Methods: Consented participants (40-75 years, Kellgren Lawrence grades 2-3, target knee pain WOMAC ≥20/50) were randomized (1:1:1:1:1) into five groups: (1: n=12) GNSC-001 $1x10^{12}$ vector genomes (vg); (2: n=11)) GNSC-001 $1x10^{12}$ vg + oral CS (prednisone 60mg/day tapered over 6 weeks); (3: n=10) GNSC-001 $1x10^{13}$ vg; (4: n=10) GNSC-001 $1x10^{13}$ vg + oral CS and (5: n=10) placebo (PBO). An open-label group (6: n=14) with target knee effusions at baseline, received GNSC-001 $1x10^{13}$ vg with IA methylprednisolone (80mg) plus oral prednisone (60mg/day for 3 days). All subjects received ultrasound-guided IA injections on Day 1. Visits, including synovial fluid (SF) draws to measure IL-1Ra expression and exploratory patient reported outcomes (PROs) occurred at Months 1, 3, 6, and 12, with planned 48-month safety follow-up.

Table 2: IL-1Ra Expression. Numbers denote % subjects expressing IL-1Ra in synovial fluid in target range (>500pg/ml)

Time following GNSC-001 injection	Placebo (N=10)	GNSC-001 (1*10^12 vg) (N=12)	GNSC-001 (1*10^12 vg, steroids) (N=11)	GNSC-001 (1*10^13 vg) (N=10)	GNSC-001 (1*10^13 vg, steroids) (N=10)	GNSC-001 (1*10^13 vg, steroids IA) (N=14)
Baseline	0	0	25	0	0	0
1 month	0	50	83	20	100	92
3 months	0	67	88	17	100	83
6 months	0	75	86	14	80	92
12 months	0	67	86	0	100	71

Results: At study completion (Month 12), 67 subjects (78% female, mean age 60.9 ± 8.5 years, mean BMI 28.6 ± 4.3 kg/m^2) had been dosed across the 6 groups. No deaths or related treatment-emergent serious adverse events were reported. Treatment-Emergent Adverse Events (TEAEs) were balanced in Groups 1-5, trending higher in Group 6. Target knee AEs (TKAEs) across Groups 1-6 were mostly mild-moderate, with one graded as a 'severe' event (recurrent knee effusion in Group 6). TKAEs included arthralgia, swelling, effusion, and stiffness. TEAEs and TKAEs at 12 months are summarized in Table 1. GNSC-001 treated groups 1, 2, 4 and 5 had elevated SF IL-1Ra levels compared to baseline and PBO (Table 2). PROs in GNSC-001 treated groups showed sustained improvement from baseline in most subjects.

Conclusion: This trial met its primary and secondary objectives, with GNSC-001 demonstrating a favorable safety profile and sustained IL-1Ra expression in SF. Corticosteroid immune conditioning was associated with increased IL-1Ra expression. Exploratory PROs in GNSC-001 treated groups showed improvements from baseline in a majority of subjects. These data support further clinical development of GNSC-001 as a promising therapeutic strategy addressing unmet clinical needs for treatment of knee OA.

Abstract Number: 0311

Time series analysis of continuous accelerometry data to determine the impact of symptomatic multiple joint osteoarthritis (MJOA) in the naturally occurring canine model

Elizabeth Kawecki-Wright[1], **Liubov Arbeeva**[2], Christina Stevens[1], Masataka Enomoto[1], Amanda Nelson[3], Margaret Gruen[1] and Duncan Lascelles[1], [1]North Carolina State University, RALEIGH, NC, [2]University of North Carolina, Chapel Hill, Carrboro, NC, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC

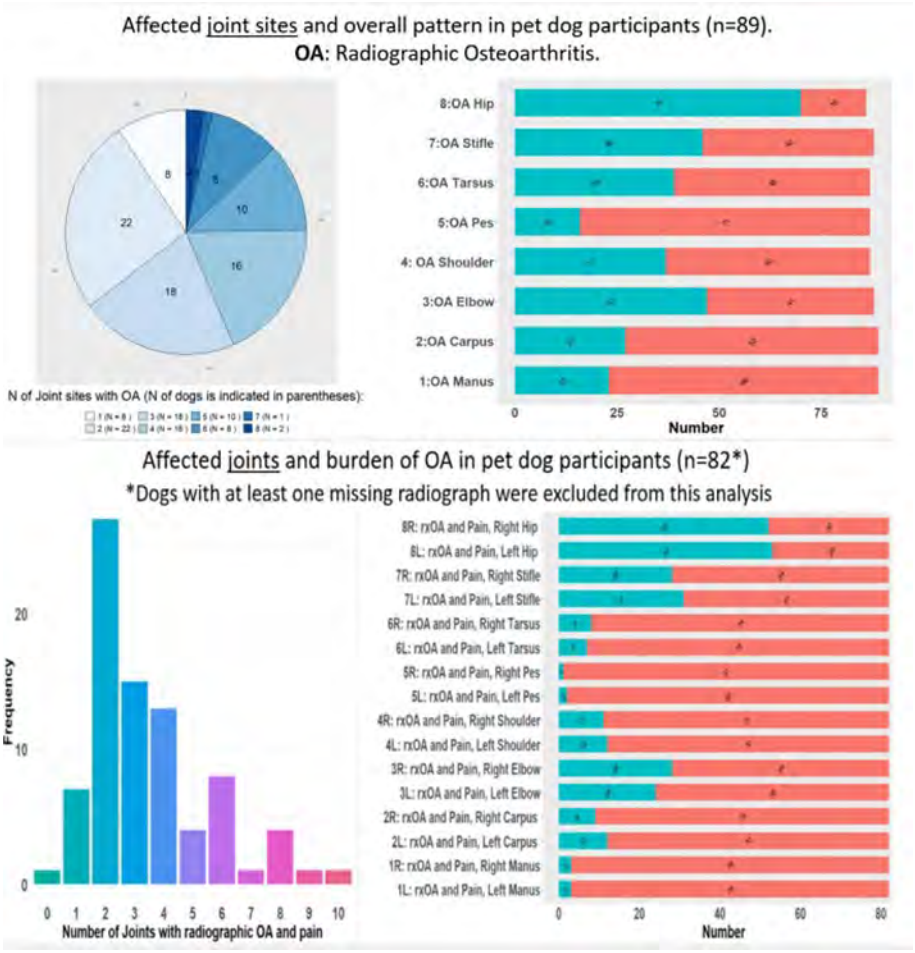
SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0306–0336) Osteoarthritis – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Pet dogs are a promising translational model for naturally occurring multiple joint osteoarthritis (MJOA). We characterized the impact of symptomatic (sx) MJOA, over the non-MJOA phenotype, on weekday physical activity (PA) patterns in pet dogs with OA pain using accelerometer-based data.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Full-body radiographs and orthopedic assessments were collected from pet dogs with evidence of OA (N=99). MJOA was defined as radiographic OA (rxOA) in 3+ unique appendicular joint sites (bilateral joints=single site) with at least one painful rxOA joint. Missing radiographs were allowed if N of OA joint sites from available images was >=3. Burden of OA was defined only for dogs with complete radiographs as the total number of **joints** with both OA **and** pain. Dogs wore a collar-mounted activity monitor (Actigraph GT3X) for at least 7 days. Per minute average vector magnitudes were recorded on weekdays and used to create composite 24-h PA profiles. Function on scalar regression (FoSR) was used to examine the association of 24-h PA (outcome) with MJOA and with burden of OA (total number of **joints** with both OA **and** pain) adjusting for age and body condition score (BCS). Coefficients and 95% confidence intervals (CIs) are interpreted analogously to a simple linear regression but **estimated per minute**. To provide an intuitive interpretation, we created the "averaged" coefficients and 95% CIs by integrating the beta and CI curves over time.

Results: Of 99 dogs, 89 had sufficient data to define MJOA and were included (48% male, 52% female, mean age 9 years). Fifty-nine (66%) dogs had MJOA; distribution of joints is shown in **Fig1**. All dogs with rxMJOA were symptomatic (sxMJOA). Age, BCS, and MJOA had negative effects on PA patterns (averaged βs [95% CIs]: -0.40 [-0.44, -0.35], -0.52 [-0.67, -0.37], and -0.86 [-1.19, -0.54]**)**. **Fig2A** shows 24-h average activity. Dogs without MJOA (red line) showed higher activity during peak hours. The CIs were below 0 from 3 am to 2 pm and from 6 pm to ~11 pm, suggesting that dogs with MJOA (blue line) are less active than those without in these time windows. The coefficient function and CI for MJOA and age were below 0 during most of the 24-h period, suggesting older dogs and those with MJOA are less active (**Fig2B**). A short period of PA around and after midnight in older dogs and those with MJOA (curves and CIs above the green line) suggests pain-related sleep interference. Similarly, dogs with higher OA-pain burden (n=82 dogs with complete radiographs) displayed less



Radiographic OA and painful joints and joint sites in client canine population.

23265203, 2025, S9, Downloaded from https://acvjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Comparison of mean activity distributions between dogs with and without multiple joint osteoarthritis (MJOA) over time. The green lines correspond to beta=0, which indicates that there is no difference between groups at the corresponding time point.

Estimated mean activity in dogs with different N of joints with rxOA and pain (<4 and >=4) and estimated coefficient function for OA burden derived from the function on scalar regression model of accelerometer data on continuous N of joints adjusted forage and BCS. The green line corresponds to beta=0, which indicates that there is no effect of OA burden on PA at the corresponding time point.

PA during daytime hours **(Fig3)**. These associations were not seen when data were collapsed to average per-minute activity (averaged β [95% CIs]: -0.01 [-0.09, -0.07]).

Conclusion: Analysis of 24-h PA patterns clearly demonstrates the negative influence of MJOA on weekday PA, as well as the greater negative influence on PA patterns when more OA joints are painful. If similar effects are seen in humans with symptomatic MJOA, our results would further support the use of the naturally occurring pet dog model of OA pain, and of PA patterns as a clinically relevant outcome measure. The FoSR approach to evaluating PA patterns identified timeframes with lower PA in dogs with MJOA which were not evident if sum scores of PA were used.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0306–0336) Osteoarthritis – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Juvenile idiopathic arthritis (JIA) encompasses various chronic inflammatory conditions in children that lead to joint discomfort and potential disability. Tocilizumab, an antibody targeting interleukin-6, has shown effectiveness in treating rheumatoid arthritis and may also help children with JIA. Due to the distinct characteristics of the disease, its efficacy and safety in children require assessment.

Methods: A systematic literature review was conducted by searching PUBMED, EMBASE, COCHRANE, SCIENCE DIRECT, and SCOPUS for RCTs and non-RCTs assessing the efficacy and safety of Tocilizumab in Juvenile Idiopathic Arthritis up to 2025. The primary outcomes assessed were disease activity improvement, joint inflammation reduction, Functional enhancements (i.e., CHAQ score), and QOL scores. Statistical analysis was conducted in R (v2025.05.0+496).

Results: A meta-analysis involving 11 studies with a total of 929 children diagnosed with Juvenile Idiopathic Arthritis (JIA) indicated that Tocilizumab led to improved disease activity, achieving a pooled risk ratio of 3.77 (95% CI 2.32-6.13, p=0.060) when compared to the control group. When examining study types, the subgroup analysis revealed proportions of 0.04 (95% CI 0.03-0.07) for non-RCTs and 0.10 (95% CI 0.07-0.14) for RCTs (p=0.0040). The average Childhood Health Assessment Questionnaire (CHAQ) score was 1.67, indicating functional improvement; the quality of life score was 45.74. In terms of JIA subtypes, the proportions were 0.11 (95% CI 0.06-0.18) for polyarticular JIA and 0.06 (95% CI 0.04-0.08) for systemic JIA (p=0.0502). Adverse events were reported in 7% of the participants (pooled proportion 0.07, 95% CI 0.05-0.09), primarily mild infections, with no serious adverse events noted. Sensitivity analysis demonstrated the stability of the results (range 0.06-0.07), with moderate heterogeneity (I^2=48.8%).

Conclusion: Our findings support using Tocilizumab in managing Juvenile Idiopathic Arthritis, demonstrating improved outcomes without significantly increasing adverse events. These results offer a clearer understanding of its clinical value and underscore the need for further high-quality randomized trials.

People with Knee Osteoarthritis Infrequently Seek Medical Care for Arthritis, Even Those With Severe Disease

Grace Lo[1], **Shunshun Yan**[2], Julieann Patarini[3], Timothy McAlington[4], Charles Eaton[5] and Jeffrey Driban[6], [1]Baylor College of Medicine / MEDVAMC, Houston, TX, [2]Baylor College of Medicine, Houston, [3]UMass Chan Medical School, Worcester, MA, [4]UMass Chan School of Medicine, Arlington, MA, [5]Brown University, Providence, RI, [6]University of Massachusetts Chan Medical School, Marlborough, NH

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0306–0336) Osteoarthritis – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Osteoarthritis (OA) is the most common form of arthritis, a condition associated with substantial disability. Providers are often uncomfortable managing arthritis, and patients with OA often do not seek care within the healthcare system. The lack of engagement with medical care for OA has yet to be quantified.

Methods: Using data from the Osteoarthritis Initiative (OAI), a cohort recruited originally to facilitate the identification of biomarkers for knee OA, we evaluated engagement of arthritis care at the baseline visit of the study. Participants were recruited into the study if they were healthy controls, were at risk for symptomatic radiographic knee OA (SOA), or already had SOA. At the baseline visit, participants had PA knee radiographs scored for Kellgren and Lawrence (KL) grade (0-4) and were asked whether they had frequent knee pain in each knee. Study staff measured each participant's weight and height and asked about their gender, race, and age. They were also asked, "Are you currently seeing a doctor or other health care professional for arthritis?" that allowed for a dichotomous response of yes or no. We performed frequency evaluations for this question for the whole cohort, then cross-tabulated based on maximal KL grade (those with a prosthetic were grouped separately). We also performed a cross-tabulation with the number of knees with frequent knee pain and chi-squared test to evaluate significant differences between groups.

Results: Of the 4796 participants within the OAI cohort, the mean age was 61.5 (9.2) years, the mean BMI was 28.6 (4.8) kg/m^2, and 58% were female. 57% had at least one knee with radiographic OA (KL$\geq$2). 58 had an arthroplasty in one knee. In this cohort, only 12% answered that they currently see a doctor or other health care professional for arthritis. Females, those with a prior diagnosis of OA, greater BMI, greater KL grade, more knee pain, and SOA were more likely to seek care for their arthritis. Those with insurance and lower income were more likely to seek care for OA.

Conclusion: In a cohort recruited to study knee OA, 56% of whom had radiographic evidence of knee OA in at least one knee, only 12% were currently seeking care for their arthritis. Those with greater disease severity, symptoms, and SOA were more likely to seek care, but even among those groups, participation was low. Interestingly, those with a lower income were more likely to seek care for knee OA. These findings confirm a substantial gap in the provision of care for knee OA using traditional healthcare systems and provide important impetus for identifying novel strategies for management of OA.

Session Title: (0306–0336) Osteoarthritis – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

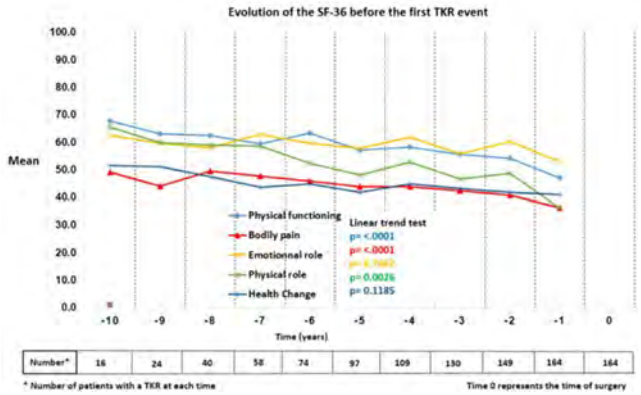
Background/Purpose: Few studies have examined how the quality of life (QoL) evolves in patients with osteoarthritis (OA) before undergoing total hip or total knee replacement surgery (THR/TKR). Although quality of life (QoL) appears to be stable in OA cohorts, patients undergo THR or TKR. This raises the question of whether it is deterioration in QoL that motivates intervention, and which specific dimensions deteriorate and lead to intervention.

The aim of the study was to analyze changes in various dimensions of QoL (especially pain, functional capacity, mental status, and social functioning) prior to THR/TKR in patients with symptomatic hip and/or knee OA.

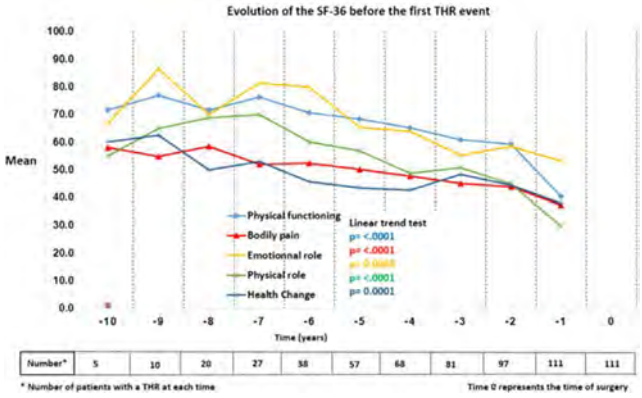
Methods: The Knee and Hip OsteoArthritis Long-term Assessment (KHOALA) cohort is a French multicenter, population-based cohort of 878 patients with symptomatic hip or knee OA. Patients were followed annually for up to 10 years using self-administered questionnaires. QOL was assessed using the SF36.

The evolution of QoL before the first THR/TKR is described by the mean (standard deviation) up to 10 years before surgery.

Results: Of the 878 patients in the cohort, 164 (18.7%) underwent TKR and 111 (12.6%) underwent THR over the 10-year follow-up: 196 (71.3%) were female, mean (SD) age 62.8 (7.5) years, mean body mass index 29.8 (6.0). 83 patients had more than one THR or TKR during follow-up.



23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



The evolution of SF-36 before the first incident THR and TKR are shown in the 2 graphs (Figure).

Prior to TKR for knee OA, deterioration in QoL was statistically significant over the entire period for physical function, bodily pain and physical role. Prior to THR for hip OA, deterioration in QoL was statistically significant over the entire period for physical function, bodily pain, physical role, and also emotional role and health change.

Changes in QoL differ from one dimension to another: rather stable trajectories until accelerated deterioration in QoL for physical function, physical pain and physical role dimensions, 2 years before TKR. Slow deterioration in the different dimensions of QoL before THR, with a sharp acceleration in the deterioration of QoL two years before surgery for the dimensions of physical function, bodily pain, physical role, emotional role, and change in health. Deterioration was greater for physical function and physical role than for pain.

Mental health, vitality, and social functioning were not found to change over time.

Conclusion: In the KHOALA cohort, impairment of physical function, pain, and physical or emotional role were well observed prior to surgery.

For hip OA, these impairments occurred progressively during several years with a sharp acceleration 2 years prior to surgery in particular for physical functional and role dimensions. For knee OA, trajectories are pretty stable up to 2 years prior to surgery.

Deterioration in QoL appears to be more gradual for THR than TKR and greater in the two years prior to surgery, particularly for functional abilities dimensions.

Table 2: Univariate and multivariable logistic regression modeling (adjusted for BMI, smoking history, statin use, diabetes). Odds ratios and 95% CIs for the case/control status variable listed. Each outcome is modeled separately. N=848 for each univariate model. N=834 for each multivariable model (14 pts are missing BMI and excluded from multivariable analysis).

Outcome	Unadjusted OR (95% CI)	p-value	Adjusted OR* (95% CI)	p-value
Any CVD	1.60 (1.12-2.28)	0.009	1.65 (1.14-2.41)	0.009
Arterial Disease	1.69 (1.23-2.32)	0.001	1.71 (1.24-2.37)	0.001
Atherosclerosis	2.40 (1.65-3.50)	<.001	2.44 (1.65-3.60)	<.001
Cerebral Infarction	1.73 (0.88-3.39)	0.111	1.66 (0.84-3.28)	0.146
Ischemic Heart Disease	1.24 (0.89-1.74)	0.206	1.25 (0.87-1.78)	0.227
HTN	1.64 (1.19-2.27)	0.003	1.63 (1.16-2.29)	0.005
MI	1.21 (0.57-2.56)	0.619	1.10 (0.51-2.38)	0.811

dysregulated immunity and cardiovascular event (CVE) risk is well established[1]. Specifically, several previous studies have found an increased risk of CVE in patients with rheumatoid arthritis (RA)[2]. Given the common denominator of inflammation in RA and EHOA, we hypothesized that EHOA is associated with increased CVE risk.

Methods: Patients with EHOA were identified from the electronic medical record by ICD code or by utilizing radiograph reports containing the term "erosive osteoarthritis". Radiographs were reviewed to confirm the characteristic changes of EHOA, namely central erosions and joint space narrowing within the distal and middle interphalangeal joints. Patients with autoimmune arthritis were excluded. Age and gender matched controls were identified in a 1:3 ratio. Study variables included BMI, smoking history, Type II diabetes and statin use. The primary outcome was any cardiovascular disease, while secondary outcomes were myocardial infarction (MI), hypertension (HTN), arterial disease, atherosclerosis, ischemic heart disease or cerebral infarction that were identified using ICD-9 and ICD-10 codes. EHOA and control groups were univariately compared using equal variance two-sample t-tests for continuous variables and Chi-square tests for categorical variables. Differences between cases and controls was estimated using logistic regression modeling adjusted for BMI and smoking history.

Results: We observed a positive association between EHOA and history of 1) any CVE, 2) arterial disease, 3) atherosclerosis, and 4) HTN. The adjusted odds ratio (OR) calculated using multivariate regression analysis was 1.65 (95% CI: (1.15-2.38); p-value 0.007) for overall prevalence of CVE, 1.71 ((95% CI: 1.24-2.37); p-value 0.001) for arterial disease, 2.51 ((95% CI: 1.70-3.69); p-value< 0.001) for atherosclerosis and 1.68 ((95% CI: 1.21-2.34); p-value 0.002) for HTN . The OR was similar without adjusting for covariates.

Conclusion: Our study shows that patients with EHOA have a higher prevalence of any CVE compared with age and gender matched controls with and without adjustment for potential confounders. Within CVEs, it shows higher prevalence of arterial disease, atherosclerosis and HTN. Our findings are in agreement with prior studies performed with RA patients, thus reinforcing the link between inflammation and increased cardiovascular link. Further studies are warranted to explore this association between EHOA and cardiovascular disease.

Background/Purpose: MRI evidence of synovitis and bone marrow lesions, but not cartilage degeneration associate with pain in osteoarthritis (OA). In this work, we integrated clinical, histological, and transcriptomic analyses of synovial tissue from patients with knee OA to explore correlations of OA pain and sex related pain differences.

Methods: We enrolled 135 patients undergoing total knee arthroplasty who met 1986 ACR classification criteria for knee OA. Demographic, clinical data, patient-reported pain outcomes, and Osteoarthritis Research Society International (OARSI) cartilage scores and synovial histology features measured by board-certified pathologists were collected and analyzed (Table 1). Cell density and cell aggregate number and size were quantified using a previously established computer vision pipeline. Bulk RNA-seq was performed on RNAlater-preserved synovial tissues, using a KAPA-Stranded RNAseqKit with RiboErase for library preparation, and sequenced on a NovaSeq with 150 base pair paired-end reads targeting 100M

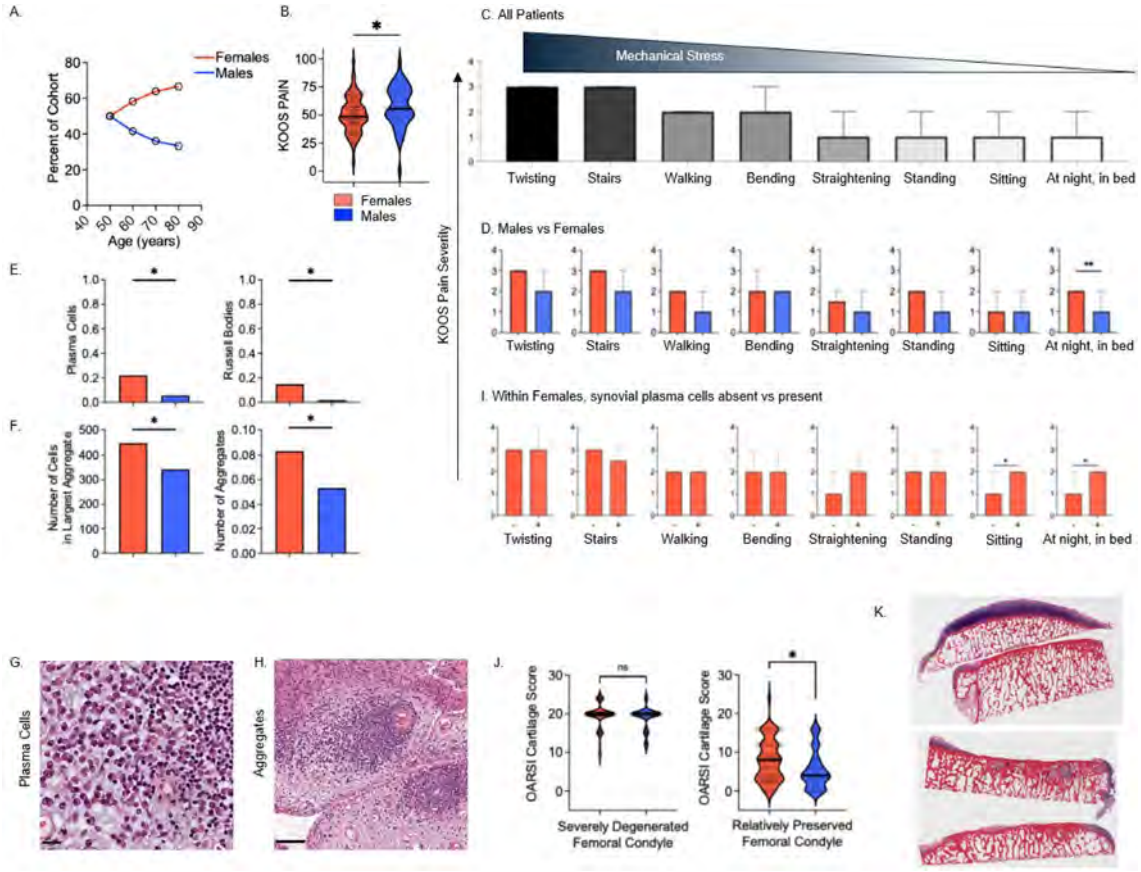

Figure 1: Percentage age distribution across different age groups. Figure B: Sex differences in knee pain as measured by the KOOS pain subscale. Females reported significantly worse knee pain compared to males mean KOOS pain score. Figure C: KOOS pain scores reported by all patients for specific activities. Pain was highest during activities involving greater mechanical stress on the knee and progressively decreased during lower-stress activities such as sitting or lying down. A mechanical stress gradient is illustrated above, highlighting the inverse relationship between stress level and pain intensity. Figure D: KOOS pain scores reported by females and males across different activities. While no significant sex differences were found in most categories, females reported significantly greater pain "at night, in bed" compared to males. Figure E: The proportion of plasma cells (left) and Russell bodies (right) in synovial tissue from females and males. Females exhibited significantly higher levels of both plasma cells and Russell bodies compared to males. Figure F: The number of cells in the largest synovial cell aggregate (left) and the number of aggregates per tissue area (right) in females and males. Females exhibited significantly larger and more numerous synovial aggregates compared to males. Figure G: High-magnification image of Hematoxylin and eosin (H&E) stain synovial tissue with plasma cell infiltrates. Figure H: Low-magnification image of Hematoxylin and eosin (H&E) stain synovial tissue with aggregates within the synovium. Figure I: KOOS pain scores for individual activities in female patients with and without synovial plasma cell infiltration. Pain during low mechanical stress activities of sitting and at night in bed was significantly higher in females with plasma cells present in their synovial tissue. Figure J: OARSI cartilage scores for male and female patients in both severely degenerated (left) and relatively preserved (right) femoral condyles. No significant differences were observed in the severely degenerated regions, females exhibited significantly higher cartilage damage in the relatively preserved condyles compared to males. Figure K: Representative low-magnification images of Hematoxylin and eosin (H&E) stained cartilage of males (top) and females (bottom) described in Figure J

reads per sample. Reads were pseudoaligned to Hg38 with Kallisto, and Limma was used to test for differentially expressed genes (DEGs). Gene set enrichment analysis (GSEA) was used to test for enrichment in GO pathways.

Results: Kellgren Lawrence (KL) grades, BMI, and symptom duration were similar between sexes. Females had higher Erythrocyte Sedimentation Rate (ESR) and reported worse Knee Injury and Osteoarthritis Outcome Score (KOOS) pain scores (p=0.01), particularly rest pain (at night, while in bed) (p=0.02) (Table 1). Rest pain was less common than mechanical pain (e.g., with twisting or stair use) but, when present, it correlated with higher total KOOS pain scores. Synovial histology revealed increased plasma cells, binucleate plasma cells, Russell bodies, and size and number of cellular aggregates in females. Females with synovial plasma cells reported increased rest pain. OARSI cartilage scores were similar in the most severely eroded femoral condyles between sexes, but females had significantly higher scores in the less eroded condyles (Figure 1). RNA-seq revealed 25 DEGs between sexes, and a pronounced enrichment in Xist escape genes in females. GSEA identified 132 pathways significantly enriched in females, including "adaptive immune response" and "complement activation". Among females, genes associated with inflammation, fibrosis, and neurogenesis pathways were positively

Figure 2A

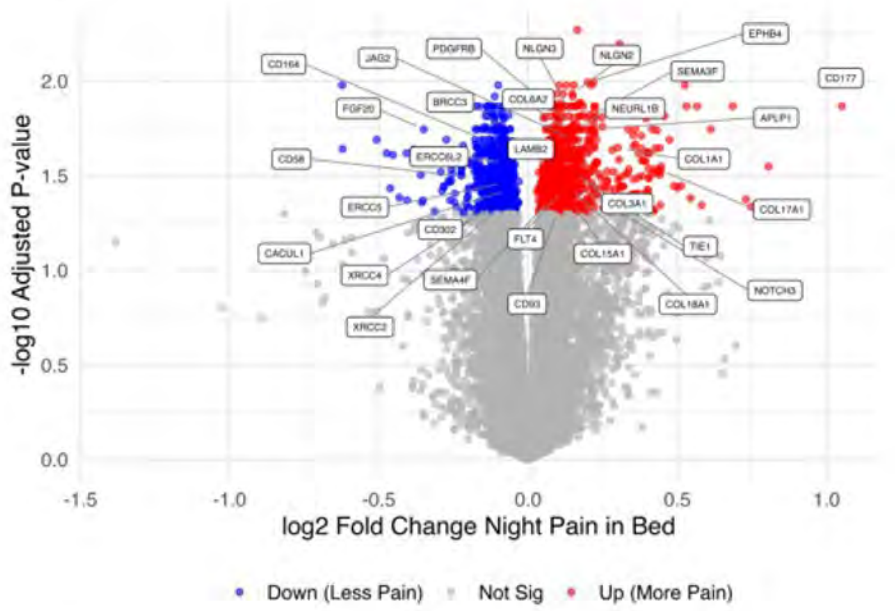

Figure 2B

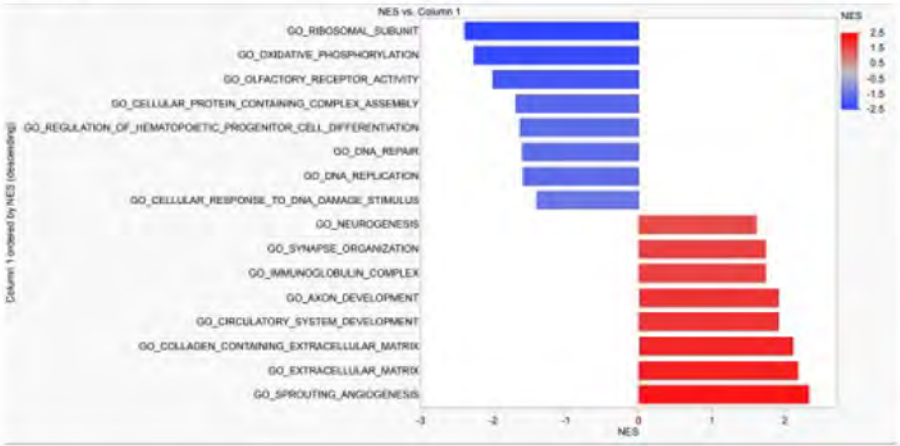

Figure 2A. Volcano plot of differential gene expression of rest pain (night pain in bed). Figure 2B. Gene Set Enrichment Analysis (GSEA) displaying pathway associated with rest pain

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. associated with rest pain, while genes associated with DNA damage response and progenitor cells were negatively associated with rest pain. There were no genes associated with rest pain in males.

Conclusion: Compared to males, females have significantly increased systemic and synovial tissue inflammation, along with increased multicompartmental cartilage degeneration. Among females, rest pain is positively associated with synovial inflammation, fibrosis, and neurogenesis pathway gene expression and negatively associated with DNA damage response and progenitor cell gene expression. This analysis provides insights into the molecular underpinnings of the clinical observation that MRI evidence of synovitis is associated with pain in knee OA.

Abstract Number: 0317

"No Matter How Great My Doctor Is, He Hasn't Had a Knee Replacement, He Doesn't Understand All That Pain" Program Evaluation of the *Moving Well* Peer Coach Intervention for Total Knee Replacement

Cara Murphy[1], Sarah Young[2], Vanessa Madrigal[3], Noelia Hernandez[4], Daniel Garcia[5], Yuliana Dominguez Paez[6], Monika Safford[3], Iris Navarro-Millan[7] and Mackenzie Brown[8], [1]HSS, New York, NY, [2]Weill Cornell Medicine, Johnson City, NY, [3]Weill Cornell Medicine, New York, [4]Weill Cornell Medicine, New York, NY, [5]Weill Cornell, Brooklyn, NY, [6]Albert Einstein College of Medicine, The Bronx, NY, [7]Weill Cornell Medicine, Hospital for Special Surgery, Poughkeepsie, NY, [8]Weill Cornell Medicine, Brooklyn, NY

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0306–0336) Osteoarthritis – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: *Moving Well* was a pre-habilitation peer coach intervention aimed at reducing levels of anxiety, depression, and pain among individuals undergoing total knee replacement (TKR)[1]. A peer coach was a person who had knee osteoarthritis and TKR who was trained[2] to guide another person in the preparation and recovery from TKR. The goal of this study was to evaluate the experience of the participants in both *Moving Well* and its attention control arm *Staying Well* to refine the interventions in preparation for a fully powered trial.

Methods: We conducted semi-structured interviews of participants in *Moving Well* and *Staying Well*. Interviews were offered regardless of completion of the intervention. The topic guide focused on barriers and facilitators to completing the intervention, the experience with the curriculum, logistics of the program, and the experience of working with a peer coach (*Moving Well*) or healthy coach (*Staying Well*). Data were analyzed thematically with two coders (CM and SRY) using NVivo software.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Ninety-two participants completed the trial (52 in *Moving Well* and 40 in *Staying Well*). Eighteen participants completed the evaluation interviews (10 from *Moving Well* and 8 from *Staying Well*). Table 1 includes their demographic information. Five themes emerged (Table 2). These were: 1) *The peer coach was a highly valued aspect of the intervention* (Tables 2 and 3 with sub-themes); 2) *Participants value the breathing exercises, mindfulness, and exercise program but have mixed feelings about the mood component and principles of cognitive behavioral therapy*; 3) *The Staying Well curriculum had mixed reviews, while there was strong appreciation for the paired healthy coach as a guide*; 4) *Perceived facilitators to completing the interventions included being motivated, being structured, and wishing for a good surgical outcome*; 5)*Time constraints and comorbidities were the perceived barriers to engage or complete either intervention*. The *Moving Well* peer coach was influential for participants due to their shared experience and their ability to act as a motivator and allow for vulnerability. The curricular components combined with the peer coaches were tools to empower participants to exercise.

Table 1: Demographic data of participants

Characteristic	Moving Well Arm (N = 10)	Staying Well Arm (N = 8)
Age, Mean (SD)	66.5 (5.64)	70 (8.18)

Table 2: Themes that Emerged from Interview Evaluations of Participants of *Moving Well* and the Attention Control Arm *Staying Well*

The peer coach was a highly valued aspect of the intervention (See Table 3 for sub-themes)	"What I found helpful was that someone who had done it and did it for similar reasons to me and was now doing what I wanted to be able to do." "I think the coach was really the most vital element of it all... compassion, understanding, and personalization in the whole approach to preparing for recovery"
Participants value the breathing exercises, mindfulness, and exercise program, but have mixed feelings about the mood component and principles of cognitive behavioral therapy	"And then I sit there, and it used to be that you pushed and then took that pain away by going back to a regular position, but now I just breathe into it, and it's interesting. I relax and I breathe into the pain and relax my body and then you can push farther" "But those things really reinforced me to just work on, what we call prehab, a little bit harder and do a little bit more and that gave me a tremendous edge over other friends of mine that had their surgery done by different physicians at different hospitals." "I didn't spend a lot of time doing it because I really couldn't analyze how my mood affected my pain. I could only analyze how my pain affected my mood." "And then working on replacing my fears with better ideas...And so it was the whole idea of identifying the problem and then coming up with a better way of 1. How to handle it so I wasn't freaking myself out and then 2. To focus on what was better for what was going to happen in the future. And I thought this really worked and it really helped."
The *Staying Well* curriculum had mixed reviews, while there was a strong appreciation for the paired healthy coach as a guide.	"It should be like a curriculum of life" "What the Staying Well program really needs is an exercise component for sure. Because to be honest, I didn't get anything out of the eating part." "Oh yeah, I wouldn't have done it if it wasn't for her (the coach) haha" "...the human touch, the human part of it, of both interacting with somebody, a live person, I think is very important."
Perceived facilitators to completing the *Staying Well* or *Moving Well* intervention included being motivated, being structured, and wishing for a good surgical outcome	"I wanted to be successful and preparing for my surgery. I really wanted to be prepared as possible, and I wanted to have the best outcome. So that was my total objective." "I have a grandbaby, and I said I really need this knee replacement because I don't want to be in a wheelchair, while he's running around saying, come on, grandma."
Time constraints and comorbidities were the perceived barriers to engage or complete either intervention	"Just keep in mind that if somebody is working full time, you don't always have the time to read and answer all the questions like the assignments" "The only problem I ran into was time constraints in my own life"

While the *Staying Well* (control arm), was not intended to have an exercise program, the fact that individuals were eager to engage in exercising supports that the focus of *Moving Well* aligns with the needs of this population.

Conclusion: Peer coaching for preparation and rehabilitation from TKR was a highly valued aspect of *Moving Well* because of the role modeling, motivation, vulnerability, and shared experiences. The major barrier for completion was time constraints, which could be an area for improvement in the next iteration of *Moving Well*.

Table 3. Theme and Sub-themes on the Evaluation of the Peer Coach Experience within *Moving Well*

Theme:	Associated Quotes:
Having a shared experience was valuable from an empathy, motivation, and preparation standpoint	*"We talked about some of her ski trips, and it was both a connection and a recognition that I was going to get to where I wanted to go"* *"I thought the biggest benefit was having somebody who had been through it before and could tell me what to expect and answer the questions that I had"* *"I don't want to just read something in the abstract as opposed to talking to somebody who can relate to your own goals and progress"*
The peer coach served as a motivator to prepare the participant for a good surgical outcome	*"I think the coach does keep you accountable."* *"I think the combination of the two really makes the most out of the program because I think just the program alone, it would be OK, but it wouldn't be as valuable as having the coach to facilitate and ask questions and get feedback on how things are going."*
The peer coach allowed for vulnerability and human connection which impacted improved well-being	*"I've never gone to a psychologist or a psychiatrist, it was nice talking to someone. I think it was sort of that kind of experience."* *"I have friends, but you don't want to bore them with all your physical troubles. There's nothing more boring, try friends my age, everybody's got a series of maladies, and it's really boring. I didn't feel bad boring him. Not that he acted bored, but he was very sympathetic and understanding and it was good to have someone to talk to, in a way I couldn't do otherwise."*
Desire to continue contact with the peer coach	*"I got a little sad when she said, oh, this is the last time we're going to talk"* *"It was wonderful...I'm really sad that I can't ever talk to her. For, was it two or three years now? I don't know if she has this experience with everybody, but it was great, I felt like I had a whole new friend"* *"And so, I understand not being able to talk to her, but it's like I want to know how the chickens are doing, you know? So, it worked out really well for us, you know. Could you just let her know that I am going to have surgery on the other knee. I don't know when yet, but he will do my other knee, just, could you forward that information to her?"*

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0306–0336) Osteoarthritis – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Lipoprotein subclasses play diverse roles in health and disease. Although lipoproteins have been implicated in knee osteoarthritis (KOA), the relationship between lipoprotein subclasses and KOA remains unexplored.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 3: Associations of the key lipoprotein subclass with the risk of incident knee replacement. HRs (per SD) were adjusted for age, sex, Townsend Deprivation Index score, body mass index, drinking status, smoking status, fasting time, lipid-lowering medication, and history of knee joint injury. HR, hazard ratio; SD, standard deviation; CI, confidence interval; HDL, high-density lipoprotein.

Methods: We conducted a cohort study of 115,237 participants from the UK Biobank to examine the associations of 85 plasma lipoprotein subclasses, defined by combinations of density (high, low, intermediate, very-low), size (extremely-large, very-large, large, medium, small, very-small), and composition (triglyceride, free cholesterol, cholesteryl ester, phospholipid), with incident KOA in the metabolome-wide analysis (**Figure 1A**). Data were analyzed using Cox proportional hazards models, correcting for multiple tests (0.05/9). We conducted the analyses using two models. Model 1 adjusted for age, sex, Townsend Deprivation Index score, body mass index (BMI; as a categorical variable), drinking status, smoking status, fasting time, lipid-lowering medication, and history of knee joint injury. Model 2 included the same covariates as Model 1, except that BMI was adjusted as a continuous variable. We subsequently conducted targeted analyses to examine the association between the key lipoprotein subclasses, which consistently showed significant associations with KOA across both models, and knee replacement, as the outcome may reflect severe OA (**Figure 1B**).

Results: During a median follow-up period of 12.8 years, 6,782 incident cases of KOA were identified. A total of 38 lipoprotein subclasses were statistically significantly associated with incident KOA (**Figure 2**). Specifically, higher concentrations of very-large and large high-density lipoproteins (HDL), excluding triglyceride, were associated with a lower risk of incident KOA (hazard ratios [HRs] range 0.87-0.94). Conversely, higher concentrations of small HDL, irrespective of composition, were associated with a higher risk of incident KOA (HRs range 1.04-1.09). Extremely-large very-low-density lipoprotein (VLDL) across all compositions, very-large VLDL excluding cholesteryl ester, and large VLDL excluding cholesteryl ester showed positive associations with incident KOA (HRs range 1.05-1.10). Additionally, medium, small, and very-small VLDL, and intermediate-density lipoprotein, as well as large, medium and small low-density lipoprotein, combined with triglyceride, were consistently positively associated with incident KOA (HRs range 1.04-1.06). After adjusting for BMI as a continuous variable, differential effects among HDL subclasses remained evident, except for the association between large HDL and KOA. Conversely, the associations between other lipoprotein subclasses and KOA become non-statistically significant. Similar findings were observed for the associations between HDL subclasses and the risk of knee replacement in the targeted analysis (**Figure 3**).

Conclusion: We provided novel evidence of diverse associations between lipoprotein subclasses and incident KOA, indicating the distinct effects of HDL subclasses.

Abstract Number: 0319

Glucagon-like Peptide-1 Receptor Agonists in Management of Knee Osteoarthritis: A Meta-Analysis

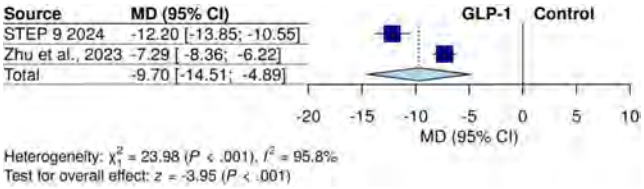
Danielle Madison[1], Adriana Morales Rivera[2], Dylon Collins[2], Isabel Lam[2], Daniel Khokhar[2], Garrett Snyder[2], Anthony Thompson[2], Mark Soliman[2], Daniela Carralero Somoza[2] and Michael Sabina[2], [1]Lakeland Regional Medical Center, Lakeland, FL, [2]Lakeland Regional Medical Center, Lakeland

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0306–0336) Osteoarthritis – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

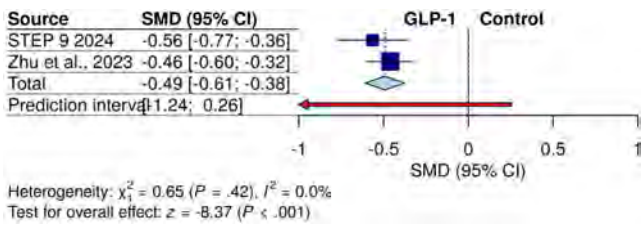
Background/Purpose: Knee osteoarthritis (KOA) is a leading cause of disability and the most common rheumatological condition worldwide. Weight management has been recognized as a key modifiable factor in disease progression and symptom burden. Glucagon-like peptide-1 receptor agonists (GLP-1RAs), primarily used for diabetes and weight loss, may offer additional benefits in KOA through weight reduction and improved joint function. We conducted a meta-analysis of GLP-1RAs versus control interventions in patients with KOA.

Methods: We included two studies — Semaglutide Treatment Effect in People with obesity (STEP) 9, a randomized controlled trial, and the Shanghai Osteoarthritis Cohort (SOC), a large observational cohort — reporting outcomes in body weight and Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) domains. Both studies utilized GLP-1RAs as their experimental variable. Data was pooled using random-effects models and heterogeneity was assessed using the I^2 statistic.

Results: GLP-1RA therapy led to a pooled reduction in body weight of -9.70 kg (95% CI -14.51 to -4.89; I^2 = 95.8%). For the WOMAC pain score, the pooled mean difference (MD) was -0.49 points (95% CI -0.61 to -0.38; I^2 = 0.0%), reflecting improvement in symptoms. Physical function demonstrated a pooled standardized mean difference (SMD) of –1.29 (95% CI -3.79 to 1.21; I^2 = 99.6%). For the total WOMAC score, the pooled SMD was –0.30 (95% CI -0.77 to 0.17; I^2 = 92.9%), and for WOMAC stiffness, the pooled SMD was -0.23 (95% CI –0.64 to 0.18; I^2 = 90.9%). Despite variable heterogeneity, the direction of benefit consistently favored GLP-1RAs across all domains.



The aggregate mean difference between GLP-1RA use and control for body weight. Presented as a forest plot.



The aggregate mean difference between GLP-1RA use and control for reported pain on WOMAC index. Presented as a forest plot.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Graphic depicting the focus of the meta-analysis and its primary end-points.

Conclusion: GLP-1RAs appear to reduce pain in patients with knee osteoarthritis, likely through weight reduction. Changes in physical function and stiffness have been reported with varying significance and should be assessed more in-depth. While the magnitude of effect varied across primary end-points and studies, the consistent direction of benefit supports further investigation of GLP-1RAs as adjunctive therapy in KOA management.

Abstract Number: 0320

Transcriptomic profiling of the skeletal muscle of knee OA patients uncovers elevated glucocorticoid and GABA signaling as mediators of skeletal muscle dysfunction in advanced disease

Gina Many[1], Tyler Mansfield[2], Tyler Sagendorf[3], Daniel Evans[2], Sameneh Farsijani[4], Bret Goodpaster[5], Lauren Sparks[5] and NANCY LANE[6], [1]Pacific Northwest National Laboratory, Richland, WA, Richland, WA, [2]California Pacific Medical Research Institute, San Francisco, CA, [3]Pacific Northwest National Laboratory, Richland, WA, [4]University of Pittsburgh, Pittsburgh, PA, [5]Translational Research Institute, AventHealth, Orlando, FL, [6]University of California at Davis, School of Medicine, Sacramento, CA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0306–0336) Osteoarthritis – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Age-related declines in muscle mass and function are leading causes for hospitalizations and mortality in elderly individuals. The risk of developing knee osteoarthritis also increases with age and those affected display reductions in skeletal muscle mass, quality and function yet the mechanisms behind these changes are broadly unknown. Characterizing the transcriptional landscape of skeletal muscle from patients with knee OA to identify molecular targets of skeletal muscle dysfunction and then formulate a targeted treatment approach.

Methods: Study participants (n=528, 56% Female; mean age 76.6 ± 4.9 years) were enrolled in the Study of Muscle, Mobility and Aging (SOMMA), a longitudinal cohort study of subjects, >70 years of age, free of life-threatening diseases and mobile. Study subjects had obtained a muscle biopsy at the baseline study visit and knee radiographs at the year 1 follow-up visit. Radiographic OA (ROA) was determined by Kellgren and Lawrence scores (0-4), and knee pain was self-reported to be at least monthly in the right knee. RNA sequencing data were analyzed using DESeq2 to assess differential

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

gene expression, contrasting a control group (Kellgren-Lawrence (KL) score 0–1, n=322) with three nested "case" groups: (1) all KL ≥2 (n=206), (2) KL ≥2 with pain (n=114), and (3) KL ≥3 with pain (n=74). Covariates in the statistical models included sex, race/ethnicity, age, weight, waist circumference, abdominal adiposity from MRI, right anterior thigh fat free muscle volume, clinical site, batch, steps per day (using GGIR actigraph), and pain medications. Resulting pathway enrichment analysis was performed using CAMERA.

Results: DESeq2 revealed differential transcript expression across the three case-control contrasts, with 20, 10 and 22 differentially expressed genes for contrasts 1-3 respectively. Two genes, Mettl21c, a methyltransferase, and pseudogene Rpl29p11 displayed differential expression in all three contrasts. Pathway enrichment analysis revealed significant differences between the three contrasts, with gene expression regulatory terms and pathways related to ribosomes and translation being downregulated in groups 2&3. Group 3 also displayed unique enrichment of GABA secretion (z-score: 3.6, FDR=0.03) and glucocorticoid (GC) signaling (z-score: 3.4, FDR< 0.05).

Conclusion: Gene expression profiling of ROA skeletal muscle reveals differential molecular profiles based on KL grade and self-reported knee pain. Patients presenting with KL 3+ and pain displayed unique pathway enrichments indicative of transcriptional and translational repression, GC signaling and GABA secretion. Given adjustment for physical activity in statistical modeling, these findings suggests that elevated GC and GABA signaling may be potential mechanisms for skeletal muscle dysfunction and atrophy in advanced stage ROA.

Session Title: (0306–0336) Osteoarthritis – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: The prevalence of hand osteoarthritis (OA) has doubled in the United States over the past half century – a finding that cannot be solely explained by increases in longevity, raising the possibility that environmental factors play a role. In cross-sectional studies, exposure to per- and polyfluoroalkyl substances (PFAS; "forever chemicals"), synthetically produced water-, grease-, or stain-resistant chemicals, has been associated with self-reported OA diagnosis. Given the ongoing use of PFAS and the scale of contamination, there is an urgent need for longitudinal studies to clarify the relationship between PFAS and specific phenotypes of OA (e.g., symptomatic hand OA) to inform public health policies and

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. [a] Adjusted for gender/menopause status (male, pre-menopausal female, peri-menopausal female, post-menopausal female), race (Black, yes/no), education level (college graduate, yes/no), age at baseline, and BMI at baseline.

Note: The analyses had inverse probability weighting to account for oversampling of cases with the case-cohort study design.

Abbreviations: confidence interval (CI); interquartile range (IQR); limit of detection (LOD); odds ratio (OR); quartile 1-4 (Q1-4); Perfluorooctane sulfonoic acid (PFOS); Perfluorooctanoic acid (PFOA); Perfluorononanoic acid (PFNA); Perfluorohexane sulfonoic acid (PFHxS); 2-(N-Methyl-perfluorooctane sulfonamido) acetic acid (MeFOSAA); Perfluoroheptanesulfonic acid (PFHpS); Perfluorodecanoic acid (PFDA); Perfluoroundecanoic acid (PFUnA)

clinical monitoring. Hence, we explored whether specific PFAS and a mixture of PFAS – reflecting the joint effects and correlations among each PFAS – relate to incident hand OA and progression.

Methods: We leveraged a case-cohort sample (n = 1,878) from the Osteoarthritis Initiative among participants with hand radiographs at the baseline and 48-month visits. We assayed baseline serum samples for 12 PFAS via online solid-phase extraction liquid chromatography tandem mass spectrometry. For analyses, we a priori included only 8 PFAS for which 60% of samples were above the limits of detection. Our 2 primary outcomes were incident symptomatic hand OA and an increased number of joints with radiographic OA (Kellgren-Lawrence≥2; yes/no). We classified a participant as having incident symptomatic hand OA if at the 48-month visit, but not at baseline, they had ≥2 finger joints (distal interphalangeal, proximal interphalangeal, or metacarpophalangeal joints) on at least 2 separate digits with at least a small osteophyte or mild joint space narrowing (modified Kellgren-Lawrence grade≥2) on radiograph and reported on a questionnaire hand/finger pain, aching, or stiffness on more than half of the 30 days prior to the radiograph. We used covariate-adjusted weighted logistic

[a] Adjusted for gender/menopause status (male, pre-menopausal female, peri-menopausal female, post-menopausal female), race (Black, yes/no), education level (college graduate, yes/no), age at baseline, BMI at baseline.

Note: The analyses had inverse probability weighting to account for oversampling of cases with the case-cohort study design

Abbreviations: confidence interval (CI); interquartile range (IQR); limit of detection (LOD); odds ratio (OR); quartile 1-4 (Q1-4); Perfluorooctane sulfonoic acid (PFOS); Perfluorooctanoic acid (PFOA); Perfluorononanoic acid (PFNA); Perfluorohexane sulfonoic acid (PFHxS); 2-(N-Methyl-perfluorooctane sulfonamido) acetic acid (MeFOSAA); Perfluoroheptanesulfonic acid (PFHpS); Perfluorodecanoic acid (PFDA); Perfluoroundecanoic acid (PFUnA)

regression models to assess single PFAS (continuous and quartiles) and quantile-based g-computation to assess the PFAS mixture in relation to our primary outcomes.

Results: rticipants were mostly female (58%), White (83%), and on average 61 years of age and overweight (mean BMI = 28.6 kg/m^2). Participants with higher serum PFDA and PFNA had greater odds of incident symptomatic hand OA [OR (95%CI) per interquartile-range increment: 1.12 (1.05, 1.20) for PFDA; 1.07 (1.00, 1.13) for PFNA], but the associations were not monotonic when represented in quartiles (Table 1). Participants with higher PFHxS had lower odds of hand OA [e.g., OR (95%CI): 0.93 (0.86, 1.00) per interquartile-range increment]. Participants in the highest quartile of PFHpS (vs. quartile 1) had lower odds of hand OA. We observed no other monotonic associations between individual PFAS or the PFAS mixture with either primary outcome (Tables 1 and 2).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: We observed possible associations of PFDA and PFNA with symptomatic hand OA incidence that warrant further study in cohorts with more nuanced measures of hand OA symptoms, but we otherwise found no consistent evidence that greater serum PFAS concentrations relate to a greater chance of developing hand OA incidence or progression.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0306–0336) Osteoarthritis – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Numerous cross-sectional and animal studies have linked an altered gut microbiome to osteoarthritis (OA). Human studies are needed to explore the association between the gut microbiome and incident OA. Assessing microbiomes can be challenging; however, blood measures (e.g., metabolites) have offered insights into the gut microbiome and its relationship with prevalent OA. Hence, we explored whether blood-based metabolites, reflective of the gut microbiome, relate to incident knee OA during the subsequent 7 years.

Methods: We performed a secondary analysis of a case-cohort study that included 603 participants from the Osteoarthritis Initiative, comprising 237 incident knee OA cases and 366 non-cases from a randomly selected sub-cohort over an 8-year follow-up. Plasma metabolomes were analyzed using liquid chromatography-tandem mass spectrometry. Among the measured metabolites, 47 were previously identified in the literature as microbial metabolites (Rushing BR et al., 2021). We averaged metabolite levels at baseline and year 1 as the exposure and identified incident OA cases as knees with a Kellgren and Lawrence grade ≥2 in subsequent follow-ups. Weighted logistic regression, which accounted for the study design and adjusted for age and gender with and without body mass index (BMI), was used to examine associations between these metabolite concentrations and knee OA incidence. As an exploratory analysis, multiple comparison correction was not applied.

Results: Among the 603 participants, 70% of OA cases (mean [SD] age = 60 [9] years, BMI = 28.6 [4.7] kg/m^2), and 55% of non-cases were female (age = 58 [9], BMI = 26.9 [8.0] kg/m^2). When adjusting only for age and gender, the upper quartile of 4 metabolites had a statistically significant association with greater odds of incident knee OA (2 had a significant p for trend; Table 1): 3-(3-Hydroxyphenyl)propanoic acid (OR = 1.90, p trend = 0.048), N,N-Dimethylglycine (OR = 1.65, p trend = 0.016), Kynurenic acid (OR = 1.51), N-Acetyl-L-phenylalanine (OR = 1.62). Only 3-(3-Hydroxyphenyl)propanoic acid remained statistically significant after adjusting for BMI (OR = 1.90, Table 2). Three metabolites had evidence suggestive that higher levels related to lower odds of incident OA: Benzoic acid (ORs range = 0.54-0.74), Butyric acid (OR range =

L-Threonic acid	1.24 [0.85, 1.83]	0.86 [0.58, 1.29]	0.67 [0.44, 1.01]	0.333
L-Prolyl-glycine	0.73 [0.49, 1.09]	0.72 [0.48, 1.08]	1.23 [0.83, 1.82]	0.543

Bold: $p \leq 0.05$

0.63-0.84), and Phenylacetic acid (OR range = 0.66-0.87). Benzoic acid (OR range = 0.62-0.74) and Butyric acid (OR range = 0.66-0.88) remained statistically significant after adjusting for BMI (Table 2). Furthermore, after adjusting for BMI, 10 other metabolites had evidence that higher levels related to lower odds of incident OA, including 3 with a p for trend < 0.05: 4-hydroxyphenylpyruvic acid, Pyruvic acid, and Glucose.

Conclusion: Our results complement a prior cross-sectional analysis using fecal metabolomes, which suggested OA was associated with perturbed pathways, including amino acid metabolism (e.g., glycine, serine, tryptophan, phenylalanine), fatty acid metabolism, dietary polyphenol metabolism, and pyruvate metabolism. Unlike the prior study, we offer longitudinal evidence that these metabolites are altered before the onset of knee OA and may be modifiable risk factors, which can be monitored in blood samples.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0306–0336) Osteoarthritis – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Semi-quantitative and semi-automated quantitative measurements of effusion-synovitis (ES) are prognostic for knee OA progression. Changes in these metrics relate to changes in knee pain. However, these traditional methods require readers to review or measure MRIs, leading to reader variability and significant time demands. An automated approach could enable quantitative ES volume measurements that can be rapidly deployed on large datasets without variations between readers. Hence, we evaluated the prognostic and construct validity of an automated quantitative measurement of ES volume by comparing its relationship to knee OA progression against that of a well-established semi-automated ES volume.

Methods: We conducted knee-based analyses among participants in the Osteoarthritis Initiative with bilateral knee MRIs and at least one knee with Kellgren-Lawrence (KL) grade ≥ 1 and a WOMAC pain score ≥ 10/100. We included participants with ES measurements at the 12- and 36-month OAI visits. A trained reader measured whole-knee ES volume on MRIs using our semi-automated software. To develop an automated measurement, we implemented a deep neural network approach based on the 3D U-Net architecture developed with the Medical Open Network for Artificial Intelligence (MONAI) framework. The model was trained using a different dataset with data augmentation techniques, including random affine transformations, spatial flips, and intensity shifts to enhance robustness. We calculated Pearson Correlation Coefficients between the automated and semi-automated ES volumes (cross-sectionally and 2-year change) and created Bland-Altman plots. To assess prognostic validity, we examined how ES volumes at the 12-month visit related to changes in radiographic severity (KL and joint space narrowing [JSN] progression) over the subsequent 3 years. To assess construct validity, we examined concurrent change in ES volumes with 2-year progression in KL grade, JSN grade, or WOMAC knee pain scores (change > 10/100 points). We performed knee-based analyses using logistic regression with repeated measures to adjust for correlations between knees within each person.

Results: Among the 506 participants (1,011 knees), 56% were female with a mean (SD) age = 61 (9) years and BMI = 29.3 (4.3) kg/m^2. The sample included 82 (8%) knees with KL progression, 103 (10%) with medial JSN progression, and 126 (12%) with knee pain worsening. Cross-sectionally, the automated method yielded smaller volumes than the semi-automated method (Figure 1B); however, these differences were attenuated when assessing longitudinal change (Figure 1D). Despite these differences, the automated ES volume strongly correlated with the semi-automated volume (r = 0.89; Figure 1A) and volume change (r = 0.84; Figure 1C). The table shows that the automated and semi-automated ES volumes had consistent statistically significant associations with every outcome.

Table. Automated quantitative measurements of effusion-synovitis volume (cm3) have similar prognostic and construct validity as well-established semi-automated effusion-synovitis volumes.

Table 1. Automated quantitative measurements of effusion-synovitis volume (cm^3) have similar prognostic and construct validity as well-established semi-automated effusion-synovitis volumes.

	Semi-automated Effusion-Synovitis Volume			Automated Effusion-Synovitis Volume		
	Outcome Absent M (SD)	Outcome Present M (SD)	Odds Ratio (95% CI) Per SD	Outcome Absent M (SD)	Outcome Present M (SD)	Odds Ratio (95% CI) Per SD
Prognostic validity (relating 12-month effusion-synovitis volume with change over the subsequent 3 years)						
Kellgren-Lawrence Progression	12.7 (8.5)	15.3 (10.2)	1.27 (1.08, 1.49)	6.2 (4.3)	7.8 (6.0)	1.32 (1.13, 1.54)
Joint Space Narrowing Progression	12.6 (8.6)	16.0 (9.1)	1.33 (1.14, 1.54)	6.2 (4.4)	8.0 (5.2)	1.35 (1.15, 1.57)
Construct validity (relating 2-year change to 2-year change)						
Kellgren-Lawrence Progression	1.4 (5.8)	4.7 (9.1)	1.58 (1.26, 1.97)	0.2 (3.2)	1.9 (5.5)	1.52 (1.20, 1.93)
Joint Space Narrowing Progression	1.4 (5.7)	3.9 (9.1)	1.41 (1.12, 1.77)	0.2 (3.1)	1.8 (5.5)	1.46 (1.15, 1.85)
WOMAC Knee Pain Worsening	1.4 (6.0)	3.8 (7.1)	1.52 (1.26, 1.83)	0.2 (3.3)	1.4 (4.1)	1.45 (1.19, 1.78)

M = Mean, SD = Standard deviation, 95% CI = 95% confidence interval

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

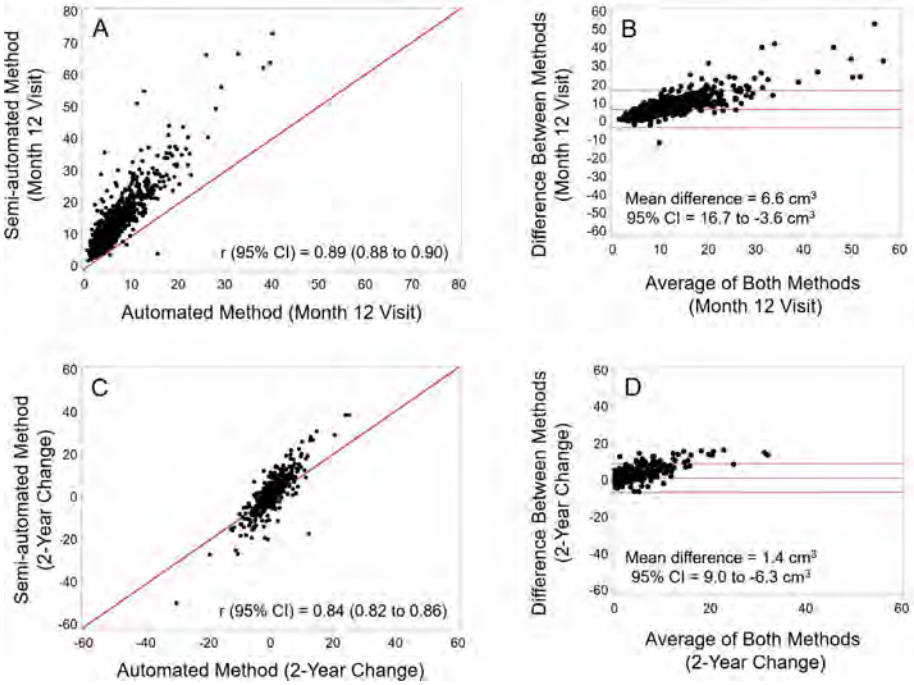

Figure 1. Cross-sectionally, the automated effusion-synovitis volumes (cm^3) are typically smaller than the semi-automated effusion-synovitis volumes (A [Scatter Plot], B [Bland-Altman Plot]); however, these differences are attenuated when examining the two-year change in both measures (C [Scatter Plot], D [Bland-Altman Plot]). In Figures A and C, the red line is the line of identity/equality, and correlations are reported with 95% confidence intervals (CI). In Figures B and D, the middle red line is the mean difference between the methods. The upper and lower red lines represent the upper and lower bounds of the 95% confidence interval, respectively.

Conclusion: The automated ES volume had strong prognostic and construct validity regarding radiographic and pain outcomes. The automated method offers an efficient strategy to quantify ES in studies with large sample sizes. It may provide a cost-effective approach to screen MRIs in future clinical trials.

Background/Purpose: Although gut microbiome dysbiosis has been implicated in symptomatic hand OA (SHOA), the potential contribution of bile acids (BAs), key metabolites in host-microbiota interactions, to SHOA pathogenesis remains unexplored. This study examined the association between plasma BA metabolism and SHOA using data from multiple cohorts, aiming to elucidate potential pathogenic mechanisms underlying SHOA and investigate potential therapeutic targets.

Methods: Participants in the discovery cohort were drawn from the Xiangya Osteoarthritis (XO) Study, a community-based observational study. SHOA was defined as the presence of both self-reported hand symptoms and radiographic hand OA in at least one hand. Individuals without SHOA in either hand served as controls. 71 SHOA and 1,288 control participants were identified in the discovery cohort. The associations between plasma BAs and SHOA were examined using logistic regression model. We replicated the analysis to validate the association between key BAs and SHOA using a case-control design that include 71 SHOA and 71 age-, sex-, and body mass index-matched control participants, who were identified in an independent validation cohort. Multi-omics analyses were conducted to explore links between SHOA-related microbes and key BAs, while mediation analysis assessed the role of BAs in the gut microbiome-SHOA relationship. Finally, to explore the potential underlying mechanisms of the associations, we conducted gene-based meta-analyses to assess the associations between key BA receptors and SHOA using data from the XO Study and Genetics of OA Consortium.

Results: In the discovery cohort, the plasma BA profiles were primarily dominated by glycochenodeoxycholic acid (GCDCA), chenodeoxycholic acid (CDCA), cholic acid (CA), glycocholic acid (GCA), and deoxycholic acid (DCA) (**Figure 1A**).

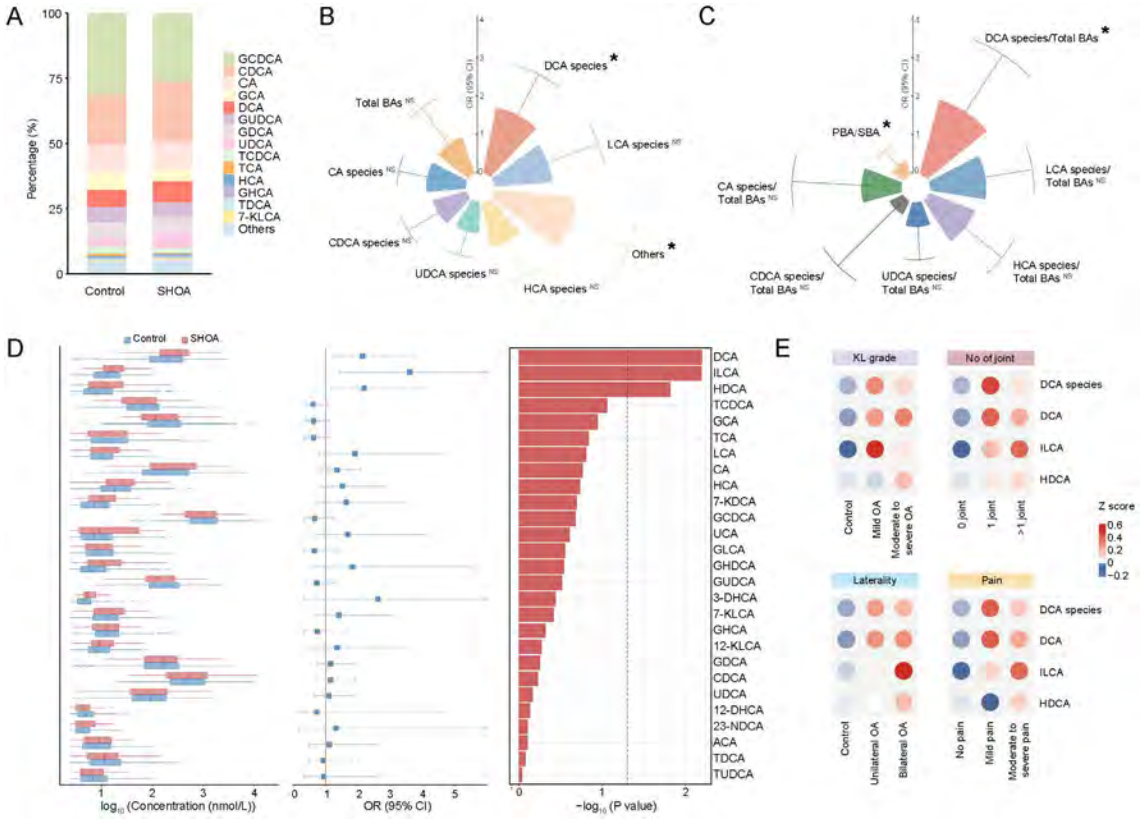

Figure 1. Associations of plasma bile acids with symptomatic hand OA in the discovery cohort. (A) Top 15 most abundant plasma bile acid categories identified in participants with SHOA and controls. (B) Associations of bile acid species, (C) bile acid species ratios, (D) and individual plasma bile acids with SHOA, adjusting for age, sex, body mass index, smoking status, alcohol consumption, and dietary intake of meat/eggs, dairy, and vegetables. (E) Associations between key plasma bile acids and the severity of SHOA. SHOA, symptomatic hand OA; GCDCA, glycochenodeoxycholic acid; CDCA, chenodeoxycholic acid; CA, cholic acid; GCA, glycocholic acid; DCA, deoxycholic acid; GUDCA, glycoursodeoxycholic acid; GDCA, glycodeoxycholic acid; UDCA, ursodeoxycholic acid; TCDCA, taurochenodeoxycholic acid; TCA, taurocholic acid; HCA, hyocholic acid; GHCA, glycohyocholic acid; TDCA, taurodeoxycholic acid; 7-KLCA, 7-Ketolithocholic acid; DCAs, deoxycholic acid species; LCAs, lithocholic acid species; HCAs, hyocholic acid species; UDCAs, ursodeoxycholic acid species; CDCAs, chenodeoxycholic acid species; CAs, cholic acid species; BA, bile acids; KL grade, Kellgren-Lawrence grade; No of joint, number of affected joints.

Elevated levels of deoxycholic acid (DCA) species (odds ratio [OR]=1.75, 95% confidence interval [CI]: 1.03–2.96), DCA (OR=2.14, 95% CI: 1.24–3.70), isolithocholic acid (OR=3.60, 95% CI: 1.43–9.04), and hyodeoxycholic acid (OR=2.20, 95% CI: 1.17–4.15) were positively associated with SHOA (**Figure 1B-D**) and its severity (**Figure 1E**). Similar associations between BAs and SHOA were found in the independent validation cohort (**Figure 2**). Multi-omics analyses revealed significant correlations between DCA species, DCA, and the DCA species/total BAs ratio with SHOA-related microbial species (**Figure 3A**).[1] Mediation analysis showed that DCA mediated the relationships of four SHOA-related microbial species, with the mediation effects ranged from 7.0% to 24.1% (**Figure 3B-E**). Gene-based meta-analyses identified a significant association between the gene encoding the Farnesoid X receptor (FXR), a key BA receptor, and SHOA.

Conclusion: Dysregulated BA metabolism, particularly elevated DCA levels, is associated with SHOA and key SHOA-related microbiomes. DCA mediates the link between gut microbiota dysbiosis and SHOA, while FXR could be a treatment target for SHOA.

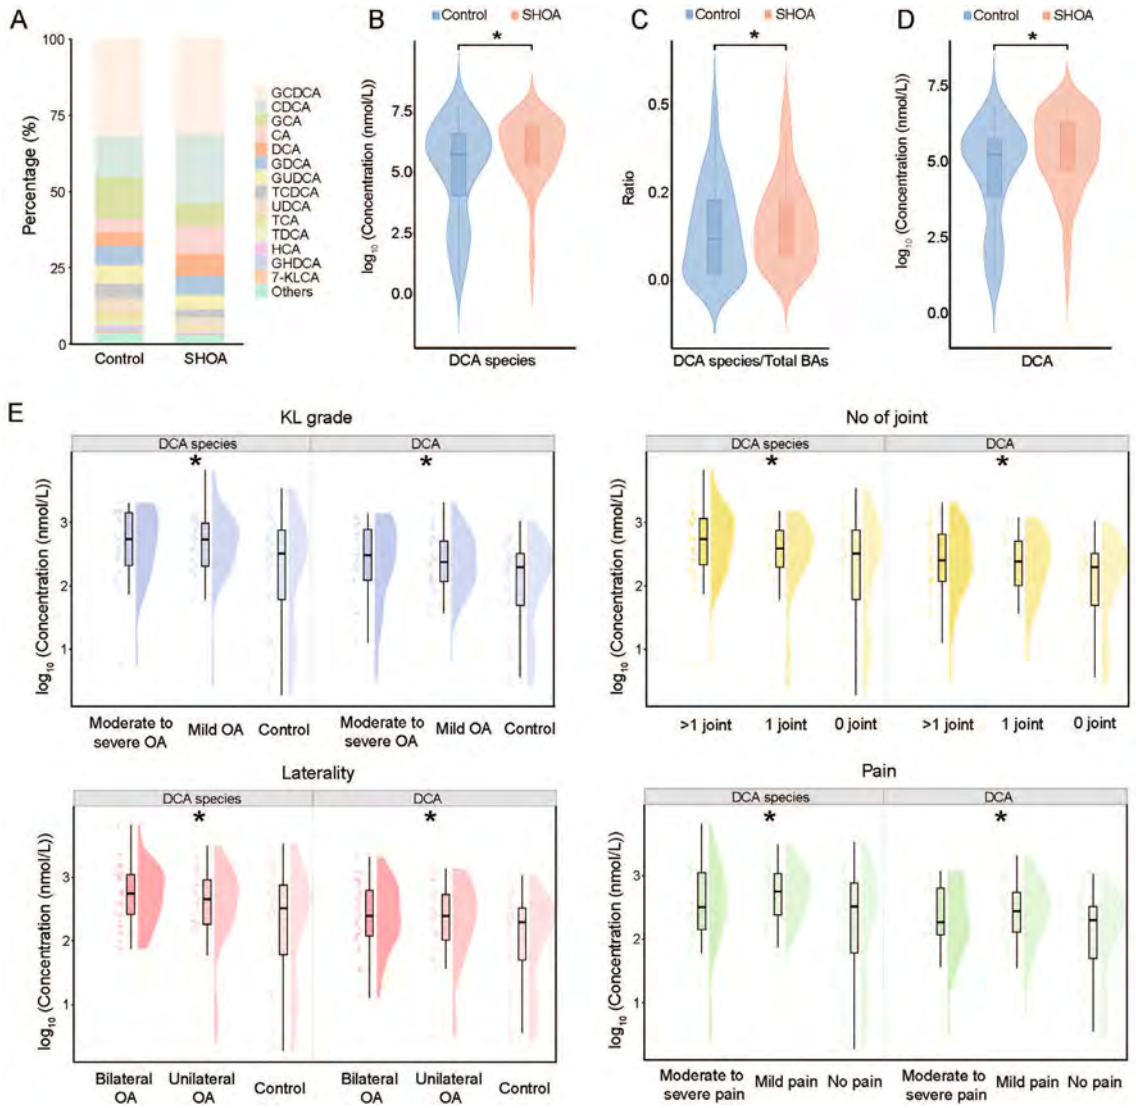

Figure 2. Associations of plasma bile acids with symptomatic hand OA in the Validation cohort. (A) Top 15 most abundant plasma bile acid categories identified in participants with SHOA and controls. (B) Bile acid species validated in the validation cohort. (C) Bile acid species ratios validated in the validation cohort. (D) Individual plasma bile acid validated in the validation cohort. (E) Associations between key plasma bile acids and the severity of SHOA. Session Date: Sunday, October 26, 2025

Session Title: (0306–0336) Osteoarthritis – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

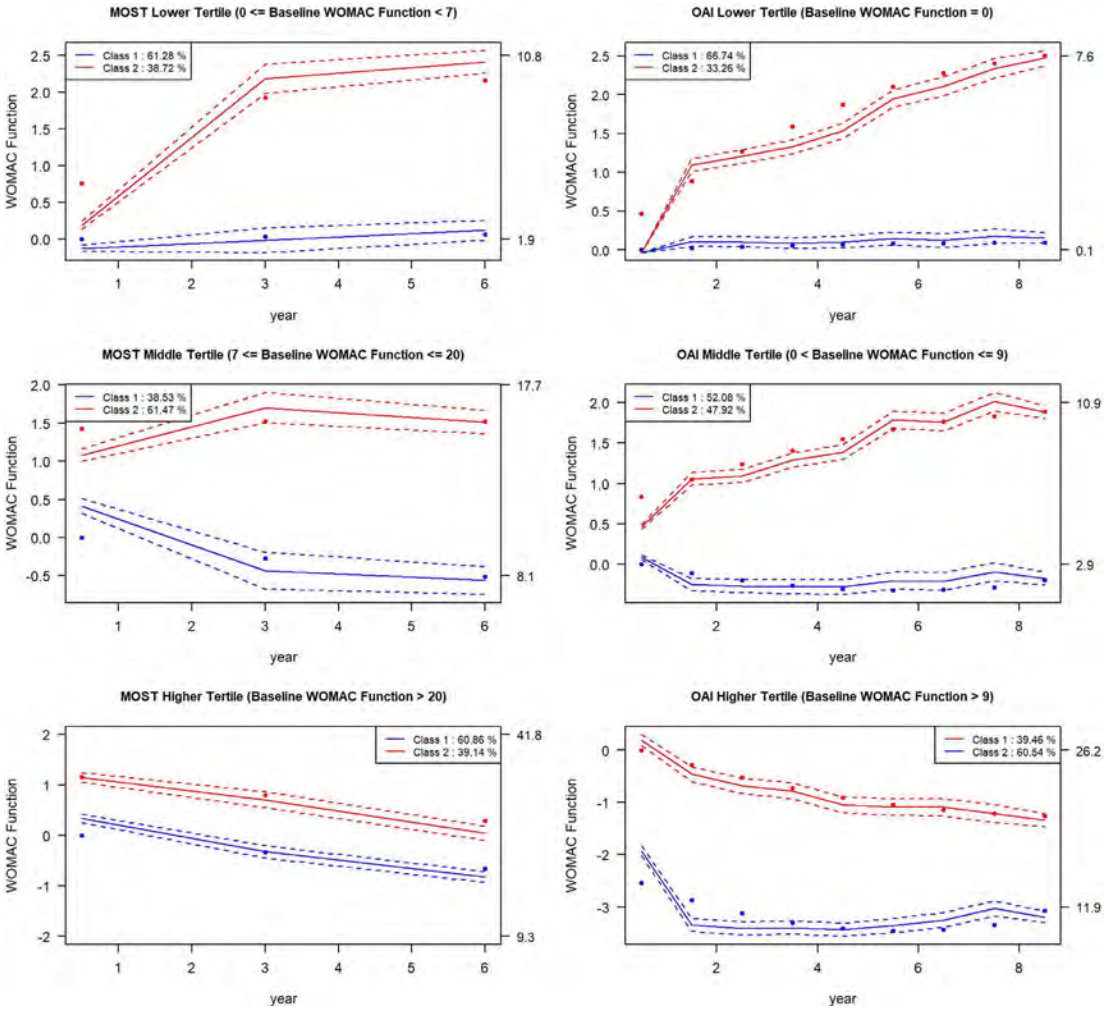

Figure 1. Knee symptom phenotyping by tertiles of baseline WOMAC function score for OAI and MOST The average trajectory (solid line) and confidence intervals (dashed lines) for WOMAC function are shown. The left column shows the trajectory results for OAI, and the right column show the trajectory results for MOST. Each row shows the tertile-specific cluster trajectories by strata of baseline WOMAC function score by tertile. The left-sided y-axis is the latent process WOMAC function score transformed using the link function. The right-sided y-axis is the actual WOMAC function score.

Background/Purpose: Knee pain and functional limitations are the most common symptoms of knee OA. Understanding the various patterns of symptoms (i.e., pain and function changes over time) can help identify individuals most in need of targeted interventions. Using OAI data, we have previously shown that there are distinct symptom trajectories for knees that start with no symptoms at baseline and there are specific predictors of a worse symptom trajectory. Our objective was to analyze knee symptoms among individuals with or at risk for knee OA with varying degrees of symptoms to identify temporal knee pain and function phenotypes using two large cohorts.

Methods: We selected 2965 knees from MOST, and 9491 knees from OAI that had the following knee pain/function measures available at baseline to develop the knee symptom phenotypes based upon trajectories of these measures over time: WOMAC function, WOMAC pain, and the Numerical Rating Scale (NRS) for knee pain severity. We used data from 0 to the 7^{th} year in MOST, and from 0 to the 9^{th} year in OAI to develop the trajectories. Knees that were already replaced at the baseline visit were excluded. Latent Class Mixed Models (LCMM) were employed to cluster the selected knees into distinct knee pain/function progression trajectories, while simultaneously using logistic regression to identify predictors associated with each trajectory. The response covariance matrix was allowed to be different for each latent class. We used tertiles of the baseline WOMAC function score as strata for LCMM analyses for each of the symptom measures.

Results: In both cohorts, two trajectories for each model were identified as optimal. For each tertile of baseline WOMAC function, the patterns of the trajectories were similar for each of the pain and function outcomes. As a sample illustration, the clusters for WOMAC function by tertile for MOST and OAI are shown in Figure 1. For the lowest tertile, there was a stable

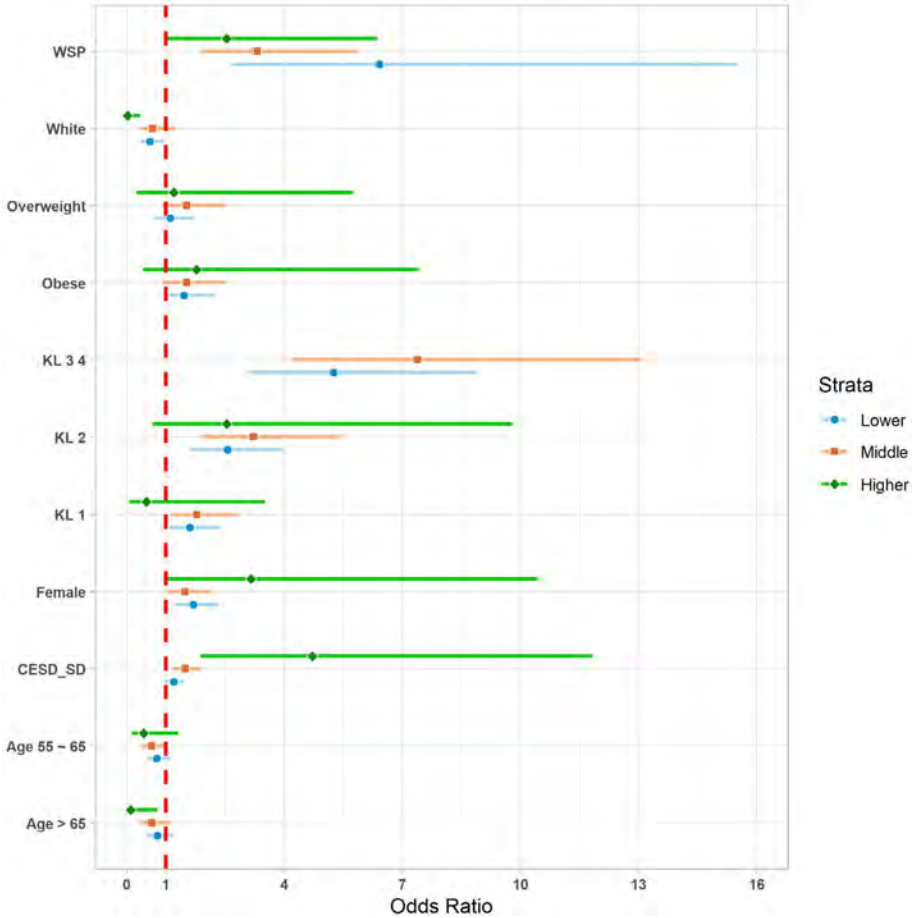

Figure 2. Summary of the predictors for being in the Red Trajectory (i.e., worse/worsening) vs. the Blue Trajectory (i.e., stable/improving) [in Figure 1] by tertiles of baseline WOMAC function score for MOST WSP = widespread pain; KL = Kellgren-Lawrence; CES-D_SD = Center for Epidemiologic Studies Depression scale by standard deviation OR of KL 3, 4 for the highest tertile is 99.48, with CI [5.26, 1881.83]. This information was not included in the plot due to scale issues.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

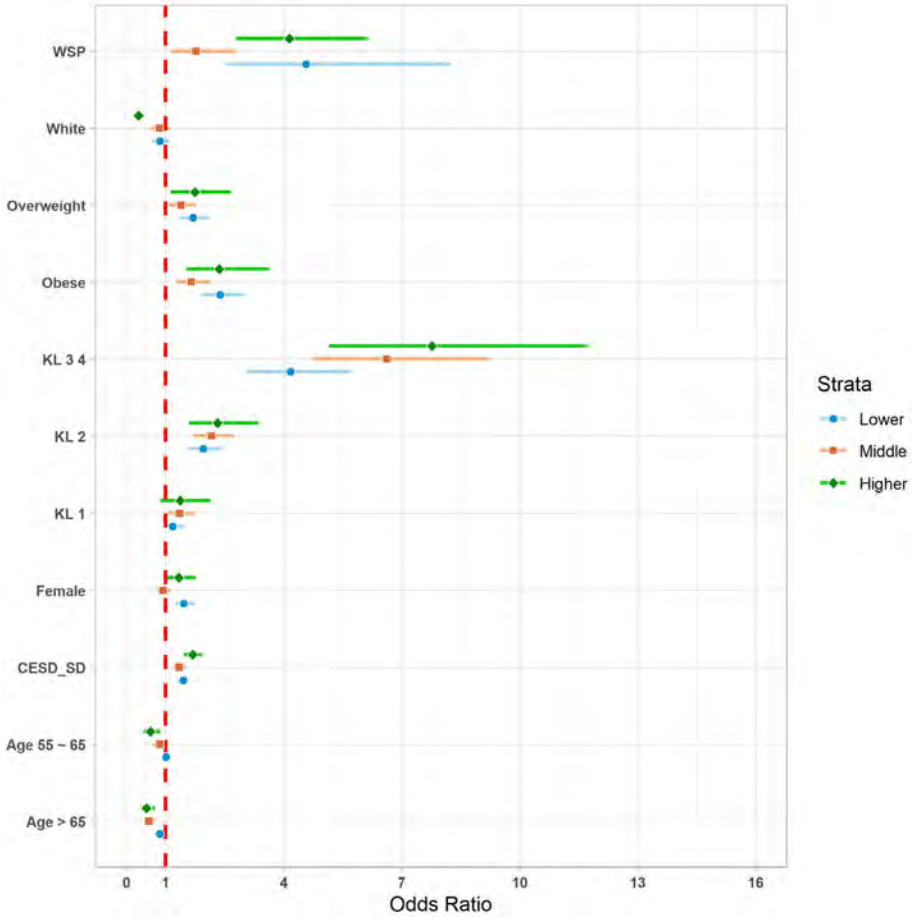

Figure 3. Summary of the predictors for being in the Red Trajectory (i.e., worse/worsening) vs. the Blue Trajectory (i.e., stable/improving) [in Figure 1] by tertiles of baseline WOMAC function score for OAI WSP = widespread pain; KL = Kellgren-Lawrence; CES-D_SD = Center for Epidemiologic Studies Depression scale by standard deviation

trajectory (blue) vs. a rapidly worsening trajectory (red). For the middle tertile, there was an improving trajectory (blue) vs. a worsening trajectory (red). For the highest tertile, both the red and blue clusters showed improving trajectories, but starting at different baseline scores. The ORs for being in the red (i.e., worse/worsening) vs. the blue (i.e., stable or improving) clusters for each tertile are summarized in Figure 2 for MOST and Figure 3 for OAI. The predictors in common across models associated with being in the red (i.e., worse) cluster were widespread pain, overweight/obese, higher Kellgren-Lawrence Grade (KLG), and more depressive symptoms (i.e., Center for Epidemiologic Studies Depression scale, CES-D).

Conclusion: For both MOST and OAI, similar symptom trajectories were identified when the cohorts were stratified using the tertile of the baseline WOMAC function score. We have also identified readily assessable predictors of the worse symptom trajectories. The trajectories with worse symptom progression may represent a group to target with interventions earlier in their disease course.

Abstract Number: 0326

Gender Disparities in Clinical Outcomes Among Older Adults with Knee Osteoarthritis: A Retrospective Cohort Study

Kinga Grzybowski[1], Ahmer Khan[2], Samuel Bonomo[3] and Arthur Lau[4], [1]Jefferson Einstein Montgomery Hospital, Maspeth, NY, [2]Jefferson Einstein Philadelphia Hospital, Philadelphia, [3]Jefferson Einstein Montgomery Hospital, East Norriton, PA, [4]Jefferson Einstein Hospital, Maple Glen, PA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0306–0336) Osteoarthritis – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Osteoarthritis (OA) is the most common type of arthritis which classically affects multiple joints, mainly the knees. About 595 million people worldwide suffer from OA which affects older individuals after the age of 50; females more frequently affected than males. The reason for the increased risk in females is suspected to be multifactorial and possibly related to genetics and environment. Many studies have found that women suffer from more severe disease compared to men. An observational, retrospective cohort study was conducted using the TriNetX database, which uses electronic health records from over 140 global collaborative networks, to explore gender differences in the diagnostic evaluation, treatment, and outcomes in patients with OA of the knees.

Methods: Inclusion criteria were limited to patients above the age of 65, assigned the ICD-10 code M17 for the diagnosis of OA of the knee. Individuals with RA, osteoporosis, gout, FM, polymyalgia rheumatica, AS and patients on steroids were excluded. Two cohorts were studied: females and males over the age of 65. The index event was defined as the initial appearance of the diagnosis of OA of the knee. Propensity matching was used for age, race/ethnicity and other comorbidities at the time of the index event. The outcomes evaluated included falls, fractures, depression, anxiety, PCP Visits, hospitalizations, mortality, chronic pain, opioid use, sleep disturbances, and visits to skilled nursing facilities (SNF Visits). Patients who experienced any of these outcomes prior to the index event were excluded and both risk and risk ratio calculations were measured.

Results: The dataset included 354,678 males, and 521,319 females. After propensity matching the average age was 70. Most males and females were White, of unknown race, or Black/African American. After propensity matching, a total of 219,227 patients were excluded from both groups and the outcomes were calculated. Analysis showed a statistically significant difference for falls (RR 1.141, 95% CI 1.105-1.178, P< 0.0001), fractures (RR 1.349, 95% CI 1.29-1.41, P< 0.0001),

Table 1: Baseline Characteristics of Both Cohorts Before (Left) and After (Right) Propensity Matching

Characteristics	Males	Females	p-value	Males	Females	p-value
Demographics						
Age at Index; mean ± SD	70.0 ± 8.89	70.8 ± 9.12	<0.0001	70.0 ± 8.89	70.0 ± 8.92	0.6920
White	59.7%	51.1%	<0.0001	59.4%	59.5%	0.6674
Unknown Race	23.4%	27.3%	<0.0001	23.6%	23.6%	0.8547
Black/African American	8.0%	11.5%	<0.0001	8.0%	8.1%	0.8418

Table 2: Differences in Diagnosis, Treatment, and Clinical Outcomes of Both Cohorts

Outcomes		Males (328,385)	Females (328,385)	RR (95% CI), P-value
Falls	*n* after matching in cohort	6,991	7,895	RR 1.141 (95% CI 1.105-1.178)
	Patients with outcome (%)	2.2%	2.5%	P<0.0001
Fractures	*n* after matching in cohort	3,356	4,489	RR 1.349 (95% CI 1.29-1.41)
	Patients with outcome (%)	1.1%	1.4%	P<0.0001
Depression	*n* after matching in cohort	7,587	10,355	RR 1.409 (95% CI 1.369-1.451)
	Patients with outcome (%)	2.4%	3.4%	P<0.0001
Anxiety	*n* after matching in cohort	9,494	13,753	RR 1.507 (95% CI 1.469-1.546)
	Patients with outcome (%)	3.1%	4.6%	P<0.0001
PCP Visits	*n* after matching in cohort	16,744	16,489	RR 0.972 (95% CI 0.952-0.992)
	Patients with outcome (%)	5.8%	5.7%	P 0.0074
Hospitalizations	*n* after matching in cohort	307	198	RR 0.645 (95% CI 0.539-0.771)
	Patients with outcome (%)	0.094%	0.06%	P<0.0001
Mortality	*n* after matching in cohort	4,395	3,760	RR 0.855 (95% CI 0.819-0.893)
	Patients with outcome (%)	1.35%	1.15%	P<0.0001
Chronic Pain	*n* after matching in cohort	15,684	15,793	RR 1.002 (95% CI 0.98-1.023)
	Patients with outcome (%)	5.3%	5.3%	P 0.8908
Opioid Use	*n* after matching in cohort	390	253	RR 0.648 (95% CI 0.554-0.76)
	Patients with outcome (%)	0.1%	0.08%	P<0.0001
Sleep Disorders	*n* after matching in cohort	14,789	12,510	RR 0.821 (95% CI 0.803-0.841)
	Patients with outcome (%)	5.0%	4.1%	P<0.0001
SNF Visits	*n* after matching in cohort	306	375	RR 1.226 (95% CI 1.054-1.426)
	Patients with outcome (%)	0.09%	0.114%	P 0.0080

depression (RR 1.409, 95% CI 1.369-1.451, P< 0.0001), anxiety (RR 1.507, 95% CI 1.469-1.546, P< 0.0001), and SNF visits (RR 1.226, 95% CI 1.054-1.426, P 0.0080) in females. Additionally, PCP visits (RR 0.972, 95% CI 0.952-0.992, P 0.0074), hospitalizations (RR 0.645, 95% CI 0.539-0.771, P< 0.0001), mortality (RR 0.855, 95% CI 0.819-0.893, P< 0.0001), opioid use (RR 0.648, 95% CI 0.554-0.76, P< 0.0001), and sleep disorders (RR 0.821, 95% CI 0.803-0.841, P< 0.0001) were determined to be statistically significant in males.

Conclusion: The study shows that females with OA are at higher risk for falls, fractures, depression, anxiety, and SNF visits. Men with OA are more likely to face sleep disorders, seek PCP visits, require more hospitalizations, have a higher mortality, and are more likely to be prescribed opioids, indicating that both genders face different consequences of OA, and that gender discrepancies exist. Additional research should be conducted specifically focusing on gender differences in osteoarthritis to explore potential contributive or causative factors that may explain these findings.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0306–0336) Osteoarthritis – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Radiomics involves the high-throughput extraction of quantitative data from medical imaging. This study aimed to develop a radiomic analysis pipeline applied to hand radiographs and evaluate its ability to classify joints according to the Kellgren-Lawrence (KL) score, a grading system for hand osteoarthritis severity. The goal was to assess whether radiomic features could enable automated and standardized KL classification, complementing expert visual assessment.

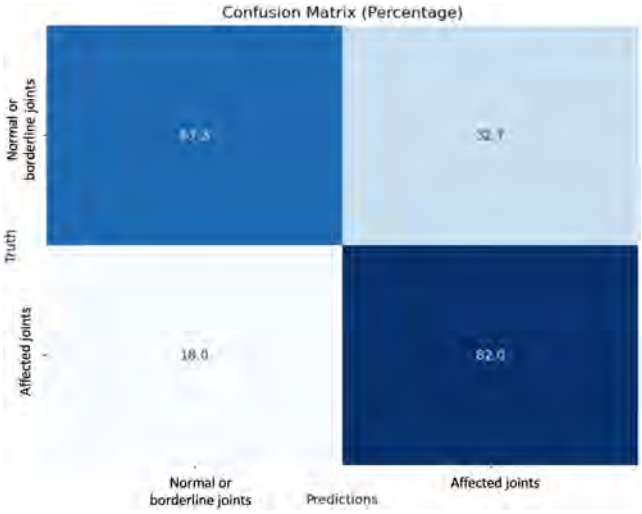
Methods: The study was based on 436 hand radiographs from the DIGICOD cohort, a prospective study of patients with hand osteoarthritis according to American College of Rheumatology criteria. After excluding 30 radiographs not found in PACS and 25 with artifacts or surgical hardware, 381 radiographs were analyzed, representing 10,531 joints (trapeziometacarpal [TMC], metacarpophalangeal [MCP], proximal interphalangeal [PIP], and distal interphalangeal [DIP] joints). KL grading was performed by an experienced radiologist at baseline.

Radiomic analysis involved several steps: (1) joint segmentation using an algorithm developed for the study. Manual segmentations from 20 patients served as ground truth to train a U-Net model with iterative training and correction; (2) extraction of 179 radiomic features (4 shape, 45 intensity histogram, and 130 texture features); (3) exclusion of texture features with relative variation < 0.05 after pixel shuffling (deemed non-informative); (4) dimensionality reduction by removing highly correlated features (Spearman > 0.9), resulting in 86 features. A random forest model with stratified cross-validation selected the 20 most relevant features for predicting KL scores. Classification performance was evaluated by comparing predicted vs. expert-assigned KL scores, using area under the curve (AUC), accuracy, and balanced accuracy. Accuracy reflects the proportion of correctly classified joints, while balanced accuracy adjusts for class imbalance.

Overview of the radiomic pipeline used in this study, from image acquisition and joint segmentation to feature extraction and classification modeling. The pipeline was designed to automate Kellgren-Lawrence scoring from standard hand radiographs in patients with hand osteoarthritis (DIGICOD cohort).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Comparison Between Manual and Automated Segmentation of Hand Joints. Comparison between manual segmentation by the radiologist (in orange) and automated segmentation using a U-Net-based model (in light blue). Concordant areas between both segmentations are shown in dark blue, indicating high overlap and supporting reliable feature extraction for radiomic modeling.



Confusion Matrix for Binary Classification of Joint Osteoarthritis Severity. Confusion matrix illustrating the performance of the radiomic model in predicting affected (KL 2–4) versus non-affected (KL 0–1) joints.

Results: The radiomic model achieved good classification performance for KL grading. Differentiation between affected joints (KL 2–4) and normal or borderline joints (KL 0–1) yielded an AUC of 0.81 and accuracy of 0.74. Discrimination between non/mildly affected (KL 0–2) and severely affected joints (KL 3–4) achieved an AUC of 0.83 and accuracy of 0.68. Considering all KL classes, the overall AUC was 0.76, with balanced accuracy of 0.37. Joint-type specific analysis (affected vs. normal/borderline) showed lower performance, with AUCs of 0.67, 0.71, and 0.49 and balanced accuracies of 0.34, 0.35, and 0.39 for MCP, PIP, and DIP joints, respectively. A downsampling strategy was applied to mitigate class imbalance, slightly improving overall classification, especially for the most frequent classes.

Conclusion: This study is the first to evaluate radiomic analysis in hand osteoarthritis. Radiomics enabled, to some extent, automated reproduction of KL classification. However, performance varied depending on joint type and severity. While this approach shows promise as a complementary tool for assessing hand osteoarthritis, external validation on an independent cohort is required before clinical application.

Abstract Number: 0328

High synovial fluid leukocyte counts and markers of TLR activation correlate with poorer response to injections in patients with knee OA

Lance Murphy[1], Baofeng Hu[2], Vu Nguyen[3], Bryant England[4], Katherine Wysham[5], Mercedes Quinones[6], Joshua Baker[3] and Carla Scanzello[3], [1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, [2]University of Pennsylvania, Wynnewood, PA, [3]University of Pennsylvania, Philadelphia, PA, [4]University of Nebraska Medical Center, Omaha, NE, [5]VA PUGET SOUND/UNIVERSITY OF WASHINGTON, Seattle, WA, [6]Washington DC VA Medical Center, Bethesda, MD

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0306–0336) Osteoarthritis – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Toll-like receptors (TLRs) are pattern-recognition receptors of the innate immune response and are important in driving the initial activation of myeloid lineage cells to both pathogenic and non-pathogenic challenges. Deficiency of TLR3, TLR4, or CD14 (a TLR co-receptor) have been shown to mitigate OA progression and pain in animal models. However, the role of TLR signaling in human knee OA (KOA) is less studied. We evaluated the levels of synovial fluid (SF) markers including sTLR4 and sCD14 from patients enrolled in a clinical trial testing the impact of corticosteroid injections to determine if these markers could predict those that are most likely to respond to injections.

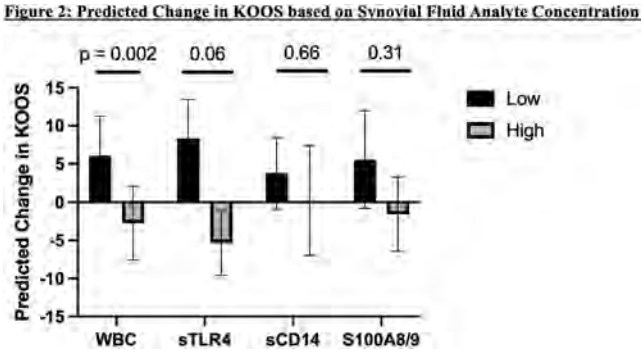
Methods: The MOVE-OK trial was a VA-funded, a multi-center blinded crossover randomized trial, comparing the effects of corticosteroid + lidocaine vs. lidocaine-only injections in Veterans with KOA . Inclusion criteria included a clinical diagnosis of KOA with a K-L X-ray grade ^{3}1, aged 40-80 years, and a clinical indication for joint injection according to the treating provider. 221 participants were randomized to receive blinded corticosteroid (CS) injections plus lidocaine (LC) (40 mg methylprednisolone) or LC-only injections then crossed-over to the other injection at 16 weeks. The primary outcome was the change in the total KOOS measured bi-weekly between 0 and 12 weeks after each injection. 196 participants received both injections, and SF was collected at the time of injection from a total of 40 patients with 14 patients having fluid collected at both injection time-points. We performed ELISAs on SF from these 14 patients measuring sTLR4, sCD14, and S100A8/9. Associations between SF biomarkers and the change in KOOS was assessed using linear regression incorporating generalized estimating equations to evaluate all time-points (2-12 weeks) after each injection, adjusting for the baseline KOOS score.

Results: Patients included in this subanalysis exhibited similar demographics to those enrolled in the main study (Table 1). SF from 4 patients had sTLR4 concentration below the limit of detection, but otherwise analytes were detectable in all samples.

Figure 1: Demographics of patients

Factor	SF subgroup	Large MOVE-OK group
N	14	221
Age	67 (8)	64 (9)
# Female Patients	1 (7%)	36 (16.3%)
BMI	32.2 (5.6)	32.6 (6.7)
KOOS Baseline	47.0 (20.8)	43.4 (16.6)
SF WBC concentration	250 (189, 340)	-
sCD14 concentration (ng/mL)	604.4 (365.5, 745.1)	-
S100A8/9 Concentration (ng/mL)	47.6 (22.8,102.3)	-
sTLR4 Concentration (pg/mL)	336.9 (0, 543.8)	-

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



The median (IQR) concentrations of sCD14, S100A8/9 and sTLR4 are shown in Table 1. Patients with high SF WBC counts at baseline were less likely to show improvement in their KOOS scores over the course of the study (Figure 2). A similar trend was shown for sTLR4 concentration in SF. While there was numerically less improvement in KOOS over time between patients with high vs. low concentrations of sCD14 and S100A8/9, differences were not significant. There were no interactions to suggest that the association between biomarkers and the change in KOOS score differed between those receiving a CS v. LC-only injection.

Conclusion: Our results suggest that patients with higher SF levels of WBC and sTLR4 demonstrate less improvement in response to knee injection. Future proteomic analyses of these samples are planned and may provide additional insights. Analysis of these markers in larger cohorts are needed to validate these findings, but our results point to a potential importance of inflammation and the innate immune response in the joint in predicting symptom improvement in response to interventions.

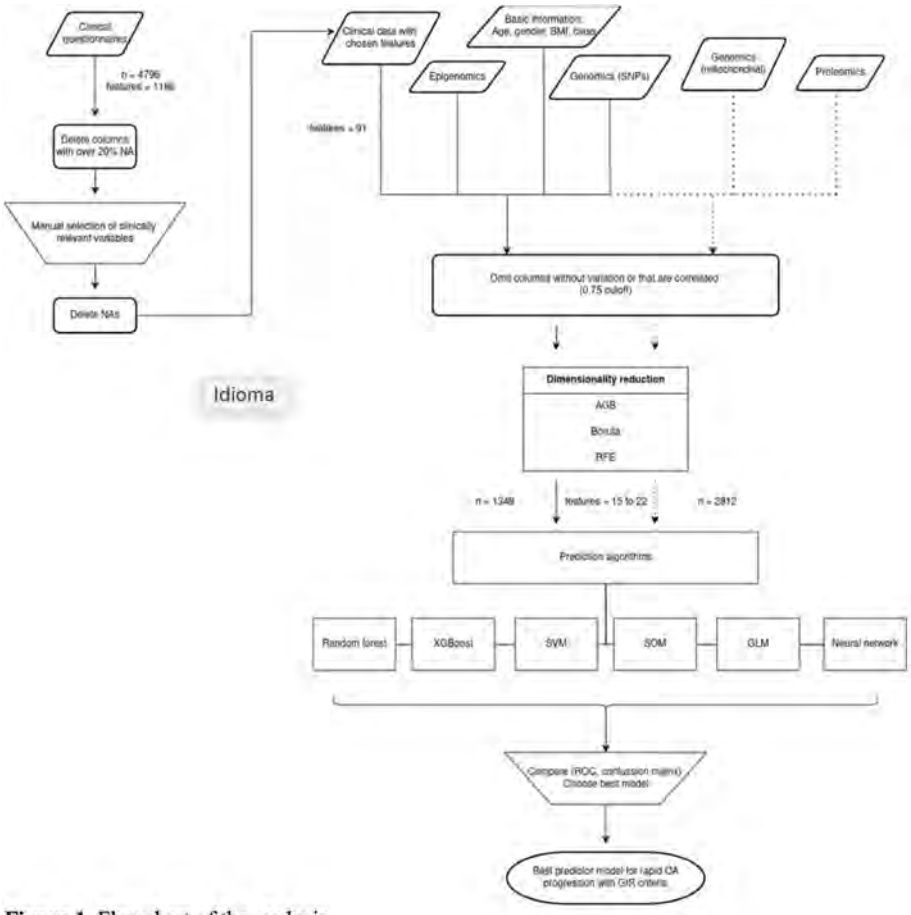

Figure 1. Flowchart of the analysis

Background/Purpose: Osteoarthritis (OA) is the most common chronic joint disorder, characterized by structural cartilage and bone damage that often causes pain and disability. However, the severity of joint damage does not always correlate with the level of pain. The limited effectiveness of current treatments may stem from difficulties in identifying patients at high risk of rapid structural progression. The Rheumatology and Health Research Group (GIR-S) defines progression as moving from a Kellgren and Lawrence (KL) grade 0–1 to ≥3, or from KL 2 to KL 4 or total knee replacement (TKR) within 48 months.

Our group has identified molecular biomarkers that, together with clinical and imaging data, may enhance the application of machine learning (ML) to detect patterns associated with OA subgroups. Advanced statistical tools enable us to extract multivariate signatures to differentiate patient phenotypes more precisely.

Our objective is to develop a predictive model for the rapid structural progression of osteoarthritis by integrating various machine learning techniques and using clinical, genomic, proteomic, and epigenetic data to predict structural progression over time in well-characterized prospective patient cohort, Osteoarthritis Initiative (OAI).

Methods: Rapid structural progression was defined according the GIR criteria, patients with an increase in the Kellgren-Lawrence (KL) score from ≤1 to ≥3, or from KL = 2 to KL = 4, or joint replacement over a follow-up period of 48 months. We used clinical, imaging, molecular biomarkers (including 20 proteins, 8 nuclear SNPs, and 3 mitochondrial haplogroups). The selected features were subsequently filtered using Recursive Feature Elimination (RFE) for dimensionality reduction. Using this data, we generated six machine learning models, dividing the data into 75% for training and 25% for testing. Figure 1.

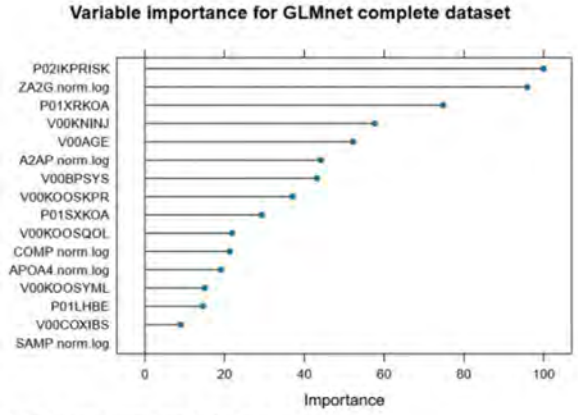

Figure 2a. Variable importance for GLMnet complete dataset.

Abbreviations: *P02IKPRISK* (Either knee symptom status at IEI); *ZA2G.norm.log* (normalized values of protein ZA2G (Alpha-2-Glycoprotein 1, Zinc- Binding); *P01XRKOA* (Baseline radiographic knee OA status by person); *V00KNINJ* (Either knee, injections for treatment of arthritis, past 6 months); *V00AGE* (Age when entering study); *A2AP.norm.log* (normalized values of protein A2AP (Alpha 2-antiplasmin); *V00BPSYS* (Blood pressure: systolic); *V00KOOSKPR* (Right knee, KOOS Pain Score); *P01SXKOA* (Baseline symptomatic knee OA status by person); *V00KOOSQOL* (KOOS Quality of Life Score); *COMP.norm.log* (normalized values of protein COMP (Cartilage oligomeric matrix protein); *APOA4.norm.log* (normalized values of protein APOA4 (Apolipoprotein A4); *V00KOOSYML* (KOOS Symptoms Score); *P01LHBE* (Left hand exam: total number of bony enlargements); *V00COXIBS* (Used COXIBS for joint pain or arthritis more than half the days of the month, past 30 days). *SAMP.norm.log* (normalized values of protein SAMP (Small Archaeal Modifier Protein).

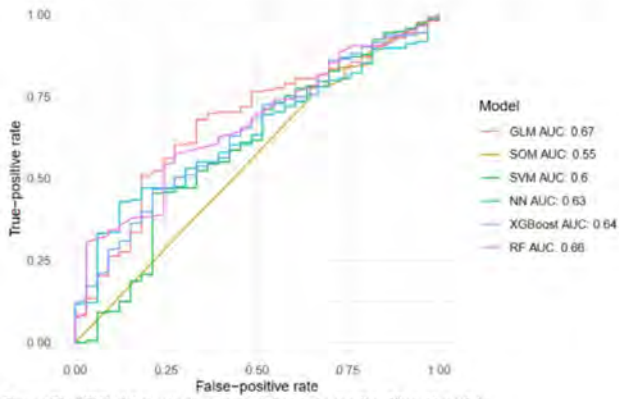

Figure 2b. *ROC plot comparison for test data between the different models.*

Figure 2. Variable importance for GLMnet dataset. Figure 2b. ROC comparison for test in the dataset.

Results: After applying Recursive Feature Elimination (RFE), the dataset included 2812 individuals and 20 variables, with 240 rapid progressors. We then applied various machine learning algorithms and compared their performance across training and testing subsets in both datasets. Among the models tested, the GLMnet model demonstrated the best performance with AUC of 0.67 (Figure 2a and 2b).

Conclusion: While promising, its full potential requires validation with additional cohorts to ensure robustness. This tool could prove invaluable for the early identification of patients at risk of rapid structural progression of OA, enabling timely interventions that could significantly improve both patient outcomes and the effectiveness of early treatment strategies.

Abstract Number: 0330

Prevalence of Radiographic and Symptomatic Osteoarthritis, and Ultrasound Features at the Knee: The Johnston County Health Study

Maya Patel[1], Carolina Alvarez[2], Todd Schwartz[3], Tessa Walker[1], Serena Savage-Guin[1], Jordan Renner[1], Jonathan Samuels[4], Janice Lin[5], Minna Kohler[6], Catherine Bakewell[7], Yvonne Golightly[8] and Amanda Nelson[1], [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]University of North Carolina at Chapel Hill, Miami, FL, [3]University of North Carolina-Chapel Hill, Chapel Hill, NC, [4]NYU Langone, Rye Brook, NY, [5]Stanford University, Palo Alto, CA, [6]Massachusetts General Hospital, Harvard Medical School, Boston, MA, [7]Intermountain Healthcare, Salt Lake City, UT, [8]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0306–0336) Osteoarthritis – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: To report sex and BMI differences among ultrasound (US) features of knee osteoarthritis (KOA), patient-reported symptoms (Ksx), radiographic KOA (rKOA), and symptomatic KOA (sxKOA), in a general population.

Methods: Johnston County Health Study participants (JoCoHS, 2019-24, n=902) provided data on demographics, comorbidities, clinical features and symptoms, along with imaging using standardized acquisition and scoring. Prevalence (weighted to the 2020 census population for Johnston County, North Carolina) estimates and 95% confidence intervals (CI) for Ksx, rKOA, sxKOA, severe rKOA, and US features were calculated overall and for sex and BMI subgroups, at the person-level under a stratified sampling design. No formal testing is performed for differences among subgroups, instead CI indicate precision of estimates and the overlap among subgroups. RKOA was defined as Kellgren-Lawrence grade ≥ 2, severe rKOA as grades 3-4, and sxKOA as both rKOA and Ksx in the same knee. Standardized US features were obtained as previously reported (PMID39989271).

Results: The population was majority female (67%), non-Hispanic white (66%) with an average age of 55 ± 10 years and average BMI of 33 ± 8 kg/m^2. Of these, 861 individuals had US imaging (no major demographic differences existed compared to the overall group). The overall weighted prevalence of Ksx, rKOA, sxKOA, and severe rKOA, were 61%, 36%, 27%, and 21%, respectively, and all were higher among females and participants with overweight/obesity (Table 1). Among both sexes, rKOA, sxKOA, and severe rKOA were more prevalent among those with severe obesity compared to those with

Table 2 Weighted* knee US prevalence estimates (%) and corresponding 95% confidence intervals (CI) by sex, of the of the JoCoHS cohort 2019-2024, N=861

US features (not mutually exclusive)	Female	Male
	Weighted % (95% CI)	Weighted % (95% CI)
GS effusion/synovitis 1: a small hypo/anechoic line beneath the capsule	47.4 (42.5, 52.3)	54.8 (48.5, 61.1)
GS effusion/synovitis 2: elevated joint capsule parallel to joint area	25.3 (21.1, 29.6)	40.5 (34.3, 46.7)
GS effusion/synovitis 3: convex distension of the joint capsule	3.5 (1.8, 5.2)	8.9 (5.5, 12.4)
GS synovitis 1: minimal distention of recess by hypo/anechoic material	42.5 (37.7, 47.4)	49.7 (43.4, 56.1)
GS synovitis 2: moderate distention with flat or concave limit	26.9 (22.5, 31.3)	40.7 (34.4, 46.9)
GS synovitis 3: severe or bulging distention of joint recess	2.7 (1.4, 4.0)	8.8 (5.4, 12.2)
GS effusion: abnormal hypo/anechoic intra-articular material	41.9 (37.1, 46.7)	64.0 (57.8, 70.1)
Suprapatellar PD for synovitis 1: trace to 10% intra-articular color signal	31.1 (26.8, 35.4)	37.7 (31.5, 43.9)
Suprapatellar PD for synovitis 2: 10% or more intra-articular color signal	5.7 (3.5, 7.9)	7.1 (3.9, 10.2)
Osteophytes, medial tibiofemoral 1: small but distinct	35.2 (30.6, 39.9)	32.6 (26.7, 38.5)
Osteophytes, medial tibiofemoral 2: medium/larger	18.3 (14.5, 22.1)	16.6 (12.3, 21.0)
Osteophytes, medial tibiofemoral 3: large, bulky, prominent	5.4 (3.8, 7.0)	7.3 (4.2, 10.4)
Osteophytes, lateral tibiofemoral 1: small but distinct	36.8 (32.0, 41.6)	34.3 (28.4, 40.2)
Osteophytes, lateral tibiofemoral 2: medium/larger	17.5 (14.0, 21.0)	13.7 (9.5, 18.0)
Osteophytes, lateral tibiofemoral 3: large, bulky, prominent	2.6 (1.3, 4.0)	2.0 (0.6, 3.3)
Meniscal extrusion, medial tibiofemoral	22.7 (18.6, 26.9)	15.6 (11.2, 19.9)
Meniscal extrusion, lateral tibiofemoral	31.3 (26.7, 35.8)	25.8 (20.6, 31.1)
Cartilage damage, medial femur/trochlea 1: hyperechoic, loss of sharpness	71.1 (66.6, 75.5)	61.5 (55.4, 67.7)
Cartilage damage, medial femur/trochlea 2: localized thinning	41.7 (36.9, 46.5)	28.3 (22.6, 33.9)
Cartilage damage, medial femur/trochlea 3: complete cartilage loss	7.1 (4.8, 9.4)	3.1 (1.1, 5.1)
Cartilage damage, lateral femur/trochlea 1: hyperechoic, loss of sharpness	68.0 (63.3, 72.7)	59.2 (53.0, 65.5)
Cartilage damage, lateral femur/trochlea 2: localized thinning	34.4 (29.8, 39.0)	22.5 (17.5, 27.5)
Cartilage damage, lateral femur/trochlea 3: complete cartilage loss	5.9 (4.0, 7.8)	5.5 (2.6, 8.3)
Popliteal cyst 1: small/possible	53.9 (48.9, 58.9)	51.9 (45.4, 58.4)
Popliteal cyst 2: definite	6.5 (4.4, 8.5)	6.3 (3.6, 9.0)
Calcium crystal deposition, any view	21.3 (17.1, 25.5)	19.1 (14.5, 23.7)

*Weighted to the 2020 target population for Johnston County, NC; ne=not estimable due to cross-tabulation cell sizes<5
GS: greyscale; PD: power doppler

obesity (Table 1). Among those with severe obesity, the prevalence of Ksx was greater among females than males with non-overlapping confidence intervals (Table 1).

Mild (grade 1) US features were seen in one-third to one-half of knees. Grey-scale (GS) effusion and synovitis were more prevalent among males compared with females, particularly when moderate or severe (Table 2). In contrast, US findings of medial and lateral cartilage damage were more prevalent in females than males (Table 2). With increasing levels of obesity, effusion/synovitis were less prevalent while osteophytes and medial cartilage damage were more prevalent (Table 3).

Table 3 Weighted* knee US prevalence estimates (%) and corresponding 95% confidence intervals (CI) by BMI group, of the of the JoCoHS cohort 2019-2024, N=861

*Weighted to the 2020 target population for Johnston County, NC; ne=not estimable due to cross-tabulation cell sizes<5; GS: grayscale; PD: power doppler

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Additionally, among knees with rKOA compared to those without, osteophytes, meniscal extrusion, calcium crystals, and moderate to severe cartilage damage were much more prevalent (data not shown).

Conclusion: We identified differences in the prevalence of US features of KOA, Ksx, rKOA, sxKOA, and severe rKOA particularly among females with severe obesity. Prior prevalence studies have not distinguished between obesity and severe obesity, due to the relatively small proportion of the population within the severe obesity category. The data above reveals non-overlapping 95% confidence intervals in outcome prevalence among levels of obesity, which should be investigated further. This differentiation could lead to the development of more effective prevention and treatment strategies, as well as a better understanding of the distinct mechanisms driving knee OA in individuals with severe obesity.

Safety and Efficacy of Colchicine in Osteoarthritis: A Systematic Review and Meta-Analysis of 6,965 Patients

Mohamed Abdelsalam[1], Bassant Elaraby Elsayed Badwy[2], Menat Alla Ayman Ali Mahdy[2], Maryam Lasheen[3], Hadeer Hafez[4], Omar Sameh Nabil El Sedafy[1] and Mohamed Reda Awad[5], [1]Misr University For Science and Technology, 6 october, Al Jizah, Egypt, [2]Misr University For Science and Technology, Nasr City, Al Qahirah, Egypt, [3]Misr University For Science and Technology, Helwan, Al Qahirah, Egypt, [4]6th October University, 6 october, Al Jizah, Egypt, [5]Al Azhar University, Cairo, Egypt, Giza, Al Jizah, Egypt

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0306–0336) Osteoarthritis – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Osteoarthritis (OA) is the most common joint disease, that leads to significant pain and affects quality of life, particularly in older adults. Current treatments primarily focus on symptom relief, as no treatment has yet demonstrated the ability to modify disease progression or restore damaged joint structures. Colchicine, a medication traditionally used to treat gout, has attracted interest as a potential therapy for OA due to its anti-inflammatory effects. Despite growing interest, the evidence regarding colchicine efficacy and safety in OA management remains inconclusive. This study aims to assess the safety and efficacy of colchicine in treating OA.

Methods: We conducted a systematic search across multiple databases, such as PubMed, Web of Science, and Scopus from inception till April 5th, 2025. We included randomized clinical trials evaluating the efficacy and safety of colchicine in OA (Fig 1). The main outcome was pain measured by visual analogue scale (VAS). We stratified the outcome into three follow-up intervals: short-term (4 and 8 weeks), medium-term (10, 12 and 16 weeks), and long-term (20 and 24 weeks or longer). We used Rayyan for identifying duplicates, title, abstract and full-text screening and Review Manager (RevMan) software Version 5.4 for meta-analysis.

Results: This systematic review and meta-analysis incorporates data from a total of 21 clinical trials encompassing 6,965 participants, with 13 contributing to the meta-analysis including 879 participants. The main objective was to assess the

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure (1) PRISMA Flow Chart Illustrating Search Strategy and Selection of Included Studies

efficacy of colchicine across multiple outcome measures. Pain relief, assessed by VAS, exhibited a significant short-term improvement at week 8 (standardized mean difference [SMD] = -1.03, 95% confidence interval [CI]: -2.01, -0.06, p=0.04), and a non-significant improvement at medium-term follow-up at week 12 (SMD = -0.34, 95% CI: -0.78, 0.10, p=0.75), and a significant long-term improvement at week 20 follow-up (SMD = -1.24, 95% CI: -1.73, -0.76, p< 0.00001), with an overall significant improvement (SMD = -0.73, 95% CI:-1.06, -0.41, p < 0.00001) (Fig 2). Similarly, quality of life indicated significant impact of colchicine treatment (SMD = -0.48, 95% CI: -0.83, -0.12, p =0.008). However, for physical dysfunction, the analysis reveals no statistically significant difference (SMD = -0.21, 95% CI: -0.45, 0.04, p=0.09), with significant difference in adverse events (AEs) (risk ratio [RR]: 1.27; 95% CI:1.07, 1.50, p=0.007) between colchicine and control groups (Fig 3).

Conclusion: This is the most recent and comprehensive systematic review and meta-analysis showing that colchicine is an effective therapeutic option for OA, with significant pain relief measured by VAS score. Additionally, it contributes to improved quality of life in patients with OA. However, physical dysfunction did not show significant differences. Future

Abstract Number: 0332

Safety, Short- and Long-Term Efficacy of Methotrexate in Osteoarthritis: A Systematic Review and Meta-Analysis

Mohamed Abdelsalam[1], Maryam Lasheen[2], Hadeer Hafez[3], Bassant Elaraby Elsayed Badwy[4], Omar Sameh Nabil El Sedafy[1] and Mohamed Reda Awad[5], [1]Misr University For Science and Technology, 6 october, Al Jizah, Egypt, [2]Misr University For Science and Technology, Helwan, Al Qahirah, Egypt, [3]6th October University, 6 october, Al Jizah, Egypt, [4]Misr University For Science and Technology, Nasr City, Al Qahirah, Egypt, [5]Al Azhar University, Cairo, Egypt, Giza, Al Jizah, Egypt

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0306–0336) Osteoarthritis – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Methotrexate (MTX), traditionally used for inflammatory conditions like rheumatoid arthritis, has well-established anti-inflammatory properties, recently gained interest as a potential therapeutic option for osteoarthritis (OA). Current treatments largely focus on symptom management, with limited options for altering disease course. This study aims to evaluate the safety and efficacy of MTX in reducing OA symptoms in both the short and long term.

Methods: We systematically searched PubMed, Web of Science, Embase, Ovid, and Scopus from inception to April 22, 2025. Studies evaluating the safety and efficacy of MTX in OA were included (Fig. 1). The primary outcome was pain, measured by the Visual Analogue Scale (VAS) or Numeric Rating Scale (NRS). Outcomes were stratified by follow-up duration: short-term (less than 6 months), medium-term (6 months and 9 months), and long-term (12 months). Data were extracted and analyzed using Review Manager 5.4 (RevMan) software.

Results: This systematic review and meta-analysis included 14 studies in the qualitative synthesis and 8 in the meta-analysis, encompassing 1251 and 649 patients, respectively. MTX significantly reduced pain (SMD: –0.47; 95% CI: –0.68 to –0.26). Subgroup analyses by treatment duration showed SMDs of –0.46 (95% CI: –0.75 to –0.17) at < 6 months, –0.75 (95% CI: –1.2 to –0.29) at 6 months, –0.42 (95% CI: –1.35 to 0.51) at 9 months, and –0.06 (95% CI: –0.46 to 0.34) at 12 months. For the WOMAC score, MTX had a significant overall effect (SMD: –0.71; 95% CI: –1.2 to –0.22), with subgroup SMDs of –0.45 (95% CI: –0.88 to –0.01) at < 6 months, –1.81 (95% CI: –4.56 to 0.94) at 6 months, –0.37 (95% CI: –0.78 to 0.04) at 9 months, and –0.27 (95% CI: –0.68 to 0.13) at 12 months. For physical function, the overall effect was significant (SMD: –0.53; 95% CI: –0.84 to –0.23), with subgroup SMDs of –0.46 (95% CI: –0.76 to –0.16) at < 6 months, –0.88 (95% CI: –1.73 to –0.03) at 6 months, –0.35 (95% CI: –0.81 to 0.12) at 9 months, and –0.19 (95% CI: –0.58 to 0.19) at 12 months. On stiffness, MTX also had an overall significant effect (SMD: –0.44; 95% CI: –0.65 to –0.23). Subgroup SMDs were –0.33 (95% CI: –0.68 to 0.01) at < 6 months, –0.52 (95% CI: –0.81 to –0.24) at 6 months, –0.39 (95% CI: –1.49 to 0.72) at 9 months, and –0.34 (95% CI: –1.43 to 0.75) at 12 months (Fig. 2). Our results stated that there is an overall significant difference in adverse events (AEs) (RR, 0.75; 95% CI, 0.60 to 0.94), with a significant difference in mild AEs (RR, 0.77; 95% CI, 0.61 to 0.97) and no significant difference in serious AEs (RR, 0.65; 95% CI, 0.31 to 1.34) (Fig. 3).

Conclusion: MTX provides significant short- and medium-term improvements in pain, stiffness, and physical function in OA, with the most pronounced benefit observed at 6 months. However, its safety profile in real-world settings requires more thorough investigation. Further large-scale randomized controlled trials are needed to confirm these findings and assess long-term efficacy.

Figure (2) Forest Plots of Treatment Effects for MTX in OA by Follow-Up Duration. (A) Pain Reduction (Fixed-Effects Model): Subgroups:<6 months: Studies included: Enteshari-Moghaddam et al. 2019, Ferrero et al. 2021, Holanda et al. 2007, Kingsbury et al. 2024, Wenham 2013. 6 months: Studies included: Enteshari-Moghaddam et al. 2019, Kingsbury et al. 2024, Wang et al. 2023, Wenham 2013. 9 months: Studies included: Kingsbury et al. 2024. 12 months: Studies included: Ferrero et al. 2021, Kingsbury et al. 2024. Overall: Significant standardized mean difference (SMD) in pain reduction: -0.46 (95% CI: -0.64 to -0.27), with low heterogeneity (I2=19%). Test for overall effect: Z=4.89 (P<0.00001). Test for subgroup differences: χ2=6.05, df=3 (P=0.11), I2=50.4%. (A) Pain Reduction (Random-Effects Model): Studies included: Same as fixed-effects model. Overall: Significant SMD: -0.47 (95% CI: -0.68 to -0.26), with a heterogeneity of (I2=19%). Test for overall effect: Z=4.33 (P<0.0001). Test for subgroup differences: χ2=5.11, df=3 (P=0.16), I2=41.3%. (B) WOMAC Improvement (Fixed-Effects Model): Subgroups:<6 months: Studies included: Enteshari-Moghaddam et al. 2019, Ghosh 2020, Holanda et al. 2007, Kingsbury et al. 2024. 6 months: Studies included: Enteshari-Moghaddam et al. 2019, Kingsbury et al. 2024. 9 months: Studies included: Kingsbury et al. 2024. 12 months: Studies included: Kingsbury et al. 2024. Overall: Significant SMD in WOMAC improvement: -0.54 (95% CI: -0.70 to -0.39), with Considerable heterogeneity (I2=90%). Test for overall effect: Z=6.89 (P<0.00001). Test for subgroup differences: χ2=12.26, df=3 (P=0.007), I2=75.5%. (C) Stiffness Reduction (Fixed-Effects Model): Subgroups: <6 months: Studies included: Enteshari-Moghaddam et al. 2019, Holanda et al. 2007, Kingsbury et al. 2024, Strebkova 2024, Wenham 2013. 6 months: Studies included: Enteshari-Moghaddam et al. 2019, Kingsbury et al. 2024, Strebkova 2024, Wang et al. 2023, Wenham 2013. 9 months: Studies included: Kingsbury et al. 2024. 12 months: Studies included: Kingsbury et al. 2024. Overall: Significant SMD in stiffness reduction: -0.44 (95% CI: -0.65 to -0.23), with no heterogeneity (I2=0%). Test for overall effect: Z=4.05 (P<0.0001). Test for subgroup differences: χ2=0.74, df=3 (P=0.86), (I2=0%) Pain, WOMAC and stiffness reduction showed consistent benefits across time points, with the largest effects at 6 months. Heterogeneity was negligible for stiffness and pain but substantial for WOMAC. CI, confidence interval; SMD, standardized mean difference; WOMAC, Western Ontario and McMaster Universities Osteoarthritis Index; I2, heterogeneity index; df, degrees of freedom.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure (3) Forest Plot of Adverse Events (AEs) Associated with MTX in Osteoarthritis. MAEs: Subgroup: Studies included: Ferrero et al. 2021, Kingsbury et al. 2024, Wang et al. 2023. Overall: Significant reduction in MAEs with MTX (RR = 0.77; 95% CI: 0.61–0.97), with no heterogeneity (I2=0%). Test for overall effect: Z=2.27 (P=0.02). SAEs: Subgroup: Studies included: Ferrero et al. 2021, Kingsbury et al. 2024, Wang et al. 2023. Overall: Non-significant reduction in SAEs with MTX (RR = 0.65; 95% CI: 0.31–1.34), with no heterogeneity (I2=0%). Test for overall effect: Z=1.17 (P=0.24). Total (MAEs + SAEs): Overall: Significant reduction in total AEs with MTX (RR = 0.75; 95% CI: 0.60–0.94), with no heterogeneity (I2=0%). Test for overall effect: Z=2.55 (P=0.01). Test for subgroup differences (MAE vs. SAE): $\chi 2=0.20$, df=1 (P=0.66), I2=0%. MTX demonstrated a significant reduction in total adverse events, driven primarily by MAEs. SAEs showed a non-significant trend toward reduction and also studies reported that SAEs were not related to MTX. No heterogeneity was observed across studies, and subgroup differences were negligible. CI, confidence interval; MAE, mild adverse event; SAE, serious adverse event; RR, risk ratio; I2, heterogeneity index; df, degrees of freedom.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0306–0336) Osteoarthritis – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Artificial intelligence (AI) rapid advancement opens new opportunities in the field of rheumatology. With better imaging, AI may help find early osteoarthritic changes that would not have been otherwise detected and help physicians with the diagnosis of early stage of knee osteoarthritis (KOA). The early diagnosis and timely intervention ultimately results in more favorable outcomes for the patients. This study aims to assess the diagnostic accuracy of AI detection and classification of radiographic Kellgren–Lawrence (KL) grades for KOA.

Figure (1) PRISMA Flow Chart Illustrating Search Strategy and Selection of Included Studies

Methods: We conducted a systematic search across PubMed, Web of Science, and Scopus databases, covering all available literature up to March 1st, 2025. Following the PRISMA guidelines (Figure 1), we screened and evaluated the methodological quality of the eligible studies, selecting only those deemed to be of high quality and excluding studies without outcome data or insufficient quality. We performed a meta-analysis to estimate pooled sensitivity, pooled specificity, and diagnostic likelihood ratios (LR+/LR-). All analyses were conducted using RStudio version 4.4.2.

Results: A total of 14 studies were included in the systematic review and meta-analysis, encompassing 45588 radiographs. As for KL grading, AI showed robust diagnostic performance across all grades. In KL Grade 0, specificity was 0.954 (95% CI: 0.877–0.984) and sensitivity was 0.829 (95% CI: 0.488–0.961) with Pre Test Probability (PP) of 30%, Post Test Probability +ve (PTP +ve) of 88%, and Post Test Probability -ve (PTP -ve) of 7%. For KL Grade 1, specificity remained high at 0.956 (95% CI: 0.880–0.984), with modest sensitivity of 0.680 (95% CI: 0.392–0.875) and (PP: 20%, PTP +ve: 79%, PTP -ve: 8%). For KL Grade 2, specificity was 0.937 (95% CI: 0.883–0.967), sensitivity was 0.850 (95% CI: 0.733–0.921) and (PP: 25%, PTP +ve: 82%, PTP -ve: 5%). KL Grade 3 yielded a specificity of 0.977 (95% CI: 0.937–0.992), sensitivity of 0.906 (95% CI: 0.793–0.961) and (PP: 15%, PTP +ve: 87%, PTP -ve: 2%). in KL Grade 4, specificity reached 0.995 (95% CI: 0.984–0.999), sensitivity 0.938 (95% CI: 0.800–0.983) and (PP: 10%, PTP +ve: 96%, PTP -ve: 1%).

Figure (2) (A) and (B):Forest Plots of Sensitivity and Specificity for KL0 and KL1, Se and Sp Forest Plot: Studies included: Panwar et al. 2024, Thomas et al. 2020, Yayli et al. 2025, Bany Muhammad et al. 2021. (C), (D) and (E) :Forest Plots of Se and Sp for KL2-4, Se Forest Plot: Studies included: Panwar et al. 2024, Thomas et al. 2020, Yayli et al. 2025, Bany Muhammad et al. 2021, and Yoon et al 2023. AI showed robust diagnostic performance across all grades. CI, confidence interval; KL, Kellgren-Lawrence; TP, true positives; TN, true negatives; FP, false positives; FN, false negatives; Se, Sensitivity; Sp, specificity.

Conclusion: This is the first systematic review and meta-analysis to evaluate the use of AI in the early diagnosis of KOA. AI demonstrates consistently good sensitivity and specificity across all KL grades. These findings support the use of AI as a valuable assistant for rheumatologists in the early diagnosis of KOA. However, further research is needed to focus on

Table (1): Pooled Diagnostic Performance Metrics of AI for OA Stratified by KL Grade. The table summarizes sensitivity (Se), specificity (Sp), area under the curve (AUC), likelihood ratios (LR), diagnostic odds ratios (DOR), and post-test probabilities for AI-based classification of OA severity across KL grades (0–4). AI was superior to the index test in most metrics (Pooled Se , Sp, AUC. Positive likelihood ratio (LR+), post-test probability) and notably had a significant post-test probability in all KL Grades with DOR increase progressively with higher KL grades. CI, confidence interval; KL, Kellgren-Lawrence.

	Pooled Se (CI 95%)	Pooled Sp (CI 95%)	AUC (CI 95%)	Prior Probability	Post Test Probability +ve	Post Test Probability -ve	LR +ve (CI 95%)	LR -ve (CI 95%)	DOR (CI 95%)

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0306–0336) Osteoarthritis – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Ultrasound (US) is an emerging, promising imaging modality offering a safe, radiation-free, and cost-effective option for diagnosing and assessing structural changes in knee osteoarthritis (KOA), potentially overcoming limitations of current gold-standard modalities such as X-ray and MRI. Despite growing interest in US capabilities, its diagnostic performance remains variable across studies, with no clear agreement on its accuracy compared to standard reference methods. This systematic review and meta-analysis aims to evaluate the diagnostic accuracy of US in detecting KOA and related parameters.

Methods: We conducted a systematic review and meta-analysis following PRISMA guidelines (Fig 1). PubMed, Web of Science, and Scopus were searched from inception to April 4th 2025, for studies evaluating US diagnostic accuracy in detecting KOA. Studies were included if they provided sufficient data to construct 2×2 tables and used a valid reference standard. A meta-analysis estimated pooled sensitivity (Se), specificity (Sp), and the summary receiver operating characteristic (SROC) curve of US for diagnosing KOA and related parameters. All analyses were performed using R software 4.4.2.

Results: We included 27 studies in the qualitative synthesis and 17 in the meta-analysis, encompassing 7,187 and 3,871 knee radiographs, respectively. US achieved a pooled Se of 0.94 (95% CI: 0.71–0.99) and Sp of 0.79 (95% CI: 0.48–0.94) for total KL grading (Fig. 2). For KL grade 0, Se was 0.47 (95% CI: 0.12–0.85) and Sp was 0.98 (95% CI: 0.19–1.00). For KL grade 1, Se was 0.95 (95% CI: 0.53–1.00) and Sp was 0.89 (95% CI: 0.44–0.99). For KL grade 2, Se was 0.99 (95% CI: 0.69–1.00) and Sp was 0.86 (95% CI: 0.48–0.97). For KL grade 3, Se was 0.87 (95% CI: 0.82–0.91) and Sp was 0.90 (95% CI: 0.67–0.98). For KL grade 4, Se was 0.94 (95% CI: 0.84–0.98) and Sp was 0.97 (95% CI: 0.42–1.00) (Fig. 3). For osteophyte detection, Se was 0.86 (95% CI: 0.76–0.92) and Sp was 0.76 (95% CI: 0.65–0.84). For cartilage degeneration, Se was 0.88 (95% CI: 0.71–0.95) and Sp was 0.76 (95% CI: 0.73–0.79). For medial meniscus protrusion (MMP), Se was 0.77 (95% CI: 0.56–0.90) and Sp was 0.70 (95% CI: 0.47–0.86) (Fig. 2).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure (1) PRISMA Flow Chart Illustrating Search Strategy and Selection of Included Studies

Conclusion: This systematic review and meta-analysis is the first to assess US diagnostic accuracy in detecting KOA and KOA-related structural changes, showing high pooled sensitivity and specificity for overall KL grading, individual KL grades, and the detection of osteophytes, cartilage degeneration, and MMP. Future research should focus on enhancing early stage KOA detection by US for more timely diagnosis and intervention, and explore the link between clinical symptoms and ultrasound findings to better understand how imaging correlates with patient reported outcomes.

Figure (2) Diagnostic Accuracy of Ultrasound for Osteoarthritis Features. (A) Total KL Grade: Pooled Se: 0.94 (95% CI: 0.71–0.99); Pooled Sp: 0.79 (95% CI: 0.48–0.94). Studies included: Uchio 2018, Mortada 2016, Brom 2020, Yanagisawa 2014, Wang 2020. SROC AUC: 0.94 (95% CI: 0.91–0.95). LR+ = 4; LR– = 0.08. Post-Test Probabilities: Post_Prob_Pos = 81%; Post_Prob_Neg = 7%. (B) Osteophytes: Pooled Se: 0.86 (95% CI: 0.76–0.92); Pooled Sp: 0.76 (95% CI: 0.65–0.84). Studies included: Sadeghian 2018, Oyamakinde 2019, Majidi 2019, Okano 2016, Podlipská 2016, Nevalainen 2018, Catay 2012. SROC AUC: 0.87 (95% CI: 0.84–0.90). LR+ = 3; LR– = 0.18. Post-Test Probabilities: Post_Prob_Pos = 94%; Post_Prob_Neg = 46%. (C) Cartilage Degeneration: Pooled Se: 0.88 (95% CI: 0.71–0.95); Pooled Sp: 0.76 (95% CI: 0.73–0.79). Studies included: Brom 2020, Okano 2016, Podlipská 2016, Nevalainen 2018, Saarakkala 2012, SHAABAN 2019, Catay 2012. SROC AUC: 0.79 (95% CI: 0.75–0.82). LR+ = 4; LR– = 0.16. Post-Test Probabilities: Post_Prob_Pos = 84%; Post_Prob_Neg = 18%. Total KL grade classification demonstrated the highest diagnostic accuracy (AUC = 0.94), with near-perfect Se (0.94) and moderate Sp (0.79). (D) MMP: Pooled Se: 0.77 (95% CI: 0.56–0.90); Pooled Sp: 0.70 (95% CI: 0.47–0.86). Studies included: Sadeghian 2018, Majidi 2019, Podlipská 2016, Nevalainen 2018, TRÄIS-TARU1 2013, Catay 2012. SROC AUC: 0.80 (95% CI: 0.77–0.84). LR+ = 3; LR– = 0.32. Post-Test Probabilities: Post_Prob_Pos = 80%; Post_-Prob_Neg = 34%. Osteophytes and cartilage degeneration showed strong Se (0.86–0.88) but weaker Sp (0.74–0.76). MMP-based detection had lower pooled Se (0.77) and Sp (0.70), reflecting challenges in disease progression follow up. All SROC curves indicated robust discriminative capacity (AUC >0.75), with LRs supporting clinical utility. AUC, area under the curve; CI, confidence interval; KL, Kellgren-Lawrence; LR+, positive likelihood ratio; LR–, negative likelihood ratio; MMP, Medial Meniscal Protrusion; Post_Prob_Pos/Neg, post-test probability (positive/negative); SROC, summary receiver operating characteristic; Sp, Specificity; Se, Sensitivity.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure (3) Forest Plots of Sensitivity and Specificity for US Detection of OA Severity by KL Grade (A) , (B), (C), (D), and (E): Forest Plots For KL grade 0, Se was 0.47 (95% CI: 0.12–0.85) and Sp was 0.98 (95% CI: 0.19–1.00). Studies included: Mortada 2016, Brom 2020, Wang 2020. For KL grade 1, Se was 0.95 (95% CI: 0.53–1.00) and Sp was 0.89 (95% CI: 0.44–0.99). Studies included: Mortada 2016, Brom 2020, Wang 2020. For KL grade 2, Se was 0.99 (95% CI: 0.69–1.00) and Sp was 0.86 (95% CI: 0.48–0.97). Studies included: Mortada 2016, Brom 2020, Wang 2020. For KL grade 3, Se was 0.87 (95% CI: 0.82–0.91) and Sp was 0.90 (95% CI: 0.67–0.98). Studies included: Mortada 2016, Brom 2020, Wang 2020. For KL grade 4, Se was 0.94 (95% CI: 0.84–0.98) and Sp was 0.97 (95% CI: 0.42–1.00). Studies included: Mortada 2016, Brom 2020, Wang 2020. Se and Sp improved with higher KL grades, reaching near-perfect performance for KL4 (Se = 0.94, Sp = 0.97). KL0 exhibited the lowest pooled Se (0.47) and widest CIs, indicating variability in early-stage detection. Abbreviations: CI, confidence interval; KL, Kellgren-Lawrence; TP, true positives; TN, true negatives; FP, false positives; FN, false negatives; Sp, Specificity; Se, Sensitivity.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0306–0336) Osteoarthritis – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background/Purpose: Osteoarthritis (OA) is rising at an alarming rate, affecting millions worldwide and threatening mobility, independence, and quality of life. High-quality evidence is essential to guide clinical decision-making and ensure the best patient outcomes. The discontinuation and non-publication of clinical studies are major contributors to research waste and incomplete data synthesis in evidence-based medicine. This study aims to assess the prevalence, characteristics, and publication history of OA clinical studies and investigate the causes for their non-publication or discontinuation.

Methods: We searched OA-related clinical trials registered in ClinicalTrials.gov using NCT identifiers up to January 2nd, 2025. We excluded the last 24 months to account for ongoing peer reviews. Studies were considered discontinued if terminated, withdrawn, or suspended and unpublished if their results were not available in a peer-reviewed journal. Data on gender, age, study type, funding, intervention, enrollment, and location were extracted. Multiple logistic regression analyzed characteristics linked to unpublished or discontinued trials. All statistical analyses were performed using Jamovi 2.6.24 software.

Results: A total of 3,818 studies were included, comprising 2,706 (70.9%) completed, 425 (11.1%) discontinued, and 687 (17.9%) with unknown status (Fig. 1). Of the completed and discontinued studies, 2,588 were interventional and 538 were observational. Among the 425 discontinued studies, 9.4% of them were published despite being discontinued, and 34.8% of unknown studies were also found published. Also, nearly half (43.3%) of completed studies remained unpublished (table 1). Logistic regression analysis revealed that non-industry-funded studies had lower odds of discontinuation than industry-funded ones (OR = 0.380, 95% CI: 0.279–0.518, $p < 0.001$). Device-based interventions were nearly three

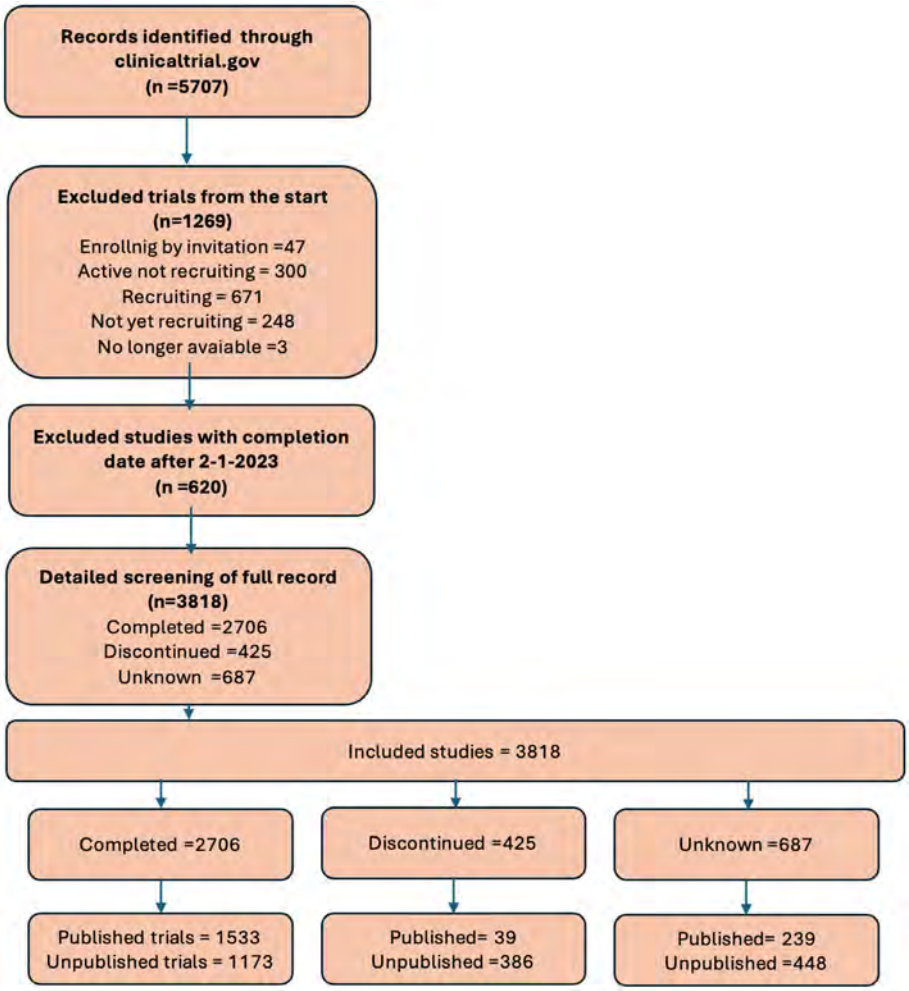

Figure (1) PRISMA Flow Chart Illustrating Search Strategy and Selection of Included Studies

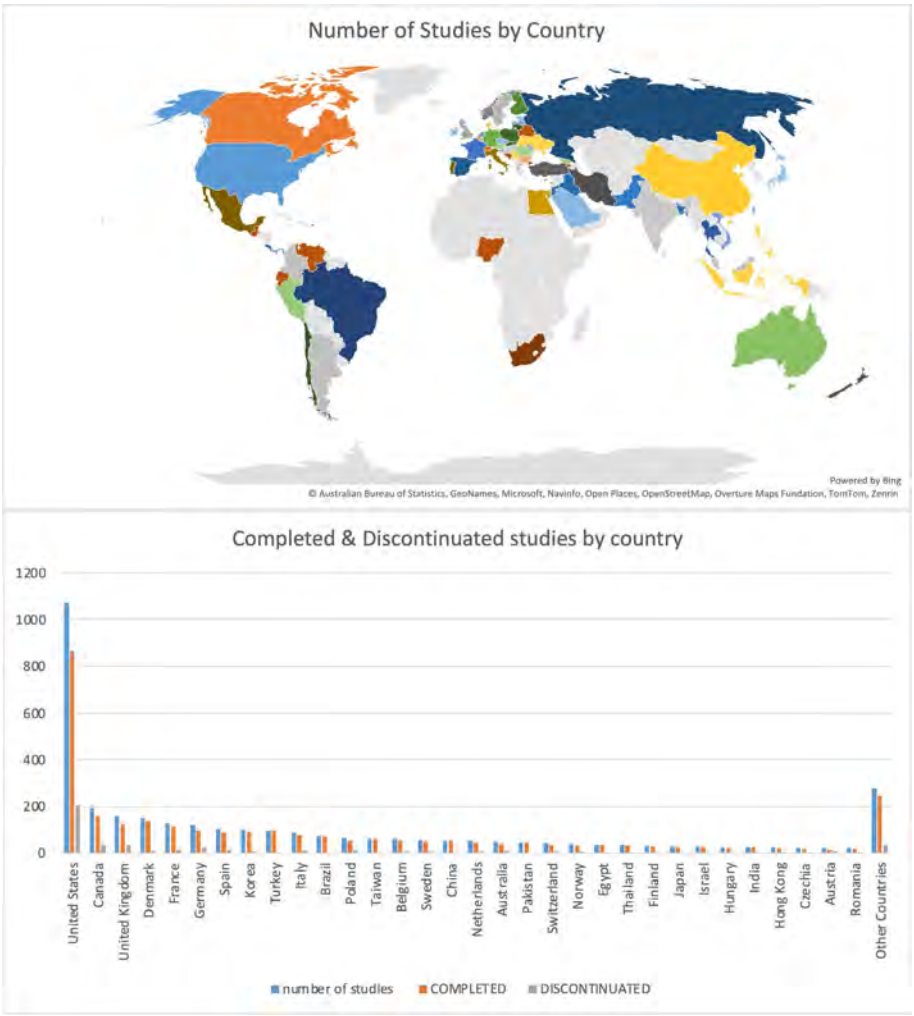
23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



(Figure 2) Global Distribution of Total, Completed and Discontinued clinicals studies by Country.

times more likely to be discontinued than behavioral interventions (OR = 2.977, 95% CI: 1.445–6.133, $p = 0.003$). Trials with >100 participants had lower odds of discontinuation than those < 100 (OR = 0.371, 95% CI 0.278, 0.495, $p < 0.001$). As for publication, behavioral interventions were significantly more likely to be published compared to device intervention (OR = 2.346, 95% CI: 1.594 to 3.451, $p < 0.001$), enrollment sizes >100 were more likely to be published than those < 100 (OR = 0.575, 95% CI: 0.479 to 0.690), and non-industry-funded studies were more likely to be published than industry-funded ones (OR = 0.409, 95% CI: 0.326 to 0.513). Notably, the United States was the most common location for conducting OA clinical trials 1,072 (28.4%), and also had the highest discontinuation rate globally (39.2%) (Fig. 2).

Conclusion: OA clinical trials are frequently discontinued and often remain unpublished, restricting access to valuable research findings. This lack of transparency not only hinders scientific progress but also raises ethical concerns about participant contributions. Ensuring transparency through mandatory reporting and stricter policies can help address publication bias and ensure that patients efforts contribute meaningfully to medical knowledge.

Abstract Number: 0336

Does Baseline Physical Function Moderate Change in Steps/day Following a Telephone-Delivered Walk With Ease Program?

Nurten Gizem Tore[1], Daniel K. White[2] and Christine Pellegrini[3], [1]University of Delaware, Newark, [2]University of Delaware, Newark, DE, [3]Arnold School of Public Health, Columbia

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0306–0336) Osteoarthritis – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Adults with knee osteoarthritis with worse physical function are known to benefit more from therapeutic exercise than those with less limitation. However, there is limited evidence on whether those with worse physical function also have more improvement in physical activity in response to physical activity interventions. This study aimed to examine the interaction effects of baseline physical function on changes in steps/day among individuals participating in the 6-week Walk With Ease by Phone (WWE-P) intervention compared to a control group.

Methods: Baseline physical function was assessed using the 30-Second Chair Stand Test (30-CST) total repetitions. Study participants in the intervention received 6 weeks of WWE-P while those in the waitlist control received no intervention until 12 months. Daily step count were measured using an Actigraph GT9X Link, collecting at the baseline, and 6 months. We examined the interaction effects between baseline physical function categorized as high and low using mean 30-CST time and treatment group with changes in steps/day from baseline to 6 months.

Table 1. Daily step count according to function level

	Steps/day	
High Function	Mean	Standard Deviation
Baseline		
Intervention	4460	1806
Control	4595	2616
6 months		
Intervention	3947	2520
Control	4149	3127
Low Function		
Baseline		
Intervention	3603	1966
Control	3822	2132

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: 267 participants (mean age = 64.1 years old, 92% female, 49.4% in the WWE-P group) were included in the overall analytic sample. The mean baseline 30-CST score for the WWE-P and control group were 8.83 ± 2.88 and 8.88 ± 3.02, respectively. No statistically significant differences were observed between groups at baseline. Baseline 30-CST significantly interacted with time and group in predicting changes in daily step count (p = 0.001). Those in the intervention and control groups with low 30-CST walked 1104 and 819 fewer steps/day over 6 months, while those with high 30-CST in the intervention and control walked 513 and 446 fewer steps/day.

Conclusion: The results of this research indicate the significant interaction between baseline 30-CST and changes in daily step count over time, such that those with low physical function walked fewer steps/day regardless of the intervention group over 6 months, while those with high physical function had less decline. These findings suggest that those with worse physical function may have the greatest decline in physical activity regardless of receiving a physical activity intervention.

Bridging the Bone Gap: A Quality Improvement Project on Osteoporosis Screening Practices in a Teaching Institution

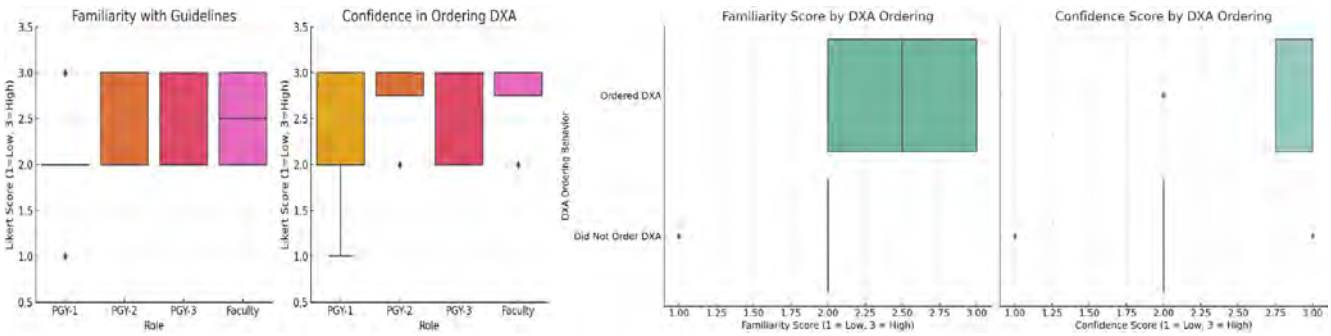
Aakanksha Pitliya[1], Alexandra Georgiana Boc[2], Hema Latha Anam[2], Richard Oletsky[2], Dipabali Chaudhuri[2] and Rajesh Thirumaran[2], [1]Mercy Catholic Medical Center, Darby, PA, Clifton Heights, PA, [2]Mercy Catholic Medical Center, Darby, PA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0337–0356) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

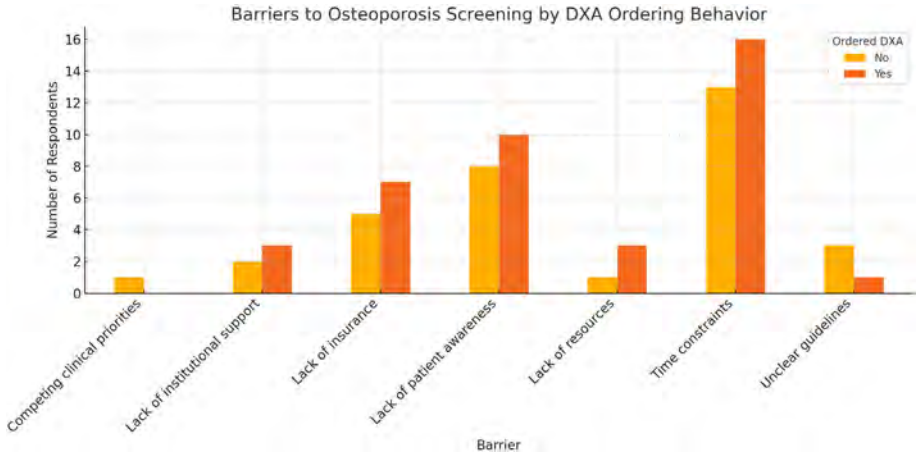
Background/Purpose: Osteoporosis remains underdiagnosed despite clear guidelines. As primary care physicians and trainees are key to preventive care, this quality improvement (QI) project aimed to assess provider knowledge, confidence in ordering Dual-energy X-ray absorptiometry (DEXA) scans, and perceived barriers to inform strategies for improving osteoporosis screening.

Methods: We conducted an anonymous survey with 44 physicians, including internal medicine residents (PGY-1 to PGY-3) and faculty members. The survey evaluated baseline knowledge of guidelines, perceived barriers and facilitators, and confidence in ordering DEXA scans. A knowledge score of 0-6 was calculated using the answers to questions based on



Comparison of familiarity and confidence scores by role and DXA ordering behavior; confidence was the stronger predictor of ordering; confidence was the stronger predictor of ordering behavior (p < 0.005).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



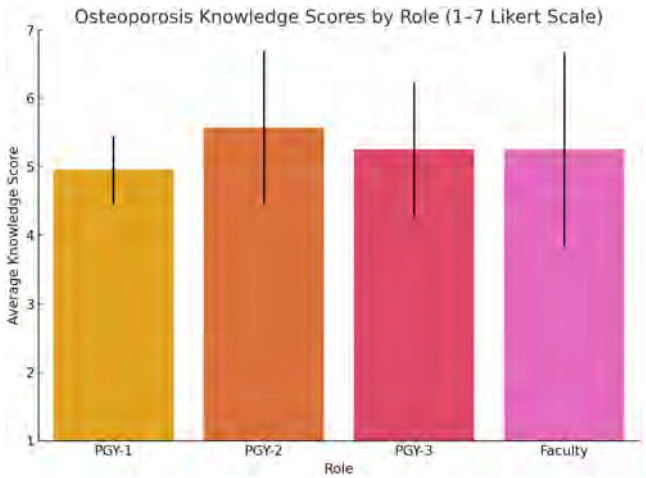
Reported barriers to osteoporosis screening, stratified by DXA ordering behavior, with both groups citing time constraints and patient awareness most frequently.

guidelines. Familiarity and confidence were scored on a 3-point Likert scale. ANOVA was used for assessing statistical significance, t-tests were used for the continuous variables (confidence and familiarity scores), Chi-square tests for evaluating categorical variables (provider role vs DEXA ordering), and logistic regression was used to evaluate the predictors of ordering behaviour. Multivariate logistic regression assessed whether confidence or familiarity predicted DEXA ordering behavior. All statistical analyses were conducted in R (v4.3.2) with $\alpha = 0.05$.

