Results: Of 332 participants initially randomized, 291 completed the main tx period and were randomized in the transition period (TVB-009/TVB-009, n=148; US-denosumab/US-denosumab, n=72; US-denosumab/TVB-009, n=71). In the transition period, comparable proportions of participants experienced tx-emergent adverse events (TEAEs) across the 3 tx groups (**Table 1**). One participant in the US-denosumab/TVB-009 group experienced a serious TEAE of cholelithiasis, which was mild and not related to the study drug. Five (3.4%) participants in the TVB-009/TVB-009 tx group experienced serious TEAEs that were unrelated to tx; none were reported in the US-denosumab/US-denosumab group. TEAEs reported in ≥5% of participants in either tx group were back pain (5.4% vs 2.8%), nasopharyngitis (2.7% vs 6.9%), and arthralgia (2.7% vs 5.6%) in the TVB-009/TVB-009 vs US-denosumab/US-denosumab groups, respectively. Notably, no TEAEs in ≥5% of participants were reported in the US-denosumab/TVB-009 group (**Table 1**). Similar proportions of participants in US-denosumab/US-denosumab and US-denosumab/TVB-009 were anti-drug antibody (ADA)-positive (7.1% vs 5.7%) and ADA-positive, not tx related (5.7% vs 1.4%; **Table 2**). None of the participants developed hypersensitivity reactions. The mean (standard deviation) percent change in LS-BMD from Week 52 to Week 78 was comparable between the US-

denosumab/US-denosumab and US-denosumab/TVB-009 groups (1.15 [3.44] and 1.24 [3.07]); similar trends were observed for femoral neck and total hip BMD.

Conclusion: Women with PMO who single-switched from reference US-denosumab to TVB-009 demonstrated a comparable safety, immunogenicity, and efficacy profile to those who remained on US-denosumab. Our results demonstrate that a single switch from reference denosumab to TVB-009 does not affect safety and efficacy in this population.

Comparing Immunogenicity Between TVB-009 and Reference Denosumab in Healthy Adults and Participants with Postmenopausal Osteoporosis

Karel Pavelka[1], **Frank Schneider**[2], Deepak S[3], Bracha Timan[4], Hadas Barkay[4] and Anton Buchner[2], [1]Institute of Rheumatology and Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, Prague, Czech Republic, [2]Teva GmbH, Ulm, Germany, [3]Teva Pharma India Private Limited, Bangalore, India, [4]Teva Pharmaceutical Industries Ltd., Netanya, Israel

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science (2591–2596)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: TVB-009 is being developed as a proposed biosimilar candidate to the reference denosumab. Denosumab is a human IgG2 monoclonal antibody that binds to the human receptor activator of nuclear factor kappa-B ligand to inhibit osteoclast formation and activation, thus reducing the risk of fracture in conditions such as osteoporosis. Biosimilarity of TVB-009 to US-licensed denosumab (US-denosumab) and EU-approved denosumab (EU-denosumab) was demonstrated in a 36-week Phase (Ph) 1 pharmacokinetic/pharmacodynamic (PK/PD) study, and no clinically relevant differences in efficacy or safety between TVB-009 and US-denosumab were demonstrated in a Ph 3 study (NCT04729621). The objective of our analysis was to demonstrate that there are no clinically meaningful differences in immunogenicity between TVB-009 and US-/EU-denosumab in the Ph 1 and Ph 3 (52-week main treatment period) studies.

Methods: In the Ph 1 study, healthy participants aged 28–55 years were randomized 1:1:1 to receive a single 60-mg subcutaneous injection of TVB-009, US-denosumab, or EU-denosumab on Day 1. In the Ph 3 main treatment period, postmenopausal women aged 60–90 years with a diagnosis of osteoporosis were randomized 1:1 to receive TVB-009 or US-denosumab on Day 1 and Week 26. Safety and immunogenicity were evaluated similarly in both studies. Blood samples for anti-drug antibody (ADA) testing were collected predose on Day 1 and throughout each study. All samples were screened for ADA using bridging ELISA; ADA-positive (ADA+) samples were then analyzed in a confirmatory assay, and confirmed samples were tested for antibody titer determination and neutralization potential.

Results: In the Ph 1 study, 345 participants were randomized and included in the safety population (n=115 per treatment group). In the Ph 3 study, 331 of 332 participants randomized in the main treatment period were included in the safety population (TVB-009, n=166; US-denosumab, n=165). Baseline characteristics were similar between treatment groups in both studies. In Ph 1, no ADAs against TVB-009 were observed, and therefore there was no impact on PK, PD, or safety related

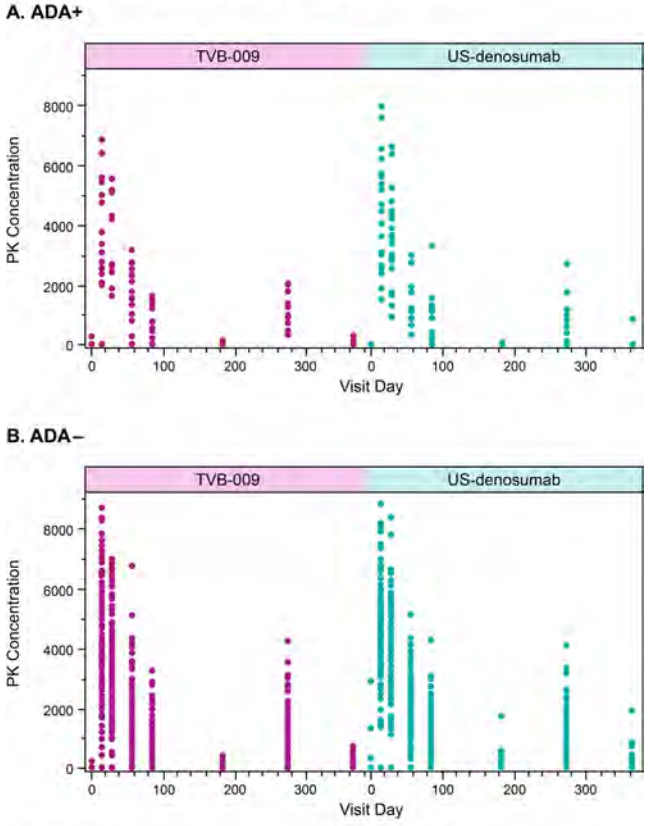
to ADA presence. In the Ph 3 main treatment period, a comparable proportion of participants on TVB-009 and US-denosumab were ADA+ (**Table 1**). One participant on TVB-009 and 2 participants on US-denosumab tested positive for neutralizing ADAs. However, ADA+ participants had a similar PD response as ADA-negative (ADA–) participants and experienced an increase in lumbar spine bone mineral density from baseline. Serum concentrations after TVB-009 and US-denosumab treatment showed high intersubject variability regardless of ADA presence, and the range of concentrations overlapped between ADA+ and ADA– participants for both treatment groups (**Figure 1**).

