classification)	Functional Luminal Imaging Probe Plethysmography	Procedure Wrap Degree
1	Normal peristaltic motion in proximal 1/3; no distinct primary wave in distal 2/3. Likely due to scleroderma.			Absent contractility	270
2	Barium tablet retained at GE junction, passed with water. Mild narrowing suspected.	12.3	Normal		270
3	Patulous thoracic esophagus; diminished stripping wave. Narrowing at GE junction; 13 mm barium tablet initially hangs then passes. Hiatal hernia present.				270
4	Frequent mid-distal tertiary contractions with ineffective peristalsis. Dysmotility.			Absent contractility	270
5	Mild dysmotility in distal third. No reflux.	7.3	Ineffective esophageal motility		240
6	Delayed transit of 13 mm barium tablet and both liquid/solid boluses through GE junction; aided by water.	10.5	Ineffective esophageal motility	Diminished contractility	270

Summary of pre-procedure esophageal function testing, including esophagram findings, pH study results (acid exposure time), high-resolution manometry (Chicago Classification), and functional luminal imaging probe (FLIP) assessment, alongside procedural wrap degree following cTIF intervention.

Methods: We retrospectively identified patients who fulfilled 2013 ACR/EULAR SSc Classification Criteria and underwent cTIF using the EsophyX System between February 2023 to March 2024. Esophagram, EGD with high-resolution manometry, 24-hour impedance testing, and functional luminal imaging probe plethysmography data were queried. At a mean (SD) post procedure follow-up of 23 (5) months, patients completed the GERD-HRQL survey, a 16-item questionnaire. Patients reported their current (post-procedure) symptoms and retrospectively assessed pre-procedure burden. Small sample sizes precluded formal statistical testing.

Results: Six patients with refractory GERD and/or dysphagia despite medical management who underwent cTIF were identified (Table 1). Esophagrams (n=6) revealed dysmotility in three, and narrowed GE junction in two, patients. Esophageal manometry (n=2) revealed ineffective esophageal motility in one patient and normal in another. pH impedance (n=2) revealed severe GERD per upright acid exposure time in both patients (Table 2). One patient had gastroesophageal intussusception that resolved post-cTIF (Figure 1).

At follow-up, one patient had died of respiratory failure, and one patient did not complete, and four completed the GERD-HRQL. The mean (SD) GERD-HRQL pre- vs. post-procedure was 62(4.39) and 19.25(16.29), respectively. Improvement in scores ranged from 30% to 90%, exceeding the minimal clinically important difference.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: cTIF appears to be a promising treatment for refractory GERD and dysphagia in SSc. No patient reported worsening dysphagia, and four patients reported overall improvement in symptoms. These outcomes suggest cTIF may safely and effectively fill a critical treatment gap for patients with refractory SSc-GERD.

Use of a Smartphone App which Incorporates Feedback to Patients to Monitor Systemic Sclerosis-related Digital Ulcers – a Potential New Tool for Remote Clinical Monitoring

Ariane Herrick[1], Paul New[2], Graham Dinsdale[3], Andy Vail[2], Joanne Manning[3], Michael Hughes[4], Will dixon[5], Chris Taylor[5], Mark Dickinson[5] and Andrea Murray[6], [1]The University of Manchester, UK, Aberdeen, United Kingdom, [2]The University of Manchester, Manchester, United Kingdom, [3]Northern Care Alliance NHS Foundation Trust, Salford, United Kingdom, [4]Division of Musculoskeletal and Dermatological Sciences, The University of Manchester, Manchester Academic Health Science Centre, Manchester, UK, Manchester, England, United Kingdom, [5]The University of Manchester, Manchester, [6]University of Manchester, Salford, United Kingdom

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: To facilitate clinical trials we previously developed a smartphone app to allow 'tracking' of systemic sclerosis (SSc)-related digital ulcers (DUs) and their associated pain and disability, via capture of a combination of photographs and patient reported outcome measures [PROMS]. Members of the patient user group who informed the study felt that the app might be helpful in routine clinical care, as this could provide a means of their clinician viewing the ulcer(s), and assessing treatment response, remotely, thus reducing the need for hospital visits. Our aim was to assess the feasibility of using the app in a clinical setting, and to gauge patient opinion of its benefits, including a newly added lesion feedback function for patients.

Methods: Patients fulfilling the ACR/EULAR 2013 criteria for SSc and who had active DUs were recruited either face-to-face or remotely. Study design throughout was informed by the patient user group. Participants were assessed twice: on study entry (when they downloaded the app on to their own smartphone and were trained in its use) and at the point of DU healing. Participants were asked to image their lesions and record PROMs (including pain score) with the app twice weekly. Specifically for this study a lesion feedback function was added to the app, showing lesion size (measured from the photographs) over time (Figure 1). Feasibility was assessed by the number of patients who elected to participate, by the number of photographs and PROMS recorded via the app, by patient questionnaire feedback (Table 1), and by verbal feedback during patient user group meetings.

Results: Of the 22 patients assessed for eligibility, 10 were recruited: 9 (90%) female, median age (range) 55 (36-74) years, median disease duration (range) 11.6 (1.7-29.7) years. Nine (90%) completed the study. One patient consented for a second time (therefore 10 'DU episodes' were included). Of the 12 patients not recruited, 2 were about to have DU surgery, in 6 the DU had almost healed, and 4 were not interested. The median duration of study participation per DU episode was 39 days (range 18-140). In total, 210 images were returned, median (range) 12 (4-87) per episode from 10 DU episodes. and 101 pain scores returned out of a possible total of 144 (70%). Patient questionnaire feedback is summarised in Table 1: most patients

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1 - Example of a lesion feedback graph sent to patients during the study. The ulcer size on the vertical axis is plotted against the date/time stamp of the image from which it was derived

Table 1 - Responses to the post-study questionnaire from the 10 'episodes' from the 9 participants who completed the study

Question [1]	Median (range)
Remembering to take photos/videos of finger ulcers (twice per week)	3 (1-6)
Taking photographs/videos at the same time on each occasion (twice per week)	3 (1-6)
Taking photographs/videos in the same place on each occasion (twice per week)	2 (1-6)
Keeping the environment and lighting the same on each occasion (twice per week)	1.5 (1-5)
Making sure the hands were in the same condition (e.g. no recent hand cream or hand washing) on each occasion(twice per week)	1 (1-4)
Overall experience of using the mobile phone to photograph/video your finger ulcer	2.5 (1-10)
Holding the phone when imaging	4 (1-9)
Pressing the button or screen to take an image	4 (1-8)
Getting a good clear image of your finger ulcer	2 (1-7)
Was it helpful to know (via app feedback) whether your ulcer was improving (getting smaller) or worsening (getting bigger) over time?[2]	1.5 (1-8)
Was it easy to understand the feedback provided via the app (was it presented in a clear and concise manner)?	2 (1-8)
Would you be keen to use the app again (to monitor the progress of any further ulcers)?[3]	1 (1-4)
How easy was it to send images/video to the research team through the SALVE app?	1 (1-3)

1. Answers on a 1-10 scale. 1 = very easy, 10 = very difficult unless otherwise stated.
2. Answers on a 1-10 scale. 1 = very helpful, 10 = not helpful
3. Answers on a 1-10 scale. 1 = very keen, 10 = not keen

found the app very easy to use, feedback was very helpful, and all were keen to use the app again. One participant required help from someone else to take the photographs, and one patient used a tripod. The patient with most difficulties reported 'cracked skin' and limited hand mobility. The 4 patients attending the final user group meeting confirmed feasibility, and made suggestions about 'next steps', including feedback on DU size being expressed as percentage change.

Conclusion: 1. Using the smartphone app was feasible for most patients despite the hand function problems of SSc.

2. Patients found the feedback function helpful in gauging 'progress' of the DU.

3. Our findings lend support to wider use of the app in routine clinical practice, thus allowing remote DU monitoring (facilitating early identification of clinical deterioration) and reducing the need for hospital attendance for many patients.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with systemic sclerosis (SSc) face increased cancer risk compared to the general population, yet current evidence on specific cancer patterns and their relationship to autoantibody status remains poorly characterized. We investigated cancer risk patterns in systemic sclerosis (SSc) patients and investigate associations between specific autoantibodies and cancer development.

Methods: This multi-center cohort study analyzed 5-year cancer incidences in adults with SSc versus matched controls with seborrheic keratosis using electronic medical record data from 128 healthcare organizations (from 2016-2024) in the TriNetX platform, a Health Insurance Portability and Accountability Act and General Data Protection Regulation-compliant federated research network. Patients were stratified by autoantibody status (anti-Scl-70, RNA polymerase III, anti-

Laceration of the Head	11	≤10	1.40 (0.54, 3.60)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

centromere) from available clinical laboratory testing. To facilitate comparative analysis, propensity score matching (1:1 using a greedy nearest neighbor algorithm) balanced cohorts on characteristics like age, sex, race and ethnicity, and comorbidities (Table 1). Primary outcomes included 5-year incidences of hematologic and solid-organ cancers, and varicose vein and trauma (laceration of the head) were selected as negative control outcomes. Hazard ratios (HRs) and their 95% confidence intervals (CIs) were calculated using Cox proportional hazards regressions.

Results: After propensity score matching, 66,637 patients were included in each cohort, with no statistically significant differences in baseline demographics and covariates between the treatment and control groups; in the SSc cohort, the mean age was 55.5 years (SD: 16.5) and 81.0% were female. SSc patients demonstrated elevated 5-year risks of any cancer compared to matched controls (HR 1.17; 95% CI 1.11–1.23) (Table 2). Hematologic cancer risk was significantly increased (HR 1.68; 95% CI 1.50–1.88), particularly for multiple myeloma (HR 2.13; 95% CI 1.61–2.81) and myelodysplastic syndromes (HR 2.03; 95% CI 1.49–2.77). For solid organ cancers (HR 1.23; 95% CI 1.16–1.31), esophageal cancer showed the highest risk (HR 3.96; 95% CI 2.36–6.65), followed by lung cancer (HR 2.32; 95% CI 2.00–2.69). Among autoantibody subgroups, anti-Scl-70 positive patients showed increased overall cancer risk (HR 1.40; 95% CI 1.09–1.79), RNA Polymerase III positive patients had higher rates of hematologic cancers (HR 2.56; 95% CI 1.19–5.54), while anti-centromere positive patients showed no increased cancer risks aside from a decreased melanoma risk (HR 0.26; 95% CI 0.10–0.69).

Conclusion: SSc patients demonstrate significantly increased risks for both hematologic and solid organ cancers, with risk profiles varying by autoantibody status. These findings suggest the need for targeted cancer screening strategies in SSc and further research to confirm the generalizability of these findings.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

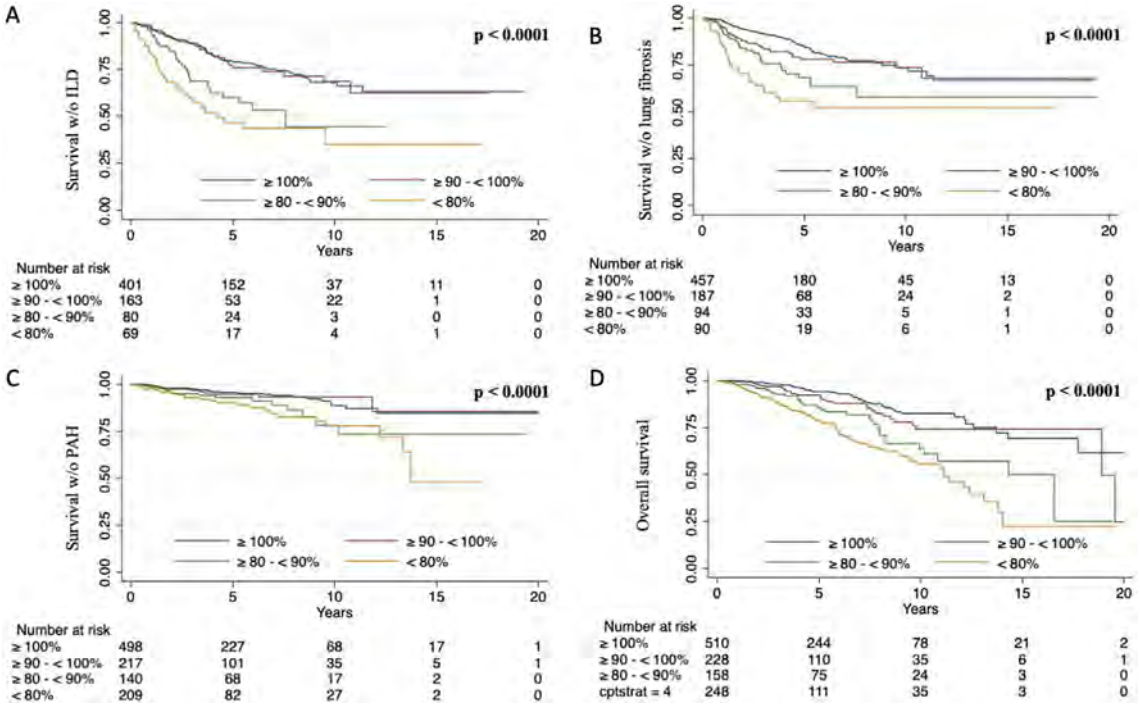

Figure 1. Overall probability of survival according to total lung capacity in patients with systemic sclerosis

Background/Purpose: Total lung capacity (TLC) is seldom assessed in the prediction of systemic sclerosis (SSc) disease severity.Herein, we utilized the French SSc national database to analyse TLC in SSc patients, examine its longitudinal trajectories, and explore its associations with organ involvement and patient survival.

Methods: We performed a retrospective multicentre study of SSc patients enrolled in the French national SSc cohort with at least one TLC assessment, described patients based on baseline TLC measurements, modelized TLC trajectories in SSc,

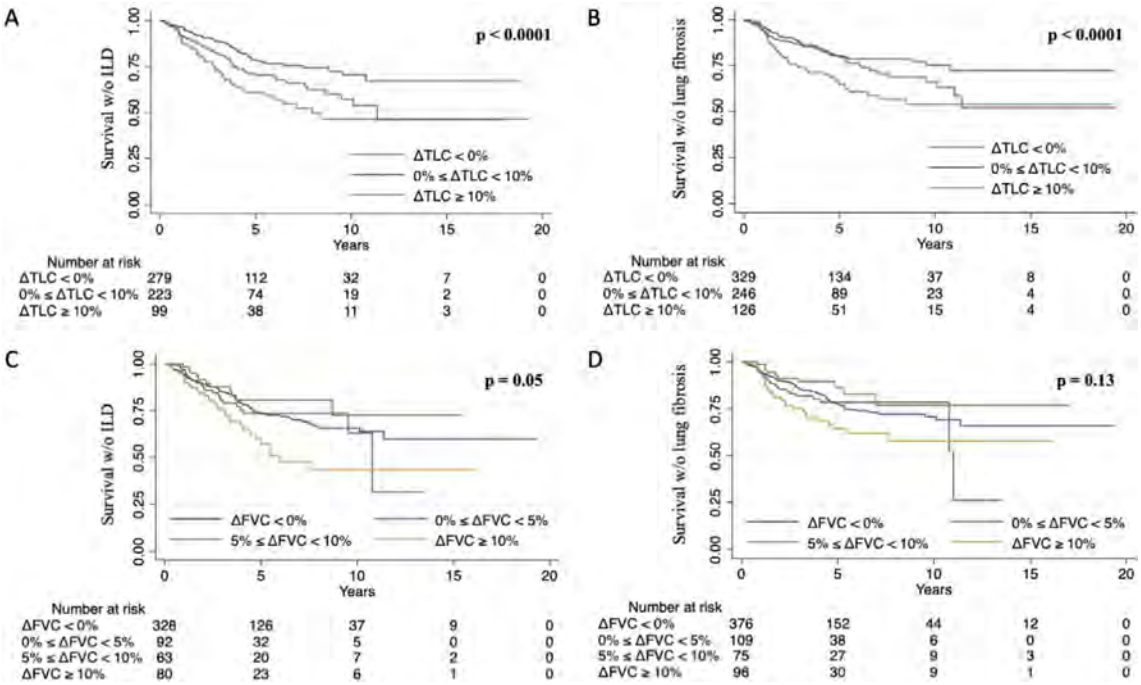

Figure 2. Overall probability of time to interstitial lung disease and lung fibrosis onset according to total lung capacity and forced vital capacity decrease in patients with systemic sclerosis

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

and associated TLC measures with disease prognosis. Only patients who met the 2013-American College of Rheumatology (ACR)/European Alliance of Associations for Rheumatology (EULAR) SSc classification criteria and had baseline TLC measure available were included in the study.

Results: Two thousand three hundred and forty-seven patients were included in the study. Median [interquartile] (IQR) age at SSc diagnosis was 52 [41-63] years. The proportion of females was 81%, and the proportion of dcSSc patients was 30%. Thirty percent, 38%, and 4% of patients were positive for ATA, anti-centromere (ACA), and anti-RNA polymerase III antibody (ARA), respectively. Thirty-nine percent and 28%, had ILD and LF, respectively.

At baseline, forty-three percent had a TLC above or equal to 100 % and 24 % had a TLC below 80%. During a median [IQR] follow-up of 4.6 [2.5-7.9] years, 190 (16%) patients died, 617 (53%) developed de novo interstitial lung disease (ILD), 499 (43%) developed de novo LF, 175 (15%) were diagnosed with PAH following right heart catheterization, and 69 (6%) developed scleroderma renal crisis (SRC). Kaplan-Meier curves showing the overall 20-year probabilities of survival and survival without ILD, LF, and PAH after SSc diagnosis according to baseline TLC showed that a lower TLC was associated with worse survival and a higher risk of ILD, LF, or PAH occurrences ($p < 0.001$) (Figure 1).

Among 2347 patients with at least one TLC measure, 988 (42%) patients had at least 2 TLC measures. Individual TLC trajectories varied among patients. Different models of TLC trajectories were assessed using latent process mixed models. The best model showed that the vast majority of SSc patients had stable TLC trajectories and clustered patients into three groups predictive of SSc survival, ILD, LF, and PAH ($p < 0.05$).

Interestingly, a 10% decrease of TLC was found to be predictive of a 5% decrease in forced vital capacity (FVC)($p < 0.0001$), a 10% decrease in DLCODLCO ($p < 0.001$), and consequently an earlier predictive marker of ILD and LF than FVC (Figure 2).

Conclusion: The present study shows that TLC measurement is associated with SSc severity and prognosis. It suggests that TLC may be an early marker of ILD and PF development, and that a 10% TLC decrease is a useful and early marker of FVC or DLCO decreases, as well as ILD or LF occurrence. Overall, our findings support the use of TLC along with FVC in monitoring and assessing ILD and LF in both clinical practice and clinical trials.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Inflammatory joint and/or tendon involvement affects up to 30% of patients with systemic sclerosis (SSc), resulting in pain, reduced joint function, and impaired patients' quality of life. The lack of standardized outcome measures for assessing articular activity in SSc hampers therapeutic development and data comparability. To bridge this gap, we aimed to develop a consensus-based composite score to assess articular activity in adult SSc, suitable for research settings and/or clinical practice.

Methods: A steering committee was convened, consisting of 12 rheumatologists, 1 epidemiologist, 1 occupational therapist, and 3 patient research partners. The development of the articular activity score followed a stepwise process (Figure 1). First, a scoping review was conducted using PubMed (January 1960 to April 2023); two reviewers (B.B. and M.E.) independently screened studies on joint/tendon involvement in SSc and extracted assessment tools. Following expert discussions, instruments demonstrating at least 70% validity and feasibility after the committee voting were further evaluated by two independent reviewers according to OMERACT (Outcome Measures in Rheumatology) guidelines. These findings were then presented to the steering committee, and a two-round online Delphi survey was used to finalize the core set.

Results: Of the 770 references initially identified, 658 were excluded based on title or abstract screening, leaving 112 articles for full-text review; ultimately, 86 studies met the inclusion criteria. From these, 46 instruments that were used in at least two studies were identified. Based on domain validity and feasibility, 9 clinical, 1 serological, 3 composite scores, and 3 patient-reported outcome measures were shortlisted for further evaluation (Table 1). Following an assessment of measurement properties according to OMERACT guidelines, the steering committee voted and excluded 10 items due to missing

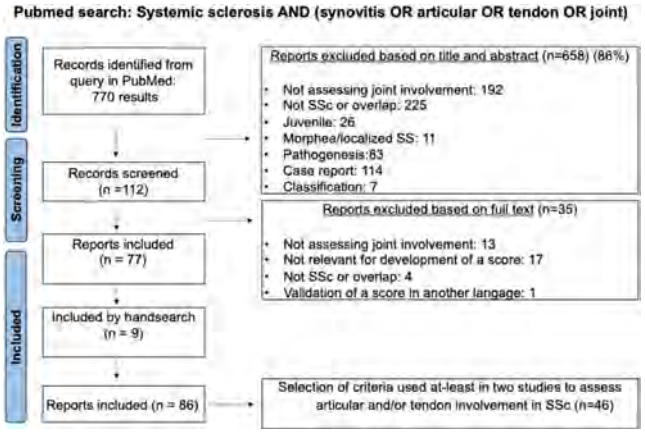

Figure 1: Scoping review search strategy.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1: Identified core instruments for assessing disease articular activity in SSc patients. The 28-joint count includes the wrists, metacarpophalangeal (MCP) joints, proximal interphalangeal (PIP) joints, elbows, shoulders, and knees. The 50-joint count builds on the 28-joint count by also including the distal interphalangeal (DIP) joints, hips, ankles, and metatarsophalangeal (MTP) joints.

Clinical	Serology	Composite score	Patient reported outcomes
○ Ritchie articular index ○ Number of tender joints (n=28, n=50) ○ Number of swollen joints (n=28, n=50) ○ Number of synovitis (n=28, n=50) ○ Presence of tendon friction rubs ○ Number of tendon frictions rubs	○ CRP	○ DAS28-ESR ○ DAS28-CRP ○ SDAI	○ Visual analogic scale for articular pain (patient) ○ Visual analogic scale for disease activity (patient) ○ Visual analogic scale for disease activity (physician)

specificity or feasibility on joint activity assessment. 6 final instruments were selected for inclusion in a composite outcome measure to assess articular activity in patients with SSc. The selected instruments covered clinical (28-joint tender/swollen joint count with the addition of distal interphalangeal joints; presence of tendon friction rubs), serologic (CRP) and patient/physician reported outcomes (VAS activity pain patient, VAS activity doctor) domains.

Conclusion: International, multi-disciplinary SSc experts and patient partners have identified 6 feasible core instruments to assess articular activity in SSc patients, covering both joint and tendon involvement. This core set provides the basis to further develop a composite score for articular involvement in SSc for use in clinical practice and clinical trials. Future steps will include performance validation within longitudinal SSc cohorts.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with early severe diffuse cutaneous systemic sclerosis (dcSSc) with interstitial lung disease (ILD) have poor prognosis. New tools are needed to improve treatment stratification and monitoring. Studies with repeated positron emission tomography-computed tomography with [^{18}F]Fluorodeoxyglucose ([^{18}F]FDG PET-CT) in this specific high-risk group have not been performed and may have clinical value. In this study we aimed to (1) assess changes in [^{18}F]FDG lung uptake between baseline and follow-up after different treatment regimens (2) identify if [^{18}F]FDG lung uptake at baseline is associated with ILD progression during follow-up.

Methods: [^{18}F]FDG PET-CT scans of the lungs were performed at baseline and repeated one year after initial randomization to cyclophosphamide pulse therapy or autologous stem cell transplantation within the UPSIDE trial (NCT04464434). All [^{18}F]FDG PET-CT scans were analyzed by manual placement of 2 cm volumes of interest (VOIs) in 22 pre-defined lung areas and mean standardized uptake values (SUVs) of [^{18}F]FDG tracer uptake were corrected for the uptake in the mediastinal blood pool.

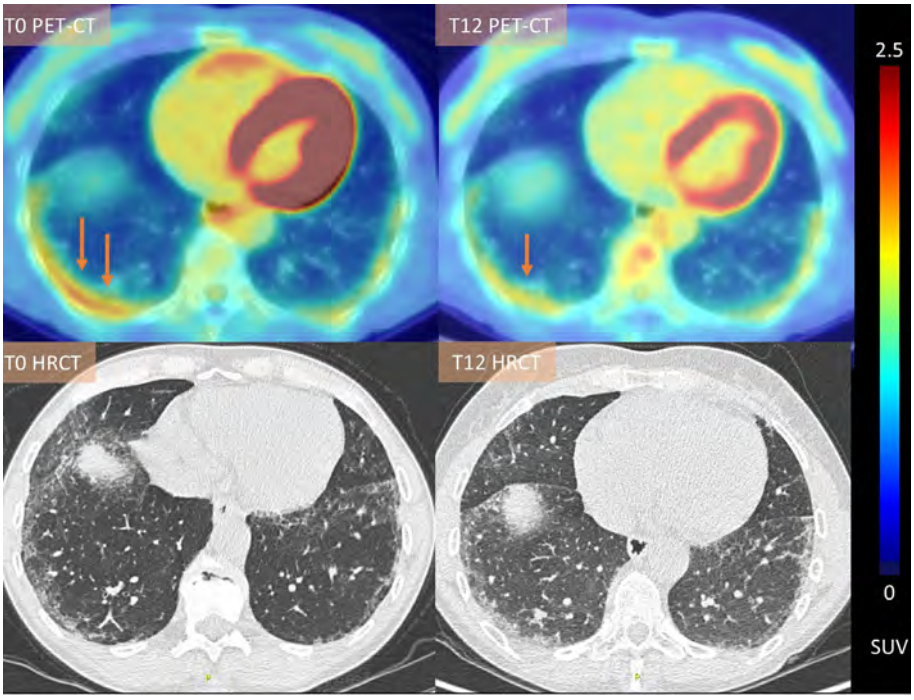

Figure 1. Visual and quantitative decrease in pulmonary [18F]FDG uptake in a patient with early severe diffuse cutaneous systemic sclerosis and interstitial lung disease with clinical improvement

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

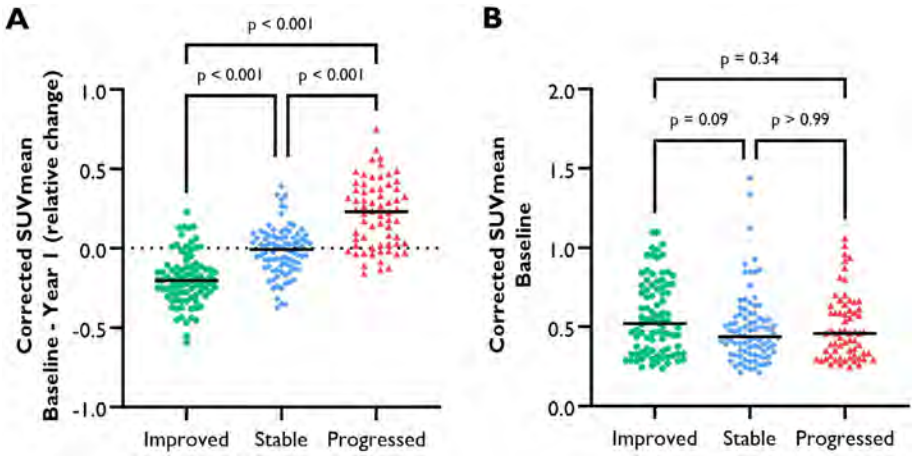

Figure 2. (Changes in) Quantitative [18F]FDG uptake between different patient groups (improved, stable or progressed interstitial lung disease)

Percentual changes after one year were calculated by the mean of all VOIs. Changes in [^{18}F]FDG lung uptake were compared to clinical assessment of ILD development. At 1 year follow-up, ILD progression was defined according to the Progressive Pulmonary Fibrosis (PPF) criteria (2 out of 3 criteria): (1) increased respiratory symptoms, (2) decreased FVC≥5% or DLCO≥10% (3) increased lung fibrosis on HRCT, while patients met criteria for ILD improvement with (2 out of 3) reversed criteria: (1) decreased respiratory symptoms, (2) increased FVC≥5% or DLCO≥10% (3) decreased lung fibrosis on HRCT. Stable ILD was defined as having neither progression nor improvement. Between group differences were analyzed using non-parametric tests.

Results: Eleven patients were included. Five patients were female, with a median age of 54 years and median disease duration of 9.5 months at baseline. Patients with ILD progression at 1 year (n=3) showed increased [^{18}F]FDG uptake (corrected SUVmean +21.7%) after 1 year, while patients with improved ILD (n=4) showed decreased [^{18}F]FDG uptake (corrected SUVmean -19.4%) over time (Figure 1 and 2A). Less evident differences were observed in patients with stable ILD (n=4; corrected SUVmean -1.5%). Finally, [^{18}F]FDG uptake at baseline did not differ between patients who did or did not progress at 1 year of follow-up (Figure 2B).

Conclusion: [^{18}F]FDG uptake in the lungs changed in line with clinical response to therapy in patients with early severe dcSSc and ILD. These results suggests that [^{18}F]FDG PET-CT has the potential to have additive value in the monitoring of SSc-ILD.

Terazosin	1/139 (0.7%)	0/84 (0.0%)	1/33 (3.0%)	0/10 (0.0%)	0/12 (0.0%)	0.40

Abbreviations: NP/NC: normal platelet/normal CRP, NP/EC: normal platelet/elevated CRP, EP/NP: elevated platelet/normal platelet, EP/EC: elevated platelet/elevated CRP, PDE5: phosphodiesterase type 5, PRAs: prostanoid receptor agonists.

* Biologics include Abatacept SQ, Abatacept Infusion, Certolizumab SQ, Rituximab, and Tocilizumab.

Steroids include Methylprednisolone and Prednisone.

† Antifibrotics include Nintedanib and Pirfenidone.

Background/Purpose: Elevated acute phase reactants such as platelets and C-reactive protein (CRP) have been used as inclusion criteria to enrich systemic sclerosis (SSc) clinical trials for patients with active disease. While elevated CRP levels have been associated with severe disease and worse survival, the role of platelet levels remains largely unexplored.

Figure 1A: Longitudinal Changes in Forced Vital Capacity (FVC, %) Over Time Using Mixed Models

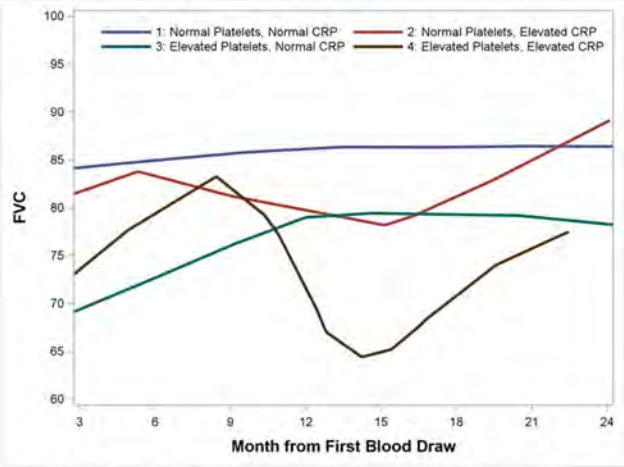

Figure 1B: Longitudinal Changes in modified Rodnan Skin Score (mRSS) Over Time Using Generalized Estimating Equation Model

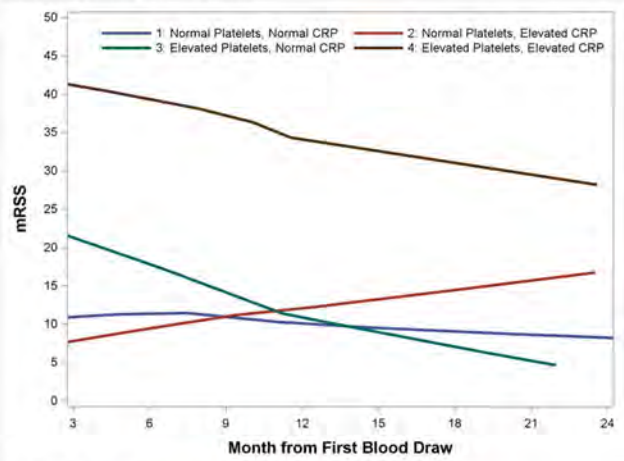

Figure 1C: Overall Survival of Patients by Four CRP/Platelet-Defined Groups

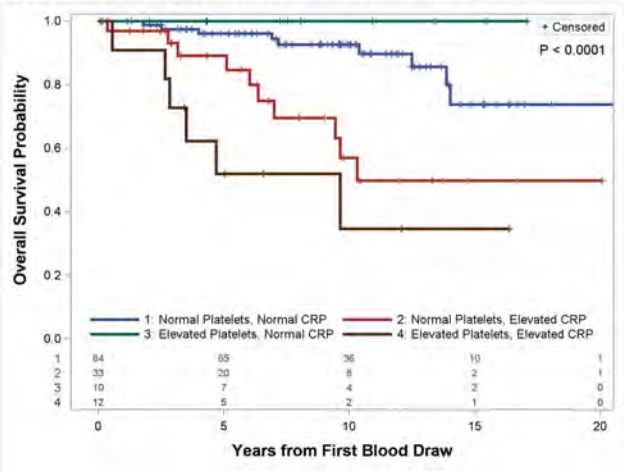

Methods: We performed a retrospective study of adult SSc patients seen at a single tertiary care center from 1996 to 2022. Based on the first available blood draw after onset of first non-Raynaud symptom, patients were categorized into four groups using cutoffs of ≥330,000/μL for elevated platelet and ≥6.0mg/L for elevated CRP: 1) normal platelet/normal CRP (NP/NC), 2) elevated platelet/normal CRP (EP/NC), 3) normal platelet/elevated CRP (NP/EC), 4) elevated platelet/elevated CRP (EP/EC). Longitudinal forced vital capacity (FVC) and modified Rodnan skin score (mRSS) were captured over two years following the initial blood draw. Survival data were collected until end of study (12/31/2024), death, or the last available

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 2: COX Model Comparing Overall Survival Across Different Groups

	HR (95% CI)	p-value
NP/EC vs NP/NC	3.94 (1.60 - 9.72)	0.003
EP/EC vs NP/NC	8.04 (2.84 - 22.79)	<0.0001
EP/EC vs NP/EC	2.04 (0.74 - 5.64)	0.17
Elevated CRP vs Normal CRP	5.44 (2.39 - 12.36)	<0.0001
Elevated Platelet vs Normal Platelet	1.98 (0.79 - 4.95)	0.15

Abbreviations: NP/NC: normal platelet/normal CRP, NP/EC: normal platelet/elevated CRP, EP/NP: elevated platelet/normal platelet, EP/EC: elevated platelet/elevated CRP.

clinic date. Fisher's exact test, Kruskal-Wallis Tests, mixed model, generalized estimating equation model, log-rank test of Kaplan-Meier, and Cox regression analyses were used, with $p< 0.05$ considered statistically significant.

Results: There was a total of 139 patients in the study, with 84, 33, 10, and 12 patients in the NP/NC, NP/EC, EP/NC, and EP/EC groups, respectively. The EP/EC group had the highest percentage of patients with Scl-70 positive antibody, diffuse skin involvement, myocarditis/cardiomyopathy, dysphagia, gastric antral vascular ectasia (GAVE), joint contracture, and digital ulcers compared to other groups ($p< 0.05$ for all) (Table 1). The EP/EC group had significantly higher use of methotrexate and antifibrotic agents compared to other groups ($p< 0.05$ for all). Over two years, the NP/NC group had the highest FVC baseline values and remained the most stable. In contrast, both elevated CRP groups (NP/EC and EP/EC) had a decline in FVC values during the first year followed by some improvement, with EP/EC group having the steepest drop during the first year. However, there were no statistically significant differences between the groups over time (Figure 1A). Over the same period, EP/EC group had the worst mRSS scores, which improved over time but remained significantly higher than the other three groups ($p< 0.05$ for all comparisons with the EP/EC group) (Figure 1B). Survival was lowest in the EP/EC group, with a median survival of 9.6 years compared to 21.3 years in the NP/NC group ($p< 0.0001$) (Figure 1C) and a hazard ratio (HR) of 8.04 (2.84-22.79, $p< 0.0001$) (Table 2). When comparing the EP/EC group to the NP/EC group, the HR was 2.04 (0.74-5.64, $p=0.17$) (Table 2).

Conclusion: SSc patients with elevated platelets and CRP developed more severe disease than the other groups. This subset had an eightfold increased risk of mortality compared to those with normal platelets and CRP. The combination of elevated platelets and CRP may have a greater impact on survival than CRP alone. Assessing CRP and platelet levels after symptom onset may help identify high-risk patients and guide clinical care.

Background/Purpose: Mycophenolate mofetil (MMF) is recommended for skin in diffuse cutaneous (dc)SSc, and for lung fibrosis in SSc, but patients with limited cutaneous (lc)SSc are not routinely started on MMF at diagnosis. This may miss an opportunity to prevent or treat major complications early. MINIMISE-Pilot tested feasibility of a randomised event-driven trial of MMF in lcSSc.

Methods: We explored recruitment and feasibility of a trial evaluating impact of MMF on a novel event-driven composite endpoint. The MINIMISE endpoint measures time to clinical worsening of lcSSc determined by one of the following: progressive lung fibrosis, pulmonary hypertension, scleroderma renal crisis, heart failure, severe gut involvement, major digital vascular complications, or death. Subjects were stratified by anticentromere antibody (ACA) status.

This study prioritised remote assessment and used the novel Patient self-Assessment of Skin Thickness of Upper Limb (PASTUL) questionnaire to measure skin fibrosis. Primary outcomes were safety and feasibility. Pre-specified "go and no-go" criteria were based on patient number and event rate with agreed thresholds of success.

Results: Recruitment was challenging and a total of 53 subjects were screened and 43 randomised, 21 to the MMF arm (**-Figure 1**). Average age of participants was 57 years, with near equal distribution between the control and MMF groups. Baseline characteristics and treatment allocation are summarised in **Table 1**. Most participants were female (84%), of White British ethnicity (81%) and had positive ACA (67%). Since recruitment was below 60 participants, MINIMISE-Pilot was terminated based upon the prespecified threshold for continuation.

There were no major safety concerns. Serious Adverse Events (SAEs) occurred in 3 patients (7%). These included 2 (9%) in the control group and one (5%) in the MMF group. SAEs reported were gastrointestinal disorders (1 on MMF), injury and procedural complications (1 control), and musculoskeletal and connective tissue disorders (1 control). During the treatment

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

period no participants experienced clinical worsening endpoints. Adherence to MMF was generally high, with 19 participants (95%) being 100% adherent at Week 1, decreasing to 9 participants (64%) at Week 24.

Conclusion: This study achieved its key goal as a feasibility pilot leading to early termination of the study due to low recruitment. This precludes interpretation of effectiveness and safety of MMF in lcSSc. Whilst emerging evidence strongly supports the use of MMF to treat skin and lung fibrosis in SSc, and other studies have validated the novel composite MINIMISE endpoint of "clinical worsening in lcSSc" and PASTUL endpoint for skin, the results of MINIMSE-Pilot suggest that a randomised prospective trial across 8 active sites in UK with relatively short duration is not feasible. This is important and will inform design of future studies testing benefit of MMF in lcSSc. Our previous power calculations suggest that around 400 patients and a treatment period of 36 months would be needed for the current study design, although emerging enrichment strategies may reduce the required subject number.

Table 2. Prevalence and Relative Risk of Diffuse and Limited Systemic Sclerosis in X Chromosome Aneuploidies

Cohort	Diffuse Systemic Sclerosis Prevalence (%)	Relative Risk (95% CI), p-value (Diffuse)	Limited Systemic Sclerosis Prevalence (%)	Relative Risk (95% CI), p-value (Limited)
Klinefelter Syndrome (47,XXY)	0.19	9.0 (5.1–15.9), p < 0.001	0.22	16.9 (9.3–28.6), p < 0.001
Triple X Syndrome (47,XXX)	0.25	5.2 (2.7–8.9), p < 0.001	0.48	14.5 (7.1–27.1), p < 0.001
Turner Syndrome (45,XO)	0.047	0.98 (0.51–1.78), p = 0.82	0.009	0.28 (0.14–0.56), p < 0.001

studies linked X chromosome aneuploidies to immune dysregulation, their specific impact on diffuse and limited SSc remains unclear. This study evaluates the relationship between Klinefelter syndrome (47, XXY), triple X syndrome (47, XXX), and Turner syndrome (45, XO) and the development of diffuse and limited systemic and limited sclerosis compared to the general population using a large-scale electronic health record database.

Methods: This multicenter, retrospective cohort study utilized TriNetX, a global federated research network comprising 141 healthcare centers. Three cohorts were analyzed: individuals with Klinefelter syndrome compared to the general male population, individuals with Turner syndrome compared to the general female population, and individuals with triple X syndrome compared to the general female population. Patients were identified using the International Classification of Diseases, Tenth Revision, Clinical Modification codes, between January 1, 2015, and January 1, 2025. The prevalence and risk of diffuse and limited SSc were assessed in each cohort. Relative risk, odds ratios, and 95 percent confidence intervals were calculated. The statistical significance was assessed using Fisher's exact test.

Results: A total of 88,951,991 patients were identified. Among individuals with Klinefelter syndrome, the prevalence of diffuse SSc prevalence was 0.19% (RR = 9.0, 95% CI: 5.1–15.9, p < 0.001), and the prevalence of limited SSc was 0.22% (RR = 16.9, 95% CI: 9.3–28.6, p < 0.001). In triple X syndrome, the prevalence of diffuse SSc was 0.25% (RR = 5.2, 95% CI: 2.7–8.9, p < 0.001), and limited SSc prevalence was 0.48% (RR = 14.5, 95% CI: 7.1–27.1, p < 0.001). In Turner syndrome, the prevalence of diffuse SSc was 0.047% (RR = 0.98, 95% CI: 0.14-0.56, p = 0.82), and limited SSc prevalence was 0.009% (RR = 0.28, 95% CI: 0.14–0.56, p < 0.001).

Conclusion: Excess X chromosome in Klinefelter syndrome and triple X syndrome is associated with significant increased risk of having diffuse and limited systemic sclerosis in a nonproportional, synergistic manner. Deficient X chromosome in Turner syndrome is associated with a lower risk of having limited systemic sclerosis but no effect on diffuse SSc when compared with the general population. These findings support the role of X chromosome dosage in susceptibility of developing systemic sclerosis and highlight the complex interplay between X chromosome dosage and immune regulation. This study underscores the need for heightened clinical awareness and targeted screening in individuals with Klinefelter and Triple X syndromes.

SESSION INFORMATION

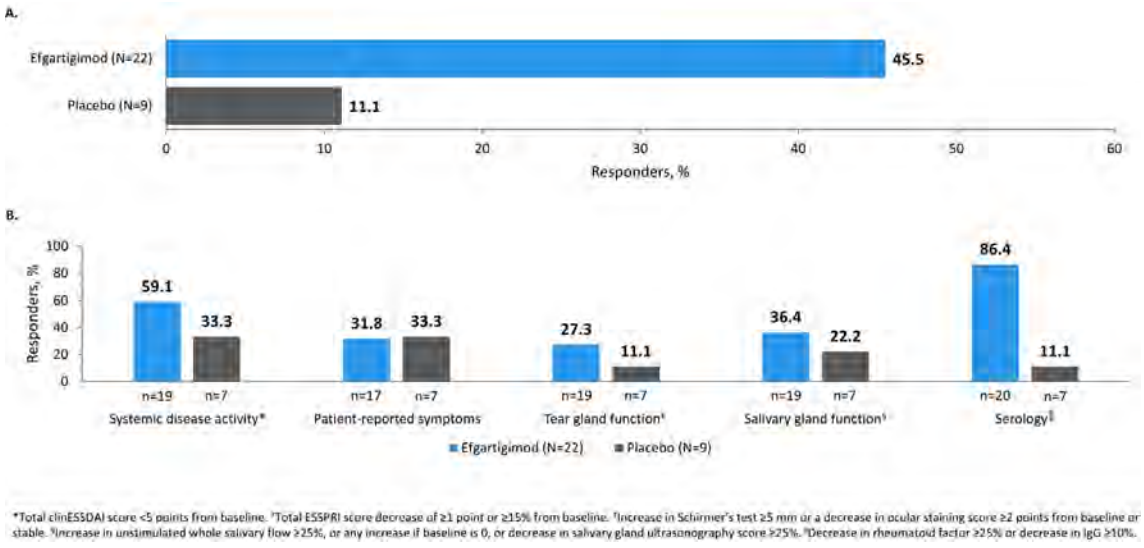
Session Date: Sunday, October 26, 2025
Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Background/Purpose

Sjögren's disease (SjD) is a chronic, systemic autoimmune disease characterized by lymphocytic infiltration and progressive, immune-mediated dysfunction of the exocrine glands. Immunoglobulin (Ig) G autoantibodies targeting Sjögren's syndrome-related antigens (A/Ro and B/La ribonuclear complexes) and RF play a pivotal role in SjD development and are produced by B-cell activation. Current SjD therapies focus on symptom management, with limited efficacy in preventing glandular damage or suppressing systemic disease activity. Efgartigimod, an IgG1 antibody Fc fragment, selectively reduces IgG by blocking FcRn-mediated IgG recycling without impacting antibody production, albumin levels, or other parts of the immune system. By targeting disease-specific IgG autoantibodies, efgartigimod may reduce disease activity and symptoms in patients with SjD. We present the results of RHO, a phase 2, multicenter, randomized, placebo-controlled, double-blind, proof-of-concept study to explore the safety and efficacy of efgartigimod in adult participants with SjD (NCT05817669).

Methods: Anti-Ro/SSA positive patients meeting ACR/EULAR 2016 Sjogren's syndrome criteria ≤7 years before screening, with EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI) ≥5 and residual salivary flow, were randomly allocated (2:1) to receive weekly intravenous efgartigimod or placebo for 24 weeks. The primary endpoint was the proportion of responders to the Composite of Relevant Endpoints for Sjögren's Syndrome (CRESS; response on ≥3 out of 5 items) at week 24. Key secondary endpoints were proportion of responders to the candidate Sjögren's Tool for Assessing Response (cSTAR), change from baseline in ESSDAI, Clinical ESSDAI (ClinESSDAI), EULAR Sjogren's Syndrome Patient Reported Index (ESSPRI) scores, and safety.

Results: Of thirty-four patients randomized, three did not meet eligibility criteria and were removed from analyses. The study met its primary endpoint, with more responders to ≥3 of 5 CRESS items in the efgartigimod than placebo group at week 24 (45.5% [10/22] vs 11.1% [1/9]). Efgartigimod treatment resulted in a positive signal for 4 of 5 individual CRESS items compared with placebo (Figure), and an increased cSTAR response at week 24 (54.5% [12/22] participants compared with 33.3% [3/9] of placebo-treated participants). All participants showed improvements from baseline in disease activity (ESSDAI and ClinESSDAI scores), and no relevant changes in ESSPRI score. Efgartigimod rapidly reduced mean (SE) IgG



*Total clinESSDAI score <5 points from baseline. †Total ESSPRI score decrease of ≥1 point or ≥15% from baseline. ‡Increase in Schirmer's test ≥5 mm or a decrease in ocular staining score ≥2 points from baseline or stable. §Increase in unstimulated whole salivary flow ≥25%, or any increase if baseline is 0, or decrease in salivary gland ultrasonography score ≥25%. ¶Decrease in rheumatoid factor ≥25% or decrease in IgG ≥10%.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. and anti-Ro52 autoantibodies by 58.3% (2.4) and 63.8% (3.9), respectively, from Week 4, and mean (SE) C1Q immune complexes by 4.0 (1.3) μg Eq/mL, and mean (SE) RF by 19.6% (4.1) compared with 6.3% (3.0) by placebo at study end. Efgartigimod was well tolerated, with no new safety signals.

Conclusion: Proof-of-concept was demonstrated using efgartigimod in patients with SjD, which was generally well tolerated. The ongoing phase 3 UNITY trial (NCT06684847) will assess efficacy and safety of efgartigimod in patients with SjD with clinESSDAI ≥6 (moderate-to-severe systemic disease activity).

Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic sclerosis (SSc) is a chronic autoimmune rheumatologic disease characterized by fibrosis and vascular complications, which significantly impact various organs, including the heart. Cardiac involvement contributes substantially to morbidity and mortality, yet early myocardial dysfunction often remains undetected due to its asymptomatic nature. While a transthoracic echocardiogram (TTE) is the standard tool for assessing ventricular dysfunction and pulmonary hypertension, it may fail to identify early/subclinical myocardial dysfunction. Strain echocardiography, particularly global longitudinal strain (LVGLS), has emerged as a more sensitive method for detecting early cardiac impairment. However, data on radial and circumferential strain—critical components of multidimensional cardiac function—remain limited. This study evaluates the progression of strain patterns over five years and compares strain echocardiography to conventional TTE.

Methods: A retrospective analysis was conducted on SSc patients (2013 ACR criteria, Table 1) with LV diastolic and/or systolic dysfunction (LVD) who underwent at least three TTEs over the past decade. Strain values were obtained using speckle-tracking echocardiography from the most recent TTE and those from three and five years prior. To ensure consistency, strain measurements were recalculated using TomTec® technology. Patients with incomplete data were excluded. Strain data was analyzed as mean values.

Results: Left ventricular global longitudinal (LVGLS) and circumferential strain (LVGCS) are expressed as a negative percentage, with normal values defined as < -18% (LVGLS) and < -15.3% (LVGCS). Radial strain (LVGRS) is expressed as a positive percentage, with normal values ≥ 25.5%. Over five years, all three mean strain patterns showed progressive decline:

- LVGLS: -17.1 -15.6 -14.4
- LVGCS: -18.8 -16.4 -14.2
- LVGRS: 20.6 18.0 15.9

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Notably, 31-44% of patients with normal LV function on conventional TTE (LVEF ≥ 50% and normal diastolic function) exhibited abnormal LVGLS or LVGRS. In contrast, LVGCS aligned more closely with conventional TTE findings (Figure 1). Though all patients in the study were diagnosed with SSc-LVD, 46.8% showed no current LVD based on conventional TTE. This discrepancy may reflect treatment-related normalization of standard TTE parameters.

Table 1: Patient Characteristics

Table 1:

Patient Characteristics	
Baseline Characteristics	
Total patients	94
Age (years)	72.0 [60.0-79.7]
Sex	
Male	18 (19.1%)
Female	76 (80.8%)
Race	
White	77 (81.9%)
Non-white	17 (18.1%)
BMI (kg/m²)	23.5 [20.2-28.3]
Hypertension	71 (75.5%)
Diabetes	15 (15.9%)
Hyperlipidemia	66 (70.2%)
Tobacco Use	
Current	2 (2.1%)

Angiotensin Receptor Blocker	39 (41.5%)
Beta-Blocker	78 (83.0%)
Calcium-Channel Blocker	81 (86.2%)

Continuous variables are presented as Median (IQR). Categorical variables are presented as N (column %).

Figure 1:

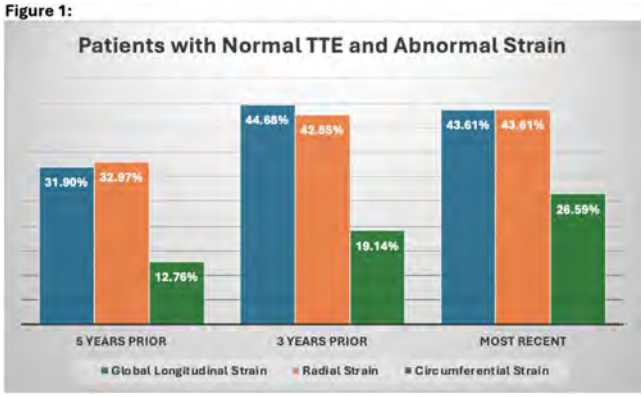

Figure 1: Patients with Normal TTE and Abnormal Strain

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Global longitudinal and radial strain measurements may outperform circumferential strain in detecting early LVD in SSc patients. These findings support the potential of strain echocardiography as a valuable, routine screening tool that may enable earlier intervention and improve patient outcomes compared to conventional TTE.

A Retrospective Comparison of Transplant Outcomes with Different Induction Methods and Maintenance Prednisone in Systemic Sclerosis Patients

Lilit Grigoryan, Sumbal Wajid, Giovanni Faddoul and Swati Mehta, Albany medical center, Albany, NY

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic sclerosis (SSc) or scleroderma is a rare systemic autoimmune disease with multiple organ involvement. Renal involvement in SSc remains a significant concern, with the most concerning complication being scleroderma renal crisis (SRC). Up to 20-50% of these patients still require long-term dialysis and subsequently kidney transplantation (KT). We performed a retrospective study using the United Network for Organ Sharing (UNOS) database, to compare the impact of different induction immunosuppression regimens and maintenance prednisone amongst our SSc cohort.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: A retrospective analysis was conducted using UNOS database from 2000 to 2022.We had a total of 211 based on diagnostic coding consistent with scleroderma related diagnoses who underwent KT from deceased donors (DD) and live donors (LD). Cox regression analyses were conducted for patient survival and graft survival for patients with SSc. In these models, we excluded interaction terms and KDPI, while including a binary indicator for donor type (live vs. deceased) as well as induction and maintenance therapies. The patients with no induction information were excluded.

Results: There were statistically significant worse outcomes in graft survival in SSc patients receiving induction therapy with alemtuzamab, and thymo+basiliximab/thymo+daclizumab as well as with maintenance prednisone. (Table 1) There was no statistically significant difference in patient survival for both induction therapies and maintenance prednisone, amongst SSc patients. (Table 1)

Conclusion: Different induction therapies in KT are chosen for either their safety profiles or immunosuppressive effects. Alemtuzumab a relatively newer agent, has recently been studied in a retrospective review of 225 SSc patients using data from 2012-2022 which demonstrated significantly poorer graft survival outcomes. This correlates with our findings for poor graft survival among SSc patients receiving alemtuzumab induction. Like alemtuzumab a recent study looked at death-censored graft failure in individuals receiving combination therapy with thymo+basiliximab and found a statistically significant increased rate of death censored graft failure. This observation also aligns with our study.

We further found that maintenance steroid use was associated with poorer graft survival as well. One hypothesis is that steroids may contribute to SRC recurrence after KT. Although the association between steroids and increased SRC risk is well established, data on post-transplant recurrence is limited. A 2005 case study documented two SRC recurrences, with the earlier event occurring in the patient on higher steroid doses. Further research is needed to clarify this potential relationship.

Abstract Number: 0699

A Retrospective Comparison of Transplant Outcomes in Patients with and Without Systemic Sclerosis

Lilit Grigoryan, Sumbal Wajid, Giovanni Faddoul and Swati Mehta, Albany medical center, Albany, NY

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Scleroderma renal crisis (SRC) is one of the life threatening complications of systemic sclerosis (SSc). Up to 20-50% require long term dialysis and subsequently kidney transplant. We performed a retrospective study using the United Network for Organ Sharing (UNOS) database, to compare graft and patient survival in kidney transplantation (KT) patients with and without systemic sclerosis. We further investigated whether different induction immunosuppression strategies had varying outcomes in above cohort.

Methods: A retrospective analysis was conducted using UNOS database from 2000 to 2022. A total of 211 patients were chosen based on diagnostic coding consistent with scleroderma related diagnoses who underwent KT from deceased donors (DD) and live donors (LD). This cohort was then matched to non-SSc recipients using a propensity score matching.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Induction immunosuppressive regimens analyzed included alemtuzumab, basiliximab/daclizumab, and combinations of thymoglobulin with either basiliximab or daclizumab, using thymoglobulin alone as the reference group. Maintenance prednisone was also analyzed following KT. Graft and patient survival were compared between the SSc and matched non-SSc cohorts using hazard ratios (HR), both overall and stratified by induction regimen.

Results: There was a statically significant association with poorer outcomes in both graft and patient survival from both DD, and LD following KT in our SSc cohort when compared to non-SSc cohort (Table 1) (Figure 1). There was no statistically significant difference in graft and patient survival between the SSc and matched non-SSc cohorts across the various induction immunosuppression regimens along with maintenance prednisone (Table 2).

Conclusion: Using UNOS data from 211 SSc patients, we found statistically significant worse outcomes in both graft and patient survival when compared to matched controls in both DD and LD groups. Our findings align with prior UNOS-based studies which also reported lower graft survival rates in SSc transplant recipients. These poorer outcomes are likely multifactorial, potentially driven by SRC recurrence and multi-organ involvement. The use of different induction methods along with maintenance prednisone had no statistically significant difference in graft and patient outcomes when compared to our non-SSc cohort.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Pulmonary arterial hypertension (PAH) is a severe complication of systemic sclerosis (SSc), associated with high morbidity and mortality. Accurate and early diagnosis of SSc-PAH is essential to initiate targeted therapies that may improve outcomes by counteracting key pathophysiological mechanisms. Breathomics, the analysis of volatile organic compounds (VOCs) in exhaled breath, has emerged as a promising non-invasive tool, as VOCs reflect underlying metabolic and pathological processes. This study investigates the potential of breathomics in SSc-PAH, both for disease understanding and diagnosis.

Methods: fourteen SSc patients with a diagnosis of PAH confirmed by right heart catheterization, 28 age- and sex-matched SSc patients without PAH, and 36 matched healthy controls (HCs)were enrolled in a single-center, case-control observational study. Exhaled breath VOCs were collected using the ReCIVA® breath sampler connected to a clean air supply

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1 – Pairwise logFC comparison of SSc-PAH vs comparators

(CASPER®). Samples were trapped on sorbent tubes and analyzed by thermal desorption gas chromatography–mass spectrometry (TD-GC-MS) at Owlstone Medical. VOCs were chemically identified according to Metabolomics Standards Initiative (MSI) criteria, and blank air samples were analyzed to distinguish true breath compounds from environmental contaminants. Data were analyzed using linear regression, adjusting for relevant covariates and excluding outliers.

Results: all SSc participants were female and predominantly affected by lcSSc (n = 23, 63.4%) and mostly tested positive for ACA (n = 40, 85%). The mean age was 68 ± 9 years, with no differences between the SSc-PAH and SSc-noPAH groups. A total of 1.382 VOCs were analyzed; of these, 186 were confirmed to be genuinely present "on breath" and annotated with high confidence (MSI tier 1 or 2). Among these, 55 VOCs significantly differentiated SSc-PAH from SSc-noPAH, and 40 differentiated SSc-PAH from healthy controls. Notably, 32 VOCs distinguished SSc-PAH from both comparator groups ($p < 0.05$ and $|\text{fold change}| > 1.5$) (Figure 1). Findings of interest included: a reduction in terpenes in SSc-PAH, potentially reflecting impaired vasodilatory capacity (Figure 2); a decrease in sulfur-containing compounds, suggestive of reduced control

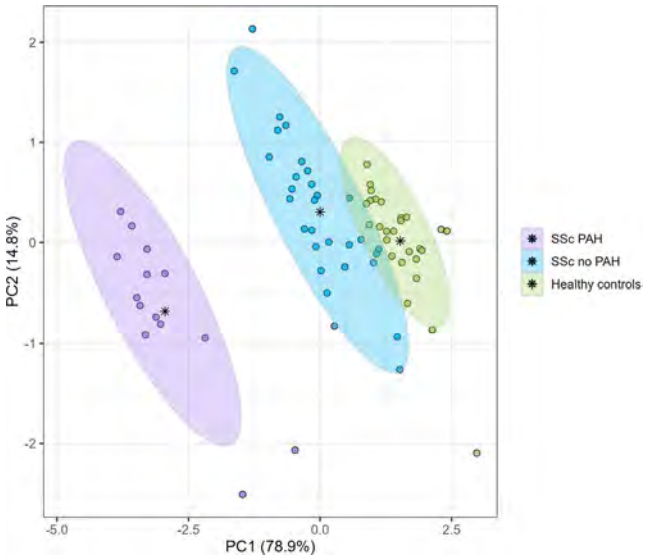

Figure 2 – Principal component analysis biplot of terpenes across study groups

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. over vasoconstriction; a reduction end-products (i.e. 1-pentene) of allyl organosulfur derivates with anti-inflammatory properties; an increase in pyrazines, possibly indicative of enhanced gut permeability; and elevated levels of the uremic toxin m-cresol, which has been associated with endothelial dysfunction.

Conclusion: breathomics revealed a distinct metabolic signature in SSc-PAH, distinguishing it from both SSc without PAH and healthy controls. The identified VOCs not only hold promise as non-invasive biomarkers for early diagnosis but also shed light on key pathogenic mechanisms of PAH, including impaired vasoregulation, increased gut permeability, and endothelial dysfunction. These findings support the role of breath analysis as a valuable tool for both clinical and mechanistic insights in SSc-PAH.

Abstract Number: 0701

Exploring Calcinosis On Hand X-Rays In Systemic Sclerosis: a Mayo Clinic Cohort

Maximiliano Diaz Menindez[1], Simran Ravindra Nimal[2], Michael Pham[2], Caroyln Harvey[3], Leroy W. Griffing[2] and Vivek Nagaraja[2], [1]Mayo Clinic School of Graduate Medical Education, Phoenix, AZ, [2]Mayo Clinic, Scottsdale, AZ, [3]Mayo Clinic, Phoenix, AZ

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Calcinosis is a vexing manifestation in patients with systemic sclerosis (SSc) with a variable prevalence among cohorts. Up to 86% of calcinosis cases are localized in the hands. This study aims to evaluate the prevalence of calcinosis on hand radiographs in a cross-sectional cohort of SSc patients at their initial evaluation and to compare clinical and laboratory features between those with and without calcinosis.

Methods: We conducted a retrospective cohort study using data from the Mayo Clinic Arizona Scleroderma Program. Only patients who underwent bilateral hand X-rays as part of baseline evaluation were included. Demographic data, clinical features, laboratory results, and treatment were collected. Descriptive statistics were stratified by calcinosis status. Categorical variables were summarized as counts and percentages, with group differences assessed using Chi-square or Fisher's exact tests. Continuous variables were reported as means with standard deviations; comparisons were made using two-sample t-tests.

Results: Of the 196 patients in our cohort who had hand x-rays, 71 (36.2%) showed evidence of calcinosis. Demographic characteristics and SSc subtypes are summarized in Table 1. Patients with calcinosis had a longer time from scleroderma diagnosis to hand X-rays (12.7 vs. 7.3 years, $p = 0.001$). Compared to those without calcinosis, patients with calcinosis had higher rates of acroosteolysis, finger ulcers, joint contractures, telangiectasias, and osteopenia (Table 2). There were no significant differences between the groups in the prevalence of Raynaud's phenomenon, ILD, pulmonary arterial hypertension, or renal involvement. Serologically, anti-Scl-70 antibodies were more common in patients without calcinosis

[1]Equal variance two sample t-test; [2]Chi-Square p-value; [3]Fisher Exact p-value;

Conclusion: In a single center cohort of SSc patients, calcinosis on bilateral hand X-rays was observed in over one-third (36.2%) of patients. This is a higher prevalence compared to 10% in prior literature. Calcinosis was associated with a longer time from scleroderma diagnosis to hand X-rays, suggesting it progresses over time and may explain variation in prevalence based on radiograph timing. Osteopenia was more frequent among patients with calcinosis, although calcinosis was not significantly associated with vitamin D deficiency or hyperparathyroidism. These findings are consistent with other studies where bone metabolism might be playing a role in the pathogenesis of calcinosis. Higher frequencies of anti-centromere and anti-SS-A 52kD antibodies were seen in patients with calcinosis, whereas anti-Scl-70 antibodies were more common in those without calcinosis. This highlights an opportunity to explore serologic distinctions in larger cohorts. This study highlights the high prevalence of calcinosis detected on baseline hand X-rays suggesting that imaging may serve as a valuable tool for early detection. Consistent early identification is required to better understand calcinosis before exploring targeted interventions for the future.

Background/Purpose: Precapillary pulmonary hypertension (PH) in systemic sclerosis (SSc) associates with severe morbidity and mortality. The prothrombotic state observed in idiopathic pulmonary arterial hypertension (PAH) has historically supported the use of oral anticoagulants (OAC) in its management. However, the benefit of OAC in SSc-related precapillary PH remains uncertain, with studies reporting conflicting results, including possible harm. The objective of this study was to evaluate whether OAC use is associated with improved survival or reduced disease worsening in SSc patients with precapillary PH.

Methods: We conducted a cohort study using the European Scleroderma Trial and Research (EUSTAR) database to investigate the impact of OAC exposure vs. non-exposure on the prognosis of SSc patients with precapillary PH confirmed by right heart catheterization (RHC- mean PAP >20 mmHg, PVR >2 WU and PWP≤15 mmHg). Exposure to OAC was defined when lasting for at least 3 months after the RHC diagnosis.

The primary outcome was a combination of all-cause death or otherwise PH worsening, the latter defined as at least one of the following: decrease of 6MWD >15%, worsening of NYHA class, onset of right heart failure, additional PAH medication, starting i.v./s.c. prostanoids, lung transplantation, or atrial septostomy. Mortality and PH worsening were also analyzed as secondary endpoints.

Table 1. Data about demographics, disease features, treatment exposure, functional and hemodynamic parameters, and outcome variables, compared between patients who received oral anticoagulants and those who did not. Categorial and continuous variables are reported as absolute numbers (%) and mean (standard deviation), respectively. BNP, brain natriuretic peptide; CI, cardiac index; DLCO, diffusion lung capacity of carbon monoxide; HR, hazard ratio; HRCT, high resolution computed tomography; ILD; interstitial lung disease; mPAP, mean pulmonary arterial pressure; NYHA, New York Heart Association; PH, pulmonary hypertension; 6MWT, 6-minute walking test. Bold represents statistical significance with p value <0.05.

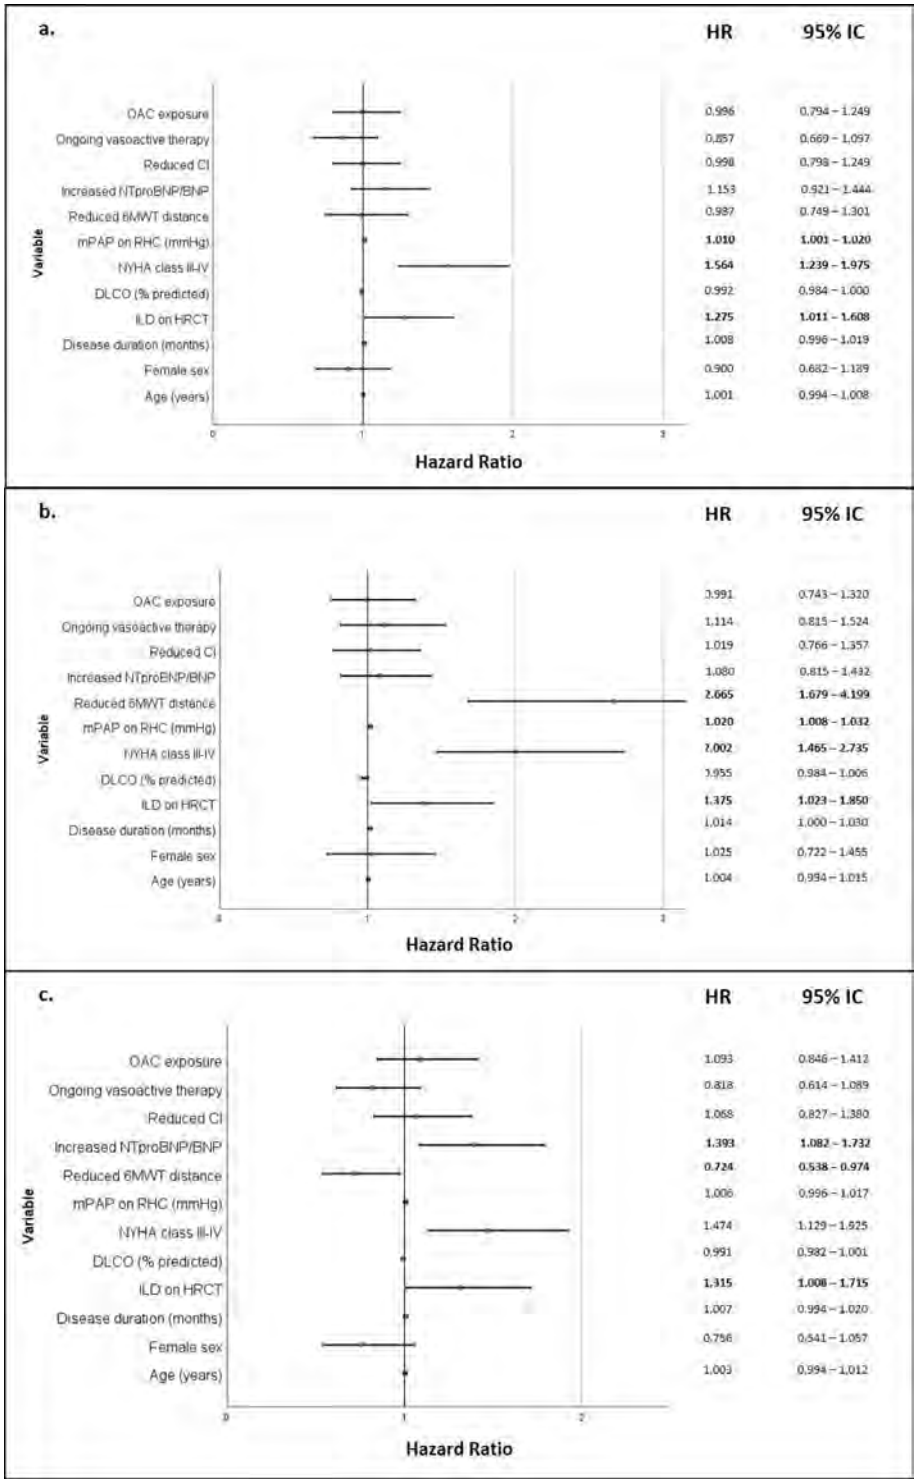

Figure 1. Forest plots of multivariable regression models testing the association between exposure to oral anticoagulants and the prognosis (panel a primary endpoint, panel b death, panel c pulmonary hypertension worsening) of patients with pulmonary arterial hypertension at right heart catheterization. BNP, brain natriuretic peptide; CI, cardiac index; DLCO, diffusion lung capacity of carbon monoxide; HR, hazard ratio; HRCT, high resolution computed tomography; ILD; interstitial lung disease; mPAP, mean pulmonary arterial pressure; NYHA, New York Heart Association; PH, pulmonary hypertension; 6MWT, 6-minute walking test. Bold represents statistical significance with p value <0.05.

Multivariable Cox regression was used to assess associations of exposure to OAC and the endpoints. Additionally, propensity score matching (PSM) was performed to balance confounding factors among OAC treated vs. untreated patients. Time to endpoints was assessed using Kaplan Mayer estimates. Covariates for both Cox regression and PSM were chosen

23265205, 2025, S9, Downloaded from https://accjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Results: Among 644 eligible patients, 173 (27%) received OAC at the time of RHC or afterwards. Patients treated with OAC were older and had more severe hemodynamic parameters (**Table 1**). During a median follow-up of 4 (2-6) years, 40% of patients died and 49% experienced PH worsening. Both events were recorded more frequently in the group treated with OAC, compared to non-treated patients (46% vs 37% and 59% vs 45%, respectively). Cox regression analysis did not show any significant association between OAC exposure and the combined endpoint (HR 0.996, 95% CI 0.794–1.249), mortality (HR 0.991, 95% CI 0.743–1.320) or PH worsening (HR 1.093, 95% CI 0.846–1.412) - **Figure 1**.

PSM identified two balanced groups of 148 patients exposed and 148 not exposed to OAC. Kaplan Meier curves (**Figure 2**) confirmed the lack of association between OAC and the explored prognostic outcomes.

Conclusion: In this large multicenter cohort of SSc patients with precapillary PH, OAC therapy did not impact survival or disease worsening. These findings argue against the routine use of anticoagulation in this population and highlight the importance of individualized treatment decisions based on comorbidities and safety profile. Prospective studies are needed to identify whether specific subgroups may benefit from OAC therapy.

Abstract Number: 0703

Trends and Disparities in Systemic Sclerosis-related Mortality Rates in the United States from 1999 to 2023

Nicolas Barnechea Alvarado[1], Khadija Mohib[1], Rameez Qasim[2] and Muhammad Ali[3], [1]Kirk Kerkorian School of Medicine at UNLV, Las Vegas, NV, [2]Allama Iqbal Medical College Lahore, Lahore, Pakistan, [3]Dow International Medical College, Karachi, Sindh, Pakistan

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

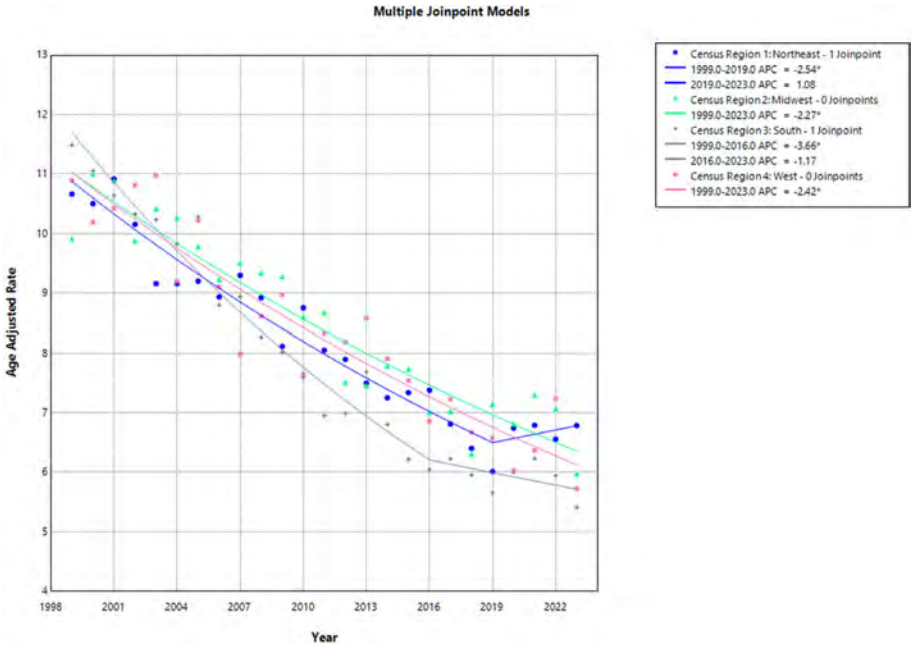
Background/Purpose: Systemic sclerosis is one of the most fatal rheumatologic diseases, with significantly higher mortality rates compared to the general population, likely due to its fibrotic nature and consequential effects on the vasculature system. Although previous observational population-based studies looked into the mortality rates of this disorder, more recent research beyond 2020 is limited, especially analyses stratified by demographic and regional distributions in the United States.

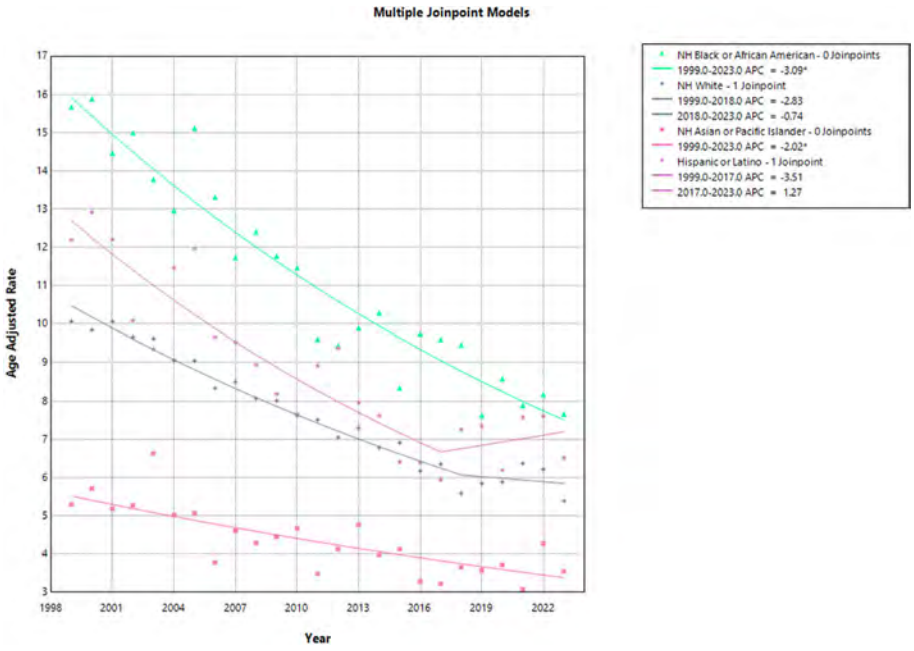
Methods: Datasets from the CDC WONDER Multiple Cause-of-Death public use records from 1999 to 2023 were used to analyze deaths in adults ≥25 years old assigning ICD-10 codes (M34 series) to systemic sclerosis by year and place of death, as well as by demographic (sex, age group, race) and regional (state, census region, rural-urban) stratifications. Age-adjusted mortality rates (AAMR) were calculated per 1,000,000 with 95% confidence intervals by standardizing crude mortality rates (CMR). Annual percent change (APC) and average annual percent change (AAPC) were evaluated using Joinpoint regression software.

Results: 44,407 deaths occurred from 1999 to 2023, mostly in medical facilities (57.3%). AAMR declined from 10.8 to 6.3 in 2018, followed by stability until 5.8 in 2023 (AAPC: -2.4; 95%CI: -2.8 to -2.2). Women had a higher average AAMR compared to men, along with a lower rate of decrease (AAPC women: -2.3; 95%CI: 2.6 to -2.0, men: -2.6; 95%CI: -3.4 to -2.1). Adults ≥65 years old had the highest average AAMR along with the lowest rate of decrease amongst the age groups

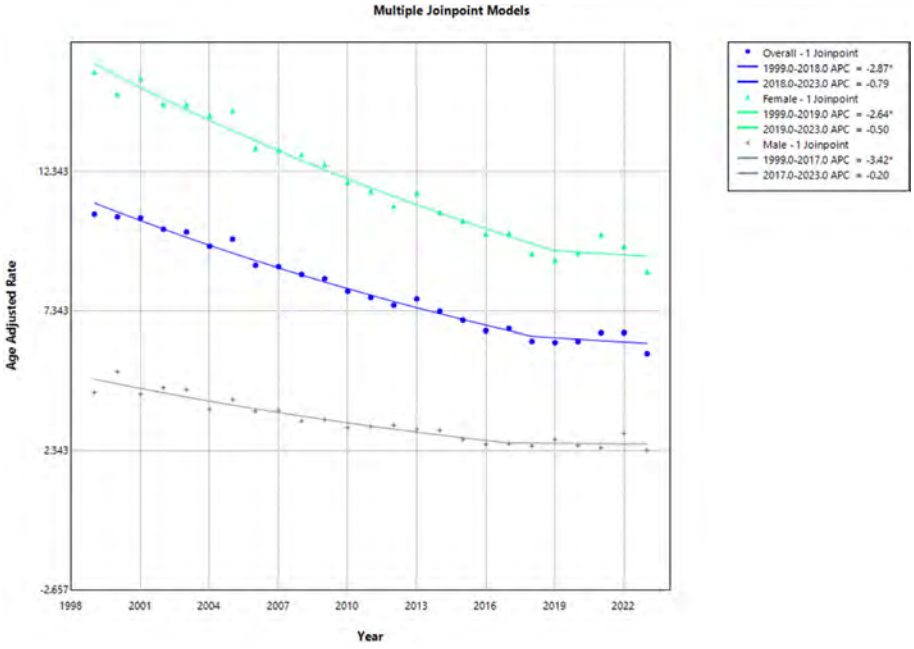
23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(AAPC ≥65 years old: -2.0; 95%CI: -2.4 to -1.6, 45-65 years old: -3.3: 95%CI: -3.6 to -3.0, 25-44 years old: -3.2; 95%CI: -3.9 to -2.6). NH Black/African Americans had the highest average AAMR, but had had the highest rate of decrease (AAPC NH Black/African American: -3.1; 95%CI: -3.5 to -2.7, NH White: -2.4; 95%CI -2.9 to -2.1, NH Asian/Pacific Islander: -2.0; 95%CI: -2.7 to -1.3, Hispanic/Latino: -2.3; 95%CI -3.5 to -1.2). Regionally, the Midwest had the highest average AAMR, though the South had the highest rate of decrease (AAPC South: -2.9; 95%CI: -3.4 to -2.5, West: -2.4; 95%CI: -2.9 to -2.0, Midwest: -2.3; 95%CI: -2.6 to -2.0, Northeast: -1.9; 95%CI: -2.4 to -1.6). From 1999 to 2020, AAMR extended from 4.8 in Nevada to 13.6 in South Dakota. From 2021 to 2023, AAMR extended from 3.3 in Alabama to 9.9 in Montana. From 1999-2020, urban areas had higher average AAMR, with a higher rate of decrease (AAPC urban: -2.9; 95%CI: -3.1 to -2.7, rural: -2.5; 95%CI: -2.9 to -2.0).





23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Conclusion: Whilst systemic sclerosis-related mortality rates in adults declined from 1999 to 2023, disparities amid demographic and regional stratifications were observed; this highlights the need to select prevention and assistance programs for at-risk communities to improve survival outcomes

Abstract Number: 0704

Human Pharmacokinetics of Inhaled Liposomal Iloprost Support a Dosing Regimen for Treating Systemic Sclerosis- Related Digital Ulcer

Pei Kan, Ko-Chieh Chen and Shin-Shin Chuang, Pharmosa Biopharm Inc, Taipei, Taiwan (Republic of China)

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Iloprost is recommended and widely used in Europe for treating systemic sclerosis (SSc)-related Raynaud Phenomena (RP) and Digital Ulcer (DU). EULAR recommendation suggests continuous intra-venous (IV) infusion at 0.5-2.0 ng/kg/min for 6 hours daily over 5 consecutive days. Prolonged systemic exposure has been associated with improved therapeutic outcomes. [1] To enable convenient at-home treatment, an inhaled liposomal iloprost was developed. This efficacy study was designed based on human pharmacokinetics (PK) to evaluate the feasibility of such a regimen. This study investigated the PK of inhaled liposomal iloprost in healthy volunteers. The repeated-dose PK simulation is established to compare the systemic exposure of the inhaled liposomal iloprost with the existing IV iloprost regimens used in Europe.

Methods: Human PK of inhaled liposomal iloprost on healthy subjects was investigated in a single ascending dose study (NCT06429930). 8 participants administered liposomal iloprost or placebo (6:2) via a breath-actuated nebulizer for each

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

cohort. Blood samples were collected over 24-hour period post-dosing and analyzed by LC-MS-MS. The PK simulation was established according to human PK data.

Results: A single dose of inhaled liposomal iloprost can prolong the detectable plasma concentration up to 12 hours. The PK parameters show a proportional increase with dose over the investigated dose range. The apparent half-life is extended to 4 hours, significantly longer than 20-30 mins reported for currently approved iloprost products. PK simulations were established based on human clinical data of iloprost administered via IV infusion and oral inhalation. The results indicate multiple inhalation doses extend the systemic exposure duration longer than 6 hours as compared with the existing IV iloprost infusion. Meanwhile, the plasma concentrations are also higher than the steady-state concentration attained via 0.5 ng/kg/min infusion.

Conclusion: Inhaled liposomal iloprost is an extended-release formulation [2] which prolongs iloprost exposure in healthy subjects as demonstrated in phase 1 clinical trial. The results support a 28-day dosing regimen for self-administration in treating patients with systemic sclerosis-related digital ulcer.

Multimodal Imaging Evaluation of Patients with Raynaud's Phenomenon meeting the Criteria for "Early" Systemic Sclerosis according to LeRoy versus Healthy Controls: a Prospective Cross-sectional study

Ramona Govender[1], Elvis Hysa[2], Rosanna Campitiello[3], Steven Wallaert[1], Matthias Vandycke[1], Emanuele Gotelli[3], Tessa Du Four[1], Maurizio Cutolo[4] and Vanessa Smith[5], [1]University of Ghent, Ghent, Belgium, [2]University of Genoa, Genoa, Italy, [3]University of Genoa, Genoa, Liguria, Italy, [4]University of Genova, Genova, Italy, [5]Ghent University Hospital, Gent, Belgium

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic sclerosis (SSc) is a complex autoimmune disorder. To date, no comparative multi-modal imaging data exist for precursor patients, those with Raynaud's phenomenon (RP) fulfilling the 2001 LeRoy and Medsger criteria[1] for early SSc but without clinical skin thickening, compared to healthy controls.

Methods: This prospective cross-sectional study included unselected RP patients (n=20) fulfilling LeRoy's criteria (RP plus SSc-specific antibodies, RP plus scleroderma pattern, or RP plus both) of the Ghent University (hospital) Raynaud's clinic. Age-, sex-, and BMI-matched healthy controls (HC) (n=20) were recruited for baseline comparison. Dermal thickness (DT) was measured using high-frequency ultrasound (HFUS, 18 MHz) at 17 anatomical sites, a reliable technique, as described by our previous findings[2]. Nailfold videocapillaroscopy (NVC ×200 magnification) was evaluated qualitatively and quantitatively using standardized Scleroderma Clinical Trial Consortium (SCTC)/ European Alliance of Associations for Rheumatology (EULAR) Study Group on Microcirculation in Rheumatic Diseases consensus definitions. Peripheral blood perfusion (PBP) was assessed by laser speckle contrast analysis (LASCA) in the volar aspect of both hands under standardized conditions, as described previously[3]. Exploratory statistical analysis included Student T-test, Wilcoxon, and Fischer exact tests for between-group comparisons as appropriate.

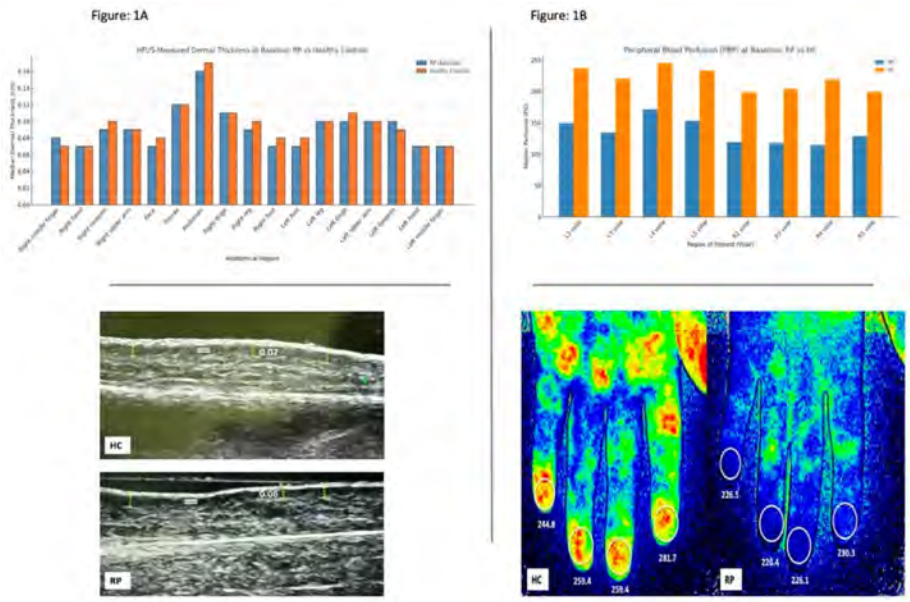
n= number; SD= standard deviation; BMI= body mass index; IQR= inter-quartile range; RMDs= rheumatic musculoskeletal diseases; SSc= systemic sclerosis; RP=Raynaud's phenomenon; SDP= scleroderma pattern; Ab= antibodies; ANA= antinuclear antibody; ILD= interstitial lung disease; PH= pulmonary hypertension; PAH= pulmonary arterial hypertension; mRSS= modified Rodnan skin score; LVEF= left ventricular ejection fraction; SRC= scleroderma renal crisis; CK= creatinine kinase; HCQ= hydroxychloroquine; MTX= methotrexate; MMF= mycophenolate mofetil; CYC= cyclophosphamide; AZA= azathioprine
* Scleroderma pattern as seen on 200X magnification nailfold videocapillaroscopy, defined as per EULAR Study Group on Microcirculation in Rheumatic Diseases (EULAR SGMC/RD).

Results: RP patients showed no evidence of SSc-related organ involvement[4], except for gastro-oesophageal reflux without oesophageal dilatation on high-resolution computerised tomography (HRCT) (Table. 1). HFUS revealed no clinically meaningful differences in DT between groups (all $p > 0.05$) (Figure. 1A). LASCA showed significantly reduced volar fingertip PBP in RP patients compared to HC (all $p < 0.005$) (Figure. 1B). Baseline NVC showed significantly lower capillary density in RP

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



(Fig. 1A) Bar graph of median DT (cm) measured by HFUS at 17 anatomical sites (left panel, above). Representative HFUS images of the right middle finger at baseline, illustrating DT measurements in a HC and an RP patient (left panel, below).
(Fig. 1B) Bar graph of median PBP, as measured in PU, on volar aspect of hands (right panel, above). Representative LASCA images of the left hand at baseline, illustrating PBP measurements in a HC and an RP patient (right panel, below).

Abbreviations: DT: dermal thickness; HFUS: high frequency ultrasound, RP: Raynaud's phenomenon, HC: healthy controls, BL: baseline, PBP: peripheral blood perfusion, PU: perfusion units

Figure 1. High frequency ultrasound (HFUS) and laser speckle contrast analysis (LASCA) findings in Raynaud's patients versus healthy controls at baseline

patients across all 8 fingers (all $p < 0.05$). RP patients exhibited higher frequencies of giant capillaries (5–21% vs 0%) and microhaemorrhages (32–35% vs 0–5%, $p < 0.05$), with no significant differences in abnormal shapes (Figure. 2). Early and active scleroderma patterns were observed exclusively in RP patients.

Conclusion: In RP patients meeting the LeRoy's criteria for early SSc, functional and structural microvascular abnormalities are detectable before skin or organ involvement. In line with the clinical absence of skin thickening in both the RP as well as in the HC groups, HFUS was indiscriminatory. Future longitudinal studies will be needed to determine at what point HFUS detects discriminatory changes compared to HC.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Ultrasound (US) abnormalities of major salivary glands are frequent in systemic sclerosis (SSc) patients. However, US role is not yet fully understood, and the data available on this topic is limited.

The aim of this study is to evaluate the role of major salivary gland ultrasound (SGUS) in patients with SSc

Methods: We consecutively recruited patients with SSc who were regularly followed in two Rheumatology and Internal Medicine centers in France between 2023 and 2024.

- SGUS was performed with a 4–15 MHz and 4–12.5 MHz linear ultrasound probe, by two operators.

- The parotid and submandibular glands were bilaterally studied and scored on a 0 to 4 scale using the Jousse-Joulin (JJ) score, based on progressive bands and hypoechoic areas.

Table: Features of our Systemic sclerosis patients evaluated

Total: 123 patients		JJ ≥ 2 56 patients (45.5%)	P-value Vs group JJ < 2	FIBROSIS SCORE ≥ 2 45 patients (36.6 %)	P-value vs group FS < 2

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

- SGUS findings were considered pathological with a JJ score ≥ 2 in at least one gland.

- Hyperechoic bands indicating fibrosis were evaluated with a 0 to 3 scoring system based on the JJ reference atlas.

- A fibrosis score ≥ 2 in at least one gland was considered pathological.

US data was compared to clinical and biochemical data of our patients.

Results: A total of 123 patients were included: 13 men (10.6%) and 110 women (89.4%), with a mean age of 58.5 ± 13.2 years. Thirty-three (26.8%) had diffuse cutaneous SSc. Subjective sicca syndrome was present in 88 patients (71.5%), with objective sicca syndrome in 77% of cases. An overlap with Sjögren's syndrome was diagnosed in 29 patients (23.6%), all of whom had pathological minor salivary gland biopsies (MSGB).

Fifty-six patients (45.5%) had a JJ score ≥ 2, while 45 (36.6%) had a fibrosis score ≥ 2.

- The group of patients presenting with a JJ score ≥ 2, compared to the group JJ < 2, presented significatively more frequently an overlap with Sjögren's syndrome in 21 cases (72%) ($p < 0.001$) with a Pathological MSGB more frequent. Higher prevalence of Objective Sicca syndrome in 58% of cases ($p = 0.044$) along with the Presence of anti-SSA antibodies in 87.5% of cases ($p = 0.014$), and a Longer disease duration ($p = 0.044$). No association was found between a JJ score ≥ 2 and visceral disease involvement.

- On the other side, patient with a Fibrosis score ≥ 2 compared to those with a fibrosis score < 2, presented a longer disease duration ($p = 0.014$).

There was no association between either score and the disease-specific antibodies or visceral involvement, such as cutaneous, pulmonary, articular, or renal involvement.

Conclusion: Ultrasound abnormalities of major salivary glands are common in patients with SSc. A global JJ score ≥ 2 should raise suspicion of an overlapped Sjögren's syndrome. However, while fibrotic lesions are common, they do not appear to be related to the severity of the SSc phenotype.

Background/Purpose: People from underrepresented groups with SLE can face barriers to health care and management, including discrimination and a lack of resources and social and financial support. This can lead to missed appointment visits. Limited data exist on factors that contribute to appointment compliance rates. This study evaluates clinical and non-clinical factors and their association with missed appointments.

Methods: Patients with SLE in the Grady Rheumatology and Lupus Clinics from 2023-2024 who completed a Georgians Organized Against Lupus (GOAL) cohort survey within six months prior to a scheduled appointment were identified as having completed or missed their scheduled appointments. Grady Health System is the only indigent care health system in Atlanta, Georgia, whose patient population is primarily Black and of lower socioeconomic status. The GOAL cohort is a Centers For Disease Control and Prevention (CDC)-supported, population-based cohort of SLE patients followed prospectively through regular surveys with validated instruments. We assessed their demographics, socioeconomic factors, and psychosocial factors that could contribute to their appointment compliance. Univariable logistic regression analysis was conducted using a generalized estimating equation model with repeated measures for each characteristic. Multivariable analyses were then performed to explore the independent effect of important clinical and psychosocial factors.

Results: We identified 222 patients with 597 appointments, of which 447 visits (75%) were completed and 150 were missed (25%). Clinical and sociodemographic characteristics are shown in Table 1. We observed higher emotional support scores in patients who missed their Rheumatology appointment with an OR of 1.14 (1.00-1.30, p-value < 0.05). Additionally, patients who missed their appointments were younger (OR of 1.12, [1.03-1.21, p-value < 0.01]) and had less years of disease duration (OR of 1.15 [1.02-1.30], p-value 0.02).

Conclusion: Our study found an unexpected association between higher levels of emotional support and missed appointments. Some studies have suggested improved outcomes in patients with chronic disease in those with higher levels of emotional support from not only their family/friends but also their healthcare providers. Although healthcare providers can play a crucial role as a surrogate for emotional support in patients with chronic diseases by providing counseling, open communication, and resources for support groups, we hypothesize that some patients with sufficient social support may lack this additional motivation and be at higher risk for missed appointments. It is also notable that, apart from shorter disease duration, no other clinical or socioeconomic factor in our model was associated with missed appointments.

