SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: The potential of B-cell-depleting therapies to diminish humoral responses is recognized, but whether this leads to an increased risk of Coronavirus Disease 2019 (COVID-19) remains unknown. Inebilizumab (INEB) is a humanized, glycoengineered, CD19-directed, monoclonal antibody that depletes B cells, including plasmablasts and some plasma cells, effectively in a targeted manner. MITIGATE (NCT04540497) is an international, randomized, blinded, placebo (PBO)-controlled Phase 3 trial that evaluates the safety and efficacy of INEB as treatment for IgG4 related disease (IgG4-RD). This ad hoc analysis examined whether INEB treatment is associated with an increased risk of COVID-19 infection in adult participants with IgG4-RD.

Methods: Primary results of the MITIGATE trial have been previously reported (Stone et al, 2024). Eligible participants were randomized 1:1 to inebilizumab or placebo and were treated on day 1, day 15, and week 26 of the 1-year randomized controlled period (RCP). Ad hoc analyses were performed to assess the risk of COVID-19 infections with INEB treatment, as COVID-related endpoints were not prespecified. First participant was enrolled October 26, 2020, after COVID-19 was initially reported (December 2019) and before the first vaccine received approval (December 2020). To determine the relationship between COVID-19 infections and immune response, the lowest recorded values of IgG, IgM, and IgA were measured and compared among participants with COVID-19 infections. Vaccination status, incidence of COVID-19, and safety were evaluated.

Results: In the trial population, 28.4% (n=19/67) of PBO-treated and 29.4% (n=20/68) of INEB-treated participants had received a COVID-19 vaccination. COVID-19 infection was reported in 13 (19.4%) PBO-treated and in 17 (25.0%) INEB-treated participants. Most infections were in participants < 65 years of age (84.6% PBO, 58.9% INEB). The majority of infections were mild [Grade 1; PBO: 7/13 (53.8%); INEB: 11/17 (64.7%)] or moderate [Grade 2; PBO: 6/13 (46.2%); INEB: 5/17 (29.4%)]. Serious COVID-19 occurred in 0 PBO-treated and 2 INEB-treated participants, both requiring hospitalizations, but were not life-threatening (Table 1). Both of these subjects had been vaccinated for COVID-19 prior to COVID-19 infection. There was no significant association between immunoglobulin reductions and occurrence of serious COVID.

Conclusion: Treatment with INEB was not associated with a higher incidence or severity of COVID-19 compared with placebo. Despite B-cell depletion, infections were mostly mild, and serious infections were infrequent. These findings support the safety of INEB in the context of the COVID-19 pandemic.

Abstract Number: 2020

Inebilizumab Efficacy and Safety in Patients with Common, Urgent, and Fibrotic Organ Manifestations of IgG4-RD: Subgroup Analyses from the MITIGATE Trial

Arezou Khosroshahi[1], Emma Culver[2], Wen Zhang[3], Kazuichi Okazaki[4], Yoshiya Tanaka[5], Matthias Lohr[6], nicolas schleinitz[7], Xinxin Dong[8], Sue Cheng[8], Daniel Cimbora[8] and John Stone[9], [1]Emory University, Atlanta, GA, [2]John Radcliffe Hospital; University of Oxford, Oxford, United Kingdom, [3]Peking Union Medical College Hospital, Dong Cheng Qu, China (People's Republic), [4]Kansai Medical University Kori Hospital, Osaka, Japan, [5]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [6]Karolinska Institutet, Stockholm, Sweden, [7]Aix Marseille university, AP-HM, Marseille, France, [8]Amgen, Thousand Oaks, CA, [9]Massachusetts General Hospital , Harvard Medical School, Concord, MA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: IgG4-related disease (IgG4-RD) is a progressive, systemic, fibroinflammatory disease characterized by unpredictable and recurring flares, leading to organ damage and decreased quality of life. Inebilizumab (INEB) is a humanized, glycoengineered, CD19-directed, monoclonal antibody that depletes CD19+ B cells, including plasmablasts and some plasma cells, effectively in a targeted manner. MITIGATE (NCT04540497) is an international, randomized, blinded, placebo (PBO)-controlled Phase 3 trial that evaluated the safety and efficacy of INEB as treatment for IgG4-RD, and met its primary endpoint (reduction in flare risk, INEB vs. PBO) and all key secondary endpoints.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Here, we evaluate the safety and efficacy of INEB across MITIGATE subgroups defined by baseline organ involvement, with a focus on organs most commonly affected in the study population, organs with potentially urgent manifestations, and organs characteristic of the fibrotic phenotype of IgG4-RD.

Methods: MITIGATE study design and results have been previously reported (Stone et al, NEJM 2024). All participants had experienced a recent flare (prior to screening) that required glucocorticoid (GC) treatment. Post hoc subgroup analyses of efficacy and safety were conducted in participants on the basis of the organs involved in this recent flare. Subgroups were defined by the most common organs (affecting at least 20% of participants), those with urgent or severe manifestations: pancreas, kidney, bile ducts, aorta and large blood vessels, and orbits; and those associated with the fibrotic phenotype of IgG4-RD: retroperitoneum, mediastinum, mesentery, thyroid, and meninges (Lanzillotta et al., 2023).

Results: 135 participants were randomized and received at least one dose of INEB (n=68) or PBO (n=67). The spectrum of organ involvement at baseline was generally well balanced between the 2 treatment groups (Table 1). INEB treatment reduced the risk of flare relative to PBO in all organ subgroups, with HR values similar to that of the overall population (HR 0.13) (Table 2). The greatest treatment effect was observed in participants with pancreatic (HR 0.03), bile duct (HR 0.00), and kidney (HR 0.08) involvement. The orbital and fibrotic organ groups also experienced clear benefit of INEB on flare risk reduction.

Proportions of participants achieving flare-free, corticosteroid-free complete remission at Week 52 were increased by INEB in all organ subgroups with sufficient representation to permit analysis (Table 3). Proportion of subjects requiring on-study

Table 1: Subgroups Defined by Baseline IgG4-RD Organ Involvement

Subgroup	PBO, N=67	INEB, N=68	Overall, N=135
Most Common (≥20%) Organs, n (%)			
Lymph node(s)	26 (38.8)	26 (38.2)	52 (38.5)
Pancreas[a]	24 (35.8)	27 (39.7)	51 (37.8)
Submandibular glands	20 (29.9)	31 (45.6)	51 (37.8)
Lacrimal glands	18 (26.9)	27 (39.7)	45 (33.3)
Kidney[a]	19 (28.4)	21 (30.9)	40 (29.6)
Bile ducts[a]	15 (22.4)	13 (19.1)	28 (20.7)
Parotid glands	10 (14.9)	17 (25.0)	27 (20.0)
Additional Urgent Organs, n (%)			
Aorta and large blood vessels	3 (4.5)	5 (7.4)	8 (5.9)
Orbits	9 (13.4)	7 (10.3)	16 (11.9)
Fibrotic Organs[b], n (%)	8 (11.9)	10 (14.7)	18 (13.3)

[a]Also classified as an urgent organ.
[b]Includes retroperitoneum, mediastinum, mesentery (sclerosing mesenteritis), thyroid, and meninges.

Table 2: Subgroup Analysis of Time to the First Treated and Adjudication Committee-determined IgG4-RD Flare During RCP

Subgroup	PBO, N=67 n (%)	INEB, N=68 n (%)	HR (95% CI)
Most Common (≥20%) Organs, n (%)			
Lymph node(s)	18/26 (69.2)	3/26 (11.5)	0.13 (0.04, 0.44)
Pancreas[a]	17/24 (70.8)	1/27 (3.7)	0.03 (0.00, 0.21)
Submandibular glands	9/20 (45.0)	3/31 (9.7)	0.17 (0.05, 0.63)
Lacrimal glands	10/18 (55.6)	2/27 (7.4)	0.10 (0.02, 0.47)
Kidney[a]	12/19 (63.2)	2/21 (9.5)	0.08 (0.02, 0.36)
Bile ducts[a]	12/15 (80.0)	0/13 (0)	0.00 (0.00, N/A[b])
Parotid glands	6/10 (60.0)	2/17 (11.8)	0.16 (0.03, 0.79)
Additional Urgent Organs, n (%)			
Aorta and large blood vessels	0/3 (0)	0/5 (0)	N/A[b]
Orbits	8/9 (88.9)	1/7 (14.3)	N/A[b]
Fibrotic Organs[c], n (%)	3/8 (37.5)	0/10 (0)	N/A[b]

[a]Classified as an urgent organ.
[b]N/A: Statistical comparisons not calculated due to very low event rates or small subgroup size.
[c]Includes retroperitoneum, mediastinum, mesentery (sclerosing mesenteritis), thyroid, and meninges.

Table 3: Subgroup Analysis of The Proportion of Subjects Achieving Flare-Free, Corticosteroid-Free Complete Remission[a] at Week 52 (RCP)

Subgroup	PBO, N=67 n (%)	INEB, N=68 n (%)	Odds ratio (95% CI)	Nominal P-value[b]
Most Common (≥20%) Organs, n (%)				
Lymph node(s)	5/26 (19.2)	12/26 (46.2)	3.37 (0.94, 11.98)	.0612
Pancreas[c]	4/24 (16.7)	18/27 (66.7)	10.84 (2.74, 42.90)	.0007
Submandibular glands	6/20 (30.0)	17/31 (54.8)	2.85 (0.85, 9.49)	.0864
Lacrimal glands	4/18 (22.2)	16/27 (59.3)	5.38 (1.35, 21.34)	.0168
Kidney[c]	4/19 (21.1)	12/21 (57.1)	5.08 (1.19, 21.68)	.0281
Bile ducts[c]	2/15 (13.3)	11/13 (84.6)	35.75 (4.30, 297.25)	.0009
Parotid glands	4/10 (40.0)	10/17 (58.8)	2.02 (0.40, 10.19)	.3926
Additional Urgent Organs, n (%)				
Aorta and large blood vessels	1/3 (33.3)	4/5 (80.0)	N/A[d]	N/A[d]
Orbits	1/9 (11.1)	4/7 (57.1)	N/A[d]	N/A[d]
Fibrotic Organs[e], n (%)	2/8 (25.0)	6/10 (60.0)	4.5 (0.59, 34.61)	.1484

[a]Flare-free, corticosteroid-free complete remission is defined as the absence of evident disease activity at week 52; defined as an IgG4-RD Responder Index score of 0 or determination by the investigator that no disease activity is present on the basis of physical, laboratory, pathology, or other evidence), no AC-determined flare during the RCP of the trial, and no corticosteroid treatment for flare or disease control beyond the protocol required prednisone taper.
[b]P-values should be interpreted with caution due to the questionable reliability of the statistical test based on the small sample sizes.
[c]Classified as an urgent organ.
[d]N/A: Statistical comparisons not calculated due to very low event rates or small subgroup size.
[e]Includes retroperitoneum, mediastinum, mesentery (sclerosing mesenteritis), thyroid, and meninges.

GCs for IgG4-RD control and mean daily dose of GCs per subject were substantially reduced with INEB vs. PBO in all organ subgroups with sufficient representation to permit analysis. Safety outcomes will be presented.

Conclusion: The MITIGATE trial demonstrates consistent safety and efficacy of INEB across all IgG4-RD subgroups defined on the basis of organ involvement at study baseline, including the most common organs, urgent organs, and organs characteristic of the fibrotic disease phenotype.

Abstract Number: 2021

Can Colchicine Be a Therapeutic Option for Patients with Ankylosing Spondylitis?

Muhammed Bahaddin Ates[1] and serdal Ugurlu[2], [1]Cerrahpasa Faculty of Medicine, Istanbul, Turkey, [2]Istanbul University-Cerrahpasa, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Ankylosing Spondylitis (AS) is a subtype of spondyloarthritis (SpA), a group of inflammatory diseases. AS is influenced by a complex interplay of factors arising from both autoimmune and autoinflammatory mechanisms, with key contributors including HLA-B27, alterations in the IL-23 signaling pathway, and mutations in the MEFV gene. Among these factors, MEFV gene mutations are the cause of familial Mediterranean fever (FMF), which is considered one

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1- Patient's clinical scores before and after the treatment

	Before colchicine therapy	After colchicine therapy	P values
Average VAS scores (total back pain), mean±SD	6,69±3,65	5,48±2,65	0,145
Average BASDAI scores, mean±SD	6,17±2,56	5,05±2,26	0,068
Average VAS scores in M694V heterozygous patients, mean±SD	6,88±3,51	5,77±2,72	0,217
Average BASDAI scores in M694V heterozygous patients, mean±SD	5,64±3,16	5,24±2,27	0,47
Average VAS scores in M694V homozygous patients, mean ± SD	8,33±1,96	4,5±2,88	0,011
Average BASDAI scores in M694V homozygous patients, mean±SD	6,68±1,94	4,38±2,38	0,048

of the prototypes of autoinflammatory diseases. In the treatment of FMF, the primary targeted pathways are microtubules and IL-1 pathways, which aim to reduce inflammation through autoinflammatory mechanisms.

In this study, we aimed to investigate whether treating FMF with drugs that inhibit autoinflammatory pathways could also lead to a reduction in the symptoms of AS in patients diagnosed with both FMF and AS.

Methods: In this study, 28 patients were enrolled, all of whom had been diagnosed with both Ankylosing Spondylitis (AS) and Familial Mediterranean Fever (FMF) based on the 1984 Modified New York Criteria and Tel-Hashomer Criteria, respectively. Each patient was contacted and asked about the severity of their AS using the BASDAI and VAS back pain scores before and after colchicine treatment, as well as other IL-1 treatments. Additional information, such as M694V mutations, was obtained from their hospital records.

Results: Twenty-eight patients were included in our study. The mean age of the patients was 44.89 ± 10,9 years. The mean duration of AS and FMF was 12.35±6,95 years and 17.71±7,72 years, respectively.

The impact of colchicine on AS severity was assessed using the BASDAI score before and after treatment. The results were not significant for the BASDAI score (p =0,068). Patients were evaluated using the VAS back pain score before and after colchicine treatment. The results were similarly non-significant (p=0,145)(Table 2).

The BASDAI score improvements before and after treatment for patients using canakinumab and anakinra showed no significant results ($p > 0.05$).

Among the 28 patients, 6 had the M694V homozygous mutation, and 9 had the M694V heterozygous mutation. BASDAI scores before and after colchicine treatment showed a significant difference in M694V homozygous patients (p=0,048). No such improvement in BASDAI scores was observed in patients with M694V heterozygous mutations (p=0,47). VAS back pain scores before and after treatment in M694V homozygous patients also showed significant improvement after colchicine treatment (p=0,011). Similarly to the BASDAI scores, VAS back pain scores remained non-significant in M694V heterozygous patients before and after treatment (p =0,217).

Conclusion: Although colchicine and other IL-1 targeted therapies did not lead to significant clinical improvement in the overall ankylosing spondylitis (AS) patient population, a notable exception was observed in individuals homozygous for the M694V mutation. In this subgroup, colchicine treatment was associated with marked reductions in both BASDAI and VAS back pain scores, suggesting a potential genotype-specific therapeutic response that warrants further investigation.

Clinical Predictors of Macrophage Activation Syndrome and Treatment Outcomes in Adult-Onset Still's Disease: A 24-Year Single-Center Experience

Oguzhan Omer Kizilkaya[1], **Beste Acar**[1], Berkay Aktas[1], Ozgur Can Kilinc[1] and serdal Ugurlu[2], [1]Cerrahpasa Faculty of Medicine, Istanbul University-Cerrahpasa, Istanbul, Turkey, [2]Istanbul University-Cerrahpasa, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Adult-onset Still's disease (AOSD) is a rare autoinflammatory disorder with heterogeneous manifestations. Its most severe complication, macrophage activation syndrome (MAS), occurs in up to 15% of cases and carries high mortality. Early identification of high-risk patients remains challenging and data on long-term outcomes are limited. This study aimed to identify clinical predictors of MAS and assess treatment outcomes and survival in a large AOSD cohort.

Methods: This retrospective study included 93 adults diagnosed with AOSD between 2000 and 2024 at a tertiary university hospital. All fulfilled Yamaguchi criteria and MAS was diagnosed per HLH-2004 and 2016 EULAR/ACR/PRINTO criteria. Demographic, clinical, laboratory and treatment data were included. Pouchot's disease severity scores were calculated based on presenting symptoms. Associations with MAS were evaluated using univariate and multivariate logistic regression.

Table 1. Demographic Features and Clinical Manifestations of Patients

MAS: Macrophage Activation Syndrome; NA: not available.

Table 3. Treatment choice and response rates of AOSD patients.

	Usage Rate	Response Rate
Stopped Corticosteroids	48.24% (41/85)	-
Methotrexate Use	91.30% (84/92)	66.67% (36/54)
Corticosteroid Use	93.33% (84/90)	NA
Leflunomide Use	10.98% (9/82)	44.44% (4/9)
Anti-TNF	12.50% (11/88)	33.33% (3/9)
Tocilizumab	31.39% (27/86)	58.33% (14/24)
Anakinra	47.19% (42/89)	55.26% (21/38)
Canakinumab	15.91% (14/88)	30.77% (4/13)
HCQ Use	38.89% (35/90)	51.85% (14/27)
JAKi	3.37% (3/89)	100% (3/3)
Lowest GC dosage, median (IQR, 25-75)	0 (0,0-5,0)	-
Highest GC dose, median (IQR, 25-75)	22,0 (10,0-40,0)	-

Anti-TNF: anti-tumor necrosis factor; GC: glucocorticoids HCQ:hydroxychloroquine;IQR: interquartile range; JAKi: janus kinase inhibitors; NA: not available.

Results: The mean age at onset was 33.6 ± 14.4 years and 64.5% of the patients were female. Common symptoms are summarized in Table 1. MAS developed in 14.1% and was associated with younger age at onset (27.7 vs. 34.9 years; p=0.037) and higher baseline ferritin (p=0.0489). Multivariate analysis confirmed elevated ferritin (p=0.0489) and higher Pouchot's scores (p=0.0204) as independent MAS predictors, as detailed in Table 2.

Diagnostic delay averaged 1.33 ± 2.8 (IQR, 25-75:0-1) years and was associated with lower methotrexate response (p=0.0457) and corticosteroid tapering success (p< 0.01). Patients with shorter delays achieved steroid-free remission more frequently (median 4 vs. 8 years; p< 0.01).

Glucocorticoids were prescribed to 93.3% of patients, methotrexate to 91.3% and anakinra to 47.2%. Tocilizumab (31.4%) and canakinumab (15.5%) were also used. JAK inhibitors achieved complete remission in all treated patients (3/3) including one with MAS. Steroid discontinuation was achieved in 37.8% of patients. Treatment responses are shown in Table 3. Overall survival was 94% with MAS accounting for two deaths.

Conclusion: Elevated ferritin and higher Pouchot's scores independently predict MAS, supporting their use in early risk stratification. Diagnostic delay reduces treatment response and remission, highlighting the importance of prompt diagnosis. Although glucocorticoids remain the initial therapy, biologics such as anakinra and tocilizumab combined with JAK inhibitors are effective for remission in refractory cases. Early diagnosis and phenotype-guided treatment, favoring IL-1 inhibitors for systemic manifestations and IL-6 inhibitors for articular involvement, may further improve outcomes.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Anti-Ro52 antibodies are frequently detected in patients with systemic autoimmune rheumatic diseases (SARDs). Emerging evidence suggests a potential link between isolated anti-Ro52 positivity and increased malignancy risk.

Our aim was to evaluate: a) the association between anti-Ro52 antibody status (negative, isolated, or combined with other autoantibodies) and malignancy risk; b) whether malignancy types differ according to anti-Ro52 status.

Methods: We conducted a retrospective study of 739 patients who underwent immunoblot testing for autoimmune inflammatory myopathies or systemic sclerosis at a university hospital between November 2017 and October 2023. Patients were stratified by anti-Ro52 status: negative, isolated positivity, or combined with other myositis- or sclerosis-related antibodies. Clinical records were reviewed to confirm SARDs diagnoses using established classification criteria and to identify

TABLE. Demographic, Clinical, and Neoplastic Characteristics of Patients Categorized by Anti-Ro52 Antibody Status

malignancies through clinical and/or pathological documentation. Associations were analyzed using logistic regression adjusted for age, sex, and SARDs diagnosis.

Results: Malignancy was identified in 61 of 739 patients (8.25%). Anti-Ro52 status distribution: negative (81.4%, n=602), isolated (12.7%, n=94), and combined positivity (5.8%, n=43). In multivariable analysis, older age and isolated Ro52 positivity were independently associated with increased malignancy risk. Each additional year of age increased risk by 5.3% (OR 1.053; 95% CI 1.031–1.076; p< 0.001). Isolated Ro52 positivity conferred a nearly fourfold increased risk versus seronegative patients (OR 3.968; 95% CI 2.049–7.687; p< 0.001). SARDs diagnosis was inversely associated with malignancy (OR 0.426; 95% CI 0.240–0.759; p=0.004). No significant associations were found for sex (OR 0.693; 95% CI 0.392–1.224; p=0.206) or Ro52 positivity combined with other antibodies (OR 1.063; 95% CI 0.297–3.807; p=0.925).

A secondary analysis revealed significant differences in malignancy types by Ro52 status (p=0.001). Ro52-positive patients showed higher frequencies of ovarian, lung, and urothelial cancers, while the Ro52-negative group exhibited a broader, more heterogeneous profile, including colorectal, gastric, and hematological malignancies.

Conclusion: Isolated anti-Ro52 positivity and advancing age are independent predictors of malignancy. The distinct cancer spectrum among Ro52-positive patients suggests the importance of tailored oncologic surveillance in this subgroup.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Neuromyelitis optica (NMO) is a rare, chronic, immune-mediated, demyelinating disorder predominantly affecting the optic nerve and spinal cord. Despite increasing awareness, racial disparities in NMO outcomes remain poorly characterized.

Methods: This retrospective cohort study used TriNetX, a global federated health research network of 144 healthcare organizations. Two Cohorts were defined: Cohort A (Black or African American with Neuromyelitis Optica; n= 2,101) and Cohort B (Hispanics or Latinos with NMO; n= 1,007). Inclusion criteria required patients to be 18 years or older with at least an NMO diagnosis within the past 20 years. Exclusion criteria included patients younger than 18 or diagnosed more than 20 years ago.

Propensity score matching (1:1) was performed to balance demographics and comorbidities, including age, sex, obesity, dyslipidemia, diabetes, hypertension, kidney disease, and chronic respiratory disease. The final matched sample included 965 patients per group.

Outcomes assessed included all-cause mortality, stroke, and myocardial infarction (MI).

Results: After matching, both cohorts had similar characteristics (mean age 46 years; 76.7% female). Inflammatory markers such as ESR and CRP were higher in Black patients. All-cause mortality was significantly higher among Black patients compared to Hispanic patients (5.0% vs. 2.7%; OR 1.89, 95% CI 1.16–3.07). MI occurred in 4.4% of Black patients vs. 2.8% of Hispanic patients (OR 1.62, 95% CI 0.98–2.66). Stroke occurred in 3.2% of Black patients compared to 1.5% of Hispanic patients, with a statistically significant difference (OR 2.15, 95% CI 1.13–4.09).

Conclusion: This study's findings underscore significant racial disparities in clinical outcomes among patients with Neuromyelitis Optica. Black patients had higher rates of all-cause mortality, myocardial infarction, and stroke compared to their Hispanic counterparts, despite comparable baseline characteristics. The elevated odds of death and cerebrovascular

Table 1. Demographic Comparison of Blacks and Hispanics – Pre- and Post-Propensity Score Matching

Characteristic	Blacks (Pre-Match, N=2,101)	Hispanics (Pre-Match, N=1,007)	Blacks (Post-Match, N=965)	Hispanics (Post-Match, N=965)
Age (Years)	49.2 ± 15.9	45.9 ± 16.0	46.2 ± 15.2	46.2 ± 15.9
Age at Index	42.0 ± 15.6	39.3 ± 15.7	39.5 ± 14.7	39.6 ± 15.7
Female (%)	83.0%	74.9%	76.7%	76.6%
Male (%)	17.0%	25.1%	23.3%	23.4%
Overweight/Obesity (%)	13.5%	12.1%	10.7%	11.7%
Diabetes (%)	9.8%	8.3%	8.1%	8.3%
Metabolic Disorders (%)	21.0%	19.4%	18.4%	19.1%
Hypertension (%)	24.1%	14.9%	15.2%	15.2%
Kidney Disease (%)	5.2%	3.2%	2.7%	3.3%
Chronic Resp. Disease (%)	10.0%	7.0%	6.4%	7.2%
ESR (mean ± SD)	—	—	29.12 ± 28.27	22.36 ± 22.40
CRP (mean ± SD)	—	—	26.52 ± 50.36	23.56 ± 46.89
Aquaporin-4 IgG Result	—	—	14 Positive 40 Negative 16 Unknown	7 Positive 42 Negative 14 Unknown

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 2. Clinical Outcomes

Outcome	Metric	Blacks (n = 965)	Hispanics (n = 965)	Statistical Test	Hazard Ratio (95% CI)	Odds Ratio (95% CI)
All-cause Mortality	Risk	48 / 965 (5.0%)	26 / 965 (2.7%)	Risk Difference: 0.023	1.764 (1.094–2.844)	1.890 (1.163-3.073)
MI (Ischemic Heart Disease)	Risk	41 / 933 (4.4%)	26 / 940 (2.8%)	Risk Difference: 0.016	1.520 (0.930–2.485)	1.616 (0.980-2.664)
Stroke	Risk	29 / 920 (3.2%)	14 / 937 (1.5%)	Risk Difference: 0.017	2.045 (1.080–3.870)	2.146 (1.126-4.088)

events in the Black cohort suggest potential underlying differences in disease progression, access to care, or treatment response. These results highlight the need for tailored interventions and equitable healthcare delivery to mitigate outcome disparities in NMO.

Spectrum of Autoantibodies in CNS Demyelinating Diseases: Clinical, Laboratory and Imaging Associations

Anna Rapti[1], Dimitris Karathanasis[2], Sylvia Raftopoulou[1], Charalampos Skarlis[1], **Clio Mavragani**[1] and Maria Eleftheria Evangelopoulos[2], [1]Department of Physiology, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece, Athens, Greece, [2]First Department of Neurology, School of Medicine, Eginition Hospital, National and Kapodistrian University of Athens, Athens, Greece, Athens, Greece

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic autoimmune diseases (SADs) may present with CNS demyelination, mimicking multiple sclerosis (MS), though driven by distinct immunopathogenic mechanisms. While ANA and aPL are commonly reported in MS, the role of specific SAD-related autoantibodies (ANA profile) in CNS demyelination remains unclear. The aims of this study were to characterize the distribution of autoantibodies in this context, investigate potential associations with clinical/ radiological/ laboratory features, compare findings with a control group of MS-spectrum patients and assess the efficacy of therapeutic strategies.

Methods: We prospectively enrolled 147 patients with CNS demyelination and ANA profile reactivity (via immunoblot) over a six-year period (CNS-autoimmune group). Patients were classified as SAD or demyelination with autoimmune features (DAF), based on whether they fulfilled criteria or not. A control group of 249 MS-spectrum patients was included. Clinical, laboratory, and imaging assessments were conducted. Univariate and multivariate analyses were performed between groups and treatment outcomes were analyzed using annualized relapse rates (ARRs).

Results: Clinical autoimmune features among CNS-autoimmune patients were generally mild, with the most common being arthralgias and sicca symptoms. Approximately 4% of unselected consecutive patients presenting with CNS demyelination and 21% of ANA profile-positive individuals were eventually diagnosed with SAD, primarily Sjögren's disease and SLE. The remaining 79% of CNS-autoimmune patients constituted the DAF subset.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Multivariate analysis identified arthritis, cerebellar signs, ANA, anti-Ro52/ Ro60 positivity and the absence of typical brain lesions as independent predictors for SAD compared to DAF diagnosis. Compared to MS-spectrum, ANA, aCL IgM and serum monoclonal band positivity, female sex and the presence of atypical brain lesions were more indicative of SAD. However, no robust model effectively discriminated between DAF and MS-spectrum groups.

Among individual antibody reactivities, anti-Ro antibodies were associated with pyramidal and cerebellar manifestations, while anti-dsDNA, anti-nucleosomes, and anti-PM-Scl100 were linked to cortical clinical features. Additionally, anti-Sm, anti-RNP and anti-PMScl100 antibodies were linked to the least purely typical for MS CNS imaging. Conversely, anti-Jo1 and anti-histones were associated with gadolinium enhancement in MRI and high cerebrospinal fluid IgG index, respectively.

Correlation analysis revealed notable antibody associations (e.g., anti-Ro52 with anti-aquaporin-4; AMA-M2 with aPL IgM). In follow-up, anti-CD20 mAbs were linked to zero relapses and the lowest ARR, significantly outperforming MS disease-modifying drugs, immunosuppression, and no treatment ($p < 0.005$).

Conclusion: Distinct autoantibody profiles in patients presenting with CNS demyelination are associated with specific clinical, radiological and laboratory features. MS-like SAD represents a clearly defined subset in contrast to DAF. Anti-CD20 therapies appear most effective in preventing neurological relapses.

Clinical Features and Treatment Outcomes in Aseptic Abscess Syndrome: A Systematic Review of 104 Cases

Eleni Papachristodoulou[1], Loukas Kakoullis[1], Ratnesh Chopra[2], Chris Derk[3] and Konstantinos Parperis[4], [1]Mount Auburn Hospital, Harvard Medical School, Cambridge, MA, [2]UMass Chan Medical School, Worcester, MA, [3]University of Pennsylvania, Philadelphia, PA, [4]University of Cyprus Medical School, Nicosia, Cyprus

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Aseptic abscess syndrome (AAS) is an inflammatory condition of unknown etiology, characterized by the formation of sterile neutrophilic abscesses that frequently respond to immunosuppressive therapy. We conducted a systematic review of all published AAS cases to describe its manifestations and outcomes.

Methods: This systematic review followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines (PROSPERO No. CRD42025641038). We searched PubMed/MEDLINE from inception through January 2025 using the terms "aseptic" and "abscess" or "abscesses" (Figure 1). Case reports and case series providing individual-level data were eligible for inclusion.

Results: A total of 73 studies describing 104 patients were included (54% female; median age: 32.5 years). The most frequently associated conditions were Crohn's disease (n = 34, 33%), ulcerative colitis (n = 21, 20%), and Sweet's syndrome

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(n = 8, 8%), which preceded the diagnosis of AAS in 50% of cases (Table 1). Common presenting symptoms included fever (n = 69, 66%), abdominal pain (n = 38, 37%), weight loss (n = 27, 26%), and pyoderma gangrenosum (n = 20, 19%).

The spleen was the most frequent site of abscess development (n = 71, 68%), followed by the liver (n = 38, 37%), skin (n = 38, 37%), and lymph nodes (n = 33, 32%). The median number of organs involved was 2 (IQR: 2–3), with 49 (47%) patients having abscesses in three or more organs. Among those with available data, the median duration of symptoms before diagnosis was 2.3 months (IQR: 0.8–12).

Most patients received corticosteroids (n = 93, 89%), with abscess resolution reported in 59 of 64 (92%) cases with available outcome data. Additional therapies included DMARDs (n = 47, 45%) and biologics (n = 29, 28%). Among the 74 patients with available data, antibiotics were administered in 42 (57%), for a median duration of 14 days (IQR: 7–26.5).

Among 95 patients with follow-up data, 53 (56%) experienced at least one relapse. The median number of relapses was 1 (IQR: 0–2), with the first relapse occurring at a median of 3 months (IQR: 1–12). Relapses were more frequent among patients with splenic abscesses (64% vs. 35%, p = 0.011), lymph node involvement (71% vs. 48%, p = 0.038), and in those with abscesses affecting ≥3 organs (69% vs. 43%, p = 0.010). Notably, among 28 patients who underwent splenectomy, 20 (71%) experienced a relapse despite the procedure. Logistic regression demonstrated that the odds of relapse increased by 70% with each additional organ involved (OR = 1.70, 95% CI: 1.16–2.48, p = 0.007), and nearly tripled among patients with involvement of ≥3 organs (OR = 2.97, 95% CI: 1.28–6.89, p = 0.011). No deaths were reported.

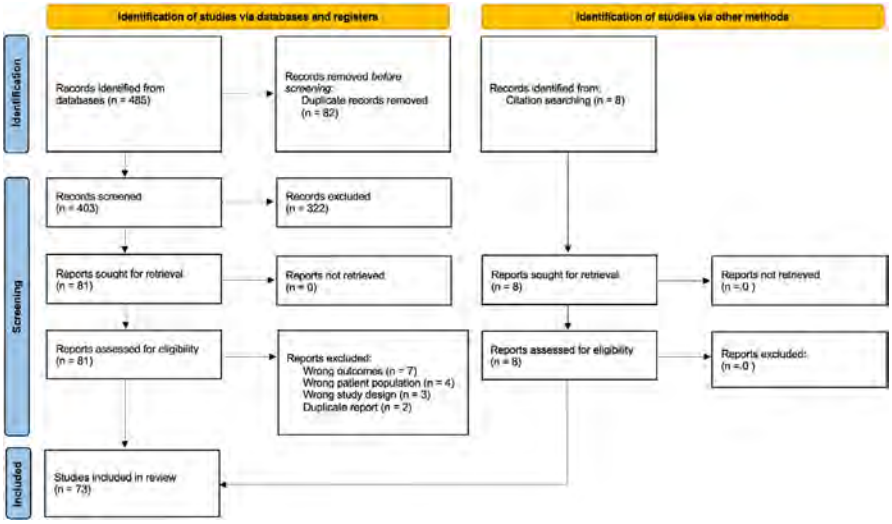

Figure 1. The PRISMA flow diagram for the systematic review

Conclusion: AAS is often associated with underlying inflammatory disorders, particularly inflammatory bowel disease. Fever and splenic abscess are the most common manifestations. Despite high initial response rates to immunosuppressive therapy, relapses are common, particularly in patients with splenic, lymph node involvement, or multi-organ disease, while splenectomy does not appear to prevent recurrence. These findings may inform risk stratification and follow-up strategies in patients with multisystem disease.

Behçet's Syndrome Beyond Endemic Borders: A 24-Year Longitudinal Analysis of Mortality in a Diverse South American Cohort

Fabio Specian[1], Carolina Ejnisman[2], Rafael Bassara Macedo[1], Pedro Araujo[3], Barbara Bayeh[2], Thiago Freitas[4], Rafael Cordeiro[5] and Henrique Giardini[4], [1]Rheumatology Division, Hospital das Clinicas da Faculdade de Medicina da Universidade de Sao Paulo (USP), Sao Paulo, Sao Paulo, Brazil, [2]Rheumatology Division, Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, Sao Paulo, SP, Brazil, Sao Paulo, Brazil, [3]Universidade de São Paulo, Sao Paulo, São Paulo, Brazil, [4]Rheumatology Division, Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, Sao Paulo, SP, Brazil, São Paulo, Brazil, [5]Rheumatology Division, Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, Sao Paulo, SP, Brazil, São Paulo, Sao Paulo, Brazil

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Behçet's syndrome (BS) is a chronic, relapsing vasculitis that contributes substantially to morbidity and mortality, primarily due to vascular and neurological complications. Most of the available mortality data in BS derive from studies conducted in endemic regions. This study aims to evaluate long-term mortality in a multiethnic South American cohort of BS patients.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: This research is a retrospective analysis of a prospective, single-center and multiethnic cohort of BS patients followed between January 2000 and December 2024. We included BS patients diagnosed according to the International Study Group and/or the International Criteria for Behçet's Disease. Mortality was analyzed according to qualitative and quantitative variables using descriptive statistics. Associations with mortality during follow-up were assessed through bivariate Cox regression, with estimation of unadjusted hazard ratios (HRs) and 95% confidence intervals.

Results: In our cohort of 303 patients, the median follow-up time was 117 months (IQR: 55–184 months); 186(61.6%) were female. Eight (2.6%) patients died during the study period. The mean age at BS diagnosis was 31.5(±10.4) in survivors and 33.4(±8) in non-survivors (p=0.662). The mean age at death among the eight patients was 47.6 years (±14.1), and the mean interval between BS diagnosis and death was 14.6 years (±10.3). Causes of death included three cases of malignancy, one of undetermined cause, and four attributed to disease activity. The presence of pulmonary artery aneurysm (HR=28.4; 95% CI: 3.32–243.53; p=0.002), parenchymal central nervous system involvement (HR=6.81; 95% CI: 1.65-28.06; p=0.008), previous use of cyclophosphamide (HR=20.4; 95% CI: 2.38-175; p=0.006) and infliximab (HR=4.87; 95% CI: 1.16-20.44; p=0.031), type 2 diabetes mellitus (DM2) (HR=6.72; 95% CI: 1.67-27.03; p=0.007) and cancer (HR=8.81; 95% CI: 2.02-38.5; p=0.004) were associated with increased mortality risk. Colchicine use was associated with a significantly reduced risk of mortality (HR=0.08; 95% CI: 0.02-0.36; p=0.001). Given the low mortality, only exploratory (unadjusted) analysis of factors associated with death were performed.

Conclusion: Although mortality was low, the relatively large number of patients for a rare disease, the long-term follow-up, and the inclusion of multiple clinical variables provided meaningful insights into mortality risk factors in our cohort. Consistent with the current literature, pulmonary artery aneurysm and central nervous system involvement were strongly associated with increased mortality. The observed association between cyclophosphamide and infliximab use likely reflects treatment of more severe disease. The apparent protective effect of colchicine may be influenced by indication bias, as this drug is frequently used in milder cases. Nonetheless, its known benefits in cardiovascular prevention raise the hypothesis that colchicine could have a broader impact on mortality reduction in Behçet's syndrome, warranting further investigation.

Background/Purpose: Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disease in childhood. Up to one-third of patients experience disease flares in adulthood, with significant clinical and therapeutic implications. The introduction of biologic therapies in the year 2000 marked a paradigm shift in managing these patients, leading to better disease control and reduced long-term sequelae. However, limited data are available on how patient characteristics at diagnosis, particularly across different periods, influence disease progression and therapeutic management.

Methods: Retrospective, cross-sectional study including patients diagnosed with JIA between 1960 and 2024 who had at least one follow-up visit in an adult rheumatology clinic at a tertiary care hospital. Sociodemographic, clinical, and laboratory data were collected. Patients with systemic JIA were excluded due to their distinct clinical characteristics.

Results: A total of 46 patients were included (Table 1), predominantly female (71%), with a mean age at diagnosis of 8.9 ± 4.7 years, slightly higher in patients diagnosed after 2000 (9.36 ± 4.5 years). No significant differences were found regarding disease subtypes or autoimmune markers between patients diagnosed in the pre-biologic era (n=21) and post-biologic era (n=25).

The first-line treatment in 58% of cases was NSAIDs, followed by corticosteroids (32%). Among post-2000 patients, 88% required concomitant methotrexate treatment.

Biologic therapy was required at some point in the disease course in 60% of post-biologic era patients, compared to 47% in the pre-biologic group (p=0.401). Disease duration and age at initiation of the first biologic were significantly higher in the pre-biologic group (28.4 ± 12.65 years and 37.4 ± 15.38 years) compared to the post-biologic group (6.4 ± 5.71 years and 16.7 ± 4.77 years) (p < 0.001 for both).

Structural joint damage at baseline and after 10 years of treatment was significantly greater in the pre-biologic group than in the post-biologic group (p = 0.019).

Among all patients who received biologic therapy, 96% were initially treated with anti-TNF agents, with etanercept being the most used (56%).

Conclusion: In our cohort, patients diagnosed with JIA in the pre-biologic era had significantly greater initial structural damage than those diagnosed in the post-biologic era, possibly due to delayed diagnosis. Furthermore, the longer disease duration before initiation of biologic therapy and older age at first biologic use observed in the pre-biologic group may have contributed to increased long-term joint damage, highlighting the potential impact of earlier biologic intervention.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Krebs von den Lungen-6 (KL6) is produced by type 2 alveolar epithelial cells. High circulating KL6 levels show a good accuracy in the diagnosis of interstitial lung diseases, including those associated to CTD (CTD-ILD). Increased levels of KL6 have been found to predict mortality in idiopathic pulmonary fibrosis, and also in some cohorts of CTD-ILD patients. Previous data from our prospective CTD-ILD cohort have shown that KL6 changes over time correlate with disease course. Our aim was to evaluate KL-6 sensitivity to change upon different therapeutic interventions

Methods: The study was conducted in CTD-ILD patients included in a multicenter prospective register (NEREA) from Madrid. Demographics and process related variables are recorded and updated with clinical visits (at 6-monthly periods on average). For the aim of the study we selected treatment-naïve incident cases and extracted data regarding underlying disease, date of ILD onset, radiographic patterns, presence of fibrosis at the time of first KL6 determination, FVC (% from reference) and DLco (% from reference). Serum KL-6 concentrations were measured at baseline ($_{bl}$KL-6) and within the following 6 to 24 months ($_{fu}$KL-6). Changes in KL6 levels (ΔKL6%) were also determined. Data are shown as mean ± SD. 95% confident intervals (95CI) were calculated to assess the effect size. Statistical analysis included t test, Wilcoxon rank sum and linear regression. Alpha value was set at 0.05.

Results: The study population comprised 57 subjects (84% women), aged 64.7 ± 10.4 years. There were 25 never smokers (44% of the cohort) and only 3 active smokers. Clinical diagnosis included 24 IPAF cases (42%), 12 patients with SSc or

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

related conditions (21%), 4 with RA (7%), and 4 classified as PM/DM (7%), 3 with SS/lupus (5%) and 10 with other autoimmune conditions (17.5%). Radiographic patterns were classified as NSIP in 18 patients (31%), UIP in 22 (39%), and others in 17 (30%). Signs of fibrotic disease were observed in 34 patients (60%). FVC at baseline was 82±21%, while DLco was 64 ±25%, with 30 patients (53%) showing DLco > 60%. 26 patients (45.6%) remained untreated during the observation period, while 31 patients (54.4%) were put on immunossupressants or/and corticosteroids related to ILD. At baseline, KL-6 levels ($_{bl}$KL-6) were 2029 ± 2118 IU/ml (median 1512 IU/ml). A second KL6 determination ($_{fu}$KL6) was availble at a median of 11.7 (6-12) months of follow-up. Patients treated with immunosuppresants showed a significant reduction in KL6 levels as compared to those remaining untreated ($\Delta KL6_{is}$%: -22.1 ± 38 [95CI: -39.1; -8.2] vs $\Delta KL6_{O}$: 9.0 ± 46.8 [95CI: -9.9; -27.9], p 0.001). After adjustment by age and sex, treatment with immunosupressants resulted in a risk reduction of KL6 increasing over time (+ΔKL6) of 25.9 ± 11.7 [95CI: 2.5; 49.3] vs no treatment (p 0.031). After adjustment for sex and age, treatment initiation was associated with a 22.0 ± 9.7 risk reduction [95CI: 2.7; 41.4] of a +ΔKL6

Conclusion: Our results support the role of KL6 as activity biomarker in CTD-ILD, and underscore its value as surrogate marker of reponse to immunosuppresants both in interventional trials and in clinical practice.

Management of Interstitial Lung Disease in People with Systemic Autoimmune Rheumatic Diseases: A Comparison of Rheumatologist and Pulmonologist Perspectives

Genna Braverman[1], Kerri Aronson[2], Charlene Thomas[2] and Robert Spiera[3], [1]Hospital for Special Surgery, New York, NY, [2]Weill Cornell, New York, NY, [3]Scleroderma, Vasculitis, and Myositis Center, Hospital for Special Surgery, Weill Cornell Medical College, New York, NY

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Interstitial lung disease (ILD) is common and important feature of systemic autoimmune rheumatic diseases (SARD). Rheumatologists and pulmonologists are central to the care of this complex condition. Specialists have unique training and expertise; whether these differences lead to distinct approaches to SARD-ILD treatment is unknown. We conducted a national, cross-sectional survey of rheumatologists and pulmonologists to assess how subspecialty affects physician management of SARD-ILD.

Methods: Surveys were electronically distributed to United States pulmonologists and rheumatologists identified through professional society memberships and social media. Surveys contained case questions on SARD-ILD management with variations of the underlying disease (mixed connective tissue disease, idiopathic inflammatory myopathy, rheumatoid arthritis, systemic sclerosis and Sjogren's) and ILD severity (asymptomatic, symptomatic, progressive). Surveys also contained

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

items on perceived importance of variables to treatment decisions, as well as opinions on ownership over aspects of management and healthcare maintenance. We analyzed responses submitted 5-9/2024.

We compared specialists' responses via univariate logistic regression, Chi-squared or Fisher's exact tests; we performed multivariable logistic regression of case questions controlling for practice setting, clinical experience and geography.

Results: Analyses included 309 participants (rheumatologists=184, pulmonologists=125) (Table 1). Compared to rheumatologists, pulmonologists were more likely to treat asymptomatic and symptomatic ILD with corticosteroids for all SARD except asymptomatic systemic sclerosis (odds ratios [OR] 2.22-7.69, all $p< 0.05$), and progressive ILD with antifibrotics (OR 3.33-3.84, all $p< 0.05$). Compared to pulmonologists, rheumatologists were more likely to add or modify immunomodulation/immunosuppression for all symptomatic and progressive SARD-ILD (OR 1.82-5.44, all $p< 0.05$) (Figure 1).

There were disciplinary differences in the relative importance of clinical variables to treatment decisions: more rheumatologists than pulmonologists rated as "very important" the extrapulmonary status of a patient's SARD (51.1% vs. 35.0%) and the specific autoantibody (26.7% vs. 19.2%), whereas more pulmonologists rated as "very important" the radiographic

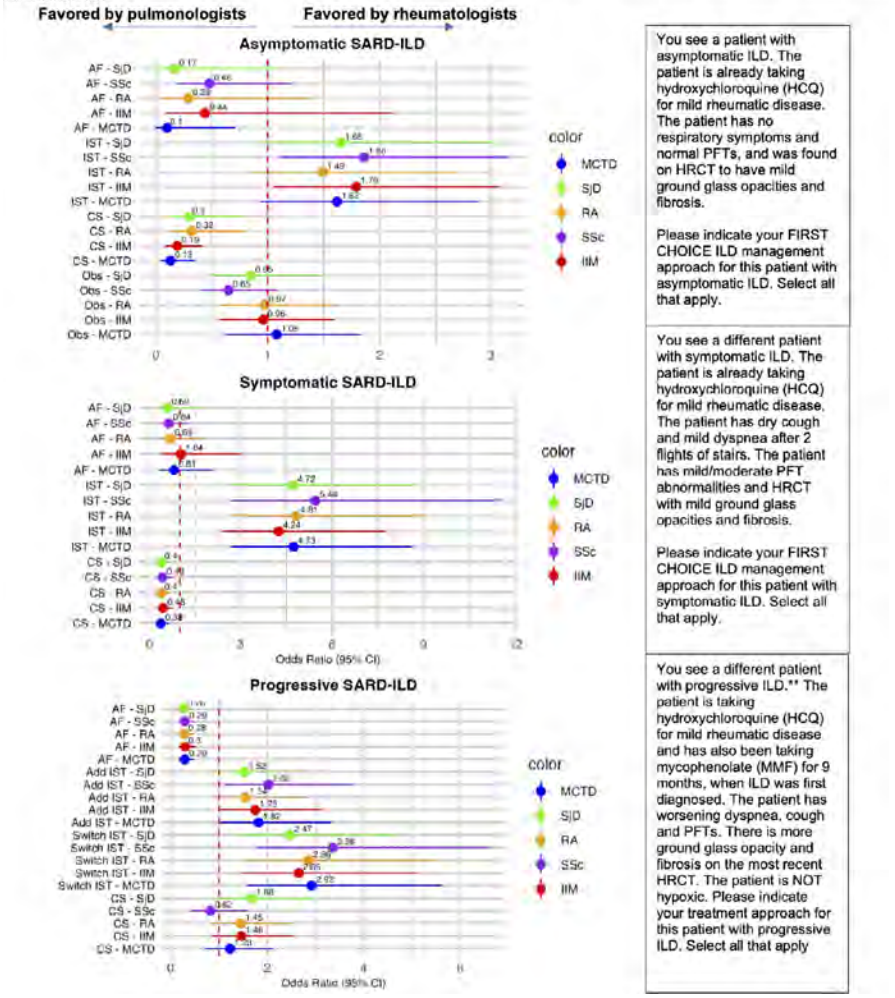
Figure 1. Case Based Questions – Multivariable Analysis*

"Controlling for region (Northeast, South, Midwest, Mountain/West Coast), practice setting (academic, non-academic), experience (<10, >=10 years)

Respondents selected their first-choice treatment approach, answering each case scenario five times varying the SARD (MCTD, IIM, RA, SSc and SjD). Responses by specialty were compared. Obs=observation; CS=corticosteroid; IST=immunosuppression/immunomodulation; AF=antifibrotic.



pattern of ILD on high-resolution computed tomography (60.0% vs. 39.9%) and the presence of fibrosis (64.7% vs. 46.6%).

Specialists also identified distinct scopes of decision-making responsibility and reported attending to disparate areas of healthcare maintenance. Rheumatologists were significantly more likely to screen for and treat osteoporosis, perform reproductive health counseling and ensure up-to-date cancer screening, whereas pulmonologists were more likely to screen for pulmonary hypertension and provide treatment for GERD, smoking cessation and PCP prophylaxis (all $p < 0.05$) (Table 2).

Conclusion: This national physician survey study suggests distinct specialty approaches to SARD-ILD management, and highlights opportunities to leverage complementary disciplinary expertise as part of a co-management framework.

Abstract Number: 2032

Validation of systemic Juvenile Arthritis Disease Activity Score 10 (sJADAS 10) in adult patients with Still's Disease

Georgia-Savina Moysidou[1], Spyridon Katechis[2], Stéphane Mitrovic[3] and Bruno Fautrel[4], [1]Sorbonne université, Service de rhumatologie, groupe hospitalier Pitié-Salpêtrière, Assistance publique-Hôpitaux de Paris, Athens, Greece, [2]National and Kapodistrian University of Athens Medical School, Athens, Greece, Athens, Greece, [3]Sorbonne université, Service de rhumatologie, groupe hospitalier Pitié-Salpêtrière, Assistance publique-Hôpitaux de Paris, Paris, France, [4]Sorbonne Université - APHP, Department of Rheumatology, Hôpital Pitié-Salpêtrière, Inserm UMRS 1136-5, PARIS, France, Paris, France

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Recent EULAR/PReS recommendations have acknowledged the lack of unique and consensual tool to quantify disease activity in Still's disease (SD). The systemic Juvenile Arthritis Disease Activity Score 10 (sJADAS10) (1) is to date the most advanced SD activity outcome measure in terms of construct validity and sensitivity to change with operable threshold already validated in children but not in adults.

The objective of our work was to validate sJADAS10 thresholds in adult patients with SD.

Methods: Post hoc analysis of the cohort of Still's patients from one unique reference center. Adult patients fulfilling Yamaguchi's or Fautrel's classification criteria, and with available clinical and biological data to calculate sJADAS10 score were included in the study.

Disease activity was elicited sJADAS calculation. As a gold standard, patients were categorized into 4 groups according to the 4 qualitative definitions of inactive disease (ID), minimal disease activity (MDA), moderate disease activity (MoDA) and high disease activity (HDA) proposed by Rosina *et al*. (2) (Table 1). The agreement between sJADAS values and disease activity categorization was tested by Cohen's kappa coefficient, to evaluate in what extent sJADAS values in adult patients fits with ID/MDA/MoDA/HDA qualitative categories.

Results: A hundred and twenty-nine visits from 93 patients were included in the study. The visits made by the same patient in a different disease activity state were considered as referring to distinct patients. Most of the patients were women (n= 89) mean aged (SD) of 36 (13) years with a mean (range) disease duration of 6,2 (0-40) years. Median (IQR) sJADAS was 12.8 (4.1-26.2). Forty-two patients were in HDA, 31 MoDA, 29 in MDA and 27 in ID according to their sJADAS-based statuses, respectively, whereas 39 were in HDA, 32 in MoDA, 20 in MDA and 38 in ID according to the qualitative disease assessment, respectively (**Figure 1**). Overall accuracy of sJADAS was 0.77 (95% CI :0.68- 0.84), whereas kappa coefficient was 0.69. Agreement was higher for patients with high disease activity.

Conclusion: sJADAS thresholds are relevant and validated by our work in adult patients with SD. These results are in favor of the use of sJADAS in both children and adults with SD and could position it as a relevant composite measure for assessing disease activity in SD.

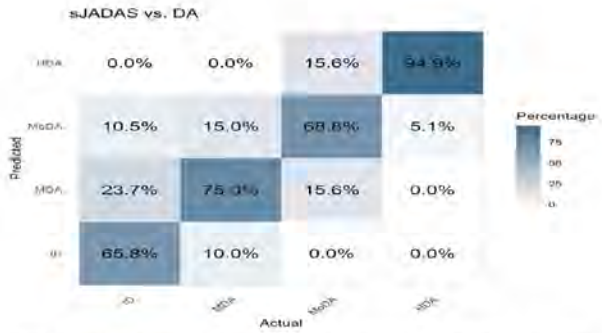
Table 1: Definitions of disease activity based on Rosina et al.

Inactive disease	Minimal disease activity	Moderate disease activity	High disease activity
Absence of fever and of any other systemic or articular manifestations attributable to sJIA. If the patient is still on medications, it may be possible to stop all therapies.	Absence of fever and of other major systemic features. Only mild systemic manifestations (i.e. faint skin rash, residual hepatosplenomegaly) and/or an active joint count of ≤1 can be present. The patient can only be receiving low-dose glucocorticoid therapy (i.e. ≤ 0.1 mg/kg/day), with further dose reduction being possible. If the patient is receiving only therapy with DMARDs or biologics, it might be possible to gradually withdraw it.	Disease activity state in between minimal disease activity and high disease activity. The level of disease activity does not allow any reduction of the ongoing therapy or may require a change or intensification of treatment.	Presence of fever ≥38°C and/or any other major systemic or articular manifestations (i.e., intense rash, severe serositis, active polyarthritis). The start of an aggressive therapy or the intensification of ongoing treatment is definitely required. Typically, a patient in the state of high disease activity is at disease onset or has a disease flare.

Figure 1: Heatmap showing the concordance between patients' status according to sJADAS- based statuses and qualitative disease assessment



sJADAS, systemic Juvenile Arthritis Disease Activity Score; DA, qualitative disease assessment, ID, Inactive Disease; MDA, Minimal Disease Activity; MoDA, Moderate Disease Activity; HDA, High Disease Activity; PPV, Positive Predictive Value; NPV, Negative predictive Value

Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Hypocomplementemia, defined as low serum C3 and/or C4 concentrations, is common in patients with IgG4-related disease (IgG4-RD). While this has historically been linked with renal involvement, recent data have shown that hypocomplementemia is more accurately associated with extent of IgG4-RD across multiple sites rather than individual organ manifestations, suggesting that complement-driven inflammation is central to the disease process. We aimed to assess whether complement is deposited locally in IgG4-RD submandibular gland lesions.

Table 1. Demographics and disease characteristics of eight patients in whom submandibular gland biopsies were stained for complement deposition. Results reported as n (%) unless noted otherwise. §At any point in disease course. *1 patient was treated with methotrexate for comorbid rheumatoid arthritis.

Characteristic	Value

Methods: We obtained submandibular gland tissue from 8 patients who fulfilled the 2019 ACR/EULAR IgG4-RD Classification Criteria and had undergone submandibular gland biopsy for diagnostic purposes. Other disease features, including sites of involvement beyond the submandibular glands and the presence or absence of hypocomplementemia, were not considered when identifying samples to be analyzed. We extracted disease features, laboratory results, demographic data, and treatment status at the time of biopsy from the medical records. All tissues were formalin-fixed and paraffin-embedded prior to sectioning. Immunohistochemistry was performed to stain for C3d, an end product of complement activation that persists in tissue longer than most other complement activation fragments. We similarly stained for C3d in a negative control (uninvolved submandibular gland) and positive control (human liver with primary sclerosing cholangitis).

Results: Demographic and disease characteristics of the 8 IgG4-RD patients studied are shown in **Table 1**. Six of the 8 patients (75%) were treatment-naïve at the time the biopsies were obtained. Five (62.5%) of the patients were female. The median disease duration at the time of biopsy was 301.5 days (IQR: 221, 1082.5). Only 3 patients (37.5%) had hypocomplementemia at any point in the disease course. Histopathologic features of the submandibular glands are shown in **Table 2** and reflect the findings that are typical of submandibular glands involved by IgG4-RD. All samples demonstrated a dense lymphoplasmacytic infiltrate and most (5, 62.5%) demonstrated an IgG4+/IgG+ plasma cell ratio ≥40% (**-Figure 1A-D**). All 8 submandibular gland biopsies showed deposition of C3d at sites of immune infiltration (**Figure 1E-F**), suggesting immune cells may be triggering complement activation. Additionally, C3d was also observed in several sites of fibrosis, suggesting complement may be contributing to fibrosis in IgG4-RD (**Figure 1F-H**). Staining patterns of positive and negative controls were as expected (**Figure 1I-J**).

Conclusion: Evidence of complement deposition was found in 8 of 8 submandibular glands included in this study. Complement activation was evident at this site of disease even in patients who demonstrated no sign of complement consumption in the peripheral blood (i.e., no C3 or C4 hypocomplementemia). These findings raise the possibility that tissue-targeted complement inhibition may be a useful treatment strategy in IgG4-RD and support the notion of complement-mediated inflammation being central to the disease mechanism of IgG4-RD.

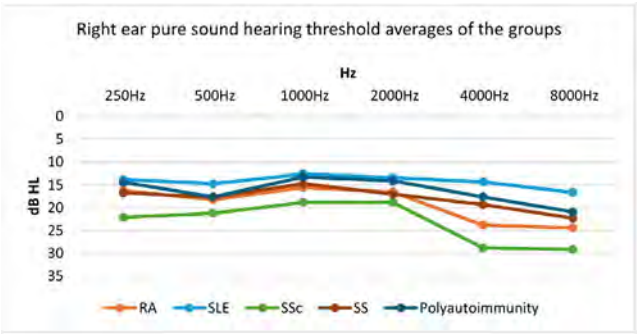
SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

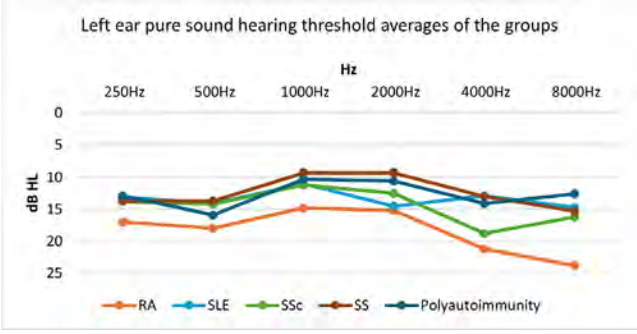
Background/Purpose: Autoimmune inner ear disease is a progressive sensorineural hearing loss of autoimmune origin, often underdiagnosed due to the lack of specific criteria, and requires further research to improve its detection and treatment. To determine the prevalence of hearing loss in adult patients with a confirmed diagnosis of systemic autoimmune rheumatic disease, seen at a Rheumatology Department in Bogotá, Colombia.

Methods: Cross-sectional observational study including 147 patients (18-60 years), selected through non-probabilistic consecutive sampling. Cases of hearing loss attributable to non-autoimmune causes were excluded. Each participant underwent pure tone audiometry (PTA) and a structured clinical interview to assess otovestibular symptoms. Demographic, clinical, audiological, and immunological variables were collected. Statistical analysis was performed using Stata® v17 with descriptive statistics and tests for comparison of proportions and ranks, considering $p < 0.05$ as the significance level.

Results: Only 4.76% (n = 7) of patients had a previously confirmed diagnosis of hearing loss; however, 46.9% (n = 69) were found to have hearing loss confirmed through PTA, of which 91.3% were sensorineural, 81.2% fluctuating, and mostly mild (69.6%) with a descending pattern (87.5%). Hearing loss rates were higher in SSc (75%) and rheumatoid arthritis (RA) (60.6%). Antinuclear antibodies were positive in 70.4% of patients, and 65.9% had received corticosteroids. A significant association was found between hearing loss and systemic sclerosis (SSc) (p = 0.042). When analyzing the pure tone average thresholds in both ears by autoimmune disease (Fig. 1 and 2), it was noted that in RA patients – Left Ear, the curve remained relatively stable between 250–2000 Hz, with a noticeable increase (worsening threshold) from 4000 Hz onward, indicating high-frequency hearing loss. In contrast, in SSc – Right Ear, thresholds were elevated across all frequencies, especially from 4000 Hz onwards, showing a consistently worse hearing profile with marked high-frequency hearing



Right ear pure sound hearing threshold averages of the groups



Left ear pure sound hearing threshold averages of the groups

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

impairment. Anti-Ro antibodies were positive in 46.7% of patients without hearing loss and in 20.4% of those with hearing loss ($p = 0.0078$).

Conclusion: This study reveals a marked underdiagnosis of hearing loss in patients with systemic autoimmune rheumatic diseases, with only 4.76% previously identified versus 46.9% confirmed through audiological assessment during the study. The predominance of sensorineural, mild, and descending-pattern hearing loss—particularly in conditions such as SSc and RA—highlights the need for systematic auditory evaluation in this population. An inverse association was found between Anti-Ro positivity and hearing loss, which may reflect a lower rate of auditory involvement among patients with Sjögren's syndrome within the cohort. As one of the few studies to comprehensively assess hearing loss across a broad spectrum of autoimmune diseases, our findings underscore the importance of increased clinical awareness and early detection strategies in rheumatologic care.

Interim Phase 1 Results for SPY002, a Novel Half-Life Extended Monoclonal Antibody Targeting TL1A, Suggest A Potential for Q3M or Q6M Maintenance Dosing for Rheumatologic Disease

Joshua Friedman[1], JD Lu[2], Bing Wang[2], Kinjal Hew[2], Preeyam Patel[2], Michael Kennedy[2], Mark Rose[2], Curtis Sheldon[2], Rachel McLean[2], Emily Svejnoha[2], MiRa Huyghe[1], Brian Connolly[2] and Deanna Nguyen[2], [1]Spyre Therapeutics, Waltham, MA, [2]Spyre Therapeutics, Waltham

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: TL1A is an inflammatory cytokine and a member of the TNF superfamily. Target cells that express DR3 and respond to TL1A include T cells, B cells, fibroblast-like synoviocytes (FLS), and osteoclasts, each of which is associated with inflammation and joint damage in rheumatoid arthritis (RA), ankylosing spondylarthritis (axSpA), and psoriatic arthritis (PsA). Synovial fluid and serum TL1A levels are highly elevated in RA, axSpA, and PsA, and TL1A promotes FLS activation, chemokine signaling, and MMP production by osteoclasts in vitro. Variants in the TL1A gene are associated with both TL1A levels and the diagnosis of RA, axSpA, and PsA or psoriasis, and multiple animal models demonstrate that TL1A inhibition is therapeutic in arthritis.

SPY002 is an investigational fully human IgG1 monoclonal antibody that specifically binds to TL1A and blocks the interaction of TL1A with its receptor, known as death receptor 3 (DR3). It includes a YTE modification in the Fc domain to increase the binding affinity to FcRn and thereby extend the antibody half-life. A Phase 1, first-in-human study in healthy volunteers is being conducted to characterize the safety, tolerability, PK, and PD properties of SPY002.

Methods: SPY002-101 is a randomized, double-blind, placebo-controlled single ascending dose (SAD) Phase 1 study in healthy volunteers aged 18 to 65. Study participants were randomized to either SPY002 or placebo in a 3:1 ratio as in dose cohorts as follows: 100 mg SC, 300 mg SC, 300 mg IV, 1000 mg IV, or 1500 mg IV. Blood was collected to evaluate safety,

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

PK, PD (serum soluble TL1A levels), and ADA assessments at scheduled study visits. Interim safety and bioanalytical data with up to four months of follow-up from the first SAD cohort were analyzed.

Results: Interim PK data from all cohorts demonstrated dose-proportional pharmacokinetics for SPY002. Noncompartmental analysis and population PK modeling suggested a half-life extension of approximately 3-fold relative to typical monoclonal antibodies. PD analysis demonstrated saturating effects on soluble TL1A levels beginning with the lowest dose tested (100 mg SC) that extend to the latest time points assessed thus far. Blinded safety data from all cohorts thus far demonstrated SPY002 to be well tolerated with no serious or severe adverse events, with most adverse events being mild in severity and unrelated to study agent.

Conclusion: Interim PK analysis following single doses of SPY002 demonstrated half-life extension supporting potential maintenance dosing at a frequency of every 3 to 6 months with a single SC injection. SPY002 resulted in saturating changes in soluble TL1A levels. SPY002 was well tolerated, with all adverse events being non-serious and typical of a Phase 1 study in healthy volunteers. These results support advancement of SPY002 into clinical trials in rheumatologic disease and in other potential indications.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Janus kinase inhibitors (JAKis) are effective therapeutic agents against chronic inflammatory arthritis (CIA). Tofacitinib and baricitinib were defined as pan-JAK inhibitors, while upadacitinib and filgotinib a JAK1 selective inhibitors. Real world data comparing retention rate across JAKi classes in CIA are limited. The aim of the present study was to compare retention rate between pan-JAK inhibitors and JAK1 selective inhibitors in CIA and to assess the role of JAKi class in the risk of discontinuation and find out other possible predictors of treatment discontinuation.

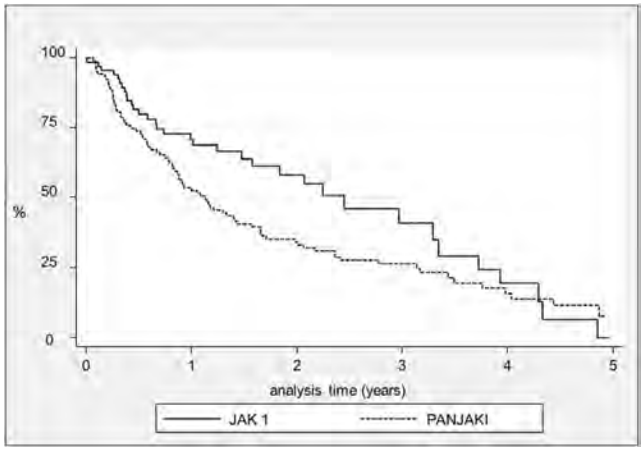
Methods: We retrospectively evaluated patients with CIA [Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA), and Spondyloarthritis (SPA)] treated with JAKis from 2017 to 2024. The independent variable was JAKi class (pan-JAK inhibitors/ JAK1 selective inhibitors). Retention rates were assessed by Kaplan–Meier method, and multivariable Cox regression hazards model was run to identified predictors of discontinuation.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Causes of JAKis discontinuation; global and stratified

Results: The study comprised 181 patients [83% women, median age 56(49-63)]. 84% had RA, 9% PsA and 7% SpA. Patients received 227 JAKi treatments courses, 96 of JAK1 selective inhibitors y 131 of pan-JAK inhibitors. Overall, 118 courses (52%) were discontinued (55% inefficacy, 42% adverse events, 3% other). The estimated IR of discontinuation was 35.5 [29.6-42.5] and 50% of them discontinued within 1.65 [1.2-2.2] years after JAKI starting. The IR of discontinuation was higher in women, and in those with cardiovascular disease or risk factors, being lower for RA vs other CIAs. Discontinuation rates were lower for JAK1-selective inhibitors (IR: 28.6; 95% CI: 20.5–39.8) vs pan-JAK inhibitors (IR: 39.6; 95% CI: 31.9–49.1). In the multivariate analysis, pan-JAK inhibitors, female gender, PsA, cardiovascular disease, previous b/tsDMARDs courses, cardiovascular risk factors, and leflunomide combined treatment were associated with higher probability of discontinuation.

Conclusion: Pan-JAK inhibitors (baricitinib and tofacitinib) may have higher discontinuation rates than JAK1 selective inhibitors is (upadacitinib and filgotinib) patients with CIAs in real-world settings. Several clinical factors, including diagnosis and comorbidities, influence JAKi retention and should guide treatment selection.



Kaplan-Meier survival estimate curve

The Largest International Cohort Study of HA20 Reveals Novel Genetic Architecture and Age-Dependent Phenotypic Evolution

Manuel Carpio Tumba[1], Tingyan He[2], Jun Wang[3], Elizabeth Kairis[1], Kyr Goyette[1], Akuti Kethri[1], Urekha Karri[4], Atif Towheed[1], Jun Yang[5], Qing Zhou[6], Daniella Schwartz[1] and HA20 Working Group, [1]University of Pittsburgh, Pittsburgh, PA, [2]Shenzhen Children's Hospital, Shenzhen, China (People's Republic), [3]Zhejiang University School of Medicine, Zhejiang, China (People's Republic), [4]School of public health, Pittsburgh, PA, [5]Rheumatology and Immunology Department of Shenzhen Children's Hospital, Shenzhen, 518100, China., Shenzhen, China (People's Republic), [6]Zhejiang University School of Medicine, Hangzhou, China (People's Republic)

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Haploinsufficiency of A20 (HA20) is a monogenic autoinflammatory disease caused by loss-of-function (LOF) mutations in *TNFAIP3*. HA20 was initially described as an early-onset form of Behçet's disease (BD)[1]; however, subsequent reports have revealed a broad clinical picture that can also include features of autoimmunity, lymphoproliferation, immunodeficiency, and allergy. The initial clinical descriptions could have led to an inaccurate representation of the natural history due to reporting or ascertainment bias. This study is the first large multicenter cohort study describing the clinical spectrum, genetic landscape, and natural history of patients with HA20.

Methods: A retrospective analysis was conducted on HA20 patients referred to the study investigators following genetic testing that revealed a pathogenic or likely pathogenic variant in *TNFAIP3*. All variants were reviewed by study investigators in consultation with geneticists at participating sites. The diagnosis of HA20 was established through the identification of either a heterozygous *TNFAIP3* pathogenic variant (ACMG PVS1) or a heterozygous deletion of 6q23 including *TNFAIP3*. Probands were identified using multigene panels, chromosomal microarrays, or next gen sequencing-based clinical assays. Some family members were diagnosed using single-gene *TNFAIP3* testing after the initial proband diagnosis. Patients were divided into three groups (≤ 6 years, 6-16 years, and ≥ 16 years) for further analysis of the phenotype distribution.

Table 1. Baseline characteristics of patients divided by cohorts and ages

General characteristics	China	US	Total
Male, sex, n (%)	62 (56.4)		
Children, n (%)	81 (73.6)		
Median age at onset (y) (n=93)	3	5	
Median age at diagnosis (y) (n=93)	5.6	21.9	9.3
Median time of follow-up (m) (n=81)	25	39.1	28
Clinical features, n (%)	n = 107	n = 47	n = 154
Short stature	43 (41.2)	8 (17.0)	51 (33.1)
Recurrent fever	55 (51.4)	23 (48.9)	78 (50.6)
Lymphadenopathy	24 (22.4)	21 (44.7)	45 (29.2)
Hepatomegaly	22 (20.6)	9 (19.1)	31 (20.1)
Splenomegaly	16 (15.0)	12 (25.5)	28 (18.2)
Recurrent infection	34 (31.8)	12 (25.5)	46 (29.9)
Mucocutaneous involvement	73 (68.2)	42 (89.4)	115 (74.7)
Gastrointestinal involvement	69 (64.5)	26 (55.3)	95 (61.7)
Hepatic involvement	17 (15.9)	22 (46.8)	39 (25.3)
Hematologic abnormalities	60 (56.1)	40 (85.1)	100 (64.9)
Musculoskeletal system	31 (29.0)	30 (63.8)	61 (39.6)
Thyroid involvement	11 (11.7)*	14 (29.8)	25 (17.7)
Neurologic involvement	13 (12.1)	12 (25.5)	25 (16.2)
Pulmonary involvement	26 (24.3)	11(23.4)	37 (24.0)
Cardiac involvement	4 (3.7)	9 (19.1)	13 (8.4)
Ophthalmologic involvement	1 (0.9)	5 (10.6)	6 (3.9)

If it was clearly labeled, the number of patients in total equalled to the number of Chinese patients in parentheses plus 47 instead of 154.
*From 94 patients.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Genetic analysis of HA20 patients. A. Genetic analysis of this cohort revealed 85 pathogenic variants in TNFAIP3. Gene variants in red and black font represented novel variants and reported variants, respectively. B. Common variants identified in HA20 patients.

Results: A total of 185 patients with HA20 from 41 rheumatology clinics across 7 countries were included. The median age at onset was 3.3 (range: 0.04-30). Detailed clinical records were available for 169 patients. Among them, 75 (44.4%) presented with an autoinflammation-predominant phenotype, 26 (15.4%) with an autoimmunity-predominant phenotype, and 56 (33.1%) exhibited a mixed autoimmune-autoinflammatory phenotype. Autoinflammation-predominant disease was most common in the youngest age group ($p = 0.029$) and in the Chinese group ($p < 0.0001$). A total of 89 *TNFAIP3* pathogenic mutations were identified, including novel variants resulting in protein truncation or heterozygous deletion. No clear association was found between clinical phenotype and genetic architecture. Anti-TNF and anti-IL-1 agents were effective in most patients (60% and 63.2% respectively), particularly in those with inflammatory arthritis or gastrointestinal ulcers. Two thirds of patients achieved complete remission at their last follow-up visit.

Conclusion: HA20 presents with highly variable phenotypes, including autoinflammation-predominant, autoimmune-predominant, and mixed phenotypes. Autoimmunity may become more common over time and have a lower incidence in individuals with specific ancestries, although these differences could still be related to ascertainment bias in specific age groups and/or countries. No definitive genotype-phenotype correlation was observed. Lastly, this comprehensive and systematic description of a large international cohort may suggest improved precision medicine strategies for the complex care of HA20 patients.

Abstract Number: 2038

Real-World Use of Dual Targeted Therapy in Rheumatic Disease: A Single-Center Case Series

Marta Aguilar Zamora[1], Karla Romelia Arévalo Ruales[2], marta Garijo Bufort[2], Maria Isabel Pastor Orduña[1], Celia Aparicio Rubio[3], Silvia Cornejo Uixeda[4] and Joaquín Borrás Blasco[4], [1]Rheumatology Department, Hospital de Sagunto, Spain, Puerto de Sagunto, Comunidad Valenciana, Spain, [2]Rheumatology Department, Hospital de Sagunto, Spain, valencia, Spain, [3]Pharmacy Department, Hospital de Sagunto, Spain, Puerto de Sagunto, [4]Pharmacy Department, Hospital de Sagunto, Spain, Puerto de Sagunto, Spain

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Combination therapy with two biologic agents (bDMARDs) or a biologic plus a Janus kinase inhibitor (JAKi) is rarely used in rheumatology due to safety concerns and limited supporting evidence. However, it may be considered for selected patients with refractory disease or those with multiple immune-mediated inflammatory diseases (IMIDs). This case series describes the efficacy and safety of dual targeted therapy in patients with rheumatic conditions, including those requiring treatment for concurrent IMIDs or non-rheumatic comorbidities.

Methods: Patients treated in the Rheumatology Department of a district hospital who received at least two biologic agents or a combination of a bDMARD and a JAKi, dispensed by the hospital pharmacy, were retrospectively reviewed.

Patients were categorized into two groups:

- **Group A:** both agents for IMIDs, (eg., spondyloarthritis [Spa] and inflammatory bowel disease [IBD]).
- **Group B:** one treatment for a rheumatic inflammatory disease and the other for a non-rheumatic condition (eg., migraine, asthma).

Demographics, indications, duration of dual therapy, clinical response (Group A), acute-phase reactants, and adverse events (both groups) were collected. Clinical efficacy was assessed globally ('yes,' 'partial,' 'no') due to population heterogeneity.

Results: 10 patients were included: 6 in Group A and 4 in Group B. One patient in Group A received two different dual therapy regimens over time (both included) and one was in both groups due to triple therapy.

Table 1

Patient Number	Sex (M/F)	Age (years)	Disease Duration (years)	Dual Therapy Exposure Duration (months)	Biologic 1	Biologic 2	Biologic 3	Diseases
1	M	40	9	6	Upadacitinib 45 mg	Risankizumab	Etenimab	Spa, IBD, Psoriasis, Migraine
2	F	46	13	19	Upadacitinib 15 mg	Guselkumab	-	RA, Psoriatic Arthritis
3	M	44	5	16	Tofacitinib 11 mg	Infliximab	-	Spa, IBD
4	F	53	2	5	Tofacitinib 11 mg	Infliximab	-	Spa, IBD
5	F	51	22	12	Upadacitinib 15 mg	Ustekinumab	-	Spa, IBD
6	F	39	12	25	Tofacitinib 11 mg	Ustekinumab	-	Spa, IBD
8	M	39	8	18	Infliximab	Ustekinumab	-	Spa, IBD
7	F	55	9	19	Etenumab	Tocilizumab	-	RA, Migraine
8	F	16	2	17	Benralizumab	Upadacitinib 15 mg	-	Spa, Asthma
9	M	35	10	29	Adalimumab	Benralizumab	-	RA, Asthma
10	F	67	19	6	Clirtolizumab	Dupilumab	-	Spa, Atopic Dermatitis

Spa: spondyloarthritis
IBD: inflammatory bowel disease
RA: Rheumatoid Arthritis

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Among the 10 patients, 4 were male and 6 female, with a mean age of 48.6 ± 18.1 years and a mean disease duration of 8.5 ± 5.4 years.

Therapy characteristics and drug combinations appear in Table 1, with the most frequent being JAK inhibitor plus an IL-23 inhibitor. Mean duration of dual therapy was 17.5 months (range: 5–29).

In Group A, 5/6 patients had Spa + IBD, one had psoriatic arthritis and rheumatoid arthritis. The average number of prior biologic treatments was 3.83 ± 1.47. Among 7 drug combinations, 2 patients showed clinical improvement, 4 partial improvement and 1 failed. One case led to treatment switch, resulting in partial benefit. The mean reduction in CRP was 7.85 ± 2.3 mg/L and in ESR 9.33 ± 15.14 mm/h. No serious adverse events were observed. Two patients experienced mild infections while on tofacitinib combinations, which resolved with dose reduction; treatment continued.

In Group B, non-rheumatic comorbidities included migraine (n=2), asthma (n=2), and atopic dermatitis (n=1). The median duration of treatment was 27 months (range 6–29). Four patients were still receiving treatment at the time of data collection and one patient discontinued due to lack of efficacy for migraine. No major adverse events were reported.

Conclusion: The expanding use of biologic therapies across multiple diseases has led to combination regimens involving biologic and targeted synthetic drugs. In our series the most frequent combination was JAKi with IL-23 inhibitor. Patients needing dual therapy often had Spa and IBD, but others with IMIDs or comorbidities like asthma or migraine also benefited. Despite the clinical complexity of these cases, dual therapy has shown a favorable safety and efficacy profile.

To Hold or Not to Hold: Variability in Management of DMARDs in the Setting of Acute Infections - A Survey of Rheumatologists

Mollie Gellman[1], Medhasweta Sen[2], Ari Schwartz[3], Peter Merkel[4] and Nadine Mbuyi[5], [1]Montefiore Medical Center, Bronx, NY, [2]University of Virginia, Charlottesville, VA, [3]Rheumatology Consultants PC, Brockton, MA, [4]University of Pennsylvania, Philadelphia, PA, [5]George Washington University, Washington, DC

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Disease-modifying antirheumatic drugs (DMARDs) vary widely in their immunosuppressive activity. Guidance on managing DMARDs during acute infections is limited, particularly regarding when to hold or resume therapy. This study aimed to investigate clinical practice patterns among rheumatologists concerning management of DMARDs during acute infections, stratified by type of immunosuppression, degree of infection, and disease severity.

Methods: A 27-question survey was distributed to rheumatologists via professional networks and academic listservs; responses were anonymous. Questions assessed clinical decisions on holding/restarting DMARDs during varying severities of acute infection, in patients with either life/organ-threatening or non-life/organ-threatening rheumatic disease. Infections were categorized as: i) outpatient non-serious (unlikely to require hospitalization, may not need treatment), ii) outpatient

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

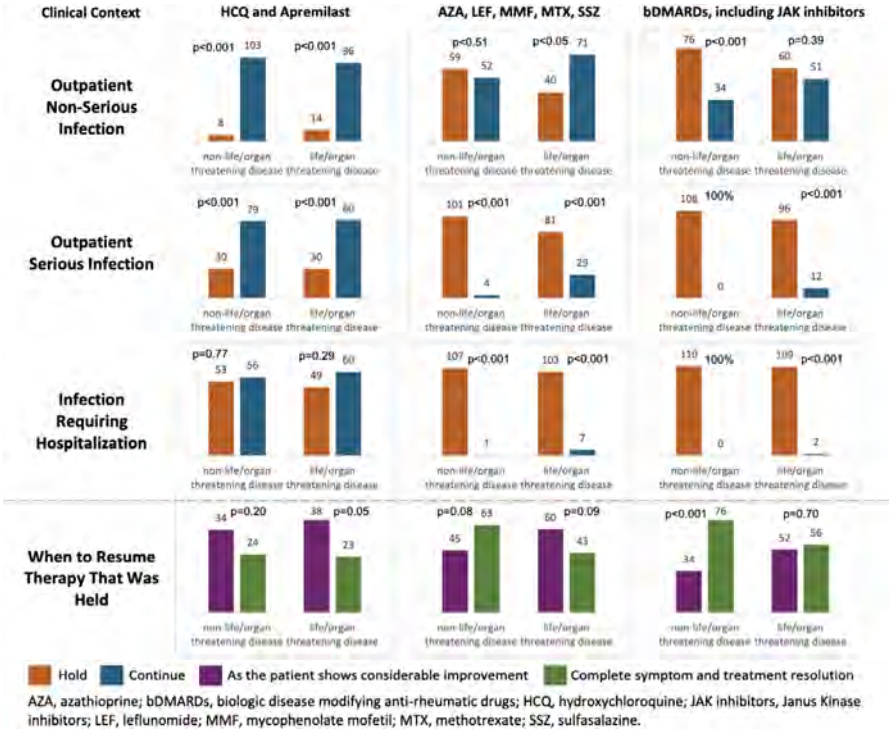

Figure 1. Rheumatologists' Views on Holding DMARDs During Infection

serious (may require hospitalization if not improving), and iii) requires hospitalization. DMARDs were grouped by immunosuppressive risk, from lowest to highest: 1) hydroxychloroquine (HCQ) and apremilast, 2) conventional synthetic DMARDs (csDMARDs: azathioprine, leflunomide, methotrexate, mycophenolate mofetil, sulfasalazine), and 3) biologic DMARDs (bDMARDs) including Janus kinase (JAK) inhibitors. Chi-square tests compared binary responses, with significance defined as $p < 0.05$.

Results: A total of 113 rheumatologists participated: 63% private practice, 34% academic; ages ~30-90 years, from 25 states and D.C. Responses are summarized in **Figure 1**. Depending on scenario, 73-93% of rheumatologists would continue HCQ and apremilast during outpatient infections ($p < 0.001$). Responses were split for infections requiring

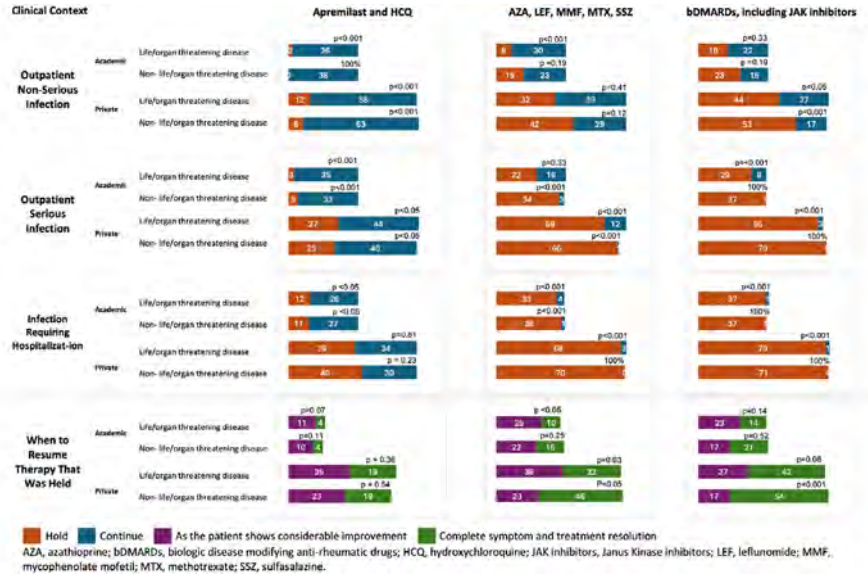

Figure 2. Rheumatologists' Views on Holding DMARDs During Infection, Based on Type of Practice

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

hospitalization in both non-life/organ-threatening and life/organ-threatening disease (49%, 51%, and 45%, 55% respectively). 64% would continue csDMARDs for non-serious outpatient infections in patients with severe diseases ($p < 0.05$); responses were split 47% and 53% in less severe disease. 69% would hold bDMARDs and JAK inhibitors in non-serious outpatient infections without severe disease ($p < 0.001$), with divergent responses (54%, 46%) for life/organ-threatening disease. Depending on the context, 74-100% would hold csDMARDs and bDMARDs/JAK inhibitors during serious outpatient infections and infections requiring hospitalization, regardless of disease severity ($p < 0.001$). 77% would restart biologics only after full resolution of symptoms and completion of treatment in non-life/organ-threatening diseases ($p < 0.001$). In all other contexts there was no significant majority regarding when to restart therapy. Academic physicians were more likely than private physicians to continue treatment in milder infections, particularly in more severe rheumatic diseases, and to resume DMARDs earlier (**Figure 2**).

Conclusion: There is substantial variability among US rheumatologists in the management of DMARDs during acute infections. These findings highlight a significant knowledge gap and suggests that development of guidelines on this topic would help inform clinical decision-making and standardize care.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Musculoskeletal (MS) corticosteroid (CS) injections are commonly used for joint inflammation with a perceived low risk of systemic toxicity, including hyperglycemia and adrenal suppression. However, rare neuropsychiatric complications, such as acute psychosis, have been reported after MS-CS injection. The exact mechanism is unclear, but systemic absorption and individual vulnerability may play roles. This study examines the incidence and predisposing factors of neuropsychiatric complications following MS-CS injections in rheumatology patients.

Methods: A retrospective analysis was performed on 5487 MS-CS injections at the University of New Mexico Hospital, supervised by one attending. Electronic medical records were reviewed to identify patients with new-onset psychiatric symptoms within seven days post-injection. Psychiatric complaints were confirmed based on provider documentation and mental health evaluations, when applicable. Data collected included the type and dose of corticosteroid, number of injection

sessions, psychiatric symptom patterns, symptom duration, and whether proactive treatment was implemented during subsequent injections. A comparison was made between patients with and without psychiatric symptoms, focusing on baseline psychiatric history, particularly anxiety disorders.

Results: Of 5487 individual MS-CS injections in 596 individuals, 221 injections (4.02%) resulted in psychiatric complaints that were relayed to a medical provider. These complaints were concentrated in 24 patients, who had recurrent symptoms on reinjection. The mean dose of TA was 73.3±43.7 mg per injection session. The psychiatric symptoms post MS-CS injection in affected patients were vasomotor symptoms (100%), anxiety (100%), paranoia (37.5%), and hallucination (25%), and in certain cases acute medical consultation and/or treatment (29.2%) was required. Preexisting clinical depression (68.4%-83.3%) and anxiety syndromes (47.4%-87.5%) were very common in all rheumatology patients undergoing MS-CS injections (**Table I**). When comparing patients with neuropsychiatric symptoms after MS-CS injection to representative group who did not develop symptoms, a pre-existing anxiety syndrome was markedly increased in the neuropsychiatric group (**-Table 1**). All symptoms typically resolved within 3 days. Because of the recurrent nature of these symptoms in individual patients on reinjection, 11/24 (45.3%) of affected patients requested proactive treatment after an injection, and lorazepam 1 mg every 8 hours after the injection for 2-3 days was prescribed with complete prevention the symptoms.

Conclusion: Preexisting neuropsychiatric disease – especially depression and anxiety syndromes – is present in majority of rheumatology patients undergoing MS-CS injections. MS-CS injections can cause significant psychiatric symptoms in about 4% of cases and typically follows a stereotypic pattern with anxiety most common though psychotic symptoms can also occur. The major predisposing factor appears to be a pre-existing anxiety disorder. For affected patients, short-term benzodiazepine treatment may provide symptomatic relief and prevention.

Evaluating Biologic Effectiveness in Co-Occurring Dermatologic and Rheumatic Disease: A Systematic Review

Nashwah Memon[1], Dylan Wambold[2], Omar Alani[3], Syed Minhaj Rahman[4] and Adel Haque[5], [1]Lake Erie College of Osteopathic Medicine, Miami, [2]Drexel University College of Medicine, Philadelphia, [3]Icahn School of Medicine at Mount Sinai, New York, [4]Department of Medicine, Northwell Health Northern Westchester Hospital, Mount Kisco, [5]Jefferson Health Northeast, Philadelphia

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Clinicians prescribing biologics must be aware of the expanding indications for biologic/systemic therapies across dermatology and rheumatology alike. Given disease-state overlap between these fields, providers should also recognize relevant medical indications beyond their specialty. There is growing evidence supporting biologic off-label use in conditions such as spondyloarthritis and systemic lupus erythematosus (SLE). This systematic review aims to guide clinicians in determining biologic and systemic therapies for patients with co-occurring dermatologic and rheumatologic conditions by summarizing available evidence on overlapping indications.

Methods: A systematic search of PubMed & Scopus databases from inception through March 2025 was conducted using the following format: (((BiologicName treat*[Title/Abstract] OR (BiologicName improve*[Title/Abstract])) NOT (Skin Diseases, Infectious[MeSH Terms])) NOT ("skin and connective tissue diseases"[MeSH Terms])). Biologics included: adalimumab, secukinumab, etanercept, infliximab, ustekinumab, ixekizumab, guselkumab, risankizumab, apremilast, baricitinib, ruxolitinib, brodalumab, dupilumab, and belimumab. Studies describing off-label treatments of patients with rheumatic conditions were included. Data extracted from eligible studies included study design, sample size, biologic dosing and duration, clinical outcomes, and efficacy measures. Studies were then evaluated for their levels of evidence according to the Oxford Centre of Evidence-Based Medicine.

Results: Multiple biologics—including adalimumab, brodalumab, etanercept, infliximab, ixekizumab, risankizumab, ustekinumab, and secukinumab—are indicated for psoriasis. Among these, all except brodalumab are also approved for psoriatic arthritis (PsA), and several are indicated for ankylosing spondylitis (AS). Secukinumab has additional approvals for non-radiographic axial spondyloarthritis and enthesitis-related arthritis, while belimumab is specifically approved for SLE. Adalimumab, etanercept, infliximab, secukinumab are also indicated for rheumatoid arthritis (RA). In a case series of 45 patients, off-label use of TNF inhibitors (infliximab, etanercept, adalimumab) for SAPHO syndrome resulted in 93.3% of patients experiencing musculoskeletal symptom relief and 72.4% showing skin symptom improvement. IL-17/IL-23 inhibitors had moderate efficacy, with ustekinumab improving skin symptoms in 50% of patients and musculoskeletal symptoms in 60%, while secukinumab led to improvements in 57.1% and 37.5%, respectively. In SLE, a randomized controlled trial of ustekinumab showed a 28% greater SRI-4 response compared to placebo. Additionally, in an open-label 28-week trial for AS, off-label ustekinumab use led to reduced symptoms and inflammation by week 24.

Conclusion: This review highlights the expanding role of biologics in the treatment of rheumatologic conditions beyond their primary dermatologic indications. Their interdisciplinary applications present new opportunities for research and clinical practice, underscoring the need for further investigation to optimize their use and broaden their therapeutic scope.

Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: The combination of biological (bDMARDs) and targeted synthetic DMARDs (tsDMARDs) has emerged as a promising approach to improve clinical outcomes in immune-mediated inflammatory diseases (IMIDs), particularly in refractory or complex cases where simultaneous targeting of multiple inflammatory pathways may be beneficial. However, this strategy raises concerns regarding safety, adverse events, and optimal drug selection. The objectives of this

	IMID	Extra-MSK involvement	Gender (age at baseline, years)	Previous DTT	Most recent DTT	DTT indication	DTT exposure (months)	Discontinuation of DTT (reason)	Baseline disease activity	Disease activity at the end of DTT or observational period	Clinical improvement of DTT indication

Clinical characteristics, DTTs used, duration of treatment, reason for discontinuation and disease activity and status at baseline (beginning of most recent DTT) and at discontinuation of treatment or at the end of the study of the included patients.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

study are to describe the clinical characteristics of IMID patients receiving dual targeted therapy (DTT) with two bDMARDs or a bDMARD plus a tsDMARD, to identify the most commonly used combinations and main adverse events and to evaluate clinical response to DTT.

Methods: We conducted a retrospective observational study including IMID patients treated with bDMARD and/or tsDMARD combinations at Hospital Universitario La Paz from October 2019 to December 2024. We collected clinical data, details of DTT combinations, treatment duration, reasons for discontinuation, and disease activity assessed by DAS28, ASDAS, and DAPSA at baseline and at discontinuation or end of follow-up.

Results: Nineteen patients with 28 DTT cycles were included; 68.4% were women, with a mean age at DTT initiation of 42.9 ±19.4 years. Diagnoses included spondyloarthritis (SpA, 36.8%), rheumatoid arthritis (RA, 21.1%), psoriatic arthritis (PsA, 15.8%), juvenile idiopathic arthritis (JIA, 10.5%), polyarthritis of possible genetic cause (10.5%), and Behçet syndrome (5.3%). A second IMID treated with bDMARD/tsDMARD was associated in 57.9% of patients: 63.3% with bowel disease (IBM), 27.3% with psoriasis, 18.2% with chronic urticaria and 9.1% with chronic angioedema. Extra-musculoskeletal manifestations were present in 21.2%: 1 case of interstitial lung disease, 1 sicca syndrome, 2 uveitis and 1 with neurological involvement. Patients had received a median of five prior DMARDs. Thirteen patients (68.4%) had a single DTT cycle, while six (31.6%) had ≥1 prior DTT cycles. The main indications for DTT initiation were active musculoskeletal disease (63%), active IBD (11.1%), combined active MSK/IBD disease (7.4%), and psoriasis (7.4%). Most frequently used combinations were TNF inhibitor (TNFi)+JAK inhibitor (JAKi, 32.1%), TNFi+vedolizumab (25.0%), and TNFi+anti-IL23 (10.7%). Median DTT duration was 10.3 months (range 0.7–60.3 months). The most common adverse events were infections (25.0%) and hypertransaminasemia (10.7%). Discontinuation occurred in 57.1% of DTT cycles, mainly due to inefficacy (31.1%) and infections (7.1%). At the end of the study, 57.9% of patients maintained TDD and clinical improvement was observed in 52.6%, as assessed by disease activity indices and clinical reports (see Table 1).

Conclusion: DTT appears to be a viable option for refractory IMID patients, achieving clinical improvement in over half of the cases. Nonetheless, the high rate of adverse events and treatment discontinuation underscores the importance of careful patient selection and close monitoring. Further research is needed to refine patient selection, optimize drug combinations, and improve risk management strategies.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Canakinumab, an interleukin-1β inhibitor, has demonstrated efficacy in treating colchicine-resistant/intolerant familial Mediterranean fever (FMF). This study aims to assess the efficacy and safety of long-term canakinumab treatment in AA amyloidosis patients with FMF managed at a tertiary center.

Methods: Adult patients diagnosed with FMF based on the Tel Hashomer criteria and treated with canakinumab, followed at the Rheumatology and Nephrology Clinics of Hacettepe University, were retrospectively evaluated. Biopsy-confirmed AA amyloidosis was identified in 25 of the 107 patients who received canakinumab. One patient who did not come for follow-up after canakinumab was excluded from the study. Data on demographics, age at diagnosis, estimated glomerular filtration rate (eGFR) (≥60 vs < 60 mL/min/1.73 m^2) and proteinuria levels (urine protein/creatinine ratio, mg/g) before and after canakinumab, use of ACE inhibitors or ARBs, presence of diabetes mellitus, history and timing of renal transplantation, colchicine dose at the last visit, canakinumab dose and interval, treatment duration were recorded.

Table 1. Demographic and clinical characteristics of the study cohort

	Study cohort (N:24)	
Gender (F/M)	15/9	
Age (years), median (IQR)	46.5 (39.5-56)	
Age at diagnosis (years), median (IQR)	19 (14.5-37.5)	
Continuation of colchicine (n,%)	22 (91.7)	
Colchicine dose at last visit (mg/day), median (IQR) (n: 22)	1.0 (0.5-1.25)	
Drug survival (months), median (IQR)	69 (30.5-88.5)	
Dose interval (n,%)		
Every 4 weeks (150 mg)	21 (87.5)	
Every 8 weeks (150 mg)	1 (4.2)	
Every 12 weeks (150 mg)	1 (4.2)	
Every 4 weeks (300 mg)	1 (4.2)	
Renal transplantation (n,%)	8 (33.3)	
Before canakinumab	7 (29.2)	
After canakinumab	1 (4.2)	
Use of ACEI/ARB treatment (n,%)	13 (54.2)	
Presence of diabetes mellitus (n,%)	4 (16.7)	
eGFR (mL/min/1.73 m²) (n,%)	**Before CAN**	**After CAN**
≥60	15 (62.5)	10 (41.7)
<60	9 (37.5)	14 (58.3)
Proteinuria	**Before CAN**	**After CAN**
Urine protein/creatinine ratio (mg/g), median (IQR)	2423.2 (454.4–4389)	724.2 (188.9–1975.4)
<3.5 g/day, (n,%)	16 (66.7)	22 (91.7)
≥3.5 g/day, (n,%)	8 (33.3)	2 (8.3)

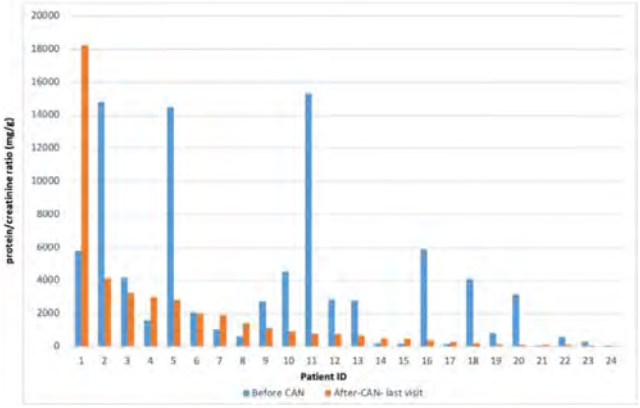

Figure 1. Comparison of baseline and final proteinuria levels in patients receiving canakinumab

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: In total 24 patients (15 F, 9 M) were included for final analysis **(Table 1)**. The median age at diagnosis was 19 (14.5-37.5) years, while the median age of the cohort was 46.5 (39.5-56) years. Of eight patients with renal transplantation, only one underwent transplantation after initiation of canakinumab. At the last visit, the median colchicine dose was 1.0 mg/day (0.5–1.25). During a median duration of 69 months (30.5–88.5), canakinumab was administered at 150 mg/4 weeks in 21 patients, every 8 weeks in one patient, and every 12 weeks in another. In one patient, the dose was escalated to 300 mg/4 weeks. The proteinuria level significantly decreased following canakinumab initiation, from 2423.2 mg/g (454.4–4389) to 724.2 mg/g (188.9–1975.4) at the final visit (p=0.034). Nephrotic-range proteinuria (>3.5 g/day) was present in 8 patients before treatment, but persisted in only two patients at the final assessment. A change in eGFR category was observed in only five patients (patients 6, 8, 14, 17, and 18)**(Figure 1)**.

Conclusion: Canakinumab therapy, administered for approximately six years, was well tolerated in patients with FMF and biopsy-proven AA amyloidosis, also patients with renal transplantation. High adherence of colchicine and canakinumab treatment was associated with a significant reduction in proteinuria and stabilization of renal function in the majority of patients.

Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Vacuoles, E1 enzyme, X-linked, autoinflammatory, somatic (VEXAS) syndrome is a late-onset, monogenic autoinflammatory disorder driven by somatic mutations in the UBA1 gene of hematopoietic stem cells. Given that the management of VEXAS syndrome often requires long-term treatment with intense immunosuppressive drugs, the overall susceptibility to infections is elevated in VEXAS patients. This systematic review aims to assess the spectrum of reported infectious pathogens and their associated complications in patients with VEXAS syndrome.

Methods: This study followed the PRISMA 2020 Statement, with its protocol prospectively registered in PROSPERO (CRD42023450442). We screened MEDLINE (via PubMed) and EMBASE from the earliest record until March 25, 2025. Cohort studies that reported infections caused by a confirmed pathogen during the follow-up of patients with VEXAS syndrome were eligible for inclusion. We excluded case reports and patients who lacked confirmation of the VEXAS diagnosis

or the infectious etiology. The primary outcome was determined as the frequency distribution of reported infectious agents, stratified by pathogen type, including bacterial, viral, and fungal categories. The secondary outcome was the infection-related mortality risk. A pairwise meta-analysis was conducted to calculate the pooled mortality risk among included patients.

Results: Five cohorts with 333 patients were included. At the time of enrollment, 299 (89.8%) of these patients were receiving glucocorticoids (Table 1). Among the included patients, 110 (33%) were reported to have experienced at least one episode of infection with a confirmed etiologic agent, and multiple infections were observed in 10 (3%). A total of 146 infectious episodes were identified in these patients. Bacterial agents were responsible for 72 (49.3%) of the cases. The most frequently isolated bacterial pathogens were Enterobacteriaceae (22.2%), Legionella pneumophila (19.4%), and non-tuberculous mycobacteria (19.4%). Among viral agents, the highest frequencies were observed for SARS-CoV-2 (41.2%), varicella-zoster virus (21.6%), and herpes simplex virus (15.7%). Pneumocystis jirovecii (73.9%) was the most

Table 2. Distribution of identified pathogens in patients with VEXAS Syndrome

Category	Pathogen	n	Frequency Among All Cases (%)	Frequency Within Category (%)
Bacterial (n =72)

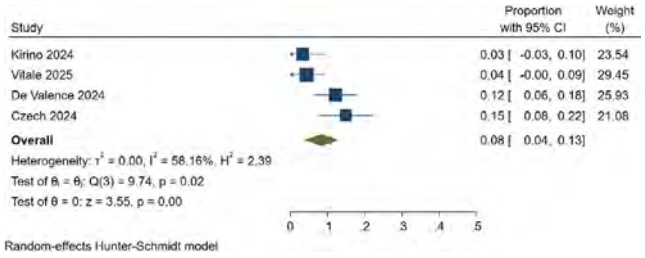

Figure 1. Infection-related mortality in patients with VEXAS syndrome

common cause of fungal infections (Table 2). Most infections were localized to the bronchopulmonary system (64.4%). In the context of glucocorticoid-sparing treatment strategies, 23 (19.3%) infectious episodes occurred during cDMARD therapy, 35 (29.4%) during bDMARD use, 41 (34.4%) during JAK inhibitor treatment, and 20 (16.8%) during azacitidine therapy. According to the meta-analysis outcomes, the overall infection-related mortality risk among included patients was 8% [95% CI (0.04,0.13), Figure 1].

Conclusion: Infections are among the significant causes of morbidity and mortality in patients with VEXAS syndrome. Physicians should closely monitor patients throughout the follow-up period and maintain careful control over immunosuppressive drug dosing. Further studies are needed to evaluate the efficacy of anti-infective prophylaxis in these patients.

Abstract Number: 2045

Malignancy in Behçet's Syndrome: A 24-Year Cohort Study In a Non-Endemicand Multiethnic Country

Pedro Araujo[1], Rafael Bassara Macedo[2], Fabio Specian[2], Carolina Ejnisman[3], Barbara Bayeh[3], Percival Sampaio-Barros[4], Thiago Freitas[4], Rafael Cordeiro[5] and Henrique Giardini[4], [1]Universidade de São Paulo, Sao Paulo, São Paulo, Brazil, [2]Rheumatology Division, Hospital das Clinicas da Faculdade de Medicina da Universidade de Sao Paulo (USP), Sao Paulo, Sao Paulo, Brazil, [3]Rheumatology Division, Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, Sao Paulo, SP, Brazil, Sao Paulo, Brazil, [4]Rheumatology Division, Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, Sao Paulo, SP, Brazil, São Paulo, Brazil, [5]Rheumatology Division, Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, Sao Paulo, SP, Brazil, São Paulo, Sao Paulo, Brazil

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Behçet's syndrome (BS) has been associated with an increased risk of malignancy, particularly in studies from endemic regions such as East Asia and the Middle East. Nonetheless, little is known about cancer risk in non-endemic, multiethnic populations. This study aimed to evaluate the frequency and profile of malignancies in a long-term BS cohort from South America.

Methods: We retrospectively conducted a data analysis of a single-center, multiethnic, prospective cohort of patients with BS followed between January 2000 and December 2024. Patients were diagnosed based on the International Study Group and/or the International Criteria for Behçet's Disease. Cancer occurrence was analyzed using descriptive statistics and

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

compared across groups with chi-square, Fisher's exact, and unpaired Student's t-tests. Unadjusted odds ratios (OR) (95% CI) were calculated through bivariate logistic regression.

Results: A total of 302 BS patients were included, of whom 14 (4.6%; 95% CI: 2.3%–7.0%) were diagnosed with cancer. The cohort was predominantly female (n=186; 61.6%), with 8 women (57.1%) in the cancer group. The mean follow-up time was 160.3 months (±92.6) in the cancer group and 122.8 months (±80.3) in the non-cancer group. Patients who developed cancer had a mean age of 33.4 years (±8.6) at the time of BS diagnosis, compared to 31.4 years (±10.4) among those without cancer. Cancer was diagnosed 18(±13.1) years after BS diagnosis, at a mean age of 49,4(±17) years. The most common malignancies were endometrial and bladder cancer (2 cases each; 14.3%). Single cases (7.1% each) included cervical intraepithelial neoplasia, breast cancer, undifferentiated soft tissue neoplasm, adenocarcinomas of the lung, colon, prostate, and a metastatic tumor with unknown primary site; chronic myeloid leukemia, large granular lymphocyte leukemia, and central nervous system lymphoma. In univariate analysis, type 2 diabetes mellitus (DM2) was the only variable significantly associated with cancer occurrence ($p = 0.004$), with an OR of 5.8 (95% CI: 1.89–17.74). No statistically significant associations were found with sex, smoking, alcohol use, clinical manifestations, or immunosuppressive therapies, including cyclophosphamide. Due to the presence of only one significant predictor, a multivariate regression model could not be created.

Conclusion: In the present long-term cohort, overall malignancy rate was 4.6%, with hematologic malignancies being the most frequent type, which is consistent with findings from other BS cohorts and raises questions about underlying immunologic mechanisms or exposure to immunosuppressive agents. The average interval between BS diagnosis and cancer onset was 18 years, underscoring the need for long-term vigilance. Notably, DM2 was the only variable significantly associated with cancer, with a nearly sixfold increased risk. This finding reinforces the established link between metabolic comorbidities and carcinogenesis. No associations were found between malignancy and other variables. However, given the relatively small number of cancer cases, the study was underpowered to detect weaker associations.

Utilization of the All of Us Research Program to Study the Impact of Genetic Background on Autoinflammatory Diseases

Song Wu[1], Zuoming Deng[2], Peter Gorevic[1] and **Qingping Yao**[1], [1]Stony Brook University, Stony Brook, NY, [2]Biodata Mining and Discovery Section, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: A widely recognized model of disease pathogenesis is the potential interplay of gene x gene x environment. Low penetrance variants in the NOD-like receptor and MEFV genes together may constitute a genetic background and contribute to genetically transitional disease. We utilized the All of Us Research Program (All of Us) to study the impact of genetic backgound in a large cohort of patients with autoinflammatory disease.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We conducted a retrospective analysis of adult patients with systemic autoinflammatory diseases (SAIDs). All patients underwent testing for a periodic fever syndrome gene panel designed to capture low penetrance variants of clinical significance. The distribution of gene variants and their frequencies were compared with 128,196 participants of European ancestry from the All of Us control.

Results: In total, 471 patients were genotyped and were divided into genotype-positive and -negative groups. Individual patients with positive genotyping carried variants in one or more SAID genes. SAIDs diagnosed among patients were Yao syndrome, Familial Medeteranean fever, Cryopyrin-associated periodic syndrome, NLRP12-Autoinflammatory disease and Mixed NOD-like receptor associated autoinflamamtory disease among others. For 265 patients who carried digenic or oligogenic variants, various combinations of these SAID genes were computed. We found the following genotype combinations NOD2/NLRP12, NOD2/MEFV, NOD2/NLRP3 and NLRP3/NLRP12, MEFV/NLRP3/NOD2, MEFV/NLRP12/NOD2 in decreasing order of prevalence. The frequencies of digenic and oligogenic variants in our patient population were compared with 128,196 controls in the All of Us dataset. We found that certain combinations of gene variants (e.g., NLRP3 Q705K/NOD2 V955I or NLRP12 F402L/NOD2 IVS8+158, NOD2 V955I/NLRP12 F402L) were significantly more frequent (**-Table to be presented**). These results indicate that digenic or oligogenic variants of low penetrance may constitute a related but divergent genetic backgroud susceptibility for several autoinflammatory diseases.

Conclusion: Comparison of a large cohort of SAID patients seen over a number years in a US referral center with the large All of Us control population underscores the impact of genetic background on disease expression. Genomic testing to search for digenic or oligogenic variants of even low penetrance is likely to significantly aid in disease diagnosis, and guide precision therapy.

Abstract Number: 2047

Trends in Lung Transplant Listing Outcomes in Connective Tissue Disease associated Interstitial Lung Disease (CTD-ILD) Across Two Decades

Sambhawana Bhandari[1], Derek E. Byers[1] and Deepali Sen[2], [1]Washington University in St. Louis School of Medicine, St. Louis, [2]Washington University in St Louis, Chesterfield, MO

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Lung transplantation represents a potential life-extending therapy for patients with advanced CTD-ILD. This study aims to characterize lung transplant listing outcomes among CTD-ILD patients over a 20-year period using the Organ Procurement and Transplantation Network (OPTN) national database.

Methods: Data analyzed from the OPTN between 2003-2023 included adults ≥18 years of age with CTD-ILD listed for lung transplantation. Patients were categorized into six subgroups based on diagnosis: scleroderma, lupus, rheumatoid arthritis (RA), myositis, Sjögren's, and "Other" (including mixed connective tissue disease, CTD, etc.). Trends in listing and outcomes were analyzed in 5-year quartiles and across diagnoses. We analyzed the proportion of patients getting successfully transplanted, wait list times, and death on transplant list.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1: Shows the number of patients listed for lung transplantation every 5-year intervals, numbers transplanted, percentage transplanted, death on the list (and percentage), and mean time to transplant in days with standard deviation (SD).

Quarter	Listed (N)	Tx (N)	Tx (%)	Death (N)	Death (%)	Mean time to transplant in days (SD)
2003-2008	185	116	62.70%	36	19.50%	233.9 (291.1)
2009-2013	443	317	71.60%	78	12.20%	195 (290.6)
2014-2018	605	459	75.90%	69	7.90%	168 (254.1)
2019-2023	744	607	81.60%	48	5.00%	120.9 (196.4)

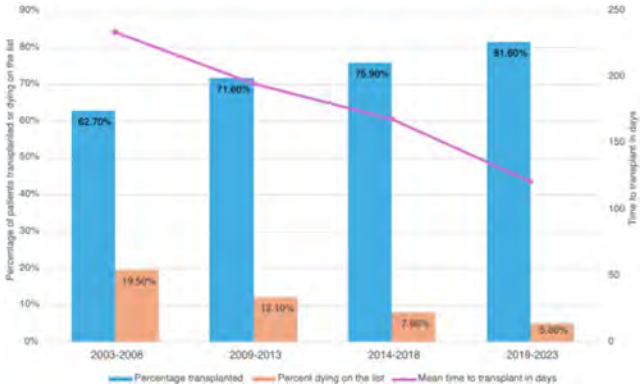

Figure 1: Line graph showing decrease in the time to transplant in days. Bar diagram showing an increase in percentage of transplanted patients and decrease in the percentage of death on the list from 2003-2023.

Results: A total of 1,977 individuals with CTD-ILD were listed for lung transplantation between 2003-2023.

Trends across time: In 5-year intervals numbers of patients listed for transplant increased from 185 in 2003-2007, 443 in 2008-2013, 605 in 2014-2018, and 744 in 2019-2023. The proportion of patients who underwent successful transplantation also steadily increased: from 62.7% in 2003-2008, 71.6% in 2009-2013, 75.9% in 2014-2018, and 81.6% in 2019-2023. The average time from listing to transplant in days decreased significantly, from 233.9 in 2003-2008 to 120.9 in 2019-2023. Death on the waitlist decreased over time: from 19.5% in 2003-2008, 12.2% in 2009-2013, 7.9% in 2014-2018, and 5% in 2019-2023.

Trends across diseases: Of the diagnosis groups listed for transplant, Scleroderma was the most common (47%, n=924) followed by "Other" (16%, n=323), RA (15%, n=293), myositis (11%, n=221), Sjögren's (7%, n=137), and lupus (4%, n=79). Rates of proceeding to transplantation were similar: "Other" (78.32%, n=253), Sjögren's (77.37%, n=106), RA

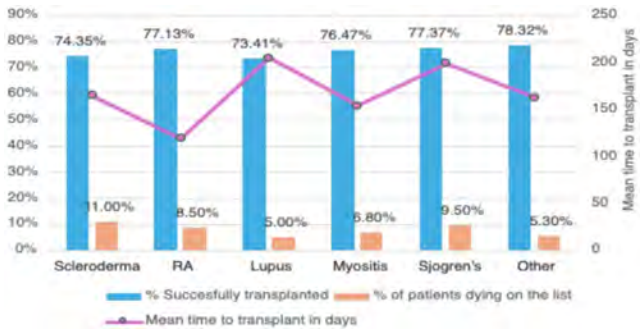

Figure 2: Bar diagram showing percentage of patients successfully transplanted (patients transplanted/patients listed *100), death on the list (%), and mean transplant time in days across various CTD types

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(77.13%, n=226), myositis (76.47%, n=169), scleroderma (74.35%, n=687), and lupus (73.41%, n=58). Mean days from listing to transplant ranged from: lupus (205 days), Sjogren's (199 days), scleroderma (165 days), other (163 days), myositis (154 days), and RA (119 days). Death while awaiting transplant ranged from Scleroderma (11%, n=101), Sjogren's (9.5%, n=13), RA (8.5%, n=25), myositis (6.8%, n=15), other (5.3%, n=17), and lupus (5%, n=4).

Conclusion: Our study suggests positive trends in lung transplant listing outcomes for CTD-ILD as reflected by an increase in the absolute number of listings and improved rates of transplantation. This is matched by shorter wait times and reduced wait list mortality. All CTD diagnoses seem equally likely to get a lung transplant. Some disease specific variability was noted in wait list times. Scleroderma patients exhibit slightly higher waitlist mortality. Limitations in OPTN registry data may impact our results.

DDR2 auto-phosphorylation in patients with Warburg-Cinotti syndrome promotes differentiation of fibroblasts into myofibroblasts and expansion of immature B cells with antibody production.

Sang Jin LEE and Yun Jeong Lee, Kyungpook National University School of Medicine, Daegu, Republic of Korea

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Warburg-Cinotti syndrome (WCS) is a rare connective tissue disorder caused by activating mutations in the DDR2 gene, characterized by progressive corneal neovascularization, keloid-like plaques, and acro-osteolysis. The mechanisms underlying these clinical features remain poorly understood.

Methods: We investigated a family with two WCS patients harboring the DDR2 c.2219A >G (p.Tyr740Cys) variant, a 25-year-old son and his 61-year-old father. Using whole-exome sequencing, single-cell RNA sequencing (scRNA-seq) of skin and peripheral blood mononuclear cells (PBMCs), and protein-level validation, we analyzed the impact of DDR2 activation on fibroblast and immune cells.

Results: Histologic and immunochemical analysis revealed extensive dermal fibrosis and increased smooth muscle actin (SMA)-positive myofibroblasts in WCS skin lesions. scRNA-seq analysis of keloid and normal scar datasets supported the role of DDR2 in promoting fibroblast-to-myofibroblast differentiation. PBMCs analysis from WCS patients showed an expansion of immature/transitional B cells with upregulated *PLCG2, PRKCB*, and *IL7R*, along with enhanced B cell receptor (BCR) signaling (Figures 1 and 2). These expanded immature B cells exhibited increased antibody production but reduced diversity of the antibody repertoire, particularly in the older patient. Serum analysis confirmed elevated IgG and free light chain levels. Immunohistochemistry demonstrated increased infiltration of CD68+ macrophages and CD79A+ B cells, with IgG deposition in WCS skin.

Conclusion: Our findings demonstrate that constitutive DDR2 auto-phosphorylation promotes myofibroblast differentiation and expansion of immature B cells, leading to excessive fibrosis and aberrant antibody production. This study advances the understanding of WCS pathogenesis and suggests potential therapeutic targets for its fibrotic and immune related manifestations.

Abstract Number: 2049

Descriptive Analysis of a Cohort of Neurosarcoidosis Mimics

Shivani Rangaswamy[1], Andrea Lopez[1], Megumi Sugita[1], Ethan Eyman[1], Elijah Lackey[1] and Jeffrey Shen[2], [1]Duke University Hospital, Durham, [2]Division of Rheumatology and Immunology, Duke University Department of Medicine, Durham, NC

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Sarcoidosis is a granulomatous multi-system disease with nervous system involvement in 5-20% of patients. Diagnosis of neurosarcoidosis is challenging due to its broad spectrum of phenotypic and radiographic manifestations. This study leverages a North American registry of patients misdiagnosed as neurosarcoidosis and provides a descriptive analysis of diagnostic tools used to evaluate patients for neurosarcoidosis.

Methods: Two hundred and forty-four patients with a diagnosis code of neurosarcoidosis were identified between 2010 and 2020 at a tertiary care academic institution. Chart review by a neurologist and rheumatologist identified 26 patients who were misdiagnosed as neurosarcoidosis and later found to have an alternative diagnosis. Twenty-three of these charts were reviewed to identify demographic data, relevant laboratory studies, neuroimaging, and pathology. Neuroimaging of a subgroup of 6 neurosarcoidosis mimics and 6 neurosarcoidosis controls were reviewed by 5 neuroimmunology specialists in a blinded survey to obtain additional data regarding radiographic diagnostic certainty of neurosarcoidosis and its mimics.

Results: Over half (52%) of the cohort was diagnosed with another primary CNS process, most commonly multiple sclerosis. Other common mimics included lymphoma (9%), infection (13%), primary ophthalmic conditions (17%), and rheumatoid arthritis (9%). Angiotensin converting enzyme (ACE) was elevated at least once in 40% of the patients. Cerebrospinal fluid (CSF) analysis showed an elevated white blood cell count and protein in approximately 1/3 of the cohort and low glucose in only 1 patient with rheumatoid arthritis. Of the 17 patients who had a biopsy of some tissue for their neurosarcoidosis workup, 12 had granulomas on pathology. Only 1 of 7 patients with a brain biopsy had granulomas on pathology. The majority of patients had MRIs of the brain and/or spine and the most common radiographic patterns were pachymeningeal and parenchymal enhancement.

In a radiographic review survey of 6 neurosarcoidosis mimics and 6 neurosarcoidosis controls, 4 out of 6 mimics and 5 out of 6 controls were correctly identified based on group consensus. The idiopathic hypertrophic pachymeningitis (IHP) case and rheumatoid arthritis case were incorrectly diagnosed as neurosarcoidosis based on group consensus. One neurosarcoidosis control was felt to be most likely IgG4-related disease (IgG4-RD) by 2 reviewers and neurosarcoidosis by 2 reviewers. Pre-existing knowledge of a pulmonary sarcoidosis diagnosis appeared to influence diagnostic certainty of neurosarcoidosis.

Table 1: Serum and CSF Studies

Serum or CSF Study	Lymphoma (n=2)	Infection (n=3)	Rheumatoid Arthritis (n=2)	Primary Ophthalmic Process (n=4)	Primary Central Nervous System Process (n=12)	Total
Elevated Serum Calcium	1/2, 50%	0/3, 0%	1/2, 50%	0/4, 0%	1/12, 8%	3/23, 13%
Elevated Serum ACE	1/1, 100%	0/2, 0%	1/1, 100%	1/3, 33%	3/8, 38%	6/15, 40%
Elevated Serum 1,25 Vitamin D	*	*	0/1, 0%	0/2, 0%	1/5, 20%	1/8, 13%
Elevated CSF White Blood Cells	2/2, 100%	0/2, 0%	1/2 , 50%	1/1, 100%	1/7, 14%	5/14, 36%
Elevated CSF Red Blood Cells	2/2, 100%	1/2, 50%	1/2, 50%	1/1, 100%	4/7, 57%	9/14, 64%
Elevated CSF Protein	2/2, 100%	0/2, 0%	2/2, 100%	0/1, 0%	1/8, 13%	5/15, 33%
Low CSF Glucose	0/2, 0%	0/2, 0%	1/2, 50%	0/1, 0%	0/8, 0%	1/15, 7%

grey shading = patient has been diagnosed with pulmonary sarcoidosis, white shading = patient has not been diagnosed with pulmonary sarcoidosis, MRI = magnetic resonance imaging IgG4-RD = IgG4 related disease, n = number of reviewers participating, SD = standard deviation			

Neuroimaging Survey Results

Conclusion: Common mimics of neurosarcoidosis include infection, lymphoma, rheumatoid arthritis, another CNS process, and primary ophthalmic processes. Laboratory and CSF studies may not be sensitive for neurosarcoidosis. MRI review by a neurosarcoidosis specialist can help differentiate neurosarcoidosis from mimics with radiographic differences, such as infection or multiple sclerosis, and spare the patient a biopsy. Biopsy may be needed to distinguish neurosarcoidosis from diseases that are radiographically similar, such as IHP or IgG4-RD. Limitations include small sample size and limited follow-up.

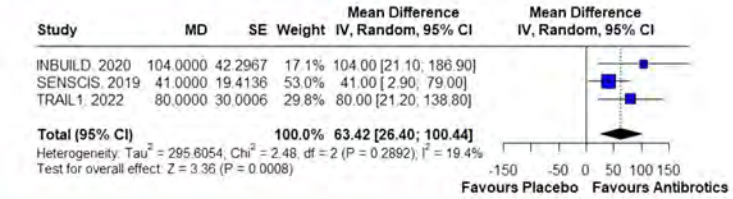

Figure 1b: Patients with an absolute decline from baseline in FVC of >10 percentage points of the predicted value at week 52

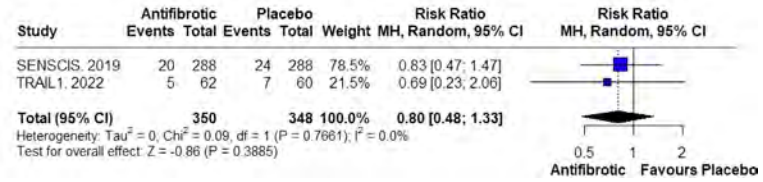

Background/Purpose: Autoimmune–associated interstitial lung disease (A-ILD) which includes Rheumatoid arthritis associated interstitial lung disease (RA-ILD), Systemic Sclerosis associated interstitial lung disease (SS-ILD), and others is a progressive fibrosing lung disease, which is associated with substantial morbidity and mortality. Modern treatment strategies rely on immunosuppression but many individuals develop progressive fibrosis. The antifibrotic agents pirfenidone and nintedanib which are approved for use in idiopathic pulmonary fibrosis, now are being studied as possible therapies for inhibiting fibrosis in A-ILD. We performed meta-analysis to evaluate the safety and efficacy of antifibrotic therapy in A-ILD.

Methods: We systematically searched PubMed, Embase, Cochrane for English-language studies involving patients being treated with antifibrotic agents, and reported at least one relevant outcome. Three studies met inclusion criteria. Data were

pooled using the inverse variance weighting method with a random-effects model in R Studio. Confidence intervals and heterogeneity were assessed, and forest plots were generated to visualise the pooled effect estimates.

Results: Three studies involving 868 patients with A-ILD were included. Analysis of antifibrotic agents demonstrated significant reduction in annual FVC decline rate (MD=63.4 ml/yr, 95% CI: 26.40–100.44, p< 0.01). The risk of experiencing >10% predicted FVC decline at week 52 was lower with antifibrotic therapy, though not statistically significant (RR=0.80, 95% CI: 0.48–1.33, p=0.39). Serious adverse events were comparable between groups (RR=1.10, 95% CI: 0.87–1.39, p=0.44), but antifibrotic therapy showed significantly higher discontinuation rates due to adverse events (RR=1.89, 95% CI: 1.32–2.71, p< 0.01).

Conclusion: Antifibrotic treatment slowed the annual FVC decline in A-ILD patients and had similar rates of serious adverse events compared to placebo. But the treatment discontinuation rates due to adverse events were higher with Antifibrotic agents. This suggests that antifibrotics provide benefit for A-ILD patients, but they have to be monitored closely due to adverse events.

Abstract Number: 2051

Clinical Burden of Illness Among Patients with Immunoglobulin-G4-Related Disease in the United States

Sushmitha Inguva[1], Emma Culver[2], Pallavi Rane[1], Laura Moore-Schiltz[3], melissa rosen[4], Kristina Patterson[4], Donna McMorrow[3], Zulkarnain Pulungan[5], Yasmin Hernandez-Barco[6] and John Stone[7], [1]Amgen Inc., Thousand Oaks, [2]John Radcliffe Hospital; University of Oxford, Oxford, United Kingdom, [3]Inovalon, Bowie, MD, [4]Amgen Inc., Thousand Oaks, CA, [5]Inovalon, Bowie, [6]Massachusetts General Hospital; Harvard Medical School, Boston, MA, [7]Massachusetts General Hospital , Harvard Medical School, Concord, MA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2015–2051) Miscellaneous Rheumatic & Inflammatory Diseases Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Immunoglobulin G4-related disease (IgG4-RD) is a multi-organ, immune-mediated condition. Timely treatment is critical, as disease flares often result in increased inflammation and organ damage. Glucocorticoids (GCs) are used as standard first-line treatment, followed by GC-sparing therapies including conventional synthetic disease-modifying antirheumatic drugs (DMARDs, such as azathioprine, mycophenolate mofetil etc.), or biologic DMARD (rituximab). This study describes patient characteristics, treatment patterns, and incidence of flares in patients with IgG4-RD using administrative claims databases in the United States.

Methods: A retrospective cohort study was conducted using 100% Medicare Fee-for-Service (FFS) and Inovalon MORE^2 Registry® claims databases. Adults with IgG4-RD were identified using a previously validated algorithm (Wallace et al. *ACR Open Rheumatol*. 2022) from January 1, 2018 through December 31, 2021 (FFS) and June 30, 2023 (MORE^2). Index date was set as the first claim for an algorithm-defined ICD-10 diagnosis code associated with IgG4-RD. Demographics at the index date and comorbidities and medication use in the 12-month pre-index period were assessed. Medication use and claims-based proxy for IgG4-RD flare were evaluated in the ≥12-month post-index follow-up period. Claims-based proxy for flare was defined as: (1) ≥1 claim for an IgG4-RD-associated diagnosis code followed by initiation of IgG4-RD medication,

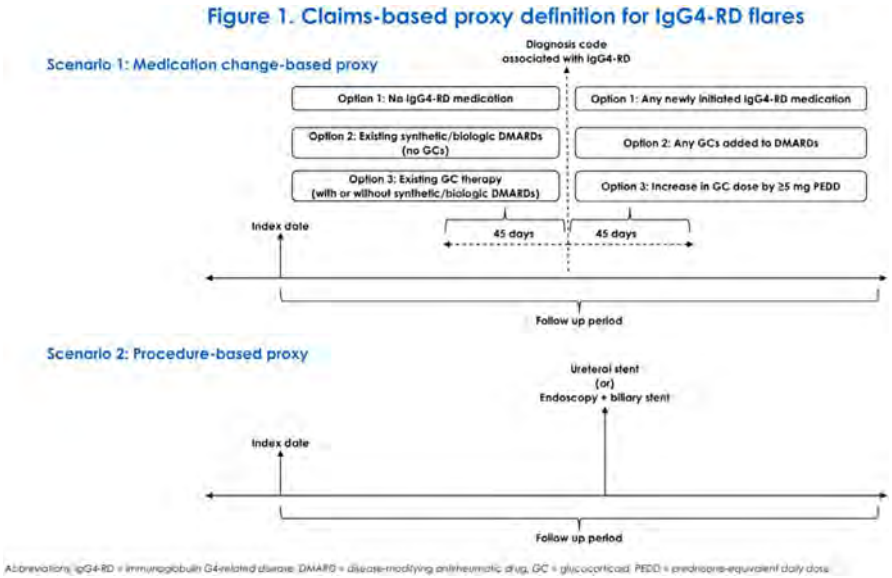

Figure 1. Claims-based proxy definition for IgG4-RD flares

Northeast	269	27.9%
South	251	26.0%
West	248	25.7%
Midwest	197	20.4%
Comorbidity burden during 12-month pre-index period		
Deyo-Charlson Comorbidity Index (Mean, SD)	2.4	2.5
Select comorbid conditions[a] (N, %)		
Hypertension	600	62.2%
Infections	539	55.9%
Hyperlipidemia	532	55.1%
Type 2 diabetes	342	35.4%
Chronic kidney disease	326	33.8%
Gastro-esophageal reflux	321	33.3%
Chronic pulmonary disease	305	31.6%
Medications related to IgG4-RD during 12-month pre-index period		
Patients with ≥1 claim for IV or oral glucocorticoids (N, %)	631	65.4%
Patients with ≥1 claim for oral glucocorticoids (N, %)	474	49.1%
Patients with ≥1 claim for conventional synthetic DMARDs (N, %)	113	11.7%
Patients with ≥1 claim for rituximab (N, %)	82	8.5%
Duration of post-index follow-up period, months (Mean, SD)	45.3	19.5

IgG4-RD = immunoglobulin G4-related disease, SD = standard deviation, IV = intravenous, DMARD = disease-modifying antirheumatic drug.
[a] Comorbidities were identified using International Classification of Diseases, Tenth Revision, Clinical Modification (ICD-10-CM) diagnosis codes.

addition of GCs to existing DMARD therapy, or ≥5mg increase in GC prednisone-equivalent daily dose (PEDD); (2) ≥1 claim for ureteral stent; or (3) ≥1 claim for endoscopy and biliary stent (**Figure 1**).

Results: Overall, 965 patients with IgG4-RD were identified: mean (SD) age 65.7 (14.2) years, 59.2% male, 61.5% white (**-Table 1**). Most patients had health insurance coverage through Medicare FFS program (64.8%). In the pre-index period,

Table 2. Treatment patterns and clinical outcomes during ≥12 months of post-index follow-up period in a national sample of patients with IgG4-RD in the United States

Characteristic	N = 965	
	Mean / Median / N	SD / IQR / %
Treatment patterns		
Patients with ≥1 claim for an IV or oral glucocorticoid (N, %)	942	97.6%
Patients with ≥1 claim for a conventional synthetic DMARD (N, %)	324	33.6%
Patients with ≥1 claim for rituximab (N, %)	340	35.2%
Patients with ≥1 claim for an oral glucocorticoid (N, %)	835	86.5%
Total number of days of oral glucocorticoid exposure[a] (Mean, SD)	356.2	433.1
Median, IQR	180.0	418.0
Oral glucocorticoid PEDD[b], mg/day (Mean, SD)	20.8	12.1
Median, IQR	17.9	17.2
PEDD categories[b], mg/day (N, %)		
< 5 mg/day	23	2.8%
5 mg/day - < 7.5	77	9.2%
7.5 mg/day - < 10	70	8.4%
10 mg/day - < 12.5	75	9.0%
12.5 mg/day - < 15	56	6.7%
15 mg/day - < 17.5	72	8.6%
17.5 mg/day - < 20	81	9.7%
≥20 mg/day	381	45.6%
Clinical outcomes		
Claims-based proxy for IgG4-RD flare[c]	873	90.5%

IgG4-RD = immunoglobulin G4-related disease, SD = standard deviation, IQR = interquartile range, IV = intravenous, PEDD = prednisone-equivalent daily dose, DMARD = disease-modifying antirheumatic drug.
[a] Total number of days of oral glucocorticoid exposure was calculated based on the days' supply of medications dispensed as recorded in pharmaceutical claims.
[b] Oral glucocorticoid PEDD was calculated as the total prednisone-equivalent dose across all glucocorticoid fills in the patient's possession divided by the total number of days of oral glucocorticoid exposure.
[c] Claims-based proxy for IgG4-RD flare was defined as: (1) ≥1 claim for an IgG4-RD-associated diagnosis code followed by initiation of IgG4-RD medication, addition of glucocorticoids to existing DMARD therapy, or ≥5mg increase in glucocorticoid PEDD; (2) ≥1 claim for ureteral stent; or (3) ≥1 claim for endoscopy and biliary stent.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

hypertension (62.2%), infections (55.9%), and hyperlipidemia (55.1%) were commonly observed. Moreover, 65.4%, 11.7%, and 8.5% received oral or IV GCs, synthetic DMARDs, and rituximab, respectively, during baseline. The mean (SD) duration of the post-index follow-up period was 45.3 (19.5) months. During follow-up, 97.6%, 33.6%, and 35.2% patients received oral or IV GCs, synthetic DMARDs, and rituximab, respectively (**Table 2**). Among patients with oral GCs (N = 835, 86.5%), the mean (SD) PEDD was 20.8 (12.1) mg. Claims-based proxy for flare was observed in 90.5% of patients during follow-up.

Conclusion: Results showed a significant clinical burden among patients with IgG4-RD during follow-up, characterized by elevated GC use which might potentially increase the risk for GC-related toxicity events, as well as a high risk of disease flares. Study findings highlight the need for therapies that better control disease activity and minimize GC exposure in these patients in the long-term.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2052–2078) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with idiopathic inflammatory myopathies (IIM) have increased production and decreased clearance of neutrophil extracellular traps (NETs), which may promote the production of anti-NETs antibodies. The aim of this study was to assess the prevalence of anti-NETs antibodies in IIM and their relationship with the clinical features and disease activity.

Methods: For this prospective cohort study, we recruited 157 IIM patients according to the ACR/EULAR or Connors' criteria. We assessed the clinical features, muscle enzymes, disease activity, damage accrual, and the myositis antibodies by Lineblot. IgM, IgG anti-NETs antibodies and NETs remnants (neutrophil elastase-DNA complexes) in serum were measured by ELISA. We determined the cutoff point of the anti-NETs antibodies assay as the 99th percentile of 26 age and sex paired healthy donors (0.183 arbitrary units (AU) for IgG and 0.772 AU for IgM). The positivity for anti-NETs antibodies was corroborated by indirect immunofluorescence (IFI). We assessed the associations between the anti-NETs antibodies, the IIM

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

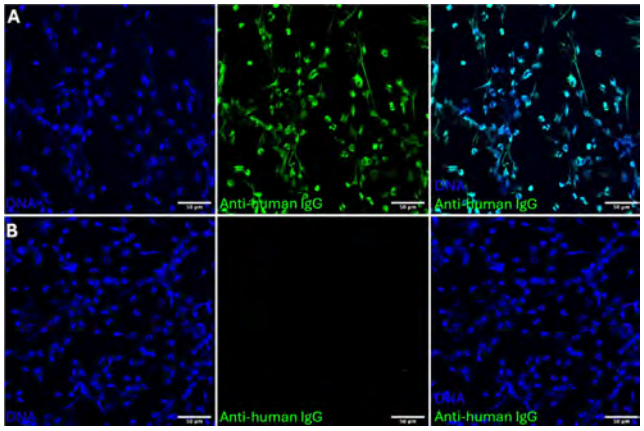

Figure 1. Representative IFI of positive (A) and negative (B) anti-NETs antibodies

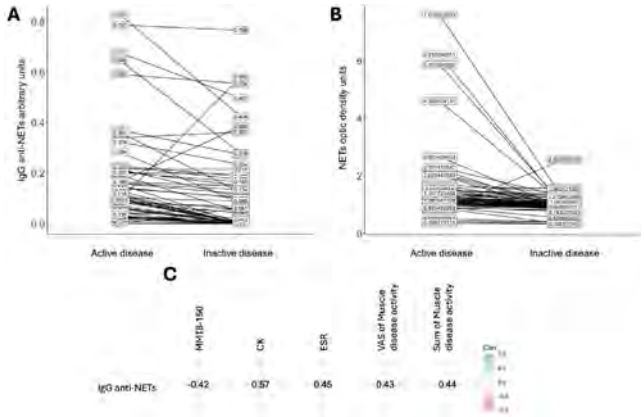

Figure 2. Changes in the concentration of anti-NETs antibodies (A) and NETs remnants (B) in paired samples of active and inactive disease. Correlations between anti-NETs antibodies and the clinical features of patients with AS (C)

phenotypes, and the clinical features using the Chi-2, Mann Whitney U, and Spearman rho. In 68 patients with paired serum samples corresponding to active and inactive disease, we compared the amount of anti-NETs antibodies and NETs remnants using the Wilcoxon test.

Results: 115 (73.2%) were women with a median and interquartile range (IQR) of age at recruitment of 52 years (40-59). The most frequent diagnosis was dermatomyositis (DM) (N=104, 66.2%), followed by anti-synthetase syndrome (AS) (N=24, 15.2%). Thirty-seven patients (23.5%) had positive IgG anti-NETs antibodies, and none were positive for the IgM isotype. Figure 1 shows a representative IFI for positive (1A) and negative (1B) anti-NETs antibodies. The positivity for anti-NETs was closely associated to the AS (Odds Ratio (OR) 6.1 (95% confidence interval 1.5-27.8), P< 0.05), and with positive anti PL12 antibodies (12.1 (95% CI 2.3-91), P< 0.05). As shown in Figure 2, IgG anti-NETs antibodies and NETs remnants decreased when disease becomes inactive (0.09 (0.02-0.19) vs 0.008 (0-0.14), P< 0.0001) (2A), and (1.19 (1.03-1.52) vs 0.95 (0.86-1), P< 0.0001) (2B), respectively. Among participants with AS, patients with anti-NETs antibodies had increased leukocytes/mm3 (7300 (5900-9600) vs 4700 (3900-6300), P=0.04), c-reactive protein (4.2 mg/dL (1.8-8.8) vs 0.7 (0.2-2.4), P=0.04), erythrocyte sedimentation rate (24 mm/hour (8-36.5 vs 5 (2.2-8), P=0.02), visual analog scale (VAS) of cardiovascular (0 (0-10) vs 0 (0-0), P=0.03) and muscular disease activity (4 (0-7) vs 0 (0-3.5), P=0.04), higher damage extension (0.18 (0.07-1) vs 0.06 (0.06-0.09, P=0.03), and VAS of skeletal damage (0 (0-1) vs 0 (0-0), P=0.05). In Figure 2C, we depict the significant correlations between anti-NETs IgG antibodies and the clinical features of patients with AS.

Conclusion: This is the first study to report the prevalence of anti-NETs IgG antibodies in IIM (23.5%). Anti-NETs antibodies were closely associated with the AS and its clinical features. Anti-NETs antibodies and NETs remnants decreased in inactive disease.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2052–2078) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are a group of autoimmune diseases characterized by muscular inflammation that can affect any organ or system. Reported mortality rates are as high as 23–73% due to delayed diagnosis, cardiac and pulmonary involvement, or severe muscle weakness, as well as associated infections and neoplasia. However, the leading causes of mortality vary globally according to the different published cohorts.

Methods: For this prospective cohort study, we recruited 219 IIM patients according to the ACR/EULAR or Connors' criteria. At recruitment (baseline), we assessed the clinical features, muscle enzymes, the myositis disease activity assessment tool (MDAAT), the myositis damage index (MDI), the health assessment questionnaire disability index, the manual muscle test 8 (MMT8), the visual analog scale (VAS) of disease activity by the patient and the physician and the myositis specific and associated antibodies by Lineblot. All patients were followed up prospectively looking for the primary outcome, which was mortality. To assess the independent predictors of mortality, we performed multivariate logistic regression and Cox analyses to calculate the Odds and Hazard ratios with 95% confidence interval.

Results: 164 patients were women (74.8%), the most frequent diagnosis was dermatomyositis (N= 157, 71.6%). After a median follow-up of 62 months, 32 patients (14.6%) died. At baseline, patients who died were older at recruitment (47 (39-52) vs 41(31-52), P=0.04), had more frequently positive anti-SRP (12.5% vs 1.6%, P=0.009), and anti-MDA5 (28.1% vs 11.7%, P=0.024), cancer (15.6% vs 3.7%, P=0.018), lower levels of serum albumin (2.9(2.5-3.6) vs 3.9(3.3-4.2), P< 0.0001), and higher median (min-max) of VAS of gastrointestinal (GI) (0 (0-10) vs 0 (0-7), P=0.0003) and cardiovascular (CV) (0 (0-10) vs 0 (0-6), P=0.04) damage. The independent predictors of mortality were SRP+ (OR 26.24 (95% CI 2.95-283.1), P=0.008), MDA5+ (4.13 (1.23-13.63), P=0.038), malignancy (6.5 (1.20-33.43), P=0.006), albumin (0.26 (0.12-0.51), P< 0.0001), VAS of GI damage (1.41 (1.12-1.81, P=0.006), and VAS of CV damage (2.01 (1.38-3.43), P=0.0001). After Cox analysis, we found the following risk factors for mortality: SRP+ (Hazard Ratio 19.8 (95% CI 5.52-71.0), P< 0.001), MDA5+ (4.92 (1.89-12.8), P=0.001), age at recruitment (1.05 (1.01-1.09), P=0.011), smoking (3.21 (1.35-7.66), P=0.009), physician's VAS of disease activity (1.27 (1.05-1.53), P=0.015), albumin (0.33 (0.17-0.66),

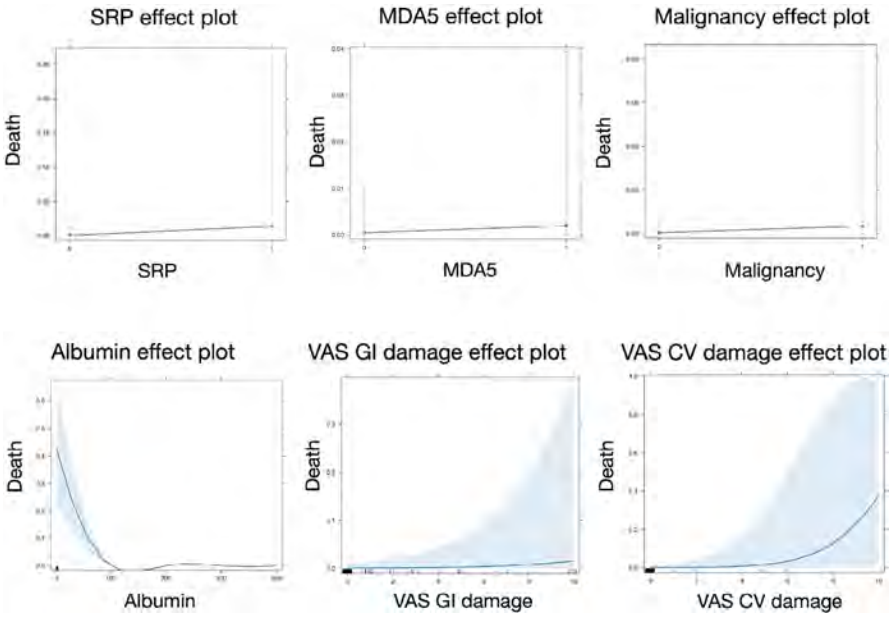

Figure 1. Graphical representation of the effect of each risk factor for mortality in patients with IIM.

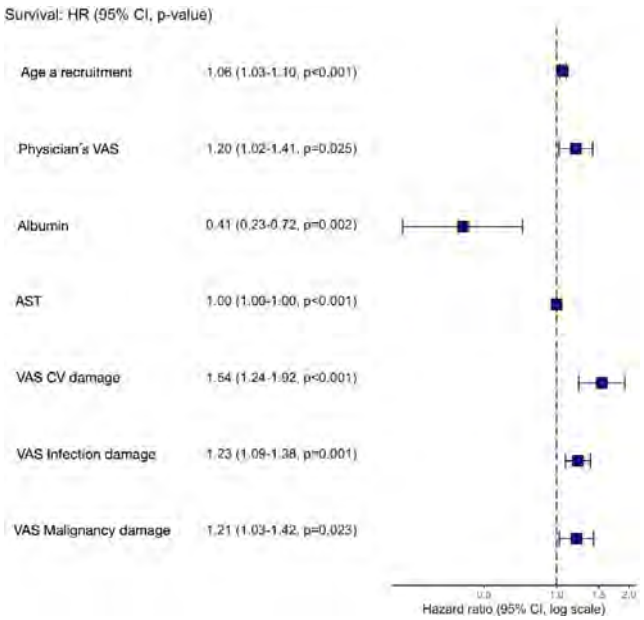

Figure 2. Hazard ratios of each variable independently associated with mortality in patients with IIM.

P=0.002), aspartate aminotransferase (1.00 (1.00-1.00), P< 0.001), VAS of CV damage (1.76 (1.37-2.24), P< 0.001), infectious damage (1.25 (1.09-1.43), P=0.002) and malignancy damage (1.41 (1.17-1.70), P< 0.001). In figure 1, we show a graphical representation of the effect of each risk factor of mortality. In figure 2, we depict the hazard ratios for mortality in patients with IIM.

Conclusion: This prospective study of well characterized IIM patients revealed anti SRP and MDA5 antibodies and the GI, CV, infectious and malignancy damage accrual as key novel risk factors of mortality in this group of diseases.

Abstract Number: 2054

A Changing Paradigm: Reassessing the Role of Muscle Biopsy in Idiopathic Inflammatory Myopathies in a Single-center Cohort

Ami Purohit[1], Najia Shakoor[2], Dmitriy Cherny[1] and Juan Schmukler[1], [1]Rush University Medical Center, Chicago, IL, [2]Rush University, Chicago, IL

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2052–2078) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Idiopathic inflammatory myopathies (IIMs) encompass a heterogenous group of autoimmune diseases characterized by inflammation of muscle and other target organs. Muscle biopsy was historically the gold standard to characterize these myopathies. With advances in serological, electrophysiological and imaging diagnostics for IIMs, the role of muscle biopsy in the evaluation of contemporary patients with suspected IIM is not clear. Here, we aim to evaluate current practice in the diagnosis of IIMs at an academic medical center with particular focus on characteristics of patients diagnosed with IIMs who underwent muscle biopsy versus those who did not and whether muscle biopsy changed diagnosis.

Table 1: Demographics and Clinical Characteristics - Muscle Biopsy Y/N

	Muscle Biopsy Performed (n=103, 68.7%)	Muscle Biopsy Deferred (n=47, 31.3%)	p values
Age, mean (SD)	58 (±14)	60 (±14)	0.990
Sex, n (%)			0.588
Female	30 (61)	12 (57)	
Male	19 (39)	9 (43)

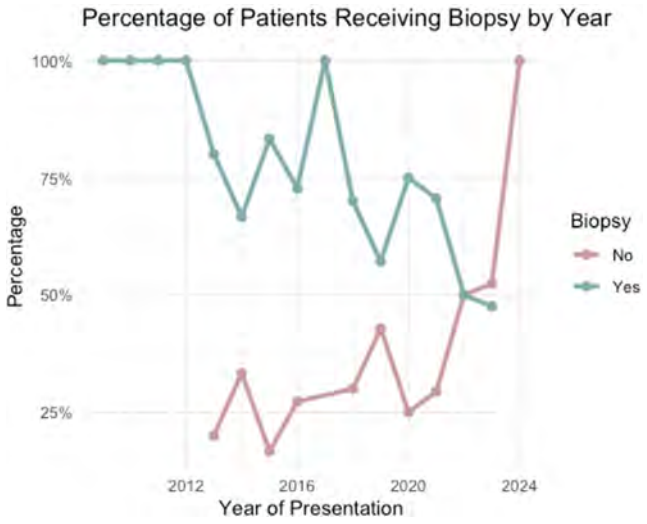

Figure 1: Line Graph Plot of Percentage of Biopsies Over Time

Methods: A retrospective cohort study of adult patients diagnosed with a primary IIM by a rheumatologist or neurologist at a tertiary care medical center was performed. Potential subjects were identified using ICD-10 codes. Demographic, serologic, imaging, histopathologic, and treatment data were collected. Patients were divided into two groups based on whether or not a muscle biopsy was performed. Demographic and clinical characteristics were initially analyzed using chi-squared tests and t-tests; adjusted logistic regression modeling was used to identify factors associated with performing muscle biopsy.

Results: A total of 150 patients with IIM were included, of which 103 patients (68.7%) underwent muscle biopsy and 47 patients (31.3%) who did not (Table 1). There were no significant differences in baseline clinical characteristics between the two groups. Muscle strength, myositis specific antibodies (MSA), gender and primary specialist (neurology vs rheumatology) were not significantly associated with biopsy performance. However, patients with positive HMG-CoA Reductase (HMGCR) antibodies were significantly less likely to have a biopsy (OR 0.2, p=0.02, Table 2). Time was also a significant factor associated with biopsy performance with lower odds of biopsy being performed in more recent years (OR 0.6, p=0.002, Figure 1). With regards to outcomes, the biopsy changed the diagnosis in only 13 cases (12.6%). Results of EMG (performed in over 85% in each group) and MRI (performed in less than 15% in each group) were not significantly associated with biopsy performance.

Conclusion: Our findings suggest a clear trend towards reduced biopsy use over time and whenever HMG-CoA reductase antibodies were present. When biopsies were performed, they infrequently changed the pre-biopsy diagnosis. Given a lack of change in diagnosis in most patients, it may stand to reason that muscle biopsy could be reserved for equivocal or atypical clinical presentations of myositis.

Abstract Number: 2055

Construct Validity of Total Improvement Score (TIS) as an Endpoint for Clinically Meaningful Improvement in Multiple Patient-Centered Outcome Measures in Dermatomyositis

Anjana Chandrasekhara Pillai[1], Shiri Keret[2], Siamak Moghadam-Kia[3], Chester V. Oddis[4] and Rohit Aggarwal[5], [1]PPCP, Pittsburgh, PA, [2]Bnai Zion Medical Center, Atlit, Israel, [3]University of Pittsburgh Medical Center, Pittsburgh, PA, [4]University of Pittsburgh, Pittsburgh, PA, [5]University of Pittsburgh, Rheumatology and Clinical Immunology, Pittsburgh, United States of America, Pittsburgh, PA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2052–2078) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Total Improvement Score (TIS), as defined by the ACR/EULAR myositis response criteria, is increasingly employed as a primary endpoint in clinical trials for dermatomyositis (DM). This study aims to assess the construct validity of TIS in a prospective, longitudinal cohort of patients with DM by examining the relationship between TIS improvement categories and Patient-Centered Outcome Measures (PCOMs) and Core Set Measures (CSMs) that assess various domains including fatigue, pain, quality of life, physical activity and physical function.

Methods: Participants met the 2017 EULAR/ACR criteria for probable or definite DM and were enrolled at the University of Pittsburgh Myositis Center between 2016 and 2018. Data collected at baseline, 3 months, and 6 months included manual muscle testing (MMT), physician and patient global activity (MDGA, PtGA), extra-muscular global activity (EMGA), the Health Assessment Questionnaire–Disability Index (HAQ-DI), and muscle enzyme levels. PCOMs included Short Form-36, PROMIS-Physical Function, sit-to-stand (STS), Timed Up-and-Go (TUG), 6-minute walk, pain and fatigue visual analogue scale (VAS), ActiGraph-based physical activity, and hand-held dynamometry. The TIS was calculated according to ACR/EULAR myositis response criteria, with TIS < 20 indicating no improvement and ≥20 indicating at least minimal improvement. Spearman correlation assessed relationships between TIS and outcome changes. Differences between the CSMs and PCOMs amongst patients with and without minimal improvements (TIS ≥20) were evaluated.

Results: Among n=24 participants, the mean age was 47 years; 71% were female and 96% were white. Patient-Reported Outcome Measures (PCOMs), including fatigue, pain, quality of life, muscle strength, disability index, and physical function, demonstrated significantly greater improvement in patients who met minimal improvement criteria by the TIS, compared to those with no improvement. Additionally, most CSMs, including MDGA, EMGA, and MMT, showed significant changes among those with minimal improvement compared to no improvement (Table 1). Among patients with active DM (defined as having active muscle activity at baseline; n=14) , those exhibiting at least minimal improvement on the TIS (≥20) at 6 months demonstrated average improvements across nearly all PCOMs. Correlations between TIS and changes from baseline in PCOMs and CSMs at 6 months revealed that improvement on most measures was associated with TIS. Strong correlations (rho > 0.5) with TIS were observed for physical function measures, handheld dynamometry, Timed Up-and -Go, and some quality of life measures.

Conclusion: The results support the construct validity of TIS and its use as a clinically meaningful endpoint in DM, capturing benefits in disease activity and aspects of pain, fatigue, function, quality of life, and overall well-being.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2052–2078) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Medical nutrition therapy significantly impacts cardiovascular risk and overall health, but effects on muscle diseases remain unclear. This systematic review evaluates nutritional interventions' safety and efficacy on muscle disease outcomes.

Methods: A multidisciplinary team conducted a PRISMA-guided systematic review registered on Prospero. Database searches yielded 107 full-text articles, with 52 meeting inclusion criteria after screening. Four reviewers assessed bias risk, with team review for appropriateness (Figure 1.1).

Results: For inflammatory myopathies, investigations primarily centered on creatine supplementation and branched-chain amino acids (Figure 2). The most notable finding came from a study demonstrating that creatine supplementation combined with exercise significantly improved aggregate functional performance time in patients with polymyositis and dermatomyositis, with a median decrease of 13% compared to only 3% in the placebo group (p = 0.029).

Studies involving congenital muscle disorders and muscular dystrophies examined a wider spectrum of interventions, including various dietary patterns, specific nutrients, supplements, and antioxidants. These studies assessed diverse outcomes from muscle strength and exercise capacity to body composition, functional tests, and quality of life measurements.

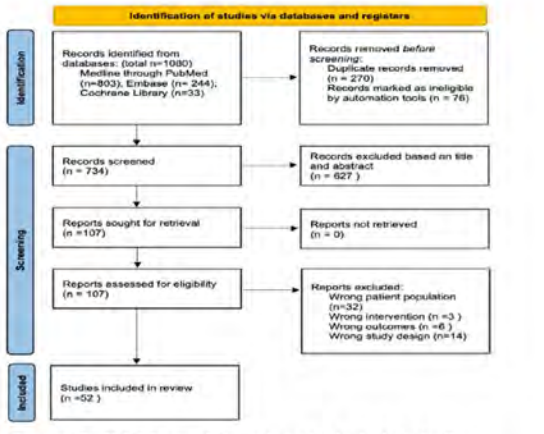

Figure 1.1: PRISMA workflow chart for included studies

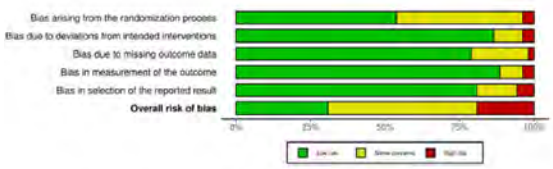

Figure 1.2: Risk of bias of included studies

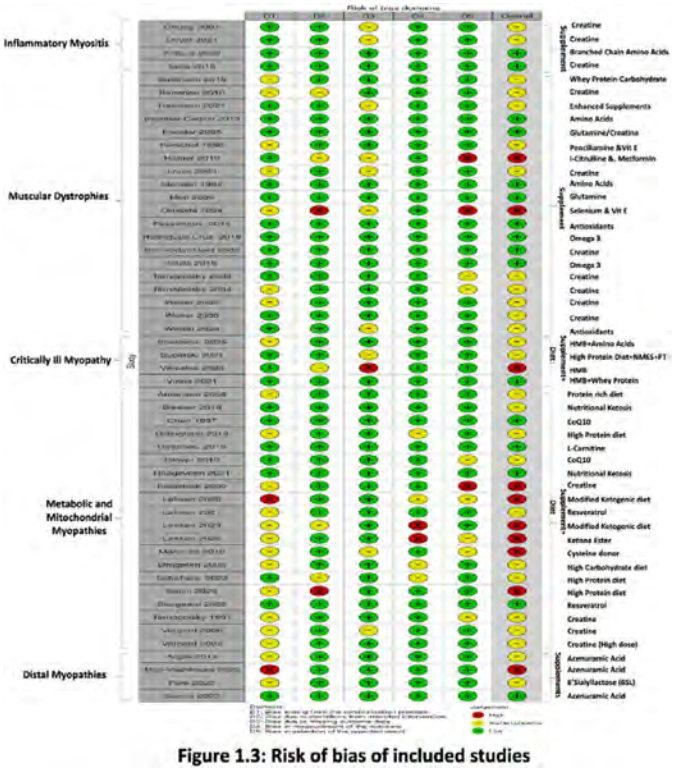

Figure 1.3: Risk of bias of included studies

Figure 1. Workflow chart and Risk of Bias

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2.1: Interventions used by disease subtype

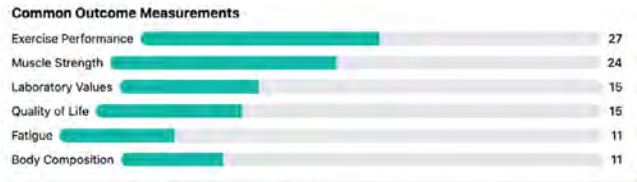

Figure 2.2: Proportion of common outcome measurements

Figure 2. Interventions and common outcome measurements

Several interventions showed promising results, particularly creatine supplementation in Duchenne muscular dystrophy, which increased maximal voluntary contraction by 15% and doubled fatigue resistance ($p < 0.05$). Additionally, ketogenic diets demonstrated improvement in fatty acid oxidation by 60% and increased maximal exercise capacity by approximately 20% in patients with McArdle disease (Table 1).

In critical illness myopathy, research investigating HMB-enriched whey protein supplementation and high-protein dietary interventions generally showed positive trends in outcomes. However, it should be noted that several of these results did not reach statistical significance, highlighting the need for more robust studies in this area.

Quality assessment of the included studies revealed varying levels of methodological rigor, with 32% of studies classified as low risk of bias, 45% raising some concerns, and 22% determined to be at high risk of bias, underscoring the need for more rigorously designed trials in this field (Figure 1.2,1.3).

Conclusion: While nutrition therapy benefits other medical fields, evidence for muscle diseases remains limited. Promising interventions include physiologic creatine, high-protein diets, ketogenic diets, and supplements (CoQ, resveratrol, L-carnitine), which improved endurance/strength in some populations. Methodological concerns highlight the need for larger, better-designed multicenter trials with standardized outcomes. More research exists on non-inflammatory versus inflammatory myopathies. Given these uncertainties, dietary guidance should be tailored to specific disease features and comorbidities.

Table 1. Summary of Nutritional Interventions and Outcomes in Muscle Diseases across included studies

Intervention	Number of RCTs	Disease	Outcome- Improvement	Outcome- No change
A) Inflammatory Myositis				
1. Supplements				
Creatine Supplements	1	Idiopathic inflammatory myopathies (IIMs)	AFPT, Functional Index of Myositis, MMT;	NHP, Short Form McGill Pain Questionnaire, Hospital Anxiety and Depression Scales, and Chalder fatigue scores.
	2	Juvenile Dermatomyositis (JDM)	-	Muscle function, strength & metabolism, aerobic capacity, disease activity, fatigue, physical activity, QoL
Branched Chain Amino Acids	1	Polymyositis and Dermatomyositis	Functional Index (FI) score	MMT, MDACS
B) Muscular Dystrophies				
1. Supplements				
Creatine Supplements	4	Myotonic dystrophy types 1 and 2	Muscle strength, daily activities; refractory muscle pain and subjective muscle performance	MRC, NSS, Lean body mass, Vital capacity, patient's global assessment of improvement, daily activities, hand-held dynamometry
	3	DMD and Becker's dystrophy	Cellular energetics, MMT, Bone mineral density, MVC, resistance to fatigue, FFM, Handgrip strength	Functional scale, Lean body mass, Activities of daily living, CK, PFT
Glutamine supplements	1	DMD	-	Walking speed, 2-minute walk test, work, power, FFM
Glutamine /creatine supplements	1	DMD	Functional timed scores, QMT in both groups	MMT
Enhanced supplements*	1	DMD	6MWD	Body composition, QoL
Antioxidants**	4	DMD, FSHD, Myotonic dystrophy	Muscle and fat volumes, Muscle Strength	Functional grade, timed-functional tests, PFT, CK levels, MMSE, SRB3, Hand grip strength, MVC, Endurance
Omega 3 Fatty Acids	2	DMD, FSHD, LGMD	Proinflammatory markers, Anti-inflammatory markers, safety, tolerability, 6MWD, Serum CK	-
Amino Acid Supplements	3	DMD	Reduction in motor function decline with combination of L-citrulline and Metformin	MMT, Functional evaluation, Joint contractures, timed-
				functional tests, PFTs, serum CK levels
Protein-carbohydrate (Whey protein)	1	FSHD	SF-36	Fitness, walking speed, workload
C) Critical Illness Myopathy				
1. Supplements				
HMB	1	Critical Illness Myopathy	Lean body mass, Global Health assessments	Muscle wasting
HMB+ Whey Protein	1	Critical Illness Myopathy	MMT	Nutritional status, Basal metabolism, Mortality
HMB+ Omega 3 Fatty Acids	1	Mechanically Ventilated Patients (Adult)	-	MMT
2. Macronutrient- based diet				
High Protein Diet With NMES and PT	1	Critical Illness Myopathy	Muscle volume	-

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

D) Metabolic and Mitochondrial Myopathies				
1. Supplements				
Creatine Supplements	2	Mitochondrial myopathy, cytopathies, CPEO	Handgrip strength, NIDFT, and postexercise lactate	Exercise performance, eye movements, or activities of daily life.
	2	McArdle disease	Muscle complaints, exercise performance during ischemic exercise, surface electromyograms	Worsening of clinical symptoms of exercise intolerance.
Coenzyme Q10	2	Mitochondrial myopathies, encephalomyopathies, cytopathies	Global MRC score, rise in lactate after cycle ergometry (attenuated), VO2/kg lean mass, gray matter choline-containing compounds	Cycle exercise Aerobic capacity, post-exercise lactate, strength, resting lactate
L- carnitine	1	Mitochondrial Myopathy	Limit of tolerance and oxygen consumption (VO2) at constant work rate exercise, inspiratory capacity indicating improved aerobic capacity and exercise tolerance	ICPET
Ketone ester supplementation	1	McArdle disease	-	Exercise capacity, perceived exertion
Cysteine donor supplementation	1	Mitochondrial myopathies and cytopathies	Oxidative stress levels	Lactate concentration, MRC, SF-36
Resveratrol	1	Mitochondrial Myopathy	-	Exercise capacity, perceived exertion, lactate concentrations, SF-36,FSS, mitochondrial biomarkers
				from muscle biopsy
	1	Fatty acid oxidation disorders- CPTII/ VLCAD deficiency	-	HR, rate of fatty acid oxidation, perceived exertion, SF-36, FSS
2. Macronutrient- based diet				
Carbohydrate-rich diet	1	McArdle's Disease	HR, perceived exertion (Borg scale), maximal oxidative work capacity	-
	1	CPT II deficiency	Perceived exertion (Borg scale), Exercise duration, HR	RER and VO2
Protein-rich diet	1	Long-chain fatty acid oxidation disorders	Blood levels of short-chain acylcarnitines, reduced intrahepatic lipid content, and maintained lean body mass	Fasting lipids, FFA, glucose and insulin levels
High protein diet+ exercise	2	Pompe disease	Absolute peak VO2, Muscle strength, core stability, QoL in both children and parents (CHQ), SF-36, FEV-1	6MWT, HR during submaximal CPET, physical activity levels
3. Other Dietary Interventions				
Modified Ketogenic Diet	2	McArdle disease	Symptom relief, SF-36, fatty acid oxidation rates, and maximal exercise capacity	HR
Nutritional Ketosis	1	VLCAD deficiency	Quadriceps glycolytic intermediate levels and in vivo Pi/PCr ratio	-
	1	Glycogen storage disease type IIIa (GSDIIIa)	Quadriceps energetic state by in vivo 31P MR spectra, in subjects with overt myopathy	RER
E) Distal Myopathies				
1. Supplements				
Aceneuramic Acid	3	GNE Myopathy	GNEM-FAS score for Upper Extremity function & mobility; Maintenance of muscle strength in UEC score, Investigator-assessed efficacy rate	LEC Strength , MRI Pathology Scores (fat infiltration), Muscle Sialic Acid levels, INQoL
6'-sialyllactose	1	GNE Myopathy	Proximal limb powers, fat fraction on muscle MRI	GNEM-FAS scores

*Enhanced supplement- protein shake (22 g whey protein), multivitamin capsules, vitamin D capsules (Vitamin D3, 2000 IU) and fish oil capsules followed by enhancement with Standard supplement plus: Creatine monohydrate (5 g), glutamine (0.6 g/kg fat free mass), and HMB (38 mg/kg/day)

**Antioxidants- Selenium, Vitamin E, Penicillamine, Vitamin C, Zinc Gluconate

Abstract Number: 2057

Clinical Associations of Anti-Ro52 Antibodies in Idiopathic Inflammatory Myopathies: A Scoping Review

Emily Sun[1], Huon Wong[2], Robin Sia[3] and Jessica Day[4], [1]Royal Melbourne Hospital, Melbourne, Victoria, Australia, [2]University of Queensland, Brisbane, Australia, [3]Royal Melbourne Hospital, Reservoir, Victoria, Australia, [4]Walter and Eliza Hall Institute, Melbourne, Victoria, Australia

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2052–2078) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Anti-Ro52 is a myositis-associated antibody increasingly linked to disease features and outcomes in idiopathic inflammatory myopathies (IIMs). Thorough characterisation of these associations is needed to clarify its clinical relevance and to guide future research. We sought to systematically review the literature on clinical associations of anti-Ro52 in IIMs.