Results: A total of 44 providers participated in the survey, including PGY-1 (47.7%), PGY-2 (15.9%), PGY-3 (27.3%), and faculty (9.1%). Most worked in ambulatory care (56.8%) or academic hospitals (29.5%). The mean knowledge scores were high (mean = 4.95 ± 0.88), highest among faculty (5.5 ± 0.58), lowest among PGY-1s (4.00 ± 1.05), but not statistically different (ANOVA F = 0.55, p = 0.65). Participants reported being somewhat familiar with guidelines (2.36 ± 0.53) and very confident in ordering DEXA (2.51 ± 0.55).

Providers who had ordered DEXA were significantly more confident (t = 7.05, $p < 0.000001$) and more familiar with guidelines (t = 4.51, p = 0.00005). Logistic regression showed confidence to be an independent predictor of ordering behavior ($\beta = 3.52$, p = 0.0047), while familiarity was not ($\beta = 1.09$, p = 0.405). No association was found between provider role and ordering behavior ($\chi^2 = 0.64$, p = 0.42).

Top barriers included lack of patient awareness (54.5%), time constraints (31.8%), and insurance issues (31.8%). Requested improvements included Electronic Health Record (EHR) based reminders (52.3%), clearer guidelines (40.9%),



Average osteoporosis knowledge scores by role showing no statistically significant difference across PGY levels and faculty (ANOVA p = 0.65).*

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

and improved DEXA access (40.9%). Most participants supported standardized protocols (72.7%) and integration into routine preventive care (65.9%).

Conclusion: Residents and faculty members had good awareness of osteoporosis screening, but confidence, rather than familiarity, is the strongest predictor of DEXA ordering. Providers experience both practical and systemic barriers, notably those linked to patient engagement and time. EHR reminders, clearer institutional protocols, and educational support could significantly enhance screening behavior, especially among trainees.

Fractures and Changes in Bone Mineral Density During Two Years of Low Dose Glucocorticoid Treatment for Rheumatoid Arthritis: A Systematic Literature Review and Individual Participant Data Meta-Analysis

Andriko Palmowski[1], Tobias Haugegaard[2], Ingiäld Hafstörm[3], Henning Bliddal[4], Judith Oldenkott[5], Siegfried Wassenberg[6], Ernest Choy[7], John Kirwan[8], Robin Christensen[9], Maarten Boers[10] and FRANK BUTTGEREIT[11], [1]Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Berlin, Germany, [2]The Parker Institute, Kopenhagen, Denmark, [3]Karolinska Institutet, Stockholm, Sweden, [4]The Parker Institute, Frederiksberg, Denmark, [5]Charité, Berlin, Germany, [6]Rheumazentrum Ratingen, Ratingen, Germany, [7]Division of Infection and Immunity, CREATE Centre, Cardiff University, Cardiff, United Kingdom, [8]University of Bristol, Bristol, United Kingdom, [9]Musculoskeletal Statistics Unit, The Parker Institute, Copenhagen, Hovedstaden, Denmark, [10]Amsterdam UMC, Vrije Universiteit, Amersfoort, Netherlands, [11]Charite University Medicine Berlin, Berlin, Berlin, Germany

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0337–0356) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: It is unclear to what extent low dose glucocorticoids (GCs) impact bone health in patients with rheumatoid arthritis (RA). RA leads to bone loss which might be mitigated with GC via disease control, but GCs themselves can negatively affect the bone. Observational studies are prone to bias and randomized controlled trials (RCTs) possibly underpowered for safety signals. We performed a protocolized (dx.doi.org/10.17504/protocols.io.6qpvr3ombvmk/v1) systematic literature review and individual participant data (IPD) meta-analysis to overcome these limitations.

Methods: MEDLINE (via PubMed), Embase (via Ovid) and the Cochrane Central Register of Controlled Trials (via Cochrane Library) were searched for RCTs that compared low dose GC (≤ 7.5 mg/d prednisone equivalent) with placebo or any other control treatment (e.g., standard of care). Search results were screened separately by two reviewers. There were two co-primary endpoints: Participants with ≥ 1 fractures (clinical/symptomatic) and change in bone mineral density (BMD; in g/cm^2, as measured by dual x-ray absorptiometry); both over two years. BMD was analysed separately for lumbar spine and femoral (total hip or femoral neck) measuring sites. Analyses were based on one-stage models and the intention-to-treat approach. Missing outcome data were handled via multiple imputations by chained equations. I^2 was estimated from standard random-effects meta-analysis models. To identify subgroups especially vulnerable to bone loss at the lumbar spine, various baseline characteristics were assessed as effect modifiers. A sensitivity analysis used data 'as observed'.

Table 1. Baseline Characteristics

	Glucocorticoids n = 548	Control n = 564
Age, years	60.7 (14.8)	62.0 (14.2)
Female	346 (69.2)	345 (66.4)
ACPA positive	193 (62.3)	209 (65.7)
RF positive	324 (65.9)	343 (67.4)
Smoking status		
Never smoked	155 (45.2)	158 (44.5)
Previous smoker	119 (34.7)	128 (36.1)
Current smoker	69 (20.1)	69 (19.4)
BMI, kg/m²	26.4 (4.5)	26.6 (4.4)
Weight, kg	73.0 (13.5)	73.6 (15.2)
DAS28, score	4.8 (1.2)	5.0 (1.2)
Disease duration, years	1.0 [0.4 – 8.0]	1.0 [0.5 – 7.0]
Pain (0-10)	5.2 (2.4)	5.2 (2.3)
ESR, mm/h	30 [16 – 48]	30 [16 – 48]
CRP, mg/l	10.0 [3.5 – 23.5]	10.0 [4.0 – 28.0]
HAQ, score	1.5 (0.8)	1.4 (0.9)
BMD lumbar spine, g/cm²	1.08 (0.20)	1.07 (0.20)
BMD femur, g/cm²	0.88 (0.15)	0.88 (0.16)

Values are mean (SD), median [IQR] or n (%). Percentages are based on patients with available data. Values are based on individual participant data that were available to the study team. Pain was measured on the visual or numerical analogue scale. In one trial, a positive latex agglutination text was considered positive for rheumatoid factor [18]. In one trial, the Hannover Functional Ability Questionnaire (FFbH) was used to evaluate disability – the scores were converted to HAQ scores according to the original publication with the following formula: HAQ = 3.16 – (0.028 x FFbH) [16]. ACPA, anti-citrullinated protein antibody, RF, rheumatoid factor, BMI, body mass index, DAS28, disease activity score 28 joints, ESR, erythrocyte sedimentation rate, CRP, C-reactive protein, HAQ, health assessment questionnaire, BMD, bone mineral density.

Results: Out of 2,336 articles, five RCTs conducted in twelve countries in Europe with 1,112 participants were included and shared IPD: [1-5]. All studies allowed concomitant treatment with DMARDs. Baseline characteristics, including lumbar spine and femoral BMD, were well balanced across groups (**Table 1**). Regarding femoral BMD, four trials provided femoral neck BMD, one trial had only total hip data available. BMD decreased in both groups over two years (**Table 2**). There was an increase in bone loss in the GC compared to the control group at the lumbar spine but not at the femur. 24 participants experienced at least one fracture, with similar odds in both groups. Sensitivity analyses yielded consistent results. Subgroup

Table 2. 2-Year changes in bone density at the lumbar spine and the femur and number of fractures in the glucocorticoid and control groups*

	Glucocorticoids (n=548)	Control (n=564)	Contrast (95%CI)	p	I² §
Change in lumbar spine BMD, g/cm²	-0.032 (0.009)	-0.011 (0.010)	-0.021 (-0.032 to -0.010)	0.001	28 %
Change in femur BMD, g/cm²	-0.016 (0.010)	-0.023 (0.009)	0.007 (-0.005 to 0.020)	0.272	0 %
Participants with fractures during the study period	0.084 (0.557) †	0.076 (0.546) †	1.111 (0.739 to 1.670) ‡	0.614	0 %

95%-CI, 95% confidence interval; GC, Glucocorticoid; BMD, bone mineral density.

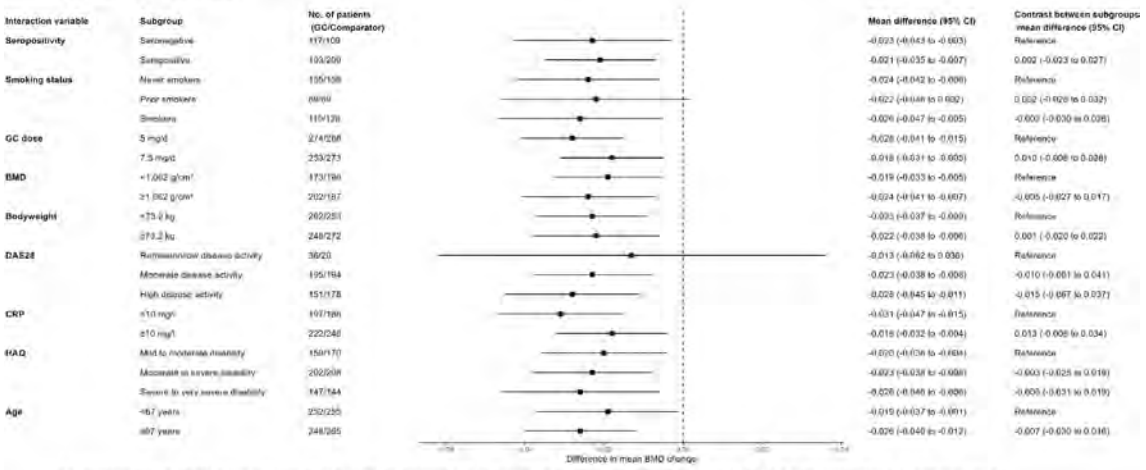
*Missing data was handled using multiple imputation. Values are reported as least squares means (standard error) unless otherwise stated.

† Values are odds (SE)

‡ Values are OR (CI)

§ I^2 signifies the percentage of variation across studies due to heterogeneity between trials rather than due to chance. It stems from additionally computed two-stage models.

Figure 2. Subgroup analyses



GC, glucocorticoid, BMD, bone mineral density, DAS28, disease activity score 28 joints, CRP, C-reactive protein, HAQ, health assessment questionnaire, CI, confidence interval

analyses did not reveal groups particularly susceptible to GC-induced bone loss at the lumbar spine (**Figure 1**). Data on anti-osteoporotic medication was available for one trial where 13% were treated with anti-osteoporotic drugs at baseline (bisphosphonates or denosumab). In those who were randomized to GC and used anti-osteoporotic drugs at baseline (n = 28), there was no bone loss at the lumbar spine.

Conclusion: Low dose GCs, used for two years to treat RA, lead to bone loss at the lumbar spine but not at the femur. Anti-osteoporotic drugs may prevent GC-induced bone loss at the lumbar spine. There was no subgroup identified to be especially vulnerable to GC-induced bone loss.

Abstract Number: 0339

Evaluating Discordance between Bilateral Hip Bone Density Measurements in Individuals with Low Bone Mass

Anupama Shahane[1], Nora Sandorfi[2] and Alexis Ogdie[1], [1]University of Pennsylvania, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA, USA, Philadelphia

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0337–0356) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Bone mineral density (BMD) measurement by dual X-ray absorptiometry (DXA) is the basis of World Health Organization (WHO) classification criteria for osteoporosis. Traditionally unilateral hip bone density has been measured and the utility of bilateral reporting remains unclear. Recent data have shown that a significant difference may be noted in bone density measurements between left and right hips with resultant failure to identify and treat individuals at high risk of fracture. In the 2023 Position Statement, the International Society of Clinical Densitometry (ISCD) noted that the impact of discordant hip bone density on diagnosis and monitoring of osteoporosis is a significant knowledge gap. This study aims to examine concordance vs discordance between left and right hip bone density measurement at a large hospital system. Results of this study may be helpful to further evaluate the impact and need for bilateral hip BMD testing as standard of care for osteoporosis screening.

Methods: A retrospective cohort study was performed using data from electronic medical record at the University of Pennsylvania. After IRB approval, patients with bilateral DXA were identified. A subset of charts with the following criteria were randomly selected for review: age 50 years or older, DXA report within the past 4 years within the health system, and diagnosis of osteopenia or osteoporosis. Manual chart review was conducted for capture of T scores for lumbar spine, left femoral neck, left total hip, right femoral neck and right total hip. We descriptively report baseline characteristics. Scatter plots were used to assess correlation between the right and left sides. Paired T tests were employed to test whether the left was significantly different from the right side for both the total hip and femoral neck.

Table 2: Difference between left and right femoral neck and total hip T scores

	Mean T-score	Std error	Std deviation	CI	
Left FN	-1.737	.091	1.049	-1.917	-1.556
Right FN	-1.704	.090	1.039	-1.883	-1.525
Difference	-.032	.042	.484	-.115	.050
Left TH	-1.409	.102	1.138	-1.613	-1.206
Right TH	-1.397	.093	1.036	-1.582	-1.212
Difference	-.012	.033	.366	-.0775	.0531

TH – total hip. FN – femoral neck.

Results: Within the health system, 29,258 patients > age 50 years had received a DXA scan at 3 primary sites between 2021 and 2024. The initial search was then narrowed to limit patients to those seen by Rheumatology providers (N=1171). Among these, 85.7% patients were female and 81% were White. 200 charts were randomly selected among these and reviewed manually. 143 (71.5%) patients had DXA results reporting bilateral hip BMD. 27 (19%) patients had a T score difference of 0.5 between left and right femoral neck or total hip. 13 patients were classified into a different category: 2 patients with normal T score on one side vs low bone mass on the other side, and 11 patients with low bone mass on one side vs

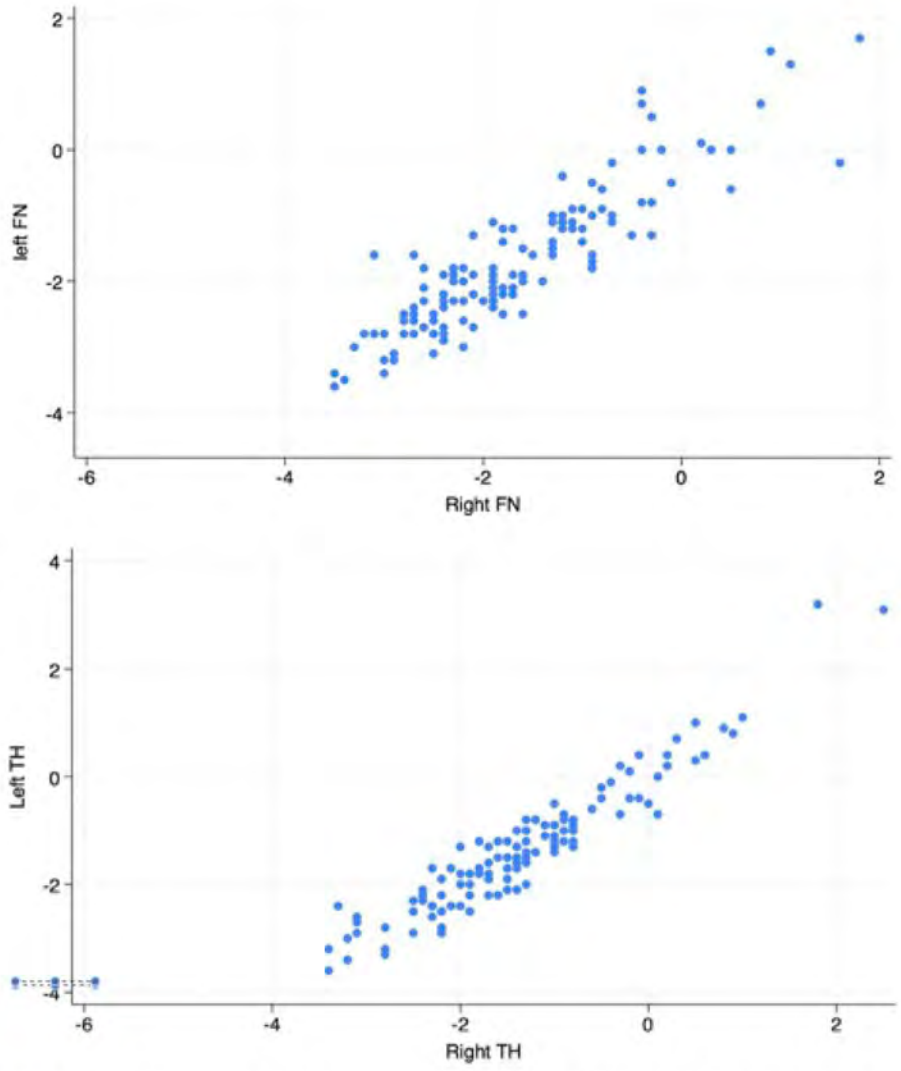

Figure 1A and 1B: Scatter plots comparing right and left sides for FN (A) and total hip (B)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. osteoporosis on the other side. This resulted in a reclassification rate of 7.8%, with 7% of patients with missed diagnosis of osteoporosis. Correlation between the two sides was high (Figure 1A and B) and there were no statistically significant differences between the left and right sides (Table 2).

Conclusion: In this retrospective study of patients >50 years, measurement of bilateral hip bone density demonstrated a high overall correlation between the two sides but resulted in a reclassification rate of 7% from low bone mass into osteoporosis when compared to measuring only one side. There may be a significant missed opportunity for primary fracture prevention which needs further examination.

Abstract Number: 0340

Associations with fragility fractures in a population with inflammatory bowel disease (IBD): An observational study.

Chern Lee Choy[1], Hamzah Amin[2] and marwan Bukhari[3], [1]University Hospitals of Morecambe Bay NHS Foundation Trust, Barrow-In-Furness, United Kingdom, [2]Lancaster University, Lancaster, United Kingdom, [3]University Hospitals of Morecambe bay NHS foundation trust, Lancaster, United Kingdom

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0337–0356) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: It is well recognized that inflammatory bowel disease (IBD) is associated with osteoporosis and fragility fractures, likely due to multiple factors, including systemic inflammation, corticosteroid use, malabsorption etc. Nonetheless, the exact mechanism for fractures in IBD patients is still unclear. There are multiple studies working with small cohorts, supporting different predictors for fracture risk, yet it remains to be elucidated. This study aims to evaluate the association of demographic and various predictors with fracture risk in IBD patients on and off steroids.

Methods: A retrospective observational study was conducted in IBD patients who had a dual-energy X-ray absorptiometry (DEXA) scan done in the North West of England between 2004 and 2019. Data analysed included demographics, family history of fractures, FRAX™ risk factors, total femur BMD, L1-L4 BMD, fat percentages at different sites including total body, abdomen and both femurs. Chi-square tests were used to assess statistically significant associations between categorical variables, while Student's t-tests were used for continuous variables. Univariate and multivariate logistic regression models were then utilised to identify significant predictors associated with the development of fractures. Results are shown in both Table 1 and 2.

Results: A total of 1827 patients with IBD were analysed, in which 1495 (81.8%) were female. The mean age at DEXA scan was 65.2 (SD 13.17) years. Fractures occurred in 674 (36.9%) patients, including 573 (31.4%) females and 101 (5.5%) males. Patient with fractures had a higher fat percentage in total, abdominal and femoral regions. Fractures were also associated with lower BMD at all measured sites including L1-L4, femoral necks and total femur.

Of the 1252 (68.5%) patients not using steroids, 501 (40.0%) reported fractures, while 88 (24.1%) of the 361 current steroid users had fractures. 65 (44.5%) of the 146 (8.0%) patients with rheumatoid arthritis also reported fractures. 64 out of the 647 patients with fractures reported previous fractures.

The multivariate model identified abdominal fat percentage, both right and left femur fat percentages, dual femur fat percentages, both right and left total femur BMD, to be significant predictors of fractures in IBD patients. The right femur fat percentage showed a wide confidence interval (OR 36.40, 95% CI: 1.13–1170.67, p = 0.042), possibly due to sample variability or multicollinearity, though the association remains statistically significant and may be clinically relevant.

Conclusion: Our study showed that lower total femoral BMD is associated with an increased fracture risk in patients with IBD, reinforcing the association between reduced BMD and higher fracture likelihood. Moreover, higher fat percentages in both femoral regions elevate fracture risk, suggesting that body fat composition at different sites may play a role in the development of fragility fractures. It is notable that fractures occurred in a significant proportion of steroid-naive patients with IBD, suggesting that IBD itself contributes to the development of fragility fractures.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0337–0356) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Osteoporosis is the most common bone metabolism disorder in developed countries. It increases the risk of fragility fractures, impairing quality of life, increasing disability, mortality, and healthcare costs. Recently approved, Romosozumab is the only treatment with dual antiresorptive and bone-forming effects.

The aim of this study is to characterize the profile of patients treated with romosozumab, as well as its safety and efficacy.

Methods: This is a retrospective, longitudinal, descriptive study of patients with osteoporosis treated with romosozumab. Baseline clinical data on bone metabolism (PTH, β-CTX, P1NP, ALP, and vitamin D) and densitometry (T-score/BMD) were collected at the start of treatment, at 6 months, and after completing 1 year.

Results: A total of 49 patients (100% women) with a mean age of 71.8 years were included. Primary osteoporosis was diagnosed in 75.5% of cases, and 70.2% had a history of fractures, most commonly vertebral (57.6%). The most frequent

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. BMD and bone biomarkers evolution during Romosozumab treatment.

	Month 0	Month 6	Month 12	
N	49	36	28	Delta BMD (%)
BMD Lumbar spine	0.72 (0.16)	0.75 (0.16)	0.81 (0.19)	+12,5%
BMD Femoral neck	0.56 (0.09)	0.56 (0.09)	0.6 (0.11)	+7,14%
BMD Total hip	0.68 (0.11)	0.7 (0.11)	0.75 (0.15)	+10,29%
Vit. D	35.01 (14.41)	40.79 (17.7)	37.02 (12.7)	
P1NP	47.94 (33.81)	70.85 (68.63)	59.18 (34.57)	
β-CTX	0.33 (0.34)	0.39 (0.85)	0.23 (0.22)	
PTH	88.49 (48.33)	152.63 (190.42)	83.8 (46.01)	
Alkaline phosphatase	134,24 (121,88)	145.24 (137.99)	78.8 (18.01)	

cardiovascular risk factors were dyslipidemia (42.9%), hypertension (40.8%), and diabetes (8.2%). Active smoking was reported by 8.2% of patients, and none reported habitual alcohol consumption. A history of malignancy was recorded in 10 patients (3 non-melanoma skin cancer, 3 breast, 1 lung, 1 kidney, 1 hematologic, and 1 parotid), and 5 patients had a history of radiotherapy.

Prior to romosozumab, the most commonly used treatments were oral bisphosphonates (38.8%), denosumab (20.4%), and teriparatide (16.3%). The mean duration of romosozumab treatment was 10.51 months (median: 12 months). A total of 5 adverse events were recorded: 1 case each of arthromyalgia, heart failure decompensation, dizziness, blurred vision, and local reaction. No pulmonary embolism (PE), major adverse cardiovascular events (MACE), or strokes were reported. Of the 49 patients who initiated treatment, 28 completed the full 12-month course. The most frequently used medications after romosozumab were denosumab (44.4%), risedronic acid (27.8%), zoledronic acid (13.9%), alendronate (5.6%), and teriparatide (2.8%).

Renal function markers and general biochemical markers remained stable throughout treatment. Regarding bone metabolism markers, β-CTX decreased from 0.33 to 0.23, as did ALP (100.12 to 90.85). Conversely, P1NP increased (from a mean of 47.94 to 59.18). PTH increased at 6 months but returned to normal by the end of treatment. Vitamin D levels remained unchanged.

For densitometry, the mean baseline T-scores were: lumbar spine -3.05, femoral neck -2.63, and total hip -2.15. Among patients who completed 12 months of treatment, BMD increased at all three sites. This resulted in a reduction in the proportion of patients with osteoporosis: from 70.45% to 46.67% at the lumbar spine, from 60% to 50% at the femoral neck, and from 34.88% to 21.43% at the total hip.

Conclusion: Romosozumab is a safe bone-forming treatment option for elderly patients with established classic cardiovascular risk factors. An increase in bone formation markers and a reduction in bone resorption were observed in blood tests, along with an increase in BMD. The most frequently used therapy after romosozumab was denosumab, followed by bisphosphonates.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0337–0356) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with inflammatory rheumatic and musculoskeletal diseases (iRMDs) are at elevated risk for osteoporotic fragility fractures. Standard assessment via dual-energy X-ray absorptiometry (DXA) does not fully capture fracture risk. Cortical Backscatter (CortBS) ultrasound is a radiation-free technique assessing viscoelastic and microstructural cortical bone properties and has shown high accuracy in detecting prior fractures in postmenopausal women. Bone material strength index (BMSi), derived from reference-point indentation, reflects mechanical bone properties. However, their comparative performance in fracture discrimination in iRMDs is unclear.

This study aimed to evaluate the performance of CortBS in detecting prevalent fragility fractures in iRMD patients, compared to DXA and BMSi.

Methods: Consecutive iRMD patients from our outpatient osteoporosis clinic, with and without prior fragility fractures and no prior anti-osteoporotic treatment, were analyzed. CortBS was measured at the anteromedial tibia using a custom ultrasound scanner. DXA-based T-scores and BMSi (via 8 indentations) were obtained at the same visit.

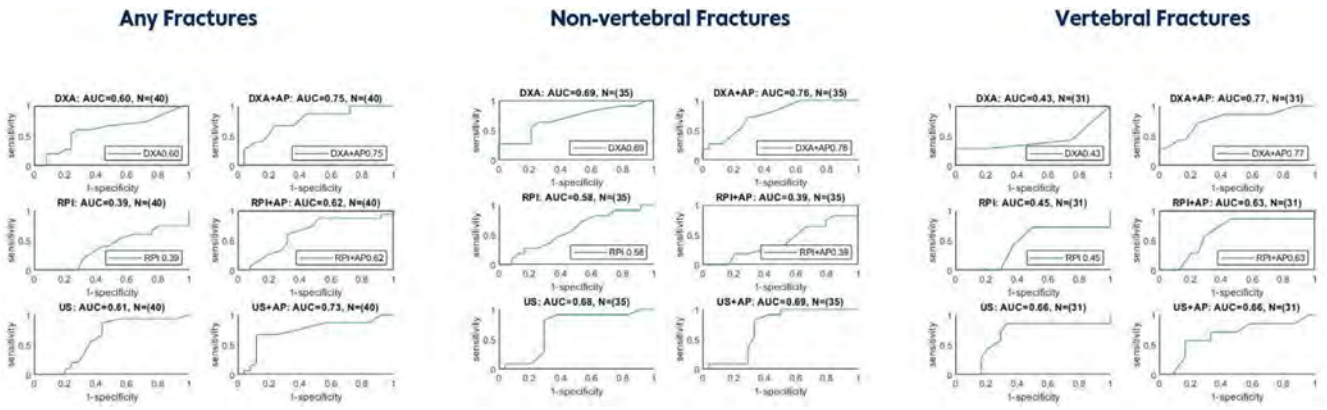

Figure 1: ROC-AUC with 5-fold cross-validation for any (left), non-vertebral (center) and vertebral (right) fragility fractures for DXA, BMSi and CortBS. AP (anthropometric data: weight, height, body mass index)

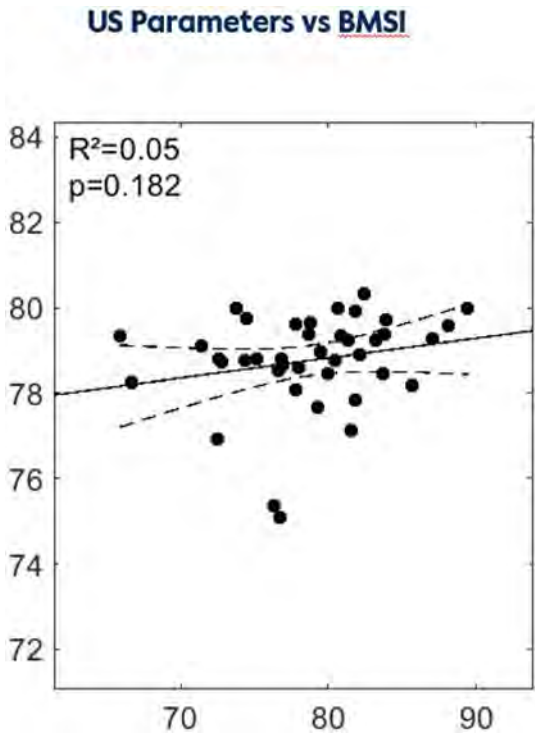

Figure 2: Predictions of aBMD at spine (A), femur neck (B), and total femur (C) based on ultrasound backscatter and anthropometric parameters using multivariate PLS regression Spearman correlation

Fracture discrimination models for vertebral, non-vertebral, and any fragility fracture were developed using multivariate partial least squares linear discrimination analysis with Leave-One-Out Cross-Validation (PLS-LDA LOOCV). For each method, the area under the curve (AUC) of the receiver operating characteristics (ROC), sensitivity, and accuracy were calculated, with and without anthropometric data (weight, height, BMI). CortBS-BMSi correlation was assessed using PLS regression with threefold cross-validation.

Results: 97 iRMD patients (mean age 64 ± 10 years) were included: 42% with rheumatoid arthritis, 23% spondyloarthritides, and 19% connective tissue diseases. 44 patients (45%) had fragility fractures (19 vertebral, 34 non-vertebral, 9 both). Complete CortBS data were available in 40 patients (15 with fractures). CortBS showed comparable discrimination to DXA for any fracture (AUC 0.61 vs. 0.60) and non-vertebral fractures (AUC 0.68 vs. 0.69). For vertebral fractures, CortBS (AUC 0.66) outperformed both DXA (0.43) and BMSi (0.45), though small sample size limits interpretation.

Adding anthropometric data improved prediction for all tools (CortBS AUC 0.73, DXA 0.75, BMSi 0.62). No significant correlation was found between CortBS and BMSi (R^2 = 0.05, p = 0.18).

Conclusion: CortBS demonstrated fracture discrimination comparable to DXA and even superior performance for vertebral fractures. In contrast, BMSi showed limited discriminatory ability. As a radiation-free and accessible technique, CortBS holds promise for improving fracture risk assessment in iRMDs. Larger and longitudinal studies are needed to evaluate whether CortBS can enhance fracture prediction by capturing cortical porosity and structural bone properties.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0337–0356) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Janus kinase (JAK) inhibitors are an important treatment option for rheumatoid arthritis (RA) and psoriatic arthritis (PsA). By disrupting pro-inflammatory cytokine signaling (e.g., IL-6, TNF-α), they reduce inflammation and may potentially mitigate bone loss. Chronic inflammation in RA and PsA leads to systemic and local imbalances in bone remodeling, characterized by increased osteoclast activity and decreased osteoblast function. While JAK inhibitors have shown promise in counteracting these processes *locally*, clinical evidence regarding their effects on systemic bone health remains limited.

Table 1: Results from the multivariable linear regression model with backward selection for minimum T-Score and trabecular bone score (TBS) forcing JAK inhibitors into the model JAK : Janus kinase, BMI : Body Mass Index, CI : confidence interval, CRP : C-reactive Protein, DAS28 : Disease-activity score 28, GC : Glucocorticoids

	T-Score		TBS

We aimed to quantify the impact of JAK inhibitors on bone health in a real-world cohort of patients with RA and PsA.

Methods: Baseline data from patients with RA or PsA from the Rh-GIOP study, a prospective observational cohort at Charité–Universitätsmedizin Berlin, were included in this cross-sectional analysis. Bone health was assessed using DXA for bone mineral density (expressed as the minimum T-Score from lumbar spine and hip measurements), trabecular bone score (TBS; enCORE V18 iNsight®, Med-Imaps SA), and 3D structural parameters of the femur (3D-Shaper v2.12, 3D-Shaper Medical). Multivariable linear regression models were used to identify clinical, serological, and treatment-related factors associated with T-Score and TBS. JAK inhibitors were included in these models to evaluate their impact on outcomes, provided that a prior stable treatment period had been established. Missing data were addressed using multiple imputation with 10 replications.

Results: The study included 856 patients (mean age 64 years, 77% female, 92% postmenopausal), with 89 receiving JAK-inhibitors (33 baricitinib, 25 tofacitinib, 21 upadacitinib, 10 filgotinib). Osteoporosis was prevalent in 24% of patients, while the majority had either normal bone mineral density (BMD) or osteopenia. Treatment with JAK inhibitors was not significantly associated with T-Score (table 1). However, vertebral trabecular microarchitecture expressed by TBS, showed that JAK-inhibition was positively associated with TBS (β (95%CI)= +0.061 (0.021;0.101), p=0.003), suggesting a potential positive impact on trabecular microarchitecture.

Conclusion: In this real-world cohort, JAK inhibitors were associated with positive impact on trabecular microarchitecture. These findings suggest that a broad cytokine inhibition may support bone health. Longitudinal studies are required to confirm these observations and evaluate their implications for fracture prevention and individualized treatment strategies.

Background/Purpose: Glucocorticoids are widely used in rheumatology and are associated with increased fracture risk. The 2022 ACR Guideline for the Prevention and Treatment of Glucocorticoid-induced Osteoporosis (GIOP) strongly recommends assessment of fracture risk for patients initiating prolonged glucocorticoid treatment with pharmacologic treatment for GIOP prevention depending on risk stratification. While many patients with new diagnoses or flares of giant cell arteritis (GCA) or idiopathic inflammatory myopathies (IIM) meet criteria for GIOP prevention, initiation of such therapy is often delayed or missed. We hypothesized that a standardized inpatient screening protocol with administration of inpatient zoledronic acid (ZA) for appropriate patients would improve timely GIOP prevention.

Methods: This project evaluated a new screening protocol for addressing GIOP prevention in hospitalized patients with active GCA or IIM (**Figure 1**). The protocol, based on the 2022 ACR Guideline, was implemented by the Massachusetts General Hospital Rheumatology Consult Service from February 2024 to January 2025 and compared to a historical cohort from February 2022 to January 2023. The primary outcome was GIOP treatment initiation within 3 months of diagnosis. Secondary outcomes included inpatient ZA use and DXA completion within 6 months of initial evaluation. Patients were

GIOP prophylaxis decision aid
(please check appropriate boxes by placing an x in the brackets [x])

Inclusion criteria (must meet all 4):
[] 40 years of age or older
- diagnosis or suspected diagnosis of:
  [] GCA, or
  [] myositis
- started on high-dose steroids during the index hospitalization with plan for either:
  [] ≥ 30 days of ≥ 30 mg qd prednisone (or equivalent), or
  [] ≥ 3 months of ≥ 2.5 mg qd of prednisone (or equivalent)
- "moderate" (or higher) fracture risk per the 2022 ACR GIOP guideline (https://assets.contentstack.io/v3/assets/bliee37abb6b278ab2c/blt8c68fa62e5f70069/giop-guideline-summary-2022.pdf):
- FRAX calculator here: https://frax.shef.ac.uk/FRAX/tool.aspx?country=9
- Patient's FRAX score is (ensure glucocorticoid use risk factor selected in calculator question #8):
  _____ % 10-y risk for major osteoporotic fracture (MOF)
  _____ % 10-y risk for hip fracture
  - FRAX score corrected for GC use (applicable if > 7.5 mg/d prednisone equiv.) is:
    (Above x 1.15) _____ % 10-y risk for major osteoporotic fracture (MOF)
    (Above x 1.2) _____ % 10-y risk for hip fracture
  - Patient is:
    [] very high fracture risk
    [] high fracture risk
    [] moderate fracture risk

PATIENT MEETS INCLUSION CRITERIA:
[] YES (meets all 4 above requirements)
[] NO

Important considerations
(please check the boxes by placing an x in the brackets [x] if any of the following apply to this patient):
[] previously treated with antiresorptive or anabolic therapy for bone health within the last 2 years (may be reasonable to continue holiday if on holiday or continue current therapy)
[] have enough uncertainty in their diagnoses at the time of discharge (e.g., still awaiting biopsy result) that it precludes reasonable estimation of duration of steroid exposure (may be reasonable to defer decision on GIOP prophylaxis)
[] women of childbearing potential (do not use bisphosphonate)
[] CrCl <35 cc/min (do not use bisphosphonate)
[] 25-OH vitamin D <28 ng/mL (replete first)
[] hypocalcemia (uncorrected) (rectify first)
[] planned invasive dental work (avoid anti-resorptive)

Treatment:
[] optimize vitamin D and calcium intake through supplements and diet. Recommend calcium and vitamin D supplementation
- consider oral (alendronate) or IV (zoledronic acid). Reasons to choose IV over oral include GERD, difficulty with adherence to oral medication, patient preference.
- for those with very high fracture risk, consider also PTH analogs (teriparatide, abaloparatide) for anabolic benefit. Reasons to avoid include elevated PTH or MGUS (send PTH and SPEP/SFLC if considering), hx of Paget's, other risk factor for osteosarcoma (hx of radiation to skeleton, skeletal mets), insurance coverage, cost.
- for those with high fracture risk, consider also denosumab. Reasons to avoid include patient at risk of adherence interruption (should not be abruptly stopped).
- for those with very high fracture risk, consider romosozumab for anabolic benefit. Reasons to avoid include CV risk (increased risk of MI, stroke, and death; absolute contraindication if MI or stroke in last yr), cost, insurance coverage.

PATIENT WILL BE STARTED ON:
[] alendronate
[] zoledronic acid
[] other: _____

THIS IS PLANNED TO START:
[] inpatient (please record date if known _____)
[] outpatient

Figure 1. GIOP Screening Protocol

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Baseline Characteristics of Intervention and Historical Cohorts

	Intervention cohort (N=19)	Historical cohort (N=20)
Demographics		
Female, n (%)	15 (78.9%)	13 (65%)
Age, mean (SD)	71.9 (12.1)	70.1 (10.5)
Race/ethnicity		
Asian	1 (5.3%)	0
Black	1 (5.3%)	0
White	17 (89.5%)	19 (95%)
Unknown	0	1 (5%)
Comorbidities		
Inpatient diagnosis		
Inflammatory myopathy	3 (15.8%)	5 (25%)
Giant cell arteritis	16 (84.2%)	15 (75%)
Known osteopenia (preceding)	6 (31.6%)	3 (15%)
Known osteoporosis (preceding)	3 (15.8%)	3 (15%)
Prior fragility fracture	3 (15.8%)	4 (20%)
Chronic kidney disease	5 (26.3%)	5 (25%)
Other		
Prior history of antiresorptive or anabolic therapy (>2y prior)	3 (15.8%)	3 (15%)
On aromatase inhibitor	1 (5.3%)	0
Tobacco use		
Never	9 (47.4%)	14 (70%)
Past	9 (47.4%)	5 (25%)
Current	1 (5.3%)	1 (5%)
EtOH use >=3 drinks/day	0	1 (5%)

identified by billing codes and chart review, with exclusions for factors including age < 40, prior anabolic or antiresorptive therapy (within the preceding 2 years), renal insufficiency with eGFR < 35 mL/min/1.73 m^2, and 25-hydroxy vitamin D < 20 ng/mL, noting the latter two factors were uncommon reasons for exclusion, resulting in only 3 excluded patients in each cohort. Fisher's exact test *p*-values were used to compare categorical outcomes between the intervention and historical cohorts.

Results: A total of 39 patients were included (19 intervention, 20 historical). Baseline characteristics were similar with respect to age (mean 71.9 versus 70.1 years, respectively), race/ethnicity, and prevalence of comorbidities (**Table 1**). GIOP preventative therapy within 3 months was more frequent in the intervention group (52.6% vs 40%, p=0.53) with higher rates of inpatient ZA administration (26.3% vs 15%, p =0.45). There were similar rates of other GIOP preventative therapy (26.3% vs 25%, p=1.00) and DXA completion within 6 months (52.6% vs 45%, p=0.75) (**Table 2**).

Conclusion: Implementation of a systematic inpatient screening protocol and provision of ZA in the inpatient setting for patients with active GCA or IIM has the potential to improve timely initiation of GIOP management. While our outcomes did not reach statistical significance, likely due to a limited sample size over a 12-month period, the increased rate of timely GIOP

Table 2. Patient Outcomes

	Intervention cohort (N=19)	Historical cohort (N=20)	*p*-value
Received GIOP within 3 months	10/19 (52.6%)	8/20 (40%)	$p = 0.53$
Received ZA inpatient	5/19 (26.3%)	3/20 (15%)	$p = 0.45$
Received other GIOP	5/19 (26.3%)	5/20 (25%)	$p = 1.00$
Alendronate	3[1]	4	
ZA outpatient	2[1]	1	
Denosumab	1	0	
Teriparatide	0	0	
Did not receive GIOP within 3 months	9/19 (47.4%)	12/20 (60%)	$p = 0.53$
Patient declined inpatient ZA and other GIOP	5	1	
GIOP discussed but not started for unclear reason	2	0	
GIOP not addressed in medical record	2	11	
DXA performed within 6 months	10/19 (52.6%)	9/20 (45%)	$p = 0.75$

[1]Note that one patient received alendronate before transitioning to ZA treatment.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. prophylaxis (noting an already-high baseline rate), particularly with inpatient ZA administration, suggests a potential clinical benefit for an undertreated patient population at risk for significant morbidity. Given its ease of implementation and potential to reduce fracture risk, this intervention will continue as part of our routine inpatient care.

Session Title: (0337–0356) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Low socioeconomic status is associated with.an increase in osteoporosis and fracture risk respectively. A multitude of factors have been proposed including income, educational attainment and cohabitation status. However, the mechanisms that drive the disparity between social deprivation and osteoporosis remain unclear. We aim to identify key socioeconomic factors that could explain the association between deprivation and osteoporosis.

Methods: We conducted a retrospective cohort study on 31,170 patients referred for Dual-Energy X-ray Absorptiometry (DEXA) between April 2006 and February 2024 in the

Table 1 outlines baseline demographics, risk factors for fragility fracture and bone mineral density between the least and most deprived cohorts.

Table 1:

Characteristic	Most deprived N = 10,278	Least deprived N= 10,388	P value	95% CI
Age (yrs)[a]	66 ± 12.4	64 ±13.3		64.60 – 64.96
Height(cm)[a]	162.3 ±8.36	161.3 ±8.73		161.70- 161.93
Female[b]	8,609 (50.06%)	8,588 (49.94%)		
Ever smoked[b]	3,157 (30.66%)	4,729 (45.35%)	0.00	
BMI (kg/m2)[a]	26.7 ± 6.5	27.7 ±27.6		27.09- 27.28
Body fat (%)[a]	29 ±7.3	30 ±7.7		2.97 – 2.99

[b]n (%)

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

North West of England. The cohort was divided into deciles based on the Index of Multiple Deprivation (IMD). The 3 most deprived deciles were compared to the 3 least deprived deciles respectively. Patient demographics, risk factors for fracture risk and bone mineral density from the femoral neck and lumbar spine were recorded. Data was analysed using chi-squared and two-sample t-test. P values of less than 0.05 were considered statistically significant.

Results: The least deprived cohort had a greater steroid use (26.98%), excess alcohol intake (7.77%) and had ever smoked (45.3%). The more deprived had a higher family history of fracture (17.83%) but a lower BMI and percentage body fat. There were no differences in bone density and total fracture rates, however, the more deprived cohorts had a greater rate of radius fracture (17.83%).

Conclusion: These results suggest that whilst there are differences in traditional risk factors for developing fractures between the most and least deprived in society, however, this does not translate towards an increase in total fracture risk nor a reduction in bone mineral density in the least deprived. This supports the evidence that there are unmeasured confounders that could predict fracture risk in groups with greater deprivation. Some limitations include that this is data on referrals to a regional scanner and not population data. Further research is needed to clarify the mechanisms between deprivation and socioeconomic status and fracture risk.

Session Date: Sunday, October 26, 2025
Session Title: (0337–0356) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Chronic kidney disease (CKD) is linked to increased vascular comorbidity and fracture risk. This study aims to assess bone status in CKD patients versus healthy controls and its relationship with intact fibroblast growth factor 23 (iFGF-23). A secondary aim is to evaluate cardiovascular risk (CVR) in CKD and its associations with bone status and iFGF-23.

Methods: Adults with CKD stages 2–4 (normal phosphate levels) were assessed for bone metabolism, iFGF-23, and bone density using DXA. Bone quality was evaluated via Trabecular Bone Score (TBS) at the lumbar spine and 3D-DXA at the proximal femur. FRAX scores and vertebral fractures were recorded. Carotid ultrasound and Kauppila vascular calcification scores assessed subclinical CVR. A matched control group (age, sex, BMI) was used for bone quality comparison via propensity score matching.

Abbreviations: aIMT: Average of right and left carotid intima-media thickness; BMD: Bone mineral density; MACE: Major adverse cardiovascular event; CKD: Chronic kidney disease; IMT: Intima-media thickness; IFGF-23: Intact fibroblast growth factor 23; BMI: Body mass index; PTH: Parathyroid hormone; SCVR: Subclinical cardiovascular risk; TBS: Trabecular Bone Score.

No significant differences in BMD, TBS, or 3D-DXA were found between CKD stages G2-G3a and G3b-G4. However, when comparing G2-G3a to controls, osteoporosis and osteopenia were more prevalent (44.7% and 13.2% vs. 15.2% and 1.3%,p=0.001). In G3b-G4 patients versus controls, lower femoral BMD (0.89 vs. 0.93,p< 0.043) and trabecular vBMD by 3D-DXA (161.90 vs. 169.45,p< 0.03) were found, with higher osteoporosis and osteopenia prevalence (52.5% and 20% vs. 15.2% and 1.3%;p=0.001).

Table 1 compares demographics and DXA, TBS, and 3D-DXA between CKD patients and controls. Table 2 presents results by CKD stage and controls.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

In 62 patients undergoing carotid ultrasound (Table 3), 67.7% had low BMD and 50% showed altered TBS. Patients with subclinical CVR and/or cardiovascular disease (CVD) (n=45) were older (p=0.007), with higher carotid intima-media thickness (cIMT, p< 0.001) and Kauppila index (p< 0.001) compared to those without (n=17). DXA, TBS, 3D-DXA did not differ significantly.

iFGF-23 inversely correlated with eGFR (r: -0.38, p=0.002). cIMT correlated inversely with 25(OH) vitamin D (r: -0.25, p=0.047), and directly with lumbar BMD (r: 0.485,p< 0.001), cortical vBMD (r: 0.27, p=0.038), cortical surface BMD by 3D-DXA (r: 0.25, p=0.053), and the Kauppila index (r: 0.42,p=0.001).

In patients with subclinical CVR and/or CVD and fragility fractures, iFGF-23 was inversely correlated with cortical vBMD (ρS: -0.9,p=0.037).

Conclusion: CKD patients show reduced bone mass compared to healthy individuals, evident even in early stages of the disease. Bone quality alterations assessed by TBS and 3D-DXA may help identify those at risk for vertebral fractures. iFGF-23 appears to contribute to both bone quality deterioration and vascular damage. In the subgroup of patients with subclinical cardiovascular disease and/or major adverse cardiovascular events (MACE) and fragility fractures, impaired bone quality parameters were observed by 3D-DXA.

Abstract Number: 0347

Identifying Risk Factors for Fragility Fractures in Patients with Coeliac Disease: An Observational Study

Kabyar Cho[1], Hamzah Amin[2] and marwan Bukhari[3], [1]University Hospitals of Morecambe Bay NHS Foundation Trust, Barrow-In-Furness, United Kingdom, [2]Lancaster University, Lancaster, United Kingdom, [3]University Hospitals of Morecambe bay NHS foundation trust, Lancaster, United Kingdom

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0337–0356) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Coeliac disease (CD) is an autoimmune disease, which has been widely reported to be associated with reduced bone mineral density (BMD), leading to an increased risk of fragility fractures. The lower bone mineral density observed in coeliac disease patients may be attributed to several factors including malabsorption, vitamin D deficiency, chronic inflammation, and associations with inflammatory conditions such as osteoporosis or rheumatoid arthritis.

Recent studies have found different risk factors of fragility fractures which are not currently recognised in FRAX™ tool. This observational study aims to evaluate parameters strongly associated with fracture risk in coeliac patients.

Methods: Data was collected from patients with coeliac disease who were referred for dual-energy X-ray absorptiometry (DEXA) scans in the North West of England between 2004 and 2019. Variables include patient demographics, FRAX™ risk factors, L1-L4 BMD, fat percentages of the whole body, abdomen and both femurs. Data analysis was conducted using a

Family history of fracture	241 (19.75%)	49 (20.3%)	192 (79.7%)

chi-square test for categorical variables, and student t-test for continuous variables. Subsequently, univariate and multivariate logistic regression analyses were performed to identify parameters independently associated with outcomes of fracture. Baseline characteristics included are tabulated by fracture status as shown in Table 1.

Results: A total of 1220 patients were analysed. Mean age at DEXA scan was 63.9 years (SD 14.1). 285 (23.4%) patients sustained a fracture, among which 239 (83.9%) patients were females. Patients with a fracture had a significantly lower BMD at both the femoral necks, across the entire femur, and the lumbar spine (all $p< 0.001$), as well as a higher fat percentage in both femurs ($p< 0.001$), abdomen ($p=0.027$), and total body fat percentage ($p=0.017$). Fractures were also significantly associated with steroid use ($p=0.026$), rheumatoid arthritis ($p=0.009$), and family history of fracture ($p=0.047$).

Our univariate regression model established that a lower BMD and higher fat percentage at all measured sites were significantly associated with an increased risk of fractures. The results can be seen in Table 2.

The multivariate model, adjusted for other covariates, revealed that lumbar spine BMD, abdominal fat percentage, total fat percentage, left femoral fat percentage, and positive family history were strong predictors of fracture in this group of patients. This is shown in Table 3.

Conclusion: Our study concluded that lower lumbar spine BMD is significantly associated with increased prevalence of fractures, a relationship that has not been widely recognised in larger cohort studies. In addition, abdominal fat percentage, total fat percentage, and left femoral fat percentage were found to be significant factors predisposing to increased fracture in

Abstract Number: 0348

Correlation between Bone Mineral Density by Dual-energy X-ray Absorptiometry at the Radius and Radius Cortical Bone Thickness using Routine Hand Radiographs in Rheumatoid Arthritis Patients

Karla Miller[1], Amani Jridi[2] and Tina Basak[3], [1]University of Utah School of Medicine, Salt Lake City, UT, [2]University of Utah, Salt Lake City, UT, [3]University of Utah Department of Radiology, Salt Lake City, UT

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0337–0356) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) patients are at higher risk of having generalized osteoporosis of the axial and appendicular skeleton assessed by dual-energy x-ray absorptiometry (DXA) but are also known to have local periarticular bone loss on hand radiographs as a typical manifestation of disease. DXA is the most common method to assess general bone mineral density (BMD) and is recommended for osteoporosis screening in RA patients, while hand radiographs are routinely obtained for RA diagnosis and monitoring. It is unknown if radius cortical bone thickness (CBT) by radiograph correlates with bone mineral density at the radius by DXA in RA patients. The aim of this study is to assess the correlation of distal radius cortical bone thickness (CBT) measurements by routine hand radiographs with DXA BMD and T-score results for osteoporosis screening in RA patients.

Methods: For this Institutional Review board approved retrospective study, RA patients who underwent a distal radius DXA scan and had a hand radiograph taken within a 5-year period were included. Distal radius CBT was ascertained by measuring the outside diameter and the inside diameter of the cortical shell at the metaphyseal/diaphyseal junction and their ratio was calculated (Figure 1). Correlation between CBT of the distal radius and the DXA bone mineral density (BMD) values and T-scores of the distal radius, spine, and femurs were analyzed using Pearson correlation coefficient. Subgroup analyses of the correlation of distal radius CBT with the overall distal radius, ultra-distal radius (UD), mid-distal radius (MD), and one-third distal radius (OT) BMD and T-scores were also performed.

Results: 27 total patients were included for this study (mean age 63.9 years, 81% women). There was moderate positive correlation ($p \leq 0.05$) between the distal radius CBT and the MD ($r = 0.44$), OT ($r = 0.38$), and overall distal radius BMD ($r=0.41$). Weak correlation was seen between the distal radius cortical thickness and the overall, UD, MD, and OT T-scores and the ultra-distal BMD without statistical significance. No significant correlation was seen between the distal radius CBT and the T-scores and BMD of the femurs or lumbar spine.

Conclusion: Opportunistic use of routine hand radiographs to measure the distal radius CBT can provide modest correlation to the BMD at the MD, OT, and overall distal radius in RA patients. Larger study population and prospective study could provide confirmation of this correlation.

Distal Radius Cortical Bone Thickness Measurement

Abstract Number: 0349

Underrecognized Glucocorticoid-Induced Osteoporosis in a Polymyalgia Rheumatica Patient Cohort

katherine Loomba[1], Emily Campbell[1], Nisha Khubchandani[1], chih Fang[1], William Rigby[2] and Vivekanand Tiwari[1], [1]Dartmouth Hitchcock Medical Center, Lebanon, NH, [2]Dartmouth-Hitchcock, Norwich, VT

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0337–0356) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Polymyalgia Rheumatica (PMR) and Giant Cell Arteritis (GCA) are systemic inflammatory disorders treated with prolonged corticosteroid therapy. Prolonged use of corticosteroids is a significant risk factor for developing osteoporosis and subsequent fractures. In adults over 40, osteoporosis is defined as the presence of a fragility fracture or a T-score < -2.5, or a high fracture risk as defined by FRAX scoring of >20% for a major osteoporotic fracture or >3% for a hip fracture. It is also suggested to increase the FRAX estimates for hip fracture and overall fracture by 20% and 15%, respectively, for patients on doses > 7.5 mg/d prednisone for at least three months. If the FRAX score is not considered or corrected for glucocorticoid exposure, this may lead to the underdiagnosis of osteoporosis. This study aimed to explore this risk by reanalyzing the FRAX scores of an osteopenic cohort of Polymyalgia Rheumatica (PMR) patients and comparing them to their original classification.

Methods: We conducted a retrospective review of PMR patients at a rheumatology clinic, focusing on those diagnosed with PMR or PMR with GCA and excluding patients with other rheumatological disorders. The study included 459 patients from 2011 to 2021. We retrospectively assessed the osteopenic patients and calculated each patient's FRAX with glucocorticoid correction, if applicable

Results: The original study included 459 PMR patients, with documentation showing that 171 (37.2%) had osteoporosis, 70 (15.3%) had osteopenia, 121 (26.4%) had normal bone mineral density, and 98 (21.4%) had no available DXA data. In the original cohort, screening for osteoporosis using DXA scans was conducted for 64.4% of patients. Among the total PMR patients, 37.3% were diagnosed with osteoporosis, and 16% had osteopenia. In the present analysis, after

Table 1. Addended Baseline Characteristics of PMR Cohort Regarding Bone Mineral Density

Classification	Variable	Value
PMR patients	Total	459
Osteoporotic	Total	200
	Mislabeled as osteopenic	14.5% *
	Mean Age	73.6
	Gender (F, M)	74%, 26%
	On Bisphosphonates	65.5%
	On Ca + Vit D	86%
Osteopenic	Total	43
	Mean Age	68.6
	Gender (F, M)	18.8%, 81.2%
	On Bisphosphonates	13.9%
	On Ca + Vit D	44.4%
No DXA available	Total	98
	Mean Age	70.1
	Gender (F, M)	33.7%, 66.3%
Normal DXA	Total	26.4%

*14.5% of osteoporotic patients were misdocumented as osteopenic; this made up 41.4% of the original osteopenic cohort (29/70) and was comprised of 15 women/14 men.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. considering FRAX scoring and glucocorticoid correction, 41.4% of the documented osteopenic patients were found to qualify for osteoporosis diagnosis, increasing the total osteoporotic subset of our PMR cohort to 200 (43.6%).

Conclusion: The FRAX calculation and glucocorticoid correction should be included in the osteoporosis diagnosis rather than relying solely on the T score; otherwise, osteopenic patients may inadvertently remain untreated.

Abstract Number: 0350

Perioperative Evaluation of Blood Tests Including Bone Turnover Markers in Patients Undergoing Surgery for Proximal Femur Fractures

KEN NAKASEKO, KUWANA CITY MEDICAL CENTER, KUWANA, Mie, Japan

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0337–0356) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Osteoporosis treatment is essential to prevent fractures. However, few patients with proximal femur fractures receive osteoporosis treatment before injury. Initiating treatment postoperatively is critical to reduce the risk of subsequent fractures, such as contralateral hip and vertebral fractures. Our institution proactively initiates osteoporosis treatment during hospitalization after proximal femur fracture surgery.

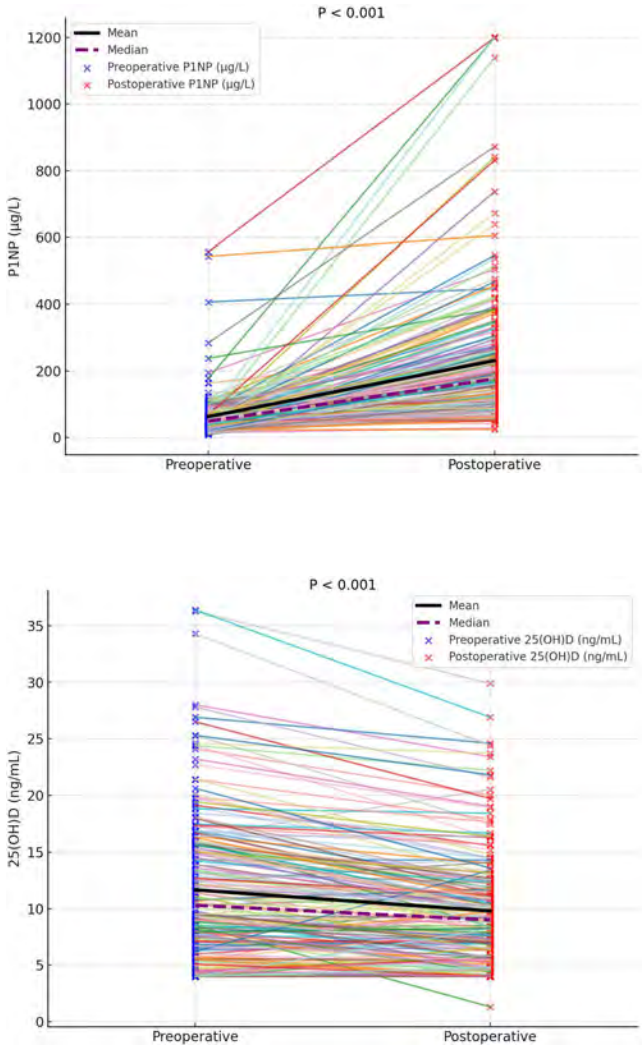
We perform bone mineral density measurements, spinal and pelvic X-rays, and blood tests, including bone turnover markers, to guide medication selection. Although bone turnover markers should ideally be measured within 24 hours of injury, postoperative measurement is sometimes unavoidable. This study evaluated differences in blood test parameters between pre- and postoperative periods, assessed differences by fracture type, and examined considerations when bone turnover markers cannot be measured early.

Methods: We included 179 patients (41 males, 138 females; mean ages 82.6, 82.8 years) hospitalized within 24 hours of a proximal femur fracture. Of these, 81 had femoral neck fractures (18 males, 63 females; mean ages 82.5, 82.7), and 98 had trochanteric fractures (23 males, 75 females; mean ages 82.9, 83.0).

All patients underwent preoperative blood tests at admission, followed by surgery (osteosynthesis, bipolar hip arthroplasty, or total hip arthroplasty). We measured procollagen type 1 N-terminal propeptide (P1NP), tartrate-resistant acid phosphatase-5b (TRACP-5b), 25-hydroxyvitamin D, alkaline phosphatase, calcium, and phosphorus at admission and 1–2 weeks postoperatively. Changes before and after surgery, and differences by fracture type, were analyzed using t-tests.

Results: Postoperative P1NP levels increased in 171 of 179 patients (76 of 81 femoral neck, 95 of 98 trochanteric fractures), averaging a 3.7-fold increase. Preoperative 25-hydroxyvitamin D levels were < 20 ng/mL in 163 patients (76 femoral neck, 87 trochanteric), declining further postoperatively in 170 patients (78 femoral neck, 92 trochanteric). A postoperative decrease was seen in 137 patients (63 femoral neck, 74 trochanteric).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Significant differences ($P < 0.001$) were observed in P1NP and 25-hydroxyvitamin D between pre- and postoperative measurements, regardless of fracture type. No significant changes were seen in TRACP-5b, alkaline phosphatase, calcium, or phosphorus, and no fracture type differences were detected.

Conclusion: We observed a marked postoperative increase in P1NP, highlighting the importance of early measurement to avoid overestimation due to fracture-induced elevation. These findings were consistent across fracture types, supporting uniform management.

When early assessment is not feasible, clinicians should interpret P1NP cautiously and consider alternative markers, recognizing that elevated P1NP alone should not preclude anabolic therapy. The postoperative decline in 25-hydroxyvitamin D underscores the need for early active vitamin D supplementation. These findings provide practical guidance for optimizing osteoporosis management in acute fracture care.

Abstract Number: 0351

Experience with romosozumab in women with osteoporosis at high risk of fracture in real-world clinical practice

MARIA DEL CARMEN ORTEGA DE LA O[1], Laura Gonzalez Hombrado[2], Marina Salido Olivares[3], Carolina Marin[4], Angel Aragon[5], Celia arconada[6], Maria Carmen Ortega de la O[7], Alvaro Garcia[8], elisabeth Castañeda[9], Patricia Castro Perez[10], alberto diaz Oca[11] and Eva Andres Esteban[12], [1]HOSPITAL UNIVERSITARIO GETAFE, GETAFE, Madrid, Spain, [2]Hospital Universitario del Tajo, Aranjuez (MADRID), Madrid, Spain, [3]Hospital Clinico San Carlos, Madrid, Madrid, Spain, [4]Hospital Infanta Leonor, Madrid, Madrid, Spain, [5]Hospital Universitario Quironsalud Madrid, Pozuelo de Alarcon, Madrid, Spain, [6]Hospital universitario de Getafe, Getafe, Madrid, Spain, [7]Hospital Universitario Getafe, Madrid, Madrid, Spain, [8]Hospital Universitario del Tajo, Aranjuez, Madrid, Spain, [9]Hospital Universitario Infanta Sofía, Madrid, Madrid, Spain, [10]Hospital de Getafe, Madrid, Madrid, Spain, [11]Hospital de Fuenlabrada, Fuenlabrada, Madrid, Spain, [12]Universidad Rey Juan Carlos, Fuenlabrada, Spain

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0337–0356) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Romosozumab (RMZ) is a recently approved dual-acting drug which has been shown to reduce fracture risk in patients with osteoporosis (OP) in clinical trials. However, data on its use in actual clinical practice remain limited. Our purposes are:

-Describe the profile of patients treated with RMZ in realworld clinical practice.
-Evaluate its efficacy based on densitometric changes and the incidence of new fractures.
-Assess the safety profile of the drug and patient satisfaction.

Methods: This multicentre retrospective observational study aimed to assess the use of RMZ and its efficacy in patients with OP in real-world clinical settings. Data were collected from the medical records of patients treated by their regular rheumatologist at the participating centres and entered into an anonymous electronic database. Demographic data, comorbidities, risk factors for OP development, the number and location of previous fractures and prior treatments performed on the patients were gathered. Laboratory tests and densitometry were conducted before and after treatment. The FRAX index was calculated for all patients prior to starting treatment. The study was approved by the ethics committee at Hospital 12 de Octubre.

Results: A total of 128 women from six centres in the Region of Madrid were included, of whom 81 have completed treatment to date. Baseline patient data are shown in Table 1. The mean age was 69.7 ±12.9 years. The mean BMI was 26.1 ± 6.8, while 39.5% were classified as obese. The most common comorbidities were hypertension and dyslipidaemia (both 35.8%). Most of the patients had no toxic habits. 88.9% had experienced one or more previous fractures, the majority of which were vertebral fractures. The mean FRAX data for hip fracture risk were 9.2 ± 11.1 and for major osteoporotic fracture they were 21.4 ± 14.7. RMZ was used as a second-line treatment in most patients (43.4%). No laboratory test changes were observed during treatment. The densitometric changes found are shown in Table 3, which illustrates the statistically significant differences between the baseline and post-treatment DEXA values for the lumbar spine and hip. Chart 1 shows the treatments after completing RMZ

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Baseline characteristics of patients at the start of the study

BASELINE CHARACTERISTICS	N=81 patients
Age	69.7 +/- 12.9
BMI	26.1 +/- 6.8
Menopausal age	47.6 +/- 5.7
Surgical menopause	5 (6.2%)
HBP	29 (35.8%)
Dyslipidaemia	29 (35.8%)
Diabetes mellitus	5 (6.2%)
Cardiovascular disease	4 (4.9%)
Drinker	2 (2.5%)
Smoker	10 (12.3%)
PREVIOUS FRACTURES	72 (88.9%)
1 fracture	26.50%
2 or more fractures	73.50%
Hip fracture	11.80%
Rheumatoid arthritis	7 (8.6%)
Hyperparathyroidism	1 (1.2%)
LINE OF TREATMENT	
1st line	17 (22.4%)
2nd line	33 (43.4%)
3rd line	14 (18.4%)
4th or more lines	12 (15.8%)
Concomitant osteopenia treatments	13 (16.1%)

Six patients reported adverse effects. The most common were local reactions at the injection site. Treatment was discontinued in two patients due to adverse effects, one due to a severe skin reaction and the other due to a stroke. None of the patients experienced a new fracture during the follow-up period. Patient satisfaction was rated at 4.6 ± 0.6 (scale 0-5).

Table 3. Densitometric data before and after RMZ

	BASELINE	AFTER RMZ	p value

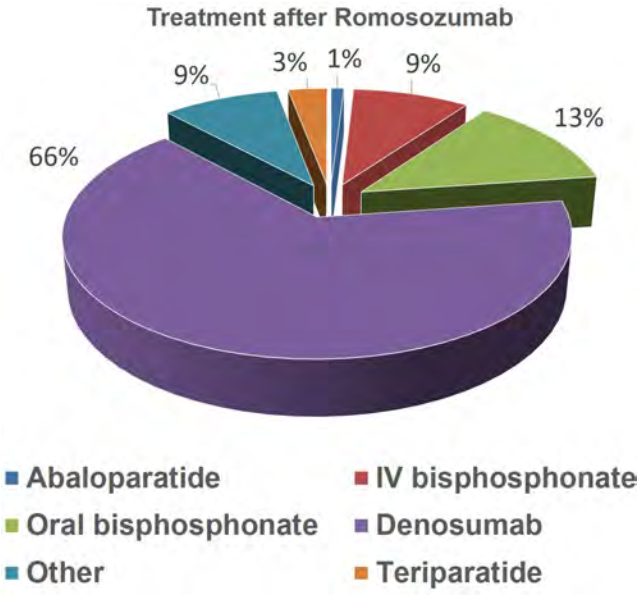

Chart 1

Conclusion: RMZ is mainly used in women with severe OP, most of whom have experienced several previous fractures and are receiving second or subsequent lines of treatment. It has shown statistically significant improvements in densitometric measurements in the lumbar spine and hip. The majority of adverse effects were mild and no patients experienced new fractures during the follow-up period

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0337–0356) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Atypical femoral fractures (AFFs) are a rare complication of bisphosphonate use and a major reason that drug holidays are recommended following bisphosphonate use. However, the extent to which post-fracture complications occur in AFFs compared to subtrochanteric femoral fractures (SFF) and typical hip fractures (THF) is not clear. This study aims to determine if time without complication differs among AFF, SFF and THF.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We conducted a retrospective study of adults aged > 50 years old who used oral or IV bisphosphonates between October 1, 1999 and December 31, 2022 in the VHA Corporate Data Warehouse who had AFF, SFF, or THF. Those with ESRD, metabolic bone diseases other than osteoporosis, cancer, a filled prescription for etidronate, pamidronate or tiludronate or those whose dose of zoledronic acid was or $\leq$ 273 days from the initial dose were excluded. Among these patients, we used ICD-9-CM and ICD-10-CM codes to find complications of fractures including osteomyelitis, pressure ulcers, fracture nonunion, and fracture malunion within 12 months of diagnosis. We then used an unadjusted semiparametric accelerated failure time (AFT) model to determine the time to complication among each cohort. We adjusted the results for age at first prescription of bisphosphonate script (FPOS), White vs. non-White racial identity, ethnicity, BMI, Charleston Comorbidity Index, VA Frailty Index, and smoking status.

Results: Of the 5,650 patients who met inclusion criteria, 21 experienced an AFF (with a median age of 68 at FPOS, and 9.52% non-White), 255 experienced a SFF (with a median age of 70 at FPOS, and 11.7% non-White), and 5,374 experienced a THF (with a median age of 75 at FPOS, and 8.19% non-White). Within 12 months of the fracture, only 1 person (4.76%) with an AFF experienced a complication (a fracture nonunion), compared to 22 (8.63%) with SFF and 283 (5.27%) with a THF. The number of complications in each group were too small to compare rates for each complication directly.

Overall time to complication did not differ between the three groups. The average time without complication following SFF was 0.520 times that for THF (95% CI: 0.455 to 0.596, $p \approx 0$). The average time without complication following AFF did not differ from THF (95% CI: 0.186 to 23.584, $p = 0.549$).

After adjusting for the above covariates, the average time without any complication following SFF was 0.381 times the estimated time without any complication following THF (95% CI: 0.190 to 0.765, $p = 0.007$). Adjusting for the same variables, the estimated time without complication following AFF did not differ from estimated time without complication following THF (95% CI: 0.056 to 35.875, $p = 0.831$).

Conclusion: The adjusted average time to complication is shorter in patients with SFF compared to THF. However, the adjusted average time to complication in patients with AFF does not differ from those with THF.

Background/Purpose: Patients with Rheumatoid Arthritis (RA) have an increased risk of osteoporosis and fragility fractures. Bone loss in RA is multifactorial and mainly determined by classical risk factors for fracture (age, previous fracture, parental hip fracture, postmenopausal period duration, proximal femur bone mineral density (BMD)), factors associated with RA (disease activity, erosions, disability) and use of glucocorticoids (GC). A recent study (*Bone. 2023;168:116654*) suggested that patients with RA treated with Rituximab (RTX) may have a higher incidence of clinical fragility fractures (CFF), compared to those receiving other DMARDs. However, this association has not been thoroughly studied.

Methods: Retrospective, single-centre observational study in patients with RA diagnosis, according to the ACR/EULAR 2010 RA classification criteria, who received at least one dose of RTX between 1 January 2010 and 31 December 2019. Two comparator groups matched by sex, age, and disease duration were included: one treated with conventional synthetic DMARDs (group 1), and the other with biological or targeted synthetic DMARDs (group 2). Patients treated with RTX were assigned to group 3. Hospital and primary care medical records were reviewed up to 31 December 2024 or until loss of follow-up. We defined CFF as those resulting in the absence of external injury, such as from falls from one's own height or walking at normal speed. Date and location of CFF were recorded, as well as the date and reason for the end of follow-up, together with data on RA characteristics and fracture risk factors.

Results: A total of 204 patients were included (68 per group), of whom 71% were women, with a mean age of 53.6 years and a mean disease duration of 2.0 years, with no significant differences between groups. The indication for RTX was RA disease activity in 62% of cases and interstitial lung disease (ILD) in 38%. Baseline characteristics of the groups are summarised in Table 1.

Fifty-eight patients had 90 CFF (39 vertebral fractures, 13 humerus, 10 distal forearm, 4 hip fractures, and 24 other locations). The incidence of CFF was 2.1, 2.4 and 2.3 per 100 person-years (ppy), in groups 1, 2 and 3 respectively, with no statistically significant differences. Patients with CFF showed a significantly higher prevalence of erosions, parental history of hip fracture, use of GC, WHO osteoporosis diagnostic category, lower BMD at lumbar spine, femoral neck and total hip, and higher FRAX scores.

The mortality rate was 0.7, 0.7 and 2.8 ppy ($p < 0.001$), respectively. In group 3, mortality was particularly high when RTX was indicated for ILD (53.9%) rather than for RA disease activity (11.9%) and in patients with vertebral fractures.

Conclusion: In our sample, there were no differences in the incidence of CFF between groups treated with RTX or other DMARDs. CFF were associated with classical fracture risk factors and erosive disease. The group treated with RTX showed higher mortality, particularly when the indication was ILD and in patients with vertebral fractures.

Abstract Number: 0354

Greater Neighborhood Walkability is Associated with Lower Incidence of Hip Fracture in Older, Community-dwelling Women in the United States: The Cardiovascular Health Study

Rachel Elam[1], Petra Buzkova[2], Howard Fink[3], Joshua Barzilay[4], Eric Roseen[5], Jane Cauley[6], John Robbins[7], Laura Carbone[1], Gina Lovasi[8] and Kenneth Mukamal[9], [1]Augusta University, Augusta, GA, [2]University of Washingon, Seattle, WA, [3]University of Minnesota, Minneapolis, MN, [4]Kaiser Permanente of Georgia, Atlanta, GA, [5]Boston University, Boston, MA, [6]University of Pittsburgh, Pittsburgh, PA, [7]University of California Davis, Davis, CA, [8]Drexel University, Philadelphia, PA, [9]Beth Israel Deaconess Medical Center, Brookline, MA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0337–0356) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Higher physical activity is linked to reduced fracture risk in older adults, especially for hip fractures. Emerging evidence demonstrates a potential role for the physical and built environment in promoting physical activity in community-dwelling, older adults. We aimed to evaluate whether neighborhood walkability and greenspace are associated with incident hip fracture in a large, community-dwelling, older adult population in the United States.

Methods: We conducted a retrospective analysis of 1992-2005 data from the prospective longitudinal Cardiovascular Health Study, a large cohort of community-dwelling adults aged ≥ 65 years from Winston-Salem, NC; Sacramento, CA; Hagerstown, MD; and Pittsburgh, PA. We included participants with a geocoded residential address at baseline (1992-1993 study visit) who were deceased as of July 2016 (to limit risks related to unintentional data disclosure). A participant's neighborhood was defined as a 1-km Euclidean radial buffer surrounding their residential address at baseline. Neighborhood walkability was the sum of the standardized population density and density of walkable destinations for daily living, truncated at 5 due to a heavy upper tail. Neighborhood greenspace was the proportion of land uses classified as green or vegetated in the 1992 National Land Cover Dataset. Incident hip fractures were identified by participant report every six months from baseline, confirmed by hospital medical record review. Participants were followed for up to 12 years or until the occurrence of hip fracture, death, or loss to follow-up, whichever occurred first. Cox hazard models were used to evaluate associations of neighborhood walkability and greenspace with incident hip fracture in sex-stratified and combined analyses, adjusting for numerous fracture risk factors and socioeconomic metrics for the individual (marital status, education, annual household income) and neighborhood (median household income, median value of housing units, and proportion of persons in managerial or professional occupations), using study site as a random effect.

Walkability	Unadjusted	0.99	(0.93, 1.06)	0.99	(0.91, 1.07)	1.02	(0.90, 1.15)
	Minimally adjusted[1]	0.99	(0.92, 1.05)	0.98	(0.91, 1.06)	0.99	(0.88, 1.12)
	Fully adjusted[2]	0.90	(0.79, 1.03)	0.84	(0.72, 0.99)	1.07	(0.84, 1.36)
Greenspace[3]	Unadjusted	0.92	(0.63, 1.35)	0.97	(0.63, 1.51)	0.75	(0.36, 1.56)
	Minimally adjusted[1]	0.96	(0.66, 1.40)	0.99	(0.64, 1.54)	0.87	(0.42, 1.83)
	Fully adjusted[2]	0.84	(0.48, 1.47)	0.90	(0.45, 1.79)	0.72	(0.27, 1.91)

HR: Hazard ratio; CI: Confidence interval

[1]Adjusted for participant age, sex, and race

[2]Adjusted for participant age, sex, race, weight, height, smoking status, current heavy alcohol use, oral corticosteroid use, osteoporosis medication use (vitamin D, calcium, selective estrogen receptor modulators, estrogens, and bisphosphonates), and other medication use affecting bone metabolism and/or fracture risk (loop diuretics, thiazide diuretics, selective serotonin reuptake inhibitors, anticonvulsants, benzodiazepines, sedative/hypnotics, proton pump inhibitors, thiazolidinediones, and thyroid medications), prevalent diabetes, estimated glomerular filtration rate, marital status, education level, annual household income, neighborhood median household income, neighborhood median value of housing units, and neighborhood proportion of persons in managerial/professional occupations

[3]Proportion of land uses consistent with greenspace (13 green or vegetated land uses included: deciduous, evergreen, or mixed forest, shrubland, orchards/vineyards, grassland/herbaceous, pasture/hay, row crops, small grains, fallow, urban/recreational grasses, woody wetlands, emergent herbaceous wetlands)

Results: Among 3,676 participants (mean age 75±5.5 years, 83% White/17% Black, 58% women) over a median 10 years of follow-up, we observed 506 hip fractures (365 in women, 141 in men). Greater neighborhood walkability was statistically significantly associated with lower incidence of hip fracture in women in fully adjusted models (hazard ratio: 0.84 per 1 unit higher neighborhood walkability, 95% confidence interval: 0.72-0.99) (Table 1). In contrast, neighborhood walkability was not statistically significantly associated with hip fracture in men (Table 1). There were no statistically significant associations between neighborhood greenspace and hip fracture (Table 1). Penalized spline plots revealed no significant non-linear relationships.

Conclusion: In this large, community-based cohort of older adults, greater neighborhood walkability was associated with lower hip fracture risk in women, highlighting a potential opportunity for urban planners to decrease fracture burden through walkable community design. No significant association was observed between neighborhood greenspace and hip fracture risk.

Abstract Number: 0355

Changes in scanographic bone mineral density in melanoma patients treated with immunotherapy

Soukayna Baddi[1], Suarez Dimitri[1], Alexis Ruet[1], Theo Van Butsel[1], Damiano Cerasuolo[1], Jean-Matthieu L'Orphelin[1] and Anne-Christine Rat[2], [1]Caen University Hospital, Caen, France, [2]Caen University hospital, UMR 1075 Caen normandy university, Caen, France

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0337–0356) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: The use of immune checkpoint inhibitors (ICIs) is becoming increasingly important in the management of melanoma. However, although ICIs are associated with various immune-related adverse events (irAEs), their potential effect on the skeleton—particularly on bone mineral density (BMD) and the occurrence of fractures—has been little described.

The aim of this study is to assess the changes in BMD on CT scans in patients with melanoma treated with ICIs at one and two years and to investigate the factors associated with these changes.

Methods: We conducted a real-world, retrospective cohort study. Patients were recruited from outpatient dermatology clinic between October 2014 and 1 December 2023. Inclusion criteria for patients were: male or female, age ≥ 18 years, histologically confirmed melanoma, first treatment with immunotherapy (according to current treatment guidelines and after discussion in a multidisciplinary tumor board), with CT imaging follow-up both before and after initiation of immunotherapy, and follow-up of at least one year after initiation of immunotherapy. Patients were excluded if they met any of the following criteria: history of bone fragility disorders or osteoporotic fractures, spinal surgery, vertebral metastases. BMD was measured at baseline (T0), 1 year (T1) and 2 years (T2) at the L1 vertebrae. Changes in CT-based BMD over time were analyzed using paired Student's t-tests, and risk factors for BMD changes were analyzed using linear regression models.

Results: 165 patients (mean age: 65 years; 44.2% women) were included. BMD decreased significantly over 2 years (mean difference: 14.02 HU, 95% CI 10.31-17.74, $p < 0.001$), with bone loss rates of 5.15% and 11.91% at 1 and 2 years, respectively.

Male gender (β 8.87; [95%CI 3.62 to 14.11]; p=0.001) and younger age (β -0.34; [95%CI -0.5 to -0.09]; p=0.005) were associated with greater BMD loss at 1 year.

Compared with patients in complete remission, those with disease progression (β 8.25 [95% CI 2.27 to 19.75]; p=0.002) or partial response (β 8.25 [95% CI 2.98 to 13.53]; p=0.002) experienced a greater decrease in BMD at 2 years.

Conclusion: ICIs are associated with significant BMD loss, particularly in men. These findings underscore the importance of osteoporosis prevention and routine BMD monitoring during ICI therapy

Abstract Number: 0356

An Analysis of Osteoporosis Screening in Males 50 and Older with Rheumatic Disease Across Stony Brook Medicine Network

Stephen Poos[1], Hoang Nguyen[2], Samuel Greenberg[3], Marcus Lee[2], Heidi Roppelt[1] and Asha Patnaik[2], [1]Stony Brook Southampton Hospital, Southampton, NY, [2]Stony Brook University Hospital, Stony Brook, NY, [3]Renaissance School of Medicine at Stony Brook University, Stony Brook, NY

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0337–0356) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Osteoporosis is under screened in men. The United States Preventive Services Task Force (USPSTF) does not publish guidelines for osteoporosis screening in men. Other professional societies only recommend screening when certain risk factors are present. The Fracture Risk Assessment Tool cites risk factors including rheumatoid arthritis (RA), smoking, alcohol use, glucocorticoid use, and family history of hip fracture. In addition to RA, literature evidence links low bone mineral density to autoimmune connective tissue disease (CTD) and seronegative spondyloarthropathy (SpA) [1]. Our study assesses provider recognition of rheumatic disease as a risk for osteoporosis by examining the prevalence of dual-energy X-ray absorptiometry (DXA) screening in men with rheumatic disease. We hypothesized that osteoporosis is under screened among men with rheumatic diseases.

Methods: We conducted a retrospective cohort study using electronic health record data from the Stony Brook system from 1/1/2000 to 12/15/2024. We identified 38,970 men with current age 50 and older with ICD-10 codes mapped to RA, SpA, osteoarthritis (OA), polymyalgia rheumatica (PMR), crystal arthropathy (CA), vasculitis, and CTD. Osteoporosis screening was defined as at least one CPT code corresponding to a DXA scan after initial documentation of a disease or risk factor. We performed bivariate logistic regression to assess the unadjusted association between DXA screening and disease groups, smoking, family history of osteoporosis, alcohol abuse/dependence, long-term systemic steroid use, and demographics. Variables meeting a relaxed Wald $p \leq 0.2$ were included in a multivariate logistic regression model to identify independent predictors of screening.

Results: The percentage of patients with DXA was low in all disease cohorts, with an average screening rate of 4.05%. The highest rates were seen in PMR (8.33%) and RA (5.10%) and the lowest in CA (1.59%). The yield of osteoporosis among those screened ranged from 20.95% (CTD) to 41.91% (SpA) with the average yield being 31.51% (Figure 1). Increasing age, long-term steroid use, RA, PMR, SpA, and CTD were all significantly associated with DXA screening (Figure 2).

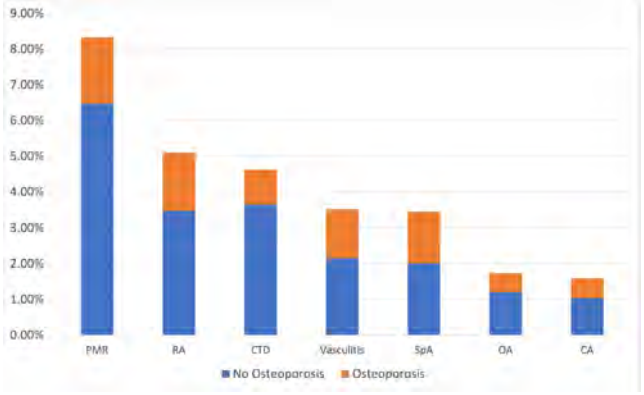

Figure 1. Total percentage of screened patients within each disease cohort, along with the percentage of those patients found to have osteoporosis.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

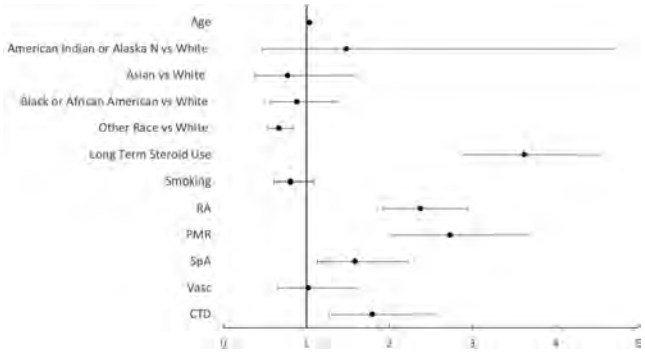

Figure 2.Variables meeting a relaxed Wald p ≤ 0.2 in bivariate logistic regression with the outcome of DXA screening were included in a multivariate logistic regression model. The resulting odds ratios and confidence intervals are displayed in this forest plot.

Conclusion: Providers screened patients with autoimmune diseases in greater percentages than patients with OA or CA, and autoimmune diseases except vasculitis were significantly associated with DXA screening. Long-term steroid use was the only significant non-disease predictor of DXA screening. One limitation is the undefined duration of "long-term" use in the associated ICD-10 code, though chronicity is implied. Family history of osteoporosis was excluded; its wide confidence interval (OR 7.6, 95% CI 1.7–33.3) reflects low documentation, likely during DXA referrals, limiting its reliability as an independent predictor. Despite low screening rates, the yield of osteoporosis among screened patients was substantial. With growing recognition of autoimmunity as an osteoporosis risk factor, we are optimistic that more patients will receive timely diagnosis and treatment.

Content validation of patient-reported outcome (PRO) measures for fatigue, physical function and disease activity in Polymyositis (PM)

Jason Xenakis[1], **Esther Yi**[1], Iyar Mazar[2], Sarah Knight[3], Harriet Makin[3], Samantha Wratten[3], Rohit Aggarwal[4] and Stephanie McKee[3], [1]Pfizer Inc., New York, United States of America, New York, [2]Pfizer, US, New York, [3]Clarivate, London, United Kingdom, [4]University of Pittsburgh, Rheumatology and Clinical Immunology, Pittsburgh, United States of America, Pittsburgh, PA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0357–0386) Patient Outcomes, Preferences, & Attitudes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Polymyositis (PM) is a subtype of idiopathic inflammatory myopathy (IIM) characterized by muscle inflammation and muscle weakness. Extra muscular manifestations like interstitial lung disease (ILD), joint pain or skin rashes may also be experienced.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

This study aimed to evaluate the content validity of patient-reported outcome (PRO) measures used in PM (encompassing ASyS, OM, Others, IMNM), i.e., whether the content of these measures 1) captures symptoms or impacts that are important to adults with PM and 2) is comprehensible to respondents.

Methods: Adult (≥18 years) patients in the US with a clinical diagnosis of PM were recruited by a clinical site to take part in individual, semi-structured, 90-minute online interviews conducted from September 2023 to June 2024. Osteoarthritis, fibromyalgia, neurological disorders, cardiac conditions, and lung conditions unrelated to IIM were excluded. The IRB-

Table 1. Overeview of findings from cognitive debriefing interviews

PRO (n participants who debriefed the measure) and response options	Instruction and item understanding	Relevance	Recall	Meaningful change
HAQ-DI (n=33) Participants selected from four options for each item ranging from 'Without ANY difficulty' (0) to 'UNABLE to do' (3). The highest score applied to each category (dressing and grooming, arising, eating, walking, hygiene, reach, grip, and common daily activities) represents the overall score for that category, with higher scores representing greater difficulty. One item assessing pain in the past week uses a 15cm VAS anchored with 'no pain' (0) to 'very severe pain' (100). Most participants were able to use the response options appropriately.	All participants interpreted the instructions and most items (23/25 items) correctly.	Most items were relevant to more than half of participants.	Most participants correctly understood the recall period.	Meaningful change was explored at the item-level. An item-level improvement of 1- or 2-points was considered meaningful to nearly all participants.
FACIT-Fatigue (n=26) Participants selected from five response options for each item ranging from 'Not at all' (0) to 'Very much' (4). Items form two domain scores or a total score ranging from 0 to 52. The Experience domain includes five items ranging in total scores from 0 to 20. The Impact domain includes the remaining eight items with scores ranging from 0 to 32, with higher scores representing greater fatigue. Most participants were able to use the response options appropriately.	All participants interpreted the instructions and most items (8/13 items) correctly.	Almost all items were relevant to more than half of participants.	Most participants correctly understood the recall period.	Meaningful change was explored at the item-level. An item-level improvement of 2-points was considered meaningful to most participants.
PGA-VAS/NRS (VAS n=26, NRS n=27)† Participants selected a response on the 10cm VAS measure by marking on a line anchored at either end by 'No evidence of disease activity' to 'Extremely active or severe disease activity.' The NRS measure used the same anchors on a scale ranging from 0 to 10, with higher scores indicating more severe activity. All participants were able to use the VAS and NRS response options correctly.	All participants interpreted the VAS and NRS versions of the item correctly.	Items were relevant to all participants.	Most participants correctly understood the recall period.	A 2-point improvement and 1-point worsening on the NRS were considered meaningful.
PROMIS-PF (n=25) Participants selected from five response options for each item ranging from 'Without any difficulty' or 'Not at all' (5) to 'Unable to do' or 'Cannot do' (1). Higher scores indicate better physical function. Items assess function capability in the upper and lower extremities and central regions, and activities of daily living. Most participants were able to use the response options appropriately.	All participants interpreted the instructions and nearly all items (19/20 items) correctly.	Most items were relevant to more than half of participants.	A range of timeframes were reported (this measure does not specify a timeframe).	Meaningful change was explored at the item-level.An item-level 1- or 2-point improvement was considered meaningful
PGA-VRS (n=8) Participants selected from five response options ranging from 'None' (0) to 'Very severe' (4). Most participants were able to use the response options appropriately.	All participants interpreted the item correctly.	Item was relevant to all participants.	All participants correctly understood the recall period.	A 1-point improvement or worsening was considered meaningful.
PGIS-PA (n=8) Participants selected from five response options ranging from 'None' (0) to 'Very severe' (4). All participants were able to use the response options appropriately.	All participants interpreted the item correctly.	Item was relevant to all participants.	All participants correctly understood the recall period.	A 1-point improvement or worsening was considered meaningful.
PGIC-PA (n=8)‡ Participants selected from five response options ranging from 'Much better' to 'Much worse.' All participants understood the response options.	All participants interpreted the item correctly.	*N/A*	All participants correctly understood the recall period.	Most participants indicated that improving to 'Much better' would be meaningful after taking a new medication.

Abbreviations: ASyS, Anti-synthetase syndrome; FACIT-Fatigue, Functional Assessment of Chronic Illness Therapy-Fatigue; IMNM, Immune Mediated Necrotizing Myopathy; OM, Overlap myositis; PGA-VRS, Patient Global Activity assessment-Verbal Rating Scale; PGIC-PA, Patient Global Impression of Change – Physical Activity; PGIS-PA, Patient Global Impression of Symptoms-Physical Activity; PROMIS-PF, Patient-Reported Outcome Measurement Information System-Physical Function.
†Exploration of meaningful change was completed using the participant's NRS response.
‡Participants were asked to imagine they were taking part in a clinical trial of a new treatment while completing the patient global impression of change items.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

approved interview guide included open-ended questions to explore the content validity (i.e., relevance, comprehensiveness, and comprehensibility) of 8 PRO measures which assess physical functioning, fatigue and disease activity (Table 1). Participants were also asked about their perceptions of meaningful changes in scores. Purposive sampling with recruitment targets were used to recruit a diverse sample in terms of age, sex, race, ethnicity, and education level. Interviews were audio-recorded, transcribed, anonymized and analyzed using qualitative framework analysis in Atlas.ti v9.

Results: Participants were mostly female (n=21/34, 62%) and/or white (n=30/34, 88%) with a mean age of 58 years (range 32 – 77 years). Most participants had a graduate/postgraduate (n=14/34, 41%) or bachelor's degree (n=10/34, 29%). Due to time constraints, not all measures were debriefed by all participants.

An overview of findings is presented in Table 1. The instructions and item wording were interpreted as intended by the majority of participants for all PRO measures debriefed. The measures were conceptually relevant to the majority of the sample. Most participants interpreted the recall periods correctly. The response options/scales were correctly interpreted by participants. Participant feedback indicated that none of the suggested changes were critical for understanding.

Meaningful change was assessed at the item level for multi-item PRO measures. For the HAQ-DI and the PROMIS-PF items, participants considered an improvement of 1- or 2-points as meaningful. A 2-point improvement on FACIT-Fatigue item(s) was considered meaningful to most participants.

A 2-point improvement on the single-item PGA-NRS and PGIC-PA, or 1-point worsening on the PGA-NRS was considered by most participants to be meaningful. A 1-point improvement or worsening on the PGA-VRS and PGIS-PA was considered meaningful.

Conclusion: All 8 PRO measures demonstrated content validity for use in research with adults with PM. For multi-item and single-item PROs, a 1- to 2-point item-level change was considered meaningful, demonstrating the value of small improvements for individuals with this debilitating condition. These insights are valuable for interpreting quantitative within-patient changes when evaluating treatments for PM.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0357–0386) Patient Outcomes, Preferences, & Attitudes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Despite therapeutic advances, major concerns and disparities persist in the care of Still's Disease (SD). Capturing both patient/caregiver and physician perspectives is essential to optimize patient-centered care. This real-life study aims to assess and compare the perspective of both groups regarding treatment goals, challenges, and unmet needs related to the treatment of SD.

Methods: As part of the METAPHOR project, a PReS/PRINTO initiative to optimize SD and Macrophage Activation Syndrome (MAS) management, 2 surveys, 1 addressed to physicians and 1 to patients/caregivers, were developed by a core team, involving physicians and patients representatives. The physician survey was forwarded through the PReS/PRINTO network, while the patient survey via the Systemic JIA Foundation to all their members. Responses were analyzed using chi-square tests to assess group differences.

Results: 197 physicians and 139 patients/caregivers participated. Most patient respondents were parents or legal guardians (94%), primarily from the United States (64%) and Europe (19%). Physicians were mainly pediatric rheumatologists (90%), from 56 countries worldwide.

Regarding treatment goals, both groups prioritized complete symptom control (84% vs 79%, p=0.28) and achieving a quality of life similar to peers (63% vs 73%, p=0.44). However, patients considered pain control a key objective more often than physicians (43% vs 13%, p< 0.001), whereas physicians placed greater emphasis on glucocorticoid reduction (79% vs 54%, p< 0.001).

In terms of glucocorticoid-related concerns, mood changes were predominantly reported by patients (65% vs 14%, p< 0.001), whereas physicians were more concerned about osteoporosis (66% vs 32%, p< 0.001), glucose intolerance (52% vs 27%, p< 0.001), and hypertension (51% vs 37%, p=0.02). Both groups highlighted growth delay and infection risk as shared concerns.

Regarding fears at treatment initiation, both groups were concerned about treatment failure (82% patients vs 66% physicians, p=0.001) and adverse events (77% vs 72%, p=0.27). However, physicians were more worried about treatment duration (57% vs 21%, p< 0.001), while patients emphasized infection risk (52% vs 27%, p< 0.001) and lack of clear information about the treatment (34% vs 23%, p=0.03).

As for future challenges, both groups stressed the need to reduce the burden of glucocorticoid use (68% patients vs 59% physicians, p=0.10). Physicians more frequently cited the inability to prevent MAS (52% vs 40%, p=0.03), while patients highlighted limited physician expertise (57% vs 15%, p< 0.001) and lack of access to psychological support (33% vs 10%, p< 0.001) as major unmet needs.

Conclusion: Besides shared perspectives, patients and physicians show relevant differences in prioritizing treatment outcomes and concerns in SD. Including patient priorities early in the disease course is essential to advancing truly patient-centered care.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0357–0386) Patient Outcomes, Preferences, & Attitudes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Shared decision-making (SDM) is the first overarching principle of the treat-to-target guidelines for rheumatoid arthritis (RA). The quality of SDM varies widely, and its adoption in practice remains limited. To address this gap, a decision aid tool for RA "RA Choice" was introduced as part of a multicomponent intervention (e.g., clinician communication training, medication summary guide, patient activation brochure) in a stepped-wedge, randomized controlled trial (RCT; NCT05530694) across multiple rheumatology clinics within the Veterans Health Administration (VHA). Prior to the launch of the intervention, during the usual care phases of the trial across multiple sites, we aimed to explore clinician attitudes and beliefs regarding SDM and the use of RA Choice.

Methods: Between June 2023 and October 2024, we conducted semi-structured interviews with clinicians prior to the implementation of the multicomponent intervention which included RA Choice. The Consolidated Framework for Implementation Research (CFIR) provided a framework for interview question development. Recorded Interviews were transcribed verbatim and analyzed using a hybrid deductive/inductive qualitative content approach, guided by iterative Rapid Research Evaluation and Appraisal Lab (RREAL) sheets. The results were then organized using the CFIR.

Results: 16 semi-structured interviews were conducted with VHA rheumatologists (n=14) and nurse practitioners (n=2) across three intervention sites: Philadelphia (n=6), Portland (n=5), and San Francisco (n=5). Many clinicians were familiar with the concept of SDM and perceived it as beneficial to patient well-being. Participants stated that an ideal RA-focused decision aid should help patients describe their symptoms, including pain levels and mobility difficulties, support clinicians in explaining medical concepts, enhance the efficiency of SDM, and be accessible in a paper format.

Participants also identified factors that would affect successful implementation of an RA-focused decision aid. These factors aligned with CFIR domains, including: Outer Setting issues like bureaucratic hurdles and national vs. clinic-level implementation, Inner Setting elements such as the VHA's culture of innovation, and Intervention Characteristics like the tool's simplicity for Veteran comprehension. They also emphasized Characteristics of the Individual, including clinician buy-in, patients' willingness to engage in decision-making, and clinicians' perceived value of the tool.

Conclusion: In this qualitative study, we identified patient, clinician, and institutional factors that may influence the use of the RA Choice decision aid during the pre-intervention phase of a multi-site, stepped-wedge RCT. This pre-intervention qualitative data identified clinician buy-in to the general usefulness of SDM as a concept and a cautious optimism around leveraging a tool to improve SDM, however this was tempered by perceptions of challenges encountered by large system bureaucracy

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1: Factors with exemplary quotes corresponding to the CFIR

CFIR Constructs	Factors	Quotes
Outer setting	Bureaucratic hurdles	*"They have elevated these goals of safety and quality... that have helped them overcome the bureaucratic barriers to implementing new health IT systems like that... so I think that it's a very slow-moving ship, but you can steer it." (9)*
	Nationwide vs. clinic implementation	*"...In our little microsystem of our rheumatology clinic and division I think there have actually been quite a few small changes that have been affected. I think changing the whole VA, that's another story." (7)*
Inner setting	VHA culture of innovation	*"I think there's a common bond behind education and wanting to provide a good learning environment... also a culture of life-long learning where we're open to new ideas and new things." (4)*
Intervention characteristics	Simplicity in the RA decision aid for Veteran comprehension	*"...it would be overwhelming to have a single tool that would communicate all of the potential options and facilitate that shared decision-making conversation in some... I think a decision tool is best if it has a concise focus on what it's trying to support in the communication." (9)*
Characteristics of the individual	Clinician buy in (to SDM and/or RA Choice)	*"...The buy-in that you get from every person within the department is also very variable. There's some people that are very, very entrenched in their ways and have no interest in changing the way that they've done practice for the last 15, 20, 30 years. Others have more stakes in it and are more willing to change..." (16)*
	Perceived patient desire to participate in SDM	*"There are Veterans who really want to know everything and make a choice, and others who say, 'You're the doctor- just tell me what to do.'" (10)*
	Clinician's perceived value of the tool	"In theory, this tool could help patients make better choices and improve adherence, but if *it's too wordy or overwhelming, it could do more harm than good." (7)*

and patient-level factors of limited literacy or low levels of engagement. Future research will focus on impacts of the intervention on Veterans' experience of SDM.

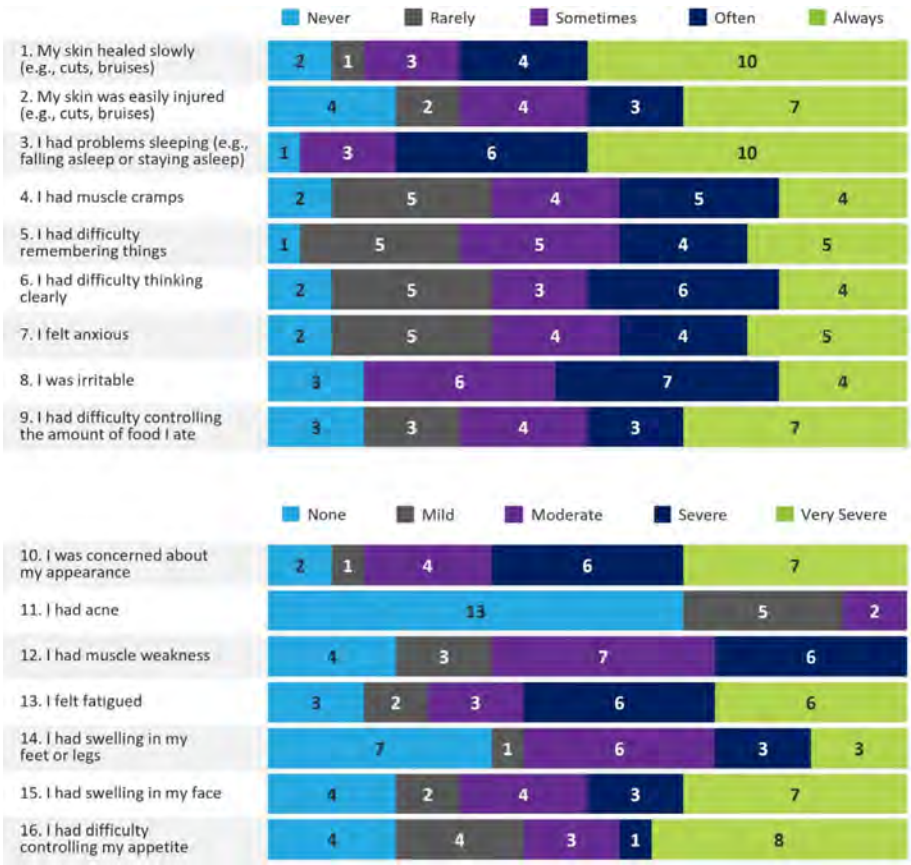
Background/Purpose: While glucocorticoids (GCs) are commonly used to treat a range of inflammatory diseases, the burden of toxicities associated with these medications is significant. The Glucocorticoid Toxicity Index is a clinician-reported outcome measure that quantifies change in steroid toxicity over time. A robust complementary patient-reported outcome measure (PRO) is needed to capture the patient perspective of steroid treatment. The purpose of this study was to develop and assess the content validity of a PRO, the Patient Reported Outcome of Steroid Experience (PRO-SE), to evaluate GC toxicity. The PRO-SE was developed following established PRO guidance.

Methods: The draft PRO-SE was developed from a pool of concepts derived from one-on-one virtual patient interviews. Individual hybrid concept elicitation/cognitive interviews were conducted with patients with a range of conditions for which GCs are prescribed. Patients were recruited through patient advocacy organizations and interviewed via telephone or video conference. During the concept elicitation portion of the interview, participants shared symptoms associated with their illness as well as toxicities associated with GC medication. Participants then completed the PRO-SE and provided feedback on their comprehension of the instrument as well as the clarity and relevance of the items.

Results: Interviews were completed with 20 participants (n=3 IgG4-related disease; n=4 vasculitis; n=1 bullous pemphigoid; n=3 systemic lupus erythematosus; n=3 chronic inflammatory demyelinating polyradiculoneuropathy; n=6 myasthenia gravis). Toxicities commonly experienced by participants included difficulty sleeping/insomnia (n=10, 50%), swelling in the face ("moon face"; n=8, 40%), weight gain (n=7, 35%), difficulty with skin healing, increased appetite, and mood swings (all n=5, 25%). Participant responses to the PRO-SE are shown in Figure 1. When asked to assess the measure, all participants (n=20, 100%) provided positive feedback, describing it as "good," "comprehensive," "easy," "simple," or "clear." Participants also demonstrated understanding of the instructions, 7-day recall period, and response options (n=20, 100%). There were no major item comprehension issues, with 95-100% of the participants clearly demonstrating



Participant Responses to the PRO-SE

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

understanding of each of the 16 items. Participants stated that the most important items were fatigue (n=16, 80%), sleep problems (n=15, 75%), facial swelling, and difficulty controlling appetite (both n=11, 55%; not mutually exclusive).

Conclusion: The PRO-SE demonstrated good content validity in this population. Participants found the PRO-SE comprehensive, easy to complete and relevant to their experience with GC toxicity. Further research should be conducted to assess psychometric validity and determine a scoring algorithm for this new instrument. The PRO-SE is a potentially useful tool for assessing patients' experience of GC toxicity in clinical practice and may serve as either a stand-alone instrument or as a complement to clinician ratings of steroid toxicity, for example, the Glucocorticoid Toxicity Index.

Transition in Focus: Health Care Utilization and Disease Status in Youth with Connective Tissue Diseases— A Single-Center Experience in British Columbia, Canada

Mercedes Chan[1], Lori Tucker[1], **Jude AlMasoud**[1], Jaime Guzman[2], Andrea Human[1], David Cabral[3], Angela How[4], Wendy Wong[5] and Jennifer Corpuz[6], [1]BC Children's Hospital, Vancouver, BC, Canada, [2]University of British Columbia and BC Children's Hospital, Vancouver, BC, Canada, [3]BC Children's Hospital and University of British Columbia, Vancouver, BC, Canada, [4]UBC, Vancouver, BC, Canada, [5]University of British Columbia, Surrey, BC, Canada, [6]UBC, New Westminster, BC, Canada

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0357–0386) Patient Outcomes, Preferences, & Attitudes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Graduating from child and family-oriented to adult-oriented health care is a vulnerable time when youth with chronic disease drop out of, or disengage from, the healthcare system. For young adults with connective tissue diseases (CTD) in Vancouver, we developed a 3-phase "transition program" beginning in the multidisciplinary pediatric clinic; at end of high school patients transfer to a Young Adult Rheumatic Disease (YARD) clinic – a pediatric-adult hybrid-care transition clinic with no parental involvement; in 3-4 years they then transfer to adult care. This study describes healthcare use and disease outcomes of youth with CTD during the early phase of their transition through to the YARD clinic.

Methods: We conducted a retrospective chart review of patients who transitioned from pediatric care to the YARD clinic between 2013 and 2023. Comparative statistics were used to assess demographics, disease activity, and healthcare utilization (FU = follow-up visits, ED = emergency department, HA = hospital admission) one year pre- and post-transition. For study purposes, the first "transition" time point equates to the first YARD clinic visit.

Results: 42 patients were included (85.7% female) with systemic lupus erythematosus (SLE) (28/42), 66.7% juvenile dermatomyositis (14.3% linear scleroderma, 4.8% mixed connective tissue disease, and one patient each with cutaneous lupus, undifferentiated connective tissue disease, primary Sjogren's, and systemic sclerosis. Mean transition age: 18 years (17.9-18).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1: Disease Activity, and Healthcare Utilization Across Transition Intervals

	12-month period prior to transition	Time from last pediatric visit to 1st YARD visit (Median 4 / (IQR 3-5.5)	12-month period post transition
Number of patients	42	40	30
Visits attended Median (IQR)	4 (3-4.25)	NA	3 (2-4)
Visits missed Median (IQR)	0 (0-1)	0 (0)	0 (0-0.5)
SLEDAI (N=28) Median (IQR)*	4 (0-6)	2 (0-4)	2 (0-4)
PGA (Mean)*	1.14	0.75	0.57
ED visits %:	26.2%	7.5%	27.5%
Disease activity	41.67%	0%	33.33%
Non-rheumatological (mental health or trauma)	41.67%	66.7%	66.67%
Infection	16.66%	33.3%	0%
Admissions %:	11.9%	2.5%	7.7%
Disease activity	60%		66.7%
Non-rheumatological (Mental health, trauma, or surgery)	40%	100%	33.3%

*Scores for SLEDAI and PGA correspond to the clinical evaluations at the 12-month pre-transition, transition, and post-transition time points.

Patients attended an average of 4.19 FU visits pre-transition and 2.90 post-transition. The mean of missed rheumatology visits was 0.38 pre- and 0.41 post-transition (Table 1).

For SLE patients, the median SLE Disease Activity Index (SLEDAI) scores were 4 pre- and 2 post-transition. Physician Global Assessment (PGA) scores were 1.14 pre- and 0.57 post-transition for all patients.

Table 2: Physician Global Assessment at the 12-month pre-transition, transition, and post-transition time points

PGA (Scale 0-10)	12 Months Prior To transition (n=42)	Time from last pediatric visit to 1st YARD visit (n=40)	12 months post transition (n=30)
0	45.2%	57.5	70.3%
1-3	50%	40%	29.7%
≥ 4	4.8%	2.5%	0%

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. ED visits occurred in 26.2% and 27.5% of patients pre- and post-transition, respectively, with 41.67% and 33.3% due to disease flare (Table 1). HA occurred in 11.9% and 7.7% pre- and post-transition, respectively, with 60% and 66.7% due to disease activity. There was no significant difference in ED or HA in the 12 months pre- vs. post-transition (p = 1.33 and 0.518).

The YARD clinic received 40/42 (95.2%) patient referrals sent to the clinic. Post-transition, 30 patients remained in follow-up, 7 relocated or were transferred to a local physician, and 3 failed to show up despite repeated appointments.

Conclusion: In this cohort, initial transition from pediatric care to the YARD clinic was associated with stable ED use and HA rates. These findings suggest that our structured transition process is initially effective with minimal loss to follow-up and stable clinical outcomes. Our results highlight the need to evaluate the longer-term success of the YARD transition and subsequently after transfer to adult care.

Drug Persistence of IL-17A Inhibitors Among Patients with PsA: Real-World Data from the CorEvitas PsA/SpA Registry

Philip J. Mease[1], Nicole Middaugh[2], Maya Marchese[3], Skyler Peterson[3], Burcu Ertugrul Vardar[4], Russel Burge[5], **Natalia Bello**[6], Marcus Ngantcha[7], Joseph F Merola[8], Louis Bessette[9] and Alexis Ogdie[10], [1]Department of Rheumatology, Providence-Swedish Medical Center and University of Washington, Seattle, WA, [2]CorEvitas, LLC, Waltham, MA, [3]CorEvitas, LLC, Waltham, [4]Eli Lilly Cork GBS Ltd, Dublin, Dublin, Ireland, [5]Eli Lilly and Company, Indianapolis, [6]Eli Lilly, Indianapolis, IN, [7]Eli Lilly GBS Cork Ltd, Cork, Ireland, [8]Department of Dermatology and Department of Medicine, UT Southwestern Medical Center, Dallas, TX, [9]Centre de l'Osteoporose et de Rhumatologie de Quebec, Quebec, QC, Canada, [10]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0357–0386) Patient Outcomes, Preferences, & Attitudes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: IL-17A inhibitors (IL-17Ai) are considered recommended biologic therapies for PsA per current treatment guidelines[1,2]. Real-world evidence (RWE) studies on IL-17Ai drug persistence among patients with PsA are limited[3]. RWE data on long-term use of biologics can support more informed treatment strategies and improve patient outcomes[4]. Here, we analyse RWE data to assess the persistence of IL-17Ai therapy in patients with PsA.

Methods: This observational study included adult patients with a diagnosis of PsA enrolled in the CorEvitas PsA/SpA Registry. Primary and sensitivity analyses were conducted among IL-17Ai initiators, defined as patients who initiated ixekizumab or secukinumab as first use within the IL-17Ai mechanism of action (MOA) and had at least 1 follow-up registry visit. The primary outcome was drug persistence defined as time from treatment initiation of a specific MOA to discontinuation (DC) of that MOA. For sensitivity analysis, persistence was redefined as continuous use of initiated therapy without DC, with cycling to another IL-17Ai therapy considered as DC. Each outcome was censored at the last available study visit or 12 months (M12), whichever occurred first. Drug persistence at M12, with corresponding 95% confidence intervals (CI), was estimated using the Kaplan-Meier method. Unadjusted Cox proportional hazards models were used to estimate hazard ratios (HR) and corresponding 95% CI between patient characteristics and DC.

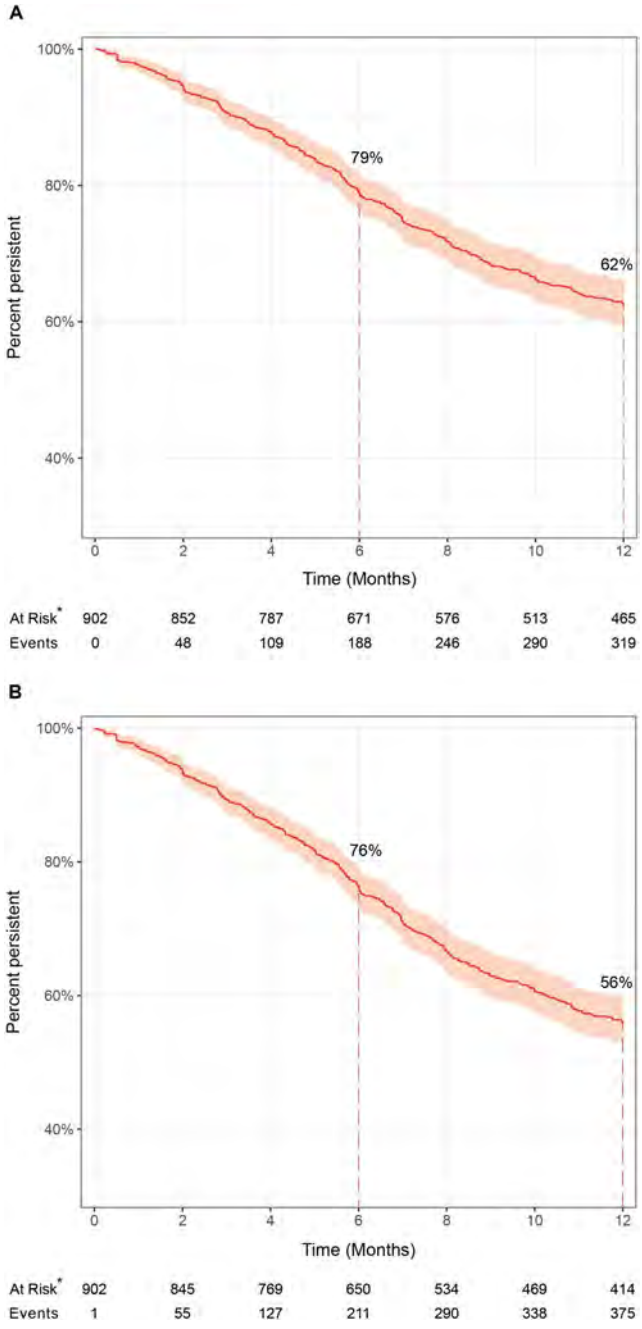

Figure 1: Kaplan-Meier plots of drug persistence among IL-17Ai initiators for the (A) primary analysis and (B) sensitivity analysis *This does not represent the outcome of interest, rather the number of patients remaining at risk for the outcome at each timepoint. The pink shaded area represents the 95% confidence interval.

Results: A total of 902 patients with PsA initiated a first IL-17Ai. Demographic, disease and treatment characteristics at index are presented in **Table 1**. Secukinumab was initiated by the majority (74.9%) of the IL-17Ai cohort, with ixekizumab accounting for 25.1%. **(Table 1)**. For the primary outcome, proportion persistent with a specific MOA at M12 was estimated to be 62.4% (95% CI: 59.2, 65.8) **(Figure 1)**. Median persistence was not reached at M12. Persistence was numerically lower in the sensitivity analysis (55.7% [95% CI: 52.4, 59.2]). Unadjusted univariate analysis showed that numerically some factors including female sex, history of fibromyalgia, depression, current smoker, >2 comorbidities, axial involvement among others had an increased risk of IL-17Ai DC (HR >1) **(Table 2)**, with similar results in the sensitivity analysis.

APR: Apremilast, BMI: Body Mass Index, BSA: Body Surface Area, cDAPSA: Clinical Disease Activity Index for Psoriatic Arthritis, csDMARDs: Conventional Synthetic Disease-Modifying Antirheumatic Drug, PhGA: Physician Global Assessment, PtGA: Patient Global Assessment, SD: Standard Deviation, VAS: Visual Analog Scale.

[a]The index visit corresponds to the registry visit where baseline variables associated with initiation of IL-17Ai are ascertained.
[b]Based on the CDC cut-offs for normal/underweight (under 25); Overweight (25.0 – 30); and Obese (30.0 and above).
[c]Comorbidities include history of cardiovascular disease, malignancies, depression, anxiety, fibromyalgia, hypertension, diabetes, uveitis, and inflammatory bowel disease
[d]csDMARDs include methotrexate, Plaquenil, Arava, Azulfidine.
[e]b/tsDMARDs include Cimzia, Humira, Remicade, Enbrel, Simponi, Taltz, Cosentyx, Skyrizi, Tremfya, Stelara, Orencia, Xeljanz, Rinvoq and biosimilars.
[f]WPI and FSS data collected as of May 1, 2020.

Conclusion: Findings from this observational study of patients with PsA demonstrate the persistence of IL-17Ai, as a class, in a real-world setting. Persistence estimates at M12 align with patient retention rates observed in clinical trials[5] and previous registry-based studies[6] for IL-17Ai cohorts. Numerous factors demonstrated a higher risk of decreased persistence, with CIs not suggesting statistical significance. This underscores the effect that disease burden in patients with PsA can have on treatment outcomes, affecting the persistence of treatments[7].

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0357–0386) Patient Outcomes, Preferences, & Attitudes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Care models that take a 'Whole Health' perspective by emphasizing personalized care focused on the individual's values, needs, and goals, rather than solely on medical conditions are sorely needed for patients with SLE. Enhancing self-care can significantly improve overall well-being but is often missing from SLE management. This study aims

Table 1. The Whole Health Self-Assessment completed by patients with SLE.

People find different components of their life make living with lupus a bit easier. We'd like to learn which of the following components are currently working for you. Rate yourself in each area.	
Movement and Exercise	0 = I have trouble moving my body or exercising 100 = I move my body or exercise regularly
Rest	0 = I have trouble sleeping and relaxing 100 = I sleep well
Nutrition	0 = I eat an unhealthy diet 100 = I eat a very healthy diet
Purpose and Meaning in Life	0 = I lack purpose & meaning in my life 100 = I have a clear sense of purpose
Personal and Professional Goals	0 = I am unable to pursue my personal and/or professional goals, 100 = I am very able to pursue my personal and/or professional goals
Stress	0 = I am frequently stressed, anxious, or depressed 100 = I manage my stress and emotions well
Relationships	0 = I do not have open, supportive relationships with the people in my life 100 = I have open, supportive relationships with the people in my life
Physical Environment	0 = My surroundings are unsafe, unstable, and/or stressful 100 = I have a safe, and comfortable home and workplace
Lupus Medications	0 = I don't take my lupus medications 100 =I always take my lupus medications
Trust in Healthcare	0 = I don't trust healthcare providers 100 = I always trust healthcare providers

Absent	<|0.1|

to identify the greatest self-care needs for individuals with SLE using a modified Whole Health Self-Assessment survey, focusing on differences by subgroups of Type 2 SLE activity (Intermittent and Persistent).

Methods: Patients with SLE enrolled in a lupus registry completed the Polysymptomatic Distress Score (PSD), FACIT Fatigue scale, PROMIS measures, and a modified Whole Health Self-Assessment, rating their health on a visual analog scale across 10 domains (Table 1). Participants also selected their three most important areas for self-care. Rheumatologists scored the SLEDAI and Type 1 & 2 physician's global assessments (PGA). Spearman's correlation coefficients measured the correlation of Whole Health domain scores with disease activity and PROMIS measures. Correlations were classified as strong (>0.5), moderate (0.3-0.5), weak (0.1-0.3), or absent (< 0.1).

High Type 1 SLE activity was defined as SLEDAI ≥6, clinical SLEDAI ≥4, Type 1 PGA ≥1, or active nephritis. High Type 2 SLE activity was defined as PSD ≥8 or Type 2 PGA ≥1. Among patients with ≥3 visits in the registry, Type 2 SLE patterns were classified as:

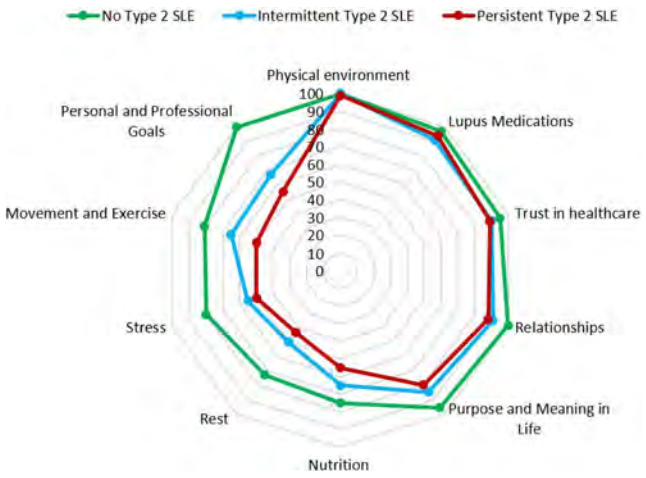

Figure 1. Differences in Median Whole Health Domain Scores by Type 2 SLE Pattern.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. - No Type 2 SLE
- Intermittent Type 2 SLE: Type 2 SLE activity at ≤2 visits and Type 1 SLE activity at ≥1 visit
- Persistent Type 2 SLE: Type 2 SLE activity at 3 visits and Type 1 SLE activity at < 3 visits, or Type 2 SLE activity at ≥2 visits and Type 1 SLE activity at 0 visits

Differences in median Whole Health Assessment scores across Type 2 pattern groups were compared using the Kruskal-Wallis test.

Results: We included 295 patients with SLE (mean age 44 years, 92% female, 60% Black, 33% White). Strong correlations were observed between Personal & Professional Goals with the SSS (r=-0.54) and FACIT Fatigue score (r=0.61; Table 2). Type 2 SLE activity measures were moderately correlated with Movement & Exercise, Rest, Purpose & Meaning in Life, Personal & Professional Goals, Stress, and Relationships. Weak correlations were found between Type 1 PGA and Purpose & Meaning in Life (r=-0.23) and Personal & Professional Goals (r=-0.23). Among 194 patients with ≥3 visits, patients with Persistent Type 2 SLE had worse scores across several Whole Health domains (Figure 1). When asked to indicate the areas of self-care most important to them, all groups selected "Rest" as the top domain (67-79%), followed by Movement & Exercise (42-51%), Nutrition (35-47%), and Purpose & Meaning in Life (39-40%).

Conclusion: Significant correlations were observed between Whole Health domains and Type 2 SLE activity measures, with scores decreasing as Type 2 SLE activity worsened. These findings helped support our development of a curriculum for a 'Whole Health' program aimed at improving self-care and quality of life for patients with SLE through education, peer support, and goal setting outside of the clinical setting. Incorporating these insights into routine care can help address what matters most to patients.

Scale: 1 Extremely Unlikely – 7 Extremely Likely. SD = Standard Deviation.

patients across all demographic groups may face medical mistrust or logistical barriers that affect trial participation. Prior research using the Thompson et al. (2004) Group-Based Medical Mistrust Scale (GBMMS) has linked higher mistrust to reduced engagement in preventive care, but its impact on rheumatology trial enrollment has not been studied. This study therefore examines whether GBMMS scores predict adult patients' willingness to enroll in a rheumatology clinical trial and, among those who decline, identifies the logistical concerns that most strongly influence their decision.

Methods: Between November 2024 and February 2025, we conducted a cross-sectional survey in a rheumatology clinic. After informed consent, adults (≥18 years) with physician-confirmed rheumatoid arthritis (2010 ACR/EULAR), systemic lupus erythematosus (2012 SLICC), or other rheumatic conditions completed the 12-item GBMMS (score range 12–60, higher score = more mistrust), 11 logistical-concern items, each rated 1 ("extremely unlikely to influence me") to 7 ("extremely likely"); and a yes/no question on willingness to participate in a clinical trial. We evaluated GBMMS reliability (Cronbach's α), compared mean mistrust by willingness status using Welch's t test, and ran a univariable logistic regression to assess whether mistrust predicted trial willingness. Among those unwilling, we ranked logistical factors by mean importance and calculated Pearson correlations between GBMMS total and each logistical rating (two-tailed $\alpha = 0.05$).

Results: Forty-seven patients (79 % women, mean age = 49.23 ± 13.63 years) participated; 66 % reported they would enroll in a clinical trial (Table 1). Internal consistency of the GBMMS was $\alpha = 0.90$. Mean mistrust scores did not differ among the groups (willing 24.74 ± 11.62 and unwilling 25.25 ± 13.36; Welch's $t(26) = 0.13$, $p = 0.893$) (Table 2) and did not predict willingness in the logistic regression model (OR = 0.996, 95 % CI 0.95 – 1.05, $p = 0.89$). Among the 16 unwilling to participate in clinical trials, the top-rated logistical factors were: stopping disease progression (mean = 5.38), doctor encouragement (4.56), travel/transportation (4.13) and shared language with doctor (4.13) (Table 3). Across the full sample, mistrust correlated most strongly (though non-significantly) with lower importance on a novel treatment option ($r = -0.28$; $p = 0.056$) and doctor encouragement ($r = -0.23$; $p = 0.11$).

Conclusion: Group-based medical mistrust did not predict patients' self-reported willingness to join a clinical trial. Instead, expectation of concrete disease improvement and personal endorsement by one's treating rheumatologist emerged as the strongest drivers of participation. These findings suggest that recruitment efforts focused on highlighting clear clinical benefits and enlisting rheumatologists to personally invite patients may outperform strategies aimed solely at reducing mistrust.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0357–0386) Patient Outcomes, Preferences, & Attitudes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: While UCTD is considered less clinically severe than SLE, our prior qualitative study reported that patients with UCTD experience significant psychosocial challenges (*J Clin Rheumatol* 2022). Here, we describe a large UCTD cohort and quantify psychosocial challenges in comparison to SLE.

Methods: This retrospective cohort study included patients aged ≥18 years enrolled in a UCTD or SLE academic hospital-based registry, January 2022-March 2025. Participants in the UCTD registry had a positive ANA, ≥1 sign/symptom of a CTD, and did not meet ACR/EULAR-endorsed classification criteria for SLE, RA, SSc, SS, Idiopathic Inflammatory Myopathy, or 2006 Revised Sapporo Criteria for APS. Participants in the SLE registry fulfilled 1997 ACR or 2019 ACR/EULAR SLE Classification Criteria. We administered the 36-Item Short Form Health Survey (SF-36) to assess health-related quality of life (HRQoL), Fatigue Severity Scale (FSS), General Anxiety Disorder-7 (GAD-7), and Beck Depression Inventory (BDI). We compared demographic and clinical variables and psychosocial questionnaire scores between patients with UCTD and SLE, and performed multivariable regression to evaluate the association between diagnosis and each psychosocial outcome, adjusting for demographic and treatment variables.

Results: Compared to individuals with SLE (N=225), those with UCTD (n=114) were older (median [IQR] age 43.1 [32.1, 53.7] vs. 38.0 [29.8, 50.3], p=0.03), more frequently White race (70.2% vs. 40.0% p< 0.01), and less frequently Hispanic/Latino ethnicity (16.4% vs. 28.9%, p=0.02). Overall, patients with UCTD had fewer CTD manifestations. The most frequent clinical and serologic manifestations in UCTD, as compared to SLE, included: Raynaud's (46.5% vs. 46.2%, p=1.00), arthritis (27.2% vs. 76.0%, p< 0.01), and lymphopenia (19.3% vs. 48.0%, p< 0.01). Patients with UCTD versus SLE were less frequently prescribed antimalarials (54.4% vs. 82.2%, p< 0.01) and immunosuppressive medications (9.6% vs. 52.4%, p< 0.01) [**Table 1**]. Compared to patients with SLE, those with UCTD had better SF-36-defined physical functioning (median [IQR] score 80.0 [60.0, 95.0] vs. 75.0 [50.0, 90.0], p< 0.05); other measures of HRQoL, fatigue, anxiety, and depression did not differ [**Table 2**].

After multivariable adjustment, no association was demonstrated for diagnosis (UCTD vs. SLE) and HRQoL (based on SF-36 physical and mental component summary scores), FSS-defined fatigue severity, GAD-7-defined anxiety, or BDI-defined depression. In the overall group, female sex and non-Hispanic/Latino ethnicity were associated with worse SF-36 mental component summary scores. Female sex was associated with worse fatigue severity, and Hispanic/Latino ethnicity with increased odds of anxiety. Lastly, immunosuppressive treatment was associated with increased odds of depression [**Table 3**].

p<0.05 was statistically significant.
1. For continuous variables, we conducted generalized linear regression analysis.
2. For categorical variables, we conducted ordinal logistic regression analysis. GAD-7 categories were defined as: None [0-5], Mild [6-10], Moderate/Severe [11-21]; BDI categories were defined as: Minimal [0-13], Mild [14-19], Moderate/Severe [20-63].

Conclusion: Patients with UCTD have fewer disease manifestations, less frequently require immunomodulatory/immunosuppressive treatment, and report better physical function than SLE comparators. Nonetheless, UCTD patients experience a similar degree of impaired HRQoL, fatigue, anxiety, and depression, suggesting they may benefit from dedicated psychosocial support.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0357–0386) Patient Outcomes, Preferences, & Attitudes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background/Purpose: Oral health conditions are frequent in patients with rheumatic diseases and can impact daily function and quality of life. Factors such as chronic inflammation and immunosuppressive therapies may contribute to dental complications, including caries, xerostomia, and temporomandibular dysfunction. While clinical assessments are essential, patient-reported outcomes offer additional perspective on perceived oral health needs. Understanding the relationship between self-perceived oral health and clinical findings can enhance screening and support integrated management in rheumatology care.

Methods: We conducted a cross-sectional study including adult patients with rheumatic diseases, consecutively recruited from a tertiary care rheumatology clinic. Patients were categorized into good perceived oral health and poor perceived oral health groups according to General Oral Health Assessment Index (GOHAI) score-based thresholds. Clinical characteristics, comorbidities, and treatments were documented. Oral health status was evaluated using the GOHAI, International Caries Detection and Assessment System (ICDAS) caries assessment, salivary parameters (pH and flow rate), xerostomia, and

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

temporomandibular joint examination. All oral examinations were performed by a board-certified dentist trained in standardized assessment protocols. Behavioral data included dental visit frequency and toothbrushing habits. Statistical comparisons were performed using chi-square and Student's t-tests, with significance defined as $p < 0.05$.

Results: A total of 201 patients with rheumatic diseases were included, divided into poor perceived oral health (n=101) and good perceived oral health (n=100) groups. The mean age was 52.27 ± 14.17 and 53.97 ± 14.10 years, respectively, with a higher proportion of women in both groups (90.09% vs. 95.00%). Rheumatoid arthritis was the most prevalent diagnosis, additional demographic and clinical characteristics are displayed in **Table 1**. The poor perceived oral health group reported a greater desire for dental referral (84.15% vs. 72.00%; p=0.037, **Table 2**). The poor perceived oral health group showed lower scores in physical function (14.00 ± 2.49 vs. 17.85 ± 2.07; p< 0.001), psychosocial function (17.62 ± 2.63 vs. 21.91 ± 2.29; p< 0.001), and pain/discomfort (9.00 ± 2.25 vs. 13.21 ± 1.53; p< 0.001, **Table 3**).

Clinically, the poor perceived group had a lower percentage of caries-free teeth (39.99% vs. 48.57%; p< 0.001), and a higher prevalence of severe caries (3.81% vs. 1.96%; p< 0.001) and missing teeth (24.39% vs. 17.82%; p< 0.001), while initial and moderate caries stages showed no significant differences between groups. Salivary flow rate was higher in the good perceived group (0.40 ± 0.58 mL/min vs. 0.20 ± 0.28 mL/min; p=0.019).

Conclusion: Poor self-perceived oral health was associated with greater impairment in oral health–related quality of life, higher prevalence of severe caries and tooth loss, and increased demand for dental referral. These results highlight the importance of combining patient-reported oral health measures with clinical evaluations to enhance detection and management of oral health issues in rheumatic patients.

Abstract Number: 0367

Differences in Self-Reported Medication Nonadherence and its Drivers in Young Adults versus Older Adults with Systemic Lupus Erythematosus

Hannah Concannon[1], Kai Sun[2], Jennifer Rogers[3], Megan Clowse[4], Rachel Randell[2], Mithu Maheswaranathan[5], Lisa Criscione-Schreiber[5], Nathaniel Harris[6], Amanda Eudy[7] and Rebecca Sadun[2], [1]Duke University School of Medicine, Chapel Hill, NC, [2]Duke University, Durham, NC, [3]Duke, Durham, NC, [4]Duke University, Chapel Hill, NC, [5]Duke University School of Medicine, Durham, NC, [6]Duke University Medical Center, Durham, NC, [7]Duke University, Raleigh, NC

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0357–0386) Patient Outcomes, Preferences, & Attitudes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Medication adherence poses a challenge for patients with SLE, especially younger patients, who often experience both more active disease and more intensive treatments than their older counterparts. Risk factors associated with nonadherence in patients with SLE have been described; however, modifiable adherence barriers specific to young adults under 30 years old remain poorly understood. Thus, this study compared medication nonadherence and drivers of nonadherence by age group.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Reasons for nonadherence per DOSE-nonadherence-SLE self-reports for patients <30 vs. patients 30 years old and over. Reasons for nonadherence are organized by reason category (Capability, Opportunity, or Motivation) and listed in descending order by odds ratios within each category. *denotes p<0.05, **denotes p<0.005

Methods: Participants in this study were enrolled in an academic SLE Registry at a large academic medical center in the United States. From February 2020 to June 2024, we prospectively collected responses to the DOSE-Nonadherence-SLE questionnaire, a clinical tool validated to measure both the *extent of* and the *reasons for* medication nonadherence in SLE. The questionnaire organizes reasons for nonadherence into Capability, Opportunity, and Motivation categories. We defined nonadherence as binary: Patients were considered nonadherent if they reported missing or skipping at least one dose of lupus medication over the past seven days in the *extent of nonadherence* domain. We calculated proportions and odds ratios for *extent of nonadherence* by decade of life and for *reasons for nonadherence* across age groups < 30 and ≥30 years old. We also used logistic regression to determine relationships of nonadherence with age and other covariates.

Table 1. Cohort demographics and characteristics. Values presented as n (%) unless otherwise indicated.

	All ages	≥30	<30
n	336	281	55
Age, years, mean (SD)	44.4 (13.4)	48.1 (11.3)	25.4 (2.7)
Race (n=335)			
Black	188 (56%)	158 (56%)	30 (56%)

Table 2. Results of logistic regression for extent of nonadherence. Significant odds ratios are bolded. *Multivariable analysis includes only those variables with p-value <0.05 in the univariate models.

	Univariate OR (95% CI)	Multivariable OR (95% CI)*
Age, years	**0.97 (0.95-0.99)**	**0.98 (0.96-0.99)**
Race		
Black	**2.05 (1.27-3.29)**	**1.94 (1.19-3.16)**
Other	1.53 (0.67-3.48)	0.78 (0.30-2.04)
White	1.0 (ref)	1.0 (ref)
Hispanic	**4.16 (1.33-13.02)**	**4.37 (1.22-15.64)**
Not married or living with partner	1.38 (0.89-2.14)	--
Medicare, Medicaid, or Uninsured	1.07 (0.69-1.66)	--
Annual household income <$50,000	1.50 (0.96-2.36)	--

Results: Of the 336 completed unique DOSE-Nonadherence-SLE questionnaires, 55 (16%) were from patients < 30 years old (Table 1). Medication nonadherence differed significantly across age groups 18-30, 30-40, 40-50, and 50+ ($p< 0.01$); for each increased year of age, self-reported nonadherence decreased by 2% ($p< 0.05$). Black race and Hispanic ethnicity were also predictive of nonadherence (Table 2). Across age groups, the most common reasons for nonadherence were "I forgot or I was busy" (69%), "I do not have a regular schedule (28%), and "I am tired of taking medicines every day" (27%). Patients < 30 were more likely to report nonadherence due to inability to fill a medication on time (41% vs. 16%, OR 3.72; 95% CI: 1.53, 9.02) and due to needing to take a medicine with food but not being able to eat (38% vs. 19%, OR 2.55; 95% CI: 1.06, 6.13) (Figure 1).

Conclusion: Younger patients reported greater extent of medication nonadherence, often due to logistical impediments. In addition to counseling on the importance of medication adherence, rheumatologists should, when possible, provide support to help young adults with SLE overcome challenges in obtaining and taking medicines. Approaches to understanding and intervening on medication nonadherence in SLE may need to be tailored by age.

Less than 22 miles	109 (51.90)
Equal to or more than 22 miles	101 (48.10)

*Health literacy was assessed by asking, "How confident are you filling out medical forms by yourself?" 'Adequate' is defined by grouping the following answers: 'extremely' and 'quite a bit'. 'Inadequate' is defined by grouping 'somewhat', 'a little bit', and 'not at all'.
**Medication adherence was assessed by asking, "How frequently do you take your medications exactly as prescribed?" 'Always adherent' is defined by 'you always take your medication exactly as prescribed'. 'Nonadherent' is determined by grouping the answer choices 'there are some days you don't take your medication exactly as prescribed,' and 'you often don't take your medication exactly as prescribed'
Data from a total of 233 patients were analyzed. Education is missing 7 responses; health literacy is missing 9 responses; medication adherence is missing 8 responses; telemedicine visit type is missing 2 responses; distance to clinic is missing 23 responses.

Background/Purpose: Home-based telemedicine is an efficient healthcare delivery approach. A recent randomized clinical trial (RCT) found that in-person visits may be preferred among rheumatology patients. Thus, it is key to understand factors influencing patient acceptability of telemedicine. We aimed to identify socioeconomic and demographic factors associated with patient acceptability of rheumatology care via telemedicine.

Methods: We utilized data from an RCT (August 2021-January 2023) comparing telemedicine to in-person rheumatology care at two U.S. academic medical centers. The primary outcome was patient acceptability of telemedicine using a 17-item validated Telemedicine Perception Questionnaire (TMPQ). TMPQ measures usefulness, reliability, ease of use, interaction quality, and satisfaction with telemedicine. Responses were scored 1-5 and summed for each respondent; higher scores represented higher acceptability. We excluded data from patients answering < 50% of the questions. For other

Table 2. Univariable and multivariable linear regression analysis of factors associated with the acceptability of telemedicine using the TMPQ score. Bolded p<0.05 represents statistical significance.

Variable	Univariable Analysis	Multivariable Linear Regression			
	p value	β	95% Confidence Interval		p value
Age (per 1 year increase)	0.13	-0.09	-0.19	0.02	0.11
Sex (Female vs Male)	0.44	-1.28	-5.38	2.83	0.54
Race (White vs Other races*)	**0.03**	**3.00**	**0.12**	**5.89**	**0.04**
Education (≥4-year degree vs ≤Some college)	0.09	2.10	-0.85	5.05	0.16
Health Literacy (Adequate vs Inadequate)	**0.01**	4.19	-0.35	8.73	0.07
Medication Adherence (Adherent vs Nonadherent)	**0.03**	**4.11**	**1.01**	**7.21**	**0.01**
Telemedicine Visit Type (Phone-only vs Video)	0.52	0.99	-1.98	3.96	0.51

*Other races include Black, Asian, Hispanic, and Native Americans.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

missing data, we used the patient's mean score for answered questions, scaled to the full scale of items (sum of items answered multiplied by 17 divided by the number of questions answered). Our independent variables were age, sex, race, telemedicine visit type (audio-only vs video), geocoded distance from patient's home to clinic, education level (≥4 years degree vs ≤some college), health literacy (adequate vs inadequate) and medication adherence (always vs non-adherent) (**-Table 1** footnote for details). We used frequencies (proportions) to describe categorical variables and means (SD) for continuous variables. We created univariable and multivariable linear regression models to analyze the association between independent variables and telemedicine acceptability via TMPQ (continuous). Statistical significance was defined as $p < 0.05$.

Results: We analyzed data from 233 patients who had telemedicine visits with TMPQ scores available. Our study population included 85.4% female and 51.9% White patients. The mean (SD) age was 54.8 (13.7) years. The mean (SD) TMPQ score was 65.9 (10.7) (**Table 1**). In univariable analysis, White (vs other) race (p=0.03), adequate (vs inadequate) health literacy (p=0.01), and high medication adherence (vs non-adherence) (p=0.03) were significantly associated with higher TMPQ scores (**Table 2**). Multivariable linear regression (**Table 2**) confirmed that high medication adherence (β=4.11, 95% CI 1.01-7.21, p=0.01) and White race (β=3.00, 95% CI 0.12-5.89, p=0.04) were associated with higher TMPQ scores. Adequate health literacy was not statistically significant but had a consistent trend toward higher TMPQ scores.

Conclusion: We observed variation in telemedicine acceptability by patient characteristics and identified high medication adherence, White race, and adequate health literacy as positive predictors. Our findings provide insight into factors associated with telemedicine acceptability in rheumatology patients and can help clinicians predict who might be receptive to telemedicine and inform future research to better understand how lower telemedicine acceptability can be mitigated in certain populations, thus enhancing a patient-centered approach to care delivery.

Real-World Persistence of Janus Kinase Inhibitors in Biologic-Experienced Patients with Rheumatoid Arthritis

Jeffrey Curtis[1], Emily Holladay[2], Nick McCormick[3], Yujie Su[4], Fenglong Xie[1] and Alexis Dineen[5], [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Edmond, OK, [3]Auburn University, Auburn, AL, [4]University of Alabama at Birimingham, Birmingham, AL, [5]Self, Portola Valley, CA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0357–0386) Patient Outcomes, Preferences, & Attitudes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Over the last decade, Janus kinase inhibitors (JAKs) for RA have been increasingly used as a treatment option for patients who do not respond to biologic DMARD (bDMARD) treatments. The introduction of orally administered drugs, like JAKs, was expected to address poor therapy persistence rates associated with self-administered,

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1: Characteristics of JAK initiators for Medicare and Marketscan claims-based persistence analysis

Characteristic	Medicare N = 11,170	Marketscan N = 9,458
Age at index date in years		
Mean (SD)	63.2 (12.2)	53.6 (10.8)
Female: N (%)	9,512 (85.2)	7,814 (82.6)
Number of prior biologic DMARDS		
Mean (SD)	2.1 (1.2)	2.0 (1.1)
Number of prior conventional DMARDS		
Mean (SD)	1.8 (1.0)	1.7 (1.0)

JAK: Janus kinase; SMD: Standard mean difference; SD: Standard deviation; IQR: Interquartile range; DMARD: Disease-modifying antirheumatic drug.

Table 2: Persistence with JAK inhibitors at 1 and 2 years

	Medicare		Marketscan	
	1 year	2 years	1 year	2 years
Overall, % (95% CI)	42.0 (41.1, 43.0)	27.2 (26.4, 28.1)	43.7 (42.6, 44.7)	26.9 (25.9, 28.0)
Baricitinib, % (95% CI)	27.4 (21.1, 35.6)	10.6 (5.8, 19.5)	41.9 (33.4, 52.6)	22.1 (14.8, 32.9)
Tofacitinib, % (95% CI)	42.2 (41.3, 43.2)	27.4 (26.6, 28.3)	43.1 (42.0, 44.2)	26.8 (25.7, 27.9)
Upadacitinib, % (95% CI)	41.1 (33.4, 50.5)	— (—, —)	50.8 (47.0, 54.9)	20.1 (13.8, 29.2)

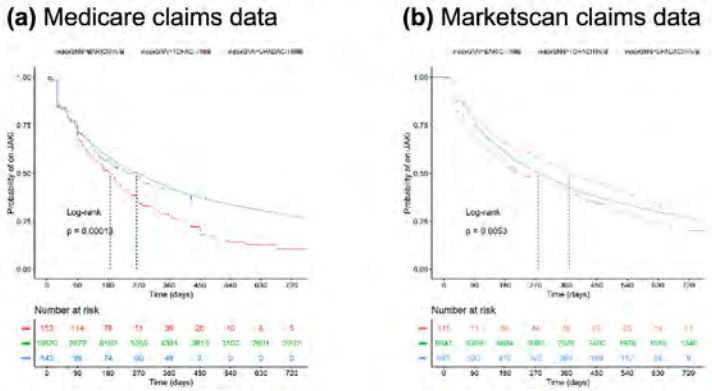
injectable bDMARDs. The purpose of this analysis is to evaluate the persistence of JAKs used to treat RA in the United States using real-world commercial (Marketscan) and government (Medicare) insurance claims data.

Methods: We conducted a retrospective analysis of patients initiating their first JAK for RA using 2006-2021 Marketscan data (commercial health plan claims data) and 2010-2020 Medicare fee for service (FFS) data to assess 2-year JAK persistence. The last index date in the claims data that was allowable was 12/31/2019 for Medicare and 12/31/2020 for

Marketscan, enabling the analysis to have the potential for at least 1 year of follow-up . Drug persistence was measured at 1 and 2 years using the following definition: continuous use of JAK without gap of >90 days (next prescription fill date is no later than previous prescription fill date + days of supply + 90) and did not switch to another JAK or bDMARD.

Results: In the Medicare cohort, there were 11,170 RA patients with an index date on or before 12/31/2019. Individuals had mean prior use of 2.1 ± 1.2 bDMARDs and 1.8 ± 1.0 cDMARDs. JAK persistence was 42.0% (95% CI: 41.1, 43.0) at 1 year and 27.2% (95% CI: 26.4, 28.1) at 2 years. Drug persistence differed across individual drugs with 1-year persistence of

Figure 1: Persistence with JAK inhibitors at 1 and 2 years for (a) Medicare data (b) Marketscan data



23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

27.4% (95% CI: 21.1, 35.6), 42.2% (95% CI: 41.3, 43.2), and 41.1% (95% CI: 33.4, 50.5) for baricitinib, tofacitinib and upadacitinib, respectively. At 2 years, 10.6% (95% CI: 5.8, 19.5) and 27.4% (95% CI: 26.6, 28.3) continued baricitinib and tofacitinib, respectively. There were no patients taking upadacitinib at 2 years, which was not unexpected given the end of the Medicare data (12/31/2020) and the timing of FDA approval of upadacitinib (2019).

In the Marketscan cohort, there were 9,458 patients with an index date on or before 12/31/2020. Patients had mean prior use of 2.0 ± 1.1 bDMARDs and 1.7 ± 1.0 cDMARDs. Among these, 43.7% (95% CI: 42.6, 44.7) initiating a JAK were persistent at 1 year, and 26.9% (95% CI: 25.9, 28.0) were persistent at 2 years. At 1 year, 41.9% (95% CI: 33.4, 52.6), 43.1% (95% CI: 42.0, 44.2), and 50.8% (95% CI: 47.0, 54.9) of patients continued baricitinib, tofacitinib and upadacitinib, respectively. At 2 years, 22.1% (95% CI: 14.8, 32.9) of patients continued baricitinib, 26.8% (95% CI: 25.7, 27.9) continued tofacitinib, and 20.1% (95% CI: 13.8, 29.2) continued upadacitinib.

Conclusion: Persistence with initial JAK for RA in real-world settings was poor for all FDA-approved JAKs as measured in two independent data sources, and 2-year estimates were comparable between commercial and government health claims sources. Drug persistence differed across individual JAKs, with lower persistence rates for baricitinib compared to tofacitinib and upadacitinib. Compared to historical data, the introduction of oral JAKs does not appear to have improved therapy persistence, with < 30% treatment persistence at 2 years.

Patient Preferences for Treatments of Rheumatoid Arthritis: A Discrete Choice Experiment Evaluating Preference for Advanced Drug Therapies and Neuroimmune Modulation Device

Jeffrey Curtis[1], Joshua Baker[2], Shilpa Venkatachalam[3], Sherry Danese[4], Julie Ulloa[5] and Ankit Shah[6], [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Pennsylvania, Philadelphia, PA, [3]Global Healthy Living Foundation, New York, NY, [4]OutcomesInsights, Calabasas, CA, [5]OutcomesInsights, Calabasas, [6]SetPoint Medical, Valencia, CA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0357–0386) Patient Outcomes, Preferences, & Attitudes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Despite broadening treatment options for RA, several challenges and unmet needs remain. The 2021 ACR guideline for the treatment of RA marked a significant step in expanding the integration of patient voices in guideline development, incorporating patient perspectives to inform treatment decisions based on their preferences. This study aimed to characterize patient satisfaction with, and preferences for, current RA treatments as well as a novel vagus nerve-mediated neuroimmune modulation device, which recently demonstrated safety and effectiveness in treating biologic-experienced RA patients.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1: Participant Characteristics

	Total (n=354)	Biologic Naive (n=103)	Biologic Experienced I (n=151)	Biologic Experienced II (n=100)
% Female	74%	83%	72%	69%
Mean Age	47.8	48.0	47.6	48.0
Years with RA Symptoms (mean)	11	10	11	11
Disease Severity (RAPID3)				
Near Remission	7%	9%	7%	5%
Low Severity	7%	9%	7%	5%
Moderate Severity	27%	23%	27%	29%
High Severity	60%	59%	59%	61%
Current Treatment (% of patients)				
cDMARDs	53%	88%	43%	35%
TNF Inhibitors	52%	-	46%	61%
JAK Inhibitors	18%	-	15%	22%
IL Inhibitors	4%	-	5%	4%
T-cell Inhibitors	3%	-	2%	4%
TSQM Score				
Dissatisfied (35 or less)	6%	8%	7%	5%
Somewhat Satisfied (36 to 79)	62%	68%	61%	56%
Satisfied (80 to 100)	32%	24%	32%	39%

Methods: A web-based patient survey was conducted in combination with a discrete choice experiment (DCE) to capture the experiences, perspectives, and preferences of patients living with RA in the US. Patient satisfaction with current RA pharmacologic therapies was determined using the Treatment Satisfaction Questionnaire for Medication (TSQM), a validated instrument to measure patient satisfaction. DCEs are widely utilized tool in economics research that can elicit an individual's distinct valuation of several options and account for trade-offs between them based on their personal experiences. The DCE in this study included 12 choice sets which contained a device profile and drug profile featuring 8 clinically relevant attributes for RA patients.

Results: 354 completed surveys were included in the analysis. Participants were stratified into three subgroups, Biologic Naïve (n=103); Biologic Experienced I, those on their first biologic (n=151); and Biologic Experienced II, those who had a history of multiple biologics (n=100). Disease severity, as measured by RAPID3, indicated 27% had 'Moderate Disease Activity' (RAPID3 > 6, ≤12) and 60% with 'High Disease Activity' (RAPID3 > 12). Based on the TSQM, only 32% were satisfied with their RA treatment; dissatisfaction increased with exposure to a greater number of biologics or JAKs (**Table 1**).

The initial impression of implantable device-based treatment option was regarded as "Positive" or "Extremely Positive" by 45%. Patient preferences were modeled for biologic-experienced patients with moderate to high disease severity who were dissatisfied or only somewhat satisfied with their current RA treatment. Neuroimmune modulation therapy was preferred over trying another drug treatment options for both Biologic Experienced I and II groups (**Figure 1**). Key drivers of treatment preference included out-of-pocket treatment cost, proportion of improvement in symptoms, level of physical function and fatigue, and effectiveness in protection from irreversible joint damage **(Table 2)**.

Conclusion: These results indicate that RA patients are accepting of a novel neuroimmune modulation approach using a surgically implanted device. Preference for neuroimmune modulation device over another biologic or JAK was particularly

Figure 1: Patient preferences based on prior biologic or JAK exposure

2 in 100 patients	-3.6	15.2		

[a]The relative importance of each treatment attribute is characterized by considering how much difference each attribute could make in the total utility of a treatment. That difference is the range in the attribute's utility values. Percentages are calculated from relative ranges, obtaining a set of attribute importance values that total 100%.

[b]While we understand the FDA does not consider cost of therapies, this data is included to provide complete data that were collected.

[c]A negative number indicates it is highly undesired

high for those who had previous exposure to, and dissatisfaction with, currently available advanced RA therapies. These results underscore the importance of discussing patients' personal preferences, their experiences with prior therapies and the attributes of treatment that are most important to them in making future treatment selections.

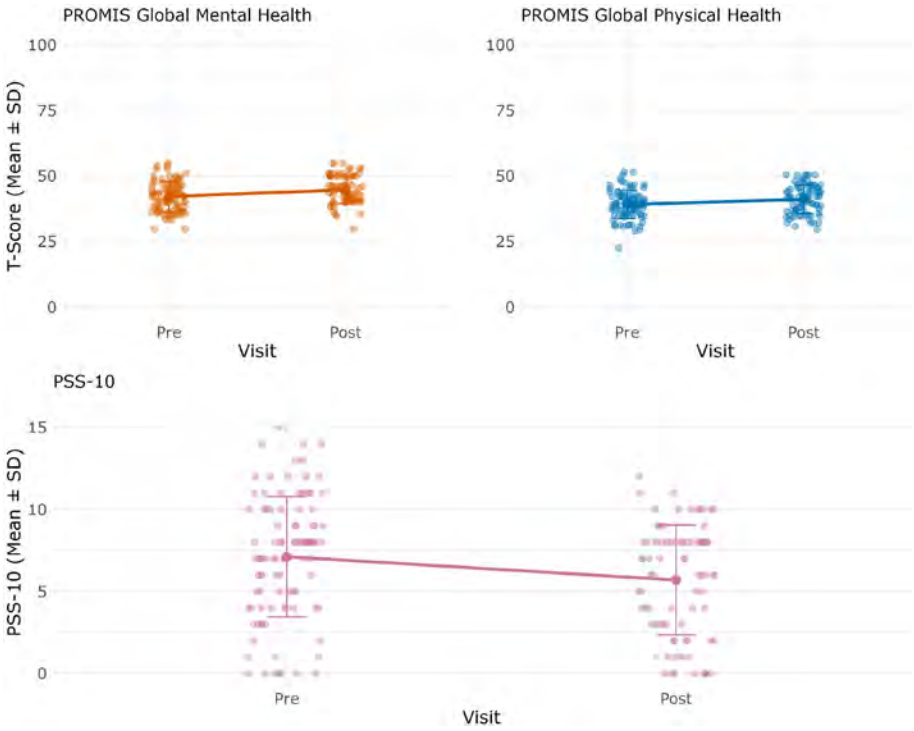
Background/Purpose: As healthcare shifts towards patient-centered care, multifactorial lifestyle interventions, though effective, often impose time and resource burdens on patients. An online program like IMMUNE STRENGTH can streamline delivery of mindfulness, sleep, nutrition and exercise support, reduce patient burden and enhancing self-management in psoriatic arthritis (PsA).

Methods: A prospective, single-arm pilot study evaluated the feasibility and preliminary efficacy of IMMUNE STRENGTH, a 10-week online, coach-led program targeting lifestyle interventions in adults (≥18 years) with PsA per ACR criteria. To enhance external validity, participants were recruited from an academic rheumatology clinic and a national patient advocacy group. Key exclusions included concomitant systemic autoimmune diseases and inability to engage in remote coaching.

The program featured weekly modules focused on four core lifestyle pillars (mindfulness, sleep hygiene, nutrition, and exercise) delivered via a platform with videos, self-guided exercises, and tracking tools such as sleep logs and dietary journals. Certified health coaches led weekly communication and provided individualized support with emails or phone calls, delivering targeted education, answering questions, and gathering feedback in real time.

Engagement was measured via module completion and coaching session attendance. Patient-reported outcomes were measured using validated PROMIS scales including pain, fatigue, and global health at baseline and post-intervention (Week 10). Feasibility was evaluated based on enrollment and retention rates. Continuous and categorical variables were described using means ± standard deviations and counts (%), respectively. Changes from baseline to Week 10 were analyzed using paired t-tests. All analyses were performed in R (v4.3.1), with a two-sided $\alpha = 0.05$.

Results: Of the 143 enrolled, 86 (60.1%) completed the program and were included in the Week 10 analysis. PROMIS Global Mental Health T-scores rose from 42.2 to 44.7 (SD = 5.20, $p < 0.001$) and Global Physical Health T-scores from 39.1 to 41.1 (SD = 4.44, $p = 0.001$), approaching the 3-point minimal clinically important difference (MCID) commonly cited for PROMIS measures. Perceived stress, as measured by the 10-item Perceived Stress Scale (PSS-10), declined from 7.12 to 5.70 (SD = 3.04, $p < 0.001$). Self-efficacy also improved: symptom-management T-scores increased by 3.45 points (SD =



Change in PROMIS Global Mental and Physical Health and PSS 10 scores from baseline to post intervention

Change in PROMIS Self Efficacy and Fatigue from baseline to post intervention.

4.89, $p < 0.001$) and medication-management scores by 3.00 points (SD = 6.55, $p < 0.001$). Participants also experienced reductions in symptom burden, with fatigue scores falling from 60.4 to 57.2 (SD = 6.38, $p < 0.001$) and pain-interference scores from 61.8 to 58.5 (SD = 5.89, $p < 0.001$). Finally, 90.6% of completers reported being "satisfied" or "very satisfied," and 87.5% would recommend IMMUNE STRENGTH to others.

Conclusion: The IMMUNE STRENGTH pilot showed significant improvements in mental and physical health, self-efficacy and symptom burden, supporting the potential of an online, coach-led lifestyle intervention as an adjunctive approach for managing PsA. Further research is needed to confirm these preliminary outcomes and evaluate long-term benefits.

Development and Implementation of a Remote Educational Program to Optimize Safe Medication Use in Older Veterans with Rheumatic Diseases

Maria Romero Noboa[1], Hannah Howell[2], Angelo Gaffo[3] and Maria I. (\"Maio\") Danila[4], [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, [3]Division of Rheumatology and Clinical Immunology, University of Alabama, Birmingham, AL, USA; Birmingham VA Medical Center, Birmingham, AL, USA, Birmingham, AL, [4]University of Alabama at Birmingham (UAB), Birmingham VA Medical Center, Birmingham, AL

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0357–0386) Patient Outcomes, Preferences, & Attitudes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Symptomatic treatment in rheumatic and musculoskeletal diseases (RMDs) – including glucocorticoids (GCs) and non-steroidal anti-inflammatory drugs (NSAIDs) – can result in improved quality of life but also increase the rates of polypharmacy. GCs and NSAIDs combination is associated with a higher risk of serious adverse events such as acute kidney injury, cardiovascular disease, dyspepsia, and gastrointestinal (GI) bleeding. This is an important safety concern for Veterans with RMDs. The aim of this project is to create and evaluate a patient-directed informational program,

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

entitled ScaLable Medication Deprescribing (SLIM-D). This program combines written education and case management to optimize safe medication use in older Veterans with RMDs and use GCs and NSAIDs in combination.

Methods: The SLIM-D program was developed in partnership with rheumatology clinic staff in preparation for its implementation at the Birmingham VA Medical Center. Existing educational materials from the VA-funded "Eliminating Medications through Patient OWnership of End Results" (EMPOWER) program were reviewed and used as template for the SLIM-D Veteran-facing informational booklet (Figure 1). We also created additional materials including program invitations for Veterans (Figure 2), scripts for Veteran calls, and provider electronic messages. Veteran-facing materials were assessed for readability level using Flesch-Kincaid Reading Ease (FKRE >60 representing being easily understood by 13 to 15 year olds) and Flesch Kincaid Grade Level (FKGL), with FKGL = 8-9 being an acceptable readability goal. Veterans seen at Birmingham VA Rheumatology clinic were invited to review the materials and complete the validated Patient Education Materials Assessment Tool (PEMAT-P) to determine the understandability and actionability scores of the written materials (highest score =100%, goal ≥ 80%).

Results: The FKGL readability of the invitation brochure was 8th grade with FKRE of 60.2 and the FKGL readability for the informational booklet was 9th grade with FKRE of 50.9. The invitation brochure and informational booklet were presented to 22 Veterans, 77% were men and 50% were ≥ 60 years of age. The invitation brochure had a mean (SD) understandability score 81.8% (19.8) and 82.4% (22.2) actionability score. The informational booklet had a mean (SD) 96.6% (5.8) understandability score and 98.5% (5.0) actionability score (Table 1).

Conclusion: The materials created for the SLIM-D program had a high understandability and actionability score. The SLIM-D program will offer a structured approach to reducing the combined use of GCs and NSAIDs in older Veterans with RMD. Providing information materials to the Veteran will encourage a discussion of safe medication use with their clinician

Abstract Number: 0373

Implementation of a Lupus Self-Management mHealth App: Using Incentives to Drive Engagement

Melissa French[1], Katherine Carpenter[2], Eric Johnson[2], Melicent Miller[2] and Mary Crimmings[2], [1]Lupus Foundation of America, Alexandria, VA, [2]Lupus Foundation of America, Washington, DC

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0357–0386) Patient Outcomes, Preferences, & Attitudes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: As part of a five-year cooperative agreement with the Centers for Disease Control and Prevention, the Lupus Foundation of America (LFA) has implemented the digital lupus self-management (SM) education program, "Strategies to Embrace Living with Lupus Fearlessly (SELF)." Launched online in January 2022, and as a mobile app in September 2023, SELF offers user-tailored SM education, tracking tools, and support. As engagement is a primary challenge for mobile health (mHealth) apps generally[1], this effort used social media promotion as a way to explore incentives to improve app engagement.

Methods: In January 2025, we launched a social media promotion to incentivize engagement by offering a gift box of lupus self-care items to new and existing SELF users who used the app at least four times during the month. Users were asked to complete any of the following actions on any four days: an SM skill-building activity, an entry in the symptom tracker, or an entry in the medication tracker. We compared this to a previous social media promotion period in September 2024 when new users were incentivized to sign-up for SELF with a similar gift.

Across the two promotion periods, September 2024 (P1) and January 2025 (P2) we examined new user sign-ups, retention beyond the initial day in new users, and engagement for four or more days in new and existing users. Categorical comparisons of new user sign-ups, retention beyond the initial day, and engagement for four plus days were assessed using Chi Square test. User feedback was evaluated qualitatively.