Comparison of Monocyte-to-HDL Ratio Between Systemic Sclerosis Patients and Healthy Controls

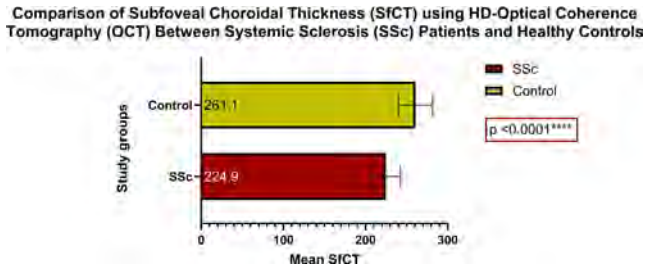
Background/Purpose: The vascular hypothesis in systemic sclerosis (SSc) posits that vasculopathy is the initial inciting event that triggers inflammation and subsequent fibrosis in the progression of the disease. The primary objective of this study was to evaluate the association of serum MHR with skin manifestations, including Raynaud's phenomenon (assessed via the Raynaud's Condition Score), digital ulcers (measured by the Digital Ulcer Score), and skin fibrosis (evaluated using the Modified Rodnan Skin Score) in patients with SSc. The secondary objectives included assessing choroidal subfoveal thickness in SSc patients and investigating the associations between choroidal thickness, MHR, and skin manifestations.

Methods: After obtaining approval from the Institutional Ethics Committee (IEC), this case-control study was conducted at ESIC Medical College and Hospital in Telangana, India. A total of 35 adult patients with systemic sclerosis and 35 age- and gender-matched healthy controls were recruited, all of whom met the inclusion criteria. Serum monocyte-to-HDL cholesterol ratio (MHR) was calculated and compared between the two groups. High-definition optical coherence tomography (HD-OCT) was used to measure choroidal subfoveal thickness, and these measurements were also compared between the groups. Correlations between serum MHR values, choroidal subfoveal thickness and skin manifestations among systemic sclerosis patients were analyzed. Statistical analysis was performed using SPSS Version 21, with significance set at $p< 0.05$.

Results: In our study, both groups consisted of 35 individuals, with 30 females in each group. The mean age was 37.6 years in systemic sclerosis patients and 38.9 years in healthy controls. The mean MHR was significantly higher in patients with systemic sclerosis compared to healthy controls ($p< 0.05$). Choroidal subfoveal thickness was significantly lower in patients than in controls ($p< 0.05$).

While MHR values showed a positive correlation with markers of peripheral microvascular involvement—such as the Raynaud's Condition Score (RCS), Digital Ulcer Score (DUS), and skin fibrosis assessed by the Modified Rodnan Skin Score (MRSS)—statistical significance was not achieved. Choroidal subfoveal thickness exhibited a negative correlation with all skin parameters asessed.

Conclusion: The findings from this study support the use of non-invasive techniques, such as high-definition optical coherence tomography (HD-OCT), for evaluating choroidal microvasculature in patients with systemic sclerosis, even at early stages of the disease. Additionally, the study suggests that the monocyte-to-HDL cholesterol ratio (MHR) may serve as a simple, cost- effective, and easily measurable serum biomarker. MHR could help identify SSc patients at higher risk for vasculopathy, including digital ulcers and more advanced skin fibrosis.



Comparison of Choroidal Sub-foveal Thickness using HD-OCT Between Systemic Sclerosis Patients and Healthy Controls

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. As an indirect marker of oxidative stress and inflammation, MHR showed a correlation with changes in choroidal microvasculature. Therefore, combining MHR with choroidal vascular evaluation provides valuable adjunctive diagnostic support for assessing overall microcirculation in patients with systemic sclerosis.

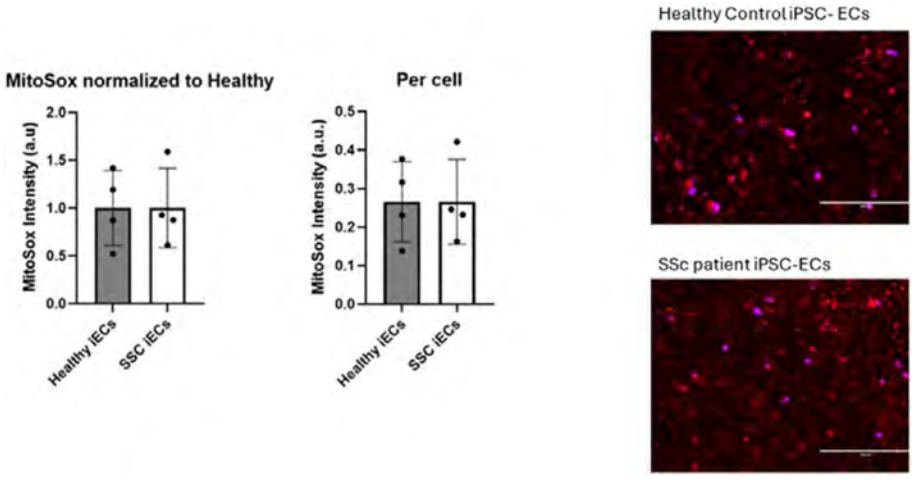
Measure of permeability in inducible pluripotential stem cells (iPSC) generated from healthy controls (HC) and systemic sclerosis (SSC) and cultured on the electric cell-substrate impedance sensing (ECIS) platform at baseline (a) and in response to interleukin-(IL) 1 alpha 10ng and 15 ng over 72 hours (b)

Background/Purpose: Systemic sclerosis (SSc) disease models that faithfully recapitulate endothelial mediated vasculopathy are critical for testing and developing novel treatments. The generation of inducible pluripotential stem cells (IPSC) from SSc patients' serum and the ability to develop those into patient specific endothelial cells (EC) allows for vasculopathy analysis. The objective of this study was to examine iPSC-EC-barrier function at baseline and in response to an inflammatory cytokine interleukin 1 (IL-1α), which may have a cardinal role in SSc cardiopulmonary dysfunction and tissue fibrosis.

Methods: SSc patients with an abnormal echocardiogram and age-and sex matched healthy controls (HC) were consented at a two SSc Centers. Peripheral blood monocytes cells (PBMC) were collected at the time of a routine care visit and clinical features were recorded. PBMC were differentiated into iPSC-EC at the Cell Therapy and Regenerative Medicine Program (CellReGen™) at the University of Utah, which adheres to quality control metrics including specimen karyotyping. Measures of mitochondrial superoxide using MitoSox in SSc-IPSC-ECs and HC were determined by the intensity of protein expression as observed through immunofluorescence. We cultured the reprogrammed cells on electric cell-substrate impedance sensing (ECIS) to provide a platform to properly study vascular barrier function. Baseline impedance and response to IL-1α was measured.



Measures of mitochondrial superoxide in reprogrammed SSc-iPSC-EC (n=13) when compared to HC (n=9).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: IPSC-EC reprogramming was attempted in 22 SSc registry patients with abnormal echocardiograms. Thirteen of 22 individual SSc cell lines were successfully reprogrammed. The SSc clinical features are shown in Table 1. For these 13 SSc patients, 9 age- and sex-matched HC samples were selected and successfully reprogrammed. Samples that did not have PBMC isolation in less than 12 hours of collection failed to reprogram. There was no significant difference in clinical features of the SSc patients that reprogrammed successfully. Under baseline conditions, IPSC-EC from SSc patients had ~20% reduced EC resistance (enhanced endothelial permeability) compared to healthy controls over the length of the experiment (Figure 1a). The treatment effect of EC with IL-1α demonstrated that there was a significant decrease in endothelial resistance (higher permeability) response to IL-1α in the HC patients, but IL-1α had no influence on SSc endothelial resistance (Figure 1b). There were no differences in Mitosox between SSc and HC patient EC (Figure 2), suggesting the baseline permeability differences in the SSc EC were not due to mitochondrial ROS.

Conclusion: In this largest to date study of SSc-IPSC-EC, we identified increased baseline permeability in SSc compared to HC. While HC had a typical IL-α increase in permeability, SSc lacked this typical physiological response. We found that despite some alterations in EC phenotype, mitochondrial ROS were similar in SSc and HC ECs. Our data suggests that genetic or epigenetic changes were preserved in SSc patient IPSCs as a patient vascular phenotype was recapitulated in cells developed into EC. IPSC-EC generated from PBMCs hold high potential in elucidating the role of vascular endothelium in the pathogenesis of SSc.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0671–0710) Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: APS is a pro-thrombotic autoimmune condition often associated with other systemic autoimmune rheumatic diseases (SARDs), most notably SLE. The link between aPL positivity and other SARDs is less understood. Specific to systemic sclerosis (SSc), the occurrence of thrombotic events is variable in aPL-positive SSc patients as per prior studies. The objective of this retrospective study is to compare the prevalence of vascular manifestations in a cohort of aPL-positive SSc patients to aPL-negative SSc patients in a North American cohort.

Methods: The electronic medical record was reviewed for eligible patients through a copyrighted data capture tool. All patients had SSc diagnosed by a rheumatologist. A total of 365 patients who were tested for at least one aPL were identified. Patients were categorized as aPL-positive patients if they had positive serologies for at least one aPL (aCL IgG/IgM, anti-beta-2-glycoprotein 1 IgG/IgM, or LA) (n=178), and as aPL-negative patients were included if they had been tested for at least one aPL and were found to be negative (n=187). Positive serologies were based on the Mayo Clinic Laboratories—at least 15 aCL or anti-beta-2-glycoprotein 1 units, or a positive LA profile interpretation. Outcomes of

*patients who were not assessed for history of miscarriage were excluded

Primary Analysis of aPL Negative vs. aPL Positive Patients

interest included: history of pulmonary embolism (PE) or deep venous thrombosis (DVT), pulmonary arterial hypertension (PAH), stroke, digital ulcers, and miscarriage. In the primary analysis, vascular outcomes were compared between the aPL-positive group (n= 178) and the aPL-negative patients who had been tested for all three aPLs (n=103). In the secondary analysis, outcomes were compared between positive and negative patients for each specific aPL.

Results: In the primary analysis, there were significantly more unprovoked PE/DVTs (75.8% vs. 45.6%) in the aPL-positive group (p=0.007, Table 2). No significant differences were found in the history of digital ulcers, PAH, renal crisis, heart failure, miscarriage, or ischemic stroke. In the secondary analysis, patients testing positive for aCL IgG/IgM had significantly greater prevalence of unprovoked PE/DVTs (p=0.037). Patients positive for anti-beta-2-glycoprotein 1 IgG/IgM had significantly greater prevalence of digital amputations (p=0.013). In LA-positive patients, mean total lung capacity (TLC) as measured by PFT was decreased (p=0.006), and mean pulmonary capillary wedge pressure (PCWP) as measured by RHC was increased (p=0.022).

aPL	Outcome	N (both positive and negative patients)	Coefficient^ (adjusted for age and sex)	p-value
Anti-cardiolipin IgG/IgM	Unprovoked DVT/PE	72	3.19	0.037
Beta-2-glycoprotein 1 IgG/IgM	Digital amputation	243	3.09	0.013
	Ischemic stroke	243	2.45	0.065
Lupus anticoagulant	TLC	118	-17	0.006
	PCWP	57	4.3	0.022

^linear/median regression coefficient for continuous outcomes, odds ratio for binary outcomes

Sensitivity Analysis of Outcomes Between Positive and Negative Patients for Specific Antibodies

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: In our retrospective cohort of SSc patients, those with positive aPLs had a stronger association with unprovoked PE/DVTs. Furthermore, there were suggestions of association with specific vascular events in the presence of certain aPLs: aCLs with unprovoked PE/DVTs, anti-beta-2-glycoprotein-1 with more severe Raynaud's disease manifestations, and LA with reduced TLC (pertinent to interstitial lung disease) and increased PCWP (pertinent to pulmonary hypertension). These findings need to be evaluated prospectively and in other cohorts.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0711–0730) Vasculitis – ANCA-Associated Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Anti-neutrophil cytoplasmic antibodies (ANCA), including those directed to myeloperoxidase (MPO) and proteinase 3 (PR3) as well as antibodies against anti-glomerular basement membrane (anti-GBM) are critical markers in the diagnosis of small vessel vasculitides and anti-GBM disease, respectively. While some multiplex platforms are available, conventional testing often involves sequential single-analyte assays, which may delay diagnosis and increase workload. There remains a clinical need for fully automated multiplexed assays capable of simultaneously detecting these key markers. This multicenter study evaluated the analytical performance of a novel, fully automated multiplexed microarray immunoassay prototype (MosaiQ AiPlex® VAS microarray; AliveDx, Switzerland), designed for the simultaneous detection of IgG autoantibodies to PR3, MPO, and GBM, in comparison with routine singleplex and multiplex methods.

Methods: The study was conducted at four sites in the United Kingdom, including three public reference laboratories (two located in England and one in Wales) and a sponsor's site in Scotland. Comparator methods varied by site and included fluorescence enzyme immunoassay (FEIA), addressable laser bead immunoassay (ALBIA) and chemiluminescent immunoassay (CLIA). De-identified, banked serum samples previously characterized as reactive or non-reactive for PR3, MPO or GBM antibodies were tested using the investigational microarray prototype on its proprietary automated platform. Analytical performance was assessed by calculating positive percent agreement (PPA), negative percent agreement (NPA) and overall percent agreement (OPA) both in comparison to each site's routine method and in aggregate across all sites and platforms. One site using CLIA did not have anti-GBM reactive samples available for testing.

95% CI	90.2-97.6	90.2-97.6	91.8-100	89.4-98.3	88.7-98.2	88.1-99.4	91.4-97.7	91.2-97.5	91.4, 100	96.6-100	95.3-100	96.2-100	94.5-97.8	94.0-97.6	96.9-99.9
OPA (%)	94.8	94.9	100	93.6	93.6	96.8	92.6	92.2	100*	99.3	99.4	100	94.8	94.8	99.2

ALBIA: addressable laser bead immunoassay, CI: confidence interval, CLIA: chemiluminescent immunoassay, FEIA: fluorescent enzyme immunoassay, NA: not applicable, NPA: negative percent agreement, OPA: overall percent agreement, PPA: positive percent agreement. *Limited to NPA (due to lack of anti-GBM reactive samples)

Results: The investigational microarray prototype consistently demonstrated high NPA across all measurands and comparator methods, ranging from 95.1% (anti-PR3 and anti-MPO, FEIA) to 100% (anti-PR3 at 1 ALBIA site and anti-GBM with FEIA, CLIA and at 1 ALBIA site). Overall NPA was 96.4% for anti-PR3 (95% CI: 94.5, 97.8), 96.1% for anti-MPO (95% CI: 94.0, 97.6) and 99.2% for anti-GBM (95% CI: 96.9, 99.9).

PPA ranged from 77.5% (anti-MPO, CLIA) to 100% (anti-GBM across methods). Overall PPA across sites and methods was 88.5% for anti-PR3 (95% CI: 81.6, 93.3), 89.1% for anti-MPO (95% CI: 82.4, 93.9) and 100% for anti-GBM (95% CI: 85.2, 100).

OPA across sites and methods ranged from 94.8% to 99.2%. Detailed results are summarized in **Table 1**.

Conclusion: In this multicenter study, the investigational microarray prototype showed high concordance with routine singleplex and multiplex methods for the detection of anti-PR3, anti-MPO, and anti-GBM autoantibodies. These findings support the potential utility of the assay as a single-platform solution for streamlined, simultaneous serologic evaluation of ANCA-associated vasculitis and anti-GBM disease. Future studies incorporating clinically characterized samples will enable expanded assessment of the assay's diagnostic performance.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0711–0730) Vasculitis – ANCA-Associated Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: The nasal microbiome has been implicated as a contributor to relapse in ANCA-associated vasculitis (AAV). Previous research on nasal bacteria, particularly *Staphylococcus aureus*, has focused on interactions with circulating immune cells and mediators in the blood. However, alterations in the antibacterial responses of nasal epithelial cells, an understudied cell population in AAV, and their contribution to systemic relapse in AAV are still poorly understood. The aim of

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

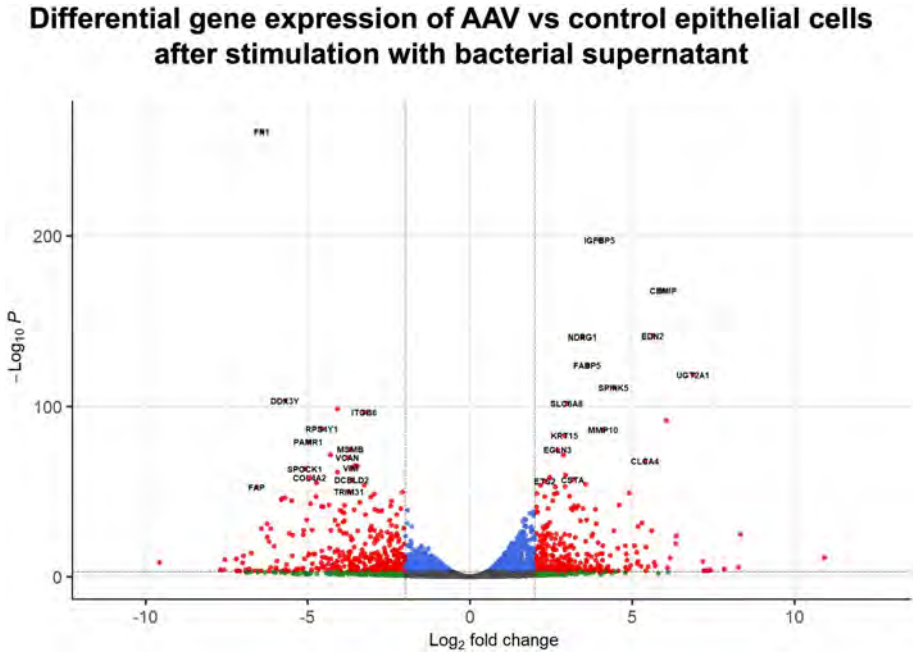

Figure 1. Transcriptional changes after bacterial challenge of primary human nasal epithelial cell cultures of ANCA-associated vasculitis vs healthy controls. Volcano plot showing log2FC on the x-axis and -log10(adjusted p-value) on y-axis. Genes meeting significance (FDR $P < 0.001$ and $|\log2FC| > 2$) are highlighted in red and labeled.

this study is to compare the effects of bacterial secreted proteins (secretome) on primary human nasal epithelial cells (HNECs) derived from patients with AAV versus healthy controls.

Methods: Primary HNECs from 3 patients with AAV and 3 healthy controls were cultured at air-liquid interface, which mimics air-facing nasal epithelium. Patients with AAV met 2022 ACR-EULAR classification criteria for granulomatosis with polyangiitis. Bacterial cell-free supernatant was obtained from a co-culture of two bacterial strains (*S. aureus* and *Corynebacterium tuberculostearicum*) isolated from a nasal swab of a patient with relapsing AAV; these two strains were selected based on a previous study of the nasal microbiome in AAV. HNECs were stimulated with the bacterial supernatants and then harvested for RNA sequencing to evaluate for differential changes in gene expression using FDR-corrected $P < 0.001$.

Results: RNA-seq of HNECs stimulated with bacterial supernatant revealed differences in transcriptional response between AAV and controls (**Figure 1**). Increased expression of genes related to angiogenesis, extracellular matrix modification, and cell cycle pathways were observed in AAV vs controls. Intracellular pathways upregulated in AAV included Wnt signaling, MAPK, and PI3K-Akt signaling, indicating a heightened activation state. Genes related to neutrophil biology were upregulated in AAV vs control including *PADI2*, *LTF*, and *CD177*. Down-regulated transcripts included pathways related to immune signaling, complement and coagulation cascade, extracellular matrix receptor interaction and adhesion, and mucin and barrier function, indicating an attenuated barrier repair and innate immune program upon bacterial challenge in AAV.

Conclusion: Nasal epithelial cell cultures derived from patients with AAV display an altered transcriptional response to bacterial secretome. Specifically, impaired host defenses, including barrier function and innate immune responses, were observed. These findings suggest antibacterial responses are significantly altered in the nasal epithelium of patients with AAV. Mechanistic studies are needed to elucidate the role of these changes in relapsing AAV, which eventually may identify novel targets for treatment or prevention of disease flares.

Abstract Number: 0713

Differentiating Primary Anti-Neutrophil Cytoplasmic Antibody (ANCA) Associated Vasculitis from Secondary Forms

Adil Vural[1], Chao Zhang[2], Yaseen Kinanah[1], Cassandra Calabrese[3] and Adam Brown[4], [1]Cleveland Clinic, Cleveland, OH, [2]Cleveland Clinic, Cleveland Heights, OH, [3]Cleveland Clinic Foundation, Cleveland Heights, OH, [4]Cleveland Clinic, Shaker Heights, OH

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0711–0730) Vasculitis – ANCA-Associated Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: ANCA associated vasculitis (AAV) is a severe autoimmune disorder with substantial morbidity and mortality. Establishing the diagnosis might be challenging due to the existence of noteworthy mimickers, most notably infective endocarditis (IE) and drug-induced AAV. We aimed to identify differences in initial labs, serologies, clinical manifestations, and histopathology findings with the goal recognizing diagnostic clues that can raise suspicion for a secondary process.

Methods: A retrospective chart review was conducted on patients with glomerulonephritis (GN) secondary to IE, drug-induced AAV and primary AAV, from January 1, 2008, to January 1, 2024. Patients were filtered using SNOMED clinical terms of vasculitis and GN and any positive ANCA test. GN diagnosis was established either histologically or clinically by elevated creatinine and new onset hematuria with active urinary sediment. IE diagnosis was established by modified Duke Criteria or positive PCR on removed valve. Primary and drug induced AAV diagnosis were established by vasculitis specialist. Blood counts, and serologies were collected prior to any treatment including glucocorticoids. Statistical analysis included the use of Kruskal-Wallis test for continuous variables and Chi-square test for categorical variables.

Table 1. Summary of study population characteristics and clinical presentation.

p-value represents overall value between all groups. [a] p > 0.05 (IE-GN vs. drug-AAV), [b] p > 0.05 (IE-GN vs. primary AAV), [c] p > 0.05 (drug-AAV vs. primary AAV).

Results: Baseline characteristics are outlined in Table 1. There were 42 patients with IE related GN, 35 with drug-induced AAV, and 50 with primary AAV. Median age at diagnosis was 58.4, 70.7, and 59.1 years, respectively. Bartonella was the most common microorganism (52.4%) in the IE-related GN group, and almost all drug-induced AAV cases (97%) were linked to hydralazine.

Baseline labs and serologies are detailed in Table 2. Initial blood counts showed that IE-related GN and drug-induced AAV patients commonly presented with leukopenia (42.8% and 48.5%, respectively) and thrombocytopenia (90.4% and 37.1%, respectively) and seldomly presented with thrombocytosis (0% and 2.8%, respectively). Primary AAV patients frequently presented with leukocytosis (80%) and thrombocytosis (68%), and rarely with leukopenia (2%) and thrombocytopenia (2%). Median initial leukocyte, neutrophil, lymphocyte, and platelet counts were higher in primary AAV compared to other groups ($p < 0.001$). Hypocomplementemia was found in 76.2% of IE-related GN and 80% of drug-induced AAV cases, compared to 22% in primary AAV ($p < 0.001$).

Majority of patients underwent renal biopsy (Table 3). C3 was the most common immunofluorescence staining in IE-related GN and drug-induced AAV. Dialysis cessation at 6 months occurred in 75% of primary AAV patients, whereas 30.7% of IE related GN patients, and 18.7% of drug-induced AAV patients (p< 0.001). Six-month mortality was significantly higher in IE related GN and drug induced AAV compared to primary AAV (p< 0.001).

Conclusion: The presence of cytopenia including leukopenia and thrombocytopenia, along with low complement levels upon presentation of IE related GN and drug-induced AAV can help clinicians to discern from primary AAV. Early recognition of these mimickers is critical, as they are associated with lower rates of renal recovery and higher six-month mortality.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0711–0730) Vasculitis – ANCA-Associated Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Depression and anxiety symptoms have been reported in 28% of patients suffering from vasculitides. However, in patients with ANCA-associated vasculitis (AAV), their frequency and their associated factors remain to be identified at global level. The aim of this study is to determine the factors associated with depression and anxiety in AAV patients from a Latin American cohort.

Methods: Patients from a single-center Peruvian AAV cohort [the Almenara Vasculitis cohort] were included. Depression symptoms were assessed by the Patient Health Questionnaire-9 (PHQ-9) questionnaire whereas anxiety symptoms were assessed by the Generalized Anxiety Disorder-7 (GAD-7) questionnaire. For both questionnaires, the higher the score, the greater the intensity of the corresponding symptoms: GAD-7 ranges from 0 to 21 while PHQ-9 ranges from 0 to 27. Potential associated factors were sex, age, ethnicity, educational level, relationship status, employment and socioeconomic status (SES), disease activity, erythrocyte sedimentation rate level, C-reactive protein level, ANCA status, glucocorticoid use and doses, immunosuppressive (IS) use and type, diagnosis and the AAV-Patient reported outcome (PRO) questionnaire domains. Cross-sectional univariable and multivariable linear regression models were performed. The multivariable models were done using a backward selection procedure with an alpha to stay in the model of 0.05.

Results: Eighty-eight patients were included; 49 (69%) were female and their mean age at diagnosis was 61.4 (13) years. The GAD-7 and the PHQ-9 scores at baseline were 6.3 (4.3) and 7.2 (4.9), respectively. In multivariable analysis, middle SES, active disease, and the social and emotional impact domain of the AAV-PRO were negatively associated with anxious

symptoms. On the other hand, low SES, relapsing and active disease, and organ-specific symptoms and the social and emotional impact domains of the AAV-PRO were negatively associated with depressive symptoms.

Conclusion: A middle-low SES, relapsing and active disease, and some domains from the AAV-PRO (social and emotional impact, organ-specific symptoms) were associated with higher intensity of anxiety and depression symptoms. Further studies are needed to evaluate these findings in other populations and seek better strategies to improve depression and anxiety symptoms in AAV patients.

Abstract Number: 0715

Supervised machine learning algorithm to identify patients with eosinophilic granulomatosis with polyangiitis in France

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0711–0730) Vasculitis – ANCA-Associated Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Identifying patients with eosinophilic granulomatosis with polyangiitis (EGPA) in claims databases such as the French National Health Data System (SNDS) is a major challenge for real-world studies. Although a specific ICD-10 diagnosis code (M301) exists, patient identification may be incomplete because i) the disease does not always require hospitalisation and ii) long-term disease (LTD) is mostly recorded under the broader code M30, which includes other vasculitis. This study aims to develop and evaluate a machine learning algorithm to identify EGPA patients in the SNDS.

Methods: Adults (>18) with a hospitalization M301 or an LTD M30/M300/M301/M302/M303/M308 in 2010-2019 were extracted from the SNDS. Among them, patients were identified as (1) EGPA with a M301 code and without any M300/M302/M303/M308/M317 code or (2) non-EGPA with a M300/M302/M303/M308 LTD or a M30 LTD with a M300/M302/M303/M308/M317 hospitalization, and without any M301 code, and were included in the labeled data used for model training and testing. Unlabeled patients were constituted of all other patients. Potential clinically relevant variables to predict EGPA diagnosis and differentiate it from other vasculitis were defined with experts and included medical visits, treatments, comorbidities and hospitalizations. Variables were pre-selected using univariate and multivariate analysis. Several supervised machine learning techniques were then implemented. For each combination, a 4-fold cross-validation method was implemented and repeated 100 times. Average metrics (accuracy, sensitivity, specificity, and precision) were calculated. As a final step, the model with the highest precision and sensitivity score was chosen among the 5 final models and the model was tested on the EGPA patients from French Vasculitis Study Group (FVSG) registry linked to the SNDS.

Results: On 8,756 individuals with a M301 hospitalization or an LTD M30/M300/M301/M302/M303/M308 in 2010-2019, 2,243 (25.6%) were labeled EGPA and 1,223 (14.0%) were labeled non-EGPA, and 5,290 were unlabeled patients.

Thirteen variables were selected and included in the supervised models, with the most significant predictive factors being glucocorticoids use, asthma and pneumologist visits. All the five supervised models resulted in good performance [metric (min-max): precision (0.79-0.82); sensitivity (0.79-0.81); specificity (0.71-0.77); accuracy (0.80-0.83)].

The model finally chosen was a random forest model which, when applied to the 5,290 unlabeled patients, identified 1,930 EGPA patients, with a precision of 0.82, a sensitivity of 0.81, a specificity of 0.75 and an accuracy of 0.83. The estimated prevalence and incidence of EGPA in France was 47.5 and 2.8 per million inhabitants, respectively, in 2019. Out of 49 incident EGPA patients from the FVSG registry, all but one (98%) were predicted as EGPA, confirming the robustness of the model.

Conclusion: This machine learning-based approach shows promising results for identifying adults with EGPA using SNDS data. The algorithm developed could serve as a valuable tool for real-world study based on comprehensive database.

Abstract Number: 0716

Utility of Follow-Up Cardiac Magnetic Resonance Imaging In Patients With Eosinophilic Granulomatosis With Polyangiitis

Chelsea Cheng[1], Justine Lafleur-Careau[2], Navneet Kang[1], Medha Soowamber[3] and Christian Pagnoux[3], [1]Mount Sinai Hospital, Toronto, Canada, [2]Mount Sinai Hospital, Saint-Augustin-de-Desmaures, Canada, [3]Mount Sinai Hospital, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0711–0730) Vasculitis – ANCA-Associated Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Eosinophilic granulomatosis with polyangiitis (EGPA) is a rare multisystem disorder characterized by asthma, rhinitis, peripheral blood eosinophilia, and necrotizing vasculitis of small vessels. Cardiac involvement occurs in approximately 10-30% of patients with EGPA and has been identified as a major predictor of mortality. Cardiac manifestations can be diagnosed clinically, as well as through electrocardiogram and echocardiogram. Cardiac magnetic resonance (CMRI) has higher sensitivity to detect cardiac involvement, especially late gadolinium enhancement (LGE), which can indicate myocardial inflammation and/or fibrosis. However, the exact role of CMRI at diagnosis and the utility of repeat CMRI to monitor evolution of cardiac manifestations in EGPA remain unclear. Our aim was to report on the use and findings of CMRI in our EGPA patient cohort, determine the added value of repeat CMRI, and evaluate the outcome and prognostic value of persistent LGE.

Methods: In this monocentric retrospective descriptive cohort study, we included 75 patients diagnosed with EGPA who were seen at least twice between 2015 and January 2023, of which 30 patients had undergone CMRI, with 11 patients undergoing repeat CMRI during follow-up. All patients satisfied the 2022 ACR/EULAR Classification Criteria for EGPA.

Results: 75 patients (male 56%, mean age at diagnosis 46 years, 2022 ACR/EULAR score range 6-13) seen at least twice in the clinic between 2015 and January 2023 were included. Antineutrophil cytoplasmic antibody (ANCA) was positive in 29 patients (39%), with 22 (39%) being anti-myeloperoxidase antibody (anti-MPO) positive and 4 (5%) being perinuclear ANCA (p-ANCA) positive. 17 (23%) had cardiac symptoms, such as chest pain, orthopnea, and syncope. 30 patients underwent CMRI, 9 (30%) of whom had cardiac symptoms. 11 underwent one or more repeat CMRI. All 30 patients (100%) were treated with glucocorticoids, with 13 (43%) also receiving cyclophosphamide. 11/11 patients who underwent repeat CMRI had LGE on first CMRI, 10/11 had persistent LGE on second CMRI, 4/4 had LGE on third CMRI, and 2/2 had LGE on fourth CMRI. The average time between first CMRI and second CMRI was 22 months (range 4-81 months). Of the 30 patients, 3 (10%) had cardiovascular events at follow-up, 2 of whom had atrial fibrillation (neither had LGE on their CMRIs), and 1 of whom had coronary artery disease requiring stenting (with LGE on his 4 CMRIs).

Conclusion: The role of initial and further serial CMRIs to study and monitor cardiac involvement in EGPA remains unclear. Late gadolinium enhancement most often persists despite treatment, with no major differences in adverse cardiac outcomes in this cohort.

Circulating Bacterial sRNAs are Altered in Patients with Anti-Neutrophil Cytoplasmic Antibody-Associated Vasculitis

Christopher Xavier[1], Kevin Byram[2], Carol Langford[3] and Michelle Ormseth[4], [1]Meharry Medical College, Nashville, [2]Vanderbilt University Medical Center, Nashville, TN, [3]Cleveland Clinic, Moreland Hills, OH, [4]Vanderbilt University Medical Center, Nashville

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0711–0730) Vasculitis – ANCA-Associated Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Anti-Neutrophil Cytoplasmic Antibody-Associated Vasculitis (AAV) is an autoimmune disease causing small vessel inflammation. Underlying mechanisms of disease are unclear, but the human microbiota may be a contributor. One way that bacteria can affect the immune system is through small RNAs (sRNAs), which are found abundantly in human circulation. The purpose of this study is to determine if circulating bacterial sRNAs are altered in patients with AAV compared to those with and without other inflammatory autoimmune diseases.

Methods: Patients with AAV were recruited from Vanderbilt University Medical Center (VUMC) and Cleveland Clinic. Participants with other inflammatory diseases (rheumatoid arthritis [RA] and systemic lupus erythematosus [SLE], termed here as "inflammatory control") and control participants were recruited from VUMC. Total RNA was extracted from plasma from all participants and libraries were constructed for next-generation sequencing. sRNAs not aligning to the human genome with up to one mismatch were aligned to bacterial genomes in RefSeq using the TIGER pipeline. sRNA sequences and sRNA counts of bacterial taxa were compared using DESeq2 and the Benjamini-Hochberg method to adjust for multiple comparisons with false discovery rate at 5%.

Results: The study included 31 AAV, 20 inflammatory control (2 RA,18 SLE) and 4 control participants (Table 1). Examining sRNA counts of bacterial taxa, sRNAs aligning to 79 orders (which is the most specific taxonomy to which sRNAs can be assigned with confidence due to the short length and conserved sequences) were altered in AAV versus control and inflammatory control participants (Figure 1). Over half of the orders came from the phyla Pseudomonadota and Actinomycetota. Examining the sRNA sequences, 23 bacterial sRNAs were altered after multiple comparison adjustment in AAV versus control and inflammatory control participants (Figure 2). Of the 23 sequences, 21 were aligned to the phylum Pseudomonadota and all were either tRNA-derived RNAs (tDR) or ribosomal RNA-derived RNAs (rDRs). Among the altered sRNAs were 4 sRNAs with the same base sequence of GGGGCUGUAGCUCAGCUGGGA (thus having the same regulatory seed region, GGGCUGU). These sRNAs were predicted to downregulate key genes involved in T-cell activation and inflammatory processes, including ICOS/ICOSL, CTLA4, NFATC2, CASP3.

Conclusion: The plasma bacterial sRNA composition is altered in patients with AAV compared to control and inflammatory control participants, and the majority of altered sRNAs were from the phylum Pseudomonadota. Among altered bacterial sRNAs were several with a similar base sequence which was predicted to downregulate multiple genes that dappen immune responses, particularly via T cells. Thus, these sRNAs could promote autoimmune inflammation. Future mechanistic studies will be needed to confirm these findings.

Abstract Number: 0718

Incidence of Venous Thromboembolism in Patients with ANCA-Associated Vasculitides – a Nationwide Registry-Based Study from Sweden

Hanna Lindberg[1], Klytaimnistra Voudouri[1], Lars Lindhagen[1], Maria K Svensson[2], Ann Knight[1] and Johanna Dahlqvist[3], [1]Uppsala University, Uppsala, Sweden, [2]Uppsala University, Uppsala, [3]Uppsala University Hospital, Uppsala, Sweden

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0711–0730) Vasculitis – ANCA-Associated Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Antineutrophil cytoplasmic autoantibody (ANCA)-associated vasculitides (AAV) are rare yet severe autoimmune diseases. Previous studies have indicated that patients with AAV have an increased risk of venous thromboembolism (VTE) including deep vein thrombosis (DVT) and pulmonary embolism (PE). However, it remains unclear whether the risk is increased equally in granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA), and across both sexes. Therefore, the aim of this study was to assess the risk and timing of VTE events in men and women with GPA and MPA, respectively.

Methods: In a nationwide case-control study, all patients >18 years old with incident GPA or MPA between January 1, 2005, and December 31, 2020, where identified from the National Patient Registers (NPRs) in Sweden. For each patient, five population controls matched for sex and age were selected from the Statistics Sweden Register of Total Population. Primary outcomes were DVT and PE following av AAV diagnosis, identified in the NPRs using ICD codes. Hazard ratios (HRs) of the primary outcomes were calculated using Cox models stratified for AAV subtype and sex, with complete follow-up time or censored after one year and 90 days follow-up post AAV diagnosis, respectively.

Results: In total, 4317 patients (3159 with GPA and 1158 with MPA and 21582 population controls were included in the study. There was no significant difference in risk of VTE between patients with GPA and MPA. Both GPA and MPA were associated with a more than three-fold increased risk of DVT and PE during the entire follow-up time, compared to population controls. This risk was increased to more than 11-fold when follow-up time was censored after one year and more than 20-fold when censored after 90 days (HR (95% confidence interval); HR 21.30 (10.67-42.52)) and PE (HR 22.84 (13.04-40.02)). In sex-stratified analyses, men with GPA and MPA, respectively, exhibited a more than four-fold increased risk of DVT (HR 4.15 (3.07-5.61); 3.49 (2.01-6.06)) and PE (HR 4.68 (3.61-6.06); HR 4.01 (2.47-6.51)). Similarly, women with GPA and MPA, respectively, showed a more than three-fold increased risk of DVT (HR 3.22 (2.28-4.55); HR 4.51 (2.56-7.92)) and PE (HR 3.24 (2.43-4.31); HR 3.54 (2.30- 5.45)). Adjusting for kidney disease had only modest effects on HRs across all comparisons.

Conclusion: Both patients with GPA and MPA exhibit an increased risk of DVT and PE following diagnosis of AAV. Our study did not reveal any significant sex differences in VTE among patients with AAV. This study highlights the importance of being aware of the risk for thromboembolic events, in particular during the first year following an AAV diagnosis.

A Combined Transcriptomics and Proteomics Approach to Identify Immune Signatures in ANCA-Associated Glomerulonephritis

Ivana Stojkic[1], Arnon Arazi[2], Huijuan Song[3], Pearlly Yan[3], Estela Puchulu-Campanella[3], Hubao Wang[3], Lynn Fussner[3], Brad Rovin[4], Stacy Ardoin[1] and Salem Almaani[3], [1]Nationwide Children's Hospital, Columbus, OH, [2]The Feinstein Institutes for Medical Research, Manhasset, [3]OSU, Columbus, OH, [4]The Ohio State University, Columbus, OH

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0711–0730) Vasculitis – ANCA-Associated Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: ANCA-associated vasculitis frequently involves the kidneys causing glomerulonephritis (AAGN). Despite advances in treatment, many patients develop end-stage kidney disease. An improved understanding of the immune drivers of AAGN has the potential to improve treatment outcomes. To achieve that goal, we utilized a combined transcriptomics/compartmental proteomics approach to identify the major immune pathways driving AAGN.

Transcriptomic Cohort (23 patients)		Proteomic Cohort (10 patients)
Age at biopsy, median (IQR)	58 (41-68)	58 (41-67)
% female	57% (13/23)	40% (4/10)
% white	96% (22/23)	90% (9/10)
Newly diagnosed	91% (21/23)	100% (10/10)
ANCA ELISA*		
anti-PR3	43% (10/22)	40% (4/10)
anti-MPO	43% (10/22)	50% (5/10)
both positive	5% (1/22)	0% (0/10)
negative	5% (1/22)	10% (1/10)
ANCA IIF		
c-ANCA	52% (12/23)	50% (5/10)
p-ANCA	30% (7/23)	30% (3/10)
Negative **	17% (4/23)	20% (2/10)
Phenotype		
GPA	52% (12/23)	60% (6/10)
MPA	35% (8/23)	30% (3/10)
EGPA	13% (3/23)	10% (1/10)
Serum Creatinine, average +/- SD	3.5 +/- 2.9	3.6 +/- 2.9

* not available in one patient

** all hed detectable ANCAs by ELISA

Abbreviations: ANCA: antineutrophil cytoplasmic antibodies

PR3: proteinase 3; MPO: myeloperoxidase; c-ANCA: cytoplasmic ANCA ; p-ANCA: perinuclear ANCA; GPA: granulomatosis with polyangiitis; MPA: Microscopic polyangiitis; EGPA: Eosinophilic granulomatosis with polyangiitis

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Methods: Formalin-fixed paraffin embedded kidney biopsies of 23 patients with AAGN and 5 healthy controls (pre-implantation kidney donor biopsy) were used. For transcriptomics, RNA was extracted and bulk RNAseq was performed on all 23 AAGN biopsies and controls. Differential expression analysis was performed using the DESeq framework. For proteomics, laser capture microdissection was utilized to collect the glomerular and tubulointerstitial compartments separately using 10 AAGN biopsies and all controls. Peptides were extracted and submitted for mass-spectrometric analysis. After normalization, differential expression analysis was done using T-tests. The Benjamini-Hochberg method was used for multiple hypothesis testing correction in all experiments. Differentially abundant mRNA and peptide spectral counts were used to identify enriched immune pathways using Ingenuity pathway analysis.

Top 20 upregulated pathways of immunologic relevance in a) transcriptomic data b) glomerular proteomic data and c) tubulointerstitial proteomic data

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Heatmap of identified canonical pathways and upstream regulators across transcriptomic and proteomic datasets

Results: Patient and disease characteristics of the full (transcriptomic) and proteomics cohort are described in table 1. The top enriched pathways in each of the 3 experiments (whole tissue transcriptomics, glomerular proteomics, tubulointerstitial proteomics) are depicted in Figure 1a-c. Comparison analysis using data from the 3 experiments demonstrated many shared enriched and upregulated pathways including complement, neutrophil degranulation, and FC gamma receptor signaling. PD-1/PDL1 and IL-10 signaling were downregulated across the 3 tissues studied. Upstream analysis demonstrated upregulation of TNF, INF-gamma, INF-alpha, and IL-6.

Conclusion: Analysis of biopsies from patients with AAGN demonstrated largely similar upregulated/downregulated immune pathways and upstream regulators when comparing transcriptomic and compartmental proteomics approaches. These may help inform patient stratification and therapy development.

Abstract Number: 0720

Current State of Racial, Ethnic, Sex, and Geographical Diversity in ANCA-associated vasculitis and Giant Cell Arteritis Trials

Manuel Carpio Tumba[1], Aida Mohamadi[2], Diana Louden[3], Victor Pimentel-Quiroz[4], Michael Putman[5], Didem Saygin[6], Raisa Lomanto Silva[7] and Sebastian E Sattui[8], [1]University of Pittsburgh, Pittsburgh, PA, [2]Tehran University of Medical Sciences, Tehran, Iran, [3]University of Washington, Seattle, WA, [4]Universidad Científica del Sur, San Isidro, Peru, [5]The Medical College of Wisconsin, Milwaukee, WI, [6]Rush University Medical Center, Chicago, IL, [7]Massachusetts General Hospital, Boston, MA, [8]Division of Rheumatology and Clinical Immunology, University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0711–0730) Vasculitis – ANCA-Associated Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Randomized controlled trials (RCTs) generate unbiased efficacy estimates and are required for regulatory approval. Understanding the degree to which they include racial, ethnic, sex, and geographical groups is important in understanding their generalizability and in addressing healthcare disparities. This systematic review summarizes the current state of representation in ANCA-associated vasculitis (AAV) and giant cell arteritis (GCA).

Methods: A systematic literature review using PubMed, EMBASE, CINAHL Complete, Europe PMC, ClinicalTrials.gov, and the International Clinical Trials Registry Platform was performed. All pharmacologic phase 2,3, and 4 RCTs in AAV and GCA (2010-2023) were included. This study followed the protocol of a larger systematic review (PROSPERO CRD42023457996), however all RCTs independent of age cut-offs were included in this analysis. Two authors independently reviewed the titles, abstracts, and full texts. Data extraction included demographics, year of publication, trial phase, sponsor category, and location of enrolling sites (continent, country, ZIP+4 for U.S. sites). U.S. enrollment sites were categorized at the county level using Urban-Rural Classification Scheme (small, medium, large metropolitan, and non-metropolitan) and into Medically

Table 1. Race, ethnicity, sex, and geographical location distribution of vasculitis (AAV and GCA*) RCTs (n=41).

	N (%) or median (range)
Race	
RCTs that reported race	14 (34.1%)
RCTs with ≥20% reported non-White participants	1 (2.4%)
Racial groups in all trials with reported race	
White	89.2% (0 – 79.4%)
Black	1.4% (0 – 7.1%)
Asian	3.7% (0 – 5.96%)
Ethnicity	
RCTs that reported ethnicity	10 (24.4%)
Hispanic or Latino participants in all trials	2% (0 – 7.1%)
Sex	
RCTs that reported sex	40 (97.6%)
RCTs with ≥45% female participation	26 (63.4%)
Female participants in all trials	49.9% (21.9 – 90.2%)
Geographical location of enrollment sites	
North America[a]	16 (39%)
Large metropolitan	69.8%
Medium metropolitan	19.2%
Small metropolitan	9.9%
Non-metropolitan	1.2%
Medically underserved area[c]	69.8%
Non-North America	25 (61%)
Europe	80.5%
Asia	19.5%
Australasia	36.6%

*AAV: ANCA-associated vasculitis; GCA: giant cell arteritis
[a]North America: RCTs that had at least one site in either Canada or the U.S.
[c]Based on the Health Resources and Services Administration designation of MUA lacking access to primary care services at the county level (last updated 2023).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 1. Geographic distribution of enrolling sites for ANCA-Associated Vasculitis (Panel A) and Giant Cell Arteritis (Panel B) RCTs worldwide.

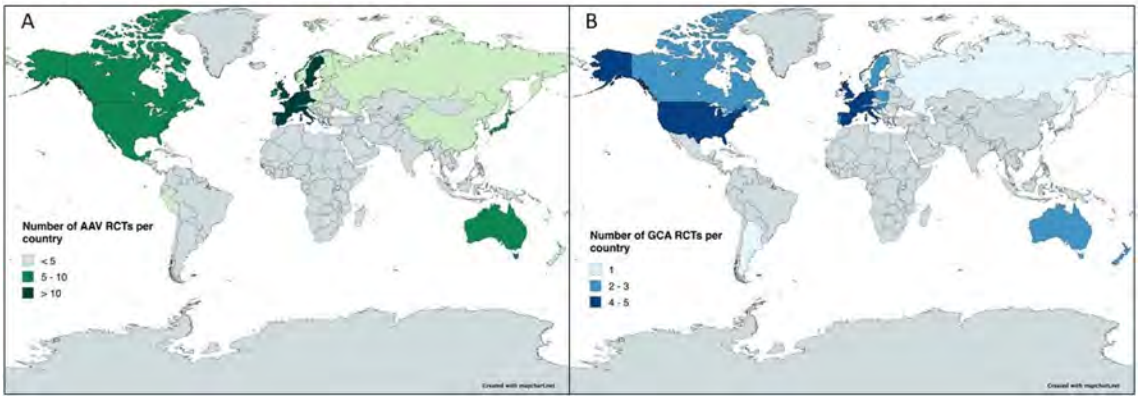

Figure 2. Geographic distribution of enrolling sites for ANCA-Associated Vasculitis (Panel A) and Giant Cell Arteritis (Panel B) RCTs in US per state.

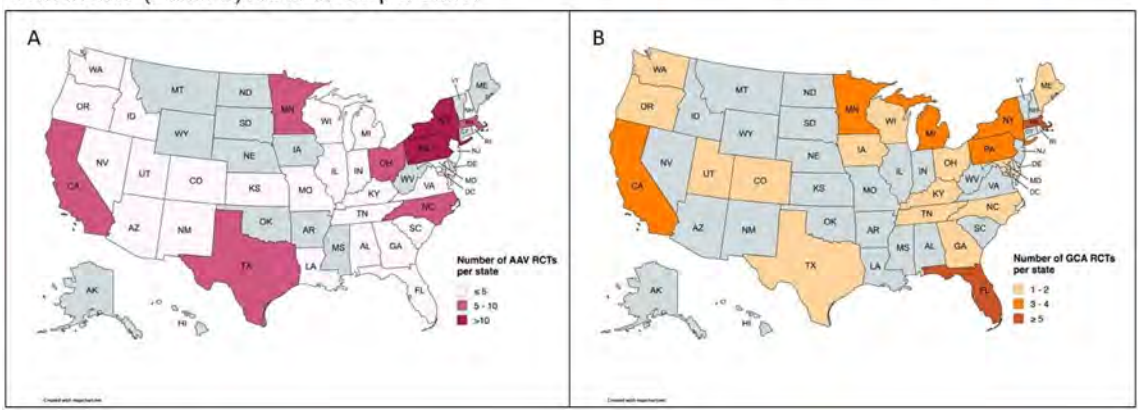

Underserved Areas (MUA) (yes/no) according to the U.S. Department of Health & Human Services data. Diverse populations were defined as enrolling ≥20% non-White and/or ≥45% female participants based on U.S. Census Data.

Results: A total of 32 AAV RCTs (3954 participants, mean age 58.6 years) and 9 GCA RCTs (773 participants, mean age 71.7) were included. Less than 35% of trials reported race or ethnicity in their results. Among 14 trials that included data on race, the median percentage was highest for white (89.2%) followed by Asian (3.7%) and Black (1.4%) participants. Among 10 trials that included data on ethnicity, the median percentage of Hispanic or Latino participants was 2.0%. Out of 40 trials that reported data on sex, 49.9% were female. The majority of RCTs were multicentric (AAV 87.5%, GCA 88.9%). European centers participated in 78.1% of AAV and 88.9% of GCA RCTs; North American centers participated in 34.4% of AAV and 55% of GCA RCTs. No trials were conducted in Africa (**Figure 1**). A total of 172 U.S. sites participated in enrollment, of which 120 (69.8%) were located in MUAs. The majority (69.8%) of sites were situated in large metropolitan areas (**Figure 2**).

Conclusion: Enrollment in AAV and GCA RCTs has been primarily concentrated in Europe, North America, and Australasia. In the U.S., most participating sites are located in large metropolitan areas. The representation of diverse racial and ethnic groups has been notably limited across these trials. Greater efforts are needed to ensure adequate representation in AAV and GCA clinical trials.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0711–0730) Vasculitis – ANCA-Associated Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: There is limited knowledge of the epidemiology and complications of pulmonary manifestations in ANCA-associated vasculitis (AAV). This analysis focused describing the range of pulmonary disease in two forms of AAV: granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA).

Methods: Patients with GPA or MPA enrolled in a prospective longitudinal cohort between April 2006 and December 2023 were included. Patients satisfied a modified ACR 1990 classification criteria for GPA or the Chapel Hill Consensus Conference definition for MPA. Comprehensive data concerning diagnosis, demographics, pulmonary manifestations at onset of disease and/or follow up, and pulmonary damage were collected in a protocolized manner.

Results: Data from 1033 individuals (865 with GPA and 105 with MPA) were included for analysis, including 4511 patient-years of follow up. The mean age at diagnosis was 51.3 years and 55.0% of patients were female. Pulmonary manifestations at any time in the disease course were seen in 70.3% of individuals with AAV: 621 (71.8%) with GPA and 105 (62.5%) with MPA (Figure 1). In GPA, 63.6% had pulmonary involvement at the time of diagnosis and an additional 11.4% at follow-up. In MPA, 56% had manifestations at diagnosis and 4.8% at follow up. Among patients with GPA with pulmonary disease, nodules/cavities were most common manifestation (62.6%); among patients with MPA with pulmonary disease diffuse alveolar hemorrhage was the most common manifestation (61%). Among patients with pulmonary involvement, 285 (45.9%) of those with GPA and 45 (42.9%) of those with MPA had more than one pulmonary manifestation at the same time. 185 (17.9%) individuals had irreversible pulmonary damage, most commonly breathlessness, loss of lung function, or interstitial lung disease (Table 1).

Conclusion: Pulmonary manifestations are common in AAV, differ in frequency between GPA and MPA, and are associated with accumulation of damage. Individuals may have multiple pulmonary manifestations concurrently, suggesting multiple pathophysiologic processes. Systematic assessments of individuals with AAV for pulmonary involvement could potentially lead to earlier detection of these manifestations and reduce pulmonary damage.

Estimating two-year risk of relapse in individuals with ANCA-associated vasculitis in a randomized controlled trial of plasma exchange and glucocorticoids

Mats Junek[1], Quazi Ibrahim[2], Peter Merkel[3], Eswari Vilayur[4], Ron Wald[5], Todd Fairhead[6], David Massicotte-Azarniouch[6], Louis Girard[7], Christian Pagnoux[8], Nader Khalidi[2], David Jayne[9], Michael Walsh[2] and The PEXIVAS Investigators, [1]St Joseph's Healthcare Hamilton, Hamilton, ON, Canada, [2]McMaster University, Hamilton, ON, Canada, [3]University of Pennsylvania, Philadelphia, PA, [4]John Hunter Hospital, Newcastle, New South Wales, Australia, [5]St Michael's Hospital, Toronto, ON, Canada, [6]University of Ottawa, Ottawa, ON, Canada, [7]University of Calgary, Calgary, AB, Canada, [8]Mount Sinai Hospital, Toronto, ON, Canada, [9]University of Cambridge, Cambridge, United Kingdom

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0711–0730) Vasculitis – ANCA-Associated Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: People with anti-neutrophil cytoplasm antibody (ANCA) associated vasculitis (AAV) vary in their risk of a relapse of disease. Estimating an individual's risk may inform decision-making around their care.

Methods: We developed and internally validated a model to predict the risk a relapse of AAV using a cohort of patients from a randomized controlled trial with severe AAV defined as an eGFR < 50 mL/min/1.73m2 or diffuse alveolar haemorrhage. We estimated risk of relapse within two years of remission. Candidate variables to estimate risk of relapse were selected using Lasso regression in Cox proportional hazard time-to-event models. Non-parametric estimates of baseline survival at two years were used to obtain absolute estimates of risk of relapse. Frequency of variable inclusion in the model was assessed using the same procedure across 1000 bootstrap samples. We assessed model discrimination using concordance statistics, and calibration using the mean calibration slope.

Table 1: Cox proportional hazard regression model studying association between relapse within 2 years for individuals with ANCA-associated vasculitis. Overall model significance: Likelihood ratio chi-squared = 53.35, p-value < 0.001 for the final model and 69.78.

Predictor	Final Model Adjusted Hazard ratio (95% CI)
Female sex	0.61 (0.40, 0.93)
ANCA type	
MPO-ANCA (reference)	1
PR3-ANCA	1.46 (0.96, 2.24)
Non-hemorrhagic respiratory involvement	1.38 (0.90, 2.11)
Mucus membrane/eye	1.39 (0.81, 2.39)
Induction therapy	
Intravenous cyclophosphamide (reference)	1
Rituximab	0.45 (0.23, 0.85)
Oral cyclophosphamide	0.46 (0.28, 0.76)
eGFR at remission (10 mL/min/1.73m^2)	1.14 (1.06, 1.21)

MPO: myeloperoxidase; PR3: proteinase 3.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1: Kaplan Meier curve of relapse-free survival based on quartile of predicted risk of relapse as well as the risk of relapse contained within each quartile

Results: 649 participants met inclusion criteria of whom 100 relapsed within 2 years. The final model included participant sex, type of induction immunosuppression, ANCA serotype, non-hemorrhagic respiratory involvement, mucous membrane/eye involvement, and eGFR at remission (Table 1). Variables selected for inclusion in the final model were selected across 76% or more bootstraps. The optimism-corrected area under the receiver operator curve statistic was 0.71 (95% confidence interval [CI] 0.71-0.71). The mean calibration slope was 0.99 (95% CI 0.65-1.34). 18 (11.1%) of individuals at the lowest quartile of estimated risk of relapse experienced relapse and 58 (35.8%) of those at the highest quartile of estimated risk of relapse (Figure 1).

Conclusion: Our model accurately estimates the risk of relapse for individuals with AAV within two years after remission.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0711–0730) Vasculitis – ANCA-Associated Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: EGPA variably presents eosinophil (EOS)-related features and vasculitic manifestations. Recent introduction of mepolizumab (MEP) has revolutionized the treatment of EOS manifestations of EGPA. However, the efficacy of MEP also in vasculitic phenotypes suggests direct interactions between EOS and neutrophilic inflammation in EGPA. Extracellular traps formed by neutrophils (NETs) are an important innate immune response and are involved in ANCA-associated vasculitis pathogenesis. Similarly, EOS produce extracellular traps (EETs), recently detected in tissues of EGPA patients.

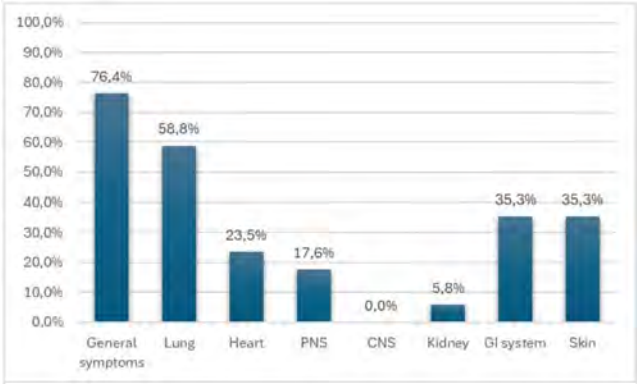

Figure 1. Distribution of patients according to organ involvement.

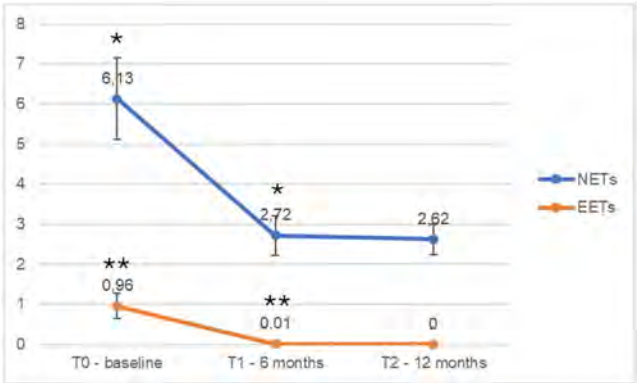

Figure 2. NETs and EETs response to mepolizumab treatment, *p=0.001, **p=0.014

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Our study aims to evaluate the efficacy of MEP in EGPA and the potential role of this treatment on NETs and EETs formation in different disease phenotypes.

Methods: Patients classified as EGPA according to MIRRA trial and/or ACR/EULAR 2022 criteria and eligible for therapy with MEP were consecutively enrolled. Clinical and routine blood chemistry data were collected before (T0) and after 6 (T1) and 12 (T2) months of treatment with MEP 300 mg/4 weeks. Oral steroid was tapered according to clinical judgement, therapy with immunosuppressants, if taken, was unchanged during the study. In parallel, we evaluated NETs and EETs on peripheral blood by immunofluorescence staining (Petretto et al., 2019). NETs and EETs were expressed as percentage of the total area of cells in the fields. Patients were stratified by disease phenotype according to the presence/absence of MPO-ANCA, asthma and nasal polyposis (CRSwNP) and organ involvement.

Results: 17 patients with EGPA and eligible for MEP were enrolled (53% female (9/17)). MPO-ANCA were detected in 29.4% of patients (5/17). 88% (15/17) were asthmatic, 60% of them had severe asthma. 53% (9/17) were atopic and 82% had CRSwNP. At T0 94% (16/17) were taking prednisone therapy (5.83±4.18 mg, average dose). Distribution of organ involvement is reported in Figure 1.

Following MEP introduction, EOS blood count reduced from T0 to T1 (p=0.036) but not from T1 to T2, while neutrophils did not vary in any period. Steroid dose was reduced to 1.04±2.59 mg at T2 (p=0.003), with 10 patients (58.8%) being steroid-free. No relapse was observed during the study.

At T0, NETs and EETs levels did not vary by ANCA status, organ involvement, EOS peak count, asthma or CRSwNP presence/severity. NETs levels were negatively correlated to total IgE titre (r=-0.52, p=0.05). EETs values are higher in atopic patients (p=0.017) regardless of steroid dose and EOS blood count.

NETs and EETs decreased at T1 (respectively p=0,001 and p=0,014) but were stable between T1 and T2 in the overall group (Figure 2). After stratification for ANCA status, NETs significantly decreased only in ANCA positive patients at T1 (p=0.01), while EETs only in ANCA negative patients at T1 (p=0,025), without any difference observed between T1 and T2. No difference was found according to asthma and CRSwNP presence.

Conclusion: In a small but representative cohort of EGPA patients, NETs and EETs vary by atopic status but not by ANCA status or organ involvement. MEP treatment, after 6 months of therapy, influences NETs and EETs formation in EGPA patients, also in relation to their ANCA profile, supporting potential utility of NETs and EETs evaluation in disease management.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0711–0730) Vasculitis – ANCA-Associated Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is a systemic autoimmune vasculitis. Avacopan, a novel oral C5a receptor inhibitor, has emerged as an adjunct therapy for AAV. However, a notable side effect of avacopan is drug-induced liver injury (DILI). This study aims to assess the risk of DILI associated with avacopan in patients with AAV.

Methods: We conducted a retrospective cohort study using the TriNetX Research Network, a de-identified, federated electronic health record database (accessed April 16, 2025). Adult patients (≥18 years) with AAV (ICD-10: M31.3, M31.7, I77.82) and DILI (K71.0, K71.1, K71.2) were included. A 1:1 propensity score matching was performed using demographics, comorbidities, and CYP3A4 inhibitor medication exposures to balance baseline characteristics of patients on standard of care treatment with or without avacopan. Continuous and categorical variables were compared using t-tests and chi-squared tests ($\alpha = 0.05$).

Table 1: Baseline demographics and comorbidities in patients with AAV treated with or without avacopan before and after propensity score matching.

	Before Matching			After Matching

Results: A total of 29,163 patients with ANCA-associated vasculitis (AAV) were identified, including 522 treated with avacopan and 28,641 who were not. Before matching, significant differences were observed between groups in several demographic and clinical characteristics. The avacopan group had higher proportions of Hispanic patients (11.5% vs. 8.5%; p = 0.017) (Table 1). Comorbid conditions such as diabetes mellitus, nonalcoholic steatohepatitis (NASH), metabolic syndrome, chronic viral hepatitis, and essential hypertension were all more common among those receiving avacopan (all p < 0.05). Additionally, avacopan group had significantly higher use CYP3A4 inhibitors including itraconazole, ketoconazole, fluconazole, posaconazole, voriconazole, nirmatrelvir, ritonavir, amiodarone, diltiazem, cimetidine, and cyclosporine (all p < 0.05) (Table 2). Following 1:1 propensity score matching, 516 patients remained in each group. No statistically significant differences were observed in age, sex, race, ethnicity, comorbidities, or medication use. The incidence of DILI was nearly identical between the two groups (2.0% vs. 1.9%), with a risk difference of 0.0% (95% CI: –0.017 to 0.017; p = 0.975). There was no significant difference in DILI-free survival between groups (log-rank p = 0.873), and the hazard ratio for time to DILI was 1.25 (95% CI: 0.078–20.07; p = 0.171).

Conclusion: In this matched cohort analysis, the incidence of DILI was low and comparable between patients treated with avacopan and those who were not. While no significant difference was observed, the limited number of events precludes definitive conclusions regarding comparative risk.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0711–0730) Vasculitis – ANCA-Associated Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Sinus and nasal symptoms are common and associated with a higher risk of relapse in patients with ANCA-associated vasculitis (AAV). Previously, our group found that a patient questionnaire called the Sino-Nasal Outcome Test-22 (SNOT-22), a validated patient-reported outcome measure in chronic rhinosinusitis, is associated with future relapse even in patients without a prior history of sinonasal disease. A detailed understanding of sinonasal symptoms is still lacking in AAV. The aim of this analysis was to evaluate sinonasal symptom profiles associated with disease activity in patients with AAV.

Methods: Patients with a self-reported diagnosis of AAV were recruited between January and March 2025 through an international research network (Vasculitis Patient-Powered Research Network). Participants rated 26 sinonasal symptoms on a scale from 0 (no problem) to 5 (problem as bad as it can be); the 26 symptoms included the original 22 items from the SNOT-22 plus four additional items related to vasculitis. The 4 vasculitis-specific items were selected based on patient and investigator input and included: nasal crusting, blood-tinged nasal discharge/crusts, nose bleeds, and nasal pain. Total and subdomain scores of the SNOT-22 were compared using linear regression. Sinonasal symptoms associated with active

vasculitis versus remission were determined using LASSO-penalized logistic regression. The penalty term (λ) was chosen by 10-fold cross-validation; variables with nonzero coefficients were carried forward into a post-LASSO unpenalized model to estimate odds ratios (ORs) and 95% confidence intervals (CIs).

Results: A total of 663 participants with AAV from 24 countries were included: 130 with active disease, 423 in remission, and 110 who had unknown disease status. Median age at enrollment was 63 years, median disease duration was 8 years, 91% had positive ANCA in the past, and 88% had a prior history of sinonasal disease related to vasculitis. Total and subdomain SNOT-22+ scores were all significantly higher in active vasculitis vs remission group (**Figure 1**) and remained significant

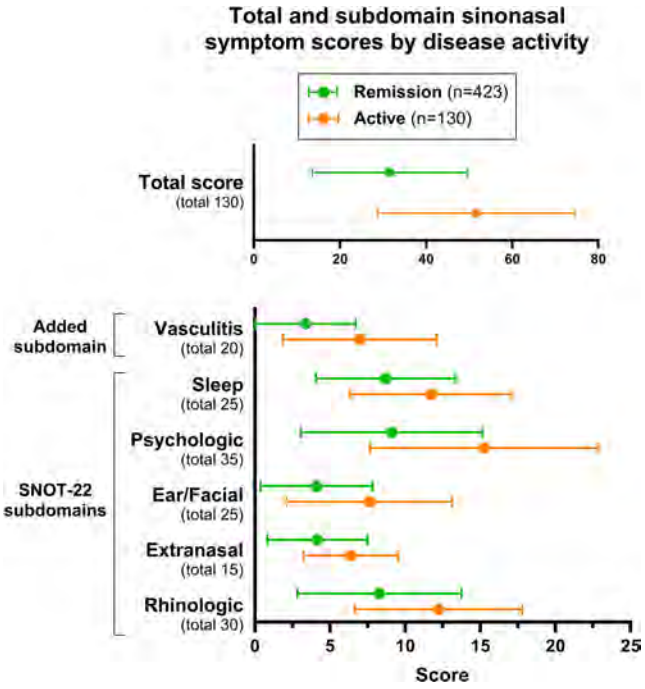

Figure 1. Comparison of Sino-Nasal Outcome Test scores by disease activity in patients with ANCA-associated vasculitis. Mean (SD) of total and subdomain scores from the SNOT-22 plus additional vasculitis-specific questions. Compared to patients with AAV in remission, patients with active disease had a greater burden of sinonasal symptoms and poorer quality of life across all domains (all $P < 0.01$).

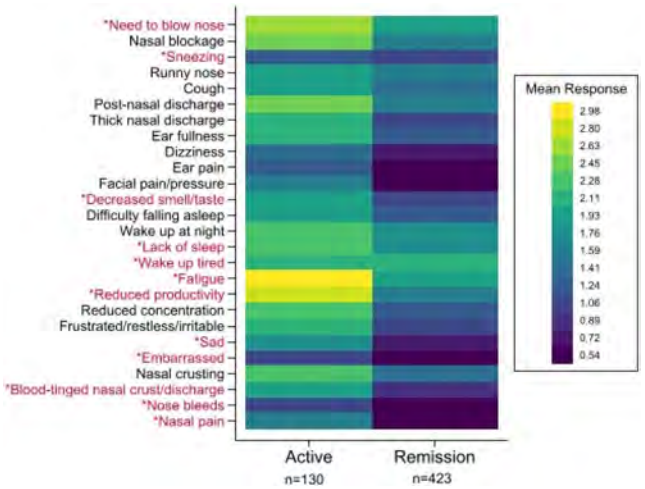

Figure 2. Mean response to individual items in the Sino-Nasal Outcome Test by disease activity in ANCA-associated vasculitis. Heatmap depicts the mean response to each item by group (active vs remission). Responses to all items except "wake up tired" were significantly higher in the active vs remission group (all $P < 0.05$). Items with asterisk and red font were retained in the final model after variable selection.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

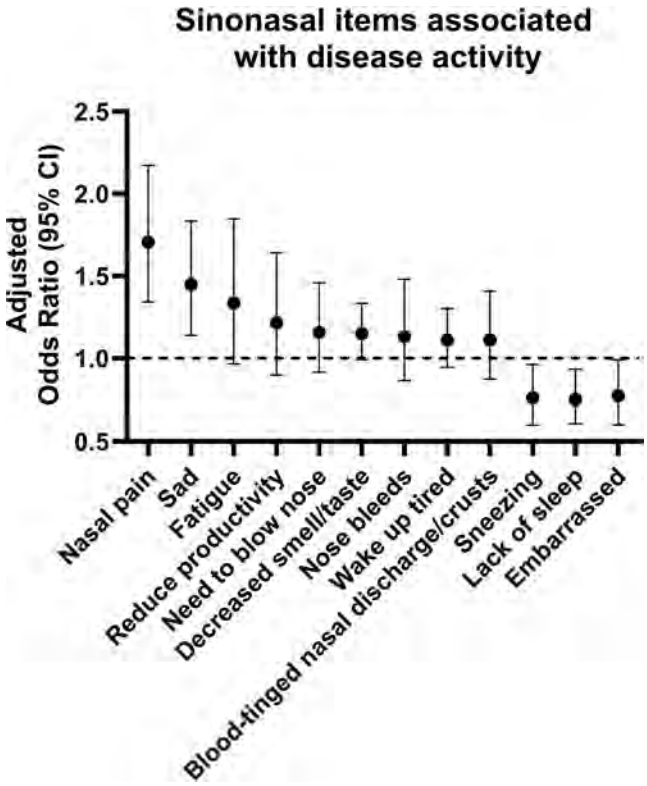

Figure 3. Odds ratio with 95% CI for association of sinonasal items with active disease in ANCA-associated vasculitis. Figure displays variables selected in post-LASSO logistic regression model. Nasal pain, feeling sad, sneezing, and lack of good night's sleep were among the items associated with disease activity in AAV in the multivariable model.

even after adjusting for age, sex, and disease duration. Both groups had higher scores compared to historical healthy control cohorts (mean score 9). Responses to 25 of 26 items were significantly higher in the active vs remission group (**Figure 2**). LASSO-based variable selection identified 12 items associated with disease activity (**Figure 3**).

Conclusion: Active AAV is associated with greater sinonasal symptom burden compared to quiescent disease although patients in remission continue to experience higher levels of symptoms compared to healthy patients. More severe nasal pain, more sadness, and less severe sneezing had the strongest association with active disease. A detailed understanding of the sinonasal symptom profile associated with active disease may improve clinical monitoring of disease activity in AAV.

Abstract Number: 0726

Real-World Avacopan Use in Granulomatosis with Polyangiitis and Microscopic Polyangiitis: Insights from United States Claims Data on Outcomes and Adherence

Sebastian E Sattui[1], Elizabeth Ibiloye[2], Niranjan Kathe[3], Sam Oh[4], Virginia Noxon-Wood[5], Iman Mohammadi[5], Laura Moore-Schiltz[5] and Tingting Li[6], [1]Division of Rheumatology and Clinical Immunology, University of Pittsburgh, Pittsburgh, PA, [2]Amgen Inc, Thousand Oaks, CA, [3]Amgen Inc, San Diego, CA, [4]Amgen Inc, South San Francisco, CA, [5]Inovalon, Bowie, MD, [6]Washington University School of Medicine, St. Louis

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0711–0730) Vasculitis – ANCA-Associated Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA) are the most common types of anti-neutrophil cytoplasmic antibody-associated vasculitis (AAV). Treatment-related toxicities, particularly from glucocorticoid (GC) exposure, are common in patients with AAV. Avacopan is an adjunctive treatment for adults with severe active GPA/MPA that can aid in achieving and sustaining remission while reducing GC use. This study aims to describe patient characteristics, real-world treatment patterns, and outcomes among adults receiving avacopan in the United States.

Methods: This retrospective analysis included administrative claims from the Medicare Fee-for-Service (FFS) and MORE^2 Registry® databases from 10/07/2021 to 12/31/2022 (FFS) or 06/30/2023 (MORE^2). Adults with ≥1 claim for avacopan (index date: first avacopan claim), continuous enrollment for 12 months prior (baseline) and 12 months after (follow-up) index

Table 1. Characteristics among all patients treated with avacopan

Characteristics	N=167
Age, mean (SD)	54.5 (17.8)
Sex, N (%)	
Female	96 (57.5%)
Male	71 (42.5%)
Race/ethnicity, N (%)	
White	82 (49.1%)
Non-Hispanic Other	56 (33.5%)
Hispanic/Latino	29 (17.4%)
Payer, N (%)	
Medicare Fee-for-Service	51 (30.5%)
Commercial	53 (31.7%)
Medicare Advantage	12 (7.2%)
Managed Medicaid	51 (30.5%)
Geographic region, N (%)	
Northeast	40 (24.0%)
Midwest	33 (19.8%)
South	42 (25.1%)
West	52 (31.1%)
Deyo-Charlson Comorbidity Index Score, median (IQR)	2.0 (3.0)
Other comorbid conditions, N (%)	
Hypertension	117 (70.1%)
Heart disease[1]	85 (50.9%)
Type 2 diabetes	37 (22.2%)
Depression	43 (25.7%)
Osteoporosis	12 (7.2%)

IQR: interquartile range; SD: standard deviation; 1. Includes heart failure, cardiovascular disease, cardiomyopathy, myocarditis and myocardial infarction.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 2. Treatment patterns among patients with ≥2 avacopan claims

Treatment Patterns	N=152
Index avacopan claim prescriber specialty, N (%)	
Rheumatologist	53 (34.9%)
Nephrologist	20 (13.2%)
Internal/Family Medicine[1]	48 (31.6%)
Other	19 (12.5%)
Unknown	12 (7.9%)
Avacopan treatment patterns	
PDC, median (IQR)	0.8 (0.6)
Adherence (PDC ≥ 0.8), N (%)	82 (53.9%)
Patients who discontinued avacopan[2], N (%)	58 (38.2%)
Time to discontinuation in days, median (IQR)	365.0 (222.5)

IQR: interquartile range; PDC: proportion days covered; 1. Includes physician assistants supervised by a specialist.; 2. Defined as ≥90-day gap in avacopan treatment.

Table 3. Renal and extrarenal manifestations, medication use, and relapses among patients who did not discontinue avacopan

	Baseline (N = 94)	Follow-up (N = 94)
Kidney Manifestations, N (%)		
Chronic kidney disease	46 (48.9%)	46 (48.9%)
Extrarenal Manifestations, N (%)		
Ear, nose and throat manifestations	34 (36.2%)	22 (23.4%)
Chest manifestations[1]	49 (52.1%)	38 (40.4%)
AAV Medication Use		
Any non-GC immunosuppressive therapy, N (%)	76 (80.9%)	81 (86.2%)
Rituximab treatment, N (%)	61 (64.9%)	68 (72.3%)
Any systemic GC use, N (%)	83 (88.3%)	83 (88.3%)
Relapse, N (%)		
Patients with a relapse during follow-up		13 (18.3%)

GC: glucocorticoid; GPA/MPA: granulomatosis with polyangiitis or microscopic polyangiitis; 1. Includes interstitial lung disease, respiratory failure, pleurisy and alveolar hemorrhage.

date were included. Information on demographics, comorbidity burden, including Deyo-Charlson Comorbidity Index (DCI), were collected. Among patients with ≥2 avacopan claims during follow-up, avacopan-specific treatment patterns (i.e., prescriber specialty, median proportion of days covered [PDC], and adherence) were reported. In patients who did not discontinue avacopan (discontinuation defined as ≥90-day gap in treatment) during follow-up, information on GC and other non-GC AAV treatments, percent change in in prednisone-equivalent daily dose (PEDD), and renal and extrarenal manifestations were assessed. Additionally, relapses based on an adapted claims-based algorithm: ≥1 inpatient, ≥1 ER or ≥2 outpatient claims for GPA/MPA, or ≥1 renal or extrarenal claim, each accompanied by ≥20% increase in PEDD within 30 days, were measured.

Results: A total of 167 patients were included. Mean age was 54.5 years, most were female (57.5%) and White (49.1%), with a median DCI of 2.0 (Table 1). Among patients with ≥2 claims of avacopan (n = 152), the most common specialists to initially prescribe avacopan were rheumatologists (34.9%) and nephrologists (13.2%). The median PDC was 0.8, and over half (53.9%) had a PDC ≥0.8 at 12 months (Table 2). Nearly half (48.9%) of patients persistent on avacopan treatment (n=94) had chronic kidney disease. Extrarenal manifestations observed during baseline and follow-up included ear, nose and throat, 36.2% and 23.4%, respectively, and chest, 52.1% and 40.4%, respectively (Table 3). These patients also had a median percent change in PEDD of 12.5% between 90 days pre- and 90 days post-index, and 18.3% experienced a relapse during follow-up (Table 3).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Among real-world patients prescribed avacopan early after its availability in the US, demographic and disease characteristics were consistent with the known epidemiologic profile of GPA/MPA. During the 12-month follow-up, most patients showed adequate adherence and did not experience a disease relapse. A reduction in PEDD was observed among patients taking avacopan. Additional studies with longer follow-up are needed to understand the long-term outcomes of this population.

Abstract Number: 0728

Incidence and Clinical Characteristics of ANCA-Associated Vasculitis: A Nationwide Study in Spain

Susana Romero-Yuste[1], Marta Domínguez-Álvaro[2], Antonio Fernndez-Nebro[3], Miquel Blasco[4], Beatriz Ventosa[5], Javier Narváez[6], Gema Fernández[7], Iñigo Rúa-Figueroa[8], Desirée Luis-Rodríguez[9], Manuel Macía[10] and RESERN/VAN collaborative group, [1]University Hospital Complex of Pontevedra, Pontevedra, Spain, [2]Sociedad Española de Reumatología, Madrid, Spain, [3]Hospital Regional Universitario de Malaga, Malaga, Spain, Malaga, Spain, [4]Hospital clinic Barcelona, Barcelona Spain, Spain, [5]Spanish Society of Rheumatology, Madrid, Spain, [6]Hospital Universitario de Bellvitge, Barcelona, Spain, [7]Hospital la Paz, Madrid, Madrid, Spain, [8]Hospital de Gran Canaria Doctor Negrin, Las Palmas GC, Spain, [9]Hospital Universitario Nuestra Señora de Candelaria, Tenerife, Spain, [10]Hospital Universitario Nuestra Señora de Candelaria,, Tenerife, Spain

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0711–0730) Vasculitis – ANCA-Associated Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: ANCA-associated vasculitides (AAV)—granulomatosis with polyangiitis (GPA), eosinophilic granulomatosis with polyangiitis (EGPA), and microscopic polyangiitis (MPA)are rare but severe systemic vasculitides with significant morbidity and mortality. Existing epidemiological data in Spain are limited to specific regions, hindering comprehensive national understanding.

Table 1. Clinical Characteristics of Included AAV Cases

Characteristic	Value
Total number of patients	840
Median age at diagnosis [IQR]	66 [55, 75]
Female sex (%)	53.7%
Most frequent subtype	Microscopic polyangiitis (MPA) (51.0%)
Fulfilled ACR/EULAR 2022 criteria (%)	84.0%
Renal involvement at diagnosis (%)	70.3%
Patients with biopsy performed (%)	79.7%
Histological confirmation of AAV (%)	68.4%

Table 2. Cumulative and Annual Incidence of AAV (per million adults ≥18 years)

Vasculitis Subtype	Cumulative Incidence (95% CI)	Annual Incidence (95% CI)
Microscopic polyangiitis (MPA)	35.8 (32.2 – 39.6)	5.7 (5.2 – 6.3)
Granulomatosis with polyangiitis (GPA)	18.8 (16.2 – 21.5)	3.0 (2.3 – 3.5)
Eosinophilic granulomatosis with polyangiitis (EGPA)	10.0 (8.1 – 12.0)	1.6 (1.3 – 1.9)
Overall	70.3 (65.1 – 75.6)	11.3 (10.4 – 12.1)

Table 3. General information and lifestyle habits.

Category	N 840 N %
Time between onset of symptoms and diagnosis	57 (19-145)
Smoking Habit	
- Smokers	99 (11.8)
- Non-smokers	660 (78.6)
Alcohol Consumption	
- Consumers	168 (20)
- Non-consumers	534 (63.6)
Cocaine Use	
- Yes	13 (1.9)
- No	674 (98.1)
Suspected Previous Drug or Toxicity Exposure	
- Yes	21 (2.5)
- No	793 (94.4)
- Unknown	26 (3.1)
Previous Infections	
- Yes	112 (13.3)
- Not recorded	728 (86.7)
SARS-CoV-2 Infection during follow-up	
- Yes	224 (26.7)
- Not recorded	616 (73.3)
Number of SARS-CoV-2 Infections	1 [1-1]
SARS-CoV-2 Vaccination	
- Yes	591 (70.4)
- No	157 (18.7)
- Unknown	92 (11)
Number of SARS-CoV-2 Vaccine Doses	4 [3-4]

Purpose: to estimate the incidence of AAV in Spain and describe its clinical, analytical, histopathological, and prognostic features, treatment patterns, and long-term outcomes.

Methods: Retrospective, multicenter cohort study involving 32 hospitals across Spain. Patients ≥18 years with newly diagnosed AAV between January 1,2015and March 31, 2021, were included. Data were extracted from medical records and

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

entered into a centralized electronic database. The follow-up period ensured a minimum follow-up of 15 months for each patient. Incidence rates were calculated based on the adult population within each center's reference area. Disease activity, organ damage, and outcomes were assessed using validated scores (BVAS, FFS, VDI).

Results: 840 patients were included (53.7% women; median age 66 years).(Table 1) After excluding patients who did not reside within the reference area of the hospital where they were treated, 695 patients were included in the incidence análisis. For the analysis of clinical characteristics, all patients were included (N = 840).MPA was the most frequent subtype (51%), followed by GPA (26.8%) and EGPA (13.7%). Most patients (84%) fulfilled the 2022 ACR/EULAR classification criteria. The cumulative incidence was 70.3 cases per million adults (95% CI: 65.1–75.6) over the study period, and the overall annual incidence was 11.3 (95% CI: 10.4–12.1) cases per million adults.

By vasculitis subtype, the annual and cumulative incidence was: MPA**:** anual 5.7 (95% CI: 5.2–6.3); cumulative: 35.8 per million(95% C: 32,2-39,6). GPA: anual 3.0 (95% CI: 2.3–3.5); cumulative: 18.8 per million (95% CI: 16,2-21,5). EGPA: anual 1.6 (95% CI: 1.3–1.9); cumulative: 10.0 per million (95% CI: 8,1-12). (Table 2). At diagnosis, 70.3% of patients had renal involvement and 64.4% were MPO-ANCA positive. The median BVAS at diagnosis was 15.0 [12.0, 20.0]. The median **Five-Factor Score (FFS)** at diagnosis was **1.0 [1.0, 2.0]**. Biopsies were performed in 79.7% of patients, with 68.4% confirming AAV-compatible histopathology. During follow-up, 35.4% experienced relapse, 42.2% achieved remission. 17.1% died; death was higher in men (p=0.006) (main causes of death were infections and active disease). Median Vasculitis Damage Index (VDI) increased from 2.0 at 6 months to 3.0 at the end of follow-up. General information and lifestyle habits are shown in table 3.

Conclusion: This is the largest AAV registry in Spain to date and the first to provide national incidence estimates. The findings confirm MPA as the predominant subtype followed by GPA and EGPA. Mortality was higher in men than in women

Abstract Number: 0729

Anca-associated Vasculitis - Does the Type Matter?

Tamanna Vinodkumar Mohta[1] and Umeh Chukwuemeka[2], [1]Hemet Global Medical Center, Irvine, CA, [2]Hemet Global Medical Center, Hemet

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0711–0730) Vasculitis – ANCA-Associated Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Antineutrophil cytoplasmic antibody (ANCA)–associated vasculitis is a heterogeneous group of rare autoimmune disorders that cause inflammation of blood vessels with various manifestations. Our study compares the differences in clinical outcomes in patients with the three main ANCA–associated vasculitis, granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA), and eosinophilic granulomatosis with polyangiitis (EGPA).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1: Comparing various demographics and complications in different types of ANCA-associated vasculitis.

	Granulomatosis with polyangiitis (GPA)	Microscopic polyangiitis (MPA)	Eosinophilic granulomatosis with polyangiitis (EGPA)	All patients	P-value
Mean Age in years	61.07	63.02	60.70	61.30	
Females	53.6%	62.4%	57.2%	55.3%	<0.001
Race					
White	76.2%	59.1%	73.3%	73.4%	<0.001
Black	7.4%	11.2%	11.5%	8.4%	
Hispanics	11.4%	19.5%	7.4%	12.1%	
Asian	1.7%	4.9%	4.2%	2.5%	
Others	3.4%	5.2%	3.7%	3.7%	
Died during hospitalization	4.7%	6.1%	2.9%	4.7%	<0.001
Pulmonary hypertension	6.5%	9.7%	5.3%	6.8%	<0.001
Congestive heart failure	24.9%	31.3%	23.3%	25.6%	<0.001
Pulmonary embolism	1.9%	1.9%	2.6%	2.0%	<0.001
Acute kidney injury	30.2%	47.9%	21.2%	31.7%	<0.001
End-stage renal disease	24.2%	31.2%	3.5%	22.8%	<0.001
Ischemic stroke	1.1%	1.1%	1.2%	1.1%	0.888
Acute myocardial infarction	4.1%	5.1%	4.1%	4.3%	<0.001
Interstitial lung disease	4.6%	11.9%	4.5%	5.6%	<0.001
Proximal deep venous thrombosis	1.5%	1.7%	1.3%	1.5%	0.028

Methods: We analyzed data of patients hospitalized with a primary or secondary diagnosis of ANCA-vasculitis admitted in United States hospitals from 2017 to 2021 using the National Inpatient Sample (NIS) data. The NIS database is the largest publicly available database of patients hospitalized in the United States.

Results: There were 77,100 patients with a diagnosis of ANCA-associated vasculitis with a mean age of 61.3 years. Of this, 56965 (73.9%) had GPA, 11020 (14.3%) MPA, and 9115 (11.8%) EGPA. In the bivariate analysis, MPA patients had more kidney, heart, and lung complications and worse outcomes compared to GPA and EGPA patients. MPA patients when compared to GPA and EGPA patients were more likely to have acute kidney injury (47.9% vs. 30.2% vs. 21.2%), end-stage renal disease (31.2% vs. 24.2% vs. 3.5%), acute myocardial infarction (5.1% vs. 4.1% vs. 4.1%), congestive heart failure (31.3% vs. 24.9% vs. 23.3%), pulmonary hypertension (9.7% vs. 6.5% vs. 5.3%) and interstitial lung disease (11.9% vs. 4.6% vs. 4.5%), all with $p< 0.001$. There was no difference in the prevalence of ischemic stroke between the MPA, GPA, and EGPA ($p=0.88$).

In the multivariate analysis with GPA as the reference group, there was no difference in in-hospital all-cause mortality between GPA and MPA patients (aOR 0.98, 95% CI 0.89-1.08). However, EGPA patients had lower mortality than GPA patients (aOR 0.67, 95% CI 0.58-0.77).

Conclusion: GPA is the most common type of ANCA vasculitis in hospitalized patients in the US. Kidney involvement, interstitial lung disease, and acute myocardial infarction appear to be more common in MPA than other ANCA vasculitis. However, MPA patients did not have worse in-patient all-cause mortality than GPA patients. EGPA patients appear to have the best in-hospital prognosis.

Abstract Number: 0730

Levels of Disease Activity and Their Relationship With Health-Related Quality of Life In ANCA-Associated Vasculitis Patients: Data from the Almenara Vasculitis Cohort

Victor Pimentel-Quiroz[1], Alvaro Oyarce-Calderon[2], Allison Figueroa-Sánchez[3], Leonor León-Yaurimucha[3], Rocío Gamboa-Cárdenas[4], Zoila Rodríguez-Bellido[5], Risto Perich-Campos[6], Graciela Alarcon[7] and Manuel Ugarte-Gil[8], [1]Universidad Científica del Sur, San Isidro, Peru, [2]Hospital Nacional Guillermo Almenara Irigoyen, San Miguel, Lima, Peru, [3]Universidad Científica del Sur, Lima, Peru, [4]Universidad Científica del Sur, Lima, Peru, [5]Hospital Nacional Guillermo Almenara Irigoyen; Universidad Nacional Mayor de San Marcos, Lima, Peru, [6]Hospital Nacional Guillermo Almenara Irigoyen; Universidad Nacional Mayor de San Marcos, La Molina, Peru, [7]The University of Alabama at Birmingham, Oakland, CA, [8]Universidad Cientifica del Sur, Lima, Peru

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0711–0730) Vasculitis – ANCA-Associated Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: It is known that health-related quality of life (HRQoL) in patients with ANCA-associated vasculitis (AAV) is impaired. Categories of disease activity levels have been proposed for these patients; however, it is unknown whether these categories might impact these patients' HRQoL. Therefore, the aim of this study is to determine the relationship between HRQoL and levels of disease activity in AAV patients.

Methods: We included patients from the Almenara Vasculitis cohort who had at least one visit between December 2022 and November 2024 and had a diagnosis of either microscopic polyangiitis (MPA) or granulomatosis with polyangiitis. Sociodemographic features, disease activity measured with the Birmingham Vasculitis Activity Score version 3 score, damage measured with the Vasculitis Damage Index score, and HRQoL assessed by the AAV-PRO (Spanish version) and the Short Form 36 (SF-36), were obtained. Levels of disease activity were categorized as complete remission, clinical remission off therapy (CROffT), clinical remission on therapy (CRonT), low disease activity (LDA) and active disease; these definitions are shown in Table 1. For these analyses, complete remission, CROffT and CRonT were examined together due to the relatively small sample size for each of them individually. Unadjusted and adjusted linear regression models were performed; possible confounders included in the adjusted model were age, sex, ethnicity, education level, socioeconomic status, type of diagnosis, ANCA status, vasculitis damage index, current prednisone dose, current immunosuppressive drug.

Results: Eighty-four patients were enrolled; female sex and MPA were more frequent. In the adjusted analyses, regarding the SF-36, active disease was associated negatively with general health, role emotional and the mental component summary domains; likewise, LDA was negatively associated with role physical. Regarding the AAV-PRO, active disease was positively associated with the treatment side effects domain.

Table 1. Definitions of levels of disease activity.

	Disease activity	New features of AAV activity	ANCA status	Prednisone dose	Immunosuppressants
Complete remission	BVAS=0	No	No	No	No
CROffT	BVAS=0	No	Yes	No	No
CROnT	BVAS=0	No	Yes/No	=5mg/d	Yes
LDA	0=BVAS=3 and no activity in major organ systems	No	Yes/No	=7.5mg/d	Yes (standard maintenance dose)
Active disease	BVAS>3	Yes	Yes/No	Yes/No	Yes/No

CROffT: clinical remission off therapy. CROnT: clinical remission on therapy. LDA: low disease activity. AAV: ANCA-associated vasculitis

The Efficacy of Leflunomide in the Treatment of Giant Cell Arteritis: A Systematic Review and Meta-Analysis

Linda Zhu[1], Arielle Mendel[2], Carolyn Ross[3] and **Jean-Paul Makhzoum**[1], [1]Universite de Montreal, Montreal, Canada, [2]McGill University Health Centre, Montreal, QC, Canada, [3]University of Montreal, Longueuil, Canada

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0731–0764) Vasculitis – Non-ANCA-Associated & Related Disorders Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: The objective of this systematic review is to assess the effectiveness of leflunomide in the treatment of new-onset, refractory or relapsing giant cell arteritis (GCA) as a glucocorticoid (GC)-sparing agent.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1: Baseline characteristics of 358 pooled patients treated with leflunomide for giant cell arteritis

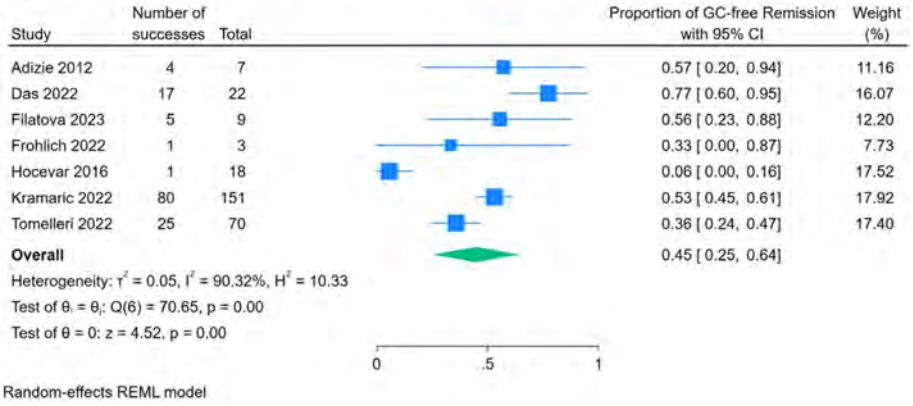
Characteristics	Patients (N=358)
Age (in years), median (IQR)	80 (73.8-77.9)
Female, n (%)	231 (69)
Disease subtype, n (%)	
New onset	233 (65)
Relapsing	83 (23)
Refractory	19 (5)
Unknown	23 (7)
Constitutional symptoms, n/N (%)	183/254 (72)
Polymyalgia rheumatica, n/N (%)	98/313 (31)
Headache, n/N (%)	159/212 (75)
Jaw claudication, n/N (%)	89/201 (44)
Visual symptoms, n/N (%)	45/206 (22)
Visual loss, n/N (%)	24/206 (12)
Stroke, n/N (%)	7/176 (4)
CRP (mg/L), median (IQR)	27 (24.1-84.3)
Radiologic findings, n/N (%)	54/92 (59)
Biopsy-proven disease, n/N (%)	32/117 (27)

All numbers are reported as *n*/group *N* (%) unless otherwise specified.
IQR: interquartile range
CRP: C-reactive protein

Figure 1: Meta-analysis of proportions for the efficacy of leflunomide to achieve GC-free remission in patients with giant cell arteritis.