Methods: A systematic search of MEDLINE and EMBASE was conducted from inception until April 2025. Studies reporting clinical associations of anti-Ro52 in adult IIM patients were included (See Figure 1 for PRISMA flow diagram).

Results: Of 1953 studies, 227 full-text articles were assessed for eligibility and 105 met inclusion criteria. All included studies were observational, with majority published since 2021 (69%, n=72) and originating from Asia (67%, n=70). Sample sizes ranged from 11-2085 patients. Considerable heterogeneity was observed in the reported clinical associations for anti-Ro52 within adult IIM cohorts (Figure 2). Anti-Ro52 was commonly associated with higher rates of interstitial lung disease (ILD) (57%, n=29/51 studies), including rapidly progressive interstitial lung disease (RP-ILD) (76%, n=19/25 studies), with nonspecific interstitial pneumonia being the predominant lung pattern among studies reporting radiographic findings (50%, n=4/8). Mechanic's hands (80%, n=8/10 studies) and severe joint involvement (57%, n=8/14 studies) were other commonly reported associations. Among studies examining disease outcomes, anti-Ro52 was frequently associated with increased mortality (65%, n=11/17 studies) and poor prognosis (59%, n=10/17 studies), as indicated by lower cumulative survival or worse functional outcomes. However, anti-Ro52 was rarely linked to malignancy risk (9%, n=1/11 studies). Among 72 studies reporting anti-Ro52 co-positivity with other myositis-specific or myositis-associated antibodies, in a

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

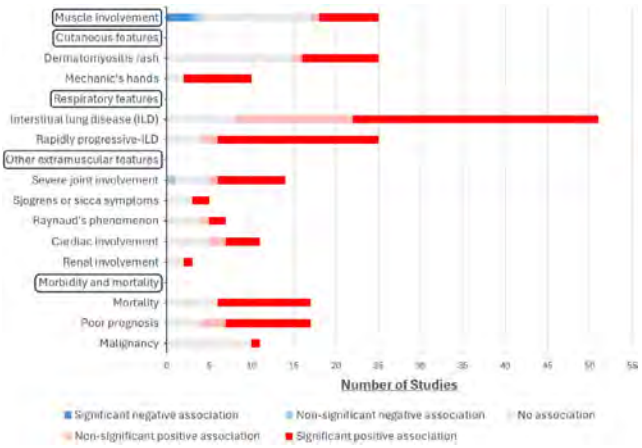

Figure 2. Common clinical associations of anti-Ro52 antibody in adult IIM patients ($p < 0.05$ for significance)

pooled cohort of 4359 patients, the most frequently co-occurring antibodies were anti-MDA5 (55%, n=2393 patients) and anti-aminoacyl-tRNA synthetases (anti-ARS) (35%, n=1537 patients), with the two most common anti-ARS antibodies being anti-Jo1 (15%, n=642 patients) and anti-EJ (5%, n=205 patients) (Figure 3). Antibody co-expression has been linked to a more severe disease phenotype, including RP-ILD, as well as poor treatment response to conventional immunosuppressive therapies, but possibly improved response to rituximab.

Conclusion: Anti-Ro52 is frequently associated with ILD and RP-ILD, poorer prognosis, and increased mortality in adult IIM patients. This review further highlights associations with key extra-muscular manifestations, notably mechanic's hands and severe joint involvement. Antibody co-positivity with anti-Ro52 may predict high-risk clinical phenotype, enabling risk stratification and early targeted therapies that may improve long-term outcomes. Future research should focus on mechanisms

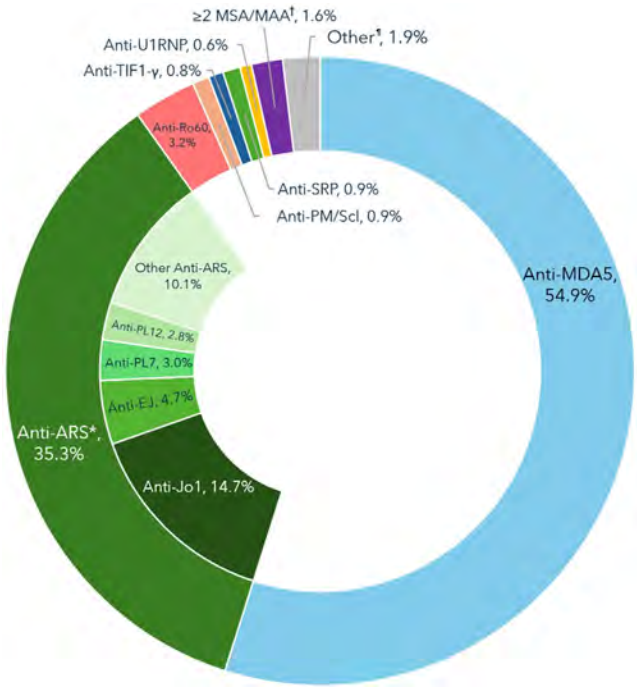

Figure 3. Frequency of myositis-specific antibodies (MSA) and myositis-associated antibodies (MAA) co-positive with anti-Ro52 antibody in adult idiopathic inflammatory myopathies (IIM) patients. * Anti-ARS (anti-aminoacyl-tRNA synthetase) antibodies include anti-Jo1, anti-EJ, anti-OJ, anti-PL7, anti-PL12, anti-KS, and dual anti-ARS antibodies (anti-Jo/anti-PL12, anti-EJ/anti-OJ). Other anti-ARS antibodies include anti-ARS antibodies of lesser frequency and anti-ARS antibody frequency from studies where specific anti-ARS subtypes were not differentiated and the data were reported collectively. † ≥2 MSA/MMA antibodies: the frequency of two or more MSA/MMA antibodies co-positive with anti-Ro52, excluding any dual anti-ARS antibodies. ¶ Other antibodies include anti-HMGCR, anti-SAE1, anti-Scl-70, anti-Sm and anti-U3RNP.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2052–2078) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are rare diseases that involve chronic muscle inflammation, weakness, and pain. Autoantibodies in IIM play a central role in disease pathogenesis and are classified as myositis-specific antibodies (MSA) or myositis-associated antibodies (MAA)[1]. While antibody-related phenotypes may vary by geographic region, data on phenotype stratification by autoantibody profile in Hispanic populations remain scarce. Recognizing distinct clinical phenotypes associated with specific autoantibodies is essential for guiding early diagnosis and individualized therapeutic decisions. We aimed to describe organ-specific disease activity patterns by serological profiles in a Hispanic IIM cohort.

Table 1. Organ involvement and mean MITAX score stratified by autoantibody in idiopathic inflammatory myopathies.

Antibody	Number of patients	Constitutional (%)	Cutaneous (%)	Skeletal (%)	Muscular (%)	Pulmonary (%)	GI (%)	Cardiovascular (%)	MITAX score mean (SD)
Ro52	15	73.3	60	80	93.3	80	33.3	6.6	7.30 (0.97)

Table 2. Clinical and damage characteristics in patients with single and multiple autoantibody positivity

	Single antibody positivity (n=16)	*Multiple antibody positivity (n=22)*	*p-value*
Age, mean (±SD)	47.13 (19.49)	50.95(12.96)	0.471
Sex, woman (%)	15 (93.8)	17 (77.3)	0.217
Time since symptoms onset in months, mean (SD)	8.96 (10.34)	13.72 (20.04)	0.392
Constitutional involvement, n (%)	9 (60)	16 (76.2)	0.298
***Cutaneous involvement*, n (%)**	8 (53.3)	13 (61.9)	0.607
***Skeletal involvement*, n (%)**	8 (53.3)	14 (66.7)	0.418
***Gastrointestinal involvement*, n (%)**	4 (26.7)	7 (33.3)	0.669
***Pulmonary involvement*, n (%)**	6 (40)	15 (71.4)	0.059
***Cardiovascular involvement*, n (%)**	1 (6.7)	1 (4.8)	0.806
***Muscular involvement*, n (%)**	9 (60)	19 (90.5)	**0.03**
MYOACT, mean (±SD)	12.63(13.90)	16.07(8.43)	0.054
MITAX, mean (±SD)	8.17(7.55)	13.43(9.77)	0.551

Methods: We conducted a cross-sectional, retrospective study of Hispanic patients with IIM diagnosis per 2017 ACR/EULAR criteria or clinical judgment. Disease activity was assessed using the MYOACT and MITAX scales. For patients with multiple antibodies, activity scores were attributed to all antibodies detected. Patients were additionally grouped as: monopositive (one autoantibody present), and multipositive (≥2 autoantibodies). Clinical and serological data were compared using Mann-Whitney U and chi-squared or Fisher's exact tests. A p-value ≤ 0.05 was considered statistically significant.

*Mortality was observed in a patient with this antibody pattern.
[a]Cancer diagnosis and mortality were both reported in a patient with this antibody pattern.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Forty patients were included (mean age 46.8 ± 15.9; 85% women). Disease activity scores and antibody profiles were available in 38 patients; two died during follow-up due to disease activity. Fifteen autoantibodies were identified, most commonly Ro52 (n=15), TIF1γ (n=11), and MDA5 (n=7). Mean MITAX and MYOACT scores were 11.2 (±9.1) and 14.59 (±11.02), respectively. The most frequently affected domains were muscular (73.7%), constitutional (65.8%), and skeletal (57.9%). Stratified by autoantibody positivity, 38 profiles were analyzed (two lacked myositis panel). Pulmonary involvement was most common in MDA5 (85.7%) and Ro52 (80%) positive patients. (Table 1) Cardiovascular involvement was rare, seen only in Ro52, MDA5, and PL12.

Sixteen patients were monopositive (TIF1γ n=4, MDA5 n=3). (Table 2). Although multipositive patients (n=22) showed a trend toward higher damage and activity scores, differences were not statistically significant. However, when stratified by organ domain, muscular involvement was significantly more frequent in this group (90.5% vs. 50%, p=0.03). Antibody profile patterns varied across our cohort (Table 3). Two patients died: one had a diagnosis of renal cancer and both Mi2β and NXP2 positivity; the other had isolated Mi2β.

Conclusion: Disease activity patterns differ by autoantibody profile. MDA5, Ro52, and TIF1y were strongly associated with pulmonary involvement, while patients with anti-synthetase (ARS) antibodies (OJ, EJ, PL12, PL7, and Jo1), Ku, and SAE associated mainly to muscular activity. These findings, though limited by small sample sizes, may support earlier recognition of high-activity phenotypes and organ-specific complications in IIM subgroups, particularly within Hispanic population.

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are a heterogeneous group of autoimmune diseases characterized by muscle inflammation and systemic involvement, often associated with specific autoantibodies. Immunoblot assays provide a simultaneous detection of multiple autoantibodies, yet the clinical implications of their positivity, particularly in the context of inflammatory myopathies and connective tissue diseases (CTD), remain incompletely understood.

Objective: To characterise the clinical and laboratory features of patients who underwent myositis immunoblot testing, with focus on the prevalence and distribution of autoantibody positivity across IIM and other CTDs.

Methods: Retrospective study with all patients who underwent immunoblot testing for myositis-specific and associated autoantibodies using the Autoimmune Inflammatory Myopathies 16 Ag kit (Euroimmun, Lübeck, Germany) between November 2017 and October 2023 at a single hospital in northern Spain. For patients with multiple tests, only the first result was considered. Patients were categorised into three diagnostic groups: no connective tissue disease (No CTD), inflammatory myopathies, and other CTDs, based on established international classification criteria. Data collection encompassed clinical symptoms, laboratory findings, and complementary tests; however, some tests were not performed in all patients. Missing data were excluded from the analysis.

Results: A total of 472 patients (66% female; median age 61 years [IQR: 47–71]) were included, with 181 (38%) testing positive for at least one autoantibody. Among these, 33 patients (7%) exhibited double antibody positivity, most frequently involving anti-Ro52 (26/33). Patients were categorised into three groups: no connective tissue disease (No CTD) (188; 40%), inflammatory myopathies (79; 17%), and other CTDs (205; 43%).

TABLE. Clinical and Serological Characteristics of Patients with Immunoblot Testing Categorised by Diagnostic Groups.

TABLE. Clinical and Serological Characteristics of Patients with Immunoblot Testing Categorized by Diagnostic Groups.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Significant differences in autoantibody specificity were observed across the diagnostic groups. Anti-Ro52, anti-Jo1, anti-PL7, anti-EJ, and anti-NXP2 were more frequently detected in patients with inflammatory myopathies, while anti-Ku was predominantly associated with other CTDs ($p< 0.001$).

Muscle-related symptoms, such as myalgia (38%) and muscle weakness (33%), were significantly more prevalent in inflammatory myopathies compared to patients with other CTDs or no CTD ($p< 0.001$). Systemic features were also notably distinct: Raynaud's phenomenon (30%), arthralgia/arthritis (44%), and cutaneous rash (33%) were more common in inflammatory myopathies, while diffuse interstitial lung disease was observed in 47% of these patients ($p< 0.001$). **Table 1** summarizes these findings, along with additional data on complementary tests and laboratory features.

Conclusion: This study underscores the clinical and laboratory differences across diagnostic groups in patients undergoing myositis immunoblot testing. The unexpected prevalence of myopathic findings in patients without CTDs suggests the need for cautious interpretation and potential longitudinal evaluation. Complementary tests remain valuable tools in identifying muscular and vascular abnormalities, supporting a comprehensive diagnostic approach for autoimmune diseases.

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Due to the rarity and heterogeneity of idiopathic inflammatory myopathies (IIM), we lack robust randomized trials to guide treatment decisions. Most of current practice is based on case reports or adapted from other diseases. The aims of this study were to investigate the occurrence of IIM subgroups over time and to characterize immunosuppressive treatment during the first year after diagnosis over different calendar periods and subgroups.

Table 1: Baseline characteristics according to diagnosis year

	Diagnosed 2008-2013	Diagnosed 2014-2019	Diagnosed 2020-2025
Total, n	136	189	220
Female, n (%)	85 (61.6)	116 (60.7)	115 (52.5)
Age at diagnosis, mean (yr) ± SD	56.9 ± 15.9	57.4 ± 15.7	62.1 ± 14.9
Subtypes, n (%)			
PM	48 (35.3)	38 (20.1)	27 (12.4)
DM	44 (32.4)	60 (31.8)	55 (25.0)
IBM	14 (10.3)	24 (12.7)	27 (12.4)
ASSD	27 (19.8)	52 (27.5)	52 (23.6)
IMNM	3 (2.2)	15 (7.9)	59 (26.9)

Methods: The SweMyoNet is a nationwide Swedish register initiated to study and follow IIM patients. Information is prospectively collected by health care providers and includes details on IIM subtype, disease manifestations, longitudinal disease activity and treatment. For this study, we included IIM patients diagnosed from 31/12/2007 to 15/03/2025, with at least two registered visits in the register, the first within six months of diagnosis. IIM was subgrouped into polymyositis (PM), dermatomyositis (DM), anti-synthetase syndrome (ASSD), immune-mediated necrotizing myopathy (IMNM) and inclusion body myositis (IBM). Unclear diagnoses were excluded. Patients were divided into three calendar periods according to year of diagnosis to compare treatment over time. Continuous variables are described as mean±SD or mean and IQR; categorical as frequencies and percentages.

Results: In total, 545 patients were identified, mostly women (58%) mean age 60 years (±15) at diagnosis. The most frequent IIM subtype was DM (n=159, 29%) followed by ASSD (131, 24%), PM (113, 21%), IMNM (77, 14%) and IBM (65, 12%). The proportion of the different subgroups has changed over time (Table 1), with a rise of ASSD and IMNM (20 and 2% in 2008-2013 to 24 to 27% in 2020-2025, respectively) and a drop in PM (35% in 2008-2013 to 12% in 2020-2025).

Glucocorticoid (GC) treatment was the most used drug the first 12 months after diagnosis (n=379, 82%) (Table 2). Methotrexate (MTX) was the most prescribed immunosuppressant (68% of patients) followed by rituximab (RTX) (23%), cyclophosphamide (CYC) (19%) and mycophenolate mofetil (MMF) (13%). 49 patients received no drug therapy the first

Table 2: Treatment received during the first year after diagnosis according to IIM subtype

	Total (n=545)	DM (n=159)	PM (n=113)	IBM (n=65)	ASSD (n=131)	IMNM (n=77)
Patients without treatment, n (%)	49 (9)	9 (6)	9 (8)	22 (34)	7 (5)	2 (3)
Patients under treatment, n (%)	496 (91)	150 (94)	104 (92)	43 (66)	124 (95)	75 (97)
Drugs, n (% amongst those receiving treatment)						
GC any form	379 (76.4)	131 (87.3)	84 (80.8)	28 (65.1)	100 (80.6)	36 (48.0)

JAK inhibitors	0	0	4 (1.9)
Other	3 (2.5)	7 (4.1)	3 (1.4)

12 months after diagnosis. During this same period 87% of all DM, 81% of PM and ASSD, 65% of IBM and 48% of IMNM patients were treated with GC.

Most IMNM patients (93%) received MTX. MTX was also the most frequent immunosuppressant in all other subgroups. 47% of ASSD patients received CYC and 44% RTX. Intravenous immunoglobulin (IVIG) was used in all subtypes except IBM but predominantly in IMNM where 77% received it in the first 12 months. Over time, GC use decreased: 82% patients in the 2008-2013 group received GC in comparison to 67% in the 2020-2025 (Table 3). In contrast, IVIG use increased from 2% of patients in 2008-2013 to almost 40% in 2020-2025. RTX was not widely used in 2008-2013 (3%) but this increased from 2014 onwards (35% and 24% respectively in 2014-2019 and 2020-2025).

Conclusion: In our cohort, ASSD and IMNM occurrence has increased and PM decreased since 2008 and onwards. Over time, drug use has changed with decrease of GC and increase of IVIG. The prescription patterns differed between IIM subtypes but MTX was the most used immunosuppressor in all subgroups of IIM.

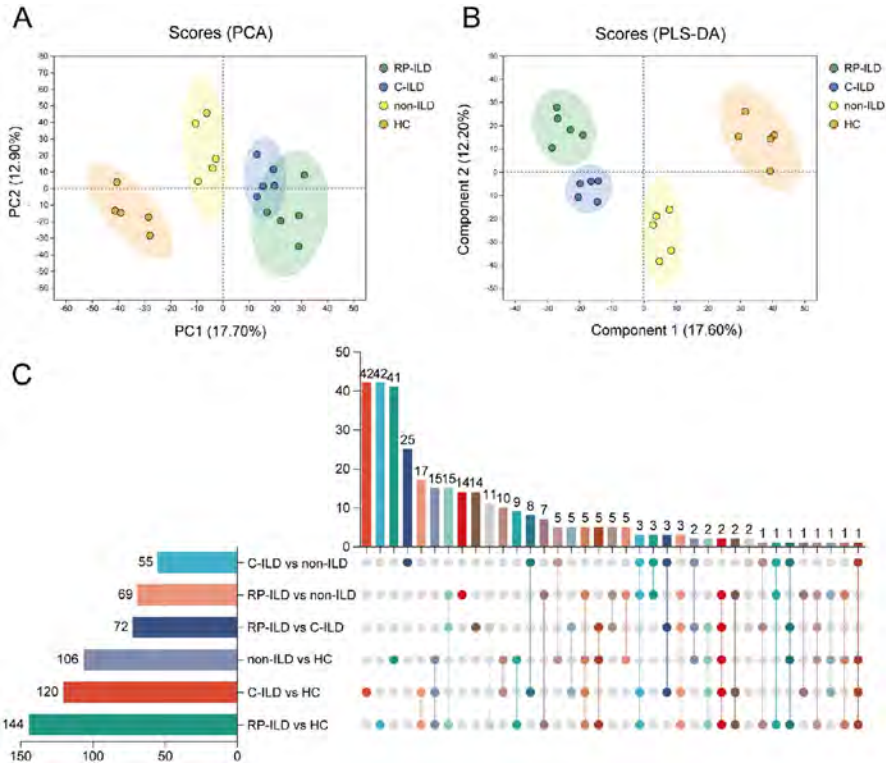

FIG 1. Non-targeted metabolomics profiling analysis of MDA5 positive dermatomyositis (MDA5+ DM) patients with rapidly progressive ILD (RP-ILD, n = 5), chronic ILD (C-ILD, n = 5), non-ILD (n = 5) and healthy controls (HCs, n = 5). (A) Score scatter plot of principal component analysis (PCA) model. (B) Score scatter plot of partial least squares discriminant analysis (PLS-DA) model. (C) Upset plot illustrating overlapping and specific metabolites in various comparison groups.

Background/Purpose: Anti-melanoma differentiation-associated gene 5-positive dermatomyositis (MDA5+ DM) is an autoimmune condition associated with rapidly progressive interstitial lung disease (RP-ILD) and high mortality. Metabolic disturbances have been reported in inflammatory myopathies, including DM. However, whether alterations of metabolomics profiling participate in ILD development in MDA5+ DM remains undetermined.

Methods: Untargeted and targeted metabolomics profiling was performed using liquid chromatography-mass spectrometry (LC-MS) to profile metabolites in distinct subtypes of MDA5+ DM patients (RP-ILD, n = 25, C-ILD, n = 25, non-ILD, n = 24) and healthy controls (HCs, n = 41). Kyoto Encyclopedia of Genes and Genomes (KEGG) enrichment analysis was used to identify altered pathways. Pearson correlation analysis was employed to investigate the correlation between metabolites and clinical/laboratory continuous variables.

Results: The metabolic imbalance observed in the plasma of MDA5+ DM patients predominantly affects amino acid metabolism. Compared to MDA5+ DM patients with chronic ILD, non-ILD, and HCs, MDA5+ DM patients with RP-ILD exhibited significant alterations in tryptophan (TRP) and its metabolites (RP-ILD vs C-ILD: $P = 0.0006$, RP-ILD vs non-ILD: $P = 0.0003$, RP-ILD vs HC: $P < 0.0001$). Further analysis revealed that the kynurenine (KYN) pathway may primarily drive abnormal TRP metabolism in MDA5+ DM patients with RP-ILD. In addition, abnormal TRP and KYN pathway metabolites were associated with disease activity indicators in MDA5+ DM patients.

Conclusion: Our results indicated that alterations in the TRP metabolism may play an active role in the pathogenesis of RP-ILD in MDA5+ DM and could be considered as a potential therapeutic approach.

Background/Purpose: Dermatomyositis (DM) is a heterogeneous multisystem autoimmune disease characterized by inflammation of the skin, muscle, and lung. Identifying the immune cells that drive disease activity is critical for advancing targeted therapies and improving clinical outcomes. Accordingly, we aimed to define immune cell populations associated with disease activity in DM across autoantibody-defined DM subtypes.

Methods: Bulk RNA sequencing analysis was performed on peripheral blood from 350 comprehensively phenotyped adult DM patients and 92 active DM skin biopsies. Type I (IFN-1) and type II (IFN-2) interferon scores were calculated as previously described. Immune cell proportions were estimated using CIBERSORT deconvolution, and associations with autoantibody subtypes, Cutaneous Dermatomyositis Disease Area and Severity Index (CDASI) scores, Manual Muscle Testing (MMT) scores, and IFN scores were evaluated.

Results: Circulating pro-inflammatory M1 macrophage scores were significantly associated with cutaneous disease activity (CDASI; r=0.30, p< 0.001, Spearman's rank correlation coefficient). Concordantly, the M1 macrophage signature was markedly elevated in DM skin compared to healthy controls (18.2 fold increase, p=0.0097, Wilcoxon signed-rank test) and positively correlated with both IFN-1 (r=0.58, p< 0.001, Spearman) and IFN-2 (r=0.69, p< 0.001, Spearman) scores, suggesting a direct role for M1 macrophages in skin inflammation. Notably, the correlation between circulating M1 macrophages and CDASI scores was evident across several autoantibody groups, including anti-TIF1γ (n=105, r=0.41, p< 0.001, Spearman), anti-Mi2 (n=30, r=0.40 p< 0.03, Spearman), and anti-NXP2 (n=20, r=0.48, p< 0.03, Spearman), but was absent in anti-PM/Scl+ or anti-synthetase+ (anti-Jo1, anti-PL7, anti-PL12) DM patients, indicating that distinct immune drivers may underlie disease activity across DM subtypes. In contrast to skin, M1 macrophages were not associated with muscle disease activity in any DM subtype. Instead, increased memory B cell and plasma cell scores were most strongly associated with reduced muscle strength (MMT; memory B cells: r=-0.25, p< 0.01; plasma cells: r=-0.20, p< 0.05; Spearman). Additional immune cell associations were identified with other pathologies.

Conclusion: Our findings implicate circulating M1 macrophages as potentially key contributors to cutaneous disease activity in DM and highlight subtype-specific differences in immune pathogenesis. These results provide new insights into potential cellular therapeutic targets and raise the question of whether organ and autoantibody-specific therapeutic strategies are necessary to effectively manage the heterogeneous clinical presentations of DM.

Background/Purpose: Dermatomyositis (DM) is a chronic inflammatory myopathy characterized by muscle weakness and skin rashes, yet its full impact on patient-reported outcomes remains under-explored. We used PROMIS instruments to systematically assess pain, fatigue, and physical function in patients with dermatomyositis, aiming to capture the multidimensional burden of disease from the patient perspective.

Methods: Adult patients with dermatomyositis (DM) fulfilling the 2017 EULAR/ACR Classification Criteria for DM were enrolled at a single center. Inclusion criteria required at least two consecutive visits (baseline and follow-up) with documented PROMIS scores. Demographic data, organ involvement and myositis-specific autoantibody status were obtained. Markers of disease severity included maximum cutaneous dermatomyositis disease area and severity index-activity (CDASI-A), maximum creatine kinase (CK), and lowest Manual Muscle Testing-8 (MMT-8) scores. Medication history of ever taking an immunosuppressant or immunomodulatory agent was also ascertained by chart review. PROMIS domains included PROMIS Short Form Fatigue 7a (v1.0), Pain Interference 6a (v1.1), Physical Function 8b (v2.0) with moderate or worse scores defined as the primary outcome. Logistic regression was performed to evaluate associations between PROMIS scores and clinical covariates, adjusting for baseline PROMIS scores. Covariates included age, race, lowest MMT-8, maximum CDASI-A, CK, medication exposures, and autoantibodies.

Results: A total of 214 patients with DM were identified with PROMIS scores taken at two visits during follow-up. Average age of diagnosis was 51.2 $\pm$ 12.6 years; 167 (76.6%) were female, and 51 (23.4%) were male. 178 (81.7%) were white, 21 (9.6%) were black, and 19 (8.7%) were Asian, Native Hawaiian/Pacific Islander). Mean CDASI-A score was 13.1 + 9.1. Among clinical and demographic variables, race was associated with PROMIS pain and fatigue outcomes. Patients identifying as Asian, American Indian/Alaska Native, Native Hawaiian/Pacific Islander were less likely to report moderate or worse pain (p=0.023) and fatigue (p=0.075). For fatigue, there was also a trend toward greater impairment with lower MMT-8 scores (p=0.059). Prior treatment with intravenous immunoglobulin (IVIG) was significantly associated with increased odds of reporting moderate or worse fatigue (p=0.001) and impaired physical function (p=0.012).

Conclusion: In this cohort of dermatomyositis patients, patient-reported fatigue and physical function impairments were associated with IVIG use and clinical weakness, while racial differences suggested potential disparities in impairment or reporting. Given the observational nature of this study, associations between treatment exposures and PROMIS outcomes should be interpreted cautiously, as they may reflect underlying disease severity rather than direct treatment effects. These findings highlight the utility of PROMIS measures in capturing patient-centered outcomes and identifying subgroups at risk for higher disease burden.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2052–2078) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Dysphagia remains a key contributor to mortality in IBM due to its connection with aspiration pneumonia and malnutrition (Shelly et al., 2021). Compared to other IIMs, IBM increases the odds of acquiring aspiration pneumonia and non-oral means of nutrition 3-fold (Ma et al., 2023). Yet, dysphagia kinematics in IBM are ill-defined, possibly leading to under-detection, misdiagnosis, and inappropriate dysphagia treatment (Ambrocio et al., 2023). Our study aimed to profile the kinematics underlying dysphagia in IBM using standardized and validated assessment methods and identify clinical predictors of dysphagia severity.

Methods: We conducted a prospective, cross-sectional study involving 15 adults with IBM (9 males) suspected of dysphagia. They had a mean age of 72.7 years (*SD*=5.9) and met the European Neuromuscular Center diagnostic criteria (Lilleker et al., 2024) and ACR classification (Lundberg et al., 2017). Their mean IBM Functional Rating Scale (IBMFRS) score and disease duration were 26.9 (*SD*=5.5) and 8.5 years (*SD*=3.8), respectively. Participants underwent a modified barium swallow study following the Modified Barium Swallow Impairment Profile (MBSImP) protocol, including 12 bolus tasks ranging from thin to highly thick liquids and a solid (Martin-Harris et al., 2008). We analyzed the images using MBSImP ratings, yielding Overall Impression (OI), Oral Total (OT), and Pharyngeal Total (PT) scores across 17 oral, pharyngeal, and esophageal kinematic components. We compared participants' OI, OT, and PT scores with data from age- and sex-matched healthy controls in a normative database (Garand et al., 2022). Mann-Whitney U tests compared OI, OT, and PT scores between groups. We analyzed dysphagia severity using the Dynamic Imaging Grade of Swallowing Toxicity (DIGEST) (Hutcheson et al., 2022). Univariate ordinal logistic regressions estimated the impact of OT and PT scores, age, sex, IBMFRS scores, and disease duration on DIGEST grades.

Results: Compared to controls, the IBM group had significantly higher (worse) OI scores for tongue motion, soft palate elevation, pharyngeal stripping, pharyngoesophageal segment opening, pharyngeal residue, and esophageal clearance, each $p < .05$, with large effects ranging from r=.51-.91 (Table 1). The IBM group had significantly higher (worse) OT (p=.001, r=.62) and PT (p=.013, r=.50) scores than controls, with large effects (Table 2). One participant had a normal DIGEST grade,

Table 1. MBSImP OI Score Summary Between IBM and Healthy Control Groups

Domain	Component	Control Group Score Median (IQR)	IBM Group Score Median (IQR)	*p* value	Effect size (r)
Oral	Lip closure	1 (0)	0 (0)	<.001 (rendered null as scores of 0-1 for this component are normal variants)	-.83
	Tongue control during bolus hold	0 (1)	0 (2)	.30	.22
	Mastication	0 (0)	0 (0)	.74	.12
	Tongue motion	0 (0)	2 (0)	<.001*	.91
	Oral residue	2 (1)	2 (0)	.061	.45
	Pharyngeal swallow initiation	2 (2)	3 (1)	.18	.29
Pharyngeal	Soft palate elevation	0 (0)	1 (1)	.007*	.59
	Laryngeal elevation	1 (1)	1 (1)	.60	.15
	Anterior hyoid excursion	1 (0)	1 (2)	.62	.14
	Epiglottic movement	0 (0)	1 (1)	.12	.36
	Laryngeal vestibular closure	0 (1)	1 (1)	.17	.32
	Pharyngeal stripping	1 (1); Rank sum=152	1 (1); Rank sum=313	.001*	.67

n=30 for all tests. * denotes significant values. Higher median scores or rank sum imply worse scores.

Table 2. MBSImP OT and PT Score Summary Between IBM and Healthy Control Groups

Domain		Control Group Score	IBM Group Score	Mean Difference	*p* value	Effect size (*r*)
OT	*M* (*SD*)	5.13 (1.51)	7.8 (2.34)	2.67	.001*	.62
	95% CI	4.30–5.97	6.51–9.09			
	Min, max	2, 8	5, 13			
PT	*M* (*SD*)	7.53 (1.96)	12.73 (5.27)	5.20	.013*	.50
	95% CI	6.45–8.62	9.81–15.65			
	Min, max	5, 11	6, 20			

n=30 for all tests. * denotes significant values. Higher scores imply worse scores.

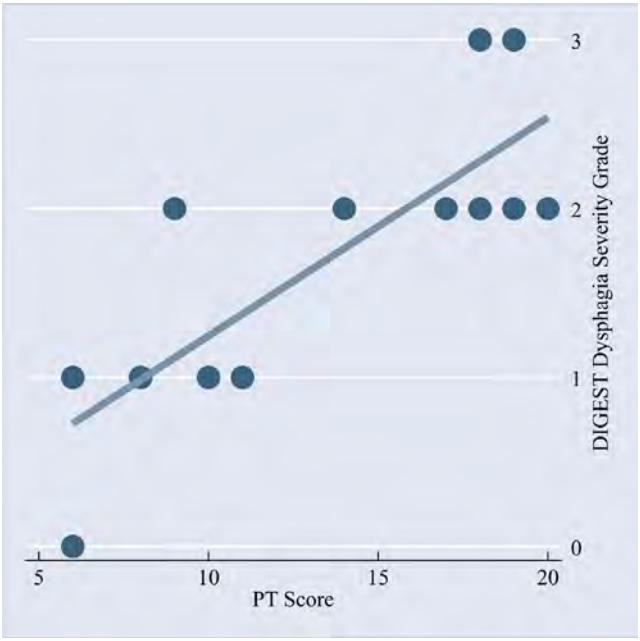

Figure 1. DIGEST Dysphagia Severity Grade Regression. The scatter plot shows the interaction between each participant's PT score and DIGEST dysphagia severity grade, while the line represents the overall trend of the fitted regression model. This trend illustrates that higher (worse) PT scores are generally associated with higher (worse) DIGEST dysphagia severity grades. DIGEST severity grade interpretation: 0=normal, 1=mild, 2=moderate, 3=severe.

but the rest spanned from mild to severe dysphagia. Only PT scores predicted DIGEST grades, with higher PT scores significantly linked to greater dysphagia severity, p=.031, OR=2.16 (Figure 1).

Conclusion: Participants with IBM exhibited kinematic deficits across swallowing phases. Surrogate kinematic markers for pressure generation and bolus propulsion mechanics were most impaired, which may be valuable for predicting dysphagia severity in IBM. Our study demonstrates the use of robust swallowing metrics to quantify and obtain a nuanced phenotypic dysphagia profile for IBM, representing an improvement over prior studies. Such findings facilitate targeted dysphagia treatment, precise symptom monitoring, and early identification of people with IBM at risk of dysphagia.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2052–2078) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Pain remains a significant yet understudied aspect of idiopathic inflammatory myopathies (IIMs), considerably reducing quality of life despite advancements in immunomodulatory therapies. Information obtained from self-reported patients' lived experiences would underscore the crucial information in improving their life quality.

Methods: We analyzed self-reported pain data within a global IIMs dataset that represent 103 countries [1]. This study used patient-experience pain visual analogue scale (VAS) with scores ranging from 0-10 and stratified the participants into mild (VAS ≤3) and moderate-severe (VAS >3) pain groups [2,3]. Socio-demographic characteristics, disease construct (type of IIM, treatment, comorbidities), and psychological construct (mental health comorbidities) were compared between groups-IIMs, RMDs, nRAIDs, and HCs. Basic multimorbidity (BM) was defined as the presence of two or more non-autoimmune comorbidities, while complex multimorbidity (CM) was defined as the presence of three or more such conditions affecting three or more different body systems. Descriptive statistics were calculated; appropriate parametric and non-parametric tests were used for comparison between groups and multivariable logistic regression was used to determine the predictors of moderate-severe pain (R studio version 2024.12.1).

Results: Among 7,847 respondents (4,709 disease controls), 1,045 (13.3%) had IIM: dermatomyositis (26.1%), overlap myositis (OM, 24.3%), inclusion body myositis (IBM, 23.4%), polymyositis (PM, 13.4%), anti-synthetase syndrome (ASyS, 6.8%), and necrotizing myopathies (IMNM, 5.6%) (Figure 1). IIMs exhibited higher pain intensity (median VAS 3.0, 1.0-5.0) than nRAIDs (1.0, 0.0-4.0) and HCs (0.0, 0.0-2.0), $p< 0.01$, but lower than rheumatoid arthritis (4.0, 2.0-6.0), psoriatic arthritis (4.0, 2.0-7.0), and Sjögren's disease (4.0, 2.0-7.0), $p< 0.01$. (Figure 2).

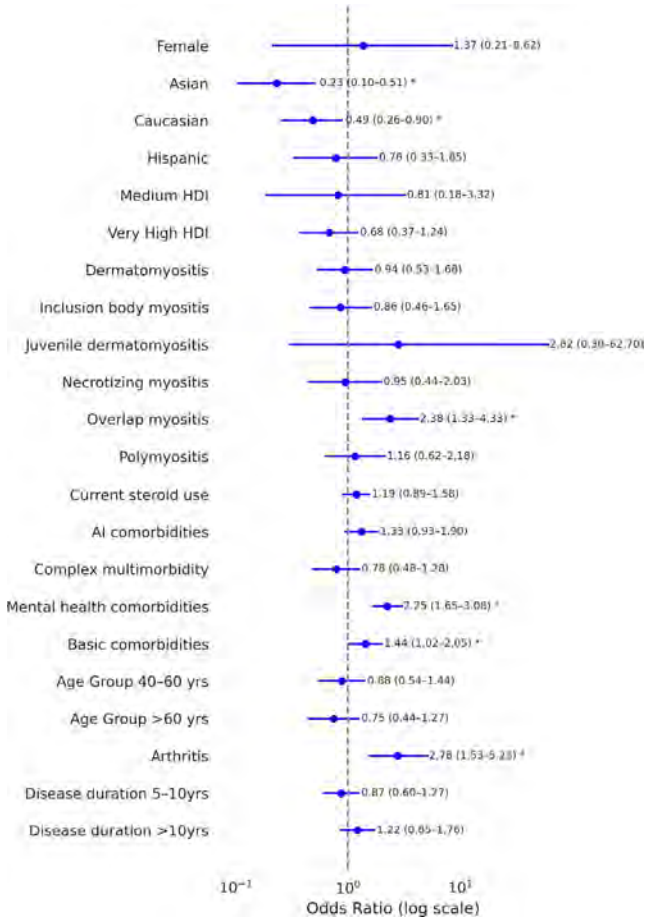

Figure 3: Forest plot showing predictors of moderate to severe pain (Pain VAS>3) in patients with IIM. *denotes p<0.05.

Overlap myositis had the highest pain levels (4.0, 2.0-6.0), while inclusion body myositis had the lowest (2.0, 0.0-4.0). Middle-aged patients (40-60 years) reported more pain than older groups. Pain primarily affected large joints (43%) and leg muscles (36.5%).

Female IIM patients reported higher pain scores than males (3.0, 1.0-5.0 vs. 2.0, 1.0-5.0). Moderate-severe pain (reported by 42.7%) was significantly associated with higher fatigue, worse physical function, and poorer quality of life across all domains (p< 0.001).

Significant predictors of moderate-severe pain included: overlap myositis (odds ratio, OR=2.38), arthritis (OR=2.78), mental health comorbidities (OR=2.25), and basic comorbidities (OR=1.44). Asian (OR=0.23) and Caucasian (OR=0.49) patients had lower odds of severe pain (Figure 3).

Conclusion: Pain represents a substantial burden in IIMs, particularly in overlap myositis. The bimodal distribution in IIM suggests heterogeneous pain mechanisms. Strong associations between pain intensity and reduced quality of life highlight the importance of comprehensive pain management. Multi-faceted interventions addressing identified predictors could significantly improve outcomes in this challenging disease group.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2052–2078) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Traditional clinical measures are well established in idiopathic inflammatory myopathies (IIM), yet exploration of subjective well-being (SWB) remains limited. SWB assessment facilitates holistic patient care and development of targeted interventions. The Satisfaction with Life Scale (SWLS), a validated tool, evaluates the cognitive aspect of well-being, offering valuable insight into patient experience. This study aimed to identify factors associated with SWB in IIM.

Methods: Patient-reported data were collected from a cross-sectional global "Collating the voice of people living with autoimmune diseases" survey covering 111 countries. SWB was assessed using SWLS, categorized as "extremely dissatisfied" (score 5-9) to "extremely satisfied" (score 30-35). We assessed socio-demographic characteristics, disease constructs and psychological constructs [Fig. 1A]. Multivariable regression analysis was performed with SWLS as the dependent variable. Cluster analysis performed using K-means algorithm after proper standardization.

Results: Data from 11,849 participants (IIM=1,252, oRMDs (Other rheumatic and musculoskeletal diseases)=6,653, nrAIDs (non-rheumatic autoimmune diseases)=997, non-autoimmune chronic diseases (CD)=973, healthy population (HC)=1,974) revealed significant differences [Fig.1B] [Table 1] . After adjusting for age, gender, income and education, SWLS scores were lowest in IIM with a median of 17 [Fig 1C,1D] with no significant differences between IIM subtypes.

In multivariable regression, psychological (self-efficacy β=0.15, $p < 0.001$, better mental health β=1.93, $p < 0.001$), and social factors (job satisfaction β=0.50, $p < 0.001$, and family functioning β=0.80, $p < 0.001$) were the strongest positive predictors of SWB. Disease-related factors like damage (β= -0.60, $p < 0.001$), fatigue (β= -0.48, $p = 0.003$), pain (β= -0.45, $p = 0.001$), and depression/anxiety (β= -1.83, $p < 0.05$) were negatively associated. Lower income (β=-3.4 to -8.8, $p < 0.001$) and loneliness (β=-0.99, $p < 0.001$) also predicted lower SWB [Fig. 2A]. Age, disease activity and duration, and comorbidities were not significant in fully adjusted models.

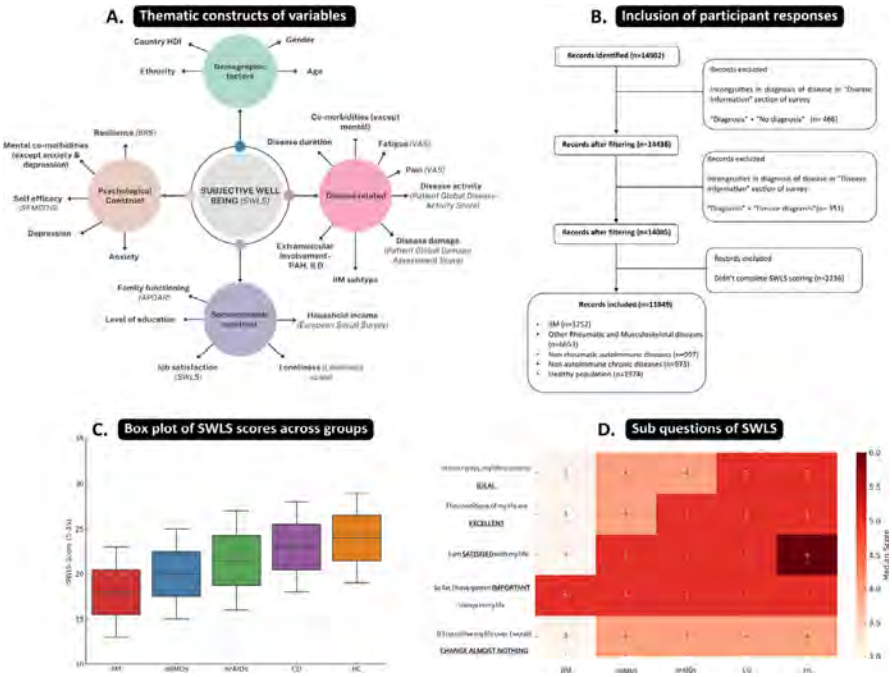

Fig 1: A- Thematic constructs of variables of interest; B- Flowchart depicting inclusion of participant responses; C- Box plot of Satisfaction with life scale (SWLS) score across groups; D- Heat map demonstrating scores for sub questions of SWLS across various groups.

K-means clustering of 851 individuals with myositis identified three distinct SWB profiles: high (24%), moderate (49%), and low (27%). High SWB was associated with better mental health, self-efficacy, and family functioning, alongside lower fatigue, pain, and loneliness, whereas the low SWB cluster exhibited significantly worse scores across these domains [Fig.2B]. Subtype-specific patterns emerged: anti-synthetase syndrome (ASyS) predominantly clustered in moderate SWB,

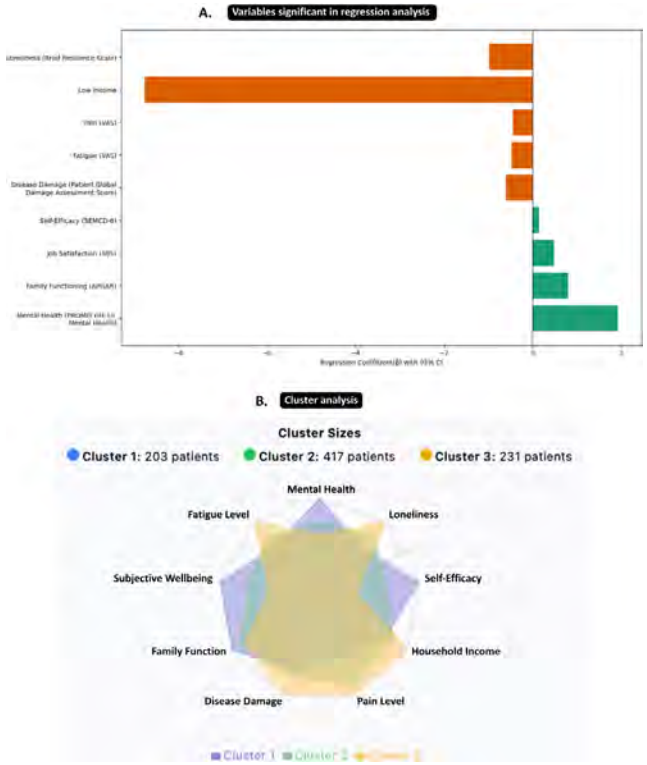

Fig.2: A- Forest plot of variables statistically significant in regression analysis for SWB; B- Radar chart showing various clusters with characteristics.

IIM= Idiopathic inflammatory myopathies; oRMD- other rheumatic and musculoskeletal disease; nRAID: non-rheumatic autoimmune disease; CD: non autoimmune chronic disease; HC: healthy controls
* CD: Non autoimmune chronic disease
**HC: psychiatric conditions were not excluded
***Comorbidity definitions. Simple (>1 diagnosis); Basic (addition of ≥1 non-rheumatic diagnosis); Psychiatric (≥1 psychiatric diagnosis); Complex (comorbidities across ≥ 3 body systems)

polymyositis (PM) in low SWB, and inclusion body myositis (IBM) in both high and low SWB clusters, underscoring heterogeneous psychosocial burden across IIM subtypes.

Conclusion: Our findings show that SWB in IIM is shaped more by psychosocial than clinical factors. Low median SWLS scores highlight the impact of IIM on life satisfaction. Despite similar disease profiles, distinct well-being clusters reveal underlying psychosocial burdens advocating for integrating holistic and person-centered care into rheumatology practice to enhance quality of life.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2052–2078) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Comorbidities contribute to the disease burden in idiopathic inflammatory myopathies (IIMs). Understanding their distribution and predictors across IIM subtypes can guide tailored strategies. This study aimed to evaluate the patterns of comorbidities across IIM subsets, identify predictors of physical and mental comorbidities, and characterize comorbidity clusters.

Methods: This cross-sectional study used data from the Collating the Voices of Patients with Autoimmune Diseases study. Adults with specialist-diagnosed, self-reported IIMs were included. The validated Functional Comorbidities Index (FCI) was used to collect information on comorbidities. Subgroup comparisons were conducted across IIM subtypes. Descriptive statistics were performed and binary logistic regression was used to identify predictors of mental and physical health comorbidities. Hierarchical cluster analysis was applied to derive composite comorbidity clusters using R.

Results: Of 14,902 respondents, 1,209 IIM patients (69.6% female) were included [Fig.1A, 1B], with a median age and disease duration of 60 and 17 years, respectively (Table 1). The most common comorbidities were mental health conditions (32.1%), cardiovascular diseases (32.0%), and musculoskeletal disorders (23.3%). Mental (41.4%) and musculoskeletal (45.2%) comorbidities were most common in overlap myositis (OM). Cardiovascular conditions were most common in inclusion body myositis (IBM) (45.2%) [Fig.1C]. Predictors of mental health comorbidities included older age (OR:0.98; 95% CI=0.96-0.99), high Human Development Index (HDI) (OR:4.35; 95%CI=1.72-1.75), and alcohol intake (2-4 times/month) (OR:0.44; 95%CI=0.24-0.79).

Predictors of physical health comorbidities were older age (OR:1.05; 95%CI=1.02-1.07), high HDI (OR:5.32; 95% CI=1.26-22.39), alcohol intake (2-4 times/month) (OR:0.45; 95%CI=0.23-0.90), and disease damage (OR:1.13; 95% CI=1.01-1.26). Hierarchical cluster analysis identified 3 comorbidity clusters. Cluster 1 was characterized by Hispanic

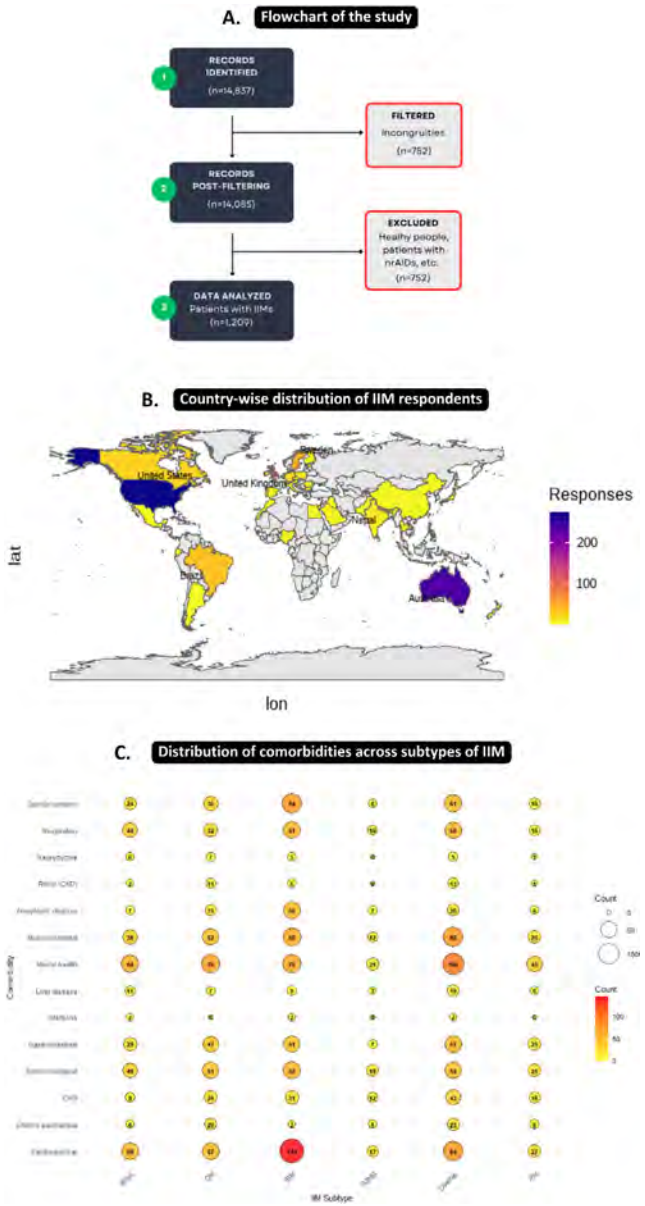

Fig.1: A- Flowchart depicting inclusion of participants; B- World map showing country-wise distribution of IIM respondents; C- Distribution of comorbidities across IIM subtypes

ethnicity, lower HDI, and low multimorbidity, with notable immune-mediated necrotizing myopathies representation but limited variance. Cluster 2 was male-dominated, had very high HDI and moderate mental and physical comorbidity levels, and included the highest proportion of IBM and polymyositis. Cluster 3 showed the highest multimorbidity burden, dominated by dermatomyositis and anti-synthetase syndrome.

Conclusion: Comorbidities vary across IIM subtypes. Older age and high HDI predict both mental and physical health comorbidities, while higher disease damage predicts physical health comorbidity. Comorbidity clusters reveal distinct IIM subtype distributions, highlighting subtype-specific comorbidity patterns that may guide personalized clinical management.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2052–2078) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III

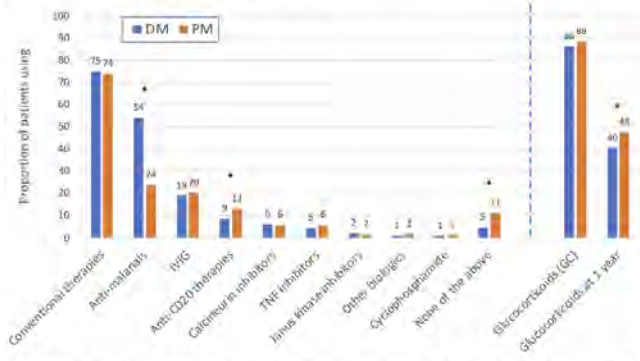
Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Studies of idiopathic inflammatory myopathies (IIM) are often based on the analysis of single cohorts at academic centers. We aimed to identify potential gaps in care by comparing testing, treatment, and outcomes of people with IIM diagnosed as dermatomyositis (DM) vs polymyositis (PM) in a nationally representative US cohort.

Methods: This retrospective cohort study used commercial claims (Komodo Healthmap data 1/1/2016-3/31/2024) to identify adults ≥18 with incident IIM, requiring one inpatient diagnosis code for DM (M33.1* or M33.9*) or PM (M33.2*) (positive predictive value 92%) or two outpatient diagnosis codes for DM or PM 7-365 days apart with use of a non-glucocorticoid immunomodulatory therapy (second outpatient diagnosis as the index date). Patients without a 12-month baseline prior to diagnosis #1 or with diagnoses of juvenile DM or inclusion body myositis were excluded. Antisynthetase syndrome and necrotizing myopathy lack specific codes but could be included if DM or PM diagnoses were coded. Standardized differences ≥|0.1| were used to identify differences between those with DM vs PM. Analyses of diagnostic testing and treatment required 12 months of continuous data after index unless limited by death. Time to event analyses for incident hospitalization and major adverse cardiac events (MACE, excluding those with prior MACE) censored at end of follow-up.

Figure 1: Treatments used by people with dermatomyositis (DM) or polymyositis (PM) diagnosis codes, using data from diagnosis #1 through 12 months after the index date



Conventional therapies include methotrexate, azathioprine, mycophenolate, and leflunomide. Anti-malarial includes hydroxychloroquine and chloroquine. Anti-CD20 includes rituximab, obinituzumab, ocrelizumab, ofatumumab, ublituximab. Janus kinase inhibitors include tofacitinib, upadacitinib, baricitinib. Other biologics includes tocilizumab, sarilumab, abatacept, anifrolumab. Glucocorticoid use at 1 year based on ≥ filled oral glucocorticoid prescription 273 to 365 days after index.
IVIG = intra-venous immune globulin; DM = dermatomyositis; PM = polymyositis.
* indicates standardized mean difference ≥0.1 or ≤-0.1, identifying a meaningful difference across groups – anti-malarial SMD 0.65, anti-CD20 SMD -0.14, none of the above SMD -0.24, continued GC use SMD 0.14. In each of these cases $p < 0.001$ by Chi-squared testing.

Results: We identified 9,195 people with incident IIM: 5,560 with DM and 3,635 with PM. People with DM were younger, more frequently female, had fewer comorbidities, and were less often diagnosed as inpatients vs PM (**Table 1**). Other rheumatic diagnoses were common in both groups, and those with PM were more likely to have prior diagnoses of rhabdomyolysis or abnormal liver function tests (possibly reflecting muscle injury not identified as IIM). Rheumatologists cared for approximately 70% of those with DM and PM, with dermatologists more frequently involved for DM and neurologists and cardiologists for PM (**Table 2**). Although 19% of patients had a diagnosis of ILD, no pulmonary testing was performed in 35% of patients. Conventional therapies were frequent in both groups, but anti-malarials were used more commonly in those with DM (**Figure 1**). IVIG (19%) and anti-CD20 therapy (10%) use in the first year was not uncommon in DM or PM. Glucocorticoid use was similar in DM and PM, with 87% using glucocorticoids within the first year of diagnosis and median cumulative glucocorticoid exposure among glucocorticoid users 1605mg (IQR 600, 2925). Glucocorticoid use at 1 year, however, was less common in DM (40%) vs PM (48%). During follow-up, incidence of hospitalization (15.1 vs 22.1/100 person-year) and MACE (1.0 vs 1.7/100 person-years) were less common in DM vs PM (both $p < 0.05$).

Conclusion: This large cohort study reveals differences in comorbidity burden and outcomes in people with DM vs PM and highlights differences in the subspecialists caring for these two populations. We found potential gaps in testing, including low rates of ILD screening. The substantial glucocorticoid burden demonstrates the need for more effective treatment.

immunoassays, especially regarding the clinical relevance of low titer positive MSA/MAA, and their consistency in repeat testing, remains to be determined.

Methods: Using an electronic database, we identified all patients who had a myositis panel assessed through Eastern Ontario Regional Laboratory Association between June 2019 and October 2024. This myositis panel includes 18 autoantibodies detected by a semi-quantitative immunoblot assay, with autoantibodies reported in terms of low, moderate, and high titers (EUROIMMUN Medizinische Labordiagnostika AG, Lübeck Germany). We performed a retrospective chart review on the subset of patients with low positive titers of MSA/MAA and multiple myositis panels performed. Concordance was determined by the stability of the antibody result between sequential testing.

Results: 1478 patients had a myositis panel done, and 166 patients were positive with low-titer MSA or MAA antibodies. A total of 25 patients had two or more myositis panels performed within this timeframe. In these patients with repeat testing, 1056 individual MSA/MAA were measured, and the overall concordance was 95.8% (573/598) [Table 1]. Of the 1056

Table 2 | Concordance of low-titer MSA/MAA

Antibody	Number of patients	Number of tests Total *n* (n^+, n^-)	Concordance (low-titer)
Anti-Ro	7	17 (14, 3)	4 / 6 (67%)
Anti-Jo-1	3	8 (8, 0)	4 / 4 (100%)
Anti-PL7	2	5 (3, 2)	0 / 3 (0%)
Anti-PL12	3	6 (6, 0)	2 / 2 (100%)
Anti-Ku	5	12 (7, 5)	2 / 6 (33%)
Anti-OJ	1	2 (1, 1)	0 / 1 (0%)

Table 3 | Idiopathic inflammatory myopathy diagnosis

Diagnosis	Total
None	17 (68%)
Juvenile Dermatomyositis (JDM)	0
Antisynthetase syndrome	2 (8%)
Immune-mediated necrotizing myopathy	2 (8%)
Overlap/non-specific myositis	0
Polymyositis	0
Dermatomyositis	1 (4%)
Amyopathic dermatomyositis	0
Cancer-associated myositis	0
Inclusion body myositis	1 (4%)
Others	2 (8%)

individual MSA/MAA, 102 were in patients with at least one MSA/MAA positive antibody result. Five patients had concomitant moderate/high positive titer MSA/MAA, though these values were excluded from the primary analysis. Concordance limited to positive low-titer findings on at least one time point was much lower at 48% (24/50) [Table 2]. Among low-titer MSA/MAA, the highest concordance was observed for Ro (4/6, 67%), PL12 (2/2, 100%), and Jo-1 (4/4, 100%), whereas concordance was < 50% for PL7 (0/3, 0%), Ku (2/6, 33%), SAE (2/5, 40%), OJ (0/1, 0%), MDA-5 (0/2, 0%) and SRP (0/2, 0%) antibodies [Table 2]. 68% of the repeat patients (17/25) did not develop any IIM and were deemed to have false positive antibodies on their myositis panel [Table 3].

Conclusion: The concordance of a positive low titer positive MSA and MAA on subsequent myositis panel testing was found to be overall low (48%) within our patient population. Only 3 of 20 patients limited to low-positive titers received an IIM diagnosis, highlighting the high frequency of clinically false positives among low positive titers. Further studies are needed to understand the clinical significance of low positive titers and repeat testing using myositis panels

Background/Purpose: Idiopathic Inflammatory Myopathies (IIM), including polymyositis and dermatomyositis, are rare systemic autoimmune disorders characterized by chronic muscle inflammation and progressive muscle weakness. Patients with IIM are at an elevated risk of fractures due to a combination of factors, including prolonged corticosteroid use, reduced bone mineral density, impaired mobility, and an increased propensity for falls. Although fracture risk in IIM is well recognized, there is limited understanding of how IIM affects hospitalization outcomes following fractures, including resource utilization, discharge disposition, and mortality. Clarifying these associations is essential to inform clinical management and optimize care strategies for this high-risk patient population. To evaluate the impact of Idiopathic Inflammatory Myopathies (IIM) on hospitalization outcomes among adults admitted with fractures by comparing demographic characteristics, comorbidity burden, resource utilization, and in-hospital mortality between patients with and without IIM using a nationally representative dataset.

Methods: We conducted a retrospective cohort study using the National Inpatient Sample (NIS) data from 2017 to 2022. Adults (≥18 years) hospitalized with a primary diagnosis of fracture were identified and further stratified based on the presence or absence of a secondary diagnosis of IIM which includes polymyositis , dermatomyositis and Inclusion body myositis. using ICD-10 Codes. Patient demographics, comorbidities, fracture types, length of stay (LOS), total hospital charges, discharge disposition, and in-hospital mortality were compared between groups. Multivariable logistic and linear regression models, adjusting for demographic and clinical variables, were used to assess the independent association of IIM with hospitalization outcomes. Adjusted odds ratios (aOR), β coefficients, 95% confidence intervals (CI), and P-values were reported.

Results: Among 5,273,033 fracture hospitalizations, 1,950 (0.04%) had a concurrent diagnosis of IIM. Compared to patients without IIM, those with IIM were older (mean age 72.1 vs. 69.5 years, p< 0.001) and more likely to be female (73.08% vs. 58.13%, p< 0.001). Osteoporosis (24% vs. 11%, p< 0.001) and steroid use (23.27% vs. 1.3%, p< 0.001) were

Table 1. Patient Demographics and Hospitalization Characteristics

Characteristic	Fracture without IIM (n = 5,271,083)	Fracture with IIM (n = 1,950)	P-value
Age, mean (years)	69.5	72.1	<0.001
Female sex (%)	58.13%	73.08%	<0.001

Osteoporosis (%)	11.00%	24.00%	<0.001
Steroid Use (%)	1.3%	23.27%	<0.001
Length of Stay, mean (days)	5.4	6.02	0.002
In-hospital Mortality (%)	1.6%	1.7%	0.77
Mean Total Hospital Charges (US$)	$74,271	581,447	0.02

Patient Demographics and Hospitalization Characteristics

Table 2. Multivariable Regression Analysis for Adjusted Outcomes

Outcome	Adjusted Odds Ratio (aOR) / Beta Coefficient	95% Confidence Interval (CI)	P-value
In-Hospital Mortality	1.29	0.60 - 2.70	0.505
Length of Stay (days)	+0.49 days	0.20 - 0.60	**0.029**
Discharge to Skilled Nursing Facility (SNF)	0.91	0.73 - 1.14	0.408
Total Hospital Charges (US$)	+$4,877	$1,156 - $4,655	**0.037**

Multivariable Regression Analysis for Adjusted Outcomes

significantly more prevalent among IIM patients. After multivariable adjustment, IIM was associated with a significantly longer hospital stay (β = +0.49 days, 95% CI 0.20–0.60, p = 0.029) and higher total hospital charges (β = +$4,877, 95% CI $1,156–$4,655, p = 0.037). No significant differences were observed in in-hospital mortality (aOR 1.29, 95% CI 0.60–2.70, p = 0.505) or discharge to skilled nursing facilities (aOR 0.91, 95% CI 0.73–1.14, p = 0.408).

Conclusion: Among adults hospitalized for fractures, the presence of IIM was associated with longer hospital stays and higher healthcare costs but was not associated with increased in-hospital mortality or skilled nursing facility disposition. These findings underscore the importance of proactive fracture prevention strategies, interdisciplinary peri-fracture management, and early rehabilitation planning in patients with IIM.

Session Title: (2052–2078) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are a rare and heterogeneous group of autoimmune diseases marked by inflammation of muscle tissue and extramuscular manifestations. Their atypical clinical presentations often lead to diagnostic delays, which hinder timely treatment and contribute to worse outcomes. Early diagnosis is essential to reduce disease activity, prevent long-term damage, and improve quality of life. In juvenile dermatomyositis (JDM), delayed

MYOACT, mean (±SD)	14.0 ± 11.0
MITAX, mean (±SD)	11.3 ± 9.1
HAQ, mean (±SD)	0.82 ± 0.7

diagnosis has been linked to greater morbidity and poorer prognosis, with emerging evidence also pointing to disparities based on race. This underscores the need for further research. We aim to examine the correlation between diagnostic delay, disease activity, and cumulative damage in patients with IIM.

Methods: A descriptive, cross-sectional, and comparative study was performed. Patients over 18 years of age diagnosed with IIM according to the 2017 ACR/EULAR classification criteria or the 1975 Bohan and Peter criteria were recruited. A clinical history was obtained, including the duration of symptoms before diagnosis and the disease duration since diagnosis. The cumulative glucocorticoid dose up to the time of recruitment was calculated.

The following scales were assessed:

1. Myositis Damage Index (MDI)
2. Myositis Disease Activity Assessment Tool (MDAAT)
3. Health Assessment Questionnaire (HAQ)
4. Fitzpatrick Scale

Table 2. Comparison of clinical and laboratory characteristics according to diagnostic delay time

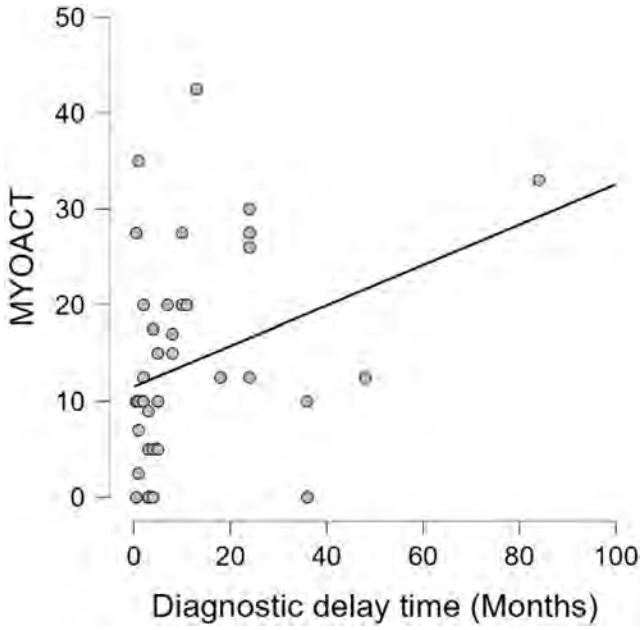

Figure 1. Correlated variables diagnostic delay time and MYOACT scale.

Patients were divided into two groups based on diagnostic delay: ≤9 months and >9 months. The Kolmogorov-Smirnov test, used to assess normality. Group comparisons were made using the Chi-square test, independent samples t-test, or Mann-Whitney U test. Correlations were analyzed using Pearson or Spearman coefficients, depending on data distribution. A p-value of < 0.05 was considered statistically significant.

Results: A total of 40 patients were included, with a mean age of 46.6 years (SD: 16.2). Most patients were female (n=34, 85%). The most frequent IIM was dermatomyositis, observed in 29 patients (72.5%). The median time from symptom onset to diagnosis was 5 months (IQR: 2–11.5). The most prevalent antibodies were anti-Ro52 (37.5%) and anti-TIFy (27.5%). Demographic and clinical characteristics and disease activity scales are shown in Table 1.

Patients with a diagnostic delay greater than 9 months had significantly higher scores on the HAQ, MYOACT, and MITAX scales (p=0.01, p=0.003, and p=0.02, respectively) (Table 2), as well as a younger age (p=0.01). A weak positive correlation was observed between diagnostic delay and MYOACT score (Spearman's $\rho = 0.357$, $p = 0.02$). (Figure 3)

Skin phototype showed differences by diagnostic delay. Among patients with a diagnostic delay ≤ 9 months, 44.4% had Fitzpatrick phototype IV or V, while 51.8% had phototype II or III. In contrast, 76.9% of patients with a delay > 9 months had phototype IV or V, compared to only 15.3% with phototype II or III.

Conclusion: According to our results, IIM is not commonly considered an initial diagnosis in younger patients with phototype IV or V. A diagnostic delay of more than 9 months was associated with higher disease activity, greater cumulative damage, and reduced quality of life, highlighting the need for timely evaluation in patients with these characteristics.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2052–2078) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Cancer risk is significantly increased in Idiopathic Inflammatory Myopathies (IIM), particularly within the first 3 to 5 years after diagnosis. Given that cancer represents the leading cause of mortality in IIM, implementing effective screening strategies is crucial for enabling early detection and timely intervention. This underscores the need to establish a comprehensive, multidisciplinary management program that incorporates risk-based cancer screening into routine care. Therefore, we aim to describe the model for the early detection of cancer in patients with IIM in our center's multidisciplinary care program for patients with rheumatic diseases.

Table 1: Screening Coverage and Time to Completion by Sex and Age Category

Table 1: Screening Coverage and Time to Completion by Sex and Age Category

	Women (18-40) (n=20)	Women >40 (n=34)	Men (18-40) (n=4)	Men (>40) (n=5)

Table 2: Screening Results of IIM patients.

Table 2: Screening Results of IIM patients.

Screening type	Positive	Negative	Not Screened*
Colon	6 (9.5)	29 (46.0)	21 (33.3)
Lung	4 (6.3)	42 (66.6)	15 (23.8)
Breast†	2 (3.7)	26 (51.6)	12 (22.2)
Cervix†	3 (5.5)	39 (72.2)	10 (18.5)
Prostate†	0 (0)	4 (44.4)	2 (22.2)

*Percentages and frequencies are calculated based on the total number of men and women. †Patients who were not yet due for screening were excluded.

Methods: The Early Cancer Detection Program, initiated on March 1st, 2024, at the Rheumatology Clinic of Dr. Jose Eleuterio González University Hospital (Nuevo Leon, Mexico), targets patients over 18 with IIM. The program has three primary objectives:

a) **Stratify cancer risk** using a digital calculator based on international guidelines, categorizing patients as high, intermediate, or low risk.

b) **Educate patients** on the importance of screening, tailored to individual risk levels, including low-dose CT, FIT, mammography, cervical cytology, and PSA testing.

c) **Identify prevalent cancers** in IIM patients through screening; those with positive results are referred to oncology, while negative results are followed up individually.

Quality indicators include:

1. The proportion of patients screened by age and sex
2. The time from IIM diagnosis to completion of screening
3. The percentage of patients with positive screening results
4. The proportion of patients not screened

Data are presented with descriptive statistics, including frequencies, percentages, mean, standard deviation, median, and interquartile range.

Results: A total of 63 IIM patients were included (54 women, 9 men; mean age 45.9 ± 16.3 years). Most patients were at intermediate cancer risk (47.6%), followed by high risk (41.2%) and low risk (11.1%). All high-risk patients underwent at least one screening, with only five patients not completing any screening. The median time from IIM diagnosis to screening was 10.0 months (IQR: 2.0–12.0).

Men had a higher overall screening rate than women (Table 1). However, 67.6% of colon cancer screenings were performed in women over 40. Lung cancer screening was completed in 100% of men over 40, while 82.3% and 67.6% of women over 40 underwent breast and cervical cancer screenings, respectively.

Regarding screening results (Table 2), lung screening had positive findings in 6.3% of patients, but no neoplasms were diagnosed. One positive breast cancer screening confirmed adenocarcinoma, and one cervical screening found a high-grade squamous intraepithelial lesion.

Conclusion: Our findings reveal that most patients with IIM were classified as high or intermediate cancer risk, underscoring the clinical importance of risk stratification. Despite these insights, gaps in cancer screening highlight the urgent need for targeted education and intervention strategies. Additionally, multidisciplinary efforts and the implementation of personalized management plans are crucial for optimizing cancer prevention strategies.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2052–2078) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are characterized by inflammatory muscle injury. Circulating cell-free DNA (cfDNA), including nuclear (cfnDNA) and mitochondrial (cfmtDNA) DNA, has been shown to increase after exercise primarily due to apoptosis or necrosis and might be a promising biomarker for inflammatory muscle injury in IIM. The aim was to explore the association between cfnDNA and cfmtDNA and muscle damage, strength, and metabolic function.

Methods: 66 patients with IIM were included: 22 male; mean (SD) age 57.6 (13.9); disease duration 2.3 (3.0) years; 21 dermatomyositis (DM)/ 29 polymyositis (PM), both without statin history/ 16 immune-mediated necrotizing myopathystatin-induced (IMNM). Follow-up at 6 months of immunosuppressive therapy included 15 patients (6 DM, 6 PM, 3 IMNM; disease duration 0.9 (1.3) years). Basal laboratory parameters, disease features, current treatment and comorbidities were recorded. Body composition was examined by bioelectric impedance analysis (BIA-2000-M). cfDNA was isolated using the Plasma/ Serum Cell-Free Circulating DNA Purification Mini Kit (Norgen Biotek). qPCR was used to analyze 2 independent markers for cfnDNA (IL6 and CTO), and cfmtDNA (ND5 and CO3). Data are presented as mean (SEM).

Results: There were no significant differences in plasma concentrations of selected cfnDNA and cfmtDNA markers among DM, PM and IMNM (Table 1). Elevated expression of both cfnDNA and cfmtDNA was associated with worse disease damage (MDI), decreased muscle strength (MMT8), higher body fat percentage (BF%), reduced basal metabolic rate (BMR), and decreased capacity for physical activity (higher ECM/BCM and lower phase angle). cfnDNA expression also positively

Interval	IL6 mean (SEM)	FTO mean (SEM)	ND5 mean (SEM)	CO3 mean (SEM)
Month 0	33,824 (5,230)	40,158 (8,088)	437,320 (66,502)	394,299 (83,451)
Month 6	31,166 (5,779)	29,628 (5,637)	312,809 (54,498)	293,759 (58,769)
p-value	0.600	0.390	0.107	0.230

correlated with disease activity (MITAX), while cfmtDNA positively correlated with age and glucose plasma levels (Table 2). The analysis of a 6-month follow-up in 15 IIM patients after immunosuppressive treatment initiation showed statistically significant reductions in disease activity, improvement of muscle strength, and decreases in levels of muscle involvement markers (CK, LD, myoglobin) ($p < 0.05$ for all) (Table 3). However, the decrease in both cfnDNA and cfmtDNA expression was not significant. Lower baseline expression of cfnDNA (IL6) predicted a trend to an increase in muscle strength (MMT8) ($p=0.09$).

Conclusion: Expression of nuclear and mitochondrial cfDNA did not vary among the IIM subtypes but was associated with disease activity and damage, muscle weakness, and physical function in patients with IIM. Although there was a significant improvement in muscle impairment (decrease in muscle markers, increase in muscle strength) along with the reduction in glucocorticoid doses observed in only 15 IIM patients after a 6-month initial immunosuppressive therapy, the expression of cfnDNA and cfmtDNA did not change, There was a promising prediction of increased muscle strength by baseline expression of cfnDNA (IL6). Therefore, both cfnDNA and cfmtDNA deserve further studies to elucidate their potential role as a marker of muscle damage, or treatment response in IIM.

Abstract Number: 2074

Increased Mortality in Hispanic Males with Lymphopenia: A Descriptive and Statistical Analysis of Anti-Melanoma Differentiation-Associated Protein 5 (MDA-5) Antibody Positive Patients

Sergio Maldonado Chaar[1] and Kelly Corbitt[2], [1]University of Miami/Jackson Health, Miami, FL, [2]University of Miami Miller School of Medicine, El Portal, FL

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2052–2078) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Anti-melanoma differentiation-associated protein 5 (MDA-5) antibody positivity in dermatomyositis (DM) is often associated with development of interstitial lung disease (ILD), with factors such as advanced age, male sex, lymphopenia, elevated ferritin and elevated lactate dehydrogenase (LDH) increasing mortality risk. Limited studies exist evaluating these risk factors in Hispanic patients. This retrospective study aims to evaluate these risk factors in a predominantly Hispanic population.

Methods: A retrospective cohort analysis was performed using electronic medical record data from 2021 to 2024 including all adult patients with a diagnosis code of either ILD and an abnormal myositis panel or DM. A total of 184 medical record numbers (MRNs) met these criteria. After confirming clinical diagnosis and filtering for positive anti-MDA5-antibodies, 17 MRNs were included. Lymphopenia was defined as an absolute lymphocyte count (ALC) less than 1000 cells/microliter. Advanced age was defined as 50 years or older. Data was analyzed using fisher exact testing.

Results: 29.4% (n=5) of patients were male and 70.6% (n=12) were female with a median age of 58 years. 76.0% (n=13) were Hispanic, including all males and 8 females. 7 patients (41.2%) had amyopathic DM, 4 (23.5%) had DM, and 6 (35.3%) had ILD without inflammatory myositis. 76.5% (n=13) of patients had ILD, including all of the males and 8 females. 23.5% (n=4) of patients were deceased, all of whom were males with ILD. Of 12 patients with advanced age, 25% (n=3) were deceased and 83.3% (n=10) had ILD. 9 patients had available LDH levels. Of these, five patients had elevated LDH and 4 were deceased. 8 patients had available ferritin levels, all of which were elevated. Of those patients, 88.5% (n=7; 3 males and 4 females) had ILD, and 37.5 % (n=3) were deceased. Lymphopenia was found in 35.3% (n=6; 4 males and 2 females). Mean ALC was 564 cells/microliter. Of these patients, 83.0% (n=5; 4 males and 1 female) had ILD and 66.7% (n=4) were deceased. A Fisher-exact-test showed significant associations between deceased and lymphopenia (p=0.006), males and lymphopenia (p=0.028), and males and deceased (p=0.002). There was no significant association of advanced age, elevated LDH level, and ILD with increased mortality. Elevated ferritin was not included in this analysis as all those tested had elevated levels.

Table 1: Comparison between males and females based on various classification groups.

Groups	Male	Female
Hispanic (%)	100.0	67.0
Median Age (years-old)	60.4	55.5
Average LDH (U/L)	255.0	301.0
Average Ferritin (ng/mL)	454.5	403.4
ILD (%)	100.0	69.0
Lymphopenia (%)	80.0	16.6
Average ALC (cells/μL) of Lymphopenic Patients	565.0	580.0
Mortality (%)	80.0	0.0

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Our cohort suggests a possible increased risk of mortality in anti-MDA5 antibody positive ILD patients who are male and have lymphopenia. We looked at a largely Hispanic population, which is underrepresented in anti-MDA5 antibody literature. Due to the limited sample size, larger cohorts should be examined to see if this association remains.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2052–2078) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Serum ferritin (FERR) is a recognized marker of immune activation and a key laboratory feature of anti-MDA5 Dermatomyositis (DM). It has been increasingly studied as a potential biomarker of disease activity, particularly due to its association with complications like rapidly progressive interstitial lung disease (RP-ILD), treatment response and prognosis. Its role in Antisynthetase Syndrome (ASS) remains less clear. This study aimed to assess the longitudinal variation of FERR and its correlation with disease activity in anti-MDA5 DM and, secondarily, to explore whether similar patterns were observed in matched anti-Jo1 ASS patients.

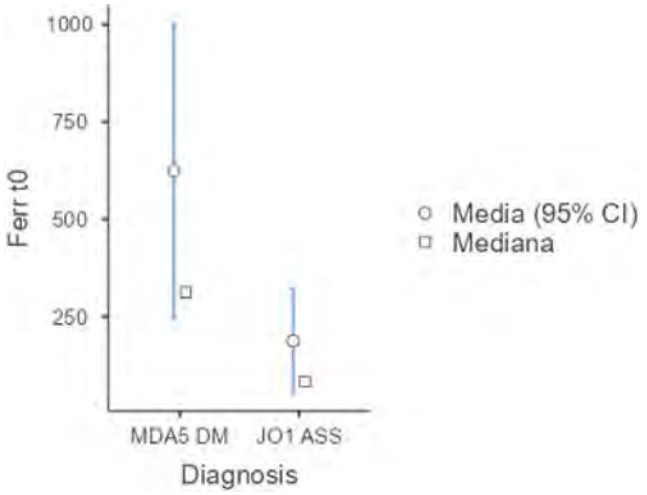

Image 1: serum ferritin levels at baseline.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

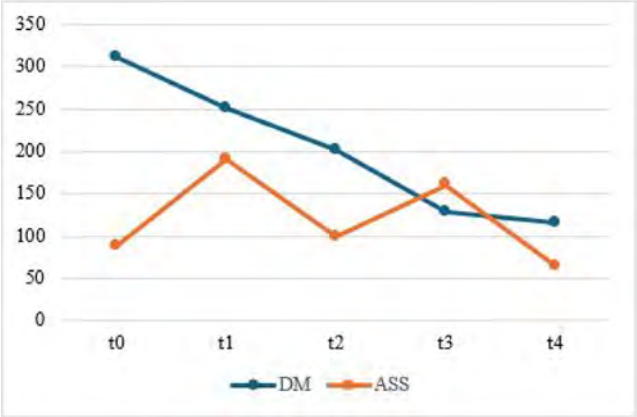

Image 2: serum ferritin levels during follow-up.

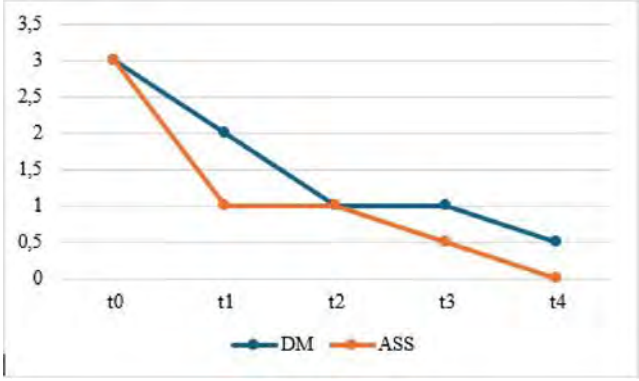

Image 3: PhGA trend during follow-up.

Methods: We retrospectively included adult patients with active anti-MDA5 DM or anti-Jo1 ASS (according to 2017 ACR/EULAR and Connor's criteria, respectively), all with ILD, evaluated across four Italian Myositis Centers. Inclusion criteria required demographic, clinical and serological data at baseline and at least two follow-up timepoints (3, 6, 12, and 18 months - t1, t2, t3 and t4, respectively). Disease activity was assessed by Physician Global Activity (PhGA). FERR, C-reactive protein (CRP), erythrocyte sedimentation rate (ESR) and creatinkinase (CK) were collected at each timepoint. Patients were treated according to local clinical practice, without a standardized therapeutic protocol.

Results: A total of 23 patients were included (11 DM, 12 ASS). Despite ASS patients exhibiting more extensive organ involvement - with 66% of them presenting ≥ 4 affected domains, compared to 36% in the DM group - baseline FERR was significantly higher in DM patients (median 312 vs 82 ng/mL, $p = 0.007$, **image 1**), while CK was increased in ASS (median 336 vs 101 U/L, $p = 0.05$). During follow-up, DM patients showed a progressive and significant reduction in FERR levels (**image 2**), with differences reaching statistical significance at 12 months (*t3 - t0*, $p = 0.025$) and 18 months (*t4 - t0*, $p = 0.017$). PhGA also significantly improved in DM group (*t2 - t0*, $p = 0.019$; *t3 - t0*, $p = 0.013$; *t4 - t0*, $p = 0.002$), closely mirroring the ferritin decline. In contrast, no significant changes in FERR were seen in ASS cohort, despite a parallel clinical improvement (*t4 - t0*, $p = 0.005$, **image 3**). CRP levels did not vary significantly in either group during follow-up and ESR showed fluctuating values without consistent trends.

Conclusion: To the best of our knowledge, this is the first study comparing longitudinal FERR trends in anti-MDA5 DM and anti-Jo1 ASS with lung involvement. In the DM cohort, FERR significantly declined over time along with disease activity, thus supporting its role as a biomarker in this subtype of myositis. The absence of a similar trend in ASS suggests differing inflammatory pathways and reinforces the need for disease-specific biomarkers. These findings may be especially relevant in the management of DM patients with lung involvement, where early and reliable indicators of response are urgently needed.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Despite limitations (small sample size, short follow-up, treatment heterogeneity), we believe that these findings offer preliminary evidence for the utility of FERR in monitoring anti-MDA5 DM: further prospective studies are needed to validate our results in larger and more diverse cohorts.

Nutritional Discourse in Online Myositis Communities: A Reddit Analysis of Patient-led Discussions

Latika Gupta[1], **Taanya Talreja**[2] and Peter Kerkhof[3], [1]School of Infection, Inflammation and Immunology, College of Medicine and Health, University of Birmingham; Royal Wolverhampton NHS Trust; Centre for Musculoskeletal Research, School of Biological Sciences, The University of Manchester, Manchester; Francis Crick Institute, London, Birmingham, UK, United Kingdom, [2]KEM Hospital, Mumbai, Maharashtra, India, [3]Department of Communication Science, Vrije Universiteit Amsterdam, Amsterdam, Netherlands

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2052–2078) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The intersection of nutrition and autoimmune myopathies represents a significant yet understudied domain in rheumatological care. We conducted a meticulous analysis of online myositis communities to characterise the prevalence, content and temporal patterns of diet-related discussions amongst patients, providing insight into self-reported nutritional priorities that may inform clinical practice.

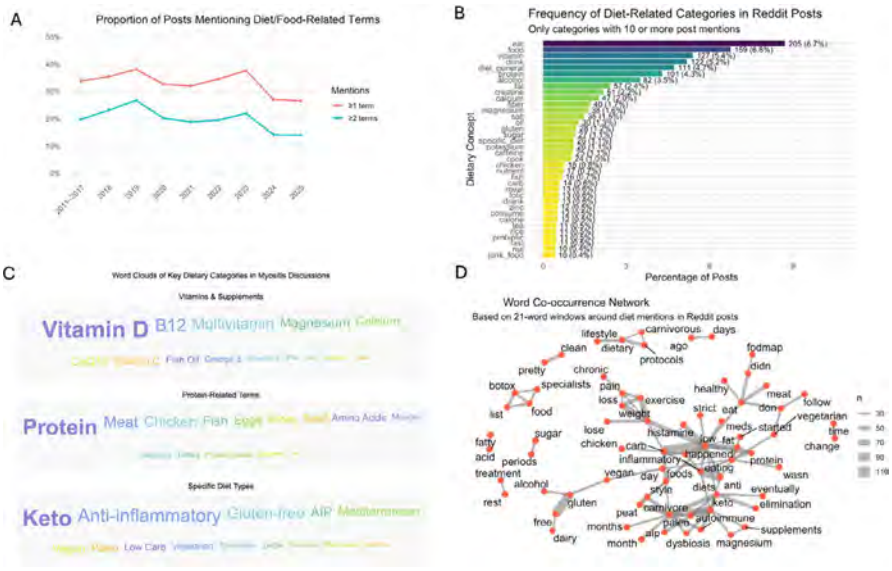
Methods: Using a bespoke Python script, we extracted all submissions (excluding comments) from the AcademicTorrents Reddit data dumps (2005–feb. 2025, ∼24 billion items), and added all posts from three myositis-focused subreddits, which in total yielded 17,902 posts. After rigorous filtering for relevance—retaining only posts explicitly mentioning myositis or related terminologies (e.g., necrotizing or inflammatory myopathy) with sufficient content—2,356 posts from 1,704 unique authors were analyzed (Figure 1A). An exhaustive lexicon of 190 precisely defined nutritional and dietary terms was systematically applied, with results subsequently classified into 77 discrete categories.

Results: Nutritional content featured prominently in myositis-related discourse, appearing in 31.5% of all posts and contributed by 36.1% of unique authors (Figure 1B). As demonstrated in Figure 1C, when categorized beyond general terminology (e.g., "eat", "food"), the most salient specific domains emerged as:

1. Vitamins and supplements, with particular emphasis on vitamin D
2. Protein consumption and its purported relationship to muscle health
3. Structured dietary approaches

Notably, within structured dietary approaches, ketogenic protocols garnered significant attention, followed by anti-inflammatory and autoimmune-specific regimens. The sophistication of these discussions reflects considerable patient engagement with nutritional literature, often citing both scientific studies and anecdotal experiences.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



We analyzed posts mentioning diet-related terms by extracting 21-word windows (±10 words) around each mention. After cleaning and filtering, we constructed a word co-occurrence network to visualize which concepts most frequently appear in close proximity to dietary references in patient-generated discussions (Fig. 1D). This word co-occurrence network, derived from Reddit posts mentioning "diet," reveals clusters of frequently associated terms, highlighting popular dietary approaches like keto and paleo, as well as the strong connection between diet and discussions around health, symptoms, and personal experiences. The thickness of the connecting lines indicates the frequency of these word pairings within a 21-word window

Conclusion: This comprehensive analysis reveals that nutritional considerations constitute a substantial component of patient-led myositis discussions, with particular emphasis on targeted supplementation and specialised diets. These findings highlight a critical opportunity for rheumatologists to address nutrition more systematically in clinical encounters and research agendas, potentially enhancing therapeutic approaches to this complex spectrum of disorders.

Background/Purpose: Immune-mediated necrotizing myopathy (IMNM) is an aggressive subtype of idiopathic inflammatory myopathy (IIM) associated anti-3-hydroxy-3-methylglutaryl coenzyme A reductase (anti-HMGCR) antibodies. Recently there have been reports of increased statin-associated IMNM in certain Native American groups. To address this, this research compared the proportion, characteristics, and clinical outcomes of Native American and non-Native American adults diagnosed with IIM and IMNM from the same Southwest region.

Methods: This is a retrospective single institution study approved by the Institutional Review Board. Myositis diagnosis was established based on the 2017 European Alliance of Associations for Rheumatology/American College of Rheumatology Classification Criteria for Adult and Juvenile Idiopathic Inflammatory Myopathies, and statin-associated IMNM diagnosis required the presence of anti-HMGCR antibodies. We identified 147 patients with IIM, with 32 patients who self-identified as Native American and 115 patients who self-identified as non-Native American. The proportion of IIM and IMNM in each group, the relevant clinical and laboratory parameters, and the outcomes were compared.

Results: Table 1 shows the baseline characteristics for the two groups. Compared to non-Native Americans, Native Americans with IIM had higher incidence of hyperlipidemia (HLD) (75% compared to 49.6%; p=0.015), statin exposure at diagnosis (71.9% compared to 40.0%; p=0.002), pre-existing diabetes mellitus (DM) (62.5% compared to 34.8%; p=0.044), and esophageal dysmotility (93.8% compared to 77.4%; p=0.042).

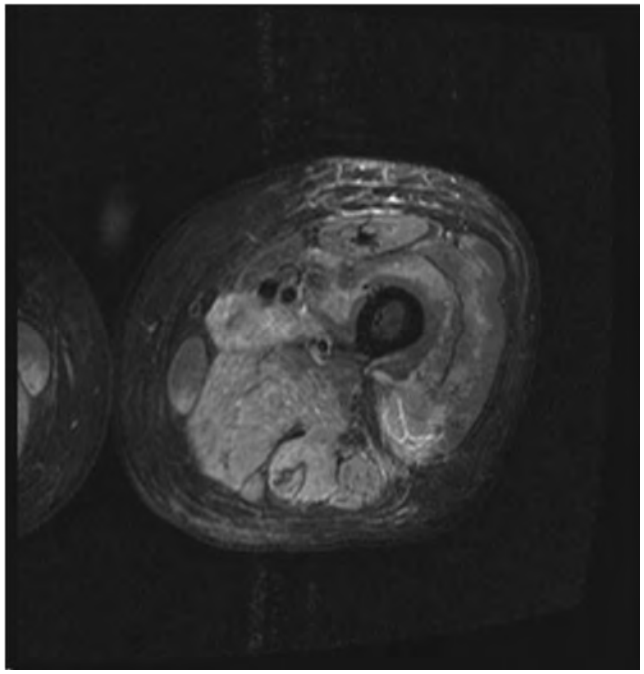

Figure 1. Muscle Edema by Magnetic Resonance Imaging in a Native American Patient Diagnosed with Immune-Mediated Necrotizing Myopathy

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Additionally, Native Americans were found to have significantly higher frequency of positive anti-HMGCR antibody, with 46.9% compared to 16.5% in non-Native Americans (p=0.0007). Native Americans also had higher frequency of positive anti-RNP antibody, with 15.6% compared to 2.6% in non-Native Americans (p=0.013). There was no significant difference in the clinical outcomes and treatment received between the two groups (Table 2). When statin-associated IMNM was specifically compared between the two groups, there were no significant differences in IMNM clinical features or outcomes. This has not been reported before.

Conclusion: Statin-associated IMNM is increased in Native Americans compared to non-Native Americans in the American Southwest. There may be underlying genetic or environmental components to explain the findings above, including certain HLA types, an increased prevalence of diabetes mellitus, hyperlipidemia, and statin exposure. However, the manifestations and outcomes of statin-associated IMNM in Native Americans and non-Native Americans appear to be similar. Given that the outcome of statin-associated IMNM depends on early initiation of appropriate therapy and that Native Americans historically have experienced healthcare disparities, it is particularly important that statin-associated IMNM in this population is recognized and treated early.

Session Title: (2052–2078) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Dermatomyositis (DM) and anti-synthetase syndrome (AS) are idiopathic inflammatory myopathies (IIM) with perifascicular pathology involving vasculopathy, macrophages, dendritic cells and an overexpression of interferon-stimulated genes. Increased production and deficient elimination of neutrophil extracellular traps (NETs) are characteristic of the IIM, but their role as inducers of proinflammatory responses in the perifascicular pathology has not been addressed. The aim of this study was to assess the potential contribution of NETs to the perifascicular pathology in IIM.

Methods: We included 5 healthy donors (HD), 13 patients with DM and 12 with AS according to the ACR/EULAR 2017 and Connors' criteria, either with moderate to severe disease activity or complete clinical response. We assessed the localization of macrophages and NETs in the muscle biopsies by confocal microscopy. From peripheral blood, we isolated normal density neutrophils to obtain spontaneous NETs and CD14+ monocytes for *in vitro* differentiation into macrophages and mDC for 7 days. Differentiated macrophages and myeloid dendritic derived cells from patients (PDM and PDmDC) and HD

Mann-Whitney U test and Kruskal-Wallis test with Dunn post-hoc test; * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$, **** $p < 0.0001$.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: As shown in Figure 1, NETs are localized in key areas of perifascicular pathology, interacting with macrophages (A), inside muscle cells (B) and in the blood vessels (C). Stimulation with NETs significantly increased IFN-scores in patient and HD-derived macrophages and mDC compared to non-stimulated (Ns) cells (Figure 2 A and F). NETs isolated from IIM patients induced significantly stronger IFN responses than NETs from HD in both macrophages and mDCs (*Figure 2B, 2G*). Stratification by disease subtype revealed that NETs from DM patients elicited higher IFN-scores than those from AS patients in macrophages ($p = 0.0354$, *Figure 2C*), though this difference was not observed in mDCs (*Figure 2H*). No significant differences were detected based on disease activity (active vs inactive disease) in either cell type (*Figure 2D, 2I*). When analyzing combinations of cell type and NET origin, NETs from IIM patients consistently induced higher IFN responses across all cell types. In mDCs, IIM-derived NETs triggered significantly higher IFN-scores than HD-derived NETs in PDmDCs ($p < 0.01$, *Figure 2J*), while the difference in macrophages did not reach statistical significance (*Figure 2E*).

Conclusion: NETs from IIM patients trigger strong type I IFN responses in macrophages and mDC, particularly in cells derived from patients. This suggests that both, the composition of IIM NETs and the heightened response of *in vivo* primed myeloid cells contribute to the sustained IFN activity characteristic of IIM, pointing to a possible pathogenic loop of NETs driving chronic inflammation.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2079–2105) Osteoarthritis – Clinical Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Knee osteoarthritis (OA) and type 2 diabetes (T2D) commonly coexist, but their combined impact on health-related quality of life (HRQoL) remains understudied. Our objective was to assess the relationship between symptomatic knee OA (yes/no) and HRQoL in persons with type 2 diabetes and, if a relationship was found, to determine if it is due to depressed mood, sleep disturbance, fatigue, and/or walking limitation, which we hypothesized could be explanatory factors.

Methods: We conducted a secondary analysis of a cross-sectional study of individuals with T2D recruited from endocrinology clinics at three academic hospitals in Canada. Participants completed standardized online questionnaires that assessed sociodemographic factors, comorbidities to calculate the Functional Comorbidity Index (FCI), depressed mood (PROMIS

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1: Linear regression modeling demonstrating the association between knee osteoarthritis and health-related quality of life before and after adjusting for potential confounders and sequential adjustment for potential explanatory factors.

Depression 8b), sleep disturbance (PROMIS Sleep Disturbance 4a), fatigue (PROMIS Fatigue 4a), walking limitation (Health Assessment Questionnaire walking difficulty item), HRQoL (EQ-VAS, 0–100), and joint symptoms. Symptomatic knee OA was defined using NICE criteria (age ≥45 years, activity-related knee pain, morning stiffness ≤30 minutes; no inflammatory arthritis). Linear regression modelled associations between knee OA and HRQoL, adjusting for age, gender, BMI, education, and comorbidities. The explanatory effects of sleep disturbance, depressed mood, and mobility limitation were assessed via sequential adjustment.

Results: Our study included 341 participants. Mean age was 66.4 (SD 9.7) years, 51.9% were women, 80.1% had post-secondary education, mean BMI was 29.1 (SD 6.7) kg/m^2, and 99 (29.0%) fulfilled NICE criteria for symptomatic knee OA (Table 1). Median HRQoL (EQ-VAS) was 68/100 (IQR 50, 80), with lower scores reported by individuals with knee OA

[1] "Asian" includes East Asian, South Asian, Southeast Asian, Central Asian, and West Asian populations
[2] "Other" includes Middle Eastern, Latin American, individuals who preferred not to answer, or those whose background was not listed
[3] Diabetes complications refer to the presence of microvascular complications, including neuropathy, nephropathy, or retinopathy (i.e., impact on nerves, kidneys, or eyes), self-reported by participant.
[4] Sleep, Fatigue, and Depression T scores were measured using the Patient-Reported Outcomes Measurement Information System (PROMIS).
[5] Dichotomized as "Yes" if participants reported walking with some, much, or complete difficulty; "No" if without any difficulty (HAQ walking item)

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(median 54 vs. 70). Compared to those without OA, participants with knee OA had worse sleep, fatigue, depressive symptoms, and higher rates of walking limitation ($p < 0.0001$ for all). After adjustment for age, gender, BMI, education, and comorbidities, the presence of symptomatic knee OA remained associated with lower HRQoL (β = −8.33, 95% CI: −12.72 to −3.94). Model performance improved with sequential adjustment, with adjusted R^2 increasing from 0.068 in the unadjusted model to 0.381 in the final model. The association was fully attenuated in the final model including sleep, mood, and walking limitation (β = −3.46, 95% CI: −7.63 to 0.71) (Figure 1).

Conclusion: Symptomatic knee OA is strongly associated with impaired HRQoL in T2D, explained by sleep disturbance, low mood, and mobility limitation. Integrated care addressing OA may improve quality of life in this population.

Abstract Number: 2080

Foot laterality does not modify outcome of knee and/or hip osteoarthritis

Simon Fondin[1], Armand Eyraud[1], Estelle Nkonda[1], Anne-Christine Rat[2], Bruno Fautrel[3], SELLAM JEREMIE[4], Christian Roux[5], Jacques Pouchot[6], Joel Coste[7], Francis Guillemin[8] and **Alain SARAUX**[9], [1]Centre Hospitalier Regional Universitaire (CHU) de Brest, Brest, France, [2]Caen University hospital, UMR 1075 Caen normandy university, Caen, France, [3]Sorbonne Université - APHP, Department of Rheumatology, Hôpital Pitié-Salpêtrière, Inserm UMRS 1136-5, PARIS, France, Paris, France, [4]Sorbonne Université, Inserm, Centre de Recherche Saint-Antoine, CRSA, F-75012 Paris, France, /Rheumatology Department, AP-HP Saint-Antoine Hospital, 184, rue du Faubourg Saint-Antoine, 75012, Paris, France., Paris, France, [5]CHU Nice, Nice, France, [6]AP-HP, Rueil Malmaison, France, [7]APHP, Paris, France, [8]CHU Nancy, Nancy, France, [9]CHU Brest, Brest, France

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2079–2105) Osteoarthritis – Clinical Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Hip and knee osteoarthritis (OA) are among the leading causes of global disability. Global OA is more prevalent on the right side. This discordance in symmetry suggests an importance of biomechanical factors, including dominant side, in the pathogenesis of OA. The objective of this study is to investigate the relationship between the foot dominant side and the most symptomatic side and location in knee or hip OA, as well as its evolution over a 10-year follow-up.

Methods: The KHOALA (Knee and Hip Osteoarthritis Long-term Assessment) cohort is a representative, population-based multicenter study that included 878 patients with symptomatic knee and/or hip OA, aged between 40 and 75 years, and established between 2007 and 2009. They were asked at year 6 whether they were right-handed, left-handed, left-handed contrarian, or ambidextrous, as well as which foot they used to kick a ball. Khi^2 or Fisher tests were used for binary variables, while Student's t-test was used for continuous variables.

Results: From 538 patients evaluated for laterality, 47 (8.7%) were left footers. Among the 47 left footers, only 14 were left handers (20 are right handers, 3 ambidextrous, and 10 frustrated left-handers). Proportion of right and left knee OA, among patients with unilateral OA, were 58.6% (212/364) and 41.8% (152/364), respectively. Proportion of right and left hip OA were 51.6% (78/151) vs 48,3% (73/151), respectively. Left footers were slightly younger (59.0 SD 8.1 vs 61.6 SD 8.0 years; p=0.04) and more frequently men (52.2% vs 30.2%; p=0.004) than right footers. At 0, 5 and 10 years, pain did not differ between left footers and right footers. In contrast, WOMAC was lower in left footers than in right footers at year 0 (24.3 SD

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Fig 1

16.6 vs 32.8 SD 19.7; p=0.002), year 5 ((26.0 SD 17.1 vs 32.3 SD 17.7; p=0.02), and year 10 (26.0 SD 14.5 vs 31.6 SD 18.9; p=0.05). WOMAC function was also lower in left footers than in right footers at year 0 (23.6 SD 18.0 vs 32.3 SD 21.0; p=0.004), year 5 (25.0 SD 17.4 vs 31.8 SD 18.4; p=0.02), and year 10 (25.4 SD 15.7 vs 31.4 SD 19.9; p=0.05). There was not any difference for radiological stage (Kellgren Lawrence). After 10 years right footers did not received significantly more hip or knee replacement of the more painful joint than left footers (29.9%, 143/478, versus 18.2%, 8/44, respectively; p=0.13) (Fig 1).

Conclusion: Womac function is lower in left than in right footers suffering from symptomatic knee and/or hip OA, but we did not observe any difference between right and left footers for pain, radiograph and evolution.

Session Title: (2079–2105) Osteoarthritis – Clinical Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: LEVI-04 is a first-in-class fusion protein (p75NTR-Fc) that supplements the endogenous p75NTR binding protein, providing analgesia via inhibition of NT-3 activity. Like p75NTR, LEVI-04 binds all the neurotrophins (NTs) with differing affinities, with highest to NT-3 and lowest affinity and reversibly to NGF, distinguishing the LEVI-04 mechanism of action from that of anti-NGF antibodies. As serious joint adverse events were seen in the anti-NGF trials, rigorous

[1]Includes 207 (left knee) and 188 (right knee) exclusions for KL<2; for inclusion only one knee was required to meet KL ≥ 2, therefore the final number excluded due to KL <2 was 108.

[2]Some patients presented more than one finding, potentially in more than one joint in the same patient, so the number of exclusions exceeds the number of people excluded.

[3]Findings suggestive of the following tumors were detected on X-ray: large benign bone tumor of the femur (unicameral bone cyst) with risk of pathological fracture (1); and on MRI: tenosynovial giant cell tumor of the Hoffa-fat pad (4), tenosynovial giant cell tumor of the patellar tendon (1), tenosynovial giant cell tumor around the knee (1) and large benign enchondroma of the femur (with possibility of low grade chondrosarcoma)

[4]HMO was reported for knees (bilateral), hip, and shoulder X-rays for one patient.

Radiologic Exclusions

surveillance of joint safety was performed in this study. In order to properly categorise the risk of adverse joint events with LEVI-04, participants with potentially confounding findings at screening were excluded. LEVI-04 was well tolerated, with no increased incidence of joint pathologies compared to placebo.[1]

Methods: This was a phase II multicentre (Europe and Hong Kong) RCT in adults with knee OA. Participants were randomized to 4-weekly IV placebo or 0.3, 1, or 2 mg/kg LEVI-04 through week 16, with the final visit at week 20 and a telephone safety follow-up at week 30. Participants who met initial clinical inclusion criteria underwent X-rays of bilateral shoulders, hips and knees, and then MRI of both knees (in some cases, MRI was performed in parallel with X-rays). All images were read centrally and assessed for eligibility. At week 20, all X-rays were repeated, and MRI of the target knee was performed.

Results: 1598 people with painful knees were screened and 518 participants enrolled. 1080 people (86%) did not proceed past screening. 345 people exited the study before X-rays were performed (151 due to not meeting initial minimum pain in at least one knee, others due to other entry criteria, or sponsor, investigator or participant decision), such that a total of 1253 participants had X-rays of the large joints (Table 1). 514 (41%) people had knee exclusion criteria on X-ray, however this included 207 (left) and 188 (right) knees of KL grade< 2. Only one knee was required to have KL grade >2, resulting in 108 (8.6%) people failing on KL grade. Excessive malalignment and atrophic OA were the next highest criteria, with 43 (3.4%) and 42 (3.3%) failures respectively. 766 people proceeded to MRI of both knees. 234 (30.5%) of these failed, 168 (22.9%) due to meniscal root tear, and 42 (5.4%) due to subchondral insufficiency fracture. There were 7 (0.9%) cases of findings suggestive of primary or metastatic tumor detected on MRI and 1 (0.1%) on knee X-ray. 30 (2.4%) people were excluded on hip and 4 (0.3%) on shoulder X-rays. 5 hip and 24 knee joints had arthroplasty, but these were not exclusionary. Several people exhibited more than one pathology, so reasons for exclusion slightly exceed the total number of people excluded.

Conclusion: A significant proportion of people with OA show radiologic findings at screening. Excluding these patients is important to distinguish existing pathologies from treatment-emergent events in early trials. Rigorous radiologic surveillance supported determination of LEVI-04 joint safety; LEVI-04 was not associated with an increase in adverse joint events compared to placebo in this study[1]. Phase 3 trials are in planning.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2079–2105) Osteoarthritis – Clinical Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: MM-II is a first-in-class investigational treatment for knee OA pain that consists of a one-time IA injection of empty liposomes comprised of phospholipids dipalmitoylphosphatidylcholine (DPPC) and 1,2-dimyristoylphosphatidylcholine (DMPC). DPPC is a major surface-activated phospholipid that is a part of the cartilage boundary lubrication system. In a phase 2b, dose-finding clinical trial, a single injection of 3 mL MM-II provided sustained reduction in knee pain (measured by weekly average of daily knee pain score as well as WOMAC pain score) compared to placebo, starting from 6 weeks after injection and sustained through 26 weeks. MM-II was safe and well tolerated, with no serious treatment-emergent adverse events, and safety profiles were consistent between placebo and MM-II. Here, we report the pharmacokinetic (PK) profiles of DMPC and DPPC from the trial following a single IA injection of MM-II compared to placebo.

Methods: In a phase 2b, randomized, double-blind, dose-ranging, placebo-controlled trial (NCT04506463), 397 participants with chronic knee OA were randomized 3:3:3:1:3:1 to receive 1, 3, or 6 mL MM-II or 1, 3, or 6 mL placebo through a single IA injection. All participants met the ACR Clinical and Radiological Criteria for chronic knee OA. Blood samples for PK measurements were taken from participants at a subset of study centers, at the following time points: pre-injection (at baseline), and post-injection at 4 hours, 2 days (48 hours), and 7 days (168 hours). Plasma DPPC and DMPC concentrations (ng/mL) were quantified at each time point and for each study arm using liquid chromatography tandem mass spectrometry. Concentrations below the lower limit of quantification were analyzed as 0 before the first quantifiable concentration and as missing after the first quantifiable concentration. Analyses were based on the modified PK analysis set, which included participants who received the single dose of IA injection, had at least 1 quantifiable post-dose concentration, and did not have major protocol deviations. PK parameters were summarized using descriptive statistics based on baseline-adjusted values.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

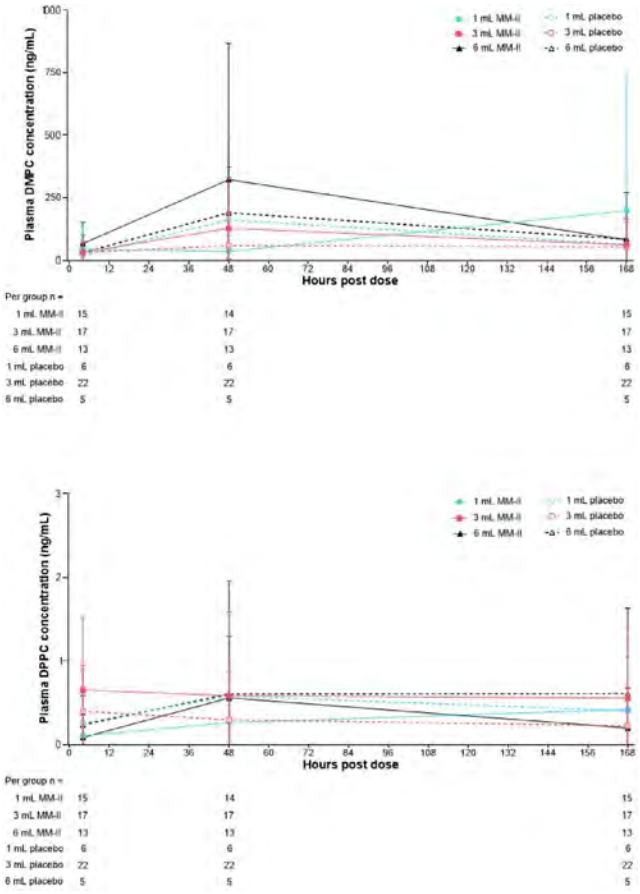

Figure 1. Mean ± SD baseline-adjusted DMPC and DPPC concentrations up to 168 h after intra-articular injection of MM-II or placebo. DMPC, 1,2-dimyristoyl-phosphatidylcholine; DPPC, dipalmitoylphosphatidylcholine; SD, standard deviation.

Results: The modified PK analysis set included 78 participants. Quantifiable levels of both DMPC and DPPC were found in pre-dose samples from MM-II and I placebo controls. There were no considerable changes in plasma DMPC and DPPC concentrations from pre-dose to post-dose time points (Figure 1). Furthermore, the concentrations of DMPC and DPPC appeared to be comparable between MM-II and corresponding placebo groups at all time points. These data suggest there was no increase in measurable DMPC or DPPC levels after administration of MM-II within the time points analyzed.

Conclusion: Based on these results, treatment of OA knee pain with a single IA injection of MM-II did not appear to increase circulating DMPC and DPPC levels compared with placebo within the time points analyzed. Further studies with additional sampling are necessary to enhance interpretation due to limited sampling time points and inherent variability in PK parameters.

Abstract Number: 2083

Evaluation of a Parent-Trial as a Run-In Period: Efficacy and Safety of Repeat Injections of Lorecivivint over Three Years

Christopher Swearingen[1] and Yusuf Yazici[2], [1]Biosplice Therapeutics, Inc, San Diego, CA, [2]NYU Grossman School of Medicine, La Jolla, CA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2079–2105) Osteoarthritis – Clinical Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Lorecivivint (LOR) is an intra-articular CLK/DYRK inhibitor in clinical development for the treatment of knee OA. A Phase 3 Trial, OA-11 (NCT03928184), assessed clinical and radiographic outcomes over one year following a single LOR injection in advanced knee OA versus placebo (PBO). Patients successfully completing OA-11 were invited to enroll into OA-07 (NCT04520607), a multi-year treatment trial providing annual study treatment injections. The purpose of this analysis was to evaluate OA-11 for any possible differences that could be associated with choosing to enroll into OA-07 or not and thereby impacted the interpretability of the OA-07 results.

Methods: Demographic, outcome and safety data from OA-11 was abstracted by enrollment status into OA-07. Equivalence testing was conducted by enrollment status into OA-07 using two one-sided t-tests. Permutation tests via Monte Carlo simulation (1000 replicated datasets) were also conducted to further assess any predictability in OA-07 enrollment status. Baseline-adjusted ANCOVA was also conducted as a part of each study's analysis plan.

Results: 501 patients enrolled into OA-11; 276 (55.1%) enrolled into OA-07 (N PBO = 138, N LOR = 138). Overall, the adverse event profile was similar between those subjects that enrolled into OA-07 and those that did not. Age, Body Mass Index, baseline WOMAC Pain and Function, as well as medial joint space width (JSW) were equivalent between those that enrolled into OA-07 and those that did not. Percentages of female, white race, Hispanic/Latino ethnicity, KL Grade 2 and unilateral symptomatic OA were similar between studies but could not be determined as equivalent. WOMAC Pain, WOMAC Function and medial JSW, however, at the end of OA-11 were also equivalent between those that enrolled into OA-07 and those that did not. Permutation tests also indicated that the population enrolled into OA-07 appeared to be a random sample, as all results were stable and not predictive of enrollment status.

Statistically significant improvements were observed for LOR vs PBO in WOMAC Pain [0-100] in OA-07 six months after injection (Visit 2E Δ=-4.52, 95% CI [-8.92, -0.13], P=0.044), as well as at twelve months (Visit 3E Δ=-5.19, 95% CI [-9.86, -0.53], P=0.029) (Figure 1). WOMAC Function [0-100] was numerically improved in OA-07 at six months but was

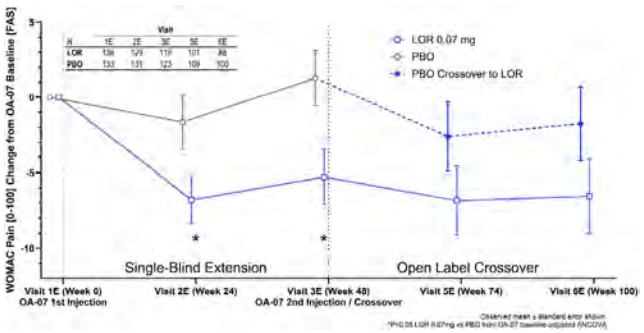

Figure 1. Change from OA-07 Baseline in WOMAC Pain

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

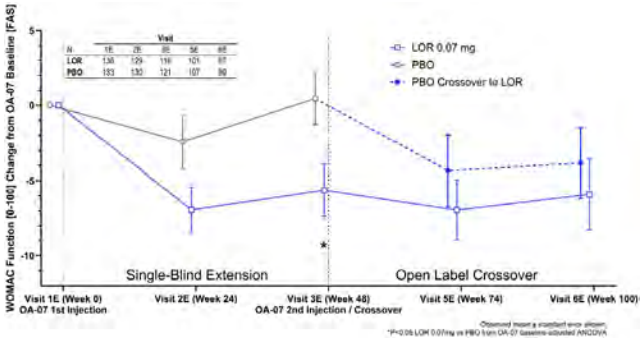

Figure 2. Change from OA-07 Baseline in WOMAC Function

significantly improved at twelve months (Visit 3E Δ=-4.86, 95% CI [-9.36, -0.35], P=0.035) (Figure 2). In Year 2 (crossover portion) of OA-07, all PBO patients receiving LOR showed mean improvements in WOMAC Pain and Function from Visit 3E observations.

Conclusion: Examining demographics, outcomes and safety data from the OA-11 trial did not elicit any prediction to patients that enrolled into OA-07 but supports OA-07 as a random sample of the OA-11 population. The impact of COVID on the conduct and results of OA-11 may have relegated the Phase 3 trial into a large run-in, possibly allowing patients to normalize over the course of a year prior to the start of OA-07. In OA-07, improvements in pain and function in LOR compared to PBO were seen at six and twelve months. LOR continues to show promise as a safe, disease-modifying knee OA treatment.

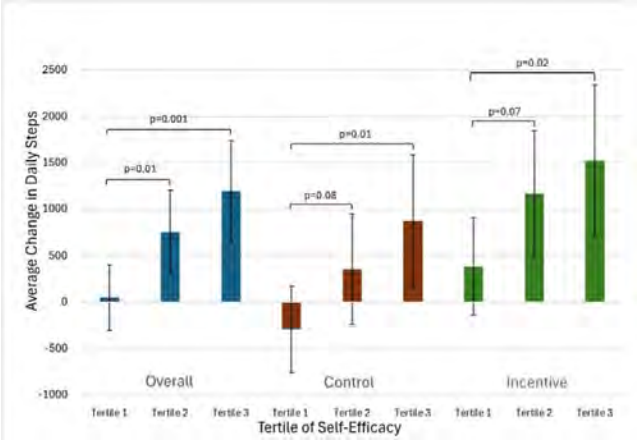

Figure 1. Average change in daily steps (with 95% CI) overall and by incentive group among Veterans with knee osteoarthritis, predicted from univariate linear regression models.

Methods: This was a multi-center randomized controlled trial with a factorial design. The study included 221 participants aged 40-85 years from 4 Veterans Affairs centers with a Kellgren-Lawrence (KL) knee radiograph grade ≥1 and clinical indication for a corticosteroid joint injection. Participants were randomized into either the incentive program or control and then further randomized to receive corticosteroid or lidocaine-only injections. A web-based platform collected daily step counts (from a Fitbit activity monitor) and patient-reported outcomes. Daily step counts were averaged over 2-week periods throughout the 28-week trial. Self-efficacy was measured at enrolment using the Exercise Self-Efficacy Scale. Linear regression incorporating generalized estimating equations was used to evaluate the association of participant characteristics with the change in average daily step counts. Variables associated with the outcome ($p< 0.1$) in univariate analyses were tested in multivariable models and removed in a backwards selection process to arrive at a final model.

Results: A total of 221 participants were randomized. Mean participant age was 64 years-old and 87% male. Unadjusted associations between participant characteristics and change in average daily steps are shown in **Table 1**. Individuals with greater self-efficacy for exercise demonstrated significantly greater increases in the average daily step count (**Figure 1**). This effect was greatest for participants in the highest tertile, whose daily step counts increased about 1145 steps more than those in the lowest tertile (**Figure 1**). This pattern was observed in both incentive and control arms and was an independent predictor in the multivariable model (**Table 2)**. Patient characteristics associated with less improvement in average daily step count included higher pain scores, worse sleep quality, greater fatigue, kidney disease, and higher BMI. Participants that lived in areas in the highest quartile of Area Deprivation Index (ADI) also failed to improve.

Conclusion: We identified predictors of improvement in physical activity level among patients with KOA in the context of a clinical trial. Higher self-efficacy for exercise was a strong predictor of greater improvement in physical activity levels throughout follow-up. Less improvement was observed among those with greater pain, comorbidity, BMI, fatigue, and among those living in unsafe areas or areas with high ADI. These observations highlight the need to address low self-efficacy and other barriers in order successfully promote exercise in this population.

Abstract Number: 2085

Estimating the Association between Effusion-synovitis and Knee Pain in a Subset of Participants with Radiographic Knee Osteoarthritis: Data from the Osteoarthritis Initiative (OAI)

Dagoberto Robles[1], Greg Gilles[2], Nathaniel H. Christiansen[3], Luke Grawer[4], Karim Jayyusi[4], Ali Shaikh[4], Rongrong Tang[5], Mihra S. Taljanovic[4], Jeffrey Duryea[6], Edward J. Bedrick[5] and C. SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2079–2105) Osteoarthritis – Clinical Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Even though knee pain is ubiquitous in knee osteoarthritis (KOA) patients, currently there are limited treatment options which are only minimally or moderately efficacious for relieving pain and may lead to undesired side effects. Effusion-synovitis (ES) is present during all stages of OA and has been reported to be associated with increased knee pain. Though the validated WOMAC-Pain subscale was the primary assessment tool in most of these studies, it was used as a composite measure (i.e., only the total score was reported) so the associations between ES and pain during specific types of activities are unknown. Therefore, the main objective of this study is to evaluate the longitudinal associations between MRI-detected quantitative ES (qES) and self-reported total and activity-specific knee pain.

Methods: This study included a random longitudinal subsample of Osteoarthritis Initiative (OAI) participants with diagnosed radiographic KOA (Kellgren-Lawrence [KL] grade 2,3) who had both X-ray and MRI assessments of both knees at baseline (n = 534). Our primary outcome was self-reported knee pain in the past 7 days, reported at baseline, 12-, and 24-month visits for each knee. Knee pain was measured using the WOMAC-Pain and Knee injury and Osteoarthritis Outcome Score (KOOS) Pain subscales. The questions on both subscales were scored from 0-4, which correspond to: None (0), Mild (1), Moderate (2), Severe (3), and Extreme (4). Our primary exposure was whole knee joint qES, assessed on non-contrast

Table 1 - Baseline characteristics of the OAI sub sample of participants with radiographic KOA at baseline by Kellgren-Lawrence (KL) grade

Characteristics, n (%)	KL=2 (N=333)	KL=3 (N=201)	Total (N=534)
Age, mean (SD), years	60.6 (8.9)	62.8 (8.7)	61.4 (8.9)
Female Gender	217 (65.2)	102 (50.8)	319 (59.7)
Ethnicity			
White or Caucasian	263 (79.0)	167 (83.1)	430 (80.5)
Black or African American	63 (18.9)	25 (12.4)	88 (16.5)
Other Non-White	7 (2.1)	9 (4.5)	16 (3.0)
Previous Knee Injury	89 (27.4)	82 (41.0)	171 (32.6)
Previous Knee Surgery	50 (15.1)	73 (36.5)	123 (23.1)
BMI (kg/m2) mean (SD)	28.9 (4.7)	29.9 (4.6)	29.2 (4.7)
Quantitative ES (mm3) median (25th and 75th percentile)	4847.1 (3148, 7597)	6763.4 (4249, 12088)	5437.5 (3410, 8983)

Acronyms: OAI Osteoarthritis Initiative, OA Osteoarthritis, ES effusion-synovitis, SD standard deviation, BMI body mass index

* Radiographic Kellgren-Lawrence score of 2 or 3

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. enhanced 3T MRI at baseline, 12-, and 24-month visits. Total qES volume (mm^3) was measured using our semi-automated multi-planar MRI quantification approach. We applied generalized estimating equations to evaluate the association between qES and the individual items of both subscales. These models were fitted using a multinomial distribution with a cumulative logit link function and unadjusted and adjusted odds ratios (ORs) with corresponding 95% confidence intervals (CIs) were reported. We adjusted for age, gender, ethnicity, previous knee injury/surgery, BMI, and KL grade. The ORs and adjusted ORs and their associated 95% CIs were reported per a 5000 mm^3 increase in qES.

Results: Whole-knee ES was significantly associated with the total WOMAC-Pain subscale score in the unadjusted and adjusted models. As shown in Figure 1, participants with greater qES had higher odds of experiencing worse knee pain (OR: 1.43 [1.15,1.77], adjusted OR: 1.37 [1.09, 1.70]). Regarding pain with specific activities, qES was significantly associated with knee pain at night while in bed (OR: 1.22 [1.08, 1.38], adjusted OR: 1.22 [1.08, 1.37]) and when going up or down the stairs (OR: 1.22 [1.08, 1.38], adjusted OR: 1.21 [1.07, 1.37]), as also shown in Figure 1. There was no significant association between pain with the three KOOS-specific activities and qES (Figure 2).

Conclusion: For KOA patients, longitudinal whole-knee qES was significantly associated with total WOMAC-Pain and particularly with knee pain during bedtime and climbing stairs. Our whole knee qES measure may be valuable for patient screening/phenotyping and outcome assessment in KOA trials.

WOMAC Physical Function and 3D MRI Bone Shape: Advancing a "Virtual" Total Knee Replacement Endpoint for Knee Osteoarthritis Clinical Trials

Dawn McGuire[1], Alan Brett[2], Neil Segal[3], Meghan Miller[4], David Rosen[1] and Yoshi Kumagai[5], [1]OrthoTrophix, Inc, Foster City, CA, [2]Imorphics, Manchester M20 2HJ, England, United Kingdom, [3]KUMC, Kansa City, KS, [4]OrthoTrophics, Foster City, CA, [5]OrthoTrophix, Foster City, CA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2079–2105) Osteoarthritis – Clinical Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: TPX-100, a peptide derived from matrix extracellular phosphoglycoprotein (MEPE), is in development as a potential disease-modifying osteoarthritis drug (DMOAD) for mild to severe knee osteoarthritis (KOA). While total knee replacement (TKR) remains the FDA's "gold standard" outcome measure for this regulatory pathway, it presents practical and ethical limitations as a trial endpoint. Surrogate markers predictive of TKR would enable more efficient clinical trials. Data from the Multicenter Osteoarthritis Study demonstrate that poor WOMAC Physical Function scores (40–68) are associated with a >15-fold increased risk of TKR, with a clear dose-response gradient across impairment levels. Longitudinal analyses from the Osteoarthritis Initiative (OAI) have shown that MRI-derived femoral bone shape predicts TKR risk over 48 months. Study TPX-100-5 was designed to evaluate these measures and their interrelationships in order to explore the idea of a surrogate marker for TKR.

Methods: Participants in TPX-100-5 met ACR diagnostic criteria for bilateral KOA based on history, examination and imaging. All had previously completed a randomized, double-blind, placebo-controlled Phase 2 study (TPX-100-1), and received four weekly injections of TPX-100 (200 mg) in one knee and saline placebo in the contralateral knee in a triple-blinded fashion. Subjects' MRIs were analyzed at a single center per published protocols, blind to treatment assignment and clinical data. Femoral bone shape, defined by "B-score", differentiates pathologic bone shapes associated with OA onset, progression and joint failure from bone shapes of normal, non-OA knees. B-score is based on a vector derived from modelling of 3-D femoral bone shape from >9,000 knee MRIs in the OAI database. Per the statistical analysis plan, finalized prior to study start, subjects with knees whose B-scores were ≥1.5 (n=70), equivalent to KL ≥2 on x ray, made up the study cohort.

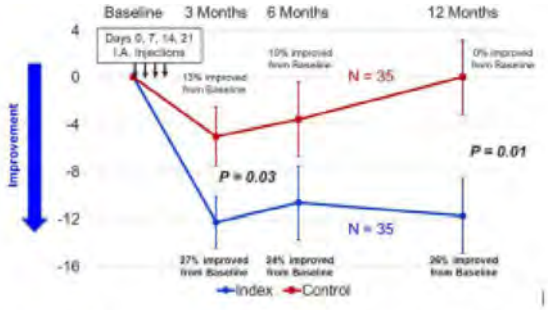

Figure 2. TPX-100 showed statistically significant reduction in WOMAC Function as compared to control in the knees with baseline B score ≥ 1.5.
Mean baseline scores were 44.8 and 37.1 of 100, respectively (p = 0.14). Error bars indicate standard errors of the mean. Statistical analyses were by Student's t-test (unpaired and unequal variance).

Comparative WOMAC Function Scores, IA TPX-100 treatment versus Placebo Controls

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

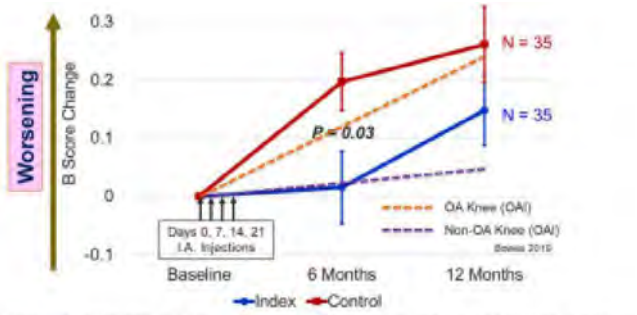

Figure 2. TPX-100 significantly reduced pathological femoral bone shape (B score) change as compared to control in the knees with baseline B score ≥ 1.5. Mean baseline B scores of Index and Control knees were 3.08 and 3.02, respectively. Error bars indicate standard errors of the mean. Statistical analyses were by Student's t-test (unpaired and unequal variance).

Bone-shape ("B") Scores, IA TPX-100 versus Placebo Controls: Comparison to Historical Controls from the Osteoarthritis Initiative

Results: Demographics of the study cohort were similar to those of the total study population from TPX-100-1. Knees that received TPX-100versus placebo were well matched in terms of baseline WOMAC function, B-scores and all other clinical measures. TPX-100 treatment was associated with WOMAC scores that demonstrated statistically significant and clinically meaningful improvements compared with controls at 6 and 12 months, and pathological B-score changes that were significantly reduced versus controls. Notably, at 6 months, the trajectory of B-score change in TPX-100-treated knees almost perfectly mirrored that of "non-OA" knees from the OAI, while placebo-treated knees followed a trajectory nearly identical to that of OAI disease progressors. (Figures 1, 2).

Conclusion: The demonstration of concordant drug-associated improvements in WOMAC function and MRI-based bone-shape scores suggest that these measures-- independently associated with knee joint failure and TKR—may be useful when appropriately combined in order to advance a viable surrogate marker for DMOAD development. Furthermore, the observed structural and functional benefits demonstrated with TPX-100 treatment, while requiring confirmatory trials, support the potential of TPX-100 as a candidate DMOAD.

Abstract Number: 2087

Does Carbamazepine Impact Risk of Developing Osteoarthritis? Results of a Real-World Data Analysis

Erfan Afshar[1] and Andrew Long[2], [1]VCUSOM, Richmond, VA, [2]Virginia Commonwealth University Health System, Midlothian, VA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2079–2105) Osteoarthritis – Clinical Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Carbamazepine has shown chondroprotective effects in OA animal models by modulating Nav1.7 channels. This study aimed to examine the association between Carbamazepine use and the risk of developing Osteoarthritis (OA). We hypothesized that Carbamazepine users would have a lower incidence of OA compared to matched controls.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Kaplan-Meier curve comparing OA-free survival between Carbamazepine users and matched controls over time.

Methods: The data for this retrospective cohort study were gathered from the aggregated electronic health records research network, TriNetX. Cohorts included patients aged 40 years or older with a history of using Carbamazepine and the control group consisted of patients with no history of exposure to Carbamazepine. Cohorts were matched through propensity score matching (PSM) for confounding variables known to influence OA risk, including age, sex, race, obesity, metabolic conditions, joint disorders, prior injury and use of cardiovascular or anti-inflammatory medications. Outcomes were assessed through risk ratio (RR), of the development of osteoarthritis at least 180 days after receiving carbamazepine.

Results: Among 385,903 patients in the initial Carbamazepine cohort, 174,970 patients remained post-PSM for the OA analysis (mean [SD] age, 67.8 [13.3] years; 77.1% female) and 174,970 in the matched control cohort (mean [SD] age, 68.3 [10.6] years; 76.5% female). In the osteoarthritis analysis, 37,746 patients were excluded in the Carbamazepine group and 42,867 patients were excluded from the control group for having the outcome prior to the study window. Osteoarthritis occurred in 20, 254 (14.8%) of the Carbamazepine group compared to 24,533 patients (18.6%) in the control group, yielding a risk ratio (RR) of 0.795 (95% CI, 0.781–0.808; $p < 0.0001$), indicating a statistically significant reduced risk of OA for Carbamazepine users.

Conclusion: This data highlights the potential for Carbamazepine to reduce the risk of developing OA. Using Carbamazepine to target chondrocytes appears to offer a promising treatment strategy in OA, and it calls for future clinical studies. This study highlights a potential role for carbamazepine as a preventative agent for OA and underscores the need for prospective clinical trials to validate this real-world observation.

Abstract Number: 2088

Aging Unevenly: National Trends and Inequities in Osteoarthritis Mortality, 1999–2020

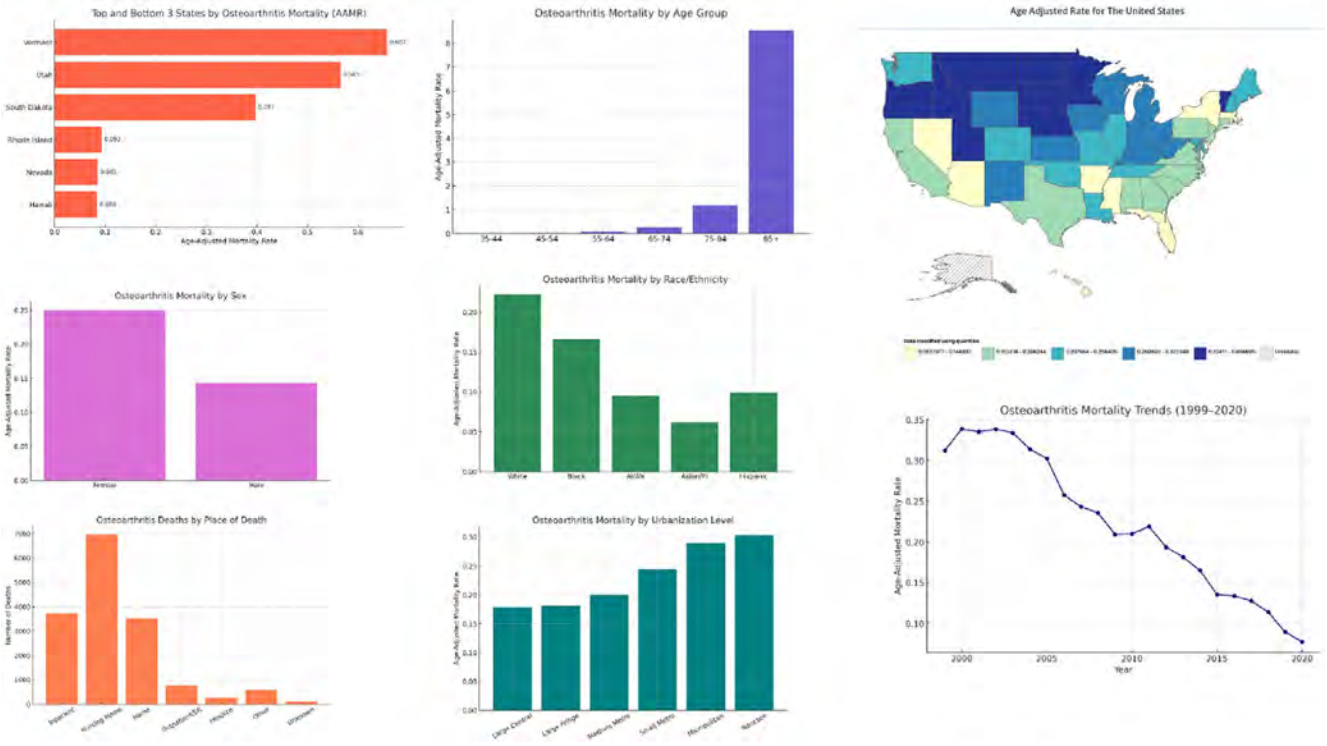
Ghassan Makhoul[1], Aziz-ur-Rahman Khalid[2], Hasan Munshi[1], Islam Rajab[1], MD Walid Akram Hussain[1], Reshma John[1], Elvira Assaf[1], Amer Al Badawy[1], Barbare Khatiashvili[1], Rouba Isshak[1], Nargis Mateen[3] and Robert Lahita[4], [1]St. Josephs University Medical Center, Paterson, [2]St. Joseph's University Medical Center, wayne, [3]St. Josephs University Medical Center, Paterson, NJ, [4]St. Josephs University Medical Center, Wayne, NJ

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2079–2105) Osteoarthritis – Clinical Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Osteoarthritis (OA) is a leading cause of disability and pain in older adults. While not traditionally viewed as fatal, OA contributes significantly to morbidity and, in some cases, mortality. This study evaluates national mortality trends and demographic disparities associated with OA (ICD-10 M15–M19) from 1999 to 2020 using U.S. death certificate data.

Methods: Mortality data were extracted from the CDC WONDER Multiple Cause of Death database. Age-adjusted mortality rates (AAMRs) per 100,000 population were calculated using census-adjusted standard populations. Deaths were stratified by year, state, sex, 10-year age group, race/ethnicity, Hispanic origin, place of death, and urban-rural classification based on the 2013 NCHS scheme.



Graphs showing state, demographic, gender, race, age group, year, place of death, mortality from Osteoarthritis

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: From 1999 to 2020, there were 15,948 deaths attributed to osteoarthritis (OA) in the United States. The age-adjusted mortality rate (AAMR) declined by 75% over the study period, dropping from 0.31 per 100,000 in 1999 to 0.08 in 2020. Despite this progress, notable disparities remain. Females experienced nearly twice the mortality burden of males, with an AAMR of 0.25 compared to 0.14. Mortality rose steeply with advancing age, reaching 8.5 per 100,000 among adults aged 85 and older. Racial and ethnic differences showed the highest AAMRs among White (0.22) and Black (0.17) individuals, while Hispanic and Asian/Pacific Islander groups had lower rates at 0.10 and 0.06, respectively. AAMRs increased with rurality, ranging from 0.18 in large metropolitan areas to 0.30 in noncore rural regions. State-level variation was substantial, with AAMRs ranging from 0.08 in Hawaii to 0.66 in Vermont, highlighting a greater burden in rural and mountain states. Regarding place of death, 43.6% of OA-related deaths occurred in nursing homes or long-term care facilities, 23.4% in inpatient medical settings, and 22.2% in the decedent's home.

Conclusion: Osteoarthritis mortality in the U.S. has declined significantly over the past two decades, likely reflecting improved awareness and comorbidity management. However, consistent disparities by age, sex, race, geography, and care setting underscore the unequal burden of this chronic disease. These findings highlight the need for targeted health policy and equitable access to supportive care, particularly in aging and rural populations.

Traction Therapy May Improve Hand Function in Those with Distal Interphalangeal Osteoarthritis

Grace Lo[1], Lauren Drillock[2], Kimberly Staines[3], Michael Strayhorn[4], Katherine Tse[5], Gerald Virtanen[6], Laura Welsh[2], Monica Seu[2], Eugene Gersh[2], Ida Kristin Haugen[7], Andrew Grainger[8] and Jonathan Samuels[9], [1]Baylor College of Medicine / MEDVAMC, Houston, TX, [2]NYU Langone Health, New York City, NY, [3]MEDVAMC, Saltburn By The Sea, United Kingdom, [4]Baylor College of Medicine, Houston, TX, [5]NYU Langone Health, Brooklyn, NY, [6]MEDVAMC, Houston, TX, [7]Diakonhjemmet Hospital, Oslo, Norway, [8]University of Cambridge, Cambridge, United Kingdom, [9]NYU Langone, Rye Brook, NY

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2079–2105) Osteoarthritis – Clinical Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Hand osteoarthritis (OA) is the most common form of arthritis affecting the hand, but therapeutic options for OA at the distal interphalangeal (DIP) joint have limited efficacy. While the primary outcome of a randomized controlled clinical trial evaluating traction of the DIPs was null, we explored whether secondary outcome measures indicated a benefit of the treatment.

Methods: In this pilot multi-center, double-blind, controlled trial, of DIP hand OA in at least 3 joints, patients were randomized to a traction device (fig 1) along with standard of care vs standard of care. Patients were evaluated at baseline and at weeks 4, 12, and 24 for multiple measures of pain as well as functional assessments using questionnaires (the Disabilities of Arm Shoulder and Hand (DASH), the Michigan Hand Questionnaires, the Functional Index for Hand Osteoarthritis

(FIHOA)) and clinical tests including the Functional Dexterity test, grip strength test, pinch strength test, and tenderness on joint palpation. All participants randomized into the study were included. We used a last observation carried forward strategy to address missing data.

Results: 33 participants were enrolled and randomized to either the experimental or control arm. Of the secondary outcome measures that we evaluated, two were statistically significant in when looking at the 24 week timepoints, these included the DASH and the Michigan Hand Outcome ADLs of both hands. The DASH scores were significantly better in the traction arm compared to the control by nearly 11 points (-10.9 (95% CI -21.8 – -0.2)), and the Michigan Hand Outcome ADLs of both hand scores were also better by 12.0 points (12.0 (1.1 - 22.8)). The 4 other functional hand outcomes, FIHOA, grip strength, AUSCAN function, and the Michigan Hand Outcome overall hand scores, did not meet statistical significance but all showed more improvement in the traction arm compared to the control arm. None of the pain outcome measures showed a signal for being more beneficial in either arm.

Conclusion: In our pilot RCT of finger traction for DIP hand OA, based on our secondary outcomes, there is a signal that function may be improved in the treatment arm. Our findings suggest that functional assessments might be a better outcome measure to evaluate treatment benefit for hand OA interventions compared to pain assessments. A larger clinical trial, perhaps with a focus on function instead of pain as an outcome, is warranted.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2079–2105) Osteoarthritis – Clinical Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Osteoarthritis (OA) is the most common form of arthritis, a condition associated with substantial disability. Radiographic severity of OA is associated with the presence or absence of frequent knee pain cross-sectionally. Our purpose was to test the prognostic potential of radiographs among knees without frequent pain by evaluating whether radiographic disease severity predicts frequent knee pain over time.

Methods: This is a knee-based longitudinal study of participants of the Osteoarthritis Initiative (OAI). We only included knees that were free of frequent pain at the baseline visit. Posterior-Anterior semi-flexed knee radiographs were obtained at the baseline visit and scored for Kellgren-Lawrence (KL) grade (0-4). At the baseline and annual visits, participants reported whether they had knee-specific frequent pain using the question, of whether the participant has had had (right/left) knee pain, aching or stiffness on more than half the days of a month in the last 12 months?

We performed knee-based logistic regression analyses, using generalized estimating equations to account for correlation between knees within a person, where the independent variable was baseline KL grade and the outcome of interest was frequent knee pain at the 12-month visit. Analyses were repeated with outcome at the 48-month visit.

Results: 6159 knees from 3714 participants were included in this study, 58% were female, mean age was 61.5 (9.2) years, mean body mass index was 28.3 (4.7) m^2/kg.

Conclusion: Radiographic disease severity, based on KL grades, is a prognostic biomarker for frequent knee pain among those without existing symptoms in as short as one year of follow-up. Radiographs could be a screening tool to identify those at high risk of developing frequent knee pain. This may be a useful strategy for testing potential therapies aimed at the preventing the onset of frequent knee pain.

Table. KL Grade at Baseline Visit Associated with Frequent Knee Pain at 12- and 48- month follow up.

KL Grade at the Baseline Visit	Frequent Knee Pain at 12 months (n = 3488 participants, 5800 knees)	Odds Ratio for Frequent knee pain at 12 months	Frequent Knee Pain at 48 months (n = 3324 participants, 5541 knees)	Odds Ratio for Frequent knee pain at 48 months
0 (n = 2529)	12%	referent	15%	referent
1 (n = 1109)	16%	1.3 (1.0 – 1.6)	18%	1.2 (1.0 – 1.5)
2 (n = 1431)	19%	1.6 (1.3 – 2.0)	25%	1.9 (1.6 – 2.3)
3 (n = 623)	25%	2.3 (1.8 – 2.9)	32%	2.7 (2.1 – 3.3)
4 (n = 96)	37%	4.2 (2.7 – 6.5)	50%	5.6 (3.6 – 8.6)
Missing	N = 476		N = 732

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2079–2105) Osteoarthritis – Clinical Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Effusion-synovitis (ES) is often seen in knee osteoarthritis (KOA), and MRI-detected ES may serve as a potential imaging biomarker of disease activity, progression, and treatment response. However, reproducible and scalable fully quantitative methods to assess ES remain limited. We developed a multiplanar, semi-automated system for trained non-expert readers to segment ES using two non-contrast enhanced (NCE) 3 T MRI sequences simultaneously and assessed its reliability and validity as an efficient method of quantifying ES in KOA patients.

Methods: OAI participants with radiographic KOA (Kellgren-Lawrence grades 2-3) at baseline were randomly selected (n=80 knees; 1 knee per participant). Following a validated single-slice ES method, a three-monitor setup was employed featuring custom post-processing algorithms to standardize homologous ES on axial DESS and sagittal TSE NCE-MRI images (Figure 1). Variable grayscale thresholding, 3D visualization/localization, and rapid refinement was facilitated by a multi-button mouse (Figure 2). Measurement was performed on both views in parallel with real-time quantification to achieve sub-millimeter volume differences across planes or simultaneously via cross-plane projective segmentation. Fifty knees were segmented in parallel by an MSK radiologist. One non-expert reader was trained using the first 20 scans and then made repeated measurements on the following 30 knees ("validity set"). Three non-experts repeated the parallel approach on 30 different knees ("reliability set"). We evaluated agreement using mean absolute difference (MAD), and intra- and inter-reader reliability using intraclass correlation coefficients (ICC) from a linear mixed model with random effects for knee, reader, and interaction between knee and reader.

Results: Scan reading times averaged < 5 minutes for simultaneous ES segmentation. ES volumes averaged between 7683 mm^3 and 8911 mm^3 across comparison groups. In the validity set, the multiplanar (axial, sagittal) inter-reader ICCs were 0.995, 0.996 (MADs: 424 mm^3, 470 mm^3) and intra-reader ICCs were 0.991, 0.993 (470 mm^3, 493 mm^3) (Figure 3).

Figure 1: Triple-monitor, multi-view effusion-synovitis (ES) quantification system showing the tile view of the axial DESS images with segmentations and cross-plane sagittal projections and scan localization on the left monitor, the tile view of the sagittal TSE images with sagittal segmentations and active slice identification on the right monitor, and semi-automated ES software with real-time ES quantification, localization and projection on the center monitor.

Figure 2: Diagram of mouse displaying software functions programmed as buttons and button combinations that can be performed rapidly to generate precise effusion-synovitis shadings.

Validity Set	Parallel Segmentation		Cross-Planar Projective Segmentation	
	Axial (95% CI)	Sagittal (95% CI)	Axial-Sagittal Overlap (95% CI)	Sagittal (95% CI)
Non-expert intra-reader ICC	0.991 (0.983, 0.997)	0.993 (0.989, 0.996)	0.993 (0.983, 0.998)	0.993 (0.988, 0.997)
Non-expert intra-reader MAD (mm³)	470 (291, 720)	493 (316, 746)	427 (269, 646)	503 (324, 733)
Expert vs. Non-expert inter-reader ICC	0.995 (0.979, 0.996)	0.996 (0.971, 0.997)	0.995 (0.975, 0.996)	0.996 (0.967, 0.997)
Expert vs. Non-expert inter-reader MAD (mm³)	424 (297, 592)	479 (336, 619)	452 (339, 592)	514 (388, 652)
Reliability Set				
Non-expert intra-reader ICC	0.989 (0.968, 0.996)	0.991 (0.969, 0.995)		
Non-expert intra-reader MAD (mm³)	567.9 (457.5, 682.1)	604.2 (469.3, 772.8)		
Non-expert inter-reader ICC	0.977 (0.966, 0.986)	0.984 (0.978, 0.989)		
Non-expert inter-reader MAD (mm³)	915.6 (762.6, 1082.2)	963.9 (805.5, 1128.7)		

Acronyms: KL Kellgren-Lawrence, MSK musculoskeletal, CI Confidence Interval, ICC Intraclass Correlation Coefficient, MAD Mean Absolute Difference, 2D two-dimensional, IW intermediate-weighted, FS fat-suppressed, TSE turbo spin-echo, 3D three-dimensional, MPR multiplanar reformation, DESS dual-echo steady-state, WE water excitation

Figure 3. Reader performance in our study. The "validity set" composed of 29 KL grade 2 and 3 (19 and 10, respectively) knees segmented in parallel by an expert MSK radiologist on sagittal 2D IW FS TSE and axial 3D MPR DESS WE images. One non-expert reader made repeated measurements on the set using parallel and cross-planar projective segmentation to assess non-expert intra-reader and inter-reader reliability and validity using both approaches. Three additional non-experts repeated parallel measurements of 29 different KL 2 and 3 knees (16 and 13, respectively, "reliability set") to assess non-expert inter- and intra-reader reliability.

When measuring both views simultaneously via projection, the multiplanar inter-reader ICCs were 0.995, 0.996 (452 mm3, 514 mm3) and intra-reader ICCs were 0.993, 0.993 (427 mm3, 503 mm3). In the reliability set, the multiplanar inter-reader ICCs were 0.977, 0.984 (916 mm3, 964 mm3) and intra-reader ICCs were 0.989, 0.991 (568 mm3, 604 mm3).

Conclusion: By employing a system with custom artifact correction, tissue standardization and hardware and software tools, non-expert readers were able to be trained to segment ES. They demonstrated high reliability and concurrent validity with excellent agreement with an expert MSK radiologist's measurements for both multi-view ES measurement methods. Our method allows for expedited simultaneous segmentation to produce rapid, detailed assessment of ES large knee MRI datasets, and facilitate the development of objective, critical measures of joint inflammation.

Abstract Number: 2092

Associations Among Biomarkers, Cytokines, and Ultrasound Features of Knee Osteoarthritis: A Cross-sectional Analysis in the Johnston County Health Study

Jasmine Kimber[1], Carolina Alvarez[2], Virginia Kraus[3], Janet Huebner[3], Liubov Arbeeva[4], Todd Schwartz[5], Yvonne Golightly[6], Richard Loeser[7] and Amanda Nelson[1], [1]University of North Carolina at Chapel HIll, Chapel Hill, NC, [2]University of North Carolina at Chapel Hill, Miami, FL, [3]Duke University, Durham, NC, [4]University of North Carolina, Chapel Hill, Carrboro, NC, [5]University of North Carolina-Chapel Hill, Chapel Hill, NC, [6]University of Nebraska Medical Center, Omaha, NE, [7]University of North Carolina, Chapel Hill, NC

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2079–2105) Osteoarthritis – Clinical Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Osteoarthritis (OA) is a leading cause of disability worldwide, characterized by progressive joint degeneration, chronic pain and functional impairment (PMID: 24024017). While imaging modalities such as radiographs are standard for OA diagnosis, emerging research suggests that ultrasound (US) imaging, potentially in combination with other disease markers such as soluble biomarkers and cytokines, may offer a more dynamic assessment of joint health (PMID: 39201072). This study aims to explore these associations utilizing data from the Johnston County Health Study (JoCoHS), a population-based cohort initiated in 2019 in North Carolina.

Methods: Participants (N=91) in JoCoHS who underwent bilateral knee US and serum and plasma biomarker assessment by ELISA as part of a substudy (**Table 1**) were included. US images were acquired by a trained sonographer and scored by two expert readers using standardized criteria for distinct structural and inflammatory joint pathologies including synovitis, osteophytes, meniscal and cartilage damage (**Table 2**, described in PMID 39989271). Separate linear regression models of associations between each log-transformed biomarker with each US feature were used to produce adjusted mean differences (betas) and 95% confidence intervals (CI), adjusted for age, sex, race/ethnicity, body mass index (BMI), education (as a proxy for socioeconomic status), Charlson Comorbidity index (CCI), and symptoms in other sites (i.e., hip, wrist, or hand).

Results: Among 91 participants (mean age 55 [range 35-70] years, 39% male, 35% Black, 12% Hispanic, mean BMI 34 kg/m^2) with US and biomarker data, joint pathology and GS synovitis were common, with 92% of participants having at least one knee with cartilage damage on US. On average, elevated cartilage oligomeric matrix protein levels (COMP) were modestly but significantly associated with the presence of mild medial osteophytes (**Table 2**). Hyaluronic acid (HA) levels were significantly higher in participants with severe effusion/synovitis, severe GS synovitis, and medial meniscal extrusion. Increased interleukin-6 (IL-6) levels were observed in association with both PD synovitis and lateral cartilage damage. Both HA and IL-6 were higher in those with severe medial cartilage damage, but this was not statistically significant. Additionally, tumor necrosis factor-alpha (TNF-a) levels were on average slightly higher in individuals with severe GS synovitis, lateral osteophytes and medial meniscal extrusion (**Table 2**).

Table 1. Descriptive statistics of the OA biomarkers and inflammatory cytokines in a subsample of the JoCoHS (n=91).

Serum Biomarker	*Vendor*	*Mean*	*±SD*	*Range*	*LLOD*	*Intra-assay CV (%)*	*Inter-assay CV (%)*
COMP ng/ml	Biovendor	682	274	282-2002	0.4	1.2	6.7
HA ng/ml	Corgenix	39.4	36.2	10-172	20	6.7	4.2
IL-6 pg/ml	MSD VPLEX	1.13	0.74	0.32-3.54	0.06	4.4	7.6
TNF-a pg/ml	MSD VPLEX	2.42	0.61	0.89-4.23	0.04	7.5	3.4

Abbreviations: SD: standard deviation; LLOD: Lower limit of detection; COMP: Cartilage Oligomeric Matrix Protein; HA: Hyaluronic Acid; IL-6: Interleukin-6; TNF-α: Tumor Necrosis Factor-alpha. COMP is a marker for cartilage turnover; HA is a marker for synovitis; IL-6 and TNF-α are pro-inflammatory cytokines.

Abbreviations: CI, Confidence Interval; GS, Gray Scale; PD, Power Doppler. Linear regression modeling natural log of each inflammatory biomarker outcome and its association with each US feature, separately. Each model adjusts for age, sex, race/ethnicity, BMI, education, CCI, hip, wrist, and hand PAS. Shown **BOLD** when significant at 0.05 level.

Conclusion: Our findings demonstrate that specific US features of joint pathology relevant to OA are associated with distinct biomarkers in a diverse population, particularly HA and GS synovitis, which had the strongest associations. These results support the role of structural changes and inflammation in the pathogenesis of OA and highlight the utility of US imaging (which allows visualization of soft tissues in a more accessible manner than does MRI) and biomarker data for characterizing disease variation and tailored avenues of assessment, monitoring and treatment.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2079–2105) Osteoarthritis – Clinical Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background/Purpose: Acetaminophen is widely recommended for osteoarthritis (OA) pain management due to its perceived safety profile. However, its long-term effects on clinical outcomes among older adults remain poorly defined. This study aimed to assess the association between acetaminophen use and mortality, cardiovascular, gastrointestinal, and laboratory outcomes in a large OA population.

Methods: We conducted a retrospective cohort study using the TriNetX Global Collaborative Network. Adults aged ≥65 years with osteoarthritis were identified between January 1, 2004, and December 31, 2024. Cohort 1 (n=1,090,625) included patients who initiated acetaminophen within one year of OA diagnosis; Cohort 2 (n=2,174,179) included patients with OA who did not receive acetaminophen. After 1:1 propensity score matching for demographics, comorbidities, and medications, 483,647 patients per cohort were analyzed. Outcomes over three years included death, peptic ulcer disease (PUD), lower gastrointestinal bleeding (LGIB), myocardial infarction (MI), stroke, and laboratory measures of creatinine and hemoglobin. Comparative analyses included measures of association and Kaplan-Meier survival.

Results: Post-matching, baseline characteristics were balanced. Acetaminophen use was associated with increased risks of death (HR 1.46, 95% CI 1.43–1.48, p< 0.001), PUD (HR 3.11, 95% CI 2.91–3.32, p< 0.001), LGIB (HR 1.98, 95% CI 1.91–2.05, p< 0.001), MI (HR 2.12, 95% CI 2.05–2.19, p< 0.001), and stroke (HR 1.70, 95% CI 1.65–1.75, p< 0.001). Survival probability at three years was lower in acetaminophen users compared to non-users (89.7% vs 92.7%). Laboratory analysis revealed higher mean creatinine (1.07 vs 1.00 mg/dL, p< 0.001) and lower mean hemoglobin (12.39 vs 13.29 g/dL, p< 0.001) among acetaminophen users.

Conclusion: In a large cohort of older adults with OA, acetaminophen use was associated with significantly increased risks of mortality, gastrointestinal bleeding, cardiovascular events, and laboratory abnormalities compared to non-use. These findings challenge the notion of acetaminophen as a universally benign analgesic in older patients with OA and highlight the need for more cautious prescribing practices and patient monitoring.

Abstract Number: 2094

Evaluating the Accuracy of Knee Acoustic Emissions Classification of Varus Thrust

Kari Falaas[1], Ahmet Emirdagi[2], Christopher Nichols[2] and David Ewart[3], [1]University of Minnesota, Minneapolis, [2]Georgia Institute of Technology, Atlanta, [3]Minneapolis Veterans Affairs Medical Center, Minneapolis

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2079–2105) Osteoarthritis – Clinical Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Osteoarthritis (OA) of the knee is a leading cause of disability, healthcare expenditures, and is associated with diminished quality of life and increased mortality. Varus thrust is a pathologic gait pattern that is more prevalent in individuals with obesity and associated with incident and progressive knee osteoarthritis. Knee acoustic emissions (KAE) is a practical, point-of-care assessment of knee health that can inform several pathological states, including early and

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

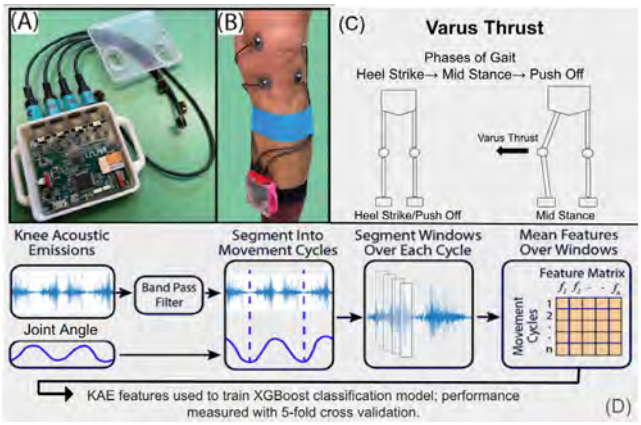

Figure 1. Workflow for measurement and extraction of KAE. A. Contact microphones and associated hardware for KAE measurement. B. Microphones and hardware mounted on participant's knee. C. Assessment for varus thrust at mid-stance phase of gait during ambulation. D. Extraction of KAE features by biomechanically-defined gait cycle into feature matrix for training classification model. KAE: knee acoustic emissions.

established knee OA. Whether KAE is sensitive to knee OA risk or prognostic factors, such as varus thrust, is unknown. This study aims to evaluate the accuracy of a KAE-based model for classification of knees with varus thrust.

Methods: We recruited 20 adult participants with obesity with or without frequent and persistent knee pain from the Minneapolis Veterans Affairs Medical Center (MVAMC), whose institutional review board approved the study. During motion analysis, KAE was measured from bilateral knees using four contact microphones placed medially and laterally on the superior and inferior aspect of the patella. The presence of varus thrust was assessed by two independent reviewers using videos

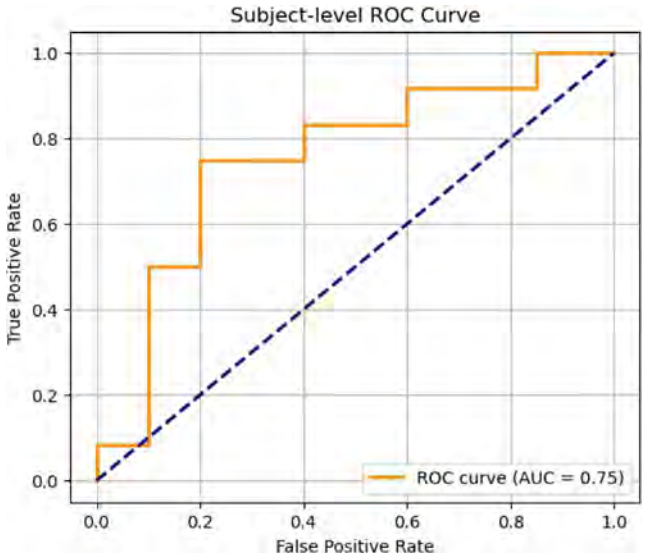

Figure 2. Receiver Operating Characteristic Curve of KAE Classification Model for Varus Thrust. Model performance area under the curve was 0.75. ROC: Receiver operating characteristic; AUC: area under the curve.

Table 1. KAE Model Results

Sensitivity	70%
Specificity	76%
Accuracy	82%

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

of ambulation. Participants ambulated at self-selected slow, medium, and fast speeds. KAE from each condition were isolated from one another to specific phases of gait using 30 ms windows with 20 ms overlap. 73 spectral, temporal, and amplitude-based features were extracted per window to train an XGBoost classifier for varus thrust detection. Knees with a percentage of positively classified windows above an empirically derived optimal threshold were classified as thrust-positive. Performance was assessed via 5-fold cross validation to obtain average values for accuracy, sensitivity, and specificity.

Results: Twenty participants (13 males) were recruited, with a mean age of 54.5 years and average body mass index (BMI) of 39.2. Eleven participants reported frequent and persistent knee pain. Twenty-three knees were graded Kellgren–Lawrence ≥2. Aggregate Knee Injury and Osteoarthritis Outcome Score (KOOS) subscale scores were: Activities of Daily Living – 80, Sports– 62, and Quality of Life – 58. Twenty-five percent of knees had varus thrust. The KAE model had a sensitivity, specificity, and accuracy of 70%, 76%, and 82%, respectively.

Conclusion: Models trained with KAE can accurately classify knees with varus thrust. KAE likely contain information about the larger biomechanical status of the knee and future studies should assess whether acoustics can predict other pathologic biomechanics of the knee.

Abstract Number: 2095

Trends in Mortality and Disability-Adjusted Life Years (DALYs) from Osteoarthritis in the United States Compared to Global Estimates: A GBD-Based Analysis (1990–2021)

Khadija Mohib[1], Rameez Qasim[2], ZAUHA FAWAD MEMON[3], Muhammad Asjad Saleem[4], Matia Fawad Memon[5] and Zaiya Waseem[6], [1]Kirk Kerkorian School of Medicine at UNLV, Las Vegas, NV, [2]Allama Iqbal Medical College Lahore, Lahore, Pakistan, [3]Peoples University of Medical and Health Sciences for Women, Tando Allahyar, Sindh, Pakistan, [4]Indus Hospital Karachi, Karachi, [5]Peoples University of Medical and Health Sciences for Women, Tando Allahyar, Pakistan, [6]AtlantiCare Regional Medical Center, New Jersey

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2079–2105) Osteoarthritis – Clinical Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Osteoarthritis (OA) represents a growing public health concern, particularly among the aging population, contributing significantly to both mortality and Disability-Adjusted Life Years (DALYs). This study evaluates trends in OA-related DALY and mortality from 1990 to 2021, utilizing data from the Global Burden of Disease (GBD) database, with a comparative focus on the United States and global trends.

Methods: Data from the 2021 Global Burden of Disease (GBD) database were analyzed to evaluate osteoarthritis-related mortality and Disability-Adjusted Life Years (DALYs) among individuals aged 65 years and older in the United States and globally. DALY and mortality rates were reported per 100,000 population. Long-term trends from 1990 to 2021 were assessed using Annual Average Percentage Change (AAPC), with statistical significance determined by 95% confidence intervals (CIs) and p-values. Annual Percentage Change (APC) was also calculated for specific time intervals to identify periods of significant deviation from the overall trend.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: DALYs attributed to osteoarthritis showed a consistent upward trend globally, with a D-AAPC of 0.30% (95% CI: 0.28–0.31, $p < 0.000001$), observed similarly in both females (0.30%) and males (0.31%). Notably, a significant spike in DALY-APC (0.85%) was recorded between 2006 and 2009.