Results: Likely due to wider promotional efforts, total SELF users was higher in P1 (n = 1946) than P2 (n = 455). The proportion of new user sign-ups decreased from P1 (91%; n = 1777) to P2 (61%; n = 301), while the proportion of existing users increased over the same period (p = 0.00) (Fig 1.). In new users, retention beyond the initial day increased from 47% in P1 to 55% in P2 (p = 0.00) (Fig. 2.). In all users, engagement for four or more days increased from P1 (4%) to P2 (16%) (p = 0.00) (Fig. 3).

During both promotion periods, the most popular areas of focus for SM skill-building activities were managing symptoms and managing stress. Satisfaction with the app was high.

Conclusion: New users in P1 were higher because of the focus on sign-ups, but the P2 effort was more effective at increasing retention and engagement. Including all users the promotion and focusing on the behavior we aimed to improve, brought more existing users back to SELF in P2. By linking the incentive to retention and engagement rather than sign-ups, we prompted users to do more in the app, use the program as intended, and depart satisfied.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. The proportion of new user sign-ups decreased from P1 (91%; n = 1777) to P2 (66%; n = 301), while the proportion of existing users increased from P1 (9%; n = 169) to P2 (34%; n = 154) (p = 0.00).

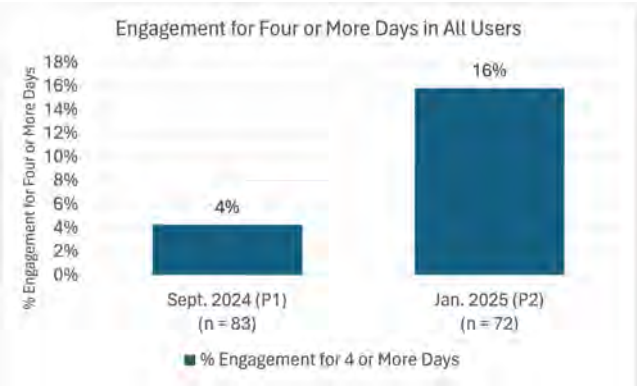
In new users, retention beyond the initial day increased from 47% in P1 (n = 834) to 55% in P2 (n = 165) (p = 0.00).



In all users, engagement for four or more days increased from 4% in P1 (n = 83) to16% in P2 (n = 72) (p = 0.00).

SESSION INFORMATION

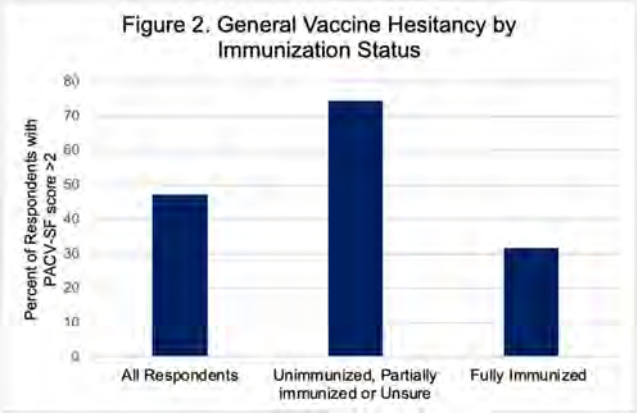
Session Date: Sunday, October 26, 2025
Session Title: (0357–0386) Patient Outcomes, Preferences, & Attitudes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Vaccine-preventable diseases pose greater risk to children with rheumatic diseases treated with immunosuppressive therapies and to those with underlying immune dysregulation. Despite the importance of vaccine protection, children with rheumatic disease often have lower vaccination rates compared to healthy populations. The drivers of decreased vaccine uptake in pediatric rheumatic disease (PRD) are poorly understood. This study examines the caregiver attitudes and barriers surrounding immunization in PRD patients.

Methods: This study included a voluntary online survey of caregivers of PRD patients recruited through online parent support groups for PRD patients from June – July 2024. General vaccine hesitancy was assessed via a modified Parental Attitudes about Childhood Vaccines – Short Form (PACV-SF), a 4-question scale designed to screen for vaccine hesitant caregivers.[1] Additional questions on barriers to vaccination were developed by the CARRA Vaccination Work Group. The

Figure 1. Modifications to the Parental Attitudes about Childhood Vaccines – Short Form (PACV-SF)[5] for Pediatric Rheumatic Disease Patients

Original Question	Modified Question	Scoring
1. Have you ever delayed having your child get a shot for reasons other than illness or allergy?	1. Have you ever delayed having your child get a vaccine for reasons other than illness or allergy?	"No" or "Not sure" = 0 "Yes" = 1
2. How concerned are you that a shot might not prevent the disease?	2. How concerned are you that a vaccine might not prevent the disease?	"Not at all concerned" or "Not too concerned" = 0 "Somewhat concerned" or "Very concerned" or "Not sure" = 1
3. Overall, how hesitant about childhood shots would you consider yourself to be?	3. Overall, how hesitant about childhood vaccines would you consider yourself to be?	"Not at all hesitant" or "Not too hesitant" = 0 "Somewhat hesitant" or "Very hesitant" or "Not sure" = 1
4. I trust the information I receive about shots.	4. I trust the information I receive about vaccines from healthcare providers.	"Strongly agree" or "Agree" = 0 "Disagree" or "Strongly disagree" or "Not sure" = 1



23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

primary outcome was caregiver report of immunization status. Associations with explanatory variables were assessed using chi-squared tests and Fisher's exact test for categorical variables and Wilcoxon rank-sum tests for continuous variables. Univariable and multivariable logistic regression analyses were used to examine the association between vaccination status and explanatory variables. Multivariable Model 1 includes all explanatory variables while multivariable Model 2 includes only those found to be significant in the univariable analysis.

Results: Of the 163 respondents, 104 (64%) reported that their child had received all recommended immunizations and 59 (36%) reported partial immunization, no immunization, or uncertain immunization status (Table 1). General vaccine hesitancy, as indicated by a score $\geq$2 on the PACV-SF (Figure 1), was strongly associated with a lower odds of immunization uptake (OR 0.16, 95% CI 0.08-0.32, $p < 0.001$) in all models (Figure 2). Age was associated with increased odds of immunization uptake in the univariable model and multivariable Model 1. Vaccine hesitancy related to rheumatic disease was associated with decreased odds of immunization uptake in the univariable model but this association became non-significant in the multivariable models.

Conclusion: General vaccine hesitancy in caregivers strongly predicted decreased odds of fully immunized status in children. While not surprising, this was the only factor undiminished in all multivariable models, suggesting a strong independent relationship. In contrast, vaccine hesitancy related to the child's rheumatic disease diagnosis was not significant in the multivariable models. The study's limitations include unknown generalizability due to convenience sampling and relatively small sample size. Nevertheless, this study suggests that general vaccine hesitancy may play a stronger role in caregiver immunization decisions than other types of barriers.

Session Time: 10:30AM–12:30PM

Background/Purpose: Glucocorticoids (GCs) are used long-term by approximately 1% of the adult population and contribute to excess morbidity and mortality. We prospectively assessed Glucocorticoid Toxicity Index (GTI) scores at 6 months in a real-world cohort of individuals using GCs in rheumatology clinic given the limited published real-world data involving GTI scores.

EQ-5D Visual Analogue Scale#	-0.20 (-0.43, 0.07)	-0.17 (-0.43, 0.13)
Clinic visits	0.09 (-0.14, 0.31)	0.03 (-0.26, 0.32)

SF-36, 36-Item Short-Form Survey; GTI CWS, Glucocorticoid Toxicity Index Cumulative Worsening Score
*Adjusted model adjusted for age, sex, categorical disease activity
#SF-36 scale and component scores range from 0-100, with mean (SD) of 50 (10) in the general population, and higher scores representing better health-related quality-of-life. EQ-5D VAS ranges from 0-100, with higher scores representing better health-related quality-of-life.

6-month GTI scores to cumulative GC exposure, quality-of-life measures, and clinic visits using unadjusted and multivariable (adjusted for age, sex, and disease activity) Pearson correlation coefficients (rho).

Results: We evaluated the first 90 patients enrolled (mean age 60 years, 62% female, 90% White, 41% with PMR and/or GCA) and the first 74 who completed 6-month follow-up (**Table 1**). The majority of patients (81%) had active disease at enrollment. The mean (SD) current GC dose was 33.4 (19.1) prednisone-equivalent mg, and most were also receiving a DMARD (65, 72%). Over the 6-month follow-up period, the median (IQR) cumulative GC exposure was 2114 (1185, 3080) prednisone-equivalent mg, or approximately 11.6 mg/day. The median (IQR) overall 6-month GTI CWS was 44 (20, 93) and GTI AIS was 3 (-42, 54). The most common GTI domain in which individuals experienced worsening was the Neuropsychiatric domain, followed by the Body Mass Index, Blood Pressure, and Skin domains (**Figure**).

The unadjusted correlation coefficient between GTI CWS scores and 6-month GC exposure was 0.28 (95% CI: 0.06-0.48); this was diminished in the adjusted analysis (**Table 2**). Higher GTI CWS was associated with numerically lower (i.e., worse) SF-36 scale and component scores. There was a weak positive association between the GTI CWS and the number of clinic visits though this was not statically significant.

Conclusion: In this real-world prospective cohort of individuals with autoimmune diseases receiving GCs, most people experienced various GC toxicities over 6 months with a predominant proportion with neuropsychiatric toxicities. Improvement in some GC toxicities was also observed, as evidenced by the markedly lower 6-month AIS value compared to the 6-month CWS value. Higher GTI CWS scores were numerically associated with worse quality-of-life. Presence of any GC toxicities correlated more strongly with outcomes than net overall change in toxicity. As shown in other studies, the relationship between cumulative GC exposure and GC toxicity is imperfect, emphasizing the importance of measuring GC toxicity directly.

Table 2. PROMIS-29 Outcomes Associated with Cannabis Use

	B	Sig.	Exp(B)
Anxiety	.014	.874	1.014
Depression	.150	.072	1.162
Fatigue	-.023	.744	0.977
Pain	-.071	.441	0.931
Participation	-.065	.375	0.937
Physical function	.115	.358	1.122
Sleep disturbance	.063	.604	1.065

Background/Purpose: The use of cannabis among individuals with rheumatologic conditions has gained increasing attention due to potential effects on pain, mood, and overall quality of life. However, data on its frequency of use, motivations, and patient-reported outcomes remain limited. We compared cannabis users and non-users by sociodemographic and arthritis characteristics and HRQL, and explored motivations for use, and assessed differences in HRQL among people with rheumatic diseases.

Methods: Data are from the baseline visit of a pilot study of people with inflammatory rheumatic diseases who volunteered for an internet-based intervention to improve sleep. Participants self-reported cannabis use, reasons for consumption, and completed the PROMIS-29 questionnaire (physical function, anxiety, depression, fatigue, sleep disturbance, pain interference, and social participation). Characteristics were compared between cannabis users and non-users using t-test and chi-square. Associations between cannabis use, demographics, and clinical characteristics were examined using multivariable regression.

Results: Our sample had a mean (SD) age of 54 (14) and 98% were female. Most had RA or PSA, with a mean disease duration of 10 (11) years; many also had OA (30%; Table 1). One third reported using cannabis use in the past year, and 24% in the past 3 months (of which 38% used weekly and 31% daily/almost daily). All participations indicated they were using for medicinal reasons only (100%), with primary motivations being to improve pain (19%), sleep (17%), fatigue (< 5%) or anxiety (< 5%). Nearly half (46%) reported a little improvement in arthritis symptoms with use, with 15% reporting a lot of improvement, 31% no change, and 8% were unsure. Compared to Non-Users, Users reported significantly higher anxiety (p=.046) and depression (p=.014). However, logistic regression results suggested cannabis use was not associated with differences in PROMIS-29 outcomes.

Conclusion: One in three participants in an online intervention to improve sleep reported using cannabis in the past year to improve their arthritis symptoms, with nearly a quarter using cannabis regularly to improve pain, sleep, fatigue and anxiety. User did not report different PROMIS-29 outcomes, although 61% reported a little to a lot of symptom improvement. Understanding the motivations and health impact of cannabis use can help guide patient counseling and future research on alternative management strategies for pain and mood disorders.

Abstract Number: 0377

New efforts to incorporate patient-reported outcomes into clinical trials for lupus therapeutics

Patti Katz[1], Anca Askanase[2], Nandan Baruah[3], Wen-Hung Chen[4], Nicole Cooper[5], Anna Fisch[3], Lili Garrard[6], Meenakshi Jolly[7], Veronica Vargas Lupo[8], Carla Menezes[9], Judith Mills[3], Hoang Nguyen[10], Teodora Staeva[5], Josephine Park[11], Zahi Touma[12] and The Lupus Voices Council of Lupus Accelerating Breakthroughs Consortium, [1]UCSF, San Rafael, CA, [2]Columbia University Medical Center, New York, NY, [3]Lupus Voices Council, Lupus Accelerating Breakthroughs Consortium, New York, [4]GlaxoSmithKline, Philadelphia, PA, [5]Lupus Research Alliance, New York, [6]FDA, CDER, SIlver Spring, MD, [7]Rush University, Chicago, [8]Lupus Voices Council, Lupus Research Alliance, New York, NY, [9]Lupus Therapeutics, New York, NY, [10]Lupus Research Alliance, New York, NY, [11]EMDSerono, Boston, MA, [12]University of Toronto, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0357–0386) Patient Outcomes, Preferences, & Attitudes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Table 1. Summary of small group discussions

What to measure and why? • Pain, fatigue, and cognitive function/brain fog were the most frequently recommended primary domains. • The next most frequent mentions were skin issues (e.g., photosensitivity, hair loss, rashes), physical functioning, mental health (depression, anxiety, and anger), treatment side effects, and quality of life. • Social functioning (e.g., work, family, "showing up") was woven through a number of responses.
What should the questionnaire burden be for trial participants? What mode of administration? Other considerations? • Most common response: 15 minutes. Acceptable questionnaire time depended on whether respondents could take breaks while completing questionnaires, whether questionnaires could be completed at home vs. at a study visit, whether questionnaires could be completed over multiple days. • Improve presentation of questionnaires (e.g., font size, screen contrast) • Electronic administration strongly preferred • Make adaptations as necessary to facilitate clinical trial participation and completion of materials by trial participants
Should PRO results and/or trial results be returned to participants? If so, when? • General agreement that trial results should be provided to participants without them having to seek them out. • Acknowledgement of the issues around participant privacy (e.g., pharma does not have participant information), but it was felt that trial sites could manage this communication • Information about trial results should be provided at appropriate health literacy levels and in accordance with plain language guidelines (e.g., length, multiple formats) • Need for real-time evaluation of some PROs, such as measures of depression • Make it clear to participants if providers do not see information from PRO measures in real time
How should PROs for a trial be selected; specifically, what are the roles of pharma, researchers, scientific evidence, and patients? • Ultimately, industry will select PROs, ideally with input from researchers and patients; be responsive to regulators and to payors to facilitate reimbursement for product • PRO selection will depend on the drug's mechanism of action.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 2. Steps needed to advance incorporation of PROs into endpoints for regulatory decision-making
• Advocate the value and importance of PROs to pertinent stakeholders
• Promote greater sharing of PRO data from clinical trials; encourage that PRO data be made public and accessible to researchers and/or published
• Involve people living with lupus in selection of PRO domains and measures.
• Come to a consensus on core domains and appropriate measures for those domains and develop an evidence package for these domains/measures

Background/Purpose: Lupus Accelerating Breakthroughs Consortium (Lupus ABC) was formed by the Lupus Research Alliance as a public private partnership of people living with lupus, investigators, pharmaceutical companies, and the FDA to accelerate lupus drug development in a precompetitive, collaborative setting and ensure that the perspectives of people with lived experience of lupus are incorporated into the drug development process. We report on the first meeting to convene broad representation of lupus community voices to focus on better integration of patient-reported outcomes (PROs) in lupus clinical trials.

Methods: A public meeting with representatives from all Lupus ABC stakeholders was held October 16-17, 2024. The current use of PROs in lupus clinical trials was presented and breakout groups discussed 4 primary topics: 1) the important concepts of interest or PRO domains to measure; 2) questionnaire burden, modes of administration, and sharing results; 3) selection of reliable and valid PRO measures for trials; and 4) steps needed to advance the goal of wider PRO incorporation into trials. Results from breakout groups were presented and discussed; these are summarized below.

Results: Pain, fatigue, and cognitive function/brain fog were the most frequently recommended primary domains by participants with lupus and were corroborated with other stakeholders (Table 1). Ideas on questionnaire burden varied, and persons with lupus suggested potential adaptations of how PRO measures are currently administered depending on frequency, mode of administration and context, including a preference for electronic administration. There was strong consensus to return information on PROs and trial results to participants and involve all stakeholders early in the trial design process to identify the appropriate PRO domains and measures. While PROs are collected in most lupus clinical trials, participants felt that they may be underutilized as primary or secondary/exploratory endpoints. A desire to change the focus in trials from disease activity and signs to include PROs to highlight patients' voices was noted. The need for balance between the mechanisms of action of a product, what is important to patients, and what aspect(s) of disease that could be changed from treatment was also discussed as a critical issue. The potential lack of concordance between standard clinical measures and PROs was felt to be a challenge to the acceptance of PROs as potential endpoints. The group noted specific steps that are needed to incorporate PROs into endpoints for regulatory decision-making: encourage PRO data to be made public and accessible to researchers; come to consensus on domain(s) and best measure(s) of those domains; and involve people living with lupus in selection of PRO domains and measures and trial design (Table 2).

Conclusion: The group, with broad lupus community representation, identified a number of steps needed to incorporate PRO measures into endpoints for regulatory decision-making. For these actions, collaborations among industry, researchers, regulators, payors, and people living with lupus are needed.

Abstract Number: 0378

Identifying Patterns of Telemedicine Readiness and Digital Health Literacy in Rheumatoid Arthritis Patients: A Latent Class Analysis

Preeti Dhanasekaran[1], Bryant Lim[2], Qai Ven Yap[2], Hafizah Ahmad[3], Siew Hwa Chong[3], Ginny Goh[3], Manjari Lahiri[4], Amelia Santosa[4], Gim Gee Teng[3], Peter Cheung[4], Siriwan Lim[1] and Margaret Ma[4], [1]National University of Singapore, Singapore, Singapore, [2]National University of Singapore, Singapore, [3]National University Hospital, Singapore, [4]National University Hospital, Singapore, Singapore

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0357–0386) Patient Outcomes, Preferences, & Attitudes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: The COVID-19 pandemic accelerated telemedicine adoption, yet readiness and digital literacy vary widely across patient populations. Understanding these differences is crucial to designing equitable and effective telehealth systems for chronic disease management.

Methods: Latent class analysis (LCA) was performed on 138 RA patients enrolled at National University Hospital, Singapore using 18 items from a Telemedicine Readiness Survey [1] and the eHealth Literacy Scale [2]. Age, sex, race, education, employment, and marital status were not part of the clustering but were compared. Cluster solutions were evaluated based on model fit indices and interpretability.

Results: We identified four distinct clusters ranging from those who were digitally disengaged and resistant to telehealth to those who were confident and ready adopters of remote care (Figure 1).

Cluster 1 (C1) (n=26, 16.3%) was digitally disengaged. Patients in this cluster demonstrated the lowest levels of telemedicine engagement and digital confidence. 95.8% reported lacking confidence in accessing or using online health information. Half of the participants found telemedicine too complicated.

Cluster 2 (C2) (n=38, 23.8%) had moderate digital literacy and occasional telemedicine use, and remained ambivalent due to concerns about communication quality during teleconsultations. Approximately 65.8% expressed difficulty or dissatisfaction with communicating effectively during virtual consultations.

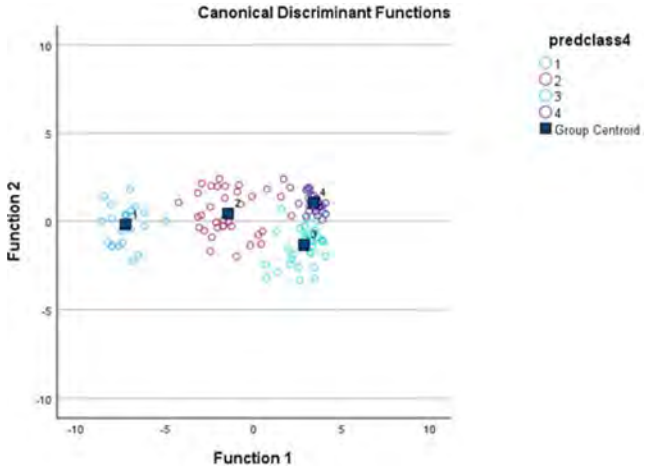

Figure 1. Canonical discriminant analysis of the 4 clusters and their group centroids. The plot shows the clear discrimination of the 4 clusters based on the discrimination functions 1 and 2.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1: Cluster distribution and baseline characteristics among the different subgroups. Data are presented as n (%) or mean (SD).

Variable	Cluster 1 *Seniors with Limited Digital Engagement* (n = 26)	Cluster 2 *Moderate Digital Adopters* (n = 38)	Cluster 3 *Digital Novices with Potential* (n = 38)	Cluster 4 *Confident Digital Adopters* (n = 36)	p-value
Age, mean ± SD	68.0 ± 10.4	58.9 ±15.2	58.0 ± 12.7	51.5 ± 15.7	<0.001
Race					0.025
Chinese	18 (69.2)	20 (54.1)	21 (55.3)	15 (42.9)	
Malay	4 (15.4)	7 (18.9)	3 (7.9)	12 (34.2)	
Indian	4 (15.4)	9 (24.3)	11 (28.9)	3 (8.6)	
Others	0 (0.0)	1 (2.7)	3 (7.9)	5 (14.3)	
Female	19 (73.1)	31 (81.6)	32 (84.2)	31 (86.1)	0.586
Ever-married	22 (84.6)	31 (81.6)	31 (81.6)	31 (83.3)	0.940
Education					<0.001
None/ Primary	13 (50.0)	11 (30.6)	3 (7.9)	0 (0.0)	
Secondary	10 (38.5)	10 (27.8)	8 (21.1)	9 (25.7)	
Tertiary	3 (11.5)	13 (36.1)	22 (57.9)	25 (74.1)	
Others	0 (0.0)	2 (5.6)	5 (13.2)	1 (2.9)	
English-speaking	18 (69.2)	31 (81.6)	34 (89.5)	34 (94.4)	0.038
Employment					0.171
Part-time	3 (12.5)	2 (5.9)	2 (5.9)	3 (8.6)	
Full-time	7 (29.2)	13 (38.2)	17 (50.0)	20 (57.1)	
Retired	12 (50.0)	9 (26.5)	9 (26.5)	8 (22.9)	
Homemaker/ Others	2 (8.3)	10 (29.4)	6 (17.6)	4 (11.4)	
Previous telemedicine experience	8 (11.3)	19 (26.8)	27 (38.0)	17 (23.9)	0.009

*Between-cluster differences were assessed using the one-way ANOVA for continuous variables and the chi-square test for categorical variables.

Cluster 3 (C3) (n=38, 23.8%) was open to remote care but demonstrated low digital self-efficacy. 38.0% reported active use of telemedicine but 97.3% lacked confidence in navigating online health information effectively. This cluster reflected a mismatch between willingness to engage with telemedicine and the digital skills required to do so.

Cluster 4 (C4) (n=36, 22.5%) demonstrated high telemedicine literacy, minimal difficulty using digital tools, and strong preference for remote care when appropriate. Notably, 94.4% agreed that time and cost savings positively influenced their decision to use telemedicine, and 97.2% preferred remote consultations over delays in care. This cluster exemplified a confident, proactive user group capable of navigating digital healthcare environments.

Demographic comparisons revealed differences between clusters. C1, the oldest group (mean age: 68.0±10.4 years), had the highest proportion of participants with only primary or no formal education (50.0%). In contrast, C4, the youngest group (mean age: 51.5±15.7 years) had the highest proportion of participants with tertiary education (74.1%). Additionally, English proficiency differed across clusters, ranging from 69.2% in C1 to 94.4% in C4 (p=0.038).

Conclusion: Four distinct patient clusters were identified, reflecting a spectrum of telemedicine readiness. Cluster membership was primarily shaped by patients' digital confidence and eHealth literacy. Our findings support targeted efforts to boost digital literacy and confidence, especially among older adults and those with less formal education.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0357–0386) Patient Outcomes, Preferences, & Attitudes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Residual fatigue highlights an unmet prevalent[1] need in rheumatoid arthritis (RA) patients despite achieving remission of disease activity according to activity indices (DAS28).

We examine associated factors that may explain residual fatigue in RA patients according to two types of predefined clinical remission and compare them.

Methods: Patients with RA (EULAR/ACR, 2010), excluding chronic fatigue syndrome, were collected for 6 months from different Rheumatology Services throughout Catalonia (ARCat study group), fulfilling 3 questionnaires:

Table. Associated factors to residual fatigue in patients with remission by SJC/CRP compared with patients in remission by DAS28, only significant data (p<0.05).

	SJC/CRP REM				DAS28 REM			
VARIABLES	VAS Fatigue < 5 (N = 74)	VAS Fatigue ≥ 5 (N = 28)	*p*-value	OR ($IC_{95\%}$)	VAS Fatigue < 5 (N = 74)	VAS Fatigue ≥ 5 (N = 18)	*p*-value	OR ($IC_{95\%}$)

1. MDHAQ: Function (FN, modified HAQ)(1-10), VAS_Pain (0-10), PGA (0-10), VAS_Fatigue (0-10, significant fatigue=VAS_-Fatigue≥5)[2], Review of 60 symptoms (ROS60), self-assessment 48 joint count (sRADAI) and integrated indices: RAPID3 (0-30), FAST3_Pain, FAST3/FAST4_Fatigue, and MDS2.

2. Global FACIT_Fatigue, for fatigue(0-64, indirect score).

3. Global RAID, for the impact of the disease (0-10).

They were studied according to 1. Remission by DAS28ESR< 2.6 (DAS28 REM) and 2. A defined "Inflammatory remission" by SJC=0 and CRP< 0.4mg/dL (=SJC/CRP REM).

Sociodemgraphics variable, evolution of the disease, concomitant rheumatic diseases and comorbidities (depression, anemia, anxiety, hypothyroidism, and diabetes mellitus), and treatments (glucocorticoids, DMARDs, antidepressants) were analyzed. Patient outcomes from questionnaires (PROMs) and joint examinations (TJC28, SJC28), laboratory markers (RF, ACPA, ESR, and CRP), and disease activity composite indices (CDAI, SDAI, and DAS28CRP/ESR) were assessed.

A univariate analysis of the different variables studied was performed on whether VAS_fatigue is ≥5 or not in these patients according to two described types of remission (SJC/CRP REM vs DAS28 REM).

Results: A total of 246 RA non-selected patients were recruited, 77,1% females, mean age of 61.3 ±10.5 years, 17.19 (20.39) years of disease, BMI of 26.5±5 kg/m2, and DAS28ESR=3.47 (1.37). Osteoarthritis (17.1%) and Sjögren Syndrome (11.4%) as concomitant rheumatic diseases, and glucocorticoids (37.4%), bDMARD (45%), Jak inhibitors (13.6%) and antidepressants (15%) treatments were the most frequent.

SJC/CRP REM definition was observed in 102 patients; 28 of them (27.4%) experienced residual fatigue, and 92 patients met remission according to DAS28 REM, 18 (19.5%) reporting residual fatigue.

In clinical disease activity, TJC and SJC, and the composite indices, PROMs scores, were significantly associated with residual fatigue even in both types of studied remission (Table). And SCJ/CRP REM patients showed a significantly higher prevalence of female sex, active smokers, and a history of depression and antidepressants, but not in DAS28 REM. However, antirheumatic DMARDb treatment was associated with fatigue in DAS28 REM (Table).

Conclusion: Clinical disease activity and PROMs scores factors are similar in explaining residual fatigue in both types of defined clinical remission. Moreover, in the group of patients without SJC and with normal CRP, we also must take into account: female sex, smoking, and history of depression.

RAID global	0.796	<0.001	0.756	**<0.001**

We describe and study the characteristics of fatigued patients compared to non-fatigued using the VAS_Fatigue scale (testing in advance as a good tool), and we assessed residual fatigue according to different activity indices in a group of RA patients.

Methods: RA patients (ACR/EULAR criteria, 2010), excluding Chronic Fatigue Syndrome, were included consecutively in different hospitals across Catalonia (ARcat study group) during 6 months, fulfilling 3 qüestionnaires (PROMs):

1. MDHAQ: Function (FN, modified HAQ) (1-10), VAS_Pain (0-10), PGA (0-10), VAS_Fatigue (0-10; fatigue=VAS_Fatigue≥ 5[3]), Review of 60 symptoms (ROS60), self-assessment 48 joint count (sRADAI) and integrated indices: RAPID3 (0-30) for disease activity, FAST3_Pain and FAST3/FAST4_Fatigue for fybromialgia, and MDS2 for depression.

2. FACIT_Fatigue (0-64, indirect score).

3. RAID for impact of the disease (0-10).

Sociodemographic and clinical variables: history of depression, disease duration, treatment (DMARDs and glucocorticoids), joint count exam (TJC, SJC: 0-28), acute reactants (ESR, CRP), immunology (RF, ANA) and activity composite indices (DAS28 CRP/ESR, CDAI, SDAI) were assessed.

Descriptive and bivariate statistical analyses of variables (quantitatives: Student's test, categorical: Chi[2]) comparing fatigued/non-fatigued patients, with a previously Spearman correlation (VAS with FACIT) were performed, and we assessed the frequency of residual fatigue according to disease activity indices.

Results: A total of 246 RA patients (77,1% females) were collected; 61.3±10,5 years, BMI of 26.5±5 kg/m2, disease duration:17.19 (SD:20.39) years and DAS28ESR=3.47 (SD:1.37), treated with glucocorticoids in 52 (37.4%), bDMARD in 63 (45.0%), and Jak inhibitors in 19 (13.6%).

Table 3. Prevalence of fatigued patients in low activity according to the different activity indices studied; (p<0.001).

Patients	DAS28≤3.2 (n=146)	DAS28>3.2 (n=86)	CDAI≤10 (n=185)	CDAI>10 (n=60)	SDAI≤11 (n=183)	SDAI>11 (n=63)	RAPID3≤6 (n=79)	RAPID3>6 (n=167)
Fatigued	**41 (28,1%)**	60 (69.8%)	**61 (33%)**	45 (75%)	**58 (31.7%)**	48 (76,2)%	**5 (6.3%)**	101 (60.5%)
Non Fatigued	105 (71,9%)	26 (30,2%)	124 (67%)	15 (25%)	125 (68.3%)	15 (23.8%)	74 (93.7%)	66 (39.5%)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

A significant level of fatigue (VAS_Fatigue≥5) was found in 106 (43.1%) patients with significant differences ($p< 0.05$) compared to non-fatigued patients in: sex, educational levels, smoking, depression history, disease activity indices, and all of the PROMs scores (Table 1).

A strong negative correlation ($r=-0.82$, $p< 0.001$) was observed between VAS_Fatigue (0-10) and FACIT_Fatigue (0-54), also good for FN, PN, PATGL, sRADAI, ROS60, RAPID3, RAID, and a moderate for TJC and SJC and composite activity indices, and no correlation for ESR and CRP. A similar level of correlation was obtained for FACIT_Fatigue (Table 2).

The presence of residual fatigue (VAS≥5) is less frequent (6,3%; $p< 0.001$) when measuring activity with RAPID3 ≤ 6 than in the rest of the indices. In all of the cases, the differences between the presence or not of fatigue in remission patients were significant (Table 3)

Conclusion: Comorbid fatigue associated with clinical activity, sociodemographics, and PROMs is prevalent in RA patients, and it is feasibly measured by a simple VAS scale included in the MDHAQ. Moreover, the RAPID3 index seems to be the more stringent index to examine residual fatigue.

Abstract Number: 0381

Improving Participation in The Lupus Foundation of America's Research Accelerated by You (RAY) Patient Registry By Understanding Patient Preference in Communication Strategies

Safoah Agyemang[1], Melicent Miller[1], Tori Justin[2], Lydia Oberholtzer[2] and Joy Buie[1], [1]Lupus Foundation of America, Washington, DC, [2]Sharp Insight LLC, Montgomery County, MD

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0357–0386) Patient Outcomes, Preferences, & Attitudes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: The purpose of Research Accelerated by You (RAY) is to amplify awareness about clinical research and trials and ensure lupus patient partnership in therapeutic development. However, Black/ African Americans (B/AA) make up only 16% of RAY participants, a notable disparity as B/AAs account for 30-43% of the lupus population. To address the lack of representativeness in race/ethnicity amongst B/AA in RAY, we explored B/AA motivations and communications preferences driving registry enrollment decision-making.

Methods: We conducted two focus groups with people living with lupus (PWL) who were already enrolled in RAY or a part of the Lupus Research Action Network (LRAN), a patient peer-to-peer network, but not enrolled in RAY. All focus group (FG) participants were B/AA females aged 25-46 years (n=4 each). Key informant (KI) interviews were also conducted with

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. How KIs navigate barriers to enrollment

To boost RAY enrollment of the target audience (i.e., B/AA ages 18-35) KIs offered a wide range of suggestions such as:

	Promoting RAY at historically black colleges and universities (HBCUs) and partnering with student health services to reach potential patients: *"Considering working with HBCUs and student health services on campus."* – KI 2
	Showcasing how the RAY and clinical trials are useful for the Black/African American population: *"Some of my patients were reluctant until I mentioned the results or research in Black patients."* –KI 1
	Engaging pediatric rheumatologists: *"One more thing about that transitioning pediatric population. If RAY is not already being advertised and promoted with pediatric rheumatology, I would do so. They actually do see a lot of those patients that are 18 to 21, [and] sometimes they see them until they're 26 and that's when you are removed from your parent's insurance. So, I would certainly engage pediatric rheumatologists and getting the word out about [RAY]."* – KI 2

When promoting RAY, participants also suggested:

	Letting users know what LFA is doing with the data and providing feedback to those who complete surveys: "People are more likely to respond to survey if they get feedback. Let them know what they're doing with the data." —KI 1
	Writing promotional messages that illustrate how the patient benefits from enrollment. These messages should be person-centered and emphasize how participation helps the patient and their community, not the research team: *"RAY needs to be clear that it serves the patients, not the research objectives."* –KI 3

PWL with no affiliation with the Lupus Foundation of America (LFA)(n=1) and registry directors at academic medical centers (n=3). Audio-recordings were transcribed and cleaned using Otter.ai. Manual content analysis followed an inductive approach, allowing themes to emerge from data rather than predetermined categories for FGs and KIs. Resulting themes with exemplary quotes are presented in Tables 1-4.

Table 2. Perceptions of RAY Communication Materials and RAY Marketing Infographics

Model Images	Likes	Recommendations for Improvement
	"Purple and white stand out nicely. Language feels welcoming." – RAY participant *"I like the word "share" and "lupus experience". The model looks like the target audience."* –KI 3	*"Hard to depict if the woman has lupus".* – RAY participant *"Looks racially ambiguous. Looks like trying to please everyone not Black people."* –LRAN participant *"Use a Black lupus patient. I have a friend where lupus is affecting the face, to me that would make me want to share my experience."* –LRAN participant *"Consider showing external lupus features."* – KI 1 *"This may be too many words, but I want to add in something at the end, 'sharing your lupus experience so we can conquer lupus!'"* – KI 2
	"This woman doesn't seem smiley which is good. I would click on this. It is vague but the picture is more inviting."— RAY participant *"This would appear more targeted to Lupus community. And, I like the "Share Your Lupus Experience." She is more focused and looking at the lupus itself and trying to tackle it."* – RAY participant	
	"It is important to show different ethnic backgrounds so this caters to everyone." – RAY participant	*"Not sure if that's freckles or rash or scar; I would not pick freckled person. Not the right model for this demographic; need to have hat or something to show that they are protecting their skin."* –KI 1 *"Maybe have a model with rash and show it on different black skin shades with texture; thinning of the hair, swelling around eyes. Show an activity of mom having to stay in shade but kids are in the sun."*–KI 3

Infographics	Likes	Recommendations for Improvement
	"I like the information better than the models. The words make me want to help in some way. I like the data approach. This makes me feel like I'm not doing my part." – LRAN participant *"I like the 10% especially."* – LRAN participant	*"The test tube is a symbol of research but it looks like you are asking them to give blood; participation is survey related. Add pen to paper instead of test tube image."* – KI 1 *"The first image is incorrect, there are 5 FDA approved treatments not 3."* –KI 3
	"I like the information; this would make me want to sign up." – LRAN participant. *"I like the quick facts; they can educate someone in less than 10 seconds."*— LRAN participant	*"There should be a conclusion image here. Put the call to action here. Missing how lupus makes you feel."*— Non-affiliated participant *"Add other organs like kidneys; add cognition and brain function. I would like to see other non-common factors. Add sex drive and sexual organs that are less talked about."* – LRAN participant *"Include kidney, more frequent than eye and muscles. Skin, joints and kidney will capture most patients."* – KI 1

Table 3. Digital Advertising Copy

Digital Advertising Copy	Likes	Recommendations for Improvement
RAY: Research Accelerated by You is an online research platform where people with lupus and caregivers share their experiences to help develop new treatments. Sign up today for this online lupus registry and help accelerate lupus research.	*"I like that it [the message] has caregivers."* – LRAN participant *"I like that it [the message] is straight forward."* –Non-affiliated participant	*"Bullet the messages, make them more concise."* – KI 2
Lupus is a cruel mystery—but together, we can solve it. With RAY: Research Accelerated by You, people with lupus and caregivers can share their experiences on an online data platform to help develop new treatments. Sign up today to be the solution to lupus!	*"This message shows community and teamwork."*—KI 2 *"This resonates with me. I like how it says 'develop new treatments'."*—LRAN participant	*"[This message is] not patient focused for this group; there is no trust here. The primary benefactor is the researchers, not the people with lupus."* – KI 3
We're on a mission to end the brutal impact of lupus. And YOU are the key to developing better treatments. We created a data platform called RAY: Research Accelerated by You to help develop new treatments. Sign up for RAY today and share your lupus experience to guide research.	*"I like how this message centers 'YOU'."* – LRAN participant *"[It is] important to have various messages that speak to a variety of people."*—KI 2	*"Brutal is a strong word. Don't replace it just state 'impact'."* – Non-affiliated participant
#DYK: 7 in 10 survey participants responded that lupus has impacted multiple organs. What about you? Share your experience through our online research platform, RAY: Research Accelerated by You. When you sign up today, see how your experience compares to others and help advance lupus research!	*"I like the comparison aspect."* – RAY participant	*"I don't like the DYK. The older Black PWL may not get the DYK."* –LRAN participant *"DYK is not a popular hashtag, so many may not know what this means."* – KI 2
You can help advance lupus research and treatments! And it's easy. Join our online lupus registry, RAY: Research Accelerated by You, and share your lupus experience to help researchers develop new treatments. Sign up today!	*"Sounds more conversational. Like the conversational approach. More energy here."* – LRAN participant	*"RAY needs to be clear that it serves the patients, not the research objectives. Especially about depression, brain fog, and fatigue. Consider clearly stating the clinical trial measures, such as suicide, quality of life, and sometimes depression."* – KI 3 *"Take out 'easy'."* –RAY participant *"Add specific language and facts related to target population."*—KI 2

Results: Three overarching themes emerged:

1.Communication Preferences: Participants receive most of their lupus information from the LFA's emails, social media, and website, in addition to email/text alerts from other research institutions. Furthermore, some participants also noted that their family members/friends have sent them lupus materials; however, most shared they **prefer** to receive lupus-related information from their healthcare team.

2.Building Trust and Rapport: KIs mentioned this theme as essential to encouraging registry and clinical trial enrollment. To build rapport, KIs discussed the importance of speaking with patients face-to-face about enrollment, educating potential participants about patient protections, and explaining the history of mistrust as it relates to the medical profession and the B/AA community in the U.S.

3.Curating Messages/Imagery that Resonate: After reviewing RAY marketing materials, participants stated models who look indisputably like the target audience (i.e., B/AA PWL) are preferred. Additionally, some participants mentioned they prefer the models to feature lupus symptoms such as having a "rash" or "swelling around the eyes." Participants preferred messaging demonstrating how RAY benefited the patient rather than the researcher, and they favored clear and straightforward content. To improve messaging, participants suggested avoiding the notion that lupus is "easy" and adding language centering the target population.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: B/AA PWL may be more inclined to enroll in registries and clinical trials if they receive clear and transparent information from their healthcare team about the benefits and risks of participation, particularly as they relate to B/AA PWL. Centering the experience of B/AA PWL in registry and clinical communication materials is a key theme of importance to potential study participants and may improve enrollment in the registry.

Abstract Number: 0382

Preventative Health Screening Practices Among 666 Women with Systemic Rheumatic Diseases from the Hospital for Special Surgery Rheumatology Women's Reproductive Health and Wellness Cohort: A Cross-Sectional Analysis

Sandhya shri Kannayiram[1], Amaya Smole[2], Lucy Masto[3], Yongjay Kim[4], Neha Nagpal[1], Naiva Manuela Piatchou Donfack[1], Deanna Jannat-Khah[1], Lisa Mandl[1], Sarah Lieber[1], Caroline Siegel[1], Michael Lockshin[5], Lisa Sammaritano[1] and Medha Barbhaiya[1], [1]HOSPITAL FOR SPECIAL SURGERY, New york, NY, [2]Hospital for Special Surgery, Brooklyn, NY, [3]Hospital for Special Surgery, San Francisco, CA, [4]Hospital for Special Surgery, Englewood Cliffs, NJ, [5]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0357–0386) Patient Outcomes, Preferences, & Attitudes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Timely preventative health screenings in women with systemic rheumatic diseases (SRDs), especially those with other chronic conditions or who are on immunosuppressive therapy, may improve outcomes through early detection. This study aimed to identify demographic, lifestyle, disease-related, and healthcare utilization factors associated with delayed preventative health screenings in this population.

Methods: We included women aged 18-65 evaluated at Hospital for Special Surgery (HSS) by a rheumatologist ≥2 times who enrolled in the HSS Rheumatology Women's Reproductive Health and Wellness Cohort between 12/2022- 5/2024 and completed a standardized questionnaire on their preventative health screening status. Patients reported being "due or overdue" for six screenings: colon, breast, cervical, and skin cancers; bone density; and retinal (eye) toxicity screening. We evaluated the degree of delay and the reasons for delay. Descriptive analyses compared demographics, lifestyle factors, SRD status, medication use, and healthcare utilization for patients "due/overdue" versus those not due/overdue for the screenings. Multivariable logistic regression analyzed factors associated with being due/overdue for each screening.

Results: Among 666 women included in this cross-sectional analysis, increased age was associated with being due/overdue for colon, breast, and skin cancer, as well as bone density screening, and patients with 'other' or Black race, but not White race were more frequently due/overdue for bone density screenings **(Table 1)**. Hispanic versus non-Hispanic women were more frequently due/overdue for breast (21% vs. 11%) and eye toxicity screenings (20% vs. 11%). Ever smokers were also more likely to be due/overdue for breast, cervical, skin cancer, bone density, and eye toxicity screenings than non-smokers, and SRD status was significantly different only for eye toxicity screenings**(Table 1)**.In multivariable analyses, factors associated with being due/overdue for a particular screening test included: increased age (OR=1.04, 95%CI 1.02–1.07) for colon cancer; increased age (OR=1.04, 95%CI 1.02–1.06), Hispanic ethnicity (OR=2.40, 95% CI 1.27–

Figure: Degree of Delay in Health Screenings Among 666 Women with Systemic Rheumatic Diseases Enrolled in the Rheumatology Women's Reproductive Health and Wellness Cohort between 2022 -2024

4.47), and < 1/year gynecology visits (OR=2.03, 95% CI 1.2–3.3) for breast cancer; ever smoking (OR=1.96, 95% CI 1.14-3.35) and < 1/year gynecology visits (OR=3.70, 95% CI 2.2–6.1) for cervical cancer; increasing age (OR=1.06, 95% CI 1.03–1.09) and 'Other' vs. white race (OR=4.36, 95% CI 2.13-8.87] for bone density; and ever smoking(OR=2.57, 95 % CI 1.37-4.81), CTD status (OR=2.30, 95% CI 1.3–4.03) and unemployment(OR=1.97, 95% CI 1.3–4.8) for eye toxicity screening **(Table 2)**. Degrees of self-reported delays were most typically < 1 year **(Figure)**. The most common reasons for delay were forgetfulness and scheduling difficulty (data not shown).

Conclusion: Preventative health screening delays in a cohort of women with SRDs were influenced by age, Race, Ethnicity, smoking history, CTD diagnosis, employment status, and infrequent gynecology visits. Targeted strategies are needed to improve adherence to suggested screenings and thereby reduce health risks in this vulnerable population.

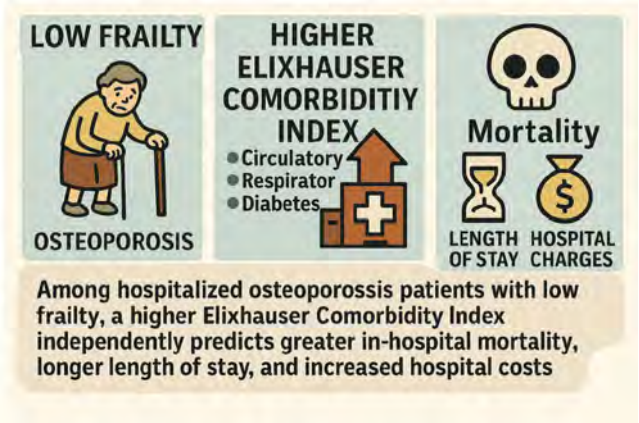
Background/Purpose: Osteoporosis is a common condition associated with increased morbidity, particularly in older adults. While frailty is a known predictor of adverse outcomes, the independent impact of comorbidities in patients with low frailty is not well defined. This study evaluated the association between the Elixhauser Comorbidity Index and in-hospital mortality among hospitalized osteoporosis patients with low frailty and examined differences in hospital utilization and demographics.

Methods: We conducted a retrospective, survey-weighted analysis using the Nationwide Readmissions Database (2016–2022) to identify hospitalized adult (>18 years) patients with osteoporosis and low frailty scores (≤5). A total of 1,378,142 patients met inclusion criteria and were categorized by the Elixhauser Comorbidity Index: < 3 vs. ≥3. Multivariable logistic regression, adjusted for sex and weekend admission, was used to evaluate the association between comorbidity burden and in-hospital mortality.

Results: Of the 1,378,142 patients included, 775,034 (56.2%) had a high Elixhauser Comorbidity Index (≥3), of whom 88.0% were female. Table 1 outlines the distribution of individual Elixhauser comorbidities across both groups. In-hospital mortality was significantly higher in the high comorbidity group (0.71% vs. 0.23%; p< 0.001). In adjusted analysis, a higher Elixhauser Comorbidity Index was significantly associated with increased odds of in-hospital death (aOR 1.31; 95% CI: 1.29–1.33; p< 0.001). Patients with greater comorbidity burden had longer hospital stays (3.8 vs. 3.1 days; p< 0.001) and higher mean hospital charges ($61,938 vs. $59,837; p< 0.001) Figure 1.



Conclusion: Among hospitalized osteoporosis patients with low frailty, a higher Elixhauser Comorbidity Index independently predicts greater in-hospital mortality, longer length of stay, and increased hospital costs. These findings emphasize the importance of comorbidity assessment for risk stratification and care planning, even in patients considered low-risk by frailty measures.

Abstract Number: 0384

Hip Fracture Hospitalization Trends in Osteoporotic Patients (2016–2022): National Data Insights

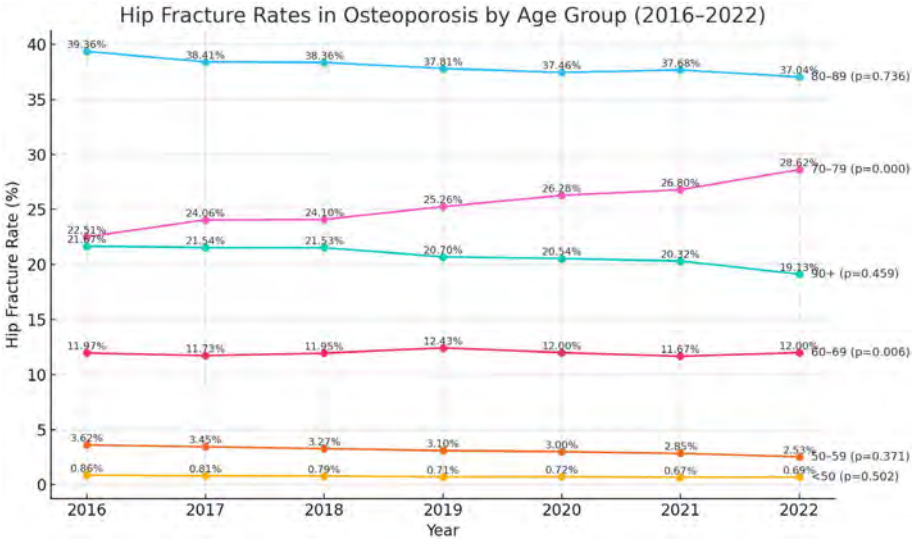
Simran Bhimani[1], Anand Reddy Maligireddy[2], Sameer Bhimani[3] and Birju Bhatt[4], [1]The Wright Center for graduate medical education, Scranton, PA, [2]The Wright Center GME, Scarnton, PA, [3]The Wright Center for GME, scranton, PA, [4]Solara Health NJ, New Jersey, NJ

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0357–0386) Patient Outcomes, Preferences, & Attitudes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Hip fractures in patients with osteoporosis are a major contributor to morbidity, mortality, and healthcare costs. While classically associated with the oldest patients, emerging trends suggest that younger elderly adults may now bear a growing share of the burden. We evaluated age-stratified trends in hip fracture hospitalizations and in-hospital mortality among osteoporotic adults in the United States.

Methods: We conducted a retrospective cohort study using the National Readmissions Database (NRD) from 2016 to 2022. We included adult patients hospitalized with osteoporosis and identified those with a primary discharge diagnosis of hip fracture using ICD-10 codes. Patients were stratified into age groups: < 50, 50–59, 60–69, 70–79, 80–89, and ≥90 years. Survey-weighted logistic regression was used to evaluate temporal trends in hip fracture hospitalizations and in-hospital mortality, comparing 2022 to 2016 within each age group.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Results: Among 5,040,169 weighted osteoporosis-related hospitalizations, 392,615 (7.8%) were for hip fractures. The 70–79 age group showed the most significant increase in hip fracture hospitalizations, rising from 22.5% in 2016 to 28.6% in 2022. Odds of hip fracture rose by 13% in this group (OR: 1.13, 95% CI: 1.06–1.20, $p < 0.001$). The 60–69 group also demonstrated a significant increase (OR: 1.12, $p = 0.006$) Figure 1. Despite these increases, in-hospital mortality rates remained unchanged across all groups Figure 2.

Conclusion: From 2016 to 2022, adults aged 70–79 with osteoporosis experienced a significant rise in hip fracture hospitalizations without increased in-hospital mortality, reflecting improved acute care. Proactive screening, earlier risk assessment, and fall prevention efforts targeting adults in their 60s and 70s may be critical in curbing the growing hospitalization burden in this increasingly vulnerable population Figure 3.

Musculoskeletal Ultrasound Enhances Patient Insight and Clinical Decisions: A Multi-Center Study

Simran Nimal[1], Meridith Balbach[2], Aslam Fawad[1], Midori Nishio[3] and Erin Chew[2], [1]Mayo Clinic Arizona, Scottsdale, AZ, [2]Vanderbilt University, Nashville, TN, [3]John Muir Specialty Medical Group, Lafayette, CA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0357–0386) Patient Outcomes, Preferences, & Attitudes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Musculoskeletal ultrasound (MSKUS) is a valuable tool for early detection and management of inflammatory arthritis.(1) Although integrated into rheumatology guidelines, training programs, and classification criteria, its impact on patient perceptions and shared decision-making is underexplored.(2, 3) We hypothesized that MSKUS improves patient understanding of disease and enhances provider confidence in management.

Methods: This prospective cohort study at 2 academic centers enrolled patients with undifferentiated joint pain referred for MSKUS between August 2023 and June 2024. Institutional review board (IRB) approval was obtained at one site and deemed exempt at the other. Patients completed pre- and post-MSKUS visit surveys assessing understanding of joint pain etiology, perceived need for treatment change, evaluation thoroughness, and treatment adherence likelihood. Referring providers completed pre- and post-surveys on MSKUS indication, immunosuppression, confidence in treatment plan, and perceived MSKUS utility. Responses, recorded on a 5-point Likert scale, were analyzed using descriptive statistics and paired t-tests.

Results: A total of 109 patients and 53 provider surveys were analyzed. Table 1 shows the rheumatologic disease diagnoses and MSKUS referral indications. The mean scores and standard deviations (SD) for key outcomes are as follows: Post-MSKUS, understanding of the ultrasound purpose significantly improved, with scores (1 = very poorly, 5 = very well) increasing from 4.339 (SD = 0.841) to 4.688 (SD = 0.588), $p < 0.001$. Understanding of joint pain cause improved, with scores rising from 3.449 (SD = 1.312) to 4.046 (SD = 1.109), $p < 0.001$. Most patients felt their problem had been more thoroughly

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1: Rheumatologic diagnosis and purpose of musculoskeletal ultrasound (MSKUS) referral.

Table 1a: Breakdown of diagnosis

Diagnosis	n (%)
Rheumatoid arthritis	20.8%
Undiagnosed	17.9%
Osteoarthritis	15.5%
Systemic sclerosis	11.9%
Carpal tunnel syndrome	7.7%
Trigger finger	6.0%
Psoriatic arthritis	4.2%
Fibromyalgia	3.6%
Osteoporosis	3.6%
Gout	3.0%
Sjogren's syndrome	3.0%
Systemic lupus erythematosus	2.4%
De Quervains tenosynovitis	1.8%
Pseudogout	1.8%
Ankylosing spondylitis	1.2%
Reactive arthritis	1.2%
Baker's cyst	0.6%
Juvenile idiopathic arthritis	0.6%
Overlap syndrome	0.6%
Vasculitis	0.6%

Table 1b: Purpose of MSKUS referral

(Percentages >100% due to multiple indications)

Purpose	n (%)
Assess disease activity and/or therapeutic response	39.6%
Help make, confirm, or clarify a specific diagnosis	58.5%
Improve patient's disease understanding, medication compliance, or assist with shared decision making	15%

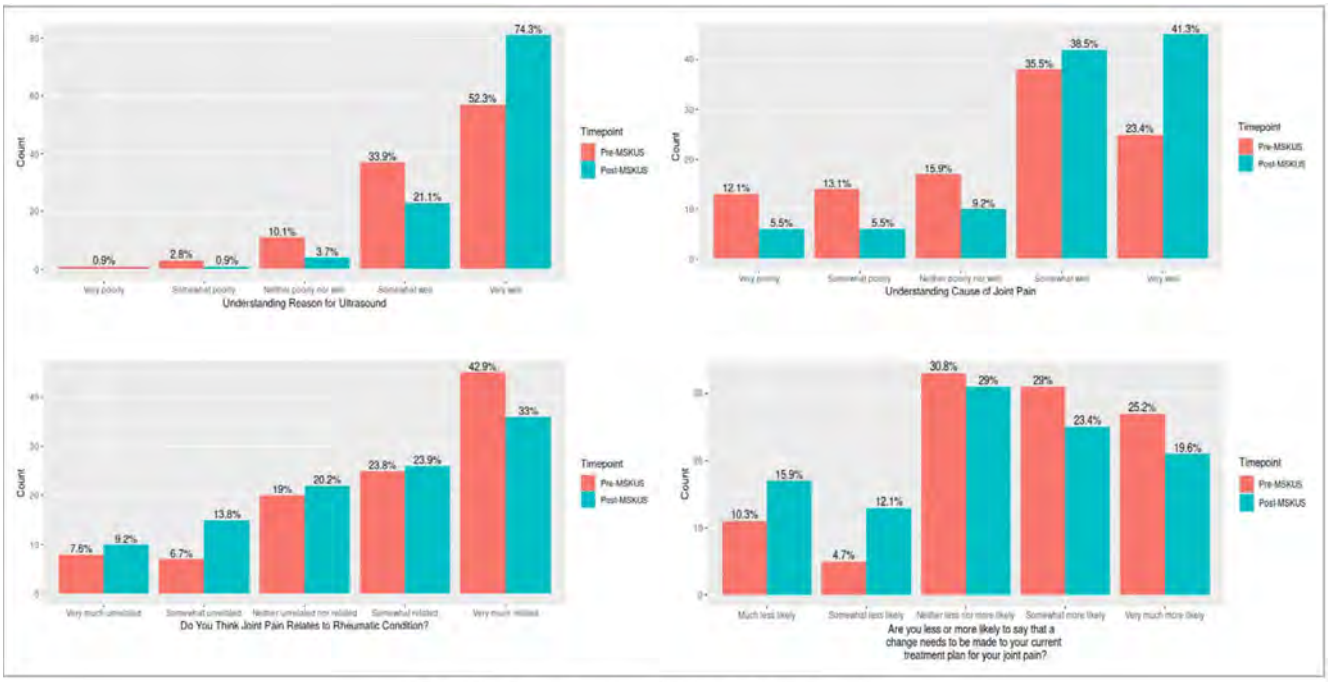

Figure 1: Effect of musculoskeletal ultrasound on patient perceptions

Figure 1: Effect of musculoskeletal ultrasound on patient perceptions.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2: Effect of musculoskeletal ultrasound on provider treatment plans

Figure 2: Effect of musculoskeletal ultrasound on provider treatment plans.

examined (94.4%) and reported to be more likely to adhere to their provider's treatment plan (75.7%). Post-MSKUS, patients were less likely to feel a need for treatment change, with scores (1 = much less likely, 5 = very much more likely) decreasing from 3.542 (SD = 1.215) to 3.187 (SD = 1.326), p = 0.006. There was a modest decline in attributing joint pain to rheumatic disease, with scores (1 = very much unrelated, 5 = very much related) decreasing from 3.876 (SD = 1.253) to 3.578 (SD = 1.321), p = 0.047. Among 15 referring providers reporting on 53 patients referred for MSKUS, confidence in treatment plans increased from 3.415 (SD = 0.795) to 4.792 (SD = 0.454), $p < 0.001$. with 32.1% changing management based on ultrasound findings.

Conclusion: Real-time MSKUS is an effective educational tool that supports shared decision-making and strengthens provider confidence in personalized treatment planning. These findings support its broader integration into routine rheumatologic care.

Abstract Number: 0386

Introducing the Multidimensional Pain Inventory as a Comprehensive Tool or Assessing Pain in Patients With Axial Spondyloarthritis

David Kiefer[1], Yade Sonkaya[2], Dietmar Krause[3], Markus Voglau[4], Bernhard Mintrop[5], Imke Redeker[6], Xenofon Baraliakos[7] and **Uta Kiltz**[7], [1]Ruhr-Universityt Bochum; Private practice of rheumatology, Hattingen, Germany, Herne, Germany, [2]Ruhr-Universität Bochum, Herne, Germany, [3]Elisabeth-Gruppe, Herne, Germany, Essen, Germany, [4]myself, Oldenburg, Germany, [5]Private rheumatology practice, Hattingen, Germany, [6]Ruhr University Bochum, Bochum, Germany, [7]Rheumazentrum Ruhrgebiet Herne, Ruhr-University Bochum, Herne, Germany

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0357–0386) Patient Outcomes, Preferences, & Attitudes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: The West Haven-Yale Multidimensional Pain Inventory (MPI) is a validated tool designed to assess the multidimensional aspects of chronic pain, including the 5 dimensions of pain: pain-related life interference, pain severity, affective distress, social support and life control. Originally developed in the US, the MPI has been successfully adapted and validated in German-speaking populations [1]. Chronic pain in rheumatic diseases often involves nociplastic and central sensitization mechanisms components. Therefore, the MPI, with its biopsychosocial framework, offers an opportunity to explore dimensions of pain in patients with axial spondyloarthritis (axSpA).

Our aim was to assess the construct validity of the MPI by examining its correlations with patient-reported outcomes (PRO) in the Assessment of SpondyloArthritis international Society-Outcomes Measures in Rheumatology (ASAS-OMERACT) core domain set for clinical trials in axSpA [2].

Methods: The five MPI dimensions were assessed in axSpA patients with a pain score ≥ 4 (NRS 0-10) and results were correlated with the ASAS-OMERACT core domain set, including disease activity (ASDAS, CRP, BASDAI, patient global assessment (PtGA) of disease activity, physical function (BASFI), health-related quality of life (ASAS Hi, of the SF36 MCS/PCS), total back pain, morning stiffness, and spinal mobility (BASMI) as well as demographic and clinical data using Pearson´s correlations. Correlations were classified as weak (r≥0.1), moderate (r≥0.3), and strong (r≥0.5).

Results: 136 patients with axSpA were included and the MPI was completed by 109 (80.2%) patients (table 1). Pain-related life interference showed significant strong correlations with ASDAS, BASDAI, BASFI, PCS, fatigue and total back pain while moderate correlations were found for PtGA of disease activity, MCS, morning stiffness, and BASMI. For pain severity, significant strong correlations were observed with ASDAS, BASDAI and total back pain. Moderate correlations were found with PtGA of disease activity, BASFI, PCS and fatigue, weak correlations were found with MCS, ASAS HI and morning stiffness. Affective distress showed strong correlations only with MCS and weak or moderate correlations with all other assessments, while social support only showed a weak correlation with the PCS and the BASMI. For life control, a strong positive correlation was only found with MCS whereas moderate negative correlations were found with PtGA of disease activity and total back pain and weak negative correlations with ASDAS, BASDAI, BASFI, ASAS HI and fatigue.

Conclusion: The MPI provides valuable insights into the multidimensional aspects of pain in axSpA. Pain-related life interference and severity demonstrated strong correlations, while affective distress and life control showed weak to moderate correlations with the ASAS core domain set and thereby demonstrating construct validity. Apart from a weak correlation of social support with the PCS, the domains of social support and life control are not yet fully captured in the axSpA core domain set or other commonly used PROs in axSpA trials.

Abstract Number: 0387

Association Between Juvenile Arthritis and Physical Activity Levels in U.S. Children: A Cross-sectional Study Using the 2016–2021 National Survey of Children's Health

William Soulsby[1] and **Carolina Tamashiro**[2], [1]University of California, San Francisco, San Francisco, CA, [2]UCSF, San Francisco, CA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Juvenile arthritis (JA) is characterized by joint pain, stiffness, and decreased mobility, potentially affecting participation in physical activity (PA). Current guidelines from the CDC and WHO recommend that children engage in at least 60 minutes of PA daily. While research in PA level and JA has been conducted in European countries, data on physical activity levels among children with arthritis in the United States remain limited. It is not well understood whether U.S. children with arthritis meet recommended PA targets or how PA engagement relates to their broader health outcomes. This study aims to assess whether a current diagnosis of arthritis is associated with lower PA levels among a nationally representative sample of U.S. children and adolescents.

Methods: This cross-sectional analysis assessed adherence to daily PA recommendations among U.S. children with JA compared to peers without JA, using 2016–2021 National Survey of Children's Health (NSCH) data, a nationally representative survey that investigates health of pediatric population in the U.S. Univariable and multivariable logistic regression models examined the association between JA and meeting daily PA recommendations. A sensitivity analysis using ordinal logistic regression assessed PA frequency ("0 days," "1–3," "4–6," "daily"). Models were adjusted for potential confounders like age, sex, race, ethnicity, and socioeconomic status.

Results: Children with JA were less likely to meet daily PA recommendations than peers without arthritis (13.5% vs. 17.0%; $p = 0.05$) and had higher rates of obesity (23.3% vs. 13.9%; $p < 0.001$), physical limitations, pain (69.9% vs. 10.3%; $p < 0.001$) and comorbidities (55.2% vs. 30.6%; $p < 0.001$). However, in adjusted analyses, arthritis was not significantly associated with meeting PA guidelines (aOR = 1.34; 95% CI: 0.78–2.32; $p = 0.29$). Similarly, arthritis was not significantly associated with PA level in ordinal logistic regression (aOR = 1.17; 95% CI: 0.81–1.69; $p = 0.41$). Female sex, older age, presence of mental health conditions, and obesity (aOR for ≥95th percentile = 0.64; 95% CI: 0.52–0.78), were negatively associated with PA. Sports participation was strongly associated with meeting guidelines for PA (aOR = 1.58; 95% CI: 1.44–1.74; $p < 0.001$)

Conclusion: In a large nationally representative U.S. sample, children and adolescents with and without arthritis demonstrated low adherence to the CDC and WHO-recommended PA levels. Overall, arthritis was not found to be a statistically significant predictor of PA levels in unadjusted or adjusted analyses. These findings might suggest that while arthritis poses challenges, it may not be a key independent barrier to PA. Efforts to increase PA should address modifiable barriers like obesity and mental health, and promote sports participation, especially among older children with JA.

Background/Purpose: Systemic autoimmune rheumatic diseases (SARD) include systemic lupus erythematous (SLE), idiopathic inflammatory myositis (IIM), systemic sclerosis (SSc), Sjögren syndrome (SS), and systemic vasculitis (SV). Patients with childhood-onset SARD (ChildSARDs) develop disease during years of growth and organ maturation, which can result in unique influences on outcomes. We aim to assess disease outcomes of adults with ChildSARDs.

Methods: With an academic librarian, we developed a peer-reviewed search strategy using MEDLINE and Embase for English articles (1 January 1990 to 30 June 2023). We tested our searches against 26 known articles on adult outcomes in ChildSARDs to confirm and refine search coverage. Childhood-onset of disease was defined by authors (< 14-18 years old). Studies with mixed populations (e.g. adolescent-adult, childhood, adult-onset) were excluded if: i) ChildSARDs adult outcomes were not reported separately, ii) studies primarily focused on non-clinical outcomes. Studies were graded for risk-of-bias using the Quality in Prognosis Studies (QuiPS) tool. Two reviewers independently graded studies before meeting to reach consensus. Any disputes were resolved by a third reviewer.

Results: The search identified 6848 papers, of which 40 met study criteria. No study meeting criteria was published before 2000, 4 (10%) between 2001-2010, 24 (60%) between 2011-2020, and 12 (30%) between 2021-2024. Most studies were conducted in Europe (43%) and North America (28%). 60% of studies were SLE, 25% IIM, 8% SSc, 5% SV, and 0% SS. 27 (68%) publications were cross-sectional in design. Commonly reported outcomes included disease activity (48%), accumulated damage (40%), cardiovascular (33%), and mortality (23%). Mean disease duration ranged from 5.5-23.9 years (N=18), and median disease duration ranged from 8.08-29 years (N=11). QuiPS identified a moderate to high risk-of-bias in the following domains: 95% of study participation, 92% of study attrition (N=13, non-cross-sectional studies), 40% of prognostic factors, 70% of outcomes, 95% of confounding, 73% of statistical analysis.

Conclusion: There is growing interest in adult outcomes of ChildSARDs but data is still relatively scarce. The majority of studies demonstrated moderate to high risk-of-bias in multiple study domains. Researchers should commit to reporting outcomes using standard disease outcome measurements to help accumulate evidence. Investigators planning studies of adult outcomes of ChildSARDs should consider bias reduction measures during the design stage and acknowledge limitations where biases cannot be substantially reduced. Readers should be aware of design limitations when interpreting results from current studies.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: To improve the current classification criteria for juvenile idiopathic arthritis (JIA), a multi-step initiative coordinated by PRINTO was launched in 2015, starting with a consensus process that culminated in the proposal of the preliminary PRINTO JIA classification criteria. The steps include a large-scale prospective data collection of patients with new-onset JIA and the ongoing validation of evidence-based criteria. To initiate the validation phase, an international Delphi survey was conducted among pediatric rheumatologists to identify the most relevant categories and candidate variables for subsequent data collection.

To identify consensus-based categories and variable sets for the evidence-based revision of JIA classification criteria.

Methods: An invitation to participate in two Delphi rounds was sent to PRINTO/PRCSG membership starting in 2020.

In Round 1, participants evaluated each ILAR category plus the additional category 'Early Onset ANA Positive Arthritis', indicating whether to retain or discard it, and suggesting revised names. They also listed variables used in practice to diagnose each category.

In Round 2, participants re-evaluated each category for retention and ranked the top three preferred names and the ten most useful variables for the category-specific diagnosis among those identified in Round 1. Based on the ranking, a median score for each variable was calculated. Variables falling above the 75th percentile of the score were identified for each category.

Results: 434 physicians responded in Round 1 and 884 in Round 2. Votes to retain the ILAR categories were 236 (73%) for Systemic arthritis, 218 (70%) for Oligoarthritis, 209 (69%) for Polyarthritis Rheumatoid Factor (RF) negative, 276 (92%) for Polyarthritis RF positive, 188 (66%) for Psoriatic arthritis, 225 (78%) for Enthesitis-related arthritis (ERA), 183 (67%) for Early-onset ANA-positive JIA, and 142 (53%) for Other arthritis.

Top ranking labels for each new category were 'Juvenile-onset Still disease', 'Oligoarticular JIA', 'Juvenile polyarthritis', 'JIA RF positive or anti-CCP positive', 'Juvenile psoriatic arthritis', 'Early onset spondyloarthritis', 'ANA positive juvenile arthritis' and 'Unclassified JIA'.

The variables identified as most useful for the diagnosis (in the top quartile of the score) were 15 for Systemic arthritis, 31 for Oligoarthritis, 33 for Polyarthritis RF negative, 33 for Polyarthritis RF positive, 45 for ERA, 26 for Psoriatic arthritis, 27 for Early-onset ANA-positive JIA and 19 for Other arthritis.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: The study yielded consensus-based categories to be considered in the new classification criteria and identified candidate variables to be included in the ongoing step of the project, namely the evidence-based validation of new classification criteria for JIA based on real new-onset patients' data.

Radiographic Assessment in Juvenile Spondyloarthritis: Evaluating the axJSpA Criteria Using Radiographs Alone Versus MRI

David M. Biko[1], Nancy A. Chauvin[2], Michael Francavilla[3], Nele Herregods[4], Walter P. Maksymowych[5], Robert G. W. Lambert[6], Timothy Brandon[1], Ozgur Kasapcopur[7], Mehmet YILDIZ[8], Hemalatha Srinivasalu[9], **Pamela Weiss**[10] and the Juvenile Axial Spondyloarthritis Research Taskforce (JAxSpRT), [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]The Cleveland Clinic, Hummelstown, PA, [3]Department of Pediatric Radiology, Children's Hospital Philadelphia, Philadelphia, PA, [4]Ghent University Hospital, Ghent, Belgium, [5]Department of Medicine, University of Alberta, 568 Heritage Building, Edmonton, AB, Canada, [6]University of Alberta, Department of Radiology & Diagnostic Imaging, Edmonton, AB, Canada, [7]Istanbul University-Cerrahpasa, Cerrahpasa Medical School, istanbul, Turkey, [8]Istanbul University-Cerrahpasa Department of Pediatric Rheumatology, Istanbul, Turkey, [9]Children's National Hospital, Washington, DC, [10]Childrens Hospital of Philadelphia, Philadelphia, PA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Radiographs are neither sensitive nor reliable for assessing axial disease in juvenile spondyloarthritis (JSpA), though they are still used in some settings due to limited access to magnetic resonance imaging (MRI). The recently validated axial JSpA (axJSpA) classification criteria include inflammatory and structural imaging domains. When both imaging modalities are available, MRI findings are prioritized over radiographic data in the structural domain. This study evaluated the performance of the axJSpA criteria when using pelvic radiographs alone and compared these results with those based on MRI.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We conducted a retrospective analysis of an international cohort of patients with JSpA and symptom onset before age 18. All participants underwent anteroposterior (AP) pelvic radiography and dedicated pelvic MRI during axial disease evaluation. A centralized panel independently reviewed cases for unequivocal sacroiliitis: structural lesions on radiograph and both inflammatory and/or structural lesions on MRI typical of axial disease (Table 1). Imaging criteria were considered met when the majority of raters agreed. Agreement between radiograph- and MRI-defined structural lesions was assessed using Cohen's kappa coefficient. For each subject, fulfillment of the axJSpA criteria was assessed using MRI data and radiographic data alone, in addition to non-imaging domains. For the assessment of radiographic data alone, the inflammatory lesions on imaging domain for criteria defaulted to a score of "0".

Results: A total of 137 subjects (59.1% male; median age 14.3 years) were included. Imaging criteria were met in 40 (29.2%) cases for MRI-defined inflammatory lesions, 33 (24.1%) for MRI-defined structural lesions, and 29 (21.2%) for radiographic sacroiliitis. Agreement between MRI- and radiograph-defined structural lesions yielded a kappa coefficient of 0.54, indicating moderate concordance (Table 2). Using MRI data, 40 subjects met axJSpA classification criteria, compared to 12 using radiographic data alone. Relying on radiographic findings altered classification status in 32 (23.4%) subjects, with 2 additional cases meeting criteria and 30 cases no longer fulfilling them (Figure 1).

Table 1. Validated definitions for axJSpA Imaging Classification Criteria.

Imaging type	AxJSpA Classification Criterion	Definition
Pelvic Radiograph	Unequivocal sacroiliitis in skeletally immature youth	Unequivocal lesion (erosion, sclerosis, or ankylosis [partial or complete]) that must include at least one iliac bone. When sclerosis is present in isolation, if measurable, should extend ≥5mm from the joint surface. The decision may be influenced by the presence of other lesions, which in themselves do not suffice to meet the criterion.
Pelvic MRI	Unequivocal inflammatory lesion typical of axJSpA	Bone marrow edema in ≥3 SIJ quadrants across all SIJ MRI slices
Pelvic MRI	Unequivocal structural lesion typical of axJSpA	Erosion in at least 3 quadrants *or* at least one of the following lesions in at least 2 SIJ quadrants across all SIJ MRI slices: sclerosis, fat lesion, backfill, ankylosis

Table 2. Agreement between radiograph- and MRI-defined structural lesions.

		Unequivocal sacroiliitis on radiograph	
		No	Yes
Unequivocal SIJ structural lesions on MRI	No	95	9
	Yes	13	20

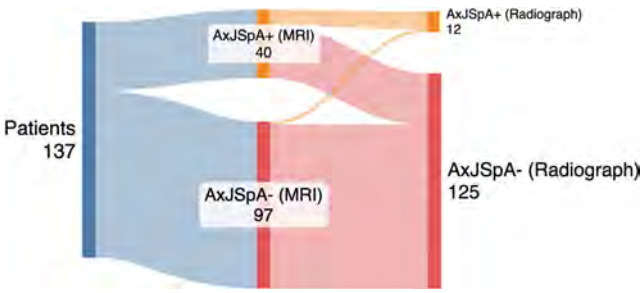

Figure 1. Re-classification of axJSpA status using MRI and radiograph as sources for imaging domain weighting. Patient classification by axJSpA status using the different imaging modality combinations were AxJSpA+ (MRI)/AxJSpA+ (Radiograph): n=10, AxJSpA+ (MRI)/AxJSpA- (Radiograph): n=30, AxJSpA- (MRI)/AxJSpA+ (Radiograph): n=2, and AxJSpA- (MRI)/AxJSpA- (Radiograph): n=95. Using radiograph-only data excluded scoring from the inflammatory lesions domain. AxJSpA+ = axial juvenile spondyloarthritis classification criteria met; AxJSpA- = axial juvenile spondyloarthritis classification criteria not met.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Although pelvic radiographs moderately align with MRI in identifying structural lesions, reliance on radiographic findings alone can misclassify a subset of patients under the axJSpA criteria. These findings underscore the importance of obtaining and prioritizing MRI for accurate classification and assessment of axial disease in JSpA when available. Nevertheless, in settings where MRI is unavailable, the criteria still perform reasonably when based solely on radiographic findings, supporting their utility in resource-limited contexts.

Which score fits best? Correlation of clinical indices of Disease Activity and Ultrasound findings in Juvenile Idiopathic Arthritis during Transitional Care

Andrea Pilato[1], Giusyda Tarantino[2], Maria Isabella Petrone[2], Angela Aquilani[2], Emiliano Marasco[2], Rebecca Nicolai[2], Fabrizio De Benedetti[3], Roberto Giacomelli[4], Luca Navarini[1] and **Silvia Magni-Manzoni**[2], [1]University of Rome Campus Bio-Medico, Rome, Italy, [2]Bambino Gesù IRCCS Children's Hospital, Rome, Italy, [3]Bambino Gesu Children's Hospital, Rome, Rome, Italy, [4]i) Clinical and Research Section of Rheumatology and Clinical Immunology, Fondazione Policlinico Campus Biomedico; ii) Rheumatology and Clinical Immunology, Department of Medicine, School of Medicine, University of Rome "Campus Bio-Medico", Rome, Italy

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Monitoring disease activity is a crucial aspect of the treat to target paradigm in the management of rheumatic diseases. There are no standardized protocols for monitoring disease activity levels in patients with Juvenile Idiopathic Arthritis (JIA) during the transition of care.

The aim of this study is to compare different disease activity indices for all JIA category (excluding systemic JIA), to evaluate their discriminative validity in a real-life setting.

Methods: Young adult JIA patients eligible for transition of care underwent a prospective clinical evaluation by both paediatric and adult rheumatologists. Disease activity was assessed using validated clinical indices. The cJADAS, JADAS10, JADAS27, and JADAS71 were applied to all patients. SDAI, CDAI, and DAS28 were used for persistent oligoarticular (oJIA-p), extended oligoarticular (oJIA-e), and RF-positive and RF-negative polyarticular JIA (polyJIA RF^-/RF^+). The DAPSA was applied to patients with juvenile psoriatic arthritis (JPsA), while jSPADA, ASDAS-CRP, and BASDAI were used for patients with enthesitis-related arthritis (ERA). Ultrasound data were collected as an additional marker of articular inflammation in all cases of clinical suspicion of arthritis or for disease monitoring, to detect active synovitis according to OMERACT paediatric definitions. Spearman's rank correlation was used to assess associations between the disease activity indices. ROC analyses were used to compare the ability of different clinical indices to reflect ultrasound-detected synovitis in selected JIA subgroups. Statistical analysis was performed using R software (version 4.5.0, released April 11, 2025; R Core Team).

Table 1. Demographic and clinical characteristics of the study cohort (total N = 124)

Age, years, median (IQR)	19 (17-23)
Sex, no. (%)	
Female	93 (75.6)
Male	30 (24.4)
JIA category, no. (%)	
Persistent oligoarthritis	27 (22)
Extended oligoarthritis	40 (32.5)
RF-positive Polyarticular JIA	4 (3.3)
RF-negative Polyarticular JIA	23 (18.7)
ERA	9 (7.3)
jPsA	19 (15.4)
Undifferentiated	1 (0.8)
Patients on csDMARDs, no. (%)	67 (54.5)
Patients on bDMARDs, no. (%)	90 (73.2)
Patients on combination therapy, no. (%)	52 (42.3)
Patients undergoing ultrasound, no. (%)	105 (84.7)
Number of joints assessed per patient, median (IQR)*	4 (3-27)
Ultrasound-detected synovitis, no. (%)	53 (43)

*The number of joints assessed refers to each individual joint scanned (e.g., MCP, PIP, and DIP joints counted separately). This approach may result in higher counts in patients with detailed hand or foot examinations.

Table 2. Summary of Disease Activity indices by JIA category. Values are expressed as median (IQR), except where indicated. RF: rheumatoid factor; PCR: C-reactive protein.

Disease Activity Index	Median (IQR)
Extended oligoarticular and RF-negative polyarticular JIA	Total N=73
cJADAS	2.50 (1.25–5.00)
JADAS10-PCR	2.50 (1.25–5.40)
JADAS27-PCR	2.50 (1.25–5.40)
JADAS71-PCR	2.57 (1.49–5.72)
DAS28	1.89 (1.42–2.41)
SDAI	3.20 (1.49–7.03)
CDAI	3.00 (1.00–6.50)
Persistent oligoarticular JIA	Total N=27
cJADAS	2.00 (0.50–8.50)
JADAS10-PCR	3.00 (0.73–8.50)
JADAS27-PCR	3.00 (0.73–8.50)
JADAS71-PCR	3.19 (1.12–8.75)
DAS28	1.96 (1.53–2.74)
CDAI	2.00 (0.50–9.00)
SDAI	3.40 (1.12–9.28)
jPsA	Total N=19
cJADAS	3.50 (2.25–5.50)
JADAS10-PCR	3.80 (2.25–5.50)
JADAS27-PCR	3.80 (2.25–5.50)
JADAS71-PCR	4.03 (2.38–5.83)
DAPSA	5.03 (2.13–10.67)
ERA	
jSpADA, median (IQR)	1.00 (0.00–2.50)
BASDAI, mean ± SD	2.58 ± 2.25
ASDAS-PCR, mean ± SD	1.37 ± 0.85

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 3. Comparison of AUC values of the Disease Activity indices by JIA subgroups.

Comparison AUC values for oJIA-e and polyJIA-FR- group	
Indices	**AUC**
cJADAS	0.836
JADAS10-PCR	0.837
JADAS27-PCR	0.837
JADAS71-PCR	0.844
SDAI	0.845
CDAI	0.803
Comparison AUC values for oJIA-p group	
cJADAS	0.935
JADAS10-PCR	0.926
JADAS27-PCR	0.926
JADAS71-PCR	0.926
CDAI	0.926
SDAI	0.932
Comparison AUC values for JPsA group	
cJADAS	0.744
JADAS10-PCR	0.744
JADAS27-PCR	0.744
JADAS71-PCR	0.784
DAPSA	0.818

Results: A total of 124 JIA patients were included (median age 19 years, IQR 17–23). Disease activity was highest in jPsA (N=19; median JADAS10 3.8, DAPSA 5.0), compared to lower values in oJIA-e/polyJIA RF$^-$ (JADAS10 2.5) and oJIA-p (JADAS10 3.0). In oJIA-p, oJIA-e, and polyJIA RF$^-$, strong correlations were observed among JADAS scores, CDAI, and SDAI ($\rho > 0.87$; $p < .001$), with slightly lower values for DAS28. In the jPsA subgroup, a moderate-to-strong correlation was observed between JADAS scores and DAPSA ($\rho \approx 0.87$, $p < .001$). In ERA, jSpADA correlated moderately with ASDAS-PCR ($\rho = 0.51$; $p = 0.161$), but not with BASDAI.

Ultrasound was performed in 84.7% of patients, with a total of 1612 assessed joints. In oJIA-e and polyJIA RF$^-$, JADAS71-PCR and SDAI yielded the highest AUCs (0.844–0.845) for ultrasound-detected synovitis. In oJIA-p, all indices performed well (AUCs ≥ 0.926). In jPsA, DAPSA showed the best discrimination (AUC 0.818).

Conclusion: In this real-life transition cohort, both paediatric (JADAS scores and jSPADA) and adult-derived indices (SDAI, CDAI, DAPSA, ASDAS-PCR, BASDAI) showed good correlation and comparable performance in assessing disease activity, in all JIA subtypes. These findings support the integration of selected adult indices into transitional care to ensure consistent and reliable disease monitoring.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with JIA are at high risk for development of chronic anterior uveitis (CAU), impacting 10-20% of this population. Although methotrexate (MTX) is the first-line systemic treatment for JIA-U patients, only 50% respond to therapy. Poor MTX response and delayed escalation of therapy can lead to sight-threatening complications. Non-white race, male sex, ANA positivity, and young age at JIA diagnosis have been associated with a lack of response. We aim to identify clinical risk factors associated with non-response to MTX in JIA-U patients.

Methods: This is a multicenter, prospective study – PEDIA-U and PROMOTE. Patients diagnosed with JIA or JIA-U who were prescribed MTX and who had 12 months follow-up were included. Patients were grouped as MTX non-responders (MTX-NR) vs responders (MTX-R). MTX-NR for CAU was defined as active or worse CAU by Standardization of Uveitis Nomenclature (SUN) criteria, presence of new or worsening complications, and/or need for > 2 drops/day of topical or oral steroids after 3 months. MTX-NR for arthritis was defined as no change in active joint count after 3 months. Clinical phenotypes were compared between MTX-NR and MTX-R using Chi-square and two sample tests. Odds ratios were calculated by multiple logistic regression.

Results: A total of 635 patients with JIA were identified, 187 (29.4%) of whom had JIA-U (Table 1). The overall cohort was predominately white (73.7%) and female (74.9%), with 298 (46.9%) being identified as MTX-NR. Average MTX oral and subcutaneous dose was similar at 16.5 mg/m^2 (SD 6.6) and 17.4 mg/m^2 (SD 5.7), respectively. White race was associated with MTX-NR on bivariate (X^2=20.0, p=0.0012) and multivariate (OR 2.429, CI 1.512-3.904) analysis, with no other significant clinical variables identified. Of the 187 JIA-U patients, 91 (48.6%) were identified as being MTX-NR (Table 2). Of the 91 JIA-U MTX-NR, a majority were non-responders due to arthritis activity (61.5%), followed by both CAU and arthritis activity (26%)

	Unknown	6	2 (33.3)	4 (66.7)
MTX Intolerance, p=0.0023[1]				
	Yes	40	28 (70.0)	12 (30.0)
	No	147	63 (42.9)	84 (57.1)
Age at JIA Diagnosis, Mean (SD), p=0.644[2]			4.0 (3.1)	4.3 (3.4)
Age at Uveitis DX, Mean (SD), p=0.2197[2]			5.3 (3.5)	6.0 (3.3)
Days between MTX start & JIA diagnosis, Mean (SD), p=0.3996[2]			561 (1485.2)	390.5 (1215.3)
Days between MTX start & CAU diagnosis, Mean (SD), p=0.1251[2]			-111 (1485.2)	-450.7 (1027.7)
Duration of arthritis at CAU DX, N, Mean days (SD), p=0.106[2]			70/91, 132.5 (364.6)	70/96, 189.9 (270.1)
[1]Chi-square testing completed for categorical variable (ie. Race)				
[2]T-test used for continuous variable (ie. Age)				

and isolated CAU activity (12%). In contrast to the overall cohort, MTX intolerance (MTX-IT) was associated with MTX-NR (X^2=9.3, p=0.00023) in the JIA-U group. The most common reason for MTX-IT being GI symptoms (76.2%), followed by laboratory abnormalities (11.9%). The most initiated biological DMARD in MTX-NR patients was adalimumab (37.9%). No significant differences in predictors of response were found between JIA and JIA-U groups across clinical and demographic variables.

Conclusion: Patients of white race and those who experience MTX-IT were significantly more likely to be MTX-NR in the combined and JIA-U cohorts, respectively. Risk factors of MTX-NR from previously reported smaller cohorts were not significant in our population. Our study does not support evidence of using clinical criteria alone to identify at-risk populations for MTX-NR. Future investigation could include ocular findings on novel imaging modalities, biomarkers, and genetics as risk factors of MTX-NR, with the potential for developing individualized JIA-U therapy plans while minimizing ophthalmic morbidity.

Abstract Number: 0393

Effects of Self-Reported Medication Barriers on Medication Adherence and Disease Activity in a Cohort of Patients with Juvenile Idiopathic Arthritis

Aditi Shaily[1], Allison R. Eckard[2], Paul Nietert[3], Emily Vara[1], Natasha Ruth[4] and Mileka Gilbert[3], [1]Division of Rheumatology, Medical University of South Carolina, Charleston, SC, [2]Departments of InternDivision of Infectious Diseases, Medical University of South Carolina, Charleston, SC, [3]Medical University of South Carolina, Charleston, SC, [4]Medical University South Carolina, Charleston, SC

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Medications used to manage juvenile idiopathic arthritis (JIA) are highly effective in preventing joint damage and provide a favorable prognosis. Many patients, however, struggle with treatment adherence. Yet, little data exist on self-reported medication barriers and how they may affect treatment adherence and disease activity in this vulnerable population.

Methods: Retrospective cross-sectional analysis was used to examine medication barriers in a cohort of patients with JIA seen in an ambulatory rheumatology clinic at a quaternary care academic institution in Charleston, SC. Pediatric Rheumatology Care and Outcomes Improvement Network Barriers Assessment Tool (BAT) was used to obtain patient/caregiver-

The treatment costs too much	7 (7.7)	4 (26.7)	3 (4.0)	**0.01**
The treatment makes me worry about future side effects/consequences	9 (10.0)	4 (26.7)	5 (6.7)	**0.04**
The treatment makes me worry about my ability to have children in the future	4 (4.4)	0 (0.0)	4 (5.3)	0.99
Other	3 (3.3)	1 (6.7)	2 (2.7)	0.43

Data are presented as N (%) or median (interquartile range). p-values in bold depict those <0.05.

reported medication barriers. Treatment adherence rates were estimated using a patient/caregiver-driven survey. 10-point clinical Juvenile Arthritis Disease Activity Score (cJADAS-10) assessed disease activity. Primary objectives were to investigate relationships among medication barriers, medication adherence, and disease activity. Secondary objective was to evaluate for health disparities associated with medication barriers. Fisher's exact or Wilcoxon rank-sum tests were used to make between-group comparisons.

Results: 90 patients were included (median age 14 years; 73.3% female); 75.6% reported taking ≥1 JIA medication. 36 of 90 patients (40%) reported the presence of at least one medication barrier; 54 (60%) reported not having any barriers. "Treatment is painful," "treatment makes me uncomfortable or upset," and "I do not like the side effects of the treatment" were the most reported barriers. Comparison groups were based on the selection of one or more medication barriers from the BAT in primary analysis; and on the response to the survey question "Do you have any barriers to, challenges with, or concerns about taking your medication(s)?" in secondary analysis. Associations between medication barriers and medication adherence rates, disease activity and sociodemographic variables were not statistically significant in the primary analysis (Tables 1 & 2). However, medication barriers were found to decrease adherence rates in the secondary analysis with a different operational definition of medication barriers (Table 3).

Conclusion: No differences were observed in treatment adherence rates, disease activity and sociodemographic factors in patients reporting medication barriers versus not reporting any barriers. However, medication adherence varied with different operational definitions of medication barriers. Hence, additional investigation is warranted to further delineate perceived medication barriers and their effects on long-term disease outcomes.

Abstract Number: 0394

Predictors of quality of Life in a longitudinal cohort of patients with Uveitis, Juvenile Idiopathic Arthritis, and JIA-associated uveitis

andressa Guariento Ferreira Alves[1], Amy Cassedy[2], Virginia Miraldi Utz[3], Alexandra Duell[3], Megan Quinlan-Waters[4], Nicole Reitz[5], Sheila Angeles-Han[6] and Melissa Lerman[7], [1]The Children's Hospital of Philadelphia, Philadelphia, PA, [2]Cincinnati Children's hospital medical center, cincinnati, OH, [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [4]Cincinnati Children's Hospital Medical Center, CCHMC, [5]Department of Mental Health, St. Louis, MO, [6]Cincinnati Children's Hospital, Cincinnati, OH, [7]Children's Hospital of Philadelphia, Philadelphia, PA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Uveitis, juvenile idiopathic arthritis (JIA), and JIA-associated uveitis (JIA-U) greatly influence children's quality of life (QOL). Our aim is to identify demographic, disease, and treatment features that may impact patient-reported outcomes (PROs) over time.

Methods: Patients with Uveitis, JIA, and JIA-U, and their caregivers enrolled in Longitudinal Outcomes of Childhood Uveitis Study (LOCUS) registry completed PROs as age-appropriate. The Effects of Youngsters' Eyesight on Quality of Life (EYE-Q) measures vision-related QOL and function, and Pediatric Quality of Life Inventory (PedsQL) measures overall QOL. Scores range 0 -100 (higher scores: better QoL). The Revised Childhood Anxiety and Depression Scale (RCADS) assesses anxiety and depression. Scores >70 indicate anxiety or depression. The Childhood Health Assessment Questionnaire (C-HAQ) measures functional disability from JIA with scores range 0 -3 (higher scores: worse function). Generalized estimating equation models were used to identify predictors of QOL.

Results: A total of 19 (21.6%) patients with uveitis, 34 (38.7%) JIA-U and 35 (39.7%) JIA completed 5 visits. The median time between baseline and last visit was 19.7 mo (IQR:15.8-28.6). There was a predominance of female sex in JIA 23 (26.2%) and JIA-U 28 (31.8%) compared to Uveitis 8 (9.1%) (< 0.001). Disease duration was longer in JIA-U 5.2 (IQR: 1.5-9.0) vs. Uveitis 0.8 (IQR: 0.2-2.8) and JIA 1.2 (IQR: 0.5-2.5) (p< 0.001). Patients with uveitis alone and active JIA had worse EYE-Q scores ($p < 0.01$) compared to JIA-U. Not being on a DMARD, being > 10 y/o, and subsequent visits from baseline were significantly associated with better EYE-Q for parents only. Predictors of better PedsQL were not being on DMARD or NSAIDs, and male sex for parents and children. Those with any form of uveitis had worse PedsQL although only for parents. Patients >10 y/o with inactive arthritis or uveitis had better CHAQ for parents and patients. The use of DMARDs was not associated with CHAQ. RCADS better outcome predictors were male sex, for parents and patients, age < 10 y/o for patients and inactive JIA disease for parents.

Conclusion: Having a diagnosis of uveitis, even more so if it was an isolated disease, was associated with worse physical functioning and vision-related QOL/function and PedsQL. Overall predictors were similar between parents and patients with few differences. Male sex, not being on DMARDS or NSAID, and having inactive JIA were associated with better outcomes. Being >10 y/o was associated with better physical functioning and vision-related QOL/function but worse RCAD. Identification of key predictors that impact quality of life over time will help us begin to tailor interventions to enhance the wellbeing of patients with chronic arthritis and uveitis.

TNFi use,[2] n(%)	9 (29)	116 (20)	31 (25)	26 (27)

Cells < 5 were not reported.
[1]BMI categories defined according to US CDC guidelines for BMI percentile by age and sex: underweight <5 percentile; healthy weight 5 to <85 percentile; overweight 85 to <95%; obese ≥95 percentile
[2]TNFi prescribed within 9 months of initial rheumatology visit; includes infliximab, etanercept, and adalimumab

Background/Purpose: Among adults, higher BMI contributes to worse outcomes and reduced response to treatment in rheumatoid arthritis (RA), but this relationship is understudied among those with Juvenile Idiopathic Arthritis (JIA). We investigated the relationship between BMI and disease activity 1-year post-diagnosis in JIA. Given that TNF inhibitors are the most commonly prescribed biologic DMARDs in JIA, we further assessed the impact of BMI category on response to treatment among those who were prescribed TNF inhibitors.

Methods: This is a retrospective cohort study from a single large quaternary center. Inclusion criteria were JIA (ages 2-16 years) diagnosed between November 2008 and September 2020 and followed for at least 12 months. Patients were identified using ICD-10 codes for JIA. Exclusion criteria were treatment with immunosuppressants before JIA diagnosis, inflammatory bowel disease, or missing data for height, weight, or disease activity at 12 months. Demographic characteristics, including height, weight, and BMI at initial rheumatology visit were extracted from a central patient database and patient clinic records. Age- and gender-specific BMI percentile was calculated for each patient and categorized according to CDC definitions as: underweight (< 5th percentile), healthy weight (5th to < 85th percentile), overweight (85th to < 95th

Table 2: Odds of active disease at 12 months among children with JIA by BMI category

	Active Disease	Inactive Disease	Odds Ratio (95% CI)[2]
Overall (N= 822)			
BMI Categories,[1] n(%)			
Healthy Weight	221 (38)	352 (62)	reference
Underweight	6 (19)	25 (81)	0.38 (0.15, 0.96)*
Overweight	50 (41)	72 (59)	1.04 (0.69, 1.57)
Obese	38 (40)	58 (60)	0.98 (0.62, 1.54)
Among TNF users[3] (N=182)			
BMI Categories,[1] n(%)			
Healthy Weight	36 (31)	80 (69)	reference
Underweight	<10	<10	0.27 (0.03, 2.28)
Overweight	13 (42)	18 (58)	1.59 (0.68, 3.71)
Obese	13 (50)	13 (50)	2.09 (0.86, 5.05)

[1]BMI categories defined according to US CDC guidelines for BMI percentile by age and sex: underweight <5 percentile; healthy weight 5 to <85 percentile; overweight 85 to <95%; obese ≥95 percentile
[2]Adjusted for ILAR category
[3]TNF prescription within 9 months of initial rheumatology visit; includes infliximab, etanercept, and adalimumab
*Statistically significant at α=0.05

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

percentile), or obese (≥ 95th percentile). Disease activity status at 12 months was extracted from patient records. Logistic regression was used to evaluate the association between BMI category and disease status overall and among those who were prescribed a TNF inhibitor (infliximab, etanercept, and adalimumab).

Results: Among 822 included patients, the majority (70%) were healthy weight (underweight: 4%, overweight: 15%, obese: 12%). Among 182 patients using TNF inhibitors, 64% were healthy weight (underweight: 5%, overweight: 17%, obese: 14%). Those who were underweight had lower odds of active disease at 12 months when compared to those with healthy weight, both overall (OR=0.38, 95%CI: 0.15-0.96) and among those taking TNF inhibitors (OR=0.30, 95%CI: 0.03-2.28). Among those taking TNF inhibitors, those who were overweight (OR=1.59, 95%CI: 0.68-3.71) or obese (OR=2.09, 95% CI: 0.86-5.05) had higher odds of active disease at 12 months compared to those with healthy weight.

Conclusion: Although it has been established in adults with RA that higher BMI contributes to worse disease outcomes, our analysis suggests that this may not be the case among children with JIA, as those who were overweight or obese had similar odds of active disease to those with healthy weight. Our study was likely underpowered to detect significant differences among those taking TNF inhibitors, but results suggest a trend, with higher likelihood of active disease found in each successively higher category of BMI. Further research in a larger cohort of JIA patients taking TNF inhibitors would elucidate the validity of this observed trend.

Abstract Number: 0396

Quantifying Burden of Uveitis Care for Pediatric Uveitis Patients and Caregivers

Catherine Lavallee[1], Samuel Garfinkle[2], Devlin Eckardt[3], Stefanie Davidson[4], Melissa Lerman[5], Nicole Reitz[6] and Kerry Hurlbut[5], [1]St. Christopher's Hospital for Children, Philadelphia, PA, [2]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, [3]Children's Hospital of Philadelphia, Philadelphia, [4]University of Pennsylvania/CHOP, Philadelphia, PA, [5]Children's Hospital of Philadelphia, Philadelphia, PA, [6]Department of Mental Health, St. Louis, MO

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Chronic noninfectious uveitis (CU) in pediatric patients is often asymptomatic and can cause vision loss, requiring frequent ophthalmologist visits and long-term treatment. This survey aimed to evaluate perception of the overall impact of CU on patients and their families and to describe the relative contributions of financial costs, healthcare access, and treatment adherence to perceived burden.

Methods: With input from patient representatives, a questionnaire was developed including ~65 questions: multiple-choice, Likert-scale, and open-ended. It was administered via REDCap at a pediatric tertiary center between April-June 2024. Participants included English-speaking guardians or adult patients (≥ 18 yo) diagnosed with CU < age 18, who received care in a coordinated ophthalmology/rheumatology clinic. Patients were asked to score "overall burden"; to categorize factors (eg. dollars spent per month, commute time to appointments), and to score perceived burdens from each category (cost, travel, obtaining medicine, giving medicine, impact on work/school/family, and emotional concerns). Data was analyzed using descriptive statistics, Wilcoxon rank sum tests, and Spearman's rank correlations.

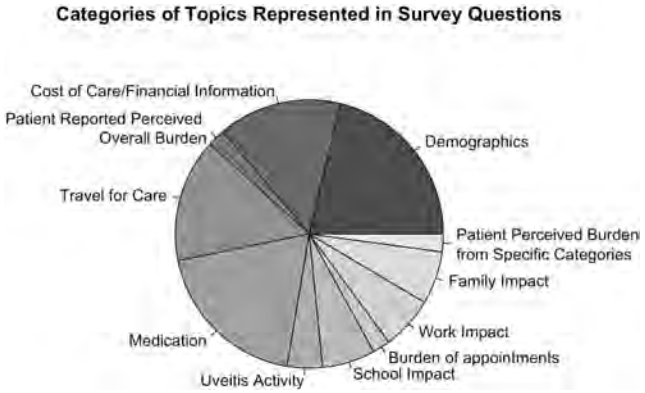

Figure 1. Categories Represented in Survey Questions. Each segment in this pie chart represents a category assessed in the survey, including Demographic information, Patient Reported Perceived Overall Burden, Patient Reported Perceived Burden from Specific Categories, Family Impact, Work Impact, School Impact, Burden of Appointments, Uveitis Activity, Medication, Travel for Care, and Cost of Care/Financial Information. The size of each segment corresponds to the proportion of survey questions dedicated to the category.

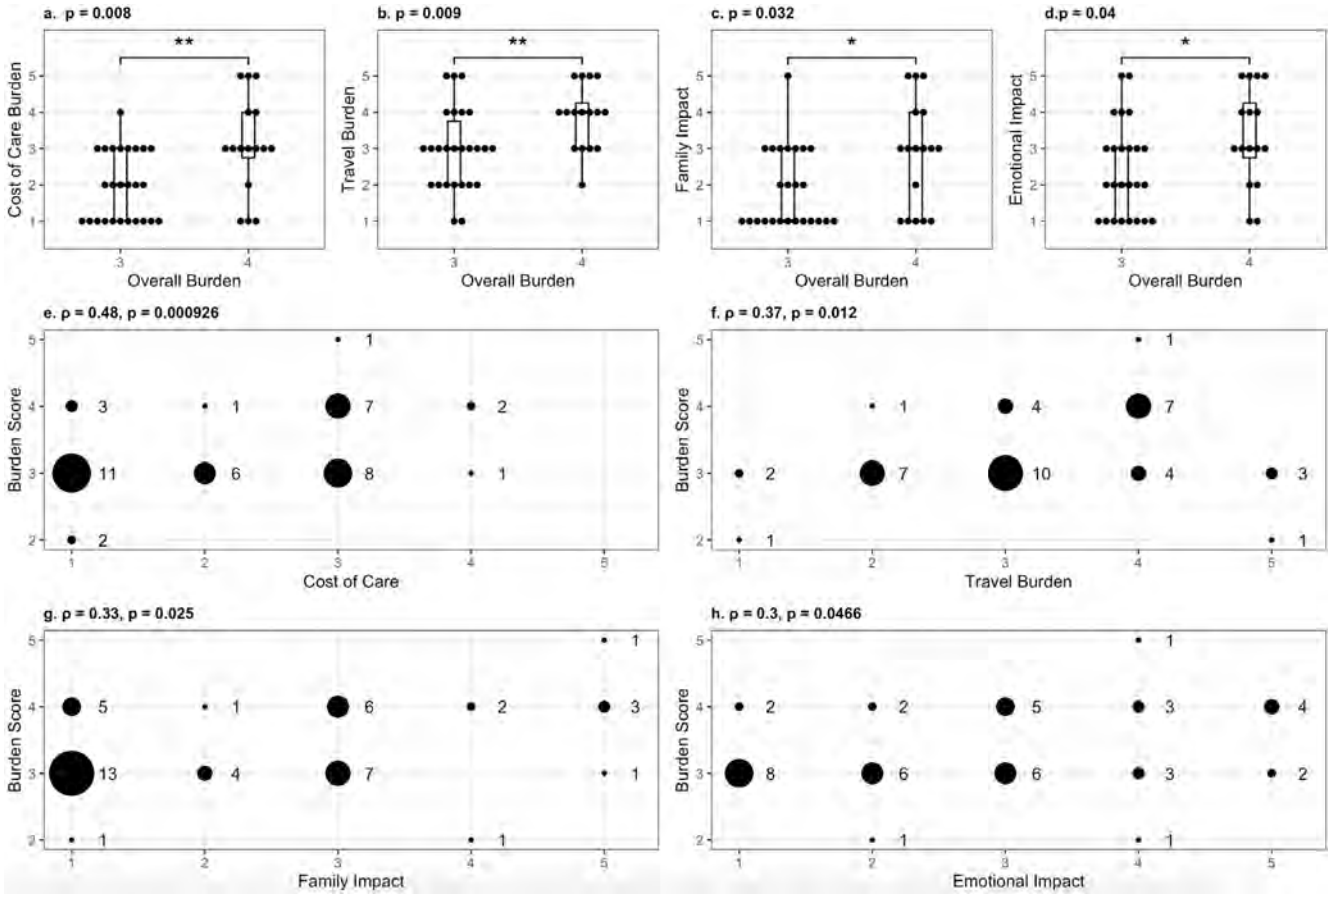
23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Panels a-d: Wilcoxon rank-sum tests of association of Overall burden (x-axis) and burden from individual categories (y-axis). Overall burden: "Considering the ways uveitis affects your life and finances, how difficult is receiving uveitis care on the patient and their family/caretaker(s)? (Note, in this survey we are not focusing on emotional burden)"; scoring: Very easy (1), Easy (2), Neutral (3), Difficult (4), Very Difficult (5). Every dot represents a patient. Panels e-h: Spearman's rank correlations of patient reported burden from individual categories (x-axis) and perceived overall burden (y-axis). Burden of individual categories: "Please rank what factors of uveitis care are most burdensome for the patient and guardian"; scoring: Not a Burden (1), Neutral (3), a Great Burden (5). Individual categories include Cost of care (E), Burden from travel to appointments (F), Burden on Family (G), Emotional Concerns (H). Rho: represents strength of correlation. P-value represents statistical significance. Larger dot size represents more patients.

Results: A total of 46 participants completed the survey. 93% of respondents (n=43) answered the question of their perceived overall burden of uveitis care. 61% reported a perceived overall burden sentiment of "neutral" while 40% reported "difficult". Higher burden (difficult vs. neutral) was significantly associated with patient reported higher burdens from categories: cost of care (p = 0.008), burden from travel to appointments (p=0.009), burden on family (p=0.032) and emotional concerns (p=0.04). There was no correlation between burden and participant age. Nearly half of participants were unaware of their uveitis subtype, and many did not know their monthly medical expenses. Spearman correlation confirmed significant positive associations of perceived overall burden with patient reported higher burdens from categories: cost of care (rh=0.48, p=0.001), burden from travel to appointments (rh=0.37, p=0.012), burden on family (rh=0.33, p=0.025), and emotional concerns (rh=0.30, p=0.047).

Conclusion: The study describes the burden faced by pediatric CU patients and their families. Cost and travel requirements were perceived as the greatest contributors. Limitations of this pilot study include it being performed at a single center and survey being restricted to patients in a coordinated uveitis clinic. Further directions include quantifying burden in a larger cohort and evaluating whether these same factors are the greatest contributors.

Abstract Number: 0397

Paediatric uveitis - Retrospective comparison of cataract surgery outcomes with or without intraocular lens implantation from two tertiary centres in United Kingdom

Chaitra Govardhan[1], Ashwini Batchu Prithvi[1], Bushra Aladaileh[1], Elizabeth Cattermole[2], Farrag Abdelsattar[2], Catherine Guly[2], Jessy Choi[3], Johannes Keller[2] and Athimalaipet V Ramanan[1], [1]Bristol Royal Hospital for Children, Bristol, United Kingdom, [2]Bristol Eye Hospital, Bristol, United Kingdom, [3]Sheffield Children's Hospital, Sheffield, United Kingdom

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Cataract is one of the most common and visually debilitating complications of paediatric uveitis developing as a consequence of chronic inflammation and steroid use. Cataract surgery can be technically challenging in patients with uveitis and the outcomes less certain.(1) Inserting an intraocular lens (IOL) is controversial for paediatric uveitis patients leading to variable practice across different institutions. This study compares the outcomes of cataract surgery associated with paediatric uveitis with or without IOL implantation.

Methods: A retrospective comparison study was conducted at two centres, Bristol Eye Hospital (Centre 1-Cataract surgery with IOL implantation) and Sheffield Children's Hospital (Centre 2-Cataract surgery without IOL implantation). All children below 18 years of age with uveitis who underwent cataract surgery between year 2011 and 2024 were included. Pre and post operative outcomes from the two groups were compared, including best corrected visual acuity(BCVA), LogMAR lines of improvement, ocular inflammation and complications. Follow up data upto 2 years post-surgery where available were recorded. Data was analysed using descriptive statistics.

Table:1 Demographic and Clinical comparison of the study groups

	Intra-ocular lens group (Centre-1)	No Intra-ocular lens group (Centre-2)
Total number of children	25	10
Total number of eyes (R:L)	30 (18:12)	13 (7:6)

No. of children >2 lines of improvement n/total (%)	N=30	N=13	24/29 (82.8)	11/13 (84.6)	27/29 (93.1)	9/12 (75)	21/26 (80.8)	9/11 (81.8)
Mean BCVA (Range)	1.16 ± 0.75	1.64 ± 0.78	0.35± 0.52	0.89± 1.03	0.25± 0.35	0.93± 1.11	0.21± 0.29	0.80± 1.07
Median BCVA (IQR)	0.84 (0.60 - 1.43)	1.60 (0.92 – 2.48)	0.20 (0.10 – 0.40)	0.38 (0.24 – 1.56)	0.20 (0.04 – 0.30)	0.50 (0.14 – 1.99)	0.10 (0.00 – 0.35)	0.15 (0.05-1.69)

NA= Not available or not measured

Results: There were total 35 children (43 eyes) identified from both centres, 25 children (30 eyes) from centre-1 and 10 children (13 eyes) from centre 2. The median age at diagnosis in years was 5.5years(centre 1) and 5years (centre 2) and median age at surgery was 9 and 5 years with M:F=2:3 and 1.6:1 respectively. JIA was the most common etiology at both centres (60% and 90% respectively). Anterior uveitis was the most common subtype of uveitis at both centres (29 eyes, 9 eyes respectively)-Table1. Surgical capsulotomy was required in 3 eyes (10%) by 24 months at centre 1. Active anterior chamber inflammation >1+ cells was recorded in 10(33%), 8(36.4%), 5(16.7%) in centre-1 and 1(7.7%), 2(15.4%), 1(7.7%) in centre-2 at 3,12 and 24 months.(Table2) Median preoperative BCVA (IQR) was 0.84 (0.60-1.43) and 1.6 (0.92- 2.48) respectively. The median post-operative BCVA at 3 months, 12 months and 24 months at centre 1 was 0.20,0.2 and 0.10 and at centre 2 was 0.38, 0.50 and 0.15. Percentage of children with 2 or more lines of improvement at 3,12 and 24 months at centre 1 was 82.8%, 93.1% and 80.8% whereas at centre 2 was 84.6%, 75% and 81.8%.(Table3)

Conclusion: Good visual improvement following cataract surgery in children with uveitis with and without IOL would support either of the practices. However, a caveat being that IOL insertion could potentially be associated with active inflammation.

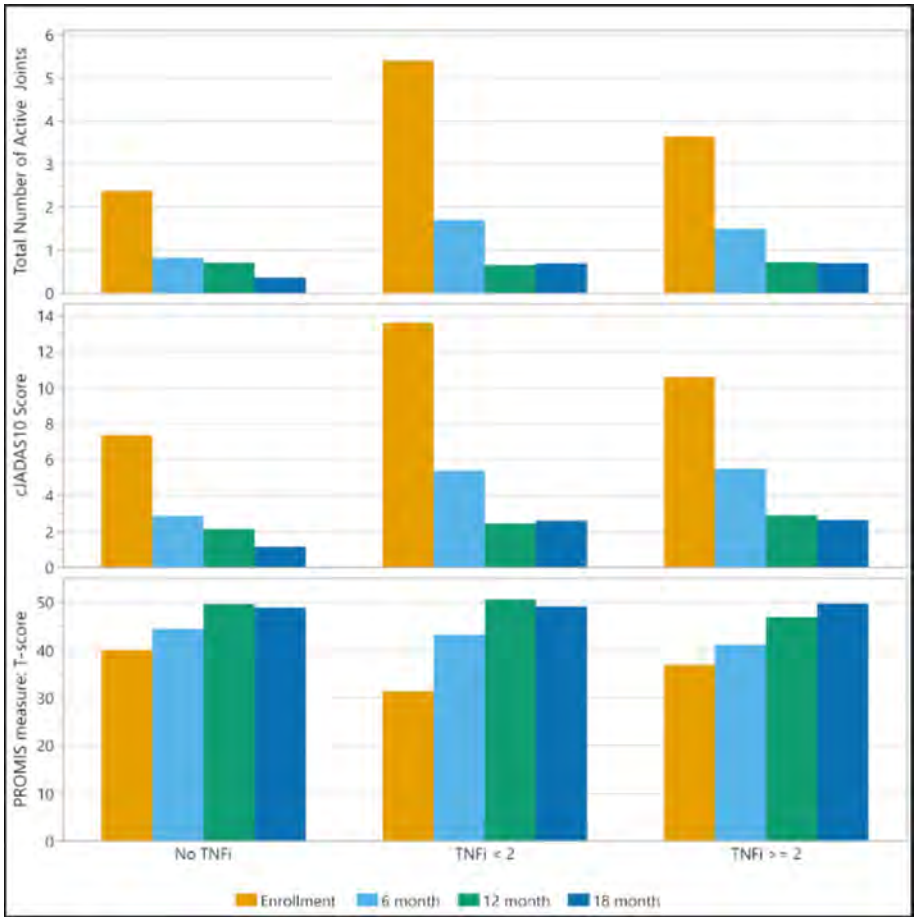

Figure 1: Disease Activity Over Time in Those That Started TNFi <2 Years Old, TNFi ≥ 2 Years Old, and Never Used TNFi

Background/Purpose: Juvenile Idiopathic Arthritis (JIA) is the most common pediatric rheumatic disease. Tumor necrosis factor inhibitors (TNFi) are key treatments in non-systemic JIA (sJIA), but patients diagnosed ≤2 years old have been underrepresented in studies thus far. Despite widespread clinical use, limited data exists on TNFi efficacy in this cohort, often leading to treatment delays. Early disease control is critical to optimize long-term outcomes and prevent damage. This study aimed to (1) describe demographics of children diagnosed with non-sJIA 0-23 mo and (2) evaluate TNFi effectiveness in improving disease activity in these patients using data from the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry, a national multicenter observational database.

Methods: Demographic and disease characteristics were described for all patients diagnosed with non-sJIA 0-23 mo from 2015-2023 in the CARRA Registry using descriptive statistics. Efficacy was analyzed in patients enrolled within 6 months of diagnosis with ≥2 follow-up visits at 0-3, 4-8, 10-14, or 16-20 months using total active joint count, clinical Juvenile Arthritis Disease Activity Score (cJADAS-10), and Patient-Reported Outcomes Measurement Information System (PROMIS) T-scores. Bivariate analysis comparing the subcohort to the entire cohort was performed using Mann Whitney U and Chi-Square tests with a significance of 0.05. Effects size was reported based on the type of statistical test used.

Results: 949 children were diagnosed with non-sJIA 0-23 mo in the CARRA registry; 29.3% were enrolled within 6 months of diagnosis and had ≥2 follow-ups. Most common subtypes at enrollment were oligoarticular JIA (54.0%) then Rheumatoid Factor (RF)-negative polyarticular JIA (35.1%). Early enrollees had higher baseline disease activity based on active joint counts (2 vs 0), physician global assessments (PGA) (2 vs 0), childhood health assessment questionnaires (CHAQ) (0.375 vs 0.125), and cJADAS10 (8 vs 3) ($p< 0.001$). They also had higher ANA positivity rates (76.9% vs. 71.3%, $p=0.02$) and lower uveitis rates (13.4% vs 32.0%, $p< 0.001$) (Table 1). At baseline, the TNFi ≤2 patients had higher mean active joint

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

counts (4 vs 3 vs 2), cJADAS10 scores (14.5 vs 10 vs 7), and lower PROMIS scores (30.5 vs 25.5 vs 39) compared to the TNFi >2 and never-TNFi groups respectively. Improvements were seen through 16-20 mo with similar joint counts (0 vs 0 vs 0), cJADAS10 (0.75 vs 1 vs 0), and PROMIS (56 vs 56 vs 45) across all 3 groups (Fig 1).

Conclusion: Patients enrolled closer to diagnosis had higher baseline disease activity, reinforcing that they represent an "enriched" cohort and more severe phenotype. Despite this, patients who started TNFi ≤2 demonstrated significant and sustained improvements in all disease activity measures by 12 months, ultimately reaching similar values as those who started TNFi >2 and did not use TNFi. This suggests that early initiation of TNFi therapy has a significant impact on disease course as it essentially corrected for the initial dramatically higher values in disease activity. These Improvements across clinical and functional measures strongly support the efficacy and early initiation of TNFi in the youngest children with non-sJIA.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Administrative claims databases enable research in large populations with JIA. We previously showed that machine learning (ML)-based algorithms accurately identify new JIA diagnoses within US commercial insurance claims data. We externally validated these algorithms within US public insurance claims data.

Methods: We performed a cross-sectional validation study using US commercial health plan data (2013-20) and national US Medicaid data (2013-18). We identified children diagnosed with JIA (ICD-9-CM: 696.0, 714, 720; ICD-10-CM: L40.5, M05, M06, M08, M45) before age 18 after ≥12 months' continuous enrollment without JIA diagnosis or immunosuppression. JIA diagnoses were based on 3 previously validated definitions: 1) rheumatologist's diagnosis plus ≥2 specific lab test orders; 2) ≥2 outpatient diagnoses 8-52 weeks apart; or 3) 1 inpatient diagnosis. A random set of available qualifying charts were abstracted and independently adjudicated as definite, probable, possible, or unlikely JIA by clinical experts; discrepancies were resolved by consensus. Incident JIA was defined as definite or probable JIA diagnosed ≤4 months before first JIA claim. ML-based algorithms used simulation-based balancing and logistic regression regularization hyperparameters with 10-fold

DMARD, disease-modifying antirheumatic drug; GC, glucocorticoid; ICD-9/10-CM, International Classification of Diseases, Version 9/10, Clinical Modification; ophtho, ophthalmologist; PPV, positive predictive value; Se, sensitivity

[1] Original algorithm: ≥2 visits with JIA diagnosis (any provider), 8-52 weeks apart

[2] Visits 8-52 weeks apart unless otherwise noted

[3] Index diagnosis not from an ophthalmologist

[4] Nonsteroidal anti-inflammatories, oral or intra-articular glucocorticoids, or synthetic or biologic DMARDs within 4 months

[5] Excluding ICD-9 714.0, 714.1, 714.4, or 714.8 used before age 16, and 714.9 (any age); ICD-10 M05 or M06 used before age 16

[6] Suggested algorithm in bold font

cross-validation. We used optimal predictive model variables to assess sensitivity (Se), specificity (Sp), and positive predictive value (PPV) (95% confidence interval [CI]). We also tested rule-based algorithms refined based on provider type, JIA diagnosis counts, laboratory test counts, and documented JIA treatment. We compared results across databases and ICD types.

Results: Of 298 eligible charts reviewed (182 commercial, 116 public), 151 had incident JIA (ICD-9 commercial 58%, public 53%; ICD-10 commercial 41%, public 52%). Optimal ML-based algorithms derived within commercial claims data enabled excellent discrimination between incident JIA and unlikely JIA (ICD-9: Se 100%, Sp 96%, PPV 97%; ICD-10: Se 100%, Sp 97%, PPV

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. 97%) (Table 1). However, the same algorithm was not accurate within the Medicaid sample (ICD-9: Se 97%, Sp 19%, PPV 67%; ICD-10: Se 100%, Sp 29%, PPV 70%), and more accurate algorithms derived within Medicaid data used distinct sets of predictive variables (Table). Moreover, optimal ML-based algorithms differed in number and types of predictors across ICD-9 and ICD-10 data. Rule-based algorithms had lower specificity and/or sensitivity, but refined algorithms were more accurate and consistent across databases and ICD types (Table 2-3). Preferred rule-based algorithms required either: 1) rheumatologist's outpatient diagnosis plus ≥4-5 specific lab orders, or 2) ≥5 outpatient JIA visits (first diagnosis not for eye care) plus any JIA treatment.

Conclusion: While ML-based diagnostic algorithms for incident JIA performed well within each database and ICD type, results differed across databases and ICD types. In contrast, refined rule-based algorithms had better external validity, with similarly high PPVs across databases and ICD code types. These preferred rule-based algorithms will improve the quality of future claims-based research on the diagnosis, management, and outcomes of newly diagnosed JIA.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Juvenile idiopathic arthritis (JIA), the most common pediatric rheumatic disease, has been tied to microbiome disruption (dysbiosis). Dysbiosis in adults with arthritis affects response to methotrexate, a common disease-modifying antirheumatic drug (DMARD), but the effects of microbiome-altering drugs (e.g., antibiotics) on methotrexate response for JIA are unknown. We tested if antibiotic exposure is associated with response to methotrexate for JIA, hypothesizing shorter times to treatment change after antibiotic exposure and larger effects with more recent, frequent, and disruptive exposures.

Methods: We conducted a retrospective cohort study using national US public insurance administrative claims data (2001-2019). We included children ages 1-17 diagnosed with JIA who were initiating methotrexate monotherapy or, for comparison, tumor necrosis factor inhibitor (TNFi) monotherapy, after ≥10 months of continuous enrollment without

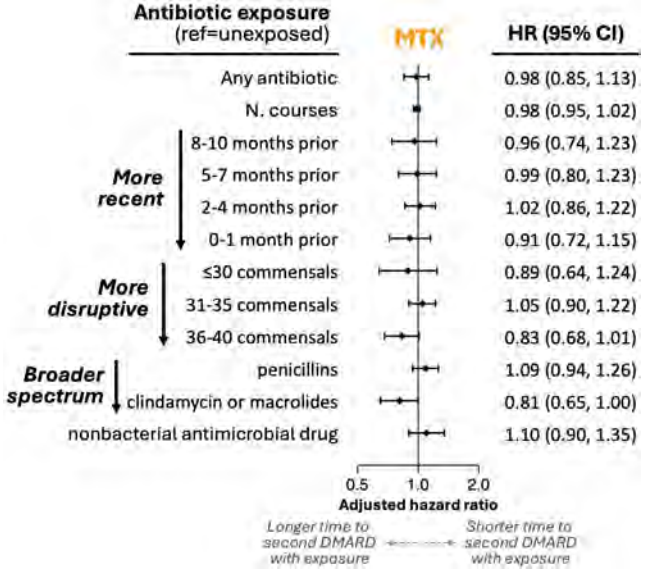
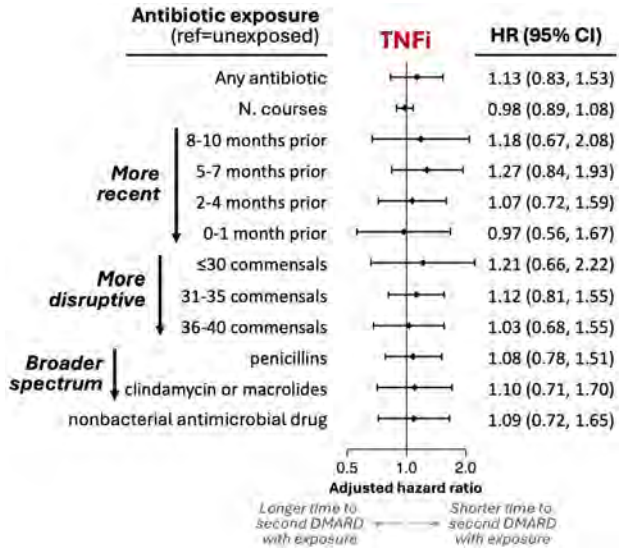
[1] Healthcare utilization during the 10-month baseline period

Figure 1. Associations between antibiotic exposure and MTX ineffectiveness. Forest plot shows associations between antibiotic exposure within 10-months before methotrexate (MTX) initiation and MTX ineffectiveness, as represented by initiation of a second DMARD after ≥1 month. Models were adjusted for baseline demographic, clinical, treatment, and healthcare-related covariates (see Table) and expressed as adjusted hazard ratios (HRs) and 95% confidence intervals (CIs). HRs >1 signify shorter times to initiation of a second DMARD with antibiotic exposure.



23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 2. Associations between antibiotic exposure and TNFi ineffectiveness. Forest plot shows associations between antibiotic exposure within 10-months before tumor necrosis factor inhibitor (TNFi) initiation and TNFi ineffectiveness, as represented by initiation of a second DMARD after ≥1 month. Models were adjusted for baseline demographic, clinical, treatment, and healthcare-related covariates (see Table) and expressed as adjusted hazard ratios (HRs) and 95% confidence intervals (CIs). HRs >1 signify shorter times to initiation of a second DMARD with antibiotic exposure.



DMARDs. Antibiotic exposure during the 10-month baseline period was assessed and characterized by timing, number of courses, and type. Nonbacterial antimicrobial drugs were evaluated as a negative control exposure. As a proxy of treatment ineffectiveness, the primary outcome was initiation of a second DMARD after at least 1 month, a lag representing hypothetical induction time between antibiotic-induced dysbiosis and altered DMARD response, allowing for delayed initiation of a DMARD intended for use in combination. Censoring occurred after a 60-day gap in DMARDs, completion of 10 months of follow-up, loss of enrollment, or death. Associations between antibiotic exposure and treatment change were estimated using Cox regression, adjusting for baseline demographic, disease, treatment, and health utilization covariates (Table), and represented by adjusted hazard ratios (HRs) with 95% confidence intervals (CIs). In sensitivity analyses, we considered outcomes occurring after a 2-month lag after initial DMARD exposure.

Results: We identified 5510 new methotrexate users (mean age 9.5±4.9 years, 68.6% female, 55.6% exposed to antibiotics, 15.9% with outcomes) and 1274 new TNFi users (mean age 11.6±4.5 years, 61.9% female, 50.2% exposed to antibiotics, 15.6% with outcomes). Children with antibiotic exposure tended to be younger and more likely to be White non-Hispanic, live in the South, and have more comorbidities, more anti-inflammatory exposure, and more baseline healthcare utilization (Table). No relationship was observed between baseline antibiotic exposure and treatment change in methotrexate users (HR 0.98, 95% CI 0.85, 1.13) or TNFi users (HR 1.13, 95% CI 0.83, 1.53). Antibiotic timing, number of courses, and type of antibiotic exposure, as well as nonbacterial antimicrobial drug exposure, were also not associated with treatment changes in methotrexate or TNFi users (Figures 1-2). Findings from sensitivity analyses were consistent.

Conclusion: Recent antibiotic exposure is not associated with changes in DMARD treatment in children with JIA, suggesting that dysbiosis does not play a major role in response to methotrexate or TNFi for JIA.

Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Abatacept is a selective T-cell co-stimulation modulator approved for use in JIA. Efficacy and safety of abatacept in patients (pts) with JIA have been demonstrated previously in 2 phase 3 trials[1,2] and earlier results from this phase 4 Abatacept JIA Registry (NCT01357668).[3] The objective of this analysis was to provide data from a real-world setting for longitudinal safety and effectiveness of intravenous (IV) and subcutaneous (SC) abatacept in pts with JIA.

Table 1. Assessment of disease activity and impact. 23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: By protocol, clinical sites in the Pediatric Rheumatology Collaborative Study Group and Pediatric Rheumatology International Trial Organization enrolled pts meeting the ILAR criteria for 1 of the categories of JIA and currently taking or starting IV or SC abatacept. Planned duration of follow-up (FU) is 10 years; data were collected up to March 31, 2024. Effectiveness was assessed at day of entry into registry (baseline [BL]), 3 and 6 months, and 1, 2, 3, 4, and 5 years. Safety data were collected at each visit.

Results: Of the 740 pts enrolled, 701 were included in the analysis (476 IV, 225 SC); 561/701 (80%) were female. At BL, median age was 13.6 years and 28 (4%) pts were aged 2–5 years; JIA disease duration was 4.5 years. Median abatacept treatment duration was 6.1 months and number of active joints was 1.0 (mean 2.7). JIA categories were systemic (2%), oligo (25%), polyarticular RF-negative (48%), polyarticular RF-positive (10%), psoriatic (5%), enthesitis-related (4%), and undifferentiated (6%). Total abatacept exposure was 1513.2 pt-years with a mean/median duration of abatacept treatment of 25.9/19.7 months. At 1-year FU, pts had low Physician Global Disease Activity, low Juvenile Arthritis Multidimensional Assessment Report scores, and improvement in the number of joints with active arthritis compared with BL (Table 1). A higher percentage of pts achieved clinically inactive disease after 1 year of FU vs BL (46% vs 32%; Table 1). This trend continued despite low numbers of pts with 4 and 5 years of FU. There were 11 serious infections reported (incidence rate [IR] 0.52/100 pt-years of FU, 95% CI: 0.26, 0.92; IR 0.73/100 pt-years on treatment, 95% CI: 0.36, 1.30). There were 17 autoimmune events (IR 0.80/100 pt-years of FU, 95% CI: 0.46, 1.28; IR 1.12/100 pt-years on treatment, 95% CI: 0.65, 1.80). There were 2 adverse event malignancies (n=1 each: medulloblastoma, T-cell lymphoma). No cases of tuberculosis were reported. There was 1 unrelated death (pre-existing cardiac problems).

Conclusion: In this real-world JIA cohort, abatacept was safe and well-tolerated with no new safety risks identified. This longitudinal analysis further supports the persistent effectiveness of abatacept in pts with JIA.

Abstract Number: 0402

Risk Factors for Anti-Adalimumab Antibody Development in Pediatric Patients Using Adalimumab for Rheumatic Disease and Associated Conditions

Dawn Gist[1], Andrea Ramirez[1], Jamie Lai[2], Duc Nguyen[1] and Kexin Guo[1], [1]Baylor College of Medicine, Houston, TX, [2]Baylor College of Medicine, The Woodlands, TX

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Adalimumab is a monoclonal antibody against TNF-α that is commonly used to treat JIA, hidradenitis suppurativa (HS), chronic uveitis, sarcoidosis, and chronic nonbacterial osteomyelitis (CNO). Anti-drug antibodies (ADAs) have been frequently reported in patients receiving adalimumab, leading to decreased therapeutic efficacy of the drug. Identifying clinical factors associated with ADA formation is essential to optimize long-term outcomes. This study aims to evaluate differences in treatment duration, flare frequency, and methotrexate use between patients with and without ADAs to adalimumab.

Methods: With IRB approval, a retrospective cohort study was done to evaluate ADA formation in pediatric patients receiving adalimumab for JIA, CNO, uveitis, sarcoidosis, or HS at a tertiary care center. A total of 119 patients were stratified into two groups based on presence or absence of ADAs. Data collected included duration of adalimumab therapy, dose frequency, flare frequency, methotrexate co-therapy, and treatment interruptions. Differences between groups were determined by chi-square test for categorical variables and Kruskal-Wallis test for continuous variables. A p-value of < 0.05 was considered statistically significant.

Results: Among 119 patients, 88 received adalimumab every 14 days, 21 every 7 days, and 10 at other frequencies. Patients on treatment every 7 days had less antibody formation than those on every 14 days ($p = 0.04$). Further analysis was done on the 88 patients on every 14-day regimen. Of those, 42 (37.17%) developed ADAs (Table 1). Patients with ADAs were of younger age than those without ADAs (12 years vs. 14 years, $p = 0.02$) (Figure 1). Flare rates were higher in patients with ADAs (69.86% vs. 97.6%; $p = 0.001$). The median duration of adalimumab use was not statistically different, though still greater in those with ADAs compared to those without (24 months [IQR 13–47] vs. 13 months [IQR 7–33]; $p = 0.02$) (Figure 2). Methotrexate was used more frequently in the ADA-negative group (43.5% vs. 21.4%, $p = 0.049$). Dosing of methotrexate in mg/m^2 was not different between the groups. Treatment interruptions of >1 month occurred in 33.3% of ADA-positive patients vs. 17.4% of ADA-negative patients ($p = 0.14$), and use of methotrexate during these interruptions did not differ.

Conclusion: ADA development was more common in patients not receiving methotrexate and was associated with increased disease flares. Although length of therapy and treatment interruption did not differ significantly, the data suggests a possible role in immunogenicity risk. Patients with frequent adalimumab dosing regimens were less likely to develop ADAs, though use of methotrexate was not analyzed in this increased frequency group and needs exploration. Younger age was associated with increased risk of antibody development. Results suggest that early use of ADA monitoring, particularly in younger patients and those on less frequent adalimumab regimens, may be helpful. The addition of methotrexate therapy or increasing the dosing frequency in patients who cannot tolerate DMARDs may help reduce immunogenicity and improve clinical outcomes in pediatric rheumatology.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Olokizumab (OKZ) is a direct interleukin-6 (IL-6) inhibitor. IL-6 is an attractive target for the treatment of pJIA. The aim of the study was to identify the subpopulation of patients with polyarticular-course juvenile idiopathic arthritis (pJIA) who can be expected to have a better treatment response compared to the whole pJIA population.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Adolescent patients with active pJIA who had failed methotrexate were included in the Phase 2 open-label multicenter study in Russia and received OKZ in a dose of 64 mg every 4 weeks (q4w) subcutaneously (SC) during the main 24-week part of the study. The following outcomes were analyzed: JIA American College of Rheumatology 30/50/70% responses (JIA ACR 30/50/70 responses), Juvenile Arthritis Disease Activity Score-71 (JADAS-71), adverse events (AEs), the associations between the baseline C-reactive protein (CRP) and IL-6 values and effectiveness outcomes. IL-6 was detected in blood with the non-commercial ELISA assay (lower limit of quantification [LLOQ] =2 pg/ml). The significance of change from baseline was tested using the Wilcoxon signed-rank test, and the difference between groups was tested using Fisher exact test.

Results: A total of 16 patients - 9 (56.3%) girls and 7 (43.8%) boys - were enrolled; the median (25%; 75%) age at inclusion was 14.0 (13.0; 16.5) years, at pcJIA onset 11.8 (5.4; 13.7) years, and pcJIA duration was 3.4 (0.4; 8.9). Baseline IL-6 level was >LLOQ in 8 patients, median 87.9 (8.0; 106.9) pg/ml; and in 7 patients was ≤LLOQ. Baseline CRP was >10 mg/l in 8 patients and ≤10 mg/l in 7 patients.

By 24 weeks of treatment, median (25%; 75%) JADAS-71 significantly decreased from 20.8 (18.4; 32.6) at baseline to 9.5 (2.65; 20.8) points, p< 0.001. JIA ACR 30/50/70 response was achieved in 80%, 73.3%, 46.7% of patients, respectively. Both JADAS-71 and JIA ACR 30/50/70 outcomes had an insignificant trend toward better results in patients with higher baseline IL-6, with a significant difference for JIA ACR70 (**Table 1, Figure 1**). In 5 (33.3%) patients inactive disease status was achieved. AEs were reported in 12 (75%) patients, mostly mild to moderate ordinary infections (37.5%), which resolved without complications. No Grade 3-4 AEs, serious AEs,or deaths were reported. One patient discontinued treatment at Week 12 due to *de novo* psoriasis.

Table 1. Baseline IL-6 and CRP levels vs JIA ACR 30/50/70 responses at Week 24

IL-6 at Baseline	**JIA ACR30**	**JIA ACR50**	**JIA ACR70**
≤LLOQ (N=7)	4 (57.1)	4 (57.1)	1 (14.3)
>LLOQ (N=8)	8 (100.0)	7 (87.5)	6 (75.0)
p-value (Fisher exact test)	0.077	0.214	0.041
CRP at Baseline	**JIA ACR30**	**JIA ACR50**	**JIA ACR70**
CRP ≤10 mg/l (N=8)	5 (62.5)	5 (62.5)	2 (25.0)
CRP >10 mg/l (N=7)	7 (100.0)	6 (85.7)	5 (71.4)
p-value (Fisher exact test)	0.200	0.569	0.132

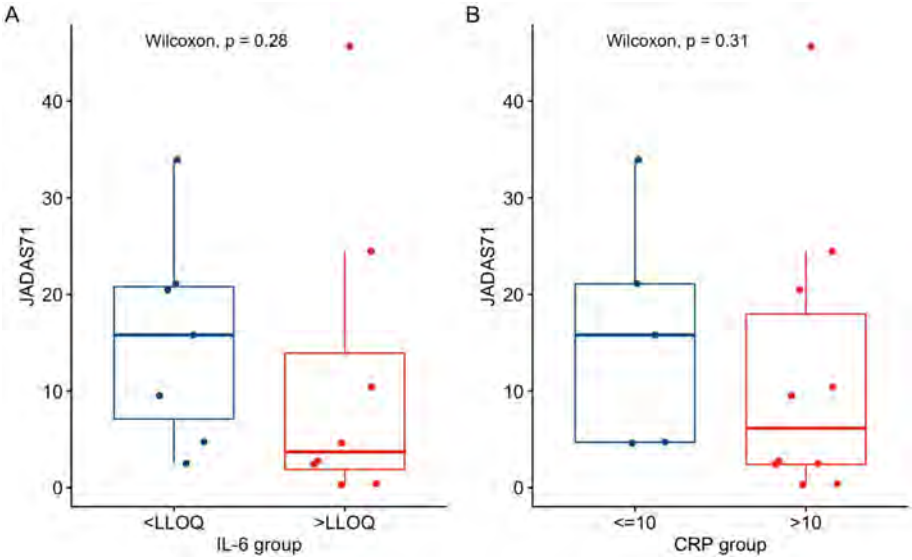

Figure 1. Baseline IL-6 and CRP levels vs JADAS-71 at Week 24

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: OKZ is a good therapeutic option for the pcJIA that leads to improvement in disease activity and has acceptable safety. It seems that OKZ response may be more successful in patients with higher baseline IL-6 levels.

Disease Extension in Children with Limited Juvenile Arthritis in the Childhood Arthritis and Rheumatology Research Alliance Registry

Eveline Wu[1], Stephen Balevic[2], Angel Marks[3], Manjushri Bhapkar[4], Baoshan Zhang[3], Alex Fist[4], Melanie Kohlheim[5], Vincent Del Gaizo[6], Laine Thomas[3], Laura Schanberg[7] and the CARRA Registry Investigators, [1]UNC Chapel Hill, Chapel Hill, NC, [2]Department of Pediatrics, Duke University, Durham, [3]Department of Biostatistics & Bioinformatics, Duke University, Durham, [4]Duke Clinical Research Institute, Duke University, Durham, [5]CARRA, Granville, OH, [6]Childhood Arthritis & Rheumatology Research Alliance (CARRA), Whitehouse Station, NJ, [7]Duke University Medical Center, DURHAM, NC

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: For children with limited juvenile idiopathic arthritis (JIA), defined as ≤4 affected joints and without uveitis, psoriasis, or sacroiliitis at presentation, it is unknown how often disease extends to polyarthritis or uveitis. The Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry is the largest prospective registry of children with JIA in North America, collecting longitudinal clinical and treatment data. The current study aimed to describe the natural history of limited JIA by estimating the proportion of recently diagnosed children who progress to develop polyarthritis, uveitis, or the need for systemic disease-modifying anti-rheumatic drugs (DMARDs), stratified by treatment status at the baseline Registry visit.

Methods: We conducted a retrospective analysis of data collected from the CARRA Registry between June 30, 2015 to July 16, 2021. Eligible children were 2-16 years at enrollment with a diagnosis of JIA within 6 months of enrollment and arthritis affecting ≤4 joints. Exclusion criteria included systemic JIA, sacroiliitis, inflammatory bowel disease, psoriasis, or uveitis. Patients were stratified based on systemic treatment status at the baseline Registry visit, defined as receipt of systemic DMARDs and/or systemic glucocorticoids for >14 days. The primary outcomes were incidence of disease extension within 12 and 18 months of enrollment, defined as the occurrence of polyarthritis (≥5 joints), uveitis, or need for systemic medications (e.g., conventional or biologic DMARDs or oral or intravenous glucocorticoids). We calculated the proportion of patients meeting each individual and the composite endpoint and conducted a Kaplan-Meier analysis.

Results: A total of 1,599 children with limited JIA were included (Table 1). At enrollment, 53% were receiving systemic treatment, including systemic steroids (9%), methotrexate (83%), and biologic DMARDs (28%). Among children who were treatment-naïve at enrollment, 7% developed polyarthritis, 5% developed uveitis, and 37% initiated new systemic treatment

Systemic DMARDs at 18 months	308 (41%)	557 (66%)	865 (54%)
Composite endpoint at 18 months	325 (43%)	568 (68%)	893 (56%)

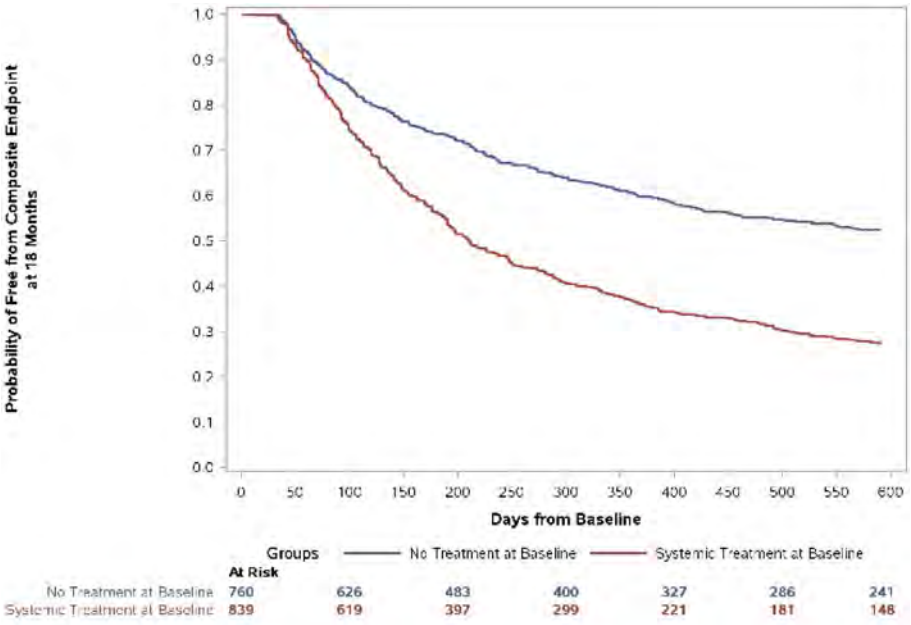

Figure 1. Kaplan-Meier Estimate for Composite Endpoint By Subgroups at 18 months.

within 12 months. By 18 months, 8% had developed polyarthritis, 5% uveitis, and 41% required new systemic treatment. The Kaplan-Meier estimate for the composite endpoint was 48% (Figure 1). Among those receiving systemic treatment at enrollment, 6% developed polyarthritis, 2% developed uveitis, and 61% were on systemic treatment at 12 months. At

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

18 months, 7% had developed polyarthritis, 2% uveitis, and 66% were on systemic treatment. The Kaplan-Meier estimate for the composite endpoint was 73% (Figure 1).

Conclusion: Among children with recently diagnosed limited JIA, nearly half received systemic DMARD within the first 6 months following disease diagnosis. Systemic medication use was not related to presence of polyarthritis or uveitis, suggesting clinicians are initiating systemic treatment early to manage persistent disease activity or prevent disease extension in limited JIA. Around 2 in 5 children who were treatment-naïve at Registry enrollment started systemic medication within 12 months. Over an 18-month period, the incidence of polyarthritis and uveitis was low across both treatment groups, with most extension occurring within the first 12 months.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Secukinumab demonstrated efficacy and safety in patients with juvenile idiopathic arthritis (JIA), including enthesitis-related arthritis (ERA) and juvenile psoriatic arthritis (JPsA), for up to 2 years in the JUNIPERA study.[1] The JUNIPERA clinical program included an extension study to assess the long-term efficacy and safety of secukinumab in patients with ERA and JPsA. Here we report the 4-year efficacy and safety results of the long-term extension (LTE) study.

Methods: Of 86 patients in the primary study, 55 deemed by the investigator to benefit from secukinumab therapy opted to enter the LTE study. Of these, 54 received secukinumab treatment (subcutaneous; 75/150 mg in patients < 50/≥50 kg) every 4 weeks up to 4 years. Secukinumab dose could be escalated from 75 to 150 mg or 150 to 300 mg, based on the investigator judgment of disease activity. Efficacy outcomes were presented as observed for JIA American College of Rheumatology (JIA ACR) 30/50/70/90/100 responses, inactive disease (ID) status over time (from weeks 104 to up to 312), and change from baseline in Juvenile Arthritis Disease Activity Score (JADAS-27 and JADAS-71) along with adverse events (AEs).

Results: The mean (SD) age of the overall JIA population was 12.5 (3.4) years, and 66.7% were male. A total of 22 patients (40%) underwent dose escalation. Most patients achieved JIA ACR 30 responses (>93%) at all visits during the LTE (-**Figure 1**). The JIA ACR 50/70/90/100 (**Figure 2**), JADAS-27 and JADAS-71 responses (**Figure 3**), as well as the ID status

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1: JIA ACR 30 response in the overall population and in each JIA subtype, ERA, and JPsA

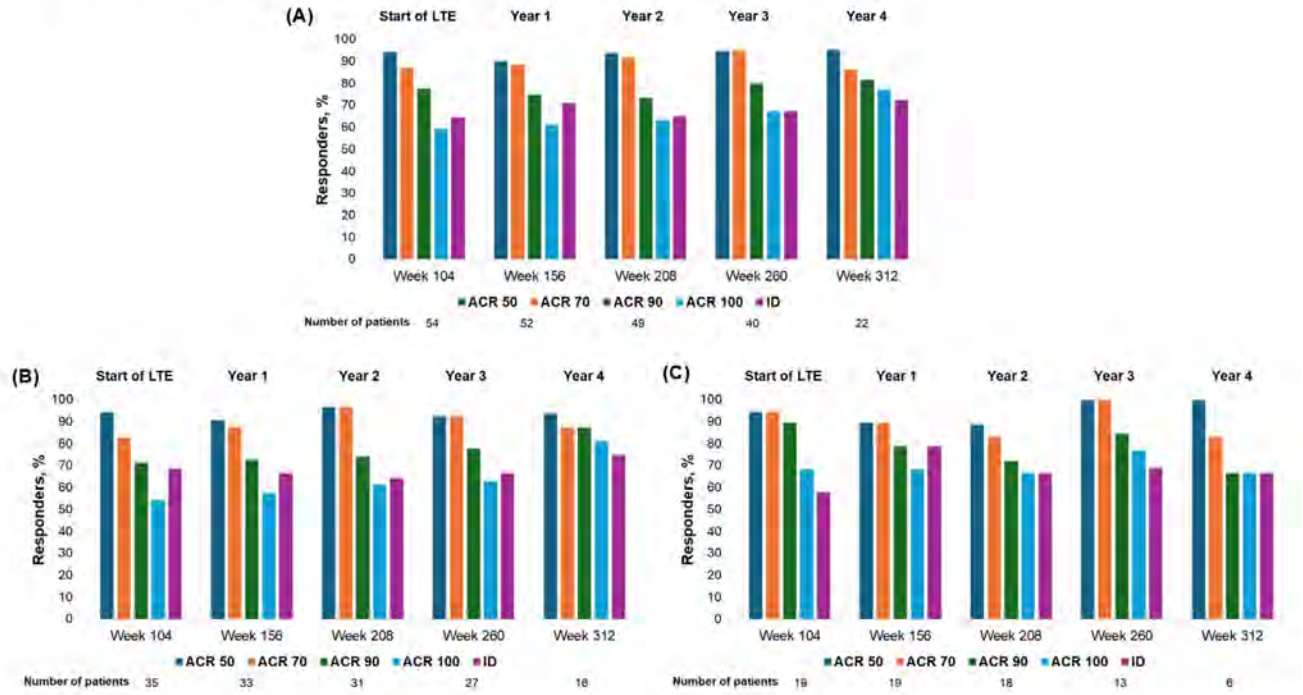
JIA ACR 30 defined as ≥30 improvement in the ACR JIA response criteria. JIA ACR response was derived relative to the primary study baseline.

ACR, American College of Rheumatology; ERA, enthesitis-related arthritis; JADAS, Juvenile Arthritis Disease Activity Score; JIA, juvenile idiopathic arthritis; JPsA, juvenile psoriatic arthritis; LTE, long-term extension; N, number of patients in the full analysis set.

Figure 1

achieved during the primary study, were maintained in the overall population and the ERA and JPsA subtypes in the LTE. Of note, the JIA ACR complete response (JIA ACR 100) was achieved by ≥50% of patients at all visits during the LTE.

Figure 2: JIA ACR 50/70/90/100 response and inactive disease status in the overall JIA population (N=54, [A]), and in the ERA (N=35, [B]) and JPsA (N=19, [C]) subtypes



JIA ACR 30/50/70/90/100 defined as ≥30%/ 50%/70%/90%/100% improvement in the ACR JIA response criteria. Clinical inactive disease definition was adapted from the ACR criteria of Wallace et al [1] which requires all the following criteria to be met: no joints with active arthritis, no uveitis, CRP (local) value within normal limits for the laboratory where tested or, if elevated, not attributable to ERA/JPsA. Physician's global assessment of disease activity score of best possible on the scale used (i.e. best possible score is defined as ≤ 10mm), and the absence of patient-reported morning stiffness attributable to JPsA or ERA lasting ≥15 minutes. JIA ACR response was derived relative to the primary study baseline.

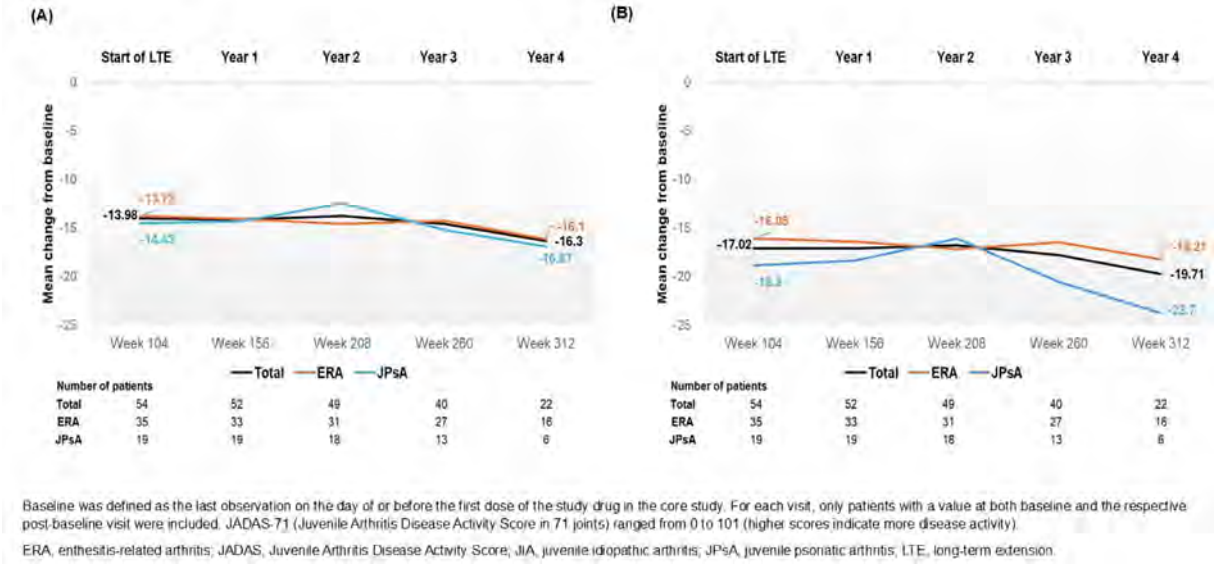
ACR, American College of Rheumatology; CRP, C-reactive protein; ERA, enthesitis-related arthritis; JADAS, Juvenile Arthritis Disease Activity Score; JIA, juvenile idiopathic arthritis; JPsA, juvenile psoriatic arthritis; LTE, long-term extension; N, number of patients in the full analysis set.

1. Wallace CA, et al. *Arthritis Care Res (Hoboken)*. 2011;63:929-936.

Figure 2

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 3: JADAS-27 (A) and JADAS-71 (B) change from baseline in the overall JIA population and in each JIA subtype



Baseline was defined as the last observation on the day of or before the first dose of the study drug in the core study. For each visit, only patients with a value at both baseline and the respective post-baseline visit were included. JADAS-71 (Juvenile Arthritis Disease Activity Score in 71 joint(s) ranged from 0 to 101 (higher scores indicate more disease activity).

ERA, enthesitis-related arthritis; JADAS, Juvenile Arthritis Disease Activity Score; JIA, juvenile idiopathic arthritis; JPsA, juvenile psoriatic arthritis; LTE, long-term extension.

Figure 3

With 182.2 patient-years of secukinumab exposure during the LTE, 46 patients (85.2%) experienced at least one AE. Most AEs were considered not related to the study treatment and were generally mild (n=25, 46.3%) to moderate (n=17, 31.5%) in severity. A total of 9 non-fatal serious AEs (SAEs) were experienced by 4 (7.4%) patients, and except for 1 event of Crohn's disease (1.9%) that led to treatment discontinuation, all SAEs were considered not related to secukinumab treatment and were recovered/resolved during study participation. The most common treatment-emergent AEs by system organ class were infections and infestations (n=33, 61.1%). No deaths were reported during the LTE period or during primary study.

Conclusion: Long-term sustained clinical benefits of secukinumab were observed in patients with JIA (ERA and JPsA subtypes) for up to 4 years of exposure in the LTE study, along with a favorable long-term safety profile.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Chronic anterior uveitis (CAU) develops in 15-20% of juvenile idiopathic arthritis (JIA) cases. Early detection may prevent vision loss. However, known clinical risk factors do not accurately predict CAU. We and others report that 50% of the same protein biomarkers detected in tear fluid of patients overlapped in paired aqueous humor. Non-invasive biomarkers that reflect eye inflammation and are easily implemented in clinic may improve prediction of CAU and influence screening. We aim to compare inflammatory mediators in tear fluid and serum of children with JIA with and without CAU.

Methods: The prospective multicenter PEDIA-U study enrolled JIA children without (JIA-no-U) and with CAU (JIA-U) ≥4 y/o. Serum was paired with tear fluid collected from both eyes at same study visit using Schirmer strips. S100A8/A9 and A12 were measured by ELISA, and IL-8, CXCL-10 (IP-10), MCP-1, sICAM-1, APRIL and VEGF-A by Luminex assays in all samples. We compared levels between JIA-no-U and JIA-U per sample type, then between serum and tear fluid where we calculated tear/blood ratios to assess the difference in abundance between both samples. As samples were collected from both eyes, we used a mixed model analysis with individuals and eyes as random effects. Data was log-transformed prior to analyses.

Results: Forty-two patients (31 JIA-no-U, 11 JIA-U) contributed 84 tear (62 JIA-no-U, 22 JIA-U) and 20 serum samples (16 JIA-no-U, 4 JIA-U) (Table 1). Two JIA-no-U patients at time of collection later developed CAU but were grouped as JIA-U.

In serum, S100A12 (JIA-no-U LS mean 76,807.11 vs JIA-U LS mean 27,455.02, p=0.0027) and S100A8/A9 (JIA-no-U LS mean 5,608.29 vs JIA-U LS mean 2,217.52, p=0.0008) were elevated in JIA-no-U (Table 2). In tears, CXCL-10 (JIA-no-U LS means 5.1 vs JIA-U LS means 4.01, p=0.001) and MCP1 (JIA-no-U LS Means 2.18 vs JIA-U LS means 1.31, p= 0.0083) were elevated in JIA-no-U (Table 2).

Comparing paired serum and tears levels in 19 patients (Table 3), S100A12 (serum mean 4.67 vs tears mean 3.09, ratio 0.66 p< 0.001) and sICAM-1 (4.24 vs 3.55, 0.83 p< 0.001) were significantly elevated in serum. Conversely, CXCL10 (serum 0.09 vs tear 2.14, ratio 22.76 p< 0.001), APRIL (1.88 vs 3.55, 1.86 p< 0.001), and VEGF (2.2 vs 2.69, 1.22 p< 0.003) were elevated in tear fluid. MCP-1 and S100A8/9 were similar in both samples (21.06 vs 0.86, 0.811 p=0.292 and 3.54 vs 3.66, 0.393 p=0.393 respectively).

BDNF (pg/ml)	0.00	1.14	0	**<0.001**
CXCL10/IP-10 (pg/ml)	2.14	0.094	22.76	**<0.001**
MCP-1 (pg/ml)	0.86	1.06	0.811	0.292
VEGF-A (pg/ml)	2.69	2.20	1.22	**0.003**
s100A12 (pg/ml)	3.09	4.67	0.66	**<0.001**
s100A8/A9 (pg/ml)	3.66	3.54	1.033	0.393
sICAM-1 (pg/ml)	3.55	4.24	0.83	**<0.001**

Conclusion: We compared levels of tear and serum-based biomarkers in children with JIA with and without CAU. Differences in S100 proteins in serum may reflect systemic inflammation. CXCL10, APRIL and VEGF were highly enriched in tear fluid, while MCP-1 and S100 proteins were similar in both samples. These tear-based biomarkers may reflect damage from inflammation, allowing an influx of inflammatory mediators into the eye. Importantly, biomarkers reported in JIA and JIA-U were detected in both sample types. Elevated baseline S100A12 in JIA children who develop CAU has been noted, as well as VEGF in cystoid macular edema. Tear and blood-based biomarkers are easily measured in various clinical settings, may complement known CAU risk factors, and improve screening. Our future studies will consider disease activity and topical and systemic treatment.

Background/Purpose: Childhood chronic non-infectious uveitis (cNIU) is a sight-threatening condition that can lead to blindness if not appropriately treated. cNIU is typically associated with Juvenile Idiopathic Arthritis or can occur in isolation when idiopathic. Adalimumab (ADA) is the only approved treatment for cNIU and TNF inhibitors (TNFi) are the recommended first line-biologic treatment of cNIU. However, 25% of patients do not achieve disease remission. In these cases, there is no consensus whether switching to another TNFi or swapping drug class is more effective. We aim to evaluate the efficacy of the switch OR swap therapeutic approach to treating cNIU refractory to primary TNFi and the efficacy of the different drugs in these patients.

Methods: In a multicentre international retrospective study involving pediatric rheumatology centres in Florence, Boston, Cincinnati, Athens and Trieste, we enrolled children with a diagnosis of cNIU unresponsive to ADA and required the use of another biologic. Remission on treatment was determined according to the grading of ocular inflammation using the

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

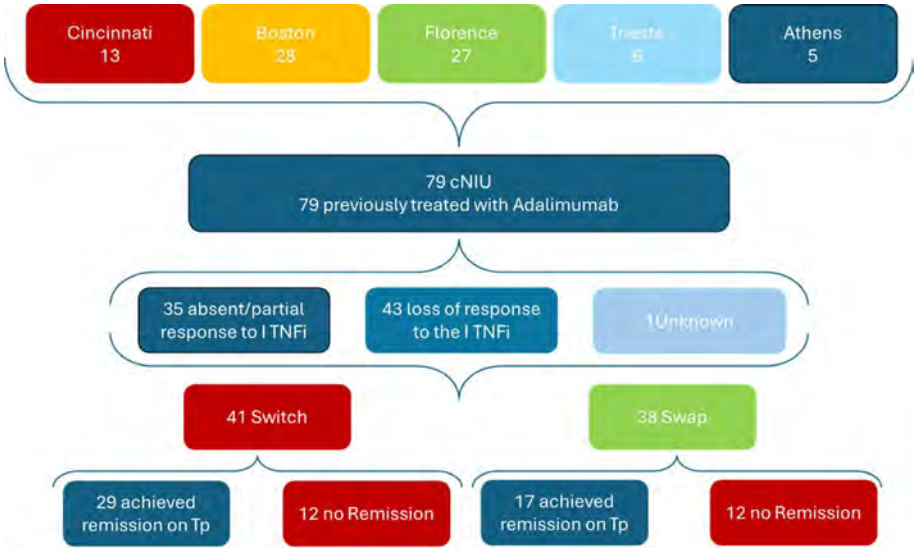

Figure 1: Figurative representation of the population included and achievement of remission with the two treatments approach

Standardization of Uveitis Nomenclature (SUN) criteria. Statistical analysis was performed using Spss 29 for windows. A p-value < 0.05 was considered significant.

Results: We collected the data of 79 children with cNIU, of whom 57 had JIA-associated uveitis (JIA-U) and 17 had idiopathic uveitis (IU) (Table 1). Seventy-nine were treated with ADA as first-line TNFi. Forty-one children did not respond to treatment and were "switched" to a second TNFi (38 infliximab, 3 golimumab), and 38 "swapped" to a non-TNFi biologic (20 tocilizumab, 2 baricitinib, 2 tofacitinib, 11 abatacept, 1 canakinumab). We identified a significant difference in treatment approach, European swapped more frequently than American (χ^2 0.078 p 0.78). We did not find significant differences in remission between switching TNFi and swapping drug class (χ^2 0.078 p 0.78) or among the different drugs (χ^2 32.87p < 0.001). On sub-analysis of the different sub-types of uveitis (JIA-U and Idiopathic), we did not find significant differences in remission of patients for either switching TNFi or swapping to non-TNFi ($\chi^2$0.021 p0.88 and χ^2 0.016 p 0.90 respectively) or for the different drugs regardless of switch/swap ($\chi^2$5.03 p0.754 and $\chi^2$2.57 p 0.463 respectively). There were no significant differences based on anatomical location- anterior NIU (switch vs swap $\chi^2$0.219 p0.64 and based on the drugs $\chi^2$4.97 p0.760) and non-anterior NIU ($\chi^2$0.117 p0.733 and $\chi^2$2.97 p0.395)., Furthermore no significant differences were assessed considering the responder to the primary TNFi ($\chi^2$0.012 p0.912 and $\chi^2$3.35 p0.851) and non-responder ($\chi^2$0.024 p0.877 and $\chi^2$5.4 p0.24)

Conclusion: Management of childhood cNIU is challenging and evidence is scarce on treatment after ADA failure. This is one of the largest multicentre international cohorts that showed that switch and swap are reasonable next treatment and there is no preference for a specific class of biologics and all are reasonable therapeutic approach for the management of cNIU. The use of the European and US cohort allowed us to make a comparison between the two treatments approach. Further data are needed to make specific comparison among drugs.