Methods: A systematic review was conducted using MEDLINE, CENTRAL, EMBASE, and conference proceedings to identify studies on leflunomide in patients with GCA. We included randomized controlled trials, cohort studies, case-control studies, and case series. The primary efficacy outcome was the proportion of patients who attained GC-free remission with leflunomide assessed at any time between 6 to 12 months of therapy. GC-free remission was defined as the absence of signs or symptoms of GCA, and/or normalization of inflammatory markers, and/or radiologic response, and complete discontinuation of GC. Our secondary efficacy outcome was the proportion of patients who attained low-dose GC remission (< 5 mg of prednisone equivalent). All included studies were appraised for risk of bias. We performed a meta-analysis of proportions using a random-effects model and a restricted maximal likelihood approach. We evaluated heterogeneity with I2 and Cochran's Q test. Publication bias was assessed by producing funnel plots for each outcome.

Results: 357 studies were screened with 10 observational studies included in the final analysis. Out of the 358 patients that we pooled for analysis, 231 (69%) were females (table 1). A total of 233 (65%) patients had new-onset GCA, 83 patients had relapsing GCA (23%), and 19 patients had refractory GCA (5%). The disease subtype was not specified for 23 patients. The proportion of patients achieving GC-free remission with leflunomide was 45%, (95% CI 0.25-0.64, p< 0.001, 7 studies) (figure 1). Substantial statistical heterogeneity was present (I2=90.3%, Q=70.7, p< 0.001). Meanwhile, the pooled proportion of patients achieving low-dose GC remission was 48% (95% CI 0.27-0.69, p< 0.001, 6 studies). Funnel plots were slightly asymmetrical, which suggested the presence of publication bias as well as possible poor methodological quality in the reporting of outcomes. All the included studies were deemed to be at serious risk of bias.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: The main challenge in treating GCA is achieving and maintaining remission with minimal glucocorticoids. Our study shows that leflunomide may offer potential benefits in achieving remission without GCs or with low-dose GCs; however, the results exhibited variability due to differences in sample sizes and inconsistent reporting. Leflunomide's role as a glucocorticoid-sparing agent is promising but needs further investigation into higher-quality studies. PROSPERO registration CRD42023490373.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0731–0764) Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Background: Giant-cell arteritis(GCA) is a chronic inflammatory disease targeting large and medium-sized arteries. Inflammation-induced vascular remodeling leads to vascular occlusion, with ischemic complications. Myofibroblasts are key cells in this process, and they differentiate from quiescent vascular smooth muscle cells under the influx of several factors, including PDGFs produced by inflammatory cells, mainly macrophages(1).

GM-CSF is a key proinflammatory cytokine with pleiotropic effects on a variety of cells. Macrophages, the predominant infiltrating cells in GCA, are among the main targets of GM-CSF. Using an ex-vivo culture of patient's arteries in 3D matrix(2), we have previously shown that intimal myofibroblasts express GM-CSF receptors and that blocking GM-CSF receptor with mavrilimumab(MAV) inhibits key pro-inflammatory pathways(3). In a phase 2 clinical trial, MAV, along with a standardized prednisone taper, was superior to placebo in reducing the risk of GCA flare and increasing the rate of sustained remission at week 26(4), indicating that MAV efficiently blocks clinically-relevant inflammatory pathways in GCA

Purpose: We aimed to investigate the impact of MAV on pathways involved in myofibroblast differentiation and vascular remodeling.

Methods: Three patients (1 placebo, 2 MAV) consented to have a second temporal artery biopsy (TAB) at the trial completion. Nineteen TAB from patients with GCA (obtained for diagnostic purposes) were cultured ex-vivo as published(2,3) and treated with placebo or MAV (20 mg/ml) for 5 days. Arteries were processed for RNA extraction, and candidate transcripts were assessed by RT-qPCR. The supernatants were processed for proteomic analysis using G-series Human cytokine array (640 proteins). Differences were analyzed by paired Wilcoxon test. GSEA, Hallmark, C2 curated gene sets, C3 motif

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1

gene sets, and C5 gene ontology gene sets were used for pathway analysis. We focused on pathways involved in myofibroblast differentiation and fibrosis.

Results: Biopsies from MAV-treated patients showed better lumen preservation than the placebo-treated. MAV significantly reduced mRNA expression of PDGFA and B. No impact was seen in other relevant growth factors, such as FGF1, FGF2 or TGFb1 at the mRNA level. Pathway analysis of the proteins released into the supernatant revealed a significant impact of MAV on proteins related to BMP pathway (figure 1). A decrease in BMP-4(p=0.004), BAMBI (p= 0.07) and XIAP(p=0.053) was detected. In addition, a significant decrease in FGF12(p=0.0018) and FGF 17(p=0.0014) was also observed. A decrease in the corresponding mRNAs was also observed.

Conclusion: MAV modulates production of molecules involved in vascular remodeling in cultured arteries from patients with GCA. Whether MAV acts directly on myofibroblasts or indirectly through impairing macrophage function is being currently investigated. Further studies are ongoing to assess the functional impact of the modulated pathways on myofibroblast biology in GCA.

Odds of Receiving IV Thrombolysis	0.57	0.42–0.78	<0.001
Odds of Mechanical Thrombectomy	0.62	0.41–0.95	0.027
Mechanical Ventilation	0.77	0.51–1.17	0.227
PEG Tube Placement	0.99	0.67-1.48	0.98
Cerebral Edema or Herniation	0.76	0.52–1.10	0.146

Background/Purpose: To assess the characteristics, interventions, and outcomes of cerebrovascular accidents (CVAs) in people with giant cell arteritis (GCA). Strokes are uncommon in this population, however, it is uncertain whether patients with GCA are at a higher risk of stroke compared to the general population.

Methods: A retrospective cohort study was performed by analyzing the National Inpatient Sample (NIS) 2017-2022 for all patients with GCA, GCA with Polymyalgia Rheumatica (PMR), and Cerebral Infarction as primary or secondary diagnoses via ICD-10 (International Classification of Diseases 10th Revision) codes. Frequencies, demographics, and trends were determined and compared between hospitalized patients with GCA or GCA with PMR and those without GCA or GCA with PMR. STATA version 17 was used for data analysis. A p-value of ≤0.05 was considered statistically significant.

Results: Hospitalized patients with stroke who had GCA or GCA with PMR were less likely to be male (32.7% vs. 50.5%, $p < 0.001$), less likely to have history of smoking (12.57% vs 19.73%, $p < 0.001$), more likely to have concomitant hypertension (89% vs 84.45%, $p< 0.001$ or concomitant peripheral vascular disease (15.26% vs 9.61%, $p< 0.001$), less likely to undergo intravenous thrombolysis (4.7% vs 8.5%, $p < 0.001$), and less likely to undergo mechanical thrombectomy (2.8% vs 4.9%,

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. p< 0.001), have a higher mortality (5.16% vs 4.65%, p=0.045) when compared to hospitalized patients with stroke who do not have GCA or GCA with PMR.

Conclusion: Hospitalized patients with stroke who had GCA or GCA with PMR were more likely to be female, older in age, have concomitant hypertension and less likely to undergo mechanical thrombectomy or intravenous thrombolysis when compared to patients with stroke without GCA or GCA with PMR. The cohort with GCA or GCA with PMR also had higher mortality when compared to the cohort without GCA or GCA with PMR.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0731–0764) Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Polymyalgia rheumatica (PMR) and giant cell arteritis (GCA) are systemic inflammatory conditions that predominantly affect individuals ≥50 years of age. The conditions share overlapping clinical features[1,2] and can significantly impact patients' quality of life. The main symptoms of PMR include pain and stiffness in the shoulder, neck, and hips; and patients with GCA present with headache, scalp tenderness, jaw claudication, and visual disturbances[2]. Both conditions are associated with significant disease burden, including cardiovascular, cerebrovascular diseases, and particularly malignancies for PMR, and a detrimental effect on vision for GCA. The primary treatment is with glucocorticoids (GC); however, unmet needs exist in GC treatments, including non-response to GC, and high relapse rate[3]. Managing the side effects of long-term GC use is also challenging, with a substantial proportion of patients experiencing disease recurrence during GC dose tapering[4]. Concerns about long-term use of GC include risk of infections, osteoporosis, cardiovascular events, and metabolic conditions[1,2]. This multi-country study aims to gain insight into the proportion of patients with PMR and GCA treated with GC and the prevalence of comorbidities across three continents.

Methods: Patients with a first diagnosis (index date) of PMR or GCA aged ≥50 years during 2014-2024 and with at least 1 year of database enrollment pre-index were identified from healthcare databases including PharMetrics Plus (United States), Longitudinal Patient Database (France), and Japan Claims Plus 2. To increase the specificity of the diagnosis, at least two diagnosis codes recorded ≥7 days apart were required. The total number of patients and the distribution by age, sex, and comorbidities during the 12 months before index date were reported. The percentage of patients with at least two GC records within six months after index date was also reported.

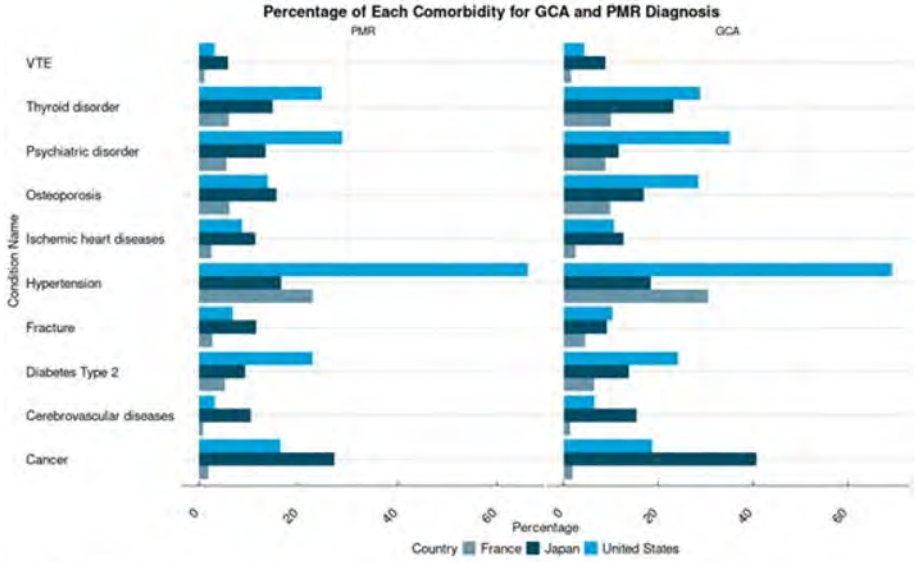
Table 1. Total number, characteristics, and percentage with at least two records of glucocorticoids (GC) in the six months following diagnosis of PMR or GCA

Database	Study period	PMR				GCA			
		N	Mean Age (years)	% Female	% treated with GC[1]	N	Mean Age (years)	% Female	% treated with GC[1]
US PharMetrics Plus	2017-2024	70,784	72.5	61.0	49.7	2,053	73.8	71.3	49.4
France LPD	2017-2024	8,920	75.2	58.2	65.8	1,693	77.1	69.5	58.9
Japan Claims Plus 2	2014 -2023	16,064	78.5	62.8	71.4	1,080	76.5	62.4	70.6

[1] Patients who had at least two records of GC within six months after the first diagnosis of PMR or GCA.
GC: Glucocorticoids; GCA: Giant cell arteritis; LPD: Longitudinal patient database; N: number of patients; PMR: Polymyalgia rheumatica.



VTE: Venous thromboembolic diseases; GCA: Giant cell arteritis; PMR: Polymyalgia rheumatica.
Figure 1. Percentage of comorbidity of interest within 12 months prior to diagnosis of GCA or PMR

Results: Overall 95,768 patients with PMR and 4,826 with GCA were included (Table 1). The mean age ranged from 72.5-78.5 years for PMR and 73.8-77.1 for GCA, and 58.2-62.8% of patients with PMR and 62.4-71.3% with GCA were female. The most common pre-index comorbidity was hypertension in France (PMR: 22.9%, GCA: 30.4%) and the US (PMR: 66.1%, GCA: 69.4%), and cancer in Japan (PMR: 27.3%, GCA: 40.7%) (Figure 1). Between 49.7-71.4% of patients with PMR and 49.4-70.6% with GCA received GC within six months after the first diagnosis.

Conclusion: Across three continents, both patients with PMR and GCA were predominantly of elderly age, with a majority being female, and exhibited a high prevalence of comorbidities. The use of GC was widespread, ranging from 49% of patients in the US to 71% in Japan. The significant burden of common comorbidities, which include diabetes, hypertension, and osteoporosis, underscores the challenges in clinical management of these two conditions. It is crucial to understand how GC are tapered in the real-life settings and to assess the associated safety burden, particularly given the comorbidity profile of these patients.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0731–0764) Vasculitis – Non-ANCA-Associated & Related Disorders Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Giant cell arteritis (GCA) relapses are frequent and often require therapeutic intensification in the form of glucocorticoids (GC) increase. GCA management has significantly evolved following the publication of the GiACTA trial and the subsequent approval of tocilizumab (TCZ) in 2017, allowing for faster GC tapering without relapse. In this study, we aimed to describe real-world diagnostic practices, management strategies and mortality outcome in patients with new-onset GCA from 2017 to 2024.

Methods: All patients diagnosed GCA between August 1st 2017 and May 30th 2024, were identified in the Clinical Data Warehouse of Assistance Publique–Hôpitaux de Paris using the French Medical Information System Program coding system. Stored data integrates clinical, biological and imaging data from patients hospitalized across all public hospitals in the Greater Paris area. To improve cohort accuracy, a natural language processing algorithm was applied to detect and exclude miscoded entries. Patients without a recorded prescription for GC were excluded. The study flowchart is presented in **Figure 1**. The risk of death was assessed using a multivariate Cox proportional hazards model.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: A total of 843 patients were included in the study, 543 (64%) of whom were female, with a median [interquartile range] age at diagnosis of 74 [68–81] years, and median follow-up 6.4 [3.0-9.9] years (**Table 1**). The use of positron emission tomography increased from 30.4% of patients in the year 2017, to 36.5% in the year 2024. Conversely, the proportion of temporal artery biopsies declined from 47.8% in 2017, compared to 38.5% in the year 2024. At diagnosis, 772 (91.6%)

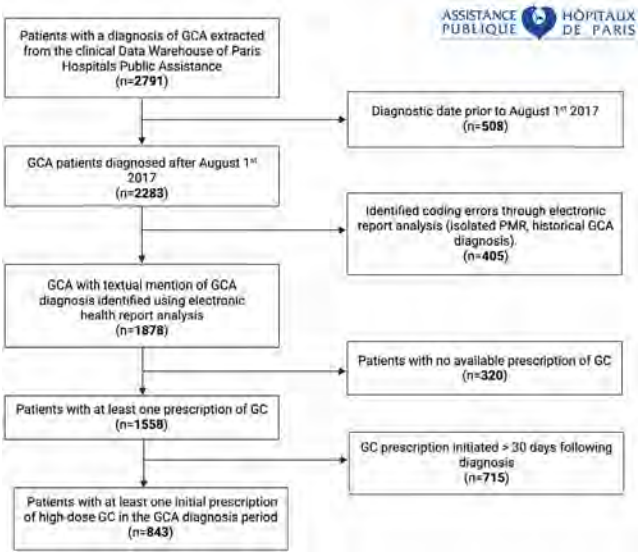

Figure 1. Study flowchart Abbreviations: GCA: giant cell arteritis; GC: glucocorticoids; PMR: polymyalgia rheumatica.

Table 1. Clinical characteristics at GCA diagnosis. Abbreviations: GCA: giant cell arteritis; CT: computed tomography; PET : positron emission tomography * Comorbidities at baseline were defined as clinical history or concomitant to GCA diagnosis.

Characteristics at baseline	**N = 843**
Demographic characteristics	
Female gender (%)	543 (64%)
Age at diagnosis (years)	74 [68 – 81]
Comorbidities at baseline*	
Stroke	73 (8.7%)
Diabetes	183 (22%)
Ischemic cardiopathy	277 (33%)
Osteoporosis	67 (7.9%)
Explorations at diagnosis	
Temporal arterial biopsy	369 (44%)
PET CT	280 (33%)
Contrast CT	263 (31%)
Treatment at diagnosis	
Aspirin	367 (44%)
Tocilizumab	71 (8.4%)
Prednisone	843 (100%)
Corticosteroid dose (mg)	40 [25 – 60]
Follow-up	
Follow-up duration (years)	6.4 [3.0 - 9.9]

Table 2. Survival analysis for risk of death among GCA patients. Results of both univariate and multivariate survival analysis for the risk of death following GCA diagnosis, using a Cox proportional hazard model. Comorbidities at baseline were defined as clinical history or concomitant to GCA diagnosis. Abbreviations: CI: confidence interval; GCA: giant cell arteritis; HR: hazard ratio

	Univariate analysis		Multivariate analysis	
	HR [95% CI]	p-value	HR [95% CI]	p-value
Male gender	1.60 [1.06 - 2.42]	**0.025**	1.43 [0.93 – 2.20]	0.1
Ischemic cardiopathy	4.43 [2.3 - 8.55]	**<0.01**	1.97 [0.99 – 3.92]	0.054
Osteoporosis at baseline	2.05 [1.16 - 3.62]	**0.014**	1.49 [0.82 – 2.71]	0.196
Cancer at baseline	2.70 [0.99 – 7.36]	0.052	-	-
Diabetes at baseline	1.64 [1.05 - 2.56]	**0.03**	1.22 [0.77 – 1.94]	0.406
Stroke at baseline	3.98 [2.46 - 6.43]	**<0.01**	2.65 [1.60 – 4.38]	**<0.01**
Aspirin at baseline	1.57 [1.04 – 2.38]	**0.031**	1.24 [0.81 – 1.88]	0.324
Tocilizumab at diagnosis	1.28 [0.64 – 2.55]	0.483	-	-
Age at diagnosis	1.10 [1.07 – 1.12]	**<0.01**	1.08 [1.05 – 1.11]	**<0.01**

received GC monotherapy while 71 (8.4%) received combined therapy with TCZ and GC. During follow-up, 400 (47.5%) GCA patients required GC intensification, including 319 (38%) at 1 year, 363 (43%) at 2 years and 380 (45%) at 3 years. The median time to first GC intensification was 1.4 [0.1–5.6] years. The median GC dose before intensification was 10 [5-20] mg/day which increased to 35 [20-50] mg/day following intensification. Overall, 91 (11%) patients died during follow-up. In a multivariate analysis (**Table 2**), older age at diagnosis (p< 0.01) and the presence of a stroke at baseline (p< 0.01) were independently associated with an increased risk of mortality.

Conclusion: In this contemporary French cohort, nearly half of patients with GCA required at least one GC intensification during the course of treatment. Stroke at baseline and older age at diagnosis were identified as independent risk factors for all-cause mortality.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0731–0764) Vasculitis – Non-ANCA-Associated & Related Disorders Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Stroke is a feared complication of giant cell arteritis (GCA). Tocilizumab (TCZ) has shown efficacy and safety in large-vessel vasculitis (LVV) including GCA. Our objective was to assess the effectiveness of TCZ in the stroke associated with GCA regarding to: i) prevent the appearance of new strokes, and ii) improve stroke if present.

	Overall (n=471)	GCA with stroke (n=7)	GCA without stroke (n=465)	P
Main demographic features				
- Age at diagnosis, years (mean±SD)	72.1±9.1	73.3±4.7	72.1±9.1	0.84
- Age at TCZ initiation, years (mean± SD)	74±9	75.9±7.9	73.5±9.0	0.71
- Sex, women/men, n (% women)	342/129 (73)	2/5 (29)	340/124 (73)	**0.019**
GCA fulfilling ACR 1990 classification criteria, n (%)	344 (73)	6 (86)	338 (73)	0.68
Time from diagnosis to TCZ initiation (months), median [IQR]	6 [2-18]	8 [2-21.5]	6 [2-18]	0.84
Biopsy-proven GCA, n (%)	201 (43)	4 (57)	197 (42)	0.99
GCA phenotypes, n (%)				
- Cranial	217 (46)	4 (57)	213 (46)	0.71
- Extracranial	80 (17)	0 (0)	80 (17)	0.61
- Mixed	174 (37)	3 (50)	171 (37)	0.71
Cardiovascular risk factors, n (%)				
- High blood pressure, n (%)	272 (58)	5 (71)	267 (57)	0.71
- Dyslipidemia, n (%)	241 (51)	6 (86)	235 (50)	0.13
- Diabetes, n (%)	81 (17)	3 (50)	78 (17)	0.12
- Previous or current smoking history, n (%)	47 (10)	3 (50)	44 (12)	**0.028**
Systemic manifestations, n (%)				
- Fever, n (%)	57 (12)	2 (33)	55 (12)	0.21
- Constitutional syndrome, n (%)	175 (37)	1 (17)	174 (37)	0.26
- PMR, n (%)	284 (60)	4 (57)	280 (60)	0.99
Cranial manifestations, n (%)				
- Visual involvement, n (%)	81 (17)	2 (29)	79 (17)	0.35
- Headache, n (%)	259 (55)	3 (50)	256 (55)	0.71
- Jaw claudication, n (%)	112 (24)	4 (67)	108 (23)	0.069
Analytical findings				
- ESR, mm/1st hour, median [IQR]	32 [12-57]	77 [44-88.5]	30 [11-54]	0.075
- CRP, mg/dL, median [IQR]	1.5 [0.5-3.4]	6.1 [1.3-7.9]	1.4 [0.4-3.4]	0.66
- Hemoglobin (g/L), mean±SD	12.6±1.5	12.2±2.0	12.6±1.5	0.85
TCZ administration schedule				
- TCZmono / TCZcombo, n (% TCZ mono)	353/118 (75)	5/2 (71)	348/116 (75)	0.99
TCZ administration route and dose				
- Intravenous (IV) 8 mg/kg/4 weeks/subcutaneous (SC) 162 mg/week (% IV)	238/233 (50)	5/2 (71)	233/231 (50)	0.45

Abbreviations: ACR: American College of Rheumatology; CRP: C-reactive protein; ESR: erythrocyte sedimentation rate; GCA: giant cell arteritis; IQR: interquartile range; n: number; PMR: polymyalgia rheumatica; SD: standard deviation; TCZcombo: tocilizumab in combination with synthetic immunosuppressant (besides glucocorticoids) agents; TCZmono: tocilizumab in monotherapy (besides glucocorticoids).

TABLE. Main features of the GCA patients with and without strokes treated with tocilizumab.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Observational, multicenter study of 471 patients with GCA treated with TCZ. Patients were diagnosed with GCA accordingly to: a) American College of Rheumatology (ACR) criteria, and/or b) positive biopsy of temporal artery, and/or c) the presence of imaging techniques consistent with LVV. Patients were divided into two groups: i) with, and ii) without stroke.

All patients in whom stroke was diagnosed had lesions on computed tomography (CT) and/or magnetic resonance imaging (MRI) scans that were read by a neuroradiologist and correlated clinically by a neurologist.

Results: 471 (342 females; 72.1±9.1 years) patients with GCA treated with TCZ were included. Stroke at any time (before and after TCZ) were observed in 7 (1.5%) patients. In 5 of them stroke was present at TCZ initiation. One patient had a stroke previously with complete recovery and another patient had a stroke after starting TCZ and died. Main features of GCA with and without stroke are shown in TABLE. Patients with stroke were predominantly male and were or had been smokers. At TCZ initiation 5 patients had a stroke in vertebrobasilar territory.

Only one patient suffered lacunar infarctions after TCZ initiation, while the 5 patients who had a stroke at TCZ initiation experienced progressive improvement.

Conclusion: Stroke in GCA is an infrequent manifestation of GCA and occur mainly in the vertebrobasilar territory. TCZ might prevent the appearance of new strokes and appears to aid recovery in existing ones.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0731–0764) Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with giant cell arteritis (GCA) can relapse despite glucocorticoids, methotrexate and tocilizumab treatment. The JAK/STAT signalling pathway is involved in the pathogenesis of GCA, and JAK inhibitors (JAKi) are a potential treatment alternative. Our Objective was to evaluate the effectiveness and safety of JAKi in GCA.

Methods: Real-world, retrospective clinical practice study of patients with GCA treated with JAKi. Outcomes assessed included clinical remission and EULAR remission (clinical remission+CRP and ESR normalization), disease relapse and safety. A literature search for other JAKi-treated GCA cases was conducted in PubMed from inception to 11/30/2024.

Results: We include 40 patients (35 females/87.5%), mean age, 72.2 years, relapsing disease 40 (100%) that received JAKi. The initial JAKi was baricitinib (n=15), tofacitinib (n=10) and upadacitinib (n=15) **(Table and Figure)**. After a mean±SD follow-up of 12.4±6.8 months, 24 (60%) achieved a maintained remission, and 16 (40%) patients discontinued the initial JAKi due to relapse (n=12, 30%) or severe adverse events (SAEs) (n=4, 10%) including elevation of liver enzymes (n=1), disseminated herpes zoster (n=1), glioblastoma multiforme (n=1), and palpitations/dyspnea (n=1). Two patients developed an urinary tract infection and one patient anemia without requiring permanent JAKi discontinuation. The 12 patients failing the initial JAKi were switched to an alternative JAKi (n=2), biologic therapy (n=8) and azathioprine (n=1). One patient discontinued JAKi therapy due to sustained remission.

The literature review identified another 37 GCA patients (26 females, mean age 71.4 years) treated with JAKi, mostly with baricitinib (n=35). Most of these patients benefited from JAKi therapy **(Table)**. With respect to relevant adverse events, one patient suffered an *Aspergillus fumigatus* infection, other patient an *Enterococcus faecalis* bacteremia, and other thrombocytopenia **(Table)**.

Conclusion: This real-world analysis suggests that JAKi could be effective and relatively safe in GCA, including patients failing to other immunosuppressive therapies.

Reference	Number of cases	Sex	Age, mean±SD	JAKi received	Previous conventional synthetic immunosuppressive drugs	Previous biologic drugs	Follow-up (months), mean±SD	Outcome	Adverse events
Herlihy et al	1	Female	75	Ruxolitinib	Methotrexate, mycophenolate mophetil	None	9	No outcome data reported	None

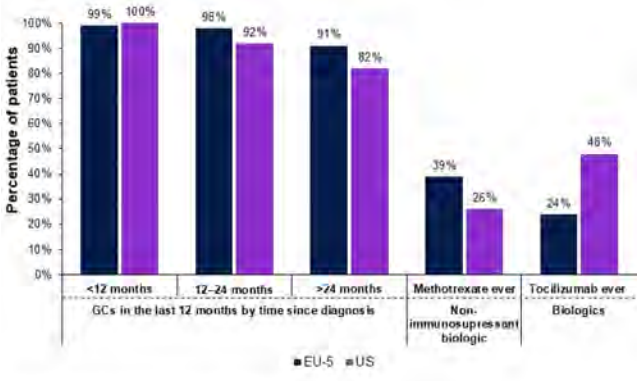
Figure 1. Treatments received by patients in the EU-5 and US



EU, Europe; GC, glucocorticoid; US, United States

Background/Purpose: Giant cell arteritis (GCA) is the most common vasculitis in patients 50 years and older. Glucocorticoids (GC) are the mainstay of treatment for GCA but can cause significant adverse events (AE). This study assessed GC burden, treatment patterns and rheumatologists' perceptions of advanced therapies (AT) for GCA.

Methods: Data were from the Adelphi Real World GCA Disease Specific Programme™, a cross-sectional, retrospective survey of rheumatologists and their adult (≥18 years) patients with GCA in France, Germany, Italy, Spain, and the United Kingdom (EU-5), and the United States (US) from 05/2024–10/2024. Rheumatologists completed patient record forms (PRF) for each patient to record demographics, treatment history and clinical characteristics. Rheumatologists were surveyed on their patient management approach and treatment perceptions. Patients for whom a PRF was completed were invited to fill in a self-assessment form.

Results: Overall, 189 rheumatologists were surveyed. Among 846 patients with GCA (EU-5: France, N=133; Germany, N=120; Italy, N=144; Spain, N=120; UK, N=129; US: N=200), 63% were female, 94% were white, mean age was 71 years and median time since diagnosis was 15.2 months. Most patients were using GCs, regardless of time since diagnosis. The next most common treatments were tocilizumab (EU-5, 24%; US, 48%) and methotrexate (EU-5, 39%; US, 26%; **Figure 1**). Median time from diagnosis to receiving tocilizumab or methotrexate was approximately 5 months. Over the last 12 months, median cumulative GC doses were 4343 mg, 5200 mg and 2196 mg for patients diagnosed < 1 year, 1–2 years, and >2 years ago, respectively. Most rheumatologists (87%) aimed to taper to low dose GCs by 12 months and 79% aimed to

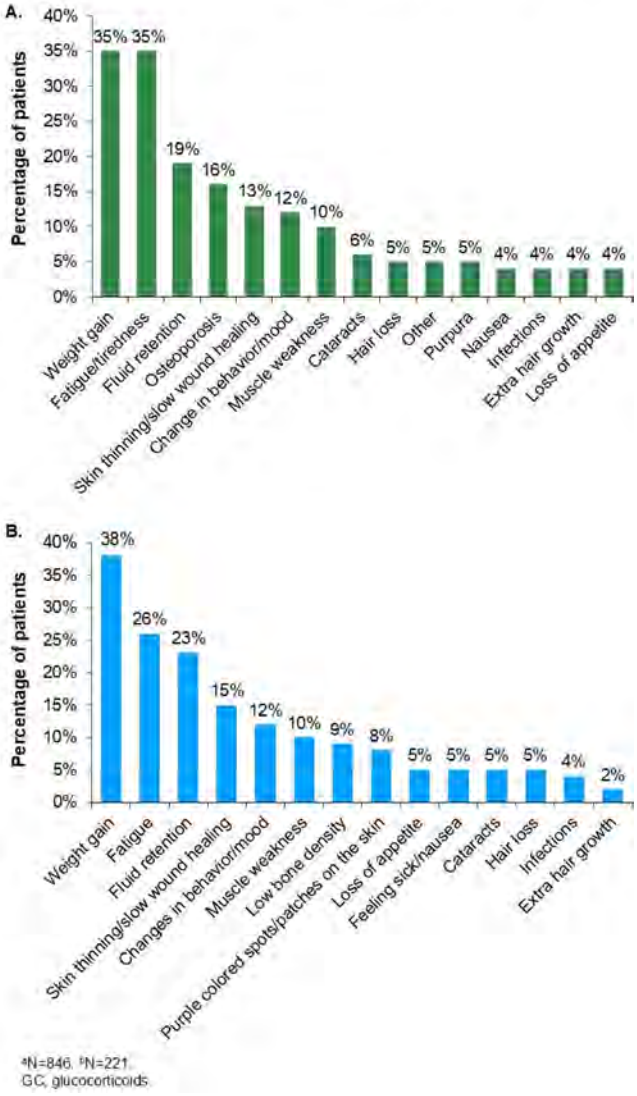
Figure 3. GC-related adverse events, reported by (A) rheumatologists[a] and (B) patients[b]



[a]N=846. [b]N=221.
GC, glucocorticoids

taper off GCs completely by 24 months post-diagnosis. At 24–< 36 months post-diagnosis, 80% of patients were on an average daily GC dose of 8.4 mg, and 75% were taking an average of 5.3 mg/day at ≥48 months (**Figure 2**). The number of patients experiencing ≥1 GC-related AE was higher when reported by rheumatologists (74%) compared to patients (55%; **Figure 3**). Most rheumatologists (EU-5, 90%; US, 94%) agreed that ATs should be given early in GCA treatment to improve outcomes and reduce GC toxicity. Over 90% of rheumatologists believed the following AT attributes were important: maintenance of remission; achievement of GC-free remission; reduction of high-dose/cumulative GC use; to allow GC cessation; and to be safe, tolerable, and patient-compliant. Most rheumatologists agreed that limited choices in AT administration routes are a barrier to widespread use (EU-5, 51%; US, 80%) and that convenient administration is an important attribute of ATs (EU-5, 65%; US, 84%). Most patients (75%) stated that they preferred receiving treatments orally rather than by injection or infusion.

Conclusion: Even though most rheumatologists aimed to taper patients off GCs completely by 24 months, 75% of patients were using GCs at 4 years. Both rheumatologists and patients reported several AEs associated with GC use, and rheumatologists recognize the need for early and effective steroid sparing intervention with ATs.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

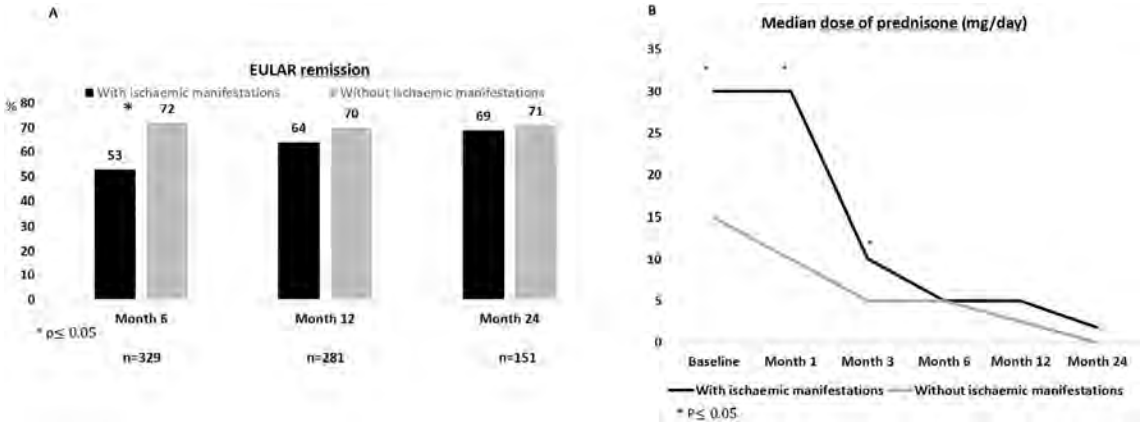
Session Title: (0731–0764) Vasculitis – Non-ANCA-Associated & Related Disorders Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Tocilizumab (TCZ) is the only approved biological drug in the treatment of giant cell arteritis (GCA). However, there are no comparative studies on the efficacy of TCZ in patients with GCA with ischaemic vs. non-ischaemic manifestations.

Our aim was to compare the effectiveness of TCZ in patients with GCA with ischaemic vs. non-ischaemic manifestations in clinical practice.



23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Multicentre observational and comparative study of 471 patients with GCA treated with TCZ. GCA was diagnosed by: i) ACR criteria, and/or ii) temporal artery biopsy, and/or iii) imaging techniques. In this case, a comparative subanalysis between patients with GCA with ischaemic manifestations (visual involvement and/or jaw claudication and/or stroke) and those with GCA with non-ischaemic manifestations was done. Remission was considered according to EULAR definitions, as the absence of signs and symptoms of GCA and the normalization of the ESR and CRP values (1).

Results: The 471 patients with GCA were divided into 2 subgroups: a) GCA with ischaemic manifestations (n=162), and b) GCA with non-ischaemic manifestations (n=309) (TABLE). Patients with ischaemic manifestations were older, met ACR1990 criteria more often, had positive temporal biopsy more frequently and the time from diagnosis to onset of TCZ was shorter. The predominant phenotype in patients with ischaemic manifestations was cranial GCA and they presented more frequently hypertension and higher mean CRP and ESR values. The mean dose of prednisone was higher in this group, while concomitant use with a conventional synthetic DMARD was more frequent in the non-ischaemic group.

No significant differences were observed between the two groups in terms of remission except within the 6 months of starting TCZ, which was higher in the non-ischaemic group (FIGURE). Glucocorticoid dose was higher in the GCA group with ischaemic manifestations during the first 3 months, but was similar in both groups thereafter.

	Overall (n=471)	GCA with ischaemic manifestations (n=162)	GCA without ischaemic manifestations (n=309)	P

Intravenous versus subcutaneous administration of Tocilizumab in aortitis associated with giant cell arteritis: multicenter open-label study of 196 patients

Carmen Secada-Gómez[1], Javier Loricera[2], Adrian Martin-Gutierrez[3], Santos Castañeda[4] and Ricardo Blanco[1], [1]Rheumatology Division, Hospital Universitario Marqués de Valdecilla, IDIVAL, Immunopathology Group, Santander, Spain, Santander, Cantabria, Spain, [2]Hospital Universitario Marqués de Valdecilla, IDIVAL, Immunopathology Group, Santander , Spain, Santander, Spain, [3]Division of Rheumatology, Hospital Universitario Marqués de Valdecilla, IDIVAL, Immunopathology Group, Santander, Spain., Renedo de Piélagos, Spain, [4]Hospital Universitario de La Princesa, IIS-Princesa, Madrid, Madrid, Spain

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0731–0764) Vasculitis – Non-ANCA-Associated & Related Disorders Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Aortitis associated to Giant cell arteritis (GCA) (GCA-aortitis) is one of the most severe manifestation of GCA. Tocilizumab (TCZ) has demonstrated efficacy in large-vessel vasculitis (LVV) including GCA, previous pharmacokinetic studies, have shown more stable and sustained levels of tocilizumab with the subcutaneous form compared to the intravenous form. However, there are no studies comparing intravenous (IV) vs subcutaneous (SC) administration of TCZ in GCA-aortitis.

Our aim was to compare the effectiveness of TCZ in GCA-aortitis according the route of administration (IV vs SC) in a wide series of patients in a clinical world setting.

Methods: Multicentre study of 196 patients diagnosed with GCA-aortitis by imaging techniques and treated with TCZ. Patients were divided in two groups according to the route of administration of TCZ: i) IV, and ii) SC. GCA was diagnosed by 1990 ACR criteria, and/or temporal artery biopsy and/or imaging techniques. Aortitis was diagnosed mainly by ^{18}F-FDG-PET/CT. Main outcomes were EULAR remission definition (clinical remission and normalization of CRP and ESR), imaging remission (considered when vascular FDG uptake was less than liver uptake in ^{18}F-FDG PET/CT) and glucocorticoid withdrawal after TCZ initiation.

administration in glucocorticoid-sparing effect after TCZ initiation. Noticeably, statistical differences in EULAR remission definition were observed after 24-month follow-up, although there were no differences in imaging remission (Figure).

Conclusion: In GCA-aortitis, SC TCZ might be more effective than IV in achieving the EULAR remission target in clinical practice conditions after 24-month follow-up.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0731–0764) Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: GCA is a vasculitis of large and medium-sized arteries that has been well-studied in populations of European descent; however, data on African American (AA) patients remain sparse. We aimed to assess racial differences in demographics, comorbidities, treatment, inflammatory markers, and outcomes in GCA.

Methods: We conducted a retrospective cohort study using TriNetX, a network of de-identified electronic medical records from 102 healthcare organizations. Adults with GCA (ICD-10-CM: M31.5, M31.6) from 2004–2024 were grouped as AA or non-African American (non-AA) (including White, Asian, Hispanic, and others). After 1:1 propensity score matching (33 covariates), cohorts were compared for comorbidities, treatments, inflammatory markers (CRP,ESR at 0/6/12 months), and mortality. Kaplan-Meier survival analysis and Cox regression were used for survival analysis.

Results: 6,507 AA and 40,683 non-AA patients were identified; after matching, 6,505 remained in each group. AA patients were younger at diagnosis (65.1 vs 68.9 years, $p< 0.001$) and more likely to be female (79 vs.67%, $p < 0.001$). Hypertension (HTN) and diabetes (DM) were more prevalent in AA, while PMR, anterior ischemic optic neuropathy (AION), and aortic aneurysms were more common in non-AA individuals. Prednisone, MTX, and tocilizumab were comparable between groups (Table 1).

After matching and at baseline, CRP was lower in AA than non-AA patients (25.4 vs. 32.7 mg/L, $p< 0.001$), while ESR was higher (54.5 vs. 42.6 mm/h, $p< 0.001$). Notably, AA patients continued to exhibit higher ESR and CRP levels at 6 and 12 months (Table 2).

Blindness of both eyes	25 (0.4%)	80 (0.2%)	0.003	25 (0.4%)	19 (0.3%)	0.365
Blindness of one eye	52 (0.8%)	226 (0.6%)	0.017	52 (0.8%)	36 (0.6%)	0.087
Unspecified visual loss	340 (5.2%)	1,462 (3.6%)	<0.001	340 (5.2%)	298 (4.6%)	0.088
Amaurosis fugax	70 (1.1%)	505 (1.2%)	0.258	70 (1.1%)	58 (0.9%)	0.286
Ischemic optic neuropathy	87 (1.3%)	858 (2.1%)	<0.001	87 (1.3%)	68 (1.0%)	0.125
Central retinal artery occlusion	74 (1.1%)	321 (0.8%)	0.004	74 (1.1%)	52 (0.8%)	0.049
Medications						
Prednisone	2,659 (40.9%)	14, 765 (36.3%)	<0.001	2,658 (40.9%)	2,582 (39.7%)	0.174
Methotrexate	227 (3.5%)	1,360 (3.3%)	0.545	227 (3.5%)	193 (3.0%)	0.092
Tocilizumab	50 (0.8%)	328 (0.8%)	0.751	50 (0.8%)	43 (0.7%)	0.466
Laboratory						
C reactive protein (mg/L)	25.4 ± 42.8	34.5 ± 53.6	<0.001	25.4 ± 42.8	32.7 ± 52.7	<0.001
Erythrocyte sedimentation rate (mm/h)	54.4 ± 31.2	40.4 ± 31.2	<0.001	54.5 ± 31.2	42.6 ± 31.3	<0.001

Survival analysis revealed a statistically significant difference in mortality between the two groups (Figure 1). Mortality risk was 11.9% in AA vs. 14.3% in non-AA, a difference of –2.4% ($p < 0.001$). The risk ratio was 0.833 and the odds ratio was 0.811, suggesting a 17–19% relative risk reduction. Kaplan-Meier analysis showed higher survival probability in AA patients (50.44% vs. 36.05%; $p = 0.001$). Cox regression showed a 14.4% lower mortality hazard (hazard ratio 0.856), with the proportional hazards assumption met.

Table 2. Inflammatory marker analysis at time of diagnosis, 6 months, 12 months in African American cohort versus non-African American cohort after matching

	African American (n=6,505)	Non-African American (n=6,505)	P-value
C reactive protein (mg/L)			
Time of diagnosis	25.4 ± 42.8 (n=1,673)	32.7 ± 52.7 (n=1,745)	<0.001
6 months after diagnosis	23.8 ± 45.9 (n=1,839)	20.7 ± 42.2 (n=1,669)	<0.001
12 months after diagnosis	23.7 ± 47.2 (n=742)	15.8 ± 33.8 (n=794)	<0.001
ESR (mm/h)			
Time of diagnosis	54.5 ± 31.2 (n=1,996)	42.6 ± 31.3 (n=2,079)	<0.001
6 months after diagnosis	43.4 ± 29.8 (n=2,124)	27.9 ± 26.4 (n=2,209)	<0.001
12 months after diagnosis	41.1 ± 29.7 (n=894)	25.6 ± 24.0 (n=1,093)	<0.001

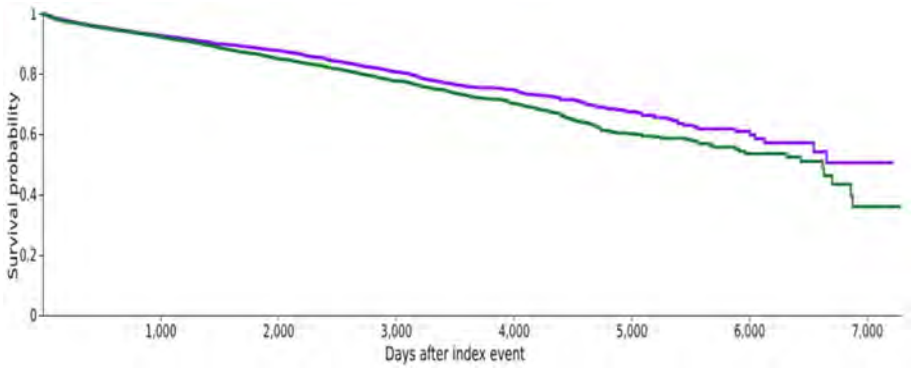

Figure 1. Kaplan-Meier Survival Analysis of Mortality in African American versus non-African American Patient's with GCA. Key: Purple = African American cohort. Green = non-African American cohort

Conclusion: In our study, AA patients with GCA were younger and more often female at diagnosis compared to non-AA patients. Comorbid HTN and DM were more common in the AA group, while PMR, AION, and aortic aneurysms were more prevalent in the non-AA group.

Despite higher inflammatory markers, AA patients had lower mortality and improved survival than other races in this matched cohort. Variations in disease phenotype, comorbidity burden, healthcare access, or other clinical and sociodemographic factors may drive these differences. Further investigation is warranted to explore potential contributors to these outcome differences.

Abstract Number: 0742

Exploring Racial Variation in the Clinical Manifestations of Giant Cell Arteritis: A Retrospective Single-Center Study

Dana Nachawati[1], Chelsea Guan[1], Amir Daneshvar[1], Ansaam Daoud[2] and Omer Pamuk[3], [1]University Hospitals Cleveland Medical Center/Case Western Reserve University, Cleveland, OH, [2]Case Western Reserve University/ University Hospitals, Cleveland, OH, [3]University Hospitals Cleveland Medical Center/ Case Western Reserve University, Cleveland, OH

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0731–0764) Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Giant cell arteritis (GCA) is a large and medium vessel vasculitis affecting older adults of Northern European descent. While GCA is well characterized in Caucasian (CA) populations, emerging data suggest possible racial differences in disease expression. This study aimed to assess racial variation in clinical and lab presentation of GCA between African American (AA) and CA patients.

Methods: We performed a retrospective chart review of patients meeting the 2022 ACR/EULAR classification criteria for GCA in the Rheumatology Department at University Hospitals. Patients were categorized as AA vs. CA. Extracted data included demographics, presenting symptoms, temporal artery biopsy (TAB) status and results, relapse, mortality, and lab parameters at diagnosis. This study was IRB approved.

Table 1. Exploration of variables including baseline characteristics, presenting symptoms, rate of biopsy-proven GCA, relapse, and all cause-mortality in Caucasian versus African American patients with GCA

Variables	Caucasian with GCA (n=55)	African American with GCA (n=10)	p-value
Characteristics			
Female	40 (72.7%)	10 (100%)	0.060
Male	15 (27.3%)	0 (0%)	0.060
Age ± Standard Deviation	78.75 ± 9.16	78.6 ± 12.39	0.972
Hyperlipidemia	48 (87.3%)	7 (70%)	0.164
Hypertension	46 (83.6%)	8 (80%)	0.778
Diabetes	13 (23.6%)	5 (50%)	0.087
Smoking	19 (34.5%)	5 (50%)	0.766
Alcohol use	19 (34.5%)	4 (40%)	0.109
Presenting symptoms			
Headaches	43 (78.5%)	8 (80%)	0.898
Temporal headache	39 (70.9%)	8 (80%)	0.555
Scalp tenderness	31 (56.4%)	7 (70%)	0.421
Jaw claudication	28 (50.9%)	4 (40%)	0.526
PMR	13 (23.6%)	5 (50%)	0.087
Visual complaint	28 (50.9%)	7 (70%)	0.265
Visual loss	11 (20%)	2 (20%)	1.000
Amaurosis fugax	10 (18.2%)	2 (20%)	0.892
Diplopia	10 (18.2%)	1 (10%)	0.526
Anterior ischemic optic neuropathy (AION)	6 (10.9%)	2 (20%)	0.421
Large vessel involvement	3 (5.5%)	0 (0%)	0.450
Fever of unknown origin	3 (5.5%)	1 (10%)	0.582
Fatigue	13 (23.6%)	2 (20%)	0.802
Night sweats	8 (14.5%)	0 (0%)	0.198
Weight loss	5 (9.1%)	0 (0%)	0.321
Biopsy proven	38 (69.1%)	2 (20%)	0.003
Relapse	19 (34.5%)	5 (50%)	0.352
All-cause mortality	5 (7.7%)	0 (0%)	0.321

Chi-square (χ^2) tests evaluated associations between race and categorical variables; Two-sided t-tests assessed continuous variables.

Results: Sixty-five patients (55 CA, 10 AA) were included. In this comparative analysis, mean age at diagnosis was similar (78.75 vs. 78.6 years, *p = 0.486*). All AA patients were female vs. 72.7% CA (p = 0.060). TAB was positive in 69.1% of CA vs. 20% of AA (p=0.003). Clinical manifestations, including headache, jaw claudication, and visual symptoms, were similar across groups.

Notable lab differences were seen at diagnosis. AA patients had higher ESR (79.8 vs. 58.4 mm/h, p = 0.005), while CRP levels were marginally higher in CA patients (8.4 vs. 4.7 mg/dL, p = 0.051). Hemoglobin and platelet counts were higher in CA patients (12.9 vs. 11.4 g/dL, p = 0.042) and (336 vs. 282 x10^3//μL, p = 0.047), respectively. No significant differences were observed in white blood cell (WBC) counts, relapse, or mortality.

Table 2. Comparison of inflammatory markers and hematologic laboratory values at time of GCA diagnosis

Lab value	Caucasian with GCA	African American with GCA	p-value
ESR (mm/h)	58.36 ± 31.74	79.80 ± 16.92	0.005
CRP (mg/dL)	8.37 ± 9.83	4.68 ± 3.74	0.051
WBC (x10*3/uL)	9.84 ± 3.12	8.68 ± 4.10	0.417
Hemoglobin (g/dL)	12.9 ± 1.29	11.4 ± 1.97	0.042
Platelets (x10*3/uL)	336.2 ± 117.24	282 ± 60.70	0.047

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Although age and clinical presentation were comparable, AA patients exhibited higher ESR and more anemia, while CA patients had marginally higher CRP and more biopsy-confirmed diagnoses. These findings may reflect biologic or system-level differences influencing disease recognition or expression. Further investigation is warranted to further clarify potential racial variations in GCA presentation and diagnostic pathways.

Giant Cell Arteritis Relapse After Treatment with Two Months of Prednisone and 12 Months of Tocilizumab

David O'Dea[1], Guy Katz[1], Belen Arevalo Molina[1], Adam Jarvie[2], Mark Matza[1], Ana Fernandes[1], John Stone[3] and Sebastian H Unizony[4], [1]Massachusetts General Hospital, Boston, MA, [2]Emory University School of Medicine, Atlanta, GA, [3]Massachusetts General Hospital , Harvard Medical School, Concord, MA, [4]Massachusetts General Hospital, Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0731–0764) Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: The optimal duration of tocilizumab (TCZ) treatment for giant cell arteritis (GCA) is unclear. Observational studies have shown that 50-60% of patients relapse after receiving TCZ for ≥12 months in combination with ≥6-10 months of glucocorticoids (GC) [1]. However, there are no data on outcomes after treatment discontinuation in patients receiving TCZ with shorter GC tapers. We investigated the relapse rate of GCA patients after treatment with 2 months of prednisone and 12 months of TCZ.

Methods: The electronic medical records of patients with GCA who completed a pilot clinical trial of TCZ in combination with a short prednisone taper (11/2018-12/2021) [1] were retrospectively reviewed. During the clinical trial, in the absence of relapse, patients weaned off prednisone within 2 months and discontinued TCZ at month 12. The primary endpoint of the

Fisher's exact and Wilcoxon rank-sum tests used for univariable comparison of categorical and continuous variables, respectively. A logistic regression model including the variables tested in univariable comparisons did not show predictors independently associated with relapse. * Biopsy-proven aortitis. ESR, erythrocyte sedimentation rate; CRP, C-reactive protein.

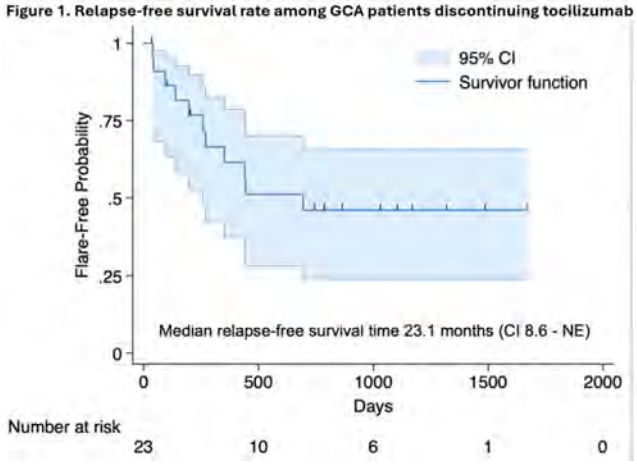
Figure 1. Relapse-free survival rate among GCA patients discontinuing tocilizumab



analysis was relapse after month 12. Relapse was defined as the recurrence of GCA signs or symptoms that required treatment, regardless of the ESR and CRP values. Time to relapse and features of relapse were assessed. Factors potentially associated with relapse were assessed in univariate analyses and multivariate logistic regression.

Results: The results of the clinical trial were published elsewhere [1]. In brief, of 30 patients receiving 12 months of TCZ and 2 months of prednisone, 23 (77.7%) maintained disease remission through month 12 and 7 (23.3%) relapsed before month 12 [1]. The 23 patients that maintained remission received a median (IQR) cumulative prednisone dose of 962.5 (682.5, 1610) mg during the trial and were followed for a median (IQR) period of 36 (22, 44) months after the trial ended. Other baseline characteristics are shown in **Table 1**. During follow-up, 11 (47.8%) patients relapsed following TCZ discontinuation (**-Table 2**). The median relapse-free survival time was 23.1 (95% CI 8.6-NE) months (**Figure 1**). At relapse, 4 (36.4%) patients had cranial symptoms and 7 (63.6%) had polymyalgia rheumatica symptoms (**Table 2**). One (9.1%) patient had biopsy-proven aortitis despite being asymptomatic. No patients reported visual symptoms at the time of relapse. The median (IQR) ESR (mm/hour) and CRP (mg/liter) values at relapse were 39 (25, 43.75) and 10.5 (5.6, 24.73), respectively. Of all relapsing patients, 10 (90.9%) received prednisone. In addition, 6 (54.5%) patients re-initiated TCZ and 2 (18.2%) patients received upadacitinib (**Table 2**). All patients regained control of their symptoms with treatment. Sex, whether

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

GCA was newly diagnosed at the onset of the clinical trial, cumulative prednisone dose in the year preceding baseline and disease duration did not predict relapse after TCZ withdrawal.

Conclusion: Nearly 50% of patients relapsed after treatment with 12 months of TCZ and 2 months of prednisone. The observed post-treatment relapse rate was similar to that reported in patients receiving TCZ in combination with longer GC tapers, suggesting that the amount and duration of GC treatment does not have a significant effect on the risk of relapse once TCZ is discontinued. Clinical trials to determine the optimal duration of TCZ treatment and assess different TCZ weaning strategies are needed.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0731–0764) Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Giant cell arteritis (GCA) is a large vessel vasculitis that predominantly affects older adults, with a higher prevalence in women. Previous studies exploring sex-related differences in clinical presentation have shown disparate results. The aim of this study was to analyze whether there are differences in the clinical presentation of GCA between men and women, stratified by age at diagnosis.

*Significant differences in bold ($p<0.05$).

Methods: ARTESER is a large Spanish multicenter epidemiological registry of GCA promoted by the Spanish Society of Rheumatology (SER*) in which 26 general hospitals participated. The recruitment period was between June 2013 and March 2019. Standardized data were included for all patients diagnosed with GCA in these centers, including demographic and clinical presentation. Age was artificially grouped into three categories (< 70, 70–80, and >80 years) to reflect the most frequent age range of presentation and to optimize the visualization of clinical patterns. This grouping also accounted for the relatively small number of patients in the youngest and oldest age groups. Differences between sexes were compared in a bivariate analysis. Statistical analysis was performed by using STATA statistical package, V.13.1 and SPSS version 21.0.

Results: A total of 1,675 patients with GCA were included in the study, of whom 1,178 were women and 497 men. Among patients younger than 70 years, men presented more frequently with visual symptoms (33.0% vs. 21.7%; p=0.038) and stroke events (7.7% vs. 1.9%; p=0.015) compared to women. In the 70-80 years group, men had a higher frequency of stroke (6.2% vs. 2.3%; p=0.013), dysphagia (7.2% vs. 2.5%; p=0.005), and transient ischaemic attacks (3.6% vs. 1.0%; p=0.024), whereas women showed a greater prevalence of polymyalgia rheumatica (46.3% vs. 33.0%; p=0.003). Weight loss was also more common among men (41.2% vs. 28.2%; p=0.001). No significant sex-based differences were observed in patients aged over 80 years. Results are shown in **Table 1**.

Conclusion: Sex-related differences in the clinical presentation of GCA were mainly observed in patients diagnosed before the age of 80. Men showed a higher frequency of cranial ischemic manifestations, such as visual symptoms and stroke, whereas women more frequently presented with polymyalgia rheumatica. These findings highlight the importance of considering both sex and age at diagnosis when assessing patients with suspected GCA.

Abstract Number: 0745

Prevalence and Clinical Significance of Low ESR and CRP in Giant Cell Arteritis: A Population Based Study

Eugenio de Miguel, Natalia López-Juanes, Maria-Eugenia Miranda-Carus, Carlota Ureta, Chamaida Plasencia-Rodríguez and Irene Monjo Henry, Hospital Universitario La Paz, Madrid, Spain

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0731–0764) Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Traditionally, elevated erythrocyte sedimentation rate (ESR) or C-reactive protein (CRP) had been considered a hallmark of GCA and both are included in the 2022 ACR/EULAR GCA classification criteria. However, emerging evidence indicates that a subset of patients even with biopsy-proven GCA may present with normal or low ESR levels. The identification and characterization of this subgroup of patients is essential to improve diagnostic accuracy and optimize the therapeutic management of GCA. The main objective of this study was to determine the prevalence of low ESR and CRP in GCA, and to investigate whether there are differences in clinical manifestations between patients with and without elevation of these acute phase reactants.

Methods: This is a retrospective population-based analysis including consecutive unselected GCA cases from a cohort diagnosed since 2017 with basal data of ESR or CRP. All patients underwent standardized bilateral ultrasound (US) of cranial arteries (common temporal artery and branches) and extra-cranial arteries (carotid, subclavian and axillary). Subtypes were classified as cranial, extra-cranial, or mixed based on vascular involvement identified by US and/or positron emission tomography (PET-CT). Demographic and clinical variables were extracted from clinical records and diagnosis required at least six months of clinical follow-up. Constitutional syndrome included weight loss, malaise, and fever. Patients included were without treatment or with less of two weeks of oral corticosteroid therapy.

Table 1: Clinical manifestations related with ESR and CRP

ESR	Sex female	Age Mean(±SD)	Headache	PMR	AION	Stroke	Jaw claudication	Fever	Constitutional syndrome	Major relapses	Minor relapses

Table 2: Influence of the acute phase reactants and the vascular subtype of GCA

	Isolated cranial			Mixed cranial and large vessel			Isolated large vessel		
ESR n (%)	All	ESR <50 mm/h	ESR≥50 mm/h	All	ESR <50 mm/h	ESR≥50 mm/h	All	ESR <50 mm/h	ESR≥50 mm/h
	109 (51.6%)	36 (42.3%)	73 (57.9%)	59 (28.0%)	23 (27.1%)	36 (28.6%)	43 (20.5%)	26 (30.6%)**	17 (13.5%)
CRP n (%)	All	CRP <10 mg/l	CRP≥10 mg/l	All	CRP <10 mg/l	CRP≥10 mg/l	All	CRP <10 mg/l	CRP≥10 mg/l
	108 (50.7%)	12 (44.4%)	96 (51.6%)	62 (29.1%)	10 (37.0%)	52 (28.0%)	43 (20.2%)	5 (18.5%)	38 (20.4%)
ESR or CRP n (%)	All	ESR <50 or CRP <10*	ESR≥50 or CRP≥10*	All	ESR <50 or CRP <10*	ESR≥50 or CRP≥10*	All	ESR <50 or CRP <10*	ESR≥50 or CRP≥10*
	117 (51.3%)	9 (33.3%)	108 (53.7%)	65 (28.5%)	11 (40.7%)	54 (26.9%)	46 (20.2%)	7 (25.9%)	39 (19.4%)

ESR=Erythrocyte sedimentation rate; CRP= C reactive protein ** p<0.01

Table 3: Sensitivity of acute phase reactants for diagnosis of GCA

Acute phase reactants combination	Sensitivity (%)
ESR ≥50 mm/h	59.7
CRP ≥10 mg/L	87.3
ESR ≥50 mm/h **or** CRP ≥10 mg/L	88.2
ESR ≥50 mm/h **and** CRP ≥10 mg/L	62.7

ESR=Erythrocyte sedimentation rate; CRP= C reactive protein

Results: A total of 228 cases were included (Table 1). 85/211 GCA patients had ESR below 50 mm/h (40.3%), 27/213 (12.7%) CRP below 10mg/L and 27/228 (11.8%) CRP or ESR below these ranges. Therefore, the sensitivity of acute phase reactants as isolated value for the diagnosis of GCA in our cohort was 59.7% for patients with ESR≥ 50 mm/h, 87.3% for patients with CRP≥ 10 mg/L, and 88.2% for patients with at least one of them elevated. Headache, stroke and fever were less frequent in patients with ESR< 50 ($p< 0.05$) and in patients with constitutional syndrome ($p< 0.01$), however polymyalgia rheumatica (PMR) was more frequent with ESR< 50 ($p< 0.01$). CRP ≥10 mg/L was significantly more frequent in patients with jaw claudication and constitutional syndrome ($p< 0.05$) and the presence of at least one acute phase reactant was significantly more frequent in patients with constitutional syndrome. Regarding the vascular subtype, a statistically significant difference was observed in the large vessel subtype, which was more frequent in patients with ESR < 50 mm/h ($p< 0.01$).

Conclusion: An ESR ≥50 mm/h showed lower sensitivity for the diagnosis of GCA (57.3%) compared to CRP ≥10 mg/L (87.3%) or the combination of elevated ESR or CRP (88.2%). Patients with low ESR values had a lower prevalence of headache, stroke, fever, and constitutional symptoms, but a higher frequency of polymyalgia rheumatica and the large-vessel vasculitis subtype. Similarly, lower CRP levels were associated with fewer ischemic and systemic symptoms, with significant differences observed in the frequency of jaw claudication and constitutional syndrome.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0731–0764) Vasculitis – Non-ANCA-Associated & Related Disorders Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Frailty, a syndrome associated with decreased physiologic reserve, is associated with adverse outcomes. The prevalence and impact of baseline frailty on the risk of mortality in patients with incident giant cell arteritis (GCA) and polymyalgia rheumatica (PMR) is unknown. The objective of this study was to describe the risk of mortality - stratified by frailty - among patients with GCA, PMR, and general population controls.

Methods: We conducted a retrospective cohort study using the US-based TriNetX electronic health records network. Adults ≥50 years with new-onset PMR or GCA were included if they had ≥2 ICD-9/10-CM codes, ≥1 year of prior follow-up, and a prednisone prescription within 30 days of the first code (index date). Matched general population control cohorts

Table 1: Demographic and Clinical Characteristics of Included Patients, n = 60,039

	Overall	PMR	General Population - PMR Comparators	GCA	General Population - GCA Comparators
Number of Patients	60,039	17,955	27,318	4,963	9,803
Age at Diagnosis, mean (SD)	69.5 (8.4)	71.2 (8.1)	67.3 (8.1)	71.7 (8.2)	71.5 (8.1)
Sex					
Male	20,672 (34.4%)	7,795 (43.4%)	8,656 (31.7%)	1,494 (30.1%)	2,727 (27.8%)
Female	39,367 (65.6%)	10,160 (56.6%)	18,662 (68.3%)	3,469 (69.9%)	7,076 (72.2%)

General Population - Non-Frail	337	34,563	9.8	Referent*
General Population - Frail	10	245	40.7	1.27 (0.67-2.42)
GCA Non-Frail	92	4,364	21.1	1.52 (1.20-1.92)
GCA Frail	23	216	106.6	2.91 (1.82-4.66)
PMR vs General Population, Stratified by Frailty Group				
General Population - Non-Frail	304	34,203	8.9	Referent*
General Population - Frail	43	606	71.0	3.04 (2.13-4.34)
PMR Non-Frail	183	16,444	11.1	0.96 (0.79-1.15)
PMR Frail	22	384	57.3	1.86 (1.17-2.96)

*Disease groups compared to their respective general population control groups

for PMR and GCA were constructed using 1:3 nearest-neighbor matching on the following variables: sex, race/ethnicity, regional location, birth year, year of cohort entry, and year of cohort exit. The exposure of interest was frailty as measured using a validated claims-based frailty index (CFI) during the year prior to the index date. Multivariable Cox proportional cause-specific hazard ratios (aHR) and 95% confidence intervals (CI) were calculated to assess the risk of mortality.

Results: Of 60,039 included patients, 17,955 had PMR, 4,963 had GCA, and 37,121 were matched controls. Compared to matched general population controls, the risk of death was elevated among patients with GCA (aHR 2.17, 95% CI 1.63-2.90) but not PMR (aHR 0.85, 95% CI 0.71-1.03). In the overall cohort, the risk of death was increased in pre-frail (aHR 2.45, 95% CI 2.03-2.96) and frail (HR 5.16, 95% CI 3.84-6.94) patients as compared to non-frail patients. In the stratified analysis, as compared to non-frail general population controls, the risk of death was not elevated for frail general population controls (aHR 1.27, 95% CI 0.67-2.42) but elevated for non-frail patients with GCA (aHR 1.52, 95% CI 1.20-1.92) and frail patients with GCA (aHR 2.91, 95% CI 1.82-4.66). In a stratified analysis, as compared to non-frail PMR general populations controls, the risk of death was elevated for frail general population controls (aHR 3.04, 95% CI 2.13-4.34) and frail

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

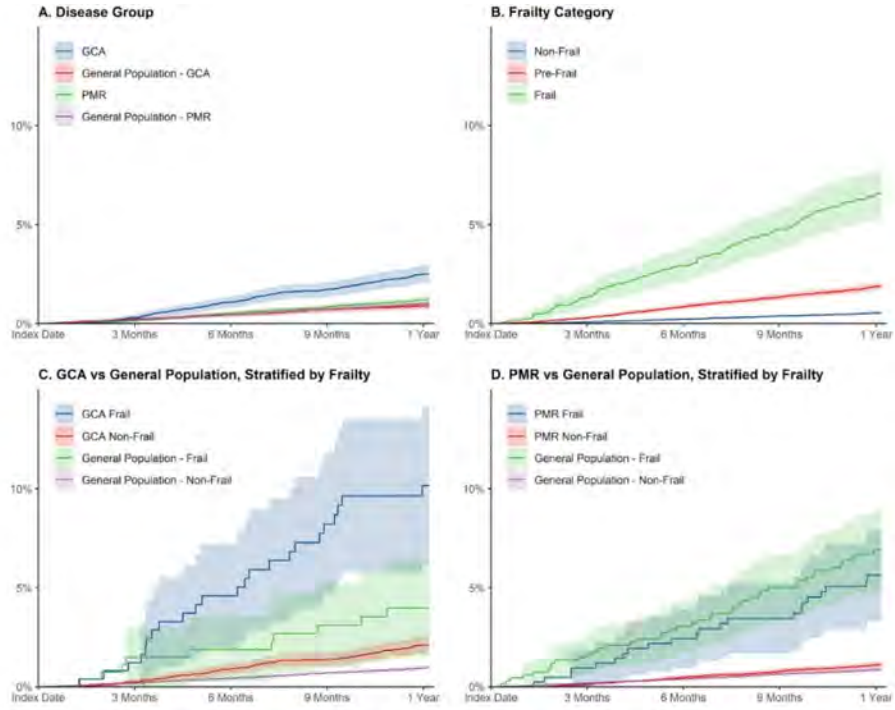

Figure 1: Cumulative incidence of mortality during the first year of therapy, stratified by (A) disease group, (B) frailty category, (C) dichotomized frailty category (frail vs. pre-frail and non-frail) among GCA and GCA controls, (D) dichotomized frailty category (frail vs. pre-frail and non-frail) among PMR and PMR controls

patients with PMR (aHR 1.86, 95% CI 1.17-2.96) but not for patients with PMR who were non-frail (aHR 0.96, 95% CI 0.79-1.15).

Conclusion: Both frailty and GCA were associated with an increased risk of mortality, but patients with PMR did not have an elevated risk of mortality unless they were also frail. Frailty in patients with GCA and PMR identifies a group of patients at risk for mortality and highlights the value of frailty assessment.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0731–0764) Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Macrophages play a central role in the pathogenesis of large-vessel vasculitides, including giant cell arteritis (GCA) and Takayasu's arteritis (TAK). Characterizing patterns of macrophage polarization induced by patient serum may uncover disease-specific immune signatures and therapeutic targets.

Methods: Purified monocytes from healthy donors were differentiated into macrophages (M0) using M-CSF and 10% fetal bovine serum for 4 days, followed by polarization toward M1 (IFNγ + LPS), M2a (IL-4 + IL-13), M2b (immune complexes + LPS), or M2c (IL-10 + dexamethasone) phenotypes. These in vitro-polarized macrophages served as the training dataset. Flow cytometry assessed CD40 (M1 marker), CD206 (M2a), HLA-DR (negative in M2b), and CD163 (M2c) expression. Macrophages exposed to serum from patients in remission with GCA (n=40), TAK (n=40), and healthy controls (HC, n=19) were analyzed (test samples).

Data were extracted from FlowJo™ workspaces using CytoML and flowWorkspace in R and arcsinh-transformed. A K-Nearest Neighbors (KNN) classifier (k=10) trained on M0–M2c macrophages predicted phenotypes in test samples. Uniform Manifold Approximation and Projection (UMAP) was used for visualization, using 250 cells/sample for training and test samples, and all available cells for other analysis. Group-level differences were assessed using Fisher's exact test, and per-sample differences with Mann–Whitney U tests.

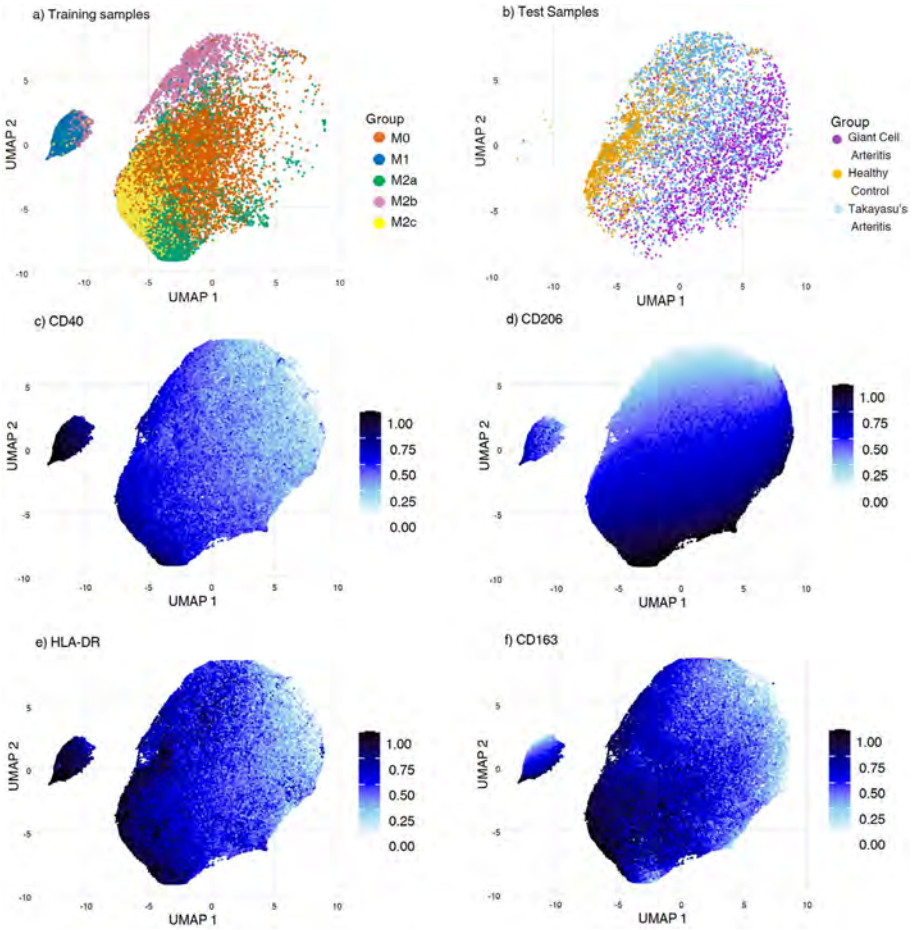

Figure 1: Uniform Manifold Approximation and Projection (UMAP) of training samples M0-M2c (a), test samples (b) and individual polarization markers (c-f).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

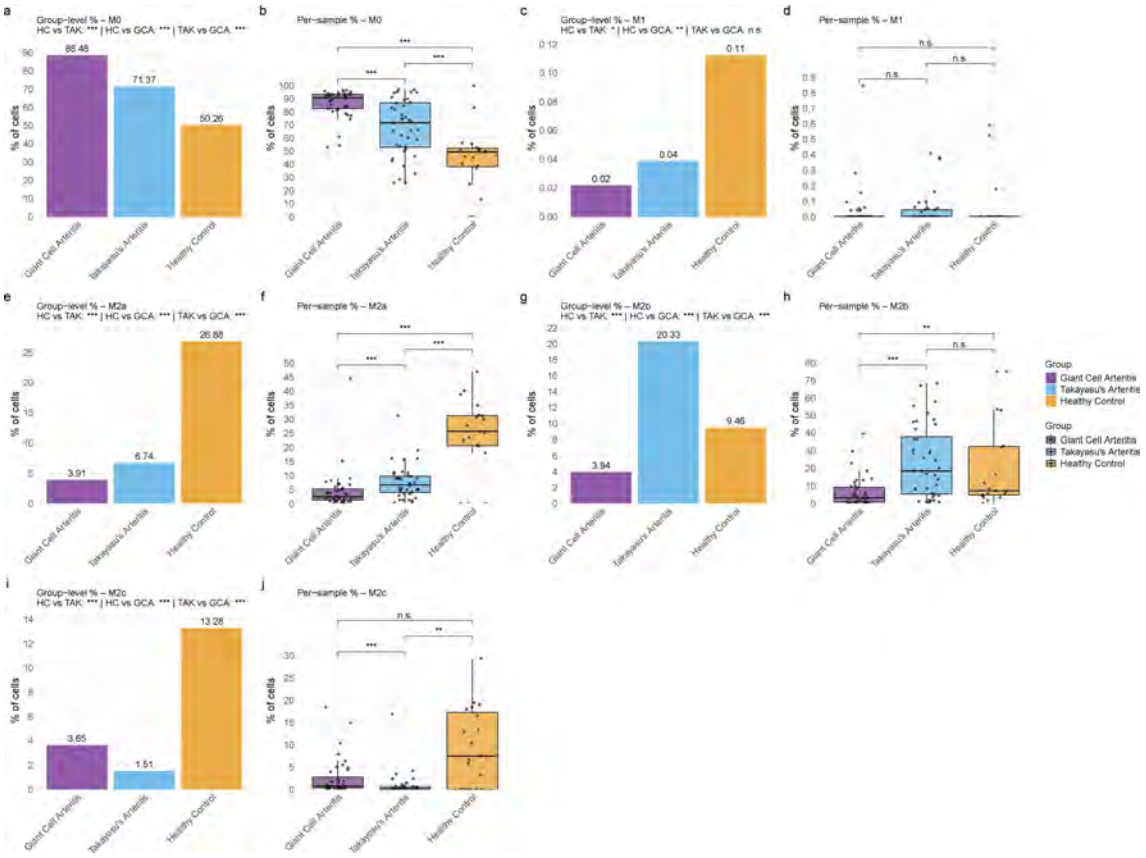

Figure 2: Percentage of each macrophage phenotype per group within all the cells of that group (a-c-e-g-i). Percentage of the median +/- inter-quartile range of each phenotype within each cell of the group (b-d-f-h-j). n.s. = non-significant; * = p-value < 0.05 – 0.01 ; ** = p-value < 0.01 – 0.001; *** = p-value < 0.001. GCA: giant cell arteritis; TAK: Takayasu's arteritis; HC: healthy control.

Results: UMAP visualization revealed distinct clustering patterns among groups. Macrophages exposed to HC serum formed a relatively compact cluster, while those exposed to serum from patients with GCA and TAK showed greater dispersion, especially TAK, indicating broader phenotypic heterogeneity (**Figure 1a-b**). Spatial distribution of individual polarization markers is shown through UMAP overlays (**Figure 1c-f**).

Quantitative analysis revealed that GCA samples retained the highest proportion of M0-like macrophages, followed by TAK, with HC showing the lowest. HC exhibited the highest proportions of M2a- and M2c-like macrophages, while TAK samples showed an increase in M2b-like macrophages. Despite tighter spatial clustering, HC macrophages polarized toward more varied phenotypes than the other groups (**Figure 2**). There were statistically significant differences among all groups, except for M1 between GCA and TAK. Although the proportion of M1 was negligible across all groups, HC showed a 6- and 4-fold increased prevalence compared to GCA and TAK, respectively.

Conclusion: Serum from patients with GCA and TAK induces distinct macrophage polarization profiles compared to HC. Serum in GCA maintains macrophages in an undifferentiated M0-like state, whereas serum in TAK promotes a modest M2b-skewed response associated with immune complex stimulation. In contrast, serum in HC predominantly favors regulatory and repair-associated macrophage phenotypes (M2a and M2c). These findings highlight macrophage phenotyping as a promising tool to uncover disease-specific immune dysregulation in large-vessel vasculitis.

Abstract Number: 0748

Does The Number Of Arteries Affected At The Disease Onset Predict Relapses Of Giant Cell Arteritis?

Iztok HOLC[1], Metka Koren Krajnc[2], Marko Gačnik[3] and Anja Lah[4], [1]University Medical Center Maribor, 2000 Maribor, Slovenia, [2]University Medical center, Maribor, Slovenia, [3]University Medical Center Maribor, Braslovče, Slovenia, [4]University Medical Center Maribor, Laporje, Slovenia

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0731–0764) Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Giant cell arteritis (GCA) is a chronic vasculitis where relapses frequently occur. The rates of relapses of GCA have not been defined by now.

We aimed to evaluate the factors associated with relapses in our cohort.

Methods: In 58 GCA patients the diagnosis was confirmed according to history, clinical signs, laboratory tests and ultrasound examination. Ultrasound of cranial, carotid and axillar arteries was performed in all participants. We collected data cross-sectionally at first evaluation and at the second evaluation 5 years later. Predictors of relapses were identified by logistic regression analysis.

Results: 58 GCA patients were included initially (62 % women, mean age 74 years). At the end 53 patients completed the study and their data have been analyzed. 2 (3,4%) patients died, 3 (5,1%) were lost (didn't show up on controls). All patients received glucocorticoid treatment (60mg of

prednisolone, or pulse treatment if the vision was impaired), during follow up 16 (30,1%) received leflunomide (non-biologic agent as steroid sparing drug), 16 (30,1%) tocilizumab (biologic agent).

Relapses occurred in 17 (33,3%) of patients. A Mann-Whitney U value of 0.46 and t test (Welch) indicates that the relationship between the number of affected arteries and the occurrence of relapses in GCA patients is weak or negligible. There were no association with relapse occurrences and the time to diagnosis (t-test value of 0.99, Mann-Whitney 0,62). Mann-Whitney U test 0,07 result provides stronger evidence for a relationship between CRP levels and relapse, while the t-test 0,12 suggests that the mean CRP difference at the time of diagnosis is not substantial enough to be considered clinically significant.

Conclusion: GCA relapses occurred in 33,3 % of patients. Relapses were not associated with number of affected arteries, with the value of CRP at the time of diagnosis or with the time to diagnosis

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0731–0764) Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: In clinical practice, ^{18}F-FDG PET-CT often reveals findings suggestive of polymyalgia rheumatica (PMR) in patients with giant cell arteritis (GCA) who lack symptoms or signs indicative of this condition. This study aimed to analyse the prevalence, characteristics, and clinical significance of subclinical PMR in patients with apparently isolated GCA.

Methods: This was a cross-sectional, single-centre study including consecutive patients with newly diagnosed, biopsy-proven GCA and no clinical features of PMR. All underwent ^{18}F-FDG PET-CT at diagnosis. FDG uptake was assessed at anatomical sites typically involved in PMR, including shoulders, sternoclavicular joints, acromioclavicular joints, hips, ischial tuberosities, greater trochanters, symphysis pubis enthesis, and cervical/lumbar interspinous bursae. Visual grading was performed by all raters using liver uptake as reference: 0 (no uptake), 1 (lower than liver), 2 (equal to or greater than liver).

Results: PET findings suggestive of PMR were identified in 57 of 99 patients (57.6%). The distribution of involved anatomical sites is shown in Table 1.

The proportion of patients meeting PET-based diagnostic criteria was 26.5% for the Leuven score (≥16), 17% for the Leuven/Groningen score (≥8), 74.0% for the Besançon score, 56.0% for the Yamashita criterion, 54.0% for the Saint-Étienne algorithm, and 42.0% for the Heidelberg algorithm.

Compared with patients with GCA without any evidence of PMR (neither clinical nor subclinical), those with subclinical PMR showed a greater frequency of involvement of the thoracic aorta (p=0.080), abdominal aorta (p=0.001), and supra-aortic

Table 1. Comparison of ^{18}F-FDG uptake across different anatomical sites between GCA patients with subclinical PMR and those with concomitant clinical PMR.

Location	Clinical PMR N=62	Subclinical findings of PMR N=57	P
Shoulders	54 (87%)	43 (75.4%)	0.102
Sternoclavicular joints	27 (43.5%)	14 (24.5%)	0.029
Acromioclavicular joints	14 (22.5%)	9 (16%)	0.349
Cervical interspinous bursae / process	27 (43.5%)	19 (33%)	0.253
Lumbar interspinous bursae / process	41 (66%)	21 (37%)	0.001
Hips	19 (31%)	6 (10.5%)	0.004
Greater trochanter / Trochanteric bursa	57 (92%)	44 (77%)	0.051
Ischial tuberosities	36 (58%)	29 (51%)	0.496
Symphysis pubis enthesis	7 (11%)	4 (7%)	0.534
Peripheral arthritis	13 (21%)	2 (3.5%)	0.005
Diffuse reactive bone marrow uptake in axial and appendicular skeleton	17 (27%)	9 (16%)	0.151

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

trunks (p=0.012). No differences were observed at diagnosis regarding cranial manifestations, severe ischaemic complications, intensity of systemic inflammation, or long-term outcomes, including relapse rates, glucocorticoid use and the need for steroid-sparing agents, or mortality.

Compared with patients with GCA and clinical PMR (n=62; see table 1), those with subclinical PMR showed lower frequencies of involvement of the sternoclavicular joints (p=0.029), lumbar interspinous bursae (p=0.001), hips (31% vs 10.5%, p=0.004), and peripheral arthritis (p=0.005). The proportion of patients requiring tocilizumab was also significantly lower in this group (29.8% vs 50%; p=0.025).

Conclusion: Subclinical PMR findings are detected by PET-CT in nearly 58% of patients with apparently isolated GCA, supporting the concept of a GCA–PMR spectrum. A substantial proportion fulfilled PMR diagnostic criteria across different PET-based scoring systems. Subclinical PMR was associated with more frequent large-vessel involvement and a distinct anatomical distribution. Its presence does not appear to influence long-term clinical outcomes.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0731–0764) Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Giant cell arteritis (GCA) is the commonest idiopathic systemic vasculitis in adults over 50 years of age. It can be associated with high morbidity. Diagnosis is typically made by clinical and laboratory assessment, supported by imaging or histopathology from a temporal artery biopsy. C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) are often used to help distinguish between cases and noncases, however between 4-10% of patients with active GCA have normal readings for both at the time of diagnosis. Furthermore, the sensitivity and specificity of both biomarkers are reduced following administration of glucocorticoids (GC), often given empirically to reduce the risk of visual loss. Fibrinogen has previously been studied for its role as a biomarker in polymyalgia rheumatica (PMR). Data support the usefulness of assessment of plasma fibrinogen in PMR diagnosis and management.

Methods: 65 patients with GCA or large vessel vasculitis (LVV) diagnosed between 2012 and 2024 were identified across three hospital sites in Dublin, Ireland; 42 of these were receiving GC at baseline. Data were retrospectively analysed from patients' electronic healthcare records. Blood values at baseline were identified for all, as well as during remission in 56 patients and during 22 flare episodes. The values for fibrinogen, CRP and ESR were analysed in comparison with 38 patients who attended with suspected GCA, but in whom an alternative diagnosis was made following rheumatologist

Area Under the ROC Curve – GCA vs non-GCA, steroid naïve only

Test Result Variable(s)	Area	Std. Error[a]	Asymptotic Sig.[b]	Asymptotic 95% Confidence Interval Lower Bound	Upper Bound
Fibrinogen	.741	.074	.001	.596	.886
CRP	.676	.074	.018	.530	.822
ESR	.725	.073	.002	.582	.868

Receiver-Operator Curves for the performance of CRP, ESR and fibrinogen in discriminating between steroid-naive individuals with and without GCA

Cutoff	Fibrinogen >4.7g/L	Fibrinogen >4.7g/L, excluding GC	ESR >54mm/hr	ESR >54mm/hr, excluding GC	CRP >42mg/L	CRP >42mg/L, excluding GC
Sensitivity	40%	62.9%	47.5%	69.7%	42.1%	63.6%
Specificity	81.5%	81.5%	65.6%	65.6%	76.3%	76.3%
Positive Predictive Value	81%	70.8%	77.6%	67.6%	79.5%	70%
Negative Predictive Value	40.7%	75.6%	33.3%	67.7%	37.7%	70.7%

Performance of fibrinogen, ESR and CRP at optimal cut-off values in diagnosis of GCA

assessment. Sensitivity and specificity were calculated for all three biomarkers, with adjustments made for whether patients were exposed to GC prior to blood collection at baseline. Receiver-Operator Curves (ROC) were generated for all three biomarkers, with an area-under-the-curve (AUC) calculated for each. The ROC were used to identify optimal cut-off values for fibrinogen, CRP and ESR.

Results: When individuals on GC at baseline were included, the mean fibrinogen level for patients with GCA was 4.64g/L, compared with 4.27g/L in individuals without GCA (p=0.198); mean ESR for patients with GCA was 52.5mm/hr compared with 44.8mm/hr (p=0.265) and mean CRP was 48.8mg/L compared with 42.4mg/L (p=0.56). When individuals on GC at baseline were excluded, the mean fibrinogen level for patients with GCA rose to 5.45g/L, compared with 4.27g/L in non-cases (p=< 0.001), mean ESR rose to 68.4mm/hr compared with 44.8mm/hr (p=0.03) and CRP to 68.8mg/L, compared with 42.4mg/L (p=0.071). In identifying flares, all three biomarkers perform comparably. Fibrinogen >4g/L had a sensitivity of 78.6% and specificity of 96%, CRP >5mg/L had a sensitivity of 95.2% and specificity of 74.5%, and ESR >20mm/hr had a sensitivity of 90% and specificity of 82%.

Conclusion: Fibrinogen may have a role in the diagnosis of GCA. The sensitivity of fibrinogen is substantially reduced by the introduction of GC prior to blood collection, as is that of CRP and ESR. Fibrinogen set at a cut-off value of 4.7g/L has comparable sensitivity and specificity for the presence of active GCA when adjusted for GC exposure, when compared with CRP and ESR. Fibrinogen may also be used in the detection of GCA flares, with lower sensitivity but greater specificity than ESR or CRP.

Abstract Number: 0751

Impact of Treatment with Upadacitinib on Biomarkers Identified by Proteomics in Giant Cell Arteritis

Lisa Christ[1], Shalina Taylor[2], Yilin Xu[2], Rhiya Sharma[2], Thierry Sornasse[2], Yingtao Bi[2], Heath Guay[2], Arathi Setty[3], Ana Romero[4], Peter Merkel[5], Eugenio de Miguel[6], Christian Dejaco[7] and Cornelia Weyand[8], [1]Department of Rheumatology and Immunology, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland., Bern, Switzerland, [2]AbbVie Inc, North Chicago, [3]AbbVie Inc, North Chicago, IL, [4]AbbVie, Barcelona, Spain, [5]University of Pennsylvania, Philadelphia, PA, [6]Hospital Universitario La Paz, Madrid, Spain, [7]Medical University of Graz, Department of Rheumatology, Graz, Austria; Department of Rheumatology, Hospital of Brunico (SABES-ASDAA), Brunico, Italy, [8]Division of Rheumatology, Department of Internal Medicine, Mayo Clinic, Rochester

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0731–0764) Vasculitis – Non-ANCA-Associated & Related Disorders Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Interleukin-6 (IL-6) and interferon-gamma (IFNγ) have been identified as key drivers in the pathogenesis of giant cell arteritis (GCA), that promote disease progression. The phase 3 SELECT-GCA study showed that upadacitinib (UPA), a Janus Kinase inhibitor, was efficacious in treating GCA with a favorable benefit-risk profile compared to placebo (PBO). This study evaluated the impact of UPA on immune mediators in GCA, including IL-6 and IFNγ pathways, in the SELECT-GCA study.

Methods: Patients from SELECT-GCA were included in this analysis, termed "Biomarker Cohort": PBO n =72/112; UPA 15 mg daily (UPA15), n =141/209. UPA15 patients underwent GC tapering over 26 weeks, while PBO patients underwent GC tapering over 52 weeks. Plasma samples were collected at baseline and weeks 2, 12, 24, and 52. A multiplexed assay platform designed for targeted detection and quantification of 45 immune related proteins was used, with significant differences identified in 30 proteins. IL-6 and IFNγ pathway proteins were assessed. A mixed model for repeated measures was used to compare biomarkers between UPA and PBO as well as to analyze treatment response and non-response. The least-square mean biomarkers between UPA and PBO were contrasted, and significant pharmacodynamic markers had a false discovery rate (FDR) ≤ 0.05.

Results: This analysis focused on proteins in the IL-6 and IFNγ pathways, core pathogenic dysregulated biomarkers in GCA. UPA significantly reduced IL-6 levels compared to PBO (Figure 1). This reduction was more pronounced in responders versus non-responders in UPA. Circulating IFNγ increased with UPA; however, IFNγ-modulated chemokines CXCL9, CXCL10, and CXCL11 decreased significantly with UPA and tended to increase with PBO (Figure 2). UPA reduced IL-18, amplifying the effect of IFNγ on CXCL9, CXCL10, and CXCL11. No significant difference was seen for these cytokines when comparing responders and non-responders to UPA. CCL7 was significantly reduced with UPA versus PBO; however, when comparing responders to non-responders with UPA, the difference was not significant by FDR. With PBO, levels of IL-6, CCL7, CXCL9, and CXCL10 progressively increased throughout the study, with no apparent reduction below baseline levels for CXCL11 and IL-18.

Conclusion: Treatment of GCA with UPA15 inhibits essential immune pathways implicated in GCA pathogenesis, including IL-6 and downstream proteins of IFNγ (CXCL9, CXCL10, CXCL11, IL-18). This reduction in activity of the IFNγ pathway is indicative of a decrease in T-helper 1 cytokines due to treatment with UPA. Although CCL7 is not considered a primary disease driver, its decrease with UPA treatment aligns with cytokines associated with disease activity. UPA's molecular effect was observed as early as week 2, suggesting rapid onset of action. While the primary focus was on IL-6 and IFNγ proteins

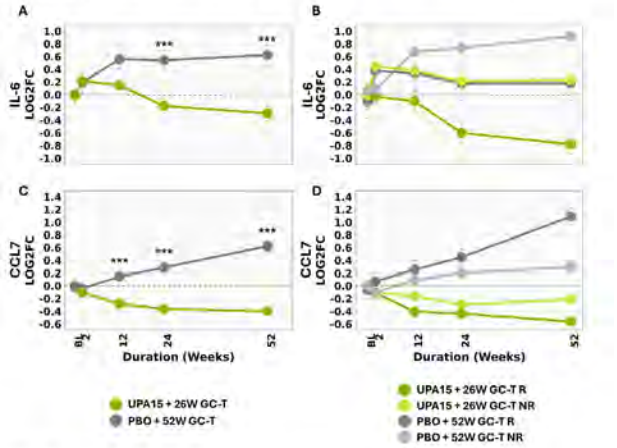
Figure 1: Levels of (A, B) Interleukin-6 and (C, D) Chemokine (C-C Motif) Ligand 7 in Patients with Giant Cell Arteritis Undergoing Upadacitinib Treatment Versus Placebo in the SELECT-Giant Cell Arteritis Trial



***P< .001

Pharmacodynamic profiles of IL-6, and CCL7 are depicted with data collected at BL and then weeks 2, 4 12, 24, and 52 comparisons between PBO and UPA treatment (A and C) as well as comparing responders (R) and non-responders (NR) (B and D). UPA 15mg treated patients completed a 26-week GC taper (T), compared to a 52-week GC taper in the PBO group. There was a significant difference observed between responders and non-responders for IL-6 (B) but not CCL7 (D) after FDR correction. The mixed model for repeated measures was employed to evaluate temporal changes in protein levels providing pharmacodynamic behavior over the study period, with an FDR of ≤ .05.

Figure 2: Impact of Treatment of Giant Cell Arteritis with Upadacitinib on the Interferon Gamma Pathway: (A, B) Interferon Gamma; (C,D) C-X-C Motif Chemokine Ligand 9; (E,F) C-X-C Motif Chemokine Ligand 10; (G,H) C-X-C Motif Chemokine Ligand 11; (I,J) Interleukin-18

***P< .001

Pharmacodynamic profiles of IFNγ, CXCL9, CXCL10, CXCL11, and IL-18 are depicted with data collected at BL and then weeks 2, 4, 12, 24, and 52 comparisons between PBO and UPA treatment (A, C, E, G, I) as well as comparing response groups (B, D, F, H, J). UPA 15mg treated patients completed a 26-week GC taper, compared to a 52-week GC taper in the PBO group. There were no observed significant differences between treatment response groups for all proteins presented in this analysis. The mixed model for repeated measures was employed to evaluate temporal changes in protein levels providing pharmacodynamic behavior over the study period, with an FDR of ≤ .05.

due to their roles in GCA biology, other modulated biomarkers warrant investigation to further characterize UPA's effect. UPA's clinical activity in GCA relates partly to its impact on IL-6, IFNγ pathway proteins, and CCL7, suggesting the efficacy of UPA for GCA is related to modulation of these cytokines.

segments of the aorta, potentially leading to pulse loss and limb claudication. Polymyalgia rheumatica (PMR) is a disease characterized by pain and stiffness in the cervical region and/or the shoulder and/or pelvic girdles (2). Approximately, 50% of patients with GCA also present with PMR (3).

The aim of this study was to define the clinical, analytical and imaging characteristics, as well as the factors associated with PMR in patients with GCA.

Methods: The ARTESER study (Arteritis of the Spanish Society of Rheumatology), promoted by the Spanish Society of Rheumatology, is a longitudinal observational study based on a review of clinical records of patients diagnosed with GCA between June 1, 2013, and March 29, 2019, in 26 hospitals of the Spanish National Health System. Sociodemographic, clinical, analytical, and imaging variables at diagnosis were collected. Additionally, treatment and outcome variables were recorded at the end of follow-up.