Figure 1. PK Concentrations in the Main Treatment Period of the Ph 3 Study by ADA Status for TVB-009 and US-denosumab in Women with Postmenopausal Osteoporosis: (A) ADA+ and (B) ADA–



ADA, anti-drug antibody; ADA+, ADA-positive; ADA–, ADA-negative; Ph, Phase; PK, pharmacokinetic.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Immunogenicity profiles of TVB-009 and US-denosumab were similar in healthy participants and women with postmenopausal osteoporosis, with no detectable impact of ADA or neutralizing ADA on PK, PD, efficacy, and safety, further confirming that there are no clinically meaningful differences between TVB-009 and the reference denosumab.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science (2591–2596)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Physical exercise helps maintain bone mineral density (BMD), prevent falls, and reduce fracture risk. Strength and weight-bearing exercises are particularly effective. However, individuals with inflammatory rheumatic diseases often face disease-related functional impairments that limit their ability to engage in such activities. The interactions between rheumatic diseases, exercise, and bone health remain underexplored.

This study aimed to assess the impact of different types of physical activity on BMD in patients with inflammatory rheumatic diseases.

Methods: We analyzed data from the Rh-GIOP cohort, a prospective observational study of patients with immune-mediated inflammatory diseases. Participants underwent dual-energy X-ray absorptiometry (DXA) and systematic bone health assessments. Self-reported physical activity was categorized as any exercise, weight-bearing, high-impact, and low-impact. Frequency-based classifications (strength, aerobic, balance training ≥65 years) followed WHO criteria.

Multivariable linear regression models assessed clinical, serological, and treatment-related predictors of lumbar spine and femoral T-score, trabecular bone score (TBS), and 3D-DXA-based femoral structure (3D-Shaper v2.12). Physical activity types were then added to these models. Missing data were handled via multiple imputation (10 replications).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: We included 1,870 patients (mean age 63 ± 13; 75% female, 90% postmenopausal) with rheumatoid arthritis (n=631), connective tissue diseases (n=424), vasculitides (n=274), and spondyloarthropathies (n=240). Median disease duration was 9.5 years (IQR 3.6–17.4). Regular exercise was reported by 63%; 59% performed low-impact, 52% weight-bearing, 34% aerobic, 23% strength, and 18% high-impact activities.

Positive associations with lumbar spine T-score were found for weight-bearing (+0.16 [0.02;0.30], p=0.03), high-impact (+0.27 [0.09;0.45], p=0.003), strength (+0.19 [0.02;0.37], p=0.033), and balance training (+0.002 [0.00;0.04], p=0.013). Only high-impact activity was associated with femoral T-score (+0.16 [0.03;0.28], p=0.017). TBS at the spine was positively linked to weight-bearing exercise (+0.018 [0.003;0.033], p=0.022). High-impact activity was associated with femoral trabecular parameters (+4.62 [0.22;9.02], p=0.040), while endurance training benefited cortical structure (+0.01 [0.00;0.03], p=0.049). Trends toward benefit were observed for strength, weight-bearing, and low-impact activities. No exercise type was negatively associated with bone outcomes.

Conclusion: In patients with inflammatory rheumatic diseases, mechanical loading activities such as weight-bearing, strength, and high-impact exercises are most beneficial for improving BMD and microarchitecture. These findings support the development of tailored exercise programs based on individual capabilities to optimize bone health. Longitudinal studies with fracture outcomes will further clarify long-term benefits.

Abstract Number: 2596

Predicting Osteoporosis Using Routine Clinical Data: A Machine Learning Approach

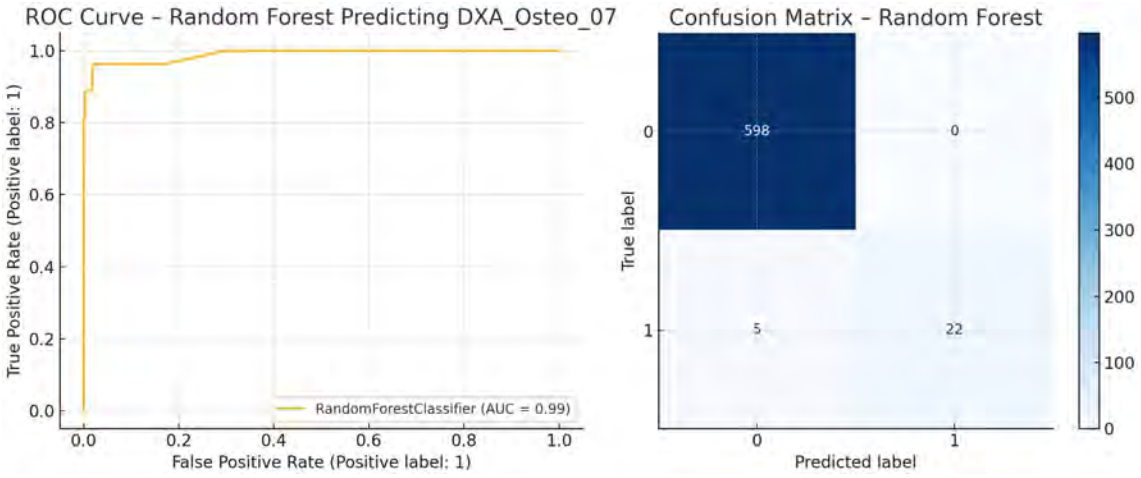
Shiza sarfraz and Hassam Ali, East Carolina University Brody School of Medicine, Greenville, NC

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science (2591–2596)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Dual-energy X-ray absorptiometry (DXA) is the gold standard for diagnosing osteoporosis but is underutilized due to access, cost, and referral barriers. We aimed to develop and evaluate a machine learning model to predict DXA-defined osteoporosis using only non-imaging clinical and lifestyle variables available in routine care.