Abstract Number: 0408

Implementing Social Drivers of Health Screening for Patients with Pediatric Systemic Lupus Erythematosus

Julia Harris[1], Susan Parish[2], Michelle Manaskie[2] and Ashley Cooper[2], [1]Children's Mercy Kansas City, Overland Park, KS, [2]Children's Mercy Kansas City, Kansas City, MO

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: There is a profound need to improve outcomes in children with systemic lupus erythematosus (SLE) given this disease is complicated by significant morbidity. Disparities in pediatric SLE (pSLE) outcomes are also rampant and may be better understood through a social drivers of health (SDOH) framework. SDOH are conditions in the environment where patients live, work, learn, and play, and they have been found to have a significant influence on health outcomes. Children's Mercy Integrated Care Solutions (CMICS), our hospital's population health management subsidiary, has created Lift Up KC, a social care platform linking patients and families to community resources. Our patients with SLE have low disease activity at 85.7% of visits, and 67.7% of SLE visits have a low patient/parent global assessment of overall wellbeing. We aimed to increase the percent of patients with SLE seen in the rheumatology clinic who receive screening of SDOH at follow-up clinic visits from 0% to 50% by June 30, 2025. We also aimed to increase the percent of patients with SLE who have low disease activity (based on SLEDAI-2k) from 85.7% to 90% by June 30, 2025.

Methods: We utilized quality improvement (QI) methodology including QI tools such as a key driver diagram (Figure 1), fishbone diagram, process map, and failure modes effects analysis. Our outcome measures include percent of SLE visits with low disease activity (SLEDAI-2k ≤4) and low patient/parent global assessment of overall wellbeing score (≤2). Process measures include SDOH screening being sent, completion of screening form, screen positive rate, patients/parents wanting

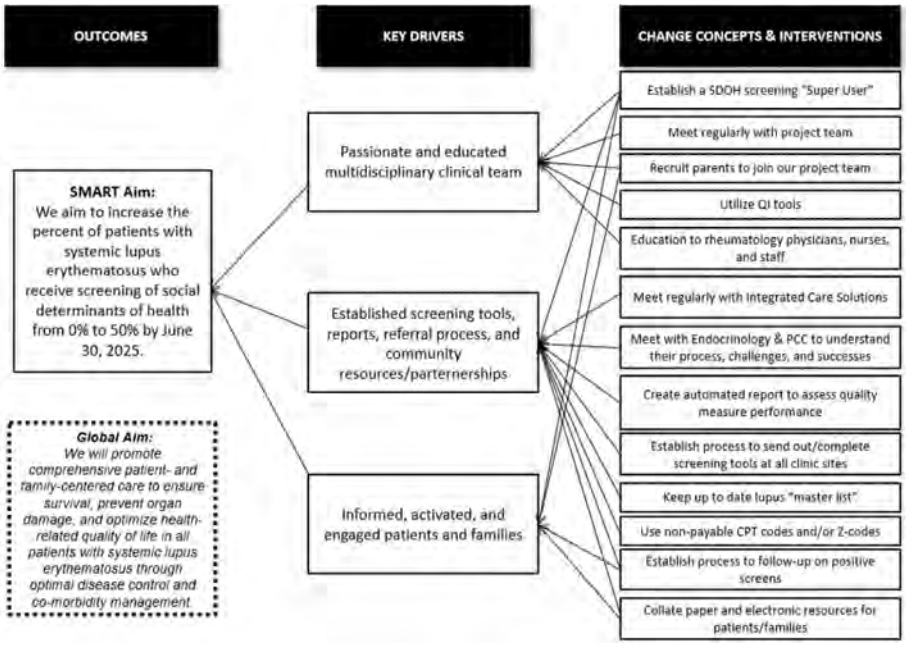

Figure 1. Key driver diagram for social drivers of health screening in patients with SLE.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

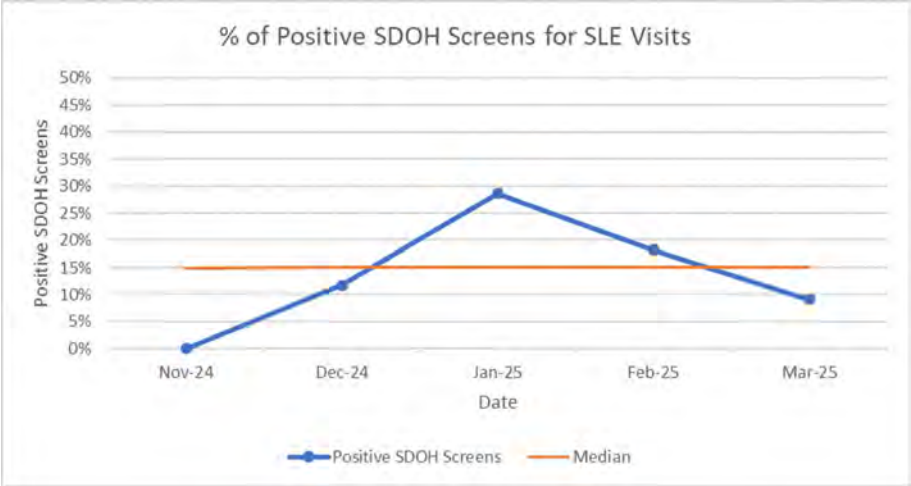

Figure 2. Run chart of positive SDOH screens.

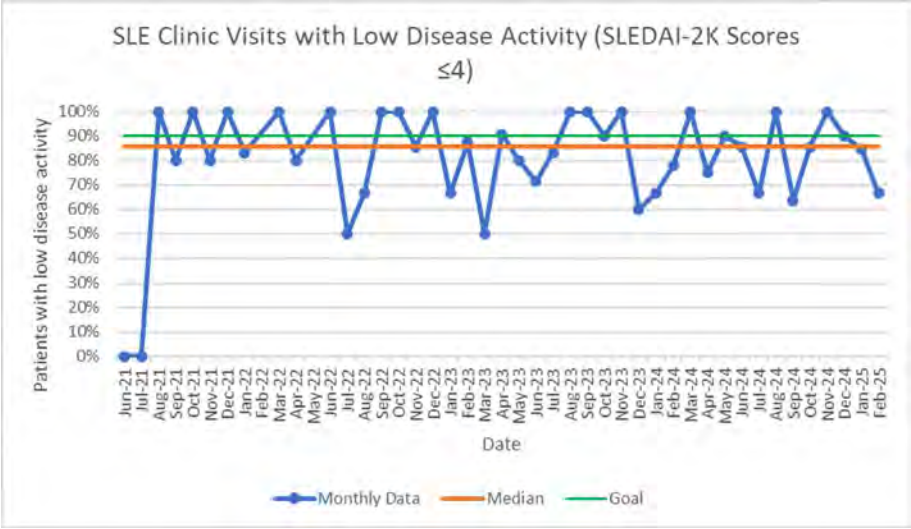

Figure 3. Annotated run chart of SLE visits with low disease activity.

assistance, successful referral to a community-based organization, and no-show rate. Our balancing measure is an average physician satisfaction score. Interventions included meeting with local experts, education on our screening tool and referral process, identification of a super user, education to physicians and nurses, and partnership with social work. We evaluated our data on run charts.

Results: SDOH screening started in November 2024 and the screening tool has been sent to 100% of patients/families since this time. The form completion rate is 63.9%. Social needs identified in 1-3 screens per month and help wanted 0-4 times per month for a positive screen rate of 9.1-28.6% (median 15%) (Figure 2). All families wanting assistance were referred to a partner community organization. No show visits and last-minute cancellations occurred in 16.7% of scheduled SLE visits. Our outcome measures remained stable – 85.7% of visits with low disease activity (Figure 3) and 67.7% with low patient/parent global assessment of overall wellbeing.

Conclusion: We have successfully implemented SDOH screening in our SLE population. Although outcomes remain stable at this point, we hope to improve the care of SLE patients over time by addressing social needs that can have a significant impact on their disease and overall health.

Abstract Number: 0409

Discordance Between Disease Activity and Patient-Reported Outcomes in Patients with Juvenile Idiopathic Arthritis

Julia Harris[1], Leslie Favier[2], Emily Fox[3], Jordan Jones[2], Michael Holland[3], Cara Hoffart[2], Maria Ibarra[3] and Ashley Cooper[2], [1]Children's Mercy Kansas City, Overland Park, KS, [2]Children's Mercy Kansas City, Kansas City, MO, [3]Children's Mercy Hospital, Kansas City, MO

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Outcome assessment is essential to optimize care for patients with juvenile idiopathic arthritis (JIA). Although disease activity and patient-reported outcomes (PROs) are different measures, patients commonly report pain and suboptimal overall wellbeing with no active arthritis on exam. We also note the converse with patients denying pain or suboptimal wellbeing with active disease being noted on physical exam. Therefore, in order to ascertain this and determine appropriate future interventions, the objective of this study was to assess for concordance between disease activity outcomes and PROs in patients with non-systemic JIA.

Methods: Data was assessed from January to August 2024. Patients with systemic JIA were excluded. Disease activity outcomes include the 10-joint clinical Juvenile Arthritis Disease Activity Score (cJADAS10), active joint count, and physician global assessment of disease activity (PhGA) value (0-10; 0=no disease activity). PROs include the Childhood Health Assessment Questionnaire (CHAQ) (0-3; 0 is optimal), arthritis-related pain intensity score (0-10; no or mild pain ≤3), and patient/parent global assessment of overall wellbeing (PtGA) (0-10; low value if ≤2).

Results: Data from 584 patients across 1149 visits were analyzed. Active arthritis was present at 31.2% of visits with a mean joint count of 1.19 (Table 1). Mean cJADAS10 was 3.5 (range 1.15 [in patients with inactive arthritis and PhGA=0] to 8.53 [in patients with active arthritis]). Mean PhGA was 0.82, and this value increased to 2.43 for those with active arthritis. Mean PROs were all lower in those with inactive arthritis although ranges remained the same. For those with no active arthritis, 34.4% had functional limitations, 37.5% had pain, and 19.4% had a moderate-high PtGA (Table 2). Conversely, for those with active arthritis, 29.5% reported no pain, 37.5% reported a CHAQ of 0, and 22.8% reported PtGA of 0.

Conclusion: For a considerable percent of patients with JIA with inactive arthritis, there are reports of pain, functional limitations, and suboptimal overall wellbeing. Additionally, many patients with JIA and active arthritis report no pain and optimal wellbeing, which suggests that PROs may be misleading if taken in isolation and physical assessment of arthritis is still paramount

Table 1. Disease activity and patient-reported outcome values.

	Overall Mean (range)	Active arthritis* mean (range)	Inactive arthritis mean (range)	Inactive arthritis & PhGA=0 mean (range)
cJADAS10	3.50 (0-27)	8.53 (0-10)	1.38 (0-10)	1.15 (0-10)

*Active joint count >0. †Not all denominators in each category are the same due to missing data. cJADAS10, 10-joint clinical Juvenile Arthritis Disease Activity Score; PhGA, physician global assessment of disease activity; CHAQ, Childhood Health Assessment Questionnaire; pain, arthritis-related pain intensity; PtGA, patient/parent global assessment of overall wellbeing.

to determine active disease. Limitations include not stratifying data by JIA subtype, disease duration, uveitis status, medication use, and/or other comorbidities such as chronic pain syndromes. Continued self-management support is imperative to address factors impacting patient wellbeing. Further studies are needed to determine why this discordance exists and to assess demographic and disease characteristics associated with the discordance between disease activity and PROs.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Outcomes for patients with juvenile idiopathic arthritis (JIA) are suboptimal with many patients having active disease, functional limitations, significant pain, and decreased health-related quality of life. We partnered with Integrated Care Solutions (ICS), our population health management subsidiary, on a chronic condition value-based care program with upfront infrastructure funding and an additional performance-based funding opportunity. ICS has 250,000 value-based pediatric lives, which encompasses about 50% of children in the Kansas City metro area. Our aim was to decrease the mean 10-joint clinical Juvenile Arthritis Disease Activity Score (cJADAS10) for patients with JIA from 2.6 to 2.55 in addition to decreasing the gap between patients with commercial insurance and Medicaid from 1.4 to 0.8 by December 31, 2025.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

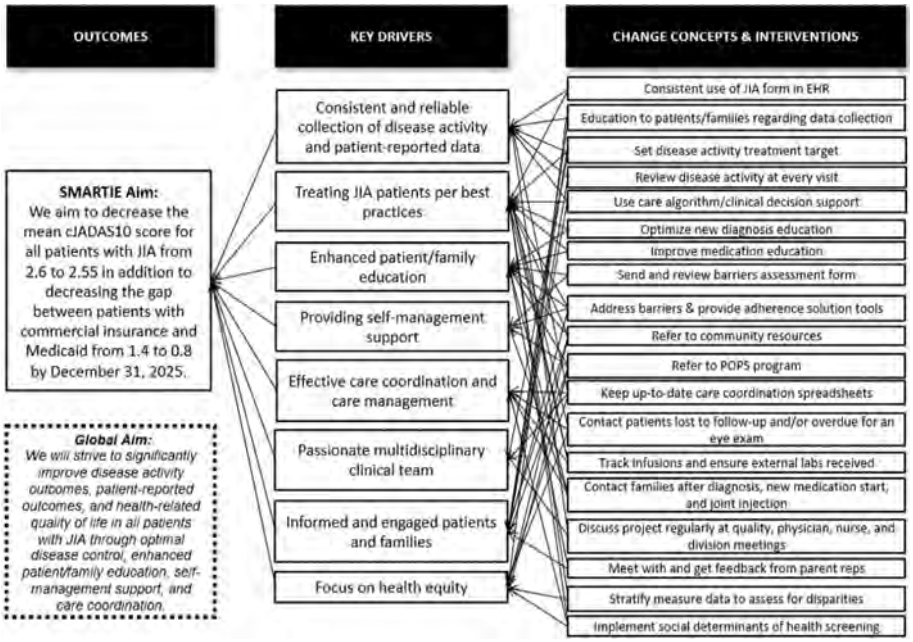

Figure 1. Key driver diagram for improving outcomes in patients with JIA.

Methods: Three outcome measures were identified – mean cJADAS10 score, active joint count, and patient/parent global assessment of overall wellbeing (PtGA). Interventions were established as our process measures: setting a treatment target of disease activity, JIA care coordination, and ICS care management. Balancing measures of physician and nurse satisfaction were established. Data from our ICS and entire JIA population were portrayed on run/control charts and stratified by insurance type, race, and ethnicity to assess for disparities.

Results: A key driver diagram was created (Figure 1). 184 patients (24.5% of our JIA population) are covered under an ICS network. Targets were established based off of baseline data and performance of a pediatric rheumatology learning health network. A cost and utilization measure was omitted this year due to the low volume of hospitalizations and the lack of reliable attribution of emergency department visits to a patient's JIA diagnosis. A quality measure dashboard for ICS patients

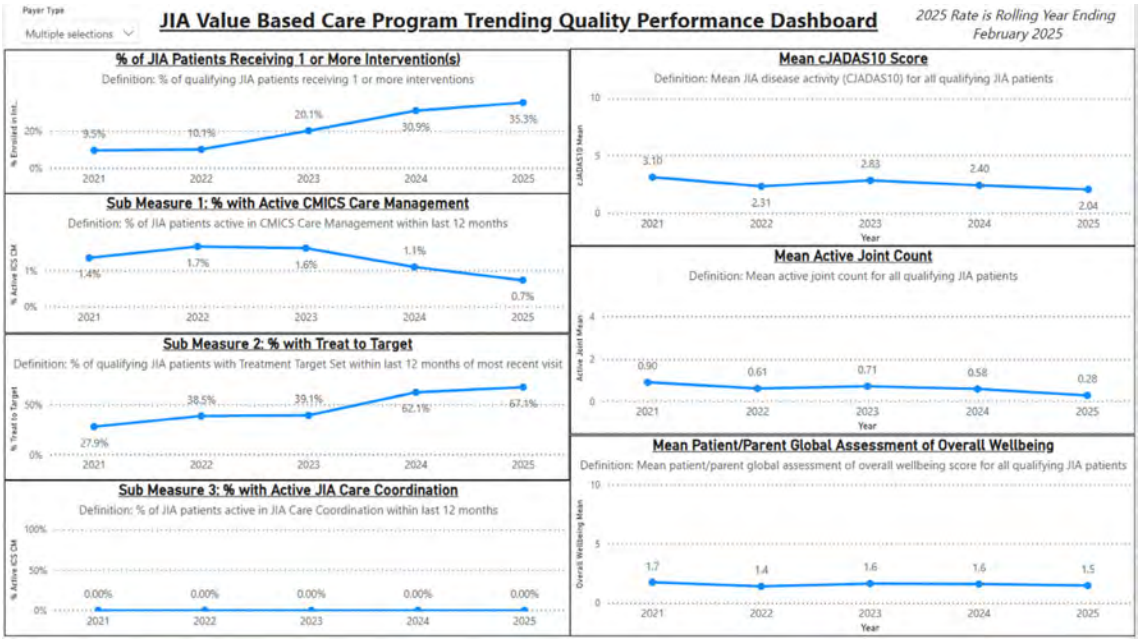

Figure 2. JIA quality measure dashboard.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

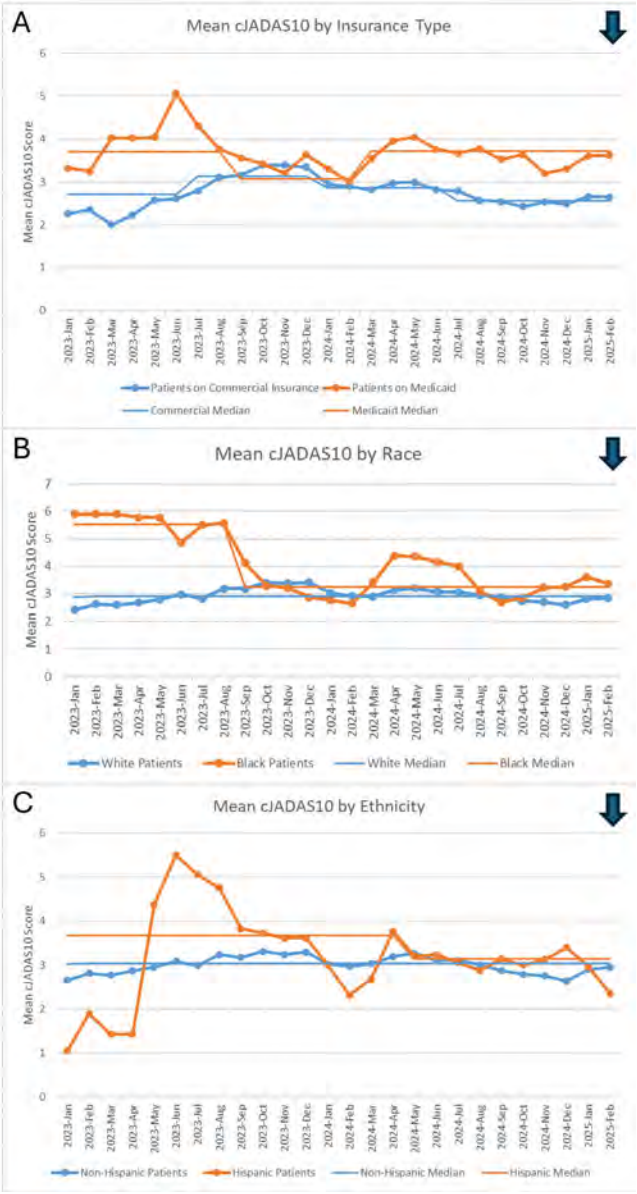

Figure 3. Run charts assessing for disparities in mean cJADAS10 by insurance type (A), race (B), and ethnicity (C).

was created (Figure 2), and additional run/control charts for the entire JIA population are tracked monthly. Our team established a new care coordination process to track patients overdue for a rheumatology appointment and to reach out to patients/families after a new JIA diagnosis, new medication start, and/or a joint injection. Baseline disparity assessment noted significant gaps in mean cJADAS10 by insurance type (0.98), race (0.36), and ethnicity (0.1) (Figure 3). Disparities based on insurance type (commercial insurance compared to Medicaid) also noted in mean active joint count (gap=0.82) and mean PtGA (gap=0.2).

Conclusion: We have partnered with our population health management subsidiary to improve outcomes in patients with JIA through a novel value-based care program. We will continue to monitor our quality measures and provide care coordination and care management in hopes of optimizing care delivery and mitigating disparities. We plan to review full cost data for JIA patients to establish a future cost and utilization metric to fully advance value-based care. Furthermore, we hope with achieving our quality measure goals, we will receive funding to support future efforts including enhanced patient/family education, social drivers of health screening, optimization of self-management support, and more.

Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: The Pediatric Rheumatology Care and Outcomes Improvement Network (PR-COIN) is a learning health network focused on improving healthcare delivery and outcomes in patients with juvenile idiopathic arthritis (JIA). Measured disease activity outcomes include inactive or low disease activity by the 10-joint clinical Juvenile Arthritis Disease Activity Score (cJADAS10), active joint count, and physician global assessment of disease activity (PhGA) score. PR-COIN also tracks patient-reported outcomes (PROs) including a patient/parent global assessment of overall wellbeing (PtGA) score, pain, and physical function. We sought to assess for any differences in disease activity and PROs based on geographic location of the PR-COIN sites.

Methods: We assessed PR-COIN registry data from 1/2023-2/2025. Geographical cohorts from the United States were divided into the following: Northeast, Midwest, South, and West. Cohort patient count, race, ethnicity, and insurance status were assessed. Run charts were created to portray data over time and medians were calculated. A low PtGA value indicates a score of ≤2 (0=very well, 10=very poor). No or mild pain is a value of ≤3 on the arthritis-related pain intensity scale (0=no pain,

Table 1. Current patient count and characteristics of patients by geographic region.

Geographic Region	Number of Sites*	Active Patients†	Race			Ethnicity			Insurance Type		
			White	Black	Other/Unknown	Non Hispanic	Hispanic	Unknown	Commercial	Medicaid	Other/Unknown
Northeast	5	2245	1646 (73.3%)	123 (5.5%)	476 (21.2%)	1747 (77.8%)	273 (12.2%)	225 (10.0%)	1246 (55.5%)	189 (8.4%)	810 (36.1%)
Midwest	4	2613	1832 (70.1%)	122 (4.7%)	659 (25.2%)	2020 (77.3%)	111 (4.2%)	482 (18.4%)	1009 (38.6%)	347 (13.3%)	1257 (48.1%)
South	4	1207	930 (77.0%)	130 (10.8%)	147 (12.2%)	1001 (82.9%)	162 (13.4%)	44 (3.6%)	719 (59.6%)	342 (28.3%)	146 (12.1%)
West	2	800	522 (65.2%)	14 (1.8%)	264 (33.0%)	569 (71.1%)	188 (23.5%)	43 (5.4%)	655 (81.9%)	52 (6.5%)	93 (11.6%)

*as of 2/2025, †as of 4/2025

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 2. Overall median performance by geographic region from January 2023 to February 2025.

Geographic Region	Inactive or Low Disease Activity	Active Joint Count	Physician Global Assessment	Low Patient/Parent Global Assessment	No or Mild Pain	Optimal Physical Function
Northeast	85.5%	0.51	0.60	80.6%	83.2%	85.5%
Midwest	79.9%	0.81	0.66	75.5%	77.9%	60.8%
South	74.9%	0.80	0.68	75.1%	85.8%	61.0%
West	78.4%	0.33	0.22	74.0%	84.1%	92.9%

10=severe pain). Optimal physical function is a score of 0 on the Childhood Health Assessment Questionnaire (CHAQ) or ≥40 on Patient-Reported Outcomes Measurement Information System (PROMIS) Mobility or Upper Extremity Function.

Results: There are 2-5 sites and 800-2613 patients per geographic region (Table 1). White patients were a majority of the reported race (65.2-77.0%), with a sizable percentage being other or unknown (12.2-33.0%). Run charts stratified by geographic region are depicted in Figure 1. Medians for each disease activity measure and PRO varied by geographic region (Table 2). The percent of patients in inactive or low disease activity ranged from 74.9% (South) to 85.5% (Northeast). The West had the lowest active joint count (0.33), and the Midwest and South had the highest (0.80-0.81). The Midwest and South also had the highest PhGA values (0.66-0.68) with the West having a considerably lower value at 0.22. The West also

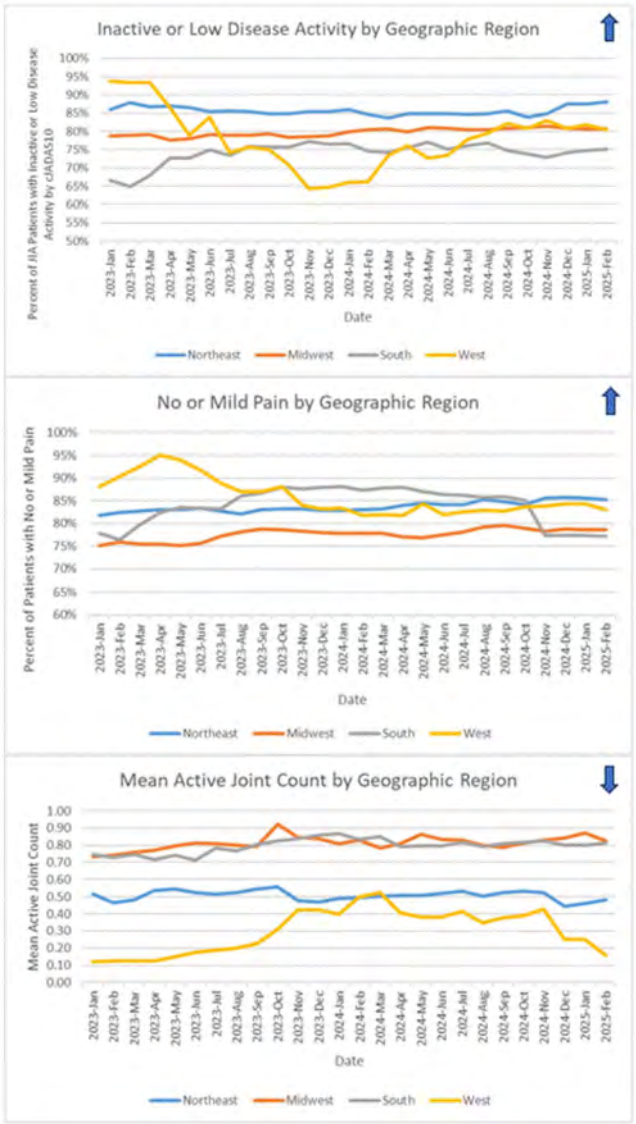

Figure 1. Examples of stratified run charts of quality measures by geographic region.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

had the least percentage of patients with a low PtGA (74.0%), and the Northeast had the highest percent (80.6%). No or mild pain ranged from 77.9% (Midwest) to 85.8% (South). Optimal physical function was bimodal with the Midwest and South ranging from 60.8-61.0% and the Northeast and West with 85.5-92.9% of their patients satisfying this measure.

Conclusion: Overall, a large proportion of patients with JIA in the PR-COIN registry are doing well with inactive or low disease activity, no or mild pain, and optimal physical function. We found differences in disease activity and PROs by geographic region. Limitations include missing data, variable data quality in relation to the percent of a site's JIA population enrolled in the PR-COIN registry, and no control for patient mix (including JIA subtype and disease duration). Next steps include assessing processes of care by geographic region, patients in rural versus urban areas, variation in medication use, impact of social drivers of health, and considering geographic-specific workgroups and/or interventions.

The Association of Obesity with Juvenile Spondyloarthritis

Katelyn Baggett[1], Timothy Brandon[2] and Pamela Weiss[3], [1]Johns Hopkins University, Newtown Square, PA, [2]Children's Hospital of Philadelphia, Philadelphia, PA, [3]Childrens Hospital of Philadelphia, Philadelphia, PA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Childhood obesity is a global public health concern that impacts the health and wellbeing of all children and particularly negatively affects children living with chronic autoimmune disease. Studies in adults have shown a significant association between obesity and ankylosing spondylitis (AS); however, the association of obesity with juvenile spondyloarthritis (JSpA) is unknown. Obesity may be a risk factor for or a consequence of JSpA. This study aims to evaluate the prevalence of obesity in children with JSpA compared to a healthy control population.

Table 1. Characteristics of children with JSpA versus healthy controls. ^ Subjects with sacroiliitis had MRI-defined inflammation but did not fulfill ILAR criteria for ERA or PsA. * Subjects with undifferentiated arthritis met ERA criteria but had a first-degree relative with psoriasis or met PsA criteria but had a diagnosis of sacroiliitis and inflammatory bowel disease.

Characteristic	All	Controls	JSpA
No. of subjects	950	760	190
Age in years, median		15 (12 to 17)	15 (12 to 17)
Female, n (%)	565	348 (45.8%)	87 (45.8%)
Disease duration (days)	--	--	56.5 (0-216)
JSpA category	--	--	
Enthesitis-related arthritis	--	--	88 (46.3%)
Psoriatic Arthritis	--	--	29 (15.3%)
Sacroiliitis^	--	--	28 (14.7%)
Undifferentiated JIA*	--	--	10 (5.3%)
IBD-associated arthropathy	--	--	35 (18.6%)
Race, n (%)			
African American	75 (7.9%)	60 (7.9%)	15 (7.9%)
Asian American	35 (3.7%)	28 (3.7%)	7 (3.7%)
Multiracial/Other	170 (17.8%)	136 (17.9%)	34 (17.9%)
White	670 (70.5%)	536 (70.5%)	134 (70.5%)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 2. Comparison of BMI Categories in children with JSpA versus healthy controls.

BMI Categories	All	Controls	JSpA	*P*-value
				< 0.001
Underweight	83 (8.7%)	32 (4.2%)	51 (26.8%)	
Normal weight	527 (55.5%)	431 (56.7%)	96 (50.5%)	
Overweight	149 (15.7%)	128 (16.8%)	21 (11.1%)	
Obese	191 (20.1%)	169 (22.2%)	22 (11.6%)	

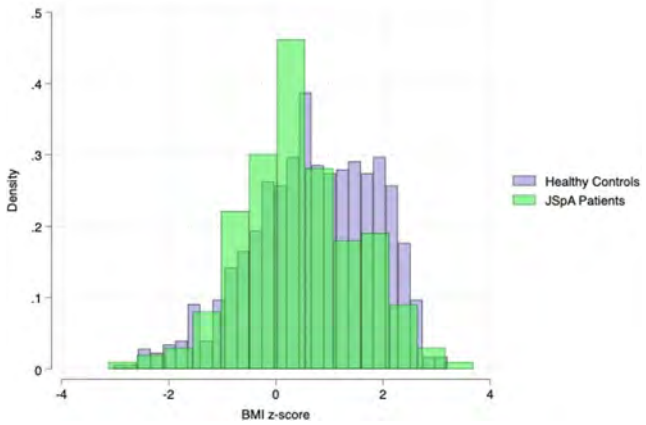

Figure 1. Histograms comparing BMI-for-age z-scores between children with juvenile spondyloarthritis (JSpA) and healthy controls. The median BMI z-score was 0.37 (IQR -0.22 to 1.13) for JSpA cases and 0.76 (IQR -0.06 to 1.63) for healthy controls (P = 0.01).

Methods: This retrospective cohort study included 190 children with JSpA and 760 healthy controls. Data on JSpA cases were drawn from a preexisting disease registry and included patients at their initial visit who met one of the following criteria: magnetic resonance imaging (MRI)-defined sacroiliitis, enthesitis-related arthritis (ERA), psoriatic arthritis (PsA), or undifferentiated arthritis. The healthy control group consisted of children without juvenile arthritis derived from the CDC National Center for Health Statistics' National Health and Nutrition Examination Survey. Cases and controls were matched by sex, race, and age, at a 4:1 ratio. Body mass index (BMI) categories were defined using CDC percentiles: obese (≥95th), overweight (85th–94th), healthy weight (5th–84th), and underweight (< 5th). BMI-for-age z-scores were calculated using the CDC 2000 growth reference in Stata and adjusted for age and sex. A Wilcoxon rank-sum test was used to compare BMI z-scores and chi-square tests assessed differences in BMI categories between children with JSpA and controls.

Results: A total of 950 children were included in the study, of whom 190 had JSpA and 760 were healthy controls. Cohort demographics are presented in Table 1. The distribution of BMI categories was significantly different between JSpA and the matched controls ($P < 0.001$). As shown in Table 2, a higher proportion of children with JSpA were underweight (26.8% in JSpA vs. 4.2% in controls), while fewer were classified as obese (11.6% in JSpA vs. 22.2% in controls). Histograms comparing BMI-for-age z-scores between children with JSpA and healthy controls are shown in Figure 1. The median BMI z-score was 0.37 (IQR -0.22 to 1.13) for JSpA cases and 0.76 (IQR -0.06 to 1.63) for healthy controls ($P = 0.01$).

Conclusion: Children with JSpA had significantly lower BMI z-scores compared to age, sex, and race-matched controls. More children with JSpA were underweight when compared with a control population. The impact of disease duration, disease activity, and concurrent medications on BMI in JSpA should be further explored.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Timely treatment for juvenile idiopathic arthritis (JIA) is essential for disease remission and decreasing risk of long-term morbidity. Intra-articular corticosteroid joint injections can treat active arthritis. If a joint injection cannot be completed in the outpatient clinic due to sedation needs, additional steps must be made to schedule the procedure, often delaying treatment. Using quality improvement (QI) methodology, this study aims to reduce the time to completion of joint injection for patients in our pediatric rheumatology clinic.

Methods: Our QI team reviewed all clinic encounters of JIA patients from September 2023 to March 2025. We obtained a baseline number of joint injections per month for the initial 8 months and the percentage of those that were completed within 30 days. A new monthly joint injection clinic was started in collaboration with the surgery center for sedated joint injections. Scheduling processes for joint injections were implemented as standardized forms for nursing and provider workflows within the electronic health record (EHR). The number of patients receiving joint injections and the time to completion were tracked monthly using control charts. To further evaluate the new workflows, a survey was administered to providers, trainees, and nurses.

Results: During the study period, 166 patients received joint injections, and 137 (82%) were completed within 30 days. During the baseline period, there was a mean completion rate of 90%. As we continued standardization processes and

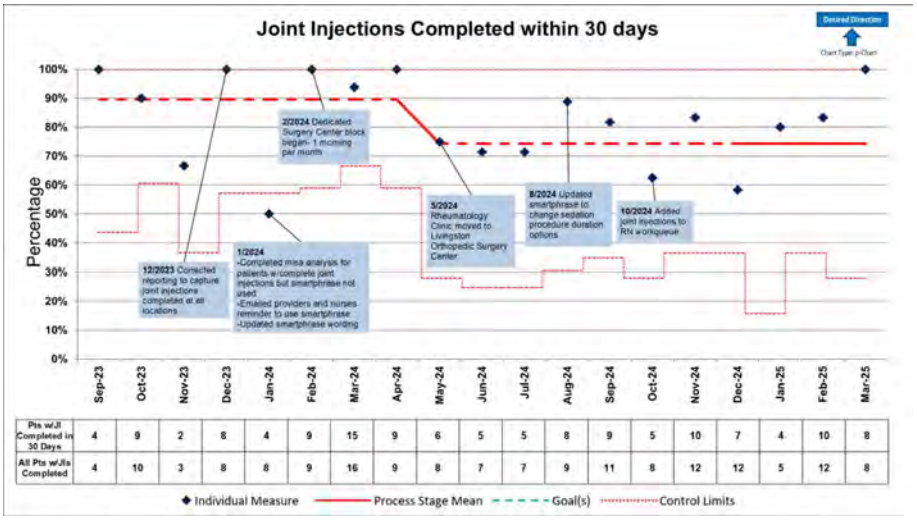

Figure 1: Control chart showing percentage of joint injections completed per month.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2: Control chart showing number of days for joint injections to be completed per month.

implementing interventions, there was a decrease in joint injections completed in 30 days resulting in a new process stage mean of 74% (**Figure 1**). When looking at average number of days until joint injection completion, the initial baseline mean was 12 days but increased to 20 days after the new process stage mean was established. The median average of days until injection completion was 15.5 days (**Figure 2**). Factors contributing to decrease in mean included: 1) transition to a new surgery center location in May 2024 and 2) decreased availability of sedated procedures over the holiday months of November-December 2024. Provider and staff survey results showed agreement that our new workflows have streamlined communication for details of the procedures to surgery center staff, simplified the scheduling process, decreased the number of messages needed to schedule procedures, and increased the procedure opportunities for fellow trainees. Respondents felt that length of time to schedule a joint injection was closely split between decreased (46%) and no difference (47%) (**Figure 3**).

Conclusion: This ongoing QI study demonstrates that implementation of a standardized form used by nursing and physician workflows within the EHR helped create a streamlined process for scheduling and completing corticosteroid joint injections within a 30-day window.

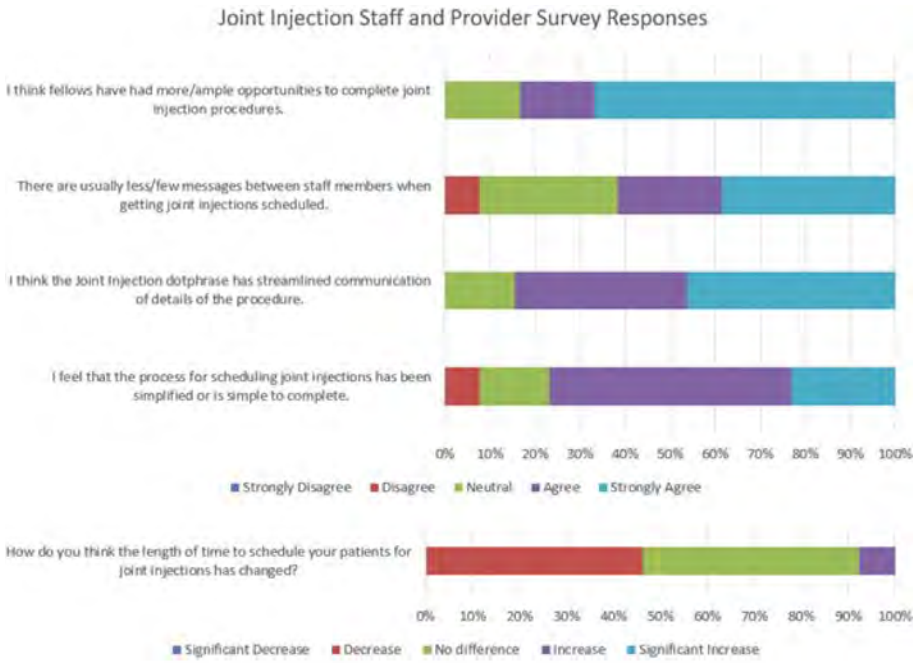

Figure 3: Survey results regarding usefulness of standardized form for joint injections within the electronic health record.

Predicting JIA-Associated Uveitis Using Tear Fluid Biomarkers: A Prospective Multicenter Study

Mariia Pavlenko[1], Mekibib Altaye[2], Hermine Brunner[3], Margaret Chang[4], Ashley Cooper[5], Stefanie Davidson[6], Alexandra Duell[3], Bharti Gangwani[4], Aimee Hersh[7], Gary Holland[8], Carl Langefeld[9], Melissa Lerman[10], Mindy Lo[4], Virginia Miraldi Utz[3], Sampath Prahalad[11], Grant Schulert[3], Megan Quinlan-Waters[12], Erin Stahl[5], Edmund Tsui[8] and Sheila Angeles-Han[13], [1]Cincinnati Children`s Hospital Medical Center, Cincinnati, OH, [2]Cincinnati Children's Hospital, Cincinnati, [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [4]Boston Children's Hospital, Boston, MA, [5]Children's Mercy Kansas City, Kansas City, MO, [6]Department of Ophthalmology, Children's Hospital of Philadelphia, Philadelphia, Pennsylvania, Philadelphia, PA, [7]University of Utah, Salt Lake City, UT, [8]UCLA Jules Stein Eye Institute and the Department of Ophthalmology, UCLA David Geffen School of Medicine, Los Angeles, [9]Wake Forest University School of Medicine, Winston Salem, NC, [10]Division of Rheumatology, Children's Hospital of Philadelphia and Department of Pediatrics, University of Pennsylvania Perelman School of Medicine, Philadelphia, Pennsylvania, Philadelphia, PA, [11]Emory + Children's Pediatric Institute, Atlanta, GA, [12]Cincinnati Children's Hospital Medical Center, CCHMC, [13]Cincinnati Children's Hospital, Cincinnati, OH

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Uveitis is the most common extra-articular manifestation of juvenile idiopathic arthritis (JIA) and can lead to vision loss if not detected early. Current clinical risk factors are insufficient for the reliable prediction of uveitis development. Tear fluid represents a non-invasive source for biomarker discovery. In this prospective study, we investigated tear-based biomarkers to enhance early prediction and monitoring of uveitis in patients with JIA.

Methods: This prospective multicenter study included children with JIA without uveitis (JIA-no-U) diagnosed within the first 4 years of JIA and JIA-associated uveitis (JIA-U) from the Predicting Eye Disease in Childhood Arthritis - Uveitis Study (PEDIA-U) cohort. Tear samples were collected from both eyes by Schirmer strips at baseline (BL) and at 4 follow-up visits (FU1-4), approximately every 3 months. Levels of s100A8/A9 and A12 were measured by ELISA; IL-8, CXCL10, MCP-1, sICAM-1, APRIL and VEGF-A by Luminex assays. Biomarker levels between JIA-U and JIA-no-U were compared at 1) BL and 2) longitudinally, including FU1 and FU2 visits only. The log-transformed data were used in mixed model analysis with individuals and eyes as random effects, adjusting for arthritis activity and testing for a time-by-uveitis status interaction for repetitive sample collection. Least square (LS) means comparisons are adjusted for multiple testing using the Tukey-Kramer method. Multivariate analysis was performed using PROC GLIMMIX.

Results: Forty-two patients (31 JIA-no-U and 11 JIA-U) contributed 142 tear samples (102 JIA-no-U and 40 JIA-U) (Table 1). All patients had a BL visit and 17 had at least one FU. Of 11 JIA-U patients, 2 had active and 9 had inactive uveitis at BL; two JIA-no-U patients developed uveitis during FU. Only two patients changed their uveitis activity status over time.

At baseline, MCP-1 and CXCL-10 levels were significantly decreased in the JIA-U group compared to JIA-no-U (LS mean MCP-1: 1.31 vs. 2.18, p=0.008; CXCL-10: 4.01 vs. 5.1, p=0.001) (Figure 1). Over time, MCP-1 levels in the JIA-U group significantly increased from BL to FU2 (LS mean: BL = 1.2, FU = 3.1, p=0.027), while no significant change was observed in JIA-no-U. In contrast, CXCL-10 levels significantly decreased in JIA-no-U group from BL to FU2 (LS mean: BL = 4.9, FU =

List of abbreviations: JIA - Juvenile Idiopathic Arthritis; JIA-no-U - JIA without uveitis; JIA-U - JIA-associated uveitis; N number; N/A non-applicable.

4.0, p=0.0002), with no distinct change in JIA-U. For two patients who developed uveitis during FU visits, their MCP-1 and CXCL-10 levels followed the same trajectory as JIA-U group. In multivariate analysis, we found that levels of CXCL-10 (p=0.0036) and APRIL (p=0.026) were significantly associated with JIA-U diagnosis, and MCP-1 (p=0.008) showed a trend to significance. Additionally, S100A12 and VEGF-A significantly increased from BL to FU for both JIA-U and JIA-no-U groups (p=0.024, p=0.044, respectively). These changes might be related to JIA progression itself.

Conclusion: This is the first prospective study evaluating tear-based biomarkers over time in JIA. We found a distinct difference in MCP-1 and CXCL10 levels in tear fluid between JIA-U and JIA-no-U patients at BL and FU. This data might be used for early uveitis prediction in JIA patients and potential treatment enhancement.

Abstract Number: 0415

The Impact of Social Vulnerability Index Scores in Pediatric Uveitis

Minal Aundhia[1], Pankaj Rajdeo[2], Michael Wagner[1], Alexandra Duell[1], Megan Quinlan-Waters[3], Virginia Miraldi Utz[1] and Sheila Angeles-Han[4], [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, [3]Cincinnati Children's Hospital Medical Center, CCHMC, [4]Cincinnati Children's Hospital, Cincinnati, OH

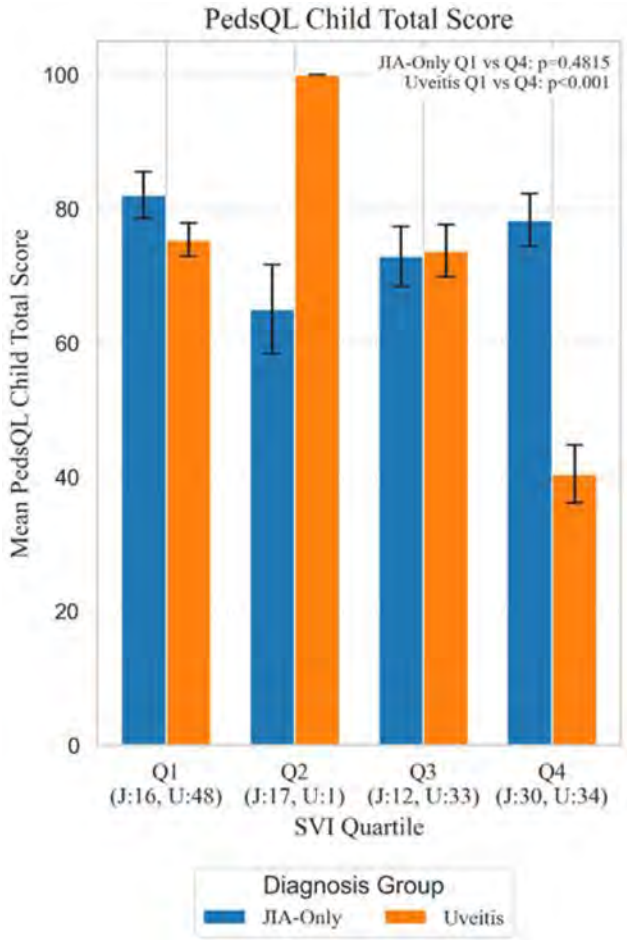

Figure 2. Association of Social Vulnerability Index (SVI Q1=Low, Q4=High) with mean PedsQL Child Total Score. Higher scores indicate better QoL. *P-values shown for comparisons.

Background/Purpose: Juvenile idiopathic arthritis (JIA) is the most common rheumatic disease in children with uveitis as the most common extra-articular manifestation. Uveitis can lead to sight-threatening complications and vision loss. While outcomes are influenced by disease phenotype and clinical risk factors, social determinants of health may significantly impact disease burden. The CDC's Social Vulnerability Index (SVI) is a composite measure of socioeconomic and demographic stressors and has not previously been applied to pediatric uveitis. This study investigates whether higher SVI is associated with delayed diagnosis, worse quality of life (QoL), and poorer clinical outcomes in affected children.

Methods: This retrospective single-center study included children diagnosed with JIA without uveitis (JIA-no-U), JIA-associated uveitis (JIA-U), and uveitis-only (Uveitis) from the Longitudinal Outcomes of Childhood Uveitis Study (LOCUS) registry. For SVI analyses, JIA-U and uveitis-only were combined as a single group (Uveitis). SVI scores (0 = low, 1 = high) were derived from addresses in the Electronic Medical Record using deGAUSS software and divided into quartiles (Q1–Q4). Analyses compared Q1 (low) and Q4 (high). Variables included demographics, age at diagnosis, time to systemic immunosuppression, and Pediatric QoL Inventory (PedsQL-Child Total) scores, an age-appropriate outcome measure. Analyses used t-tests and ANOVA. Some dates were recorded only by year, limiting precision.

Results: Of 509 patients, 357 had JIA-no-U, 127 JIA-U, and 25 uveitis-only (Table 1). Compared to JIA-only, JIA-U patients were more likely to be ANA-positive (49.6% vs 26.3%, p< 0.001) and female (78.0% vs 64.4%, p< 0.0001).

SVI Q4 was linked to later mean uveitis onset (Q4: 6.8 vs Q1: 4.1 yrs; p=0.0004) but not JIA-only onset (Q4: 5.8 vs Q1: 4.5 yrs; p=0.1347) (Figure 1A). Time to systemic immunosuppression showed opposite SVI associations (Figure 1B): in JIA-only,

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

systemic treatment for Q4 was delayed (52.2 vs 11.6 weeks; p=0.000); for the Uveitis group, Q4 had shorter time to systemic treatment (27.8 vs 49.3 weeks; p=0.000).

For QoL, Uveitis patients in Q4 reported significantly worse PedsQL scores (Q4: ∼40 vs Q1: ∼75; p< 0.01). In JIA-only, scores did not differ significantly (Q4: ∼79 vs Q1: ∼82; p=0.4815) (Figure 2).

Conclusion: Social vulnerability significantly impacts key clinical outcomes and QOL in pediatric uveitis. Higher SVI patients with uveitis received systemic therapy more quickly, perhaps indicating severity at onset and rapid need for treatment escalation to prevent vision loss. Further, they are at risk for delayed uveitis diagnosis and poorer QOL. The SVI may serve as a valuable risk stratification tool to guide early intervention and targeted care coordination in at-risk children. Further study is warranted to evaluate subtype-specific mechanisms and treatment adherence patterns.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: We aimed to study the outcomes (remission, flare, and adverse events) of biological disease-modifying anti-rheumatic drugs (bDMARD) in children with JIA from a low-middle-income country setting, and explore the factors associated with these outcomes.

Methods: The Pediatric Rheumatology Clinic bDMARD register (2009 to August 2024) was screened to enrol children with JIA and at least 3 months of follow-up whilst on bDMARDs. Participant characteristics and clinical responses were collected in a pre-designed proforma to evaluate the primary objective i.e. studying outcomes among children with JIA on bDMARDs. The secondary objective was to study factors associated with time-to-remission (TTR) and flare-after-stopping-bDMARDs. The study was approved by the Institute Ethics Committee (IECPG-596/20/09.2023, RT-02/21.02.2024). Consent was waived for this retrospective study.

Results: One-hundred-fifteen children (59.1% boys) with 168 patient-years of bDMARD use were enrolled for this study. Enthesitis-related-arthritis was the commonest subtype of JIA (n=44, 38.3%). The most commonly used bDMARD was adalimumab (n=43, 37.3%). The median (IQR) delay to initiation of bDMARD from the perceived need was 2 (0-6) months, primarily due to financial impediments (n=81, 70.4%). Fifteen (13%) children screened positive for tuberculosis infection. One hundred ten (95.6%) children achieved remission on bDMARD, after a median (IQR) of 7.5 (4-12) weeks. Macrophage

Flares during therapy	2.60	0.78-8.6	0.11	2.3 (0.6-8.5) p=0.2

Analyses for factors associated with time-to-remission (A), flare after stopping (B)

adverse events were serious infections requiring hospitalisation (n=13, 11.3%) and tuberculosis (n=4, 3.4%). All children who developed tuberculosis were on TNFi (Adalimumab).

Conclusion: : Though children on bDMARDs showed comparable remission rates, we noted a higher frequency of serious infections and tuberculosis, compared to the experience described from high-income countries. These observations highlight the need for further surveillance of outcomes of bDMARD use in JIA in an LMIC setting.

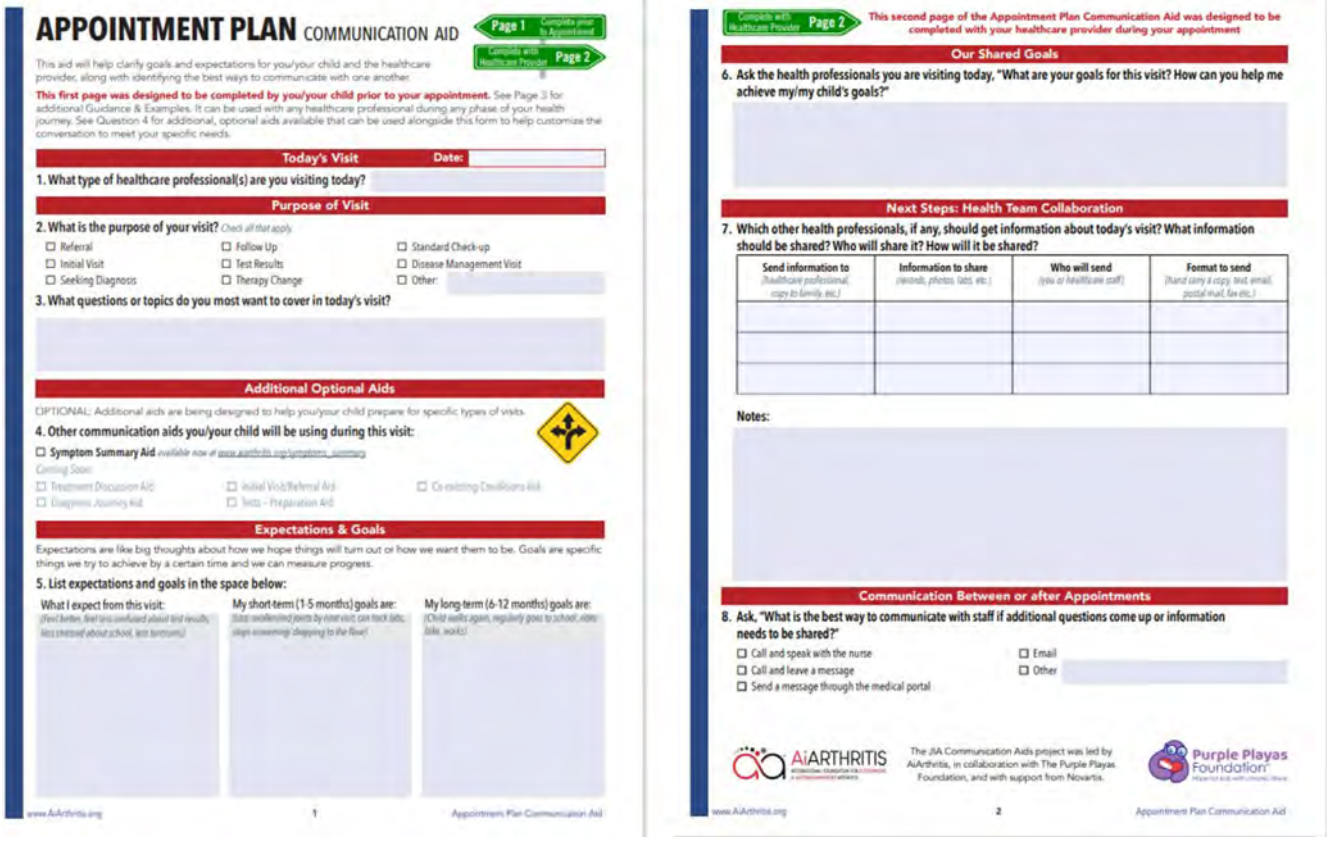
Background/Purpose: Juvenile idiopathic arthritis (JIA) is a childhood onset autoimmune disease requiring long-term care and personalized treatment. Through a rigorous series of mixed patient and provider workgroups, AiArthritis developed communication aids to improve communication and decision making between JIA families and their providers. The aid clarifies the patient's clinical questions, and their short- and long-term goals of care (Fig 1). We aimed to evaluate the feasibility and effectiveness of this communication aid in pediatric rheumatology clinics.

Methods: Following approval from the Washington University Institutional Review Board, this quality improvement (QI) study enrolled patients through the pediatric rheumatology clinic with JIA and suspected JIA of any age, with parental consent. The communication aid was provided at check-in for the patient (age ≥12) or the parent to complete. The provider reviewed the responses during the visit. Afterward, both the patient/parent and the provider team completed anonymous surveys. Primary outcome measures were set at ≥ 50% of patients finding the aid easy to use, helpful in communicating goals, and improving the quality of experience, and ≥75% of provider responses indicating an improved therapeutic alliance without adversely affecting clinic workflow. The first Plan-Do-Study-Act cycle enrolled 10 patients, and the second enrolled 20. The third cycle has ongoing enrollment.

Results: Of 31 patient/parent participants, 93% found the handout very easy to use. Majority of participants (64%) felt the aids greatly or somewhat helpful in preparing their appointment goals (Fig 2). Two-thirds reported an improved overall experience during their appointment, and 70% wanted the aid used in future visits. Among 56 provider responses, 50%, 30%, and 19% were from attending physicians, fellows, and nurses, respectively. The majority (93%) reported that the aid did not adversely affect workflow (Fig 3); none indicated a negative impact. Moreover, 79% of the providers felt the communication aid improved therapeutic relationship with patients, and 91% of the respondents supported the continued use of the communication aid in the clinic.

Figure 1- Communication aid



APPOINTMENT PLAN COMMUNICATION AID

Page 1 Complete prior to Appointment

Complete with Healthcare Provider Page 2

This aid will help clarify goals and expectations for you/your child and the healthcare provider, along with identifying the best ways to communicate with one another.

This first page was designed to be completed by you/your child prior to your appointment. See Page 3 for additional Guidance & Examples. It can be used with any healthcare professional during any phase of your health journey. See Question 4 for additional, optional aids available that can be used alongside this form to help customize the conversation to meet your specific needs.

Today's Visit Date:

1. What type of healthcare professional(s) are you visiting today?

Purpose of Visit

2. What is the purpose of your visit? *Check all that apply*

☐ Referral ☐ Follow Up ☐ Standard Check-up
☐ Initial Visit ☐ Test Results ☐ Disease Management Visit
☐ Seeking Diagnosis ☐ Therapy Change ☐ Other:

3. What questions or topics do you most want to cover in today's visit?

Additional Optional Aids

OPTIONAL: Additional aids are being designed to help you/your child prepare for specific types of visits.

4. Other communication aids you/your child will be using during this visit:

☐ **Symptom Summary Aid** *available now at* www.aiarthritis.org/symptoms_summary

Coming Soon:

☐ Treatment Discussion Aid ☐ Initial Visit/Referral Aid ☐ Co-existing Conditions Aid
☐ Diagnosis Journey Aid ☐ Tests – Preparation Aid

Expectations & Goals

Expectations are like big thoughts about how we hope things will turn out or how we want them to be. Goals are specific things we try to achieve by a certain time and we can measure progress.

5. List expectations and goals in the space below:

What I expect from this visit:	My short-term (1-5 months) goals are:	My long-term (6-12 months) goals are:
(Feel better, Brief less confused about test results, less stressed about school, less tantrums)	*(Make weekend/work plans by next visit, can track labs, stops screaming/dropping to the floor)*	*(Child walks again, regularly goes to school, rides bike, works)*

www.AiArthritis.org 1 Appointment Plan Communication Aid

Complete with Healthcare Provider Page 2

This second page of the Appointment Plan Communication Aid was designed to be completed with your healthcare provider during your appointment

Our Shared Goals

6. Ask the health professionals you are visiting today, "What are your goals for this visit? How can you help me achieve my/my child's goals?"

Next Steps: Health Team Collaboration

7. Which other health professionals, if any, should get information about today's visit? What information should be shared? Who will share it? How will it be shared?

Send information to *(healthcare professional, copy to family, etc.)*	Information to share *(records, photos, labs, etc.)*	Who will send *(you or healthcare staff)*	Format to send *(hand carry a copy, text, email, postal mail, fax etc.)*

Notes:

Communication Between or after Appointments

8. Ask, "What is the best way to communicate with staff if additional questions come up or information needs to be shared?"

☐ Call and speak with the nurse ☐ Email
☐ Call and leave a message ☐ Other
☐ Send a message through the medical portal

AiARTHRITIS

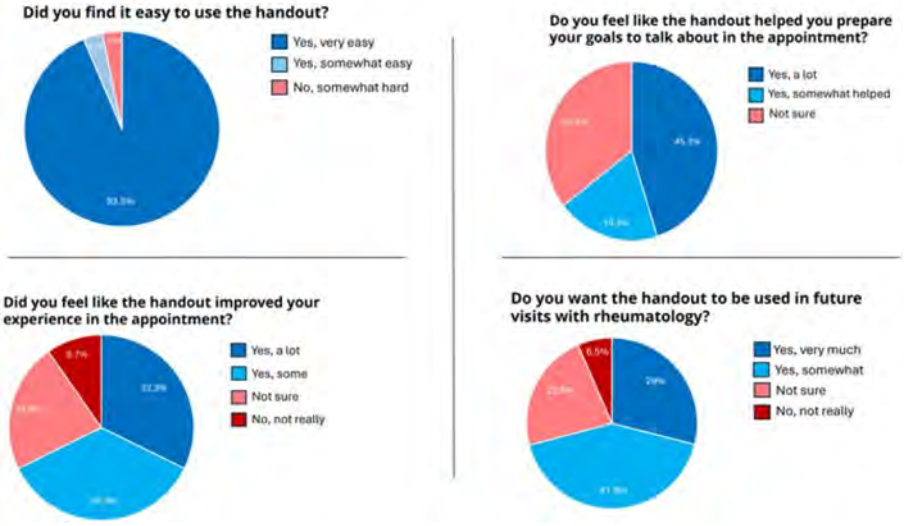
The JIA Communication Aids project was led by AiArthritis, in collaboration with The Purple Playas Foundation, and with support from Novartis.

Purple Playas Foundation

www.AiArthritis.org 2 Appointment Plan Communication Aid

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 2- Patient responses



Conclusion: This QI study has met the primary outcome measures. We have found that the communication aid was feasible to use in outpatient clinic for patients with JIA or suspected JIA. It facilitates development of personalized treatment plans and should be considered for implementation more widely in the pediatric rheumatology clinic.

Areas for improvement include providing communication aid in advance of the appointment. Limitations of the study are lack of long-term follow up to assess for durable communication improvement and progress towards reaching patient-made goals.

Acknowledgement: AiArthritis (International Foundation for Autoimmune & Autoinflammatory Arthritis) for developing the JIA Health Journey Communication Aids and allowing us to use these aids for the study. AiArthritis would also like to acknowledge Purple Playas Foundation for their role in co-designing the aids.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Clinical, radiologic and biomarker data are measurements used in the assessment of juvenile idiopathic arthritis (JIA) disease activity. The development of ultrasound-guided synovial biopsy (USGSB) in children has accelerated synovial histopathology research. Investigate the relationship between clinical features of arthritis, radiologic synovitis, synovial fluid (SF) biomarkers of inflammation, and histologically confirmed synovitis in children with JIA.

Methods: JIA patients requiring a knee joint injection were enrolled. Patients underwent standardized clinical assessment (cJADAS, range 0-30), a musculoskeletal ultrasound (MSUS) examination, and USGSB of the affected knee with collection of synovial fluid (SF). MSUS images were collected and scored by pediatric MSUS experts. MSUS synovitis was scored using a validated semiquantitative MSUS scoring system for the knee joint (MSUS-knee score, range 0-6). Synovial biopsy inflammation was determined by Krenn's score (KS, which examines for synovial hyperplasia, stromal cellularity/reactivity and inflammatory infiltrate, range 0 to 9, higher scores indicating greater severity. Biomarkers measured in SF included: TNFR1, IL-6, IL-10, MCP-1, ANG-1, ANG-2, MMP-2, MMP-8, CCL18, CCL20, IFNg, IL-17a, IL-2Ra, IL-23, IL-18, resistin, CXCL9, VEGF, TIMP-1 by Luminex, and S100A12, S100A8/A9 by ELISA. Wilcoxon Rank Sum test was used to compare group differences. Spearman correlation (r_s) was used to assess the relationship between the studiedvvariables

Results: Thirty-four patients [mean age 10 (SD 5.1)] were enrolled. Their median cJADAS score was 4 (IQR 2-8) while 32% of them had no pain at the affected joint (Table 1). All patients had presence of MSUS synovitis with a median MSUS-knee score of 5 (IQR 4-6). Median KS was 6 (IQR: 4-7). Children receiving conventional and/or biologic disease modifying medications (DMARDs) had similar median KS compared to children not on these treatments [6, (IQR 3-7) and 6 (IQR 5-8), respectively] (p=0.962). Children with polyarticular JIA had a median KS of 5 (IQR 5-6) while the KS for children with oligoarticular was 6 (IQR 4-8) (p=0.725). Children with oligoarticular JIA taking NSAIDs at the time of the USGSB had a significantly lower KS than oligoarticular JIA children not on an NSAID [median 3.5 (IQR 3-4) v 6.5 (IQR 4.2-7.7), respectively] (p=0.033). A significant moderate correlation was found between the MSUS-knee score and the KS r_s: 0.45 (0.12 -0.7), with the highest association being between the KS stroma domain and the MSUS-knee score [r_s: 0.5 (0.17-0.720] (Table 2). Strong significant correlations (r_s>0.8, p< 0.05) were found between SF levels of S100A12, S100A8A9, CCL18, IL-6, MMP-8 and the KS (Table 3). S100A8A9 also had a significant correlation with the MSUS-knee score [r_s 0.55 (0.08-0.82)].

IL-23	0.62 (0.11-0.87)	**0.022***
IL-18	0.77 (0.39-0.93)	**0.001***
Protein	0.25 (-0.35-0.7)	0.418

Matrix metalloproteinases (MMP), Chemokine ligand (CCL), Angiopoeitin (Ang), Tissue inhibitor of metalloproteinases 1 (TIMP-1), Interleukin (IL), monocyte chemoattractant protein (MCP), interferon (IFN), monokine induced by gamma interferon/chemokine (C-X-C motif) ligand (CXCL9), vascular endothelial growth factor (VEGF), tumor necrosis factor receptor 1(TNFR1). *Strength of the correlation calculated using Spearman correlation (rs). p-value significant (<0.05).

Conclusion: This pilot study suggests that the degree of inflammation as measured by the KS does not associate with JIA disease category or DMARDs use but may be modified by concomitant NSAID use The association of the MSUS-knee score and SF biomarkers of inflammation with the KS detected in this study suggest that these measurements may have a role as surrogate markers of histologically confirmed active synovitis.

Abstract Number: 0419

Ultrasound-Guided Synovial Biopsy in Children and Adolescents with Juvenile Arthritis: Initial Results

Patricia Vega-Fernandez[1], Kelly Rogers[2], Megan Quinlan-Waters[3], Sheila Angeles-Han[2], Alexei Grom[1], Daniel Lovell[1], Jennifer Huggins[4], Ekemini Ogbu[1], Amy Cassedy[5], Sara Szabo[1], Tracy Ting[1], Grant Schulert[1], McKenzie Vater[6], Hermine Brunner[1], Jackeline Rodriguez-Smith[1] and Katelyn Banschbach[7], [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Cincinnati Children's Hospital, Cincinnati, OH, [3]Cincinnati Children's Hospital Medical Center, CCHMC, [4]Cincinnati Children's Medical Center, Cincinnati, OH, [5]Cincinnati Children's hospital medical center, cincinnati, OH, [6]Cincinnati Children's Hospital Medical Center, Fort Thomas, KY, [7]cincinnati Children's hospital, Villa Hills, KY

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Ultrasound-guided synovial biopsy (USGSB) has been recently implemented for clinical and research purposes in adults with inflammatory arthritis. The current use of USGSB in the pediatric population is very limited. Here we report our USGSB experience at Cincinnati Children's Hospital Medical Center (CCHMC).

Methods: Children with a diagnosis of Juvenile Idiopathic Arthritis (JIA) that were to receive a clinically indicated therapeutic knee joint injection were eligible for this study. USGSB was approved by the CCHMC IRB, and all patients/parents provided informed consent. At the time of the joint injection, a musculoskeletal ultrasound (MSUS), USGSB and steroid injection of the affected joint was performed by a pediatric rheumatologist. Clinical and procedure data were collected to determine feasibility. Synovial biopsy inflammation was determined by Krenn's score. To evaluate procedural safety and tolerability, a questionnaire was administered to the patient/family 2-4 days after the procedure.

Results: A total of 34 children [mean age 10 years (SD 5.1)] with JIA were enrolled in this study. The majority of participants had oligoarticular JIA (68%) with the youngest patient in which an USGSB was completed being 2 years old. While 58% (n=20) of the procedures were done in the operative room under general anesthesia, 42% (n=14) were completed in clinic under local anesthesia. The USGSB and steroid injection was completed in all participants. In general, USGSB were well tolerated. One patient developed a subcutaneous hematoma that resolved within 1 week. The median Krenn's score was 6 (IQR: 4-7). When patients/families were asked about knee joint pain after the USGSB and steroid injection, they reported that the joint pain had improved in 73% of the cases, while 27% felt the pain after the procedure was the same or worse. After the procedure, all participants/family reported feeling glad being a part of the study and 93% (14 of 15 responders) felt that other children could tolerate the biopsy while pain during the procedure is under control. Of note, 2 patients had a repeat biopsy with no complications.

Conclusion: USGSB are safe and well-tolerated in children. USGSB has been successfully implemented for research purposes in children and adolescents with JIA in our center.

Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Modern therapies have improved outcomes in patients with JIA, but up to 60% of patients treated with TNF-α inhibitors (TNFi) have persisting disease activity underscoring the need for improved therapeutical approaches. Intra-articular (IA) triamcinolone hexacetonide injections are often used as adjunctive therapy to TNFi treatment even though no controlled studies have examined their potential added benefit. We aim to assess the efficacy and safety of IA triamcinolone hexacetonide injections compared to no injections in children with JIA starting TNFi therapy.

Table 1. Baseline demographics and disease characteristics.

	Intra-articular triamcinolone hexacetonide injections (intervention) (n=92)	No intra-articular injections (control) (n=95)
Age at randomization, years	10.5 (4.3)	10.4 (4.5)
Disease duration, years	2.0 (3.7)	1.7 (2.9)
Female gender	58 (63%)	61 (64%)
JIA category		
Oligoarticular persistent	29 (32%)	25 (26%)
Oligoarticular extended	13 (14%)	12 (13%)
Polyarticular RF positive	8 (9%)	10 (11%)
Polyarticular RF negative	23 (25%)	22 (23%)
Enthesitis-related arthritis	8 (9%)	13 (14%)
Psoriatic arthritis	4 (4%)	3 (3%)
Undifferentiated arthritis	7 (8%)	10 (11%)
Concurrent methotrexate therapy at baseline	80 (87%)	80 (84%)
Previous biologic DMARD therapy	6 (7%)	6 (6%)
Number of joints with active arthritis, 0-71. Median (IQR)	3 (5)	2 (4)
Physician's global assessment of disease activity, 0-100 mm.	43.7 (21.9)	41.5 (18.8)
Disease activity assessed by the Juvenile arthritis disease activity score 10, 0-40.	13.9 (7.4)	12.9 (6.1)
Erythrocyte sedimentation rate, mm/hr. Median (IQR)	10 (18)	12 (17)
C-reactive protein, mg/L. Median (IQR)	2.2 (8.6)	1.7 (8)

Data are mean (SD) or n (%) unless otherwise stated.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Methods: The MyJIA trial (NCT 04614311) is a randomized, controlled, multicenter, parallel group, blinded-assessor, open-label, phase 4 clinical trial. Main inclusion criteria were non-systemic JIA, age 1 to 18 years, clinical indication for TNFi therapy, and at least one joint with arthritis suited for IA steroid injection. Participants were assigned by a computer randomization procedure (1:1) to IA triamcinolone hexacetonide injections of active joints or no joint injections. Core outcome variables for JIA were collected at baseline, weeks 6, 12, 24, 36 and 48. Participants randomized to IA injections had joints with arthritis injected at baseline and if clinically indicated at follow-up visits with triamcinolone hexacetonide (large joints 0.5-1 mg/kg (max 40mg), medium joints 0.3-0.5 (max 20mg), small joints, 0.1-0.3 (max 15mg), maximum total dose per visit 3.5mg/kg or < 140mg). Primary endpoint was the proportion of patients in sustained inactive disease, as defined by the JIA-ACR/Wallace 2011 criteria, at both weeks 24 and 36, analysed using logistic regression adjusted for study site.

Results: In total 187 children with non-systemic JIA were randomized; 92 (49%) to the injection group, and 95 (51%) to the no-injection group. Baseline characteristics are summarized in **Table 1**. The primary endpoint, the proportion of patients achieving JIA-ACR inactive disease at weeks 24 to 36, was 35% in the IA steroid injection group compared to 33% in the no-injection group (risk difference (RD) 0.02, 95% CI -0.12-0.15, p 0.80) (**Figure 1**). The mean time to JIA-ACR inactive disease was similar between groups (mean difference -4.5 days, 95% CI -37.4-28.5). JIA-ACR30 response rates were significantly higher in the IA steroid injection group when compared to the no-injection group with a risk difference of 12% (95% CI 0.01-0.24, p=0.03) at week 6, 16% at week 12 (95% CI 0.06-0.26, p< 0.01), 9% (95% CI 0.01-0.17, p=0.03) at week

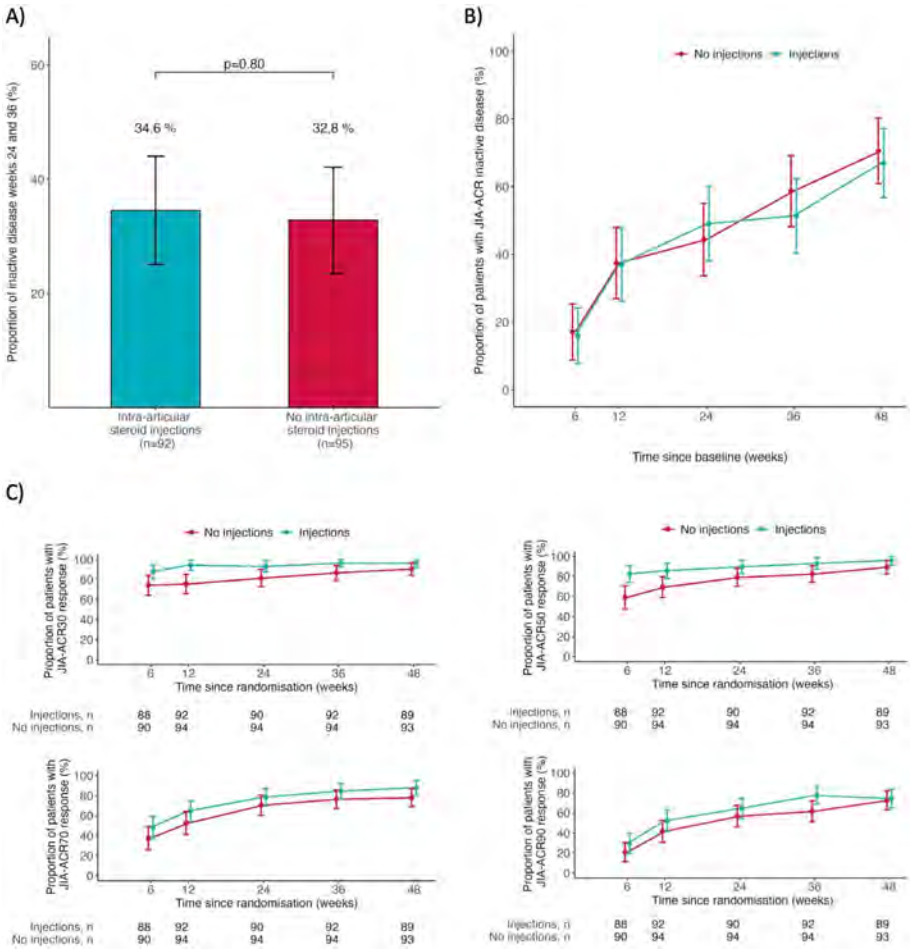

Figure 1. Efficacy of intra-articular triamcinolone hexacetonide injections in juvenile idiopathic arthritis (JIA) patients starting tumor necrosis factor inhibitor (TNFi) therapy. A) Primary endpoint: Bar chart of the proportion of patients in sustained JIA-ACR/Wallace inactive disease at both weeks 24 and 36 for patients receiving intra-articular steroid injections versus no injections (n=187). Estimates (95% CI) from logistic regression model adjusted for study center. B) JIA-ACR inactive disease response rates with estimates (95% CIs) from logistic mixed model including weeks 6, 12, 24, 36 and 48 by treatment group (n=163). C) JIA-ACR30, 50, 70, and 90 response rates with estimates (95% CIs) from logistic mixed model including weeks 6, 12, 24, 36 and 48 by treatment group (n=163).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

24, and 6% (95% CI 0.00-0.13, p=0.04) at week 36. At week 48, JIA-ACR30 response rates were similar (RD 0.03, 95% CI -0.01-0.08, p=0.08). (**Figure 1**). JIA-ACR 70/90 and JIA-ACR core set variables showed no between-group differences at any time point. AEs/SAEs occurred in 67%/7% in the injection group, and in 75%/8% in the no-injection group. Subcutaneous atrophy occurred in 8 of 288 steroid injected joints (3%).

Conclusion: IA triamcinolone hexacetonide injections did not increase the proportion of JIA patients with sustained inactive disease up to 48 weeks after starting TNFi therapy. These findings show that added intra-articular steroid injections is redundant in children with JIA starting TNFi therapy.

Abstract Number: 0421

Inflammatory Orbital Diseases: Pediatric Case Series From a Tertiary Care Center

Rasha Elrefai[1], Katherine Williams[2] and Hannah Bradfield[3], [1]Baylor College of Medicine, Houston, TX, [2]Texas Children's Hospital, Houston, TX, [3]Baylor College of Medicine/Texas Children's Hospital, Houston, TX

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Orbital inflammatory diseases in the pediatric population present diagnostic and therapeutic challenges due to variable clinical manifestations, limited prospective data, and lack of standardized treatment protocols. This case series describes clinical features and outcomes in children with orbital inflammatory disease, with particular attention to recurrence, therapeutic approaches, and visual prognosis.

Methods: We retrospectively reviewed the medical records of 12 pediatric cases (ages 3–18 years; all female) with orbital inflammatory disease seen at Texas Children's Hospital between October 2015 and June 2024. Data collected includes clinical presentation, laterality, lacrimal gland and optic nerve involvement, treatment regimens, recurrence, and outcomes. All patients underwent biopsy by an oculoplastic surgeon with histopathology reviewed with an ocular pathologist.

Results: The most common presenting symptoms were eyelid swelling (75%), proptosis (50%), ptosis (42%), and blurry vision (33%) (Table 1). The presenting symptoms were bilateral in 5 patients. Lacrimal gland involvement was common (75%), particularly in patients with ANCA vasculitis or IgG4-related disease. Optic nerve involvement was noted in 2 cases.

Treatment regimens varied by diagnosis and response. Most ANCA-associated cases were managed with methotrexate and glucocorticoids, with escalation to rituximab, surgery, or additional immunosuppressant. Among these, 3 of 4 patients experienced disease recurrence, and one had progressive vision loss requiring a change in therapy. Patients with IgG4-related disease were primarily managed with rituximab or mycophenolate, with favorable outcomes and no recurrences reported (Figure 1).

12	NSOI	12/ Female	21	Eye swelling Pain Proptosis Blurry vision	Unilateral	Yes	No	Methotrexate and steroid (failed) Rituximab	Yes	Improved lacrimal gland swelling and resolution of intraocular muscle inflammation Off treatment

*NSOI: Nonspecific orbital inflammation

Nonspecific orbital inflammation (NSOI) cases demonstrated a heterogeneous response. Three of 4 patients required escalation beyond methotrexate and glucocorticoids, with rituximab leading to partial improvement in 2.

Overall, recurrence occurred in 42% of cases predominantly in ANCA and NSOI diagnoses. Patients with IgG4-related disease did not require escalation of therapy.

Conclusion: Pediatric orbital inflammatory diseases exhibit diverse clinical presentations and outcomes. ANCA-associated orbital disease demonstrates a higher risk of recurrence and treatment escalation compared to IgG4-related disease. Of note, ANCA-associated vasculitis in pediatric patients did not manifest the bony sinonasal obliteration observed in adult patients. Lacrimal gland involvement is frequent; optic nerve compromise is rare. Rituximab appears effective across etiologies, particularly in refractory cases. This case series highlights the rarity of these diseases in children, importance of early recognition, and close longitudinal follow-up in managing these complex disorders.

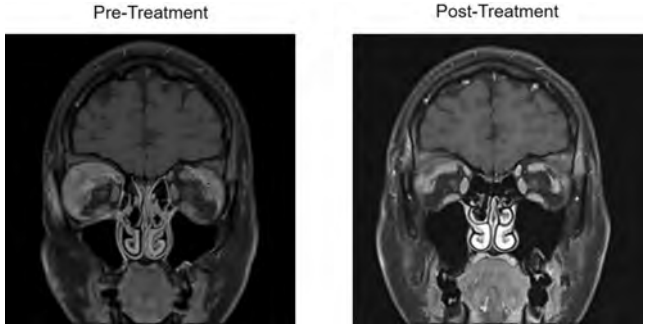

Figure 1. MRI Brain and Orbits Coronal T1 FS images showing bilateral inflammatory orbital masses pre- and post-treatment with rituximab and glucocorticoids in a patient with IgG4-related ocular disease.

	Lateral (evertor) tendon	2 (3)	0 (0)	
	Anterior (extensor) tendon	1 (2)	0 (0)	
	Posterior tendon	0 (0)	0 (0)	
*Ankle joint that was injected	Subtalar	19 (40)	4 (5)	<0.001
	Tibiotalar	28 (60)	73 (95)	
Injected medication	Triamcinolone	51 (81)	21 (28)	<0.001
	Triamcinolone hexacetonide	1 (2)	55 (72)	
	Methylprednisolone acetate	11 (18)	0 (0)	

All values are represented as number (%).

Background/Purpose: Intra-articular corticosteroid injections (IACI) are used to treat active ankle or midfoot inflammation in juvenile idiopathic arthritis (JIA). Ultrasound (US) can help identify the specific joint or periarticular tendon that is inflamed and facilitate precise delivery of the medication. This study compared short-term clinical efficacy between US-guided and non-US-guided injections performed by rheumatologists.

Methods: This retrospective case-control study compared clinical outcomes between US-guided and non-US-guided IACI of the ankle and midfoot joint or tendon sheath in patients with JIA at a single quaternary center. We included patients who received an injection between January 1, 2009 and January 1, 2024, without a systemic medication change 28 days before or after the injection, and with at least 1 clinic follow-up visit. Fisher's exact test was used to compare proportion of arthritis or tenosynovitis resolution at the immediate post-injection clinic visit (within 6 months). Resolution was defined as absence of swelling, warmth, and/or decreased range of motion thought to be due to active inflammation on a rheumatologist's documented physical exam. Mann–Whitney U test was applied to analyze the change in physician global assessment (PGA).

Results: 64 US-guided and 77 non-US-guided IACI, from 37 and 54 patients respectively, were included. Polyarticular JIA patients were less likely to have US-guided IACI (**Table 1**). Non-US-guided IACI were more likely to have been done in patients with a positive cyclic citrullinated peptide (CCP) antibody or positive HLA-B27 antigen. No tendon sheaths were injected in the non-US-guided group (**Table 2**). In the US-guided group compared to the non-US-guided group, subtalar joints were more likely to be injected, and triamcinolone was more likely to be used than triamcinolone hexacetonide

Table 3: Clinical outcomes observed at first follow up visit within 6 months of injection

	Ultrasound-guided (n = 64)	Non-ultrasound-guided (n = 77)	p-value
Days between injection and clinic visit	50 [37, 65]	44 [37, 61]	0.14
Inflammation resolved in injected compartment (%)	50 (78)	51 (67)	0.19
PGA before injection	30 [20, 50]	20 [20, 30]	0.01
PGA after injection	8 [0, 30]	5 [0, 10]	0.35
Change in PGA after injection	-20 [-30, -10]	-20 [-30, -10]	0.65

All values are represented as median [IQR] unless otherwise specified. IQR = interquartile range; PGA = physician global assessment (range 0 – 100).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(**Table 2**). **Table 3** demonstrates that arthritis and tenosynovitis clinically resolved at the follow up visit in 78% of US-guided and 67% of non-US-guided IACI, which was not statistically significant (p = 0.19). Evaluation of change in PGA after injection demonstrated that both groups had an average decrease of 20/100 (p = 0.65).

Conclusion: Our study found no significant difference in post-injection remission between US-guided and non-US-guided IACI into the ankle and midfoot from a single center over a 15-year span. The results of this study support our current institutional guidelines which do not explicitly recommend diagnostic and procedural US during IACI for all patients with ankle and midfoot inflammation. A multicenter trial with randomization will be preferred to validate our findings.

Abstract Number: 0423

Macrophage activation syndrome-associated proteins and enhanced interferon gamma responsiveness characterize the plasma proteome of patients with Multisystem Inflammatory Syndrome in Children (MIS-C) in a pre-treatment replication single center cohort

Sarah McCuaig[1], Cara Toland[2], Katharine Konvinse[3], Emily Yang[3], Paul Utz[4], Laura Vella[1], Audrey R. Odom John[1], Hamid Bassiri[1] and Edward Behrens[5], [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]Children's Hospital of Philadelphia, Philadelphia, [3]Stanford University School of Medicine, Palo Alto, CA, [4]Stanford University, Stanford, CA, [5]CHOP, West Chester, PA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Multisystem inflammatory syndrome in children (MIS-C) is a rare hyperinflammatory syndrome that follows SARS-CoV-2 infection. Prior plasma proteomic analysis from a 2020 cohort of MIS-C patients at our center revealed a profile characterized by macrophage-activation syndrome (MAS)-associated proteins, dysregulated interferon gamma responses and thrombotic microangiopathy. However, a limitation of that study, as well as most others at the time, was that samples were often acquired post-treatment. In this study, we interrogate the plasma proteome in untreated MIS-C patients versus pediatric patients with other viral syndromes in an independent cohort to identify signatures that uniquely define MIS-C unconfounded by treatment effects.

Methods: Plasma samples were collected from patients presenting to the Children's Hospital of Philadelphia Emergency Department with fever upon their first blood draw and prior to any therapies. Samples were subsequently annotated based on final hospital diagnosis of MIS-C (N=12) or viral syndrome (N=30) as adjudicated by an expert panel. Analysis of 5400 plasma proteins was performed using the O-link Explore HT platform. Plasma auto-antibody analysis was performed using a customized Luminex auto-antibody array. Differential protein expression and pathway analysis were performed in R.

Results: Differential protein expression analysis confirmed that the MIS-C plasma proteome is distinct from that of patients with viral syndromes (Figure 1A) and pathway analysis revealed up-regulation of cytokine signaling pathways (Figure 1B).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1 – The plasma proteome of MIS-C is distinct from other viral syndromes. (A) Differential protein expression analysis comparing plasma from patients with MIS-C (N=12) and viral syndromes (N=30). Differentially expressed proteins were considered significant when absolute log2 fold change was greater than 1 and Benjamini-Hochberg adjusted p-value less than 0.05. (B) Reactome pathway analysis of significantly differentially expressed proteins. (C) Hierarchical clustering of significantly differentially expressed proteins.

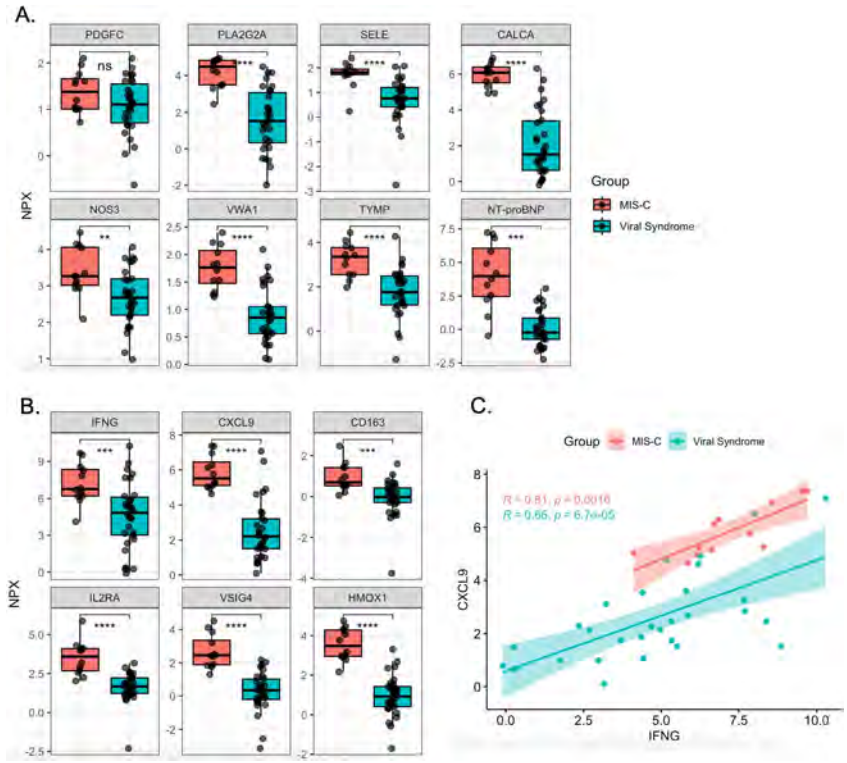

Figure 2 – sC5b9 and macrophage activation syndrome (MAS)-associated plasma protein expression in MIS-C patients compared to patients with other viral syndromes. (A) Box and whisker plots of sC5b9-related proteins and NT-proBNP comparing MIS-C to other viral syndromes. p-values computed using Welsh's T-test. Dots are individual patient normalized protein expression (NPX) values. (B) Box and whisker plots of MAS-associated proteins comparing MIS-C to other viral syndromes. p-values computed using Welsh's T-test. Dots are individual patient NPX values. (C) Pearson correlation analysis between IFNg and CXCL9. Dots are individual patients colored by disease state. Colored areas represent 95% confidence intervals. ****p<0.0001, ***p<0.001, **p<0.01.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

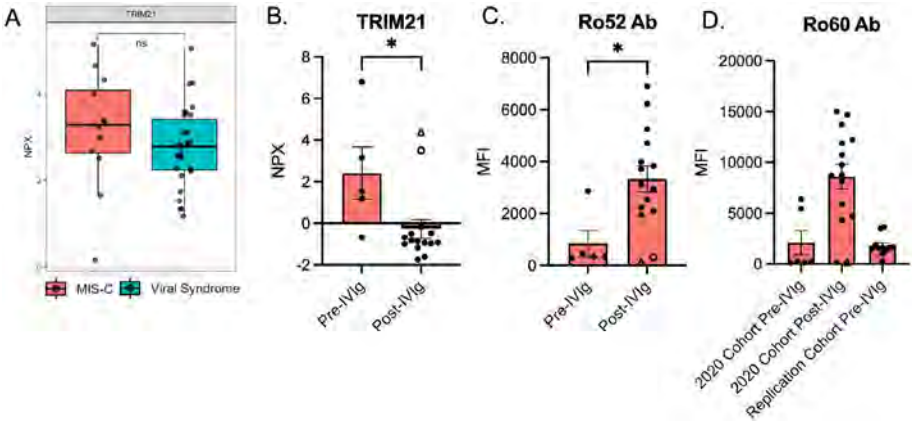

Figure 3 – TRIM21/Ro52 expression and anti-Ro52, anti-Ro60 autoantibody levels in MIS-C patients stratified by IVIg treatment status. (A) Box and whisker plots of TRIM21 comparing MIS-C to other viral syndromes. P-value computed using Welsh's t-test. Dots are individual patient NPX values. (B) TRIM21 expression in MIS-C patients in 2020 cohort stratified by IVIg treatment status (untreated [pre-IVIg], treated [post-IVIg]). P-value computed using Welsh's t-test. Dots are individual patient normalized protein expression (NPX) values. (C) Anti-Ro52 Ab MFI in MIS-C patients in 2020 cohort stratified by IVIg treatment status. Patients denoted by open triangles and open circles are the same patient in the TRIM21 and Ro52 Ab plot. (D) Anti-Ro60 Ab MFI in MIS-C patients in 2020 cohort stratified by IVIg treatment status (untreated [pre-IVIg], treated [post-IVIg]) and in replication cohort (all patients untreated [pre-IVIg]). *p<0.05.

Unsupervised hierarchical clustering of differentially expressed proteins classified MIS-C from viral syndrome (Figure 1C). Consistent with findings in the 2020 cohort, sC5b9-associated proteins and MAS-associated proteins are more highly expressed and there is a disproportionally higher CXCL9 response to IFNg in MIS-C compared to viral infection (Figure 2A, B, C). Patients with MIS-C had lower expression of the IFNg suppressive protein TRIM21 in the 2020 cohort, however this was not reproduced in the current cohort (Figure 3A). Closer inspection revealed that only patients who received IVIg treatment prior to sampling had low TRIM21 expression in the 2020 cohort (Figure 3B). TRIM21 (also known as Ro52/SSA) is the antigen for anti-Ro52 autoantibodies. Plasma autoantibody profiling revealed anti-Ro52 antibodies in patients who had received IVIg (Figure 3C). Related anti-Ro60/SSA antibodies were low in samples collected prior to IVIg treatment and high in those sampled after IVIg (Figure 3D).

Conclusion: We have validated several unique features of the plasma proteome of MIS-C patients first identified in 2020. MIS-C plasma show high sC5b9 and MAS-associated protein expression and enhanced IFNg responsivity. Discrepant TRIM21 expression in these two cohorts is due to the presence of anti-Ro52 autoantibodies in IVIg-treated patients. These data support the use of plasma cytokine profiling and possibly a CXCL9/IFNg ratio to rapidly identify MIS-C patients. Furthermore, they highlight the presence of autoantibodies in IVIg and the need to interpret plasma proteomic data with caution in patients with prior IVIg exposure.

Juvenile Idiopathic Arthritis Mimics: A Case Series on Progressive Pseudo-Rheumatoid Dysplasia and CACP Syndrome in Pediatric Patients from a Tertiary Center in South India

Sreelekha Kambhampati[1], keerthi vardhan yerram[2], Kavitha Meesala[1], Phani Kumar Devarasetti[2] and Liza rajasekhar[3], [1]Nizams institute of medical sciences, hyderabad, India, [2]Nizams institute of medical sciences, hyderabad, Andhra Pradesh, India, [3]Nizam's Institute of Medical Sciences, Hyderabad, Telangana, India

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Juvenile Idiopathic Arthritis (JIA) is the most prevalent chronic arthritis in children, but its diagnosis is often challenging due to overlapping symptoms with other conditions that mimic it.Among these mimics, Progressive Pseudo-Rheumatoid Dysplasia (PRD) and Camptodactyly - Arthropathy-Coxa Vara-Pericarditis (CACP) syndrome are particularly noteworthy due to their potential to cause significant diagnostic confusion and subsequent mismanagement.

Methods: This study aims to elucidate the clinical and genetic characteristics of pediatric patients diagnosed with PRD and CACP syndrome, highlighting the critical need for accurate differential diagnosis to avoid misdiagnosis and improve management strategies.–A retrospective case series was conducted at NIMS Hospital, Hyderabad,reviewing pediatric patients who presented to the outpatient department over a two-year period with symptoms initially suggestive of JIA.Seven patients with clinical presentations, including multiple joint pains and back pain, were evaluated. Comprehensive clinical assessments, imaging studies, and Whole Exome Sequencing (WES) were utilized to establish definitive diagnoses.

Results: RESULTS - Out of the seven patients evaluated, five were diagnosed with PPD and two with CACP syndrome.The age of onset ranged from 1 to 10 years, with a mean age of 4.7 years.3 rd degree consanguinity was found in all patients, and 2 nd brothers were of same family, 2 females and 3 male children in PPD and 1 male and 1 female child in CACP cluster Clinically, all patients presented with chronic joint pain; additional features included back pain, bilateral knee joint swelling, and, in CACP patients, characteristic

camptodactyly, joint contractures.Inflammatory markers were normal Genetic analysis done for 5 patients , it identified mutations in the CCN6 gene in three PRD patients and in the PRG4 gene in the two CACP patients.

Conclusion: PPD and CACP syndrome are critical differential diagnoses in pediatric patients presenting with JIA-like symptoms, especially in cases that deviate from typical JIA presentations or are unresponsive to standard treatments. These disorders were inherited in

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Cardiovascular disease remains the leading cause of mortality in patients with Rheumatoid Arthritis (RA). Normally, high density lipoprotein (HDL) acts in a cardioprotective capacity through various anti-inflammatory and anti-oxidative functions. Research has shown that the antiinflammatory capacity of HDL is impaired in states of chronic inflammation, such as RA. Abnormal lipid profiles have been described in patients with JIA, however, qualitative studies on HDL in this population are lacking. We aim to investigate if the antiinflammatory function of HDL is impaired in JIA patients as compared to healthy controls. We also aim to investigate if HDL dysfunction correlates with JIA subtype and disease activity.

Active Joint Count	4.1 (3.9)	1.1 (1)		0.0036*

Methods: We performed a cross-sectional study on 30 patients with JIA and 15 controls between 9 and 17 years of age. Disease activity was assessed based on the juvenile arthritis disease activity score (JADAS-10) and the childhood health assessment questionnaire (CHAQ). HDL's antiinflammatory function (HII) was measured using a cell-free assay assessing the ability of the patient's HDL to inhibit oxidation of low-density lipoprotein. Circulating oxidized biproducts of arachidonic and linoleic acid were measured by liquid chromatography-electrospray ionization, tandem mass spectroscopy. HDL-associated apoprotein A-1 (ApoA1) levels were measured by sandwich ELISA. Levels and activity of HDL associated antioxidant enzymes PON-1 (paraoxonase, arylesterase and lactonase) were quantified using spectrophotometry.

Results: Total HDL and total cholesterol were not significantly different between cases and controls. Joint count in the 22 patients with poly-JIA was higher than the 8 patients with other subtypes of JIA (63% ERA, 38% psoriatic JIA) [mean (s.d.)] (4.5 (4.3), 1.1 (1), p=0.002). ESR was significantly higher in the poly JIA group (17 (19), 6 (6), p=0.022). The HII was

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

higher JIA subtypes associated with spondyloarthropathy as compared to poly-JIA and controls (p=0.0447, p=0.0179). HDL concentration correlated significantly with the HII (r_s= -0.63, p= 0.0003) in all JIA patients and correlated with disease activity. Several circulating bioactive lipid mediators were significantly higher in JIA patients compared with controls with 9HODE,15HODE and 11HETE showing positive correlation with the HII (r_s = 0.36-0.44, p= 0.05-0.02). Arylesterase and Lactonase activity negatively correlated with joint count (r_s= -0.41, p=0.026; r_s=-0.38, p=0.041) and ESR (r_s=-0.40, p=0.027; r_s=-0.41, p= 0.023) respectively in all JIA patients.

Conclusion: This pilot study demonstrates that chronic inflammation in patients with JIA may contribute to HDL dysfunction, particularly in patients with axial involvement. Larger cohort studies are needed to further characterize patients with axial disease as well as aide in our understanding of how PON-1 changes over time in children with chronic inflammation.

Session Date: Sunday, October 26, 2025
Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: This study aims to evaluate the efficacy and safety of tofacitnib, a JAK inhibitor, in a multicentric cohort of patients with juvenile idiopathic arthritis (JIA).

Methods: Patients with JIA attending a pediatric rheumatology clinic who were treated with tofacitnib at some point of their follow-up were retrospectively included. Data collection: at Baseline, sociodemographics, JIA features and subtype and immunology status, JIA disease course of treatments and time on tofacitinib and number of previous therapies, JIA disease status variables and ongoing treatment/discontinuation were collected at 3 and 12 months of follow-up (Wallace criteria); and overall time on tofacitinib (drug survival). Descriptive and comparative statistical analysis comparing baseline and 3- and 12- months variables (JAMOVI (R)) were performed.

Results: N=23 (60% female), mean age 16.5 years (SD 5.02), age at diagnosis 7 years (SD 5.02), mean disease duration 114 months (SD 71.1), age at tofacitinib onset 13.8 years old (SD 4.61). JIA subtypes: RF- poly 26%, ERA 21%, persistent

CRP	7.43	2.05	3.5

oligo 17%, RF+ polyarthritis 13%, soJIA 13% and psoriatic 4%; 65% ANA positive. Previous failure to biologicals (BT): 48%, 2; 26%, 1; 22%, 3; 4%, 5. Mean time on last therapy: 21.1 months (SD 18.8), 95% innefficacy.

Concomitant therapy: at baseline, 65% DMARD, 43% oral steroids; at 3 months, 58% DMARD, 30% oral steroids; at 12 months, 54% DMARD, 15% oral steroids.

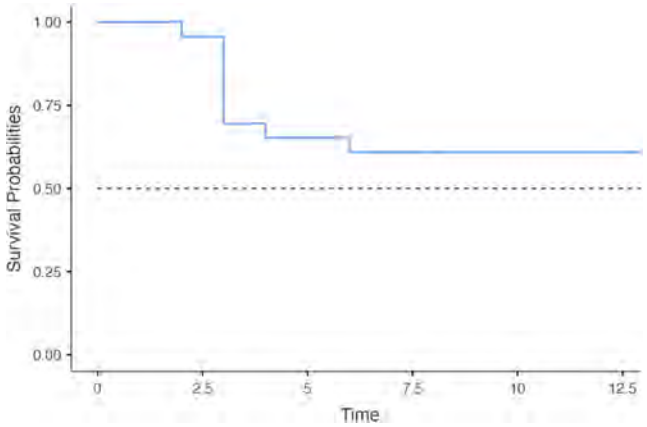
At 12 months, 56% were still receiving tofacitinib, 58% fulfilled inactivity criteria, 58% clinical remission on treatment, 8% clinical remission off treatment.

No adverse event were recorded.

Drug survival (from onset to current date): median of 13 months (range: 2-96).

No differences were found among all variables, except for the significant reduction on oral steroids intake from baseline to 12-months follow-up (p=0.040).

Conclusion: Our results show that very refractory JIA patients who received tofacitinib after biological therapy failure (75% failed to ≥2 biologicals), either combined (DMARD) or in monotherapy, showed clinical statistical significant benefit in all JIA assessments (TJC, SJC, PGA, JADAS-71), both at 3 and 12 months of follow-up. Drug retention was 13 months



1st-year Survival tofacitinib rate.

(2-96). Safety profile was very positive with no adverse events recorded, specially with the higher rates of combined therapy (tocilizumab and canakinumab). Both an 11% and 28% of patients were allowed to discharge DMARD and oral steroids through follow-up, respectively. No particular subsets of patients were found to predict tofacitinib response. Further studies with larger cohorts are recommended to confirm our data.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Maternal smoking during pregnancy has been associated with a seemingly lower risk of juvenile idiopathic arthritis (JIA) in the child (1), contrasting with smoking's established role as a risk factor for rheumatoid arthritis (RA) (2). Using large pregnancy and birth cohorts, we investigated the association between in-utero tobacco exposure and JIA and assessed the role of unmeasured confounding using a Mendelian Randomization (MR) framework.

Methods: We used three Scandinavian cohorts:

1) The Norwegian Registry Linkage Cohort (NRC): All births in Norway from 2004-2020 (n >1 million children).

2) The Norwegian Mother, Father, and Child Cohort Study (MoBa): A pregnancy cohort from 1999-2009 (n >110 000 mother-infant pairs).

3) The Danish National Birth Cohort (DNBC): A pregnancy cohort from 1996-2002 (n >90 000 mother-infant pairs).

JIA cases were identified by ≥2 ICD-10 codes (M08/M09) by linking each cohort to national patient registries. Smoking was self-reported during pregnancy, and categorized as "none", "1st trimester only", and "beyond 1st trimester". In MoBa, maternal genotyping data (n=41,887) enabled estimation of the association between maternal polygenic risk scores (PRS) for smoking initiation (3) and JIA in the child based on MR principles.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Results of Analyses of Maternal Smoking Exposure and Child Risk of Developing JIA

Maternal Smoking During Pregnancy	Unadjusted OR (95% CI)	Adjusted OR (95% CI)
NRC[1]	**JIA n= 976, non-JIA n= 782,769**	
None	Reference	Reference
Only 1st trimester	1.69 (1.29-2.23)	1.09 (0.82-1.44)
Beyond 1st trimester	1.71 (1.38-2.12)	1.20 (0.96-1.50)
MoBa[1]	**JIA n= 281, non-JIA n= 86,669**	
None	Reference	Reference
Only 1st trimester	0.86 (0.60-1.23)	0.81 (0.56-1.17)
Beyond 1st trimester	1.01 (0.70-1.47)	0.87 (0.59-1.29)
Polygenic risk score for smoking	N/A	0.97 (0.84-1.13)
DNBC	**JIA n= 221, non-JIA n= 58,813**	
None	Reference	Reference
Only 1st trimester	1.02 (0.60-1.61)	1.01 (0.60-1.60)
Beyond 1st trimester	1.07 (0.75-1.50)	1.04 (0.72-1.48)

[1]There is an overlap of 221 JIA patients in these two cohorts and result should therefore be interpreted with caution

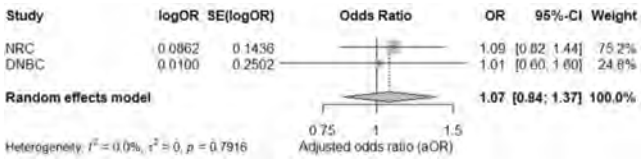

Figure 1. Meta-analysis of NRC and DNBC: Associations between maternal smoking in 1st trimester and JIA (both sexes combined)

Associations were estimated using logistic regression, adjusting for maternal education, parity, inflammatory rheumatic disease (MoBa and DNBC), region of birth (NRC and MoBa), and birth year. In the PRS-analyses, we only adjusted for the first 10 principal components. NRC and DNBC were meta-analyzed to increase precision, here excluding MoBa due to partial overlap with NRC (~220 JIA cases).

Results: 9.5% infants in the NRC, and 25% in both MoBa and DNBC, were exposed to in-utero tobacco exposure. We found no robust evidence that maternal smoking influenced JIA-risk in the child, with meta-analysis yielding an aOR of 1.07 (95% CI 0.84–1.37) for exposure only during the 1st trimester, and 1.15 (95% CI 0.95–1.39) for exposure beyond 1st trimester (**Table 1; Figures 1 and 2**). Maternal PRS for smoking initiation was strongly associated with self-reported smoking during pregnancy in MoBa ($p < 0.001$), supporting its validity as an instrument, but showed no associations with JIA (**Table 1**).

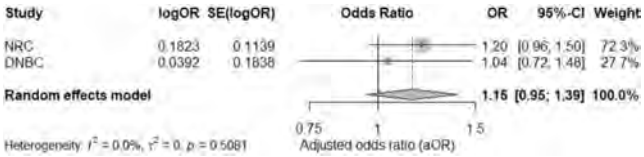

Figure 2. Meta-analysis of NRC and DNBC: Associations between maternal smoking beyond 1st trimester and JIA (both sexes combined)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Across three prospective birth cohorts, using a triangulation approach, we find no evidence of a protective effect of maternal smoking during pregnancy on JIA risk, as previously reported. These findings underscore the importance of prospective designs and multiple approaches when investigating complex, confounding-prone exposures.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: The OMERACT Juvenile Idiopathic Arthritis MRI (JAMRIS) Working group has defined a spectrum of MRI lesions in the sacroiliac joint (SIJ) in youth with spondyloarthritis and axial disease (axJSpA) that can be included in a scoring method. Previous reports have described the application of Spondyloarthritis Research Consortium of Canada (SPARCC) methodology to quantify MRI SIJ lesions in axJSpA, where assessment of inflammation is limited to bone marrow edema (BME) and lesions are assessed in a limited number of semicoronal slices. We aimed to assess the impact of including all inflammatory lesions and SPARCC methodology versus an all-slice method on the metrology of JAMRIS in two longitudinal cohorts of youth with axJSpA treated with a tumor necrosis factor inhibitor (TNFi).

Methods: The two cohorts recruited youth with axJSpA who had a rheumatologist diagnosis of axJSpA. All subjects underwent MRI as part of a diagnostic evaluation for axial disease. MRI lesions were assessed on semicoronal slices through the SIJ from the most anterior (≥1cm vertical height of cartilaginous portion) to the most posterior (≥1cm visible cartilaginous portion) slice. Structural lesions were assessed first on the T1-weighted scan followed by inflammatory lesions on a fluid-sensitive sequence. Scans were obtained at baseline and 3 months-1 year follow up after initiation of treatment with TNFi and assessed blinded-to timepoint and clinical details by 7 readers (4 pediatric and 1 adult MSK radiologists, 1 adult and

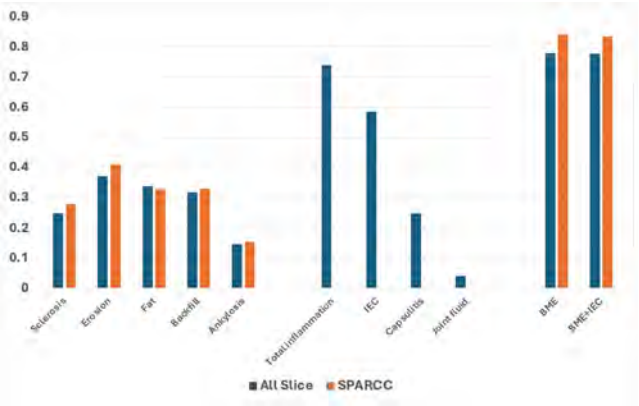

Figure 2. Standardized response means for MRI SIJ inflammatory and structural lesions scores after TNFi assessed across all SIJ slices or limited to the slices selected in the SPARCC method. IEC inflammation in an erosion cavity

Results: Pre- and post-treatment scans (mean(SD) duration between scans 46.6(47.1) weeks) were available from 60 cases, 30 from each cohort. An inflammatory lesion in addition to BME was recorded in 41(68.3%) cases by a majority of readers. But only 1 case had an inflammatory lesion without any BME. For change in structural lesion scores after TNFi treatment, minimal differences were evident between SPARCC and all slice methodologies (Figure 1A). The major contributor to change in inflammatory lesion scores was BME followed by inflammation in an erosion cavity (IEC), though differences between SPARCC and all slice methodologies were minimal (Figure 1B). Reliability for detection of change scores was comparable between SPARCC and all slice methodologies (Table). Responsiveness was comparable between methodologies and combining scores for inflammatory lesions was not superior to BME alone (Figure 2).

Conclusion: BME is the most responsive lesion to treatment with TNFi in axJSpA followed by IEC and then erosion. Responsiveness is not enhanced by assessment of all slices as compared to SPARCC nor by scoring additional inflammatory lesions beyond BME.

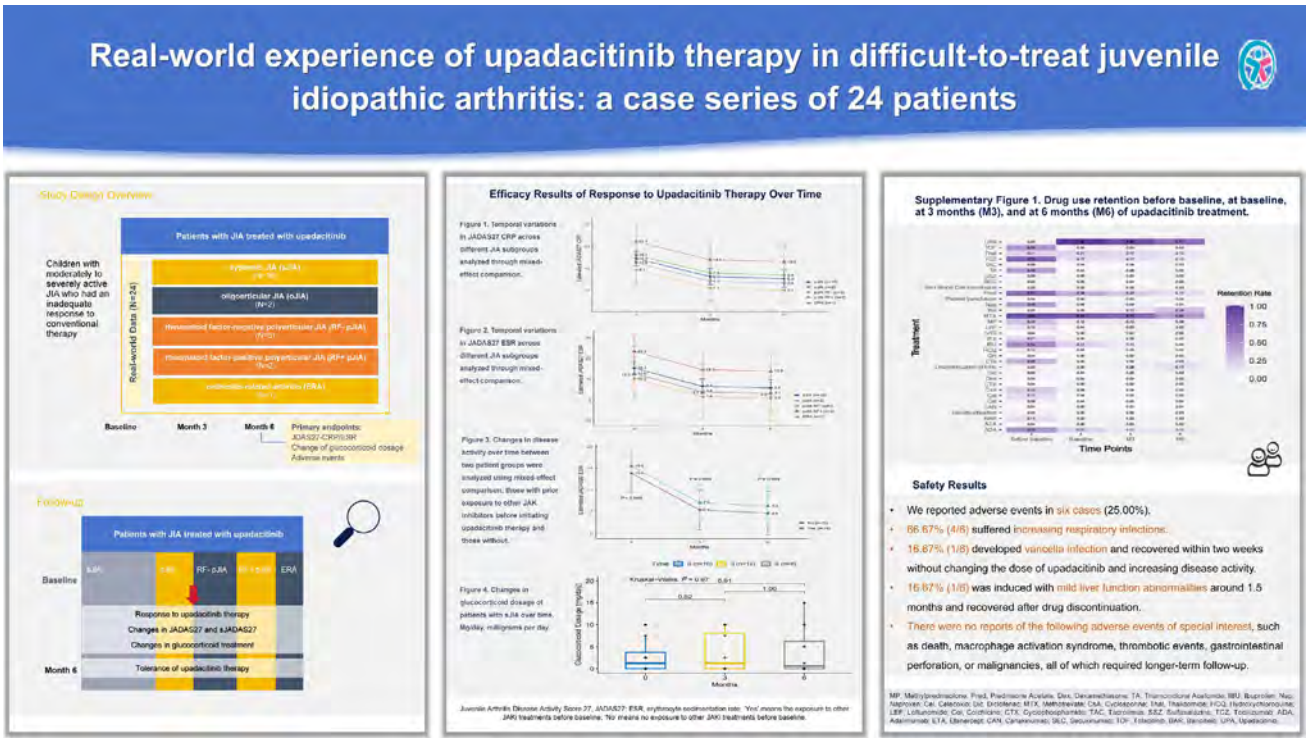
SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0387–0429) Pediatric Rheumatology – Clinical Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Juvenile idiopathic arthritis (JIA) is a chronic rheumatic disease. Some patients experiencing active disease due to inadequate responses to conventional treatments. Studies have demonstrated effectiveness of JAK inhibitors (JAKis) among JIA patients. This study aimed to evaluate the efficacy and safety of upadacitinib in JIA patients.

Methods: We included 24 difficult-to-treat JIA patients in China treated with upadacitinib from January 1, 2024, to December 31, 2024. Juvenile arthritis disease activity scores (JADAS) and efficacy outcomes were collected. Differences between groups were analyzed using univariable and mixed-effect model analyses. A two-sided P value < 0.05 was considered statistically significant in this study.

Results: Total patients received upadacitinib for a median duration of 7.00 (range: 3.50-10.50) months. Baseline median JADAS27 CRP and JADAS27 ESR were 14.59 (range: 8.00-18.61) and 15.05 (range: 12.50-19.60), respectively. Both scores significantly decreased to 3.75 (range: 2.00, 10.00) and 3.75 (range: 2.25, 7.85) at 3 months and sustained



Graphical Abstract Image of Real-world experience of upadacitinib therapy in difficult-to-treat juvenile idiopathic arthritis a case series of 24 patients. Figure 1. Temporal variations in JADAS27 CRP across different JIA subgroups analyzed through mixed-effect comparison. Juvenile Arthritis Disease Activity Score 27, JADAS27; CRP, C-reactive protein. Figure 2. Temporal variations in JADAS27 ESR across different JIA subgroups analyzed through mixed-effect comparison. Juvenile Arthritis Disease Activity Score 27, JADAS27; ESR, erythrocyte sedimentation rate. Figure 3. Changes in disease activity over time between two patient groups were analyzed using mixed-effect comparison: those with prior exposure to other JAK inhibitors before initiating upadacitinib therapy and those without. Juvenile Arthritis Disease Activity Score 27, JADAS27; ESR, erythrocyte sedimentation rate; 'Yes' means the exposure to other JAKi treatments before baseline; 'No' means no exposure to other JAKi treatments before baseline. Figure 4. Changes in glucocorticoid dosage of patients with sJIA over time. Mg/day, milligrams per day. Supplementary Figure 1. Drug use retention before baseline, at baseline, at 3 months (M3), and at 6 months (M6) of upadacitinib treatment. MP, Methylprednisolone; Pred, Prednisone Acetate; Dex, Dexamethasone; TA, Triamcinolone Acetonide; IBU, Ibuprofen; Nap, Naproxen; Cel, Celecoxib; Dic, Diclofenac; MTX, Methotrexate; CsA, Cyclosporine; Thal, Thalidomide; HCQ, Hydroxychloroquine; LEF, Leflunomide; Col, Colchicine; CTX, Cyclophosphamide; TAC, Tacrolimus; SSZ, Sulfasalazine; TCZ, Tocilizumab; ADA, Adalimumab; ETA, Etanercept; CAN, Canakinumab; SEC, Secukinumab; TOF, Tofacitinib; BAR, Baricitinib; UPA, Upadacitinib.

improvements at 6 months ($P < 0.001$). Median prednisone dose decreased from 1.88 (range: 0.00, 7.50) mg/day to 0.63 (range: 0.00, 7.50) mg/day at 3 months and 0.00 (range: 0.00, 5.00) mg/day at 6 months. Tolerance was acceptable with several cases of elevated transaminases and increased upper respiratory tract infections.

Conclusion: This is the largest real-world study of upadacitinib in JIA to date and provides encouraging evidence of the drug's efficacy and safety. The study also indicates that irrespective of prior treatment with other JAKis, switching to upadacitinib may help regain control of disease activity in patients with difficult-to-treat JIA.

Retrospective evaluation of the clinical impact of democgraphic , serological , clinical , radiological parameters and treatment modalities in patients with RA-ILD

fatih ŞAhiner[1], Mine Nokay[2], funda erbasan[2], Veli Yazisiz[3] and **Ender terzioglu**[2], [1]Akdeniz University, Antalya, [2]Akdeniz University, Antalya, Turkey, [3]Akdeniz University, Faculty of Medicine, Antalya, Turkey

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: RA-ILD is significant determinants of morbidity and mortality. This study aims to evaluate the demographic and serological characteristics of RA-ILD patients and investigate the relationship with smoking, phenotypic features and lung involvement using HRCT, treatments administered, and parameters affecting mortality.

Methods: We evaluated 65 patients with RA-ILD who showed interstitial changes on HRCT imaging. We collected data on demographics, clinical findings, laboratory results, pulmonary function tests, HRCT images, and treatments from the hospital information system patient records. We analyzed the relationships between disease progression, mortality, and factors such as age, gender, smoking history, serological test results, disease duration, HRCT findings, DAS28-ESR, pulmonary function tests, and treatments.

Results: The study included 65 patients, with a mean age of 67.14 ± 9.52 years. 60% were female and 40% were male. Of the total, 26.2% had died, with 58.8% of these deaths attributed to ILD. Patients who had lung involvement exceeding 20% on HRCT had a significantly higher mortality rate. Serological evaluations showed high positivity rates for RF at 60% and ACPA at 71.4%. The mean duration between diagnoses of RA and ILD was 7.82 ± 10.16 years. The most common HRCT pattern observed was UIP, present in 46.2% of patients, while 32.3% had lung involvement exceeding 20% on HRCT. At the time of ILD diagnosis, 33.3% of patients were in remission, which increased to 71.9% at the final follow-up. The proportion of patients exhibiting high disease activity decreased from 3.5% initially to none at the last evaluation. Additionally, FVC and diffusing capacity of the lungs for DLCO values declined over time, with the final mean DLCO value recorded at 56.69 ± 21.68. In terms of treatment, 90.8% of patients received MTX, 75.4% received HCQ, and 56.9% received RTX.

*Pearson Chi-Square Test, Fisher's Freeman Halton Exact Test, *n (%)*

Conclusion: Our study findings indicating that RA-ILD is more common in older patients, males, seropositive individuals, and with a smoking history. RA-ILD mortality is higher than non-ILD. Among ILD phenotypes, UIP is the most frequently observed pattern, with higher lung involvement percentages in this group. As lung involvement increases, pulmonary function declines, and mortality rises. Consistent with previous studies, no correlation was found between seropositivity, DAS28 score, and ILD phenotype. However, although numerically significant, the finding that patients with high-titer seropositivity may have more extensive lung disease was not statistically significant.

In deceased patients, pulmonary function test results were lower, disease activity was higher, and the interval between RA and ILD diagnoses was shorter. Patients with high disease activity at RA diagnosis had lower FVC values at ILD diagnosis, while those in remission had higher FVC values. Patients with UIP and NSIP patterns exhibited greater declines in pulmonary function, with UIP associated with higher mortality.

Unlike similar studies, no significant decline in FVC and DLCO values was observed with increased smoking history. Furthermore, in contrast to previous research, no statistically significant relationship was found between TNFi agents and mortality.

Calprotectin Serum levels: a potential neutrophil activation biomarker to monitor treatment response in Rheumatoid Arthritis

Sangeeta Kumari[1], **Eric meldrum**[1], Josephine Stein[1], Tirza Bruurmijn[1], Robin de Jong[2], Katerina Pardali[1], Maarten Kraan[1], Renato Chirivi[1], Rogier Thurlings[3] and Michael Nurmohamed[2], [1]Citryll BV, Oss, Netherlands, [2]Reade, Amsterdam, Netherlands, [3]Radboudumc, Nijmegen, Netherlands

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Calprotectin is a protein highly expressed in myeloid cells and its elevated presence in blood, and the GI tract is associated with immune mediated inflammatory diseases. In autoimmune diseases such as rheumatoid arthritis (RA), elevated levels of calprotectin have been previously reported in patient serum. Furthermore, calprotectin is often

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

associated with neutrophil-mediated inflammation, and in RA disproportionate neutrophil activation exacerbates disease progression with associated elevated calprotectin levels in affected patients. This study aimed to evaluate the utility of calprotectin as a biomarker for monitoring response to different treatments in two longitudinal cohorts of RA patients.

Methods: Serum samples stored at -80°C were obtained from the biobanks of Reade and Radboud University Medical Centre (RUMC). A total of 231 RA serum samples from 33 participants across seven time points over a one-year follow-up period were collected from Reade, while 153 RA samples from 36 participants at various time points over a similar period were obtained from RUMC. At baseline, all samples in the Reade cohort were from treatment-naïve participants, whereas in the RUMC cohort two participants had prior treatment. Throughout consecutive sampling, patients underwent various DMARD treatments. Calprotectin levels were measured using the R&D Biosystems S100A8/A9 ELISA kit following the manufacturer's protocol. Data analysis was performed using Prism 10 and Spotfire Desktop Analyst software, and statistical analysis was performed using the Friedman test.

Results: Baseline calprotectin levels showed a gradual decline following the introduction of treatment. In both cohorts, stratification based on treatment response revealed a significantly greater reduction in calprotectin levels among responders compared to non-responders. In the Reade cohort, the median calprotectin level decreased from **4270 ng/ml at baseline to 1812 ng/ml** after one year ($p< 0.01$), while in the RUMC cohort, it dropped from **5498 to 2021 ng/ml** over a similar period ($p< 0.01$). In contrast, non-responders exhibited minimal changes, with median values shifting from **2920 to 2822 ng/ml** in the Reade cohort and from **2413 to 2670 ng/ml** in the RUMC cohort over one year. Furthermore, the change or delta calprotectin showed a positive correlation with delta CRP (R=0.55), delta ESR (R=0.61) and delta DAS28-CRP (R=0.37).

Conclusion: Our data obtained from the analyses of two longitudinal RA cohorts demonstrate that serum calprotectin and its change can be used as a biomarker for disease activity and response to treatment. Citryll is developing a novel antibody therapeutic mAb (CIT-013) that targets release of extracellular traps from neutrophils. It is our intention to further probe the utility of calprotectin, along with other conventionally used endpoints, as a marker of response to therapy in an RA phase 2a proof of concept study which will begin in 2025.

SD = Standard deviation; **IQR** = Interquartile range; **RF** = Rheumatoid factor; **ACPA** = Anti-citrullinated protein antibodies; **DAS28** = Disease Activity Score using 28 joints; **SDAI** = Simplified Disease Activity Index; **CDAI** = Clinical Disease Activity Index; **HAQ-A** = Health Assessment Questionnaire – Argentine version.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic systemic inflammatory disease that primarily affects synovial joints but may also involve extra-articular organs. Ocular involvement is one of the most common extra-articular manifestations and may result from disease activity or treatment-related complications. The aim of this study was to describe the ophthalmologic manifestations in a cohort of patients with RA and to evaluate their association with sociodemographic and disease-related characteristics.

Methods: A cross-sectional, observational, descriptive and analytical study was conducted. Consecutive patients ≥ 18 years old with RA (2010 ACR/EULAR criteria) were included. Sociodemographic data, disease characteristics, history of ocular involvement and current treatment were recorded. All patients were asked to complete the Ocular Surface Disease Index (OSDI) and underwent a comprehensive ophthalmologic evaluation performed by the same specialist, including tear break-up time (TBUT), Schirmer's test, slit-lamp biomicroscopy, fundoscopy and intraocular pressure measurement. Descriptive statistics were used to summarize results. Associations between ocular dryness severity and clinical variables were analyzed using Chi-squared and Spearman correlation tests. A p-value ≤ 0.05 was considered statistically significant.

Results: A total of 50 patients were included. Patient's characteristics are shown in Table 1. Fifty percent reported previous sicca symptoms, with xerophthalmia being the most frequent (46%). Sjögren's syndrome associated with RA was identified in 6% of patients. The median OSDI score was 8.3 (IQR 4.2–38.0), classifying 40% of patients as having moderate-to-severe ocular dryness. Ophthalmologic examination revealed xerophthalmia in 94% of cases (78% mild, 12% moderate, 4% severe). Cataracts were observed in 46% of patients, with nuclear cataracts accounting for 32%. All ophthalmologic evaluations are detailed in Table 2. Patients with moderate-to-severe dryness based on OSDI had significantly higher disease activity by DAS28 (p = 0.025) and SDAI (p = 0.018).

• Incipient cataract	2 (4)
• Cortical cataract	3 (6)
• Nuclear cataract	16 (32)
• Corticonuclear cataract	2 (4)
• Tear film alteration	17 (34)
• Superficial keratitis	3 (6)
• Blepharitis	1 (2)
• Corneal leucoma	1 (2)
• Pseudophakia with posterior chamber IOL	2 (4)
• Conjunctival hyperemia (tarsal and bulbar)	2 (4)
• Meibomian gland dysfunction	1 (2)
Fundoscopy findings, n (%)	
• Normal	43 (86)
• Vascular narrowing/tortuosity	2 (4)
• Slightly pale optic nerve	1 (2)
• Degenerative myopic retinopathy	1 (2)
• Decreased macular brightness	1 (2)
• Angiosclerosis and arteriovenous crossings	1 (2)
• Media opacities	1 (2)
Ophthalmologic diagnosis, n (%)	
• No signs of xerophthalmia	3 (6)
• Mild dry eye syndrome (Grade I)	39 (78)
• Moderate (Grade II)	6 (12)
• Severe (Grade III)	2 (4)

IQR = Interquartile range; **SD** = Standard deviation; **OSDI** = Ocular Surface Disease Index; **TBUT** = Tear Break-Up Time; **IOL** = Intraocular lens.

Conclusion: In our cohort of RA patients, the most frequent ocular manifestation was xerophthalmia, which was mild in 78% of cases. Cataracts were present in 46% of patients, with the nuclear subtype being the most common. Moderate-to-severe dry eye symptoms were associated with higher disease activity. These results highlight the importance of identifying ocular symptoms in RA and suggest that ocular surface involvement may reflect a higher systemic inflammatory burden.

Abstract Number: 0433

In-hospital outcomes of patients admitted due to First-Time Pulmonary Embolism with preexisting Rheumatoid Arthritis: A Nationwide Analysis 2016-2022

John Langley[1], **Karuna Bista**[2], Clarisse Yapp[2], Nisha Sapkota[3], Shukranta Shrestha[2] and Sulav Pyakurel[1], [1]Montefiore New Rochelle Hospital, New Rochelle, NY, [2]Montefiore New Rochelle Hospital, New Rochelle, [3]Interfaith Medical Center, One Brooklyn Health, Brooklyn, NY

SESSION INFORMATION

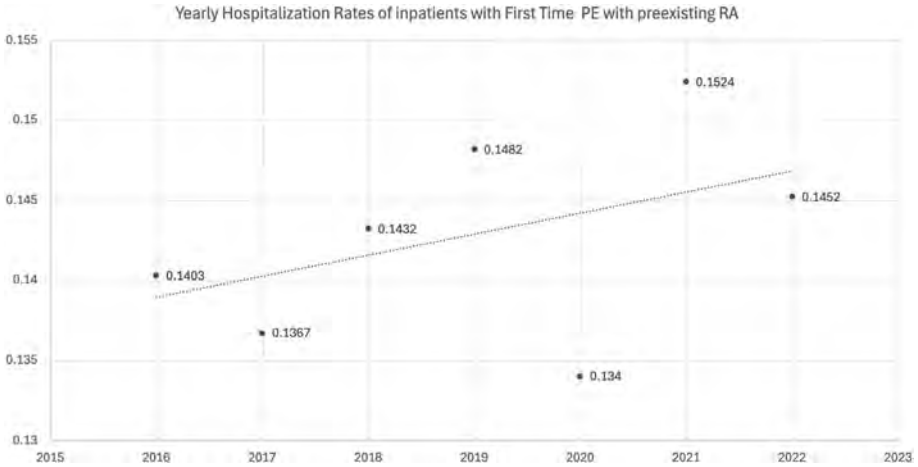
Session Date: Sunday, October 26, 2025

Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

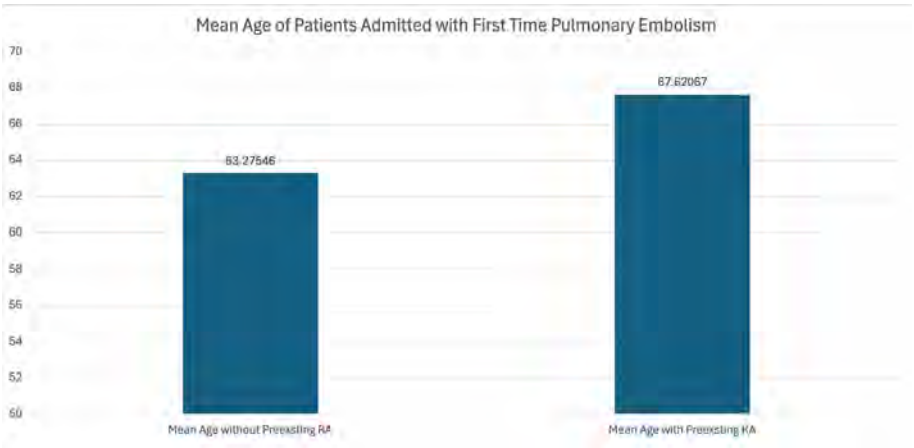
Background/Purpose: Although it has been documented that patients with Rheumatoid Arthritis may be at increased risk of Pulmonary Embolism, other inpatient outcomes remain largely unexplored. We aimed to better identify the impact of Rheumatoid Arthritis on hospital outcomes in patients admitted for first-time Pulmonary Embolism.



Hospitalization Rates of patients admitted for First Time PE with preexisting RA steadily increased from 2016 to 2022.

The majority of inpatients were White followed by Black and Hispanic individuals.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Individuals without preexisting RA were hospitalized at earlier ages.

Methods: A retrospective cohort analysis using the U.S. HCUP NIS Database from 2016-2022 was conducted. Patients admitted with a primary diagnosis of a first episode of Pulmonary Embolism with preexisting Rheumatoid Arthritis were identified using ICD-10 codes. The primary outcome was in-hospital mortality. Secondary outcomes were length of stay, resource utilization and need of various interventions. Univariate analysis was done and variables with $p< 0.2$ were considered for multivariate analysis, adjusting by age, gender, race, Charlson comorbidity index, hospital location and teaching status, size, region and insurance status. Data was considered statistically significant with p-value < 0.05.

Results: From 2016 to 2022, a total of 1,315,394 patients were admitted for a first-time pulmonary embolism (PE). Out of these, 30,474 patients, or 2.32%, had a preexisting diagnosis of rheumatoid arthritis (RA). Notably, these RA patients demonstrated a 35.19% reduction in the odds of mortality (p-value = 0.00). Additionally, they experienced an average decrease in the length of hospital stay by 0.3764 days (p-value = 0.001) and a significant reduction in mean total charges for their hospital stay, amounting to $6,886.12 (p-value = 0.00). Furthermore, RA patients had a 27.87% lower likelihood of undergoing intubation during their hospitalization (p-value = 0.001).

Conclusion: Our research revealed that Rheumatoid Arthritis is associated with improved inpatient outcomes with patients with first-time Pulmonary Embolism. These findings suggest that Rheumatoid Arthritis may confer a protective effect in this population, warranting further investigation.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Since 2021, patients with new-onset rheumatoid arthritis (RA) at the Department of Rheumatology, Skåne University Hospital, Lund, Sweden, are invited to participate in a ”tight control” and ”treat-to-target” (TC+T2T) follow-up strategy (TINDRA study). This strategy includes follow-up visits to a rheumatologist (at diagnosis and 3, 6, 12, 18, 24 months) and rheumatology nurse-led physical/telephone consultations between physician visits every other week for 3 months and thereafter when needed. Visits include disease activity assessments and adjustment of anti-rheumatic treatment when needed, aiming for remission. The aim of the current study was to explore possible advantages of implementing this TC+T2T strategy over routine clinical practice in new-onset RA patients regarding achievement of remission (DAS28< 2,6, DAS28CRP< 2,4, CDAI≤2,8, and remission defined as 0 swollen joints in the 28-joint count score [“0 swollen joints of 28” remission]).

Methods: RA patients with symptom duration < 12 months at diagnosis were eligible. Data on disease-, treatment characteristics and outcome measures for patients included in the TINDRA study and controls were retrieved from the Swedish Rheumatology Quality register (SRQ). Controls comprised early RA patients followed according to routine clinical practice at the rheumatology out-patient clinics elsewhere in the Skåne region during the same period. In total, 103 patients were followed according to the TC+T2T strategy and 740 according to routine care. Achievement of remission at 1 year after diagnosis was compared between the two strategies using logistic regression, adjusted for sex, age, symptom duration, number of swollen and tender joints, CRP, ACPA status and HAQ at diagnosis.

Results: Disease and treatment characteristics at diagnosis are summarized in Table1.

Percentage females/mean age/mean symptom duration at inclusion were 73%/58 years/5,9 months (TC+T2T) and 69%/60 years/5,7 months (routine care).

Figure 1 illustrates proportion (%) of patients reaching remission (green area) according to the “0 swollen joints of 28” definition at different follow-up times in patients and controls.

Percentages of patients reaching DAS28, DAS28CRP and CDAI remission criteria increased in both groups over time, but the differences between the TC+T2T strategy and routine care were not significant. However, at 12 months of follow-up, the TC+T2T strategi was associated with significantly higher odds of reaching “0 swollen joints of 28” remission compared to routine care (Table2).

Table 1. Disease and treatment characteristics at diagnosis

	TC+T2T group (n=193)	Controls (n=143)
Swollen 28 joint count	6.1 (4)	5.8 (5)
Tender 28 join count	8.4 (6)	7.3 (6)
ESR	46.8 (29)	41.3 (28)
CRP	21.7 (30)	20.6 (32)
DAS28	5.4 (1)	4.9 (1)
DAS28CRP	4.7 (1)	4.4 (1)
CDAI	23.5 (11)	21.6 (12)
HAQ	1.0 (0.6)	1.1 (0.7)
Fatigue (VAS)	32.3 (28)	38.1 (30)
Pain (VAS)	28.8 (25)	34.1 (27)
Smoking (ever) (%)	42%	30%
Methotrexate started at diagnosis (%)	75%	66%
Prednisolone started at diagnosis (%)	68%	42%

Mean and standard deviation (SD) if not otherwise stated.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

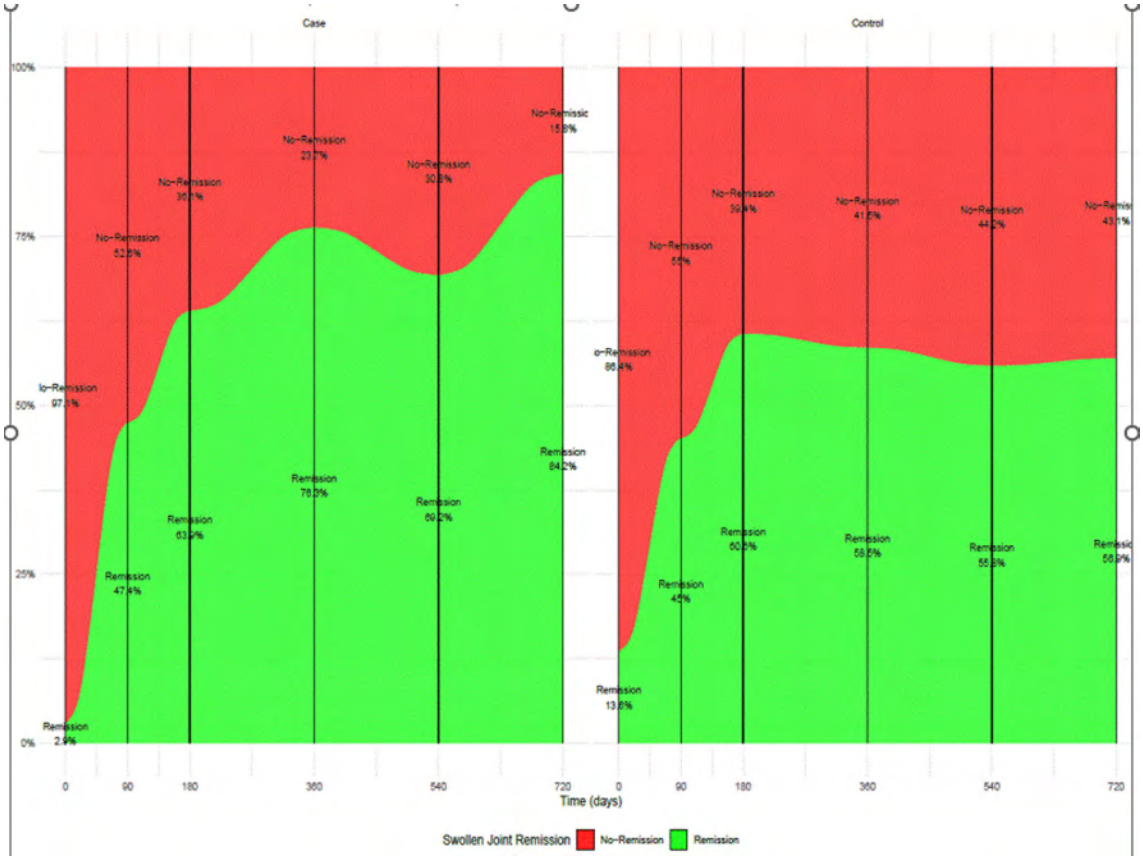

Figure. illustrates proportion (%) of patients reaching remission (green area) according to the "0 swollen joints of 28" definition at different follow-up times in patients and controls.

Table2. Predictors of achieving remission according to the "0 swollen joints of 28" definition, at 12 months of follow-up

	p-value	OR	95% CI
TC+T2T vs routine care	**0,003**	**2,4**	**1,36-4,30**
**Age (years)	0,921	1,0	0,99-1,10
Sex (men versus women)	0,084	1,6	0,94-2,73
Swollen 28-joint count at diagnosis	0,500	1,0	0,94-1,10
Tender 28-joint count at diagnosis	0,872	1,0	0,93-1,10
CRP (mg/L)	0,574	1,0	0,99-1,01
ACPA positivity	0,847	1,0	0,60-1,43
HAQ (0-3)	0,203	0,91	0,59-1,005

*TC+T2T = tight control and treat-to-target

Conclusion: Compared to routine rheumatology care, the "tight control" and "treat-to-target" follow-up strategy resulted in larger proportions of patients reaching remission throughout the first two years after RA diagnosis and a more than doubled probability of reaching the strict target of "no swollen joints" one year following the diagnosis. These findings suggest that such a strategy should be considered for implementation in routine care of patients with new-onset RA.

Session Date: Sunday, October 26, 2025
Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disease that manifests as either seropositive or seronegative subtypes. Seropositive RA, characterized by the presence of autoantibodies such as RF and ACPA, is often linked to more severe joint damage and systemic complications. In contrast, seronegative RA has a less defined clinical profile but may still present with significant comorbidities. This study aims to compare clinical outcomes between these RA subtypes using real-world data from the TriNetX Research Network.

Methods: A retrospective cohort study was conducted to analyze adult patients diagnosed with rheumatoid arthritis (RA) between 2015 and 2025. Patients were categorized as either seropositive or seronegative based on the International Classification of Diseases, 10th Revision (ICD-10) codes. To reduce confounding and ensure comparability between

Figure 1. Flowchart of the Selection Process

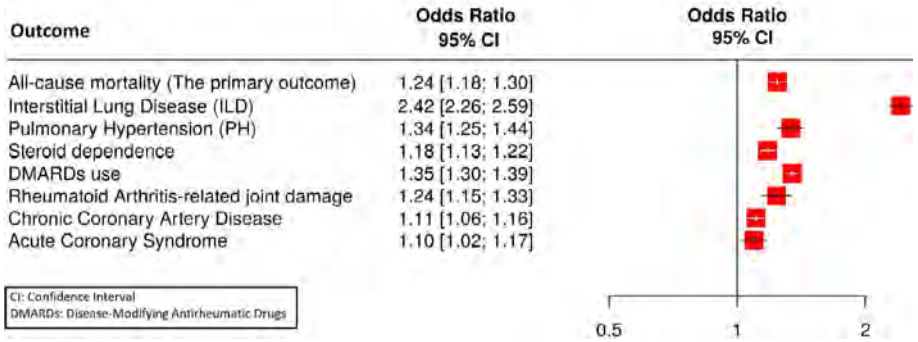
Outcome	Number of Patients with Event (%)		Odds Ratio (95% CI)	P Value
	Seropositive RA	Seronegative RA		
All-Cause Mortality	12,478 (23.4%)	10,048 (18.9%)	1.24 (1.16–1.27)	<0.001
DMARD Use	45,216 (84.9%)	39,872 (74.9%)	1.35 (1.30–1.40)	<0.001
Steroid Dependence	20,486 (38.5%)	17,184 (32.3%)	1.18 (1.13–1.23)	<0.001
RA-Related Joint Damage	15,927 (29.9%)	12,738 (24.0%)	1.24 (1.19–1.29)	<0.001
Interstitial Lung Disease (ILD)	7,329 (13.8%)	3,029 (5.7%)	2.42 (2.30–2.55)	<0.001
Chronic CAD	16,214 (30.5%)	14,516 (27.2%)	1.11 (1.06–1.16)	<0.001
Acute Coronary Syndrome (ACS)	5,479 (10.3%)	4,912 (9.2%)	1.10 (1.02–1.17)	0.008

Comparative Outcomes in Seropositive and Seronegative Rheumatoid Arthritis

Figure 3: Forest Plot showing Odds Ratio (OR) and Confidence Intervals (CI)



groups, propensity score matching (PSM) was applied to balance key baseline characteristics, such as age, sex, comorbidities, and other rheumatologic diseases. Following matching, outcomes were compared between the two groups over a follow-up period of 10 years. Figure 1 illustrates the selection process. The primary outcome was all-cause mortality. Other outcomes included steroid dependence, disease-modifying antirheumatic drug (DMARD) use, RA-related joint damage, interstitial lung disease (ILD), and coronary artery disease (CAD).

Results: Among 106,492 matched patients (53,246 per cohort), seropositive RA patients had significantly higher all-cause mortality (OR: 1.24; $p < 0.001$). Kaplan-Meier analysis demonstrated lower survival probabilities in the seropositive group (76.51% vs. 81.68%; log-rank $p < 0.001$), with a hazard ratio of 1.21 (95% CI: 1.16–1.27), indicating a significantly increased risk.

The use of DMARDs was more frequent in seropositive patients (OR: 1.35; $p < 0.001$), and steroid dependence was more common (OR: 1.18; $p < 0.001$). Additionally, seropositive patients had a higher risk of RA-related joint damage (OR: 1.24; $p < 0.001$). Furthermore, the incidence of ILD (OR: 2.42; $p < 0.001$), chronic CAD (OR: 1.11; $p < 0.001$), as well as acute coronary syndrome (ACS) (OR: 1.10; $p = 0.008$) were significantly higher (Table1) (Figure 2).

Conclusion: This study highlights significant differences in clinical outcomes between seropositive and seronegative RA patients. Seropositive RA was associated with higher all-cause mortality, greater steroid dependence, and more frequent use of DMARDs. Additionally, seropositive patients had a higher risk of RA-related joint damage, interstitial lung disease, and coronary artery disease. These findings highlight the more aggressive nature of seropositive disease and its extra-articular involvement, emphasizing the need for early and targeted interventions in this subgroup and reinforce the importance of autoantibody status in prognostication and risk stratification for RA patients.

Abstract Number: 0436

Why Do Patients with Rheumatic Disease Have MACE and Thrombotic Events?

Andrea Mazariego and Maria Greenwald, Desert Medical Advances, Rancho Mirage, CA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with rheumatic disease have an increased risk for thrombotic events and major adverse cardiac events (MACE) due to systemic inflammation. Bleeding time is a test performed in the clinic and consistently confirms a short time to clot with known risk factors such as estrogen, cox-2 inhibitors, JAK inhibitors, and factor V Leiden. Historically, a short bleeding time under 3 minutes is associated with an increased risk of thrombotic disease. We explored whether patients with rheumatic disease have a short bleeding time. This may be the physiologic mechanism leading to clotting events.

Methods: All sequential 239 patients over age 50 with rheumatic disease had a bleeding time test (BT). This included patients with rheumatoid arthritis, psoriatic arthritis, ankylosing spondylitis, and lupus. Data was collected between September 2022- December 2024. Patients who began low dose aspirin 81 mg daily in 2023 had a repeat BT to confirm compliance. No patients had a history of cardiovascular disease but 15 developed MACE or a thrombotic event prior to aspirin therapy, and this resulted in death for three patients. BT at baseline (prior to the event) and BT after the event were compared. Cohorts were analyzed by assigned treatments for rheumatic disease including methotrexate, JAK inhibitors, TNF inhibitors, abatacept, secukinumab, IL-1 inhibitors, and PD-1 agonist.

Results: Rheumatic disease patients at baseline had shorter BT results compared to historical normal controls (1.52 $\pm$ 0.77) versus 4-7 minutes which is found in the normal general population ($p < 0.01$). There was no difference in the short BT among patients with rheumatoid arthritis, psoriatic arthritis, ankylosing spondylitis, or lupus. Cohorts were analyzed by treatment and BT did not discriminate between treatment assigned (Table 1). The addition of low dose aspirin 81 mg daily dramatically

Table 1

Table 1: BT at baseline before aspirin and after low dose aspirin

RA	BT without aspirin	BT with aspirin	p (compared to asp)
Methotrexate (age 70)	1.74± 1.00	2.98± 0.69	<0.0001
JAKi (age 58)	1.38± 0.51	3.47± 1.36	<0.001
TNFi (age 59)	1.10± 0.31	3.05± 0.84	<0.001
Abatacept (age 70)	1.15± 0.50	3.47± 0.11	<0.0001
IL-1i (age 60)	1.91± 1.10	3.11± 0.59	<0.01
PD-1 agonist(age 59)	1.78± 0.93	3.76± 1.16	<0.002

Table 2

Table 2: BT at baseline without aspirin and after anti-coagulants for patients who developed MACE or Thrombotic events

Rheumatic disease	age/gender	event	BL BT	BT with anti-coag
PsA	72 M	PE	1.06	3.6
Lupus	63 F	TIA	1.88	2.48
RA	48 F	PE	2.48	3.44
RA	78 M	TIA	1.97	4.3
Lupus	63 F	TIA	2.88	5.01
Lupus	63 F	CVA	2.48	3.01
RA	68 M	MI	3.01	4.02
RA	73 M	MI	1.06	4.12
RA	77 M	PE	2.53	4.3
RA	78 M	MI	1.55	4.22
RA	67 M	MI	3.02	4.5
Lupus	64 F	DVT	2.39	5.3
RA	54 F	DVT	2.31	2.38
RA	60 M	MI	2.87	7.21
RA	74 F	DVT/ MI	1.99	25.5

Legend: Deep vein thrombosis (DVT), myocardial infarction (MI), pulmonary embolism (PE), transient cerebral accident (TIA). Three of these events resulted in death. N=15, average age 68.

nearly doubled BT. The patients who developed MACE or a thrombotic event had short BT test results but did not differ from those who did not have a clotting event. The only significant findings in the MACE/thrombotic group was older age by almost a decade, predominantly male gender, and 80% were smokers (Table 2).

Conclusion: All patients with rheumatic disease with systemic inflammation tested had short BT results. BT did not identify a specific individual who would develop MACE or a thrombotic event. BT tests did revert to normal with the addition of low dose aspirin 81 mg daily. Aspirin is now recommended prophylactically in all lupus with phospholipid syndrome. Perhaps it is time to consider low dose aspirin for patients over age 50 with rheumatic disease.

Abstract Number: 0437

Lipid Screening in Rheumatoid Arthritis: A Retrospective Cohort Study Highlighting Gaps in Cardiovascular Risk Prevention

Anokhi Saklecha[1], Amelia Khoo[2], Sierra Mendelsohn[2], Abhijeet Danve[3], Mei Xue Dong[4] and Lisa Suter[2], [1]Yale University, New Haven, CT, [2]Yale School of Medicine, New Haven, CT, [3]Section of Rheumatology, Department of Medicine, Yale School of Medicine, New Haven, CT, [4]Yale-New Haven Medical Center, new haven, CT

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is associated with a 1.5 to 2 fold increased risk of cardiovascular disease (CVD) due to systemic inflammation and endothelial dysfunction. This level of cardiovascular threat is comparable to—and may even exceed—that of traditional risk factors such as diabetes. The European Alliance of Associations for Rheumatology (EULAR) recommends adjusting CVD risk scores by a factor of 1.5 in patients with RA, emphasizing the importance of cardiovascular risk screening in this population, including lipid testing. The American College of Cardiology (ACC) and American Heart Association (AHA) recommend lipid screening every 4 to 6 years in all adults, and as often as every 2 years when risk factors are present. In this study, we aimed to assess the prevalence and patterns of lipid screening in RA patients.

Methods: We conducted a retrospective cohort study using electronic health records from a large academic health system. Adults (≥18 years) with RA who had at least one outpatient rheumatology visit between 1/1/2020 and 12/31/2024 were included. Lipid screening was defined as any recorded lipid panel over the five year period. Relevant demographic and clinical factors were extracted, including age, sex, BMI, and comorbidities. Chi-squared tests were then used to compare the rates of lipid screening across different subgroups.

Results: We analyzed 1,686 patients with RA, of whom 81.7% were female and 18.3% were male. Overall, 1,182 patients (70.1%) underwent lipid screening over the 5-year period, while 504 (29.9%) did not. Screening rates were significantly higher among patients with traditional cardiovascular risk factors. RA patients with diabetes were more likely to be screened than those without (77% vs. 60%, $p< 0.0001$), as were those with hypertension (77% vs. 60%, $p< 0.0001$). Screening was also more common among patients with obesity (BMI ≥30) compared to those with lower BMIs (76% vs. 72%, $p=0.03$). Patients under 40 were less likely to be screened than middle-aged or older patients (45% vs. 72%, $p< 0.0001$).

Conclusion: Despite the well-established cardiovascular risk, nearly one in three RA patients in our health system did not undergo lipid screening over a 5-year period. When screening did occur, it was more strongly associated with the presence of traditional risk factors, including hypertension, diabetes, and obesity, than with RA alone. This suggests that clinicians may not fully recognize RA itself as an independent driver of cardiovascular risk, leading to missed opportunities for disease prevention. To address this gap, our health system is implementing an Epic Best Practice Alert (BPA) to prompt regular lipid testing in all RA patients. Through such tools, we aim to facilitate earlier risk management and ultimately reduce cardiovascular morbidity and mortality in RA.

Abstract Number: 0438

Exploring the Potential for Cardiorenal-Metabolic Therapies to Target Comorbidities in Early Rheumatoid Arthritis

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Cardiorenal-metabolic (CRM) therapies, such as SGLT-2 inhibitors and GLP-1 agonists, are medications that target interconnected pathways between cardiovascular, renal, and metabolic systems and may provide additional benefits for patients with rheumatoid arthritis (RA) by potentially reducing systemic inflammation. Our objectives were to (1) To assess the prevalence of CRM conditions and eligibility for CRM therapies based on approved indications and investigational (off-label) use in early RA (ERA). (2) To examine differences in clinical characteristics, including sex-based variations, for patients with and without CRM conditions.

Methods: Data were from the Canadian Early Arthritis Cohort, a cross-sectional study of patients recruited between 2017 and 2023, including baseline BMI, creatinine, Clinical Disease Activity Index (CDAI), and CDAI at 12 months. We estimated the baseline prevalence of approved Canadian CRM indications: (1) type 2 diabetes, (2) obesity (BMI ≥30 kg/m^2), (3) heart failure, or (4) overweight (BMI ≥27 and < 30 kg/m^2) + ≥ 1 weight-related complication of hypertension and/or dyslipidemia. Off-label indications included (5) chronic kidney disease (< eGFR < 60 mL/min/1.73 m^2), (6) overweight BMI with elevated C-reactive protein (CRP >5mg/L), or (7) large joint osteoarthritis[1]. Descriptive statistics were done for the overall cohort. Stratification by sex was used to identify differences associated with CRM conditions.

Table. Baseline prevalence of approved and off-label cardiorenal-metabolic (CRM) indications, stratified by sex.

	Approved CRM Indications				Approved and Off-Label CRM Indications			
	Total N = 278	Female N = 185	Male N = 93	P-value	Total N = 278	Female N = 185	Male N = 93	P-value
Any CRM Condition	126 (45%)	79 (43%)	47 (51%)	0.22	151 (54%)	94 (51%)	57 (61%)	0.09
Type 2 Diabetes	31 (11%)	16 (9%)	15 (16%)	0.0615	31 (11%)	16 (9%)	15 (16%)	0.06
Obesity	88 (32%)	62 (34%)	26 (28%)	0.35	88 (32%)	62 (34%)	26 (28%)	0.34
Heart Failure	0	0	0	NA	0	0	0	NA

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Out of 855 recruited patients, the final sample included 278 patients and 67% were female. The mean age was 57 ± 14 years, and mean symptom duration was 5.1 ± 2.7 months. At baseline, nearly all patients (90%) had moderate or high Clinical Disease Activity Index (CDAI) scores. Overall, 54% had one CRM condition and 45% met approved indications for CRM therapy, primarily for obesity (Table). Overlapping conditions increased (14% had ≥2 CRM) when off-label indications such as knee OA or overweight BMI + elevated CRP were considered. Patients with CRM conditions were older and had more non-metabolic comorbidities. However, there were no significant differences in disease activity components beyond inflammatory makers (mean CRP 9.5 mg/L vs. 4.8mg/L, p=0.01), nor were there differences in initial DMARD or corticosteroid strategies. In sex stratified analyses, no differences were observed between male and females for the number or type of CRM conditions (Table).

Conclusion: In this real-world ERA cohort, 45% of patients met criteria for approved CRM therapy, primarily for obesity and diabetes. Obesity is known to negatively affect RA disease activity and treatment response, making it a critical target for intervention. The lack of significant sex-based differences in CRM conditions further highlights the universal relevance of CRM conditions in RA management. Future research should explore how CRM therapies, particularly those targeting obesity, could improve metabolic health and RA outcomes, warranting their study in this population.

Background/Purpose: Despite advances in therapeutic strategies, a subset of patients with rheumatoid arthritis (RA) continues to experience persistent symptoms. In 2022, the EULAR proposed a standardized definition and and points to consider for the management of difficult-to-treat (D2T) RA. Distinguishing whether persistent symptoms are due to active inflammation or other conditions is essential to guide therapeutic decisions.

The aim of this study was to assess the prevalence of non-inflammatory causes of persistent joint symptoms and to explore both patient and physician perspectives on symptom origins.

Methods: This cross-sectional study was conducted from November 2023 to January 2025 in two hospital centers. Inclusion criteria were a confirmed diagnosis of RA according to the 2010 ACR/EULAR criteria and fulfillment of the 2022 EULAR definition of D2T RA.

Comprehensive assessments were performed as recommended by the EULAR "points to consider." Collected data included demographics, comorbidities, treatment history, clinical evaluation, and patient-reported outcomes (including SF-12 for quality of life, MARS-5 for treatment adherence, PCS for pain catastrophizing, and WPI for fibromyalgia symptoms).

All patients underwent a standardized diagnostic work-up, including laboratory tests, radiographic, and ultrasound assessment.

Persistent inflammatory refractory RA (PIRRA) was defined by the presence of Doppler-positive synovitis. Other patients were categorized as having non-inflammatory refractory RA (NIRRA).

Results: A total of 52 patients were included, with a median age of 61.2 years. The majority were female (76.9%) with severe, erosive disease (78.8%) and seropositivity (88.4% ACPA positive).

Methotrexate had been prescribed to 96% of patients, though only 48% were still receiving it at the time of assessment. Patients had received an average of 4.4 targeted therapies. Daily corticosteroid use was reported in 60% of patients, with a mean dose of 6.2 mg/day.

Table 1. Patient Characteristics and Perceived Causes of Articular Symptoms (Physician vs Patient Assessment)

Variable	All (n=52)	PIRRA (n=40)	NIRRA (n=12)
Patient Characteristics			
Age (years), mean	61.2	60.9	67.3
ACPA positive, n (%)	46 (88.4%)	36 (90.0%)	10 (83.3%)
Smokers, n (%)	18 (34.6%)	14 (35.0%)	4 (33.3%)
Number of targeted DMARDs, mean	4.4	4.4	4.2
DAS28-CRP, mean	4.2	4.38	3.7
Clinical synovitis count, mean	4.2	4.9	1.3
Mode B synovitis count, mean	9.2	11.2	2.3
Doppler-positive synovitis count, mean	3.7	4.8	0.0
Causes Contributing to Articular Symptoms — Physician Assessment			
RA sequelae, n (%)	27 (51.9%)	21 (52.5%)	6 (50.0%)
Osteoarthritis, n (%)	21 (40.4%)	14 (35.0%)	6 (50.0%)
Fibromyalgia, n (%)	7 (13.5%)	5 (12.5%)	2 (16.7%)
Causes Contributing to Articular Symptoms — Patient Self-Assessment			
RA sequelae, n (%)	29 (55.8%)	24 (60.0%)	5 (41.7%)
Osteoarthritis, n (%)	19 (36.5%)	12 (30.0%)	7 (58.3%)
Fibromyalgia, n (%)	2 (3.8%)	2 (5.0%)	0 (0.0%)

The mean DAS28-CRP was 4.2. Based on ultrasound findings, 41 patients (76.9%) were classified as PIRRA.

Osteoarthritis was present in 40.4% of patients and was deemed to contribute to symptoms in 35.0% of PIRRA patients. RA-related structural damage (sequelae) was observed in 51.9% of patients and contributed to symptoms in 52.5% of PIRRA cases. Fibromyalgia criteria were met by 9.6% of patients.

Most patients (94.2%) — including all PIRRA patients — perceived their disease as active, compared to 78.8% based on the physician global assessment.

Pain catastrophizing was identified in 48.1% of patients, and 17.3% had poor treatment adherence. These patterns were similarly distributed between PIRRA and NIRRA groups.

Conclusion: In this cohort, a significant proportion of patients with D2T RA experienced symptoms attributable to non-inflammatory causes, particularly osteoarthritis and RA-related joint damage, either alone or in combination with active disease. These findings underscore the importance of a comprehensive and integrated approach to the management of D2T RA.

Abstract Number: 0440

The Painful Truth: Non-Articular Pain's Impact on Rheumatoid Arthritis Assessment after Initiating a new DMARD for Active Disease

Charis Meng[1], Jing Song[2], Lutfiyya muhammad[3], Caci Julia[4], Tuhina Neogi[5], Marcy Bolster[6], Wendy Marder[7], Clifton Bingham[8] and Yvonne Lee[9], [1]Hospital for Special Surgery, New York, NY, [2]Northwestern University Feinberg School of Medicine, Worthington, MN, [3]Northwestern University Feinberg School of Medicine, Chicago, IL, [4]Hospital for Special Surgery, New York, [5]Boston University School of Medicine, Boston, MA, [6]Massachusetts General Hospital, Concord, MA, [7]University of Michigan, Ann Arbor, MI, [8]Johns Hopkins University, Baltimore, MD, [9]Northwestern University, Chicago, IL

Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: RA-related pain is typically thought of as pain in the joints. However, non-articular pain (NAP) is also common, persisting in 1/3 of patients with early RA despite treatment (1). NAP may prevent patients from achieving treatment goals by contributing to elevated pain intensity and patient global assessment (PtGA). Overestimation of disease activity may lead to changes in DMARD treatment without associated improvements in disease outcomes. Recognizing NAP as a driver of pain intensity and PtGA may help prevent overtreatment with DMARDs, lead to earlier recognition of and addressing treatment with greater specificity for different types of pain. Our aims were to evaluate the cross-sectional association of NAP with elevated pain intensity and PtGA in patients 3-months after initiating a new DMARD for active RA.

Methods: The Central Pain in Rheumatoid Arthritis study is a prospective cohort of patients fulfilling 2010 ACR/EULAR criteria for RA, who have active disease and are initiating a new DMARD. At the 3-month visit, patients indicated any areas of

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. pain or tenderness that they were experiencing on a body pain diagram (BPD), derived from the Widespread Pain Index which assesses 19 body areas (jaw, neck, shoulder (girdle), upper arm, lower arm, upper back, chest, abdomen, lower back, hip (buttock), upper leg and lower leg). Prespecified NAP patterns were classified based on pain reported in 5 sections (4 quadrants and axial, excluding hands and feet) and grouped as: 1) no NAP (no sections selected), 2) regional (1-3 sections) or 3) widespread NAP (4-5 sections) (1). Patients completed synchronous assessments of pain intensity and PtGA. Separate median regression models were used to examine the associations between NAP groups and the two outcomes. Both unadjusted and adjusted models (controlling for age, sex, education, smoking status, comorbidity, seropositivity, and study site) were fitted.