Patients with and without PMR were compared through a bivariate analysis. To identify potential factors associated with PMR, a multivariate logistic regression model was performed. Statistical significance set at $p< 0.05$.

Results: A total of 1,527 patients with GCA were included in the analysis, of whom 43.6% presented with PMR at the time of diagnosis (Table 1).

When comparing patients with and without PMR at diagnosis, it was observed that patients with PMR had a higher proportion of women, were younger, and had a longer duration of symptoms ($p< 0.05$). Regarding comorbidities, patients with PMR showed lower rates of smoking and a higher frequency of osteoporosis. They also more frequently presented scalp hypersensitivity, jaw claudication, and constitutional syndrome ($p< 0.05$).

Regarding treatment, the initial dose of corticosteroids at diagnosis was lower in patients with PMR ($p< 0.001$).

When evaluating outcomes, patients with PMR experienced more relapses, with minor relapses being particularly more frequent in this group ($p=0.024$).

In the multivariate analysis, factors associated with PMR were longer symptom duration at diagnosis, the presence of jaw claudication, asthenia, and synovitis. Conversely, the initial dose of glucocorticoids was associated with a lower risk of PMR (Table 2).

Conclusion: Patients with GCA and PMR present a longer duration of symptoms at diagnosis, higher prevalence of osteoporosis, scalp hypersensitivity, jaw claudication, constitutional syndrome, cranial phenotype and a lower initial corticosteroid dose. Factors associated with PMR included longer symptom duration, jaw claudication, asthenia and synovitis, while the initial corticosteroid dose was associated with a lower risk of PMR.

Abstract Number: 0753

Incidence of Ischemic Vision Loss Among Patients with Polymyalgia Rheumatica and Giant Cell Arteritis

Mary Peng[1], Kylie Carlson[2], Sebastian E Sattui[3] and Michael Putman[4], [1]Medical College of Wisconsin, Wauwatosa, WI, [2]Medical College of Wisconsin, Milwaukee, WI, [3]Division of Rheumatology and Clinical Immunology, University of Pittsburgh, Pittsburgh, PA, [4]The Medical College of Wisconsin, Milwaukee, WI

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0731–0764) Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Ischemic vision loss affects up to one quarter of patients with giant cell arteritis (GCA). The incidence of ischemic vision loss among patients with isolated polymyalgia rheumatica (PMR) is poorly defined. This study aimed to quantify the risk of ischemic vision loss among patients with PMR, GCA, and matched population controls.

Methods: We conducted a retrospective cohort study using the US-based TriNetX electronic health records network. Adults ≥50 years were included if they had ≥2 ICD-9/10-CM codes for GCA or PMR, ≥1 year of prior follow-up, and a prednisone prescription within 30 days of their first diagnostic code. Matched general population control cohorts for PMR and GCA were constructed using 1:3 nearest-neighbor matching on the following variables: sex, race/ethnicity, regional location, birth year, year of cohort entry, and year of cohort exit. The primary outcome was ischemic vision loss, which was defined by ICD-9/10 codes for ischemic optic neuropathy and retinal artery occlusion. Multivariable Cox proportional cause-specific adjusted hazard ratios (aHR) and 95% confidence intervals (CI) were calculated to define the risk of ischemic vision loss.

Table 1: Demographic and Clinical Characteristics of Included Patients, n = 56,899

	Overall	PMR	General Population - PMR Controls*	GCA	General Population - GCA Controls*
Number of Patients	56,899	16,001	31,113	3,054	6,731
Median Follow-Up Time	3.39 [1.4-6.2]	3.69 [1.7-6.5]	3.21 [1.1-6.0]	3.39 [1.5-6.1]	3.52 [1.5-6.3]
Age at Diagnosis, mean (SD)	70.0 (8.4)	71.1 (8.1)	69.0 (8.5)	71.3 (8.0)	71.1 (8.3)
Sex					
Male	21,797 (38.3%)	7,036 (44.0%)	11,958 (38.4%)	882 (28.9%)	1,921 (28.5%)

Results: Of 56,899 patients, 16,001 had PMR, 3,054 had GCA, and 37,844 were matched controls. Median follow-up time was 3.4 years (interquartile range, 1.4-6.2). The incidence of ischemic vision loss over the entire follow-up period (10 years) was highest for GCA (9.2 per 1,000 person-years) followed by PMR (1.7 per 1,000 person-years), GCA controls (1.5 per 1,000 person-years), and PMR controls (1.4 per 1,000 person-years). Ischemic vision loss was increased in GCA as compared to PMR (aHR 5.36, 95% CI 4.09–7.02) and GCA as compared to matched-controls (aHR 5.69, 95% CI 3.95–8.18). No significant differences were observed for PMR as compared to matched controls (aHR 1.10, 95% CI 0.86–1.41). Sensitivity analyses over the first one year and the first 5 years of therapy supported the primary analyses.

Conclusion: In this large retrospective cohort study, patients with PMR had no increased risk of ischemic vision loss as compared to the general population or to patients with GCA. In contrast, patients with GCA were significantly more likely to suffer ischemic vision loss. These findings support the current approach of ophthalmology referral for patients with GCA and screening by symptoms alone for PMR.

Table 2: Unadjusted Incidence of Ischemic Vision Loss Among Included Patients, n = 56,899

Analysis	Events	Follow Up Time	Incidence / 1000py
Total Follow Up			
PMR	113	65,673	1.7
General Population (PMR)	158	116,755	1.4
GCA	111	12,022	9.2
General Population (GCA)	41	27,140	1.5
One Year Outcomes			
PMR	21	14,774	1.4
General Population (PMR)	32	25,581	1.3

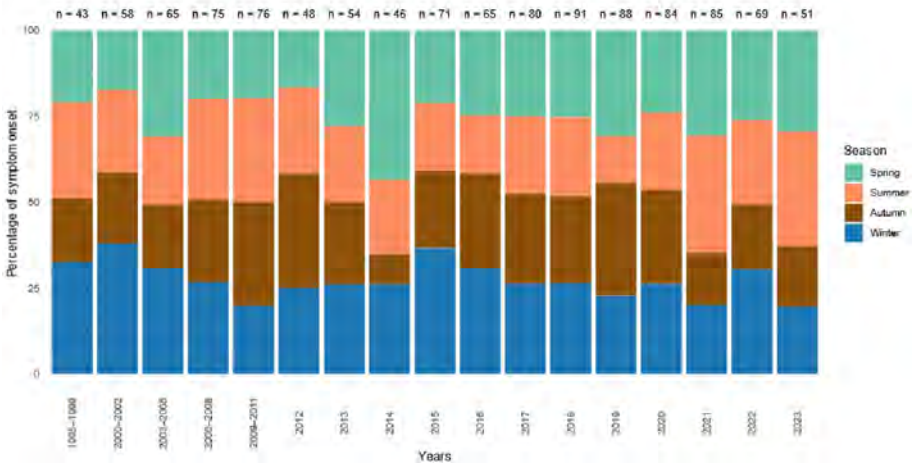
*Sensitivity analysis p values corrected by Bonferroni Holms correction

Figure 1. Seasonal Distribution of Symptoms Onset



Background/Purpose: Whether the disease onset in giant cell arteritis (GCA) exhibits a seasonal pattern remains unclear. Previous studies have yielded conflicting evidence: some report no seasonality, while others suggest seasonal variation, though findings are inconsistent and difficult to compare, especially due to methodological limitations, including small cohort sizes and reliance on diagnosis or biopsy dates rather than symptoms onset. We aimed to clarify whether a seasonal pattern exists by analyzing a large cohort using the date of symptom onset as the temporal reference.

Methods: Consecutive patients from a large German monocentric GCA cohort in Berlin-Buch (1994–2024) with a documented date of symptom onset were included. To ensure balanced seasonal representation, patients with symptom onset outside the period of December 1, 1994, to November 30, 2023, were excluded. Meteorological seasons were used for the analysis (spring: Mar–May; summer: Jun–Aug; autumn: Sep–Nov; winter: Dec–Feb). To assess whether symptom onsets were equally distributed across seasons (25% per season), we applied an exact multinomial test using the "ExactMultinom" package in R. Sensitivity analyses were performed for subgroups by sex and clinical phenotype (cranial vs extracranial involvement), with Bonferroni-Holm correction for multiple testing.

Results: Of 1203 patients in the full cohort, 1149 fulfilled the inclusion criteria and were included in the main analysis (population's characteristics are reported in Table 1). The overall seasonal distribution of symptom onset was: spring 292 (25.4%), summer 276 (24.0%), autumn 271 (23.6%), winter 310 (27.0%) (p = 0.36). Figure 1 illustrates the seasonal distribution of symptom onset stratified by years across the study period. Subgroup analyses revealed no overall significant seasonal variation as shown in Table 2.

Conclusion: This large, single-center cohort study using symptom onset data found no evidence of a significant seasonal pattern in the disease onset of GCA patients.

Abstract Number: 0755

Sex Differences in Subtypes of Vascular Involvement and Clinical Manifestations in Giant Cell Arteritis

Natalia Lopez Juanes, Carlota Ureta, Irene Monjo Henry, Maria-Eugenia Miranda-Carus, Chamaida Plasencia-Rodríguez and Eugenio de Miguel, Hospital Universitario La Paz, Madrid, Spain

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0731–0764) Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Recognizing gender-specific differences in diseases is critical to improve diagnostic and therapeutic strategies. Giant cell arteritis (GCA) has been traditionally considered a predominantly female disease, but this predominance may be declining with new classification criteria and advanced imaging. While gender-related differences in cranial and extra-cranial GCA phenotypes have been observed, most studies have focused mainly on clinical patterns. The objective of this study is to assess gender-specific differences in GCA clinical presentation, particularly patterns of vascular involvement, age at diagnosis and clinical manifestations.

Methods: This is a retrospective population-based study including consecutive unselected GCA cases from a cohort diagnosed since 2017. Standardized bilateral ultrasound (US) of cranial arteries (common temporal artery and branches) and extra-cranial arteries (carotid, subclavian, axillary) were performed in all patients. Subtypes were categorized as cranial, extracranial, or mixed according to the pattern of vascular involvement identified by ultrasound (US) and/or positron emission tomography-computed tomography (PET-CT). Demographic and clinical data were obtained from medical records, and a confirmed diagnosis required a minimum of six months of clinical follow-up.

Results: A total of 249 GCA cases (table 1) were analyzed (mean age 78.9±8.3 years, range 58–105), with 134 females (53.8%). Cranial involvement was present in 195/249 cases (78.3%), significantly more common in males (84.3%) than females (73.1%, p=0.03). Large vessel involvement was detected in 128/249 patients (51.4%) without significant sex differences (56.5% males vs. 47.0% females, p=0.16)

Table 1: Sex, age and subtypes of GCA.

Sex	Cases	Age (mean±SD)	Subtype of GCA		
			Isolated cranial	Mixed	Isolated large vessel
All	249	78.9±8.3	121 (48.6%)	74 (29.7%)	54 (21.7%)
Female (F)	132 (53.4%)	78.6±8.5	71 (53.0%)	27 (20.1%)	36 (26.9%)*
Male (M)	115 (46.6%)	79.4±8.1	50 (43.5%)	47 (40.9%)**	18 (15.7%)

* = p < 0.05, ** = p < 0.01 between males and females.

		F	21 (77.8%)*	13 (48.1%)	6 (22.2%)	5 (18.5%)	7 (25.9%)	5 (18.5%)	10 (37.0%)	2 (7.4%)	12 (44.4%)	2 (7.4%)	10 (37.0%)
		M	20 (42.6%)	24 (51.1%)	7 (14.9%)	5 (10.6%)	6 (12.8%)	10 (21.3%)	10 (21.3%)	2 (4.3%)	19 (40.4%)	4 (8.5%)	17 (36.2%)
	Isolated large vessel	All	22 (40.7%)	36 (66.7%)	3 (5.6%)	1 (1.9%)	5 (9.3%)	15 (31.5%)	14 (25.9%)	3 (5.6%)	20 (37.7%)	6 (11.3%)	17 (32.1%)
		F	16 (44.4%)	22 (61.1%)	3 (8.3%)	0 (0%)	4 (11.1%)	11 (36.1%)	11 (30.6%)	1 (2.8%)	15 (42.9%)	5 (14.3%)	12 (34.2%)
		M	6 (33.3%)	14 (77.8%)	0 (0%)	1 (5.6%)	1 (5.6%)	4 (22.2%)	3 (16.7%)	2 (11.1%)	5 (27.8%)	1 (5.6%)	5 (27.8%)

* = $p < 0.05$, ** = $p < 0.01$ between males and females.

Analysis by subtype showed isolated cranial involvement in 121 patients (48.6%), isolated large vessel vasculitis in 54 (21.7%), and mixed patterns in 74 (29.7%). Significant sex differences were observed: mixed pattern was more frequent in males (40.9% vs. 20.1%, $p< 0.01$), while isolated large vessel vasculitis was more common in females (26.9% vs. 15.7%, $p=0.03$). Isolated cranial involvement was also more frequent in females, though not statistically significant.

No significant age differences were found between sexes (78.6±8.5 years in females vs. 79.4±8.1 in males) or within vascular subtypes. Clinical manifestations (table 2) were generally more common in women, with significant differences in headache ($p< 0.01$) and jaw claudication ($p=0.04$). Women also tended to present more relapses, though this did not reach statistical significance.

Conclusion: GCA shows only a mild female predominance (53.6%). Important sex differences exist in vascular involvement patterns: cranial involvement was more common in males, isolated large vessel vasculitis more frequent in females, and mixed patterns predominated in males ($p< 0.01$). Age at diagnosis did not differ between sexes. Women tended to present significantly more headache ($p< 0.001$) and jaw claudication ($p=0.04$). These findings highlight the need for sex-specific considerations in the diagnosis and management of GCA.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0731–0764) Vasculitis – Non-ANCA-Associated & Related Disorders Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: In giant cell arteritis (GCA) and Takayasu arteritis (TA), strokes occur in approximately 7.4% and 15.8% of cases, respectively. Although these two large-vessel vasculitides share similarities, stroke presentation may differ in terms of clinical and radiological characteristics. This study aimed to compare the epidemiological, clinical, and prognostic features of stroke in patients with GCA and TA

Methods: This was a multicenter retrospective cohort study conducted in France, including patients meeting the 2022 ACR/EULAR classification criteria for GCA and either the 2022 ACR/EULAR criteria or modified Ishikawa criteria for TA. Eligible patients had at least one stroke confirmed by imaging, occurring either at the time of or within 4 weeks of vasculitis flare.

Results: A total of 108 patients (68 with GCA and 40 with TA) were analyzed. The female-to-male ratio was 0.78 in GCA and 5.2 in TA ($p< 0.001$). The mean age at stroke onset was 76+/-9 years in GCA and 35±10 years in TA ($p< 0.001$).

At the time of stroke, cardiovascular risk factors in GCA versus TA were as follows: overweight (22.4% vs. 10.3%, p=0.174), obesity (7% vs. 2.6%, p=0.645), smoking (40.9% vs. 39.4%, p=0.885), hypertension (64.7% vs. 32.4%, RR=1.99, p=0.003), dyslipidemia (36.8% vs. 8.8%, RR=4.2, p=0.002), and diabetes (14.7% vs. 2.9%, p=0.095).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Stroke occurred at the time of vasculitis diagnosis in 95.6% of GCA cases and 81.1% of TA cases (RR=1.18, p=0.031). All strokes were ischemic. The initial clinical presentation in GCA versus TA included motor deficits (47.1% vs. 30%, p=0.207), sensory deficits (14.7% vs. 16.7%, p=0.754), ophthalmologic symptoms (39.7% vs. 34.2%, p=0.677), cerebellar syndrome (29.4% vs. 0%, p=0.001), cranial nerve involvement (19.7% vs. 0%, p=0.017), language impairment (41.2% vs. 12.5%, RR=3.3, p=0.012), and neurosensory disturbances (55.9% vs. 18.4%, RR=3.04, p< 0.001).

Strokes involved the carotid territory in 35.3% of GCA cases and in 79.5% of TA cases (RR=0.44, p< 0.001) while the vertebrobasilar territory was involved in 75% of GCA cases and 20.5% of TA cases (RR=3.7, p< 0.001). Stroke recurrence occurred in 14.7% of GCA cases and 7.5% of TA cases (p=0.364), with a median recurrence time of 6 months (IQR: 1–10 months) after the initial stroke. Vascular surgery was required in 6% of GCA cases and 41% of TA cases (RR=0.14, p< 0.001). The mean follow-up duration was 5 ± 6.1 years, with mortality rates of 14.5% in GCA and 5% in TA (p=0.194). The survival curve for both groups is presented in Figure 1.

In multivariate analysis excluding age, independent factors associated with TA diagnosis were the absence of dyslipidemia (OR=0.085, p=0.035), carotid territory involvement (OR=13.7, p=0.003), and the need for vascular surgery (OR=10.6, p=0.009).

Conclusion: Stroke presentation differs between GCA and TA. In GCA, strokes predominantly affect older individuals with cardiovascular risk factors and mainly involve the vertebrobasilar territory. While in TA, carotid involvement is more frequent and often necessitates vascular intervention. These clinical and prognostic differences are crucial for optimizing patient management

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0731–0764) Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Giant cell arteritis (GCA) is the most common large-vessel vasculitis, and its cornerstone treatment is the use of corticosteroids (CS). Various therapies have been proposed as CS-sparing agents, with methotrexate (MTX) being the only conventional synthetic drug that has received favorable recommendations in clinical practice guidelines. However, results from clinical trials and observational studies have been inconsistent. The aim of this study was to evaluate the role of MTX added to standard CS therapy in facilitating CS withdrawal in real-world clinical practice, by analyzing data from the Spanish national ARTESER registry.

Table 1. Baseline clinical and treatment characteristics at the time of GCA diagnosis, stratified by MTX use (CS monotherapy vs CS+MTX).

	CS monotherapy N=615	CS+MTX N=270	p value
Female sex, n (%)	405 (65.85%)	202 (74.81%)	**0.008**
Age at diagnosis (years), mean (SD)	77.97 (7.83)	75.72 (7.94)	**<0.001**
Symptoms duration (months), median [IQR]	1.05 [0.46 - 2.54]	1.48 [0.69 - 3.05]	**0.004**
ACR 2022 classification criteria, n (%)	575 (93.50%)	248 (91.85%)	0.378
Clinical manifestations, n (%)			
New-onset headache	487 (79.71%)	205 (76.21%)	0.244
Temporal artery tenderness or reduced pulse	315 (55.46%)	119 (47.41%)	**0.033**
Scalp tenderness	164 (31.60%)	76 (31.28%)	0.929
Jaw claudication	207 (36.06%)	90 (33.96%)	0.554
Visual symptoms	245 (40.97%)	78 (29.21%)	**0.001**
Polymyalgia rheumatica	222 (38.68%)	122 (46.04%)	**0.044**
Fever	123 (22.57%)	69 (27.38%)	0.14
Risk factors, n (%)			
Smoking status			
Current smoker	48 (8.35%)	16 (6.40%)	
Former smoker (>1 year)	124 (21.57%)	49 (19.60%)	0.461
Never smoker	403 (70.09%)	185 (74.00%)	
Treatment			
Corticosteroids			
Oral, n (%)	612 (99.51%)	270 (100.00%)	0.25
Intravenous, n (%)	145 (23.58%)	71 (26.30%)	0.386
Mean initial CS dose at diagnosis, mean (SD)	638.81 (1319.08)	507.26 (1152.04)	0.156
Cumulative CS dose, mean (SD)	7555.35 (4846.31)	8865.47 (4645.97)	**<0.001**
Methotrexate			
Initial MTX dose, n (%)			
<=10 mg/week	-	182 (67.41%)	-
>10 y <=15 mg/week	-	69 (25.56%)	-
>15 mg/week	-	19 (7.04%)	-

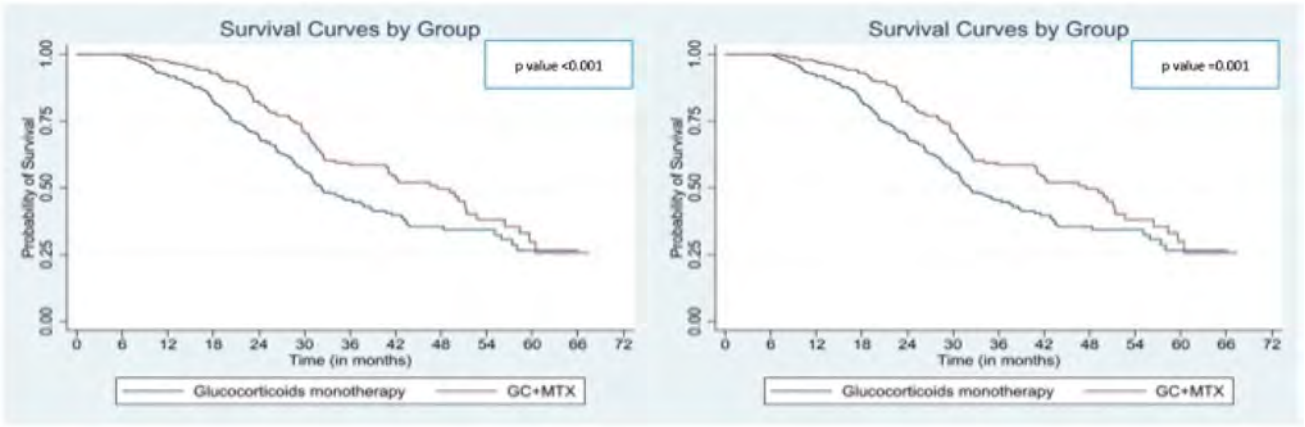

Figure 1. Kaplan-Meier survival curves: a) CS discontinuation and b) CS-free sustained remission (last 6 months).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 2. Multivariable Cox regression models (parsimonious models).

	Hazard Ratio (HR)	95% CI	p-value
CS discontinuation			
CS+MTX (Ref. CS monotherapy)	0.563	0.434 - 0.732	**<0.001**
Female sex (Ref. male)	0.750	0.583 - 0.963	**0.024**
Extracranial manifestation	1.387	0.916 - 2.098	0.122
Positive temporal artery biopsy	0.774	0.604 - 0.992	**0.043**
CS free-sustained remission (last 6 months)			
CS+MTX (Ref. CS monotherapy)	0.724	0.533 - 0.983	**0.039**
Female sex (Ref. male)	0.696	0.515 - 0.942	**0.019**
Smoker (Ref. never smoker)	1.581	0.955 - 2.618	0.075
Time from symptoms onset until diagnosis (months)	0.959	0.911 - 1.010	0.113
New-onset headache	0.668	0.481 - 0.926	**0.015**
Visual symptoms	0.784	0.568 - 1.083	0.140

Methods: Descriptive, observational, multicenter study of patients diagnosed with GCA undergoing treatment with corticosteroids in real-life settings. Baseline characteristics and treatments were compared between patients on CS monotherapy and those receiving concomitant MTX (CS+MTX). A survival analysis was performed using the Kaplan-Meier method, and the groups were compared using the log-rank test. Additionally, a Cox regression analysis was conducted to identify factors associated with complete CS withdrawal and CS-free sustained remission for at least 6 months.

Results: A total of 885 patients with GCA were included (615 treated with CS monotherapy and 270 with CS+MTX). Compared to those receiving CS monotherapy, patients in the CS+MTX group were younger, predominantly female, had a higher prevalence of concomitant polymyalgia rheumatica, and experienced a longer symptom duration before diagnosis (Table 1).

A higher relapse rate was observed in patients treated with CS+MTX compared to those on CS monotherapy (32.9% vs 12.5%, $p< 0.001$). Similarly, the cumulative dose of corticosteroids during follow-up was higher (8.87 g vs 7.56 g, $p< 0.001$). Time to reach doses of 5 mg, 7.5 mg, complete CS withdrawal, and CS-free remission for over 6 months was longer in the CS+MTX group.

Survival analysis revealed statistically significant differences in time to CS withdrawal ($p< 0.001$) and CS-free remission sustained for more than 6 months ($p< 0.001$) (Figure 1). No significant differences were observed between the groups in time to reach 5 or 7.5 mg of prednisone.

In the Cox regression models, the use of MTX (HR 0.563; 95% CI: 0.434–0.732; $p< 0.001$), female sex, and positive temporal artery biopsy were associated with a lower likelihood of achieving CS-free remission. Furthermore, MTX use was associated with a lower probability of achieving CS-free remission sustained for over 6 months (HR 0.724; 95% CI: 0.533–0.983; $p< 0.001$), along with female sex and headache (Table 2).

Conclusion: In the ARTESER registry, the use of MTX was not associated with a higher probability of achieving complete CS withdrawal or sustained CS-free remission compared to CS monotherapy. Additionally, patients did not show a lower cumulative dose of CS or a reduced relapse rate. Therefore, MTX use did not seem to be associated with better CS sparing outcomes in our real-life registry. Further research is needed to confirm our results and explore specific subgroups.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0731–0764) Vasculitis – Non-ANCA-Associated & Related Disorders Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Giant cell arteritis (GCA) is the most common form of vasculitis in patients over the age of 50. Interleukin-6 (IL-6) has been shown to play a potential role in the pathogenesis and prognosis of GCA, becoming a key therapeutic target. Moreover, some studies have suggested a potential prognostic value.

This study explores the association between baseline IL-6 concentrations and the clinical phenotype of the disease, with the aim of identifying patients who may benefit from anti–IL-6 therapies.

Methods: We conducted a cross-sectional study of a cohort of patients diagnosed with GCA between 2020 and 2024 in a tertiary care hospital. Patients were classified into two groups: those with exclusively cranial involvement (cranial GCA) and those with extracranial fluorodeoxyglucose (FDG) uptake at a PET-CT scan with or without cranial involvement (extracranial/mixed GCA).

A multiple linear regression model was used to evaluate the association between IL-6 levels and the clinical phenotype of GCA, adjusting for potential confounding and interaction variables (age, BMI, smoking status, type 2 diabetes mellitus, and prior corticosteroid therapy).

Regression coefficients (β), 95% confidence intervals (95% CI), and p-values were calculated, using a significance threshold of $p < 0.05$.

Model fit was assessed using the adjusted R-squared (adjusted R^2) and the F-test.

Results: A total of 39 patients were included. Epidemiological, clinical and diagnostic variables are detailed in Table 1. In the multiple regression analysis, no significant association was found between IL-6 levels and clinical phenotype ($p = 0.673$).

A significant negative association was observed between IL-6 levels and age ($\beta = -1.059$, 95% CI: -1.741 to -0.376, $p = 0.003$), as well as between IL-6 le levels and prior corticosteroid therapy ($\beta = -16.398$, 95% CI: -26.709 to -6.086, $p = 0.003$).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Patient's epidemiological, clinical, and diagnostic characteristics.

	Total	Cranial GCA	Extracranial/Mixed GCA	p value
Age at diagnosis (years), *mean (SD)*	75.2 (8.0)	76.2 (6.5)	74.7 (8.8)	0.591
Female sex, *n (%)*	31 (79.5)	8 (61.5)	23 (88.5)	0.05
Headache, *n (%)*	34 (87.2)	12 (92.3)	22 (84.6)	0.498
Jaw claudication, *n (%)*	20 (51.3)	7 (53.9)	13 (50.0)	0.821
Scalp tenderness, *n (%)*	14 (35.9)	6 (46.2)	8 (30.8)	0.345
Stroke, *n (%)*	2 (5.1)	0 (0.0)	2 (7.7)	0.305
Amaurosis fugax, *n (%)*	4 (10.3)	1 (7.7)	3 (11.5)	0.709
Permanent visual loss, n (%)	10 (25.6)	4 (30.8)	14 (53.8)	0.640
Polymalgia rheumatica, *n (%)*	23 (59.0)	7 (53.8)	16 (61.5)	0.645
Constitutional symptoms, n (%)	18 (46.2)	4 (30.8)	14 (53.8)	0.173
Fever, *n (%)*	4 (10.3)	0 (0.0)	4 (15.4)	0.135
ESR (mm), *mean (SD)*	65.9 (33.8)	56.7 (41.8)	70.2 (29.3)	0.256
CPR (mg/L), *mean (SD)*	59.9 (63.4)	42.2 (64.9)	68.8 (62.0)	0.222
IL-6 (pg/mL), *mean (SD)*	15.61 (18.9)	11.54 (14.7)	17.6 (20.7)	0.349
Doppler vasculitis signs, *n (%)*	14 (35.9)	6 (46.2)	8 (30.8)	0.253
PET-CT positivity, *n (%)*	26 (66.7)	0 (0.0)	26 (100.0)	<0.001
Positive temporal artery biopsy, n (%)	15 (38.5)	4 (30.8)	11 (42.3)	0.439

A significant positive correlation was found between IL-6 and CRP ($r = 0.4546$, $p = 0.0032$) and between IL-6 and ESR ($r = 0.3754$, $p = 0.0185$).

Other clinical and diagnostic variables did not reach statistical significance.

Conclusion: In our cohort, no significant association was found between IL-6 levels and the clinical phenotype of GCA. Patients with constitutional symptoms and PMR tended to have higher IL-6 levels, which may suggest a greater inflammatory burden—an observation that should be confirmed in studies with larger sample sizes.

Notably, IL-6 levels were inversely associated with age, a finding that contrasts with current literature and may open new avenues for research.

This study reinforces the importance of further exploring the role of IL-6 to identify patients who may benefit most from targeted therapy against this molecule.

P-values were calculated using Chi-Square and Kruskal-Wallis tests

Table 3: Comparison with Temporal artery biopsy cohort

fluorodeoxyglucose (FDG) positron emission tomography (PET) / computed tomography (CT), and to compare PET-positive patients with those diagnosed with temporal artery biopsy (TAB).

Methods: A retrospective cohort of patients with GCA diagnosed by (FDG) PET/CT between 01/01/1990 and 12/30/2022 was assembled. The comparator cohort included patients with GCA diagnosed with temporal artery biopsy (TAB) at the same institution. The study was approved by the local Institutional Review Board (IRB). For statistical analysis, categorical variables were expressed as number (percentage) and continuous variables were expressed as mean (standard deviation) or median (interquartile range). Comparisons between cohorts were performed using chi-square and Kruskal-Wallis tests. A two tailed p value less than 0.05 was considered significant.

Results: The PET-positive cohort included 62 patients; demographics and baseline variables are presented in Table 1. Mean age was 70.1 years (SD 8.9), with 61% (38/62) female and 97% White (60/62). 71% (44/62) of patients met the 2022 ACR Classification Criteria for GCA. 65% (24/37) patients had a positive CT angiogram, and 67% (14/21) patients had a positive magnetic resonance angiogram (Table 2). A minority of patients underwent TAB, with 39 % (9/23) positive. Aortic ectasia and/or aneurysms were present in 24% (15/62) patients at diagnosis. 23% (14/62) patients had an abnormal FDG uptake consistent with polymyalgia rheumatica.

The comparator cohort included 286 patients with TAB-positive GCA (Table 3). Compared to patients with TAB-positive GCA, the PET-positive patients were significantly younger ($p< 0.001$), more often males ($p=0.036$) and had longer time from symptom onset to GCA diagnosis ($p< 0.001$). PET positive patients had more frequent extremity claudication ($p=0.026$). Cranial manifestations were significantly less frequent among the PET-positive patients ($p< 0.001$), and none had permanent vision loss.

Conclusion: Patients with GCA diagnosed by PET scan were younger, more males and had less cranial manifestations compared to those diagnosed by TAB with a longer time to diagnosis. None of the patients diagnosed by PET had permanent vision loss. In clinical practice, distinct clinical GCA phenotypes tend to influence choice of diagnostic evaluation.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0731–0764) Vasculitis – Non-ANCA-Associated & Related Disorders Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: To assess the sustained remission rates of the targeted therapies in 52th week in patients with giant cell arteritis (GCA).

Methods: We performed a systematic literature review in PUBMED and Scopus databases and performed a metanalysis using Revman. A total of 1085 articles were scanned. We included 60 articles for review. Retrospective studies, non-randomised prospective studies were excluded and only randomised-controlled trials (RCT) were involved. In the meta-analysis 10 RCTs were included. Two independent reviewers extracted the data. The primary outcome was sustained remission (SR) rate at the 52th week of the treatment. The SR rates for similar glucocorticoid tapering arms in the targeted therapy and placebo groups were compared.

Results: A total of 869 patients were included in the involved studies. All the studies compared the outcomes with placebo. No head-to-head comparison was performed. SR rates were significantly higher compared to placebo in the patients who received tocilizumab (tocilizumab IV RR(CI 1.90 (1.01-3.56), tocilizumab SC 1.45 (1-06-1.99)), mavrilumab (RR (CI) 1.67 (1.12-2.47)), secukinumab (RR(CI): 7.41 (1.89-29.02)) and upadacitinib 15 mg (RR (CI) 1.58 (1.14-2.17). On the contrary, the sustained remission rate was found to be similar to placebo with the study drug in studies conducted with sarilumab and sirukumab. Safety outcomes of targeted drugs were similar with placebo in all of the involved studies.

Conclusion: Tocilizumab, mavrilumab, secukinumab and upadacitinib appear to increase the rate of 52-week sustained remission rate. Sarilumab and sirukumab has not shown significant efficacy.

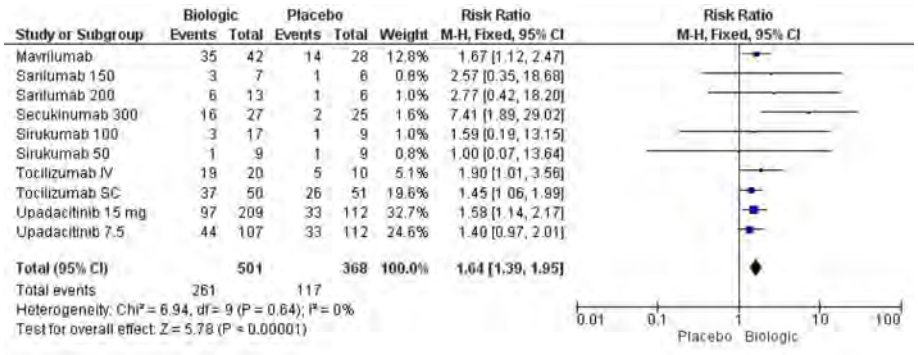

Figure 1. Meta-analysis of the effect of the targeted therapies on the sustained remission at the 52th week of treatment

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0731–0764) Vasculitis – Non-ANCA-Associated & Related Disorders Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: The diagnosis and management of giant cell arteritis (GCA) has significantly evolved over the last decades, mainly due to advances in imaging techniques and the introduction of new treatment modalities, respectively. Herein, we addressed the relapse rate, factors influencing relapses and the effect of introduction of interleukin-6-receptor targeting on relapse rates in GCA.

Methods: The REATS (GCA- Real-Life Assessment of Treatment Efficacy and Safety in GCA Patients) observational cohort included patients with a confirmed clinical diagnosis of GCA or a GCA flare between the first of January 2013 and 31st of December 2021. Six highly experienced German vasculitis centers participated and sequentially documented the disease course and treatment of GCA patients. Using a structured chart survey, we collected data on various outcomes, i.e. symptoms, treatments, acute-phase response, relapses. We used unsupervised clustering methods to identify symptom-based disease clusters and generalized additive models to analyze glucocorticoid dose and acute-phase response over time. Time-to-relapse was analyzed using survival methods.

Results: We included 395 patients with newly diagnosed GCA or a GCA flare. Diagnosis was supported by temporal artery ultrasound (37%), 18F-FDG-PET/CT (29%), temporal artery biopsy (14%) and by MRI (5,8%). The mean C-reactive protein value at disease onset or flare was 72,1 mg/dl, indicating a highly active cohort at the start of the documentation. The median total follow-up was 22.2 (CI 11.7-40.6) months. During this follow up time 97 of the 395 patients relapsed including 15 patients

Symptoms at relapse

who relapsed more than once (Figure 1). The median (IQR) time to first relapse was 12.5 (CI 7.1-21.8) months. Most common symptoms at relapse were headache (31%) and PMR symptoms (20%) (Table 1). Though over 90 different baseline characteristics were analysed to identify risk factors for a future relapse, no significant predictors could be identified. None of the applied treatment regimes showed any superiority in preventing disease relapses. Looking at the relapse rates before (2013-2017) and after interleukin-6-receptor targeting (2017-2021) was introduced more relapses occurred after 2017 (Figure 2).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Relapses are frequent in GCA and did not decrease with introduction of interleukin-6-receptor targeting in GCA. No risk factor for relapses could be identified, despite many different risk factors were assessed. Also, none of the treatment regimens used appear to be superior in preventing relapses. Interestingly, since the introduction of interleukin-6-receptor targeting, relapse rate increased in GCA. This finding could be based on a less stringent use of pharmacotherapies in GCA, including glucocorticoids, considering that treatment options have become larger with the introduction of interleukin-6-receptor targeting.

Abstract Number: 0763

Diagnostic Utility of Temporal Artery Biopsy in Giant Cell Arteritis: A Single Center Experience

Wendy Perdomo, Sean Welch and Timothy Wilson, Thomas Jefferson University, Philadelphia, PA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0731–0764) Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Giant cell arteritis (GCA) is predominantly large vessel vasculitis that has a specific prediliction for vasculature of the head, eyes and jaw and if untreated can lead to permanent vision loss. The gold standard for diagnosis is a temporal artery biopsy (TABx) although only a portion of patients have a positive biopsy and the biopsy itself can be associated with additional morbidity. There is a significant need to more clearly understand the clinical features that are most specific to clinical presentation and positive biopsy as this has significant implications on treatment strategies.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We completed a single center large cohort (n=138) retrospective analysis of patients who underwent a TABx based on the clinical suspision for GCA. All biopsies were done within the Thomas Jefferson University Health System between August 2023 and June 2024. After IRB approval, chart review was completed to identify a variety of patient related characteristics including demographics, clinical features on presentation, lab and imaging results. Indepdent sample t-tests and both univariate and multivariate logistic regression models were used where appropriate to characterize differences between subjects with positive and negative TABx results.

Results: The demographics and clinical features are summarized in table 1. The most common symptoms on presentation were vision changes (78%), vision loss (50%), temporal headache (50%) and scalp tenderness (23%). In 33% of patients, vision changes or vision loss was the only manifestation. The mean duration of steroid exposure prior to completion of biopsy was 3.8 days. The mean TABx length was 2.7 cm and a biopsy consistent with GCA was identified in 17/138 patients (12.1%). Of the 121 patients with a negative biopsy, 8 (6.6%) were treated for presumed GCA based on high clinical suspicion for the disease process. In simple logistic regression analysis, age ($p< 0.01$), jaw claudication ($p< 0.01$), grossly abnormal TA on exam ($p=0.04$), C-reactive protein (CRP) levels (0.04) and platelet count (0.05) were associated with increased odds of having a biopsy consistent with GCA (Table 2). In multivariate models, age, jaw claudication and platelet count remained independeltly

significantly associated with odds of having a positive biopsy. Despite this, 3/17 (18%) patients with a positive TABx had 1) normal sedimentation rate (ESR) or CRP and 2) the only clinical feature on presentation was vision changes.

Conclusion: In this large retrospective analysis, we found several clinical features (age, jaw claudication, TA enlargement, CRP levels and platelet count) associated with pathology consistent with GCA with the most specific features being age, jaw claudication and increased platelets. A small portion of patients with a positive biopsy only exhibited vision changes and at least one normal inflammatory marker (ESR or CRP). Future studies are needed to more reliably characterize the full spectrum of the presentation of GCA and thus more expansive indications for invasive diagnostic studies such as a temporal artery biopsy.

Abstract Number: 0764

Frequency of large vessel vasculitis in giant cell arteritis with and without adventiitis of temporal artery - Is the presence of temporal arteritis sufficient to diagnose giant cell arteritis?

Yoichiro Akiyama, Jun Nakamura, Ayako Kokuzawa, Hiroi Kusaka, Sho Tani, Fuminori Taniguchi, Kohei Morikawa, Haruka Kondo, Shotaro Yamamoto, Yasuyuki Kamata and Kojiro Sato, Jichi Medical University, Shimotsuke, Tochigi, Japan

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0731–0764) Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Takayasu arteritis (TAK) and giant cell arteritis (GCA) belong to the large vessel vasculitis group. Differences between the two diseases have been reported based on age, clinical presentation, and HLA. ACR/EULAR classification criteria for GCA have been reported, but no pathological criteria for the temporal artery (TA) have been proposed. Pathologically, inflammation of the aorta in TAK starts from the adventitia and inflammation of the temporal artery (TA) in GCA starts from the tunica media, indicating different sites of inflammation in the two diseases. Therefore, it is important to classify TAK and GCA based on pathological findings rather than distinguishing between them based on age. In this study, it was examined whether there is a difference in the presence or absence of aortitis depending on the site of inflammation of the TA (presence or absence of adventitial inflammation) in cases diagnosed with GCA.

Methods: The study included patients admitted to our hospital from 2004 to 2023, who underwent temporal artery biopsy (TAB) and contrast-enhanced thoraco-abdominal computed tomography, and were diagnosed with GCA. According to the pathology of the TAB, the patients were divided into two groups: those with (Ad+ group) and without (Ad- group) adventitial inflammation. In those two groups, clinical symptoms, laboratory findings, and the presence of aortitis were compared between the groups.

Results: Thirty-two patients were included in the study, 21 in the Ad+ group and 11 in the Ad- group. The median age in the Ad+ and Ad- groups was 73 and 69 years, respectively (p=0.010), the frequency of clinical findings were as follows: fever (52.4% vs. 36.4%, p=0.472), headache (81.0% vs. 90.9%, p=0.637), polymyalgia rheumatica (PMR) symptoms (23.8% vs. 36.4%, p=0.681), and TA symptoms (42.9% vs. 81.8%, p=0.061). Blood test findings (median values) showed no

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

significant differences in WBC (7,900 /μl vs. 7,800 /μl, p=0.984) or CRP (9.60 mg/dl vs. 9.26 mg/dl, p=0.736); however, ALP levels in Ad+ group were lower than those in the Ad- group (244 U/L vs. 446 U/L, p=0.009). The frequency of aortitis in the Ad+ group was significantly higher than in the Ad- group (81.0% vs. 27.3%, p=0.006). The initial dose of glucocorticoid (GC) tended to be higher in the Ad+ group (1.0 mg/kg vs. 0.6 mg/kg, p=0.066).

Conclusion: In this study, the Ad- group may have true GCA and the Ad+ group may have TAK; it may be important to distinguish between GCA and TAK based on TAB pathology rather than age.

Abstract Number: 0765

Rural Access to Physical Therapy for Osteoarthritis Rehabilitation (RAPTOR): A Pilot Feasibility Study

Allyn Bove, Emma Zavacky, Hallie Zeleznik, Christopher Bise, Charity Patterson, Bambang Parmanto and G Kelley Fitzgerald, University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0765–0771) Orthopedics, Low Back Pain, & Rehabilitation Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Individuals who live in rural areas are more likely to experience knee osteoarthritis-related disability and less likely to be referred to physical therapy for osteoarthritis. Limited access to physical therapy due to lack of licensed professionals in the area and long distances from home to the nearest clinic may exacerbate the underutilization of physical therapy among rural residents with knee osteoarthritis. Increasing uptake of telerehabilitation may mitigate these challenges, but telerehabilitation can be challenging in rural areas due to lower availability of LTE wireless coverage and broadband internet service. In this study, we aimed to evaluate feasibility and future trial design parameters for a novel hybrid in-person + telerehabilitation program (RAPTOR) for rural residents with knee osteoarthritis.

Methods: The study was a single-arm pilot feasibility study with pre-post design. Twenty rural-dwelling adults with knee osteoarthritis were eligible to participate in the RAPTOR program, consisting of up to 10 visits with a physical therapist: two visits delivered in-person and eight visits delivered using a secure, HIPAA-compliant telehealth platform. Feasibility was defined as a combination of acceptability, demand, implementation, integration, and safety. Clinical outcomes entailed a combination of patient-reported (Knee Injury and Osteoarthritis Outcome Score, or KOOS) and performance-based (OARSI-OMERACT core set of performance-based measures) functional measures. Satisfaction with telerehabilitation was assessed using the Telehealth Usability Questionnaire.

Results: RAPTOR was feasible and safe based on meeting recruitment and attendance targets and having no adverse events during the study, and participants reported high satisfaction with the telerehabilitation component of the program. Eighty-one percent (13/16) of participants who completed the RAPTOR program demonstrated clinically important improvement in patient-reported physical function, and more than half (7-10/14) demonstrated clinically important improvement on the various performance-based physical function tests.

FIGURE 1. Study enrollment and attrition flow chart

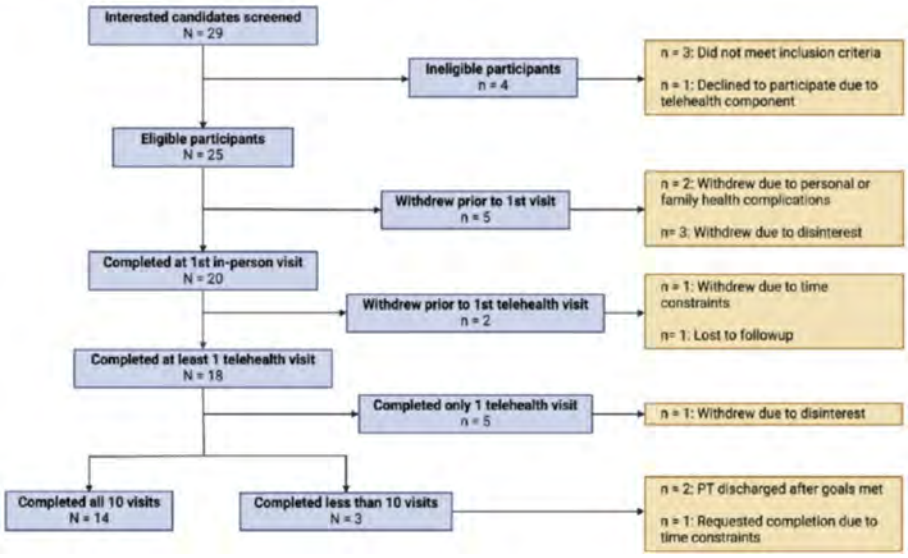

TABLE 1. Feasibility outcomes assessed in RAPTOR pilot study

Outcome(s)	How Outcome was Measured	Definition of Successful Outcome
Demand*	Recruitment progress	Recruitment target met within 1-year timeline
Implementation*, Integration*	Attendance rate	Mean visit attendance of at least 75%
Acceptability*	Post-study Telehealth Usability Questionnaire completed by participants	Average item rating of at least 5/7 on Likert scale items
Safety*	Number of study-related adverse events and/or serious adverse events	Zero study-related adverse events or serious adverse events
Clinical Outcome Change and Variability	Participant-reported outcome measures and performance-based outcome measures	Achievement of minimum clinically important difference

*denotes outcome included in the overall study definition of "feasibility"

TABLE 2. Participant-reported and performance-based outcomes

Outcome Measure	Sample Size	Baseline, mean (SD)	Follow-Up, mean (SD)	Change, mean (95% CI)
KOOS ADL subscale	13	68.2 (18.6)	81.9 (11.8)	13.7 (4.4-22.9)*
KOOS Pain subscale	14	64.3 (17.6)	75.8 (12.5)	11.5 (-0.6-23.6)
30-Second Chair Rise Test, # of rises	14	11.3 (5.0)	13.6 (5.8)	2.4 (0.2-4.6)*
Stair Climbing Test, in seconds	14	18.0 (7.2)	14.5 (6.3)	3.5 (2.2-4.7)*
Timed Up and Go, in seconds	14	9.5 (1.8)	8.0 (1.4)	1.5 (0.8-2.2)*
6-Minute Walk Test, in meters	14	388.0 (112.4)	460.3 (108.3)	72.3 (39.5-105.1)*

*indicates statistical significance of paired samples t-test.

KOOS = Knee Injury and Osteoarthritis Outcome Score; ADL = Activities of Daily Living; SD = standard deviation; 95% CI = 95% confidence interval

Conclusion: A novel hybrid in-person + telerehabilitation program was safe and feasible. A high proportion demonstrated improvements in function. Participants expressed high degrees of satisfaction with telerehabilitation and minimal barriers to using the platform, supporting the use of telerehabilitation among rural-dwelling older adults. Further testing of this hybrid approach is needed in a comparative trial.

Abstract Number: 0766

Effects of Walking During the 6-Minute Walk Test on Cognition in Adults with Knee Replacement

Christine Pellegrini[1], Jongwon Lee[1], Chih-Hsiang Yang[1], Scott Jamieson[2], Clare Kennerley[1] and Sara Wilcox[1], [1]University of South Carolina, Columbia, SC, [2]The University of South Carolina, Columbia, SC

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0765–0771) Orthopedics, Low Back Pain, & Rehabilitation Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: The majority of adults with knee replacement remain physically inactive after surgery and are at high risk for Alzheimer's and related dementias (ADRD). This study investigated the acute effects of a 6-minute walk on processing speed, visuospatial memory, and visual memory in adults with a history of TKR ≤6 months ago.

Methods: Within a cross-over design, participants were randomized to either first engage in the 6-minute walk test or rest. Cognition was assessed via brief phone-based tests 3 times (baseline and after walking and resting). Symbol search, grid memory, and color shape tests from the NIH Mobile Toolbox were used to measure processing speed, visuospatial memory, and visual memory, respectively.

Results: Participants (n=52) were 77% female, 65.1 (9.1) years, 85% completed some college or higher, and were on average 94.1 (21.7) days since knee replacement. Participants walked 1126.67 (205.69) feet during 6-minute walk test. Controlling for demographics and potential learning effects, mixed-effects models revealed that 6 minutes of walking was associated with improved visuospatial memory, as indicated by shorter error distances on the grid memory test (b=-3.87, p=0.04). The walking effect was not observed for processing speed (b=178.8, p=0.45) or visual memory (b=0.01, p=0.92).

Conclusion: Although the physiological mechanisms to which exercise benefits domain-specific cognition remain unclear, the results of this study suggest that a short bout of walking may immediately improve visuospatial memory in adults with knee replacement. Healthcare providers could highlight this cognitive benefit and encourage short walking bouts in this population.

Session Date: Sunday, October 26, 2025
Session Title: (0765–0771) Orthopedics, Low Back Pain, & Rehabilitation Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Foot and ankle involvement in patients with rheumatoid arthritis is a common yet often underexplored and underrecognized manifestation. This can negatively affect patients' quality of life and functional capacity. We aimed to describe the effect of foot and ankle joint involvement on the quality of life in patients with rheumatoid arthritis.

Methods: An observational, cross-sectional study was conducted at a university hospital rheumatology and traumatology outpatient clinics. Patients >18 years with a diagnosis of rheumatoid arthritis (ACR/EULAR 2010) were included. Health-related quality of life concerning foot health was assessed using the Foot Health Status Questionnaire (FHSQ), with higher scores indicating a better result. The Foot Function Index (FFI) was used to measure the impact of the disease on foot function, higher scores indicate worse foot function. Pain was evaluated using a visual analog scale (VAS). To measure the involvement of the foot, x-rays of both feet were taken in three projections and evaluated by an unaffiliated radiologist. The modified Sharp/van der Heijde (vdH-S) was utilized to evaluate the radiological findings of the lower extremity joints, separating high and low scores with a cutoff point of 4. Descriptive analysis was performed. Mann-Whitney´s U test and Chi-Square test were applied as appropriate, with a p-value < 0.05 considered statistically significant.

Results: A total of 81 patients were included, of whom 77 (95.1%) were women, with a median age of 59 years (IQR: 51–65). At the time of evaluation, the majority of patients (n=43, 53.1%) were in remission. The most common comorbidity was obesity (n = 28, 34.6%), followed by osteoarthritis (n = 16, 19.8%). Additionally, 62.79% of participants described living a sedentary lifestyle. The mean body weight was 69.2 ± 15.5 kg, with a median BMI of 28.2 (IQR: 24–32).

Radiological findings revealed that 69 patients (85%) experienced some degree of lower extremity joint involvement. The median score of vdH-S was 4 (IQR: 2–20), with a median erosion subscale score of 2 (IQR: 0–4.5) and a median joint space narrowing subscale score of 3 (IQR: 2–16). Among patients with lower-extremity joint involvement, subluxations were

IQR: Interquartile range; SD: Standard Deviation; FHSQ: Foot Health Status Questionnaire; FFI: Foot Function Index; VAS: Visual Analog Scale; vdH-S: Sharp/van der Heijde.; Involvement: > 4 points on the modified vdH-S method

observed in 63 cases (77.8%), while 38 patients (46.9%) had evidence of osteoporosis and subchondral cysts, and 12 patients (14.8%) presented with synovitis. Patients with a score in vdH-S > 4 points, had a higher number of erosions and space joint narrowing compared to patients with a score < 4 points (p= < 0.001). Patients with a score of vdH-S >4 points had a significantly higher prevalence of osteoporosis (62% vs. 22.6%) than those with a score < 4 points (p= < 0.001). Regarding the quality of life and foot functionality, there was no differences in the involvement of the foot and ankle (p= 0.631, p=0.560, respectively).

Conclusion: Most patients (85%) had radiologic findings in the lower extremity joints, with subluxations in 77.8% and osteoporosis and subchondral cysts in 46.9%. There was no significant difference between quality of life and foot functionality in patients with foot and ankle joint involvement compared to those without.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0765–0771) Orthopedics, Low Back Pain, & Rehabilitation Poster

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Compared to the general population, Veterans have higher prevalence of knee osteoarthritis, comorbidities, activities of daily living limitations, and healthcare utilization following total knee arthroplasty (TKA). Despite these limitations, there is a significant gap in knowledge regarding how physical therapy care is delivered and what factors influence recovery for Veterans. To address this gap, we examined Veteran outcomes and physical therapy care delivery after TKA.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We recruited 86 Veterans [74 male, age 68±8 (mean ± standard deviation), body mass index 31±4.5, Charlson Comorbidity Index 1±1] who attended rehabilitation following TKA for ≥1 session in two Veterans Integrated Service Networks. We collected preoperative outcomes for knee range of motion, the timed up and go test, and the Knee Injury and Osteoarthritis Outcome Score for Joint Replacement (KOOS JR). The KOOS JR was collected postoperatively at 90-days (primary outcome) and at 180-days. Physical therapy care outcomes were collected from the electronic medical record from April 2022 to April 2025 including time to physical therapy evaluation, duration of care, and number of visits.

Paired t-tests were performed to assess changes in KOOS JR scores from preoperative values at 90-day and 180-day. Pearson correlation coefficients were calculated on the relationship between the 90-day KOOS JR scores and preoperative characteristics (KOOS JR scores, the timed up and go test, knee flexion, knee extension) as well as time to outpatient evaluation, number of visits, and duration of care.

Results: Prior to surgery the Veterans were recorded to have 115 ± 11^{0} of knee flexion, 11.5±4 seconds on the timed up and go test, and a KOOS JR interval score of 49.9±13. On average, 90-day KOOS JR scores were 18.6±2.0 points higher than preoperative scores (95% Confidence Interval 14.8, 22.9, $p< .001$). On average, the 180-day KOOS JR scores were 26.9±3.4 points higher than preoperative scores (95% CI 20.0, 33.8, $p< .001$) and 8.1±2.0 points higher than the 90-day KOOS JR scores (95% CI 3.9, 12.4, $p< .001$). Number of visits (11±6 visits, $r= -0.26$, $p< 0.001$) and time to outpatient evaluation from (15±14 days, $r = -0.25$, $p< 0.001$) were negatively correlated with 90-day KOOS JR scores. Preoperative KOOS JR scores ($r = 0.26$, $p< .001$) and preoperative knee flexion ($r = 0.16$, $p< .001$) were positively correlated with 90-day KOOS JR scores.

Conclusion: Despite the significant change in scores following TKA, on average these Veterans did not meet the threshold associated with meaningful change in physical function on the 90-day KOOS JR (≥ 27). The negative correlation between the number of visits and time to outpatient evaluation may result from these Veterans having poor recovery, increasing the need for additional services such as home health rehabilitation, sub-acute rehabilitation, or skilled nursing facility stays prior to outpatient physical therapy. Veterans with worse preoperative KOOS JR scores and reduced knee flexion may benefit from enhanced postoperative care. Additionally, factors related to postoperative care pathways should be explored to improve outcomes.

Abstract Number: 0769

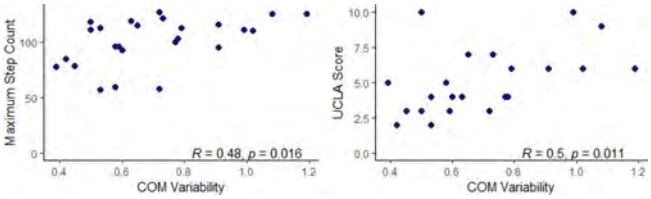
Increased Gait Variability at Preferred Walking Speeds is Associated with Increased Physical Activity Measures in People with Knee Osteoarthritis

Ogundoyin Ogundiran, Steven Garcia, Joy Itodo, Oiza Peters and Kharma Foucher, UNIVERSITY OF ILLINOIS, CHICAGO, Chicago, IL

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0765–0771) Orthopedics, Low Back Pain, & Rehabilitation Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: People with knee osteoarthritis (OA) often exhibit reduced physical activity levels and increased fall risk. Gait variability, specifically center of mass (COM) variability is a measure of balance and stability; characteristics that may

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



be impaired with OA. Higher COM variability has been linked to better adaptability to environmental perturbations. It is plausible that more physically active people with OA will exhibit more typical levels of gait variability compared to less active individuals. The association between gait variability and physical activity measures in individuals with knee OA, nonetheless, remains unclear. The purpose of this study was to evaluate the associations between physical activity and COM variability during walking in people with knee OA. We hypothesized that greater amounts of physical activity will be associated with greater amounts of COM variability in people with knee OA.

Methods: We studied 25 people with knee OA (57 ± 8 years: 9 M, 16 W) using 3D gait analysis and physical activity monitoring. Physical activity was assessed through self-reported UCLA scores, and a wrist-worn Actigraph accelerometer. Using the UCLA Scale, Participants rated themselves from 1 (inactive) to 10 (highly active). Steps per day were calculated through Actigraph software. Participants walked on an instrumented treadmill collecting kinetic data at 1200 Hz, synced to an 8-camera system set up collecting kinematic data at 120 Hz. A full-body modified Helen Hayes marker set was used for biomechanical analysis. Gait variability was quantified using the coefficient of variation of the vertical COM trajectory displacement, over ten consecutive steps. We used Pearson's correlation to test for associations between COM variability and activity measures.

Results: Aligned with our hypotheses, higher COM was associated with higher levels of activity in both the self-reported (R=.500, p=.011) and objective activity measures (R=.476, p=.016). This suggests individuals with more physical activity may retain more robust gait patterns, evidenced by the association to higher COM variability. No significant association found between COM variability and intensity measures such as total MVPA (R=-1.92, p=.358) or percentage in MVPA (R=-.200, p=.337), indicating that global activity levels may be more relevant than intensity.

Conclusion: People with knee OA face a lack of physical activity due to multifactorial influences. Our previous work has indicated that kinesiophobia can be a potential explanatory factor of physical inactivity in the population. Center of mass variability may also provide insight into the physical inactivity people with knee OA face. Increased gait variability has been linked to improved efficiency in responding to environmental perturbations. It known that individuals with knee OA have a greater fall prevalence, balance/stability deficits, and lower amounts of physical activity. Findings from this study illustrated a positive correlation between increased amounts of physical activity, and gait variability. This study illustrates how better understanding gait variability can provide insight into novel physical activity and fall interventions trainings for this population.

Abstract Number: 0770

Interrelationships of Depression, Pain, and Gait Mechanics and their Associations with Physical Activity Levels Among People with Knee Osteoarthritis

Oiza Peters, Steven Garcia, Joy Itodo, Ogundoyin Ogundiran and kharma Foucher, UNIVERSITY OF ILLINOIS, CHICAGO, Chicago, IL

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0765–0771) Orthopedics, Low Back Pain, & Rehabilitation Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Depression is associated with low physical activity (PA) levels in people with knee osteoarthritis (KOA)[1]. Pain contributes to both depression and PA levels in people with knee OA[1,2] but can also influence gait biomechanics which may, in turn, adversely impact PA. Understanding how depression, pain, gait biomechanics, and PA are interrelated in KOA could guide more effective interventions. This study, therefore, investigated the relationships among these factors. We focused on joint powers as a relevant aspect of gait biomechanics because they are directly related to force absorption and generation during motion and may be directly related to the ability to be physically active. We hypothesized that (i) depression, pain, and affected limb hip, knee, and ankle joint powers are all associated with PA, and (ii) that more depression and pain are associated with lower joint powers.

Methods: We evaluated 34 people with knee OA (20 Women, 56±8 years, 34.7±7.1 kg/m^2) walking at self-selected speeds on an instrumented split-belt treadmill, using standard motion capture methods. We calculated sagittal plane peak positive joint powers of the hip, knee, and ankle during terminal stance. Participants reported their PA levels using the UCLA activity scale which ranges from 1 (“wholly inactive”) to 10 (“regularly participate in impact sports”). Participants also completed the KOOS pain subscale, where 100 indicates the absence of pain and the PROMIS Depression Computerized Adapted Test, (US average = T score of 50, higher scores indicate more depression). We used Spearman correlations to quantify the associations among variables.

Results: Surveys indicated that, on average, participants were moderately active (UCLA 5±2), reported an average level of depression symptoms (T score 50±11) and reported moderate pain (KOOS Pain 54.0±22.6). UCLA scores were significantly correlated with pain, depression, and all joint powers (Table 1). More depression and pain were associated with lower PA levels but, surprisingly, depression and pain were not correlated with each other. Finally, more pain was associated with lower joint powers but there were no associations with depression.

These findings support our hypothesis that depression, pain, and joint powers are associated with PA levels in KOA. Pain may lower PA levels directly as well as indirectly through its influence on joint mechanics. Hip and ankle powers had moderate to strong associations with PA indicating the need to include a multi-joint rehabilitative strategy to preserve power

Table 1. Spearman correlation coefficients and p values quantifying associations among PA levels, joint powers, pain, and depression in people with knee OA. Greater joint powers, less pain, and less depression are associated with higher levels of PA. Shading highlights statistically significant correlations.

generation along the entire kinetic chain, rather than the knee only. Further, the association of PA levels with depression amplifies its independent importance. Multi-factored interventions that include depression management may be helpful to improve PA in this population.

Conclusion: There is an interplay of psychosocial and structural factors that influence PA in people with knee OA. Effective clinical intervention should include a well-defined holistic approach.

Radiographic Knee Osteoarthritis and Corticosteroid Injection Use: The Moderating Role of Physical Activity

Sydney Liles[1], Jennifer Copson[2], Daniel K. White[1] and Jason Jakiela[3], [1]University of Delaware, Newark, DE, [2]University of Delaware, Wilmington, DE, [3]Winston-Salem State University, Winston-Salem, NC

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0765–0771) Orthopedics, Low Back Pain, & Rehabilitation Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Knee osteoarthritis (OA) is a chronic disease with no current cure and a leading cause of disability among adults. Treatment for knee OA focuses on symptom management, with physical activity (PA) and Corticosteroid (CS) injections being strongly recommended. However, increased utilization of CS injections may increase the risk of total joint replacement, and those with higher Kellgren-Lawrence (KL) grades have been shown to have higher odds of receiving a CS injection. Further, it is unknown if PA mitigates the use of CS injections for those with worse radiographic evidence of knee OA. The purpose of this study was to determine if PA modifies the relationship between radiographic OA (ROA) presence and utilization of CS injections during a 5-year follow-up period in adults with or at high risk for knee OA.

Methods: We performed a secondary analysis of Osteoarthritis Initiative (OAI) data. Our exposure was ROA presence (KL grade ≥ 2 vs < 2), at the 48-month visit (analytic baseline, BL). Our outcome was receiving a CS injection assessed using the question "In the past 6 months, have you received a CS injection?" from BL to the 108-month follow-up visit. We excluded participants who answered yes to the CS injection question at BL. PA, measured using an Actigraph GT1M at BL, was examined as an effect measure modifier between ROA presence and CS injection, and 6000 steps/day was used to stratify the sample. We produced Kaplan-Meier survival curves for cumulative incidence of not receiving a CS injection and used Cox proportional hazards regression to calculate discrete-time hazard ratios (HR) adjusted for confounders.

Results: 1763 participants (mean age = 65.0 years old, 55% female, mean BMI =28.5 kg/m^2) were included in the overall analytic sample. 204 participants received at least one CS injection over 5 years of follow-up. For participants with ≥ 6000 steps/day, survival probability was 82% for those with ROA and 92% for those without ROA (Figure 1a). Those with ROA had 223% increased hazard of receiving a CS injection compared to those without ROA (adjusted HR [95% CI] = 3.23 [2.05, 5.08]) (Table 1). For participants with < 6000 steps/day, survival probability was 67% for those with ROA and 91% for those without ROA (Figure 1b). Those with ROA had a similar hazard of CS injection whether they walked < 6000 steps/day (3.45 [1.73, 6.89]) or ≥ 6000 steps/day (3.05 [1.66, 5.61]) (Table 2). The interaction term for ROA presence and steps/day was not significant (p = 0.68).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 1: Kaplan-Meier survival curves for not receiving a CS injection, for total sample and by ROA exposure group, in those who walked ≥ 6000 and < 6000 steps/day at baseline.

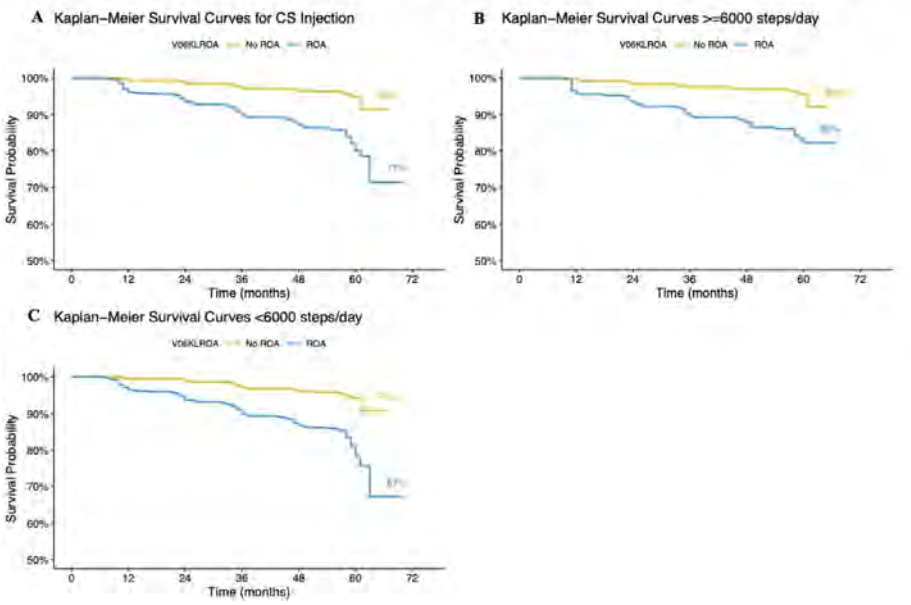

Table 1: Hazard ratios and 95% confidence intervals for ROA and KL Grade exposure groups for receiving a CS injection

	CS Injection n/N (%)	HR [95% CI] (unadjusted)	HR [95% CI] (adjusted)
ROA			
No ROA (< 2)	33/703(4.7%)	1.0 [REF]	1.0 [REF]
ROA (≥ 2)	171/1060(16.1%)	**3.82 [2.63, 5.54]**	**3.23 [2.05, 5.08]**

Note: models were adjusted for age, sex, BMI, race, education, comorbidity, function measured by the Knee Osteoarthritis Outcome Score (KOOS), baseline steps/day, and pain

Table 2: Hazard ratios and 95% confidence intervals for receiving a CS injection, ROA and KL Grade exposure groups, stratified by steps/day at baseline.

	CS Injection n/N (%)	HR [95% CI] (unadjusted)	HR [95% CI] (adjusted)	Interaction *P*
ROA				
≥ 6000 steps/day				
No ROA (< 2)	15 / 348(4.3%)	1.0 [REF]	1.0 [REF]	
ROA (≥ 2)	68 / 441 (15.4%)	**3.97 [2.27, 6.94]**	**3.05 [1.66, 5.61]**	0.68
< 6000 steps/day				
No ROA (< 2)	18 / 355 (5.1%)	1.0 [REF]	1.0 [REF]	
ROA (≥ 2)	103 / 619(16.6%)	**3.60 [2.18, 5.93]**	**3.45 [1.73, 6.89]**	

Note: models were adjusted for age, sex, BMI, race, education, comorbidity, function measured by the Knee Osteoarthritis Outcome Score (KOOS), and pain

Conclusion: Physical activity does not seem to modify the relationship between ROA presence and CS injection utilization. However, for people with ROA, those who were more active had a slightly attenuated risk of receiving a CS injection than those who were less active as those with ROA who were more active had an 82% chance of not receiving a CS injection compared to a 67% chance for those who were less active over a 5-year period.

Redefining When to Biopsy the Kidney in Patients with SLE

Michelle Petri[1], Andrea Fava[2], Mohamed Atta[3], Avi Rosenberg[3], Sanchit Sanyal[3], Peter Izmirly[4], Erin Carter[5], Mala Masson[6], Michael Belmont[7], Jennifer Barnas[8], Jennifer Anolik[9], Brad Rovin[10], Jill Buyon[4] and Accelerating Medicines Partnership: Autoimmune and Immune-Mediated Diseases Network (AMP AIM), [1]Johns Hopkins University School of Medicine, Timonium, MD, [2]Johns Hopkins University, Baltimore, MD, [3]Johns Hopkins University School of Medicine, Baltimore, MD, [4]NYU Grossman School of Medicine, New York, NY, [5]New York University Grossman School of Medicine, New York, NY, [6]NYU Langone Medical Center- Division of Rheumatology, New York, NY, [7]NYU Langone Health, New York, NY, [8]University of Rochester, Rochester, NY, [9]University of Rochester Medical Center, Rochester, NY, [10]The Ohio State University, Columbus, OH

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: Plenary I (0772–0776)

Session Type: Plenary Session

Session Time: 9:30AM–11:00AM

Background/Purpose: Current ACR, EULAR and KDIGO guidelines recommend kidney biopsy in SLE patients with urine protein to creatinine (UPCR) ratio of $\geq$ 0.50 g/g. However, SLE patients who undergo kidney biopsy at lower levels of UPCR are frequently found to have proliferative lupus nephritis (Wang S, et al. Clin J Am Soc Nephrol. 2022;17:1150-1158). As part of the Accelerated Medicines Partnership we investigated first onset of UPCR 0.250-0.499 g/g.

Methods: SLE patients with no history of LN and UPCR of 0.250 to 0.499 g/g PLUS another predictor of lupus nephritis (LN) including non-White race, serologies (low C3, low C4, or anti-dsDNA). or active urine sediment, were enrolled. Kidney biopsies were done at the site institution and reported as ISN Class I-VI with NIH Activity and Chronicity Index, if LN.

Results: Twenty-eight patients were enrolled: 24 (86%) females, 6 (21%) Hispanic, and 13 (46%) African-American, 7 (25%) White, 2 (7%) Asian and 6 (21%) Other race. Twenty-five (89%) were anti-dsDNA positive, 20 (71%) had low C3 and 19 (68%) had low C4 at enrollment. All had GFR >60, no immunosuppression and prednisone < 10mg/day. Seven patients were taking ACEi/ARBs, two SGLT2 inhibitors (both were no LN on subsequent biopsy) and 23 hydroxychloroquine. Twenty had LN: two Class I; five Class II; six Class III; and seven Class V. Eight did not have LN (Table 3): 6 (75%) had a history of positive anti-dsDNA; 3 (38%) had a history of low C3; and 3 (38%) had a history of low C4. Table 1 shows the NIH Activity

Table 2. Comparison of inclusion criteria between those with lupus nephritis vs those without lupus nephritis

Criteria	LN pos (n=19)	Not LN (n=8)	P-value
Age at Biopsy (yrs)	42.0 ± 15.1	52.1 ± 18.7	0.1976
Race (Black/Other)	16 (80%)	5 (63%)	0.3715
History of anti-dsDNA positive	19 (95%)	6 (75%)	0.1880
History of low C4	**16 (80%)**	**3 (38%)**	**0.0296**
History of low C3	**17 (85%)**	**3 (38%)**	**0.0223**
History of low Complement (C3 or C4)	**18 (90%)**	**4 (50%)**	**0.0384**
Anti-dsDNA positive at visit	17 (85%)	5 (63%)	0.3107
C4 low at first AMP visit	11 (55%)	2 (25%)	0.2218
C3 low at first AMP visit	10 (50%)	1 (13%)	0.0987
Complement low (C3 or C4) at first AMP visit	12 (60%)	2 (25%)	0.2087

Table 3. Histology of non-lupus nephritis biopsies

Histology	UPCR (g/g)	Serum Creatinine	GFR	Low C3	Low C4	DsDNA
Glomerulomegaly, segmental foot process effacement, swollen endothelial cells, ?TMA	0.293	0.68	92.4	Normal	Normal	Positive
Arteriosclerosis (mild-moderate), thin GBM disease	0.38	0.86	81.6	Normal	Normal	Negative
Histologically unremarkable, rare TRI, 20-25% foot process effacement	0.30	0.51	130.9	Normal	Normal	Positive
Glomerulosclerosis (50%), unquantifiable IFTA, arteriosclerosis (severe), 20-30% foot process effacement	0.411	0.79	73.2	Normal	Low	Positive
Arteriosclerosis (mild), 25% foot process effacement	0.358	0.86	72.4	Normal	Normal	Negative
Global Glomerulosclerosis (38%) and mild IFTA, mild mesangial matrix and cells increased, 20% foot process effacement	0.38	1.1	54.1	Normal	Normal	Negative
Arteriosclerosis (mild-moderate), early diabetic glomerulopathy (thick GBM, increase mesangial matrix), 20-25% foot process effacement	0.265	0.9	92.5	Low	Low	Positive
IgA nephropathy	0.26	0.69	123.6	Normal	Normal	Positive

and Chronicity Indices, UPCR and serologies by ISN Class. There were no biopsy complications. Patients with LN were more likely to have had a history of low C3 (p=0.0223) or low C4 (p=0.0296) prior to enrollment (Table 2).

In longitudinal follow up, two Class II, two Class III and three Class V have progressed to greater than 0.5 g/g of UPCR (in spite of treatment of Class III and Class V).

Conclusion: The 0.50 g/g UPCR cut-off for kidney biopsy in LN guidelines is arbitrary, omitting an opportunity to identify early LN before accrual of kidney damage. Earlier biopsy of LN, as defined by the AMP algorithm (UPCR between 0.250 and 0.499 g/g PLUS another LN predictor), found LN in 69%, with 61% initiating mycophenolate (6 Class III and 5 Class V) and 17% already showing some degree of chronicity. History of low C3 or C4 was the most important component of the AMP algorithm. The AMP early LN algorithm identified a high incidence of patients with consequential pathology and strongly support an adjustment to the UPCR cutoff for kidney biopsy in LN guidelines.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: Plenary I (0772–0776)

Session Type: Plenary Session

Session Time: 9:30AM–11:00AM

Background/Purpose: Melanoma differentiation-associated gene 5 (MDA5) is a cytoplasmic RNA sensor and activates the innate immune response. Autoantibodies against MDA5 are associated with rapidly progressive interstitial lung disease (ILD) in dermatomyositis (DM). Moreover, MDA5 protein expression is upregulated in the lungs of patients with MDA5-positive-ILD and idiopathic pulmonary fibrosis. We hypothesized that specific antibody reactivity against certain MDA5 epitope peptides correlates with severe ILD phenotypes and could serve as biomarkers not only in anti-MDA5-positive DM-ILD but also in idiopathic interstitial pneumonias (IIPs).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

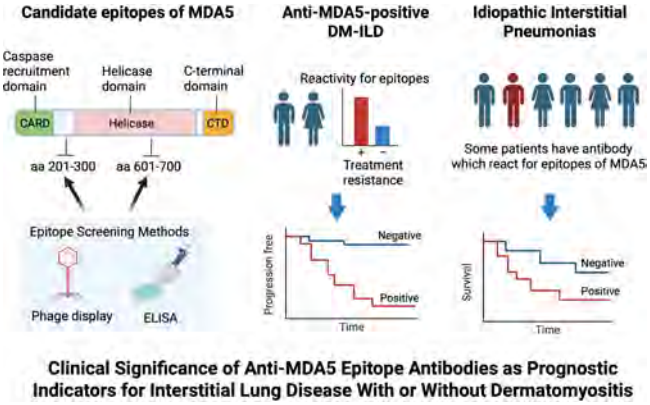

Figure 1. Graphical abstract

Methods: We screened sera from patients with anti-MDA5-positive DM-ILD to identify epitopes using T7 phage display and ELISA with recombinant MDA5 fragments. Two candidate regions, MDA5 (amino acids 201–300) and MDA5 (amino acids 601–700), were identified (Figure 1). We retrospectively analyzed 30 anti-MDA5-positive DM-ILD patients treated with unified therapy (discovery cohort) and validated findings in 54 patients from a multicenter cohort (validation cohort). Resistance to initial triple therapy (glucocorticoid, calcineurin inhibitor, cyclophosphamide) was defined as the need for additional therapy or death within 6 months. Moreover, we examined 288 IIP patients for reactivity to MDA5 (201-300 and 601-700) and assessed their clinical significance in predicting survival outcomes.

Results: In the discovery cohort, high reactivity to MDA5 (201-300) and MDA5 (601-700) was significantly associated with resistance to initial therapy. ROC analysis showed strong predictive ability (sensitivity and specificity were 88% and 71% in MDA5 (201-300), and 63% and 93% in MDA5 (601-700), respectively). In the validation cohort, MDA5 (201-300) positivity was significantly associated with lower 6-month progression-free survival (43% vs. 74%, $p < 0.05$, Figure 2). Reactivity to MDA5 (601-700) trended toward poorer outcomes but was not statistically significant. Among IIP patients, MDA5 (201-300) and MDA5 (601-700) positivity were significantly more frequent in non-survivors. Patients positive for MDA5 (201-300) or MDA5 (601-700) had lower 5-year survival rates (34% vs. 66%, $p < 0.01$; 42% vs. 67%, $p < 0.01$, respectively, Figure 3).

Conclusion: We identified two MDA5 epitope regions—MDA5 (201-300) and MDA5 (601-700)—that are strongly associated with treatment resistance and poor prognosis in anti-MDA5-positive DM-ILD. Furthermore, reactivity to these epitopes also predicted poor outcomes in IIPs. Epitope-specific reactivity may reflect underlying pathogenic mechanisms and serve as novel biomarkers for risk stratification and treatment decision-making in ILD with or without obvious autoimmune disease background.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: Plenary I (0772–0776)
Session Type: Plenary Session
Session Time: 9:30AM–11:00AM

Background/Purpose: Seropositive rheumatoid arthritis (RA) has an at-risk stage identifiable by elevations of antibodies to cyclic citrullinated peptide (CCP). Identifying the immunologic factors that distinguish CCP(+) at-risk individuals who progress to RA (Converters) from those who do not (Nonconverters) is crucial to develop strategies for prediction and prevention of clinical RA.

Methods: We used longitudinal data from CCP3(+) individuals in the StopRA trial (NCT02603146) that found hydroxychloroquine (HCQ) was not effective in preventing clinical RA. We used single-cell multi-omics on peripheral blood mononuclear cells from pre-RA/baseline and incident RA-like synovitis timepoints in Converters and at baseline and follow-up in Nonconverters (**Fig 1A-C**). For T cell analysis, we integrated CITE-seq and mass cytometry (CyTOF) data to identify shared T cell clusters, confirming concordant expression patterns across technologies (**Fig 1D-E**). We also developed a composite predictive model for clinical RA (**Fig 1F**).

Results: 47 Converters and 53 Nonconverters underwent CyTOF analyses, and 24 Converters and 12 Nonconverters iCITE-seq/scASAP-seq. At baseline (V0), T peripheral helper (Tph) cells (T-14) were significantly elevated in Converters vs Nonconverters; Converters also had expanded *GZMK+XCL1+CD57+* CD8+ T cells (**Fig 2A-B**). Differential gene expression analysis also showed that at baseline Converters had upregulation of cytotoxic genes (e.g., *GZMB*) in CD8+ T cells, Th2-associated genes (e.g., *CCR4*) and *TNF* in CD4+ T cells, among others, indicating broad dysregulation of inflammatory and cytotoxic pathways (**Fig 2C-D**). Single-cell chromatin accessibility profiling showed that specific chromatin regions were accessible at baseline in Converters, particularly in immune regulatory loci (**Fig 2E-F**). Notably, the *PTPN22* locus exhibited enhanced chromatin accessibility in NK cells at baseline in Converters (**Fig 2G-I**). In longitudinal analyses, TCR analysis showed expanded clones dominated by Tph cells and *GZMB*+ and *GZMK*+ CD8+ T cells in Converters at baseline and at synovitis onset (V1) (**Fig 2J-M**).

A predictive model using baseline Tph frequency, CCP3 levels, and rheumatoid factor (RF) distinguished Converters from Nonconverters with an AUC of 0.771 (**Fig 3A**). A decision tree model further identified those with CCP3 ≥108 units and Tph ≥2.45% of CD3+ T cells had the highest risk for conversion (**Fig 3B**). Kaplan-Meier demonstrated that, at baseline, Converters in the top 20% for Tph or CCP3 levels had a significantly shorter time to RA onset compared to the bottom 20% (**Fig 3C-D**).

Conclusion: Alterations in cellular subsets, gene expression, chromatin accessibility and clonal expansion are present in at-risk individuals with CCP3 elevations who develop synovitis. These findings inform potential targets for preventive interventions in clinical trials as well as prediction models to identify CCP3(+) individuals at highest risk for developing clinical RA. Notably, while HCQ did not show clinical effect, future studies will evaluate HCQ effect on cells and other biomarkers.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Fig.1: Study design for longitudinal single-cell omic data collection from RA-Converters and Nonconverters. A, The study cohort was selected from 144 individuals with anti-CCP3 levels ≥2 times the upper limit of normal who were enrolled and followed longitudinally in the StopRA trial that evaluated the efficacy of hydroxychloroquine (HCQ) in a placebo-controlled fashion to prevent clinical RA. A subset of 36 individuals (24 Converters and 12 Non-Converters) was profiled using single-cell ASAP-seq and 137-plex CITE-seq, including paired single-cell TCR and BCR sequencing. Another subset of 100 individuals (47 Converters and 53 Non-Converters) was analyzed with mass cytometry (MDIPA panel) across 1–3 visits. B, Time points of sample collection per individual. The time to clinical RA diagnosis (day 0) is shown for Converters, and a follow-up visit is indicated for Nonconverters. Data are presented separately for individuals analyzed by CITE-seq/scTCR-seq/scBCR-seq/scASAP-seq (left) and those analyzed by mass cytometry (right). Colored points represent visit status: baseline/follow-up (green) or post-RA (purple). C, Broad immune cell-type identification presented in the UMAP, showing major immune cell types identified across CITE-seq, scASAP-seq, and mass cytometry datasets. D, Strategy to integrate CITE-seq and mass cytometry data for T cell analysis. UMAP projection of integrative T cell subclusters projected into a shared embedding space using overlapping measured 33 proteins with CITE-seq data as reference and mass cytometry as query. Clusters in CITE-seq and joint-space are color-coded and labeled consistently across modalities. E, Normalized protein expression in joint T cell subclusters from CITE-seq (left) and mass cytometry data (right). F, Schematic of the predictive modeling approach. Two research questions were addressed: (RQ1) distinguishing Converters from Nonconverters at baseline (V0) and (RQ2) predicting time to RA onset among Converters. Predictors such as Tph proportions were incorporated into random forest model to prioritize them. Note: CyTOF analyses included study participants who received HCQ or placebo, while CITE-seq and ASAP-seq only included participants who received placebo.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Fig. 2: T cell subcluster analysis by integrating single-cell datasets from CITE-seq, mass cytometry, scASAP-seq, and TCR. A, B, Generalized linear mixed model (GLMM) analysis comparing RA Converters and Nonconverters at each visit point. The odds ratio and 95% confidence intervals (CIs) for each T cell subcluster are shown separately for CD4+ T cells (left) and CD8+ T cells (right). Differences in datasets (CITE-seq or CyTOF), age, gender, batch, individual, and HCQ were corrected by including them as covariates. A, Comparison at baseline (V0). B, Comparison after RA onset (V1). C, D, Differentially expressed genes in CD4+ and CD8+ T cells between Converters and Nonconverters at baseline (V0) and post-RA (V1) stages. T-cell marker genes are annotated. E, Graphical representation of the Converter-related peak analysis. Open chromatin regions associated with RA conversion were identified by comparing chromatin accessibility between Converters and Nonconverters at baseline (V0) and post-RA (V1) stages. F, Venn diagram illustrating the number of significant peaks identified at V0 and V1 (adjusted p-value < 0.05). G, UMAP plot showing the expression of PTPN22, a Converter-associated locus, identified at V0 using CITE-seq data. H, Violin plot showing the PTPN22 mostly expressed by NK cells. I, Illustration of a Converter-associated open chromatin region within the PTPN22 locus. J, UMAP projection of T cells in CITE-seq data colored by CD4T (purple) and CD8T cells (green). K, Clonal expansion of TCR repertoires across visit points. L, M, The composition of the top 20 expanded T cell clones is shown for CD4+ T cells and CD8+ T cells at V0 and V1. The dominant Tph (T-14) clones are highlighted in Converters and Nonconverters.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Fig. 3: Predictive modeling for RA conversion. A, ROC analysis of a composite predictive model incorporating multiple predictors using samples available CyTOF or CITE-seq data (47 Converters and 53 Nonconverters). For cell type frequencies such as Tph cells, values from CITE-seq were prioritized. For samples lacking CITE-seq data, cell type frequencies predicted via integration— as described in Figures 1—were used instead. B, Decision tree model for RA conversion. A classification tree showing hierarchical decision rules based on CCP3 levels, Tph cells (T-14), and RF status to predict RA conversion risk. Pie charts at terminal nodes indicate the proportion of Converters (blue) and Nonconverters (gray). C-D, Survival analysis of RA conversion stratified by Tph and CCP3 levels. Kaplan-Meier curves showing time to RA onset based on (C) top and bottom 20% of Tph proportions and (D) top and bottom 20% of CCP3 levels. Statistical significance was assessed using log-rank tests.

Abstract Number: 0775

Increased Circulating Microbial Small RNA tDR-1 is Associated with Decreased Progression to Future Clinical Rheumatoid Arthritis In High Risk Individuals and Reduces In Vitro Type 1 Interferon Response Gene Expression

Anastasiia Phothisane[1], Tulsi Joishy[2], Carolina Ramirez-Becerra[1], Zuofei Wang[2], Qiong Wu[3], Jennifer Seifert[4], Marie Feser[5], Jill Norris[6], Kristen Demoruelle[7], LauraKay Moss[5], Kevin Deane[8], V. SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: Plenary I (0772–0776)
Session Type: Plenary Session
Session Time: 9:30AM–11:00AM

Background/Purpose: Microbial small RNAs (sRNAs) can regulate human genes, often with anti-inflammatory effects. We previously showed that an increased plasma concentration of a tRNA-derived RNA (tDR-1), produced by multiple bacteria from the phylum Proteobacteria, was associated with lower RA disease activity, particularly fewer tender joints, in 2 independent cohorts, and better treatment response to multiple disease modifying antirheumatic drugs. The purpose of this study was to determine if tDR-1 is a biomarker associated with decreased future development of clinical RA among individuals at-risk for the disease and exhibits *in vitro* anti-inflammatory effects which may affect RA development.

Methods: Archived longitudinal plasma and clinical data from participants from the Studies of the Etiology of Rheumatoid Arthritis cohort were used for this study. Microbial tDR-1 was measured in plasma by quantitative PCR by investigators blinded to clinical details. Human THP-1 monocyte-derived macrophages were treated with tDR-1, scramble control or

Table. Participant demographics

	Control (n= 123)	CCP3+, no RA (n=35)	CCP3+, pre-RA (n=25)
Age, years	46 ± 16	48 ± 15	51 ± 12
Race/ethnicity, # non-Hispanic White	92 (77)	28 (82)	18 (72)
Gender, # Female	85 (69)	26 (74)	15 (60)
BMI, kg/m2	26 ± 5.8	26.9 ± 5.3	27.8 ± 5.3
First degree relative with RA, #	9 (7)	19 (54)	9 (36)
Shared epitope, # positive	53 (45)	11 (31)	18 (72)
Smoker, # ever	28 (23)	13 (39)	14 (56)
RF IgA, # positive	0 (0)	3 (9)	4 (16)
RF IgG, # positive	0 (0)	6 (17)	7 (28)
RF IgM, # positive	0 (0)	6 (17)	7 (28)
Anti-CCP2, # positive	0 (0)	3 (9)	16 (64)
Anti-CCP3, # positive	0 (0)	35 (100)	25 (100)
Anti-CCP3.1, # positive	0 (0)	27 (77)	24 (96)

Data presented as number (percent) for categorical variables and mean ± standard deviation for continuous variables. CCP3+, pre-RA = anti-CCP3+ participants who later developed RA. CCP3+, no RA = anti-CCP3 positive participants who did not develop RA. Missing data: Age for 1 control. Race/ethnicity for 4 control, 1 CCP3+ no RA. BMI for 2 control, 3 CCP3+ no RA, 2 CCP3+ pre-RA. Shared epitope for 4 control. Ever smoker status for 3 control, 2 CCP3+ no RA. CCP2 status for 16 control.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

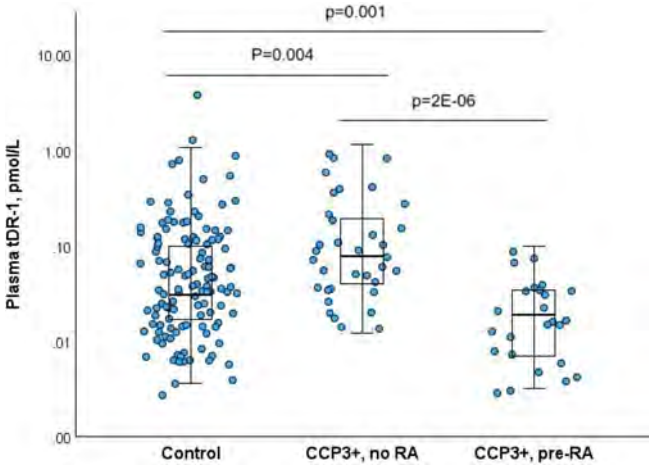

Figure 1. Plasma tDR-1 concentration in seronegative controls, CCP3+ participants who did not develop future RA (CCP3+, no RA), and CCP3+ participants who later developed RA (CCP3+, pre-RA). The Y axis is presented in log-scale. Comparison by Mann-Whitney U test.

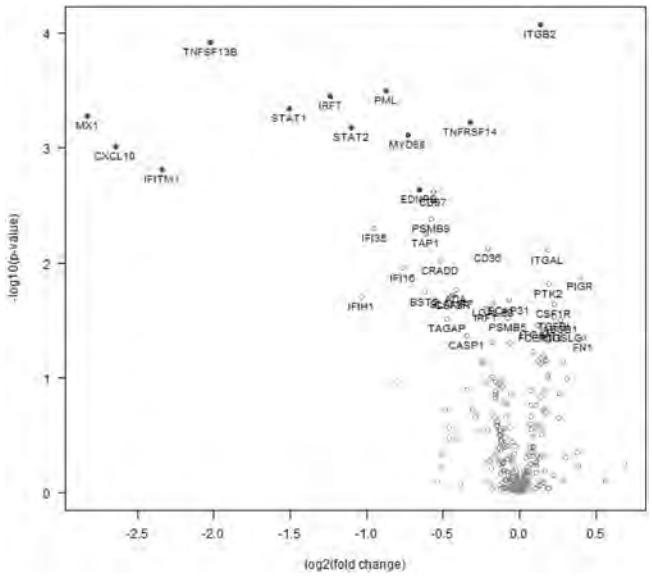

Figure 2. Change in gene expression in human THP-1 monocyte derived macrophages after treatment with tDR-1 versus scramble control. The majority of significantly downregulated genes are interferon response genes.

transfection reagent alone in triplicate. After 24 hours, gene expression was assessed by the Nanostring Immunology panel. Pathway analysis was performed using Ingenuity Pathway Analysis.

Results: The study included 60 participants at-risk for development of RA with anti-CCP3 antibody positivity (CCP3+) without synovitis at baseline and 123 seronegative control participants. Among the CCP3+ participants, 25 later developed clinical RA (defined by meeting 2010 classification criteria or presence of inflammatory arthritis) and 35 did not (**Table**). Microbial tDR-1 was 7.7-fold (p=2E-06) (**Figure 1**) enriched at baseline among CCP3+ participants who did not develop RA versus those who did, and remained independently associated with decreased RA development after adjustment for the presence or absence of any other autoantibody (including CCP2, CCP3.1, RF IgA, RF IgM, or RF IgG), shared epitope, and ever smoker status (p=0.006). Among CCP3+ at-risk participants, plasma tDR-1 concentration had an area under the receiver operating characteristic curve of 0.856 (95% CI 0.768, 0.951) for prediction of not developing RA (p=1.2E-14). Compared to scramble control, tDR-1 significantly downregulated many interferon response genes including *MX1* (**Figure 2**), and pathway analysis identified interferon signaling as most downregulated by tDR-1.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Enrichment of circulating microbial tDR-1 is independently associated with decreased development of future RA among those at high risk for disease. Its ability to reduce interferon response genes, which are typically elevated in early RA, suggests a potential mechanism by which the microbiome could affect the development of RA via sRNAs.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: Plenary I (0772–0776)
Session Type: Plenary Session
Session Time: 9:30AM–11:00AM

Background/Purpose: In the SELECT-GCA phase 3 trial, treatment of patients with GCA with upadacitinib 15 mg (UPA15) demonstrated superior rates of disease remission, fewer disease flares, and reduced glucocorticoid (GC) use compared with placebo (PBO).[1] The current study analyzed the 2-year outcomes in this trial.

Methods: SELECT-GCA included a 52-week randomized, PBO-controlled period 1 and a 52-week randomized, blinded extension period 2. Patients aged ≥ 50 years with a diagnosis of active GCA were randomized (2:1:1) to UPA15 or UPA 7.5 mg (UPA7.5) once daily with a 26-week GC taper or PBO with a 52-week GC taper. Period 2 involved patients in remission (absence of the signs or symptoms of GCA and adherence to the protocol-defined GC taper) for ≥ 24 consecutive weeks before the week 52 visit. Patients originally randomized to UPA7.5 or UPA15 were re-randomized (2:1) to continue the same dose of UPA or to switch to PBO in period 2. Patients originally randomized to PBO continued PBO. Efficacy outcomes were evaluated through week 104 and included remission (defined in period 2 as the absence of the signs or symptoms of GCA and no GC use for GCA), disease flare-related endpoints, and cumulative GC exposure. The safety analysis included all patients who received ≥ 1 dose of study drug in period 1 and continued the same treatment in period 2. Exposure-adjusted treatment-emergent adverse events (TEAEs) are reported through 2 years in this population.