In the United States, 44,590 OA-related deaths were reported between 1990 and 2021. The AAPC for mortality increased by 0.76% (95% CI: 0.11–0.41, $p = 0.0215$), aligning with the global trajectory. However, mortality trends showed fluctuations over time, with the lowest APC of -2.90% (95% CI: -3.93 to -1.18, $p = 0.000035$) between 2011 and 2018 and the highest APC of 13.03% (95% CI: 4.33–20.08, $p = 0.0068$).

In the U.S., the D-AAPC over the last three decades increased by 1.68% (95% CI: 0.04–0.29, $p = 0.0707$), with a gender-specific increase of 0.12% for men and 0.24% for women. Several intervals showed declining mortality rates, notably between 1993–1996, 1996–1999, and 1999–2005 with D-APCs of -0.11%, -2.19%, and -1.08% respectively.

Conclusion: This study demonstrates a rising burden of osteoarthritis, reflected in both DALY and mortality trends, in the United States and globally over the past three decades. While some fluctuations exist, the overall trajectory suggests worsening impact, especially among older adults. These findings underscore the urgent need for targeted prevention strategies, improved access to musculoskeletal care, and investment in early intervention programs to reduce long-term disability and mortality. Further research is warranted to identify modifiable risk factors and health system inefficiencies contributing to these escalating trends.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2079–2105) Osteoarthritis – Clinical Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Promotion of physical activity is important in the management of knee osteoarthritis (KOA), though effective strategies for behavioral change to promote exercise are lacking. The aim of the study was to determine if an incentive program based on principles from behavioral economics including gamification and social incentivization could promote physical activity and reduce self-reported pain and disability in adults with KOA.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

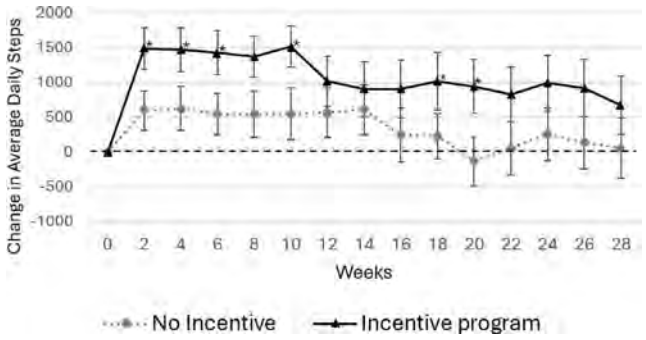

Figure 1: Change in average weekly step count changes in incentive (black triangles) and control groups (grey circles). Brackets indicate 95% confidence interval.

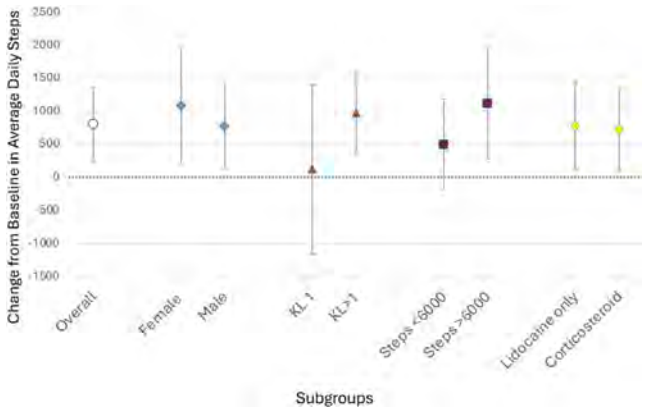

Figure 2: Effect of the intervention (difference between incentive and control by subgroup). Brackets indicate 95% confidence interval.

Methods: This was a factorially-designed multi-site randomized controlled clinical trial. Participants were randomized to receive an incentive program to promote greater physical activity or an attention control. Participants received a Fitbit monitor and completed patient-reported outcomes through a web-based platform. Participants who were randomized into the incentive program received points for achieving step goals and advanced in a game on a weekly basis based on their success. The control arm received a Fitbit and answered surveys but did not receive an incentive. Participants were also randomized to receive blinded corticosteroid injections v. lidocaine only in a factorial design. The analysis used mixed-effects models to evaluate the time-averaged effect of the intervention over a 28-week study follow-up on both average daily step counts (averaged over 2 weeks) as well as secondary patient-reported outcomes, including the Knee Osteoarthritis

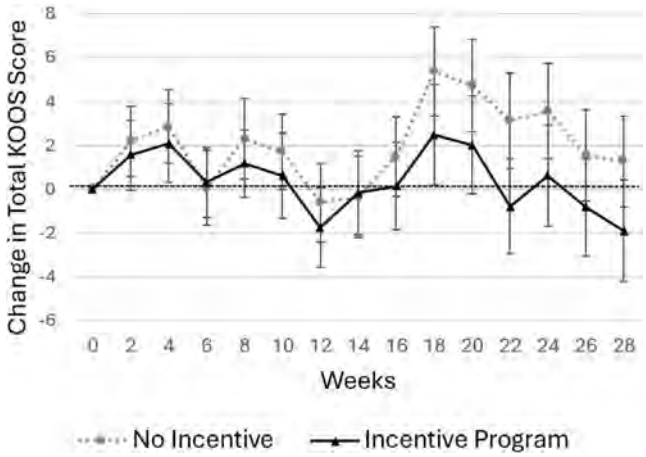

Figure 3: Change in the total KOOS score over 28 weeks among the incentive (black triangles) and control (grey circles) groups. Brackets indicate 95% confidence intervals.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Outcome Score (KOOS). Secondary outcomes also included the Patient-Reported Outcomes Measurement Information System (PROMIS) pain assessments.

Results: Of 231 that were enrolled, 221 were randomized with an average age of 64 years and 84% male. Those that were randomized to the incentive (N=110) walked an average of 830 (95% CI: 254, 1405) more steps/day than the control arm (N=111) (p=0.005). The increase in steps/day compared to the control arm was similar across the 28-week study (Figure 1), though step counts generally declined with time in both groups. There were no significant differences in the effect of the intervention on the change in step counts by gender, Kelgren-Lawrence grade, baseline step count, or receipt of corticosteroid (v. lidocaine only) (Figure 2). While the incentive program resulted in an improvement in average daily step counts, there was no difference in the change in KOOS scores over the study period in the incentive group compared to the control group [β: -1.59 (95% CI: -4.51, 1.33) p=0.29] (Figure 3). The incentive group also did not report significant differences in change in pain intensity, pain behavior, or pain interference.

Conclusion: An incentive program designed with elements of gamification and social incentivization resulted in a significant increase in average daily steps compared to a control arm in participants with KOA. This difference equates to about a 10–15-minute walk or ½ mile a day and is considered meaningful. While there was improvement in activity, this study does not support prior evidence suggesting that an increase in walking will result in an improvement in symptoms. However, longer duration of sustained increased activity may be needed for symptomatic benefits. Notably the greater activity in the incentive arm did not result in worsening of symptoms.

Trajectories of psychological symptoms during an 18-month Diet + Exercise intervention in overweight or obese adults with osteoarthritis

Lily Alomari[1], Daniel Beavers[2], Kate Queen[3], Shannon Mihalko[4], Gary Miller[4], Elena Losina[5], Paul DeVita[6], david Hunter[7], Jovita Newman[4], Sara Quandt[8], Mary Lyles[8], Sandra Soto[3], Joanne Jordan[9], Leigh Callahan[3], Stephen Messier[10] and Becki Cleveland[11], [1]Kansas City University, Raleigh, [2]Wake forest university, Winston Salem, [3]UNC, Chapel Hill, [4]WFU, Winston Salem, [5]BWH, Boston, MA, [6]East Carolina University, Greenville, [7]Sydney Musculoskeletal Health, University of Sydney, St Leonards, New South Wales, Australia, [8]WFU, Winston-Salem, [9]University of North Carolina at Chapel Hill, Chapel Hill, NC, [10]WFU, Winston-Salem, NC, [11]University of North Carolina, Chapel Hill, NC

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

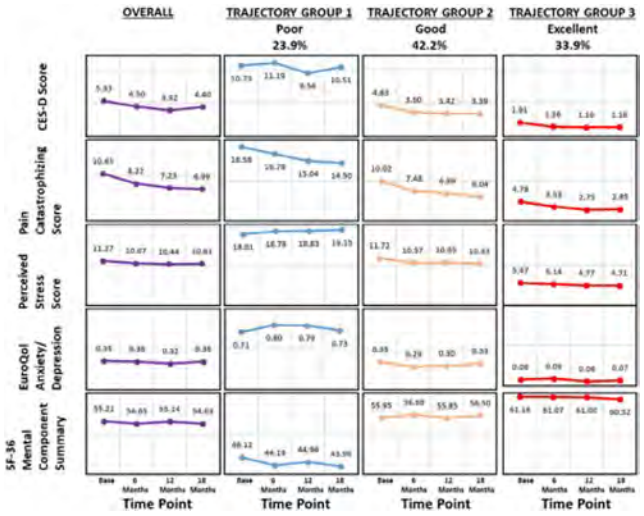
Session Title: (2079–2105) Osteoarthritis – Clinical Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Psychological symptoms (PsySx) have been associated with osteoarthritis (OA), and exercise may improve PsySx. We aimed to identify unique trajectories of PsySx over the course of 18-months,and examine whether randomization to Diet and Exercise (D+E) vs. attention control (AC) was associated with trajectory class.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Methods: We used data from WE-CAN, a randomized trial of overweight/obese individuals aged 50+ years diagnosed with OA. Outcomes were assessed at baseline and at 6, 12, and 18 months. PsySx assessmentincluded Center for Epidemiological Studies-Depression Scale, Pain Catastrophizing Scale, SF-36 MentalComponent Summary, Perceived Stress Scale, and EuroQol Quality of Life Anxiety/Depression. Group-basedmulti-trajectory model analysis (GBMTM) was used to identify subgroups of individuals with similar change patterns across the 5 PsySx measures. Multinomial logistic regression was used to evaluate the association between randomization group and trajectory class. We further explored associations when stratified by social determinants of health (education, occupation, income, area deprivation).

Results: Among 616 participants, GBMTM identified 3 trajectory classes for PsySx: "poor" [GRP 1;REFERENT], "good" [GRP 2], and "excellent" [GRP 3]. Compared with AC, participants in the D+E groupwere more likely to belong to GRP 2 (adjusted odds ratio [OR] 1.57, 95% confidence interval [CI] 1.02-2.43).This association was stronger among individuals with an income less than $50K per year (OR 1.80, 95% CI1.00-3.24) and living in a low deprivation area (OR 1.75, 95% CI 1.00-3.06).

Conclusion: Our results suggest that OA patients with moderate PsySx may experience improved symptomswith a D+E program. However, those who had severe PsySx at baseline (GRP1) may not experienceimprovements with D+E, possibly due to more serious underlying problems that would require treatments beyond D+E. Further, D+E may not have an effect in those mild PsySx, possibly due to little room for improvement.

Session Title: (2079–2105) Osteoarthritis – Clinical Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Intra-articular (IA) corticosteroid injections are commonly utilized for pain management in knee osteoarthritis (KOA). However, clinical characteristics associated with a greater benefit from corticosteroid above placebo are not well defined. We aimed to identify participant characteristics associated with superior response to corticosteroid plus lidocaine compared to lidocaine-only, leveraging data from a large multi-site crossover trial.

Methods: In this factorially-designed, double-blinded, randomized trial also evaluating an exercise incentive program, participants were randomized to IA corticosteroid injections with lidocaine or a lidocaine-only placebo, followed by crossover to the other injection at 16 weeks. Participants were age 40-80 years with KOA recruited from 4 VA Medical Centers, had a clinical indication for joint injection, and a Kellgren-Lawrence (K-L) radiographic grade of $\geq$1. The primary outcome was the change in the total Knee Osteoarthritis Outcome Score (KOOS) measured over multiple time points (bi-weekly) for

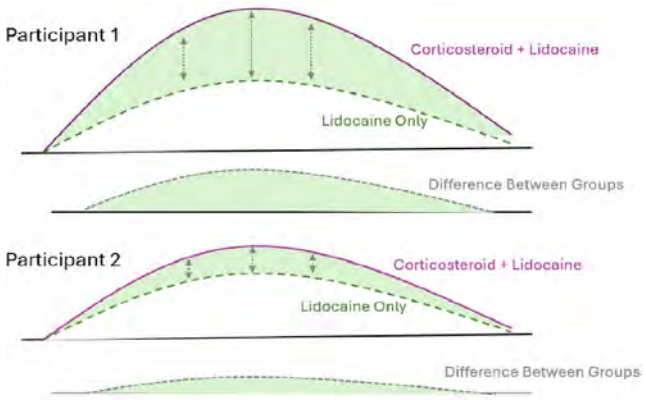

Figure 1. Visualization of "Corticosteroid-Attributable Benefit" (CAB) as Difference in Change in Total KOOS Score at Each Weekly Interval. The CAB was calculated as the average difference in change in total KOOS score at each weekly interval.

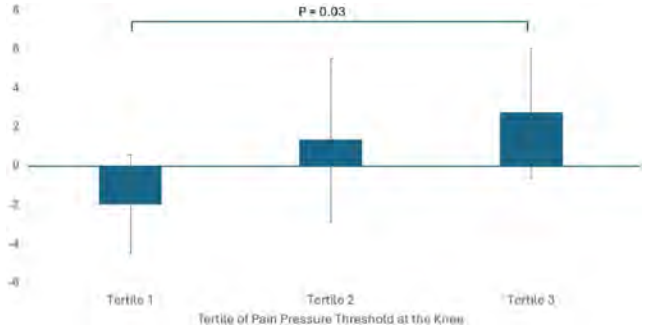

Figure 2. Corticosteroid-Attributable Benefit (CAB) for Each Tertile of Knee Pain Pressure Threshold (PPT). The lowest tertile of PPT demonstrated significantly lower CAB than the highest tertile (p=0.03).

12 weeks after each injection (~1 month washout). The minimal clinically important difference (MCID) was defined as a change of $\geq$10. Participants that received both injections were included in the crossover trial analysis. For each participant, we determined the difference in the change in total KOOS score at each bi-weekly interval to determine the 'corticosteroid-attributable benefit (CAB)' (**Figure 1**). Linear regression incorporating generalized estimating equations identified participant characteristics associated with higher CAB 2-12 weeks after injection.

Results: Among 196 participants, several clinically relevant participant characteristics were associated with CAB (**Table 1**). For example, fibromyalgia (N=11) was associated with lower CAB [B: -6.41 (95% CI: -12.55, -0.27), p=0.04] (**Table 1**). Participants in the lowest tertile of pain pressure threshold (PPT) (N=63), suggesting greater pain sensitization, also had lower CAB (p=0.03) (**Table 1**); the lowest PPT tertile demonstrated smaller CAB compared to the highest (**Figure 2**). Never smokers (N=103) (compared to current smokers) had higher CAB (p=0.02), and CAB was numerically greater among those with higher waist circumference per 1 cm (p=0.06) and among those with a KL grade of 2 (v. 1) (N=42) (p=0.06), though these were not statistically significant (**Figure 2**). When excluding patients with fibromyalgia, KL-scores < 2, and current smokers, there was a significantly greater likelihood of achieving MCID when receiving corticosteroid compared to placebo [OR 2.02 (95% CI: 1.20, 3.40) p=0.008; NNT=10], while no benefit was observed in the overall sample [OR 1.36 (0.93, 1.98) p=0.11; NNT= 23].

Conclusion: In this analysis from a large crossover trial, KOA participants with fibromyalgia and greater pain sensitization experienced significantly less added benefit from IA corticosteroid compared to lidocaine only. These findings suggest reduced benefits of corticosteroids among those with evidence of pain sensitization and may help clinicians select patients most likely to benefit from IA corticosteroids for KOA.

Incidence and Prevalence of Osteoarthritis in the United States Compared to Global Trends: Insights from the Global Burden of Disease Study (1990–2021)

Khadija Mohib[1], Rameez Qasim[2], **Nicolas Barnechea Alvarado**[1], ZAUHA FAWAD MEMON[3] and Muhammad Asjad Saleem[4], [1]Kirk Kerkorian School of Medicine at UNLV, Las Vegas, NV, [2]Allama Iqbal Medical College Lahore, Lahore, Pakistan, [3]Peoples University of Medical and Health Sciences for Women, Tando Allahyar, Sindh, Pakistan, [4]Indus Hospital Karachi, Karachi

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2079–2105) Osteoarthritis – Clinical Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Osteoarthritis (OA) is the most prevalent musculoskeletal condition, predominantly affecting individuals over the age of 55. According to the World Health Organization (WHO), OA has a global prevalence of 7.6%, with women comprising approximately 60% of cases. This study evaluates the global and U.S. trends in osteoarthritis incidence and prevalence from 1990 to 2021 using data from the Global Burden of Disease (GBD) study, highlighting the evolving burden on aging populations.

Methods: Data from the 2021 GBD database were analyzed to assess age-standardized incidence and prevalence rates of OA per 1,000,000 individuals aged 55 years and older. Trends from 1990 to 2021 were examined using the Annual Average Percentage Change (AAPC), with 95% confidence intervals (CIs) and p-values reported to determine statistical significance. Annual Percent Change (APC) was calculated across selected time intervals to capture fluctuations in trend patterns.

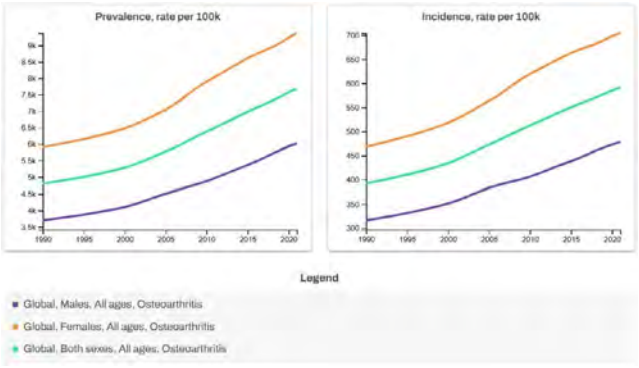
Results: Incidence:

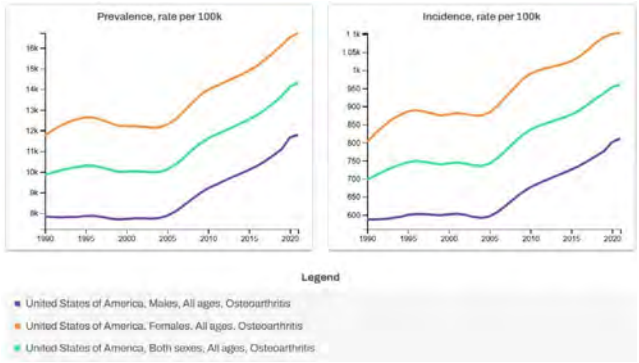
Globally, the incidence of OA increased significantly over the 31-year period, with an overall I-AAPC of 0.28% (95% CI: 0.26–0.30, $p < 0.000001$). Incidence rose by 0.286% in females and 0.28% in males, indicating similar upward trends across sexes. The global I-APC remained relatively stable, with no major deviations.

In the United States, the I-AAPC was slightly lower at 0.20% (95% CI: 0.12–0.29, $p < 0.000001$). Males showed a lower rate of increase (0.16%) compared to females (0.28%), aligning closely with global female trends. However, APC varied significantly across intervals:

- **1990–1995:** Increase of 0.78% per year (95% CI: 0.49–0.94, $p = 0.000002$)
- **1995–2005:** Decline of -1.24% (95% CI: -1.32 to -1.15, $p < 0.000001$)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License





- **2005–2009:** Sharp increase of 1.84% (95% CI: 1.38–2.29, $p < 0.000001$)

Prevalence: The global prevalence of OA also rose steadily, with a P-AAPC of 0.277% (95% CI: 0.26–0.27, $p < 0.000001$). Prevalence increased similarly among both males (0.28%) and females (0.29%). The most significant rise occurred between 2006–2009 with a P-APC of 0.69% (95% CI: 0.58–0.80, $p < 0.000001$), while the smallest change occurred between 2015–2018 (0.05%; 95% CI: -0.05 to 0.15, $p = 0.315$).

In the United States, the P-AAPC was 0.1737% (95% CI: 0.0912–0.2563, $p = 0.000037$). Males showed a lower rate (0.14%) compared to females (0.24%). While overall prevalence increased, notable declines occurred:

- **1995–1999:** -1.46% (95% CI: -1.83 to -1.09, $p < 0.000001$)
- **1999–2005:** -0.89%
- The most significant rise occurred from 2005–2009, with a P-APC of 1.99%.

Conclusion: Between 1990 and 2021, both incidence and prevalence of osteoarthritis have increased among individuals aged 55 and older, in both the United States and globally. Despite some temporal fluctuations, the overall trend is upward, especially among women. These findings emphasize the growing burden of OA on aging populations and highlight the need for public health strategies focused on prevention, early diagnosis, and long-term management of osteoarthritis to reduce disability and healthcare costs associated with this chronic condition.

Abstract Number: 2100

Trabecular Bone Texture is Associated with Structural and Pain Progression in Later Stages of Knee Osteoarthritis: Longitudinal Data from the FNIH OAI Cohort

Pawel Podsiadlo[1], C. Kent Kwoh[2], Marcin Wolski[1], Justin Crawmer[3], Rongrong Tang[4], Shen Liu[5], Xiaoxiao Sun[2], Tuhina Neogi[6], Amanda Nelson[7], Jean Liew[8] and Jeffrey Duryea[9], [1]Curtin University, Bentley, Western Australia, Australia, [2]The University of Arizona Arthritis Center, University of Arizona, Tucson, AZ, [3]Mass General Brigham, Boston, [4]The University of Arizona Arthritis Center, University of Arizona, Tucson, [5]University of Arizona, Tucson, AZ, [6]Boston University School of Medicine, Boston, MA, [7]University of North Carolina at Chapel Hill, Chapel Hill, NC, [8]Boston University, Boston, MA, [9]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2079–2105) Osteoarthritis – Clinical Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Trabecular bone has been increasingly recognized as being important in the pathogenesis of OA. Although an earlier study has shown that medial trabecular bone texture (TBT) predicted OA progression, the predictive validity of medial and lateral TBT regions as structural biomarkers for radiographic and pain progression at different stages of radiographic knee OA is not clear. Therefore, we investigated the predictive validity of longitudinal compartmental changes in TBT at different KL stages, as these have important implications for prognosis and treatment.

Methods: We used data from the FNIH OAI sub-study of 600 participants selected based on their 48-month progression status: Group 1: radiographic and pain, Group 2: radiographic-only, Group 3: pain-only, Group 4: non-progressors. Regions of interest (ROIs) were defined with anatomical landmarks based on an automated delineation of the tibial plateau as shown in Figure 1. The inter-edge tibial plateau distance (D) was used to consistently define ROI size and placement in each compartment. For each knee image, an augmented variance orientation method was applied to the ROIs. For each region, the mean (FD_{MEAN}), vertical (FD_V) and horizontal (FD_H) fractal dimensions were calculated. The FD_{MEAN} was the average of FDs in all directions. Minor axis FD (FD_{Sta}) was also calculated, quantifying texture roughness in the direction of the roughest part of trabecular bone, which contains the shortest bone length components. Higher values of FDs indicate rougher texture, i.e., more complex and irregular bone architecture. TBT assessments were performed at the baseline and

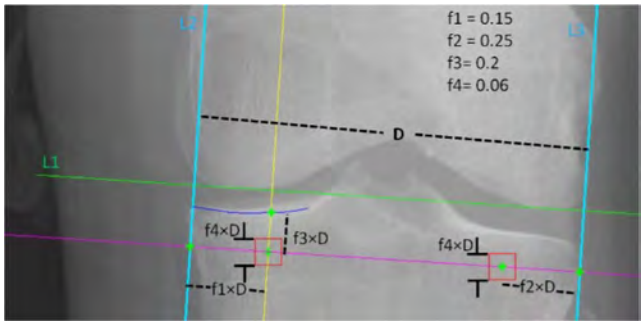

Figure 1. Coordinate system for ROI (red square) positioning The system is flexible in that f1, f2, f3 and f4 are arbitrary distances that can be adjusted automatically once D, L1, L2 and L3 are placed. L1 (green line) = line parallel to the inferior edge of the femoral condyles L2 (left blue line) = line parallel to the medial edge of the tibial plateau L2 (right blue line) = line parallel to the lateral edge of the tibial plateau D (black dotted line) = distance between L2 and L3 and used as a constant to place the region of interest (ROI) f1 = proportion used to place the medial tibial ROI from the medial edge of the tibial plateau f2 = proportion used to place the lateral tibial ROI from the lateral edge of the tibial plateau f3 = proportion used to place the ROI inferior to the rim of the tibial plateau f4 = proportion used to determine the size of the ROI red square = region of interest (ROI) defined as squares with side length of f4×D

* radiographic and pain progressors † radiographic-only progressors ‡ pain-only progressors **non-progressors

Table 2. Summary of the results obtained for group comparisons stratified by KLG and compartment

FD	KLG	Group Comparisons	OR_{adj} (95% CI)
FD_{Sta} L	2	1 vs. 4	0.77 (0.63 – 0.93)
FD_{Sta} M		(Radiographic and pain progression vs. non-progressors)	1.32 (1.06 – 1.64)
FD_{Sta} L	2	1 vs. 2, 3, 4	0.81 (0.69 – 0.95)
FD_{Sta} M		(Radiographic and pain progression vs. all other comparators)	1.20 (1.01 – 1.44)
FD_{Sta} L	2	1, 2, 3 vs. 4	0.84 (0.72 -0.98)
FD_{Sta} M		(All progressors vs. non-progressors)	1.16 (0.99 – 1.4)
FD_{mean} L	2	1, 3 vs. 2, 4	1.18 (1.01 – 1.38)
FD_{mean} M		(Any pain progression vs. no pain progression)	0.9 (0.77 – 1.05)
FD_{Sta} L			0.81 (0.69 – 0.94)
FD_{Sta} M			1.16 (0.99 – 1.36)
FD_{V} L	3	2 vs. 3	1.34 (1.06 – 1.70)
FD_{V} M		(Radiographic only progression vs. pain only progression)	1 (0.76 – 1.32)
FD_{H} L			1.27 (1.04 – 1.54)
FD_{H} M			0.87 (0.7 – 1.08)

L = lateral; M = medial; FDSta = roughest fractal dimension; FD mean = the average of the fractal dimensions in all directions : FDV = vertical fractal dimension; FDH = horizontal fractal dimension. Higher fractal dimension indicates rougher bone texture (i.e. more complex and irregular bone architecture). ORadj = odds ratio adjusted for baseline age, sex, race, BMI, WOMAC pain, pixel spacing and ROI size; 95% CI = 95% confidence interval. ORs are based on every 0.01 increase in the fractal dimension.

24-month time points. Multiple logistic regression models were used to examine the associations between pain and/or radiographic progression and baseline to 24-month changes in FDs stratified by Kellgren-Lawrence grade (KLG) 2 and 3 and by compartment. The models were adjusted for baseline age, sex, race, BMI, WOMAC pain, pixel spacing and ROI size.

Results: The demographic characteristics and the significant results are summarized in Tables 1 and 2, with the roughest FDs identified as the strongest predictors of combined pain and radiographic progressor status. The associations were most evident between radiographic and pain progressors (Group 1) vs. non-progressors (Group 4) and vs. all other comparators (Groups 2, 3 and 4) for both the medial and lateral compartments at KLG2. The mean and roughest FDs were identified as the predictors of pain progressor status (1, 3 vs. 2, 4) and the roughest FD was identified as the predictor of any OA progressor status (1, 2, 3 vs. 4) for the lateral compartment at KLG2. The vertical and horizontal FDs were identified as predictors that differentiate structural progression without pain from pain progression without structural change (2 vs. 3) for the lateral compartment at KLG3.

Conclusion: The risk of radiographic OA and pain progression increases with increasing medial trabecular bone texture roughness in knee joints; the risk of radiographic OA and pain progression with lateral roughness is variable. Our results suggest that fractal bone texture analysis may serve as a potential biomarker for risk prediction for structural and symptomatic knee OA progression.

Abstract Number: 2101

LEVI-04, a Novel Neurotrophin-3 Inhibitor, Demonstrates Clinically Meaningful Improvements in Pain and Physical Function across a Range of OA Outcomes, Including the Staircase-Evoked Pain Procedure (StEPP)

Philip Conaghan[1], nathaniel katz[2], Asger Bihlet[3], Laus W Wullum[4], Kerry af Forselles[5], C Michael Perkins[5], Bernadette Hughes[6], Claire Herholdt[7] and Iwona Bombelka[8], [1]University of Leeds, Leeds, United Kingdom, [2]Rin Sof Innovation, Ltd, Boston, MA, [3]NBCD A/S, Herlev, Denmark, [4]Omicron A/S, Copenhagen, Denmark, [5]Levicept, Sandwich, United Kingdom, [6]Levicept, Ashtead, United Kingdom, [7]Levicept Ltd, Ashtead, United Kingdom, [8]Levicept, Sandwich, Kent, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2079–2105) Osteoarthritis – Clinical Poster II

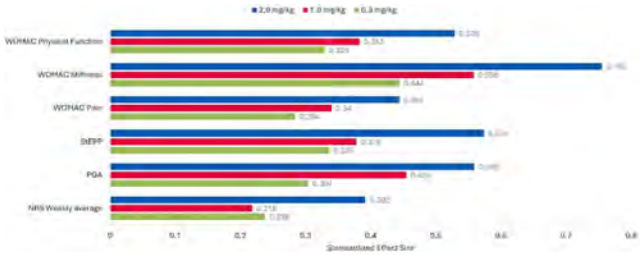
Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: When evaluating new osteoarthritis (OA) therapies, we need to understand their clinical meaningfulness. LEVI-04, a first-in-class p75 neurotrophin receptor-Fc fusion protein that primarily inhibits neurotrophin-3, demonstrated statistically significant benefits on pain and function in a phase II RCT in people with moderate-to-severe knee OA. Pain and physical function are usually assessed by patient-reported measures with varying recall periods and no allowance for variable activity levels. This trial also included the Staircase-Evoked Pain Procedure (StEPP) as a standardized measure of evoked pain on movement. The purpose of this study was to explore the clinical meaningfulness of improvements in pain and physical function with LEVI-04 and determine the proportion of participants achieving the minimum clinically important difference (MCID) in the StEPP for LEVI-04 compared to placebo.

Methods: These analyses were based on data from a multicentre, randomized controlled trial[1]. Adults with painful (≥4/10 WOMAC and ≥4/10 average weekly NRS pain), and radiographic (KL≥2) knee OA were included. Participants received IV placebo or LEVI-04 (0.3, 1.0 or 2 mg/kg) at baseline and every 4 weeks (wks) to wk16. The primary endpoint was change in WOMAC pain to wk17, with changes in WOMAC function, StEPP (where participants walk up and down a single, standardised stair 24 times, rating their pain intensity at the end), patient global assessment (PGA), WOMAC stiffness and average weekly NRS pain were also assessed. Clinical meaningfulness was examined using effect size, calculated using Cohen's d. The proportion of LEVI-04-treated participants achieving a MCID of 2 points in the StEPP (on a 0–10 NRS for pain severity after performing the task) was calculated.

Results: The primary results from this trial are presented elsewhere[1]. 518 participants were randomized to 0.3, 1.0, and 2.0 mg/kg LEVI-04 or placebo. LEVI-04 significantly improved the primary endpoint, WOMAC pain at wk17 for all doses vs placebo. Calculated effect sizes were greater with LEVI-04 vs placebo and increased with dose (Figure 1). Similarly, a greater



Standardized Effects (Cohen's d) by Outcome and Treatment Arm at Week 17

	0.3 mg/kg N = 111	1.0 mg/kg N = 110	2.0 mg/kg N = 113	Placebo N = 110
Achieved StEPP MCID, n (%)	71 (64%)	83 (75%)	86 (76%)	61 (55%)
Chi-square test vs placebo	0.29	0.046	0.0019	

StEPP, staircase-evoked pain procedure; MCID, minimum clinically important difference

Proportion of Participants who Achieve Minimum Clinically Important Difference in StEPP Assessment

proportion of participants achieved the MCID for the StEPP with higher doses of LEVI-04, and statistical significance from placebo was seen in LEVI-04 1.0 and 2.0 mg/kg groups (Table 1).

Conclusion: Effect sizes at or above those reported for NSAIDs[2] were observed with LEVI-04, especially with higher doses. LEVI-04 1.0 and 2.0 mg/kg resulted in significantly more patients achieving StEPP MCID, and at levels comparable or better than naproxen[3].Phase 3 trials are in planning.

Session Date: Tuesday, October 28, 2025
Session Title: (2079–2105) Osteoarthritis – Clinical Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Knee osteoarthritis (OA) significantly affects physical function, making function a core outcome in OA research. The Osteoarthritis Research Society International recommends the six-minute walk test (6MWT) as a performance-based measure of physical function in knee OA. Originally developed for cardiopulmonary conditions, the 6MWT is now used in OA populations, though its validity in this context remains unclear. Limited and conflicting evidence regarding its correlation with other function measures in OA raises questions about its utility and interpretation. This study aimed to evaluate the construct validity of the 6MWT in individuals with symptomatic knee OA and identify patient factors influencing six-minute walk distance (6MWD).

Methods: In this cross-sectional study within the BEST-Knee cohort, participants with knee OA completed standardized questionnaires and the 6MWT one month before total knee arthroplasty. Construct validity was assessed per COSMIN guidelines. Convergent validity was tested through hypothesized moderate-to-strong Spearman correlations ($r > 0.4$) between 6MWD and patient-reported physical function (KOOS-PS), pain (WOMAC pain subscale), and perceived walking

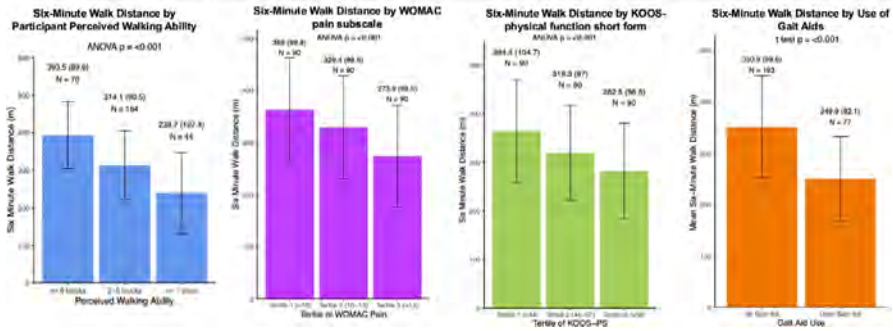
Figure 1: Associations Between Mean Six-Minute Walk Distance and Patient-Reported Measures of Knee OA Severity



Bars represent mean six-minute walk distance (6MWD) for each category. Error bars indicate standard deviations. Mean (standard deviation) and sample size (N) indicated for each bar.

ability (in blocks). Discriminant validity was tested examining correlation between 6MWD and the Lubben Social Network Scale, a measure unrelated to physical function. Known-groups validity compared 6MWD in participants who used gait aids versus not. A multivariable linear regression model assessed the association between demographic (age, sex), OA-related

Table 2: Multivariable linear regression analysis assessing the association between patient factors with the six-minute walk distance in individuals with knee osteoarthritis.

	Dependent variable: Six-minute Walk Distance		
Independent variables	**Beta-Estimate**	**95% Confidence Interval**	
Age, per year	-4.167	-5.467	-2.866
Female sex	45.018	22.802	67.234
Attainment of post-secondary education	21.215	0.336	42.094
WOMAC pain subscale (0-100), per unit	-1.147	-1.954	-0.341
KOOS-PS (0-100), per unit	-0.850	-1.688	-0.012
Number troublesome joints	2.009	-5.542	9.559
Presence of back pain	-5.693	-27.437	16.052
Obesity	-46.531	-68.525	-24.537
Number non-musculoskeletal comorbidities	-10.232	-19.851	-0.614
PHQ8 (depressive symptoms), per unit	-1.640	-4.233	0.954
Gignac Arthritis Coping Efficacy, per unit	5.135	1.605	8.666

Positive beta-estimates indicate greater walking distance associated with higher values or presence of the respective independent variable; negative estimates indicate reduced distance. Confidence intervals that do not include zero suggest statistically significant associations. KOOS-PS = Knee Injury and Osteoarthritis Outcome Score–Physical Function Shortform; WOMAC = Western Ontario and McMaster Universities Osteoarthritis Index; PHQ8 = Patient Health Questionnaire–8. Obesity was defined as a BMI ≥30 kg/m2

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(WOMAC pain, KOOS-PS), biomedical (symptomatic joints, comorbidities, obesity, back pain), and psychosocial (PHQ-8, coping, social network, education) factors with 6MWD.

Results: Among 278 participants (mean age 67 years, 65% female; Table 1), greater perceived walking difficulty, higher WOMAC pain, worse KOOS-PS, and gait aid use were associated with lower 6MWD (Figure 1). Correlations were moderate with perceived walking ability (ρ = -0.451, $p < 0.001$) and fair with WOMAC pain (ρ = -0.323, $p < 0.001$) and KOOS-PS (ρ = -0.328, $p < 0.001$). No correlation was seen with the Lubben scale (ρ = 0.067, $p = 0.281$) as hypothesized. In multivariable analysis, WOMAC pain, KOOS-PS, age, sex, obesity, comorbidities, education level, and arthritis coping were associated with 6MWD (Table 2).

Conclusion: While 6MWD declines with increasing OA symptom severity, its correlations with patient-reported function are only fair-to-moderate so we cannot confirm construct validity. Performance on the 6MWT is influenced by multiple biomedical and psychosocial factors which should be accounted for in knee OA research.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2079–2105) Osteoarthritis – Clinical Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Knee OA is a common disease affecting ~15 million people in the United States. There is an urgent unmet need for additional OA treatments as current treatments provide only short-term pain relief often associated with unwanted side effects and contraindications. Gene therapy using viral vectors has emerged as a novel therapeutic modality with the potential to treat many diseases. PCRX-201 (enekinragene inzadenovec) is a novel high-capacity adenovirus serotype 5 (Ad5) vector carrying a transgene encoding for the inflammation-inducible expression of IL-1 receptor antagonist (IL-1Ra) that is under investigation to treat knee OA via IA injection. This open-label phase 1 trial (NCT04119687) investigated the safety and efficacy of PCRX-201, for which long-term follow-up is ongoing.

Methods: Patients aged 30-80 years (N=72) with painful OA of the index knee and Kellgren/Lawrence (K/L) grade 2, 3, or 4 were eligible. The first group (n=36) received IA injection of PCRX-201 in the target knee at 1 of 3 doses (low: 1.4E10 genome copies [GC]; middle: 1.4E11 GC; high: 1.4E12 GC); the second group (n=36) was pretreated with IA methylprednisolone 40 mg immediately before PCRX-201 administration at the same doses. WOMAC pain (WOMAC-A) and stiffness (WOMAC-B) subscale scores and Knee Injury and Osteoarthritis Outcome Score Activities of Daily Living (KOOS ADL) were measured up to 156 weeks. Anti-Ad5 neutralizing antibody (NAb) titers in serum were measured at baseline before PCRX-201 administration and up to 52 weeks.

Musculoskeletal pain	0 (0)	0 (0)	0 (0)	2 (15.4)	0 (0)	2 (25)
Osteoarthritis	0 (0)	0 (0)	0 (0)	1 (7.7)	2 (13.3)	3 (37.5)
Synovial cyst	3 (25)	1 (6.2)	1 (12.5)	0 (0)	0 (0)	0 (0)

Data are the n (%), where n is the number of participants in each category. Participants who reported >1 TEAE are counted only once per category. N is the number of participants in each steroid-pretreatment status and dose cohort and is used as the denominator for percents.

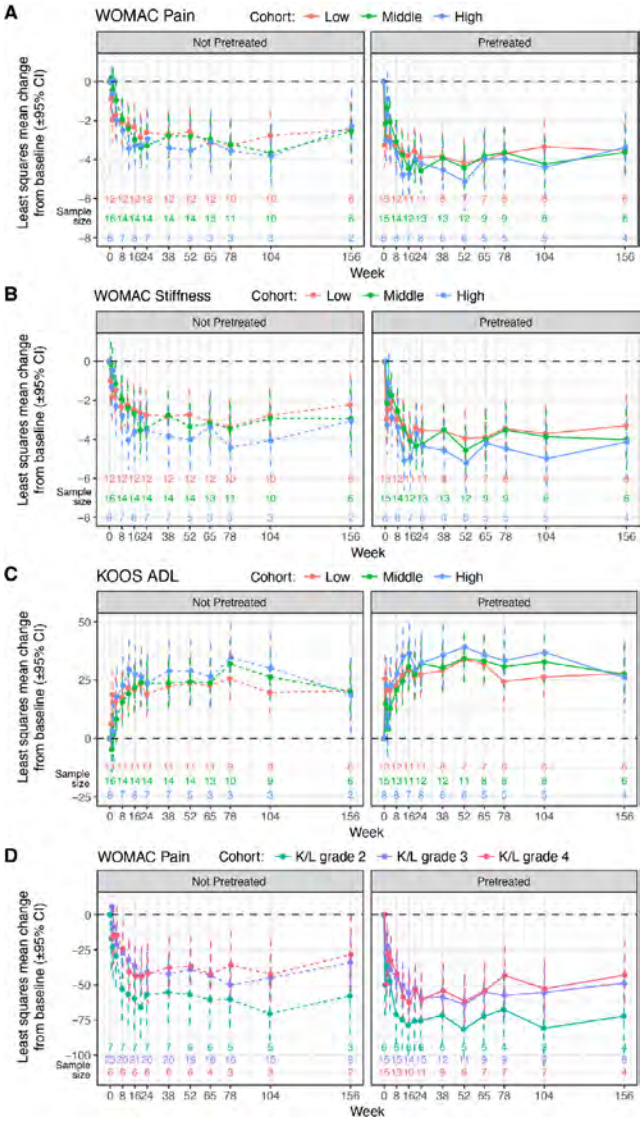

Figure 1. (A) WOMAC pain scores over time by dose for each cohort. (B) WOMAC stiffness scores over time by dose for each cohort. (C) KOOS ADL scores over time by dose for each cohort. (D) WOMAC pain scores by K/L grade for each cohort.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

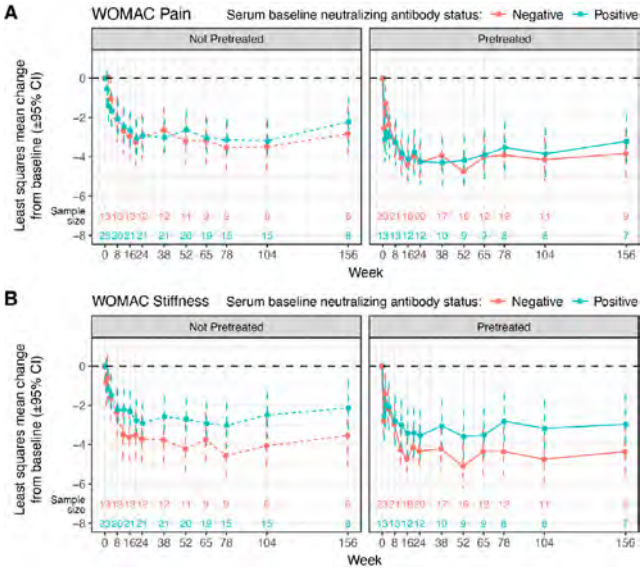

Figure 2. WOMAC pain scores (A) and WOMAC stiffness scores (B) by serum baseline neutralizing antibody status for each cohort.

Results: Pain and function improvements were observed at all doses and across both the not pretreated and corticosteroid pretreated groups up to 156 weeks after PCRX-201 IA administration (Figure 1). The pretreated group showed greater improvements for WOMAC-A (range of least squares mean [LSM] improvement from baseline across dose levels, 3.37-3.62 [of 10] points; Figure 1A), WOMAC-B (3.31-4.13 [of 10] points; Figure 1B), and KOOS ADL (Figure 1C) than the not pretreated group. Patients in the pretreated group with K/L grades of 2, 3, and 4 showed LSM reductions from baseline in WOMAC-A, with greater numerical reductions observed in those with K/L grade 2 than those with K/L grades 3 or 4 (Figure 1D). Importantly, preexisting serum NAbs did not affect PCRX-201 efficacy as determined by WOMAC-A pain (Figure 2A) and WOMAC-B stiffness (Figure 2B). The most commonly reported treatment-related adverse event (AE), index joint effusion, occurred less frequently for participants in the pretreated (15/36; 42%) than the not pretreated group (24/36; 67%) (Table 1).

Conclusion: A single IA injection of PCRX-201 with corticosteroid pretreatment in patients with knee OA had an acceptable safety profile and sustained clinical efficacy for up to 156 weeks. Preexisting NAbs did not affect PCRX-201 efficacy or safety at all 3 doses, and corticosteroid pretreatment demonstrated greater improvement in the clinical scores than no pretreatment. These results support the ongoing phase 2 study strategy of PCRX-201 with a 10-fold lower dose (1.4E11 GC) and steroid pretreatment.

Abstract Number: 2104

Pain 0-10 visual analog scale (VAS) and RAPID3 (routine assessment of patient index data) in OA and RA are similar in 2024 to 1979 and 1989

Theodore Pincus[1], Tengfei Li[2] and Juan Schmukler[1], [1]Rush University Medical Center, Chicago, IL, [2]Rush, chicago, IL

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2079–2105) Osteoarthritis – Clinical Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: A 1979 report by Huskisson, who developed the 0-10 pain visual analog scale (VAS) , entitled "Another look at osteoarthritis" indicated mean pain VAS scores of 5.3 in osteoarthritis RA (OA) and 5.25 in rheumatoid arthritis (RA) (Table). The earliest RAPID3 (routine assessment of patient index data) scores compiled in OA were 11.0 in 2009 and 11.7-13.6 in RA in 1989-2009. We analyzed subsequent databases from routine care which included pain and RAPID3 scores in patients with OA or RA, some of which also included 28 swollen joint counts (SJC) in patients with RA, presented to support credibility of the RA findings with recognized considerable improvement in inflammatory activity in RA, for comparisons of pain scores over time.

Methods: Available reports from routine care databases which included a 0-10 pain VAS in patients with RA or OA from 1979-2024, RAPID3 from 1989-2024, and 28 SJC in RA from 1985-2024 were compiled. Some reports presented mean and others median data; differences between median and mean values were less than 10% in reports which included both. Many reports were from a single investigator, and all but one of the databases were from the United States.

Results: Mean pain 0-10 VAS score reported in OA was 5.3 in 1979 and medians and means ranged from 3.9 to 7.0 through 2024, including 7.0 in 2024. Mean pain VAS in RA was 5.25 in 1979 and medians and means ranged from 2.5 to 5.5 through 2024, including 5.5 in 2024. Initial mean RAPID3 scores were 12.7 in OA and 13.6 in RA in 1989 (retrospectively computed according to group data); medians and means and ranged from 10.3 to 16.8 in OA and 6.2 to 13.3 in RA through 2024, including 14.0 in OA and 13.3 in RA in 2024. By contrast, mean SJC in RA was 12/28 in 1989 and ranged from 1.4 to 6.2 through 2024, including 1.4 in 2024 (data included to support credibility of non-SJC data).

Year	Pain VAS (0-10)		RAPID3 (0-30)		Swollen 28 Jt ct
	OA	RA	OA	RA	RA
1979	5.3	5.25	NA	NA	NA
1985	NA	5.2	NA	NA	12
1989	6.0	5.2	12.7	13.6	NA
1999	4.3	3.7	NA	10.5	NA
2000	NA	5.0	NA	NA	5
2009	4.0	3.6	11.0	11.7	2
2013	3.9	3.9	10.3	9.2	NA
2017a	7.0	4.3	16.8	9.7	NA
2017b	7.0	5.0	15.5	11.8	NA
2017c	5.0	4.7	11.7	11.0	NA
2017d	5.0	2.5	12.2	6.2	NA
2019	6.1	4.9	14.3	11.9	NA
2021	NA	NA	NA	8.2	2.7
2021	NA	NA	NA	7.6	6.2
2023	NA	4.6	NA	11.6	1.7
2024	7.0	5.5	14.0	13.3	1.4

Mean or median pain 0–10 visual analog scale (VAS) and 0-30 RAPID3 (routine assessment of patient index data) in routine care patients with osteoarthritis (OA) or rheumatoid arthritis (RA), and 28 swollen joint counts in RA from 1979 to 2024; initial and most recent values in each column are highlighted

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Mean or median pain scores were similar in reports of OA and RA databases over 45 years from 1979 to 2024. Furthermore, RAPID3 in OA and RA were similar over 35 years from 1989 through 2024, whereas mean SJC in RA declined from 12 to 1.4 over this period. These findings document the effectiveness of modern anti-inflammatory therapy for RA, but suggest that the perception of status and illness experience for most OA and RA patients have improved minimally over decades. Important limitations of this review include comparisons of mean or median scores, although results were within 10% in databases which included both mean and median, and that all databases were from the USA other than one from Australia. These results are presented in part to encourage reporting of pain scores in OA and RA to recognize and account for possible differences from data presented in this abstract, toward better care and outcomes for OA and RA patients.

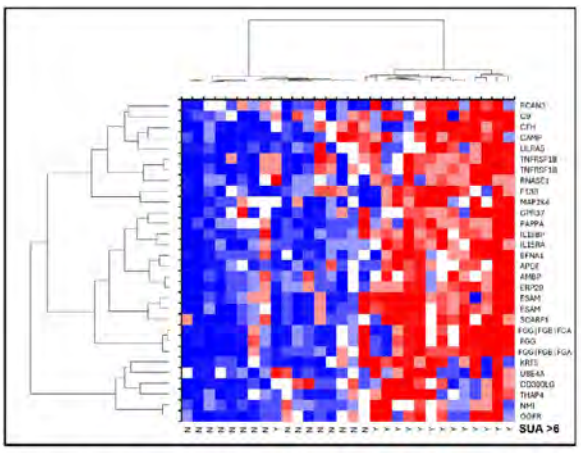
Stratification for elevated urate identifies a pro-inflammatory synovial fluid proteome in knee osteoarthritis: a pilot study

Tuhina Neogi[1], Sayali Dhamne[2], Robert Terkeltaub[3], Virginia Kraus[4], Simon Dillon[5] and Towia Libermann[5], [1]Boston University School of Medicine, Boston, MA, [2]Boston University Chobanian & Avedisian School of Medicine, Boston, MA, [3]Retired, San Diego, CA, [4]Duke University, Durham, NC, [5]Beth Israel Deaconess Medical Center, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2079–2105) Osteoarthritis – Clinical Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The causes of inflammation, pain fluctuations, and disease progression in osteoarthritis (OA) are not well understood. Soluble urate is a "danger signal", and synovial fluid urate and IL-18, which along with IL-1β is a product of NLRP3 inflammasome activation, are associated with OA severity on imaging (PMID: 21245324) . In a pilot study, we evaluated differences in proteomic profiles of OA synovial fluid stratified by serum urate among people with OA but without gout to examine potential distinct OA phenotypes. We further explored whether the profiles differed by obesity or age as potential confounders in the association between urate and OA.



*note: some proteins appear twice because >1 aptamer in SomaScan detected the particular protein

Figure 1: Hierarchical Clustering of the Top 30 proteins* that had an absolute fold-change of ≥1.3 and p<0.05 in differentiating the elevated urate group (>6mg/dL) from lower urate group

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

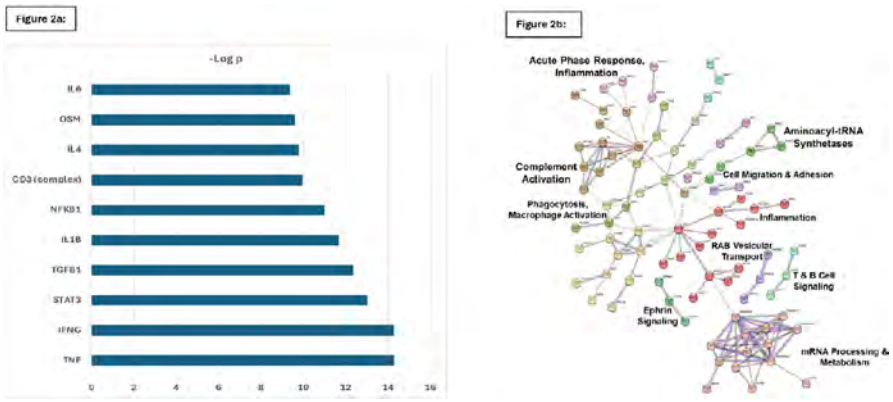


Figure 2a: Upstream Regulators identified with Ingenuity Pathways Analysis (IPA) from among the top 30 proteins that had an absolute fold-change of ≥1.3 and p<0.05 in differentiating the elevated urate group (>6mg/dL) from lower urate group based upon gene expression data. Proteins are listed in ascending order of statistical significance Figure 2b: Clusters of Protein-Protein Interaction Networks identified with STRING Analysis from among the top 30 proteins that had an absolute fold-change of ≥1.3 and p<0.05 in differentiating the elevated urate group (>6mg/dL) from lower urate group based upon protein expression data.

Methods: We obtained synovial fluid from individuals with knee OA but without a diagnosis of gout (and on no urate-lowering therapy) who had knee aspirations performed as part of standard clinical care (no crystals detected), and who consented to having their synovial fluid used for this pilot research study. The synovial fluid was immediately stored at 4°C, processed within 4 hours of collection, and then stored at -80°C. The samples were prepared with hyaluronidase and analyzed using the 11k SomaScan v5.0 proteomics assay that measures 10,778 proteins. Differentially expressed proteins were identified by t-tests and further evaluated using XLSTAT statistical software. Systems biology analysis used Ingenuity Pathway analysis (IPA) and STRING to define enriched pathophysiological pathways.

Results: We enrolled 30 participants (mean age 67 ± 11.6, 77% female, mean BMI 32.3 ± 6.9), of whom 47% (n=14) had serum urate >6 mg/dL (Elevated Urate Group (EUG). SomaScan analysis identified 186 proteins associated with the EUG that had an absolute fold change of at least 1.3 and p< 0.05. The top 30 proteins accurately discriminated between EUG and lower urate (Fig.1). IPA (Fig.2a) revealed enrichment of inflammatory response, particularly enhanced activity of the myeloid lineage and phagocytosis as key pathophysiological pathways in the EUG. Upstream regulator analysis confirmed that the predicted regulators with highest statistical significance involved enhanced activity of pro-inflammatory cytokines such as IL-1β and TNF and their downstream signaling mediators such as STAT3 and NFKB1. STRING analysis (Fig.2b) defined clusters of interacting proteins linked to inflammation, acute phase response, complement activation, and mRNA processing as key pathways. BMI-and age-associated protein signatures showed only limited overlap with the hyperuricemia-associated protein signature (Fig.3).

Figure 3: Venn Diagram comparing differentially expressed proteins identified with p<0.05 in the EUG vs. lower urate group, with differentially expressed proteins based upon obesity (BMI>30 vs. not) or Age (>65 vs. younger), demonstrating minimal overlap.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: The synovial fluid proteome associated with higher urate in patients with OA included differential upregulation of pathways related to inflammation, phagocytosis, and the complement cascade compared with those whose serum urate was lower than 6.0 mg/dL. Furthermore, the protein signature associated with the EUG had minimal overlap with synovial fluid protein signatures associated with obesity or older age. Elevated urate, a biomarker of OA disease severity, may therefore contribute to an inflammatory profile in OA synovial fluid.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2106–2123) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Most vertebral fractures (VFs) are asymptomatic. Vertebral Fracture Assessment (VFA) using DXA is a low-radiation method to detect morphometric vertebral fractures (MVFs). This study aimed to estimate MVF prevalence in Spanish adults aged ≥40 years and characterize affected individuals.

Methods: This population-based, cross-sectional study included individuals aged 40-80 years from 15 primary care centers across six Spanish provinces. VFA was performed with a mobile DXA unit (Hologic® Horizon W). Two rheumatologists independently evaluated vertebrae T10-L4 using Genant's method (grade 1: 20-25% height loss; grade 2: 26-40%; grade 3: >40%), resolving discrepancies by consensus. Bone mineral density (BMD), clinical data, and fracture risk factors were recorded. After VFs were identified, primary care centers reviewed spine imaging and clinical records, and interviewed patients to classify fractures as fragility, traumatic, or morphometric.

Results: Among 1082 participants (50.3% male; mean age 60.4 years), MVFs were found in 171 (16%), totaling 244 fractures.

MVFs were more frequent in men and associated with older age, prior fragility fractures, and osteoporosis. Proximal femur BMD was significantly lower in those with MVFs.

Fracture severity was grade 1 in 63%, grade 2 in 31%, and grade 3 in 6%, with higher grades linked to older age and lower BMD. Most MVFs were wedge-shaped (type A, 80%), followed by biconcave (type M, 18%) and crush (type P, 2%). Type A was more frequent in men and younger individuals; types M/P were linked to osteoporosis and lumbar location. Most MVFs occurred at the thoracolumbar region (D12-L2).

After review, 52 participants (4.8%) were classified as having clinical fragility VFs (CFVFs); 30 were undiagnosed, although 14 had prior radiographic evidence; 19 were traumatic and 100 morphometric VFs.

CFVFs were mostly grade 2, type A, and thoracolumbar; traumatic VFs were mainly grade 1 and type A; morphometric VFs were predominantly grade 1, type A, with a dorsal-thoracolumbar distribution. Grade 3 and type P were rare but more common in CFVFs.

CFVFs were more frequent in women and occurred at older age. They were associated with more prior non-vertebral fragility fractures, without significantly lower BMD or increased osteoporosis prevalence compared to other VF types.

Conclusion: In Spanish adults ≥40 years, MVFs were identified in nearly one-sixth of participants, more common in men and older individuals, and associated with lower BMD and prior fragility fractures. CFVFs represented an underdiagnosed subset, more prevalent among older women and associated with prior fragility fractures. Fracture characteristics differed by etiology.

Background/Purpose: Fracture Coordination Units typically function within a single hospital using a multidisciplinary approach. Our unit, established in February 2024, pioneers a model coordinating care between two hospitals: University Hospital of Donostia (UHD) and Matía Hospital (MH). It integrates Rheumatology (REU), Internal Medicine (I.M.), and

Traumatology at UHD, alongside Orthogeriatrics (OG) at MH, ensuring a patient-centered approach. Patients at UHD are assessed by I.M.; those with a geriatric profile transfer to MH for OG management, while others receive osteoporotic treatment from REU at UHD. After over a year of operation, evaluating clinical differences and therapeutic approaches between REU and OG group to understanding the impact of multidisciplinary coordination on patient care and osteoporosis treatment.

Methods: This study analyzes the clinical differences and management of patients treated by REU and OG between February 1, 2024, and April 15, 2025, using a cross-sectional descriptive design. Clinical, analytical, and treatment variables were collected, with statistical analyses performed in SPSS. Categorical variables were expressed as frequencies and percentages, continuous variables were presented as medians with confidence intervals. Chi-square and Mann-Whitney U tests assessed associations. Missing data were handled through regression-based imputation to ensure result integrity.

ZOL: Zoledronate; Dmab: Denosumab; TPTD: Teriparatide; ROMO: Romosozumab, ALN: Alendronate; ABL: Abaloparatide; PD: Pending

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Significant differences were observed between the RHE (n=192) and OG (n=249) groups. OG were older (87 vs. 80 years; p< 0.0001), and hip fractures were more prevalent (96.4% vs. 82.3%; p< 0.0001). Risk factors were more common in RHE, including early menopause (p=0.012), family history of hip fracture (p< 0.0001), smoking (p< 0.0001), and alcohol consumption (p=0.041). Previous fractures were more frequent in RHE (50.5% vs. 31.7%; p=0.023), with greater variability in fracture count (Table 1).

Biochemically, RHE showed higher serum calcium levels (9.3 mg/dL vs. 8.9 mg/dL; p< 0.0001), while OG had slightly higher total protein levels (6.2 g/dL vs. 6 g/dL; p=0.009) (Table 2).

Discharge treatment, RHE patients received higher rates of calcium and vitamin D supplementation (94.3% vs. 61.4%; p< 0.0001) and osteoporosis therapy (79.2%; p< 0.0001). Zoledronate and denosumab were more commonly prescribed in RHE, while alendronate was the predominant treatment in OG. Reasons for lack of treatment differed between groups: in RHE, the primary reason was pending bone mineral density (BMD) evaluation before initiating therapy (65% vs. 4.7%; p< 0.0001). In OG, limited life expectancy was the most cited reason (41.27%) (Table 3).

Conclusion: These findings highlight distinct management approaches: REU follows a structured osteoporosis treatment strategy, while OG prioritizes patient stability. Higher fracture prevalence in REU correlates with greater risk factors, and rheumatologists tend to be more precise in fracture identification than geriatricians. A multidisciplinary approach is essential for optimizing osteoporosis care and tailoring treatments effectively.

receive Rheumatology management at UHD. This study analyzes fragility fracture (FF) risk factors and compares clinical differences between patients with and without previous fractures (pFF) admitted from February 2024 to April 2025.

Methods: A cross-sectional descriptive study was conducted. Clinical, analytical, and treatment variables were collected and processed using the SPSS statistical software. Categorical variables were presented as frequencies and percentages, while continuous variables were expressed as medians with confidence intervals. Associations were evaluated using Chi-square and Mann-Whitney U tests, while ANOVA, logistic regression, and multinomial regression were applied to identify factors related to FF.

Table 2: Location and Age Distribution of Previous Fragility Fractures

Location of pFF	1st FF	2nd FF	3rd FF	4th FF	5th FF
Hip	35 (19.9%)	7 (3.98%)	3 (1.70%)	1 (0.57%)	
Humerus	12 (6.82%)	6 (3.41%)	4 (2.27%)	1 (0.57%)	
Radius	35 (19.9%)	4 (2.27%)	5 (2.84%)	2 (1.14%)	
Pelvis	9 (5.11%)	7 (3.98%)	1 (0.57%)	2 (1.14%)	2 (1.14%)
Vertebra	45 (25.6%)	26 (14.77%)	14 (7.95%)	10 (5.68%)	6 (3.41%)
Multiple	31 (17.61%)	11 (6.3%)	9 (5.11%)	1 (0.57%)	1 (0.57%)
Missing	9 (5.1%)	115 (65.3%)	140 (79.5%)	159 (90.3%)	167 (94.9%)
Age at pFF	75 (57-80)	75 (59-80)	75 (59-83)	75 (63-85)	77 (63-86)

Results: A total of 176 patients with pFF and 218 without were analyzed. Women were more prevalent in pFF group (88.1% vs. 68.8%, $p < 0.0001$). Hip fractures were the most common in both groups ($p = 0.108$). Early menopause was more frequent in pFF (9.7% vs. 3.7%, $p < 0.0001$), as were familial hip fractures ($p = 0.006$). Prior osteoporosis treatment was more common in pFF group (28.4% vs. 3.2%, $p < 0.0001$) (Table 1).

Most patients had one pFF (59.1%), while 14.8% had two, 10.2% had three, and 9.09% had between four and six (Table 2).

Biochemical analysis showed no significant differences in calcium or phosphorus levels. Total protein levels were lower in pFF ($p = 0.028$), PTH was significantly reduced (44.5 pg/mL vs. 50 pg/mL, $p = 0.029$), while vitamin D was lower in both group (14 ng/mL vs. 11.5 ng/mL, $p = 0.012$).

Upon discharge, Ca + VitD supplementation was more frequent in pFF group (86.4% vs. 81.2%, $p = 0.040$). Differences in prescribed treatments were significant ($p < 0.0001$), with a higher prescription rate of ZLN and Dmab in pFF group.

Age was the key factor in FF, with medians of 85 years for hip fractures, 72.5 for humerus, and 65 for others ($p < 0.0001$). PTH was highest in multiple fractures ($p = 0.013$), while TSH showed a marked increase in vertebral FF ($p < 0.0001$). Dairy intake, alcohol consumption, and smoking had no significant impact ($p > 0.05$). Regression analysis confirmed that hip fracture risk increases by 15.6% per year ($p = 0.015$, OR = 1.156) (table 3).

Table 3: Distribution of Demographic, Clinical, Biochemical, and Treatment-Related Characteristics in Patients Hospitalized for Different Types of Fractures

Variable		Type of fracture						p-value
		Hip (n=398)	Humerus (n=19)	Radius (n=3)	Vertebra (n=2)	Multiple (n=9)	Others (n=8)

Conclusion: The results reveal significant differences between the groups. Women, with early menopause or a family history of hip FF, face a higher risk. Both groups had insufficient VitD, emphasizing the need for better detection and treatment. Prior osteoporosis treatment was more frequent in pFF group, where fracture recurrence underscores the importance of adherence and treatment optimization.

In the pFF group, the first FF occurred at a median age of 75 years. As fracture count increased, tracking patient history became more challenging.

The multinomial logistic regression model confirms age as the primary determinant of fracture risk.

These findings highlight the need for prevention and clinical monitoring, as patients with a pFF are at greater risk of future fractures.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2106–2123) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Individuals with giant cell arteritis (GCA) and polymyalgia rheumatica (PMR) are at increased risk for osteoporosis and fragility fractures due to long-term glucocorticoid (GC) use and underlying Interleukin-6 (IL-6)–driven inflammation. IL-6 inhibition is an effective treatment that also reduces GC exposure. In rheumatoid arthritis, IL-6 receptor blockade with tocilizumab reduces bone resorption markers and increases femoral neck bone mineral density (BMD). However, longitudinal data on the effects of IL-6 blockade on bone health in large-vessel vasculitis are lacking, and no study has yet compared its impact to methotrexate (MTX) or GC monotherapy.

This study aimed to compared the effects of IL-6 inhibition, MTX and GC monotherapy on bone health in patients with GCA and PMR.

Methods: This longitudinal analysis uses data from the prospective Rh-GIOP study at Charité–Universitätsmedizin Berlin (2015–2024). Patients with GCA or PMR undergoing osteoporosis checkup were included up to the second follow-up visit. Bone health was assessed using dual-energy X-ray absorptiometry (DXA), trabecular bone score (TBS), 3D structural femur parameters (3D-Shaper v2.12), and bone turnover markers (bone-specific alkaline phosphatase, osteocalcin and desoxypyridinoline [DPD]).

Linear mixed-effects models were used to assess associations between treatment (IL-6 inhibitors, MTX, GC monotherapy) and bone outcomes, adjusting for age, sex, BMI, GC dose, erythrocyte sedimentation rate (ESR), prior fragility fractures, and anti-osteoporotic therapy. Estimated marginal means compared adjusted group differences.

Results: A total of 203 patients (81 with GCA; mean age 72 years; 66% female, all postmenopausal) were included. At baseline visit for osteoporosis check-up 22 received IL-6 inhibitors (21 tocilizumab, 1 Sarilumab), 36 MTX, and 131 GC monotherapy; 14 received no immunosuppressive treatment. Seventy-five patients had at least one follow-up visit (mean follow-up: 2.6 ± 1.3 years), and 27 had a second (4.6 ± 1.3 years). Osteoporosis by DXA and fragility fracture prevalence at baseline were 20% and 36%, respectively. Baseline characteristics were balanced across treatment groups.

Table 2: Estimated marginal means (EMM) for the comparison between GC monotherapy and IL-6 inhibition vBMD: volumetric bone mineral density

Table 2: Estimated marginal means (EMM) for the comparison between GC monotherapy and IL-6 inhibition

vBMD: volumetric bone mineral density

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Male sex and higher BMI were positively associated with lumbar spine T-scores (estimate: +1.427, SE: 0.235, p < .005; and +2.754, SE: 0.028, p = .007), femoral T-Scores and bone structure. Higher age correlated with increased DPD levels (+0.071, SE: 0.036, p = .048).

No significant overall effect was observed for IL-6 inhibitors, MTX, or GC treatment. However, compared to IL-6 inhibitors, GC monotherapy was associated with lower cortical volumetric BMD (–20.38, SE: 9.41, p = .036) and integral vBMD (–13.9, SE: 4.96, p = .006). No significant differences were found between IL-6 inhibitors and MTX, nor between MTX and GC monotherapy.

Conclusion: In patients with GCA and PMR, sex and BMI were key predictors of BMD and femoral bone structure. Treatment with IL-6 inhibitors was associated with more favorable cortical and trabecular bone parameters than GC monotherapy. This suggests that GC-sparing IL-6 blockade may help preserve bone microarchitecture in patients with inflammatory vasculitis.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2106–2123) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with inflammatory rheumatic and musculoskeletal diseases (iRMDs) are at increased risk of osteoporosis and fragility fractures due to systemic inflammation and glucocorticoid (GC) use. Proton pump inhibitors (PPIs), frequently prescribed in this population, have also been linked to fracture risk, although findings remain inconsistent. Our previous cross-sectional analysis suggested a negative impact of PPIs on bone mineral density (BMD) but not on microarchitecture in iRMDs.

This study aimed to assess the longitudinal effects of PPI use on BMD and bone microarchitecture.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: The prospective Rh-GIOP cohort includes patients with iRMDs fulfilling German guidelines for osteoporosis check-up. Participants underwent dual-energy X-ray absorptiometry (DXA) and evaluation of microstructure by trabecular bone score (TBS) and 3D-DXA. This analysis included all patients with IRMDs who had data available up to the second follow-up visit (2015–2024). Follow-up timing was determined by clinical routine. Patients with manifest hyperparathyroidism and hyperthyroidism were excluded.

Daily intake of PPI was ascertained via chart review and self-report. As-needed PPI use was combined with regular use to form the composite variable "any PPI use". Primary outcomes were T-scores at the lumbar spine, total hip, TBS and 3D-DXA parameters of the femur. Linear mixed-effects models assessed the effect of any PPI use as well as daily PPI use on the primary outcomes and were weighted by propensity scores accounted for potential confounders such as age, sex, BMI, GC dose, C-reactive protein, disability and comorbidity. Missing data was handled by multiple imputation (predicitive mean matching).

Results: At baseline, 1,909 patients (74% women; mean age 63 ± 13 years) were included; 45% reported daily and 51% any PPI use. 713 had at least one follow-up (mean 2.7 ± 1.3 years), and 267 had a second (mean 4.6 ± 1.4 years).

Any PPI use was associated with lower T-Scores at the lumbar spine (estimate: –0.115; standard error (SE): 0.052; P = .029). In contrast, total hip T-Score was not significantly affected by any PPI use (–0.027; SE: 0.024; P = 0.258) or daily use (–0.038; SE: 0.026; P = 0.37). TBS was related to a negative impact by any PPI use (–0.017; SE: 0.006; P = .004), and daily use (–0.021; SE: 0.006; P = .001). Femoral cortical thickness was also negatively affected by both any PPI use (–0.012; SE: 0.006; P = .050) and daily PPI use (–0.015; SE: 0.006; P = .017).

Adjusted interaction analysis showed that PPI-related reduction in TBS also occurred in low-dose GC users (0-7.5 mg/day), suggesting a synergistic impact. For cortical thickness, PPI effects were particularly relevant in the absence of GC use.

Daily PPI use was further linked to lower calcium levels (–0.010; SE: 0.004; P = .016) and higher parathyroid hormone levels (2.275; SE: 0.964; P = .019).

Conclusion: Our results indicate that PPIs may also impair bone microarchitecture in patients with iRMDs. This effect appears to be most prominent in individuals without GC use or on low-dose GCs, potentially linked to reduced calcium absorption. This underscores the need for cautious PPI use, especially in patients already at high risk for osteoporosis.

Abstract Number: 2111

Cost-effectiveness Analysis of Biosimilar Denosumab for the Treatment of Women with Post-menopausal Osteoporosis in the United States: A Risk Based Analysis

Edward Li[1], Rebecca McTavish[2], Fatemeh Mirzayeh fashami[2], Sarah Kane[2] and Marion Schauf[3], [1]Sandoz Inc., West Princeton, NJ, [2]EVERSANA, Burlington, ON, Canada, [3]Sandoz International GmbH, Holzkirchen, Bayern, Germany

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2106–2123) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Post-menopausal osteoporosis (PMO) significantly increases the risk of fractures in women, necessitating effective treatment strategies. The introduction of biosimilar denosumab offers the opportunity to re-evaluate the value of common treatments for PMO. This study evaluates the cost-effectiveness of biosimilar denosumab versus bisphosphonates and no intervention across groups of women with PMO who have different underlying risks of fracture.

Methods: A previously developed Markov model was used. Subjects were stratified to 4 risk categories (i.e., from risk 1 [lowest risk] to risk 4 [highest risk]) based on occurrence of a prior vertebral fracture (yes/no) and T-score (-2.5 or ≤ -2.5; **Table 1**). Model inputs, including baseline fracture risks, drug efficacy, administration costs, and utility values were estimated from publicly available data and literature. Biosimilar drug acquisition costs were assumed, based on trends of previously available biosimilars. The incremental costs, incremental quality-adjusted life-years (QALYs), and incremental cost-utility ratio (ICUR) were calculated from a US payer perspective.

Table 1: Stratification of Women with Post-Menopausal Osteoporosis and the Related Relative Risks of Fracture Used in the Model

Risk Category	Prior VF	T-score	Age Group	Relative Risk of Fracture			
				HF	VF	WF	OF
Risk 1	No	-2.5	65 – 69	1.82	1.21	1.06	1.06
			70 – 74	1.42	1.04	0.94	0.94
			75 – 79	1.11	0.89	0.82	0.82
			80 – 84	0.86	0.76	0.73	0.73
			85 +	0.66	0.65	0.64	0.64
Risk 2	No	≤ -2.5	65 – 69	3.51	2.34	2.05	2.05
			70 – 74	2.95	2.16	1.96	1.96
			75 – 79	2.43	1.97	1.81	1.81
			80 – 84	2.09	1.85	1.77	1.77
			85 +	1.8	1.58	1.56	1.56
Risk 3	Yes	-2.5	65 – 69	3.90	4.29	1.59	1.59
			70 – 74	3.04	3.69	1.41	1.41
			75 – 79	2.36	3.16	1.23	1.23
			80 – 84	1.84	2.70	1.10	1.10
			85 +	1.41	2.31	0.96	0.96
Risk 4	Yes	≤ -2.5	65 – 69	7.51	8.31	3.08	3.08
			70 – 74	6.31	7.67	2.94	2.94
			75 – 79	5.20	7.00	2.72	2.72
			80 – 84	4.47	6.57	2.66	2.66
			85 +	3.42	5.61	2.34	2.34

Abbreviations: HF = hip fracture; OF = other fractures; VF = vertebral fracture; WF = wrist fracture.

Table 2: Deterministic Results for Women with Post-Menopausal Osteoporosis Across Different Fracture Risk Categories

Risk Category	Outcome	Biosimilar Denosumab vs. Alendronate	Biosimilar Denosumab vs. Risedronate	Biosimilar Denosumab vs. Ibandronate	Biosimilar Denosumab vs. Zoledronic acid	Biosimilar Denosumab vs. No intervention
Risk 1	Incremental QALYs	0.021	0.021	0.021	0.015	0.026
	Incremental costs	$5,748	$5,444	$5,647	$5,561	$5,597
	ICUR ($ per QALYs)	$272,031	$257,435	$273,624	$364,346	$213,660
Risk 2	Incremental QALYs	0.042	0.042	0.041	0.030	0.052
	Incremental costs	$4,445	$4,123	$4,318	$4,430	$4,036
	ICUR ($ per QALYs)	$105,129	$97,572	$104,149	$149,478	$77,088
Risk 3	Incremental QALYs	0.051	0.051	0.050	0.034	0.063
	Incremental costs	$4,294	$3,967	$4,208	$4,419	$3,854
	ICUR ($ per QALYs)	$83,755	$77,550	$83,660	$130,787	$60,976
Risk 4	Incremental QALYs	0.091	0.090	0.090	0.059	0.112
	Incremental costs	$1,160	$792	$1,070	$1,838	$107
	ICUR ($ per QALYs)	$12,799	$8,760	$11,925	$31,337	$954

Abbreviations: ICUR = incremental cost-utility ratio; QALYs = quality-adjusted life-years.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: The use of biosimilar denosumab in women with PMO across risk categories 1, 2, 3, and 4 resulted in ICURs of $272,031, $105,129, $83,755, and $12,799, respectively, compared to alendronate. When compared to no intervention, biosimilar denosumab yielded ICURs of $213,660, $77,098, $60,976, and $954 for risk categories 1, 2, 3, and 4, respectively. This trend was consistent across all other comparators, demonstrating that as fracture risk increases, the ICURs for biosimilar denosumab compared to bisphosphonates and no intervention decrease (**Table 2**). Further decreases in biosimilar denosumab price led to improved cost-effectiveness and in some cases, domination.

Conclusion: Relative to common willingness-to-pay thresholds of $100,000 and $150,000, biosimilar denosumab is cost-effective for patients in risk categories 2, 3 and 4 when compared to bisphosphonates and no intervention in the treatment of PMO.

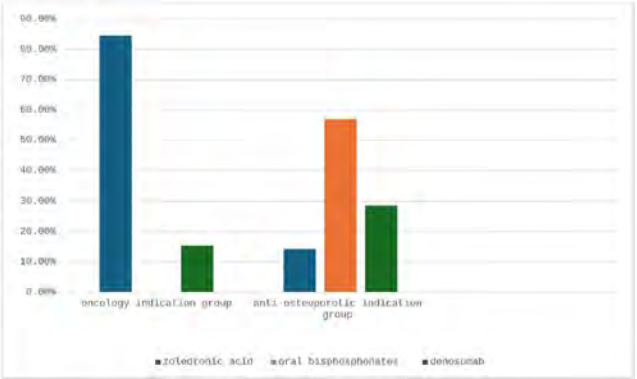
Abstract Number: 2112

Which drugs are associated with the development of osteonecrosis of the jaw? clinical and epidemiological analysis of a cohort of patients diagnosed with osteonecrosis of the jaw.

Esther Monleon Acosta[1], Alicia Pérez González[2], José Andrés Rodríguez Fernández[2], Pedro José Manuel Hernández[2], María del Rosario Oliva Ruiz[2], José María Andreu Ubero[2], Paloma Valentina Castillo Dayer[2], Gloria Albaladejo Paredes[3], Carlos Fernández Díaz[4], Angela Egea Fuentes[2], Montserrat Fernández Salamanca[2] and Vicente Cogolludo Campillo[5], [1]Hospital Santa Lucia, Cartagena, Spain, [2]Hospital General Universitario Santa Lucia, Cartagena, Spain, [3]Hospital General Universitario Santa Lucia, CARTAGENA, Spain, [4]H.U. Santa Lucia, Murcia, Spain, [5]Hospital General Universitario Santa Lucia, Santa Lucia, Cartage, Spain

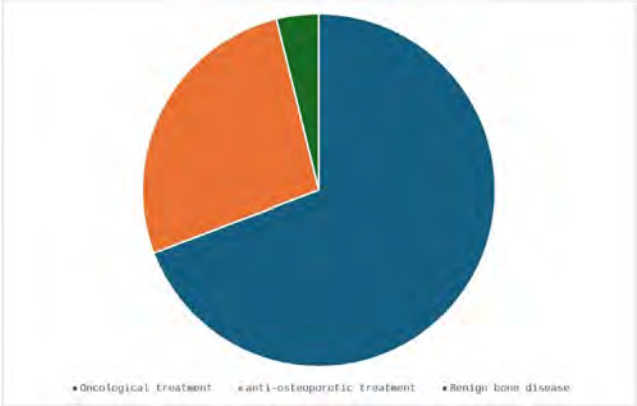
SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2106–2123) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Osteonecrosis of the jaw (ONJ) is defined as avascular necrosis of bone located in the maxillofacial region with the presence of exposed bone or bone accessible through an extra or intraoral fistula that does not heal within 8 weeks and excludes osteoradionecrosis secondary to radiotherapy. ONJ can be secondary to drugs and it is referred to



1. Distribution of cases of MRONJ according to antiresorptive drug and clinical indication.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



2. Distribution of patients (with MRONJ) treated with bisphosphonates according to clinical indication.

Medication-related osteonecrosis of the jaw (MRONJ). To define a MRONJ is required a current or previous treatment with antiresorptive therapy alone or in combination with immune modulators or antiangiogenic medications.

With this study we want to analyse which drugs are associated with the development of MRONJ as well as to describe the clinical and epidemiological characteristics of patients diagnosed with MRONJ.

Methods: A descriptive, observational and retrospective study was carried out at the Santa Lucia hospital in Cartagena. Individuals with MRONJ was collected from 2015 to 2024 at the Santa Lucia Hospital, in Cartagena. Clinical-epidemiological variables were collected and a statistical analysis was carried out using SPSSv21.

Results: 24 individuals with a diagnosis of MRONJ was collected. Fifty-six per cent of the blind were women and the remainder (44 per cent) were men. The average age was 69 +- 13.2 years. Of these patients 56% were hypertensive, 20% diabetic, 32% had dyslipidaemia and 12% had stage 3-4 chronic kidney disease. 78.1% of the individuals had an underlying oncological disease and 4.9% had a rheumatological disease. Of all people, 22% had previously had an invasive dental procedure.

At the time of MRONJ diagnosis, 100% of the individuals were being treated with antiresorptive drugs: 85.2% were treated with bisphosphonates and 14.8% with denosumab. The average treatment time with these drugs was 4.15 +- 3.7 years.

Of those on bisphosphonate therapy, 66.6% were on intravenous bisphosphonates (zoledronic acid) and the remainder on oral therapy (11,1% risendronate, 11,1% Alendronate and 11,1% other). These treatments were indicated as oncological treatment in 69.23% of cases, while only 26.9% were used as anti-osteoporotic treatment. In 3.87% of cases they were indicated as a treatment for benign bone disease.

In the oncology indication group, 84.6% of the MRONJ cases were due to the use of zoledronate, while in the anti-osteoporotic indication group only 14.2% of the MRONJ cases were caused by zoledronate. These differences were statistically significant ($p< 0.001$). Therefore, the development of ONMR in patients treated with zoledronate was more frequent when it was used as an oncology treatment.

In the anti-osteoporotic indication group the 57,8% of the patients with MRONJ were on oral bisphosphonate therapy and 28,57% with denosumab.

Conclusion: The drug most associated with the development of MRONJ in our sample of patients was zoledronic acid, being the development of this entity much more frequent when it is administered as an oncological treatment. Therefore, it could be hypothesised that the risk of MRONJ does not depend so much on the drug as on the indication and administration schedule, but more studies are needed to clarify the association between MRONJ and the different drugs.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2106–2123) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Hip fracture is the second most common osteoporotic fracture and the one with the highest socio-economic cost. It is associated with high morbidity and mortality rates, reaching a mortality rate of 30% in the first year. It should be noted that the presence of a fracture with an osteoporotic profile is one of the most important risk factors for the appearance of new fractures. Despite this, less than 25% initiate treatment for osteoporosis (OP). These data reflect the importance of applying both primary and secondary prevention measures, as well as the creation of fracture units (FU).

With this study we want to evaluate the need to establish a fracture unit as well as a system of referral to rheumatology after the existence of a fragility fracture. And secondly, to analyse the clinical-epidemiological characteristics of a cohort of patients with a history of osteoporotic hip fracture.

Methods: A descriptive, observational and retrospective study was conducted at the Santa Lucia hospital in Cartagena. Individuals with osteoporotic hip fracture were included from January 2017 to January 2023. A total of 28 clinical-epidemiological variables were collected and a statistical analysis was carried out using SPSSv21.

Results: 615 patients were collected, 72.8% of whom were women and 27.2% men. The mean age was 81 ±10.5 years. 72.5% were hypertensive, 41.5% were dyslipidaemic and 68.8% diabetic. 17.8% were diagnosed with chronic kidney disease , with Stage 3 being the most frequent.

Table 1. Summary of the percentage of individuals with osteoporotic treatment and supplements before and after suffering an osteoporotic hip fracture (OP: osteoporosis, Ca/VitD; calcium/vitamin D).

	YES	NO
Previous OP treatment	2,7%	97,4%
Previous Ca/VitD supplementation	11,9%	88,1%
Later OP treatment	11,8%	88,2%
Later Ca/VitD supplementation	38,3%	61,7%

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 2. Summary of epidemiological, clinical and therapeutic characteristics of patients who suffered an osteoporotic femoral neck fracture.

CLINICAL-EPIDEMIOLOGICAL CHARACTERISTICS	% OF PATIENTS IN WHOM THEY ARE PRESENT
Women	72,8%
Men	27,2%
Hypertension	72,5%
Dyslipidaemia	41,5%
Diabetes	68,8%
Chronic kidney disease	17,8%
Rheumatological pathology	2,76%
Oncological pathology	13,17%
Haematological pathology	3,08%
Respiratory pathology	8,78%
Previous osteoporotic fracture	22,1%
Surgical treatment	95,9%
Exitus during admission	6,8%
Mortality at 5 years	43,8%%
Subsequent osteoporotic fracture	24,3%
Follow-up in rheumatology	7,95%
Follow-up in Rehabilitation	23,21%
Follow-up in geriatrics	19,48%

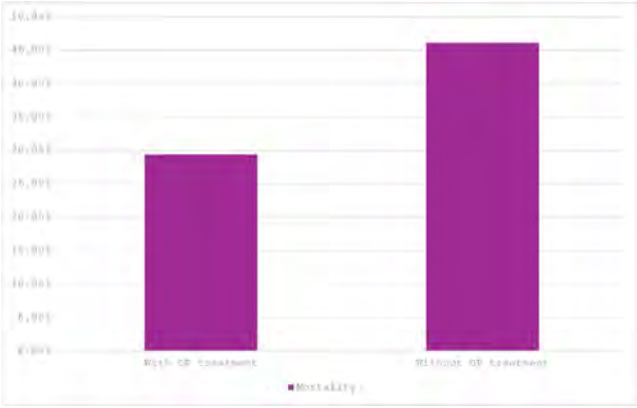
2.27% of the individuals who suffered a hip fracture had previously been prescribed osteoporotic treatment, despite the fact that 22.1% of them had a history of previous osteoporotic. 11.9% were taking calcium and vitamin D supplements and none underwent a densitometric study.

After the hip fracture, 38.3% started calcium and vitamin D supplements and 11.8% osteoporotic treatment. 24.3% of the individuals suffered a new osteoporotic fracture, the most frequent location being at the vertebral level followed by the hip. Of the patients who suffered new fractures, 76.69% were not receiving osteoporotic treatment.

Mortality during hospital admission was 6.8%, at one year it was 23.6%, at 3 years 39.7% and at 5 years 43.8% of the individuals. When we analysed mortality according to the establishment of osteoporotic treatment after hip fracture, we found a mortality rate of 28.3% in those in whom osteoporotic treatment was established, rising to 45.8% when it was not, these differences being statistically significant (p=0.21). It should be noted that only 3.1% of the individuals had been referred to rheumatology.

Conclusion: Osteoporotic treatment had been prescribed in only 2.27% of the cases, despite the fact that 22.1% of the individuals had already suffered a previous fragility fracture. After the hip fracture, osteoporotic treatment was initiated in 11.8% of the individuals, finding in these individuals a lower mortality at 5 years compared to those in whom it was not

Table 3. Percentage of mortality at 5 years according to having received osteporotic treatment after hip fracture (OP: osteoporosis).



23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. initiated. Bearing these data in mind, it would be advisable to set up a fracture unit for the assessment of osteoporotic treatment by a doctor with expertise in bone metabolism, as well as the establishment of a referral system after suffering a fracture of this type.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2106–2123) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Fragility fractures are a critical outcome for people ageing with HIV (PAH). Studies demonstrate higher prevalence, incidence, and earlier onset than for the general population. Current fragility fracture prediction models for the general population underestimate risk in PAH. To address this gap, we developed one- and three-year predictive models for risk of fragility fracture that better capture risk among PAH.

Methods: We used data from the Veterans Aging Cohort Study (VACS), a national electronic health records-based cohort that includes all individuals diagnosed with HIV receiving care within the Veterans Health Administration. We included all PAH (≥50 years of age) and followed them from 01/01/2009 through 12/31/2019. Observations consisted of one-year person-intervals and three-year person-intervals. Fragility fracture outcomes (at the spine, hip/femur, wrist/forearm, and shoulder/upper arm) were identified using validated ICD9 and ICD10 codes. From an initial pool of 27 candidate predictors (including HIV-specific variables) selected from the literature, clinical experience, and prior research, multivariable logistic regression chose 15 predictors that were subsequently reduced to a set of 10 based on statistical criteria and feedback from HIV providers. This feedback motivated two versions of each model that permit optional inclusion of race.

Results: The cohort included 32,842 individuals contributing a total of 223,607 person-years of data. **Table 1** shows the distribution of the 15 short-listed candidate predictors in the first year of follow-up. Over the follow up period, there were 2,355 incident fractures. The ten final predictors, with odds ratios from the one year model, included: age OR = 1.02 (95% CI 1.01 – 1.02), albumin OR = 0.7 (0.64 – 0.76), alcohol use ≥3 drinks per day OR = 1.19 (1.11 – 1.27), BMI OR = 0.96 (0.95 – 0.97), chronic medication count OR = 1.05 (1.05 – 1.06), COPD OR = 1.36 (1.23 – 1.50), fall in previous year OR =

[a] p<0.01; [b] p=0.12; [c] p=0.49

P-values derived from t-test for age, albumin, BMI, and chronic medication count, Fisher's exact test for female sex, chi-square test for all others

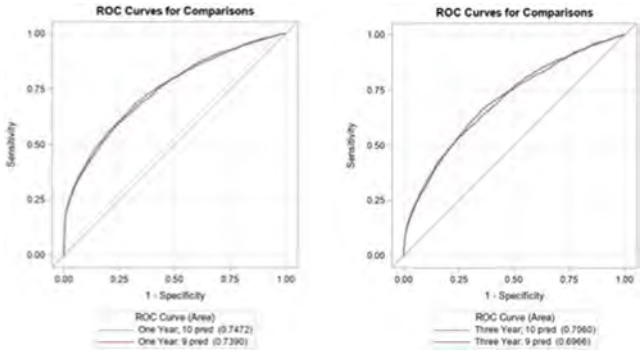

Figure 2. Receiver Operating Characteristic (ROC) Curves of Models for Risk of Fragility Fracture in One- (left) and Three-Year (right) Periods.

1.57 (1.35 – 1.82), female sex OR = 1.66 (1.33 – 2.08), fracture in previous year OR = 15.46 (13.45 – 17.77), and nonwhite race OR = 0.62 (0.57 – 0.68). The one-year and three-year models with race exhibited good discrimination, with areas under the curve (AUC) of 74.7% and 70.6%, respectively. For the models without race, the AUCs were 73.9% and 69.7% for the one- and three-year models. **Figure 1** presents the ROC curves for all four models; all four exhibited excellent calibration.

Conclusion: Based upon rigorous statistical analysis and provider input, we present a new risk prediction model for fragility fracture that is statistically robust and uniquely optimized for the care of PAH. Future studies will externally validate this model using datasets from outside the VA.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2106–2123) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Methotrexate-induced osteopathy is a rare condition. The clinical presentation is often typical, associating lower limb involvement with metaphyseal bone fractures/cracks, mainly of the tibia or foot bones. The main aim of this study was to identify the affected population and to better describe patients and fracture characteristics and possible risk factors leading to poor clinical evolution.

Methods: We conducted a multicenter retrospective study including all patients identified by a GRIO (osteoporosis research and information group, group of osteoporosis and bone disease specialists) member as a MTX-induced osteopathy. Were included all patients with suggestive clinical and/or imaging presentation, confirmed by a bone expert. Patients not already included and identified by national pharmacovigilance as being suggestive of methotrexate-induced osteopathy were also included, after analysis of the medical file by the principal investigator. The data collected included imaging features (characteristic, location and evolution of the bone lesions), clinical (search for classic causes and risk factors for bone fragility, treatment methods after diagnosis), results of bone mineral density (BMD) at diagnosis and during follow-up if available, biochemical (mainly phosphocalcic metabolism, kidney function).

Results: Between 2012 and 2024, we included a total of 92 patients, identified as affected by MTX-induced osteopathy. Population affected was mainly post-menopausal women (86/92, 93%) with seropositive RA (68/92, 74%), with previous history of major fracture in 22% of patients, and BMD osteoporosis at diagnosis in 56% of patients. The underlying rheumatism was classically considered as inactive or with low disease activity (93%). Prednisone was used in only 34 patients (37%) at diagnosis, with a mean dose of 8 mg (± 7) per day. Site of fracture was mainly on tibial metaphyseal region (88%) or foot bones (49%), with frequent multiple sites at diagnosis (76%) and with frequently repeated fractures in the patient's recent history (63%). Diagnosis was mainly done using MRI of painful site (84%), but bone scintigraphy was also used (41 patients, 45%) for general skeletal mapping. Management was the discontinuation of methotrexate (79%) with the addition of a

Comparison between good and poor evolution of fracture. N= number, SD = standard deviation.

complementary treatment in 51 patients (55%). In global population, evolution of fracture (decrease pain and fracture healing) was good in 77% of cases. The critical information was that evolution was good in 91% in case of MTX discontinuation against only 29% in case of MTX continuation (p< 0.001). If we compared patients with good evolution of fracture (n=57) and without good evolution (n=16), only main significant difference between group was MTX continuation (p< 0,001).

Conclusion: Methotrexate-induced osteopathy remains a rare condition but has to be known and searched, especially in cases of pain in the lower limbs of postmenopausal women, not explained by inflammatory activity of the underlying rheumatism. MRI of painful sites or bone scintigraphy appear to be the best choice for diagnosis. In the majority of cases, stopping methotrexate leads to rapid improvement of symptoms and above all avoids the risk of further fractures.

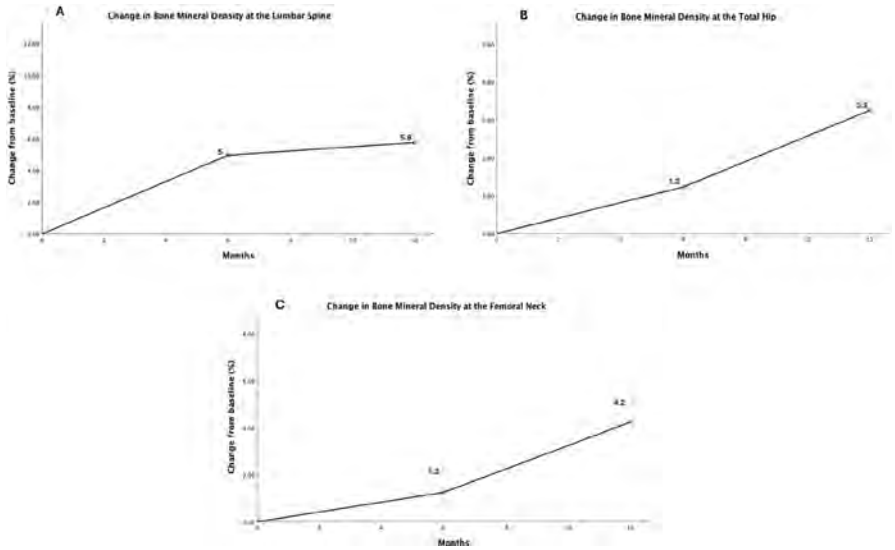
Baseline characteristics of the study population

Background/Purpose: Bone damage is a key feature of multiple myeloma (MM). Romosozumab (ROMO), a sclerostin inhibitor, has dual anabolic and antiresorptive properties and may offer benefit in this group with high fracture risk.

Methods: We did a 12-month prospective observational study in patients with multiple myeloma (MM) and osteoporosis treated with ROMO. Inclusion criteria were: (1) diagnosis of MM according to the International Myeloma Working Group (IMWG) definition, (2) absence of CRAB disease, (3) treatment with ROMO deemed necessary by the treating physician. The primary outcome was bone mineral density (BMD) change at 12 months, other outcomes were bone turnover markers (BTMs) change, high-resolution peripheral computed tomography (HR-pQCT) parameters and MM related parameters (M-protein, immunoglobulins free light chains, β2-microglobulin). We used mixed model for repeated measures analyses with random intercepts by participant with time as independent variables with an unstructured correlation matrix.

Results: Eight female patients with MM (mean age 67.4±9.9 years) completed 12 months of ROMO (**table 1**). A significant BMD increase was observed at all evaluated sites over the study period (**figure 1**). Lumbar spine BMD increased by 5.8% (7.7) at 12 months (p=0.048). Femoral neck increased by 4.2% (3.9) (p=0.020) and total hip by 3.3% (2.4) (p=0.002). Bone-alkaline phosphatase (B-ALP) showed a significant decrease by month 12 (13.5 (9.3-17) to 9 (6.12) ng/mL, p=0.022). P1NP rose sharply by month 3, from 60 (49.5-70.3) to 98 (77-115.5) ng/mL (mean change of 117.8%), but then declined, approaching baseline by month 12 (p=0.006). Conversely, CTX showed a tendency for reduction at all time points (p=0.060), with a maximal decrease at the end of the 12 months (-53.6%, **figure 2**). No significant changes occurred in immunoglobulins, M-protein, or light chains. β2-microglobulin showed a downward trend (from 2.35 to 2.1mg/L at month 12, p=0.042), though overall changes were not significant (p=0.092). HR-pQCT parameters remained stable throughout



Percentage Change from Baseline in Bone Mineral Density at the lumbar spine (A), total hip (B) and femoral neck (C)

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Percentage Change from Baseline in P1NP levels (A) and CTX levels (B)

the study, revealing no changes in volumetric BMD, microarchitecure or biomechanical properties of the bone assessed with this method.

Conclusion: In this exploratory study of patients with MM and osteoporosis, ROMO significantly improved BMD and modulated BTMs, without any evidence of disease progression over the 12-month period. These findings support ROMO as a potential bone-targeted therapy in patients with osteoporosis and plasma cell disorders.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2106–2123) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Prompt anti-resorptive treatment with bisphosphonates after denosumab discontinuation is generally recommended. Glucocorticoid users may not require longer term denosumab and are at greater fracture risk, yet the timing and route of bisphosphonate (BP) administration after denosumab (DMAB) discontinuation in glucocorticoid users has not been studied. A strategy of delayed administration of a pulse (IV) BP could be of greater benefit than other strategies.

Objective: To test different exit strategies in patients on chronic glucocorticoids who discontinued denosumab

Methods: We conducted an open-label, randomized, parallel group, multicenter, clinical trial in which participants with ≥2 doses of DMAB 60 mg were assigned 1:1:1 to weekly oral alendronate for 6 months (70 mg; started 6 months after last DMAB dose, ALN group) OR 1 dose of IV zoledronic acid (5 mg; 6 months after last DMAB dose, EARLY ZA) OR 1 dose of IV zoledronic acid (5 mg; 9 months after last DMAB dose, LATE ZA). Participants were recruited at 2 sites. Inclusion criteria: post-menopausal women and men ≥50 years; on prednisone ≥7.5 mg /day; baseline BMD T-score of ≤ -1.0 at the

lumbar spine, total hip, or femoral neck. Exclusion criteria: no past BPs, > 24 months (> 4 injections) of prior DMAB treatment. Primary outcome was difference in CTX between randomization (baseline) and 6 months post randomization (+6M) between groups. Secondary outcomes were markers changes at follow-up times and bone mineral density (BMD) changes. We used repeated measures models with random intercepts by participant, time, and time x treatment as independent variables with an unstructured correlation matrix.

Results: A total of 45 patients were randomized (N=15 to ALN, N=14 to EARLY ZA, N=16 to LATE ZA). Baseline characteristics are reported in **Table 1**. Median glucocorticoid dose at baseline (DMAB discontinuation) was 5.0 mg/day (IQR 5.0-10.0). Groups were well balanced except for BMD at femoral neck and total hip. **Figure 1** shows the bone turnover markers (**Figure 1**) data by group at baseline, +3M and +6M. **Figure 2** shows the BMD data for groups at +6M. At 6 months, we found a non-significant trend for change in CTX in the LATE ZA compared to ALN (p=0.07), but there was no difference in CTX between the LATE ZA and EARLY ZA groups (p=0.12). However, at 3 month there was a significant difference in change in CTX between LATE ZA vs ALN (p=0.0182) but not between LATE ZA and EARLY ZA (p=0.757). For lumbar spine BMD, at 6 months, we observed a non-significant trend between LATE ZA and EARLY ZA (p=0.059), but there was no statistically significant difference in the BMD between LATE ZA and ALN (p=0.28). At 12 months, there was a statistically significant difference in BMD between LATE ZA and ALN (p=0.04), but not between LATE ZA and EARLY ZA (p=0.11).

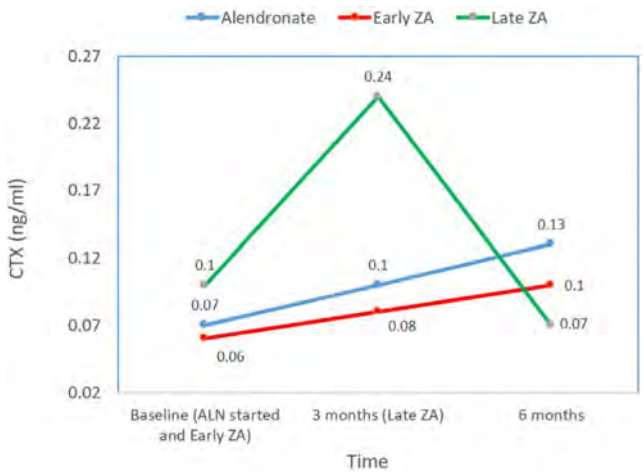

Figure 1. CTX changes over the study periodchanges over the study period

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 2. Bone mineral density (BMD) in gm/cm2 at lumbar spine at baseline, 3-, 6- and 12 months

Conclusion: Among those receiving delayed ZA, an escape in bone turnover at 3 months could create a window for fractures. However, it could be offset by greater BMD gain at 6 months, which, however, was not sustained at12 months, albeit not significantly greater than the other two groups. Larger studies are needed to assess relative safety and benefit of different post-DMAB strategies among this higher risk population.

Abstract Number: 2118

Risks of Fracture in Current and Previous Anticonvulsant Users, An Observational Study

Grace Hyeyeon Lee[1], Hamzah Amin[2] and marwan Bukhari[1], [1]University Hospitals of Morecambe bay NHS foundation trust, Lancaster, United Kingdom, [2]Lancaster University, Lancaster, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2106–2123) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Anticonvulsants are commonly used to manage neurological and psychiatric disorders such as epilepsy, migraines and bipolar disorder. These medications are often prescribed long-term, and in some cases, lifelong. Prolonged anticonvulsant use has been associated with an increased risk of fractures in adults and lower bone mineral density in children, likely due to their effect on bone metabolism. This study aimed to investigate the association between fracture risk and anticonvulsant use in each group of patients who are currently taking anticonvulsants with those who have previously used them.

Methods: This retrospective study was conducted at a district general hospital in the northwest of England, from July 2004 to February 2024. There were 1,368 patients, with 332 patients who were previous anticonvulsant users and 1,036 patients who were current anticonvulsant users. In both groups, the predictors of fracture risk were examined, including age, gender,

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

height, weight, body mass index (BMI), percentage total body fat, current smoker, current alcohol drinker, current steroid use, previous fractures and bone mineral density (BMD) values at the L1-L4 vertebrae, right and left femur neck, and right and left femur total. These factors were compared between the two groups of current and previous anticonvulsant users using independent t-tests for continuous factors and chi-square tests for categorical factors. A logistic regression model was used to assess the relationship between anticonvulsant use (current and previous users) and fracture risk (history of fracture), taking into account the predictors of fracture.

Results: The mean age was 65, and 87% were female in both groups. Initially the predictors of fracture were compared between current and previous anticonvulsant users; right and left femur neck and total BMD were found to be significantly lower in current anticonvulsant users ($P< 0.05$). In the first logistic regression analysis, the fracture risk was assessed in previous and current anticonvulsant users, taking into account the predictors of fracture. Current anticonvulsant users were associated with increased odds of fracture (OR = 1.48, 95% CI: 1.06–2.07, p = 0.020). Another independent factor, percentage total body fat, was also found to be significantly associated with fracture (p = 0.007). Second logistic regression analysis examined the interaction between anticonvulsant use and percentage body fat, which was not found to be significant (p = 0.288). This suggests that percentage body fat did not significantly change the association between anticonvulsant use and fracture risk.

Conclusion: In conclusion, the results show current anticonvulsant use is associated with an increased fracture risk, compared to previous users. In addition, the current anticonvulsant users were found to have lower femur neck and femur total BMD, which is likely to have an increased risk for major fractures. Percentage total body fat was an independent factor which was found to be a significant predictor of fracture risk.

Fracture rates in 6475 individuals with osteogenesis imperfecta stratified by age, sex and clinical severity

Winnie Liu[1], **Jeffrey Curtis**[2], Lars Folkestad[3], Emily Holladay[4], Jingyi zhang[2], Shanette Daigle[5], Ye Liu[2], Fenglong Xie[6] and Eric Orwoll[1], [1]Oregon Health and Science University, Portland, OR, [2]University of Alabama at Birmingham, Birmingham, AL, [3]University of Southern Denmark, Odense, Denmark, Odense, Denmark, [4]Foundation for Advancing Science Technology Education and Research, Hoover, AL, [5]Foundation for Advancing Science, Technology, Education and Research (FASTER), Hoover, AL, [6]The University of Alabama at Birmingham, Birmingham, AL

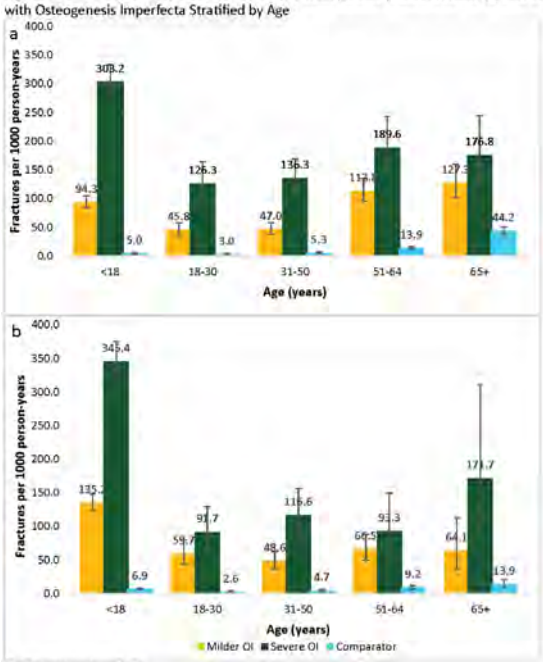
SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2106–2123) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Osteogenesis imperfecta (OI) is a rare genetic disorder characterized by bone fragility caused by mutations related to type 1 collagen biosynthesis. Fractures are a cardinal manifestation of OI, but fracture incidence across the lifespan is poorly understood. We used a large US-based cohort to describe fracture rates in individuals living with OI, stratified by clinical severity.

Methods: Individuals with OI were identified by ICD-9 (756.5) and/or ICD-10 (O78.0) diagnosis codes among ~30 million people included in MarketScan claims data (2006-2022) and a 5% random sample of US Medicare Fee-for-Service

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 1: Follow-Up Fracture Incidence Rates per 1000 patient-years in Female (a) and Male (b) Patients with Osteogenesis Imperfecta Stratified by Age



OI: Osteogenesis Imperfecta.
Note: Vertical error bars depict the 95% confidence intervals (CIs).

data (2006-2021). Severe OI was defined by long-term wheelchair use, identified using durable medical equipment (DME) claims. Incident fractures were identified using an adaptation of a previously validated algorithm with high specificity.

Results: We included 6,475 individuals with OI. Median age was 21.0 years (IQR: 8.0, 43.0) and severe OI was present in 20%. A reference cohort (N=32,375) was matched 5:1 within each data source to those with OI by age, sex, race, index calendar year, and baseline length of continuous coverage. Median follow-up time was 2.1 years (IQR: 0.9, 4.5) in OI and 2.0 years (IQR: 0.8, 4.3) in the comparator group. In OI, the overall fracture rate was 129.6 (95% CI: 124.7, 134.6) per 1000 person-years (py) vs 8.0 (95% CI: 7.4, 8.6) in the reference cohort (incidence rate ratio (IRR): 16.2, 95% CI: 15.0, 17.2). Across all ages, the fracture rates were higher in severe vs milder OI (IRR: 238.6, 95% CI: 226.1, 251.7) vs 87.8 (95% CI: 83.2, 92.8) per 1000py (Figure 1). In both sexes, fracture rates were highest in childhood and lowest in early adulthood. In women with milder OI, fracture rates were highest at age 51 years and older, which coincides with the typical age range of menopause. In women with severe OI, the rates of fracture also increased in those aged 51 years and older. In men with milder OI fracture rates were stable with increased age, but were higher in older men with severe OI.

Conclusion: We report fracture rates stratified by sex, age and clinical severity in one of the largest datasets ever assembled of US individuals living with osteogenesis imperfecta. These data provide unique and necessary information for the clinical care of individuals living with OI and for the design of trials for new therapeutics.

Analyzing Gender and Racial Disparities in Paget's Disease of Bone: A Large-scale Observational Study

Kinga Grzybowski[1], Ahmer Khan[2] and Arthur Lau[3], [1]Jefferson Einstein Montgomery Hospital, Maspeth, NY, [2]Jefferson Einstein Philadelphia Hospital, Philadelphia, [3]Jefferson Einstein Hospital, Maple Glen, PA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2106–2123) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Osteitis deformans, commonly referred to as Paget's Disease of the Bone (PDB), affects adults over the age of 55, mainly of European descent and is characterized by accelerated turnover of bone with abnormalities to remodeling and overgrowth involving multiple regions of the body. Studies have shown a slight male predominance, although others have found equal distributions between genders. Most PDB cases are asymptomatic, however some may develop complications such as arthritis, fractures and diffuse pain. An observational, retrospective cohort study using the TriNetX database was conducted which uses electronic health records from over 140 global collaborative networks to explore both racial and gender differences between patients with PDB.

Methods: Patients 18 years and older were included using ICD-10 code M88 for the diagnosis of PDB. Two cohorts were studied: males and females above the age of 18. The index event was defined as the first appearance of the diagnosis of PDB. Propensity matching included age, race/ethnicity, hypertension, obesity, diabetes, tobacco use, acute myocardial infarction, cerebral infarction, hyperlipidemia and medications commonly used in the treatment of PDB. Outcomes evaluated included mortality, chronic pain syndrome, heart failure, hearing loss, osteosarcoma, osteoporosis, fractures, chronic kidney disease, anxiety, depression and OA. Those who experienced any of the above outcomes prior to the index event were excluded from the study and a risk/risk ratio calculation was measured.

Results: The dataset included 10,972 females and 11,904 males. After propensity matching a total of 4,862 people were excluded, which left 9,007 in each group. The average age after matching was 70.7 in the female group, and 71 in the male group respectively. Most patients were not Hispanic or Latino and were mostly White or of unknown ethnicity. Analysis of the outcomes showed a statistically significant difference in chronic pain (RR 1.18, 95% CI 1.09-1.278, P< 0.0001), osteoporosis (RR 2.44, 95% CI 2.188-2.721, P< 0.0001), anxiety (RR 1.62, 95% CI 1.464-1.794, P< 0.0001), depression (RR 1.49, 95% CI 1.336-1.671, P< 0.0001) and OA (RR 1.295, 95% CI 1.202-1.395, P< 0.0001) in females. Additionally, heart failure

Table 2: Differences in the Outcomes of Both Cohorts

Outcomes		Males (9,007)	Females (9,007)	RR (95% CI), P-value
Mortality	*n* after matching	365	317	RR 0.87 (95% CI 0.751-1.009)
	Patients with outcome (%)	4.1%	3.6%	P 0.0649
Chronic Pain	*n* after matching	974	1,126	RR 1.18 (95% CI 1.09-1.278)
	Patients with outcome (%)	12.6%	14.8%	P<0.0001
Heart Failure	*n* after matching	759	662	RR 0.864 (95% CI 0.782-0.954)
	Patients with outcome (%)	9.6%	8.3%	P 0.0038
Hearing Loss	*n* after matching	419	440	RR 1.042 (95% CI 0.915-1.187)
	Patients with outcome (%)	5.0%	5.2%	P 0.5359
Osteosarcoma	*n* after matching	28	26	RR 0.927 (95% CI 0.544-1.58)
	Patients with outcome (%)	0.31%	0.29%	P 0.7808
Osteoporosis	*n* after matching	440	931	RR 2.44 (95% CI 2.188-2.721)
	Patients with outcome (%)	5.2%	12.7%	P<0.0001
Fractures	*n* after matching	137	150	RR 1.102 (95% CI 0.876-1.386)
	Patients with outcome (%)	1.6%	1.7%	P 0.4086
CKD	*n* after matching	776	737	RR 0.9 (95% CI 0.818-0.991)
	Patients with outcome (%)	10.5%	9.4%	P 0.0315
Anxiety	*n* after matching	569	846	RR 1.62 (95% CI 1.464-1.794)
	Patients with outcome (%)	7.0%	11.4%	P<0.0001
Depression	*n* after matching	489	680	RR 1.49 (95% CI 1.336-1.671)
	Patients with outcome (%)	6.0%	8.9%	P<0.0001
Osteoarthritis	*n* after matching	1,049	1,230	RR 1.295 (95% CI 1.202-1.395)
	Patients with outcome (%)	16.0%	20.7%	P<0.0001

(RR 0.864, 95% CI 0.782-0.954, P 0.0038) and chronic kidney disease (RR 0.9, 95% CI 0.818-0.991, P 0.0315) were found to be statistically significant in males. There was no difference in the incidence of mortality, hearing loss, osteosarcoma or fractures between the two cohorts.

Conclusion: The findings demonstrated females with PDB are at a higher risk for chronic pain, osteoporosis, anxiety, depression and OA, whereas men are at higher risk for heart failure and chronic kidney disease. Most participants in this study were non-Hispanic and White, consistent with previous demographic data. However, there was also significant representation from Black/African American and Asian patients. This study signifies that racial and gender differences exist in patients with PDB and more research needs to be conducted to further explain these findings and to potentially identify any confounding or causative variables which may have influenced the observed findings.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2106–2123) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Treatment with aromatase inhibitors (AIs) in patients with breast cancer is associated with accelerated bone mineral density (BMD) loss, leading to an increased risk of fracture, even in patients with BMD levels in the osteopenic range. In this context, treatment algorithms with higher BMD thresholds (T-score ≤ -2.0) than general population recommendations have been proposed. However, the implementation of these recommendations in clinical practice has been poorly evaluated.

Methods: Prospective observational study. Postmenopausal women with breast cancer receiving AIs who initiated antiresorptive therapy between October 2021 and April 2025 were included. Demographic, laboratory, and bone densitometry data (baseline and at 18 months) were collected from electronic medical records. Two groups were established based on

Age (mean ± SD)	66.2 ± 9.7
BMI (mean ± SD)	26.3 ± 7.0
Age at cancer diagnosis (mean ± SD)	60.8 ± 11.1
Smoker, n (%)	25 (22.3)
Previous fractures, n (%)	9 (8.0)
Parental hip fracture, n (%)	17 (15.1)
Type of AI Letrozole (%)	93 (83.0)
Antiresorptive treatment	
Alendronate n (%)	88 (78.5)
Risedronate n (%)	2 (1.7)
Zoledronic acid n (%)	14 (12.5)
Denosumab n (%)	8 (7.1)
Time in AI before antiresorptive therapy	
≤ 6 months n (%)	43 (38.3)
> 6 months n (%)	69 (61.6)
BMD T-score	
≤-2,0 and > -2,5 n (%)	17 (15.1)
≤ -2.5 n (%)	95 (84.8)
Median baseline T-score lumbar spine (p50, p25-p75)	-2.6 (-3, -2.2)
Median baseline T-score femoral neck (p50, p25-p75)	-2.05 (-2.7, -1.5)
Median T-score at 18 months lumbar spine (p50, p25-p75)	-2.2 (-2.7, -1.85)
Median T-score at 18 months femoral neck (p50, p25-p75)	-1.8 (-2.4, -1.2)
Percentage BMD gain at 18 months lumbar spine (p50, p25-p75)	3.95 (1.83, 8.54)
≤ 6 months	3.78 (1.67, 8.21)
> 6 months	4.49 (1.87, 8.79)
≤-2,0 and > -2,5	5.85 (2.79, 8.91)
≤ -2.5	3.95(1.54, 8.54)
Percentage BMD gain at 18 months femoral neck (p50, p25-p75)	3.21 (-1.01, 8.23)
≤ 6 months	3.77 (-0.5, 7.73)
> 6 months	2.88 (-1.1, 8.64)
≤-2,0 and > -2,5	5.67 (0, 16.5)
≤ -2.5	3.11 (-1.13, 7.77)
Fractures during treatment, n (site)	1 (hip)

Patients characteristics.

T-score at initiation of antiresorptive therapy: T-score ≤ -2.0 and > -2.5, and T-score ≤ -2.5. Comparisons between groups were performed using the Mann-Whitney test (for two variables) or the Kruskal-Wallis test (for three or more variables).

Results: A total of 220 women met inclusion criteria by April 2025; 129 completed the 18-month follow-up, with 17 excluded due to discontinuation of antiresorptive therapy before 18 months. Mean age was 66.2 ± 9.7 years; 88 (78.5%) were treated with alendronate. 38.3% had been on AIs for less than 6 months before initiating antiresorptive therapy. 84.8% started therapy with a T-score ≤ -2.5 and 15.1% with a T-score ≤ -2.0 and > -2.5. At 18 months, the median percentage increase in BMD at the lumbar spine (LS) was 3.9% (1.8; 8.5), and at the femoral neck (FN) 3.2% (-1.0; 8.2). BMD gain was higher in the group initiating antiresorptive treatment at T-score ≤ -2.0 and > -2.5 compared to the ≤ -2.5 group, both at LS and FN (5.85% vs. 3.95%, p=0.31 at LS; and 5.67% vs. 3.11%, p=0.12 at FN). No statistically significant differences in BMD gain were found based on AI exposure duration (< or > 6 months) prior to antiresorptive therapy. Similarly, no significant differences were observed based on osteoporosis risk factors or the type of antiresorptive agent used.

Conclusion: Our findings suggest a greater increase in BMD among patients who begin antiresorptive therapy at a T-score of ≤ -2.0 compared to those who start at the general population threshold of ≤ -2.5. Initiating antiresorptive therapy in AI-treated patients is recommended regardless of the duration of AI use, as it does not appear to significantly affect BMD gain.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2106–2123) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Romosozumab (RSZ) is a dual osteoanabolic agent that stimulates bone formation and reduces bone resorption, emerging as a promising option for treating osteoporosis (OP) in patients at very high fracture risk.

This study aims to analyze the safety and efficacy of RSZ treatment in patients with severe OP under real-world clinical conditions.

Methods: This is a single-center, ambispective, and observational study. Patients who initiated RSZ treatment between December 2022 and August 2024 were included, with prospective follow-up until March 2025. Data were collected from

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Characteristics of the population treated with romosozumab.

Characteristics	N = 68 patients (67 women)	
Age at initiation, mean ± SD	71.3 ± 7.5	
Patients with CVRF, n (%):	45 (66.1)	
1 CVRF / ≥2 CVRF, n (%)	25 (36.7) / 20 (29.4)	
Osteoporosis risk factors:		
Smoker, n (%)	15 (22.0)	
Early menopause (n = 67 women), n (%)	15 (22.1)	
Family history of hip fracture, n (%)	8 (11.7)	
Hyperparathyroidism, n (%)	4 (5.8)	
Hypothyroidism, n (%)	16 (23.5)	
Chronic lung disease*, n (%)	7 (10.3)	
Rheumatic or autoimmune diseases, n (%)	10 (14.7)	
Treatment with OP-inducing drugs, n (%)	30 (44.1)	
Previous history of fractures:		
Vertebral fractures, n (%)	53 (77.0)	
Hip fractures, n (%)	6 (9.1)	
Other osteoporotic fractures**, n (%)	15 (22.0)	
Prior osteoporosis treatments:	54 (79.4)	
Antiresorptives, n (%)	51 (75.0)	
Bisphosphonates (oral or IV), n (%)	48 (70.6)	
Denosumab, n (%)	22 (32.3)	
Teriparatide, n (%)	21 (30.9)	
Romosozumab treatment		
Completed (12 doses), n (%)	38 (55.9)	
Active (<12 doses), n (%)	24 (35.3)	
Discontinuation, n (%)	9 (8.8)	
Number of total AEs, n (%)	12 (17.6) in 11 patients (16.1)	
Type of AEs	2 CV events, 5 skin reactions, 3 myalgia, 1 headache	
Discontinuation due to AEs, n (%)	6 (8.8)	
Dual x-ray densitometry and bone markers	**Baseline**	**12 months**
Femoral Neck T-score, mean ± SD (n=34)	-2.70 ± 0.9	-2.72 ± 0.8
Lumbar Spine T-score, mean ± SD (n=25)	-3.48 ± 1.17	-2.66 ± 1.06
TBS, mean ± SD (n=19)	1.180 ± 0.106	1.208 ± 0.099
Calcium (mg/dL), mean ± SD (n=35)	9.32±0.54	9.21±0.36
Alkaline Phosphatase, mean ± SD (U/L) (n=33)	89±27	83±30
PTH (pg/mL), mean ± SD (n=18)	81.5±28	82±29
Osteocalcin (ng/mL), mean ± SD (n=8)	19.9±7	29.2±11
CTX (ng/mL), mean ± SD (n=8)	0.397±0.26	0.148±0.03

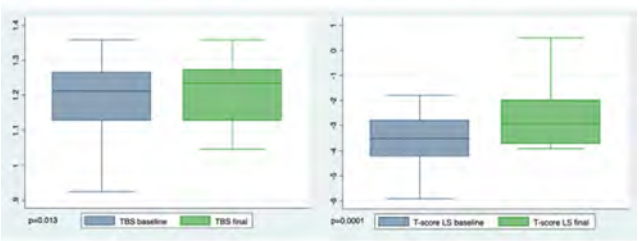
*Chronic lung disease refers to patients with COPD, chronic bronchiectasis, and asthma.
**Including radius and humerus.
Abbreviations: AEs: adverse events; BMD: bone mineral density; CTX: C-terminal telopeptide of type 1 collagen; CV: cardiovascular; COPD: chronic obstructive pulmonary disease; CVRF: cardiovascular risk factors; OP: osteoporosis; PTH: parathyroid hormone; SD: standard deviation; TBS: trabecular bone score.

electronic medical records, including demographic information, OP-related data, laboratory results (bone remodeling markers [BRM]), bone mineral density (BMD) of the lumbar spine (LS) and femoral neck (FN) measured by dual x-ray densitometry (DXA) (Hologic Horizon®), and Trabecular Bone Score (TBS) at LS (Medimaps®). Data related to RSZ use, such as adverse events (AEs) and clinical fractures, were also registered. Changes in BRM and BMD from baseline to the end of follow-up were analyzed, and a bivariate analysis was conducted to assess factors associated with higher BMD gain in LS.

Results: Sixty-eight patients (Table 1) were included, with a marked prevalence of vertebral fractures (VF) (77.9%). Cardiovascular risk factors (CVRF) were present in 66.1% of the cohort. Prior to RSZ therapy, 75% of patients had received antiresorptive therapy, and 31% had received teriparatide.

At the time of analysis, 38 patients (56%) had completed 12 doses of RSZ, while 21 patients (30%) were still receiving treatment. RSZ was discontinued in 9 patients (13.2%), 6 of them due to AEs. Two elderly patients with >1 CVRF experienced ischemic strokes, occurring one month and seven months after completing RSZ, respectively.

Figure 1. Evolution of LS bone dual x-ray densitometry under romosozumab therapy.



Abbreviations: LS: lumbar spine; TBS: trabecular bone score.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

In patients who completed RSZ and had BMD data (34 for FN and 25 for LS), BMD was stable in FN without significant T-score changes (p=0.808). However, the LS T-score showed a significant increase (-3.48 at baseline vs. -2.66 at the end; p=0.0001) (Figure 1). Additionally, LS BMD gain was >5% in 84% (21/25) of patients and >10% in 40% (10/25) of them. Factors associated with LS-BMD improvement included no prior anti-OP treatment with bisphosphonates (p=0.02) and fewer previous anti-OP therapies (p=0.20), but no correlation was found with age, OP risk factors, or the number/type of previous fractures. TBS also showed significant improvement (1.180 at baseline vs. 1.208 at 12-month follow-up; p=0.01). Only one osteoporotic fracture (Colles' fracture) was reported in a patient eight months after completing RSZ.

Regarding BRM, significantly lower carboxy-terminal telopeptide of type 1 collagen (CTX-I) levels (p=0.01) and a trend toward lower alkaline phosphatase (p=0.09) were observed post-RSZ, with no differences in osteocalcin (p=0.83), calcium (p=0.19), or PTH (p=0.80).

Conclusion: In our experience, RSZ treatment for severe OP demonstrated acceptable tolerance, with significant densitometric gain in LS and stabilization in FN. Long-term real-world studies are needed to assess RSZ effectiveness in reducing fractures and its long-term cardiovascular safety profile.

Abstract Number: 2123

Sclerostin in Aging Bone and Muscle: A Comparative Study of Osteoporosis, Sarcopenia, and Osteosarcopenia

Mohamed Tharwat Hegazy[1], Fatma Fayed[1], Shirihan Mahgoub[1], Yasmin El Ebrashy[2] and Maha Hossam Al-Din Ibrahim[1], [1]Faculty of Medicine, Cairo University, Cairo, Egypt, [2]National institute of Diabetes and Endocrinology, Cairo, Egypt

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2106–2123) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Osteoporosis, sarcopenia, and frailty are the 3 determinants of aging. A novel syndrome of combined osteosarcopenia has negative health outcomes among geriatric populations. In the last decades, studies have been conducted to assess sclerostin role in the bone and muscle cross-talk. Sclerostin is a protein produced by osteocytes, but recently it has been proposed to be secreted from myocytes as well. This study aimed to assess the level of serum sclerostin in osteoporosis, sarcopenia, and osteosarcopenia to address its possible dual role on bone and muscle units.

Methods: This cross-sectional study included 66 females aged ≥ 60 years old equally divided into 3 groups: "osteoporosis", "sarcopenia" and "osteosarcopenia" as follows: (a) females with osteoporosis were assessed by dual-energy X-ray absorptiometry (DXA) scan at the hip, lumbar spine, or distal 1/3 of the radius with a T-score ≤ -2.5 standard deviation (SD). (b) Females with sarcopenia were diagnosed according to the 2018 revised criteria of the European Working Group on Sarcopenia in Older People (EWGSOP). (c) Females with osteoporosis or osteopenia (T-score -1 to < -2.5) **and** sarcopenia were in osteosarcopenia group. Fracture risk assessment score (FRAX) was done using an online FRAX calculator

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1: Mean sclerostin (ng/ml) in the 3 study groups

according to our geographic region. Anthropometric measurements and comprehensive geriatric assessment, including frailty, nutritional, functional assessment, and serum sclerostin level, were done for all subjects.

Results: We determined the optimum cut-off value of sclerostin in differentiating between each 2 groups. Results were adjusted for age and BMI. Serum sclerostin showed the highest level in the osteoporosis group with a cutoff level ≥ 1.29 ng/ml (sensitivity 66.7%, specificity 68.2%). The lowest level was among the sarcopenia group with a cutoff level < 0.7 ng/ml (sensitivity 75%, specificity of 59.1%). In osteosarcopenia, we found that sclerostin level was ≥ 0.7 ng/ml and < 1.29 ng/ml (sensitivity of 66.7%, specificity of 68.2%). Osteosarcopenia group had the least serum albumin, body mass index (BMI), muscle mass, bone mineral density (BMD), and android/gynecoid (A/G) ratio. They had the most advanced age, the highest fracture risk (FRAX) score of major osteoporotic and hip fractures. They had the worst nutritional state and the most functional impairment.

Conclusion: Sclerostin could have an anabolic effect on muscles and a catabolic effect on bone. Advanced age, low serum albumin, low body weight, and poor nutritional state are highest in osteosarcopenia. Osteosarcopenia patients are at higher risk for developing future fractures.

Table 1: Summary of the group that had the highest and the lowest statistically significant mean values for each variable.

Variable	Highest Significant mean	Lowest significant mean	P- value
Age	Osteosarcopenia	Sarcopenia	0.003
Weight	Sarcopenia	Osteosarcopenia	< 0.001

Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: The physician global assessment of lung disease (PGALD) is a recently proposed disease activity measure for patients with systemic juvenile idiopathic arthritis-associated lung disease (SJIA-LD) – a significant cause of morbidity and mortality in SJIA. This study evaluates the reliability and construct validity of the PGALD.

Methods: 20 SJIA-LD clinical vignettes were created, informed by historical patient encounters as templates. Vignettes included brief patient medical histories, physical examination findings, a list of prescribed medications, laboratory results, diagnostic imaging, pulmonary function test results, and biopsy results – when available. Fifty-seven pediatric rheumatologists and pulmonologists with experience caring for children with SJIA-LD were invited to rate vignettes utilizing the PGALD, a 10-point Likert scale (0 = inactive SJIA-LD; 10 = highly active SJIA-LD). Raters who completed the initial round of 20 vignettes were asked three days later to rate a subset of 8 repeat vignettes. Inter- and intra-rater reliability were assessed using intraclass correlation coefficients (ICC). Based on the 95% confidence interval of ICC estimates, values less than 0.5

TLC (<80%)	5	77 (64, 94)	-0.92	0.01
DLCO (<80%)	6	71 (61, 89	-0.97	0.0002

Sp02 – Peripheral saturation of oxygen; MAS – macrophage activation syndrome; IL-18 - Interleukin 18; CRP – C-reactive protein; CXCL9 chemokine c-x-c-motif; FVC - forced vital capacity; TLC – Total Lung capacity; DLCO – lung diffusion capacity. Unpaired t test performed for Clinical Variables, Laboratory Elevation and Diagnostic Imaging Features; Pearson Correlation Coefficient performed for Laboratory Values and Pulmonary function Test Values; ANOVA performed for Number of Medications Prescribed.

indicated poor reliability, between 0.5-0.75 moderate-, between 0.76-0.9 good-, and >0.9 excellent reliability. SJIA-LD features influencing PGALD ratings were assessed in univariate analysis.

Results: The ICC for all raters was 0.678 (0.543, 0.819), indicating moderate to good inter-rater reliability. The intra-rater ICC was 0.863 (0.823, 0.893) indicating good intra-rater reliability. Factors associated with higher mean PGALD scores included the presence of crackles on auscultation (5.7 vs. 2.9; p=0.001), hypoxemia on pulse oximeter (5.6 vs. 3.2; p=0.01), current oxygen requirement (6.3 vs. 3.5; p=0.04), suggestive diagnostic imaging features (p≤0.01), and three or more prescribed medications for SJIA-LD (p≤0.01). Pulmonary function measures demonstrated significant negative correlations with mean PGALD scores, including forced vital capacity (r=–0.71; p=0.01), total lung capacity (r=–0.92; p=0.01), and diffusion capacity (r=–0.97; p=0.0002). Only the CRP was weak-to-moderately correlated with PGALD scores (r=0.39; p=0.09), while other laboratory values including ferritin, IL-18, CXCL9, and sIL2R were not significantly correlated.

Conclusion: The PGALD is a novel measure of SJIA-associated LD activity. Its initial validation suggests acceptable construct validity and reliability. Additional studies are needed to assess its responsiveness to change over time.

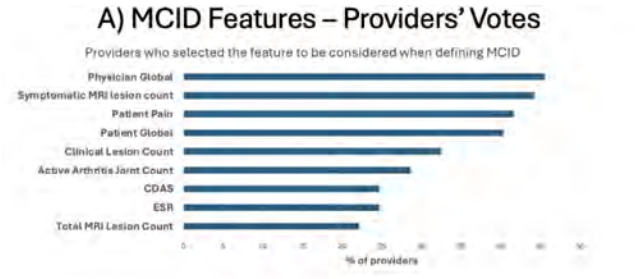
SESSION INFORMATION

Session Date: **Tuesday, October 28, 2025**
Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Chronic nonbacterial osteomyelitis (CNO) is an inflammatory bone disease that can result in bone deformity, persistent pain and pathological fractures which is frequently treated empirically. Clinical trials to compare and evaluate medication efficacy necessitates quantifying a minimal clinically important difference (MCID). We aimed to develop and validate this metric in CNO.

Methods: A Delphi survey on priorities for defining MCID was sent to providers via the Childhood Arthritis and Rheumatology Research Alliance (CARRA's) CNO Workgroup (180 members). Using the survey's results, 664 cases were identified from over 3000 real world patient visits from our multisite prospective registry (CHronic nonbacterial Osteomyelitis International Registry, CHOIR) to define MCID. The interval between visits was between 3 and 12 months. At least 1 or more values at the follow up visits had improved while no more than 1 value worsened. An expert panel of 13 international pediatric rheumatologists and 7 patient/caregivers reviewed the cases individually to determine if they showed MCID. Cases which did not



B) Thresholds of MCID Features – Providers

Feature	Absolute change Median [IQR] (N)	% change Median [IQR] (N)
Patient pain score improved by greater than or equal to...	2 [2, 3] (31)	30 [20, 50] (32)
Patient global assessment improved by greater than or equal to...	2 [2, 3] 30)	30 [21, 50] (34)
Total clinical lesion count improved by greater than or equal to...	1.5 [1, 2] (22)	30 [25, 50] (26)
Physician global assessment improved by greater than or equal to...	2 [2, 2.5] (31)	30 [20, 50] (35)
Symptomatic MRI lesion count improved by greater than or equal to...	1 [1, 2] (28)	28 [20,50] (34)
Total MRI lesion count improved by greater than or equal to...	2 [2, 3] (13)	30 [25,50] (20)
Inflammatory markers, ESR, improved by greater than...(mm/hr)	10 [6, 14] (14)	40 [30,50] (21)
CDAS (clinical disease activity score)	3 [3, 5] (15)	30 [25, 50] (21)

Figure 1: Provider Priorities in Defining Minimal Clinically Important Difference in CNO Delphi Survey Results: Frequencies and Thresholds

Table 1: Characteristics of Cohorts Used to Develop Definitions of Minimal Clinically Important Difference in CNO

n= 664	MCID Cohort (baseline visit)*	MCID Cohort (followup visit)	p-values^
Age: median [IQR]	12 [9,14]		
Sex: n (%)	Female: 391 (60) Male: 257 (40)		
Extracted Parameters			
Pain Level (0-10): median [IQR]	5 [3, 6]	2 [0, 4]	<0.0001
Patient global assessment (PAGA) (0-10): median [IQR]	5 [3, 6]	2 [0, 4]	<0.0001
Physician global assessment (PHGA) (0-10): median [IQR]	2 [1, 4]	1 [0, 2]	<0.0001
CNO clinical lesion count: median [IQR]	1 [0, 2]	0 [0, 1]	<0.0001
Total MRI lesion count: median [IQR]	3 [2, 5]	2 [1, 3]	<0.0001
Active spinal lesion on MRI: n (%)	No: 510 (77) Yes: 154 (23)	No: 588 (89) Yes: 76 (11)	<0.0001
Active sacroiliitis on MRI: n (%)	No: 544 (82) Yes: 120 (18)	No: 610 (92) Yes: 54 (8)	<0.0001
New spinal lesion on MRI: n (%)	N/A	No: 647 (97) Yes: 17 (3)	N/A
New non-spinal lesion on MRI: n (%)	N/A	No: 366 (55) Yes: 298 (45)	N/A
Erythrocyte Sedimentation Rate (ESR): n (%)	Abnormal: 205 (31) Normal: 459 (69)	Abnormal: 73 (11) Normal: 591 (89)	<0.0001
C-Reactive Protein (CRP): n (%)	Abnormal: 75 (11) Normal: 589 (89)	Abnormal: 30 (5) Normal: 634 (96)	<0.0001
CNO Disease Activity Score (CDAS)*: median [IQR]	10 [7, 14]	4 [1, 8]	<0.0001

*Inclusion criteria for baseline visit were: MRI lesion count and the sum of patient pain and PHGA as well as the sum of PAGA and PHGA are >0
^p-values calculated using Wilcoxon signed rank test for continuous variables and McNemar's test for categorical variables
*CDAS: Sum of patient pain score (0-10), PAGA (0-10), and total number of active CNO clinical lesions defined as focal tenderness, and/or swelling, and/or warmth

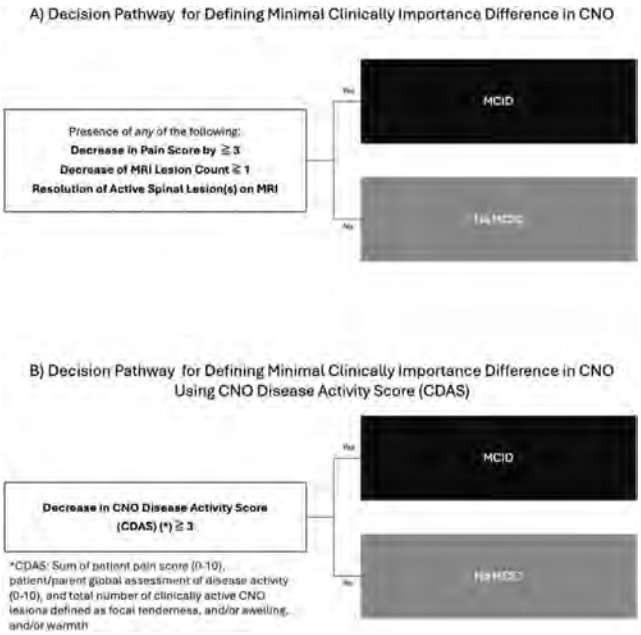

Figure 2: Decision Pathways for Defining Minimal Clinically Important Difference in CNO

reach consensus (80% agreement) were evaluated by >5 reviewers at an in-person consensus meeting. Reviewers were asked to vote whether a case demonstrated MCID. A decision tree was used to determine the cutoff point that best differentiated patients with and without MCID, and the model was validated using 10-fold cross-validation to ensure generalizability.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: A total of 80 providers (44% response rate) from 5 continents completed the survey. The frequency of items selected were listed and the absolute and relative change were reported (Figure 1). Cohort characteristics and parameters extracted from paired baseline and follow up visits are in Table 1. 638 (96%) of 664 paired visits reached consensus. 423 were classified as MCID, 215 as no MCID and 26 were inconclusive. A generalized linear model analysis showed that the change of pain level (p=0.03), baseline MRI lesion count (p=0.02), change of MRI lesion count (p< 0.001) and change of active spinal lesion on MRI (p< 0.02) were associated with the classification of MCID. The median [IQR] change of clinical disease activity score (CDAS) was -7 [-11,-4] in cases with MCID, compared to -2 [-5, 0] in those without MCID (p< 0.001). Decision trees based on all parameters or CDAS alone with accuracy of 0.73 and 0.71, respectively are in Figure 2.

Conclusion: A Delphi survey identified important variables to include when defining MCID per providers. We developed definitions for MCID, and specified measurement characteristics. A 30% improvement in these variables with improvement of CDAS by 3 were considered meaningful by providers and consensus data.

Preliminary Results of a Large, Global Registry Characterizing Childhood-Onset Takayasu Arteritis

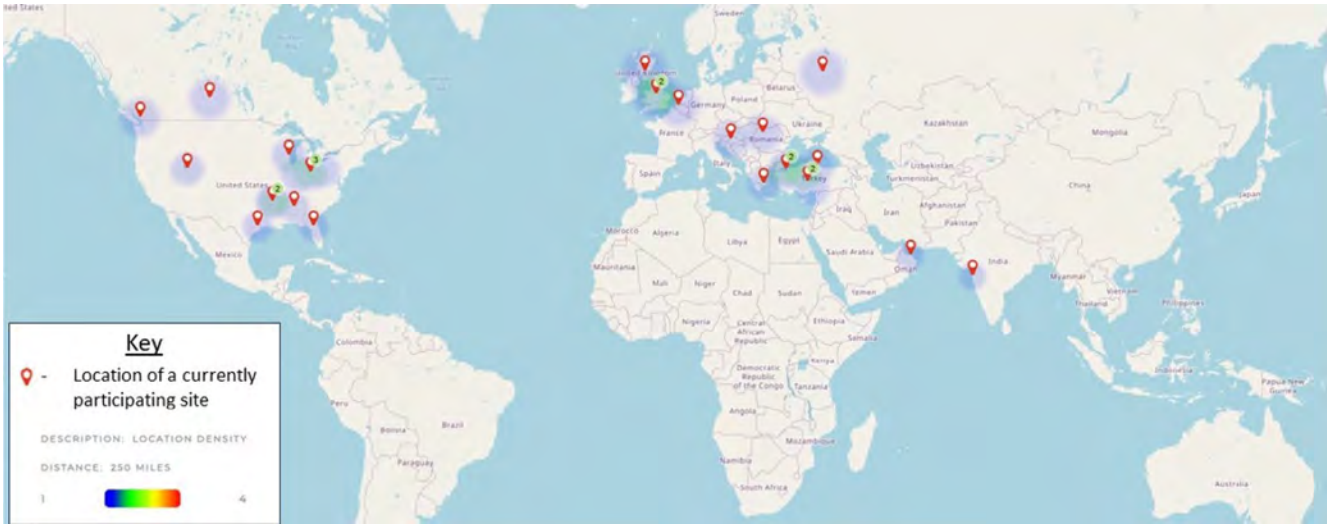
Muserref Kasap Cuceoglu[1], **James Bistolarides**[2], Mario Sestan[3], Samuel Gagne[4], Nick McPhate[5], Kimberly Morishita[6], Vidya Sivaraman[7], Linda Wagner-Weiner[8], Seza zen[9], Marija Jelusic[10], David Cabral[11] and International childhood-onset Takayasu Arteritis (IcTAK) Workgroup, [1]Hacettepe University, Ankara, Turkey, [2]Medical College of Wisconsin, Wauwatosa, WI, [3]University of Zagreb School of Medicine, Zagreb, Croatia, [4]University of Pittsburgh, Pittsburgh, PA, [5]BC Children's Hospital, Vancouver, Canada, [6]University of British Columbia, Vancouver, BC, Canada, [7]Nationwide Children's Hospital/ The Ohio State University, Columbus, OH, [8]University of Chicago, Chicago, IL, [9]Hacettepe University Medical Faculty, Ankara, Turkey, [10]University of Zagreb School of Medicine, University Hospital Centre Zagreb, Zagreb, Zagreb, Croatia, [11]BC Children's Hospital and University of British Columbia, Vancouver, BC, Canada

SESSION INFORMATION

Session Date: **Tuesday, October 28, 2025**
Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The rarity of childhood-onset Takayasu arteritis (c-TAK) has resulted in small cohorts for study that has limited the potential for evaluating its course and outcomes. The objective of this study is to engage Pediatric Rheumatologists internationally to contribute patient data to a research network targeted to characterizing c-TAK and improving

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Location of clinical sites that have patients included in the current abstract submission

disease outcomes. This will be achieved through the following: *Aim 1*: Create an international c-TAK registry, *Aim 2*: Evaluate the performance of existing disease activity measures, and *Aim 3:* Create and validate a preliminary disease activity score specifically for c-TAK.

Methods: Member sites of Childhood Arthritis Rheumatology Research Alliance (CARRA) and Pediatric Rheumatology European Society (PReS) are invited to enroll patients in this c-TAK registry. The registry is to capture children with a physician diagnosis of c-TAK aged ≤ 18 years at disease onset. Data entry is hosted on Research Electronic Data Capture (REDCap) platform. Registry data includes demographic characteristics, clinical symptoms, organ involvement, laboratory features, vascular imaging, treatment, physician global assessment (PGA) of disease activity, and the features needed to calculate the Pediatric Vasculitis Activity Score (PVAS), Indian Takayasu Activity Score (ITAS2010 and ITAS-A), and 2018 European League Against Rheumatism (EULAR) criteria for active large vessel vasculitis. The assessment of damage using the pediatric vasculitis damage index (PVDI) is collected at follow-up. Data is collected retrospectively from patient medical records at diagnosis, 12-months, and at the final visit on file beyond 15 months (if applicable).

Results: As of abstract submission, the registry has collected data on 72 patients from 12 countries and 31 unique clinical sites. Additional enrollment has begun at 40 other sites, including from 13 additional counties. To date the cohort comprises 80% females. The average age at diagnosis is 12.14 +/- 4.81 years; the average time to diagnosis after first symptoms is 7.53 +/- 13.07 months; 66% received intravenous pulse glucocorticoids (GC) at time of diagnosis, while 85% were started on oral GC. Primary treatments (n=63) prescribed at time of diagnosis include methotrexate (62%), anti-TNF biologic (27%) cyclophosphamide (24%), ongoing intermittent pulse IV GC (11%), and tocilizumab (11%). Secondary treatments included antihypertensives (54%) and anti-coagulants (48%).

Conclusion: Creation of an international c-TAK registry is feasible owing to global collaborations between member sites of CARRA and PReS, and the capabilities for electronic communications and data transmission. Registry data will improve knowledge of presenting symptoms and treatment of c-TAK and increase understanding of the value of current disease activity measures. The successful realization of further project aims is expected.

Abstract Number: 2127

Chronic Non-Bacterial Osteomyelitis of the Petrous Bone: A Case Series

Jeanine McColl[1], Ingrid Goh[2], Helen Branson[3], Karen Peralta[4], Dorsa Aeenfar[4], Sharon Cushing[3], Rayfel Schneider[3] and Ronald laxer[5], [1]University of Calgary, Calgary, Canada, [2]University of Toronto The Hospital for Sick Children, Toronto, ON, Canada, [3]University of Toronto The Hospital for Sick Children, Toronto, Canada, [4]University of Toronto, The Hospital for Sick Children, Toronto, [5]The Hospital for Sick Children, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Chronic Nonbacterial Osteomyelitis (CNO) is an autoinflammatory disorder of bone usually beginning in children between the ages of 7-12. It typically affects metaphyses of the long bones, vertebral bodies, and the clavicle. Although, any bone can be affected, involvement of the skull is extremely uncommon. The objectives of our study are to 1) illustrate presenting features associated with CNO of the temporal bone, its treatment, & response to therapy. 2) Increase awareness that CNO can involve the temporal bone to facilitate earlier diagnosis and treatment.

Methods: Patients diagnosed with CNO between June 2002-May 2022 at The Hospital for Sick Children were identified by searching Bialogics,™ the Electronic Medical Records Epic, and Chart Maxx. Charts were searched for the term "skull" to identify cases. To obtain records prior to 2018 (prior to the Epic electronic medical record) we ran a word search of pertinent synonyms to identify cases of CNO involving the temporal bone in the ISYS word text search program. Research Ethics Board approval was obtained for this study.

Results: Three cases of CNO affecting the petrous temporal bone were identified. All had been previously diagnosed with CNO. Age of onset of CNO was 2.3 to 9 years of age; all were female (Table 1). Time from CNO diagnosis to onset of petrous bone lesions ranged from 6-17 months. Two patients developed a Bell's Palsy and hearing loss. All patients were treated with a non-steroidal anti-inflammatory drug (NSAID) and the one patient with hearing loss also received anti-TNF therapy (adalimumab) and responded well with resolution of hearing loss. The other patient received NSAID therapy and has persistent bilateral hearing loss, in the context of recurrent otitis media.

Conclusion: The skull is rarely involved in CNO, with ∼1% of patients presenting with lesions in the frontal bone. Temporal bone involvement has rarely been reported with only two cases to our knowledge . It is unknown why CNO rarely affects the skull. One presumption is that CNO tends to affect the metaphyses and epiphyses of the long bones which the skull does not have, although, the pelvis also does not have a metaphysis and is a common site for CNO lesions. Another thought is the increased metabolic activity and blood supply at the epiphysis with chondrocyte maturation could result in increased propensity of immune dysregulation and inflammatory lesions. With less osteo metabolic activity the risk of dysregulation may be less. Interestingly all three cases developed skull involvement while on treatment for CNO.

There is no standardized treatment for CNO. Consensus guidelines provide options including non-steroidal anti-inflammatories (first line), glucocorticoids, disease modifying drugs (methotrexate, sulfasalazine), Tumor Necrosis Factor (TNF) inhibitors with or without methotrexate, and bisphosphates (pamidronate or zolendronic acid). In case one anti-TNF therapy was used due to the severity of hearing loss. CNO is challenging to diagnose, with 7% of patients being diagnosed five years after symptom onset.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

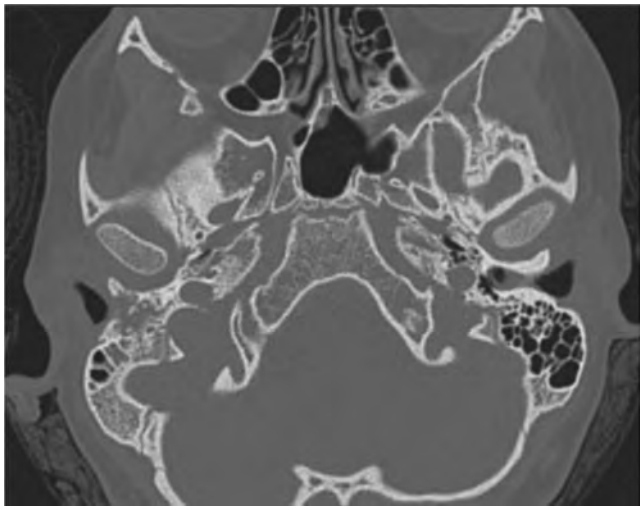

Figure 1: Case 1 Right Temporal Bone Erosion

Table 1: Results

Demographic	Case 1	Case 2	Case 3
Age at onset Skull lesions (years)	10	8	2
Sex (M/F)	F	F	F
7th Cranial Nerve involvement	Yes	No	Yes
Conductive Hearing Loss	Yes	No	Yes
Previous CNO Treatment	Pamidronate & NSAIDs	NSAIDs, Zoledronate & Prednisone	NSAIDs
Bone Biopsy Findings	Bone & granulation tissue with chronic inflammation	Trabecular bone with acute and chronic inflammation suggestive of osteomyelitis	Lymphocytic infiltrate with histiocytic cells and abundant eosinophilic neutrophils
Bone Cultures	Negative	Gram + bacilli (normal flora)	Negative
Treated with anti TNF (adalimumab)	Yes	Yes	No
Hearing loss resolution post anti TNF therapy	Yes	N/A	No

It is important to consider CNO on the differential in patients who present with cranial nerve abnormalities, hearing loss, and those with presumed infectious osteomyelitis.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Chronic nonbacterial osteomyelitis (CNO) is associated with various comorbidities and long-term complications. The CHronic nonbacterial Osteomyelitis International Registry (CHOIR) is a multi-national database that allows researchers to determine the prevalence of long-term risks, growth outcomes, and medication use and related adverse effects over time in children with CNO.

Methods: Children with CNO enrolled in CHOIR across 17 global sites between August 1, 2018 to December 31, 2024. Demographic and disease-related data were collected at baseline and follow-up visits. Data were summarized via descriptive statistics.

Results: A total of 585 children with CNO were included with a median age of 9.5 years at disease onset (**Table 1**). Of these, 171 had follow-up for greater than 5 years. Whole body (WB) MRIs were done in 469 patients at least once, and 233 at diagnosis. Rate of active spinal lesions confirmed by MRI decreased from 12% at diagnosis to 2% at 5 years. At baseline, height, weight, and body mass index (BMI) were within normal ranges and persisted over 5 years (**Table 2**).

Of 459 patients with a total of 1,649 patient-years of follow-up and complete data on comorbidities and adverse events, the mean follow-up was 3.6 years since diagnosis. Prior to diagnosis of CNO, the most common comorbidities were inflammatory bowel disease (IBD) (32), inflammatory arthritis (27), and psoriasis (26). After diagnosis, new autoimmune conditions that

Table 1: Demographic and clinical data of patients at baseline and 5-year follow-up

Demographics	At Diagnosis (n=585)	5 Year Follow-Up (n=171)
Female, n (%)	332 (57)	93 (55)
Race (White)	471 (81)	133 (78)
Age at Onset	9.5 [7.3, 12.0]	8.8 [6.5, 10.0]
Age at Diagnosis	11.0 [8.1, 13.0]	9.4 [7.1, 12.0]
Time Between Onset and Diagnosis (months)	5.6 [2.3, 15.0]	5.5 [2.1, 14.8]
Bone Biopsy Obtained	244 (42)	101 (60)
Active Spinal Lesion on MRI	68 (12)	3 (2)

Table 2: Distribution of height, weight, and BMI z-scores at diagnosis and 5-year follow-up

	At Diagnosis	5 Year Follow-Up
Height (n)	352	91
Median, [IQR]	0.16 [-0.59, 0.84]	0.36 [-0.37, 0.95]
Above 2, (%)	20 (6)	9 (10)
Below -2, (%)	11 (3)	0 (0)
Weight (n)	352	92
Median, [IQR]	0.26 [-0.63, 1.00]	0.40 [-0.42, 1.30]
Above 2, (%)	23 (7)	9 (10)
Below -2, (%)	12 (3)	1 (1)
BMI (n)	353	91
Median, [IQR]	0.27 [-0.62, 1.00]	0.36 [-0.42, 1.30]
Above 2, (%)	17 (5)	9 (10)
Below -2, (%)	16 (5)	5 (5)

Chi square analysis showed no significant difference in frequency of z score >2 or <-2 between baseline and follow-up

developed were psoriasis (37), arthritis (18), IBD (5), and less commonly (< 5) pustulosis, hidradenitis, celiac disease, and type 1 diabetes (**Table 3**). Amplified pain syndrome occurred in 13 patients at baseline and 15 more during follow-up. Vertebral compression fractures occurred in 25 patients initially and 6 more during follow-up. Seven had vertebral plana prior to diagnosis of CNO. Additionally, 12 patients prior to and 17 more after diagnosis experienced fractures at non-lesion sites related to trauma. Of these, 81% of vertebral and 41% of non-vertebral fractures occurred before diagnosis. The most

[a]Includes Abatacept, Canakinumab, Tocilizumab, Ustekinumab
[b]4 of the 5 patients were simultaneously treated with TNFi for CNO
[c]Most common were hand (8), tibia (5), femur (4), clavicle (3), arm (2)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

common vertebral and non-vertebral fracture sites were the thoracic spine (81%) and hand (26%) (Table 3). During follow-up, 333 patients received second-line treatments with one or more conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs), tumor necrosis factor inhibitors (TNFi), bisphosphonates, or JAK inhibitors. Twenty-four (65%) of 37 patients who developed psoriasis after diagnosis were exposed to csDMARDs and/or TNFi at a mean of 2 years post-diagnosis. Additionally, four of five patients requiring intravenous antibiotics for infection were treated with TNFi within 60 days.

Conclusion: We were able to leverage CHOIR to estimate the frequency of various comorbidities, long-term risks, and growth impacts on children with CNO. Over 5-years of follow-up, the number of active spinal lesions on MRI decreased and fewer compression fractures occurred after diagnosis compared to before diagnosis. Growth metrics remained within normal range at the population level. The most common medical events after diagnosis of CNO were psoriasis and inflammatory arthritis.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Syndrome of Undifferentiated Recurrent Fevers (SURF) refers to patients with recurrent fevers who do not meet clinical or classification criteria for Periodic Fevers, Aphthous stomatitis, Pharyngitis, and Adenitis (PFAPA) syndrome or Hereditary Recurrent Fever syndromes (HRFs). Most studies on patients with SURF reveal heterogeneous presentations and responses to treatment. The aims of this study were to define endotype groups within SURF, and their treatment responses.

Methods: SURF was defined as at least 3 stereotypical recurrent fever episodes not fitting clinical criteria for PFAPA or HRFs. Patient data were collected from Cincinnati Children's Hospital Medical Center (CCHMC), University of Michigan (UofM), Texas Children's Hospital (TCH), and Boston Children's Hospital (BCH). Cytokine analysis was performed on

Patient Demographics

available samples. Patients were clustered using age and clinical characteristics by Partitioning Around Medoids (PAM), Hierarchical, and K-prototype clustering methods. Characteristics associated with treatment responses were analyzed using univariable and multivariable regression.

Results: A total of 110 patients were included (CCHMC=65, UofM=15, BCH=15, TCH=15). PAM clustering showed three main groups: group 1 (n=57) largely resembled PFAPA but with frequent abdominal pain and myalgia; group 2 (n=30) had rash and arthralgias; and group 3 (n=23) was fever predominant. Cytokine analysis of these clusters showed elevated levels of IFN- β in group 3, a group that was also more likely to have complete response to on demand steroids. Regression analyses supported that patients without musculoskeletal complaints tended to have a complete response to on demand steroids, patients without GI complaints tended to have complete response to colchicine, patients with anorexia tended to have a complete response to tonsillectomy/adenoidectomy, and that patients with headache and arthralgias tended to receive anti-IL1 treatment and have a complete response. Genetic analysis showed high enrichment for genes associated with innate immunity in Groups 1 and 2 (enrichment score 5.75 and 4.72, respectively).

Conclusion: We found three distinct groups of SURF patients: 1. PFAPA-like, 2. rash and arthralgias, and 3. fever predominant. This third group was immunologically distinct and most likely to respond to on-demand steroids. Groups 1 and 2 tended to have high enrichment scores for genes important in innate immunity. Larger prospective studies are needed to better define the groups that exist within SURF.

Systemic juvenile idiopathic arthritis- Fifteen-year experience from a tertiary centre at Bristol, United Kingdom

Ashwini Batchu Prithvi, Chaitra Govardhan, Bushra Aladaileh and Athimalaipet V Ramanan, Bristol Royal Hospital for Children, Bristol, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic juvenile idiopathic arthritis (sJIA) is a chronic disease that results in significant morbidity and mortality in children1. Improved understanding of the pathophysiology of sJIA has led to recent therapeutic advances including a growing evidence base for the earlier use of IL-1 or IL-6 blockade2. We aim to describe our experience of sJIA over a period of 15 years which includes clinical presentation, therapeutic interventions and the heterogeneity around the use of biologics spanning over this period, and the clinical outcomes at different time points over the course of the disease.

Methods: Children with a diagnosis of sJIA treated at Bristol Royal Hospital for children from 2010 to 2025 were included. Electronic medical records were reviewed retrospectively. Details regarding patient demographics, clinical features, laboratory parameters, treatment and outcomes were recorded. Patients were categorized as monocyclic, polycyclic and persistent depending on the disease course. Data was analyzed using descriptive statistics.

Results: A total of 80 children diagnosed with sJIA-29 (36.25%) monocyclic, 12(15%) polycyclic, 39(48.75%) were persistent. The mean age of diagnosis 7.6 (0.8-16) years. 43(53.75%) were females. Apart from fever (in 100%), other common presentations included rash 67(83.8%), arthritis 54(67.5%), splenomegaly 23(28.8%). Median(IQR) laboratory investigations at diagnosis included haemoglobin 98gm/L(85-112), white cell count $18*10^9$(10-26), platelets 411 $*10^9$(288-549), C-reactive protein 121mg/L(63-195), ESR 75mm/hr(25-136),D-dimer 3089ng/mL(1359-6106), LDH 501U/L(345-902), fibrinogen 5.2ng/mL(3.4-6.4), ferritin 1443mcg/L(459-4415), triglycerides 1.5mmol/L(1-2.3), ALT 26 U/L(12-65). Treatment received primarily was variable over the 15 year span and included combination of corticosteroids, disease modifying anti-rheumatic drug, IL-1 and IL-6 blockade. IL-1/IL-6 blocker therapy initiated in 15(18.8%) within 3 months of diagnosis and 39(48.7%) by the end of 1 year. Maximum disease inactivity off treatment was achieved in the monocyclic group(80.8%). Disease activity controlled on treatment was achieved in 62.5% in polycyclic and 56.4% in persistent group. At the end of 5 years, 5/8 in polycyclic and 6/30 in persistent achieved clinical remission off treatment.

Conclusion: sJIA is a disease with the variable course that determines the outcome. Based on our study, it has been observed that children in persistent category required combination of therapies to keep the disease under control.

Transition from Juvenile Dermatomyositis to Spondyloarthritis: A Novel Overlapping Inflammatory Phenotype

Austen Grooms[1], Ioannis Karageorgiou[2], Kerry Mychaliska[2] and James Birmingham[3], [1]William Beaumont University Hospital, Auburn Hills, MI, [2]William Beaumont University Hospital, Royal Oak, MI, [3]River City Rheumatology, Grand Rapids, MI

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Juvenile Dermatomyositis (JDM) is a rare inflammatory disease primarily affecting muscle, skin, and vasculature. Characterized by muscle weakness, distinctive skin lesions, and autoantibodies, it is thought to be driven predominantly by adaptive immunity. Conversely, Spondyloarthritis (SpA) represents a group of inflammatory disorders involving the axial skeleton and peripheral joints that are driven by both innate and adaptive immune mechanisms. Here we describe features in patients initially diagnosed with JDM who later developed SpA. The transition from JDM to SpA has not previously been reported.

Methods: This IRB (2024-180) exempt retrospective study collected demographic information, clinical symptoms, laboratory findings, imaging, treatments, and outcomes from a convenience sample of patients with JDM who subsequently developed SpA. Inclusion criteria were patients meeting diagnostic criteria for JDM before age 18 who later developed SpA using the Assessment of Spondyloarthritis International Society (ASAS) classification criteria and Classification Criteria for Psoriatic Arthritis (CASPAR). Exclusion criteria were patients who developed SpA before JDM or did not meet ASAS or CASPAR criteria. Descriptive statistics were used to examine data from patients with JDM to explore potential predictors associated with the subsequent development of SpA.

Results: A total of 7 patients met inclusion criteria; 57 % (4/7) were female, 86 % (6/7) were Caucasian. The mean age at diagnosis of JDM was 7.4 years (SD = 3.6) and the mean interval from JDM onset to SpA diagnosis was 11.7 years (SD = 6.9). In all patients with JDM diagnosis, neopterin was elevated in 100 % (4 /4) of patients tested and 100% (7/7) had myositis on Magnetic Resonance Imaging. Of these patients, 71 % (5/7) had additional complications prior to SpA onset (table 3).

Of those diagnosed with SpA, 100% (7/7) met ASAS criteria for peripheral SpA and 29 % (2/7) met CASPAR criteria. Lastly, 83 % (5/6) responded to standard treatment protocols for SpA, 1 was treated with rituximab and azathioprine for calcinosis, and 1 was lost to follow up. HLA-B27 was positive for 14 % (1/7) of patients.

CK Range: Case 1 (80-225 U/L); Case 2 (20-175 U/L); Case 4 (26-175 U/L); Case 5 (26-180 U/L); Case 6 (29-143 U/L); Case 7 (80-225 U/L); LDH Range: Case 1 (186-228 U/L); Case 3 (188-210 U/L); Case 4 (160-229 U/L); Case 5 (140-280 U/L); Case 7 (180-280 U/L)

Conclusion: This preliminary small study identified a cohort of patients diagnosed with JDM, an adaptive immune disease, who later were diagnosed with SpA, an innate driven illness. The clinical and serologic data examined offer some data points that may support the novel idea that there are predictors of disease overlap. However, future research is required to better understand this possible evolution from an adaptive to an innate immune disease state and inform predictive models.

Abstract Number: 2132

The Bridge to Adult Care from Childhood for Young Adults with Rheumatic Disease (BACC YARD) Program, a Pediatric-To-Adult Rheumatology Transition Program, Reduces Median Time between Final Pediatric, First Adult, and Second Adult Visits

Ayah Eltoum[1], Eileen Rife[2], Livie Timmerman[3], Emily Smitherman[4], Melissa Mannion[4] and John Bridges[5], [1]University of Alabama at Birmingham, Hoover, AL, [2]University of Alabama Birmingham, Vestavia Hills, AL, [3]University of Alabama at Birmingham, Gardendale, AL, [4]University of Alabama at Birmingham, Birmingham, AL, [5]University of Alabama at Birmingham/Children's of Alabama, Birmingham, AL

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: The transition from pediatric to adult-oriented rheumatology care is a critical period for young adults with childhood-onset rheumatic diseases. The Bridge to Adult Care from Childhood for Young Adults with Rheumatic Disease (BACC YARD) Program offers a dual provider pre-transfer visit to facilitate successful transition. This study evaluates whether the dual provider pre-transfer visit improves intervals for subsequent adult rheumatology visits, compared to historical controls without a formal pre-transfer visit.

Methods: We conducted a retrospective cohort study of 189 young adults with childhood-onset rheumatic disease who transferred from Children's of Alabama to the University of Alabama, Birmingham adult rheumatology clinic. The intervention group (n=144) enrolled in the BACC YARD Program between July 2020-April 2024 and completed a dual provider pre-transfer visit. The historical control group (n=45) transferred between March 2018-February 2020 without a structured pre-transfer visit. The primary exposure was participation in the BACC YARD program and the primary outcome was the number of days from the last pediatric visit to the first adult visit. Secondary outcomes included the interval (in days) between first and second adult visits, and adherence to provider-recommended follow-up intervals. Wilcoxon rank-sum and Kruskal-Wallis tests were used to compare median intervals between groups. Logistic regression models were used to estimate associations between successful adherence to provider-recommended intervals, adjusted for age, sex, race, ethnicity, and diagnosis in the BACC YARD group.