Results: The 192 RA patients were mostly female (84%) with mean (SD) age of 55 (14) years; 70% were seropositive, mean RA disease duration was 10.8 (212.8) years and mean (SD) CDAI was 14.9 (12.6) (Table 1). NAP was prevalent in 92.7% (n=178), with regional NAP 44.3% (n=85) and widespread NAP 48.4% (n=93). Compared to other groups, those with widespread NAP were more frequently White women who reported more comorbidities and longer disease duration. At follow-up, NAP was associated with higher median values [IQR] for pain intensity and for PtGA in a dose-dependent fashion across

Table 3: Multivariable regression analysis showing association of NAP with elevated Pain Intensity and PtGA in RA Patients Changing DMARDs

	Pain Intensity				PtGA

pain groups: no NAP, regional NAP and widespread NAP (Table 2). In median regression analyses, compared to no NAP, widespread NAP was associated with higher median levels of both pain intensity and PtGA: difference in medians 95% [CI] was 1.9 (0.3, 3.6) and 2.4 [0.8, 3.9], respectively (Table 3).

Conclusion: NAP was associated with higher pain intensity and PtGA in RA in a dose-dependent fashion. Despite changing DMARD treatment to manage active RA, widespread NAP was identified as a significant driver of pain intensity and PtGA. A limitation includes a lack of validated tool to screen for NAP in RA, calling for improved reporting of NAP. Early identification and intervention of NAP may help patients to reach their treatment goals.

Charting the Course of Worsening: Utilizing Standard Outcomes to Define Worsening for Pathophysiological Insights into RA

Charis Meng[1], Caci Julia[2], Kelsey Gripp[2], Deanna Jannat-Khah[1], Yvonne Lee[3], Susan J. Bartlett[4], Clifton Bingham[5] and Vivian Bykerk[1], [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, New York, [3]Northwestern University, Chicago, IL, [4]McGill University, Beaconsfield, QC, Canada, [5]Johns Hopkins University, Baltimore, MD

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: RA disease worsening contributes to joint damage and cardiovascular disease. While measures of improvement are established in RA, we do not have uniform definitions for disease worsening. Robustly identifying RA disease worsening reported by clinicians and patients could facilitate future translational studies of its pathophysiology (i.e. using -omics data). The OMERACT RA-FLARE questionnaire (RAFQ) is a valid patient-reported outcome (PRO) of RA worsening. Patients reporting they were "a lot worse" had a mean RA-FQ increase of 8.9 points[1]. We aimed to evaluate associations with stringent definitions of RA disease worsening using composite clinical outcomes and the level of change in RAFQ, in order to understand if the RAFQ could be used to identify subjects with clear RA worsening and whose samples to include for translational studies.

Methods: Patients with early (e) RA (symptom duration< 2 years, CDAI >2.8) enrolled in the Consortium of Early Arthritis Cohorts US with $\geq$ two recorded CDAI or DAS28 measures from $\geq$2 separate protocolized visits. We defined stringent RA worsening using 1) DAS28: an increase in DAS28 >1.2 and worsening of disease state by $\geq$ 1 category (remission or low disease activity to moderate disease activity or moderate disease activity to high disease activity) or 2) CDAI: an increase in CDAI>10 and worsening of disease state by $\geq$1 category. To further ensure stringency, patient outcomes and change in RAFQ scores were compared between their pre-RA worsening visit (one with the lowest DAS28 or CDAI score before worsening) and their designated RA worsening visit (one with the maximal DAS28 or CDAI score) using paired t-tests. An alpha of 0.05 was used to determine statistical significance. All analyses were done using STATA version 18.0.

Table 1: Baseline characteristics of real-world early RA cohort comparing those who later develop RA worsening vs not

	N=153	Later develop RA worsening* (N=41)	Do not worsen (N=112)	p-value
Age, mean (SD)	49.5 (16.7)	53.4 (16.2)	48.1 (16.8)	0.084
Female, n (%)	126 (82.4)	32 (78.0)	94 (83.9)	0.47
White, n (%)	115 (75.2)	32 (78.0)	83 (74.1)	0.68
BMI, mean (SD)	26.1 (5.8)	26.3 (6.7)	26.1 (5.4)	0.83
Regular use of tobacco products (past or present), n (%)	55 (35.9)	20 (48.8)	35 (31.2)	0.13
Comorbidities RDCI (0-9), mean (SD)	**0.88 (1.3)**	**1.3 (1.4)**	**0.73 (1.3)**	**0.02**
Osteoarthritis, n (%)	**25 (16.3)**	**12 (29.3)**	**13 (11.6)**	**0.012**
Symptom duration (months), mean (SD)	8.9 (6.7)	7.6 (5.8)	9.4 (7.0)	0.15
Seropositive (RF or CCP), n (%)	113 (73.9)	32 (78.0)	81 (72.3)	0.54
TJC28, mean (SD)	3.6 (4.6)	3.7 (5.5)	3.6 (4.2)	0.93
SJC28, mean (SD)	4.1 (5.2)	5.2 (5.8)	3.7 (4.9)	0.11
DAS28, mean (SD)	3.0 (1.4)	3.0 (1.5)	3.0 (1.4)	0.9
CDAI, mean (SD)	14.3 (11.8)	16.2 (12.7)	13.6 (11.4)	0.25
RAFQ, mean (SD)	15.8 (11.5)	16.4 (11.2)	15.6 (11.7)	0.7
Pain intensity (0-10), mean (SD)	3.5 (2.5)	3.4 (2.4)	3.5 (2.5)	0.79
MD global (0-10), mean (SD)	3.6 (2.2)	3.9 (2.0)	3.5 (2.3)	0.38
Patient global (0-10), mean (SD)	3.2 (2.5)	3.2 (2.3)	3.2 (2.6)	0.85
ESR (mm/hr), mean (SD)	18.5 (18.6)	18.7 (24.2)	18.5 (16.2)	0.95
Methotrexate, n(%)	106 (69.3)	30 (73.2)	76 (67.9)	0.69
Oral Steroids, n(%)	61 (39.9)	20 (48.8)	41 (36.6)	0.2
Advanced therapy in first 9 months, n (%)	57 (37.3)	19 (46.3)	38 (33.9)	0.19

RDCI Rheumatic Disease Comorbidity Index; TJC tender joint count; SJC swollen joint count; MDGA MD global assessment; PTGA patient global assessment; CDAI Clinical Disease Activity Index; *Stringent RA worsening denote those who meet 1) an increase in DAS28 >1.2 and worsening of disease state by > 1 category (remission or low disease activity to moderate disease activity or moderate disease activity to high disease activity) or 2) an increase in CDAI>10 and worsening of disease state by >1 category

[Δ] Treatments (biologics and Janus Kinase inhibitors) reported at later timepoint as low frequencies expected at baseline visit

Results: The 153 eRA patients were mainly White (75%) women (82%) with a mean (SD) age of 50 (17). Initial DAS28 was 3.0 (1.4), and CDAI was 14.3(11.8). Most (70%) received an MTX (Table 1). Compared with those who did not worsen, subjects who later worsened had higher baseline mean (SD) comorbidity scores 1.3(1.4) vs 0.73(1.3), (p=0.02). More had osteoarthritis, 29.3% vs 11.6% (p=0.012). Significant differences in patient outcomes including RAFQ, joint counts and pain scores were observed between pre-RA worsening and RA worsening visits (Table 2). A mean increase in RAFQ of 9.7 (95%CI 5.1, 14.3) was seen for DAS28-defined worsening and 13.2(95%CI 5.9, 20.6) for CDAI-defined worsening (Table 3).

Conclusion: Significant worsening in RA is consistently observed using multiple RA clinical outcomes and PROs between pre-worsening and worsening visits, demonstrating the stringency and clinical relevance of applied definitions of RA worsening. An increase in the RAFQ of 10-13 in patients meeting clinical definitions of worsening is similar to that of patients reporting they were "a lot worse"[1]. These findings demonstrate a consistent value of measures indicating a patient's worsening of RA between clinician- and patient-based composite measures. These data suggest that any of these measures can inform designation of clear RA disease worsening for future translational research.

Table 2: Comparing Clinical Outcomes between Pre-RA worsening and RA Worsening Visits (N=41)*

	Pre-RA worsening visit	RA worsening Visit	p-value
RAFQ, mean (SE)	13.2 (1.7)	22 (2.2)	0.000
Swollen joint count, mean (SE)	1.4 (0.6)	6.5 (1.0)	0.000
Tender joint count, mean (SE)	0.7 (0.3)	8.9 (1.2)	0.000
ESR, mean (SE)	12.4 (2.3)	22.4 (3.5)	0.000
Patient Global Assessment, mean (SE	2.2 (0.3)	4.4 (0.4)	0.000
Rapid 3, mean (SE)	1.9 (0.3)	3.7(0.4)	0.000
Pain intensity, mean (SE)	2.4 (0.3)	4.8 (0.5)	0.000

*Stringent RA worsening criteria 1) an increase in DAS28 >1.2 and worsening of disease state by > 1 category or 2) an increase in CDAI>10 and worsening of disease state by >1 category Change in outcomes determined from their pre-worsening (lowest DAS28 or CDAI score prior to worsening) visit and their designated RA worsening visit (maximal DAS28 or CDAI score) using paired t-tests using either DAS28 or CDAI flare; for those meeting both definitions, data for DAS28 was used

SE standard error

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: A third of patients with early (e)RA report pain outside the joint or non-articular pain (NAP) despite RA treatment(1). NAP, both regional and widespread, impairs HR-QOL and negatively impacts remission outcomes in eRA(1). Patients with eRA report having NAP in both upper body areas nearly twice as often as both lower body areas(1). How NAP, both regional and widespread, impacts physical function, including that of upper extremities, is not well understood. We aim to evaluate the impact of NAP, regional and widespread, on physical function using 3 instruments 1) Multi-Dimensional Health Assessment Questionnaire (MDHAQ) 2) PROMIS29 Physical Function (PF) 3) Neuro-QOL Upper Extremity (UE) Function (assesses reach function and ADLs) (2), at baseline and over the first year of RA diagnosis and treatment.

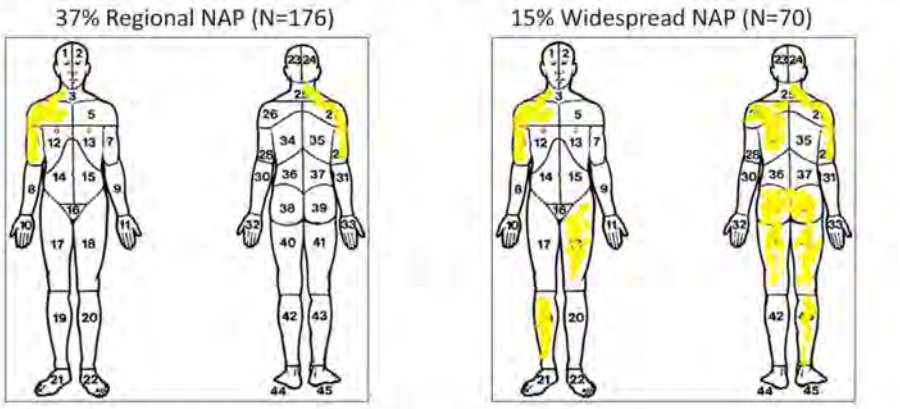
Table 1: Baseline Characteristics across NAP patterns in Early RA Cohort

	Total Sample (N = 472)	No NAP (N = 226)	Regional NAP (N = 176)	Widespread NAP (N=70)
Age (year), mean (SD)	57 (14)	58 (14)	56 (14)	56 (14)
Female, n (%)	313 (66)	146 (65)	118 (67)	49 (70)
White, n (%)	380 (81)	174 (77)	149 (85)	57 (81)
BMI (kg/m^2) mean (SD)	28.45 (7.0)	28.0 (6.9)	28.7 (6.9)	29.6 (7.5)
Rheumatic Disease Comorbidity Index (0-9), mean (SD)	1.4 (1.4)	1.2 (1.3)	1.4 (1.3)	1.8 (1.6)
Current smoker, n(%)	70 (15)	29 (13)	27 (15)	14 (20)
CDAI, mean (SD)	27.0 (14.1)	26.6 (14.9)	26.4 (12.8)	29.4 (14.5)
MDHAQ, 10 items (0-3)	0.8 (0.6)	0.7 (0.6)	0.9 (0.5)	1.2 (0.6)
PROMIS29 Physical function (T-score), mean (SD)*	40.8 (7.9)	42.4 (8.3)	39.9 (6.9)	38.1 (8.2)
NeuroQol UE Function (T-score), mean (SD)*	37.6 (10.5)	39.9 (11.1)	36.2 (9.6)	34.0 (9.4)

*Reported by MD or patient; RDCI Rheumatic Disease Comorbidity Index; CDAI Clinical Disease Activity Index; MDHAQ Multi-Dimensional Health Assessment Questionnaire; Neuro-QOL UE Neuro-Quality of Life Upper Extremity
* Lower T-scores for function reflect worse perceived function

Figure: Baseline prevalence of regional and widespread NAP in early RA cohort (N=472)



Figures are illustrative examples of regional and widespread NAP, adapted from Margolis body pain diagram
Prevalence calculated for total cohort N=472

Table 2: A Mixed Effects Model* of Mean-Change in Patient-Reported Function by 3 Instruments across NAP groups over First Year of RA

	Mean-Change	(95% CI)
MDHAQ (0-3)		
No NAP	Reference	
Regional NAP	**0.5**	**(0.3, 0.6)**
Widespread NAP	**1.3**	**(1.0, 1.6)**
PROMIS29 Physical Function T-Score		
No NAP	Reference	
Regional NAP	**-1.7**	**(-2.4, -1.0)**
Widespread NAP	**-3.5**	**(-4.8, -2.3)**
NeuroQoL Upper Extremity T-score		
No NAP	Reference	
Regional NAP	**-1.6**	**(-2.5, -0.6)**
Widespread NAP	**-5.2**	**(-6.8, -3.5)**

*fullly adjusted multivariate mixed effects model adjusted for baseline age, sex, education, smoking, comorbidities, seropositivity and time-variant CDAI
CI confidence interval; MDHAQ Multidimensional Health Questionnaire
Worse function reflected in higher MDHAQ scores and lower T-scores for PROMIS and NeuroQOL

Methods: Data were from patients with active early RA (symptoms< 1 year, CDAI >2.8) enrolled in the Canadian Early Arthritis Cohort between Jan/2017-10/2023. Patients were instructed to indicate any non-joint pain they experienced on a body pain diagram (BPD) at baseline (BL), and 6- and 12-month follow-up visits. Prespecified NAP patterns were classified based

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

on pain reported in 5 sections (4 quadrants and axial, excluding hands and feet) and grouped as: 1) no NAP (no sections selected on BPD), 2) regional (1-3 sections) or 3) widespread NAP(3+sections). Patients completed synchronous assessments of physical function: MDHAQ (0-3), PROMIS29 PF and Neuro-QoL UE function T-scores (mean is 50, 1 standard deviation is 10) over 1-year. Adjusted associations between NAP and physical function were estimated in separate multivariable mixed effects models adjusted for baseline age, sex, education, smoking, comorbidities, seropositivity and time-variant CDAI.

Results: The 472 eRA patients were mostly female (66%) with a mean (SD) age of 57(14) and had active disease at baseline, with a mean (SD) CDAI 27.0 (14.1) (Table 1). Most (79%) were treated with methotrexate. Regional NAP was more prevalent than widespread (Figure). Compared to other groups, those with widespread NAP more often had higher BMI, reported more comorbidities, smoked and had higher CDAIs. NAP was associated with worse baseline function assessed by MDHAQ, PROMIS29 PF and Neuro-QOL UE function in a dose-response manner across pain groups (none, regional and widespread NAP). The adjusted regression analyses similarly exhibited a dose-response effect of NAP on physical function with worsening in all 3 outcomes over 1-year (Table 2). All relationships were statistically significant. Neuro-QoL UE T-scores worsened by close to half a standard deviation in those with widespread NAP (Table 2).

Conclusion: NAP is common in eRA and negatively impacts physical function, including that of upper extremities, at baseline and over the first year of RA diagnosis and treatment. Worse physical function by all 3 instruments were observed with greater NAP distribution. Early identification and targeted intervention of NAP is recommended to help prevent long-term disability in patients with RA.

SESSION INFORMATION

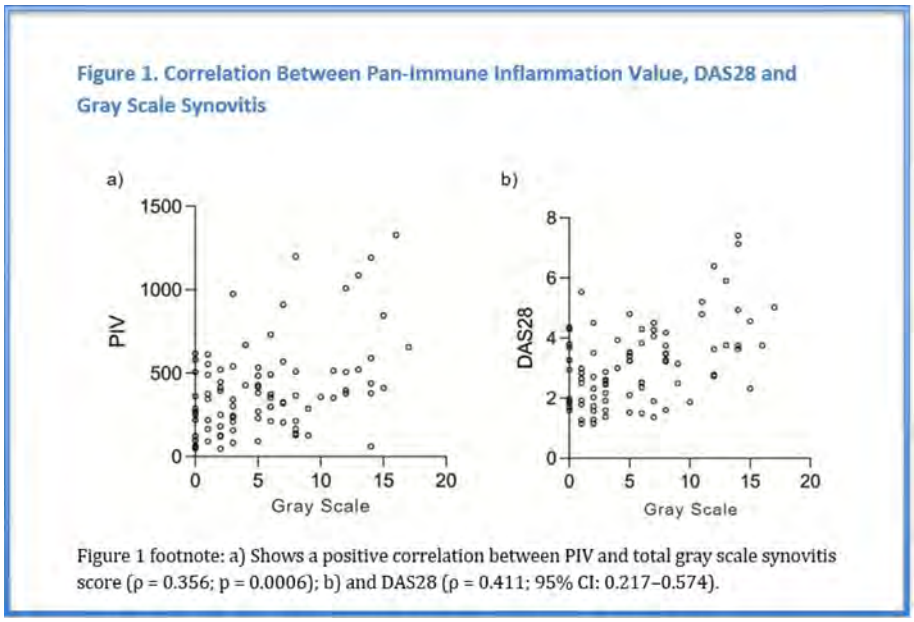
Session Date: Sunday, October 26, 2025
Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: The pan-immune-inflammation value (PIV) is a novel composite biomarker derived from blood count parameters, reflecting the systemic balance of immune-inflammatory activity. Although it has been explored in various inflammatory conditions, its association with ultrasound-detected synovitis in rheumatoid arthritis (RA) remains uncharacterized. Musculoskeletal ultrasound provides a sensitive modality for detecting synovitis through semiquantitative grading of gray scale (GS) and power Doppler (PD) signals on a 0–3 scale for each joint.

To evaluate the association between PIV and synovitis, as assessed by GS and PD scores, and to compare these correlations with clinical disease activity (DAS28) and functional disability (HAQ-DI) in patients with RA.

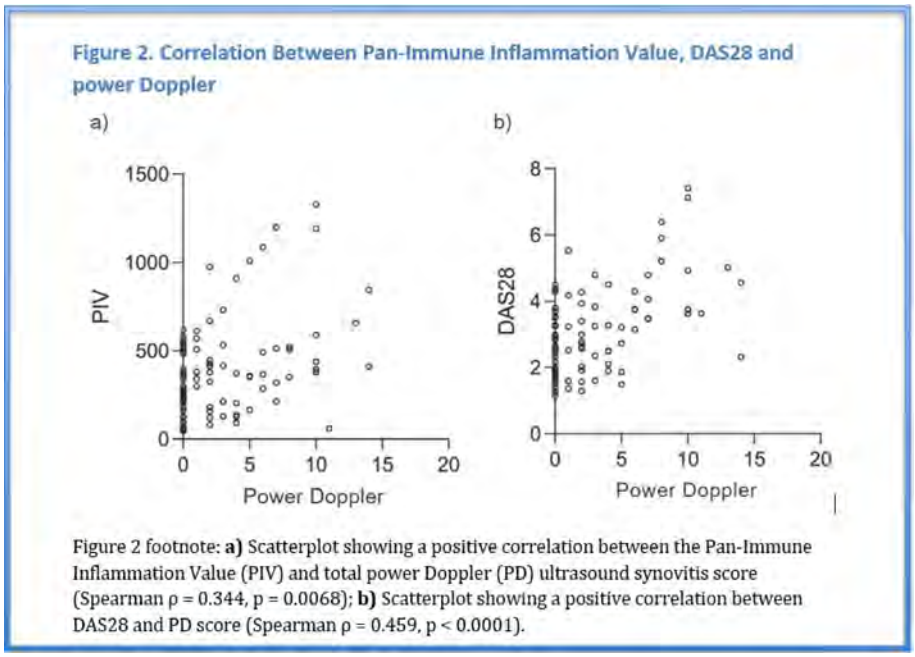
Methods: RA patients were prospectively recruited from a single-center cohort. Bilateral wrists and the second and third metacarpophalangeal (MCP) joints were assessed using the EULAR-OMERACT semiquantitative scoring system. PIV was calculated as: (neutrophils × monocytes × platelets) / lymphocytes). Spearman's ρ coefficients with 95% confidence intervals (CIs) were used to assess relationships between PIV, DAS28, HAQ-DI, and ultrasound scores. Multivariable linear regression models were developed using GS and PD scores as dependent variables. PIV values were also compared against a reference population of healthy adults from Mexico City.

Results: Seventy patients with RA were recruited and compared with 2,170 healthy adults. GS scores were significantly correlated with PIV (ρ = 0.356; 95% CI: 0.155–0.529) and DAS28 (ρ = 0.411; 95% CI: 0.217–0.574), but not with HAQ-DI (ρ = 0.027; 95% CI: –0.180 to 0.239). Similarly, PD scores correlated with both PIV (ρ = 0.344; 95% CI: 0.141–0.519) and DAS28 (ρ = 0.459; 95% CI: 0.273–0.612), but not with HAQ-DI (ρ = 0.069; 95% CI: –0.145 to 0.279). In multivariable models, PIV (β = 0.0061, p = 0.001) and DAS28 (β = 1.120, p = 0.014) were independently associated with GS scores; both PIV (β = 0.0043, p = 0.004) and DAS28 (β = 0.960, p = 0.007) also emerged as independent predictors of PD scores. Notably, 42% of RA patients had PIV values exceeding the 75th percentile (285.3) of the healthy reference population.



Correlation Between Pan-Immune Inflammation Value, DAS28 and Gray Scale Synovitis

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Correlation Between Pan-Immune Inflammation Value, DAS28 and power Doppler

Conclusion: Ultrasound-detected synovitis is independently associated with systemic inflammatory activity as measured by the PIV and with clinical disease activity assessed by DAS28, but not with patient-reported functional disability. These findings suggest that PIV may represent a useful, non-invasive biomarker for quantifying inflammatory burden in RA.

Low Disease Activity: Good Enough?

Emily Thoman[1], Sebastiano Porcu[1] and Martin Bergman[2], [1]Lankenau Medical Center, Wynnewood, PA, [2]Drexel University College of Medicine, Philadelphia

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Treat-to-target is the guiding principle and therapeutic strategy for rheumatoid arthritis (RA) treatment. Escalation of treatment is based on the regular assessment of disease activity to attain and maintain an established target. Although remission is the preferred target of treatment, low disease activity (LDA (CDAI >2.8 and ≤10)) may be an acceptable target. It remains unclear if patients attaining LDA have incremental benefit after 1 to 2 years, if they can remain with a CDAI < 10. This study aims to evaluate differences in outcomes among patients with RA treated to LDA and then followed over a two-year period.

Methods: Data were collected from 522 adult patients in a private practice with established RA treated with advanced therapies, who completed a questionnaire at every visit and were evaluated with a physical exam. Those who attained LDA at

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. VLDA: very low disease activity; HLDA: high low disease activity; RA: rheumatoid arthritis

baseline = 1 year a low disease activity

baseline and remained with CDAI < 10 at 1 and 2 years were studied. Data included patient demographics, disease duration, smoking status, CDAI, DAS28, RAPID3, MDHAQ function (FN), pain VAS, patient global VAS (PtGlb), MDHAQ fatigue, joint replacements, depression, swollen joints, tender joints, physician global VAS (DocGlb), ESR and CRP. At Year 1 and 2, Remission was defined as CDAI < 2.8, Very Low Disease Activity (VLDA) was defined as CDAI ≥ 2.8 and ≤ 6, and High LDA (HLDA) was defined as CDAI > 6 and ≤ 10. Data were analyzed with two-sample T tests.

Results: 143 patients with established RA with low CDAI at baseline receiving DMARD therapy (CS-DMARD, B-DMARD, or TS-DMARD) were followed at 1 and 2 years. 47 (33%) patients achieved remission, 53 (37%) achieved VLDA, and 43 (30%) patients achieved HLDA at follow-up. Patients who achieved remission had improved documented global scores and MDHAQ function scores compared to patients in VLDA and HLDA at both 1 and 2 years (p< 0.05), and less damaged joints

Table 2: Unadjusted Univariate Results by Disease Activity Status at Year 1 & 2

	n	Remission (CDAI ≤ 10 at baseline & ≤ 2.8 at Year 1)	VLDA (CDAI ≤ 10 at baseline & ≥ 2.8 and ≤ 6 at Year 1)	HLDA (CDAI ≤ 10 at baseline & > 6 and ≤ 10 at Year 1)	P-value (remission vs. VLDA CDAI)	P-value (remission vs. HLDA CDAI)

VLDA: very low disease activity; HLDA: high low disease activity; MDHAQ: Multidimensional Health Assessment Questionnaire

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

compared to patients in HLDA at 1 year ($p< 0.05$). Remission was not significant for less damaged joints compared to VLDA. There was no observable difference at 1 or 2 years in age, sex, duration of disease, self-reported joint replacements or depression scores between patients who achieved remission vs VLDA vs HLDA. Similarly, patients in VLDA did better than those in HLDA. At year 1: Swollen Count, Pain, PtGlb, Fatigue and RAPID3, and at Year 2: Swollen Count, DocGlb, Fn, Pain, PtGlb, Fatigue, DAS28-CRP and RAPID3 were all significantly better in VLDA vs. HLDA ($p< 0.05$).

Conclusion: Patients who successfully achieved remission from a baseline of low disease activity were found to have improved functional and clinical outcomes after 1 and 2 years. Patients who achieved VLDA had improvement but to a lesser degree. Finally, while remaining in LDA, patients in HLDA had worse outcomes compared to Remission or VLDA.

Abstract Number: 0445

GLP-1 Receptor Agonists Reduce Mortality and Cardiovascular Events in Patients with Rheumatoid Arthritis

Giorgos Loizidis and Ross summer, Thomas Jefferson University, Philadelphia, PA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Obesity significantly increases cardiovascular morbidity and mortality in rheumatoid arthritis (RA), yet effective strategies for managing obesity-related risks in this population remain limited. Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) offer substantial cardiometabolic benefits in diabetic populations, but their effects in obese RA patients without diabetes are not well defined. This study investigated whether GLP-1 RA therapy reduces one-year all-cause mortality and major adverse cardiovascular events (MACE) in non-diabetic obese RA patients.

Methods: This retrospective cohort study utilized the TriNetX platform, selecting adults (≥18 years) with RA, obesity (BMI ≥30 kg/m^2), and no history of diabetes mellitus. Patients initiating GLP-1 RA treatment (semaglutide, liraglutide, tirzepatide) were propensity score–matched (1:1) with RA controls not receiving GLP-1 RA therapy, balancing demographics, BMI categories, cardiovascular comorbidities, immunosuppressive therapies, and cardiometabolic medications. The primary endpoint was all-cause mortality at one year; secondary outcomes included new-onset MACE (heart failure, myocardial infarction, stroke) (Table 1)

Results: The matched analysis included 2,698 patients per group (Table 2). GLP-1 RA treatment was associated with significantly reduced one-year all-cause mortality compared to matched controls (0.37% vs. 0.93%; HR, 0.14; 95% CI, 0.04–0.47; p=0.0002). Additionally, MACE incidence was significantly lower in the GLP-1 RA group (1.09% vs. 2.19%; HR, 0.60; 95% CI, 0.38–0.95; p=0.026), driven primarily by fewer heart failure events (0.74% vs. 1.71%; HR, 0.52; 95% CI, 0.31–0.90; p=0.017). Myocardial infarction and cerebrovascular infarction rates were not significantly different between groups. (Table 3)

Conclusion: In obese, non-diabetic RA patients, GLP-1 RA therapy significantly reduced one-year all-cause mortality and cardiovascular events, particularly heart failure. These results highlight GLP-1 RAs as a promising therapeutic option for cardiometabolic risk reduction in RA. Prospective trials are warranted to confirm these findings.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Frailty, a state of decreased physiological reserve and heightened vulnerability to stressors, occurs prematurely in rheumatoid arthritis (RA) and is associated with poor health outcomes. The concept of "resilience," defined as the ability to draw on internal and external resources to cope with stress, is inversely associated with frailty in the general population. We evaluated the relationship between resilience and frailty in RA.

Methods: Data were from a single-center RA longitudinal cohort. The outcome, frailty, was measured using the Fried Frailty Phenotype (FFP)1 which assessed hand grip strength, exhaustion, walking, physical activity, and weight loss. The FFP was categorized as robust, prefrail, and frail. The predictor, resilience, was measured using the Resilience In Midlife (RIM) questionnaire2 and assessed self-efficacy (0-40), coping/adaptability (0-16), perseverance (0-16), internal locus of control (0-12), and family/social support (0-28); total scores ranged 0-100, with higher scores indicating greater resilience. Scores

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

were divided by 10 and grouped into tertiles to describe the cohort. Patient-reported behavioral characteristics including stress, anxiety, depression, sleep, and cognition were also collected. Unadjusted and adjusted ordinal logistic regression was used to assess the cross-sectional relationship between continuous resilience score and frailty level. These models were repeated to assess the relationship between the individual resilience category scores and frailty level. Models were adjusted for age and sex.

Results: 127 participants were included, aged 64.5±11.8 years, 73% male, and 71% White (Table 1). Those in the lowest resilience tertile had numerically greater pain (5.5±2.5 vs. 3.7±3.6), stress (7.2±2.9 vs 2.0±1.9) and sleep scores (1.4±0.8 vs 0.7±0.8) and were more likely to be exhausted (76% vs. 29%) than the highest tertile. Those who had low resilience also had higher prednisone dosage (1.1±3.5 mg vs. 0.5±1.5 mg) and were more likely to be on bDMARDs (61% vs 46%) than those with high resilience. For every 10% increase in resilience, the odds of being in a higher frailty category decreased by

Table 2. Unadjusted and adjusted ordinal logistic regression models evaluating the association of resilience score and frailty level (N=127).

Table 2. Unadjusted and adjusted ordinal logistic regression models evaluating the association of resilience score and frailty level (N=127).						
	OR	95% CI	p-value	aOR*	95% CI	p-value
Resilience	0.65	0.51-0.84	0.001	0.60	0.46-0.78	<0.001
Values are odds ratios which represent the odds of being in a higher frailty level per unit increase in resilience score (0-10). *Models were adjusted for age and sex.						

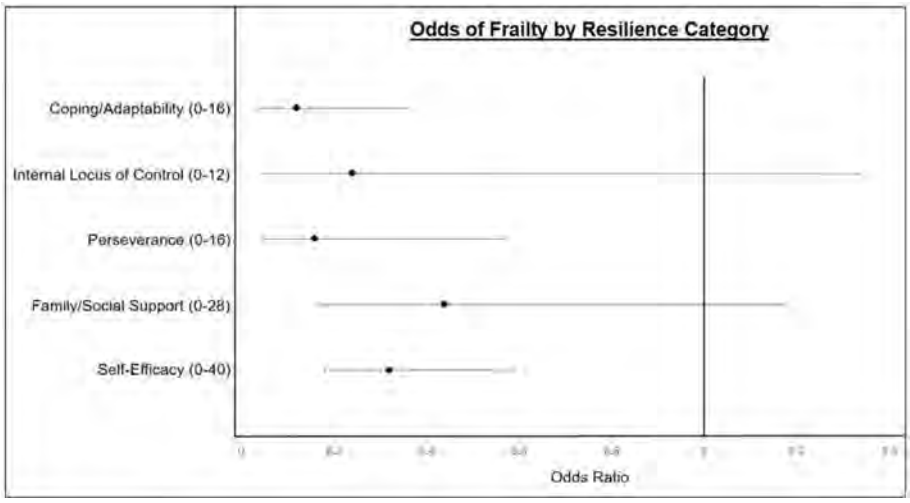

Figure 1. Multivariable ordinal logistic regressions evaluating the association between resilience category and frailty status (N=127). Odds ratios represent odds of higher frailty level per unit increase in the resilience category. Models are adjusted for age and sex. Resilience category scores were each divided by 10.

40% (aOR: 0.60 [0.46-0.78] p< 0.001) (Table 2). Although all resilience categories had an inverse relationship with frailty, only the coping/adaptability (aOR 0.12, p< 0.001), perseverance (aOR 0.16, p=0.004), and self-efficacy (aOR 0.33, p< 0.001) categories reached statistical significance (Figure 1).

Conclusion: Greater resilience was associated with a lower odds of physical frailty in RA, suggesting that coping strategies and the ability to utilize internal resources to cope with stress may be protective against frailty. Future work should examine the longitudinal relationship between resilience and frailty.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) and Seronegative Spondyloarthritis (SSA), the most common types of inflammatory arthritis, have significant ankle and foot joint involvement. However, these joints are underrepresented in routine disease activity tools. Conventionally, these joints are assessed either clinically or radiologically (radiographs and MRI). However, their utility in outpatient clinics is limited due to subjectivity, time constraints, and 2-dimensional limitations of radiographs. Foot pressure distribution dynamics is a novel approach to assessing foot and ankle joint-related arthritis, using a wearable insole with sensors to collect high-frequency foot pressure data during walking. This method identifies joints that are less weight-bearing due to synovitis, reflecting improper joint functionality. The aim of this study was to assess the differential foot pressure distribution using wearable devices in patients with foot arthritis and to develop a machine learning model for diagnostic use.

Methods: Adult patients with RA (ACR/EULAR 2010 criteria) or SSA (ASAS criteria) with foot involvement were enrolled. Inclusion criteria were disease duration ≥ 3 years and unilateral/bilateral ankle/foot pain/swelling. Only those patients who could walk for 5 minutes on a flat surface wearing the foot device were included. Patients with foot ulcers, corns, callosities, overriding/deformities of toes, and a history of ankle joint surgery were excluded. The foot device was constructed with 10 Force Sensing Resistors (FSRs). The data was separately collected for walking towards the corner (walk 1) and away (walk 2), each for 1 minute. A total of 20 subjects were recruited for the arthritis class, and 20 subjects as healthy controls. The number of samples for each subject, for each walk, was truncated at 3600 samples to maintain uniformity. Walk 1 and walk 2 of each subject were combined to create a 4-dimensional tensor containing subjects, feet, sensors, and recorded samples. Tensor decomposition was used for dimensionality reduction, thereby reducing the 4-dimensional tensor to a 2-dimensional tensor. Support Vector Machine (SVM) was used for classification. The performance of the model was analyzed using 10-fold cross-validation (CV) and leave-one-out (LOO) CV.

Results: The method successfully classified arthritis patients from normal individuals, achieving the best results when the decomposed tensor had three features after dimensionality reduction. Although SVM's performance was mediocre with 75% accuracy with an 80-20 train-test split, tuning the hyperparameters inflated the results to 100%. The model also showcased its efficiency by achieving 97% accuracy in 10-fold CV and 100% in LOO CV. These results underscore the method's effectiveness in distinguishing arthritis patients from healthy individuals.

Conclusion: The foot pressure distribution method using a wearable device can detect foot arthritis with moderate to high accuracy. This may be useful in devising machine learning models to diagnose foot arthritis correctly and in preparing footwear for these patients according to the altered pressure distribution.

The setup (foot insole with Force Sensing Resistors) connected to a laptop

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Although Large Language Models (LLMs) have been successfully used in the analysis of data from Electronic Health Records (EHRs), their implementation in the field of rheumatology has been very limited. Most information on disease activity of patients with rheumatologic conditions is recorded in medical notes instead of structured data. Recently, new LLMs have been created that can be deployed locally without transmitting information to external servers (Privacy-Preserving Large Language Models, PP-LLMs). We aim to test how accurate these LLMs can be in the identification of disease flares of rheumatic diseases using EHR notes.

Methods: For the pilot study, discharge notes of hospitalized patients with known history of Rheumatoid Arthritis (RA) from the de-identified MIMIC IV dataset were retrieved via Google's BigQuery API. A specialized prompt was developed using prompt engineering techniques such as chain of thought and few-shot prompting based on the OMERACT workgroup recommendations on flare identification. Next, the state-of-the-art QwQ 32B parameter reasoning model with 8-bit quantization was loaded through the Ollama engine utilizing the llama.cpp framework and subsequently received the discharge notes for analysis. Manual chart review was performed to verify the correct identification of flares, if present.

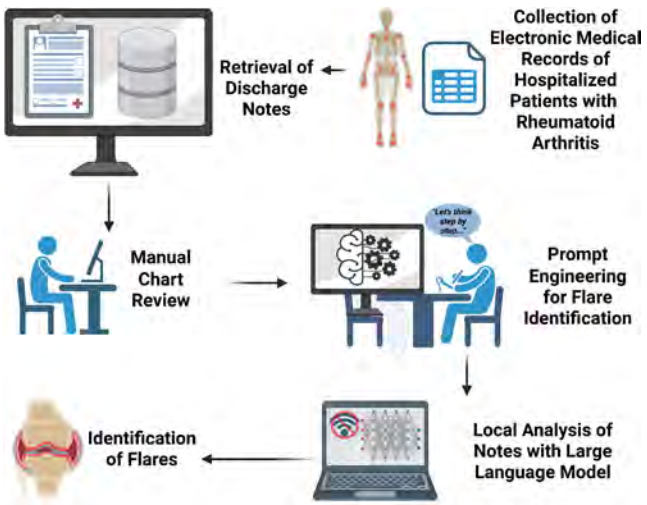

Figure 1: Overview of the Study

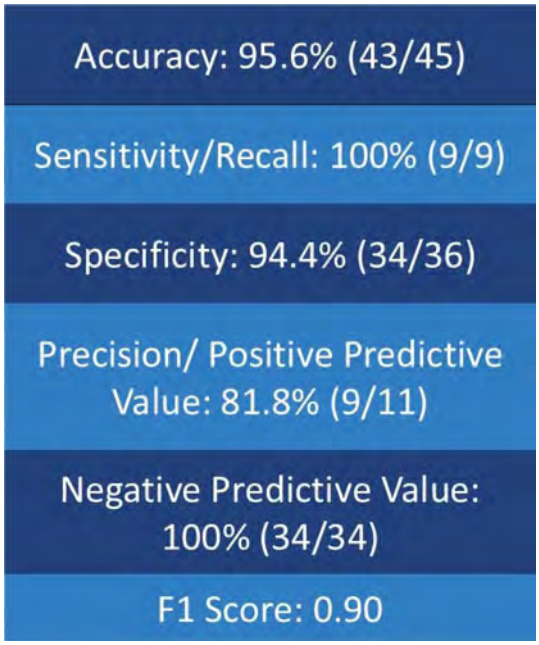
23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1: Confusion Matrix. Columns represent the classification results by the large language model, rows represent the classification based on manual chart review

	Predicted Flare	Predicted No Flare	Total
Flare	9	0	9
No Flare	2	34	36
Total	11	34	45

Table 2: Model Evaluation Metrics



Results: 45 discharge summaries containing the word "flare" were randomly selected, of which 9 had an RA flare and 36 did not have a flare. The LLM correctly identified 43/45 of the cases with an accuracy of 95.5% without any fine-tuning or human feedback, (Sensitivity/Recall: 100% (9/9), Precision/Positive Predictive Value: 81.8% (9/11), Specificity: 94.4% (34/36), F1 Score: 0.90). Detailed outputs were generated for each case stating whether a flare was identified, the confidence level and the key evidence supporting flare identification. Regarding the 2 cases that the LLM misclassified, the reasoning output was able to highlight the uncertainties identified during the manual chart review of these cases.

Conclusion: Our work represents the first successful use of local LLMs in identifying RA flares from discharge summaries of hospitalized patients. Furthermore, these models can be fine-tuned for other rheumatologic conditions with simple modification of the prompts.

Abstract Number: 0449

Consistency of CDAI Low-Disease Activity (LDA) Outcomes with Time in a Large US Registry: Association With Patient-Reported Clinical Outcomes and Measures of Quality of Life

Joel Kremer[1], Kevin Kane[2], George Reed[3] and Michael Weinblatt[4], [1]The Corrona Research Foundation, Delray Beach, FL, [2]U of Mass Medical School, Worcester, MA, MA, [3]University of Massachusetts Chan Medical School, Worcester, MA, [4]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Low disease activity has been identified as a treatment goal for the treatment of RA. A single center RA registry (BRASS) reported a difference in outcome in RA pts who achieved remission versus low disease activity 1 . When LDA was subdivided between very low disease activity (VLDA >2.8< 6) and LDA scores from >6< 10 and remission CDAI < 2.8 there were also differences in outcome between those pts in VLDA versus LDA suggesting that the threshold for "true" LDA should be lowered. This study further examined this issue in a large US RA registry

Methods: Population: RA patients from the US-based CorEvitas RA registry (122 private sites, 21 academic sites). Inclusion: Patients (pts) on a biologic (baseline) and a 1-year (9-15 mos) and 2-year (21-27 mos). Target defined as LDA (CDAI ≤10). Pts at one year divided into 1) Consistently on target 2) Lose target; 4) Gain Target 5) Consistently not at target. The sub-population consistently on target were divided into remission (≤2.8), very low disease activity (VLDA: >2.8 and ≤6) or high LDA (HLDA >6 and ≤10) at one year. Baseline characteristics, HAQdi, pain and fatigue at 1 and 2 years were compared across groups. Linear regression analysis examined these outcomes at 1 year adjusting for age, gender, RA duration, Charlson Comorbidity Index(CCI) and CDAI (all at baseline).

Results: 13,513 pts with baseline visits between 2001-2023 were included in the analysis. 5,570 (41.4%) "consistently at target",1,330 (9.8%) "Flare/Lose Target", 2,542 (18.8%) "Gain Target" , and 4,071 (30.13%) "Consistently not at Target" . "Consistently at Target", 2,690 (48.3%) pts were classified at one year as "Remission" , 1,694 (30.4%) VLDA , and 1,186 (21.3%) HLDA. Baseline characteristics are seen in Table 1. Groups with CDAI > 10 at 1-year had worse functional outcome

in HAQdi, pt reported pain and fatigue at both year 1 and 2 than the two groups who had CDAI < 10 at 1-year in both unadjusted and adjusted models (p< 0.01).Within the consistently at target group, HLDA (CDAI >6 and < 10) pts had significantly worse functional outcome on HAQdi, pt reported pain, and fatigue than the VLDA and remission groups at year 1 and 2 years (p< 0.01). The VLDA patients had worse functional outcome than the remission group (p< 0.01). Figure 1.

Conclusion: This very large observational study demonstrates that there are meaningful patient-reported differences in the consistency of the categories of "LDA" response including HAQdi, pt pain and fatigue, that are significantly associated with LDA subcategory status (remission, VLDA and HLDA). These significant and meaningful differences in "LDA status" with treatment are lost when considering only a broad definition of LDA. Our results show that the LDA cutpoint should be lowered from CDAI ≤10 to CDAI ≤6 for a more realistic evaluation of patient functional outcomes when judging what is now called LDA.

González-Gay[4] and Ivan Ferraz Amaro[5], [1]Hospital Universitario de Canarias, Tenerife, Canarias, Spain, [2]Fundación Jiménez Díaz, Madrid, Madrid, Spain, [3]Hospital Doctor Negrín, Las Palmas de Gran Canaria, Canarias, Spain, [4]Department of Rheumatology and Joint and Bone Research Unit, Hospital Universitario Fundación Jiménez Díaz, and Instituto de Investigación Sanitaria-Fundación Jiménez Díaz, Madrid, Spain, and Medicine and Psychiatry Department, University of Cantabria, Santander, Spain, [5]Hospital Universitario de Canarias, Santa Cruz de Tenerife, Spain

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: The Fibrosis-4 index (FIB-4), a non-invasive tool for assessing liver fibrosis, has been linked to cardiovascular (CV) risk in the general population. This is due to the association of chronic liver diseases, particularly fibrosis or non-alcoholic fatty liver disease, with systemic inflammation, metabolic syndrome, and atherosclerosis. In this study, we calculated the FIB-4 index in patients with rheumatoid arthritis (RA), a condition associated with increased CV disease risk. We then examined its association with disease characteristics and CV comorbidities, including lipid profile, subclinical carotid atherosclerosis, and insulin resistance indices.

Methods: 465 RA patients underwent evaluations, including disease-related features, lipid profile, insulin resistance indices (using HOMA), metabolic syndrome criteria, and carotid ultrasound for intima-media thickness and carotid plaque detection. FIB-4 was calculated and categorized into low (< 1.45), indeterminate (1.45-3.25) and high risk (>3.25) for fibrosis. A multivariable linear regression analysis was used to examine the associations between the disease characteristics and FIB-4.

Results: FIB-4 score had a median value of 0.95 (IQR 0.72-0.95). According to this score categories, 81% of patients had a low risk of fibrosis, while 18% and 1% had an indeterminate risk and high risk, respectively.

Body mass index, obesity as BMI >30, and waist and hip circumferences, showed no significant association with FIB-4. SCORE2 CV risk calculator disclosed significant positive correlations with FIB-4 values (beta coef. 0.04, 95%CI 0.03-0.05, p< 0.001). Similarly, SCORE2 patients within moderate risk category showed higher FIB-4 values compared to those with low risk (beta coef. 0.3, 95%CI 0.2-0.4, p=< 0.001). Regarding classic CV risk factors, after multivariable analysis, while diabetes, dyslipidemia, and smoking did not demonstrate a significant association with FIB-4 scores, hypertension was associated with higher FIB-4 values. None of the lipid profile molecules demonstrated a significant association with FIB-4 scores. However, insulin resistance markers, including serum insulin, C-peptide levels, and HOMA2-IR index (beta coef. 0.04, 95% CI 0.009-0.06), p=0.009), showed significant positive correlations with FIB-4 values after adjustment for covariates. This was also the case for the presence of metabolic syndrome and statin use that were associated with significantly higher FIB-4 index levels.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Relationship between RA disease data and subclinical carotid atherosclerosis with FIB-4 was adjusted for age, sex, waist to hip ratio, dyslipidemia, hypertension, triglycerides, apolipoprotein A1 and HOMA2-IR. The presence of carotid plaque and intima-media thickness were associated with higher FIB-4 values in univariable analysis. However, when adjusted for classic CV risk factors, this significance was lost. Acute phase reactants, the presence of rheumatoid factor or ACPA, and disease activity measured by several different scores did not demonstrate significant associations with FIB-4.

Conclusion: Up to 20% of RA patients show an abnormal FIB-4 index, which correlates with cardiovascular risk and insulin resistance.

Menopause Status and Disease Activity in Rheumatoid Arthritis

Katherine Bracamontes[1], David Kellner[2], Lucia Chen[3], David Elashoff[4], Jenny Brook[5] and Veena Ranganath[2], [1]Division of Internal Medicine, UCLA, Los Angeles, CA, [2]UCLA, Los Angeles, CA, [3]UCLA, Division of General Internal Medicine and Health Services Research, Los Angeles, CA, [4]UCLA, Division of General Internal Medicine and Health Services Research, Los Angeles, [5]UCLA, Division of General Internal Medicine and Health Services Research, Los Angeles, CA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: In women, rheumatoid arthritis (RA) commonly presents around menopause, a timing thought to be influenced by the decline of estrogen and progesterone. However, the impact of menopausal status on disease activity and treatment response remains poorly studied. To address this, our study examined differences in baseline RA disease activity measures between pre- and post-menopausal women, as well as examining 3-month treatment response to DMARDs.

Methods: This was a retrospective study of female RA patients enrolled in one of two open-label clinical trials using tofacitinib or tocilizumab. Patients receiving oral contraceptives or hormone replacement therapy upon enrollment were excluded. Patient demographics and questionnaires were evaluated, and chart review was performed to obtain age at menopause. Patients were categorized as either pre- or post-menopausal. Post-menopausal status was defined as the absence of menses for greater than 12 months or bilateral oophorectomy.

Table 1: Baseline Characteristics by Menopausal Status

Characteristic	Pre-menopausal N=33	Post Menopausal N=48	P-value
Age, mean (SD), years	42.2 (9.7)	61.6 (9.5)	
Age at menopause, mean (SD), years		49.1 (6.2)	
Duration of RA, mean (SD), years	8.6 (9.4)	12.6 (11.6)	0.052
Seropositivity (ACPA or RF), n (%)	25 (75.8%)	43 (89.6%)	0.18
BMI, mean (SD)	28.8 (7.2)	29.7 (8.1)	0.63
csDMARD at Baseline, n (%)	22 (66.7%)	34 (70.8%)	0.88
bDMARD at Baseline	3 (9.1%)	0 (0.0%)	0.06
tsDMARD at Baseline	0 (0.0%)	0 (0.0%)	1
Prednisone at Baseline	13 (39.4%)	14 (29.2%)	0.47

Analysis performed using t-test for continuous variables and chi-squared for categorical variables. Except Wilcoxon's rank sum test for disease duration due to non-normality SD: standard deviation; BMI: body mass index; cDMARDs: conventional DMARDs; tsDMARD: targeted synthmethic DMARD; bDMARD: biologic DMARD

Table 2:Baseline Disease Activity Measures and Menopausal Status

Disease Activity Measure	Pre-Menopausal, N=33	Post-Menopausal N=48	P-value
HAQ-DI, mean (SD)	1.5 (0.6)	1.5 (0.6)	0.94
DAS28 (ESR), mean (SD)	6.0 (1.0)	6.4 (0.9)	**0.04**
ESR,mean (SD)	35.8 (24.1)	39.7 (26.9)	0.51
CDAI,mean (SD)	34.8 (12.2)	40.1 (10.6)	**0.04**
SJC28,mean (SD)	9.9 (5.7)	12.7 (5.2)	**0.02**
TJC28,mean (SD)	12.6 (6.8)	13.5 (5.9)	0.55
Patient Global Assessment,mean (SD)	6.7 (2.3)	7.5 (1.8)	0.08
Physician Global Assessment,mean (SD)	5.5 (1.8)	6.4 (1.7)	**0.03**
PDUS,mean (SD)	20.2 (13.6)	26.8 (15.6)	**0.04**
Stiffness Level,mean (SD)	5.7 (2.9)	5.5 (2.4)	0.83
Fatigue Level,mean (SD)	6.1 (2.2)	6.0 (2.5)	0.83
Pain Level,mean (SD)	6.9 (2.2)	7.2 (2.4)	0.53

Analysis performed using t-test for continuous variables and chi-squared for categorical variables. Except Wilcoxon's rank sum test for SJC28 and PDUS due to non-normality. SD: standard deviation; HAQ-DI: HAQ-disability index; DAS28: disease activity score in 28 joints; CDAI: clinical disease activity index; SJC28: swollen joint count in 28 joints; TJC28: tender joint count in 28 joints; PDUS: power doppler ultrasonography

We assessed RA outcomes including composite disease activity indices (disease activity score [DAS28], clinical disease activity index [CDAI]), functional disability (health assessment questionnaire-disability index [HAQ-DI]), and musculoskeletal ultrasound (MSUS) power doppler ultrasonography (PDUS), swollen joint count (SJC28), tender joint count (TJC28), patient/physician global assessment visual analogue scales (VAS), STIFFNESS, FATIGUE, AND PAIN. OUTCOMES were compared between pre- and post-menopausal patients. We also compared DMARD treatment response using DAS28, CDAI, PDUS and pain at 3 months follow-up.

RA duration, SJC28 and PDUS were compared with Wilcoxon's rank sum test due to non-normality. All other continuous variables were compared with t-tests, and all categorical variables were compared with chi-squared tests. Multivariate linear regression was performed to control for potential confounding variables such as age, disease duration, and seropositivity.

Results: A total of 81 RA patients were included of whom 48 (60%) were post-menopausal. The average baseline age in the menopausal group was 62 and the average age of menopause onset was 49.

Composite disease activity scores (DAS28, CDAI) and PDUS were significantly higher in the post-menopausal group (all $p< 0.05$. However, there were no differences between groups for functional outcomes (HAQ-DI), pain, fatigue, and stiffness. After adjusting for age, disease duration, and seropositivity, these baseline differences were no longer apparent between pre-/post-menopausal RA patients. Disease modifying anti-rheumatic drug (DMARD) treatment response at three months, assessed by DAS28, CDAI, and PDUS, did not differ between groups.

Conclusion: To our knowledge, data examining composite RA disease activity measures, PDUS, and menopausal status have not been previously reported. This study found higher baseline RA disease activity (DAS28, CDAI, PDUS) in post-menopausal women, which was no longer significant after adjusting for confounding factors. RA outcomes after 3-months of DMARD therapy were not affected by menopausal status. Our findings suggest menopausal status may not impact treatment decisions, though further research is warranted.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Despite advancements in rheumatoid arthritis (RA) and osteoporosis management that have improved patient outcomes, osteoporosis continues to be a significant clinical concern in RA. This study aims to evaluate the effects of RA treatments and osteoporosis medications on changes in bone mineral density (BMD) over a 10-year period, using real-world longitudinal data from an RA cohort.

Methods: We conducted a retrospective analysis of RA patients enrolled in a single-center cohort at a university hospital in Japan. Patients who underwent at least two dual-energy X-ray absorptiometry (DXA) scans between 2010 and 2024 were included and followed up to 10 years. At every scan point, data on RA treatments (targeted synthetic DMARDs [tsDMARDs],

Table 1. Baseline Characteristics of RA patients with multiple DXA scans (n=445).

Characteristics	RA patients (n=445)
Age, years, median (IQR)	65 (54 to 70)
Female, n (%)	350 (78.7%)
RA duration, years, median (IQR)	8 (0.4 to 12)
Age at RA onset, years, median (IQR)	55 (45 to 65)
Seropositivity, n (%)	359 (80.7%)
BMI, kg/m^2, mean (SD)	22.1 (3.8)
Current Smoking, n (%)	29 (6.5%)
Alcohol (daily), n (%)	32 (7.2%)
RA treatment at baseline*	
tsDMARDs +- csDMARDs, n (%)	7 (1.6%)
bDMARDs +- csDMARDs, n (%)	76 (17.1%)
Methotrexate +- csDMARDs, n (%)	226 (50.8%)
Other csDMARDs, n (%)	136 (30.6%)
Dose of prednisolone, mg/day, mean (SD)	2.5 (4.7)
Femoral BMD at baseline, g/cm^2, mean (SD)	Female: 0.611 (0.124) Male: 0.733 (0.149)
Lumber spine BMD at baseline, g/cm^2, mean (SD)	Female: 0.853 (0.176) Male: 1.035 (0.219)

csDMARDs^	Ref.	
tsDMARDs +- csDMARDs	2.04 (-3.06 to 7.13)	0.44
bDMARDs +- csDMARDs	0.04 (-2.59 to 2.68)	0.98
Methotrexate +- csDMARDs	2.47 (0.14 to 4.82)	0.04
Osteoporosis medications		
None	Ref.	
Denosumab	10.78 (7.50 to 14.01)	<0.01
Bisphosphonates	8.10 (6.07 to 10.12)	<0.01
Vitamin D supplements	2.88 (0.79 to 4.98)	<0.01
Other bone medications	15.91 (6.62 to 25.23)	<0.01

^ csDMARDs other than methotrexate

¶ Adjusted for age, gender, smoking status, alcohol consumption, body mass index, seropositivity, BMD at baseline, use of non-steroidal anti-inflammatory drugs and dose of prednisolone at each scan point.

β: standardized regression coefficient; bDMARDs: biologic disease-modifying antirheumatic drugs; BMD: bone mineral density; BMI: body mass index; CI: confidence interval; csDMARDs: conventional synthetic disease-modifying antirheumatic drugs; tsDMARDs: targeted synthetic disease-modifying antirheumatic drugs; RA: rheumatoid arthritis

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

associated with increased change rate in BMD by 7.44 (95% CI: 3.15 to 11.70) and 3.17 (95% CI: 1.00 to 5.33) mg/cm^3/year, respectively, compared to csDMARDs. Among osteoporosis treatments, the use of BPs and vitamin D supplements was associated with positive BMD changes in the femur by 2.84 (95% CI: 1.15 to 4.50) and 2.05 (95% CI: 0.31 to 3.78) mg/cm^3/year, respectively (Table 2). At the lumbar spine, methotrexate showed an association with increased BMD. All categories of osteoporosis medications were strongly associated with positive BMD change at the spine (Table 3).

Conclusion: This 10-year longitudinal real-world analysis underscores the protective effect of osteoporosis medications, particularly at the lumbar spine, in patients with RA. Furthermore, treatment with tsDMARDs or bDMARDs demonstrates superior efficacy in maintaining or enhancing femoral BMD compared to csDMARDs. These findings support the integration of targeted osteoporosis management alongside RA treatment strategies to mitigate bone loss in this vulnerable population.

Abstract Number: 0453

Safety of DMARDs in Rheumatoid Arthritis: A Nationwide Study of ILD Risk and Outcomes in RA-ILD

kyung-Ann Lee[1], Bora Lee[2], Hyun-Sook Kim[3] and Se Hee Kim[4], [1]Soonchunhyang University Hospital Seoul: Soonchunhyang University Hospital, Seoul, Republic of Korea, [2]Chosun University, GwangJu, Republic of Korea, [3]Soonchunhyang University Seoul Hospital, Seoul, Republic of Korea, [4]Kyung Hee University College of Medicine, Seoul, Republic of Korea

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis-associated interstitial lung disease (RA-ILD) is a potentially life-threatening extra-articular manifestation of RA. The comparative safety of disease-modifying antirheumatic drugs (DMARDs) in RA patients, particularly those with coexisting ILD, remains unclear. We aimed to assess the risk of ILD development and serious adverse events across DMARD classes using a nationwide claims database.

Methods: We conducted a nationwide cohort study using the Korean National Health Insurance Service database (2011–2020). DMARD treatment episodes were analyzed in RA patients aged ≥19 years without baseline ILD to assess the risk of incident ILD. In RA-ILD patients, treatment episodes initiated after ILD diagnosis were used to evaluate safety outcomes. A detailed flowchart of patient selection and episode classification is shown in Figure 1. DMARD exposure was categorized into four groups: conventional synthetic DMARDs (csDMARDs), tumor necrosis factor inhibitors (TNFi), non-TNF biologic agents (non-TNFi), and Janus kinase inhibitors (JAKi). Drug exposure was modeled as time-varying, and adjusted hazard ratios (aHRs) were estimated using IPTW-weighted Cox regression.

Results: Among 209,852 treatment episodes in RA patients without baseline ILD, the overall incidence rate of ILD was 3.19 per 1,000 person-years. In time-varying IPTW-adjusted Cox models, none of the DMARD classes were significantly associated with ILD development compared to csDMARDs (non-TNFi aHR 1.51, 95% CI 0.91–2.50; JAKi aHR 0.94, 95% CI 0.44–

2.02; TNFi aHR 0.89, 95% CI 0.51–1.56). Among 1,688 treatment episodes in RA-ILD patients, non-TNF biologics were associated with significantly increased risks of all-cause hospitalization (aHR 1.35, 95% CI 1.02–1.80), infection (aHR 1.51, 95% CI 1.06–2.15), and death (aHR 4.31, 95% CI 2.21–8.41) compared to csDMARDs (Table 1). Non-TNFi use was also associated with a higher risk of infection recurrence (aHR 1.35, 95% CI 1.01–1.79) and pneumonia-related hospitalization (aHR 1.90, 95% CI 0.98–3.69). In contrast, hospitalization due to ILD exacerbation did not differ significantly across treatment groups. The risk of major adverse cardiovascular events was also comparable between groups.

Conclusion: In RA patients without baseline ILD, the risk of developing ILD did not significantly differ across DMARD classes. In RA-ILD patients, while rates of hospitalization due to ILD exacerbation were comparable across groups, non-TNFi use was associated with increased risks of infection and pneumonia-related outcomes. Given that pneumonia is a leading cause of death in RA-ILD, close infection surveillance and preventive strategies are warranted when using non-TNF biologics in this population.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Optimization of biologic DMARDs (bDMARDs) in patients with rheumatoid arthritis (RA) may be feasible in those who have maintained remission for at least six months. However, this approach carries the risk of disease flare, underscoring the need for reliable predictors to guide clinical decisions. Identifying robust clinical and molecular markers can help design personalized strategies that enhance safety and therapeutic success.

The aim of this study was to identify clinical and molecular predictive variables and develop two models (one for sustained remission and another for joint flare) in RA patients undergoing bDMARD optimization. Both models integrated clinical and molecular data.

Anti-IFNγ	1·00	1·00-1·00	0·031

Joint flare prediction model

Methods: Data were obtained from the OPTIBIO clinical trial (Eudra-CT 2012-004482-40) and the REMRABIT Project (PMP15/00032), a multicenter, open-label, randomized, phase IV trial. Adults with RA (1987 ACR criteria), in remission for ≥6 months on TNFi or tocilizumab, were randomized (1:1) to continue or taper bDMARD. The optimization group (n=96) was analyzed. Logistic and Cox regression models were developed for sustained remission and flare, respectively. Model performance was assessed using AUC-ROC and concordance index (C-index) over a 12-month follow-up. Analyses were performed using SPSS v28 and R v4.3.1.

Results: Of 195 randomized patients, 74/96 in the optimization group achieved successful tapering after 12 month follow up. In the remission model, older age (8% lower odds per year) and higher 3v-DAS28-CRP (90% lower odds per unit) were significant predictors. The C allele of rs5746065 (TNFRSF1B) and the G allele of rs1560011 (CLEC2D) were associated with sustained remission, with a potential role for rs6555900 (KCNIP1). This model yielded an AUC of 0.88, sensitivity 84%, specificity 83%, and NPV/PPV of 60% and 95%. In the flare model, significant predictors included higher 3v-DAS28-CRP, joint erosions, pain VAS, low hemoglobin, systolic blood pressure, anti-IFN-γ antibodies, and two SNPs. The C allele of

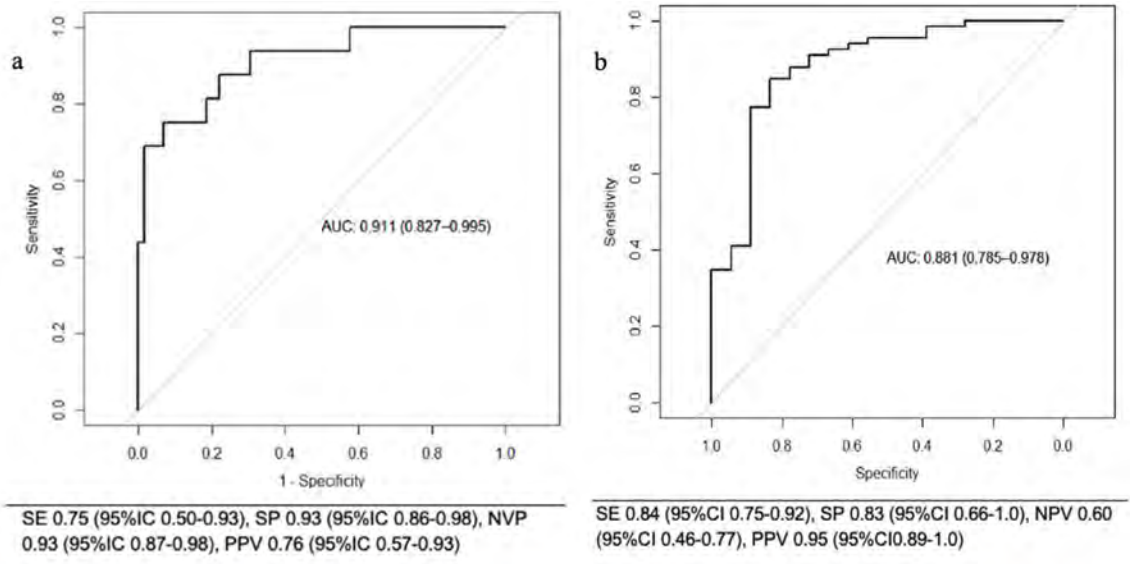

Figure 1a. AUC for joint flare prediction model b. AUC for sustained remission model

Image 1 AUC of prediction models a. Joint flare prediction model b. Sustained remission model

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

rs5746065 (TNFRSF1B) reduced flare risk by 69%, and the C allele of rs9594987 in gene ENOX1 (T/C) by 85%. The model showed a C-index of 0.884, AUC of 0.911 (95% CI: 0.82–0.99), sensitivity 75%, specificity 93%, and NPV/PPV of 93% and 76%.

Conclusion: Combination of predictive clinical, proteomic and genomic biomarkers are crucial for guiding treatment optimization in RA. These models provide promising tools to support personalized bDMARD dose reduction. Further external validation is needed to confirm their generalizability across diverse populations and clinical settings.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Patients rate pain as one of the most important aspects of psoriatic arthritis (PsA). Pain signaling involves a series of cytokines, including those downstream of tyrosine kinase 2 (TYK2) inhibition. Deucravacitinib, an oral, selective allosteric inhibitor of TYK2, mediates signaling of key cytokines in PsA pathogenesis. Deucravacitinib was efficacious vs placebo in phase 3 trials in patients with active PsA. Deucravacitinib is approved for the treatment of adults with plaque psoriasis and is currently under investigation in two phase 3 trials in PsA (POETYK PsA-1 [NCT04908202] and POETYK PsA-2 [NCT04908189]). This analysis includes pooled data from both trials to characterize the effect of deucravacitinib on pain across 3 pain measures for the overall population and by sex to examine its relationship to pain intensity and differences in response to therapies.

Methods: Patients with PsA were randomized to receive deucravacitinib 6 mg (n = 648) or placebo (n = 646). All patients met the CASPAR classification criteria for PsA as part of study enrollment. Pain was assessed at baseline and Week 16 using the Patient Global Assessment (PGA) of Pain visual analog scale (VAS; scored from 0-100); Psoriatic Arthritis Impact of Disease (PsAID) pain instrument (scored from 0-10); and the 36-Item Short Form Survey (SF-36) Bodily Pain questionnaire (6-item Likert scale from "none" [0] to "very severe" [6]). Adjusted mean change in scores from baseline and proportion of patients with different levels of change to Week 16 were reported. Correlations among pain scales and disease activity were also evaluated.

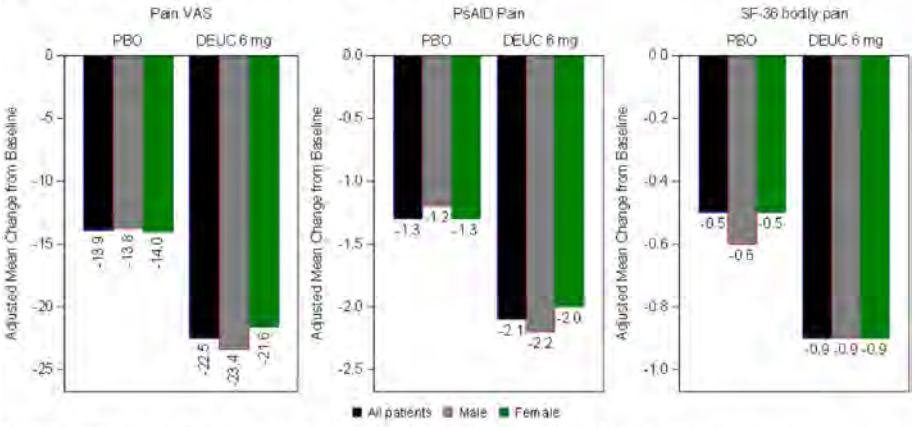
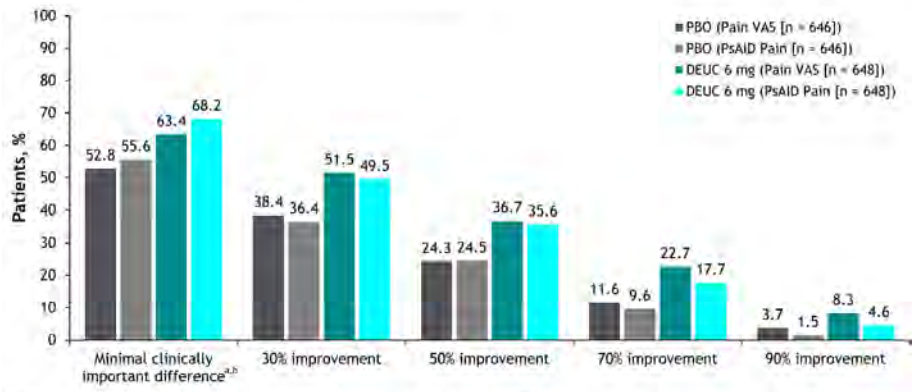
Figure 1. Mean change from baseline to Week 16 in pain across instruments



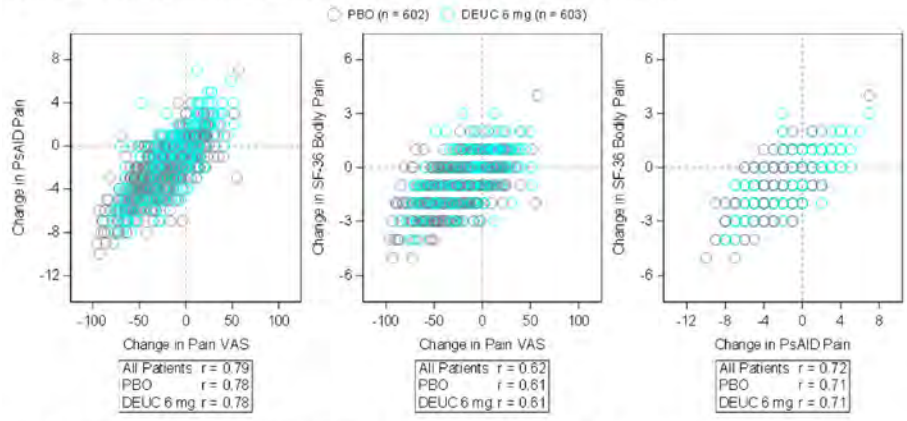
DEUC, deucravacitinib; PBO, placebo; PsAID, Psoriatic Arthritis Impact of Disease; SF-36, 36-Item Short Form Survey; VAS, visual analog scale.

Figure 2. Within-patient improvement in pain at Week 16, as measured by pain VAS and PsAID



[a]For Pain VAS, minimal clinically important difference was defined as ≥10 point reduction in change from baseline or ≥15% reduction in percentage change from baseline on a scale of 0-100.
[b]For Pain PsAID, minimal clinically important difference was defined as ≥1-point reduction in change from baseline or ≥15% reduction in percentage change from baseline on a scale of 0-10.
DEUC, deucravacitinib; PBO, placebo; PsAID, Psoriatic Arthritis Impact of Disease; VAS, visual analog scale.

Figure 3. Pearson's correlation of change from baseline to Week 16 in pain assessment



DEUC, deucravacitinib; PBO, placebo; PsAID, Psoriatic Arthritis Impact of Disease; SF-36, 36-Item Short Form Survey; VAS, visual analog scale.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: At baseline, mean pain scores in the deucravacitinib vs placebo groups were: pain VAS 61.8 (20.45) vs 61.4 (20.68); PsAID Pain 6.3 (2.04) vs 6.3 (2.08); and SF-36 Bodily Pain 4.3 (0.96) vs 4.3 (0.98). All assessments of pain were strongly correlated with the disease activity at baseline. Overall, mean improvements in pain at Week 16 were greater in patients treated with deucravacitinib vs placebo across all measures. No consistent differences were observed between sexes in mean improvements in pain measures (**Figure 1**). In patients treated with deucravacitinib, nearly two-thirds reported improvements ≥ minimal clinically important difference, and >20% reported a 70% improvement in pain (**Figure 2**). Mean changes in patient-reported pain were highly correlated among pain instruments, demonstrating consistency (**Figure 3**).

Conclusion: Pooled data from 2 trials demonstrated a higher proportion of patients treated with deucravacitinib reported improvement in pain vs placebo, regardless of the instrument used. Improvements were generally consistent between males and females. These findings demonstrate that the use of deucravacitinib resulted in pain relief in patients with PsA.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disease associated with systemic inflammation and increased cardiovascular risk, particularly heart failure (HF). Patients with RA and cardiopulmonary involvement face worse outcomes, including higher HF incidence, mortality, and healthcare use. While earlier studies link RA to adverse cardiac events, large-scale, recent analyses on both mortality and resource utilization are limited. This study fills that gap by analyzing nationwide data (2016–2021) to compare in-hospital mortality in HF admissions with and without RA.

Methods: We conducted a retrospective cohort study using the Nationwide Inpatient Sample (2016–2021) to identify adult hospitalizations with a primary diagnosis of heart failure. Patients were stratified by the presence of rheumatoid arthritis involving the heart or lung (RAHL), defined by ICD-10 codes. In-hospital mortality was assessed using unadjusted and multivariable logistic regression analyses comparing RAHL and non-RA groups. Subgroup analyses were performed for systolic, diastolic, and combined heart failure types.Healthcare utilization (total charges and costs) was evaluated via

Table 1 shows Adjusted and unadjusted logistic regression models

Adjusted and unadjusted logistic regression models of mortality in Heart failure admissions in patients with RA involving the heart or lung (RAHL) vs without RA

		95% CI		
	OR	Lower limit	Upper limit	p value
Unadjusted	2.09	1.79	2.43	<.01
Adjusted	2.12	1.80	2.48	<.01

Adjusted and unadjusted logistic regression models of Combined systolic and diastolic Heart failure admissions in patients with RA involving the heart or lung (RAHL) vs without RA

		95% CI		
	OR	Lower limit	Upper limit	p value
Unadjusted	2.38	2.25	2.51	<.01
Adjusted	1.51	1.42	1.61	<.01

Adjusted and unadjusted logistic regression models of Systolic Heart failure admissions in patients with RA involving the heart or lung (RAHL) vs without RA

		95% CI		
	OR	Lower limit	Upper limit	p value
Unadjusted	1.21	1.10	1.34	<.01
Adjusted	0.91	0.81	1.01	0.09

P < 0.05 indicates statistical significance. Multivariable regression models were adjusted for age at admission, gender, race, median household income, national quartile for patient ZIP Code, Charlson Comorbidity Index, location/teaching status of the hospital, region of the hospital, patient's residence, insurance. CI: 95% confidence interval; OR: Odds ratio.

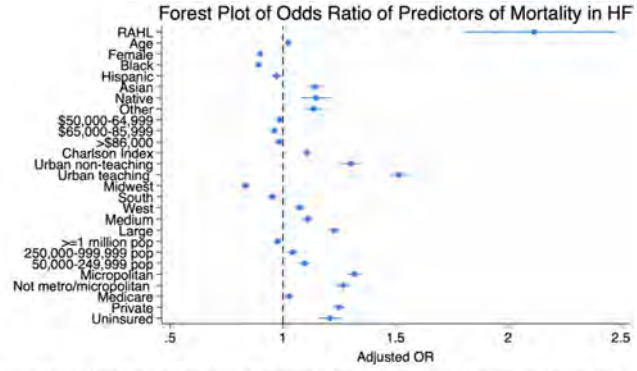
P < 0.05 indicates statistical significance. Multivariable regression models were adjusted for age at admission, gender, race, median household income, national quartile for patient ZIP Code, Charlson Comorbidity Index, location/teaching status of the hospital, region of the hospital, patient's residence, insurance. CI: 95% confidence interval; OR, Odds ratio.

unadjusted and adjusted linear regression. All models adjusted for demographics, comorbidities, hospital factors, and illness severity.

Results: Logistic regression models were used to examine mortality and heart failure subtypes. In unadjusted analyses, RAHL was associated with a more than twofold increased odds of mortality (OR 2.09, 95%,$p < 0.01$). This association persisted after adjustment for confounders (adjusted OR 2.12, 95%, $p < 0.01$). For combined systolic and diastolic heart failure admissions, the unadjusted model yielded an OR of 2.38 (95%, $p < 0.01$), which was attenuated controlling for confounders resulting in an adjusted OR of 1.51 (95%, $p < 0.01$). Interestingly, while systolic heart failure admissions demonstrated a significant association in the unadjusted model (OR 1.21, 95%, $p < 0.01$), the adjusted odds ratio was not statistically significant (OR 0.91, 95%, $p = 0.09$). However, diastolic heart failure admissions remained significantly elevated in both the unadjusted (OR 3.07, 95%, $p < 0.01$) and adjusted (OR 1.89, 95%, $p < 0.01$) models. Linear regression showed that RAHL was linked to higher healthcare utilization, with significantly increased total hospital charges (adjusted coefficient: $9,472.21) and costs (adjusted coefficient: $2,232.58) in both unadjusted and adjusted models ($p < 0.01$) among RAHL patients. From the Forest plot, RAHL, hospital type, insurance type, and certain racial/ethnic groups were strong predictors of mortality, while female sex, higher income brackets, and Midwest location showed protective associations.

Table 3 shows Forest Plot of Odds Ratio of Predictors of Mortality in HF



Forest Plot of Odds Ratio of Predictors of Mortality in HF (adjusted model). The vertical dashed line represents the null value (OR = 1.0). Horizontal lines represent 95% confidence intervals for each variable

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Our analysis indicates that heart failure patients with rheumatoid arthritis have more than double the odds of mortality and higher healthcare utilization than those without RA. Despite the retrospective design and reliance on ICD coding, these results underscore the need for enhanced clinical surveillance, tailored treatment strategies, and further studies incorporating detailed therapeutic and cardiac data to better guide management.

Pulmonary Profiles: Characterizing Lung Findings in Rheumatoid Arthritis Patients Undergoing Lung Cancer Screening

Pratyusha Banik[1], Melody Andrews[1], Sudhakar Pipavath[1] and Namrata Singh[2], [1]University of Washington, Seattle, WA, [2]University of Washington, Bellevue, WA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) has been associated with an increased risk of lung cancer with shared risk factors being heavy smoking history and possibly interstitial lung disease (ILD). They highlight the importance of lung cancer screening in persons with RA that meet age and smoking history criteria. However there have not been many studies examining the radiographic findings among persons with RA that undergo chest computed tomography (CT) for lung cancer screening. The objectives of our study were to evaluate the yield of lung cancer diagnoses in those with RA that underwent lung cancer screening with low dose CT chest, and to characterize the pattern of lung nodules and pulmonary parenchymal findings in this cohort.

Methods: We identified all adults (>18 years of age) with an ICD10 diagnostic code of RA between March 2021 and October 2023, that follow with rheumatology providers at our academic center. We then used the procedure code for lung cancer screening with chest CT (72171) to identify patients with RA that met the United States Preventative Task Force (USPSTF) criteria for lung cancer screening CT, and who had undergone at least one CT scan. We conducted chart review

Table 1: Patient characteristics

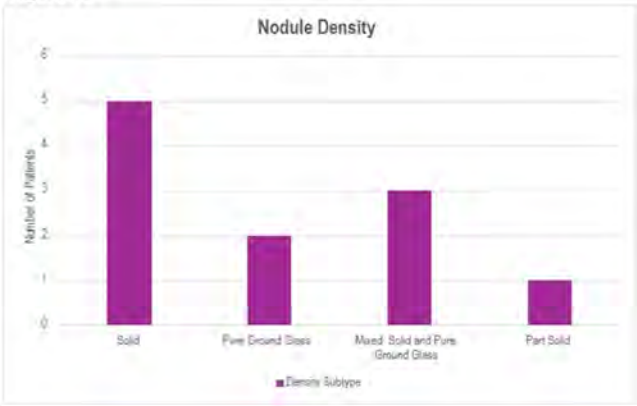

Figure 1B: Nodule Density

to extract patient characteristics and lung imaging data such as age, sex duration of RA, rheumatoid factor (RF) and cyclic citrullinated peptide (CCP) status, smoking pack year history, nodule characteristics, presence of ILD, and lung cancer diagnosis.

Results: 42 patients met the inclusion criteria. The majority were female (62%). 66% were RF positive and 64% were CCP positive. Of the 42 patients with RA who underwent lung cancer screening, one (2.4%) was diagnosed with lung cancer (squamous cell carcinoma) on follow up imaging. The majority (80%) had benign lung nodules with Lung-RADS(Lung Imaging Reporting and Data System) category 1 or 2, and 9.5% had suspicious findings (Lung-RADS 4A). Nodules > 6 mm were found in 17% and calcified nodules suggestive of prior granulomatous disease were seen in five patients. Nodule density varied with solid, pure ground glass, part solid, and mixed patterns observed. Interstitial lung abnormalities or interstitial lung disease was seen in 17%, and showed no association with Lung-RADS category.

Conclusion: Among patients with RA who met criteria for lung cancer screening, the diagnostic yield for malignancy was low, and most lung nodules were benign. Nonetheless, a notable proportion had suspicious findings requiring follow-up. These results highlight the importance of targeted lung cancer screening in RA, particularly for individuals with significant smoking history, and support ongoing vigilance in radiographic surveillance for early detection and management.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: The Triglyceride-Glucose-BMI index (TyG-BMI) is a reliable method for detecting insulin resistance (IR), with effectiveness comparable to the gold standard. Elevated TyG-BMI levels have been associated with subclinical atherosclerosis and cardiac dysfunction. Both IR and rheumatoid arthritis (RA) promote a state of hyperglycemia. Therefore, the use of TyG-BMI as a screening tool for CV risk assessment in this population is proposed, offering a practical and effective alternative for screening. For this reason, we aim to evaluate the association of the TyG-BMI Index with carotid plaque (CP), left ventricular geometry, and subclinical cardiac dysfunction in patients with RA.

Methods: A Cross-sectional, descriptive, comparative study was conducted. Patients aged 30 to 75 with RA criteria were included. Those with CV disease history were excluded. Carotid ultrasound and transthoracic echocardiogram were performed in 297 and 238 participants, respectively. CP was defined as a diffuse carotid intima-media thickness (IMT)

Table 1. Demographic and clinical characteristics of carotid ultrasound.

SD, standard deviation; IQR, interquartile range; BMI, Body mass index; LV, left ventricle; RRP, reversible restrictive pattern; IRP, irreversible restrictive pattern; TAPSE, tricuspid annular plane systolic excursion; LVEF, left ventricular ejection fraction; GLS, global longitudinal strain; SSD, subclinical systolic dysfunction

≥1.2 mm or focal thickness ≥0.8 mm. The echocardiographic assessment included left ventricular mass index (LVMI), relative wall thickness (RWT), tricuspid annular plane systolic excursion (TAPSE), and left ventricular ejection fraction (LVEF). Subclinical diastolic dysfunction (SDD) was defined according to the 2016 American College of Cardiology classification, and subclinical systolic dysfunction (SSD) of the left ventricle (LV) was defined as a global longitudinal strain (GLS) >-18%.

To calculate the TyG-BMI index, serum triglyceride (TG) levels, fasting blood glucose (FBG), and body mass index (BMI) were used with the following formula: TyG-BMI Index = Ln [TG (mg/dL) × FBG (mg/dL)/2] × BMI.

Participants were categorized into tertiles based on the TyG-BMI. Group distribution was evaluated using the Kolmogorov-Smirnov test. Comparisons were made using the Chi-square test, ANOVA, or Kruskal-Wallis test. A p-value ≤0.05 was considered statistically significant.

Results: Most patients with RA were women aged between 53 and 57 years. Among the 297 patients who underwent carotid ultrasound (Table 1), a higher prevalence of diabetes, hypertension, and obesity was observed in the third tertile. However, the prevalence of CP was similar across all groups and was not statistically significant.

Regarding the 238 patients who underwent transthoracic echocardiography (Table 2), a similar prevalence of CV risk comorbidities was observed. From the second tertile onward, there was an increase in the prevalence of subclinical diastolic dysfunction and concentric remodeling changes, although these differences were not statistically significant.

Conclusion: The TyG-BMI index was not associated with the presence of CP, significant changes in echocardiographic parameters. However, higher TyG-BMI levels were related to traditional CV risk comorbidities. Despite these findings, studies with larger sample sizes are needed to confirm these associations. Integrating echocardiographic and carotid ultrasound assessments into CV risk evaluation remains essential for the early detection of structural and functional abnormalities.

Risk Factors for Acute Exacerbation in Patients with Rheumatoid Arthritis-associated Interstitial Lung Disease

Rinko Katsuda[1], Akiko Kitagawa[1], Masayuki Azukizawa[2], Musuzu Fujimori[1] and Tetsuji Kawamura[3], [1]Department of Rheumatology, NHO Himeji Medical Center, Japan, Himeji, Japan, [2]Department of Orthopaedic Surgery, NHO Himeji Medical Center, Japan, Himeji, Japan, [3]Department of Respiratory Medicine, NHO Himeji Medical Center, Japan, Himeji, Japan

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis-associated interstitial lung disease (RA-ILD) is a common and serious extra-articular manifestation of RA, contributing to ∼10% of RA-related mortality. Acute exacerbation (AE) of RA-ILD is often fatal, but its clinical risk factors remain poorly defined.

Methods: We retrospectively analyzed RA-ILD patients treated at our center. The AE group included patients hospitalized for AE between 2013 and 2022. The non-AE group comprised patients attending outpatient care in 2013 who were not hospitalized for AE during the same period. Clinical variables included age, age at RA onset, RA duration, sex, smoking history, use of methotrexate (MTX) and prednisolone (PSL), DAS28-ESR, RF, and ACPA. Univariate analyses were performed using t-tests or chi-square tests. Logistic regression was used for both univariate and multivariate analyses (Forward: LR method). Given a strong correlation between age and age at RA onset ($r = 0.719$), only the latter was included in multivariate analysis.

Results: Univariate analysis identified age and age at RA onset as significantly associated with AE ($p< 0.001$ and $p=0.003$, respectively). Multivariate analysis revealed age at RA onset (OR 1.264, 95% CI 1.099–1.455, $p=0.001$) and RA duration (OR 1.226, 95% CI 1.067–1.409, $p=0.004$) as independent risk factors. The model showed moderate explanatory power (Nagelkerke $R^2 = 0.425$) and high predictive accuracy (85.7%). In-hospital AE mortality was 40%.

Conclusion: Later onset of RA and longer disease duration independently increased the risk of AE in RA-ILD. These findings highlight the importance of early risk stratification and close monitoring in susceptible patients.

Abstract Number: 0460

The Impact of Early and Artificial Menopause on Dementia Risk Among Women with Rheumatoid Arthritis

Ryan Salama[1], Cassondra Hulshizer[2], Cynthia Crowson[3] and Elena myasoedova[1], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Rochester, [3]Mayo Clinic, Stewartvillle, MN

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Alzheimer's disease and related dementias present an increasing global health concern, with increasing incidence and prevalence. Hormonal fluctuations associated with menopause may exacerbate inflammatory and cerebrovascular changes, contributing to neurocognitive decline. Early and artificial menopause have been linked to elevated dementia risk and neurocognitive decline in the general population. Rheumatoid arthritis (RA) has been separately established as a risk factor for dementia. However, the specific relationship between menopause characteristics and dementia in populations with RA remains unclear. We aimed to evaluate the association between artificial and early menopause on occurrence of dementia in a population with RA.

Methods: This retrospective population-based study included women /=50 years of age with incident RA in 1980-2014 who met 1987 ACR criteria and had no previous diagnosis of dementia. Age at menopause was categorically defined as the age bracket of an individual (< 45, 45–54, and ≥55 years) at 6 months post-menstruation cessation for natural cases or at the time menopause was induced for artificial cases. Menopause data was manually collected from medical records. Women with unknown age at menopause were assigned to the 45-54 age bracket; women with unknown causes of menopause were classified as natural. Artificial menopause included those with bilateral oophorectomy or chemotherapy-induced menopause. Dementia was defined as two relevant ICD-9/ICD-10 codes at least 30 days apart.

Cox proportional hazards models were used to estimate the adjusted hazard ratio (aHR) and 95% confidence intervals (CI) between menopause and dementia. Individuals with early (< 45 years) or artificial menopause were compared to referents with natural or unknown-cause menopause at ≥45 years. Primary covariates included age and index year of RA incidence. To assess effect modification by RA severity and treatment, separate interaction models were performed examining the effects of RF/CCP positivity, erosions and/or destructive changes, severe extra-articular RA manifestations, or large joint swelling within one year.

Results: A total of 458 women were included, with a median age at RA incidence of 63.2 years. Sixty-six women had an outcome of dementia following RA diagnosis. Early and/or surgical menopause was present in 82 women (17.9%). Early or surgical menopause was associated with an increased risk of dementia (aHR 1.96; CI 0.99-3.89). Results were similar when adjusting for RF/CCP positivity, obesity, smoking, and education. For the interaction analyses, no statistically significant effect modifications were observed (all interactions P >0.05).

Conclusion: In women with RA, early or surgical menopause was associated with a nearly two-fold increase in risk of dementia, suggesting the need for increased awareness of increased risk for cognitive decline in this population of patients with RA. This association was not significantly modified by RA severity factors, smoking, education, or obesity.

Right Diagnoses For the Wrong Reasons: Limitations of Current Large-Language Model based Agentic Frameworks for Screening of Rheumatoid Arthritis

Sarthak Verma[1], Avarna Agarwal[1], Umakanta Maharana[2], Murari Mandal[3], Prasanta Padhan[1], Prakashini Mruthyanjaya[4] and Sakir Ahmed[1], [1]Department of Clinical Immunology and Rheumatology, Kalinga Institute of Medical Sciences, Bhubaneswar, Orissa, India, [2]School of Computer Engineering, KIIT University, Bhubaneswar, India, [3]School of Computer Engineering, KIIT University, Bhubaneswar, Orissa, India, [4]Department of Clinical Immunology and Rheumatology, Kalinga Institute of Medical Sciences, Bhubaneswar, India

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: In India, Rheumatoid arthritis (RA) is often diagnosed late. Artificial Intelligence (AI) driven Large Language models (LLMs) can be deployed via widely available mobile phone devices, offering a potential screening solution. Here, we attempted to explore various AI agentic frameworks to identify the most effective model SARA (Screening Agent for RA), and also to validate how these models arrive at a diagnosis of RA.

Methods: We had developed the PreRAID (Pre-Screening Rheumatoid Arthritis Information Database) from consenting patients with joint pain, classifying patients into RA or not RA as per treating physician diagnosis. The dataset was split into 280 cases for the knowledge base (KB) and 70 for testing. A Neo4j vector database enabled embedding-based retrieval.

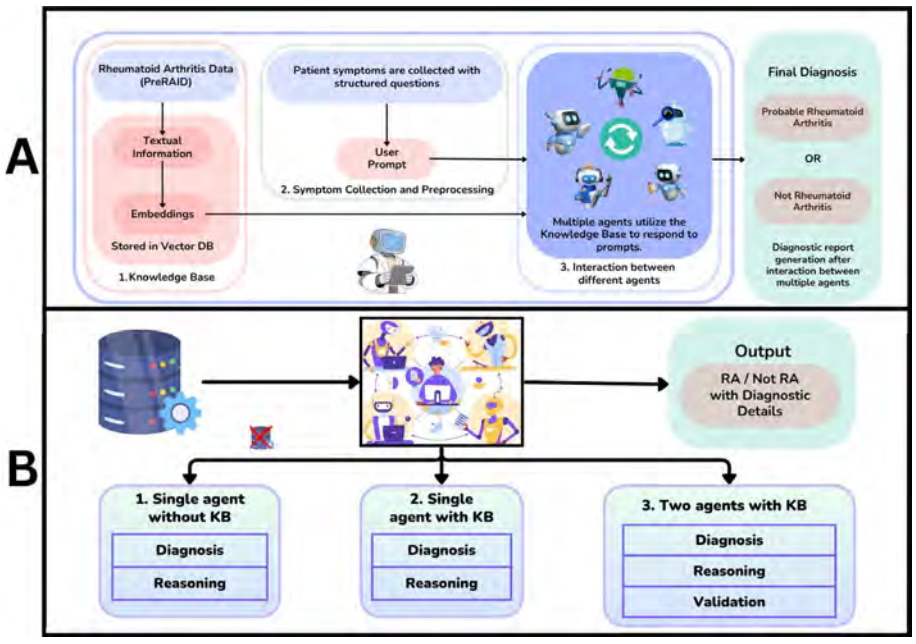

Figure 1: Agentic framework. (A) Workflow of the SARA framework and (B) Illustration of the sequential steps involved in diagnosing RA with single agent without knowledge base (KB), single agent with KB and Two agents with KB

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

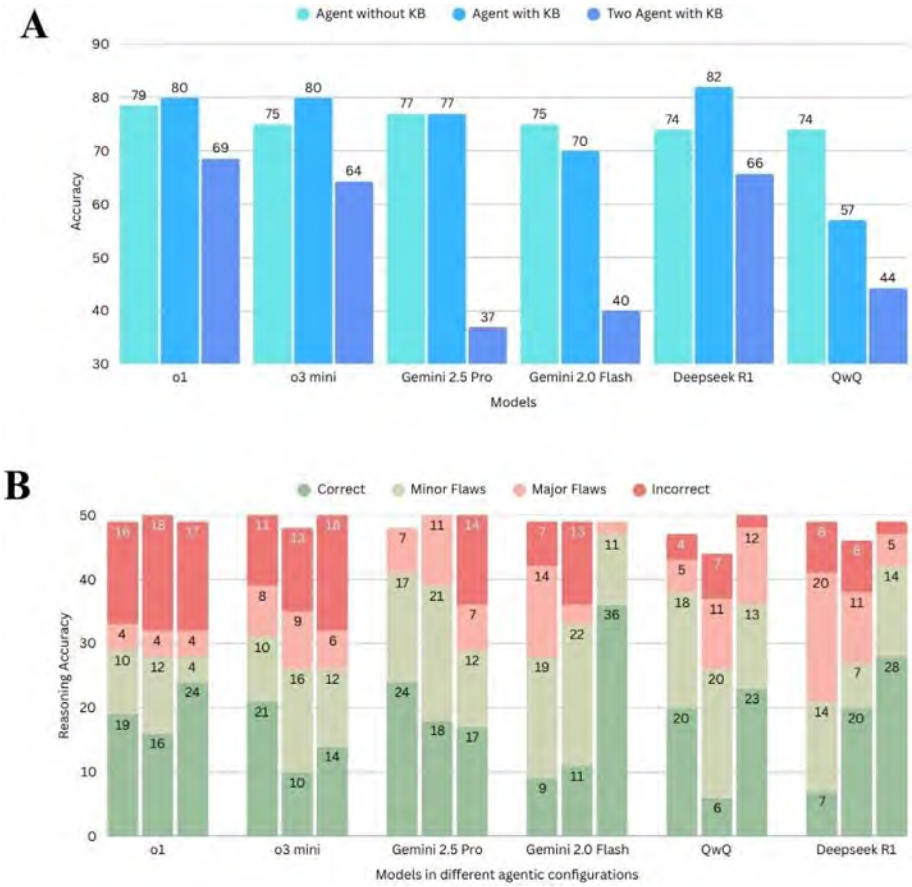

Figure 2: Validation of the different models. (A) Accuracies of different LLM models under different agentic configurations and (B) Accuracies of reasonings provided by different models as validated by clinicians

Six LLMs were evaluated—four closed-source (OpenAI o1, OpenAI o3 mini, Gemini 2.5 Pro, Gemini 2.0 Flash) and two open-source (QwQ, Deepseek R1 70B). Each model was tested under three agentic configurations: (1) a single agent without knowledge base (KB) access; (2) a single agent with retrieval-augmented generation (RAG); and (3) a dual-agent setup, where the first agent generated a diagnosis and reasoning, validated by a second agent. [Figure 1]

Each model-configuration pair was evaluated on 50 new cases. The models were also asked to explain the reasons behind each diagnosis, which was independently assessed by two fellows and one consultant rheumatologist using a four-point Likert scale.

Results: The PreRAID dataset included 84% RA-confirmed cases and 16% controls. Deepseek R1 showed the highest accuracy (82%) in the single-agent with KB setting, followed by o1 and o3 mini (80% each). Accuracy dropped in the two-agent setup, most notably in Gemini 2.5 Pro (37%) and Gemini 2.0 Flash (40%) [Figure 2].

Despite moderate to high accuracy, Gemini models underperformed in reasoning when agentic complexity increased. Reasoning quality was suboptimal across all models. Gemini 2.0 Flash (36/50) and Deepseek R1 (28/50) had the most correct justifications, while QwQ and Gemini 2.5 Pro scored the lowest (6 and 10, respectively). Many outputs showed minor or major reasoning flaws, indicating a disconnect between diagnostic accuracy and reasoning integrity.

Conclusion: Deepseek R1 achieved the highest diagnostic accuracy (82%) in the single-agent with KB configuration. However, reasoning quality across all models was suboptimal, with many correct diagnoses attributed to flawed reasons. The dual-agent setup, intended to enhance reasoning, led to decreased diagnostic performance. Though we built a robust

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Frailty predicts mortality in RA. In the general population, males have a higher risk of death than females despite lower levels of frailty.[1] We evaluated how sex modifies the relationship between frailty and mortality in RA.

Methods: Participants from the Veterans Affairs Rheumatoid Arthritis (VARA) Registry enrolled between 1/2003 to 12/2020 were included. Follow up ended in 12/2022, allowing for at least 2 years of observation for each participant. Frailty was measured annually throughout the observation period using the VA Frailty Index (VA-FI), a validated deficit accumulation score based on >6000 diagnostic codes.[2] Participants were categorized as robust or frail at enrollment using the established VA-FI cutoff of >0.2. Our primary model used multivariable Cox regression to evaluate the relationship between baseline frailty and mortality, with sex as an interaction term. A subsequent multivariable Cox model, including only those who have new onset frailty, evaluated sex differences in the risk of death starting at the time of frailty onset. Models were adjusted for baseline age (categorized by decade), race, BMI (normal/low vs. high), RF positivity, RA disease duration, DAS28-ESR, rheumatic disease comorbidity index (RDCI), prednisone use, conventional synthetic DMARDs and biologic DMARDs.

Results: 2,601 males and 344 females were included in the primary analysis, with average age 66 (10) for males and 55 (12) for females. Disease duration was 11.6 (11.5) years for males and 9.8 (9.8) years for females. An equal proportion of males and females were frail at baseline (28% and 27%, respectively). During follow-up, 1,301 (50%) males and 66 (19%) females died. Compared to robust males, robust females were less likely to die (aHR 0.45, [0.32-0.63]). Frailty was associated with an increased risk of death in frail males compared to robust males (aHR 1.37, [1.20-1.57]). The risk of death did increase in frail females, however, it was not significantly higher than that of robust males (aHR 1.01, [0.70-1.45]). The risk of death conferred by frailty was higher in females than males as represented by the significant interaction term between sex and frailty of 1.64 (p=0.051). The incident frailty analysis included 948 males with mean age 67.6

- CI = confidence interval

Table 3. Risk of death in in males and females with incident frailty.

	Total	Died	aHR [95%CI]*	Median Time to Death (years) [95%CI]
Male	948	526 (55%)	Ref	6.50 [6.10-7.08]
Female	95	26 (27%)	0.53 [0.35-0.79]	>16.40**

- aHR = adjusted hazard ratio for baseline age, race, BMI, RF positivity, RA disease duration, DAS28-ESR, use of prednisone, conventional synthetic DMARDs and biologic DMARDs, and RDCI
- CI = confidence interval
**Median death unable to be calculated due to <50% death in females

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(0.39) and 95 females with mean age 64.9 (2.43) with 526 (55%) males and 26 (27%) females dying during follow-up. Females with incident frailty were less likely to die than males with incident frailty (aHR 0.59, [0.39-0.91]). Median survival time was shorter in newly frail males than females (6.50 vs >16.40 years, respectively); exact median could not be calculated for females due to less than 50% death among females.

Conclusion: Frailty in RA is associated with mortality and this relationship differs by sex. Males, regardless of frailty status, have a higher risk of death than females, yet frailty confers a higher relative risk of death in females. Males with incident frailty have a higher risk of death and shorter median survival times than females with incident frailty with RA, highlighting the need for early recognition and intervention in this group.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Synovial tissue pathotype may indicate treatment response in RA, but synovial biopsies are not widely available. Synovial fluid (SF) is a promising surrogate. We sought to identify SF features that reflect histopathological and clinical characteristics in RA.

Methods: SF and synovial tissue were prospectively collected from patients meeting RA criteria undergoing total knee replacement. SF white blood cell (WBC) count and differentials were analyzed in the clinical laboratory. Patients were stratified into three groups by medication history: "biologic naïve," "on biologic" and "refractory." Synovial Lymphocytic Inflammation (SLI) was graded from low (0-2) to high (3) inflammation by a board-certified pathologist. Descriptive statistics, correlations, ROC curve, and multivariate regressions were used to assess associations with SF cell counts.

Separately, a retrospective review of the electronic medical record (EMR) extracted SF parameters, clinical characteristics, and patient reported outcome measures (PROMs) from patients who underwent joint aspirations between 2017 and

[1]Low SLI- score of 0-2 is classified as low inflammatory (0 indicates no inflammation or less than 1 perivascular aggregate in at least 2 fields, 1 indicates mild inflammation or 1 perivascular aggregate in at least 2 fields, 2 (moderate) indicates greater than or equal to 2 perivascular aggregates or interstitial inflammation)

[2]High SLI- SLI score of 3 is classified as high inflammatory (widespread perivascular / interstitial aggregates or band-like bridging between blood vessels)

[3]Kruskal-Wallis p-value; [4]Chi-Square p-value; [5]Fibrin is measured as present or absent

2023. Infections, gout, and CPPD were defined by positive cultures or appropriate crystal identification; other diagnoses were determined using ICD-10 codes. PROMs included the Multidimensional Health Assessment Questionnaire (MDHAQ), and Routine Assessment of Patient Index Data 3 (RAPID3).

Results: In 64 RA patients with paired synovial tissue histology and SF cell counts, mean SF WBC was 5,661 cells/μL, and mean CDAI was 17.9 (Table 1). 29 (45%) had high SLI, which correlated positively with SF WBC (Figure 1A). Patients in the high SLI group had higher mean CRP (2.4 vs. 0.6, p< 0.0001), swollen joint count (5.7 vs. 3.8, p=0.021), CCP positivity (86% vs 63%, p=0.035), and DAS28-CRP (4.2 vs 3.3, p=0.014) compared to patients in the low SLI group. There were no differences in disease activity or SLI between medication groups. SF WBC ≥ 1400 cells/μL was sensitive (0.86) and specific (0.91) for high SLI (AUC 0.91) (Figure 1B).

The proportion of aspirations with WBC ≥ 1400 cells/μL varied by diagnosis in the retrospective chart review (Figure 1C). Of 2,171 aspirations, 823 were from RA patients, of whom 492 (60%) had WBC ≥ 1400 cells/μL. Septic arthritis and OA had

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

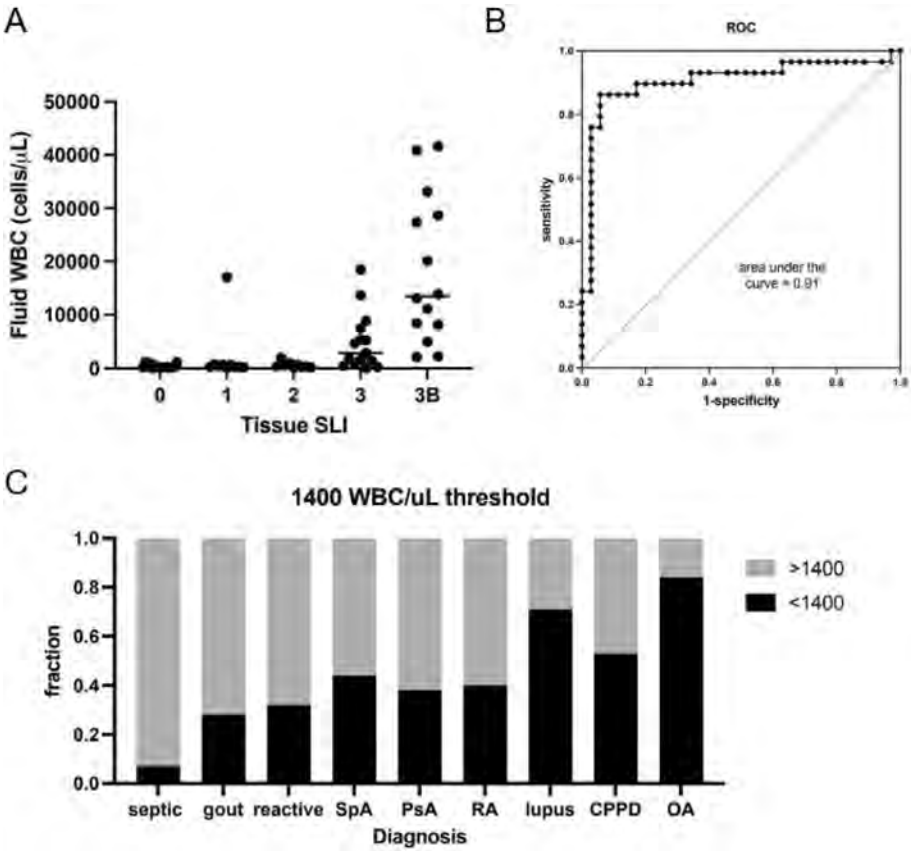

Figure 1. Synovial fluid cellularity predicts synovial tissue inflammation in RA and varies by diagnosis. 1A) Scatterplot depicting increasing synovial tissue lymphocytic inflammation (0-3B) vs. synovial fluid white blood cell (WBC) count (cells/μL). B = SLI 3-band. Kruskal-Wallis chi-square = 36.9, df = 4, p<0.001. 1B) Synovial fluid cellularity predicts the degree of tissue inflammation. Receiver Operator Curve using synovial fluid threshold ≥ 1400 WBC/μL to classify synovial tissue with grade 3 SLI. 1C) Fraction of aspirations associated with each diagnosis with > 1400 WBC/μL.

the highest and lowest proportion of WBC ≥ 1400 cells/μL, respectively. Compared to those with WBC < 1400 cells/μL, RA patients with WBC ≥ 1400 cells/μL had higher mean ESR (38.7 vs 23.0, p< 0.0001), CRP (10.9 vs 6.7, p=0.0008), and SF PMN% (61.1 vs. 17.8, p< 0.0001) (Table 2). RA patients with WBC ≥ 1400 cells/μL had significantly lower mean RAPID3 scores (11.9 vs 14.1, p=0.0213) compared to those with WBC < 1400 cells/μL. Mean MDHAQ scores did not differ significantly between the two WBC groups.

Conclusion: SF WBC is sensitive and specific for differentiating high and low SLI in RA. SF WBC ≥ 1400 cells/μL was associated with higher measures of systemic inflammation when collected intra-operatively and during routine aspiration but not with composite measures of disease activity or PROMs, suggesting that the SF WBC count provides distinct information that may be useful in selecting appropriate anti-inflammatory targeted therapy.

Abstract Number: 0464

Synovial Inflammation is not Associated With Reoperation in Patients With Rheumatoid Arthritis Undergoing Total Hip or Knee Arthroplasty

Solana Cushing[1], Kelsey Gripp[2], Edward DiCarlo[3], Deanna Jannat-Khah[1], Yoshimi Endo[3], Jose Rodriguez[3], Mark Figgie[3], Bella Mehta[4] and Susan Goodman[3], [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, New York, [3]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY, [4]Hospital for Special Surgery, Weill Cornell Medicine, Jersey City, NJ

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Reoperations following arthroplasty are a significant burden to patients and surgeons. In patients with RA who receive total hip (THA) or knee (TKA) arthroplasty, radiographic loosening, a common cause of reoperation, has been linked to increased disease activity.[1,2] We sought to determine if synovitis in the operated joint at time of THA/TKA was associated with increased risk of reoperation.

Methods: RA patients who underwent primary THA/TKA and a reoperation on the same joint at our institution were identified via the EMR and clinical characteristics were extracted. Synovium specimens from THA/TKA were graded by a board-certified musculoskeletal pathologist for Synovial Lymphocytic Inflammation (SLI), Synovial Lining Hyperplasia (SLH), and Krenn synovitis score. SLI was graded from 0 (none) to 4 (band-like), with SLI 0–1 classified as non-inflammatory and 2–4 as inflammatory. Radiographs preceding reoperation were graded as loose or not loose by a board-certified radiologist based on a combination of periprosthetic lucency and implant position. Kaplan-Meier (KM) survival curves estimated risk of reoperation over time among subjects with a diagnosis of aseptic loosening, implant dislocation, or failure. Log rank tests were performed to assess differences in KM survival curves. Continuous and categorical variables were compared using two-tailed t-tests and Fisher's exact tests, respectively. Logistic regression models assessed odds of reoperation within 5 years. Analyses were performed using STATA 18.0 with an alpha of 0.05.

Results: Thirty-nine patients meeting eligibility criteria were included; 109 cases were excluded due to secondary surgery on a different joint and 5 because index surgery occurred at another institution. Inflammatory synovium was present in 19 cases. 34 (85%) were female with mean ± SD age of 59± 10 years, BMI 30 ± 8.4 kg/m^2; 15 (38.5%) had a loose implant, and 33 (82%) reoperations were revisions (Table 1). Time to reoperation did not differ between inflammatory and non-inflammatory groups (log-rank p-value > 0.05) (Figure 1). Neither diagnosis at reoperation (p-value = 0.24) nor radiographic loosening (53% vs. 25%, p-value = 0.10) differed between groups (Table 2). Inflammatory synovium was not associated with increased odds of reoperation within 5 years (OR 0.98, 95% CI 0.17, 5.83). Neither SLI, SLH, or Krenn score were associated with odds of reoperation within 5 years.

Conclusion: In this small cohort with a low incidence of secondary surgery, synovial inflammation at the time of primary surgery was not associated with increased risk of reoperation. Other factors, including systemic inflammation, may play a role in aseptic loosening and reoperation risk for RA patients undergoing THA or TKA and merit further investigation in a larger cohort.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: RA-associated lung diseases (RA-LD) such as RA-associated interstitial lung disease (RA-ILD) and RA-associated bronchiectasis (RA-BR) are more common in men, but risk rises with age for both men and women. However, no studies have examined the role of reproductive factors, such as time since menopause, in RA-LD risk among women.

Methods: We performed a case-control study of reproductive factors and RA-LD risk in women from two established US prospective RA cohorts (an institutional registry and a health care system biobank) who had clinically indicated high-resolution chest computed tomography (CT) imaging. All women had RA by 2010 ACR/EULAR criteria. RA-LD cases were identified using research review of chest CT images by thoracic radiologists and detailed medical record review confirming that participants met criteria for RA-LD. Controls had RA and no evidence of lung disease based on medical record review and were matched to cases by age and RA duration. The index date for cases was the date of RA-LD diagnosis and the index date was assigned to RA-noLD controls. We analyzed women who answered surveys about reproductive health. The primary analysis investigated years since menopause for RA-LD risk. Secondary analyses included age at menarche, pregnancies, ovulatory-years, type of menopause, and age at menopause as well as RA-ILD and RA-BR risk. We used logistic regression to estimate odds ratios for RA-LD, adjusting for chronological age, smoking, and serostatus.

Results: We analyzed 99 RA-LD cases (mean age 65.5 years) and 170 RA-noLD controls (mean age 63.4 years) who answered surveys about female reproductive factors. RA-LD cases had shorter duration of ovulatory-years (mean 33.8 vs. 35.4 years, p=0.037), younger age at menopause (mean 47.0 vs. 48.5 years, p=0.038), and longer time since menopause (mean 18.4 years vs. 14.8 years, p=0.013) than RA-noLD controls (**Table 1**). In the primary analysis, time since menopause was significantly associated with RA-LD (adjusted OR 1.05 per year, 95%CI 1.004 to 1.10; p=0.034) (**Table 2**). In the secondary analyses, menarche at age 10 years or younger was associated with higher RA-LD risk than menarche at

BR, bronchiectasis; CI, confidence interval; ILD, interstitial lung disease; OR, odds ratio; RA, rheumatoid arthritis

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

age 11 to 14 years (adjusted OR 2.54, 95%CI 1.15 to 5.60). Higher ovulatory-years had a trend towards lower RA-LD risk but was not statistically significant after adjustment (OR 0.96 per year, 95%CI 0.92 to 1.003). Younger age at menopause was associated with RA-LD risk (adjusted OR 2.06, 95%CI 1.03 to 4.11 for onset < 45 years vs. 50 to 54 years). There was no association of iatrogenic menopause (surgical, radiation, or chemotherapy) with RA-LD risk. When analyzing RA-ILD and RA-BR separately, results for RA-ILD risk were similar to RA-LD risk (**Table 3**).

Conclusion: In this first study examining reproductive factors and RA-LD risk in women, longer time since menopause was associated with higher RA-LD risk. Younger ages at menarche and at menopause were each associated with higher RA-LD risk, and results were similar for RA-ILD. Results were not explained by chronological age, RA duration, serostatus, or smoking. These findings suggest that menopausal factors, such as lack of estrogen, may place older women with RA at risk for LD.

Abstract Number: 0466

Pilot Study Demonstrates Altered Intestinal Mucosal Microbiome in Patients with Rheumatoid Arthritis versus Control Subjects

Tulsi Joishy[1], Anastasiia Phothisane[2], Phicharmon Kulapatana[2] and Michelle Ormseth[1], [1]Vanderbilt University Medical Center, Nashville, [2]Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is a systemic autoimmune disease that is thought to originate at the mucosa. Despite the mucosa's importance, few studies have examined the microbiome of the intestinal mucosa in patients with RA, instead assessing stool microbiome as a surrogate. The purpose of this pilot study is to determine if the mucosal microbiome differs in patients with RA compared to control participants and by site.

Methods: Patients with RA and without RA or other inflammatory autoimmune disease who were undergoing routine colonoscopy were recruited at Vanderbilt University Medical Center as part of the Vanderbilt GI Repository. Mucosal tissue biopsies were obtained from terminal ileum, and ascending, transverse and descending colon. Specimens were flash frozen immediately after collection and stored at -80°C until processing. DNA was extracted from all four mucosal biopsy samples and 16S rRNA long-read DNA sequencing (V1-V8 regions) was performed using Oxford Nanopore Technology. Counts of bacterial taxa were compared using DESeq2 and the Benjamini-Hochberg method was used to adjust for multiple comparisons with a false discovery rate at 5%.

Results: This pilot study included 5 RA (mean age 56 ± 14 years, 100% female) and 5 control (mean age 44 ± 21 years, 60% female) participants. Measures of alpha diversity across sites were not significantly different in RA vs control participants;

Figure: Mucosal site-specific microbiome alterations in patients with RA versus control participants

however, there were significant differences in the microbiome composition at the 4 mucosal sites. At all sites, *Prevotella*, Christensenellales, *Megaspharera massiliensis, and Odoribacter splanchnicus* were significantly decreased in RA versus control participants. Within all sites of the colon *Eubacterium callanderi*, *Veillonella* and *Bacteroides ovatus* were increased, and *Shigella dysenteriae* was decreased significantly in RA versus control participants. While there were these commonalities by site, there were many site-specific significant alterations in mucosal microbiome (Figure).

Conclusion: Several taxa including *Prevotella* and Christensenellales were decreased at all mucosal sites in patients with RA versus control participants, while there were many site-specific mucosal microbiome alterations. Further studies will be needed to validate these findings in a larger cohort and to assess whether mucosal site-specific alterations in microbiome are associated with development of RA, disease activity and features.

*RA Disease Duration: Early (0-2 years), Established (2.1-10 years), and Longstanding (> 10 years)

Background/Purpose: Early diagnosis of rheumatoid arthritis (RA) enables prompt intervention, significantly mitigating risk for disease progression, joint damage, and associated morbidity. Conventional biomarkers, anti-CCP and rheumatoid factor (RF), have high specificity but limited sensitivity. Novel biomarkers such as RA33 (heterogeneous nuclear ribonucleoprotein A2/B1) and PAD4 (peptidyl arginine deiminase 4) antibodies have demonstrated diagnostic potential, though their combined utility remains unclear. This study evaluates the performance of novel biomarkers individually and in combination with traditional markers using machine learning algorithms.

Methods: A total of 760 subjects were enrolled, including 350 RA patients meeting 2010 ACR criteria (205 seropositive, 145 seronegative), 215 apparently healthy volunteers (AHV), and 195 disease controls (107 SLE meeting 1997 ACR criteria, 43 primary Sjögrens disease, and 45 psoriatic arthritis [PsA]). Serum samples were tested for anti-CCP IgG, RF IgM and IgA,

Table 2. Performance characteristics

Marker	Sensitivity for RA: Seropositive (N=205)	Sensitivity for RA: Seronegative (N=145)	Specificity for RA: AHV (N=215)	Specificity for RA: SLE (N=107)	Specificity for RA: Sjogren (N=43)	Specificity for RA: PsA (N=45)	RA vs AHV: LR+	RA vs AHV: LR-
RA33 IgA	5%	5%	97%	93%	95%	91%	1.55	0.98

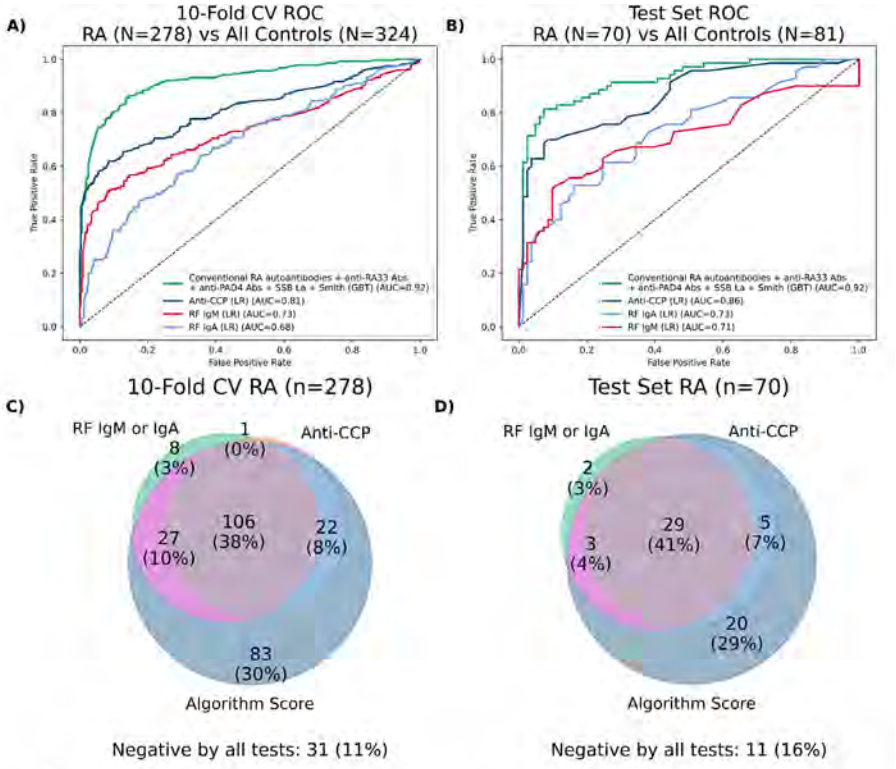

Figure 1. (A) An 80% sampling of the dataset was subjected to 10-fold cross-validation. The optimal probability cutoff achieving the maximum F1 score balancing sensitivity and specificity was 0.35. (B) The Test set reflects an independent 20% subset of the dataset that was not shown to the GBT model during training used to assess model generalizability. (C) The Venn diagram illustrates the percentage of RA patients testing positive for either RF, anti-CCP or the GBT algorithm score based on the F1 maximized threshold in the 10-fold cross validation set. (D) The Venn diagram illustrates the percentage of RA patients testing positive for either RF, anti-CCP or the GBT algorithm score based on the F1 maximized threshold in the test set.

Figure 1. ROC analysis comparing algorithm performance to conventional biomarkers and sensitivity overlap analysis

RA33 (IgA, IgG, IgM), PAD4 (IgA, IgG), anti-SSB/La, and anti-Smith. Diagnostic cutoffs for anti-CCP and RF followed manufacturer recommendations; novel biomarker cutoffs were determined based on at least 95% specificity vs. AHVs. We evaluated multiple machine learning models and biomarker combinations using 10-fold cross-validation and independent test validation. Logistic regression models were built for individual conventional markers to compare against a Gradient Boosted Tree (GBT) classifier, which was ultimately selected based on superior AUC performance. Sensitivity and specificity were calculated at the optimal F1-maximized threshold.

Results: The RA cohort was predominantly female (77%), white (68%), with a mean age of 51 years (SD = 15) and a mean disease duration of 9 years (SD = 9) (Table 1). Anti-CCP was highly specific (99–100%) and RF IgM also showed high specificity (91–98%) (Table 2). RA33 markers were generally specific (71–98%), with RA33 IgG showing the highest sensitivity among them (13% in seronegative RA). PAD4 markers also had high specificity (92–98%), with PAD4 IgG demonstrating the highest sensitivity overall (44% in seropositive RA). PAD4 IgG had the highest positive likelihood ratio (+LR = 20.43), followed by PAD4 IgA (4.57), RA33 IgG (2.41), RA33 IgM (1.77), and RA33 IgA (1.55). The GBT classifier combining conventional and novel biomarkers (RA33s, PAD4s, anti-SSB La, Smith) achieved an AUC of 0.92 in both cross-validation and test sets (Figure 1A-B). The algorithm was 86% sensitive and 86% specific in cross-validation, and 81% sensitive and 90% specific in the test set. The GBT algorithm identified an additional 30% of RA cases in cross-validation (Figure 1C) and 29% in the test set (Figure 1D) that were missed by conventional biomarkers alone, leaving only 11–16% of RA patients undetected by any marker.

Conclusion: Integrating conventional biomarkers with novel RA33 and PAD4 antibodies through machine learning improves RA diagnostic accuracy, capturing ~30% of cases missed by conventional biomarkers alone. This enhanced diagnostic performance highlights the potential of advanced classifiers for earlier identification and timely management of RA.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with rheumatoid arthritis (RA) are at increased risk of developing cardiovascular (CV) events compared to the general population. However, this risk is often underestimated by current CV event risk prediction algorithms that do not take the characteristics of RA into account. The expanded cardiovascular risk prediction score for rheumatoid arthritis (the ERS-RA) has been shown to be superior to models that only incorporate traditional risk factors in predicting the risk of CV in patients with RA. This study aims to externally validate the ERS-RA for predicting 10-year CV event risk in Chinese patients with RA.

Methods: Patients with RA from a Chinese nationwide, multicenter, prospective cohort, enrolled between October 2008 and May 2024 were included as the external validation cohort. Discrimination was evaluated using C-index, and calibration was examined using comparisons of observed versus predicted risks.

Results: A total of 10,721 patients with RA were included. The incidence rate of CV events was 5.65 per 1,000 person-years. The C-index of the ERS-RA in this Chinese cohort was 0.831 (95% confidence interval [CI] 0.801 – 0.861). The overall

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Study flow chart. *RA, rheumatoid arthritis; CREDIT, The Chinese Registry of Rheumatoid Arthritis; CV, cardiovascular; CVD, cardiovascular disease

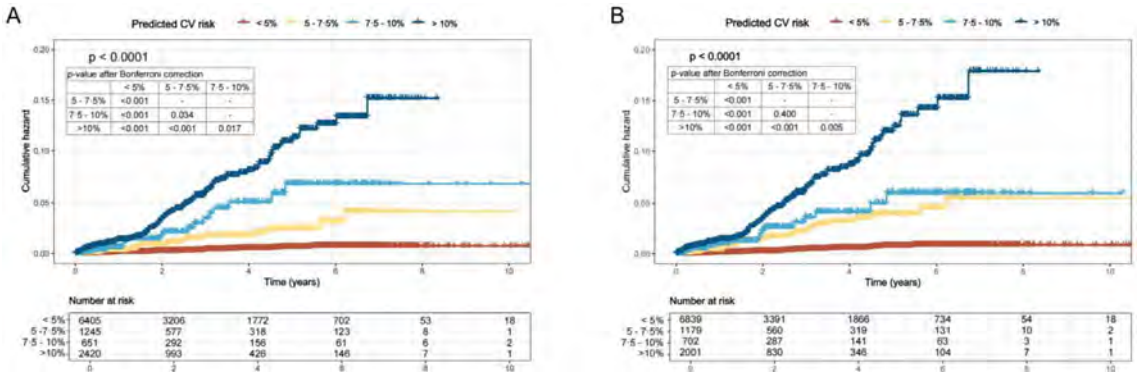

Figure 2. Comparison of cumulative hazard of cardiovascular events between four predicted 10-year cardiovascular event risk levels (<5%, 5.0-7.5%, 7.5-10%, and ≥10.0%) in the CREDIT-CVD cohort with imputed mHAQ (A) and without mHAQ (B) * CVD, cardiovascular disease.

calibration slope was 1.012 (95% CI 0.873 – 1.152), and the observed-to-expected ratio was 0.796 (95% CI 0.676 – 0.937). Across clinically relevant risk intervals, the ERS-RA slightly overestimated CV event risk by 1.41%–2.18% for patients with the predicted risks of < 5%, 5–7.5%, and 7.5–10%, but underestimated CV risk by 10.46% for patients with the predicted risk ≥10%.

Conclusion: The ERS-RA model demonstrated excellent discrimination and calibration for 10-year CV risk prediction in Chinese patients with RA. These results add to growing evidence for the clinical utility of ERS-RA in US, European, and now Chinese populations.

Abstract Number: 0469

Evaluating Large Language Models for Automated Joint Involvement Analysis in Rheumatoid Arthritis

Xingyi Liu[1], Sunghwan Sohn[1] and Cynthia Crowson[2], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Stewartvillle, MN

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0430–0469) Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: In rheumatoid arthritis (**RA**), delaying initiation of treatment for 12 weeks or longer may lead to permanent joint damage and make remission harder to achieve. Therefore, it's essential to develop strategies that improve early detection of RA in primary care setting. Joint involvement ("synovitis") is a core domain of the 2010 American College of Rheumatology/European League Against Rheumatism (ACR/EULAR) classification criteria for RA. Manual extraction of joint counts from unstructured clinical notes is time-consuming and labor-intensive. We evaluated Llama 3.1—a state-of-the-art large language model (LLM)—for automated identification, quantification, and dating of swollen/tender joints documented in electronic health record (EHR) notes.

Methods: We selected 200 patients meeting RA criteria by manual chart review and 200 non-RA controls. All clinic notes from 1990-01-01 to 2024-05-22 were processed by LLM prompted to act as an expert rheumatologist and provided with the exact same information used during manual chart review—including definitions of large and small joints and the exclusion criteria for certain joints—to extract counts of swollen/tender large and small joints. These counts were then mapped to the five joint involvement levels defined by the 2010 ACR/EULAR criteria (1 large joint = 0 point; 2–10 large joints = 1 point; 1–3 small joints = 2 points; 4–10 small joints = 3 points; >10 joints with at least one small joint = 5 points). Model-derived results were compared to the manual gold standard: we computed true positives (TP), true negatives (TN), false positives

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table. Performance Metrics of LLM for Joint Involvement Analysis.

Joint involvement	TP	FP	TN	FN	Acc	Pre	Rec	F1	Date Diff (days) Med	Q1	Q3
1 large joint	167	44	38	38	0.71	0.79	0.81	0.80	0	-187.75	8.5
2-10 large joints	95	50	100	42	0.68	0.66	0.69	0.67	0	-23.5	0
1-3 small joints	201	22	24	40	0.78	0.90	0.83	0.87	0	-152	14
4-10 small joints	107	4	82	94	0.66	0.96	0.53	0.69	0	0	57
11+ joints	22	2	172	91	0.68	0.92	0.19	0.32	0.5	0	366.5

*TP: True positive, FP: False positive, TN: True negative, FN: False negative, Acc: Accuracy, Pre: Precision, Rec: Recall, F1: F1-score, Med: Median, Q1: the 25th percentile, Q3: the 75th percentile.

(FP), false negatives (FN), accuracy, precision, recall, and F1-score for each level. For cases correctly identified (TP), we calculated the distribution of days between the LLM's first detected date and the manual review date of joint involvement.

Results: LLM achieved level-specific accuracies ranging from 0.66 (4-10 small joints) to 0.78 (1-3 small joints), with F1-scores spanning 0.32 (11+ joints) to 0.87 (1–3 small joints) (**Table**).

When we compared the LLM's first detected date and the manual review date among true positives, the median absolute difference was zero days for all levels except the 11+ joint level (0.5 days). For the 25th percentile, LLM's first detected date was 187.75 days, 23.5 days and 152 days earlier than the manual review date for 1 large joint, 2-10 large joints and 1-3 small joints, respectively, detection timing was identical for 4–10 small joints and 11+ joints. For the 75th percentile, it trailed manual review by 8.5 days for 1 large joint, 14 days for 1–3 small joints, 57 days for 4–10 small joints, and 366.5 days for 11+ joints, with 2–10 large joints detected at the same date (**Table**).

Conclusion: LLMs demonstrate potential to extract and classify joint involvement levels from unstructured EHR notes, matching manual review in both classification performance and temporal accuracy. These results support the promise of LLMs, especially with continued refinement, to accelerate and automate RA phenotyping.

Characterization of Patients With Rheumatoid Arthritis Based on Distinct Patterns of Pain Improvement Following Treatment With Filgotinib: A *Post Hoc* Analysis of FINCH 1

Peter Taylor[1], Yoshiya Tanaka[2], Louis Dron[3], Katrien Van Beneden[4], Gerd Burmester[5] and **Bruno Fautrel**[6], [1]University of Oxford, Oxford, United Kingdom, [2]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [3]Cytel, Toronto, Canada, [4]Alfasigma S.p.A., Bologna, Italy, [5]Department of Rheumatology and Clinical Immunology, Charité – Universitätsmedizin Berlin, Berlin, Germany, [6]Sorbonne Université - APHP, Department of Rheumatology, Hôpital Pitié-Salpêtrière, Inserm UMRS 1136-5, PARIS, France, Paris, France

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Janus kinase inhibitors have been shown to ameliorate pain as well as inflammation in patients with rheumatoid arthritis (RA). Pain response trajectories were modeled in patients treated with filgotinib in the FINCH 1 trial.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure. Pain trajectories in patients from FINCH 1 receiving filgotinib 200 mg

CI, confidence interval; VAS, visual analog scale

Methods: FINCH 1 (NCT02889796) was a 52-week trial in which patients with RA and an inadequate response to methotrexate (MTX) received filgotinib 200 mg or 100 mg, adalimumab or placebo, each with MTX. Patients reported pain on a visual analog scale (VAS) ranging from 0 mm (no pain) to 100 mm (worst possible). Moderate pain was defined as a score of 40–60 mm, with scores >60 mm indicating severe pain. Group-based trajectory modeling[1] was used to identify patient groups with similar pain responses over a 12-month period.

Results: Among patients receiving filgotinib 200 mg (n=475), modeling produced five distinct groups of pain response trajectory (**Figure**). Age, disease duration and erosion score were similar across all groups at baseline. Groups A and B (45% of patients) had a rapid reduction in pain in the first 3 months, with the improvement maintained over 12 months. Group A had the greatest reduction in pain. Groups C and D (35% of patients) had a slower response but achieved a 50% pain reduction after 6 months. Group E (20% of patients) had severe pain at baseline (mean VAS pain approx. 75 mm) and persistent, moderate pain over 12 months. Mean VAS pain score was < 40 mm at Month 3 in Groups A, B and C (approx. 60% of patients) and at Month 6 in Groups A, B, C and D (80% of patients).

At Months 3, 6 and 12, the greatest absolute changes in Disease Activity Score in 28 joints using C-reactive protein (DAS28-CRP) and 36-Item Short Form Survey (SF-36) Physical Component Summary (PCS) scores were seen in patients with the most rapid pain responses (Groups A and B) (**Table**). At Month 6, 50% of patients in Group A and 53% in Group B were in remission (by Clinical Disease Activity Index), compared with 3% in Group E (noted for highest median DAS28-CRP and lowest [worst] median SF-36 PCS score at baseline). At Months 6 and 12, the greatest improvements in patient's and physician's global assessment of disease activity occurred in Group A.

Lack of efficacy was the most common reason for discontinuation in Group E (10.5%); 2.1% discontinued due to adverse events. In Groups A, B, C and D, the leading reason for discontinuation was adverse events (6.1%, 4.4%, 7.0% and 8.5%, respectively), followed by lack of efficacy (5.1%, 2.7%, 5.8% and 7.3%, respectively).

Similar pain trajectories were observed in patients receiving filgotinib 100 mg (n=480).

Conclusion: Of patients with prior inadequate response to MTX treated with filgotinib 200 mg, 80% achieved a substantial reduction in pain within 6 months. The most rapid pain responses with filgotinib were associated with the greatest improvements in other disease-related measures. Overall, these data illustrate the heterogeneity of treatment response in patients with RA and underscore the importance of communicating realistic expectations and timelines to patients.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid Arthritis (RA) is a chronic autoimmune disease characterized by autoreactive B cells that produce anti-citrullinated protein antibodies (ACPA), contributing to sustained synovial inflammation and joint destruction. Recent clinical reports indicate that anti-CD19 chimeric antigen receptor (CAR) T-cell therapy shows promise in

Table 1. Screening characteristics of apheresed RA patients

Parameter	Pat. 1	Pat. 2	Pat. 3	Pat. 4	Pat. 5	Pat. 6	Mean (SD)

inducing drug-free clinical remission in difficult-to-treat RA (D2T-RA, Lidar 2025; Li 2025). The COMPARE (COMparison of B-cell dePletion by rituximAb and anti-CD 19 CAR-T therapy in Patients with rhEumatoid arthritis) trial was designed to (i) evaluate the safety and efficacy of the anti-CD19 CAR-T cell therapy KYV-101 in ACPA-positive patients with active, treatment refractory D2T-RA and (ii) to compare the impact of KYV-101 on disease activity to the standard-of-care anti-CD20 monoclonal antibody rituximab (RTX). KYV-101 is a fully human, autologous anti-CD19 CAR T-cell therapy with CD28 costimulation, which is under investigation in B-cell driven autoimmune disease. With a single administration, KYV-101 has potential to achieve durable drug-free and disease-free remission via deep B-cell depletion and immune reset. Preliminary data suggest its potential for durable effects across rheumatic (Albach 2025, Minopoulou 2025, Haase 2025) and neuroimmune indications (Haghikia 2023; Faissner 2024).

Methods: COMPARE, an open-label, randomized, controlled Phase 1/2 trial (EU CT:2024-514955-13-00) is currently enrolling the safety run-in of the trial (Phase 1; n=6) during which all participants receive 1×10^8 CAR T cells after lymphodepletion. The primary endpoint in Phase 1 is safety (Cytokine Release Syndrome (CRS), Immune Cell Associated Neurotoxicity Syndrome (ICANS), adverse events). Additional endpoints include pharmacokinetics of KYV-101, B-cell and autoantibody levels, and disease activity scores.

Results: At the time of submission, Phase 1 is fully recruited with 6 participants apheresed; two participants have received KYV-101 by 12 May 2025, with follow-ups up to 28 and 56 days. Participants had active disease for a mean of 10.8 (±6.9) years duration and 5.8 (±1.7) prior therapies (Table 1). Both treated participants experienced expected transient cytopenias due to lymphodepletion and CRS (grade I and II), which promptly resolved following tocilizumab and dexamethasone administration. No ICANS, serious adverse events or deaths occurred. CAR T-cells expanded rapidly, reaching peaks of 479 and 122 cells/mL at days 21 and 10 after KYV-101 infusion. Both patients exhibited complete peripheral B-cell depletion and a decline in ACPA values to 19% and 5% of screening values at the latest follow-up.

Conclusion: Preliminary data from the COMPARE trial suggest that KYV-101 has a favorable safety profile and leads to robust CAR T-cell expansion and complete peripheral B-cell depletion in seropositive, active, treatment refractory D2T-RA. With apheresis completed and planned KYV-101 infusion for all Phase 1 patients by July 2025 completion of safety run-in is anticipated shortly, followed by the randomized portion of the trial. Updated data summarizing Phase 1 experience with estimated follow-up post-infusion of 4 months will be presented.

Detrimental Effects of Umbilical Cord Blood-derived Mesenchymal Stem Cells Intra-articular Injections on Pannus Invasiveness

Sung Eun Kim[1], Hye Lim Kang[1], Min Jung Kim[2], Hyung-Sik Kim[3] and **Kichul Shin**[4], [1]Division of Rheumatology, Department of Internal Medicine, SMG-SNU Boramae Medical Center, Seoul, Republic of Korea, [2]Seoul Metropolitan Government Boramae Medical center, Dongjak-gu, Seoul, South Korea, [3]Department of Oral Biochemistry, Pusan National University School of Dentistry, Yangsan, Republic of Korea, [4]Seoul National University, Seoul, South Korea

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Studies have shown that mesenchymal stem cell (MSC) infusion ameliorates arthritis in animal models. However, the first-pass effect in the lung has directed attention to other routes of administration for MSCs. We aimed to investigate the impact of intra-articular MSC injections in mice with arthritis and its underlying mechanism.

Methods: An indirect co-culture of umbilical cord blood-derived (UCB-) MSC and fibroblast-like synoviocytes from patients with rheumatoid arthritis (RA-FLS) was conducted to study the altered traits of proliferation, migration, and invasion of RA-FLS. We utilized proteomics to analyze the outcomes of the co-culture in both cell types. CIA was induced in DBA/1 mice, followed by a single intra-articular injection in the ankle on day 28. The mice were euthanized on day 42 for histological analyses. Recombinant transforming growth factor-beta-1-induced transcript 1 (TGFB1I1) and anti-TGFB1I1 were employed in subsequent experiments to investigate the mechanisms of the transformed milieu in the synovium.

Results: The proliferation, mobility, and invasiveness of RA-FLS were enhanced when co-cultured with UCB-MSC (Figure 1). While intravenous UCB-MSC reduced the severity of arthritis in mice, intra-articular injection of UCB-MSC resulted in significant arthritis in the injected ankle compared to the contralateral side (Figure). The proteomic analysis revealed a substantial expression of TGB1I1 in RA-FLS co-cultured with UCB-MSC and even higher levels in UCB-MSCs. Indeed, TGB1I1 was highly expressed in UCB-MSC-injected ankles of CIA mice. Furthermore, TGB1I1 not only induced cytoskeletal rearrangement in RA-FLS but also promoted the gene expression of IL-1beta, IL-8, MMP-3, and MMP-13, thereby contributing to both joint inflammation and damage. TGB1I1 knockdown resulted in significantly reduced mobility of FLS co-cultured with UCB-MSC.

Conclusion: Intra-articular injection of UCB-MSCs into inflamed joints inexplicably induces detrimental effects that may expedite joint damage and perpetuate systemic inflammation. MSC therapy may act as a double-edged sword depending on its route of administration in patients with rheumatoid arthritis.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Peresolimab, a humanized IgG1 mAb, activates programmed cell death protein 1. In a phase 2a study, peresolimab demonstrated efficacy in participants (pts) with RA who had an inadequate response to prior DMARDs.[1] Here, we present data from a phase 2b dose-ranging study of peresolimab.

Methods: This double-blind, placebo (PBO)-controlled study in adults with moderately to severely active RA (N=490) randomized pts (1:2:2:2) to 100 mg (n=68), 400 mg (n=141), or 1000 mg (n=141) peresolimab or PBO (n=140) subcutaneously (SC) every 4 weeks (Q4W). At Week 12, pts receiving peresolimab continued their assigned dose; those receiving PBO switched (1:1) to 400 mg (n=67) or 1000 mg (n=73) peresolimab SC Q4W. The primary endpoint was 20% improvement in ACR response (ACR20) at Week 12; secondary endpoints included ACR50 and DAS28-CRP change from baseline (BL) at Week 12. Safety through 12 weeks and malignancies and possible major adverse cardiovascular events (MACE) through Week 60 are presented. A logistic regression model with treatment group, BL disease activity, and stratification factors as covariates was used for dichotomous endpoints. Missing data were imputed as non-response. A mixed-effects model for repeated measures with treatment group, BL disease activity, stratification factors, visit and treatment-by-visit interaction as fixed factors and pts as a random factor was used for continuous endpoints. Nominal p values are reported.

Results: At BL, the mean (SD) age was 54.0 (11.3) yrs, RA duration was 11.6 (8.2) yrs, and DAS28-CRP score was 5.97 (0.86); 92.4% were RF positive and 85.9% were anti-CCP positive, 33.5% were biological/target synthetic (b/ts) DMARD

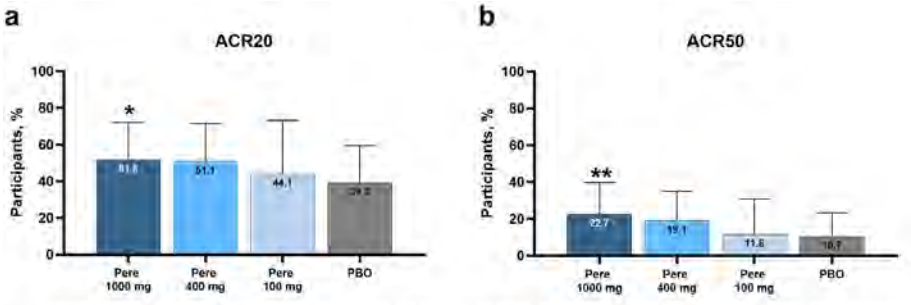

Figure 1. Proportion of participants with ACR20 and ACR50 response at Week 12.

Serious infection	2 (1.4)	1 (0.7)	0	2 (1.4)
Infection leading to permanent discontinuation	0	1 (0.7)	0	0
Potential OI	1 (0.7)	1 (0.7)	0	0
Confirmed OI	0	0	0	0
Malignancies	2 (1.4)	2 (1.4)	0	0

Data are n (%).
[a]Participants with multiple occurrences of the same event are counted under the highest severity.
AESI, adverse event of special interest; OI, opportunistic infection; SAE, serious adverse event; TEAE, treatment-emergent adverse event

naïve, and 82.4% were female. A total of 30 (44.1%; p=0.534), 72 (51.1%; p=0.098), and 73 (51.8%; p=0.014) pts who received 100, 400, or 1000 mg peresolimab, respectively, achieved ACR20 at Week 12 vs 55 (39.3%) who received PBO (Figure 1a). Similarly, ACR50 at Week 12 was significantly different (p=0.003) in pts receiving 1000 mg peresolimab vs PBO but not for 400 mg (p=0.102) or 100 mg (p=0.741) peresolimab vs PBO (Figure 1b). The least squares mean (standard error) change from BL to Week 12 in DAS28-CRP was greater for pts receiving peresolimab 100 mg (-1.29 [0.15]), 400 mg (-1.41 [0.11]; p=0.030), and 1000 mg (-1.67 [0.11]; p< 0.001) vs PBO (-1.08 [0.11]). Treatment-emergent adverse events (AEs) were similar across groups through Week 12 other than 2 malignancies in each the 400 mg and 1000 mg peresolimab dose groups (Table 1). After Week 12, an additional 4 malignancies (non-melanoma skin cancer events excluded) were reported up to Week 60; 9 possible MACEs were reported in pts receiving peresolimab through Week 60.

Conclusion: Peresolimab was superior to PBO at Week 12 for several key endpoints, but efficacy was not differentiated from existing treatment options. In context of observed efficacy combined with the number of reported malignancies and possible MACEs through week 60, the study was stopped based on the non-favorable benefit/risk profile for peresolimab in treating RA patients.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: The use of Janus Kinase inhibitors (JAKi) to treat RA and PsA in a real-world setting has not been well described. Our aim was to investigate the place in treatment pathway, retention and factors associated with discontinuation of JAKi prescribed for RA and PsA in routine care.

Methods: A retrospective review of all patients treated with Baricitinib (B), Filgotinib (F), Tofacitinib (T) and Upadacitinib (U) in 6 centres was conducted from time of first use of any of these agents in routine care until November 2024. Standardized data was collected including demographics, place in treatment pathway, concurrent MTX and CS use, duration of treatment and reason for discontinuation. Retention rate was calculated using Kaplan-Meier analysis. Factors associated with JAKi discontinuation were assessed by multivariable Cox regression analyses.

Results: The case notes of 985 patients were reviewed, 79.5% female, mean age 60 (range 19 - 89) years. The JAKi was B in 658 (67%), F in 127 (13%), T in 100 (10%) and U in 100 (10%). The disease indications were RA in 849 (86%; B 648, F

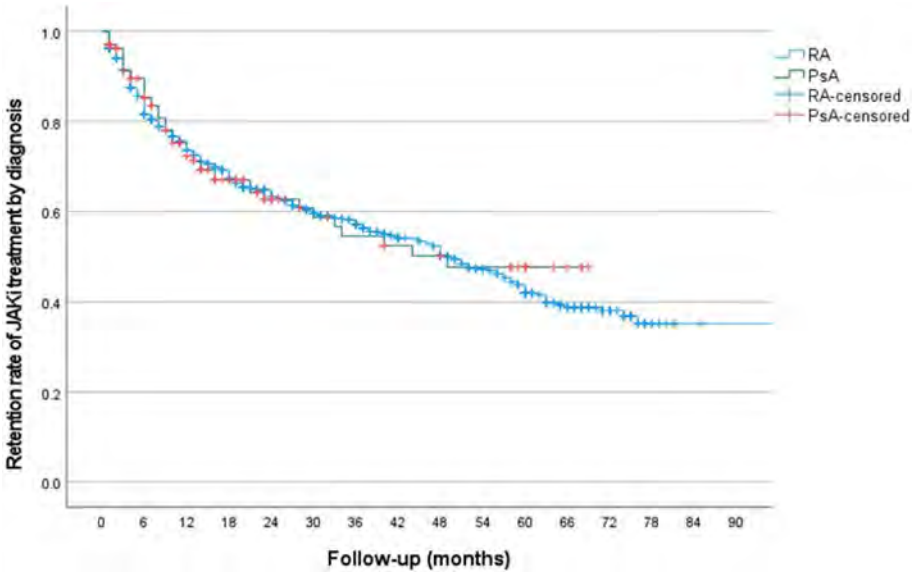

Figure 1. Kaplan Maier retention curve for patients with RA and PsA treated with any JAK inhibitor

127, T 47, U 27), PsA in 136 (14%; B 10, F 0, T 53, U 73). MTX was co-prescribed in 43%, subsequently discontinued in 6%. CS was co-prescribed in 34%, subsequently tapered in 18% and discontinued in 62%.

For all cases, JAKi were prescribed 1st line before biologic DMARD in 7.5%, 2nd line after bDMARD 13.7%, 3rd line 29% and 4th line or later in 49.8%. Median retention for all JAKi was 49 months (range 1-85, 95% C.I. 42.62-55.37), and 52.8% remained on treatment at time of analysis, with no difference between RA and PsA populations. The median retention on B was 52 months and T 24 months ($p< 0.0011$), with no difference in retention between other pairwise JAKi comparisons. See Figures 1 and 2.

Multivariable regression analyses showed a significantly higher relative risk of JAKi discontinuation for older age, female sex and treatment with Tofa compared to Bari. For RA patients co-prescription with MTX had a significantly lower risk of JAKi discontinuation, Table 1.

JAKi were discontinued in 46.4%; primary inefficacy 9.8%, secondary inefficacy 11.8%, adverse events 18.5% and 6.3% pre-emptively due to the Oral Surveillance study findings. There were no significant differences in reasons for discontinuation

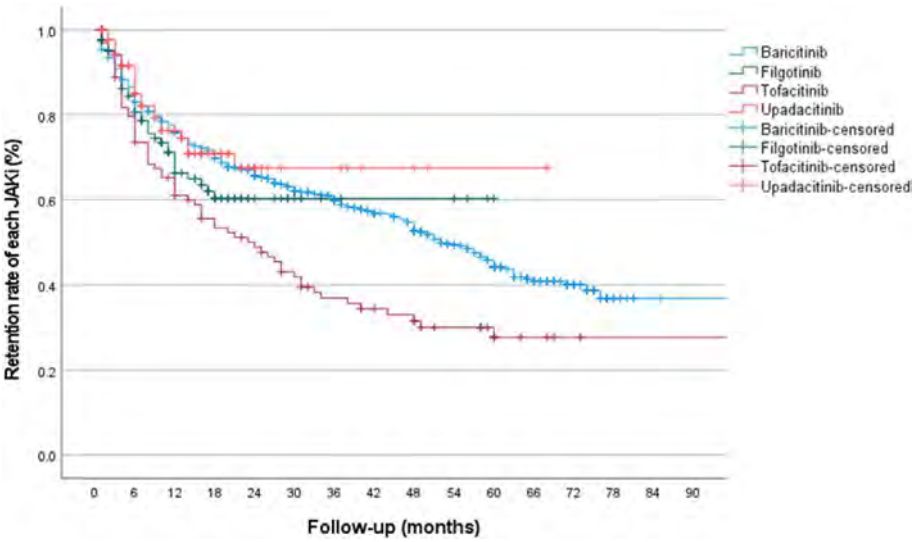

Figure 2. Kaplan Maier retention curve for all patients treated with individual JAK inhibitors

MTX co-prescription when JAKi started (yes vs no)	0.84 (0.70-1.01)	0.066	**0.81 (0.66-0.98)**	**0.032**	1.24 (0.66-2.34)	0.51
Steroid co-prescription when JAKi started (yes vs no)	1.11 (0.91-1.34)	0.32	1.10 (0.90-1.35)	0.36	1.10 (0.55-2.20)	0.78

JAKi: Janus kinase inhibitors; PsA: Psoriatic arthritis; RA: Rheumatoid arthritis

between RA and PsA, nor individual JAKi. Venous thromboembolic events (VTE) occurred in 1.4%, event rate 0.57 / 100 patient years; 10 pulmonary embolism (PE) and 4 deep vein thrombosis (DVT), with mean time to event 29 months, range 6 – 75 months. Other adverse events included cerebrovascular events in 1.2%, 0.49 / 100 patient years, cardiac events in 0.7%, 0.29 / 100 patient years and cancer in 0.9%, 0.37 / 100 patient years.

Conclusion: JAKi are generally used late in the DMARD treatment pathway in routine care, with high retention rates and a CS sparing effect was evident. Significantly higher risks for discontinuation were female sex, older age, Bari versus Tofa treatment, and in RA patients use without MTX. The place in treatment pathway conferred no effect on retention. Adverse events were in line with this class of immune suppressive therapies including VTE, where PE outnumber DVT events.

Table 1: Baseline characteristics of individuals transitioning from bio-originator to biosimilars.

Characteristic	N (%), mean (SD), or median (IQR)
Biosimilar, N (%)	
Adalimumab	75 (68.2)
Etanercept	22 (20.0)
Rituximab	12 (10.9)
Infliximab	1 (0.9)
Female sex, N (%)	67 (60.9)
Age in years, mean (standard deviation, SD)	56.9 (15.8)
Disease duration in years, mean (SD)	19.3 (12.6)
Body mass index, mean (SD)	29.0 (6.6)
Current smoker, N (%)	18 (16.4)
Current alcohol drinker, N (%)	21 (19.1)
Use of biologic (other than the originator) in the past year, N (%)	33 (30.0)
Current use of synthetic disease-modifying antirheumatic drugs, N (%)	58 (53.2)
Health Assessment Questionnaire (HAQ) score, median (interquartile range, IQR, Q1-Q3)	1.1 (0.6-1.6)
Modified HAQ* score, median (IQR)	1.1 (0.9-1.6)

*HAQ for the RHUMADATA cohort and Modified HAQ for EUPA cohort and USRAT

Background/Purpose: In April 2022, the Canadian province of Quebec introduced a mandatory non-medical switch to biosimilars for persons on bio-originators to manage healthcare costs. Our objective is to describe real-world experience with biosimilars used for inflammatory arthritis in the context of this policy change.

Methods: We used data from three adult clinical registries in Quebec: the RHUMADATA prospective arthritis registry, the Early Undifferentiated Polyarthritis (EUPA) cohort, and the University of Sherbrooke Registry of Advanced Therapies (USRAT). We studied individuals who transitioned from the originator biologics to their equivalent biosimilars – infliximab, etanercept (ETA), adalimumab (ADA), and rituximab– from the time of the non-medical switching policy (April 2021) through May 2023. The study period began one year before the implementation of the non-medical switching policy to capture the transition phase leading up to and following the policy's introduction.Baseline characteristics were assessed at the time of biosimilar initiation, including age, sex, underlying condition (ankylosing spondylitis, rheumatoid arthritis, psoriatic arthritis), disease duration, body mass index, alcohol and tobacco use, and quality of life (Health Assessment Questionnaire for RHUMADATA, and the Modified HAQ for EUPA and USRAT). Prior medication history, including other biologics, corticosteroids, and non-biologic immunosuppressants, was also reviewed. Reasons for discontinuation were documented by treating physicians. Discontinuation was estimated using Kaplan-Meier methods.

Results: We studied 110 individuals with inflammatory arthritis, most switching to ADA (68%) or ETA (20%) biosimilars. Females were 61% of the cohort, and at biosimilar transition, the mean age was 56.9 years (standard deviation 15.8). Additional baseline characteristics are presented in Table 1. Individuals were followed for a median of 1.5 years (interquartile range 0.5 to 1.9 years). During this time, 16 individuals discontinued their treatment, for a discontinuation rate of 115.7 (95% confidence interval, CI 66.1-187.8) events per 1,000 person-years. As seen in Figure 1, the probability of discontinuation was 11.2% (95% CI: 4.4%-17.6%) by Year 1 and 18.2% % (95% CI: 9.3% to 26.2%) by Year 2. The most common reason for discontinuation was treatment failure in 7 individuals.

Conclusion: Among individuals with arthritis who underwent mandatory non-medical switching from bio-originators to biosimilars, about 80% remain on the biosimilar at 2 years. Thus, discontinuation rates appear consistent with those observed among experienced biologic users, suggesting relative stability despite the policy-driven switch.

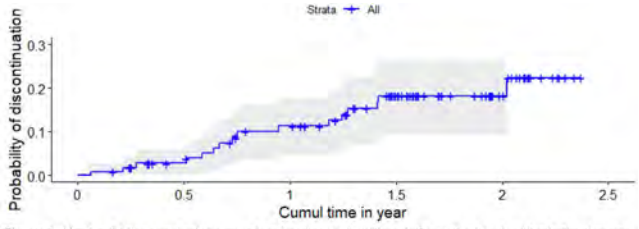

Figure 1. Kaplan-Meier survival curves showing the probability of discontinuing the biosimilar therapy over follow-up, with shaded areas representing 95% confidence intervals (95% CI).

Impact of Comorbidity Burden on the Efficacy of, a Direct Interleukin 6 Inhibitor, Olokizumab: Real World Evidence

Maxim Korolev[1], Alexander Dubikov[2], Daria Bukhanova[3], Alina Egorova[3], Eugenyi Alekseev[4], **Sofia Kuzkina**[5] and Mikhail Samsonov[3], [1]Research Institute of Clinical and Experimental Lymphology – Branch of the Institute of Cytology and Genetics, Siberian Branch of Russian Academy of Sciences, Novosibirsk, Russia, [2]Rheumatology clinic of Professor Dubikov A.I., Vladivostok, Russia, [3]R-Pharm JSC, Moscow, Russia, [4]"R-Pharm", JSC, Moscow, Russia, [5]R-Pharm, Moscow, Russia

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Comorbidities may affect the efficacy of bDMARDs in rheumatoid arthritis (RA). Post-hoc analysis of the randomized clinical trial (RCT) data shows that the efficacy of the direct IL-6 inhibitor olokizumab (OKZ) does not depend on the comorbidity burden [1,2]. However, information about the impact of comorbidities on the OKZ effectiveness in routine clinical practice is lacking. The study purpose was to determine the impact of comorbidity burden on the OKZ efficacy in RA patients in the real-world data (RWD) study.

Methods: Biologic DMARDs (bDMARD)-naive patients with RA on methotrexate ± glucocorticoids (GC) inefficacy who received OKZ for at least 24 weeks were included in our retrospective RWD study.

To assess the impact of comorbid conditions on effectiveness, we used Rheumatic Disease Comorbidity Index (RDCI). Patients were stratified into two groups based on the baseline RDCI score: "RDCI-L" (RDCI ≤ 1) vs "RDCI-H" (RDCI ≥ 2). The following effectiveness variables were analyzed at Week 24 after treatment initiation: proportion of patients that achieved SDAI ≤ 3.3, CDAI ≤ 2.8 and ≤ 10, DAS28(ESR) ≤ 2.6 and ≤ 3.2. To address the imbalance in baseline parameters across comorbidity groups, an optimal 1:1 propensity score matching algorithm based on logistic regression model was employed. Odds Ratios (ORs) with 95% Confidence Intervals (CIs) were estimated using logistic regression to present the study findings. A p value < 0.05 was considered statistically significant.

Results: In the general group of patients, 77.9% had comorbidities: cardiovascular diseases - 41.4%, osteoarthritis-24.3%, osteoporosis-16.4%, gastrointestinal diseases-11.5%, diabetes-7.4%, kidney damage-4.2%, lung damage-3.9%.

Overall, 222 patients treated with OKZ 64 mg q2w or q4w were included in the analysis (per 111 patients in RDCI-L and RDCI-H groups). The baseline characteristics were similar in both groups and are presented in the Table 1. The median values of baseline RA activity corresponded to high disease activity.

There was no significant difference in the effectiveness results between RDCI-L and RDCI-H groups (Table 2), similar proportions of patients achieved low disease activity and remission in both groups (p > 0.05). These findings align with the general trend observed in previous research of OKZ efficacy in relation to comorbidity burden in RCT.

Background/Purpose: Previous studies, including TASER and ARTIC (1,2), failed to demonstrate a significant benefit of ultrasound (US) compared to clinical evaluation in achieving clinical remission or slowing structural progression in rheumatoid arthritis (RA). Despite these findings, the role of US in the follow-up of RA patients remains debated. This study aimed to determine whether radiographic progression at 1 year (primary end point) and 2 years, differs in RA patients followed by rheumatologists aiming for remission without synovitis (including the 28 articulations included in the SDAI and the 10 MTPs), using either Doppler-mode US, B-mode US, or clinical evaluation alone.

Methods: The BCD study (NCT02410304) was a prospective, multicenter, randomized, pragmatic clinical trial conducted across 10 hospitals in France from 2014 to 2018. RA patients, diagnosed with RA according to the 2010 ACR/EULAR criteria and on stable treatment, were randomized in a 1:1:1 ratio. Patients were followed every 3 months for 1 year with a remission target (no synovitis, no painful joints, patient visual analog scale ≤1/10, and normal C-reactive protein) assessed through:

1. **D-mode US**: Doppler evaluation of 38 joints (10 PIP, MCP, 2 wrists, 2 elbows, 2 shoulders, 2 knees, 10 MTP).
2. **B-mode US**: A combination of clinical evaluation for 26 joints and B-mode US for MTP and shoulders.
3. **C-mode**: Clinical evaluation only.

All patients underwent US and radiographic assessments (Sharp-van der Heijde scores: SvHD) at baseline, 12 months, and 24 months. Radiographic progression, the primary endpoint, was defined as an increase of >1 point in the SvHD score at 12 months. Between-group comparisons of radiographic evolution were conducted using a generalized linear model with binary distribution and log link, adjusted for center as a random effect.

Results: 545 patients were randomized, and 513 were analyzed at 12 months (169 C-mode, 171 B-mode, 173 D-mode). Baseline characteristics were similar across groups. Mean age was 58.12 (12.05 SD) years and mean RA duration was 11.79 (9.89 SD) years. 41.9% of patients were in remission according DAS-CRP. Radiographic progression (>1 point increase in Sharp score) at 12 months did not significantly differ between groups (Table 1). In contrast, B-mode US was associated with a higher proportion of global high radiographic progression compared to C-mode at 24 months.

Conclusion: Although US detect more synovitis than clinical evaluation, neither D-mode nor B-mode US guided therapy slowed radiographic progression during follow-up compared to clinical evaluation guided therapy alone.

Table 1: radiographic evolution at M12 according to the follow-up

	C-Mode N= 183	B-Mode N=179	D-Mode N= 183	RR (IC 95%) B versus C	p-value	RR (IC 95%) D versus C	p-value
Erosion and narrowing (>1pt) n (%)	40 (28.2%)	42 (30.2%)	49 (33.3%)	1.02 [0.71, 1.45]	0.9343	1.13 [0.8, 1.58]	0.4927

Racial and Ethnic Disparities in DMARD Use and in Medicare Part B-Covered Options Among Medicare Beneficiaries with Late-Onset Rheumatoid Arthritis

ashkan ara[1], John FitzGerald[2] and Susan Ettner[2], [1]UCLA Health, Los Angeles, CA, [2]UCLA, Los Angeles, CA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Biologic and targeted synthetic DMARDs can substantially improve the quality of life for Medicare beneficiaries with rheumatoid arthritis (RA). However, racial and ethnic disparities in their use, particularly those covered by Part B, have not been well studied in this population. Medicare defines any drug costing over $670 per patient per month as a "specialty" drug, which encompasses all biologic and targeted synthetic DMARDs. We examined racial and ethnic differences in 12-month use of any DMARD, specialty DMARDs, and the Part B-covered subset in a large cohort of Medicare enrollees with late-onset RA.