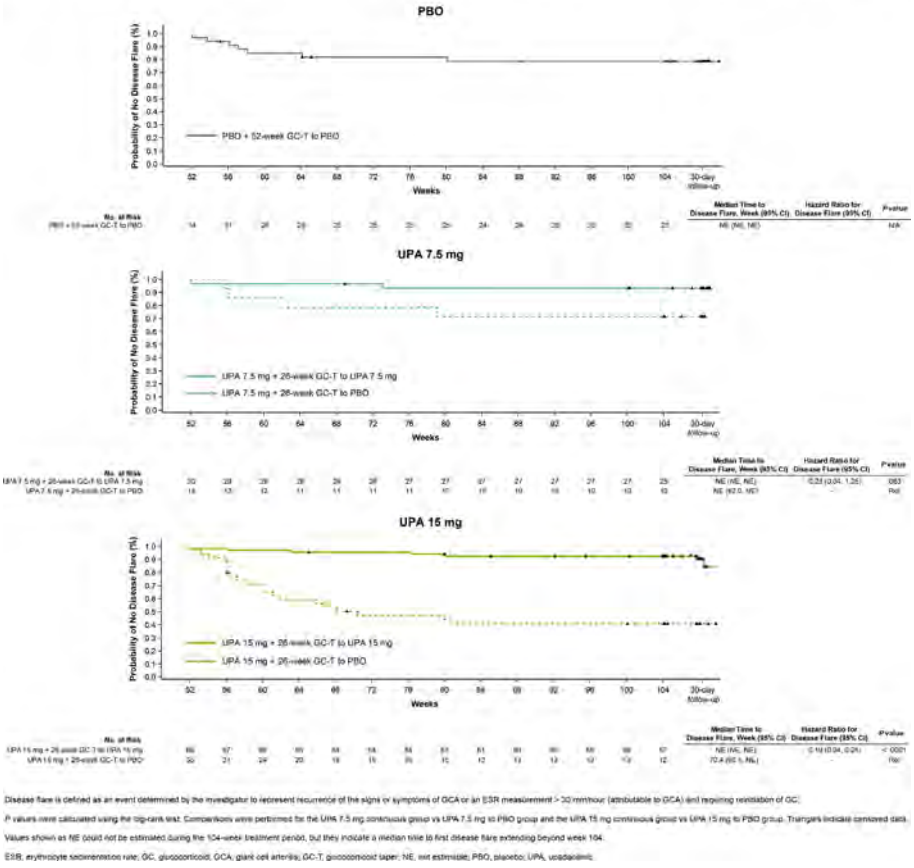
Figure 1. Kaplan-Meier Curves for Time to First Disease Flare for Patients Who Achieved ≥ 24 Consecutive Weeks of Remission in Period 1 and Entered Period 2



Disease flare is defined as an event determined by the investigator to represent recurrence of the signs or symptoms of GCA or an ESR measurement > 30 mm/hour (attributable to GCA) and requiring reinitiation of GC.

P values were calculated using the log-rank test. Comparisons were performed for the UPA 7.5 mg continuous group vs UPA 7.5 mg to PBO group and the UPA 15 mg continuous group vs UPA 15 mg to PBO group. Triangles indicate censored data.

Values shown as NE could not be estimated during the 104-week treatment period, but they indicate a median time to first disease flare extending beyond week 104.

ESR, erythrocyte sedimentation rate; GC, glucocorticoid; GCA, giant cell arteritis; GC-T, glucocorticoid taper; NE, not estimable; PBO, placebo; UPA, upadacitinib.

Results: Of 428 patients randomized and treated in period 1, 181 (42%) achieved ≥ 24 consecutive weeks of sustained remission in period 1 and entered period 2 (PBO continuous, n = 34; UPA7.5 continuous, n = 30; UPA7.5 to PBO, n = 14; UPA15 continuous, n = 68; UPA15 to PBO, n = 35). Most (91%) of these patients completed the study, with 82% remaining on study drug. From week 52 through week 104, 68.6% of patients on continuous UPA15 maintained remission vs 28.6% who switched from UPA15 to PBO (**Table 1**). Patients on continuous UPA15 showed a 90% reduction in risk of disease flare from week 52 through week 104 compared with those who switched from UPA15 to PBO (**Figure 1**). The continuous UPA15 group also showed greater improvements across most other endpoints (**Table 1**), including those related to disease flare and cumulative GC exposure.

Safety was generally similar for UPA and PBO groups among patients who continued the same treatment in period 2 (**-Table 2**). Rates of serious TEAEs were lower for both UPA doses than PBO. Compared to PBO, UPA15 showed lower rates of serious infections but higher rates of herpes zoster and elevated creatine kinase. One venous thromboembolism event occurred with UPA15 in a patient with multiple risk factors and none in the other treatment groups. No major adverse cardiovascular events or deaths occurred in period 2 in any treatment group.

Conclusion: For patients with GCA receiving UPA15, continued use of UPA in those who were in remission for ≥ 24 weeks during period 1, rather than switching to placebo, was associated with maintenance of remission and an approximately 1-gram reduction in the cumulative use of GCs in period 2. In this population (mean age: 71 yrs), no new clinically significant safety risks were identified with use of UPA for 2 years.

[a]At baseline, 428 patients (N = 112; PBO; N = 107; UPA 7.5 mg; N = 209; UPA 15 mg) were originally randomized and treated in the SELECT-GCA trial. This table reports efficacy outcomes for the 181 patients who achieved remission for ≥ 24 consecutive weeks in period 1 and entered period 2.

[b]Data are reported as percentage for categorical endpoints, LS mean for continuous endpoints (except for cumulative GC exposure), and median for cumulative GC exposure. The proportion of patients maintaining remission from week 52 through week 104 and the proportion of patients in complete remission at week 104 were evaluated by nonresponder imputation using multiple imputation. *$P \leq .05$; **$P \leq .01$; ***$P \leq .001$.

[c]PBO + 52-week GC-T to PBO, n = 31; UPA 7.5 mg + 26-week GC-T to UPA 7.5 mg, n = 29; UPA 7.5 mg + 26-week GC-T, n = 12; UPA 15 mg + 26-week GC-T to UPA 15 mg, n = 64; UPA 15 mg + 26-week GC-T to PBO, n = 31.

[d]Values shown as NE could not be estimated during the 104-week treatment period, but they indicate a median time to first disease flare extending beyond week 104.

[e]Complete remission was defined as follows: (1) absence of the signs and symptoms of GCA; (2) normalization of ESR (to < 30 mm/hour), although if ESR > 30 mm/hour and the elevation was not attributable to GCA, this criterion could still be met; (3) normalization of hsCRP (to < 1 mg/dL); and (4) no GC use for GCA.

[f]PBO + 52-week GC-T to PBO, n = 25; UPA 7.5 mg + 26-week GC-T to UPA 7.5 mg, n = 25; UPA 7.5 mg + 26-week GC-T, n = 9; UPA 15 mg + 26-week GC-T to UPA 15 mg, n = 57; UPA 15 mg + 26-week GC-T to PBO, n = 14.

ESR, erythrocyte sedimentation rate; GC, glucocorticoid; GCA, giant cell arteritis; GC-T, glucocorticoid taper; hsCRP, high-sensitivity C-reactive protein; LS, least-squares; NE, not estimable; PBO, placebo; PCS, physical component score; TSQM, Treatment Satisfaction Questionnaire for Medication; UPA, upadacitinib.

Table 3. Exposure-Adjusted Rates of Treatment-Emergent Adverse Events Through 2 Years in the SELECT-GCA Trial[a, b]

Variable—Events (E/100 PY)	PBO + 52-week GC-T to PBO (N = 43; PY = 82.5)	UPA 7.5 mg + 26-week GC-T to UPA 7.5 mg (N = 39; PY = 79.3)	UPA 15 mg + 26-week GC-T to UPA 15 mg (N = 92; PY = 184.1)
Overall TEAEs			
Any AE	438 (530.9)	305 (384.6)	938 (509.6)
Serious AE	21 (25.5)	16 (20.2)	32 (17.4)
AE leading to study drug discontinuation	4 (4.8)	2 (2.5)	9 (4.9)
Death	0	0	0
TEAEs of special interest			
Serious infection	6 (7.3)	3 (3.8)	5 (2.7)
Opportunistic infection[c]	1 (1.2)	0	1 (0.5)
Herpes zoster	2 (2.4)	4 (5.0)	8 (4.3)
Malignancy excluding NMSC[d]	0	2 (2.5)	2 (1.1)
NMSC	4 (4.8)	1 (1.3)	6 (3.3)
VTE (adjudicated)[e]	0	0	1 (0.5)
MACE (adjudicated)[f]	0	0	0
Gastrointestinal perforation	0	0	0
Renal dysfunction	1 (1.2)	0	0
Hepatic disorder	3 (3.6)	1 (1.3)	7 (3.8)
Anemia	4 (4.8)	4 (5.0)	12 (6.5)
Lymphopenia	0	0	1 (0.5)
Creatine kinase elevation	0	0	8 (4.3)
Retinal detachment	4 (4.8)	2 (2.5)	9 (4.9)
Bone fracture	3 (3.6)	1 (1.3)	2 (1.1)

[a]Safety results are not from the overall SELECT-GCA population but include all adverse events through 2 years (ie, both period 1 and 2) for patients originally randomized to PBO, UPA 7.5 mg, or UPA 15 mg and who received continuous treatment thereafter. All events are reported as TEAEs, which are defined as any adverse event with an onset date or worsening in severity date after initiation of study drug and no more than 30 days after the last dose of study drug in the trial.

[b]No TEAEs of active tuberculosis, lymphoma, or neutropenia, were reported in any treatment group through the end of the study.

[c]Excludes herpes zoster.

[d]UPA 7.5 mg: 1 lung adenocarcinoma and 1 papillary thyroid cancer; UPA 15 mg: 1 lentigo maligna and 1 prostate cancer.

[e]Includes pulmonary embolism and deep vein thrombosis.

[f]Defined as cardiovascular death, non-fatal myocardial infarction, and non-fatal stroke.

AE, adverse event; E, event; GC-T, glucocorticoid taper; TEAE, treatment-emergent adverse event; NMSC, nonmelanoma skin cancer; PBO, placebo; PY, patient-years; UPA, upadacitinib.

Table 1. VEXAS-DAI domains		
Domain	Items	Max Score
Inflammatory-type rash	2	4
Chondritis	3	3
Periorbital involvement	1	2
Ophthalmologic involvement	5	4
Joint involvement	1	2
Pulmonary involvement	3	4
Cardiovascular involvement	3	4
Genitourinary involvement	1	3
Neurological involvement	5	4
Oral/gastrointestinal involvement	3	4
Renal involvement	1	4
New thrombosis / thromboembolism	1	0
Constitutional symptoms	2	2
Total	30 scored items	40

Background/Purpose: VEXAS syndrome is a recently described severe disease characterized by a complex overlap of inflammatory and hematologic features. Due to the severity and refractory nature of inflammation in VEXAS patients, establishing effective treatment strategies is challenging, particularly in the absence of validated tools to assess disease activity. Standardized disease activity indices (DAIs) are crucial for patient care and advancing clinical research in inflammatory disorders. To date, the only proposed – though not validated – DAI for VEXAS is the VEXASCAF, which evaluates disease activity based on the presence or absence of 11 equally weighted manifestations (Kirino Y, et al. *Rheumatology (Oxford)*. 2024 Sep 28). While the VEXASCAF represents an important first step, it has limitations: it may not capture less commonly involved organ systems or be sufficiently sensitive to changes in disease severity. A more comprehensive and sensitive DAI could aid in clinical research and improve patient care.

Methods: Manifestations of VEXAS syndrome were previously identified by systematic literature review and expert feedback. The VEXAS-DAI was developed based on an expert advisory committee using modified Delphi methodology until consensus was reached (defined as ≥75% concurrence). All items were graded based on adapted Common Terminology Criteria for Adverse Events (CTCAE) criteria. Scoring was developed based on Physician Global Assessment of inflammation on 158 test cases. The final instrument was developed based on input from 24 VEXAS expert physicians worldwide.

Results: Consensus on the novel VEXAS-DAI was achieved after 4 rounds of interactive revisions. Scoring is based on severity of symptoms at the time of examination. The VEXAS-DAI includes 12 scored domains, each with a specified number of items **(Table 1)**: inflammatory-type rash (2), chondritis (3), ophthalmologic involvement (5), periorbital involvement (1), joint (1), pulmonary (3), cardiovascular (3), genitourinary (1), neurologic (5), oral and gastrointestinal (3), renal (1), and constitutional symptoms (present or absent). Additionally, a thrombosis and thromboembolism domain is included but remains unscored. Scores range from 0 to 40.

Conclusion: The VEXAS-DAI is designed to measure active inflammation in patients with VEXAS syndrome. Work is ongoing to validate this instrument in the context of a clinical trial.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases I: Focus on Auto-Inflammatory Diseases (0777–0782)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Still's disease (SD) is a autoinflammatory disease (AID) characterized by a wide range of clinical manifestations and can exhibit life-threatening macrophage activation syndrome (MAS). Procalcitonin (PCT), a potential biomarker in SD, may be increased even in the absence of infection. The nature of PCT in AIDs remains unclear. We aimed to reveal the relationship between non-infectious increased PCT and the clinical features of SD.

Methods: In this retrospective study, patients with available PCT data at the time of diagnosis and fulfilling the Yamaguchi criteria were enrolled, as well as age- and sex-matched healthy individuals. Patients with any suspicious or documented infection at the time of diagnosis and/or during the active disease course and other factors that increase PCT, such as impaired renal function, were excluded from the study. Patients were classified into two groups based on the cut-off value of PCT, which was 0.5 ng/dl. Findings during the active disease, treatment, and laboratory parameters were evaluated.

Results: This study was conducted with 110 patients. PCT levels in SD, SD without MAS, and SD with MAS were significantly higher compared with healthy control (0.04 [0.03-0.04] ng/ml) (all three p< 0.001). PCT levels in SD with MAS were also significantly higher than SD without MAS (p=0.002) (Figure 1). Seventy-five (68%) patients were in the PCT < 0.5 group, and 35 (32%) patients were in the PCT ≥0.5 group. Patients' characteristics are shown in Table 1. Pleuritis and MAS were more frequent in the PCT ≥0.5 group (p=0.004, p=0.001, respectively). mPouchet score was significantly higher in the PCT ≥0.5 group (p=0.017). The requirement for bDMARD, especially anakinra, was higher in the PCT ≥0.5 group (p=0.051, p=0.008, respectively). Laboratory parameters of the patients are presented in Table 2. Platelet count was lower; thus, thrombocytopenia was higher in the PCT ≥0.5 group (p=0.008, p=0.011, respectively). AST and LDH levels were significantly higher in the PCT ≥0.5 group (p=0.006, p< 0.001, respectively). CRP and ferritin levels were significantly higher in the PCT ≥0.5 group, whereas albumin was lower (p=0.013, p< 0.001, and p=0.002, respectively). There was a positive correlation between PCT levels and AST, LDH, CRP, and ferritin levels (r=0.339, p< 0.001; r=0.584, p< 0.001; r=0.288, p<

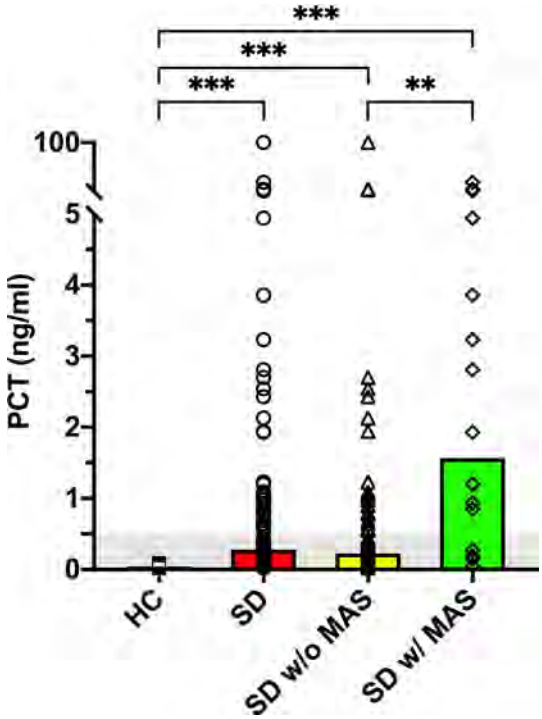

Figure 1. Procalcitonin (PCT) levels of patients with Still's disease (SD) (n=110), SD without macrophage activation syndrome (MAS) (n=94), and SD with MAS (n=16) at the time of diagnosis and healthy control (HC) (n=50). Bars show the median value. Mann-Whitney U; ** p<0.01, *** p<0.001.

0.01; and r=0.499, $p< 0.001$, respectively). In univariate logistic regression analysis, the risk for development of MAS was up to 6.4-fold in the PCT ≥0.5 group (crude OR 6.4 [CI 95% 2.0-20.4], p=0.002), while up to 4.3-fold in multivariate logistic regression analysis (adjusted OR 4.3 [CI 95% 1.1-16.8], p=0.038). Normalization of PCT levels occurred in all patients after immunosuppressive treatment.

†Fisher's Exact, ‡Chi-Square, ¢Mann-Whitney U, and ¥Student's-t test. Abbreviations: ALT, alanine aminotransferase; AST, aspartate aminotransferase; CRP, c-reactive protein; ESR, erythrocyte sedimentation rate; IQR, interquartile range; LDH, lactate dehydrogenase; LFT, liver function tests; med, median; n, number of patients; PCT, procalcitonin; PMNL, polymorphonuclear leukocytes; SD, standard deviation; ULN, upper limit of normal; WBC, white blood cell.

Conclusion: According to the results of this preliminary study, the high risk of developing MAS and the requirement of bDMARD are indicative of a high inflammatory response in patients with increased PCT. Our results provide evidence that high PCT in SD is a potential independent predictor of MAS. PCT may be a convincible marker in AIDs like other well-known inflammatory parameters. Further studies are warranted to confirm the study findings in larger cohorts and to explain the mechanism of PCT elevation in AIDs.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases I: Focus on Auto-Inflammatory Diseases (0777–0782)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Goflikicept (GFC; RPH-104) is a novel fusion protein inhibiting interleukin-1 (IL-1). This study aimed to investigate its efficacy and safety in IL-1β-driven monogenic autoinflammatory disorder of Familial Mediterranean Fever (FMF).

Methods: Adult patients with FMF who were resistant or intolerant to colchicine and had ongoing attacks were randomized in the international, multicenter phase 2 double-blinded study to receive GFC subcutaneously in a dose of 160 mg (day 0), 80 mg (day 7), 80 mg (day 14), and 80 mg every 2 weeks (q2w) thereafter or matching injections of placebo for 16 weeks. Marker attack was defined as the combination of Physician Global Assessment (PGA) ≥2 and CRP >10 mg/l. If the marker FMF attack was not resolved or a recurrent attack occurred, the patients were unblinded, and those on placebo switched to GFC. The primary endpoint was a proportion of patients with complete treatment response (marker attack resolution and development of no new attacks).

Results: In total, 28 patients were randomized. Of them, 24 patients completed the study per protocol, 4 patients discontinued treatment prematurely, and 3 of them were in the GFC arm: 1 due to prohibited treatment; 1 due to lack of efficacy; 1 due to an adverse event (AE). The complete response was achieved in 9 (64.3%) patients in the GFC arm and in 1 (7.1%) patient in the placebo arm (p=0.004). No recurrent attack occurred after switching from placebo to GFC in 12 of 13 patients (92%). Minimal or no disease activity (PGA < 2) and CRP decrease ≤10 mg/l were achieved in the majority of patients in the GFC arm but not in the placebo arm (*Fig. 1, Fig. 2*). At least one AE was reported in 11 (78.6%) patients in the GFC arm, in 3 (21.4%) patients in the placebo arm, and in 8 (61.5%) patients who were switched from placebo to GFC. The majority of AEs were mild to moderate in severity. In one patient (switched from placebo to GFC), there was a serious AE of inflammation during the safety follow-up period. In one of the GFC arm patients, diarrhea led to premature treatment discontinuation. GFC treatment was safe and overall well tolerated. Safety profile of GFC was consistent with other IL-1 inhibitors; no new safety signals were reported.

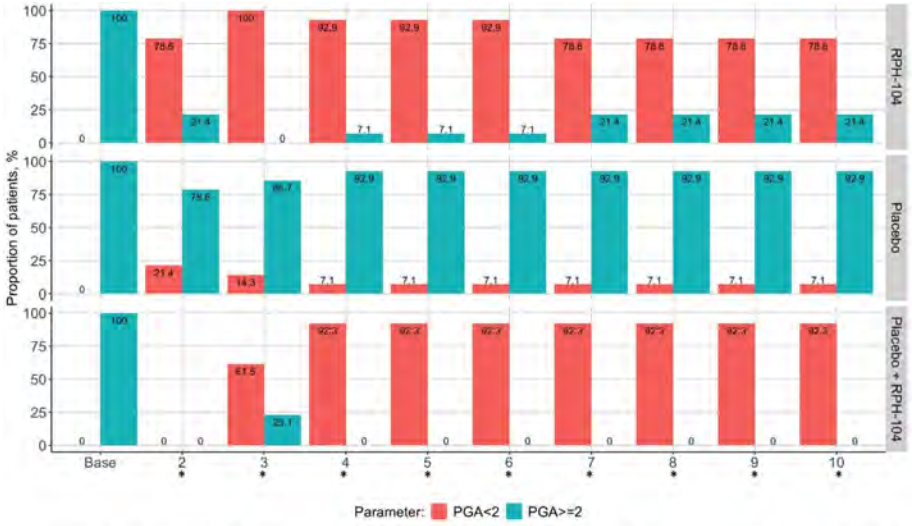

Figure 1. Proportion of subjects with minimal disease activity/ inactive disease (PGA score < 2) during the treatment period

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

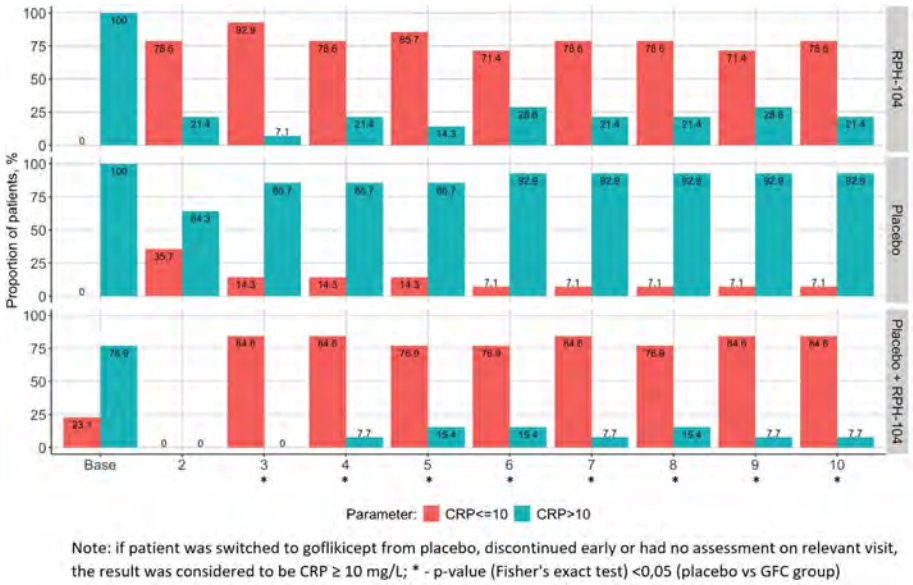

Figure 2. Proportion of subjects with CRP ≤ 10 mg/L during the treatment period

Conclusion: GFC provided a significant improvement in the disease activity of colchicine-refractory/intolerant FMF patients compared to placebo, and its safety profile was similar to other IL-1 inhibitors.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases I: Focus on Auto-Inflammatory Diseases (0777–0782)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: MAS is a life-threatening complication of Still's disease, characterized by IFNg-driven macrophage activation and systemic hyperinflammation. Chemokine C-X-C motif ligand 9 (CXCL9) is released in response to IFNg and can be used as a marker of IFNg activity. Emapalumab binds free and receptor-bound IFNg, providing rapid and targeted neutralization of IFNg. Emapalumab achieved rapid control of MAS in a pooled patient population from two open-label, single-arm interventional studies (NI-0501-06 [NCT03311854] and NI-0501-14 [EMERALD; NCT05001737]). Changes in key PD markers in this population were evaluated according to achievement of response and time to response.

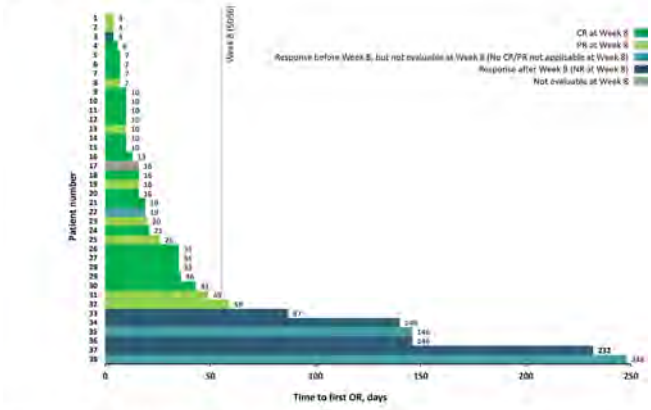
Methods: Patients with MAS in Still's disease who had an inadequate response to high-dose glucocorticoids (GCs), or investigator-assessed rapid worsening of clinical condition and/or laboratory parameters, were treated with emapalumab for 4 weeks: a 6 mg/kg loading dose, followed by 3 mg/kg every 3 days from days 4–16, then 3 mg/kg twice weekly until Day 28 (or longer if insufficient clinical response). The primary efficacy endpoint was complete response (CR) at Week 8, defined as resolution of clinical signs according to investigator assessment (visual analog scale [VAS] ≤1/10 cm) and normalization of 7 MAS-related laboratory parameters. Overall response (OR) was defined as a CR or partial response (PR; VAS < 4 cm and normalization of ≥3 abnormal baseline laboratory parameters included in the composite primary endpoint).

Results: 39 patients were enrolled (31 [79.5%] females; median age, 12 years [range, 9 months–64 years]). At Week 8, 21/39 (53.8%) patients treated with emapalumab achieved a CR (95% confidence interval, 37.2–69.9%) and 29/38 patients (76.3%) had an OR at Week 8.

The median time to first OR was 16 days with 32/39 patients achieving an OR before Week 8 and 6 patients had their first response after Week 8. (**Figure 1**). Once an OR was reached, response was generally maintained through Week 8 and most patients were able to reach CR (**Figure 2**).

Patients with CR (n=20) or PR (n=9) at Week 8 had higher geometric mean levels of CXCL9 (CR, 3206 ng/mL; PR, 2371 ng/mL), ferritin (CR, 8186 µg/mL; PR, 8452 µg/mL) and soluble CD25 (sCD25; CR, 5654 ng/mL; PR, 7436 ng/mL) at baseline versus Week 8 non-responders (n=5) (CXCL9, 291 ng/mL; ferritin, 2633 µg/mL; sCD25, 1531 ng/mL).

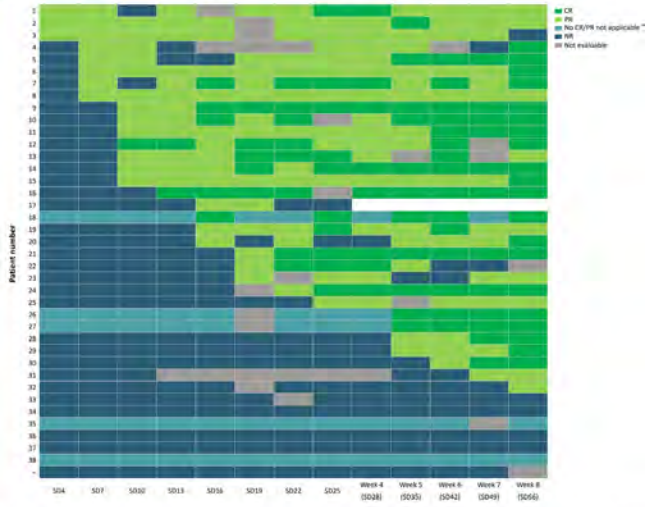
Figure 1. Time to first OR (n=38)



Patient #3 lost PR at Week 8, Patient #17 died before Week 8. CR, complete response; NR, no response; OR, overall response; PR, partial response.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 2. Heatmap of patient-level response to emapalumab in patients with MAS in Still's disease with an inadequate response to glucocorticoids through Week 8



*A PR was not applicable for patients who could not meet the definition of a PR because <3 abnormalities in laboratory parameters were present at baseline. Patient #17 died before Week 8. 84.6% of patients received concomitant biologics alone or in combination, mainly anti-IL-1 (66.6%) and Cyclosporin A (43.6%). CR, complete response; PR, partial response, SD, study day.

All patients had rapid and sustained CXCL9 and ferritin declines over time: at Week 8, CXCL9 and ferritin median percentage reductions from baseline were -99% and -92% in patients with CR or PR, respectively. NR had similar declines in CXCL9 (n=2; -86%) and ferritin (n=5; -89%) at Week 8, though sCD25 remained relatively unchanged vs baseline (n=2; +21%).

Conclusion: Half of the patients with MAS secondary to Still's disease with an inadequate response to high-dose GCs treated with emapalumab achieved a first OR within 16 days and most patients having a sustained treatment effect reaching a CR at Week 8. Emapalumab treatment rapidly reduced key PD markers, including CXCL9 and ferritin, aligning with IFNγ's role in MAS and emapalumab's mechanism of action.

Abstract Number: 0781

Comprehensive mass cytometry analyses of disease-related cells in adult-onset Still's disease

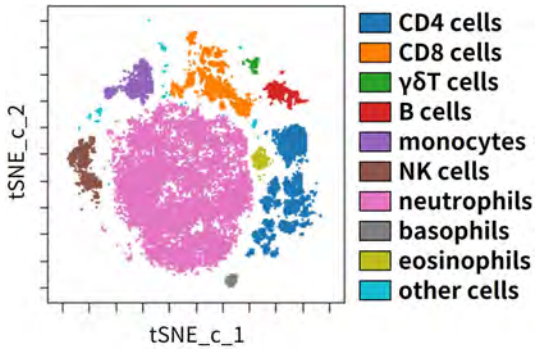
Hiroto Yoshida[1], Mayu Magi[1], Hiroya Tamai[2], Kotaro Matsumoto[2], Keiko Yoshimoto[2], Tetsuhiro Soeda[1] and Yuko Kaneko[2], [1]Chugai Pharmaceutical Co., Ltd. Product Research Dept., Yokohama, Kanagawa, Japan, [2]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Shinjuku-ku, Tokyo, Japan

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases I: Focus on Auto-Inflammatory Diseases (0777–0782)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Adult-onset Still's Disease (AOSD) is a rare autoinflammatory disorder characterized by high fever, rash, and arthritis. Although overactivation of macrophages, an increase in specific neutrophils, disruption of Th17/Treg cell balance, and decreased NK cell function have been reported in the pathogenesis of AOSD, the detailed roles and interactions of these immune cells in various aspects of the disease pathogenesis remain unclear. This study aimed to identify disease-related cell populations through comprehensive immunophenotyping analysis by mass cytometry.

Methods: Mass cytometry of peripheral whole blood was performed using 50 samples from patients with AOSD (six untreated active and forty-four in clinically inactive disease [CID]) and 21 control samples from healthy subjects (HC). Whole blood was stained with Maxpar Direct Immune Profiling Assay from Standard BioTools which contains antibodies of 30 markers and measured by Helios. The data was analyzed in Cytobank from Beckman Coulter. Dimensionality reduction and clustering analysis was performed using tSNE-CUDA and FlowSOM.

Results: The proportions of B cells, NK cells, and gamma delta T cells were significantly decreased in the active AOSD group compared to the HC group. These changes in cell subset proportions were persistent even after achieving CID. For more detailed analysis, we used FlowSOM clustering to divide those cells into 400 clusters. In the active AOSD group, the proportions of 66 clusters were significantly higher compared with the HC group. Among the increased cell clusters, 21 clusters were not different between the CID and HC groups, including CD4 cells, CD8 cells, monocytes, neutrophils, and eosinophils. Based on the expression patterns, the monocytes were characterized as intermediate monocytes with upregulated CD11c and HLA-DR and downregulated CD38. The CD4 cells exhibited features of effector memory cells, characterized by upregulation of CXCR3, CCR4, CD28, CD38, and HLA-DR, along with downregulation of CD27 and CD127. Similarly, the CD8 cells were also classified as effector memory cells, showing upregulation of CXCR3, CD27, CD28, CD38, and HLA-DR, and downregulation of CD57 and CD127.



Dimensionality reduction by tSNE-CUDA in mass cytometry data of peripheral blood cells

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Cell subsets increased in untreated active AOSD and normalized upon CID

Heatmap of marker expression in cell subsets normalized upon CID

Conclusion: Comprehensive and detailed mass cytometry analysis of peripheral blood cells from patients with AOSD identified characteristic intermediate monocytes and effector memory T cells were increased in the active phase and normalized after achieving CID. Those cell subsets may play an important role in the pathogenesis of AOSD and can be a new therapeutic target.

Expansion of T bet Age-Associated B Cells Is Associated with Clinical Complications in Stills Disease

Krisztian Csomos[1], Boglarka Ujhazi[1], Mariana Correia Marques[2], Emily Rosenbaum[1] and Michael Ombrello[3], [1]National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), NIH, Bethesda, MD, [2]Translational Genetics and Genomics Section, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, [3]National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health (NIH), North Bethesda, MD

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases I: Focus on Auto-Inflammatory Diseases (0777–0782)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Still's disease is a rare and severe autoinflammatory disorder characterized by daily spiking fevers, arthritis, an evanescent rash, and prominent systemic features, including lymphadenopathy, hepatosplenomegaly, serositis, and systemic inflammation mediated primarily by IL-1, IL-6, and IL-18. Still's disease can lead to severe and often fatal

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. complications, such as Still's disease-associated lung disease (Still's-LD). Still's-LD is a chronic and severe pulmonary disorder, particularly observed in patients treated with modern biologic therapies. It is characterized by interstitial lung disease (ILD), pulmonary alveolar proteinosis (PAP), pulmonary arterial hypertension, and chronic respiratory failure. Although extensive innate immune dysregulation, T cell activation, and an IFN--driven inflammatory milieu have been implicated in the pathogenesis of Still's-LD, the immunopathologic basis of the disease remains poorly understood. CD21low T-bet+ atypical or Age-Associated B cells (ABCs) are known to expand under conditions of chronic antigen exposure and inflammation, such as chronic infections (e.g., malaria, HIV) and autoimmune diseases (e.g., systemic lupus erythematosus and rheumatoid arthritis). We aimed to investigate the potential role of ABCs in Still's disease and related clinical complications.

Methods: Single-cell RNA sequencing (scRNA-seq) data of peripheral blood mononuclear cells (PBMCs) of Still's disease patients (n = 21) and healthy individuals (n = 5) were studied in silico to assess B cell composition and characterize ABCs. In parallel, 36-color spectral flow cytometry immunophenotyping was performed on a separate cohort of Still's disease patients (n = 61) and healthy individuals (n = 27) to further evaluate B cell subset distribution, class-switching, activation status, and ABC phenotype.

Results: scRNA-seq analysis revealed an expansion of ABCs in Still's disease patients compared to healthy controls (7.46 +/- 5.58% vs. 3.69 +/- 1.3%), that was more prominent in active vs inactive patients (8.19 +/- 6.09% vs. 5.13 +/- 2.72%). Notably, ABCs were more abundant in patients with Still's disease-associated lung disease (Still's-LD) than in those with active or inactive Still's disease without pulmonary involvement (9.86 +/- 8.45% vs. 5.54 +/- 2.82%). Flow cytometry analysis revealed widespread B cell activation, confirmed the expansion of ABCs across the patient cohort ($p = 0.0049$), and identified a significant correlation between ABC frequency and the presence of lung disease ($p = 0.0066$).

Conclusion: These findings suggest that ABC expansion is associated with Still's disease and correlates with both disease severity and the presence of lung complications. This previously unrecognized association implicates ABCs in the pathogenesis of Still's-LD and indicates that their abundance may serve as a potential biomarker for disease progression and clinical status.

Abstract Number: 0784

Physical Activity and Exercise Therapy Reduce the Transition from Acute to Chronic Low Back Pain in the Community

Katlin Harker[1], Rebecca Fillipo[2] and Adam Goode[2], [1]Durham VA, Durham, [2]Duke University, Durham

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: Abstracts: Orthopedics, Low Back Pain, & Rehabilitation (0783–0788)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Physical activity (PA) and exercise therapy are guideline-supported interventions for chronic LBP, but their influence on the transition from acute to chronic LBP is unclear. This study aimed to determine if baseline self-reported exercise therapy or sufficient PA during the acute LBP phase would prevent a transition to chronic LBP at 3 or 6 months.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table. Interventions used at baseline and transition to chronic low back pain at 3 and 6 months

	3-months		OR	aOR	6-months		OR	aOR
Chronic LBP	Yes (n=38)	No (n=80)			Yes (n=31)	No (n=80)		
NSAIDS	30 (79.0%)	62 (77.5%)	1.06 (0.55, 2.02)	1.12 (0.58, 2.16)	23 (74.2%)	62 (77.5%)	0.84 (0.43, 1.73)	0.90 (0.48, 1.76)
Muscle Relaxers	7 (18.4%)	13 (16.3%)	1.12 (0.57, 2.15)	1.09 (0.57, 2.10)	5 (16.1%)	12 (15.0%)	1.09 (0.35, 3.40)	1.14 (0.36, 3.59)
Opioids	2 (5.3%)	6 (7.5%)	0.77 (0.22, 2.61)	0.65 (0.18, 2.34)	2 (6.5%)	6 (7.5%)	0.85 (0.16, 4.56)	0.81 (0.15, 4.35)
Injections	3 (7.9%)	2 (2.5%)	1.94 (0.90, 4.17)	1.58 (0.70, 3.57)	2 (6.5%)	2 (2.5%)	2.68 (0.56, 20.0)	2.61 (0.54, 20.2)
Exercise Therapy	9 (23.7%)	36 (45.0%)	**0.51 (0.27, 0.99)**	**0.45 (0.25, 0.92)**	9 (29.0%)	33 (45.8%)	0.64 (0.33, 1.27)	0.57 (0.28, 1.16)
Manipulation or Chiropractic	4 (10.5%)	17 (21.3%)	0.54 (0.22, 1.47)	0.55 (0.22, 1.39)	6 (19.4%)	14 (17.5%)	1.13 (0.39, 3.27)	1.23 (0.42, 3.70)
CBT	2 (5.3%)	3 (3.8%)	1.39 (0.57, 4.38)	1.48 (0.52, 4.18)	1 (3.2%)	3 (3.8%)	0.84 (0.09, 8.25)	0.69 (0.09, 9.06)

OR=odds ratio
aOR= adjusted odds ratio, adjusted for age, sex, race, and comorbidities
NSAIDS= non-steroidal anti-inflammatory drugs
CBT= cognitive behavioral therapy

Methods: Participants were recruited from Durham and Kannapolis, NC communities from February to November 2022 and followed at 3 and 6 months. Participants were nonpregnant adults aged 18+ with acute LBP (< 4 weeks before screening and ≥30 days without LBP before acute onset) without systemic inflammatory or autoimmune conditions, non-skin cancer, lumbar spine surgery, low back trauma, congenital/acquired spinal defects. Baseline PA was measured via the Exercise Vital Signs (EVS) tool and dichotomized into sufficiently active (≥150 minutes of moderate to vigorous PA) versus not. Baseline interventions were captured as yes/no from the NIH LBP Task Force Measure. Comorbidities were measured with the Charlson Comorbidity Index. Chronic LBP was defined as pain most/every day over the past 3 months, and high impact chronic LBP as pain limiting daily work or activities most/every day. Descriptive statistics (counts, proportions, means ± SD), t-tests, or Fisher's exact tests were used for comparisons across groups. Multiple binary logistic regression models were used to estimate odds ratios (OR) and 95% confidence intervals (CI) adjusted for age, sex, ethnicity, race, and comorbidities.

Results: We enrolled 131 participants with a transition from acute to chronic LBP of 32.2% (38/118) at 3 months and 27.9% (31/111) at 6 months. Most were female sex at birth (58.8%) with a mean age of 56.9 (SD= 13.8; range 19 to 81 years). 22.9% identified as Black/African American and 67.9% as White; 6.1% reported Hispanic ethnicity. At baseline, 39% (n=51) reported exercise therapy and 33% (n=42) were sufficiently active. These groups differed significantly (p=0.03).

Mean baseline EVS was 125.1 minutes (limits 9, 750; median 90.0). Those who transitioned to chronic LBP had a lower mean EVS (96.9 min; range 0, 350; median 85) than those who did not (139.6 min; range 0, 750; median 100), p=0.09. Participants insufficiently active at baseline (n=6, 75% vs n=0, 0.0%, exact p< 0.001) and with lower mean exercise time (37.5 ± 29.9 SD vs 122.9 ± 21.6 SD; p=0.04) were more likely to transition to high impact chronic LBP at 6 months; no differences were found at 3 months. Participants using exercise therapy were 49% less likely to transition to chronic LBP (OR=0.51, 95% CI 0.27, 0.99), and the effect strengthened when adjusted for age, sex, race, and comorbidities (0.48, 95% CI 0.25, 0.92). No other intervention showed a significant association (see table).

Conclusion: This longitudinal study is the first to examine PA and exercise therapy in the transition from acute to chronic LBP in the community. Findings suggest strong clinical utility for exercise therapy in risk reduction of chronic LBP at 3 months, and PA may help prevent high impact chronic LBP at 6 months.

Abstract Number: 0785

It Takes a Community: Exploring the Importance of Community-Level Social Determinants of Health in Total Knee Arthroplasty Outcomes

Chloe Heiting[1], Yiyuan Wu[2], Susan Goodman[3], Peter Sculco[4], Fei Wang[2], Rich Caruana[5], Peter Cram[6], Said Ibrahim[7] and Bella Mehta[8], [1]Northwell Health, New Hyde Park, NY, [2]Weill Cornell Medicine, New York, NY, [3]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY, [4]Hospital for Special Surgery, New York, NY, [5]Microsoft, Redmond, WA, [6]University of Maryland School of Medicine, Baltimore, MD, [7]Thomas Jefferson University, Philadelphia, PA, [8]Hospital for Special Surgery, Weill Cornell Medicine, Jersey City, NJ

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: Abstracts: Orthopedics, Low Back Pain, & Rehabilitation (0783–0788)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Despite changing trends and increased utilization of total knee arthroplasty (TKA) in the United States,[1] there are still prominent racial and ethnic disparities in utilization and outcomes. This highlights the importance of exploring the social determinants of health (SDOH) that may play a role in disparities in TKA outcomes, especially as postoperative complications are of paramount concern in patient and provider consideration of TKA. We aimed to utilize prediction modeling to elucidate the relationship between adverse total knee arthroplasty outcomes – including 90-day readmission, 90-day mortality, 1-year revision, and length of stay (LOS) – and multiple community-level SDOH.

Methods: Patients who underwent TKA between 2012-2018 were identified from the Pennsylvania Health Care Cost Containment Council Database by ICD codes. Census-tract level community factors were extracted from the US census via geocoding. These SDOH variables included internet access, percent of unpaid family worker, with computer access, percent with no computer access, percent of having high school and above education, percent of having college and above education, national walking index, median income, living alone, total foreign born and percent of speak other language than English. This retrospective cohort study used explainable boosting machine (EBM), a modern form of generalized additive model (GAM), to predict 90-day readmission, 90-day mortality, and 1-year revision, and LOS. Area under the receiver operating curve (AUROC) and root mean squared error (RMSE) were used as evaluation metrics. Models were trained and tested using random train and test split and cross validation techniques to reduce overfitting and ensure robustness.

Table 1. Patient-level characteristics by outcome

Variable	90-day readmission			90-day mortality			Revision		
	No (n=198896)	Yes (n=16518)	p-value	No (n=214917)	Yes (n=497)	p-value	No (n=213694)	Yes (n=1720)	p-value

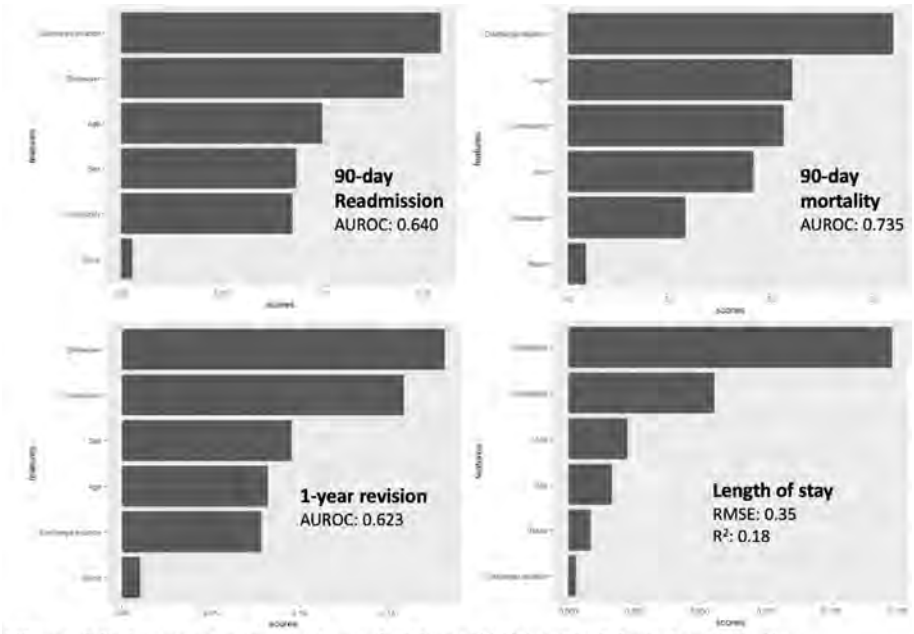
Categorical variables N (%). Continuous variables median [IQR].
*p-value < 0.05. ** p-value < 0.01. *** p-value < 0.001. p-value calculated with Chi-squared test, Fisher's exact test, and Wilcoxon rank sum test. p-values compare groups with and without the outcome for each variable.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



* "Community" is the aggregate mean absolute score for % householder living alone, % foreign born, % speaking language other than English, % with computer access, % with internet access, national walkability index, % not in labor force without insurance, % above high school, % above college, % with unpaid family workers, and median household income. These variables were extracted from American Community Survey or calculated by the National Walkability Index software from patient zip code.

Figure 1. Variable importance plots in the prediction of total knee arthroplasty outcomes*

Results: We identified 215,414 patients undergoing TKA between 2012-2018 (Table 1). Model predictive performance was highest for mortality (AUROC=0.74), and was moderate for readmission (AUROC=0.64), revision (AUROC=0.62), and LOS (RMSE=0.35, R^2=0.2) (Figure 1). Community factors were among the top five predictors of mortality, revision, and LOS.

For readmission, the top 3 predictors were discharge location, comorbidities, and age (mean absolute scores = 0.16, 0.14, 0.10, respectively). For mortality, they were discharge location, community factors, and age (mean absolute scores = 0.31, 0.21, 0.21, respectively). The top 3 predictors of revision were comorbidities, community factors, gender (mean absolute scores = 0.18, 0.16, 0.09, respectively). Lastly, the top predictors for LOS were comorbidities, community factors, and age (mean absolute scores = 0.12, 0.05, 0.02, respectively).

Conclusion: In the prediction of 90-day readmission, 90-day mortality, 1-year revision, and LOS after TKA, community factors were more important than race in each of our examined models. This study provides additional nuance to the racial disparities within TKA outcomes and may suggest that community-level factors should also be considered and addressed to improve adverse TKA outcomes.

Abstract Number: 0786

A Machine Learning Approach to Understand Age as a Risk Factor for Complications After Total Hip Arthroplasty

Chloe Heiting[1], Yiyuan Wu[2], Susan Goodman[3], Peter Sculco[4], Fei Wang[2], Rich Caruana[5], Peter Cram[6], Said Ibrahim[7] and Bella Mehta[8], [1]Northwell Health, New Hyde Park, NY, [2]Weill Cornell Medicine, New York, NY, [3]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY, [4]Hospital for Special Surgery, New York, NY, [5]Microsoft, Redmond, WA, [6]University of Maryland School of Medicine, Baltimore, MD, [7]Thomas Jefferson University, Philadelphia, PA, [8]Hospital for Special Surgery, Weill Cornell Medicine, Jersey City, NJ

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: Abstracts: Orthopedics, Low Back Pain, & Rehabilitation (0783–0788)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Utilization of total hip arthroplasty (THA) has grown rapidly in the United States and worldwide. Postoperative complications and patient risk is of great consideration by patients and clinicians. The risk associated with patient-level factors such as age has traditionally been examined using regression models, yet these models lack nuance necessary for detailed risk quantification. We aimed to examine the effect of age as a risk factor for adverse THA outcome through the application of modern machine learning algorithms.

Methods: Patients undergoing THA from 2012-2018 were identified from the Pennsylvania Cost Containment Database using ICD codes and included in the analysis. Patient-level covariates (demographics, discharge location, admission source, insurance, comorbidities) were extracted. Age was examined as a risk factor for the binary outcomes 90-day readmission, 90-day mortality, and 1-year revision as well as the continuous outcome length of stay (LOS) using an explainable boosting machine (EBM). EBMs are a form of generalized additive models characterized by high accuracy and full interpretability, mitigating effects for collinearity and allowing for automatic interaction detection. The predictive performance of the EBM model was described by area under the receiver operating curve (AUROC) for binary outcomes and root mean square error (RMSE) for continuous outcomes. The marginal relationship of age on adverse outcomes was characterized by partial dependency plots.

Results: We analyzed a cohort of 105,336 patients. The median age was 65.0 years, and most patients were White (90.1%), Medicare-insured (51.6%), and discharged home or to health home care (78.1%) (Table 1). The incidence of 90-day readmission was 8.00%, 90-day mortality was 0.29%, and 1-year revision was 1.54%. The EBM prediction model

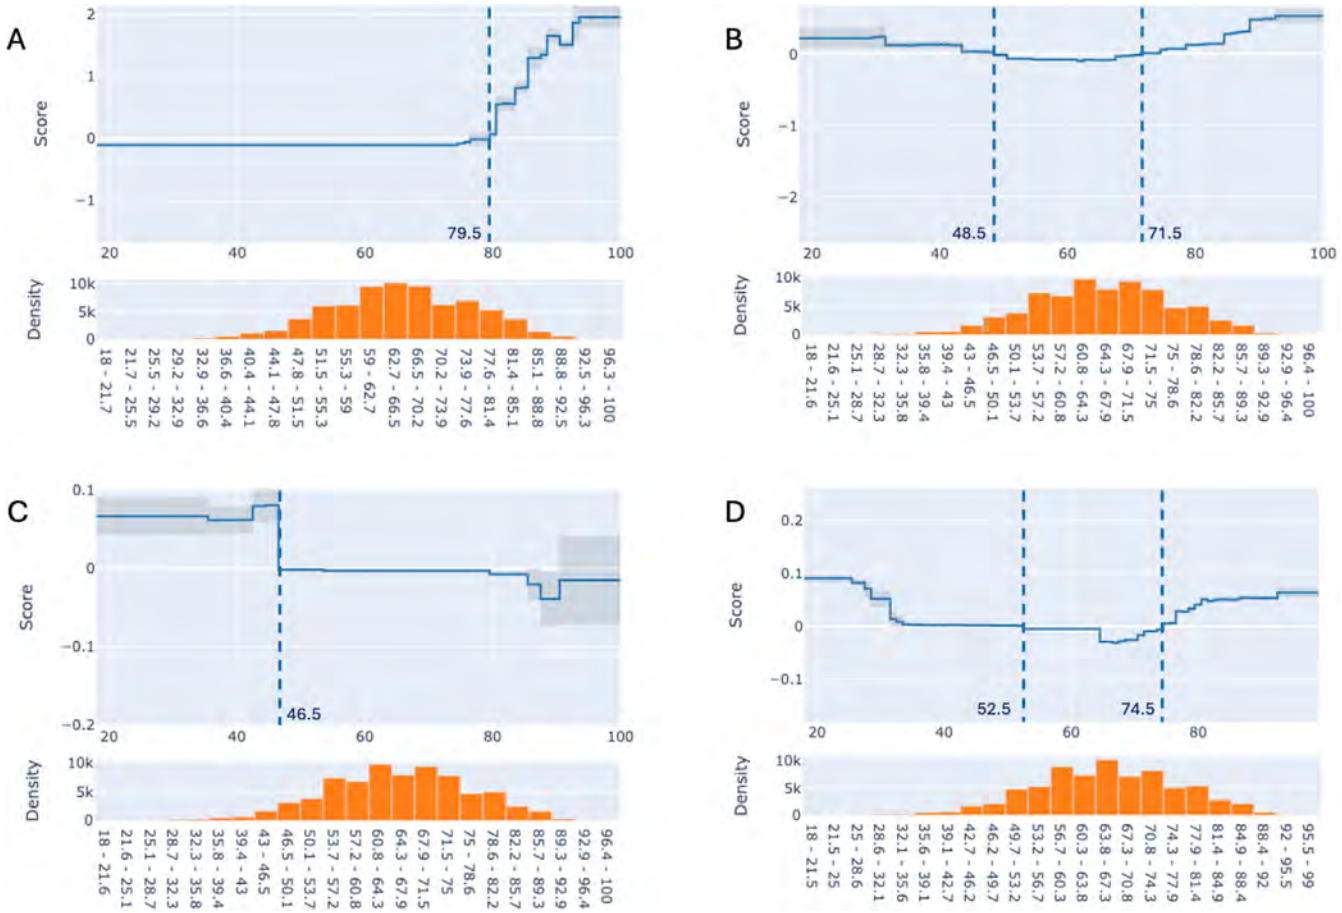

Figure 1. Partial dependency plots illustrating the marginal effect of age (years) on (A) 90-day mortality, (B) 90-day readmission, (C) 1-year revision, and (D) length of stay from the supervised explainable boosting machine models. Y-axis score in log scale. Vertical lines demonstrate where risk score is equal to 0, and show the average contribution of age to risk.

yielded highest prediction for mortality (AUROC=0.80), followed by readmission (0.68), revision (AUROC=0.60), and LOS (RMSE=0.41, R^2=0.19). Of the examined patient-level demographics and covariates, age was identified as one of the most important factors in the prediction of each adverse outcome. 90-day mortality risk increased at 79.5 years, and again dramatically at 80.5 years. Conversely, risk of revision decreased at the age of 46.5 years, whereas risk of readmission decreased at 48.5 years but increased at 71.5 years. LOS risk decreased at 52.5 years and increased at 74.5 years (Figure 1).

Conclusion: Despite decreased rates of postoperative complications in THA, age remains a prominent risk factor for consideration in clinical decision making. Modern machine learning analysis demonstrated that the relationship between age and adverse THA outcomes is nonlinear, and risk for each outcome changes drastically at different ages. This finding provides a deeper and more nuanced model compared to logistic regression, which traditionally describe fixed changes in risk with age. This study can support personalized decision-making for patients and physicians in THA.

Abstract Number: 0787

The Cost-effectiveness of Physical Therapy for Patients with Meniscal Tear and Osteoarthritis

Samantha Chin[1], **Sasha Aronson**[1], Jamie Collins[1], Faith Selzer[1], Ying Heidi Yang[1], Leslie Bisson[2], Antonia Chen[3], Morgan Jones[4], Clare Norton[1], Karen Smith[1], Kurt Spindler[5], Jeffrey Katz[6] and Elena Losina[7], [1]Brigham and Women's Hospital, Boston, MA, [2]University of Buffalo, Buffalo, [3]Brigham and Women's Hospital, Newton, MA, [4]Mass General Brigham, Boston, [5]Cleveland Clinic, Cleveland, [6]Brigham and Women's Hospital, Brookline, MA, [7]BWH, Boston, MA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: Abstracts: Orthopedics, Low Back Pain, & Rehabilitation (0783–0788)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Based on several RCTs comparing outcomes of arthroscopic partial meniscectomy (APM) to non-operative management in persons with meniscal tears and OA, physical therapy (PT) is now considered the first line treatment. The TeMPO (Treatment of Meniscal Tears in Patients with Osteoarthritis) trial established that an in-clinic PT program with home exercise component led to a small incremental pain reduction at 6 and 12 months compared to home exercise alone. We sought to determine the cost-effectiveness of PT with home exercise compared to home exercise alone using data from the TeMPO trial.

Methods: We used the Osteoarthritis Policy (OAPol) Model, a widely published and validated microsimulation of knee OA, to compare two strategies: 1) home-based exercise (HE) vs. 2) Physical Therapy focused on strengthening (PT) plus HE. The 5-year outcomes included quality-adjusted life expectancy and costs. Patients in both strategies could subsequently transition to APM, corticosteroid injections, opioids, total knee replacement (TKR), and revision TKR, if the initial treatment did not lead to meaningful pain relief. We modeled pain trajectories at baseline, 3, 6, and 12 months based on strategy-specific data from TeMPO (HE: 47, 29, 28 and 24 vs. PT: 45, 26, 22, 20 points, on a scale 0-100, 0 being no pain). We also derived APM, 1-year TKR, and opioid utilization from the overall TeMPO cohort, due to negligible observed difference across arms (11% had APM, 1% had TKR, 2% used opioids). We derived 5-year TKR utilization from the non-operative arm in the MeTeOR trial, which followed patients with meniscal tear and concomitant OA over 5 years (TKR use $\sim$ 4% over 5 years). The cost of the home exercise regimen included analgesic medications, home exercise guides and materials ($213). In addition to these costs, the cost of the PT regimen included exercise bands, pamphlets, reminder texts, and evaluation and treatment visits ($1,540).

We conducted the analysis for a cohort with mean age 59, KOOS pain 46 (0-100, 100 worst), and mean BMI 30 kg/m^2. We calculated incremental cost-effectiveness ratios (ICERs) as the difference in lifetime costs (2024 USD) divided by the difference in quality-adjusted life years (QALYs) between two strategies. We used a health care perspective and discounted clinical benefits and costs at 3% annually. We conducted sensitivity analyses to determine how uncertainty in input parameters might affect our findings.

Table 1. Clinical benefits, costs, and incremental cost-effectiveness ratios for PT compared to home exercise in patients with knee OA and meniscal tear

Strategy	QALYS	Cost	ICER ($/QALY)
Home exercise	3.290	$38,994	
Home exercise + PT	3.315	$40,330	$53,800

PT = physical therapy, OA = knee osteoarthritis, QALY = Quality Adjusted Life Year, ICER = Incremental Cost-Effectiveness Ratio. ICERs rounded to the nearest 100.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Adding PT increased the 5-year quality-adjusted life expectancy by 0.03 QALYs at the additional cost of $1,300/person, resulting in an estimated ICER for PT of $53,800/QALY (Table 1). The two parameters with the largest effect on the ICER were the difference in pain efficacy between the two regimens and the starting pain of the cohort. When the difference in pain efficacy decreased by 50%, the ICER for PT increased to $142,500/QALY. If starting pain would be reduced by about 25%, the ICER would increase to $72,700/QALY.

Conclusion: Despite relatively small incremental clinical benefits, physical therapy with the home exercise component could be a cost-effective strategy at any cost-effectiveness threshold exceeding $53,800/QALY.

Spatiotemporal Gait Differences Between Fallers and Non-Fallers in People with Knee Osteoarthritis

Joy Itodo, Steven Garcia, Oiza Peters, Ogundoyin Ogundiran and Kharma Foucher, UNIVERSITY OF ILLINOIS, CHICAGO, Chicago, IL

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: Abstracts: Orthopedics, Low Back Pain, & Rehabilitation (0783–0788)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: People with knee osteoarthritis (OA) have higher fall rates than their age-matched peers. Studies in another at-risk group, healthy older adults, have linked fall risk to shorter step lengths, narrower stride width, and slower walking speed. These spatiotemporal gait characteristics are also affected by knee OA, but it remains unclear whether they differ between those with a history of falls and those without. Therefore, we tested the hypothesis that spatiotemporal gait characteristics would differ between fallers and non-fallers with knee OA. We also investigated the potential influence of pain catastrophizing and physical activity as representative psychological and behavioral variables that may either influence or be influenced by a history of falls.

Table 1. Spatiotemporal gait characteristics during level treadmill walking at self-selected speeds for fallers (N = 12) and nonfallers (N = 24) with knee OA.

	Fallers	NonFallers	p value	Effect size (Cohen's d)
Walking Speed (m/s)	0.591 ± 0.206	0.512 ± 0.174	0.236	0.427
Step Length (m/height in m)	0.238 ± 0.074	0.193 ± 0.049	**0.039***	0.760
Step Width (m/height in m)	0.092 ± 0.025	0.114 ± 0.027	**0.025***	0.831
Cadence (steps/min)	99.397 ± 15.518	90.227 ± 11.448	**0.052***	0.711
Double Limb Support Time	0.486 ± 0.134	0.571 ± 0.132	0.079	0.639

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1: Association between normalized step length and walking among fallers and non-fallers with knee osteoarthritis.

Methods: We categorized 22 women and 14 men with knee OA (age 57 ± 9 years) into fallers and non-fallers based on the question: "Have you experienced a fall in the past 12 months?" Gait data were collected during walking trials on an instrumented split-belt treadmill at each participant's preferred speed. Spatiotemporal variables included walking speed, step length and step width normalized to height, cadence, and double limb support time. Surveys were completed prior to testing, and we used the KOOS pain sub-score, the Pain Catastrophizing Scale, and the UCLA activity score for this analysis. We used independent T-Tests to compare variables between fallers and non-fallers, and linear regression, controlling body mass, for further analyses.

Results: Twelve participants (33%) were classified as fallers. Although walking speeds were similar between the groups (Table 1), fallers walked with significantly shorter steps and higher cadences than non-fallers. Fallers also had significantly narrower step widths. A regression model in which walking speed was the independent variable and step length, cadence, fall status, and fall interaction terms were the dependent variables, showed that the association between step length and speed differed by fall status. Additional models demonstrated that higher UCLA scores were associated with longer step lengths ($p=0.054$) and faster walking speeds ($p = 0.005$), and lower double limb support times ($p < 0.000$). Higher pain catastrophizing was associated with lower cadence in fallers ($p = 0.052$).

Conclusion: Gait patterns differ between fallers and non-fallers with knee OA, with fallers taking shorter, narrower, and more frequent steps, despite similar speeds. While this strategy may help maintain pace, it may come at the cost of balance and stability. Narrower step width is especially concerning as it reduces the base of support during walking. Psychological and behavioral factors had a complex relationship with fall history. For example, higher physical activity levels were associated with both more favorable and less stable gait attributes. Taken together, these results suggest that addressing modifiable psychological and behavioral factors in conjunction with gait biomechanics may be important for improving function and reducing fall risk in this population.

Abstract Number: 0789

Short Form 36 (SF-36) Health Survey Questionnaire in Health-Related Quality of Life Assessment in Patients with Inflammatory Myopathies

Almurtada Razok[1], Jasmin Taylor[2], Ethan Ritz[3], Kristin Wipfler[4], Kaleb Michaud[5] and Didem Saygin[6], [1]John H Stroger Jr Hospital of Cook County, Chicago, IL, [2]Rush Medical College, Chicago, IL, [3]Rush Research Informatics Core, Rush University Medical Center, Chicago, IL, [4]FORWARD, The National Databank for Rheumatic Diseases, Omaha, NE, [5]University of Nebraska Medical Center, Omaha, NE, [6]Rush University Medical Center, Chicago, IL

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: Abstracts: Patient Outcomes, Preferences, & Attitudes (0789–0794)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Patients with idiopathic inflammatory myopathies (IIM) experience significant impairment in their health-related quality of life (QoL); however, there are currently no validated measures to assess QoL in these patients. This study aims to examine the measurement properties of short form (SF)-36 in QoL assessment of adults with IIM.

Methods: FORWARD is a U.S.-based databank collecting biannual patient-reported data on rheumatic diseases, including sociodemographics, health-care utilization and forms related to patients' symptoms and experiences including patient global disease activity (visual analog scale [VAS]), pain (VAS), fatigue (VAS), physical functioning (Health Assessment Questionnaire [HAQ-II]), health satisfaction and quality of life (SF-36). SF-36 produces physical (PCS) and mental (MCS) component scores, ranging 0-100 with higher scores indicating a better QoL. Floor and ceiling effects were calculated based on the proportion of patients who have the lowest and the highest possible SF-36 score, respectively. Discriminant validity was assessed by comparing the median subgroups of patients using t test. Construct validity was assessed by Pearson correlation between the SF-36 and other relevant outcome variables based on a priori hypotheses. Adequate validity was defined as ≥70% agreement between the results and a priori hypotheses. Responsiveness was assessed using linear mixed models to examine the relationship between change in SF-36 and other outcome variables over time.

Results: A total of 168 patients with IIM were included (77.3% female, 78.5% White), with an average (± standard deviation [SD]) age of 54.3 (±13.8). No floor or ceiling effect was observed for SF-36 PCS and MCS. SF-36 PCS was significantly different between median groups with low vs high physical functioning, disease activity, fatigue and pain, while MCS was significantly different between patients with and without depression and anxiety, and low vs high fatigue and pain levels (Table 1). Over 90% of a priori hypotheses for construct validity were met (Table 2). SF-36 PCS and MCS had moderate to strong correlations with pain, fatigue, physical function, disease activity, and health satisfaction. Longitudinal changes in SF-36 were significantly associated with changes in in pain, fatigue, patient global disease activity, and physical functioning (Table 3).

Table 1. Discriminant validity assessment with comparison of SF-36 PCS and MCS across median groups of patients with IIM.

Groups	SF-36 PCS		Groups	SF-36 MCS	
	Mean (SD)	p value		Mean (SD)	p value
HAQ-II <1	44.4 (8.9)	<0.0001	Depression	36.8 (11.3)	<0.0001
HAQ-II ≥1	29.2 (7.5)		No depression	51.3 (9.7)	
Patient global <3.5	43.1 (9.9)	<0.0001	Anxiety	36.1 (11.1)	<0.0001
Patient global ≥3.5	30.2 (8.3)		No anxiety	50.2 (10.4)	
Fatigue <4.5	42.8 (9.9)	<0.0001	Fatigue <5	52.0 (9.7)	<0.0001
Fatigue ≥4.5	29.9 (7.9)		Fatigue ≥5	42.2 (12.2)	
Pain <2.5	42.5 (10.4)	<0.0001	Pain <5	52.0 (9.3)	<0.0001
Pain ≥2.5	31.9 (9.3)		Pain ≥5	43.4 (12.3)

Diabetes Risk in Psoriasis Patients Treated with Biologic Disease-Modifying Antirheumatic Drugs: Target Trial Emulation Using Nationwide Data

Arjun Mahajan[1], David Bates[2], Vinod Nambudiri[3], Avery LaChance[2], Jeffrey Sparks[4] and Evan Piette[3], [1]Harvard Medical School, Boston, [2]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [3]Brigham and Women's Hospital, Harvard Medical School, Boston, [4]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: Abstracts: Patient Outcomes, Preferences, & Attitudes (0789–0794)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Psoriasis is a chronic inflammatory skin disease associated with increased risk of metabolic complications, such as diabetes mellitus. However, the impact of specific biologic DMARD therapies on these metabolic outcomes remains poorly understood. Importantly, understanding how psoriatic treatments affect metabolic outcomes may guide therapeutic choices; thus, this study evaluates the risks of diabetes and kidney disease across biologic DMARD therapies.

Methods: Utilizing data from 128 healthcare organizations in the TriNetX network (2016-2024), we conducted an emulated trial to evaluate diabetes-related disease incidence among psoriasis patients (n=20,120) treated with interleukin-23 (IL-23i), interleukin-17A (IL-17Ai), or tumor necrosis factor-alpha (TNFi) inhibitors. To emulate randomization, we applied 1:1 propensity score matching using a greedy nearest neighbor algorithm to balance cohorts on demographics, comorbidities,

Table 1. Baseline Patient Characteristics in IL-23i vs TNFi Psoriasis Cohorts

Characteristic	Before PSM, n (%)			After PSM, n (%)		
	IL-23i (n=6,489)	TNFi (n=20,120)	SMD	IL-23i (n=6,457)	TNFi (n=6,457)	SMD

Laceration of the head	18	23	1.72 (0.91, 3.28)	21	14	1.05 (0.53, 2.07)	18	15	1.72 (0.91, 3.28)

laboratory data, and medication use (Table 1). Primary outcomes included new-onset type 2 diabetes, diabetic nephropathy, chronic kidney disease (CKD), and stage 3–5 CKD. Varicose vein and head laceration diagnoses served as negative control outcomes. Hazard ratios (HRs) and 95% confidence intervals (CIs) were calculated using Cox proportional hazards models.

Results: In an emulated trial of IL-23i versus TNFi treatment (n=6,457 matched pairs), IL-23i treatment was associated with lower risks of diabetes (HR 0.91; 95% CI 0.75–0.99), diabetic nephropathy (HR 0.71; 95% CI 0.48–0.98), and stage 3–5 CKD (HR 0.75; 95% CI 0.58–0.98) (Table 2). In the TNFi versus IL-17Ai emulated trial (n=6,425 pairs), TNFi-treated patients had a higher risk of diabetes (HR 1.16; 95% CI 1.01–1.22) and associated kidney disease outcomes. No significant differences were observed between IL-23i and IL-17Ai treatment. Compared to systemic therapy naïve (STN) patients (n=6,489 pairs), IL-23i treatment was associated with reduced risks of diabetes (HR 0.89; 95% CI 0.80–0.98), diabetic nephropathy (HR 0.78; 95% CI 0.60–0.97), and stage 3–5 CKD (HR 0.76; 95% CI 0.62–0.92) (Table 3); IL-17Ai treatment showed similarly protective effects for diabetes (HR 0.90; 95% CI 0.83–0.98), diabetic nephropathy (HR 0.74; 95% CI 0.57–0.96), and stage 3–5 CKD (HR 0.88; 95% CI 0.75–0.99) risk (n=6,402 pairs). TNFi treatment showed no significant differences compared to STN patients. No differences were observed in negative control outcomes across comparisons.

Table 3. Risk and Occurrence of Diabetes and Diabetic Complications in Biologic-Treated vs. Systemic Therapy-Naïve Psoriasis Patients

	IL-23i vs Systemic Therapy Naïve (STN)			IL-17i vs Systemic Therapy Naïve (STN)			TNFi vs Systemic Therapy Naïve (STN)		
Outcome	IL23i Cohort Outcome Count (n=6,489)	STN Cohort Outcome Count (n=6,489)	HR (95% CI)	IL-17i Cohort Outcome Count (n=6,402)	STN Cohort Outcome Count (n=6,402)	HR (95% CI)	TNFi Cohort Outcome Count (n=20,005)	STN Cohort Outcome Count (n=20,005)	HR (95% CI)
Type 2 Diabetes	145	250	**0.89 (0.80, 0.98)**	230	278	**0.90 (0.83, 0.98)**	823	843	0.97 (0.88, 1.07)
Diabetic Nephropathy	27	70	**0.78 (0.60, 0.97)**	37	72	**0.74 (0.57, 0.96)**	172	181	0.96 (0.78, 1.18)
Chronic Kidney Disease (Any Stage)	88	218	**0.73 (0.60, 0.89)**	168	232	**0.89 (0.78, 0.99)**	573	633	0.91 (0.82, 1.02)
Stage 3-5 Chronic Kidney Disease	73	180	**0.76 (0.62, 0.92)**	130	178	**0.88 (0.75, 0.99)**	463	469	0.99 (0.88, 1.13)

Conclusion: These emulated target trials suggest that IL-17Ai and IL-23i therapies are associated with lower risks of incident type 2 diabetes and kidney disease compared to TNFi or systemic therapy naïve approaches. These findings may support the consideration of metabolic outcomes in biologic DMARD treatment selection for psoriasis patients.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: Abstracts: Patient Outcomes, Preferences, & Attitudes (0789–0794)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: We previously described the top-line results of our study and the high correlations between virtual SLE disease activity measures (DAM) and those obtained during face-to-face (F2F) visits. Here we describe the more granular data on disagreements between telemedicine (TM) and F2F DAM across 2 visits in order to better understand the reasons for these discrepancies and improve TM assessments of SLE activity.

Methods: This was an observational, longitudinal study of SLE patients from 4 academic lupus centers serving diverse populations supported by a grant from the US DoD. Each study participant was evaluated at a baseline and follow-up visit as dictated by usual care. Virtual physical exam guidelines were established and relied upon clinician-directed patient self-examination. At each visit, participants were evaluated by the same provider via a videoconference-based TM and then a F2F encounter. SLE DAM were completed after the TM and the F2F encounters. Disagreements in DAM domains between the encounters were noted and verified with the evaluator, as were changes in treatment plan. Tandem provider and patient feedback tools for encounters probed satisfaction, comfort, and problematic evaluation.

Results: 163 racially and ethnically diverse participants were enrolled and completed the first visit, 145 completed the follow-up visit as previously described (Table 1). Briefly, while intraclass correlation coefficients (ICC) showed high correlation between TM and F2F (0.877-0.998), paired T-tests showed differences for SLEDAI (mean difference -0.19 +/-1.33, p=0.011) and CLASI activity (mean differences -0.18 +/-0.76, $p < 0.001$); the main drivers were difficulty with virtual arthritis and rash evaluations. For the 145 baseline/follow-up pair visits, there were 63 disagreements across all DA instruments: 25 musculoskeletal (10 overestimating [OE], 15 underestimating [UE] DA), 25 mucocutaneous (7 OE, 18 UE), 3 cardiorespiratory [3 UE], 3 vasculitis [3 UE], 6 constitutional [3 OE/3 UE], 1 ophthalmologic [1 UE] (Fig. 1). These resulted in inconsistencies in SLEDAI 38 (pleurisy-1, arthritis-14, ulcers-5, rash-9, alopecia-6, vasculitis-3) and BILAG 36 (constitutional-6, mucocutaneous-14, musculoskeletal-14, cardiorespiratory-1, ophthalmologic-1). Sometimes, arthritis not recorded on the

virtual SLEDAI, upon F2F evaluation swollen and tender joints were elicited by the clinician and resulted in SLEDAI scoring of arthritis, but arthralgia/mild arthritis was recorded on the BILAG. Following the F2F visit 52.9% clinicians were highly confident that their virtual DA assessment was accurate, 41.0% confident/moderately confident, 4.4% minimally confident, and 1.7% not confident at all.

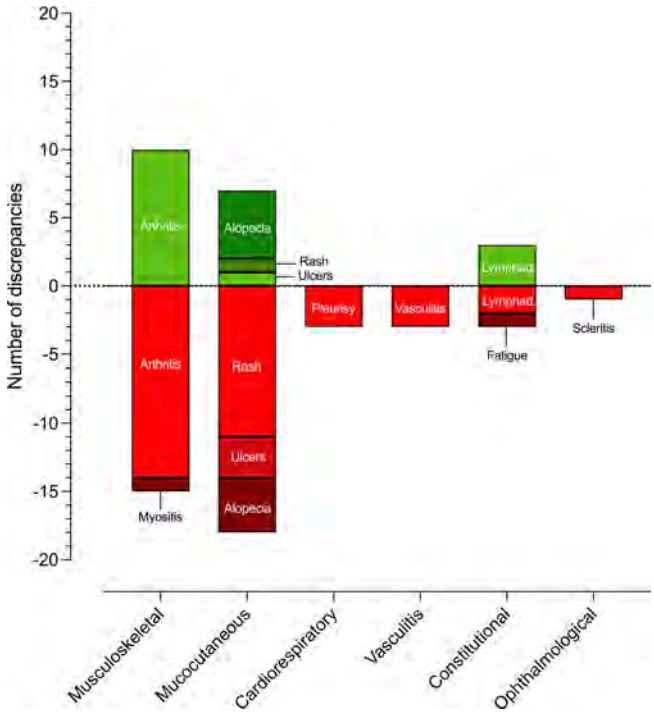

Figure 1. Discrepancies in disease activity scores between telemedicine and face-to-face visits.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: These data discuss lack of agreement for the mucocutaneous and arthritis findings, despite high overall correlations between virtual and F2F DA. TM tended to slightly underestimate DA. These data emphasize the need to further refine virtual DA assessments to provide improved agreement between TM and F2F evaluations and allow for increased adoption of telemedicine in SLE clinical care and clinical trials.

Abstract Number: 0792

Real-World Assessment of Glucocorticoid-Induced Skin Toxicity in Individuals with Rheumatic Diseases

Tania Chiha[1], Jiaqi Wang[2], Isha Jha[3], Grace McMahon[3], John Stone[4] and Naomi Patel[3], [1]Mount Auburn Hospital, Boston, MA, [2]Massachusetts General Hospital, BOston, [3]Massachusetts General Hospital, Boston, MA, [4]Massachusetts General Hospital , Harvard Medical School, Concord, MA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: Abstracts: Patient Outcomes, Preferences, & Attitudes (0789–0794)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Glucocorticoids (GC) are used to treat various inflammatory and autoimmune diseases, though despite widespread use, real-world data on skin-specific GC toxicity are limited. To better characterize the burden of GC-related skin adverse effects, we prospectively evaluated GC-related skin toxicity over 6 months in a rheumatology clinic setting.

Methods: We obtained data from the Longitudinal Glucocorticoid Toxicity (LONG-TOX) prospective cohort, which enrolls adults with rheumatic diseases receiving or initiating GC therapy (≥3 month expected duration) at a large academic hospital. The domains of the Glucocorticoid Toxicity Index (GTI) were used to assess the GT-SNAPSHOT, a comprehensive baseline assessment of GC toxicity, at baseline, and the GTI at 6 months. GC exposure was tracked using patient diaries and electronic health records. GTI-defined skin toxicities (acneiform rash, easy bruising, hirsutism, atrophy/striae, and erosions/tears/ulcerations) were assessed by a study team member at both visits. We used the GTI Skin Toxicity domain to evaluate changes in GC-related skin toxicity and examined factors associated with baseline skin toxicity and worsening in skin toxicity (i.e., new and/or worsened skin manifestation) over 6 months using univariable logistic regression.

Results: Of 90 enrolled individuals, 74 completed 6-month follow-up. The mean (SD) age was 60.0 (16.6) years, 62.2% were female, median prednisone-equivalent GC dose was 30.0 mg daily, and most (64.4%) were receiving concomitant immunomodulatory therapy (**Table 1**). Those with skin toxicity at baseline had higher median GT-SNAPSHOT scores (195 vs. 141, $p< 0.01$) and significantly more neuropsychiatric (90.7% vs. 61.1%, $p< 0.01$) and infection-related toxicity (20.4% vs. 0.0%, $p< 0.01$) than those without baseline skin toxicity.

Asian	0 (0.0)	2 (6.3)	
More than one race	0 (0.0)	0 (0.0)	
Hispanic ethnicity, n (%)	2 (4.8)	1 (3.1)	1.00
BMI, mean (SD)	29.6 (5.6)	29.3 (6.8)	0.90
Baseline disease activity, n (%)			
Remission	18 (42.9)	20 (62.5)	
Mild	11 (26.2)	10 (31.3)	0.048
Moderate	10 (23.8)	1 (3.1)	
Severe	3 (7.1)	1 (3.1)	
Cumulative 6-month GC exposure, prednisone-equivalent mg, median (IQR)	2167.00 (1196.5, 3940.0)	2013.50 (1183.5, 2831.0)	0.27
Current GC dose among those still on GCs, prednisone-equivalent mg, median (IQR)	5.0 (0.0, 10.0)	3.0 (0.0, 5.5)	0.11
Baseline concomitant immunomodulatory therapy, n (%)	32 (76.2)	25 (78.1)	0.84
GTI CWS, median (IQR)	58.5 (28.0, 116.0)	30.5 (5.5, 55.0)	<0.01
GTI Domain CWS > 0			
Body mass index score, n (%)	16 (38.10)	6 (18.75)	0.07
Glucose tolerance, n (%)	4 (9.52)	6 (18.75)	
Blood pressure, n (%)	11 (26.19)	12 (37.50)	0.30
Lipid metabolism, n (%)	9 (21.43)	3 (21.43)	0.21
Glucocorticoid Myopathy, n (%)	10 (23.81)	2 (6.25)	0.04
Skin, n (%)	18 (42.86)	0 (0.0)	<0.01
Neuropsychiatric, n (%)	18 (42.86)	6 (18.75)	0.03
Infection, n (%)	3 (7.14)	2 (6.25)	1.00

GC, glucocorticoid; GTI CWS, Glucocorticoid Toxicity Index Cumulative Worsening Score

Over 6 months, those with worsening skin toxicity (56.8%) had higher overall GTI Cumulative Worsening Scores (median 58.5 vs. 30.5, p< 0.01), higher baseline disease activity (42.9% in remission vs 62.5%, p=0.048), and numerically higher cumulative GC exposure (2167 vs. 2014 prednisone-equivalent mg, p=0.27) compared to those without worsening skin toxicity **(Table 3)**. There were no differences in sex, body mass index, race, or baseline immunomodulatory therapy between groups. Those with worsening skin toxicity had more worsening in the Neuropsychiatric (42.9% vs. 18.8%, p=0.03) and Myopathy (23.8% vs. 6.3%, p=0.04) domains.

Conclusion: Skin-related adverse effects are common with GC use and highlight the need for routine assessment in long-term GC users. Neuropsychiatric GC toxicity was more common in individuals with skin toxicity. Routine assessment of the skin manifestations of the GTI may enhance detection and guide interventions to mitigate morbidity associated with GC treatment.

PGA, Median (Q1-3)	0.25 (0-1)	0.25 (0-0.75)	0.25 (0-1.25)	0.2[4]
Active Lupus Nephritis, n (%)	24 (10%)	11 (9%)	13 (11.7%)	0.4[2]
Symptom Severity Score, Median (Q1-3)	5 (2-7)	4 (2-7)	6 (3-8)	0.03[1]
Areas of Widespread Pain, Median (Q1-3)	3 (0-6)	2 (0-6)	3 (1-6)	0.3[1]
Total Fibromyalgia Severity Score, Median (Q1-3)	8 (3-13)	7 (3-12)	9 (5-13)	0.1[1]
Trauma, n (%)				< 0.001[2]
No trauma	39 (16%)	24 (19%)	15 (14%)	
Non-abusive trauma	101 (42%)	65 (51%)	36 (32%)	
Abusive trauma	98 (41%)	38 (30%)	60 (54%)	
Resilience, n (%)				0.9[3]
High resilience	3 (1%)	2 (2%)	1 (1%)	
Low resilience	82 (35%)	45 (35%)	37 (33%)	
Normal resilience	153 (64%)	80 (63%)	73 (66%)	

Statistical Tests used include: 1. Wilcoxon rank-sum test, 2. Pearson's Chi-squared test, 3. Fisher's Exact Test for Count Data, as appropriate

* *Adherence was assessed using the DOSE-Nonadherence-SLE survey via three Likert-scale items on missed, skipped, or not taking medication (1 = Never to 5 = Always). Patients were classified as adherent if all responses were "Never"; others were nonadherent. See Methods for full criteria.*

Background/Purpose: Medication adherence in SLE is suboptimal and contributes to increased disease activity, organ damage, and mortality. Trauma exposure is common among those with SLE and may undermine adherence behaviors by disrupting patients' sense of stability and future orientation. As a result, trauma-exposed patients may be more likely to focus on immediate needs over long-term planning, reducing the effectiveness of adherence messaging centered on future outcomes such as flare prevention or organ preservation. Resilience—the capacity to adapt to adversity—may buffer these effects. However, the relationship between trauma, resilience, and medication adherence in SLE remains underexplored.

Methods: We conducted a cross-sectional study of patients with SLE (2012 SLICC or 2019 ACR/EULAR criteria) enrolled in an academic lupus registry. The *extent of* and *reasons for* nonadherence were measured by the DOSE-Nonadherence-SLE. Patients also completed the polysymptomatic distress (PSD) scale, the Brief Resilience Scale, and the Trauma History Screen. Rheumatologists assessed SLE activity using the Physician's Global Assessment (PGA). Trauma exposure history

Table 2: Association between Trauma and Medication Nonadherence

	Model 1: Unadjusted RR (95% CI)	Model 2: Covariate Adjusted RR (95% CI)
Trauma Category		
No Trauma	(Ref)	(Ref)
Non-abusive Trauma	0.93 (0.58,1.49)	0.95 (0.59,1.52)
Abusive Trauma	1.59 (1.04,2.44)	1.58 (1.04,2.42)
Hispanic Ethnicity		
Non-Hispanic	--	(Ref)
Hispanic	--	1.57(1.08,2.26)
Race		
White	--	(Ref)
Black	--	1.77 (1.25,2.51)
Asian	--	1.71 (0.62,4.68)
Other	--	1.81 (1.04,3.15)

Note: RR = Relative Risk; CI = Confidence Interval; Ref = Reference Category

Table 3: Reasons for nonadherence based on the DOSE-Nonadherence-SLE by trauma history.

I missed my lupus pills because…	Total (N=111)	No trauma (N=15)	Non-abusive trauma (N=36)	Abusive trauma (N=60)	P-Value
Access barriers					
I could not fill in time	27 (29%)	8 (62%)	7 (25%)	12 (24%)	0.02[2]
It cost too much	11 (12%)	3 (21%)	2 (7%)	6 (12%)	0.4[1]
Logistic barriers					
I forgot or was busy	69 (71%)	10 (77%)	20 (69%)	39 (71%)	0.9[2]
I do not have a regular schedule	30 (32%)	3 (23%)	9 (32%)	18 (33%)	0.8[2]
I needed to take them with food but could not eat at that time	26 (28%)	1 (8%)	9 (33%)	16 (30%)	0.2[2]
I was too tired	17 (19%)	2 (15%)	2 (7%)	13 (27%)	0.1[1]
I take too many pills	13 (14%)	1 (8%)	1 (4%)	11 (21%)	0.09[1]
Medication instructors were too hard to follow	2 (2%)	0 (0%)	1 (4%)	1 (2%)	1.0[1]
I had a hard time swallowing them	5 (6%)	0 (0%)	1 (4%)	4 (8%)	0.7[1]
I was too stiff	5 (6%)	0 (0%)	1 (4%)	4 (8%)	0.7[1]
I had no one to help me	2 (2%)	0 (0.0%)	1 (4%)	1 (2%)	1.0[1]
Motivational barriers					
I am tired of taking medicines every day	20 (23%)	2 (15%)	1 (4%)	17 (35%)	0.004[1]
I don't feel any difference	17 (19%)	1 (8%)	4 (14%)	12 (25%)	0.4[1]
It caused side effects	16 (17%)	0 (0%)	5 (17%)	11 (21%)	0.2[1]
I feel that nothing will get better even if I take them	14 (16%)	1 (8%)	0 (0%)	13 (26%)	0.003[1]
I felt too sick	14 (16%)	0 (0%)	2 (7%)	12 (25%)	0.03[1]
I felt well	13 (14%)	2 (15%)	3 (11%)	8 (16%)	0.8[1]
I was worried about possible side effects	11 (12%)	1 (8%)	3 (11%)	7 (14%)	1.0[1]
I felt so bad, thought medicine was not working	8 (9%)	1 (8%)	1 (4%)	6 (12%)	0.6[1]
I felt too depressed	8 (9%)	0 (0%)	1 (4%)	7 (15%)	0.2[1]
I do not understand why need to take them	4 (4%)	0 (0%)	1 (4%)	3 (6%)	1.0[1]
I was worried it would affect fertility in the future	2 (2%)	0 (0%)	0 (0%)	2 (4%)	0.7[1]
My family or friend said not to	1 (1%)	0 (0%)	0 (0%)	1 (2%)	1.0[1]
I heard someone had a bad experience	1 (1%)	0 (0%)	0 (0%)	1 (2%)	1.0[1]

Statistical Tests used include: 1. Fisher's Exact Test for Count Data, 2. Pearson's Chi-Squared Test, as appropriate.

was categorized into abusive (physical, sexual, and emotional trauma as an adult or child), non-abusive, or no trauma. We used Fisher's exact test, Chi-squared test, and Wilcoxon rank sum test for group comparisons and multivariable regression models to examine the association between trauma exposure and medication nonadherence, including an interaction term for resilience.

Results: Among 238 patients (median age 42, 92% female, 36% White, 57% Black, 6% Hispanic), 111 (47%) reported non-adherence, 98 (41%) reported abusive trauma, and 101 (42%) reported non-abusive trauma. Nonadherent patients were more likely to be younger, identify as Black or Other race or Hispanic ethnicity, have higher symptom severity scores, and report a history of abusive trauma (Table 1).

In adjusted models, abusive trauma was associated with 58% higher risk of nonadherence compared to no trauma (Table 2). Black and Other race and Hispanic ethnicity also remained significantly associated with nonadherence. Resilience moderated the relationship between trauma and medication nonadherence (p=0.02); patients with abusive trauma as well as low resilience had the highest risk of nonadherence.

Nonadherent patients with abusive trauma, compared to those with non-abusive trauma or no trauma, more frequently reported missing SLE medications because "I am tired of taking medicines every day," "I feel that nothing will get better even if I take them," and "I felt too sick." They were less likely to report "I could not fill the medicines on time." (Table 3)

Conclusion: Abusive trauma was common and independently associated with greater risk of medication nonadherence in SLE, and resilience was a protective moderator. Patients with abusive trauma tended to endorse motivational barriers to adherence but were less likely to endorse difficulty filling medicines on time. These findings underscore the importance of trauma-informed, resilience-enhancing approaches to improve medication adherence for trauma-exposed patients.

Abstract Number: 0794

Using Artificial Intelligence to Analyze Multilingual Qualitative Data in Lupus Pregnancy Research: A Proof of Concept with Large Language Models

Romina Boers[1], Grace Terry[2] and **Bella Mehta**[3], [1]Weil Cornell Medicine, New York, [2]Weil Cornell Medicine, Ne wYork, [3]Hospital for Special Surgery, Weill Cornell Medicine, Jersey City, NJ

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: Abstracts: Patient Outcomes, Preferences, & Attitudes (0789–0794)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Women with systemic lupus erythematosus (SLE), particularly those of childbearing age, face heightened risks during pregnancy, including disease flares, adverse maternal-fetal outcomes, and emotional stress. Understanding how these women perceive pregnancy is essential for delivering personalized and empathetic care. While qualitative research is ideal for capturing such patient perspectives, analyzing interview data analyzing interview data is labor-intensive and often exclude non-English speakers. To evaluate the use of large language models (LLMs) in translating, analyzing, and summarizing qualitative interviews on pregnancy experiences in women with SLE, and to quantitatively compare LLM-generated themes with those identified by human researchers.

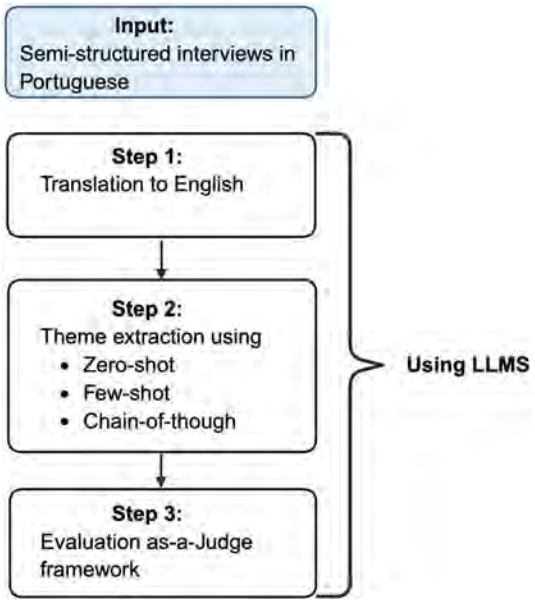

Figure 1. Workflow for LLM-Assisted Multilingual Qualitative Analysis in Lupus Pregnancy Research

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Reference Study Results	Our Results
1. Unplanned pregnancy and nonuse of contraception • family planning • reasons for pregnancy • partner's personal fulfillment • miracles-religiosity	3. Pregnancy as a Source of Hope and Transformation
2. Feeling healthy despite doctor's warning of disease worsening because of pregnancy • Doctor's opinion • Self-image • Self-perception • Willingness to engage in self-care • Treatment control	1. Diagnostic Challenges and Uncertainty 6. Everyday Struggles and Adaptation 7. Personal Growth and Acceptance
3. Joy couple with fear of the future and pregnancy • Fear of pregnancy complications • Afraid of not being able to take care of the child • Pregnancy losses • Neonatal losses • Death • Job loss • Loss of autonomy • Loss of decision-making power	2. Emotional Impact and Psychological Burden 4. Fear of Harm to the Baby and Maternal Responsibility
4. Self-perception and straight perception • Perception of the significant people • Perception of the woman herself	5. Importance of Social and Medical Support

Table 1. Comparison of themes from the reference qualitative study with themes generated by ChatGPT 4.0. The left column shows human-derived themes from Rodrigues et al. (2020), while the right column presents corresponding LLM-derived themes. This alignment confirms that use of LLM can identify relevant themes from qualitative semi-structured interviews.

Methods: We used semi-structured interviews originally conducted in Portuguese by Rodrigues et al.(1) with 26 women with SLE to explore their prenatal care experiences. Transcripts were translated into English using LLMs, and three types of prompting—zero-shot, few-shot, and chain-of-thought—were tested across four state-of-the-art LLMs (GPT o3-mini-high, Claude 3.7 Sonnet, Gemini 2.0 Flash and DeepSeek R1) to generate key themes and supporting quotes. (Figure 1) Each output was evaluated using an LLM-as-a-judge framework on five dimensions/ metrics: theme accuracy, theme coverage, semantic similarity, factual consistency, and coherence, using the published reference themes as ground truth.

Results: LLM-derived themes included: (1) diagnostic uncertainty, (2) emotional and psychological burden, (3) pregnancy as a source of hope, (4) fear of harming the baby, (5) importance of support systems, (6) everyday adaptations, and (7) personal growth. These themes aligned well with those from the original qualitative study. (Table 1) Few-shot prompting with GPT-4 yielded the highest overall performance across all five evaluation metrics - with strong theme accuracy (7.5/10), coverage (7.0/10), and coherence (9.0/10). (Table 2) .