Table 1: Patient Characteristics, BACC YARD and Historical Control Cohorts

	Overall	BACC YARD Cohort	Historical Control Cohort
Total (n)	189	144	45

SLE	39	92 (59-365)	128 (63-488)	
Other*	27	122 (31-366)	152 (22-605)	
Total	**144**	122 (31-488)	148 (22-605)	

^Requested timing for adult rheumatology visits was determined by joint decision between the adult/pediatric rheumatologist and the childhood pediatric rheumatologist
[1]p <0.05 indicates significance. Kruskal-Wallis test was used to compare medians.
*Other included vasculitis, uveitis, inflammatory myopathy, relapsing polychondritis, morphea, and autoinflammatory syndrome
BACC YARD: Bridge to Adult Care from Childhood for Young Adults with Rheumatic Disease; JIA: juvenile idiopathic arthritis; SLE: systemic lupus erythematosus

Results: The median age was 20 years in both cohorts. Females comprised 75% of the BACC YARD group and 89% of the control group. Juvenile idiopathic arthritis (JIA) was the most common diagnosis (56%, n=105) in both cohorts, followed by systemic lupus erythematosus (SLE) (30%, n=56). The BACC YARD group demonstrated significantly shorter median time from the last pediatric to the first adult visit compared to controls (143 vs. 261 days, p=0.0049), particularly among patients with JIA (148 vs. 316 days, p=0.0145). No significant difference was observed for patients with SLE. Among the BACC YARD group, the median interval between the first and second adult visits was 148 days (range: 22 to 605), with no significant differences across diagnosis groups. 71% (n=102) had their first adult visit within 30 days of their recommended follow-up date with no factors significantly associated with first visit adherence. 58% (n=83) had a second visit within 30 days of their recommended follow-up date. Hispanic patients were 80% less likely to adhere to the second visit compared to non-Hispanic patients (OR= 0.2, 95% CI: 0.05-0.90, p=0.035).

Conclusion: Participation in the BACC YARD program was associated with a shorter time interval to initial adult rheumatology clinic visit, particularly for patients with JIA. While most patients in the program continued to adhere to recommended timing for follow-up, disparities were observed by ethnicity in second visit adherence. These findings support embedding pre-transfer coordination into transition models to improve continuity for adolescents with rheumatic disease.

Examination of HLA-DRB1*15-linked Candidate Antigens in Still's Disease with and without Lung Disease and Features of Drug Hypersensitivity

Dale Kobrin[1], Garrett Brown[2], Mariana Correia Marques[1], Carol Lake[3], Michelle Millwood[4], Lisa Workman[5], Monica Lawrence[5], Zuoming Deng[6], Sanchita Das[2] and Michael Ombrello[7], [1]Translational Genetics and Genomics Section, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, [2]Department of Laboratory Medicine, National Institutes of Health, Bethesda, MD, [3]NIH, GAITHERSBURG, MD, [4]National Institutes of Health (NIH), Bethesda, MD, [5]Division of Asthma, Allergy, and Immunology, University of Virginia School of Medicine, Charlottesville, VA, [6]Biodata Mining and Discovery Section, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, [7]National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health (NIH), North Bethesda, MD

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Lung disease in systemic juvenile idiopathic arthritis and adult-onset Still's disease (Still's-LD) is a severe manifestation that strongly associates with features of drug hypersensitivity reactions (fDHR), including eosinophilia, non-Still's rashes, and elevated liver function tests. In patients with Still's disease, both LD and fDHR are strongly associated with HLA-DRB1*15 alleles; however, the pathogenesis of these phenomena remain unknown. This study investigates whether Still's-LD and fDHR are associated with pathogenic antigens through hypersensitivity reactions to *Aspergillus*

Table 1: Clinical characteristics and results of testing for Aspergillus fumigatus antibodies and viral nucleic acids Continuous variables are presented as mean ± standard deviation (range), categorical variables are presented as N (% of non-missing values). LD: lung disease, fDHR: features of drug hypersensitivity reactions, PAH: pulmonary arterial hypertension, TTE: transthoracic echocardiography, RHC: right heart catheterization, LFT: liver function test, EBV: Epstein-Barr virus, CMV: cytomegalovirus, HHV-6: human herpesvirus 6. Anti-Aspergillus fumigatus IgE via ImmunoCap Allergen m3 assay. EBV, CMV, and HHV-6 nucleic acids by PCR and/or VIRTUS.

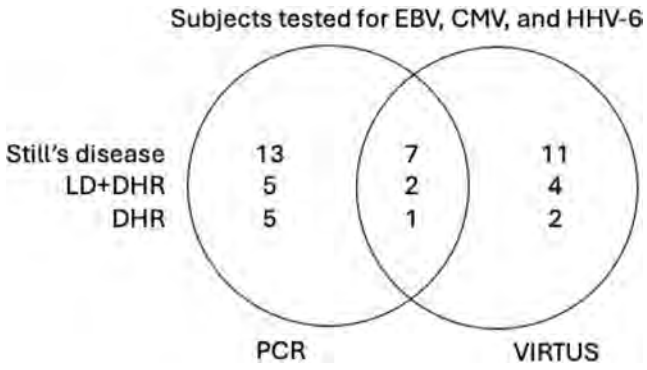

Figure 1: Subjects tested for EBV, CMV, and HHV-6 by PCR and VIRTUS

fumigatus, for which HLA-DRB1*15 is a known risk allele, or drug reaction with eosinophilia and systemic symptoms (DRESS), which is frequently associated with human herpesvirus reactivation.

Methods: Pediatric and adult subjects were drawn from the NIH Still's disease cohort, subjects with Still's-LD and/or fDHR were identified by chart review. Serum samples were analyzed for anti-*Aspergillus fumigatus* IgE via ImmunoCap assay. Subjects were screened for EBV, CMV, and HHV-6 by PCR assay for viral nucleic acids and/or Viral Transcript Usage Sensor (VIRTUS) analysis of whole blood RNAseq data for viral transcripts. The prevalence of anti-*Aspergillus fumigatus* IgE antibodies and viral nucleic acids were compared between groups using two-tailed Fisher's exact tests with a significance level set at 0.05.

Results: Fifty-five subjects were included in the study, 11 had LD and fDHR and 8 had fDHR alone. Thirty-three subjects were tested for anti-*Aspergillus* antibodies and all were negative. Fifty subjects were tested for EBV, CMV, and HHV-6, 23 by PCR only, 17 by VIRTUS only, and 10 by both PCR and VIRTUS. All subjects were negative for CMV and HHV-6 by PCR and VIRTUS. Two subjects without LD or fDHR had detectable EBV nucleic acids by PCR and no subjects with LD or fDHR had detectable EBV by PCR or VIRTUS, a difference which was not statistically significant ($p = 0.52$). Of those tested for viral nucleic acids, 11/19 (58%) had testing performed within 1 year of active LD or fDHR.

Conclusion: The absence of anti-*Aspergillus* IgE antibodies and detectable herpesvirus nucleic acids in subjects with Still's-LD and fDHR does not support a mechanistic association with hypersensitivity to *Aspergillus fumigatus* or with human herpesvirus reactivation. Additional work is needed to improve the mechanistic understanding of Still's-LD and fDHR.

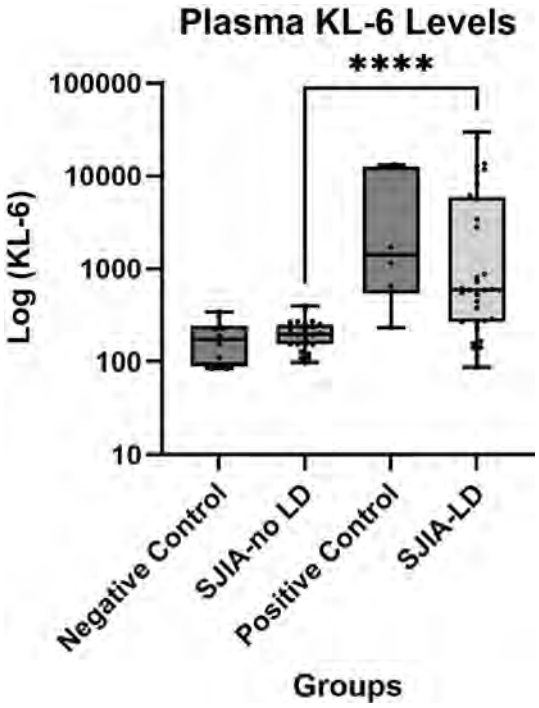
SESSION INFORMATION

Session Date: **Tuesday, October 28, 2025**
Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Children with Systemic Juvenile Idiopathic Arthritis (SJIA) who develop lung disease (LD) are at significantly increased risk of serious complications and even death. Early detection and intervention are critical for improving outcomes and stabilizing disease progression. However, diagnosing LD in children presents many unique challenges. No single pulmonary measurement can be easily applied for diagnosis and conventional methods are not always safe or feasible in young children. Krebs von den Lungen 6 (KL-6) is a promising diagnostic and prognostic blood-based biomarker of LD in adult studies, however its utility in pediatric LD is unclear. This study evaluates KL-6 as a diagnostic biomarker for LD in pediatric patients with SJIA.

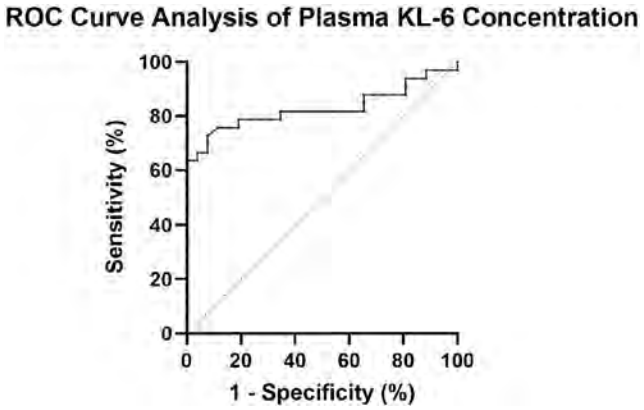
Methods: Thirty-three patients enrolled in the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry (from 18 US clinical sites) SJIA-LD cohort were included. As comparators, we included 26 patients with SJIA and no LD (SJIA-no LD) from the CARRA First-Line Options for SJIA Treatment (FROST) study, 6 children with primary protein alveolar proteinosis (PAP) as positive controls and 10 healthy children as negative controls. The primary outcome was plasma KL-6 concentration in each group as quantitated by ELISA. Secondary outcomes included clinical characteristics associated with elevated KL-6 levels.

Results: Median plasma KL-6 level in SJIA-LD was 593 U/mL (interquartile range [IQR]:268-5,896), compared to 194 U/mL (IQR:152-253) in the SJIA-no LD group (p< 0.0001) and 172 U/ml (IQR:89-245) in healthy controls (p=0.0003). No significant difference was observed between SJIA-LD and PAP patients (593 vs. 1430, p=0.258). At a cut-off of 260 U/mL by receiver operating curve (ROC), plasma KL-6 yielded a sensitivity of 79% and specificity of 81% for SJIA with LD (area under



Box and Whisker plot of Plasma KL-6 Concentrations within each group - median, interquartile range (IQR), and outliers displayed. Median plasma KL-6 concentration in SJIA-LD was 593 U/mL (IQR:268-5,896); 194 U/mL (IQR:152-253) in the SJIA-no LD group (p<0.0001) and 172 U/ml (IQR:89-245) in healthy controls (p=0.0003). **** = p<0.0001

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



ROC analysis of the plasma KL-6 concentration in systemic juvenile idiopathic arthritis-associated lung disease (SJIA-LD) with SJIA-no LD as the control. At a cut-off of 260 U/mL, plasma KL-6 yielded a sensitivity of 79% and specificity of 81% for SJIA-LD (area under the curve = 0.83, p<0.0001). A cut-off of 421 U/mL yielded a sensitivity of 63% with specificity reaching 100%.

the curve = 0.83, p< 0.0001). At a cut-off of 421 U/mL, sensitivity was 63% with specificity reaching 100%. Clinical features in SJIA-LD associated with higher mean KL-6 levels included tachypnea on examination (7,627 vs. 1,719, p=0.03), hypoxemia on pulse oximeter (9,769 vs. 3,096, p=0.049), abnormal chest-Xray findings (3,177 vs. 198, p=0.04), and steroid requirement at any point (6,156 vs. 449, p=0.01). The Physician Global Assessment of Lung Disease (PGALD) was strongly correlated with mean KL-6 (r=0.75, p< 0.0001). KL-6 levels were not significantly associated with the presence of macrophage activation syndrome (p=0.66) or markers of systemic inflammation: C-reactive protein, ferritin, interleukin (IL)-18, CXCL9, or sIL2r. We were unable to evaluate the relationship between computed chest tomography (CT) abnormalities and KL-6 levels as there was an insufficient number of CT scans performed within a month of the blood sample.

Conclusion: KL-6 is a useful diagnostic biomarker of LD in pediatric SJIA; a cut-off level of 421 U/mL yielded a specificity of 100% in our cohort. Future efforts should focus on the utility of KL-6 for monitoring disease progression, evaluating treatment response, and for predicting long-term disease trajectories.

* Effect size calculated using Phi (interpretation: Small = 0.1, Medium = 0.3, Large = 0.5)

** Effect size calculated using Cohen's d (interpretation: Small = 0.2, Medium = 0.5, Large = 0.8)

Background/Purpose: Historically, treatment for systemic juvenile idiopathic arthritis (sJIA) included high dose glucocorticoids (GC) and conventional systemic (cs) disease modifying anti-rheumatic drugs (DMARDs) with significant side effects and poor outcomes. While studies of sJIA patients treated with biologic (b) DMARDs (i.e. IL-1 inhibitors (IL-1i) and IL-6 inhibitors (IL-6i) demonstrated decreased GC use and improved outcomes, less is known regarding longer term outcomes. Using data from the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry, we aimed (1) to describe longitudinal trends in medication use over the first 24 months of disease and (2) assess the impact of increased early biologic use on GC use & disease activity (DA) in this observational registry.

Methods: Patients with sJIA enrolled in the CARRA Registry between 2015-2024 were stratified based on disease duration at enrollment. Those enrolled within 60 days of diagnosis and had clinical data at enrollment visit (EV), 6 mo and 12 mo were included in medication and DA analysis. DA assessments included fever, use of systemic GC, and clinical juvenile arthritis disease activity score based on 10 joints (cJADAS10). Chi-Square and Mann–Whitney tests were used to compare the

Figure 1: Medication use over time

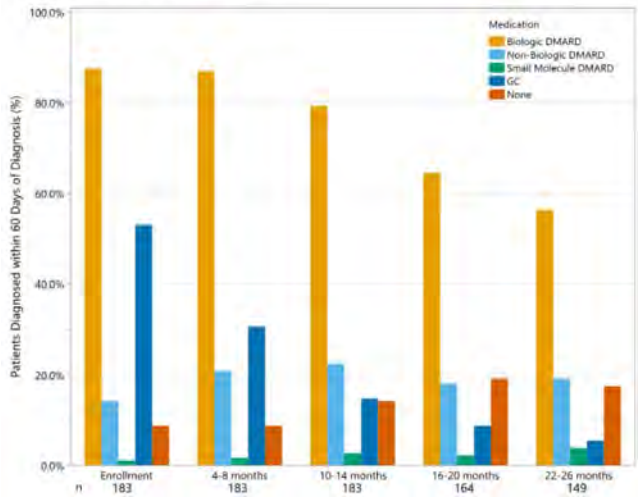

Figure 1: Medication use over time

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2: DA over time

study cohort with all SJIA patients enrolled in the registry. Summary statistics were used to describe medication usage and DA at 6 mo intervals.

Results: Of 920 patients with sJIA, 183 patients (19.9%) met recent diagnosis criteria. Median time from symptom onset to diagnosis was 1 mo (IQR 1-2mo) (Table 1). 87.4% were started on a bDMARD within 60 days of diagnosis (37.7% anakinra and 16.9% canakinumab), and 79.2% were on a bDMARD at some point during their 2 year course (Fig 1). 56.6% of patients who started anakinra switched to canakinumab and 6.5% started on canakinumab switched to anakinra. Of the 12 patients whose first bDMARD was an IL6i, 16.7% switched to an IL1i. bDMARD use decreased over time 79.2% at 12 mo and 18.3% at 24 mo). 14.2% were off all medications by 12 mo and 17.5% by 24 mo (Fig 1). GC use decreased over time, with 64.5% at EV, 30.6% at 6 mo and 13.6% at 12 mo. 14.8% had inactive disease per cJADAS10 (< 2.5) at EV, with 83.2% achieving inactive disease by 12 mo (Fig 2).

Conclusion: Overall, baseline features of recently diagnosed sJIA patients were not significantly different from other sJIA patients in the Registry. Despite the high incidence of bDMARD use within the first 60 days of diagnosis, nearly half of all patients were exposed to GC early in disease course. The proportion of patients achieving inactive cJADAS10 with or without fever reached 64% and 59.6% respectively by 12mo. At 2 years of follow-up, 17.5% of patients were off all medication.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Chronic nonbacterial osteomyelitis (CNO) is a noninfectious autoinflammatory bone disease which remains a diagnosis of exclusion, as existing diagnostic criteria are not widely accepted. Recently, the European Alliance of Associations for Rheumatology (EULAR) and the American College of Rheumatology (ACR) developed new classification criteria for CNO, demonstrating 82% sensitivity and 98% specificity in an initial study.

We aimed to investigate sensitivity and specificity of the new EULAR/ACR classification criteria for pediatric CNO, in a distinct real-world clinical setting and compare it to the sensitivity and specificity of the existing Jansson and Bristol diagnostic criteria.

Methods: This was a single-center cross-sectional study including children ≤18 years, diagnosed with CNO, acute infectious osteomyelitis (AOM) and bone malignancy from June 1, 2018 to May 31, 2024. Patients with other mimicking conditions, immunodeficiency, sickle cell disease, or those previously included in the original development cohort were excluded. Patients were divided into two groups: a CNO group and a non-CNO group (AOM and bone malignancy), from the latter a representative, random, sample was selected (www.random.org). Demographic, clinical, laboratory, imaging and pathology data were collected at disease onset. EULAR/ACR criteria were retrospectively applied to the entire cohort, independently from the initial diagnosis. Patients with an aggregate score ≥ 55 points were classified as having CNO. A sensitivity analysis was also conducted where patients with criteria with missing data were excluded. Classification results using the new criteria were compared with the final clinical diagnosis based on physician assessment (criterion standard). The same analysis was applied to Jansson and Bristol criteria. From contingency tables, sensitivity and specificity were calculated.

Results: Of the 164 children included, 82 had CNO, 41 were randomly selected from 274 cases of AOM, and 41 from 849 cases of bone malignancy. The median age was 10 years (IQR 3–16), with 62% girls and 37% boys, 66% had a bone biopsy. Overall, 40% scored ≥ 55 and 60% did not, with 3 false positive and 19 false negative (Table 1). The EULAR/ACR criteria demonstrated 77% sensitivity and 96% specificity, with a positive predictive value (PPV) of 95% and negative predictive value (NPV) of 80%. In our sensitivity analysis excluding patients with incomplete data, results remained consistent (sensitivity 79%, specificity 96%, PPV 95%, NPV 81%). In comparison, the Jansson criteria showed 78% sensitivity, 67%

Table 1. Contingency Table of EULAR/ACR Criteria Performance in Classifying Pediatric CNO

Category	EULAR/ACR CNO Positive (≥ 55)	EULAR/ACR CNO Negative (<55)
CNO	63	19
Non-CNO	3	79

Table 2. Comparison of Diagnostic Performance Across CNO Classification Criteria

Criteria	Sensitivity	Specificity	PPV	NPV
EULAR/ACR	77%	96%	95%	80%
EULAR/ACR (sensitivity analysis)	79%	96%	95%	81%
Jansson	78%	67%	70%	75%
Bristol	89%	70%	86%	74%

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

specificity, PPV of 70%, and NPV of 75%. The Bristol criteria yielded 89% sensitivity, 70% specificity, PPV of 86%, and NPV of 74% (Table 2).

Conclusion: Based on its favorable sensitivity and specificity, especially in comparison to existing criteria, the new EULAR/ACR criteria appeared to be more effective in distinguishing CNO from AOM and bone malignancy at disease onset. These results were consistent with findings from the original validation cohort.

Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Despite continuous advances in care and the recent publication of updated international recommendations, relevant discrepancies in the management of Still's disease (SD) may still exist, due to different clinical presentation and practice setting. The aim of the study is to assess current intial treatment strategies in SD worldwide, and to identify factors influencing clinical decision-making.

Methods: As part of the METAPHOR project, a PReS/PRINTO initiative to optimize treatment in SD and macrophage activation syndrome, a global survey on SD treatment was developed and distributed (Dec 3, 2024–Feb 14, 2025). Topics were selected by 22 experts. The survey included demographic data, clinical practice insights, a patient-led section on unmet needs. International physicians part of the PReS/PRINTO network and adult rheumatologists involved in SD care were invited to complete the anonymous online survey (Dec 3, 2024–Feb 14, 2025).

Results: A total of 206 clinicians, mainly pediatric rheumatologists (91%), from 56 countries completed the survey. In newly diagnosed SD patients without MAS, 34% of respondents would initiate anti-IL1/IL6 biologic without glucocorticoids (GCs); the rest would use GCs alone (24%) or in combination with biologics (42%). Factors favoring GCs use included severe pericarditis (64%), severe arthritis (55%), and refractory disease risk factors (16%), as hyperferritinemia, lung involvement, early onset and Trisomy 21.Anakinra was the most frequently used biologic in 1st line (59%), followed by Tocilizumab (25%). Only 1.5% reported unavailability of any anti-IL1/IL-6 therapy. Factors driving anakinra's choice were safety (72%), cost (41%), and predominant systemic phenotype (73%), while Tocilizumab was chosen for compliance (56%) and arthritis-dominant profile (80%). Difficult access to medication influenced decisions for Rilonacept (67%), Canakinumab (27%), Anakinra (17%); Tocilizumab was rarely unavailable (1.5%).In systemic-predominant SD, clinicians used NSAIDs (50%), GCs (46%), GCs pulses (42%),

and Anakinra (45%) as first-line options. Second-line strategies included Tocilizumab (39%), GCs (31%), Anakinra (29%), GCs pulses (22%), and MTX (21%), while Tocilizumab (37%), JAK inhibitors (29%), and cyclosporin (24%) were the most selected options as third-line therapies. In SD patients with a prominent articular involvement at onset, half of the respondents would not change their therapeutic approach. Physician who modified thor strategy would use as a first line f therapies GCs (47%), oral steroids (44%), Tocilizumab (39%), MTX (34%), and intra-articular steroids (31%). Second-line choices were mostly Tocilizumab and MTX (~40%). Differences in management by clinical phenotype are detailed in Figure 1.

Conclusion: Still's disease still represents a therapeutic challenge, mainly due to its heterogeneity in clinical expression. Our data reveals significant differences in treatment approaches, driven by clinical phenotype and drug availability. Future research is essential to optimize clustering of patients to foster tailored target treatments, while ensuring equitable access to effective therapies worldwide.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Despite continuous improvement in care and the recent update of international recommendations, relevant discrepancies in the diagnostic and treatment approach to Still's disease (SD) may still exist, in particular in the timing and factors influencing treatment start and withdraw. The study was aimed to explore current global treatment strategies for SD, focusing on parameters driving the decision-making process at treatment start and at withdrawal

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: As part of the METAPHOR project, a PReS/PRINTO initiative to optimize treatment in SD and macrophage activation syndrome, a global survey on SD treatment was developed based. Topics were selected by 22 experts, including 1 patient representative and 1 adult rheumatologist. The survey included demographic data, clinical practice insights, a patient-led section on unmet needs. International physicians part of the PReS/PRINTO network and adult rheumatologists involved in SD care were invited to complete the anonymous online survey (Dec 3, 2024–Feb 14, 2025).

Results: A total of 206 responses, mainly from pediatric rheumatologists (91%) from 56 countries were collected. Infectious tests performed at SD onset included TB, EBV, and blood cultures (80%), parvovirus, HBV, HCV, and SARS-CoV-2 (50%). Most physicians performed peripheral blood smears (85%), while 54% bone marrow aspiration, 38% immunophenotyping and 17% bone marrow biopsy. Imaging was commonly performed, with chest X-ray, abdominal ultrasound, and echocardiography as the most frequent investigations (∼80%). Among biomarkers, ferritin was almost always tested, while IL-18 (25%), S100 proteins (19%), and HLA-DRB1*15 (17%) were less frequently assessed. Before starting glucocorticoids (GCs) 68% of clinicians deemed certain investigations mandatory: bone marrow aspiration (74%), blood coltures and TB screening (50%), chest-abdomen CT scan and bone marrow biopsy (∼20%).

Beginning of steroid tapering was guided mostly by clinical and laboratory parameters: acute phase reactants (95%) and ferritin (87%) reduction, fever resolution (82%, ≥1 week: 37%; ≥72h: 29%; ≥2 weeks: 16%), arthritis improvement (75%), steroid side effects (42%); 29% and 25% requires normalization of acute phase reactants and ferritin, respectively, to start GCs tapering. More than half of physicians took patient/parent-reported outcomes (51% global VAS, 35% pain VAS) in consideration.

Steroid discontinuation required at least 4-6 weeks of inactive disease for 40% of participants, and ≥3 months for 34%. Biologics withdrawal was considered after at least 6 months (35%), 1 year (35%) and 3 months (36%) of inactive disease. Factors driving biologics withdrawal were similar to ones influencing steroid tapering.

Conclusion: A considerable heterogeneity in clinical practice still exist, in particular in

timing and factors guiding treatment tapering and withdrawal. Fostering harmonization of management of SD is essential to ensure consistent and optimal care for patients across different clinical settings

SESSION INFORMATION

Session Date: **Tuesday, October 28, 2025**
Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The outcome of Still's disease (SD) has significantly improved due to new therapeutic options [37923864], early biologic initiation [24623686] and treat-to-target strategies [39317417]. Nonetheless, a substantial proportion of patients still experiences a refractory course, severely impacting their quality of life. Treatment strategies in these

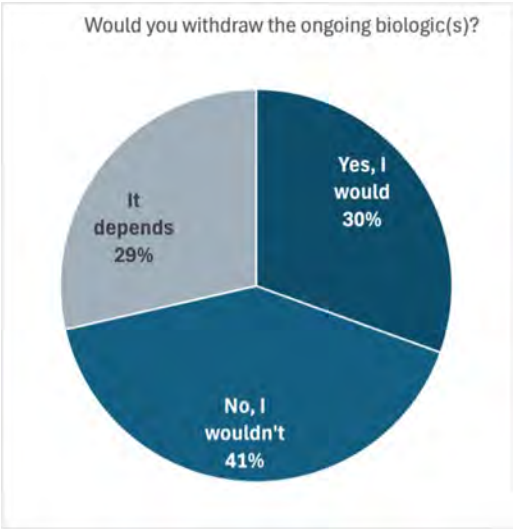

Figure 1 – Answer to the question "In a patient with Still disease and first detection of lung involvement while on therapy with IL-1 or IL-6 inhibitors, would you withdraw the ongoing biological treatment?"

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

cases are not standardized and are affected by medication availability and clinician experience. This real-life study aims to describe current treatment practices and major unmet needs, fostering a uniform approach to refractory SD.

Methods: As part of the METAPHOR project, a PReS/PRINTO initiative to optimize therapy in SD and Macrophage Activation Syndrome (MAS), a global survey on refractory SD treatment was developed, with the following proposed subtypes: 1) persistent arthritis, 2) recurrent/refractory MAS and 3) SD-associated lung disease (SD-LD). Topics were selected by 22 expert pediatric rheumatologists, including 1 patient representative and 1 adult rheumatologist. The survey covered demographic data, clinical practice insights and a patient-focused section on unmet needs. International physicians part of the PReS/PRINTO network together with adult rheumatologists involved in SD care were invited to complete the web-survey between 3/12/24 and 14/2/25.

Results: A total of 206 physicians completed the survey, predominantly pediatric rheumatologists (91%), from 56 countries. Methotrexate was the most common 1st-line choice for SD-refractory arthritis, followed by anti-TNF agents and intra-articular steroids. JAK inhibitors (JAK-i) were considered mainly as 2nd- or 3rd-line option. If systemic symptoms co-occurred, 62% of respondents would modify their strategy, favoring methylprednisolone (MPN) pulses, JAK-i and ciclosporin. In SD patients with recurrent/refractory MAS, ciclosporin, anakinra, and MPN pulses were the most frequently selected medications. Treatment decisions were mainly guided by clinical severity, inflammatory markers, history of ICU admission and concomitant complications. Biomarkers played a minor role, partly due to limited access, reported by 22% of clinicians. For SD-LD, 41% would continue ongoing biologics, 30% withdraw and 29% decide case by case (figure 1).

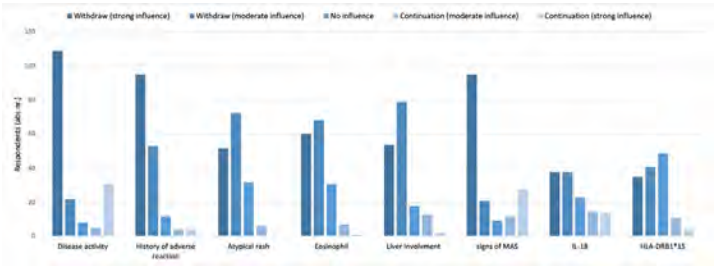

Figure 2 - Answer to the question: "In a patient with Still disease and first detection of lung involvement while on therapy with IL-1 or IL-6 inhibitors, which parameters influence your decision regarding withdrawal/continuation of IL-1 or IL-6 blockade"

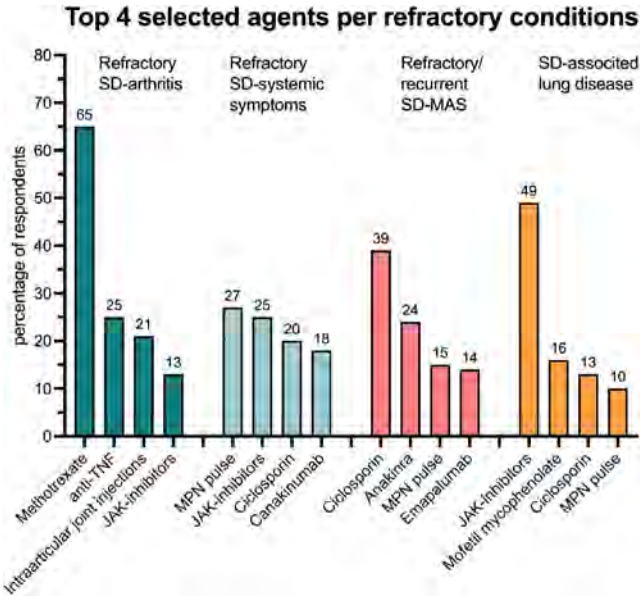

Figure 3 - Top 4 most commonly used first line agents for each subtype of refractory SD

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Factors influencing withdrawal included persistent disease activity, history of adverse reactions and impending MAS. HLA genotyping was rarely considered relevant (figure 2). The most used 1st-line agents for SD-LD included JAK-i, mycophenolate mofetil, and ciclosporin and only 8% would add Pneumocystis Jiroveci prophylaxis. Most respondents (82%) would consider Hematopoietic Stem-Cell Transplantation (HSCT) in difficult-to-treat SD patients, particularly for refractory MAS or SD-LD. Differences in management by clinical phenotype are detailed in figure 3.

Conclusion: Management for refractory SD is widely heterogeneous and varies by phenotype. JAK-i are the most commonly used agents alongside standard therapies and HSCT is increasingly considered a potential option, especially for refractory MAS and SD-LD. A consensus effort is essential to refine the definition and identify optimal treatment strategies for refractory cases.

Table 1: High Parameter Flow Cytometry Panel

encompasses interstitial lung disease, pulmonary fibrosis, pulmonary arterial hypertension, and pulmonary alveolar proteinosis, and associated with poor prognosis. The immunopathogenesis of sJIA lung disease (sJIA-LD) is poorly understood but has been associated with unique lymphocyte activation signatures. Our objective was to define myeloid and lymphoid subsets from sJIA-LD patients using high-parameter flow cytometry, and to correlate differences with disease activity.

Methods: Peripheral blood mononuclear cells (PBMC) were obtained from the CARRA Registry sJIA-LD cohort, after informed consent and approval from the CARRA Biorepository. Controls were healthy control children enrolled at CCHMC after informed consent. Full spectrum flow cytometry using the Auora platform was utilized, and cell populations were identified using manual gating. Previously reported from our lab, a high parameter flow cytometry panel (28-parameters) was created to investigate myeloid and lymphoid cell subsets (Table 1). Graph Pad PRISM was used to visualize and analyze the data. Statistical analysis utilized unpaired two-tailed t-test or Mann-Whitney for data that was not normally distributed. Relationships between physician global assessment of lung disease (PGALD) and cell populations used simple linear regression.

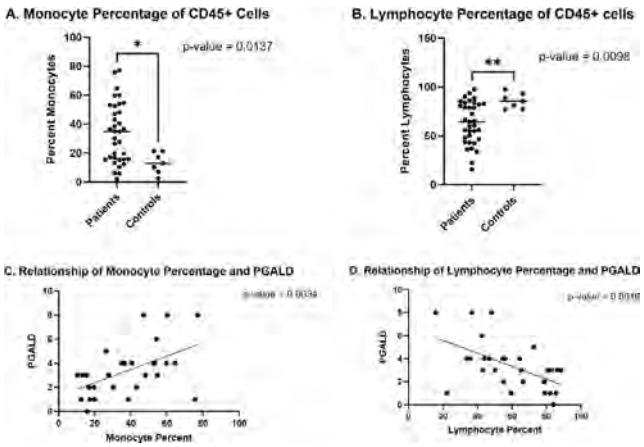

Figure 1: A. Percent monocytes of CD45+ cells B. Percent lymphocytes of CD45+ cells C. Relationship between PGALD and monocyte percentage D. Relationship between PGALD and lymphocyte percentage

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

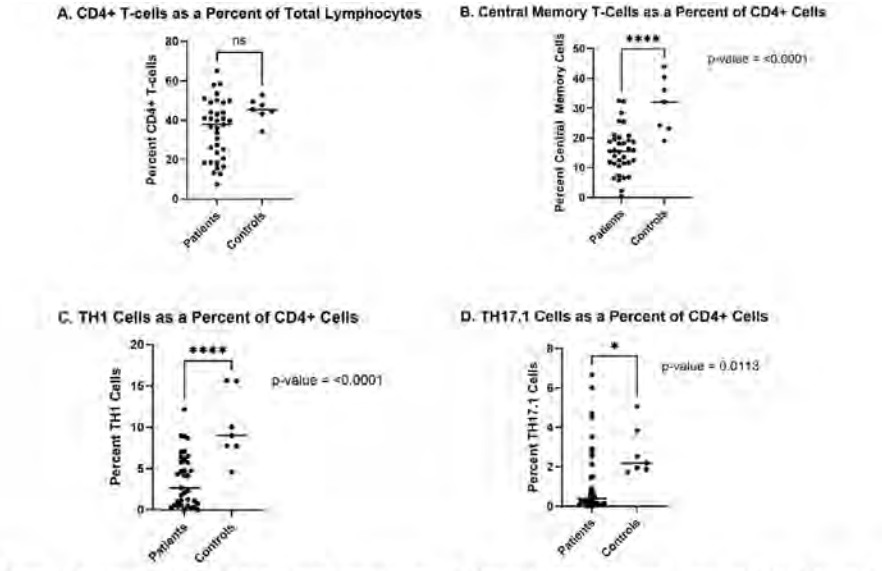

Figure 2: A. Percent CD4+ T-cells of total lymphocytes B. Percent central memory T-cells of CD4+ T-cells C. Percent TH1 cells of CD4+ T-cells D. Percent TH17.1 cells of CD4+ cells. Mann-Whitney analysis was used given data was not normally distributed

Results: We examined samples from 35 sJIA-LD patients and 7 controls. There was no significant difference between the number of live singlet cells and percentage of CD45+ cells in patients compared to controls. Overall, sJIA-LD patients had a significant increase in circulating monocyte percentage compared to controls, but no difference in relative abundance of monocyte subpopulations. There was a significant positive correlation between monocyte percentage and PGALD score, where a higher monocyte percentage correlates with higher PGALD score (R^2=0.2761, p< 0.0034). We also found a significant decrease in lymphocyte percentage, with lower percentages similarly correlating with a higher PGALD score (Fig. 1). The sJIA-LD patients had similar percentages of CD4+ cells compared to controls. Further subdivision of CD4+ T-cells revealed a significantly lower percentages of central memory T-cells, Th1 cells, and Th17.1 cells in patients compared to controls (Fig. 2). We did not find any significant differences between CD8+ cells and their subsets.

Conclusion: Our results demonstrate an increase in peripheral monocytes in SJIA-LD patients, the degree of expansion positively correlated with higher disease activity. We also find differences in circulating lymphocyte profile in sJIA-LD patient versus controls. The consequences of this decrease in Th1, Th17.1, and central memory T-cells is unknown. Our future work involves comparison with SJIA patients without lung disease, as well as unsupervised analysis and evaluation of activation markers – all in hopes to better understand disease pathogenesis and predictors of disease severity in sJIA-LD.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Despite major advances in the understanding, diagnosis, and treatment of Still's disease (including Systemic Juvenile Idiopathic Arthritis, sJIA), many patients experience a refractory course. Among potential organ-involvements, sJIA-associated lung disease (sJIA-LD) has arisen as a major comorbidity, prompting some patients to seek stem cell transplantation. Herein, we report the safety and efficacy of an investigational bi-specific IL-1b/IL-18 neutralizing antibody (aIL-1b/18, MAS825) in 7 refractory sJIA patients.

Methods: All patients received bimonthly MAS825 infusions via single-patient extended-use protocols at The Children's Hospital of Philadelphia (CHOP), University of Pittsburgh, or Hackensack University Medical Center. Parents/guardians provided informed consent for a registry study approved by The CHOP Institutional Review Board. Clinical, laboratory, radiologic, and pathologic information were extracted from electronic medical records.

Results: Disease onset was observed between 1.25 and 11 years of age. All patients met provisional classification criteria for refractory sJIA prior to MAS825 treatment. Other baseline characteristics included a systemic course with at least one Macrophage Activation Syndrome (MAS) episode (7/7), persistent itchy rash (6/7), sJIA-LD (6/7), and peak total IL-18 levels from 77,000 to >650,000 pg/mL. All patients had received high-dose glucocorticoids, IL-1 blockade, and at least one JAK inhibitor prior to MAS825 (Table 1).

Six of 7 patients remained on MAS825 at the time of data acquisition, with a duration of 0.9 to 3.6 years exposure. One patient stopped MAS825 after 4 months for lack of efficacy. Of the 6 patients remaining on MAS825, all made substantial systemic glucocorticoid dose reductions, and 5 weaned off entirely (Figure 1). All showed a substantial reduction or discontinuation of other Still's therapy. Five of 6 patients' Still's biomarkers improved and had clinically significant functional improvement (physician global and/or pulmonary function test). Chest CT's were stable or improved in 5/6 (Figure 2).

No infusion reactions were reported. One patient developed pseudomonal line infection. Another was found to have *S. Aureus* vertebral osteomyelitis 5 months after MAS825 initiation. Symptoms and inflammatory markers initially improved with antibiotics and holding MAS825, but MAS soon flared. Re-initiation of MAS825 with antibiotics led to clinical improvement, but the infection has required long-term antibiotic treatment.

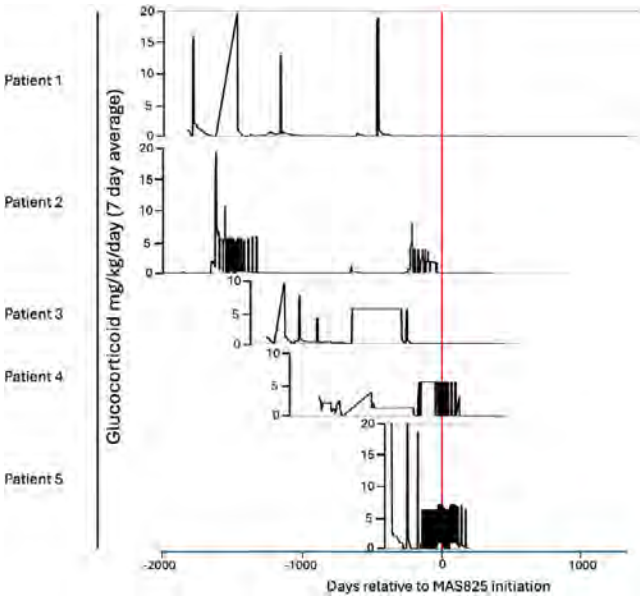

Figure 1: Steroid exposure (rolling 7-day average) relative to MAS825 initiation for patients 1-5.

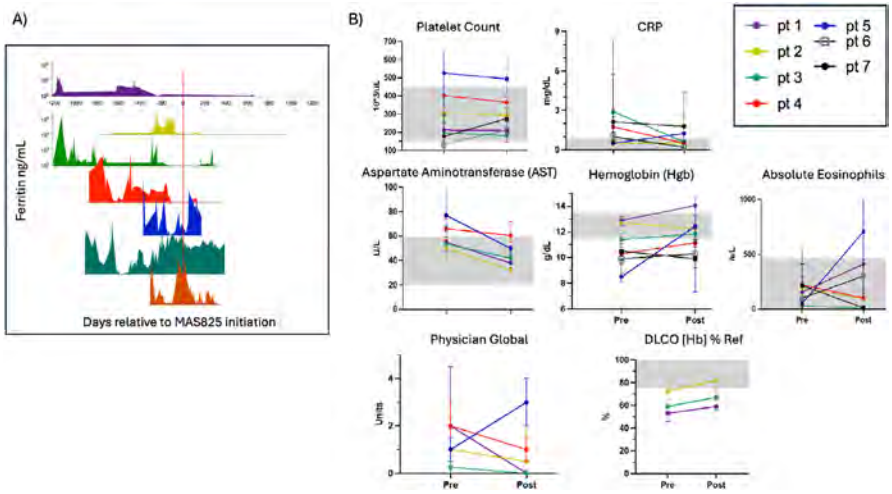

Figure 2: A) ferritin values relative to MAS825 initiation. B) Pre- and Post- MAS825 disease activity markers, physician global assessment, and DLCO [Hb] % Ref of patient's pulmonary function tests. (Median, interquartile-range).

Conclusion: In this highly refractory cohort, MAS825 was overall well-tolerated, and 5/7 patients showed clinical improvement and significant reduction in glucocorticoid and other Still's therapies. These data strongly support prospective trials, with careful monitoring particularly for invasive bacterial infection, in this immunosuppressed population with life-threatening sJIA disease.

Acknowledgment: All patients were provided MAS825 via Managed Access Program. Novartis has conducted a scientific accuracy and intellectual property review of this abstract, but has not otherwise instigated or influenced the content of this publication.

Abstract Number: 2142

Multidisciplinary Rheumatology Transition Clinic for Young Adults Shows Improved Experience, Utilization, and Health Maintenance: A Mixed-Methods Evaluation

Hannah Concannon[1], Jasmine Oesch[2], Sara Mazzarelli[2], Anne Fields[2], Keisha-Gaye O'Garo[2] and Rebecca Sadun[3], [1]Duke University School of Medicine, Chapel Hill, NC, [2]Duke University School of Medicine, Durham, NC, [3]Duke University, Durham, NC

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The transition from pediatric to adult care can pose a challenge for patients with SLE and other rheumatic diseases. These patients often face preventable disease flares, unintended pregnancies, depression, anxiety, and other complications. The Young Adult Rheumatology Clinic (YARC) was established in 2020. Based on the medical home model, the YARC provides integrated primary care and social work to young adults with pediatric-onset rheumatic diseases. This study investigated the impact of the multidisciplinary, transition-focused YARC for the care of recently transferred patients.

Methods: We generated descriptive statistics for YARC patients and control patients who transferred without enrolling in the YARC. Over the three years following transfer, we tracked immunizations, contraception, and unintended pregnancy among YARC and control patients. We also looked for changes in inpatient admissions, ED visits, and rheumatology show/cancellation rates, comparing patients in their third year after transfer to themselves before transfer. To identify the YARC's strengths and areas for improvement, we administered a post-clinic survey and conducted interviews.

Results: YARC (n=22) and control (n=13) patients who transitioned to adult care between July 2017 and October 2023 were included. Age, race, and ethnicity were similar between groups. Most (59%) YARC patients had SLE, as did all control patients (Table 1).

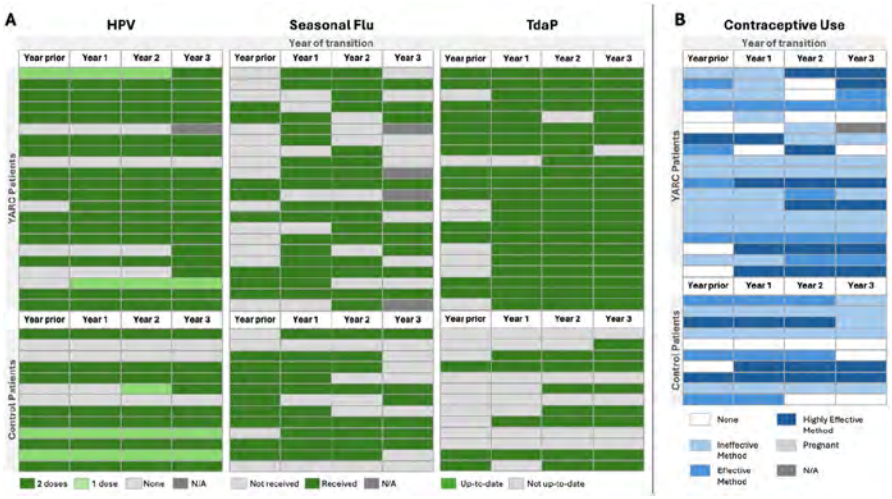

Figure 1. Vaccination status (A) and contraception use (B) among YARC patients and control young adult SLE patients Contraception use is shown only for female patients. "N/A" indicates lack of data for year 3 due to later transfer of care in some YARC patients.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Female	19 (86%)	11 (85%)	10 (77%)
Primary Rheumatologic Diagnosis			
SLE	13 (59%)	13 (100%)	13 (100%)
Juvenile Idiopathic Arthritis	7 (32%)	0 (0%)	0 (0%)
Other*	2 (9%)	0 (0%)	0 (0%)
Co-diagnosis of fibromyalgia	3 (14%)	2 (16%)	1 (8%)
Positive depression screen**	9 (41%)	7 (54%)	2 (15%)
Positive anxiety screen**	6 (27%)	3 (23%)	4 (of 7 screened)
SLEDAI at transition, median (IQR)	--	3 (1-6)	4 (4-10)

Table 2. Rheumatology visit attendance and high-cost healthcare utilization among YARC patients before and after transfer of care

	Year Relative to Date of Pediatric-to-Adult Transfer						
	Before Transfer	After Transfer	*Two Years Prior*	*One Year Prior*	*Year One After Transfer*	*Year Two After Transfer*	*Year Three After Transfer*
Rheumatology Clinic No-Shows (% of scheduled visits)	12.9%	9.5%	10.2%	15.4%	11.3%	9.6%	5.8%
Rheumatology Clinic Cancellations (% of scheduled visits)	26.2%	19.0%	24.5%	27.9%	14.2%	20.5%	26.9%
Rheumatology Clinic Attended Visits (% of scheduled visits)	60.9%	71.4%	65.3%	56.7%	74.5%	69.9%	67.3%
ED Visits (per patient per year)	0.8	0.8	1.0	0.7	1.3	0.7	0.6
Hospital Admissions (per patient per year)	0.4	0.2	0.1	0.7	0.3	0.1	0.3

YARC patients attended 61% of scheduled visits prior to transition and 71% after transition. No-show rate decreased from 13% to 10% and cancellation rate fell from 26% to 19%. ED visits were similar before and after transition, but hospitalizations decreased from 0.4 to 0.2 per patient per year (Table 2).

Use of highly effective contraception (implant or intrauterine device) among YARC patients increased from 5% to 33% but was unchanged in the control group (20%) (Figure 1). There were two unintended pregnancies after transition to the YARC and four unintended pregnancies in the control group.

More YARC patients were up to date on TDaP (96% vs. 62%, p=0.02) and had received at least two doses of HPV vaccine (91% vs. 62%, p=0.08). Flu vaccine uptake was similar between YARC and controls (Figure 1).

In surveys and interviews, patients said the most useful aspect of the clinic was having a "one stop shop." Many also said that they appreciated a non-judgmental attitude and respect from YARC providers. However, multiple patients thought the facility was outdated; other pain points were travel times to and wait times at the clinic.

Conclusion: We saw promising signs that multidisciplinary, coordinated management of the pediatric-to-adult transition can improve clinical and economic outcomes for young adults with rheumatic disease, though conclusions are limited by sample size and availability of control data. YARC patients had improved pregnancy prevention and immunization rates compared to SLE patients who did not attend a transition clinic. Overall utilization also improved among YARC patients, despite literature suggesting that hospitalizations typically increase following transfer. Thus, the YARC model may reduce unnecessary healthcare utilization while maintaining rheumatology continuity.

Abstract Number: 2143

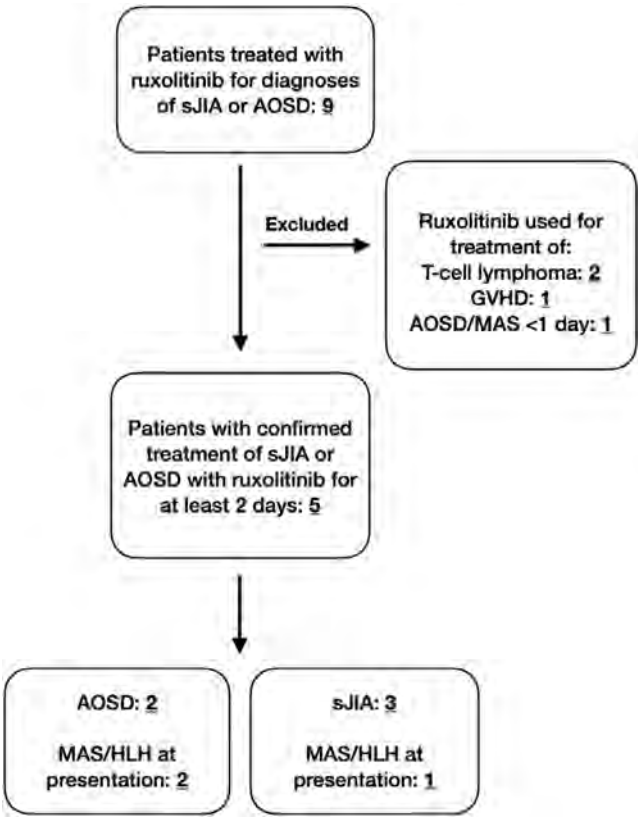
Ruxolitinib for Refractory sJIA/AOSD: A Single Center Case Series

Jacqueline Madison[1], Andrew Grim[2] and **Janna Shim**[3], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan Medicine, Ann Arbor, MI, [3]Midwestern University Chicago College of Osteopathic Medicine, Downers Grove

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic Juvenile Idiopathic Arthritis (sJIA) and Adult-onset Still's disease (AOSD) are rare, chronic, autoinflammatory diseases distinct from other forms of chronic inflammatory arthritis. Potential life-threatening complications include macrophage activation syndrome (MAS)/secondary hemophagocytic lymphohistiocytosis (HLH) and interstitial lung disease (ILD). Despite advances in targeted therapies, there remain patients with refractory disease. JAK inhibitors offer a promising new treatment option, with case reports and series suggesting efficacy and safety in treating refractory sJIA and AOSD, but the amount of information on ruxolitinib is limited. We present a case series of three patients with sJIA and two with AOSD who were treated with ruxolitinib at a single center.

Methods: We queried the electronic medical record (EMR) of a large tertiary health system for patients who received ruxolitinib within the past ten years for diagnosed sJIA or AOSD. Nine patients were identified, five older than 16 and four younger



Patients included in the series were those treated with Ruxolitinib for at least one day for diagnoses of sJIA or AOSD, with or without MAS/HLH. sJIA, systemic juvenile idiopathic arthritis; AOSD, Adult Onset Still's Disease; MAS, Macrophage Activation Syndrome; HLH, Hemophagocytic Lymphohistiocytosis; GVHD, Graft-Versus-Host Disease.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. 	Patient 1	Patient 2	Patient 3	Patient 4	Patient 5
Diagnosis	AOSD	sJIA	AOSD	sJIA	sJIA
Age at start of Ruxolitinib	18 yo.	7 yo.	33 yo.	7 yo.	16 yo.
Complications of Disease	MAS	MAS, ILD	MAS	None	Pericarditis, Pleural Effusion
Medications prior to Ruxolitinib	Systemic corticosteroids, Anakinra, Tofacitinib, Canakinumab, MAS/IOS	Systemic corticosteroids, Methotrexate, Anakinra, Tocilizumab, Cyclosporine, Canakinumab	Systemic corticosteroids, Anakinra	Systemic corticosteroids, NSAIDs, Tocilizumab, Anakinra, Abatacept, Methotrexate, Canakinumab, Tofacitinib, Leflunomide	Systemic corticosteroids, NSAIDs, Anakinra, Canakinumab, Methotrexate, Tocilizumab, Cyclosporine, Tacrolimus, Hydroxychloroquine, Abatacept, Infliximab, Adalimumab, Etanercept, Golimumab, Azathioprine, Ruxolitinib, Tofacitinib
Reason for starting Ruxolitinib	Persistent disease activity, elevated inflammatory markers, multiple admissions for MAS	Persistently elevated inflammatory marker elevation, and recurrent MAS	MAS not responding to systemic steroids and anakinra	Continued arthritis, elevated IL-1β	Continued systemic symptoms with daily rash, fever, ankle arthritis
Efficacy: Clinical Improvement	Unclear, self-discontinued, reported minimal improvement	Able to wean off supplemental O2, weaned off anakinra and cyclosporine. Weaning canakinumab	Reached clinical remission without recurrence	Improvement and near resolution of systemic symptoms, more active. Arthritis/arthralgia with muted clinical improvement	Clinically inactive on medications
Efficacy: Lab improvement	Unclear due to poor adherence and self-discontinuation	Normalization of ESR and CRP in 7 and 2 months respectively. Normalization of ferritin in 6 months.	Normalization of ferritin in 55 days, normalization of sIL-2r in 13 days (in conjunction with steroids)	Normalization of sIL-2r and IL-1β	Labs prior to starting were in normal range
Safety/Adverse Events	Possible GI bleed	None	None	None	None
Duration on Ruxolitinib	7 months	35 months	91 months	12 months	9 months
Medication Regimen at time of writing	Tofacitinib, Cyclosporine, Systemic corticosteroids	Ruxolitnib, Canakinumab	Ruxolitinib	Ruxolitinib, Canakinumab, Leflunomide	Ruxolitinib, Azathioprine, Cyclosporine, Hydroxychloroquine

Clinical characteristics of patients included in series. sJIA, systemic Juvenile Idiopathic Arthritis, AOSD, Adult Onset Still's Disease; MAS, Macrophage Activation Syndrome; ILD, Interstitial Lung Disease; ESR, Erythrocyte Sedimentation Rate, CRP, C-reactive protein

at the time of diagnosis (Figure 1). Then via record review, we confirmed that ruxolitinib was specifically used for treating sJIA or AOSD, excluding three adults who were treated for T cell lymphoma (2) and graft vs host disease (1). One patient was excluded for receiving one dose of ruxolitinib hours before dying from systemic organ failure. For the remaining five patients (3 sJIA, 2 AOSD), we collected data on demographics, previous medications used, laboratory abnormalities, disease complications and clinical outcomes.

Results: All five patients were treated with other medications prior to starting ruxolitnib including systemic steroids (5), conventional DMARDs (4), biologics (5), and other JAK inhibitors (3). Three of five patients had adverse effects to other medications prior to starting ruxolitinib.

Disease complications prior to the use of ruxolitinib included: MAS/HLH (3), ILD confirmed by CT (1), pericarditis and pleural effusion (1), and opportunistic infection (1). All patients had refractory disease prior to starting ruxolitinib. The mean length of treatment with ruxolitinib was 30.8 months (median 12 months, range 7-91 months).

Since starting ruxolitinib, 4 of 5 demonstrated clinical response to therapy according to clinical documentation and remained on ruxolitinib with good disease control and no adverse effects at the time of last follow-up. One is on monotherapy and three on combination therapy. One patient discontinued ruxolitinib in the context of severe MAS with concern that ruxolitinib could have contributed to a GI bleed, though there were other risk factors. Inflammatory markers, cytokines, and chemokines improved in some patients, though lab acquisition was inconsistent between patients (Table 1).

Conclusion: Ruxolitinib represents an alternative treatment employed for refractory sJIA or AOSD that in our case series led to a favorable outcome regarding safety and efficacy. Our ability to evaluate response was limited by the data available in an EMR chart review. This series highlights the need for more rigorous study of ruxolitinib as a possibly safe and effective treatment strategy for treatment-refractory sJIA and AOSD.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: ANCA-associated vasculitis (AAV) is a chronic autoimmune condition that significantly impacts patients' quality of life. It is unknown whether this impact varies based on age at diagnosis, from childhood through older adulthood. This study examined the relationship between age at diagnosis of AAV and health-related quality of life (HRQoL).

Methods: The data source was the Vasculitis Patient-Powered Research Network, an online, longitudinal, prospective cohort of adults with AAV (granulomatosis with polyangiitis, microscopic polyangiitis, and eosinophilic granulomatosis with polyangiitis) enrolled from 2014-2024. Cohorts were stratified by age (years) at diagnosis: children (< 18), young adults (18–40), middle-aged adults (41–65), and older adults (> 65). Descriptive statistics were summarized. Differences were tested via Student's t-tests or Kruskal-Wallis tests for continuous variables and Pearson's chi squared tests or Fisher's exact tests for categorical variables. Multivariable linear regressions assessed associations between age at diagnosis and Patient-Reported Outcomes Measurement Information System (PROMIS) results at last follow-up visit. Models were adjusted for gender and age at HRQoL assessment.

Table 1. Characteristics of patients with ANCA-associated vasculitis based on age at diagnosis.

	Age at Diagnosis				
	Child *<18 years old*	Young Adult *18-40 years old*	Middle-Aged *>40-65 years old*	Older Adult *>65 years old*	All
	N = 110	N = 507	N = 1172	N = 220	N = 2009
Characteristic	*Mean (standard deviation) or n (percentage)*				***p*-value***
Age at diagnosis (years)	13.3 (3.7)	30.7 (6.6)	53.5 (6.8)	69.9 (3.7)	47.4 (15.9)	< 0.001
Sex (male)	21 (19.1%)	125 (24.7%)	368 (31.4%)	83 (37.7%)	597 (29.7%)	0.008
Disease category						< 0.001
GPA	78 (70.9%)	375 (74.0%)	761 (64.9%)	137 (62.3%)	1351 (67.2%)	
MPA	21 (19.1%)	49 (9.7%)	177 (15.1%)	54 (24.5%)	301 (15.0%)	
EGPA	11 (10.0%)	83 (16.4%)	234 (20.0%)	29 (13.2%)	357 (17.8%)	
Time since diagnosis at quality of life assessment (years)	12.6 (13.3)	11.3 (10.5)	8.1 (6.5)	5.1 (4.7)	8.8 (8.3)	< 0.001

GPA, granulomatosis with polyangiitis; MPA, microscopic polyangiitis; EGPA, eosinophilic granulomatosis with polyangiitis.
Unknown or missing responses for each score were not included.
*Statistical significance was set at 0.05.

Table 2. Differences in PROMIS scores among Patients with ANCA-associated vasculitis based on age at diagnosis.

		Differences[1] by Age at Diagnosis*		
PROMIS Measure	**N**	**Child vs Young Adult**	**Child vs Middle Age**	**Child vs Older Age**
Lower score indicates better health-related quality of life				
Fatigue	1983	-4.38 (-6.82, -1.94)	-7.47 (-10.32, -4.63)	-8.39 (-11.97, -4.81)
Sleep Disturbance	1363	-4.39 (-6.69, -2.09)	-7.14 (-9.83, -4.45)	-6.16 (-9.64, -2.69)
Depression	1985	-4.24 (-6.36, -2.13)	-7.06 (-9.51, -4.6)	-8.11 (-11.2, -5.02)
Anxiety	1982	3.25 (1.4, 5.1)	5.88 (3.73, 8.04)	7.77 (5.06, 10.48)
Pain Interference	1984	-3.21 (-5.51, -0.92)	-5.52 (-8.19, -2.85)	-5.00 (-8.37, -1.63)
Higher score indicates better health-related quality of life				
Social Satisfaction	1363	3.87 (1.11, 6.63)	10.03 (6.78, 13.27)	11.23 (7.03, 15.44)
Physical Functioning	1991	0.72 (-1.36, 2.79)	3.07 (0.66, 5.49)	4.1 (1.07, 7.14)

PROMIS, Patient-Reported Outcomes Measurement Information System
*Child: < 18 years, Young Adult: 18-40 years old, Middle-Aged: >40-65 years old, Older Adult: >65 years old
Unknown or missing responses for each score were not included. *Statistical significance was set at 0.05.
[1]Differences in scores between age at diagnosis groups were assessed via multivariable linear regression adjusting for gender and age at time of quality-of-life assessment. If the confidence interval includes zero, the difference is not significant. A positive estimated difference in scores represents a higher score for those diagnosed in childhood compared to the reference group, while a negative difference represents a lower score for those diagnosed in childhood compared to the reference group.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Patient-Reported Outcomes Measurement Information System T-Scores Based on Age at Diagnosis with ANCA-associated vasculitis. Boxplot of the distribution of Patient-Reported Outcomes Measurement Information System T-Scores stratified by age at diagnosis with ANCA-associated vasculitis. The boxes represent the 25th to 75th percentile T scores, with the middle line within each box representing the median T score. The solid lines extending out signify the range with dots representing possible outliers. The dashed gray line represents the mean score of the referent general pediatric population (50), with one standard deviation above and below represented in gray. Better health-related quality of life is represented by a lower score in the top five measures and a higher score in the bottom two measures. Statistical significance indicates that the median T score for at least one age at diagnosis group is different from another age at diagnosis group within that measure. *statistical significance at $p < 0.05$; **statistical significance at $p < 0.01$.

Results: Analysis included 2009 patients with AAV. The majority had GPA and there was a female predominance that decreased with age at diagnosis. Those diagnosed at younger ages had longer follow-up at time of last PROMIS measure (Table 1). All cohorts had impaired HRQoL in every domain (Figure 1). When adjusted for gender and age at HRQoL assessment, those diagnosed with AAV in childhood had worse HRQoL related to anxiety than those diagnosed as young, middle-aged, or older adults. Additionally, those diagnosed in childhood had better HRQoL related to fatigue, sleep disturbance, depression, pain interference, satisfaction with participation in social roles, and physical functioning (Table 2).

Conclusion: Patients with AAV have impaired HRQoL, especially related to anxiety. Additionally, age at diagnosis with AAV is associated with differences in HRQoL. Compared to patients diagnosed with AAV at older ages, those diagnosed at younger ages have worse HRQoL related to anxiety and better HRQoL related to fatigue, sleep disturbance, depression, pain interference, satisfaction with participation in social roles, and physical functioning. Understanding the mechanisms by which age at diagnosis impacts HRQoL will be useful for developing targeted clinical interventions in AAV.

EOS® Imaging System Is a Novel, Rapid, Safe, and Effective Technique To Detect And Assess Calcinosis In JDM

Jessica Perfetto[1], Ciara Maguire[2], Carli Needle[3], Shailee Lala[4], Vikash Oza[2] and Philip Kahn[5], [1]Pediatric Rheumatology, Hassenfeld Children's Hospital at NYU Langone, New York, [2]Pediatric Dermatology, Ronald O Perelman Department of Dermatology, NYU Grossman School of Medicine, New York, [3]NYU Grossman School of Medicine, New York, [4]Department of Radiology, NYU Grossman School of Medicine, New York, [5]Pediatric Rheumatology, Hassenfeld Children's Hospital at NYU Langone, New York

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Calcinosis, reported in up to 47% of children with juvenile dermatomyositis (JDM), can cause significant morbidity, including ulceration, infection, and contractures. Given associations of diagnostic delay and duration of active disease with risk of developing calcinosis, early identification and treatment are critical. However, there is no standardized approach to assess or quantify calcinosis. Various imaging modalities, including conventional radiographs (X-rays), computed tomography (CT), magnetic resonance imaging (MRI), and ultrasound (US), are used to assess calcinosis. However, they have not been directly compared, and they have limitations including 2-dimensional (2D) nature (X-rays), radiation (CT), cost and potential need for sedation (MRI), limited ability to detect deep lesions (US). The EOS® imaging system involves whole body evaluation via 2D X-rays in ~20 seconds with much lower doses of radiation than conventional X-rays. It is used for disorders of the spine, legs, and hips; however, its use in assessing calcinosis has not been assessed. Our objectives were to compare the ability of EOS® versus conventional X-rays in detecting calcinosis in children with JDM.

Methods: Children diagnosed with JDM before age 19 with calcinosis (confirmed with conventional X-rays and/or physical exam) at Hassenfeld Children's Hospital at NYU Langone with at least one EOS® scan for calcinosis were included. Sociodemographics, clinical information (including detailed information on calcinosis), imaging modalities, and treatment were collected retrospectively via manual chart review. X-ray and EOS® images were independently assessed by two radiologists blinded to patient information; evaluation of calcinosis by each modality was recorded and compared. Descriptive statistics were used to summarize each variable. Bivariate analysis was performed using t-test or Chi-squared test, or their nonparametric equivalents (Mann Whitney or Fisher's exact tests).

Results: Seven children with calcinosis and JDM had at least one EOS® scan for calcinosis; 57% of children had an EOS® within one year of JDM diagnosis. All patients were receiving systemic therapy. Three patients (43%) had clinically active skin and/or muscle disease at the time of EOS®. In most children, calcinosis was initially detected by physical exam; however, in 57%, additional calcinosis was detected by EOS® that was missed on physical exam. There were no significant differences in detection of any given calcinosis lesion by EOS® compared to X-rays; however, EOS® detected additional calcinosis lesions compared to X-rays.

Conclusion: This is the first study to explore the use of EOS® in detecting calcinosis in JDM and to compare EOS® to conventional X-rays. Our single-center retrospective study suggests that EOS® may be comparable to X-rays in detecting a

given calcinosis lesion with the advantage of detecting additional lesions given whole-body imaging with much less radiation than conventional X-rays or ultra-low dose whole body CT. Future prospective multi-center studies with a larger sample size comparing other imaging modalities will be critical to further understand the role of EOS® in detecting and monitoring calcinosis.

Impact of a Clinical Pathway on Medication Use and Outcomes in Kawasaki Disease

Jonathan Yu[1], Matthew Elias[1], Deborah Whitney[1], Sanjeev Swami[1], Kaylie Shojaie[1], Caroline Burlingame[1], Isabel Armendi[1], Malki Peskin[2], Melissa Lerman[1], Jerri Miller[1], Jane Lavelle[1], Brandon Ku[1] and Jon Burnham[3], [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]Children's Hospital of Philadelphia, Bala Cynwyd, PA, [3]Children's Hospital of Philadelphia, Bryn Mawr, PA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Kawasaki disease (KD) is an acute, systemic vasculitis which can lead to coronary artery (CA) aneurysms in young children. In 2018, we developed a clinical pathway to standardize KD care and improve outcomes. In this retrospective quality improvement (QI) study, we aimed to assess patients admitted with KD and determine the impact of the pathway on medication use and outcomes to inform QI initiatives.

Table 1. Cohort characteristics among index admissions for Kawasaki disease (January 1, 2017 to March 31, 2025)

Demographics	Total (n=413)	Normal initial echo (n=328)	Abnormal initial echo (n=85)	p
Age at admission, years, mean (SD)	3.7 (2.8)	3.9 (2.9)	3.0 (2.6)	<0.05
Sex, n (%)				
Male	241 (58)	187 (57)	54 (64)	0.28
Race, n (%)				
Asian	45 (11)	37 (11)	8 (9)	<0.05
Hispanic or Latino	54 (13)	40 (12)	14 (16)	
Non-Hispanic Black	137 (33)	114 (35)	23 (27)	
Non-Hispanic White	130 (31)	105 (32)	25 (29)	
Other	47 (11)	32 (10)	15 (18)	
Process measures				
ED order set usage, n (%)	160 (39)	130 (40)	30 (35)	0.46
Inpatient order set usage, n (%)	319 (77)	255 (78)	64 (75)	0.63
Number of echos done, mean (SD)	3.2 (1.9)	3.0 (1.3)	4.3 (3.1)	<0.001
Treatment				
Multiple IVIG administrations, n (%)	89 (22)	76 (23)	13 (15)	0.12
Infliximab administration, n (%)	45 (11)	29 (9)	16 (19)	<0.01
Steroid administration, n (%)	177 (43)	114 (35)	63 (74)	<0.001
Echo findings and outcomes				
Normal initial echo, n (%)	328 (79)	-	-	-
Normal final echo, n (%)	354 (86)	296 (90)	58 (68)	<0.001
Highest severity of CA abnormality, n (%)				
No involvement	304 (74)	296 (90)	8 (9)	<0.001
Dilation only	30 (7)	11 (3)	19 (22)	
Small aneurysm	62 (15)	15 (5)	47 (55)	
Medium aneurysm	11 (3)	3 (1)	8 (9)	
Large/giant aneurysm	6 (1)	3 (1)	3 (4)	
Developed CA aneurysm, n (%)	79 (19)	21 (6)	58 (68)	<0.001
Length of stay, days, mean (SD)	4.5 (2.2)	4.5 (1.9)	4.8 (2.9)	0.25

Echo = echocardiogram; CA = coronary aneurysm. Z-score classification of CA abnormalities is defined as: no involvement: <2; dilation only: ≥2 and <2.5; small: ≥2.5 and <5; medium: ≥5 and <10; large: ≥10. p values were calculated using Chi-square tests for categorical measures and two-tailed t tests for continuous measures.

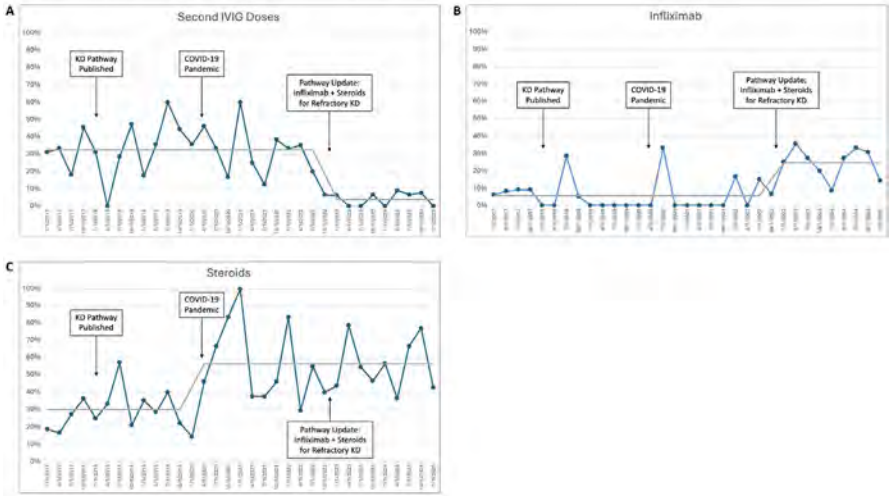
Figure 1. Medication Administration in All KD Admissions (2017-2025)



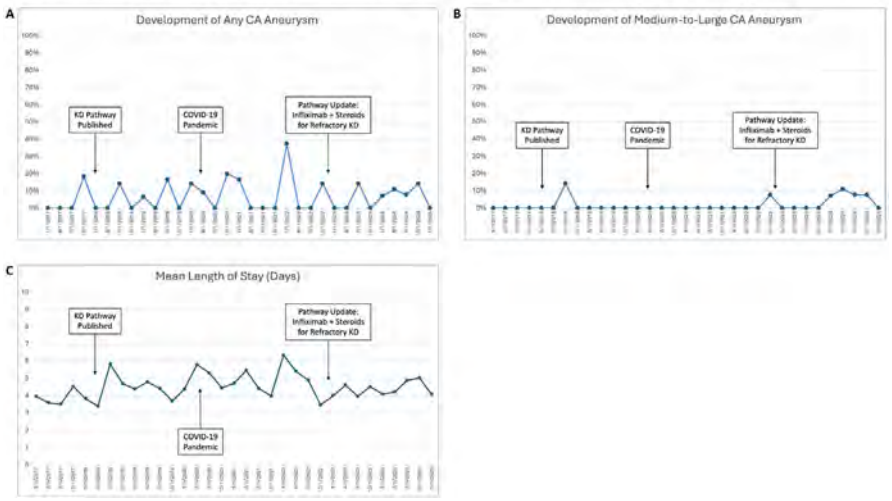
Methods: We examined index admissions for KD with IVIG administration from January 2017 to March 2025. All echocardiogram (echo) data ≤60 days after the admission date were included. The right coronary and left anterior descending arteries were assessed. CA changes were classified based on 2024 American Heart Association guidelines. A normal initial echo was defined as CA Z-scores between -2 and 2 on the first echo within 3 days of admission.

The KD pathway was published in January 2018 and updated in November 2022. The original pathway standardized steroid use for patients less than 6 months of age and those with CA aneurysms (Z-score ≥2.5). The updated pathway recommended infliximab and steroids for all IVIG-resistant patients. Electronic health record (EHR) order sets were created to implement the pathway's diagnostic and treatment recommendations. All EHR and echo data are updated daily and displayed in a data visualization tool.

Standard run chart rules were used to analyze process and outcome measures over time. p values were calculated using the Chi-square and t-tests for categorical and continuous measures, respectively, and the F-test to compare variances.

Results: Demographic, echo, and treatment data are shown in Table 1 (n=413). The mean age at admission was 3.7 ± 2.8 years, and 58% of patients were male. The emergency department and inpatient KD pathway order sets were used in 39% and 77% of cases, respectively. Abnormal initial echos were observed in 85 patients (21%), who were younger (3.0

Figure 2. Outcomes in KD Patients with Normal Initial Echocardiograms (2017-2025)



23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

vs 3.9 years, $p< 0.05$), had more echos (4.3 vs 3.0, $p< 0.001$), and were more likely to develop aneurysms (68% vs 6%, $p< 0.001$) and receive steroids (74% vs 35%, $p< 0.001$) and infliximab (19% vs 9%, $p< 0.01$).

After the 2022 pathway update, second IVIG doses decreased from 33% to 4%, while infliximab administration increased from 6% to 25% (Figure 1). Steroid use increased after the onset of the COVID-19 pandemic in 2020 and remained higher after the pathway update. Among patients with normal initial echos, there was no change in the rate of CA aneurysm development or length of stay (LOS) (Figure 2). However, there was a decrease in LOS variance (0.16 vs 0.64, $p< 0.05$). In 2024, we identified 4 patients with normal initial echos who developed medium or large CA aneurysms.

Conclusion: After KD pathway implementation, we observed an increase in steroid and infliximab use and a decrease in second doses of IVIG. Though LOS remained stable, its variation decreased after updated pathway recommendations on management of IVIG-resistant KD, which may represent improved standardization of care. Though CA aneurysm development has not changed overall, we are currently using our real-time data visualization tools to investigate recent cases of medium and large aneurysms to further optimize KD care.

Abstract Number: 2147

Elevated fMET and GDF-15 Circulating Levels in Pediatric CNO Patients with Psoriasis Define a Distinct Mitochondrial-Inflammatory Signature

Arpit Rathee[1], Noor Kaur[1], **Jorge A. Gonzalez-Chapa**[2], Ryan D. Stultz[1], Emily Deng[3], Ian Muse[4], Yongdong Zhao[3] and Christian Lood[2], [1]University of Washington, Division of Rheumatology, Seattle, WA, [2]University of Washington, Division of Rheumatology, Seattle, [3]University of Washington, Department of Pediatrics, Seattle Children's Hospital, Seattle, WA, [4]University of Washington, Department of Pediatrics, Seattle Children's Hospital, Seattle

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Chronic nonbacterial osteomyelitis (CNO) is a pediatric autoinflammatory bone disorder marked by sterile skeletal inflammation. A subset of CNO patients presents with comorbid psoriasis, suggesting the existence of overlapping inflammatory circuits beyond the musculoskeletal system. Mitochondria-derived formyl peptides (fMET) and the stress-responsive cytokine GDF-15 are emerging as biomarkers of cellular damage and mitochondrial dysfunction, yet their role in CNO, particularly in psoriasis-associated cases, remains poorly defined.

Methods: We analyzed plasma samples from 120 pediatric participants: 30 healthy controls, 30 with inactive CNO, 30 with active CNO, and 30 juvenile idiopathic arthritis (JIA) patients serving as disease controls. Twenty-two participants had comorbid psoriasis (9 CNO-inactive, 11 CNO-active, 2 JIA). Levels of GDF-15 and fMET were analyzed using ELISA. Statistical analysis was conducted in R using ANOVA, Dunn's multiple comparisons, and unpaired t-tests.

Results: The CNO cohort included 54.2% female participants, with a mean age of 12.56 years. Active and inactive subgroups showed consistent distributions in age and sex. fMET concentrations were significantly elevated in CNO-active

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

patients compared to healthy controls ($p < 0.05$). GDF-15 levels were significantly higher in participants with comorbid psoriasis compared to those without ($p = 0.0312$). Notably, within the psoriasis subgroup, patients with active CNO exhibited the highest GDF-15 levels compared to those with inactive disease ($p = 0.0044$), suggesting enhanced mitochondrial stress when both skeletal and cutaneous inflammation are present.

Conclusion: These findings uncover a distinct immunometabolic profile in pediatric CNO patients with psoriasis, characterized by elevated fMET and GDF-15. This mitochondrial-inflammatory axis may represent a novel endotype within CNO, providing mechanistic insights into extra-skeletal involvement and offering potential avenues for biomarker-guided stratification and targeted therapy.

Initial MRI Findings as Predictors of Disease Phenotype in Juvenile Dermatomyositis: A Comparative Study of Myositis Specific Antibodies NXP2-Positive and Myositis Specific Antibody-Negative Patients in a Large Tertiary Hospital

Juan Torres Sanchez[1], Pritish Bawa[2], Andrea Ramirez[1], MaiLan Nguyen[3], Amit Thakral[4], Xiaofan Huang[1], J Herman Kan[2] and Marietta De Guzman[1], [1]Baylor College of Medicine, Houston, TX, [2]Texas Childrens Hospital, Houston, TX, [3]Baylor College of Medicine, Austin, TX, [4]Texas Children's Hospital, Houston, TX

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Juvenile dermatomyositis (JDM) is the most common idiopathic inflammatory myopathy of childhood, characterized by proximal muscle weakness and distinctive cutaneous findings. Magnetic resonance imaging (MRI) has emerged as a valuable, noninvasive diagnostic tool, reducing the reliance on interventional procedures such as muscle biopsy. Myositis-specific antibodies (MSAs) have become important in characterizing disease phenotypes, predicting prognosis, and guiding management strategies. Among these, NXP2 antibodies are associated with a more severe disease course, including higher disease burden, chronicity, and an increased risk of calcinosis. However, although MSA testing may not be as costly as MRI, limited access and specialized processing makes testing potentially challenging, whereas MRI is more routinely accessible in clinical settings. This study aims to evaluate whether pretreatment MRI findings can serve as early predictors of disease phenotype by correlating imaging patterns with MSA status, specifically comparing NXP2-positive and MSA-negative JDM patients.

Methods: With IRB approval, we conducted a retrospective review of NXP2-positive and MSA-negative JDM at Texas Children's Hospital over the past 10 years. Included patients had at least 1 year of data and initial MRI without prior systemic treatment. All patients met 2017 EULAR/ACR criteria for probable or definite idiopathic inflammatory myopathies. MRI scans of the pelvis and thighs were assessed by a musculoskeletal radiologist blinded to MSA status and clinical outcomes. MRI findings were evaluated using the Ladd et al. scoring tool, focusing on muscle and fascial signal abnormalities and reticulated

subcutaneous fat changes. Associations between MRI findings and clinical outcomes, including the Disease Activity Score (DAS)—a validated tool—were analyzed.

Results: Thirty-three patients with JDM met inclusion criteria: 18 NXP2-positive and 15 MSA-negative. Initial MRI scores did not identify significant differences between the two groups. However, when analyzed irrespective of MSA status, pretreatment MRI of the anterior thigh ($p < 0.001$), adductors ($p = 0.006$), pelvis ($p = 0.006$) and fat signal abnormalities ($p=0.047$) were associated with higher disease activity scores. At six months, NXP2-positive patients continued to exhibit upper, truncal, and neck muscle weakness, though not statistically significant. At two years, they showed persistently elevated muscle enzymes (AST/ALT and aldolase) and a higher prevalence of calcinosis (28% vs. 5.6%). MSA-negative patients had more mucocutaneous features, including Gottron's papules (93% vs 50%) and heliotrope rash (80% vs 39%).

Conclusion: Pretreatment MRI findings did not differentiate NXP2-positive from MSA-negative JDM. However, abnormalities in subcutaneous fat and specific muscle groups were linked to higher disease activity regardless of antibody status. Limitations include retrospective design, small sample size, and single-center cohort, which may limit the generalizability and statistical power of subgroup comparisons. Larger, multicenter studies are needed to confirm whether initial MRI can serve as a prognostic tool in JDM.

Abstract Number: 2149

Rheumatology Transitions of Care: Patient Stability and Follow-Up at a Single Center

Julia Witowska[1], Marianne Kerski[1], Uzochi Nwoko[2], Lakshmi Meyyappan[2], Catherine McDermott[2] and Jacqueline Madison[1], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan, Ann Arbor

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The transition period for adolescents transferring from pediatric to adult care is a recognized period of vulnerability. In rheumatology, the majority of adolescents reach adulthood with ongoing disease activity, and patterns of healthcare utilization during this time remain poorly understood. The aim of this study was to evaluate how rheumatology patients interact with the healthcare system during the period of transfer from pediatric to adult care and assess how systemic factors may affect transfer outcomes.

Methods: A retrospective chart review was conducted of patients aged 18-27 who transferred from pediatric to adult rheumatology between 2020 and 2023 at a single tertiary care center without a formal transition program. Data collected included sociodemographic characteristics, healthcare utilization during the transition period, and logistical aspects of the transfer process. Descriptive statistics were used to analyze the data.

Results: A total of 230 young adults with rheumatic disease transferred from pediatric to adult rheumatology in our study period. The cohort included 118 (51.3%) patients with JIA, 39 (17%) with SLE, 33 (14.3%) with connective tissue disease (excluding SLE), 20 (8.6%) with vasculitis, 9 (3.9%) with autoinflammatory disease inclusive of systemic JIA, and 11 (4.7%) with other diagnoses (sarcoidosis, antiphospholipid syndrome, chronic recurrent multifocal osteomyelitis, idiopathic uveitis). An average of 276 days (median 170 days) elapsed between the final visit with pediatrics and the first adult visit; this is more than twice the average duration between visits before (every 114 days) or after (every 122 days) transfer. Almost half (47.8%) of patients had more than six months and 20% had over a year elapse prior to establishing with adult rheumatology. During this period of transfer, 28 (12.1%) presented to the emergency department and 27 (11.7%) were prescribed a burst of corticosteroids. Eight (3.5%) patients did not have a second adult rheumatology visit.

Conclusion: The results of our review demonstrate a need for greater patient support in their transfer between seeing pediatric and adult rheumatologists. When connected with a physician, patients saw their rheumatologist about every 3-4 months, but during the transfer period, the average patient went longer than twice this duration without seeing a rheumatologist. Though the ramifications of this delay are not yet clear, the rates of emergency department utilization and steroid prescriptions during transition suggest that ensuring a more expedited and supported transfer process may be important for maintaining disease control and improving patient satisfaction. This study lays the groundwork for the development of a formalized transition program and provides a baseline for evaluating its impact, reinforcing the need for more structured support during the vulnerable period of transferring from pediatric to adult rheumatologic care.

Rheum to Grow:An Approach Towards Human Centered Design through a Qualitative Analysis on the Transition from Pediatric to Adult Rheumatology

Lillian Chang[1], Rhea Sharma[2], Elyse Guziewicz[1], Jordan Jackson[3], Katrina Romagnoli[1], Gemme Campbell[1], Saritha Korukonda[1], Priyanka Pawar[1], Jonida Cote[4], Thomas Davis[1], Emily Brunner[1] and Geisinger Medical Center Rheumatology Department, [1]Geisinger, Danville, PA, [2]Geisinger Medical Center Internal Medicine Residency, Danville, PA, [3]Geisinger Medical Center Medicine-Pediatrics Residency, Danville, PA, [4]Geisinger Health System, Wilkes-Barre, PA

SESSION INFORMATION

Session Date: **Tuesday, October 28, 2025**
Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Up to half of patients who transition to adult care are lost to follow up within 2 years of transfer from pediatric to adult rheumatology (Hart, *Clin. Pediatr*. 2019; 58 (11-12): 1277-1283). Complicating matters is the lack of training for pediatric and adult specialists in transition, with nearly 50% of adult rheumatologists reporting no transitional care training (Zizman, *Arth. Care Res*. 2020; 72:432–40) .

The goal of this exploratory pilot study is to assess patient independence, transition readiness, understanding of disease and attitudes towards existing transition documents through qualitative interviews. Through input from providers, patients and their parents, we intend to apply human-centered-design to create a single page transfer summary and tools for transition to be incorporated into clinical practice.

Table 2: Examples of Abstractions

Theme	Description	Quote
Medical Independence	Transportation to appointments is a barrier to medical independence.	"Mom and dad drive to appointments."
	Shyness with communication and lack of self-advocacy is a barrier to medical independence.	"Hate talking to people and hate talking to doctors"
	Barriers to medical independence include unwillingness to take on more responsibility despite having capability	"She's just rather be dependent on us until she can't anymore .. She just loves being catered to. She calls herself a "Passenger Princess" she doesn't need to get a license because she wants to be driven everywhere. There's no reason to why she doesn't want to do it, she can eat on her own she can do laundry, she can sew she can cook. She just doesn't want to. . . . . .She can read it all and gets alerts on my chart, she feels its one less responsibility so she doesn't want to do it. She's 18 but the less responsibility the less she has to worry about. She needs to have less stress in her life. At least the less stress she has the better her health is. .. She knows that if she doesn't have someone there, like taking medication, She will do it herself, like she will know to remember to take an medication. Put it in her reims or set alarms, she knows how to do it herself."
Impression of Pediatric Clinic	Pediatric clinics are associated with a warm peaceful environment with attention to detail and care for the patient	"[Pediatric clinic] is a very nice place and very happy and very caring about your well being. Every time I was hospitalized someone came to check up on me every appointment the staff was very kind to me, environment is very friendly and peaceful." "They're very attentive to every little thing that you know that a child is going through, no matter what the smallest thing it is. It can be the smallest detail and they take it to consideration. They're very good at making a child understand things. Serenity opens up in ways that she didn't before. Peaceful and Friendly. Make her feel comfortable in all her appointments I have no complaints Pediatrics is amazing."
Impression of Adult Clinic	Adult clinics are associated with long wait times, less attention to detail, lack of insurance coverage.	"[What comes to mind when I think of the adult clinic is] scary. Adult health care has a really bad name on it. You hear that doctors don't care, you hear [people] complain about the health care system." "You can clearly see the difference, and from the staff to the doctors to everything. As an adult things are overlooked, adults they push things back wait 3-4 months, will wait again. . . For children they're determined to find the answers. . . the health insurance will cover anything any treatment up until 21. Past 21 then what? Are they going to decide what is beneficial or not or what I have to pay for? That basically just sums it up. . . As she is getting older, the only time its serious is when health insurance is going to pay for."
Transition readiness barriers	Barriers to transition to adult clinic include lack of emotional/mental readiness, reluctance to more responsibility	"Like no one wants to actually transfer. So unless they dislike the provider or dislike the clinic or the staff, they're not really ready to transfer. None of them want to mentally transfer....we just tell them, like, hey, it's kind of like part of life. It's part of growing up." -Provider "Just that I'm getting up there in age, eventually will want to be take responsibility. Everyone feels not ready, [don't] want to take on responsibility if you don't have to"
Transition readiness tactics	Informal transition tactics include mentally preparing patients for subsequent transition	"We mentally prepare them by just saying that you're going to be sitting with like 60 and 70 year olds instead of other like cute kids. " "Well, we again we try to have them act more like adults and the, you know, we prepare them like a few that have gone over to the adult world. We sort of prepare them .... I mean these adult providers staff are not going to baby you like we were . . [we] try to have them act more like adults we prepare them. .
	Facilitators of transition readiness include attending appointments solo and allowing patients to speak independently	"It would be great to teach the kids to be independent in their teens. ... I wouldn't mind dropping them off and sitting in the car. Maybe things would be missed but it would make the patient speak more. . . . it would end up being a win-win situation. --you got to make these kids talk"
SLE document for providers	SLE document is useful for physicians to understand patient disease	"Seems it like would be helpful for doctors." "I think this would certainly make it a little easier to hold together a summary of your of the patient" "I loved it, I thought it was pretty comprehensive, with all the checkboxes."
SLE document for patients	SLE document may be too technical for patients to understand	"I . . kids will be confused. . . .the medical terms a child won't understand"
Transition document attitudes	Documents with additional personal details are useful to build rapport	"One key fact that you can give the adult rheumatologist to help build rapport "loves dog"; has "six cats", something they can build on to build rapport; something the pediatric rheumatologists has done when they're at the sickest. The adult rheumatologist is trying to build rapport in 30 minutes." "Like the demographics, and the personal details that might help the doctor connect with you" "This letter is [not] just about the medical part, its more about the personality part. This is more about her as a person as who she is. So it allows the doctor to understand her in both ways personally and medically"

Methods: Semi-structured interviews were conducted on rheumatologists, pre and post-transfer young adult patients (aged 14-26 with an established pediatric rheumatic disease diagnosis, with at least two visits with a pediatric or adult rheumatology provider within the last 24 months) and their parents/guardians (Table 1). Open-ended and Likert scale questions were asked regarding topics ranging from independence, transfer readiness, understanding of disease and opinions towards existing medical summaries on Systemic Lupus Erythematosus (SLE), and Juvenile Idiopathic Arthritis (JIA). Themes were analyzed using the Rapid Data Analysis and Reporting (RADaR) approach by 2 independent reviewers (Table 2). Descriptive analysis of exploratory pilot data was done with top-box scoring and median.

Results: Barriers to medical independence included lack of self-transportation, socio-economic factors, inability to self-administer medications, schedule appointments, self-advocate and an unwillingness to take on increased responsibility despite having capability to do so.

There was a discrepancy between providers rating of patients' general independence as compared to medical independence (Table 3).

Pediatric clinics were associated with attentiveness, friendly staff, peaceful environment and caring doctors. Adult clinics were associated with fear, lack of insurance coverage, less attention to detail and long wait times.

Transfer readiness was facilitated by mentally preparing patients for adult clinic expectations, patients' ability to self-advocate, attend appointments alone, rapport with adult physician and adult physician's knowledge of patient.

Table 3. Views on Independence: adls vs medical

3a. Independance, as ascertained by providers:

	What percentage of pediatric patients > 18 years of age are independent with their care (ADLS) prior to transferring to the adult clinic?	[illegible]
Provider 2001	35	50
Provider 2002	90	70
Provider 2003	NA	NA
Provider 2004	100	NA
Provider 2005	98	65
Provider 2006	90	20
Provider 2008	95	10
Median:	96.50	50
Top box scoring: Percentage Rating 80/100 or above	85.71	0

3b. Independence, as ascertained by parents:

	How independent do you feel your child is (adls)?	Overall how independent is your child with medical care?
1003G Guardian	10	10
1010G Guardian	8	5
1011G Guardian	10	7
1013G Guardian	10	9
1025G Guardian	5	7
1026G Guardian	9	7
1031G Guardian	10	5
Median:	10.00	7.00
Top box scoring: Percentage Rating 8/10 or above	85.71	28.57

3c. Independence as ascertains by patients:

	How independent do you feel overall (adls)?	Overall, how independent are you with your medical care?
1003 Patient	5	10
1010 Patient	0	2
1011 Patient	10	10
1012 Patient	7	10
1013 Patient	8	5
1025 Patient	8	5
1026 Patient	9	9
1028 Patient	7	7
1031 Patient	10	10
Median:	8.00	9.00
Top box scoring: Percentage Rating 8/10 or above	66.67	55.56

SLE document was useful for physicians' understanding of patient disease, yet cumbersome for physicians to fill out and difficult for patients to understand. Documents with additional personal patients' details were deemed useful to build rapport.

Limitations include patient population in rural healthcare system as well as small sample size though further interviews are currently in progress.

Conclusion: Through semi-structured interviews we identified key barriers in transition readiness, independence and gained insight on existing transition documents. We intend to apply principles of human centered design to create an improved transition document and transition process.

Abstract Number: 2151

Real-World Experience with IL-1 Blockade in Children with Undifferentiated Systemic Autoinflammatory Diseases (uSAIDs)

Maryam Ashoor[1], Kosar Asna Ashari[2], Kyle McBrearty[2], Joyce Chang[3], Jonathan Hausmann[4] and Fatma Dedeoglu[2], [1]Division of Immunology, Boston Children's Hospital, Harvard Medical School, Brookline, MA, [2]Boston Children's Hospital, Boston, MA, [3]Boston Children's Hospital, Boston, [4]Boston Children's Hospital, bosto, MA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic Autoinflammatory Diseases (SAIDs) are a group of rare disorders caused by dysregulation of the innate immune system. Over 50 genes have been identified as causative for SAIDs. However, 40-60% of patients presenting with features consistent with SAIDs remain without a definitive diagnosis and are often categorized as undifferentiated SAIDs (uSAIDs).

Treatment can be challenging due to heterogeneous presentations and uncertain disease mechanisms. This study aimed to evaluate the clinical and laboratory response to IL-1 blockade in pediatric patients with uSAIDs.

Methods: We conducted a retrospective chart review of patients diagnosed with uSAIDs and treated with IL-1 inhibitors (anakinra, canakinumab, or rilonacept) at a single tertiary pediatric center between January 2010 and December 2023. Inclusion required a clinical diagnosis of uSAID, treatment with IL-1 blockade, and documented follow-up within one year of initiation of treatment. Data collected included demographics, clinical phenotype, flare frequency and severity, laboratory markers (CRP, CBC), treatment characteristics, and adverse events. Response to treatment was assessed through laboratory values, clinical presentation, the need for rescue medications, and the overall physician assessment of improvement.

Results: Thirty-three patients (51.5% female) with uSIADs who contributed to fifty-five IL-1 blockade treatment instances were identified. The mean age at symptom onset was 4.3 years (range 0–20), and the mean age at diagnosis was 7.8 years (range 0.6–21). All patients underwent genetic testing not revealing a known monogenic systemic autoinflammatory disease. Common clinical features included recurrent fevers (87.9%), arthralgia (57.6%), abdominal pain (51.5%), and urticarial rash (42.4%). Most patients (75.8%) had trialed colchicine before starting IL-1 blockade. Treatments included Anakinra (49%), canakinumab (45.5%), or Rilonacept (5.5%). Rescue medications were used in 49.1% of instances with corticosteroids being the most common in 55.6%, NSAIDs in 37.0% and Anakinra in 7.4%. Flares occurred a mean of 4.11 per month (range 0.5–30) at baseline which reduced to a mean of 0.8 (range 0-3) per month on first follow up after initiating treatment. Physician-assessed clinical improvement was noted in 92.7% of treatment instances. CRP levels decreased from a mean of 3.38 ± 7.06 mg/dL pre-treatment to 0.45 ± 1.49 mg/dL post-treatment (normal < 0.5 mg/dL). Treatment was generally well-tolerated; adverse events occurred in 11% of instances, most commonly injection site reactions and elevated liver enzymes. At last follow-up, 97% remained on IL-1 therapy, most commonly canakinumab.

Conclusion: Our study demonstrates that IL-1 blockade therapy can yield favorable outcomes in patients with uSAIDs, as reflected by improvements in flare frequency and decreased reliance on rescue medications clinically and improved inflammatory markers. These findings underscore the potential of IL-1 blockade as an effective therapeutic strategy for this challenging patient population. Nevertheless, additional research is essential to validate these results and establish standardized treatment protocols for uSAIDs.

Blau Syndrome: features beyond the classic triad and proposal for clinical criteria

Narendra Bagri[1], Nawazish Shaikh[2], Manisha jana[3], Sushain kalsotra[4], Krithika Rajkumar[2], Madhumita Roy Chowdhury[2], Neerja Gupta[2], Danveer Bhadu[5], Vishal Gupta[2] and Rohan Chawla[2], [1]All India Institute of Medical Sciences(AIIMS), New Delhi, Delhi, India, [2]All India Institute of Medical Sciences, Delhi, Delhi, India, [3]ALL INDIA INSTITUTE OF MEDICAL SCIENCES, Delhi, [4]All India Institute of Medical Sciences, Delhi, India, [5]All India Institute of Medical Sciences, New Delhi, New Delhi, Delhi, India

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: This study describes the characteristic clinical and radiological findings and outcomes of patients with Blau syndrome from a single tertiary care hospital.

Methods: A retrospective chart review of patients with Blau syndrome with NOD2 mutation was conducted to describe key clinical and imaging findings.

Children diagnosed with Blau syndrome and followed in the Pediatrics Rheumatology clinic, Department of Pediatrics, XXX, from January 2022 to July 2024, were enrolled for this retrospective chart review.

The inclusion criteria included children with clinical features consistent with Blau syndrome (boggy synovial swelling and dermatitis ± ocular features such as uveitis) and pathogenic or likely pathogenic variants in the NOD 2 gene. The molecular analysis was done on the peripheral blood sample drawn after obtaining written consent. Mutational hotspot, exon 4 of the *NOD2* gene, was amplified using previously reported primers and Bi-directional Sanger sequencing was carried out. The variants were classified according to the American College of Medical Genetics and Genomics guidelines. The variant calling was performed using the Franklin platform (https://franklin.genoox.com, accessed 8 May 2024).

Results: The diagnosis of Blau syndrome in all nine patients (8 children and one adult) was confirmed genetically. The mean (range) age of children at diagnosis was 60 months (24-108 months). The mean (SD) age of symptom onset was 13 (7.7) months, with an age range of 3 to 24 months. The classic triad of uveitis, arthritis and dermatitis was present in 75% of children. The other manifestations include fever (n=4), cervical lymphadenopathy (n=1), hepatosplenomegaly (n=3) and dysmorphism (n=2). The ultrasound of joints showed synovial proliferation, giving a rounded or globular contour similar to the "sac of marbles". The most common debilitating morbidity noted was visual impairment. We propose a clinical criterion to facilitate early diagnosis of Blau syndrome in resource-limited settings. Table 1 summarises the key clinical features of our study subjects.The skin lesions include dull-red micropapular eruption on face and extremities and icthyosiform scaling on bilateral legs (Fig 1E,F,I & J).On US imaging, the wrist was the most affected joint (7/8), followed by the knee (6/8). Synovial thickening with a characteristic echogenic appearance was a universal observation in all subjects (Figure 2). A distinct nodular/ finger-like projection of synovium was noted in all cases.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1: Representative Features of Blau Syndrome in Case 4 – Ocular features: Posterior synechiae and festooning of pupil (A&B;) Focal patches of chorioretinal atrophy in the mid-periphery, periphery (black arrow, C & D) and peripheral vasculitis (blue arrow, C & D). Dermatological features: Scaly ichthyotic patches on bilateral legs and hands(E&F). Features seen in Case 7: Superficial nummular corneal opacities (white arrow, G & H) with no other ocular features. Dermatological features: Flat-topped erythematous micropapules on face and extremities (I & J)

Ultrasonographic features of Blau syndrome. A-C. Tenosynovitis in 3 different patients (A-Case 4; B-Case 7;C-Case 8). There is minimal fluid in the tendon (t) sheath, along with significant filiform echogenic synovial thickening (arrows). D-G. Intra-articular synovitis in 4 patients (D-Case 1;E-Case 2;F-Case 4; G-Case 5).Knee joint US showing finger-like echogenic projection in the suprapatellar bursa (arrows), along with some joint effusion (D). The synovial proliferation was bright echogenic and nodular (E) in some cases and undulated globular in others (F). The nodular lobulated appearance of intra-articluar synovial proliferation (G), akin to 'sac of marbles'; as seen in H

Conclusion: Based on our findings and existing literature, we propose clinical criteria to facilitate early diagnosis of Blau syndrome in such settings.

Arthritis with boggy synovial swelling ***plus two of the following***
· Skin lesions: flat-topped red-skin coloured micropapules
· Uveitis: Anterior uveitis with superficial nummular corneal opacity or Panuveitis with focal chorioretinal atrophy patches in mid-periphery/periphery or granulomatous uveitis
· Fever

And either of two**:**
· Biopsy (Synovial/ Skin) suggestive of granulomatous inflammation
· USG joints: exuberant nodular echogenic synovial proliferation out of proportion to joint effusion

Giant Coronaries in Children with Kawasaki Disease: A Single Centre Experience

Pavneet Kaur[1], Mayank Goyal[2], Shivaprasad P Mohankumar[2], Lamk Kidyani[2], Sanjeev Kumar[2], Saurabh Gupta[3], Sivasubramanian Ramakrishnan[2] and Narendra Bagri[4], [1]All India Institute of Medical Sciences, New Delhi, India, [2]AIIMS, New Delhi, India, New Delhi, Delhi, India, [3]All India Institute of Medical Sciences, New Delhi, Delhi, [4]ALL INDIA INSTITUTE OF MEDICAL SCIENCES, New Delhi, Delhi, India

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Coronary artery abnormalities (CAA) are a dreaded yet potentially preventable stigmata of Kawasaki disease (KD). Giant CAA are rare but at higher risk of complications and adverse outcomes. We aimed to evaluate the medium-term outcomes of children with KD with giant coronary aneurysms (Z score >10).

Methods: KD cases registered in our tertiary care centre were retrospectively reviewed, and data of children with giant CAA was analysed.

Results: Of the 34 KD cases in our register (2018-2024), we encountered 5 children (14.7%) with giant coronaries. All children presented as incomplete KD, with delayed immunomodulation and IVIg resistance. One patient had extensive systemic vascular involvement beyond the coronaries. The high proportion of children with giant coronaries as opposed to the reported literature might be due to a referral bias. The diagnosis of KD and initiation of immunomodulation took a median (IQR) of 12 (10-14) days. All received IVIg and oral steroids, with IV methylprednisolone pulse in two. All but one received primary intensification with Infliximab. CAAs persisted in all, noted during the 22 patient-years of follow-up. There was one mortality owing to a cardiovascular event. Our experience, although limited, was concordant with published literature suggesting that male sex, aneurysms at onset, delayed IVIG therapy and IVIg resistance are heralds of giant CAAs in KD. Similarly, systemic vascular involvement was associated with a poor outcome.

Volume rendered 3 D reconstructed in coronal view showing bilateral axillary arteries (indicated)- tortuous and dilated with small saccular aneurysms

(Case described in publication: Kadiyani L, Mohankumar SP, Arumugam P, Gupta SK, Bagri NK, Pandey N, et al. Systemic artery aneurysms – A marker of high-risk Kawasaki disease. Ann Pediatr Card 2024;17:377-pou)

Figure 2 (Case 2) Computed tomography angiographic images showing dilatation of RCA and LAD (a), and RCA and LCX (b) in the axial view, and LAD in the sagittal oblique view (c)

Figure 3 (Case 3) Computed tomography angiographic images showing dilatation of RCA in the coronal oblique view (a) and LAD in the sagittal oblique view (b). Volume rendered 3D reconstructed CT angiogram showing dilated LAD and RCA (c)

Figure 4 (Case 4) - CT angiography sagittal oblique view showing dilated LAD (a), RCA and LCX in the coronal oblique view and volume rendered 3D reconstructed section with aneurysmal dilatation of RCA(entire), LAD(proximal and mid), and LCX(ectatic)

Figure 5 (Case 5) Computed tomography angiography showing dilated LAD in axial (a), coronal (b) and volume rendered 3D reconstructed views respectively.

CT images of children with Kawasaki disease with giant coronaries

Conclusion: Incomplete KD may have a high propensity to develop giant coronaries, possibly refractory to immunomodulation. As is evident in our series, delayed diagnosis and immunomodulation (12 (10-14) days) are important factors determining CAA prognosis. Although rare, giant and systemic arterial aneurysms in KD are life-threatening and difficult to manage. They may progress despite appropriate immunomodulation.

Whole-Body MRI Findings in a Cohort of Children with Chronic Nonbacterial Osteomyelitis

Mara Rodriguez[1], Maurice Davenport Munoz[2], Kiery Braithwaite[3], Lori Ponder[4], Kelly Rouster-Stevens[5], Solveig Argeseanu Cunningham[6] and **Sampath Prahalad**[7], [1]Emory University School of Medicine / Children's Healthcare of Atlanta, Atlanta, GA, [2]Emory University School of Medicine, Pediatrics, Atlanta, [3]Children's Healthcare of Atlanta, Atlanta, GA, [4]Emory University, Atlanta, GA, [5]Emory University/Children's Healthcare of Atlanta, Peachtree Corners, GA, [6]Emory Rollins School of Public Health Department of Global Health, Atlanta, GA, [7]Emory + Children's Pediatric Institute, Atlanta, GA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Chronic nonbacterial osteomyelitis (CNO) is an autoinflammatory bone disorder characterized by multifocal, sterile bone inflammation in childhood. Whole-body magnetic resonance imaging (WB-MRI) allows for a comprehensive assessment of skeletal involvement in CNO, which can enhance our understanding of the disorder and its implication for child wellbeing. Our objective was to provide a novel perspective of CNO, leveraging WB-MRI methods linked with clinical records to identify the demographic, clinical, and imaging characteristics of the children receiving care at a tertiary pediatric center.

Methods: We conducted a retrospective review of the pediatric patients diagnosed with CNO over a 10-year period (n=76). To be included children had to have a diagnosis of CNO confirmed by a pediatric rheumatologist, be less than 18 years old at time of diagnosis, and had a WB-MRI within 12 months of symptom onset. Demographic data, clinical features, extraosseous involvement, diagnostic and treatment modalities, and lesion distribution were ascertained by review of the electronic medical record. Lesion counts and locations were extracted from MRI reports and were validated by a musculoskeletal radiologist.

Table 1: Characteristics of the CNO Cohort	Frequency (%) *n = 76*
Race	
White	52 (68%)
Black or African American	19 (25%)
Asian	4 (5%)
American Indian/Alaskan Native	1 (1%)
Gender: Female	42 (55%)
Modalities of Diagnosis	
Whole Body MRI	76 (100%)
XRAY	66 (87%)
Bone Biopsy	31 (41%)
Bone Scan	2 (3%)
Age	
Age of onset of symptoms; years, Median (IQR)	10.2 (7.7 – 12.8)
Age of diagnosis in years; years, Median (IQR)	10.7 (8.2 – 13.4)
Time to WB-MRI; months, Median (IQR)	2.2 (0.5 – 5.7)
No. of lesions per patient; Median (Range)	4 (1 - 23)
Extra Osseous Features	
Arthritis	6 (8%)
Psoriasis	6 (8%)
IBD	3 (4%)
HLA B27 Positive (Total tested n=50)	8 (16%)
Medications	
Non-steroidal anti-inflammatory drugs (NSAIDS)	71 (93%)
Tumor Necrosis Factor-Inhibitors (TNF-I)	29 (38%)
Disease-modifying antirheumatic drugs (DMARDS)	21 (28%)
Pamidronate / Bisphosphonates	2 (3%)

Characteristics of the CNO cohort

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 2: Characteristics of skeletal lesions in patients with CNO

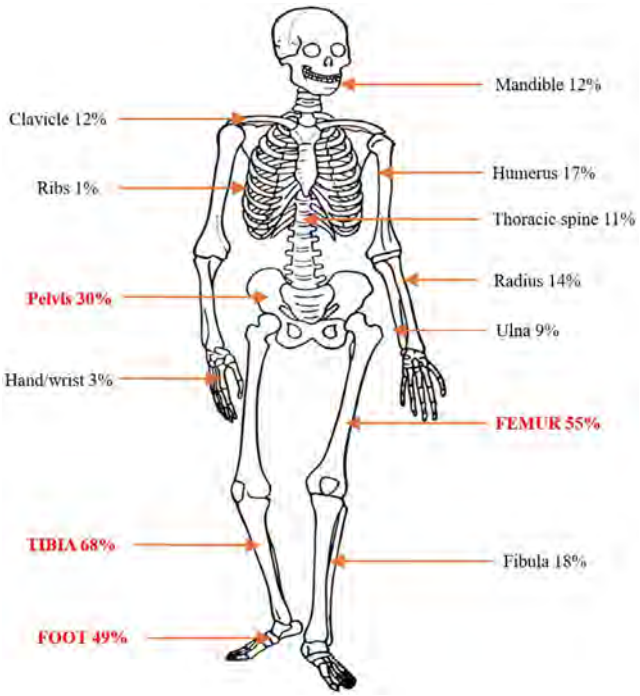
Bone involved	Patients affected (%) *n = 76*	Total lesions at site *n = 410*
Mandible	9 (12%)	9
Clavicle	9 (12%)	9
Ribs	1 (1%)	3
Thoracic Spine	8 (11%)	14
Pelvis	23 (30%)	43
Humerus	13 (17%)	21
Ulna	7 (9%)	9
Radius	11 (14%)	15
Hand/Wrist	2 (3%)	5
Femur	42 (55%)	81
Tibia	52 (68%)	109
Fibula	14 (18%)	20
Foot	37 (49%)	72

Characteristics of skeletal lesions in patients with CNO

Results: Among the 76 patients (55% female), the median age at symptom onset was 10.2 years (Inter quartile range 7.7–12.8), and the median age at diagnosis was 10.7 years (IQR 8.2-13.1). WB-MRI was performed within a median 2.2 months after onset (IQR 0.5-5.7 months) and identified 410 lesions across the cohort. Asymptomatic lesions were common, highlighting the diagnostic value of WB-MRI. The median number of lesions per patient was 4 (range 1-23). The tibia (68%), the femur (55%) and the foot (49%) were the most frequently involved sites. Thoracic vertebral lesions were seen in 8 children. The mandible was involved in 9 children; interestingly 5 patients (56%) had extra-mandibular lesions. Extraosseous features including arthritis, psoriasis, and inflammatory bowel disease were seen only in a small subset of patients. HLA-B27 was positive in 16% of those tested. NSAIDs were the most used medication (93%), followed by TNF inhibitors (38%) and DMARDs (27%). At the last visit 19% were described by their pediatric rheumatologist as being in remission.

Conclusion: This is one of the largest single center cohorts of CNO with WB-MRI evaluation. Among children with CNO attending a tertiary care clinic, WB-MRI revealed a high burden of multifocal disease, often with clinically asymptomatic lesions. Confirming other published reports, CNO was more common in girls and onset age was around 10. Tibia, femur and the bones of the feet were frequently affected comparable to several multicenter CNO cohorts. Mandibular lesions were



Distribution of lesions in patients with CNO

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. A Novel TNFAIP3 Mutation Associated with Large Vessel Vasculitis: Expanding the Phenotypic Spectrum of A20 Haploinsufficiency

Sirada Panupattanapong[1], roshini Abraham[2], Urekha Karri[3], Harry Lesmana[1] and Daniella Schwartz[4], [1]Cleveland Clinic Foundation, Cleveland, OH, [2]Nationwide Children's Hospital, Columbus, OH, [3]School of public health, Pittsburgh, PA, [4]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Loss-of-function pathogenic variants in *TNFAIP3* lead to haploinsufficiency of A20 (HA20), a complex immune dysregulation disorder that can mimic Behcet's disease, IBD, periodic fever syndrome, and varied other rheumatic diseases. This study, we describe a novel *TNFAIP3* variant in an adolescent diagnosed with large vessel vasculitis.

Methods: A targeted genetic panel on the proband and parental single-gene testing were conducted by Invitae. Variant effect on canonical function was evaluated by NF-kB luciferase reporter (Cignal) in A20-deficient HEK293T cells transfected with empty vector, WT, and mutant *TNFAIP3*, and then stimulated with TNF-a. A20 protein expression was measured in primary cells using Western blot. NFkB and inflammasome activity in patient's cells were evaluated after stimulating PBMCs (monocytes) with LPS or LPS+ATP for 2h or 24h. Then cytokine production (IL-18, IL-1b, TNF-a and IL-6 in pg/mL) was measured at each time-point, using clinical ELISA testing, and compared to data from 73 pediatric and adult healthy controls.

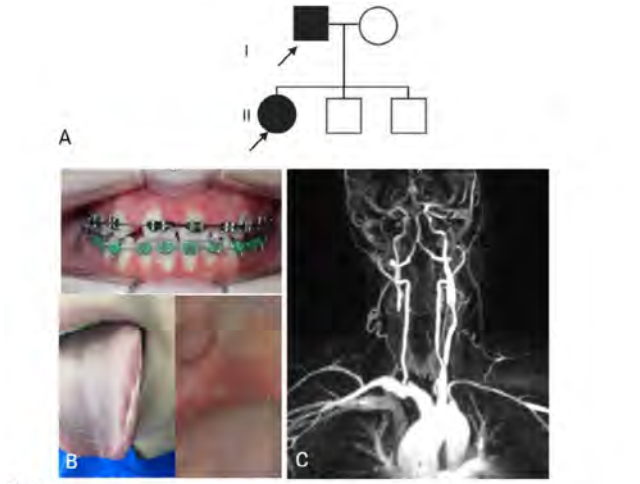

Figure 1
A. Pedigree of patient/family shows segregation of genotype and phenotype
B. Photo of the patient showing gum swelling (with histopathology revealing granulomatous inflammation), along with tongue and oral ulcers
C. MRA brain and carotid arteries revealed abnormalities in aorta, carotid arteries, subclavian arteries and other branches, consistent with large vessel vasculitis

Figure 1 Clinical presentation of the proband and the family pedigree

Abbreviations: VC = vehicle control/unstimulated, LPS = lipopolysaccharides, ATP = adenosine triphosphate
Cytokines were measured in pg/mL
Data highlighted in **Bold** indicates patient's cytokine levels that are significantly higher than the median levels in healthy controls

Results: The proband presented at age 16-year with chronic anemia, progressive oral ulcers, corneal ulcers, erythema nodosum, granulomatous gingivitis, and ultimately large vessel vasculitis involving thoracic/abdominal aorta and branches (Figure 1). She had history of hyperinflammatory skin reactions to injections/bug bites since age 2, and an episode of severe aseptic meningitis at age 5. Clinical genetic testing revealed a paternally-inherited heterozygous missense variant in *TNFAIP3*, c.1504C >T (p. Arg502Trp, NM_006290.3). The patient's father reported a history of childhood onset oral ulcers, a self-resolving PFAPA-like syndrome, adult-onset psoriasiform rash, IBD, and arthritis (Figure 1).

This variant has CADD score of 26.2 and REVEL score of 0.356. It is listed in ClinVar as a VUS and has an ACMG score of 5 (VUS), PM1, PM2 and PP3. *In vitro*, the variant was weakly hypomorphic (p = 0.04); basal A20 expression was normal in PBMC from patient and her father. Proband's cells stimulated with LPS +/- ATP displayed enhanced production of TNF-a, IL-6 and IL-18 at 2 hours and 24 hours. For IL-1b, there was an increase observed at 24h after LPS stimulation and at 2h and 24h with LPS+ATP (Table 1). Consistent with this result, S100A8/9 were elevated in proband and her father. The proband's cells also exhibited enhanced expression of Siglec-1, indicating Type 1 interferon activation. Expression of interferon-stimulated genes (ISG) was elevated in the proband and her father relative to healthy volunteers. Together, these data suggest acute and chronic activation of canonical NFkB, inflammasome, and Type 1 interferon signaling align with prior immunologic findings in *TNFAIP3* loss-of-function variants.

Conclusion: The clinical phenotype, pedigree, and functional immune evaluation of the patient and her father provide evidence supporting a pathogenic role for the *TNFAIP3* variant. Further, we extend the HA20 clinical phenotype to include large-vessel vasculitis. This case also underscores the essential role of comprehensive functional evaluation in interpreting novel VUS which is crucial for advancing our understanding of their impact on key biological pathways.

Jansson	0 (0.0%)	40 (62.5%)	14 (70.0%)	<0.001

Background/Purpose: The relationship between juvenile spondyloarthritis (JSpA) and chronic nonbacterial osteomyelitis (CNO) remains poorly defined. This study aimed to assess the proportion of pediatric patients who meet classification criteria for both JSpA and CNO, characterize the clinical and radiologic overlap between the two conditions, and compare initial treatment approaches within the first 6 months following diagnosis.

Methods: This was a retrospective cohort study conducted on children (≤18 years) diagnosed with JSpA and CNO between 2016 and 2024 at a tertiary care children's hospital. Subjects were identified by electronic health record coding and included if they had: at least 2 rheumatology visits, no prior biologic therapy, and met at least one set of classification criteria: ILAR PsA/ERA or European Spondyloarthropathy Study Group (ESSG) (for JSpA), or Bristol or Jansson (for CNO). Overlap was defined as present if at least one set of JSpA and CNO criteria were met. The index visit was defined as the first clinical encounter with a JSpA or CNO diagnostic code. Data from the 6 months following the index visit - including demographics, clinical symptoms, family history, lab values, and imaging - were abstracted into a REDCap database. Descriptive statistics were calculated using medians and interquartile ranges (IQR) and proportions. Between-group comparisons were conducted using Mann-Whitney U and Chi-square tests, as appropriate.

Figure 1. Sites of active disease were identified through clinical examination and/or imaging. Statistically significant values ($p < 0.05$) are highlighted in blue and red.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

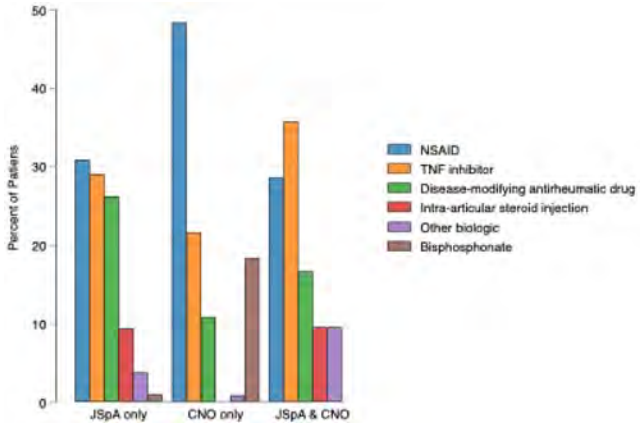

Figure 2. Treatments prescribed in the first six months after the index visit.

Results: A total of 137 subjects met inclusion criteria. Of these, 20 (14.6%) met criteria for both JSpA and CNO. This overlap group was significantly older ($p< 0.001$) and predominantly female (75.0%) (Table 1). Psoriasis was observed significantly more frequently in the overlap group compared to JSpA or CNO alone (55%, 20.8%, 3.1%, respectively; $p< 0.001$). In contrast, peripheral arthritis and enthesitis were significantly less common in the CNO cohort (both $p< 0.001$). Whole-body/pelvic MRI were obtained in 13.2%/50.9% of JSpA, 89.1%/25.0% of CNO, and 30.0%/30.0% of overlap patients, respectively. Figure 1 shows the distribution of the most frequently involved sites of disease activity across the 3 groups. Pelvic osteitis and/or sacroiliitis affected approximately one-third of cases across all groups, with sacroiliitis significantly more common in JSpA ($p=0.003$). NSAIDs and TNF inhibitors were the most frequently prescribed therapies in all 3 groups (Figure 2). DMARDs were used more often in the JSpA and overlap groups, while bisphosphonates were more commonly prescribed for CNO. The most commonly met criteria in each diagnosis was ESSG criteria (66.0%) for JSpA patients, Bristol criteria (85.9%) for CNO patients, and ESSG (70.0%) and Jansson (70.0%) for overlap patients.

Conclusion: A subset of pediatric patients fulfilled classification criteria for both JSpA and CNO, with overlapping clinical and radiologic features. The co-occurrence of these conditions may represent a distinct phenotype, characterized by older age, female predominance, and a higher prevalence of psoriasis. Differences in imaging use and treatment strategies highlight the importance of recognizing this overlap for appropriate diagnostic clarity, evaluation and therapeutic decision-making.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Through a single-center retrospective cohort study and systematic literature review, we aimed to evaluate the applicability of current diagnostic criteria (HLH-2004/2009 and 2016 sJIA-MAS) for Kawasaki disease-associated macrophage activation syndrome (KD-MAS) and assess the clinical value of immunomodulatory treatment strategies.

Methods: A dual-cohort design was employed: (1) Retrospective analysis of pediatric patients treated at our institution from 2015 to 2025 who met the 2024 AHA Kawasaki disease diagnostic criteria and at least one MAS diagnostic criterion (HLH-2004/2009 or 2016 sJIA-MAS); (2) Systematic literature search for KD-MAS case reports. Data on demographic characteristics, clinical manifestations, biomarker dynamics, treatment responses, and outcomes were collected. Treatment efficacy was stratified and compared based on glucocorticoid dosage (Mann-Whitney U test).

Results: Analysis of 44 KD-MAS cases (22 from our center and 22 from literature) revealed an incidence rate of 0.6% (22/3,786) at our institution, with a male-to-female ratio of 2.1:1 and median age of 4.2 years. Diagnostically, 72.7% (32/44) met all diagnostic criteria, 93.2% (41/44) fulfilled the 2016 sJIA-MAS criteria, and 72.7% (32/44) met the HLH-2004/2009 criteria. All patients received IVIG, with 90% requiring additional immunomodulatory therapy. Among 13 patients treated with methylprednisolone alone at our center, no significant difference in CRP improvement was observed between high-dose (≥10 mg/kg/day, n=7) and low-dose (< 10 mg/kg/day, n=6) groups (P=0.23). The overall cure rate was 95% (39/41, excluding 3 lost-to-follow-up cases), with two fatal cases at our institution associated with treatment delay.

Conclusion: This study is the first to demonstrate the superior sensitivity of the 2016 sJIA-MAS criteria for KD-MAS diagnosis. Initial low-dose glucocorticoids (< 10 mg/kg/day) are effective for mild KD-MAS, but treatment escalation is warranted if no clinical improvement is observed. Treatment delay was identified as an independent risk factor for poor prognosis.

Table 1. Clinical manifestations in KD-MAS patients: comparison of our center with literature cases

	Our center	literature-reported cases	Total
fever	(22/22, 100%)	(22/22, 100%)	(44/44, 100%)

Evaluating Nailfold Capillary Changes as Indicators of Disease Activity in Juvenile Dermatomyositis

Zilan Zheng[1], Laila Metni[2], Susan Kim[3] and Jessica Neely[4], [1]University of California, San Francisco, San Francisco, CA, [2]University of California, Berkeley, Berkeley, CA, [3]UCSF Benioff Children's Hospital, San Francisco, CA, [4]UCSF, San Francisco, CA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2124–2158) Pediatric Rheumatology – Clinical Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Juvenile dermatomyositis (JDM) is a rare pediatric autoimmune myopathy characterized by skin and muscle inflammation, resulting in microvascular changes that can be visualized in the nailfold capillaries. Nailfold video capillaroscopy (NVC) at 200x magnification is a promising non-invasive measure to study disease activity. Here, we studied the association of nailfold capillary measurements with disease activity and compared rheumatologists' examination (RE) at 10x magnification to NVC.

Methods: Patients diagnosed with JDM at a single tertiary care pediatric rheumatology center had nailfold capillaries imaged during clinic visits following published protocols. Clinical data (e.g., skin assessments and visual analog scale (VAS) scores) and notes on capillary appearances were extracted from medical records. Two cohorts were defined based on disease activity status at time of imaging: active JDM (physician VAS score $\geq$ 0.5) and inactive JDM (physician VAS score < 0.5).

Anti-Io1, SRP, HMGCR, La (SSB), and Ku are excluded because no patients were positive for these antibodies. Extensive cutaneous erythema, cutaneous ulceration, mucus membrane lesions, mechanics hand, subcutaneous oedema, and panniculitis are excluded because no patients had these symptoms. VAS scores for pulmonary and cardiovascular systems were 0 for all patients.

Significant results are italicized.

Automated analysis of the NVC images were completed by Capillary.io, measuring capillary limb widths and apical diameters, followed by manual review for accuracy, apex widths, and internal diameters (Table 2, Fig 1). Each capillary characteristic was averaged per patient before analysis. Fisher and Wilcoxon rank sum tests were applied for categorical and continuous variables respectively. Data was stratified by RE at 10x: normal, mild-minimal, and abnormal. One-way ANOVA on ranks was applied, to assess for differences across the groups (P-value < 0.01). NVC measurements were compared to a published study of healthy pediatric capillaries.

Results: 29 JDM patients (mean age 11.79 ± 5.81) had 169 images analyzed, divided into 2 groups of 14 active and 15 inactive patients. Analysis of clinical variables between the two cohorts revealed active JDM exhibited more active skin disease and presence of periungual capillary loop change, active calcinosis, malar erythema, and chronic muscle weakness (Table 1). Active JDM was associated with decreased capillary density and enlarged arterial limb widths, apex widths, and internal diameters on NVC (Table 2, Fig 1). There was no significant difference in abnormal morphology between the two groups, but inactive JDM had significantly more normal capillaries per millimeter (Table 2). Between 80% to 100% of inactive

[`]Dundar HA, Adrovic A, Demir S, et al. Description of the characteristics of the nailfold capillary structure in healthy children: a multi-centric study. Rheumatology (Oxford). 2024;63(SI2):SI152-SI159. doi:10.1093/rheumatology/kead296

Significant results are italicized.

JDM had NVC measurements within normal ranges, compared to about half of those with active JDM. Analysis of RE revealed patients described as "normal" on 10x met 4-5 of the normal 200x ranges, while "abnormal" met none.

Conclusion: Abnormal capillaries observed at 10x and 200x magnification were associated with active skin disease and muscle weakness in JDM, suggesting that nailfold capillaries, specifically arterial limb and apex widths, may serve as a clinical biomarker of disease activity. In addition, NVC showed abnormal measures could be detected and quantified in patients described clinically as "abnormal" or "mild-minimal" changes. Determining the clinical utility added by NVC will be an important area of future study along with identifying features that can help predict future flares, remission, and guide medications tapering.

Teaching Musculoskeletal Ultrasound Improves Knowledge and Confidence in the Knee Exam: A Pilot Session with Internal Medicine Trainees

Ann Cameron Barr[1], David Leverenz[1], Lisa Criscione-Schreiber[2] and Philip Chu[3], [1]Duke University, Durham, NC, [2]Duke University School of Medicine, Durham, NC, [3]Duke University Hospital, Raleigh, NC

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2159–2194) Professional Education Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Poor confidence in musculoskeletal (MSK) care among practicing internists and internal medicine (IM) trainees is well described in the literature. A needs assessment of IM residents at our institution showed similar results with little training and low confidence in MSK physical examination (ACR 2024, abstract #1291). We implemented and evaluated a pilot MSK ultrasound (US) session on the knee for IM interns with the goals of improving knowledge of MSK anatomy, improving MSK physical examination, and optimizing arthrocentesis skills.

Methods: The pilot MSKUS session occurred in the fall of 2024 at a single academic residency program. The session included 30 minutes of didactic teaching on anatomy and an overview of 5 standard US views of the knee with both normal findings and common pathology. Following the didactic session, the interns split into small groups for 90 minutes of hands-on US practice, supervised by a rheumatologist. We surveyed participating interns on prior instruction in MSK exam and US, pre-post confidence in physical examination of the knee on a 1-6 scale (1 = not at all confident, 6 = extremely confident), and pre-post confidence in performing arthrocentesis of the knee on the same 1-6 scale. Survey questions were adapted from a survey on resident MSK exam confidence with evidence for validity (ACR 2014, abstract #1983). Finally, we administered an eight question pre- and post-session test to assess their knowledge of physical exam, anatomy, and US pathology of the knee. We analyzed data in aggregate using paired two sample T-tests.

Table 1: Interns were asked to quantify their experiences learning musculoskeletal physical exam and ultrasound by answering the following questions: "How much training have you had in physical examination of the following joints?", "How much ultrasound training have you received in your medical training?", and "Did your previous ultrasound training include any training in musculoskeletal ultrasound?"

	None	Some (2-3 sessions)	A lot (> 2-3 sessions)	Extensive	Total
Physical exam experience					
Knee	6 (17%)	25 (69%)	5 (14%)	0 (0%)	36
Hand/wrist	12 (33%)	22 (61%)	2 (6%)	0 (0%)	36
Foot/ankle	16 (44%)	19 (53%)	1 (3%)	0 (0%)	36
Ultrasound experience	8 (22%)	14 (39%)	11 (31%)	3 (8%)	36
Musculoskeletal ultrasound experience	32 (89%)	4 (11%)*	N/A	N/A	36

* Prior training in musculoskeletal ultrasound was assessed on yes/no basis

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1: Intern knowledge about physical exam, anatomy, and musculoskeletal ultrasound pathology of the knee pre- and post-musculoskeletal ultrasound (MSKUS) session.

Results: Thirty-six of 39 (92%) interns responded to the pre-session survey, and 34 of 39 (87%) interns responded to both pre- and post-session surveys. Most reported having 3 or fewer sessions in physical examination of the knee (n=31, 86%), hand/wrist (n=24, 94%), and foot/ankle (n=35, 97%) during their medical training (Table 1). Although 78% of interns reported prior POCUS training, only 11% reported prior training in MSKUS. Pre-session intern confidence in examination and arthrocentesis of the knee was very low, with fewer than 25% rating >3/6 for any domain. Confidence in all domains was significantly improved post-session (Figure 1). MSK knowledge of the knee was significantly improved post-session for 6 of 8 questions, including those focused on physical exam (2 of 2), MSKUS pathology (1 of 1), anatomy (3 of 5). For the remaining 2 questions focused on anatomy, there was a trend toward improvement (Figure 2).

Conclusion: IM residents receive little training in MSK physical exam or MSKUS, and their confidence in performing MSK examination and procedures is low. Our prior needs assessment data suggests that this improves minimally over three years of IM residency. Intern participation in a targeted MSKUS training session was associated with improved confidence in MSK skills and improved MSK knowledge of the knee. Next steps include implementation of a longitudinal curriculum incorporating additional joint regions and the opportunity for time-distributed practice of MSKUS.

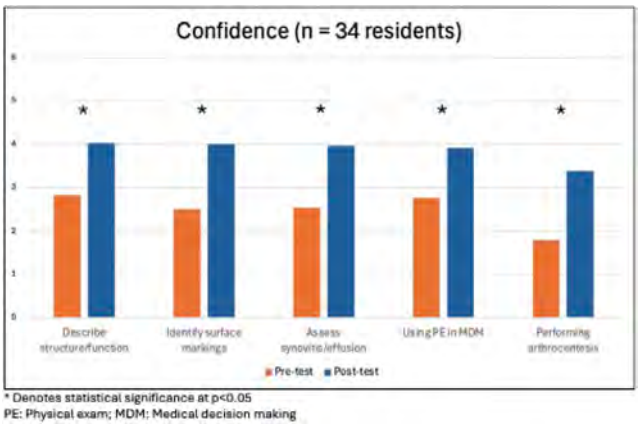

Figure 2: Resident confidence in performing musculoskeletal physical exam and arthrocentesis of the knee pre- and post-musculoskeletal ultrasound (MSKUS) session.

Abstract Number: 2160

RadRheum: Improving Resident and Medical Student Musculoskeletal Radiology Interpretation Skills Utilizing an Interactive Module

Elizabeth Konon[1], Laura Nichols[2] and Meredith Morcos[2], [1]University of Colorado Internal Medicine Residency Program, Denver, CO, [2]University of Colorado, Aurora, CO

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2159–2194) Professional Education Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Plain radiographs remain a cornerstone for diagnosis in rheumatology. Despite the importance of radiograph interpretation in rheumatology, there is little formalized instruction documented in the literature. The purpose of this curricular quality project was to develop and assess a virtual, instructional module for teaching internal medicine residents and medical students both general and rheumatology-specific radiology skills.

Methods: An interactive virtual module including musculoskeletal (MSK) radiographs was created and administered voluntarily to internal medicine residents and medical students at a single academic site. Participants were asked to complete a pre- and post-test to evaluate their knowledge and confidence in interpreting radiographs prior to and after participation in the module. Participants were also asked about their prior instructional experiences with MSK radiology. High-yield and commonly seen topics in the field of rheumatology including rheumatoid arthritis, psoriatic arthritis, gout, spondyloarthritis, and osteoarthritis were chosen based on relevance in terms of representation in the American College of Physicians Medical Knowledge Self-Assessment Program (MKSAP) and rheumatology attending decision. Fellows (n=4) and attendings (n=5) also completed the pre/post-test to evaluate whether this information is used in practice and learned over time.

Results: Forty-three trainees completed the pre-test. Thirty-three trainees completed the post-test. The average scores on the pre-test compared to the post-test improved from 4.5/10 to 6.5/10. Fellows and attendings scored 7.8/10 and 9.8/10, respectively. Student and resident scores on multiple topics, including identifying osteoarthritis, psoriatic arthritis, and rheumatoid arthritis on hand radiographs, improved after participation in the program (Table 1). Formal didactics reported in MSK radiology were low, particularly during residency (Figure 1). In the post-test survey, 52% of participants selected "somewhat agree" and 33% selected "strongly agree" when asked whether the module increased their ability to interpret MSK

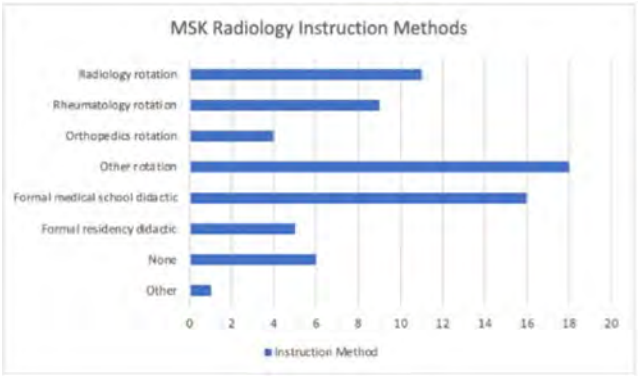
Topic Assessed	Pre-Test Correct N (%) Total N=43	Post-Test Correct N (%) Total N=33
Identify osteoarthritis on hand x-ray	20 (47%)	26 (79%)
Diagnose osteoarthritis on hand x-ray	31 (72%)	30 (91%)
Identify changes of erosive osteoarthritis on x-ray	4 (10%)	7 (21%)
Diagnose psoriatic arthritis on hand x-ray*	10 (24%)	10 (30%)
	12 (29%)	19 (58%)
Identify chondrocalcinosis on knee x-ray and associate with disease	23 (55%)	32 (97%)
Identify changes of rheumatoid arthritis on hand x-ray	4 (10%)	14 (42%)
Diagnose spondyloarthritis on sacroiliac joint x-ray*	36 (86%)	29 (88%)
	18 (44%)	16 (48%)
Identify erosions typical of gout on x-ray	17 (43%)	31 (94%)

Pre and post test scores for topics assessed in interactive module. *Two separate questions were asked on diagnosis of psoriatic arthritis and spondyloarthritis

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

	Pre-Test N (%) Total N=39	Post-Test N (%) Total N=33
Very confident	0 (0%)	0 (0%)
Somewhat Confident	3 (8%)	11 (33%)
Neutral	3 (8%)	6 (18%)
Somewhat unconfident	17 (44%)	11 (33%)
Very unconfident	16 (41%)	5 (15%)

Self-reported confidence level in diagnosing musculoskeletal conditions using radiographs



Musculoskeletal radiograph instruction methods reported by trainees

radiographs. Furthermore, confidence levels also increased (Table 2). One study limitation is that 10 participants did not complete the post-test.

Conclusion: Participating in this interactive module improved trainee scores and self-reported confidence in interpreting radiographs and diagnosing MSK conditions such as osteoarthritis, rheumatoid arthritis, psoriatic arthritis, and spondyloarthritis. Though scores improved after participation in the module, many remained low. Next steps include reviewing content to improve identification of erosive OA, RA, and PsA changes and disseminating to other institutions to assess reproducibility. A structured curriculum surrounding the use of radiography in rheumatology is a useful tool for medical students and residents.

Table 2. Key Alumni Survey Responses

	Overall (n=102)	Less exposure (n=84)	More exposure (n=13)	p-value
Thinking back to your time as a pediatric resident, how important did you think learning pediatric rheumatology topics were to your education as a general pediatrician at that time?				
Not at all important	1 (1.0)	0 (0.0)	0 (0.0)	0.355
Somewhat important	54 (54.0)	49 (58.8)	5 (41.7)	
Very important	45 (45.0)	35 (41.7)	7 (58.3)	
Thinking back to your time as a pediatric resident, how confident were you at the time of graduation that you had the pediatric rheumatology knowledge you needed for your next phase of clinical practice?				
Not at all confident	13 (13.0)	12 (14.3)	0 (0.0)	0.378
Somewhat confident	75 (75.0)	63 (75.0)	10 (83.3)	
Very Confident	12 (12.0)	9 (10.7)	2 (16.7)	
In your current clinical practice, how important is knowledge of pediatric rheumatology topics?				
Not at all important	9 (5.0)	4 (4.8)	0 (0.0)	0.053
Somewhat important	52 (52.0)	48 (57.1)	3 (25.0)	
Very important	43 (43.0)	32 (38.1)	9 (75.0)	
In your current clinical practice, how confident are you that you have the pediatric rheumatology knowledge you need?				
Not at all confident	16 (16.0)	15 (17.9)	1 (8.3)	0.033
Somewhat confident	73 (73.0)	63 (75.0)	7 (58.3)[λ]	
Very Confident	11 (11.0)	6 (7.1)	4 (33.3)	
In your current clinical practice, how confident are you that you have the musculoskeletal exam skills you need?				
Not at all confident	28 (28.0)	24 (28.6)	3 (25.0)	0.421
Somewhat confident	52 (52.0)	45 (53.6)	5 (41.7)	
Very Confident	20 (20.0)	15 (17.9)	4 (33.3)	
In your current clinical practice, how confident are you that you consider rheumatologic diagnoses when they should be considered?				
Not at all confident	1(10.0)	1 (1.2)	0 (0.0)	0.008
Somewhat confident	69(69.0)	63 (75.0)	4 (33.3)	
Very confident	30(30.0)	20 (23.8)	8 (66.7)[λ]	
In your current clinical practice, how confident do you feel in your ability to start a workup before consulting rheumatology, when a rheumatologic diagnosis is on your differential?				
Not at all confident	22(22.0)	21 (25.0)	1 (8.3)	0.055
Somewhat confident	61(61.0)	52 (61.9)	6 (50.0)	
Very confident	17(17.0)	11 (13.1)	5 (41.7)	
If you did not complete a pediatric rheumatology elective (2 or more weeks of total time in residency dedicated to pediatric rheumatology) during residency, do you now wish you did?				
Yes	46(46.0)	46(58.2)	NA	NA
No	34(34.0)	33(41.8)	NA	NA

opinions on its importance and effectiveness are unknown. This study aimed to describe the perceived importance of PR education and current programs' effectiveness in preparing UCPR graduates for their next phase of practice via needs assessment surveys sent to residents and residency alumni.

Methods: Anonymous surveys were sent to (1) current trainees and (2) alumni (graduated 2014 - 2023) in spring 2024. Results were analyzed using descriptive statistics. To explore possible effects from exposure to the PR elective, respondents were split into groups based on total PR elective time: less exposure (0 to < 2 weeks) versus more exposure (≥ 2 weeks). Differences between groups were analyzed using ANOVA.

Results: The survey response rate was 47.9% (56/117) and 36.0% (102/283) for residents and alumni, respectively. Most residents (78.6 %) and alumni (82.4%) completed < 2 weeks of a PR elective. Overall, 41.1% of residents felt not at all confident they have the PR knowledge needed after graduation while only 15.7% of alumni felt not at all confident that they have the PR knowledge needed in their current clinical practice. Both residents and alumni in the more exposure groups reported greater confidence that they have the PR knowledge they (will) need compared to peers in the less exposure groups (p = < 0.001 and p= 0.033). 30.4% of residents and 27.4% of alumni were not at all confident they have the MSK exam skills

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

needed after graduation or in their current clinical practice and confidence did not differ between exposure groups. Alumni in the more exposure group were more confident that they consider rheumatologic diagnoses when they should be on the differential (66.7% vs. 23.8%, p=0.008).

Conclusion: Although patient access to PR specialists is limited, most UCPR pediatric residents do not complete a 2 or more-week PR elective. This may disadvantage graduates and patients, as alumni who had less exposure to PR training reported less confidence in their PR knowledge. Results also suggest that current PR education opportunities do not significantly improve MSK examination skill confidence. Results highlight the importance of resident PR education and illuminate curricular improvement opportunities, specifically with respect to the MSK exam. Planned next steps include curricular revision focusing on MSK exam training and development of novel learning tracks for future generalists and subspecialists.

Abstract Number: 2162

An Updated Needs Assessment for the Virtual Rheumatology Program for Fellows in Training (V-FIT)

Laura Arneson[1], M. Dave Dimachkie[2], Juliet Aizer[3], Janet Mitchell[4], David Leverenz[5], Anisha Dua[6], Lisa Zickuhr[7] and The American College of Rheumatology Committee on Training, [1]Northwestern University, Chicago, IL, [2]Washington University in Saint Louis, St. Louis, MO, [3]Hospital for Special Surgery, New York, NY, [4]ACR, Winston-Salem, NC, [5]Duke University, Durham, NC, [6]Northwestern University Feinberg School of Medicine, Chicago, IL, [7]Washington University/B-JH/SLCH Consortium, St. Louis, MO

SESSION INFORMATION

Session Date: **Tuesday, October 28, 2025**
Session Title: (2159–2194) Professional Education Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The American College of Rheumatology (ACR) created the Virtual Rheumatology Program for Fellows in Training (V-FIT) in 2020 to provide rheumatology fellowship training programs with virtual curricular resources during the COVID pandemic. V-FIT includes two lecture series: the Virtual Practicum for Adult Rheumatology Fellows (ViP) on foundational topics, and the Virtual Rheumatology Teaching Lessons (ViTLS) on advanced topics. Sessions were delivered via Zoom from 2020-2025, and made available in a video archive. The educational landscape has shifted post-pandemic, prompting this study to re-assess fellowship curricular needs and how V-FIT can evolve to meet them.

Methods: We conducted an online survey of program directors (PDs) and virtual focus groups of PDs and fellows in training (FITs). Invitations were shared with all PDs and FITs via ACR email listservs between August-November 2024. Participants provided electronic consent for surveys and verbal consent for focus groups. Survey results were analyzed with descriptive statistics. Focus group leaders took notes summarizing discussion content. Focus group recordings were transcribed with Trint software. The notes and transcriptions were reviewed to identify themes and representative quotes. The study protocol was approved by the Washington University in St. Louis IRB.

Results: Survey responses were received by 17 of 123 PDs, with a median of 4 fellows per program (range 2-9); 10 PDs completed all questions. Of the responding PDs, 7/17 (41%) indicated they did not have sufficient resources to create a

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1: Themes, application to future ViP and ViTLs programming, and representative quotes from fellow-in-training and program director focus groups. ViP = Virtual Practicum for Adult Rheumatology Fellows, ViTLs = Virtual Rheumatology Teaching Lessons, PD = program director, FIT = fellow in training.

Theme	Summary of Theme	Quotes
Content	A large amount of foundational content exists; future direction should expand advanced topics in rheumatology that feature rare diseases and expert opinion, landmark trials, and musculoskeletal radiology.	"We don't have a radiologist right now who has time to go over cases on a regular basis." (PD) "You can... partner topics when you make your curriculum. So the first year is going to watch the basic RA stuff. And then the challenging RA cases, that's what gets directed to the second year." (PD) "Having a time to like sit down with an expert on something and pick their brain is really interesting to me because there's only so much we see in fellowship in the two years that we're here and depending where you are geographically, you may see more conditions more than others and there's just certain things you don't see all that often." (FIT)
Session Duration	FITs and PDs preferred short lectures lasting 20-30 minutes, and FITs suggested podcasts.	"It's just hard to focus on a YouTube lecture for over 20 minutes." (PD) "I do like comprehensive lectures, but at the same time, the shorter the better." (FIT)
Active Learning Methods	All participants emphasized the value of engagement in the learning process through tools such as flipped classrooms, case discussions, access to expert clinicians' clinical reasoning, and board review questions.	"There just aren't enough board review questions. It's a big problem. It's one of the things that used to be [in] ACR CARE questions, and *that* was... not enough. And now that that's been...disbanded, we're just ... having to make it up ourselves, which is... a lot of work." (PD) "If you had...a 20-minute talk and then 20 minutes of ...practicum stuff, I think it'd be really cool." (PD) "Having that feedback from an attending and going through [cases] is good... being able to ask questions and see things in real time." (FIT)
Virtual Learning Environment	Virtual learning is advantageous only when it supports active learning while preserving psychological safety. Examples include anonymous participation (e.g., polling) and eliminating fellow requirements for pre-work or presentations.	"[For] new fellows, having this expectation you may have to participate in the discussion. I think people are going to be very shy about that, especially when they're just entering fellowship." (FIT) "For residency, we used to do like anonymous clicker [questions]... And then when everybody had submitted, it would show like the percentage of people who answered each option. And so then that kind of would spawn a discussion." (FIT)
Program Administration	Scheduling is an obstacle, though programs are most able to commit their fellows to virtual learning over the noon hour. FITs and PDs have trouble navigating the American College of Rheumatology website	"I think that noontime is probably the best time for most programs because most people have breaks for lunch, and people can lunch and learn." (PD) "The ACR website...it's not that easy to find stuff." (PD) "You have to like log on to the ACR website and it's just like a lot of clicking and getting into stuff and it's not the most convenient." (FIT)

comprehensive curriculum (Figure 1); limitations in faculty expertise and faculty time to lead sessions were the top obstacles identified. ViP sessions were required by 6/13 (46%) PDs, and 5/10 (50%) PDs incorporated 16 or more ViP sessions per year in their curriculum. Several approaches and barriers to ViP utilization were identified (Figure 1). Two FIT focus groups were conducted with 6 total participants, and three PD focus groups were conducted with 8 total participants. Themes and representative quotes are presented in Table 1. Participants expressed interest in lectures ≤30 minutes, with active learning methods that preserve psychological safety, such as anonymous polls and review questions. In both survey and focus group responses, board review content and opportunities to learn from content experts were highly valued, while scheduling conflicts and difficulty navigating the ACR website were obstacles to V-FIT use (Figure 2, Table 1).

Conclusion: PDs of large and small rheumatology fellowship programs expressed a need for curricular resources. Both PDs and FITs would value virtual programming that is ≤30 minutes, promotes active learning while maintaining psychological safety, provides access to content experts, and addresses board exam preparation.

Abstract Number: 2163

Enhancing Post-Conference Engagement Through Expert Q&A: A Pilot Collaboration Between ACR Convergence & theMednet.org

Nina Couette[1], Herveen Singh[2], Melissa Briones[3], Nadine Housri[4] and Rebecca Manno[5], [1]The Ohio State University, Columbus, OH, [2]theMednet.org, New York, NY, [3]Loyola University, Maywood, IL, [4]theMednet.org, New York, [5]University of The Virgin Islands / The Arthritis and Rheumatology Center of the Caribbean, St. Thomas

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2159–2194) Professional Education Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: ACR Convergence is a key platform for sharing cutting-edge research and clinical insights in rheumatology. To extend the educational value of select sessions beyond the meeting itself, a pilot collaboration between ACR and theMednet.org was developed. The initiative, titled "Continue the Conversation," aimed to foster enduring post-conference engagement. This was accomplished by posing timely clinical questions from ACR Convergence sessions to theMednet experts and distributing their answers, sometimes paired with interactive polls, via email to the broader rheumatology community.

Summary of engagement per question

	QUESTION	VIEWS	UNIQUE VIEWERS	INSTITUTIONS	UNIQUE VOTERS
1	How do you screen rheumatoid arthritis patients for lung disease (modality, frequency, patient selection)?	975	305	272	-
2	What is the most impactful career advice you have received from a colleague or mentor?	793	262	233	-
3	How long do you continue rituximab in patients with ANCA associated vasculitis who have achieved remission? **Poll Question:** *How long do you continue rituximab in patients with ANCA associated vasculitis who have achieved remission?*	679	252	222	98
4	What is the role of the rheumatologist in recommending and providing GLP-1 medications to their patients given the benefits across many disease domains including osteoarthritis? **Poll Question:** *How do you plan to utilize GLP-1 analogs in patients with knee OA and obesity in your rheumatology practice?*	660	247	216	104
5	How do you determine which patients with ANCA associated vasculitis may be good candidates for reduced dose glucocorticoid tapering?	619	223	200	-
6	What strategies or initiatives do you think could be most effective in addressing the rheumatology workforce shortage?	604	189	165	-
7	Do you pursue coronary artery calcium scoring in patients with metabolic risk factors and autoimmune disease in order to guide decisions regarding GLP-1 medications? **Poll Question:** *Do you pursue coronary artery calcium scoring in patients with metabolic risk factors and autoimmune disease in order to guide decisions regarding GLP-1 medications?*	250	104	96	57
8	Do you continue biologics in sJIA patients who develop lung disease on anti IL-1 or anti IL-6 therapies? **Poll Question:** *Do you continue biologics in sJIA patients who develop lung disease on anti IL-1 or anti IL-6 therapies?*	157	59	53	12
9	What is your approach to screening patients with sJIA for associated lung disease?	108	53	50	-
	TOTAL	4,845	675	560	201

Image 1: Summary of Engagement Per Question

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

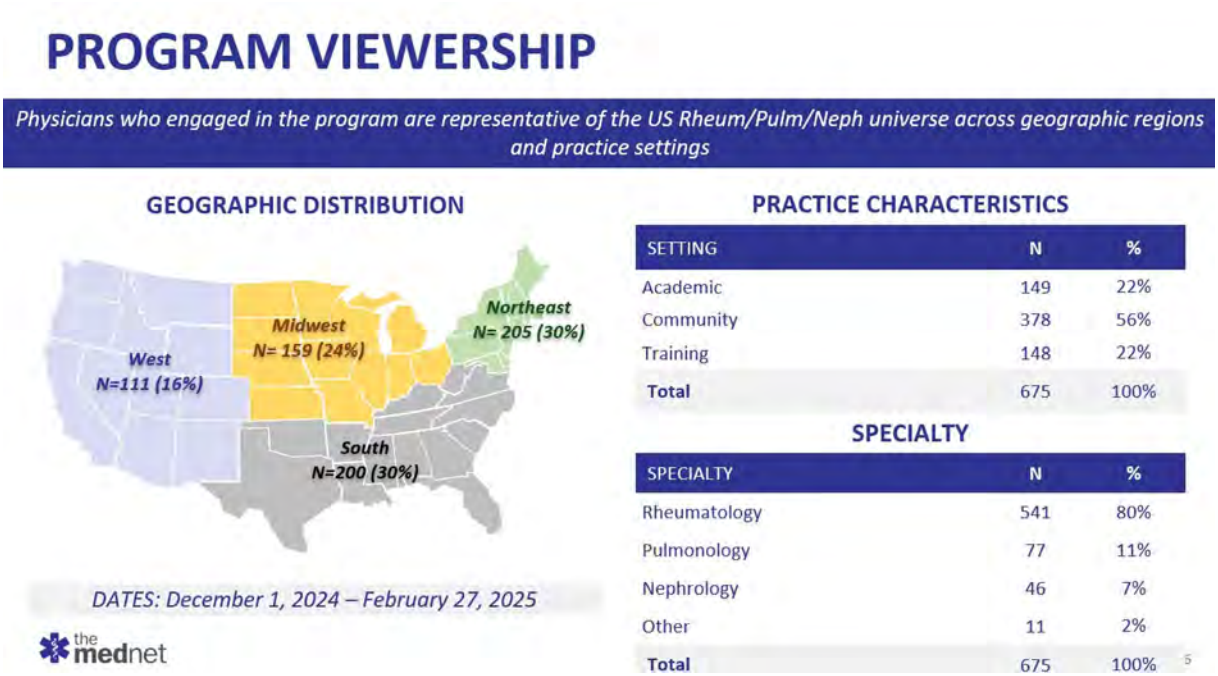

Image 2: Program Viewership

Methods: Clinically relevant questions were curated by theMednet editorial team based on pre-selected presentations from ACR Convergence 2024. These questions were sent to experts (including session presenters) for commentary. Polls were created for some questions to encourage participation, and a custom ACR-specific program tag was added to promote visibility and searchability. Each question included contextual information and direct reference to the corresponding ACR session. The Q&A was disseminated via email newsletters over a 6-8 week period, and a comprehensive summary was shared with physicians at the end of the program. Engagement metrics were tracked across multiple domains. CME credit claims were also reviewed.

Results: A total of nine questions and four polls were created based on the ACR Convergence presentations. During the program, 675 physicians engaged with Q&A content. The content reached a broad audience, with 4,845 total views across the nine questions with an average of 2.7 views per physician per question. Individual Q&A posts received an average of 538 views, and engagement with associated polls came from 201 unique voters with participation spanning 560 institutions (Image 1). Viewers spent an average of 12 minutes on the site viewing program content. Engagement was broad-based with poll participants and viewers representing diverse geographic regions and practice settings across rheumatology, pulmonology, and nephrology (Image 2). A total of 345 CME credits were claimed for 169 unique physicians. Of those claims, in regard to*impact* on clinical practice, 37% of respondents stated they gained a deeper understanding of a topic, 37% learned something new, 10% stated they understand how to apply what they know to clinical practice, 8% stated there was no impact, and 8% responded "other" (Image 3).

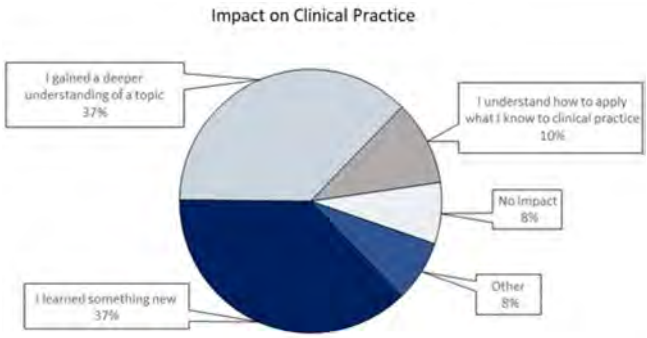

Image 3: Impact on Clinical Practice

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: The "Continue the Conversation" initiative effectively extended the impact of ACR Convergence 2024 by fostering sustained engagement with key clinical topics through expert-led Q&A on theMednet.org. High levels of participation, CME activity, and reported practice relevance demonstrate that digital platforms can play a critical role in translating conference content into lasting educational value. These findings support continued innovation in post-conference learning and highlight opportunities to further integrate digital engagement into future ACR educational strategies.

Abstract Number: 2164

East Meets West: A Novel Tofu-Pasta-Cardstock Phantom Model for Teaching Ultrasound-Guided Procedures

Philip Chu[1], Erin Chew[2], Lily Kao[3], Karina Torralba[4], Fawad Aslam[5] and Janeth Yinh[6], [1]Duke University Hospital, Raleigh, NC, [2]Vanderbilt University Medical Center, Nashville, TN, [3]Evergreen Medical Group, San Jose, CA, [4]Loma Linda University School of Medicine, Redlands, CA, [5]Mayo Clinic, Arizona, Scottsdale, AZ, [6]Massachusetts General Hospital, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2159–2194) Professional Education Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Certain ultrasound (US)-guided procedures may be integral to the diagnosis and management of arthritis. US-guided carpal tunnel (CT), flexor tendon sheath (FTS), and hip injections are more accurate than landmark-guided injections, but they can be more challenging to perform. Soft tissue phantom models simulating anatomic areas give trainees the opportunity to practice. However, cadaver-based models, commercial phantoms, and homemade models require special handling. Affordable, accessible, and soft tissue consistency type phantom models are needed. The tofu phantom model has been used to simulate scenarios of basic categories of US-guided procedures. In this study we use a Tofu-Pasta-Cardstock (TPC) phantom model to simulate challenging scenarios of avoiding neurovascular structures (CT), navigating a superficial narrow target (FTS), and navigating a deep angle (hip).

The purpose of this study is to assess improvements to learner confidence in performing CT, FTS and hip US-guided injections after receiving instruction using a practical TPC phantom anatomic simulation model.

Methods: Dried pasta, such as rigatoni, bucatini, and fettuccine (simulating transverse carpal ligament, arteries, and bony contour, respectively), and cardstock (simulating the hip joint) were used for anatomic representation (Figure 1). Locations of insertion within the tofu were approximated to simulate the location and scale of real-world anatomy. Tofu blocks were submerged under water to improve echogenicity of the tofu and to avoid the problem of phantom needle tracks encountered in existing models (Figure 2).

Prior to the hands-on training workshop, participants in a beginner/intermediate US course underwent a 20-minute lecture regarding US-guided procedure techniques pertinent to each region. With a learner-to-instructor ratio of 5:1, each participant rotated for 15 minutes through the 3 tofu models, guiding the needle to the target site with sonographic guidance. Immediate feedback related to handling of the syringe, proper ergonomics, US image optimization, and needle approach

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

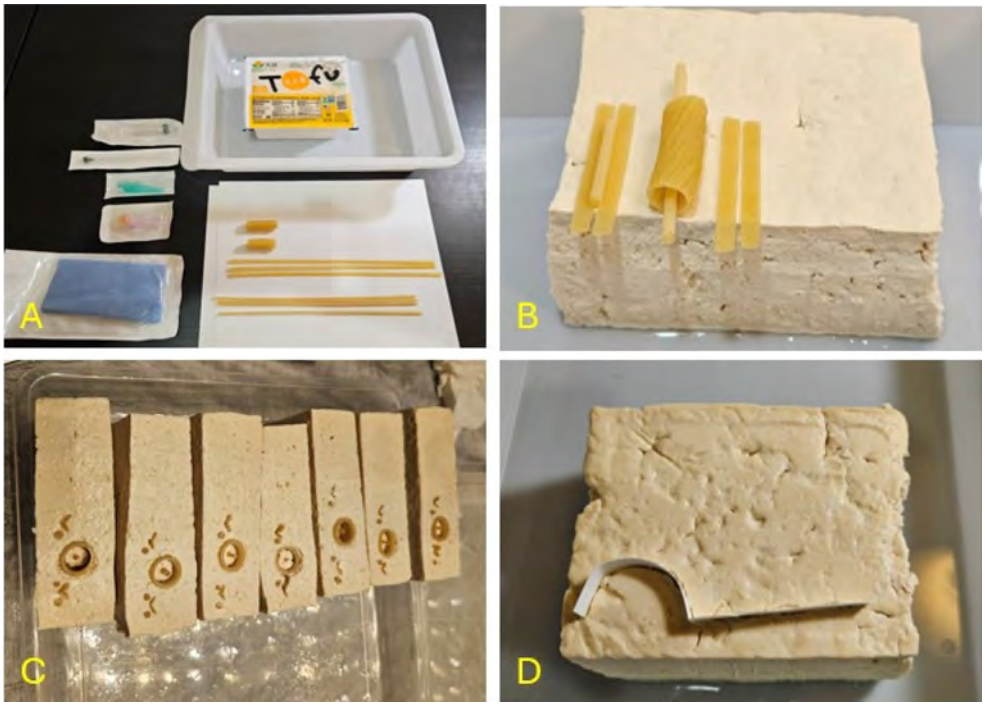

Figure 1. A) Materials needed for set up. B) Dried pasta approximated and arranged prior to insertion into the tofu. C) Multiple tofu pasta cardstock models can be produced relatively quickly. D) Cardstock inserted into tofu to simulate the hip joint.

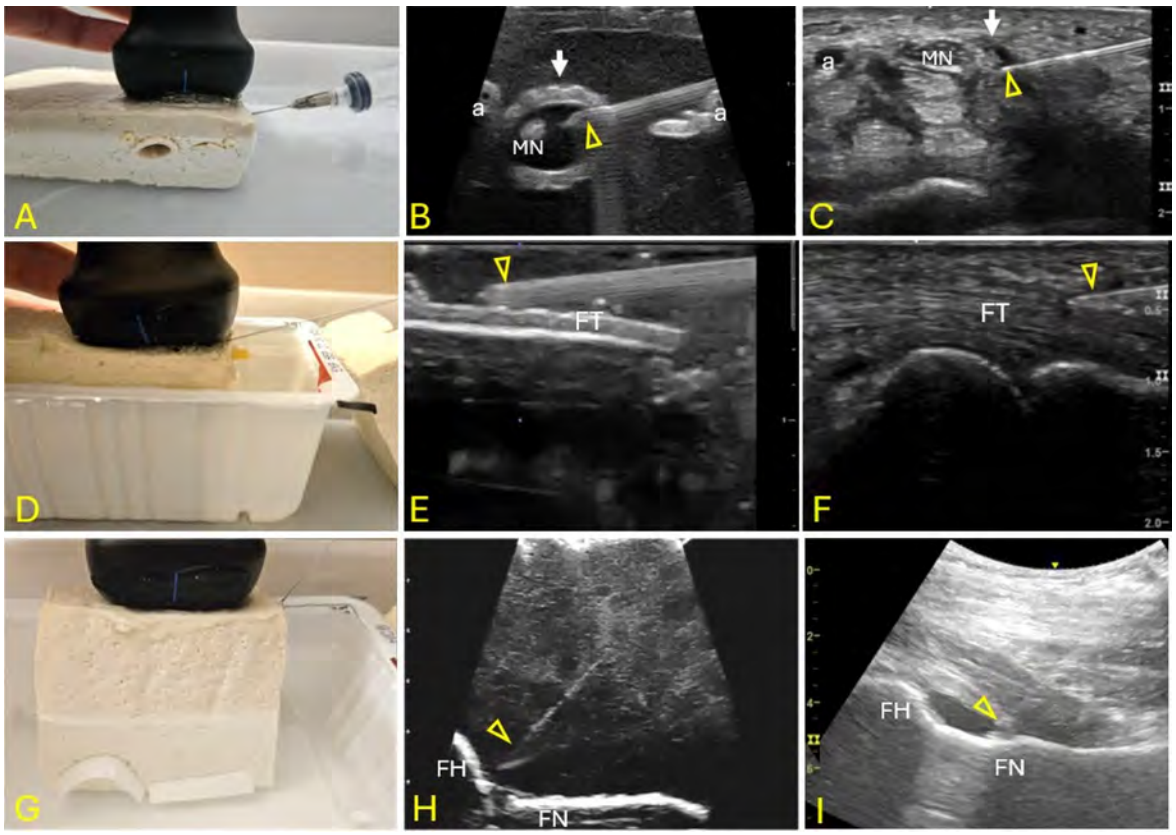

Figure 2. A) TPC model, B) corresponding US image, and C) patient example of carpal tunnel injection. D) TPC model, E) corresponding US image, and F) patient example of flexor tendon sheath injection. G) TPC model, H) corresponding US image, and I) patient example of hip injection. White solid arrow = transverse carpal ligament/rigatoni, yellow arrowhead = needle, a = artery/bucatini, FH = femoral head/cardstock, FN = femoral neck/cardstock, FT = flexor tendon/bucatini, MN = median nerve/spaghetti.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

to the targeted injection site were provided by the instructor. Post workshop, participants were invited to complete a survey accessed via Redcap QR code.

Results: Out of 35 participants, 68.6% responded. 70.8% had less than 1 year of US-guided injection experience. Pre and post workshop confidence of participants increased 75%, 87.5%, and 79% in their US-guided CT, FTS, and hip injection skills, respectively. 58.3% of participants felt that the models were easy to use and that they were likely to recreate this model for personal practice. The TPC models remained intact for the full 90 minutes with at least 5 learners and 1 instructor using each model with multiple needle passes.

Conclusion: The novel combination of tofu, dried pasta, and cardstock is effective in improving learner confidence in their US-guided CT, hip and FTS injection skills and demonstrates many advantages compared to existing phantom models. This accessible and affordable model can simulate challenging injections commonly encountered in rheumatology by demonstrating structures to avoid, depth adjustments and more precise placement of the needle tip.