Methods: We used 20% Sample Medicare claims from 2016-2020 to establish an incident cohort of late-onset RA, defined as ≥2 outpatient ICD-10 RA codes 7-365 days apart following a 12-month washout. Eligible beneficiaries were ≥65 years old, continuously enrolled in Medicare Parts A/B/D, and had no other indication for DMARD use. Outcomes included receipt of (1) any DMARD, (2) specialty DMARDs, and (3) Part B-covered subset within 12 months of case identification. The main

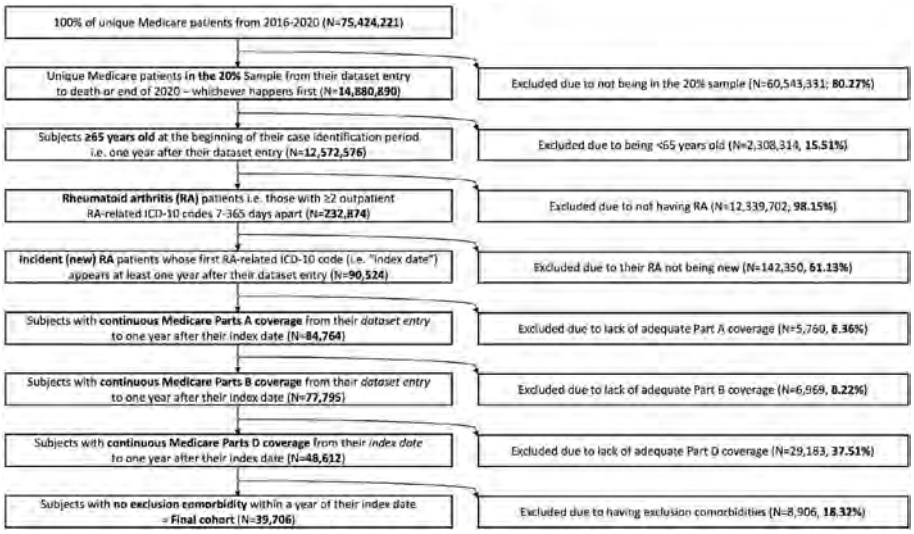

Figure: Flow diagram depicting the establishment of a cohort with incident late-onset RA among Medicare beneficiaries (2016-2020).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1: Baseline characteristics of the included patients, overall and by receipt of first DMARD (any), first specialty DMARD, and first Part B-covered specialty DMARD (i.e. office- or infusion-center–administered) within 12 months of case identification.

Characteristic	All Participants (N=39,706)	Received DMARD (N=14,190)	Received Specialty DMARD (N=1,906)	Received Part B-covered DMARD (N=1,363)
Race & Ethnicity: N (%)				
Non-Hispanic White	30,723 (77.4 %)	11,147 (78.6 %)	1,489 (78.1 %)	1,176 (86.3 %)
Black or African-American	3,688 (9.3 %)	1,241 (8.7 %)	171 (9.0 %)	84 (6.2 %)
Hispanic	3,201 (8.1 %)	1,057 (7.4 %)	145 (7.6 %)	61 (4.5 %)
Other	2,094 (5.3 %)	745 (5.3 %)	101 (5.3 %)	42 (3.1 %)
Sex: N (%)				
Male	10,847 (27.3 %)	3,946 (27.8 %)	586 (30.7 %)	378 (27.7 %)
Female	28,859 (72.7 %)	10,244 (72.2 %)	1,320 (69.3 %)	985 (72.3 %)
Low-income Subsidy (LIS): N (%)				
No	28,893 (72.8 %)	10,679 (75.3 %)	1,455 (76.3 %)	1,226 (89.9 %)
Yes	10,813 (27.2 %)	3,511 (24.7 %)	451 (23.7 %)	137 (10.1 %)
Age at Index Date: Mean (SD)	75.9 (7.2)	74.7 (6.7)	73.8 (6.5)	73.2 (5.6)

regressor was race and ethnicity (non-Hispanic White reference). Covariates included age, sex, and low-income subsidy status (LIS). We performed multivariable logistic regressions for each outcome, incorporating calendar-month and calendar-year fixed effects, and reporting adjusted ORs (aORs) with 95% CIs.

Results: Among 39,706 beneficiaries with incident late-onset RA (Figure), 14,190 (35.7%) received any DMARD, 1,906 (4.8%) a specialty DMARD, and 1,363 (3.4%) a Part B–covered specialty DMARD within 12 months (Table 1). The most common first DMARDs included:

- *Any DMARD*: methotrexate (6,154), hydroxychloroquine (5,229), and leflunomide (850);
- *Specialty*: abatacept (278; both formulations), certolizumab (274; both formulations), and infliximab (259);
- *Part B-covered subset*: certolizumab (270), infliximab (255), and abatacept (253).

In multivariable models (Table 2) Black patients (aOR: 0.92) had significantly lower odds of receiving any DMARD than non-Hispanic White patients. Race and ethnicity were not associated with differential receipt of specialty DMARDs. However, in the Part B-covered subset, Black (aOR 0.78), Hispanic (aOR 0.75), and Other (aOR 0.63) patients had significantly lower odds of receiving these agents compared to non-Hispanic White patients.

Also, LIS was associated with 14%, 15%, and 67% lower odds of any DMARD use, specialty DMARD use, and the Part B-covered subset, respectively. Moreover, each additional year of age was associated with 4%, 5%, and 6% lower odds of any DMARD use, specialty DMARD use, and Part B therapy use, respectively (with mild nonlinearity modeled via age^2). Furthermore, female sex was associated with 13% lower odds of specialty DMARD use.

Conclusion: Part B-covered DMARDs exhibited the most pronounced disparities: Black, Hispanic, and Other non-White patients were 22-37% less likely to receive these therapies. This gap is particularly concerning because, despite the inconvenience of office or infusion-center administration, Part B agents carry lower coinsurance than Part D's specialty tier, representing a key cost-saving opportunity that non-White beneficiaries may be missing.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Abstract Number: 0479

Risk of Arrhythmias Following IL-6 Inhibitor Use; A Pharmacosurvellience Study of FDA Adverse Event Reporting System (FAERS)

Asim Khanfar[1], Omar Hamdan[2], Shiamak Cooper[3], Sanjana Thimmannagari[1] and Anthony Ocon[4], [1]Rochester General Hospital, Rochester, NY, [2]University of Jordan, Az-Zarqa, Jordan, [3]Rochester General Hospital, Irondequoit, NY, [4]Rochester Regional Health, Fairport, NY

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Interleukin-6 (IL-6) inhibitors, including tocilizumab and sarilumab, are immunomodulatory agents commonly used in the treatment of rheumatoid arthritis and COVID-19. Prior studies have implicated IL-6 signaling in the pathogenesis of various cardiovascular disorders, including atrial fibrillation and other arrhythmias, raising concerns about potential pro-arrhythmic effects of IL-6 inhibition. To further characterize this risk, we conducted a pharmacovigilance analysis using the FDA Adverse Event Reporting System (FAERS) to evaluate the incidence and nature of arrhythmias associated with IL-6 inhibitor use.

Methods: The FAERS database was searched for cardiac arrhythmias (Tachycardia, bradycardia, atrial fibrillation, QRS complex abnormalities, QT interval abnormalities, bundle branch block (BBB), atrioventricular blocks (AV blocks) and supraventricular tachycardia (SVT)) associated with the use of IL-6 inhibitors (tocilizumab, sarilumab, and siltuximab). Data were reported as frequencies and as reporting odds ratios (ROR) with a 95% confidence interval (95% CI).

Results: We analyzed 30,179,725 adverse event reports from the FAERS database. A total of 107,540 reports were associated with the use of the three anti-IL-6 drugs; 78.3% of them were females, with cardiac arrhythmias being reported in 1% of them. Most of the cases were associated with tocilizumab (85.5%), followed by sarilumab (13.8%). Tachycardia was the most common arrhythmia among tocilizumab users, which was reported in 668 cases, followed by bradycardia, which was reported in 134 cases. Among all arrhythmias tested, only tachycardia and BBB were significantly higher among tocilizumab users compared to all other drugs (ROR=1.959; 95% CI: 1.815 – 2.114) and (ROR=3.599; 95% CI: 2.364 – 5.479), respectively. In addition, siltuximab users had significantly higher odds of atrial fibrillation compared to all other drugs users (ROR=1.3.114; 95% CI: 1.163 – 8.339) (Table 1). When the three anti-IL-6 medications were put into a head-to-head comparison, tocilizumab had the highest ROR of causing tachycardia, bradycardia, SVT, and AV block. However, siltuximab users had the highest odds of causing QT prolongation (ROR=18.73; 95% CI: 6.770 – 51.80) (Table 2).

Conclusion: IL-6 inhibitors, particularly tocilizumab and siltuximab, are associated with increased reporting of specific arrhythmias. These findings highlight the need for arrhythmia monitoring in susceptible patients receiving IL-6 inhibitors. Further studies are needed to clarify causality and the mechanisms underlying these associations.

Abstract Number: 0480

Efficacy and safety of tacrolimus and its serum concentration in patients with rheumatoid arthritis with inadequate response to methotrexate

Chan-Bum Choi, Hanyang University Hosptial for Rheumatic Diseases, Seoul, Republic of Korea

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Addition of a biologic disease-modifying antirheumatic drug (bDMARD) or targeted synthetic DMARD (tsDMARD) is recommended in patients with rheumatoid arthritis (RA) with inadequate response to methotrexate.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Current reimbursement, but the Korean National Health Insurance Service requires moderate to high disease activity with at least 6 months' treatment with at least two conventional synthetic DMARDs (csDMARDs). Triple therapy with the addition of hydroxychloroquine and sulfasalazine is often used. Methotrexate plus leflunomide or tacrolimus is also used. Drug levels of tacrolimus in patients with RA and their correlation with efficacy and safety were assessed

Methods: A retrospective medical record review of patients with RA who had fulfilled the 2010 ACR/EULAR classification criteria for RA and had initiated treatment with tacrolimus was performed. Serum tacrolimus concentration was measured after six months of treatment with tacrolimus. Disease Activity Score 28 (DAS28) and renal function were assessed at initiation of tacrolimus and after six months. ACR20 responses were assessed at 6 months.

Results: A total of 189 patients were assessed. The mean age was 61.4 ± 11.7 years, and 88.9% were female. Mean DAS28 at baseline was 3.48 ± 1.77 with a mean serum creatinine level of 0.7 ± 0.2 mg/dl and a mean Glomerular Filtration Rate (GFR) of 98.9 ± 15.0. Mean dose of tacrolimus was 1.3 ± 0.5 mg. At six months, the mean DAS28 was 2.98 ± 1.33 with a mean serum creatinine level of 0.7 ± 0.6 mg/dl and a mean GFR of 99.4 ± 14.8. Mean tacrolimus concentration at six months was 3.5 ± 2.6 ng/ml, with the highest being 14.8 ng/dl. A total of 117 (63.9%) patients showed tacrolimus levels below 3 ng/dl, 51 (27.9%) patients showed 3 -7 ng/d, and 21 (11.1%) showed over 7 ng/dl. ACR20 response rates at six months were 44.9% for patients with tacrolimus levels less than 3 ng/dl and 34.7% for those with greater than 3 ng/dl without significant differences. There was no significant increase in serum creatinine levels and GFR at six months, and the differences were not significant according to the serum tacrolimus drug concentration levels.

Conclusion: Tacrolimus at low doses showed clinical efficacy in patients with RA with inadequate response to methotrexate, and there was no significant increase in serum creatinine. All patients showed serum tacrolimus levels below the recommended 15 ng/dl, and there were no significant differences in efficacy and renal function by serum tacrolimus concentration.

Intracellular Methotrexate Polyglutamate Profiles Do Not Correlate with Early Clinical Response in Treatment-Naïve Rheumatoid Arthritis: A Prospective Study

Chandrashekara MN[1], AASTHA KHULLAR[2], Bidyalaxmi Leishangthem[3], Shankar Naidu[4], Varun Dhir[5] and Sanjay Jain[4], [1]PGIMER, Chandigarh, Chandigarh, India, [2]Postgraduate Institute of Medical Education and Research, CHANDIGARH, Chandigarh, India, [3]PGIMER, Chandigarh, India, Chandigarh, Chandigarh, India, [4]Post graduate Institute of Medical Education and Research, Chandigarh, Chandigarh, Chandigarh, India, [5]PGIMER, CHD, INDIA, CHANDIGARH, Chandigarh, India

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Methotrexate (MTX) polyglutamates (MTX-PGs), the intracellular active forms of MTX, are hypothesized to reflect cumulative exposure and potentially predict therapeutic efficacy in rheumatoid arthritis (RA). Prior studies have shown contrasting results. This study aimed to assess association of total MTX-PG levels, PG1–PG5 with EULAR response at 16 weeks in treatment-naïve RA patients undergoing standardized MTX escalation.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1: Univariate analysis to identify predictors of response from baseline variables and MTX-PG levels.

Variable	Responders (Mean ± SD)	Non-responders (Mean ± SD)	p-value
BMI, Kg/m	23.97 ± 5.02	27.14 ± 8.05	0.108
Duration of RA (months)	15.91 ± 12.56	24.00 ± 11.31	0.062
Age (years)	42.04 ± 11.73	41.90 ± 10.65	0.973
Baseline DAS28-CRP	6.00 ± 1.05	5.47 ± 1.67	0.189
CRP (mg/L)	26.64 ± 28.60	36.75 ± 31.77	0.316
Total MTX-PG (nM)	112.05 ± 54.08	112.26 ± 73.08	0.992
Short-chain MTX-PG (MTX PG1-2) (nM)	36.48 ± 21.97	41.38 ± 31.40	0.547
Long chain MTX PG (MTX PG3-5) (nM)	75.56 ± 43	69.86 ± 58.74	0.73

Methods: This was a prospective observational cohort study including 65 treatment-naïve RA patients initiated on oral or subcutaneous MTX using a standardized protocol. At 16 weeks, MTX-PG levels (total, PG1–PG5, short-chain-MTX PG1-2, long-chain-MTX PG3-5) were measured using HPLC. The primary outcome was EULAR response at week 16 (Good, Moderate, None). Descriptive statistics, independent t-tests, ANOVA, Tukey post hoc analysis, and logistic and linear regression were used to explore associations between MTX-PG levels and response, adjusting for age, sex, BMI, RA duration, route of administration, baseline CRP, and DAS28.

Results: A total of 65 seropositive treatment-naïve rheumatoid arthritis (RA) patients were included. The median age was 44.5 years (interquartile range [IQR]: 38–53), and 76.9% were female. 86.2% were RF-positive and 95.4% were anti-CCP–positive. The median disease duration at baseline was 17.2 months (IQR: 12–24), and the median baseline DAS28-CRP was 5.9 (IQR: 5.2–6.6)

Among 65 patients, 21 (32.3%) achieved Good response, 34 (52.3%) Moderate, and 10 (15.4%) No response. **No significant difference** was found in total MTX-PG levels between responders (good and moderate) and non-responders (112.05 ± 54.1 vs 112.26 ± 73.1 nM; p = 0.992). Also, short-chain and long-chain MTX-PG levels did not differ significantly. Univariate analysis showed a trend toward higher BMI and longer RA duration in non-responders.

Table 2. Multivariable Logistic Regression for EULAR Response at 16 Weeks

Variable	Adjusted OR (95% CI)	p-value
Total MTX-PG (nM)	1.00 (0.99–1.01)	0.831
Short-chain MTX-PG (PG1–2)	1.01 (0.97–1.06)	0.627
Long-chain MTX-PG (PG3–5)	1.01 (0.99–1.03)	0.211
BMI (kg/m²)	1.03 (0.91–1.16)	0.607
RA Duration (months)	1.00 (0.94–1.07)	0.909
MTX Route (SC vs Oral)	0.52 (0.10–2.61)	0.430
Cumulative MTX Dose (mg)	1.01 (0.99–1.03)	0.413
Baseline CRP (mg/L)	1.00 (0.97–1.03)	0.841
Baseline DAS28-CRP	1.24 (0.67–2.31)	0.487

Note: OR = Odds Ratio, CI = Confidence Interval, SC = Subcutaneous,

MTX = Methotrexate. Multivariable logistic regression model adjusted for listed variables.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

However, ANOVA revealed significant higher PG3 levels with moderate responders showing higher PG3 than good responders (p = 0.025, Tukey). Multivariable logistic regression did not identify any independent predictors of EULAR response. In linear regression, age was the only significant predictor of total MTX-PG levels (p = 0.033).

Conclusion: In this real-world prospective study, neither total MTX-PG levels nor specific PG subtypes independently predicted EULAR response at 16 weeks. Further studies incorporating longitudinal sampling, genetic polymorphisms, and safety outcomes are warranted to clarify the pharmacodynamic utility of MTX-PG monitoring in RA.

Abstract Number: 0482

R-2487, a Synthetic Biology-Based Oral Immunotherapy, Promotes Treg-Mediated Immune Rebalancing and Reduces Disease Activity in Rheumatoid Arthritis Patients

Christian Furlan Freguia[1], Janet Stephens[1], Sathya Janardhanan[1], Chuck Bourne[1], Kaitlyn Skeie[1], Hudson Lowe[1], David Pascual[2] and Gary Fanger[1], [1]Rise Therapeutics, Rockville, MD, [2]University of Wyoming, Laramie, WY

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: R-2487 is a novel, orally delivered, synthetic biology-based immunotherapy that utilizes *Lactococcus lactis* as a carrier vehicle to deliver Colonization Factor Antigen I (CFA/I) to harness immune control via intestinal immune architecture. CFA/I is a recently identified bacterial adhesin, which engages dendritic cells (DCs) and promote systemic regulatory T cell (Treg) expansion. Designed to correct the dysfunctional DC–Treg axis underlying autoimmunity, R-2487 has demonstrated robust immunomodulatory activity and disease protection in the preclinical model of collagen-induced arthritis. These studies showed that oral administration of R-2487 expanded Tregs, reduced inflammatory cytokines, and improved disease outcomes via bystander tolerance in an antigen-independent manner. R-2487 was evaluated in a first-in-human Phase I clinical trial in patients with active Rheumatoid Arthritis (RA). Here, we report preliminary safety, immunological activity, and clinical efficacy data from that clinical study.

Methods: This open-label study enrolled adult patients with RA across three dosing cohorts. Clinical endpoints included DAS28-CRP, CDAI, and RAPID3 scores. Immunophenotyping assessed Treg expansion via flow cytometry. Safety was monitored through adverse event reporting and laboratory values.

Results: R-2487 was well tolerated across all cohorts with no serious adverse events or clinically meaningful laboratory abnormalities. The majority of subjects demonstrated peripheral Treg expansion, confirming the expected mechanism of action. Clinically, patients showed improvement in disease activity as early as 2 weeks post-treatment. Eleven out of 12 subjects reached low disease activity or remission per DAS28-CRP. Among Cohort 2 and 3, all the subjects exhibited robust reduction in CDAI scores (≥6 points) as well as an improvement in the RAPID3 score (>3.6 points). Upregulation of Treg populations correlated with clinical improvement and supports the hypothesized bystander tolerance mechanism.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Oral administration of R-2487 was safe, well tolerated, and induced meaningful improvements in RA disease activity. The observed peripheral Treg expansion suggests that R-2487 rebalances immune homeostasis through a tolerogenic DC–Treg pathway, illustrating the novel mechanism of action of R-2487. These findings validate the utility of a synthetic biology approach to immune modulation in autoimmune disease, highlight the potential of leveraging microbiome-associated immune control mechanisms, and support continued development of R-2487 in RA.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA), psoriatic arthritis (PsA), and spondyloarthritis (SpA) are chronic inflammatory arthritis (CIAs). Janus kinase inhibitors (JAKis) have emerged as a promising therapeutic option for managing these conditions. However, their safety profile remains under ongoing investigation due to adverse events (AEs) reported in clinical trials and real-world data. This study aimed to evaluate the safety of JAKis in patients with CIA in a real-life setting.

Methods: A retrospective observational study was conducted on patients diagnosed with RA, PsA, or SpA who received treatment with JAKis—baricitinib (BAR), tofacitinib (TOF), upadacitinib (UPA), or filgotinib (FIL)—between 2017 and 2024. The primary outcome was the incidence and causes of treatment discontinuation due to AEs. Clinical, sociodemographic, and treatment-related variables were analyzed. Incidence rates (IR) were calculated per 100 patient-years using survival analysis techniques, along with 95% confidence intervals (CI).

Results: A total of 181 patients were included (83.4% female; mean age: 56.2 ± 12.7 years). The most common comorbidities were dyslipidemia (43%), hypertension, and thyroid disorders; 8.3% had cardiovascular disease. A total of 227 JAKi treatment courses were recorded: BAR (41.8%), TOF (15.8%), UPA (37.5%), and FIL (4.8%). Treatment was discontinued due to AEs in 49 courses among 42 patients (23%). Respiratory infections were the leading cause (36.7%), followed by general malaise (28.5%). Ten AEs were classified as serious (e.g., diverticulitis, pneumonia requiring hospitalization, gastric cancer, and pulmonary embolism), including three deaths (two due to COVID-19 pneumonia and one due to gastric cancer). The overall IR for AE-related discontinuation was 14.74 per 100 patient-years (95% CI: 11.14–19.51), with 50% of cases occurring within the first 1.65 years of therapy. Discontinuation rates were higher among women and patients with

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

cardiovascular disease. Compared to TOF (IR: 21.8; 95% CI: 11.7–40.5), BAR and UPA/FIL showed lower discontinuation rates (IR for UPA/FIL: 13.6; 95% CI: 8.0–21.3; IR for BAR: 13.03; 95% CI: 9.3–21.1).Multivariate analysis identified cardiovascular disease as a significant predictor of AE-related discontinuation (HR: 4.07; 95% CI: 2.17–7.63; p< 0.001). No significant differences were found based on sex, age, or specific JAKi agent.

Conclusion: JAK inhibitors showed an overall acceptable safety profile in patients with chronic inflammatory arthritis. Cardiovascular comorbidity was the most relevant risk factor associated with AE-related discontinuation, independent of JAKi type or patient demographic characteristics.

Abstract Number: 0484

Comparable Efficacy of FK-Tocilizumab and Reference Tocilizumab in Rheumatoid Arthritis Patients With and Without Prior Biologic Exposure

Ernest Choy[1], Marco Gattorno[2], Kamila Klama[3], Andras Illes[4], Peter Baker[5], Maria Romanova Michailidi[6] and Anna Zubrzycka-Sienkiewicz[7], [1]Division of Infection and Immunity, CREATE Centre, Cardiff University, Cardiff, United Kingdom, [2]IRCCS G. Gaslini, Genova, Genoa, Italy, [3]Solumed Clinical Research Center, Poznan, Poland, [4]Fresenius Kabi SwissBioSim, Eysin, Switzerland, [5]Fresenius Kabi Biopharma, Eysins, Switzerland, [6]University of Geneva, Eysins, Switzerland, [7]Reumatika - Centrum Reumatologii, Warszawa, Poland

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Biosimilars offer comparable efficacy and safety to their originators, thereby improving patient access to affordable treatments. FK-Tocilizumab (FK-toci) is the first tocilizumab biosimilar approved by both FDA and EMA for the treatment of autoimmune diseases including moderate-to-severe Rheumatoid Arthritis (RA). Therapeutic equivalence of FK-toci to reference tocilizumab was shown in subjects with moderate to severe RA in APTURA-1, a randomized, double blind efficacy study. Since its launch in 2024, FK-toci has accumulated ~50,000 patient-treatment-years of exposure with no new safety information affecting its benefit-risk balance. This analysis assessed the efficacy of FK-toci in patient subgroups with and without prior biologic use to support a broader patient access, including for patients with more refractory disease histories.

Methods: Subjects (M/F) over 18 years with moderate to severe RA were randomized to subcutaneous (SC) injections of 162 mg FK-toci or reference tocilizumab (originator) for 24 weeks (W). Randomization was stratified by previous exposure to biological treatment for RA (yes/no). A cohort of patients were switched from the originator to FK-toci at W24. The primary objective was to demonstrate therapeutic equivalence, with 90% and 95% CIs for the difference in DAS28-ESR LS mean change from baseline at W24 falling within predefined equivalence intervals ([-0.6, 0.5] and [-0.6, 0.6], respectively). ACR20 response at W24 was an important secondary endpoint. Both endpoints were analyzed in the subgroups with and without previous exposure to biologic treatment for RA.

Results: 604 patients were randomized, 302 on FK-toci and 302 on originator; 54 (28 and 26, respectively) were previously exposed to biologic treatment for RA. Gender, race, ethnicity, age and disease characteristics were all well balanced at

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

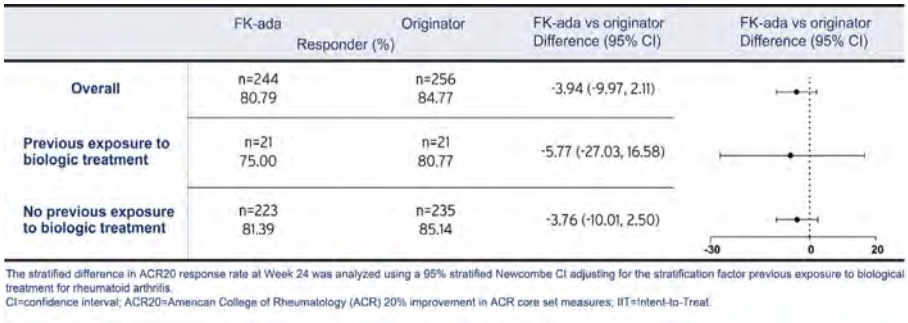

Figure 1 - ACR20 Response at Week 24 by Previous Exposure to Biologic Treatment for Rheumatoid Arthritis (ITT Analysis Set)

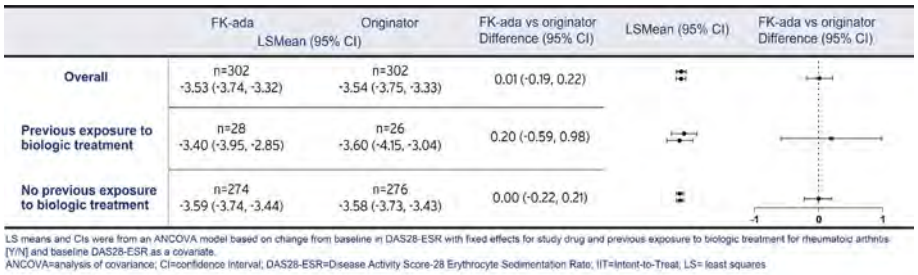

Figure 2 - DAS28-ESR Change from Baseline at Week 24 by Previous Exposure to Biologic Treatment for Rheumatoid Arthritis (ITT Analysis Set)

baseline. In total, 77.8% of patients with previous biologic exposure reached ACR20 at W24, versus 83.3% for subjects without previous biologic exposure, with similar ACR20 response rates in the two treatment groups (Figure 1). Similar reduction of DAS28-ESR at W24 were observed in both subgroups and in the two treatment groups (Figure 2).

Conclusion: Subgroup analyses by prior biologic exposure support the therapeutic equivalence of FK-tocilizumab and the originator, with no clinically meaningful differences in efficacy. These findings reinforce the reliability of FK-tocilizumab across a range of patient profiles, including those with previous biologic treatment, and underscore its potential to expand access to effective RA therapy.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumathoid Arthritis (RA) is a chronic inflammatory disease that affects the musculoskeletal system. Early and effective treatment is important to improve the quality of life of patients and prevent irreversible damage. Upadacitinib (UPA) is a Janus Kinase inhibitor (JAKi) selective for JAK1, approved for RA in 2019. In the Basque Country, since May 2022, UPA has been the prioritized after Adalimumab biosimilar failure in RA patients.

The aim of this study was to evaluate the efficacy of UPA in RA patients treated with JAKi previously and to describe the characteristics of the patients and clinical response.

Methods: 7 hospitals in our region (1.5M inhabitants) participated in a multicenter, observational and ambispective study that included patients with UPA prescription from June 2021 to May 2024, with follow-up until Dec 2024.

In our study, 248 patients were divided into two groups based on who received a previous JAKi treatment or not. We used SDAI to measure the disease activity at six visits.

Results: Of the 248 RA patients included, 84.1% were women, the mean age was 55.9 years (SD 12.30). The rest of the baseline characteristics are reflected in Table 1. The first group contained 91 patients who received JAKi previously (JAKi group), 94.5% Baricitinib suspended for lack of efficacy. The other group containing 157 patients did not receive JAKi before the treatment (No JAKi group). When both groups were compared, the JAKi group showed a higher refractory rate (55% needed two or more biologicals compared to 17%) and a longer disease duration (140 months vs 107 months). At the beginning of the treatment with UPA, 91.1% (226) of the patients had a high/moderate activity (SDAI) with no difference between both groups (91.2% vs 90.4%). As shown in Figure 1, the No JAKi group achieved a higher percentage of patients with a low activity and remission. However, these differences did not reach statistical significance. Both groups showed similar trends regarding treatment continuation and reasons for discontinuation with inefficiency as the primary cause in the later visits. Most adverse effects appeared in the first 3 months. Although JAKi showed a lower suspension rate at 3 months, there were no statistically significant differences. Median UPA persistence in RA was 22.71 months (SE 1.67148 and 95%

Table 1. Patients' baseline characteristics.

Baseline Characteristics	JAKI	No JAKI	P value
Patients	91	157	
Disease duration (Months) (Mean;SD)	107.89 (91.52)	139.50 (101.01)	0,013[a]
Gender (Female %)	87.8	82.1	0,279[b]
BMI (Mean;SD)	27.00 (4.66)	27.67 (5.24)	0,466[a]
Never Smoked (%)	54.0	56.2	0,269[b]
DM (%)	18.8	22.0	0,792[b]
HTA (%)	50.0	51.4	1,000[b]
Regicor (Mean;SD)	3.79 (3.07)	3.38 (2.31)	0,295[a]
Seropositive for RF (%)	76.7	73.7	0,650[b]
Seropositive for ACPA (%)	72.2	76.3	0,543[b]
EPID (Number of patients)	4	6	1,000[b]
Herpes Zoster Vaccination (%)	82.6	89.0	0,169[b]
Corticosteroids (%)	54.4	49.0	0,832[b]
csDMARDS (%)	45.6	58.3	0,063[b]

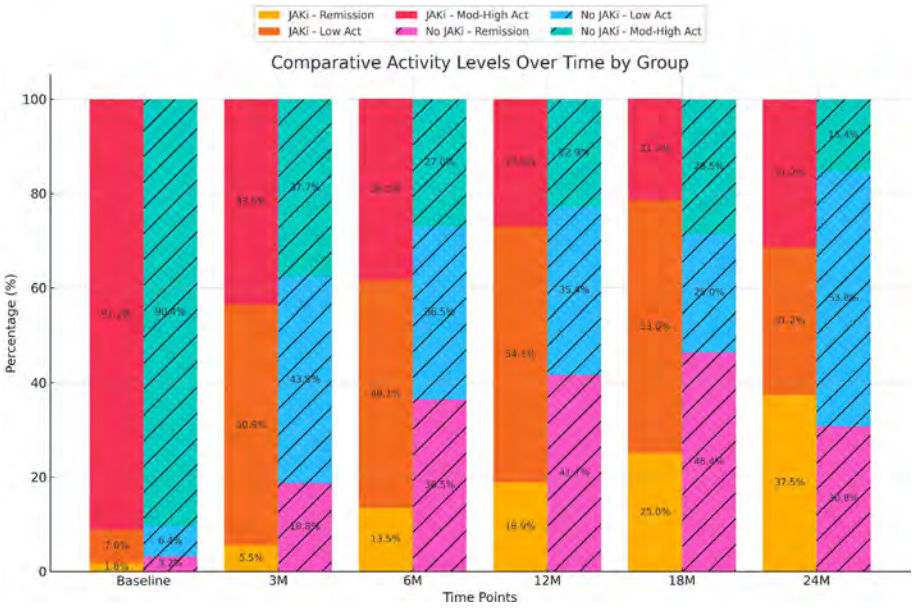

Figure 1. Comparative activity levels over time by group.

CI 18.5733), slightly shorter for the JAKI group (22.02 months; SE 1.6571 and 95% CI 18.2774), but not reaching statistical significance. No differences were found in terms of adherence to the treatment in the first two years (91% vs 93%).

Conclusion: In our study, the JAKi-experienced group showed no significant differences in terms of patient characteristics, comorbidities, baseline disease activity, or co-treatment with Prednisone and csDMARDs. Only the disease duration and refractoriness to previous biologic treatments were significantly higher in the JAKi-experienced group. Clinical response and drug persistence (median almost 2 years) were good and comparable between both groups, as were discontinuation rates and causes (inefficacy). Therefore, in our study, UPA appears to be a good treatment option for RA patients who are refractory and have been previously treated with Baricitinib.

Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background/Purpose: Sarilumab (SAR) is approved as monotherapy or in combination with conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) for treatment of patients (pts) with moderate-to-severely active rheumatoid arthritis (RA). In this post-marketing surveillance (PMS), real-world study in Japan, safety and effectiveness of SAR therapy for pts with RA were investigated.

Methods: Pts treated with SAR (200 or 150 mg once every 2 weeks) between June 2018 and November 2021 were enrolled and followed to November 2024. This analysis stratified pts by age (< 65 years [yrs], ≥65 to <75 yrs, ≥75 yrs) and evaluated treatment emergent adverse events (TEAEs) as priority surveillance items per the risk management plan of SAR in Japan. Serious infections, for which a causal relationship to treatment could not be excluded, were analyzed by stratification of pts by their lowest absolute neutrophil count (ANC) below/above the lower limit of normal (LLN; $1.96\times10^3/\mu L$) during the observation period for pts aged < 65 or ≥65 yrs. Effectiveness was assessed by 28-joint disease activity score with C-reactive protein (DAS28-CRP).

Results: Data were collected for 1121/1125 enrolled pts, with 62.1% (696/1121) who completed 1 yr of treatment (<65 yrs, 62.6% [288/460]; ≥65 to <75 yrs, 63.9% [228/357]; ≥75 yrs, 59.2% [180/304]). Major reasons for discontinuation varied by age for insufficient clinical effect (All, 15.3% [171/1121]; <65 yrs, 17.4% [80/460]; ≥65 to <75 yrs, 14.6% [52/357]; ≥75 yrs,

Table 1. Patient background

ANC, absolute neutrophil count; COVID-19, coronavirus disease 2019; LLN, lower limit of normal; PT, preferred term; yrs, years

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

12.8% [39/304]) and TEAEs (All, 12.3% [138/1121]; <65 yrs, 9.3% [43/460]; ≥65 to <75 yrs, 12.3% [44/357]; ≥75 yrs, 16.8% [51/304]). The safety analysis included 1118 pts (female, 76.7% [858/1118]) (**Table 1**). Prior treatment with biologic DMARDs was observed in 63.6% (711/1118) of pts and was similar by age. Most pts received SAR 200 mg (95.9% [1072/1118]), with similar use of concomitant medications by age (All: 86.1% [963/1112] <65 yrs, 88.0% [402/457]; ≥65 to <75 yrs, 84.6% [302/357]; ≥75 yrs, 85.2% [259/304]). The incidence of priority surveillance items was 13.5% (151/1118) and tended to increase with age (< 65 yrs, 10.9% [50/457]; ≥65 to < 75 yrs, 15.4% [55/357]; ≥75 yrs, 15.1% [46/304]) (**Table 2**). Serious infections tended to increase slightly with age (< 65 yrs, 2.2% [10/457]; ≥65 to < 75 yrs, 4.2%, [15/357]; and ≥75 yrs, 5.6% [17/304]). Incidence of drug-related serious infections was similar when stratified by ANC (>LLN, 2.9% [15/512] and < LLN, 1.7% [9/530]) (**Table 3**), with a similar trend by age (<65 yrs: >LLN, 2.0% [4/196] and < LLN, 1.3% [3/230]; ≥65 yrs: >LLN, 3.5% [11/316] and < LLN, 2.0% [6/300]). The incidence of treatment-related grade ≥3 neutropenia was also similar (< 65 yrs: 3.5% [16/457]; and ≥65 yrs: 3.9% [26/661]). In 1037 pts eligible for effectiveness analysis, DAS28-CRP mean scores improved from 4.2 at baseline to 2.7 (low disease activity) after 1 month and to 2.3 (remission) at the final evaluation.

Conclusion: These results show that SAR treatment was well tolerated by pts in Japan with RA regardless of age, and no new safety concerns were identified. Additionally, no link was established between occurrence of neutropenia during SAR treatment and the development of serious infections.

Abstract Number: 0487

Efficacy of sarilumab in patients with rheumatoid arthritis of different disease activity at treatment initiation: a post-hoc analysis of a Phase 3 trial of sarilumab in Japan

Hideto Kameda[1], Toshiya Takahashi[2], Naoki Soeda[2] and Yoshiya Tanaka[3], [1]Department of Internal Medicine, Toho University, Tokyo, Japan, [2]Medical Affairs, Asahi Kasei Pharma Corporation, Tokyo, Japan, [3]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: The efficacy and safety of sarilumab (SAR) and methotrexate (MTX) in patients (pts) in Japan with moderate-to-severely active rheumatoid arthritis (RA) and inadequate response to MTX have been demonstrated in the phase 3 KAKEHASI trial (NCT02293902). This *post hoc* analysis evaluated the efficacy of sarilumab in pts with RA by disease activity at treatment initiation.

Methods: In the KAKEHASI study of SAR with MTX, pts were randomized 2:2:1:1 to receive SAR 150 or SAR 200 mg every 2 wks (q2w) for 52 weeks (wks), or placebo for 24 wks followed by SAR 150 or SAR 200 mg q2w for 28 wks. Here, pts from

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Mean CDAI scores, mean change in CDAI score from BL, and percentage change in CDAI score from BL for BL-HDA and BL-MDA subgroups. BL, baseline; HDA, high disease activity; LDA, low disease activity; MDA, medium disease activity.

the efficacy analysis population were stratified by Clinical Disease Activity Index (CDAI) scores at SAR initiation (baseline [BL]) as: low disease activity (BL-LDA), CDAI >2.8 and ≤10; moderate disease activity (BL-MDA), CDAI >10 and ≤22; and high disease activity (BL-HDA), CDAI >22. Differences in baseline characteristics and SAR response measured by CDAI, DAS28-CRP, American College of Rheumatology [ACR]20/50/70, HAQ-DI and visual assessment score [VAS]) were assessed. Pts with high disease activity were further stratified into two (LHDA: >22 and ≤35.7; HHDA: >35.7) and four subgroups (HDA1, CDAI >22 and ≤29.5; HDA2, CDAI >29.5 and ≤35.7; HDA3, CDAI >35.7 and ≤43.3; and HDA4, CDAI >43.3).

Results: In total, 243 pts (female, 76.3–81%; mean age, 51.9–56.1 years) were randomized to receive SAR 150 mg q2w (n=81), SAR 200 mg q2w (n=80), or placebo followed by SAR 150 mg q2w (n=42) or SAR 200 mg q2w (n=40). The pooled efficacy analysis population (n=242) was stratified as: BL-HDA, n=204 (84.3%), BL-MDA, n=37 (15.3%), and BL-LDA, n=1 (< 1%). BL characteristics were similar between BL-MDA and BL-HDA groups (female, 73.0% and 78.5%; ≥65 years, 81.1% and 77.6%, respectively). Mean CDAI scores at BL for BL-HDA and BL-MDA groups were 37.8 (n=133) and 18.6 (n=27), decreasing to 8.8 (n=105) and 5.6 (n=17), respectively, by 52 wk (**Figure 1**). Change in mean (%) CDAI scores over 52 wks was similar between groups (BL-HDA, −28.4 [−75.1%]; BL-MDA, −12.7 [−68.3%]). Of all SAR-treated pts, >50%

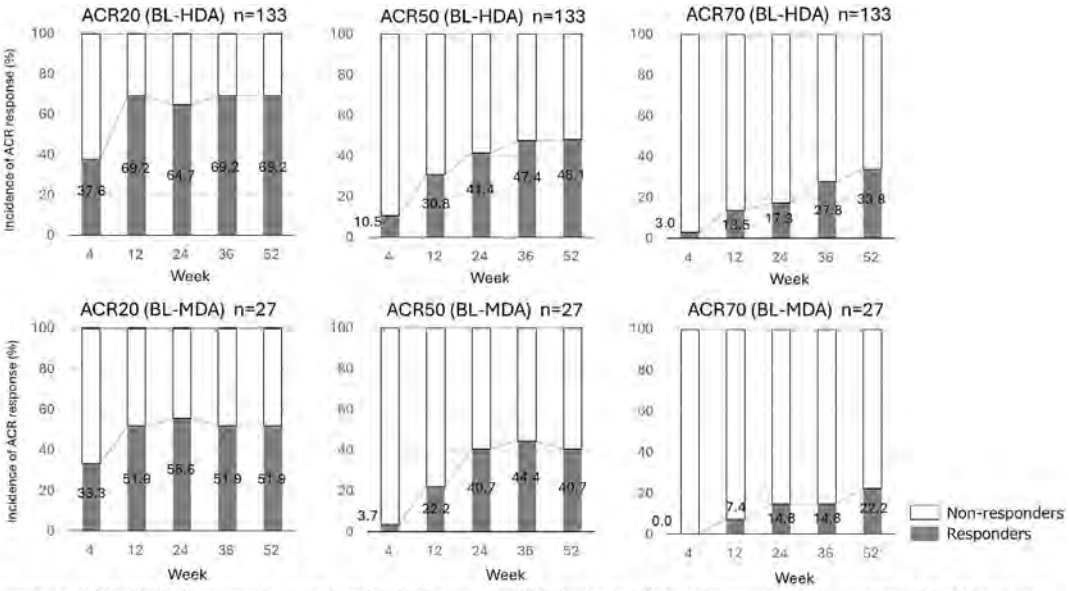

Figure 2. Incidence of ACR20/50/70 response for BL-HDA and BL-MDA subgroups. ACR, American College of Rheumatology; BL, baseline; HDA, high disease activity; LDA, low disease activity; MDA, medium disease activity.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

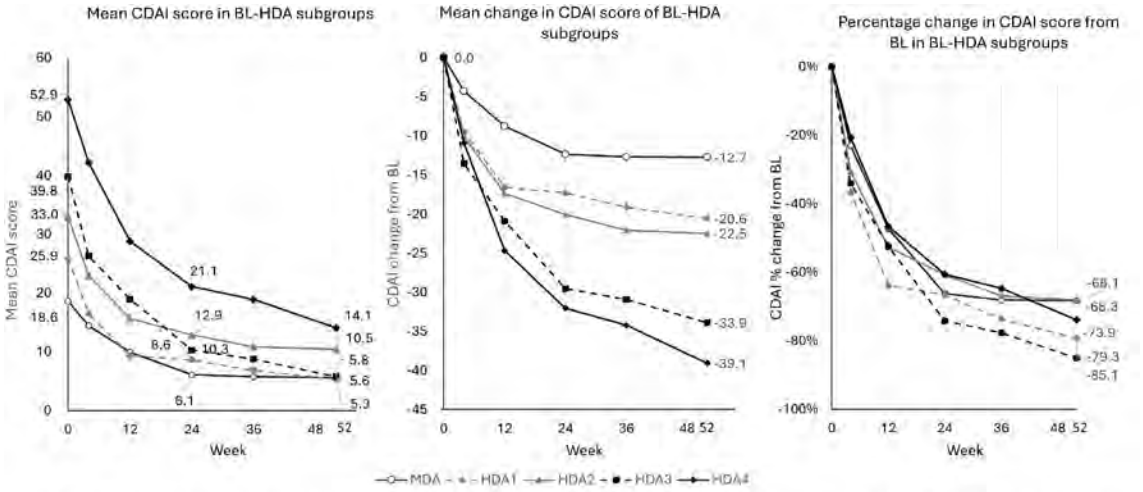

Figure 3. Mean CDAI scores, changes in mean CDAI score from BL, and percentage change in mean CDAI score from BL in the HDA-1 to HDA-4 subgroups with BL-MDA for comparison. BL, baseline; HDA, high disease activity; LDA, low disease activity; MDA, medium disease activity.

achieved LDA or remission at 52 wks (BL-HDA, 56.4% [75/133]; BL-MDA, 55.6% [15/27]). The trends in changes of mean (%) CDAI score were also reflected in those of DAS28-CRP scores (BL-MDA, –2.2 [–51.0%]; BL-HDA, –3.4 [–58.7%]) and HAQ-DI scores (BL-MDA, –0.41 [–48.6%]; BL-HDA, –0.67 [–54.2%]). Physician Global VAS also followed this trend for the BL-MDA (–34.5 [–76.0%]) and BL-HDA (–49.7 [–77.5%]) groups. Incidence of ACR20/50/70 response was similar regardless of BL-CDAI activity (HDA/MDA), but slightly higher in the BL-HDA group (**Figure 2**). In the two-subgroups, although the mean change of CDAI from BL at 52 wks was higher in the HHDA (–36.7) than the LHDA group (–21.4), the percentage change was notably similar (–72.9% and –79.1%, respectively), as per the HDA/MDA groups. In the four-subgroups, pts in HDA-3 and HDA-4 subgroups with the highest disease activity had a greater absolute decrease of CDAI than other groups with a similar percentage change, yet no plateau by 52 wks (**Figure 3**).

Conclusion: These results indicate that the efficacy of SAR is generally similar across pts with RA of different disease activity.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: FILOSOPHY (NCT04871919) and PARROTFISH (NCT05323591) are ongoing, prospective, observational Phase 4 studies of filgotinib in patients (pts) with rheumatoid arthritis (RA) in Europe. In this interim analysis, pooled data from the studies are reported up to 2 years.

Table 1. Baseline characteristics and cardiovascular risk factors/comorbidities of interest (all treated patients)

Characteristic	N=1,423
Age, years	56.0 (49.0–64.0)
Female sex, n (%)	1,091 (76.7)
Body mass index, kg/m^2	26.4 (23.1–30.5); N=1,275
TJC28	6.0 (3.0–12.0); N=1,365
SJC28	4.0 (2.0–7.0); N=1,363
DAS28-CRP	4.5 (3.7–5.3); N=1,122
CDAI score	23.0 (16.0–32.0); N=1,118
VAS pain score	62.0 (48.0–76.0); N=475
FACIT-Fatigue score	27.0 (18.0–35.0); N=469
HAQ-DI score	1.3 (0.8–1.8); N=335
RA disease duration, years	8.1 (3.2–15.7); N=1,411
RF and/or ACPA positive, n (%)*	831 (58.4)
Smoking status, n (%)†	
Former smoker	239 (16.8)
Current smoker	244 (17.1)
Family history of myocardial infarction, n (%)‡	96 (6.7)
Comorbidities of interest/medical history, n (%)	
Hypertension	398 (28.0)
Dyslipidemia	191 (13.4)
Diabetes	100 (7.0)
Cardiovascular disease	82 (5.8)
Peripheral vascular disease	35 (2.5)
Ischemic CNS vascular disorders	33 (2.3)
Prior use of DMARDs for RA, n (%)	
At least one bDMARD	870 (61.1)
At least one tsDMARD	249 (17.5)
Study treatment at baseline, n (%)	
Filgotinib monotherapy	741 (52.1)
Filgotinib + csDMARDs for RA	663 (46.6)
Concomitant glucocorticoids at baseline, n (%)	520 (36.5)

Data are median (IQR) unless stated otherwise.
*164 patients (11.5%) were both RF and ACPA negative; data were missing for 428 patients (30.1%).
†Nonsmoker, n=642 (45.1%); data on smoking status were missing for 298 patients (20.9%).
‡Data were missing for 314 patients (22.1%).
ACPA, anti-citrullinated protein antibody; (b/cs/ts) DMARD, (biologic/conventional synthetic/targeted synthetic) DMARD; CDAI, Clinical Disease Activity Index; CNS, central nervous system; DAS28-CRP, Disease Activity Score in 28 joints using C-reactive protein; FACIT-Fatigue, Functional Assessment of Chronic Illness Therapy–Fatigue; HAQ-DI, Health Assessment Questionnaire–Disability Index; RF, rheumatoid factor; S/TJC28, swollen/tender joint count based on 28 joints; VAS, visual analog scale

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 2. Treatment-emergent adverse events up to Month 24

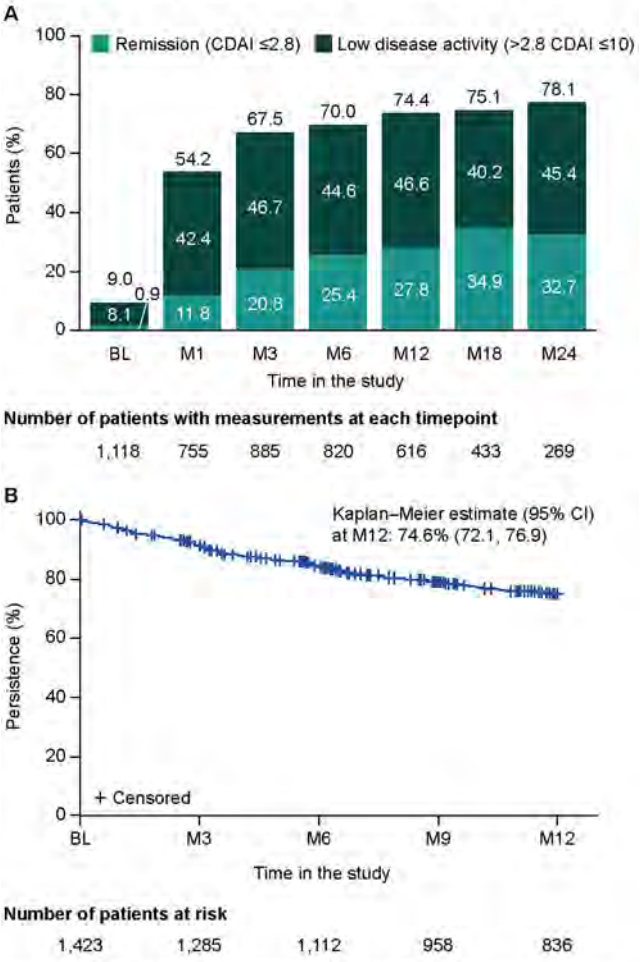
TEAE	Incidence rate per 100 patient-years of exposure (95% CI) N=1,423
Any TEAE	96.8 (90.5, 103.5)
Serious TEAE	9.8 (8.3, 11.5)
TEAE leading to premature discontinuation of filgotinib	9.6 (8.2, 11.2)
TEAEs of interest	
Fractures	1.8 (1.2, 2.6)
Herpes zoster	1.4 (0.9, 2.2)
MACE*	1.1 (0.6, 1.7)
Malignant or unspecified tumors (excluding NMSC)	0.7 (0.4, 1.3)
Pulmonary embolism	0.3 (0.1, 0.7)
Opportunistic infections	0.2 (0.1, 0.6)
Serious infections	0.1 (0.0, 0.3)
Deep vein thrombosis	0.1 (0.0, 0.4)
Cardiac failure	0.1 (0.0, 0.4)

*Non-adjudicated MACE, including acute myocardial infarction, stroke and cardiovascular death (MedDRA v26.0).
MACE, major adverse cardiovascular events; MedDRA, Medical Dictionary for Regulatory Activities; NMSC, nonmelanoma skin cancer; TEAE, treatment-emergent adverse event

Figure. Proportion of patients with CDAI remission or low disease activity up to M24 (**A**) and treatment persistence up to M12 (**B**)



As observed at the time of the data cut. No imputation of missing data was performed. The Kaplan–Meier plot (part B) illustrates time to treatment discontinuation or death within a 12-month follow-up period. In the absence of documented treatment discontinuation or death events, patients were censored at their last recorded treatment end date. Due to the interim nature of these data, some disposition records may still be incomplete. Kaplan–Meier estimates may therefore change as additional follow-up data become available.
BL, baseline; CDAI, Clinical Disease Activity Index; CI, confidence interval; M, Month

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: The studies enrolled adults with moderate to severe active RA who were prescribed filgotinib for the first time in daily practice. Disease activity assessments included Clinical Disease Activity Index (CDAI) and Disease Activity Score in 28 joints using C-reactive protein (DAS28-CRP). The following patient-reported outcomes (PROs) were collected: visual analog scale (VAS) pain, Functional Assessment of Chronic Illness Therapy (FACIT)–Fatigue and Health Assessment Questionnaire–Disability Index (HAQ-DI) scores. A ≥10-mm reduction in VAS pain score or a ≥4-point increase in FACIT-Fatigue score were considered clinically meaningful changes from baseline. Outcomes were assessed in biologic (b) DMARD-naïve and -experienced pts. Treatment persistence (Kaplan–Meier estimate) and treatment adherence (5-Item Compliance Questionnaire for Rheumatology [CQR5]) were reported up to Month 12. CQR5 scores >80% indicate good adherence. Treatment-emergent adverse events (TEAEs) were reported. All data are on-treatment.

Results: From May 2021 to September 2024, 1,423 pts were treated with filgotinib (median follow-up: 550 days); baseline characteristics are shown in **Table 1**. 38.9% of pts were bDMARD naïve; 61.1% were bDMARD experienced. 91.2% received filgotinib 200 mg; 8.8% received filgotinib 100 mg. The proportion of pts with a CDAI score ≤10 increased from baseline to Month 24 (**Figure A**). In bDMARD-naïve pts, median (IQR) CDAI score decreased from 22.0 (16.0–31.0) at baseline (n=424) to 8.0 (4.0–14.0) at Month 1 (n=311) and 3.0 (0.0–7.5) at Month 24 (n=112), and in bDMARD-experienced pts from 24.0 (17.0–33.0) at baseline (n=694) to 10.5 (6.0–18.0) at Month 1 (n=444) and 6.0 (3.0–12.0) at Month 24 (n=157). Similar improvements were seen for DAS28-CRP. For PROs, median (IQR) HAQ-DI score decreased from 1.3 (0.8–1.8) at baseline (n=335) to 0.8 (0.3–1.3) at Month 1 (n=227) and 0.6 (0.3–1.1) at Month 18 (n=73). A clinically meaningful change in VAS pain score occurred in 43.9% of pts (177/403) at Week 1 and 63.5% (54/85) at Month 24; for FACIT-Fatigue, the proportions were 43.6% (175/401) at Week 1 and 55.3% (47/85) at Month 24. Improvements in PROs were seen in bDMARD-naïve and -experienced pts. At Month 12, treatment persistence (95% CI) was 74.6% (72.1, 76.9) (**Figure B**), and 79.8% of pts had a CQR5 score >80%. There were 9 deaths, 7 of which were considered unrelated to study treatment by the investigator. TEAEs of interest are shown in **Table 2**.

Conclusion: Pts treated with filgotinib in FILOSOPHY and PARROTFISH showed improvements in disease activity and HAQ-DI from Month 1, and in pain and fatigue from Week 1. Improvements were maintained up to Month 24 (Month 18 for HAQ-DI) and were seen regardless of prior bDMARD exposure. At Month 12, treatment persistence was high (75%) and 80% of pts showed good adherence. Safety data were consistent with those previously reported from randomized controlled trials of filgotinib.

Abstract Number: 0489

Efficacy and safety profile of JAK inhibitors in current practice in rheumatoid arthritis

Omar Al Tabaa[1], Salomé Abdellaoui[1], Sophie Hecquet[1], Marion Thomas[2], Sandrine Carves[1], Alice Combier[1], Olivier Fogel[3], Yannick Allanore[4] and **Jérôme Avouac**[5], [1]Rheumatology department, Cochin Hospital, Paris, France, [2]APHP, Paris, France, [3]AP-HP, Paris, France, [4]University Paris City, Paris, France, [5]Hôpital Cochin, AP-HP Centre - Université Paris Cité, Paris, France

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: JAKi have been used in rheumatoid arthritis in current practice for several years now, with the progressive arrival on the market of 4 molecules. The use of JAKi has also been hindered by successive safety alerts, which have restricted their use in elderly patients or those with risk factors. The aim of this study was to assess the therapeutic maintenance of the 4 JAKIs available, as well as their efficacy and safety in current RA practice.

Methods: A retrospective study was conducted at a single center, encompassing all RA patients who received a first JAKI between April 2018 and June 2022. The primary endpoint was treatment maintenance at 12 and 24 months, as analyzed using the Kaplan-Meyer survival curve.

Table 1: Characteristics of patients treated with JAKi

	Total (n=108)	BARI (n=30)	TOFA (n=10)	UPA (n=48)	FILGO (n=20)
Baseline demographics					
Age (years), mean ± SD	57± 11	62± 11	58± 11	55± 16	55± 10
Women, n (%)	91 (84)	23 (77)	7 (70)	41 (85)	20 (100)
Baseline disease characteristics					
Disease duration (years), mean ± SD	19± 12	22± 13	17± 10	17± 12	19± 15
Positive rheumatoid factor, n (%)	91 (84)	25 (83)	8 (80)	42 (88)	16 (80)
Positive anti-CCP2 antibodies, n (%)	95 (88)	26 (87)	8 (80)	45 (94)	16 (80)
Bone erosions on hand/foot x-rays, n (%)	83 (77)	25 (83)	6 (60)	38 (79)	14 (70)
Extra-articular manifestations	37 (34)	7 (23)	3 (30)	18 (38)	9 (45)
Baseline disease activity:					
Tender joints, mean± SD	5.7± 5.8	6.3± 6.0	3.6± 4.0	6.4± 6.5	4.2± 4.1
Swollen joints, mean± SD	4.6± 5.2	4.3± 4.6	4.4± 3.8	5.0± 5.1	4.2± 6.56
Patient Global Assessment (0-100), mean±SD	62± 25	65± 23	56± 41	62± 24	59± 22

Table 2: Efficacy of JAKi on DAS28-CRP

	Baseline	6 months	Final	Delta baseline-6m	P-value	Delta baseline-final	P-value
JAKi	**4.05± 1.24**	**2.79± 1.00**	**2.98± 1.58**	**-1.46± 1.28**	**<0.001**	**-1.05± 1.67**	**<0.001**
BARI	4.05± 1.07	3.15± 0.69	3.26± 1.63	-0.85± 1.12	0.032	-0.79± 1.75	0.079
TOFA	4.28± 1.46	3.21± 1.77	3.57± 1.89	-1.07± 1.16	0.089	-0.85± 1.93	0.14
UPA	4.23± 1.29	2.56± 1.04	2.96± 1.57	-1.73± 1.15	<0.001	-1.01± 1.85	0.006
FILGO	3.85± 1.27	2.76± 1.13	2.44± 1.39	-1.57± 1.64	0.009	-1.53± 1.04	<0.001

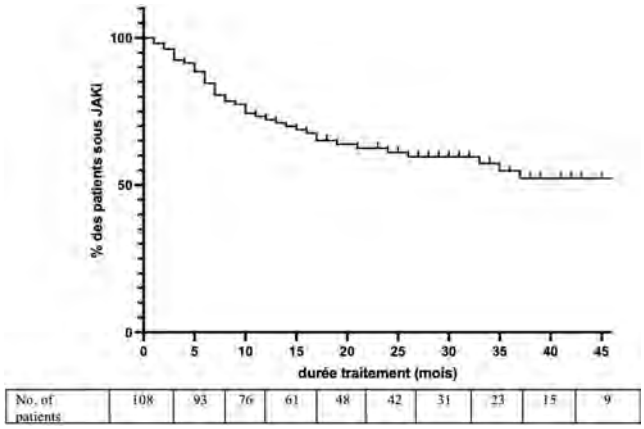

Figure 1: Therapeutic maintenance of JAKi

Secondary endpoints included the efficacy of JAKi and each molecule at 6 months and at the last available visit (until June 2024), as assessed by the DAS28-CRP (Wilcoxon) score, and the number of treatment discontinuations due to inefficacy or intolerance.

Results: We included 108 patients (91 women, 84%) treated with JAKi with a mean age of 57± 14 years and a disease duration of 19± 12 years; rheumatoid factors and ACPA were positive in 91 (84%) and 95 (88%) patients respectively, 83 (77%) had erosions and 37 (34%) extra-articular involvement (**Table 1)**. JAKi were predominantly used in combination with a csDMARD (83/108, 77%) and beyond the 3rd line of targeted therapy (**Table 1)**. The characteristics of patients treated with the 4 JAKi were comparable and are presented in **Table 1**. Therapeutic maintenance in JAKi was 72% at 12 months and 61% at 24 months. Median treatment survival was 47 months (**Figure 1)**.

A significant reduction in DAS28-CRP was observed at 6 months (-1.46± 0.28 vs. inclusion visit, p< 0.001) and at the last visit, which occurred 21± 15 months following JAKi initiation (-1.05± 1.67 vs. inclusion visit, p< 0.001) (**Table 2**). This decrease in DAS28-CRP appears to be numerically greater with the more selective JAKi (Upadacitinib, Filgotinib) than with Baricitinib and Tofacitinib.

During the follow-up period, 45 patients (42%) discontinued JAKi (including 16 patients on Baricitinib, 53%, 6 on Tofacitinib, 60%, 21 on Upadacitinib, 44% and 2 on filgotinib, 10%). The primary reasons for discontinuation included lack of efficacy (26 cases) and intolerance (15 cases). Noteworthy side effects included a myocardial infarction, three pulmonary embolisms, and the detection of breast cancer.

Conclusion: The present study demonstrated that the therapeutic maintenance of JAKi in RA exhibited a relatively high rate of occurrence at 12 and 24 months. Primarily utilized as a third-line targeted therapy, JAKi has been demonstrated to significantly improve RA activity, yielding favorable outcomes. However, a considerable proportion of patients discontinued treatment due to lack of efficacy or adverse effects, underscoring the necessity for ongoing, personalized evaluation of these therapies in routine clinical practice.

Infection Risks Associated with Monotherapy and Combination Therapies Using Biological or Targeted - DMARD in RA: A Systematic Review and Network Meta-analysis

Li Liu[1], Xue-Mei Zhang[1], Zhi-Chun Gu[1] and **Jia Li**[2], [1]Ren Ji Hospital, Shanghai Jiao Tong University School Of Medicine, Pu Dong Xin Qu, Shanghai, China (People's Republic), [2]Department of Rheumatology, Renji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China (People's Republic)

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: This study aimed to evaluate the infection risks in patients with rheumatoid arthritis (RA) treated with biological or targeted synthetic disease-modifying antirheumatic drugs (b/tsDMARDs), either as monotherapy or in combination with conventional synthetic DMARDs (csDMARDs).

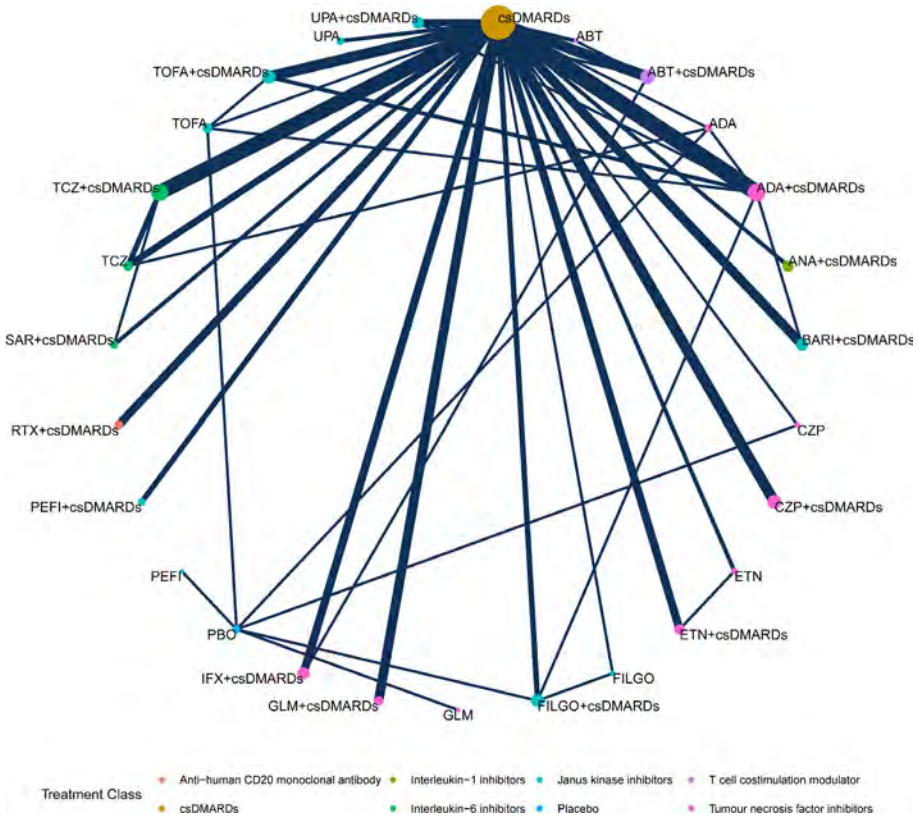

Figure 1 Network map of treatment comparisons for Serious infections Links between the nodes indicated the available direct comparisons between different treatments. ABT, Abatacept; ADA, Adalimumab, ANA, Anakinra, BARI, Baricitinib; CZP, Certolizumab; ETN, Etanercept; FILGO, Filgotinib; GLM, Golimumab; IFX, Infliximab; PEFI, Peficitinib; PBO, Placebo; RTX, Rituximab, SAR, Sarilumab; TCZ, Tocilizumab; TOFA, Tofacitinib; UPA, Upadacitinib; csDMARDs, conventional synthetic disease-modifying antirheumatic drugs.

Table 1 A heat map ranking b/tsDMARDs ± csDMARDs based on the risk of serious infections, any infection, and specfic infectious outcomes Numbers reflect P-score, which rank b/tsDMARDs ± csDMARDs on a continuous scale from 0 to 1. A higher P-score indicates a greater increase in risk of infection. Transverse line indicate that data were not available. ABT, Abatacept; ADA, Adalimumab, ANA, Anakinra, BARI, Baricitinib; CZP, Certolizumab; ETN, Etanercept; FILGO, Filgotinib; GLM, Golimumab; IFX, Infliximab; PEFI, Peficitinib; PBO, Placebo; RTX, Rituximab, SAR, Sarilumab; TCZ, Tocilizumab; TOFA, Tofacitinib; UPA, Upadacitinib, bDMARDs, biological disease-modifying antirheumatic drugs; tsDMARDs, targeted synthetic disease-modifying antirheumatic drugs; csDMARDs, conventional synthetic disease-modifying antirheumatic drugs.

Methods: A comprehensive literature search of MEDLINE, EMBASE, and the Cochrane Central Register of Controlled Trials (CENTRAL) was conducted to identify randomized controlled trials (RCTs) assessing infection risks in RA patients treated with b/tsDMARDs. The primary outcome was the incidence of serious infections, while the secondary outcomes included any infection and specific events such as respiratory tract infections, gastroenteritis and herpes zoster. A frequentist network meta-analysis was performed to calculate odds ratios (ORs). This study was registered with PROSPERO (CRD42023435681).

Results: In this network meta-analysis of 127 RCTs involving 55,749 patients, b/tsDMARD monotherapy showed a similar risk of serious infections compared with csDMARDs. By contrast, combining csDMARDs with adalimumab, infliximab, tofacitinib, or upadacitinib (though not with other b/tsDMARDs) significantly increased the risk of serious infections (OR 1.51, 95% CI: 1.04-2.19; OR 1.75, 95% CI: 1.09-2.81; OR 2.52, 95% CI: 1.26-5.03; OR 2.31, 95% CI: 1.13-4.73, respectively). For any infection, b/tsDMARD monotherapy posed a similar risk to csDMARDs, except for etanercept. Regarding specific risks, tsDMARDs were associated with an increased incidence of herpes zoster compared to csDMARDs, except for filgotinib and peficitinib. Although rare, pneumonia, tuberculosis, and sepsis were observed more frequently with infliximab combined with csDMARDs than with other b/tsDMARD regimens.

Conclusion: Compared to csDMARDs, b/tsDMARD monotherapy showed no elevated serious infection risk, whereas specific combination therapy regimens with csDMARDs increased the risk of serious infections in RA patients. A specialized clinical pathway with detailed recommendations was developed to assess infection risks and optimize drug selection for RA patients undergoing b/tsDMARD treatment.

Abstract Number: 0491

Association Of short Chain Fatty Acids and diet with Disease Activity and Methotrexate Response in New Onset Rheumatoid Arthritis: A Proof of Principle Study

Kaci French[1], Luz Alvarado[2], Rebecca Haberman[3] and Rebecca Blank[3], [1]NYU Langone, New York, NY, [2]NYU Langone, New York, [3]NYU Langone Health, New York, NY

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Diet, the gut microbiome, and gut microbial metabolites have been implicated in rheumatoid arthritis (RA) development and modulation. Seafood based-omega-3 fatty acids modulate inflammatory cytokines in RA. Fiber rich diets, such as Mediterranean and vegetarian diets, are associated with increased short chain fatty acid (SCFA)-producing bacteria. In turn, SCFAs have been shown to modulate the gut microbiome, enhance anti-inflammatory mediators in murine RA models, and be associated with decreased risk of progression to clinical RA in at-risk individuals. Until now, most studies of SCFA supplementation have been in animal models. In this proof of principle study, we aimed to address this gap by analyzing the effects of diet and butyrate supplementation in new onset RA (NORA) patients, hypothesizing that butyrate supplementation in NORA with healthier diets will improve disease activity, ultimately leading to better treatment response.

Methods: Clinical, dietary, and metabolomic data were obtained from NORA patients meeting 2010 ACR/EULAR RA criteria. Participants took methotrexate (MTX) plus butyrate (1 gm butyrate, 3 times daily) over 4 months (Table 1). MTX responders (MTX-R) were defined by either a change in DAS-28 ESR of > 1.8 from baseline and/or DAS28 < 2.6 (remission) at 4 months. Clinical data, dietary data (based on a modified NHANES Food Frequency Questionnaire), and fecal samples were collected at month 1, 2, and 4. Fecal metabolite quantification was performed by 1^{H} NMR spectroscopy. Between group differences were analyzed using Mann Whitney U tests and Fischer's exact tests as appropriate. Relationships between variables were calculated using Spearman's correlations. Adherence to multiple healthy diets, including fish/seafood, Mediterranean, and vegetarian diets was assessed to examine associations between diet quality, SCFA, and disease activity.

Results: 17 patients were enrolled: 11 responders and 6 non-responders. Increase in fecal SCFA concentration correlated with improvement in DAS28 scores at 1 month (r= -0.749, p=0.001, Figure 1A). In a group of 12 patients, those with higher quality diet had an increase in fecal acetate after 4 months of butyrate supplementation, while those who had the lowest

Table 1. Characteristics of NORA cohort taking MTX and butyrate.

Characteristic	Total (n=17)	MTX Non-Responders (n=6)	MTX Responders (n=11)	p-value
Age- Median (IQR)	55 (48, 62)	46.5 (27, 62)	57 (51.5, 62)	0.216

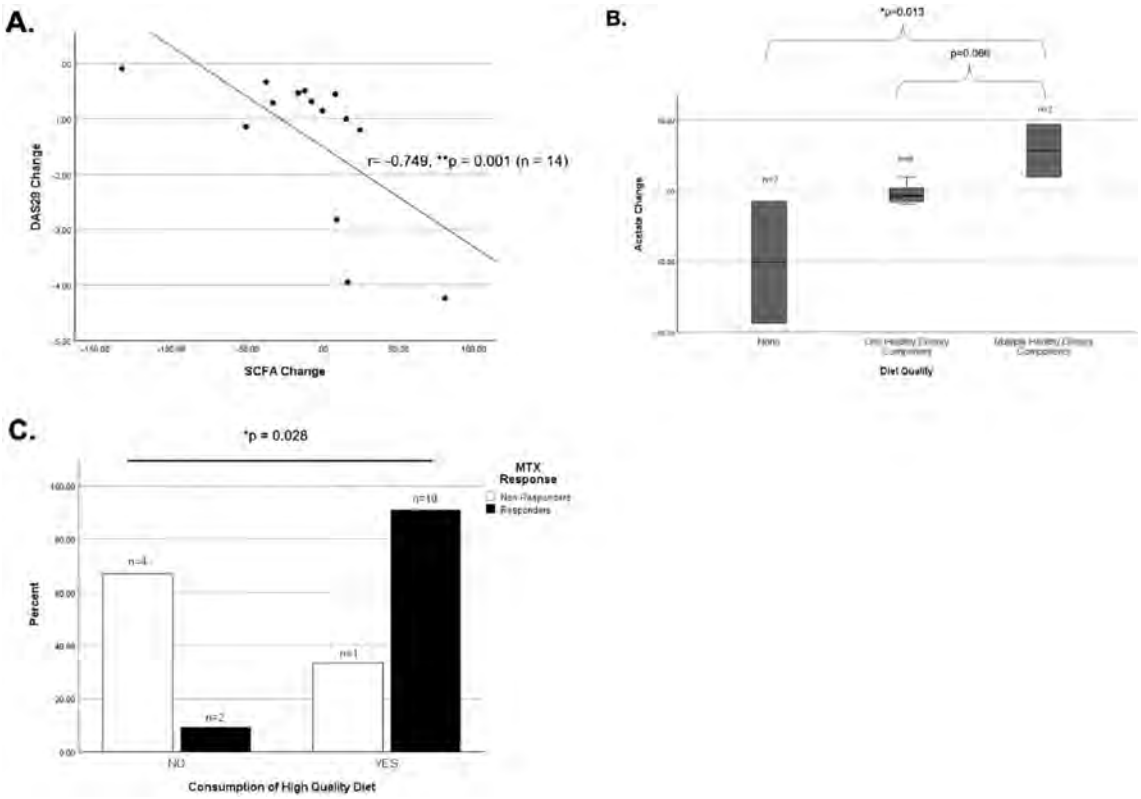

Figure 1. Associations between disease activity, SCFA, and diet. (A) Change in fecal SCFA is negatively correlated with change in DAS28 scores after 1 month of butyrate supplementation. (B) Participants who consumed multiple foods groups containing fish/omega-3, mediterranean, or vegetarian diets had increased change in fecal acetate after 4 months of MTX and butyrate supplementation when compared to those who did not consume these diets (C) MTX responders were more likely to report consumption of diets rich in fish, omega-3, legumes, whole grains, vegetables, and/or fruits compared to non-responders.

quality diet had a decrease in acetate (p=0.013, Figure 1B). Patients with high quality diets were more likely to be MTX-R (p=0.028, Figure 1C).

Conclusion: In this small, proof of principle study, we found that increased fecal SCFA concentration was associated with improvement in disease activity after only 1 month of MTX and butyrate, reinforcing the connection between SCFA and disease activity. Furthermore, only those consuming diets rich in SCFA precursors had improvement in acetate levels which may indicate that these diets are essential for butyrate supplementation to be effective. In fact, high quality diets, irrespective of SCFA changes, were associated with response. While thought provoking, larger studies are needed to explore and confirm these hypothesis-generating results.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic, inflammatory disease of the joints with an estimated prevalence of 0.5% of people. Nearly 25% of RA patients undergo joint replacement/arthroplasty within 22 years of diagnosis. The hip and knee are the most frequently replaced joints. Total knee replacement (TKR) effectively treats advanced joint destruction in RA patients, significantly enhancing mobility and quality of life. Other common TKR indications include symptomatic moderate-to-severe osteoarthritis, advanced symptomatic osteonecrosis with arthritis, and limb deformity correction. Studies on outcomes of TKR in RA patients are limited. This study uses the national inpatient sample (NIS) database to compare characteristics, comorbidities, perioperative complications, and outcomes in TKR patients with and without RA.

Table 1: Patient characteristics and co-morbidities

Characteristics	TKR with RA (n=127080)	TKR with out RA (n=3288610)	p-value

Post procedure septic shock	0	0.003	0.35

Table 3: Primary outcomes

Outcome	TKR with RA (n=127080)	TKR with out RA (n=3288610)	p-value
Mortality n (%)	105(0.08)	1405(0.04	0.003
Length of Stay (LOS), days (mean ±SD)	2.54 ±2.29	2.31 ± 2.07	0.01
Total Charges, $, (mean ±SD)	72002 ± 52750	67185 ± 50232	<0.001

Methods: A retrospective cross-sectional study was conducted using data from NIS (2016-2021). Primary and secondary diagnoses were identified using International Classification of Diseases (ICD-10) codes. All patients aged >18 years undergoing TKR were included in the study. TKR patients with and without RA were compared for demographics, comorbidities, complications, and outcomes, including mortality, length of stay, and hospitalization charges. Statistical analysis was done using STATA v.17.

Results: A total of 3,415,690 patients underwent TKR during the study period. Patients with RA undergoing TKR (n=127080) were more likely to be female (76.0% vs 60.6%, p< 0.001) and non-White. The most common sites were urban teaching hospitals. RA patients had significantly higher prevalence of comorbidities; congestive heart failure (5.2% vs 4.0%), COPD (22.3% vs 15.7%), and renal disease (8.7% vs 7.6%) - and significantly more complications including blood loss anemia (19.0% vs 15.0%, p< 0.001), blood transfusions (3.0% vs 1.6%), peri-prosthetic infection (2.9% vs 1.5%), dislocation (1.26% vs 0.89%), fracture (0.81% vs 0.38%), and superficial surgical site infection (0.03% vs 0.01%). RA patients had higher postoperative mortality (0.08% vs 0.04%, p=0.003), longer hospital stay (2.54 vs 2.31 days, p=0.01), and higher hospital charges ($72,002 vs $67,185, p< 0.001).

Conclusion: This study found that RA patients undergoing TKR experience higher perioperative complications, prolonged hospitalization, and higher costs. The study also demonstrated that patients with RA undergoing TKR had more comorbidities, with no significant age difference between those with and without RA. These findings underscore the importance of preoperative optimization and vigilant postoperative care in this vulnerable population. More studies are required to accurately identify the outcomes and complications of the TNR in RA patients.

Abstract Number: 0493

Phase I Trial in Participants with Rheumatoid Arthritis and Healthy Volunteers with CIT-013, a First in Class NETosis Inhibitor

Maarten Kraan[1], Salah Hadi[2], Leonie Middelink[3], Renato Chirivi[3], Eric meldrum[3], Naomi Klarenbeek[4] and Patrick Round[3], [1]Citryll BV, Den Dolder, Netherlands, [2]ICON Netherlands BV, Groningen, Netherlands, [3]Citryll BV, Oss, Netherlands, [4]CHDR, Leiden, Netherlands

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Aberrant Neutrophil Extracellular Trap (NET) production contributes to the pathophysiology of multiple inflammatory and autoimmune diseases including rheumatoid arthritis (RA). We report data of a phase 1 trial (EudraCT number:2020-005848-36) with a humanized monoclonal antibody (CIT-013) targeting the citrullinated histones H2A and H4. CIT-013 inhibits NET formation and accelerates the clearance of NETs and netting neutrophils, thus lowering NET tissue burden with significant anti-inflammatory consequences (Chirivi et al 2021; van der Linden et al 2024).

Methods: Prospective, randomized, double-blind, placebo-controlled, phase I trial in participants with RA and healthy volunteers (HV). After obtaining informed consent and completion of baseline assessments, placebo, 25 mg or 50 mg of CIT-013 was administrated subcutaneously at days 1 and 15. Endpoints at day 29 were safety, tolerability, pharmacokinetics (PK) and effect on disease activity as measured with the disease activity score counting 28 joints and CRP (DAS28-CRP).

Results: In total 9 participants with RA and 3 HV were dosed with CIT-013, 3 participants received placebo, 3 participants 25 mg CIT-013 and 6 participants 50 mg CIT-013. Two participants with RA received placebo, 3 received 25 mg CIT-013 and 4 received 50 mg CIT-013. All 9 participants with RA met the ACR/EULAR criteria and were on stable synthetic disease modifying anti-rheumatic drugs (sDMARDs).

In general, CIT-013 was well tolerated, reported adverse events were mild (grade 1) injection site reactions (all resolved spontaneously) and headache. There was one serious adverse event in a placebo participant with RA that required surgery and hospitalization for a fracture. Anti-drug antibodies were only observed at Day 56 in 2 partcipants with RA, 1 in the 25 mg group and 1 in the 50 mg group, both with low titres (< 4).

The half life of CIT-013 was approximately 6 days and all PK parameters were comparable between HV, participants with RA in remission, and participants with RA and active disease.

Table 1. Mean DAS28-CRP ± Standard Deviation at baseline and at day 29 and DAS28-CRP response status at Day 29 for the included participants with RA.

Cohort	Disease status at baseline	n	DAS baseline	DAS Day 29	No DAS Response Day 29	DAS Response/Remission Day 29
Placebo	Remission	1	1.6	1.7	1	0
	Active	1	5.4	4.6	1	0
25 mg	Remission	3	1.9 ± 0.3	1.9 ± 0.9	3	0
50 mg	Remission	1	2.3	3.4	1	0

At baseline 4 out of 9 participants with RA (44%) had active disease, defined as a DAS28-CRP of 2.6 or higher. Of these, 1 participant received placebo and continued having active disease, 3 participants received 50 mg CIT-013 and all these had a clinical relevant reduction in disease activity. The clinical activity as observed on day 29 for all 9 participants with RA is captured in Table 1.

None of the HV and only 1 RA participant with active disease (8% of total, 25% of participants with active RA) had detectable serum CIT-H3 levels at baseline. In this participant the level dropped below the lowest level of detection (LLD) immediately after the 1st dose.

Conclusion: CIT-013 was well tolerated and a DAS28-CRP reduction was observed in participants with RA and active disease. These findings support further clinical development.

LFD-200, an Antibody Drug Conjugate that Selectively Delivers a Glucocorticoid Payload to Immune Cells, Provides Sustained Anti-inflammatory Effects Without Systemic Toxicity in Non-human Primates

Matt McClure[1], Catherine Carriere[1], Kierstin Bell[1], Rex Williams[2], Geoff Kuesters[2], Emily Sansevere[2], Dave Nichols[2], Arthur Tzianabos[2] and Jay Rothstein[1], [1]Lifordi Immunotherapeutics, Lebanon, NH, [2]Lifordi Immunotherapeutics, Burlington, MA

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Glucocorticoids (GCs) are the most versatile and efficacious anti-inflammatory drugs rheumatologists have available for patients. Unfortunately, prolonged systemic GC exposure leads to unacceptable toxicities, which have reduced GC use in favor of biologics that sacrifice efficacy for improved safety. LFD-200 is an antibody-drug conjugate that limits systemic toxicities through selective delivery of a modified, potent GC payload to immune cells via an antibody to VISTA, a cell surface protein mainly expressed on immune cells. In multiple prior mouse studies, including models of autoimmune disease (e.g., diabetes, asthma, arthritis), LFD-200 is rapidly internalized, resulting in reduced serum GC exposure and increased intracellular exposure in immune cells as well as enhanced efficacy compared to conventional GCs. Safety and pharmacodynamic studies of LFD-200 have now also been conducted in non-human primates (NHPs).

Methods: Three NHP studies evaluating subcutaneously administered LFD-200 were conducted in cynomolgus macaques.

Study 1: NHPs received one dose of LFD-200 (5 or 20 mg/kg). The control group received one dose of vehicle followed by 2 doses of dexamethasone (Dex; 3 mg/kg) given 6 and 7 days post vehicle. Ex vivo cytokine stimulation with lipopolysaccharides (LPS) was conducted on pre- and post-dosing tissue samples. Tissue exposure was assessed via immunohistochemistry using an antibody to the payload. **Study 2**: Toxicology study in which NHPs were dosed every 2 weeks (Q2W) with

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

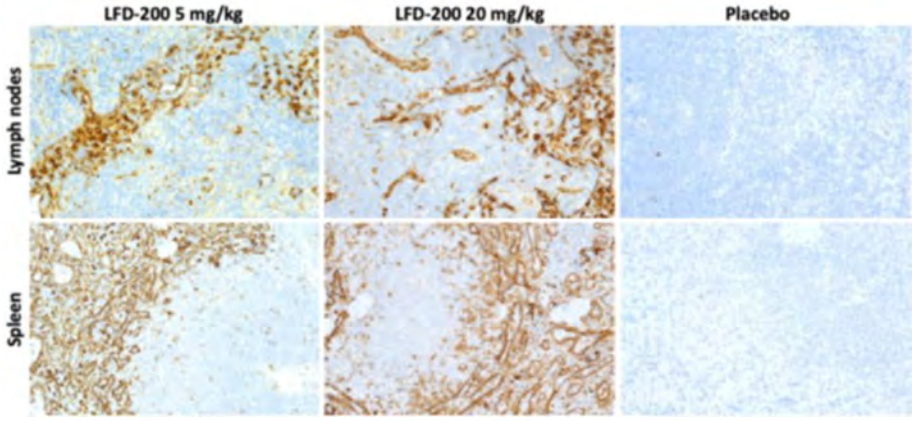

Figure 1: LFD-200 payload accumulation in lymph nodes and spleen. Immunohistochemistry for LFD-200 payload was conducted on lymph nodes and spleen that were collected 7 days after a single dose of 5 or 20 mg/kg LFD-200. Payload-specific antibody staining (brown) was detected in the spleen and lymph node at both doses but was absent in the placebo group. Slides were counterstained with hematoxylin (blue).

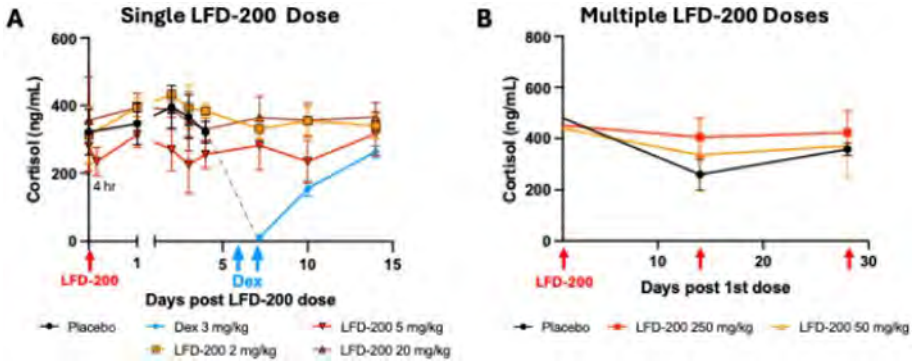

Figure 2: Serum cortisol levels following LFD-200 administration. A) Cortisol levels observed in Study 3 following a single dose (2, 5 or 20 mg/kg) of LFD-200 (n=4/group); the control group received one dose of vehicle followed by two doses of dexamethasone (3 mg/kg) 6 and 7 days post vehicle dosing (4 hrs before the final tissue collection). B) Cortisol levels (collected before each dose) observed in Study 2 following repeated doses of LFD-200 (50 or 250 mg/kg) (n=2 for the vehicle and n=4 for LFD-200). Red and blue arrows indicate LFD-200 and dexamethasone dosing, respectively.

placebo or LFD-200 at 50 or 250 mg/kg for 4 weeks. **Study 3**: Same dosing design as Study 1, but with an additional 2 mg/kg in LFD-200 group. Circulating cortisol levels were assessed in Studies 2 and 3 via ELISA or liquid chromatography/tandem mass spectrometry.

Results: LFD-200 achieves durable GC exposure in immune cells. A single dose of 5 or 20 mg/kg LFD-200 resulted in GC payload detection in immune tissues for ≥7 days post-dose (Figure 1).

LFD-200 achieves durable cytokine suppression. Compared to baseline, LFD-200 dosing resulted in up to 75% decrease in LPS-stimulated cytokines (e.g., IL-1β, IP-10, TNFa) in whole blood through 4 days post-dose, with up to 43% reduction observed 7 days post-dose.

LFD-200 treatment showed no evidence of systemic GC effects. In Study 3, after a single dose of LFD-200, no impact on cortisol levels was observed at any dose or time point tested. Comparatively, dexamethasone suppressed cortisol levels well below baseline for >3 days (Figure 2A). In Study 2, repeated high doses of LFD-200 (50 and 250 mg/kg Q2W) showed no changes in cortisol (Figure 2B) and no histopathological changes in heart, brain, liver, bone, eye, kidney, or intestine (thymic cellularity was decreased at 250 mg/kg).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: In these NHP studies, LFD-200 selectively delivered sustained GC levels in immune tissues, resulting in inhibition of ex vivo induced inflammatory cytokines without evidence of systemic toxicity. LFD-200 has the potential to provide a safer, less frequently dosed GC treatment option for patients living with autoimmune or inflammatory diseases.

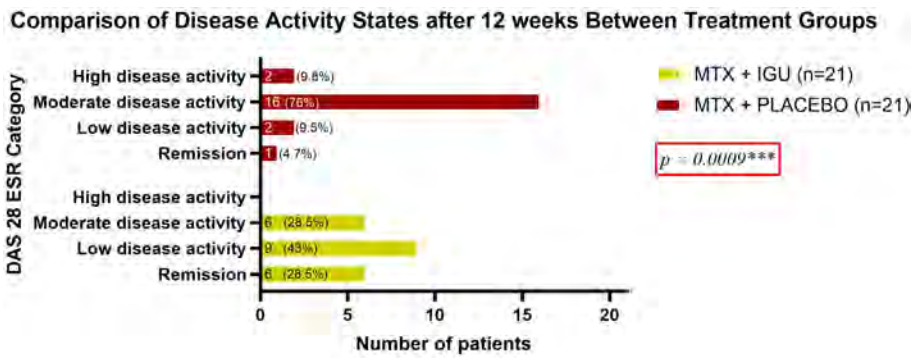
Effectiveness and Safety of Iguratimod with Background Methotrexate Therapy in Indian Patients with Rheumatoid Arthritis: A Randomized Double Blinded Placebo Controlled Study

MIDHUN SAKRAVARTHY JALANATHAN[1], Mehdi Ali Mirza[1], Vijaya prasanna Parimi[2], Seethalakshmi S[1] and Tejaswini Ramineni[3], [1]ESIC Medical College and Hospital, Sanathanagar, Hyderabad, Telangana, India, [2]ESIC Medical College and Super Specilaity Hospital, hyderabad, Telangana, India, [3]Esic Medical College And Hospital, Sanathnagar, Hyderabad, Telangana, India

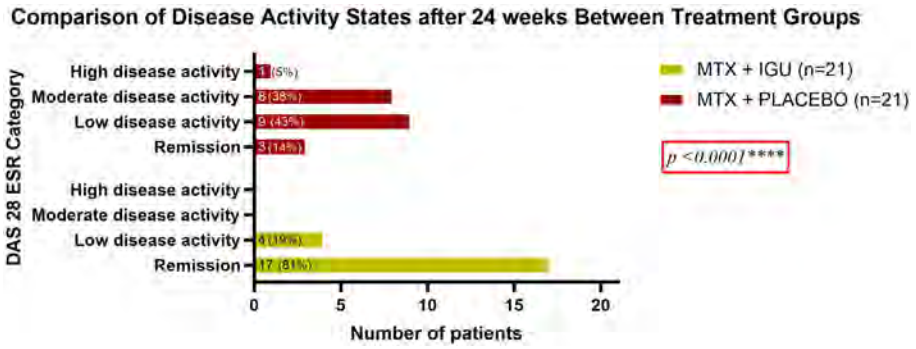
SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Iguratimod (IGU), an oral synthetic disease-modifying antirheumatic drug (DMARD), has shown significant efficacy and safety in rheumatoid arthritis (RA) when combined with methotrexate (MTX) or as monotherapy in Japanese studies [Ishiguro et al, 2013]. RA is a chronic autoimmune disease that, without early intervention, leads to irreversible joint damage and disability. Prompt initiation of DMARDs is crucial to achieving remission and preventing complications. Despite IGU's therapeutic benefits, no randomized controlled trial (RCT) has evaluated its role in Indian RA patients. This study aims to assess the efficacy and safety of IGU with MTX in newly diagnosed, DMARD-naïve Indian patients with active RA.

Methods: In this randomized, double-blind, placebo-controlled, single-centre trial, eligible Indian patients (≥18 years, either gender) with DMARD-naïve, early active RA (ACR-EULAR 2010 criteria, DAS28-ESR ≥3.2, disease duration < 1 year) were



23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



randomized 1:1 to receive either IGU (25 mg twice daily) plus MTX or placebo plus MTX. MTX was initiated at 20mg/week for 12weeks and increased to 25mg/week for the next 12weeks. Randomization was performed using computer-generated block randomization. The primary endpoint was the proportion of patients achieving remission or low disease activity (LDA) per DAS28-ESR at 12 and 24 weeks. Secondary endpoints included ACR20/50/70 response rates at 24 weeks and incidence of adverse events. Statistical analysis was performed using GraphPad Prism v10, with p< 0.05 considered significant.

Results: A total of 42 patients were randomized and treated. Baseline characteristics were comparable: mean age was 49 ±12 years (test) and 48±10 years (placebo); females constituted 90% and 86%, respectively. High disease activity was observed in 90% (test) and 95% (placebo). At 12weeks, remission or LDA was achieved in 71% of the test group (28% remission, 43% LDA) versus 14% (5% remission, 9% LDA) in the placebo group (p=0.0009). By 24weeks, 100% in the test group (81% remission, 19% LDA) and 57% in the placebo group (14% remission, 43% LDA) achieved remission or LDA (p< 0.0001). ACR20/50/70 responses were significantly higher in the test group (100%, 88%, 59%) than in the placebo group (71%, 57%, 9%) (p< 0.0001). Adverse events were comparable (test: 5, placebo: 4, p >0.99), including leukopenia, transaminitis, GI symptoms, and mouth ulcers.

Conclusion: Iguratimod plus methotrexate demonstrated superior efficacy and safety in newly diagnosed DMARD-naïve Indian RA patients, with incremental benefits over placebo for remission or LDA (57% at 12weeks, 43% at 24weeks) and ACR responses (ACR20:29%, ACR50:31%, ACR70:50%). These findings align with Japanese studies [Ishiguro et al, 2013].

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid factor (RF) is an antibody directed against the Fc fragment of IgG that plays a key role in the development of rheumatoid arthritis (RA). Elevated RF levels have been associated with greater disease severity and higher cardiovascular risk. In this context, patients with high RF levels may present a higher inflammatory burden and a lower response to JAK inhibitors (JAKi), possibly due in part to the use of these drugs at low doses. However, previous studies have shown that certolizumab pegol (CZP) offers comparable efficacy in patients with both high and low RF levels.

The objectives of this study were: a) to compare, in RA patients with high RF levels, the efficacy of CZP vs. JAKi after 12 months of treatment and b) to compare the drug retention rate between both groups after 3 years of follow-up.

Methods: Longitudinal, retrospective, multicenter study including RA patients treated with CZP or JAKi (tofacitinib, baricitinib, upadacitinib, or filgotinib) between 2010 and 2024. Baseline RF levels and disease activity (DAS28) were collected at baseline, 6 months, and 12 months, along with treatment start and discontinuation dates. Propensity score (PS) matching was used to match CZP and JAKi groups based on age, prior use of b/tsDMARDs, and concomitant methotrexate use. Change in DAS28 was compared between groups using Student's t-test. Log-rank tests and Kaplan-Meier curves were used to evaluate treatment retention rates in both groups according to RF levels, considering RF ≥200 IU/mL as "very high" levels.

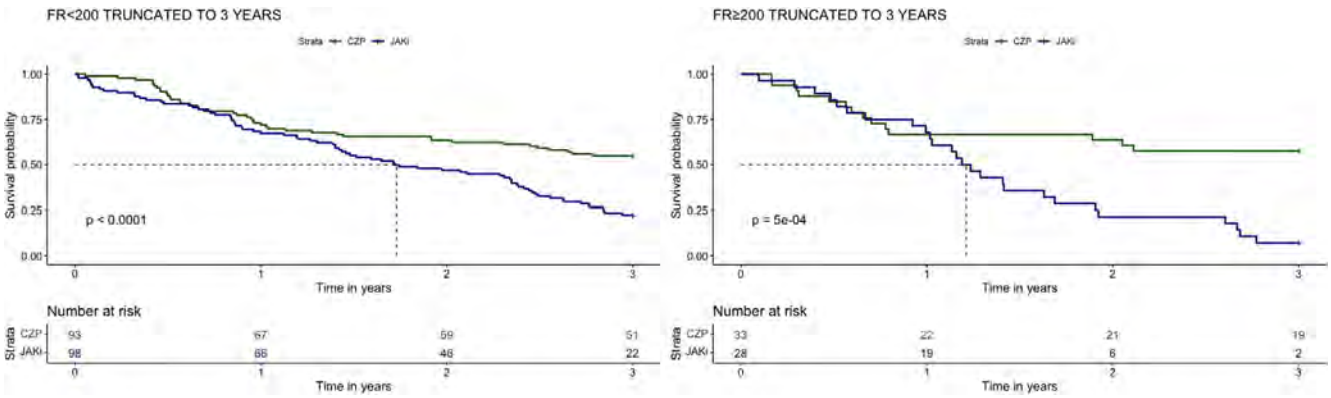

Figure 1. Three-year drug retention rate in patients with (A) RF ≥200 IU/mL and (B) RF <200 IU/mL.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: A total of 364 patients (234 CZP and 126 JAKi) with available RF titers were included. After PS matching, both groups (126 patients each) were comparable in age, sex, disease duration, baseline DAS28, concomitant methotrexate use, and prior b/tsDMARD use.

In patients with RF ≥200 IU/mL, those treated with CZP showed a greater reduction in DAS28 compared to JAKi (-2.12 ±1.29 vs. -1.41±1.38, p=0.098), although this did not reach statistical significance. In patients with RF < 200 IU/mL, the change in DAS28 was similar between groups (-1.66±1.38 vs. -1.89±1.41, p=0.339).

In patients with RF ≥200 IU/mL, the 3-year drug retention rate was significantly higher in CZP vs. JAKi (survival probability 57.6% [95%CI 43.0–77.2] vs. 7.1% [95%CI 1.9%–27.2], p< 0.001). Similarly, in patients with RF < 200 IU/mL, CZP also showed a higher retention rate (survival probability 54.8% [95%CI 45.6%–66.0%] vs. 22.5% [95%CI 15.5%–32.4%], p< 0.001).

Conclusion: In patients with high RF levels (≥200 IU/mL), CZP showed a trend toward greater clinical efficacy after 12 months compared to JAKi. In addition, CZP demonstrated a higher drug retention rate than JAKi in both high and low RF subgroups, suggesting greater persistence of CZP regardless of RF levels in the general RA patient population.

Abstract Number: 0497

Drug Survival and Discontinuation Reasons of Eight Biological Disease-Modifying Antirheumatic Drugs in 1,182 Patients with Rheumatoid Arthritis: A Retrospective Study Using the Niigata Orthopedic Rheumatoid Arthritis Database (NOSRAD)

Nariaki Hao and Naoki Kondo, Division of Orthopedic Surgery, Niigata University Medical and Dental General Hospital, Niigata, Japan

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: To retrospectively evaluate drug survival and reasons for discontinuation of eight biological disease-modifying antirheumatic drugs (bDMARDs) in rheumatoid arthritis (RA) patients using the Niigata Orthopedic Rheumatoid Arthritis Database (NOSRAD).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Methods: Of 1,517 RA patients registered in NOSRAD from May 2001 to August 2022, 1,182 who received at least one of the following bDMARDs were included: abatacept (ABT), adalimumab (ADA), certolizumab pegol (CZP), etanercept (ETN), golimumab (GLM), infliximab (IFX), sarilumab (SAR), and tocilizumab (TCZ). We analyzed patient backgrounds, drug survival, and discontinuation reasons in three groups: the overall cohort, bDMARDs-naïve group, and switch group. The chi-square test and Kruskal–Wallis test were used for categorical and continuous variables, respectively. Drug survival was estimated using the Kaplan–Meier method, and compared by log-rank test. A p-value < 0.05 was considered statistically significant. All statistical analyses were performed using EZR (Saitama Medical Center, Jichi Medical University, Saitama, Japan).

Results: In the naïve group (n = 784), significant inter-drug differences were observed in sex, age, disease duration, the 28-joint Disease Activity Score with erythrocyte sedimentation rate (DAS28-ESR), concomitant methotrexate (MTX) use, concomitant prednisolone (PSL) use, and PSL dose. In the switch group (n = 398), significant differences were found in age, disease duration, DAS28-ESR, MTX use, PSL dose, and whether the drug was used as a second or fourth-line agent.

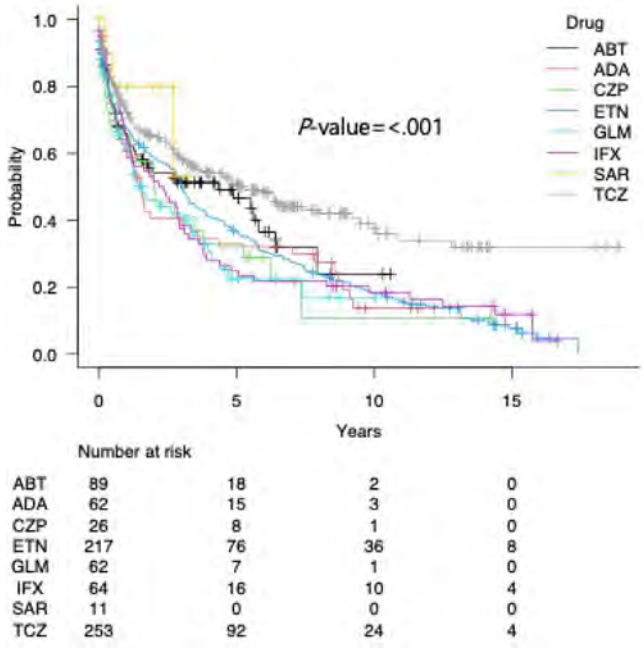

Figure 1. Kaplan-Meier drug-survival rates for each drug in bDMARDs-naïve group.

Others, n (%)	7 (9.5)	17 (6.1)	13 (3.3)	2 (2.3)	4 (2.8)	3 (3.2)	5 (9.4)	3 (5.1)	.091
Remission/good response, n (%)	2 (2.7)	15 (5.4)	14 (3.6)	6 (7)	1 (0.7)	2 (2.1)	2 (3.8)	1 (1.7)	.180
Patient preference, n (%)	0	10 (3.6)	13 (3.3)	0	6 (4.1)	2 (2.1)	1 (1.9)	1 (1.7)	.409
Transfer, n (%)	15 (20.3)	64 (22.9)	47 (12.1)	5 (5.8)	13 (9)	16 (16.8)	2 (3.8)	5 (8.5)	<.001
Others, n (%)	1 (1.4)	3 (1.1)	3 (0.8)	0	0	3 (3.2)	1 (1.9)	0	.277
Unknown, n (%)	4 (5.4)	4 (1.4)	22 (5.6)	5 (5.8)	7 (4.8)	1 (1.1)	1 (1.9)	1 (1.7)	.072

Among the naïve group, TCZ showed the highest drug survival rate (50.8% at 5 years and 37.6% at 10 years). The 5-/10-year survival rates of other bDMARDs were as follows: ABT 46.6%/24.0%, IFX 25.0%/18.5%, ETN 36.6%/18.1%, GLM 22.6%/17.0%, ADA 32.3%/13.7%, and CZP 33.0%/10.8%. In the switch group, ABT had the highest survival rate (42.6% at 5 years and 21.3% at 10 years), followed by TCZ (38.2%/21.1%), ADA (18.3%/18.3%), ETN (15.1%/8.1%), CZP (17.3% at 5 years; 10-year data unavailable), GLM (14.8%; 10-year data unavailable), and IFX (10.0%; 10-year data unavailable). The proportion of discontinuation due to insufficient efficacy was 40.5% for IFX, 34.3% for ETN, 16.7% for TCZ, 38.4% for ADA, 22.8% for ABT, 28.4% for GLM, 41.5% for CZP, and 23.7% for SAR. Discontinuation due to adverse events was 20.3%, 20.0%, 16.7%, 17.4%, 13.1%, 16.8%, 24.5%, and 8.5%, respectively. Discontinuation due to non-adverse reasons (remission or good response, patient preference, transfer, others, or unknown) was 29.7%, 34.3%, 25.4%, 18.6%, 18.6%, 25.3%, 13.2%, and 13.6%, respectively.

Conclusion: In the naïve group, TCZ had the highest survival; in the switch group, ABT did. Switching was associated with lower survival. ABT was often used in older patients and had fewer discontinuations due to adverse events, suggesting its potential utility in elderly RA. This large-scale, single-center, long-term study highlights the importance of selecting and dosing bDMARDs appropriately to maintain long-term efficacy.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Dr. Reddy's-abatacept (DRL_AB) is being developed as a biosimilar to the reference product (RP) (RP-US licensed Orencia®) and the reference medicinal product (RMP) (RMP-EU approved Orencia®). The primary objective of this study was to demonstrate PK similarity of DRL_AB compared to RP and RMP as well as between RP and the RMP following a single 750 mg intravenous (i.v.) dose.

Methods: This Phase I study included healthy male subjects assigned to DRL_AB, RP, or RMP in a randomized, double-blind, parallel group design. The primary objective was to demonstrate PK similarity in terms of $AUC_{0\text{-}inf}$, with secondary objectives including other PK parameters ($AUC_{0\text{-}t}$, C_{max}, t_{max}), safety, tolerability and immunogenicity comparison.

Results: A total of 114 male subjects aged 18 and 50 years with a BMI between 19.3 kg/m^2 and 29.6 kg/m^2 participated in the study. Baseline characteristics were similar between groups. The $AUC_{0\text{-}inf}$ for abatacept following treatment with DRL_AB was comparable to RP and RMP. The 90% CI of T/R ratio for $AUC_{0\text{-}inf}$ fell within the bioequivalence criteria (80.00%, 125.00%) when DRL_AB compared with RP or RMP. After correcting for the protein content differences, the 90% CI of T/R ratio for $AUC_{0\text{-}inf}$ being 105.27% [99.00%, 111.93%]) for DRL_AB compared to RP and 111.29% [105.15%, 117.78%]) for DRL_AB as compared to RMP. The 90% CIs for $AUC_{0\text{-}inf}$ were maintained within the bioequivalence criteria after excluding ADA positive subjects. The secondary PK endpoints ($AUC_{0\text{-}t}$, C_{max}, t_{max}) were also comparable between groups. The 90% CI of T/R ratios for $AUC_{0\text{-}t}$ and C_{max} fell within the bioequivalence criteria (80.00%, 125.00%) when DRL_AB was compared with RP or RMP. The tmax for abatacept was similar for DRL_AB versus RP or RMP and this was confirmed by non-parametric analysis. A total of 84 subjects experienced at least one Treatment-emergent adverse event (TEAE), with a similar proportion across the DRL_AB (68.4%), RP (81.1%), and RMP (71.8%) groups. Most of the TEAEs (222 out of 238) were of mild severity, while 16 were considered moderate. The incidence of moderate TEAEs was 15.8% in DRL_AB, 8.1% in RP, and 7.7% in RMP groups. Adverse events of special interest (AESIs) like hypersensitivity, viral infections, and other infections were similar between groups. Eight AESIs were reported in 8 subjects (7.0%); 2 (5.3%) in DRL_AB, 2 (5.4%) in RP, and 4 (10.3%) in RMP groups. No deaths or serious adverse events (SAEs) were reported, and all TEAEs resolved without sequelae. The incidence of treatment-emergent ADA positivity was 15.8% in the DRL_AB group, 8.1% in the RP group, and 10.3% in the RMP group. Number of subjects reporting ADA CTLA-4 tested positive with the treatments DRL_AB, RP and RMP were 5 (13.2%), 1 (2.7%), 3 (7.7%) on Day 85 respectively and all these were reported first time at Day 85. The number of subjects reporting neutralizing antibody (NAb) positivity with DRL_AB, RP, and RMP were 0, 1 (2.7%), 0 on Day 15, and 2 (5.3%), 2(5.4%), 3 (7.7%) on Day 85, respectively. The incidence of ADA and NAb, as well as ADA titer, were comparable following treatment with DRL_AB, RP, and RMP.

Conclusion: The study demonstrated PK similarity of DRL_AB with RP and RMP in healthy subjects, with comparable safety and immunogenicity profiles.

Abstract Number: 0499

Olokizumab Improves Patient-Reported Outcomes in Rheumatoid Arthritis MTX-IR and TNF-IR Patients up to 106 Weeks (Results from Clinical Phase III Program)

Roy Fleischmann[1], Eugen feist[2] and Josef Smolen[3], [1]Metroplex Clinical Research Center and University of Texas Southwestern Medical Center, Dallas, TX, [2]Helios Department of Rheumatology, Vogelsang-Gommern, Germany, [3]Division of Rheumatology, Department of Medicine 3, Medical University of Vienna, Vienna, Austria, Vienna, Austria

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Olokizumab (OKZ), an interleukin-6 inhibitor approved in several countries for managing rheumatoid arthritis (RA), was evaluated in previous phase III RCTs, demonstrating changes in patient-reported outcomes (PROs) for MTX-IR and TNFi-IR patients with active disease [1-3]. This study extends those findings to assess the long-term sustainability of OKZ's effects on PROs up to 106 weeks (ClinicalTrials.gov number, NCT03120949).

Methods: We included all randomized for OKZ or PBO in phase III clinical program patients (with active rheumatoid arthritis and fulfilled the ACR/EULAR 2010 revised classification criteria). We analyzed data using the Intent-To-Treat population, utilizing a mixed model for repeated measures to assess changes from baseline. Results are expressed as least squares mean (LSM) and standard error. The proportion of patients reporting improvement from baseline at week 24 ≥ the minimal clinically important difference (MCID) in HAQ-DI scores was determined using thresholds of ≥0.22 and ≥0.3 points. Post hoc responder analyses were conducted to estimate the percentages of patients who reported improvement from baseline ≥ MCID of 10 mm for PtGA and pain VAS scores; 2.5 points for SF-36 PCS and MCS scores, 5 points for individual domains; and 4 points for the FACIT-F. Discontinuations or use of rescue medication classified subjects as non-responders.

Results: Overall 1982 patients were included. MTX-IR and TNFi-IR populations were comparable at baseline with a mean age of 53 years, mostly women (77-90%), 56-61% using glocucorticoids, and DAS28-CRP approximately 5.87-5.99 (RA duration, CDAI, intolerance to ≥15 mg/week MTX dose and HAQ-DI were numerically higher in TNFi-IR patients). At week 12, OKZ biweekly (q2w), and every four weeks (q4w), compared with placebo showed significantly greater LSM improvements in all PROs for MTX-IR patients (Table 1). For TNFi-IR patients, improvements were not as large as in MTX-

Table 1. Change from baseline in patient-reported outcome scores at weeks 12, 24 and 106 (as observed). MTX-IR #p<0.050 compared to the baseline value within the group. All p values are nominal. Figure 1. SF-36 domain changes from baseline to week 106 Abbreviations: AGNorms, age- and gender-matched normative values; BP, bodily pain; GH, general health; MTX-IR, methotrexate irresponsive; MH, mental health; OKZ, olokizumab; PF, physical functioning; PBO, placebo; RE, role emotional; RP, role physical; SF-36, the Short Form health survey is a 36-item, patient-reported survey; SF, social functioning; TNFi-IR, tumor necrosis factor inhibitors irresponsive; VT, vitality

IR population (Table 2). PRO improvements were sustained through week 106. Post hoc analyses demonstrated a higher proportion of patients receiving OKZ attained improvements ≥ MCID vs. placebo ($p< 0.05$) at week 12 in all (except EQ-5D) reported PROs for both MTX-IR and TNFi-IR. Numbers needed to treat (NNT) ranged from 4.6 to 11.6 with OKZ q2w vs 10.6 to 13.5 with OKZ q4w (MTX-IR), and from 7.6 to 27.8 and 7.5 to 34.5 (TNFi-IR), accordingly. SF-36 domain changes from baseline to week 106 presented (Figure 1).

Conclusion: Treatment with OKZ over 106 weeks resulted in statistically significant and clinically meaningful improvements in PROs compared to baseline in both MTX-IR and TNFi-IR RA patients. The improvements in PRO's were observed as early as week 12, were sustained and improved further to week 106. There were no discernible differences between the two regimens of OKZ regarding patient reported outcomes.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: In our previous Rheumatoid Arthritis Medication TAPering (RheumTAP) cohort study of patients with stable RA in remission on biologics +/- methotrexate at Allegheny Health Network (AHN), we found that the risk of flare was the lowest and insignificant with tapering methotrexate (MTX) alone (13%) compared to tapering biologics1. This result needed to be confirmed in larger studies given that current guideline recommendations on this topic are based on low level evidence. Thus, we built a collaborative cohort between AHN and Penn State Health (PSH) of patients with stable RA on MTX. A patient and provider survey within both cohorts demonstrated interest in MTX tapering2.

Methods: A retrospective cohort of adult patients with RA in sustained remission or low disease activity for at least 6 months while on MTX was created at both centers. The data were longitudinally followed between 1/1/2020-12/31/2022. The following tapering related variables were analyzed: reasons for MTX taper (remission, conception, infection, surgery, CKD, malignancy, side effect), tapering strategy (reduction vs. discontinuation), and tapering speed (gradual vs. rapid) along with others listed in Table 1. Clinical outcomes were compared between the groups at 3 and 6 months and the end of follow-up. Flare was defined as CDAI >10 and/or any worsening of disease activity leading to initiation of rescue therapy i.e. restoration of MTX dose or change of current therapy.

Results: Our cohort included a total of 100 patients with stable RA in remission or low disease activity while on MTX. Of these, 77 underwent MTX tapering. Baseline comparisons are listed in Table 1. MTX taper was initiated by the providers in

Improvement on MTX initiation	75 (97.4%)	20 (90.9%)

Comparison of MTX taper vs Continuation groups

Variable	MTX taper group (N=77)	MTX continuation group (N=23)	p-value (Chi-square)
Flare rate, 3 months	32 (41.55%)	3 (13.04%)	0.01
Flare rate, end of follow up period	34 (44.16%)	9 (37.5%)	0.67
Proportion in remission, 6 months	61 (79.22%)	13 (56.52%)	0.029
Re-achieved remission after flare	30 (88.24%)	5 (55.5%)	0.44

Clinical Outcomes of MTX taper vs Continuation Groups

62 (80.5%) patients with the most common reason for tapering being remission (64%), followed by side effects/transaminitis (25%). Most patients had a MTX dose reduction (85.7%) vs stoppage (4.29%). Tapering was gradual (< 50% reduction over >4 weeks) in most patients. Median reduction in MTX dose was by 25% and 24 (31.58%) patients reduced MTX by at least 50%. There was no statistically significant difference in overall flare risk between MTX taper vs continuation groups at the end of follow-up period [n=34 (44.16%) vs 9 (37.5%), p=0.67] (Table 2). However, risk of flare was significantly higher in taper vs continuation group at 3 months [32 (41.55%) vs 3 (13.04%), RR 3.1, 95%CI 1.07-9.45, p=0.036]. There was no significant difference in proportion of patients in remission at 6 months [61 (79.2%) vs 13 (56.5%), RR 1.4, 95%CI 0.96 to 2.04, p=0.078]. In the taper group, most patients (88.24%) re-achieved remission with restoration of MTX dose.

Conclusion: In our retrospective cohort study on the outcomes of MTX tapering in well-controlled RA, patients who tapered or stopped MTX were no more likely to experience a flare by end of follow up period or sustain remission at 6 months after tapering than patients that continued MTX. However, the risk of flare after 3 months of MTX tapering was 3 times higher than MTX continuation which highlights the importance of close follow up after tapering. Most patients re-achieved remission with restoration of MTX after a flare.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Regulatory T cells (T_{regs}) modulate inflammation, maintain self-tolerance, and promote tissue repair, and thus hold promise as a versatile therapeutic tool. Autologous polyclonal T_{regs} have a favorable safety profile but equivocal efficacy in autoimmune disorders.

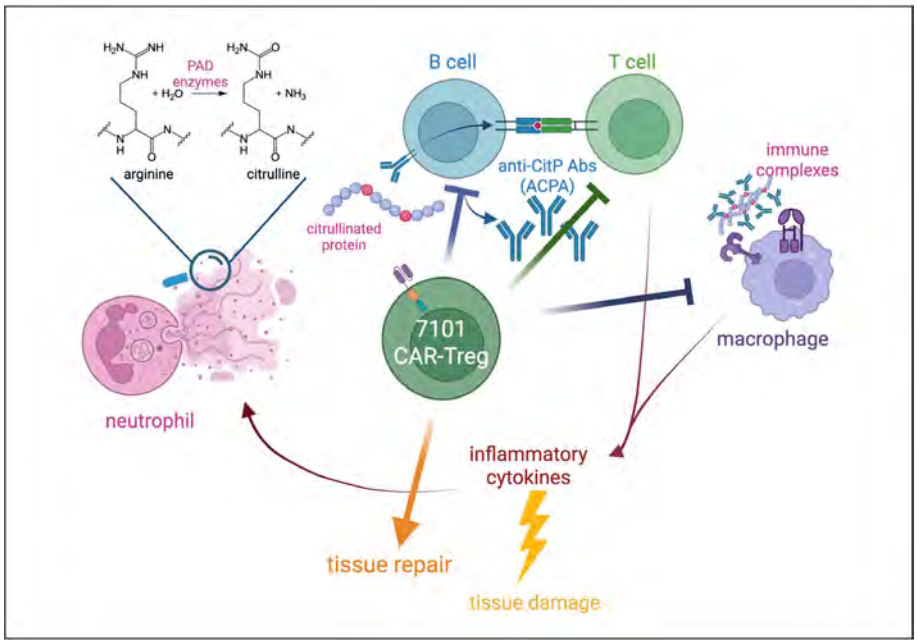

Figure 1: SBT777101 CAR-T regulatory cells target citrullinated intracellular proteins (Cit-P). Cit-P are released by activated neutrophils undergoing NETosis. Cit-P can serve as autoantigens leading to the formation of anti-CitP antibodies (ACPA), citrullinated peptides presented on HLA-DRB*01 "shared epitope" alleles activate T cells, and Cit-P-ACPA immune complexes activate macrophages. These innate and adaptive immune processes amplify inflammation leading to tissue damage. Engineered Tregs expressing a CAR reactive to Cit-P are hypothesized to down-modulate multiple inflammatory processes and promote tissue repair.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

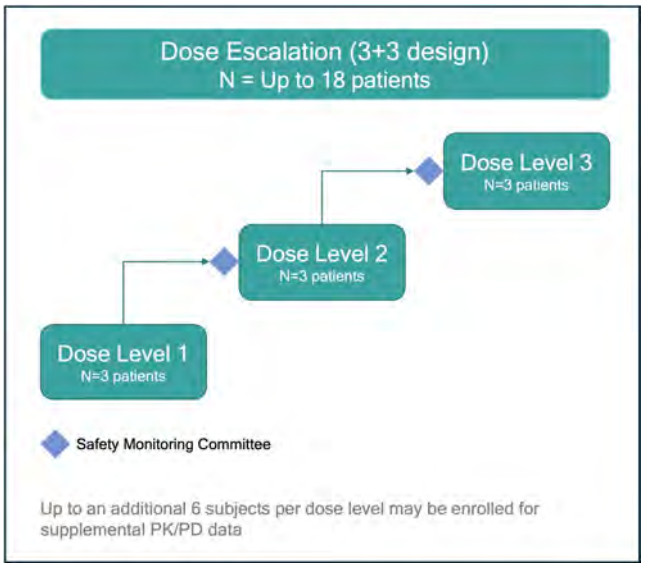

Figure 2: REGULATE-RA is a first-in-human phase 1 dose-escalation study. Each dose level cohort comprises three participants, with a safety monitoring committee evaluation prior to escalation to the next dose cohort.

Engineered T_{regs} offer a novel approach by introduction of a chimeric antigen receptor (CAR) specific for tissue- or disease-associated antigens. SBT777101 is an autologous T_{reg} product transduced with a CAR specific for citrullinated proteins (Cit-P), which are present in the inflamed synovium of participants with rheumatoid arthritis (RA, Figure 1). Unlike cytotoxic CAR-T therapies, SBT777101 may restore balance to the immune system without cell destruction. Potential mechanisms of action include bystander suppression of antigen presenting cells and effector T cells, IL2 consumption, and immunomodulatory cytokine production to promote immune homeostasis and tissue repair.

REGULATE-RA is an ongoing first-in-human, phase 1 study to evaluate the safety and tolerability of autologous CAR-T_{reg} therapy targeting Cit-P in patients with refractory RA. Exploratory endpoints include the assessment and characterization of SBT777101's pharmacokinetic (PK) profile, pharmacodynamic (PD) parameters, mechanism of action (MOA), and preliminary efficacy.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: The study includes RA participants aged 18-70 with moderate-to-severe active disease (DAS28-CRP≥3.2). Participants must have demonstrated an inadequate response to, or intolerance of, at least 3 biologic or targeted synthetic disease-modifying antirheumatic drugs with differing MOA.

SBT777101 is prepared by transduction of autologous T_{regs} with a Cit-P-specific CAR and is administered in a 3+3 dose-escalation design (figure 2).

Participants are monitored for adverse events and clinical response over a 48-week study period. PK, PD, and MOA are evaluated in peripheral blood and, where available, synovial biopsies. All participants are encouraged to enter a 15-year long-term follow-up study for safety evaluation.

Results: Prior to patient enrollment, a manufacturing process for SBT777101 was established and shown to produce consistent yield, functionality, and molecular signatures from both healthy donors and RA participants. For dosed participants, the yield and molecular signatures of manufactured products have remained consistent with the preclinical manufacturing results.

As of April 2025, four participants have received infusions of SBT777101, and no dose-limiting toxicities have been observed. Four additional participants are enrolled but are not yet dosed. Patient characteristics are summarized in Table 1.

All four dosed participants tolerated the infusion, with no cytokine release syndrome, neurotoxicity, or other immune-mediated toxicities detected. Clinical assessments and biomarker analyses are ongoing to assess changes in disease activity, systemic inflammation and T_{reg} activity.

Conclusion: To date, CAR-T_{reg} therapy targeting Cit-P demonstrates a favorable safety profile in this early phase study. Ongoing enrollment and follow-up will provide additional insights into characterization, pharmacodynamics and efficacy outcomes.

Abstract Number: 0502

Real-World Comparative Safety of Tocilizumab and Sarilumab in Rheumatoid Arthritis: A Multi-Center Observational Study

Satani Sharkas[1], Saeed Abughazaleh[2] and Dariush Jahandideh[3], [1]Boston Medical Center - Brighton, Brighton, MA, [2]Boston Medical Center - Brighton, Brighton, [3]Boston Medical Center - Brighton, Boston

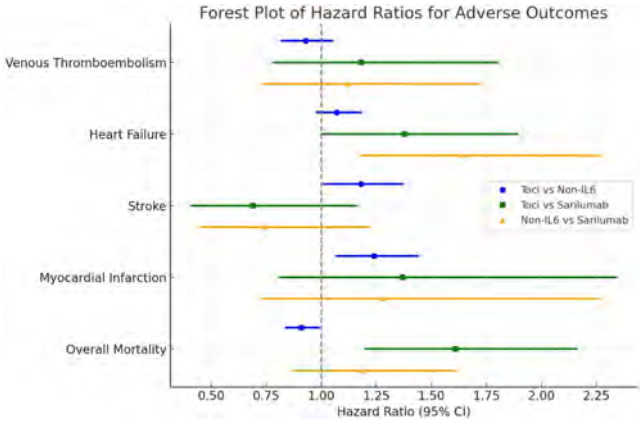
SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Interleukin-6 (IL-6) inhibitors, including tocilizumab and sarilumab, are approved treatments for rheumatoid arthritis (RA). However, comparative safety data on cardiovascular outcomes and all-cause mortality in real-world settings remain limited. We conducted a multi-cohort analysis to evaluate the safety profiles of IL-6 inhibitors compared to non-IL6 regimens, including sensitivity analyses by follow-up duration and sex.

Methods: We performed a retrospective cohort study using the TriNetX Global Collaborative Network, including adult RA patients treated with tocilizumab, sarilumab, or no IL-6 inhibitors. Patients were grouped into three matched cohorts: Non-IL6, Tocilizumab-only, and Sarilumab-only. Propensity score matching (1:1) was conducted using demographics, comorbidities, medications, and laboratory variables. Outcomes included all-cause mortality, myocardial infarction (MI), stroke, heart failure (HF), and venous thromboembolism (VTE) over a 5-year follow-up. Sensitivity analyses included a truncated 3-year window and sex-stratified comparisons.

Results: Matched cohorts included 17,958 patients per group (non-IL6 vs Tocilizumab), 1,855 per group (non-IL6 vs Sarilumab), and 1,992 per group (Tocilizumab vs Sarilumab). Tocilizumab was associated with higher mortality than Sarilumab (5.6% vs 3.7%; risk difference [RD]: 1.9%; hazard ratio [HR]: 1.61; 95% CI: 1.20–2.16; p = 0.001), and higher mortality than non-IL6 (6.4% vs 5.5%; RD: –1.0%; p < 0.001). Mortality did not significantly differ between Sarilumab and Non-IL6. MI, stroke, HF, and VTE risks were comparable across all groups, with findings consistent in the 3-year analysis. In sex-stratified analyses, mortality was significantly higher in males treated with Tocilizumab versus Sarilumab (8.3% vs 4.8%; RD: 3.5%; p = 0.049; HR: 1.86; 95% CI: 1.04–3.32), while the difference in females was not significant.



Forest Plot of Hazard Ratios for Adverse Outcomes: Tocilizumab vs Non-IL6, Tocilizumab vs Sarilumab, and Non-IL6 vs Sarilumab

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Outcome	Tocilizumab (n)	Events (%)	Sarilumab (n)	Events (%)	Risk Difference (95% CI)	Risk Ratio (95% CI)	Hazard Ratio (95% CI)	P-value
Overall Mortality	1,986	112 (5.6%)	1,985	74 (3.7%)	+0.019 (0.006–0.032)	1.51 (1.14–2.02)	1.61 (1.20–2.16)	0.001
Myocardial Infarction	1,936	31 (1.6%)	1,942	24 (1.2%)	+0.004 (–0.004–0.011)	1.30 (0.76–2.20)	1.37 (0.81–2.34)	0.242
Stroke	1,941	24 (1.2%)	1,952	37 (1.9%)	–0.007 (–0.014–0.001)	0.65 (0.39–1.09)	0.69 (0.41–1.16)	0.159
Heart Failure	1,834	86 (4.7%)	1,843	68 (3.7%)	+0.010 (–0.003–0.023)	1.27 (0.93–1.74)	1.38 (1.00–1.89)	0.049
Venous Thromboembolism	1,895	46 (2.4%)	1,908	42 (2.2%)	+0.002 (–0.007–0.012)	1.10 (0.73–1.67)	1.18 (0.78–1.80)	0.428

Clinical Outcomes: Risk Differences, Hazard Ratios, and Odds Ratios for Adverse Events Across Matched Cohorts

Conclusion: In this large real-world RA cohort, sarilumab was associated with lower all-cause mortality than tocilizumab, particularly among male patients. Cardiovascular outcomes were similar across treatments. These findings support the need for individualized IL-6 inhibitor selection, with consideration of treatment duration and patient sex.

Disclosure: S. Sharkas: None; **S. Abughazaleh**: None; **D. Jahandideh**: None.

Abstract Number: 0503

Impact of Olokizumab on Pain in Rheumatoid Arthritis: a Meta-analysis

Andrey E. Karateev[1], **Sofia Kuzkina**[2], Alina Egorova[3] and Elena Y. Polishchuk[1], [1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, [2]R-Pharm, Moscow, Russia, [3]R-Pharm JSC, Moscow, Russia

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Pain is one of the most debilitating symptoms of rheumatoid arthritis (RA) and a major contributor to reduced quality of life. Persistent joint pain severely limits daily activities and can lead to work disability, emotional distress, and diminished overall well-being. Olokizumab (OKZ) is a humanized anti-interleukin-6 monoclonal antibody approved for RA. We aimed to evaluate the impact of OKZ on patient-reported pain in RA through a meta-analysis of clinical and observational studies.

Methods: We systematically searched PubMed and eLibrary databases for studies reporting pain outcomes in RA patients treated with OKZ (Figure 1). Eligible sources included 3 randomized controlled trials (RCTs) and 4 real-world observational studies with pain assessments at 12 and 24 weeks. 3 RCTs and 2 observational studies were included for evaluation, while other 2 observational trials were currently withdrawn due to need in recalculation of certain measures of variance. A random-effects model (DerSimonian–Laird) was used to pool mean changes from baseline and mean differences versus placebo with corresponding 95% confidence intervals. When necessary, medians were converted to means and standard deviations based on Wan et al.'s method. All analyses were conducted in R (v4.4.1).

Results: In the RCTs, OKZ treatment led to clinically meaningful pain improvement compared to placebo. At 12 weeks, the mean reduction in patient pain (VAS) from baseline was greater in OKZ groups than in placebo by –14.05 points (95% CI –19.51 to –8.58) for 64 mg q2w and –13.89 (95% CI –19.52 to –8.56) for 64 mg q4w (both $p < 0.001$). These benefits were sustained or enhanced by Week 24, with OKZ-treated patients maintaining significantly greater pain reduction than placebo.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

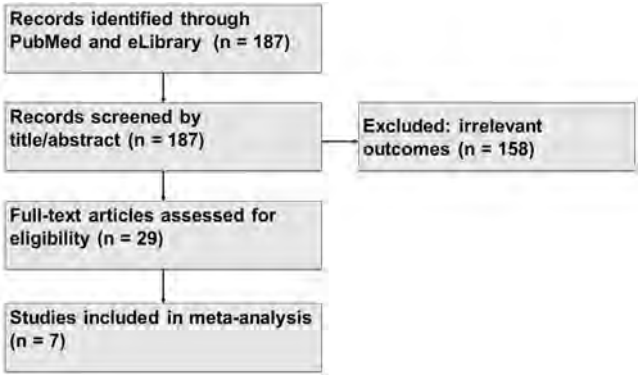


Figure 1. Literature search and study selection flowchart for pain outcomes

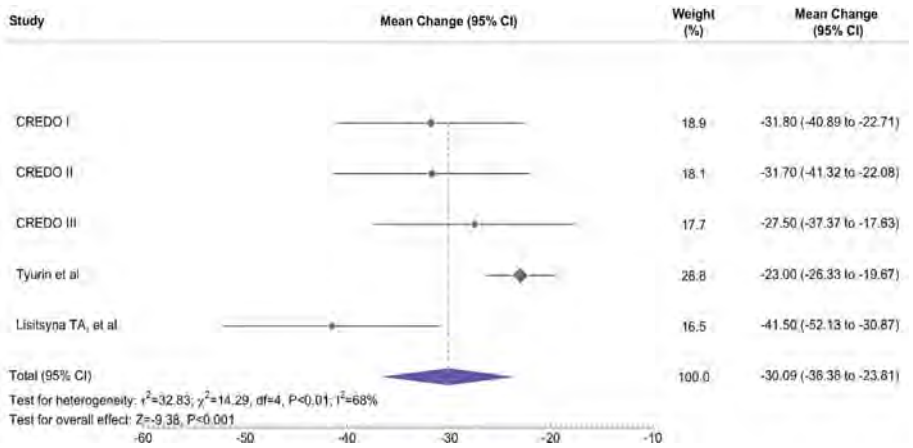

Figure 2. Pooled mean change in pain (VAS 0–100) at Week 12 with OKZ 64 mg q4w. CI- confidence interval

Due to the non-comparative nature of observational studies they only revealed changes of pain in OKZ groups vs baseline. Real-world data echoed the findings in RCTs: patients on OKZ experienced robust pain relief over 12 weeks (figure 2), and the changes were sustained through week 24 when the mean pain reduction with OKZ reached -37.13 (-42.66 – 31.59) mm from baseline (Tyurin et al had data by 12 weeks only) (figure 3). All the changes vs baseline were significant (p< 0,001).

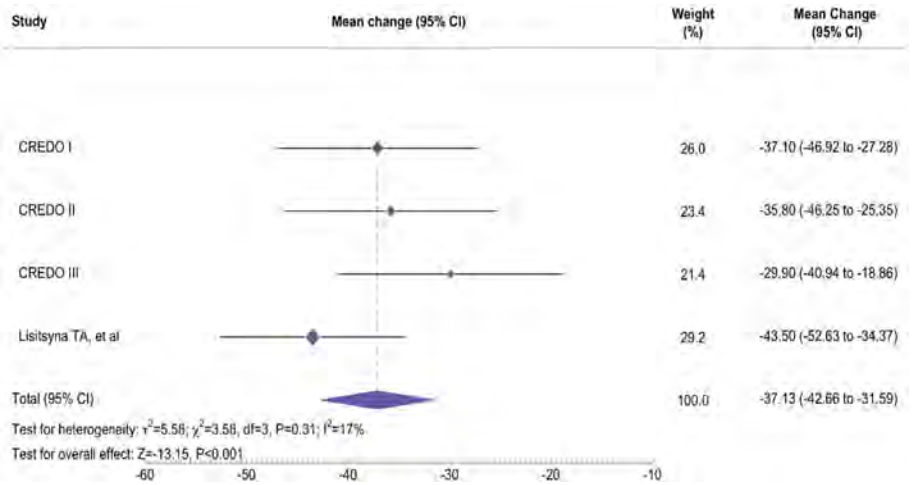

Figure 3. Pooled mean change in pain at Week 24 with OKZ 64 mg q4w CI- confidence interval

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: OKZ significantly reduces patient-reported pain in RA, with greater improvements than placebo observed in clinical trials and similarly robust pain relief reported in real-world studies. These meta-analytic findings underscore the value of OKZ as an effective therapy for managing pain in RA.

Abstract Number: 0504

Spatial profiling of gene signatures in synovial tissue informs treatment strategy for Rheumatoid Arthritis

Vincent Wong[1], Katie Lowe[2], Annabelle Small[3], Christopher Altmann[3], Susanna Proudman[4], Malcolm Smith[2], Wittaya Suwakulsiri[5], Ranjeny Thomas[5], Chung Hoow Kok[6] and Mihir Wechalekar[7], [1]College of Medicine and Public Health, Bedford Park, South Australia, Australia, [2]Flinders University, Adelaide, South Australia, Australia, [3]Flinders University, Bedford Park, South Australia, Australia, [4]The University of Adelaide, Adelaide, Victoria, Australia, [5]Frazer Institute, University of Queensland, Brisbane, Queensland, Australia, [6]Centre for Cancer Biology, and Clinical Health Sciences, University of South Australia, Adelaide, South Australia, Australia, [7]Flinders Medical Centre and Flinders University, Bedford Park, South Australia, Australia

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) shows heterogeneous therapeutic responses that may reflect diversity within synovial tissue (ST). We aimed to identify gene signatures that predict Adalimumab response and provide an initial spatial transcriptomic validation of their cellular context.

Methods: ST biopsies were obtained from 30 anti-citrullinated protein antibody–positive, treatment-naïve RA patients (symptom duration ≤ 12 months) classified by immunohistochemistry as TNF- or T-cell-dominant. Bulk RNA-seq data for all protein-coding genes were analysed with glmnet LASSO-regularised logistic regression to derive a small set of genes predictive of remission versus non-remission using baseline samples from patients targeted for Adalimumab treatment (remission and non-remission at 3 months; DAS CRP< 2.6). The resulting model was also applied on baseline samples from Abatacept and triple-DMARD non-responders. The predictive genes were mapped onto high-resolution Stereo-seq spatial transcriptomic sections. Spatially resolved expression was assessed against cell-type annotations derived from unsupervised clustering and marker genes.

Results: A concise set of genes clearly separated early-remission from non-remission cases in the Adalimumab cohort. When applied to baseline samples from other treatment arms, the predictive model identified one patient in the Abatacept cohort and six patients in the triple-DMARD cohort as having remission-like profiles, indicating scope for treatment re-stratification. Preliminary Stereo-seq analysis suggests these genes may be more locally enriched in baseline ST from early-remission cases (Figure 1).

Conclusion: This study identifies key synovial gene signature that predicts clinical response to Adalimumab and demonstrate, for the first time, its restricted spatial expression in specific ST cell populations. Although preliminary, these Stereo-seq data strengthen the biological plausibility of the signature and support future validation in larger spatial cohorts. Incorporating qPCR-based testing of these genes in routine biopsies could expedite personalised therapeutic decisions in RA.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0470–0505) Rheumatoid Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: While clinical trials have demonstrated the efficacy of upadacitinib (UPA), real-world data are essential to understand patient characteristics and assess its effectiveness in routine clinical practice.

This study aims to describe a real-world cohort of patients with rheumatoid arthritis (RA) initiating treatment with UPA, analyzing cohort characteristics, UPA efficacy, and its glucocorticoid (GC)-sparing effect.

Methods: This was a multicenter observational study of patients with active RA who started UPA. Prescription decisions were made at the discretion of rheumatologists, and patients were included consecutively. Epidemiological and clinical data were collected. Concomitant GC treatment was assessed at baseline and at follow-up visits after 1, 3, 6, and 12 months.

Table 1. Baseline demographics, RA characteristics and treatment for total cohort

	Patients n=99
Demographics	
Age	55.17 ± 12.0
Age ≥ 65 years old	19.2%
Female	89.9%
BMI	26.1 ± 5.4
Ever smoker	37.9%
RA Characteristics	
Age at diagnosis	41.61 ± 12.9
RA duration	13.52 ± 9.2
RF+	70.7%
ACPA+	67.7%
TJC	7.81 ±6.8
SJC	6.12 ± 6.0
CRP mg/L	4.9 ± 11.7
ESR mm/h	23.81 ± 20.4
DAS28-ESR	4.75 ± 1.5
CDAI	25.91 ± 14.6
Erosive disease	61.6%
Treatment	
Use of GC	69.7%
GC dose mg/d	7.37 ± 5.0
Combination with scDMARD	53.5%
Number of previous DMARD	1.59 ± 0.8
Number of previous b/tsDMARD	2.80 ± 2.0
UPA as 1st line of advanced therapy	7.0%
UPA as 2nd line of advanced therapy	22.2%
UPA as ≥3rd line of advanced therapy	70.7%
Comorbidities	
RCDI	1.07 ± 1.5
Hypertension	21.2%
DM2	6.1%
Fragility fracture	3.0%
Depression	15.2%
Lung disease	15.6%

Data presented as mean ± 1 standard deviation or n (%). BMI: body mass index, RF: rheumatoid factor, ACPA: anti-citrullinated peptides antibodies, TJC: tender joint count, SJC: swollen joint count, CRP: C reactive protein, PHS: patient global health, ESR: erythrocyte sedimentation rate, GC: glucocorticoid, b/ts DMARD: biologic or targeted synthetic Disease-Modifying Antirheumatic Drugs, RCDI: rheumatic disease co-morbidity index, DM2: diabetes mellitus type 2.

Data presented as mean ± 1 standard deviation or n (%). BMI: body mass index, RF: rheumatoid factor, ACPA: anti-citrullinated peptides antibodies, TJC: tender joint count, SJC: swollen joint count, CRP: C reactive protein, PHS: patient global health, ESR: erythrocyte sedimentation rate, GC: glucocorticoid, b/ts DMARD: biologic or targeted synthetic Disease-Modifying Antirheumatic Drugs, RCDI: rheumatic disease co-morbidity index, DM2: diabetes mellitus type 2.

Results: A total of 99 patients were included, 89.9% of whom were female, with a mean (SD) age of 55.17 (12.0) years. Among them, 19.2% were ≥65 years old. At UPA initiation, patients generally had moderate to high disease activity, with a mean (SD) DAS28 score of 4.75 ± 1.5. UPA was used in combination with csDMARDs in 53.5% of patients and with GCs in 69.7%, with a mean (SD) dose of 7.37 ± 5.0 mg/dL. Seventy percent of patients started UPA as ≥3rd-line advanced therapy (additional data in Table 1). At 3, 6, and 12 months, 82%, 71%, and 61% of patients continued UPA treatment, while 60.5%, 65%, and 67% had achieved low disease activity or remission, respectively.

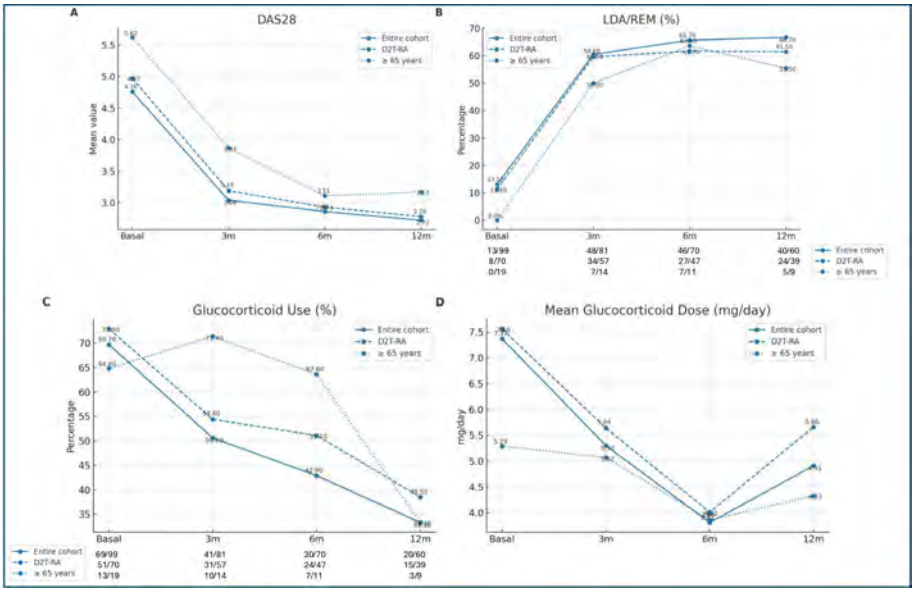
Table 2. Evolution of disease activity and GC use and dose

	DAS28	LDA/REM	GC	Dosis GC
Entire cohort				
Basal n=99	4.76 ± 1.5	13.1% (13/99)	69.7% (69/99)	7.37 ± 5.0 mg/d
3m n=81	3.04 ± 1.3	60,5% (49/81)	50.6% (41/81)	5.30 ± 3.4 mg/d
16m n=70	2.86 ± 1.2	65.7% (46/70)	42.9% (30/70)	3.81 ± 1.9 mg/d
12m n=60	2.72 ± 0.9	66.7% (40/60)	33.3% (20/60)	4.91 ± 3.5 mg/d
D2T-RA (UPA started as ≥3rd line of advanced therapy)				
Basal n=70	4.97± 1.4	11.4% (8/70)	72.9% (51/70)	7.56 ± 5.2 mg/d
3m n=57	3.19 ± 1.4	59.6% (34/57)	54.4% (31/57)	5.64 ± 3.6 mg/d
6m n=47	2.93 ± 1.2	61.7% (29/47)	51.1% (24/47)	4.01± 1.9 mg/d
12m n=39	2.78 ± 0.9	61.5% (24/39)	38.5% (15/39)	5.66 ± 3.8 mg/d
≥ 65 years old				
Basal n=19	5.62 ± 1.3	0%	64.8% (13/19)	5.29 ± 3.0 mg/d
3m n=14	3.87 ± 2.0	50% (7/14)	71.4% (10/14)	5.07 ± 3.8 mg/d
6m n=11	3.11 ± 1.6	63.6% (7/11)	63.6% (7/11)	3.86 ± 1.4 mg/d
12m n=9	3.17 ± 0.8	55.5% (5/9)	33.3% (3/9)	4.33 ± 1.2 mg/d



Evolution since baseline and up to 12 months of follow up of: A DAS28, B proportion of patients in LDA (low disease activity)/ REM (remission), C proportion of patients in treatment with GC and D mean dose of GC, in de entire cohort (full line), D2T-RA (dashed line) and patients ≥65 years old (dotted line).

A GC-sparing effect was observed throughout the study period. At baseline, nearly 70% of patients were receiving GC therapy. By 3 months, 20% had discontinued GC, and by 12 months, only 33% remained on GC. The mean GC dose also decreased (Table 2).

A secondary analysis compared patients who started UPA as ≥3rd-line advanced therapy (D2T-RA) with those who initiated it as 1st or 2nd-line treatment. Patients in the ≥3rd-line group had significantly longer disease duration (15.1 vs. 9.58 years, p=0.005) and had received more csDMARDs before starting advanced therapy. However, they were more likely to start UPA as monotherapy (45% in D2T-RA vs. 70% in non-D2T-RA). No significant differences were observed in baseline disease activity or GC use. Treatment response and GC-sparing effects were similar in both groups.

Among patients ≥65 years old, combination therapy with csDMARDs was used in 50% of patients, and 65% received GC, with a mean (SD) dose of 5.29 ± 3.0 mg/d. Treatment response and GC-sparing effects were comparable to those in

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. patients ≤65 years old. Over the follow-up period, nine infections were reported, including two severe cases. UPA was discontinued in two patients.

Conclusion: Most patients in this real-world cohort initiated UPA as ≥3rd-line advanced therapy. Half started UPA in combination with csDMARDs, and 70% received concurrent GC therapy. A significant early reduction in GC use was observed, with over half of GC-treated patients discontinuing GC by 12 months. UPA was effective in both older patients and those with refractory disease.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0506–0521) Sjögren's Disease – Basic & Clinical Science Poster I: Etiology, Pathogenesis, Diagnosis

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Clinical tests for Sjögren's disease (SjD) often overlook Ro-seronegative (Ro^{Neg}) cases, leading to delayed or missed diagnoses. Identifying additional serum autoantibodies could improve diagnostic accuracy and enhance disease management. Proteome-wide autoantibody screening in Ro^{Neg} SjD cases was previously reported using HuProt 3.2 arrays (CDI Labs) with 19,500 proteins[1]. This expanded study utilizes HuProt 4.0 arrays with >21,000 human proteins. The aim of the study was to identify 24 autoantibody specificities that best discriminate Ro^{Neg} SjD (n=86; 30% ESSDAI≥5) from healthy control (HC, n=24) and other rheumatic disease (OD, n=44; 45% SLE, 39% RA, 9% SSc, 7% other) groups for further development of a multiplex Luminex assay.

Methods: Arrays were probed as per the manufacturer except serum incubations were for 18h at 5°C. IgG (635 nm), and IgA (532 nm) signals were collected using anti-human, heavy chain-specific IgG and IgA secondary antibodies. After assisted alignment of signals with array templates using a novel algorithm-based alignment tool, data were quantile-normalized, and positive thresholds (avg + 3*SD of HCs) for antibody binding to each protein established. Fisher's exact tests ($p< 0.1$) identified specificities bound more commonly in the Ro^{Neg} group compared to HC and OD groups. Protein specificity enrichments were explored using STRING. A machine learning pipeline (2/3 training, 1/3 testing) incorporating chi-square selection, random forest-based feature selection, and logistic regression was used for classification.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. A panel of 24 IgG autoantibody specificities selected by machine learning and manual curation distinguishes Ro seronegative Sjögren's disease (RoNEG SjD) from healthy control (HC) and other rheumatic disease (OD) groups with ROC AUC = 0.95.

Results: Fisher's analysis revealed 27 specificities bound by IgG more commonly in RoNeg SjD (14-22%) vs HC (0-4%), with a subset of 4 (CBX3, CBX5, NAV3, NUSAP1) also bound more commonly by IgG from RoNeg SjD vs OD, and significant enrichment in specificities located in pericentric heterochromatin by STRING analysis. The RoPos SjD group bound 57 proteins more commonly than HC, with a subset of 14 recognized more commonly than in the OD group, and STRING enrichment in RNA and miRNA regulation. Common specificities overlapping between RoNeg and RoPos groups included ATAT1, CBX3, PAIP1, PNPLA1, PTK6 and SLC19A1. Machine learning was applied to RoNeg SjD, OD and HC groups.

* Specificities curated solely from manual analysis. All others were identified by the machine learning pipeline. ** p<0.1 indicates common specificiteis prevalent in RoNeg SjD.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

IgG binding to 121 proteins discriminated the RoNeg group with ROC AUC=0.88. IgA and combined IgG + IgA specificities yielded lower ROC AUC values. A panel of 24 IgG specificities selected from one end of the distribution of logistic regression coefficients yielded ROC AUC=0.83. Replacement of 6 specificities with others showing high prevalence among RoNeg SjD by manual analysis yielded a ROC AUC=0.95 for distinguishing RoNeg SjD cases from HC and OD groups (Table 1; Figure 1).

Conclusion: Using proteome arrays, a novel array alignment algorithm, and machine learning pipelines, we developed an advanced approach for autoantibody biomarker discovery in Ro^{Neg} SjD, defining a curated panel of 24 autoantibodies with potential diagnostic significance.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0506–0521) Sjögren's Disease – Basic & Clinical Science Poster I: Etiology, Pathogenesis, Diagnosis
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Sjögren's disease (SjD) is a chronic systemic autoimmune disease primarily affecting the exocrine glands. There is an increasing use of salivary gland ultrasound in SjD due to its good diagnostic yield and noninvasive, radiation-free, low-cost, and reproducible nature. Limited information exists on lacrimal gland ultrasound. The objective was to determine the usefulness of lacrimal and salivary gland ultrasound in diagnosing patients with primary SjD of recent onset compared to primary sicca syndrome.

Tear gland greater than or equal to 3 points		15 (100)	0	0.000

TABLE 1. Demographic and clinical characteristics of patients with SjD and SICCA syndrome.

Methods: We included primary SjD patients of recent onset (≤5 years) who fulfilled the 2016 ACR/EULAR criteria attending a tertiary reference center. We also included sicca controls matched by age(±5 years), sex, and disease duration (±5 years). An ophthalmologist evaluated keratoconjunctivitis sicca, including Schirmer test, OSS score, and Van Bijsterveld Score. We scored the ESSPRI and the Ocular Surface Disease Index [OSDI] questionnaire. We excluded both patients and controls with diabetes mellitus or with a body mass index ≥30.

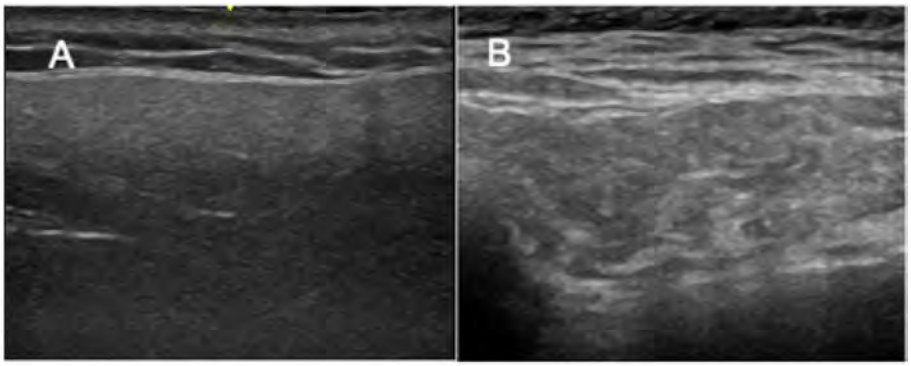
Ultrasound evaluation of the lacrimal and salivary glands (parotid and submandibular) was performed using a GE LOGIQe device with an 8-18 MHz linear probe. The OMERACT and Hocevar ultrasound scales were used for the salivary glands, and the scale reported by Kim et al. (1) for the lacrimal glands.

Results: We included 15 patients with primary SjD and 15 sicca controls. Patients and controls had similar symptoms, disease duration (60 months vs 40 months), and ESSPRI scores (6 points and 5 points). SjD patients had a higher degree of tear dysfunction than sicca controls (46.7% and 53.3% vs. 0% and 80% with moderate and mild damage, respectively; p=0.005). However, both groups had similar OSDI scores. Baseline characteristics are shown in Table 1.

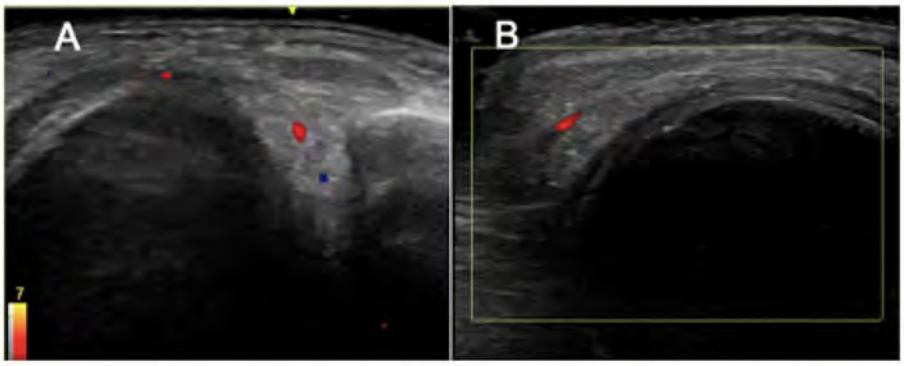
The OMERACT score had good diagnostic performance, with an AUC of 0.97 (95% CI: 0.89–1; $p < 0.0001$). The Hocevar scale, using two cut-off points of 14 and 17 points, had a good, adequate diagnostic performance, with an AUC of 0.93 (95% CI: 0.82-1; $p < 0.0001$) and 0.9 (95% CI: 0.77-1; $p < 0.0001$), respectively.

Regarding the lacrimal gland, the presence of an intraglandular arterial branch, loss of homogeneity, hypoechoic areas, hyperechoic bands, and loss of glandular demarcation were features mainly observed in patients with SjD vs sicca controls

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



A) Healthy parotid gland (OMERACT 0). B) Parotid gland with moderate loss of parenchymal homogeneity with focal hypo/anechoic areas, surrounded by normal tissue (OMERACT 2).



A) Presence of intraglandular branch of the lacrimal artery. B) Extra glandular branch of the lacrimal artery.

Figure 1. Examples of glandular ultrasounds performed on patients with SjD and sicca syndrome.

($p < 0.0001$ for each of them). Finally, we observed a strong correlation between the tear gland and Hocevar scores (rho = 0.83, $p< 0.001$).

Conclusion: Ultrasonography of both the lacrimal and salivary glands is a valuable diagnostic tool for identifying patients with primary SjD of recent onset from sicca controls.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0506–0521) Sjögren's Disease – Basic & Clinical Science Poster I: Etiology, Pathogenesis, Diagnosis

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Fc-gamma receptor (FcγR) activation by soluble IgG immune complexes (sICs) is considered to play a pivotal pathogenic role in B-cell-mediated autoimmune diseases, such as primary Sjögren's disease (SD). Previous indirect ELISA assays based on the affinity of sICs to C1q or C3d, were not sensitive enough and did not allow a correct discrimination between IgG monomers and sICs.

Methods: In serum at enrollment from 369 patients with primary SD prospectively followed up since 2005, FcγR activation was measured. Briefly, reporter cells transfected with human-FcγRIIA were incubated with patient's serum (1). Incubation was performed in a 96-well ELISA plate for 1 h at 4°C. Reporter cell IL-2 secretion was quantified after 20 h of incubation using ELISA. The area under curve (AUC) of IL2 secretion was compared to that resulting from incubation of synthetic ICs (hTNFa with infliximab) to obtain an equivalent quantification (pM).

Results: Serum levels of sICs were significantly correlated with serum levels of IFN-alpha assessed by digital ELISA (r=0,5 ; p= $2.5*10^{-19}$). In multivariate analysis, taking notably anti-SSA, rs9273012 (a HLA class II gene polymporphism previously reported to be associated with serum IFN-alpha level) and clinESSDAI into account, sICs remained significantly and independently associated with serum levels of IFN-alpha(p=$7,6*10^{-7}$).

Median serum levels of sICs were higher in patients with moderate or high systemic disease activity (ESSDAI≥5) at enrolment than in patients with no or low systemic disease activity (ESSDAI< 5) (121 pM/L vs 88 pM/L, p= 0.03). Median serum levels of sICs were higher in patients with B cell activation markers and no systemic disease activity or in patients with moderate to severe systemic disease activity than in patients with high symptom burden and no systemic disease activity (121 pM/L, 90 pM/L and 51 pM/L, respectively, p< 0.001), these 3 patient clusters defined as recently published (2). No association was observed between serum ICs and history of previous lymphoma. Ten incident lymphoma have occured since patients were enrolled in the cohort. Among patients with incident lymphoma, serum levels of sICs were significantly higher than in patient without lymphoma (225 vs 94, p=0,025)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Serum sICs assessed using a cell-based assay are associated with activation of type I interferon pathways, systemic disease activity, and incident lymphoma in Sjogren's disease.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0506–0521) Sjögren's Disease – Basic & Clinical Science Poster I: Etiology, Pathogenesis, Diagnosis
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Sjögren's disease (SjD) is a systemic autoimmune disease characterized by immune-mediated damage to salivary and lacrimal glands. While autoantibodies against muscarinic type 3 receptor (M3R) have long been implicated in disease pathogenesis, their clinical relevance remains unclear. We hypothesized that pathogenic anti-M3R antibodies originate in inflamed salivary glands and are detectable in both circulation and saliva, where their presence correlates with objective measures of disease activity.

Methods: Recombinant monoclonal antibodies (mAbs) were generated from single cells infiltrating labial salivary glands of classified SjD, NSS (non-Sjögren's sicca), and overlap SjD subjects and screened for binding to linear and conformational M3R epitopes. Monoclonal antibodies along with matched plasma and saliva samples, as well as an expanded plasma cohort, were screened using a conformational On-Cell Western assay. Functional effects were assessed via inhibition of M3R signaling in a cell-based activity assay. Associations with clinical features and disease activity were evaluated.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Results: A subset of IgG^+ mAbs from SjD glands bound conformational M3R and inhibited signaling. These features were reflected in matched plasma and, to a lesser extent, saliva. In the larger cohort, plasma anti-M3R reactivity was significantly elevated in SjD and showed association with ocular staining scores, focus scores, and higher ESSDAI biological domain activity. ROC analysis supported moderate diagnostic potential (AUC = 0.736).

Conclusion:

These findings demonstrate that anti-M3R antibodies are functionally relevant and detectable in both salivary gland tissue and the circulation. Their association with key glandular and systemic disease features underscores the importance of conformational assays in identifying clinically meaningful autoantibodies. These results suggest that anti-M3R reactivity may define distinct immunopathologic subtype within SjD and serve as a potential biomarker of disease activity.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0506–0521) Sjögren's Disease – Basic & Clinical Science Poster I: Etiology, Pathogenesis, Diagnosis
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Interstitial lung disease (ILD) affects 10-15% of Sjögren disease (SjD) patients, leading to increased morbidity and reduced survival. The true prevalence may be higher due to underdiagnosis, partly due to the lack of effective risk factor–based screening tools compared to other connective tissue diseases. Current guidelines recommend screening at-risk SjD patients using high-resolution computed tomography (HRCT), but effective risk factor estimation tools are lacking, leaving it unclear which patients should be referred for HRCT in practice. The objective was to develop a decision support tool for estimating the risk of ILD in SjD patients, guiding HRCT referrals in clinical practice.

Methods: We included all SjD patients from three European expert rheumatology centers (Zurich, Oslo and Vienna) with available HRCT images of the chest. All HRCT images were reviewed by expert radiologists at each site for the presence of ILD. Available data included demographic, serological and laboratory data, clinical SjD manifestations, and other comorbidities. To create the decision support tool, we developed a nomogram based on a logistic regression model (with Odds ratio (OR) and 95% confident interval (CI)) to estimate patient-specific probabilities, translating multivariable relationships into

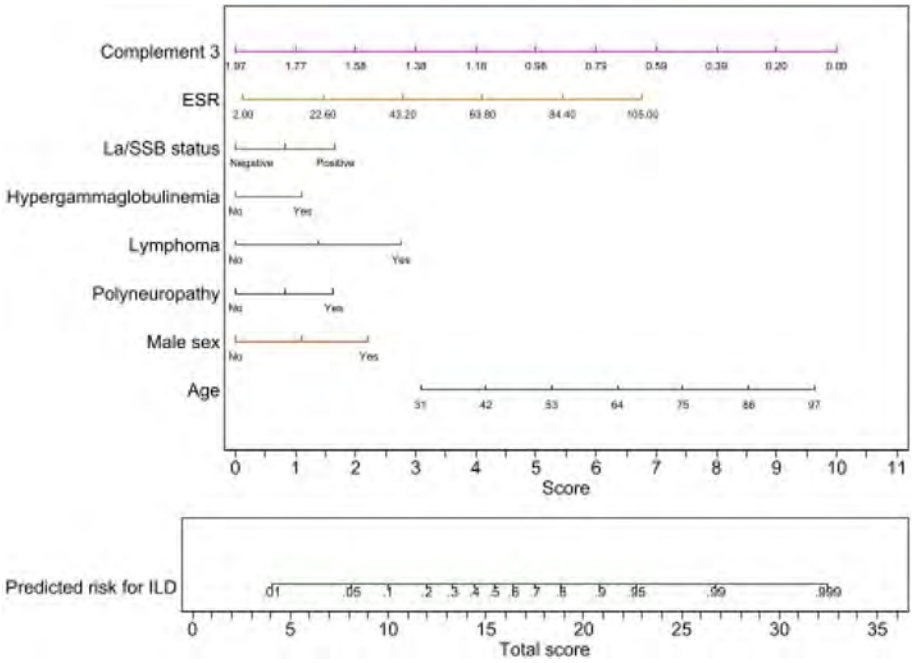

Figure 1: Nomogram estimating the ILD probability in SjD patients, informing HRCT referrals based on individual risk

a graphical tool for clinical application. Predictor variables were selected based on clinical relevance, statistical significance and the area under the ROC curve (AUC) of the final multivariable logistic model.

Results: We included 547 SjD patients with HRCT, of which 163 (29.8%) had ILD. Demographic and clinical characteristics are presented in Table 1. In multivariable regression, age (OR 1.01, 95%CI 1.01-1.07, p< 0.001), erythrocyte sedimentation rate (ESR) (OR 1.03, 95%CI 1.01-1.04, p=0.003), and complement C3 (OR 0.13, 95%CI 0.05-0.35, p< 0.001) were significantly associated with the presence of ILD, adjusted for male sex, polyneuropathy, lymphoma, hypergammaglobulinemia and anti-La/SSB antibodies. The model was deemed acceptable (AUC 0.8). Based on this multivariable model, we built a nomogram which is a practical decision support tool estimating the probability of ILD in SjD patients, informing HRCT referrals based on individual risk.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

An example patient who is female, 50 years old, positive for anti-La/SSB, has hypergammaglobulinemia, an ESR of 40 mm/hour, and C3 of 0.8g/L has a total score of 15.5, which corresponds to a 50% predicted risk of having ILD.

Conclusion: We developed a nomogram-based decision support tool that effectively estimates the risk of ILD in SjD patients using key predictors such as age, sex, hypergammaglobulinemia, antibodies, extrapulmonary organ manifestation, ESR and complement C3 levels. This tool aids clinicians in making informed HRCT referral decisions, addressing potential underdiagnosis in at-risk SjD patients and improving early detection and outcomes. Future validation in broader populations is necessary to confirm its clinical utility.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0506–0521) Sjögren's Disease – Basic & Clinical Science Poster I: Etiology, Pathogenesis, Diagnosis

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: In primary Sjögren's syndrome (pSS), the histologic focus score reflects immune infiltration but does not capture irreversible glandular damage. We evaluated a submandibular gland (SMG) gland ratio—defined as the proportion of preserved parenchyma in biopsy sections—as a marker of structural integrity, and assessed its associations with salivary function, serology, and imaging.