Methods: Data were drawn from the 2021–2022 National Health and Nutrition Examination Survey (NHANES(. Adults ≥20 years with complete DXA data (femoral and spine bone mineral density [BMD]) and clinical/laboratory variables were included. Osteoporosis was defined as minimum BMD < 0.7 g/cm^2 at either site. Predictors included demographics (age,

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Model Performance in Predicting DXA-Defined Osteoporosis. ROC curve (left) shows excellent discrimination (AUC = 0.99), and the confusion matrix (right) confirms strong sensitivity and perfect specificity using non-DXA features.

sex, race/ethnicity), anthropometrics (BMI, waist circumference), lifestyle (smoking, alcohol, physical activity), diet (calcium, vitamin D intake), biomarkers (serum vitamin D, CRP, cholesterol), and weight change. DXA variables were excluded from predictors. A random forest classifier was trained on a 70% split and evaluated on a 30% held-out test set. Logistic regression using the same inputs served as a comparator.

Results: Among 2,083 eligible adults, 90 (4.3%) met the DXA-defined osteoporosis threshold (minimum BMD < 0.7 g/cm^2 at spine or femur). The random forest model, trained without DXA data, achieved an AUC of 0.99 on the test set (n=625), with sensitivity of 81.5%, specificity of 100%, and F1-score of 0.90. Model accuracy was 99.2%, and all predicted positives were true positives (PPV: 100%). In contrast, logistic regression using the same features yielded an AUC of 0.87, but failed to reliably detect positive cases (sensitivity: 11.1%, F1-score: 0.18). The random forest model identified age, BMI, serum vitamin D, CRP, smoking history, physical activity, and calcium intake as the most influential predictors (Figure 2). Feature importance analysis revealed strong nonlinear effects of inflammatory and nutritional biomarkers, alongside classical osteoporosis risk factors. Notably, the model detected subtle combinations of risk even in participants without overt clinical suspicion. ROC and confusion matrix plots demonstrated excellent calibration and discrimination (Figure 1).

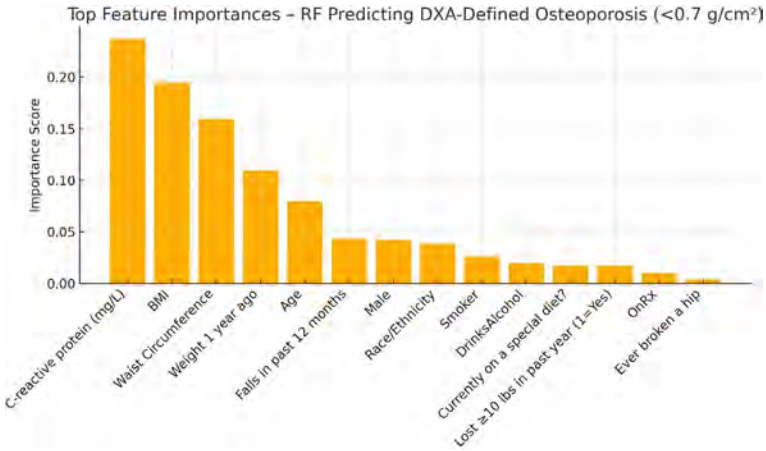


Figure 2. Top Predictors of DXA-Defined Osteoporosis. Feature importance plot from the random forest model highlights age, BMI, vitamin D, CRP, smoking, and physical activity as leading contributors.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: A random forest model using non-imaging data accurately identified individuals with DXA-defined osteoporosis, outperforming traditional regression approaches. This approach may assist in screening and triage, particularly in settings where DXA access is limited or underused.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Systemic Lupus Erythematosus – Etiology and Pathogenesis (2597–2602)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Patients with neuropsychiatric systemic lupus erythematosus (NPSLE) experience impaired quality of life, whereas the underlying cause(s) remain unclear. The heterogeneity within NPSLE subtypes poses challenges for diagnosis, treatment, and research into disease pathogenesis[1]. While altered tryptophan metabolism has been reported in SLE[2], this study focuses on measuring tryptophan metabolites in specific NPSLE patients to identify clinically relevant subgroups.

Methods: Serum levels of tryptophan (TRP), kynurenine (KYN), and serotonin were measured by ELISA in two independent cohorts. The Peking Union Medical College Hospital (PUMCH) cohort included patients with NPSLE (n=46), lupus nephritis (LN, n=15), SLE without major organ involvement (WMOI, n=30), and healthy controls (HC, n=45). The University of Washington (UW) cohort consisted of patients with NPSLE (n=9), non-NPSLE (n=10), and HC (n=20). IDO activity was assessed indirectly via the KYN/TRP ratio. Unsupervised hierarchical clustering was performed using R4.4.0 and the cluster quality was assessed using the Hopkins's statistic. Statistical analysis utilized Mann-Whitney U tests and Spearman's correlation.

Results: TRP metabolite patterns were similar between two cohorts. TRP and serotonin levels were significantly decreased in NPSLE compared to WMOI and HC (Figs. 1, 2A-B), while KYN/TRP ratios were significantly elevated in NPSLE compared to non-NPSLE and HC (Figs. 1, 2C-D). Lower serotonin levels were correlated with higher SLE disease severity and activity (Figs. 2E-F). Clustering of 13 neuropsychiatric symptoms and 4 tryptophan metabolism biomarkers yielded three distinct patient subgroups (Hopkins=0.757). Cluster 1 (n=26) was characterized by the highest prevalence of seizure, cerebrovascular disease, and headaches, alongside the lowest KYN levels and KYN/TRP ratio. Cluster 2 (n=7) exhibited markedly elevated KYN and KYN/TRP ratio and high rates of cognitive impairment, psychosis, and delirium, accompanied by decreased TRP and serotonin levels. Cluster 3 (n=4) featured myelopathy, demyelination, and cranial neuropathy symptoms with the highest KYN levels and increased KYN/TRP ratios, combined with reduced serotonin levels.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Serum levels of tryptophan metabolites and correlations between serotonin and clinical scores in patients from PUMCH cohort. Serum levels of (A) Tryptophan; (B) Serotonin; (C) Kynurenine; (D) the Kynurenine/Tryptophan ratio were analyzed in patients with Neuropsychiatric Systemic Lupus Erythematosus (NPSLE, n=46), lupus nephritis (LN, n=15), SLE without major organ involvement (WMOI, n=30), and healthy controls (HC, n=45). Correlations between serotonin and (E) Physician Global Assessment (PGA) total scores; (F) Systemic Lupus Erythematosus Disease Activity Index (SLEDAI). For statistical analyses, *p<0.05, **p<0.01, ***p<0.001, **** p<0.0001.