Targeted Needs Assessment of Provider Medical Knowledge of Juvenile Scleroderma, a Mixed Methods Study

Rachel Guess[1], Megan Curran[2], Lisa Zickuhr[3], Rachel Moquin[1] and Childhood Arthritis and Rheumatology Research Alliance (CARRA) Scleroderma Workgroup, [1]Washington University School of Medicine, St. Louis, MO, [2]University of Colorado | Children's Hospital Colorado, Aurora, CO, [3]Washington University/B-JH/SLCH Consortium, St. Louis, MO

SESSION INFORMATION

Session Date: **Tuesday, October 28, 2025**
Session Title: (2159–2194) Professional Education Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Juvenile scleroderma (JS) is an autoimmune disease that can cause skin sclerosis leading to deformity, disability, and early mortality especially with delayed diagnosis. A general needs assessment performed by the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Scleroderma Workgroup identified gaps in provider medical knowledge as the main barrier to diagnosis and treatment of the child, from the caregiver perspective. The aim of this study is to characterize the knowledge gap, barriers to referral and preferred educational methods to inform the production of provider-facing educational materials. The researchers hypothesize that pediatric primary care providers harbor low awareness and disease misconceptions regarding JS.

Methods: A targeted needs assessment was built to survey providers in pediatrics, family medicine, and dermatology. After 8 rounds of expert review, pilot testing with 7 physicians, and approval by the Washington University Institutional Review Board, the consent and survey were distributed through email invitation to provider groups and on social media. Providers were recruited and consented via email to participate in 15-minute-long interviews to better understand providers' knowledge and preferences for education on JS. Interviews were recorded, transcribed, and inductively analyzed by 3 team members to reduce bias.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: 88 of 1092 invited providers (8%) from all 5 geographic regions of the United States (Figure 1) responded to the survey, with 58 physicians out of training, 25 physicians-in-training, and 5 advanced practice providers. The responses came from 63 providers in pediatrics, 10 in family medicine, and 14 in dermatology. 24% of respondents didn't know or thought that juvenile localized scleroderma (jLS) was not a serious disease (Figure 2). 38% didn't know or thought jLS would burn out without needing treatment. 49% either didn't know or thought some jLS patients do not need to see pediatric rheumatology. 5/12 participants that treat jLS incorrectly chose the most common subtype of jLS. 38% of providers felt that rheumatology wait list was a barrier to referral. 70% felt that additional education in scleroderma would be very or somewhat useful (Figure 3). 65% preferred an interactive online module for education and 70% preferred it be less than 15 minutes in duration. The qualitative analysis identified time and low prioritization on rare conditions as barriers to education on scleroderma, recommended education be focused on presenting features, and conference presentations as preferred delivery.

Conclusion: This study demonstrates knowledge gaps regarding JS among pediatric primary care providers. Opportunities for education include the presentation and seriousness of the disease in children, and differences from adult disease. Limitations of this study include limited responses and response bias. Next steps include making educational resources such as a brief interactive module to address the gap and reduce barriers to referral. This has the potential to increase early diagnosis, which would improve outcomes of children with JS.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2159–2194) Professional Education Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The Clinical Disease Activity Index (CDAI) is one of six assessment measures for rheumatoid arthritis (RA) recommended for management of RA in clinical practice. RA assessment measures were developed and validated for clinical research but since adoption of treat-to-target (TTT) principles as the standard of care for RA, there is a need for professional education to implement these measures in the clinic. As the CDAI does not require laboratory data, this RA composite outcome measure is preferred for the point-of-care management of RA. Standardization of joint examination technique has been shown to decrease interobserver variability in performing the CDAI. The purpose of this study was to create a medical educational workshop curriculum for learners and providers to improve knowledge and familiarity with the CDAI in RA management.

Methods: An educational workshop for the CDAI was developed and this curriculum proposal was presented at our institutional Rheumatology grand rounds for process improvement. Based on the feedback from this presentation, a 6-minute video demonstrating a 28 joint count exam was then developed (Image 1). 8 months later, Rheumatology providers and

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

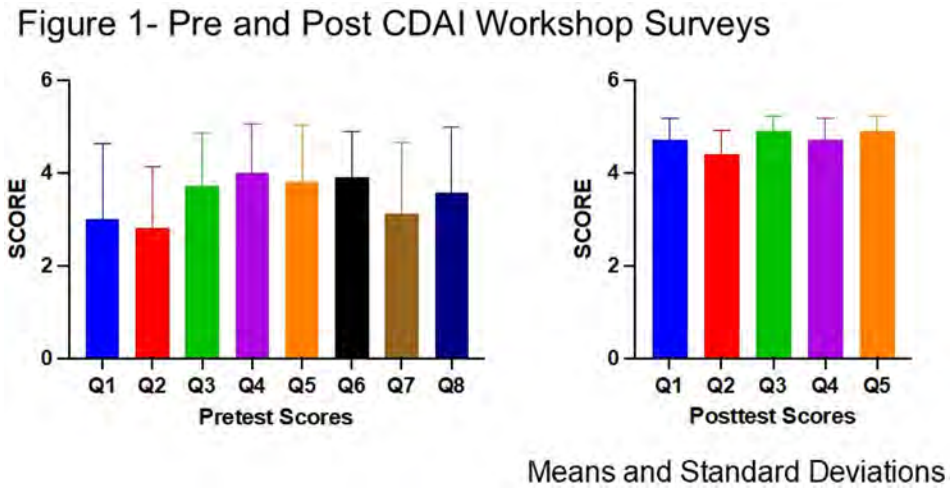

Figure 1

learners, including rheumatology fellows, were invited to a CDAI education workshop. The workshop included learning objectives, an 8-question pre-and 5 question post-workshop questionnaire, didactic presentation, a joint examination video followed by a series of three RA case discussions. Time was built in for group discussion on CDAI score on the RA cases. The workshop ended with a post-workshop questionnaire. Data were analyzed using descriptive statistics and t-tests to compare groups. A P value of < 0.05 was considered significant.

Results: The workshop was facilitated by a second-year rheumatology fellow and a rheumatology attending physician. There were 10 participants including rheumatology fellows, advanced practice providers, and attending physicians. All participants completed the pre and post-knowledge questionnaire (Table 1). The mean participant response for confidence in performing CDAI prior to the curriculum was a mean of 3 (SD 1.63), based on a 5-point Likert scale. After the curriculum, the likelihood of performing CDAI in clinic was a mean of 4.7 (SD 0.48). Prior to the workshop, confidence in performing

Table 1

Table 1: CDAI Workshop Knowledge Surveys

Pre-workshop Questionnaire			
Question		Mean	Standard Deviation
1	Overall, I can perform CDAI accurately	3	1.63
2	I can perform and assess tender and swollen joints of the shoulders	2.8	1.32
3	I can perform and assess tender and swollen joints of the elbows	3.7	1.16
4	I can perform and assess tender and swollen joints of the wrists	4	1.05
5	I can perform and assess tender and swollen joints of the small joints of hands	3.8	1.23
6	I can perform and assess tender and swollen joints of the knees	3.9	0.99
7	Overall, I can perform provider global activity	3.11	1.54
8	Overall, I can perform patient global activity	3.56	1.42
Post-workshop Questionnaire			
1	After the teaching intervention, I am more likely to perform CDAI score	4.7	0.48
2	After the teaching intervention, I am confident that I can perform a 28 joint count exam appropriately	4.4	0.52
3	After the teaching intervention, my understanding of provider global assessment of disease activity has improved	4.9	0.32
4	After the teaching intervention, my understanding of patient global assesment of disease activity has improved	4.7	0.48
5	Overall, this course has been resourceful for my knowledge	4.9	0.32

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Image 1

the provider global was 3.1 (SD 1.54) and improved to 4.9 (SD 0.32). Similarly, confidence in assessing patient global activity, increased from 3.6 (SD 1.42) to 4.9 (SD 0.31) after the workshop. Overall, the participants responded that the course was helpful in increasing awareness and confidence in performing the CDAI. Pre and post means improved significantly after the workshop (p=0.0001) suggesting generalized knowledge improvement from the training workshop.

Conclusion: A clinical educational workshop on CDAI for Rheumatology providers improved self-reported knowledge of the CDAI for rheumatology training. Further investigation is needed to know if the education workshop translates into higher and proper utilization of CDAI in clinical care.

Abstract Number: 2167

Rheum4Games: A Game-Based Rheumatology Board Review for Internal Medicine Residents

Sonam Kiwalkar[1], Megan Schermerhorn[2], Sarah Donohue[3] and Christine Sharkey[4], [1]The Vancouver Clinic, Portland, OR, [2]Providence Portland Medical Center, Portland, OR, [3]University of Wisconsin, Madison, WI, [4]UNIVERSITY of Wisconsin School of Medicine and Public Health, Madison, WI

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2159–2194) Professional Education Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatology is often viewed as a niche and intellectually demanding subspecialty in internal medicine (IM). Consequently, there is a trend toward lower In-Training Examination (ITE) scores in this area, which are predictive of American Board of Internal Medicine (ABIM) exam performance. Structured electives improve outcomes but are not mandatory, leading to variable rheumatology exposure. Traditional lectures dominate teaching, however, with a new generation of learners, gamification, described as the of applying game elements in education, has shown promise in enhancing engagement, motivation, and knowledge retention. To date, its application in rheumatology board preparation remains underexplored. We developed Rheum4Games (R4G), a Snakes-and-Ladders-style game to reinforce high-yield rheumatology concepts. We hypothesized that this format would enhance resident engagement, confidence, and ITE performance.

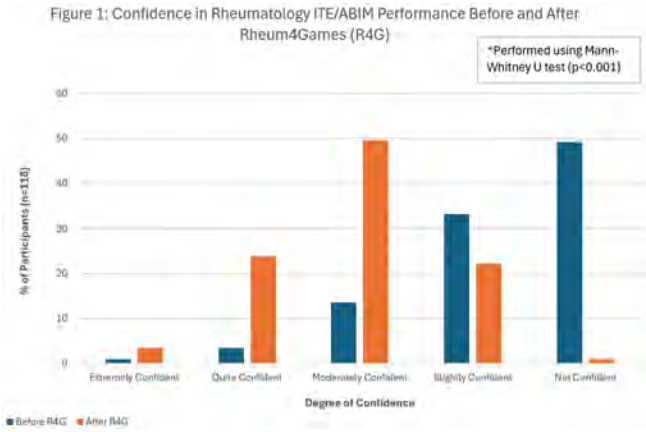
Methods: This pre-post intervention study examined the impact of a gamified rheumatology board review on resident satisfaction and ITE scores. Five IM residency programs (4 community, 1 university) incorporated R4G into their didactic

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

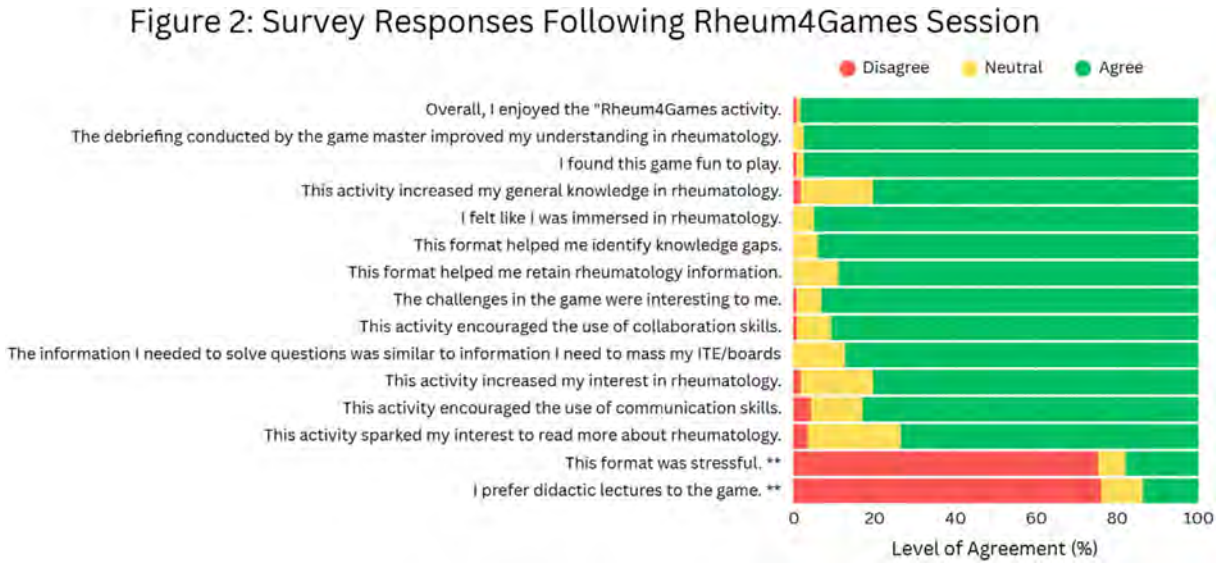
Table 1: Comparison of Median Rheumatology Score Improvements Between R4G Participants and Non-Participants

Group	n	Median Rheumatology Percent Change (2024-2023)	Q1-Q3	p-value*
Attended R4G	68	9	4-21	0.63
Did not attend R4G	38	9	5-18	

*Performed using Mann-Whitney U test.



curricula. A total of 12 sessions were conducted with 121 participants. A total of 45 questions with short explanations were developed using ABIM blueprint, reviewed by experts (5 rheumatologists, 2 internists), and piloted prior to implementation. Sessions included a pre-survey, R4G session, and post-survey. ITE scores and confidence levels were compared pre- and post-intervention utilizing Mann-Whitney U tests, while descriptive statistics were used for survey results.



23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: A total of 121 residents participated, with high pre- and post-session survey completion rates (97.5% and 96.7%, respectively). Among the 106 residents with matched ITE data (defined as those with available scores for both the 2023 and 2024 ITE exams), there was no significant difference in the median score change between R4G participants and non-participants (Table 1). However, a subgroup analysis revealed that R4G participants from community-based programs demonstrated significantly greater score improvement compared to those from university settings. In addition, self-reported confidence in the rheumatology section of the ITE/ABIM improved significantly post-session ($p < 0.0001$; Figure 1). Residents rated the session highly for enjoyment, engagement, and educational value (Figure 2), and open-ended responses highlighted the activity's interactivity, effectiveness, and novelty.

Conclusion: R4G effectively enhanced resident engagement, confidence, and satisfaction, as evidenced by high survey ratings and significant self-reported gains in preparedness for the ITE/ABIM rheumatology content. While overall ITE score improvements were not statistically significant, the greater gains observed in community programs suggest that R4G may be beneficial in settings with less structured rheumatology exposure. Further studies should explore the long-term retention effects of game-based learning as well as potential strategies to optimize its effectiveness in diverse training environments.

Training Objective Structured Clinical Examinations in a Clinical Immunology department: Expectations and Perceptions of Medical students at Graduating Level

Aïcha Kante[1], Damien Sène[2], Venceslas Bourdin[3], Dikélélé Elessa[3], William Bigot[3], Valentine Pagis[3], Frédéric Truffinet[3], Stéphane Mouly[3] and Cloé Comarmond[1], [1]Department of Internal Medicine, Lariboisière University Hospital, Université Paris Cité, Assistance Publique Hôpitaux de Paris, INSERM U942, Paris, France, [2]Department of Internal Medicine, Lariboisière University Hospital, Université Paris Cité, Assistance Publique Hôpitaux de Paris, Paris, Ile-de-France, France, [3]Department of Internal Medicine, Lariboisière University Hospital, Université Paris Cité, Assistance Publique Hôpitaux de Paris, Paris, France

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2159–2194) Professional Education Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Objective Structured Clinical Examinations (OSCEs) are based on various starting clinical scenarios conducted in a simulated environment that allow for the standardized assessment of medical students' competencies, recently introduced in France. Our aim was to evaluate expectations and perceptions of medical students at graduating level regarding this new method of clinical education.

Methods: Medical students participated in a weekly training OSCE station during their Clinical Immunology rotation. A questionnaire assessing expectations and perceptions regarding this new teaching method during clinical placements was distributed to medical students who completed a rotation in the Department of Clinical Immunology between January 2024 and January 2025. The questionnaire consisted of 10 questions estimated on a Likert scale or open-ended written response. Responses were analyzed using the Chi-squared test for qualitative variables and the Wilcoxon test for ordinal variables.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Over their 10-week clinical immunology rotation, 10 training OSCE stations were offered to medical students, covering various initial clinical scenarios relevant to clinical immunology: single and multiple lymphadenopathy, erythema nodosum, dyspnea, hyperthermia, headaches, weight loss, joint pain, visual disturbances, discoloration of the extremities, purpura, corticosteroid prescription, writing a prescription, elevated CRP, leukocyte abnormalities, and calcium metabolism disorders. In total, 63 consecutive medical students completed the questionnaire. The clinical scenarios addressed in the OSCE stations were rated as highly relevant to their curriculum, receiving a Likert score ≥ 4/5 from 59 students (93%), including 45 (71%) who gave a score of 5/5 and 14 (22%) a score of 4/5. The scenarios were considered better suited for reinforcing theoretical rather than practical training, with 45 students (71%) rating them 5/5 for theoretical consolidation, *versus* 35 (56%) for practical consolidation. Medical students at graduating level expressed a greater demand for more training OSCEs, with a median of one session per week ($p = 0.002$). The training OSCEs in clinical immunology were rated as highly useful for future clinical practice by 44 students (70%) with a score of 5/5 and by 13 students (21%) with a score of 4/5 on the Likert scale, with no significant difference between academic years ($p=0.7$). Among open-ended responses, 13 sixth-year students (54%) mentioned stress as the main difficulty encountered with this type of teaching, compared to 9 fifth-year students (23%) ($p = 0.012$). Difficulties related to time constraints ($p > 0.9$), organization ($p > 0.9$), and knowledge application ($p > 0.7$) were similar between the different academic years.

Conclusion: Over 90% of medical students acknowledged the high usefulness of training OSCEs during clinical immunology rotations for their future clinical practice. Training OSCEs were associated with increased performance anxiety especially when students are at graduating level.

Bridging the Gap: A National Needs Assessment of Rheumatology Fellowship Training in Adolescent and Young Adult Care

Amanda Moyer[1], Megha Tandel[1], Michelle Benjamin[1], Rufei Lu[2], Julia F Simard[3] and Rebecca Sadun[4], [1]Stanford University, Palo Alto, CA, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]Stanford Medicine, Stanford, CA, [4]Duke University, Durham, NC

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2159–2194) Professional Education Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Adolescents and young adults (AYAs) with rheumatic diseases require specialized care, particularly when transitioning from pediatric to adult healthcare. However, most residents and fellows receive little to no formal education in AYA care. One study found that over half of internal medicine trainees reported no instruction in AYA transition care, resulting in low confidence and potentially suboptimal patient outcomes. Targeted, high-quality transition education has been shown to improve trainee performance, but data on rheumatology fellowship training remain limited.

Methods: A national survey of pediatric, adult, and med-peds (MP) rheumatology fellows and program directors (PDs) was conducted from 2/2024–7/2024 to assess AYA training, priorities, exposure, beliefs, confidence, and practices. Survey items used Likert scales. Quality of AYA education and clinical tools was assessed using weighted scoring systems (high-quality education: exposure to ≥4 education techniques; high-quality transition tools: use of ≥3 transition tools). Fellows were

considered prepared if ≥66% of skill items were endorsed as "prepared" or "completely prepared." Frequent AYA best practice use was defined as performing ≥4/7 care tasks ≥60% of the time. Data was analyzed descriptively and with non-parametric approaches.

Results: Surveys were distributed to 167 programs (130 adult, 37 pediatric/MP). Of those, 75 PDs and 173 fellows responded (47% and 29% response rates, respectively). Among respondents, 22% of adult fellows and 20% of adult PDs lacked an affiliated pediatric rheumatologist. Adult PDs estimated only 13% of their patients were aged 16–26 years, compared to 50% for pediatric/MP PDs; fellows reported similar trends (Table 1).

Table 2.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

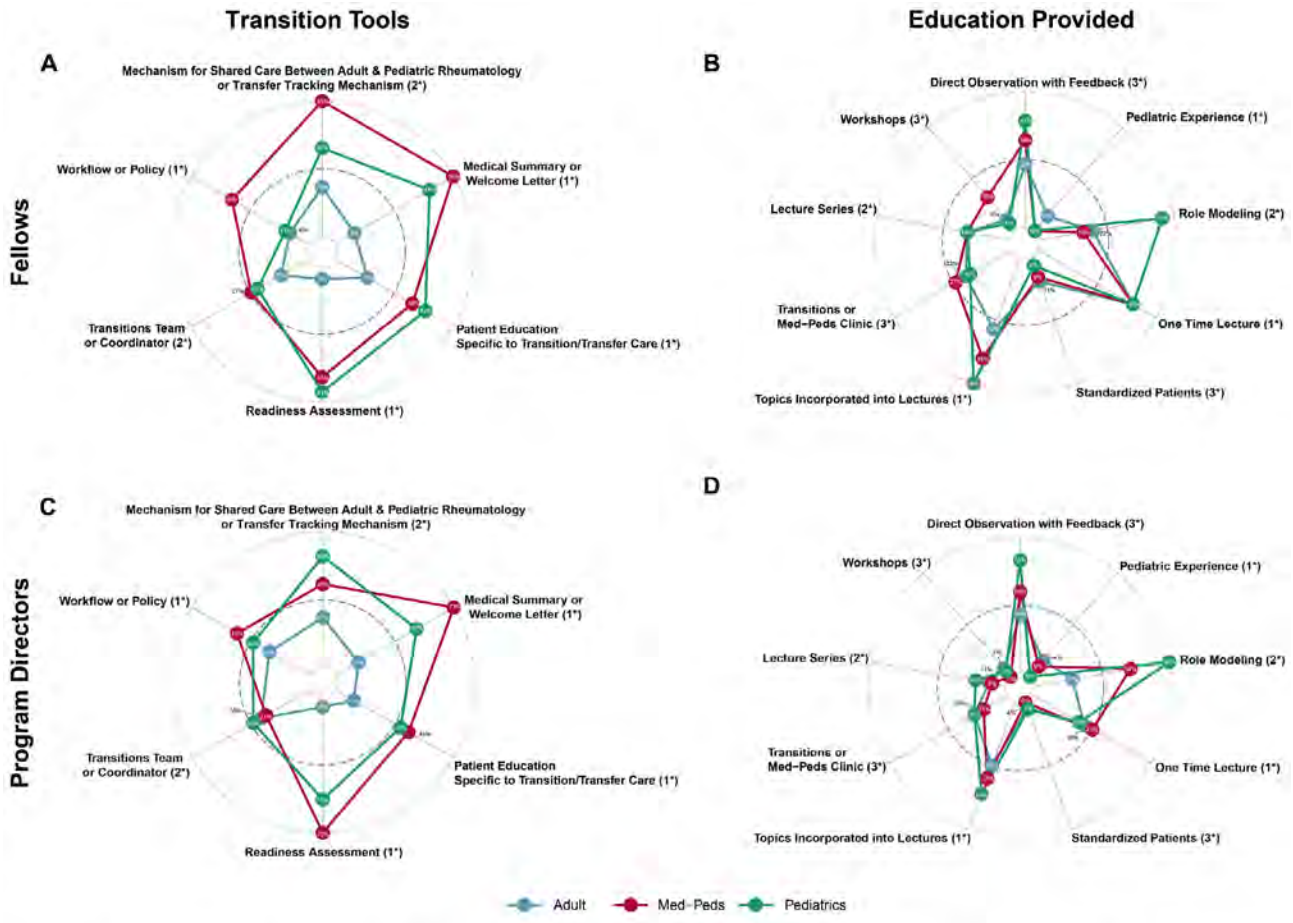

Figure 1: Reported Available AYA-Specific Clinical Tools and Education Provided. * Weight assigned to each clinical tool available and education modality provided as reported by rheumatology fellowship program directors (PDs) and fellows. High-quality education: weighted score ≥4. High-quality transitions tools: weighted score ≥3. *Not shown: Some PDs and fellows reported no access, or were unsure the availability, to listed clinical tools (40% and 9%, respectively) or educational modalities (3% and 6%, respectively).*

Figure 1.

All respondents rated AYA topics (transition, reproductive health, bone health, cardiovascular disease risk, vaccination) as important for training. Only 38% of adult fellows felt prepared to optimally care for AYA patients vs. 64% of pediatric/MP fellows. Preparedness was highest among MPs (Table 2). Fellows caring for more AYA patients reported greater preparedness.

Pediatric/MP fellows reported more diverse and higher quality AYA education than adult fellows (61% vs. 39%). Exposure to high-quality education was associated with more frequent AYA best practice use in pediatric/MP fellows, compared to those who received lower quality education (68% vs. 32%), but less so with self-reported preparedness.

Pediatric/MP fellows reported more access to high-quality transition tools (Figure 1) than adult fellows (50% vs. 17%). Additionally, pediatric/MP fellows with access to these tools used clinical best practices more frequently than those without (55% vs. 45%).

Conclusion: Despite broad recognition of the importance of AYA care, rheumatology fellowship training in these skills remains insufficient, especially in adult programs. Direct exposure to AYA patients, access to high-quality education and clinical tools, and MP training were all associated with increased preparedness and best practice adherence. A standardized, structured framework for AYA-focused training is needed to prepare rheumatology trainees to best care for this vulnerable patient population.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2159–2194) Professional Education Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Visual diagnosis, based on both physical exam and imaging studies, is of great importance in clinical practice and for board exam purposes in rheumatology. The rarity of many rheumatologic diseases limits fellow exposure to the full range of physical and radiologic disease manifestations during training. There is a continued need to develop high-quality learning materials within rheumatology training programs. We report on a quality improvement education project which aims to develop and continually improve a question-based visual diagnosis curriculum.

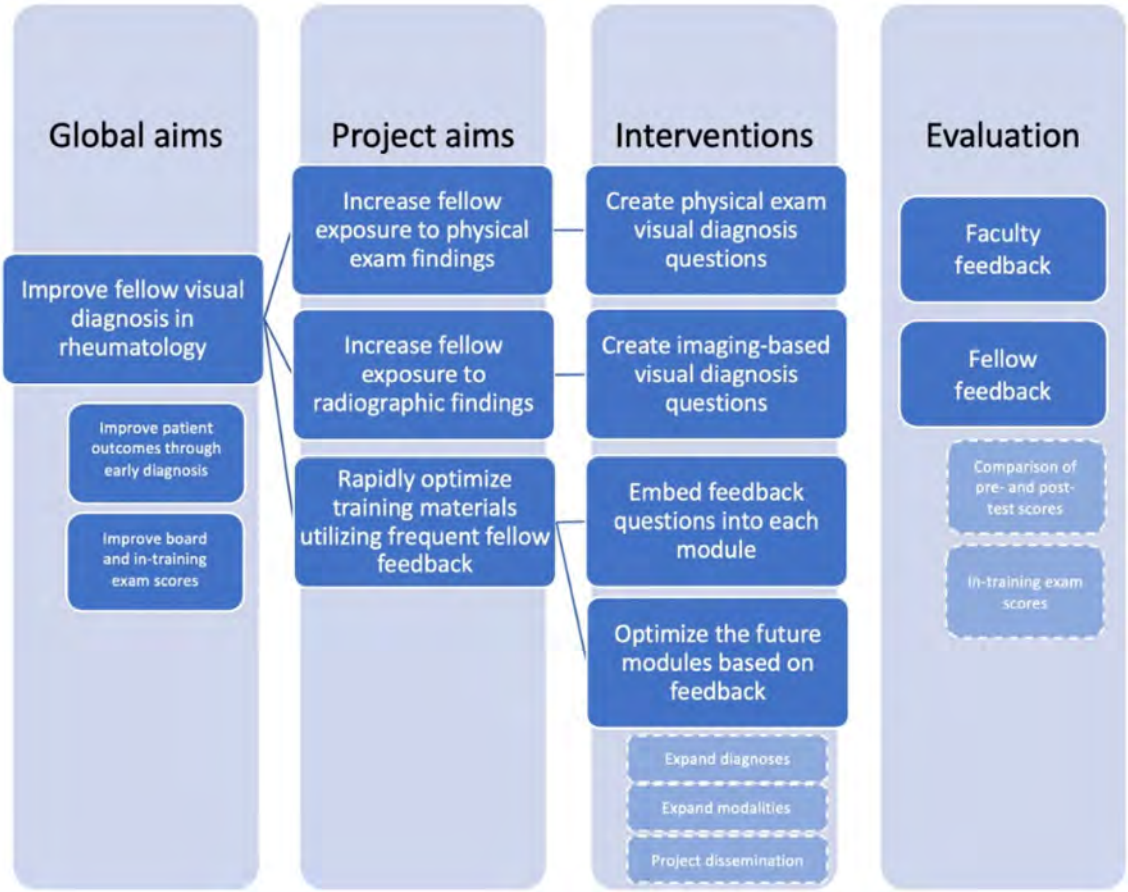

Figure 1: Project aims, interventions and evaluation. Future directions noted in lighter, dashed boxes.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

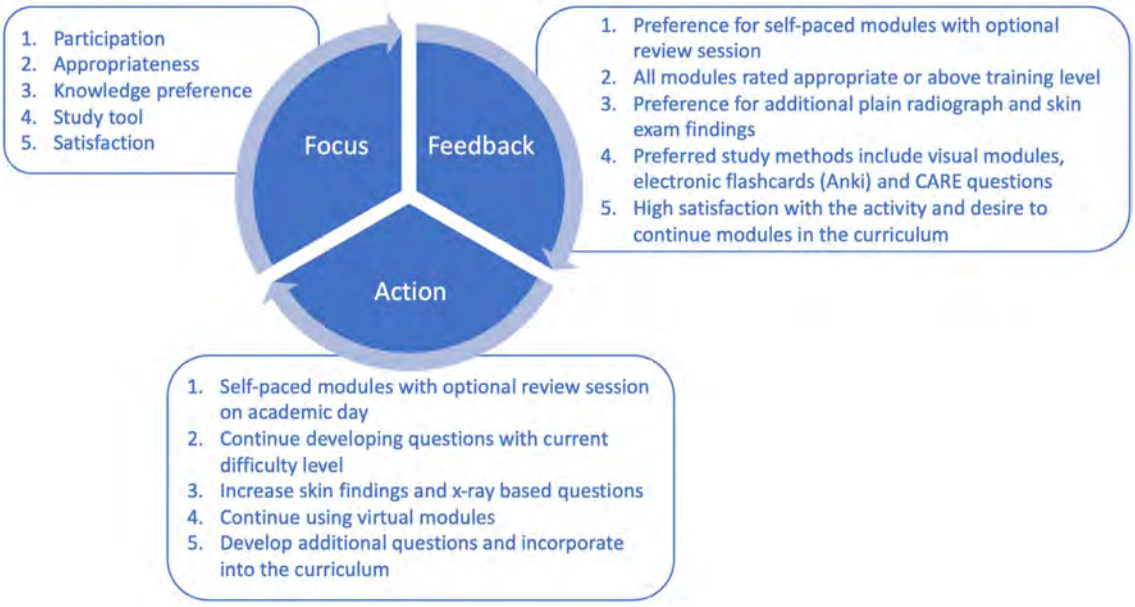

Figure 2: Process of module modification using a focus, feedback and action cycle.

Methods: Visual diagnosis questions were created using the American College of Rheumatology Image Library as well as clinical cases at a single academic center. Topics were chosen based on relevance with a focus on rheumatoid arthritis, dermatomyositis, systemic lupus erythematosus, crystalline arthropathy and spondylarthritis. Questions were created by two fellows and reviewed by faculty for content accuracy. Visual diagnostic modalities included physical exam findings, plain radiographs, and advanced imaging such as MRI and CT. Five separate modules consisting of seven questions each were delivered to six fellows between March 21, 2025 and May 5, 2025 via Qualtrics. Survey questions were embedded into each module and feedback incorporated into the next PDSA cycle.

Results: Five to six fellows completed each module. Project aims, interventions, and evaluation are outlined in Figure 1. Continuous improvement of the modules based on focused areas of feedback took place throughout the project period as noted in Figure 2. Fellows demonstrated a measurable increase in confidence from pre-module to post-module assessments (Figure 3). Prior to module dissemination, fellows rated level of satisfaction with visual diagnosis curriculum as "somewhat

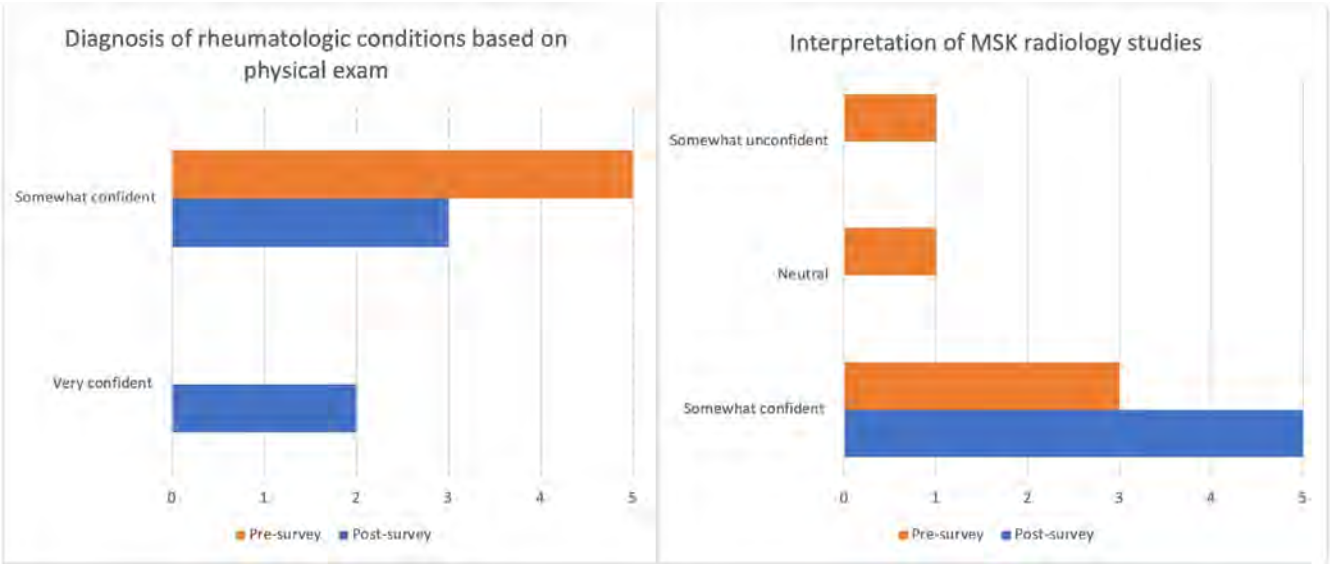

Figure 3: Self-reported confidence levels before and after the module, measured through surveys using a 5-point Likert scale.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

satisfied" (n=3) or "neutral" (n=2). Conversely, all respondents (n=5) were "very satisfied" with the module questions for their training and preferred to continue this as a part of the fellowship curriculum.

Conclusion: There were high levels of engagement in this visual diagnosis curriculum utilizing fellow-generated, faculty-reviewed questions. Integration of feedback with curricular material for rapid changes into the curriculum may serve as a model for future educational quality improvement. Next steps include expanding topics to include additional imaging modalities such as ultrasound and diagnoses such as vasculitis, increasing the number of questions for expansion as a broader curriculum within the fellowship and eventually creating modules that can be disseminated to other institutions.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2159–2194) Professional Education Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatic diseases frequently affect individuals of reproductive age, and up to 40–70% may experience fertility issues related to disease activity, medications, delayed childbearing, and sexual dysfunction. Fertility knowledge among physicians is often limited, emphasizing the need for education in reproductive health when managing autoimmune conditions. This study aimed to assess fertility and infertility treatment knowledge among physicians treating women with rheumatic diseases in Mexico using the validated Fertility and Infertility Treatment Knowledge Score (FIT-KS).

Methods: A cross-sectional survey was conducted among residents and specialists in Internal Medicine, Rheumatology, Dermatology, Nephrology, Gynecology, Obstetrics, Maternal-Fetal Medicine, and Reproductive Biology. After accepting the informed consent, the physicians completed an online survey including sociodemographic items and the 29-item FIT-KS, which evaluates knowledge of natural fertility (21 items) and infertility treatments (8 items). Scores ranged from 0 to 29, with higher scores reflecting greater knowledge. Descriptive statistics, t-tests, and ANOVA were used for analysis. A p-value < 0.05 was considered significant.

Results: Ninety physicians participated (mean age 39.8 ± 13.3 years; 64.4% female). The most common specialties were rheumatology (47.8%), internal medicine (24.4%), and obstetrics/gynecology (18.9%). Most correctly identified the fertile

Table 1. Sociodemographic characteristics and mean FIT-KS score and average

	N = 90	Mean FIT-KS score and average (maxscore 29 and 100%)	p-value
Age, n (%)			
<35	44 (48.9)	19.11 ± 2.79 (65.90%)	**p = 0.008**
>35	46 (51.1)	17.48 ± 2.89 (60%)	
Sex, n (%)			
Female	58 (64.4)	18.88 ± 2.70 (65.10%)	**p = 0.012**
Male	32 (35.6)	17.19 ± 3.09 (59.26%)	
Marital Status, n (%)			
Single	48 (53.3)	18.85 ± 2.79 (65.01%)	p = 0.150
Married	30 (33.3)	17.93 ± 3.33 (61.83%)	
Divorced	5 (5.6)	16.40 ± 2.07 (56.55%)	
Common-Law	7 (7.8)	17.14 ± 1.86 (59.11%)	
Level of training, n (%)			
Specialty resident	31 (34.4)	18.94 ± 2.67 (65.29%)	p = 0.318
Subspecialty resident	6 (6.7)	19 ± 2.44 (65.51%)	
Specialist	11 (12.2)	17.36 ± 2.87 (59.87%)	
Subspecialist	42 (46.7)	17.93 ± 3.18 (61.82%)	
Specialty area, n (%)			
Internal medicine	26 (28.9)	17.69 ± 2.81 (61%)	p = 0.053
Rheumatology	43 (47.8)	17.98 ± 3.13 (61.98%)	
Obstetrics and gynecology	21 (23.3)	19.62 ± 2.37 (67.65%)	

age range (91.1%), optimal timing for intercourse (94.4%), egg release per cycle (87.7%), and infertility risks related to smoking (95.6%), obesity (98.9%), and STIs (96.7%). However, fewer were aware of the sharp fertility decline at 35–39 years (52.2%) or monthly conception chances at age 30 or 40 (35.6%). Misunderstandings included miscarriage rates (28.9% correct) and effects of moderate alcohol (33.3%) and caffeine intake (77.8%). While knowledge of in vitro fertilization (IVF) (92.2%) and intrauterine insemination (IUI) (93.3%) was generally accurate, fewer participants knew IVF success rates by age, cost (21.1%), or live birth rates from frozen eggs (15.6%). The study revealed a trend toward higher knowledge in OBGYNs compared to rheumatologists (p = .064) and internists (p = .917), though differences were not statistically significant.

Conclusion: Physicians treating women with rheumatic diseases demonstrated notable gaps in fertility knowledge critical to patient counseling, especially among non-OBGYN specialties. These findings support the need for targeted reproductive health education in rheumatology and internal medicine training programs to enhance fertility-related care in this vulnerable population.

23265205, 2025, 59, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 2. Fertility and Infertility Treatment Knowledge Score (FIT-KS) correct answers.

Question	Answer	Correct
1. At what age are women most fertile?	20-29	82 (91.1)
2. Over which age range does a woman's ability to get pregnant decline most precipitously?	35-39	47 (52.2)
3.- Over the course of 1 month, what is the percent chance that a 30-year-old woman who is trying to get pregnant will get pregnant?	20%	32 (35.6)
4.- Over the course of 1 month, what is the percent chance that a 40-year-old woman who is trying to get pregnant will get pregnant?	≤5%	32 (35.6)
5.- On average, for a woman in her peak reproductive years, what is the percent chance that a pregnancy (recognized or unrecognized) will end in a miscarriage?	16-25%	26 (28.9)
6. A woman and a man can both contribute to a couple's infertility	True	88 (97.8)
7. A man's age is a factor that affects a couple's fertility.	True	62 (68.9)
8.- Having less than 9 periods in a year can be normal for some women and doesn't require any further evaluation:	False	62 (68.9)
9.- What is the average survival time of normal sperm in the female reproductive tract?	3-5 days	39 (43.3)
10.- When is the optimal time to have sexual intercourse in order to get pregnant?	About halfway through the cycle	85 (94.4)
11. Where does fertilization most commonly occur?	In the Fallopian tubes	78 (86.7)
12.- How many eggs are typically released per cycle?	1	79 (87.7)
The following are likely to decrease a woman's chance of fertility:		
13. Smoking	True	86 (95.6)
14.- Occasional caffeine intake	False	70 (77.8)
15.- Moderate alcohol consumption	False	30 (33.3)
16.- Safe pregnancy termination	False	49 (54.4)
17. Obesity	True	89 (98.9)
18. Gonorrhea/Chlamydia infection	True	87 (96.7)
19. Prior use of contraceptive pills	False	42 (46.7)
20.- Being underweight due to frequent exercise or limited caloric intake	True	78 (86.7)
21. Using certain types of sexual lubricants	True	39 (43.3)

23265205, 2025, 59, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The remainder of questions relate to infertility treatment:		
22.- In vitro fertilization (IVF) refers to a treatment in which:	A man's sperm and a woman's egg are combined inside a laboratory and the resulting embryo is transferred into the uterus	83 (92.2)
The following 3 questions refer to the most recent national statistics published by the Centers for Disease Control & Prevention and the Society for Assisted Reproductive Technology:		
23.- For a woman under 35 years old, undergoing IVF with her own eggs, what is the pregnancy rate per cycle?	41-60%	23 (25.6)
24.- For a woman over 44 years old, undergoing IVF with her own eggs, what is the pregnancy rate per cycle?	≤5%	35 (38.9)
25.- In women who are undergoing IVF, what is the percent of pregnancies that result in twins?	21-35%	39 (43.3)
26. What is the average cost of an IVF cycle in the USA?	$12,000	19 (21.1)
27.- Intrauterine insemination (IUI) refers to a treatment in which:	A thin catheter is used to deposit a man's sperm past the cervix directly into the uterus	84 (93.3)
28.- Egg cryopreservation (freezing) refers to an infertility treatment in which:	Eggs are frozen following ovarian stimulation and egg retrieval	66 (73.3)
29. When using frozen eggs from women less than 37 years old, what is the live birth rate per thawed egg?	≤10%	4 (15.6)

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2159–2194) Professional Education Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The rheumatology medical fellowship application review process requires significant time from program directors and faculty who manually analyze dozens of multi-part applications each year. A typical year may yield ∼200 applicants and require 50+ hours for fellowship program director(s) to pre-screen them and decide which should be offered interviews. Each application typically includes a 40-page PDF document and a structured Excel export from (ERAS) with > 2,500 columns of data per applicant. The possibility that artificial intelligence (AI) and large language models (LLMs) might concisely summarize fellow applications, protect applicant privacy, and highlight criteria to make subsequent interview decisions remains unexplored.

Methods: We developed an AI pipeline to help automate the fellowship screening process. It uses GPT-4o combined with GPU-accelerated optical character recognition (OCRs) to reduce manual review time. For each applicant, the two de-identified text files were concatenated and fed into an AI agent that uses GPT-4o to generate 1-2 page summaries aligned to specific feature domains (e.g., Clinical Potential, Awards, USMLE scores, Research Output) developed as part of the project and curated by subject matter experts (e.g. program directors and clinical faculty) in Table 1.

The output of the pipeline was a concise narrative summary that reduced each ∼40 page application to 1-2 pages. A GPT 4o-mini HIPAA-complaint Azure instance was then used to analyze a 169-document corpus of previously reviewed fellowship applications. Reduction in the amount of time for the narrative pre-review was the primary endpoint for evaluation. As a secondary metric, each applicant was scored on a scale of 1-100, where a score of at last 70 would receive an interview to align with institutional reviewing capacity. The scores were then compared to the manually annotated corpus, relating the scores to applicants who received interviews and those who did not receive interviews, versus what the model predicted.

Results: Across the 2017-2024 application cycles, and after implementation of the AI pipeline, the amount of manual effort to pre-screen fellow applicants for a single annual cycle (n = 180 fellow applicants) was decreased from approximately 50 hours to approximately 2 hours total The analysis finished in 2 minutes and 26 seconds using the Azure OpenAI API and is scalable to larger datasets. Overall accuracy compared to who was offered interviews was 0.69 with recall of 0.59 (Figure 1), with the confusion matrix shown in Figure 2.

Conclusion: Results indicate that this novel pipeline can assist with rheumatology fellowship screening and save dramatic amounts of human reviewer time. Ongoing refinement is underway to improve model performance compared to the both the interview outcome and subsequent program director and faculty reviews, and to make this tool more widely available.

Table 1: Themes Developed by Subject Matter Experts for AI-based Curation of Rheumatology Program Fellow Application Content

- Demographics & Geography
- International considerations
- Standardized Scores (e.g. USMLE, COMLEX)
- Achievements/Awards
- Professional Experience
- Research Interest
- Publications
- Training performance (from LLM)
  - Medical school performance
  - Residency performance
  - Letters of recommendation
- Overall summary (from LLM)

AI = artificial intelligence; LLM = large language model
USMLE = U.S. Medical Licensing Exam; COMLEX = Comprehensive Osteopathic Medical Licensing Examination of the United States

Background/Purpose: Musculoskeletal ultrasound (MSKUS) conveys diagnostic and therapeutic value in rheumatology, sports medicine, and other specialties. However, formal MSKUS training is rarely integrated into undergraduate medical education (UME) curricula in the United States, with scant literature in this setting. Our institution incorporates MSKUS into its pre-clinical curriculum to facilitate integration of gross anatomy and MSK physical exam skills. To address the gap between our pre-clinical MSKUS learning experience and the clinical curriculum, we developed two structured electives offering exposure to clinical applications of MSKUS.

These electives vertically and horizontally integrate clinical skills and reasoning with the basic sciences, including gross anatomy and MSK radiology. This improves UME learners' understanding of anatomy, develops their US diagnostic and procedural skills, and provides more in-depth exposure to rheumatology and other specialties.

Methods: The shoulder, wrist, knee, and ankle were selected as body sites based on course developer consensus as the highest yield across a variety of specialties. Content was divided into two 2-week electives with upper extremity covered in the fall semester and lower extremity in the spring semester. Each week focuses on one joint. Content is delivered by self-study materials, hands-on practice scanning, guided MSK radiology imaging interpretation, and observation of clinical applications. UME learners study pre-recorded didactic materials covering standard US views of the joint, common pathologic findings, and a demonstration scan. One rheumatologist and one MSK radiologist serve as content experts demonstrating and supervising hands-on practice scanning on peers and volunteers. UME learners then practice MSK image interpretation (radiograph, MSKUS, CT, MRI) with the MSK radiologist and rotate through sports medicine clinics to practice integrating physical exam, MKSUS findings and clinical decision-making. Lastly, cadaver-based arthrocentesis training teaches additional procedural skills. Competency is assessed via a checklist evaluating image acquisition and identification of key anatomical structures.

Results: 100% of UME learners who enrolled in our MSKUS elective successfully completed the MSKUS skills checklist for each body site.

Conclusion: Based on our results of all UME learners demonstrating proficiency in fundamental MSKUS image acquisition skills, our elective presents a replicable framework for further integration of MSKUS education within medical curricula and reinforces both vertical and horizontal integration, allowing a bridge between the basic sciences and clinical practice. In addition to enhancing learners' anatomical and US knowledge, this elective also gives UME learners earlier exposure to procedural aspects in the field of rheumatology in hopes of increasing interest in rheumatology careers, while equipping them with invaluable clinical and diagnostic skills.

Background/Purpose: Holistic review is an approach to candidate selection that emphasizes alignment of candidate attributes to a program's mission. Identifying character strengths in personal statements and letters of recommendation within fellowship applications is a vital but time-consuming and subjective task. The increasing volume and competitiveness of rheumatology fellowship applications raises the stakes even further. We describe a natural language processing (NLP) approach to identify VIA (Values in Action) Character Strengths in fellowship application personal statements and letters of recommendation, providing a data-driven method to support holistic applicant review based on the principles of positive psychology.

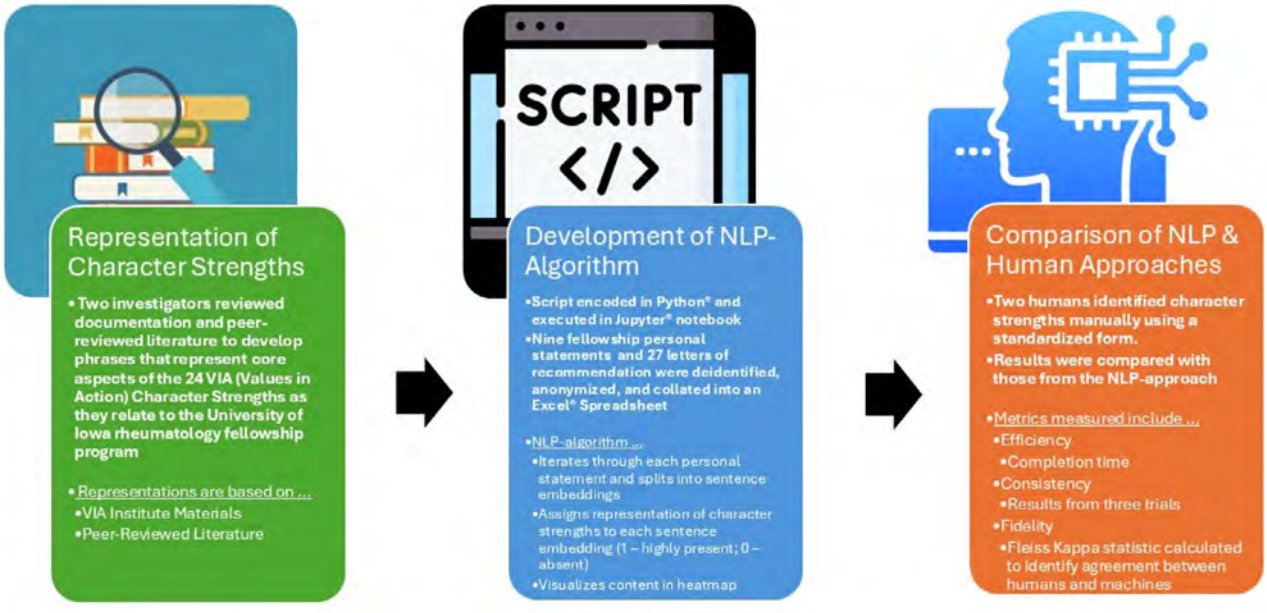
Methods: This feasibility study was conducted in three steps: (1) representation of character strengths, (2) computer assignment of character strengths, and (3) comparison to human-based approaches.

First, two physicians first represented the 24 VIA character strengths using documentation from the VIA Institute and peer-reviewed literature. For each character strength, five phrases were developed that aligned with the University of Iowa rheumatology fellowship program's mission statement.

Secondly, an algorithm using NLP was devised using the python computer language that employed sentence-BERT (SBERT) embeddings. The algorithm analyzes semantic similarity of sentences within the personal statements and letters of recommendation to each of 24 VIA Character Strengths. For each candidate, a score between 0 and 1 was assigned for the presence of each strength. This was then represented as a heat map for easy visualization of each candidate's character strengths.

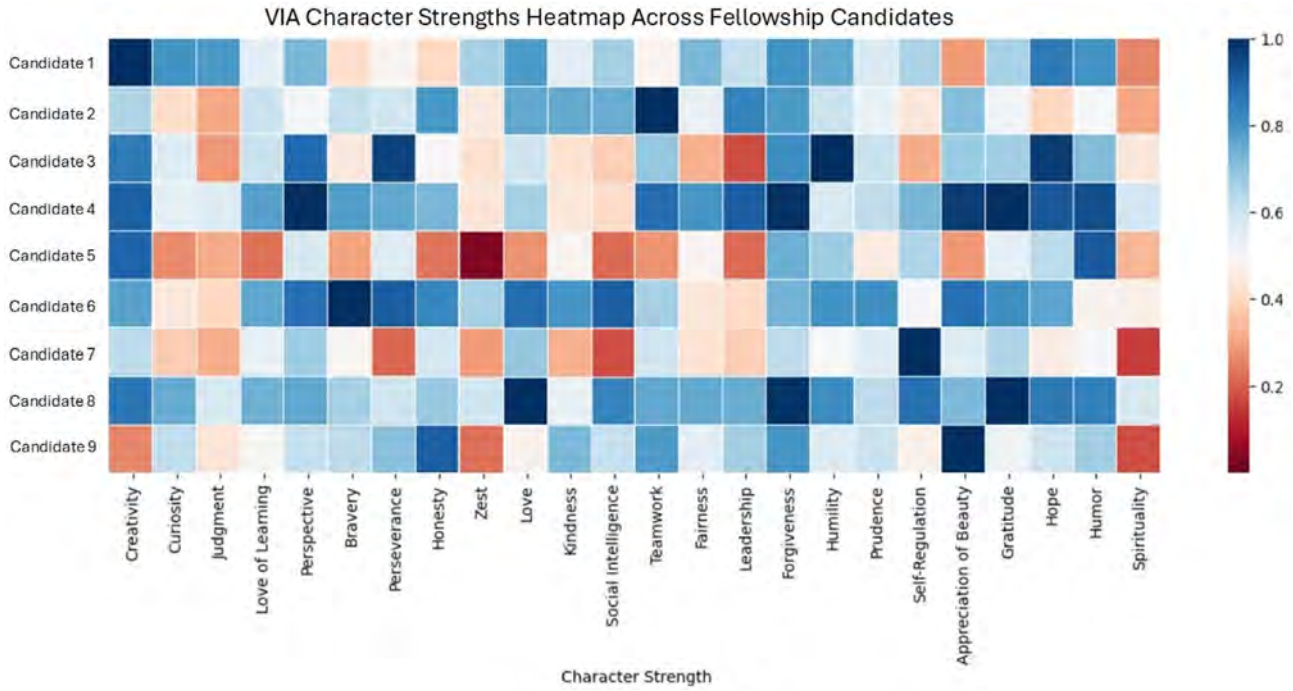
Lastly, this was repeated three times to ensure consistency of computer-generated results. Two physicians independently reviewed the personal statements and letters of recommendation for character strengths. Results of the human- and computer-based approaches were then compared for consistency and for time to complete the task.

Results: The algorithm successfully identified character strengths across 9 personal statements and 27 letters of recommendation from a sample of 9 prior applications, demonstrating individual differences in the representation of character strengths within candidate applications.



This feasibility study consisted of three steps: (1) Representation and calibration of character strengths with the program mission statement, (2) Development of the NLP-algorithm, and (3) Comparison of NLP & human approaches

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



This heatmap illustrates the distribution of character strengths among the documents for each of the fellowship candidates. Such a heatmap can be used to rapidly appreciate representations of character strengths within candidate applications.

There was high concordance between character strengths assigned by human reviewers and those identified by the algorithm (kappa=0.89). The strengths with highest concordance between the algorithm and human reviewers were *teamwork* and *leadership*, while the lowest were *spirituality* and *forgiveness*.

Output and performance of the model was consistent and reduced the time to identify strengths from 240 minutes to 35 seconds.

Conclusion: This study presents a novel NLP-based algorithm for analyzing personal statements, offering a scalable and customizable approach for rheumatology program directors and other leaders to rapidly evaluate character strengths. By integrating machine learning into holistic review based on a positive psychology framework, this method provides structured insights into applicants' personal attributes, complementing holistic selection processes in a rapid and reproducible manner.

Background/Purpose: Among pediatric patients with scleroderma, there is a significant delay between onset of symptoms and diagnosis ranging from 1.2-1.6 years for Localized Scleroderma (LS) to 1.9-2.8 years for Systemic Sclerosis (SSc). Stubbs et al explored caregivers' perceptions of navigating their child's diagnosis with LS and SSc: their work identified that the number one barrier parents identified was lack of provider knowledge(1). Our aim is to create an intervention for front-line providers to improve the recognition of rashes associated with rheumatologic disease with the ultimate goal to improve referral patterns and decrease time to diagnosis.

Methods: Using Kern's Model of curriculum development, we created a needs assessment to evaluate competency among a range of pediatric providers by querying their skills, knowledge, and attitudes surrounding rash identification. We also obtained qualitative data which was coded and used to generate themes to inform the quantitative results.

Results: We received 39 responses (53% resident, 28% attending, 18% APP). Approximately a third were currently practicing or planning to become primary care providers, another third planned to go into subspecialties other than rheumatology, and the remaining third were planning to continue or pursue hospitalist or ED positions. The majority of respondents (61.5%) did not feel they received adequate training in rheumatology during their pre-clinical years. On recall, most reported 5-10 hours of pre-clinical education spent on rheumatology.

Regarding skill identifying rashes, the majority of respondents (64%) rated themselves as only slightly knowledgeable, 25.6% as moderate and 10% having no knowledge/skill identifying rheumatic skin disease. Reassuringly, 100% of participants responded that identification of rashes was somewhat important or very important.

Additionally, we queried respondents for qualitative responses. Themes that emerged included that rheumatology was frequently taught as an "afterthought", with inadequate content, and without pediatric-specific examples. Many also identified that their skills identifying rashes were poor because they had little experience.

Conclusion: A needs assessment of front-line pediatricians revealed that there is a lack of knowledge and skill surrounding rheumatic diseases and the common rashes that can provide clues to their diagnosis. More education is needed to ensure that providers are familiar with these rare diagnoses to facilitate early and appropriate rheumatology referral to prevent accumulation of damage with delayed diagnosis. Our group is creating a 45min didactic intervention dedicated to recognizing skin manifestations of key pediatric rheumatic conditions to further address these needs. We will assess efficacy via pre- and post-testing as well as qualitative responses.

Abstract Number: 2176

Addressing Hesitancy in JAK Inhibitor Use: Outcomes from Continuing Medical Education Reveal Confidence-knowledge Gaps Among Community Rheumatologists

Carole Drexel[1], Eve Wilson[2], Vibeke Strand[3] and Jon Giles[4], [1]Medlive, Pasadena, MD, [2]Medlive, Needham, MA, [3]Stanford University School of Medicine, Palo Alto CA, Portola Valley, CA, [4]Cedars Sinai Medical Center, Los Angeles, CA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2159–2194) Professional Education Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Despite supportive real-world evidence, the use of Janus kinase inhibitors (JAKi) for rheumatoid arthritis (RA) remains limited in community settings. Concerns stemming from the ORAL Surveillance Trial and related regulatory restrictions have contributed to clinician hesitation. To better understand persistent barriers to the use of JAK inhibitors in clinical practice, we analyzed outcomes data from a continuing medical education (CME) program focused on JAKi use in RA.

Methods: A 60-minute expert panel discussion was launched online in December 2024 and remains available on-demand for one year. The activity is targeted to rheumatologists and primary care providers (PCPs) with experience managing RA. Targeted outreach included short video segments delivered via social media to NPI-verified rheumatologists. Change in knowledge, confidence (via Likert scale), and remaining educational needs post activity were assessed. Paired responses were analyzed using chi-square tests (pre vs post; $P < 0.05$).

Results: As of May 2025, 926 HCPs had participated (41% rheumatologists; 28% PCPs), with most reporting care of ≥10 RA patients per month. The activity significantly improved awareness of the JAK1 selectivity of upadacitinib (28% pre vs 50% post). However, knowledge of the relationship between venous thromboembolism and associated risk factors with tofacitinib and efficacy of baricitinib in clinical trials remained unchanged (pre 46% vs post 47% and pre 43% vs post 47%). Key educational needs identified post-activity included: selecting appropriate JAKi candidates (37%), managing side effects and risks (37%), and differentiating among JAK inhibitors by safety and efficacy (33%). Confidence in prescribing JAKi increased from 2.0 to 3.7 (5-point scale).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Knowledge surrounding the efficacy and safety risks JAKi remained largely unchanged following the activity, and participants continued to identify unmet educational needs in selecting appropriate candidates, managing risks, and differentiating among JAKi. These persistent gaps suggest that key aspects of JAKi use remain poorly understood. Notably, this limited knowledge stood in contrast to a substantial increase in self-reported prescribing confidence, indicating a potential overestimation of preparedness that underscores the need for deeper, more targeted educational interventions.

[Support from an independent medical education grant from AbbVie was provided for the CME activity, not for the work associated with the abstract.]

Abstract Number: 2177

A Rheumatologic Ultrasound (RhUS) Educational Framework: Expert Consensus on Rhus Skills for Adult Rheumatology Fellows in the United States

Christine Parsons[1], irene Ma[2], Amy Cannella[3], Eugene Kissin[4], Paul DeMarco[5], Midori Nishio[6], Edward Oberle[7], Catherine Bakewell[8], Ralf Thiele[9], Anthony M. Reginato[10], Norman Madsen[11], Jonathan Samuels[12], Patricia Vega-Fernandez[13], Clara Lin[14], Marcy Bolster[15] and Minna Kohler[16], [1]Massachusetts General Hospital, Boston, MA, [2]University of Calgary, Calgary, Canada, [3]University of Nebraska Medical Center, Omaha, NE, [4]Boston University, Newton, MA, [5]Mobile Medical Care, Olney, MD, [6]John Muir Specialty Medical Group, Lafayette, CA, [7]Nationwide Children's Hospital, Columbus, OH, [8]Intermountain Healthcare, Salt Lake City, UT, [9]University of Rochester, PITTSFORD, NY, [10]Brown University, Providence, RI, [11]URMC, Rochester, NY, [12]NYU Langone, Rye Brook, NY, [13]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [14]Children's Hospital Colorado, Aurora, CO, [15]Massachusetts General Hospital, Concord, MA, [16]Massachusetts General Hospital, Harvard Medical School, Boston, MA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2159–2194) Professional Education Poster

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Over the past decade, point-of care ultrasound (POCUS) has expanded rapidly within fellowship training programs. There is strong interest in rheumatology ultrasound (RhUS) education among U.S. rheumatology fellowship training programs, however there is inconsistency in curricular offerings and not all programs are able to offer a formal RhUS curriculum. The 2019 American College of Rheumatology (ACR) RhUS Mini-Curriculum offers an optional, comprehensive model curriculum for educators[1]. However, learners vary in their interest and available time for RhUS practice. Educators face the challenge of tailoring their teaching to a broad array of learners, from those seeking only basic knowledge to those pursuing advanced mastery. This project aimed to gain expert consensus on an updated set of RhUS skills and stratify them by level to provide a structured educational framework for trainees with a range of learning goals.

Methods: An application to update the 2019 RhUS Mini-Curriculum was approved by the ACR Curriculum Subcommittee. The project was approved by the Massachusetts General Hospital Institutional Review Board. RhUS experts were invited to participate in three virtual focus group meetings. Experts had extensive RhUS teaching experience and were RhMSUS

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1. Summary of RhUS skills designated as All Fellows – Fundamental. Strong agreement was defined as agreement of 70% or greater. Moderate agreement was defined as agreement of 51-69%. Dark Blue: Strong Agreement. Light Blue: Moderate agreement.

All Fellows - Fundamental	Agreement (%)
Reasonable Use of RhUS	
Recognize indications for and limitations of musculoskeletal ultrasound	100
Recognize the association between musculoskeletal ultrasound findings and rheumatic disease states	100
Recognize the role of vascular ultrasound in diagnosis of Giant Cell Arteritis	80
Image Interpretaton	
Recognize the following anatomic structures on an ultrasound image: joint, tendon, ligament, bursa, bone, vessel, nerve, fat	90
Recognize effusion	80
Recognize Baker's Cyst	80
Recognize double contour sign	80
Recognize bursitis	70
Recognize grade 3 synovial thickening	70
Recognize positive Doppler signal	60
Recognize erosion	60
Procedural Skills	
Identify appropriate target	80
Mark area for arthrocentesis when indirect visualization is used	70

certified. All were Ultrasound School of North American Rheumatologists (USSONAR) faculty with more than 5 years of RhUS teaching experience, the majority (80%) of whom had more than 10 years of experience. The experts reviewed RhUS skills adapted from the 2019 ACR RhUS Mini-Curriculum as well as additional skills recommended by the expert panel. The modified Nominal Group Technique (NGT) was used to reach consensus on which RhUS skills to include and how to classify them by level. Participants were identified through non-probability sampling. Strong agreement was defined a priori as agreement of 70% or greater. Moderate agreement was defined a priori as agreement of 51-69%.

Results: The NGT comprised 10 experts who voted on a total of 83 RhUS skills. Thirteen RhUS skills were designated as "All Fellows–Fundamental" (11 with strong agreement, 2 with moderate agreement) (Table 1). Thirty-four skills were designated as "Ultrasonographer Fellow-Advanced" (21 with strong agreement, 13 with moderate agreement) (Table 2). Seventeen skills were designated as "Ultrasonographer-Aspirational" (13 with strong agreement, 4 with moderate agreement) (Table 3). Moderate agreement supported removal of one skill. Consensus on level was not reached for 19 skills. Additionally, there was strong consensus (90% agreement) around adding ultrasound images alongside joint scanning protocols to enhance the 2019 ACR RhUS Mini-Curriculum.

Conclusion: This study establishes expert consensus on a tiered set of RhUS skills, enhancing the 2019 ACR RhUS Mini-Curriculum by adding a practical framework to tailor rheumatology ultrasound education to varying learner needs and performance goals, enabling more scalable training in rheumatology ultrasound.

Table 2. Summary of RhUS skills designated as Ultrasonographer Fellow – Advanced. Strong agreement was defined as agreement of 70% or greater. Moderate agreement was defined as agreement of 51-69%. Tier 1 and Tier 2 views reference previously published consensus of North American rheumatologists (Bethina NK, et al 2022; Yinh J et al, 2021). Dark Blue: Strong Agreement. Light Blue: Moderate Agreement.

Ultrasonographer Fellow - Advanced	Agreement (%)
Image Interpretaton	
Understand basic ultrasound physics	60
Recognize grade 1 synovial thickening	60
Recognize grade 2 synovial thickening	90
Grade Doppler signal	60
Recognize tenosynovitis	60
Recognize tendinopathy	70
Recognize tendon tear	60
Recognize paratenonitis	80
Recognize joint subluxation	70
Recognize loose body	80
Recognize prosthetic joint	70
Recognize foreign body	90
Recognize calcium pyrophosphate deposits based on shape, echogenicity, localization, and dynamic assessment	70
Recognize hyperechoic aggregates (HAGs) and micro crystalline deposition	90
Recognize the ultrasound appearance of tophi	60
Recognize linear calcification in tendon	90
Recognize erosive osteoarthritis	70
Recognize rheumatoid nodule	70
Recognize meniscal degeneration	70
Recognize dynamic view of trigger finger	70
Recognize PIP/DIP enthesitis	60
Recognize anechoic/hypoechoic foci in salivary gland	80
Image Acquisition	
Maneuver probe to optimize image (i.e. translation, rotation, angulation, pressure, compression, heel-toe, rocking)	70
Understand how machine settings can be adjusted to optimize an image (i.e depth, frequency, focal zones, gain, pulse repetition frequency)	70
Adjust machine setting to optimize Doppler sensitivity and specificity	80
Demonstrate pathology in orthogonal planes	60
Perform a directed set of ultrasound views specific to a consult question	80
Obtain Tier 1 Views	60
Obtain Tier 2 Views	90
Obtain medial subtalar view	60
Obtain lateral subtalar view	60
Obtain midfoot transverse view	60
Procedural Skills	
Ultrasound-guided aspiration and injection of medium joints	60
Ultrasound-guided aspiration and injection of small joints	70

Abstract Number: 2178

Online Education Significantly Improved Rheumatologists' Knowledge of the Diagnosis and Management of Sjögren's Disease

Elaine Bell[1], michele Bombardieri[2] and Alessia Piazza[3], [1]MEDSCAPE GLOBAL, LONDON, United Kingdom, [2]Experimental Medicine and Rheumatology, William Harvey Research Institute, Queen Mary University of London, UK, London, United Kingdom, [3]Medscape, london, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2159–2194) Professional Education Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Sjögren's disease is a chronic autoimmune disease affecting multiple organ systems beyond the eyes and mouth. Diagnosis is challenging and therapy is often initiated late. The need for a patient-centered individualized management approach is often underappreciated.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Our goal was to assess whether online accredited education could improve rheumatologists' understanding of the heterogeneous clinical presentation of Sjögren's disease, the diagnostic approach and the role of B cells in the pathogenesis of Sjögren's disease, and enhance their confidence in implementing a tailored, patient-centric management approach.

Methods: This online educational activity titled 'Challenges and Opportunities in the Management of Sjögren's Disease' was a 30-minute roundtable discussion with 3 panelists and a patient, accompanied by slides and video. Responses to 3 multiple-choice knowledge questions and 1 self-efficacy, 5-point Likert scale confidence question were analyzed. Educational effect was assessed using a repeated-pair design, pre-/post-assessment. A paired samples t-test was conducted for significance testing on overall average number of correct responses and for confidence rating. A series of McNemar's tests were conducted at the question level (5% significance level, $P < .05$). Cohen's d with correction for paired samples estimated the effect size of the education on number of correct responses (< .20 modest, .20-.49 small, .59-.79 moderate, ≥.80 large). The activity was launched on 13 August 2024 with data collection through 3 October 2024.

Results: Of 1205 rheumatologists who viewed the education within this time period, 80 completed all pre- and post-assessment questions. The average percentage of correct responses across all questions increased from 76% at baseline to 88% post-activity ($P < .001$), and there was a moderate educational impact (Cohen's d=0.59). The proportion of rheumatologists answering all 3 questions correctly rose from 49% at baseline to 71% post-activity.

Rheumatologists significantly improved their knowledge of the diagnostic approach for Sjögren's disease (68% correct responses at baseline rising to 85% post-activity; $P < .001$) and the presence of germinal centers in the salivary glands as an indicator of the role of B cells in the pathogenesis of Sjögren's disease (66% pre- vs 81% post-activity; $P < .001$). Knowledge of the heterogeneous clinical presentation of Sjögren's disease was high at baseline and did not change post education (95% pre- vs 96% post-activity; $P = .317$).

After completing the activity, 33% of rheumatologists reported improved confidence in implementing a tailored, patient-centric management approach in Sjögren's disease.

Conclusion: This online activity significantly improved rheumatologists' knowledge of the diagnostic approach for Sjögren's disease and the role of B cells in the pathogenesis of disease. Given the evolving treatment landscape, rheumatologists would benefit from additional education to build their confidence in managing this challenging condition & improve their knowledge of emerging B-cell targeted therapies.

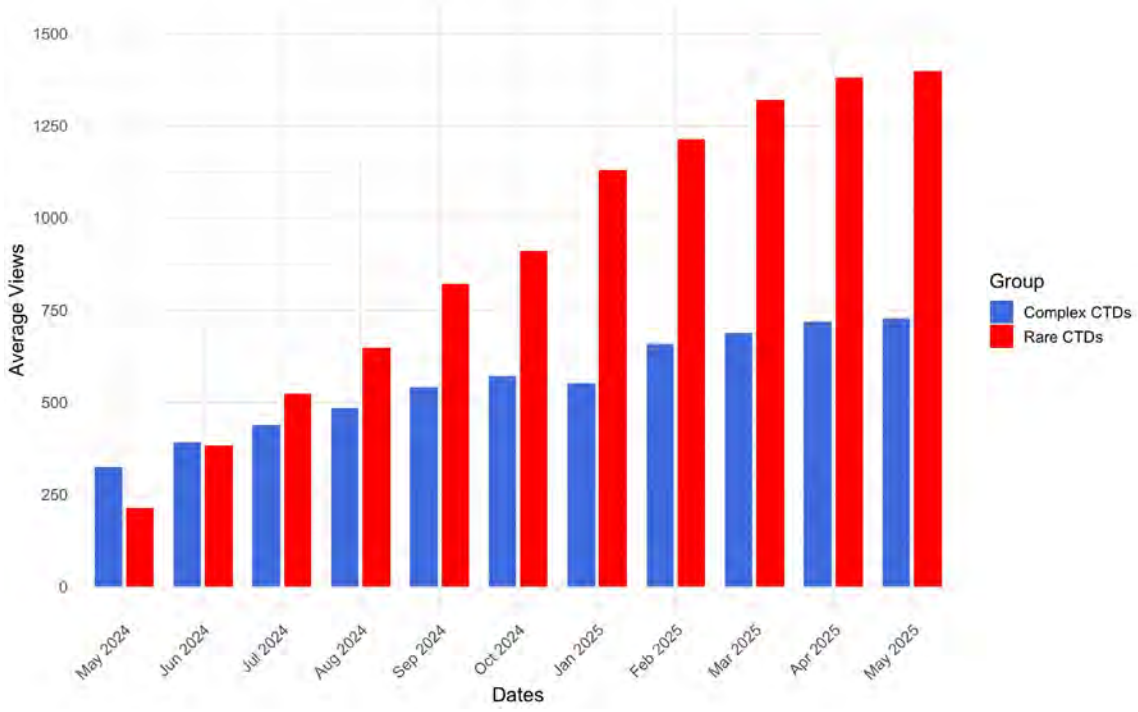
SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2159–2194) Professional Education Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The European Reference Network on Connective Tissue and Musculoskeletal Diseases (ERN ReCONNET), founded in 2017 by the European Union (EU) Commission, aimed to improve the management of rare connective tissue diseases (CTDs) across the EU. ReCONNET includes rare (Ehlers-Danlos Syndromes, IgG4-Related Diseases, Mixed Connective Tissue Disease, Relapsing Polychondritis) and complex with low prevalence (Antiphospholipid Syndrome, Idiopathic Inflammatory Myopathies, Sjögren's Syndrome, Systemic Lupus Erythematosus, Systemic Sclerosis, and Undifferentiated Connective Tissue Disease) CTDs. Since 2019, ReCONNET Educational Committee organized free online webinars accessible live on Zoom platform and recorded on ReCONNET YouTube (YT) page.

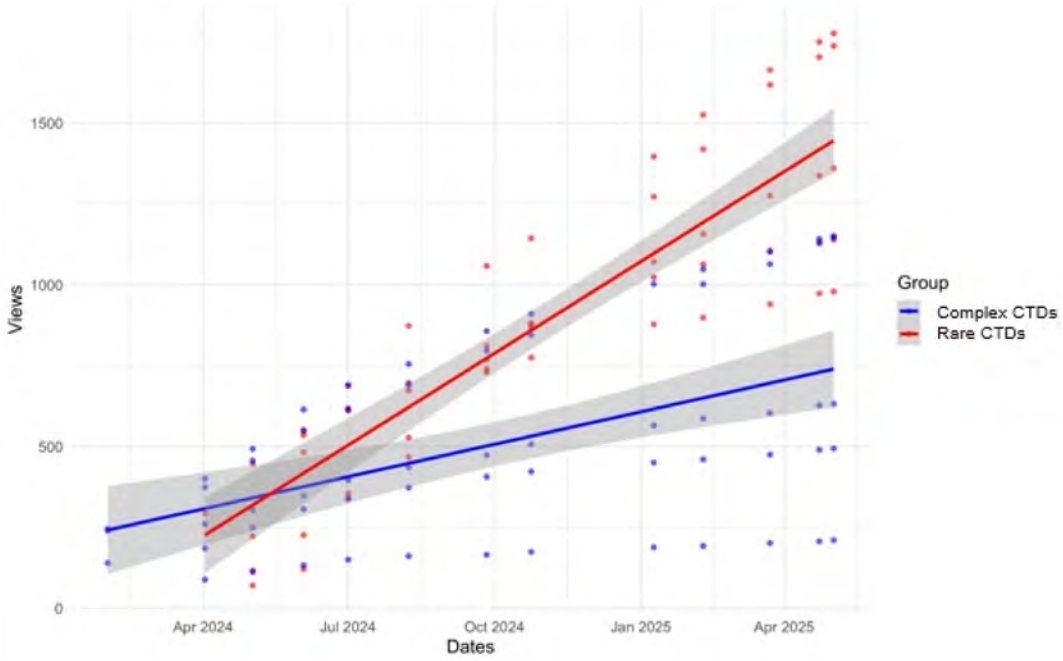
So, the aim of the current study was to assess the interest and size of webinar viewers (wv) and views from ReCONNET patients/caregivers, HCPs, or both, for the different CTDs.

Methods: Live view data (available from October 2023) were obtained from Zoom, while YT views (available from 2019) were collected as of 2nd May 2025.



One-year average views (2024-2025) on YouTube recordings in rare (red bar) and complex low-prevalence (blue bar) connective tissue diseases from ERN ReCONNET achieving the ERN target for an increased education on rare connective tissue diseases (CTDs).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Linear regression analysis shows the increase overtime of YouTube views in rare and complex low-prevalence connective tissue diseases (CTDs) (one-year views). The initial number of views did not differ significantly between disease groups (β=84.54, p=0.487), while the rare CTDs group exhibited a significantly steeper increase of views over time compared to the complex CTDs group (β=1.85, p<0.001). β in regression shows how much the dependent variable (YouTube views) changes when the independent variable (time) increases by one unit. Figure created with R software.

Results: From 2019 up to 2nd May 2025, ERN ReCONNET organized 73 webinars, totaling 147,030 YT views. Webinars on rare CTDs (n=20) collected 70,307 YT views (average 3,515±4,271 per webinar), and webinars on complex CTDs (n=53) totalized 76,723 YT views (average of 1,447±1,838 per webinar), the former with a significantly higher number of YT views per webinar (p< 0.01).

By considering Zoom data available from October 2023, live webinars targeted at patients/caregivers got a total number of 158 wv (6 webinars, average 26±18 per webinar); those for HCPs got a total of 265 wv (11 webinars, average 24±9 per webinar) and finally those for both classes got a total of 132 wv (6 webinars, average 22±15 per webinar) without statistically significant differences interclasses.

The YT recording of the above webinars for patients/caregivers averaged 541±507 views (total of 3,244), those for HCPs averaged 902±816 views (total of 9,925), and those for both classes averaged 581±598 views (total of 3,486), again without statistically significant differences interclasses.

Finally, when the number of live wv and YT views was counted for the webinar on rare and complex CTDs, then rare CTDs got a total of 172 wv (5 webinars, average 34±17 per webinar) together with 6,993 YT views (average 1,399±345 per webinar). The webinars on complex CTDs collected 383 live wv (18 webinars, average 21±10 per webinar) and 9,662 YT views (average 537±642 per webinar) (Figure 1). The difference between rare and complex CTDs was statistically significant for YT views (p< 0.01), but not for wv.

Linear regression analysis of YT views showed that the rare CTDs group exhibited a significantly steeper increase of views over time compared to the complex CTDs group (β=1.85, p< 0.001) (Figure 2).

Conclusion: ERN ReCONNET's online webinars achieved a considerable number of views on YT, with significantly higher interest shown for webinars on rare CTDs compared to complex low-prevalence CTDs. Main users of this earlier six years'

Helping Hands: Curriculum using Simulators to Teach the Hand Exam and Assessment of Small Joint Swelling in Inflammatory Arthritis

Ibtissam Gad[1], Christopher Podgorski[2], Kylie Springer[3], amita Bishnoi[4] and Lisa Zickuhr[5], [1]University of Michigan, Ann Arbor, MI, [2]Park Nicollet, Lake Elmo, MN, [3]Henry Ford Health, Detroit, [4]Henry Ford Health System, Troy, MI, [5]Washington University/B-JH/SLCH Consortium, St. Louis, MO

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2159–2194) Professional Education Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The hand examination is crucial for internal medicine (IM) residents to learn, as it is important for the diagnosis and treatment of patients with inflammatory arthritides. However, there is mounting evidence that trainee confidence in the musculoskeletal examination is low. Moreover, there are limited curricula available to teach the hand physical examination, none of which leverage simulation as an educational strategy. We describe a feasible and effective simulation-based curriculum, utilizing a hand model, to teach IM residents the hand examination and assessment of small joint swelling, as seen in inflammatory arthritis.

	Pre (N=36)	Post (N=36)	P-value
Assessing Small Joint Swelling, n (%)			**<0.01**
Very Unconfident	5 (13.9%)	0 (0.0%)	
Unconfident	23 (63.9%)	2 (5.6%)	
Confident	7 (19.4%)	20 (55.6%)	
Very Confident	1 (2.8%)	14 (38.9%)	
Performing a Hand Examination, n (%)			**<0.01**
Very Unconfident	5 (13.9%)	0 (0.0%)	
Unconfident	23 (63.9%)	1 (2.8%)	
Confident	6 (16.7%)	21 (58.3%)	
Very Confident	2 (5.6%)	14 (38.9%)	

The distribution of responses for self-perceived confidence on a 4-point Likert scale before and after our educational initiative. Trainees rated confidence in two specific skills: performing a hand examination and assessing small joint swelling as seen in inflammatory arthritis. Improved confidence was reported after completion of the curriculum, which included a video, live demonstration, hand-on practice, and a 3-station assessment ($p<0.01$).

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We designed a physical examination curriculum for IM residents rotating through their rheumatology elective. Residents watched a short video, viewed a real-life demonstration, and then participated in hands-on practice with the hand model. Residents then participated in a three-station objective structured clinical exam (OSCE) with clinical vignettes and hand models to assess knowledge. IM residents examined the hand models at each OSCE station and identified sites of perceived palpable small joint swelling on an accompanying worksheet. Afterwards, residents completed a pre-post survey evaluating perceived confidence in performing a hand examination and assessing small joint swelling.

Results: During the duration of the study, 36 IM residents participated in the workshop and completed the survey. There was a statistically significant improvement in resident self-reported confidence in performing a hand examination and assessing small joint swelling ($p< 0.01$). All IM residents (100%) reported that they would use the skills learned in this curriculum in their clinical practice.

Conclusion: After participating in our simulation-based curriculum, IM residents reported improved confidence in performing a hand examination and assessing small joint swelling as seen in inflammatory arthritis. This workshop is feasible and may be an effective method to teach trainees these important skills. This workshop shows potential for teaching other groups of learners including medical students, early rheumatology fellows, and advanced practice providers. Future studies should compare our simulation-based curriculum with conventional methods in the teaching of the hand musculoskeletal examination.

Abstract Number: 2181

A Pilot High-fidelity Simulation for Pediatric Rheumatology Learners

John Bridges[1], Livie Timmerman[2] and Nicholas Rockwell[3], [1]University of Alabama at Birmingham/Children's of Alabama, Birmingham, AL, [2]University of Alabama at Birmingham, Gardendale, AL, [3]University of Alabama at Birmingham, Birmingham

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2159–2194) Professional Education Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The ACGME's core competencies for pediatric residency training include medical knowledge, patient care, and interpersonal communication skills. At our institution, residents only spend two weeks or fewer rotating through pediatric rheumatology. A needs assessment among pediatric rheumatology attendings identified key rare disease states that are unlikely to be clinically encountered by learners during this short time. High-fidelity simulation is an effective tool in pediatric medical education[1]. We designed a simulation module to expose pediatric learners to two such rheumatologic diseases with clinically distinct, recognizable disease presentation patterns. Learning objectives included: 1) Recognize juvenile dermatomyositis (JDM); 2) Recognize macrophage activation syndrome (MAS); 3) Successfully consult a subspecialist. This intervention was developed to increase learner exposure to rare rheumatologic diseases during limited time on the pediatric rheumatology rotation.

Methods: We collaborated with our institution's pediatric simulation center to create these educational modules focused on pediatric rheumatology. After several months of development, we piloted the modules with final- year medical students and pediatric residents during their clinical rotations.. Local IRB approval was obtained. Participants completed the simulation

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1

Table 1: Pre- and Post-Simulation Multiple Choice Scores by Topic

Topic	Pre-Simulation Scores, N=25 *Mean (SD)*	Post-Simulation Scores, N=16 *Mean (SD)*	*p*-value
Juvenile Dermatomyositis	65.3 (29.1)	84.4 (23.9)	<0.05
Macrophage Activation Syndrome	50 (50.8)	68.8 (47.9)	0.12
One sided t-test, assuming equal variance			

Table 2

Table 2: Pre- and Post-Simulation Confidence Ratings by Topic

Confidence Categories	Pre-Simulation, N=25 *Mean (SD)*	Post-Simulation, N=16 *Mean (SD)*	*p*-value
Diagnostic suspicion of JDM	2.78 (1.07)	3.8 (0.74)	<0.005
Diagnostic suspicion of MAS	2.88 (1.28)	3.9 (0.83)	<0.005
Subspecialist Consultation	3.45 (0.87)	4.3 (0.48)	<0.005
All (100%) post-simulation survey respondents found the simulation module to be a helpful learning activity for the rotation			

module as a group and underwent botha pre- and post-simulation questionnaire assessing knowledge pertaining to subject material covered in the module. A post-simulation debriefing simulation in accordance with the standard simulation teaching modality. Descriptive statistics and one-sided t-tests assuming equal variance were used for data analysis.

Results: A multiple choice questionnaire was distributed as a pre- and post-module assessment of learner knowledge regarding MAS and JDM. Learner confidence in diagnostic recognition and in subspecialist consultation was measured using a 5 point Likert scale. Mean percent correct responses increased from 65.3 (SD 29.1) to 84.4 (SD 23.9) for JDM and from 50 (SD 50.8) to 68.8 (SD 47.9) for MAS, respectively. Confidence in diagnostic suspicion of JDM increased from mean of 2.78 to 3.8 and for MAS increased from 2.88 to 3.9. Confidence in subspecialist consultation increased from 3.45 to 4.3. 100% of learners surveyed reported that the simulation module was a helpful learning activity for the rotation.

Conclusion: This pilot module of high-fidelity simulation for pediatric learners demonstrates knowledge acquisition and increased learner confidence in important core competencies. The long-term goal of this work is to design additional sessions into a modular curriculum for utilization by any training program with access to a simulation center. High-fidelity simulation in pediatric rheumatology is a promising educational method that has the potential to increase access to pediatric learning during medical school and residency training, which could lead to significant improvements in disease recognition and prompt referral in the setting of pediatric rheumatology workforce challenges and large numbers of unnecessary referrals[2,3].

Abstract Number: 2182

Rheum for Improvement: A Needs Assessment Survey for an Internal Medicine Resident Curriculum

Kailey Singh[1], Lara El Khoury[2], Karen Friedman[3] and Julie Schwartzman-Morris[4], [1]Northwell Health-NS/LIJ, Queens, NY, [2]Zucker School of Medicine at Hofstra/Northwell Health, Great Neck, NY, [3]Zucker School of Medicine at Hofstra/Northwell Health, Manhasset, NY, [4]Northwell Health Physician Partners, roslyn heights, NY

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2159–2194) Professional Education Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatology is a core Internal Medicine (IM) residency requirement, yet IM residents report low confidence in their knowledge and skills. This project aimed to identify areas of weakness in resident rheumatology education with a needs assessment to develop a targeted curriculum to improve resident confidence and competency.

Methods: We surveyed IM residents and rheumatology faculty at a single academic center and analyzed resident in-training exam (ITE) rheumatology scores from 2021-2024. Residents completed a 10-item questionnaire that assessed resident confidence and interest in five American Board of Internal Medicine-based rheumatology topics from a list of topics. Faculty completed a 7-item questionnaire, ranking five topics from a list based on their perceived resident understanding and importance to resident education. Correlation between resident confidence and faculty perceived proficiency was analyzed with a Pearson correlation coefficient. Both surveys included open-ended questions on preferred teaching methods.

Results: 28 IM residents completed the survey, including 12 PGY-1s, 9 PGY-2s and 7 PGY-3s. Most residents had no exposure (n=6, 21.4%) or limited exposure (n=15, 53.6%) to rheumatology in residency, and few (17.9%, n=5) had pursued a rheumatology elective. Three rheumatology fellows and seven attendings completed the survey, with most attendings having over 5 years of experience (n=5, 71.4%). Median ITE rheumatology percentile scores from 2021-2024 were lower at our institution (61st) compared to nationally (65th), with deficits in scleroderma, systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA). Our residents scored higher in osteoarthritis (OA) and gout. Residents reported high confidence in OA (n=10, 36%), consulting rheumatology inpatient (n=7, 25%) and when to order autoimmune serologies (n=7, 25%), but lower confidence in connective tissue disorders (n=7, 25%), vasculitis (n=6, 21.4%) and interpreting autoimmune serologies (n=6, 21.4%). High interest was expressed in learning how to interpret serologies (n=17, 61%) and when to order them (n=8, 29%). Interest was lower in topics they reported higher confidence in, including OA (n=6, 21.4%) and crystal arthropathy (n=5, 18%) (Figure 1). Faculty identified ordering serologies (n=5, 50%) and interpreting them (n=4, 40%) as key areas for improvement. Ordering serologies (n=7, 70%) and crystal induced arthropathy (n=4, 40%) were perceived as most important to resident education compared to unrated topics including OA and myositis (Figure 2). No significant correlation was found between resident confidence and faculty perceived proficiency (r= -0.38, p=0.153) (Figure 3). Both residents and faculty favored workshops and clinical experience as preferred teaching methods (n=20, 71%), (n=7, 70%).

Conclusion: This needs assessment identified areas of improvement in rheumatology including interpreting autoimmune serologies, connective tissue disorders and vasculitis based on objective ITE data and subjective assessments from residents and faculty. These findings highlight the need for a tailored curriculum and will be used to develop and implement a curriculum in the upcoming academic year.

Bridging the Musculoskeletal Ultrasound Training Gap: Analysis of Confidence, Competency, and Clinical Readiness

Kamini Shah[1], Jonathan Samuels[2], Jennifer Medlin[3], Philip Chu[4], Midori Nishio[5], Norman Madsen[6], Michelene Hearth-Holmes[3], Shivani Shah[7], Catherine Bakewell[8], Anthony M. Reginato[9] and Minna Kohler[10], [1]Northwell Health, New York, NY, [2]NYU Langone, Rye Brook, NY, [3]University of Nebraska Medical Center, Omaha, NE, [4]Duke University Hospital, Raleigh, NC, [5]John Muir Specialty Medical Group, Lafayette, CA, [6]URMC, Rochester, NY, [7]University of Chicago, New York, NY, [8]Intermountain Healthcare, Salt Lake City, UT, [9]Brown University, Providence, RI, [10]Massachusetts General Hospital, Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2159–2194) Professional Education Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose:

While point-of care ultrasound (POCUS) training is increasingly introduced during rheumatology fellowship, limited exposure may not provide the depth or continuity needed to build clinical readiness. Structured, mentored experiential learning, grounded in hands-on skill building and real-time feedback, may help bridge this gap by fostering both technical proficiency and learner confidence.

Methods: Survey data were collected from participants in the 2024 and 2025 Ultrasound School of North American Rheumatologists (USSONAR) Fundamentals Musculoskeletal Ultrasound (MSKUS) workshops, part of a national hands-on training program in rheumatology-focused ultrasound. Participants included fellows and post-fellowship clinicians in academic and private practice settings. Demographic characteristics were comparable across cohorts, supporting the validity of pooled confidence analysis. Retrospective pre-post surveys (administered post-course) assessed perceived knowledge, confidence in scanning and interpretation, and clinical application. Due to a split survey format in 2024, knowledge and application responses could not be individually paired, limiting analysis to confidence data only. 2025 survey data included all survey domains. Confidence scores from both years were pooled for aggregate analysis. Knowledge and clinical

TABLE.1 Demographic Characteristics of Workshop Participants in 2024 and 2025

application scores were converted to a 0-10 scale to align with the confidence variable. Responses were analyzed using paired t-tests and Spearman correlations.

Results: Among the 2025 cohort (n = 69), perceived knowledge increased by a mean of 2.25 points (SD = 1.7, $p < 0.0001$), with a post-course mean of 8.33 (SD = 1.4). Post-course confidence in scanning and interpretation, available from both 2024 and 2025 cohorts, averaged 7.34 across the combined group (SD= 1.38, n = 116), suggesting moderate-to-high technical assurance. Correlation analyses, conducted using 2025 data, showed post-course knowledge was positively

Figure 1: Relationship between perceived knowledge and confidence in scanning (2025 cohort, n = 69)

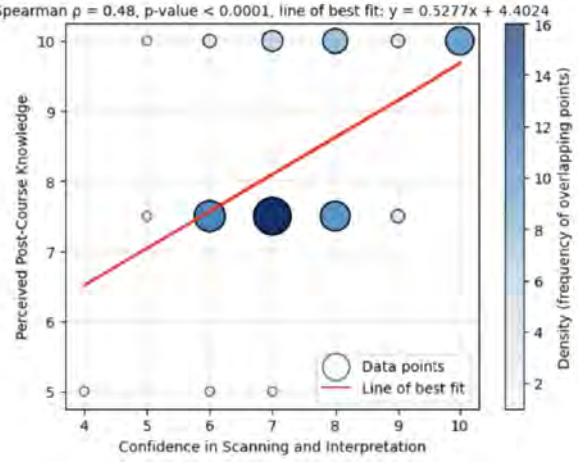

Figure 1: Relationship between perceived knowledge and confidence in scanning

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

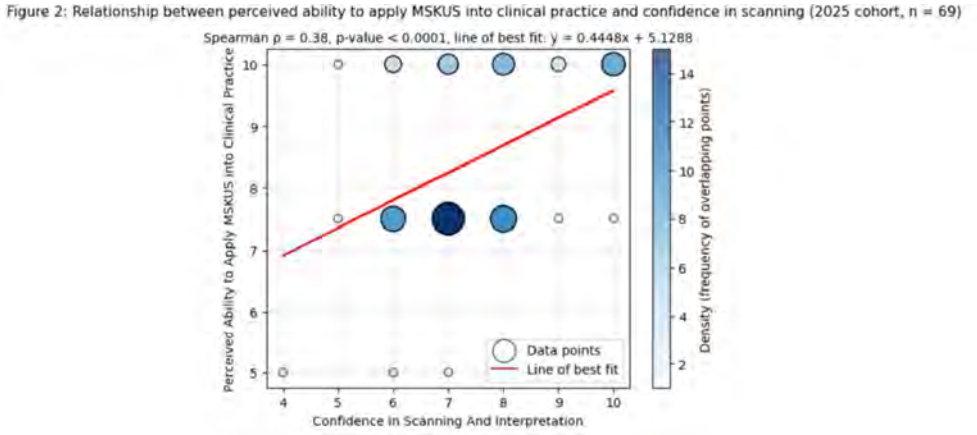

Figure2: Relationship between perceived ability to apply MSKUS into clinical practice and confidence in scanning

associated with confidence in MSKUS scanning and interpretation (Spearman's ρ= 0.48, p < 0.0001). Confidence in scanning also correlated with perceived ability to apply ultrasound skills in clinical practice (ρ = 0.38, p < 0.0001). A one-point increase in confidence was associated with a 0.5-point increase in perceived knowledge. There was no significant difference in post-course confidence scores between fellows and post-fellowship clinicians (p= 0.30), suggesting a reproducible and equitable impact across training levels.

Conclusion: These findings suggest that structured, mentored hands-on training increases learner confidence and technical proficiency, and supports clinical utilization of POCUS in clinical practice. The results support a confidence-driven development model in which experiential learning contributes to clinical readiness. Consistent confidence scores across cohorts support the reproducibility of this model and highlight reliable learning patterns. As POCUS becomes more integrated into rheumatology practice, these findings underscore the need to expand structured training and promote curriculum alignment with competency benchmarks, as reflected in the RhMSUS certification pathway.

Diagnosing the Deficit: Addressing Gaps in Rheumatology Training for Internal Medicine Residents

Kristen Young[1], Samantha Kohn[2] and Brenda Shinar[3], [1]Mayo Clinic, Phoenix, AZ, [2]University Nebraska Medical Center, Omaha, [3]University of Arizona College of Medicine Pheonix, Phoenix

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2159–2194) Professional Education Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatologic diseases are common and complex, requiring internal medicine physicians to develop skills in musculoskeletal examination, diagnosis, and management. Despite this, exposure during residency is often limited, leading to low confidence and variable competence. We conducted a needs assessment among residents to

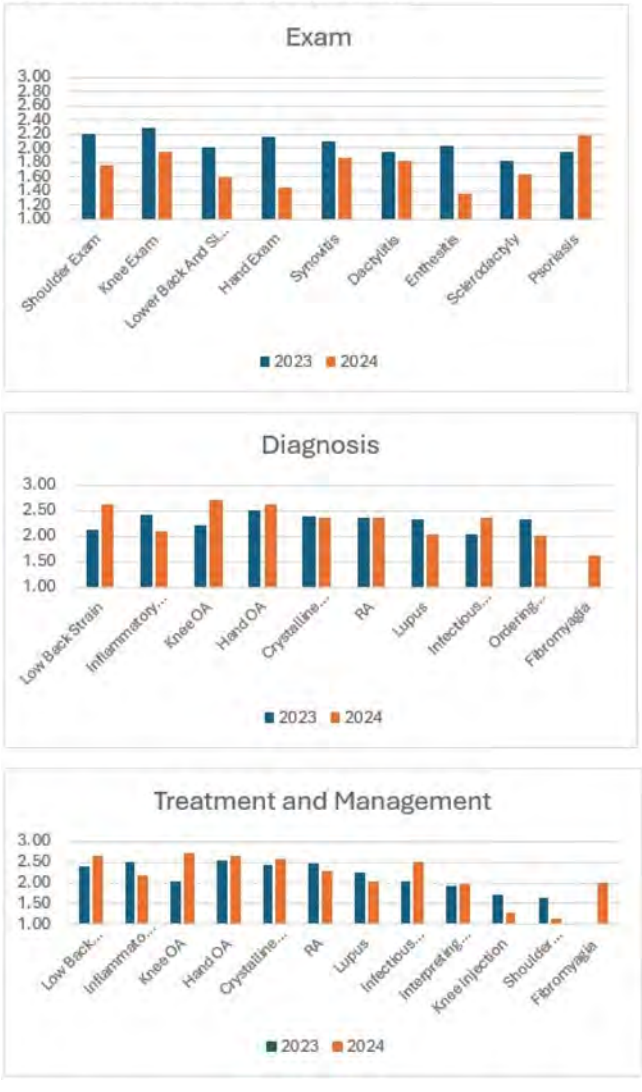
23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

evaluate prior exposure, perceived confidence in core domains, and learning sources. This informed a targeted rheumatology curriculum implemented over one academic year, with evaluation of its impact on resident confidence.

Methods: In May 2023, an anonymous 31-item Likert scale (1-3) survey was administered to internal medicine residents at a large academic center to assess confidence across three domains: physical exam, diagnosis, and treatment. Based on survey data and in-training exam performance, targeted educational interventions were developed. These included a joint injection workshop with Sports Medicine and Rheumatology faculty, low back pain and SI exam sessions, and enhanced didactic content with small-group learning and structured feedback. Included in the survey were questions about preferred learning modalities and where they felt that they gained rheumatology knowledge during residency. The same survey was repeated in May 2024, with additional questions on preferred learning methods and perceived sources of rheumatology learning.

Results: Of 77 eligible residents, 36 (47%) responded in 2023 and 22 (29%) in 2024. In 2024, 32% had completed a rheumatology rotation during residency, compared to 19% in 2023. Confidence in musculoskeletal exams remained low, with declines in hand (–0.71), SI/lower back (–0.44), and enthesitis (–0.68) exams. Modest gains were seen in psoriasis exam (+0.24). In diagnosis, confidence improved in low back strain (+0.50) and knee OA (+0.51), but decreased for lupus

Figure 1. Confidence ratings by residents.



23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(–0.27) and inflammatory back pain (–0.34). Treatment confidence improved for knee OA (+0.67), and infectious arthritis (+0.47), while decreasing for knee (–0.44) and shoulder injections (–0.48). Residents reported highest confidence in diagnosing/treating knee OA, hand OA, and low back strain; lowest in performing joint injections and specialized physical exams.

Residents preferred case-based instruction, followed by patient narratives, lectures, and question banks. Least preferred were journal articles, flashcards, and podcasts. University inpatient wards were the most cited learning setting (86%), followed by Academic Half Day (AHD) lectures (57%), rheumatology rotations (33%), and ambulatory clinics (29%) for gaining new rheumatology knowledge. When asked which most contributed to their knowledge, the top responses were rheumatology rotation (29%) and AHD/simulations (24%).

Conclusion: Targeted didactics improved confidence in diagnosis and management of common rheumatologic conditions, but gaps persist in musculoskeletal and procedural skills. Residents value case-based and narrative instruction, with inpatient and elective experiences being key learning sources. A multifaceted curriculum integrating clinical exposure, hands-on practice, and engaging didactics is essential for building rheumatology competence.

Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Social media (SoMe) has become an indispensable tool in healthcare, providing platforms for information sharing, networking, and education. However, its use presents challenges including misinformation, professional boundaries, and platform-specific limitations. Building upon the EULAR EMEUNET survey, we aimed to characterize SoMe utilization within rheumatology globally, identifying variations in usage patterns and integration into practice.

Methods: The EULAR study group on social media (SoMeR) convened in July 2023 with global, multiprofessional representation, identifying key priorities: advocacy, understanding SM use, and developing a position statement on appropriate use. A 30-item survey was designed with group inputs following adoption from the previous EMEUNET survey, validated by professionals and public, translated into 6 languages, and distributed via mailing lists and social media channels of EMEUNET,

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Respondent characteristics	N =597 mean (SD) or n (%)
Age	40.35 (10.07)
Gender F: M	1:1.12
Region (%)	
Asia Pacific	342 (57.28)
Europe	112 (18.76)
South America	65 (10.88)
Africa	39 (6.53)
North America	39 (6.53)
HDI, n (%)	
Very High	391 (65.60)
High	114 (19.12)
Medium	46 (7.71)
Low	45 (7.55)
Professional title, n (%)*	
Student	37 (6.79)
Practicing physician rheumatologist	387 (64.82)
Non-clinical academic/researcher	32 (5.36)
Clinical academic/researcher	210 (35.17)

16.7%), while higher HDI cited legal restrictions (24.4%) (Fig 1C and F). IFI analysis showed countries with restricted internet freedom paradoxically reported higher positive impact from SoMe (4.04/5 vs 3.86/5, p=0.008). Female professionals showed higher SoMe adoption (94.4% vs 88.8%, p=0.016). Longitudinal analysis (2015-2023) revealed trends toward professional applications and away from networking functions (Fig 2A). Respondents increasingly reported feeling overwhelmed by SoMe content (56.9%), particularly in South America and Africa (73.3%/70.3%, p=0.007). Following these results, the SoMeR Study Group developed a consensus "Digital Equity Declaration for Rheumatology" (Fig 2C) focusing on professional integrity, evidence-based communication, cohesive platforms, patient dignity, and inclusive engagement. Interest in SoMe training was high (83.3%), with webinars preferred (41.1%) (Fig 2B).

Conclusion: This global survey demonstrates SoMe's integral role in rheumatology with significant regional variations. The disparities call for targeted interventions addressing connectivity in lower-resource settings and legal concerns in higher-resource regions. Through strategic engagement with social media while upholding professionalism and scientific integrity, we can transform rheumatology's digital presence from isolated efforts to a cohesive global community. Future projects include revision of the EMEUNET X course and focused group interviews to enhance digital engagement in rheumatology.

Abstract Number: 2186

Developing Rheumatology Specific Anki Electronic Flashcards for Teaching Preclinical Students United States Medical Licensing Examination Board Relevant Topics

Madison Bellamy[1], Grant Stalker[2], Laura Nichols[3], Jennifer Strouse[2], Miriah Gillispie-Taylor[4], Beth Scholz[5] and Sonam Kiwalkar[6], [1]University of Iowa, Coralville, IA, [2]University of Iowa, Iowa City, [3]University of Colorado, Aurora, CO, [4]Baylor College of Medicine/Texas Children's Hospital, Houston, TX, [5]Baylor Scott and White Health, Temple, TX, [6]The Vancouver Clinic, Portland, OR

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2159–2194) Professional Education Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Electronic flashcards (EF) have become a widely used study tool by medical students. One of the most well-known is the spaced repetition program Anki. There are many widely available online decks with thousands of cards that have been crowd sourced. Of the decks available, there is a lack of vetting by experts in the field of rheumatology to confirm the accuracy of the information. The aim of this project is to develop a free and accurate resource to aid medical students in learning relevant teaching points related to adult and pediatric rheumatology.

Methods: A collaborative group of four rheumatologists, one rheumatology fellow, one internal medicine resident, and one medical student was assembled. The decision was made to target United States Medical Licensing Examination (USMLE) Step content with the intention of developing an EF deck for undergraduate medical education. Using a backward design approach questions were developed based on USMLE content outlines. Learning objectives and subsequent testing points were created. These were reviewed by the rheumatologist and rheumatology fellow co-authors for accuracy.

A pilot deck of Anki flashcards was created for crystalline arthritis. These were again reviewed. The approved deck is being distributed to medical students to provide quantitative and qualitative feedback.

Results: We identified 12 USMLE organ systems with rheumatology related content, 29 categories within these, 15 subcategories, and subsequent listed conditions were then identified. From these listed conditions, 15 topic condition groups were developed. Through the selection process, crystalline arthritis was selected for a pilot deck. Fifteen learning objectives pertaining to crystalline arthritis were created using Bloom's taxonomy followed by 50 testing points. After review and feedback by co-authors 55 questions were developed from the testing points. Ranking of the fifteen highest yield questions by team members narrowed this to the 15 most relevant questions. During the development of Anki cards to best fit this format 28 cards were created.

Conclusion: Using backward design to work from content outline topics to objectives to testing points was helpful in guiding the development of a comprehensive yet succinct deck of Anki EFs. Having diverse levels of training in the collaborative group was helpful given the student's and resident's experience using Anki cards. Students provided faculty development sessions regarding effective use of Anki EFs. Creation of a deck of EFs by experts in rheumatology was feasible.

These cards are being piloted with medical students to obtain both qualitative and quantitative student feedback. Based on feedback from this pilot the goal is to have multi-center implementation of a standardized and broadly applicable deck.

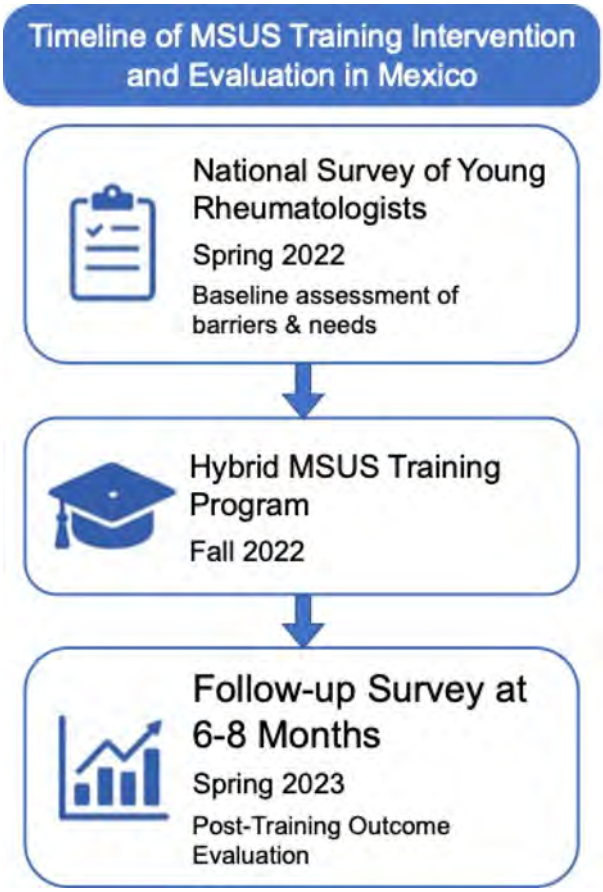
SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2159–2194) Professional Education Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Musculoskeletal ultrasound (MSUS) is a valuable diagnostic tool in rheumatology, yet access to formal MSUS training in Latin America remains limited. In a 2022 national survey, early-career Mexican rheumatologists reported high interest in MSUS but faced substantial barriers. To address this gap, we implemented and evaluated a hybrid MSUS training course. This study compares national survey data with outcomes from course participants to assess the impact of targeted hybrid training on clinical use, training exposure, and institutional integration of MSUS.

Methods: We conducted a cross-sectional analysis of two cohorts. The 2022 cohort (N=96) consisted of early-career rheumatologists across Mexico who responded to a national survey on MSUS access, training, and clinical use. The 2023 cohort (N=21) included participants who completed a structured hybrid MSUS training program (online modules + in-person workshop) and completed a follow-up survey three months post-course. Surveys assessed prior training, current MSUS use, educational preferences, institutional context, and barriers. Descriptive statistics and chi-square or Fisher's exact tests were used to compare groups.



Timeline of a hybrid MSUS training intervention and evaluation in Mexico. Figure 1. Timeline of a hybrid MSUS training intervention and evaluation in Mexico. A three-phase study was conducted to assess access to musculoskeletal ultrasound (MSUS) training and the impact of a hybrid education intervention among early-career rheumatologists in Mexico. In Phase 1 (Spring 2022), a national needs assessment survey (N = 96) identified barriers to MSUS training and utilization. In Phase 2 (Fall 2022), a structured hybrid MSUS course combining online modules and in-person workshops was delivered. In Phase 3 (Spring 2023), a follow-up survey of course participants (N = 21) evaluated changes in MSUS practice, training exposure, and institutional support. The intervention was associated with higher MSUS usage and training engagement relative to national trends.

>4 years	16 (23.19%)	13 (23.64%)	3 (21.43%)	
Unknown	17 (24.64%)	17 (30.91%)	0 (0.00%)	
Attitudes				
Believe MSUS is or should become a standard tool in Rheumatology	113 (97.41%)	93 (97.89%)	20 (95.24%)	0.5
Believe MSUS is a standard tool in Rheumatology	98 (85.22%)	79 (83.16%)	19 (95.00%)	0.3
Believe MSUS should become a standard tool in Rheumatology	109 (93.16%)	89 (92.71%)	20 (95.24%)	>0.9

Results: Participants in the hybrid training intervention demonstrated significantly higher MSUS utilization (47.6% vs. 20.8%, p=0.011) and more frequently had ≤1 year of MSUS experience (80% vs. 34.2%). Prior MSUS training was also more common (76.2% vs. 57.3%), while awareness of workshops (19.1% vs. 55.2%, p=0.003) and online courses (14.3% vs. 39.6%,

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

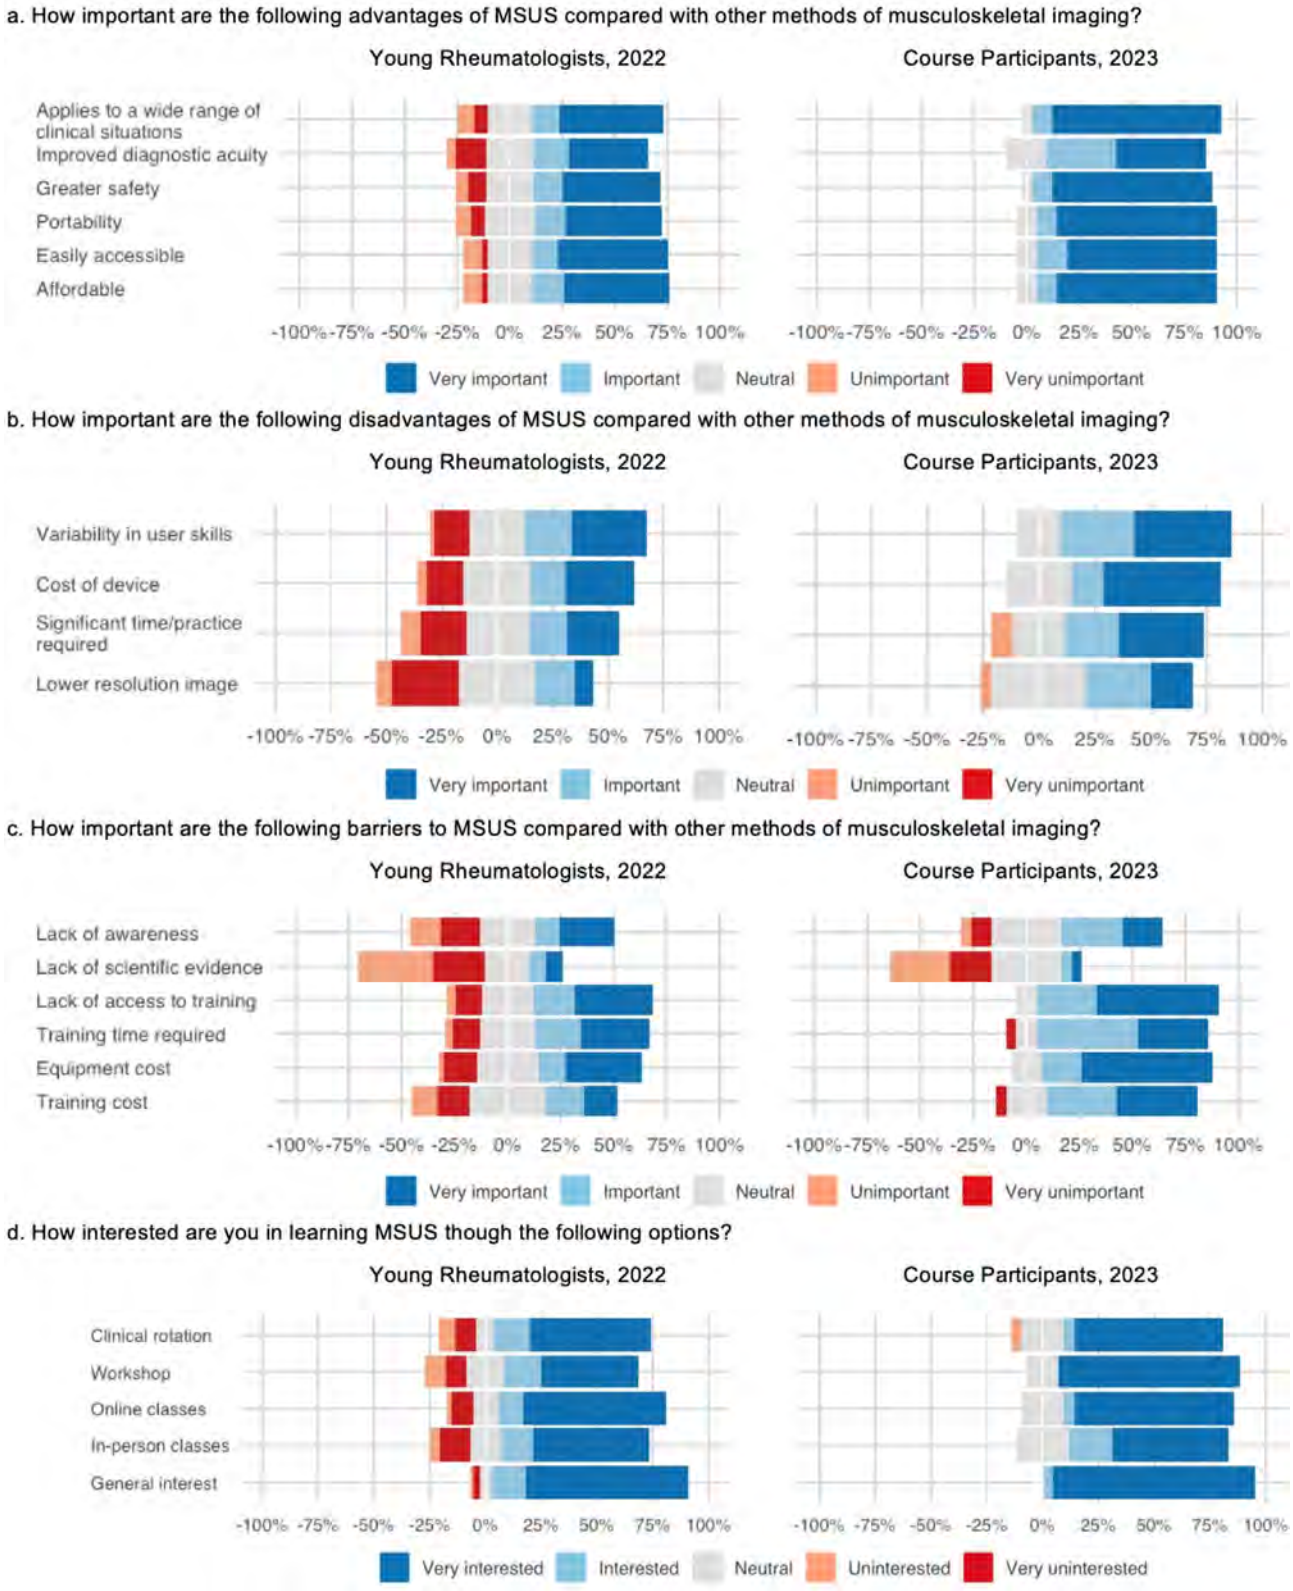

Figure 2. Comparative perceptions of musculoskeletal ultrasound among early-career rheumatologists following a national survey and a hybrid training intervention. Perceptions of MSUS access, training, and clinical use were assessed in two cohorts of early-career rheumatologists in Mexico. The figure illustrates differences in reported advantages, disadvantages, barriers, and preferences for future education modalities. Between-group comparisons highlight the potential impact of targeted hybrid training on early adoption and institutional integration of MSUS.

23265205, 2025, 59, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

p=0.028) was lower. Hybrid participants showed greater preference for online training formats (p=0.014), and more frequently cited training cost (p=0.018) and equipment access (p=0.064) as barriers. Institutional MSUS use and departmental experience were also significantly more prevalent in the course cohort (p=0.026).

Conclusion: A hybrid MSUS training intervention for early-career rheumatologists in Mexico led to increased MSUS utilization, institutional integration, and training exposure compared to national trends. These findings highlight the potential of scalable hybrid education models to address training gaps and promote equitable MSUS adoption in underserved settings. This underscores the need for broader implementation strategies and institutional investment to build rheumatologic imaging capacity across Latin America.

Abstract Number: 2188

Enhancing Pediatric Rheumatology Education Through Case-Based Learning: Impact on Knowledge, Confidence, and Elective Interest

Nayimisha Balmuri, Hopkins, Baltimore

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2159–2194) Professional Education Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Pediatric rheumatic diseases are rare and frequently under-recognized by trainees, leading to delayed diagnosis and referral. To address this gap, we developed a case-based curriculum to enhance resident knowledge, confidence, and interest in pediatric rheumatology. The objective of this study was to evaluate the impact of a four-

Figure 1. Pre- and Post-session knowledge scores by session topic.
Mean knowledge scores (out of 5) improved for all topics. Paired t-tests showed statistically significant improvements for JDM (p = 0.0097) and SLE (p = 0.0021), a strong trend for JIA (p = 0.055), and no significant change for Systemic Vasculitis (p = 0.31).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

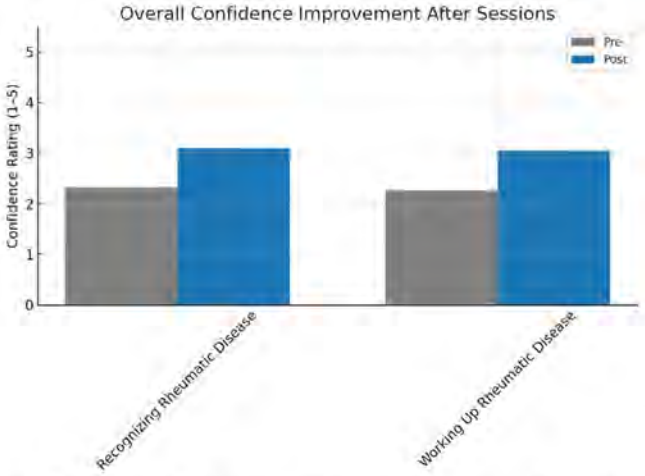

Figure 2. Overall confidence improvements across all sessions.
Across all sessions, confidence in recognizing rheumatic disease improved from a mean of 2.37 to 3.13, and confidence in working up disease improved from 2.36 to 3.10. Both differences were statistically significant ($p < 0.001$, Wilcoxon signed-rank tests).

session case-based curriculum on resident knowledge, confidence in recognizing patients with rheumatic disease and initiating workup for pediatric rheumatology patients, and creating subspecialty interest in pediatric rheumatology.

Methods: Four interactive, case-based group learning sessions were delivered on systemic vasculitis, juvenile idiopathic arthritis (JIA), systemic lupus erythematosus (SLE), and juvenile dermatomyositis (JDM). Participants completed identical pre- and post-session knowledge assessments (5-item quizzes) and a post-session survey assessing retrospective pre- and post-confidence in recognizing and working up pediatric rheumatic diseases (5-point Likert scale). The survey evaluated session usefulness, prior pediatric rheumatology elective experience, and elective interest. Paired t-tests and Wilcoxon signed-rank tests were used for pre/post comparisons; ANOVA and Kruskal-Wallis tests were used for PGY-level comparisons.

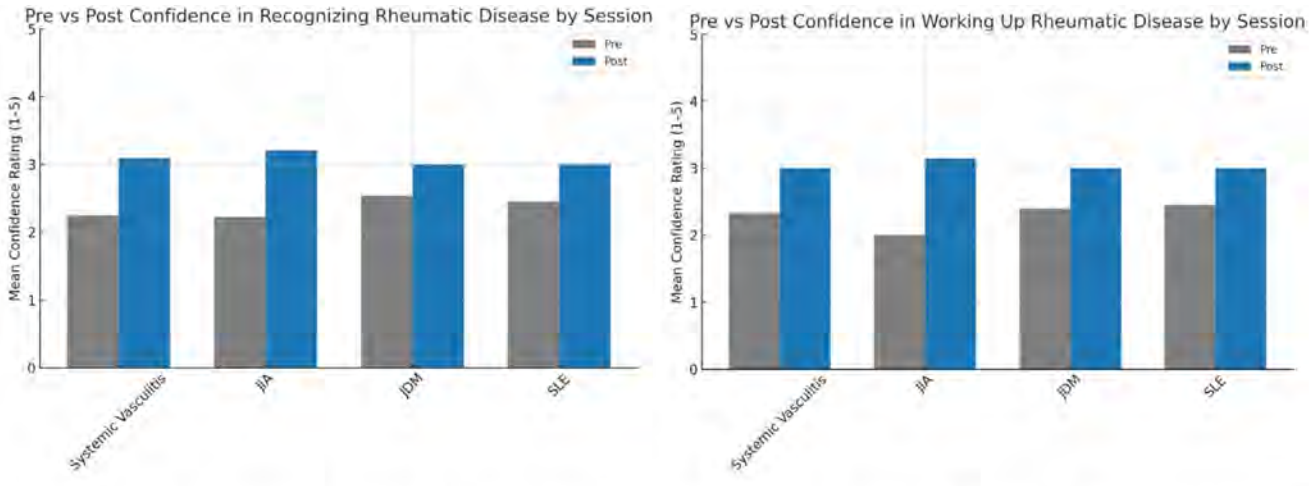

Figure 3. Pre - and Post-session confidence in recognizing rheumatic disease and working up rheumatic disease by session topic. Mean confidence ratings (1–5 scale) improved across all topics. Wilcoxon signed-rank tests showed statistically significant increases for all sessions. All changes were statistically significant ($p < 0.05$).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Forty-six evaluations were collected. Knowledge scores significantly improved for JDM (p= 0.0097) and SLE (

p= 0.0021); JIA showed a positive trend (p= 0.055), while vasculitis did not reach significance (p= 0.31). Confidence significantly improved in all sessions for both recognizing and working up rheumatic disease ($p < 0.05$ for all). PGY2 residents had the highest post-session knowledge scores (p= 0.034); PGY3s had the lowest baseline confidence in recognizing disease (p= 0.040), though post-session confidence was similar across PGY levels. All participants reported that the sessions were helpful for general pediatrics. While only 8–33% had previously completed a pediatric rheumatology elective, 67–78% reported increased interest in pursuing one after the session.

Conclusion: A brief, structured case-based curriculum significantly improved resident knowledge and confidence in evaluating pediatric rheumatic disease and enhanced interest in subspecialty electives. These findings support broader integration of targeted rheumatology education into pediatric residency training.

Physician Practices and Perspectives in the Diagnosis and Management of Fibromyalgia: A US Chart Review Study

Daniel Clauw[1], **Parul Houston**[2], Zhao Yang[2], Todd Grinnell[2] and Lesley Arnold[3], [1]Chronic Pain and Fatigue Research Center, University of Michigan, Ann Arbor, MI, [2]Axsome Therapeutics, Inc, New York, NY, [3]University of Cincinnati College of Medicine, Cincinnati, OH

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2159–2194) Professional Education Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Fibromyalgia (FM) is a chronic, widespread pain disorder driven by dysregulated central pain processing, which impairs daily function and quality of life. Current understanding of clinicians' knowledge, practices, and perceptions towards FM in the real world is critical to identifying gaps in FM management and informing future treatment strategies. A national chart review was conducted among US-based healthcare providers (HCPs) caring for patients with FM to characterize their views and understanding of FM, diagnostic and treatment practices, and satisfaction with current therapies.

Methods: An online chart review was conducted from December 2023 to January 2024 among 199 US HCPs with FM expertise, including primary care physicians (PCPs), rheumatologists, pain specialists, and aligned nurse practitioners and physician assistants. Eligible HCPs had been practicing ≥2 years, treated ≥20 adult patients with FM over the past 3 months, and were aware of duloxetine, milnacipran, or pregabalin. Each HCP contributed data from 2 patient charts.

Results: A total of 398 patient charts were reviewed by 199 HCPs, including 99 rheumatologists, 50 pain specialists, and 50 PCPs. Respondents were highly experienced, managing an average of 91 patients with FM each over the past 3 months. Among all respondents, 70% of treating rheumatologists had also diagnosed the patients themselves (vs 58% of PCPs and 38% of pain specialists). Across specialties, multiple diagnostic tools were used: tender point exams (79%), diagnosis by exclusion (69%), and American College of Rheumatology or ACTTION-APS Pain Taxonomy criteria (68%).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The average age of patients with audited charts was 48 years, with most respondents agreeing that the age of their newly diagnosed patients had decreased in recent years. Across specialties, pain (81%), followed by fatigue (57%) and muscle tenderness (51%) were key drivers of treatment decisions. There was no clearly defined standard of care among pharmacotherapies. Across all respondents' treated patients, duloxetine, gabapentin, and pregabalin were evenly used across lines of therapy; use of opioids (including tramadol) was more common in the third line and beyond (33% of ≥third line patients). Most respondents (88%) were comfortable prescribing multiple pharmacotherapies for FM, despite 76% expressing concern about drug-drug interactions. Respondents reported that 39-51% of patients were dissatisfied or coping but interested in switching treatments. Most (59%) viewed FM patients as time-consuming to manage, and 32% believed most of their patients were unlikely to improve despite treatment. A large majority (85%) believed FM is stigmatized by the HCP community.

Conclusion: This recent patient chart review among US-based HCPs who are highly experienced in managing patients with FM shows continuing variability in diagnostic and treatment practices, limited satisfaction with current therapies, and concern that patients are unlikely to improve despite treatment even though progress has been made in disease area knowledge and earlier identification. Greater knowledge of FM, its diagnosis and management, and new treatment options will help further support patient care and improve outcomes.

Abstract Number: 2190

Successful Implementation of an Innovative Rheumatology Curriculum for Internal Medicine Residents: Fellow-Initiated Rheumatology EDUcation Project (FIRED UP)

Raeann Bowman[1], Edward Huddleston[2], Bailey Lipham[3] and Amanda Alexander[4], [1]University of Alabama Birmingham / UT Southwestern, Gardendale, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]University of Alabama Medical School, Vestavia Hills, AL, [4]University of Alabama at Birmingham, Homewood, AL

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2159–2194) Professional Education Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatology is an important field with topics encountered commonly on board exams and clinically, yet it remains an area of low confidence for trainees. This innovative project seeks to increase resident competency and confidence in rheumatology topics. As a part of this unique project, fellows also expand and gain confidence in their teaching skills.

Methods: Internal medicine residents rotating on the rheumatology consult service at University of Alabama Birmingham (UAB) were asked to answer a pre-rotation quiz and survey to gauge initial rheumatology knowledge and confidence. Rheumatology fellows voluntarily signed up to develop and deliver weekly didactics to the residents on common or high-yield rheumatology topics of their choice.

The primary outcome was residents' gain in rheumatology knowledge as measured by changes in objective quiz assessment and subjective self-assessment obtained at baseline compared with assessments obtained after rotation completion. The pre- and post-tests contained similar, but not identical, questions randomized from a set in order to best gauge learners'

Table 1: Resident assessments show increased rheumatology knowledge by objective measures and self-assessed measures. Objective assessment was based on percent correct of 10 randomized unique multiple choice quiz questions both before and after rotation. Self-assessments were rated on a 1 to 10 scale, with 10 being the highest.

	Before Intervention	After Intervention	Difference
Objective Assessment			
Average % correct (range)	*n=12*	*n=8*	
Knowledge Assessment	62.5% (30-90%)	83.8% (70-100%)	+21.3%
Self Assessment			
Score on 10-point scale (range)	*n=13*	n=7	
Interest in Rheumatology	6.15 (2-10)	5.14 (1-10)	-1.01
Importance of Rheumatology	7.38 (4-10)	7.86 (5-10)	+0.48
General Rheumatology Knowledge	4.83 (2-7)	5.86 (3-8)	+1.03
Ability to Recognize Rheumatic Disease	5.62 (2-8)	6.86 (3-10)	+1.24
Confidence in diagnosis of:			
Gout	6.85 (4-9)	7.57 (4-10)	+0.72
Rheumatoid Arthritis	5.77 (3-9)	6.71 (4-10)	+0.94
Lupus	5.38 (3-9)	6.43 (3-10)	+1.05
Systemic Sclerosis	4.15 (1-6)	5.86 (2-8)	+1.71
Confidence in treatment of:			
Gout	6.92 (5-9)	7.57 (5-9)	+0.65
Osteoarthritis	7.62 (5-10)	8.29 (5-10)	+0.67
Scleroderma Renal Crisis	3.31 (1-8)	6.29 (2-9)	+2.98

increase in knowledge rather than recalling the correct answers. We also evaluated changes in learner confidence in diagnosing common rheumatic diseases (gout, rheumatoid arthritis, lupus, scleroderma), and confidence in treating common or important diseases encountered in rheumatology (gout, osteoarthritis, scleroderma renal crisis). First year fellows completed surveys before and after participation in the project regarding career plans and confidence in teaching skills.

Table 2: Fellows gained confidence in overall teaching skills and ability to plan and deliver a teaching session after implementation of the program. Self-assessments were rated on a 1 to 10 scale, with 10 being the highest. Post-fellowship plans were determined by a multiple-choice question, absolute difference is reported.

Self-Assessment	**Before Intervention**	**After Intervention**	**Difference**
Score on 10-point scale (range)	*n=3*	*n=3*	
Interest in Medical Education	8 (7-10)	8 (7-9)	0
Confidence in:			
Overall Teaching Skills	6 (6-6)	7.33 (7-8)	+1.33
Planning a Session	6.33 (6-7)	8.66 (7-10)	+2.33
Delivering a Session	6 (6-6)	8 (7-10)	+2
Post-fellowship plans			
Multiple choice n(%)			
Private practice	0	0	
Academics - research	0	0	
Academics - clinical educator	0	2 (67%)	+2 clinical
Academics - undecided focus	1 (33.3%)	0	educators
Undecided	2 (67.%)	1 (33.3%)	

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

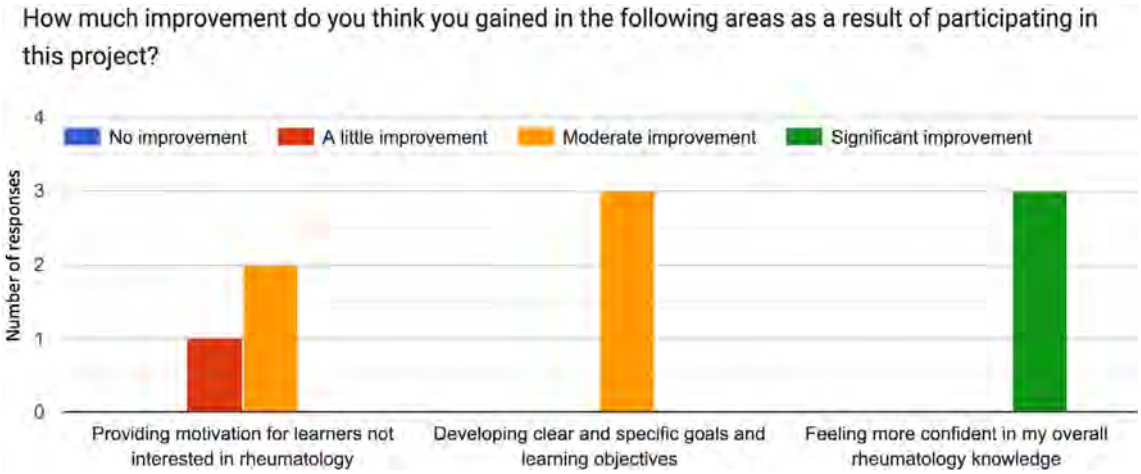

Figure 1: All fellows reported some level of improvement in key teaching skills. All fellows reported significant improvement in their personal overall rheumatology knowledge.

Results: A total of 15 internal medicine residents voluntarily completed at least one portion of the evaluations (n=12 pre-rotation quiz, n=8 post-rotation quiz; n=13 pre-rotation survey, n=7 post-rotation survey). Average pre-rotation quiz scores were 62.5% correct compared with 83.8% correct post-rotation (Table 1). The lowest area of confidence for learners was perception of the ability to treat scleroderma renal crisis (3.31 out of 10 confidence). The area of highest confidence for learners was perception of the ability to treat osteoarthritis (7.62 out of 10 confidence). Post-rotation, there was observed increase in self-assessed confidence in all surveyed areas, with the largest increase in treatment of scleroderma renal crisis (from 3.31 out of 10 confidence to 6.29 out of 10 confidence). Fellows reported increased confidence in overall teaching skills as well as ability to plan and deliver a successful teaching session (Table 2). All fellows reported significant improvement in their overall rheumatology knowledge as a result of participating in the project (Figure 1).

Conclusion: This project highlights the importance of dedicated rheumatology education within internal medicine and provides a unique way to directly engage rheumatology fellows in the education of medicine residents with mutually beneficial effects.

29.	Energy conservation in RA	35.8	40.7	23.5	70.7	18.6	10.7	Y

Background/Purpose: Long-term outcomes in rheumatic diseases are impacted by their timely diagnosis, institution of correct treatment, management of complications and rigorous joint preservation strategies. The first point of contact in countries like India is the primary care physicians (PCP) who is either a general physician or an orthopaedician. Therefore, we designed this study to assess their knowledge base about various aspects of RA management and to show if this knowledge base could be improved by giving a short information course.

The aim of the study is to develop, validate and assess the performance of a self-prepared questionnaire for assessing PCP's knowledge about managing various aspects of RA and to use this tool to assess the impact of an information course in improving the above-mentioned elements among them.

Methods: A self-prepared questionnaire (in English) containing 29 multiple choice or true-false type questions with single correct answer assessing PCP's knowledge about RA in 3 domains (a. etiology, disease process, signs & symptoms b. drug therapy & monitoring c. joint protection, exercise, coping) was prepared. All questions had an item-level content validity index (I-CVI) of at least 0.9. The scale-level content validity index based on the universal agreement method (S-CVI/UA) was 0.8 for the whole questionnaire as assessed by 6 experts. All questions had an option of 'I don't know' which would prevent them from guessing the answer from the available options. Each question was given a score of 1 if answered correctly. The questionnaire was applied 2 times: at baseline and immediately after an information course to see the immediate impact. Information on the PCP's experience with treating RA and their specialty was also collected. Frequency data were compared using McNemar test for paired nominal data & kappa statistics for ordinal data. Student's paired t-test was used for comparison of mean scores to see the impact.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: At baseline, the questionnaire was applied to 293 PCPs (General Physicians: Orthopedicians = 81.2:18.8) and the mean(±SD) score was modest (16.68±6.027). Among these, 76 PCPs recorded a response after the information course. The option 'I don't know' was exercised 998 times (11.74%) before the information course which reduced to 127 (5.76%) times after the course.

After the information course, 26 out of 29 questions recorded a higher absolute number of correct responses than before the course. This increase in 20 out of 29 questions achieved statistical significance (Table–1). The mean(±SD) score for the questionnaire improved from 16.68(±6.027) to 22.2(±7.17) ($p< 0.001$) (Table-1).

The scores before the information course were significantly different among general physicians and orthopedics. However, after the information course, no difference was noted among their scores, which suggests that the information course was equally effective for PCPs from both specialties.

Conclusion: Indian PCPs have a modest knowledge base about various aspects of RA management which can be improved significantly by short information course. The information course is equally effective irrespective of their specialization background.

Abstract Number: 2192

Survey of Healthcare Providers' Knowledge and Attitudes Toward the Management of Uncontrolled Gout

Shilpa Sharan[1], Clare Sonntag[2], Beth Miller[1], Kaitlyn Mayer[1] and Nissreen Elfadawy[3], [1]The HWP Group, Upper Saddle River, NJ, [2]The HWP Group, Upper Saddle River, [3]University Hospitals, Geauga Medical Center, Chardon, OH

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2159–2194) Professional Education Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Although uncontrolled gout (UG) is an inflammatory arthritis triggered by crystallization of monosodium urate within joints following hyperuricemia, increasing evidence supports its classification as a systemic disorder with significant renal implications.[1] Despite this evolving paradigm, UG management remains fragmented across the specialties of rheumatology and nephrology. We deployed a survey intended to evaluate rheumatologists' and nephrologists' understanding of UG, elucidate their attitudes toward evolving UG management paradigms, and identify barriers to nephrology-led care across specialties.

Methods: A 10-question online survey was distributed to practicing rheumatologists and nephrologists. The survey assessed respondents' clinical demographics, UG classification preferences, UG management strategies, perceptions of nephrologists' role in UG care, and resources needed to support nephrologists' involvement. Descriptive statistics were used to summarize results.

Results: In total, 48 nephrologists and 13 rheumatologists completed the survey. The majority of respondents currently work in an academic setting (82%) and have been practicing for over 10 years (52%; **Fig. 1**). Although both specialties

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

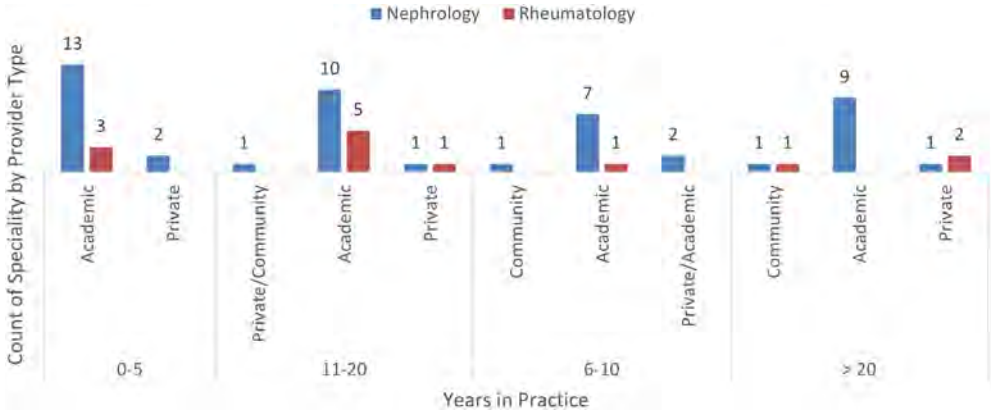

Figure 1. Respondents' clinical practice demographics.

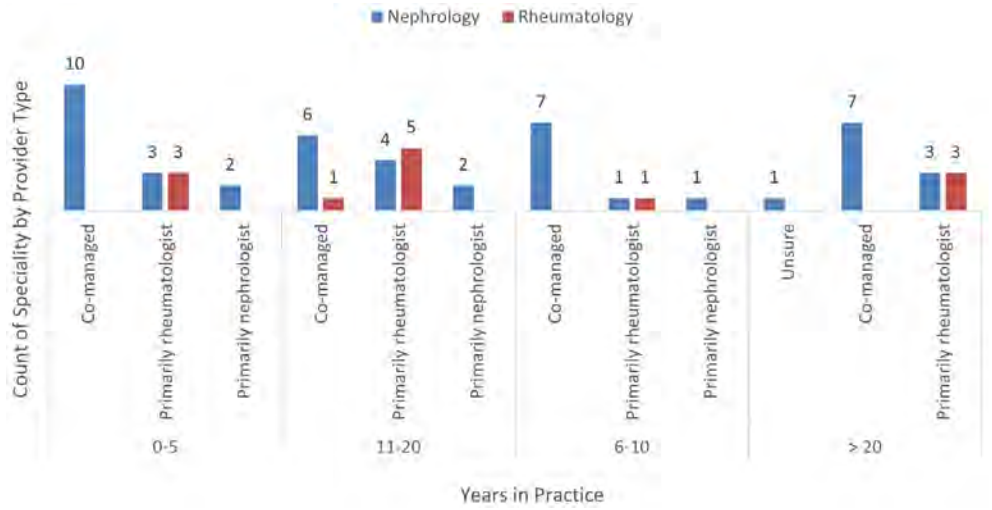

Figure 2. Respondents' preferred uncontrolled gout management approach.

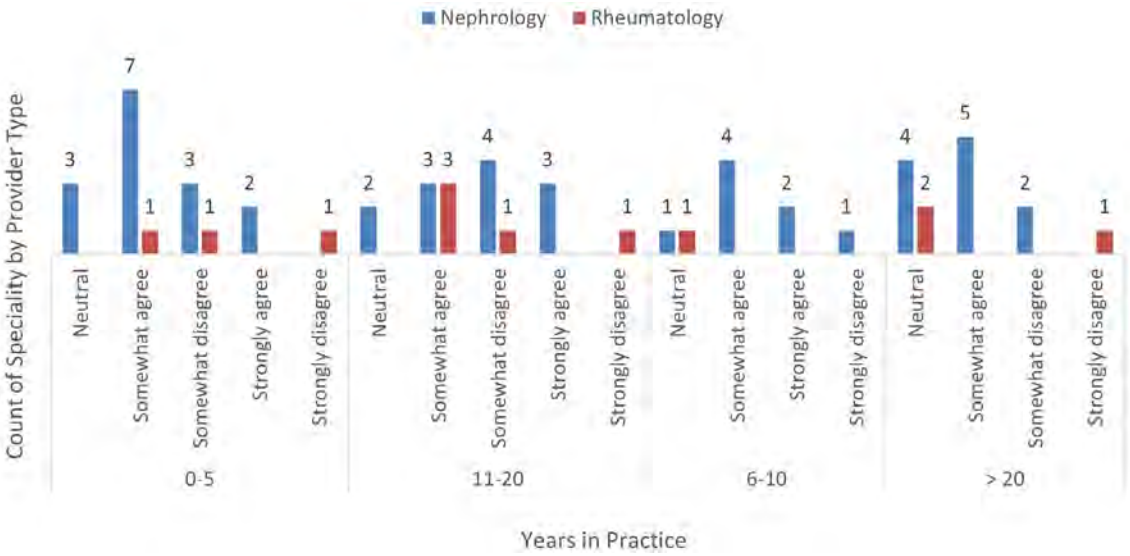

Figure 3. Respondents' expectations of nephrologist-led uncontrolled gout care over the next 5 years.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

largely agreed on the systemic nature of UG, respondents diverged sharply on preferred strategies for disease management. Rheumatologists overwhelmingly supported rheumatology-led care (92%). In contrast, 23% of nephrologists favored rheumatology-led care, 63% preferred co-management with a rheumatologist, and 10% believed that nephrologists should primarily manage UG (**Fig. 2**). Support of co-management across specialties was highest among early-career nephrologists (57% in 0-10 years) but declined with seniority (23% in >20 years). Similarly, 50% of early-career nephrologists (0-10 years) vs 20% of nephrologists practicing for over 10 years believe nephrologists will increasingly manage UG over the next 5 years. Only 31% of rheumatologists anticipated growing nephrology involvement in care over the next 5 years (**Fig. 3**).

Barriers to nephrology-led care were consistent across groups: unclear treatment guidelines, limited renal-safe therapies, and insufficient education/training. Academic nephrologists prioritized guidelines and renal-safe options, whereas those in private/community settings cited medication access as a barrier. Both groups emphasized the need for stronger collaboration to bridge specialty silos.

Conclusion: This survey reveals a shared recognition of the systemic complexity of UG, but specialists are not precisely aligned in how they envision its care. Although this expectation is not supported by rheumatologists, nephrologists—especially those early in their careers and in academic settings—anticipate playing a larger role in UG care. Across both groups, the lack of clear nephrologist-focused treatment guidelines, renal-safe treatment options, and formal collaboration pathways remain formidable obstacles. Empowering nephrologists through education, collaborative frameworks, and tailored treatment guidance may accelerate adoption of this evolving paradigm.

Inpatient Rheumatology Consultations at a Tertiary Academic Medical Center: A Retrospective Cohort Study

Shivang Chaudhary[1], Ruizhi Huang[2], Roxann Kirkwood[2], Laura Upton[1], Paula Buchanan[2] and Adam Kilian[1], [1]Saint Louis University, St. Louis, MO, [2]Advanced Health Data (AHEAD) Institute, St. Louis, MO

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2159–2194) Professional Education Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatology consultations are essential for managing complex inpatient cases, yet patterns and outcomes remain understudied. Prior work has shown that consult data can inform fellowship curricula. This study characterizes the timing, indications, and diagnoses of inpatient rheumatology consults at a large academic hospital, with the goal of informing future educational initiatives and improving inpatient rheumatology care and training.

Methods: We performed a retrospective cohort study of inpatient rheumatology consults at a tertiary academic medical center from July 2021 to July 2024. Adult patients (≥18 years) admitted to non-rheumatology services and received an inpatient rheumatology consult were included. We analyzed timing, diagnostic categories, and impact using descriptive

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

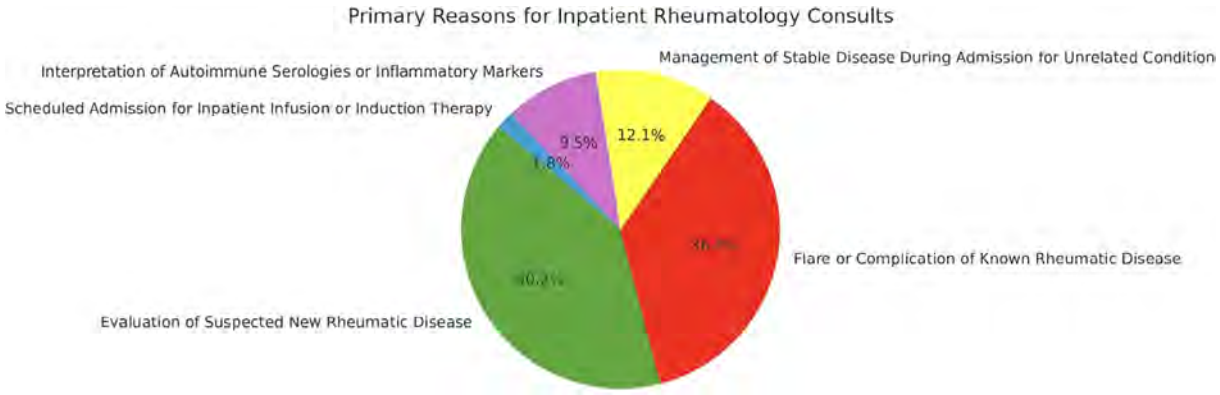

Figure 1: Distribution of the primary reasons for inpatient rheumatology consults

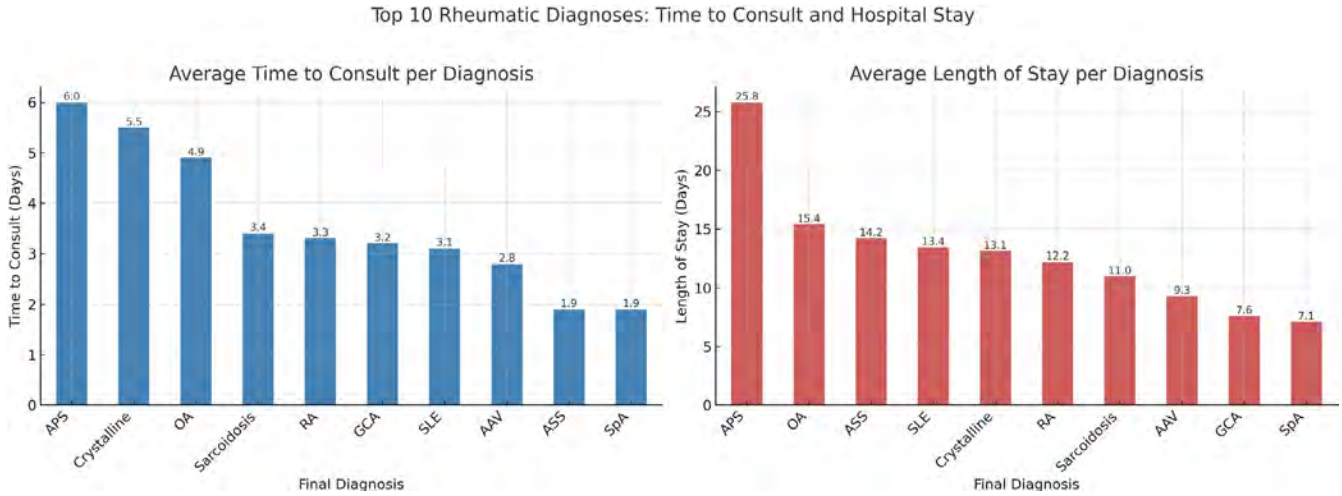

Figure 2: Average time to rheumatology consultation and hospital length of stay for the ten most common rheumatic diagnoses among inpatient consults.

statistics. Mann–Whitney U tests compared hospital stay duration and time to consult between patients with and without prior outpatient rheumatology follow-up. Significance was set at $p < 0.05$. All analyses were performed using RStudio (version 2023).

Results: Among 503 consults reviewed, the median time to consult was 1 day (mean 3.0), and average length of stay was 12.5 days. Most consults occurred on day 4 or later. The most common consult indications were suspected new rheumatic disease (40%) and flares of known disease (36%) (Figure 1). New rheumatic diagnoses were made in 21% of cases, most often crystalline arthritis (18), SLE (11), and necrotizing myopathy (8). Suspected new disease consults frequently resulted in non-rheumatic diagnoses (50%), while SLE (22%) and crystalline arthritis (10%) were the most common diagnoses among flares.

The most common rheumatic diagnoses were SLE (75), crystalline arthritis (36), RA (36), ANCA-associated vasculitis (15), spondylarthritis (14), OA (10), sarcoidosis (10), antisynthetase syndrome (9), GCA (9), and APS (8). Among these, APS had the longest average hospital stay (25.8 days) and longest mean time to consult (6.0 days). Crystalline arthritis and

Table 1: Impact of prior outpatient rheumatology follow up on inpatient consult timing and hospital stay

Variables	*Overall*	Yes	No	p
	N = 222	N = 92	N = 130	
Time to Consult, IQR	*2(1, 4)*	2(1, 3)	3(2, 5)	0.001
Length of Stay, IQR	*9(6, 16)*	9(6, 15)	9(5.25, 16)	0.873
Notes: Mann-Whitney U test				

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

sarcoidosis also had delayed consultations (5.5 and 3.4 days, respectively), while antisynthetase syndrome and SLE were linked to longer stays (14.2 and 13.4 days, respectively) (Figure 2).

Among patients with these diagnoses, those with outpatient rheumatology follow-up within 12 months were evaluated more promptly, with a median time to consultation of 2.0 days (IQR 1.0–3.0) versus 3.0 days (IQR 2.0–5.0) for those without ($p = 0.001$). Median length of stay was similar between groups (9.0 days; $p = 0.873$) (Table 1).

Conclusion: Inpatient rheumatology consults are often delayed and frequently involve diagnostic uncertainty, particularly for suspected new disease. Among the most common rheumatic diagnoses, conditions like APS, crystalline arthritis, and SLE were associated with longer consult times and extended stays, highlighting opportunities for earlier recognition. Patients with recent outpatient rheumatology follow-up were seen significantly earlier, underscoring the value of continuity. We hope to use these findings to identify data-driven educational targets for hospital providers and improve inpatient rheumatology care.

Abstract Number: 2194

Utilizing Case-Based Learning to Teach the Teacher and Improve Health Insurance Literacy

Tyler Reese, Vanderbilt University Medical Center, Madison, TN

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2159–2194) Professional Education Poster
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: It is expected that pediatric rheumatology providers prepare adolescent and young adult (AYA) patients to successfully navigate the transition from a pediatric to an adult model of care. Health insurance literacy, and how to acquire health insurance, is one often neglected topic in this preparation. The loss of health insurance can be a highly disruptive event when transitioning to adult care and preparation in the pediatric clinic could reduce the incidence and duration of such an event. The Health Insurance Marketplace is a new way for many individuals to acquire health insurance at a significant discount; however, many pediatric providers have themselves never needed to navigate the health insurance marketplace and as a result may be unprepared to counsel patients on this topic.

Methods: This educational intervention utilized a case-based learning (CBL) technique to navigate the Healthcare.gov and consider health plans for an AYA in need of health insurance amongst pediatric rheumatology providers. It was hypothesized the pediatric rheumatology providers will have high health insurance literacy (as measured by the validated Health Insurance Literacy Measure (HILM)) but low familiarity with the health insurance marketplace (as measured by a novel Affordable Care Act (ACA) instrument) that will be improved following the CBL activity. Self-reported abilities were analyzed before and after as well. Two-tailed t-tests were used. Feasibility data were gathered for using the CBL tool in clinic with AYA patients.

Results: A total of 11 pediatric rheumatology providers, representing all providers in the division, participated in the intervention. 2 participants had incomplete data that was excluded. The minority of participants had ever needed to acquire individual health insurance (33.3%) or to navigate Healthcare.gov (33.3%). Time (100%) and knowledge (88.9%) were the most

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

HILM = Health Insurance Literacy Measure. 21 items with 4 item choices converting numerically to 1-4 with higher numbers indicated greater health insurance literacy. Possible scores range from 21 to 84. ACA = Affordable Card Act. 7 items (see Table 4 for individual items) with 1 correct and 3 incorrect answer choices. Possible scores range from 0 to 7 with higher numbers indicating a greater percentage of correct answers. Abilities were self-reported on 5 items (see Table 5 for individual items) on a score range from 0 to 100 using a sliding scale where 0 = strongly disagree, 50 = neutral, and 100 = strongly agree. Possible scores range from 0 to 500 with higher numbers indicating greater self-reported abilities.

Table 1 – Pre- and Post-Intervention Results

Participant	HILM Pre	HILM Post	ACA Pre	ACA Post	Abilities Pre	Abilities Post
2	70	77	4	7	239	423

Standard Deviation	11.10	5.74	0.97	0.67	52.45	43.82
p-value (t-test)		0.016		7.91E-06		3.24E-05

Table 2 - Feedback and Feasibility

(100 point sliding scale (0=strongly disagree, 50=neutral, and 100 = strongly agree))	Mean	SD
This learning activity could help patients learn more about health insurance	94.22	6.59
This learning activity could help providers learn more about health insurance.	96.11	5.44
I could complete this activity in clinic with patients.	58.00	23.99

frequent barriers to having health insurance discussions with patients. The pre-intervention and post-intervention results are displayed in Table 1 with significant improvements in the HILM, ACA instrument, and self-reported abilities. Quantitative feedback shown in Table 2 indicated that participants strongly agreed that the learning activity could help both patients and providers learn more about health insurance (mean 94.22 ± 6.59 and mean 96.11 ± 5.44 respectively on 100-point sliding scale). The result was more neutral if providers felt that they could complete this same learning activity in clinic with their patients (mean 58.00 ± 23.99). Time was noted as the greatest barrier by all participants in a free text response.

Conclusion: This study piloted the use of a CBL activity focused on navigating Healthcare.gov with pediatric rheumatology providers. It was hypothesized that most pediatric rheumatology providers would have a high health insurance literacy measured by the HILM but would have improvements in knowledge specific to the Affordable Care Act and Healthcare.gov. Contrary to the hypothesis, there were statistically significant improvements in both the HILM and ACA measures suggesting that providers may benefit more from this activity than anticipated.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2195–2226) Reproductive Issues in Rheumatic Disorders Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The rates of contraceptive counseling and treatment in immunosuppressed women of childbearing age remain low in the United States, despite ACR's Reproductive Health Guidelines on recommended contraception and pregnancy planning. This study evaluated contraceptive counseling, treatment rates, and the role of a rheumatology-pharmacy collaborative effort in a rheumatology clinic.

Methods: This cross-sectional study of reproductive-aged women on MTX or LEF, examined the rates of contraception counseling and use. Patients were screened from the rheumatology clinic schedule from 11/1/2024-1/31/2025 for female gender at birth, age 14-45, rheumatic diagnosis, and prescribed MTX or LEF. They completed a survey assessing demographics, contraceptive counseling, and treatment. Review of the electronic health record (EHR) provided information on health insurance, education level, established gynecological care, and enrollment in rheumatology-pharmacy co-managed care. We compared the counseling and contraceptive treatment rates for all patients, co-managed patients, and usual care for patients with rheumatologist alone. Comparison of co-managed care vs rheumatologist care alone for counseling and treatment were made with Fisher's exact test.

Results: One hundred three patients were identified by EHR. Sixty-eight patients completed the survey, of which 22 were excluded due to hysterectomy or tubal ligation. The study population consisted of the remaining 46 patients, requiring contraceptive counseling. Of these patients,16 were excluded post-counseling due to reporting partner vasectomy or abstinence, leaving 30 patients with indication for contraception (Figure 1). The patient characteristics were average age of 36.1 years, 85% white, 41% receiving gynecologic care, 63% with commercial insurance, 70% with college or higher education, and 39% enrolled in rheumatology-pharmacy co-management vs 61% rheumatology care alone (Figure 2). Contraceptive counseling was documented in 40/46 (87%) of patients (Figure 3). Rheumatology-pharmacy co-management counseling was documented in 18/18 (100%) vs rheumatology alone 22/28 (79%) (p=0.0678) (Figure 3). Of the 30 patients indicated for contraception, 24/30 (80%) were using contraception (Figure 3). Contraceptive use was reported in 10/11 (91%) of co-managed patients vs 14/19 (74%) of rheumatologist managed alone (p=0.3717) (Figure 3). Comparing to national data, our rates were superior for both contraceptive counseling (87% vs 35-56%) (Thiel de Bocanegra, Health Serv Res Manag Epidemiol.2018;5) and contraceptive treatment (80% vs 45-52%) (Ingram, JCR.2019; 27(3), 97-101).

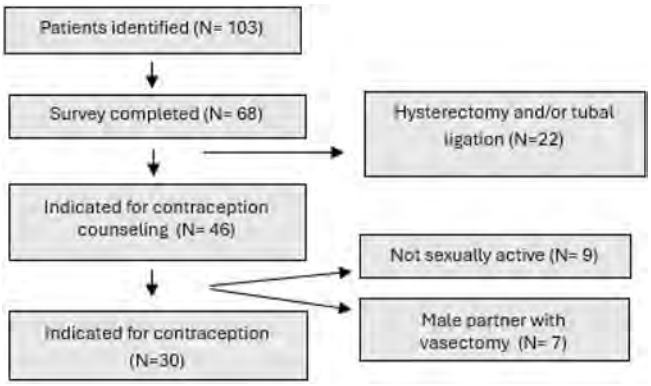

Figure 1. Patient stratification for contraception counseling and contraception use analysis. The initial patient screening revealed 103 qualifying patients. Only 68 surveys were completed. Patients who underwent a hysterectomy and/or tubal ligation were excluded from contraception counseling analysis, resulting in 46 patients indicated for counseling. Patients who endorsed they were not sexually active or had a male partner with a vasectomy were excluded from contraception use analysis, resulting in 30 patients indicated for contraception.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 2. Patient characteristics. * The group categorized as "Other" included reported ethnicites of Asian, Black/African American, Multi-ethnic, and Arabic. The remaining patient characteristics, including patient age, receiving gynecologic care, primary insurance type, presence of higher education, and enrollment in the pharmacy co-management program, were obtained via EHR review of the 46 patients indicated for contraceptive counseling.

Patient characteristics	N (%)
Reported race/ethnicity	
Caucasian/White	39/46 (84.8%)
Hispanic, Latino, Spanish	2/46 (4.3%)
Other*	5/46 (10.9%)
Patient age range	
30-39	21/46 (45.7%)
<30	11/46 (23.9%)
>= 40	14/46 (30.4%)
Receiving regular gynecologic care	
Yes	19/46 (41.3%)
No	27/46 (58.7%)
Primary insurance	
Commercial	29/46 (63.0%)
Medicaid	14/46 (30.4%)
Medicare	1/46 (2.2%)
Unknown	2/46 (4.3%)
Presence of higher education	
Grade 12 or less	13/46 (28.3%)
Higher education	32/46 (69.6%)
Unknown	1/46 (2.2%)
Enrolled in pharmacy co-management program	
Enrolled	18/46 (39.1%)
Not enrolled	28/46 (60.9%)

Table 3. Contraception counseling and treatment rates with usual care of rheumatologist alone versus rheumatology-pharmacy co-managed care. We compared the counseling and contraceptive treatment rates for all patients, co-managed patients, and usual care patients with rheumatologist alone. Comparison of co-managed care vs rheumatologist care for counseling and treatment were made with Fisher's exact test. *The lower section of the table is limited to the subset of patients indicated for contraception.

	Total patients	Pharmacy co-management	No pharmacy co-management	p-Value
Indicated for counseling	46	18/46 (39%)	28/46 (61%)	
Documented contraception counseling	40/46 (87%)	18/18 (100%)	22/28 (79%)	p=0.0678
No documented contraception counseling	6/46 (13%)	0/18 (0%)	6/28 (21%)	
Indicated for contraceptive treatment	30*	11/30 (37%)	19/30 (63%)	
Reported contraceptive use	24/30 (80%)	10/11 (91%)	14/19 (74%)	p=0.3717
No reported contraceptive use	6/30 (20%)	1/11 (9%)	5/19 (26%)	

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Our overall contraceptive counseling and treatment were superior to the national average. All patients who enrolled in the rheumatology-pharmacy co-management received counseling and 91% received treatment. This trend suggests that our co-management has contributed to our higher rates of both contraceptive counseling and treatment; however the analysis is underpowered due to the small co-managed population. This study indicates that we have made meaningful progress toward enhancing the safety of care provided to women with rheumatic diseases.

Abstract Number: 2196

Recognition and Treatment of Idiopathic Granulomatous Mastitis: A Case Series

Jenny Solomon[1], Julie Piccione[1], Julie Nusbaum[2], Steven Carsons[3] and Gregg Blumberg[1], [1]NYU Langone Long Island, Mineola, [2]NYU Langone Health, New York, NY, [3]NYU Long Island School of Medicine, Mineola, NY

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2195–2226) Reproductive Issues in Rheumatic Disorders Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Idiopathic Granulomatous Mastitis (IGM) is a rare benign inflammatory condition of the breast usually affecting women of childbearing age with a history of breastfeeding. It is characterized clinically by breast pain, erythema, mass(es), and recurrent or non-healing wounds, and is diagnosed histologically by the presence of non-necrotizing granulomatous lesions. It is theorized that when ductal epithelium is damaged, like in milk stasis, luminal secretions leak into surrounding lobular connective tissue and trigger the recruitment of macrophages and lymphocytes, causing local inflammation. It can be difficult to distinguish IGM from infectious mastitis or inflammatory breast cancer, often delaying diagnosis. The treatment of IGM largely consists of surgical intervention, local steroids, systemic steroids, and/or disease modifying anti-rheumatic drugs (DMARDs) without a universally accepted treatment algorithm.

Methods: Here, we present 8 patients evaluated in the NYU-Langone Long Island rheumatology academic office in 2025 diagnosed with IGM via histology and explore the patients' demographics, management, and outcomes after referral to rheumatology via chart review. We obtained IRB approval, s25-00399. We reviewed imaging of the affected areas, histopathology, and microbiology data.

Results: 8 cases were included, all of which were biological females. 3 patients (37.5%) identified as Hispanic, 3 (37.5%) identified as Asian (including East and Southeast Asian), and 2 (25%) identified as European/Caucasian. 50% used oral contraception. Radiographic information from patients' ultrasounds and/or mammograms was especially notable for 62.5% of cases containing tubular components, which is a more unique finding to IGM. 100% of patients underwent biopsy and histopathologic features included granulomatous inflammation (100%), fibrosis (25%), mastitis (25%), and necrosis (12.5%). All 8 patients in the series had healing of wounds, resolving of pain, and diminishing mass sizes. 7 patients (87.5%) were treated with prednisone with symptom improvement, with the addition of methotrexate in the 4 refractory cases (50%). 4 patients (50%) underwent multiple procedures including incision and drainage.