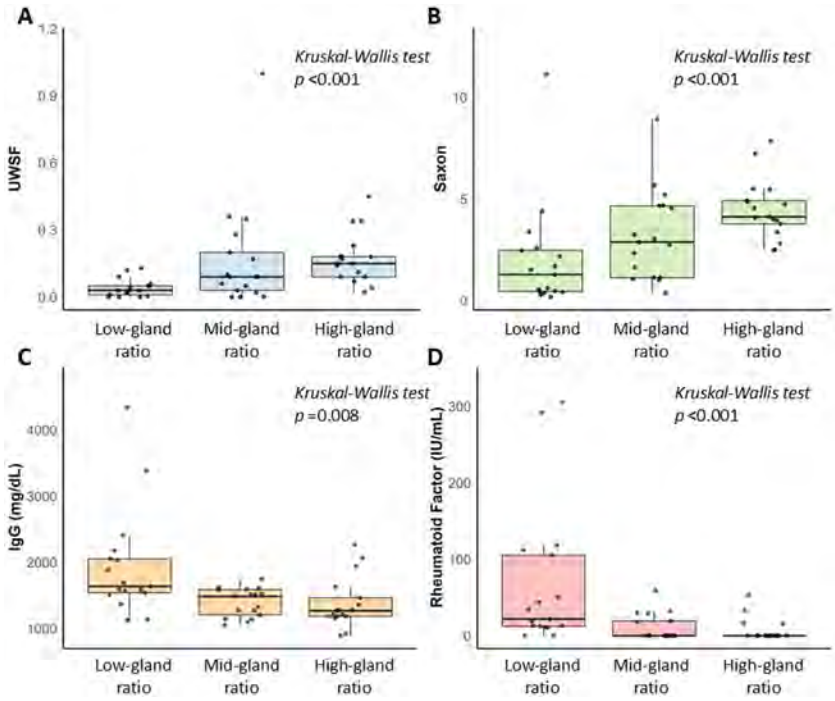

Figure 1. Salivary function and serologic activity across tertiles of submandibular gland (SMG) gland ratio. (A–B) Saxon test and unstimulated whole salivary flow (UWSF) improved with increasing gland preservation. (C–D) Serum IgG and rheumatoid factor decreased across tertiles. SMG, submandibular gland; UWSF, unstimulated whole salivary flow.

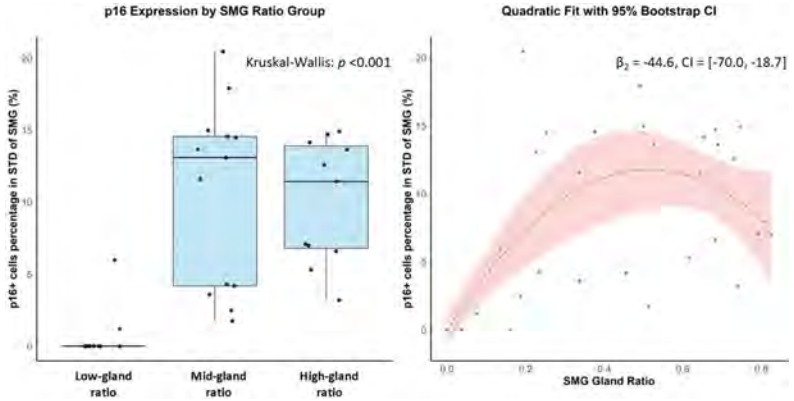

Figure 2. p16^{+} cell percentage in striated ducts (STD) across submandibular gland (SMG) gland ratio tertiles in anti-SSA^{+} pSS (n = 36). (Left) Boxplot showing increased p16^{+} burden in mid- and high-tertile groups. (Right) Quadratic regression model reveals a bell-shaped association, peaking near gland ratio 0.5 (95% bootstrap CI shaded). No similar pattern was observed in anti-SSA^{-} patients (not shown).

Table 1. Clinical, serologic, and imaging features across submandibular gland (SMG) gland ratio tertiles. Gland ratio was defined as the preserved parenchymal area over total biopsy section. p-values based on Kruskal–Wallis test. UWSF, unstimulated whole salivary flow; ESSDAI, EULAR Sjögren's syndrome disease activity index.

Characteristics	Low gland ratio (T1, n = 17)	Mid-gland ratio (T2, n = 17)	High gland ratio (T3, n = 17)	p-value
Female, n (%)	16 (94)	17 (100)	13 (76)	0.111
Age, year, median (IQR)	57.0 (16.0)	55.0 (15.0)	46.0 (20.0)	0.065

*p < 0.05

ESSDAI, EULAR Sjögren's syndrome disease activity index; IQR, interquartile range; SMG, submandibular gland; PG, parotid gland; UWSF, unstimulated whole salivary flow

Methods: We analyzed 51 anti-SSA$^+$ pSS patients who underwent SMG core needle biopsy (CNB); 46 had paired parotid gland (PG) CNB. The gland ratio was calculated as the area of preserved acini and ducts divided by total tissue area, including stroma, adipose, and fibrosis. Patients were stratified by SMG gland ratio tertiles. Salivary function was assessed by unstimulated whole salivary flow (UWSF) and Saxon test. Serologic markers included IgG, rheumatoid factor (RF), complement, and CK. Among 29 patients, SMG sialoscintigraphy was performed. In 36 patients, p16$^+$ cells were quantified in striated ducts by immunohistochemistry.

Results: Lower SMG gland ratios were associated with impaired salivary function. UWSF increased from median 0.02 to 0.20 mL/min across tertiles (p< 0.001); Saxon test rose from 1.3 to 4.1 mL/2 min (p< 0.001). IgG (p=0.008) and RF (p< 0.001) decreased with greater gland preservation. Echography scores (OMERACT) also declined with increasing gland ratio (p=0.011). SMG gland ratio correlated with sialoscintigraphy uptake (ρ=0.55–0.61) and maximal secretion (ρ=0.63–0.65). PG gland ratio showed marginal association with Saxon (p=0.067) but not UWSF. In a subset (n=36), p16$^+$ cells in striated ducts showed a bell-shaped association with gland ratio, peaking near 0.5, suggesting senescence may rise before overt tissue loss.

Conclusion: The SMG gland ratio stratifies salivary function, immune activity, and imaging findings in anti-SSA$^+$ pSS, supporting its potential as a histologic anchor for structural damage staging. Preliminary findings further suggest senescence may peak in moderately preserved glands, highlighting its possible role in early irreversible injury.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0506–0521) Sjögren's Disease – Basic & Clinical Science Poster I: Etiology, Pathogenesis, Diagnosis

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Dry eye is a multifactorial disease of the ocular surface characterized by a loss of homeostasis of the tear film. This is commonly observed in patients with rheumatic diseases, particularly among patients with Sjögren's Syndrome (SS). SS is an autoimmune disease that mainly affects exocrine glands such as the salivary and lacrimal glands, causing chronic dryness of the ocular surface resulting in inflammatory reaction and gradual destruction of conjunctival epithelium. According to the 2016 ACR/EULAR classification criteria, a positive minor salivary gland (MSG) biopsy is considered the criterion with the highest weight, along with positive serology. However, the relationship between MSG involvement and dry eye disease (DED) is poorly understood. We aimed to determine the DED severity among patients with SS with a positive or negative MSG biopsy.

Methods: We performed a cross-sectional study, including patients of 18 years or older, with DED symptoms and primary SS (according to 2016 ACR/EULAR criteria), between 2015-2024. MSG biopsy, Unstimulated Whole Salivary Flow rate (UWSF), tear film osmolarity, tear matrix metalloproteinase 9 (MMP-9), Ocular Surface Disease Index (OSDI), tear break-up time (TBUT), SICCA ocular surface staining (SICCA OSS), and Schirmer tear test with and without anesthesia (STT) were evaluated. Only the worst eye was included, which was selected based on the SICCA OSS score. We used descriptive statistics (frequencies [%], mean ± SD, median [IQR]) to present the results and compared the patients with positive or negative biopsies with Chi^2, Mann-Whitney U, or Student's tests as appropriate. A p-value < 0.05 was considered statistically significant. This study was approved by the institutional review board and all participants provided written informed consent.

Results: We included 142 patients, the mean age was 52.93 ± 12.62 years, and 97.2% (n=138) of patients were women. One hundred twenty-one (85.2%) had a positive MSG biopsy, and 21 patients were biopsy negative. Patients with positive biopsy had similar OSDI scores (39.6 [IQR: 0-100]) than those with negative biopsies (47.91 [IQR: 4-79.2]; p=0.505; Table 1). Similarly, biopsy-positive patients had similar SICCA OSS (7.0 [IQR: 0-15] vs. 6.0 [IQR: 1.0-12]; p=0.443) and tear film osmolarity (307 [IQR: 277-397] vs 307 [IQR: 284-345]; p=0.392) than biopsy-negative patients. Positivity to tear MMP-9 (29, 24.0% vs 4, 19.0%; p=0.440), STT with anesthesia (5, 1-35 vs 7.0, 1-25; p=0.399) or without anesthesia (5, 0-35 vs 7, 1-35; p=0.290), and the TBUT (4, 1-15 vs 4, 2-10; p=0.289) were no different between patients with positive or negative MSG biopsy.

Conclusion: Positive minor salivary gland biopsy was not associated with worse dry eye disease in patients with primary SS.

Hematologic, Chemistry, Autoantibody, and Immunologic Laboratory Comparison

Background/Purpose: While Sjögren's disease is commonly associated with anti-SSA (anti-Ro) and/or anti-SSB (anti-La) antibodies, these autoantibodies are not disease-specific and may be present in various autoimmune conditions. Emerging evidence suggests that isolated anti-SSB positivity is not strongly associated with Sjögren's or other connective tissue diseases, whereas dual positivity for anti-SSA and anti-SSB may indicate a more severe disease phenotype [1-4]. This study aimed to compare the clinical and serologic profiles of patients with isolated anti-SSB antibodies to those with concurrent anti-SSA and anti-SSB positivity in a real-world clinical setting.

Symptoms	Anti-SSA/SSB	Anti-SSB	p-value
Joint pain	1.5 (0.2 - 12.2)	0.7 (0.1 - 5.7)	0.725
Joint swelling	0.89 (0.1 - 5.3)	1.1 (0.2 - 6.8)	0.896
Joint stiffness	1.2 (0.1 - 10.3)	0.8 (0.1 - 7.0)	0.86
Xeropthalmia	21.5 (2.5 - 185.4)	0.1 (0.0 - 0.4)	0.005
Xerostomia	4.0 (0.7 - 24.1)	0.2 (0.0 - 1.5)	0.126
Hair loss	1.5 (0.2 - 14.8)	0.6 (0.1 - 6.2)	0.705
Skin rash	0.3 (0.1 - 1.7)	3.1 (0.6 - 15.9)	0.181
Serositis	5.1 (0.2 - 116.0)	0.2 (0.0 - 4.5)	0.31

Odds Ratio (OR) for Clinical Symptomology between Groups

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Diagnosis	Anti-SSA/SSB (n=206)	Anti-SSB (n=109)	p-value
Sjogren's Disease	134 (65%)	27 (24%)	<0.001
Systemic Lupus Erythematosus	68 (33%)	8 (7%)	<0.001
Rheumatoid arthritis	25 (12%)	2 (2%)	<0.001
Other rheumatologic diagnosis*	27 (13%)	19 (17%)	0.318
No rheumatologic diagnosis	62 (30%)	86 (79%)	<0.001

*Includes: polymyositis, dermatomyositis, undifferentiated connective tissue disease, mixed connective tissue disease, axial spondyloarthritis, or systemic sclerosis.

Comparison of Clinical Diagnoses between Groups

Methods: A retrospective analysis of electronic medical records from January 1, 2018, to December 31, 2022 was conducted. Adults (≥18 years) with positive serologic testing for anti-SSA and anti-SSB antibodies were included. Patients with isolated anti-SSA, negative repeat serology within six months, or insufficient clinical data were excluded. Demographic data, clinical manifestations, autoantibody profiles, and diagnostic outcomes were compared between groups. Statistical analysis included Student's t-test and chi-squared tests for group comparisons, and univariate and multivariate logistic regression to estimate odds ratios (OR), with a significance threshold of $p < 0.05$.

Results: A total of 315 patients were included: 109 with isolated anti-SSB and 206 with both anti-SSA/SSB positivity. The groups were similar in age and sex distribution (83% vs. 85% female). Compared to the dual-positive anti-SSA/anti-SSB, patients with isolated anti-SSB antibody were significantly less likely to exhibit anemia, leukopenia, proteinuria, or positive ANA. Other autoantibodies (anti-Smith, anti-RNP, RF, anti-CCP) were also less frequent in the isolated anti-SSB group. Additionally, this group had lower rates of xerophthalmia and diagnoses of Sjögren's disease, systemic lupus erythematosus, and rheumatoid arthritis, and were more often left without a rheumatologic diagnosis.

Conclusion: Isolated anti-SSB positivity is associated with a significantly lower likelihood of Sjögren's disease, SLE, and RA. These findings suggest that isolated anti-SSB may lack diagnostic utility in connective tissue diseases and could represent a benign serologic finding in many patients.

Background/Purpose: Blood immunophenotyping reveals systemic immune alterations and therapeutically actionable molecular endotypes in Sjögren's Disease (SjD). Reported changes include reduced memory B cells, plasmacytoid dendritic cells (pDC), and myeloid dendritic cells (mDC). Prior studies focused on Ro seropositive (Ro^{Pos}) SjD and utilized peripheral blood mononuclear cells, which are prone to processing artifacts. To avoid this limitation, we used mass cytometry with a point-of-care whole blood assay to compare immune cell frequencies in both Ro^{Pos} and Ro seronegative (Ro^{Neg}) SjD participants.

Methods: Blood samples from multiple sites were stained using the 30-marker Maxpar Direct Immune Profiling Assay (MDIPA) for broad immune phenotyping, then shipped to a central lab for CyTOF XT acquisition. Data were processed with OMIQ software, using FlowCut for quality control. Manual gating followed manufacturer guidelines to quantify total and lineage-specific immune cell subsets. Absolute cell counts were derived using individual white blood cell (WBC) counts. This study included 10 HC, 12 Ro^{Neg} SjD, and 31 Ro^{Pos} SjD participants, with cases meeting 2016 ACR/EULAR criteria. Principal component analysis (PCA) and heatmaps were used for dimension reduction and clustering.

Results: Novel findings included increased frequencies of transitional monocytes within the monocyte lineage in Ro^{Pos} vs. Ro^{Neg} SjD (p=0.022), with selective increases in Ro^{Pos} SjD cases with elevated disease activity (ESSDAI≥5) (p=0.032). Absolute counts of transitional monocytes trended higher in Ro^{Pos} SjD (p=0.13) despite reduced WBC counts in Ro^{Pos} vs. Ro^{Neg} SjD (p=0.025). In addition, absolute numbers of TCRγδ+ T cells were selectively increased in Ro^{Neg} SjD compared to both HC (p=0.009) and Ro^{Pos} SjD (p=0.025), while numbers of $CD28^{+}CD161^{hi}$ MAIT/NKT cells were selectively reduced in Ro^{Pos} SjD (p=0.013). Based on PCA, Ro^{Pos} participants with moderate to high ESSDAI scores clustered together at least in part due to increased transitional monocyte frequencies and decreased MAIT/NKT and γδT cells. In agreement with previous studies, we also found that frequencies, but not absolute numbers of memory and naïve B cells were reduced (p=0.018) and increased (p=0.015), respectively, in Ro^{Pos} SjD compared to HC. Absolute numbers of pDC were reduced in Ro^{Pos} SjD compared to both Ro^{Neg} SjD (p=0.02) and HC (p=0.024), and these reductions were driven by Ro^{Pos} cases with ESSDAI≥5 (p=0.013). Myeloid DC showed similar results, with reductions occurring in Ro^{Pos} patients with ESSDAI≥5 (p=0.012).

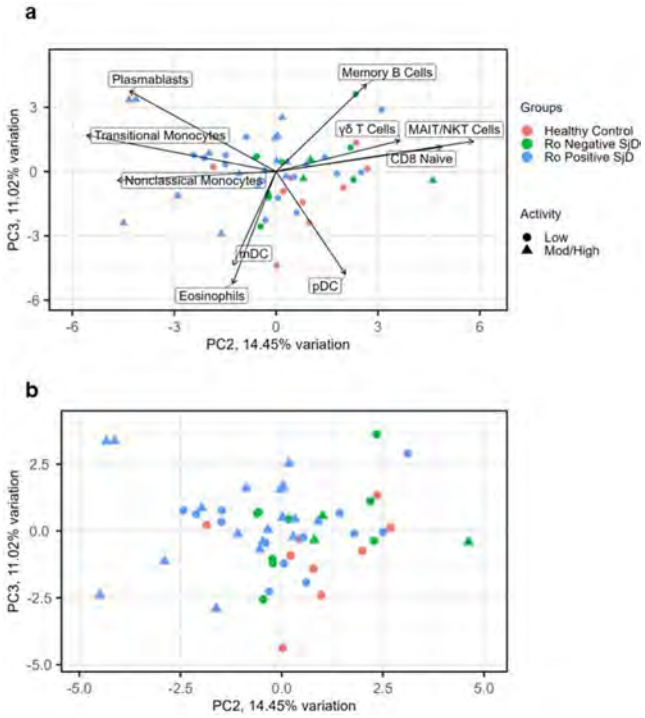

Figure 1: PCA highlights cell types important in distinguishing different endotypes of SjD. (a): PCA of SjD cases and controls using PC2 and PC3 to discriminate disease group and severity, both with the top six loadings. (b): PCA without loadings.

Conclusion: Point-of-contact whole blood immunophenotyping reveals transitional monocytes as a novel marker of systemic disease activity in Ro^{Pos} SjD. The differential abundance of transitional monocytes, γδ T cells, and MAIT/NKT cells between Ro^{Pos} and Ro^{Neg} patients suggests distinct underlying pathogenic mechanisms. These findings enable more precise patient selection for immuomodulatory therapies targeting monocyte- and innate T cell-driven dysregulation, Planned studies aim to validate these signatures longitudinally and assess their utility in predicting treatment response or disease progression.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0506–0521) Sjögren's Disease – Basic & Clinical Science Poster I: Etiology, Pathogenesis, Diagnosis

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Oral and ocular dryness are hallmarks in patients with Sjögren's disease (SjD). Given that activation of interferon (IFN) pathways has been shown to be involved in SjD pathogenesis, we aimed to explore whether demographic, clinicopathological, and laboratory features, as well as type I IFN-inducible gene expression, are associated with impaired salivary secretion in a cohort of patients presenting with sicca complaints.

To exp

Methods: 623 consecutive patients with sicca symptoms that were evaluated in the Department of Physiology, Medical School of Athens, NKUA were included in this study after informed consent. Demographic, clinicopathological and laboratory data were thoroughly collected. Immune profile testing, chronic viral infections (HIV, HCV), chest X-ray and minor salivary gland (MSG) biopsy were also performed. Unstimulated whole salivary (UWS) flow rate was considered low with a threshold of ≤ 0.5 mL/5min. 110 MSG biopsies were subjected to real-time PCR to quantify IFN I and IFN II inducible genes (IFIGs). Moreover, IFIGs derived from the peripheral blood of these patients were evaluated. For ten patients with SjD, six of

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1-Gene Ontology (GO) analysis of upregulated genes in patients with low versus normal unstimulated salivary flow rates.

whom with normal and four with low UWS, besides next-generation sequencing (NGS), a pilot bulk RNA-sequencing study was performed. Total RNA was extracted from blood leukocytes, for which quality control was first performed. Statistical analysis was performed by SPSS 29.0. and bioinformatics analysis in R programming language.

Results: UWSF was inversely correlated to both type I IFIG transcripts (IFIT1: r=-0.446, p= 0.043, IFI44: r= -0.46, p=0.03, MX-1: r=-0.487, p=0.02) and IFN II (MIG: r= -0.592, p=0.006). Furthermore, this inverse correlation was detected against subjective oral dryness (r=-0.199, p=0.002), age at symptom onset (r=-0.146, p=0.046), Rose Bengal stain (r=-0.244, p=0.005), and Schirmer's test (r=-0.339, p< 0.001). Additionally, UWSF was inversely correlated to the presence of anti-Ro/SSA (r=-0.246, p< 0.001) and anti-La/SSB (r=-0.199, p=0.003) serological reactivities, as well as ESR (r=-0.170, p=0.012), IgG (r=-0.278, p=0.003) IgA (r=-0.245, p=0.01) and C4 (r=-0.161, p=0.018). Finally, MSG biopsy parameters, such as Focus score (FS) (r=-0.370, p< 0.01, Tarpley (r=-0.381, p< 0.01) and fat score (r=-0.448, p=0.013) were also inversely correlated to UWSF. Following differential gene expression (DEG) analysis, the upregulated DEGs in patients with low UWS compared to normal UWS were subjected to gene ontology analysis (GO) (Fig.1). Interestingly, the patients with low UWS had upregulated GOs regarding innate immunity such as defense response to virus and symbiont. Additionally, an upregulation of processes, such as response to type I IFN and regulation of IFN production, was illustrated.

Conclusion: These data highlight a negative correlation of UWSF to components of the IFN pathway as well as demographic, laboratory, and clinicopathological features in a cohort of patients with sicca symptoms. Furthermore, SjD patients with low UWS are characterized by upregulated antiviral defense and interferon signaling pathways in their peripheral blood, highlighting the link between IFN pathway and low UWS.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0506–0521) Sjögren's Disease – Basic & Clinical Science Poster I: Etiology, Pathogenesis, Diagnosis

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: There is an unmet clinical need for identification of novel biomarkers of systemic complications and lymphoma in primary Sjögren disease (SD). Anti-cytosolic 5'-nucleotidase 1A (anti-cN1A) antibodies have been reported in SD but their clinical significance in this specific context is currently unknown. Anti-cN1A have been originally described in

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

inclusion body myositis (IBM). Both SD and IBM are associated with hematological malignancies. The objectives of this study were to determine the clinical significance of anti-cN1A antibodies and their value as a predictive biomarker of non-Hodgkin lymphoma (NHL) in SD.

Methods: Baseline serum levels of anti-cN1A were measured in a prospective discovery cohort of 377 patients with SD, from the French ASSESS cohort, whose primary objective was to prospectively examine the incidence and predictors of systemic complications and lymphoma in SD. The significance of anti-cN1A positivity in the ASSESS cohort was analyzed in univariate and multivariate models. Multivariate analysis included variables associated with anti-cN1A positivity in univariate analyses with a p-value < 0.2.

An independent validation case-control cohort of 58 SD patients (26 patients with untreated SD-NHL at the time of blood sampling and 32 patients with SD and no lymphoma despite ≥10-year follow-up), from the Athens' University Hospital SD cohort, was also screened for anti-cN1A antibodies.

Results: Twenty-nine SD patients tested positive for anti-cN1A (29/377 [7.7 %] [95% CI: 0.05-0.11]).

Only one patient in the anti-cN1A positive group was diagnosed with myositis during the follow-up, which fulfilled IBM criteria (1/29 [3.4 %] vs. 1/348 [0.3%] in the anti-cN1A negative group, p = 0.024).

Anti-cN1A positive patients had more frequently lymphadenopathy at baseline (8/29 [27.6 %] vs. 44/346 [12.7 %], p = 0.026) and more frequently developed lymphoma during follow-up (incident NHL: 3/29 [10.3%] in the anti-cN1A positive vs. 6/348 [1.7%] in the anti-cN1A negative patients, p = 0.003). The association between SD-NHL and anti-cN1A positivity remained significant (p=0.008) in multivariate analysis taking into account some previously reported predictors of lymphoma including lymphadenopathy, beta2-microglobulin and BAFF serum levels.

In the validation cohort, patients with SD-NHL had more frequently anti-cN1A positivity as compared with SD patients and no lymphoma (4/26 [12%] vs 0/32 [0%], p= 0.039).

Conclusion: In two independent cohorts of well-phenotyped SD patients, anti-cN1A positivity was associated with lymphoma. Anti-cN1A positivity might therefore represent a novel predictive biomarker of SD-related lymphoma.

Abstract Number: 0517

Gut Microbiota Dysbiosis and Clinical Predictors of Fatigue in Primary Sjögren's Syndrome: A Multi-Omics Study

Qiguo Cui[1], Pan Wang[2], Bin Zhou[1] and QIn Huang[3], [1]Southern Medical Univercity Nanfang Hospital, guang zhou, China (People's Republic), [2]southern medical university Nanfang Hospital, Guangzhou, China (People's Republic), [3]Nanfang Hospital, Guangzhou, China (People's Republic)

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0506–0521) Sjögren's Disease – Basic & Clinical Science Poster I: Etiology, Pathogenesis, Diagnosis

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Fatigue affects 70% of primary Sjögren's syndrome (pSS) patients, but its mechanisms remain unclear. We investigated clinical predictors and gut microbiota associations in pSS-related fatigue.

Methods: 196 pSS patients were stratified by ESSPRI and Profile of Fatigue (ProF) scores. Univariate/multivariable logistic regression identified fatigue predictors. Fecal samples from 57 patients underwent 16S rRNA sequencing.

Results: 1.ESSPRI fatigue dimension: Fatigue was associated with SAS (OR = 1.06, 95% CI: 1.01–1.12, p = 0.032) and IFN-γ (OR = 1.72, 95% CI: 1.34–2.2, p < 0.001). Fatigue improvement was linked to the use of total glucosides of paeony (OR = 1.98, 95% CI: 1.03–3.81, p = 0.041) and IgG levels (OR = 0.94, 95% CI: 0.90–0.99, p = 0.014).

2.Profile of Fatigue-Somatic Dimension: Fatigue was associated with SAS (OR = 1.10, 95% CI: 1.04–1.16, p < 0.001), IFN-γ (OR = 1.37, 95% CI: 1.12–1.68, p = 0.003), and anti-SSB antibodies (OR = 2.72, 95% CI: 1.39–5.69, p = 0.008). Fatigue improvement correlated with total glucosides of paeony use (OR=2.32, 95%CI 1.07 ~ 5.01, p=0.032) and CH50 levels (OR=1.06, 95%CI 1.03-1.10, p<0.001).

3.Profile of Fatigue-Mental Dimension: Fatigue was associated with SAS (OR = 1.06, 95% CI: 1.01–1.11, p = 0.019) and SDS (OR = 1.05, 95% CI: 1.01–1.09, p = 0.016). Fatigue improvement was linked to male sex (OR = 0.10, 95% CI: 0.01–0.85, p = 0.035), hematologic involvement (OR = 0.44, 95% CI: 0.21–0.92, p = 0.029), CH50 (OR = 1.04, 95% CI: 1.01–1.07, p = 0.019), and anti-SSB antibody positivity (OR = 0.45, 95% CI: 0.21–0.95, p = 0.036).

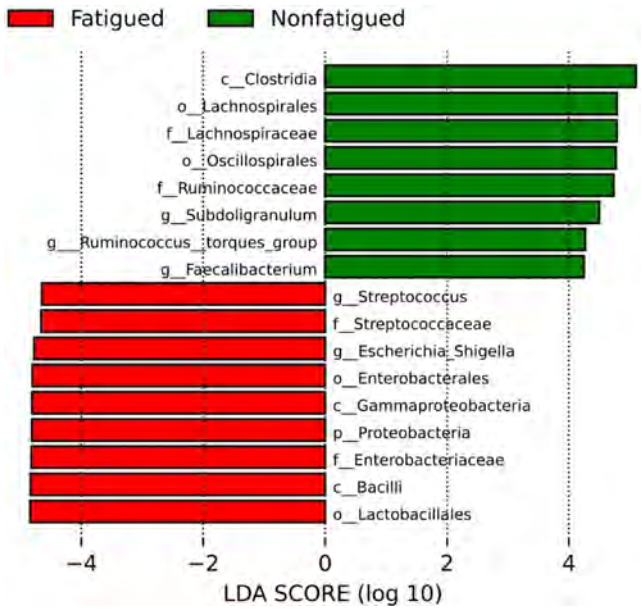
Binary logistic regression based on Profile of Fatigue-Mental improvement grouping



LEfSe analysis of gut microbiota between two groups

4.16S rRNA sequencing revealed significant differences in α- and β-diversity of gut microbiota between fatigue and non-fatigue groups. Escherichia-Shigella and Streptococcus were significantly enriched in the fatigue group, and their abundances showed a strong positive correlation with fatigue severity scores. In contrast, Ruminococcus torques group, Faecalibacterium, and Subdoligranulum were predominantly enriched in the non-fatigue group, with their abundances negatively correlated with fatigue scores.

Conclusion: This study, through a multi-dimensional assessment framework encompassing the ESSPRI fatigue dimension and the ProF physical/mental fatigue subscales, revealed that SAS, SDS, IFN-γ, and anti-SSB antibodies are associated with pSS-related fatigue. Total glucosides of paeony use, IgG levels, CH50 levels, sex(male), anti-SSB antibody status, and hematologic involvement significantly influence fatigue improvement in pSS patients. Gut microbiota may contribute to the pathogenesis of pSS-related fatigue. These findings provide critical insights into the mechanisms underlying pSS-related fatigue and suggest novel strategies for diagnosis and therapeutic intervention.

Deregulation of PSGL-1, HLA-DR and IFNα expression in peripheral innate immune cells of primary Sjögren Syndrome patients

Santos Castañeda[1], Alejandra Ramos-Manzano[2], Ines Sanchez-Abad[3], Miren Uriarte-Ecenarro[4], M. Paula Alvarez-Hernandez[4], Esther San-Antonio[4], Esther Vicente-Rabaneda[5] and Ana Urzainqui[4], [1]Hospital Universitario de La Princesa, IIS-Princesa, Madrid, Madrid, Spain, [2]Hospital Unversitario de la Princesa, Madrid, Madrid, Spain, [3]Hospitla de la Princesa, Madrid, Spain, [4]Hospital de la Princesa, Madrid, Madrid, Spain, [5]Hospital Universitario de La Princesa, Madrid, Spain

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0506–0521) Sjögren's Disease – Basic & Clinical Science Poster I: Etiology, Pathogenesis, Diagnosis

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Primary Sjögren's Syndrome (pSS) is an autoimmune disease characterized by lymphocytic infiltration of exocrine glands and systemic manifestations including cutaneous and renal involvement. Phagocytes--monocytes, neutrophils, and dendritic cells-- are innate immune cells playing crucial roles in both innate defence and modulation of adaptive immunity. Dysregulation of these cells in pSS has been linked to altered inflammatory response, although the mechanisms driving disease progression remain unclear. PSGL-1 is a leukocyte adhesion molecule and a checkpoint for the immune system. High expression level of HLA-DR is a sign of immune activation. Additionally, higher production of IFNα has been related to pSS pathogenesis

Methods: We obtained the peripheral blood of 44 pSS patients and 26 healthy donors (HD). The percentage of cells expressing PSGL-1, HLA-DR and IFNα mean fluorescence intensity (MFI) was analysed by flow cytometry in neutrophils, monocytes (both classical and non-classical), and plasmacytoid dendritic cells (pDC).

Statistical differences between HD and patients were calculated using Mann-Whitney U test or Student's T-test. Association of the different variables with the presence of the disease was assessed by binary logistic regression (BLR). Then, we performed its receiver operating characteristic (ROC) curves. Statistical significance was set at $p< 0.05$. Statistical analyses were performed using SPSS 25.0 and GraphPad Prism 8 software.

Results: Compared to HD, the percentage of HLA-DR-expressing cells was increased in neutrophils, monocytes, and pDC of pSS patients. The expression level was higher in pDC and monocytes, suggesting constitutive immune activation in pSS patients. The percentage of neutrophils and pDCs expressing PSGL-1 and PSGL-1's MFI of non-classical monocytes were reduced compared to HD. This reduction may contribute to higher leukocyte activation. However, the expression level of PSGL-1 in non-classical monocytes was increased. Regarding IFN-α, we found an elevated percentage of neutrophils, classical monocytes and pDC producing IFNα in pSS patients and reduced percentage of non-classical monocytes.

BLR analyses identified percentage of neutrophils expressing HLA-DR (79.6% sensitivity, 56.7% specificity and AUC 0.756), percentage of pDC expressing IFNα (92.7% sensitivity, 13.6% specificity and AUC 0.634) and ratio of conventional dendritic cells (cDC) and pDC (83.7% sensitivity, 60% specificity and AUC 0.75) as potential biomarkers for pSS diagnosis.

Conclusion: Our findings underscore an important role of phagocytes in maintaining chronic immune activation in pSS patients. The altered expression of these molecules in innate cell populations might contribute to disease's pathogenesis. The results contribute to our understanding of phagocyte involvement in pSS and offer potential new avenues for diagnostic strategies.

A Multi-criterion Feature Integration Framework for Accurate Diagnosis of Primary Sjögren's Syndrome Using Routine Laboratory Tests: A Multicentre, Retrospective Cohort Study

Shu Liu[1], Guanhao Wu[1], Mengge Pan[1], Qi Sun[2], Jingchen Gao[1], Xianming Long[3], Chaogui Tang[4], Xinran Yuan[1] and Lingyun Sun[1], [1]Department of Rheumatology and Immunology, Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, China (People's Republic), [2]Department of Endocrinology and Metabolism, Affiliated Hospital of Nantong University, Nantong, China, Nantong, China (People's Republic), [3]The Affiliated Suzhou Hospital of Nanjing Medical University, Suzhou Municipal Hospital, Gusu School, Nanjing Medical University, Suzhou, China (People's Republic), [4]The Affiliated Huaian First People's Hospital of Nanjing Medical University, Huai'an First People's Hospital, Nanjing Medical University, Huaian, China (People's Republic)

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0506–0521) Sjögren's Disease – Basic & Clinical Science Poster I: Etiology, Pathogenesis, Diagnosis

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Primary Sjögren's syndrome (pSS) is a prevalent systemic autoimmune disorder. However, the early and accurate diagnosis of pSS remains challenging due to its non-specific clinical manifestations, the absence of definitive molecular markers, and the limitations of current diagnostic tests. The present study aims to evaluate the diagnostic utility of routine laboratory tests for predicting pSS and to develop a robust, cost-effective and generalizable integrated artificial intelligence (AI) model to assist in the identification of pSS.

Methods: This multicentre, retrospective cohort study included data from 99 laboratory items of 27,432 patients with and without pSS who were admitted to one regional centre hospital and two local hospitals in China between January 1, 2013, and January 31, 2023. The construction of Sjögren Multi-criterion Feature Integration Framework (SMFIF) model was based on 16 optimal features, using multi-algorithm feature selection, SHAP value analysis, model performance evaluation, and ensemble learning strategies. The model was evaluated using an internal validation set comprising 9,329 individuals, and an external validation set consisting of 545 individuals. The primary outcome was the prediction accuracy of the model in identifying pSS.

Results: The SMFIF model attained an area under the receiver-operating characteristic curve (AUC) of 0.929 (95% CI, 0.923-0.935) in the testing set, 0.934 (95% CI, 0.929-0.939) in the internal validation set, and 0.964 (95% CI, 0.943-0.986) in the external validation set. The model demonstrated higher AUC, ACC and sensitivity in comparison with anti-SSA/Ro, anti-SSB/La, antinuclear antibodies (ANA), Globulin (GLO), Rheumatoid factor (RF), immunoglobulin G (IgG), and Complement (C3 and C4) in the diagnosis of pSS. The superior performance of SMFIF in pSS prediction was confirmed

Study flowchart

through calibration curves and confusion matrices. The SMFIF was developed as a publicly available prediction tool that will provide an estimated probability of pSS based on input laboratory data.

Conclusion: The SMFIF model has been shown to consistently achieve satisfactory performance in the prediction of pSS when utilising routine laboratory tests from the testing set and two validation sets. This model offers a low-cost, easily accessible, and accurate diagnostic tool for pSS.

Abstract Number: 0520

Implementation of Salivary Gland Ultrasound by General Radiology can Improve Detection of Glandular Inflammation in Patients with Sicca

Stephanie Lee[1], Chadwick Johr[2], Nora Sandorfi[2], Ali Dhanaliwala[2] and Dana DiRenzo[2], [1]University of Pennsylvania & Children's Hospital of Philadelphia, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0506–0521) Sjögren's Disease – Basic & Clinical Science Poster I: Etiology, Pathogenesis, Diagnosis
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Salivary Gland Ultrasound (SGUS) can be useful in the evaluation and management of Sjögren's Disease (SjD) but its use has been limited to trained rheumatologists. We hypothesized that implementation of a standardized scanning protocol and graded according to the Outcome Measures in Rheumatology Clinical Trials (OMERACT) scoring

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Disease characteristics of patients with sicca who had salivary gland ultrasounds scored as OMERACT grade 3 vs grade 0 at initial visit to the Sjögren's center of an academic rheumatology division.

Patient Characteristics	Grade 3	Grade 0	P value
	n=54	N=54	
Age, mean (SD)	54.9 (17.2)	52.8 (14.4)	0.49
Sex, n (%) F	48 (89%)	45 (83%)	0.40
Race, n (%)			0.021
White	31 (57%)	38 (76%)	
Asian	4 (7%)	5 (10%)	
Black	16 (30%)	3 (6%)	
Other	3 (6%)	4 (8%)	
SSA+, n (%)	49 (91%)	13 (24%)	<0.001
ANA+, n (%)	41 (85%)	11 (22%)	<0.001
RF+, n (%)	37 (73%)	7 (16%)	<0.001

system by an academic radiology department can improve sensitivity for detecting glandular inflammation that may be missed by physical exam.

Methods: This was a retrospective, case-control study of patients with sicca seen in an academic Sjogren's Center. Patient with SGUS scored as OMERACT grade 3 (≥1 parotid +/- submandibular gland) were compared to OMERACT grade 0 (all glands) with complete serologies (ANA, SSA, RF) available for review. Charts were screened consecutively. For patients with SjD, the EULAR Sjögren's Disease Activity Index (ESSDAI) and the Routine Assessment of Patient Index Data-3 (RAPID-3) were extracted with demographic, treatment, and laboratory data available either any time prior to the encounter (serologies) or completed up to 3 months after the same encounter. Descriptive statistics, including means and proportions, were calculated and comparisons made by t-test.

Results: Fifty–four patients with grade 3 OMERACT SGUS changes and complete antibody profiles were compared to 54 patients with grade 0 changes. Patients with grade 3 changes had a mean (SD) age of 54.9 years (17.2), were predominantly female (89%), about half met the ACR/EULAR SjD classification criteria (55.6%), and had current use of conventional

Table 2. Sjögren's Disease activity per EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI) for patients with OMERACT grade 3 changes on salivary gland ultrasound at initial visit. PNS (peripheral nervous system), CNS (central nervous system).

Disease Activity (ESSDAI) n=36	No activity	Low activity	Medium Activity	High Activity
Constitutional	29 (81%)	7(19%)		
Lymphadenopathy	32 (89%)	2 (6%)	1 (3%)	1 (3%)
Glandular	26 (72%)	5 (14%)	5 (14%)	
Articular	30 (83%)	4 (11%)	2 (6%)	
Cutaneous	35 (97%)	1 (3%)		
Pulmonary	34 (94%)	2 (6%)		
Renal	35 (97%)	1 (3%)		
Muscular	36 (100%)			
PNS	35 (97%)	1 (3%)		
CNS	36 (100%)			
Hematological	35 (100%)			
Biological	27(82%)	2 (6%)	4 (12%)	
Total, median (IQR)	3 (0, 6.5)			

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Qualitative examples of echotexture changes over time from patients who completed 2 SGUSs with grade 3 OMERACT scores.

Disease Activity	Scan 1	Scan 2
Improving			9/3/19, right parotid sagittal views noting gland heterogeneity with diffuse anechoic lesions and hyperechoic bands, OMERACT grade 3. ESSDAI 12.	7/5/22, right parotid sagittal views noting gland heterogeneity with scattered anechoic lesions and hyperechoic bands, OMERACT grade 2. ESSDAI 0; s/p treatment with rituximab for MALT lymphoma (2/2019 to 1/2021).
Worsening			9/14/23, left parotid sagittal views noting a large anechoic lesion with hyperechoic density with smaller hypo-/anechoic lesions concerning for lymphoma, OMERACT grade 3. ESSDAI 12.	2/26/24, left parotid sagittal views noting severe gland heterogeneity with multiple and new, large anechoic lesions and hyperechoic densities concerning for recurrent lymphoma, OMERACT grade 3. ESSDAI 16; s/p excisional biopsy (MALT lymphoma) and radiation; no B-cell depletion received.

disease modifying agents (cDMARDs) (48.2%) (**Table 1**). Patients with grade 3 changes were more likely to have positive serologies (anti-SSA, ANA, RF). In addition, Patients with grade 3 changes had a mean (SD) RAPID-3 score of 9.4 (6.9), indicating moderate disability and symptom burden. For patients diagnosed with SjD with grade 3 changes and completed ESSDAIs (n = 36), the median (IQR) ESSDAI was 3 (0, 6.5) with low activity (>10%) present in the constitutional, glandular, and articular domains (**Table 2**). Notably, only 28% of patients with grade 3 SGUS changes had elevated activity levels on the glandular domain of the ESSDAI which is obtained through physical exam (swelling/enlargement of glands).

Conclusion: Patients with OMERACT grade 3 changes on SGUS more often had positive SSA, ANA, and RF compared to those with grade 0 changes. Despite grade 3 changes on SGUS, only 28% of patients had elevated disease activity per ESSDAI glandular domain (physical exam). This may suggest that adoption by general radiology of an SGUS scanning protocol and use of the OMERACT scoring system may improve rheumatologists' detection of glandular activity, compared to physical exam alone.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0506–0521) Sjögren's Disease – Basic & Clinical Science Poster I: Etiology, Pathogenesis, Diagnosis

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Primary Sjögren's disease (pSD) is characterized by lymphocytic infiltration of the salivary and lacrimal glands, leading to functional loss and gradually causing dry mouth and dry eyes. In this study, we investigated the anti-inflammatory effects of umbilical cord-derived mesenchymal stem cells (MSCs) on salivary gland pathology and the involvement of Bach2.

Methods: Peripheral blood mononuclear cells (PBMCs) from pSD patients were co-cultured with MSCs under various stimulatory conditions to evaluate the inhibition of cell differentiation and cytokine production. $CD4^+$ T cells and B cells were isolated from the peripheral blood of pSD patients and co-cultured with MSCs stimulated with pSD-associated autoantigens. The changes in cell subsets and the suppression of IgG production due to MSC inhibitory effects were evaluated. Cell damage was induced in human salivary gland cell lines (HSGs) using H_2O_2, and the frequency of dead cells was compared. The above experiment was performed under conditions with and without contact cell-to-cell. Bach2 expression in T cells, B cells, and monocytes was also evaluated by Western blotting.

Results: MSCs decreased the production of IFN-γ and IL-4 on T cells and TNF-α on monocytes without cell-to-cell contact with MSCs. Co-culturing B cells from pSD patients with MSCs in the presence of CpG-ODN significantly reduced the proportion of plasma cells and increased the proportion of memory B cells compared to B cell monocultures. Similar results were obtained under non-contact cell-to-cell conditions. Furthermore, when $CD4^+$T cells and B cells were co-cultured in the presence of pSD-associated autoantigen, IgG production was suppressed under cell-to-cell contact with MSCs compared to without MSCs. In the induction of cell damage against HSGs, the frequency of dead cells was significantly reduced under non-contact with MSCs. In addition, Bach2 expression in T cells, B cells, and monocytes was enhanced when co-cultured with MSCs in the presence of various stimulations.

Conclusion: In this study, we found that the critical function of MSCs is to induce Bach2 expression in target cells through cell-independent, soluble factors. MSCs control cytokine production and excessive autoantibody production in target cells by inducing Bach2 expression, and even prevent cell death in salivary gland cells. Conventional pSD therapy has not achieved sufficient improvement in salivary gland secretion flow through the use of immunosuppressive drugs. MSCs hold potential as an innovative pSD therapy, including for salivary gland disorders.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0522–0553) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with psoriatic arthritis (PsA) are at increased risk of developing cardiovascular diseases, including arrhythmias. Given that traditional cardiovascular disease risk factors are prevalent in patients with PsA, it remains unclear if arrhythmia development risk in this population is due to these factors or PsA disease activity. We therefore aimed to assess the incidence and risk factors for tachy- and bradyarrhythmias in patients with PsA.

Methods: We performed a retrospective cohort analysis of PsA patients followed prospectively from 1994 to 2024. Patients were assessed every 6 to 12 months following a standard protocol where demographics, measures of PsA disease activity, comorbidities and medication information were collected. Arrhythmia events were identified via review of patients charts and linkage with provincial hospitalization databases. The following arrhythmia endpoints were assessed: atrial tachyarrhythmia (defined as atrial fibrillation, atrial flutter or supraventricular tachycardia); bradyarrhythmia/pacemaker (defined as second degree atrioventricular block, complete heart block or pacemaker placement); ventricular tachyarrhythmia (defined as ventricular tachycardia, ventricular fibrillation or placement of implantable cardioverter-defibrillator). The cumulative incidence rate (CIR) of each type of arrhythmia was calculated. Cox regression hazard models were used to evaluate the association between PsA disease activity measures (either single time-point level prior to event or cumulative average over time) and arrhythmia endpoints. Each model was hierarchically adjusted for age and sex, PsA duration, cardiovascular risk factors and PsA therapies.

Results: Of 1670 PsA patients (mean age 46.3 years, 54.2% male, **Table 1**) included in this analysis, a total of 80 atrial, 17 brady and 11 ventricular arrhythmias were identified. By age 70, the overall CIRs were 7.82%, 0.45% and 0.67% for atrial, brady and ventricular arrhythmias, respectively (**Figure 1**). Arrhythmias occurred predominantly in older patients, with a marked increase in the rate of atrial tachyarrhythmias after age 60. Bradyarrhythmia and ventricular tachyarrhythmia also occurred predominantly in older population, with a marked increase in the rate of these events after age of 70. In the fully adjusted multivariable analysis (**Table 2**), remission/low vs. high disease activity state was associated with lower risk of atrial tachyarrhythmia (single-point Hazard Ratio (HR) 0.49, 95% CI 0.26, 0.92; cumulative mean HR 0.46, 95% CI 0.23, 0.91). Similarly higher 3-item Visual Analog Scale (3-VAS) was associated with higher risk of atrial tachyarrhythmia (single-point

Table 2 - The association between PsA-related variables and the risk of atrial tachyarrhythmia in patients with PsA using Cox proportional hazards models

Table 2: The association between PsA-related factors and the risk of atrial tachyarrhythmia in patients with PsA using Cox proportional hazards models (Total population=1670 patients, n= 80 events).

Variable		Cumulative average co-variates*		Single time point co-variates*	
		HR (95% CI)	P value	HR (95% CI)	P value
DAPSA-Categories	Moderate vs. High disease activity	0.59 (0.33, 1.05)	0.076	0.65(0.34, 1.27)	0.214
	Remission/low vs. High disease activity	**0.46 (0.23, 0.91)**	**0.03**	**0.49 (0.26, 0.92)**	**0.031**
PASI-Category	Moderate vs. Mild	0.82 (0.46, 1.46)	0.498	1.29(0.73, 2.27)	0.388
	Severe vs. Mild	1.51 (0.85, 2.66)	0.165	1.44(0.75, 2.75)	0.276
3-VAS	1-unit increase	**1.22 (1.04, 1.44)**	**0.019**	**1.18(1.04, 1.33)**	**0.011**
CRP, mg/L	1-unit increase	1.01 (0.99, 1.03)	0.329	1.01(0.99, 1.02)	0.463

*Each model is adjusted for age, sex, PsA disease duration, diabetes, hypertension, dyslipidemia, thyroid disease, heart disease, smoking status and body mass index, NSAIDs, csDMARDs and b/tsDMARDs. **Significant results are bolded**

Abbreviations: CI, confidence interval; CRP, c-reactive protein; DAPSA, disease activity in psoriatic arthritis; HR, Hazard Ratio; PASI, psoriasis area severity index; PsA, psoriatic arthritis; 3-VAS, 3-component visual analogue scale.

Conclusion: Higher PsA disease activity is associated with higher atrial tachyarrhythmia risk. These findings reinforce the importance of controlling inflammation in PsA to prevent these events.

Session Title: (0522–0553) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background/Purpose: Even low body surface area (BSA) psoriasis can be extremely bothersome to patients and can have a significant impact on their lives just as much as more extensive disease. SPECTREM is an ongoing, Phase 3b, multicenter, randomized, double-blind, placebo-controlled study evaluating the safety and efficacy of guselkumab in participants with low BSA (2%-15%), moderate (Investigator's Global Assessment [IGA]=3) psoriasis involving ≥1 special site (scalp, face, intertriginous, or genital).

Methods: A total of 338 participants were randomized 2:1 to receive guselkumab 100 mg (n=225) or placebo (n=113) at Week 0 and Week 4, then every 8 weeks. Patient-reported outcomes (PROs) assessed at Week 16 included change from baseline in Psoriasis Symptoms and Signs Diary (PSSD; range, 0-100), and Dermatology Life Quality Index (DLQI; range, 0-30).

Results: At baseline, participants had mean (standard deviation [SD]) BSA of 7.6% (3.7%); mean (SD) PSSD total symptoms score of 53.8 (23.2), mean (SD) PSSD itch score of 6.8 (2.2), and a mean (SD) DLQI of 11.5 (6.7). On average, participants had a disease duration of 17 years, and the majority of participants had never received systemic therapy (86.3%). At Week 16, guselkumab-treated participants achieved significantly greater mean change from baseline in the PSSD total symptoms score (guselkumab –36.08 vs placebo 0.37; $p< 0.001$). Among participants with PSSD itch score ≥4 at baseline, a significantly greater proportion of guselkumab-treated participants achieved ≥4-point reduction at Week 16 (guselkumab 62.7% vs placebo 12.5%; $p< 0.001$). A significant proportion of guselkumab-treated participants with PSSD symptom score >0 achieved a PSSD symptom score of 0 at Week 16 (21.9% vs placebo 2.7%; $p< 0.001$). Similarly, a significantly greater proportion of guselkumab-treated participants achieved DLQI 0/1 (guselkumab 48.9% vs placebo 3.5%; $p< 0.001$) and DLQI 0 (guselkumab 28.4% vs placebo 3.5% $p< 0.001$) at Week 16. No new safety signals were identified.

Conclusion: In this low BSA, moderate psoriasis population, quality of life impact significantly improved after just 3 doses of guselkumab.

Session Title: (0522–0553) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: This study aimed to assess the rate of progression in sacroiliac joints in non-radiographic axial spondyloarthritis (nr-axSpA) and to identify the predictive factors for the progression.

Table 1: Baseline demographic, disease related clinical, and laboratory characteristics of non-radiographic axSpA patients

Characteristics (N=194)	
Male sex n (%)	84/194 (43.3)
Age, years mean ± SD	44.6 ± 10.3
Symptom duration, yıl mean ± SD	16 ± 8.8
Time since diagnosis, years, mean ± SD	10.1 ± 5.5
Education duration, years mean ± SD	10.8 ± 4
Current smoking n (%)	74/181 (40.9)
BMI kg/mZ mean ± SD	28.3 ± 21.1
HLA-B27 positivity n (%)	78/159 (49.1)
C-reactive protein mg/dl mean ± SD	9.5 ± 17.9
BASDAI mean ± SD	4.3 ± 2.3
BASFI mean ± SD	3.1 ± 2.6
ASDAS-CRP mean ± SD	2.6 ± 1.1
BASMI mean ± SD	2.8 ± 1.3
ASQOL mean ± SD	8.7 ± 5.1
HAQs mean ± SD	0.8 ± 0.6
Dactylitis, n (%)	5/184 (2.7)
Peripheral arthritis n (%)	58/177 (32.8)
Heel pain n (%)	89/170 (52.4)
Radiographic hip involvement, n (%)	8/194 (4.1)
Psoriasis n (%)	8/147 (5.4)
Inflammatory bowel disease n (%)	15/166 (9)
Uveitis n (%)	19/184 (10.3)
NSAID use n (%)	140/171 (81.9)
Biologic treatment use, n (%)	88/193 (45.6)
Positive ASAS family history,n (%)	54/168 (32.1)

Table 2: Univariable and multivariable longitudinal analysis results of factors influencing progression from nr-axSpA to r-axSpA

	Univariable analysis				Multivariable analysis			
	B	%95 CI		P	B	%95 CI		P
Symptom duration	0.033	-0.002	0.067	0.065	0.031	-0.008	0.115	0.088
Education level	-0.052	-0.222	-0.014	**0.026**	-0.052	-0.159	0.056	0.347
Body Mass Index	0.016	-0.002	0.034	0.075	0.014	0.000	0.028	**0.043**
BASFI score	0.169	0.031	0.307	**0.016**	0.035	-0.169	0.239	0.735
C-reaktive protein	0.023	0.003	0.044	**0.027**	0.019	0.806	1.680	**0.038**
BASMI score	0.329	-0.049	0.708	0.088	0.372	-0.240	0.983	0.195
ASAS Family History for SpA	-0.099	-1.913	-0.80	**0.033**	-0.715	-1.619	0.189	0.121

Methods: In total 321 patients classified as nr-axSpA and who had at least one follow-up pelvic radiograph among 695 patients followed in an axSpA cohort were included in the present analysis. A total of 647 radiographs were evaluated by two independent readers (blinded for the chronological order) according to the modified New York criteria. Discrepancies were resolved by a third experienced rheumatologist. Progression rates from nr-axSpA to r-axSpA and the related factors were assessed over a follow-up period of two and five years. Potential factors influencing progression to r-axSpA at the five-year follow-up were tested by using the Generalized Estimating Equations (GEE) method. Factors/covariates has a significance level of < 0.10 were included in the multivariate analysis.

Results: Of the 321 nr-axSpA patients followed in the axSpA cohort, 194 had radiographic follow-up at two years and 116 at five years. At two years follow up progression to r-axSpA was observed in 17.5% of patients at and at five years in 24.1%. In univariate analysis symptom duration, education level, body mass index, Bath Ankylosing Spondylitis Function Index score, score, C-reactive protein levels, Bath Ankylosing Spondylitis Metrology index scores and the presence of family history for SpA according to ASAS proposal were found to be associated with the radiographic progression. However in multivariate model only elevated C-reactive proteine and body mass index were identified as significant predictors of progression to r-axSpA (Table 2).

Conclusion: In our study, the 5 year progression rate from nr-axSpA to r-axSpA was 24.1%. Previous studies have reported progression rates ranging from 2% to 43.5%, depending on variations in patient selection, imaging frequency, and disease duration at diagnosis (1). The recently published PROOF study, which included axSpA patients who were diagnosed within 1 year, reported a 5-year progression rate of 16% (2). The relatively higher rate observed in our cohort may be attributed to the longer symptom duration Importantly, among the factors analyzed, body mass index (BMI) emerged as a significant predictor of radiographic progression, which has not been consistently emphasized in previous studies. Serum CRP levels was also associated with progression, in line with established risk factors. The identification of BMI as a significant factor in our cohort highlights the potential role of metabolic and mechanical stress in disease progression and warrants further investigation. Our results reinforce the importance of integrating clinical, laboratory, and imaging parameters to improve prediction of progression in nr-AxSpA.

Abstract Number: 0525

Cost-of-Illness Among Newly Diagnosed Patients with Psoriatic Arthritis in Sweden

Sofia Wittgren[1], Sofia Exarchou[2], Daniela Di Giuseppe[3], Ulf Lindström[4], **Tor Olofsson**[1], Lennart T. H. Jacobsson[4], Johan Askling[3] and Johan Karlsson Wallman[1], [1]Lund University, Skane University Hospital, Department of Clinical Sciences Lund, Rheumatology, Lund, Skane Lan, Sweden, [2]Lund University, Akarp, Skane Lan, Sweden, [3]Karolinska Institutet, Department of Medicine Solna, Clinical Epidemiology Division, Stockholm, Stockholms Lan, Sweden, [4]Gothenburg University, Sahlgrenska Academy, Department of Rheumatology and Inflammation Research, Gothenburg, Vastra Gotaland, Sweden

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0522–0553) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Up-to-date information on the cost-of-illness of psoriatic arthritis (PsA) is important for healthcare/social insurance system budgeting and to highlight unmet needs in PsA care. Here, we aimed to estimate societal costs (for healthcare/work disability) during one year (yr) from diagnosis among all working-age (18-64yr) individuals diagnosed with PsA in Sweden 2016-2019, and to relate these to costs during the preceding yr and in the general population (GP).

Methods: Newly diagnosed PsA patients were identified from the Swedish National Patient Register (NPR) and the Swedish Rheumatology Quality register (SRQ): ≥1 ICD-10 code for PsA (L40.5/M07.0-M07.3) as main diagnosis from rheumatology/internal medicine units in NPR or PsA diagnosis registered in SRQ 2016-2019, and no prior such diagnoses. Each PsA case was matched by sex/age/county to 5 GP comparators without PsA according to NPR/SRQ, and costs (inflation-adjusted to 2019 US Dollars [$]) from 1yr before to 1yr after PsA diagnosis (and the same period for comparators) were estimated. Costs for all dispensed prescription drugs were retrieved from the Prescribed Drug Register, while intravenous bDMARDs were priced based on doses in SRQ. For specialized (non-primary) out-/inpatient care (retrieved from NPR), costs were calculated via the Swedish 2019 Diagnosis Related Group (DRG) system. Work disability costs were estimated as accumulated net sick leave/disability pension days (Social Insurance Agency) multiplied with the average daily salary (plus social fees) in

Table. Resource use and mean annual costs during the year following diagnosis of PsA (or the corresponding time-period for matched general population comparators)

	PsA (n=5196)		GP comparators (n=25 740)		Between-group cost difference
	Resource use[a]	Mean cost (SD)	Resource use[a]	Mean cost (SD)	Mean (95%CI)[b]
Total drug use	**99%**	**2560 (5052)**	**67%**	**294 (1830)**	**2265 (2135 to 2418)**
b/tsDMARDs	27%	1853 (3931)	0.1%	3.5 (169)	1849 (1743 to 1962)
csDMARDs	60%	105 (219)	0.5%	1.0 (31)	104 (98 to 110)
All other drugs	98%	602 (3116)	67%	290 (1819)	312 (234 to 407)
Total specialized healthcare utilization[e]		**3285 (5483)**		**1178 (5194)**	**2104 (1957 to 2268)**
Outpatient care visits[f]	5.4 (4.7)	2383 (2315)	1.2 (3.1)	519 (1483)	1862 (1800 to 1928)
Inpatient care days[g]	0.7 (7.9)	905 (4332)	0.5 (5.4)	659 (4481)	244 (129 to 376)
Total healthcare costs[c,e]		**5842 (8195)**		**1472 (5744)**	**4366 (4143 to 4617)**
Total work disability costs		**9272 (17 896)**		**4581 (13 968)**	**4695 (4216 to 5229)**
Sick leave days	32 (77)	5092 (12 428)	10 (45)	1611 (7278)	3481 (3156 to 3856)
Disability pension days	26 (87)	4180 (13 974)	18 (76)	2970 (12 182)	1214 (819 to 1597)
Societal costs[d,e]		**15 101 (21 505)**		**6051 (16 324)**	**9048 (8468 to 9680)**

Costs in 2019 US Dollars. [a] % with any such drug use, or mean (SD) visits/days, during the year prior to diagnosis (or the corresponding time-period for matched GP comparators). [b] Assessed by non-parametric bootstrapping (1000 iterations), accounting for the matched design. [c] Drug + healthcare utilization costs. [d] Healthcare + work disability costs. Missing data PsA/GP: [e] n=5/12; [f] n=2/0; [g] n=3/12. b/tsDMARDs, biologic or targeted synthetic disease-modifying anti-rheumatic drugs; csDMARDs, conventional synthetic disease-modifying anti-rheumatic drugs; GP, general population; PsA, psoriatic arthritis

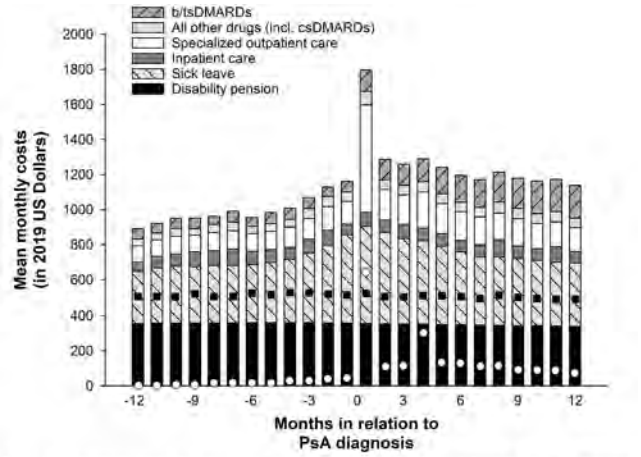

Figure 1. Mean monthly costs (by cost categories) from 12 months before until 12 months after the diagnosis of PsA among working-age (18-64 years) patients diagnosed in Sweden 2016-2019. For comparison to the mean monthly societal costs among the PsA patients (represented by the top of each bar), the corresponding mean costs in matched general population comparators (assessed during the same time-period as their respective index cases) are denoted by black squares. In the PsA group, median monthly societal costs are also indicated by white dots. b/tsDMARDs, biologic or targeted synthetic disease-modifying anti-rheumatic drugs; csDMARDs, conventional synthetic disease-modifying anti-rheumatic drugs; incl., including; PsA, psoriatic arthritis.

Figure 1

Sweden 2019. Despite skewness, costs are reported as arithmetic means, considered most informative for cost studies. Cost comparisons between PsA and comparators were done by non-parametric bootstrapping, accounting for the matched design; between subsets of PsA by Mann-Whitney U-test; and between years by Wilcoxon's matched-pair signed-rank test.

Results: During the yr following diagnosis, societal costs were significantly higher in PsA (n=5196; mean cost $15 101) than in the GP comparators (n=25 740; mean cost $6051; mean between-group difference: $9048), with elevations of all cost categories and dominated by work disability costs (61% of societal costs in PsA; **Table**). Costs were highly skewed, with 11% of cases accounting for 50% of all societal costs in PsA. The monthly costs for all categories (except inpatient care) were significantly elevated compared to the GP already 12 months prior to PsA diagnosis. Costs increased gradually (mainly

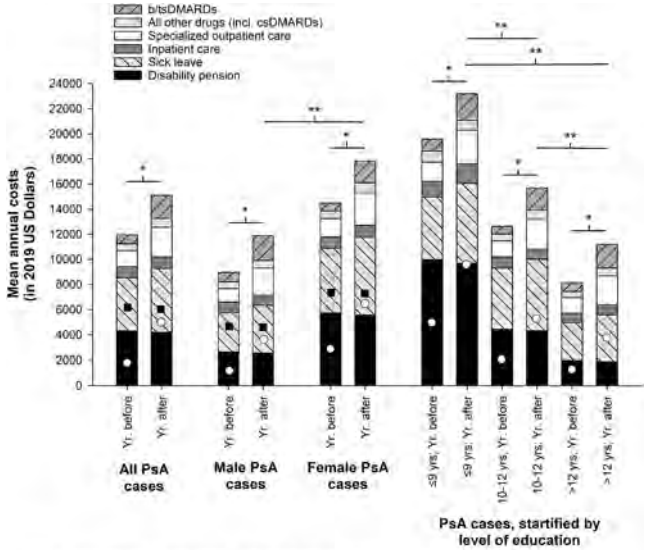

Figure 2. Mean annual costs (by cost categories) during the year before and the year following the diagnosis of PsA, respectively, among working-age (18-64 years) patients diagnosed in Sweden 2016-2019; displayed for all patients, as well as stratified by sex and level of education. For comparison to the mean societal costs among the PsA patients (represented by the top of each bar), the corresponding mean costs in matched general population comparators (assessed during the same time-period as their respective index cases) are denoted by black squares. In the PsA group, median societal costs are also indicated by white dots. * p<0.001 for comparison of yearly societal costs by Wilcoxon's matched-pair signed-rank test. ** p<0.001 for between-group comparisons of yearly societal costs by Mann-Whitney U-test. b/tsDMARDs, biologic or targeted synthetic disease-modifying anti-rheumatic drugs; csDMARDs, conventional synthetic disease-modifying anti-rheumatic drugs; incl., including; PsA, psoriatic arthritis; Yr., year.

Figure 2

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. due to rising sick leave) to a peak at diagnosis, and then slightly decreased during the following 11 months (**Figure 1**). Except for inpatient care and disability pension costs, all annual cost categories increased significantly from the yr before to the yr after diagnosis (**Figure 2**). Societal costs were higher in females and individuals with lower education (**Figure 2**).

Conclusion: Already in the year following diagnosis, PsA (at a group level) imposes a substantial health economic burden on society, with societal costs 2.5 times higher than in the GP and with work disability as the dominant cost driver. Whether earlier diagnosis/interventions could bring about a more favorable cost trajectory should be a focus of future studies.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0522–0553) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Currently available diagnostic tests for inflammatory arthritis lack sufficient sensitivity and specificity, often requiring the integration of clinical manifestations with physician expertise for accurate diagnosis. Urine is a noninvasive and easily accessible specimen that represents a promising diagnostic tool. This study aimed to identify novel urinary proteomic biomarkers in ankylosing spondylitis (AS) and evaluate their associations with clinical parameters and disease activity.

Methods: Urine protein profiling was performed on samples from 20 patients with AS and 10 control subjects, each with rheumatoid arthritis (RA), gout, or healthy controls (HC), using label-free quantitative proteomics. Differentially expressed proteins were identified using MaxQuant and the UniProt database (fold change ≥ 1.5, $p < 0.05$). Selected proteins were

validated by Western blot analysis and further assessed by ELISA in an independent cohort of 75 AS patients and 37 HC. Associations between protein levels and clinical parameters, including BASDAI and ASDAS-CRP, were also analyzed.

Results: Urine proteins were analyzed by liquid chromatography and tandem mass spectrometry, identifying 1,975 proteins. Among them, AMY1A, SDC1, and PIK3IP1 were selected as candidate biomarkers based on high-fold changes and statistical significance. Western blot analysis confirmed significantly higher expression of these proteins in AS patients compared to those with RA, gout, and HC, supporting the proteomic findings (Figure 1). Receiver operating characteristic (ROC)

curve analysis demonstrated good diagnostic performance, with the individual area under the curve (AUC) values of 0.812 (AMY1A), 0.875 (SDC1), and 0.852 (PIK3IP1). Notably, the combination of all three markers yielded an improved AUC of 0.973, indicating enhanced diagnostic accuracy with multiplexed analysis. In the validation cohort, ELISA assay confirmed that PIK3IP1 and SDC1 levels were significantly elevated in AS patients ($p = 0.0082$ and 0.0179, respectively), whereas AMY1A showed no significant difference ($p = 0.7058$) (Figure 2). No significant correlations were found between the three biomarkers and disease activity indices such as BASDAI or ASDAS-CRP. However, AMY1A levels were related to a history of enthesitis, and PIK3IP1 levels were associated with underlying hypertension (Table 1).

Conclusion: AMY1A, SDC1, and PIK3IP1 were identified as potential urinary biomarkers for AS. Among them, PIK3IP1 and SDC1 showed significantly higher levels in AS patients and demonstrated good diagnostic performance. While these markers were not associated with disease activity scores, these results suggest their potential utility in AS diagnosis.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0522–0553) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: To apply current treatment recommendations for psoriatic arthritis (PsA), clinicians must perform a comprehensive assessment of psoriatic disease domains, including a musculoskeletal exam (tender and swollen joints, dactylitis, enthesitis, axial disease) and a skin and nail exam for psoriasis (PsO). Documentation in the electronic medical record (EMR) serves as a proxy for these assessments. Additionally, ICD coding of psoriatic disease influences administrative database research. This study aimed to compare documentation of psoriatic domains and ICD coding practices between PsA specialist providers and general rheumatologists at two academic centers.

Methods: We identified patients with ICD-coded diagnoses of PsA who were seen by either general rheumatologists or PsA combined-clinic specialist providers at two established PPACMAN (Psoriasis and Psoriatic Arthritis Clinics Multicenter Advancement Network) sites. Clinical notes were reviewed for documentation of musculoskeletal and cutaneous PsA domains. We also evaluated the accuracy and completeness of ICD coding for PsA and/or PsO to assess the reliability of EMR-derived discrete data. Fisher's exact tests were used to assess relationships between provider type, documentation practices, and ICD coding.

Results: Across multiple academic centers, PsA combined-clinic specialist providers documented psoriatic disease domains significantly more consistently than general rheumatologists. Musculoskeletal domains—including tender and

swollen joint counts (p< 0.001), assessment of spondyloarthritis (p=0.017), dactylitis (p< 0.001), and enthesitis (p< 0.001)—were more routinely documented by PsA specialists. Cutaneous domains were also more consistently documented by specialists, including PsO location (p< 0.001), phenotypic subset (p< 0.001), and use of standardized psoriasis assessment tools such as BSA, PGA, and PASI scores (p< 0.001). Furthermore, PsA specialists more frequently applied appropriate ICD codes for PsO (p< 0.001) and for both PsA and PsO (p< 0.001).

Conclusion: In this multicenter retrospective study, PsA specialist providers more thoroughly documented musculoskeletal and cutaneous disease domains and more accurately coded for PsA and PsO compared to generalists. These findings highlight gaps in documentation among general rheumatologists and underscore the need for enhanced training in psoriatic

disease assessment. Despite significant efforts from multiple organizations, patient advocacy foundations and academics to increase awareness, improvement in both assessment and documentation are still needed. Improved documentation tools may facilitate both better clinical evaluation and more reliable research using EHR or claims-based data.

Background/Purpose: Psoriatic arthritis (PsA) is associated with increased cardiovascular risk and a pro-atherogenic lipid profile. We hypothesize that alterations in lipid metabolism combined with systemic inflammation are present in the early disease stages of the disease and reflect pathophysiologic, metabolic changes characteristic for PsA. We investigated serum lipid profile in early PsA and examined whether changes in the profile or apolipoproteins are specific to early disease.

Methods: Adult patients with newly diagnosed treatment naïve PsA were included in the multicenter cohort study (N=75). Clinical, demographic characteristics and comorbidities were collected. The serum lipids were measured: total cholesterol (TC), non-HDL-cholesterol (non-HDL-c), LDL-cholesterol (LDL-c), HDL-cholesterol (HDL-c), triglycerides (TAG), apolipoprotein B (ApoB) and apolipoprotein A1 (ApoA1). The results were compared to sex- and age matched healthy controls (HC) (N=61) and rheumatoid arthritis (RA) patients (N=50)(Kruskall-Wallis). The lipid measurements were re-evaluated in PsA patients after 1 year follow-up.

Results: The three groups were matched by age; HC and PsA patients were matched by age and sex. PsA patients had mainly oligoarticular disease, low PASI scores and a short symptom duration (median: 0.6 years). The mean DAPSA score (SD) was 19.5(10.8), corresponding to moderate disease activity. Early RA patients (disease duration (median: 0.5 years) all had polyarticular disease and moderate disease activity, mean(SD) DAS-28-CRP of 4.61(2.0).

Among lipid measurements, HDL-c levels were lower in PsA than in HC and RA (df2, $c^2$10, p=0.006, PsA vs HC p=0.013) (Fig 1A-E), the levels of TC, LDL-C, TAG were not different in the three groups. Significant differences in ApoA1 and ApoB levels were observed between PsA, RA and controls. ApoB was higher in PsA than in RA patients but lower than in controls (df2, $c^2$43.8; p< 0.001). ApoA1 was markedly lower in PsA patients compared to both RA and controls (df2, $c^2$118.9; p< 0.001)(Fig 1 F-H). In regression models, the levels of ApoA1, adjusted for age, sex, BMI, statin use, smoking status, CRP levels and interaction between them, were predictive of PsA diagnosis with 90.6% accuracy. In ROC analysis, ApoA1 was

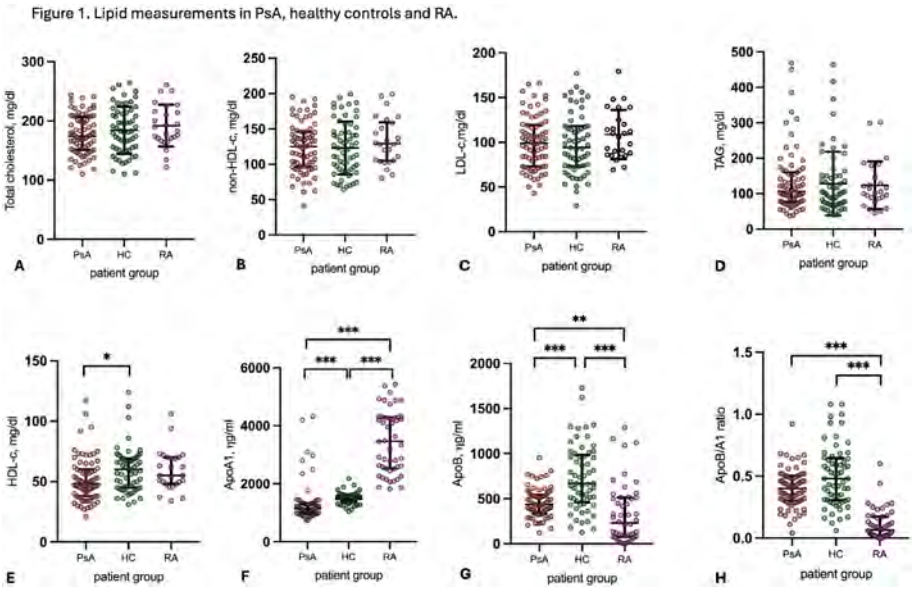

Figure 1. Lipid measurements in PsA, healthy controls and RA. A. TC measurements (mg/dl, median[IQR]) were comparable in PsA (174[56]), RA (187 [49]) and HC(183 [63]), p=0.205. B. non-HDL-c measurements (mg/dl, median[IQR]) in PsA (125 [49]), RA (129[55]) and HC (121[58]), p=0.47. C. LDL-c measurements (mg/dl, median[IQR]) in PsA (99[46]), RA (108[43]) and HC (94 [45]), p=0.291. D. TAG measurements (mg/dl, median[IQR]) in PsA (107 [83]), RA (104 [70]) and HC (99[80]), p=0.734). E. HDL-c measurements (mg/dl, median[IQR]) in PsA (48 [22]), RA (55 [22]) and HC (60 [24]), p=0.006). HDL-c levels in PsA were lower as compared to HC (p=0.013), no differnce between RA vs HC and RA-PsA was observed. F. ApoA1 levels (µg/ml, median[IQR]) were lower in PsA (1141 [317]), than in HC (1473[187]) and RA (3468[1071]), , p<0.001; p<0.001 for all pairwise). G. Apo B levels (µg/ml, median[IQR]) were higher in PsA (438 [209]) as compared to RA (231 [436]) (p<0.001) and lower as compared to HC (669 [528]), p<0.001 (pairwise: PsA vs HC and RA vs HC p<0.001, PsA vs RA p=0.009). H. ApoB/ApoA1 ratio (median(IQR] was higher in PsA (0.4 [0.2] and HC (0.5[0.3]) than in RA (0.06[0.15]), p<0.001; pairwise PsA vs RA p<0.001, RA vs HC p<0.001, PsA vs HC p=0.368). * p<0.05; ** p<0.001; *** P<0.0001

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. ROC analysis for HDL-C and ApoA1 in PsA, RA and HC.

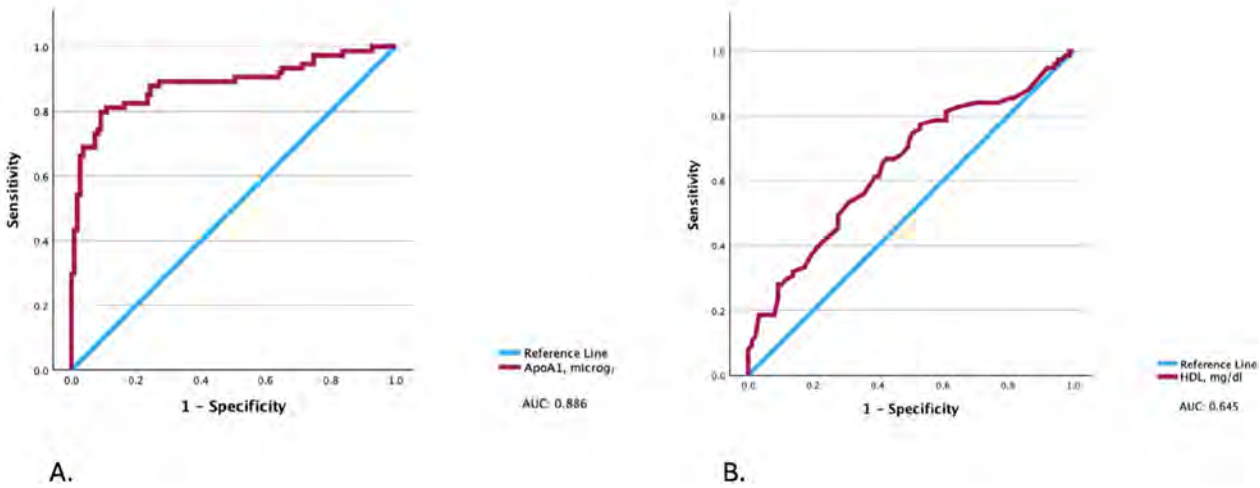

Figure 2. ROC analysis for HDL-C and ApoA1 in PsA and HC. A. ROC analysis for ApoA1 and diagnosis (PSA; RA vs HC), the diagnosis of PsA being positive classifier. AUC[95%CI] 0.886 [0.83-0.941]. Overal model quality: 0.83. Sensiticity 82.4% and specificity of 83.8 % at an optimal cut off limit of 1403 g/ml . B. ROC analysis for HDL-cholesterol and diagnosis (PSA; RA vs HC), the diagnosis of PsA being positive classifier. AUC[95%CI] 0.645 [0.83-0.941]. Overal model quality: 0.83.

predictive of the diagnosis of PsA with a specificity of 82.4% and a sensitivity of 83.8% at an optimal cut-off value of 1403 µg/ml (AUC[95%CI] 0.886[0.83-0.941]) (Fig 2). At 1 year follow-up only ApoA1 levels, but not other lipid measurements, increased in PsA patients achieving DAPSA LDA, while ApoB levels remained comparable to baseline (Fig 3).

Conclusion: Decreased levels of ApoA1 and increased levels of ApoB are specific to early and treatment naïve patients with PsA and distinguish them from early RA patients and non-arthritic controls. In particular, circulating levels of ApoA1 are strongly predictive for the diagnosis of PsA. The ApoA1 levels increase after 1 year in PsA patients achieving DAPSA low disease activity suggesting link with active disease. These findings suggest that specific changes in lipid profile are present in early stages of PsA and that apolipoprotein measurements might be better markers of pro-atherogenic profile in PsA than classical serum lipids.

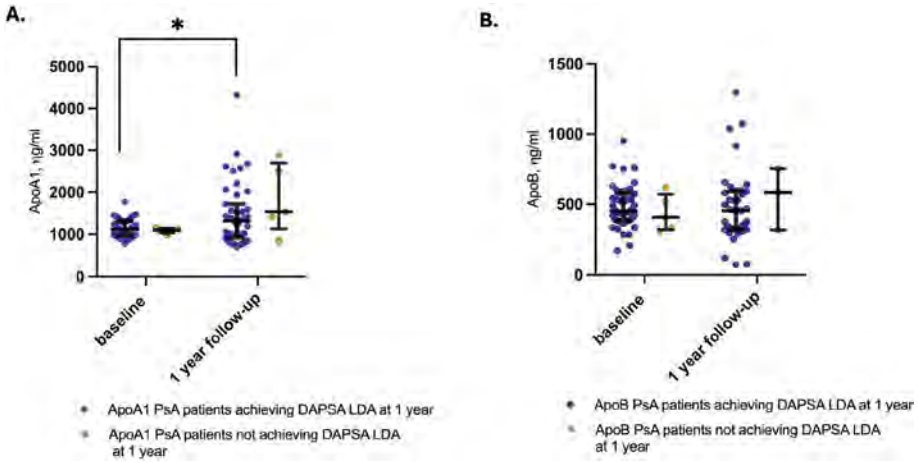

Figure 3. Change in ApoA1 and ApoB levels in patients achieving DAPSA low disease activity at 1 year-follow up. A. The levels of ApoA1 (µg/ml, mean(±SD)) increased at 1-year follow-up (1336±543) as compared to baseline (1160±217) in patients achieving DAPSA LDA (t1=2.5; p=0.016) and remained comparable to baseline in patients not-achieving DAPSA-LDA (baseline: 1052±67, 1-year: 1264±375; t=-2.01, p=0.106). B. The ApoB levels were comparable at baseline (486±162) and at 1-year (482±258) in patients achieving DAPSA LDA (t=0.114; p=0.910) and not achieving DAPSA LDA (baseline: 442±160; 1-year: 551±220; t=-0.904, p=0.461). 1 – paired samples t-test was used to compare baseline and 1-year follow-up data

Anti-peptidylarginine deiminase-2 (anti-PAD2) Autoantibodies in Psoriatic Arthritis

Ana-Maria Orbai[1], Hong Wang[2], Maria Grecu[3], Ning Meng[4], Ji Soo Kim[5], Clifton Bingham[4], Uzma Haque[2], John Miller[4], Felipe Andrade[2], Erika Darrah[6] and Eleni Tiniakou[7], [1]Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]River Hill High School, Clarksville, MD, [4]Johns Hopkins University, Baltimore, MD, [5]Johns Hopkins, Baltimore, MD, [6]Astra Zeneca, Gaithersburg, MD, [7]UT Health Science Houston, Houston, TX

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0522–0553) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Citrullinated cathelicidin (LL37), a human-derived antimicrobial peptide, is an autoantigen in psoriatic arthritis (PsA).[1] LL37 citrullination by peptidylarginine deiminase (PAD) enzymes attenuates immune activation and downregulates inflammatory responses. PAD2 is the most effective at LL37 citrullination.[2] Anti-PAD2 autoantibodies have been described in rheumatoid arthritis[3] and Lyme disease[4] and are thought to inhibit citrullination of autoantigens such as LL37. This study aimed to identify anti-PAD2 in PsA and to study their association with patient characteristics in a longitudinal PsA registry and biobank.

Methods: Participants in a PsA registry fulfilling CASPAR classification criteria and having banked serum samples were included. We assayed serum anti-PAD2 using an in-house anti-PAD2 ELISA[4] in 200 PsA patients and 75 healthy controls (HC). Anti-PAD2 positive cutoff was set at the 90-percentile of HCs. We compared the distribution of patient characteristics in the anti-PAD2 positive and negative groups, using the Wilcoxon rank-sum and Fisher's Exact tests.

Results: Anti-PAD2 were found in 29% PsA and 9.3% HC sera (p=0.004) (Figure1). 44 (of 58) anti-PAD2 positive and 124 (of 142) anti-PAD2 negative patients had clinical data for analysis. Fifty-nine sera matched with disease activity measured within 48 hours of the serum sample, an additional 9 sera within 6-months, while remaining sera matched with future clinical data (Figure 2). Patients with anti-PAD2 positive compared to negative were older, less likely to have low articular disease activity, and less likely to have active plaque psoriasis affecting the extremities (Table). Considering that 68/168 patients were assessed within 6-months of anti-PAD2 testing, these differences could be attenuated. There were no significant differences in observed treatments.

Conclusion: We discovered anti-PAD2 autoantibodies in PsA. Among PsA patients 29% were positive for anti-PAD2. Anti-PAD2 was associated with more active joint disease and less active skin disease. The clinical significance of anti-PAD2 in PsA needs evaluation in a larger sample using simultaneous measurements with musculoskeletal and skin disease activity.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0522–0553) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Low back pain (LBP) is a multifactorial condition managed by various specialists. AI chatbots like ChatGPT may help clinicians identify probable diagnoses. Given that query phrasing can influence outputs, we hypothesized that ChatGPT's responses may vary depending on the specialty stated in the prompt.

We aimed to evaluate whether ChatGPT's diagnostic output changes when simulating different specialties in LBP assessment, and to compare its diagnostic accuracy to that of clinicians.

Methods: A total of 10 clinical cases related to LBP were included from official public exams for rheumatologists in Spain, designed to assess expertise for permanent specialist positions. These included 5 cases of rheumatologic diseases and

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

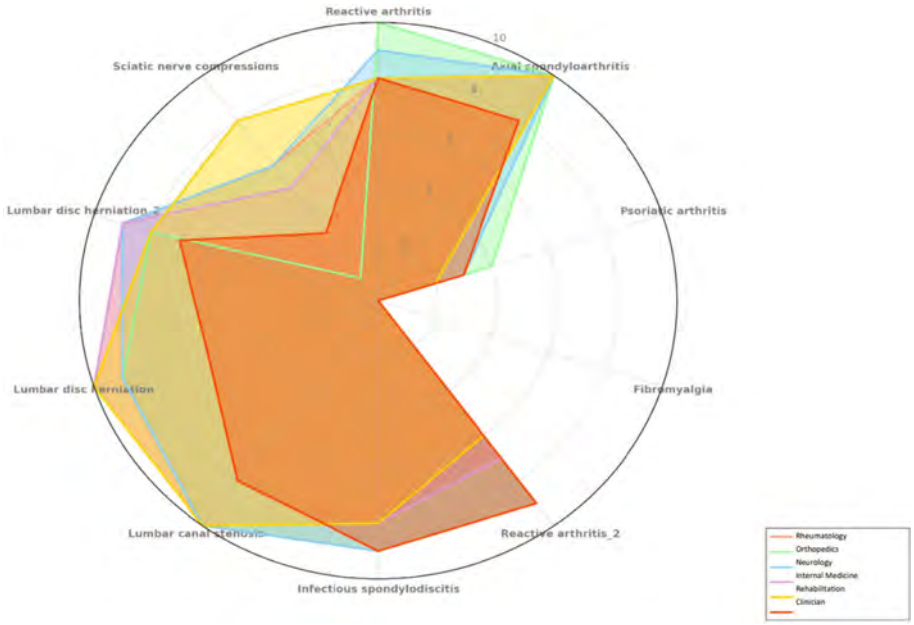

Figure 1. Percentage of the correct score for each participant and each prompted speciality

5 representing other causes. The exercise was conducted in December 2024 using ChatGPT version 4.o. Ten clinicians with at least 5 years of experience in managing rheumatic and musculoskeletal diseases (RMDs) participated in the study. Each question was answered independently by clinicians, and at a later stage by each participant asking ChatGPT, simulating five specialties (Rheumatology, Neurology, Internal Medicine, Rehabilitation, and Orthopedics). The gold standard was the official answer listed as diagnosis for each exam question. Diagnostic performance was evaluated using precision (percentage of cases where the top diagnosis matched the gold standard) and sensitivity (percentage of cases where the gold standard was included in the top three probable diagnoses). The time taken to answer all 10 clinical cases was recorded for both clinicians alone and using ChatGPT, starting when the case was reviewed and stopping when three differential diagnoses and the most probable diagnosis were finalized.

Results: In total, 528 free-text diagnoses were generated and standardized into 39 diagnostic categories. The percentage of the correct score for each participant and each prompted specialty is illustrated in Figure 1. Median precision ranged from 70% to 80% across the five specialties simulated by ChatGPT, and median sensitivity ranged from 80% to 90%. Statistical analysis revealed no significant differences in precision ($p = 0.80$) or sensitivity ($p = 0.68$) between the specialties simulated by ChatGPT, indicating consistent performance regardless of the prompted specialty. For clinicians, the median precision was 60%, and median sensitivity was 80%. When comparing ChatGPT to clinicians, ChatGPT had significantly higher diagnostic precision (median = 75% vs. 60%, $p < 0.001$) and significantly higher sensitivity (median = 85% vs. 80%, $p = 0.02$). The mean time taken by participants to complete the task was 12.35±5.62 minutes, compared to 2.33±0.03 minutes for ChatGPT ($p< 0.01$).

Conclusion: ChatGPT provides consistent diagnostic performance across simulated specialties, unaffected by the prompt's semantic framing. It may outperform clinicians in both diagnostic precision and sensitivity, highlighting its potential as a valuable complementary tool for generating fast, accurate and comprehensive differential diagnoses in cases of low back pain. Further research is needed to explore its application in clinical practice and its ability to enhance diagnostic workflows.

Evaluating the Diagnostic Utility of 14-3-3 eta Autoantibodies in Axial Spondyloarthritis: A Multiplex Assay Approach

Anthony Marotta[1], Walter P. Maksymowych[2], Stephen Bleakley[1], Stephanie Wichuk[3] and Norma Biln[4], [1]Augurex Life Sciences Corp, Vancouver, BC, Canada, [2]Department of Medicine, University of Alberta, 568 Heritage Building, Edmonton, AB, Canada, [3]University of Alberta, Edmonton, AB, Canada, [4]Augurex Life Sciences, Vancouver, BC, Canada

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0522–0553) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Novel biomarkers for axSpA are urgently needed to enable earlier diagnosis and improve patient outcomes. An assay for quantifying 14-3-3η autoantibodies (AAbs) has been developed, utilizing peptides derived from the 14-3-3η protein with distinct specificities. This study aims to establish cut-off values in a training cohort and apply them to an evaluation cohort to assess the diagnostic utility of the 14-3-3η multiplex AAb assay (MAAA) alone and with HLA-B27 and C-reactive protein (CRP).

Methods: The performance of the 14-3-3η MAAA was evaluated using a training cohort of 105 axSpA patients and 74 healthy controls (HC); N=179. ROC AUCs, sensitivity, and specificity for each peptide were generated. Positivity cut-offs for each of the five peptides were defined using the Youden Index, and these were summed to yield a composite score. The strength of the association for axSpA diagnosis was assessed by comparing the composite positivity status of axSpA patients to healthy controls (HC) using Fisher's Exact test. Diagnostic utility was further assessed in an evaluation cohort of 101 axSpA patients. CRP positivity was defined as >5 mg/L. Statistical significance was set at $p < 0.05$.

Table 1. Performance Metrics of the 14-3-3η MAAA in the Training Cohort

Parameter	Peptide 1	Peptide 2	Peptide 3	Peptide 4	Peptide 5
Cut-off (U/mL)	>2.054	>0.077	>0.515	>0.031	>0.081
Sensitivity (N, %)	90 (86%)	93 (89%)	81 (77%)	79 (75%)	87 (83%)

Table 2. Relative Risk (RR) of AxSpA Diagnosis Based on Composite Positivity: Comparison of AxSpA Patients and Healthy Controls (Results Expressed as RR and 95% CI)

	Diagnosis	
Composite Score	**axSpA (n=105)**	**Healthy (n=74)**
Positive	2.9 (1.8 - 4.8)	0.3 (0.2 - 0.5)
Negative	0.3 (0.2 - 0.6)	3.0 (2.0 - 4.5)

Table 3. Integration of 14-3-3η Autoantibody Composite with ASAS Diagnostic Markers

Positive (or for any positive)	**Training Cohort, n=105 (n,%)**	**Evaluation Cohort, n=101 (n,%)**
CRP	52 (51.5%)	53 (52.5%)
14-3-3η AAb Composite	70 (66.7%)	60 (57.7%)
HLA-B27	88 (84.6%)	85 (84.0%)
CRP and/or 14-3-3η AAb Composite	86 (81.9%)	58 (57.4%)
CRP and/or HLA-B27	98 (93.3%)	85 (81.0%)
HLA and/or 14-3-3η AAb Composite	101 (96.2%)	96 (91.4%)
CRP and/or HLA-B27 and/or 14-3-3η AAb Composite	104 (99.0%)	96 (91.4%)
HLA B27 -ve	**n=17 (n,%)**	**n=20 (n,%)**
14-3-3η AAb Composite +ve	12 (70.6%)	11 (55.0%)
CRP +ve	9 (52.9%)	6 (30.0%)
14-3-3η AAb Composite +ve and/or CRP +ve	15 (88.2%)	11 (55.0%)
14-3-3η AAb Composite +ve and CRP +ve	6 (35.3%)	6 (30.0%)

14-3-3η AAbs were positive in 23 (31%) of the 74 healthy controls. CRP was available on 68 of the 74 healthy controls. Of the 68, only 3 patients were positive for CRP, one of which was negative for 14-3-3η AAbs.

Results: All five 14-3-3η peptides exhibited significant areas under the curve (AUC) in distinguishing axSpA patients from HC in the training cohort (Table 1). The assay showed high precision, with intra-laboratory precision %CVs ranging from 8.3% to 14%. The assay showed minimal interference from normal serum elements (hemoglobin, bilirubin, triglycerides, cholesterol, and albumin), non-target antibodies (HAMA, heterophile, and infliximab), and organic chemicals (ibuprofen, sulfasalazine, and dexamethasone).

In the training cohort, the composite score yielded 67% TP and 69% TN with 33% FN and 31% FP. Fisher's Exact test produced a Chi-Square value of 31.8, with a p-value of less than 0.0001, and an Odds Ratio of 8.7 (95% CI: 3.9 - 19.6). Table 2 shows that patients with composite positivity have a significantly higher relative risk of axSpA compared to healthy controls.

Table 3 shows that adding 14-3-3η AAb composite positivity to HLA-B27 and CRP increases axSpA detection from 93.3% to 99.0% in the training cohort and from 81.0% to 91.4% in the evaluation cohort. In HLA-B27 negative patients, 14-3-3η AAb improves detection to 70.6% in the training cohort and 55.0% in the evaluation cohort. Combined with CRP, detection increases to 88.2%, highlighting its potential for early diagnosis.

Conclusion: The 14-3-3η MAAA significantly enhances the early diagnosis of axSpA, especially when combined with HLA-B27 and CRP, demonstrating its potential as a valuable diagnostic tool. This combined approach could lead to better patient outcomes through earlier and more accurate detection. Future research should focus on validating the 14-3-3η multiplex autoantibody assay in larger, diverse cohorts to confirm its diagnostic utility across different populations.

Abstract Number: 0532

Generative artificial intelligence provides synthetic data to discriminate patients with seronegative rheumatoid arthritis versus psoriatic arthritis *sine* psoriasis

Antonio Tonutti[1], Saverio D'Amico[2], Pierandrea Morandini[2], Cosimo Faeti[2], Elisa Barone[1], Nicoletta Luciano[1], Victor Savevski[2] and Carlo Selmi[3], [1]Humanitas University, Pieve Emanuele, Italy, [2]IRCCS Humanitas Research Hospital, Rozzano, Italy, [3]Humanitas University, Milan, Italy

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0522–0553) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

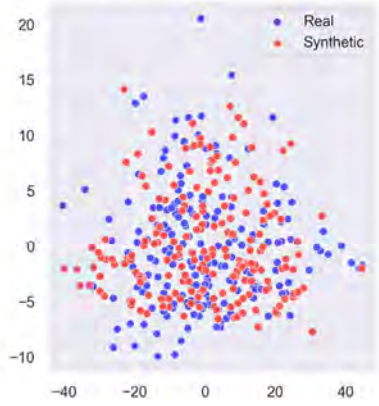
Session Time: 10:30AM–12:30PM

Background/Purpose: Distinguishing seronegative rheumatoid arthritis (RA) from psoriatic arthritis (PsA) *sine* psoriasis remains challenging, often relying on pathognomonic features (axial involvement, enthesitis) present in only few cases and causing diagnostic changes over time.

Generative artificial intelligence (AI) creates synthetic patient profiles to enhance the detection of subtle differences that may elude clinical observation. We applied generative AI for the first time in Rheumatology to evaluate statistical fidelity, privacy preservation, and clinical utility of synthetic data, and to test its potential to differentiate seronegative RA vs PsA sine psoriasis.

Methods: Leveraging data of 105 PsA sine psoriasis and 95 seronegative RA patients, a proprietary synthetic data generation platform was used to implement an optimized Conditional Tabular Wasserstein Generative Adversarial Networks (GAN) to produce 200 synthetic patients balanced across diagnostic groups. These were evaluated using Synthetic vAlidation FramEwork (SAFE) (D'Amico S, 2023). MOSAIC framework (D'Amico S, 2024) was employed for classification (PsA vs. RA), using demographic and baseline clinical variables. A Random Forest model was developed and tested on a real validation dataset using 3-fold cross-validation, then was re-evaluated after incorporating synthetic data into the training set to assess any performance enhancement using the same validation set. Model outputs were interpreted with Shapley Additive exPlanations (SHAP).

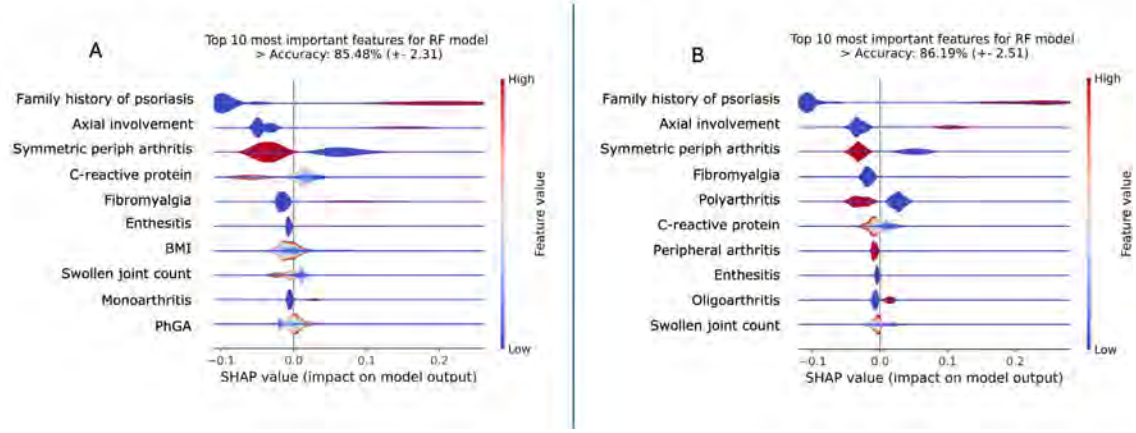
Figure 1. Principal component analysis of demographic and clinical variables of the synthetic and real cohort. While the distribution of the two principal components is similar between real and synthetic patients (mirroring clinical consistency of generated data), no overlap is observed (mirroring absence of duplication and privacy safety).



Principal component analysis of demographic and clinical variables of the synthetic and real cohort. While the distribution of the two principal components is similar between real and synthetic patients (mirroring clinical consistency of generated data), no overlap is observed (mirroring absence of duplication and privacy safety).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 2. SHAP summary plot showing the top 10 most influential features for the Random Forest model trained on real (Panel A) and real+synthetic (Panel B) data to distinguish PsA sine PsO (right in the plot) from seronegative RA (left in the plot). Each dot represents a patient; colors indicate feature value (red = high/high frequency, blue = low/low frequency).



SHAP summary plot showing the top 10 most influential features for the Random Forest model trained on real (Panel A) and real+synthetic (Panel B) data to distinguish PsA sine PsO (right in the plot) from seronegative RA (left in the plot). Each dot represents a patient; colors indicate feature value (red = high/high frequency, blue = low/low frequency).

Results: Generation of 200 synthetic patients had 73% privacy preservation score (nearest neighbor distance ratio; optimal 65-85) and 92% statistical fidelity, indicating that the synthetic cohort mirrored the real one without duplication with similar distributions in principal component analysis (**Fig 1**).

In the real dataset, Random Forest achieved accuracy 85.5% ± 2.3% in distinguishing PsA sine psoriasis from seronegative RA. Random Forest identified family history of psoriasis, monoarthritis, axial disease, enthesitis, fibromyalgia, and high BMI as strong PsA predictors and captured the discrepancy between inflammatory and noninflammatory mechanisms as proper of PsA (higher baseline PhGA, low swollen joint count and CRP). Symmetric arthritis favored classification as RA (**Fig 2A**).

Incorporating synthetic patients, Random Forest accuracy increased to 86.2% ± 2.5%, retained key predictors including typical PsA features (enthesitis, axial and asymmetric involvement), family history of psoriasis, and discrepancy between pain and inflammatory measures (low CRP and swollen joint count, fibromyalgia). Notably, peripheral polyarthritis vs oligoarthritis favored RA and PsA, respectively (**Fig 2B**).

Conclusion: The first-ever application of generative AI in Rheumatology provided a synthetic data cohort of seronegative RA and PsA sine psoriasis, consistent with real data and privacy-safe. Synthetic data improved classification accuracy. Key variables for intercepting PsA sine psoriasis included family history of PsO, axial/entheseal involvement and mismatch between pain measures and inflammatory markers.

Reactive Arthritis Transcriptomics: Enriched Enterobacteriaceae-related Pathways in Synovial Fluid and in Blood is Associated with Drug-free Remission

Avarna Agarwal[1], Phanidhar Dhanekula[1], Sarthak Verma[1], Subham ravi Nayak[2], Prakashini Mruthyanjaya[1], Prasanta Padhan[1], A Rajkumar Patro[2], Ramnath Misra[1] and Sakir Ahmed[1], [1]Department of Clinical Immunology and Rheumatology, Kalinga Institute of Medical Sciences, Bhubaneswar, Orissa, India, [2]Department of Microbiology, Kalinga Institute of Medical Sciences, Bhubaneswar, Orissa, India

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0522–0553) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: In reactive arthritis (ReA) approximately a half of patients achieve drug-free remission (DFR), while others develop chronic disease. To identify predictive biomarkers for DFR, we performed a baseline transcriptomic analysis of whole blood and synovial fluid in ReA and undifferentiated peripheral spondyloarthritis (pSpA) and followed them up for 3 months each. Key differentially expressed genes (DEGs) were validated.

Methods: Fifty-seven patients meeting Braun criteria for ReA or ASAS criteria for pSpA (excluding IBD-related or psoriatic arthritis) were recruited. Baseline whole blood and synovial fluid (SF) samples from inflamed joints were collected. Drug free remission (DFR) was defined as being completely symptom-free at three months while off all medications. Patients were grouped as chronic ReA or DFR.

Transcriptomics was performed on whole blood (n=14) and paired SF (n=10) using Illumina NovaSeq for RNAseq, X Plus and DRAGEN for demultiplexing/alignment, DESeq2 for DEG analysis, and cluster Profiler for KEGG pathway enrichment in R.

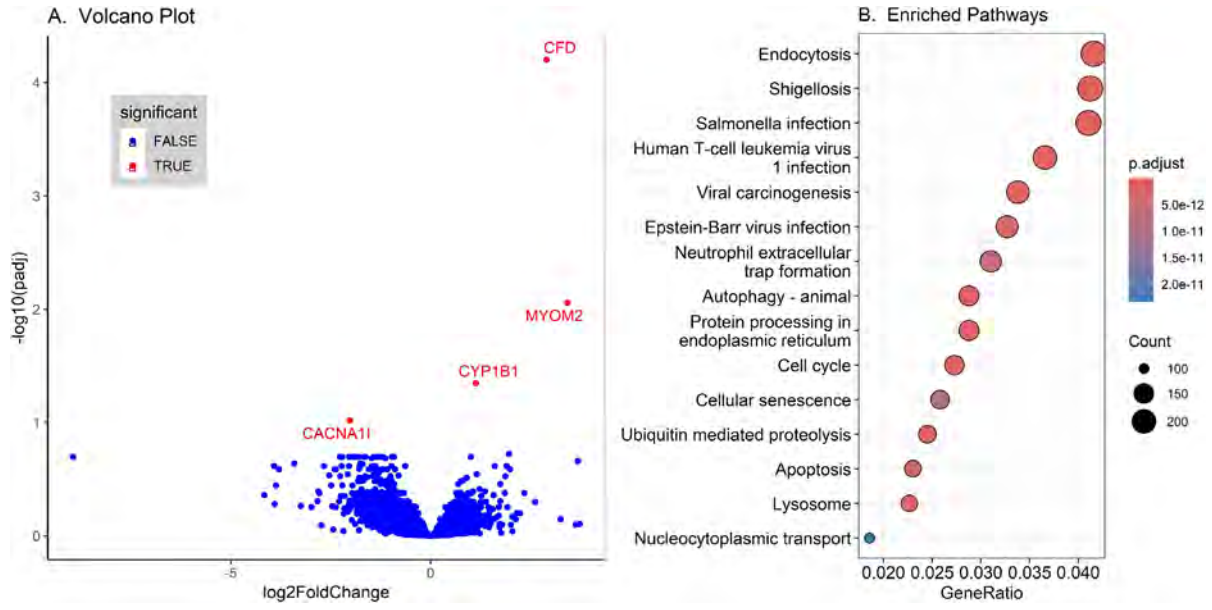

Figure 1: Comparison between whole blood transcriptome profiles of patients with chronic reactive arthritis and those with drug-free remission. (A) Volcano plot showing differentially expressed genes and (B) Showing the top 15 enriched pathways (KEGG)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

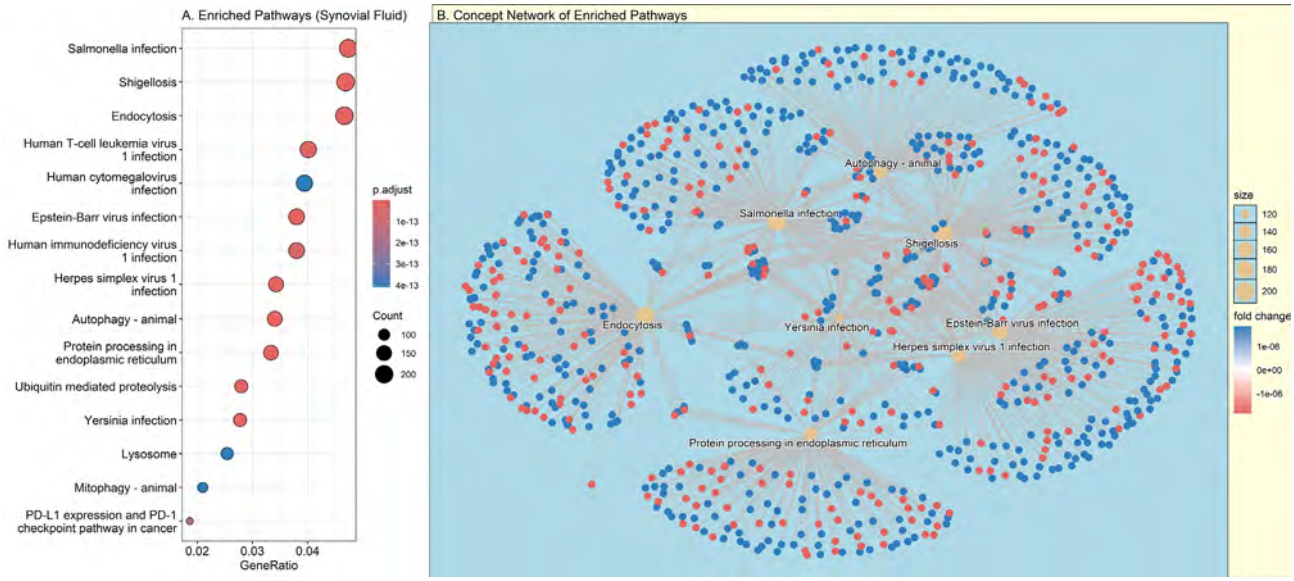

Figure 2: Comparison between synovial fluid transcriptome profiles of patients with chronic reactive arthritis and those with drug-free remission. (A) Dot plot of the top 15 enriched pathways (KEGG) and (B) showing a Concept network map between the top 8 enriched pathways.

Amongst the top differentially expressed genes, Complement factor D (CFD) and Cytochrome enzyme CYP1B1, were validated internally in the RNAseq cohort (n=14) along with another external validation (n=5) using a SYBRGreen- TaqMan system. Mann-Whitney U test compared ΔCT values between DFR and chronic groups.

Results: Out of total 57 patients [75% males; median age 32 (IQR12-40) years], 37 were ReA and 20 were undifferentiated pSpA. Fifty-two percent (n=30) of patients achieved DFR. We selected baseline whole blood (n=14) and paired synovial fluid (SF, n=10) samples based on RNA quality for RNAseq. Of these, 6 had attained DFR (SF available for 3). There was no difference in the transcriptome profiles of ReA versus undifferentiated pSpA.

Whole blood transcriptomics identified four differentially expressed genes associated with DFR (Upregulated: CFD, MYOM2, CYP1B1. Down-regulated: CACNA1I) [Figure 1A]. KEGG enrichment analysis revealed pathways related to Endocytosis, Shigellosis, Salmonellosis and certain viral-related pathways were enriched in patients who ultimately attained DFR [Figure 1B].

Differentially expressed genes in the synovial fluid were not statistically significant (not shown). However, the KEGG analysis also showed the enrichment of pathways associated with Salmonellosis, Shigellosis, Endocytosis and different viruses [-Figure 2A]. Figure 2B shows the concept maps of the top 8 upregulated pathways in the KEGG analysis.

In the preliminary validation, CFD [median ΔCT DFR: 6.48 (IQR 4.63-12.87), chronic: 9.20 (IQR 7.27-12.65); p=0.2] and CYP1B1 [median ΔCT DFR: 6.95 (IQR 6.63-8.76), chronic: 10.25 (IQR 7.98-11.69); p=0.055] did not reach statistical significance in DFR patients compared to chronic ReA.

Conclusion: Baseline whole blood gene expression profiles predict DFR in ReA. Enrichment of bacterial and viral pathways in DFR patients, despite the absence of live bacteria in SF, suggests a potential role for bacterial exosomes or other pathogen-associated molecular patterns (PAMPs) in the resolution of ReA. The role of CFD and CYP1B1 needs to be elucidated.

Prevalence and Impact of Fibromyalgia on Disease Outcomes and Treatment in Axial Spondyloarthritis: 10-year Follow-up Data From the DESIR Cohort

Clementina López Medina[1], Sylvie Chevret[2], Cedric Lukas[3], Anna Molto[4] and Maxime Dougados[2], [1]Department of Medicine, Hospital Universitario Reina Sofia, University of Cordoba, IMIBIC, Cordoba, Spain, [2]Université Paris-Cité, Paris, France, [3]CHU Montpellier, Montpellier, France, [4]Assistance Publique Hôpitauxde Paris, Paris, France

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0522–0553) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Concomitant fibromyalgia (FM) can be suspected in patients (pts) with axial SpA (axSpA) using the Fibromyalgia Rapid Screening Tool (FiRST).

The objective of this study was to evaluate the prevalence of suspected FM and its impact on the disease, including first TNFi initiation and retention rates, PROs and disability, over the first 10 years of follow-up in pts with axSpA.

Methods: This analysis included pts diagnosed with axSpA by a rheumatologist for less than 3 years. Collected data: The FiRST tool became available starting from the seventh year (M84) and was then administered annually until year 10 (M120). Statistical analysis: *a) Estimation of FM prevalence*. The percentage of FM+ pts was estimated for the entire cohort (n=708). Missing data were imputed using multiple imputation for longitudinal data at each of the four visits (M84 to M120). A patient was classified as FM+ if he/she was identified as FiRST+ at least twice during the four visits (M84-M120) after multiple imputation. *b) Impact of FM:* The impact of FM was assessed as follows: b.1.) at the start of the cohort (visit M0): by comparing objective signs of axSpA (HLA-B27 status, structural damage on X-rays, inflammation on MRI-SIJ and abnormal CRP); b.2.) over the 10 years of follow-up: by analysing disease activity, PROs and disability using mixed models for repeated measures; b.3.) therapeutic impact: by evaluating the percentage of patients treated with a first TNFi and their therapeutic maintenance using Kaplan-Meier analyses.

Results: After the multiple imputation of visits M84 to M120, the estimated prevalence of FM+ pts was 144/663 (21.7%). At baseline, the presence of FM was associated with a lower frequency of HLA-B27 positivity and radiographic sacroiliitis, but a

ASDAS: Axial Spondyloarthritis Disease Activity Score; BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; BASFI: Bath Ankylosing Spondylitis Function Index; MM: Mixed Model for Repeated Measures; SF36-MCS: Mental Component Score from the SF-36 questionnaire; SF36-PCS: Physical Component Score from the SF-36 questionnaire; SD: Standard Deviation; TNFi: Tumour Necrosis Factor inhibitors.

Figure 1. Mixed models for Repeated Measures (MMRM) with random effects to compare disease activity and PROs over 10 years of follow-up between FM+ and FM-.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

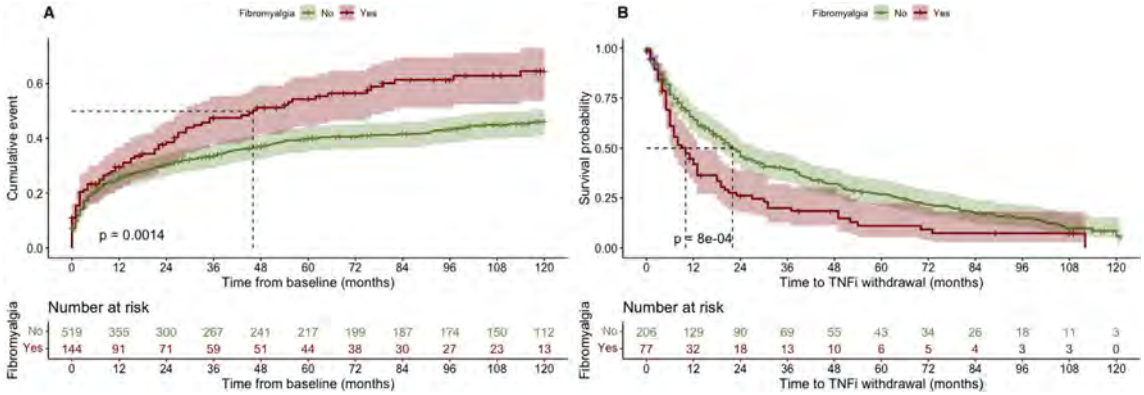

Figure 2. Impact of concomitant FM on the probability of TNFi initiation (A) and on the retention rate to the first TNFi (B).

similar prevalence of positive MRI-SIJ findings and abnormal CRP levels. Furthermore, the level of confidence in the SpA diagnosis by the rheumatologist was similar in FM+ and FM- groups (6.9 vs. 7.1 on a 0-10 scale).

The presence of FM was also associated with higher disease activity and poorer quality of life over the 10 years of follow up (Figure 1). Pts with FM showed a significant greater likelihood of reporting permanent disability after 10 years compared to FM- pts (26.4% vs. 9.4%, p< 0.001).

Finally, FM+ was associated with a higher likelihood of initiating biologic therapy during the 10 years of follow-up (64.4% vs. 46.1%). However, therapeutic maintenance was poorer in the FM+ group, with a lower percentage of pts remaining on treatment one year after initiation [FM+: 42.0% (95%CI 32.1-54.9) vs. FM-: 64.2% (95%CI 57.9-71.2)] (Figure 2).

Conclusion: This study confirms the high prevalence of FM in axSpA. The similarity of certain objective disease markers (e.g., MRI-SIJ positivity and abnormal CRP) between FM+ vs. FM- pts, as well as the comparable diagnostic confidence, suggests that FM is more likely a comorbidity than a diagnostic error. The presence of FM negatively impacts disease activity scores and quality of life, resulting in a higher likelihood of permanent disability. FM is also associated with an increased likelihood of initiating biologic therapy; however, therapeutic maintenance is lower in these pts.

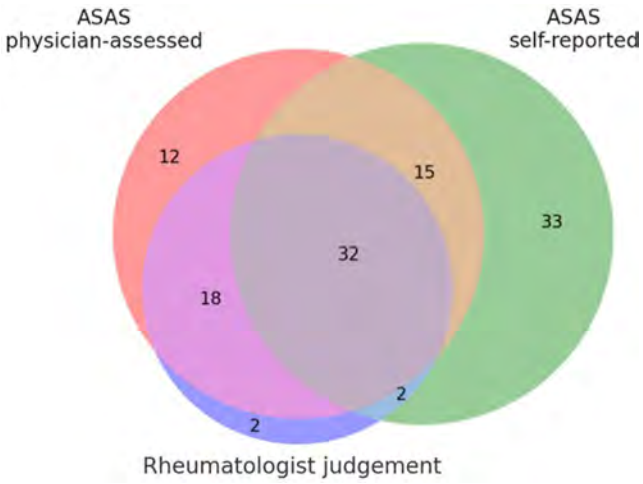

Figure 1. Number of patients with IBP according to each method of assessment

Background/Purpose: Inflammatory back pain (IBP) is very relevant for identifying patients at risk of axial spondyloarthritis (axSpA). Mounting evidence has indicated substantial variability in sensitivity and specificity among different methods of IBP assessment (1). The aim of this study is to evaluate the concordance and correlation between physician-based ASAS IBP criteria and self-reported IBP, comparing each against expert clinical judgement in a prospective cohort of patients with chronic low back pain.

Methods: A prospective, observational study was conducted at a tertiary hospital (July 2021- October 2023). Patients aged 18–40 years with chronic back pain (≥ 3 months) who underwent spine magnetic resonance imaging (MRI) requested by non-rheumatology specialists were enrolled, and completed a questionnaire capturing variables relevant to axSpA, including characteristics of IBP. Within two weeks, patients underwent a rheumatology evaluation. IBP was evaluated independently using three different approaches: physician-assessed ASAS IBP criteria as a checklist (ASAS-IBP-phy), self-reported ASAS IBP questionnaire (ASAS-IBP-self), and the rheumatologist's clinical judgement (IBP-rheumatologist). ASAS-IBP-phy and ASAS-IBP-self were evaluated through structured questionnaires completed by the physician and the patient, respectively ,while IBP-rheumatologist relied exclusively on the clinician's global assessment. Cohen's and Fleiss' kappa statistics, along with tetrachoric correlation, assessed the agreement among these methods.

Results: Among 268 enrolled patients, mean age was 35.6 years (SD 5.6), with 149 (55.6%) females. Mean duration of symptoms was 5.1 years (SD 4.6), and 64.2% had symptom duration greater than two years. ASAS-IBP criteria were positive in 79 (29.5%) patients by rheumatologist checklist evaluation (ASAS-IBP-phy), and 82 (30.6%) through self-report

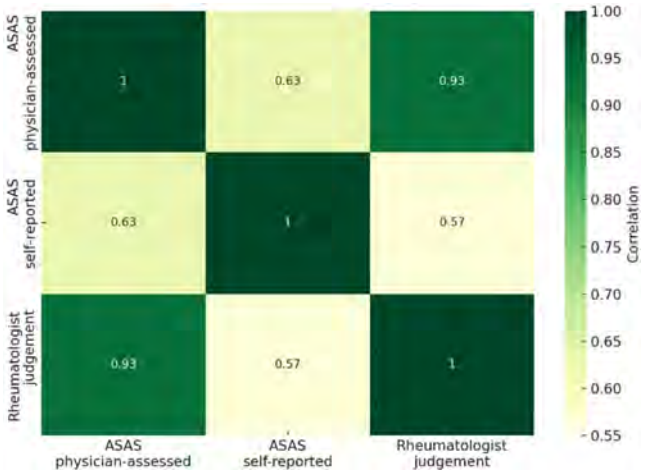

Figure 2. Correlation between IBP assessment methods

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(ASAS-IBP-self). Clinical judgement by rheumatologist identified IBP in 54 (20.1%) patients. Among patients with axSpA (n = 8), 7 (87.5%) presented IBP according to the rheumatologist, and among those without axSpA (n = 260), 47 (18.1%) did. 32 patients (11.9%) fulfilled IBP criteria across all three methods (**Figure 1**). Agreement between physician-based and self-reported IBP criteria was moderate (kappa = 0.42, p< 0.001) with a strong tetrachoric correlation (rt=0.63) (**Figure 2**). ASAS-IBP-phy showed substantial agreement with IBP according to rheumatologist clinical judgement (kappa = 0.69, p< 0.001), and a very strong tetrachoric correlation (rt=0.93). In contrast, agreement between ASAS-IBP-self and clinical IBP assessment was fair (kappa = 0.34, p< 0.001), with moderate tetrachoric correlation (rt=0.57). Fleiss' kappa for overall agreement among the three assessment methods was 0.31 (p< 0.001).

Conclusion: In this cohort, physician-based ASAS IBP criteria showed higher concordance and correlation with rheumatologist clinical judgement than self-reported criteria. Given these results, clinician-led evaluation should be prioritized when identifying IBP in clinical and research contexts, with cautious interpretation of self-reported data, particularly in remote or digital healthcare settings.

Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Enthesitis is a hallmark feature of psoriatic arthritis (PsA). Chronic inflammation in the entheses can lead to the formation of enthesiophytes (bony spurs), and this new bone formation may result in functional loss over time. Although substantial improvements in clinical response has been observed using the treat-to-target (T2T) management strategy, limited studies have demonstrated its effect on radiographic outcomes, particularly regarding new bone formation. Therefore, the objective of this study was to ascertain the effect of achieving Sustained Disease Activity in PSoriatic Arthritis (DAPSA) low disease activity (LDA) on the progression of enthesiophyte in MCP2-4 using HR-pQCT.

Methods: One hundred consecutive PsA patients were recruited to this 2-year prospective study. They received protocolized T2T treatment aiming at DAPSA-LDA. Sustained DAPSA-LDA (SDL) was defined as achievement of DAPSA-LDA at month 12, 18 and 24. HR-pQCT of the MCP2-4 were performed at baseline, one and two years,. Enthesiophytes were

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1 - Enthesiophyte volume over time between patient who achieved and did not achieve sustained LDA

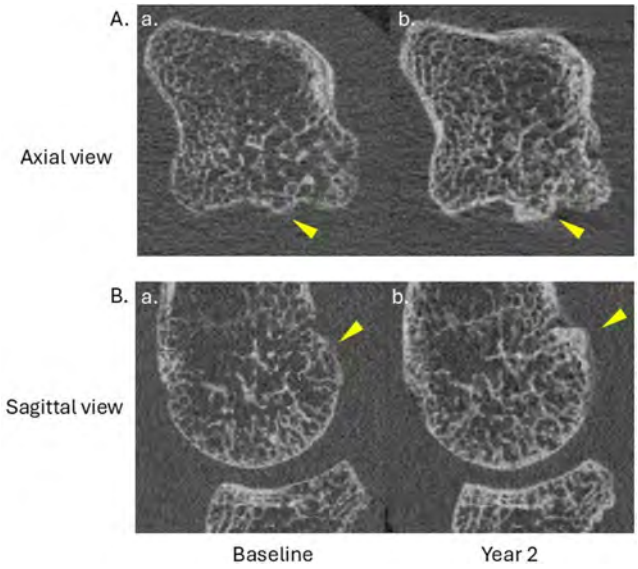

Figure 2 – Representative image showing progression of enthesiophyte from baseline to year 2 in axial and sagittal view

defined as new bone formation arising from the periosteal bone cortex at the insertion sites of the capsule, ligament, or tendons or at the location of functional enthesis.(1) Enthesiopyte volume was quantified were quantified semi-automatically. Progression of pre-existing enthesiophyte were defined as increase in enthesiophyte volume exceeding least significant change (LSC, 1.1mm^3).

Results: Ninety-five patients (age: 51±14 years, 57 (60%) male, disease duration: 3.9±6.1 years) who completed 2-year follow-up were included. After 2-years of T2T management, a significant decrease in disease activity (DAPSA - baseline: 25.1±12.7 vs Year 2: 8.4±6.8, $p< 0.001$) were observed, and 59 (62.1%) patients achieved SDL. The use of biologic disease modifying anti-rheumatic drug (bDMARDs) increased from 5% at baseline to 64% at year 2. Regarding enthesiophyte, a total of 64 and 47 enthesiophytes were identified at baseline for patients in SDL and non-SDL group respectively. After 2 years, enthesiophyte volume in non-SDL group progressed [median (IQR) of change: 0.77mm^3 (-0.19, 2.22)] and that in SDL group remained stable [median (IQR) of change: 0.08 mm^3 (-0.61, 0.73), p=0.035]. Enthesiophyte volume progression was significantly higher in non-SDL group (40% vs 19% in SDL group, (p=0.031). Using generalized estimating equation (GEE), after accounting for within subject variance, achieving SDL protected against enthesiophyte volume progression (OR=0.35, 95% CI: 0.14-0.88, p=0.025), independent of age, sex, disease duration and bDMARDs use.

Conclusion: Achievement of sustained disease activity control protects against progression of enthesiophyte in PsA.

HLA-B27 and Axial Involvement as Independent Risk Factors for Uveitis in Spondyloarthritis: New Insights from a 15-Year Real-Life Study

Kent LE[1], Hervé LOCRELLE[1], Myriam NORMAND[1], Irina COMAN[1], Louis DELENTE[1], Tiphany NEEL[1], Adamah AMOUZOUGAN[1], Thierry THOMAS[1] and Hubert Marotte[2], [1]Service Rhumatologie Hôpital Nord, Saint-Etienne, France, [2]INSERM 1059/University of Saint-Etienne, Saint-Etienne, France

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0522–0553) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: To assess the prevalence, risk factors and treatment-related outcomes of uveitis in patients with spondyloarthritis (SpA), using data from a 15-year real-life cohort.

Methods: We conducted a retrospective study including all patients treated for SpA at the Rheumatology Department of Saint-Etienne University Hospital, between January 2008 and July 2022. Demographic, clinical, biological, radiographic, and treatment data were collected. Patients were classified according to uveitis history and timing relative to treatment initiation (absent, recurrent, de novo). Multivariate analysis identified factors associated with uveitis and treatment outcomes.

Results: Among the 1,571 patients included (mean age 50.6 ± 14.7 years; 52.7% male; mean disease duration 13.6 ± 10.6 years), 46% were diagnosed with ankylosing spondylitis, 33.9% with non-radiographic axial SpA, and 20.1% with peripheral SpA. HLA-B27 was positive in 59.5% of patients. Uveitis prevalence was 12.3% (95% CI: 10–14%), rising to 20.7% (95% CI: 17.7–24%) among HLA-B27 positive patients. Independent risk factors for acute anterior uveitis (AAU) included axial involvement (OR = 3.34; 95% CI: 1.46–7.65; p = 0.004), HLA-B27 positivity (OR = 3.65; 95% CI: 2.30–5.82; p < 0.01), and longer disease duration (OR = 1.03/year; 95% CI: 1.01–1.05; p < 0.001). Uveitis recurrence occurred in 33.3% of patients treated with IL-17 inhibitors vs. 10.4% with anti-TNF agents (p = 0.02).

Conclusion: In this extensive cohort, our study confirmed the independent association of HLA-B27, axial phenotype, and disease duration as the key predictors of uveitis in SpA. Among bDMARDs, monoclonal anti-TNF agents were the most effective in preventing uveitis, while recurrence was significantly higher under anti-IL17 therapy. Notably, this study is the first to demonstrate the independent association between HLAB27 positivity and axial involvement, offering new insights for personalized treatment strategies.

Session Title: (0522–0553) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Axial spondyloarthritis (axSpA) is a chronic immune-mediated inflammatory disease primarily affecting spine and sacroiliac joints (SIJ), leading to pain and disability. Magnetic resonance imaging (MRI) has transformed axSpA diagnosis in non-radiographic cases–undetectable on X-rays–, guiding treatment and improving long term outcomes.

As per the Assessment of Spondyloarthritis international Society (ASAS), "active sacroiliitis" requires bone marrow edema (BME) on T2-weighted MRI, indicating SIJ inflammation highly suggestive of axSpA. However, "positive MRI" definitions vary, with high inter-/intra-observer variability and frequent underdiagnosis, contributing to a mean 7-year delay. Thus, standardized, automated tools are needed. This study aimed to develop an artificial intelligence (AI)-based model to detect active axSpA on MRI.

Methods: This retrospective, observational study (NCT06591481) used real-world data from six international sites. The dataset included 684 SIJ MRIs, each with coronal-oblique T2 short tau inversion recovery (STIR) or T2 fat-saturated (FS) sequences acquired at diagnosis and follow-up. Imaging data were collected and processed using Quibim platform (Quibim SL, Valencia, Spain). All scans underwent quality checks by three radiographers with >5 years of experience on image interpretation.

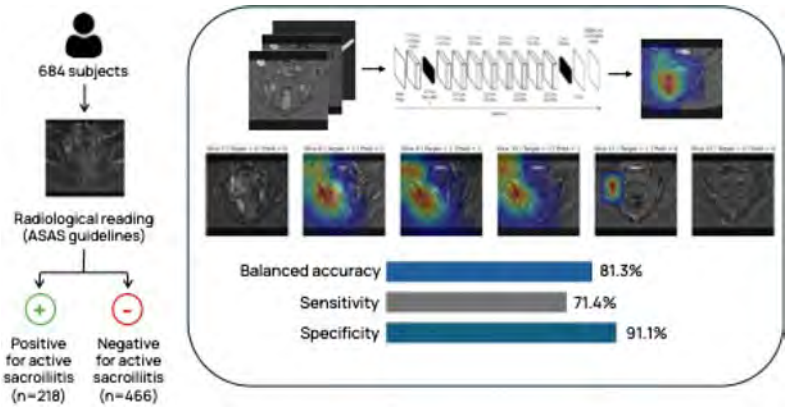

Figure 1. Development of AI-based tool for lesion detection in axSpA patients with active sacroiliitis using MRI

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Following ASAS criteria, MRIs were double read by radiologists with >12 years of experience, with adjudication by a third reader. Scans were classified as positive active sacroiliitis on MRI (ASAS-positive MRI; BME on two consecutive slices) or negative, and structural damage (ankylosis, erosion and fat metaplasia) were noted. A deep-learning-based AI classification model was developed to identify axSpA patients with ASAS-positive MRI. Of the total 684 cases, 563 were used for training and validation, and 121 for testing. The model performs automated sacroiliac joint segmentation on T2 imaging to predict BME presence across patient slices. Detection of two consecutive positive slices yields a positive patient diagnosis. To enhance interpretability, heat maps highlight the regions that most influence the model's predictions.

Results: Overall, 32% of patients (*n* = 218) fulfilled the ASAS classification criteria for axSpA. The model achieved high balanced accuracy (bal acc = 81.3%), sensitivity (se = 71.4%) and specificity (sp = 91.1%) for ASAS-positive MRI detection. Performance was higher (bal acc = 89.3%; se = 84% and spe = 94.5%) in cases with consensus readings and clearly visible lesions on at least two consecutive slices. However, performance declined (bal acc = 51.5%) in cases with poor image quality, motion artifacts, or subtle lesions, highlighting the need for expert oversight. In such cases heat maps can assist in achieving a correct diagnosis.

Conclusion: We developed an AI-based classification model with high diagnostic performance in detecting MRI-positive axSpA, especially in terms of specificity (91.1%). This tool could support radiologists by standardizing MRI interpretation. Its integration into clinical workflows may enhance diagnostic accuracy and improve patient care.

Background/Purpose: The assessment of structural damage progression is an important part of outcome assessment in axial SpA (axSpA). In order to test whether interventions can potentially inhibit structural damage progression, an outcome measurement instrument that is sensitive to change is essential. We aimed at comparing the sensitivity to change of different methods assessing structural lesions on conventional radiographs and on MRI of the sacroiliac joints (SIJ) and the spine in patients with early axSpA.

Methods: Patients with chronic back pain (≥3 months; ≤2 years; onset < 45 years) from the SPondyloArthritis Caught Early (SPACE) cohort received a rheumatologist's diagnosis of axSpA or non-axSpA after two years follow-up. Only patients with an axSpA diagnosis were included in this analysis. Radiographs and MRIs of the SIJ (MRI-SIJ) and spine (MRI-spine) were obtained at baseline, 3 months, 1 and 2 years of follow-up, and scored for structural lesions (Table 1) by at least 2 and a maximum of 3 readers in two reading rounds. All patients with ≥1 score from ≥1 reader from ≥1 timepoint from ≥1 reading round were included in the analysis. To allow comparison across outcomes, the standardized rate of change was calculated using integrated multilevel generalized estimating equations while considering the individual readers and reading round. To facilitate the comparison across imaging outcomes, the relative standardized rate of change was calculated by dividing the standardized rate of change of the imaging outcome by that of an outcome chosen as the reference. Additionally, one

outcome was chosen as a reference for each anatomic site for comparison of the outcomes at the site level. The imaging outcome with the highest standardized rate of change per year was chosen as reference, both overall and for each anatomic site. A sensitivity analysis was conducted in patients with all scores from ≥2 timepoints available.

Results: In total, 332 patients with axSpA (mean age 30 (SD 8) years; 53% males) were included in the main analysis, of which 295 (89%) had all scores from ≥2 timepoints. The yearly (relative) standardized rate of change of each imaging outcome is shown in Table 1. From all outcomes, MRI-SIJ total structural lesions without sclerosis had the highest standardized rate of change per year, also meaning that SIJ structural lesions were more sensitive to change than spinal lesions. From the spine outcomes, MRI total fat lesions had highest standardized rate of change. In addition, total fat lesions were highly sensitive both in the SIJ and spine (Figure 1). In contrast, outcomes with erosions or (partial) ankylosis were less sensitive to change. The sensitivity analysis showed similar findings.

Conclusion: Compared to MRI-spine and radiographs SIJ and spine, MRI-SIJ structural lesions are generally most sensitive to change. Fat lesions are most sensitive to change, especially on the MRI-SIJ. Erosions and ankylosis are less sensitive outcomes.

Session Title: (0522–0553) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Low-dose computed tomography (ldCT) has not previously been used to assess pt with axial spondyloarthritis (axSpA) early in their disease course, especially those with minimal structural damage at baseline. We assessed spinal damage progression using ldCT and evaluate inter-reader reliability in patients (pt) with axSpA.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

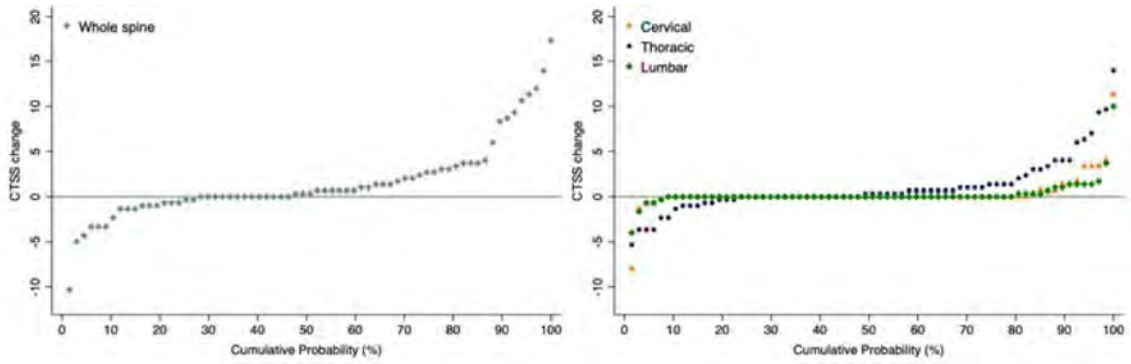

Figure 1. Cumulative probability plots of the change in computed tomography syndesmophyte score (CTSS) over 2 years for the whole spine (left) and separate spinal segments (right), based on aggregated scores derived from the average of individual reader scores

Methods: In SPondyloArthritis Caught Early (SPACE) cohort, 67 axSpA pt underwent two whole spine ldCT scans over a 2-year follow-up. First scan (T0) took place 0–10 years after inclusion, varying by pt. Regardless of T0 timing, second scan (T2) two years later.

Three central readers independently assessed CT syndesmophyte score (CTSS). Readers were blinded to image order and pt data. CTSS calculated per vertebral unit (VU) using eight quadrants, scoring syndesmophytes from 0 (absent) to 3 (bridging the intervertebral disc space), with a maximum CTSS of 552. Inter-reader reliability for CTSS change was calculated using intraclass correlation coefficients (ICC).

	Patients with new/growing syndesmophytes after 2 years				
VU	Reader 1	Reader 2	Reader 3	Consensus	Spinal level
1	0	1	3	0	C2-C3
2	1	1	1	1	C3-C4
3	1	0	1	1	C4-C5

22	1	0	1	1	L4-L5
23	3	1	2	2	L5-S1

Figure 2. Heatmap of spinal progression on ldCT: number of pt with new/growing syndesmophytes (increased red intensity reflects a higher number), based on consensus scores derived from a 2 out of 3 reader majority agreement

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Changes in CTSS (continuous data) were based on average reader scores and visualized in cumulative probability plots. Dichotomous data (new/growing syndesmophytes) were based on ≥2/3 consensus of readers at vertebral corner level. New syndesmophytes were defined by a score change from 0 to 1, 2, or 3; growth from 1 to 2 or 3, or 2 to 3. Net progression was calculated by subtracting regressors from progressors, divided by total pt, for cut-offs (≥1 to ≥5).

Results: Among 67 pt, 57% were male, 84% was HLA-B27 positive, mean age of 36 (8) years and symptom duration of 6 (3) years. 21% had early axSpA (≤2 years symptoms).

For the whole spine, the ICC for the change CTSS was 0.67 (95% CI: 0.50 to 0.78). Segment-specific ICCs showed good reliability for lumbar (0.91, 95% CI: 0.87 to 0.94) and thoracic spine (0.77, 95% CI: 0.65–0.85). Cervical spine showed poor reliability (ICC -1.69 (95% CI: -3.06 to -0.73).

Mean CTSS for whole spine increased from 9.6 (18.5) at T0 to 11.2 (20.7) at T2, resulting in a total mean change of 1.6 (4.5). When examining per spinal segments, thoracic spine showed the largest progression with a mean change of 1.0 (3.1), accounting for 63% of total change in the spine. Remaining 38% of spinal damage progression was equally accounted for by cervical and lumbar segments, each showing a mean CTSS change of 0.3 (1.9) and 0.3 (1.5), respectively. Figure 1 shows distribution of CTSS change, with smallest detectable changes of 3.93 (whole spine), 2.42 (cervical spine), 2.33 (thoracic spine) and 0.99 (lumbar spine).

Figure 2 shows number of pt with new/growing syndesmophytes per VU. Net progression of new/growing syndesmophytes (consensus) for whole spine was 22% at cut-off ≥1, 18% at cut-off ≥2, 15% at cut-off ≥3, 10% at cut-off ≥4, and 12% at cut-off ≥5.

Conclusion: Whole spine ldCT can detect progression in axSpA, even in pt with short symptom duration and minimal baseline prevalence of damage. Over two years, syndesmophyte progression occurred throughout the entire spine, with net progression rates between 10% and 22%, depending on severity cut-off. The thoracic spine showed the most change, accounting for nearly two-thirds of total progression—more than the cervical and lumbar segments combined

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0522–0553) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Inflammatory back pain (IBP) is a hallmark symptom of axial spondyloarthritis (axSpA) and is frequently used as a clinical entry point for further evaluation, including HLA-B27 testing and inflammatory marker assessment. However, the specificity of IBP for identifying individuals with immunogenetic or biochemical features of axSpA in the general population remains uncertain.

Methods: We analyzed data from the 2009–2010 cycle of the National Health and Nutrition Examination Survey (NHANES), a cross-sectional, nationally representative dataset. IBP was defined using Calin, ESSG, Berlin 7b, and Berlin 8a criteria, based on self-reported responses to the NHANES Arthritis Questionnaire. HLA-B27 typing and high-sensitivity CRP (hsCRP) were measured in a subset of 2,320 participants aged 20–69. We conducted logistic regression models adjusting for age, sex, race/ethnicity, smoking, alcohol use, diabetes, and hypertension. Causal mediation analysis was performed to assess whether CRP levels mediated any relationship between HLA-B27 and IBP.

Results: Among 746 participants with complete data, the prevalence of HLA-B27 was 6.1%. IBP prevalence ranged from 5.0% to 6.0% depending on the criteria used. In fully adjusted models, HLA-B27 positivity was not significantly associated with IBP by any of the criteria (e.g., Berlin 8a: OR 0.88 [95% CI 0.13–5.98], p=0.876) (Figure 1). Similarly, CRP levels were not associated with IBP (e.g., Berlin 8a: OR 0.94 [95% CI 0.63–1.39], p=0.694) (Figure 2). Mediation analysis showed no significant indirect effect of CRP on the HLA-B27–IBP relationship (indirect effect OR ≈ 1.00, p > 0.6 across all models) (Figure 3).

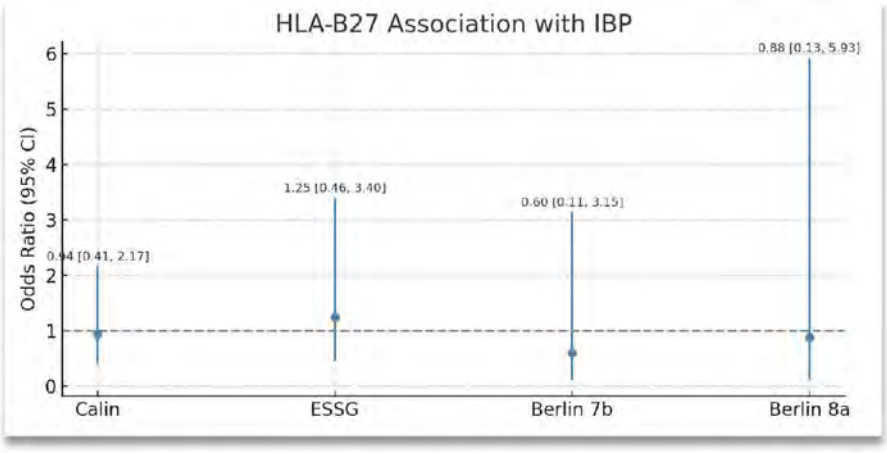

Figure 1. HLA-B27 association with Inflammatory Back Pain Criteria adjusted OR for age, sex, race, smoking, DM, HTN.

Figure 1. HLA-B27 association with Inflammatory Back Pain Criteria adjusted OR for age, sex, race, smoking, DM, HTN.

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

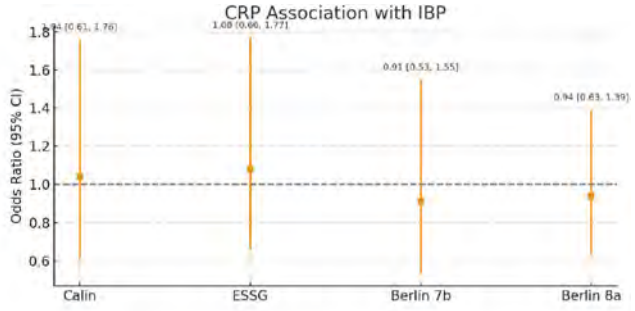

Figure 2. CRP association with Inflammatory Back Pain Criteria adjusted OR for age, sex, race, smoking, DM, HTN.

Figure 2. CRP association with Inflammatory Back Pain Criteria adjusted OR for age, sex, race, smoking, DM, HTN.

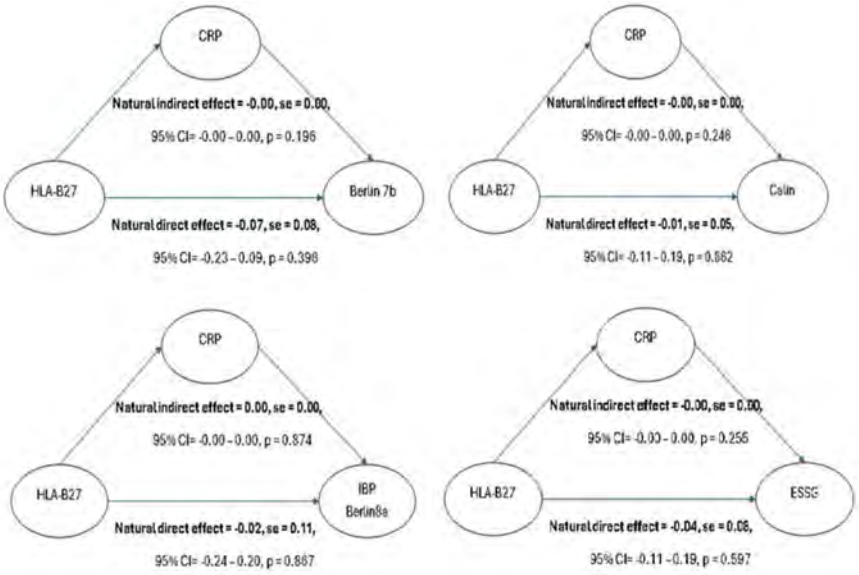

Figure 3. Causal Mediation Analyses for IBP. HLA-B27 association with IBP was not signficant after adjustment (natural direct effect). CRP does not mediate the association as well (natural Indirect effect)

Figure 3. Causal Mediation Analyses for IBP. HLA-B27 association with IBP was not signficant after adjustment (natural direct effect). CRP does not mediate the association as well (natural Indirect effect).

Conclusion: In a nationally representative U.S. sample, IBP as defined by established criteria was not associated with either HLA-B27 positivity or CRP levels. These findings suggest that IBP symptoms alone may have limited utility for identifying individuals with immunogenetic or inflammatory features of axSpA in the general population. Future strategies for early recognition of axSpA may require multimodal approaches that integrate clinical, laboratory, and imaging data beyond symptom-based screening alone.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0522–0553) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Psoriatic arthritis (PsA) is a debilitating disease that occurs in up to one-third of patients with psoriasis (Pso), generally manifesting after the onset of Pso. Numerous studies have analyzed the risk factors for the development of PsA in patients with Pso, highlighting family history. However, there is little evidence about what determines the latency period between the onset of Pso and the development of arthritis.

Therefore, the following objectives have been established for this study:

a) To analyze the clinical phenotype of PsA based on the presence or absense of a family history of Pso or PsA (FH Pso/PsA)

b) To determine which factors (including FH Pso/PsA) influence the speed of onset of arthritis after the initial presentation of Pso

Methods: We conducted a retrospective analytical study including 359 patients diagnosed with PsA according to the "Classification Criteria for Psoriatic Arthritis" (CASPAR). These patients were divided based on the presence or absence of a family history of Pso/PsA (FH Pso/PsA). We collected clinical, radiographic, and treatment variables for each patient, as well as the dates of onset of Pso and arthritis. For the comparison of variables, Student's t-test (for quantitative variables) and Chi-square test (for qualitative variables) were used. We designed a survival analysis with Cox multiple regression to determine which factors influence the speed of onset of arthritis after the initial presentation of Pso.

Results: Of the 359 patients included, 37.5% had a family history of Pso/PsA (FH Pso/PsA). Patients with FH showed cutaneous-onset forms of PsA more frequently than those without FH (86.4% vs. 70%; $p< 0.001$), as well as a younger age at disease onset (Table 1). The latency period between the onset of Pso and the development of arthritis was longer in patients with FH (median time: 9.6 vs. 4.3 years; log-rank: $p< 0.001$; Figure 1). In the multivariable analysis, FH Pso/PsA (HR 0.88 (95% CI 0.78–0.99)) and a younger age at Pso onset (HR 1.03 (95% CI 1.02–1.04)) were associated with a delay in the onset of arthritis relative to Pso (Omnibus test: $p< 0.001$).

Conclusion: Family history of Pso/PsA in patients with Pso is associated with a longer time until the onset of arthritis. Therefore, patients with FH not only require a higher index of suspicion for PsA but also need longer follow-up periods to detect it. Collaboration between Dermatology and Rheumatology will be essential for early diagnosis and optimal management.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0522–0553) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Axial involvement in psoriatic arthritis (axPsA) is associated with more severe disease and greater pain compared to PsA with only peripheral disease. However, a consensus definition of axPsA is lacking, complicating diagnosis and treatment. This study aims to describe the occurrence and characteristics of MRI and radiographic sacroiliac joint (SIJ) involvement in a European cohort of patients with PsA.

Methods: Patients with a clinical diagnosis of PsA (clin-PsA) or axial spondyloarthritis with psoriasis (axSpA+Pso), who had available routine care SIJ MRIs and clinical data, were included from five European registries in the EuroSpA collaboration. SIJ MRIs and radiographs were centrally evaluated by two experienced readers for inflammatory and structural lesions, differential diagnoses, and a global assessment for SpA-indicative findings. Disagreements were adjudicated by a third expert reader. Associations between MRI-detected axPsA (defined as MRI findings indicative of SpA) and clinical characteristics were analysed using logistic regression with multiple imputations for missing data.

Results: Among the 581 included patients (Clin-PsA: n=373; axSpA+Pso: n=208), 47% were male, with a mean age of 45 years (Table 1). At the time of MRI examination, 76% had not received biological treatment.

In 31% of patients, MRI findings were indicative of SpA (MRI-axPsA). Inflammatory SpA-indicative lesions were present in 21% of patients, and structural lesions in 28%, with 76% of affected patients having both lesion types. Common differential

diagnoses included osteitis condensans ilii (8%), probable strain-related bone marrow edema (BME) (11%), and degenerative changes (16%). In 35% of patients, SIJ MRIs were normal, showing no SpA-related lesions or alternative diagnoses.

Among patients with MRI-axPsA the SIJ MRI findings were predominantly bilateral, with BME (69%), erosion (68%), and fat lesions (58%) being the most common. BME (≥1 cm), inflammation in an erosion cavity, capsulitis, fat lesions (≥1 cm), backfill, and ankylosis were observed almost exclusively in this group (Figure 1).

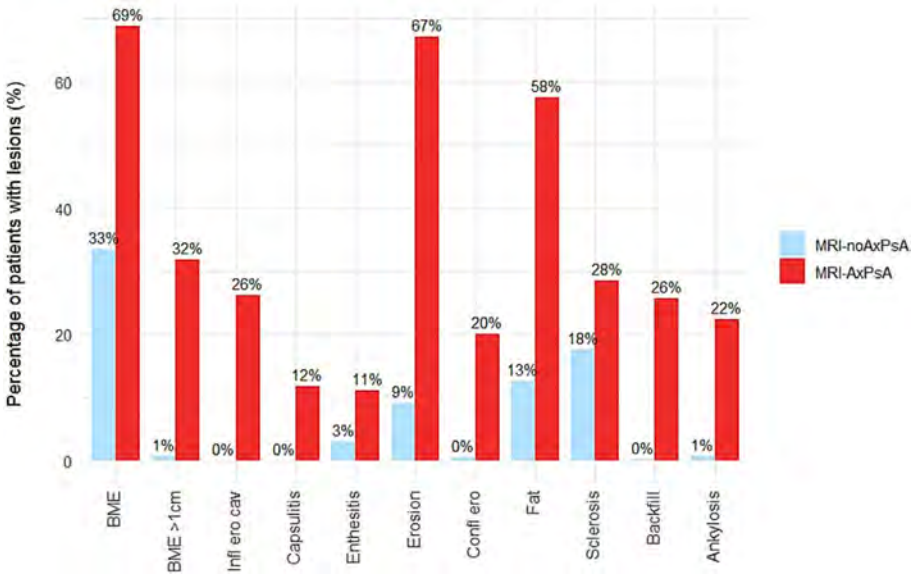

Figure 1. Inflammatory and structural MRI lesions in PsA patients with an MRI indicative of SpA (MRI-AxPsA group) versus not indicative of SpA (MRI-noAxPsA) BME, bone marrow edema; Infl Ero cav, inflammation in an erosion cavity; Confl Ero, confluent erosion; Fat, fat lesion

Various definitions of axPsA	All patients (n=581)		Central MRI assessment				
			MRI-AxPsA (n=179)		MRI-noAxPsA (n=402)		
	n		n		n		p
1. Clinical definitions (as reported by the registries):							
A. BASDAI Question 2 (back pain ≥ 4)	262	214(82%)	106	83(78%)	156	131(84%)	0.2
B. Inflammatory back pain (by ASAS criteria)	479	263(55%)	145	102(70%)	334	161(48%)	0.01
C. Fulfilment of ASAS classification criteria for axSpA	452	206(46%)	142	108(76%)	310	98(32%)	0.01
2. Radiographic definitions (central reading):							
A. Fulfilment of the radiographic part of mNY criteria	259	74(29%)	95	57(59%)	160	17(11%)	0.01
B At least grade 2 unilateral radiographic sacroiliitis	259	84(32%)	95	58(60%)	160	26(16%)	0.01
3. MRI "global" definition (central reading):							
Overall MRI findings indicative of SpA	581	179(31%)	179	100%	402	0	-
4. MRI definitions of active inflammation (central reading):							
A. ASAS-positive MRI	581	107(18%)	179	104(58%)	402	3(1%)	0.01
B Inflammatory lesions indicative of axSpA	581	121(29%)	179	114(64%)	402	7(2%)	0.01
5. MRI definition of structural lesions (central reading):							
Structural lesions indicative of axSpA	581	165(28%)	179	155(87%)	402	10(2.5%)	0.01

Among 259 patients with available radiographs, 29% met the radiographic component of the modified New York criteria (r-mNYc) for ankylosing spondylitis, while 38% had an MRI indicative of SpA. Radiographic SIJ involvement was predominantly bilateral (91%) in patients meeting the r-mNYc.

Male sex, HLA-B27 positivity, elevated CRP and history of inflammatory back pain, but not current back pain were independently associated with MRI-AxPsA, while peripheral arthritis showed a negative association.

Various clinical, radiographic, and MRI-based definitions of axial PsA were applied and compared (Table 2), using overall MRI findings indicative of SpA as the reference (Table 1, 5. MRI 'global' definition). No clinical or radiographic definition performed similarly to this MRI definition.

Conclusion: In this large European cohort, approximately one-third of routine care PsA patients had an SIJ MRI indicative of SpA. Integrating MRI into future axPsA definitions may facilitate earlier detection, and guide treatment choices in clinical practice.

Prevalence and Baseline Characteristics associated with Difficult-to-Manage Axial Spondyloarthritis in the DESIR Cohort

Olivier Fakih[1], Anna Molto[2], Frank Verhoeven[1], Clément Prati[1] and WENDLING Daniel[1], [1]CHU de Besançon, Besançon, Franche-Comte, France, [2]Assistance Publique Hôpitauxde Paris, Paris, France

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0522–0553) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Despite a choice of multiple targeted DMARDs, with different modes of action (MoA), a number of patients with axial spondyloarthritis (axSpA) have failed several treatments. This seems to correspond to a population with specific characteristics that can be termed Difficult to Manage (D2M). A definition of D2M axial spondyloarthritis (D2M-axSpA) has been proposed by the ASAS. Studies using variable definitions estimated a D2M-axSpA prevalence between 10–30%. However, no large cohort study has been conducted based on the ASAS definition. The objective of this study was to determine the prevalence of and factors associated with D2M-axSpA in the DESIR cohort of early inflammatory back pain.

Methods: Patients from the DESIR inception cohort who met the 2009 ASAS criteria for axSpA were included. The baseline characteristics and follow-up data were collected for up to 10 years. Patients were considered to have D2M-axSpA if they failed ≥ 3 bDMARDs and at least one of the sub-criteria making up criterion 2 of the ASAS D2M-axSpA definition (ASDAS ≥ 2.1, signs or symptoms suggestive of active disease, rapid radiographic spinal progression, and reduction in quality of life). This choice reflected limited access to IL-17 inhibitors in this cohort (inclusion in the late 2000s), making it difficult to apply a definition with failure of two different MoA (criterion 1 of the ASAS D2M-axSpA definition). Perception of difficult management (criterion 3) was not assessed. The prevalence of D2M-axSpA was determined, followed by bivariate analysis of the baseline factors associated with the existence of D2M-axSpA. A multivariate analysis using logistic regression was also performed. Quantitative variables were compared using the Mann-Whitney U test and qualitative variables were compared using Fisher's exact test.

Results: A total of 420 patients were included, mean age of 31.5±7.33 years. A total of 221 (52.6%) patients were women and 368 were HLA-B27 positive (87.62%). The mean follow-up duration was 8.9±2.4 years. The mean ASDAS-crp at

Table: Comparison of characteristics between D2M-axSpA and non-D2M-axSpA patients.

Characteristics at baseline	D2M-axSpA (n=15)	Non-D2M-axSpA (n=415)	p-value
Age	33.6±8.0	31.4±7.3	0.27
Disease duration	1.73±0.99	1.58±0.89	0.53
Female sex	**12 (80.0%)**	**187 (46.2%)**	**0.02**

Venn diagram of sub-criteria 2 of the D2M-axSpA definition.

inclusion was 2.61±0.98, BASFI was 28.8±22.4, and ASQOL 8.87±5.05. 84 (20%) patients had radiographic sacroiliitis. Fifteen patients (8.4% of bDMARD-treated; 3.6% of all) met the D2M-axSpA definition. D2M-axSpA was associated with female sex and higher ASDAS-CRP, BASFI, and ASQOL at baseline (Table). In a multivariate model adjusted for follow-up duration, only ASQOL at baseline was associated with the occurrence of D2M-axSpA (Odds-ratio 1.28 [1.04-1.63], p=0.03). All included patients met several sub-criteria of the definition, including impairment of the quality of life. None of the patients showed rapid radiographic spinal progression (Figure). A sensitivity analysis showed that seven (1.6%) patients met criteria 1 (failure of ≥ 2 bDMARDs with different MoA) and 2 of the ASAS definition of D2M-axSpA.

Conclusion: The prevalence of D2M-axSpA was low in this cohort of patients with early axSpA, although it was not possible to prescribe a class other than TNF inhibitors during the early years of follow-up. Female sex and high activity, functional, and quality of life scores at baseline were associated with a higher probability of D2M-axSpA, unlike peripheral or extra-musculoskeletal involvement.

Background/Purpose: The phenotypes of axial spondyloarthritis (axSpA) and clinical responses to placebo and study drugs in randomized controlled trials (RCTs) have changed over time. We conducted a systematic literature review and meta-analysis to evaluate changes in phenotypes and outcomes of axSpA patients participating in RCTs over a 20-year period.

Methods: Systematic search of PubMed, EMBASE, and Cochrane Library, following PRISMA guidelines (PROSPERO registration: CRD42024621406), updated to January 2025. Baseline characteristics were summarized as weighted means or proportions and transformed into standardized mean differences or Log odds ratios for meta-analytic comparisons. To assess temporal trends, categories were based on the first year of recruitment rather than the publication year. Meta-regression was conducted across 5-year intervals (P1:1999-2003, P2:2004-2008, P3:2009-2013, P4:2014-2019). Efficacy outcomes (ASAS20 and ASAS40) were assessed using adjusted models, incorporating comparator group, treatment type, age, BASDAI, radiographic axSpA / Ankylosing Spondylitis, and ASAS classification criteria. Sensitivity analyses used the RoB2 tool.

Results: Ninety RCTs (n=20,411 participants) were included. Descriptive analysis showed that weighted mean ages were lowest during P3 (38.3±5.3 years, 95%CI: 38.1-38.5) and P4 (39.2±4.6 years, 95%CI: 39.2-39.3). Longest disease duration was in P1 (11.6±2.6 years, 95%CI: 11.3-11.6). Male proportion was lowest in P3 (69.2%, 95%CI: 67.8-70.6%) and P4 (71.2%, 95%CI: 70.4-72.0%), and highest HLA-B27 positivity in P4 (79.1%, 95%CI: 78.3-79.8%).

Meta-regression showed a significant progressive decrease in male participants (p=0.028, I^2=50.2%), A trend towards younger patients was found in recent years, with a significant age decrease in P3 compared with earlier periods (p=0.039). Although meta-analysis revealed a temporal decrease in PtGA scores and an increase in spinal inflammation, no significant temporal trends were detected in meta-regression.

Adjusted meta-regressions demonstrated significant efficacy for treatment versus comparator as expected. For ASAS20, efficacy decreased in more recent periods (P3-P4), while no such temporal decrease was observed for ASAS40 (Figure 1A-B). In both adjusted models, bDMARD use as a comparator led to a lower efficacy than placebo as comparator (p< 0.001). Additionally, Higher male proportion was associated with greater efficacy (p< 0.010 in both response criteria).

Conclusion: We report temporal changes in axSpA phenotypes in RCTs over a 20-year period. Progressive reduction in male suggests increased inclusion of women, likely reflecting greater nr-axSpA representation in recent studies. Additionally, a trend toward younger patients was observed, although disease duration remained stable.

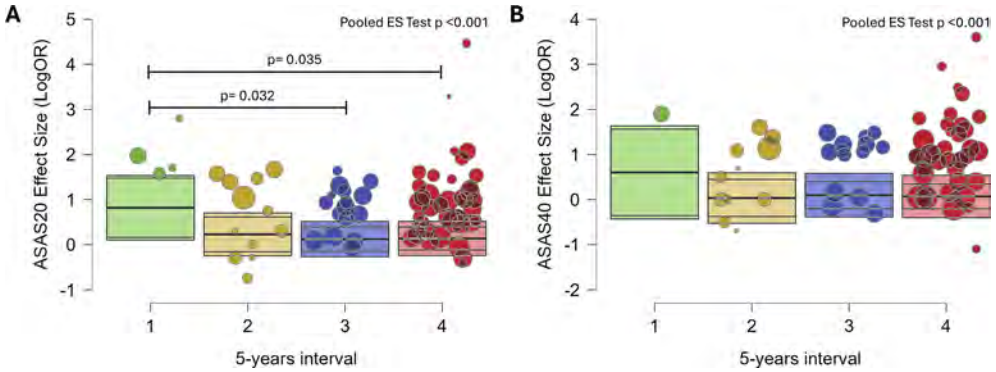

Figure 1. Temporal trends in treatment effect size for ASAS20 and ASAS40 responses across 5-year intervals. (A) Multivariable-adjusted meta-regression of ASAS20 effect sizes (log odds ratios: LogOR) stratified by 5-year recruitment intervals (P1: 1999–2003; P2: 2004–2008; P3: 2009–2013; P4: 2014–2019). (B) Multivariable-adjusted meta-regression of ASAS40 effect sizes across the same intervals. Each circle represents an individual study, with circle size proportional to study weight in the meta-regression. Boxplots indicate median, interquartile range, and variability of effect sizes within each interval. A significant decline in ASAS20 effect size was observed across periods (p for trend 0.032 and 0.035 for P3 and P4, respectively), whereas ASAS40 effect sizes remained stable over time (p≥0.05).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Despite decreased ASAS20 responses, treatment efficacy remained consistent when assessed by the stricter ASAS40 criteria, particularly after adjusting for key covariates. These findings reflect dynamic changes in recruitment patterns and diagnostic timing, with implications for cross-trial comparability and therapeutic evaluations.