Conclusion: Our study is the first to classify NPSLE into three main subgroups based on differential expression of tryptophan metabolites, which simultaneously influence the mental health, nervous, and immune systems[3]. Variations in biomarker profiles among subgroups can inform clinical diagnosis and treatment strategies. Further studies are needed to determine whether subtypes within each subgroup share similar pathogenic mechanisms.

Keratinocyte-Secreted Leukemia Inhibitory Factor Counteracts Type I IFN-Induced Antigen-Presenting Phenotype in Melanocytes: Utility in Cutaneous Lupus Skin

Rezvan Moallemian[1], Lin Zhang[2], Mehrnaz Gharaee-Kermani[1], Rachel Holle[3] and J. Michelle Kahlenberg[1], [1]University of Michigan, Ann Arbor, MI, [2]Michigan Medicine, Ann Arbor, MI, [3]University of Michigan, Ann Arbor

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Systemic Lupus Erythematosus – Etiology and Pathogenesis (2597–2602)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Current therapies for cutaneous lupus erythematosus (CLE) are limited, highlighting the need for novel approaches. CLE lesions commonly exhibit photosensitivity and heightened type I interferon (IFN) activity. Persistent type I IFN exposure amplifies the inflammatory response of keratinocytes (KCs) to ultraviolet (UV) radiation, triggering further IFN production and worsening skin lesions. Interactions between KCs and other skin cells, such as melanocytes, are key to modulating inflammation and providing protection against environmental stressors. In this study, we investigated novel regulatory pathways between KCs and melanocytes.

Methods: We performed single-cell RNA sequencing (scRNA-seq) to characterize gene expression in melanocyte populations derived from skin biopsies of systemic lupus erythematosus (SLE) patients and healthy individuals, both with and without UV exposure. To investigate keratinocyte–melanocyte interactions, primary keratinocytes were treated with UV radiation, IFN-α, or a combination of both. The resulting conditioned media were applied to primary melanocytes along with specific inhibitors targeting JAK1 (Baricitinib), STING (H151), or cGAS (G140). MHC class II and pro-inflammatory cytokine expression in melanocytes were assessed via RT-qPCR. In parallel, cytokine profiles of the keratinocyte supernatants were analyzed using the Luminex Human Discovery Assay to identify soluble factors that may contribute to melanocyte activation.

Results: Analysis of single-cell RNA sequencing data identified leukemia inhibitory factor (LIF) as a key upstream regulator in SLE keratinocytes, with elevated LIF expression observed in primary keratinocytes. Supernatants from UV-treated keratinocytes induced upregulation of antigen-presenting markers in melanocytes in a JAK1-dependent manner. Given that LIF signals through the LIF receptor to activate the JAK-STAT pathway, we hypothesized that LIF would promote inflammatory responses in melanocytes. Unexpectedly, however, the addition of LIF to keratinocyte supernatants significantly reduced MHC-II expression in primary melanocytes.

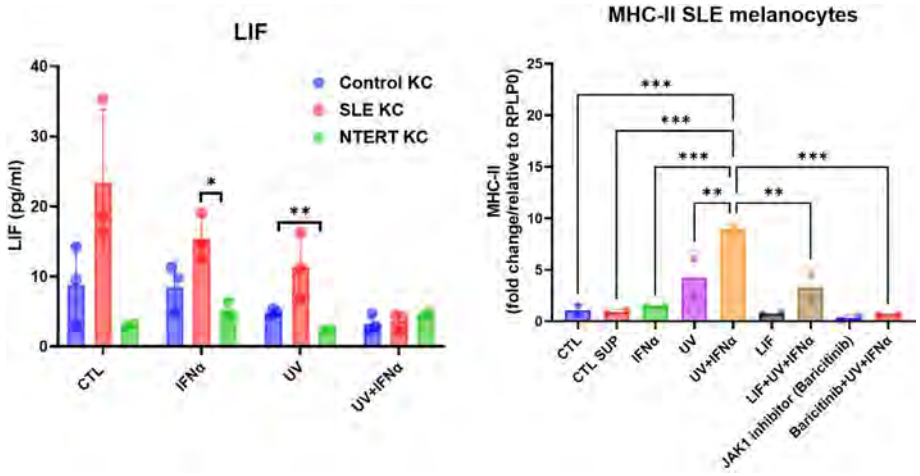

Figure 1. LIF attenuates MHC-II expression in melanocytes stimulated with UV/IFN-α–treated keratinocyte supernatants. (a) Primary keratinocytes from healthy controls (HC), SLE patients, and NTERT KC cells were exposed to IFN-α, UV, or UV+IFN-α. LIF levels in the supernatants were quantified using the Luminex Human Discovery Assay. SLE keratinocytes showed a significant reduction in LIF secretion following UV+IFN-α treatment. (b) Primary melanocytes were stimulated with keratinocyte-conditioned media from the indicated treatments. Supernatants from UV+IFN-α–treated KCs strongly induced MHC-II expression in melanocytes, which was significantly reduced by the addition of LIF (250ng/ml) or JAK1 inhibitor (5uM). MHC-II levels were measured by RT-qPCR. *P ≤ 0.05, **P ≤ 0.01, **P ≤ 0.001.

Conclusion: Melanocytes isolated from SLE lesions exhibit abnormal features, including heightened type I interferon exposure and upregulation of MHC class II molecules. Our data suggest that type I IFNs drive this upregulation and may shift melanocyte function away from pigmentation and keratinocyte support toward immune activation. Importantly, we show that the addition of LIF or JAK1 inhibitor significantly suppresses MHC-II expression in melanocytes, revealing potential regulatory pathways that may limit aberrant immune activation in CLE. Cytokine profiling confirmed that LIF is actively secreted by keratinocytes and modulated in inflammatory conditions. These findings support a model in which LIF acts as a brake on IFN-driven immune activation, a function that may be compromised in lupus skin, contributing to aberrant immune activation. Ongoing studies aim to further define the role of LIF in CLE.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Systemic Lupus Erythematosus – Etiology and Pathogenesis (2597–2602)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: This study aims to:

1- Characterize the circulating metabolomic signature in APS patients; 2- Investigate the role of hepatic involvement in the pathophysiology of APS; 3- Evaluate the direct effects of aPLs on the metabolism of hepatic cells *in vitro*; 4- Examine the short-term impact of ubiquinol (reduced CoQ_{10}) supplementation both *in vivo* and *in vitro* on the disrupted liver–metabolome axis.