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 2. Performance scores Across Prompting methods

Prompt Type	Model	Theme Accuracy	Theme Coverage	Semantic Similarity	Factual Consistency	Coherence
Zero-Shot	GPT-4	6.5	5.0	0.65	7.0	8.5
	Claude	5.0	4.0	0.50	5.5	7.0
	Gemini	6.0	5.5	0.60	6.5	7.5
	DeepSeek	5.5	4.5	0.55	6.0	8.0
Few-Shot	GPT-4	7.5	7.0	0.75	8.0	9.0
	Claude	7.0	7.5	0.75	8.0	9.0
	Gemini	6.5	4.0	0.60	6.0	8.0
	DeepSeek	6.5	6.5	0.65	7.0	8.5
Chain-of-Thought	GPT-4	6.5	6.0	0.65	7.0	8.0
	Claude	7.0	6.5	0.70	7.5	8.5
	Gemini	6.0	5.5	0.60	6.5	7.5
	DeepSeek	6.5	6.5	0.65	7.0	8.0

Conclusion: LLMs show strong potential for supporting qualitative research in rheumatology by facilitating multilingual data processing, theme extraction, and instrument development. This approach can significantly reduce the labor required for traditional qualitative analysis while preserving depth and rigor, especially in studies addressing sensitive and complex experiences such as lupus pregnancy. Lastly, these methods help amplify the voices of patients who are often underrepresented in research due to language barriers, making this a valuable tool for promoting equity.

Session Title: Abstracts: Rheumatoid Arthritis – Etiology and Pathogenesis (0795–0800)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: To characterize molecular profiles of RA patients through multi-omics integration and evaluate their associations with disease status and therapeutic response to csDMARDs, TNF inhibitors (TNFi), and JAK inhibitors (JAKi).

Methods: Transcriptomic profiling was performed on PBMCs from established RA patients (n=206; 177 starting TNFi or JAKi), early RA (n=53; 30 initiating csDMARDs), and healthy donors (HD, n=42) using RNA-seq (Illumina). Serum levels of 92 inflammatory proteins were measured via Proximity Extension Assay (Olink). Therapeutic responses were assessed at six months according to EULAR criteria. Multivariate and machine learning approaches identified molecular subgroups and predictive biomarkers.

Results: Unsupervised clustering of PBMC transcriptomes identified three patient groups with distinct gene module involving innate and adaptive immune responses, inflammation, and cellular metabolism, most notably in cluster 1 (CL1) (Figure 1A).

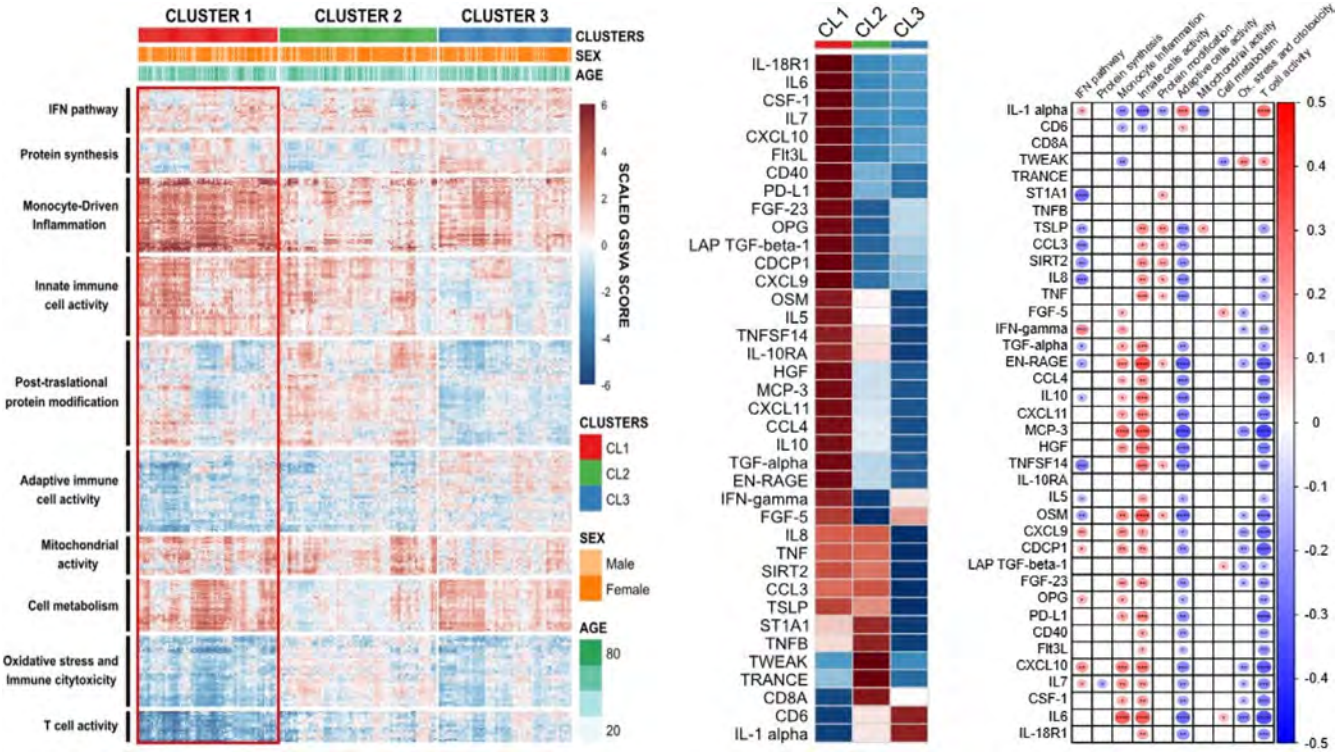

Figure 1. (A) Unsupervised clustering of PBMC transcriptomes with functional annotation of associated gene modules. (B) Differential expression profile of circulating inflammatory proteins across patient subgroups. (C) Correlation between altered inflammatory proteins and PBMC transcriptomic modules.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Circulating proteomic profiles supported these findings; 38 proteins were differentially expressed, highlighting a strong inflammatory signature in CL1 (Figure 1B & 1C).

These molecular features correlated significantly with disease activity (DAS28, SDAI), autoantibodies, and cardiovascular risk, with CL1 patients exhibiting higher activity, autoantibody titres, and systemic inflammation.

Established RA showed a greater number of differentially expressed genes and proteins compared to early RA, indicating increasing immune complexity.

Stronger correlations between molecular alterations and clinical outcomes in established RA underscored progressive molecular deregulation.

Machine learning models achieved an AUC over 0.8 in predicting response, featuring specific transcriptomic signatures: i) csDMARDs: high metabolic gene expression and low oxidative stress genes; ii) TNFi: high inflammatory and low cytotoxicity gene expression. Iii) JAKi: elevated interferon-related and decreased mitochondrial gene expression.

Clinically applicable predictive models, combining proteomic and clinical data demonstrated high accuracy: i) csDMARDs: five dysregulated inflammatory proteins, elevated monocyte count, and high SDAI; ii) TNFi: nine proteins and high disease activity scores; iii) JAKi: four proteins, high lymphocyte count, and tender joint count. Baseline inflammatory burden predicts response to csDMARDs and TNFi, while lymphocytic activity is more predictive for JAKi response.

Conclusion: Molecular profiles allow stratification of RA patients based on disease stage and clinical features. Progression involves increased molecular complexity, and treatment responses correlate with specific pre-treatment signatures. These findings highlight the potential of integrative omics to inform personalized therapy in RA.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: Abstracts: Rheumatoid Arthritis – Etiology and Pathogenesis (0795–0800)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Rheumatoid arthritis (RA) is driven by complex inflammatory pathways involving immune cell infiltration into synovial tissue and fluid. Synovial fluid (SF) provides direct insight into local disease mechanisms. Few studies have applied multiplex or single-cell transcriptomic technologies to dissect its cytokine and cellular composition.

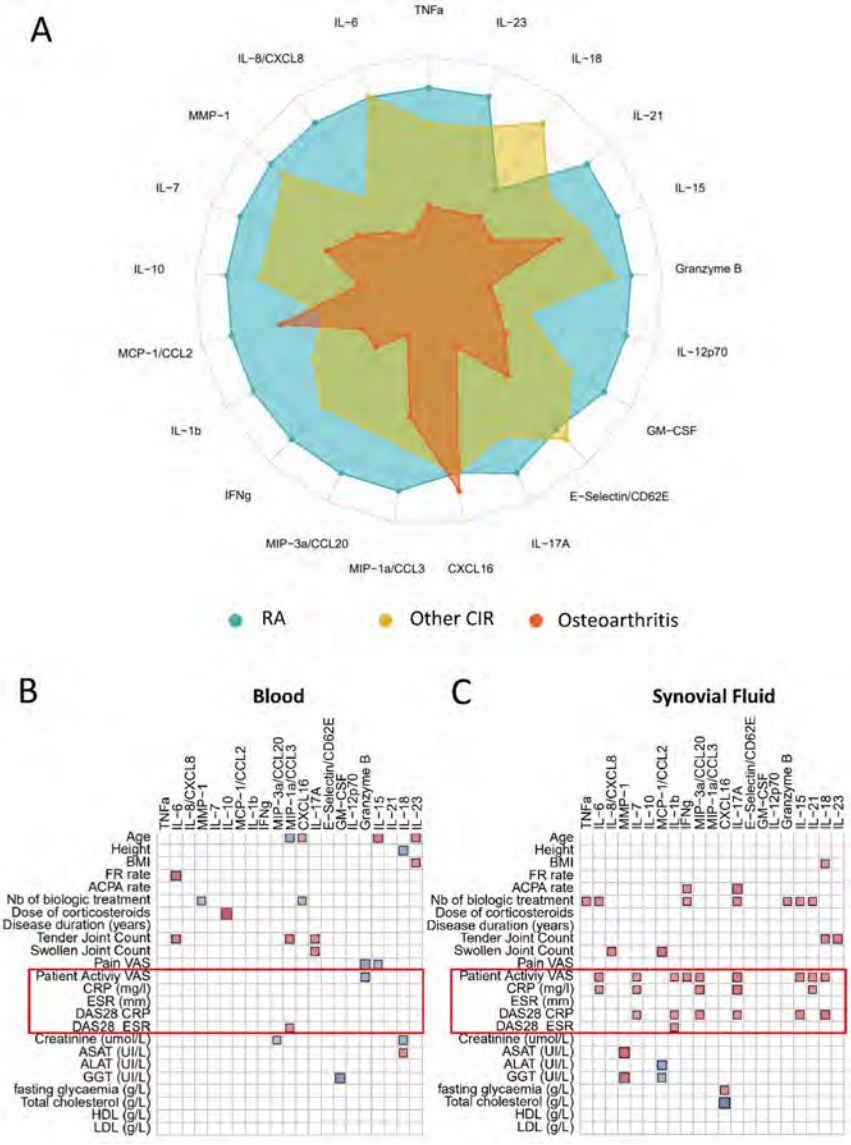

Figure1. Cytokine profiles and correlations with clinical and biological parameters in RA. (A) Radar plot illustrating the relative concentrations of 21 cytokines in synovial fluid (SF) from rheumatoid arthritis (RA, blue), other chronic inflammatory rheumatic diseases (CIR, yellow), and osteoarthritis (OA, orange). Each axis represents a specific cytokine, with values normalized to highlight differences between disease groups. (B) Correlation matrix (corrplot) between cytokines measured in blood and various clinical and biological parameters in RA patients. (C) Correlation matrix (corrplot) between cytokines measured in blood and various clinical and biological parameters in RA patients. Only significant Spearman correlation coefficients are represented by the intensity of the colour and the size of the square. Red: positive correlation. Blue: negative correlation. The boxed area highlights strong correlations between cytokines and markers of clinical disease activity, including CRP, DAS28-CRP, and patient-reported pain (VAS). ACPA: Anti-citrullinated protein antibodies. CRP: C-reactive protein. DAS28: Disease Activity Score in 28 joints. ESR: Erythrocyte sedimentation rate. VAS: Visual Analog Scale. TNF-α: Tumor Necrosis Factor-alpha. IL: Interleukin. CXCL/CCL: Chemokines.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. The objective was to (1) characterize the cytokine profile of SF in RA vs other chronic inflammatory rheumatic diseases (CIRD) and osteoarthritis (OA); (2) compare SF and serum cytokines in RA; (3) explore the single-cell transcriptomic signature of RA SF mononuclear cells (SFMCs) vs. peripheral blood mononuclear cells (PBMCs).

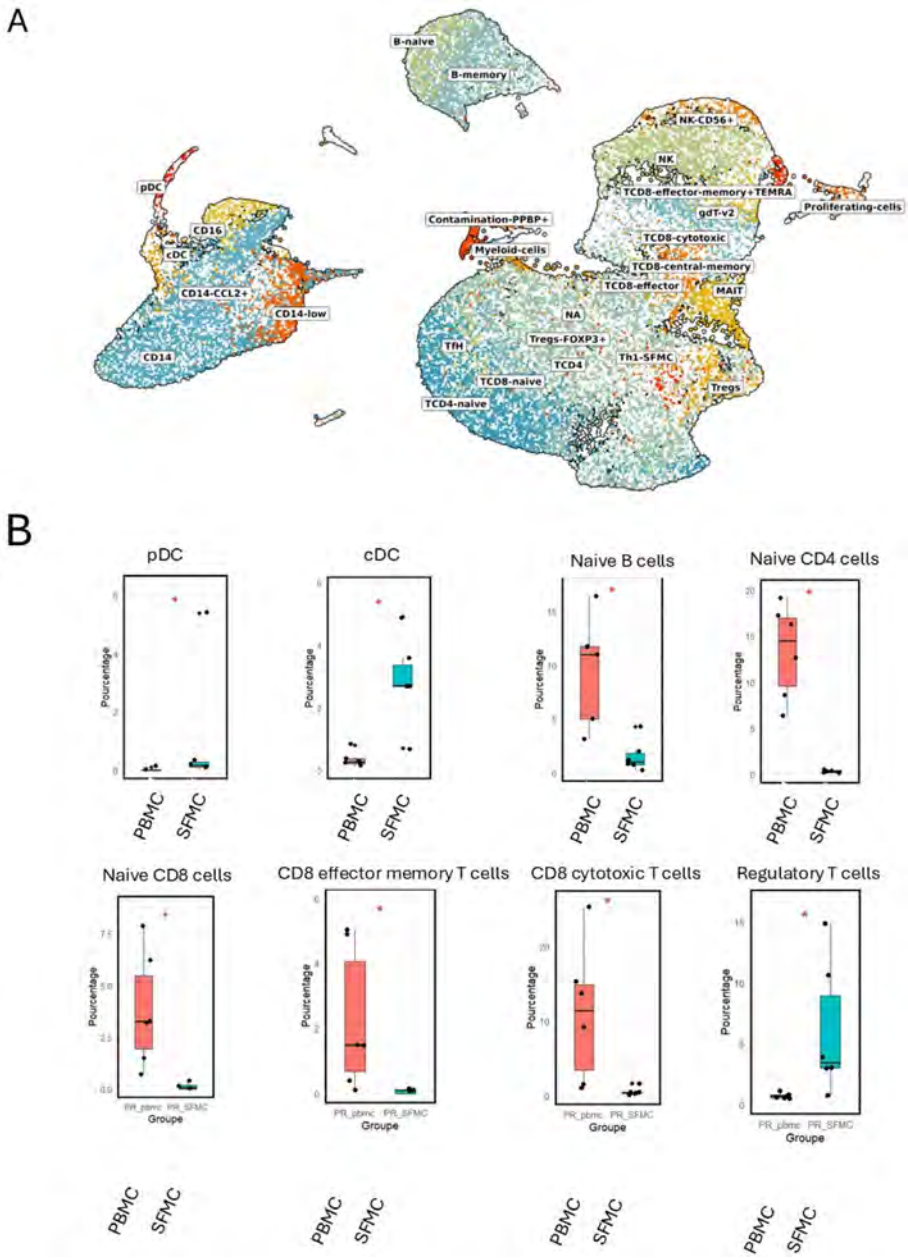

Figure 2. Immune cell composition in peripheral blood and synovial fluid of rheumatoid arthritis patients (A) Uniform Manifold Approximation and Projection (UMAP) visualization of immune cell populations from peripheral blood mononuclear cells (PBMCs) and synovial fluid mononuclear cells (SFMCs) of patients with rheumatoid arthritis. Distinct cell populations are annotated based on marker expression, including dendritic cells (pDC, cDC), B cells (naive, memory), T cells (CD4-naive, CD8-naive, CD8-effector, CD8-cytotoxic, regulatory T cells, Tregs), MAIT cells, and others. (B) Boxplots showing the proportions of specific immune cell subsets in PBMCs versus SFMCs. Cell subsets analyzed include pDC, cDC, naive B cells, naive CD4 T cells, naive CD8 T cells, CD8 effector memory T cells, CD8 cytotoxic T cells, and regulatory T cells. Significant differences between PBMCs and SFMCs are indicated by an asterisk (*). PBMCs: Peripheral blood mononuclear cells. SFMCs: Synovial fluid mononuclear cells. pDC: Plasmacytoid dendritic cells. cDC: Conventional dendritic cells. Tregs: Regulatory T cells. MAIT: Mucosal-associated invariant T cells. UMAP: Uniform Manifold Approximation and Projection

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Methods: SF samples from 115 patients (45 RA, 48 CIRD, 22 OA) were analyzed using Luminex (21 cytokines including TNF-α, IL-1β, IL-6, IL-17, GM-CSF, IL-23, and CCL20). Paired serum samples were available for 29 RA patients. scRNA-seq was performed on freshly isolated SFMCs and PBMCs from six RA patients using 10X Chromium and CellRanger pipelines. Unsupervised clustering and differential expression analyses were used to define cellular subpopulations and compare their distribution.

Results: RA SF showed significantly higher levels of pro-inflammatory cytokines (TNF-α, IL-1β, IL-6, IL-17, Granzyme B, CCL20) than OA (Fig.1A). IL-8, CCL2, and CCL3 were also elevated compared to CIRD. In RA, cytokines were consistently higher in SF than in serum and strongly correlated with CRP and DAS28-CRP, while no significant correlations were observed in serum (Fig. 1B). Heatmap analysis identified two distinct cytokine profiles in RA SF: one characterized by high cytokine secretion and elevated leukocyte count and CRP, and another with lower or moderate cytokine levels, reflecting heterogeneity in local inflammatory responses among RA patients.

scRNA-seq identified 27 immune cell clusters: 7 myeloid, 20 lymphoid (Fig. 2A). SFMCs were enriched in conventional (FC = 3.5) and plasmacytoid dendritic cells (FC = 5.5), and depleted in naïve B and T cell subsets, including CD4+ and CD8+ T cells (Fig. 2B). A distinct CD4+ T cell subset expressing PD-1, IL-17, Granzyme A, and IFN-γ was identified in SFMCs, indicating a pro-inflammatory phenotype. Regulatory T cells were enriched, while cytotoxic and effector memory CD8+ T cells were reduced (Fig. 2B).

Conclusion: RA SF exhibits a compartmentalized immune response characterized by cytokine enrichment and effector cell activation. Elevated levels of CCL20, CCL2, CCL3, and CCL8 may support dendritic cell and effector T cell recruitment into the joint. Despite this chemotactic environment, naïve T cells were markedly depleted, suggesting selective homing or local maturation. Increased IL-17 and Granzyme B at both protein and transcript levels were consistent with the presence of an inflammatory CD4+ T cell cluster co-expressing IL17A, GZMA, and PRF1. These findings reveal a coordinated inflammatory network in RA synovium, linking chemokine-mediated recruitment to local T cell activation, and highlight potential therapeutic targets identified through integrated cytokine and single-cell analysis.

Background/Purpose: The synovial lining is crucial for joint homeostasis, forming a barrier and producing lubricants through specialized fibroblasts. These fibroblasts differ from sublining fibroblasts, which are involved in inflammation and matrix remodeling. While vascular Notch signaling helps define vascular fibroblast positional identity (Wei et al. 2020), the factors shaping synovial lining fibroblast identity are unclear. Using spatial transcriptomics on synovial biopsies from RA patients in remission, we identify a density-dependent mechanism regulating lining fibroblast identity and suggest CREB5, SOX5, and FOXO1 as key transcriptional regulators.

Methods: Synovial tissue and synovial fibroblast micromasses were processed using the Xenium In Situ Gene Expression protocol (10X Genomics, CG000582 Rev D) with a custom 400-gene panel (Bhamidipati et al. 2025). For bulk RNA-seq and qRT-PCR, synovial fibroblasts were seeded at densities of 75–600 cells/mm^2 in 96-well plates for 3 days. For siRNA knockdown, cells were transfected with siRNA at 200K/well in 6-well plates and then re-seeded at varying densities.

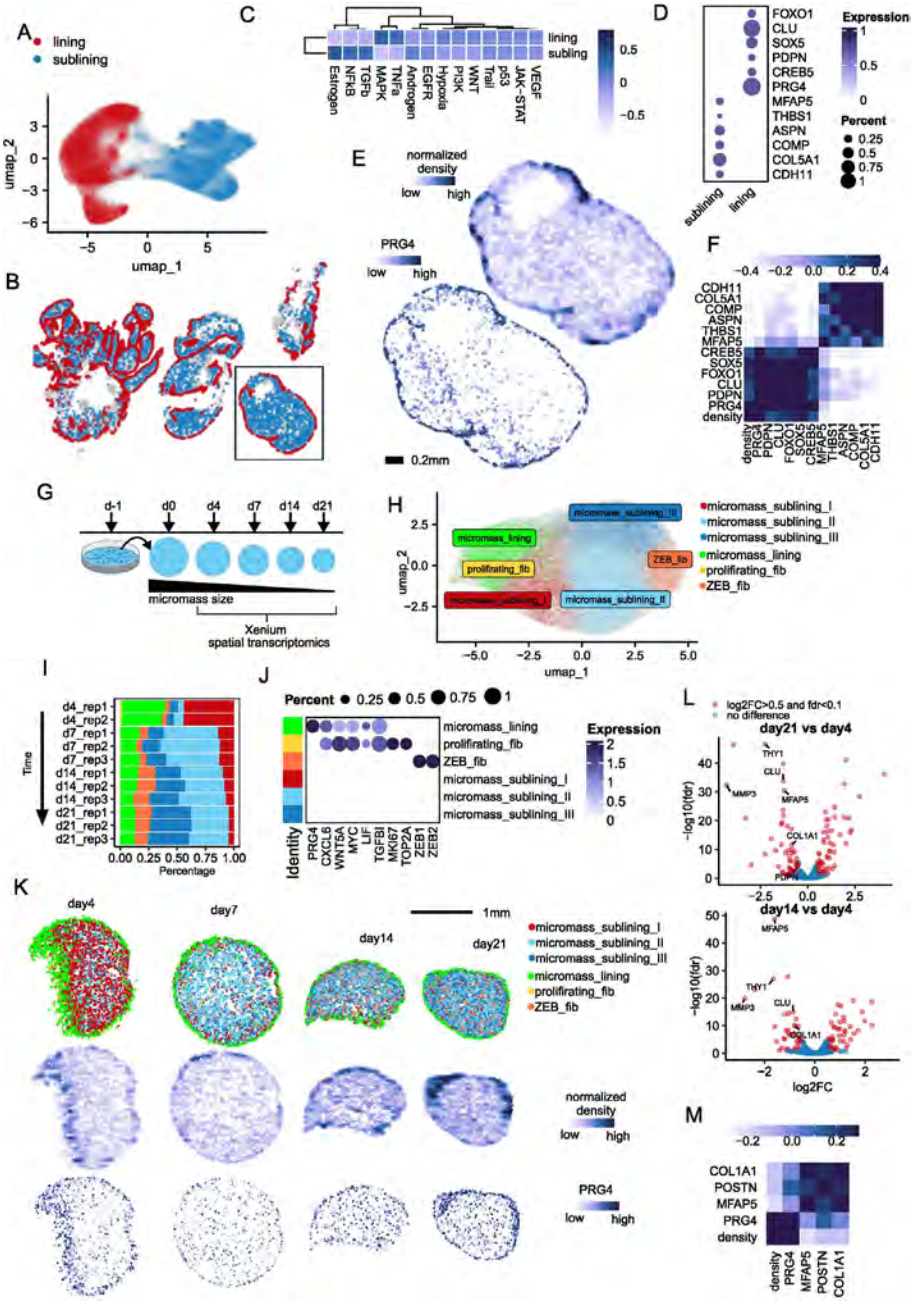

Figure 1. Characterization of fibroblast populations in RA synovial tissue and synovial fibroblast micromass culture system

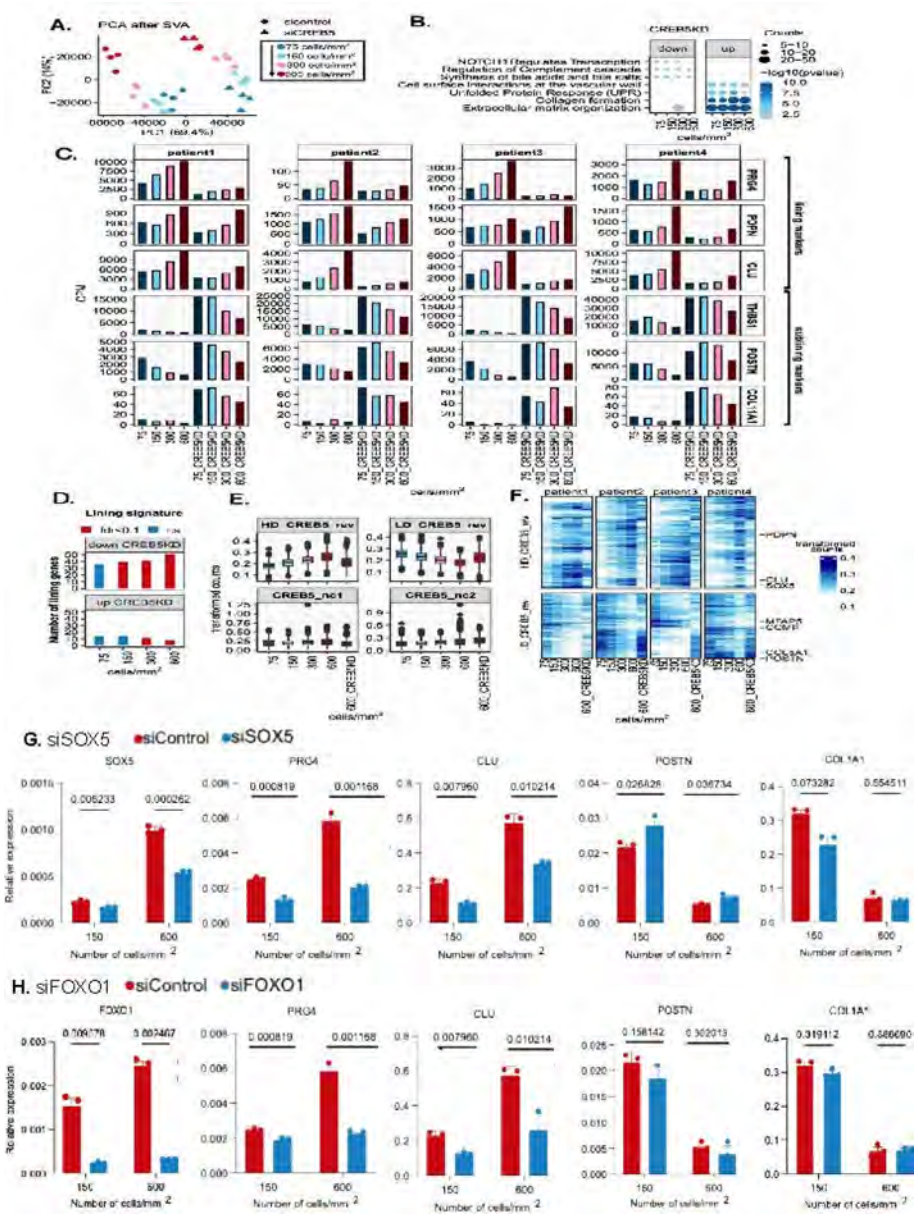

Figure 2. Bulk RNA-seq analysis of CREB5 KD (A-F) and qRT-PCR analysis of SOX5 and FOXO1 KD in synovial fibroblasts

Results: Spatial transcriptomics identified two fibroblast clusters in synovial tissue from RA patients in clinical remission: lining fibroblasts in dense, peripheral regions and sublining fibroblasts in less dense, central areas. A similar spatial organization was observed in synovial fibroblast micromass cultures maintained for 21 days. Extended culture led to increased accumulation of sublining fibroblasts in the central region, while lining fibroblasts remained localized to the periphery. Among the genes enriched in high-density regions of synovial tissue and fibroblast micromass cultures were the transcription factors CREB5, SOX5, and FOXO1, which exhibited spatial distribution patterns similar to canonical lining markers (PRG4, CLU, PDPN). These factors emerged as key candidates for regulating fibroblast identity. *In vitro* knockdown of CREB5 significantly reduced lining marker expression and increased sublining markers in a density-dependent manner. Similarly, knockdown of SOX5 and FOXO1 decreased lining marker expression without significantly affecting sublining marker levels.

Conclusion: In summary, our findings identify a density-responsive subset of lining fibroblasts defined by elevated CREB5, SOX5, and FOXO1 expression. We propose that increased cell density may activate as-yet-unidentified upstream signaling pathways that modulate the expression and/or activity of CREB5, FOXO1, and SOX5. Acting individually or synergistically,

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. these transcription factors appear to mediate a cell density–dependent phenotypic transition from sublining to lining fibroblast states, thereby contributing to fibroblast identity.

Session Title: Abstracts: Rheumatoid Arthritis – Etiology and Pathogenesis (0795–0800)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Fibroblasts are critical in promoting pathogenic synovial inflammation and bone erosion in rheumatoid arthritis (RA). Moreover, recent studies have pointed to their potential contribution to treatment-refractory disease, highlighting the value of targeting these cells therapeutically. Our prior work identified Wnt signaling as a novel mechanism

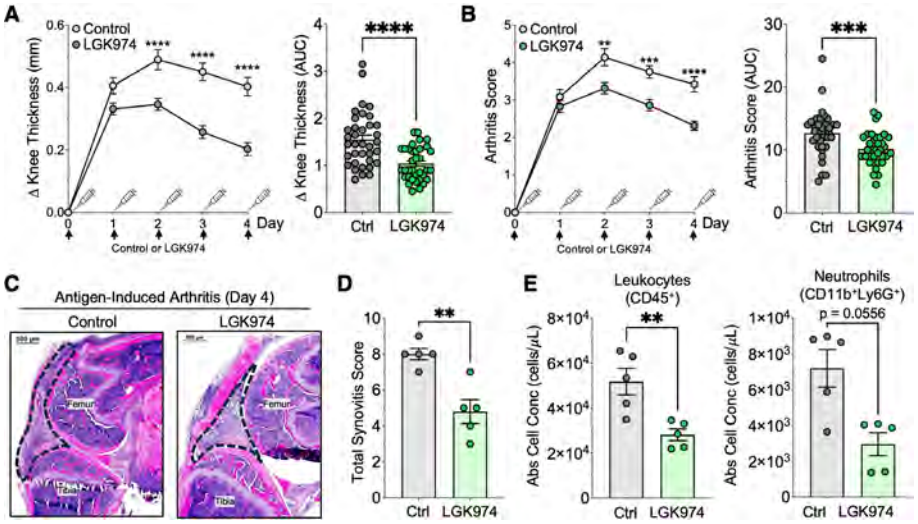

Figure 1: Inhibition of Wnt signaling reduces arthritis severity and leukocyte infiltration in a mouse model of inflammatory arthritis. (A-B) Plots and AUC calculations for knee thickness measurements (A) and clinical arthritis scores (B) at the time points indicated from mice that underwent antigen-induced arthritis (AIA) and have been treated with the Wnt signaling inhibitor LGK974 (n=35) or a vehicle control (n=36). (C-D) Representative H&E images (C) and histology synovitis scores (D) from knee joints taken from AIA mice treated with LGK975 (n=5) or control (n=5). Dotted lines indicate outline of synovial infiltrate. (E) Flow cytometry data showing absolute numbers of leukocytes and neutrophils derived from knee synovial tissue of AIA mice treated with LGK974 (n=5) or control (n=5).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2: Wnt pathway blockade decreases the inflammatory potentiation of synovial fibroblasts during arthritis. (A) Flow cytometry showing absolute numbers of fibroblast populations in AIA mice treated with LGK974 (n=5) or vehicle control (n=5). (B) UMAP showing 34,728 fibroblasts from AIA mice treated with LGK974 (n=3) or vehicle control (n=3). PRG4+ lining, THY1+ sublining, and MKI67+ proliferative fibroblast subpopulations are depicted. (C-D) Violin plots showing expression of the chemokine CXCL5 (C) and immune regulators SOCS1 and SOCS3 (D) in sublining and lining fibroblasts from single-cell RNA sequencing of synovial tissue from AIA mice treated with LGK974 (n=3) or control (n=3).

driving stromal inflammation. In response to non-canonical Wnt activation, human synovial fibroblasts markedly increase production of inflammatory cytokines and chemokines *in vitro*. Further, we found that Wnt activation increases inflammatory arthritis severity and duration *in vivo* in a mouse model. Our analyses of human disease show that fibroblast Wnt activation signatures are increased in RA synovium and across other inflammatory conditions. Here, we investigate the therapeutic potential of Wnt pathway blockade and demonstrate that inhibiting Wnt signaling reduces arthritis severity and synovial inflammation in a mouse model of inflammatory arthritis.

Methods: C57Bl/6 mice underwent antigen-induced arthritis (AIA) by subcutaneous administration of methylated BSA (mBSA) at day -21 followed by intraarticular knee injection of mBSA at day 0. Mice were given daily intraperitoneal injections of the Wnt signaling inhibitor LGK974 or a vehicle control on days 0-4. Knee thickness and clinical scores were assessed. Synovial tissue was collected at day 4 and processed for H&E, flow cytometry analysis, cell sorting and single-cell RNA sequencing.

Results: To investigate whether the abrogation of Wnt signaling would reduce the severity of inflammatory arthritis, we utilized the AIA model and treated mice with LGK974, a pharmacologic inhibitor of Wnt ligand secretion. Mice treated with LGK974 exhibited a marked decrease in knee swelling (Fig 1A) and clinical arthritis scores (Fig 1B) compared to vehicle controls. Histologic analyses of knee joints collected at day 4 revealed decreased lining hyperplasia and leukocyte infiltration (Fig 1C-D). Moreover, flow cytometry analyses of cells isolated from synovial tissue showed decreased absolute numbers of leukocytes and a trend towards reduced neutrophil counts (Fig 1E). While total numbers of fibroblasts did not significantly differ in synovial tissue from LGK974- and control-treated mice (Fig 2A), both lining and sublining fibroblasts (Fig 2B) exhibited changes in transcriptomic phenotype. Specifically, synovial fibroblasts from LGK974-treated mice showed decreased expression of CXCL5, a chemokine that participates in neutrophil recruitment in RA and that is increased upon Wnt administration (Fig 2C). They also upregulated SOCS1 and SOCS3, inhibitors of JAK signaling (Fig 2D). These results suggest that

blocking Wnt signaling dampens synovial fibroblast inflammatory activation during arthritis and, in turn, their ability to recruit and activate infiltrating leukocytes.

Conclusion: Collectively, our findings demonstrate the utility of Wnt pathway inhibition in reducing inflammatory arthritis severity. This work identifies a novel fibroblast-targeted therapeutic avenue for RA with a compelling potential value for patients whose disease is recalcitrant to conventional treatment modalities.

Citrullination of neutrophil serine proteases enhances proteolytic activity, stability and autoantigenicity in Rheumatoid Arthritis

Mario Navarrete Lagos, Ramiza Zaman, Jun Kim, Jeba Atkia Maisha, Hani El-Gabalawy and **Liam O'Neil**, University of Manitoba, Winnipeg, MB, Canada

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: Abstracts: Rheumatoid Arthritis – Etiology and Pathogenesis (0795–0800)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: In Rheumatoid Arthritis (RA), autoantibodies develop against endogenous proteins containing the amino acid citrulline, which results from a post-translational modification of arginine catalyzed by a family of peptidyl arginine deiminase (PAD) enzymes. Although citrullination is a ubiquitous physiological process, its impact on the structure and function of specific proteins is not well understood. Neutrophils contain 2 isoforms of PAD (2/4) and readily form citrullinated RA antigens during neutrophil extracellular trap (NETs) formation. However, the effects of citrullination on neutrophil protease activity have not been studied. We hypothesized that citrullination influences the activity of neutrophil serine proteases, namely Neutrophil Elastase (NE), Proteinase-3 (PR3) and Cathepsin G (CTG), which in turn may contribute to the pathogenesis of RA.

Methods: The activity of proteases and various biospecimens were analyzed using fluorogenic substrate after citrullination with PAD2/4 (confirmed by a cit-specific probe). Active protease sites were labelled and visualized using a probe (TAMRA-FP). Degradation of aggrecan, a proteoglycan found in cartilage, was determined. Cultured fibroblast-like synoviocytes (FLS) were treated with cit-PR3. IL-6/TNF and ACPA targeting cit-proteases were measured with ELISA.

Results: Using both recombinant proteases and neutrophil supernatant, proteolytic activity of NE, PR3 and CTG increased markedly after citrullination with PAD2, and to a lesser extent, PAD4 (Fig1A). For example, the activity of PAD2 cit-PR3 increased by 13-fold compared to native PR3. PAD2 also lead to enhanced stability of proteases, with detectable activity after 72 hours *in-vitro*, and evidence of protection from autoproteolysis (Fig1B-D) and exogenous proteases (trypsin, Fig

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

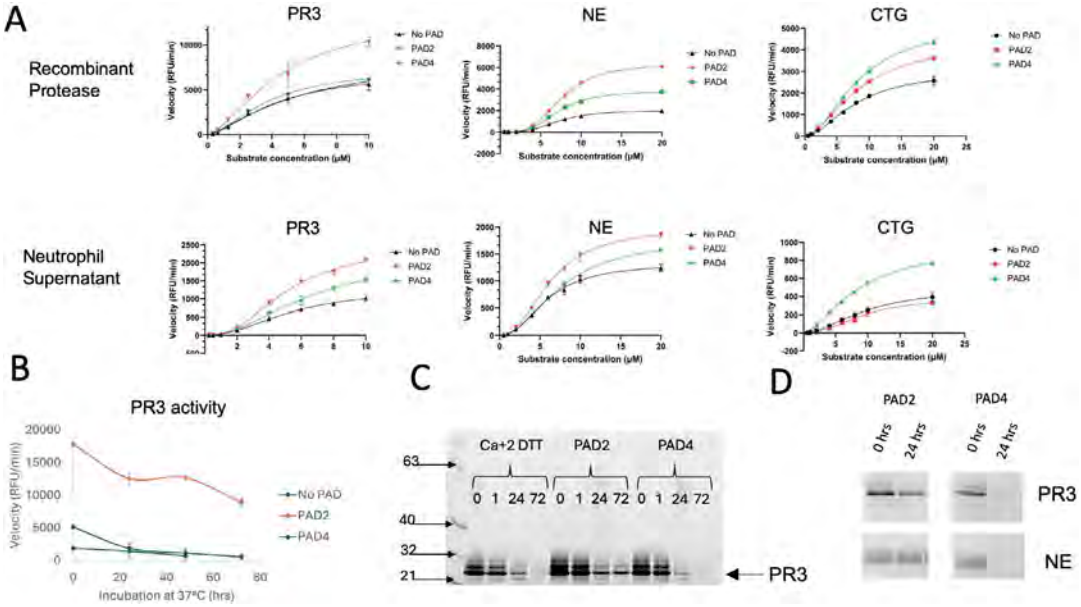

Figure 1: PAD2-citrullination enhances neutrophil serine protease activity and stability. (A) The effect of PAD2 and PAD4 on recombinant serine protease activity (upper) and neutrophil supernatant protease activity (lower) measured with a fluorogenic substrate (increasing concentrations x-axis) and enzyme velocity. (B) Proteinase-3 activity after citrullination with PAD2 (orange) and PAD4 (green) up to 72 hours in-vitro. Only PAD2 citrullinated PR3 had detectable activity at 48 and 72h. (C) Protein staining (sypro-ruby) or citrullinated PR3 by PAD2 or PAD4 compared to buffer (Ca/DTT), measured every 24 hours, revealing protection of autoproteolysis mediated by PAD2 citrullination. (D) A 24-h analysis comparing PAD2/4 citrullination in neutrophil elastase (NE) and PR3. PR3: Proteinase 3, NE: Neutrophil Elastase, CTG: Cathepsin G, DTT: Dithiothreitol (reducing agent).

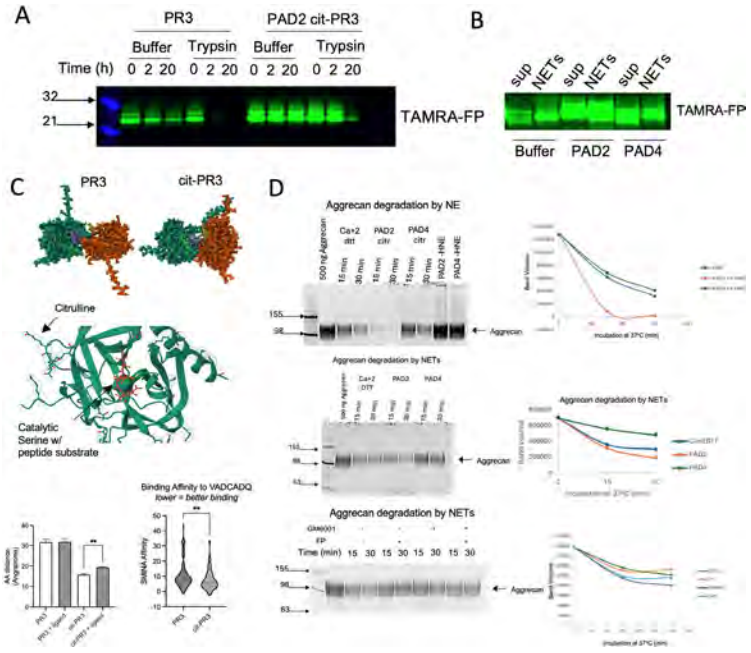

Figure 2: Citrullination induces a conformational change in neutrophil serine proteases which opens new catalytic sites to enhance activity, allowing for the degradation of aggrecan a proteoglycan in cartilage. (A) PAD2 citrullination of PR3 reveals new catalytic sites as evidenced by increased signal from a specific serine protease probe called TAMRA-FP. PR3 is protected from degradation by Trypsin, a common serine protease. (B) Evidence of new catalytic sites in neutrophil supernatants and NETs using TAMRA-FP in PAD2/PAD4 treated samples. (C) In-silico models of multimeric (dimer) proteinase-3 (upper structures) and a peptide ligand (VADCADQ, purple) which increases the distance between the 2 active sites in citrullinated PR3 but not native PR3 (lower left bar graph). Monomeric model (lower structure) revealing the peptide ligand (orange), citrulline (ball-stick) and the active serine (green sphere). SMINA affinity measure using a docking algorithm reveals a higher binding energy between the peptide substrate and cit-PR3 (lower right violin plot, $P<0.01$). (D) Degradation of aggrecan and cartilage proteoglycan by recombinant NE (upper), NETs (middle) and NETs treated with an aggrecanase (matrix metalloproteinase) inhibitors called GM6001 or a biotinylated form of the FP probe which inhibits protease function (lower).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 3: Proteases in RA serum, synovial fluid which serve as autoantigens. (A) Serum citrullinated proteinase-3 is higher in RA compared to controls (P<0.0001) (B) Detection of PR3, NE, and CTG in RA synovial fluid compared to OA. (C) Treatment of fibroblast-like synoviocytes (FLS) with PR3 and cit-PR3 (PAD2) leads to increased IL-6 production, which is reduced with pre-treatment with a protease activated receptor (PAR2) inhibitor. (D) Autoantibodies targeting various citrullinated neutrophil proteases via PAD4 (upper) or PAD2 (lower) (* P<0.05, ** P <0.01, *** P<0.001).

2A) in PR3 and NE. In the recombinant proteases, supernatant, and NETs, PAD2 citrullination enhanced the allosteric capacity of the protease multimers by opening new catalytic sites (Fig2A/B). This is suggestive of a conformational change induced by PAD which was confirmed by *in-silico* modelling (Fig2C). Models also suggested a higher binding energy between cit-PR3 and a peptide substrate. Aggrecan degradation was enhanced by PAD2-citrullination of NE and NETs. Using MMP and serine protease inhibitors, we found that degradation by NETs was undertaken by serine proteases, rather than aggrecanases (Fig2D). Serum cit-PR3 levels were elevated in RA than controls, and synovial fluid PR3, NE, and CTG activity were higher in RA compared to OA. FLS treated with cit-PR3 significantly increased the release of IL-6/TNF, and this was mediated by a protease activity receptor, PAR2 (Fig3C). Autoantibodies to PAD4 cit-proteases, but not PAD2, were higher in RA than controls (Fig3D).

Conclusion: PAD citrullination results in a gain of function for neutrophil serine proteases through conformational changes that result in enhanced proteolytic activity and stability. Although this process may provide a biological advantage for host defense, in the context of RA, this leads to degradation of cartilage components, inflammation and autoantibody formation.

Microbiota-Derived Indole Promotes Collagen-Induced Arthritis Type-17 Immunity through Intestinal Dendritic Cell Cytokine Production

Jing Li[1], Sucai Liu[2], Brenda Seymour[3], Brendan Allen[2], Le Yiphyo[2], Cassandra Levens[1] and Kristine Kuhn[4], [1]Rheumatology, Aurora, CO, [2]University of Colorado School of Medicine, Aurora, CO, [3]University of Colorado School of Medicine, Denver, CO, [4]2022 - 2023 / Adult/ University of Colorado, Aurora, CO

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: Abstracts: Rheumatoid Arthritis – Etiology and Pathogenesis (0795–0800)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: One of the most substantial impacts of microbe-host interactions at the intestinal mucosa is the development of type 17 immunity. A Th17 signature has been observed in pre-clinical RA, suggesting that type 17 immunity may play a role in the initiation of pre-clinical autoimmunity. Yet, the mechanistic connection between RA-associated bacteria and Th17 immunity remains a knowledge gap. Our prior work in the collagen-induced arthritis (CIA) model of inflammatory arthritis connected microbial dysbiosis with the catabolism of dietary tryptophan to indole, which was necessary for disease

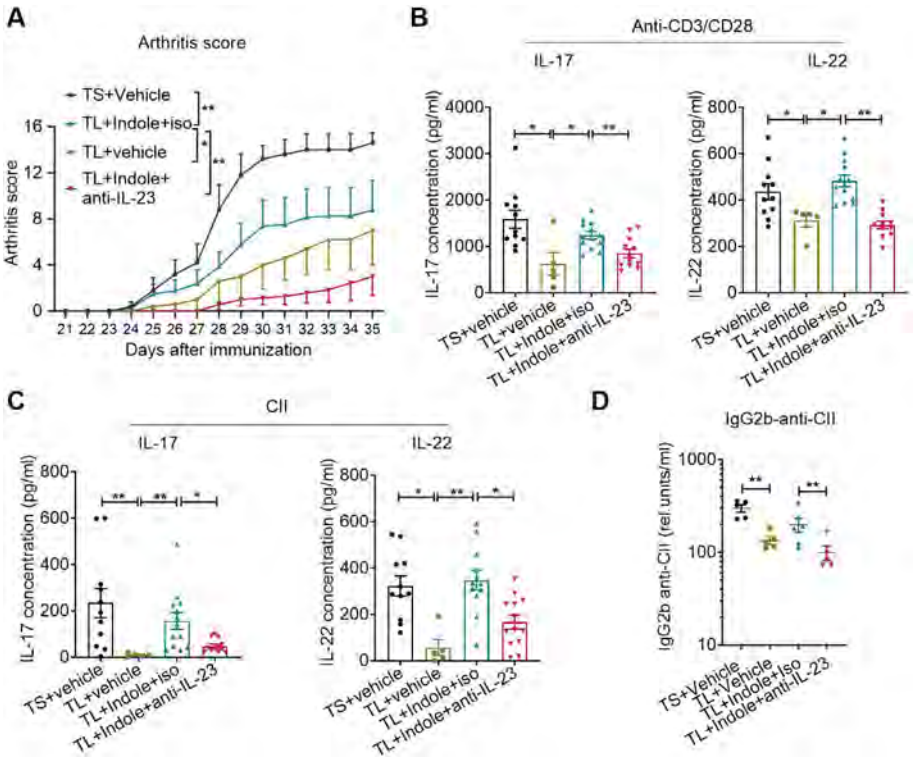

Figure 1. IL-23 neutralization suppresses indole-induced Th17 responses and autoantibodies. CIA was induced in 6–8-week-old male DBA/1 mice maintained on a tryptophan-low (TL) diet, followed by oral gavage of indole (200 µl of 10 mM, every other day). Mice were immunized intradermally on days 0 and 21 with type II bovine collagen (CII) emulsified in complete Freund's adjuvant (CFA). In addition, mice received intraperitoneal injections of either an isotype control antibody or anti–IL-23 neutralizing antibody (100 µg/mouse) once weekly on days 0, 7, 14, and 21. (A) Neutralization of IL-23 significantly reduced arthritis scores in indole-treated CIA mice compared to isotype control. (B) Ex vivo stimulation of splenocytes with anti-CD3/CD28 antibodies or (C) CII showed reduced production of IL-17 and IL-22 in the anti-IL-23 group, as measured by ELISA. (D) Serum levels of CII-specific IgG2b antibodies were also decreased in the anti–IL-23–treated group compared to controls. Data were expressed as mean ± SEM. Statistical significance was determined by two-way ANOVA with Tukey's multiple comparisons test (A), or Mann-Whitney test (B-D). *P < 0.05, **P < 0.01, ns: non-significant.

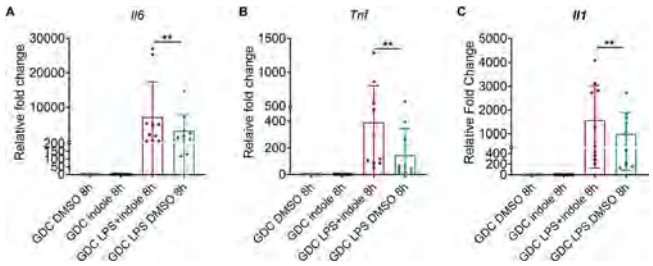

Figure 2. Indole enhances LPS-induced Th17-inducing cytokine expression in human GDCs. $CD14^+$ monocytes were isolated from peripheral blood mononuclear cells obtained from 10 healthy donors (5 male, 5 female). Cells were cultured in RPMI medium supplemented with 20 ng/ml recombinant human GM-CSF and IL-4 to generate GDCs. On day 3, retinoic acid (100 nM) was added to the culture. On day 5, GDCs were harvested and stimulated with the indicated stimuli for 8 hours. RNA was then extracted, and gene expression was analyzed by qPCR. Results showed that indole significantly enhanced the LPS-induced expression of IL-6, IL-1, and TNF in human GDCs. Data were expressed as mean ± SEM. Statistical significance was determined by Wilcoxon test (A-C). **P < 0.01.

via Th17 immunity and pathogenic autoantibody development. In this study, we aimed to examine the mechanism by which indole stimulates Th17 immunity.

Methods: Indole-CIA was induced in male 6-8-week old DBA/1 mice fed a tryptophan-low diet with every-other-day indole gavage (200μl of 10mM) and injected intradermally on days 0 and 21 with type II bovine (CII) emulsified in complete Freund's adjuvant. Mice also received intraperitoneal injections of 100μg/mouse either isotype control or anti-IL-23 neutralizing antibody once weekly at days 0, 7, 14, and 21 of CIA. Arthritis severity, immune cells, cytokines, and anti-CII antibodies were evaluated by flow cytometry and ELISA. Murine bone marrow–derived dendritic cells (BMDCs) and human gut-like dendritic cells (GDCs) from peripheral blood mononuclear cells were stimulated in vitro with 1μg/ml dose LPS plus 1μl DMSO or LPS plus 1 mM indole for 8-24 hours. The expression of cytokines was measured by qPCR. Signaling pathways were interrogated by RNA sequencing and immunoblot.

Results: IL-23 neutralization, compared to control antibody, significantly reduced the severity of indole-CIA, diminished Th17 cell and DC frequencies, and decreased CII autoantibodies (Fig 1). Upon ex vivo stimulation of splenocytes with CII or anti-CD3/CD28 antibodies, the anti-IL-23 treatment group exhibited significantly lower production of IL-17 and IL-22 compared to the control group (Fig 1). DCs produced Th17-differentiating cytokines at days 7-14 of indole-CIA. In vitro, qPCR analysis showed that indole significantly amplified LPS-induced expression of IL-23, IL-6, IL-1β, and TNF-α in both BMDCs and human GDCs (Fig 2). RNA sequencing of indole-stimulated GDCs followed by immunoblot analysis suggested that indole signaled through non-canonical pathways of aryl hydrocarbon receptor (AhR).

Conclusion: These findings suggest that microbiota-derived indole promotes CIA via priming of intestinal DCs to produce Th17-differentiating cytokines. Non-canonical signaling through AhR results in increased DC production of cytokines that are likely to induce Th17 cells. Blockade of Th17 cell differentiation by IL-23 neutralizing antibody resulted in significantly reduced disease through reduced Th17 cells producing IL-17 and IL-22. Reduction in IL-22 is likely the cause for reduced CII antibodies, although this has yet to be formally tested. Altogether, our data mechanistically connect microbial dysbiosis to the development of inflammatory arthritis, demonstrating one mechanism by which altered microbial ecology can lead to RA.

Abstract Number: 0801

Achieving Sustained Lupus Low Disease Activity State and Remission with Ianalumab (VAY736) in Patients with Systemic Lupus Erythematosus: A Post Hoc Analysis from a Phase II Study

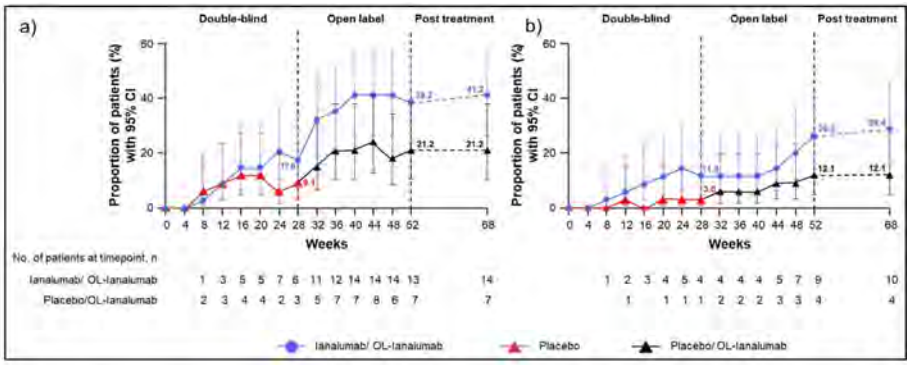
Eric Morand[1], Corine Gaillez[2], Stephen Oliver[3], Swati Ghanshani[4], Marilia Pozzobon[5], Weibin Bao[6] and **Ed Vital**[7], [1]Centre for Inflammatory Diseases, Monash University and Monash Health, Melbourne, Victoria, Australia, [2]Novartis Pharma AG, Basel, Switzerland, Croissy Sur Seine, France, [3]Novartis Pharma AG, Basel, Switzerland, [4]Novartis Healthcare Private Limited, Hyderabad, India, Hyderabad, India, [5]Novartis Pharma AG, Basel, Switzerland, Basel, Switzerland, [6]Novartis Pharmaceuticals Corporation, Hanover, NJ, [7]University of Leeds, Leeds, England, United Kingdom

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: Abstracts: Systemic Lupus Erythematosus – Treatment I (0801–0806)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Ianalumab, a fully human monoclonal antibody against the B cell–activating factor receptor (BAFF-R), has a dual mechanism of action of B cell depletion through antibody-dependent cellular cytotoxicity and BAFF-R blockade. A treat-to-target approach, targeting Definition of Remission in SLE (DORIS) and Lupus Low Disease Activity State (LLDAS), has demonstrated potential in reducing organ damage progression and improving quality of life.[1] Here, we investigated the 52-week impact of ianalumab on attainment of LLDAS, DORIS, and glucocorticoid (GC) taper in patients with active SLE enrolled in a phase IIa study (NCT03656562).

Methods: Patients with SLE were randomized 1:1 to subcutaneous ianalumab 300 mg or placebo every 4 weeks (W). The study included two treatment periods consisting of a double-blind period with a comparison between ianalumab and placebo for 28W followed by a 24W open-label (OL) period with continued ianalumab 300 mg in the active arm (ianalumab/OL-ianalumab) and switch from placebo to ianalumab 300 mg (placebo/OL-ianalumab). Following 52W treatment, patients entered a post-treatment (PT) period up to W68. Patients on stable GC were required to undergo GC tapering from W4 to W16 and remain on the dose achieved through Week 28. Endpoints evaluated include: proportion of patients achieving LLDAS, DORIS, and tapered GC ≤5 mg at each visit; time-to-first LLDAS; cumulative time (defined as 20%/50% of time) spent in LLDAS and DORIS during the placebo-controlled period (28W) and the overall 52W treatment period; and

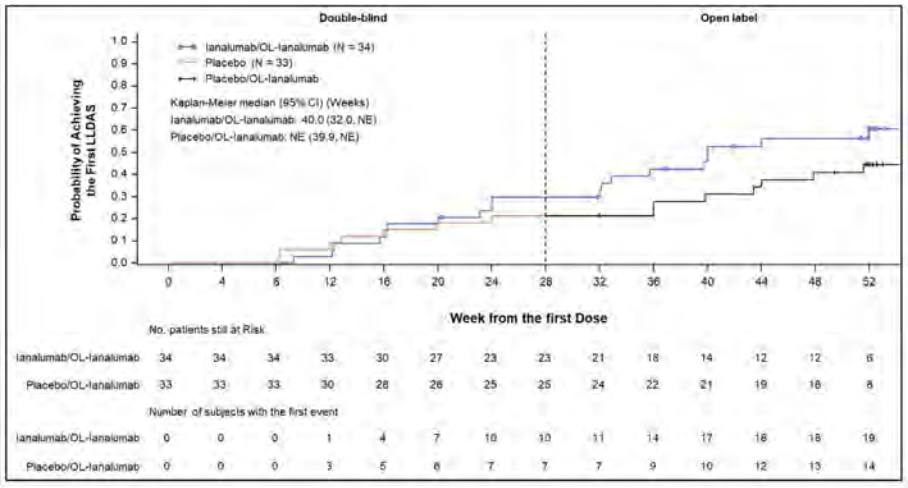


CI, confidence interval; DORIS, Definitions of Remission in Systemic Lupus Erythematosus; LLDAS, Lupus Low Disease Activity State; OL, open-label.
CIs were calculated using the Wilson score method with continuity correction.

Intermittent missing values are imputed by the worse of the two adjacent values only when both are observed and treated as non-responders otherwise.

Fig. 1. Proportion of patients who achieved a) LLDAS and b) DORIS by treatment and visit over the 52-week treatment period

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



CI, confidence interval; LLDAS, Lupus Low Disease Activity State; NE, not estimable; OL, open-label. Patients who did not achieve LLDAS were censored at the end of the treatment.

Fig. 2: Time to first LLDAS over the 52-week treatment period

cumulative time with GC taper (≤5 mg and ≤ baseline dose). All efficacy outcomes are summarized descriptively. Time-to-event endpoints were assessed using Kaplan-Meier analysis.

Results: This analysis included 67 patients: 34 in ianalumab/OL-ianalumab and 33 in placebo/OL-ianalumab. Although LLDAS/DORIS attainment increased after switching, at W52, more patients in the ianalumab/OL-ianalumab group had achieved LLDAS and DORIS (38.2% and 26.5%) than those in placebo/OL-ianalumab (21.2% and 12.1%); this trend was maintained in the PT period (ianalumab/OL-ianalumab: 41.2% and 29.4%; placebo/OL-ianalumab: 21.2% and 12.1%; **Fig. 1a,1b**). Median time to first LLDAS was 40W in the ianalumab/OL-ianalumab group (**Fig. 2**). At W52, more patients in ianalumab/OL-ianalumab (85.3%) achieved GC taper than in placebo/OL-ianalumab (72.7%). During the 52W treatment period, cumulative time spent on LLDAS, DORIS, and tapered GC ≤5 mg was higher in ianalumab/OL-ianalumab than in placebo/OL-ianalumab (**Table 1**).

Table 1: Cumulative time spent on LLDAS, DORIS, and tapered GC ≤5 mg during the 28-week double-blind period and during the 52-week study period

	28-Week double-blind period		52-Week study period (double-blind + open-label)	
Assessment*	Ianalumab (N=34)	Placebo (N=33)	Ianalumab/OL-ianalumab (N=34)	Placebo/OL-ianalumab (N=33)
Time spent on LLDAS				
Cumulative time spent (days), mean (SD)	20.1 (37.0)	14.0 (33.4)	88.9 (102.9)	46.4 (86.0)
Percentage of patients who had ≥20% time spent, n (%)	7 (20.6)	4 (12.1)	14 (41.2)	6 (18.2)
Percentage of patients who had ≥50% time spent, n (%)	3 (8.8)	2 (6.1)	8 (23.5)	4 (12.1)
Time on DORIS remission				
Cumulative time spent (days), mean (SD)	13.7 (36.1)	2.8 (12.2)	44.6 (84.0)	14.9 (41.2)
Percentage of patients who had ≥20% time spent, n (%)	5 (14.7)	1 (3.0)	7 (20.6)	3 (9.1)
Percentage of patients who had ≥50% time spent, n (%)	1 (2.9)	0	3 (8.8)	0
Time with GC ≤5 mg and less than baseline level (whichever is lower)				
Cumulative time spent (days), mean (SD)	91.1 (74.7)	82.9 (85.3)	201.8 (138.2)	168.9 (159.3)
Percentage of patients who had ≥20% time spent, n (%)	22 (64.7)	18 (54.5)	25 (73.5)	19 (57.6)
Percentage of patients who had ≥50% time spent, n (%)	18 (52.9)	14 (42.4)	19 (55.9)	16 (48.5)

DORIS, Definitions of Remission in Systemic Lupus Erythematosus, GC, glucocorticoids; LLDAS, Lupus Low Disease Activity State; N, total number of patients; n, number of patients who spent time on the given assessment; SD, standard deviation.

*The patients on stable GC regimen were required to undergo guided GC tapering from Week 4 until Week 16 and remain on lowered GC dose achieved at Week 16 through Week 28.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: A 52W week of ianalumab treatment was associated with more time in LLDAS and DORIS, as well as higher attainment of GC taper goals compared to 28W placebo followed by 24W ianalumab exposure. This suggests that earlier ianalumab exposure led to cumulative clinical benefit in patients with SLE. Larger studies are required to confirm these findings.

Session Title: Abstracts: Systemic Lupus Erythematosus – Treatment I (0801–0806)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Cutaneous manifestations of lupus are highly prevalent and have a significant impact on patients' physical and mental health and wellbeing; however, no targeted therapy is available. Toll-like receptor (TLR) 7/8 signaling has a role in regulating interferon (IFN) induction; elevated type I IFN gene transcripts in lupus skin lesions highlight the importance of the IFN signaling pathway in disease pathogenesis. Enpatoran is a first-in-class oral small molecule TLR 7/8 inhibitor. In a Phase II randomized double-blind placebo-controlled dose-finding parallel adaptive basket study (WILLOW [NCT05162586]), enpatoran improved Cutaneous Lupus Disease Area and Severity Index-Activity (CLASI-A) scores from baseline (BL) and increased CLASI-50 and CLASI-70 response rates in patients with CLASI-A ≥8 SLE and CLE (Cohort A).[1] Enpatoran also improved attainment of BICLA response with glucocorticoid taper vs placebo in patients with moderate-to-severe active SLE (Cohort B), despite no statistically significant dose response in this cohort.[2] Here we report an exploratory post-hoc analysis of pooled data for all patients from Cohort A and Cohort B who had active cutaneous manifestations (CLASI-A ≥8 at BL).

Methods: The WILLOW study design and patient enrollment criteria are summarized in Table 1. Cutaneous outcomes assessed at Week 16 and 24 were predefined secondary/exploratory endpoints in WILLOW and included: CLASI-50 and

Attainment of remission based on CLASI-A total score 0–1, n (%)				
Week 16	4 (6.0)	11 (21.2)	12 (19.0)	17 (21.3)
Week 24	11 (16.4)	14 (26.9)	19 (30.2)	23 (28.8)
Attainment of remission based on CLASI-A total score 0–3, n (%)				
Week 16	11 (16.4)	22 (42.3)	27 (42.9)	38 (47.5)
Week 24	18 (26.9)	27 (51.9)	35 (55.6)	45 (56.3)
Change from BL in PGA of cutaneous lupus disease activity, mean (SD)				
Week 16	-20.1 (20.5)	-33.6 (22.0)	-32.6 (23.9)	-38.1 (22.4)
Week 24	-22.3 (21.0)	-38.2 (21.3)	-37.4 (22.3)	-42.4 (23.2)

[a]CLASI-50 response defined as ≥50% improvement from BL in CLASI-A total score; [b]CLASI-70 response defined as ≥70% improvement from BL in CLASI-A total score; [c]Based on a logistic model with treatment group, region and Cohort as independent variables. There was no adjustment for multiplicity and all p-values are nominal; [d]95% CI computed using the Wald method; [e]Crude difference of response rate expressed as a percentage with 95% CI computed using non-stratified Miettinen-Nurminen method.
BID, twice daily; BL, baseline; CI, confidence interval; CLA-IGA, Cutaneous Lupus Activity Investigator's Global Assessment; CLASI-A, Cutaneous Lupus Disease Area and Severity Index Activity; FAS, full analysis set; PGA, Physician Global Assessment; SD, standard deviation.

of patients in each enpatoran dose group attained remission based on CLA-IGA score 0–1 (nominal p< 0.025 enpatoran 50 mg and 100 mg vs placebo). A higher proportion of patients with remission based on CLASI-A total score with enpatoran was also observed, with up to 30.2%/56.3% achieving CLASI-A 0–1/0–3 (compared with 16.4%/26.9% for placebo) by Week 24. At Week 16 and 24, mean change from BL in PGA of cutaneous lupus disease activity numerically improved across enpatoran doses vs placebo (Table 2).

Conclusion: Patients receiving enpatoran achieved higher rates of CLASI-50/70 response, CLA-IGA and CLASI-A remission vs placebo. Findings support further investigation of enpatoran efficacy and safety in patients with lupus and active cutaneous manifestations.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: Abstracts: Systemic Lupus Erythematosus – Treatment I (0801–0806)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Chronic GC and IS use increases damage accrual and mortality. The 2023 EULAR SLE recommendations support initiation of biologics such as BEL, a human IgG1λ monoclonal antibody that selectively binds to soluble B-lymphocyte stimulator (BLyS) with proven efficacy in SLE, without prior IS failure in AM- and GC-non-responders. Real-world evidence has shown benefits of initiating BEL without prior IS treatment. This study assessed the efficacy and safety of initiating BEL relative to being on IS at baseline of clinical trials (combined with AM and GC) in patients with SLE.

Methods: This post hoc summary pooled Week 52 data from five Phase 3 trials (BLISS-52: NCT00424476; BLISS-76: NCT00410384; North East Asia: NCT01345253; BLISS-SC: NCT01484496; EMBRACE: NCT01632241) with similar study designs and eligibility criteria, where adults with active SLE were randomized to receive BEL or placebo (PBO) in addition to AM and GC, with or without IS. This summary grouped patients by baseline treatment into an IS cohort (PBO and IS, defined as pre-treatment) and a BEL cohort (BEL 10 mg/kg intravenous or 200 mg subcutaneous and no IS); all patients received AM and GC. Efficacy endpoints were: proportion of patients with SLE Responder Index-4 (SRI-4) response through 52 weeks, time to first SELENA-SLEDAI Flare Index (SFI) flare over 52 weeks, and cumulative and mean GC dose change between baseline and Week 52. AEs and SAEs, inclusive of Phase 2 (NCT00071487) data, and baseline demographic and outcome data were summarized descriptively for the BEL and IS cohorts.

Results: Baseline demographics and clinical characteristics were similar between BEL (N=552) and IS cohorts (N=358) (**-Table 1**). Patients had mean (SD) SDI of 0.3 (0.73) and 0.5 (1.03), and median (IQR) duration of SLE of 3.9 [1.2–7.4] and 4.2 [1.6–8.8] years in the BEL and IS cohorts.

More patients were SRI-4 responders in the BEL vs IS cohort at most time points (Week 52 difference: 22%) (**Figure 1A**). In the BEL cohort, numerically fewer patients experienced any SFI flare (BEL: 59% vs IS: 81%), and had longer median [IQR] time to first on-study flare (any severity) (BEL: 85.0 [44.0–168.0] vs IS: 69.0 [32.0–134.0] days). The BEL cohort had a numerically lower cumulative baseline GC dose (× 365 days) vs IS cohort (mean [SD]: 4729 [3268.2] vs 5340 [3613.8] mg), and cumulative dose through Week 52 (mean [SD]: 4536 [3092.1] vs 5679 [5361.2] mg); mean (SD) cumulative GC change from baseline: −192 (2510.8) mg (BEL cohort), and 339 (4725.5) mg (IS cohort) (**Figure 1B**).

Conclusion: In line with 2023 SLE EULAR recommendations for earlier biologic use in the treatment paradigm, this post hoc summary adds clinical data supporting the benefits of initiating BEL in patients not receiving IS, in those not well controlled with AM and GC.

Covariates assessed within the six months prior to the index date. Non-renal lupus defined by meeting SLE definition (≥2 SLE ICD codes ≥2 months and ≤2 years apart) and not meeting lupus nephritis definition (defined by ≥1 LN code (ICD-10 M32.14) or ≥2 nephritis codes (e.g., ICD-9 580-586, 791.0 or ICD-10 N00, N04-5, N17-18, R80.9) prior to the index date.
MTX, methotrexate. CKD, chronic kidney disease, defined by ≥1 ICD codes or GFR <60 on ≥2 occasions. ER, emergency room. SLE Severity Index is adapted from Garris algorithm for administrative data, based on ICD codes and not including medication dosing. Other oral immunosuppressant use includes leflunomide, sulfasalazine, cyclosporine, tacrolimus, abatacept, tocilizumab, TNF inhibitors, IL17 inhibitors, IL12/23 inhibitors, and JAK inhibitors

mortality with belimumab use versus oral immunosuppressants (azathioprine, methotrexate or mycophenolate) for the treatment of non-renal SLE.

Methods: We performed a target trial emulation study of adult patients with SLE (defined as ≥2 ICD codes ≥2 months and ≤2 years apart) but without lupus nephritis who initiated belimumab, azathioprine, methotrexate, or mycophenolate using

Table 2. Comparative Risk of All-Cause Mortality with Belimumab versus Oral Immunosuppressant use in Non-Renal Systemic Lupus Erythematosus

Treatment arms	Number of Events	Cumulative Incidence (%)	Adherence-Adjusted Hazard Ratio (95% CI)
Per-protocol analysis			
Belimumab vs Azathioprine			
Azathioprine	113	3.35	1.00 (ref)
Belimumab	17	1.58	0.45 (0.26-0.80)
Belimumab vs Methotrexate			
Methotrexate	81	2.14	1.00 (ref)
Belimumab	15	1.46	0.66 (0.36-1.21)
Belimumab vs Mycophenolate			
Mycophenolate	187	3.35	1.00 (ref)
Belimumab	18	1.58	0.46 (0.27-0.79)
Intention-to-treat analysis

observational data from a U.S. multi-center electronic health record database (TriNetX) between 2011-2021. We evaluated the comparative risk of all-cause mortality with belimumab versus each of three oral immunosuppressants (azathioprine, methotrexate, or mycophenolate) for the treatment of SLE. In each comparison, we excluded patients who had previously used belimumab or the comparator oral immunosuppressant. Patients were followed until the earliest of the event (death), 5-year follow-up, or the end of the study period. We estimated the cumulative incidence and hazard ratios (HRs) of all-cause mortality comparing belimumab to each oral immunosuppressant. Propensity score overlap weighting was used to balance baseline covariates (including age, sex, race/ethnicity, geographic region, year of initiation, use of concomitant SLE medications [other oral immunosuppressants, glucocorticoids, hydroxychloroquine, rituximab, cyclophosphamide], Charlson comorbidity index, SLE severity index, chronic kidney disease, healthcare utilization, and prior infection history). In a primary per-protocol analysis, we adjusted for adherence to treatment strategy using inverse probability of treatment weighting.

Results: We identified 21,481 patients with non-renal SLE who met eligibility criteria (Figure 1). In these three hypothetical target trials, we compared 1) initiators of belimumab (n=2841) and azathioprine (n=6343), 2) initiators of belimumab (n=2642) and methotrexate (n=8242), and 3) initiators of belimumab (n=2813) and mycophenolate (n=8407). After propensity score overlap weighting, all covariates were balanced in each comparison group, with mean age 45 years and 94% females (Table 1). In the per-protocol analysis, belimumab was associated with a lower risk of all-cause mortality compared to azathioprine (HR 0.45 [95% CI 0.26-0.8]) and mycophenolate (HR 0.46 [95% CI 0.27–0.79]) (Table 2). In the intention-to-treat analysis, belimumab was associated with a lower risk of all-cause mortality compared to all three oral immunosuppressants: belimumab vs. azathioprine (HR 0.40 [95% CI 0.25-0.63]), belimumab vs. methotrexate (HR 0.61 [95% CI 0.38-0.96]), and belimumab vs. mycophenolate (HR 0.47 [95% CI 0.31–0.73]).

Conclusion: Belimumab use was associated with reduced all-cause mortality compared with oral immunosuppressants in this large cohort of patients using rigorous propensity score overlap weighting to emulate a target trial. These findings suggest that targeted immunomodulatory therapy with BLyS inhibitors in SLE has favorable outcomes.

Abstract Number: 0805

Safety and Efficacy of Hydroxychloroquine According to Weight-based Dose: Results of a Global Systematic Review and Meta-analysis

Jacquelyn Nestor[1], Zahraa Qamhieh[2], Shivani Garg[3] and April Jorge[1], [1]Massachusetts General Hospital, Boston, MA, [2]University of Wisconsin, Madison, Department of Medicine, Madison, WI, [3]University of Madison, School of Medicine and Public Health, Madison, WI

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: Abstracts: Systemic Lupus Erythematosus – Treatment I (0801–0806)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Hydroxychloroquine (HCQ) is a foundational therapy in systemic lupus erythematosus (SLE) treatment, as it prolongs disease-free and damage-free survival. However, the optimal dose is debated due to dose-related risks for toxicity, and the efficacy of lower dosing (≤5 mg/kg/day) needs to be further elucidated. Therefore, we designed a systematic review and meta-analysis to assess the impact of HCQ dose on risks of HCQ-related toxicities and adverse SLE outcomes.

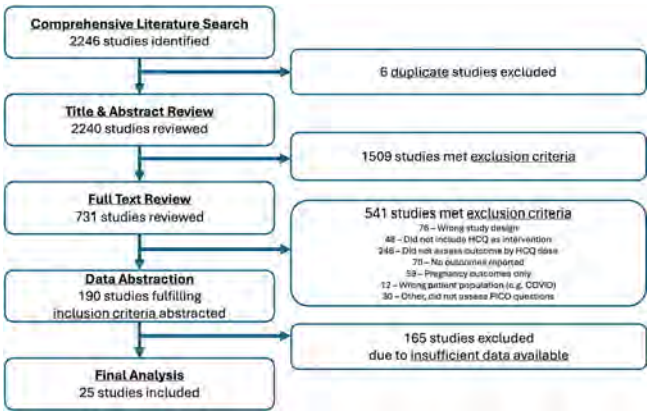

Figure 1. Literature Review and Included Studies

Methods: A comprehensive search was performed using MeSH headings and keywords (e.g., lupus, SLE, hydroxychloroquine, toxicity, flares, death or mortality, etc.) in Medline, Embase, CINAHL and Web of Science. We included observational and interventional studies associations between HCQ dose and: i) toxicity (cardiac or eye); ii) poor SLE outcomes defined as SLE flares, acute care utilization for active SLE, disease activity, death, cardiovascular disease, kidney failure, or thrombotic events in subjects with SLE. Risk of bias was assessed using standard tools for all studies. We examined pooled hazard ratios (HR) of HCQ retinopathy (primary outcome) and pooled odds ratios (OR) of toxicity when time-to-event data was not available (secondary outcome) in high vs. low HCQ dose groups (>5 vs. ≤5 mg/kg/day) using a random effects model.

Table 1. Included Studies Addressing the Association of Hydroxychloroquine Dose and Clinical Effectiveness, Safety

Author, Year (Ref)	Study Design	Study Population	HCQ Dose Cutoff	Outcomes Reported	Bias Assessment
Abdelbaky et al., 2021	Cross-sectional	N=18; Age 31.24±7.41 y; F=90%	N/A	HCQ retinopathy- assessed by FAF	NOS: Good
Ahn et al., 2017	Retrospective case series	N=99 SLE; Age= 42.4±11.6; F=91.9%	N/A	HCQ retinopathy- assessed by OCT or FAF with corresponding VF changes	NOS: Good
Akhlaghi et al., 2021	Cross-sectional	N=61 (40 SLE, 21 RA); Age 46.9±11.62; F=93.4%	N/A	HCQ retinopathy- assessed by mfERG	NOS: Good
Almeida-Brasil et al., 2022 (Nov)	Prospective cohort	N=1460; Age= 34.7 (SD 12.3); F=87%; White=51.7%; Black=17%; Asian=16%; Other=14.3%	5 mg/kg	HCQ retinopathy- assessed by retinal damage recorded on the SLICC Damage Index and attributed to HCQ per treating physician	NOS: Good
Almeida-Brasil et al., 2022 (Mar)	Prospective cohort	N=1460; Age= 34.7 (SD 12.3); F=89%; White=51.7%; Black=17%; Asian=16%	5 mg/kg	SLE flare- assessed by increase of ≥4 on SLEDAI-2K	NOS: Good
Balbi et al., 2022	Prospective cohort	N=60; Age 16.6±3.13; F=80%; Non-Caucasian=41.7%	N/A	SLE flare- assessed by increase of ≥3 in SLEDAI-2K and/or increase in steroid dose or more intensive immunosuppression	NOS: Good
Fasano et al., 2023	Prospective cohort	N=66; Age= 42.01±11.2; F=95%; Caucasian=100%	5 mg/kg	SLE flare- assessed by SLEDAI-2K	NOS: Good
Garg et al., 2024	Prospective cohort	N=181; Age=47±16; F=92%; Non-white or Hispanic=33%	5 mg/kg	Lupus-related acute care visits (ER visits/hospitalizations)	NOS: Good
Garg et al., 2023	Prospective cohort	N=158; Age=46±16; F=92%; White=68%; Black=16%; Asian=8%; Hispanic=9%	N/A	SLE flare- assessed by 3-point increase in SLEDAI with clinical symptoms requiring therapy change	NOS: Good
Hsu et al., 2017	Prospective cohort	N=8397; Age= 35.7 (16); F=88.2%	200 mg	Cardiovascular outcomes-ACS, Ischemic Stroke, PE, DVT, composite	NOS: Good
Jimenez et al., 2023	Retrospective cohort	N=254; Age=30.6y; F=90%; AA=45%, Hispanic=49%, White= 6%	5 mg/kg; 400mg	Cardiac toxicity assessed as arrhythmias, heart failure, or cardiac death	NOS: Good
Jin et al., 2021	Retrospective cohort	N=2446; Age=30.1y; F=93.8%	400 mg	Mortality	NOS: Good
Jorge et al., 2022	Case cross-over	N=342; Age= 43 (SD 14.7); F=88%	5 mg/kg	SLE flare-assessed by revised SELENA-SLEDAI flare index	NOS: Good
Jorge et al., 2024	Retrospective cohort	N=1604; Age=46.0 (SD 13.9); F=89.7%; White: 39%, Hispanic: 20%, Asian: 19%, Black: 16.0%	5 mg/kg	HCQ retinopathy- assessed on masked review of screening OCT exams by expert ophthalmologist and adjudicated by a second expert	NOS: Good
Kao et al., 2022	Retrospective observational	N=92; Age=42.9 (37.8-52.6)	N/A	HCQ retinopathy- assessed by ≥2 typical abnormal findings on OCT, VF, FAF, mfERG and confirmed by two ophthalmologists	NOS: Fair
Kisaoglu et al., 2024	Retrospective observational	N=124; Age=12.6±3.7; F=79.8%	5 mg/kg	SLE flare- assessed as SLEDAI ≥ 4	NOS: Good
Lenfant et al., 2020	Case-control study	N=23; Age= 52 (41-59); F= 96%	N/A	HCQ retinopathy- assessed by ≥2 typical abnormal findings on OCT, VF, FAF, mfERG	NOS: Good
Lo et al., 2021 (May)	Retrospective case control	N=193; Age= 50.4 (17.9) cases vs 49.1 (17.4) controls; F=81%	400 mg	Cardiac toxicity- assessed as arrhythmias	NOS: Good
Lo et al., 2021 (April)	Retrospective cohort	N= 579; Age= 55.1 (SD 13); F=80%	400 mg	Cardiac toxicity- assessed as arrhythmias	NOS: Good
Melles et al., 2023	Retrospective cohort	N=606; Age=47.5 (SD 14); F=90.1%; White=29.5%; Hispanic=19.8%; Asian=22.3%; Black=20.5%	5 mg/kg	HCQ retinopathy- assessed on masked review of screening OCT exams by an expert ophthalmologist and adjudicated by a second expert	NOS: Good
Nestor et al., 2024	Retrospective Case-crossover	N=122; Age= 36.5 (SD 14.3); F=91.8%; White=41.8%; Black=31.1%; Asian=9%	5 mg/kg; 400 mg	Hospitalizations for active SLE	NOS: Good
Shaharir et al., 2014	Case-control	N=150; Age=35.6±10.5; F=80%; Asian=100%	6 mg/kg	Damage progression per the SLICC Damage Index (SDI) ≥ 1	NOS: Good
Vazquez-Otero et al., 2020	Retrospective observational	N=60; Age=43.8 (SD 15.1); F=100%	5 mg/kg	Disease activity per SLEDAI; Damage accrual per SDI; ER visits and hospitalizations for SLE	NOS: Good
Wakiya et al., 2020	Retrospective observational	N=77; Age= 40.3±12.4 in usual dose group vs 46.1±9.3 in low HCQ dose group; F=72%	N/A	Disease activity per mean SLEDAI	NOS: Good
Xie et al., 2023	Prospective observational	N=489; Age= 44.18 (SD 15.39); F=86.3%; Asian=100%	200 vs 400 mg	Disease activity per mean SLEDAI	NOS: Good

FAF, fundus autofluorescence; OCT, optical coherence tomography; VF, visual fields; mfERG, multifocal electroretinography

Forest Plots for A) pooled HRs for HCQ retinopathy, B) pooled ORs for SLE flares/acute care utilization for active SLE

Additionally, we calculated the pooled odds of SLE flares/acute care utilization for active SLE by low vs. high HCQ dose groups. Heterogeneity was assessed using I^2.

Results: Among 2246 manually reviewed studies, 190 met initial inclusion. Of these, 25 studies compared HCQ-related toxicities or poor SLE outcome by weight-based HCQ dose and were included in the meta-analysis (Figure 1). Eight studies assessed the outcome of HCQ retinopathy in SLE patients, of which two assessed HRs by weight-based dose. Among eight studies assessing outcomes of SLE flares/acute care utilization, five had available data for inclusion in pooled HRs for the 5 mg/kg weight-based dosing threshold (Table 1). The pooled HR for HCQ retinopathy associated with >5 vs ≤5 mg/kg dosing was 3.83 (95% CI 1.82-8.08), Fig. 2). At the same time, the pooled HR of SLE flare/acute care utilization for active SLE associated with ≤5 vs >5 mg/kg dosing was 1.84 (95% CI 1.18-2.87). Other outcomes of interest were each assessed by fewer than two studies that compared the 5 mg/kg weight-based dosing threshold.

Conclusion: In this systematic review and meta-analysis of HCQ dose and SLE outcomes, we found that higher HCQ dosing >5 mg/kg is associated with over three times higher risk of HCQ retinopathy but nearly two times lower risk of SLE flare/acute care utilization for active SLE. These findings indicate the need for clinicians and patients to weigh the potential harms versus benefits when determining the optimal dose of HCQ in SLE treatment.

*Hazard ratio for outcomes among Anifrolumab users group compared to Belimumab users group subjects (after propensity score matching).
*95% CI, 95% confidence interval.
*propensity score matching include Age at index, Sex, Ethnicity, Race, BMI, Medical utilization, Socioeconomic, Lifestyle, and Comorbidities.
* If the patients count is 1–10 or less, the results indicate a count of 10.

Background/Purpose: Anifrolumab and belimumab are biologic agents approved for systemic lupus erythematosus (SLE), yet their comparative safety profiles, particularly regarding infection risks, remain inadequately characterized in real-world settings.

Methods: We conducted a retrospective cohort study using data from the TriNetX research network. Patients diagnosed with SLE between January 1, 2000, and June 30, 2024, with at least two diagnoses were included. We identified new users of anifrolumab or belimumab between August 1, 2021, and June 30, 2024, excluding patients with infection before the index date, patients hospitalized within 6 months before the index date, and patients who died before the index date. Propensity score matching was employed to control for confounding factors. Cox proportional hazards models were used to estimate

Table 3. Hazard ratio and 95% CIs for the risk of Second outcome

	Patients in cohort	Patients with outcome	Hazard ratio* (95% CI)
Mortality			
Anifrolumab user	481	10	1.081(0.417, 2.804)
Belimumab user	481	10	reference
Hospital Inpatient Services			
Anifrolumab user	481	74	1.273(0.900, 1.802)
Belimumab user	481	56	reference

*Hazard ratio for outcomes among Anifrolumab group compared to Belimumab group subjects (after propensity score matching).
95% CI, 95% confidence interval.
*propensity score matching include Age at index, Sex, Ethnicity, Race, BMI, Medical utilization, Socioeconomic, Lifestyle, Comorbidities and Medication.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

hazard ratios (HR) and 95% confidence intervals (CI), and Kaplan-Meier analysis was used to assess cumulative infection probabilities. The primary outcome was infection occurrence (including herpes zoster, influenza, pneumonia, tuberculosis, sepsis, urinary tract infection, and COVID-19), while secondary outcomes included mortality and hospital inpatient services utilization.

Results: After applying exclusion criteria and propensity score matching, the final analytic cohort included 481 patients in each treatment group. After matching, anifrolumab users showed a significantly higher risk of infection compared to belimumab users (HR 1.40, 95% CI: 1.05-1.88), with 3-year cumulative infection rates of 38.3% and 21.3%, respectively. Analysis of specific infections revealed significantly increased risks of herpes zoster (HR 3.944, 95% CI: 1.111-13.996) and COVID-19 (HR 1.663, 95% CI: 1.042-2.653) associated with anifrolumab use. Subgroup analysis showed significantly higher infection risk in White patients receiving anifrolumab (HR 1.64, 95% CI: 1.09-2.48). Time-dependent analysis suggested that certain infection risks, such as herpes zoster, may develop or intensify with longer treatment duration. No significant differences in mortality or hospital inpatient services utilization were observed between the treatment groups.

Conclusion: Anifrolumab use in SLE is associated with a higher risk of specific infections, particularly herpes zoster and COVID-19, compared to belimumab, especially with prolonged exposure. These findings underscore the need for vigilant infection monitoring, region-specific preventive strategies, and further research to optimize biologic therapy safety across diverse populations.

Session Title: Abstracts: Systemic Sclerosis & Related Disorders – Basic Science (0807–0812)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Synovitis is a common manifestation of systemic sclerosis (SSc), driving disability and predicting disease progression and mortality. Current immunosuppressive strategies, largely extrapolated from rheumatoid arthritis (RA), offer limited efficacy. A deeper understanding of the pathomechanisms underlying SSc synovitis is therefore needed to enable the development of more effective, targeted therapies.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Overview of main results.

Methods: Synovial tissue from 11 SSc patients (91% limited cutaneous SSc, excluding overlap syndromes), 7 RA patients (all anti-CCP and RF positive), and 6 non-inflammatory controls (NIC) underwent histological classification. For single-cell RNA sequencing (scRNA-seq), synovium from 6 SSc, 6 RA, and 6 NIC samples was dissociated, yielding 78,128 cells (SSc: 21,248; RA: 32,062; NIC: 24,818) across nine cell types. Data were analysed using Seurat (v4.3) and integrated using Harmony and STACAS for subpopulation annotation. Bioinformatic analyses included differential expression analysis (MAST), pathway over-representation analysis (ORA), gene module scoring (MSigDB hallmark), and transcription factor activity inference (decoupleR). *In vitro* qPCR validation was performed on synovial fibroblasts (SF) stimulated with TNF, interferon (IFN)-α, IFN-β, and IFN-γ.

Results: Histology revealed a pauci-immune pathotype in 10/11 SSc synovial biopsies, with significantly lower Krenn scores (p=0.01) and less acute inflammation compared to RA (p< 0.01).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Graphical abstract of proposed mechanism of SSc synovitis and RA compared to non-inflammatory controls (NIC). Created with BioRender.

Given the stromal predominance in SSc, we focused our analysis on SF (n= 15'502, Fig. 1A) and observed a lower expression of invasion-associated genes in PRG4$^+$ lining SF (Fig. 1B), which may explain the lower frequency of radiographic erosions in SSc patients compared to RA (36% vs. 50%).

Across all SF, we identified a prominent IFN-α and IFN-γ signature in SSc (both FDR< 0.05, ORA) relative to RA, where TNF response was the dominant signal (FDR< 0.001, ORA). IFN-associated genes (Fig. 1C), JAK/STAT signalling, and IFN-related transcription factors (Fig. 1D) were specifically enriched in FOSB$^+$ SF in SSc. Moreover, we observed a complex expression pattern of alternative complement genes and regulators in SSc, particularly in MFAP5$^+$/CXCL14$^+$ SF (Fig. 1E), which was recapitulated following stimulation of SFs with IFN *in vitro* (Fig. 1F).

Genes specifically overexpressed in SSc SF, including canonical IFN-stimulated genes and complement-related targets, overlapped largely with transcripts previously shown to be downregulated in the skin of SSc patients after Anifrolumab treatment (Fig. 1G), indicating therapeutic potential.

Notably, a canonical IFN signature (Fig. 1C), marked by genes such as IRF1, MX1, IFI27, STAT1, and STAT2, was also evident across other synovial cell types in SSc compared to RA and NIC, including endothelial cells and infiltrating MERTK$^-$/SPP1$^+$ macrophages and S100A12$^+$ monocytes.

Conclusion: Our findings provide the first in-depth characterisation of SSc synovitis, revealing a pauci-immune, less-invasive phenotype marked by a dominant IFN signature across SF, macrophages, monocytes and endothelial cells (Fig. 2). This tissue-wide IFN response supports IFN blockade as a promising therapeutic strategy for SSc synovitis.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: Abstracts: Systemic Sclerosis & Related Disorders – Basic Science (0807–0812)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune, fibroinflammatory disease of skin and visceral organs. Current SSc therapies have limited efficacy for progressive fibrosis. Our prior work showed that LIF receptor (LIFR, a member of the IL-6 receptor superfamily) and its ligand LIF were expressed by synovial fibroblasts in rheumatoid arthritis and amplified pathogenic inflammation. We hypothesized that the fibroblast LIF/LIFR axis also drives fibrotic pathobiology in SSc.

Methods: We applied three 10x Genomics platforms (single-cell, Visium CytAssist spatial, and Xenium spatial transcriptomics (curated genes)) and immunofluorescence staining (IF) to explanted lung and skin biopsies from patients with SSc interstitial lung disease(ILD). We examined a published, plasma proteomic dataset of SSc-ILD patients with longitudinal follow-up. Primary lung fibroblast cell lines from control and SSc-ILD lung tissue were used for in vitro studies. Our experimental model of murine SSc (lung, skin, esophageal fibrosis) used intraperitoneal bleomycin (2x/week for 4 weeks). For testing LIFR in vivo, we compared fibroblast-specific *Lifr*-deficient mice (*Pdgfra*-CreERT2$^{+/-}$ *Lifr* $^{flox/flox}$ and *Col1a2*-CreERT$^{+/-}$ *Lifr* $^{flox/flox}$ mice) to *Lifr*$^{+/+}$ sibling controls. To therapeutically silence *Lifr*, we administered lipid nanoparticles (LNP) with si*Lifr* payload i.v. from day 7-28 after bleomycin initiation and assessed tissue at day 33.

Results: Xenium spatial analysis of SSc-ILD lungs (N=4) found *LIFR*$^{+}$ *and LIF*$^{+}$ fibroblasts enriched in inflammatory, interstitial spatial niches in regions of lung injury and fibrosis. The *LIF*$^{+}$*LIFR*$^{+}$ spatial niches were colocalized with myofibroblast-enriched spatial niches. Using IF, we validated the enrichment of LIF^{+}LIFR^{+} fibroblasts in "leading edge" regions of fibrosis

Spatial transcriptomic analysis, re-analysis of multi-omics datasets, and validation studies using immunofluorescence staining, in vitro assays, and animal model revealed fibroblast LIFR as an amplifier of organ fibrosis and inflammation in SSc.

in both SSc-ILD lung (N=12) and SSc skin (N=6) tissue. Plasma LIFR level was higher in SSc-ILD patients with progressive fibrosis compared to stable disease (N=72).

We moved to in vitro and in vivo studies to understand the function of LIFR. SSc-ILD lung fibroblasts had increased constitutive expression of *LIF* in vitro; stimulation with TGFβ further increased LIF expression in SSc, but not in control fibroblasts. Silencing *LIFR* with siRNA suppressed collagen expression in SSc-ILD lung fibroblasts following in vitro profibrotic stimuli (IL-4, IL-13, or TGFβ). LIFR also drove increased expression of IL-6 and IL-8 in SSc-ILD lung fibroblasts following stimulation with IL-1β and TNFα. In the murine model of SSc, mice with fibroblast-specific *Lifr* deletion had reduced lung,skin, and esophageal fibrosis compared to $Lifr^{+/+}$ control. Therapeutic intervention with LNP-si*Lifr* reduced lung and skin fibrosis in a murine model of SSc.

Conclusion: A LIF/LIFR autocrine circuit drives both inflammatory and fibrogenic programs in SSc skin and lung fibroblasts. Targeting LIFR in a murine model of SSc reduced organ fibrosis. LIFR is a candidate therapeutic target for SSc.