Multimorbidity clusters in psoriatic arthritis, psoriasis, and axial spondyloarthritis and their association with healthcare utilization: A population-based study

Paras Karmacharya[1], Dilli Poudel[2], Daniel Shin[3], Robert Fitzsimmons[3], Leslie Crofford[4] and Alexis Ogdie[5], [1]Vanderbilt University, Nashville, TN, Hermitage, TN, [2]Vanderbilt University Medical Center, Nashville, TN, [3]University of Pennsylvania, Philadelphia, [4]Vanderbilt University Medical Center, Melbourne, AR, [5]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0522–0553) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Multimorbidity (≥ 2 chronic conditions) is common in inflammatory diseases such as psoriatic arthritis (PsA), psoriasis (PsO), and axial spondyloarthritis (AxSpA), increasing patient burden and healthcare costs. Understanding specific comorbidity clusters beyond simple counts is crucial for insights into disease heterogeneity and impact. The objective of this study was to identify and compare multimorbidity clusters in PsA, PsO, and AxSpA from a large population database, assess their stability, compare them with matched controls, and examine associations with healthcare utilization (HCU).

Methods: This population-based, retrospective cohort study from the UK THIN database included incident adult PsA (N=5,096), PsO (N=73,751), and AxSpA (N=2,413) patients (identified using validated Read Codes) with ≥1 year follow-up, alongside 1:5 matched controls. Morbidities chosen based on clinical relevance and prior reports were identified using Read codes. Optimal number of clusters was determined by evaluating the balance between within-cluster and between-cluster variance reduction for each level of the hierarchical clustering tree (tree method). K-median clustering identified

Psychiatric (18054)	6 (4–8)	1.86 (1.82–1.89)	2.11 (2.01–2.22)	2.28 (2.22–2.33)
MM5+ (33126)	NA	2.21 (2.18–2.24)	2.56 (2.45–2.66)	3.15 (3.09–3.21)
Axial Spondyloarthritis (2,413)				
Cardiovascular (371)	3 (2–4)	1.42 (1.25–1.61)	1.50 (1.13–1.98)	2.02 (1.74–2.36)
Osteoarthritis (208)	2 (2–3)	1.50 (1.29–1.76)	0.97 (0.67–1.40)	1.38 (1.14–1.66)
High Multimorbidity* (178)	6 (4–7)	2.44 (2.07–2.89)	2.70 (1.88–3.89)	3.15 (2.56–3.88)
MM5+ (215)	NA	2.16 (1.86–2.50)	2.14 (1.55–2.95)	2.49 (2.07–3.00)

multimorbidity clusters at 1 and 5 years post-diagnosis. Cluster stability and comparisons with control groups were assessed. Age- and sex-adjusted negative binomial regression were performed to examine the association of year 5 clusters to HCU (outpatient visits, hospitalizations, total prescriptions).

Results: Distinct and stable multimorbidity clusters were identified in each disease cohort at years 1 and 5 (Figure 1). PsA (N=5,096) clusters included Cardiometabolic, Low-Comorbidity, Chronic Pain, and Psychiatric. The Chronic Pain cluster was unique to PsA cases versus controls. PsO (N=73,751) clusters were Low Comorbidity, Allergy-Asthma, Back Pain, and Psychiatric. The Allergy-Asthma cluster was specific to PsO cases. AxSpA (N=2,413) clusters included Cardiovascular, Osteoarthritis, High Multimorbidity (characterized by severe cardiometabolic conditions, cancer, depression, COPD), and Low Comorbidity. Osteoarthritis cluster was unique to AxSpA cases. All identified multimorbidity clusters, as well as substantial multimorbidity (MM5+; ≥5 conditions), were associated with significantly higher HCU compared to respective Low-Comorbidity reference groups (Table 1).

Conclusion: Our study reveals that PsA, PsO, and AxSpA are characterized by distinct, stable multimorbidity clusters, featuring both shared background patterns (e.g., Low-Comorbidity, Psychiatric, Cardiometabolic components) and disease-specific architectures (e.g., PsA-Chronic Pain, PsO-Allergy-Asthma, AxSpA-Osteoarthritis). In terms of healthcare utilization, the findings indicate that the total number of concurrent chronic conditions is a more significant driver than the specific type of multimorbidity cluster. Consequently, while distinct clinical phenotypes are evident, addressing the overall burden of high morbidity (such as in patients with MM5+) is crucial for mitigating excessive healthcare utilization and guiding the development of effective management strategies in these populations.

Session Title: (0522–0553) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: The Assessment of SpondyloArthritis international Society (ASAS) group has recently introduced a consensus-based definition for difficult-to-manage (D2M) axial spondyloarthritis (axSpA) to identify patients with active disease despite being treated according to the current standard. This comprehensive definition incorporates not only the number of therapeutic failures but also uncontrolled disease features and the perspectives of both rheumatologists and patients on disease control. However, the real-world frequency of the problem remains unexplored, and little is known about the clinical profiles and factors associated with D2M axSpA. In this study, we aimed to determine the frequency of D2M axSpA and to identify factors associated with D2M disease in a longitudinal clinical cohort.

Methods: This retrospective analysis of a prospective cohort study included patients with a rheumatologist's diagnosis of axSpA presenting within one year of follow-up (from October 1, 2023 to September 30, 2024) at the Toronto Western Hospital Spondylitis Clinic who received at least 6 months of advanced therapy with a biological and/or targeted synthetic disease-modifying anti-rheumatic drug (b/tsDMARD). Variables were collected at the last follow-up visit. Since MRI was not routinely performed as part of the standard of care, data were unavailable and, therefore, excluded from the definition of "treatment-refractory" disease in this cohort. Sociodemographic and clinical profiles of patients meeting D2M criteria according to the ASAS definition were compared to non-D2M axSpA patients using bivariate analyses. Multivariate logistic regression was used to identify factors associated with D2M.

Results: Among 465 axSpA patients fulfilling the entry criteria, a total of 47 (10.1%) fulfilled all three ASAS D2M criteria. Within the D2M group, 14 (29.8%) had "treatment-refractory" disease, defined as non-response to treatment after excluding fibromyalgia and accounting for elevated CRP levels. Compared to non-D2M, D2M patients had significantly longer symptom duration, higher ASDAS, BASDAI, BASMI, and BASFI, as well as elevated CRP (in approximately 50% of the cases) (Table 1). At the same time, patients in the D2M group were less likely to be employed and had more comorbidities, higher body mass index, as well as a greater prevalence of mechanical back pain and fibromyalgia (Table 1). Logistic regression identified higher BASMI (OR 1.35, 95% CI 1.10 to 1.65, p = 0.004) and fibromyalgia (OR 3.03, 95% CI to 1.01 to 9.05, p = 0.048) as factors significantly associated with meeting D2M criteria (Figure 1).

Conclusion: The results of this study suggest that approximately 10% of patients with axSpA receiving advanced treatment have D2M disease. Half of these patients exhibit objective signs of inflammatory activity, potentially indicating the presence of treatment-refractory disease. In contrast, non-axSpA-related factors (including fibromyalgia, other comorbidities, mechanical issues in the back, and socioeconomic factors) may contribute to the D2M situation in other cases.

Session Title: (0522–0553) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: The Assessment of SpondyloArthritis International Society (ASAS) criteria define positive MRI findings based on the presence of bone marrow edema (BME) in the sacroiliac joints. However, BME may lead to false positives in situations such as post-exercise or postpartum and false negatives in chronic axial spondyloarthritis (axSpA) cases. Criteria for categorizing chronic changes as indicative of axSpA remain unclear. While artificial intelligence (AI) has shown promising performance in medical imaging diagnostics, previous studies on axSpA have mainly focused on detecting specific imaging features, particularly BME, rather than predicting clinical diagnoses. This study aims to propose a deep learning model that integrates inflammatory and structural changes in sacrum MRI to address the gap between BME detection and clinical diagnosis of axSpA.

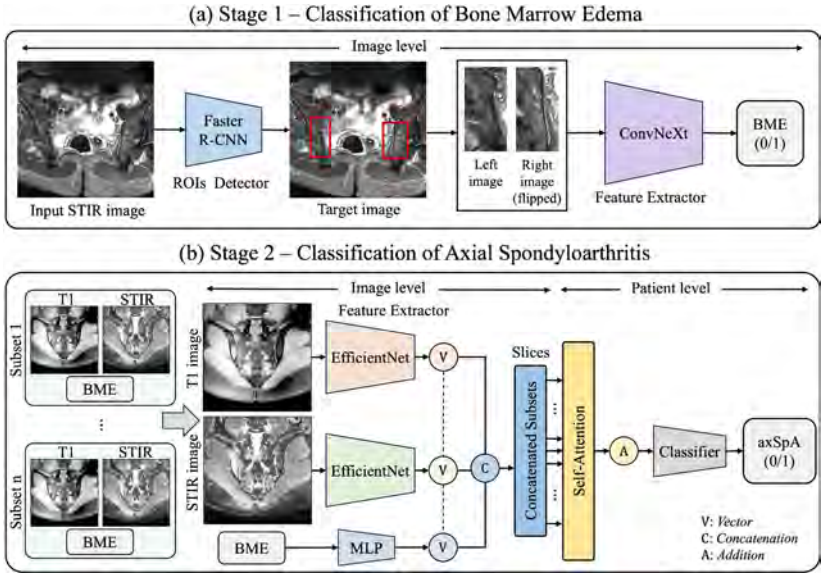

Figure 1. Overview of the proposed model.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Result of the BME classification and axSpA classification

	BME Classification	AxSpA Classification
Accuracy	0.8175 (233/285)	0.8596 (49/57)
Sensitivity	0.8162 (151/185)	0.8750 (28/32)
Specificity	0.8200 (82/100)	0.8400 (21/25)
AUROC	0.8181	0.9412

Methods: Data were collected from patients with chronic back pain who underwent sacrum MRI at Samsung Medical Center from January 2010 to December 2021. Clinical diagnosis of axSpA was defined based on ASAS criteria for axSpA. BME was identified using the ASAS definition. An end-to-end deep learning framework (Figure 1) was developed, utilizing short tau inversion recovery (STIR) and T1-weighted MRI sequences to reflect inflammatory and structural changes, respectively.

In Stage 1 (Figure 1a), Faster R-CNN detected regions of interest (ROIs) in the sacroiliac joints, and ConvNeXt identified BME within these ROIs. In Stage 2 (Figure 1b), features from STIR and T1-weighted MRI were extracted using an EfficientNet-based network to capture inflammatory and structural changes. Simultaneously, BME data were processed using a multilayer perceptron (MLP). These features were integrated to classify axSpA, combining slice-level information for final diagnosis. Model performance was evaluated using accuracy, sensitivity, specificity, and the area under the receiver operating characteristic curve (AUROC) metrics.

Results: MRI data from 291 patients, with an average of 14 slices per patient (total: 4,086 slices), were analyzed. Among the participants, 163 were clinically diagnosed with axSpA, while 128 had nonspecific back pain. The BME detection model achieved a sensitivity of 81.62%, specificity of82.00%, AUROC of 0.82, and accuracy of 81.75% (Table 1a). The axSpA classification model demonstrated a sensitivity of 87.5%, specificity of 84.0%, AUROC of 0.94, and accuracy of 85.96% (Table 1b). Notably, the model identified 6 out of 9 axSpA patients who met clinical criteria but not ASAS-defined positive MRI criteria, indicating its ability to detect features beyond conventional criteria.

Conclusion: This study demonstrated that integrating STIR and T1-weighted MRI with BME data effectively reflects both inflammatory and structural changes, enabling the AI model to predict clinical diagnoses of axSpA. Additionally, the proposed model successfully identified axSpA patients who did not meet the ASAS criteria for positive MRI. These findings highlight the potential of AI not only to detect specific imaging features but also to predict clinical diagnoses, suggesting promising applications in real-world clinical practice.

Background/Purpose: Background: Obstructive sleep apnea (OSA) is increasingly recognized in patients with psoriatic arthritis (PsA), yet few studies have used polysomnography (PSG)—the gold-standard diagnostic method. This study bridges this gap by employing PSG to definitively characterize OSA prevalence and its relationship with PsA disease activity.

Objective: To determine OSA prevalence in PsA using PSG and evaluate associations with disease activity.

Methods: This two-stage cross-sectional study included adult PsA patients.

Stage 1: Participants were screened using the STOP-BANG questionnaire for OSA risk and the Epworth Sleepiness Scale (ESS) for daytime sleepiness. Disease activity was assessed using DAPSA and DAS28-CRP, and functional status by HAQ.

Stage 2: All patients at high risk and a random 50% sample of low/intermediate-risk patients underwent overnight PSG. OSA was defined by apnea–hypopnea index (AHI) ≥5 events/hour and categorized as mild (5–14), moderate (15–29), or severe (≥

Comparison of participants with OSA to those without.

PSG: Polysomnography, OSA: Obstructive Sleep Apnea, BMI: Body Mass Index, DAPSA: Disease Activity in Psoriatic Arthritis; (Remission ≤ 4, Low Disease Activity > 4 and ≤ 14, Moderate Disease Activity > 14 and ≤ 28, High Disease Activity > 28), DAS: Disease Activity Score; (Remission < 2.6, Low Disease Activity ≥ 2.6 and < 3.2, Moderate Disease Activity ≥ 3.2 and ≤ 5.1, High Disease Activity > 5.1), HAQ: Health Assessment Questionnaire; (Mild Disability 0–1, Moderate Disability > 1–2, Severe Disability > 2–3), STOP-BANG: (Snoring, Tiredness, Observed Apnea, Blood Pressure, BMI, Age, Neck circumference, Gender); (Low Risk of OSA: 0–2, Intermediate Risk of OSA: 3–4, High Risk of OSA: ≥ 5), ESS: Epworth Sleepiness Scale; (Low Risk of EDS: <10, High Risk of EDS ≥ 10), EDS: Excessive Daytime Sleepiness, TST: Total Sleep Time, REM: Rapid Eye Movement, SE: Sleep Efficiency, AHI: Apnea-Hypopnea Index, MinO2: Minimum Oxygen Saturation, T90: Time Spent Below 90% Oxygen Saturation, ODI: Oxygen Desaturation Index.
Statistical analyses performed were independent t-test for continuous variables and chi-square test for categorical variable. P-value < 0.05 indicates statistical significance.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Sixty-eight patients (69% female, mean age 46 years, mean BMI 29 kg/m^2) were enrolled. Sleep-related symptoms were reported by 77% (snoring 53%, morning fatigue 68%). Mean disease activity scores: DAPSA 20±14, DAS28-CRP 2.8 ±1.0, HAQ 0.6±0.8. Based on STOP-BANG, 19% were high-risk, 35% intermediate, and 46% low-risk. PSG was performed in 42 patients (all high-risk and selected low/intermediate-risk). OSA was confirmed in 50%: 14% mild, 19% moderate, 17% severe. The estimated prevalence of moderate-to-severe OSA in the full cohort was 36%. Higher STOP-BANG scores (OR 2.35, p = 0.016) and older age (OR 1.13 per year, p = 0.007) were significant predictors of OSA. No significant correlation was found between OSA and PsA disease activity or comorbidities.

Conclusion: OSA is highly prevalent among PsA patients, with 50% testing positive by PSG. Despite this burden, OSA showed no association with disease activity. Routine screening and early sleep specialist referral for at-risk PsA patients may improve recognition and management. Further longitudinal, multicenter studies are needed to explore the role of psoriasis severity and treatment effects on OSA risk.

Session Title: (0522–0553) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: To identify clinical and genetic factors associated with the initiation of anti-TNF (tumor necrosis factor) therapy in patients with radiographic axial spondyloarthritis (r-axSpA) who respond poorly to NSAIDs (non-steroidal anti-inflammatory drugs).

Methods: A total of 445 Korean r-axSpA patients were enrolled and analyzed through genome-wide association studies (Table 1). The observation period started at the initial visit and continued until the initiation of anti-TNF therapy or the last follow-up, spanning 15 years. Multiple linear regression was utilized to identify clinical and genetic predictors of initiating anti-TNF therapy. Pathway analysis was also conducted.

Results: During 3658.8 person-years of observation, 277 patients initiated anti-TNF therapy. Clinical factors significantly associated with the initiation of anti-TNF therapy included younger age at symptom onset (β = -0.008, p = 3.91×10^{-5}), presence of peripheral arthritis (β = 0.181, p = 1.39×10^{-7}), and higher all-time averaged CRP levels (β = 0.022, p = 0.009). Additionally, several functional SNPs were nominally associated with anti-TNF therapy initiation. These included a synonymous

Abstract Number: 0551

Enthesitis Beyond the Surface: Ultrasonographic Unmasking of Preclinical Psoriatic Arthritis in Cutaneous Psoriasis

Victor Cazac[1] and Eugeniu Russu[2], [1]Norwalk Hospital, Nuvance Health, Connecticut, [2]"Nicolae Testemitanu" State Medical and Pharmaceutical University; "Timofei Moşneaga" Republican Clinical Hospital, Chisinau, Moldova

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0522–0553) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Psoriatic arthritis (PsA) develops insidiously from psoriasis (PsO), with enthesitis representing a critical initial site of inflammation. Musculoskeletal ultrasonography (MSUS) enables the identification of subclinical entheseal abnormalities and offers potential for stratifying PsA evolution into preclinical phases, long before clinical arthritis is apparent. This study aimed to determine whether inflammatory ultrasonographic changes are present in the absence of clinically overt enthesitis among patients with early PsA and PsO.

Methods: A cross-sectional observational study enrolled 153 subjects. The PsA group included 87 patients (58.6% female, mean age 44.3±8.2 years), diagnosed per CASPAR criteria within 3 years of onset. The PsO-only group comprised 66 patients (62.1% female, mean age 42.1±10.3 years) without musculoskeletal symptoms. Mean age at psoriasis onset was 27.4 ±6.1 years in the PsA group and 25.9±7.3 years in the PsO group. Mean age of arthritis onset in PsA was 41.2±7.8 years. All participants underwent clinical and MSUS evaluation of peripheral entheses (Achilles tendon, plantar fascia, patellar ligament, quadriceps tendon, lateral epicondyle), with scoring of entheseal thickness, hypoechogenicity, erosions, enthesophytes, and Power Doppler (PD) signal. Early PsA patients were subclassified as: preclinical (n=12); subclinical (n=31) and prodromal (n=44).

Results: In the PsA group, 71/87 (81.6%) had active enthesitis on MSUS, including 58.3% with PD signal. Among them, Achilles enthesitis (64.6%) and plantar fascia (48.9%) were most affected. In the PsO group, 29/66 (43.9%) had subclinical enthesitis, and 11 (16.7%) demonstrated PD positivity (Table 1).

Enthesophytes were detected in 34.2% of PsA and 19.6% of PsO (p=0.031). Bone erosions were present in 17.6% of PsA vs. 3.0% in PsO (p< 0.001). A significantly higher mean entheseal thickness (4.6 ± 0.9 mm vs. 3.2 ± 0.6 mm, p< 0.001) and frequency of bilateral involvement were found in PsA.

Conclusion: MSUS enables precise phenotyping of early PsA, detecting entheseal inflammation in both symptomatic and asymptomatic PsO patients. The stratification of patients across preclinical, subclinical, and prodromal phases supports enthesitis as an early marker of transition to PsA. Routine ultrasound surveillance in PsO may facilitate timely diagnosis and therapeutic interception of PsA progression.

Table 1. Ultrasonographic Enthesitis Features Across PsA and PsO Patients

Group/Subgroup	N (patients)	MSUS enthesitis (%)	PD (+) (%)	Enthesophytes (%)	Bone erosions (%)	Mean entheseal thickness (mm)
PsA – total	**87**	**81.6**	**58.3**	**34.2**	**17.6**	**4.6±0.9**
Preclinical	12	58.3	8.3	25.0	8,3	3.5±0.9
Subclinical	31	70.9	22.6%	32,3	12,9	3.9±0.9
Prodromal	44	95.4	97.7	45,5	31,8	4.3±0.9
PsO - total	**66**	**43.9**	**16.7**	**19.6**	**3.0**	**3.2±0.6**

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0522–0553) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I

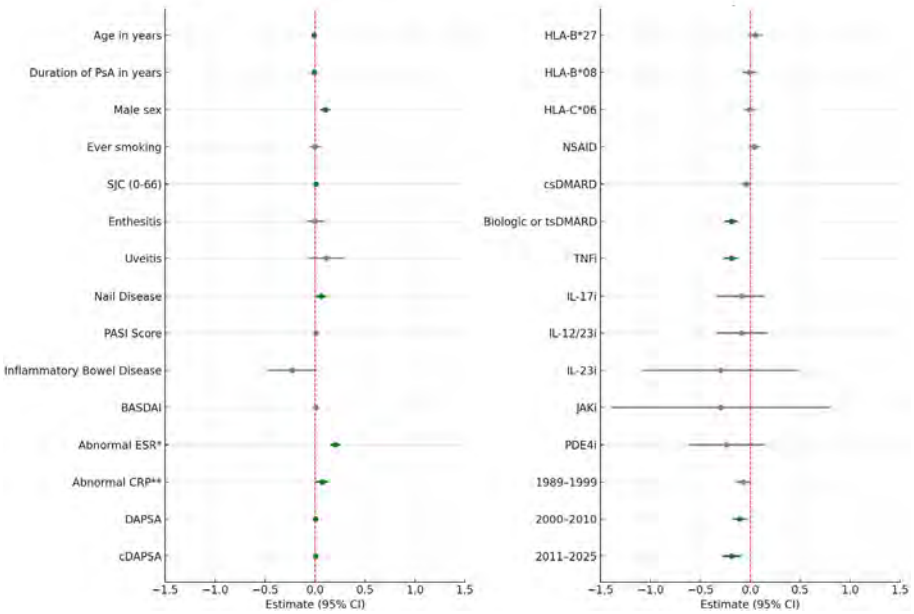
Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Radiographic sacroiliitis is an important indicator of axial involvement psoriatic arthritis (PsA), but only little is known about factors associated with progression of sacroiliitis. This study aimed to assess radiographic sacroiliitis progression in PsA and identify demographic, clinical, and genetic factors influencing its progression.

Methods: We included individuals from an observational Psoriatic Arthritis cohort (1978–2025). Pelvic radiographs were collected biannually. The Sacroiliitis Sum Score (SSS, 0–8) was calculated as the total sacroiliitis grades for the left and right sacroiliac joints, based on the modified New York (mNY) radiographic system. Radiographs were assessed by consensus.

Figure 1. Association of Demographic, Clinical and Genetic Factors with Radiographic Progression of Sacroiliitis Over Time: - Univariable Linear Mixed Model -



23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Association of Demographic, Clinical and Genetic Factors with Radiographic Progression of Sacroiliitis Over Time: - Multivariable Linear

Progression was defined as an increase in the SSS by at least 1 point. Linear mixed models were used to evaluate factors influencing sacroiliitis progression, with the change in SSS as the outcome variable.

Results: A total of 1,554 patients without an SSS of 8, with a median follow-up duration of 6 years (range: 0.00–13.30), were included. Among them, 475 (30.6%) showed progression of radiographic sacroiliitis (SSS change ≥1). At baseline, 22% of all patients had sacroiliitis according to the mNY criteria, and 20% were HLA-B*27 positive.

Variables positively associated with progression included male sex, swollen joint count (SJC), Psoriasis Area and Severity Index (PASI), nail psoriasis, abnormal ESR, abnormal CRP, Disease Activity Index for PsA (DAPSA), and clinical DAPSA (Figure 1). Longer PsA duration was negatively associated with progression. HLA alleles, including HLA-B*27, were not significantly associated with progression.

Patients who received biologic or targeted synthetic DMARDs had significantly lower odds of progression. TNF inhibitors demonstrated a protective effect against sacroiliitis progression compared to other treatments. An analysis of the calendar effect showed a decline in sacroiliitis progression over time, with a greater reduction observed in the 2011–2025 period.

In multivariable analysis, male sex remained significantly associated with greater sacroiliitis progression, while biologic and targeted synthetic therapies continued to show a protective effect. (Figure 2)

Conclusion: Radiographic sacroiliitis progression occurred in one-third of patients. In univariable and multivariable analyses, male sex was associated with greater progression, while biologic and targeted synthetic therapies were protective.

Abstract Number: 0553

Modified A-Tool: An online self-screening tool for axial spondyloarthritis for patients with chronic back pain

Zeyu Tang[1] and Abhijeet Danve[2], [1]Yale School of Medicine, New Haven, CT, [2]Section of Rheumatology, Department of Medicine, Yale School of Medicine, New Haven, CT

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0522–0553) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Lack of timely rheumatology referral of chronic back pain (CBP) patients with suspected axial spondyloarthritis (axSpA) is a major contributor to delayed diagnosis. We previously developed and validated an axSpA online self-screening tool (A-Tool) for patients with CBP to expedite self-referrals and evaluation [1].The original A-Tool consists of 3 pre-screening questions and 8 screening questions pertaining to high yield clinical features of axSpA without lab or imaging data. Here, we present a modified version of A-tool, that incorporates diagnostic testing and estimates post-test probability for patients.

Methods: We modified the A-tool based on the results of our prospective validation study [1]. "Unexplained joint swelling" and "Heel pain" questions were removed, while "Gradual onset" was added. We then ascribed weighted scores to each modified A-Tool item using the known positive likelihood ratios of axSpA features from literature: greater weight was put on prior diagnoses of psoriasis, inflammatory bowel disease, and uveitis (Table 1). A logarithmic model converted scores into post-test probabilities (Figure 1A). Pre-test and maximum post-test probabilities in the model were set to 5% and 45%,

Table 1. Modified A-Tool, composed of a Symptom Questionnaire (required) and Diagnostic Questionnaire (optional).

Symptom Questionnaire (Yes/No)	Score
Did your back/hip pain start gradually?	1
Does your back/hip pain improve with activities, exercise or movement	1
Does the back/hip pain wake you up at night?	1
Does your back/hip pain resolve or get much better 24 to 48 hours after taking NSAIDs (like Advil, ibuprofen, Aleve, diclofenac or meloxicam)?	1
Has a dermatologist or other physician ever diagnosed you with psoriasis of the skin or nails?	1
Has a gastroenterologist (GI doctor) ever diagnosed you with Crohn's disease or Ulcerative colitis or inflammatory bowel disease (IBD)?	1
Has an eye doctor ever diagnosed you with acute uveitis or iritis? (This is inflammatory condition of eye that causes redness, tearing, sensitivity to light and usually treated with steroid eye drops)	2
Do any of your first- or second-degree relatives have any of the following: psoriasis, IBD (Crohn's disease or ulcerative colitis), acute uveitis or ankylosing spondylitis? A first degree relevant is a parent, child, brother or sister. A second degree relative is grandparents, grandchildren, aunts, uncles, nephews, nieces or half-siblings.	1
Optional Diagnostic Questionnaire (Yes/No)	
Elevated CRP > 3.0mg/L	1
Positive HLA-B27	2
Sacroiliitis by any imaging	3

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. A.

$$P_{post\text{-}test} = \frac{e^{score} \times P_{pre\text{-}test}}{P_{max} + (e^{score} - 1) \times P_{pre\text{-}test}} \times P_{max}$$

Variable	Description	Symptom-only	Diagnostics
Score	Total score	Self-Screening	Optional Diagnostic
$P_{pre-test}$	Pre-test probability	0.05	$P_{post-test}$ of Symptom-only (range 0.05 – 0.45)
P_{max}	Post-test probability	0.45	1.00

B.

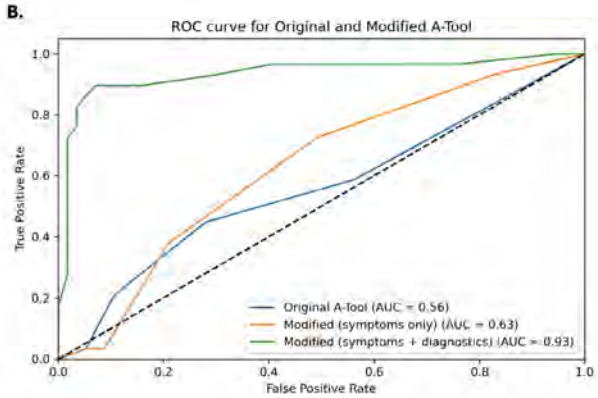

Figure 1. A) Mathematical model for post-test probability of self-screening tool. B) ROC curves for original and modified A-Tool.

respectively, based on prior literature [2]. We added an optional section for diagnostic test results: CRP, HLA B-27 and imaging sacroiliitis. When diagnostic data are included, the maximum post-test probability can increase to 100%. For analysis, we used the original A-Tool cohort to evaluate Receiver Operator Characteristic (ROC) curves, sensitivity, and specificity.

Results: There were 86 patients in the original A-Tool cohort; 29 had axSpA. All patients had CRP, HLA-B27 testing; 78 had axial MRI. ROC curves were generated for the original A-Tool, symptom-only modified A-Tool, and full modified A-Tool: area under the curve (AUC) were 0.56, 0.63, and 0.93, respectively (Figure 1B). At a post-test probability threshold of 80%, the modified A-Tool yielded a sensitivity of 86%, specificity of 95%, and positive predictive value of 89%.

Conclusion: We modified a previously validated online symptom-based axSpA self-referral tool, A-Tool, to include diagnostic testing and calculate post-test probabilities. The modified version had high sensitivity and specificity in an existing cohort. We aim to distribute the modified A-Tool as an publicly available online calculator for patients and primary care providers to facilitate rheumatology referrals (Figure 2). Future validation studies are needed to evaluate the modified A-Tool's test characteristics on a larger cohort.

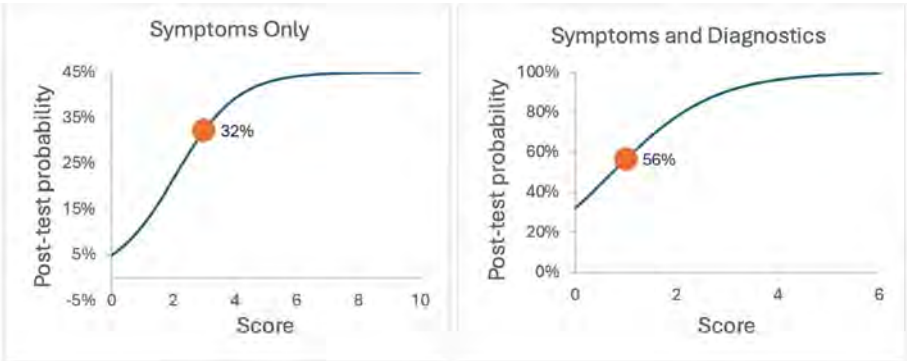

Figure 2. Example graphs generated for a hypothetical patient with symptom score of 3 and diagnostic score of 1.

Real world experience with generic Tofacitinib in Axial Spondyloarthritis from North India

Sanjeev Kapoor[1], Babita Bondage[1], Niti Kedia[1], Mariya Patel[1] and **Akanksha Kapoor**[2], [1]Indian Spinal Injuries Centre (ISIC), New Delhi, India, [2]Bharati Vidyapeeth (Deemed to be University) Medical College and Hospital, Pune, India

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Axial spondyloarthritis (AxSpA) is an inflammatory condition that falls under the category of spondyloarthritis (SpA) and significantly affects quality of life, causing symptoms like fatigue, sleep disturbances, depression, and sexual dysfunction, which can greatly diminish health-related quality of life and restrict work, leisure activities, and daily living.

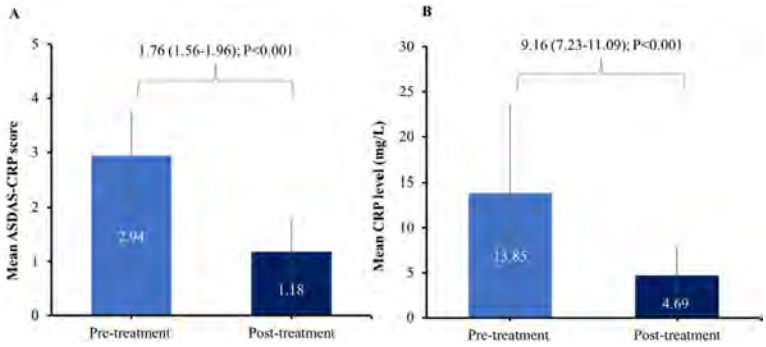

Figure 1: A) Mean ASDAS-CRP scores and B) Mean CRP level at pre-treatment and post-treatment with tofacitinib at 24 weeks (N=100)

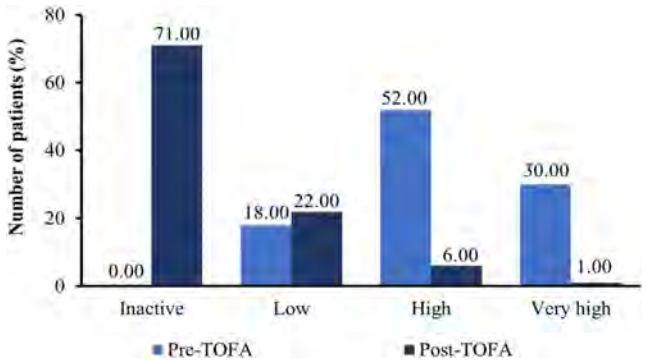

Figure 2: Disease activity at baseline and 24 weeks (post-treatment with tofacitinib) in AxSpA patients (ASDASC-CRP, axial spondyloarthritis disease activity score C-reactive protein; CRP, C-reactive protein

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1: Baseline characteristics

Characteristics	No. of patients (N=100)
Gender	
Male	77 (77.00)
Female	23 (23.00)
History of Smoking	23 (23.00)
HLA B27	84 (84.00)
Presence of	
Peripheral arthritis	58 (58.00)
Uveitis	25 (25.00)
Psoriasis	1 (1.00)
Data represented as n (%). HLA, human leukocyte antigens.	

This underscores the urgent need for effective treatment strategies. Tofacitinib, a Janus kinase inhibitor, is used for various inflammatory conditions, but there is limited real-world evidence on its efficacy and safety for AxSpA in Indian patients. This retrospective study aimed to evaluate the effectiveness and safety of tofacitinib in Indian patients diagnosed with AxSpA in a real-world setting.

Methods: A single-centre, retrospective, observational study was conducted on patients with active AxSpA in India, spanning from November 2023 to April 2024. The clinical and laboratory records of AxSpA patients who were treated with generic tofacitinib at a dosage of 5 mg twice daily for 24 weeks were reviewed and analysed. The efficacy of tofacitinib was assessed based on the improvement in disease activity, specifically the change in the Ankylosing Spondylitis Disease Activity Score C-Reactive Protein (ASDAS-CRP) after 24 weeks. Adverse events (AEs) were monitored throughout the treatment period.

Results: A total of 100 patients with active AxSpA participated in the study, with a mean age of 35.95 years and an average disease duration of 8.20 years. Of these, 77 were males and 23 were females. All patients received tofacitinib 5 mg twice daily for 24 weeks. The majority of the patients were biologic-naive, with only 12 having prior biologic therapy. Additionally, 23 patients received tofacitinib monotherapy without nonsteroidal anti-inflammatory drugs (NSAIDs), while 77 patients received tofacitinib along with on-demand NSAIDs but without any concomitant conventional disease-modifying antirheumatic drug therapy. It showed a significant decrease in the ASDAS-CRP score from 2.94 to 1.18 by week 24, with a mean difference of 1.76 (95% confidence interval [CI]: 1.56-1.96, P< 0.001). The CRP levels also dropped significantly, from 13.85 mg/L to 4.69 mg/L at week 24, with a mean difference of 9.16 (95% CI: 7.23-11.09, P< 0.001). Notably, nearly 71% of patients achieved inactive disease status (ASDAS-CRP < 1.3) after 24 weeks of treatment, and tofacitinib was well tolerated in this cohort, with a low incidence of AEs like non-serious herpes zoster (6.00%), respiratory system-related infections (3.00%), and pulmonary thrombo-embolism (1.00%).

Conclusion: This retrospective real-world study supports the efficacy and safety of generic tofacitinib as an NSAID-sparing agent for Indian patients with active AxSpA. Its cost-effectiveness compared to expensive biologics and the convenience of oral administration make it an appealing option, especially in areas with limited access to biologics. Tofacitinib could improve patient outcomes and provide an affordable therapy option for managing AxSpA.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Icotrokinra (ICO), a first-in-class, targeted oral peptide that binds and inhibits the interleukin (IL)-23R, was evaluated in ICONIC-TOTAL (NCT06095102).

Methods: This Phase 3 trial included plaque psoriasis (PsO) severity of body surface area (BSA) ≥1%/Investigator's Global Assessment (IGA) ≥2 and employed a novel basket-like design to evaluate 3 cohorts of adults & adolescents (≥12 to < 18 years) with at least moderate, difficult-to-treat, high-impact skin sites: scalp (scalp-specific [ss]-IGA ≥3), genital (static Physician Global Assessment of Genitalia [sPGA-G] ≥3), and/or hand/foot (hf-PGA ≥3). Primary (IGA 0/1: clear [0]/almost clear [1] & ≥2-grade improvement) and key secondary (ss-IGA 0/1, sPGA-G 0/1, hf-PGA 0/1) endpoints were assessed at Week 16.

Results: 311 randomized patients (ICO=208/placebo=103) with scalp (n=252), genital (n=140), and/or hand/foot (n=71) PsO received once-daily ICO 200 mg or placebo through Week 16. ICO vs placebo met primary (IGA 0/1: 57% vs 6%; P< 0.001) and scalp and genital key secondary endpoints (ss-IGA 0/1: 66% vs 11%; sPGA-G 0/1: 77% vs 21%; both P< 0.001), and showed higher hf-PGA 0/1 (42% vs 26%; P=0.144). Patient-reported scalp and genital PsO improvements were statistically significantly superior to placebo. Proportions of ICO and placebo patients with ≥1 adverse event (AE) were 50% & 42% (the most commonly reported AE was nasopharyngitis) and GI AE were 7.2% & 7.8%, respectively.

Conclusion: ICO demonstrated significantly higher rates of overall skin, scalp, and genital PsO clearance vs placebo with a favorable safety profile. Basket-like trial designs can be used to efficiently study special skin sites in patients with PsO and other diseases.

Abstract Number: 0556

Evaluating the Efficacy of Sulfasalazine Compared to Placebo in the Treatment of Psoriatic Arthritis in Adults: A Systematic Review and Meta-Analysis

Rameez Qasim[1], **Khadija Mohib**[2], Umme Abeeha Naqvi[3], Ahmad Furqan Anjum[4] and Moeeza Fatima[4], [1]Allama Iqbal Medical College Lahore, Lahore, Pakistan, [2]Kirk Kerkorian School of Medicine at UNLV, Las Vegas, NV, [3]Jinnah Sindh Medical University Karachi, Karachi, Pakistan, [4]Shaikh Khalifa Bin Zayed Al-Nahyan Medical College, Shaikh Zayed Postgraduate Medical Institute (SZPGMI), Lahore, Lahore, Pakistan

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

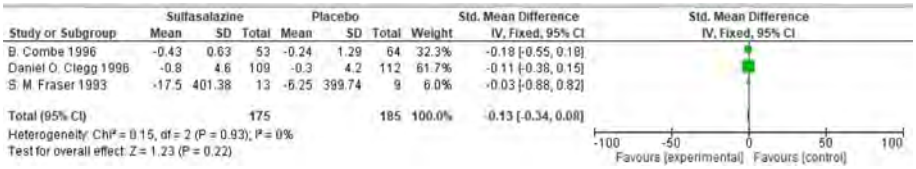
Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

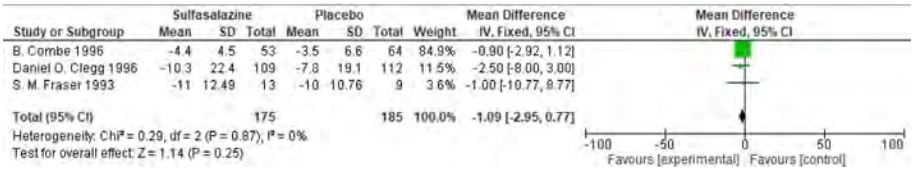
Background/Purpose: Available evidence hints towards the positive results of the use of sulfasalazine in the management of patients with psoriatic arthritis (PsA). We did a systematic review and meta-analysis to determine the possible safety and effectiveness of sulfasalazine for the treatment of PsA.

Methods: We conducted a thorough literature search using PubMed and Cochrane Library to retrieve and review all the articles through July 2024. Each of the studies in our review was to report different measures to determine the safety and efficacy of sulfasalazine by using 95% CIs. PRISMA flow guidelines were followed and used to assess the methodological quality of evidence and reporting Quality. The GRADE system was used to appraise the certainty of evidence.

Results: Our literature search produced 17 results and a final of 3 studies were included in our analysis. All the studies were prospective RCTs with a total population of 380 patients with male dominant population. There was a significant and persistent treatment effect on ESR, as evidenced by the overall standardized mean difference (SMD) of -0.47 (95% CI: [-0.68, -0.26], Z = 4.41, P < 0.0001) and low heterogeneity (Chi^2 = 1.88, P = 0.39, I^2 = 0%). The overall pooled mean difference was found to be -1.09 (95% CI: -2.95 to 0.77) and a p-value of 0.25 in case of Ritchie Index, showing no statistically significant benefit of Sulfasalazine over placebo. Based on the three studies included, overall effect size was found to be -0.13 (95% CI: -0.34 to 0.08), showing no notable variation among the groups. Heterogeneity was low (I^2 = 0%, p = 0.93), and thus result was not statistically important (Z = 1.23, p = 0.22). Two of the studied showed a low risk of bias where as one showed a high risk.



Forest Plot of effect on Morning Stiffness



Forest Plot of effect on Ritchie Articular Index

Forest Plot of effect on ESR

Conclusion: Sulfasalazine has some benefits in reducing systemic inflammation in people with psoriatic arthritis (PsA), as shown by an improved erythrocyte sedimentation rate (ESR). However, its efficacy as a stand-alone treatment is limited due to its negligible effect on important clinical symptoms such as joint pain, stiffness, and soreness. For mild to moderate PsA, sulfasalazine may be helpful as adjuvant therapy, but in more severe instances, it is not enough for complete management. To elucidate its function in PsA management, more studies involving bigger and more varied populations are required.

Efficacy of Upadacitinib in Male and Female Patients with PsA: Results from the SELECT-PsA 1 and 2 Trials

Lihi Eder[1], Axel Hueber[2], **Lucia Novelli**[3], Tianming Gao[3], Jayne Stigler[4], Zhiyuan Du[3], Rodrigo García Salinas[5], Grace Wright[6] and Sofia Ramiro[7], [1]University of Toronto, Toronto, ON, Canada, [2]Klinikum Nuernberg, Nuernberg, Germany, [3]AbbVie, North Chicago, IL, [4]AbbVie, Round Lake, IL, [5]Hospital Italiano La Plata, La Plata, Argentina, [6]Grace C Wright MD PC, New York, NY, [7]Leiden University Medical Center, Bunde, Netherlands

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Biologic sex can impact both clinical phenotype and therapeutic response in PsA.[1–3] Previous studies have suggested that male patients (pts) may achieve better treatment outcomes with biologic agents including TNFi and IL-17 inhibitor therapies compared with female pts.[1–3] This post hoc analysis evaluated potential differences in the efficacy of upadacitinib (UPA), an oral Janus kinase inhibitor, between male and female pts with PsA.

Methods: Data were drawn from 2 phase 3 studies, SELECT-PsA 1 (NCT03104400) and SELECT-PsA 2 (NCT03104374).[4,5] In SELECT-PsA 1, pts were randomized to UPA 15 or 30 mg once daily (QD), adalimumab 40 mg every other week, or placebo (PBO); in SELECT-PsA 2, pts were randomized to UPA 15 or 30 mg or PBO QD. In both studies, pts receiving PBO switched to UPA 15 or 30 mg QD at Week (W) 24. UPA 15 mg QD data were analyzed for the current analysis. Efficacy endpoints were assessed at W12 and W24, stratified by sex. Statistical analyses included the Cochran–Mantel–Haenszel test for binary endpoints and mixed-effect model for repeated measurement for continuous endpoints. Response rates for binary endpoints were calculated using non-responder imputation. UPA vs PBO in both studies, and UPA vs adalimumab in SELECT-PsA 1, was assessed within each sex by relative risk (RR) or mean difference, and treatment comparison between sexes was assessed by the RR ratio (RRR) or difference between differences, with 95% confidence intervals (CIs) (comparability is indicated where intervals cover 0 [RR] or 1 [RRR]).

Results: 1,386 pts were included, of whom 640 (289/351 male/female), 317 (162/155), and 429 (207/222) received UPA, PBO, and adalimumab, respectively. At baseline, male and female pts generally have comparable disease characteristics,

ADA, adalimumab; EOW, every other week; PBO, placebo; QD, once daily; SD, standard deviation; UPA, upadacitinib.

with some numeric differences between sexes across most scores (Table 1). Higher efficacy was observed with UPA vs PBO in both sexes for the majority of endpoints (Figure & Table 2). At W12 and W24, efficacy of UPA was consistent between male and female pts for all efficacy endpoints analyzed (Figure & Table 2). The proportion of male and female pts achieving ACR20, the primary efficacy outcome, was similar in both studies and at both W12 (SELECT-PsA 1: RRR [95% CI] 1.33 [0.89–1.98]; SELECT-PsA 2: 1.69 [0.70–4.07]) and W24 (1.39 [0.99–1.95] and 1.38 [0.53–3.62], respectively). Comparable percentages of male and female pts achieved ACR50, ACR70, minimal disease activity, and Leeds Enthesitis Index=0 with similar improvements in PASI75, Visual Analog Scale pain, and HAQ-DI at both W12 and W24; numerically greater improvements for male vs female pts were observed across most endpoints (UPA vs PBO; Figure & Table 2).

Conclusion: UPA was associated with higher efficacy vs PBO in both sexes among pts with PsA. UPA was associated with consistent efficacy between male and female pts across SELECT-PsA 1 and 2 at W12 and W24 for the majority of endpoints evaluated in this post hoc analysis.

Table 2. Efficacy outcomes at W24 stratified by sex in SELECT-PsA 1 and 2 trials

Response rates for binary endpoints were calculated using non-responder imputation.
For continuous endpoints, an as-observed mixed-effect model for repeated measures was applied.
For binary endpoints, an RR above 1 indicated better outcomes with UPA vs PBO and UPA vs ADA. For all continuous endpoints, a between-group difference lower than 0 indicated better outcomes with UPA vs PBO and UPA vs ADA.
For binary endpoints, an RRR above 1 indicated better outcomes with males vs females; while an RRR below 1 indicated worse outcomes with males vs females. For all continuous endpoints, a between-treatment group difference above 0 indicated worse outcomes with males vs females; while a between-treatment group difference below 0 indicated better outcomes with males vs females.
ACR 20, ≥20% improvement in American College of Rheumatology response criteria; ADA, adalimumab; CI, confidence interval; EOW, every other week; LEI=0, Leeds Enthesitis Index=0; MDA, minimal disease activity; N/A, not applicable; PASI 75, 75% improvement in Psoriasis Area Severity Index score; PBO, placebo; QD, once daily; RR, relative risk; RRR, relative risk ratio; UPA, upadacitinib; VAS pain, Visual Analog Scale pain; W, Week.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Icotrokinra (ICO), a first-in-class targeted oral peptide that blocks the interleukin (IL)-23R and inhibits IL-23 pathway signaling, is being evaluated in the phase 3 ICONIC-LEAD study in participants ≥12 years with moderate-to-severe plaque psoriasis (PsO). Study co-primary endpoints were met, with ICO demonstrating significantly higher Investigator's Global Assessment (IGA) 0/1 (64.7% vs 8.3%) and Psoriasis Area and Severity Index (PASI) 90 (49.6% vs 4.4%) response rates vs placebo at Week (W) 16 (both $p< 0.001$). ICO pharmacodynamics were assessed via serum protein and skin transcriptomic analyses.

Methods: Participants (N=684) were randomized 2:1 to once-daily ICO 200 mg or placebo through W16. After W16, placebo participants transitioned to ICO (placebo®ICO). Serum collected at W0, W4, and W16 from a sub-cohort (n=166 for IL-22; n=167 for other analytes) and a distinct healthy control cohort (n=30; BioIVT, Hicksville, NY) was analyzed to determine soluble IL-17A, IL-17F, IL-19, IL-22, and BD-2 concentrations. Skin biopsies collected at W0 and W24 from consenting participants of an optional sub-study (n=65) were analyzed for mRNA expression. Comparisons between ICO and placebo used linear mixed-effect modeling that included effects for W0 levels, treatment-over-time interaction, and participant random effect.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Serum IL-17A, IL-17F, IL-19, IL-22, and BD-2 levels were significantly higher in participants with PsO at baseline (W0) vs healthy control ($p< 0.05$). ICO significantly reduced serum biomarker levels vs placebo (all $p< 0.05$ at W4 and W16) and relative to W0 levels as early as W4 ($p< 0.0001$ for all analytes). Serum biomarker concentrations continued to decrease in participants receiving ICO, with levels at W16 (all $p< 0.0001$ vs W0) approaching those of healthy control. At W0, 1026 genes were significantly upregulated and 970 significantly downregulated (adjusted $p< 0.05$) in lesional vs non-lesional skin. At W24, ICO significantly reduced PsO-related gene set enrichment (MAD-3, MAD-5) and gene expression, including *IL17A, IL17F, IL22, IL19, IL23A*, and *DEFB4A* (all $p< 0.0001$ vs W0 lesional) to levels approaching those seen in W0 non-lesional skin. Similar significant reductions were observed after 8 weeks of ICO treatment in the placebo®ICO cohort (all $p< 0.0001$ vs W0 lesional).

Conclusion: Consistent with its mechanism of action of selectively and potently blocking the IL-23R, ICO significantly attenuated systemic and skin biomarkers related to IL-23 pathway activation and PsO disease severity. Findings demonstrated both early and substantial ICO effects, with levels of IL-23 pathway biomarkers of systemic and skin inflammation normalizing to a healthy state. Overall, these comprehensive biomarker findings are consistent with significant skin clearance achieved with this first targeted oral peptide to selectively inhibit IL-23 pathway activation.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Psoriasis, psoriatic arthritis (PsA), and axial spondyloarthritis (axSpA) are associated with increased risk of cardiovascular (CV) disease driven by chronic systemic inflammation, with IL-17A thought to play a central pathogenic role. This inflammation contributes to endothelial dysfunction, an early and pivotal step in the development of atherosclerosis, as well as increased arterial stiffness, an important factor in its progression. Secukinumab, a selective IL-17A inhibitor approved across the three indications, may have potential implications for CV health. This review aimed to evaluate the evidence available in the scientific literature on the impact of secukinumab on CV disease in patients with psoriasis, PsA and axSpA, including its effects on vascular function, inflammatory markers, and long-term safety.

Methods: A systematic review of PubMed was performed from database inception to May 2025 according to a pre-defined search strategy (**Table 1**). Results were screened and evaluated for inclusion according to the following criteria: publications describing prospective or retrospective studies or meta-analyses; studies including at least 10 patients treated with secukinumab; studies reporting on at least one of the outcomes of interest (endothelial function, arterial stiffness, systemic inflammation, vascular imaging outcomes, and incidence of major adverse CV events [MACE] including CV death, acute myocardial infarction, stroke, unstable angina, and heart failure). Systematic reviews without meta-analysis, case studies, letters to the editor and commentaries were excluded, as were non-English language publications.

Results: From 198 articles initially returned by the search, 46 were eligible for inclusion (**Figure 1**). These comprised 9 meta-analyses or other pooled analyses, 13 randomised controlled trials, 11 retrospective studies or analyses, 9 prospective studies and 4 observational studies. Twenty publications included patients with psoriasis, 5 included patients with PsA, 11 included patients with axSpA, and 10 included multiple indications. Based on data from over twenty thousand patient-years of exposure, secukinumab did not associate with increased MACE in patients with psoriasis, PsA, or axSpA. Additionally, multiple studies reported improvements in systemic inflammatory markers including C-reactive protein, neutrophil to lymphocyte ratio and markers of oxidative stress, with others reporting favorable impact on vascular health including improvement in endothelial function, reduction in arterial stiffness, and improvement in coronary flow reserve.

Conclusion: Secukinumab was associated with a reduction in systemic inflammation and oxidative stress in multiple studies which also reported a consistent CV safety profile across psoriasis, PsA, and axSpA in terms of incidence of MACE.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Emerging evidence from vascular imaging suggests that secukinumab may benefit risk factors of CV disease and markers of vascular health; however, larger, prospective randomized trials are needed to confirm this. Finally, these data suggest that secukinumab may provide benefit beyond the primary disease treatment through important reductions in systemic inflammation.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Ankylosing Spondylitis (AS) is a type of chronic inflammatory arthritis affecting the spine and peripheral joints. Although tumor necrosis factor inhibitors (TNFi) substantially improve symptoms, 40% fail to respond. Predictors of treatment response could help make well-informed choices about TNFi treatment at baseline, elucidate mechanism of resistance and explore potential alternative therapeutic targets for TNFi non-responders.

This study aims to identify biomarkers correlating with TNFi treatment response using single cell sequencing in AS patients at baseline.

Methods: PBMCs derived from 7 biologic naïve AS patients (4 responders and 3 non-responders to TNFi treatment) were profiled using droplet-based single cell RNA sequencing technology (10X Genomics). Statistical analysis was carried out using Seurat R package (v5.2.0). The results were then validated using Nanostring nCounter gene expression assay, a highly reproducible and sensitive technique. The cytokines levels were validated using ELISA in the serum of AS patients and the protein expression of CXCR4 and CD74 were determined using flow cytometry on CD14+CD16- monocytes.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: As compared to responders, non-responders had a higher proportions of B cells, dendritic cells and monocytes but a lower proportion of T cells. In total PBMCs, 5020 differentially expressed genes were identified among responders and non-responders. CXCR4 and CD74 were found to be upregulated in the monocytes of non-responders which has been further validated in the validation cohort using Nanostring nCounter gene expression assay. Pathway enrichment analysis (i.e., gene set enrichment analysis) of the most significantly changed genes in each response outcome revealed that regulation of osteoclast function, innate immune response, and regulation of T cell activation pathways are among the most enriched pathways in responders. Interferon regulated genes (IRGs) expression and MHC class II regulation was upregulated in non-responders at baseline compared to responders. Upregulated expression of MIF receptor, CD74, in non-responders suggests that monocytes in these patients are activated before the start of treatment and they are involved in the formation of inflammasome, resulting in enhanced inflammatory response. This has been further confirmed by assessing the levels of inflammatory cytokines and chemokines in the serum of patients before and after TNFi treatment using ELISA. We observed that after TNFi treatment, there is a decrease in the levels of CXCL10, CCL4, IL-1b, TNFa and MIF in responders, but not in non-responders.

Conclusion: In non-responders, elevated expression of inflammatory cytokines like IL-17A and IL1b, MIF and its receptors (CXCR4 and CD74)and chemokines like CXCL8, CXCL10 even prior to the commencement of the treatment may be the crucial in preconditioning the immune system towards TNFi treatment resistance in AS patients.

Patient Characteristics and Treatment Patterns of Traditional and Advanced Therapies Prior to First Secukinumab Intravenous (IV) Administration in Patients with Spondyloarthritis (SpA) in US Real-World Clinical Settings

Alan Kivitz[1], Linda Grinnell-Merrick[2], Tim Nguyen[2], Ariane Faucher[3], Riley Taiji[3], Francis Vekeman[3] and Atul Singhal[4], [1]Altoona Center for Clinical Research, Duncansville, PA, [2]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [3]STATLOG, Inc, Montreal, QC, Canada, [4]SouthWest Arthritis Research Group, Mesquite, TX

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Since most approved biologics are administered subcutaneously, there is a need for alternate routes of delivery to treat patients with SpA. Secukinumab is an IL-17A inhibitor that was additionally approved for IV administration for SpA. This study described the demographic, clinical and treatment characteristics of patients with SpA who initiated IV secukinumab in real-world clinical settings.

Methods: This retrospective cohort study using HealthVerity claims database included patients who initiated IV secukinumab between Oct 6, 2023 and Oct 31, 2024 (index date = first record), with ≥1 SpA diagnosis code, including psoriatic

axSpA, axial spondyloarthritis; IQR, interquartile range; IV, intravenous; PsA, psoriatic arthritis; SpA, spondyloarthritis. a Measured at index date or <12 months prior to index. b Measured at index date, <12 months prior to index, or up to 14 days after index date. c Measured <12 months or ≥12 months prior to index.

arthritis (PsA) and axial SpA (axSpA) in 12 months prior to or up to 14 days after index date. Patients had ≥12 months of continuous enrollment (CE) prior to the index date (baseline period) and ≥3 months post-index CE. Patient demographic, clinical, and treatment characteristics were described at the index date, within 12 months prior to index date, or beyond 12 months (baseline period), as indicated. Traditional therapies included corticosteroids, NSAIDS, or conventional synthetic (cs)

Table 2. Traditional and Advanced Therapy Characteristics

Therapy patterns[a]	IV Secukinumab (N=255)
Traditional therapies	
Traditional therapy in 12 months prior to index, n (%)	
Any traditional therapy	188 (73.7)
NSAIDs	94 (36.9)
NSAIDs and no other traditional therapy	8 (3.1)
Corticosteroids	166 (65.1)
Corticosteroids and no other traditional therapy	62 (24.3)
csDMARDs	77 (30.2)
csDMARDs and no other traditional therapy	9 (3.5)
Time from first date of supply to index, median (IQR), months	64.3 (31.0-89.9)
Time from last date of supply to index, median (IQR), months	1.9 (0.5-8.7)
Advanced therapies	
Advanced therapy in 12 months prior to index, n (%)	
Any advanced therapy	95 (37.3)
bDMARDs	85 (33.3)
bDMARDs and no other advanced therapy	72 (28.2)
≥2 bDMARDs	14 (5.49)
tsDMARDs	23 (9.0)
tsDMARDs and no other advanced therapy	10 (3.9)
≥2 tsDMARDs	1 (0.4)
bDMARDs and tsDMARDs	13 (5.1)
Time from first date of supply to index, median (IQR), months	34.2 (17.2-62.3)
Time from last date of supply to index, median (IQR), months	5.4 (2.2-14.1)

bDMARDs, biologic disease-modifying antirheumatic drugs; csDMARDs, conventional synthetic disease-modifying antirheumatic drugs; IQR, interquartile range; IV, intravenous; NSAIDs, non-steroidal anti-inflammatory drugs; tsDMARDs, targeted synthetic disease-modifying antirheumatic drugs. a Measured <12 months or ≥12 months prior to index.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

DMARDs. Advanced therapies included biologic (b)DMARDs, targeted synthetic (ts)DMARDs, or both during the baseline period. Time from the start and end of therapy prior to the index date is reported.

Results: Overall, 255 patients with SpA who initiated IV secukinumab met the eligibility criteria and were included. Most patients were diagnosed with PsA (65.5%), 25.5% of patients were diagnosed with axSpA, and 9.0% of patients had both PsA and axSpA. The mean (SD) age at index date was 55.5 (13.1.) years, and 73.3% were female (**Table 1**). During the 12 months prior to index, the mean (SD) Deyo-Charlson Comorbidity Index score (DCCI) was 2.8 (2.6), and 43.9% of patients had a score of >3.0. Common comorbidities included osteoarthritis/osteopenia (64.7%), neurological disorder (56.1%), plaque psoriasis (52.2%), and obesity (48.6%). The median (interquartile range [IQR]) time from first observed SpA diagnosis to index was 34.6 (14.7-66.7) months. During the 12 months prior to index, 73.7% of all patients used traditional therapies, which included corticosteroids (65.1%), NSAIDs (36.9%) and csDMARDs (30.2%, **Table 2**). The median (IQR) time from first supply of traditional therapy to index was 64.3 (31.0-89.9) months and from last supply was 1.9 (0.5-8.7) months. During the 12 months prior to index, advanced therapies were used by 37.3% of all patients, which included bDMARDs (33.3%), tsDMARDS (9.0%), or a combination of both (5.1%). The median (IQR) time from first supply of advanced therapy to initiation of IV secukinumab was 34.2 (17.2-62.3) months and from last supply was 5.4 (2.2-14.1) months.

Conclusion: In this population of patients with SpA who initiated IV secukinumab, patients were generally older with long-standing disease and high prevalence of comorbidities (e.g., osteoarthritis/osteopenia, neurological disorder, plaque psoriasis, or obesity), which underscores the complexity of SpA disease burden in a diverse group of patients with varied characteristics and health conditions. IV secukinumab was initiated soon after previous treatments, possibly in response to disease progression.

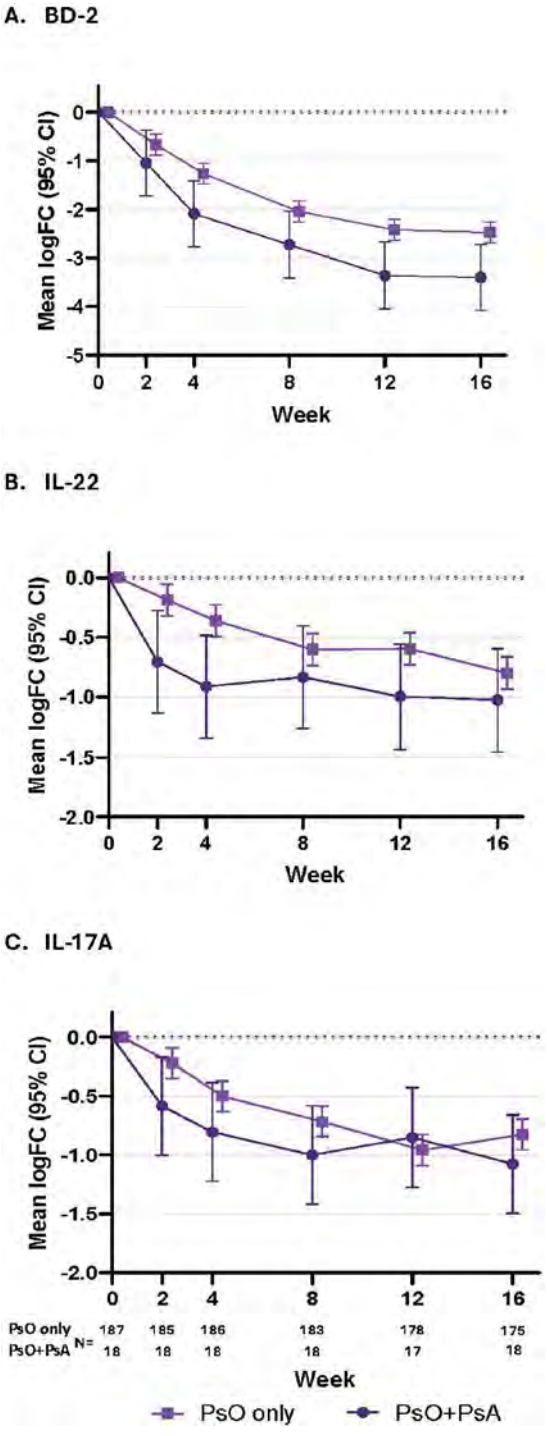
SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM



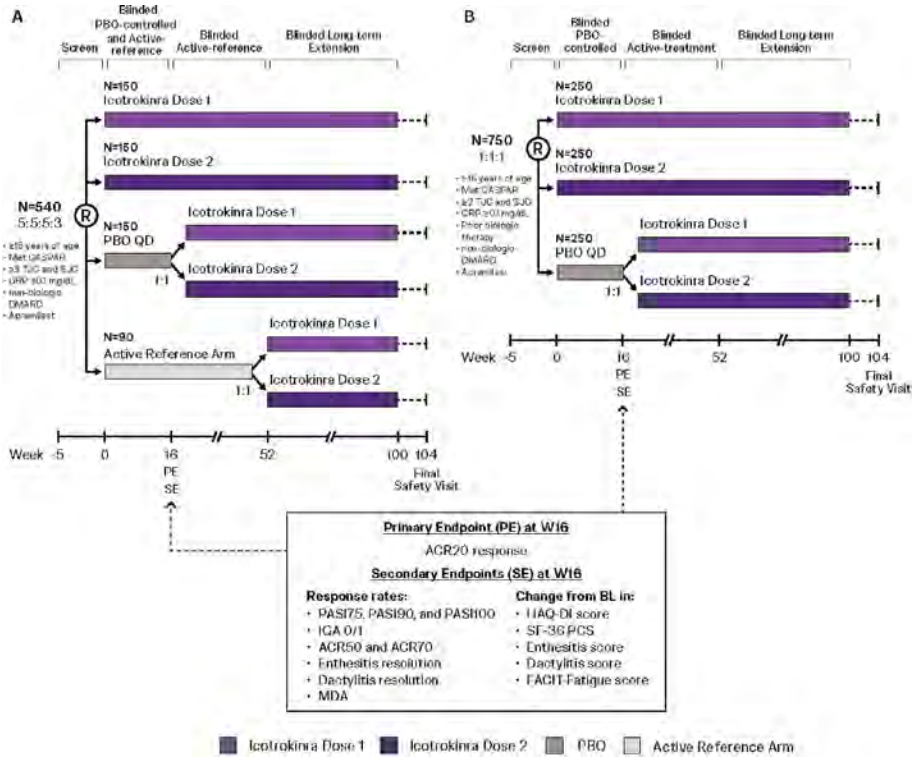
Mean change in serum BD-2 (A), IL-22 (B), and IL-17A (C) levels through W16 in FRONTIER 1 participants with PsO only and PsO+PsA

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background/Purpose: PsA affects ~20-30% of pts with PsO, causing articular inflammation/damage, and impaired health-related quality of life (HRQoL). ICO, a novel targeted oral peptide that binds IL-23 Receptor, showed greater clinical response rates vs placebo (PBO) and a favorable safety profile in pts with moderate-to-severe plaque PsO in the Ph 2 FRONTIER 1&2 studies. We leveraged exploratory serum biomarker, Pt Reported Outcomes Measurement Information Systems (PROMIS-29), and Psoriasis Area and Severity Index 75% improvement (PASI75) data from a subset of FRONTIER 1 pts with PsO and PsA medical history (PsO+PsA) to support Ph 3 ICONIC-PsA 1 and ICONIC-PsA 2 studies.

Methods: Mean log fold-changes (logFC) in serum β-Defensin-2 (BD-2), IL-22, IL-17A, and IL-17F levels were summarized for FRONTIER pts with PsO only, and with PsO+PsA. Pts reported HRQoL via PROMIS-29 questionnaire. Improvements ≥5-points in PROMIS-29 domain scores (or ≥2 for pain), and physical/mental component summary (PCS/MCS) scores, are considered clinically meaningful. ICO PsA Ph 3 sample sizes were informed by ample safety data to support regulatory submission and estimates from model-based analyses, including a meta-analysis that bridged FRONTIER 1 PASI75 to expected American College of Rheumatology 20% improvement (ACR20) at Week (W)16 (primary endpoint) and meta-regression modeling that bridged ACR20 to secondary endpoints, ACR50/70, PASI90/100, Minimal Disease Activity.

Results: 23/91 (25%) FRONTIER 1 pts had PsO+PsA (ICO, n=20; PBO, n=3). Among pts with evaluable biomarker data, mean logFC in serum BD-2, IL-22, IL-17A (**Fig 1A-C**), and IL-17F (data not shown) over time indicated consistent ICO pharmacodynamic (PD) effect between pts with PsO only and with PsO+PsA. ICO-treated PsO+PsA pts reported numerically greater mean changes from baseline (BL) at W16 vs PBO across PsA relevant PROMIS-29 domains, ie, improvements in physical function (7.7 vs 1) and reductions in fatigue (-7.4 vs 2.3 [worsening]), pain interference (-10.7 vs -1.3), and pain intensity (- 3.5 vs -1.5). In 20 ICO-treated pts with PsO+PsA, 45% and 70% reported ≥5 point improvement from BL in PROMIS-29 PCS and MCS scores, respectively, vs no pts receiving PBO. ICONIC-PsA 1&2 sample sizes of 540 (5:5:5:3 to ICO Dose 1/2/PBO/active reference arm with no formal statistical comparisons; **Fig 2A**) and 750 (1:1:1 to ICO Dose 1/2/PBO; **Fig 2B**) were estimated to provide ≥90% power to detect significant ICO vs PBO difference between ICO and PBO. Given minorities are often under-recruited in PsA trials, the ICO PsA program aims to assess diverse pts, of different racial/ethnicities.



ICONIC PsA-1 (biologic-naïve [A]) and ICONIC PsA-2 (biologic-experienced [B]) study designs

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Exploratory assessments from the Ph 2 FRONTIER 1 study showed comparable ICO PD effects between pts with PsO only, and with PsO+PsA. ICO-treated pts with PsO+PsA reported numerically greater improvements in PsA-relevant PROMIS-29 domains vs PBO. Informed by these post hoc analyses and model-based meta-analyses that bridged data from PsO to PsA, the multicenter, double-blind, PBO-controlled ICONIC-PsA 1 and ICONIC-PsA 2 studies will comprehensively evaluate the novel targeted oral peptide ICO in diverse population of pts with active PsA.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Guselkumab (GUS), a fully human IL-23p19-subunit inhibitor, has demonstrated efficacy in significantly improving psoriatic arthritis (PsA) signs and symptoms with two dosing regimens: 100 mg every 4 weeks (Q4W) or 100 mg at Week (W)0, W4, then Q8W, in the pivotal Phase 3 DISCOVER-1&2 studies.[1,2] SOLSTICE, an ongoing Phase 3b, multicenter, randomized, double-blinded placebo-controlled study, was designed to evaluate the efficacy and safety of GUS Q4W and Q8W in a dedicated participant (pt) population with active PsA who were inadequate responders (IR [inadequate efficacy and/or intolerance]) to one prior tumor necrosis factor inhibitor (TNFi).

Methods: Adults (≥18 years) with active PsA (≥3 swollen joints; ≥3 tender joints; C-reactive protein [CRP] ≥0.3 mg/dL) who were TNFi-IR to one prior TNFi were eligible to be enrolled from 128 sites across 12 countries. Pts were randomized 1:1:1 to GUS 100 mg Q4W; GUS at W0, W4, then Q8W; or placebo (PBO) with crossover to GUS 100 mg Q4W at W24. Randomization was stratified by baseline use of conventional synthetic disease-modifying antirheumatic drugs. The primary endpoint was defined as achievement of an ACR20 response at W24. Major secondary endpoints included the proportions of pts achieving ACR50/70, Investigator's Global Assessment of psoriasis response (IGA 0/1 and ≥2-grade improvement), ≥90% improvement in Psoriasis Area and Severity Index (PASI 90), and minimal disease activity (MDA) at W24.

Table. Baseline Demographics and Disease Characteristics by Treatment Group

	GUS 100 mg Q4W	GUS 100 mg Q8W	PBO
Participants, N	150	151	150
Age, years	50.6 (13.3)	51.9 (12.9)	49.2 (12.6)
Female, n (%)	75 (50.0)	77 (51.0)	85 (56.7)
Weight,[a] kg	86.5 (20.8)	89.5 (19.8)	85.9 (21.1)

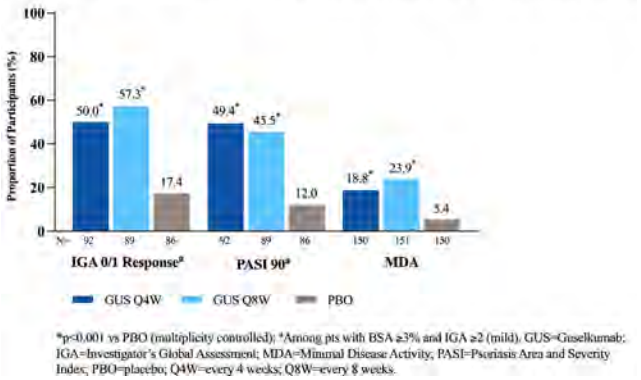
See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 2. Proportion of Participants Achieving IGA 0/1 Response, PASI 90, and MDA at Week 24



*p<0.001 vs PBO (multiplicity controlled); *Among pts with BSA ≥3% and IGA ≥2 (mild). GUS=Guselkumab; IGA=Investigator's Global Assessment; MDA=Minimal Disease Activity; PASI=Psoriasis Area and Severity Index; PBO=placebo; Q4W=every 4 weeks; Q8W=every 8 weeks.

Results: A total of 451 pts (Q4W n=150, Q8W n=151, PBO n=150) were included in the analysis set. Baseline characteristics were well balanced among treatment groups (mean at baseline: 50.6 years, 87.3 kg, 52.6% female; Table). Discontinuation rates were comparable between GUS Q4W (5.3% [8/150]), Q8W (4.6% [7/151]), and slightly higher for PBO (7.4%, [11/149]). Significantly greater proportions of pts in the Q4W and Q8W vs PBO groups achieved ACR20 at W24 (58.6% and 62.2% vs 34.8%, respectively), ACR50 (31.4% and 32.1% vs 12.2%, respectively), and ACR70 (17.5% and 17.3% vs 2.0%, respectively); p< 0.001 for all (Figure 1a). Through W24, Q4W and Q8W groups start achieving ACR20 as early as W4, compared to the PBO group (Figure 1b). GUS-treated pts in the Q4W and Q8W treatment groups also had significantly greater response rates at W24 vs PBO for MDA (18.8% and 23.9% vs 5.4%, respectively), IGA 0/1 response (50.0% and 57.3% vs 17.4%, respectively), and PASI 90 (49.4% and 45.5% vs 12.0%, respectively); p< 0.001 for all (Figure 2). Through W24, 49.5% of pts had ≥1 adverse event (AE), and 2.6% had ≥1 serious adverse event (SAE). Overall, the frequency of AEs and SAEs was similar across treatment groups and comparable to PBO.

Conclusion: In the TNFi-IR PsA population from SOLSTICE, GUS demonstrated superior efficacy vs PBO for improving signs and symptoms of peripheral arthritis and skin psoriasis. Both the GUS Q4W and Q8W dosing regimens were equally efficacious in this treatment refractory PsA population. Safety findings were consistent with the known safety profile of GUS in pts with psoriatic disease.[3]

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Guselkumab (GUS), a fully human IL-23p19-subunit inhibitor, has demonstrated efficacy in significantly improving psoriatic arthritis (PsA) signs and symptoms in participants (pts) with active PsA irrespective of prior tumor necrosis factor inhibitor (TNFi) experience. SOLSTICE is an ongoing Phase 3b, multicenter, randomized, double-blinded placebo-controlled study designed to evaluate the efficacy and safety of GUS on signs and symptoms of PsA disease specific patient reported outcomes (PROs), with two maintenance dosing regimens of 100 mg every 4 weeks (Q4W) and Q8W, in a dedicated PsA pt population who were inadequate responders (IR [inadequate efficacy and/or intolerance]) to one prior TNFi.

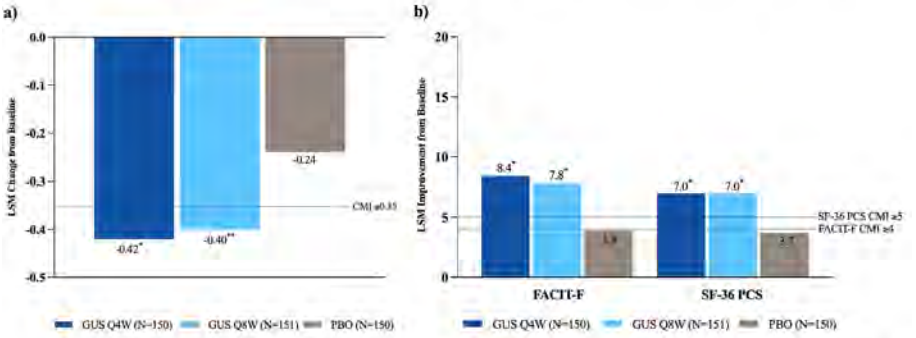
Table. Baseline Disease Characteristics and Patient Reported Outcomes by Treatment Group

	GUS 100 mg Q4W	GUS 100 mg Q8W	PBO
Participants, N	150	151	150
HAQ-DI			
Baseline (0-3)	1.3	1.3	1.3
LSM change from baseline at W24	-0.4	-0.4	-0.2
Response (improvement ≥0.35) at W24, n (%)	55.8	52.8	35.4
SF-36 PCS			
Baseline (0-100)	34.2	33.6	33.9
LSM change from baseline at W24	7.0	7.0	3.7
FACIT-F			
Baseline (0-52)	28.3	28.2	27.6
LSM change from baseline at W24	8.4	7.8	3.9
Response (improvement ≥4) at W24, n (%)	63.0	63.9	38.0

Data presented as mean (standard deviation) unless otherwise noted. FACIT-F=Functional Assessment of Chronic Illness Therapy-Fatigue; GUS=Guselkumab; HAQ-DI=Health Assessment Questionnaire-Disability Index; LSM=Least Squares Mean; PBO=placebo; Q4W=every 4 weeks; Q8W=every 8 weeks; SF-36 PCS=36-item Short-Form Health Survey Physical Component Summary; W=Week.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 1. a) Least Squares Mean Change from Baseline in HAQ-DI at Week 24; b) Least Squares Mean Change from Baseline in FACIT-F and SF-36 PCS at Week 24



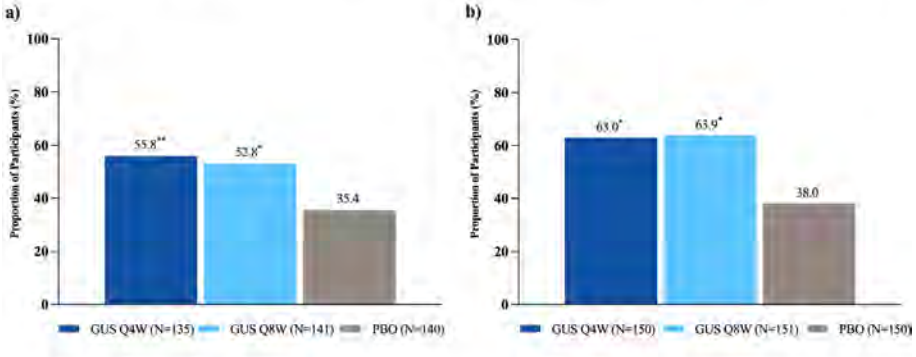
*p=0.003 vs PBO, **p=0.008 vs PBO (both multiplicity controlled); CMI=Clinically Meaningful Improvement; GUS=Guselkumab; HAQ-DI=Health Assessment Questionnaire-Disability Index; LSM=Least Squares Mean; PBO=placebo; Q4W=every 4 weeks; Q8W=every 8 weeks.

*p<0.001 vs PBO (multiplicity controlled); CMI=Clinically Meaningful Improvement; FACIT-F=Functional Assessment of Chronic Illness Therapy-Fatigue; GUS=Guselkumab; LSM=Least Squares Mean; PBO=placebo; Q4W=every 4 weeks; Q8W=every 8 weeks; SF-36 PCS=36-item Short-Form Health Survey Physical Component Summary.

Methods: Adults (≥18 years) with active PsA (≥3 swollen joints; ≥3 tender joints; C-reactive protein [CRP] ≥0.3 mg/dL) who were TNFi-IR to one prior TNFi were eligible to be enrolled from 128 sites across 12 countries. Pts were randomized 1:1:1 to GUS 100 mg Q4W; GUS at Week (W)0, W4, then Q8W; or placebo (PBO) with crossover to GUS 100 mg Q4W at W24. The major secondary PRO endpoints at W24 were mean change from baseline in Health Assessment Questionnaire-Disability Index (HAQ-DI; physical function), 36-item Short-Form Health Survey Physical Component Summary (SF-36 PCS; overall Health-related Quality of Life [HRQoL]), and Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT- F) scores. Proportions of pts achieving clinically meaningful improvements for HAQ-DI response (improvement ≥0.35) and FACIT-F response (improvement ≥4) were prespecified endpoints, but not multiplicity-controlled.

Results: A total of 451 participants (Q4W n=150, Q8W n=151, PBO n=150) were included in the analysis. On average, pts had moderate to severe impairment of physical function at baseline that is consistent with an active PsA population (Table). At W24, greater improvements in HAQ-DI, SF-36 PCS, and FACIT-F scores were observed in both treatment groups vs the PBO group (Table). A significantly greater reduction from baseline in HAQ-DI score was observed at W24 in the Q4W (-0.42, p=0.003) and Q8W (-0.40, p=0.008) groups, vs PBO (-0.24) group (Figure 1a). Furthermore, significantly greater improvement from baseline was observed in the Q4W and Q8W groups vs PBO group for SF-36 PCS (7.0 and 7.0 vs 3.7, respectively) and FACIT-F (8.4 and 7.8 vs 3.9, respectively); p< 0.001 for both (Figure 1b). Among pts with a baseline score of ≥0.35, the proportion of pts who achieved HAQ-DI response at W24 in the Q4W and Q8W groups vs PBO group were,

Figure 2. a) Proportions of Participants Achieving Clinically Meaningful Improvements in HAQ-DI Response at Week 24 Among Participants with a Baseline Score of ≥0.35; b) Proportions of Participants Achieving Clinically Meaningful Improvements ≥4 in FACIT-F Response at Week 24



*p=0.001 vs PBO, **p=0.003 vs PBO; GUS=Guselkumab; HAQ-DI=Health Assessment Questionnaire-Disability Index; PBO=placebo; Q4W=every 4 weeks; Q8W=every 8 weeks.

*p=0.001 vs PBO; GUS=Guselkumab; FACIT-F=Functional Assessment of Chronic Illness Therapy-Fatigue; PBO=placebo; Q4W=every 4 weeks; Q8W=every 8 weeks.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

55.8% (p< 0.001) and 52.8% (p=0.003) vs 35.4%, respectively (Figure 2a). Greater proportions of pts achieved clinically meaningful improvement in FACIT-F response in the Q4W (63.0%) and Q8W (63.9%) groups (p< 0.001 for both) vs PBO (38.0%) group (Figure 2b).

Conclusion: In the TNFi-IR PsA population from SOLSTICE, both GUS dosing regimens demonstrated superior efficacy vs PBO for improving physical function, overall HRQoL, and fatigue at W24. These data reinforce the effectiveness of GUS irrespective of dosing regimen in the TNFi-IR population across multi-domain measures of efficacy and PROs.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Despite advances in psoriatic arthritis (PsA) treatment, remission remains elusive for many patients. This has prompted growing interest in combining biologic and targeted synthetic DMARDs (b/tsDMARDs). However, real-world data on such combinations are limited. This case series evaluates clinical outcomes and safety of b/tsDMARD combinations in PsA patients.

BMI, body mass index; csDMARDs, conventional synthetic disease-modifying antirheumatic drugs; b/tsDMARDs, biologic/target synthetic DMARDs; TJC, tender joint count; SJC, swollen joint count; DAPSA, Disease Activity in Psoriatic Arthritis; PASI, psoriasis area and severity index; IXE, ixekizumab; TOFA, tofacitinib; UPA, upadacitinib; GUS, guselkumab; DEUC, deucravacitinib; BIME, bimekizumab; RIS, risankizumab; CER, certolizumab; SEC, secukinumab; PeA, peripheral arthritis; PsO, plaque psoriasis; Ent, enthesitis; PPP, palmoplantar psoriasis; IL23i, interleukin 23 inhibitor; IL17i, interleukin 17 inhibitor; JAKi, janus kinase inhibitor.

Methods: Case series of PsA patients receiving combined b/tsDMARD therapy, including TNFi, JAKi, TYK2i, IL17i, IL23i, IL-12/23i for effectiveness and safety. Combinations with Apremilast (APR) were analyzed for safety. Clinical and safety data were prospectively collected using standardized instruments within a longitudinal PsA cohort, and supplemented via chart review. Effectiveness was assessed by changes in joint counts, DAPSA, PASI, BSA, and patient-reported outcomes (NRS for pain, skin, and global) at 3-6 and 6-12 months. Safety outcomes included infections and non-infectious adverse events (AEs).

Results: We identified 22 patients treated with bDMARDs + JAKi or TYK2i, some with multiple regimens. Eleven (50%) were female. Complete information on PsA measure of activity was available for 9 patients (**Table 1**), while 13 had partial data, including age, sex, skin activity, and AEs. Numerical improvements were observed across disease activity measures, with **Figure 1** showing patients with visits in the prespecified timeframes, and **Table 2** showing the safety data.

Table 2. Safety analysis. IL17i, interleukin 17 inhibitor; tsDMARD, target-synthetic disease-modifying antirheumatic drug; IL23i, interleukin 23 inhibitor; TNFi, tumor necrosis factor inhibitor; IL12/23i, interleukin 12/23 inhibitor; JAKi, janus kinase inhibitor.

Drug Combination	Total Duration (days)	Total Duration (patient-years)	Adverse events (number)	Side Effect Description	Incidence Rate (per 100 patient-years)
IL17 + TYK2	3,229	8.5	2	Two upper respiratory infections (Bimekizumab + Deucravacitinib)	25.3
IL17 + JAKi	4,145	11.35	1	Infectious stomatitis (Ixekizumab + Tofacitinib)	8.81
IL23 + TYK2	3,215	9.1	4	Two upper respiratory infections One worsening of folliculitis (Guselkumab + Deucravacitinib)	32.97
IL23 + JAKi	1,337	3.7	0	None	0.00
TNF + TYK2	324	0.89	0	None	0.00

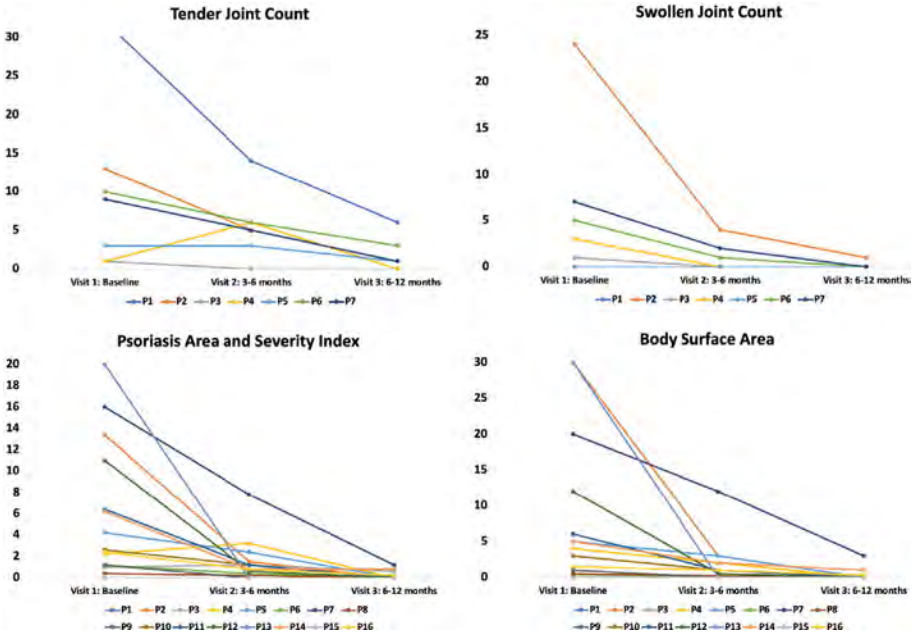

Figure 1. Individual trajectories after starting combined therapy for patients with follow-ups according to protocol.

In the bDMARD + JAKi group (n=6), IL17i + JAKi were the most frequent combinations (n=4), used for 4,145 days (11.35 patient-years [PY]). One case of mild infectious stomatitis was reported, but treatment was not discontinued. IL23i + JAKi (n=2), used for 1,337 days (3.7 PY), had no AEs.

For the bDMARD + TYK2i group (n=19), IL-17i + TYK2i (n=9) were used for 3,229 days (8.5 PY). One patient experienced two mild upper respiratory infections (URIs) on bimekizumab and deucravacitinib, prompting a switch for risankizumab with deucravacitinib. IL-23i with TYK2i (n=10) were used for 3,325 days (9.1 PY), with two cases of mild URIs leading to a switch to bimekizumab monotherapy, and one case of folliculitis, where therapy was continued. One patient received TNFi + TYK2i for 324 days (0.9 PY), with no AEs.

We identified 16 patients on bDMARDs + APR (total of 22 combinations, with a median duration of 825 days), including IL12/23i or IL23i + APR (8 combinations, duration: 360–2,250 days), IL17i + APR (8 combinations, duration: 90–2,790 days), TNFi + APR (5 combinations, duration: 180–2,340 days), and JAKi + APR (1 combination, 540 days). Two cases of diarrhea were observed, but no infections occurred.

Conclusion: Overall, the safety profile of bDMARD combinations with tsDMARDs was favorable. Infections, primarily URIs, were the most common AEs – mild in severity, non-hospitalized, and rarely requiring treatment change. Short-term improvements were observed in both musculoskeletal and skin domains. Our findings, drawn from a prospective cohort with standardized data collection, support the effectiveness and safety of combination therapy in selected PsA cases. Randomized controlled trials are needed to confirm long-term efficacy and safety.

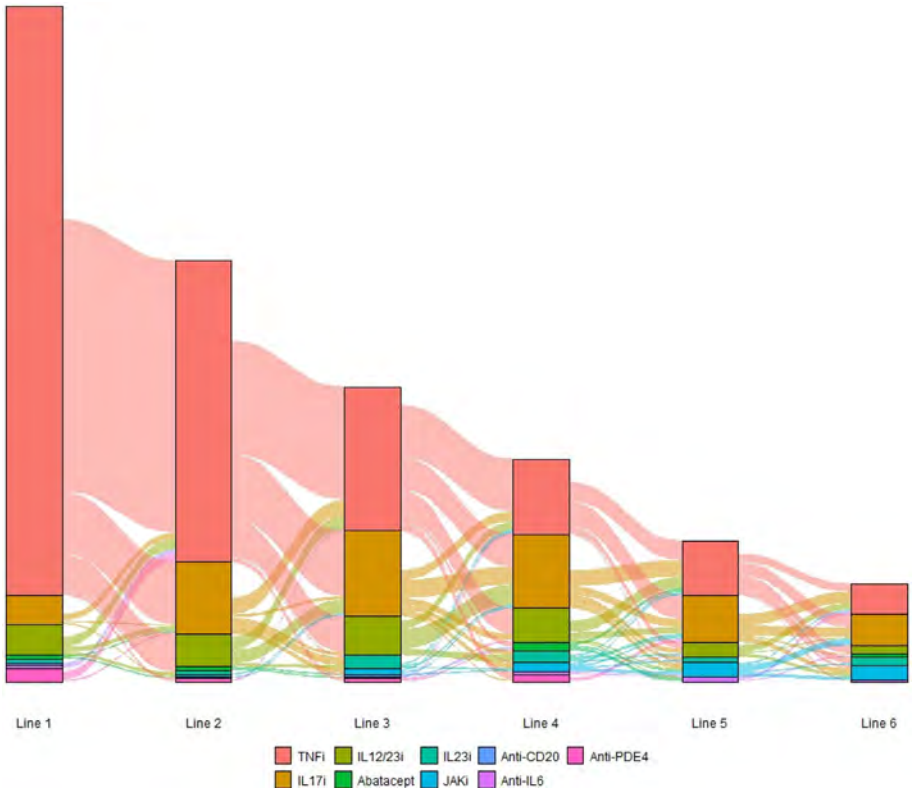

Figure 1 Treatment trajectories from first to sixth line

Background/Purpose: Risk factors to identify patients who will develop a difficult-to-treat (D2T) psoriatic arthritis (PsA) are still lacking when initiating a first bDMARD. There are ongoing GRAPPA/EULAR definitions of D2T PsA. The primary endpoint of this work was to determine the risk factors for developing D2T PsA in patients initiating a first bDMARD using the definition from Philippoteaux et al [1]. The second objective was to determine the risk factors for developing refractory PsA in the same population.

Methods: A retrospective study was conducted at three secondary and tertiary centres in France and one tertiary centre in the United Kingdom. Patients with PsA aged 18 years or older who initiated b/tsDMARDs and had at least a five-year follow-up were included. D2T PsA was defined as failure of ≥ 2 b/tsDMARDs with different mechanisms of action, including TNF, IL-

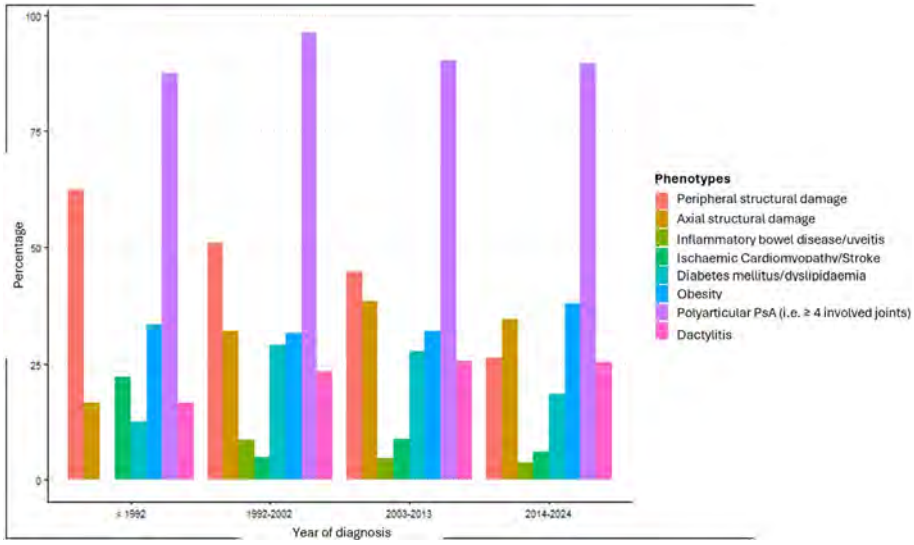

Figure 2 Evolution of phenotypes depending on the year of diagnosis

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

17, IL-23, and JAK inhibitors. Refractory PsA was defined as the failure of TNF, IL-17, IL-23, and JAK inhibitors. Patients with D2T PsA's characteristics were compared with patients without D2T Patients with D2T PsA's characteristics were compared with patients without D2T using logistic regression models adjusted for country (France vs. the United Kingdom). Factors significant at the 0.05 level were introduced into a multivariate logistic regression model also adjusted for country. The same methods were applied to compare patients with refractory PsA to those without refractory PsA. However, multivariate analysis was not performed due to limited sample size. The evolution of baseline characteristics was also assessed during four periods: before 1992, 1992 to 2002, 2003 to 2013, and 2014 to 2024.

Results: Four hundred and twelve patients were included: 92 with D2T PsA (22.3%; 95% confidence interval [CI], 18.3-26.7) and 320 without D2T PsA (77.7%). The median disease duration was 12.0 (8.0; 18.5). Treatment trajectories of the patients were reported from the 1st to the 6th line (**Figure 1**). A higher proportion of patients with D2T PsA had dactylitis, fibromyalgia and ischaemic cardiomyopathy (**Table 1**). In multivariate analysis, fibromyalgia (OR = 2.62; 95% CI 1.09-6.28) and ischemic cardiomyopathy (OR = 2.95; 95% CI 1.04-8.36) were found to be risk factors for D2T PsA. On the contrary, dactylitis was a protective factor for D2T PsA (OR=0.49; 95% CI 0.26-0.94). The proportion of patients with peripheral structural damage, inflammatory bowel disease, uveitis, diabetes mellitus, and dyslipidaemia at baseline decreased over time, where the proportion of patients with axial structural damage, ischaemic cardiomyopathy, stroke, obesity, polyarticular PsA (i.e ≥ four involved joints) and dactylitis were stable over time (**Figure 2**).

Fourteen patients (3.4%; 95% CI 1.9-5.6) were categorised as refractory. A refractory phenotype was associated with axial radiographic structural damage at baseline (OR = 5.65; 95% CI, 1.69-18.89).

Conclusion: In this retrospective binational study, fibromyalgia and ischaemic cardiomyopathy were found to be potential risk factors for D2T PsA, whereas dactylitis was a potential protective factor for D2T PsA. The prevalence of patients with refractory PsA was rare (< 5%) and was associated with axial radiographic structural damage at baseline.

SESSION INFORMATION

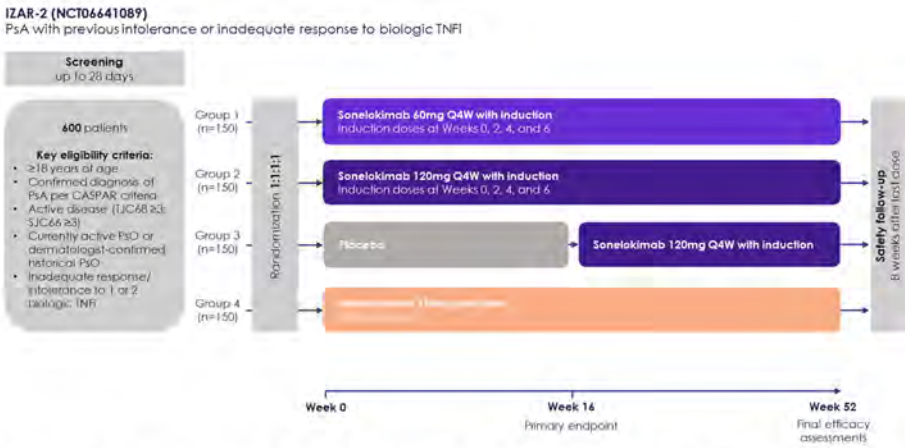
Session Date: Sunday, October 26, 2025
Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Sonelokimab (SLK), a novel Nanobody that binds to both IL-17A and IL-17F with similarly high affinity, is designed to target difficult-to-reach sites of inflammation. The Phase 2 ARGO study demonstrated robust joint and skin responses with SLK in PsA. We report Week (W) 24 data for patients with prior biologic exposure in the ARGO trial and describe the design of the Phase 3 IZAR-2 trial that will further evaluate SLK in patients with active PsA after prior biologic TNFi therapy.

Methods: ARGO (NCT05640245) was a 24-week, global, randomized, placebo (PBO)-controlled double-blind trial of adults with active PsA. Three SLK doses were assessed: 60mg with no induction (NI; Q4W), SLK 60mg with induction (WI), and SLK 120mg WI (induction doses at W0, 2, 4, and 6; Q4W from W8). Patients with >2 prior biologics or primary failure of TNFi or IL-17i were excluded. In this exploratory analysis, W24 outcomes in patients with prior bDMARD exposure treated with SLK 120mg or 60mg WI (IZAR-2 doses) were assessed.

Results: 207 patients were enrolled. Of the 84 patients treated with SLK 120mg (n=43) or 60mg WI (n=41), 15 (17.9%) had exposure to ≥1 bDMARD (TNFi n=10, IL-23i n=7, IL-17i n=5). Among these patients, the primary endpoint of ACR50 was achieved by 53% of patients with exposure to ≥1 bDMARD and 61% of patients with no prior bDMARD exposure. Similar

Figure. Study design



CASPAR, Classification Criteria for Psoriatic Arthritis; PsA, psoriatic arthritis; PsO, psoriasis; Q4W, every 4 weeks; SJC66, 66 swollen joint count; TJC68, 68 tender joint count; TNFi, tumor necrosis factor inhibitor.

Figure. Study design

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

results were seen for minimal disease activity (MDA), which was achieved by 53% of patients with prior bDMARD exposure and 57% of patients with no prior bDMARD exposure who received SLK 120mg or 60mg WI. Of the 5 patients receiving SLK 120mg or 60mg WI with PsO at baseline (≥3% BSA) and prior bDMARD exposure, 4 (80%) achieved PASI 90 (75% for those with no prior bDMARD exposure). SLK was well tolerated, with a safety profile consistent with IL-17 inhibition. To further assess outcomes in this patient population, we designed a 52-week, global, randomized, double-blind, PBO-controlled, Phase 3 trial (IZAR-2; NCT06641089; **Figure**). An estimated 600 participants will be randomized 1:1:1:1 to SLK 60mg WI, SLK 120mg WI, PBO (SLK 120mg WI from W16), or risankizumab (RZB). Given the results from ARGO, this sample size should provide sufficient power to demonstrate a statistically significant difference vs. PBO on the primary outcome of ACR50 at W16. Eligible participants will have PsA fulfilling CASPAR criteria, active disease (TJC68 ≥3 and SJC66 ≥3), currently active or historical PsO, and inadequate response or intolerance to 1 or 2 biologic TNFi. Key secondary outcomes (all vs. PBO at W16) include ACR20, PASI 90, MDA, and HAQ-DI. RZB, an approved IL-23 p19i PsA therapy commonly used after prior inadequate response to TNFi, will be the active reference arm. A secondary endpoint of ACR50 at W16 with SLK vs. RZB will provide insights into treatment choices with IL-17A/F and IL-23i after TNFi failure.

Conclusion: In patients with active PsA and prior exposure to $\geq$1 bDMARD in the Phase 2 ARGO trial, SLK 120mg and 60mg WI showed efficacy in controlling signs and symptoms of PsA and achieving MDA response. Interpretation is limited by patient numbers; hence, a larger Phase 3 trial specifically in patients with prior inadequate response or intolerance to biologic TNFi (IZAR-2) is ongoing and actively recruiting at sites across the USA.

Drug-Free Remission in Early Peripheral Spondyloarthritis: 10-year follow-up from the CRESPA-trial

Caroline Damen[1], Philippe Carron[2], Ann-Sophie De Craemer[3], Filip Van den Bosch[3] and Dirk Elewaut[4], [1]Department of Internal Medicine and Pediatrics, Ghent University, Ghent, Belgium, [2]Ghent University and VIB Center for Inflammation Research, Ghent, Belgium, [3]Department of Internal Medicine and Pediatrics, Ghent University and VIB Center for Inflammation Research, Ghent, Belgium, [4]VIB Center for Inflammation Research, and Ghent University Hospital, Department of Rheumatology, Ghent, Belgium

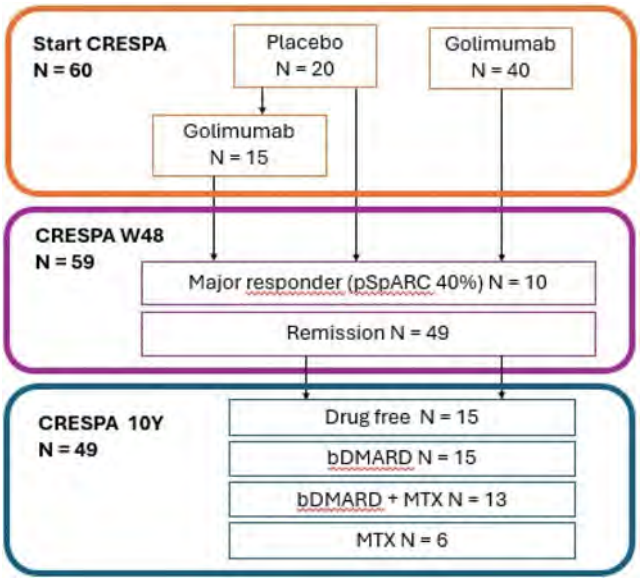
SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Peripheral spondyloarthritis (pSpA) is a neglected clinical entity with few therapeutic or clinical management trials available to date. In the CRESPA-trial (1) very early pSpA patients, all fulfilling the Assessment of SpondyloArthrtis international Society (ASAS) classification criteria for pSpA and having a symptom duration ≤12 weeks, were randomized to golimumab (n=40) or placebo (n=20). Placebo-treated patients were switched to golimumab at week 24 if no sustained clinical remission was achieved (primary end point) (1). In patients achieving sustained clinical remission, treatment was stopped to assess the possibility of drug-free remission (2). In those not achieving the primary endpoint at week 48, treatment with golimumab was continued (2). The objective of this study was to determine the percentage of patients achieving a status of clinical remission after a follow-up of 10 years.

Methods: In this 10-year follow-up study patients that participated in the CRESPA-trial were evaluated through clinical examination assessing arthritis, enthesitis and dactylitis. All evaluations were done between March 2024 and September 2024. Clinical remission was defined as the absence of arthritis, enthesitis or dactylitis. A secondary aim was to identify baseline differences between patients currently in remission and those not in remission.

Results: As reported previously, sustained clinical remission was achieved in 82% (49 of 60) of patients after an induction regimen, 15 placebo treated patients needed golimumab (1) ***(figure 1)***. 1 patient was excluded due to progression to seronegative rheumatoid arthritis.

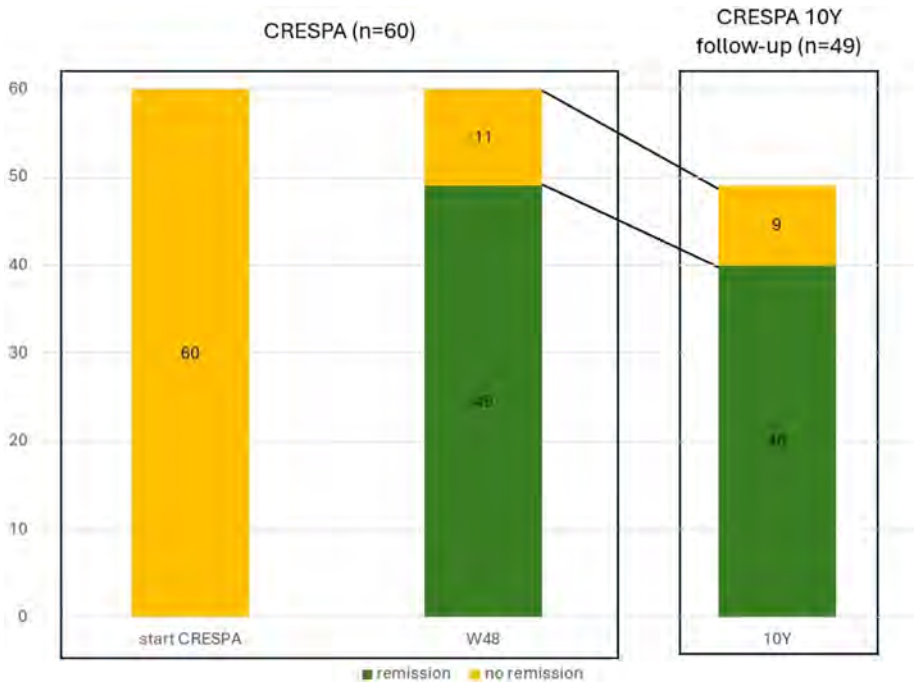
23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Medication use during CRESPA trial and after 10 year follow-up

Of those 60 patients originally included in the CRESPA study, we were able to evaluate 49 patients within an average of 10.5 years (SD 0.87 years) of follow-up. Clinical remission was observed in 82% (40 of 49) patients, with 37.5% (15 of 40) of them in drug-free remission ***(figure 2)***. 6 patients were on MTX monotherapy and 28 patients on bDMARD (57% monotherapy, 43% in combination with MTX). 21 patients still use golimumab, with no unsuspected serious adverse effects reported. Of the 9 patients not in clinical remission after 10 years of follow-up, 7 experienced enthesitis, 1 arthritis and 1 both enthesitis and arthritis.

There were no baseline differences regarding sex, age, HLA B27-positivity, psoriasis, or initial treatment allocation between patients in clinical remission and those not in clinical remission. However, drug-free remission was significantly less common in patients with psoriasis compared to those without (OR = 0.11, 95% CI: 0.02–0.55, $p = 0.005$).



Remission at the end of the CRESPA trial and after 10 year follow-up

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: After 10 year follow-up, the vast majority of patients are in clinical remission with 37.5% of them even in drug-free remission. The presence of psoriasis at baseline was associated with a lower likelihood of achieving drug-free remission.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: The recently updated Assessment of SpondyloArthritis international Society (ASAS) core outcome set (COS) includes an agreed minimum set of instruments that should be used in all axial spondyloarthritis (axSpA) trials. However, recommendations on how to report outcomes of the 16 COS instruments is lacking. Aim of the project is to develop expert endorsed recommendations on how outcomes of COS instruments should be reported.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table Reporting outcomes of instruments in the ASAS Core Outcome Set

Item	At baseline	At follow-up timepoint(s)
For all trials		
1. ASDAS	mean (SD)	mean (SD) + mean (SD) change from baseline + n (%) of patients with improvement of ≥1.1 and ≥2.0*
2. ASDAS disease status	n (%) per category†	n (%) per category + n (%) <2.1 and ≥2.1
3. Patient global disease activity	mean (SD)	mean (SD) + mean (SD) change from baseline
4. Total back pain (BASDAI Q2)	mean (SD)	mean (SD) + mean (SD) change from baseline
5. Mean stiffness severity (BASDAI Q5) and duration (BASDAI Q6)‡	mean (SD)	mean (SD) + mean (SD) change from baseline
6. Fatigue (BASDAI Q1)	mean (SD)	mean (SD) + mean (SD) change from baseline
7. BASFI	mean (SD)	mean (SD) + mean (SD) change from baseline
8. ASAS 20 and ASAS 40 responses	not applicable	n (%)
9. ASAS health Index	mean (SD)	mean (SD) + mean (SD) change from baseline + n (%) of patients with improvement ≥3
10. ASAS health Index status §	n (%) per category	n (%) per category
Mandatory for DMARD trials only		
11. SPARCC MRI-SIJ activity	mean (SD)	mean (SD) + mean (SD) change from baseline
12. SPARCC MRI-spine activity	mean (SD)	mean (SD) + mean (SD) change from baseline
13. Acute anterior uveitis	n (%) with history	n (%) since baseline /rate per 100 pt yrs + split by patients with and without history
14. Psoriasis	n (%) with history	n (%) new onset since baseline /rate per 100 patient years (pt yrs) + rate split by patients with and without history
15. IBD	n (%) with history	n (%) since baseline /rate per 100 pt yrs + split by patients with and without history
16. 44 swollen joint count	mean (SD)	mean (SD) + mean (SD) change from baseline ¶
17. MASES	mean (SD)	mean (SD) + mean (SD) change from baseline ¶
18. Dactylitis count	mean (SD)	mean (SD) + mean (SD) change from baseline ¶
19. mSASSS	mean (SD)	mean (SD) + mean (SD) change from baseline
20. Syndesmophytes	n (%) with ≥1	n (%) with ≥1 syndesmophyte + n (%) with a new syndesmophyte

*If flares are reported: n (%) of pts. with ASDAS of ≥0.9; † ASDAS categories: <1.3 inactive disease, ≥ 1.3 and <2.1 low disease, ≥ 2.1 and ≤3.5 high disease, >3.5 very high disease activity; ‡ BASDAI (Q5+Q6)/2; § ASAS health index categories: good ≤ 5, moderate <5 to <12, poor ≥12; ¶ in pts with swollen joint count>0, MASES>0 or dactylitis count>0 at baseline
ASAS: Assessment of SpondyloArthritis international Society; ASDAS: Axial Spondyloarthritis Disease Activity Score; BASFI: Bath Ankylosing Spondylitis Functional Index; IBD: inflammatory bowel disease; MASES: Maastricht Ankylosing Spondylitis Entheitis Score; mSASSS: modified Stoke Ankylosing Spondylitis Spinal Score ; pt: patient; Q: question; SPARCC: Spondyloarthritis Research Consortium of Canada;

Methods: A steering group (SG) (FvG, VNC, DvH) convened a workgroup (WG) consisting of thirteen ASAS members including rheumatologists, methodologists, epidemiologists, and two Young ASAS (Y-ASAS) members (all other co-authors). Recommendations on reporting instrument outcomes were developed in three steps: the SG formulated a proposal on how outcomes related to the instruments should be presented. ii) the proposal was presented, discussed and modified in a WG meeting. iii) the WG proposal was discussed and voted on by ASAS members.

Results: Reporting 20 trial outcomes at baseline and follow-up timepoints are recommended: 10 for all clinical trials and 10 for DMARD trials only (Table). The most common format is to report the mean plus the standard deviation (SD) at all timepoints while adding the mean change (SD) from baseline for each timepoint. For ASDAS it is recommended to also report the number and percentage of patient with decrease of ≥1.1 and ≥2.0 units, an increase of 0.9 for flares, and ASDAS status at all timepoints (inactive (< 1.3), low (≥1.3 and < 2.1), high (≥2.1 and ≤3.5), and very high (>3.5) plus the number and percentage of patients with scores < 2.1 and ≥2.1). For ASAS health index it is recommended to also report the number and percentage of patients with decrease in the score of ≥3 and status (good (≤ 5), moderate (< 5 to < 12), and poor (≥12)) at all timepoints. It is recommended for psoriasis, uveitis, and IBD to be reported as the number and percentage of patients with flare or (re) occurrence since baseline plus the rate per 100 patient-years while also splitting the results by patients with and without a history of that particular extra-musculoskeletal manifestations. For spinal syndesmophytes it is recommended to report the number and percentage of patients with at least one at baseline and outcomes plus the number and percentage of patients with a newly developed syndesmophyte which, if not scored separately, can be derived from the mSASSS scoring with a vertebral unit over time developing an mSASSS score of 2 or 3 from a score less than 2 counting as the development of a syndesmophyte. At the 2024 annual ASAS workshop recommendations were voted in by 81 full ASAS members with 85% in favour, 9% against, and 6% abstaining.

Conclusion: These ASAS endorsed recommendations provide a consensual approach to reporting outcomes of axSpA clinical trials. Adherence to these recommendations will standardize presentation of results and thereby provides better insight into trial outcomes and facilitate the comparison of outcomes across studies.

Phyto- and Endo-cannabinoids Exhibit Ex Vivo Anti-Inflammatory Effects in Refractory Rheumatic inflammatory/Autoimmune Patients: Toward Personalized Cannabinoid Therapy

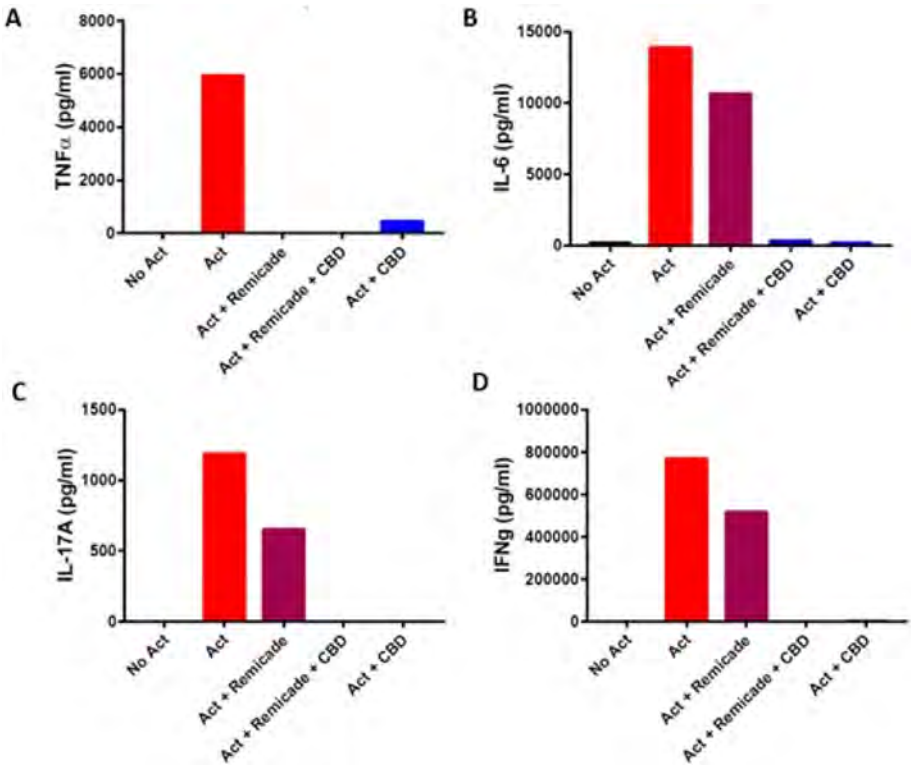
Gilad Halpert[1], Eri Govrin[1], Omer Gendelman[1], Abdulla Watad[2], Yehuda Shoenfeld[1] and Howard Amital[1], [1]Sheba Medical Center, Ramat Gan, Israel, [2]Tel Hashomer Medical Center, Ramat Gan, Israel

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: A substantial number of patients with rheumatic inflammatory/autoimmune diseases, do not achieve adequate symptom control with current standard-of-care therapies, including biologics. The endocannabinoid system may offer an alternative therapeutic target. Recently we found a significant change in the circulating level of endogenous cannabinoids (endocannabinoids) in rheumatoid arthritis (RA) and fibromyalgia syndrome (FMS) patients as compared to healthy controls. The current study aimed to evaluate *ex vivo* anti-inflammatory effects of non-psychoactive phytocannabinoids and endocannabinoids in peripheral blood mononuclear cells (PBMCs) from patients with refractory rheumatic inflammatory/autoimmune conditions.

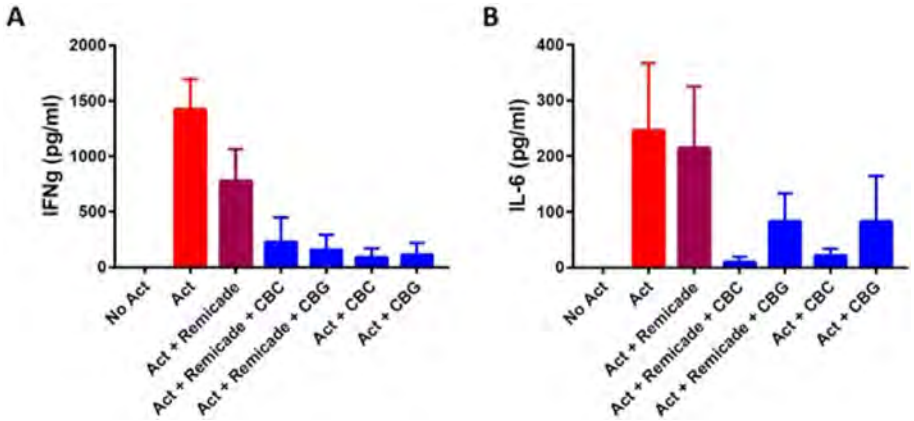
Methods: PBMCs were isolated from psoriatic arthritis (PsA) and ankylosing spondylitis (AS) patients who were unresponsive to anti-TNFα treatment, as well as from FMS patients. PBMCs were activated *ex-vivo* using PHA and LPS, and treated

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



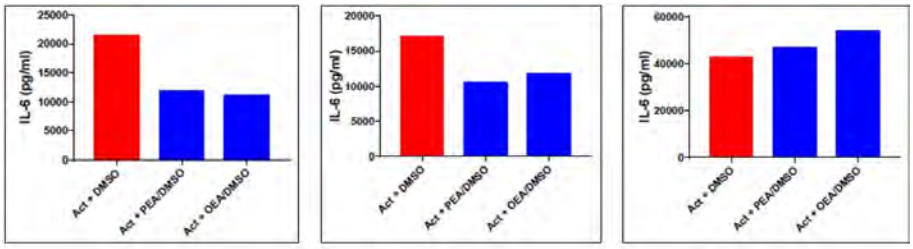
with either phytocannabinoids (CBD, CBC, CBG) or endocannabinoids (AEA, PEA, OEA). Cytokine levels (TNF-α, IFN-γ, IL-17, IL-6 and IL-1β) were measured in cell supernatants and plasma using ELISA assay.

Results: In PBMCs from severe refractory PsA patient, the phytocannabinoid CBD demonstrated superior suppression of pro-inflammatory cytokines (IL-6, IL-17, and IFN-γ) compared to the corresponding anti-TNFα biologics while both CBD and anti-TNFα abrogate TNFα secretion (Fig. 1). In PBMCs from refractory AS patients (n=3), phytocannabinoids (CBC and CBG) demonstrated superior suppression of IFN-γ and IL-6 compared to the corresponding anti-TNFα biologics (Fig. 2). In FMS patients (n=3), endocannabinoids (AEA, PEA, and OEA) modulated IL-6 secretion in a patient-specific manner, with variable cytokine responses observed (Fig. 3).



The cannabinoids (CBG and CBC) show superior reduction in the level of secreted IFNγ and IL-6 from activated PBMCs of refractory ankylosing spondylitis (AS) patients (n=3) vs. the non-effective Anti-TNFα mAb (Remicade®). Human PBMCs were isolated from severe (refractory to Anti-TNFα therapy) AS patient, seeded (500,000 cells/0.5ml/well) and activated using LPS (100ng/ml) + PHA (10μg/ml) for 24h. Anti-TNFα mAb (Remicade®) or CBC/CBG (1/3 less concentrated than Remicade) were added concomitantly to activation, for a total of 24h. IFNγ and IL-6 cytokine levels were measured in the supernatants, 24 h after activation, by ELISA assay. Act – Activation using LPS/PHA.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



The effect of N-arachidonoylethanolamine (AEA) on IL-6 secretion from LPS/PHA-induced activated PBMCs of FMS patients. Human PBMCs were isolated from FMS patients, seeded (500,000 cells/0.5ml/well) and activated using LPS (100ng/ml) + PHA (10μg/ml) for 24h. AEA (10^-6M) was added 5h after the intial activation, for a total of 24h. IL-6 cytokine level was measured in the supernatants, 24 h after activation, by ELISA assay. Act – Activation using LPS/PHA; Eth – Ethanol which used to dissolve the AEA.

Conclusion: Non-psychoactive phytocannabinoids exhibit robust *ex vivo* anti-inflammatory activity in PBMCs from refractory PsA and AS patients, surpassing anti-TNFα biologics. Additionally, individualized endocannabinoid responses in FMS support a precision medicine approach. These findings highlight the potential of integrating phytocannabinoids and endocannabinoid profiling to guide personalized therapeutic strategies in rheumatic inflammatory/autoimmune diseases.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Biologics have transformed the management of axial spondyloarthritis (axSpA). Currently, it is challenging to identify patients who would benefit from early biologics, resulting in trial-and-error use of NSAIDs followed by a response evaluation over months before initiating biologics. This study aimed to characterize patients requiring early biologics through single-cell RNA sequencing (scRNA-seq) analysis of peripheral blood mononuclear cells (PBMCs) obtained from newly diagnosed axSpA patients.

Methods: PBMCs were collected at baseline from axSpA patients newly diagnosed. Patients initiating biologics within six months were categorized as early biologics users, while those who did not were categorized as non-early biologics users. Single-cell RNA sequencing data were processed using Cell Ranger, and quality control was performed using Seurat.

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

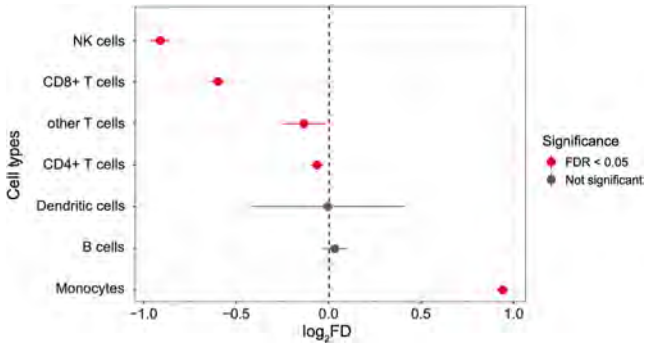

Figure 1. Single-cell proportion test results. To compare cell type proportions between early and non-early users, a single-cell proportion test was performed using the R package scProportionTest.

Differences in cell proportions were analyzed with scProportionTest, and differentially expressed genes (DEGs) were identified using the Wilcoxon Rank Sum test. Pathway enrichment analyses were conducted using KEGG and GO terms.

Results: Nineteen patients with axSpA were enrolled, of whom seven were categorized as early biologics users and twelve as non-early biologics users. A total of 157,029 single cells passed quality control and were included in subsequent analyses.

Differential cell proportion analysis revealed marked differences between early and non-early biologics users. Specifically, early biologics users exhibited a significant increase in monocyte proportions, along with a decrease in NK and CD8+ T cells, suggesting an altered balance in both innate and adaptive immunity. Monocytes had the highest number of differentially expressed genes (DEGs), highlighting the potential importance of monocytes in determining early treatment responses (Figure 1).

Enrichment analyses of monocyte-specific DEGs indicated significant activation of pathways closely linked to the pathogenesis of axSpA, including NF-κB signaling, the Toll-like receptor signaling pathway, the response to tumor necrosis factor, and MAPK signaling (Figure 2).

In CD8+ T cells, DEGs were enriched in the HIF signaling pathway in the KEGG gene set. These findings are consistent with previous reports emphasizing the necessity of increased glycolysis in supporting CD8+ T cell activation and differentiation. Similarly, NK cells in early biologics users displayed DEGs such as FPR1, XCL2, CYBB, CD14, FOS, LYZ, S100A9, AIF1, and S100A8, which are enriched in inflammatory response pathways. NK cells have been implicated in several immune-mediated diseases, and these results suggest that their dysregulation may contribute to the early disease process in axSpA.

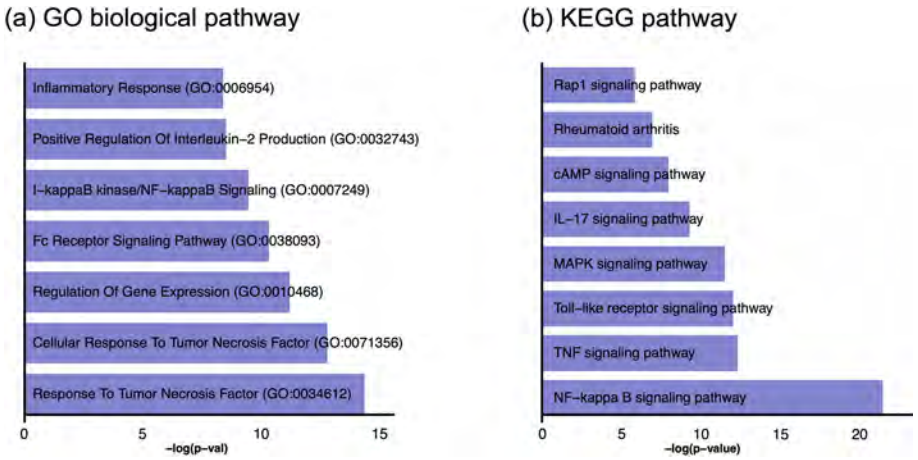

Figure 2. Results of the enrichment analysis. Enrichment analyses using (a) GO Biological Process and (b) KEGG gene sets.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: These data indicate that early biologics users exhibit a distinct immunological profile characterized by enhanced monocyte-driven inflammation and concurrent alterations in CD8+ T cell and NK cell populations. These findings underscore the critical role of innate immunity, particularly through monocyte-mediated pathways, in identifying patients who may benefit from early biologics therapy, offering a basis for personalized therapeutic strategies.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: A treat-to-target (T2T) strategy in psoriatic arthritis (PsA) is supported by International PsA recommendations but not widely practiced in clinic. The aim of the Multicentre Observational Initiative in Treat-to-Target Outcomes in Psoriatic Arthritis (MONITOR-PsA) cohort was to assess clinical and patient-reported outcomes with a pragmatic implementation of a T2T approach.

Methods: Adult patients from 11 UK rheumatology departments were included if they had a clinical diagnosis of active PsA (≥ 1 tender or swollen joints or enthesis); not previously had treated with DMARDs for articular disease. The MONITOR-PsA cohort patients were assessed every 12 weeks for one year and were treated with current standard step-up care. Initial treatment consisted of methotrexate, then the addition of or switch to another csDMARD, and then potentially a switch to a bDMARD dependent on disease activity(**Figure 1**). The primary outcome was the proportion of patients achieving the PsA Disease Activity Score (PASDAS) 'good' response at 48 weeks. Key secondary endpoints were the proportion achieving PASDAS moderate response at 48 weeks and PASDAS continuous outcome 48 weeks. Exploratory outcomes included the proportion achieving MDA and DAPSA remission (≤4) at 48 weeks, the number of patients achieving a 50% decrease in 50% in dactylitis/enthesitis scores, the proportion achieving PSAID patient acceptable symptom state (≤4) and the difference between baseline and 48 weeks for radiographic outcomes (score of erosions, joint space narrowing score, modified Sharp-van der Heijde score).

Smoker		
Never	122/225 (54.2%)	83/161 (51.5%)
Former	62/225 (27.6%)	47/161 (29.2%)
Current	41/225 (18.2%)	31/161 (19.3%)
TJC	299, 6.0 [3.0, 14.0]	233, 6.0 [2.0, 13.0]
SJC	299, 3.0 [1.0, 6.0]	233, 3.0 [1.0, 6.0]
Patients with enthesitis	145/277 (52.3%)	119/211 (56.4%)
Leeds Enthesitis Index (n/6)	101, 2.0 [1.0, 3.0]	82, 2.0 [1.0, 3.0]
Patients with dactylitis	73/277 (26.4%)	54/207 (26.1%)
Dactylitis count	73, 2.0 [1.0, 2.0]	54, 2.0 [1.0, 2.0]
PASDAS	223, 5.2 [4.4, 6.0]	159, 5.1 [4.1, 5.8]
DAPSA	229, 24.8 [17.6, 35.3]	165, 23.2 [16.0, 31.9]
cDAPSA	292, 23.5 [15.8, 34.4]	226, 21.4 [15.0, 31.1]
BASDAI	74, 5.5 [3.8, 7.3]	71, 5.5 [3.6, 7.2]
BASFI	75, 3.7 [1.2, 6.7]	72, 3.5 [1.2, 6.6]
PASI	278, 2.1 [0.6, 4.2]	213, 2.1 [0.5, 4.5]
CRP (mg/L)	230, 4.4 [2.0, 13.0]	166, 4.0 [1.7, 12.0]
PsAID-12	287, 4.9 [3.0, 6.8]	221, 4.8 [2.9, 6.8]
HAQ - Standard disability index	289, 0.9 [0.4, 1.4]	223, 0.8 [0.4, 1.4]
Erosion score	74, 3.0 [1.0, 5.0]	46, 2.5 [1.0, 5.0]
Joint Space Narrow Score	197, 5.0 [2.0, 11.0]	141, 4.0 [1.0, 9.0]
Modified Sharp-van der Heijde score	238, 4.0 [0.0, 10.0]	181, 3.0 [0.0, 8.0]

Three hundred patients with a clinical diagnosis of PsA were recruited, and 66 patients were in an embedded trial of intensive medication, so 234 patients were analysed and received step-up T2T care. Data are n (%) for categorical variables and n, median (IQR) for continuous variables. Body Mass Index (BMI) categories are defined as follows: underweight: BMI<18.5/kg/m²; normal: BMI between 18.5 and 24.9 kg/m²; overweight: BMI between 25 and 29.9kg/m² and obese: BMI ≥30kg/m². BASDAI: Bath Ankylosing Spondylitis Disease Activity Index. BASFI: Bath Ankylosing Spondylitis Functional Index. cDAPSA: clinical DAPSA. DAPSA: Disease Activity in PsA. HAQ: Health assessment questionnaire. PASDAS: PsA Disease Activity Score. PASI: Psoriasis Area and Severity Index.PsA: psoriatic arthritis. PsAID: Psoriatic Arthritis Impact of Disease. SJC: swollen joint count. TJC: tender joint count.

Results: We recruited 300 patients, 197 with polyarticular PsA and 103 with oligoarticular (< 4 active joints) PsA from 18th April 2018 to 23rd August 2022. Sixty-six patients were in an embedded trial of intensive medication, so the analysis population consisted of 234 patients receiving step-up T2T care. At baseline, PsA was moderately active with a median PASDAS of 5.1 [4.1, 5.8] and a median DAPSA of 23.2 [16.0, 31.9], and 19.7% of patients had structural damage (**Table**). At 48 weeks, 77/234 patients (33.0%) were treated with methotrexate alone and 45/234 (19.0%) were treated with bDMARDs, mainly TNFi (38/45; 84.5%) (**Figure 2**). The proportion of patients achieving the PASDAS 'moderate' and 'good' responses at 48 weeks were 49/146 (33.6%) and 54/146 (37.0%), respectively. DAPSA remission and MDA were achieved in 35/107 (32.7%) and 70/147 (47.6%) patients at 48 weeks, respectively. 37/54 (68.5%) and 68/119 (57.1%) of patients achieved a

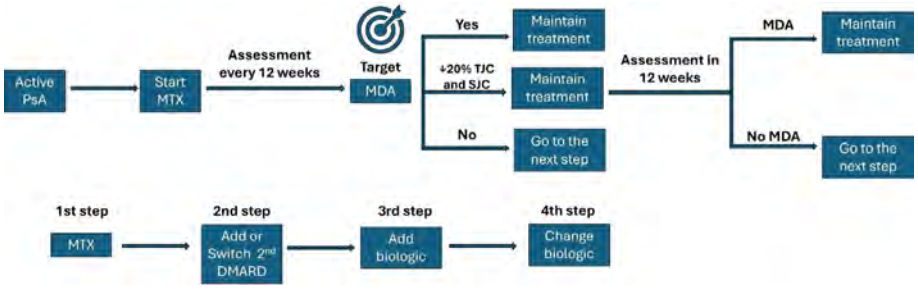

Figure 1 Treat to target strategy

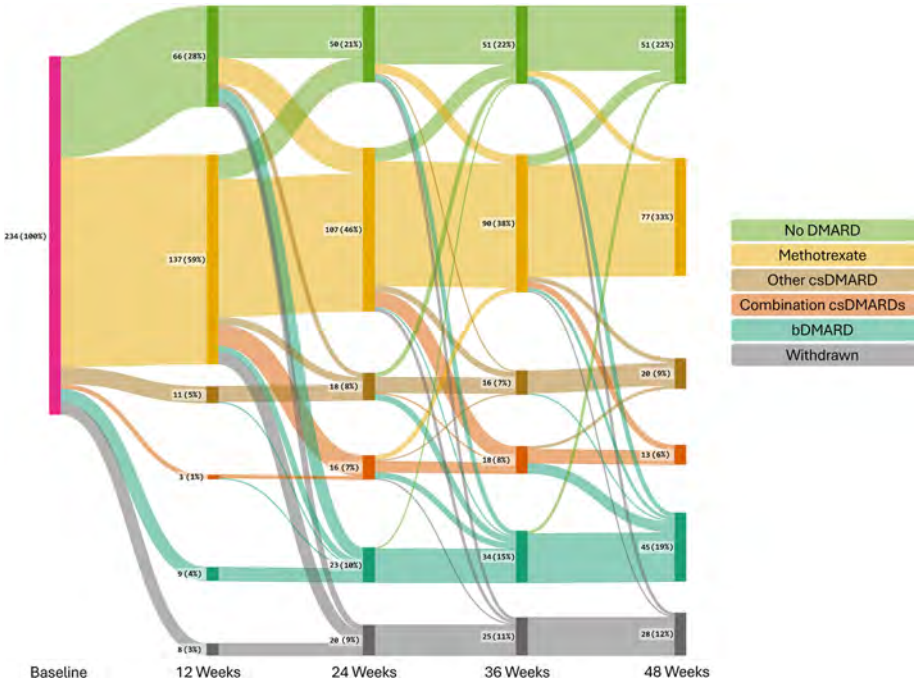

Figure 2 – Medication use in the MONITOR cohort

50% decrease in dactylitis and enthesitis counts, respectively. The majority of patients (117/168 or 69.6%) achieved PSAID patient acceptable symptom state (≤4). No structural progression was noted from baseline to 48 weeks.

Conclusion: In this pragmatic routine implementation of a T2T approach, we report results close to the T2T outcomes in the TICOPA trial (a PASDAS 'good' response, 37.0% vs 46% and or a PASDAS 'moderate' response 33.6% vs 33%), respectively MONITOR-PsA vs TICOPA), suggesting that a pragmatic T2T approach can be implemented with good outcomes in routine practice.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

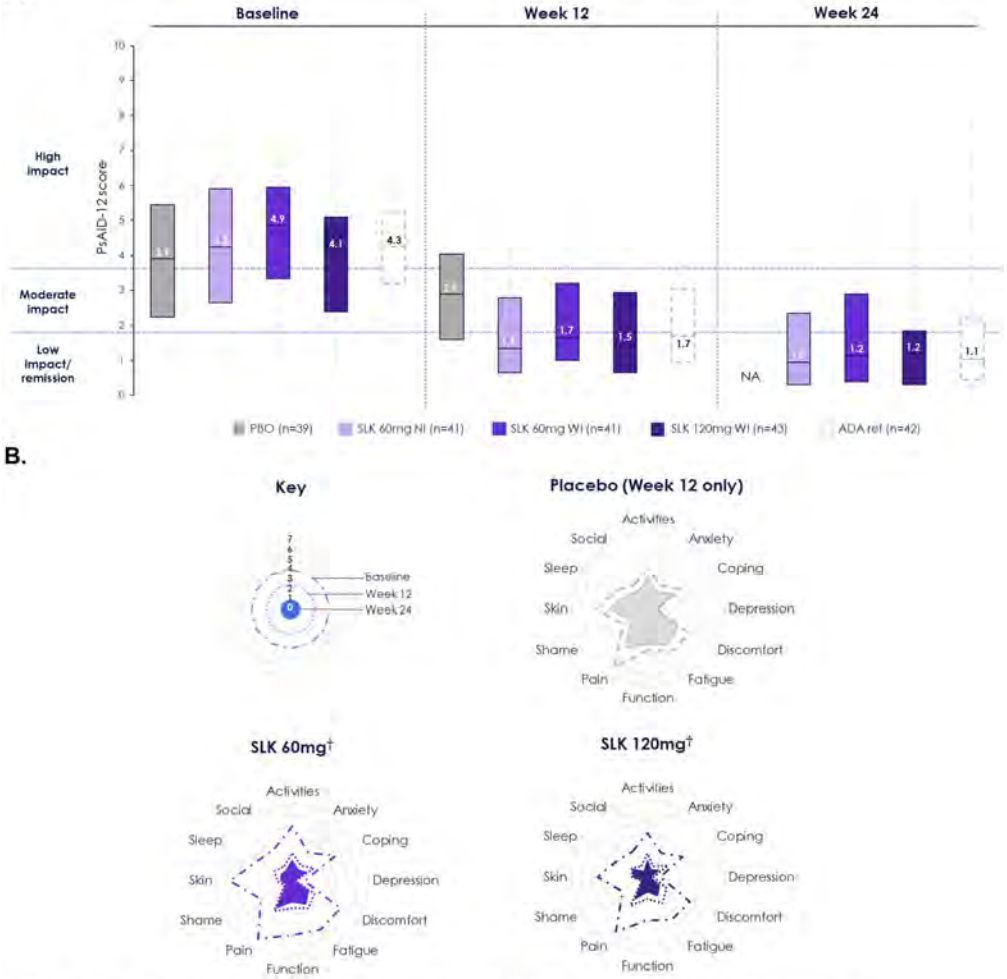
Background/Purpose: Sonelokimab (SLK) is a novel IL-17A- and IL-17F-inhibiting Nanobody designed to target difficult-to-reach sites of inflammation due to its small size and albumin-binding domain. The Phase 2 ARGO trial in patients with active PsA demonstrated the efficacy of SLK on both joint and skin outcomes (McInnes *et al*, EULAR 2024). SLK resulted in robust multidomain clinical responses that have been associated with improved QoL. We assess the effect of SLK on patient-reported outcomes (PROs) from ARGO.

Methods: ARGO (NCT05640245) was a 24-week, global, randomized, double-blind, placebo (PBO)-controlled trial that enrolled adults with active PsA. Patients were randomized to SLK 120mg Q4W (with induction [WI] doses at Weeks [W] 0, 2, 4, and 6), SLK 60mg Q4W WI, SLK 60mg Q4W with no induction (NI), PBO, or adalimumab 40mg Q2W (reference arm; not powered for statistical comparisons). W0–12 were PBO controlled, after which patients originally randomized to PBO switched to SLK 120mg NI; patients with < 20% improvement in SJC and TJC were reassigned treatment at W12 (except patients in the US who completed the study at W12). PROs including PsA Impact of Disease (PsAID)-12 (score range [SR] 0–10), Patient's Assessment of Arthritis Pain (PtAAP; SR 0–100), Patient's Global Assessment of Disease Activity (PGA; SR 0–100), and HAQ Disability Index (HAQ-DI; SR 0–3) were assessed Q4W until W24. Statistical comparisons vs. PBO were conducted at W12 using an MMRM analysis. Analyses at W24, and for patients with skin and joint responses, were observational.

Results: 207 participants were randomized. Patient-reported PsA symptom burden, as assessed by PsAID-12 score, is shown in **Figure 1A** (baseline median PsAID-12 total scores: 3.9–4.9). SLK resulted in significant improvements in PsAID-12 scores at W12, with mean improvements of 2.2–2.5 vs. 1.3 points with PBO (**Table**) and benefits across most individual domains (**Figure 1B**). Continued SLK treatment resulted in further improvements; most patients achieved PsAID-12 low impact (score >1.15–1.95) or remission (score ≤1.15) by W24 (median score: 1.0–1.2; **Figure 1A**). Improvements in PsAID-12 were pronounced (mean [SD] change from baseline [CfB] of –3.3 [1.9] points) in patients who achieved ACR50 + PASI 100, with a median score of 0.35 at W24 across pooled SLK arms. Significant improvements in pain by W12 were observed with SLK, with decreases in PtAAP scores of 30.1–30.9 vs. 18.8 points with PBO (**Table**). Improvements

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 1. (A) Change from baseline in PsAID-12 total score through Week 24* and (B) response across individual PsAID-12 items through Week 24



*Data show median (horizontal line), interquartile range (box), and minimum/maximum (whiskers). LOCF from Week 12 to 24 has been applied to patients who either switched treatment arm due to lack of response at Week 12 or completed the study at Week 12. All other missing data were imputed using LOCF. A score of ≤1.15 denotes remission/no symptoms/no impact, >1.15–1.95 denotes low symptom/impact severity, >1.95–3.60 denotes moderate symptom/impact severity, and >3.60 denotes high symptom/impact severity (Gossec *et al*, RMD Open 2024).
†With induction doses.
ADA ref, adalimumab reference; LOCF, last observation carried forward; NI, no induction; PBO, placebo; PsAID, Psoriatic Arthritis Impact of Disease; SLK, sonelokimab.

continued to W24, with mean CfB of –36.2 [–64.2%] to –40.0 [–65.6%] points with SLK. Significant improvements in patient-reported disease activity (PGA) scores by W12 were observed with SLK, with decreases of 27.8–31.9 vs. 18.7 points with PBO (**Table**). These improvements continued to W24, with a mean CfB ranging from –32.7 (–52.1%) to –39.7 (–35.6%) points. HAQ-DI scores improved through W24 (mean CfB at W24 of 0.47 [–47.4%] to 0.60 [–59.1%] points with SLK), although responses did not reach statistical significance vs. PBO at W12.

Conclusion: Patients treated with SLK in ARGO reported significant improvements in the symptoms and impact of PsA. Ongoing Phase 3 studies (IZAR-1: NCT06641076; IZAR-2: NCT06641089) will further assess the effect of SLK on PROs and QoL in larger patient populations.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: Psoriatic arthritis (PsA) affects up to one-third of patients with psoriasis;[1] early identification and intervention for patients with psoriasis and risk factors (RFs) for progression to PsA, or those screening PsA-positive, may reduce progression.[1]

Methods: Data were pooled from the BE VIVID (NCT03370133), BE SURE (NCT03412747), and BE READY (NCT03410992) phase 3 trials, their open-label extension (OLE) BE BRIGHT (NCT03598790), and the BE RADIANT phase 3b trial (NCT03536884; including its OLE).[2–6] Included patients received bimekizumab (BKZ) 320 mg every 4 weeks (Q4W) to Week 16, then Q4W or Q8W, and entered the OLE (BKZ Total). Data are also reported for the subset of patients who received BKZ Q4W to Week 16 then Q8W continuously (Q4W/Q8W).

Achievement of 100% improvement from baseline in Psoriasis Area and Severity Index (PASI 100) was evaluated through Year 3 (OLE Week 96) in patients with baseline nail involvement (modified Nail Psoriasis Severity Index [mNAPSI] >10), and in patients screening PsA-positive at baseline (Psoriatic Arthritis Screening and Evaluation [PASE] ≥47).

Patients with ≥3 RFs, including mNAPSI >10, scalp Investigator's Global Assessment ≥3, PASI ≥20, and BMI >30 kg/m^2, were also analyzed. [7–10]

Modified non-responder imputation was used: patients discontinuing due to lack of efficacy or treatment-related adverse events were considered non-responders; multiple imputation was used for other missing data.

Results: Among 1,107 BKZ Total patients, 377, 189, and 320 had mNAPSI >10, PASE ≥47, or ≥3 RFs, respectively. Among Q4W/Q8W patients (N=374), 129, 53, and 99 had mNAPSI >10, PASE ≥47, or ≥3 RFs, respectively.

At Week 16, 61.8%, 68.8%, and 59.7% of BKZ Total patients with mNAPSI >10, PASE ≥47, or ≥3 RFs achieved PASI 100, respectively, consistent with the overall BKZ Total population (65.5%). At Year 3, 68.6%, 63.5%, and 66.9% achieved PASI 100, generally consistent with 70.2% overall.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Responses were similar in Q4W/Q8W patients with mNAPSI >10/PASE ≥47/≥3 RFs at Week 16 (72.1%/69.8%/66.7%) and Year 3 (73.8%/66.3%/70.4%), consistent with Q4W/Q8W patients overall (Week 16/Year 3: 71.5%/74.0%).

Conclusion: Rates of complete skin clearance were high through Year 3 in BKZ-treated patients with psoriasis and PsA RFs at baseline, and those screening PsA-positive at baseline, consistent with the overall BKZ-treated group. These patients may benefit from highly effective psoriasis treatment, to help prevent progression in the long term.

Abstract Number: 0575

Why Do Some Psoriatic Arthritis Patients Fail Treatment? Exploring the Profile of D2T Patients

Laia De Daniel Bisbe[1], Jesús Rodriguez[2], Laura Berbel[3], Joan Miquel Nolla[1], Aina Fabregat[2], Monica Cubells[2] and Diego Benavent Nuñez[2], [1]Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, Spain, [2]Hospital Universitari de Bellvitge, Barcelona, Spain, [3]Hospital Universitari de Bellvitge, Barcelona, Catalonia, Spain

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Psoriatic arthritis (PsA) is a chronic inflammatory disease combining psoriasis (Pso) and arthritis. Despite the availability of multiple therapeutic options, many patients experience residual disease activity and fail to achieve remission or low disease activity. Similar to rheumatoid arthritis, where the concept of "difficult-to-treat" (D2T) has emerged, studies are exploring its application to PsA.

Methods: A retrospective analysis of patients with PsA followed during at least two years treated with at least one bDMARD between 2010 and 2024 at Bellvitge University Hospital was conducted. Patients were stratified into two groups (D2T-PsA vs. "Good Responders" (GR)). D2T was defined as failure to ≥1 conventional synthetic DMARD (csDMARD) and ≥2

Table 1. Comparison of demographic, clinical and therapeutical characteristics of good responders and D2T PsA patients

Variables	Good responders n=63	D2T n=40	p-value
Women (n,%)	30 (47.6)	21 (52.5)	0.688
Age, years, mean ± SD	58.1 ± 12.5	51.4 ± 12	**0.022**
Cardiovascular risk factors			
Smoker (ever) (n,%)	49 (78)	30 (75)	0.661
Hypertension (n,%)	17 (28)	12 (30)	1
Dyslipidemia (n,%)	26 (43)	17 (42.5)	1
Diabetes (n,%)	10 (17)	5 (12.5)	0.776
BMI (kg/m2), mean ± SD	26.2 ± 3.9	27.7 ± 6	0.206
PsA disease duration, year, median	15.7 ± 10.5	16.9 ± 10.9	0.730
Psoriasis duration, year, median	26.7 ± 13.5	27.8 ± 15	0.837
PsA types			
Axial involvement, n (%)	3 (5)	3 (8)	0.675
Polyarticular involvement, n (%)	31 (49)	18 (45)	0.683
Oligoarticular, n (%)	25 (40)	18 (45)	1
Distal interphalangeal, n (%)	26 (36)	10 (28)	0.516
Enthesitis, ever, n (%)	32 (52)	21 (52)	1
Dactylitis, ever, n (%)	28 (45)	14 (36)	0.410
Nail involvement, ever, n (%)	40 (68)	25 (68)	1
Serological features			
RF positivity, n (%)	6 (10)	4 (10)	1
Anti-CCP positivity, n (%)	3 (5)	0 (0)	0.262
HLA-B27 positivity, n (%)	4 (7)	4 (11)	0.707
Presence of fibromyalgia	5 (8)	12 (30)	**0.006**

ANA: antinuclear antibody; Anti-CCP: anti-cyclic citrullinated peptide; BMI: Body Mass index; D2T: Difficult-to-treat; RF: rheumatoid factor; PsA: psoriatic arthritis; HLA-B27: human leukocyte antigen B27; SD: standard deviation. n: number of patients.
Bold values are significant at $p<0.05$.

Table 2. Comparison of disease activity characteristics of good responders and D2T PsA patients

Variables	Good responders n=63	D2T n=40	p-value
DAPSA			
Before bDMARDs	28.59 ± 12.64	30.79 ± 9.73	0.628
After 6 months	11.08 ± 8.82	17.9 ± 8.40	**0.010**
After 12 months	7.31 ± 5.45	17.47 ± 13.96	**0.048**
PASI			
Before bDMARDs	9.47 ± 5.91	15.58 ± 8.45	**0.017**
After 6 months	3.2 ± 4.13	3.26 ± 3.85	0.967
After 12 months	0.98 ± 1.39	1.44 ± 2.16	0.530
CPR (mg/L)			
Before bDMARDs	8.91 ± 11.50	7.54 ± 7.09	0.824
After 6 months	5.15 ± 6.79	3.66 ± 6.17	0.142
After 12 months	2.76 ± 3.00	6.01 ± 8.36	0.416

ASDAS: Ankylosing Spondylitis Disease Activity Score; bDMARD: biologic disease-modifying antirheumatic drugs; CRP: C-reactive protein; DAPSA, Disease Activity Score for Psoriatic Arthritis; PASI: Psoriasis Area Severity Index

Bold values are significant at p<0.05. All values are expressed as mean and standard deviation

bDMARDs, and "GR" as those who failed to ≥1 csDMARD and <2 bDMARD that used during at least two years. Demographic, clinical, diagnostic, disease activity scores (including DAPSA, PASI) at baseline, 6 and 12 months, and therapeutic data were collected. Besides, bDMARDs number and reasons for their discontinuation were registered. Data were presented as frequencies and percentages for qualitative variables and as mean and standard deviation (SD) for quantitative variables. Chi-squared or Fisher's exact tests were used for the comparative analysis of qualitative variables, while the Student's t-test was applied to quantitative variables to identify differences between both groups.

Results: A total of 103 patients with PsA were included, of whom 40 (38.8%) were categorized as D2T. Clinical characteristics of both groups are shown in Table 1. While gender distribution was similar between groups (47.6 vs 51.5%), patients in the D2T group were significantly younger than the GR (p=0.022). Mean duration of Pso was around 28 years and PsA ranged 16-17 years in both groups. Cardiovascular risk factors did not differ between groups. Nonetheless, fibromyalgia (FM), as diagnosed by the rheumatologist, was more prevalent in the D2T group (p=0.006). No differences were observed in peripheral or extra-musculoskeletal manifestations, nail involvement, or serological features, including HLA-B27 positivity. Regarding disease activity, baseline DAPSA scores were similar between groups, while at 6 and 12 months post-bDMARD initiation, DAPSA scores were significantly higher in the D2T group than in GR (p=0.010 and 0.048, respectively). Baseline PASI scores were significantly higher in the D2T group at baseline (15.58 ± 8.45, p=0.017), although differences were not observed at 6 and 12 months. Tumour necrosis factor inhibitors were the most used bDMARDs in both groups. As seen in Figure 1, the most frequent reason for discontinuation was the primary inefficacy (52%) in the group of GR, while in the D2T group secondary inefficacy (40%) was the most frequent cause.

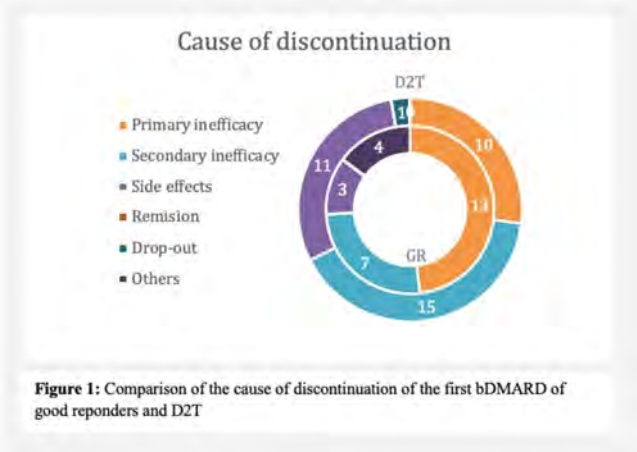

Figure 1: Comparison of the cause of discontinuation of the first bDMARD of good reponders and D2T

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Around one third of PsA patients requiring bDMARDs met D2T criteria. This subset was characterised by younger patients with higher disease activity, greater severity of Pso, and a higher prevalence of FM, while we found no differences in baseline activity by DAPSA or other variables.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: (0554–0592) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 10:30AM–12:30PM

Background/Purpose: FOREMOST (NCT03747939)[1] offers novel insights on early oligoarticular (oligo, ≤4 active joints) PsA. Our aim was to analyse progression to polyarticular (poly; >4 active joints) disease and predictors of progression in FOREMOST.

Table 1. Covariates included in multivariable regression of disease progression at Week 16 of the FOREMOST study

Covariate	Categories
Treatment	APR, PBO
Sex	Male, female
Age	<50 years, ≥50 years
BMI	<30 kg/m², ≥30 kg/m²
csDMARD use prior to FOREMOST	Yes, no
csDMARD use during FOREMOST	Yes, no
Baseline cDAPSA score	>4 to ≤13 (low disease activity), >13 to ≤37 (moderate disese activity)
Patient pain VAS	≤ median (=53), > median
Baseline HAQ-DI score	≤0.5 (remission/disease control), >0.5
Baseline PASS	Yes, no
Baseline PASDAS	<5.4 (low disease activity), ≥5.4
Baseline PtGA VAS	≤ 50, > 50
Baseline LEI	0 (no enthesitis), >0
Baseline SPARCC	0 (no enthesitis), >0
Baseline LDI	0 (no dactylitis), >0
Nail psoriasis at baseline	Yes, no

BMI, Body Mass Index; cDAPSA, clinical Disease Activity in PsA; HAQ-DI, Health Assessment Questionnaire Disability Index; LDI, Leeds Dactylitis Index; LEI, Leeds Enthesitis Index; PASDAS, Psoriatic Arthritis Disease Activity Score; PASS, Patient-Acceptable Symptom State; PtGA, Patient Global Assessment VAS; SPARCC, Spondyloarthritis Research Consortium of Canada; VAS, visual analogue score

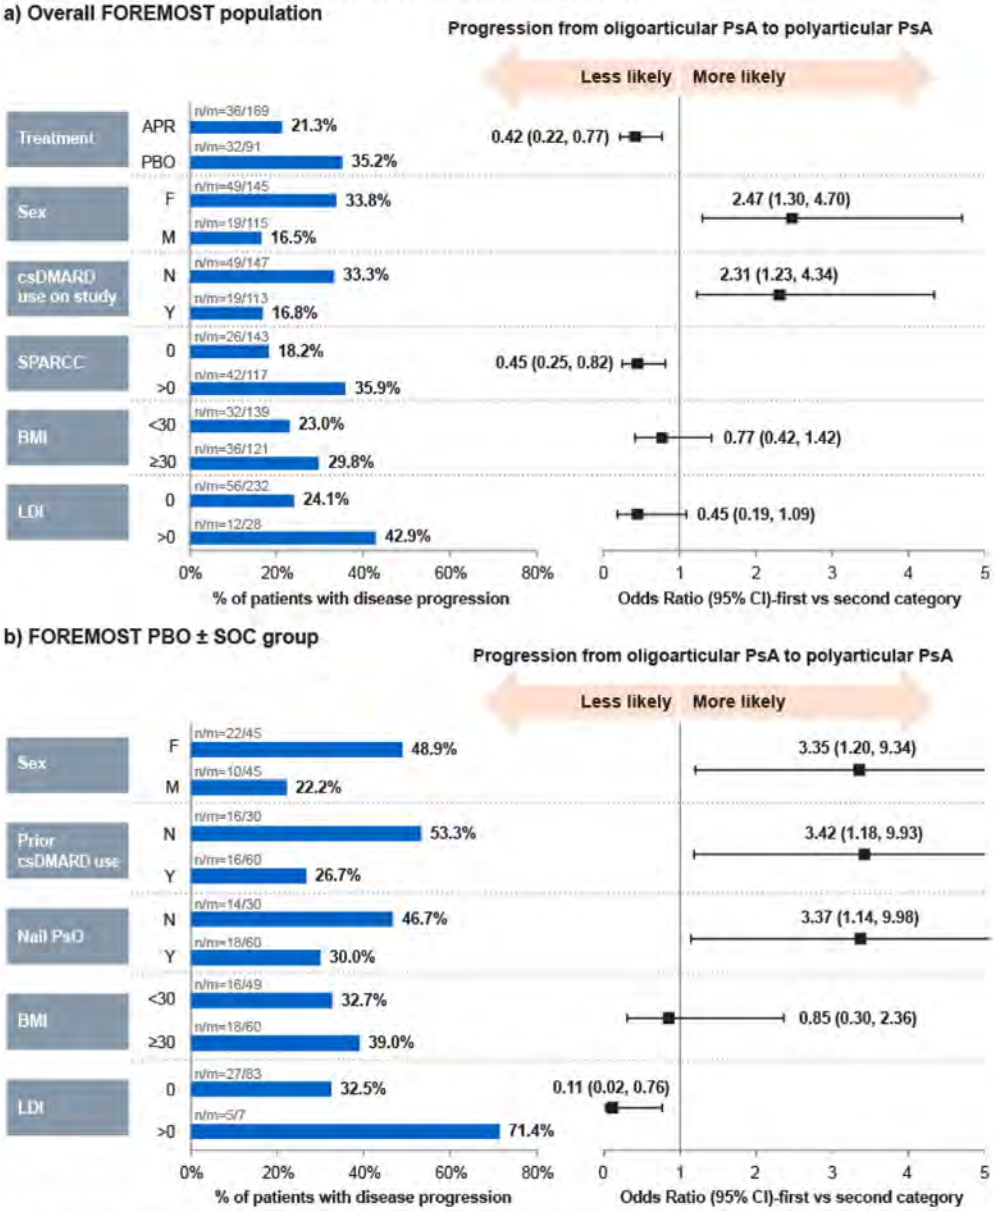
Methods: FOREMOST is a randomized trial of 308 patients with early (duration ≤5 years) oligo PsA and limited joint involvement (>1 to ≤4 swollen and >1 to ≤4 tender joints; 66–68 joints assessed) who received apremilast (APR) (n=203) or placebo (PBO) (n=105) for 24 weeks, with a primary outcome at 16 weeks[1]. Standard of care (SoC) NSAIDs and/or conventional synthetic (cs) DMARDs were permitted if taken at a stable dose through Week 24. Progression to poly disease was defined as changing from ≤4 active (swollen and/or tender) joints at baseline to >4 active joints at Week 16. In a post hoc, multivariable regression analysis, we assessed predictors of progression in the overall FOREMOST population and the placebo (PBO)±SOC group (as a surrogate for natural history). Variables of interest were selected on clinical relevance (Table 1) and backward selection used to identify statistically significant predictors of progression ($p < 0.05$ threshold); based on clinical relevance, body mass index (BMI) and enthesitis (Leeds index, LDI) were forced to remain in the model. Missing joint data were imputed using last observation carried forward.

Figure 2. Multivariable regression of disease progression



APR, apremilast; BL, baseline; BMI, Body Mass Index (kg/m²); csDMARDs, conventional synthetic disease modifying antirheumatic drugs; F, Female; LDI, Leeds Dactylitis Index; m, number of patients in category; M, Male; n, number of patients in category with disease progression; N, No; PBO, placebo; SPARCC, Spondyloarthritis Research Consortium of Canada; Y, Yes.

Results: In FOREMOST, most patients had ≤4 active joints at baseline (overall, 268/308 [87%]; APR, 176/203 [87%]; PBO ±SOC, 92/105 [88%]) and baseline characteristics were similar between APR and PBO±SOC[1]. In the overall population, APR was associated with statistically significant lower odds of progression *vs* PBO±SOC (Odds Ratio [OR] [95% CI], 0.42 [0.22, 0.77]; Fig 2a; adjustment for other covariates). After adjusting for treatment, being female (*vs* male), not receiving (*vs* receiving) csDMARDs during the study, and enthesitis (SPARCC >0; *vs* no enthesitis) were associated with statistically significantly higher odds of progression; patients with dactylitis (LDI >0) showed a non-significant trend towards higher odds of progression *vs* patients without dactylitis. In the PBO±SOC group, being female, being csDMARD-naive (*vs* prior csDMARD use), dactylitis (LDI > 0; *vs* no dactylitis), and not having nail psoriasis (*vs* having nail psoriasis) were associated with statistically significant higher odds of progression (Fig 2b).

Conclusion: Our data provides novel insights into factors driving progression from oligo to poly PsA, with female sex, enthesitis and dactylitis found to increase the risk of progression. These data may help clinicians identify patients with poor prognosis who require close monitoring and more intensive treatment. Among patients in FOREMOST receiving PBO, prior csDMARD use decreased the likelihood of progression more than three-fold. Compared with PBO±SOC, APR more than halved the likelihood of progression. These findings highlight the importance of early intervention in oligo PsA and the benefit of APR in delaying/preventing progression to poly disease. Our results should be validated using other PsA cohorts.