Methods: Serum metabolomic profiling of 129 primary APS patients and 43 healthy donors (HDs) was performed using nuclear magnetic resonance (Nightingale), quantifying over 250 metabolites. Longitudinal changes were assessed in a subgroup of 15 APS patients who received ubiquinol supplementation for one month (clinical trial NCT02218476). The involvement of liver function was explored *in vivo* and *in vitro*. Correlations between circulating metabolites, liver-related biomarkers, and aPLs were carried out. *In vitro*, HepG2 cells were treated with purified aPLs, and their functional responses were assessed (Seahorse XF Palmitate Oxidation Stress Test Kit, WB, RT-PCR), both alone and in combination with CoQ_{10}.

Results: Metabolomic profiling revealed 53 significantly altered metabolites in APS patients including decreased atheroprotective lipids (HDL-related lipids) and elevated pro-atherogenic mediators (VLDL, LDL). These alterations were associated with arterial thrombosis, atheroma plaques, and recurrent thrombotic events. Evidence for liver involvement was supported by significant correlations between circulating metabolites, liver transaminases, FIB-4 index, and aPL levels.

In vitro studies reinforced the hypothesis of liver involvement. Exposure of HepG2 cells to purified aPLs increased the secretion of LDL and VLDL and upregulated hepatic injury markers. Functional metabolic assays demonstrated enhanced fatty acid oxidation under metabolic stress, accompanied by increased pACC1/ACC1 ratio and ACAA2 expression. This metabolic shift may promote triglyceride synthesis and facilitate the export of proatherogenic VLDL particles.

Moreover, in APS patients, ubiquinol supplementation partially corrected the altered lipidomic profile by decreasing pro-atherogenic and increasing anti-atherogenic markers. *In vitro*, pre-treatment of hepatocytes with CoQ_{10} effectively prevented the liver alterations induced by aPLs exposure.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: 1- APS patients display a distinct pro-atherogenic serum metabolomic profile
2- Liver involvement in APS is supported by clinical correlations and *in vitro* evidence showing that aPL promote hepatocyte dysfunction, induce metabolic reprogramming and enhance atherogenic lipid export.
3- Ubiquinol supplementation mitigates metabolic and hepatic disturbances in APS both *in vivo* and *in vitro*,
These findings reveal a novel liver–metabolism–autoantibody axis in APS, which appears to be attenuated by ubiquinol supplementation.

Deconstructing Lupus Nephritis Kidney Tissue at Single-Cell Resolution

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Systemic Lupus Erythematosus – Etiology and Pathogenesis (2597–2602)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Lupus nephritis (LN) is a heterogeneous disease driven by diverse immune and tissue cell types. We defined the cell states in the tissue and blood and tested their association with histopathological indices.

Methods: We obtained 538K single-cell and 143K single-nuclear profiles from kidney biopsies of 156 LN patients and 30 controls from pre-implantation transplant biopsies. We also obtained 327K single-cell blood profiles from a subset of 119 cases and 19 controls (**Figure 1**). All LN patients were >18 years, had urine protein/creatinine ratio >0.5 at biopsy, and were International Society of Nephrology (ISN) class III, IV, V, or combined III or IV with V.

Results: We built an atlas of kidney tissue cell types in LN encompassing 55 immune and 36 tissue states. Integrating tissue immune single cell data with blood data enabled classification of tissue-specific immune cell states (**Figure 2**). For example, we identified autoimmune-associated B cells (ABCs, B5) as a cell state shared between tissue and blood while plasma cell populations (P6-8) were tissue-specific. In the myeloid compartment, we identified plasmacytoid dendritic cells (DC20) as a shared population, while macrophage cell states were tissue-specific (M5-14).

Using Covarying Neighborhood Analysis, we identified LN pathological features associated with cell state changes (**-Figure 3**). Increasing chronicity tracked with the most dramatic changes in both tissue and immune states. The proportion of proximal tubule cells that were injured or degenerating (PT0, PT7) expanded with chronicity, reflecting ongoing, irreversible tissue damage. Increasing chronicity was associated with an expansion of tissue-specific CD56 bright NK cells (NK1), GPNMB^{high} NUPR1^{high} Macrophages (M5), and CLEC10A^{low} cDC2 (DC17). Most expanded immune populations were tissue-specific states.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

It was essential to identify activity-associated populations since they may be driving reversible inflammation in LN. Adjusting away chronicity, we identified specific activity-associated cell states in the myeloid compartment. Highly tissue-specific macrophage populations were expanded, including M5, *GPNMB*^{high} *LYVE1*^{low} (M11), *C1Q*^{low} *SPP1*^{high}, SPP1^{high} FABP5^{high} (M7), and MERTK^{high} FABP5^{high} (M9). We speculate that M5 may be a profibrotic pathogenic population that may be targeted for therapeutic benefit.

After adjusting for chronicity and activity, ISN classes were not independently associated with specific changes in cell states. Blood cell states minimally associated with activity or chronicity. We observed case-status associated with interferon signatures in both blood and tissue.

Conclusion: Our results define key cell states in the tissue and immune compartments and argue that profound changes in kidney tissue and immune cell states are associated with increasing chronicity. Specific myeloid compartment changes are associated with activity. These features are not associated with substantial changes in the blood. Our results argue that myeloid populations may be targeted, in addition to B cell therapies, to prevent progression of tissue inflammation and ongoing tissue damage in LN.