Conclusion: Greater understanding and recognition of IGM may expedite diagnosis and reduce morbidity. When histopathologic diagnosis of IGM is made, rheumatology referral should be made promptly. Our patients had a gap of approximately

Lobulocentric mastitis with acute and chronic inflammation evidenced by neutrophils and lymphocytes including few giant cells and focal ill-defined granuloma formation.

10 weeks from diagnosis of IGM to first rheumatology visit, with no further surgical procedures after rheumatology medical management. Patients often underwent multiple procedures including incision and drainage prior to diagnosis, which in conjunction with the inflammatory state of the breast, led to high risk of poor wound healing. This suggests earlier rheumatological evaluation may lead to swift treatment with glucocorticoids and DMARDs, resolution of symptoms, and prevention of deformity from repetitive surgical procedures. Our case series adds data to the knowledge base about IGM and may contribute to the development of treatment guidelines for the future.

Abstract Number: 2197

Mechanisms of Fetal Growth Restriction in Rheumatologic Autoimmune Diseases: Insights into Placental Pathology and Immune Dysregulation

Larabe Farrukh[1], Ananya Venkatesh[2], Mana Parast[2] and Chelsey Smith[3], [1]University of California San Diego, San Diego, CA, [2]University of California San Diego, San Diego, [3]University of California San Diego, LA JOLLA, CA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2195–2226) Reproductive Issues in Rheumatic Disorders Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Fetal growth restriction (FGR) significantly contributes to adverse pregnancy outcomes (APOs) in women with rheumatologic diseases. Understanding the immunopathologic mechanisms underlying FGR is critical for risk stratification and management. The objective of this study is to systematically review the immunologic/vascular mechanisms underlying FGR in systemic lupus erythematosus (SLE), antiphospholipid syndrome (APS), rheumatoid arthritis (RA), systemic sclerosis (SSc), ANCA-associated vasculitis (AAV), and seronegative spondyloarthropathies (SpA), and to characterize mechanistic pathways linking autoimmunity to FGR.

Methods: We conducted a systematic search of PubMed and Google Scholar for studies published between 1995 and 2024 that evaluated placental pathology, immune dysregulation, and pregnancy outcomes in women with rheumatologic diseases. Eligible studies included prospective cohorts, retrospective analyses, and placental histopathology investigations. Findings were synthesized narratively due to the heterogeneity of mechanisms.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: In SLE and APS, abnormal complement activation, impaired angiogenic signaling, and trophoblast dysfunction contribute to placental insufficiency and FGR. Elevated levels of complement activation products (Bb, sC5b-9) throughout gestation were associated with APOs. In APS, anti-phospholipid antibodies induce trophoblast apoptosis, impair spiral artery remodeling, promote thrombosis, and placental infarction. In RA, cytokine dysregulation, including elevated IL-6 and TNF-α levels and decreased IL-10, were linked to decidual vasculopathy and reduced pro-angiogenic signaling, contributing to low birth weight and preterm birth. In AAV, injury to the syncytiotrophoblasts and endothelial cells of the spiral veins can lead to chorangiosis and focal placental infarction associated with FGR and pre-eclampsia. In SSc, extensive decidual vasculopathy, stromal fibrosis, and hypoperfusion of chorionic villi led to high rates of FGR, preterm birth, and stillbirth. In SpA, elevated rates of preterm birth and cesarean delivery were observed, with limited but suggestive evidence of inflammatory placental lesions. Across diseases, impaired trophoblast function, vascular remodeling, and angiogenic imbalance emerged as overlapping mechanisms of placental insufficiency.

Conclusion: Autoimmune rheumatic diseases contribute to fetal growth restriction through diverse pathways involving immune-mediated placental injury and vascular dysfunction. Early identification of at-risk pregnancies and targeted therapeutic interventions addressing these mechanisms may improve neonatal outcomes. Further research is warranted to delineate disease-specific versus shared pathways to guide precision management strategies.

Abstract Number: 2198

Sociocultural Influences on Pregnancy Planning for Individuals Diagnosed with SLE in an Urban Hispanic Population: A Qualitative Study with Considerations for a Holistic Approach

Andrew Ramirez[1], Alexa Montes de Oca[1], Martha Delgado[1], Mellissa withers[1] and **Leanna Wise**[2], [1]University of Southern California, Los Angeles, [2]LAGMC/Keck Medicine of USC, Los Angeles

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2195–2226) Reproductive Issues in Rheumatic Disorders Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: As systemic lupus erythematosus (SLE) often affects women of child-bearing age, understanding how this population makes reproductive health decisions is critical for well-rounded healthcare. Individuals often need more than just SLE medical optimization to feel comfortable with attempting pregnancy; many extrinsic, non-medical factors play a role. In this qualitative thematic analysis study, we explored the perspectives of female participants of Hispanic ethnicity diagnosed with SLE to understand sociocultural non-clinical factors that influence pregnancy planning and contraception use.

Methods: We conducted a qualitative study using semi-structured interviews with 30 Hispanic women diagnosed with SLE, recruited from Los Angeles General Medical Center and LupusLA. Eligible participants were aged 18–45, of Hispanic ethnicity, sexually active with a male partner or considering pregnancy within three years, and fluent in English or Spanish. Interviews were conducted virtually in the participant's preferred language, recorded, and transcribed; Spanish interviews were translated into English. Interviews were conducted from June 2024 – March 2025. Sociocultural influences were collected via interview questions asking what non-clinical factors play a role in participants' decision-making to attempt pregnancy and/or use contraception, with a focus on participants' significant others, family, and sociocultural background. Data

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Participant demographics and clinical characteristics

Characteristics	English Interview Participants (n = 17)	Spanish Interview Participants (n = 13)
Age at time of interview (years)	32.47 ± 7.22	36.08 ± 7.71
Average length of time since SLE diagnosis at time of interview (years)	12.64 ± 6.60	12.46 ± 6.82
U.S. born	9 (52.94)	1 (7.69)
LAGMC recruitment	10 (58.82)	13 (100)
Any college education	12 (70.59)	3 (23.08)
Ever pregnant	9 (52.94)	11 (85.62)
Unplanned pregnancy after SLE diagnosis*	4 (23.53)	7 (53.85)
Desire for future pregnancy	11 (64.71)	8 (61.54)
Ever diagnosis of lupus nephritis	5 (29.41)	9 (69.23)

Data presented as mean ± SD or number of patients (%).

*Unplanned pregnancy defined as a pregnancy conceived when the individual was not actively intending/expecting to become pregnant with intercourse

Table 2. Themes, subthemes, and representative quotes from grounded theory analysis on sociocultural influences for pregnancy planning

Theme	Representative quotes
1. Financial, and to some, career stability, are extremely crucial when planning to conceive	"I wouldn't consider having a kid until I'm closer to 30 with a stable partner in a stable home with a stable income and little more used to and acclimated to my profession and everything". (25yo; English-speaking, 1 child; SLE for 13 years) "A human being comes into the world, and if you make that decision, it should be so that this human being can have a full life. And now, in these times, we think a lot about the economic aspect, about whether they'll have the opportunities they deserve." (34yo; Spanish-speaking; 2 children; SLE for 18 years)
2. Family support – significant other and primarily female family members have varying input	"Basically, [my partner] always told me, 'Whatever you decide, it's your body.] He saw how bad things were for me. I was in a life-threatening situation—essentially, one foot on the other side. He had to decide between me or the baby, and he chose me. But thank God, my son is fine […] it was scary for him too. I think that's why we decided not to have more children. We talked about it a lot beforehand and just decided no." (43yo; Spanish-speaking; 2 children; SLE for 18 years) "I've mentioned to my mom and my sister that we were discussing maybe having another child [...] my mom doesn't think it's a good idea. She's really, 'no, no, no, no, no. You're doing well like it is, and, you know, we're thankful everything went well with [your son]. And then I think you should just stop right there'. My sister, same thing" (44yo; English-speaking; 1 child; SLE for 25 years)
3. Background religious/cultural views have some influence on reproductive health *This participant noted the following regarding reproductive health in contemplation of her first and only pregnancy after SLE diagnosis.* *This participant was asked about how she would approach an unintended pregnancy regardless of disease control.* *A Spanish-speaking patient noted that reproductive health topics may be communicated less well because of cultural stigma (similar concerns were also voiced by English-speaking participants).*	"At the end of the day, you're not in control of it. The only person who's in control of it is God. And you know, if you're going to decide to let it go and just let him be the one to kind of take the wheel, then you got to do it, like 100%. It was those conversations where it's like you can't just keep going into the what ifs, because you're not in control anymore, you know. So I think that was helpful for me, where it was like, okay, God, let's do this together and figure this out. You're here by my side, just like the whole time I was pregnant, going to church every Sunday and seeing it through and taking it day by day [...] If you keep thinking you're going to be able to control everything, you're going to make yourself sick" (38yo; English-speaking; 1 child; SLE for 15 years) "Oh, look, I'm going to keep [him, past unplanned male pregnancy] because it's a miracle. I said, I didn't think I was going to get pregnant anymore. So yeah, it was more like that's my third child. That's how it happened. Oh, well, he's already here, you know? God sent him for a reason. I'm, you know, like, I'm going to keep this baby" (41yo; English-speaking; 3 children; SLE for 21 years) "It's very important that we know about [reproductive health and lupus] because there are a lot of fears, a lot of dread. I think there are women who decide, 'Oh, I'd rather not get pregnant because I don't want to know what could happen to me.' They don't even ask the questions they need to ask because they're afraid, or because the information isn't out there, or because it's not communicated well. And in our culture, I feel like it's still a taboo subject to talk about these things." (34yo; Spanish-speaking; 2 children; SLE for 18 years)
4. Online resources provide a diversity of information; some helpful/encouraging and some overwhelming *These quotes were in response to participants being asked about any other sources of reproductive health information that influence the way they view pregnancy.*	"Honestly, now that I'm thinking about it, it really was that support group that I was like ok, I think I can do this [attempt conception] [...] You're giving me that emotional and mental strength to be able to be like, I'm not alone, I can do this. Yes, it might not be a pretty picture. But they would talk about their kids and how much joy, and I was like, yes. Like I want this, and I want to try" (38yo; English-speaking; 1 child; SLE for 15 years) "I've actually kind of strayed away from the support groups because it's a lot of bad news. And sometimes it's hard to willingly sign up to listen to bad news." (28yo; English-speaking; no children; SLE for 10 years) "And the internet, really—all the tools and information you could possibly need, the internet is a very good source. Like Google or ChatGPT, things like that. They're good tools for accessing any kind of information you might want." (26yo; Spanish-speaking, no children; SLE for 11 years)

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

collection continued until thematic saturation was reached, and transcripts were analyzed using a grounded theory approach to identify sociocultural themes related to reproductive health decision-making. Coding was conducted by a multilingual, multidisciplinary team.

Results: A total of 17 English-speaking participants and 13 Spanish-speaking participants were interviewed (Table 1). Four sociocultural themes (Table 2) arose in both language groups which strongly influence patients' views on pregnancy: 1) financial/career security; 2) support of their family (significant others and extended family support); 3) underlying cultural or religious beliefs (largely being against termination for unexpected pregnancy unless absolutely necessary, as well as divine control of the reproductive journey; 4) virtual media (a spectrum of both positive/negative influence). These themes emerged consistently among both English- and Spanish-speaking participants.

Conclusion: For women diagnosed with SLE, addressing reproductive health decision-making requires the clinician to approach the patient from a holistic perspective that considers the complex social and cultural factors influencing pregnancy decisions. While many patients with SLE should be timing pregnancy to be medically safe, our patient-reported qualitative data also demonstrates that pregnancy planning (or avoiding) is heavily influenced by non-medical extrinsic factors. Clinicians who acknowledge and address these factors may be better equipped to support patients in navigating pregnancy planning safely and confidently, promoting shared decision-making that aligns with patients' lived experiences and values.

Disparities in Reproductive Health Counseling Among Hispanic Women with Autoimmune Rheumatic Diseases: Insights from a Patient-Reported Survey in an Urban Safety-Net Setting

Eaman Alhassan[1], Laura Kobashigawa[2], Vanessa Ramos[2], Jack Rodman[2] and **Leanna Wise**[3], [1]University of Pittsburgh Medical Center, Pittsburgh, PA, [2]University of Southern California, Los Angeles, [3]LAGMC/Keck Medicine of USC, Los Angeles

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2195–2226) Reproductive Issues in Rheumatic Disorders Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Reproductive-age Hispanic women with rheumatoid arthritis, juvenile idiopathic arthritis (combined, inflammatory arthritis; IA), and systemic lupus erythematosus (SLE) often bear a higher disease burden and experience worse outcomes compared to other populations. In addition, careful attention must be given to appropriate medication use and contraception use during childbearing years. While the 2020 ACR Reproductive Health Guideline provides recommendations for contraception counseling, little is known about how these are experienced by patients in under-resourced settings. We examined patient-reported experiences with reproductive health counseling and contraceptive practices in an urban safety-net clinic.

Methods: An anonymous survey was administered to 304 women (aged 18–50) with SLE or IA at Los Angeles General Medical Center, a public hospital serving a predominantly Hispanic, state-insured population in urban east Los Angeles. The survey was based on topics from the 2020 ACR Guideline for the Management of Reproductive Health in Rheumatic

and Musculoskeletal Diseases, and was administered in English or Spanish. Multivariable logistic regression was used to assess factors associated with receiving contraception counseling and patients' perceptions of their physicians' reproductive health knowledge.

Results: Most respondents (91%) identified as Hispanic, and 63% completed the survey in Spanish (Table 1). Only 51% reported receiving contraception counseling in the past year. English-speaking participants had significantly *higher* odds of receiving such counseling compared to Spanish speakers (OR 3.93; 95% CI 1.82-8.51; p< 0.01) (Table 2). Spanish-speaking individuals were *less likely* to perceive their physician as knowledgeable about reproductive health (OR 0.46; 95% CI 0.22-0.95; p=0.04) (Table 3). Furthermore, each additional year in age was associated with a 4% *lower* odds of reporting contraception counseling in the past year (OR: 0.96; 95% CI 0.92-0.99; p=0.02), as well as a 5% *lower* odds of confidence in their rheumatologist's knowledge to address reproductive health and rheumatic disease (OR 0.95; 95% CI 0.91-0.99; p< 0.01) (Table 2, Table 3). Among sexually active patients on teratogenic medications who were not trying to conceive, those who received contraception counseling had increased odds of using long-acting reversible contraception (OR 5.69; 95% CI 1.38-23.48; p=0.02). Notably, 27% of these patients reported no contraceptive use.

Table 2. Multivariable analysis of factors influencing patient-reported contraception counseling

Variable	Adjusted Odds Ratio** (95% CI)	P value
Disease type: Arthritis vs. Lupus (ref)	0.92 (0.53, 1.61)	0.77
Age	0.96 (0.92, 0.99)	0.02*
Survey Language: English vs Spanish (ref)	3.93 (1.82, 8.51)	<0.01*
Marital Status (married ref)		
Never Married	1.23 (0.64, 2.39)	0.41
Widowed	0.78 (0.09, 7.05)	0.83
Divorced or separated	0.91 (0.43, 1.94)	0.94
Prefer not to state	0.83 (0.28, 2.45)	0.80
Place of birth: United States (US) vs. Not in the United States (US) (ref)	0.59 (0.26, 1.35)	0.21

*Indicates significant p value
**Each factor is adjusted for all covariates in the model

Table 3. Multivariable analysis of influences on patient-reported perception of physician knowledge on reproductive health and rheumatic disease

	Adjusted Odds Ratio** (95% CI)	P value
Disease type: Lupus vs. Arthritis (ref)	2.35 (1.30, 4.24)	<0.01*
Age	0.95 (0.91, 0.99)	<0.01*
Survey Language: Spanish vs. English (ref)	0.46 (0.22, 0.95)	0.04*

*Indicates significant p value
**Each factor is adjusted for all covariates in the model

Conclusion: Spanish-speaking and older patients with SLE or IA were significantly less likely to receive reproductive health counseling or feel confident in their rheumatologist's ability to address the intersection of reproductive health and rheumatic disease. However, counseling was strongly associated with the use of highly effective contraception for patients on teratogenic medications. These findings underscore the importance of integrating proactive and culturally informed reproductive health counseling into the rheumatology clinic to improve patient safety and equity.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2195–2226) Reproductive Issues in Rheumatic Disorders Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Women with axial spondyloarthritis (axSpA) are frequently diagnosed during their childbearing years. While studies have reported on pregnancy complications in this population, deriving generalizable prevalence estimates has been hampered by smaller study cohorts. Where reported, there is a concerning trend toward increased pregnancy complications in axSpA compared to the general population. Severe maternal morbidity (SMM) is a serious adverse physical or psychological event related to pregnancy which negatively impacts maternal health. Clinically recognized in the general population, SMM has not been studied in women with rheumatic diseases, including axSpA.

The aim of this study was to determine if there is a higher prevalence of pregnancy and neonatal complications, including SMM, in women with axSpA compared to women in the general population.

Methods: This was a population-based cohort study of administrative healthcare data from Ontario, Canada. Primary data source was the Mombaby Database, allowing near-complete capture of all hospital-based livebirths and stillbirths. The study included all women aged 10 to 55 years with a livebirth recorded between April 1st, 2002 and March 31st, 2020. Diagnosis of axSpA was based on the presence of an axSpA diagnosis code on at least two healthcare claims within a two-year period with at least one made by a Rheumatologist. Pregnancies in axSpA women were matched in a 1:5 ratio with pregnancies of women without axSpA (controls) according to maternal age, year of first pregnancy, and geographic location. Prevalence of pregnancy and neonatal outcomes were compared between axSpA women and controls. Multivariable logistic regression was used to identify factors associated with SMM in axSpA pregnancies.

Table 1: Pregnancy characteristics & maternal outcomes among women with axSpA and matched controls

	Controls	AxSpA Pregnancies	*p value*
n	26,350	5,176	
Maternal age at delivery (years) *Mean (SD)*	31.24 ± 5.09	31.20 ± 5.12	0.60

Table 2: Neonatal Outcomes in axSpA and non-axSpA (control) pregnancies

	Control Pregnancies	AxSpA Pregnancies	p value
n	26,350	5,176	
Birthweight (grams)			
Mean (SD)	3,365.64 ± 593.21	3,352.98 ± 596.63	0.16
Median (IQR)	3,391 (3,055-3,730)	3,385 (3,040-3,735)	0.24
Preterm Birth	2,129 (8.1%)	503 (9.7%)	<0.01
Spontaneous	849 (3.2%)	189 (3.7%)	0.11
Physician Induced	1,230 (4.7%)	301 (5.8%)	<0.01
Very PTB (<32 weeks)	387 (1.5%)	81 (1.6%)	0.60
Low Birth Weight	276 (1.0%)	53 (1.0%)	0.88
NICU admission	3,435 (13.0%)	711 (13.7%)	0.17
Congenital abnormality	1,112 (4.2%)	231 (4.5%)	0.43
Neonatal death	77 (0.3%)	10 (0.2%)	0.21
Severe Neonatal Morbidity	1,591 (6.0%)	337 (6.5%)	0.19
Sepsis	191 (0.7%)	37 (0.7%)	0.94
Respiratory Distress	365 (1.4%)	70 (1.4%)	0.85
Need for resuscitation	50 (0.2%)	12 (0.2%)	0.53
Need for ventilatory support	1,061 (4.0%)	219 (4.2%)	0.50

Results: In total, 3,010 women with axSpA were matched with 15,050 non-axSpA controls, each contributing 5,176 and 26,350 study pregnancies, respectively. Most of axSpA and control women were nulliparous (70.9% vs 72.7%, p=0.72), and median age was 31 years. For pregnancy complications, gestational diabetes (7.5% vs 6.6%, p=0.03), antepartum haemorrhage (0.9% vs 0.6%, p=0.03), and SMM (4.4% vs 3.7%, p=0.02) were significantly more prevalent in axSpA pregnancies (Table 1). For neonatal complications, preterm birth was more prevalent in axSpA pregnancies (9.7% vs 8.1%, p< 0.01) (Table 2). In multivariable analyses, factors associated with SMM in axSpA women were maternal age (aOR 1.03, 95% CI 1.00-1.06), comorbidity burden (defined by the Elixhauser Comorbidity Index; aOR 1.27, 95% CI 1.16-1.38), and gestational age at delivery (aOR 0.76, 95% CI 0.73-0.78) (Table 3).

Table 3: Factors associated with Severe Maternal Morbidity (SMM) in AxSpA Pregnancies

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: In this large, population-based cohort study, women with axSpA were more likely to experience SMM, preterm birth, gestational diabetes and antepartum haemorrhage compared to controls. Furthermore, experiencing SMM was associated with increasing maternal age, lower gestational age and increasing comorbidity burden. These results are concerning and call for further studies to identify and develop strategies to limit SMM in women with axSpA. To the best of our knowledge, this is the largest population-based study of pregnancy in axSpA women and the first study of SMM in axSpA.

Adherence to Reproductive Health Guidelines in Lupus Care: Insights from Patient and Physician Surveys

Akhil Sood[1], Leanna Wise[2], Sadaf Sediqi[1], Alyssa Howren[1], Amanda Moyer[1], Ellie Diamond[1], Yashaar Chaichian[3] and Julia F Simard[4], [1]Stanford University, Palo Alto, CA, [2]LAGMC/Keck Medicine of USC, Los Angeles, [3]Stanford University, Stanford, CA, [4]Stanford Medicine, Stanford, CA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2195–2226) Reproductive Issues in Rheumatic Disorders Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The American College of Rheumatology has established guidelines for managing reproductive health in patients with rheumatic diseases. We assessed contraception use and counseling of patients with systemic lupus erythematosus (SLE) through two parallel surveys of patients and physicians in alignment with these guidelines.

Methods: Females with SLE (ages 18-50 years) who received care from a rheumatologist at an academic medical center were invited to complete a survey assessing contraception use, including effective or highly effective contraception (EHEC), and whether they received contraception counseling from their rheumatologist. Contraception counseling was defined as: a) discussion of contraception in the past year, or b) explanation of contraception given their SLE by a rheumatologist. The survey also asked about sources of reproductive health information and perceived barriers to reproductive health counseling with their rheumatologist. The physician survey invited rheumatologists and obstetricians/gynecologists (OBGYN) to complete a survey about confidence in contraception counseling rated on a Likert-scale (1= Least Confident, 5= Extremely Confident). Rheumatologists were specifically asked about timing of contraception counseling after initiating a teratogenic medication. Descriptive statistics were summarized as frequency (n, %) or median [interquartile range]. Chi-square, Fisher's exact, and Student's t tests were used for bivariate comparisons.

Results: Among 102 females with SLE who completed the survey, the majority identified as White (37, 36%) or Asian/Pacific Islander (33, 32%), and had a bachelor's degree or higher (71, 69%). Most (67, 66%) reported being sexually active and avoiding pregnancy or neutral towards pregnancy. Only 33% of all participants reported receiving contraception counseling within the past year. Fewer participants reported using EHEC (34, 33%) compared to less effective methods (47, 46%). Use of EHEC significantly differed by race ($p< 0.05$), with higher use among Whites (20, 54%) and lower among Asians/Pacific Islanders (7, 21%). Contraception counseling significantly differed by age, employment status, marital status, and teratogenic medication use, but these factors were not associated with the use of EHEC. Despite identifying rheumatologists as

the primary source of information on SLE and reproductive health (64, 63%), many patients viewed being directed to their OBGYN as a barrier to engaging in these discussions with their rheumatologist (31, 30%).

Among 200 physician respondents (rheumatologists: 116, (58%), OBGYN: 84, (42%)), rheumatologists reported higher confidence in contraception counseling (Median 4 [IQR 3–4]) compared to OBGYNs (Median 3 [3–4]). While most rheumatologists (88, 76%) reported contraception counseling at the initiation of teratogenic medications, fewer (40, 35%) reported also counseling at follow-up visits.

Background/Purpose: Systemic lupus erythematosus (SLE) is a multisystem autoimmune rheumatic disease, predominately affecting women during their reproductive years. Despite widespread evidence that individuals with SLE have a significantly increased risk for depression and anxiety, insight into postpartum depression (PPD) and postpartum anxiety (PPA) is limited. This highlights a significant quality-of-care issue given these conditions are associated with several negative maternal and fetal health outcomes and is a leading cause of maternal death. To address this, we examined national claims data to estimate PPD/PPA prevalence among publicly-insured women with SLE.

Methods: We identified all singleton live births among females aged 15-44 years in Medicaid TAF (T-MSIS Analytic File) between 01/01/2014 and 12/31/2019 applying validated algorithms to inpatient and outpatient files for diagnostic and procedure claims related to end of pregnancy. SLE was defined prior to delivery using the following algorithm: ≥2 SLE coded outpatient visits or ≥1 inpatient visit (ICD9: 710.0; ICD10: M32.1, M32.8, M32.9). PPD, PPA, and post-traumatic stress

Table 2 Prevalence of postpartum depression, postpartum anxiety, and post-traumatic stress disorder among systemic lupus erythematosus pregnancies in the 60-day and 365-day postpartum Medicaid coverage periods, stratified by parity. Presented as No.(%)

	60-day coverage postpartum			365-day coverage postpartum		
	All (N= 7870)	Nullipara (N= 3727)	Multipara (N= 4143)	All (N= 5180)	Nullipara (N= 2515)	Multipara (N= 2665)
Prevalence of PPD	449 (6)	159 (4)	290 (7)	834 (16)	362 (14)	472 (18)
Prevalence of PPA	290 (4)	111 (3)	179 (4)	722 (14)	305 (12)	417 (16)
Prevalence of PTSD	115 (2)	38 (1)	77 (2)	219 (4)	88 (4)	131 (5)

disorder (PTSD) were conservatively defined as ≥2 outpatient claims or ≥1 inpatient claim coded as depression, anxiety, and PTSD, respectively. All outcomes were assessed within the 60-day postpartum coverage period and up to 365-days postpartum (for those with ongoing coverage). To examine heterogeneity we stratified by parity, and race and ethnicity.

Results: We identified 7870 singleton live births among 6914 women with a diagnosis of SLE. The median maternal age was 29 years (IQR, 8 years), with the majority of participants identifying as White (32%), Black (28%), and Hispanic (17%). (**-Table 1**). The prevalence of PPD for SLE pregnancies was estimated at 6% within the 60-day postpartum coverage period and 16% among those with up to 365 days of continuous coverage. We observed heterogeneity by parity, with a slightly higher prevalence of PPD observed among multipara SLE pregnancies (**Table 2**). Stratification by race and ethnicity showed the highest prevalence of PPD among White SLE pregnancies (7%, 178/2549), followed by Black (5%, 111/2238) and Hispanic individuals (5%, 68/1321) during the 60-day postpartum period. The prevalence of PPA was 4% within 60-days postpartum, increasing to 14% among those with 365-days of coverage. PTSD was less prevalent, affecting 2-4% of SLE pregnancies in the postpartum period.

Conclusion: Findings highlight that PPD and PPA are important comorbidities to consider in SLE patients and underscores the need for appropriate screening and management strategies. Future analyses will include comparisons with the general obstetric population to enhance the interpretation of these results.

Maternal and Fetal Outcomes Associated with IL-17 Inhibitor Exposure During Pregnancy in Patients with Seronegative Arthritis: A Case Series of Nine

Arshdeep Waring[1], Sofia Rieger-Torres[2], Jeremiah Tan[3], Viktoria Pavlova[4] and Neda Amiri[5], [1]University of British Columbia, Abbotsford, BC, Canada, [2]University of British Columbia, Vancouver, BC, Canada, [3]Arthritis Research Canada, Vancouver, BC, Canada, [4]McMaster University, Ancaster, ON, Canada, [5]University of British Columbia, North Vancouver, BC, Canada

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2195–2226) Reproductive Issues in Rheumatic Disorders Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Interleukin-17 (IL-17) inhibitors, such as ixekizumab and secukinumab, are increasingly used in the treatment of seronegative inflammatory arthritis, including psoriatic arthritis and axial spondyloarthritis. However, data on their safety and outcomes during pregnancy remain limited. Given the expanding use of IL-17 inhibitors in individuals of reproductive age, further characterization of maternal and fetal outcomes is needed to inform clinical decision-making.

Methods: Nine pregnant individuals with seronegative inflammatory arthritis who were treated with IL-17 inhibitors were identified through the Pregnancy and Rheumatic Diseases Clinics at two Canadian centers. Clinical data were prospectively extracted by a trained research assistant using REDCap, electronic medical records, and relevant consult notes. Outcomes of interest included maternal disease activity during pregnancy, pregnancy complications, neonatal outcomes, and the presence of congenital anomalies.

Table 1. Patient characteristics including: maternal age at conception, diagnosis, gravidity, current biologic therapy, gestational age (GA) at delivery, mode of delivery, fetal birth weight, congenital malformations.

Patient	Maternal Age at Conception	Diagnosis	Gravidity	Current Biologic Therapy	GA at delivery	Mode of delivery	Fetal birth weight (g)	Congenital Malformations
P1	31	PsA	G1	Ixekizumab	36+2	Emergency C-Section	3004	None
P2	33	PsA	G2	Ixekizumab	41+3	Emergency C-Section	3390	None
P3	31	PsA	G4	Secukinumab	40+0	Emergency C-section	3645	None
P4	41	SpA	G1	Secukinumab	40+3	SVD	3550	None
P5	32	SpA	G1	Secukinumab	Pregnant	Pregnant	N/A	N/A
P6	34	PsA	G2	Ixekizumab	39+0	Vacuum assisted vaginal delivery	3592	None
P7	30	PsA	G2	Secukinumab	39+1	Emergency C-section	4000	None
P8	34	PsA	G6	Secukinumab	38+1	SVD	3590	None
P9	37	SpA	G1	Secukinumab	38+1	Elective C-Section	2720	None

PsA=psoriatic arthritis; SpA=Spondyloarthropathy; SVD=spontaneous vaginal delivery

Results: These patients were managed throughout all trimesters of pregnancy, and followed for six weeks postpartum. The mean maternal age at conception was 34 years. Patient characteristics are summarized in Table 1. No birth defects were observed in any of the infants. One infant was noted to have jaundice (not requiring phototherapy). Another infant required a brief admission to neonatal intensive care unit for hypoglycemia and transaminitis (P7).

Conclusion: In this prospective case series, IL-17 inhibitor exposure during pregnancy was not associated with an increased risk of congenital anomalies or adverse neonatal outcomes. These findings suggest that IL-17 inhibitors may be a safe treatment option for select patients with seronegative inflammatory arthritis during pregnancy. Larger, multicenter studies are needed to confirm these observations and better inform clinical guidance.

Participant Characteristics

Background/Purpose: Prior studies demonstrate low levels of knowledge and reported counseling regarding teratogenicity among AYAs with rheumatic disease. The aim of this study was to explore the teratogenicity counseling experiences of AYAs on teratogenic medications treated in pediatric rheumatology clinics and explore on how to best address their needs in teratogenicity counseling.

Methods: AYAs age 14-21 years, assigned female at birth, with a rheumatic disease, and taking teratogenic medications were recruited from pediatric rheumatology clinics in Indiana to participate in semi structured interviews in 2024 assessing teratogenicity knowledge, counseling experiences, and recommendations to improve counseling in the clinical setting. Interviews were recorded and transcribed by a professional transcription service. Data were analyzed in Dedoose by two of the authors (BH, EP) who engaged in inductive initial coding to identify themes from the data, resolving differences through discussions until theoretical saturation was reached. After identifying key themes and creating a codebook ,categories were developed through exploration of how key concepts fit together. Analysis proceeded using constant comparison analysis, the standard analysis technique utilized in grounded theory as described by Charmaz (2008). Hypothesized relationships among categories were explored through reexamination of the data using an iterative approach. We then reanalyzed the transcripts to perform a priori coding to develop and confirm our theoretical framework.

Results: 21 AYAs with a variety of rheumatic diseases participated in interviews. Participants were on average 16.3 years of age. 29% knew the reproductive effects of their medication, 24% had limited knowledge, and 43% no knowledge. 43% reported counseling on teratogenicity by their rheumatologist.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. SPIKE STAR Teratogenicity Counseling Framework

The key theme that emerged is teratogenicity counseling is seen as receiving bad news due to AYAs' interpretation of this information to mean it will be challenging to plan a future pregnancy. This was rooted in weighing the challenges of navigating a disease they perceive will be poorly controlled without use of their current teratogenic medication. Notably, most participants frame teratogenicity information in terms of their future family planning with few recognizing the risk of unintended pregnancy.

This finding drew us to the SPIKES (Setting, Perception, Invitation, Knowledge, Empathy, Strategy) framework for breaking bad news, which further mapped onto central themes from AYA recommendations on teratogenicity counseling. We used this model and adapted it for AYAs receiving news on teratogenicity based on subsequent themes that emerged to produce the SPIKES-STAR framework for teratogenicity counseling. This model includes the following additions: Stigma reduction, Tailoring, Agency, and Revisiting counseling.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: We present a novel framework for teratogenicity counseling of AYAs on teratogenic medications treated in pediatric rheumatology clinics. Next steps include development of a model for implementation in clinical practice, evaluation of model, and application to the broader population of AYAs with chronic disease on teratogenic medication.

Session Title: (2195–2226) Reproductive Issues in Rheumatic Disorders Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic autoimmune diseases are often treated with medications that have known teratogenic effects or unknown safety profiles in pregnancy. As these diseases frequently affect women of childbearing potential, it is important for rheumatologists to provide reproductive health counseling to patients. While studies have shown variable rates of reproductive health counseling by rheumatology providers, less is known about the effectiveness of that counseling. In this study, we used patient-reported questionnaires to evaluate the effectiveness of prior reproductive health counseling of rheumatology patients.

Methods: Female patients followed at an academic rheumatology outpatient practice were invited to complete on-line questionnaires if they were of childbearing potential (i.e., 18-50 years without surgical sterilization, hysterectomy, or menopause), had an established autoimmune condition, and had no plans for pregnancy in the next year. To assess prior reproductive health counseling, patients were asked if they had ever received contraception counseling or been counseled about the pregnancy risks of their medications by their rheumatologist. Counseling effectiveness was assessed by asking "Do you think you are safe to become pregnant now?" and "If you decided to become pregnant in the future, would you talk to your

Table 1. Reproductive health questionnaire results stratified by patient-reported history of prior reproductive health counseling by a rheumatologist

	Prior counseling (N=71)	No prior counseling (N=30)	p-value
Women who answered 'Unsure' when asked "Do you think you are safe to become pregnant now?"			
• All women	6 (8.5%)	11 (36.7%)	<0.01
• Women currently taking teratogenic medications*	0/27 (0%)	2/5 (40.0%)	0.02
Women who answered 'Yes' when asked "If you decided to become pregnant in the future, would you talk to your rheumatologist about those plans?"			
• All women	70 (98.6%)	25 (83.3%)	<0.01
• Women currently taking teratogenic medications*	27/27 (100.0%)	4/5 (80.0%)	0.16

*Teratogenic medications could include methotrexate, leflunomide, cyclophosphamide, mycophenolate mofetil or warfarin

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

rheumatologist about those plans?" Demographics, medication use, and contraception use were also collected by questionnaire. Results were compared between women who did vs. did not report prior reproductive health counseling.

Results: One hundred and one patients completed the questionnaire. Seventy-one (70.3%) reported having ever received reproductive health counseling by their rheumatologist. Reproductive health counseling rates were higher in women < 40 years of age ($p< 0.01$) and in women currently or previously taking teratogenic medications ($p=0.01$). We found that women who had received reproductive health counseling were less likely to be 'unsure' whether they were safe to become pregnant compared to women who did not report prior reproductive health counseling (8.5% vs. 36.7%, $p< 0.01$). This difference was also present in the subset of 32 women currently taking teratogenic medications (0% vs. 40%, $p=0.02$) (Table 1). Women who had previously received reproductive health counseling from their rheumatologist were also more likely to report that they would talk to their rheumatologist if they decided to become pregnant in the future (98.6% vs. 83.3%, $p< 0.01$) (Table 1).

Conclusion: This study demonstrates the significant impact that reproductive health counseling by rheumatologists can have on patient outcomes. Patients who received prior counseling reported greater confidence regarding the safety of a potential pregnancy, which may contribute to improved pregnancy outcomes. Additionally, our findings emphasize the importance of counseling all patients about reproductive health, regardless of their current pregnancy intentions, as those not actively planning pregnancy were still more likely to engage in discussions about future pregnancy plans with their rheumatologist, which can also support better outcomes.

Adolescents with Systemic Lupus Erythematosus at Highest Risk of Adverse Pregnancy Outcomes

Catherine Deffendall[1], Sarah Green[2], Ashley Suh[2], Bryan Han[2] and April Barnado[2], [1]Vanderbilt University, Nashville, TN, [2]Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2195–2226) Reproductive Issues in Rheumatic Disorders Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Few studies exist that examine pregnancy outcomes in adolescents with SLE. To our knowledge, there have been no studies comparing SLE adolescent pregnancies to both adolescent control and adult SLE pregnancies. Using a de-identified electronic health record (EHR), we compared rates of pregnancy outcomes in adolescents ≤ 21 years with and without SLE to older individuals with SLE.

Methods: We identified SLE pregnancies in a de-identified EHR with >3.8 million individuals using a validated algorithm of ≥ 4 SLE ICD billing codes and ≥ 1 pregnancy or delivery codes. On chart review, we confirmed SLE diagnosis by a rheumatologist and excluded deliveries occurring before SLE diagnosis. Pregnancies at a maternal age ≤ 21 years were counted as adolescent pregnancies and pregnancies at a maternal age ≥ 22 years were considered adult pregnancies. We identified control individuals as those without ICD codes for autoimmune diseases and ≥ 1 pregnancy or delivery codes. Maternal

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

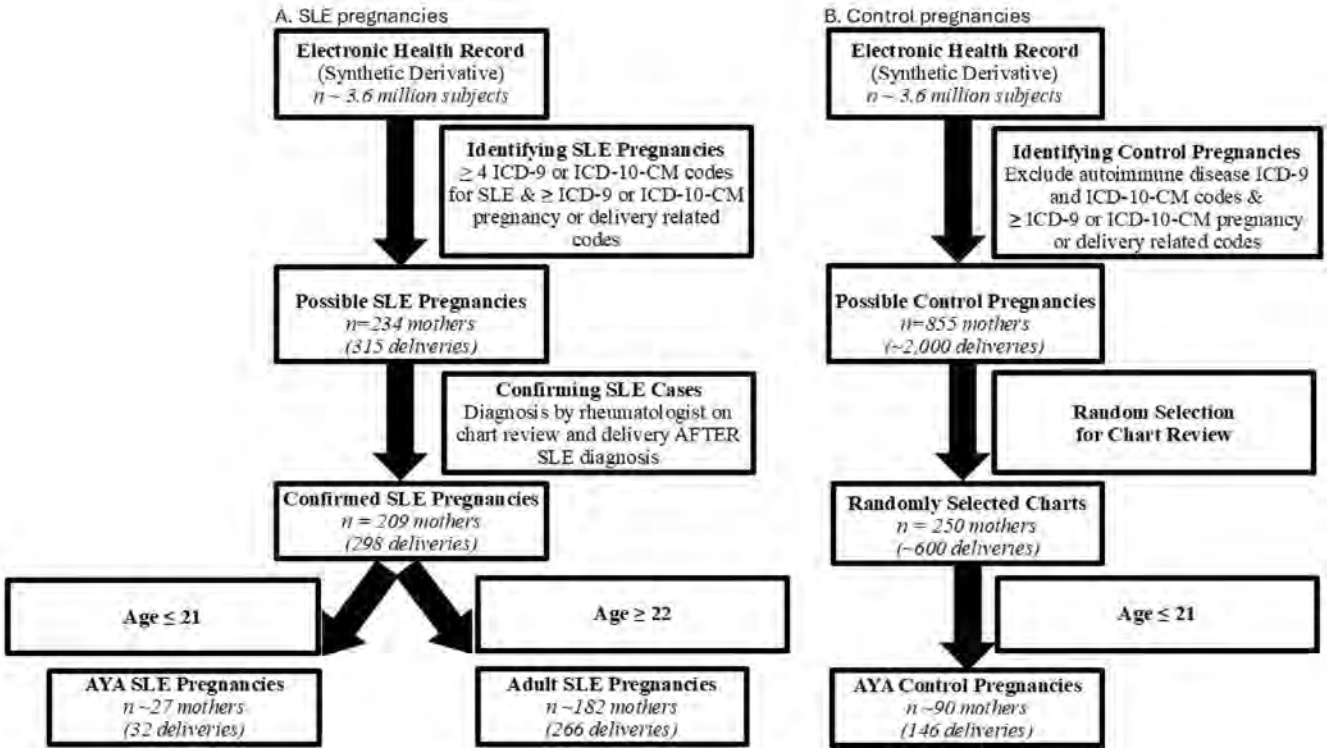

Figure 1. Flowchart of study individuals. (A) SLE pregnancies were selected from the de-identified electronic health record (EHR) using four or more SLE ICD-9 or ICD-10-CM codes while also requiring one or more ICD-9 or ICD-10-CM pregnancy or delivery-related codes. We then performed chart review to confirm SLE diagnosis by a rheumatologist and ensure pregnancy occurred after SLE diagnosis. After applying age criteria, we identified adolescent SLE pregnancies and adult SLE pregnancies. (B) Control pregnancies were selected from the same de-identified EHR as the SLE pregnancies. Controls were required to have the same pregnancy and delivery-related codes used for SLE deliveries and to not have ICD-9 or ICD-10-CM codes for autoimmune diseases. We then performed chart review on a random set of 250 controls to ensure no autoimmune diseases. After applying age criteria, we identified adolescents without SLE.

outcomes included gestational diabetes, preeclampsia, postpartum hemorrhage, peripartum infection. Fetal outcomes were pregnancy loss, which included elective termination, spontaneous abortion, and stillbirth. Other fetal outcomes were premature birth, defined as delivery < 37 weeks, and small for gestational age, defined as birth weight < 10th percentile for gestational age. Covariates were assessed on chart review. Using Chi-square and Kruskal-Wallis tests, we compared demographics and pregnancy outcomes. Since individuals could contribute multiple pregnancies and parity can impact outcomes, we performed mixed effects models to estimate the association of pregnancy loss, preterm birth, and preeclampsia with age at delivery, race, and SLE case status.

Results: We identified 32 pregnancies to 27 individuals with SLE ≤ 21 years, 146 pregnancies to 90 adolescent control individuals without SLE, and 266 pregnancies to 182 individuals with SLE aged ≥ 22 years (Table 1). Adults with SLE were more likely to be White than adolescents with or without SLE ($p < 0.001$), and SLE pregnancies were more likely to be complicated by hypertension compared to controls ($p < 0.001$). Compared to adolescent control pregnancies, adolescent SLE pregnancies were more likely to experience preeclampsia ($p < 0.001$), postpartum hemorrhage ($p = 0.001$), and preterm delivery ($p = 0.001$). Among SLE pregnancies, SLE adolescents were more likely to have antiphospholipid antibody syndrome ($p = 0.01$) and nephritis ($p = 0.001$) compared to SLE adults. Adolescents with SLE were more likely to have pregnancy loss than adults with SLE ($p = 0.02$). In mixed effects models, SLE cases were more likely to experience preterm delivery (OR = 9.11, 95% CI 4.10-20.22) and preeclampsia (OR = 5.55, 95% CI 2.38 – 12.92) after adjusting age at delivery and race.

Conclusion: Adolescent SLE pregnancies were more likely to have preterm birth, preeclampsia, and post-partum hemorrhage than control adolescents and more likely than adults with SLE to have pregnancy loss. Adolescents with SLE represent a high-risk pregnancy group that needs close monitoring.

Abstract Number: 2207

Menopause Experiences of Veterans from Minoritized Populations with Rheumatoid Arthritis

Catherine Sims[1], Yujung Choi[2], Abigail Shapiro[3], Jennifer Gierisch[1], Elizabeth Strawbridge[2], Teresa Howard[2], Ankoor Shah[1] and Karen Goldstein[1], [1]VA Durham Healthcare System, Duke University, Durham, [2]VA Durham Healthcare System, Durham, [3]VA Durham Healthcare System, Cleveland

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2195–2226) Reproductive Issues in Rheumatic Disorders Posters

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: There is a significant gap in understanding the reproductive health experiences of women Veterans with rheumatoid arthritis (RA). This study explores their experiences with menopause within the VA healthcare system, including perceptions of rheumatologists' roles in symptom management and care coordination between rheumatology and other providers.

Methods: Semi-structured interviews with 9 VA healthcare providers (5 rheumatologists, 4 primary care providers) and 7 Veterans with RA explored reproductive healthcare experiences and needs within the VA. All Veterans self-identified as Black and had been evaluated by a rheumatologist for RA. Veterans were identified via the Corporate Data Warehouse. Of the 128 Veterans contacted, 31 consented. Interview guides were developed using the Chronic Care and Cumulative Complexity Models to explore contraception, pregnancy, and menopause. Interviews were audio-recorded and transcribed using Microsoft Teams. Data were analyzed using Hamilton's rapid qualitative method. Two analysts summarized individual and cross-participant levels, with input from a third analyst. Overall themes were identified through structured matrix analysis.

Results: We interviewed 7 Veterans about experiences with menopause symptoms and therapies, median age 61 years (**-Table 1**). Veterans reported joint pain and swelling that disrupted daily activities related to their RA. Veterans described difficulty with differentiating menopause symptoms from RA and relied on rheumatologists for guidance. They valued discussions with their rheumatologists about menopause and hormone therapy (HT) and its impacts on RA. Veterans drew on clinical advice and personal considerations when making decisions about menopause therapy. Some utilized supportive care, supplements, or HT to address menopausal symptoms. Some Veterans decided against HT due to medication burden or history of thrombosis. VA rheumatologists and PCPs expressed lower confidence in managing menopause compared to other reproductive health concerns and reported a generalized approach, as opposed to a disease-tailored approach, to

Table 1. Patient Characteristics

Demographic (n=7)	
Age	Median: 61 years (range 28-66)
Race	Black: 7 (100%)
Ethnicity	Not Hispanic: 7 (100%)
Age at RA diagnosis	Median: 30 years (range 21-52)
Age at menopause (n=3)	Median: 52 years (range 35-58)
Years receiving VA healthcare	Median: 16 years (range 5-34)
Current rheumatology care	Within VA: 5 (71%) Outside VA: 2 (29%)

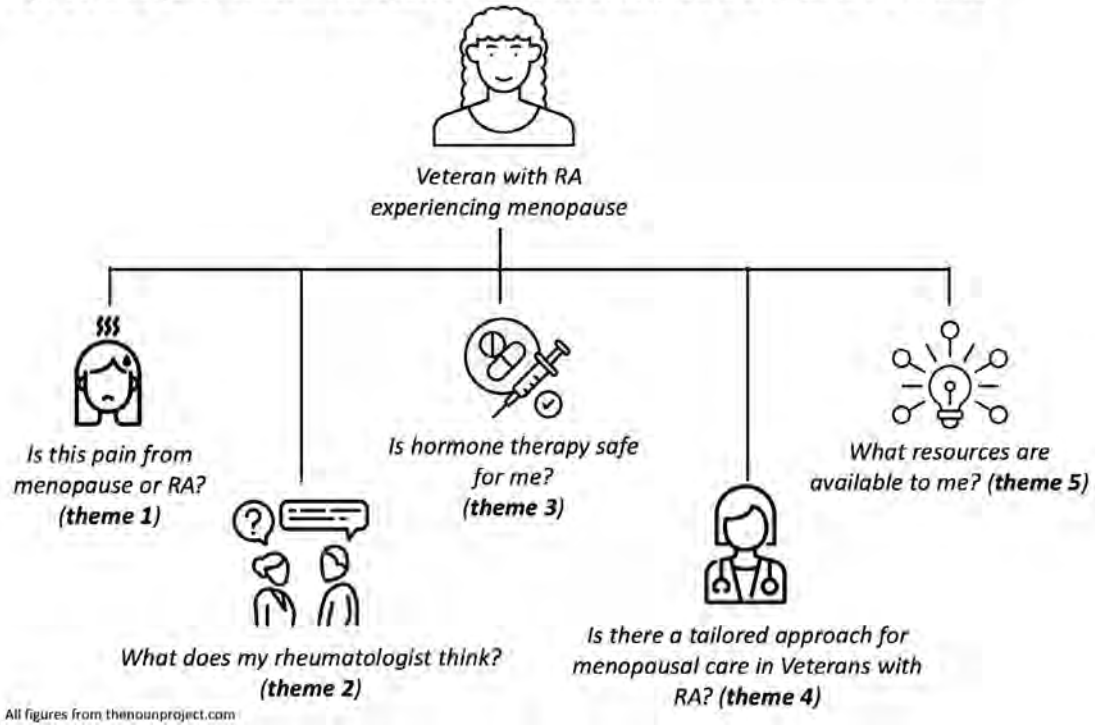
Figure 1. Emergent Themes in Menopause Experiences of Veterans with Rheumatoid Arthritis



menopause in Veterans with RA. Both Veterans and providers noted a lack of patient and provider resources for women with autoimmune disease undergoing menopause. Veterans believed that better access to reliable, personalized resources would have enhanced their menopause experience (**Figure 1**).

Conclusion: These findings highlight the challenges faced by Veterans with RA in managing menopause symptoms, particularly in distinguishing between RA-related and menopause-related symptoms. Veterans valued the involvement of their rheumatologists and want more guidance on menopause and HT, especially in relation to its impact on RA. Both Veterans and VA providers identified a gap in tailored resources and personalized approaches for women with RA undergoing menopause.

Breastfeeding with prior live births (n=5)	Yes: 5 (100%)

Background/Purpose: More than 8,500 women Veterans carry a diagnosis of rheumatoid arthritis (RA), however, there are limited data on the reproductive health and experiences of this population. We engaged these Veterans and Veterans Affairs (VA) providers to examine the impact of RA on reproductive healthcare and identify gaps in services provided by the VA.

Methods: We conducted semi-structured interviews with 9 VA healthcare providers (5 rheumatologists, 4 primary care providers (PCPs)) and 13 Veterans with RA between February-October 2024. Veterans were identified through the Corporate Data Warehouse; 31 of 128 contacted via mail consented to participate. All patients self-identified as Black and/or Hispanic and were seen by a rheumatologist in the VA Healthcare System. Interview guides, informed by the Chronic Care Model and

Figure 1. Veteran Identified Areas for Improvement of Reproductive Healthcare

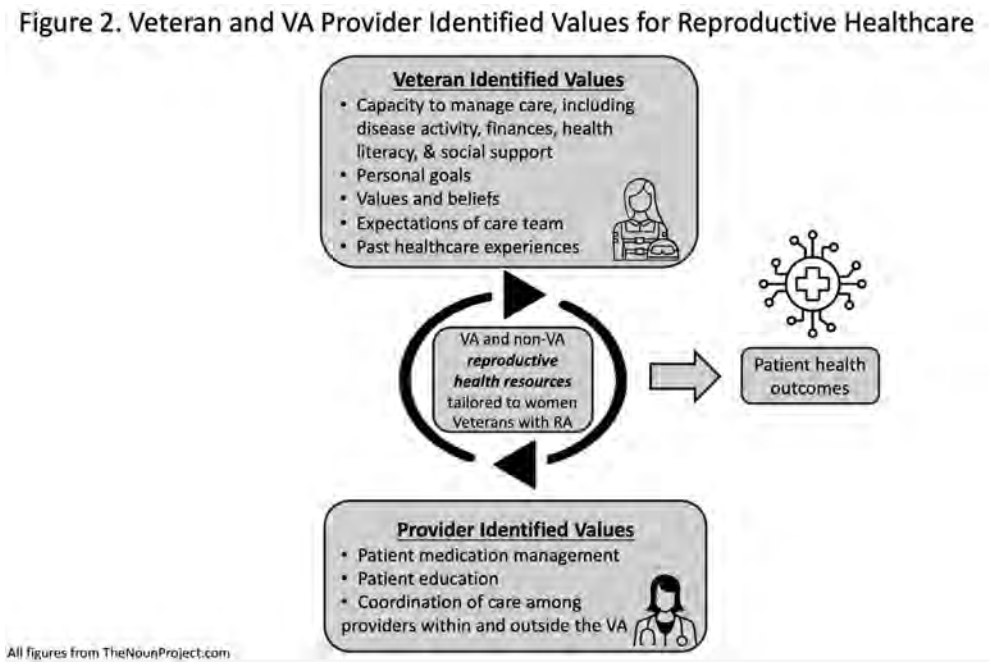

Figure 2. Veteran and VA Provider Identified Values for Reproductive Healthcare

the Cumulative Complexity Model, explored how rheumatic disease affects reproductive healthcare and gaps in VA services. Interviews lasted 45–60 minutes, focused on 2 of 3 reproductive milestones (contraception, pregnancy, menopause), and were audio-recorded and transcribed via Microsoft Teams. Data were analyzed using Hamilton's rapid qualitative method, with summaries by participant and question. Summaries were organized in a matrix to facilitate memo writing and thematic analysis.

Results: We interviewed 13 Veterans, ages 25-66 years, about contraception (n=9) and/or pregnancy/breastfeeding (n=8) depending on their reproductive history and experiences (**Table 1**) and 9 VA healthcare providers. Analysis identified 7 key takeaways. (1) Veterans considered reproductive health relevant to managing their RA including disease activity, physical capabilities, immunosuppression, and family planning goals. (**Figure 1**). (2) Navigating tradeoffs between chronic condition management and family planning felt overwhelming and emotionally burdensome. (3) Women Veterans reported taking between 0-3 types of contraceptives throughout their lifetime. Most had not discussed contraception with a VA rheumatologist, assuming obstetrics (OB) providers or PCPs would address this. When discussed, rheumatologists focused on teratogenic medications and pregnancy safety. (4) Veterans valued input from PCPs and rheumatologists when making reproductive decisions. (5) Rheumatology support during pregnancy varied; some saw only OBs and PCPs while others maintained rheumatology care. When providers communicated, Veterans reported improved care, less adverse impacts, and more shared decision-making among providers and with patients. (6) Breastfeeding decisions were influenced by provider input, immunosuppression safety, and personal preferences. (7) Veterans identified gaps in postpartum rheumatology care such as disease-specific resources, care coordination, and difficulty reengaging with VA after delivery (**Figure 2**).

Conclusion: Veterans with RA highly value their rheumatologists' advice on reproductive health and emphasized the importance of provider communication when making decisions about contraception, pregnancy, and breastfeeding. Care coordination was seen as especially critical during pregnancy.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2195–2226) Reproductive Issues in Rheumatic Disorders Posters

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Pregnancy in patients with systemic lupus erythematosus (SLE) is associated with significant maternal and obstetric risks, particularly in the context of antiphospholipid syndrome (APS). While these risks are well-documented, the impact of isolated antiphospholipid antibodies (aPL) without overt APS remains unclear. Bridging this knowledge gap is critical to tailoring management strategies for this subgroup of patients, who may face unique clinical challenges. This study aimed to compare clinical characteristics, maternal comorbidities, obstetric complications, and pregnancy outcomes among three groups of SLE patients: those without aPL, those with isolated aPL, and those with secondary APS, using data from a multicenter Spanish registry of pregnancies.

Methods: A multicenter retrospective cohort study included pregnancies in women fulfilling the 2012 SLICC or 2019 ACR/EULAR classification criteria for SLE. Patients were classified into three subgroups: SLE without aPL, SLE with isolated aPL, and SLE with secondary APS. Data were collected at preconception visits, during each trimester, and post-delivery.

	SLE without APL	SLE with APL	SLE-APS	P value
Age (years), m ± SD	32.5±3.8	33.2±3.4	34.2±5.2	0.83
Time to diagnosis, mean (IQR)	30 (14.2-57.3)	28.4 (9.7-54.3)	32 (15.2-57.2)	0.65
Follow-up (months), m±SD	120 (81.4-206.8)	98 (34.2-201)	194 (78-234)	**0.04**
Obesity (n, %)	5 (12%)	2 (6%)	5 (20%)	0.14
Smoking (n, %)	15 (35%)	12 (39%)	9 (45%)	0.35

Ectopic pregnancies (n, %)	5 (5%)	1 (2%)	0	0.15

Table 2: Maternal and Pregnancy Outcomes in SLE Patients Stratified by aPL and APS Status

Key variables included clinical and immunological profiles, maternal comorbidities, obstetric history, pregnancy complications, and delivery outcomes. Comparative analyses were performed to evaluate maternal and fetal outcomes across the subgroups

Results: A total of 201 pregnancies were analyzed across three groups: SLE without aPL (n=43), SLE with isolated aPL (n=31), and SLE-APS (n=20). While the groups were similar in demographic characteristics and comorbidities, there were striking differences in pregnancy outcomes. The SLE-APS group, experienced the highest rates of adverse pregnancy outcomes. In fact, 60% of pregnancies in this group faced complications, a stark contrast to only 20% in the SLE without aPL group and 5% in the SLE with isolated aPL group ($p< 0.0001$).

The SLE-APS group also had significantly higher rates of preterm delivery (27%) and fetal death before 10 weeks (30%) compared to SLE without aPL (14% and 9%, respectively) and SLE with isolated aPL (6% and 5%, respectively, $p=0.04$ and $p=0.02$). The risk of fetal death before 10 weeks was particularly concerning in the SLE-APS group, with nearly one-third of pregnancies affected.

Interestingly, despite the increased risk of complications, live birth rates remained relatively similar across all groups, with 70–77% of pregnancies resulting in live births ($p=0.34$). However, the SLE-APS group showed a notable trend towards higher IVF failure rates (30% compared to 3% in the SLE without aPL group), which may suggest a more complex reproductive challenge for women with APS ($p=0.06$).

Conclusion: This multicenter study highlights the increased risk of adverse pregnancy outcomes in women with SLE-APS, particularly fetal death before 10 weeks and preterm delivery. Although women with isolated aPL also face higher pregnancy risks compared to those without aPL, their outcomes are less severe than those with APS.

Session Title: (2195–2226) Reproductive Issues in Rheumatic Disorders Posters

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Women with SLE experience higher rates of adverse pregnancy outcomes. Among those with active SLE during pregnancy, lupus nephritis (LN) is associated with particularly poor pregnancy outcomes. Despite the significant impact of LN on pregnancy and offspring, treatment modalities have remained largely unchanged over the past decades. This study aims to utilize data from six international prospective pregnancy registries to describe changes in treatment patterns **for active LN during pregnancy** over several decades.

Methods: We identified prospective cohorts of pregnancies among women with SLE. We included data from six international prospective registries from the US (North Carolina, Maryland), Italy, Germany, Canada and Israel. Data from each cohort were collected and extracted individually into a harmonized dataset. Active LN was defined as proteinuria scored on the SLEDAI during pregnancy or urine protein–creatinine ratio >500 during any trimester. Pregnancies spanned over

	1987-1990 n=28	1991-2000 n=46	2001-2010 n=65	2011-2020 n=40	2021-2025 n=11

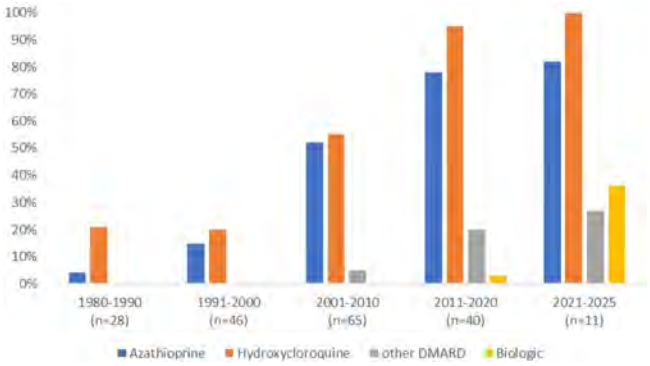
Pattern of prednisone dosing across time for pregnancies with active LN.



Use of DMARDs and biologics across time for all pregnancies with active LN.

three decades (thirty-seven years) and were divided within five time periods. Only pregnancies with active LN, medication data, and known delivery dates were included, allowing for comparison of medication trends over time. Differences in pregnancy outcomes and medication use across time periods were measured using simple statistics.

Results: We included 190 pregnancies with active LN during pregnancy. Overall, the average maternal age was 28 years, ranging from 19 to 44 years, and maternal age was unchanged over time (Table 1). Included pregnancies were multiracial, with most identifying as Black (40%). When evaluating pregnancy outcomes, among those with delivery after 20 weeks gestation, 29% developed preeclampsia, ranging from 23% to 44% over time periods. Rates of miscarriage and stillbirth stayed similar across time periods.

While overall exposure to prednisone remained relatively stable over time, the percent of active LN pregnancies treated with high-dose prednisone (≥20 mg/day) was variable across time (Figure 1). An increasing trend for both hydroxychloroquine and azathioprine was observed, with hydroxychloroquine increasing from 21% to 100% and azathioprine increasing from 4% to 82% over time. This trend remained similar in analyses stratified by racial groups. Use of other pregnancy compatible DMARDs and/or biologics, including tacrolimus and cyclosporine, are more recent (Figure 2).

Conclusion: Our descriptive study indicates that treatment patterns for active LN during pregnancy across the past three decades have predominately included prednisone, azathioprine and hydroxychloroquine. Despite these treatments, outcomes remain poor, with nearly one-third of pregnancies among women with active LN complicated by preeclampsia. Future research will focus on investigating specific medication dosages and evaluating the treatment effects of azathioprine

Maternal Adverse Pregnancy Outcomes and Risk Factors in Patients with Systemic Lupus Erythematosus in the United States

Grace Haeun Lee[1], Jacquelyn Nestor[2], Baijun Zhou[3] and April Jorge[2], [1]Division of Rheumatology, Allergy, and Immunology, Department of Medicine, Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital, Boston, MA, [3]Massachusetts General Hospital, Boston

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2195–2226) Reproductive Issues in Rheumatic Disorders Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Despite significant advances in SLE management, women with systemic lupus erythematosus (SLE) are at risk of adverse pregnancy outcomes (APOs). We sought to determine the risk and risk factors for maternal APOs among females with SLE in the US.

Methods: Using a large, multicenter, electronic health record (EHR) database (TriNetX), we performed a retrospective cohort study of reproductive-age females (age 15-44 years) with SLE. SLE was defined by ≥2 ICD codes >30 days and < 2 years apart. We identified pregnancies occurring before and after SLE diagnosis using ICD and CPT codes. We assessed APOs identified by ICD codes, including pre-eclampsia, preterm delivery, peripartum infection, venous thromboembolism, cardiomyopathy, maternal death, and a composite outcome including any of these events. We also assessed postpartum hospitalizations for SLE. We assessed potential risk factors, including demographics, geographic region, SLE severity index, SLE manifestations of lupus nephritis (LN) and antiphospholipid antibody syndrome (APS), and medication use in the six months prior to pregnancy onset, including hydroxychloroquine, oral glucocorticoids, belimumab, and known teratogenic immunosuppressant medications (i.e., methotrexate, mycophenolate, or leflunomide). We used multivariate logistic regression analysis to compare the odds of APOs according to potential risk factors.

Rituximab	364 (0.9)
Belimumab	474 (1.1)
Other immunosuppressant	903 (2.2)
Healthcare Utilization	
Outpatient encounters, median (IQR)	2 (6)
ER/Inpatient visits, n (%)	15,302 (36.8)

Assessed in 12-months prior to date of meeting SLE definition unless otherwise specified. Early LN is defined as diagnosis within 6 months after SLE onset. SLE Severity Index is adapted from Garrison algorithm for administrative data. Other immunosuppressant use includes sulfasalazine, cyclosporine, tacrolimus, abatacept, tocilizumab, TNF inhibitors, IL17 inhibitors, IL12/23 inhibitors, and JAK inhibitors

Results: From January 2000 to August 2021, we identified 41,558 females of childbearing age with SLE and 9,180 with ≥1 pregnancy before or after the first SLE code (Table 1). There were 12,598 total SLE pregnancies, with 7,539 occurring before and 5,059 occurring after SLE diagnosis. Among pregnancies that occurred after diagnosis, 15.7% were exposed to teratogens within 6 months prior to pregnancy. The incidence of composite APOs among total SLE pregnancies was 22.8% (Table 2). Pre-eclampsia (11.4%), hospitalization for SLE (8.5%), and thromboembolism (8.0%) were the most common adverse maternal outcomes. Black and Hispanic patients were at increased risk for composite APOs and SLE hospitalizations (aORs for composite APOs: 1.34 [95% CI 1.17-1.53] and 1.20 [1.03-1.41]) for Black and Hispanic patients compared to White patients, respectively, and aORs for SLE hospitalizations: 1.42 [1.19-1.69] and 1.32 [1.07-1.62] for

Table 2. Maternal Adverse Pregnancy Outcomes in Patients with Systemic Lupus Erythematosus

Outcomes	Total SLE pregnancies N (%)	SLE Pregnancies Before SLE Diagnosis N (%)	SLE Pregnancies After SLE Diagnosis N (%)
Pre-Eclampsia/ Eclampsia	1240 (11.4)	767 (11.2)	473 (11.5)
Pre-term Delivery	718 (5.7)	461 (6.0)	257 (5.1)
Peripartum Infection	156 (1.2)	97 (1.3)	59 (1.2)
Thromboembolism	1007 (8.0)	489 (6.5)	518 (10.2)
Cardiomyopathy	88 (0.7)	59 (0.8)	29 (0.6)
Maternal Death	72 (0.6)	28 (0.4)	44 (0.9)
Composite APO Outcome	2,767 (22.8)	1,578 (20.9)	1,189 (23.5)
Hospitalization for SLE	1,076 (8.5)	541 (7.2)	535 (10.6)

Denominator is 12,598 total pregnancies for all outcomes other than pre-eclampsia/eclampsia outcome, which was assessed among pregnancies that were at least 26 weeks long, excluding spontaneous/elective abortions (n = 10,840).
APO, adverse pregnancy outcomes. Composite APO Outcome includes pre-eclampsia/eclampsia, pre-term delivery, peripartum infection, thromboembolism, cardiomyopathy, and maternal death.

Lupus nephritis	1,171 (10.8)	469 (40.1)	2.52 (2.19-2.90)	1.75 (1.48-2.07)
Medication Use				
Hydroxychloroquine	2,021 (18.6)	552 (27.3)	1.33 (1.18-1.51)	0.96 (0.84-1.11)
Glucocorticoids	1,985 (18.3)	576 (29.0)	1.48 (1.31-1.67)	1.05 (0.93-1.20)
Teratogenic immunosuppressant†	534 (4.9)	210 (39.3)	2.28 (1.85-2.81)	1.26 (0.98-1.63)
Belimumab	81 (0.7)	31 (38.3)	2.09 (1.30-3.35)	1.38 (0.86-2.21)

Denominator includes pregnancies of duration ≥ 26 weeks, excluding spontaneous/elective abortions (total n = 10,840). *Adjusted for age, race and ethnicity, geographic region, SLE severity, lupus nephritis. † Includes methotrexate, mycophenolate, and leflunomide. Variables were assessed in the 12 months prior to pregnancy onset, other than medication use which was assessed in the 6 months prior to pregnancy onset.

Black and Hispanic patients compared to White patients, respectively). Patients with severe disease were at 3 times higher odds of APOs (Table 3) and a higher risk of SLE hospitalization (aOR 1.73, CI 95% 1.37-2.20). APS and LN also increased the risk of APOs and hospitalizations. When adjusted for SLE severity, medication use was not associated with the risk of composite APOs.

Conclusion: In this large EHR-based cohort of SLE pregnancies, we identified a high burden of composite and specific APOs. Patient factors associated with higher risks of APOs included Black race, Hispanic ethnicity, higher SLE severity, and disease manifestations of LN and APS. These findings highlight the importance of pregnancy counseling for reproductive-age females with SLE and efforts to improve maternal pregnancy care and outcomes.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2195–2226) Reproductive Issues in Rheumatic Disorders Posters

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Women with systemic lupus erythematosus (SLE) are at increased risks for adverse pregnancy outcomes (APOs) including preterm birth, low birth weight and preeclampsia (1,2). We previously reported that these APOs are related to uncontrolled high disease activity and specific treatments, particularly the dose of glucocorticoid (3,4). In 2020, the American College of Rheumatology (ACR) published guideline for the management of reproductive health, emphasizing the importance of preconception care and transitioning to pregnancy-compatible medication (5). This study aimed to assess whether treatment strategies and pregnancy outcomes in women with SLE changed after the publication of the 2020 ACR guideline at a single center.

Methods: We analyzed the data from SLE patients who had been treated at our institution during planning for pregnancy and subsequently gave birth from rheumatic disease pregnancy registry. Patients were divided into two groups: those who conceived before 2020 and those who conceived after 2020. We retrospectively compared patients' characteristics, disease activity, treatments, and pregnancy outcomes between the two groups.

Results: A total of 73 pregnancies in 55 patients were included: 54 pregnancies occurred before 2020 and 19 after 2020. Table 1 showed patients' characteristics and disease activity. There were no significant differences in age at conception or disease duration between two groups. However, the rate of preconception care implementation was significant higher after 2020 (P=0.031). No significant differences were observed in any disease activity parameters between two groups. Regarding treatment before and during pregnancy, the proportion of glucocorticoid (GC) use was significantly higher after 2020 (P=0.008 and 0.016, respectively, Figure a), although the mean GC dose was lower compared to the group before 2020 (P=0.067 and 0.022, respectively, Figure b). The use of immunosuppressants and hydroxychloroquine was significantly more common after 2020 (P< 0.001, Figure c,d). While no significant differences in pregnancy outcomes were found (Table 2), the incidence of SLE flares and preterm premature rupture of membrane tended to be lower in the cases after 2020 (P=0.126, 0.182, respectively), whereas the rate of hypertensive disorder of pregnancy tended to be higher (P=0.078).

Conclusion: Following the publication of the 2020 ACR guideline, preconception care became more widely implemented Additionally, the use of immunosuppressants and hydroxychloroquine during pregnancy increased, while lower doses of

Abstract Number: 2213

Awareness Regarding Contraceptive Measures, Drug Usage And Factors Affecting Pregnancy Among Patients With Autoimmune Rheumatic Diseases

Juhi Dixit, Shri Balaji Institute of Medical Sciences, Mowa Raipur, Raipur, Chhattisgarh, India

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2195–2226) Reproductive Issues in Rheumatic Disorders Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: This study aims to find out knowledge, attitude, practices and beliefs of patients with autoimmune rheumatic diseases regarding family planning, contraception, drug use and various factors which can affect pregnancy.

Methods: It was a cross-sectional observational study conducted in a tertiary care center of North India. A validated questionnaire-based survey was filled by 255 married females in the reproductive age group attending rheumatology OPD

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

over a period of one year. Postmenopausal women, widowed/divorced/separated couple and those not giving consent were excluded from the study.

Simple descriptive analysis of data was performed using absolute numbers and percentages for categorical variables and mean ± standard deviation for continuous variables.

Results: Section 1: Contraceptive awareness and usage

Most of the patients (245/255, 96%) were aware regarding family planning and contraception with most information sourced from mass media or the internet (136/255, 53.3%) followed by friends or relatives (87/255, 34%). Only 61/255 (24%) learned about contraception from physicians, suggesting a potential gap in physician-patient discussions on family planning. 198/255 (77.64%) patients reported that they were never told anything about the contraceptives during OPD visits. Barrier method (condoms) was most widely known (204/255, 80%) and most preferred (160/212, 75.47%). The most common reasons for not using contraception included lack of knowledge (32/96, 33.3%) and safety concerns (22/96, 22.91%).

Section 2: Awareness regarding rheumatological drugs and their impact on fertility and breastfeeding

Over half of patients (142/255, 55.68%) were unaware of the medications they were prescribed for their rheumatological condition and majority of them (220/255, 86.27%) were unaware of the availability of safe drugs for use during pregnancy. Nearly two third of the patients (165/255, 64.7%) believed that taking medications during pregnancy could adversely affect fetal growth. More than half of them (151/255, 59.21%) thought breastfeeding could lead to disease transmission.

Section 3: Awareness of the impact of rheumatic diseases on pregnancy and vice versa

Table 1: Baseline Characteristics

Baseline characteristics	
Age (years, mean±SD)	34.17 ±5.76
Education (Percentage, (n))	
Illiterate	5.8 (15)
School education (primary/middle/high school)	30.98 (79)
Graduate	32.15 (82)
Post-graduate	23.92 (61)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

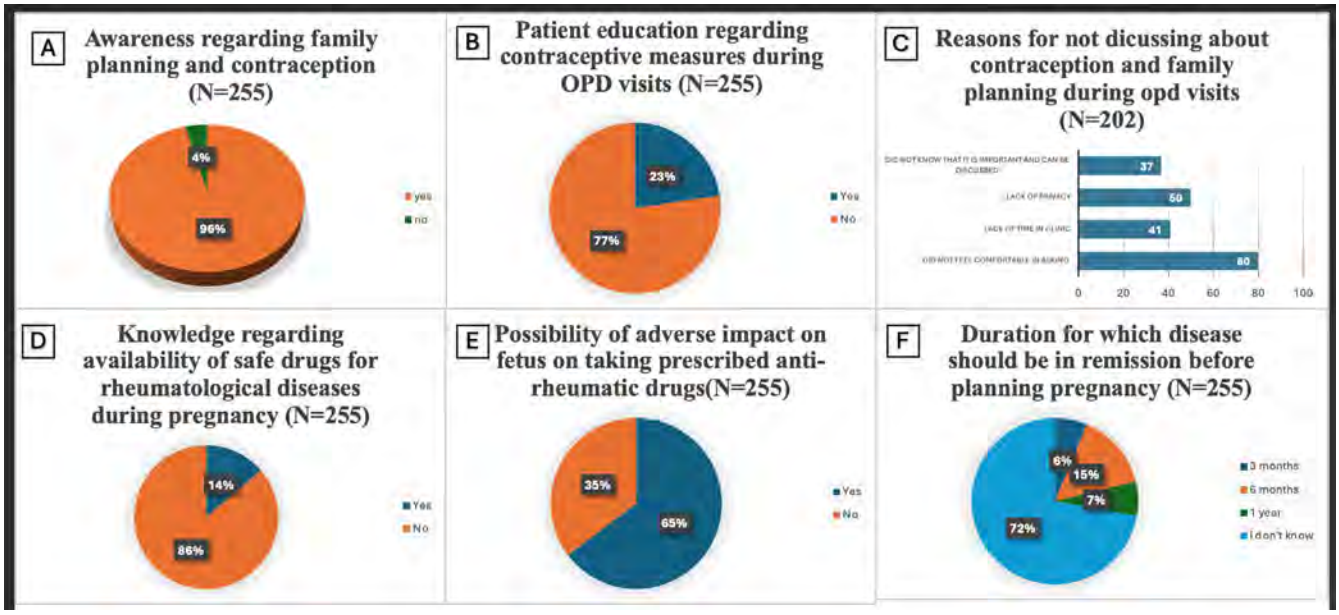

Figure 1 A : Pie chart showing awareness regarding family planning and contraception in patients attending rheumatology OPD, 1B : Pie chart showing physician initiated discussions for patient education regarding contraceptive measures in OPD, 1C: Bar graph showing reasons stated by patients for not initiating discussions regarding family planning and contraception by themselves during OPD visits, 1D : Pie chart showing knowledge among patients regarding the availability of safe drugs for rheumatologic diseases during pregnancy, 1E: Pie chart showing patients' belief regarding possibility of adverse impact on fetus on taking prescribed anti-rheumatic drugs, 1F: Pie chart depicting awareness among patients regarding the duration of remission of rheumatologic disease prior to planning pregnancy

More than two third of the patients (176/255, 69.01%) were unaware of how disease activity could affect pregnancy. Similarly, 174/255 (68.23%) were unaware of how pregnancy could affect disease activity. A significant number (184/255, 72.15%) were unaware of the duration of disease remission needed before conceiving, and only 38/255 (14.9%) were aware of the recommended six months of remission.

Conclusion: Study highlights the need for improved physician-patient communication which could significantly enhance the reproductive health and outcomes for patients with rheumatological conditions

Session Title: (2195–2226) Reproductive Issues in Rheumatic Disorders Posters

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background/Purpose: Systemic lupus erythematosus (SLE) can pose an increased risk of adverse pregnancy outcomes such as preeclampsia and preterm delivery. Hydroxychloroquine (HCQ), commonly used to manage SLE, especially during pregnancy, has shown conflicting associations with pregnancy outcomes, highlighting an important knowledge gap. In this study, we explored the association between HCQ use and the risk of preeclampsia/eclampsia and preterm delivery, while accounting for important maternal covariates in a cohort of SLE pregnant patients.

Methods: We studied SLE singleton pregnancies among publicly insured patients in the British Columbia Perinatal Data Registry (BCPDR). We studied pregnancies where SLE was recorded before pregnancy and defined HCQ treatment during pregnancy multiple ways, including at least two fills or minimum of 60 days' supply during the first 20 weeks of pregnancy. For binary outcomes modified Poisson models estimated risk ratios (RRs) and 95% confidence intervals (CIs) using propensity scores to address confounders. For preterm delivery, we also conducted a time-to-event analysis using a Cox proportional hazards model. Multiple sensitivity analyses explored definitions of SLE, HCQ exposure, and outcomes and stratified analyses examined effect modification.

Results: We studied 847 pregnancies to 597 women with SLE during pregnancy. Most pregnancies were among non-smokers at the start of pregnancy (93.9%). The mean age was 33 years old (SD=4.6 years). Use of HCQ, defined as ≥2 fills

Table 1. Association between hydroxychloroquine use in the first 20 weeks of pregnancy and adverse pregnancy outcomes in patients with SLE (RR: Risk Ratio; 95% CI: 95% confidence intervals; HR: Hazard Ratio)

All Pregnancies			
	Preeclampsia/Eclampsia		
Exposure	N cases/at risk	RR (95% CI)*	
2+ fill or over 60 days	20/303 vs. 20/490	0.92 (0.47, 1.80)	
1+ fill or any day	23/357 vs. 20/490	0.93 (0.49, 1.76)	
	Preterm Delivery (34 Weeks Cut-off)		
Exposure	N cases/person-weeks	HR (95% CI)*	RR (95% CI)*
2+ fill or over 60 days	18/4951 vs. 20/8144	1.06 (0.54, 2.10)	1.05 (0.53, 2.09)
1+ fill or any day	23/5812 vs. 20/8144	1.31 (0.68, 2.54)	1.29 (0.68, 2.44)
	Preterm Delivery (37 Weeks Cut-off)		
Exposure	N cases/person-weeks	HR (95% CI)*	RR (95% CI)*
2+ fill or over 60 days	74/4951 vs. 72/8144	1.40 (0.98, 2.00)	1.40 (0.99, 1.98)
1+ fill or any day	83/5812 vs. 72/8144	1.36 (0.97, 1.93)	1.35 (0.96, 1.89)
Parity: Nulliparous			
	Preeclampsia/Eclampsia		
Exposure	N cases/person-weeks	HR (95% CI)*	
2+ fill or over 60 days	16/148 vs. 14/194	0.92 (0.41, 2.03)	
1+ fill or any day	17/171 vs. 14/194	0.88 (0.42, 1.87)	
	Preterm Delivery (< 34 weeks)		
Exposure	N cases/person-weeks	HR (95% CI)*	RR (95% CI)*
2+ fill or over 60 days	11/2419 vs. 9/3219	1.14 (0.45, 2.93)	1.15 (0.45, 2.94)
1+ fill or any day	14/2783 vs. 9/3219	1.42 (0.56, 3.60)	1.42 (0.59, 3.41)
	Preterm Delivery (< 37 weeks)		
Exposure	N cases/person-weeks	HR (95% CI)*	RR (95% CI)*
2+ fill or over 60 days	39/2419 vs. 26/3219	1.70 (0.97, 2.97)	1.69 (1.00, 2.85)
1+ fill or any day	44/2783 vs. 26/3219	1.73 (1.01, 2.98)	1.70 (1.02, 2.81)

*Propensity score adjusted

Primary analysis results

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

or ≥60 days' supply compared to no fills, had an adjusted RR of 0.92 (95% CI: 0.47, 1.80) for preeclampsia/eclampsia overall. Results were similar when expanding the exposure window to include three months preconception. In sensitivity analyses, the RR for the early-onset phenotype was smaller (0.72 CI: 0.27, 1.92) although based on smaller numbers. For preterm delivery, we found generally no association across different definitions and approaches. For example, ≥2 fills had an adjusted hazard ratio (HR) of 1.06 (95% CI: 0.54, 2.10). The stratified analyses results showed no appreciable differences.

Conclusion: HCQ use during early pregnancy was not significantly associated with the risk of preeclampsia or preterm delivery. Like past work, the RR was below the null for preeclampsia, but not statistically significant. Residual confounding and misclassification cannot be excluded, and further larger studies with detailed clinical data may shed light on these findings as the potential impact of HCQ on pregnancy outcomes is needed.

Placenta Abnormalities in Systemic Lupus Erythematosus: Novel Marker of Adverse Pregnancy Outcomes

Kaitlin Nuechterlein[1], Karl Grenier[1], Luisa Ciofani[2], Kalliopi Panaritis[2], Sasha Bernatsky[2] and Evelyne Vinet[2], [1]McGill University, Montreal, QC, Canada, [2]Research Institute of the McGill University Health Centre, Montreal, QC, Canada

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2195–2226) Reproductive Issues in Rheumatic Disorders Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Placenta-mediated adverse pregnancy outcomes (APO) are a huge concern in SLE. Recent efforts to understand APO include the establishment of the 2016 Amsterdam classification criteria, developed to standardize placental pathology evaluation. No study to date evaluated the Amsterdam criteria in SLE. Using the prospective "Lupus prEGnAnCY (LEGACY)" biobank, we assessed the relationship between placental abnormalities, lupus anticoagulant (LAC), and APO, applying the Amsterdam criteria.

Methods: LEGACY is a prospective cohort enrolling SLE pregnancies (before the 17th gestational week). Relevant information is collected at each trimester and/or end-of-pregnancy visits. We evaluated pregnancies delivered beyond 17 weeks at the Montreal site. Placenta pathology was defined as abnormal if fulfilling at least one of the 4 main Amsterdam classification subtypes: 1) maternal vascular malperfusion, 2) fetal vascular malperfusion, 3) acute chorioamnionitis, and/or 4) villitis of unknown etiology. Pregnancies with and without abnormal pathology were further characterized based on presence of LAC and APO (i.e. stillbirth, placental insufficiency, gestational hypertension, preeclampsia, small-for-gestational age neonate < 5%).

Results: Of 44 LEGACY pregnancies delivered (beyond 17 weeks), 30 (68%) had placenta pathology available. Among these 30, 13 (43%) had abnormal pathology. Of those with abnormal pathology, 6/1 (46%) had maternal vascular malperfusion, 5/13 (38%) acute chorioamnionitis, 4/13 (31%) villitis of unknown etiology, and 1/13 (8%) fetal vascular malperfusion. Mean gestational age at delivery was substantially lower in pregnancies with abnormal pathology [mean 33.7 weeks, standard deviation (SD) 6.8] versus those with normal pathology (mean 37.8 weeks, SD 1.7), with a difference in mean gestational age of -4.1 weeks (95% CI -0.6, -7.6). LAC was more frequent in pregnancies with abnormal pathology (4/13; 31%) as opposed to pregnancies with normal pathology (2/17; 12%). APO occurred in 8/13 (62%) pregnancies with abnormal pathology (including 3 with early preterm preeclampsia < 34 weeks) as opposed to 7/17 (41%) pregnancies with normal

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

pathology (none with early preterm preeclampsia). Maternal vascular malperfusion was strongly associated with APO (odds ratio 8.1; 95% CI 0.8, 83.7), although the CI included the null.

Conclusion: In this cross-sectional analysis, SLE pregnancies with abnormal placental pathology, particularly maternal vascular malperfusion, experienced shorter gestation and more severe placenta-mediated APO, including early preterm preeclampsia. Future studies will aim to expand the sample, and investigate if placental abnormalities in one pregnancy helps predict APO in subsequent pregnancies.

Expanding Reproductive Health Assessments in Rheumatic Diseases: A Comparative Analysis of Demographic and Disease-Specific Factors

Krista Topalsky[1], Chelsea Guan[2], Lindsay Frumker[3], Dana Nachawati[2], Areeb Tiwana[4], Meghan Gump[2], Omer Pamuk[5] and Marina Magrey[6], [1]University Hospitals, Shaker Heights, OH, [2]University Hospitals Cleveland Medical Center/Case Western Reserve University, Cleveland, OH, [3]University hospitals Cleveland medical center, Highland Heights, OH, [4]Canton Medical Education Foundation, Canton, OH, [5]University Hospitals Cleveland Medical Center/ Case Western Reserve University, Cleveland, OH, [6]Case Western Reserve University School of Medicine/University Hospitals Cleveland, Richfield, OH

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2195–2226) Reproductive Issues in Rheumatic Disorders Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Building on our 2024 ACR study (Topalsky et al.) that described broad knowledge gaps and interest in reproductive health education among women with rheumatic diseases, we designed a follow-up study to assess whether these needs vary across clinical and demographic subgroups. This study aimed to explore whether disease type, time since diagnosis, or age significantly influence sexual and reproductive health (SRH) concerns amongst our patients.

Methods: In this follow-up study, a revised survey was sent to our female patients aged 18-45 years with autoimmune rheumatic diseases seen in the Rheumatology Department at our institution. We developed a mixed-format questionnaire expanding on the 2024 survey to further assess demographic, clinical, and attitudinal data.

Subjects were identified using Slicer Dicer, a data exploration tool in the EPIC EMR that allows for customized searches on large patient populations. Surveys were sent and patient responses collected through REDCap, a secure web application for building and managing online surveys and databases. We conducted chi-square analyses comparing outcomes across subgroups (disease type, time since diagnosis, age group) to identify any differential needs. The study received IRB approval at our institution.

Results: 200 patients received an online survey, of which 61 replied, yielding a 30.5% response rate. Respondents were predominantly middle-aged white patients with a range of rheumatologic diagnoses, most of whom felt their disease was stable (Figure 1). About half reported ever receiving pregnancy-related information and understanding of pregnancy risks

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

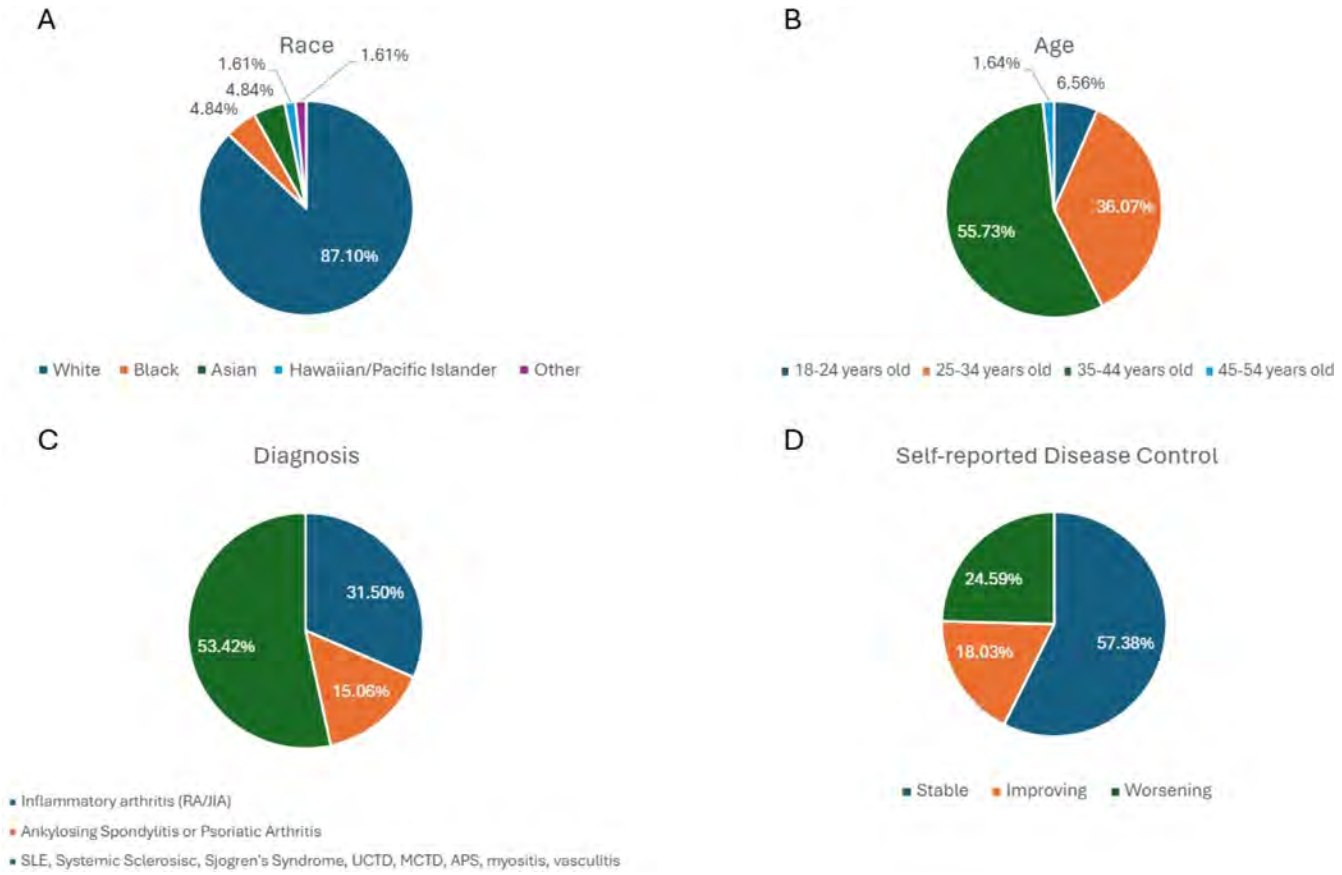

Figure 1. Demographic and Clinical Characteristics of Respondents

varied, with a large portion feeling only somewhat or not informed (Figure 2). Interest in targeted reproductive-health education was high across all subgroups, particularly around fertility and conception as well as managing parenthood with a chronic illness (Figure 3).

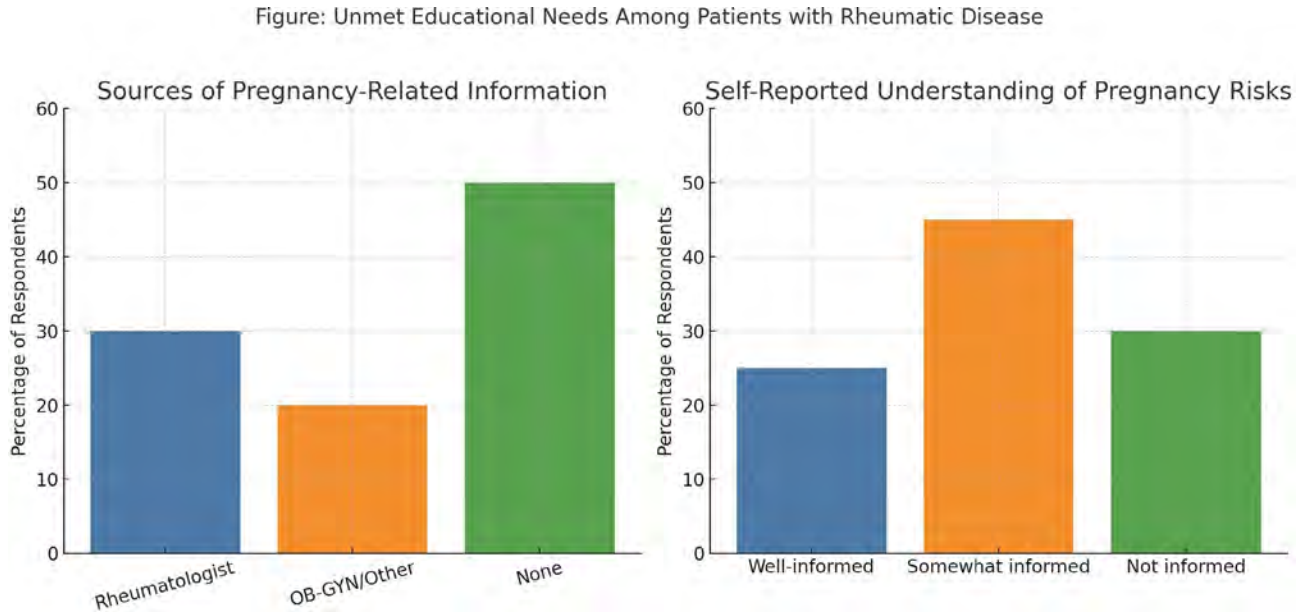

Figure 2. Unmet Educational Needs: Information Sources and Risk Understanding

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

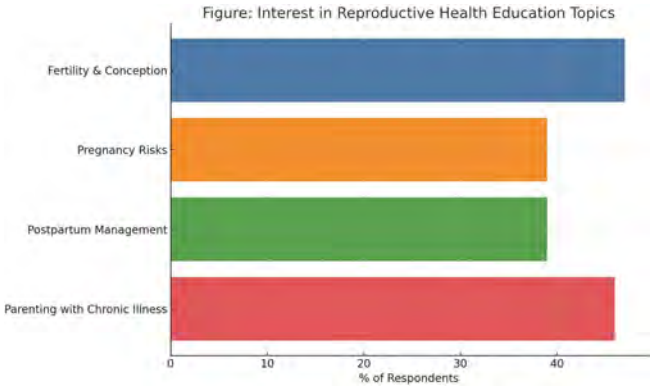

Figure 3. Interest in Reproductive Health Education Topics

Subgroup analyses revealed no significant differences by disease type, diagnosis duration, or age in disease control, contraception use, pregnancy concerns, information receipt, risk understanding, or interest in educational sessions (all $p > 0.05$), suggesting that reproductive-health needs are uniformly shared across all patient subgroups.

Conclusion: While our 2024 abstract described widespread informational gaps and a strong preference for online education, this follow-up with novel subgroup analysis reveals that these gaps and needs are uniformly experienced across all patient groups. This supports the development of universally accessible reproductive health education for rheumatology patients. These insights go beyond earlier descriptive findings and directly inform the design of inclusive educational interventions.

Improving Patient Counseling on Medication Safety During Reproductive Years

Lauren He[1], Anne Carlton[2], Rocio Bautista-Sanchez[1], Yasmin Khader[3] and Puja Khanna[4], [1]University of Michigan, Ann Arbor, [2]University of Michigan, Ann Arbor, MI, [3]University of Michigan/VA Ann Arbor, Ann Arbor, [4]Division of Rheumatology, University of Michigan, Ann Arbor, MI

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2195–2226) Reproductive Issues in Rheumatic Disorders Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with rheumatic diseases require dedicated counseling on reproductive planning from their rheumatologist.[1] Information shared on safety of medications during pregnancy and lactation can be disparate depending on clinical setting, educational sources, method of communication, and type of provider. This wide variability can lead to patients receiving inconsistent information and miscommunications contributing to psychosocial distress, provider mistrust, and medication non-adherence, ultimately resulting in poor outcomes.[2] The objective of this study was to evaluate current practices of patient counseling on medication safety during reproductive years at a large academic institution.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Root Cause Analysis: Stakeholder focus groups and surveys

Methods: Electronic medical records of patients ages 18-45 years who were prescribed methotrexate, azathioprine, leflunomide, mycophenolate, tacrolimus, or adalimumab from July 2023 - December 2024 were analyzed to quantify demographics, prescription patterns, and documented medication counseling processes. Stakeholder focus groups including physicians, registered nurses (RNs), and pharmacists were conducted to understand workflows in use to counsel patients, with a specific focus on pregnancy and lactation. A provider survey was created to appraise common educational resources in use and quantify incidence rates of inaccurate information being given to patients.

Results: There were 2448 patients of reproductive age during the study period: 58.6% (n=1436) of this population had been historically prescribed a teratogenic medication, and 616 were currently on an active prescription of methotrexate (n=296), mycophenolate (n=246), or leflunomide (n=74). Forty percent of clinicians reported at least one instance of a patient receiving incorrect information regarding medication safety. Resources used were evidence-based, however geared toward specific audiences and provider categories, leading to significant discrepancy in reliable translation of this information at the patient's level. Nurses and pharmacists had predetermined workflows, therefore counseled patients differently compared

to clinicians (Figure 1). There were at least 13 resources with contrasting levels of accuracy used to educate patients on this topic (Table 1).

Conclusion: There are fundamental variances in patient-oriented educational protocols and practice patterns among practitioners including clinicians, nurses and pharmacists at a large academic practice despite existing guidelines. Standardization of accurate evidence-based resources is key to help eliminate discrepancies when providing reliable and quality education on medication related safety to patients.

Background/Purpose: IgA vasculitis (IgA-V) is a systemic vasculitis involving small vessels, most frequently affecting children. There is few information about pregnancy outcomes in women with history of IgA-V and no data regarding placental findings in these pregnancies.

The aim of this study is to compare vasculitic, maternal and fetal outcomes, and placental findings in pregnant patients with IgA-V and healthy patients.

Methods: We conducted a retrospective case-control study in a single third level center in Mexico City. We included pregnant women and prior IgA-V diagnosis (cases), with placental histopathology available. Control group included healthy

pregnant patients matched by age, number of pregnancies, number of fetuses, BMI and smoking status. Placental findings were categorized per the 2016 Amsterdam Working Group: 1) Maternal vascular malperfusion (MVM), 2) fetal vascular malperfusion (FVM), 3) inflammation/infection, and 4) villitis of unknown etiology.

Results: We analyzed 20 pregnancies in patients with history of IgA vasculitis and 60 matched controls. The median age at IgA-V diagnosis was 12.0 [IQR 7.5, 15.5] years and mean age at gestation was 25.10 ± 4.90 years. During pregnancy two patients (10%) flared, presenting cutaneous manifestations. No differences were observed in hypertensive disorders of pregnancy (5% vs 6.7%; p=0.99), gestational diabetes (0% vs 3.3%; p=0.99), preterm delivery (mean gestational age at birth 38.83 ± 0.99 vs 38.49 ± 2.16; p=0.50), fetal growth restriction (15% vs 5%; p=0.16), stillbirth (0% vs 1.7%; p=0.99),

SD = Standard deviation; IQR = Interquartile range; EFW = Estimated fetal weight; NICU = Neonatal intensive care unit admission.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

NICU admission (5% vs 6.8%; p=0.99) and perinatal death (5% vs 1.7%; p=0.44). Placental weight averaged 443.62 ± 85.61 grams in IgA-V group, similar to control group (p=0.45). Maternal vascular malperfusión (45% vs 36.7%; p=0.599) and fetal vascular malperfusion (40% vs 23%; p=0.16) were the main placental findings in both groups.

Conclusion: Women with a history of IgA-V have favourable maternal and fetal outcomes, similar to the healthy population matched by age. Placental findings, such as MVM and FVM, were not more frequent in patients with IgA-V.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2195–2226) Reproductive Issues in Rheumatic Disorders Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Recurrent pregnancy loss (RPL) and unexplained infertility (UIF) are significant reproductive health challenges in patients with systemic lupus erythematosus (SLE). SLE causes systemic inflammation and multi-organ involvement, potentially affecting reproductive outcomes. This study uses transcriptomic data to analyze the pathogenesis of RPL and UIF in patients with SLE.

Methods: Datasets GSE185047, GSE26787, and GSE165004 were downloaded from the Gene Expression Omnibus. Table 1 summarizes dataset characteristics. Dysregulated genes (DEGs) were identified using GEO2R with thresholds: false discovery rate < 0.05, log2 fold change > 1 for upregulated genes, and < -1 for downregulated genes. Enrichment analysis was performed using Metascape to retrieve enriched terms. Shared upregulated DEGs were visualized with a Venn diagram.

A gene activation network of overlapping upregulated DEGs was constructed using Cytoscape. The top ten hub genes (HGs) were identified using five algorithms: DMNC, Degree, Eccentricity, Stress, and Radiality. Validation was conducted in GSE165004. Immune profiling analyzed 22 immune cell types using CIBERSORT. A two-way ANOVA with the two-stage step-up method compared immune cell abundances across groups. Spearman correlation tests analyzed relationships between gene expression and immune cell proliferation, using mean fluorescence intensity values and immune cell percentages as variables.

Results: We identified 74 upregulated and 75 downregulated DEGs. Upregulated DEGs were enriched in pathways related to cytokine production, myeloid differentiation, and immune response signaling (Figure 1A). Downregulated DEGs were enriched in osteoblast differentiation, breast cancer, and cardiac muscle development (Figure 1B). 72 upregulated genes

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. overlapped across datasets, and ten HGs were consistently identified by at least three algorithms: STAT5B, CD38, PRKCB, INPP5D, SPTBN1, SIRPA, IKZF1, HAVCR2, PLEK, and CASP (Figure 1D)

Immune profiling revealed decreased CD38 expression in RPL and UIF groups compared to healthy controls (Figure 1E). Correlations were observed between gene expression and immune cell proportions: PRKCB with eosinophils, macrophages M0, and T cells gamma delta; INPP5D with naïve B cells, plasma cells, follicular helper T cells, and neutrophils; SPTBN1 with activated mast cells; SIRPA with eosinophils; IKZF1 with memory B cells; HAVCR2 with naïve B cells,

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. macrophages M0, resting mast cells, and neutrophils; and PLEK with CD4+ memory T cells, follicular helper T cells, T cells gamma delta, resting NK cells, and macrophages M2 (Figure 1F).

Conclusion: This study analyzed the pathogenesis of RPL and UIF in SLE patients using transcriptomic data. Ten candidate hub genes were identified that may predict reproductive risks in SLE patients. Decreased CD38 expression was observed in RPL and UIF groups. Correlations between hub genes and infiltrated immune cell proportions highlight their role in disease mechanisms. These findings provide a molecular framework for understanding pregnancy loss and infertility in SLE, warranting validation in longitudinal cohort studies.

Human Milk Fatty Acid Profiles Among Breastfeeding Mothers With and Without Systemic Autoimmune Rheumatic Diseases

Rashmi Dhital[1], Kerri Bertrand[2], Dilli Poudel[3], Christina Chambers[4] and Monica Guma[2], [1]Vanderbilt University Medical Center, Brentwood, TN, [2]University of California San Diego, San Diego, CA, [3]Vanderbilt University Medical Center, Nashville, TN, [4]University of California, San Diego, La Jolla, CA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2195–2226) Reproductive Issues in Rheumatic Disorders Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic autoimmune rheumatic diseases (SARDs) such as systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) are characterized by chronic systemic inflammation and often require immunomodulatory therapies, both of which may affect lipid metabolism and influence breast milk composition, However, data on milk lipidomics in SARDs are scarce. We aimed to characterize and compare fatty acid (FA) profiles in breast milk of mothers with and without SARDs.

Methods: We analyzed archived milk samples from 29 breastfeeding women with SARDs (15 RA, 11 SLE, 3 both) and 15 healthy controls in the UCSD Human Milk Biorepository (HMB). FA (pmol/ml of milk) was assessed using liquid chromatography-mass spectrometry, and median FA levels compared between groups using the Wilcoxon rank-sum test. To estimate the association between FAs and SARDs, FAs were log-transformed to approximate normality and multivariable linear regression was performed. Model[a] adjusted for maternal and child age, maternal body mass index, parity, gestational age at delivery, infant sex, frequency of feeds, time of milk collection, and hours since last feed. Model[b] incorporated variables in Model[a] plus the milk storage length, and Model[c] also accounted for SARD therapies. In subgroup analyses, median FA levels were evaluated by SARD type (RA and SLE) and sample storage length.

Results: Baseline characteristics were comparable, except for earlier gestational age at delivery (38.40 vs. 39.72 weeks) and markedly longer storage duration (40.42 months vs 3.24 months) among SARDs versus controls. Conventional DMARDs (55.17%) and biologic DMARDs (41.38%) were exclusive to SARDs, and corticosteroid use (34.48% vs 6.67%, p=0.07) was more common. Milk macronutrient content did not differ by SARD status. Individual FAs, specifically, medium and long-chain saturated FAs [*lauric acid* (12:0) and *myristic acid* (14:0), *palmitic acid* (16:0)], and long-chain

Table 1. Comparison of fatty acids in archived milk samples from 44 women with and without systemic autoimmune rheumatic diseases (SARDs)*

Common name (notation)	Controls (Median (IQR); n=15	SARDs (Median (IQR); n=29	Direction	P-value (Wilcoxon rank-sum test)
Lauric acid (12:0)	1,059,555 (919,174–1,285,811)	1,683,464 (1,231,623–1,983,149)	**Higher in SARD**	**0.002**
Myristic acid (14:0)	928,499 (821,597–1,291,536)	1,525,263 (876,807–1,905,784)	**Higher in SARD**	**0.019**
Pentadecylic acid (15:0)	48,613 (31,573–63,743)	64,315 (29,919–94,983)	Higher in SARD	0.238
Palmitic acid (16:0)	1,881,974 (1566216–2160036)	2,334,708 (1,763,990–2,786,549)	Higher in SARD	**0.039**
cis-9 Palmitoleic acid (16:1)	383,823 (266,737–629,569)	445,479 (255,710–744,560)	Higher in SARD	0.540
Margaric acid (17:0)	24,496 (20,905–33,215)	31,846 (21,444–41,161)	Higher in SARD	0.280
Margaroleic acid (17:1)	23,783 (17,145–40,950)	34,862 (19,869–52,402)	Higher in SARD	0.302
Stearic acid (18:0)	506,802 (443,258–655,859)	597,666 (419,388–755,890)	Higher in SARD	0.540
Oleic acid (18:1)	2,587,443 (2,299,441–3,144,863)	3,488,529 (2,980,145–4,566,587)	**Higher in SARD**	**0.006**
Linoleic acid (18:2)	2,171,870 (1,736,661–2,544,474)	2,821,638 (1,878,426–3,545,425)	Higher in SARD	0.063
Alpha-linolenic acid (18:3 N3)	257,205 (185,409–303,024)	311,614 (166,836–430,059)	Higher in SARD	0.248
Gamma-linolenic acid (18:3 N6)	15,153 (9,873–27,649)	26,468 (12,348–32,210)	Higher in SARD	0.132
Stearidonic acid (18:4)	4,691 (2,494–5,759)	5,705 (2,808–7,581)	Higher in SARD	0.219
Arachidic acid (20:0)	4,411 (3,632–5,070)	5,505 (3,294–7,883)	Higher in SARD	0.351
cis-Gondoic acid (20:1)	12,217 (8,989–15,139)	14,700 (10,177–24,740)	Higher in SARD	0.092
Eicosadienoic acid (20:2)	13,501 (10,849–19,863)	16,146 (12,050–29,018)	Higher in SARD	0.103
Dihomo-alpha-linolenic acid (20:3 N3)	2,819 (2,202–3,733)	3,294 (2,548–6,644)	Higher in SARD	0.153
Bis-homo-gamma-linolenic acid (20:3 N6)	29,590 (25,462–45,416)	43,767 (26,718–65,345)	Higher in SARD	0.120
Mead acid (20:3 N9)	2,205 (1,550–4,233)	2,425 (1,221–6,007)	Higher in SARD	0.864
Arachidonic acid (20:4)	50,756 (37,826–85,257)	64,609 (46,986–82,862)	Higher in SARD	0.404
Eicosapentaenoic acid (20:5)	14,422 (11,025–18,829)	16,543 (9,921–34,963)	Higher in SARD	0.433
Behenic acid* (22:0)	1,348 (798–1,445)	1,004 (686–2,071)	Lower in SARD	0.831
cis-Erucic acid (22:1)	1,559 (1,358–2,218)	2,455 (1,457–3,697)	Higher in SARD	0.059
Docosadienoic acid (22:2)	1,095 (926–1,860)	1,382 (953–2,360)	Higher in SARD	0.351
Docosatrienoic acid (22:3)	93 (83–154)	128 (77–212)	Higher in SARD	0.520
Adrenic acid (repeat) (22:4)	12,919 (10,189–20,109)	16,028 (10,762–21,517)	Higher in SARD	0.291
Docosapentaenoic acid (22:5 N3)	23,080 (18,724–32,567)	35,164 (24,187–54,562)	Higher in SARD	0.079
Docosapentaenoic acid 22:5 N6	10,695 (8,817–14,308)	11,313 (5,475–15,452)	Higher in SARD	0.769
Docosahexanoic acid (22:6)	56,050 (42,578–118,873)	64,792 (41,384–102,530)	Higher in SARD	0.732
Tricosylic acid* (23:0)	93 (83–154)	128 (77–212)	Higher in SARD	0.520
Lignoceric acid (24:0)	1,138 (982–1,169)	958 (813–1,410)	Lower in SARD	0.607
Nervonic acid (24:1)	233 (157–313)	282 (179–589)	Higher in SARD	0.168
Cerotic acid (26:0)	2,301 (1790–2813)	1,476 (1,244–1,757)	**Lower in SARD**	**0.0001**
Total fatty acids	10,591,091 (8,394,532–12,384,802)	13,600,972 (9,884,785–18,077,326)	Higher in SARD	0.017

Bold when p<0.05
For **each fatty acid**, the tests were run **only on the subset** of patients who have a non-missing value for that fatty acid

monounsaturated FA *oleic acid* (18:1) were significantly higher in SARDs. Very-long-chain saturated FA - cerotic acid (26:0) was lower (**Table 1**). Compared to controls, those with SLE, but not RA, had significantly higher levels of lauric, myristic, oleic, and linoleic acids. Most FAs showed peak levels at ~ 12-24 months storage duration. In multivariable regression analysis, SARD remained associated with higher levels of many of the FAs studied. Furthermore, the magnitude of associations generally increased with sequential model adjustments (**Figure 1**).

Conclusion: Breast milk in SARDs, particularly SLE, showed higher levels of several medium and long-chain FAs compared to controls. The associations persisted and generally became stronger after sequential adjustments for maternal and infant characteristics, milk storage length, and SARD therapies, providing some indication that inflammatory diseases and therapies may affect the milk FA environment. However, given the marked difference in storage length in our sample and the observed impact of prolonged storage on milk FAs, future studies should match controls on storage length to reduce bias and improve data interpretability.

[a]Not calculated when n < 5
aRR adjusted for race/ethnicity propensity score created from age, primary payer, maternal education, pre-pregnancy BMI, clinical comorbidities (preexisting and gestational DM and HTN, pregnancy-induced HTN, hyperlipidemia, depression, alcohol, tobacco, and drug use during pregnancy), presence of LN, presence of APS

Background/Purpose: Pregnant individuals with systemic lupus erythematosus (SLE) face an increased risk of cardiovascular events (CVEs) as well as adverse pregnancy outcomes (APOs). While racial differences in various SLE outcomes are known, the relationship between race/ethnicity, maternal CVEs, and APOs remains poorly understood.

Methods: Utilizing a California population-based birth cohort from 2005-2020, we identified pregnant individuals with SLE via International Classification of Diseases codes on maternal discharge records. The primary exposure was self-reported race/ethnicity, categorized as Asian, Hispanic, non-Hispanic Black, non-Hispanic White, and Other. Outcomes of interest included the occurrence of CVEs and APOs across racial groups. We also assessed APOs by race, separately for SLE pregnancies with and without CVEs. To assess how CVEs affect APO risk within each race, we estimated adjusted relative risks (aRRs) for APOs in SLE by CVE status for each race category. aRRs were adjusted using a propensity score created for race/ethnicity, incorporating age, payer, maternal education, clinical, and SLE-related variables.

Results: Among 8,422 live-born singletons from women with SLE, majority were from Hispanic (42.7%), followed by non-Hispanic White (27.7%) individuals. Private insurance was more common among Asian (78.7%) and non-Hispanic White (68.6%) women, while Hispanic and non-Hispanic Black patients more often had public insurance (51.4% and 52.2%, respectively). Non-Hispanic Black women had the highest prevalence of hypertensive disorders (**Table 1**). Compared to other racial groups, non-Hispanic Black women had the highest prevalence of CVEs during pregnancy (4.0% vs 1.6-2.0%), maternal APOs (24.6% vs 13.5-15.6%) and infant APOs (54.6% vs 34.6%-49.4%), including the highest infant death rate (1.8%) (**Table 2**).

Stratified analysis by race/ethnicity and CVE status showed the highest occurrences of maternal and infant APOs in non-Hispanic Black women, regardless of CVE status (23.4% and 42.1% without CVEs; 51.6% and 83.9%, with CVEs, respectively). In non-Hispanic White women, maternal and infant APOs occurred in 13.4% and 27.7% without CVEs, and 25.6% and 58.1% of those with CVEs, respectively. (**Table not shown**).

In the subanalysis, CVEs in SLE were associated with higher risks of most APOs across all groups. The aRR for maternal APOs was 3.1-fold in Asian patients, 2.5-fold in Hispanic patients, and 1.9-fold in both non-Hispanic Black and White

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

patients. For infant APO, aRRs ranged from 1.4- 1.7-fold in SLE pregnancies with CVEs compared to those without, across all groups (**Table 3**).

Conclusion: CVEs in SLE were linked to higher APO risks. The relative impact of CVEs on maternal APOs was higher for Asian (aRR 3.1) and Hispanic (aRR 2.5) women than the 1.9-fold higher risk of maternal APO observed in non-Hispanic Black and White women with CVEs as compared to those without CVEs. However, non-Hispanic Black women consistently experienced the highest absolute burden of CVEs and maternal and infant APOs, including infant deaths. These findings underscore the importance of integrating cardiovascular disease risk and social determinants of health into the clinical care of pregnant patients with SLE.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2195–2226) Reproductive Issues in Rheumatic Disorders Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) increases the risk of placenta-mediated adverse pregnancy outcomes (APO) and may impact offspring cardiovascular health. Transplacental maternal anti-Ro antibodies can affect fetal cardiac function, while hydroxychloroquine (HCQ), though protective against APO, has been linked to cardiotoxicity in adults at high cumulative doses. Speckle tracking echocardiography (STE), a sensitive tool for detecting early cardiac dysfunction, remains underused in neonates. We used STE to assess the influence of maternal anti-Ro antibodies, gestational cumulative HCQ exposure, and APO on neonatal myocardial strain.

Methods: Participants were recruited from the Montreal site of the Lupus prEGnAnCY (LEGACY) cohort, a multicenter prospective cohort enrolling SLE pregnancies at < 17 gestational weeks. APO was evaluated at each trimester and postpartum, and included: 1) gestational hypertension, preeclampsia and/or eclampsia, 2) placental insufficiency, 3) placental abruption, and/or 4) small for gestational age (SGA < 5^{th} percentile). Neonatal cardiac function was assessed ≤4 weeks postpartum using STE, with global longitudinal strain (GLS) reported via apical endocardial GLS or apical four-chamber peak longitudinal strain. GLS is expressed as a negative percentage, with more negative values indicating better myocardial contractile function. We summarized maternal and neonatal characteristics using descriptive statistics and evaluated GLS with univariable and multivariable regression analyses.

Results: This study included 26 pregnant women with SLE (each with a singleton pregnancy), of mean maternal age 35.9 ± 4.7 years and disease duration 9.9 ± 7.4 years. Most were in Lupus Low Disease Activity State (LLDAS) at baseline (85%), and 65% (15/26) maintained LLDAS throughout pregnancy. Live birth occurred in 89% (23/26) and fetal death in 11% (3/26). APO occurred in 42% (11/26), including gestational hypertension (15%), preeclampsia (23%), placental insufficiency (8%), placental abruption (8%), and SGA < 5th percentile (12%). Among 23 live births, 3 missed the STE assessment and 4 had suboptimal images preventing GLS estimation. Thus, GLS was assessed in 16 neonates of mean age 11.8 ± 26.2 days at STE. HCQ was used by all mothers (16/16), with mean cumulative gestational exposure of 1103.2 ± 294.6 mg x days/kg. Mean GLS was -26.3 ± 4.2%, with term neonates at -26.2 ± 4.3%. Lower mean GLS was observed in neonates born to mothers with APO (-25.2 ± 4.3%), anti-Ro antibodies (-24.8 ± 4.5%), and cumulative HCQ exposure in highest quartile (-24.6 ± 5.2%) versus their respective counterparts (-27.2 ± 4.1%, -27.9 ± 3.4%, and -28.2 ± 3.1%). GLS was not significantly associated with cumulative HCQ exposure, APO, or anti-Ro positivity in multivariable models adjusting for neonatal age and birth weight.

Conclusion: We observed lower GLS in neonates born to SLE mothers with anti-Ro antibodies and those with APO. Though not statistically significant, potentially due to small sample size, the trends may reflect subclinical cardiac alterations. These findings support the need for larger studies to clarify the impact of maternal antibodies, APO, and HCQ on fetal cardiac health.

Abstract Number: 2223

Improving collaboration between rheumatology and OBGYN in the reproductive health care of patients with rheumatic disease

Sara Heard[1], Isha Vasudeva[2], Juvena Hitt[2] and Jeanne Gosselin[3], [1]University of Vermont Medical Center, Burlington, VT, [2]University of Vermont Medical Center, Burlington, [3]University of Vermont Medical Center, Waterbury, VT

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2195–2226) Reproductive Issues in Rheumatic Disorders Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Contraception management, preconception planning, and prenatal, antenatal, and postnatal care vary significantly in clinical practice for patients with rheumatic disease. Rheumatologists recognize the need for efficient referral systems to facilitate collaboration with reproductive health providers; however, they may not have professional relationships with obstetrician-gynecologist (OBGYN) colleagues and an established referral pathway. We conducted a needs assessment at our institution, including surveys of OBGYN residents and OBGYN generalists, to better understand their access to resources and referral patterns to maternal-fetal medicine (MFM) and rheumatology. This quality improvement project aims to improve collaboration between women's health providers and rheumatologists to improve the reproductive health care of patients with rheumatic disease within our health system.

Methods: Online REDCap surveys were administered to OBGYN residents (N=16, 9 pre-intervention, 7 post-intervention) and OBGYN generalists (N=8). OBGYN residents and generalists were asked about resources and access to specialist (MFM and rheumatology) assistance when managing patients with rheumatic disease, when they refer patients to MFM and rheumatology, and preference for electronic versus in-person rheumatology consults. Our primary intervention was a lecture on reproductive health in rheumatic disease for OBGYN residents. Resident survey results were collected pre- and post-intervention and analyzed using Stata 18 software.

Results: Post-intervention data showed an increase in the percentage of OBGYN residents who feel they have the knowledge, skillset, and resources to manage patients with rheumatic disease during pregnancy, from 0% to 57%. The percentage of residents who knew when to refer patients with rheumatic disease to MFM and/or rheumatology increased from 0% to 100%, and those who felt they could identify teratogenic medications in patients with rheumatic disease increased from 33% to 86% post-intervention. Preconception, OBGYN generalists report referring patients with rheumatic disease to rheumatology only (50%), or to both rheumatology and MFM (33%), and less often to MFM only (17%). When referring patients to rheumatology, 50% of generalists choose in-person consults and 50% choose both in-person and electronic consults.

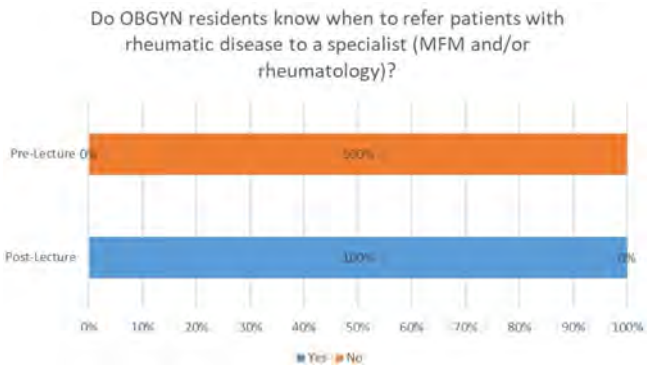

Figure 1

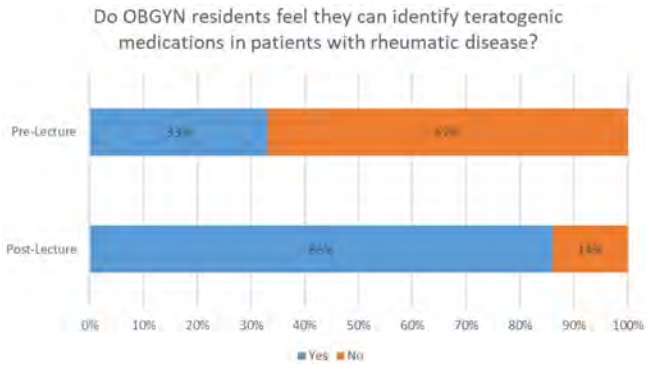

Figure 2

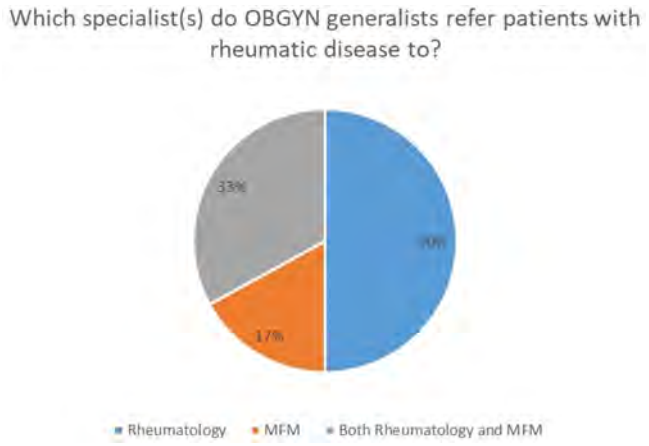

Figure 3

Conclusion: We implemented an effective educational intervention that improved OBGYN resident knowledge regarding when to refer patients to rheumatology, with post-intervention data showing a 100% increase from baseline. The intervention also increased the percentage of residents who felt they could identify teratogenic medications. The OBGYN generalist survey served as a needs assessment and showed that generalists typically refer patients to rheumatology, or both rheumatology and MFM, preconception. Next steps in this quality improvement project include examination of bidirectional referral pathways, indications for referral to rheumatology and OBGYN, and access to each specialty for urgent and non-urgent indications, including contraception and high-risk pregnancy management, to streamline referral processes and improve collaboration.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2195–2226) Reproductive Issues in Rheumatic Disorders Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is associated with an increased risk of placental insufficiency and adverse pregnancy outcomes, even when the disease is clinically quiescent. This suggests the existence of underlying molecular pathologies not reflected by standard clinical disease activity measures or serological markers. This study aimed to determine whether steroid and hydroxychloroquine (HCQ) exposure during pregnancy has the potential to restore placental transcriptomic abnormalities compared to healthy controls.

Methods: We analyzed publicly available RNA-seq data from the NCBI GEO dataset (GSE177029), which included placental samples obtained from 8 SLE patients matched to healthy donors (HD) following delivery. Differential gene expression analysis was performed using the DESeq2 R package. Benjamin & Hochberg correction (false discovery rate) was applied, with significance set at $p < 0.05$. Out of 19,151 genes, the analysis identified 1,051 differentially expressed genes between the SLE and HD groups.The interferon signature was calculated using a standard set of genes (IFI27, IFI44L, ISG15, RSAD2, IFIT1, MX1, OAS1). For other statistical comparisons between groups, a t-test was used.

Results: Characteristics of the SLE patients are shown in Table 1. On average, disease duration was 57 months prior to delivery (IQR: 10–157). The median SLEDAI score was 3. All SLE patients were on daily prednisone (< 15 mg) and HCQ (200–400 mg). Aspirin was used by 3 patients. There were no differences in maternal age, gestational age, or BMI between the SLE and HD groups (30 ± 2 years; 28 ± 1 weeks; 27 ± 2; $p > 0.05$). There was no history of preeclampsia in either group. Newborn weight was significantly lower in the SLE group (2,950 ± 491 g vs. 3,378 ± 261 g; $p < 0.05$). Despite low SLEDAI scores and steroid or HCQ use, placentas obtained from SLE patients showed almost a threefold increase in the type I interferon gene signature (IFN score 1.566, $\log_2$ fold change; *padj* = 0.0034), indicating unresolved immunological activation. Additionally, genes encoding epithelial cytoskeletal proteins, such as keratin 14 and keratin 24, were significantly upregulated—by more than 5- and 7-fold, respectively—in SLE placentas compared to HD, suggesting impaired maturation and dedifferentiation in response to inflammation. Importantly, angiopoietin-2 (ANG-2), a critical regulator of angiogenesis, was significantly downregulated in SLE placentas ($\log_2$ fold change = –1.59; *padj* = 0.0296), corresponding to a 67% reduction in expression compared to healthy controls. This suggests persistent defects in placental vascular remodeling and endothelial homeostasis. In SLE patients with SLEDAI scores of 4–6, there was a 19% reduction in ANG-2 expression compared to those with SLEDAI scores of 0–4.

Conclusion: Low disease activity and the use of steroids or HCQ were insufficient to normalize placental gene expression in SLE pregnancies. Persistent interferon signaling, angiogenic dysregulation, and impaired cytoskeletal remodeling highlight a disconnect between clinical disease control and molecular placental health, underscoring the need for biomarkers and interventions targeting subclinical placental inflammation.

Table 1. Clinical and serological characteristics

Patient #	Disease duration (month)	SLEDAI score	Gestation age (weeks)	Fetal weight (gram)	ANA	dsDNA	SSA	ApL	Proteinuria	Hypocomplementemia

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2195–2226) Reproductive Issues in Rheumatic Disorders Posters

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is associated with a higher risk of adverse pregnancy outcomes (APOs) compared to the general population. Although several APO risk factors have been identified in SLE pregnancies, standardized criteria for pregnancy planning remain undefined. The 2024 EULAR guidelines recommend tapering glucocorticoids to a prednisolone-equivalent dose of ≤5 mg/day prior to conception; however, the optimal threshold for pregnancy planning remains unclear. This study aimed to address these gaps.

Methods: This retrospective cohort study included patients with SLE who received care and delivered at three tertiary referral centers in Japan. Logistic regression and receiver operating characteristic (ROC) curve analyses were used to identify preconception factors associated with APOs. Odds ratios (ORs) were calculated based on pregnancy planning status.

Results: We analyzed 130 pregnancies in 123 women. Based on exploratory analysis, planned pregnancy was defined by the absence of teratogenic medications, clinical disease inactivity for ≥6 months before conception, prednisolone dosage ≤5 mg/day, and absence of proteinuria (≤0.5 g/day). According to this definition, 44.6% (58/130) was classified to planned pregnancy. This model was associated with significantly lower APO rates. Compared to unplanned pregnancies, planned pregnancies had reduced overall APOs (OR 0.29, 95% CI 0.13–0.61, p = 0.0012), maternal APOs (OR 0.50, 95% CI 0.22–1.13, p = 0.097), neonatal APO (OR 0.33, 95% CI 0.16–0.68, p = 0.0026), and low birth weight (OR 0.46, 95% CI 0.21–1.01, p = 0.053).

Multivariate analysis adjusted for hydroxychloroquine use, aspirin use, and renal involvement confirmed a lower risk of APOs: overall APO (aOR 0.30, 95% CI 0.13–0.70, p = 0.0055), maternal APO (aOR 0.50, 95% CI 0.19–1.27, p = 0.15), and neonatal APO (aOR 0.39, 95% CI 0.17–0.86, p = 0.019). Additionally, analysis using multiple models demonstrated that a prednisolone dosage ≤5 mg/day at conception was not significantly associated with an increased risk of APOs or SLE flares during pregnancy, even when compared with higher dosage thresholds.

Conclusion: Planned pregnancy is significantly associated with improved outcomes in SLE. These findings support the 2024 EULAR recommendation and highlight the importance of structured preconception planning

Factors Associated with Contraceptive Counseling by Rheumatologists for Reproductive-Aged Female Patients Prescribed Teratogenic Medications

Yongjay Kim[1], Kelsey Gripp[2], Deanna Jannat-Khah[3], Emily Wu[4], Mehret Birru Talabi[5], Nancy Pan[3], Lisa Sammaritano[3] and Caroline Siegel[3], [1]Hospital for Special Surgery, Englewood Cliffs, NJ, [2]Hospital for Special Surgery, New York, [3]Hospital For Special Surgery, New York, NY, [4]Hospital for Special Surgery, Union City, NJ, [5]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2195–2226) Reproductive Issues in Rheumatic Disorders Posters

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Guidelines advise rheumatologists to provide contraceptive counseling for all patients with pregnancy potential prescribed teratogenic medications, however, adherence is inconsistent. We assessed the frequency of, and factors associated with, rheumatologists' documented contraceptive counseling for this group to elucidate opportunities for intervention.

Methods: This single-center retrospective chart review included premenopausal females aged 18-45 seen by a rheumatologist ≥2 times, December 2022-December 2024, with a prescribed teratogenic medication at the most recent visit. We compared patient demographic and clinical variables and rheumatology provider characteristics between patients with and without documented contraceptive counseling. We performed logistic regression to predict receipt of contraceptive counseling, adjusting for age, race, insurance, preferred language, diagnosis, teratogenic medication, and provider gender and experience level.

Comparisons done using t-tests for continuous and Fisher's Exact tests for categorical variables (no contraceptive counseling vs. contraceptive counseling columns); a p-value <0.05 was considered statistically significant.
1. Excluded from analysis.
2. No patients were prescribed cyclophosphamide, lenalidomide, or thalidomide.
3. Least effective (N=50): condom; Moderately effective (N=40): combined estrogen-progestin pill, vaginal ring, progestin-only pill; Highly effective (N=51): intrauterine device, subdermal progestin implant, injection, abstinence; Permanent (N=6): tubal ligation, partner vasectomy

Results: Of 338 rheumatology female patients aged 18-45 prescribed a teratogen, 107 (31.7%) received contraceptive counseling at their most recent visit. Patients who received vs did not receive counseling were more frequently non-White race (21.6% vs 11.4% Black; 14.7% vs 12.3% Asian; 25.5% vs 19.6% Other; p=0.01), publicly insured (29.0% vs 13.9%, p< 0.01),

A p-value of <0.05 was considered statistically significant

non-English-speaking (8.4% vs 2.2%, p=0.02), had SLE and/or APS (39.3% vs 21.2%, p< 0.01), and were seen by a rheumatology fellow (25.2% vs 8.2%) or by an attending with < 10 years of experience (42.1% vs 27.3%) (p< 0.01). Overall, 231 (68.3%) patients reported no/least effective contraception (n=121) or had no contraception documentation (n=110) [**Table 1**].

In multivariable analysis, the odds of receiving contraceptive counseling decreased 5% with each increasing year of age (OR 0.95, 95% CI [0.92-0.99], p=0.01). Counseling was more likely for patients with Black vs White race (OR 2.5, 95% CI [1.09-5.73], p=0.03), SLE and/or APS vs other diagnoses (OR 3.65, 95% CI [1.66-8.04], p< 0.01), and—as compared to those seen by an attending with >10 years' experience—for patients seen by a rheumatology fellow (OR 5.31, 95% CI [1.82-15.47], p< 0.01) or by an attending with < 10 years' experience (OR 3.13, 95% CI [1.7-5.77], p< 0.01). Compared to methotrexate use, use of another teratogen was associated with decreased odds of counseling that was not statistically significant (for leflunomide: OR 0.28, 95% CI [0.07-1.07], p=0.06; for mycophenolate: OR 0.48, 95% CI [0.23-1.03], p=0.06; for warfarin: OR 0.19, 95% CI [0.04 – 1.01], p=0.05) [**Table 2**].

Conclusion: In this study, most reproductive-aged female patients prescribed a teratogenic medication did not have documentation of effective contraception, and less than one-third received contraceptive counseling at their most recent rheumatology visit. Patients with Black race, SLE and/or APS, and those seen by rheumatology providers closer to training were more likely to receive contraceptive counseling. Although documentation may not fully reflect practice, our findings suggest a need for quality improvement interventions to increase contraceptive counseling and consistent documentation for all high-risk rheumatology patients.

Background/Purpose: Rheumatoid arthritis (RA) has a pre-clinical state. In particular, elevation of antibodies to citrullinated proteins (ACPA) is a strong risk factor for future clinically-apparent inflammatory arthritis that can be termed 'clinical RA', however not all ACPA+ individuals who are 'at-risk' develop clinical RA. Furthermore, we have limited understanding into which factors drive the transition from preclinical to clinical RA. Paraoxonase-1 (PON1) is an HDL-associated enzyme which metabolizes pro-inflammatory oxidized lipids. We have previously shown that increasing PON1 activity over time is associated with decreased risk of incident clinical RA in ACPA+ at-risk individuals (ARI) (Razmjou, et al. ACR Abstract #464, 2024). The PON1 Q192R polymorphism (rs662) has been shown to affect PON1 enzyme activities. This study aimed to investigate if the PON1 Q192R polymorphism associates with incident clinical RA in an ACPA+ ARI population.

Methods: ACPA+ (determined by the anti-CCP3 assay) ARI who did not have clinical RA at baseline were evaluated; 49 (37%) of whom developed clinical RA during longitudinal follow-up. PON1 Q192R polymorphism ('Q192R') were tested as previously described (Charles-Schoeman, et al. *J Rheumatol*, 2023). PON1 activity was measured as previously described (Charles-Schoeman, et al. *Sci Rep*, 2020) by its paraoxonase, lactonase, and arylesterase enzymatic functions. Cox-proportional hazards models were used to evaluate the effect of Q192R on time to clinical RA, with multivariate models including variables with p-values < 0.05 in univariate models. Q192R was analyzed as an ordinal variable (0, 1, or 2 R alleles), and a categorical variable (QR or RR v QQ, ref QQ).

Results: The baseline characteristics of ACPA+ ARI are in Table 1. A greater proportion of ARI with QR, and RR genotypes developed clinical RA (Figure 1). In univariate Cox-proportional hazards models with Q192R, the # of R alleles and RR vs QQ were significantly associated with increased risk of developing clinical RA over time. Significance was maintained in multivariable models after including shared epitope (SE) positivity, and RF IgA/IgM positivity (Table 2). Multivariable models including change in PON1 enzyme activity, SE, RF IgA/IgM, age, sex and BMI also showed that increased # of R alleles were associated with an elevated risk of clinical RA ($p < 0.05$) (Table 2).

Conclusion: In a population of ACPA+ ARI, the PON1 Q192R genotype was significantly associated with increased risk of developing clinical RA, even after controlling for the presence of SE and RF positivity as well as PON1 activity. PON1 activity by lactonase function was inversely associated with the development of clinical RA. Future studies include validating these findings in additional cohorts and incorporating these findings into predictive models for future clinical RA, as well as evaluating the mechanisms of the effect of the PON1 Q192R polymorphism on clinical RA development.

Background/Purpose: Rheumatoid Arthritis (RA) is an autoimmune disease characterized by immune system dysregulation, and it is commonly treated with either conventional or biologic Disease-Modifying Antirheumatic Drugs (DMARDs). Because RA and its therapies suppress the immune system, patients are more susceptible to infections, including COVID-19. However, it remains unclear whether conventional DMARDs or biologic DMARDs confer some benefit with respect to COVID-19 outcomes. This study aims to compare COVID-19 outcomes in RA patients treated with biologic versus conventional DMARDs. We hypothesize that the broader, less targeted immunosuppressive effects of conventional DMARDs may play a more protective role for patients who develop COVID-19 infections.

Methods: The TriNetX Database was queried to identify patients ≥ 18 years old with RA and a COVID-19 diagnosis. These individuals were then divided into two subgroups: those prescribed biological DMARDs (adalimumab, etanercept, infliximab, rituximab, and tocilizumab, n=4,166) and those who were prescribed conventional DMARDs (methotrexate, sulfasalazine, hydroxychloroquine, leflunomide, and azathioprine, n=35,792) within 1 year of the COVID-19 diagnosis. These groups were 1:1 propensity score matched (n=4,163) for demographics and relevant comorbidities. Primary outcomes included 30-day, 90-day, and 1-year medical complications following a COVID-19 diagnosis, and these were compared using risk ratios (RR) with statistical significance set to $p< 0.05$.

Results: RA patients prescribed biological DMARDs before COVID-19 diagnosis had a significantly higher 30-day risk of ventilator use (RR=2.295, $p< 0.001$), mortality (RR=1.907, $p< 0.001$), and pulmonary fibrosis (RR=2.389, p=0.001), an increased 90-day risk of ventilator use (RR=2.092, $p< 0.001$), mortality (RR=1.819, $p< 0.001$), and pulmonary fibrosis (RR=2.528, $p< 0.001$), and an increased 1-year risk of ventilator use (RR=2.076, $p< 0.001$), mortality (RR=1.726, $p< 0.001$), and pulmonary fibrosis (RR=2.137, $p< 0.001$).

Conclusion: Our study suggests that patients with RA taking biological DMARDs have worse COVID-19 outcomes than those taking conventional DMARDs. Patients receiving conventional DMARDs required less ventilatory support during COVID-19 infection, indicating a milder disease course. This may be attributed to the less specific immunosuppressive mechanism of conventional DMARDs when compared to the more targeted mechanism of biological DMARDs, which potentially could lead to a weaker immune response against COVID-19.

SESSION INFORMATION

Session Date: **Tuesday, October 28, 2025**
Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Interstitial lung disease (ILD) in Rheumatoid Arthritis (RA) determines a worse prognosis with an increased mortality. Abatacept and rituximab may be the preferred therapies. JAK inhibitors (JAKi) have demonstrated effectiveness in observational studies of RA-ILD, especially with tofacitinib or baricitinib (BARI). While both articular and pulmonary domains may respond to JAKi, some patients experience ILD progression. Identifying this subgroup of patients is essential for early detection and appropriate management. In a large series of RA-ILD patients treated with BARI, we aimed to **a)** study the effectiveness, and **b)** characterize the subgroup with progressive ILD.

Methods: From a large observational multicenter study of 72 RA-ILD patients treated with BARI, we selected those with available pulmonary function tests (PFTs) follow-up data. Progressive ILD was defined as an absolute decline of forced vital capacity (FVC) of ≥10% within 1 year of follow-up since BARI initiation **(Figure)**. We compared patients with and without progressive ILD. *Results are expressed as percentage, mean±SD or median [IQR], as appropriate*.

Table. Baseline characteristics of RA-ILD patients treated with BARI.

Baseline characteristics	Overall (n=72)	Progressive ILD (n=11)	Non-progressive ILD (n=31)	Progressive vs non-progressive ILD p

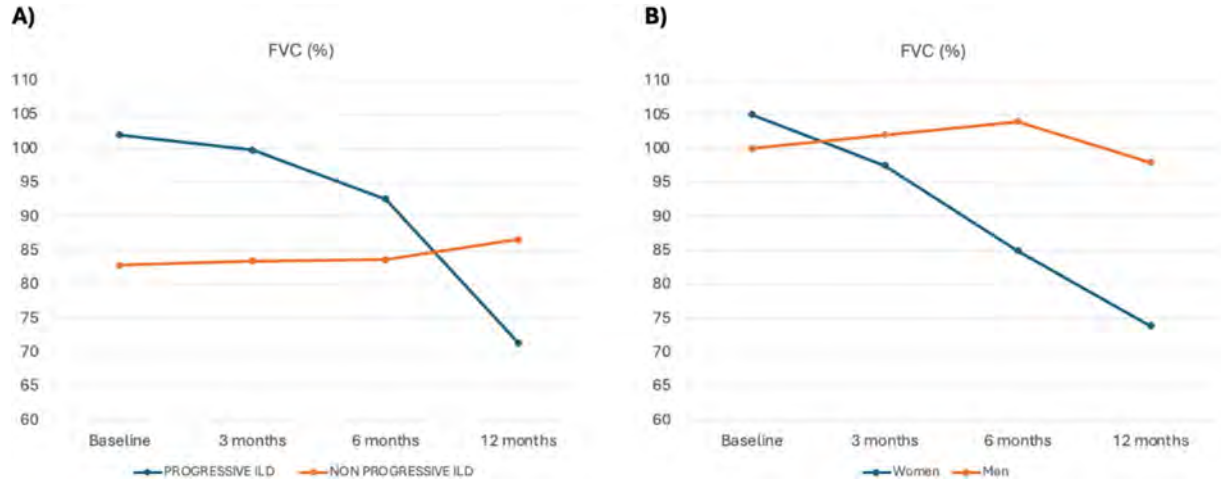

Figure. FVC evolution in A) both groups (progressive and non-progressive ILD) and B) by sex. Progressive ILD was defined as an absolute decline of forced vital capacity (FVC) of ≥10% within 1 year of follow-up since BARI initiation).

Results: A total of 42 patients with available data on FVC evolution were included. Progressive and non-progressive ILD was observed in 11 (26%) and 31 (74%) patients, respectively. The baseline general features are summarized in **Table**. Both groups were similar in age, smoking, positivity of rheumatoid factor or anti-citrullinated protein autoantibodies, ILD duration up to BARI initiation, prednisone dose, baseline PFTs or radiological pattern. Progressive ILD was more frequent in women and as expected required more combined treatment with antifibrotics. FVC evolution in both groups (progressive and non-progressive ILD) and by sex is displayed in **figure**.

Conclusion: BARI may be useful in RA-ILD. However, progression may be present in around a quarter of patients, especially in women. Effectiveness should be closely monitored with PFTs to early detect progressive ILD.

Abstract Number: 2230

Racial and Ethnic Disparities in Rheumatoid Arthritis-Associated Interstitial Lung Disease and Their Impact on Antifibrotic Therapy

Andrea Galecio Chao, Baylor College of Medicine, Houston, TX

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis-associated interstitial lung disease (RA-ILD) is a significant cause of morbidity and mortality among patients with rheumatoid arthritis (RA), often leading to progressive pulmonary function decline. Although antifibrotic therapies, such as pirfenidone and nintedanib, are being used in managing RA-ILD, disparities in their use and clinical outcomes persist across different racial and ethnic groups.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: This retrospective study analyzed data from the BCM ILD Registry with 215 CTD-ILD patients in total. FVC and DLCO values were compared across racial/ethnic groups (White, African American, Hispanic/Latino, others). ANOVA and Ridge regression are used to examine pulmonary function differences and predictors of antifibrotic use.

Results: Within RA-ILD group, the cohort was racially and ethnically diverse: 45.2% Hispanic, 16.1% White, 12.9% Black, and 22.6% Multiracial. The mean FVC and mean DLCO were lowest in Hispanic and Black patients, respectively. Mean FVC for Hispanic patients was 50.5%, and mean DLCO for Black patients was 45.2%, while White patients had the highest mean FVC of 61.25% and mean DLCO of 50.59%. 67% of African American and Hispanic/Latino patients did not receive pirfenidone or nintedanib despite severe impairment. ANOVA showed significant differences in FVC and DLCO, with White patients showing better pulmonary function. Ridge regression analysis identified race/ethnicity as a significant predictor of antifibrotic therapy use, with minority patients less likely to receive treatment even after adjusting for disease severity.

Conclusion: Racial and ethnic disparities in **RA-ILD** care contribute to unequal access to treatment, resulting in poorer pulmonary outcomes for **minority patients**. These disparities are likely influenced by **socioeconomic**, and **healthcare access** factors, including lack of insurance, limited access to healthcare providers, and underrepresentation in clinical trials. To address these gaps, actions are needed such as expanding healthcare coverage, enhancing clinical trial representation, and providing cultural competence training to healthcare providers.

Abstract Number: 2231

Inverse Correlation Between Neutrophil Activation and Rheumatoid Factor Concentrations in Rheumatoid Arthritis (RA)

Anne-Christine Bay-Jensen[1], Dovile Sinkeviciute[2], Christian Thudium[2], shu Sun[1], Mathilde Christensen[1], Morten Karsdal[1], marta Alexdottir[1] and Joachim mortensen[1], [1]Nordic Bioscience A/S, Herlev, Denmark, [2]Nordic Bioscience, Herlev, Denmark

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Neutrophils are crucial in fibro-inflammatory diseases like Crohn's disease (CD) and rheumatoid arthritis (RA), but their biomarkers are better established in CD than in RA. Neutrophils are present in the inflamed synovium of the joints, however data on neutrophil count and assessment of blood levels of calprotectin – an alarmin released from neutrophils and monocytes – have pointed in different directions, which may be attributed to patient heterogeneity and/or treatment effect. The novel biomarker CPa9-HNE is a fragment of calprotectin generated by human neutrophil elastase during neutrophil activation and offers potential insight into neutrophil activity in RA. This study aims to explore the association between neutrophil activity, as measured by CPa9-HNE, and disease activity in patients with moderate to severe RA.

Methods: Serum samples from 76 predominantly white (90%), female (76%), seropositive RA patients and active disease (DAS25-CRP >3.4) aged 22-85 years were retrieved from several different biorepositories (Discovery Lifesciences, BioIVT LLC, Protogenex Inc.). None of the patients were biological naïve. CPa9-HNE was measured in the serum sample using the NordicCPA9™ manual ELISA. The markers of fibrogenesis and fibrolysis, PRO-C3 and C3M, were measured to study the link between fibro-inflammation and neutrophil activity. Data from a published Crohn's disease study (n=65), including

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

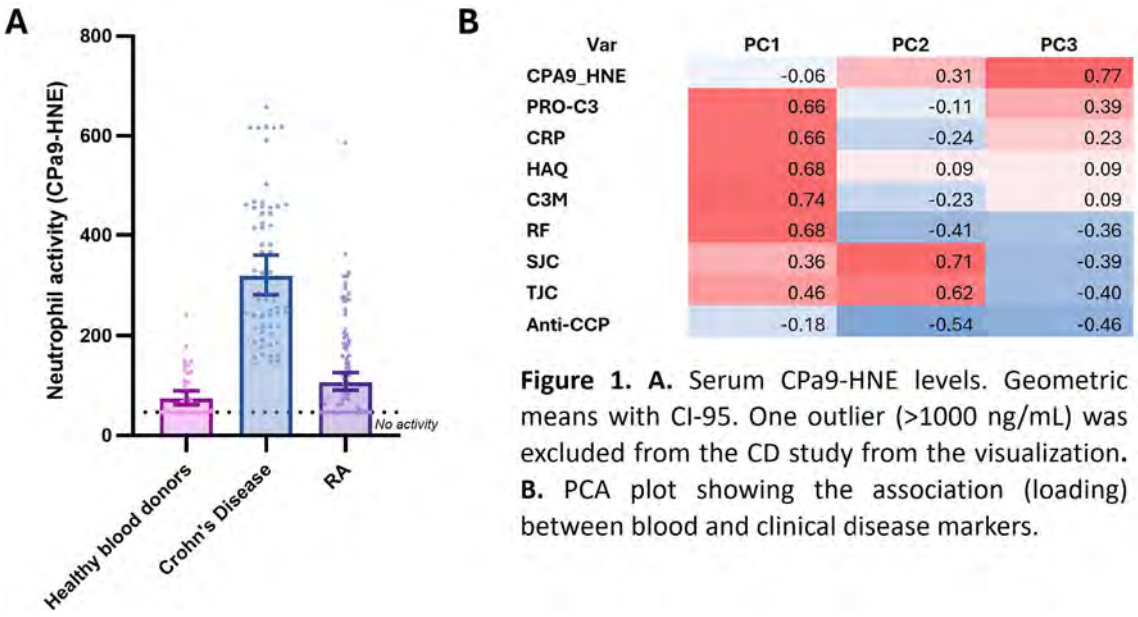

Figure 1. A. Serum CPa9-HNE levels. Geometric means with CI-95. One outlier (>1000 ng/mL) was excluded from the CD study from the visualization. **B.** PCA plot showing the association (loading) between blood and clinical disease markers.

healthy blood donors (n=32), was used to compare levels of CPa9-HNE between CD and RA (Mortensen et al. 2022). Undetectable samples were given the value of the assay detection limit (47 ng/ml).

Results: Of the RA patients, 23 out of 76 had undetectable levels of CPa9-HNE, compared to 14 out of 32 healthy donors and none in the of the CD group. The geometric mean [95%-CI] levels were significantly lower in RA patients (107.2 [90.9-126]) than in CD (319 [281-361]), but higher than healthy controls 74.5 [61.7-90.0] (Figure 1A). CPa9-HNE was inversely correlated with rheumatoid factor (rho =-0.62) and to a lesser degree with anti-CCP levels (rho = -0.40). CPa9-HNE showed no correlation (rho >0.4) or association with age, BMI, gender, disease duration, DAS28, CRP, or swollen or tender joint count (SJC/TJC). Nor the fibro-inflammatory markers PRO-C3 and C3M. PCA analysis revealed three clusters explaining 64% of the variation in the dataset: PC1, fibro-inflammatory driven by C3M, RF, HAQ, CRP and PRO-C3, BUT not CPa9-HNE; PC2, symptomatic driven by SJC and TJC; PC3, neutrophilic driven by CPa9-HNE (Figure 1B).

Conclusion: The observation of high RF and low neutrophil activity in RA patients may be due to the heterogeneity of RA, differing immune pathways, treatment effects and disease stage. Thus CPa9-HNE is a relevant biomarker for the neutrophilic RA endotype, as precision medicine tool for RA.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: There are limited data regarding the recent trends and risk factors for hospitalization in patients with rheumatoid arthritis (RA). Our aim was to estimate the rate, causes and predictors for hospitalizations in a real world, contemporary RA patient cohort.

Methods: Data from a multi-center, longitudinal cohort of RA patients regarding patient and disease characteristics were collected at baseline, 1 and 3 years later. The number and causes for hospitalizations by ICD-10 categories were recorded and the incidence rate was calculated. Risk factors for hospitalizations were evaluated with multivariable poisson regression analysis.

Results: 1195 RA patients were included; 78% were females with a mean age of 62 and a median disease duration of 7 years, repsectively. At baseline, 83% were on conventional synthetic DMARDs, 46% on biologic DMARDs and 39% on prednisolone (median dose: 5 mg/day). Baseline DAS28-ESR was 3.1 (median) and HAQ-DI 0.25 (median), respectively. During follow-up (3585 patient-years), 262 hospitalizations were recorded in 204 patients (17.1%) with an estimated incidence rate of 7.3/100 patient-years. The most frequent causes of hospitalization were infections (2/100 patient-years, primary of the respiratory tract), cardiovascular diseases (0.84/100 patient-years, mainly acute myocardial infarction and stroke), arthroplasties (0.78/100 patient-years) and gastrointestinal diseases (0.72/100 patient-years). By multivariable analysis, seropositivity was associated with a lower incidence (IRR=0.66, 95% CI: 0.47–0.94) while a higher disease activity status (DAS-28-ESR: 3.2-5.1 - Medium Disease Activity: IRR=1.88, 95% CI: 1.27–2.79 or High Disease Activity: IRR=2.74, 95% CI: 1.61–4.56 *vs*. DAS-28-ESR< 3.2: Low disease activity or remission), a higher baseline HAQ (IRR=1.64, 95% CI: 1.06–2.48), male sex (IRR=1.88, 95% CI: 1.22-2.84) and diabetes (IRR=1.99, 95% CI: 1.32–2.94, p = 0.003) were associated with a higher risk of hospitalizations, respectively.

Conclusion: In this large, longitudinal, prospective, real-life cohort of RA patients, the incidence of hospitalizations was 7.3/100 patient-years, with infections being the most common cause. Higher disease activity, impaired functional status, male sex and diabetes were independently associated with hospitalizations. These findings underscore the critical importance of tight disease control and close monitoring for infectious complications in RA patients.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Autoimmune diseases affect more than 23.5 million Americans involving nearly every organ system of the human body. To identify shared, unique, and novel pathways underlying the pathogenesis of common autoimmune diseases, The Accelerating Medicines Partnership: Autoimmune and Immune-Mediated Diseases Network (AMP AIM) was launched to investigate Rheumatoid Arthritis (RA), Systemic Lupus Erythematosus (SLE), Psoriatic Disease (PsD), and Sjogren's Disease (SD) using single-cell and spatial technologies.

Methods: The Disease Teams, Technology Cores, System Biology Groups, Tissue Research Center, and Research Management Units collaborated on pilot projects to evaluate spatial and single-cell technologies for their feasibility, sensitivity, and scalability. These assessments aimed to inform the selection of omics approaches that would provide the greatest utility and reproducibility across the network's diverse research settings.

Results: Following two years of focused investigation, the AMP AIM network developed a standard operating procedure which enables a multi-institutional, spatial multi-omics workflow of deep phenotyping of study participants. This protocol

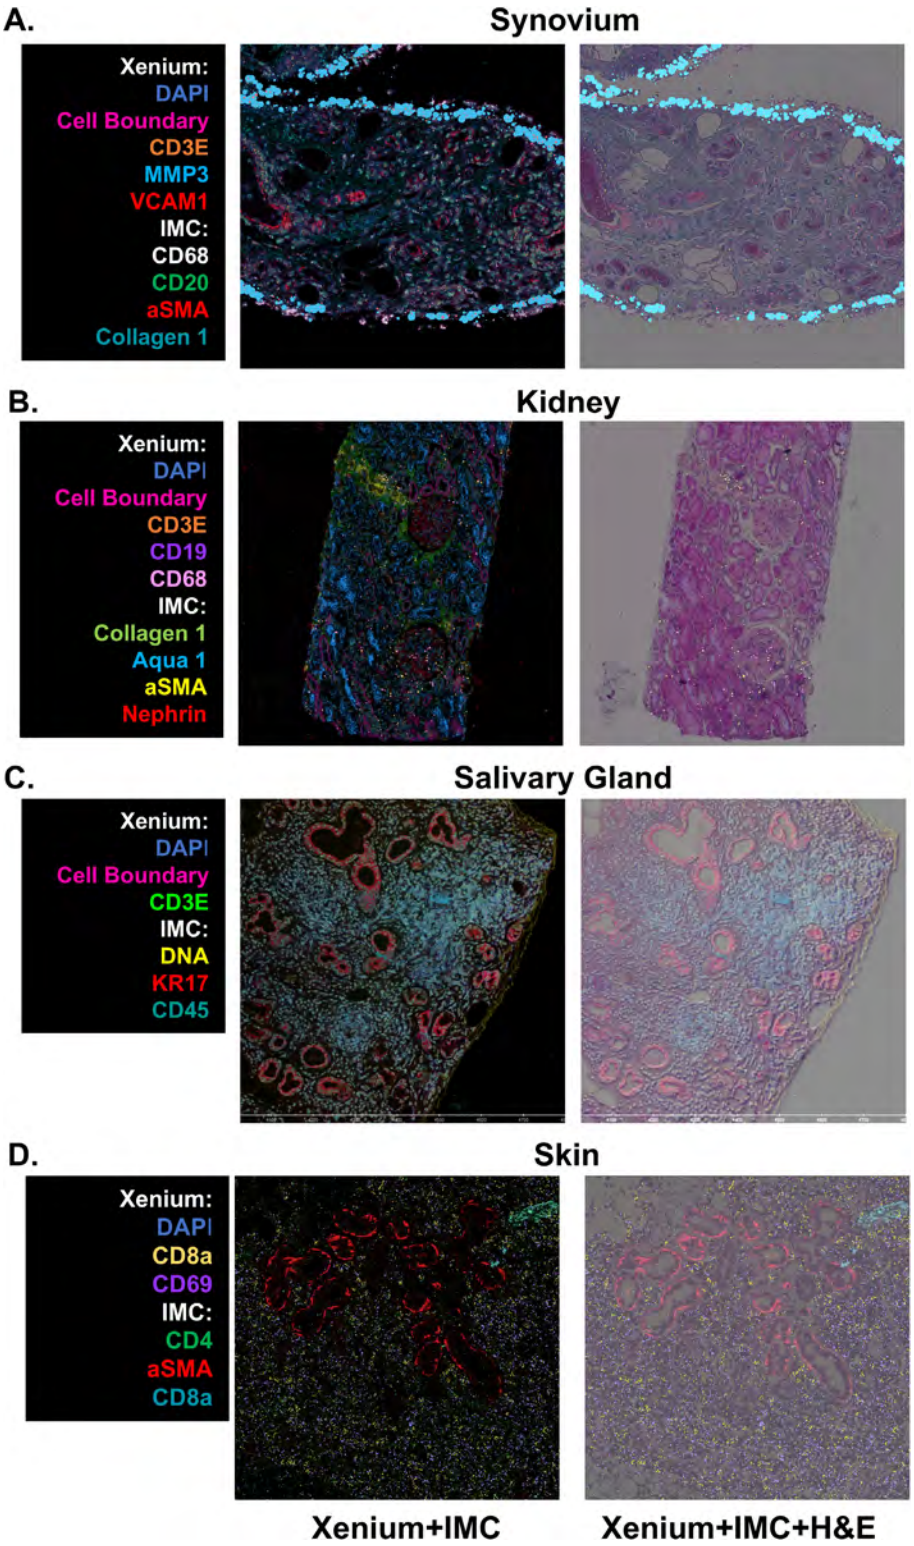

Figure 1: Spatial Characterization of Target Tissues. Representative images from all four target tissues (Synovium, Kidney, Salivary Gland, and Skin) processed and imaged on the Xenium spatial transcriptomics (10X Genomics), stained and whole slide imaged for H&E, and then stained and imaged for ~40 surface proteins via Imaging Mass Cytometry (Standard Biotools), all on the same tissue section and slide. Similar cell types (IMC) or transcripts (Xenium) are highlighted in the example projections to demonstrate agreement across technologies.

leverages centrally collected, FFPE-preserved target tissues (e.g., synovium, skin, salivary gland, and kidney) and integrates spatial transcriptomics (ST) using Xenium (10x Genomics), histological evaluation via H&E staining, and protein-level spatial profiling with Imaging Mass Cytometry (IMC) on the Hyperion platform (Standard BioTools), all on the same slide.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

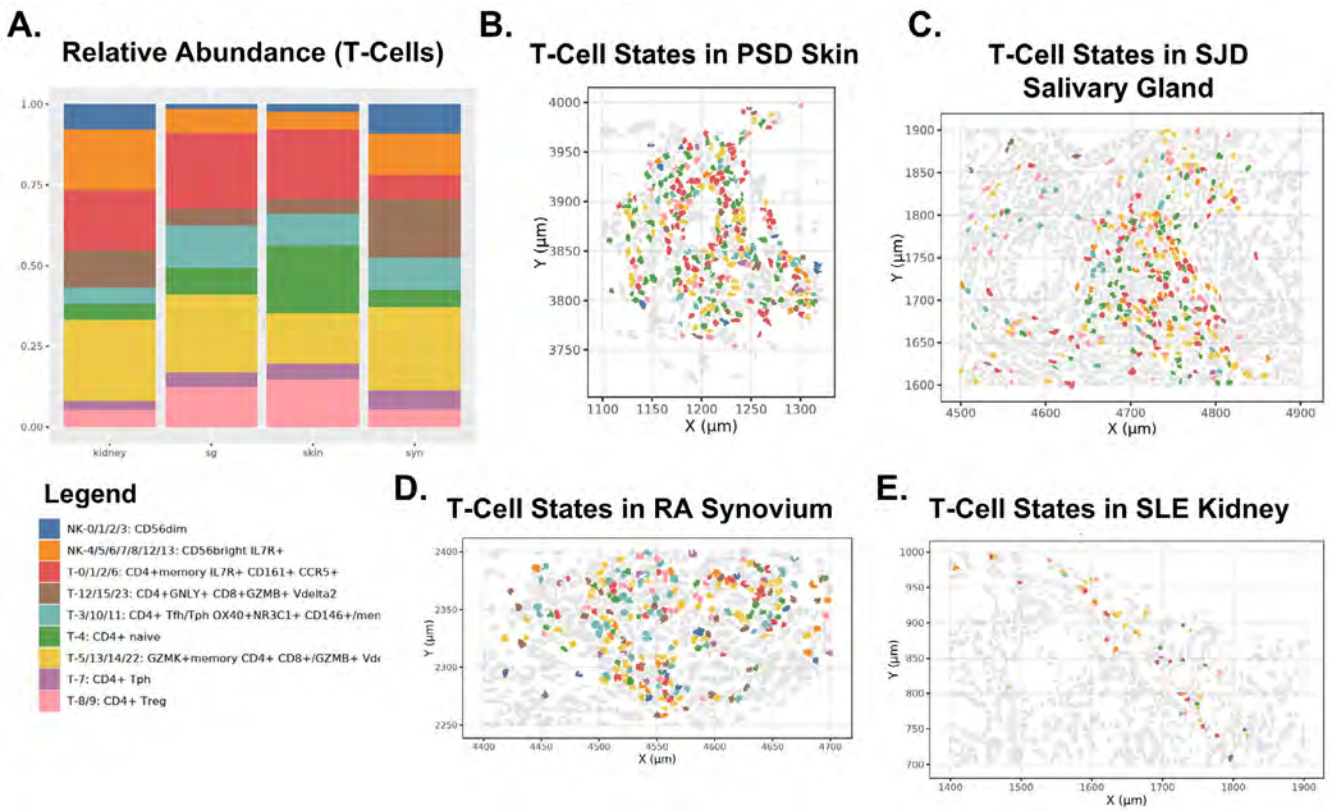

Figure 2: Assessment of Spatial Transcriptomics Technologies demonstrates shared T-cell states across tissues. (A) Median abundance of T-cell states, shown as the proportion relative to the number of T-cells within each tissue. (B-E) Spatial localization of T-cell states within selected regions of interest. in: (B) skin, (C) salivary gland, (D) synovium, and (E) kidney tissues. T-cells are colored by their state, and non-T-cells are colored in grey.

1. Successful implementation of combined spatial transcriptomics and proteomics. With the network selecting Xenium as the preferred ST platform and post-run H&E stain, we developed a workflow which integrates Xenium and IMC from the same tissue section. This results in a unified dataset comprising ~5,000 spatially resolved transcripts, 40 protein markers, and histological context, enabling single-cell level correlation of gene and protein expression within intact tissue architecture (**Fig 1**).

2. Defining shared immune cell states in target tissues across RA, SLE, PSD, and SD. To identify shared immune cell states across autoimmune diseases and target tissues, we implemented a computational pipeline for robust cell type and state annotation in spatial transcriptomic datasets. To evaluate the generalizability of this pipeline, we used a unified scRNA-seq reference to annotate T and NK cell states across spatially profiled tissues. This approach identified 9 distinct T cell states (**Fig 2A**), each exhibiting comparable transcriptional signatures across RA, SLE, PSD, and SD.

Conclusion: This integrated spatial multi-omics platform is being applied across disease-specific (e.g., RA, SLE, PSD, and SD) and cross-disease studies to uncover shared and distinct cellular programs in autoimmune pathogenesis. Through robust, high-resolution, single cell analyses within the tissue context, our approach lays the foundation for discovering common and unique mechanisms and advancing targeted therapeutics across autoimmune diseases.

Abstract Number: 2234

Early Sustained Remission Resulted in Superior Long-term Patient-Reported Outcomes in Rheumatoid Arthritis

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: This study compared the impact of achieving early sustained remission (sREM) versus early sustained low disease activity (sLDA) on patient-reported outcomes (PROs) after 5 years in early rheumatoid arthritis (RA) patients, according to DAS28-CRP, SDAI, and Boolean 2.0 remission criteria. It also assessed PRO differences among patients achieving sREM across these criteria.