SESSION INFORMATION

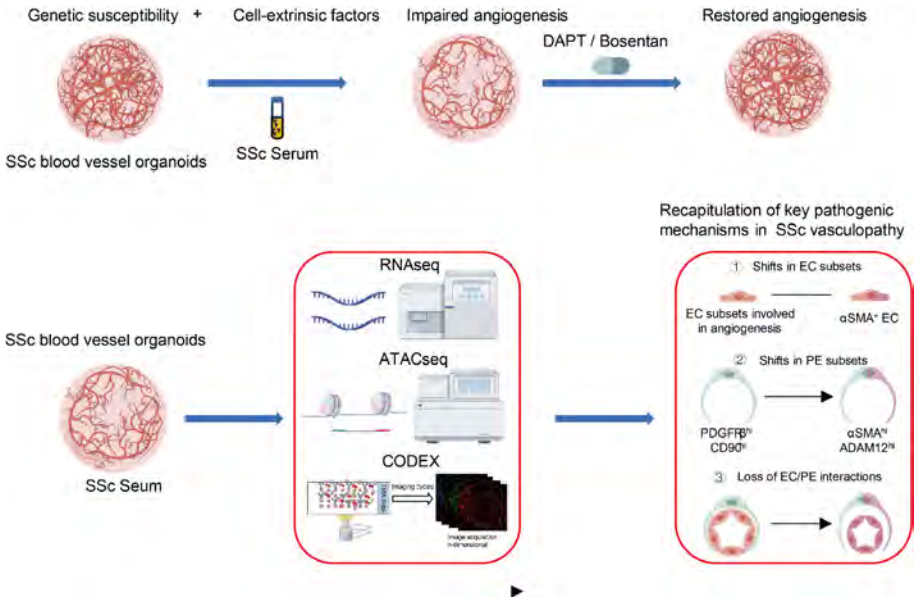
Session Date: Sunday, October 26, 2025

Session Title: Abstracts: Systemic Sclerosis & Related Disorders – Basic Science (0807–0812)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: While several pathogenic processes involved in vasculopathy in systemic sclerosis (SSc) have been described[1-3], the mechanisms that underlie the SSc microvasculopathy remain incompletely understood. Human models of sufficient complexity to recapitulate the key disease-relevant cell types and their interactions are currently lacking. Thus, the preclinical testing of novel therapeutic approaches for SSc microvasculopathy remains challenging.



SSc blood vessel organoids reveal mechanisms of vasculopathy and responses to targeted therapy

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Our study aimed to evaluate whether blood vessel organoids (BVOs) could be employed as a novel, multicellular tissue-like three-dimensional model for studying SSc vasculopathy in vitro.

Methods: BVOs were differentiated from iPSCs of SSc patients (SSc-BVOs) and healthy individuals (healthy-BVOs) and treated with serum from healthy donors or SSc patients with active digital ulcers (SSc_aDU). Angiogenesis parameters, including vessel density, vessel length, and number of junctions, were quantified using AngioTool. Transcriptomic changes and chromatin accessibility were assessed by RNA-seq and ATAC-seq, respectively. Co-detection by indexing (CODEX), a spatial proteomics technique, was employed for cell phenotyping, evaluation of functional markers and of cell-cell interactions. The endothelin receptor antagonist bosentan (BST) and the γ-secretase inhibitor DAPT were tested for their effects in preventing angiogenesis defects in BVOs.

Results: SSc-BVOs, but not healthy-BVOs demonstrated angiogenic defects, with decreased vessel density, vessel length and number of junctions, when exposed to SSc_aDU serum.

Exposure of SSc-BVOs to SSc_aDU serum triggers concerted changes at epigenetic, mRNA and protein levels to induce upregulation of endothelial-to-mesenchymal transition (EndMT)-related pathways and proteins, such as αSMA, SNAIL1, TWIST1 and collagen synthesis, and downregulation of markers and pathways related to an endothelial cells (ECs) phenotype, such as CD31, VWF or tight junctions.

CODEX analysis demonstrated that BVOs recapitulate ECs and pericyte populations in SSc, along with their disease-specific changes in frequencies. Two αSMA^+ ECs subsets were upregulated in SSc BVOs exposed to SSc_aDU serum, as previously shown in SSc[4]. The $Tie2^+$ ECs lost interactions with pericytes, whereas the two αSMA^+ ECs were spatially avoiding pericytes in SSc-BVOs exposed to SSc_aDU serum, recapitulating the impaired ECs-pericytes interactions previously described in SSc[5].

Treatment with BST and DAPT prevented the angiogenesis defects induced by SSc_aDU serum in SSc-BVOs.

Conclusion: This study demonstrates that SSc-BVOs recapitulate key features of SSc vasculopathy, including impaired angiogenesis and enhanced EndMT, increases in pathologic ECs populations, as well as loss of ECs -pericytes interactions when exposed to SSc_aDU serum. This study further validates SSc-BVOs as a human model system for drug testing and employs this system to demostrate that γ-secretase inhibition is a potential therapeutic approach in SSc microvasculopathy.

Session Title: Abstracts: Systemic Sclerosis & Related Disorders – Basic Science (0807–0812)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

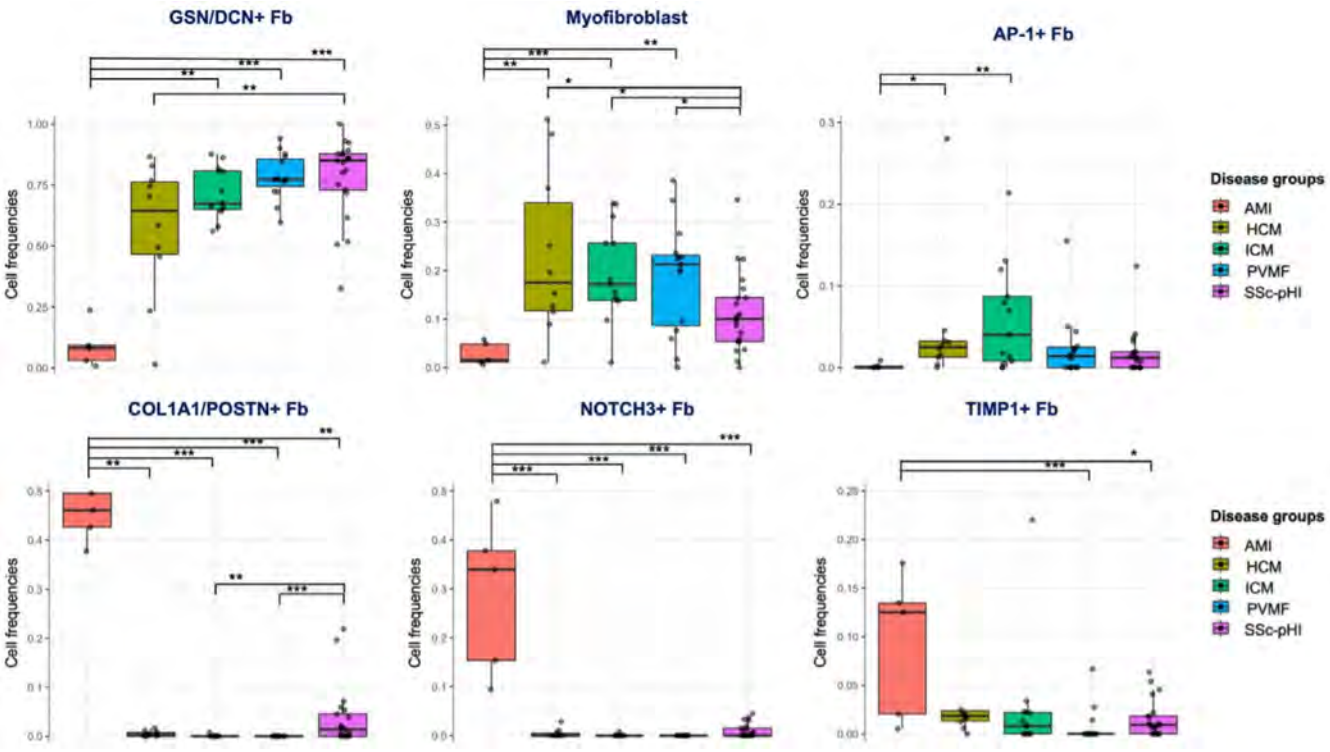

Figure 1. Distribution of fibroblast populations across diseases. Statistical significance was assessed using the Kruskal-Wallis test followed by Dunn's post hoc test with Holm adjustment. * – p-value <0.05, ** – p-value <0.01, *** – p-value <0.001.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

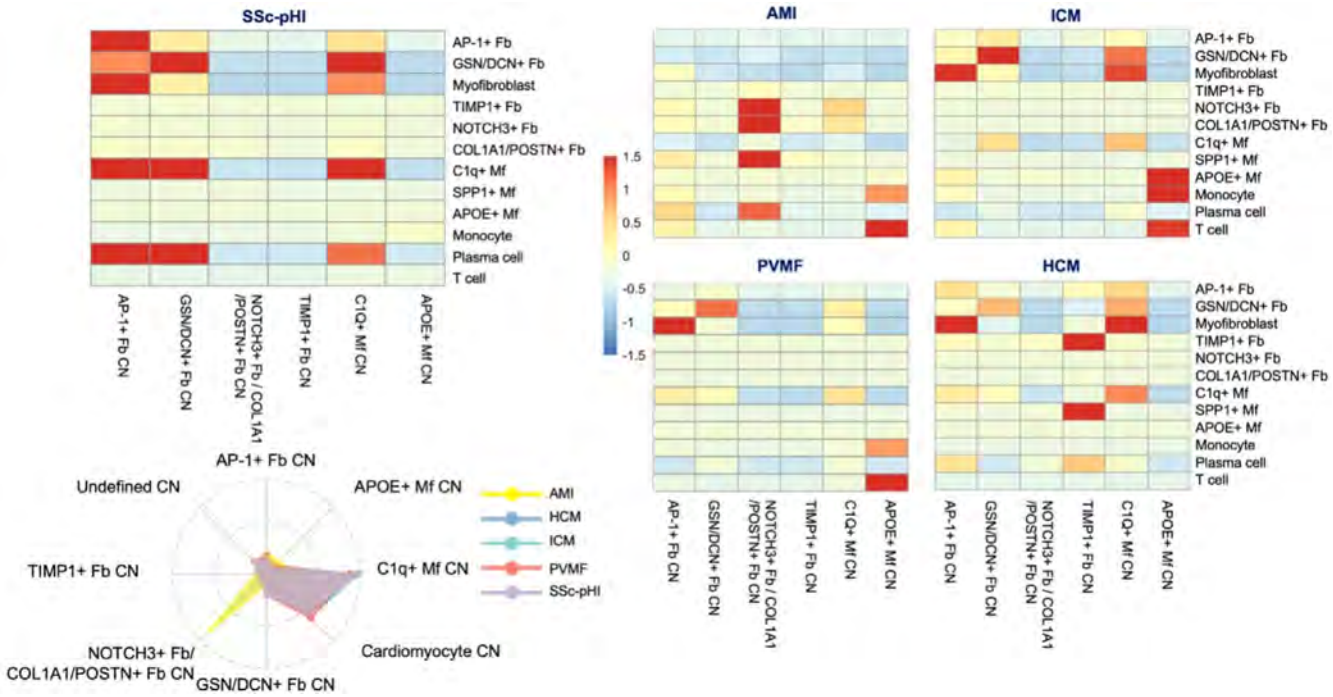

Figure 2. Cellular niche composition and frequencies across diseases.

Background/Purpose: Systemic sclerosis (SSc)-associated primary heart involvement (SSc-pHI) is one of the leading causes of mortality in SSc, yet its underlying cellular and molecular pathomechanisms are poorly understood (1, 2). We aimed to characterize the fibroblast (Fb) subpopulations, their niches and associated cellular networks in SSc-pHI and compare them to those present in other myocardial diseases which associate chronic (postviral myocardial fibrosis (PVMF), hypertrophic cardiomyopathy (HCM), and ischemic cardiomyopathy (ICM)), or acute (acute myocardial infarction (AMI)) fibrotic remodeling using cyclic-in-situ-hybridization.

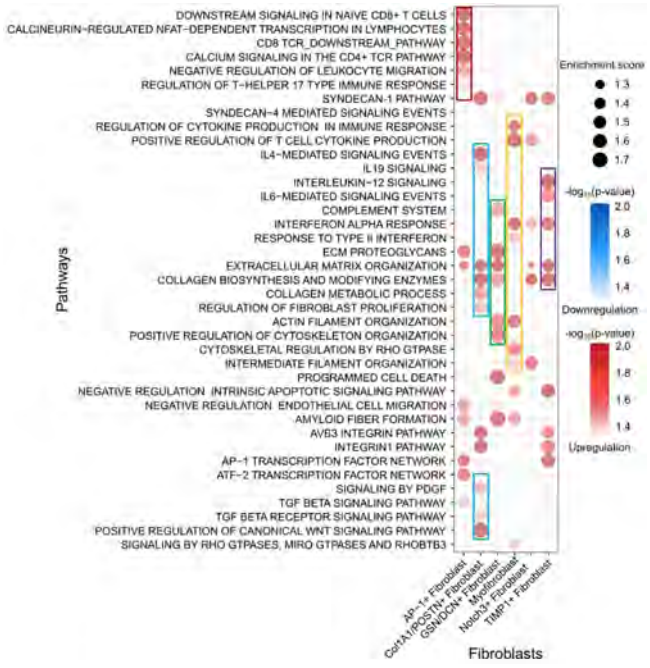

Figure 3. Functional analysis of fibroblast populations.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We employed the CosMx SMI platform to analyze FFPE myocardial biopsies from 15 SSc-pHI, 10 PVMF, 5 HCM, 5 ICM and 3 AMI patients, examining two 1.8mm^2 regions per sample. Gene expression profiling used the Human Universal Cell Characterization RNA Core Panel (950 genes), supplemented with 19 Fb subset markers (3). Data analysis was performed as described previously (4).

Results: We identified 11672 Fb. Spatially informed clustering revealed six Fb populations: GSN/DCN$^+$, AP1$^+$, TIMP1$^+$, COL1A1/POSTN$^+$, NOTCH3$^+$, and myofibroblasts. GSN/DCN$^+$ Fb and myofibroblasts were significantly enriched in SSc-pHI and other forms of chronic compared to acute fibrotic remodeling, while TIMP1$^+$, COL1A1/POSTN$^+$, and NOTCH3$^+$ Fb were significantly upregulated in acute compared to chronic conditions (Figure 1). GSN/DCN$^+$ Fb and AP1$^+$ Fb CNs were enriched and colocalized in the perivascular and the subendocardial areas in chronic conditions, while the NOTCH3$^+$ Fb/COL1A1/POSTN$^+$ Fb CN was enriched in the periinfarct zone in AMI. Furthermore, we observed significant disease-specific changes in the composition of the Fb niches (Figure 2). Functional analyses revealed distinct functions of the Fb populations while spatial interaction analyses showed profound differences in their signaling network in SSc-pHI compared to both other forms of chronic fibrotic remodeling and AMI (Figure 3).

Conclusion: We demonstrate significant alterations in the cellular composition of fibroblasts in SSc-pHI, with altered cellular interactions and signaling in their local niches, compared with other myocardial diseases with acute or chronic fibrotic remodeling. Furthermore, we identified functionally distinct fibroblast populations and uncovered subsets with disease-specific topologies. Our findings provide new insights into the pathophysiology of fibrotic myocardial remodeling and offer potential therapeutic targets.

Methods: Single-cell counts and metadata were downloaded from the GEO repositories for each dataset (**Table 1**); each was then processed and normalized independently using Seurat. Cell typing was performed, hierarchically and then sub-clustered for detailed analysis (differential expression, CAMML, and SingleR). Gene set enrichment was performed on each dataset and cell subpopulation (VAM). Differential expression and gene set enrichment comparisons were performed using the Wilcoxon Rank Sum test. A cohort of these datasets were processed using uniform genome alignment and counts generation (CellRanger 9.0.0, GRCh38) to generate a novel integrated dataset for disease-based comparisons at a single-cell level.

Results: We standardized and reprocessed all publicly available single-cell datasets analyzing dcSSc skin biopsies. These data were optimized for efficient loading into a user-friendly web interface for gene expression and pathway querying (**Fig. 1a-c**). From individual objects, we successfully recapitulated the findings presented in the original primary research articles, such as the enrichment of SFRP4 in specific fibroblast subpopulations (Wilcoxon Rank Sum Test, p.adjust = 3.9e-151) (**Fig 1d**). This tool also enables gene set enrichment tests in specific cell subtypes that were not previously presented in the original manuscripts, such as the enrichment of the complement system in SSc macrophages (Wilcoxon Rank Sum Test, p.-adjust 1.95e-203) (**Fig. 1e-f**). Finally, we generated a fully integrated single-cell dataset across multiple studies as a novel source for comparing SSc skin samples.

Conclusion: The SSc Skin Single Cell Atlas is a user-friendly web application for rapid and detailed analysis of publicly available datasets. This tool enables users to easily ask questions regarding gene and gene set differential expression without the need to download, process, and analyze the data locally. Furthermore, given the heterogeneous nature of SSc, accessing a large cohort of patients for single-cell comparison is paramount to better understand cellular dynamics that drive SSc fibrosis. This novel study integrates publicly available datasets from multiple research reports to provide a more comprehensive understanding of SSc skin fibrosis.

Session Title: Abstracts: Systemic Sclerosis & Related Disorders – Basic Science (0807–0812)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Systemic sclerosis (SSc) is a progressive, chronic multi-system disorder of unknown etiology that is characterized by immune dysfunction, fibrosis, and loss of dermal white adipose tissue (DWAT), which is an early event in SSc that precedes the onset of skin fibrosis. Despite advances in disease management, the overall prognosis for SSc

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. remains significantly worse than for other rheumatic diseases. While cooperative interactions between macrophages (MØs) and fibroblasts have been implicated in disease pathogenesis, no therapies that specifically target pathological MØs are in current clinical use for SSc.

Methods: Because our prior studies demonstrate a critical role for CD206^{high} MØs in SSc pathology, we developed a novel therapeutic approach to eliminate these cells using chimeric antigen receptor (CAR) T cells. CAR T cell efficacy was tested in the bleomycin (BLM) mouse model of SSc. BLM was delivered via osmotic pump, and a single dose of anti-CD206 or control CAR T cells was administered systemically via tail vein injection 7 days post-initiation of BLM to assess effects on established dermal pathology. Skin tissues were fixed and paraffin-embedded for single cell RNA-seq (scRNA-seq) and spatial transcriptomic analyses, and for quantification of adipose and dermal thickness by H&E. An *in vitro* co-culture model system was developed to assess the mechanisms by which CD206^{high} MØs mediate SSc pathology, and antibody blockade studies were performed to identify the MØ-derived soluble mediators that contribute to skin disease pathogenesis.

Results: We now show that CAR T cell-mediated elimination of CD206^{high} MØs to BLM mice resulted in restoration of DWAT to levels observed in mice not treated with BLM. Notably, administration of control CAR T cells failed to rescue DWAT loss. scRNA-seq and spatial transcriptomics analyses demonstrated anti-CD206 CAR T treatment increases mature adipocyte populations and alters representation of extracellular matrix (ECM)-secreting fibroblast and inflammatory myeloid subsets. In vitro modeling demonstrated that CD206^{high} MØs redirect lineage commitment of adipocyte stem cells (ADSCs) from adipocytes toward fibroblasts in a mechanism dependent, at least in part, on IL-6 receptor engagement.

Conclusion: Our new findings demonstrate that anti-CD206 CAR T cell therapy significantly attenuates dermal pathology in SSc through restoration of DWAT, implicating a novel function for MØs in the regulation of early fibrotic disease. *In vitro* mechanistic studies are supportive of a model in which CD206^{high} macrophages provide signals mediated by IL-6 that alter ADSC commitment from adipogenic to fibrogenic. Activated fibroblasts then secrete excessive extracellular matrix (ECM), culminating in fibrotic disease. Collectively, our results suggest MØ-targeted therapies may be effective in ameliorating SSc.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: Abstracts: Pain in Rheumatic Disease Including Fibromyalgia (0813–0818)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Tirzepatide is a dual GIP/GLP-1 receptor co-agonist approved for weight loss in patients with obesity or body mass index (BMI) > 27 kg/m^2 with comorbidities. GLP-1-based therapies may ease osteoarthritis symptoms indirectly via weight loss and directly through anti-inflammatory effects [1-3]. The STEP 9 trial demonstrated improvement in knee pain and function as well as reduced NSAID use in patients with obesity and knee osteoarthritis treated with semaglutide [4]. Tirzepatide differs from semaglutide in its dual agonism and greater weight loss [5]. No studies have examined musculoskeletal pain or analgesic use with tirzepatide. This study evaluated whether patients treated with tirzepatide had reduced joint pain and analgesic use than those receiving phentermine, the most prescribed anti-obesity medication in the U.S.

Methods: We conducted a cohort study using the TriNetX Research network, a large network of U.S. electronic health records and claims data. ICD-10 codes identified non-diabetic patients with BMI > 27 kg/m^2. Using an intention-to-treat approach, we analyzed the overall rate of musculoskeletal pain encounters and risky analgesic use, as well as cardiovascular endpoints following initiation of tirzepatide or phentermine, excluding patients with prior history of the outcomes of interest. Outcomes were defined as > 1 encounter with applicable ICD-10 code occurring one day or more after treatment initiation. Nausea served as a positive control outcome. Propensity score matching adjusted for > 400 factors including demographics, comorbidities, medications, and baseline BMI; key covariates are included in Table 1. Kaplan-Meier and Cox models estimated the risk of the outcomes of interest.

Table 1. Baseline Characteristics 0f Patients Receiving Tirzepatide versus Phentermine, after 1:1 Propensity-Score Matching

	Tirzepatide (n = 27,930)	Phentermine (n = 27,930)	Std diff.*
Age at index, mean (SD)	45.9 (12.9)	45.6 (13.1)	0.024
Male	16.7%	16.1%	0.016
Female	73.7%	74.3%	0.012
Unknown gender	9.6%	9.6%	0.001
Comorbidities			
Hypertension	40.0%	38.7%	0.026
Chronic kidney disease	2.8%	2.5%	0.007
Ischemic heart disease	5.4%	5.0%	0.021
Heart failure	2.0%	1.8%	0.015
Liver disease	11.9%	11.5%	0.013
Cerebrovascular disease	3.0%	2.8%	0.011
Nicotine dependence	13.1%	13.2%	0.002
Alcohol-related disorders	3.0%	2.8%	0.010
Osteoarthritis	24.8%	24.2%	0.016
Knee osteoarthritis	12.7%	12.6%	0.004
Knee pain	25.0%	24.9%	0.002
Low back pain	27.2%	26.9%	0.006
Medications			
Beta blockers	26.9%	26.2%	0.014
ACE inhibitors	14.3%	13.8%	0.014
NSAIDs	62.1%	62.1%	0.001
Opioid analgesics	58.4%	58.3%	0.003
Measures			
BMI, mean (SD)	37.9 (6.5)	37.8 (6.5)	0.026
A1c, mean (SD)	5.6 (1.2)	5.6 (1.3)	0.004

* Std diff. (standardized mean difference) <0.1 indicates negligible difference between groups. Baseline characteristics were defined as occurring any time up to one day prior to the index event.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 2. Outcomes Among Patients Receiving Tirzepatide versus Phentermine

Pain/analgesic outcomes	Unmatched, HR (95% CI)	Matched, HR (95% CI)
Joint pain	1.00 (0.95, 1.05)	0.91 (0.84, 0.99)
Low back pain	0.84 (0.79, 0.89)	0.89 (0.80, 0.98)
Hip pain	1.08 (1.00, 1.16)	0.88 (0.78, 0.999)
Knee pain	0.93 (0.88, 0.995)	0.84 (0.76, 0.93)
NSAID script	0.84 (0.81, 0.89)	0.88 (0.81, 0.95)
Opioid analgesics	0.82 (0.78, 0.86)	0.86 (0.79, 0.93)
Other outcomes		
Mortality	0.74 (0.54, 1.02)	0.48 (0.28, 0.80)
Major adverse cardiac events	1.29 (1.11, 1.51)	0.77 (0.61, 0.99)
Nausea	1.33 (1.25, 1.41)	1.22 (1.10, 1.35)
Achieved normal BMI	3.24 (3.01, 3.50)	3.02 (2.61, 3.49)

Note: Phentermine serves as the reference group. Abbreviations: HR, hazard ratio; CI, confidence interval; NSAID, nonsteroidal anti-inflammatory drug

Results: A total of 62,722 patients started on tirzepatide and 119,020 patients started on phentermine were included. After 1:1 matching, 27,930 patients per group had balanced baseline characteristics (**Table 1**). Mean follow-up was 276 days among patients on tirzepatide and 318 days among patients on phentermine. Tirzepatide users were more likely to achieve normal BMI (HR 3.02; 95% CI: 2.61, 3.49) with lower risk of joint pain (HR 0.91; 95% CI: 0.84, 0.99), especially knee pain (HR 0.84; 95% CI: 0.76, 0.93), and lower risk of NSAID (HR 0.88; 95% CI: 0.81, 0.95) and opioid prescriptions (HR 0.86; 95% CI: 0.79, 0.93) (**Table 2**). Risk of nausea was increased among tirzepatide users (HR 1.22; 95% CI: 1.10, 1.35), while risks of mortality and overall major adverse cardiac events (acute myocardial infarction, cerebral infarction, and/or mortality) were reduced (respectively, HR 0.48 with 95% CI of 0.28, 0.80; and HR 0.77 with 95% CI of 0.61, 0.99).

Conclusion: This large population-based study of non-diabetic patients with overweight or obesity demonstrates improvement in musculoskeletal pain requiring clinical care, reduced risky analgesic use, and better cardiovascular outcomes, among those receiving tirzepatide compared to phentermine. These findings support tirzepatide's role in reducing musculoskeletal pain and the need for NSAID and opioid medications in this population.

Session Title: Abstracts: Pain in Rheumatic Disease Including Fibromyalgia (0813–0818)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Emerging data indicate an uncoupling between pain and inflammation during the RA disease course, and comorbid fibromyalgia – thought to stem from central pain sensitization – is displayed in up to 25% of patients. It has been hypothesized that sensitization could be induced by a period of insufficiently treated inflammation, although this remains to be explored. The current study thus aimed to 1) investigate the dynamics of persistent pain with and without inflammatory control after RA onset; and 2) examine if cumulative inflammation during the first 6 months is linked to subsequent non-inflammatory pain.

Methods: NORD-STAR is an investigator-initiated, open-label trial of early (<24 months symptom duration) RA patients randomized to methotrexate combined with (a) other csDMARDs/corticosteroids or steroids alone, (b) certolizumab pegol, (c) abatacept, or (d) tocilizumab. Here, the latter group was omitted to allow for CRP analysis, and patients were analyzed irrespective of randomized therapy. Assessment was performed at 0, 4, 8, 12, 16, 24, 32, 40 and 48 weeks (w) including *unacceptable pain* (>40 mm [0-100] on a Visual Analogue Scale [VAS]), and *refractory pain* (unacceptable pain despite inflammation control: VAS pain >40 mm + CRP< 10 mg/L + swollen joint count [SJC; of 66] ≤1)[1]. Differences in pain outcomes between EULAR response groups were analyzed by Chi-2/Fisher's exact test. Associations between cumulative inflammatory load (area-under-the-curve [AUC] from 0-24w for CRP/SJC) and unacceptable/refractory pain at 48w, as well as 48w *fibromyalgic RA* (by the published definition tender joint count [TJC]-SJC ≥7 [of 68/66][2]), were respectively estimated by logistic regression, adjusted for age, sex, ACPA positivity and BMI.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

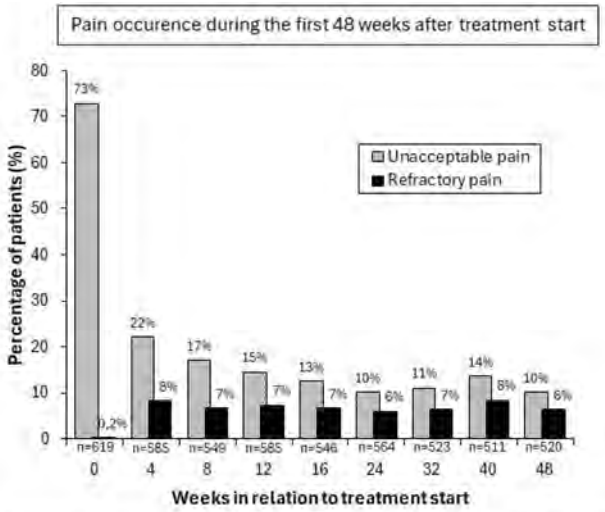

Figure 1. Occurence of unacceptable and refractory pain during the first 48 weeks after treatment start in patients with early RA. Numbers below bars indicate number of patients with complete data for all pain outcomes at the respective time-points. Unacceptable pain: VAS pain>40 mm (0–100); refractory pain: VAS pain>40 + CRP <10 + SJC ≤1 (of 66), SJC, swollen joint count (of 66); TJC, tender joint count (of 68); VAS, visual analogue scale.

Results: Included RA patients (n=624) were 69% women, 82% ACPA positive and with mean age/symptom duration of 55/0.6 years. At baseline, 73% reported unacceptable pain, declining to 10% after 48w, whereas the fraction with refractory pain was 0% (baseline) and 6% (48w). Refractory pain constituted 62% of all remaining unacceptable pain at 48w (Figure 1). Further, unacceptable pain at 12w was strongly linked to EULAR 12w response (7% in good responders versus 67% in non-responders; p< 0.001), while for refractory pain the relationship was weaker (6% versus 17%, p=0.074), with refractory pain accounting for 88% of remaining unacceptable pain in good responders (Figure 2). AUC for SJC (0-24w) was positively

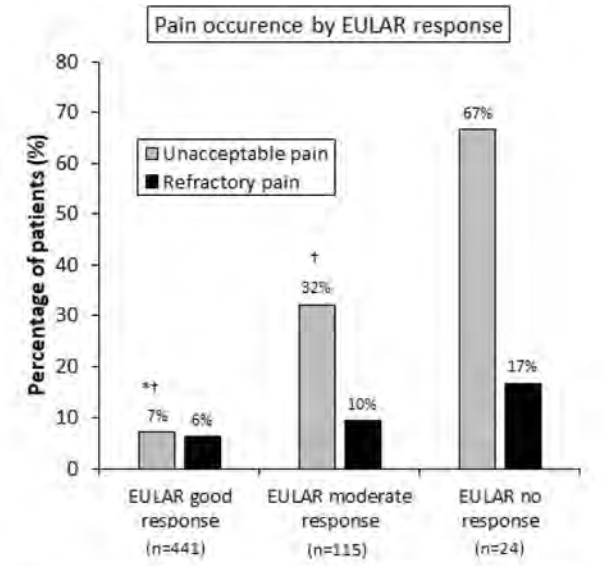

Figure 2. Pain occurence at 12 weeks in relation to EULAR 12-week response in patients with complete data for all pain outcomes both at baseline and at the 12-week follow-up. Unacceptable pain: VAS pain >40 mm (0–100); refractory pain: VAS pain >40 + CRP <10 + SJC ≤1 (of 66). Group comparisons by chi-square test and Fisher's exact test, as appropriate. *p<0.05 versus EULAR moderate response. † p<0.05 versus EULAR no response. SJC, swollen joint count (of 66); VAS, visual analogue

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1. Associations between cumulative inflammatory load from baseline to week 24 and pain outcomes at week 48 in early RA patients from the NORD-STAR trial.

	Unacceptable pain		Refractory pain		Fibromyalgic RA	
	OR	P value	OR	P value	OR	P value
AUC for SJC (per AUC-unit increase)						
Univariate	1.007	0.009	1.006	0.106	1.006	0.033
*Adjusted**	1.008	0.007	1.006	0.083	1.007	0.018
AUC for CRP (per AUC-unit increase)						
Univariate	1.000	0.557	1.000	0.820	0.99	0.548
*Adjusted**	1.000	0.570	1.000	0.740	0.99	0.496

Unacceptable pain=VAS pain>40 mm (0-100). Refractory pain=VAS pain>40 mm + CRP<10 mg/L + SJC <=1 (of 66). Fibromyalgic RA=TJC-SJC >=7. AUC denotes the period from baseline to week 24 with AUC units computed for (a) SJC (y; 0-66) multiplied by number of weeks (x; 0-24) with a maximum value of 66*24=1584; and (b) CRP (y; CRP-value) multiplied by weeks (x; 0-24); in both cases adopting the trapezoid method. Results from logistic regression. *Adjustment for sex, age, ACPA status and BMI. AUC, area-under-the-curve; OR, odds ratio; SJC, swollen joint count (of 66); TJC, tender joint count (of 68); VAS, visual analogue scale.

associated with 48w unacceptable pain (p=0.007) and fibromyalgic RA (p=0.018) in adjusted analysis, with a trend also for refractory pain (p=0.083). AUC for CRP (0-24w) was not associated with the pain outcomes (Table 1).

Conclusion: A relevant proportion of early, aggressively treated RA patients have persistent unacceptable pain after 1 year, with pain indicative of a non-inflammatory mechanism accounting for over 60% of this pain load. Our findings also suggest that a prolonged inflammatory period could entail more future non-inflammatory pain, underscoring the importance of rapid and sustained inflammation resolution.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: Abstracts: Pain in Rheumatic Disease Including Fibromyalgia (0813–0818)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Despite effective control of inflammation in rheumatoid arthritis (RA), persistent and severe pain remains a clinical challenge. Dysregulated pain processing in the central nervous system ("central sensitization") may underlie this disconnect. The PainDETECT questionnaire, originally developed to identify neuropathic pain, may capture features of central sensitization. We hypothesised that neuropathic-like pain at diagnosis predicts worse pain prognosis in early RA, independent of inflammation. We also explored associated brain activation patterns using functional neuroimaging.

Methods: In this prospective cohort study, adults with newly diagnosed RA in Oxfordshire completed the PainDETECT questionnaire at baseline. The primary outcome, bodily pain, was measured using the SF-36 Bodily Pain Subscale (BPS) at baseline, 3, 6, and 12 months. Inflammatory markers (CRP) were monitored longitudinally. Linear mixed-effects models examined associations between PainDETECT and BPS and CRP over time. A subset of 27 participants underwent task-based fMRI, assessing brain responses to evoked pressure pain.

Results: Among 158 participants (mean age 58.4 years; 35% male), higher baseline PainDETECT scores were associated with significantly worse bodily pain throughout follow-up (adjusted β= -0.43; 95%CI: -0.84 to -0.02; P=0.043), independent of socio-demographics, lifestyle, comorbidities, depression, and anxiety. No association was found between PainDETECT and CRP. On neuroimaging,

higher PainDETECT scores correlated with increased activation in the left insula, dorsal anterior cingulate cortex (dACC), and left amygdala during evoked wrist pain.

Conclusion: Neuropathic-like pain at diagnosis predicts a worse pain prognosis in early RA, independently of inflammation. Early identification may support more targeted and effective pain management.

Schematic of the task-based functional MRI (tfMRI) protocol. Participants received alternating blocks of pressure pain (50 N) and light touch stimuli to the left wrist (typically affected in RA) and the left index finger nailbed (control site), during two 10-minute

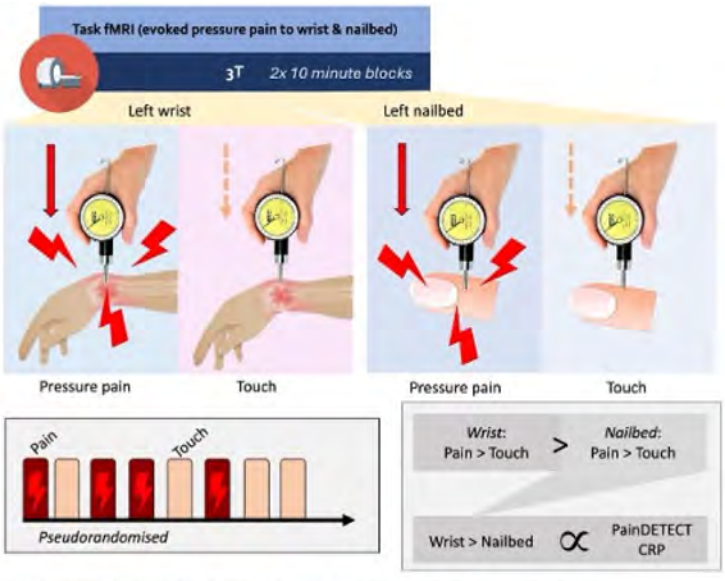

Figure 1. Task-based fMRI protocol for evoked pressure pain at RA-affected and control sites.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Higher baseline PainDETECT scores predict worse pain severity, but not inflammation, in early rheumatoid arthritis.

scan sessions on a 3T MRI scanner. Stimuli were applied manually using an MR-compatible algometer in a pseudorandomised order, guided by auditory cues. First-level contrasts modelled pain > touch at each site. Second-level contrasts compared wrist > nailbed activation, and group-level analyses examined associations with PainDETECT across the whole brain.

Lines represent individual raw patient trajectories of bodily pain (A) and C-reactive protein (CRP, B) over time, with mean values in bold. Shaded areas indicate 95% confidence intervals. Participants (N = 158, 91 scoring ≥13) were followed for one year. Neuropathic-like pain measured using the PainDETECT questionnaire (cutoff: ≥13 indicates probable neuropathic

pain). Note higher values of SF36-BPS indicate more severe bodily pain. CRP values were taken from linked healthcare records during follow-up, and were grouped into average CRP in each time period.

Higher PainDETECT (PDQ) scores are associated with greater activity in the left Insula, dorsal anterior cingulate cortex (dACC), and left amygdala after whole brain correction. Whole brain group-level activation maps for painful vs. non-painful stimulation of the left wrist vs. left nailbed contrast with PainDETECT scores. Maps are overlaid on a standard MNI152 T1-weighted brain template and thresholded at Z > 3.1. Higher PainDETECT scores at baseline are associated with significantly greater neuronal response in the left insula, dACC, and left amygdala. The y-axes show the induced effects of painful stimulation to the left wrist as a percentage BOLD signal change, defined as X = (Xpain (wrist) – Xno pain (wrist)) - (Xpain (nailbed) – Xno pain (nailbed)). Shaded areas represent the 95% confidence interval. Pearson correlation coefficients (r) are reported. N=27 participants who underwent neuroimaging.

Persistent Pain Despite Inflammatory Control in RA: A Pooled Analysis of 7 RCTs

Andreas Kerschbaumer[1], Marlene Steiner[2], William H. Robinson[3], Josef Smolen[4] and Daniel Aletaha[5], [1]Stanford University / Medical University of Vienna, Stanford, CA, [2]Medical University of Vienna, Vienna, Wien, Austria, [3]Stanford University, Palo Alto, CA, [4]Division of Rheumatology, Department of Medicine 3, Medical University of Vienna, Vienna, Austria, Vienna, Austria, [5]Medical University Vienna, Wien, Austria

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: Abstracts: Pain in Rheumatic Disease Including Fibromyalgia (0813–0818)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Joint swelling and tenderness are clinical hallmarks of rheumatoid arthritis (RA) and central to disease assessment. Regardless of treatment type, stringent remission based on the ACR/EULAR index (SDAI, CDAI) and Boolean definitions is associated with a reduction in joint damage and an increase in physical function. Using the patient global assessment in defining remission may hinder achieving it, as some patients experience high pain despite resolved inflammation, potentially not benefitting from immune-directed therapies. To date, it is unclear how many patients in randomized controlled trials (RCTs) reach an inflammation-free state but continue to report high pain levels.

Here, we analysed patients achieving inflammatory control while still reporting high pain levels at endpoints in RA RCTs and compared their characteristics at baseline and longitudinally to those with inflammatory control without residual pain.

Methods: We analyzed data from 2,640 patients receiving biologic DMARDs across 7 RCTs. Patients achieving inflammatory control (CRP≤0.5 mg/dL & SJC66=0) at trial endpoint (24 weeks) were divided by pain levels: low (≤5/10 VAS) vs high (>5/10 VAS). We then compared demographics and outcomes of these groups at baseline (disease activity, PROs, CRP, ESR and radiographic damage). Between-group comparisons used t-tests or Mann-Whitney U tests. We also assessed longitudinal differences between the groups using longitudinal linear mixed models.

Results: Of 2,405 patients with 24-week data, 305 (13%) achieved inflammatory control. Only 15 (< 1% of all; 5% of those with resolved inflammation) showed persistently elevated pain levels despite control of inflammation (Figure 1). These patients

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1: Flow chart of patient selection for analysis of pain discordance in RA.

showed a trend toward older age (52.8±11.1 vs 47.6±12.4) and a higher subjective disease burden at baseline (Figure 2) in TJC68 (31.8±16 vs 24.3±12.8), HAQ-DI (1.6±0.5 vs 1.2±0.6) and PGA (6.7±1.8 vs 5.1±2.2). Notably, objective measures including CRP (2.1±5.2 vs 1.9±2.2), ESR (30.5±23.4 vs 37.1±20.4), SJC66 (14.0±10.7 vs 14.5±8.6) and EGA (5.6±1.9 vs 5.6±1.7) and composite measures (CDAI, DAS28) were nearly identical between groups. However, erosion scores were twice as high in the high-pain group (19.0±23.4 vs 9.7±15.2) suggesting a higher disease burden. Longitudinal analyses (Figure 3) revealed persistent and significant differences in TJC68, pain, PGA, EGA HAQ-DI as well as composite measures (CDAI, SDAI, DAS28-ESR). Results using a lower cut-off for pain (≤3/10cm VAS) were confirmatory (data not shown).

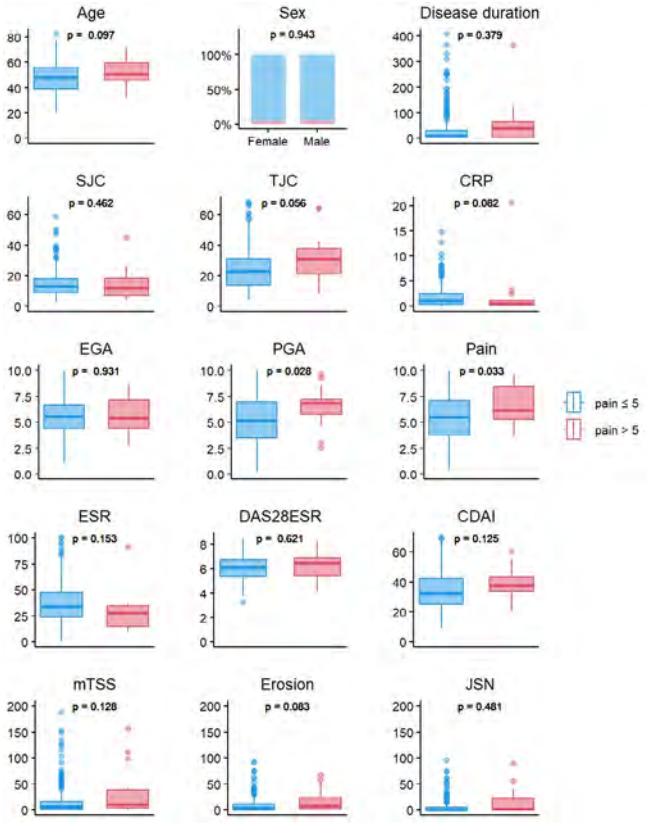

Figure 2: Comparison of baseline disease activity measures between patients who have achieved complete inflammatory control with high (>5; n=15) versus low (≤5; n=290) pain at week 24. Box plots show median (horizontal line), interquartile range (box), and range (whiskers). Dots represent outliers.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 3: Longitudinal analyses of disease activity measures between patients who have achieved complete inflammatory control with high (>5; n=15) versus low (≤5; n=290) pain at Week 24. The mean linear mixed model estimates of different disease activity parameters over time are graphed.

Conclusion: In this pooled analysis of 7 RCTs, < 1% of patients treated across 7 RCTs experienced high pain levels despite complete inflammatory control revealing that such discrepancy is very rare. Patients with persistent pain had higher subjective disease burden as well as radiographic damage at baseline, suggesting that persistent pain may be attributed to structural damage and/or potential central pain sensitization, rather than inflammation.

Background/Purpose: Patients with rheumatic diseases commonly experience acute or chronic pain that may lead to both short- and long-term opioid use. Many patients do not experience benefit in function or pain from increasing opioid dosages to ≥50 morphine milligram equivalents (MME)/day but do have increased risks, including dependence or overdose as the dose is increased. We used national data from the Rheumatology Informatics System for Effectiveness (RISE) registry linked to Medicare claims to quantify the prevalence and risk factors of receiving opioids including high dose prescriptions (Rx's) among older adults with rheumatic conditions associated with pain.

Methods: Adults ≥65 years old with ≥2 visits to a RISE practice in 2021, continuous Medicare enrollment (Parts A, B, & D) in 2021, and at least one rheumatic diagnosis of RA, OA, axSpA, SLE, PsA, PMR, SS, SSc, or gout were included. Patients with ≥2 ICD-10 codes for cancer were excluded. Outcomes were evaluated in Medicare claims and included: (1) any opioid dispensation, (2) chronic Rx (≥90 days), (3) max 90-day average morphine equivalent dose (MED), (4) and the MED for each claim was calculated and dichotomized into Rx's for ≥50 MME per day or less. Prescriber specialty (rheumatologist (rheum),

non-rheum physician, rheum affiliated physician assistant (PA)/nurse practitioner (NP) and non-rheum affiliated PA/NP) was determined by linking to National Provider Identifiers (NPIs). We modeled chronic opioid use as a dichotomous outcome using logit linear models using generalized estimating equations to adjust for patients nested within practices.

Results: Among 43,825 patients (mean age 75.9±6.4, 77.5% female, 87.7% non-Hispanic white), 18,991 (43.3%) filled ≥1 opioid Rx (112,791 total claims). Hydrocodone (19.6%), tramadol (19.1%), and oxycodone (12.1%) were the most common opioid Rx's. Chronic opioid Rx's were written in 7,922 patients (18.1%) and the mean maximum 90-day dose was 17.1 mg MED. A quarter of patients receiving opioids (23.8%) had Rx's written only by rheum providers, 13.4% received Rx's from a mix of rheum and non-rheum providers, and 5.4% were missing the specialty of the provider. Most Rx's for ≥50 MME per day were prescribed by non-rheum affiliated NPs/PAs and non-Rheum physicians (Table 2). In the adjusted model, patients with axSpA had more than 50% higher odds of chronic opioid Rx's compared to those with RA (OR 1.51; 95% CI 1.25-1.82) (Table 3). The odds of chronic opioid Rx increased incrementally with worsening patient socioeconomic deprivation; and fibromyalgia, mood disorders, anxiety disorders and higher comorbidity index were all significantly associated with chronic opioid Rx (Table 3).

Conclusion: In this national sample of older adults with rheumatic diseases, 43% received at least one opioid Rx; patients with axSpA were the most likely to receive an opioid Rx. Among patients receiving opioids, high dose Rx ≥50 MME/day were

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Risk of Cardiovascular Events is Higher in Pregabalin Users Versus Duloxetine: A Cohort Study Among Veterans with Chronic Musculoskeletal Pain

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: Abstracts: Pain in Rheumatic Disease Including Fibromyalgia (0813–0818)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Pregabalin and duloxetine are among the most prescribed non-opioid medications for patients with chronic pain. Pregabalin may raise the risk for heart failure, and duloxetine increases heart rate and blood pressure; however, little is known about their comparative cardiovascular safety. This study aimed to compare cardiovascular outcomes between new users of pregabalin and duloxetine in US Veterans with chronic musculoskeletal conditions.

Methods: This was a retrospective cohort study of US Veterans, ages 18-89 years, with chronic non-cancer musculoskeletal pain who were new users of pregabalin or duloxetine between 2014 and 2021. We excluded Veterans who were in long-term care or hospice, hospitalized for a month or more, and afflicted with serious illnesses in the year before their first prescription. The primary outcome was a major adverse cardiovascular event (MACE) – a composite of acute myocardial infarction, stroke, congestive heart failure, or cardiac death. For mortality causes, we used data from the National Death Index. For cardiac events, we used Veterans Affairs (VA) data and linked Medicare data. We created a propensity score using 153 covariates from ICD codes based on literature review and past studies and used it to adjust for confounding with inverse probability of treatment weighting (IPTW). Cox proportional hazard regression model was used to analyze outcomes over time.

Results: This study included 26,684 new users of pregabalin and 152,808 new users of duloxetine. The cohort was predominantly male (83%) and of reported White race (70%). The median age was 56 years old for both medications

Table: Rates of cardiovascular outcomes in new users of pregabalin vs duloxetine

	Pregabalin		Duloxetine		Hazard Ratio (95% CI)			
Model	N events	Rate/ 1000 yrs	N events	Rate/ 1000 yrs	Unadjusted		Adjusted

(IQR:44-67 for pregabalin, 42-67 for duloxetine). Prior to IPTW, rates of neuropathic pain, diabetes, and hypertension were higher among users of pregabalin, whereas rates of stress and anxiety were higher in users of duloxetine. Following IPTW, all covariates were balanced, indicated by standardized differences of less than one percent. During the study period, there were 1,798 MACE events. Follow-up time was 17,978 patient-years for pregabalin users and 123,134 patient-years for duloxetine users. The rate of MACE was higher for pregabalin users when compared to duloxetine users [unadjusted HR: 1.61 (CI: 1.43, 1.81), adjusted HR: 1.23 (CI: 1.08, 1.40)]. These differences were explained by higher rates of congestive heart failure and acute myocardial infarction among pregabalin users compared to duloxetine users.

Conclusion: In this retrospective cohort study of US Veterans ages 18-89 with chronic non-cancer musculoskeletal pain, new users of pregabalin had an increased risk of heart failure and acute myocardial infarction compared to new users of duloxetine.

Session Title: Abstracts: Pediatric Rheumatology – Basic Science (0819–0824)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Juvenile idiopathic arthritis (JIA) is the most common chronic pediatric rheumatic disease, yet the spatial immune architecture of inflamed synovium remains poorly characterized. Prior studies in adult rheumatoid arthritis (RA) have revealed spatial niches of immune–stromal interactions that correlate with treatment response. However, whether similar pathogenic circuits exist in JIA is unknown. We aimed to map cellular ecosystems in the JIA joint using high-resolution spatial transcriptomics and to identify microanatomical features associated with inflammation and disease-relevant cell–cell interactions.

Methods: Synovial tissue biopsies were obtained from 9 children with oligoarticular or RF-negative polyarticular JIA (Fig. 1A). Subcellular-resolution spatial transcriptomic profiling was performed using the 10x Genomics Xenium Prime 5K platform, capturing >430,000 cells across all samples. Data were processed using a custom pipeline enabling cell-type annotation, spatial neighborhood enrichment, and ligand–receptor colocalization analysis.

Results: We identified diverse immune and stromal cell populations, including pro-inflammatory macrophages, THY1+-NOTCH3+ sublining fibroblasts, and cytotoxic T cells (Fig. 1B-H). Covarying neighborhood analysis revealed sublining fibroblasts and endothelial cells were enriched in JIA synovium with systemic high-inflammatory state (Fig. 1I-J). A newly developed R package, named Spatial Neighborhood Analysis (SNA) (Fig. 2A), revealed cell-cell spatial interaction in JIA

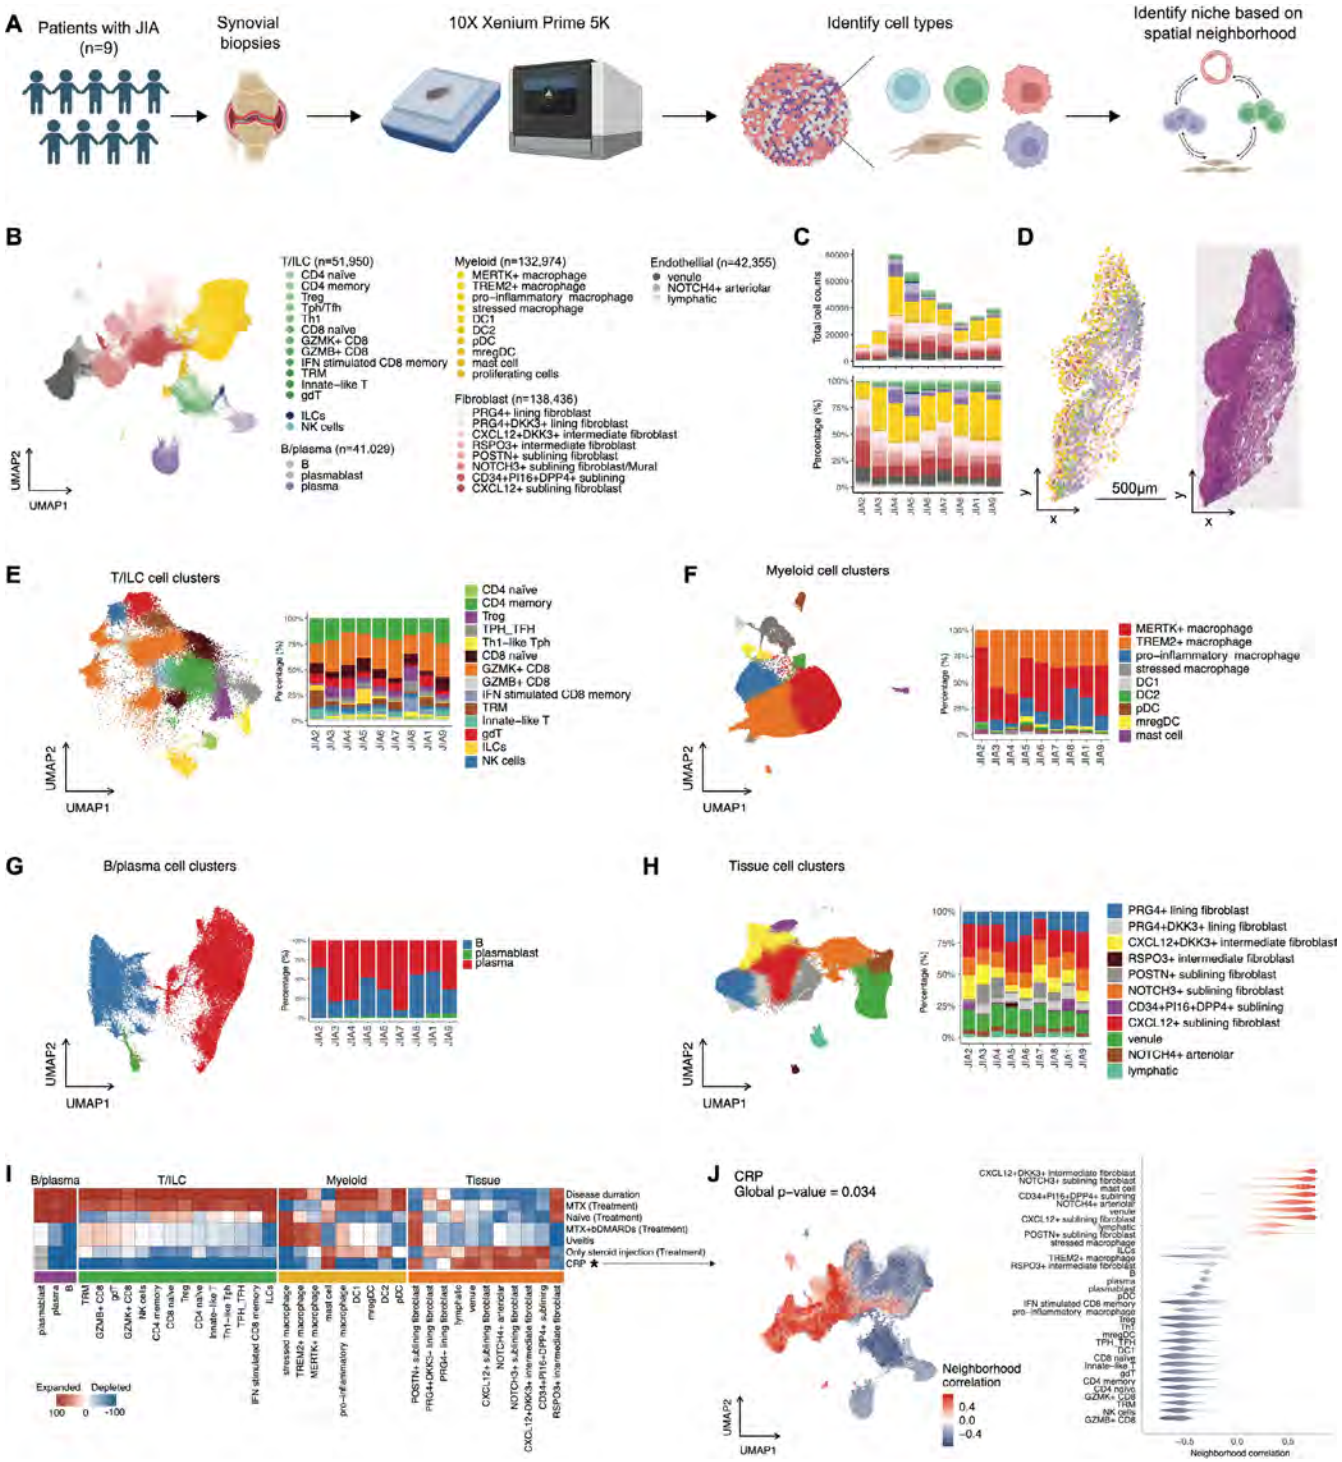

Fig.1: Spatial transcriptomic profiling of synovial tissue in JIA patients. A, Synovial biopsy samples were collected from nine patients diagnosed with JIA. Subcellular resolution spatial transcriptomic data was acquired from FFPE biopsy samples using the 10X Xenium Prime 5K platform. Cell types within synovial tissues were identified, and spatial neighborhoods were characterized based on spatial proximity analysis. B, Identified major immune and tissue-associated cellular compartments in synovium, including T cells, B cells, myeloid cells, and stromal tissue cells (endothelial and fibroblast subsets). Within each broad cell type, fine-scale cell subpopulations were annotated. C, Composition of cell-types across samples. D, Representative example of the FFPE histological slide of synovial biopsy sample and spatial mapping of identified cell clusters. Colors are corresponding with panel B. E-H, Identified fine-scaled cell clusters on UMAP (left) and composition across samples (right) for T cells (E), Myeloid cells (F), B/plasma cells (G), and stromal tissue cells (H). I, Heatmap of covarying neighborhood analysis (CNA) associations of specific cell states with each clinical variable. All testing was adjusted for age and sex. Colours represent the percentage of cell neighbourhoods from each cell state with positive phenotype correlations from white to red (expanded) or blue (depleted). Clinical variables associated globally (permutation p-value < 0.05) are annotated by asterisk (*). J, CNA for CRP association with cell states. Cells in UMAP are colored for expansion (red) or depletion (blue).

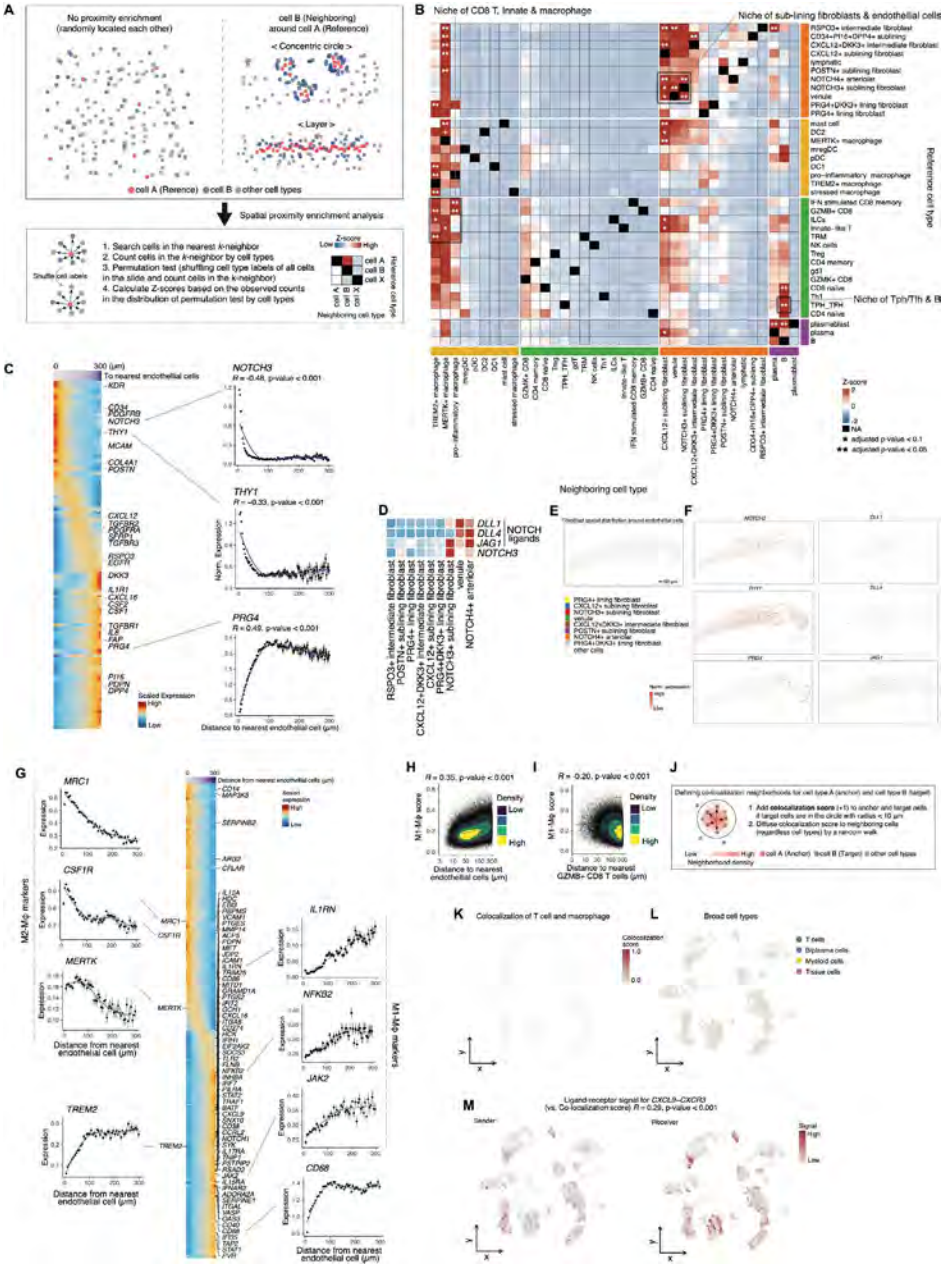

Fig.2: Spatial neighborhood enrichment and niche characterization in JIA synovium. A, Schematic description of the spatial neighborhood enrichment analysis pipeline. The procedure includes identifying nearest neighbors, quantifying neighborhood cell-type composition, performing permutation tests by shuffling cell-type labels, and calculating enrichment Z-scores. B, Spatial neighborhood enrichment in JIA synovium. Statistical significance is indicated as * (adjusted p-value < 0.1 by Benjamini-Hochberg method) and ** (adjusted p-value < 0.05). The highlighted black square indicates the niche of sub-lining fibroblasts and endothelial cells. C, Heatmap displaying the relationship between distances to nearest endothelial cells (purple bar above, 0–300 μm) and fibroblast gene expression. Rows represent fibroblast-associated genes, and columns represent individual cells. Fibroblast marker genes are labeled. Line plots depicting binned distance to nearest endothelial cells (x-axis) and normalized gene expression (y-axis) of representative fibroblast genes. Correlation coefficients and p-values indicate statistical significance. D, Heatmap of gene expressions related to Notch signaling pathway components across different cell types. E, Representative spatial coordinates of a identified niche of sub-lining fibroblasts and endothelial cells, matching pathological images. Cells are colored according to their cluster assignments. F. Spatial expression patterns of fibroblast-related and Notch signaling-related genes within the identified niche location. G, Scaled gene expression of selected M2-like (left) and M1-like (right) macrophage markers plotted as a function of distance from the nearest endothelial cell. Center heatmap shows scaled expression of macrophage-related genes in individual cells ordered by proximity to endothelial cells (0–300 μm), with representative M2- and M1-associated genes annotated. H–I, Correlation between M1-like macrophage module scores and distance to endothelial cells (H) or GZMB+ CD8 T cells (I). Each dot represents a cell. Spearman's correlation coefficient and p-values are shown. J, Schematic illustrating spatial colocalization scoring between anchor cells and target cells within a 10 μm radius. K, Spatial heatmap of colocalization scores between T cells and macrophages. L, Spatial map of broad cell type annotation including T cells, myeloid cells, B/plasma cells, and tissue cells. M, Spatial ligand–receptor analysis results for CXCL9–CXCR3, which exhibited the strongest correlation with macrophage–T cell co-localization scores.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Fig.3: Identification and characterization of tertiary lymphoid structures (TLS) using T and B cell colocalization scores in JIA synovium and comparative analysis of JIA and RA synovium. A, Images of synovial tissue, illustrating representative TLS as identified by a blinded pathologist. B, Spatial distribution of broad-scale T and B cell colocalization scores. Scale bar, 1 mm. The highlighted black square indicates the TLS-enriched region. C, Colocalization scores for T and B cells. D, Spatial ligand–receptor interactions specifically involving CXCL13-CXCR5. E, Zoomed-in visualization of the area with the highest TLS density highlighted in panel B, colored by T and B cell colocalization score. F-G, Same region as in panel E, displayed according to fine-scale cell cluster assignments. H, Violin plots showing the expression levels of key TLS-related genes across different cell clusters identified within the TLS. I, Cell-type level label transfer results, where RA synovium scRNA-seq (Zhang et al.) was used as the reference and JIA synovium Xenium data as the query. RA-derived annotations were transferred to individual JIA cells using a k-nearest neighbors (kNN) approach in the integrated latent space. J, Match rate between transferred RA scRNA-seq cell types and original Xenium-based annotations in JIA synovium. Matrix shows percentage overlap between each transferred and original broad cell type. K, Box plots showing the proportion of cell clusters across individual samples, stratified by condition (JIA vs RA synovium). P-values were calculated using Wilcoxon rank-sum tests.

synovium (Fig. 2B), including fibroblast–endothelial niches with enriched NOTCH3 signaling, paralleling RA pathology (Fig. 2C-F). Analysis focusing on macrophages showed that pro-inflammatory macrophages were enriched in regions distal from vasculature but proximal to GZMB+CD8+ T cells (Fig. 2G-I), with colocalization scores strongly implicating the CXCL9–CXCR3 axis in macrophage–T cell crosstalk (Fig. 2J-M). The SNA framework also automatically captured tertiary lymphoid structures (TLS) in JIA synovium (Fig. 3A), with dense B and T cell colocalization and CXCL13-CXCR5 signalling (Fig. 3B-H), suggesting active germinal centre-like activity. Moreover, integration with public RA-synovium single-cell data revealed enrichment of NOTCH3+ fibroblasts in JIA, whereas Tph/Tfh and GZMB+ CD8 T cells were more abundant in RA (Fig. 3I-K).

Conclusion: Subcellular spatial transcriptomics uncovers conserved and disease-specific immune–stromal architectures in JIA synovium. Vascular-fibroblast niches and macrophage–T cell crosstalk may be key drivers of inflammation. The presence of TLS and unique myeloid–stromal features in JIA highlight potential biomarkers and therapeutic targets distinct from adult RA. These findings offer new insight into pediatric synovial immunopathology and pave the way for precision therapies in childhood arthritis.

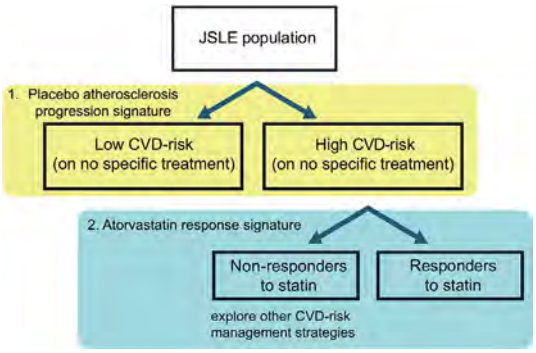

Figure 2: Algorithm for potential use of the novel autoantibody signatures in clinical practice for stratification of JSLE patient population based on CVD-risk and prediction of response to statin treatment.

Background/Purpose: Cardiovascular disease (CVD) is a leading cause of morbidity and mortality in juvenile-onset systemic lupus erythematosus (JSLE). There is an urgent need to identify biomarkers that can predict atherosclerosis progression and therapeutic responses, enabling personalised CVD-risk management in JSLE. This study aimed to investigate whether novel autoantibody signatures can predict atherosclerosis progression and atorvastatin response in children and young people with JSLE.

Methods: We conducted a biomarker discovery study using baseline serum samples from a sub-cohort of the APPLE trial (Atherosclerosis Prevention in Paediatric Lupus Erythematosus), a multi-centre, randomised, double-blind, placebo-controlled clinical trial of atorvastatin versus placebo (1:1) to prevent atherosclerosis progression in JSLE, conducted across 21 sites in North America. Unsupervised cluster analysis based on carotid intima media thickness (CIMT) progression over 36 months was used to identify groups with high and low atherosclerosis progression within each treatment arm. Baseline differential autoantibody expression was assessed using Empirical Bayes moderated t-tests. Predictive performance was evaluated using logistic regression and ROC analysis.

Results: Ninety-four JSLE patients (mean [SD] age 15.3 [2.4] years; 78% female), with matched baseline serum samples and complete longitudinal CIMT measurements over 36 months, were included (45 randomized to the placebo and 49 to the atorvastatin arm) (**Table 1**).

A total of 579 autoantibodies were identified as true signals in the 94 baseline serum samples analysed. In the placebo arm, six autoantibodies (STK24, RAD23B, HDAC4, STAT4, SEPTIN9 and NFIA) were significantly associated with high versus low CIMT progression over 36 months in the placebo arm, achieving a combined area under the curve (AUC) of 87% (**Figure 1A-C**). In the atorvastatin arm, a distinct autoantibody profile was identified, which predicted response to statin treatment. Eight autoantibodies (ABI1, ATP5B, CSNK2A2, NRIP3, PRKAR1A, PDK4, BATF and NUDT2) were significantly associated with CIMT progression despite atorvastatin therapy, achieving an exceptional combined AUC of 96% (**Figure 1D-F**). Enriched pathway analysis of the autoantibodies that differentiated responders vs. non-responders to atorvastatin revealed lipid-independent mechanisms, such as accumulation of vascular smooth muscle cells within neointima (CSNK2A2) or vascular calcification and regulation of cell proliferation/apoptosis (PDK4).

Based on the predictive models generated from these distinct autoantibody profiles in both the placebo and atorvastatin arms, a two-step stratification strategy was proposed to enable precision risk assessment and guide treatment decisions for CVD-risk management in JSLE **(Figure 2)**.

Conclusion: In this biomarker discovery cohort study, novel autoantibody signatures were identified as the first JSLE-specific serum markers for atherosclerosis progression and prediction of statin response (currently under patent protection). These findings support the potential application of autoantibody profiling for precision medicine approaches for CVD-risk management in JSLE.

Flipping The Switch – Classical Complement Activation closely linked to IFN-signalling in Stills Disease

Freya Huijsmans[1], Alejandra Bodelón de Frutos[1], Lyanne Sijbers[1], Susanne Benseler[2], Joost Swart[3], Rae Yeung[4], Sebastiaan Vastert[5] and Jorg van Loosdregt[1], [1]Pediatric Rheumatology & Immunology, University Medical Center Utrecht, Wilhelmina Children's Hospital, Utrecht, Utrecht, Netherlands, [2]Cumming School of Medicine, Department of Pediatrics, University of Calgary, Calgary, AB, Canada, [3]Wilhelmina Children's Hospital / UMC Utrecht, Utrecht, Utrecht, Netherlands, [4]The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada, [5]University Medical Center Utrecht, Utrecht, Utrecht, Netherlands

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: Abstracts: Pediatric Rheumatology – Basic Science (0819–0824)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Stills disease (SD) is an autoinflammatory syndrome characterized by severe innate immune dysregulation. The complement system, an essential component of innate immunity, can drive inflammatory cascades through the classical, lectin or alternative pathway. Although complement activation has been implicated in various inflammatory disorders, its involvement in SD remains largely undefined. Elucidating the role of complement in SD may provide valuable insights into disease mechanisms and uncover novel therapeutic targets.

Methods: To determine whether the complement pathway is activated in SD patients, we conducted transcriptomic analysis, proteomic measurements, and in vitro stimulation assays. RNA was extracted from whole blood of SD (active n=27, inactive n=26) and active non-systemic juvenile idiopathic arthritis (JIA) patients (n=538). Gene expression of classical complement components C1QB, C1QC and IFN-regulated genes (IFN-score) was quantified by NanoString. Additionally, RNA sequencing was conducted on sorted monocytes from SD patients (active n=7, inactive n=7). Inflammatory mediators (IL-18, CXCL9, CXCL10) and complement activation products (C1q, C3a, C5a) were quantified using Luminex and ELISA. Classical complement activity was evaluated in sera of SD (active n=32, inactive n=66) and non-systemic JIA patients (active n=12, inactive n=12). To explore potential mechanisms underlying complement activation, in vitro experiments were conducted to assess which inflammatory stimuli could induce C1q production in monocytes.

Results: RNA expression of classical complement protein C1q is upregulated in both whole blood and isolated CD14+ monocytes from active SD patients compared to those with inactive disease (NanoString: C1QB 43 vs. 11, $p< 0.01$; C1QC 24 vs. 6, $p< 0.01$; Monocytes: C1QB log2FC 3.6, $p< 0.01$; C1QC log2FC 3.9, $p< 0.01$) and to active non-systemic JIA patients (C1QB 43 vs 15, $p< 0.01$; C1QC 24 vs 8, $p< 0.01$). Moreover, whole blood C1QB and C1QC expression levels positively correlate with the IFN-score ($r=0.34$, $p=0.01$), plasma levels of IL18 ($r=0.5$, $p< 0.01$) and IFN related chemokines CXCL9 ($r=0.4$, $p< 0.01$) and CXCL10 ($r=0.6$, $p< 0.01$) in SD. Protein analysis revealed elevated levels of C1q, C3a, and C5a, as well as enhanced classical complement activity in active SD compared to inactive SD (94% vs 74%, $p< 0.01$) and active non-systemic JIA patients (94% vs 81%, $p=0.02$). Furthermore, in vitro stimulation of healthy control monocytes with IFNγ robustly and specifically induces C1q mRNA expression. Flow cytometry analysis confirmed that IFNγ stimulation promotes the emergence of a distinct monocyte subset characterized by high C1q expression.

Conclusion: Our findings indicate activation of the classical complement pathway in SD, closely linked with IFN-signalling. Obtaining a better understanding of the role of the complement system, particularly the role of C1q-high monocytes, may open novel avenues for personalized therapeutic approaches in SD.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: Abstracts: Pediatric Rheumatology – Basic Science (0819–0824)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Most children with juvenile dermatomyositis (**JDM**) have chronic disease despite multi-drug immunosuppression, highlighting the need for targeted therapies. Neutrophil extracellular traps (**NETs**) are key in autoimmunity, but their role in JDM is unclear. This study examined neutrophil activation and NET formation, focusing on calprotectin as a candidate biomarker and mediator of tissue damage.

Methods: Plasma calprotectin was measured in JDM patients (n=51) and healthy controls (n=10). Sixteen endothelial cell analytes were assessed in 48 JDM patients. Proteomic profiling of six treatment-naïve samples was done using the Olink 3072 panel. Ex vivo and in vitro assays tested JDM plasma and recombinant calprotectin on muscle cell injury. Anti-NXP2 antibodies from treatment-naïve patients were evaluated for their ability to induce NETs by SYTOX Green-based assay.

Results: Circulating calprotectin levels were significantly elevated in JDM patients compared to healthy controls ($p < 0.0001$). Calprotectin strongly correlated with absolute neutrophil counts ($r = 0.63$, $p < 0.0001$), consistent with its origin from activated neutrophils and its link to NET formation. Notably, higher calprotectin levels were also associated with established biomarkers of muscle injury, including creatine phosphokinase ($r = 0.34$, $p = 0.036$), aldolase ($r = 0.40$, $p = 0.013$), and lactate dehydrogenase ($r = 0.37$, $p = 0.023$). Clinically, elevated calprotectin reflected reduced muscle strength, as assessed

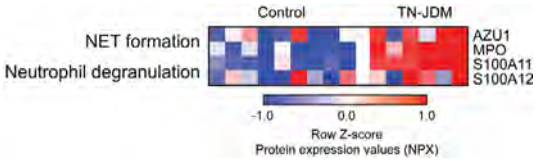

Figure 1. Upregulation of neutrophil activation and NET formation protein expression signature in JDM. Heatmap displaying individual-level Z-score Normalized Protein Expression (NPX) values of select neutrophil-specific proteins in treatment-naïve (TN) JDM plasma (n = 6) compared to healthy controls (n = 9). These proteins were also significantly associated with global disease activity, highlighting a neutrophil-driven inflammatory signature at the time of JDM diagnosis.

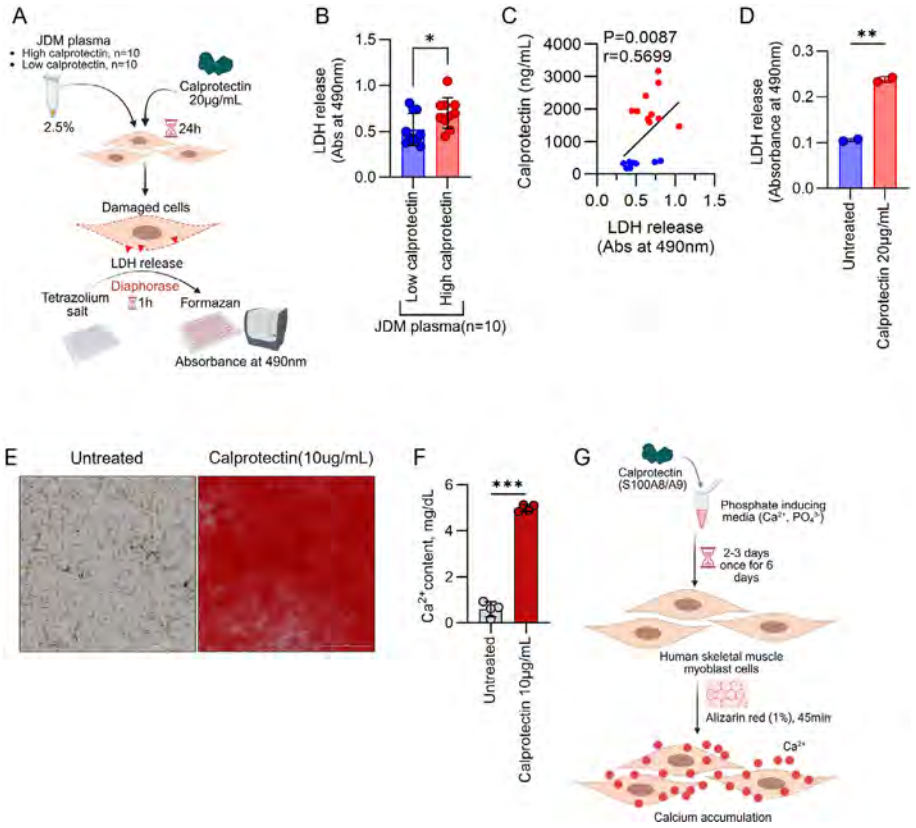

Figure 2. Impact of elevated calprotectin—both from high-calprotectin JDM samples and recombinant protein—on cytotoxicity and calcification in human skeletal muscle myoblasts (HSMMs). (A) Schematic of the skeletal muscle cell cytotoxicity assay. (B) Cytotoxicity of HSMMs was assessed via LDH release after 24-hour treatment with 2.5% plasma from JDM subjects with high (n=10) or low (n=10) circulating calprotectin. (C) Correlation between plasma calprotectin levels and LDH release in JDM samples. (D) LDH release from HSMMs following treatment with recombinant calprotectin (20μg/mL). (E) Alizarin Red staining of HSMMs treated with recombinant calprotectin (10 μg/mL) in calcification medium (PI) for 6 days, with media refreshed every 2–3 days. (F) Calcium content was quantified in parallel wells; calcium deposits were dissolved with 1N HCl for 3 hours at 4°C and measured using the QuantiChrom Calcium Assay Kit. (G) Schematic of intracellular calcium accumulation assay. *Statistical significance: *P < 0.05; **P < 0.01; ***P < 0.001.

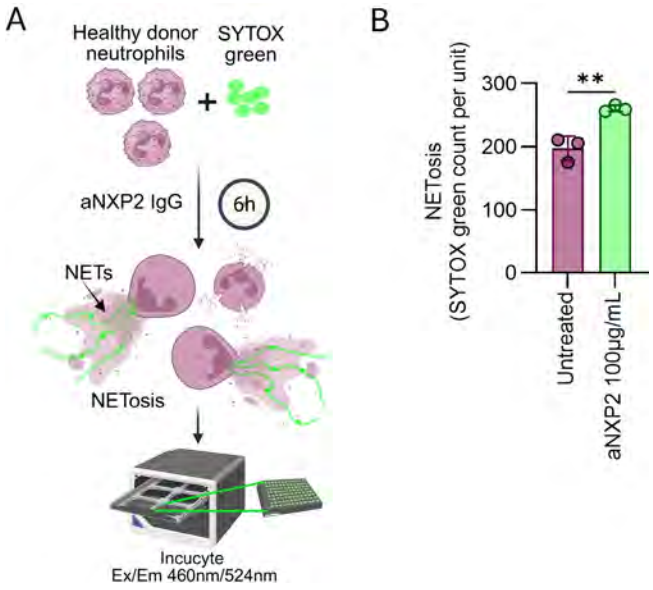

Figure 3. The JDM-specific autoantibody anti-NXP2 IgG induces NETosis in healthy donor neutrophils. (A) Schematic of the SYTOX Green-based NETosis assay. (B) Healthy donor neutrophils were treated with anti-NXP2 IgG (100 μg/mL) for 6 hours in the presence of SYTOX Green, which labels extracellular DNA released during NETosis. *Significance: **P < 0.01.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

by lower Manual Muscle Testing-8 scores (r = –0.44, p = 0.007), and higher Physician's Global Activity Assessment scores (r = 0.36, p = 0.023), underscoring its potential as a biomarker of disease activity. Furthermore, calprotectin levels showed strong correlations with multiple soluble EC analytes—including Ang-2, Tie2, Gal-9, and sTNFR-II—suggesting a role in endothelial activation or injury. Plasma proteomic expression profiling in TN JDM patients also revealed significant upregulation of multiple neutrophil activation proteins (AZU1, MPO, S100A11, S100A12) (**Fig. 1**). Mechanistic studies demonstrated that calprotectin-rich JDM plasma induced marked cytotoxicity and microcalcification in cultured human skeletal muscle cells (**Fig. 2 A-G**). These effects were recapitulated by recombinant calprotectin, confirming a direct pathogenic role. Additionally, anti-NXP2 antibodies purified from JDM plasma robustly induced NET formation when incubated with neutrophils from healthy donors, implicating this JDM-specific autoantibody in neutrophil activation and NETosis (**Fig. 3 A-B**). Ongoing experiments aim to assess the potential direct pathogenic effects of anti-NXP2 on endothelial cells and muscle tissue.

Conclusion: Calprotectin is a mechanism-informed biomarker in JDM that reflects neutrophil activation and correlates with muscle disease activity, endothelial dysfunction, and muscle damage. Anti-NXP2 autoantibodies trigger NETosis, linking adaptive immunity to neutrophil-driven pathology. These findings reveal a novel pathogenic axis at the intersection of innate and adaptive immunity with vascular health, suggesting new targets for biomarker-guided therapy.

Longitudinal model of paired peripheral blood CITE-seq and skin scRNA-seq data in juvenile systemic sclerosis (jSSc) patients following autologous stem cell transplant (ASCT) reveals reduced expression of SSc marker genes

Julia Elrod[1], Theresa hutchins[2], Anwesha Sanyal[2], Paul Szabolcs[2], Paulina Horvei[2], Jon Li[2], F. William Townes[1] and Kathryn Torok[2], [1]Carnegie Mellon, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: Abstracts: Pediatric Rheumatology – Basic Science (0819–0824)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Juvenile systemic sclerosis (jSSc) is a rare, life-threatening autoimmune disease characterized by fibrosis and immune dysregulation. Autologous stem cell transplant (ASCT) is an emerging treatment aimed at resetting immune homeostasis. Here, we present the first integrated longitudinal single-cell analysis of paired peripheral blood and skin samples in jSSc patients undergoing ASCT, using Cellular Indexing of Transcriptomes and Epitopes by sequencing (CITE-seq) in context with skin single-cell RNA sequencing (scRNA seq) data.

Methods: Peripheral blood mononuclear cell (PBMC) and skin samples were collected from three jSSc patients pre-ASCT and at 6, 12, and 24 months post-ASCT. Samples were multiplexed per patient including the different timepoints. PBMC and skin samples underwent CITE-seq and scRNA-seq respectively. Data were processed using CellRanger, Seurat, SoupX, DSB, Harmony, and RPCA. PBMCs were clustered using a shared RNA and protein weighted nearest neighbors (WNN) graph (Figure 1A), skin cells were clustered using a standard Seurat pipeline (Figure 1B), and cell types were annotated. RNA counts were subsetted by tissue and cell type and then pseudobulked to aggregate expression across cells

Figure 1. Longitudinal transcriptomic changes in paired peripheral blood and skin of juvenile systemic sclerosis (jSSc) patients following autologous stem cell transplant (ASCT) Legend: A. Weighted nearest neighbor (WNN) UMAP of peripheral blood CITE-seq data from all time points, annotated by major immune cell type. B. UMAP of skin scRNA-seq data, annotated by major stromal and immune cell populations. C. SERPINE1 expression trajectories over time in peripheral blood monocytes (left) and skin macrophages (right). Top panels show log-linear longitudinal model fits for each patient, while bottom panels display SERPINE1 feature plots at each time point, including healthy controls and post-ASCT time points. D. Longitudinal expression and feature plots for LGMN, a fibrosis-associated gene, in peripheral blood monocytes and skin macrophages, using the same layout as panel C. E. Gene ontology (GO) enrichment analysis of genes downregulated following ASCT, highlighting biological processes such as cell adhesion, monocyte chemotaxis, fibrinolysis, and cell differentiation. These results highlight dynamic and coordinated downregulation of profibrotic and inflammatory gene programs in skin and blood compartments post-ASCT, with SERPINE1 and LGMN among the top differentially expressed genes associated with disease resolution.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. per gene, patient, and time point. A negative binomial GLM was fit using glmGamPoi, with time post-ASCT as the primary variable, adjusting for patient and library size. Differential gene expression was assessed using quasi-likelihood ratio tests.

Results: Monocytes (PBMC) and macrophages (skin) demonstrated the most robust transcriptomic changes over time. In PBMCs, the top differentially expressed gene was *SERPINE1* (Plasminogen Activator Inhibitor-1), a known SSc biomarker (LFC -3.48, $p = 7.86\times10^{-6}$). Figure 1C shows longitudinal model fits of *SERPINE1* in peripheral blood monocytes and skin macrophages, as well as expression feature plots across time points. Expression of *LGMN*, another fibrosis-associated gene, followed a similar trajectory (Figure 1D). Gene set enrichment analysis (GSEA) of gene expression downregulated post-ASCT identified pathways related to cell adhesion, monocyte chemotaxis, fibrinolysis, and cell differentiation (Figure 1E). Notably, *RGCC*, *LGMN*, and *FOSL1*, previously implicated in fibrotic and immune processes, were significantly downregulated in both PBMC and skin. These findings align with prior studies implicating macrophage-fibroblast crosstalk in adult SSc pathology.

Conclusion: Our integrated single-cell analysis reveals that ASCT results in significant reduction of fibrotic and inflammatory gene signatures in both blood and skin of jSSc patients. The longitudinal decrease in *SERPINE1* and other SSc-associated genes supports ASCT's role in molecular disease reversal. These transcriptomic findings, combined with parallel clinical improvement, underscore the therapeutic potential of immune reset strategies in modifying disease trajectory in jSSc.

Session Title: Abstracts: Pediatric Rheumatology – Basic Science (0819–0824)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Our ability to tailor treatments to individual patients with JIA remains limited. To identify candidate biomarkers that may be associated with treatment response, we characterized circulating lymphocytes in patients treated with abatacept in the Improving Outcomes in Limited JIA (LIMIT-JIA) study.

Methods: LIMIT-JIA is a multicenter trial conducted within the Childhood Arthritis and Rheumatology Research Alliance (CARRA) comparing abatacept treatment for 24 weeks to usual care in patients with limited arthritis (< 5 joints at disease onset). Study subjects were diagnosed within 6 months, had no history of uveitis, and were DMARD naïve. Blood samples were collected from 12 different CARRA sites at baseline (before treatment) and at 6 months and shipped to the CARRA

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1: Abatacept treatment modulates circulating T cell subsets in patients with limited JIA. A) UMAPs generated from mass cytometry data of the 48-marker panel used to immunophenotype T and NK cells. Samples were from JIA patients at baseline (n=50) and those treated with abatacept (n=36) or usual care (n=14) at 6 months. B) UMAPs generated after filtering for T and NK cells and unsupervised clustering. C) Heatmap showing the median expression of a given marker in each cluster. D) Volcano plots showing differential abundance of the clusters in the given study groups. JIA, juvenile idiopathic arthritis; UMAPs, uniform manifold approximation and projections; mo, months; Treg, regulatory T; Tfh, T follicular helper; Tph, T peripheral helper; DN T, double negative T

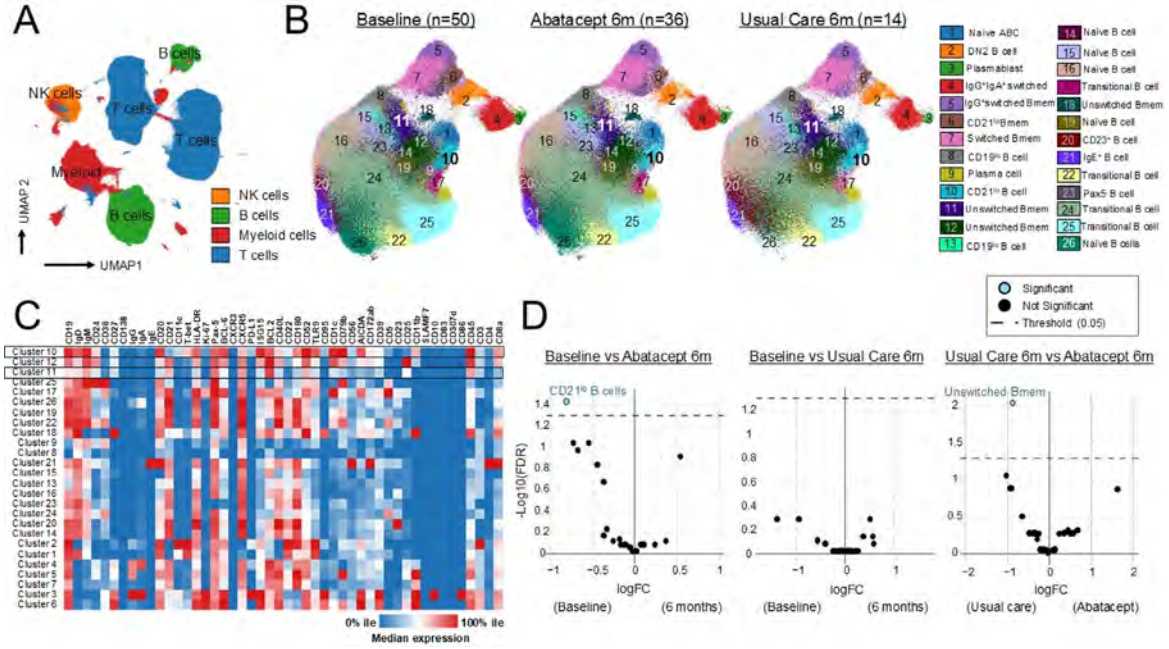

Figure 2: Abatacept treatment decreases circulating CD21lo B cells in patients with limited JIA. A) UMAPs generated from mass cytometry data of the 48-marker panel used to immunophenotype B cells. Samples were from JIA patients at baseline (n=50) and those treated with abatacept (n=36) or usual care (n=14) at 6 months. B) UMAPs generated after filtering for B cells and unsupervised clustering. C) Heatmap showing the median expression of a given marker in each cluster. D) Volcano plots showing differential abundance of the clusters in the given study group. JIA, juvenile idiopathic arthritis; UMAPs, uniform manifold approximation and projections; mo, months; ABC, age-/autoimmune-associated B cells; DN, double negative; Bmem, memory B cell

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Biobank for cryopreservation. Peripheral blood mononuclear cells (PBMCs) were then thawed, stained with antibodies from 2 panels to characterize T/B/NK cells (48 markers/panel), barcoded for mass cytometry, and acquired on a CyTOF XT instrument. Samples were processed in 5 batches with each batch containing samples from multiple study groups/time points. After compensation and debarcoding, CyCombine corrected and integrated the results from the batches. OMIQ software was used for unsupervised clustering with FlowSOM and results were visualized with a uniform manifold approximation and projections (UMAP) and heatmaps. EdgeR in OMIQ was used for statistical analysis.

Results: Patients in the abatacept (n=36) and usual care (n=14) arms provided paired samples at baseline and 6 months. T, B, NK, and myeloid cells were identified with data from each panel (Fig 1A, 2A). After gating on $CD3^+$ or $CD56^+$ cells, 23 clusters of T/NK cells were identified (Fig 1B-C). Three clusters were significantly more abundant in patients at baseline compared to those treated with abatacept at 6 months. These clusters contained cells with features of regulatory T (Treg) (cluster 5), T follicular helper (Tfh) (cluster 6), and double negative (DN) T cells (cluster 10) (Fig 1C-D). There was no difference in cluster distribution in patients at baseline vs. those receiving usual care at 6 months (Fig 1D). When comparing patients at 6 months, T cells were more frequent in the Tfh cell cluster in the usual care vs. abatacept groups (Fig 1D). Clustering on $CD20^+CD19^+$cells revealed 26 different B cell populations (Fig 2B). Cluster 10 contained $CD21^{lo}$ B cells with features of age-/autoimmune-associated B cells (ABCs) and was overrepresented in patients at baseline compared to those treated with abatacept at 6 months. There was no difference in B cell cluster abundance in patients at baseline vs. usual care at 6 months. Cluster 11, containing unswitched memory B cells, was enriched in usual care vs. abatacept at 6 months.

Conclusion: Abatacept treatment in JIA patients with limited arthritis modulated the frequency of circulating Treg, Tfh, DN T, and $CD21^{lo}$B cells. These results suggest that interactions between B cell helper T cells and $CD21^{lo}$B cells are important in the pathogenesis of this form of arthritis and may be regulated by T cell costimulatory inhibition. Further studies are needed to determine if these lymphocyte populations can predict and track treatment response in JIA patients.