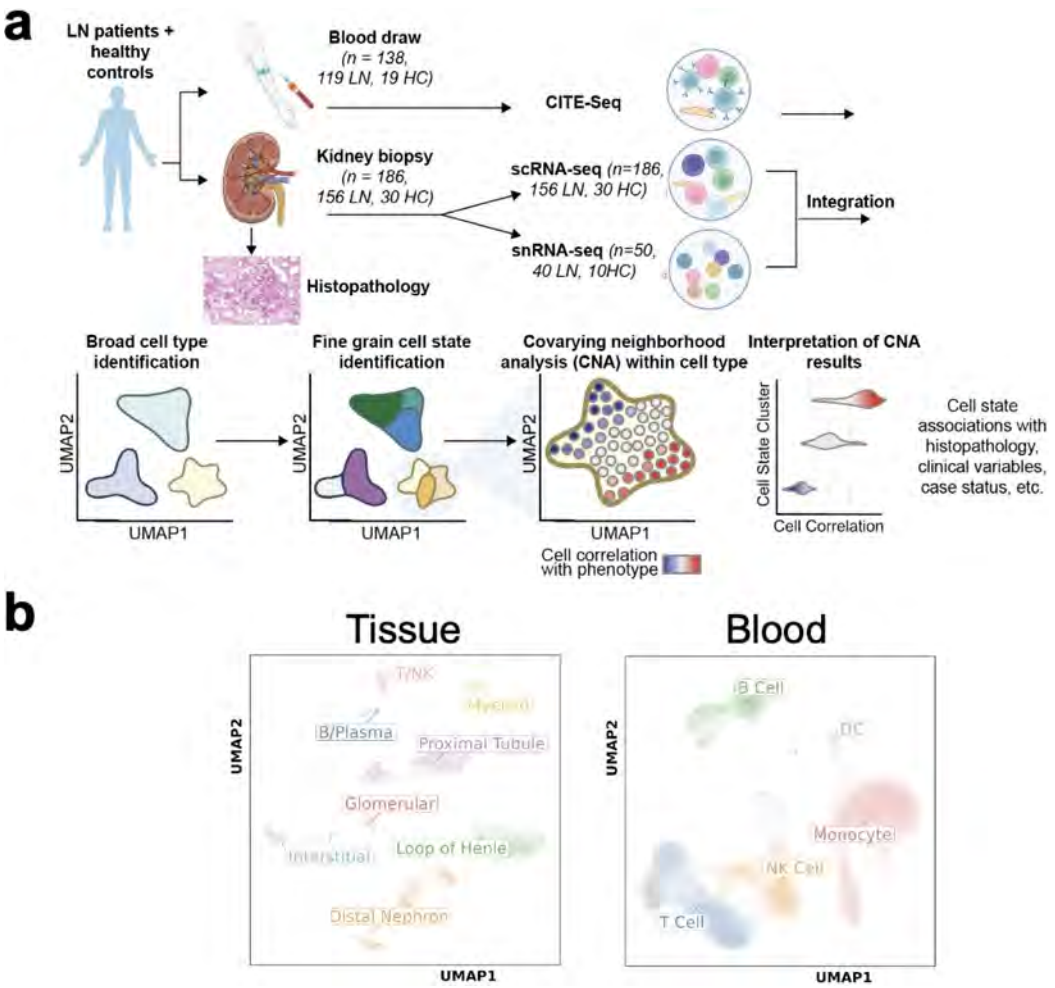

Figure 1. a, Schematic overview of the data collection and analysis pipeline. Blood and kidney samples were collected from LN patients and healthy controls (HC). Histopathology and clinical scoring was performed on renal biopsies. CITE-sequencing was performed on blood samples, and scRNA-sequencing and snRNA-sequencing were performed on tissue samples. Both tissue modalities were integrated with Harmony (PMID: 31740819). Broad cell types were annotated separately in tissue and blood. Fine grain clustering for cell state annotation was performed on each broad cell type. For each tissue, covarying neighborhood analysis was performed within each cell type to define cell state associations with various clinical variables. b, UMAPs of all single cell or single nuclear annotations in tissue (left) and blood (right), colored by broad cell type annotation.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Background/Purpose: Systemic lupus erythematosus (SLE) is characterised by innate immune activation and autoantibodies against nucleic self-antigens. The metabolic state of immune cells is emerging as a critical checkpoint of their effector functions, including proliferation, activation, secretion of cytokines, and escalation of inflammation. Previously described transcriptomic data suggested significant alterations in the metabolic profile of SLE immune cells, but there is lack of single-cell data confirming the changes at the protein level. The aim of this study was to create a detailed single-cell immunometabolic map in different stages of lupus disease activity and in ANA-positive individuals at risk of SLE.

Methods: Blood samples were obtained from patients from high disease activity SLE (n = 20), low disease activity SLE (n = 20), primary Sjogren's Syndrome (n = 7), Rheumatoid Arthritis (n = 8), age- and sex-matched healthy donors (n = 20), and at-risk individuals before (n = 23) and after (n = 23) developing SLE. SLE patients met 2012 SLICC classification criteria and disease activity was evaluated using BILAG-2004. Cryopreserved human peripheral blood mononuclear cells (PBMCs) were thawed and subsequently stained with 50 distinct heavy metal-conjugated antibodies before they were processed by mass cytometry (CyTOF). Raw data were normalised using CyTOF software and were subsequently debarcoded using Premessa R package. Clustering, differential abundance, and differential expression was performed by using FlowSOM R package incorporating key clinical and immunological parameters in the data analysis.

Results: Principal analysis identified 36 distinct cellular components (B cell and T cell subsets, monocytes, NK cells, myeloid and plasmacytoid dendritic cells) and 6 key metabolic pathways (glycolysis, OxPHOS, PPP, TCA & ETC, fatty acid metabolism, amino acid metabolism). Cellular composition was significantly different among the patient groups with plasmablast expansion being a key element within the high disease activity SLE and the at-risk individuals who progressed to SLE. There were significant differences in the expression of the metabolic enzymes among different cellular components within the same individual; for instance, monocytes appeared more metabolically active compared to B cell populations. Patients with established autoimmune disease (e.g. SLE and primary Sjogren's syndrome) were characterised by changes in several metabolic enzymes, mainly in glycolysis and OxPHOS pathways. These metabolic changes were correlated with differences in disease activity of SLE patients. Cellular and metabolic changes were observed in at-risk individuals highlighting an early immunometabolic reprogramming prior to the development of clinically overt autoimmune disease.