Methods: Data were analyzed from 336 early RA patients (symptom onset < 2 years) in the Clinical Rheumatology Systematic Treat-to-Target in Asia Leadership (CRYSTAL) study who completed 5-year follow-up. Patients were classified into sREM, sLDA, or active disease (AD) groups based on DAS28-CRP and SDAI criteria, and sREM or AD for Boolean 2.0, at

Table 1. Baseline Characteristics and Patient-Reported Outcomes by DAS28-CRP Disease Activity Status in Early Rheumatoid Arthritis

Characteristic	sREM (n=99)	sLDA (n=83)	AD (n=154)	P-value
Demographic Characteristics				
Gender (female), n (%)	77 (77.8%)	64 (77.1%)	110 (71.4%)	0.444
Age (years), mean ± SD	50.15 ± 13.85	53.65 ± 11.79	54.47 ± 11.38	0.073
Disease Characteristics				
Disease duration (days), median (IQR)	32.0 (15.0–76.0)	32.0 (13.0–69.0)	32.0 (16.0–63.0)	0.874
Positive RF, n (%)	73 (73.7%)	65 (78.3%)	131 (85.1%)	0.084
Positive ACPA, n (%)	80 (80.8%)	65 (78.3%)	129 (83.8%)	0.707
Disease Activity				
DAS28-CRP Score, mean (SD)	4.03 ± 1.29	4.45 ± 1.18	4.67 ± 1.11	**<0.001**
SDAI score, mean (SD)	19.87 ± 12.18	23.98 ± 13.01	25.94 ± 12.41	**<0.001**
Tender joint count 28, median (IQR)	5.0 (2.0–10.0)	6.0 (3.0–9.0)	7.0 (4.0–12.0)	**0.003**
Swollen joint count 28, median (IQR)	3.0 (1.0–5.0)	4.0 (2.0–6.0)	3.0 (2.0–6.0)	0.065
ESR (mm/hour), median (IQR)	22.0 (16.0–35.0)	30.0 (18.0–55.0)	35.0 (21.0–60.0)	**0.008**
CRP (mg/L), median (IQR)	5.0 (2.2–12.4)	9.0 (4.0–22.8)	11.3 (4.3–34.7)	**<0.001**
Patient global assessment (VAS), median (IQR)	50.0 (30.0–70.0)	50.0 (40.0–70.0)	51.0 (39.0–70.0)	0.275
Physician global assessment (VAS), median (IQR)	40.0 (20.0–61.0)	50.0 (35.0–71.0)	50.0 (35.0–70.0)	**0.009**
Patient Reported Outcomes				
Pain (VAS), mean ± SD	42.40 ± 24.96	47.29 ± 21.81	50.31 ± 22.48	**0.034**
Fatigue (FACIT-Fatigue), mean ± SD	15.53 ± 9.62	16.23 ± 9.37	20.52 ± 10.34	**<0.001**
Functional ability (HAQ-DI), mean ± SD	0.74 ± 0.62	0.79 ± 0.55	0.97 ± 0.66	**0.005**
Work ability (WAI), mean ± SD	4.10 ± 2.40	5.80 ± 7.60	5.30 ± 2.60	**0.001**
Anxiety (HADS-A), mean ± SD	5.28 ± 3.54	5.64 ± 3.48	6.46 ± 3.91	0.066
Depression (HADS-D), mean ± SD	5.34 ± 3.72	5.66 ± 3.46	6.81 ± 4.03	**0.014**
Physical function (SF-36 PCS), mean ± SD	31.43 ± 13.74	27.53 ± 10.32	24.38 ± 11.85	**<0.001**
Mental Function (SF-36 MCS), mean ± SD	44.81 ± 10.19	43.20 ± 10.64	42.10 ± 11.30	0.073

P-values derived from ANOVA, Kruskal-Wallis, or chi-square tests as appropriate

Abbreviations:

- sREM: Sustained Remission
- sLDA: Sustained Low Disease Activity
- AD: Active Disease
- SD: Standard Deviation
- IQR: Interquartile Range
- RF: Rheumatoid Factor
- ACPA: Anti-Citrullinated Protein Antibody
- DAS28-CRP: Disease Activity Score 28-joint count with C-Reactive Protein
- SDAI: Simplified Disease Activity Index
- ESR: Erythrocyte Sedimentation Rate
- CRP: C-Reactive Protein
- VAS: Visual Analog Scale
- FACIT-Fatigue: Functional Assessment of Chronic Illness Therapy-Fatigue
- HAQ-DI: Health Assessment Questionnaire-Disability Index
- WAI: Work Ability Index
- HADS-A: Hospital Anxiety and Depression Scale-Anxiety
- HADS-D: Hospital Anxiety and Depression Scale-Depression
- SF-36 PCS: Short Form-36 Physical Component Summary
- SF-36 MCS: Short Form-36 Mental Component Summary

Baseline Characteristics and Patient-Reported Outcomes by DAS28-CRP Disease Activity Status in Early Rheumatoid Arthritis

6, 9, and 12 months. PROs, including fatigue (FACIT-Fatigue), functional disability (HAQ-DI), joint pain (VAS), anxiety and depression (HADS), work ability (WAI), and health-related quality of life (SF-36 physical [PCS] and mental [MCS] components), were evaluated over 5 years. Generalized estimating equations (GEE) models, adjusted for age, gender, and baseline disease activity, compared PROs between sREM and sLDA groups for DAS28-CRP and SDAI, and among sREM groups across DAS28-CRP, SDAI, and Boolean 2.0 criteria.

Table 2. Longitudinal Effects of Sustained Remission vs. Low Disease Activity on Patient-Reported Outcomes Over 5 Years by DAS28-CRP and SDAI Criteria

Patient-Reported Outcome	DAS28-CRP sREM vs. sLDA β (95% CI)	P-value[1]	SDAI sREM vs. sLDA β (95% CI)	P-value[1]
Pain (VAS)	-8.48 (-11.44, -5.52)	**<0.001**	-9.59 (-13.52, -5.66)	**<0.001**
Fatigue (FACIT-Fatigue)	-2.02 (-3.88, -0.15)	**0.034**	-2.18 (-4.17, -0.18)	**0.032**
Functional Ability (HAQ-DI)	-0.08 (-0.16, 0.00)	0.060	-0.04 (-0.16, 0.08)	0.517
Work Ability (WAI)	-0.89 (-1.38, -0.40)	**<0.001**	-0.66 (-1.22, -0.09)	**0.022**
Anxiety (HADS-A)	-0.44 (-1.28, 0.40)	0.306	-0.55 (-1.62, 0.51)	0.307
Depression (HADS-D)	-0.56 (-1.35, 0.22)	0.160	-0.32 (-1.25, 0.61)	0.501
Physical Function (SF-36 PCS)	5.12 (2.74, 7.51)	**<0.001**	3.78 (0.61, 6.95)	**0.019**
Mental Function (SF-36 MCS)	1.85 (-0.42, 4.13)	0.110	1.37 (-1.10, 3.83)	0.276

[1]P-value for the difference between sustained remission (sREM) and sustained low disease activity (sLDA) under the respective remission criteria (DAS28-CRP or SDAI), with sLDA as the reference group.

Abbreviations:

- β: Beta coefficient
- CI: Confidence Interval
- sREM: Sustained Remission
- sLDA: Sustained Low Disease Activity
- DAS28-CRP: Disease Activity Score 28-joint count with C-Reactive Protein
- SDAI: Simplified Disease Activity Index
- VAS: Visual Analog Scale
- FACIT-Fatigue: Functional Assessment of Chronic Illness Therapy-Fatigue
- HAQ-DI: Health Assessment Questionnaire-Disability Index
- WAI: Work Ability Index
- HADS-A: Hospital Anxiety and Depression Scale-Anxiety
- HADS-D: Hospital Anxiety and Depression Scale-Depression
- SF-36 PCS: Short Form-36 Physical Component Summary
- SF-36 MCS: Short Form-36 Mental Component Summary

Longitudinal Effects of Sustained Remission vs. Low Disease Activity on Patient-Reported Outcomes Over 5 Years by DAS28-CRP and SDAI Criteria

Results: Of 336 patients, 99 (29%) achieved DAS28-CRP sREM, 38 (11%) SDAI sREM, and 36 (11%) Boolean 2.0 sREM, with 27 (8%) achieving sREM across all three criteria. Compared to DAS28-CRP sLDA, the DAS28-CRP sREM group had significantly better PROs in pain (β = -8.48, $p < 0.001$), fatigue (β = -2.02, $p = 0.034$), work ability (β = -0.89, $p < 0.001$), and SF-36 PCS (β = 5.12, $p < 0.001$) at year 5. Similarly, the SDAI sREM group outperformed SDAI sLDA in pain (β = -9.59, $p < 0.001$), fatigue (β = -2.18, $p = 0.032$), work ability (β = -0.66, $p = 0.022$), and SF-36 PCS (β = 3.78, $p = 0.019$). No significant differences were observed in functional disability, anxiety, depression, or SF-36 MCS for either comparison.

All patients achieving SDAI or Boolean 2.0 sREM also achieved DAS28-CRP sREM. Compared to DAS28-CRP sREM (n = 99), SDAI sREM (n = 38) was associated with significantly lower pain (β = -6.84, $p = 0.002$) but no other PRO differences. Compared to DAS28-CRP sREM, Boolean 2.0 sREM group (n = 36) had better PROs in pain (β = -10.43, $p < 0.001$), fatigue (β = -2.91, $p = 0.016$), work ability (β = -0.75, $p = 0.017$), SF-36 PCS (β = 3.90, $p = 0.022$), and SF-36 MCS (β = 3.51, $p = 0.018$) after 5 years, but not in functional disability, anxiety, or depression.

- SF-36 MCS: Short Form-36 Mental Component Summary

Longitudinal Effects of SDAI and Boolean 2.0 Sustained Remission vs. DAS28-CRP Sustained Remission on Patient-Reported Outcomes Over 5 Years

Conclusion: Early sustained remission, as defined by DAS28-CRP and SDAI criteria, is associated with significantly better pain, fatigue, work ability, and physical health-related quality of life compared to sustained low disease activity in early RA patients over 5 years. DAS28-CRP sREM is less stringent, as all patients achieving SDAI or Boolean 2.0 sREM also met DAS28-CRP criteria. However, SDAI sREM is associated with lower pain, and Boolean 2.0 sREM offers broader PRO benefits compared to DAS28-CRP sREM. These findings highlight the importance of early tight disease control using stricter criteria like SDAI or Boolean 2.0 to maximize long-term patient outcomes in early RA.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Several lung diseases are associated with rheumatoid arthritis (RA), including interstitial lung disease (ILD) and emphysema. In RA-ILD baseline lung function and decline in lung function may act as predictors of survival. We aimed to explore change in lung function over 1 year in cohort of participants with early RA.

Methods: SAIL-RA (Study of Inflammatory Arthritis and ILD in Early RA) is a prospective, longitudinal, multicenter study of patients with RA within 2 years of RA diagnosis. Participants were enrolled from 2017 to 2025 at 5 U.S sites. We analyzed participants who completed baseline and 1 year assessments; including baseline high-resolution CT chest (HRCT) as well as pulmonary function tests (PFT) and disease activity assessment (DAS28-ESR) at both visits. We assessed changes in lung function by evaluating mean change in % predicted forced vital capacity (FVC) and diffusion capacity of carbon monoxide (DLCO) from baseline to 1 year using student's T-test. We categorized participants into 3 groups based on change in PFTs (improved, stable, worsened). 'Improved' and 'worsened' FVC were defined as an increase or decrease of >5% predicted from baseline to 1 year. 'Improved' and 'worsened' DLCO were defined as an increase or decrease of >10% predicted from baseline to 1 year. We compared change in lung function based on baseline disease activity and presence/absence of ILD using Chi-square and Fisher's exact tests. We compared distribution of participants with worsened, stable or improved lung function based on presence/absence of lung disease and continuation/discontinuation of methotrexate (MTX) in baseline MTX users by ANOVA. Low and moderate/high disease activity were defined as DAS28-ESR of $\leq$3.2 and $\geq$3.3. ILD was defined by radiologists' interpretation of HRCT. Obstructive lung disease was defined as emphysema on HRCT or $FEV_1/FVC < 0.7$.

Results: 121 participants completed baseline and 1 year assessments with PFTs (**Table 1**). In the whole cohort approximately half of participants had worsened or improved FVC and/or DLCO at 1 year (**Fig 1**). The percentage of participants with worsened, stable, or improved FVC was 27.3%, 46,3%, and 26.4%. For DLCO 12.6%, 65%, and 22.3% had worsened, stable, or improved values. In participants with ILD versus no ILD at baseline there was a trend toward worsened FVC % predicted at 1 year in participants with ILD (p=0.089), although mean absolute change in FVC did not differ (2.26% vs 0.16%, p=0.44). There was no difference in the change FVC or DLCO % predicted from baseline to 1 year based on presence or absence of lung disease nor MTX continuation at 1 year (**Fig 2**). In participants with low versus moderate/high

Abstract Number: 2236

Treatment-induced autoantibodies in Rheumatoid Arthritis patients receiving anti-TNF inhibitors or JAK inhibitors

EVRIPIDIS KALTSONOUDIS[1], Nikolaos Kougkas[2], Panagiota Karagianni[3], Tereza Memi[4], Nikolaos Koletsos[5] and Eleftherios Pelechas[6], [1]Rheumatology Clinic, University of Ioannina, IOANNINA, Ioannina, Greece, [2]4th Department of Internal Medicine, Aristotle University, Thessaloniki, Thessaloniki, Greece, [3]BioAcuHealth.gr, Ioannina, Ioannina, Greece, [4]University Hospital of Ioannina, Ioannina, Ioannina, Greece, [5]School of Health Sciences, Faculty of Medicine, University of Ioannina, Department of Rheumatology, Ioannina, Greece, Ioannina, Ioannina, Greece, [6]Hatzikosta General Hospital of Ioannina, Ioannina, Ioannina, Greece

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) can coexist with other autoimmune disorders such as Sjögren's syndrome and systemic lupus erythematosus (SLE). In these cases, the terms secondary Sjögren's syndrome or Sjögren's syndrome overlap and lupus-like syndrome or Rupus are applied. All available biological treatments aim to suppress the autoimmune responses locally as well as systematically. On the other hand, they may interfere with the immune system by inducing autoantibodies such as the ANAs by the use of the anti-TNF inhibitors. To compare the risk of autoantibody-induction in RA patients under treatment with anti-TNFs and JAK inhibitors, as well as to evaluate their importance at a clinical level.

Methods: 83 patients with a new diagnosis of RA and were about to be treated with a biological agent were divided in 2 groups and were followed for 2 years. Patients' age was 40-50 years. 42 patients with seropositive RA and without the presence of other autoantibodies (Group 1) and 42 with/without RA seropositivity but with ANA/ENA positivity (Group 2). 21 of both groups received an anti-TNF inhibitor and 21 received a JAK inhibitor.

Table 1

Table 1

	TNF inhibitor	JAK inhibitor
ANA	7	0
ENA	2	0
SSA/Ro (52)	1	0
SSA/Ro και SSB/La	1	0
dsDNA	0	0

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: In group 1, no patient under treatment with JAK inhibitors showed any new autoantibodies. In contrast to those receiving anti-TNF, 7 showed ANA+ in a titer >1/80 and 2 of them ENA+ (1 with Ro52 and the other Ro52 and La). In group 2, the autoantibodies remained unchanged in all patients under JAK inhibitors and none of them manifested symptoms of the overlap syndrome. In contrast, in the anti-TNF treated patients, 8 experienced symptoms of secondary Sjögren's syndrome (6 only sicca syndrome and 2 lung disease) and one patient manifested a lupus-like syndrome (rash, weakness and serositis).

Conclusion: This is the first study to show the different effects on autoantibodies in a series of patients with RA and other connective tissue disease under biological and targeted-synthetic therapy. The effect of non-anti-TNF bDMARDs on autoantibodies (ANA, ENA) is clearly smaller, which reflects possibly the different mechanism of action leading to a less possible autoimmune derangement. Further studies are needed to confirm these findings.

Safety of DMARD therapy in veterans with rheumatoid arthritis following melanoma diagnosis: a survival analysis

Gabriella Girolami[1], Shamey Kassim[2], Alexander Peterson[3], Aaron Baraff[3], Alexandra Schmidt[3], Shailender Bhatia[4], Natalie Miller[4], Jennifer Barton[5], Jeffrey Curtis[6], Christopher Li[4] and Namrata Singh[7], [1]University of Washington, Seattle, [2]University of Washington, Seattle, WA, [3]VA Puget Sound Health Care System, Seattle, WA, [4]Fred Hutch Cancer Center, Seattle, [5]VA Portland Health Care System/OHSU, Portland, OR, [6]Foundation for Advancing Science, Technology, Education and Research, Birmingham, AL, [7]University of Washington, Bellevue, WA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: While disease-modifying anti-rheumatic drugs (DMARDs) are critical in managing rheumatoid arthritis (RA), their immunosuppressive effects raise concerns about cancer-related outcomes. In patients with RA who develop melanoma, evidence is limited on how post-diagnosis use of conventional synthetic (csDMARDs), biologic (bDMARDs), or targeted synthetic (tsDMARDs) DMARDs impacts mortality. This study aimed to evaluate the association between DMARD use after melanoma diagnosis and 3-year all-cause mortality in patients with RA.

Methods: This retrospective cohort study utilized data from the national Veterans Affairs (VA) Corporate Data Warehouse (CDW), spanning 2002 to 2024. Included patients had ≥2 RA International Classification of Diseases (ICD) codes within a period of 7-365 days. Patients with melanoma and their stage at diagnosis were identified through the VA Oncology Raw Domain. The main exposure was type of DMARD use, categorized as none, csDMARDs, or b/tsDMARDs (with or without csDMARDs). The primary outcome was all-cause mortality three years after melanoma diagnosis. Demographic and clinical variables–including age, sex, marital status, race, ethnicity, region, rurality, tobacco use, comorbidities, cancer stage (American Joint Committee on Cancer, AJCC)–were included. Kaplan-Meier survival analysis and multivariable Cox proportional hazards models were used to assess the association between DMARD exposure and mortality, adjusting for relevant confounders.

Urban	125 (59.2%)	147 (55.1%)	97 (58.4%)	369 (57.3%)
Rural	85 (40.3%)	120 (44.9%)	69 (41.6%)	274 (42.5%)
Cohort Entry Date				
2002-2009	29 (13.7%)	58 (21.7%)	17 (10.2%)	104 (16.1%)
2010-2015	60 (28.4%)	75 (28.1%)	46 (27.7%)	181 (28.1%)
2016-2021	96 (45.5%)	111 (41.6%)	76 (45.8%)	283 (43.9%)
2022-2024	26 (12.3%)	23 (8.6%)	27 (16.3%)	76 (11.8%)

cs: conventional synthetic; DMARDs: disease modifying anti-rheumatic drugs

Results: We identified 644 patients with RA and incident melanoma. The cohort had a mean age of 71 years, with 39% aged 70-79 years. It was predominantly male (95.5%), with most residing in urban areas (57.3%). Cancer stage distribution was 46.4% Stage 0, 38.2% Stage I, 7.9% Stage II, 4.8% Stage III, and 2.6% Stage IV. Most patients entered the cohort between 2016-2021 (43.9%) (**Table 1**).

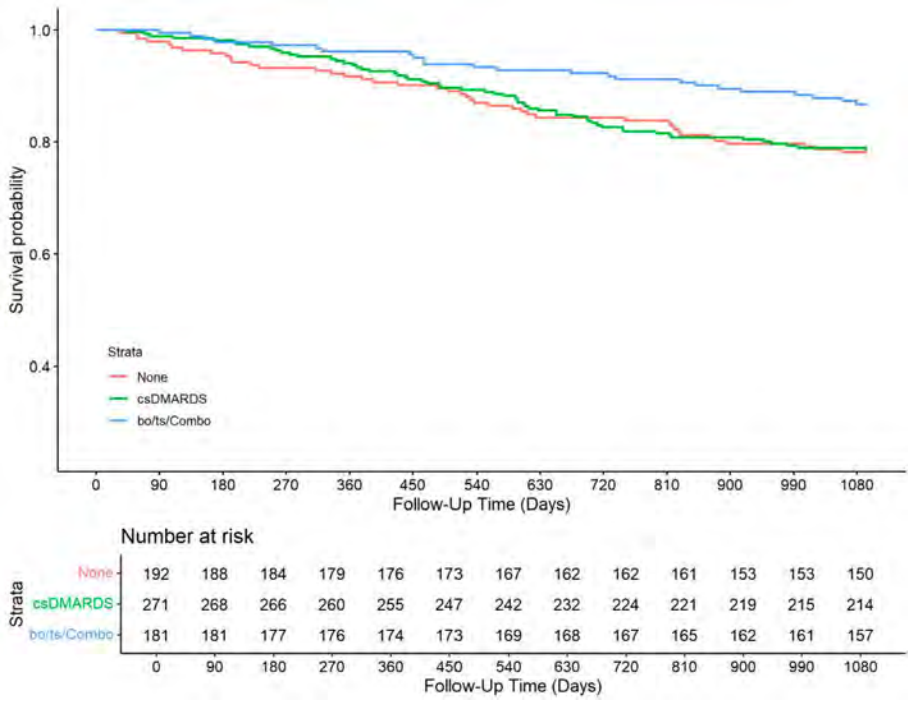

Figure 1. Kaplan-Meier Survival Curves by DMARD Use Within 12 Months of Melanoma Diagnosis.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

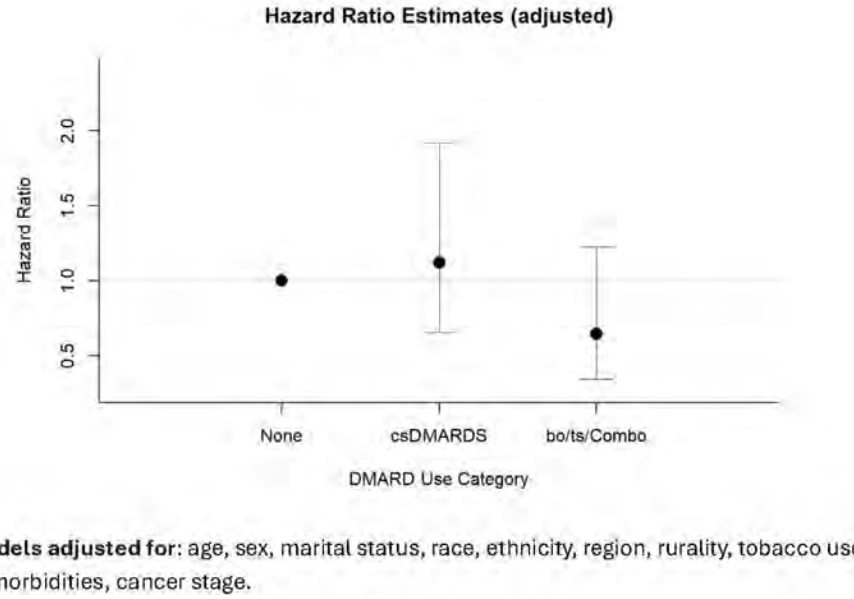

Figure 2. Hazard Ratio estimates (adjusted) for the association between DMARD use and three-year mortality after melanoma diagnosis in RA.

Twelve-month post-melanoma DMARD exposure was categorized as no use (n=211, 32.8%), csDMARD use only (n=267, 41.4%), or b/tsDMARD/combination use (b/ts/Combo, n=166, 25.8%). Kaplan-Meier survival curves suggested lower three-year all-cause mortality among patients treated with b/ts/Combo compared to those receiving csDMARDs or no DMARD (**Figure 1**). Adjusted models showed hazard ratio (HR) of 1.12 (95% CI: 0.65–1.92) for csDMARDs relative to those on no DMARDs, and 0.65 (95% CI: 0.34–1.23) for b/ts/combination DMARDs (**Figure 2**).

Conclusion: In this retrospective cohort study of veterans with RA who developed melanoma, cs/b/tsDMARD use after melanoma diagnosis was not associated with increased three-year all-cause mortality. However, the study is limited by the lack of melanoma-specific mortality data and the relatively short follow-up period. These findings may help guide clinical decision-making regarding DMARD use in RA patients with a history of melanoma, particularly when balancing treatment efficacy with cancer risk.

Background/Purpose: Rheumatoid arthritis (RA) is associated with increased cardiovascular risk, but the additional impact of type 2 diabetes mellitus (T2DM) on the cardiorenal outcomes in this population remains insufficiently characterized. This study aimed to quantify the additional risk conferred by T2DM in RA patients for developing specific cardiovascular and renal complications.

Methods: We performed a retrospective cohort study using the TriNetX global federated health research network, comprising electronic health records from 100 healthcare organizations. We identified adult patients (18-99 years) with RA (ICD-10 M06.9), stratified by T2DM status (ICD-10 E11). After propensity score matching for demographic and clinical factors, 129,630 patients were included in each cohort. Patients were followed for up to 5 years to evaluate cardiorenal outcomes.

Results: RA patients with T2DM had significantly higher risk of acute kidney failure (HR 2.57, 95% CI 2.49-2.66, p< 0.001) compared to those without diabetes. The T2DM cohort also showed increased risk of heart failure (HR 1.93, 95% CI 1.86-1.96, p< 0.001), cerebral infarction (HR 1.67, 95% CI 1.60-1.75, p< 0.001), and pulmonary hypertension (HR 1.93, 95% CI 1.84-2.03, p< 0.001). Additionally, patients with both conditions demonstrated higher incidence of acute pulmonary edema (HR 1.93, 95% CI 1.84-2.03, p< 0.001) and sepsis (HR 2.57, 95% CI 2.49-2.66, p< 0.001). Mortality was significantly elevated in the comorbid group (HR 1.73, 95% CI 1.69-1.78, p< 0.001).

Conclusion: The coexistence of T2DM in RA patients substantially increases the risk of adverse cardiorenal outcomes and mortality. These findings emphasize the importance of early screening and aggressive management of cardiovascular and renal risk factors in RA patients with comorbid T2DM. Collaborative care models involving rheumatologists, endocrinologists, and cardiologists may be essential for optimal management of this high-risk population.

Increased Cardiovascular Morbidity in Patients with Rheumatoid Arthritis and Type 2 Diabetes: A Large-Scale Electronic Health Record Analysis

Godbless Ajenaghughrure[1], Sila Mateo Faxas[2], **Gurjot Singh**[3], Nirys Mateo Faxas[4], Kim Nguyen[3], Nicole Tejeda[5] and Kimberly Ramirez Bonetti[6], [1]Trihealth Good Samaritan Hospital, Cincinnati, OH, [2]Good Samaritan Hospital, Cincinnati, OH, [3]Trihealth Good Samaritan Hospital, Cincinnati, [4]Independent Author, Santo Domingo, Dominican Republic, [5]Independent Author, Cincinnati, [6]Independent Author, cincinnati, OH

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is associated with increased cardiovascular risk, but the additional impact of comorbid type 2 diabetes mellitus (T2DM) on cardiovascular outcomes in this population remains incompletely characterized. This study evaluated the cardiovascular burden in patients with both RA and T2DM compared to patients with RA alone.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Using the TriNetX global federated health research network, we conducted a retrospective cohort study of 187,967 patients with RA from 100 healthcare organizations. Patients aged 18-99 years with RA (ICD-10 M06.9) were stratified by T2DM status (ICD-10 E11). After propensity score matching for cardiovascular risk factors and comorbidities, we analyzed 129,630 patients in each cohort. Cardiovascular outcomes were assessed over a 5-year follow-up period.

Results: Patients with comorbid RA and T2DM demonstrated significantly higher risk of mortality (HR 1.73, 95% CI 1.69-1.78, p< 0.001), cardiac arrest (HR 2.85, 95% CI 2.61-3.10, p< 0.001), and heart failure (HR 1.93, 95% CI 1.86-1.96, p< 0.001) compared to patients with RA alone. Additionally, the comorbid group showed increased risk of atrial fibrillation (HR 1.97, 95% CI 1.92-2.02, p< 0.001), ventricular arrhythmias (HR 2.18, 95% CI 2.05-2.32, p< 0.001), cerebral infarction (HR 1.67, 95% CI 1.60-1.75, p< 0.001), and acute kidney failure (HR 2.57, 95% CI 2.49-2.66, p< 0.001). Patients with both conditions also required more cardiac device implantations (HR 2.65, 95% CI 2.50-2.80, p< 0.001).

Conclusion: Coexisting T2DM in patients with RA substantially increases the risk of major adverse cardiovascular events and mortality. These findings highlight the need for aggressive cardiovascular risk assessment and management strategies in this high-risk population. Interdisciplinary care involving rheumatologists and endocrinologists may be crucial for optimal management of this patient group.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Both rheumatoid arthritis (RA) and type 2 diabetes mellitus (T2DM) are independently associated with increased cardiovascular risk. However, the impact of T2DM on cardiac arrhythmia development specifically in patients with RA remains poorly understood.

Methods: We conducted a retrospective cohort study using the TriNetX global federated health research network, analyzing electronic health records from 100 healthcare organizations. We identified patients aged 18-99 years with RA (ICD-10 M06.9) with and without T2DM (ICD-10 E11). After propensity score matching for demographic factors and relevant comorbidities, we compared 129,630 patients in each cohort. Patients were followed for up to 5 years to assess arrhythmia-related outcomes.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Patients with both RA and T2DM demonstrated significantly increased risk of atrial fibrillation (HR 1.93, 95% CI 1.88-1.98, p< 0.001) compared to patients with RA alone. Similarly, the risk for ventricular arrhythmias was substantially higher, with a hazard ratio of 2.18 (95% CI 2.05-2.32, p< 0.001) for ventricular tachycardia and 2.72 (95% CI 2.46-3.01, p< 0.001) for ventricular fibrillation. The comorbid group also demonstrated a 2.11-fold increased risk (95% CI 1.94-2.29, p< 0.001) for sick sinus syndrome and required significantly more pacemaker implantations (HR 2.65, 95% CI 2.50-2.80, p< 0.001).

Conclusion: The presence of T2DM in patients with RA is associated with a substantial increase in risk for multiple cardiac arrhythmias. Our findings suggest that patients with both RA and T2DM should undergo more intensive cardiac monitoring and may benefit from early interventions to prevent arrhythmia development. These results highlight the importance of integrated care across specialties for patients with these comorbid conditions.

Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is a persistent inflammatory disorder inducing joint space narrowing and erosion at both hands and feet. Reading of X-ray images remains extremely time-consuming and subject to interobserver variability.

Methods: Data were obtained from a subset of a large prospective multicentric cohort of RA patients (BCD study). All hand and foot radiographs were scored using the modified van der Heijde score by four trained readers. We developed a deep learning pipeline called RADAR to detect joints and classify radiographs from hands and feet: we employed a YOLO-based object detection for the joints used as input for a classification model. We trained two models: a binary classifier to

Table 1: RADAR classification results for binary and multiclass tasks.

		AUC (Binary)	Accuray (Binary)	Accuray (Multiclass)
Erosion	Hand	0.9988	0.9893	0.9728
	Feet	0.9640	0.9255	0.8669
Joint space narrowing	Hand	0.9994	0.9888	0.9863
	Feet	0.9789	0.9477	0.9233

Figure 1 : Example of heat maps showing the ability to detect joints – a) reading by a rheumatologist evaluated by eye-tracking b) reading by RADAR

	A (Eye tracking)	B (RADAR)
joint space narrowing		Erosion		
distinguish erosion and joint space narrowing (present or absence), and a multi-class classifier for joint space narrowing [Mild (scores 1–2) and Moderate (3–4)] and an additional severe category (score 5+) for erosion. The models were implemented in PyTorch. The dataset of 140 patients was split into training, validation, and test sets. We also used the Pytorch Gradcam library to develop explainability heatmaps. Reader reliability was evaluated using both kappa statistics and the intraclass coefficient.

Results: Reliabilities between the four human experts evaluated on 30 radiographs were good (0.7-0.9). A total of 7560 joints were analysed using RADAR . Figure 1 shows examples of joint detection by both readers and RADAR. Table 1 shows that results were excellent for both binary classification and score. This was true in the absence of lesions as well as for elevated scores.

Conclusion: Our results demonstrate the pipeline's ability to identify the presence and absence of joint damage with high accuracy, giving the opportunity to avoid a large number of human readings in a cohort of patients. The global score is also reliable.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The lung disease associated with systemic JIA (SJIA-LD) remains poorly understood. Measurement of cytokine levels in bronchoalveolar lavage fluid (BALF) may offer insights into disease pathogenesis, activity, and progression. However, there is currently limited data on the bronchoalveolar inflammatory environment in children with SJIA-LD. The purpose of the study was to measure levels of proinflammatory cytokines and chemokines in BALF from patients with SJIA-LD.

Methods: Children with SJIA-LD were included in the study at the time of diagnostic bronchoscopy as part of routine clinical care. As controls we included patients undergoing routine bronchoscopy for tracheostomy surveillance or other known inflammatory diseases, including SJIA without LD, autoimmune alveolar proteinosis, IBD with lung disease, and lymphoma. Children from the control group were divided into inflammatory (IC, n=9) and non-inflammatory (NIC, n=7) controls based on underlying disease. Interleukin-6, 8 and 18, S100A8/9, S100A12, CD25, CCL25, CCL17, CCL11, MMP7 and CXCL-9 were measured by ELISA or Multiplex.

CRP, mg/dL	<0.4, neg*	<0.4, neg	<0.4, neg	<0.4, neg
Clinical status Girl with SJIA. Recurrent MAS. PAP/ILD	Uncontrolled disease with worsening of hypoxia and findings on high-resolution chest CT; *-measured 10 days after bronchoscopy	Therapeutic WWL of one lung due to worsening of the respiratory status	Therapeutic WWL of another lung done 7 days after the first lavage.	Worsening of respiratory status

Results: BALF samples were obtained from 14 patients with SJIA-LD (mean age 7.4±1.98 years and disease duration 4.4 ±0.9 years) and 16 patients without SJIA-LD (mean age 8.6±0.24 years). Seven (50%) SJIA-LD patients required O2 support intermittently or continuously and one patient required BiPAP. Serial samples were obtained for two patients before and after whole lung lavage and BMT, respectively.

BALF levels of IL-18, CD-25, CCL-11 and MMP-7 were significantly elevated in patients with SJIA-LD compared to controls, while CXCL-9 was significantly higher in controls and IL-6 and IL-8 were significantly higher in the NIC group (Table 1). Levels of CD-25, CXCL-9, CCL-11 and CCL-17 were undetectable in most patients from both groups, but detection of CD25 ($\chi 2=2.16$, p= 0.0027) occurred more often in SJIA-LD.

Linear regression analysis didn't show the relationship between BALF IL-18 level and disease duration (p=0.15), oxygen requirement (p=0.11), dose of Anakinra (p=0.4) or plasma levels of ferritin (p=0.9), CXCL-9 (p=0.6) and IL-18 (p=0.9). However, there was a direct relation with daily prednisone dose (p=0.03, CI 13.93 to 230.1) and number of immunosuppressive medications (p=0.0015, CI 288.6 to 935.9).

Of the 3 SJIA-LD patients who underwent BMT, we observed a higher BALF/plasma IL-18 ratio compared to other patients, although this was not significant (176±99 vs 34±16.5 (p=0.1)).

For two SJIA-LD patients with serial samples, the changes of cytokine profile for one during disease flare-up and after therapeutic WLL are shown in Table 2, and before and after bone marrow transplant are in Table 3.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 3 Levels of cytokines and chemokines in BALF and plasma in a patient before and after bone marrow transplant

Marker	Pre-BMT	Post-BMT
IL-18, pg/mL	1182	532.99
S100A8/9, ng/mL	10500	3028.5
S100A12, mcg/mL	672000	49339.5
IL-6, pg/mL	0.29	8.51
IL-8, pg/mL	83.95	105.675
CD-25, pg/mL	30.25	26.695
CCL-11, pg/mL	undetectable	undetectable
CCL-17, pg/mL	undetectable	undetectable
CCL-25, pg/mL	undetectable	undetectable
MMP-7, pg/mL	17589.36	19808.8

Conclusion: Patients with SJIA-LD showed a distinct BALF cytokine profile, with elevated IL-18, MMP-7, and CCL-11 but lower levels of other cytokines. These profiles also vary with flares and management, including WLL and BMT. Further prospective work is needed to determine the relationship with disease course and treatments.

Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Depression is a common comorbidity in rheumatoid arthritis patients and has a significant effect on the disease course. [Brock J, et al. *Nat Rev Rheumatol*. 2023;19(12):790-804]. Growth differentiation factor 15 (GDF-15), a member of the TGFβ family, has been associated not only with endothelial dysfunction but also with several mental diseases, such as depression and psychosis [Kumar P, et al. *Sci Rep*. 2017;7(1):7906]. This study aimed to determine the differences in GDF-15 levels between RA patients with and without depressive symptoms and to explore the correlation between GDF-15 levels and depression symptoms.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. GDF-15 levels between RA patients with and without depressive symptoms

Methods: Patients fulfilling the 2010 ACR/EULAR classification criteria for seropositivity RA were included in this cross-sectional observational study. Patients with moderate or severe disease activity according to DAS28 and fibromyalgia were excluded. The PHQ-9 was used for the evaluation of depressive symptoms, and a score of 10 was considered the cutoff point. GDF15 was measured in the serum by ELISA and is expressed in picograms/milliliters. Exploratory bioinformatics analysis was conducted via the miRNet 2.0 platform (https://www.mirnet.ca/) in order to explore shared microRNA regulators potentially linking these conditions in patients with RA. This analysis was performed by selecting "Diseases" as the input category to include rheumatoid arthritis and depression and "Genes" to include GDF-15. The data are presented as percentages, means ± standard deviations or medians, and interquartile ranges (IQRs) according to their distributions. The Mann–Whitney U test was used for comparison. The correlation between the GDF-15 score and PHQ-9 score was evaluated via Spearman's method. A value of $p \leq 0.05$ was considered statistically significant.

Results: Fifty-six patients were invited; however, 2 were excluded because they were negative for RF and ACPA, 10 because they had moderate or severe RA disease activity, and 5 because they had fibromyalgia. A total of 39 patients were analyzed. Thirty-six (92%) were female. The mean age was 58 ± 11 years. Thirty-four patients were in remission, and only 5 had mild disease activity according to the DAS28. The most common comorbidities were hypertension (41%), diabetes (26%) and Sjögren´s syndrome (15%). In the group of patients with fewer depressive symptoms (PHQ-9 < 10, n=30), the mean GDF-15 score was 1410 (993–2359), whereas it was 1027 (697–1236) in the group with severe depressive

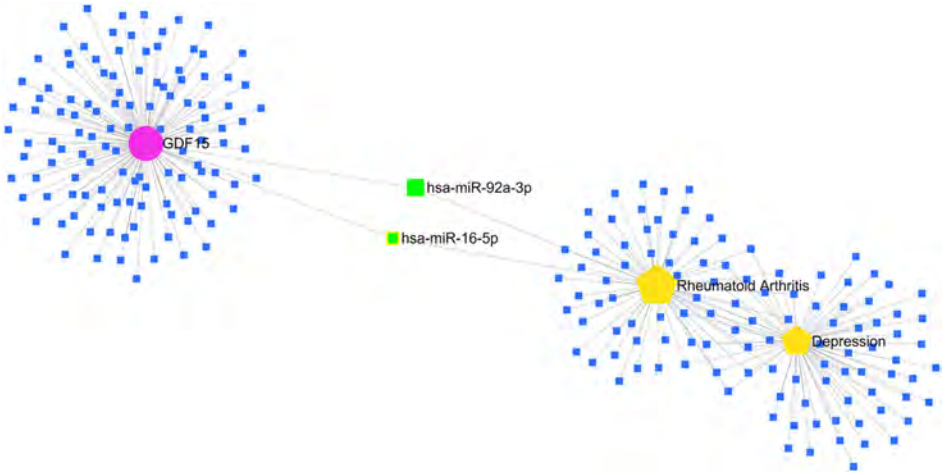

Figure 2. Interaction network: bioinformatic analysis

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

symptoms (PHQ-9 ≥10, n=9), figure 1 (p=0.007). A negative correlation between PHQ-9 and GDF-15 levels was found (Rho= -0.377, p=0.018). According to bioinformatics (figure 2), the analysis identified two microRNAs, hsa-miR-16-5p and hsa-miR-92a, as shared elements associated with RA, GDF-15, and depression.

Conclusion: The levels of GDF-15 are inversely correlated with the severity of depression, and similar results in other mental diseases (psychosis) have been reported. A possible molecular connection may exist between RA and depressive symptoms, primarily through GDF15-related mechanisms and independent of active inflammatory status. However, further studies are needed.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is a well-established risk factor for fractures, due to both systemic inflammation and treatment-related effects on bone metabolism. This study aimed to identify clinical factors contributing to BMD decline and fracture under current RA and osteoporosis treatment strategies.

Methods: We conducted a retrospective cohort study at a university hospital in Japan, including RA patients with at least two dual-energy X-ray absorptiometry (DXA) scans of the femoral neck between 2010 and 2024. Group-based trajectory modeling (GBTM) was used to classify patients according to longitudinal BMD changes over 7 years since the initial measurement. Baseline characteristics and treatment exposures during follow-up were compared across the identified trajectory groups. Factors associated with BMD trajectory were explored using multinomial logistic regression. Incident fractures during the observation period were also assessed for each group.

Results: We analyzed 1,681 BMD measurements from 435 RA patients (mean age: 62 years; 78% female; 81% seropositive). GBTM identified three distinct BMD trajectory groups: Stable (n=211), Slow Decline (n=149), and Rapid Decline (n=75) (Figure 1). The Stable group had the lowest baseline BMD (mean: 0.59 g/cm^3), while the Rapid Decline group had the highest (mean: 0.76 g/cm^3). Use of denosumab and vitamin D supplements was significantly higher in the Stable group, whereas

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Trajectories of change from baseline BMD at the femoral neck among patients with RA patients (n=435)

BMD: bone mineral density; RA: rheumatoid arthritis.

glucocorticoid use was more prevalent in the Rapid Decline group (Table 1). Multivariable analysis revealed that older age, female sex, and higher baseline BMD were independently associated with the Rapid Decline trajectory (ORs: age 1.05 [95%CI 1.02 to 1.09], female 2.79 [95%CI 1.10 to 7.05], BMD 3.92 [2.76 to 5.58]). Additionally, the use of osteoporosis medications was negatively associated with decline trajectories (Table 2). The incidence of new fractures per 100 person-years was 1.49 in the Stable group, 2.79 in the Slow Decline group, and 2.06 in the Rapid Decline group, with no statistically significant difference (p=0.20).

Conclusion: This 7-year longitudinal analysis identified three distinct BMD trajectories in RA patients. Notably, those in the Rapid Decline group had relatively high baseline BMD but did not exhibit lower fracture rates. The higher prevalence of glucocorticoid use and lower use of osteoporosis treatment in the decline groups suggest that suboptimal osteoporosis

Add-on of Coronary Artery Calcium Score Significantly Improves the Risk Prediction of Cardiovascular Diseases in Patients with Rheumatoid Arthritis: From a Real-world Cohort Study

Yao-Wei Zou, Ying Yang, Zhi-Ming Ouyang, Ran Shi, Tao Wu, Kui-Min Yang, Jian-Da Ma and **Lie Dai**, Department of Rheumatology and Immunology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China (People's Republic)

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Cardiovascular diseases (CVD) are the first cause of death in patients with rheumatoid arthritis (RA). The guidelines recommend risk prediction in all RA patients. However, there is currently no precise prediction model for RA patients. Coronary artery calcium (CAC) score by coronary angiography or chest computed tomography (CT) can improve CVD risk prediction in the general population, but no report in RA patients. We aimed to investigate whether adding CAC score to risk algorithms could improve CVD risk prediction in RA patients.

Table 1 The CVD Risk Prediction Models in RA patients

Table 1 The CVD Risk Prediction Models in RA patients

Variables	Clinical model			CAC model		
	HR (95% CI)	Beta Coefficient	*P* value	HR (95% CI)	Beta Coefficient	*P* value
Age, years	1.085 (1.058,1.113)	0.082	<0.001	1.061 (1.031,1.091)	0.059	<0.001
Male	2.492 (1.568,3.959)	0.913	<0.001	2.592 (1.626,4.129)	0.952	<0.001
BMI, kg/m^2	1.072 (1.002,1.146)	0.069	0.043	1.079 (1.006,1.158)	0.076	0.033
Hypertension	2.938 (1.798,4.799)	1.078	<0.001	2.626 (1.591,4.336)	0.966	<0.001
CRP, mg/L	1.005 (1.000,1.009)	0.004	0.034	1.005 (1.001,1.009)	0.005	0.017
CDAI	1.017 (1.004,1.029)	0.016	0.009	1.016 (1.003,1.028)	0.015	0.016
Glucocorticoid	2.094 (1.333,3.291)	0.739	0.001	2.122 (1.348,3.340)	0.752	0.001
Ln (CAC score+1)	-	-	-	1.521 (1.210,1.912)	0.419	<0.001

The *P* values are based on a standard Cox proportional hazards model. To estimate the CVD risk for a particular person, multiply the values of the risk factors by the corresponding beta coefficient and sum these quantities up to yield a value (call it A). Then calculate: B = exp (A). Finally, the CVD risk is given by 1 - S (10) [B].

Abbreviations: CVD, cardiovascular disease; RA, rheumatoid arthritis; BMI, body mass index; CRP, C-reactive protein; CDAI, clinical disease activity index; CAC, coronary artery calcium.

Methods: RA patients from January 1, 2010 to September 30, 2024 were included retrospectively from a RA cohort at the Department of Rheumatology and Immunology, Sun Yat-sen Memorial Hospital, Guangdong, China (SYSEC-2009-06). The inclusion criteria included free of CVD at baseline, and having intact clinical data. CAC scores based on chest CT at baseline were calculated by the Agatston method. The endpoint was CVD, which included coronary heart disease, stroke, heart failure, peripheral arterial disease, and CVD death.

LASSO-Cox regression were performed to construct prediction model for CVD. The list of candidate covariates included traditional CVD risk factors (age, sex, BMI, history of hypertension and diabetes, TC, HDL-C, LDL-C), RA-related factors (disease duration, RF, ACPA, ESR, CRP, CDAI, HAQ-DI, and the use of glucocorticoid, csDMARDs, and biologic agents), and CAC score. Harrell's C-statistic and NRI were used to compare the performance between models with and without CAC, as well as existing RA specific model (ESR-RA).

Results: A total of 822 RA patients were enrolled in this study, with mean age at baseline 54.5 ± 12.0 years, 79.8% females, and median RA disease duration 6.3 years. During a mean follow-up time of 3.9 years, 81 (9.8%) incident CVD events occurred. The LASSO-Cox regression was performed to identify risk factors associated with CVD, and the final clinical model consisted of age, male, BMI, history of hypertension, CRP, CDAI, the use of glucocorticoid, and CAC score (**Table 1**). **Table 2** illustrates the internal discrimination properties of CAC model, with a C-index of 0.888 (95% CI 0.844-0.933), indicating excellent discrimination between events and non-events. The C-index of CAC model was significantly higher than that of the clinical model (0.859) and the ESR-RA model (0.847, both $P < 0.05$). While, no significant difference was found

Table 2 The ability of CAC score to predict CVD risk in RA patients

Table 2 The ability of CAC score to predict CVD risk in RA patients

	C-index (95% CI)	Change in C-index (95% CI)		NRI (95% CI)

Abbreviations: CVD, cardiovascular disease; RA, rheumatoid arthritis; CAC, coronary artery calcium; NRI, net reclassification improvement. * $P < 0.05$.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

between the clinical and ESR-RA models, supporting the significant improvement achieved by incorporating CAC. When comparing the CAC model against clinical model, the NRI showed that the accuracy of the model was improved 31.6% (95% CI 15.9-0.62.8) after adding CAC scores to the clinical model, while no significant improvement was observed when comparing the clinical model with the ESR-RA model (**Table 2**).

Conclusion: Add-on of CAC score significantly improves the prediction of CVD risk in RA patients. Further validation in large-sample, multi-center prospective cohorts are needed in future.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Remission criteria in Rheumatoid Arthritis (RA) have continuously evolved to balance the risks of both overtreatment and undertreatment. The most recent update includes the revised ACR/EULAR Boolean Criteria 2.0 (BC 2.0).

While most RA activity indices include patient-reported outcomes such as pain and global assessment, these measures are inherently subjective and can be influenced by cultural, socioeconomic, and ethnic factors. This study aimed to evaluate the agreement between commonly used RA activity indices (DAS28-CRP, DAS28-ESR, CDAI, SDAI) and the BC 2.0, as well as determine the most accurate cut-off values for remission in Brazilian patients, using data from a large, multicenter real-world cohort.

Methods: This cross-sectional analysis used baseline data from a national multicenter observational study conducted across 11 public hospitals in Brazil. All participants met the 2010 ACR/EULAR Classification Criteria for Rheumatoid Arthritis.

Sociodemographic and clinical variables were analyzed using descriptive statistics. Agreement between remission definitions was assessed using the Kappa coefficient, and ROC curves were constructed to determine the most sensitive and specific cut-off points for each index, using BC 2.0 as a reference.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1: ROC curve illustrating the sensitivity and 1-specificity of the different metrics in relation to BC 2.0.

Metric	Cut-off	Sensitivity (%)	Specificity (%)
DAS28-CRP	≤2.6*	97.6	75.0
	≤2.3	86.0	85.9
DAS28-ESR	≤2.6*	75.6	84.8
	≤2.8	81.7	79.9
CDAI	≤2.8*	77.4	93.2
	≤3.9	88.4	88.3
SDAI	≤3.3*	81.1	95.9
	≤4.3	90.9	91.7

*Current reference threshold

Figure 2: Sensitivity and Specificity of of Proposed Cut-off Points for Remission.

Results: A total of 840 RA patients were included (89.8% female; mean age 57 years, SD ±11; median disease duration: 12.2 years, IQR 6.8–19.3). Rheumatoid factor was positive in 78.1%, and methotrexate was used by 68.1%, corticosteroids by 44.5%, and biologic DMARDs by 37.7%. Remission rates varied widely across indices: DAS28-CRP (39.2%), DAS28-ESR (27.0%), CDAI (20.6%), SDAI (19.2%), BC 2.0 (19.5%), and Boolean 1.0 (15.1%).

SDAI showed the highest agreement with BC 2.0 (Kappa: 0.775), followed by CDAI (K: 0.692), while DAS28-CRP and ESR demonstrated moderate agreement (K: 0.525 and 0.527, respectively).

In ROC analysis (figure 1), SDAI had the highest accuracy (AUC = 0.973; 95% CI 0.964-0.983), outperforming the other indices: DAS28 CRP (AUC = 0.947; 95% CI 0.933-0.962), DAS28 ESR (AUC = 0.888; 95% CI 0.864-0.912) and CDAI (AUC = 0.951; 95% CI 0.937-0.964). The optimal SDAI threshold was ≤4.3, superior to the conventional ≤3.3 cut-off (figure 2).

Conclusion: Conventional SDAI remission thresholds may underestimate disease control in Brazilian RA patients. A revised cut-off of SDAI ≤4.3 demonstrated greater accuracy and better alignment with BC 2.0, suggesting they are more appropriate remission cut-off for clinical use and research in Brazilian RA patients. These results have potential implications for both clinical care and international RA research, particularly for underrepresented populations.

A Pilot Study to Identify Novel Autoantibody Biomarkers in Rheumatoid Arthritis (RA) Patients Using Immunome Protein Array

Margaret Ma[1], Peter Cheung[1], ee tzun koh[2], janique peyper[3], bermet abylova[3] and Khai Pang Leong[2], [1]National University Hospital, Singapore, Singapore, [2]Tan Tock Seng Hospital, Singapore, Singapore, [3]Standard BioTools, Singapore, Singapore

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: RA is a heterogenous condition with variable outcomes. The identification of novel autoantibodies and autoantibody signatures could help us identify potential diagnostic and prognostic biomarkers which could guide treatment decisions. We carried out this pilot study using a high-throughput protein microarray platform to identify autoantibodies against native autoantigens in RA patients.

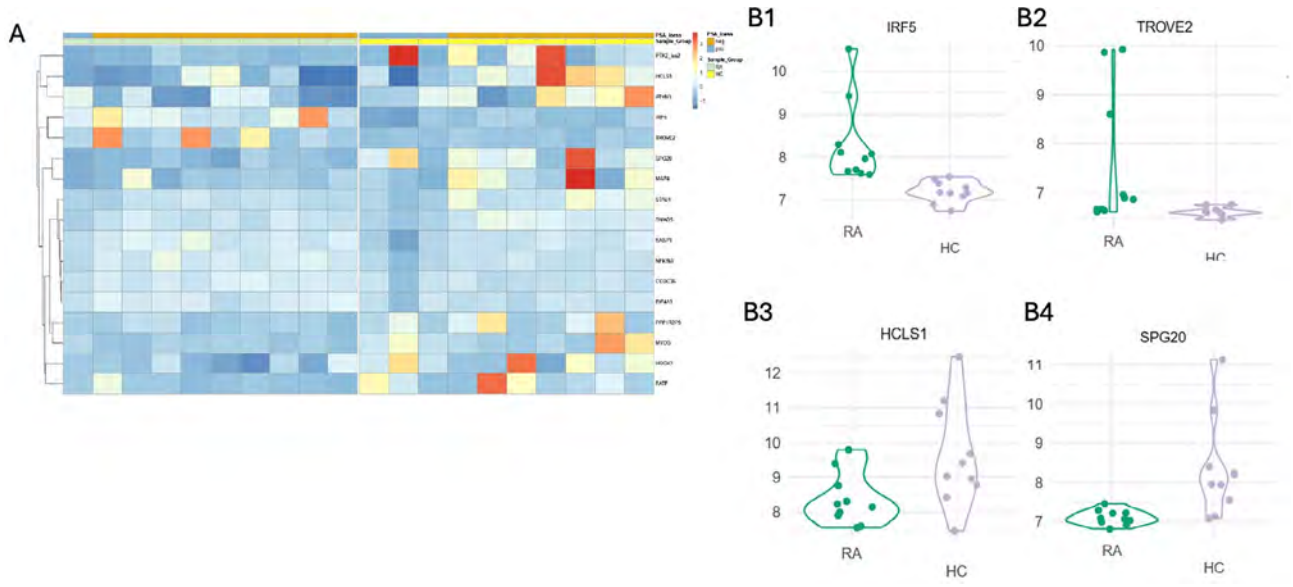

Figure: A = annotated heatmap of the signals for antigens surpassing significance threshold during linear modeling analysis, with both row and column clustering. B1-4 = violin plots of the autoantibodies of the most significance.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Sera from 10 RA and 10 gender-, age-, and ethnicity-matched healthy controls (HC) were screened for seroreactivity (IgG) to more than 1,600 disease-associated protein antigens in their native conformation. R package limma was used to perform a linear modeling analysis between comparison classes across all signals representing cognate antibody-antigen interactions. This analysis employs a moderated t-statistical method which calculates, for each antigen, the difference between two specified classes, and determines the significance of these differences by measure of fold changes and p-values .The significance threshold for identifying differential Abs (DAbs) was set at $p < 0.05$ and $|\text{fold-change}| > 1.1$. ROC analysis was performed between comparison classes across all antigens surpassing significance threshold during the above-described linear modeling analysis.

Results: 17 antibodies were identified to be differentially expressed (Figure A heatmap). Of note, higher levels of anti-TROVE2 IgG (fold change of 1.97, p value = 4.09e-02, ROC AUC = 0.89) and anti-IRF5 IgG (fold change of 2.06, p value = 3.2e-03, ROC AUC = 1) were observed solely among RA patients, whereas higher levels of anti-HCLS1 IgG (fold change of 1.54, p value = 6.16e-03, ROC AUC 0.79) and anti-SPG20 IgG (fold change of 1.26, p value = 4.63e-03, ROC AUC 0.91) were nearly unique to HC (Figure B1-4).

Conclusion: A high-throughput protein microarray platform allows detection and quantification of autoantibodies which maybe of potential pathophysiological and prognostic significance in RA patients. TROVE2 is a well-known classical rheumatological autoantigen and has been shown to be a biomarker for predicting ADAb

development and therapeutic response in adalimumab-treated patients. IRF5 is involved in signal transduction eliciting type I IFN expression. Additionally, upregulation of antibodies targeting HCLS1 (involved in leukopoiesis and leukocyte clonal deletion) and SPG20 (involved in lipid degradation and mitochondrial function) in HC suggests possible protection against RA by pathways incorporating those proteins, or indeed by the antibodies that target them. Our preliminary findings suggest a complex relationship between autoantibody signatures and RA.

Abstract Number: 2248

Elevated Anti-PAD Autoantibodies in a Singaporean Chinese Rheumatoid Arthritis (RA) Cohort with Rheumatoid Factor (RF) and Anti-Citrullinated Protein Antibodies (ACPA) Positivity: A Case-control Exploratory Study

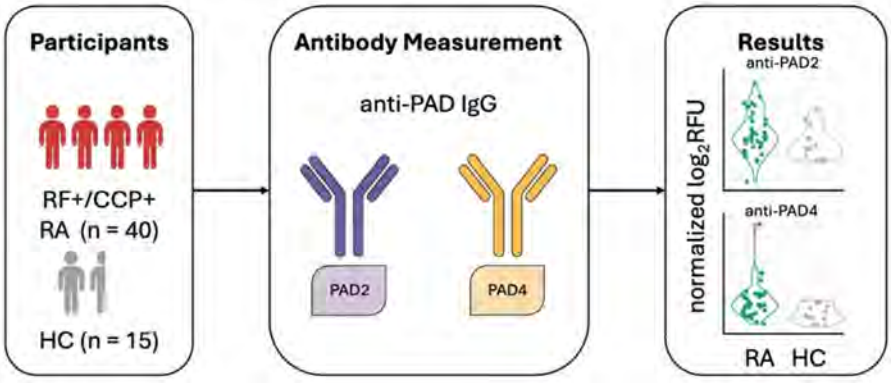
Margaret Ma[1], Khai Pang Leong[2], ee tzun koh[2], Preeti Dhanasekaran[3], janique peyper[4], bermet abylova[4], Anselm Mak[3] and Peter Cheung[1], [1]National University Hospital, Singapore, Singapore, [2]Tan Tock Seng Hospital, Singapore, Singapore, [3]National University of Singapore, Singapore, Singapore, [4]Standard BioTools, Singapore, Singapore

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Autoantibody-based biomarkers including ACPA and RF are of established clinical use in rheumatoid arthritis (RA) and are ingrained in international classification criteria. However, other antibodies are also likely to be of relevance. The presence of autoantibodies in Chinese RA populations has not been well studied. The aim of this study was to

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 1: Elevated anti-PAD antibodies in a Chinese seropositive rheumatoid arthritis cohort: a case-control exploratory study



determine an autoantibody signature in a homogenous population of ACPA/RF-positive Chinese RA patients by using a broad explorative screen of IgG antibodies to autoantigen specificities.

Methods: We selected 40 RA patients and 10 matched healthy controls. Plasma samples were screened only for IgG seroreactivity, against a panel of >1,800 protein autoantigens using the KREX technology-based i-Ome Discovery array. Differential analysis was performed using R package limma. The significance threshold for identifying differential Abs (DAbs) was set at $p < 0.05$ and $|\text{fold-change}| > 1.1$. ROC analysis was carried out for each DEAb, yielding discriminative performance metrics e.g., sensitivity, specificity, area under the curve (AUC), and accuracy.

Results: Anti-PAD2 and anti-PAD4 autoantibodies exhibited significantly higher signals in the RA class. Class-wise, anti-PAD4 exhibited a fold-change of 1.54 (p = 5.46e-3), while anti-PAD2 exhibited a fold-change of 1.22 (p = 3.9e-2). Because only a proportion of individuals within a target class typically exhibits the signal of interest, class-wise autoantibody fold-changes are often diluted, and are therefore still meaningful at a threshold of 1.20. Both autoantibodies exhibited good sensitivity in discriminating RA from HC (0.90 and 0.74, respectively), although specificities were moderate (0.60 and 0.67, respectively). The ROC AUC were 0.79 for anti-PAD4 and 0.69 for anti-PAD2.

Conclusion: PAD2 and PAD4 have been reported as the most strongly implicated PAD enzymes in RA pathogenesis on the basis of genetic, histological and animal studies (1). In addition, anti-PAD4 antibodies are associated with severe joint damage, and anti-PAD2 antibodies are associated lung involvement but less severe joint disease (1). Elevated anti-PAD2 and anti-PAD4 autoantibody prevalence in our Singaporean Chinese RA patients are consistent with Western cohort findings (1,2), as well as a China cohort (3). This supports the diagnostic relevance of these autoantibodies beyond Western populations and highlight the potential role of PAD 2/4 autoantibodies to enhance early RA diagnosis and prognosis in a Singaporean Chinese population.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Interstitial lung disease (ILD) is the second leading cause of mortality in rheumatoid arthritis (RA) but often goes underdiagnosed due to its variable clinical presentation, ranging from subclinical involvement to progressive fibrosis. Despite its impact on prognosis, data to guide evidence-based screening and treatment remain limited. Recently, The American College of Rheumatology (ACR) and the American College of Chest Physicians (CHEST) issued conditional recommendations for RA-ILD management, reflecting low-certainty evidence. The real-world application of these therapies is not well understood. This study aims to evaluate a risk factor–based screening tool for RA-ILD and compare treatment patterns between RA patients with and without ILD in a real world-setting.

Methods: We conducted a cohort study at a single academic centre including patients with RA receiving targeted therapies. Risk factors for ILD development and treatment patterns were compared between RA patients with and without ILD using chi-square and Student's *t*-tests. A risk score incorporating age, sex, smoking status, RA duration, rheumatoid factor, and anti-cyclic citrullinated peptide antibodies was calculated. Receiver operating characteristic (ROC) curve analysis was used to determine optimal cut-off points for identifying patients at risk for subclinical ILD.

Results: Among 688 RA patients treated with targeted therapies, 31 (4.5%) had ILD. RA-ILD patients were older at disease onset (mean 54.9 vs. 45.2 years, $p< 0.05$) and more frequently smokers (48.4% vs. 14%, $p< 0.05$). Treatment patterns differed: RA-ILD patients more often received abatacept (32%), tocilizumab (22%), and JAK inhibitors (19%) versus patients with RA without ILD. Guideline-recommended first-line therapies for RA-ILD were infrequently used in our cohort. Three different cut-off points for the risk score were evaluated: 5 (Sens 86.7%, Spec 48.7% LR+1.7), corresponding to 228 patients (36.5%) in our cohort; 6 (Sens 76.7%, Spec 63.5% LH+ 2.1), corresponding to 59 patients (9.5%), and 7 (Sens 36.7%, Spec 90.5% LH+ 3.9), corresponding to 14 patients (2.2%).

Table. Characteristics of patients with RA with and without ILD

	Overall RA N= 688	RA-no ILD N= 657	RA-ILD N = 31	p
Sex (female)	567 (82.4)	547 (83.3)	20 (64.5)	0.007
Age, mean (SD)	62.3 (13.9)	62.0 (14.1)	68.7 (9.0)	0.004
Age at RA onset, mean (SD)	45.6 (14.8)	45.2 (14.7)	54.9 (12.2)	<0.001
RA duration, median (IQR) years	15 (9-23)	15 (9-23)	11 (8-19)	0.05
ACPA positive high titer	354 (54)	334 (53.4)	20 (66.7)	0.68
RF positive	489 (73.2)	462 (72.4)	27 (90)	0.034
Ever smoker	107 (15.5)	92 (14.0)	15 (48.4)	<0.001
Treatment, n (%)				
Methotrexate	254 (37)	247 (37)	7 (22)	<0.001
TNFi	379 (55)	375 (57)	4 (13)	<0.001
JAKi	104 (15)	98 (15)	6 (19)	
Tocilizumab	99 (14)	92 (14)	7 (23)	
Abatacept	56 (8)	46 (7)	10 (32)	
Rituximab	50 (7)	46 (7)	4 (13)	
Number of previous biologics	1 (1-3)	1 (1-3)	2 (1-3)	0.52
Risk score value (median (IQR)	5 (3-6)	5 (3-6)	6 (6-7)	<0.001
*Except where indicated otherwise, values are the number (%)				

Conclusion: The prevalence of ILD in this cohort of RA patients receiving targeted therapies was 4.5%. The risk score stratified 36% of patients as low risk, 9.5% as moderate risk, and 2.2% as high risk for subclinical RA-ILD. Risk-based screening tools may facilitate earlier detection and intervention, potentially improving clinical outcomes. Real-world treatment patterns varied from current ACR/CHEST guideline recommendations, underscoring the need for further research to individualized treatment decisions based on patient characteristics and ILD severity.

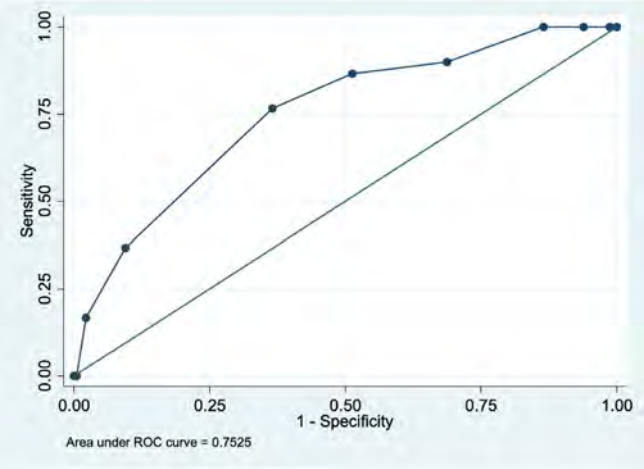

Figure. Performance of the proposed risk score for detection of RA-ILD. Result is shown as area under the receiver operating characterize curves (AUC) with 95% confidence interval (Stata roctab). AUC: 0.75 95%CI (0.67-0.84)

Clinical and Serological Predictors of Interstitial Lung Disease in Rheumatoid Arthritis: Are Anti-Citrullinated Protein Antibodies Truly Relevant?

Martí Aguilar-Coll[1], Javier Narváez[2], Montserrat Roig Kim[1], Laia De Daniel Bisbe[1], Pol Maymó-Paituvi[1], Judith Palacios-Olid[1] and Joan Miquel Nolla[1], [1]Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, Spain, [2]Hospital Universitario de Bellvitge, Barcelona, Spain

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Evidence on which risk factors predict the development of interstitial lung disease (ILD) in patients with rheumatoid arthritis (RA) is scarce and of low scientific quality. This study examines whether several clinical and serological variables are associated with an increased risk of developing this complication.

Methods: A prospective study was performed in a cohort of patients with early RA (1987 ARA or 2010 ACR/EULAR criteria and symptom duration ≤12 months) diagnosed between 2003 and 2023. All patients underwent ILD screening at diagnosis, which included targeted anamnesis for respiratory symptoms, chest auscultation for fine "velcro-like" crackles, chest X-ray

Table 1. Comparison of cumulative incidence curves of each variable using Log-Rank test

	Log-Rank p-value
Male sex	0.001
Age (≥60 years)	0.024
Smoking	
Ever vs never smoker	0.164
1-20 vs 0 pack-years	0.249
>20 vs 0 pack-years	0.137
>20 vs 1-20 pack-years	0.923
Rheumatoid factor (RF)	
(+) vs (-)	0.728
(+) ≤3 times the ULN vs (-)	0.232
(+) >3 times the ULN vs (-)	0.511
(+) >3 times the ULN vs (+) ≤3 times the ULN	0.108
Anti-citrullinated protein antibodies (ACPA)	
(+) vs (-)	0.493
(+) ≤3 times the ULN vs (-)	0.352
(+) >3 times the ULN vs (-)	0.408
(+) >3 times the ULN vs (+) ≤3 times the ULN	0.265

Abbreviations: (+) = positive; (-) = negative; ULN = upper limit of normal

Table 2. Cox regression model including all five variables

	HR	95% CI	p-value
Male sex	3.62	1.44-9.15	0.006
Age (10-year increase)	1.45	1.03-2.04	0.034
Smoking	0.92	0.56-1.49	0.722
Rheumatoid factor (RF)	1.34	0.68-2.63	0.392
Anti-citrullinated protein antibodies (ACPA)	0.95	0.52-1.74	0.875

Abbreviations: HR = hazard ratio; 95% CI = 95% confidence interval

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Cumulative incidence curve of ILD according to sex

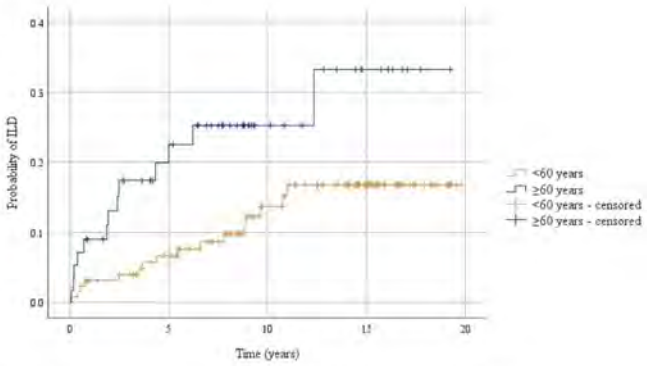
The time of RA diagnosis was used as a starting point, with censoring at death or last follow-up appointment.

Figure 2. Cumulative incidence curve of ILD according to age at RA diagnosis



The time of RA diagnosis was used as a starting point, with censoring at death or last follow-up appointment.

(CXR) and pulmonary function tests (PFTs) with spirometry and DLCO. A thoracic high-resolution computed tomography (HRCT) was performed in case of symptoms, crackles or alterations in CXR or PFTs. In patients without initial abnormalities, screening was repeated between the second and fifth year of follow-up. Sex, age at RA onset, smoking history and cumulative dose, rheumatoid factor (RF), and anti-citrullinated protein antibodies (ACPA) variables were collected. Cumulative incidence curves (i.e. 1 minus Kaplan-Meier-estimated probability), Log-Rank test and a Cox regression model were applied to determine whether or not these variables are associated with an increased risk of ILD.

Results: One hundred and eighty-eight RA patients without known ILD were included in the study. After a median follow-up time of 10.2 years (IQR 7.0 to 15.0), 30 new cases of ILD (16.0%) were diagnosed. The risk of developing lung involvement was higher among males and in patients aged ≥60 years (unadjusted Log-Rank p-value of 0.001 and 0.024, respectively) [table 1]. Cumulative incidence curves for these two variables are displayed in figures 1 and 2, respectively. In contrast, smoking, RF and ACPA showed no statistical differences, neither when tobacco dose or antibody titre were considered (p >0.05 in all scenarios). The results of a Cox regression model including all five variables is shown in table 2. Male sex showed a hazard ratio (HR) of 3.62 (95% CI 1.44 to 9.15) for the development of ILD compared to females (p=0.006). A 10-year increase in the age at the time of RA diagnosis entailed a risk 45% higher (95% CI 1.03 to 2.04) for the development of this complication (p=0.034). Smoking, RF and ACPA also failed to show significant results in the multivariate analysis (p >0.05 in all three cases).

Conclusion: In accordance with published evidence, both male sex and older age at diagnosis are associated with a greater risk of developing ILD. However, the increased risk attributed to tobacco exposure and the presence of RF and/or ACPA, especially at high titres, has not been demonstrated in this prospective study.

Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is associated with an increased risk of malignancies, particularly lung cancer, relative to the general population[1]. However, the association between RA and overall survival in those who develop lung cancer has not been well characterized. The objective of this study was to evaluate the relationship between RA and overall survival among older adults diagnosed with lung cancer.

Methods: Data spanning 2005-2023 was obtained from the Veteran's Health Administration's (VHA) electronic medical records, commonly referred to as the Corporate Data Warehouse (CDW). Patients with lung cancer were identified from the Oncology Raw domain, which contains records of patients diagnosed with cancer and associated information, such

Table 2: Age-Adjusted Mortality Rates and Multivariable Adjusted Hazard Ratio

Table 2: Age-Adjusted Mortality Rates and Multivariable Adjusted Hazard Ratio

	Deaths	Person-Years (in 1,000)	Mortality Rate (95% CI)	Adjusted Hazard Ratio*
Non-RA Patients	103,840	280.37	370.38 (368.13, 372.64)	Referent
RA Patients	2,375	5.89	402.97 (386.70, 419.73)	1.09 (1.05,1.14)
Total Patients	106,215	286.25	371.05 (368.82, 373.29)	

*Models adjusted for age, sex, race, ethnicity, tobacco use, cohort entry, hypertension, coronary artery disease, stroke, asthma, bronchitis/emphysema, renal disease, diabetes, liver disease, depression, heart failure, hepatitis B, hepatitis C, other hepatitis, HIV, tuberculosis, prior cancer, and lung cancer staging.

as cancer stage and treatments. The cohort included patients aged 50 years or older at the time of lung cancer diagnosis. Pre-existing rheumatoid arthritis (RA) was identified based on the presence of ≥ 2 ICD-9 or ICD-10 codes for RA, 1 to 365 days apart, prior to the lung cancer diagnosis.

The association between RA and all-cause mortality was evaluated using Cox proportional hazards regression models, adjusting for demographic characteristics, smoking status, comorbid conditions, prior history of malignancy, and cancer stage at diagnosis.

Results: Among 128,291 patients with lung cancer, 2,864 (2.2%) had pre-existing RA. The cohort was predominantly male (97.4%), White (75.4%) and current smokers (52%) (Table 1). During follow-up, mortality rates were 370.4 and 403.0 per 1,000 person-years in the non-RA and RA groups, respectively. After adjusting for demographics, smoking status, comorbidities, prior malignancy, and lung cancer stage, RA was associated with increased all-cause mortality (adjusted hazard ratio 1.09; 95% CI: 1.05-1.14) (Table 2).

Conclusion: In this study using national VA data, pre-existing RA was associated with a modest but statistically significant increase in all-cause mortality. After adjusting for key clinical and demographic factors, patients with RA had a 9% higher risk of death compared to those without RA. These findings suggest that RA may independently contribute to poorer survival in patients with lung cancer, highlighting the need for integrative care strategies that address both oncologic and rheumatologic complexities in this high-risk population.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Individuals with rheumatoid arthritis (RA) have a higher prevalence of frailty, even at younger ages, compared to the general population[1]. Among persons with lung cancer, frailty is associated with decreased survival[2]. However, this association has not yet been assessed among patients with lung cancer and pre-existing RA. The objective of this study was to better characterize the contribution of frailty to survival differences among older adults with RA and lung cancer.

Methods: Using nationwide electronic medical records data from the Veterans Health Administration, we included patients aged ≥ 50 years with a lung cancer diagnosis. RA was defined by ≥ 2 RA ICD-9/10 codes 1–365 days apart prior to cancer diagnosis. The validated Veterans Affairs Frailty Index (VA-FI) was used to characterize patient's frailty status. VA-FI is a validated electronic frailty index developed to measure frailty using administrative claims and electronic health records data in Veterans. Patients were characterized as robust, pre-frail, or frail. Cox proportional hazards regression models were used to assess the association between frailty status and survival, adjusting for demographics, smoking history, rheumatic disease comorbidity index (RDCI), prior cancer history, and tumor stage.

Table 1: Baseline Characteristics of Patients with RA and Frailty Veterans Affairs Frailty Index

Results: We identified 2,864 patients with pre-existing RA and lung cancer; 77.7% were > 65 years, 94.9% were male, 79.2% were White, 93.1% non-Hispanic. Based on the VA-FI, 34% were categorized as robust, 26% pre-frail, and 39% frail (Table 1).

Age-adjusted mortality rates per 1,000 person-years were 403.3 for robust, 398.9 for pre-frail, and 410.8 for frail patients. In multivariable analysis, compared with robust persons, pre-fail persons had a mild increased risk of mortality (aHR 1.11; 95% CI: 1.00-1.24), while frail patients had a statistically significant higher risk (aHR 1.27; 95% CI: 1.12-1.43) (Table 2).

Conclusion: Among Veterans with RA and lung cancer, frailty was common and associated with worse survival. These findings highlight the prognostic importance of frailty and suggest it may be routinely assessed to guide risk stratification and clinical decision-making in this population.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Previous studies have estimated physical and mental states using wearable device data such as from smartwatches [1–3]. This study aimed to identify digital biomarkers for RA to support telemedicine and clinical care.

Methods: Patients with RA who consented to participate in the study at the 3 sites wore a wristwatch-type wearable device for 3 months, and their RA-related patient-reported outcomes were prospectively recorded daily on a smartphone application which the authors had developed [1]. Attending physicians examined the participants every month for 3 months and the clinical data were also collected. From the wearable device, data on number of steps, metabolic equivalents (METs), heart rate-related data, and sleep- related data were obtained. Relationship between wearable device data and clinical disease activity index (CDAI) were evaluated, as well as the relationship between inflammation blood biomarkers (C-reactive protein (CRP), erythrocyte sedimentation rate (ESR)) and CDAI as controls. Correlation was analyzed univariately. Machine learning (ML) techniques, which included Lasso regression, Ridge regression, Random Forest, and XGBoost, were employed to model disease activity indices such as CDAI and simplified disease activity index (SDAI), using daily data from the wearable

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

device. We also implemented a ML classifier to detect elevated CRP (>0.14 mg/dL), and validated its performance with ROC analysis.

Results: A total of 129 patients successfully completed the 3-month observation period. At the start of the study, the mean age of patients was 55±13 years with a mean disease duration of 8.5±10.3 years. The mean CDAI and CRP levels were 13.5 ±10.7 and 0.39±0.71 mg/dL, respectively. Statistical analysis revealed that an increased number of daily steps was associated with lower disease activity (CDAI) (r = -0.28; 95% CI [-0.46, -0.047]; P = 0.018). In contrast, elevated heart rate during sleep (r = 0.23; 95% CI [0.03, 0.41]; P = 0.025), increased sympathetic activity (r = 0.33; 95% CI [0.09, 0.53]; P = 0.009), and a trend toward higher overall heart rate (r = 0.32; 95% CI [0.12, 0.50]; P = 0.002) were correlated with higher CDAI scores. Additionally, inflammation markers including CRP and ESR showed moderate correlations with CDAI (CRP: r = 0.33, 95% CI [0.24 to 0.42] P < 0.001) (ESR: r = 0.32, 95% CI [0.23 to 0.41]; P < 0.001). ML approaches demonstrated predictive ability, achieving an AUC of 0.90 for CDAI remission and a median absolute error (MAE) of 5.04 in predicting CDAI values. Similarly, performance for SDAI was strong, with an AUC of 0.82 and MAE of 5.12.

Conclusion: Metrics from wearable devices, including step counts and heart rate, were significantly associated with RA disease activity, supporting their potential as digital biomarkers. These correlations were comparable to those of traditional markers like CRP and ESR. Moreover, ML models using wearable data accurately predicted disease activity and inflammation, demonstrating their utility in practice and telemedicine.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with rheumatoid arthritis (RA) often experience not only joint-related symptoms but also systemic issues such as insomnia, depression, and fatigue [1–3]. These symptoms may persist despite therapeutic advances and significantly impair quality of life [1]. This study aimed to clarify the prevalence of insomnia, depression, and fatigue in RA and examine their relationship with disease activity.

Methods: This prospective study enrolled RA patients who could respond to a structured questionnaire. Insomnia was assessed using the Athens Insomnia Scale (AIS), depressive symptoms were evaluated via the Patient Health Questionnaire-9 (PHQ-9), and fatigue was measured using both the Brief Fatigue Inventory (BFI) and the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F). Disease activity of RA was measured by the Disease Activity Score in 28 joints with CRP (DAS28-CRP), Clinical Disease Activity Index (CDAI), and Simplified Disease Activity Index (SDAI). Functional status of RA was determined through the Health Assessment Questionnaire-Disability Index (HAQ-DI). All patients met the 2010 American College of Rheumatology/ European League Against Rheumatism classification criteria [4] for RA.

Results: A total of 107 RA patients (90 female, 17 male) participated, with a mean age of 55 years and a mean disease duration of 82 months. The median DAS28-CRP was 2.9, CDAI was 10.2, SDAI was 10.2, and HAQ-DI was 0.5. Insomnia was reported in 85% of participants, and the AIS score was significantly associated with DAS28-CRP ($r=0.22$, $p=0.03$), CDAI ($r=0.23$, $p=0.03$), SDAI ($r=0.22$, $p=0.03$), and HAQ-DI ($r=0.22$, $p=0.03$). Depression was reported in 13% of participants, and the PHQ-9 score was significant associations with DAS28-CRP ($r=0.34$, $p< 0.01$), CDAI, ($r=0.34$, $p< 0.01$) and SDAI ($r=0.34$, $p< 0.01$). Severe fatigue was also reported in 85% of participants, with BFI scores significantly correlated with DAS28-CRP ($r=0.43$, $p< 0.01$), CDAI ($r=0.35$, $p< 0.01$), SDAI ($r=0.37$, $p< 0.01$), and HAQ-DI ($r=0.31$, $p< 0.01$). FACIT-F scores showed inverse correlations with DAS28-CRP ($r=0.47$, $p< 0.01$), CDAI ($r=0.42$, $p< 0.01$), SDAI ($r=0.43$, $p< 0.01$), and HAQ-DI ($r=0.25$, $p=0.01$). In addition, the components of disease activity assessment, especially the patient global visual analogue scale, were correlated with AIS ($r=0.32$, $p< 0.01$), PHQ-9 ($r=0.40$, $p< 0.01$), FACIT-F ($r=0.45$, $p< 0.01$), and BFI ($r=0.42$, $p< 0.01$).

Conclusion: Insomnia and fatigue were highly prevalent among RA patients, affecting over 80% of patients, while depression was identified in 13%. All symptoms showed associations with disease activity and functional impairment. These findings suggest that optimal RA management should also address psychological and fatigue-related symptoms.

Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Anti-carbamylated protein antibodies (anti-CarP Ab) are emerging serologic markers in rheumatoid arthritis (RA). Anti-CarP Ab has a controversial diagnostic utility in RA but may be particularly useful in patients who are negative for traditional markers such as rheumatoid factor and anti-citrullinated protein antibodies (ACPA). This study aimed to evaluate the diagnostic accuracy of anti-CarP Ab in RA patients with both ACPA-negative (ACPA-) and ACPA-positive (ACPA+) subgroups.

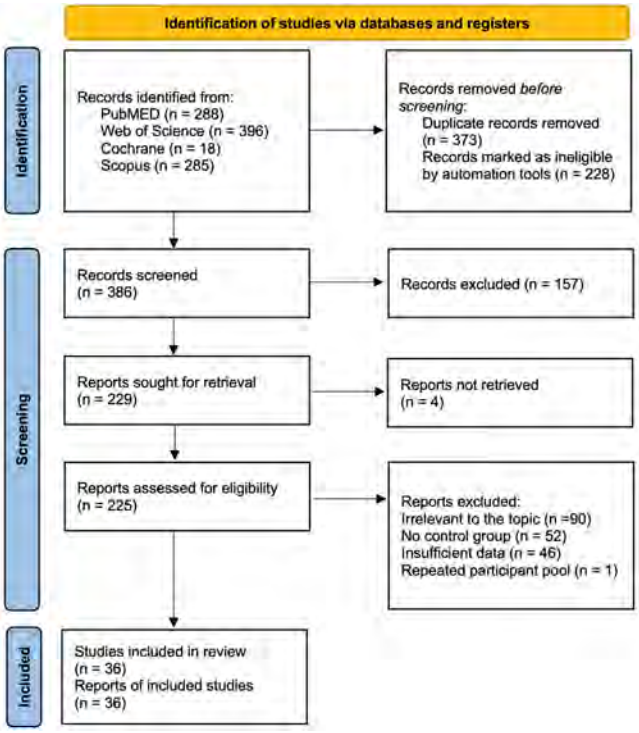

Figure 1. PRISMA Flow Diagram of Studies Included In the Meta-analysis

Diagnostic Accuracy of Anti-carbamylated Protien Antibodies in Rheumatoid Arthritis Patients
ACPA, anti-citrullinated protein antibodies; FCS, fetal calf serum; PLR, positive likelihood ratio; NLR, negative likelihood ratio; DOR, diagnostic odds ratio; SROC, summary receiver operating characteristic curve; AUC, area under the curve

Methods: We systematically searched MEDLINE, Scopus, Web of Science and the Cochrane Library through April 2025. Studies reporting sensitivity and specificity of anti-CarP Ab testing in established RA patients were included. The primary outcome was diagnostic accuracy compared to healthy controls. Secondary outcomes included subgroup analyses of ACPA- and ACPA+ patients.

Results: Thirty-six studies comprising 7431 RA patients and 3347 healthy controls were included. Most used in-house ELISA platforms; fetal calf serum (FCS) was the most common antigen, and IgG was the predominant isotype for detection. Primary outcomes: Anti-CarP Ab showed high accuracy as a diagnostic tool in detecting RA with pooled sensitivity and specificity of 44% (95% CI: 39-49%, I^2 = 91.5%) and 96% (95% CI: 94-97%, I^2 = 65.5%), respectively. The positive likelihood ratio was 9.27 (95% CI: 7.17–11.36, I^2 = 99.3%), negative likelihood ratio was 0.62 (95% CI: 0.55–0.68, I^2 = 0.0%), and diagnostic odds ratio (DOR) was 14.72 (95% CI: 10.75–20.15, I^2 = 62.1%). The area under the curve (AUC) of the summary receiver operating characteristic curve (SROC) was 0.825. Subgroup analysis among studies using FCS (n = 16) showed pooled sensitivity of 41% (95% CI: 38-45%, I^2 = 82.3%) and specificity of 96% (95% CI: 95-98%, I^2 = 59.6%). In studies detecting IgG only (n =19), sensitivity was 43% (95% CI: 38-48%, I^2 = 92.8%) and specificity was 96% (95% CI: 94-98%, I^2 = 60.7%). Secondary outcomes: **ACPA- group:** pooled sensitivity and specificity were 24% (95% CI: 18-31%, I^2 = 87.2%) and 95% (95% CI: 93-97%, I^2 = 70.3%). DOR was 5.29 (95% CI: 3.64-7.67, I^2 = 41.3%) and AUC of SROC was 0.755 **ACPA+ group:** pooled sensitivity and specificity were 49% (95% CI: 41-57%, I^2 94.0%) and 95% (95% CI: 93-97%, I^2 = 72.0%). DOR was 18.38 (95% CI: 10.36-32.61, I^2 = 82.0%) and AUC of SROC was 0.855.

Conclusion: Anti-CarP Ab demonstrates high specificity but low sensitivity for RA diagnosis. Anti-CarP Ab is recommended as a complementary diagnostic tool, particularly in patients who are negative for ACPA.

Abstract Number: 2256

Improved Outcomes of Acute Myocardial Infarction Among Patients with Rheumatoid Arthritis: A Propensity Matched National Study

Qurat Ul Ain[1] and MIrza faris Ali Baig[2], [1]Medstar Georgetown University Hospital, Arlington, VA, [2]Medstar Health, Arlington, VA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The increased risk of cardiovascular morbidity and mortality with rheumatoid arthritis has been increasingly acknowledged over the past decades. Cardiovascular disease risk management for patients with rheumatoid arthritis is essential. This retrospective population-based study investigated in-hospital outcomes among adult patients admitted with acute myocardial infarction (AMI), with a specific focus on the impact of rheumatoid arthritis (RA) on these outcomes.

Methods: Data was derived from the National Inpatient Sample (NIS) database, between January 1, 2018 and December 31, 2021,

encompassing a large and diverse cohort of hospitalized individuals. The primary outcome analyzed was in-hospital mortality, with secondary outcomes being the utilization of diagnostic angiography, rates of percutaneous coronary intervention (PCI), and the incidence of complications such as acute kidney injury (AKI), cardiogenic shock, cardiac arrest, ventricular tachycardia (VT), ventricular fibrillation (VF), as well as requirements for mechanical ventilation, tracheal intubation, and mechanical circulatory support (MCS). Additional parameters examined were length of stay (LOS) and total hospitalization charges.

The study population comprised of 2,275,150 patients, predominantly Caucasian (71%), followed by African American patients (11%), with females representing 36.4% of the cohort. The mean age across the population was 66.5 years (±2.8 years). Among these patients, 39,270 (1.7%) had a documented history of rheumatoid arthritis. Owing to the significant difference in sample size between patients with AMI in the presence and absence of RA, a propensity score matching

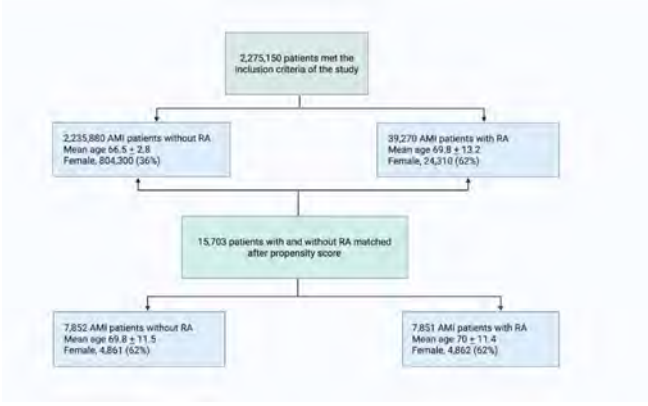

Figure 1.0 Schema representing study population pre and post propensity score matching.

COPD, no. (%)	1,956 (25%)	1,980 (25.2%)	0.65
Chronic kidney disease, no. (%)	1,395 (17.7%)	1,439 (18.3%)	0.36
Chronic liver disease (CLD), no. (%	52 (0.6%)	76 (1%)	0.03
Atrial fibrillation, no. (%)	1,429 (18.2%)	1,603 (20.4%)	<0.001
Coronary artery disease (CAD), n	6,147 (78.2%)	6,122 (78%)	0.26

Figure-2 Post propensity pateint characteristics

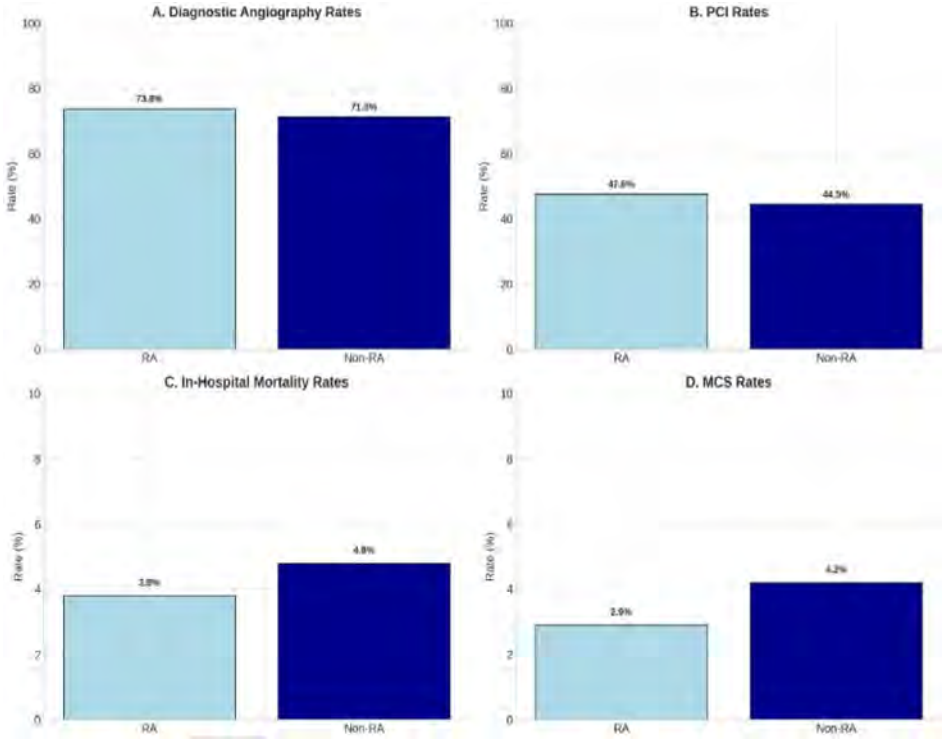

Figure-3 Outlines lower rate of Acute myocardial infarction (AMI) moratality, lower utilization of mechanical circulatory support, higher rates of diagnostic angiography and PCI in RA group.

(PSM) algorithm was employed to generate comparable groups. Post-matching, 15,703 patients from each cohort were selected, ensuring a similar distribution of age, sex, race, and Charlson Comorbidity Index score.

Results: Comparative analysis of the matched cohorts revealed notable differences in outcomes. Patients with RA experienced a lower rate of in-hospital mortality (3.8% vs. 4.8%, $P < 0.001$) compared to those without RA. Additionally, the utilization of mechanical circulatory support was lower in the RA group (2.9% vs. 4.2%). In contrast, the RA cohort demonstrated higher rates of diagnostic angiography (74% vs. 71%, $P < 0.001$) and PCI (48% vs. 44%), suggesting a more aggressive diagnostic and interventional approach.

Conclusion: The study highlights that despite previous associations of rheumatoid arthritis with increased mortality largely due to cardiovascular complications, advancements in disease management and therapeutic interventions may have contributed to improved in-hospital outcomes in this subgroup. The observed higher utilization of diagnostic and interventional

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Impact of Family History of RA in Patients Evaluated for Arthralgia: A Comprehensive Analysis of the Reuma-check Cohort

Rodrigo García Salinas[1], Juan Arguello[2], Santiago Ruta[3], Ronald Perez[2] and Sebastian Magri[4], [1]Hospital Italiano La Plata, La Plata, Argentina, [2]Hospital Italiano de La Plata, La Plata, Argentina, [3]Hospital San Martin de La Plata, La Plata, Argentina, [4]Hospital Italiano La Plata, Melchor Romero, Argentina

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: First-degree family history of rheumatoid arthritis (RA) is a relevant factor in genetic predisposition and early diagnosis of the disease. Objectives: 1)Estimate the frequency of family history (FH) in consecutive patients with arthralgia and its association with the final diagnosis of RA. 2) Analyze the differences between patients diagnosed with RA, according to the presence or absence of FH. 3) Compare the characteristics of patients with arthralgia without a diagnosis of RA, differentiating those with and without FH.

Methods: This was an observational study where patients with arthralgia were admitted to the Reuma-check program. At baseline, laboratory tests (ESR, CRP, RF, and ACPA), ultrasonography (US), and X-ray were performed. Sociodemographic,

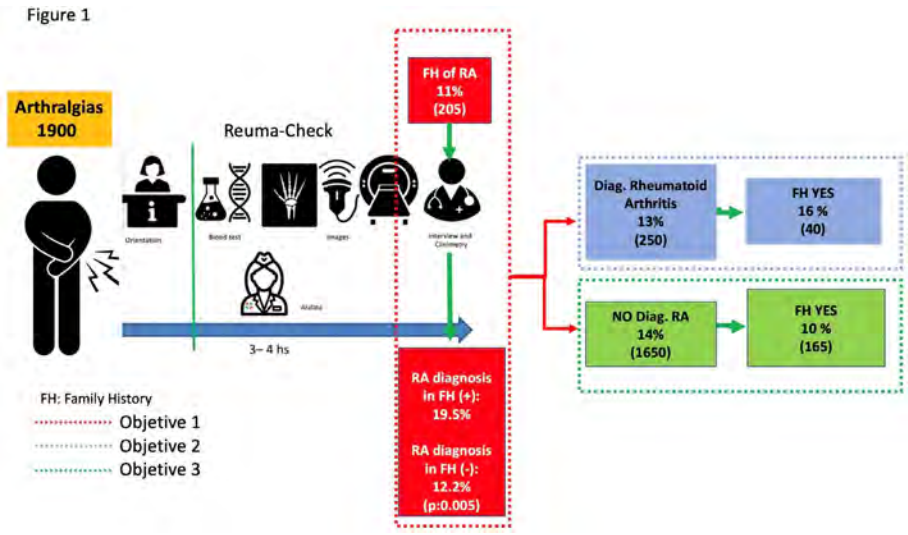
ANA+, %	26	19	0.04	1.5 (1.1-2.3)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



clinical, and clinimetry data (28-joint count – HAQ), including first-degree family history of RA, were also collected. Each evaluator was blinded to the results of the other studies (fig1). Once the circuit was completed, the diagnosis of RA was established. Descriptive statistics and logistic regression were performed.

Results: A total of 1900 patients with arthralgia were evaluated: 77% were women, with a mean age of 52 years (SD 14). 10.8% (n=205; 95% CI: 9.5%-12.3%) had FH. Patients with FH showed a higher prevalence of RA (19.5% vs. 12.2%; OR: 1.75; 95% CI: 1.2-2.55; p=0.005).

Patients diagnosed with RA (n=250) and FH (16%, n=40) presented distinct characteristics compared to those without FH, showing a more severe RA, Significant differences in univariate analysis between patients diagnosed with RA with and without FH are shown in Table 1. Significant variables in the univariate analysis were included in the multivariate logistic regression model. The results showed that involvement of metacarpophalangeal (MCP) joints presented an independent association in patients with RA and FH (OR = 4.24, 95% CI: 1.35–13.31, p = 0.013).

In patients with arthralgia without a diagnosis of RA (n=1651), those with FH (10%, n=165) showed more severe features in the univariate analysis (Table 1). Logistic regression showed an independent association with positive MCP squeeze (OR: 2.26; 95% CI: 1.57-3.27; p< 0.001), female sex (OR: 1.92; 95% CI: 1.14-3.21; p=0.013) and Youngest age at consultation (OR: 0.8 CI: 0.78-0.9; p=0.001).

Conclusion: The frequency of FH is 11% in patients with arthralgia and is associated with a higher risk of RA diagnosis. Patients with RA and FH present distinct severity characteristics. In patients with arthralgia without a diagnosis of RA, the presence of FH is associated with more severe clinical features of arthralgia.

Clinical Associations of Pulmonary Hypertension in RA Patients with and Without Interstitial Lung Disease

Sanjita Gowda[1], Yuri Matusov[2], Amara Seng[1], Nunzio Bottini[3] and Jon Giles[4], [1]Cedars-Sinai Medical Center, Los Angeles, CA, [2]Cedars-Sinai Medical Center, Los Angeles, [3]Cedars Sinai Medical Center, Beverly Hills, CA, [4]Cedars Sinai Medical Center, Los Angeles, CA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Pulmonary diseases are contributors to the morbidity and mortality of RA. Despite the recent surge in studies of RA-associated interstitial lung disease (RA-ILD), there have been few studies of pulmonary hypertension (PH) in and out of the context of symptomatic RA-ILD. We explored clinical associations and mortality of PH in RA.

Methods: Data were extracted from the electronic medical record of a large, urban, referral medical system between 1/1/2012 and 10/25/24. RA, ILD, and PH were defined based on ICD-10 codes at two distinct time points. We compared clinical characteristics within the RA cases according to the presence/absence of ILD and/or PH. These were further compared with non-RA controls with ILD and/or PH. Generalized linear models were used to adjust for relevant confounders.

Results: A total of 10,824 RA patients were identified. ILD was diagnosed in 526 (5%), among whom 171 (33%) were also diagnosed with PH. PH without ILD was diagnosed in 595 (6%). Among 6,954 non-RA controls with ILD, only 1,649 (24%) also had PH (OR 1.55; p< 0.001 compared with RA). This difference was maintained after adjustment for demographics and smoking (OR=1.41; p=0.001). Within the RA group, those with RA+ILD were less likely to be female than those with RA only (72% vs 78%, respectively, p=0.007), while those with RA+PH and RA+ILD+PH did not differ significantly on sex compared with those with RA only. Black race was more frequent in those with RA+PH and RA+ILD+PH compared with those with RA only (23% and 25% vs. 12%, respectively; p< 0.0001 for both comparisons). Ever smoking was more common for all subtypes of RA lung involvement compared with those with RA only, but current smoking did not differ substantially. Current alcohol use was lower among those with all subtypes of RA lung disease compared with those with RA only. Median CRP was highest in those with RA+ILD and RA+ILD+PH (4.2 and 4.0 mg/L, respectively), and was higher than in those with RA only and RA+PH. Age at death was the lowest for those with RA+ILD+PH (Fig. 1), with a trend to lower age at death for those

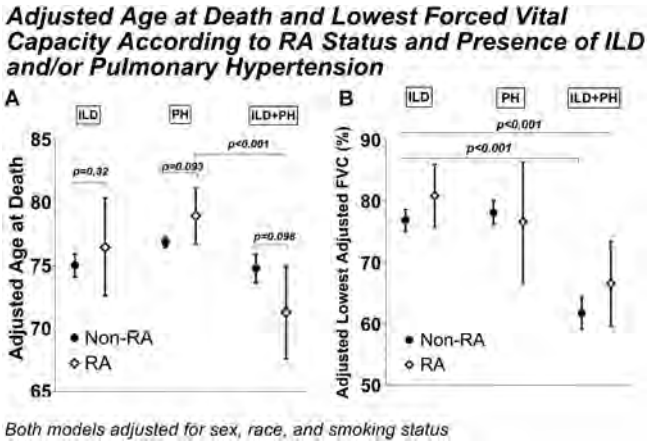

Figure 1: Adjusted Age at Death and Lowest Forced Vital Capacity According to RA Status and Presence of ILD and/or Pulmonary Hypertension

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. with RA+ILD+PH compared with those without RA with ILD+PH. Compared with those with ILD, those with ILD+PH, regardless of RA status, had lower adjusted FVC % predicted (Fig. 1).

Conclusion: The combination of ILD and PH may be more prevalent among RA patients compared with those with ILD who do not have RA and is associated with higher morbidity and mortality. Improved screening and management of PH in RA-ILD may reduce this burden.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Interstitial lung disease (ILD) is a frequent complication of rheumatoid arthritis (RA), ranging from subclinical ILD to advanced fibrosis, and is associated with significant morbidity and mortality. Despite advancing immunosuppressive and antifibrotic therapies, many progress to end-stage respiratory failure and may require lung transplantation. The aim of this study was to compare clinical characteristics and lung transplant outcomes in patients with RA to idiopathic pulmonary fibrosis (IPF). In addition, a meta-analysis was performed to evaluate RA-ILD lung transplant outcomes in the literature.

Methods: We retrospectively analyzed clinical data collected in patients with ILD diagnosed with RA and IPF who underwent bilateral lung transplant between January 1, 2014 and April 30, 2024 at the Vancouver General Hospital, and between January 1, 2012 and December 31, 2024 at the Centre hospitalier de l'Université de Montréal. All RA patients satisfied their respective ACR classification criteria. Continuous variables were analyzed using the Mann-Whitney U test, categorical variables with Fisher's Exact test, and survival using Kaplan-Meier analysis.

For meta-analysis, we searched MEDLINE, Embase and the Cochrane Database of Systematic Reviews from database inception to April 6, 2025. Participants were individuals with RA-ILD who underwent lung transplants. The outcomes studied were overall survival and morbidity following transplant. Bibliographies of selected articles were hand-searched for additional

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. references. Data were extracted using a standardized extraction form. Study quality was assessed using the Newcastle-Ottawa Scale. Pooled post-transplant survival was combined for RA-ILD and IPF individually using a random effects model.

Results: In the retrospective analysis, we identified 27 RA and 64 IPF patients. RA patients were younger than IPF patients at ILD diagnosis (median age 57 vs 60.5, p=0.0028), more likely to be on pre-transplant immunosuppression (92.6% vs 6.2%, p< 0.001), and less likely to receive antifibrotics (22.2% vs 64.1%, p< 0.001). No difference was seen in one-year or cumulative survival. Post-transplant lung function, acute rejection, infection-related hospitalization, malignancy, and chronic lung allograft dysfunction (CLAD) were similar. IPF patients had more UIP patterns on explant pathology, whereas RA patients had more NSIP or mixed NSIP/UIP patterns.

Table 1. Patient baseline characteristics, pre-transplant variables and post-transplant outcomes.

Variables	RA (n=27)	IPF (n=64)	P value
Demographics			
Age at RA diagnosis, median [IQR]	52.5 [40.3-59.3]	NA	
Age at ILD Diagnosis, median [IQR]	57 [47.8-60.5]	60.5 [58 - 64]	**0.0028**
Age at lung transplant, mean [IQR]	62.2 [54.5-67.7]	65 [62 – 68]	0.054

Figure 1. Kaplan Meier survival curve

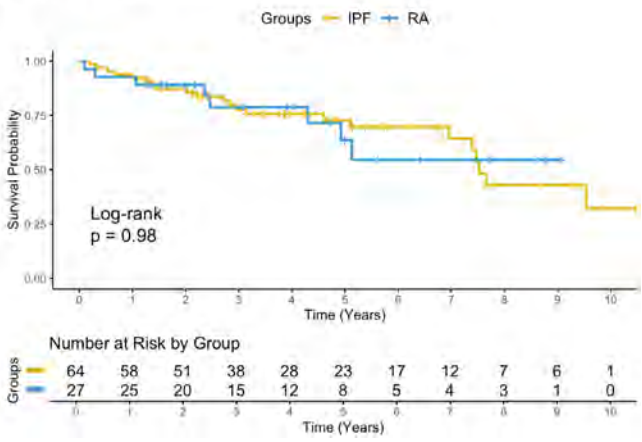

Figure 2: Meta-analysis forest plot of one-year post-transplant survival rate of RA-ILD patients and IPF patients.

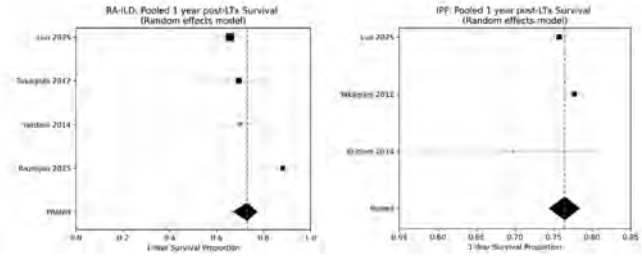

For our meta-analysis, four studies met inclusion criteria. At one year post-transplant, the pooled survival rate of RA-ILD patients was 72.1% (60.5-82.3% 95% CI, I^2=45.8%), whereas in IPF patients, the pooled survival was 76.5% (74.6-78.2% 95% CI, I^2=61.8%).

Conclusion: Post-transplant survival, lung function, and complication rates were comparable between RA and IPF patients at one year and at last follow-up, with the median follow up duration being 3.9 years and 3.6 years respectively. Our meta-analysis demonstrated improved short-term survival following lung transplantation compared to previously reported studies.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Clinical notes typically contain a valuable trove of information which is rarely used in predictive modeling given the complexity of working with unstructured data. As artificial intelligence (AI) advances and multimodal models become necessary to discern complex clinical relationships, the data encoded in clinical notes become extremely important to use. We aimed to apply a generative AI model, i.e. Jina-embeddings –V3 (Jina) model to medical records of patients with rheumatoid arthritis (RA) and show its ability to extract relevant phenotypic features of RA, testing the hypothesis that the model will be able to predict RA diagnosis before the clinical diagnosis.

Methods: The study included 4100 patients with RA diagnosis between 2000 and 2024 mean age was 61.1 (13.4) , 2870 (70%) females, 2450 (59.7%) RF and/or CCP antibody positive). RA was defined as 2 ICD 9/10 codes at least 30 days apart, and each case was confirmed by manual record review, as well as around 80000 persons without RA with notes from the same time period. The notes were arranged in chronological order. Jina was chosen as the embedding model to fine tune given its excellent performance as compared to its relatively small size of 570 million parameters. The model was hosted on a Google cloud container which also hosted a separate storage bucket for all clinical notes extracted for the manually curated dataset of patients with and without RA. The Jina model was fine-tuned on 70% of these notes while the rest of the notes were saved for testing and validation. The fine tuning was performed on the equivalent of 8 H100 GPU (graphic processing units) over the course of 12 hours.

Results: The total number of notes used during the fine-tuning process was 7.8 million. This included 1.2 million notes from patients with RA and 6.6 million notes from persons without RA. These notes included all physician provider notes from any specialty, as well as allied health notes such as nursing notes and clinical communications, as summarized in Table 1. After the model was trained, it was tested on 3.2 million notes (2.6 million non RA and 650K RA patients). Mean duration of available follow up prior to RA diagnsis was: 8.7 yrs (SD 11 yrs). The model was able to discern between patients with RA and without RA with an average precision of 0.8 up to 12 months in advance of their RA diagnosis date.

Conclusion: We showed the ability of the generative AI model (i.e., the fine-tuned Jina embedding model) to predict RA onset months prior to the clinical diagnosis, based on clinical notes. Such predictions can be used to alert a non-rheumatological provider about a concern for RA in advance, enabling earlier referral to a rheumatologist. The work is ongoing on benchmarking this model against a manually curated set of phenotypic characteristics specifically as it relates to the model's ability to encode clinically relevant information which can be used in different clinical predictive models.

Note type	Training (%)	Testing(%)
Progress	50.25	21.54
H&P (including consult)	4.48	1.92

Palindromic Rheumatism and Predictors of Progression to Rheumatoid Arthritis: Experience from a Tertiary Care Center in Northern India

Sryla Punjadath[1], Venkatesh Srinivasa Pai[1], Prativa Priyadarshani Sethi[1], ritu sangwan[2], Abhishek Rai[3] and Ravi Kant[1], [1]All India Institute of Medical Sciences, Rishikesh, Rishikesh, Uttarakhand, India, [2]AIIMS ,Rishikesh, Rishikesh, Uttarakhand, India, [3]AIIMS ,RISHIKESH, Bhilai, Chhattisgarh, India

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Palindromic Rheumatism (PR) is recognized as a clinical syndrome of intermittent episodes of pain, swelling, and erythema in and around joints, which are severe and unpredictable. It has been historically associated with Rheumatoid Arthritis (RA), with many considering PR as a pre-RA stage. We conducted the first-ever study on PR in Northern India to identify the risk factors for progression to RA.

Methods: Electronic medical record data were collected from the Rheumatology clinic at our tertiary care hospital. Thirty patients were identified as having PR. Patients having a history or examination findings consistent with synovial swelling that returned to normal in between episodes without any alternative diagnosis, as determined by a rheumatologist, were included

Table 1: The characteristics of selected demographic, clinical, laboratory, and treatment in patients remaining as PR and progressing to RA. Data expressed as frequency (percentage) for categorical variables and mean (SD) for continuous variables {*t-test or chi2 test as applicable, ** Logistic regression; applied to RF, CRP and number of joints involved and adjusted for duration of follow up, # Age at onset of disease, ESR, CRP, RF, ANA and Anti-CCP expressed as positive or negative as per laboratory cut-off values (ESR- 0-30mm and corrected for age; CRP: 0-1mg/L; RF: >20 IU/L, positive or negative by latex agglutination in 12 patients; ACCP: >10 IU/L), ANA: 5 available values, RF: 28 available values, Anti-CCP: 29 available values}[Abbreviations: ANA: Anti-nuclear antibodies, RF: Rheumatoid Factor, Anti-CCP: Anti- Citrullinated peptide, ESR: Erythrocyte Sedimentation Rate, CRP: C- reactive protein]

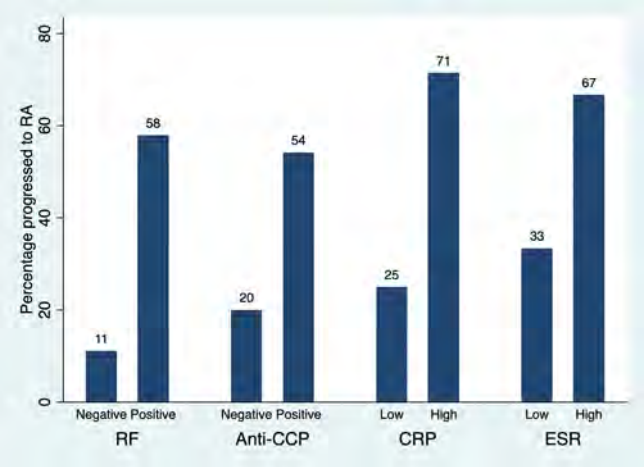

Figure 1: Laboratory characteristics of patients progressing to RA [Abbreviations: RF: Rheumatoid Factor, Anti-CCP: Anti-Citrullinated peptide, ESR: Erythrocyte Sedimentation Rate, CRP: C-reactive protein]

in the study. History, examination findings, and all available laboratory data were collected. Comparisons were made between the group that remained stable as PR and the group that progressed to RA according to the ACR/EULAR 2010 criteria. Comparisons were made using a t-test or chi-squared test, as per data type. Multivariate logistic regression was performed on the significant risk factors. Data were analyzed using STATA version 14 (StataCorp, College Station, TX, USA).

Results: Out of 30 patients, 16 (53.3%) remained as PR and 14 (46.7%) progressed to RA. One patient progressed to primary Sjögren's syndrome, with the arthritis remaining palindromic. The average duration of classification as RA from a diagnosis of PR was 48.50 months (SD-33.92). Age of onset, gender, duration of an arthritis flare, and time interval between the attacks were not different in the two groups. The total number of joints involved ever was higher in the group that progressed to RA (p-value: 0.0005; T-test). The results are tabulated in Table 1. Wrist and metacarpophalangeal joints were most frequently involved. ESR, CRP, RF, and ACCP values were recorded as elevated or normal as per laboratory cutoff values. CRP and RF positivity were significantly higher in the RA progression group, as depicted in Figure 1. The multivariate adjusted Odds Ratio for the number of joints involved was significant for the progression to RA [OR: 1.34 (1.10- 1.75)]. CRP and RF positivity were not statistically significant predictors for progression to RA in multivariate analysis. Additionally, two patients with erosions and deformity developed them after progression to RA. The acute arthritis responded to steroids in 24(80%) and to NSAIDS in 13(43%). As expected, only the patients progressing to RA required treatment with the tsDMARDs (4 out of 14).

Conclusion: In this cohort of patients with PR, approximately half progressed to RA. Raised CRP, RF positivity, and a higher number of joints involved may increase the risk of progression to RA. Being a retrospective study of a small sample size, we acknowledge its low power to capture differences in the other domains. It could also represent a difference in the progression of PR in the Indian Subcontinent as compared to studies published from elsewhere. Our study contributes to the management and follow-up of these patients and also lays the groundwork for future studies in PR.

SESSION INFORMATION

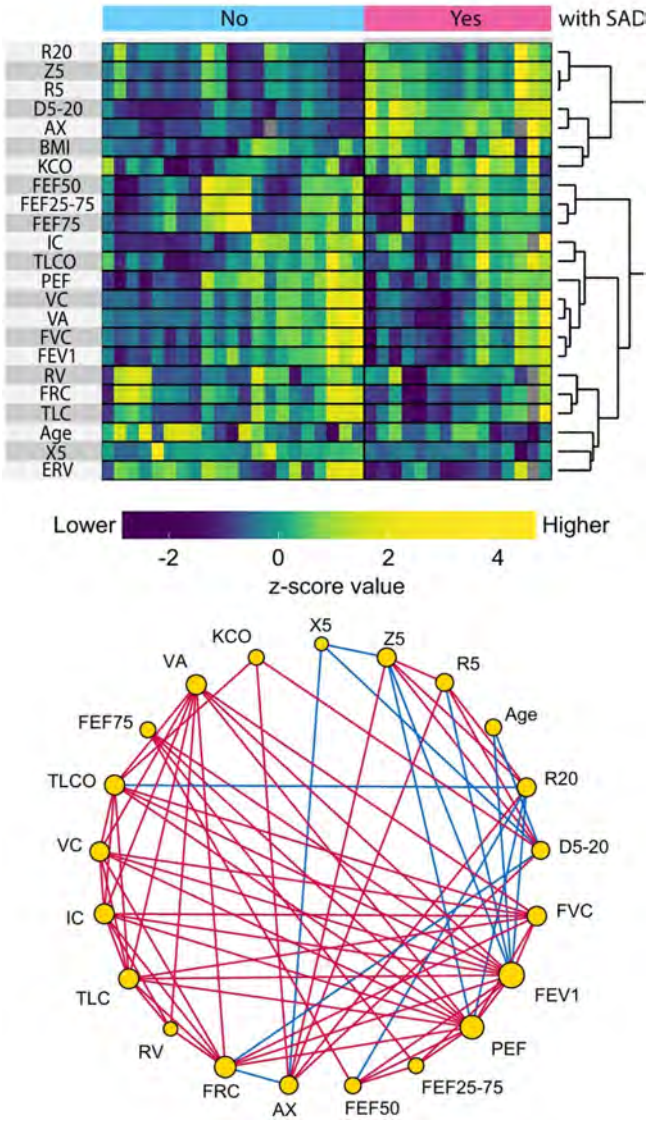
Session Date: Tuesday, October 28, 2025

Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: The risk of interstitial lung disease is well established in Rheumatoid Arthritis (RA). Less is known about the airway involvement which has been estimated to occur in 39% to 60%, varying according to populations and investigative tools [1]. Small airways are defined as non-cartilaginous airways with an internal diameter less than 2 mm, and are characterized by lesions affecting the smallest bronchi and bronchioles [2]. Pulmonary function tests (PFT) are



23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

commonly used to measure small airway disease (SAD) but impulse oscillometry (IOS) appears as an innovative technique to more accurately determine SAD. IOS is a very sensitive measure of airway resistance particularly developed in asthma. This latter tool has never been used so far in RA patients.

We sought to explore the distribution of key PFT and IOS features and the structure of their interrelationship in a cohort of RA patients

Methods: Included patients were followed for RA, with the exclusion of those with documented ILD. They were offered screening for RA airway using chest computed tomography (CT), PFT, and iOS. SAD involvement on CT was assessed by expert radiologists. Mosaic perfusion and expiratory air trapping were considered indicative of SAD.

Key parameters from forced spirometry, body plethysmography, diffusing lung capacity for carbon monoxide, and IOS were obtained RA patients without known ILD. Hierarchical clustering and correlation network analysis were performed. Distal airway involvement is assessed using iOS with the R5-R20 parameter, where a value > 0.07 kPa/L/s indicates small airway disease [3].

Results: The study population included 36 patients with RA (78% of female, mean age of 61.5 ± 10.5 y-o). A history of smoking was reported in 64% of patients. Seropositivity for rheumatoid factor and/or anti-citrullinated protein antibodies (ACPA) was observed in 97% of cases. At the time of inclusion, 44% of patients were receiving biologic DMARDs, mainly TNF inhibitors (9/36 patients). Respiratory symptoms (cough and/or dyspnea) or abnormal lung auscultation were present in 14% of patients. CT scans revealed SAD in 4 patients and ILD was observed in 5 out of 36 patients, predominantly with a pattern consistent with NSIP (3/5).

Visually the data structure (Figure) showed that each PFT modality independently contributed to identify respiratory physiological status in RA. Although most PFT outcomes stayed within normal limits, the overall distribution clearly differentiated patients with SAD (n=15, 42%) from those without (n=21). The correlation network (Figure) revealed a robust interrelationship pattern among 20 PFT parameters, identifying 74 statistically significant correlations, predominantly positive (60 links), with 50 exhibiting strong correlations (r > 0.5).

Conclusion: Lung involvement appears as one of the key extra-articular damages occurring in RA. Beyond the risk of ILD, combined PFT and IOS can be efficient and complementary for detection of SAD in RA patients. This is offering a valuable strategy for identifying accurately subclinical respiratory involvement. Further studies are needed to clarify the prevalence, the prognosis and the management of SAD in RA.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid Arthritis (RA) is a systemic autoimmune disease characterized by chronic inflammation of synovial joints with extra articular manifestations. Disease activity indices in Rheumatoid arthritis are composite tools to assess disease activity and ascertain if treatment targets are met. Patient reported outcomes are increasingly recognized in medicine and have been incorporated in RA treatment guidelines. Routine Assessment of Patient Index3 (RAPID3) is a validated patient reported outcome measure calculated in less than 10 seconds, with no need for acute phase reactants. Previous studies comparing RAPID3 with the traditional physician measured disease activity indices have all been outside sub-Saharan Africa. We compared RAPID3 with physician measured indices in RA patients attending the Lagos State University Teaching Hospital (LASUTH) Rheumatology clinic.

Methods: A comparative study of 72 Rheumatoid Arthritis patients who presented to the outpatient Rheumatology clinic. Consenting patients who fulfilled the 2010 ACR/EULAR classification criteria for Rheumatoid Arthritis were recruited consecutively. Each participant was required to fill out the Multidimensional Health Assessment Questionnaire (MDHAQ), from which the RAPID3 score was calculated. For the physician-measured disease activity, the DAS 28 ESR, DAS 28 CRP, Simplified Disease Activity Index, and Clinical Disease Activity Index were calculated by the investigator following clinical and laboratory evaluations, then disease activity determined. Historical data about the disease and patient demographics were recorded in a proforma. Data was analyzed with SPSS version 25, using Spearman's correlations and kappa statistics. A p-value of < 0.05 was considered significant for statistical tests.

Results: The mean age of the study participants was 48.40 ± 14.46 years, with a median of 50 years and a range of 18-79 years. There was a female-to-male ratio of 17:1. There was fair to moderate agreement between RAPID3 and the physician-driven indices in classifying participants into four disease activity categories (k=0.27- 0.52; p< 0.001). This increased to substantial agreement when disease activity was dichotomized into active versus inactive (k=0.63-0.71; p=0.0001). Overall, 83.3%–92.1% of patients who met moderate/high activity criteria according to the physician-measured indices met similar RAPID3 criteria, and 70.6%–100% who met remission/low disease activity criteria according to the physician-measured indices also met similar RAPID3 criteria. Patient-reported disease activity correlated significantly with the physician-measured indices. ($r > 0.79$, $p < 0.001$).

*Statistically significant

Comparison of RAPID3 with Physician measured indices in classifying as active versus inactive disease in the study population

Conclusion: RAPID3, although not a perfect substitute for the traditional indices, provides an alternative for Rheumatoid arthritis disease activity assessment, with potential usefulness in busy clinic settings and areas with paucity of Rheumatologists like Nigeria. It has shown significant correlation and substantial agreement with the traditional indices in classifying as active versus inactive disease.

Male Sex and Obesity Are Risk Factors for Sarcopenia in RA: Korea National Health and Nutrition Survey 2008–2011

Yoon-Jeong Oh[1], Jin-Wuk Hur[2] and Chang-Nam Son[3], [1]Uijeongbu Eulji Medical Center, Eulji University School of Medicine, Uijeongbu, Republic of Korea, [2]Nowon Eulji Medical Center, Eulji University School of Medicine, Seoul, Republic of Korea, [3]UIJEONGBU EULJI MEDICAL CENTER, EULJI UNIVERSITY, UIJEONGBU, Republic of Korea

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2227–2264) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Sarcopenia is a medical condition characterized by the progressive loss of skeletal muscle mass, strength, and function. It is primarily associated with aging, but is also influenced by chronic diseases, malnutrition, and physical inactivity. In the absence of timely and adequate management, sarcopenia can impair the ability to perform activities of daily living, contributes to mobility limitations, and leads to a reduced quality of life. Sarcopenia is a prevalent but often underrecognized comorbidity in patients with rheumatoid arthritis (RA). In this study, we aim to investigate the risk factors associated with sarcopenia in patients with RA.

Methods: We analyzed data from the 2008–2011 Korea National Health and Nutrition Examination Survey (KNHANES) to investigate factors associated with sarcopenia in RA patients. Sarcopenia was defined based on appendicular skeletal muscle mass (ASM) adjusted for body weight using the formula ASM/weight * 100, with cutoffs of < 29.0% for men and < 22.9% for women. Obesity was defined as a body mass index (BMI) ≥ 25 kg/m^2, according to the Asia-Pacific criteria. Multivariate logistic regression was used to identify independent predictors of sarcopenia, incorporating sample weights and complex survey design.

Values are presented as mean (95% confidence interval) for continuous variables and percentage for categorical variables. P-values are from complex-samples general linear model (CSGLM) adjusted for sample weights, strata, and clusters.

Table 2 Logistic regression analysis of factors associated with sarcopenia in RA patients

Variables	Univariate		Multivariate	
	OR (95% CI)	*p* value	OR (95% CI)	*p* value
Male	6.785 (2.762–16.667)	<0.001	4.166 (1.475–11.765)	0.007
Age	0.984 (0.957–1.012)	0.256	0.995 (0.961–1.030)	0.781
Obesity	3.373 (1.511–7.527)	0.003	3.059 (1.159–8.071)	0.024
Meets WHO physical activity guideline	0.373 (0.125–1.117)	0.078	0.385 (0.141–1.056)	0.064
Daily protein intake	1.001 (0.987–1.014)	0.919	0.996 (0.981–1.011)	0.597

Values are presented as odds ratio (OR) with 95% confidence interval (CI) for univariate and multivariate logistic regression models. Multivariate analysis includes adjustments for age, sex, obesity, physical activity, and daily protein intake, along with sample weights, strata, and clusters based on the complex survey design.

Values are presented as odds ratio (OR) with 95% confidence interval (CI) for univariate and multivariate logistic regression models. Multivariate analysis includes adjustments for age, sex, obesity, physical activity, and daily protein intake, along with sample weights, strata, and clusters based on the complex survey design.

Results: Among 238 RA patients included in the analysis, 44 (18.5%) had sarcopenia. The sarcopenia group had a significantly higher proportion of males (55.0% *vs*. 15.3%, $p < 0.001$), higher BMI (26.06 *vs*. 23.30 kg/m^2, $p < 0.001$), and greater waist circumference (86.88 *vs*. 79.02 cm, $p < 0.001$) compared to the non-sarcopenia group. In multivariate logistic regression adjusted for age, sex, obesity, physical activity, and daily protein intake, male sex (OR 4.17, 95% CI 1.48–11.77, $p = 0.007$) and obesity (OR 3.06, 95% CI 1.16–8.07, $p = 0.024$) were independently associated with sarcopenia. Adherence to the World Health Organization (WHO) physical activity guidelines was associated with a trend toward a protective effect, although the association did not reach statistical significance (OR 0.39, 95% CI 0.14–1.06, $p = 0.064$).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Male sex and obesity are significant factors associated with sarcopenia in Korean patients with RA. These findings underscore the critical role of male sex and obesity in the development of sarcopenia in RA patients. Future studies should explore the mechanisms underlying these associations and investigate the effectiveness of targeted interventions to mitigate sarcopenia in this population.

Session Title: (2265–2289) Rheumatoid Arthritis – Treatment Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Interstitial lung disease (ILD) is a severe extra-articular manifestation of rheumatoid arthritis (RA). Abatacept (ABA) has demonstrated effectiveness in the treatment of RA-ILD, regardless radiological pattern. Although global results are satisfactory, there are patients who present progression of ILD. The early identification of this group of patients is crucial for a prompt and adequate treatment. In a wide series of RA-ILD treated with ABA, our aim was to characterize the subgroup of patients with progressive RA-ILD.

Methods: From a large observational multicenter study of 526 RA-ILD patients treated with ABA, we selected those with available pulmonary function tests (PFTs) at baseline and in follow-up. Progressive ILD was defined as an absolute decline of forced vital capacity (FVC) of ≥10% within 2 years of follow-up since ABA initiation. Results are expressed as percentage, mean±SD or median [IQR] as appropriate. A comparative study and multivariable analysis of patients with progressive ILD and the remaining patients was performed.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. NSIP pattern, n (%)	20 (25)	78 (30)	
Previous immunosuppressive therapy, n (%)			
MTX / SSZ / LFN	50 (63); 11 (14); 31 (39)	186 (76); 34 (13); 123 (47)	**0.02**; 0.85; 0.21
Anti-TNF drugs // RTX // TCZ	17 (80); 8 (10); 4 (5)	77 (29); 38 (14); 34 (13)	0.16; 0.3; **0.048**
JAK inhibitors	1 (1)	12 (5)	0.16
ABA monotherapy/combined with cDMARD, n (%)	31 (39)	127 (49	0.29
Route of ABA administration, iv/sc, n/n	12 (15); 66 (85)	48 (20); 193 (80)	0.37
Concomitant antifibrotics, n (%)	8 (13)	22 (10)	0.64
Prednisone at baseline, mg/day, median [IQR]	7.5 [5-10]	5 [5-10]	0.69

ACPA, anti-citrullinated protein antibodies; DLCO, diffusing capacity of the lung for carbon monoxide; cDMARD, conventional disease-modifying antirheumatic drug; FVC, forced vital capacity; HRCT, high-resolution computed tomography; ILD, interstitial lung disease; IQR, interquartile range; iv, intravenous; mMRC, modified Medical Research Council scale; MTX, methotrexate; NSIP, non-specific interstitial pneumonia; RA, rheumatoid arthritis; RF, rheumatoid factor; RTX, rituximab; sc, subcutaneous; SD, standard deviation; TCZ, tocilizumab; TNF, tumor necrosis factor; UIP, usual interstitial pneumonia.

Results: We finally included a total of 343 patients with available data on FVC of which 80 (23.3%) presented progressive ILD and 263 (76.7%) had a favorable lung function course (**Figure**). The differential baseline general characteristics between both groups are displayed in **Table 1**. We found no statistically differences in age, sex, smoking, ILD duration up to ABA initiation, positivity of rheumatoid factor or anti-citrullinated protein autoantibodies, combined treatment, prednisone dose, baseline PFTs or radiological pattern. Patients with progressive-ILD had a statistically higher dyspnea score and a lower proportion of patients had received previously methotrexate (63% vs 76%, p=0.02) and tocilizumab (5% vs 13%, p=0.048). Multivariable analysis (**Table 2**) showed that previous treatment with methotrexate or golimumab or joint activity (measured by DAS28ESR) multiplies by 0.453, 10.009 or 1.284, respectively, the probability of progressive ILD.

Conclusion: Almost a quarter of patients with ABA therapy presented progressive ILD. The main general features at ABA initiation are very similar in progressive and non-progressive ILD groups. Previous treatment with methotrexate seems to be a protective factor for ILD progression. Although ABA has consistently demonstrated effectiveness in the treatment of RA-ILD, its response, including joint inflammation, should be closely monitored.

Impact of Rheumatoid Arthritis Therapeutic Classes on Risk of All-Cause Mortality and All-Cause Cancer: A Population-Based Cohort Study

Mohammad Movahedi[1], Angela Cesta[1], Sibel Aydin[2], Pooneh Akhavan[3], Tetyana Kendzerska[4], Claire Bombardier[1] and **Bindee Kuriya**[5] on behalf of OBRI investigators, [1]Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada, [2]Department of Medicine, University of Ottawa, The Ottawa Hospital Research Institute, Ottawa, ON, Canada, [3]self-employed, Toronto, ON, Canada, [4]Ottawa Hospital Research Institute, Mississuaga, ON, Canada, [5]University of Toronto - Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2265–2289) Rheumatoid Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Observational studies on RA therapeutic classes have shown conflicting results on their impact on mortality and cancer. When analyzing long-term outcomes, it is essential to account for changes in patient treatment over time. We assessed the association between RA therapeutic classes and risk of all-cause mortality and cancer in a large, population-based RA cohort.

Methods: Patients with RA were identified from the Ontario Rheumatoid Arthritis Database (ORAD), a population-based registry derived using a validated algorithm and maintained at ICES. We included individuals aged >67 years diagnosed between January 1, 2008, and December 30, 2013, and followed them through to December 30, 2023, with a minimum of 6 months follow-up. The outcomes of interest were all-cause mortality and health care utilization due to all-cause cancer requiring hospital admission, emergency department (ED) visits, or physician encounters. RA therapeutic class was treated as a time-varying exposure and categorized into 4 mutually exclusive groups: (1) No csDMARDs or AT use, (2) oral glucocorticoid (GC) use, (3) csDMARDs use only (reference), or (4) AT use (with or without csDMARDs). Given that CVD is the leading cause of death in RA and shares risk factors with cancer, the cohort was stratified by CVD risk at RA diagnosis. High-risk patients had established CVD, diabetes, or hypertension. Associations between treatment class and outcomes were evaluated using the Andersen-Gill Cox model, adjusted for baseline covariates and csDMARD use.

Results: A total of 10,020 RA patients (mean age 75.5 years; 67.3% female) were included in the study. Of these, 80% were classified as high CVD risk and 20% as low CVD risk. Over a median follow-up period of 9.4 years, there were 5,004 deaths and 1,762 cancer events in the high-risk group, compared to 845 deaths and 436 cancer events in the low-risk group. In the high-risk group, no csDMARD/AT use (HR: 2.37) and oral GC use (HR: 2.32) were significantly associated with increased all-cause mortality, while AT use was associated with a lower mortality hazard (Table). Similar findings were seen in the low-risk cohort. Lack of csDMARD/AT use was associated with a higher likelihood of cancer-related hospitalizations or visits in both high and low CVD risk groups (Table).

Conclusion: In this population-based cohort of older RA patients, treatment choice was significantly associated with mortality hazard. Advanced therapies were protective, while GC use and lack of RA treatment were associated with higher mortality. RA treatment had no significant impact on cancer hazard.

Abstract Number: 2267

Impact of Baseline Cardiovascular Risk Factors Comorbidities on an Adalimumab Biosimilar Efficacy, Quality of Life and Safety In Patients with Patients with Moderately to Severely Active Rheumatoid Arthritis: Results from the AURIEL-RA study

Chris Edwards[1], Janet Pope[2], Joelle Monnet[3] and Maria Romanova Michailidi[4], [1]University Hospital Southampton, Southampton, United Kingdom, [2]University of Western Ontario, London, ON, Canada, [3]Fresenius Kabi SwissBioSim, Eysins, Switzerland, [4]University of Geneva, Eysins, Switzerland

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2265–2289) Rheumatoid Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: RA has been associated with an increase risk of cardiovascular morbidity and mortality[1]. The present analysis was performed to assess the efficacy (on ACR response and DAS28), safety (adverse events) and quality of life (QoL) (HAQ-DI) of an adalimumab biosimilars (FK-Ada) in patients with baseline cardiovascular (CV) diseases risk factors. Biosimilars offer similar efficacy and safety compared to their originators, thereby improving patient access to affordable treatments. K-ada was approved for the treatment of inflammatory diseases including Rheumatoid Arthritis. FK-ada development included 1,234 subjects treated up to 52 weeks (420 patients-year). Since first FK-ada approval in 2019 in EU and in 2022 in US, no unexpected safety signals have been reported. AURIEL-RA study evaluated the safety, immunogenicity and efficacy of FK-ada in patients with moderately to severely active rheumatoid arthritis (RA) compared to reference adalimumab up to 52 weeks[2].

Methods: Patients with moderately to severely active RA receiving treatment with methotrexate were randomised 1:1 to FK-ada or reference adalimumab in the double-blind, multicentre, phase III AURIEL-RA study (NCT03052322). Safety, efficacy and immunogenicity endpoints were assessed at scheduled visits up to week 52, safety being the study primary objective. Following baseline CV risk factors were assessed: Age ≥ 65 y, BMI ≥ 30kg/m2, Smoking status, and diagnostic of

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

hypertension, cardiac disorders or Diabetes). Patients were categorized as "No", "One" or " >1" reported CV risk(s) at baseline and efficacy, safety and QoL were summarized for these subgroups.

Results: 288 patients with RA were randomised (FK-ada, n = 143; reference, n = 145). The 3 baseline CV diseases risk factors subgroups were similarly represented in the two treatment groups, each subgroup representing about 1/3 of each treatment arm. Patient baseline characteristics including CV diseases risk factors were comparable between treatment arms (Table 1). After one year, DAS28-ESR decreased in all subgroups in the two F-ada and reference treatment arms. However more subjects with no baseline CV risk were in DAS28-ESR remission status compared to subjects with CV risks. QoL improved in all patients. (Table 2). Subjects with several baseline CV risk factors experienced more adverse events compared to subjects without risks factors. (Table 3).

Conclusion: FK-ada and reference adalimumab were effective across subjects with and without CV risk factors. The safety profile of subjects with and without CV risks factors at baseline was as expected for these categories of patients.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2265–2289) Rheumatoid Arthritis – Treatment Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid factor (RF) is an antibody that contributes to the development of rheumatoid arthritis (RA) and is associated with greater disease severity. Seroconversion of RF after biological DMARD (bDMARD) treatment has been reported as infrequent. However, little is known about changes in serological status and their association with disease activity across different TNF inhibitors (TNFi).

The objectives of this study were: a) To compare the change in RF levels and the rate of seroconversion over 6 months of treatment with certolizumab pegol (CZP), etanercept (ETN), and adalimumab (ADA); and b) To evaluate the association between the reduction in RF levels and the change in disease activity.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Longitudinal, retrospective, multicentre study including RA patients treated with CZP, ETN, or ADA between 2010 and 2024. RF levels and DAS28-ESR scores before TNFi initiation and after 6 months were collected. Two propensity score (PS) matching approaches (CZP vs. ETN and CZP vs. ADA) were used to balance the groups based on baseline imbalances. Paired t-tests evaluated changes in RF levels within treatments groups, and Pearson correlations assessed association between RF and DAS28 changes after confirming data normality. The proportions of seropositive patients who converted to seronegative and those achieving >50% reduction in RF after 6 months were compared using chi-square tests.

Results: A total of 1,185 RA patients treated with TNFi (246 CZP, 343 ETN, and 513 ADA) were included. After PS matching, 203 CZP vs. 203 ETN and 224 CZP vs. 224 ADA were analyzed, achieving balance in age, sex, disease duration, concomitant MTX use, and TNFi treatment line.

ETN showed no significant difference in mean RF change after 6 months, whereas CZP showed a significant reduction (Figure 1A-B). Among seropositive, CZP-treated patients more often achieved >50% RF reduction than those on ETN (21.7% vs. 8.6%, p=0.010) (Figure 2A), and showed a numerically higher rate of seroconversion (9.4% vs. 5.2%). After 6 months, a direct association between RF and DAS28 reductions was observed in CZP-treated patients, whereas an inverse association was found in ETN-treated patients (Figure 3A–B), suggesting RF reduction was linked with an increase DAS28 in the ETN group.

In the ADA vs. CZP comparison (Figure 1C–D), CZP showed a significant reduction in RF levels, while ADA did not. Among seropositive patients, more CZP-treated patients achieved >50% RF reduction than those on ADA (24.4% vs. 11.1%, p=0.028), and showed a numerically higher seroconversion rate (9.4% vs. 5.9%) (Figure 2B). After 6 months, RF and DAS28 changes were not associated in ADA-treated patients, while a significant association was seen in CZP group (Figure 3C–D).

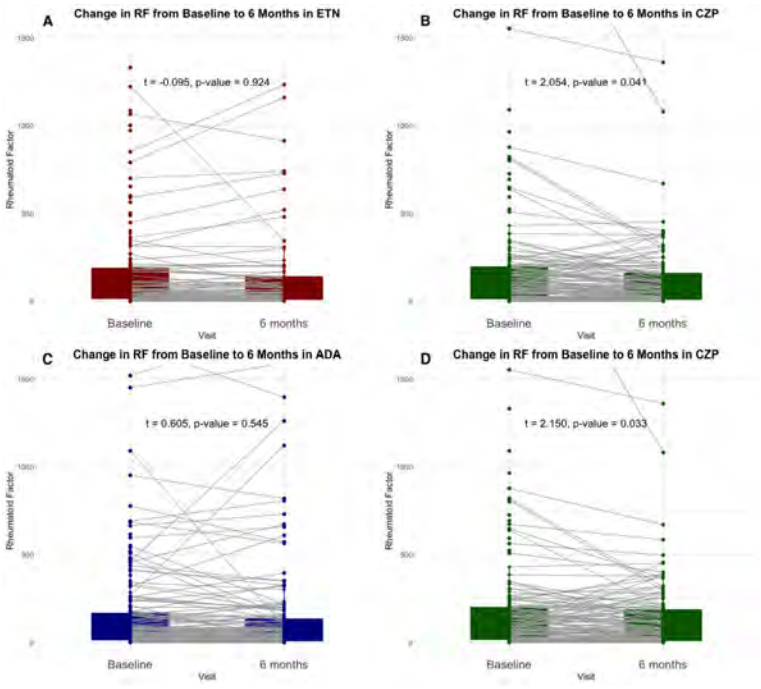

Figure 1. Paired t-Test Analysis of Rheumatoid Factor Changes at 6 Months in Propensity Score-Matched Comparisons Between ETN vs. CZP (A,B) and ADA vs. CZP (C,D).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

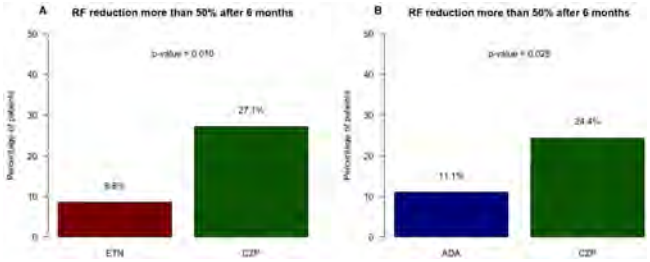

Figure 2. Proportion of Patients Achieving >50% Reduction in Rheumatoid Factor at 6 Months in Propensity Score–Matched Comparisons: ETN vs. CZP (A) and ADA vs. CZP (B)

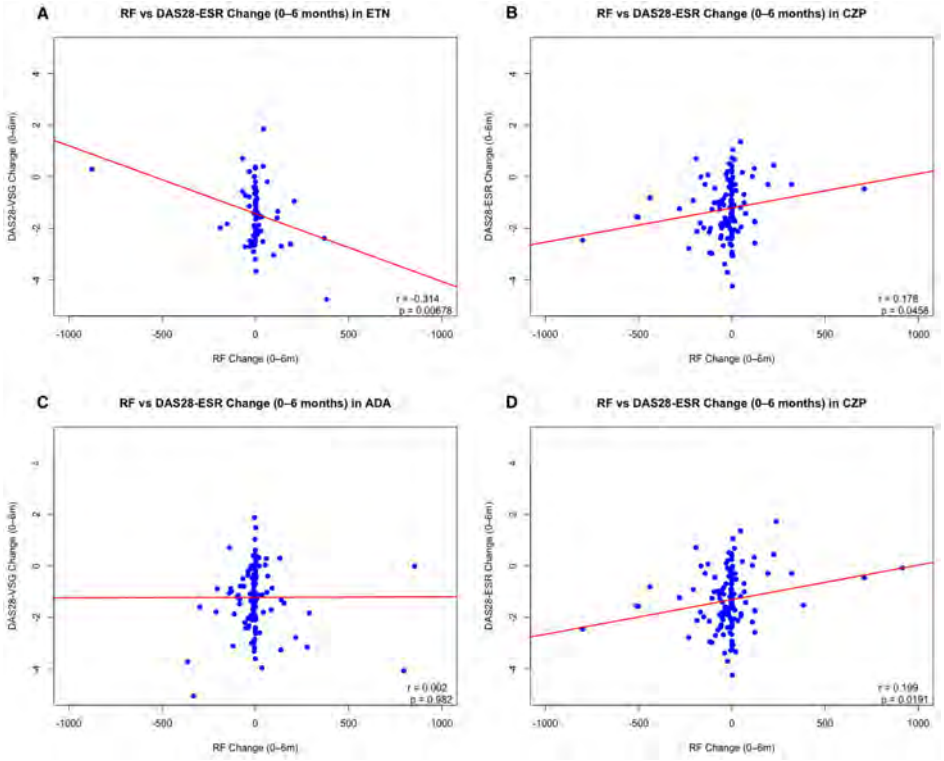

Figure 3. Correlation Analysis of Rheumatoid Factor Changes and DAS28-ESR changes at 6 Months in Propensity Score-Matched Comparisons Between ETN vs. CZP (A,B) and ADA vs. CZP (C,D).

Conclusion: CZP treatment was associated with a significant reduction in absolute RF levels and in the proportion of patients achieving >50% RF reduction compared to both ETN and ADA after 6 months. In CZP-treated patients, RF reduction was positively associated with improved in disease activity, suggesting a potential biomarker role for RF in CZP therapy follow-up. These findings suggest that RF reduction and seroconversion may vary across TNFi, with CZP showing a more favorable serological and clinical profile.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2265–2289) Rheumatoid Arthritis – Treatment Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Baricitinib, a selective JAK1/JAK2 inhibitor, has demonstrated efficacy in rheumatoid arthritis (RA). In patients with stable disease control for at least six months, reducing the dose by half (dosage optimization, OP) may improve safety and cost-effectiveness. Since the literature on this approach is limited, it is crucial to analyze the factors that influence the time required to implement this optimization.

Methods: A single-center retrospective study was conducted at the Donostia University Hospital, Spain, in patients with rheumatoid arthritis (RA) treated with Baricitinib between October 2017 and December 2023. Demographic and clinical-analytical variables were analyzed to identify factors associated with dose optimization. Using logistic regression and survival analysis with Cox regression, the probability and time to dose reduction were evaluated. Furthermore, safety and tolerance were compared between patients with optimized dose (OP) and full dose (DP), providing information on the clinical benefits of therapeutic optimization.

Results: 149 patients were found, mostly women (79.9%), with a mean age of 63.3 years, 38 were optimized (OP), while 111 continued with full dose (DP). The duration of treatment was significantly longer in the OP group, with a mean of 4.6 years compared to 2.6 years in the DP group (p = 0.0001) (Table 1).

In the univariate and multivariate analysis using logistic regression, no variable showed a statistically significant influence on the probability of dose optimization. However, in Cox regression analysis, the presence of anti-CCP antibodies was associated with a higher likelihood of optimization (HR = 2.12; 95% CI: 1.08 - 4.15; p = 0.028) (Table 2).

No significant difference in safety was observed between the two groups, indicating comparable outcomes (Table 3).

Conclusion: Baricitinib dose optimization appears to be influenced by the presence of anti-CCP antibodies, while factors such as previous treatments, number of drugs used, monotherapy and markers of poor prognosis did not show a significant association. Furthermore, patients on optimized doses demonstrated better tolerance to the treatment without an increase in adverse effects supporting its safety and clinical benefit in the management of rheumatoid arthritis.

Abstract Number: 2270

ACKR1 and Leukopenia in Patients with Rheumatoid Arthritis Treated with Disease Modifying Antirheumatic Drugs

Daniela Chavez de Paz Solis[1], Puran Nepa[2], Laura Daniel[3], Yan Guo[4], Jonathan Mosley[5], Michael Stein[6] and Cecilia Chung[4], [1]University of Maine, Caribou, ME, [2]University of Miami, Research Service, Miami VA Healthcare System, Miami, FL, [3]University of Miami, Nashville, TN, [4]University of Miami, Miami, [5]UT Southwestern Medical Center, Dallas, [6]Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2265–2289) Rheumatoid Arthritis – Treatment Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Disease-modifying antirheumatic drugs (DMARDs) such as methotrexate, sulfasalazine, and leflunomide are commonly prescribed for RA treatment but carry the risk of leukopenia. The ACKR1 promoter genotype (rs2814778-CC) has been associated with leukopenia and is predominantly present among individuals of African ancestry. This study aimed to examine whether leukopenia is more frequent among patients with RA who carried the rs2814778-CC genotype compared to patients without the rs2814778-CC genotype when using these DMARDs.

Methods: Retrospective cohort study using the All of Us research program data. We collected genetic and EHR data, including reported race, as well as laboratory data including white blood cell (WBC) and platelet counts after starting sulfasalazine, leflunomide, or methotrexate. Leukopenia was defined as a WBC count <3,000 cells/mm^3, and thrombocytopenia as a platelet count <100,000 cells/mm^3. We utilized short-read whole- genome sequencing (srWGS) data from the All of Us Curated Data Release (v7), with direct genotyping of the ACKR1 SNP rs2814778 (C/T). We compared patients of EHR reported Black race with the CC genotype to those with TT/TC genotypes, as well as to patients of EHR reported White race, because of the known association of the CC genotype with lower WBC counts among patients of Black race.

Results: Among RA patients, 463 individuals who were prescribed sulfasalazine, leflunomide, or methotrexate and had recorded WBC counts after diagnosis were included in the study. The median age at RA diagnosis was 66 years [IQR: 58.0,73.0], and more than 80% of patients were female. Notably, the rs2814778-CC genotype was absent in the patients of EHR reported White race but found in 68% of the patients of EHR reported Black race. The overall leukopenia rate was 36.0% in patients of Black race and 30.9% in patients of White race (p= 0.39). patients of Black race with the CC genotype had the highest leukopenia risk (45.6%), followed by patients of White race with the TT/TC genotypes (30.9%), while patients of Black race with the TT/TC genotypes had the lowest risk (15.6%) (P = 0.01), indicating a significant correlation between genotype and leukopenia risk. The rates of thrombocytopenia were statistically similar across all groups (P = 1.00).

Table 1. Characteristics of RA Patients with Usage of Sulfasalazine, Leflunomide, and Methotrexate

Variable	Overall (n=463)	CC	TT/TC	P
Age, median [Q1, Q3]	66.0 [58.0,73.0]	66.0 [57.0,70.2]	66.0 [58.0,74.0]	0.386
Leukopenia (WBC <3,000 cells/mm³), n (%)	148 (32.0)	31 (45.6)	117 (29.6)	0.014
Leukopenia (WBC < 4,000 cells/mm³), n (%)	259 (55.9)	46 (67.6)	213 (53.9)	0.048
Thrombocytopenia (platelet count < 100,000 cells/mm³), n (%)	29 (6.9)	<20	<20	1.000

Conclusion: Our findings emphasize that individuals of black race with the CC genotype had the highest rates of leukopenia; highlighting the potential impact of the ACKR1 rs2814778-CC genotype on the risk of leukopenia in patients with RA treated with sulfasalazine, leflunomide, or methotrexate.

Abstract Number: 2271

Assessing the Real-world Impact of Earlier Initiation of Adalimumab vs. Conventional Synthetic Dmards on Healthcare Resource Utilization in Patients with Rheumatoid Arthritis in Europe

Daniel Aletaha[1], **Dr. Carmen Bremer**[2], Jack Milligan[3], Zichun Cao[4], Rachael Meadows[3] and Xenofon Baraliakos[5], [1]Medical University Vienna, Wien, Austria, [2]Sandoz International GmbH, Holzkirchen, Germany, [3]Adelphi Real World, Macclesfield, United Kingdom, [4]Sandoz Incorporated, Princeton, [5]Rheumazentrum Ruhrgebiet Herne, Ruhr-University Bochum, Herne, Germany

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2265–2289) Rheumatoid Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Early use of targeted therapy (TT), such as anti-tumor necrosis factor (anti-TNF) biologics, show improved outcomes for RA[1], but costs often limit access. Biosimilars, such as Sandoz adalimumab (SZ-ADL), are generally less expensive than their reference medicines and offer comparable efficacy[2]. Early initiation of anti-TNF biosimilar therapy could yield higher cost efficiency than conventional synthetic DMARDs (csDMARDs).

This study compared healthcare resource utilization (HCRU) and costs of RA patients (pts) receiving SZ-ADL as first line TT (1L) with csDMARD pts never prescribed a TT (TT-naïve).

Methods: Data were drawn from the Adelphi RA Disease Specific Programme (DSP™), a cross-sectional survey of rheumatologists and their next consulting pts with RA in a real-world clinical setting in France, Italy, Germany, Spain and the United Kingdom between July 2023 and August 2024. Rheumatologists, referring to pt medical records, provided information on demographics, disease and treatment history, HCRU and clinical outcomes.

HCRU was assessed in SZ-ADL pts (1L) using inverse probability weighted regression adjustment (IPWRA) with csDMARD (TT-naïve) pts as a comparison group. Both groups had been receiving their therapy for ≥3 months. Pts were weighted for age, DAS-28 at treatment initiation, sex, Charlson Comorbidity Index, autoimmune comorbidities, total duration of prior csDMARDs and time from diagnosis to treatment initiation. Weighted regression adjusted for these variables and for treatment duration. Costs were sourced per country from diagnostic-related groups, national tariffs and government reports. Pre-weighting was performed to account for population and cost differences between countries. Results are reported as weighted means along with p-values.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Mean Number of Tests, Consultations and Hospitalizations Since Initiating Current Treatment

Figure 2. Mean Per-Patient Cost of Tests, Consultations and Hospitalizations Since Initiating Current Treatment

Results: A total of 329 pts were included in the analysis, 172 in the SZ-ADL and 157 in the csDMARD group. SZ-ADL pts had significantly fewer tests to monitor their RA during their treatment (8.59 vs 11.53, p< 0.0001) and fewer hospitalizations (0.19 vs 0.36, p=0.001) than csDMARD patients, but more consultations (4.00 vs 3.44, p< 0.0001) (Figure 1).

This translated to significantly lower per-pt cost of tests to monitor RA (€4.99 vs €9.85, p< 0.0001), consultations (€226.65 vs €324.59, p< 0.0001) and hospitalizations (€265.04 vs €323.26, p=0.0032) for SZ-ADL pts (Figure 2).

Conclusion: Earlier initiation of SZ-ADL may provide cost savings to healthcare systems in Europe by reducing costs of testing, consultations and hospitalizations compared to pts remaining on csDMARDs. Residual confounding variables within the groups may be a potential limitation of the analysis.

Combination Therapy with TNF Inhibitors and JAK Inhibitors in Multi-Drug-Resistant Rheumatoid Arthritis: A Case Series from the RA UCLouvain Brussels Cohort

Francesco NATALUCCI[1], Cécile VAN MULLEM[1], Aleksandra AVRAMOVSKA[1], Tatiana SOKOLOVA[2] and Patrick Durez[1], [1]Cliniques Universitaires Saint-Luc – Université catholique de Louvain (UCLouvain) – Institut de Recherche Expérimentale et Clinique (IREC), Rheumatology, Brussels, Belgium, [2]Cliniques Universitaires Saint-Luc – Université catholique de Louvain (UCLouvain) – Institut de Recherche Expérimentale et Clinique (IREC), Rheumatology, Brussels, Brussels Hoofdstedelijk Gewest, Belgium

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2265–2289) Rheumatoid Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid Arthritis (RA) is a chronic autoimmune disease with persistent synovial inflammation.

Several bDMARDs and tsDMARDs target different key players in the immune-regulatory pathways, including cytokines, JAK, T cells, and B cells. These molecules enable the achievement of remission or LDA in the majority of patients. However, about 20% to 40% of patients fail to achieve remission, and a smaller percentage, recognized as (multi-drug resistance) MDR-RA, fail several bDMARDs and tsDMARDS. In this subset of severe and multi-resistant patients, the combination of a TNFi and a JAKi might be a promising approach, despite not risk-free.

Methods: We performed a descriptive study of patients from the RA UCLouvain Brussels Cohort, who received a combination of TNFi and JAKi. Disease activity trajectory and tolerability, as well as different therapeutic agents received over time, were recorded.

Results: We report five patients (3F, 2M). They received a combination therapy after a median time of 184 months (IQR 116) from diagnosis. The demographic and clinical features for each patient are reported in Table 1. Figure 1 shows disease activity at the moment of each b/tsDMARDs discontinuation (A), reason for discontinuation (B), and the sequence of the b/tsDMARDs (C) for each patient. All of these pts were refractory to 7 bDMARDs and to 2 JAKi. Of note, all the patients received csDMARDs alongside b/tsDMARDs. Variable-dose glucocorticoids have been part of the therapeutic strategy in combination with standard therapy. None of the patients suffered from major adverse events due to b/tsDMARDs as severe infection. All the patients were treated with a TNFi (infliximab or etanercept) associated with a JAKi (Upatacitinib or Filgotinib). Three patients had a minimum follow-up time of 3 months after the combination and then a second evaluation. Pt 1 achieved a persistent remission state up to 3 years of follow-up. We observed a significant decrease in disease activity in two patients, reaching disease remission. None of the patients developed major side effects, including severe infection or hospitalisation, in the observation period.

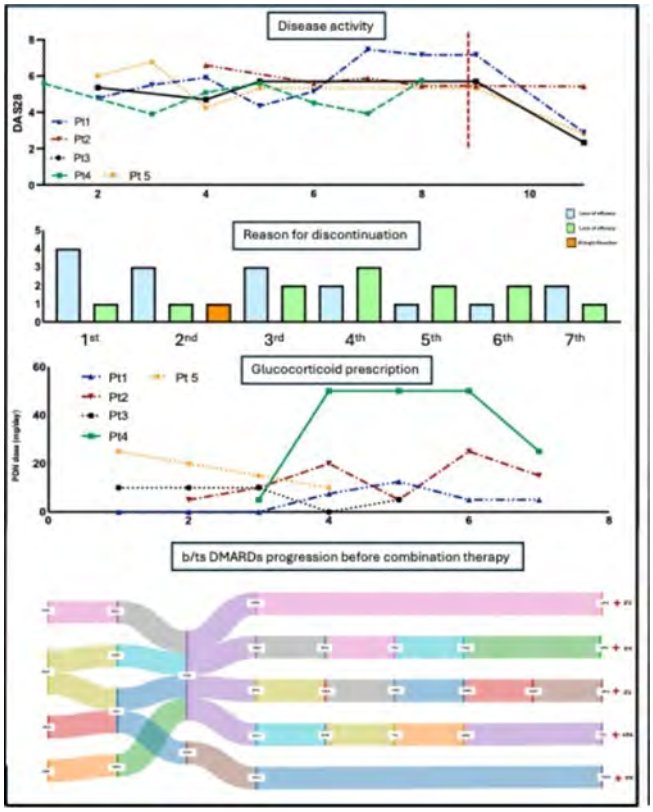

Figure 1 A-D A. Disease activity for each patient according DAS28 disease activity score before starting combination therapy (left) and after initiation of combination therapy (right). B. Reason for discontinuation for each b/tsDMARDs. From the 5th b/tsDMARDs on, only 3 patients are considered. C. b/tsDMARDs prescription progression for each patient. D. Glucocorticoid dosage at each b/tsDMARD change

Table 1. Demographic and disease feature for each patient

	Pt 1	Pt 2	Pt 3	Pt 4	Pt 5
Sex	Female	Male	Female	Female	Male
ACPA	No	No	Yes	Yes	No
FR	No	1	Yes	Yes	No
Erosive	Yes	Yes	Yes	Yes	Si
Age at combination (years)	36 years	35 years	43 years	56 years	35 years
Extra articular manifestation	No	No	No	No	No
Time to combination	204 Months	164 Months	156 Months	348 Months	216 Months
csDMARDs	Ye	Ye	Ye	Yes	Yes
Follow-up after combination	36 months	4 months	3 months	–	12 months
Infection after combination therapy	No	No	No	No	No

Conclusion: Our preliminary results indicate that a combination therapy of a TNFi and a JAKi provided good clinical results without safety concerns. In severe and multi-resistant patients, when all classical approach fails to reach a good disease control, the combination therapy could be an option. As infection is the major risk for those patients, a b/tsDMARDs combination should be restricted to young patients with a low infection risk and after adequate vaccinations.

Impact of Upadacitinib on Glucocorticoid Reduction in Patients with Moderate-to-Severe RA Who Achieved and Maintained Clinical Remission in the 2-Year UPHOLD Study

FRANK BUTTGEREIT[1], Andrew Ostor[2], Philip Conaghan[3], Ana Romero[4], Ivan Lagunes[5], Andrew Garrison[6], Tianming Gao[7] and Suzan Attar[8], [1]Charité University Medicine Berlin, Berlin, Berlin, Germany, [2]Australian National University, Canberra, Australia, [3]University of Leeds, Leeds, United Kingdom, [4]AbbVie, Barcelona, Spain, [5]Abbvie Inc, North Chicago, IL, [6]AbbVie, USA, North Chicago, IL, [7]AbbVie, North Chicago, IL, [8]King Abdulaziz University, Saudi Arabia, Jeddah, Saudi Arabia

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2265–2289) Rheumatoid Arthritis – Treatment Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Glucocorticoids (GCs) are fast-acting drugs used to support csDMARD therapy for RA, but should be used sparingly and for short periods.[1] Upadacitinib, an oral Janus kinase inhibitor, is approved for the treatment of adults with moderate-to-severe RA.[2] This post hoc analysis assessed the real-world impact of upadacitinib on GC discontinuation, and the effect of GC discontinuation on efficacy and safety, in patients with RA taking GCs at study onset, who achieved and maintained remission through 2 years in the UPHOLD study.

Methods: UPHOLD (NCT04497597), a 2-year, non-interventional, multi-country, observational, cohort study, assessed the real-world effectiveness and safety of upadacitinib (15 mg QD) in upadacitinib-naïve adults with moderate-to-severe RA. This post hoc analysis assessed the impact of upadacitinib in achieving and maintaining GC-free clinical remission (defined as 28-joint DAS with CRP [DAS28-CRP] < 2.6, Clinical Disease Activity Index [CDAI] ≤2.8, and Simplified Disease Activity Index [SDAI] ≤3.3) at 6, 12, and 24 months (mo) among patients taking GCs at baseline. Safety was assessed by DAS28-CRP remission status subgroup (yes/no) and reported as exposure-adjusted events/100 patient-years. Data are presented as observed.

Results: At baseline, 455 patients had concomitant GC use; mean (standard deviation [SD]) GC dose: 8.1 (7.6) mg/day; patient number (%) by GC dose (mg/day): 65 (14.3), < 5; 207 (45.5), 5; 120 (26.4), >5–10; and 63 (13.8), >10; mean (SD) disease duration: 9.8 (8.8) years; and mean (SD) disease activity scores: DAS28-CRP, 4.76 (1.2); CDAI, 27.9 (12.4); SDAI, 30.2 (13.7). At 6 mo, DAS28-CRP remission was achieved by 58.5% (n/N: 158/270), CDAI remission by 22.4% (64/286), and SDAI remission by 24.6% (61/248) of patients. Of patients achieving DAS28-CRP, CDAI, and SDAI remission at 6 mo, 28.5% (45/158), 39.1% (25/64), and 41.0% (25/61), respectively, were GC-free. Of patients with GC-free remission at 6 mo, who maintained remission and had data available at 12 mo (DAS28-CRP, 90.9% [30/33]; CDAI, 72.2% [13/18]; SDAI, 81.3% [13/16]), most were GC-free (DAS28-CRP, 93.3% [28/30]; CDAI, 100.0% [13/13]; SDAI, 84.6% [11/13]) (**-Figure 1**). At 12 mo, 64.6% (144/223) patients had DAS28-CRP, 27.3% (65/238) had CDAI, and 28.8% (62/215) had SDAI remission, and almost half were GC-free (DAS28-CRP, 41.0% [59/144]; CDAI, 49.2% [32/65]; SDAI, 48.4% [30/62]). Of patients with GC-free remission at 12 mo, who maintained remission and had data available at 24 mo (DAS28-CRP, 80.4% [37/46]; CDAI, 83.3% [20/24]; SDAI, 77.3% [17/22]), 100% were GC-free (DAS28-CRP, 37/37; CDAI, 20/20; SDAI, 17/17) (**Figure 2**). Treatment-emergent adverse events were similar regardless of DAS28-CRP remission status at 6, 12, and 24 mo, and consistent with previously published UPHOLD dat

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2265–2289) Rheumatoid Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: In patients affected by rheumatoid arthritis (RA), it has been studied a relation between high rheumatoid factor (RF) and a favorable response to anti-TNF therapy, regarding the presence of Fc region in the drug (1,2). Nonetheless, there is limited evidence about the therapeutic survival in function of the kind of anti-TNF and the levels of RF in these patients.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The goal of this investigation is to analyze the survival and persistence of anti TNF drugs, depending on whether they have Fc region and the levels of RF in RA.

Methods: Observation cross-sectional study of anti-TNF treatments administered in RA patients between 2001 and 2022. We collected levels of RF and anti-citrullinated peptide antibodies (ACPAs) at start of medication, clinical activity, duration of treatment and withdrawal cause from the clinical record.

Results: We have included 377 anti-TNF treatments corresponding to 310 RA patients (79% female), with a mean age at diagnosis of 45 (13) years.

Of 377 treatments, 87% were drugs with Fc region in their structure, 75% associated DMARD (mainly methotrexate) and 67% have not received prior biologic therapy. Mean time of evolution of RA until the start of anti-TNF was 110 (103) months and the mean duration of treatment was 75 (71) months, finalizing treatment 64,2%. When initiating therapy, 64% were RF positive (RF) and 72%, ACPA positive (table 1).

We have classified patients according to the positivity of RF and the presence of Fc region in the therapy. We have observed a tendency towards discontinuing treatment in patients with high RF titers (P=0,06), which are treated mainly with an anti-TNF with Fc fraction (P=0,06).

Finally, we have conducted a Kapplan-Meier analysis to evaluate the drug survival considering the presence of Fc region in the medication, with no observed differences between groups. We came up with the same result when comparing treatment regarding RF positivity at beginning of therapy. We classified patients combining the presence of Fc and RF positivity, discovering a greater therapeutic survival in treatments with Fc region and RF negativity (P=0,018). Furthermore, in treatments without Fc region, we report a tendency towards greater therapeutic survival in RF negative cases in comparison with RF positives (P=0,07) (view Image 1).

Table 1

Variable	No Fc fraction N=49	Fc fraction N=328	P-valor
	Mean (SD) / n(%)	Mean (SD) / n(%)	
Age at diagnose (years)	43,49 (13,91)	45,66 (12,31)	0,26
Age at start of treatment (years)	53,22 (12,73)	54,57 (11,88)	0,464

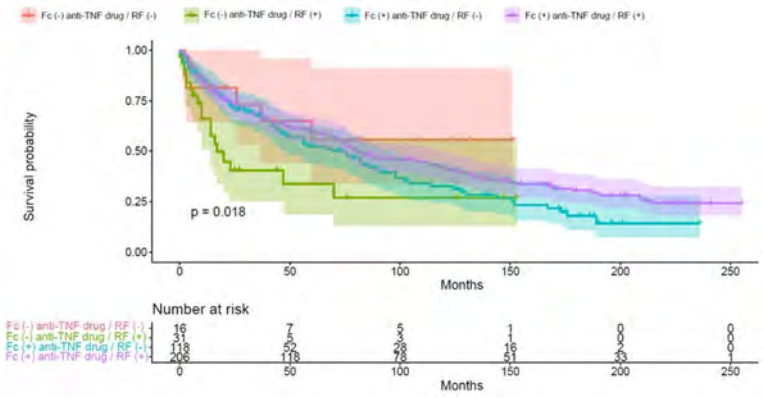

Image 1

Conclusion: We report on a higher percentage of drug withdrawal in patients with RA and anti-TNF treatment with Fc region in their structure, as well as in those cases with higher titers of RF. In addition, we observed a greater therapeutic survival in treatments with low titers of RF and anti-TNF drug without Fc region than in other groups.