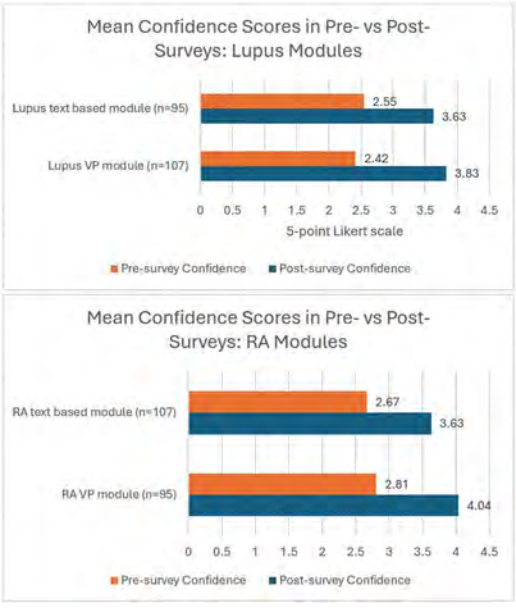
Table 1 Comparison of Pre- and Post-Test Scores for VP and Text-Based Modules in lupus and RA

Condition	Timepoint	Group A Mean (SD)	Group B Mean (SD)	p-value
Lupus	Pre-test	35.6% (10.47)	36.7% (11.43)	
	Post-test	47.5% (6.33)	46.3% (6.02)	
	Difference (Post - Pre)	+11.9% (8.01)	+9.6% (8.5)	**0.05**
RA	Pre-test	40.4% (7.88)	40.1% (7.79)	
	Post-test	45.7% (6.60)	47.8% (5.51)	
	Difference (Post - Pre)	+5.3% (7.81)	+7.7% (7.21)	**0.02**

Background/Purpose: Internal medicine (IM) residents often receive limited rheumatology training, contributing to low confidence in managing rheumatologic conditions and suboptimal performance on standardized examinations. Virtual patient (VP) modules—interactive, multimedia cases simulating real-life scenarios—offer a promising alternative by promoting clinical reasoning and learner engagement. Rooted in cognitive load and multimedia theories, VP modules may offer advantages over traditional text-based learning, which often lacks interactivity and real-world complexity. While prior research has demonstrated the effectiveness of VPs compared to no intervention, evidence comparing VPs to text-based modules in graduate medical education, particularly in rheumatology, remains limited.

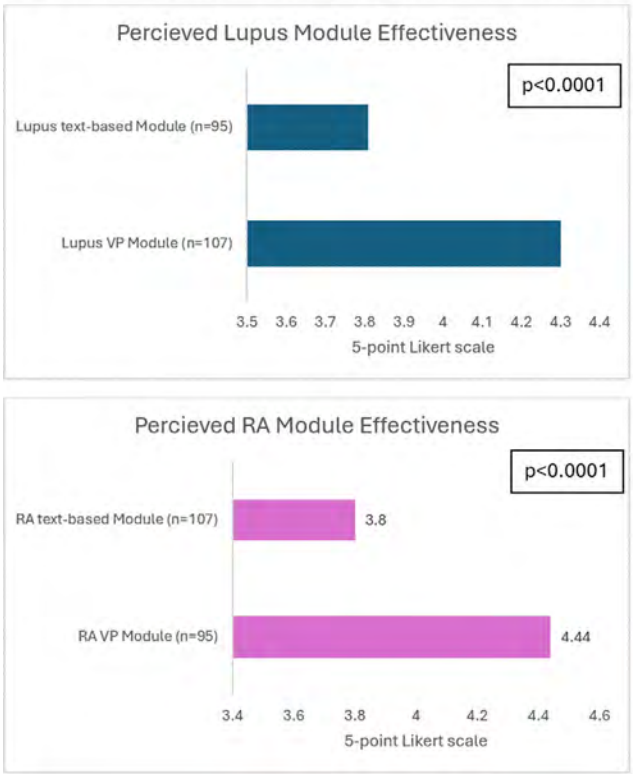
Methods: In a multi-site, randomized crossover study, 202 IM residents from 16 U.S. residency programs were randomized into two groups: Group A completed a VP module on systemic lupus erythematosus (SLE) and a text-based module on rheumatoid arthritis (RA), while Group B completed a VP module on RA and a text-based module on SLE. Clinical reasoning was assessed via 10-item multiple-choice pre- and post-tests. Self-reported confidence was measured using 5-point Likert-scale items. Learner perceptions were evaluated through a pre-validated survey and open-ended questions. Student's t-tests compared change in pre- and post-test scores, self-rated confidence, and perceived module effectiveness. These abstract reports interim results from data collected between Feb'24 and Jan'25.

Figure 1 Comparison of Mean Confidence Scores in Pre- and Post-Surveys for Lupus and RA Modules



23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Fig. 2 Residents' perceptions of VP compared to text-based modules



Likert scale: 1 = strongly disagree, 2 = Disagree, 3 = Neither agree or disagree, 4 = Agree, 5 = strongly Agree.

Results: Interim analysis indicates that both module types improved knowledge. However, VP modules led to greater gains in post-test scores compared to text-based modules in both RA and SLE; differences were statistically significant in SLE ($p = 0.05$) and in RA ($p = 0.02$) modules. (Table 1). Compared to pre-survey confidence, residents who completed VP modules reported significantly higher post-survey confidence in diagnosing, evaluating, and managing both SLE and RA ($p < 0.0001$; Figure 1). They also rated VP modules as significantly more effective in reinforcing diagnostic reasoning and clinical decision-making skills ($p < 0.0001$; Figure 2). Open-ended feedback reflected a strong learner preference for VP modules, describing them as more engaging and realistic. Key benefits included interactive dialogue, clinical decision-making prompts, and visual content. Some residents described the VP format as lengthy or repetitive, while others appreciated its alignment with real-world reasoning.

Conclusion: Preliminary findings suggest that VP modules led to greater knowledge and confidence gains compared to text-based modules and VPs were preferred by learners. These findings support integrating VP-based learning into rheumatology education, especially in settings with limited faculty or clinical exposure as they offer a scalable, engaging approach to preparing IM residents for real-world rheumatologic care. Although long-term retention and sustained confidence were not assessed, future studies will be important to determine their lasting impact.

Data are presented as mean percent correct (standard deviation). P-values based on unpaired t-tests comparing Group A and Group B at each timepoint. Difference reflects the absolute change from pre- to post-test scores. *Group A - VP module on lupus (highlighted in grey) and text-based module on rheumatoid arthritis; Group B - text-based module on lupus and VP module on rheumatoid arthritis (highlighted in grey).

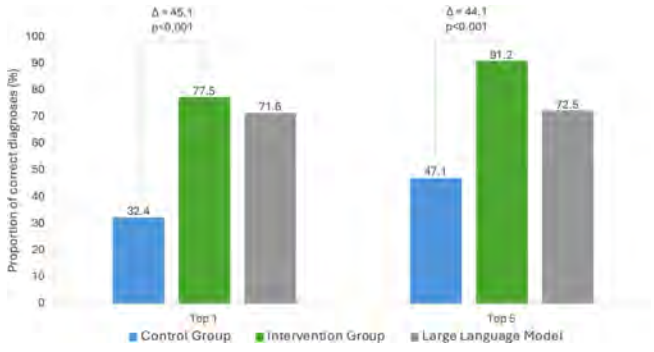
SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: Abstracts: Professional Education (0825–0830)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

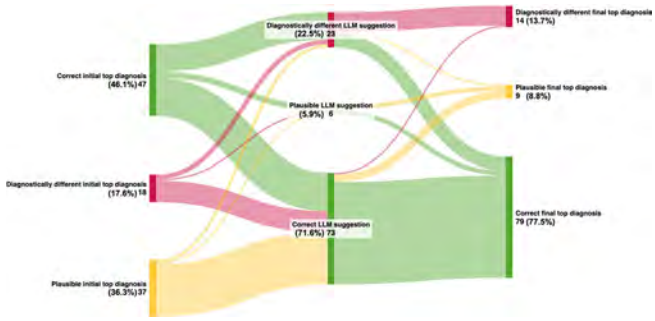
Background/Purpose: Although not certified as medical devices, Large Language Models (LLMs) such as ChatGPT-4 provide rapid support in diagnostic reasoning and may facilitate scalable upskilling of healthcare professionals and laypersons alike. This trial evaluated the impact of LLM assistance on the diagnostic reasoning of medical students solving rheumatology case vignettes.

Methods: In this RCT (NCT06748170), 68 medical students were allocated between January 7 and March 30, 2025, to either an intervention group (IG), with access to ChatGPT-4o, alongside conventional diagnostic resources, or a control group (CG), with access to conventional resources only. Participants in the IG first generated diagnostic suggestions using conventional resources and then revised their suggestions after consulting the LLM. All participants completed 3 rheumatology case vignettes—GPA , RA and SLE—originally published in the ACR's online learning center. Each vignette required a top diagnosis, and optionally up to five diagnostic suggestions in total. The suggested diagnoses were independently and blindly reviewed by two board-certified rheumatologists. Diagnostic accuracy was additionally scored by awarding two points for correct diagnoses and one point for plausible alternatives, generating a cumulative diagnostic score. Time to case completion and diagnostic confidence (0–10) were also recorded.



Proportion of correct diagnoses ranked first or within the top five suggestions

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Distribution of top diagnosis categories in the intervention group across study phases

Results: The mean (SD) age was 24.8 (2.6) years; 62% (42/68) of participants were female. Prior use of LLMs was reported by 96% (65/68) of students. Interrater agreement was substantial (Cohen's κ = 0.79). Students in the IG identified the correct top diagnosis significantly more often than those in the CG (77.5%, mean 2.3/3 [SD 0.8] vs. 32.4%, mean 1.0/3 [SD 0.8]; independent t-test = 7.3, $P < 0.001$) and were also more likely to include a correct diagnosis among their top five suggestions (91.2%, mean 2.7/3 [SD 0.5] vs. 47.1%, mean 1.4/3 [SD 0.7]; independent t-test = 8.5, $P < 0.001$), see **Figure 1**. The standalone performance of the LLM exceeded that of students using conventional resources, listing the correct diagnosis first in 71.6% of cases and within the top five in 72.5%. Median diagnostic scores per case were 4 (IQR, 3–5) in the IG, 2 (IQR, 1–3) in the CG, and 5 (IQR, 3.3–6) for the LLM. Median time to case completion was 498 seconds (IQR, 371–609) in the IG and 253 seconds (IQR, 175–395) in the CG. LLM use significantly increased the proportion of correct top diagnoses in the IG, from 46.1% (mean 1.4/3 [SD 0.7]) to 77.5% (mean 2.3/3 [SD 0.8]); paired t-test = 7.1, P < 0.001, see **Figure 2**. Diagnostic confidence in the IG also increased significantly following LLM use (mean 5.2/10 [SD 1.5] to 7.0/10 [SD 1.3]; paired t-test = –9.4, P < 0.001). Among IG participants, 97% (33/34) reported they would use the LLM again for diagnostic support, and 91% (31/34) found it easy to use.

Conclusion: To our knowledge, this is the first RCT to evaluate the diagnostic assistive potential of LLMs in rheumatology. Providing medical students with access to an LLM significantly improved diagnostic accuracy compared to conventional resources alone. Further research is warranted to determine how LLMs can be implemented to safely empower healthcare professionals as well as patients.

1) What is the day of the week? _____

2) Which of the following best describes your main area of clinical practice or level of training?
- ○ Internal medicine resident - First year
- ○ Internal medicine resident - Second year
- ○ Internal medicine resident - Third year
- ○ Primary care physician

3) How would you identify your race? Select all that apply.
- ☐ American Indian or Alaska Native
- ☐ Asian
- ☐ Black or African American
- ☐ Native Hawaiian or Other Pacific Islander
- ☐ White
- ☐ Other, not listed
- ☐ Prefer not to answer

4) How would you identify your ethnicity?
- ○ Hispanic or latino
- ○ Not hispanic or latino
- ○ Prefer not to answer

5) How would you identify your gender?
- ○ Male
- ○ Female
- ○ Non-binary
- ○ Other
- ○ Prefer not to answer

Please indicate which of the following you identify as barriers preventing you from making vaccine recommendations for patients with rheumatic disease in your clinical practice. Please choose your level of agreement with the following statements as barriers from strongly disagree to strongly agree.

	Strongly disagree	Disagree	Agree	Strongly agree
6) Vaccinating this population was not part of my medical education or training	○	○	○	○
7) I am unsure about the efficacy of vaccines in patients who are on immunosuppression.	○	○	○	○
8) I am unsure about the safety of vaccines for patients who are on immunosuppression.	○	○	○	○
9) I am unsure about the impact of vaccines on the patient's underlying rheumatic disease.	○	○	○	○
10) My clinic visits are already too busy to make vaccine recommendations for this group.	○	○	○	○
11) I believe it is the sole responsibility of the rheumatologist and not the primary care physician to make vaccination recommendations for this population.	○	○	○	○
12) Patients with rheumatic disease are hesitant to accept/discuss vaccinations with me and prefer to discuss them with their rheumatologist	○	○	○	○

13) If there are other barriers you have experienced that prevent you from recommending vaccinations for patients with autoimmune rheumatic disease not listed above please describe them here. _____

14) How many patients with rheumatic disease do you estimate you see in your primary care clinic every year?
- ○ None
- ○ 1-20
- ○ 21-40
- ○ 41-60
- ○ >60

15) Do you ever make vaccine recommendations for patients with rheumatic disease?
- ○ Yes
- ○ No
- ○ I never see patients with rheumatic disease in my clinic.

16) Are you aware of the American College of Rheumatology guidelines from 2022 for vaccinating patients with rheumatic disease?
- ○ Yes
- ○ No

17) Do you use guidelines other than the American College of Rheumatology vaccination guidelines to vaccinate patients with rheumatic disease?
- ○ Yes
- ○ No

18) How confident are you in applying the American College of Rheumatology guidelines in order to vaccinate a patient with rheumatic disease?
- ○ I am not aware of these guidelines
- ○ Not confident at all
- ○ Slightly confident
- ○ Fairly confident
- ○ Completely confident

Figure 1. Needs assessment survey distributed to IM residents and faculty

role in engaging patients in shared decision-making on vaccination, yet the degree of guideline awareness and guideline-concordant practice among internal medicine (IM) trainees is unknown. We performed a needs assessment in an IM residency clinic to inform future educational interventions related to ACR vaccination guideline implementation.

Methods: We reviewed the literature on uptake of ACR vaccination guidelines in IM residency clinic, and barriers to vaccination. Based on barriers described in the literature for vaccinating patients with SARD, we designed an 18-item questionnaire (Figure 1) inquiring about attitudes toward vaccinating patients with SARD, ACR vaccination guideline awareness and barriers to implementation, as well as demographics. The questionnaire was distributed electronically via REDCap to all IM residents and faculty involved in outpatient clinic precepting in a large academic center between 12/2024 – 5/2025. Survey

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1. Barriers to providing vaccinations in IM residency clinic among residents and attendings.

Barrier	Number of Residents Who Agree (n=11)	Percent of Attendings Who Agree (n=13)
Responsibility of the rheumatologist	1 (9%)	1 (8%)
Clinic is too busy	5 (45%)	2 (15%)
Not part of education	8 (73%)	5 (38%)
Patient prefers conversation with rheumatologist	4 (36%)	6 (54%)
Aware of ACR guidelines (percent aware)	3 (27%)	3 (23%)

results were analyzed using descriptive statistics and differences between residents and faculty were examined with the Fisher exact test. The study was deemed exempt by the local Institutional Review Board.

Results: Survey responses were received from 13 out of 35 faculty (37%) and 11 out of 131 residents (8%). Among participants, 79% of faculty compared with 45% of residents reported they felt confident about their knowledge of vaccine efficacy, safety, and impact on disease (p=0.0035). Only 9% of residents and 8% of faculty felt that rheumatologists should be the sole provider of vaccinations for patients with SARD (Table 1). Only 45% of residents and 15% of faculty felt their clinic was too busy to provide vaccines for this population. A total of 73% of residents and 38% of faculty reported they did not receive training in this topic in their medical education. Only 27% of residents and 23% of faculty were aware of the ACR vaccination guidelines. Among residents, 64% reported making vaccination recommendations for this population in their clinic compared with 92% of faculty.

Conclusion: A majority of IM residents and precepting faculty participating in this single-center needs assessment reported making vaccine recommendations in clinic for their patients with SARD, and most respondents felt that vaccine guidance was a shared responsibility between rheumatologists and internists. However, over 70% were unaware of the ACR vaccination guidelines. A potential limitation of this study is the low response rate. These data help inform educational interventions to improve ACR vaccination guideline implementation by IM residents in this setting.

Two Common AI Models Create Poor Rheumatology Board Style Questions

Catherine Deffendall[1], Narender Annapureddy[2], Kevin Byram[2], Erin Chew[2] and Tyler Reese[3], [1]Vanderbilt University, Nashville, TN, [2]Vanderbilt University Medical Center, Nashville, TN, [3]Vanderbilt University Medical Center, Madison, TN

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: Abstracts: Professional Education (0825–0830)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Rheumatology fellows frequently prepare for board examinations using case-based, multiple-choice questions. However, there are few resources with enough questions to prepare and those currently available can be costly. In this pilot study, we aim to evaluate if artificial intelligence (AI) generated questions are suitable for use.

Methods: We provided 5 identical prompts to the free versions of both Gemini and ChatGPT[1,2]. Each prompt requested one board style question using an uploaded PDF of ACR guidelines including glucocorticoid induced osteoporosis, vaccination, interstitial lung disease, rheumatoid arthritis and perioperative management. The following is an example of one such

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1. Average model performance of 5 questions evaluated by 3 Rheumatology Attendings

Question	Combined	Gemini	ChatGPT	p value
On a scale of 1-10 what is your overall rating of this question? (1-10)	5.5	5.72	5.28	0.94
Using Likert scale (1-5), mean				
• Is the question factually correct?	3.53	3.72	3.34	0.76
• Is there enough information provided in the question stem to answer the question?	4	3.92	4.08	1.0
• Is there redundant information in the question stem that could be eliminated? (reverse coded)	4.43	4.6	4.26	0.40
• Are all of the answers approximately the same length?	4.34	4.4	4.28	0.76
• Are the questions clinically relevant?	4.59	4.62	4.56	0.76
• Are the questions easy to understand?	4.5	4.68	4.32	0.21
• Do the wrong answer choices represent commonly mistaken choices in clinical practice?	3.87	3.86	3.88	0.92
• Is the question grammatically correct?	4.65	4.68	4.62	0.76
Is the question negatively worded? (Yes, the question is negatively worded or No, the question is positively worded)	100% No	100% No	100% No	
Compared to the similar question developed using a different model, which question do you prefer?	• 2 questions favored Gemini • 2 questions favored Chatgpt • 2 questions had no agreement*	—	—	

*One participant wrote in "Neither"

prompt, "Using the 2023 American College of Rheumatology clinical practice guidelines for Interstitial Lung Disease create one rheumatology board style question using reasonable alternatives as detractors". AI generated questions were arranged in two separate forms labeled Form 1 (Gemini) and Form 2 (ChatGPT) to blind the reviewer to which AI model created it. Ten rating metrics covering both accuracy and technical aspects of question writing were developed by an experienced question writer. Rating metrics included answer choices on a 5-point likert scale (ranging from strongly disagree to strongly agree) for 8 questions, yes/no choices for if the question was negatively worded, a 10-point scale for overall acceptability of the question and whether the Gemini or ChatGPT question was preferred. Three of the authors, who are board-certified rheumatologists engaged in medical education, independently rated questions on paper surveys. For each of the AI generated questions, the average rating metric of all three interviewers was calculated. This question average was used to calculate overall averages for each AI model. Assuming nonparametric data, Mann Whitney U was used to compare averages between models.

Results: Gemini and ChatGPT created 5 questions each with 4-5 answer choices per question. Attending rheumatologists rated these questions lowest on whether or not the question was factually correct (Combined 3.53 vs Gemini 3.72 vs ChatGPT 3.34) and if the wrong answer choices represented commonly mistaken choices in clinical practice (Combined 3.87 vs Gemini 3.86 vs ChatGPT 3.88). Technical aspects of question writing were the highest rated including if the question was negatively worded (100% No), and if the question was grammatically correct (Combined 4.65 vs Gemini 4.68 vs ChatGPT 4.62). The overall score out of 10 was low for both models (Combined 5.5 vs Gemini 5.72 vs open AI 5.28).

Conclusion: While both AI platforms created 10 grammatically correct board style questions and were rated highly on technical aspects of question writing, rheumatology attendings rated them poorly for correctness, relevant detractors and overall score. Learners should take caution when using AI to study by reviewing the original text or having experts assess questions for accuracy and validity. Improvements could be made with refining prompts and iterative modifications to the questions, however, that was not pursued in the current study.

Abstract Number: 0829

Multi-Center Use of an Online Case-Based Simulation to Evaluate Medical Trainee Use of Diagnostic Imaging and Lab Tests to Correctly Diagnose MSK Complaints

James McCarthey[1], Kyla Driest[2], erin frank[1], Allayne Stephans[1], Stacey Tarvin[3] and Angela Robinson[4], [1]Rainbow Babies and Children's Hospital, Cleveland, OH, [2]Nationwide Children's Hospital, Columbus, OH, [3]Riley Hospital for Children at Indiana University, Indianapolis, IN, [4]Cleveland Clinic Foundation, Cleveland, OH

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: Abstracts: Professional Education (0825–0830)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Our goal is to teach medical trainees high value care concepts and musculoskeletal (MSK) disease states and then implement online case-based simulations to evaluate trainee utilization of laboratory tests and imaging to make diagnoses.

Methods: We recruited pediatric trainees from 4 institutions to participate in this simulation. Learners listened to a lecture on either pediatric MSK complaints or high value care. Participants were then asked to complete an online simulation that presented six vignettes of pediatric MSK complaints and prompted them to select diagnostic tests. The presented cases included rheumatic fever, Lyme arthritis, transient synovitis, Osgood-Schlatter's Disease, juvenile ankylosing spondylitis, and benign nocturnal limb pains of childhood. We analyzed trainee ability to identify the correct diagnosis from the available clinical information compared to pattern of diagnostic evaluation. In addition, we analyzed how exposure to high value care principles affected their likelihood of ordering diagnostic tests. We conducted an exploratory analysis using Student's t-test for comparison of groups, with p-values less than 0.05 judged as statistically significant.

Results: Within the study, 160 trainees started and completed the first case, 90 completed all cases, and 87 completed all cases and the post-simulation survey. 32 received a lecture on high value care (HVC) and 55 received a lecture on pediatric MSK complaints. 41% of trainees selected the correct diagnosis in the rheumatic fever vignette, 47% in the Lyme arthritis vignette, 77% in transient synovitis, 95% in Osgood-Schlatter's disease, 69% in juvenile ankylosing spondylitis, and 92%

Table. Rate of ANA ordering and reaching correct diagnosis and ANA ordering rate between HVC and MSK lecture exposure

Case	ANA ordered (n, %)	ANA ordered and correct dx	ANA not ordered and correct dx	P-value	ANA ordered with HVC* lecture	ANA ordered with MSK** lecture	P-value
1. Rheumatic fever	69/160 (43%)	39%	42%	P = 0.74	21%	51%	p <0.01
2. Lyme disease	20/134 (15%)	60%	45%	P = 0.21	4%	22%	p <0.01
3. Transient Synovitis	8/118 (7%)	63%	78%	P = 0.31	3%	7%	p = 0.14
4. Osgood Schlatter's	7/102 (7%)	71%	97%	P <0.01	1%	9%	p < 0.01
5. Juvenile Ankylosing spondylitis	46/93 (49%)	61%	77%	p = 0.10	10%	59%	p < 0.01
6. Nocturnal growing pains	5/90 (6%)	60%	94%	p < 0.01	2%	5%	p = 0.24

Table 1. Data of ordered ANA with correct diagnosis and ordering of ANA with exposure to HVC vs MSK simulation exposure. p<0.05 is statistically significant *: High Value Care **: Musculoskeletal

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

in growing pains. Among the six cases, antinuclear antibody (ANA) levels were ordered 6 to 49% of the time per vignette (see Table). Ordering an ANA level was associated with a decreased likelihood of selecting the correct diagnosis in Osgood-Schlatter's disease (71 versus 97%, $p < 0.01$) and growing pains (60 versus 94%, $p < 0.01$). For each of the six cases results from ANA ordering was not associated with increases in selecting the correct diagnosis. In all six cases, trainees were less likely to request ANA levels if they were exposed to an HVC lecture prior to simulation, and this was statistically significant in 4 out of 6 vignettes.

Conclusion: Overall, trainees tended to order ANA more frequently in cases with higher diagnostic uncertainty and lower likelihood of selecting the correct diagnosis. Despite this, ordering an ANA had no significant difference on the trainee reaching the correct diagnosis. For the Osgood Schlatter's and growing pains vignettes, there was a higher ratio of correct trainees who did not order an ANA, suggesting that ANA was only ordered if the trainee was uncertain. For test ordering, exposure to lectures on MSK pain in children was associated with increased lab and imaging orders, but exposure to HVC concepts was associated with decreases in testing. In summary, this research is important to share as it provides valuable insights for bettering diagnostic practices among trainees, which ultimately could lead to improved healthcare outcomes for children with MSK disease.

Rheum2Listen: Leveraging Podcasts to Teach Rheumatology to Internal Medical Residents

Nikita Ivanov[1], Beeta Shasti-Nazem[2], Moriah Gottman[1] and Sonam Kiwalkar[3], [1]Legacy Emanuel Internal Medicine Residency Program, Portland, OR, [2]Legacy Salmon Creek Internal Medicine Residency Program, Vancouver, WA, [3]The Vancouver Clinic, Portland, OR

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: Abstracts: Professional Education (0825–0830)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Podcasts are an increasingly popular tool in medical education, shown to match or exceed traditional lectures in short term retention and learner satisfaction. Despite abundant high-quality rheumatology content, no structured podcast-based curriculum exists for internal medicine (IM) residents. This shortfall is noteworthy as rheumatology consistently emerges as one of the weakest areas of knowledge among IM residents. While podcasts are a flexible and engaging learning tool, passive listening alone may limit deeper understanding and long-term retention of key concepts. To address this, we developed a structured rheumatology curriculum that combines high-quality podcasts with active learning worksheets. This dual approach aims to foster greater engagement and enhance durable retention of rheumatology concepts among IM residents.

Methods: Curriculum development was guided by Kern's Six-Step Approach (**Figure 1)**. A targeted literature review conducted by one IM resident and one rheumatologist identified key rheumatology topics for IM residents based on four criteria: poor performance on standardized exams, low self-reported confidence among trainees, perceived importance by rheumatologists, and frequency of rheumatology consultations. These high-yield topics were queried in *Listen Notes*, a

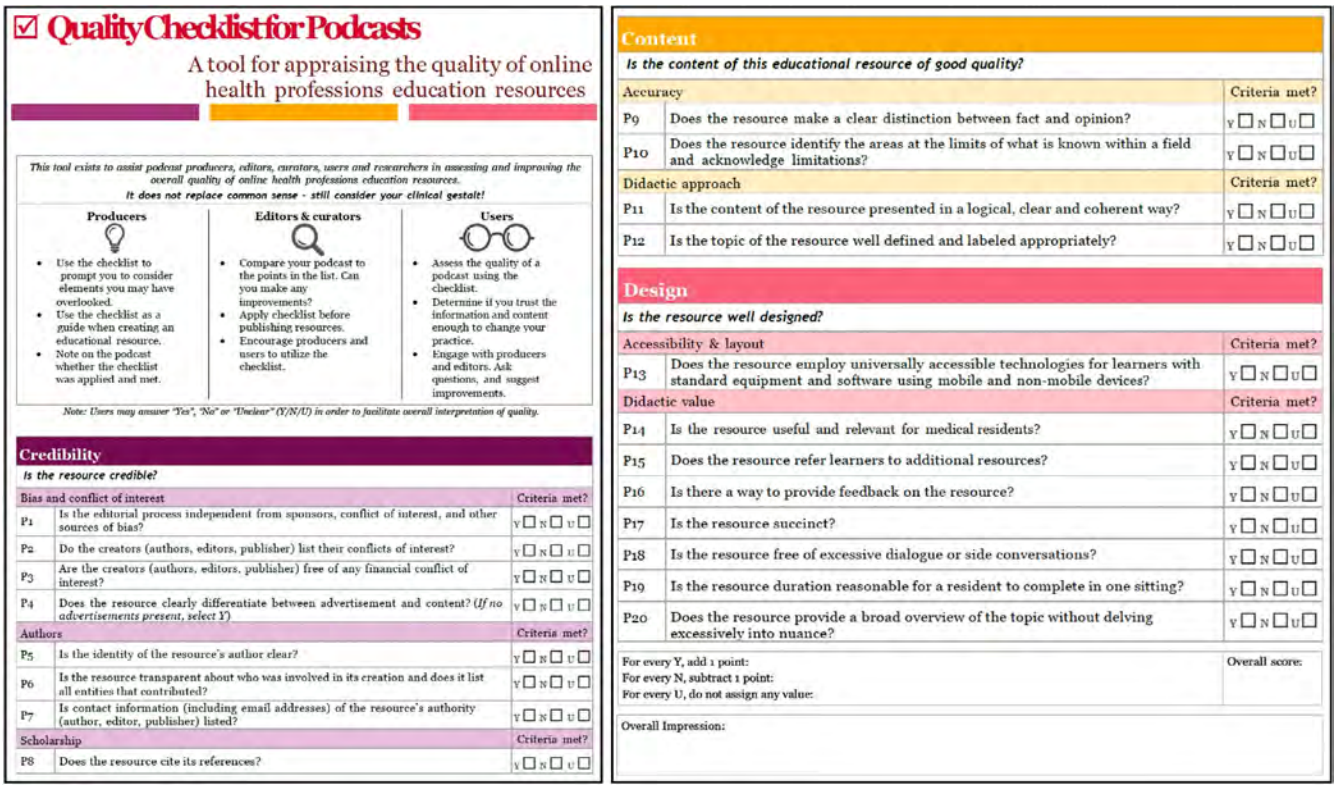
Figure 1. Curriculum development guided by Kern's Six-Step Approach.



☑ Quality Checklist for Podcasts

A tool for appraising the quality of online health professions education resources

This tool exists to assist podcast producers, editors, curators, users and researchers in assessing and improving the overall quality of online health professions education resources.
It does not replace common sense - still consider your clinical gestalt!

Producers
- Use the checklist to prompt you to consider elements you may have overlooked.
- Use the checklist as a guide when creating an educational resource.
- Note on the podcast whether the checklist was applied and met.

Editors & curators
- Compare your podcast to the points in the list. Can you make any improvements?
- Apply checklist before publishing resources.
- Encourage producers and users to utilize the checklist.

Users
- Assess the quality of a podcast using the checklist.
- Determine if you trust the information and content enough to change your practice.
- Engage with producers and editors. Ask questions, and suggest improvements.

Note: Users may answer "Yes", "No" or "Unclear" (Y/N/U) in order to facilitate overall interpretation of quality.

Credibility

Is the resource credible?

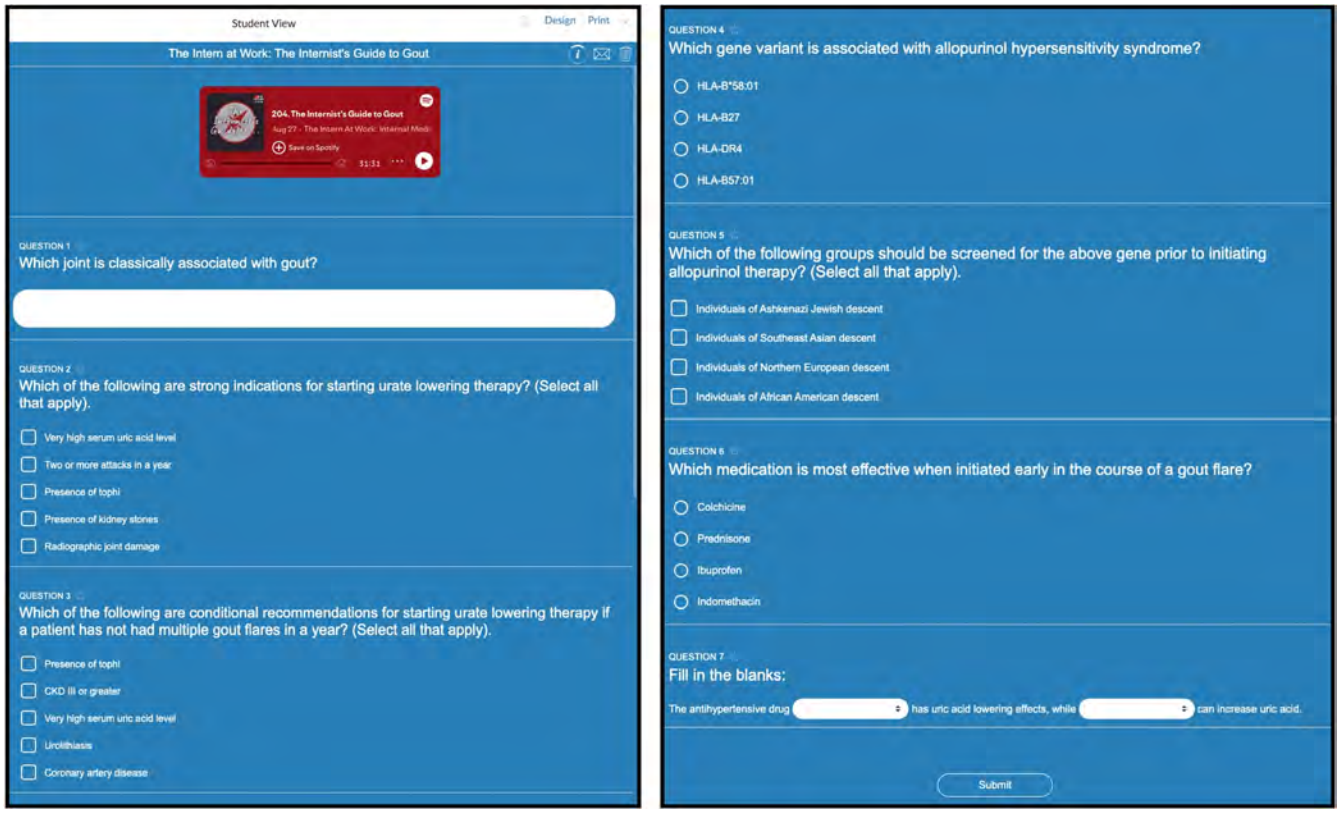

Figure 3. Example of an online quiz with embedded podcast episode.

comprehensive podcast database. Podcasts affiliated with an academic institution and targeting a generalist physician audience were prioritized. Additional episodes were identified through manual screening of titles and show notes from reputable independent podcasts. Three IM residents independently assessed each episode using a modified, validated rubric "The Quality Checklist for Health Professions Blogs and Podcasts," evaluating quality, accuracy, and educational relevance with a scoring system (**Figure 2**). Top episodes were selected based on average scores, score variability, succinctness, and alignment with the target audience. Using backward design, an accompanying online worksheet was developed to encourage active learning. This incorporated multiple-choice, short-answer, and fill-in-the-blank questions (**Figure 3**).

Results: Nine core topics were included in the final curriculum: gout, osteoarthritis, rheumatoid arthritis, spondyloarthritis, lupus, fibromyalgia, vasculitis, rheumatologic lab interpretation, and approach to joint pain. From an initial pool of 25 to 300 episodes per topic, 30 underwent evaluation using the rubric **(Figure 2)** and 12 were selected for inclusion in the study.

Conclusion: A structured, podcast-based rheumatology curriculum has been developed for IM residents, integrating high-quality curated episodes with active learning worksheets. This dual approach is designed to increase engagement and promote long-term retention of core rheumatology concepts. The curriculum is currently being piloted with IM residents, with plans for future refinement and expansion to other institutions.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: Abstracts: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes II: Look What You Made Me Do (Prediction) (0831–0836)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Preclinical phases of rheumatoid arthritis (RA), including therapeutic interventions, have been extensively studied. There is a growing focus on individuals at risk for psoriatic arthritis (PsA). We previously observed changes in monocyte subsets in the peripheral blood of individuals at risk for RA. CD11c and HLA-DR reflects monocyte activation and both are involved in inflammatory autoimmune disease mechanisms. The objective of this study was to evaluate their expression on subsets of monocytes in individuals at risk of RA and PsA.

Methods: The study included 284 individuals at risk of RA (having arthralgia with either ACPA positivity and/or meeting EULAR criteria for clinically suspect arthralgia), 37 individuals at risk of PsA (identified via PEST questionnaire and considered at risk based on psoriasis severity) and 57 ACPA-negative healthy controls (HC). All at-risk individuals had no arthritis on the examination of 66 joints at baseline. Peripheral blood samples were analyzed by flow cytometry. Monocytes were categorized into classical (CD14++CD16–), intermediate (CD14++CD16+/++), or nonclassical (CD14–/+CD16++) subsets. The membrane expression of CD11c and HLA-DR was quantified in each subset as median fluorescence intensity. Data were analyzed using the Mann-Whitney test and Kruskal-Wallis test with Dunn's post-hoc test.

Results: Of the 284 individuals at risk of RA, 52 developed clinical arthritis (progressors) within a median of 9 months of follow-up and after 30.5 months of symptoms duration. Of the remaining individuals without arthritis, the 217 with a symptoms duration longer than 12 months were classified as non-progressors. Among the 37 individuals at risk of PsA (PSA-risk), only 1 progressed to PsA within 7 months of follow-up and after 44 months of symptom duration. There were no significant differences in CD11c or HLA-DR expression between RA progressors and non-progressors in any of the monocyte subsets. However, compared to PsA-risk and HC, individuals at risk of RA (RA-risk) had significantly lower expression of CD11c in all monocyte subsets, regardless of progression to arthritis or ACPA status. PsA-risk individuals showed a trend to higher CD11c expression on classical and nonclassical monocytes compared to HC. Conversely, HLA-DR expression on these monocyte subsets was significantly higher in RA-risk compared to PsA-risk individuals, with a trend towards higher expression on intermediate monocytes. HLA-DR expression was lower in all monocyte subsets in PsA-risk individuals compared to HC.

Conclusion: Individuals at risk of RA exhibit lower expression of the pro-inflammatory integrin CD11c and higher expression of major histocompatibility complex HLA-DR in monocytes compared to individuals at risk of PsA. These findings suggest distinct immune activation mechanisms in RA and PsA, with elevated CD11c expression in PsA-risk individuals potentially reflecting ongoing innate inflammatory responses in the skin, while increased HLA-DR expression in RA-risk individuals may indicate adaptive immune responses involved in RA pathogenesis.

Session Title: Abstracts: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes II: Look What You Made Me Do (Prediction) (0831–0836)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Anti-Cyclic Citrullinated Peptide (anti-CCP) antibodies are one of the strongest risk factors for the development of rheumatoid arthritis (RA). Anti-CCP antibodies are generated against citrullinated proteins, which arise when peptidylarginine deiminases (PADs) make post-translational modifications to proteins by the deamination of arginine residues to citrulline. PAD2 and PAD4 isomer expression is associated with RA and serum anti-PAD4 antibodies are strongly associated with anti-CCP antibody positivity and aggressive disease phenotype. However, the specific role of serum PAD4 in anti-CCP antibody positive (CCP+) at-risk individuals who do not have synovitis, and its relationship with arthritis development, is unclear.

Our objectives were to (i) investigate baseline serum PAD2/4 levels in CCP+ at-risk individuals with musculoskeletal symptoms but no synovitis, compared with CCP+ early RA patients and healthy controls and (ii) to investigate the relationship between serum PAD2/4 levels and future arthritis development.

PAD4 level (mean (ng/mL), SD)	13.3 ± 18.1	31.7 ± 49.2 CCP+ at-risk future non-progressor: 13.3 ± 14.3 CCP+ at-risk future progressor: 42.4 ± 58.4	46.5 ± 69.9	Healthy control vs CCP +ve at-risk: 0.084[d] CCP +ve at-risk vs Early RA: 0.243[d] **Healthy control vs Early RA: 0.00922[d]**

Methods: Stored serum samples were selected from the Leeds CCP study. We selected: (i) CCP+ at-risk individuals with high anti-CCP antibody levels (>100 U/ml) and Early Morning Stiffness (EMS) lasting ≥30 minutes (n=79) (ii) early, treatment-naïve RA patients (n=34) and (iii) asymptomatic healthy controls (n=44). Follow-up data was collated for all CCP + at-risk individuals to determine future arthritis progression status. PAD2/4 levels were assayed via Enzyme-linked Immunosorbent Assay (ELISA), performed in triplicate, following manufacturer's instructions, Cayman Chemicals PAD2 (Item No. 501450) and PAD4 (Item No. 501460). All results were analysed using R (version 4.3.1).

Results: All groups were balanced for age, sex and smoking status (Table 1). Anti-CCP antibody levels and duration of EMS were similar for CCP+ at-risk individuals and early RA patients (Table 1). PAD4 but not PAD2 levels were higher in early RA

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

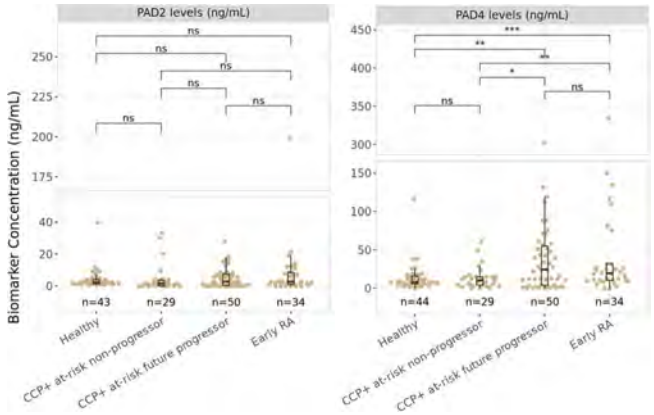

Figure 1 – PAD2 and PAD4 levels according to patient group. Plot completed via Wilcoxon rank sum test with no additional covariate adjustments. Definitions: ns: no statistical significance; * statistical significance at p<0.05; **: statistical significance at p<0.01; ***: statistical significance at p<0.001.

patients compared with healthy controls (p=0.00922). There was no statistically significant difference in PAD4 levels between CCP+ at-risk individuals and healthy controls (p=0.084). However, when CCP+ at-risk individuals were separated according to future arthritis progression status, a significant increase in PAD4 levels in future progressors (n=50) compared to both future non-progressors (n=29) (p=0.022) and healthy controls (p=0.01) was observed (Figure 1). PAD4 levels were similar in healthy controls and future non-progressors (p=0.888) as well as in future progressors and early RA patients (p=0.975). There was no statistically significant difference in PAD2 levels between any of the groups.

Conclusion: These data suggest serum PAD4 levels are increased in CCP+ at-risk individuals who progress to RA compared with CCP+ future non-progressors and healthy controls. Serum PAD4 levels are also similar in Pre-RA and RA. PAD4 levels may therefore have utility in predicting arthritis development and PAD4 may also be a potential therapeutic target for arthritis prevention in those at high risk.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: Abstracts: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes II: Look What You Made Me Do (Prediction) (0831–0836)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: The presence of serum anti-CCP-IgG antibodies can predict the future development of clinically evident RA. Neutrophil extracellular trap (NET) formation can be a source of extracellular citrullinated (cit) proteins that can be antigenic targets of anti-CCP. Our group previously reported increased NET formation of sputum neutrophils from the lungs of individuals with RA and at-risk for RA that correlated with sputum anti-CCP levels. The objective of this study was to evaluate the relationship between sputum anti-CCP, sputum NET-associated proteins, and the risk and timing of transitions from an 'at-risk' state of systemic autoimmunity to clinical RA.

Methods: We included 98 individuals who were serum anti-CCP-IgG(+) (CCP3, Werfen), without examination evidence of inflammatory arthritis (IA) at baseline, had at least one follow-up visit with a joint examination, and had a baseline induced sputum sample. Nineteen individuals (19.4%) met 2010 ACR/EULAR classification criteria for RA (Classified RA) and 71 (72.4%) did not develop RA after at least 12 months of follow-up. There were 8 individuals who developed unclassifiable IA and were excluded from this analysis. Baseline sputum cell-free supernatant was tested by ELISA for anti-CCP-IgG (CCP3) and anti-CCP-IgA (CCP3.1 plate with research modification to detect IgA only). In a subset with adequate sample remaining, sputum supernatant was tested by immunoassays for NET-associated proteins, including calprotectin (Werfen), extracellular DNA (exDNA, Invitrogen), extracellular neutrophil elastase (exNE, Invitrogen), nucleosomes (Nu.Q H3.1, Volition) and cit-nucleosomes (Nu.Q H3R8Cit, Volition).

Results: Baseline sputum anti-CCP levels were higher in individuals who later transitioned to Classified RA compared to those who did not develop RA (anti-CCP-IgA, p< 0.001; anti-CCP-IgG, p=0.003, Table 1, Figure 1A-B). Sputum nucleosome and cit-nucleosome levels were also higher in individuals who transitioned to RA (Table 1, Figure 1C-D), but were not independently associated after adjusting for sputum anti-CCP-IgA level. Within individuals who transitioned to RA, sputum calprotectin and exNE levels correlated with time to RA onset (Figure 2A-B), with lower levels in those who developed

Table 1. Baseline clinical features, serologic biomarkers and sputum biomarkers associated with developing Classified RA in serum anti-CCP-IgG positive individuals

	Did not develop RA (N=71)	Developed Classified RA (N=19)	p-value
Clinical Features			
Age, in years	62 (46-70)	57 (44-65)	0.360
Female	53 (74.6)	15 (78.9)	1.000
Ever smoker	23 (32.4)	4 (21.1)	0.453
Chronic lung disease	5 (7.0)	3 (15.8)	0.360
Serologic Biomarkers			
≥ 1 shared epitope allele[1]	30 (44.8)	12 (63.2)	0.157
Serum anti-CCP-IgG level, in ELISA units	43.1 (28.2-85.1)	163.3 (48.3-870.4)	**<0.001**
Serum RF-IgM or RF-IgA+	20 (28.2)	13 (68.4)	**0.001**
Plasma calprotectin, in ug/mL	1.0 (0.8-1.6)	1.4 (0.9-1.7)	0.110
Sputum Biomarkers[2]			
Sputum anti-CCP-IgA level	21.6 (15.6-34.9)	52.9 (26.3-172.4)	**<0.001**[3]
Sputum anti-CCP-IgG level	18.0 (18.0-18.0)	18.0 (18.0-95.8)	**0.003**
Sputum calprotectin, in ug/mL[4]	47.2 (21.0-93.4)	44.5 (28.4-127.3)	0.477
Sputum exDNA[4]	1,543.8 (604.3-3,069.9)	1,778.7 (696.9-4,184.3)	0.620
Sputum exNE[4]	1,461.9 (835.2-3,150.4)	3,335.9 (788.9-7,529.9)	0.125
Sputum nucleosomes, in ng/mL[5]	157.2 (0.0-574.8)	530.5 (185.6-3,626.5)	**0.023**
Sputum citrullinated nucleosomes, in ng/mL[5]	43.1 (12.8-72.7)	106.4 (34.4-770.6)	**0.046**

All values are median (IQR) or N (%)

1. SE testing was available for all 19 who developed RA and 67 of 71 who did not develop RA.
2. All met the definition for adequate sputum sample (i.e. <80% squamous epithelial cells on cell differential)
3. Sputum anti-CCP-IgA level remained significantly associated with development of RA after adjusting for serum anti-CCP level and serum RF positivity (p=0.006)
4. Sputum calprotectin, exDNA and exNE levels were available in 17 who developed RA and 66 who did not develop RA
5. Sputum nucleosome levels were available in 14 who developed RA and 64 who did not develop RA. sputum cit-nucleosomes levels were available in 12 who developed RA and 63 who did not develop RA

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

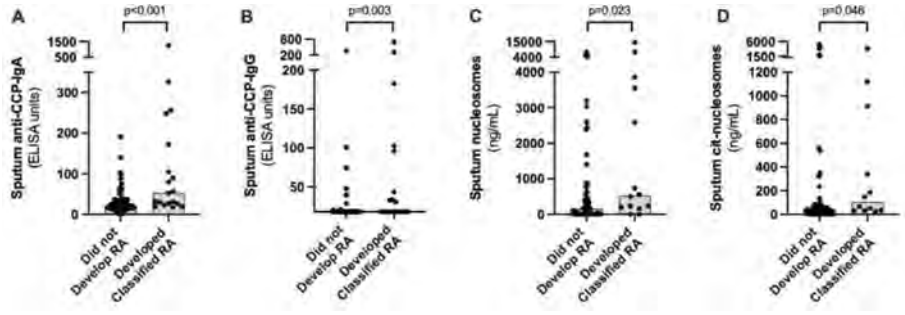

Figure 1. Sputum anti-CCP and nucleosome levels in individuals at-risk for RA. The figure depicts baseline sputum anti-CCP-IgA (Panel A), sputum anti-CCP-IgG, (Panel B), sputum nucleosome (Panel C) and sputum citrullinated nucleosome (cit-nucleosome, Panel D) in serum anti-CCP-IgG positive individuals who did vs. did not develop Classified RA during follow-up. P-values calculated by Wilcoxon rank sum test.

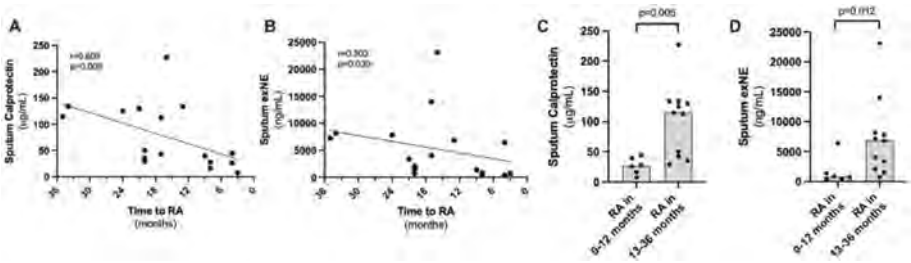

Figure 2. Sputum calprotectin and extracellular neutrophil elastase (exNE) levels associated with timing of RA onset. In serum anti-CCP-IgG positive individuals who developed Classified RA within 36 months of follow-up, the figure depicts correlations between time to RA onset (in months from baseline visit) and baseline sputum calprotectin (Panels A) or sputum exNE (Panels B). P-values by Spearman's correlation. Baseline sputum calprotectin (Panel C) and sputum exNE (Panel D) levels are compared between individuals who developed Classified RA in 0-12 months vs. 13-36 months after baseline sputum. P-values calculated by Wilcoxon rank sum test.

RA within 12 months (Figure 2C-D). Sputum anti-CCP-IgA, exDNA, nucleosome, and cit-nucleosome and plasma calprotectin levels did not correlate with time to RA onset (p >0.05).

Conclusion: We found that anti-CCP and NET-associated nucleosomes in the sputum are increased in serum anti-CCP3+ individuals who transitioned to Classified RA. Sputum NET-associated proteins calprotectin and exNE correlated with time to RA onset, though surprisingly were lower in the 12 months preceding RA onset. These data support an important role of lung immunobiology and NETosis in transitions from systemic autoimmunity to RA and identify sputum biomarkers that can enhance prediction and timing of RA. Longitudinal studies are needed to determine whether decreasing sputum calprotectin and exNE levels result from enhanced local clearance and whether this process plays a role in imminent RA onset.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: Abstracts: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes II: Look What You Made Me Do (Prediction) (0831–0836)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: The impact of genetic risk factors on rheumatoid arthritis (RA) phenotype is incompletely understood. Comparing individual genetic variants associated with RA susceptibility to a polygenic score (PGS), we hypothesized that higher genetic risk for RA would correlate with more severe disease.

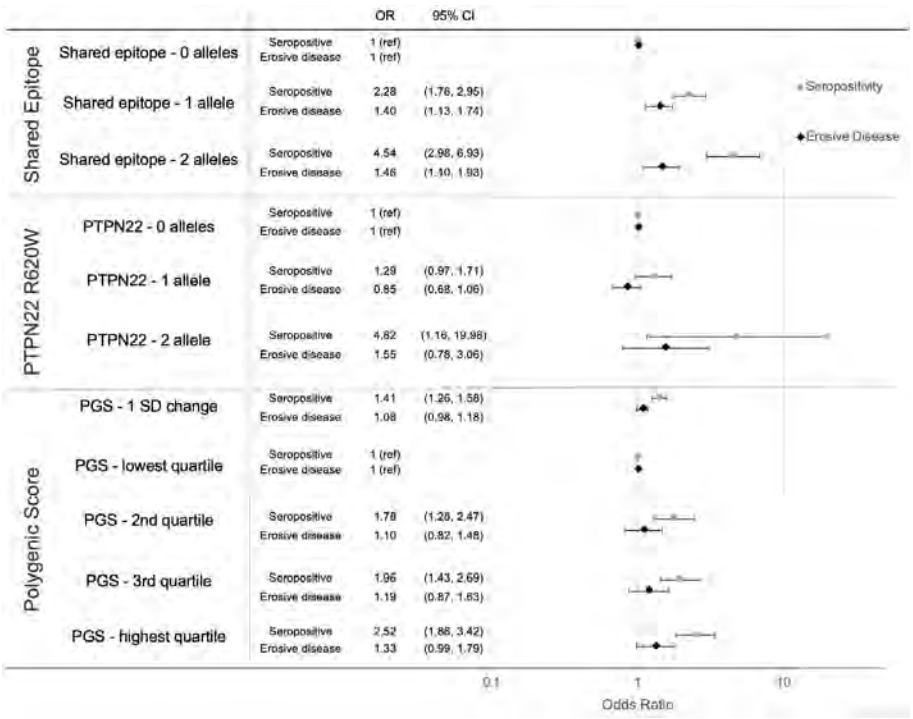

Figure 1. Effect of HLA-DRB1 SE, PTPN22 R620W, and non-HLA PGS on seropositivity and erosive disease at VARA enrollment. Effect determined by linear regression in a genotype model, adjusted for age, sex, and top 5 PCs of population structure. All genetic models demonstrated increased odds for seropositivity, whereas only SE was significantly associated with erosive disease. Abbreviations: PGS – polygenic score SE – shared epitope PC – principal components OR – odds ratio CI – confidence interval

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

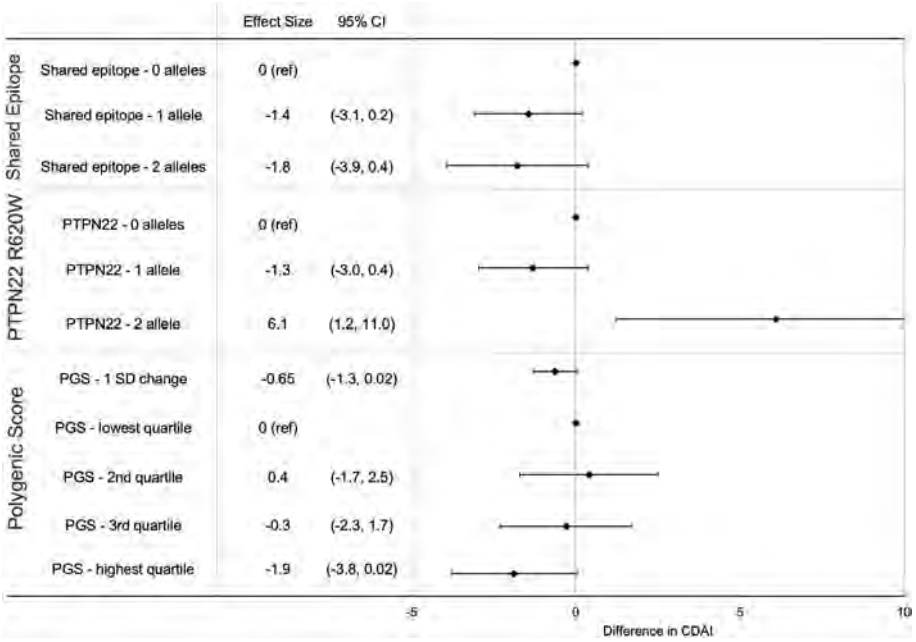

Figure 2. Effect of SE, PTPN22 R620W, and non-HLA PGS on CDAI at enrollment. Participants with 2 copies of PTPN22 demonstrated a higher CDAI (p = 0.014). A trend toward a negative association with CDAI is observed for 1 standard deviation change of PGS (p = 0.057) and in those at the highest quartile of risk by PGS) (p = 0.053). Effect at enrollment determined by linear regression in a genotype model, adjusted for age, sex, and top 5 PCs of population structure. Abbreviations: CDAI – clinical disease activity index PGS – polygenic score SE – shared epitope PC – principal components CI – confidence interval

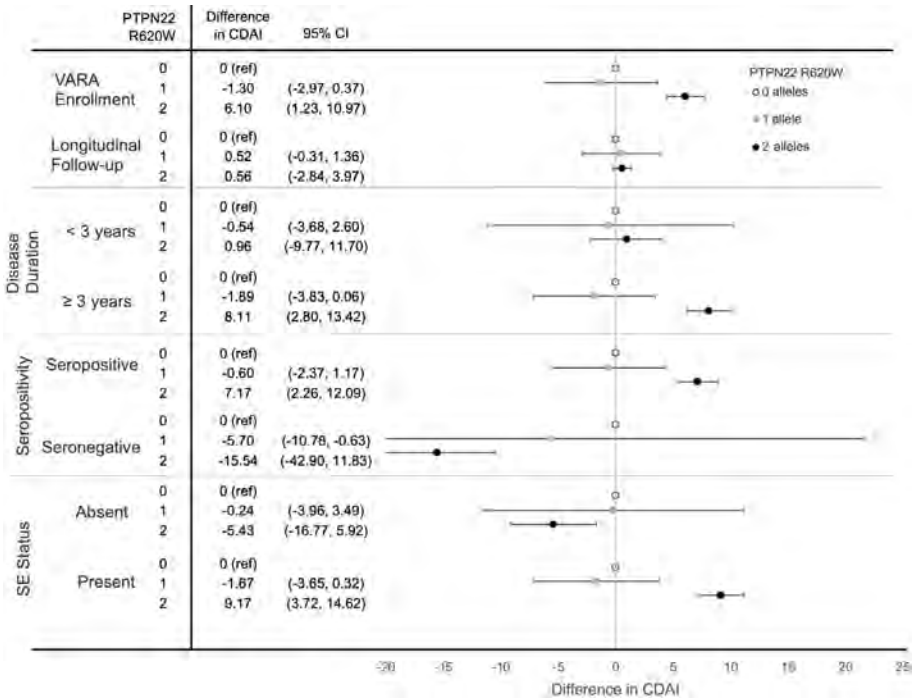

Figure 3. Subgroup Analysis for PTPN22 R620W and CDAI. Subgroup analysis performed by stratification in linear regression in a genotype model, adjusted for age, sex, and top 5 PCs of population structure. Longitudinal disease activity was analyzed using generalized estimating equations adjusting for these same factors as well as enrollment CDAI. Participants with 2 copies of PTPN22 demonstrated a higher CDAI at enrollment, but not in longitudinal disease activity corrected for the enrollment CDAI. This effect was predominant in those with seropositive RA, those with 1 or 2 shared epitope HLA alleles, and with disease duration ≥ 3 years. There was not a significant effect of genotype in early disease. Those with 1 PTPN22 R620W allele with seronegative RA had significantly lower disease activity, and a trend toward lower disease activity in those who were seronegative or without shared epitope with 2 PTPN22 R620W alleles, though this was not statistically significant. Abbreviations: CDAI – clinical disease activity index VARA – Veterans Affairs Rheumatoid Arthritis Registry SE – shared epitope PC – principal components

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We genotyped participants from the Veterans Affairs RA (VARA) registry, a prospective multicenter RA cohort. We evaluated the association between an existing non-HLA PGS (PGS Catalog PGS002745) and RA disease activity measured by the clinical disease activity index (CDAI), using linear regression adjusted for sex, age, and genetic background. We applied similar linear models to evaluate the association between individual genetic risk factors *PTPN22* R620W or *HLA*-DRB1 shared epitope (SE) and disease activity scores. We tested the association with these genetic risk factors and binary outcomes (RF or anti-CCP seropositivity, erosive disease) at enrollment using logistic regression adjusted for the same covariates. To understand the potential for gene-phenotype interactions, we tested for an interaction of genetic exposure with a) disease duration and b) seropositivity (RF or anti-CCP). We also tested for interaction of SE with *PTPN22* R620W and PGS.

Results: Among 2597 VARA participants, 50 (2%) were homozygous for *PTPN22* R620W, and 1603 (62%) had a PGS >50th percentile compared to the 1000 Genomes reference population. *PTPN22*, SE, and the PGS were strongly associated with seropositivity (PGS OR= 1.41, 95% CI 1.26-1.58, p< 0.001, **Fig. 1**). Those with 2 *PTPN22* alleles had higher disease activity (CDAI β 6.10, 95% CI 1.23-10.97, p=0.014); no difference was observed for those with one *PTPN22* allele, SE, or by PGS (**Fig. 2**).

Higher genetic risk appeared more strongly associated with disease severity in those with longer disease duration at enrollment. The association between 2 copies of *PTPN22* and higher disease activity was only observed in those with >3 years disease duration (**Fig. 3**). The association between 2 *PTPN22* alleles and higher disease activity was also primarily observed among seropositive patients (**Fig. 3**).The association between presence of 2 *PTPN22* alleles and higher disease activity was stronger in the presence of SE (CDAI: effect with SE 9.39, 95% CI 3.75-15.0, p interaction 0.01, **Fig. 3**). No interactions were observed between seropositivity or SE and the PGS.

The presence of SE was associated with erosive disease at study enrollment [1 allele: OR 1.40, 95% CI 1.13-1.74, p = 0.002; 2 allele OR 1.46, 95% CI 1.10-1.93, p = 0.009]; higher PGS and *PTPN22* were not (**Fig. 1**). A higher PGS was associated with higher odds of erosive disease in those with >3 years duration (1 SD change OR 1.12, 95% CI 1.01-1.26, p = 0.035), but not among those with shorter disease duration.

Conclusion: Genetic risk factors for RA demonstrate heterogeneous associations with resultant disease phenotypes among RA patients. Genetic effects were most significant after the early RA period and among those who were seropositive. Individual genetic variants and pathway-specific genetic risk may be more informative than the genome-wide genetic risk for RA in understanding phenotype and disease activity in RA.

Session Date: Sunday, October 26, 2025

Session Title: Abstracts: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes II: Look What You Made Me Do (Prediction) (0831–0836)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Glycosylation is a post-translational enzymatic process important for protein function. Glycosylation patterns range from anti-inflammatory to inflammatory, and have been used to derive a measure of biologic age, the Glycan age (GlycAge). In patients with rheumatoid arthritis (RA), the immunoglobulin G (IgG) glycome is characterized by decreased galactosylation, possibly reflecting RA immune dysfunction. Our goals were to identify 1) alterations in the IgG glycome in patients with early RA (symptom duration < 6 months), 2) changes in glycome following a supervised lifestyle modification

Table 1: Clinical, physiologic, and glycome characteristics in patients with early RA and age-, sex-, and BMI-matched controls

**all values in Table 2 are reported as percent change*

in older RA patients with overweight/obesity, and 3) associations between RA glycome and clinical and physiologic parameters.

Methods: IgG glycome was analyzed using ultra-high-performance liquid chromatography (GENOS) and plasma samples from two recent studies: 1) MusculRA: early RA (n=10) versus age-, sex- and BMI-matched healthy controls (n=10); and 2) SWET-RA: older, established RA with overweight/obesity (n=20), randomized to 16 weeks of remotely supervised weight loss and exercise training or lifestyle counseling. Group differences and post-intervention changes were evaluated using t-tests and Wilcoxon tests, depending on data normality. Participants with RA from MusculRA and SWET-RA studies were combined (n=29; one participant completed both studies) to analyze associations between glycome with clinical and physiological parameters using linear regression, controlling for age and sex. Relationships between parameter changes following SWET-RA study lifestyle intervention (n=20) were assessed using Spearman's correlations.

Results: As compared to age-matched controls (mean age=53.2 years), early RA (mean age=53.6 years) had a GlycAge corresponding to 18.1±22.6 years older (p=0.03) (Table 1). Early RA GlycAge was not significantly different from older, established RA (mean age=66.65 years; p=0.32). RA GlycAge was negatively associated with cardiorespiratory fitness (VO_2 peak, mL/kg/min; beta=-1.66, p=0.005) and lean mass (kg; beta=-1.77, p=0.004). Baseline IgG digalactosylated glycan (IgG-G2) was positively associated with log lean mass (beta=17.9, p=0.008) and right hand grip strength (beta=0.16, p=0.04), and negatively associated with log CRP (beta=-1.05, p=0.02) and ESR (beta=-0.06, p=0.02). While diet and exercise lifestyle intervention did not significantly alter overall RA GlycAge (mean GlycAge percent change=1.7±7.9, p=0.34; Table 2), reductions in GlycAge associated with increases in lean mass (Spearman rho=-0.46, p=0.04).

Conclusion: Changes in the RA glycome occur early in the RA disease process, leading to almost two decades of biological aging via GlycAge. Our findings suggest the IgG glycome and GlycAge may be useful as biomarkers for RA diagnosis and

Session Title: Abstracts: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes II: Look What You Made Me Do (Prediction) (0831–0836)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: RA is associated with premature aging and frailty. Growth differentiation factor-15 (GDF-15) is a biomarker that increases in response to cellular stress and inflammation and is associated with cachexia, frailty, and death in the general population. A recent trial of an anti-GDF-15 antibody demonstrated improved weight gain and lower cachexia symptoms in participants with cancer[1]. GDF-15 is elevated in RA compared to controls and is associated with disease activity. We aimed to evaluate the association of GDF-15 with frailty and death in a national RA cohort.

Methods: Participants from the Veterans Affairs Rheumatoid Arthritis (VARA) Registry, a multicenter prospective RA cohort, enrolled between 1/2003 through 12/2022 with baseline GDF-15 levels were included. Frailty was measured at baseline and annually throughout observation using the VA Frailty Index (VA-FI), a validated deficit accumulation score based on >6000 diagnostic codes. Participants were categorized as frail using the established VA-FI cutoff of >0.2. Vital status was assessed using the National Death Index. Serum GDF-15 was measured on biobanked baseline samples using the MesoScale platform and divided into quartiles for analysis. Multiple imputation with chained equations addressed missing data. Multivariable logistic regression evaluated the cross-sectional association between GDF-15 quartile and frailty. Multivariable Cox modeling also evaluated the association between GDF-15 quartile and incident frailty or death, in those not frail at baseline. Both models controlled for age, sex, race, BMI, disease duration, DAS28ESR, CCP positivity, prednisone use, csDMARD use, b/tsDMARD use and Rheumatic Disease Comorbidity Index (RDCI).

Results: In total, 2,866 participants were included in the cross-sectional analysis (mean age of 64.6±11.1, 88% male, 76% White and 29% frail) (Table 1). Compared to the lowest quartile, those in the highest quartile of GDF-15 were older (70.9±9.2 vs. 56.3±11.5 years), more frequently male (95% vs. 74%), White (80% vs 68%), had longer disease duration (12.7±12.0

Values are reported as mean (SD) or n (%)
[1]Other: Included American Indian or Alaskan Native, Asian, Native Hawaiian or Other Pacific Islander as well as missing.
Abbreviations: BMI: Body Mass Index; DAS28-ESR: Disease Activity Score in 28 joints with Erythrocyte Sedimentation Rate; RDCI: Rheumatic Disease Comorbidity Index; anti-CCP: Cyclic Citrullinated Peptide antibody; RF: Rheumatoid Factor; csDMARD: conventional synthetic Disease-Modifying Antirheumatic Drug; b/tsDMARD: biologic/targeted synthetic Disease-Modifying Antirheumatic Drug.

vs. 9.6±10.0), and had more comorbidities (RDCI 4.1±1.8 vs. 2.6±1.9). Compared to the lowest quartile, the 3rd quartile of GDF-15 was associated with 1.5 times the odds of frailty (aOR 1.50 [95%CI 1.1-2.1], p=0.016) and the highest quartile was associated with 2.2 times the odds of frailty (aOR 2.18 [95%CI 1.57-3.04], p< 0.001) (Figure 1). The incident frailty subcohort was comprised of 2,448 participants (mean age 62.7±11.2), of whom 61% (N=1,493) became frail (N=1130) or died (N=363) over 13,631 person-years of observation. Compared to the lowest quartile, the highest quartile of GDF15 was associated with a 2.6-fold increase in the risk of incident frailty or death (aHR: 2.59, 95%CI 1.68-3.98, p< 0.001) (Figure 2).

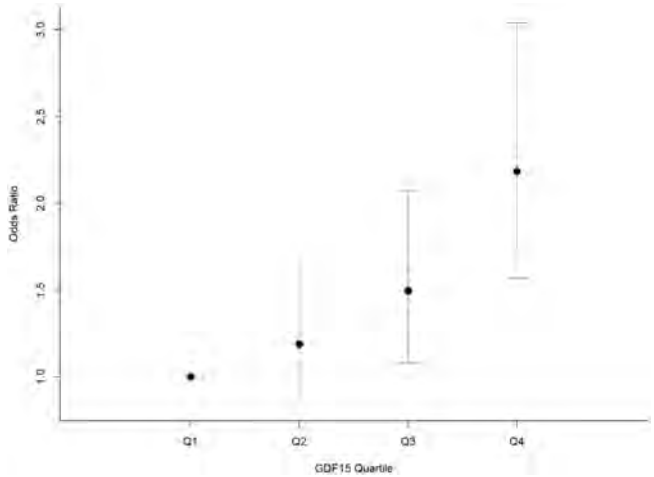

Figure 1. Adjusted logistic regression models evaluating the cross-sectional association between baseline GDF-15 quartiles and frailty at baseline. Models were adjusted for baseline age category, sex, race, BMI category, RDCI, disease duration, DAS28ESR, anti-CCP positivity, prednisone use, csDMARD use, and b/tsDMARD use. Trend analysis p<0.0001.

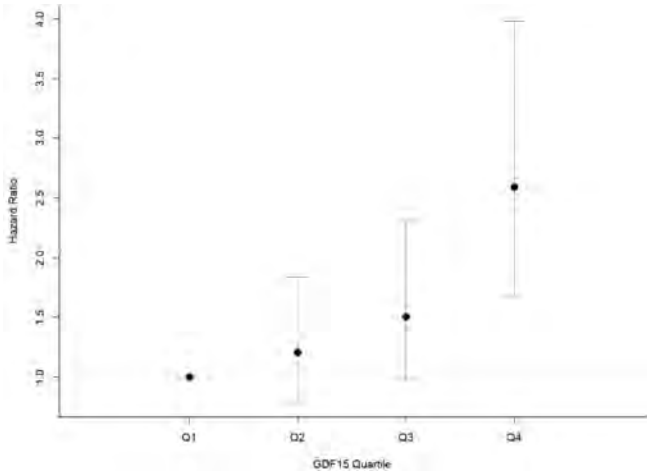

Figure 2. Adjusted Cox models evaluating the longitudinal association between baseline GDF-15 quartiles and incident frailty or death (N=1,493). Models were adjusted for baseline age category, sex, race, BMI category, RDCI, disease duration, DAS28ESR, anti-CCP positivity, prednisone use, csDMARD use, and b/tsDMARD use. Trend analysis p<0.0001.

Conclusion: Elevated GDF-15 was associated with baseline frailty and predicted incident frailty or death in a large RA cohort, independent of important demographic and disease characteristics. Further work is needed to evaluate the effect of GDF-15 on frailty onset to determine its relevance as a therapeutic target in at-risk individuals with RA.

Abstract Number: 0837

Risk of New Proteinuria in Next Ten Years in SLE

Michelle Petri[1], Ilayda Demirayak[2], Andrea Fava[3], Daniel Goldman[1] and Laurence Magder[4], [1]Johns Hopkins University School of Medicine, Timonium, MD, [2]Istanbul University, Istanbul, Turkey, [3]Johns Hopkins University, Baltimore, MD, [4]University of Maryland, Baltimore, Baltimore, MD

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: Abstracts: Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes I: Advances in Nephritis (0837–0842)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: The current 2024 ACR Lupus Nephritis guidelines recommend checking the urine protein to creatinine ratio (UPCR) every 6-12 months. Early recognition of lupus nephritis (LN), though, would lead to earlier introduction of treatment and better outcomes. A risk formula to project a patient's risk of incident proteinuria within 10 years of SLE diagnosis would allow more frequent UPCR checks in the highest risk population.

Table 1. Association between various manifestations in the first year after SLE diagnosis and eventual incidence proteinuria

Variable	Comparison	Hazard Ratio (95% CI)	P-value
Age of SLE diagnosis	30-44 vs <30	0.62 (0.48, 0.80)	0.0002
	45-59 vs <30	0.51 (0.32, 0.80)	0.0032
	60+ vs ,30	0.95 (0.35, 2.59)	0.9266
Race	Black vs. White	1.98 (1.58, 2.49)	<.0001
	Other vs. White	3.40 (2.42, 4.76)	<.0001
Sex	Male vs. Female	1.54 (1.09, 2.19)	0.0155
Anticardiolipin	Present vs. Absent	0.84 (0.58, 1.21)	0.3382
Anti-dsDNA	Present vs. Absent	1.91 (1.53, 2.38)	<.0001
Low C3	Present vs. Absent	1.85 (1.43, 2.39)	<.0001
Low C4	Present vs. Absent	2.08 (1.62, 2.68)	<.0001
Anti-Sm	Present vs. Absent	3.51(2.83, 4.35)	<.0001
Anti-RNP	Present vs. Absent	2.65 (2.15, 3.28)	<.0001
Anti-Ro	Present vs. Absent	1.62 (1.31, 2.00)	<.0001
Anti-La	Present vs. Absent	1.35 (1.02, 1.79)	0.0343
Lupus anticoagulant	Present vs. Absent	0.58 (0.32, 1.06)	0.0774
Coombs	Present vs. Absent	1.13 (0.75, 1.70)	0.5453
Anemia	Present vs. Absent	1.47 (1.16, 1.87)	0.0017
Hemolytic Anemia	Present vs. Absent	1.33 (0.78, 2.28)	0.2921
Hematuria	Present vs. Absent	1.60 (0.93, 2.73)	0.0869
Leukopenia	Present vs. Absent	1.12 (0.87, 1.43)	0.3954
Lymphopenia	Present vs. Absent	1.16 (0.87, 1.55)	0.3008
Thrombocytopenia	Present vs. Absent	0.80 (0.54, 1.18)	0.2565
Lymphadenopathy	Present vs. Absent	1.22 (0.93, 1.61)	0.1554
Abn. Liver Function	Present vs. Absent	1.06 (0.73, 1.56)	0.7468
Discoid Rash	Present vs. Absent	0.89 (0.65, 1.21)	0.4481
Malar Rash	Present vs. Absent	1.03 (0.83, 1.27)	0.7794
Photosensitivity	Present vs. Absent	0.68 (0.54, 0.84)	0.0005
Oral Ulcers	Present vs. Absent	0.75 (0.59, 0.96)	0.0196
Alopecia	Present vs. Absent	1.18 (0.95, 1.48)	0.1412
Arthritis	Present vs. Absent	1.13 (0.91, 1.40)	0.2652
Pericarditis	Present vs. Absent	1.12 (0.78, 1.61)	0.5344
Pleuritis	Present vs. Absent	0.92 (0.71, 1.21)	0.5640
Seizures	Present vs. Absent	0.80 (0.47, 1.37)	0.4134
Psychosis	Present vs. Absent	1.15 (0.37, 3.60)	0.8045
Sjogrens Syndrome	Present vs. Absent	0.76 (0.48, 1.19)	0.2258
Elevated ESR	Present vs. Absent	1.11 (0.85, 1.44)	0.4401

Table 2. Multivariable model to predict incident proteinuria

Variable	Comparison	Rate Ratio (95% CI)	P-value
Anti-Sm	Present vs. Absent	2.25 (1.72, 2.95)	<0.0001
Race	Black vs. White	1.57 (1.24, 2.00)	0.0002
	Other vs. White	2.32 (1.64, 3.27)	<0.0001
Anti-dsDNA	Present vs. Absent	1.51 (1.18, 1.92)	0.0009
Anti-RNP	Present vs. Absent	1.53 (1.18, 2.00)	0.0016
Low C4	Present vs. Absent	1.45 (1.10, 1.90)	0.0086
Sex	Male vs. Female	1.56 (1.09, 2.22)	0.014

Methods: The analysis is based on 1,418 members of the Hopkins Lupus Cohort who had been followed for longer than one year since SLE diagnosis. Subjects who developed proteinuria before or in the year of SLE diagnosis were excluded. A multivariate equation to predict the risk of incident proteinuria was developed using a forward-stepwise approach, considering each of the univariate associates in turn, and adding the variable that led to the greatest reduction in Akaike's Information Criterion (AIC).

Results: Univariate associates of incident (new) proteinuria after 1 year from SLE diagnosis are shown in Table 1. Table 2 shows the multivariate predictors of incident proteinuria. Major risk factors included non-Caucasian race and anti-Sm. Moderate risk factors included male sex, anti-RNP, anti-dsDNA, and low C4 at the time of SLE diagnosis. Based on this model

Table 3. Risk of incident proteinuria within 10 years of SLE diagnosis as a function of the number of risk factors (Each row in Table 2 counts as 1 risk factor except Anti-Sm and "Other" race which count as 2 risk factors)

Number of Risk Factors	10-year risk
0	2.6%
1	3.9%
2	5.8%
3	8.5%
4	12.5%
5	18.1%
6	25.9%
7	36.2%
8	49.1%

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

we estimated the 10-year risk as a function of the number of risk factors a patient has (Table 3). A person with no risk factors has only a 2.6% chance of developing proteinuria in 10 years, whereas a person with all 8 risk factors has a 49% chance.

Conclusion: We built a risk score for proteinuria in the next 10 years that would allow clinicians to identify a high risk subset of SLE patients to target for more frequent measurement of urine protein to creatinine AND to consider earlier renal biopsy at even low levels of proteinuria. The risk factors include well accepted demographic variables (non-Caucasian race, male sex) and serologic tests that are easily available (low C4, anti-Sm, anti-RNP and anti-dsDNA).

Complete Renal Response and Long-Term, Progression-Free Survival in Adult Patients With Lupus Nephritis: A Retrospective Cohort Study in the United States

Lisa Lindsay[1], Shu Wang[2], Huong Trinh[1], Yunru Huang[1], William Pendergraft[1] and **Brad Rovin**[3], [1]Genentech, Inc., South San Francisco, CA, [2]Genesis Research LLC, Hoboken, NJ, [3]The Ohio State University, Columbus, OH

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: Abstracts: Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes I: Advances in Nephritis (0837–0842)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Complete renal response (CRR) and flare prevention, as early markers of long-term kidney survival, are important outcomes in lupus nephritis (LN) clinical trials.

Methods: This US-based retrospective cohort study (January 1, 2000 to October 15, 2024) used deidentified patient-level electronic health records from a national network of healthcare organizations (118 million patients) to assess time to initial CRR, LN flare, estimated glomerular filtration rate (eGFR) slope and unfavorable kidney outcomes. Patients were ≥18 years old with newly diagnosed LN (index), had baseline urine protein-to-creatinine ratio (UPCR) and eGFR within 90 days of index plus an additional UPCR and eGFR >90 days post index. Patients were required to have a baseline UPCR of ≥0.5 g/g. Patients with pre-existing end-stage kidney disease (ESKD), dialysis or kidney transplant were excluded. CRR was defined as UPCR < 0.5 g/g and eGFR ≥85% of baseline and no pre-CRR ESKD, dialysis or kidney transplant. LN flare was defined as eGFR decrease of >20%, increase in UPCR of >1 g/g if UPCR < 0.2 g/g or >2.0 g/g if UPCR ≥0.2 g/g or doubling if UPCR >1 g/g compared with baseline or receipt of intravenous methylprednisolone ≥100 mg within 14 days of a LN/systemic lupus erythematosus (SLE) diagnostic code. Unfavorable kidney outcomes included doubling of serum

AA, African American; AZA, azathioprine; BEL, belimumab; CKD, chronic kidney disease; CNI, calcineurin inhibitor; CYC, cyclophosphamide; eGFR, estimated glomerular filtration rate; ESKD, end-stage kidney disease; IS, immunosuppressant; mCCI, modified Charlson Comorbidity Index; MTX, methotrexate; MMF/MPA, mycophenolate mofetil/mycophenolic acid; RTX, rituximab; UPCR, urine protein-to-creatinine ratio.

*P<0.05 based on Pearson χ^2 test; Fisher exact test; Wilcoxon rank sum test.

[a]Any unfavorable kidney outcome including doubling of serum creatinine; [b]CKD stage 3b/4 allowed at study entry; new onset indicates such patients did not have diagnosis or eGFR values indicative of CKD 3b/4 at index (anytime pre-index through 90 days post index); [c]mCCI; connective tissues and renal categories excluded; [d]Observed in electronic health records but may exclude biopsy procedures performed outside the participating healthcare network; [e]Within ±90 days of index (LN diagnosis).

creatinine, new-onset chronic kidney disease (CKD) Stage 3b/4, ESKD, dialysis, transplant and death. Week 52, 76 and 104 sub-cohorts included patients with follow-up data and ≥1 UPCR and eGFR during the post-index Week 52, 76 and 104 (±90 days) periods.

Results: Of 3279 patients, unfavorable kidney outcomes occurred in 37% and were more frequent in the following patients: older, longer disease duration, Black, greater comorbidities and poor baseline renal function Mean time in months (mo) from pre-index SLE diagnosis to index was 23 (SD 40). Baseline kidney biopsy (index ±6 mo) occurred in 49% of patients and more frequently in those diagnosed after 2021, with higher baseline UPCR, subsequent CRR and less frequent unfavorable kidney outcomes (P< 0.001). Immunosuppressant (IS) use (index +90 days) was 68%; mean time post-index to IS use, mo (SD) was: 5 (14); and a longer time to IS treatment was associated with poor outcomes (Table 1). Mean time from index to event, mo (SD) was: doubling of serum creatinine, 35 (33); CKD Stage 3b/4, 38 (37); ESKD, 42 (37); dialysis, 46 (38); transplant, 65 (44) and death, 61 (46).

Analyses were restricted to patients with follow-up data until the end of each time period of interest (eg, post-index Week 52 ±90 days, post-index Week 76 ± 90 days, and post-index Week 104 ±90 days) ***and*** who had ≥1 UPCR and eGFR during the specified time window. Unfavorable kidney outcomes and LN flares were identified that occurred after the end of the Week 52, 76 and 104 time periods, eg, post-week 52+12 weeks (eg, 90 days), post-week 76+12 weeks and post-week 104+12 weeks.
CKD, chronic kidney disease; CRR, complete renal response; ESKD, end-stage kidney disease; LN, lupus nephritis.
[a]*P* value based on Log rank test.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

CRR was achieved in 53% of patients; mean time to initial CRR, mo (SD) was 16 (19) and varied by baseline UPCR (**-Figure 1a**). CRR at Week 52, 76 and 104 was 36%, 38% and 38% respectively. **Figure 1b** shows median time to initial flare. **Figure 1c** shows time to event according to 20, 30 and 40% eGFR decline. **Figure 1d** shows time to unfavorable kidney outcome.

Patients who achieved CRR were significantly less likely to experience an unfavorable kidney outcome or flare (**Table 2**).

Conclusion: Achieving CRR significantly reduced future severe kidney outcomes; however, a minority of patients who achieved CRR at Week 52, 76 or 104 had disease progression. Patients with high baseline UPCR had delayed CRR and those with longer time to initial IS treatment had worse long-term outcomes.

Session Title: Abstracts: Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes I: Advances in Nephritis (0837–0842)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Lupus nephritis (LN), a severe complication of systemic lupus erythematosus (SLE), lacks reliable non-invasive biomarkers for early detection and monitoring. This study investigates plasma cell-free DNA (cfDNA) methylation and fragmentation signatures as potential LN biomarkers.

Methods: We performed whole-genome methylation profiling of plasma cfDNA from distinct cohorts: SLE patients with biopsy-proven LN (active: n=10 and inremission: n=7), SLE patients without LN (>10 years post-diagnosis, n=13), and healthy controls (n=10). Two novel methylation-based deconvolution methods were developed to quantify kidney-derived cfDNA and compared to classical non-negative least square (NNLS)algorithms. Fragmentation patterns were analyzed using cfDNA size profiles to differentiate active LN from remission.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Results: Our novel deconvolution methods outperformed NNLS in detecting low-abundance cell types. Active LN patients exhibited significantly elevated kidney-derived cfDNA levels compared to remission, never-LN SLE, and healthy cohorts ($p< 0.05$ for all) (Figure 1). The reads ratio-based method achieved high diagnostic accuracy for active LN (AUC=0.91) (Figure 2). All three methods strongly correlated kidney-derived cfDNA levels with LN disease activity. Active LN patients also exhibited increased short cfDNA fragments (30–157 bp) compared to remission ($p< 0.001$) (Figure 3). Combining NNLS-derived kidney cfDNA levels with short fragment proportions enabled exceptional discrimination between active and remission LN (AUC=1).

Conclusion: Kidney-derived cfDNA levels and short fragment proportions are robust biomarkers for distinguishing active LN from remission and never-LN SLE. These findings underscore the clinical potential of cfDNA methylation and fragmentation profiling as a non-invasive tool for LN diagnosis, monitoring, and personalized treatment strategies.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: Abstracts: Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes I: Advances in Nephritis (0837–0842)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Urine collects the byproducts of kidney biology and has emerged as a valuable, noninvasive source of molecular information that reflects intrarenal pathology. In lupus nephritis (LN), multiple urinary signatures have been identified that associate with histologic activity, immune cell infiltration, and response to therapy. However, many of these biomarkers are not disease-specific and may also be elevated in other glomerular conditions. Comparing urinary proteomic profiles across inflammatory and non-inflammatory kidney diseases may uncover shared mechanisms of injury, while also revealing LN-specific signatures that could aid in diagnosis, monitoring, and therapeutic targeting.

Methods: Urine samples from patients with glomerular diseases including LN (ISN classes I–V), ANCA-associated glomerulonephritis, IgA nephropathy (IgAN), membranous nephropathy (MGN), and focal segmental glomerulosclerosis (FSGS) were collected near the time of biopsy and after screening for healthy controls (HC). Proteomic profiles were quantified using the Olink Explore HT platform (5,400 proteins). Here, we report findings for six candidate biomarkers previously linked to LN histological activity and progression: CD163, IL-16, Galectin 1 (LGALS1), Tenascin C (TNC), BAFF (TNFSF13B), and C9.

Results: We analyzed urine samples from 383 patients, including 234 with LN (21 Class I/II, 81 Class III ± V, 70 Class IV ± V, and 62 Class V), 17 with ANCA, 30 with IgAN, 30 with MGN, 30 with FSGS, and 31 healthy controls.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

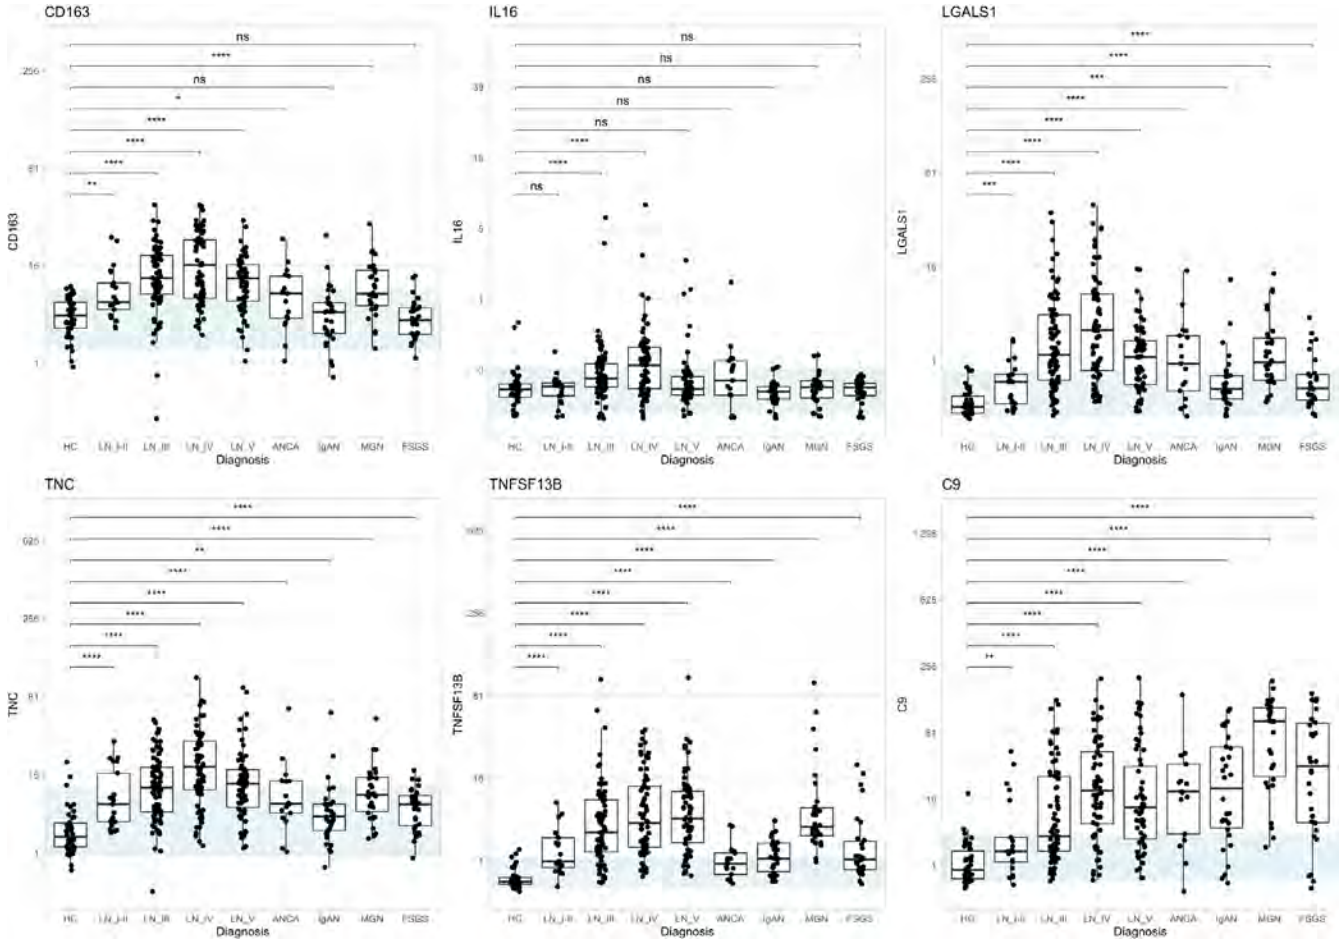

Figure 1. Urinary expression of inflammation- and fibrosis-associated proteins across glomerular diseases. Boxplots show normalized protein expression (NPX) of six urinary biomarkers—CD163, IL-16, Galectin-1 (LGALS1), Tenascin-C (TNC), BAFF (TNFSF13B), and C9—in healthy controls (HC) and patients with lupus nephritis (LN I–V), ANCA-associated vasculitis (ANCA), IgA nephropathy (IgAN), membranous nephropathy (MGN), or focal segmental glomerulosclerosis (FSGS). Each box depicts the median and interquartile range. The light-blue band marks the 5th–95th percentile range of HC values. Wilcoxon rank-sum tests comparing each disease group to HC are shown above each panel (ns, not significant; * $p < 0.05$; ** $p < 0.01$; *** $p < 0.001$; **** $p < 0.0001$).

IL-16, previously linked to histologically active LN, was elevated in Class III/IV LN and in a subset of ANCA patients. CD163 was elevated in proliferative LN, in a subset of ANCA, and unexpectedly in MGN, but remained low in most IgAN cases . Galectin-1 was broadly elevated across glomerular diseases, but class II LN, IgAN and FSGS had relatively lower levels. TNFSF13B (BAFF) was increased in all conditions, but it was relatively higher in Class III, IV, and V LN, and in MGN, suggesting a stronger role in B cell–driven pathology in these conditions. C9 was elevated across all disease groups, indicating widespread complement activation. Tenascin C was highest in Class IV LN but also elevated in other LN classes and the other glomerular diseases, consistent with activation of prorepair and profibrotic pathways. Complement activation was enriched in all conditions.

Conclusion: Urinary biomarkers reveal both shared and disease-specific molecular pathways across glomerular diseases. The presence of common inflammatory and profibrotic signals—such as complement activation, macrophage involvement, and B cell–driven responses—highlights overlapping mechanisms of injury. At the same time, distinct expression patterns suggest unique pathogenic processes. These findings offer mechanistic insight into glomerular inflammation and fibrosis and, importantly, raise the potential for repurposing targeted therapies across traditionally distinct kidney diseases. Ongoing analysis of the full urinary proteome (~5,400 proteins) is expected to further expand our understanding of disease mechanisms and therapeutic opportunities.

Abstract Number: 0841

Comparing the Impact of GLP-1 Agonists and SGLT-2 Inhibitors on Outcomes in Lupus Nephritis: A Retrospective Cohort Study

Kinga Grzybowski[1] and Irene Tan[2], [1]Jefferson Einstein Montgomery Hospital, Maspeth, NY, [2]Einstein Healthcare Network Philadelphia - Jefferson Health, Bala Cynwyd, PA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: Abstracts: Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes I: Advances in Nephritis (0837–0842)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Lupus Nephritis (LN) is one of the most serious complications of SLE (Systemic Lupus Erythematosus) characterized by an attack of the kidneys by the immune system which typically develops within 5 years of the initial diagnosis of SLE. It is suspected that up to 60% of those with SLE develop kidney-related complictions. Some complications of Lupus Nephritis include kidney failure requiring dialysis or transplantation, among other cardiovascular complications. Many medications exist for the management of some of the comorbidities associated with LN patients, but not much is known on the benefits on the condition itself. An observational, retrospective cohort study was designed which

Table 1: Complications and Outcomes in Patients with LN on SGLT2 inhibitors versus GLP-1 agonists

Outcomes[a,b]	LN on SGLT2	LN on GLP-1	RR (95% CI)	P-value
Dialysis (n,%)	36 (5.8%)	36 (6.26%)	0.926 (0.592-1.449)	0.7362
ESRD (n,%)	37 (6.38%	31 (5.91%)	1.08 (0.68-1.715)	0.7431
CKD (n,%)	75 (43.35%)	73 (28.4%)	1.526 (1.179-1.976)	0.0014
Renal Transplant (n,%)	<10 (1.59%)	12 (2.1%)	0.759 (0.331-1.744)	0.5146
Mortality (n,%)	48 (6.96%)	24 (3.48%)	2 (1.239-3.227)	0.0037
Acute MI (n,%)	37 (6.3%)	18 (2.8%)	2.248 (1.294-3.904)	0.0030
Stroke (n,%)	21 (3.541%)	13 (2.0%)	1.754 (0.886-3.472)	0.1018
Heart Failure (n,%)	39 (10%)	40 (7.1%)	1.421 (0.932-2.166)	0.1013