Conclusion: We identified immunometabolic changes at the single cell level, which can influence immune function, associated with disease activity in SLE and related diseases. Further, this immunometabolic reprogramming preceded clinically overt SLE or therapy suggesting a fundamental role in pathogenesis. Future analysis will explore the effect of these changes on longitudinal immune function and clinical status.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Systemic Lupus Erythematosus – Etiology and Pathogenesis (2597–2602)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex autoimmune disease with unknown etiology. While we previously identified key gene signatures of SLE using bulk RNA-seq from 27 immune cell types (*Cell* 2022), we failed to identify more granular disease-relevant cell states within each cell type. Although single-cell RNA-seq (scRNA-seq) can address this problem, recent studies ended up defining ~20 coarse cell types and relied on cell-type-level pseudo-bulk analysis, which has hindered the discovery of new drug targets. Our in-depth investigation strategy for single-cell data, cellular and molecular fine mapping, aimed to identify new disease-relevant cell states in SLE and to perform a detailed functional characterization of them.

Methods: We applied our strategy to the largest-scale single-cell data of SLE with ~1.8 million peripheral blood mononuclear cells from 97 healthy controls and 191 SLE cases (Figure 1). We identified granular cell states that expanded in SLE (cellular fine mapping) and investigated their molecular profile using in silico and experimental approaches (molecular fine mapping).

Results: After we identified 118 granular cell states in 25 cell types with fine-grained clustering, we discovered that previously uncharacterized cell states such as *FAM13A*$^{+}$*ARID5B*$^{+}$ naive CD4^{+} T cells, *ARHGAP15*$^{+}$*CAMK4*$^{+}$ T cells, *GZMK*$^{+}$*GZMH*$^{+}$*HLA-DR*$^{+}$ effector memory CD8^{+} T cells, and *C1Q*$^{+}$ monocytes, expanded especially in clinically active SLE (covarying neighborhood analysis, Figure 2).

Next, our new statistical model, which can decompose conventional pseudobulk-level differential expression into cell state abundance signature genes (quantitative change) and dysregulated signature genes (qualitative change) at single-cell level, showed that classical immunological pathways were more enriched in cell state abundance signature genes rather than dysregulated signature genes. Integrative analysis using genome-wide association studies (SLE-GWAS) with sc-linker pipeline also revealed that SLE polygenic signals were more linked to cell state abundance signature genes, suggesting that these expanded cell states can exert causal effects on SLE pathogenesis.