Agreement Between Two Rheumatoid Arthritis Response Measures Across Bts DMARD Treatment Classes in a Large, Prospective Observational Study Supporting the Development and Clinical Validation of a Novel Blood based Precision Medicine Test

Peter Taylor[1], **Jason Carlson**[2], Shirley Vu[2], Signe Fransen[3], Diana Abdueva[4] and Jeffrey Curtis[5], [1]University of Oxford, Oxford, United Kingdom, [2]Aqtual Inc, Hayward, CA, [3]Aqtual, sf, CA, [4]Aqtual, Hayward, CA, [5]Foundation for Advancing Science, Technology, Education and Research, Birmingham, AL

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2265–2289) Rheumatoid Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Contemporary pharmacological management of rheumatoid arthritis (RA) is set within a treat-to-target framework. This requires quantitative, longitudinal assessments of disease activity with a view to treatment adjustment where necessary. There are many composite scores of RA disease activity and methods to assess response, including improvement in CDAI based on its minimum clinically important difference (MCID) and EULAR response criteria based on the DAS28-CRP. These response measures were employed in the PRIMA-102 (NCT05936970) study supporting development of a novel blood-based assay to predict response to biologic and targeted synthetic DMARDs. The objective of the study is to investigate the agreement between the CDAI MCID and EULAR response criteria and identify correlates of discordance.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: An interim analysis was performed on 636 participants treated with ≥ 1 prior cs/b/tsDMARD who initiated a new b/tsDMARD, TNFi (n=187), JAKi (n=178), Anti T-Cell (n=171), Anti IL-6R (n=77), Anti B-Cell (n=23), contributing data to a prospective, multi-center, observational cohort requiring baseline (BL) blood collection and clinical outcome measures at BL and week 12. Agreement between the two clinical response measures was computed using kappa (k) coefficients and correlates of discordance were assessed using analysis of variance (continuous variables) or chi-square variance (categorical variables) and Hedges' g values were computed to estimate the magnitude of the difference between the groups, with positive values indicating a higher mean in the MCID-only subgroup and negative values corresponding to a higher mean in the EULAR-only subgroup.

Results: 410 participants (64%) had a CDAI MCID response, and 431 participants (68%) had moderate or good DAS28-CRP EULAR response (Table 1). 34 participants (5.3%) were responders per CDAI MCID only, and 55 participants (8.6%) were responders per EULAR response criteria only. Agreement between the two measures was substantial and did not differ by MOA (overall κ=0.69, 95% CI [0.63-0.75], TNFi κ=0.68, JAKi κ=0.67, Anti T-Cell κ=0.69, Anti IL-6R κ=0.72, Anti B-Cell κ=0.68). Baseline characteristics and RA disease activity measures associated with discordance included serostatus, line of therapy, joint counts, and patient/provider global assessment; changes from baseline that were associated with discordance with large relative effect sizes included swollen joint count, provider global assessment, patient VAS, and CRP (Table 2).

Table 1: Agreement Between Response Measures for Each Drug Class

Category	n	No Response on Either Measure	Response on MCID Only	Response on EULAR Only	Responses on Both Measures	Percent Agreement	Percent Discordance	Kappa*	95% CI
All b/ts DMARD Classes	636	171 (26.9%)	34 (5.3%)	55 (8.6%)	376 (59.1%)	86	14	0.69	0.63 - 0.75
TNFi	187	54 (28.9%)	15 (8%)	13 (7%)	105 (56.1%)	85	15	0.68	0.57 - 0.79
JAKi	178	37 (20.8%)	10 (5.6%)	13 (7.3%)	118 (66.3%)	87.1	12.9	0.67	0.55 - 0.79
Anti T-Cell	171	47 (27.5%)	9 (5.3%)	15 (8.8%)	100 (58.5%)	86	14	0.69	0.57 - 0.81
Anti IL-6R	77	28 (36.4%)	0 (0%)	11 (14.3%)	38 (49.4%)	85.7	14.3	0.72	0.56 - 0.88
Anti B-Cell	23	5 (21.7%)	0 (0%)	3 (13%)	15 (65.2%)	87	13	0.68	0.35 - 1.01

* Concordance was measured using kappa coefficients. Conventional interpretation of the kappa coefficient is: < 0 poor agreement; 0 – 0.20 slight agreement; 0.21 – 0.40 fair agreement; 0.41 – 0.60 moderate agreement; 0.61 – 0.80 substantial agreement; and 0.81 – 1.00 near perfect agreement

Table 2: Correlates of Discordance Between MCID CDAI and EULAR DAS CRP Response Labels in the PRIMA-102 Study Population

	Neither Response	MCID CDAI Only	EULAR DAS CRP Only	Both Responses	P	Hedges' g
n = 636 Patients	171	34	55	376		
% Women	86 (2.7)	73.5 (7.6)	85.5 (4.8)	83 (1.9)	0.330	-0.301
% Seropositive	48 (3.8)	38.2 (8.3)	49.1 (6.7)	59 (2.5)	0.016	-0.215
Age, years	58.3 (13.2)	58.8 (13.8)	57 (13.8)	58.5 (13.5)	0.887	0.126
RA Duration, years	8.8 (9.4)	6.2 (8.5)	9.4 (10.2)	9 (9.6)	0.400	-0.335
% with 0-2 Prior b/ts DMARDs	69.6 (3.5)	79.4 (6.9)	70.9 (6.1)	80.6 (2)	0.027	0.191
Measures at study entry						
Tender joint count (0-28)	12.5 (6.7)	17.7 (7.9)	9.8 (4.6)	12.1 (6.8)	< 0.001	1.294
Swollen joint count (0-28)	8.7 (4.5)	14.2 (6.6)	6.5 (2.7)	9.3 (5.1)	< 0.001	1.655
Patient global score (1-10)	6.7 (2.2)	7.8 (1.7)	6.2 (2.3)	6.4 (2.3)	0.003	0.755
Provider global score (0-10)	6.3 (2.1)	7.8 (1.6)	5.7 (1.7)	6.4 (1.9)	< 0.001	1.224
Patient VAS (0-100)	65.5 (23.5)	66.3 (27.3)	69.6 (24)	65.6 (23.6)	0.692	-0.131
CRP, mg/L	8 (14.7)	8.1 (16.1)	13 (17.7)	10.3 (21.3)	0.307	-0.283
Absolute changes during the study						
Tender joint count	-1.3 (4.9)	5.6 (4.6)	3.2 (2.5)	8.7 (5.5)	< 0.001	0.665
Swollen joint count	0.3 (4.2)	7.5 (5.5)	2 (3.4)	7.4 (4.9)	< 0.001	1.261
Patient global score	0 (2.4)	1.9 (2.9)	0.8 (2.7)	2.8 (2.6)	< 0.001	0.397
Provider global score	0.3 (2.3)	3.1 (2.3)	0.9 (1.5)	3.7 (2.3)	< 0.001	1.187
Patient VAS	-4.5 (26.7)	-0.9 (26.3)	23.6 (26.6)	29.9 (29.1)	< 0.001	-0.918
CRP, mg/L	0.9 (13.3)	-10.8 (27.6)	7.3 (15.1)	5.4 (18.9)	< 0.001	-0.863

Values are mean (standard error). Continuous variables (e.g., joint counts) were compared between response groups using one-way analysis of variance. For categorical variables (e.g., serostatus), associations with the response groups were assessed using the chi-square test. Hedges' g was also computed for each of the variables.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Conclusion: There was generally good agreement between CDAI MCID and EULAR Response criteria, suggesting that either method could support development of a precision medicine test to predict treatment response. However, the higher percentage of positive responses unique to the DAS28-CRP EULAR criteria suggests that EULAR response based on DAS28-CRP may introduce bias when assigning response status for drug classes (e.g., IL-6R) that directly modulate CRP levels.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2265–2289) Rheumatoid Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Tumor necrosis factor inhibitors (TNFi) are often avoided when treating rheumatoid arthritis (RA) patients with decompensated heart failure (HF), based on increased rates of HF exacerbation in a trial of advanced HF patients without RA. In RA, recent data suggest that reducing inflammation, including with TNFi, is beneficial for HF risk reduction. We sought to leverage a unique cohort with data from an RA randomized clinical trial (TNFi vs triple therapy), linked to longitudinal electronic health records (EHR), enabling comparison of major adverse cardiovascular events (MACE) and HF events after trial completion.

Methods: We studied subjects from the Therapies for Active Rheumatoid Arthritis after Methotrexate (MTX) Failure (RACAT) trial, where 16 of the 36 sites were Veteran Affairs (VA) hospitals; participants were randomized to etanercept (ETA) plus MTX or triple therapy (hydroxychloroquine, sulfasalazine, MTX) for 48 weeks. Exclusion criteria included subjects with New York Heart Association class III or IV HF. Participants in the trial were linked to longitudinal VA EHR data, allowing assessment of outcomes after trial completion (4/2011). Participants were followed in the VA EHR from randomization (index date), for up to 5 years after trial completion. HF events and MACE related to atherosclerotic cardiovascular disease were defined by previously published ICD and CPT codes. As cross-over was allowed in RACAT at 24 weeks, the primary exposure was defined based on intention-to-treat (ITT) and as-treated (within the trial). We used unadjusted Cox regression to evaluate the association between the primary exposure (randomization to ETA+MTX versus triple therapy (referent)) and MACE, HF or death.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Baseline characteristics of the Therapies for Active Rheumatoid Arthritis after Methotrexate Failure (RACAT) trial participants in the VA with EHR follow-up based on intention-to-treat, at randomization.

Characteristic	Etanercept + methotrexate (49%)	Triple therapy (51%)
Age, mean (SD)	60 (11)	63 (10)
Male	85%	92%
White self-reported race	83%	87%
RA duration, mean years (SD)	5.8 (8.6)	6.8 (11)
DAS28, mean (SD)	5.9 (0.8)	5.9 (0.9)
History of MACE	3%	3%
History of HF	7%	3%
Statin use	51%	54%
TNFi use, post-study (intention-to-treat population)*	79%	43%
TNFi use, post-study (as-treated population)**	83%	35%

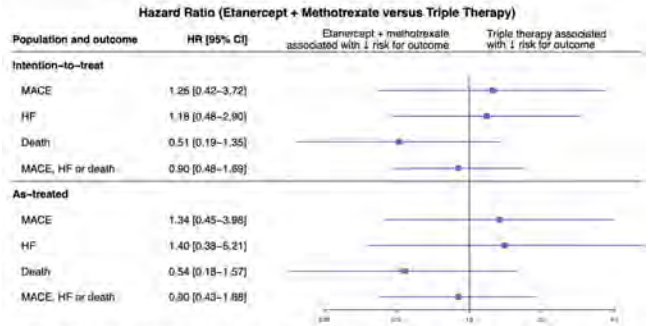
RA: rheumatoid arthritis; MACE: major adverse cardiac events; HF: heart failure; DAS28: disease activity score in 28 joints. Subjects were considered as having either continued or initiated a TNFi post-study if ≥2 TNFi prescriptions were present in the 5 years after the trial. *Intention-to-treat population defined by randomization to etanercept + methotrexate versus triple therapy. **As-treated population defined by continuation of assigned treatment, rather than crossover, at 24 weeks.

Table 2. Incident MACE and HF events 5 years after trial completion in the intention-to-treat and as-treated populations.

Characteristic	Etanercept + methotrexate	Triple therapy
Intention-to-treat population*		
MACE	9%	8%
HF	13%	11%
Death from any cause	8%	15%
MACE, HF or Death	24%	27%
As-treated population**		
MACE	14%	10%
HF	10%	7%
Death from any cause	10%	17%
MACE, HF or Death	25%	28%

MACE: major adverse cardiac events; HF: heart failure. *Intention-to-treat population defined by randomization to etanercept + methotrexate versus triple therapy. **As-treated population defined by continuation of assigned treatment, rather than crossover, at 24 weeks.

Figure 1. Hazard ratios for major adverse cardiac events and heart failure in patients randomized to etanercept plus methotrexate versus triple therapy in the intention-to-treat and as-treated populations.



MACE: major adverse cardiac events. HF: heart failure. HR: hazard ratio. 95% CI: 95 percent confidence interval.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Of 353 participants in RACAT, 66% were rheumatoid factor positive, and 44%* were followed at VA. Of these participants, 49% were randomized to ETA+MTX and 51% to triple therapy (**Table 1**). The mean age at randomization was 62 years, 89% were male, and 85% were self-reported White. Prior diagnoses of HF or MACE were present in 5% and 3% of the population, respectively, before randomization. After the 48-week trial period, TNFi use was more frequent in the group randomized to ETA+MTX (79%) compared to the triple therapy (43%).

For ITT, incident MACE occurred in 8% of participants within 5 years of trial completion (**Table 2**), and the risk for incident MACE was comparable between the treatment groups (HR 1.25, 95% CI 0.42-3.72; **Figure 1**). Incident HF events occurred in 12% of participants within 5 years, and the risk for HF was comparable between the two treatment groups (HR 1.18, 95% CI 0.48-2.90). MACE, HF or death occurred in 25% of participants, and the risk was comparable between groups (HR 0.90, 95% CI 0.48-1.69). Similar effect estimates were observed in the as-treated analysis.

* VA data privacy regulations require reporting as percentages due to some groups with n < 11

Conclusion: In this post-hoc analysis of a randomized controlled trial using EHR data to extend long term follow-up to 5 years after trial completion, we observed a similar incidence of MACE and HF irrespective of randomization to ETA+MTX or triple therapy.

Immunophenotyping of peripheral blood mononuclear cells reveals potential cellular biomarkers of disease in rheumatoid arthritis

John Bui[1], Jason Dubovsky[2], Jennifer Abrams[3], Sara Charmsaz[4], Michelle Blake[1], Joshua Beilke[4], Anne-Renee van der Vuurst de Vries[1], Joseph Arron[5], Jonathan Graf[6] and Jeffrey Bluestone[7], [1]Sonoma Biotherapeutics, Seattle, WA, [2]Sonoma Biotherapeutics, South San Francisco, [3]Sonomabio, San Francisco, CA, [4]Sonoma Biotherapeutics, Seattle, [5]Sonoma Biotherapeutics, San Francisco, CA, [6]UCSF, San Francisco, CA, [7]Sonoma Biotherapeutics, South San Francisco, CA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2265–2289) Rheumatoid Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Emerging cell-based therapies for rheumatoid arthritis (RA) target the underlying immunologic activity of disease. Objective biomarkers to-date are downstream sequelae of RA immunologic drivers. In this study, we sought to identify direct cellular biomarkers in RA by comprehensively profiling immune subsets from whole blood.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Here, three flow cytometry panels measuring 18 markers were used to identify T cell subsets. PBMC were profiled from 30 RA subjects with varying disease severity measured by DAS28-CRP, DAS28-ESR and CDAI in addition to 23 age-, gender-, and race-matched healthy donor control subjects (HD). A two-tiered approach was applied for data analysis: Tier 1) Identify cell subsets significantly different between RA and HD and Tier 2) Correlate cell subsets identified in Tier 1 with RA clinical disease severity.

Results: The analysis revealed a significant difference ($p \leq 0.001$) between RA (12%) and HD (39%) in the frequency of an effector regulatory T cells (Treg) phenotype defined by $CD4^{+}FOXP3^{+}CD25^{hi}CD45RA^{-}$. Furthermore, the frequency of these cells was inversely correlated with disease severity measured by DAS28-CRP ($r = -0.525$, $p = 0.039$). Activation and proliferation markers on the Tregs in the RA subjects were similarly inversely correlated with DAS28-CRP (r= -0.53 HLA-DR, r= -0.49 CTLA-4, r= -0.52 Ki67). In contrast, the T effector cell subset phenotype data reveal significantly higher frequency ($p=0.001$) of CD4+CD45RA-CCR7+ central memory $CD4^{+}$ T cells (Tcm) in RA (31%) compared to HD (20%). Moreover, the frequency of $CD4^{+}$ Tcm was positively correlated with DAS28-ESR ($r = 0.615$, $p = 0.037$).

Conclusion: We show that, compared to healthy subjects, RA patients have significantly reduced proportion of Tregs with an effector phenotype and a higher proportion of CD4 Tcm. These phenotypic frequencies correlate with disease severity, highlighting a relationship of these immune subsets to the pathogenesis of RA. Additional characterization of these subsets will be pursued to determine their potential utility as pharmacodynamic biomarkers.

Background/Purpose: Neuroimmune modulation by electrical stimulation of the left cervical vagus nerve represents a novel treatment option for rheumatoid arthritis (RA). We present 12-month efficacy and safety outcomes for an implantable vagus nerve stimulation device to treat biologic-experienced patients with RA (the RESET-RA study, ClinicalTrials.gov, NCT04539964).

Methods: In this multicenter, randomized, double-blind, sham-controlled, pivotal trial, patients with prior inadequate response or intolerance to at least one biologic or targeted synthetic disease-modifying antirheumatic drug (b/tsDMARD) were randomly assigned to stimulation (treatment) or sham. The primary endpoint of ACR20 response was assessed 3 months after randomization. After 3 months, sham crossed over to treatment, and all patients received stimulation during open-label follow-up, with results reported through 12 months. Secondary endpoints included safety measures, disease activity scores, and use of RA drugs in combination with stimulation.

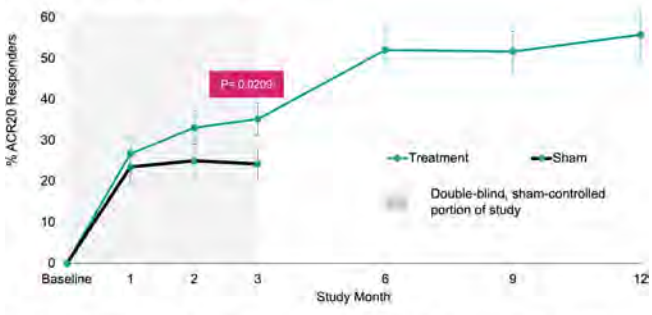
Results: 242 participants across 41 US study sites were consented and underwent device implantation followed by 1:1 randomization to treatment or sham. Baseline characteristics were well-balanced with mean age of 56 years, 86% female, RA duration 12.4 years, 15 tender joints, and 10 swollen joints (28 joint count). Overall, 39% of patients had been treated with exactly 1 prior b/tsDMARD, 22% with exactly 2, and 39% with 3 or more. 43% of all patients were exposed to b/tsDMARDs with differing mechanisms of action.

At 3 months, a significantly greater percentage of patients in the treatment group were ACR20 responders (treatment 35.2% [43/122] vs. sham 24.2% [29/120], p=0.0209). Response rates continued to improve for treatment group: 52.1% at 6 months, 51.7% at 9 months, and 55.8% at 12 months (**Figure 1**). Disease activity scores showed a similar trend with 49.3% attaining DAS28-CRP low disease activity or remission, 47.4% attaining CDAI low disease activity or remission and 77.3% attaining EULAR good/moderate response at 12 months (**Figure 2**).

Augmentation of stimulation therapy with a b/tsDMARD was allowed without restriction following the 3-month, controlled portion of participation. By 12 months, only 24.8% of patients added a b/tsDMARD to stimulation therapy and 97.5% of all patients remained persistent with stimulation therapy.

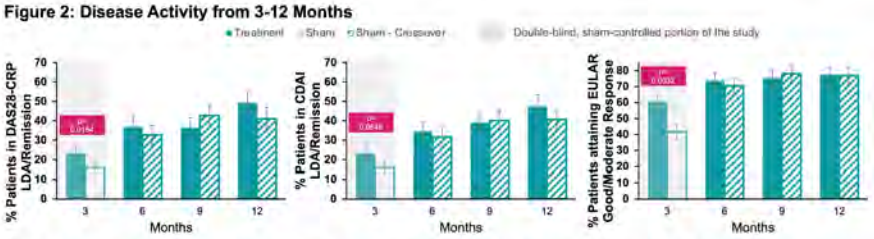
The implant procedure was well-tolerated, with a serious adverse rate of 1.7%, all occurring during the perioperative period. The most common, related adverse event was transient vocal cord paresis presenting as hoarseness following the implant procedure. Stimulation was well-tolerated, with few non-serious events, such as pain or sleep disturbance. These were typically managed by adjusting the stimulation dose. No deaths or unanticipated adverse device effects occurred (**Table 1**).

Figure 1: ACR20 Response Rates



ACR20 response rates at 3 months, 6 months, 9 months, and 12 months. Patients imputed as non-responders if missing or rescued with high-dose steroid or b/tsDMARDs up to 3 months. 6, 9, and 12-month results exclude patients that augmented stimulation with a high-dose steroid or b/tsDMARD.

Figure 2: Disease Activity from 3-12 Months



Percentage of patients in low disease activity or remission (DAS-28-CRP </+ 3.2 [left], CDAI </= 10 [center]), and EULAR good to moderate response (right) at 3, 6, 9, and 12 months. Patients imputed as non-responders if missing or rescued with high-dose steroids or b/tsDMARDs up to 3 months. 6, 9, and 12 Month results exclude patients that augmented stimulation therapy with high-dose steroid or b/tsDMARD.

Table 1: Summary of Safety by Adverse Event Reporting

	Sham-Control, Blinded Period through Month 3		Open-Label through Month 12		
	Treatment N=122	Sham N=120	Treatment N=121	Sham-Crossover N=120	All N=241
Number of pts (%) with Adverse Event	81 (66.4%)	86 (71.7%)	84 (69.4%)	88 (73.3%)	172 (71.4%)
Procedure or Device Related[1]	16 (13.1%)	22 (18.3%)	1 (0.8%)	2 (1.7%)	3 (1.2%)
Stimulation Related[2]	10 (8.2%)	0	4 (3.3%)	5 (4.2%)	9 (3.7%)
Serious Adverse Events	4 (3.3%)	5 (4.2%)	7 (5.8%)	14 (11.7%)	21 (8.7%)
Related, Serious Adverse Event[3]	3 (2.5%)	1 (0.8%)	0	0	0
Unrelated, Serious Adverse Event	2 (1.6%)	4 (3.3%)	7 (5.8%)	14 (11.7%)	21 (8.7%)
Serious Infection (unrelated)	0	1 (0.8%)	0	5 (4.2%)	5 (2.1%)
AE leading to study discontinuation	0	0	0	1 (0.8%)	1 (0.4%)
Death	0	0	0	0	0

[1] AEs with frequency ≥3% included mild/moderate vocal cord paresis or dysphonia, resolved or stable with no significant sequelae

[2] AEs with frequency ≥3% included mild/moderate pain, managed with adjustment to stimulation level

[3] SAEs included incision site swelling where participant was hospitalized for evaluation, but no infection was identified (resolved); vocal cord paresis with dysphagia that led to hospitalization (resolved); dysphonia at worse severity deemed by investigator significant enough to impair daily activities (resolved, mild sequelae), and pharyngeal injury repaired intraoperatively, no hospitalization required (resolved).

Conclusion: RESET-RA met its primary efficacy and safety endpoints, demonstrating that vagus nerve-mediated neuroimmune modulation by electrical stimulation using an implantable device is well-tolerated with durable efficacy through 12-months among adults with active RA disease and inadequate response or intolerance to at least one b/tsDMARD.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2265–2289) Rheumatoid Arthritis – Treatment Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: A 6-month intervention with abatacept in the ARIAA trial (EUDRA-CT 2014–000555–93) significantly retarded the development of RA compared to placebo in ACPA-positive individuals with joint pain and subclinical

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

inflammation on hand MRI. This inhibitory effect peaked at the end of the 6-month treatment period and was still discernible after 1-year of follow-up without any intervention. The durability of the inhibitory effect on development of RA is not known.

Objectives: To assess the durability of the inhibitory effect of abatacept to develop RA observed in the ARIAA trial.

Methods: The ARIAA trial recruited individuals with positive ACPA antibodies, joint pain and findings of synovitis, tenosynovitis or bone marrow edema on the MRI of the dominant hand. Subjectswere randomized to receive a 6-month course of abatacept 125 mg sc weekly or placebo and followed without any treatment for additional 12 months. Individuals who did not develop RA during the study period of December 2014 and June 2021 were contacted up to November 2024 to ascertain their latest status for RA diagnosis based on the discretion of their primary physician. We used survival analysis methods and calculated restricted mean survival time difference, net average RA-free time gained due to treatment over time to evaluate the durability of treatment effect and compared the characteristics of participants who developed RA during study to those who developed RA later and who never developed RA

Results: 98 individuals with a positive ACPA were randomized to abatacept (49) or placebo (49). At the end of treatment (6 months) and observation (18 months) periods, RA developed in 4 (8%) and 17 (35%) participants in the abatacept group as opposed to 17 (35%) and 28 (57%) participants in the placebo group resulting in 15.3 weeks (95%CI, 4.3 to 26.3) of RA-free time gain on average in the abatacept group compared to placebo by the end of the study. After the closure of the study, 17 participants in the abatacept group and 8 participants in the placebo group developed RA during a median follow-up duration of 5.3 years after randomization (IQR, 1.9 to 7.2 years) which cumulated to 34/49 (69%) in the abatacept group and 36/49 (73%) in the placebo group. During this period the RA-free survival gain in the Abatacept group persisted for up to 5 years (figure 1A) increasing to ∼40 weeks (figure-1B). The first derivative (Figure-1C) of the RMST difference curve

Table-1 Characteristics of the study population by RA status at long-term follow-up.

Characteristic	Overall N = 98[1]	No RA N = 28[1]	RA after study N = 25[1]	RA during study N = 45[1]	p-value[2]
Age	49 (42, 59)	49 (46, 62)	52 (41, 59)	49 (42, 56)	0.5

Figure-1 A) Kaplan-Meier Curve showing RA-free survival during and after ARIAA. B) Restricted-mean-survival difference between Abatacept and Placebo arms showing average RA-free time gained over follow-up. C) Slope of the restricted mean survival time ratio over time. Positive values indicate diverging survival curves i.e., accelerated gain of RA-free time in the treatment arm, negative values indicate convergence of survival curves. Dashed vertical lines indicate the end of study treatment and solid vertical lines indicate end of study. Error bands indicate 95% CI

indicates that the inhibitory effect (a positive slope for RA-free time gain) of abatacept during the treatment-period is offset initially during the first year after treatment cessation but then persisted for up-to five years after randomization and waned afterwards resulting in an ultimate catch-up of the placebo arm. A descriptive comparison of participants who never developed RA indicate that these had a lower ESR, lower RF levels, lower pain scores and better functional status at baseline (Table-1).

Conclusion: Abatacept showed a delayed inhibitory effect against the development of RA lasting for up-to 5 years after the initial 6-month intervention. Systemic inflammation, autoimmunity, pain, and function could help improve risk stratification while selecting individuals at risk of RA for a preventive intervention

Session Title: (2265–2289) Rheumatoid Arthritis – Treatment Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Abatacept, an efficacious therapy for rheumatoid arthritis (RA), inhibits the interaction between CD28 on T cells and CD80/CD86 on antigen-presenting cells (APCs). The aim of our study was to examine the effect of abatacept on B cell subtypes in patients with RA.

Methods: Twenty-five patients with RA, not responding to conventional DMARDs, received Abatacept and included in the study. DAS28 (ESR), DAS28(CRP) and SDAI were measured at baseline and at 6 months post-treatment. Serum sample and peripheral blood mononuclear cells were collected at baseline and at 6 months post-treatment.

ACPA were tested using commercial ELISA and LINEBLOT (for CCP3, citrullinated vimentin, citrullinated a-enolase peptide). Five subsets of B cells including regulatory B cells (Bregs) were analyzed at baseline and 6-months post-Abatacept treatment by flow cytometry using a FACS Calibur cytometer (Becton Dickinson): B cells, naive B cells, PDL-1^{+}B cells, PDL-1^{+}CD27^{+}B cells, PDL-1^{+}CD27^{-}B cells, PDL-1^{hi}Bregs (CD19+ PD-L1++).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: At baseline ACPA positivity was found in 52% of patients. All patients who were positive for ACPA at baseline remained positive at 6 months post-treatment without significant changes of their titers. In addition, none of ACPA-negative patients become positive at 6-months post-treatment.

Response to therapy was found in 84.6% ACPA(+) patients and in 58.3% of ACPA(-) (p=0.0034). DAS28(ESR), DAS28 (CRP) and SDAI scores at baseline were (mean±SD, 5.64±1.36, 5.19±1.40, and 34.13±18.23, respectively and significantly decreased at 6-months post-treatment (3.03±1.14, 2.9±1.02 and 9.06±7.82, respectively).

At baseline, levels of B cell subtypes were higher in ACPA(+) compared to ACPA(-) patients (naïve Bregs, 44.89±11.48 vs 35.66±14.6, p=0.095; PDL1^{+}B cells, 24.19±9.13 vs 17.7±5.73, p=0.044; PDL-1^{+} of CD27^{+}B cells, 29.37±8.41 vs 18.45 ±7.13, p=0.002; PDL-1^{hi}Bregs, 7.64±2.29 vs 5.84±2.00, p=0.048).

At 6 months post-treatment, ACPA(+) patients compared to ACPA(-) patients exhibited higher percentage increase in PDL-1^{+} of CD27^{-}B cells (39.3±28.04 vs 14.45±18.87, p=0.016) and in PDL-1^{hi}Bregs cells (38.02±23.2 vs 12.9±15.38, p=0.004).

High levels of B cell subtypes at baseline were associated with SDAI remission at 6 months post-Abatacept treatment. At baseline, responders compared to non-responders had higher levels of naïve B cells (45.01±10.37 vs 28.64±14.56, p=0.025), PDL-1^{+}B cells (24.07±7.61 vs 13.4±3.3, p< 0.001), PDL-1+ of CD27+ B cells (27.51±8.51 vs 15.44±5.58, p=0.001), and PDL-1^{hi}Bregs (7.69±1.94 vs 4.40±1.25, p< 0.001).

At 6-months post-treatment PDL-1+ of CD27-Bcells increased in responders vs non-responders (36.26±26.13% vs 4.52 ±9.39, p< 0.001). Finally, DAS28(ESR) score during treatment was negatively correlated with change of levels of PDL-1^{+}CD27^{-}B cells (p=0.029, r=-0.437).

Conclusion: In patients with RA treated with Abatacept, remission was higher in ACPA(+) than ACPA(-) patients. High levels of B cell subtypes at baseline were associated with SDAI remission at 6 months. DAS28(ESR) score during treatment was negatively correlated with PDL-1^{+}CD27^{-}B cells.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2265–2289) Rheumatoid Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Upadacitinib (UPA) is an oral, selective Janus kinase (JAK)-inhibitor proven effective and well-tolerated in patients with rheumatoid arthritis (RA) in 6 randomized clinical trials. The objective of the CLOSE-UP study was to evaluate the real-world effectiveness and safety of UPA among Canadian patients with prior exposure to conventional synthetic (cs)DMARD, biologic (b)DMARD, and targeted-synthetic (ts)DMARD experienced patients in real-world settings.

Methods: CLOSE-UP was a prospective, multicenter, observational post-marketing study in adults with moderate-to-severe RA who were treated with UPA 15 mg once daily, with the decision to initiate UPA therapy made prior to study participation. Patients were followed for 24 months after UPA initiation with data collected at routine clinic visits. The primary endpoint was the proportion of patients achieving a Disease Activity Score 28 Joint Count – C-reactive protein (DAS28-CRP) < 2.6 at 6 months. Secondary endpoints included pain score using a visual analog scale, fatigue (FACIT-F), physical function as measured by the Health Assessment Questionnaire-Disability Index (HAQ-DI) and other assessments of disease activity including Clinical Disease Activity Index (CDAI) score. Per protocol, eligible subjects were grouped by

Figure 1a. Proportion of Patients Achieving DAS28-CRP <2.6 (Solid Bars) or ≤3.2 (Shaded Bars) by Patient Group and Study Visit (Efficacy Population)

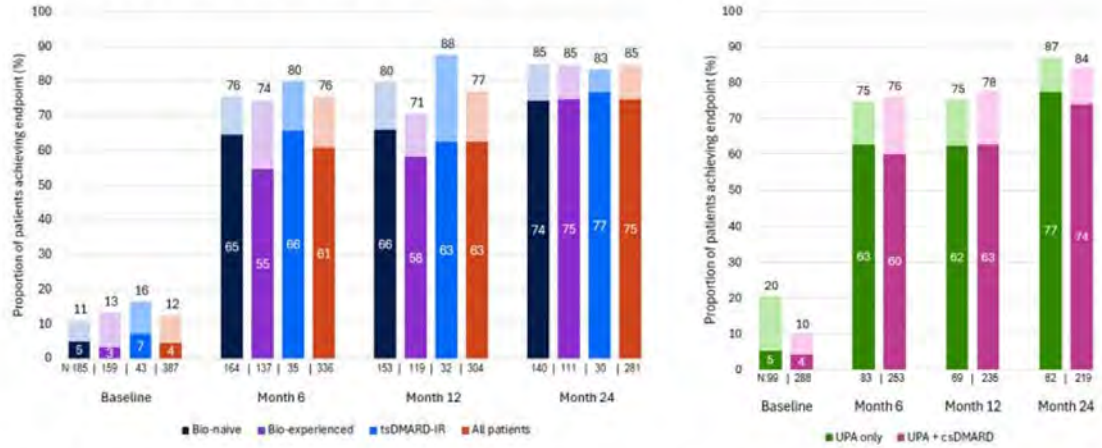

Figure 1b. Proportion of Patients Achieving ≥50% Improvement in Pain, MCID in FACIT-F, and MCID in HAQ-DI[a] (Efficacy Population)

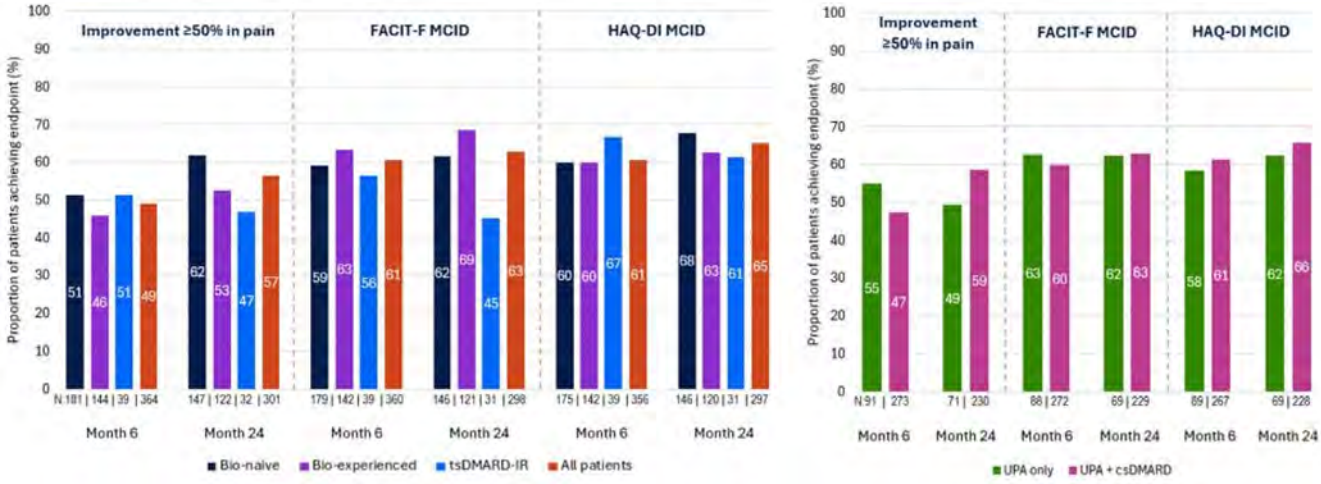

Abbreviations: CDAI, Clinical Disease Activity Index; CRP, C-reactive protein; cs, conventional synthetic; DAS28, Disease Activity Score – 28 Joint Count; DMARD, disease-modifying antirheumatic drugs; FACIT-F, Functional Assessment of Chronic Illness Therapy – Fatigue; HAQ-DI, Health Assessment Questionnaire-Disability Index; IR, inadequate response; MCID, minimal clinically important difference; N, sample size; ts, targeted synthetic; UPA, upadacitinib. Bio-naïve patients have not been previously exposed to any bDMARD or tsDMARD. Bio-experienced patients have not been previously exposed to tsDMARD and have been previously exposed to ≤ 2 bDMARDs. tsDMARD-IR patients have been previously treated with 1 tsDMARD and ≤ 1 bDMARD prior to treatment with that tsDMARD. a - MCID for FACIT-F was defined as a change from baseline ≥ 3.56; MCID for HAQ-DI was defined as a change from baseline ≥ 0.22.

prior/most recent exposure to no b/tsDMARDs (bio-naïve); ≤2 bDMARDs but no tsDMARD (bio-experienced), and a maximum of 1bDMARD followed by a tsDMARD (tsDMARD-inadequate response [IR]). Data are presented as observed and summarized descriptively.

Results: Analysis included 412 patients, with 47.1% identified as bio-naïve, 41.3% as bio-experienced, and 10.7% as tsDMARD-IR (Table 1). At baseline, most patients (84.5%) exhibited a DAS28-CRP > 3.2. After 6 months of UPA treatment initiation, 60.7% of patients achieved a DAS28-CRP < 2.6 (primary endpoint) and 75.6% achieved a DAS28-CRP ≤ 3.2, (Figure 1a) with a response rate maintained for up to 24 months. Similar trends were observed using CDAI definitions for clinical remission and LDA. The type of prior/most recent DMARD exposure did not impact response rates. Additionally, the proportion of patients achieving a DAS28-CRP < 2.6 at the 6-month visit were similar between those on UPA monotherapy (62.7%) and those on UPA in combination with a csDMARD (60.1%). Improvements in pain score, fatigue, and physical

Table 2. Safety Summary

Patients, rate/100 PYs [n]	**N = 412** **682.6 PY**
Any TEAE	37.2 [254]
Any treatment-emergent SAE	5.1 [35]
Serious infections	2.2 [15]
Death [a]	0.6 [4]
Any TEAEs leading to UPA discontinuation	8.6 [59]
TEAEs of special interest	
Any infections	16.6 [113]
Herpes zoster	2.3 [16]
Malignancy excluding NMSC	0.4 [3]
NMSC	0.9 [6]
Gastrointestinal perforation	0.3 [2]
VTE	0.3 [2]
MACE	0.7 [5]

Abbreviations: MACE, major adverse cardiovascular events; NMSC, non-melanoma skin cancer; PY, patient-years; SAE, serious adverse events; TEAE, treatment-emergent adverse event; UPA, upadacitinib; VTE, venous thromboembolic events. a - 1 patient had cardiac arrest (not related); 1 patient had acute myocardial infarction, COVID-19, acute kidney injury, and respiratory failure (all not related, main cause of death was identified as complications related to dialysis); 2 patients had pneumonia (1 possibly related, 1 not related)

function were observed throughout the study (Figure 1b). At 6 months, 86.5% of patients persisted in their treatment on UPA and 67.5% persisted up to Month 24. The safety profile of UPA was consistent with that seen in Phase 3 trials with no new safety signals (Table 2).

Conclusion: Consistent with clinical trial findings, this real-world Canadian study demonstrated a reduction in disease activity and improvements in patient-reported outcomes, supporting a favorable benefit-risk profile for patients treated with UPA. Notably, response rates were consistent irrespective of prior bDMARDs/tsDMARDs use or concomitant csDMARD.

Background/Purpose: In recent years, an increasing number of cytokines and their function in the pathophysiology of immunologic conditions have been identified, leading to the development of new targeted therapies such as the Janus kinase (JAK) inhibitors that may provide better patient-centric treatment options. The objective of this study was to determine if an online, continuing education curriculum could advance the care of patients with rheumatoid arthritis in real world clinical practice with appropriate use of JAK inhibitors after inadequate response or intolerance to anti-TNF inhibitors.

Methods: The educational program consisted of 4 CME activities in various formats including panel discussions, clinician-patient video-vignettes with expert faculty commentary, and virtual patient simulation case-studies that allow learners to order lab tests, assess disease, and prescribe treatments in a manner matching the scope and depth of actual practice. This real-world outcome study (RWO) was designed to assess the impact of the CME activities on the appropriate use of JAK inhibitors in patients who have failed an anti-TNF therapy by rheumatologists, physician assistants, and nurse practitioners. A retrospective matched case-control study was conducted using medical and pharmacy claims aggregated with patients and the coding clinicians between December 2023 through November 2024. Learners and non-learners were matched based upon specialty, geographic location, number of patients with RA, number of treated with biologics, and number of patients treated with JAK inhibitors. Independent t-tests were used to assess significance between the number of patients receiving JAK inhibitors by clinicians in the CME group and those in the control group. Data were pulled for 3 months pre and 3 months-post first CME activity participation date ("index date").

Results: The sample includes 654 CME learners who participated in at least 1 of the 4 CME activities between March 2024 and August 2024, and 654 matched comparison non-participants. All data are time aligned 3 months pre-/post-index date. After participating in case-based education, rheumatologists demonstrated 20% increase in evidence-based selection of individualized pharmacologic therapy for patients with RA who have failed a TNF inhibitor. Learners who participated in 1 or more activity were more likely to switch patients to JAK inhibitors following an anti-TNF therapy . Patients of CME learners were 26% more likely to be treated with JAK inhibitors versus the control group (P< .05).

Conclusion: The results of this RWO study confirms that participation in 1 or more CME activities within a curriculum is associated with improving the adoption of the latest evidence-based recommendations for use of novel therapies such as JAK inhibitors by rheumatologists, NPs, and PAs, aiming to improve the management and outcomes of patients with rheumatoid arthritis.

Background/Purpose: Background: Both rheumatoid arthritis (RA) and type 2 diabetes mellitus (T2DM) are independently associated with increased cardiovascular risk, including cardiac arrhythmias. The impact of different biologic therapies on arrhythmia risk in patients with both conditions remains unclear. This study evaluates arrhythmia outcomes in RA patients with T2DM treated with IL-6 inhibitors (IL-6i) versus TNF-α inhibitors (TNFi).

Methods: Methods: We conducted a retrospective cohort study using TriNetX, a global federated health research network. Adult patients with RA and T2DM receiving either IL-6i (sarilumab/tocilizumab) without TNFi or TNFi without IL-6i were identified. After propensity score matching (n=1,579 per cohort), we compared the incidence of various arrhythmias including atrial fibrillation, ventricular tachycardia, ventricular fibrillation, supraventricular tachycardia, and sick sinus syndrome over a 5-year follow-up period.

Results: Results: IL-6i treatment was associated with significantly higher risk of ventricular tachycardia compared to TNFi (HR=1.419, 95% CI: 1.006-2.002, p=0.045). Though not statistically significant, there were trends toward increased risk with IL-6i for atrial fibrillation (HR=1.104, 95% CI: 0.894-1.365, p=0.357), supraventricular tachycardia (HR=1.138, 95% CI: 0.767-1.688, p=0.521), and ventricular fibrillation (HR=1.628, 95% CI: 0.964-2.747, p=0.066). Notably, the need for pacemaker implantation was higher in the IL-6i group (HR=1.394, 95% CI: 1.006-1.933, p=0.045). The 5-year arrhythmia-free survival rate was lower in IL-6i-treated patients compared to TNFi-treated patients (p< 0.05).

Conclusion: Conclusions: In RA patients with comorbid T2DM, treatment with IL-6i was associated with higher risk of cardiac arrhythmias, particularly ventricular tachycardia, compared to TNFi therapy. These findings suggest that TNFi may offer a more favorable cardiac safety profile in this high-risk population. Clinicians should consider arrhythmia risk when selecting biologic therapy for patients with both RA and T2DM, and closer cardiac monitoring may be warranted for those receiving IL-6i.

Cardiovascular Outcomes in Diabetic Rheumatoid Arthritis Patients: TNF-α Inhibitors versus IL-6 Inhibitors

Sila Mateo Faxas[1], Godbless Ajenaghughrure[1], Gurjot Singh[2], Kim Nguyen[2], Nirys Mateo Faxas[3], Nicole Tejeda[4], Kimberly Ramirez Bonetti[5] and Erick Perez Mejias[4], [1]Trihealth Good Samaritan Hospital, Cincinnati, OH, [2]Trihealth Good Samaritan Hospital, Cincinnati, [3]Independent Author, Santo Domingo, Dominican Republic, [4]Independent Author, Cincinnati, [5]Independent Author, cincinnati, OH

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2265–2289) Rheumatoid Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with rheumatoid arthritis (RA) and type 2 diabetes mellitus (T2DM) face increased cardiovascular risk. Different biologic disease-modifying antirheumatic drugs (bDMARDs) may have varying effects on cardiovascular outcomes in this high-risk population. This study compared cardiovascular outcomes between RA patients with T2DM treated with IL-6 inhibitors (IL-6i) versus TNF-α inhibitors (TNFi).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Using the TriNetX global federated health research network, we conducted a retrospective cohort study of adult patients with RA and T2DM. Patients were divided into two cohorts: those receiving IL-6i (sarilumab or tocilizumab) without TNFi (n=1,579) and those receiving TNFi without IL-6i (n=1,579), matched using propensity score on 20+ potential confounders. Outcomes included mortality, major adverse cardiovascular events (MACE), arrhythmias, heart failure, and other cardiovascular conditions over a 5-year follow-up period.

Results: IL-6i-treated patients demonstrated significantly higher risk for mortality (HR=1.626, 95% CI: 1.308-2.021, p< 0.001), acute kidney failure (HR=1.772, 95% CI: 1.420-2.212, p< 0.001), and heart failure (HR=1.399, 95% CI: 1.193-1.640, p< 0.001) compared to TNFi-treated patients. Additionally, IL-6i recipients had higher risk for ventricular arrhythmias (HR=1.459, 95% CI: 1.006-2.175, p=0.045), pulmonary embolism (HR=2.092, 95% CI: 1.420-3.081, p< 0.001), and infections/inflammatory reactions related to cardiac devices (HR=3.485, 95% CI: 1.122-10.821, p=0.021). However, TNFi-treated patients had significantly higher frequency of diabetes-related follow-up visits (17.46 vs 14.69 visits, p=0.004).

Conclusion: In this propensity-matched analysis of RA patients with T2DM, treatment with IL-6i was associated with significantly higher risk of mortality and multiple cardiovascular adverse events compared to TNFi treatment. While both drug classes effectively manage RA symptoms, our findings suggest TNFi may be preferable for this specific patient population from a cardiovascular safety perspective. These results highlight the importance of considering cardiovascular risk profiles when selecting biologic therapy for RA patients with comorbid T2DM.

Synovium-on-a-chip – Development of a Humanized Rheumatoid Arthritis Model that Mimics Disease and Patient Biological Heterogeneity

Theresa Wampler Muskardin[1], Ruiqi Chen[2], Yeji Lee[3], Azka Ali[3], Andrra Nimoni[3], Christele Felix[3], Hattie Heiland[3], Romy Kallas[3], Daniel Ramirez[4], David Mayman[3], Timothy Niewold[5] and Weiqiang Chen[6], [1]Hospital for Special Surgery and Weill Cornell Medicine, New York, NY, [2]New York University - Tandon School of Engineering, New York, NY, [3]Hospital for Special Surgery, New York, NY, [4]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY, [5]Hospital for Special Surgery, New York, New York, [6]New York University, Tandon School of Engineering, New York, NY

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2265–2289) Rheumatoid Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: In rheumatoid arthritis (RA), reasons for treatment resistance and alternate strategies that would be more effective in treatment-resistant patients remain unknown. Accurate methodology to study mechanisms of treatment resistance and screen novel therapies in individual patients remains a critical unmet need.

Methods: We engineered a microfluidic synovium-on-a-chip device incorporating a central synovial fluid region, a pericentral lining region, and an outer sublining zone (Fig. 1). The chip was seeded with fibroblast-like synoviocytes (FLS) from patient synovial tissue and matched immune cells (T cell, B cell, monocyte, and monocyte-derived macrophage), embedded with HUVECs in a 3D fibrin hydrogel to reconstruct spatially organized niches. Migratory dynamics of the immune cells were

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

monitored in real time using time-lapse fluorescence microscopy. Upon niche maturation on day 8, devices were processed for further analysis of inflammatory states and cell subset-specific marker expression. Morphological analysis was performed at multiple time points, and supernatants were collected daily for cytokine profiling. We stratified RA synovial chips into high-, mixed-, and low-inflammatory groups based on histological synovitis scores derived from H&E stains from the same patient tissues.

Results: RA FLS exhibited hyperplastic morphology and spatial heterogeneity similar to in vivo tissues, including $PRG4^{+}$ lining FLS, $CD90^{+}$ sublining FLS, and immune cell infiltration (Fig. 2). Notably, progressive ECM degradation was significantly greater in RA chips compared to osteoarthritis (OA) chips.

Compared to the OA niche, **i**mmune cells in RA-derived chips exhibited more directed and enhanced immune cell migration toward the sublining region. Concurrently, immune cells within the RA synovial niche underwent pro-inflammatory differentiation, including Th17 cells, plasma cells, $CD16^{++}$ monocytes, and M1-like macrophages. RA synovial chips exhibited increased in IL-6 secretion following immune cell addition on Day 7. Cytokine secretion profiling revealed upregulation of pro-inflammatory cytokines, chemokines, and matrix-degrading enzymes in RA chips compared to OA controls.

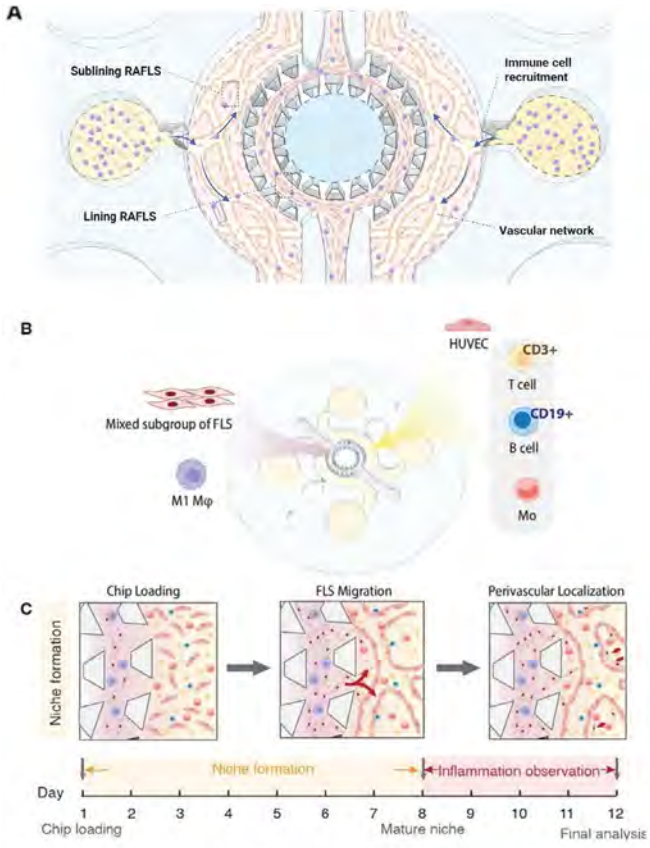

Figure 1. (A) Microfluidic chip layout consisting of four spatially organized zones: a central synovial fluid region, a pericentral lining region, an outer sublining region, and side immune recruitment ports. Regions are partitioned by trapezoidal micropillars that permit cell migration and interaction. (B) Patient-derived RA-FLS and M1 macrophages were encapsulated in fibrin hydrogel and loaded into the lining region, while HUVECs, $CD3^{+}$ T cells, $CD19^{+}$ B cells, and monocytes were introduced into the sublining region to reconstruct a 3D inflamed synovial niche. (C) Experimental timeline showing an 8-day niche formation phase followed by an inflammation observation window from Day 8 to 12, during which tissue morphology and inflammatory responses were analyzed.

Figure 1

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. (A) FLS exhibited spatial heterogeneity similar to *in vivo* tissues, including PRG4^{+} lining FLS, CD90^{+} sublining FLS, and immune cell infiltration. (B) RA FLS demonstrated hyperplastic morphology, with increased Ki67 expression compared to OA FLS on the microfluidic organ-on-a-chip platform. (C) ECM degradation was progressive and greater in RA chips compared to OA chips. (D) Compared to the OA niche, immune cells in RA-derived chips exhibited more directed and enhanced immune cell migration toward the sublining region.

Figure 2

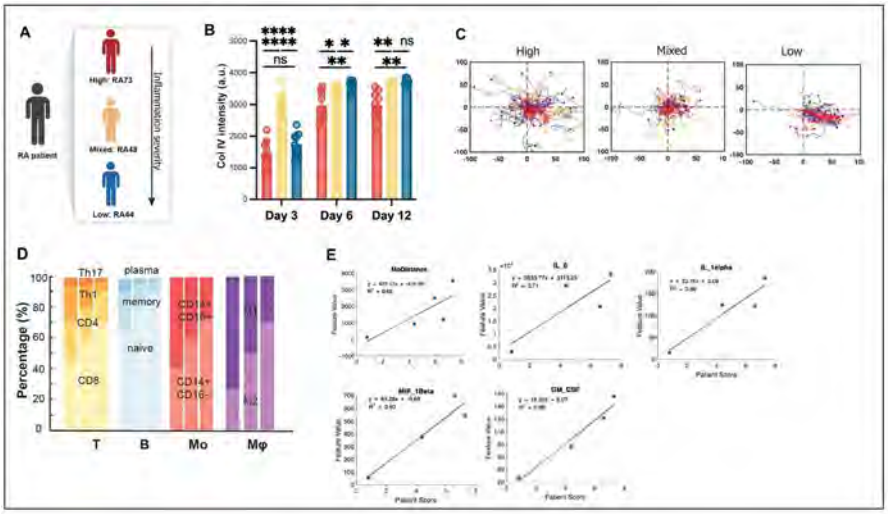

Figure 3. Patient-specific inflammatory variation characterized using synovium-on-a-chip models. (A) Schematic of RA patient stratification into high (RA73), mixed (RA48), and low (RA44) inflammation groups. (B) Quantification of collagen IV intensity over time across RA patients with distinct inflammatory profiles (two-way RM ANOVA, time: ****p < 0.0001; group: ****p < 0.0001; interaction: ****p < 0.0001; n = 9). (C) The migration trajectory of high, mixed, and low inflammation groups. Individual T cells

Figure 3

Across RA patient groups, the high-inflammatory group had the most collagen IV loss, enhanced migration of immune cells , and a higher proportion of Th17/Th1 T cells, plasma B cells, CD16^{++} monocytes, and M1-like macrophages, in contrast to the mixed and low-inflammatory chips (Fig. 3). High inflammation chips had higher levels of pro-inflammatory cytokines and chemokines (IL-6, IL-1α, TNF-α,MCP-3, MIP-1β, IL-2, IL-7, IL-15) compared to the low-inflammation chip.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Conclusion: Our synovium-on-a-chip recapitulates the human stromal and immune cellular organization of the vascularized synovium niche. We establish an immunologically active synovial niche in our RA chip model, capable of capturing key cellular interactions and molecular outputs observed in RA patient tissues and characteristics that differ amongst RA endotypes.

Abstract Number: 2286

Association of Semaglutide Prescription with Improved Joint Outcomes in Rheumatoid Arthritis Patients

Faissal Stipho[1], **Yazin Hindosh**[2], Jonathan Sayegh[2], Akram Hindosh[2], Bassam Mitri[2] and Issa Batarseh[1], [1]Department of Internal Medicine, Banner University Medical Center / University of Arizona, Tucson, Arizona, Tucson, AZ, [2]University of Arizona College of Medicine Tucson, Tucson, AZ

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2265–2289) Rheumatoid Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid Arthritis (RA) is an autoimmune disorder that results in immune dysfunction and swelling of major joints, leading to discomfort, pain, stiffness, and loss of function1. Semaglutide is a GLP-1 agonist increasing in popularity for its metabolic benefits and ability to reduce inflammation and swelling2. However, the potential benefit of semaglutide use for RA flare-ups has not yet been investigated.. The objective of this study was to quantify this relationship by assessing the risk of RA flare-ups in patients prescribed semaglutide.

Methods: The TriNetX Database was queried to identify patients ≥ 18 years old with RA. These individuals were then divided into two subgroups: those prescribed semaglutide (n=12,139) and those who were not (n=292,558). These groups were 1:1 propensity score matched (n=12,125) for age, sex, ethnicity, BMI, diabetes mellitus, nicotine dependence, and mood disorders. Primary outcomes included 30-day, 90-day, and 1-year risk of synovitis, stiffness of joints, swelling of joints, and pain in joints within one year of semaglutide prescription. Risk Ratios (RR) were calculated between each cohort, and statistical significance was set to $p< 0.05$.

Results: RA Patients prescribed semaglutide had a significantly lower 30-day risk of stiffness of joints (RR=0.635, p=0.023), pain in joints (RR=0.605, p< 0.001), and swelling of joints (RR=0.588, p< 0.001),a significantly lower 90-day risk of synovitis (RR=0.729, p=0.001), stiffness of joints (RR=0.716, p=0.019), pain in joints (RR=0.728, p< 0.001), and swelling of joints (RR=0.704, p< 0.001), and a significantly lower 1-year risk of synovitis (RR=0.806, p< 0.001), stiffness of joints (RR=0.800, p=0.019), pain in joint (RR=0.884, p=0.004), and swelling of joints (RR=0.769, p< 0.001).

Conclusion: RA patients with a semaglutide prescription had lower risks of RA flare-ups such as synovitis, stiffness, swelling, and pain of joints compared to those without. This may be attributed to semaglutide's mechanism of action, which has been shown to modulate the immune system and reduce inflammatory cytokine levels. Future studies should be conducted to further investigate the efficacy of semaglutide as a potential agent against RA.

Abstract Number: 2287

Interpretable Ensemble Machine Learning Explaining Nonadherence and the Risk of Nonpersistence of Targeted Disease-Modifying Antirheumatic Agents in Older Adults with Rheumatoid Arthritis

yinan huang[1] and Sandeep Agarwal[2], [1]Department of Pharmacy Administration, University of Mississippi, Oxford, MS, US, MS, [2]Baylor College of Medicine, Houston

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2265–2289) Rheumatoid Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Interpretable machine learning (ML) method can identify factors associated with biological or targeted synthetic disease modifying antirheumatic drugs (b/tsDMARDs) nonadherence and nonpersistence for rheumatoid arthritis (RA) based on big data. This study is to develop and validate several interpretable ML models in evaluating the nonadherence and the risk of nonpersistence of b/tsDMARDs among older adults with RA.

Methods: This retrospective, new-user study used 5% national Medicare administrative claims data between 2012-2020, and included older (≥65) patients initiating b/tsDMARDs (the index date) between 2013-2019 and having a diagnosis of RA identified using the International Classification of Diseases, Ninth and Tenth revision codes. Nonadherence outcome was defined as medication possession ratio (MPR) < 80%, evaluated during the 12-month follow-up. Nonpersistence, defined as time from the index date until treatment gap ≥ 60 days observed during the follow-up, or censored for loss to follow-up. Patient-level data was split into 75% for model training and 25% for evaluation, with patients' demographics and clinical characteristics measured in the baseline period. ML classification models (random forest [RF], eXtreme Gradient Boosting [XGBoost] and prediction rule ensembles [PRE]) evaluated the binary nonadherence outcomes and the ML survival model (random survival forest [RSF] and regularized Cox regression [RegCox]) assessed time on nonpersistence. Using the testing cohort, C-index and integrated Brier Score were reported for the ML survival model and AUROC was reported for ML classification models. Top influential predictive features for nonadherence and the risk of nonpersistence were identified according to variable importance (VIMP) procedure from both types of ML algorithms, respectively.

Results: We identified 3,927 eligible patients with RA (mean age 73 ±6; female 75%). Approximately 18.5% of RA patients had the risk of nonpersistence after initiating their index b/tsDMARDs (mean time to nonpersistence 1,110 ±670 days). RSF (C-index 0.6629, iBS 0.1629) and Reg-Cox model (C-index 0.6810) found index year, age, Elixhauser score, frailty score, inpatient visit, outpatient visits, the type of b/tsDMARDs, and CIRAS as top 8 influential predictors for nonpersistence. 53.65% of RA patients were adherent (MPR 0.72 [0.31]; 0.01-1) in the 12-month follow-up. Compared to ML-based classification models (PRE 0.5407 [0.509-0.5722]; RF 0.6029 [0.5715-0.6336]; XGBoost 0.6018 [0.5704-0.6326]) had comparable performance in predicting nonadherence. Frailty score, CIRAS, age, index_year and Elixhauser comorbidity index were ranked commonly as the top influential features for nonadherence.

Conclusion: We effectively developed ML-based survival and classification models to explain the nonadherence and the risk of nonpersistence of b/tsDMARDs, respectively for older adults with RA. There is potential to leverage ML models for understanding patients' behavior of utilizing b/tsDMARDs treatment with a goal to improve RA care.

Abstract Number: 2288

Efficacy of Ivarmacitinib in Patients with Moderate-to-severe Rheumatoid Arthritis Stratified by Baseline Characteristics: A Post-hoc Study of a Phase III Clinical Trial

Yuan Xue, Bo Wei, Xiaojing Huang and Rui Ding, Zhongshan Hospital Xiamen University, Xiamen, China (People's Republic)

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2265–2289) Rheumatoid Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Ivarmacitinib (SHR0302), a selective Janus kinase 1 inhibitor, has demonstrated efficacy in patients with moderate-to-severe rheumatoid arthritis (RA). This post-hoc study aimed to evaluate the efficacy of Ivarmacitinib stratified by baseline patient characteristics.

Methods: This post-hoc analysis was based on data from a phase III clinical trial (NCT04333771, Liu J, Jiang Y, Zhang S, et al. Ivarmacitinib, a selective Janus kinase 1 inhibitor, in patients with moderate-to-severe active rheumatoid arthritis and inadequate response to conventional synthetic DMARDs: results from a phase III randomised clinical trial. Ann Rheum Dis. Published online November 27, 2024. doi:10.1136/ard-2024-226385). Patients were randomized to receive Ivarmacitinib 4 mg (n=189), Ivarmacitinib 8 mg (n=189) or placebo (n=188) for the initial 24-week treatment period. After week 24, patients on placebo switched to Ivarmacitinib 4mg, while the other groups continued their initial regimen until 52 weeks. Efficacy outcomes were analyzed by subgroups based on demographic factors, disease characteristics, and treatment history.

Table 1. Comparison of ACR20 response at W24 and W52 based on subgroups. *, P <0.05 between placebo vs. Ivarmacitinib 8 mg; **, P <0.01 between placebo vs. Ivarmacitinib 8 mg; ***, P <0.001 between placebo vs. Ivarmacitinib 8 mg. #, P <0.05 between placebo vs. Ivarmacitinib 4 mg; ##, P <0.01 between placebo vs. Ivarmacitinib 4 mg; ###, P <0.001 between placebo vs. Ivarmacitinib 4 mg. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: At week 24, both Ivarmacitinib 4 mg and 8 mg demonstrated significantly higher American College of Rheumatology (ACR) criteria improvement of 20% (ACR20) response rate compared to placebo across all subgroups, including age, sex (except for males who received Ivarmacitinib 8 mg), disease duration, ACR functional class (grades II and III), C-reactive protein (CRP), 28-joint Disease Activity Score-CRP (DAS28-CRP), and prior exposure to biologic disease-modifying antirheumatic drugs (DMARDs). By week 52, both Ivarmacitinib 4 mg (e.g., 93.8% in males) and 8 mg (e.g., 90.9% in patients with ACR functional class of I and 86.5% in patients with RA duration < 3 years) achieved high ACR20 response rates across all subgroups. Patients who switched from placebo at week 24 also achieved substantial benefits in week 52 ACR20 response across subgroups (Table 1). Regarding safety, the incidences of adverse events were generally comparable between Ivarmacitinib 4 or 8 mg versus placebo across all subgroups.

Conclusion: Ivarmacitinib provides consistent efficacy across various subgroups in patient with moderate-to-severe RA.

Effects of Transcutaneous Auricular Vagus Nerve Stimulation on Disease Activity in Patients with Rheumatoid Arthritis: A Pilot Study

Yuichiro Fujieda[1], Kaoru Murakami[2], Hiroki Tanaka[2], Yuichi Kojima[2], Yuki Kudo[1], Kohei Karino[1], Hiroyuki Nakamura[1], Ryo Hisada[1], Michihito Kono[1], Masaaki Murakami[2] and Tatsuya Atsumi[1], [1]Department of Rheumatology, Endocrinology and Nephrology, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo, Hokkaido, Japan, [2]Institute for Genetic Medicine, Graduate School of Medicine, Hokkaido University, Sapporo, Japan

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2265–2289) Rheumatoid Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Vagus nerve stimulation (VNS) has emerged as a potential therapeutic strategy for inflammatory diseases by modulating inflammatory reflex pathways. Transcutaneous auricular vagus nerve stimulation (taVNS) is a non-invasive approach that may offer symptomatic relief for rheumatoid arthritis (RA). This study aims to investigate the effects of taVNS on disease activity, pain, and inflammation in RA patients.

Methods: This exploratory, open-label clinical study enrolled patients diagnosed with RA who required treatment modification. Participants received daily taVNS treatments (25Hz, 1-10mA, 1 hour/day) for 12 weeks. Clinical assessments, including swollen and tender joint counts, Visual Analogue Scale (VAS), Clinical Disease Activity Index (CDAI), and Simplified Disease Activity Index (SDAI), Disease Activity Score 28-erythrocyte sedimentation rate (DAS28-ESR), and DAS28-C-reactive protein (DAS28-CRP), were conducted at baseline, weeks 4, 8, and 12. Laboratory analyses included inflammatory markers and immune cell profiling. Additionally, an exploratory proteomic analysis was performed using SomaScan® Assay to comprehensively measure plasma proteins in both RA patients and Collagen Antibody-Induced Arthritis (CAIA) model mice before and after VNS treatment. Proteins commonly elevated in both species following taVNS were identified.

Results: Seven RA patients (mean age: 61.9 years; 100% female) were included in this analysis. Baseline disease activity scores were as follows: CDAI median [IQR] 24 [12:49.5], SDAI 25.1 [12.4:49.8], DAS28-ESR 4.66 [3.92:5.16], DAS28-CRP 3.94 [3.16:4.62], tender joint count 5 [4:21], swollen joint count 5 [2:14], VAS 24 [12:49.5]. After 12 weeks of taVNS, disease activity scores showed a decreasing trend; however, the differences did not reach statistical significance.

Disease activity in rheumatoid arthritis during 12 weeks of transcutaneous auricular vagus-nerve stimulation. Mean (±SD) CDAI, SDAI, DAS28-ESR, and DAS28-CRP for seven patients are plotted at baseline and at weeks 4, 8, and 12; none of the observed declines reached significance (repeated-measures ANOVA, $p > 0.05$).

Proteomic analysis by using SomaScan® Assay revealed that Protein X was significantly upregulated in both RA patients and CAIA mice following taVNS. Notably, plasma levels of Protein X increased significantly in CAIA mice treated with taVNS (1007.0 ± 49.4) compared to untreated CAIA mice (886.5 ± 13.5, p=0.02). In contrast, no significant changes were observed in inflammatory proteins related to RA pathogenesis (TNF-α, IL-1β, IL-6, IL-17A, GM-CSF) or pain-associated neuropeptides (Substance P, CGRP, β-Endorphin, Enkephalin, Neuropeptide Y).

Conclusion: Protein X is a protein that modulates inflammatory pathways, particularly via STAT1 signaling. Preliminary findings suggest a potential association between taVNS and disease activity in RA, possibly involving Protein X and STAT1 signaling.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2290–2304) Sjögren's Disease – Basic & Clinical Science Poster III: Treatment and Trial Outcome Measures

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Assessing clinical improvements in Sjögren's Disease (SjD) is challenging. Our objective was to describe patterns of improvement in SjD using ESSDAI and ESSPRI indices and identify factors associated with these improvements.

Methods: Patients from the prospective SSAD cohort, which collects biological and clinical data from SjD cases, were included. ESSDAI improvement (ESSDAI-I) was defined by improvement in ≥1 ESSDAI domain (transition from high (H) or moderate (M) to low (L) or no activity (NA) in most domains; from M to L or NA in the glandular domain; and from H to M or NA in the CNS domain) without worsening in any other. ESSPRI improvement (ESSPRI-I) was defined as a reduction ≥2 points or ≥30% from baseline.

Patients were classified as improvers if improvement between two visits (3 months apart) was maintained at a subsequent visit 3 months later; the visit preceding improvement was considered baseline. Non-improvers (NI) were defined as patients with baseline ESSDAI or ESSPRI >0 but without observed improvement.

Among ESSDAI-I patients, clinical (ClinESSDAI) and isolated biological improvements were analyzed separately. As not all patients received therapeutic interventions at baseline, analyses were conducted for the entire cohort and separately for a subgroup initiating rituximab (RTX) at baseline.

Logistic regression models assessed the association of clinical variables with improvement status, adjusting for sex, age, disease duration, and baseline ESSDAI and ESSPRI scores. Fisher's exact test and Kruskal–Wallis tests were used for categorical and continuous variables, respectively. Unadjusted p-values < 0.05 were considered statistically significant. Analyses were performed using R v4.4.

Results: A total of 363 patients susceptible to improvement were analyzed. Improvement was observed in 30 patients (8.3%): 15 (4.1%) showed ESSDAI-I, 14 (3.86%) ESSPRI-I, and 1 patient (0.27%) showed simultaneous improvement in ESSDAI and ESSPRI. Four of the 16 ESSDAI-I cases improved only in the biological domain.

Glandular_Baseline	1,72 (1,06-2,80)	0,02	0,24
Methotrexate_Baseline	4,85 (1,16-20,26)	0,03	0,28
SerologyCryoglobulinemia_Baseline	0,03 (0,00-1,21)	0,05	0,40
ESSPRI-I *vs.* NI			
Articular_Baseline	0,24 (0,07-0,91)	0,04	0,96
ESSDAI-I *vs.* ESSPRI-I			
Articular_Baseline	0,25 (0,08-0,78)	0,02	0,61
RTX-I *vs.* RTX-NI			
Biological_Baseline	4,30 (1,29-14,36)	0,02	0,53
SerologyAntiRoSSA52kd_Baseline	9,74 (1,05-90,27)	0,05	0,53

Overall improvement (ESSDAI or ESSPRI) was positively associated with higher baseline biological domain scores, initiation of RTX at baseline, and improvements in hypergammaglobulinemia and Schirmer's test, but negatively with elevated β2-microglobulin (B2M).

ESSDAI-I patients showed higher baseline scores in articular, biological, and glandular domains and more frequent RTX or MTX initiation than NI patients. Negative associations were noted with low C3 levels and cryoglobulinemia.

ESSPRI-I was positively associated with RTX initiation, higher peripheral nervous system domain and lower articular domain scores. ESSDAI-I patients had significantly higher baseline articular domain scores compared to ESSPRI-I patients.

In patients initiating RTX therapy, higher baseline biological scores predicted improvement, and Ro52 positivity trended toward significance.

Conclusion: ESSDAI and ESSPRI improvements rarely coincided in our cohort. Higher baseline biological and articular domain scores predicted ESSDAI improvement. Initiation of RTX strongly correlated with improvement, whereas elevated B2M, low C3 levels, and cryoglobulinemia negatively predicted improvement.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2290–2304) Sjögren's Disease – Basic & Clinical Science Poster III: Treatment and Trial Outcome Measures

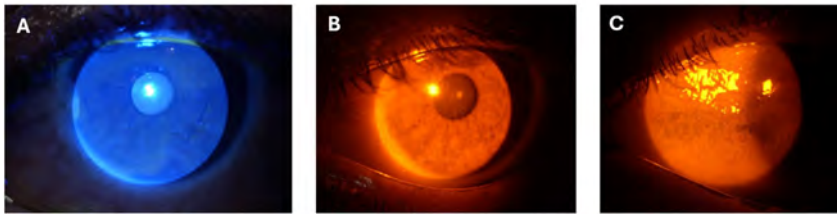
Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Sjögren's Disease (SjD) is a systemic autoimmune disorder marked by mucosal dryness and ocular surface damage. For diagnosis, the ACR-EULAR 2016 criteria require the Ocular Staining Score (OSS) or the van Bijsterveld score (vBs), both rarely used in routine care. The Oxford Grading Scale (OGS), a simpler and widely applied tool, may offer a more accessible alternative. The objective of this study is to assess the correlation and diagnostic agreement of OGS with OSS and vBs in patients fulfilling the ACR-EULAR 2016 criteria for SjD, aiming to support its use as a practical screening method.

Methods: We conducted a cross-sectional study of 20 patients from the SSAD project at a single center (June–December 2024), all meeting ACR-EULAR 2016 criteria for SjD. Each underwent ocular surface staining assessments using the OSS, vBs, and OGS on the same day, following standardized protocols (Figures A-C).

OSS evaluates corneal and conjunctival staining (0–12) with fluorescein and lissamine green; vBs scores three conjunctival zones (0–9) using the same dyes; OGS assesses corneal epithelial damage (0–5) via fluorescein staining. Positive thresholds were OSS ≥5 or vBs ≥4 per ACR-EULAR criteria. OGS thresholds were explored to determine optimal concordance with OSS and vBs.



Figures A–C: Simultaneous ocular surface staining in a patient with Sjögren's disease (SjD). A: Fluorescein staining of the ocular surface. B–C: Lissamine green staining of the cornea (B) and conjunctiva (C).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

We analyzed correlations using Spearman's rho for continuous scores and assessed agreement through percentage concordance and Cohen's kappa for binary classifications. OGS positivity was determined across various thresholds, selecting the one maximizing Cohen's kappa for further analysis. OSS and vBs served as reference standards to calculate OGS's positive and negative predictive values at different thresholds.

Results: A total of **20 patients** (mean age 57 years, 16 women [80%]) who met the classification criteria for SjD, regardless of their OSS or vBS results, were included.

- A **Near-perfect agreement** between standard scoring systems (OSS and vBs) was observed (rho = 0.94, $p < 0.001$ for both eyes).
- A **Moderate-to-good agreement** was observed for positive/negative classification based on ACR-EULAR thresholds (OSS ≥5, vBS ≥4), with 85% concordance (kappa = 0.67). Discrepancies were partially atributable to the treshold differences; for instance, some cases had a vBS of 4 (classified as positive) but an OSS of 3 or 4 (negative).
- **OGS** showed **Moderate correlations** with both OSS and vBs, ranging from rho=0.44 to rho=0.6, slightly higher for OSS than for vBS.
- An **OGS threshold of ≥1** in at least one eye yielded the **highest agreement** with OSS and vBS (kappa: 0.5 for OSS, 0.6 for vBS), with **excellent negative predictive values** (NPV: 1.0 for OSS, 0.9 for vBS) but modest positive predictive values (PPV: 0.5 for OSS, 0.7 for vBS).
- The **PPV-maximizing cutoffs** were OGS ≥3 for OSS (PPV = 1) and OGS ≥2 for vBS (PPV = 0.70). These are conservative thresholds with only 1 and 3 positive cases, respectively.
- Notably, all patients with a positive vBS were also OSS-positive, suggesting OSS may be the more conservative assessment.

Conclusion: OGS moderately correlates with OSS and vBs and shows excellent rule-out capability when the score is 0. Given its simplicity and high NPV, OGS could serve as a practical screening tool for ocular damage in SjD, especially in settings lacking access to OSS or vBs.

Session Title: (2290–2304) Sjögren's Disease – Basic & Clinical Science Poster III: Treatment and Trial Outcome Measures

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background/Purpose: Immunosuppressed Sjögren's disease (SjD) patients are at increased risk of herpes zoster (HZ). Despite this vulnerability, data on safety and immunogenicity of the recombinant HZ vaccine (RZV, Shingrix®) in these patients remain limited. Concerns about disease flares following vaccine, as highlighted in studies of COVID-19 vaccination, further underscore the need for target evaluation. **Purpose:** To evaluate the safety and immunogenicity of RZV in immunosuppressed SjD.

Methods: In this randomized, double-blind, placebo-controlled trial, 67 adults immunosuppressed SjD patients (excluding rituximab) were enrolled, alongside 201 non-immunosuppressed control individuals (CG). SjD patients were randomized to receive vaccine (P1) or placebo (P2) at day 0 (D0) and D42, with placebo recipients vaccinated after unblinding (D84 and D126). CG were immunized at D0 and D42. Disease activity [ESSDAI (European League Against Rheumatism-EULAR Sjögren's Syndrome Disease Activity Index)] and adverse events (AEs) were monitored at all visits. Humoral immunogenicity was assessed by serum anti-gE antibody concentrations using a GSK ELISA. The humoral response to VZR was defined as anti-gE concentration ≥4-fold the pre-vaccination concentration. Geometric Mean Titer (GMT) and Factor Increase (FI-GMT) were calculated.

Results: Vaccine (P1) and placebo (P2) groups were comparable in terms of age (p=0.5), sex (p=1.0), prednisone use (p=0.3) and dosage (0.6), as well as treatment with hydroxychloroquine (p=0.7), methotrexate (p=0.5), leflunomide (p=0.4), azathioprine (p=0.5), and mycophenolate mofetil (p=0.8). Baseline disease activity, assessed by ESSDAI, was similar between P1 and P2 [2.0 (0.0-2.0) vs. 1.0 (0.0-2.5), p=0.7], and most patients presented low disease activity (ESSDAI< 5) in both groups (87.1% vs. 88.9%, p=1.0), respectively. No significant changes in ESSDAI were observed six weeks after the 1st (p=0.5) or 2nd (p=0.2) RZV dose. Flare rates, defined as increase ≥3 points in ESSDAI and/or increased glucocorticoid/immunosuppressant therapy, were also comparable between groups throughout the study (p >0.05). Regarding AEs, after the 1st RZV dose, local reactions were less frequent among SjD than in CG (70.1% vs. 84.6%, p=0.009), as were systemic reactions (50.7% vs. 62.2%, p=0.1). After the 2nd RZV dose, the rates were comparable between groups (p >0.05). No serious AEs were observed. Analysis of immunogenicity comparing SjD and age [55.0 (48.3-63.8) vs. 55.0 (52.0-64.0) years, p=0.1] and sex (female: 95.5% vs. 90.5%, p=0.3, respectively) balanced CG revealed a reduced humoral response in SjD patients (90.6% vs. 99.5%, p=0.0009). Furthermore, GMT and FI-GMT were significantly lower in SjD patients compared to controls (Table).

Table. Humoral response rates 6 weeks after the 2nd RZV dose and anti-gE IgG titers before (D0) and after two doses in patients with SjD and CG
CG – control group, SjD – Sjögren's disease. RZV – recombinant herpes zoster vaccine, GMT – geometric mean titers (mIU/mL). Frequencies of humoral response are presented as number (%) and they were compared using two-sided chi-square test between SjD and CG at 6 weeks after the 2nd RZV dose. Anti-gE IgG titers and factor increase (FI) in GMT are expressed as geometric means with 95% confidence interval (95%CI). Data regarding anti-gE titers were analyzed using ANOVA with repeated measures and 2 factors [2 groups (SjD vs. CG), at 2 time points (D0 and 6 weeks after the 2nd RZV dose)], followed by Bonferroni's multiple comparisons at neperian logarithm (ln)-transformed data. GMT and FI-GMT were compared using Mann-Whitney test for intergroup comparisons in ln-transformed data at pre-specified time points (D0 and 6 weeks after de 2nd dose). All analyses were two-sided. P1 – SjD patients who received the RZV on the day of randomization (D0) and after 6 weeks (D42). P2 – SjD patients who initially received placebo and were vaccinated 12 weeks after randomization, on D84 and after 6 weeks (D126).

	Humoral response 6 weeks after 2nd dose	GMT			FI-GMT
		D0	6 weeks after 2nd dose	p (D0 vs. 6 weeks after 2nd dose)	D0 to 6 weeks after 2nd dose
SjD (P1 +P2), n=64	58 (90.6)	0.30 (0.21-0.43)	7.11 (5.27-9.61)	<0.001	23.94 (16.0-35.8)
CG, n=201	200 (99.5)	0.18 (0.15-0.21)	12.58 (11.43-13.85)	<0.001	70.43 (58.60-84.35)
p (SjD vs. CG)	<0.001	0.019	<0.001		<0.001

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: RZV demonstrated an excellent safety profile in immunosuppressed SjD patients, without triggering significant disease flares. Although the vaccine induced a high rate of humoral response, the magnitude of the response was significantly lower compared to healthy controls, which may have implications for long-term protection. (ClinicalTrials NCT05879419).

CLN-978, a CD19 x CD3-Directed T Cell Engager, Leads to Rapid and Deep B Cell Depletion In Vitro and In Vivo, Supporting Clinical Development Across Multiple Autoimmune Diseases

Ella Ioffe, Karsten Sauer, Todd Shearer, Jennifer Michaelson, Jeffrey Jones, Yue Zhang, Stephen Wax and **Antoine Sreih**, Cullinan Therapeutics Inc, Cambridge, MA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2290–2304) Sjögren's Disease – Basic & Clinical Science Poster III: Treatment and Trial Outcome Measures
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Treatments depleting CD19-expressing B cells have shown benefit in a range of autoimmune diseases. T cell engagers (TCE) offer off-the-shelf convenience, the predictable pharmacokinetic/pharmacodynamic properties of monoclonal antibodies, and the potential to achieve deep target cell depletion as seen with chimeric antigen receptor (CAR) T cell therapy. CLN-978 is a T cell engager comprised of tandemly arranged CD19- and CD3-specific single-chain fragment variable domains and a single-domain albumin binder for serum half-life extension. CLN-978 has high affinity for CD19 and moderate affinity for CD3 (Meetze K, et al. J Immunother Cancer 2023;11:e007398) and is administered via subcutaneous (SC) injection. In a phase 1, first-in-human study (NCT05879744), patients with B cell non-Hodgkin lymphoma (B-NHL) were treated with the starting dose of 30 micrograms (mcg) SC weekly of CLN-978, which demonstrated a favorable safety profile and a complete metabolic response in 1 of 3 treated patients. We report preclinical and translational studies in autoimmune diseases.

Methods: Peripheral blood mononuclear cells (PBMC) derived from healthy donors and patients with Sjögren's disease (SjD), SLE, or RA, were cultured in the presence of CLN-978 for 48 hours. In a mouse model of SLE, NOD scid gamma (NCG) mice engrafted with PBMC from a patient with SLE were treated with CLN-978 weekly for 3 weeks. Cynomolgus monkeys were administered single and up to 4 weekly SC doses of CLN-978 at dose levels ranging from 2 to

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1: CLN-978 induces similar B cell killing in PBMCs across patients with autoimmune diseases and healthy donors

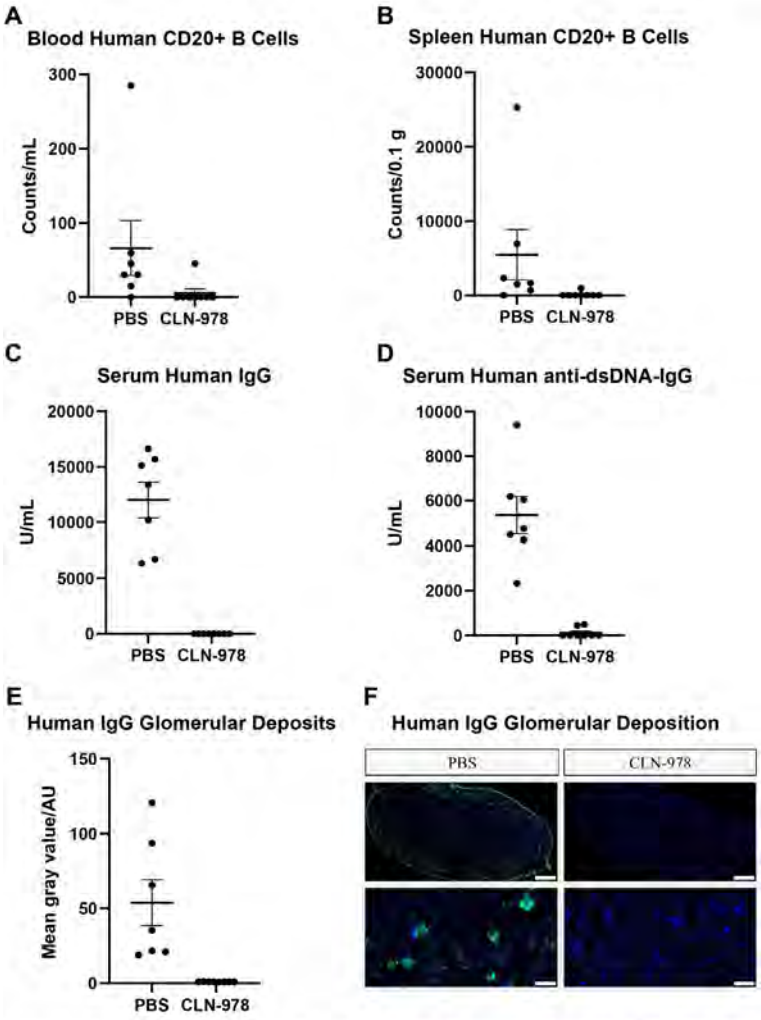
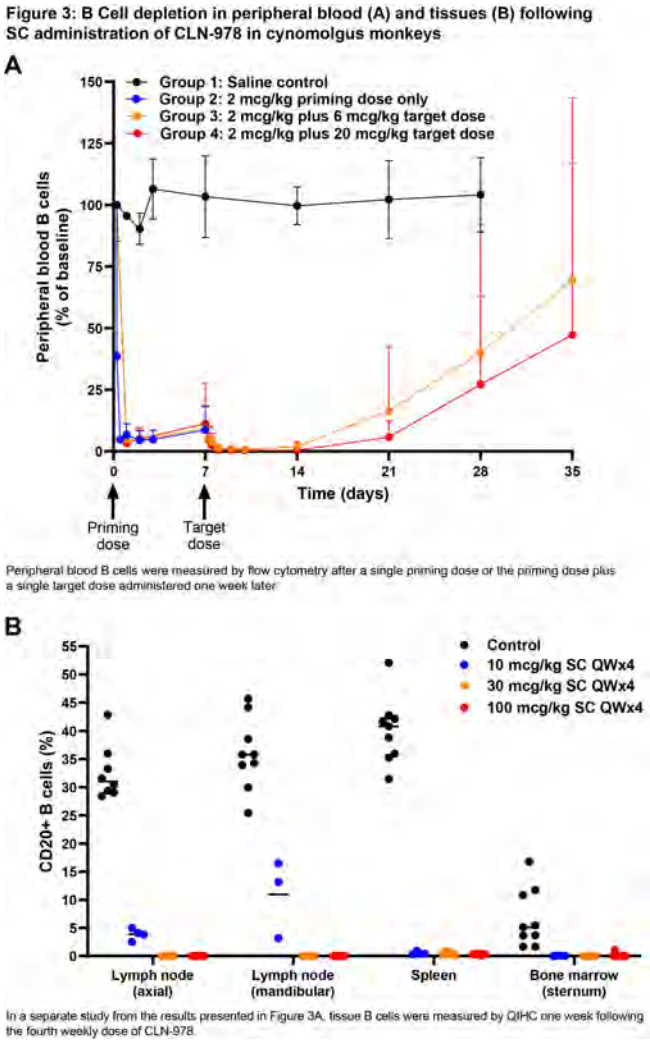
PBMC from healthy volunteers or patients with SjD, SLE, or RA were cultured in the presence of CLN-978 for 48 hours. B cells were analyzed by flow cytometry and normalized to PBMC-only control. Error bars denote standard error of the mean.

Figure 2: CLN-978 treatment depletes human B cells, reduces anti-dsDNA antibodies, and abrogates human IgG deposition in the kidneys of NCG mice engrafted with PBMC from SLE patients



NCG mice harboring PBMC from a patient with SLE were injected SC with phosphate-buffered saline (PBS) or CLN-978 (30 mcg/kg) on days 7, 14, and 21 before analysis on day 28. (A-E) Levels of human CD20+ B cells in blood (A) and spleen (B), human IgG (C) and anti-dsDNA IgG (D) in serum, and human IgG deposits in kidney glomeruli (E). Dots denote values for individual mice, and horizontal lines the means (n=7 or n=8, respectively, for PBS or CLN-978 treatment). Error bars denote standard error of the mean. (F) Representative immunofluorescence microscopic images of human IgG deposits (green) and cell nuclei (blue) in kidneys. Scale bars, 1 mm (top) or 0.1 mm (bottom).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



100 mcg/kg. Peripheral blood and tissues (lymph nodes, spleen, and bone marrow) were assessed for B cell depletion by flow cytometry and quantitative immunohistochemistry (QIHC), respectively.

Results: In vitro, CLN-978 induced similar B cell killing (Figure 1) and T cell activation in PBMCs from healthy donors and in patients with SjD, SLE, or RA. In mice engrafted with human SLE PBMC, CLN-978 treatment depleted human B cell populations in blood and spleen, reduced human IgG and anti-dsDNA IgG blood levels, and abrogated human IgG deposition in kidney glomeruli compared with controls (Figure 2).

In cynomolgus monkeys, a dose-related B cell depletion was observed in peripheral blood following administration of a single priming dose +/- a single target dose of CLN-978 (Figure 3A). Dose-related B cell depletion was also observed in lymphoid tissues, spleen, and bone marrow following administration of 4 weekly SC doses (Figure 3B). CLN-978 was well tolerated in monkeys following multiple weekly SC doses up to 100 mcg/kg.

Conclusion: CLN-978 is a highly potent, SC-administered, CD19-directed TCE. Preclinical in vitro and in vivo data including deep B cell depletion in both peripheral blood and tissue, along with existing clinical data in B-NHL patients, support broad development across autoimmune diseases. Phase 1b studies of CLN-978 are currently being conducted in patients with CLN-978 in SjD, SLE, and RA.

Comparative Analysis of Patients Included in Trials Utilizing Biologic Drugs in the Treatment of Primary Sjögren's Syndrome

Carlota Navarro Joven[1], Silvia Piunno[2], Maryia Nikitsina[3], CARMEN SAN JOSE MENDEZ[4] and David A. Isenberg[5], [1]Hospital Universitario Puerta de Hierro Majadahonda, Madrid, Spain, [2]Fondazione Policlinico Universitario Agostino Gemelli, Rome, Italy, [3]University Hospital La Princesa, Madrid, Madrid, Madrid, Spain, [4]Complejo Hospitalario Universitario de A Coruña (CHUAC), A Coruña, Spain, [5]University College London, London, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2290–2304) Sjögren's Disease – Basic & Clinical Science Poster III: Treatment and Trial Outcome Measures
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Sjögren's syndrome is a heterogeneous autoimmune disease with no approved disease-modifying treatments. The aim of this systematic review was to evaluate primary Sjögren's syndrome (pSS) patient characteristics included in clinical trials (CTs).

Methods: This systematic review was undertaken according to the Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA) guidelines. The search was performed using PubMed, EMBASE, OVID, and ClinicalTrials.gov for phase II and III clinical trials of biologic drugs in pSS including ≥30 adult patients and published between 2010 and 2024. Baseline characteristics of participants and trial-related information were collected. Descriptive statistics were used for analysis.

Results: A total of 16 publications were eligible to be included in this review, with 87.5% being published after 2017. The CTs were predominantly randomized controlled trials with a placebo arm (93.8%) and phase II trials (62.5%). The mean follow-up period was 32 weeks. The majority of the CTs (56.3%) were fully sponsored by industry sources. A summary of the main characteristics of CTs selected is shown in **Table 1**.

Inclusion criteria often focused on high disease activity, as measured by the ESSDAI score, with 62.5% requiring an ESSDAI score ≥5. Salivary flow measures were also common, used in 43.8% of the CTs. The primary outcomes were diverse, but 56.3% of the CTs focused on reducing ESSDAI scores.

The CTs included in the analysis reported a total of 1607 patients, predominantly female (94%), with a mean age of 51.0 (4.04) years. The mean time from diagnosis was 6.47 (2.48) years. Racial diversity was underreported, with only 37.5% of CTs providing data on race. Among those, 77.8% of participants were White, 11.9% were Asian, and 5.2% were Black.

Disease characteristics included high anti-SSA/Ro antibody positivity (92.9%), while other immunological and serological features are shown in **Table 2**. Mean ESSDAI score was 9.6 (2.8) and mean ESSPRI score was 6.3 (0.88). Other measurements of subjective symptoms notably a numerical rating scale (NRS) were also assed, including an NRS for dryness, fatigue and pain mean values of 7.2/10, 6.7/10 and 5.7/10, respectively. Patient-reported measures of disease burden are shown in Table 3.

Dörner T et al.	2024	RCT, phase II	Remibrutinib	73
Fisher BA et al.	2024	RCT, phase II	Iscalimab	273

Table 2 : Serological features of patients included in the CTs Data are mean (SD), median (min, max), or percentages. ANA=antinuclear antibodies; anti-La/SSB= antibodies against Sjögren's Syndrome B; RF=Rheumatoid Factor; IgG=Immunoglobulin G

Serological feature	Statistical measures	Trials reporting
ANA positivitiy	83.1	4/16
Anti-La/SSB positivity	61.2	9/16
RF positivitiy	58.7	6/16
RF (U/mL)	116.3 (60.1)	3/16
C3 (g/L)	113.7 (20.9)	3/16
C3 (g/L)	105.0 (97.0, 130.0)	3/16
C4 (g/L)	21.6 (4.4)	6/16
C4 (g/L)	20.0 (20.0, 25.0)	2/16
IgG (g/L)	18.4 (4.4)	11/16
IgG (g/L)	20.7 (17.4, 22.9)	2/16
Hypergammaglobulinemia	63.1	3/16
Cryoglobulinemia	10,3	1/16
β2-microglobulin (nmol/L)	245.7 (41.5)	1/16

Table 3: Patient-reported measures of disease burden Data are mean (SD), median (min, max), or percentages. SF-36: Short Form-36; PCS: Physical Component Summary of SF-36; MCS: Mental Component Summary of SF-36; MFI-20: Multidimensional Fatigue Inventory-20.

Scale assesed	Statistical measures	Trials reporting
SF-36 total	52.4 (11.5)	2/16
PCS	37.8 (1.7)	5/16
PCS	50.4 (50.3, 50.4)	1/16
MCS	40.8 (3.5)	4/16
MCS	47.0 (44, 50.1)	2/16
MFI-20 score	56.4 (4.949)	1/16
MFI-20 score	51.3 (51.0, 51.5)	1/16

Concomitant treatments were common, with 87.5% of the CTs allowing simultaneous therapies. Despite most of the CTs being multicentric (75%), global representation was limited: only five CTs recruited patients in more than two continents and no CTs recruited in Africa.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: This review highlights key challenges in pSS CTs: notably limited patient diversity, high subjective symptom burden, and heterogeneous outcomes measures. While the use of ESSDAI/ESSPRI is rising and reporting of race and ethnicity is improving, standardization remains incomplete. Earlier intervention and broader recruitment are needed to advance pSS therapies.

Autoantibody Profiles and Their Association with Organ Involvement in Primary Sjögren's Syndrome: Insights from ESSDAI

Deepak Rath[1], Sholen Acharya[2] and Dr Alakendu Ghosh[3], [1]John H Stroger Hospital Jr of Cook County, Chicago, Illinois, USA, 60612, Chicago, IL, [2]Department of Reproductive Medicine and Surgery, Government Medical College Thiruvananthapuram, Kerala, India, 695004, Chicago, IL, [3]Self employed, Kolkata, West Bengal, India

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2290–2304) Sjögren's Disease – Basic & Clinical Science Poster III: Treatment and Trial Outcome Measures
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: To evaluate the clinical manifestations, systemic disease activity, and serological profile of patients of Primary Sjögren's syndrome, and to assess associations between specific autoantibodies and ESSDAI domain involvement, with the aim of identifying patterns that could guide diagnosis, disease monitoring, and management.

Methods: This prospective observational study was conducted in the Department of Rheumatology at XYZ Hospital from July 2017 to January 2019, following institutional ethical approval. Patients diagnosed with primary Sjögren's syndrome based on ACR classification criteria[1] were included. Exclusion criteria encompassed coexisting infections, malignancies, radiation history, or other autoimmune conditions. Informed consent was obtained from all participants.

Each patient underwent a detailed clinical evaluation, laboratory testing (including ANA, RF, ACPA, and a panel of autoantibodies), and additional assessments like Schirmer's test, imaging, and minor salivary gland biopsy. Systemic disease activity was assessed using ESSDAI and patient-reported symptoms via ESSPRI. Data analysis was performed using Jamovi software.[2] Categorical data were presented as frequencies; continuous data as mean ± SD. Associations were tested using chi-square and t-tests.

Results: Out of 144 screened individuals, 105 were included in the final analysis. The mean age was 38.5±11.1 years; 95.2% were female. Sicca symptoms (ocular and oral dryness), dental caries (61.9%), fatigue (30.5%), and glandular swelling were common. Mild to moderate breathlessness was reported by 19%. (Table 1A)

Laboratory findings (Table 1B) showed elevated ESR (mean 48.3 mm/hr), mild anemia (mean hemoglobin 10.8 g/dL), and low vitamin D levels (mean 20.7 ng/dL). IgG was elevated in many patients (mean 1853.7 mg/dL), with RF positivity in 45 (42.9%) and anti-CCP positivity in 35 (49.3%). ANA patterns were predominantly coarse speckled (48 patients).

ESSDAI analysis revealed minimal disease activity in most domains (Figure 1), except articular (43.8% had moderate to high activity), biological (50.5% had low/moderate activity), and lymphadenopathy domains.

Chi-square test values of the various auto-antibodies and ESSDAI domains. Chi-square test p-values showing associations between various auto-antibodies and ESSDAI domains in patients with Sjögren's Syndrome. This table presents the statistical significance (p-values) of associations between the presence of different autoantibodies and disease activity across 12 ESSDAI domains. Significant associations ($p < 0.05$) are highlighted in green and marked with an asterisk (*). Notable associations include SSA with the Glandular domain ($p = .032$), PCNA with the Glandular domain ($p = .033$), and AMA with the Renal ($p = .002$) and Muscular ($p = .001$) domains. These findings may indicate domain-specific immunological patterns in Sjögren's Syndrome.

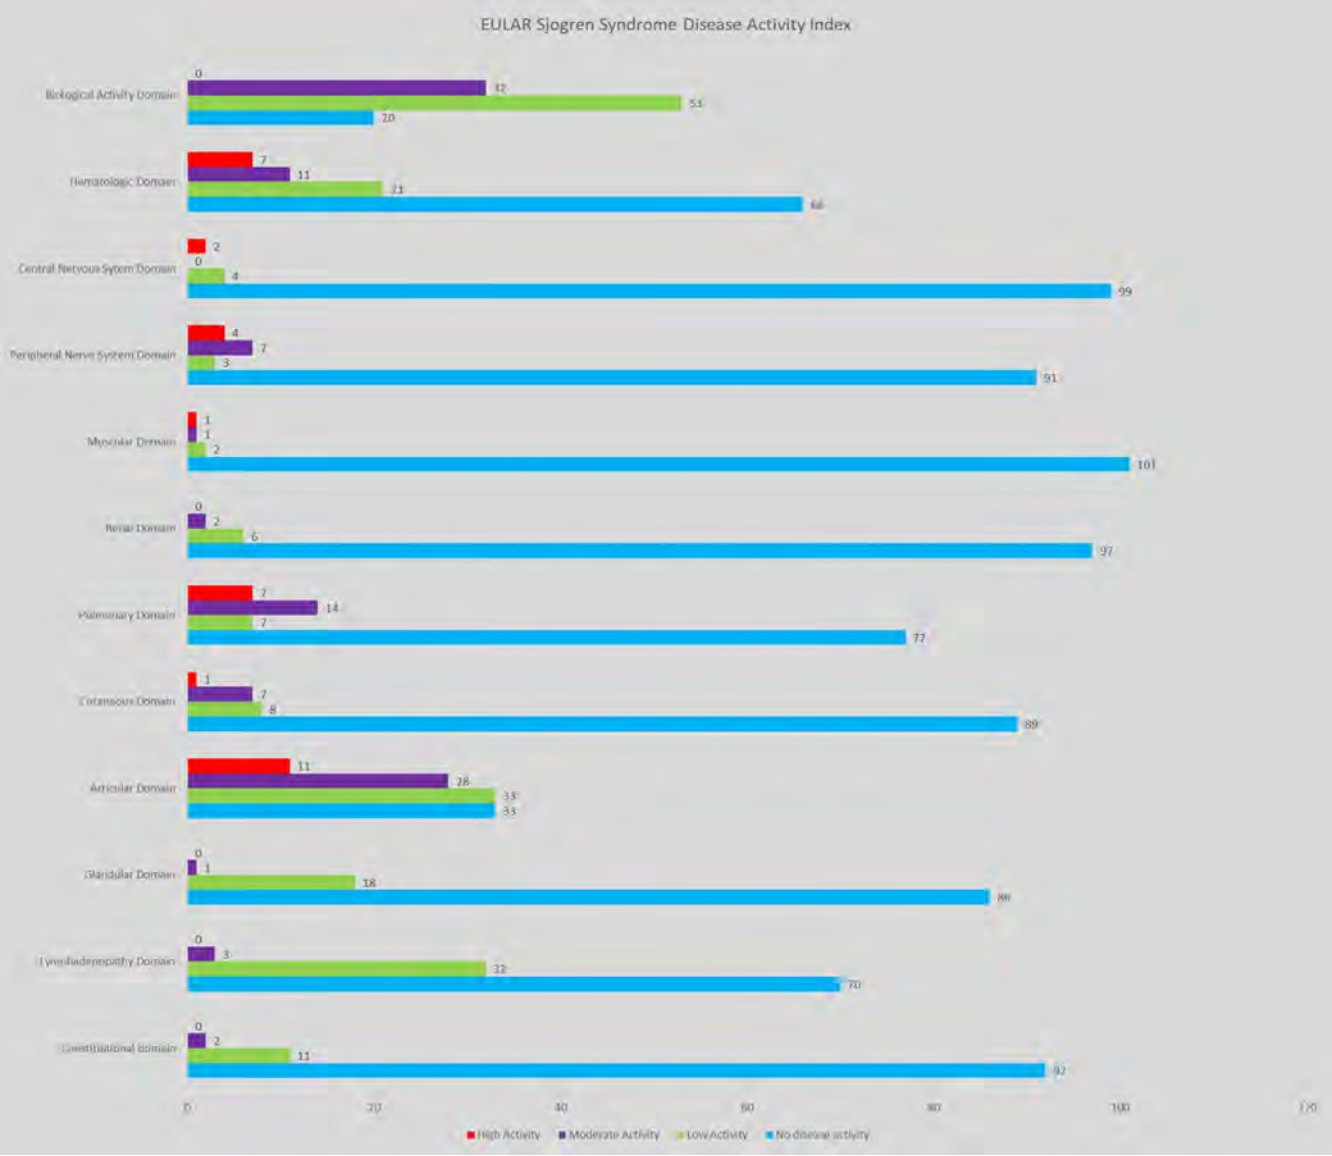

Figure 1: Distribution of disease activity across domains of the EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI). The bar chart illustrates the frequency of disease activity levels—high (red), moderate (purple), low (green), and no activity (blue)—across 12 clinical domains of ESSDAI in a cohort of patients. The Central Nervous System, Muscular, and Renal domains show the highest number of cases with no disease activity, whereas domains such as the Articular and Biological Activity domains demonstrate a wider distribution across all activity levels. The data highlights the heterogeneity of systemic involvement in Sjögren's Syndrome.

Significant associations were observed between autoantibodies and ESSDAI domains (Table 2): anti-SSA with glandular (p=0.032), anti-Ro52 and anti-SCL70 with biological (p=0.020, p=0.017), anti-nucleosome with pulmonary (p=0.001), anti-histone with pulmonary and cutaneous (p=0.026, p=0.049), and anti-AMA with glandular and muscular (p=0.002, p=0.001) domains.

Conclusion: This study demonstrates the systemic heterogeneity of Sjögren's syndrome, with prominent articular and biological domain involvement. Significant associations between autoantibody profiles and specific organ/system involvement can help to identify distinguishing disease subgroups.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2290–2304) Sjögren's Disease – Basic & Clinical Science Poster III: Treatment and Trial Outcome Measures

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Ianalumab, a glycoengineered, fully human, IgG1 mAb directed against B cell-activating factor (BAFF)-receptor (BAFF-R), targets B cells and their functions via a dual mechanism of action: depletion of B cells through enhanced antibody-dependent cellular cytotoxicity, and blockade of BAFF:BAFF-R–mediated signals. The purpose of this study is to better understand the dual mechanism of action of ianalumab in the blood and labial salivary gland (SG) tissue of patients with Sjögren's disease (SjD).

Methods: This is an open-label, single-center, non-randomized, phase 2 mechanistic study (NCT05124925) with a 5-week screening period, a 6-month treatment period, and a follow up period of up to 2 years after the last dose. Eligible participants included those who fulfilled the 2016 ACR/EULAR classification criteria for SjD with anti-Ro/SSA autoantibodies, EULAR Sjögren's Syndrome Patient Reported Index score of ≥5, labial SG focus score (FS) of ≥0.3/4mm^2, and B/B+T cell ratio of ≥0.2 at screening. This interim analysis reports the results of patients who completed the 24-week treatment period (ianalumab 300 mg monthly subcutaneous injection). The primary outcome was change in B/B+T cell ratio from baseline (BL) to week (W) 25. Other outcomes included mass cytometry and single-cell RNA sequencing of circulating immune cells, biomarkers of B cell activation, and labial SG histologic parameters, as well as clinical evaluations, safety, and tolerability.

Results: In the safety analysis set (N=21), ianalumab was well-tolerated with no drug-related serious adverse events (AEs) and one AE leading to discontinuation. Overall, 17 participants completed 24-week open-label treatment, underwent paired screening and W25 labial SG biopsy, and were analyzed. Clinical outcomes and biomarkers of B cell hyperactivity improved numerically. Total CD19+ B cell counts in blood decreased by 99% vs BL. B cells were almost completely depleted in most subsets, notably in naïve B cells, but to a lower extent in double negative effector memory cells (89.5%) and plasmablasts (69.5%; **Figure 1a**). Median depletion was significantly correlated with median BAFF-R expression in these subsets at BL (p=0.008; **Figure 1b**). Gene expression analysis revealed downregulation of B cell signaling, proliferation, and chemotaxis, and upregulation of oxidative phosphorylation and mitochondrial/cellular stress in the remaining naive B cells present at W25. IFN pathway genes were downregulated in plasmablasts at W25. While the FS was slightly reduced, based on regression analyses, the B/B+T cell ratio was statistically significantly reduced by 41% (80% CI: 22, 55) and the B cell density was reduced by 84% (80% CI: 68, 91) at W25 vs BL (**Figure 2**).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Extent of depletion of circulating B cells and B cell subsets at W25 (A) in relation to BAFF-R expression at BL (B). ActNA, activated naïve cells; BAFF-R, B cell-activating factor-receptor; BL, baseline; CD, cluster of differentiation; DN1–3, double negative effector memory cells; NARB; naïve cells (CD45RB); SW, switched memory cells; T1–3, transitional cells; UnSW, unswitched memory cells.

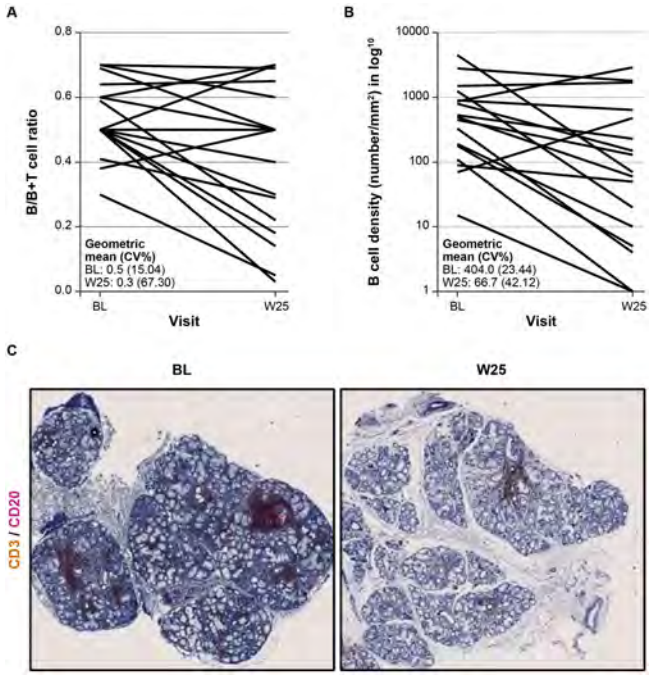

Figure 2. Labial SG B/B+T cell ratio (A), B cell density in log scale of base 10 (B), and a representative example of immunohistochemistry staining for CD3/CD20 (C) at BL and W25. BL, baseline; CD, cluster of differentiation; CV, coefficient of variation; SG, salivary gland; w, week.

Conclusion: Ianalumab 300 mg monthly treatment almost completely depleted B cells in the circulation, and to a large extent in labial SG tissue, in line with improvement in clinical and serological parameters at W25 vs BL. These observations suggest direct and relevant effects of ianalumab 300 mg monthly on the target tissue in patients with SjD. Additionally, ianalumab 300 mg monthly modified the phenotype of the remaining B cells in circulation, shedding new light on the dual mechanism of action of ianalumab.

Abstract Number: 2297

Clinically Relevant Anti-Vaccine and Virus Antibodies in Patients with Sjogren's Disease Treated with Nipocalimab: Post-Hoc Analysis of the DAHLIAS Study

Faye Yu[1], Eugene Myshkin[1], Jonathan J. Hubbard[2], Kim Campbell[2], Matthew Loza[3], Dessislava Dimitrova[2], Carolyn Cuff[1] and Sheng Gao[3], [1]Johnson & Johnson, Cambridge, MA, USA, Cambridge, MA, [2]Johnson & Johnson, Spring House, PA, USA, Spring House, PA, [3]Johnson & Johnson, Spring House, PA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2290–2304) Sjögren's Disease – Basic & Clinical Science Poster III: Treatment and Trial Outcome Measures
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Nipocalimab is a fully human, high affinity, aglycosylated, effectorless IgG1 monoclonal antibody designed to selectively block neonatal fragment crystallizable receptor (FcRn), thereby lowering serum IgG levels. Results from a randomized, open-label vaccine study in healthy volunteers suggest that nipocalimab does not impact the development of IgG responses to T-cell–dependent/–independent vaccines.[1] In the DAHLIAS study (NCT04968912), participants with moderate to severe Sjögren's Disease received nipocalimab 5 mg/kg, 15 mg/kg, or placebo intravenously every 2 weeks for 22 weeks; 15 mg/kg nipocalimab treatment led to significant improvement over placebo in ClinESSDAI (Clinical European League Against Rheumatism Sjögren's Syndrome Disease Activity Index) at 24 weeks and was well-tolerated.[2] Here, we assessed the impact of nipocalimab on pre-existing clinically relevant anti-vaccine antibodies against tetanus toxoid (TT), varicella zoster virus (VZV), and Severe Acute Respiratory Syndrome Coronavirus-2 (SARS-CoV-2) spike protein and on the humoral response to SARS-CoV-2 vaccination or infection in DAHLIAS participants.

Methods: Serum IgG antibody levels against TT and VZV were measured at baseline and post-treatment samples in a subset of participants. In participants with documented SARS-CoV-2 vaccination or infection during the study, antibodies against different epitopes of SARS-CoV-2 were measured. Participants with available samples were included in the analysis.

Results: Nipocalimab reduced pre-existing anti-TT and anti-VZV antibodies to a similar extent as total IgG (observed median pre-dose/minimal reduction: ~61%), consistent with its mechanism of action. Anti-TT and anti-VZV antibody levels returned to baseline by Week 30, 8 weeks post-last dose. All participants receiving SARS-CoV-2 vaccination in the 15 mg/kg nipocalimab group (n=2) elicited a humoral response as indicated by increases in anti-spike antibodies, while all participants with SARS-CoV-2 acute infection in the 15 mg/kg nipocalimab group (n=3, 2 mild and 1 moderate, all recovered) had increased levels of anti-spike and anti-nucleocapsid antibodies.

Conclusion: In nipocalimab-treated participants, preexisting anti-TT and anti-VZV antibodies followed a similar pattern as total IgG, consistent with its mechanism of action. Additionally, nipocalimab did not prevent humoral responses to SARS-CoV-2 infection or vaccination in participants with Sjögren's Disease in the DAHLIAS study. These observations suggest that patients treated with nipocalimab can follow recommended vaccination schedules concomitant with nipocalimab treatment as appropriate.

When Imaging and Biopsy Disagree: Diagnostic Value of Doppler Ultrasound and Histologic Features beyond the Focus Score

kyung-Ann Lee[1], Yeonhee Kim[1], Se Hee Kim[2] and Hyun-Sook Kim[3], [1]Soonchunhyang University Hospital Seoul: Soonchunhyang University Hospital, Seoul, Republic of Korea, [2]Kyung Hee University College of Medicine, Seoul, Republic of Korea, [3]Soonchunhyang University Seoul Hospital, Seoul, Republic of Korea

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2290–2304) Sjögren's Disease – Basic & Clinical Science Poster III: Treatment and Trial Outcome Measures

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Salivary gland ultrasound (SGUS) and minor salivary gland biopsy (MSGB) are widely used in the diagnosis of primary Sjögren's syndrome (pSS). However, discordance between these modalities is frequently encountered, raising questions about their respective diagnostic value and the optimal strategy for resolving inconsistencies. This study aimed to investigate the prevalence and diagnostic relevance of discordance between SGUS and MSGB in pSS, and to evaluate whether Doppler ultrasound and histologic markers beyond the focus score provide additional diagnostic value in discordant cases.

Methods: Methods

We retrospectively analyzed 128 patients (91 pSS, 37 non-pSS) who underwent both SGUS and MSGB within 12 months. SGUS was scored using the OMERACT system; grayscale ≥2 in at least one gland was defined as positive. Color Doppler signals were graded 0–3, and both total scores and a binary threshold (≥2 in any gland) were assessed. Patients were categorized into four groups: SGUS+/MSGB+ (Group 1), SGUS+/MSGB– (Group 2), SGUS–/MSGB+ (Group 3), and SGUS–/MSGB– (Group 4). MSGB was evaluated for focus score and additional histologic features (atrophy, fibrosis, ductal dilatation, lymphoepithelial lesions and germinal centers). The final diagnosis of pSS was determined by expert clinical judgment

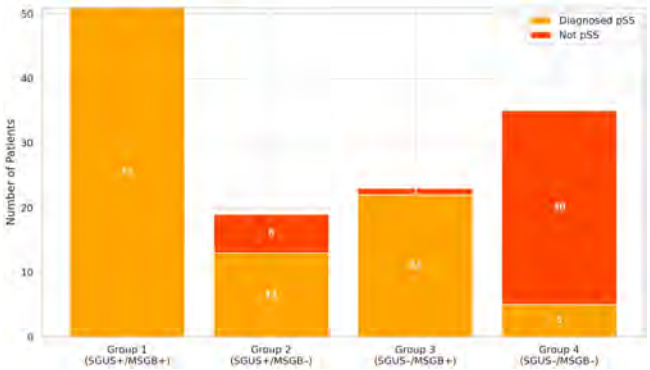

Figure 1. Diagnostic Distribution Across SGUS/MSGB Discordant Groups Bar graph showing the number of patients diagnosed with primary Sjögren's syndrome (pSS) versus not diagnosed, across discordant SGUS/MSGB groups. Group 2: SGUS positive / MSGB negative Group 3: SGUS negative / MSGB positive Group 3 exhibited a significantly higher pSS diagnosis rate (95.7%) compared to Group 2 (68.4%), with an odds ratio (OR) of 10.18 (95% CI: 1.03–100.0, p = 0.047).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

based on comprehensive evaluation, and served as the diagnostic gold standard for this study. Agreement between SGUS and MSGB was assessed using Cohen's kappa. Logistic regression and ROC analysis were performed to evaluate the diagnostic value of Doppler in SGUS-negative patients and of extended histologic markers in MSGB-negative patients.

Results: Among the 128 patients, Group 1 included 51, Group 2 had 19 (13 pSS), Group 3 had 23 (22 pSS), and Group 4 had 35 (5 pSS). The overall discordance rate was 32.8%, and agreement between SGUS and MSGB was fair (κ = 0.334, $p < 0.001$). Among discordant cases, Group 3 (SGUS–/MSGB+) had a significantly higher pSS diagnosis rate than Group 2 (SGUS+/MSGB–) (95.7% vs. 68.4%, OR = 10.15, p = 0.034) (Figure 1), despite no significant differences in age, sex, USFR, or serologic status. In SGUS-negative patients (OMERACT grade 0–1), color Doppler signal showed a trend toward increased odds of pSS diagnosis (aOR = 1.57, p = 0.090), though its discriminatory power was limited (AUC ≈ 0.55). In the MSGB-negative subgroup (n=57), SGUS positivity (aOR = 1.51, p = 0.027) and fibrosis (aOR = 1.18, p = 0.040) were independently associated with pSS diagnosis and had the highest diagnostic performance (AUC = 0.666 and 0.621), whereas color Doppler signal and other extended histologic features showed limited diagnostic utility.

Conclusion: Diagnostic discordance between SGUS and MSGB is common in suspected pSS, with histologic positivity more strongly associated with diagnosis than SGUS findings alone. While OMERACT-based color Doppler ultrasound offered limited additional value in grayscale-negative patients, grayscale SGUS positivity and histologic fibrosis may help support the diagnosis in biopsy-negative cases. No significant clinical differences were found between discordant subgroups.

Background/Purpose: To evaluate the real-world, long-term effectiveness of rituximab (RTX) as rescue therapy in patients with primary Sjögren's syndrome-associated interstitial lung disease (pSS-ILD).

Methods: Multicentre observational retrospective longitudinal study of a cohort of pSS-ILD patients who initiated RTX due to progressive or refractory ILD despite treatment with glucocorticoids and conventional immunosuppressants.

Results: To date, 16 patients have been treated with RTX. The main demographic, clinical, functional, serological, and therapeutic characteristics of the entire cohort are summarised in Table 1.

Oxygen requirement (n = 13)	5 (38.46)
ILD treatment	
GC initial dose, mg; mean (SD)	26.9 (11.8)
Mycophenolate, n (%)	14 (87.5)
Rituximab, cycles; median [Q1-Q3]	2 [1-4]
antifibrotic,n (%)	4 (25)
Lung transplant, n (%)	2 (12.5)
ILD follow-up characteristics:	
Follow-up FVC, %; mean (SD)	82.91 (25.55)
Follow-up DLCO, %; mean (SD)	46.66 (14.10)
6 min walking distance, mts; mean (SD)	328.82 (136.65)
Progresive lung fibrosis criteria	8 (50)
CT follow-up	
Improvement	2 (16.66)
Stable	3 (25)
Worsening	7 (58.88)

The most frequent ILD pattern on high resolution CT-scan was Nonspecific interstitial pneumonia (NSIP) (88%), while lymphoid interstitial pneumonia (LIP) and combined pulmonary fibrosis and emphysema were each observed in one patient (6%). The median follow-up from ILD diagnosis to the last visit was 55.2 months (IQR: 30.3–69.2).

RTX was administered in combination with mycophenolate mofetil (31%), azathioprine (19%), or tacrolimus (13%), while one patient (6%) received RTX as monotherapy. Four patients (25%) were treated concurrently with antifibrotic agents (nintedanib, n=3; pirfenidone, n=1).

At last follow-up, 7 patients (44%) remained on RTX. Treatment was discontinued in 9 patients (56%) due to lack of efficacy (n=3; 19%), death (n=3; 19%), lung transplantation (n=2; 13%), or adverse events (n=1; 6%).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Among patients who continued RTX, mean declines in %FVC and %DLCO from ILD diagnosis to RTX initiation were –11.7% and –11.4%, respectively, followed by mean improvements of +7.8% (FVC) and +6.3% (DLCO) from RTX initiation to the last available follow-up. However, these improvements did not reach statistical significance (p=0.31 for FVC; p=0.34 for DLCO). Adverse events were reported in 5 patients (31%), mostly consisting of non-severe infections.

Conclusion: RTX achieved stabilisation or improvement in only 44% of patients, indicating limited overall effectiveness and underscoring the need for more effective therapeutic strategies in progressive pSS-ILD.

Session Title: (2290–2304) Sjögren's Disease – Basic & Clinical Science Poster III: Treatment and Trial Outcome Measures

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Ianalumab, a glycoengineered, fully human IgG1 mAb directed against B cell-activating factor (BAFF)-receptor (BAFF-R), targets B cells and their functions through dual mechanism of action: depletion of B cells through enhanced antibody-dependent cellular cytotoxicity and blockade of BAFF:BAFF-R–mediated signals. Here we present a

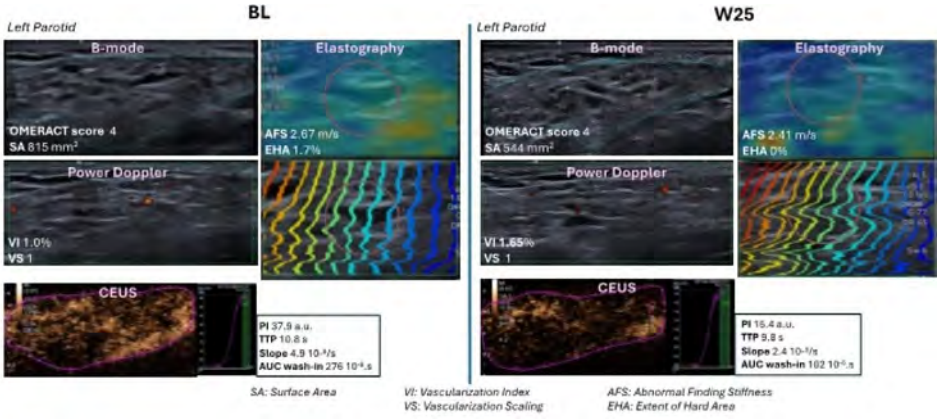

Figure 1. Multimodal SGUS from a single patient at BL and W25

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Mean (SD) SGUS parameters at BL and W25

Parameters		Baseline	W25
B-mode	OMERACT Score (0-4) PGs	2.53 (1.053)	2.12 (1.153)
	OMERACT Score (0-4) SMGs	2.24 (1.120)	2.00 (1.275)
	Surface Area (mm2) PGs	632 (143)	587 (166)
	Surface Area (mm2) SMGs	226 (75)	199 (65)
Doppler	Vascularization Index (%) PGs	2.86 (3.808)	1.34 (1.132)
	Vascularization Index (%) SMGs	5.44 (4.834)	4.13 (2.821)
	Vascularization Scaling (0-3) PGs	1.03 (0.672)	0.76 (0.752)
	Vascularization Scaling (0-3) SMGs	0.74 (1.017)	0.50 (0.771)
Stiffness	Stiffness Of Abnormal Finding (m/sec) PGs	2.55 (0.405)	2.45 (0.264)
	Stiffness Of Abnormal Finding (m/sec) SMGs	2.06 (0.358)	2.09 (0.424)
	Relative Hard Area (%) PGs	5.37 (8.740)	3.04 (4.569)
	Relative Hard Area (%) SMGs	0.99 (3.008)	1.08 (2.385)

PGs: Parotid glands; SMGs: Submandibular glands

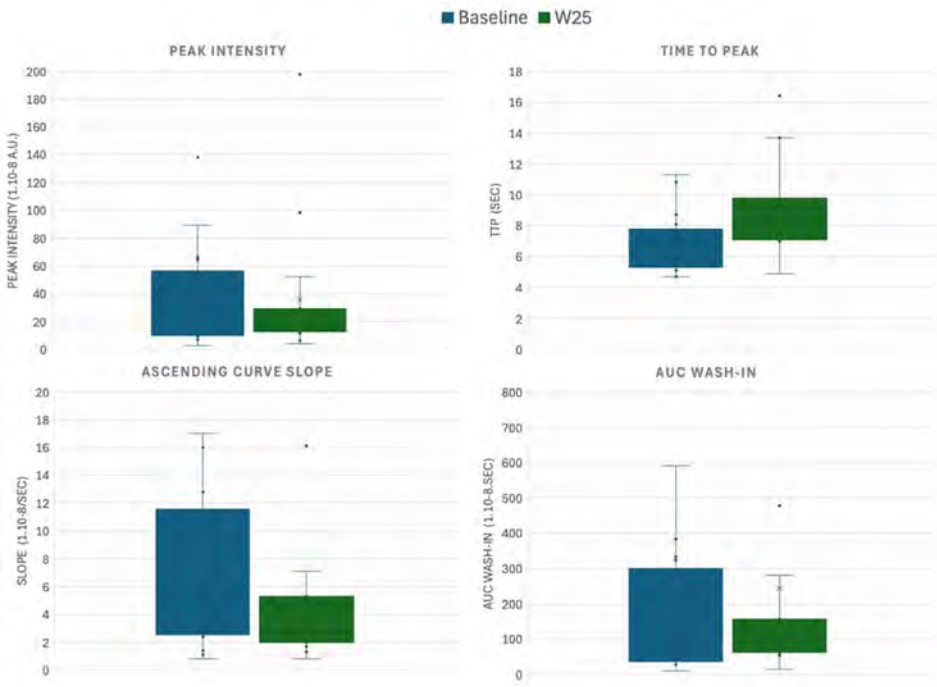

Figure 2. Left parotid CEUS parameters at BL and W25

multi-modal ultrasound (US) assessment of major salivary glands (SG) to better understand the mode of action of ianalumab on parotid (PGs) and submandibular glands (SMGs) in patients with Sjögren's disease (SjD).

Methods: This is an open-label, single-center, non-randomized, phase 2 mechanistic study (NCT05124925) with a 5-week screening period, a 6-month treatment period, and a follow up period of up to 2 years after the last dose. Eligible participants included those who fulfilled the 2016 ACR/EULAR classification criteria for SjD with anti-Ro/SSA autoantibodies, EULAR Sjögren's Syndrome Patient Reported Index score of ≥5, labial SG focus score (FS) of ≥0.3/4mm2, and B/B+T cell ratio of ≥0.2 at screening. This interim analysis reports the results of patients who completed the 24-week treatment period (ianalumab 300 mg monthly subcutaneous injection). As secondary outcome of the study, multimodal US assessment of major SGs was evaluated at W25 compared with BL. PGs and SMGs were assessed individually and analyzed by pairs for the following SGUS parameters: 1) B-mode (size and OMERACT score[1]), 2) Power Doppler (macrovascularization scaling and index), 3) contrast-enhanced US (CEUS) (microvascularization parameters derived from microbubbles injection for PGs only) and 4) sonoelastography (stiffness).

Results: In the safety analysis set (N=21), ianalumab was well-tolerated with no drug-related serious adverse events (AEs) and one AE leading to discontinuation. SGUS assessment and contrast agent administration were well tolerated. Overall, 17 participants completed the 24-week open-label treatment, underwent paired screening and W25 labial SG biopsy, and

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

were analyzed. **Figure 1** displays multimodal SGUS acquisitions from a single patient pre and post treatment. Overall, BL SGUS features indicated moderate glandular involvement, with mean OMERACT scores of 2.53 and 2.24, and Doppler Vascularization Scaling of 1.03 and 0.74, in PGs and SMGs, respectively (**Table 1**). At W25, B-mode, Doppler and CEUS vascularization and elastography stiffness parameters numerically decreased, and to a larger extent in the PGs compared with SMGs (**Table 1**). Notably, the mean OMERACT score reduced by -0.41 and -0.24, and the mean Doppler Scaling reduced by -0.26 and -0.24, in PGs and SMGs, respectively. The reduction in tissue perfusion was further supported by CEUS measurements derived from the time intensity curve observed in response to the microbubble injection, as shown for the left PGs in **Figure 2**.

Conclusion: Patients treated with ianalumab 300 mg monthly showed improvement in PGs structure and vascularization at W25 vs BL using multimodal ultrasound assessment. Innovative measures with CEUS display a good sensitivity to change after treatment and should be considered in future clinical trials.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2290–2304) Sjögren's Disease – Basic & Clinical Science Poster III: Treatment and Trial Outcome Measures

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Childhood Sjogren Disease (cSjD) is a rare disease that presents with a wide variety of symptoms. Compared to adult SjD, cSjD more frequently manifests with parotitis and glandular swelling. Despite causing marked morbidity and mortality, no treatments are currently approved for cSjD. In this work, we develop a personalized N-of-1 design to compare cSjD therapies. Our innovative design generates patient-level randomized evidence to inform individualized treatment decision and allows for evaluation of comparative effectiveness between drugs when aggregating data across participants. Moreover, to capture the full spectrum of the treatment effects on the multiple cSjD manifestations, we incorporate patient-prioritized outcomes in the design. The purpose of this abstract is to perform item development and reduction as

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

the next step to development of patient-focused outcome measures. Here, we present the tools we developed to elicit from patients how they rank outcome measures by importance.

Methods: To design surveys for patients, caregivers, and providers about cSjD symptoms, we systematically reviewed the literature to delineate common signs and symptoms of cSjD and to ensure we were not missing any major symptoms (item generation). We then compared this list to the ESSDAI, a validated outcome measure for adult SjD, which includes signs and a wide variety of symptoms, but does not emphasize those glandular features that are more prominent in cSjD. The resulting cSjD symptom survey was reviewed by research professionals and a patient/parent dyad engaged as research partners.

Results: The survey uses the Q-methodology that asks participants to sort 10 symptom domains in relation to each other according to a predetermined distribution. Participants can adjust their ranking until they are satisfied with the ordering of symptoms by importance. The Q-sort will be distributed to an online cSjD group that is validated by the parent of a cSjD patient and contains > 250 parents of children with cSjD and will also be disseminated via the Childhood Arthritis and Rheumatology Research Alliance (CARRA) which champions collaborative research to prevent, treat, and cure pediatric rheumatic disease. After two survey rounds, responses will be adjudicated at an in-person meeting to reach consensus on endpoint prioritization. Administration of the surveys and consensus meetings will be compliant with the Declaration of Helsinki.

Conclusion: An N-of-1 trial of two therapeutic agents will use these prioritized outcome measures to determine the efficacy of both agents with each patient serving as their own control. Data will be aggregated to determine if one or both agents meet the primary outcome, using either each personalized prioritized endpoint or the consensus-derived hierarchical endpoint. The trial will serve as a platform to evaluate additional agents in cSjD and other rare childhood rheumatic diseases.

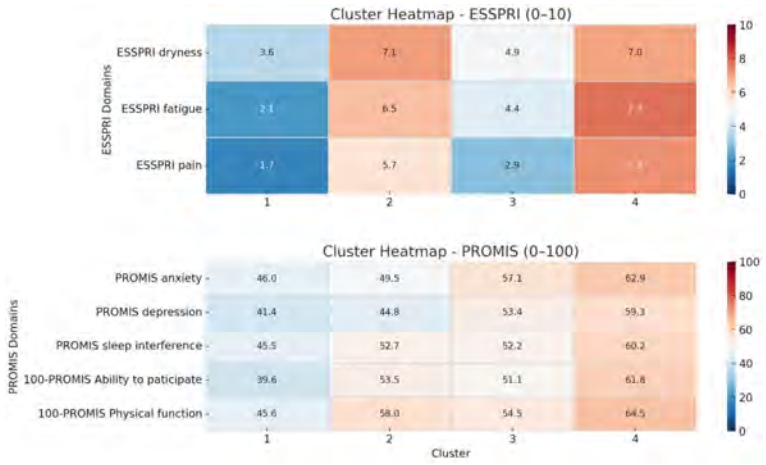

Figure 1:Heatmap of clusters 1-4. Average values of each PRO measure are shown. PROMIS Ability to Participate and Physical Function values are subtracted from 100 to reflect reverse significance.

Background/Purpose: Patient-reported outcomes (PROs) measure a patient's health-related quality of life. The role of ESSPRI and PROMIS measures in identifying subsets of patients with Sjogren's disease is not established and longitudinal stability of these measures has not been assessed. This study uses PRO-based clustering to define distinct patient populations and measure cluster attribution in individual patients over time.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

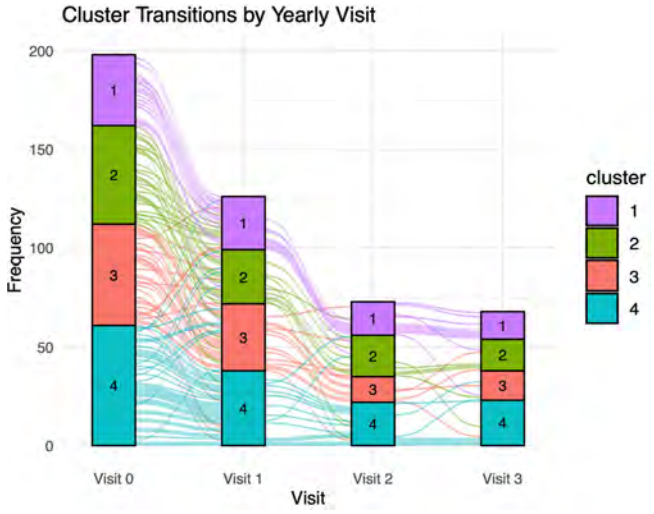

Figure 2: Alluvial plot demonstrating cluster attribution of individual patients over time.

Methods: Data from 467 patients meeting ACR2016 criteria for Sjogren's disease with at least 1 complete set of PRO data (ESSPRI Dryness/Fatigue and Pain and PROMIS Physical function/Ability to participate/Sleep Interference/Anxiety and Depression) were extracted from the Epic Electronic Health Record system. Baseline Clustering was completed using k-means clustering algorithm. For longitudinal analysis, an alluvial plot of 198 patients with at least two visits with complete PRO data was created to visualize transitions of patients between clusters. Statistical analysis between clusters was done using ANOVA, Chi-squared, and Fisher's exact tests.

Results: K-means algorithm identified 4 clusters of patients at baseline: cluster 1 (77/467; 16.5%), Low symptoms/high function (LSHF), cluster 2 (130/467; 27.8%), High symptoms/balanced function (HSBF), cluster 3 (116/467; 24.8%), Moderate symptoms/balanced function (MSBF), and cluster 4 (144/467; 30.8%), High symptoms/poor function (HSPF) (Figure 1). Demographic variables, including age, sex, and race, anti-SSA/Ro positivity, disease phenotypic markers and DMARD exposure did not differ between clusters (Table 1). Abnormal salivary flow was least frequent in the LSHF cluster (29/77; *p=0.008* by Chi-squared test). Abnormal Schirmer's and hypergammaglobulinemia were least frequent in the HSPF cluster (95/144;70.4% *p=0.012* and 40/144; 28.6% *p=0.025* by Chi-squared test, respectively). Longitudinal analysis of cluster stability in 198 patients over 2 to 4 visits demonstrated that most patients (54.0%) remained in the same cluster over time (Figure 2). Transitions between extreme clusters (LSHF and HSBF) were significantly less frequent than other transitions (3/35 vs 93/96; $p< 1X10^{22}$, Fisher's exact test).

Conclusion: ESSPRI and PROMIS measures define distinct clusters in patients with Sjogren's disease. Cluster attribution of individual patients remains relatively stable over time and changes between extreme clusters is rare. Prospective studies are needed to further define the relationship between cluster stability, disease flares and response to therapy.

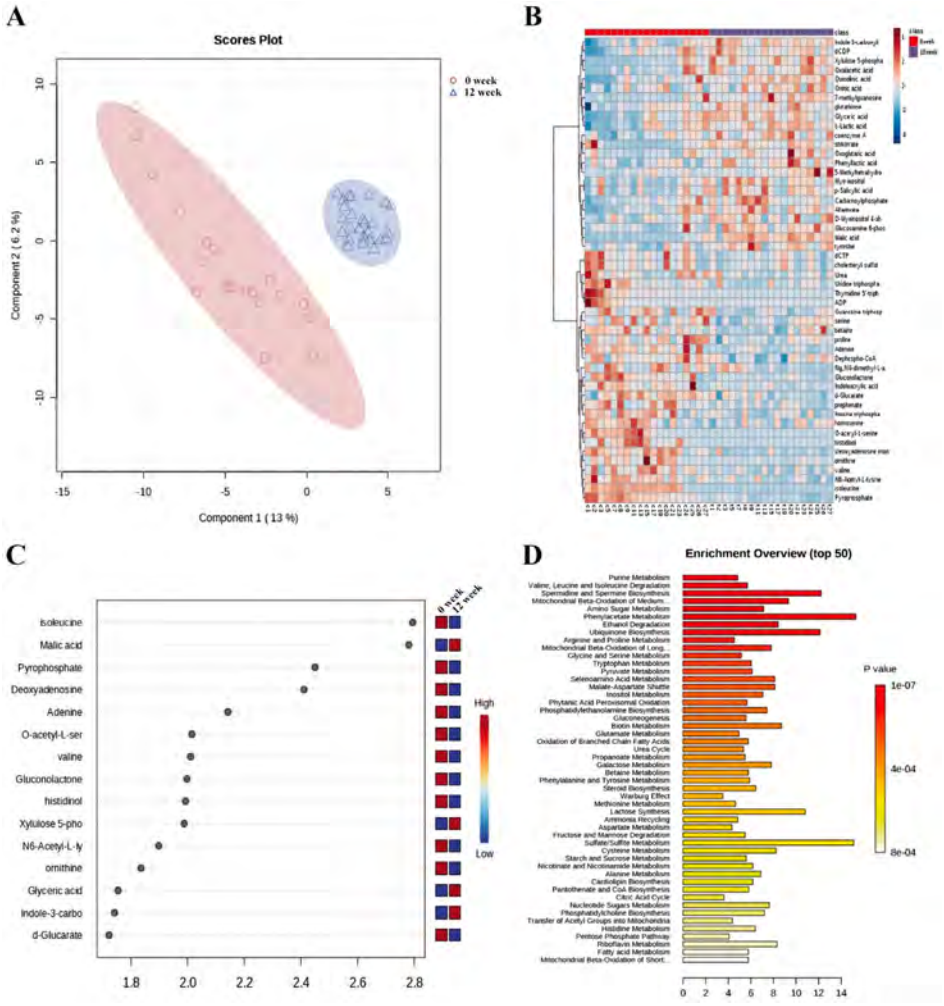
Session Date: Tuesday, October 28, 2025
Session Title: (2290–2304) Sjögren's Disease – Basic & Clinical Science Poster III: Treatment and Trial Outcome Measures
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Low-dose interleukin 2 (Ld-IL2) is increasingly being explored as an immune-modulating treatment for autoimmune diseases which mainly affect T cell subsets. This study investigates the metabolic effects of Ld-IL2 therapy in patients with primary Sjögren's disease (pSjD).

Methods: A total of 60 patients were recruited to conduct a double-blind, randomized clinical trial. Of these patients, 50% (30/60) received Ld-IL2 therapy along with standard treatment for 12 weeks, followed by 12 weeks of follow-up. The effectiveness was evaluated by Sjögren's Tool for Assessing Response (STAR). An untargeted analysis was performed to profile hydrophilic metabolites.

Results: Metabolic profiling revealed significant alterations post-treatment, notably in metabolites like acetyl-CoA, ascorbic acid, and glutathione, which are beneficial in managing autoimmune diseases. In addition, the levels of metabolite accumulation were correlated with variations in immune cell subsets ($p < 0.05$), particularly Tregs. Moreover, patients exhibiting a



Impact of Ld-IL2 on serum metabolites from pSjD patients.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Updates in the local treatments in Primary Sjögren's Syndrome "Efficacy and Safety"

Marta Ramírez[1], Maryia Nikitsina[2], Rym Abadi[3] and David A. Isenberg[4], [1]Univeristy Hospital Principe de Asturias, MADRID, Madrid, Spain, [2]University Hospital La Princesa, Madrid, Madrid, Madrid, Spain, [3]University College London, London, UK, London, England, United Kingdom, [4]University College London, London, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2290–2304) Sjögren's Disease – Basic & Clinical Science Poster III: Treatment and Trial Outcome Measures
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Primary Sjögren's syndrome (pSS) is a chronic autoimmune disease characterised by lymphocytic infiltration of exocrine glands, leading to sicca symptoms that severely impact quality of life. While systemic immunomodulatory therapies continue to evolve, local treatments remain the mainstay for symptom relief. This systematic literature review evaluated the efficacy and safety of currently available and emerging local interventions for dryness in ocular, oral, and other mucosal domains in pSS.

Methods: A systematic search was conducted across PubMed, Ovid Medline, and the Cochrane Library from 2010 to 2024. Eligible studies included randomised clinical trials, systematic reviews, and meta-analyses assessing local therapies for dryness symptoms in adult patients diagnosed with pSS according to 2016 ACR/EULAR criteria. Studies were screened based on pre-defined inclusion criteria, with a minimum sample size of 10 participants. Outcomes included both subjective symptom scores and objective measures of glandular function.

Results: Assessing a total of 44 trials of xeropthalmia it was evident that sodium hyaluronate with trehalose, lipid-based drops showed superior efficacy over standard artificial tears. Topical cyclosporine A, tacrolimus, and low-potency corticosteroids were effective in moderate to severe cases, while biologic tear substitutes (e.g., autologous for ocular dryness serum, PRP) demonstrated potential in refractory disease. Novel agents such as lifitegrast, diquafosol, and lacritin reported favourable results with minimal adverse effects. In the management of xerostomia, pilocarpine and cevimeline improved salivary output (pilocarpine concentrations significantly increased whole salivary flow compared to placebo ($p < 0.01$)) and symptom perception (but were limited by systemic adverse effects. Non-pharmacologic approaches—including xylitol-based lozenges, malic acid tablets, mentholated gum, and intraoral electrostimulation devices—proved beneficial in selected patients with residual gland function. Saliva substitutes, while safe, provided only short-lived relief and were often limited by palatability or low adherence. For dryness in other mucosal domains (nasal, vaginal, pharyngeal), evidence remains sparse and largely empirical.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Conclusion: Local therapies remain a cornerstone in the management of sicca symptoms in pSS, particularly given the limited access to systemic immunomodulatory drugs. While several interventions demonstrated promising efficacy and safety profiles, most evidence was derived from small, heterogeneous studies. Further research is needed to establish standardised outcome measures, clarify long-term benefits, and guide personalised therapeutic strategies.

Background/Purpose: Patients with psoriasis and psoriatic arthritis (PsA) are at increased risk for metabolic comorbidities and poorer long-term outcomes compared to the general population. Identifying patients at risk for adverse outcomes can facilitate targeted interventions to improve quality of life.This study aimed to evaluate the risk of hospitalization and emergency department (ED) visits among adults with psoriatic disease and identify predictors of these outcomes.

Methods: We utilized data from the Forward Psoriasis Registry, a cohort recruited from U.S. dermatology practices, two academic institutions, and the Forward registry website. Participants enrolled between August 2023 and March 2025 completed baseline and monthly surveys, with longer assessments every six months. Surveys included comorbidity data, psoriasis severity (measured by the Patient Report of Extent of Psoriasis Involvement [PREPI]), patient-reported outcomes (Psoriasis Symptoms and Signs Diary [PSSD]), medication changes, and adverse events, including hospitalization and ED visits. Participants with psoriasis (with or without PsA) who completed enrollment and had at least one follow-up visit were included. We report baseline demographics, disease characteristics, treatments, and comorbidities. Cox proportional hazards models were used to identify predictors of hospitalization and ED visits, with a multivariable model developed using purposeful selection modeling.

Results: ong 2,606 enrollees, 1,354 had at least one follow-up visit, with a mean follow-up time of 213 days (SD 145). The cohort had a mean age of 51 years (SD 16), 66% were female, and 56% were from the southern United States. Most had mild to moderate psoriasis (23% with < 1% BSA, 40% with 1-2% BSA, 30% with 3-10% BSA, and 6% with >10% BSA). A total of 135 participants experienced an ED visit (incidence 0.18 per person-year), and 59 were hospitalized (incidence 0.08 per person-year). Predictors of ED visits and hospitalization were similar. Lower psoriasis severity (< 1% BSA) was

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

associated with the lowest risk for both outcomes. Higher PSSD scores, depression, and female sex were significantly associated with increased risk. Although a diagnosis of ADHD was initially significant, it was removed from the final model due to lack of consistency.

Conclusion: In this cohort with psoriatic disease, predictors of hospitalization and ED visits included higher PSSD scores, depression, and female sex. The PSSD, a patient-reported outcome, demonstrated predictive value beyond the psoriasis severity measured by body surface area, underscoring the importance of patient-reported outcomes in assessing disease impact.

Abstract Number: 2306

Prevalence and Clinical Significance of the Gastrointestinal Fat Halo Sign in Patients with Psoriatic Arthritis: A Cross-Sectional Study

Amir Haddad[1], Kathrien Mousa[1], Kateryna Milman[1], Najwan Nassrallah[1], Devy Zisman[2] and Sharbell Hashoul[3], [1]Carmel Medical Centre, Haifa, Israel, [2]Carmel Medical Center, Haifa, Israel, [3]The Faculty of Humanities and Social Sciences. Uno Academic College, Haifa, Israel

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2305–2337) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The existence of a gut-joint axis is widely described in spondyloarthritis, linking intestinal dysbiosis, subclinical gut inflammation, and arthritis. The fat halo sign is believed to arise from chronic inflammation, leading to transmural edema and infiltration of the bowel wall by inflammatory cells and fat. This radiologic finding has a high prevalence in patients with inflammatory bowel disease(IBD). This study aims to define the prevalence of the fat halo sign in a well-defined cohort of patients with psoriatic arthritis (PsA) and assess its potential clinical significance.

Methods: This is a cross-sectional study involving PsA patients followed prospectively from a collaborative site of an international cohort. All patients fulfilled the CASPAR criteria. Patients who have undergone routine abdominal CT scan for various clinical indications constituted the study population. Two radiologists have independently recorded the presence of the fat halo sign in the stomach, terminal ileum, and the ascending/transverse/descending colon and rectum. Demographics and disease characteristics of patients with positive fat halo were compared to patients without fat halo using descriptive statistics as appropriate.

Results: Of the 328 patients followed, 101 completed an abdominal CT scan. The mean age was 63.7±15 of whom 49 (48.5%) were males with a disease duration of 8.4±8.7 years, 19% on non-steroidal anti-inflammatory drugs, 55% were on disease-modifying anti-rheumatic drugs and 57% were on biologics. 3.9% had a history of IBD, and 4.2% had a history of uveitis. 38/101 (37.6%) patients had a positive halo sign in at least one section (as illustrated in Figures 1 and 2). The presence of halo sign was more common in males (65.8 vs. 31.8%, p=0.007) and more likely in patients with nail lesions (31.6 vs 15.9%, p=0.06). Other patient's demographic and disease characteristics, disease activity parameters and treatment regimen were not statistically different.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Contrast-enhanced coronal CT image shows fatty infiltration within the bowel wall of the descending colon at the level of the left colic flexure.

Non-contrast axial CT image shows fatty infiltration within the bowel wall of the ascending colon at the level of the right colic flexure

Conclusion: Fat halo is common in patients with psoriatic arthritis and was observed in 38% of patients, of whom only a minority had IBD. It was more frequent in males, however, not associated with any of other patient's demographics, disease characteristics, disease activity parameters or treatment regimen.

Peripheral Manifestations In Axial And Peripheral Spondyloarthritis: A Systematic Literature Review On Their Assessment In Clinical Trials

AUGUSTA ORTOLAN[1], Casper Webers[2], Elena Nikiphorou[3], Alexandre Sepriano[4], Louise Falzon[5], Clementina López Medina[6], Dafne capelusnik[7], Désirée Van Der Heijde[8], Anna Molto[9] and Sofia Ramiro[10], [1]Policlinico Universitario Agostino Gemelli IRCSS, Rome, Italy, [2]Maastricht University Medical Centre, Maastricht, Netherlands, [3]King's College London, London, United Kingdom, [4]Department of Rheumatology, Leiden University Medical Centre, Portela Loures, Portugal, [5]Sheffield Centre for Health and Related Research, University of Sheffield, Sheffield, United Kingdom, [6]Department of Medicine, Hospital Universitario Reina Sofia, University of Cordoba, IMIBIC, Cordoba, Spain, [7]Tel Aviv Sourasky Medical Center, Ramat Gan, Israel, [8]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [9]Assistance Publique Hôpitauxde Paris, Paris, France, [10]Leiden University Medical Center, Bunde, Netherlands

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2305–2337) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Peripheral manifestations (peripheral arthritis, enthesitis, dactylitis) of axial spondyloarthritis (axSpA) and peripheral spondyloarthritis (pSpA) represent a significant burden for patients, but are understudied. Our aim was to evaluate the frequency of 1) assessment and reporting of peripheral manifestations in clinical trials of axSpA and pSpA (psoriatic arthritis excluded) 2) use of specific instruments for each peripheral manifestation.

Methods: A systematic literature review (SLR) was carried out, starting from available SLRs conducted for the 2016/2022 updates of the ASAS-EULAR axSpA management recommendations (≤2021).[1-3] The search was updated to March 2024 (PROSPERO CRD42024532666). The research question followed the PICOT framework: Population: adult patients with axSpA or pSpA; Intervention: biological and targeted synthetic DMARDs; Comparator: active comparator, placebo; Outcomes: Frequency of assessment of each peripheral manifestation, and of use of various specific instruments (e.g swollen joint count [SJC] for arthritis); Type of studies: randomised controlled trials (RCTs), controlled clinical trials. Study protocols, if available, or trial descriptions from ClinicalTrials.gov were checked for information on peripheral manifestations assessment. Risk of bias (RoB) was assessed by the Cochrane tool. For synthesis, descriptive statistics were used.

Results: In total, 100 trials were included for axSpA and 4 for pSpA (55 and 2 at low RoB, respectively). In axSpA, n=54 trials assessed peripheral arthritis, n=64 enthesitis and n=10 dactylitis. Not all of the studies actually reported these results, and only few addressed the subpopulation with the peripheral manifestation at baseline (**Fig 1**). The most frequently used instruments for peripheral arthritis (out of n=54) were SJC based on 44 (50%), 66 (11%) and 64 (9%) joints, and tender joint counts (TJC) based on 44 (24%), 46 (15%) and 68 (11%) joints. No studies assessed composite scores involving joint counts (e.g. DAS). For enthesitis (n=64 trials), the majority of studies used the MASES (87%), followed by the SPARCC enthesitis index (11%), question 4 of the BASDAI (8%) and the LEI (3%). The main instrument used for dactylitis was digit count (4/10, 10%); in 3/10 trials dactylitis was collected as adverse event. There was a tendency towards a higher frequency of reporting, and reporting in subpopulations with peripheral manifestations, in RCTs at lower RoB (**Fig 2**). In pSpA, all 4 trials assessed (and reported on) peripheral arthritis; 2 also assessed enthesitis and dactylitis.

Conclusion: In axSpA, peripheral manifestations were assessed as outcome in less than 2/3 of trials. The most frequently used instruments were SJC and TJC for peripheral arthritis, MASES for enthesitis and digit count for dactylitis. Outcomes were typically not reported in the subpopulation with known peripheral arthritis/enthesitis/dactylitis at baseline.

Session Title: (2305–2337) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Health-related quality of life (HRQoL) is an overarching outcome in axial spondyloarthritis (axSpA), and is considered influenced by disease activity and physical function. However, this relationship has never been demonstrated in a longitudinal framework. The impact of disease activity on HRQoL may be either direct, or occur indirectly by

Table 1. Mediation analysis considering a direct and indirect (mediated by function, BASFI) effect of disease activity (ASDAS) on HRQoL, according to the main mediation hypothesis (ASDAS and BASFI influence HRQoL one year later)

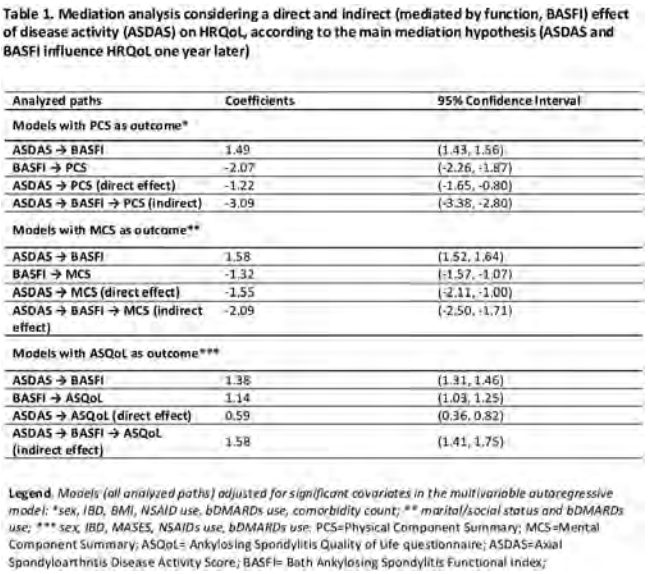

Table 1. Mediation analysis considering a direct and indirect (mediated by function, BASFI) effect of disease activity (ASDAS) on HRQoL, according to the main mediation hypothesis (ASDAS and BASFI influence HRQoL one year later)

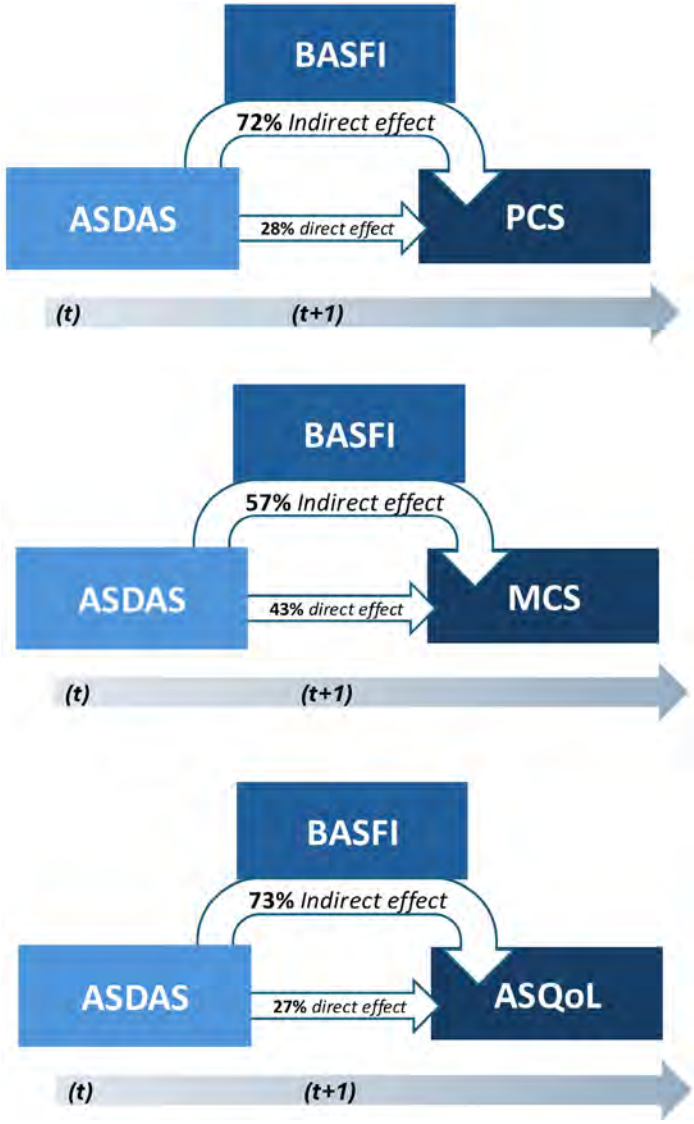

Figure 1. Mediation structure, with estimation of direct and indirect effects Legend. t = time point; t+1 = time point plus 1 year

worsening physical function. The aim of this study was to investigate whether the effect of disease activity on HRQoL is primarily direct or mediated by physical function over time in early axSpA.

Methods: AxSpA patients from the DESIR cohort were analysed over 10 years of follow-up. Disease activity (assessed by the Ankylosing Spondylitis Disease Activity Score, ASDAS), physical function (Bath Ankylosing Spondylitis Functional Index, BASFI), and HRQoL outcomes (Physical Component Summary [PCS] and Mental Component Summary [MCS] of the SF-36, with higher values representing better HRQoL, and Ankylosing Spondylitis Quality of Life [ASQoL], with higher values corresponding to worse HRQoL) were assessed. Structural equation modeling (SEM) was performed to assess mediation, including direct and indirect (i.e. mediated) effects of disease activity on HRQoL. The hypothesis regarding mediation was that ASDAS and BASFI (assessed at the same time point) impact HRQoL at a subsequent time point (ie one year later). All models were adjusted for significant covariates (eg sex, marital/social status, BMI, NSAID use, bDMARDs use, enthesitis, IBD, comorbidity count) .Results are presented as beta coefficient (95% confidence intervals).

Results: A total of 663 patients were analysed, 46% males, mean age 33.5 (8.6) years. At 10 years, both ASDAS and BASFI were on the low range (ASDAS 2.0 [1.0] BASFI 2.3 [2.2]), and QoL scores were moderate at the group level (PCS 42.9 [10.4], MCS 45.0 [10.5], ASQoL 6.5 [5.5]). BASFI significantly mediated the association between ASDAS and HRQoL (**Table 1**).

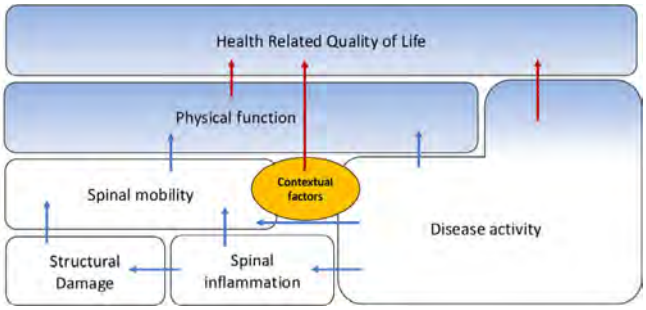

Figure 2. Longitudinal framework with Health Related Quality of Life as the overarching outcome Legend. The shadowed blocks represent the main variables of interest for this analysis. Red arrows represent the longitudinal relationships clarified by this current analysis. Blue arrows represent (longitudinal) associations previously described in the literature.

The indirect effects through BASFI were consistently larger than the direct effects. For PCS, the indirect effect was -3.09 (-3.38,-2.80) and the direct effect was -1.22 (-1.65,-0.80). For MCS, the indirect effect was -2.09 (-2.50,-1.71) versus a direct effect of -1.55 (-2.11,-1.00). For ASQoL, the indirect effect was 1.58 (1.41,1.75) and the direct effect was 0.59 (0.36, 0.82). Despite the majority of the effect of ASDAS on HRQoL being mediated, about a quarter of the effect was direct (**Figure 1**). These findings confirm HRQoL as a higher-order outcome, supported by its longitudinal association with both ASDAS and BASFI. We then propose a model of disease outcomes in axSpA, with proven longitudinal relationships (**Figure 2**).

Conclusion: In early axSpA, disease activity impacts HRQoL mainly through its negative influence on physical function; however a direct, independent effect also exists. These findings reinforce the hierarchical model of disease outcomes and emphasize the central role of targeting disease activity to optimize HRQoL, through its direct and indirect effects.

Table 1. Multivariable associations between baseline lifestyle risk score and one year PsA disease activity

	β, 95%CI	P-value
PASDAS	**0.15 (0.08, 0.23)**	**<0.0001**
DAPSA	**1.18 (0.65, 1.71)**	**<0.0001**
	OR, 95%CI	P-value
PASDAS-LDA	**0.59 (0.45, 0.77)**	**<0.0001**
DAPSA-LDA	**0.74 (0.59, 0.92)**	**0.009**
PASDAS remission	0.77 (0.55, 1.07)	0.123
DAPSA remission	0.76 (0.58, 1.01)	0.059
MDA	**0.72 (0.57, 0.90)**	**0.004**

Number of patients with at least one disease activity measurement during follow-up: PASDAS, n=642; DAPSA, n=773; MDA, n=837. Abbreviations: DAPSA, Disease Activity index for Psoriatic Arthritis; LDA, low disease activity; MDA, minimal disease activity; PASDAS, Psoriatic Arthritis Disease Activity Score.
Model adjusted for baseline disease activity, study visit, age, sex, geographic origin, education, and medication.
Covariates are imputed using mice predictive mean matching and classification and regression trees (pmm and CART; M=20)

Background/Purpose: Comprehensive assessment of multiple lifestyle behaviours and disease activity outcomes in psoriatic arthritis (PsA) is scarce. We aim to investigate lifestyle behaviours in patients with PsA and their association with disease activity measurements.

Methods: This multicenter cohort included 938 patients newly diagnosed with PsA from the DEPAR study, between 2013 and 2023. Lifestyle behaviours were assessed at baseline and included: body mass index (BMI), waist circumference, smoking, alcohol consumption and physical activity. A comprehensive lifestyle risk score was calculated (range 0 to 5) using these five lifestyle behaviours (BMI outside normal range, abdominal obesity, current smoking, no alcohol consumption, physical inactivity), with higher scores indicating more risk behaviours. No specific treatment protocols were applied. Disease activity was assessed every three months over the course of one year and included: Psoriatic Arthritis Disease Activity Score (PASDAS), disease activity in psoriatic arthritis (DAPSA), PASDAS and DAPSA low disease activity (LDA) and remission, and minimal disease activity (MDA). The associations between the lifestyle risk score and disease activity were analyzed using mixed models adjusted for baseline disease activity, study visit, age, sex, geographic origin, education and medication. Multiple imputations to handle missing data for all covariates were performed in R (version 4.4.2) using mice predictive mean matching and classification and regression trees (pmm and CART; M=20).

Results: The rate of overweight/obesity was 72%, abdominal obesity was 39% in men and 64% in women, current smoking was 22% (of them 41% classified as moderate-to-heavy smoking (>10 cigarettes per day)), and alcohol consumption was 82% (of them 22% classified as heavy consumption) with 3% of patients physically inactive. Using multivariable analyses, a higher lifestyle risk score was associated with higher PASDAS (βadj 0.15; 95%CI 0.08, 0.23), and lower odds for achieving PASDAS-LDA (ORadj 0.59; 95%CI 0.45, 0.77), and MDA (OR adj 0.72; 95%CI 0.57, 0.90) at one year of follow-up. Similar associations were observed for DAPSA and DAPSA-LDA. Analysis of individual lifestyle behaviours showed that obesity, abdominal obesity and moderate-to-heavy current smoking, were also significantly associated with higher PASDAS and DAPSA, and lower odds for achieving PASDAS-LDA and MDA.

Conclusion: Lifestyle behaviours seem to influence one year disease activity in PsA. Adiposity and smoking were associated with higher disease activity. Patients newly diagnosed with PsA also showed unhealthy lifestyle behaviours.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2305–2337) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: NGFβ and CGRP are neuropeptides with a significant role in peripheral inflammation, pain modulation and immune responses. Neuropeptides regulatory mechanisms in spondyloarthritis (SpA) remain poorly characterized, however, they may influence inflammatory processes indirectly through immune system modulation. Notably, their interaction with cytokines may contribute to chronic inflammation and heightened pain sensitivity observed in SpA.

Aim: to evaluate the association of NGFβ and CGRP serum levels with nociception, immune system modulation and clinical Spa activity.

Methods: A longitudinal, observational prospective study with evaluations at baseline and 2 months follow-up in SpA patients initiating biological therapy (BT) was performed. In SpA patients complete laboratory test, BASFI, BASDAI, HAQ and VAS pain scale and ASDAS score in each visit was carried out. We analyzed by colorimetric methods cytokine (TNFa,

Variable	Healthy controls N=67	SpA patients V0 N=69	SpA patients V1 N=69	P-Value SpA vs HC	P-Value V0 vs V1
	Mean (SD) / n(%)	Mean (SD) / n(%)	Mean (SD) / n(%)		
CGRP	84.22 (74.52)	279.64 (633.57)	289.18 (634.37)	<0.001

Table. Clinical activity and molecule levels throughout the follow-up

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

IFNg, IL2, IL10, IL17a and IL23) and neuropeptide (CGRP and NGFb) serum levels in SpA patients and in healthy controls (HC).

Results: 69 SpA patients (65.2% male) were recruited with a mean age of 48 (12) years and a mean time of disease evolution of 7 (8) years. 67 HC with a mean age of 45 (13) years (43.2% male) were also recruited. At baseline the 39.1% of patients showed elevation of CRP and the 21.7% ESR. The 86.9% displayed high/very high clinical activity by ASDAS score. The 66.7% were under anti-TNF therapy and 33.3% under anti-IL17 treatment, the 31.9% with previous BT administered, 21.7% treated with DMARDs and 4.4% with corticoids.

There are significant differences in the analyzed molecules levels between patients and HC (table). Age and sex do not appear to influence molecule levels.

CGRP and NGFb showed no correlation and no differences during the follow-up. No association between neuropeptide levels and clinical activity was found, but a tendency where incremented CGRP was associated to low HAQ (P=0.06) and incremented NGFb was associated to low pain perception (P=0.06) was observed.

Analyzing the neuropeptides influence on cytokines, high CGRP and NGFb levels were related to high IL10 levels (P=0.047 and P=0.005) and low IL2 levels (P=0.003 and P=0.025). Moreover high CGRP was associated to low IFNg (P=0.002).

Differences in cytokine levels during the follow-up were only seen for IL17a (P=0.003) and TNFa (P< 0.001), as well as a decrease of CRP and ESR levels (P< 0.001), VAS pain (P=0.009), BASDAI (P=0.006) and ASDAS score (P< 0.001). Clinical activity was associated to IFNg (P=0.038) and IL17a (P=0.005) levels, and elevated ESR with high IL2 (P=0.019).

Related to BT, patients treated with anti-TNF showed low TNF levels (P=0.006) and those treated with anti-IL17 showed low IL17a levels (P=0.008).