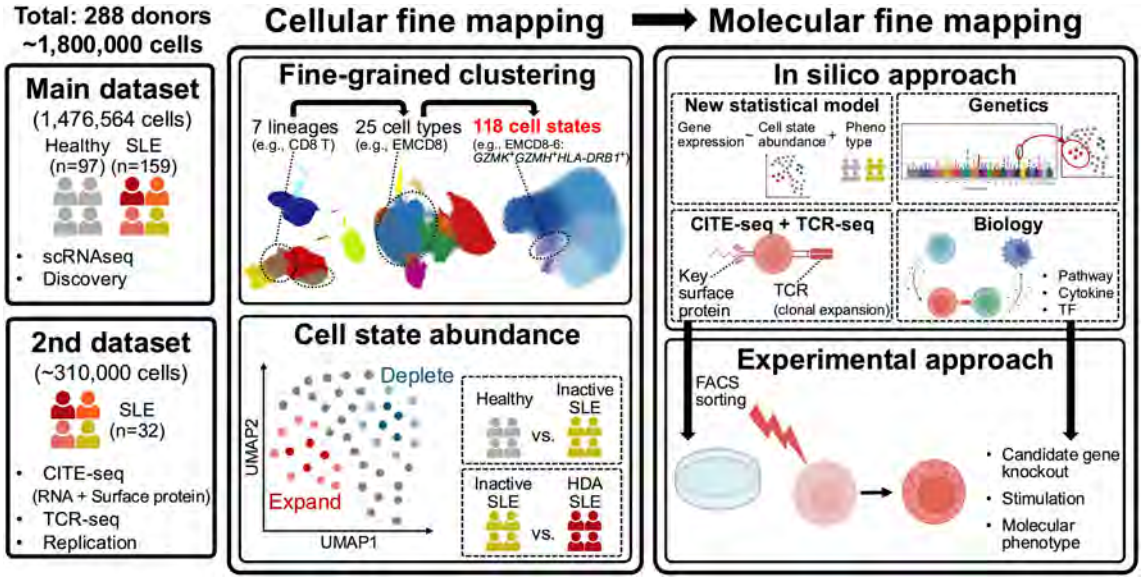

Figure 1. Overview of this study

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

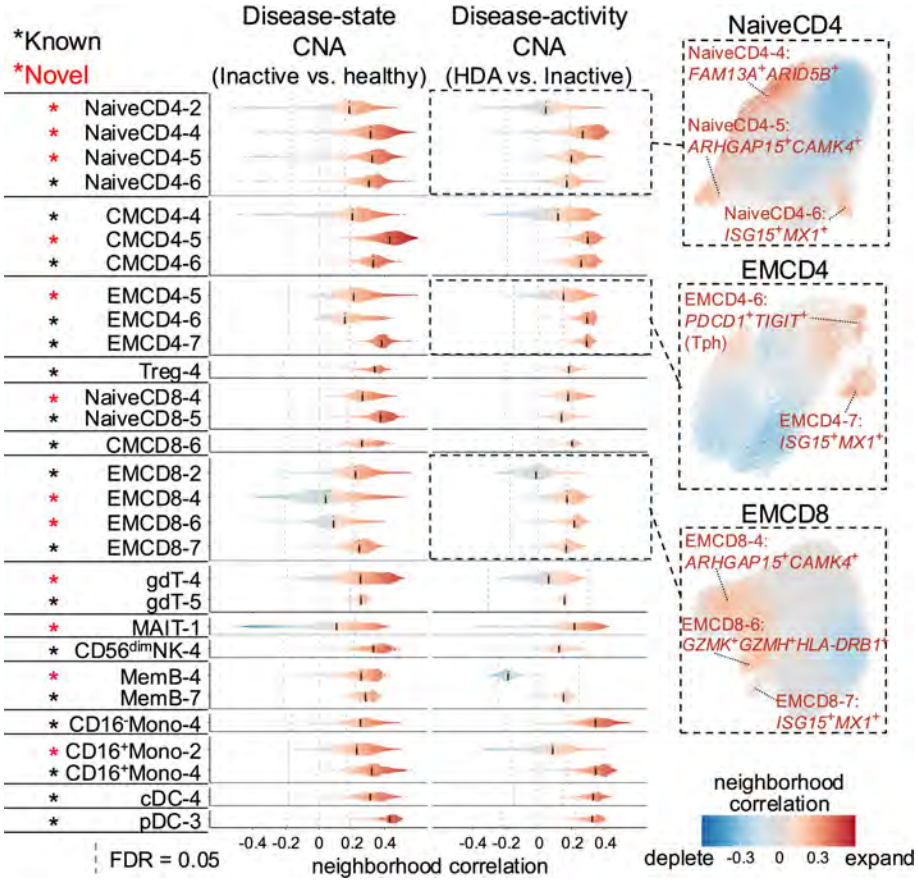

Figure 2. Granular cell states that expanded in SLE

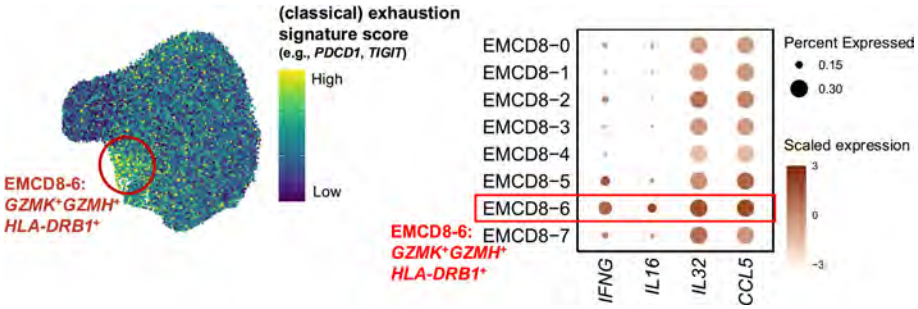

Figure 3. Molecular profiles in GZMK+GZMH+HLA-DR+ effector memory CD8+ T cells

Finally, we investigated detailed molecular profiles of these new disease-relevant cell states. For example, *GZMK*$^{+}$*GZMH*$^{+}$*HLA-DR*$^{+}$ effector memory CD8^{+} T cells exhibited the highest expression of exhaustion signatures (*PDCD1* and *TIGIT*) and key cytokines (*IFNG* and *IL16*, Figure 3). Integrative analysis with 137 cell surface markers identified four key surface markers of this subpopulation, which enabled us to perform in-depth functional characterization through experimental approaches such as in vitro stimulation. Furthermore, CRISPR gene knockout screening also identified several transcriptional regulator candidates of these cell states.

Conclusion: Our intensive cellular and molecular fine-mapping approach successfully pinpointed new disease-relevant cell states in SLE and their key molecules, which could be the next treatment targets.

Abstract Number: 2603

Evaluating the Feasibility, Acceptability, and Behavioral Impact of Brief Action Planning (BAP) Coaching for Physical Activity in Adults with Chronic Knee Symptoms: A Qualitative Study

Moath Alshahrani[1], Kristin Haglund[2], Miranda McIlheran[2], Rowland Chang[3], Pamela Semanik[4], Sheikh Iqbal Ahamed[2] and Daniel Pinto[5], [1]Marquette University/ King Khalid University, Milwaukee, WI, [2]Marquette University, Milwaukee, WI, [3]Northwestern University Feinberg School of Medicine, Chicago, IL, [4]Rush uUniversity, Chicago, IL, [5]Marquette University, Wauwatosa, WI

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: ARP II: Perception, Prediction, and Prevention (2603–2608)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Physical activity (PA) improves chronic knee symptoms (CKS) by decreasing pain and improving function, yet many interventions to increase PA are resource-intensive or poorly tailored to individual motivation. Brief Action Planning (BAP) offers is a self-management support tool based on motivational interviewing that remains understudied in real-world contexts. This study aimed to explore the feasibility, acceptability, and perceived impact of a computer-supported coaching program to support action planning for physical activity among adults with CKS in workplace

Methods: Employees (N=9) were recruited via health portal to participate in a 12-week randomized controlled trial assessing health coaching plus Fitbit. The coaching program consisted of an initial 30-minute rapport-building session and 10-minute follow-up sessions delivered remotely by trained health coaches. Number of follow-up sessions ranged between 4-11 based on participant preference. Participants were invited to engage in semi-structured interviews post-intervention which were transcribed and analyzed using qualitative content analysis. Codes were developed independently by two trained researchers. Self Determination Theory's (SDT) three psychological needs autonomy, competence, and relatedness were used to interpret the motivational mechanisms supporting behavior change. Data were examined within and across codes to identify three themes and nine sub-themes

Results: Theme 1, value and sustainability of the BAP program included subthemes of acceptability, positive experience with coaching, and anticipated sustainability of behavioral change. Theme 2, active ingredients that facilitated physical activity behavior, included subthemes of coaching accountability, goal-setting structure, and behavioral monitoring. Theme 3, contextual conditions influencing motivation and program fit, included personal motivation, knee pain management, and workplace or lifestyle integration. Participants viewed the coaching relationship as the central driver of behavior change. Coaching enhanced personal accountability, enabled adaptive goal setting, and fostered supportive dialogue. Fitbit use complemented goal adherence but was secondary to interpersonal support. Mapping to SDT, autonomy was supported by individualized goal-setting; competence through iterative plan refinement and feedback; and relatedness through an empathic, nonjudgmental coaching relationship. Internalized motivation and increased self-efficacy supported sustainability of behavior change

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Brief action planning-based coaching paired with Fitbit PA feedback was perceived as feasible, highly acceptable, and impactful for promoting physical activity in employed individuals with chronic knee symptoms

Cross-Sectional Relationship Between Sarcopenic Obesity and Knee Osteoarthritis: The Johnston County Osteoarthritis Project

David Werner[1], Carolina Alvarez[2], John Batsis[3], Reece Blay[4], Laura Bilek[5], Amanda Nelson[3] and Yvonne Golightly[5], [1]University of Nebraska Medical Center, Mason, OH, [2]University of North Carolina at Chapel Hill, Miami, FL, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC, [4]University of Nebraska Medical Center, Council Bluffs, IA, [5]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: ARP II: Perception, Prediction, and Prevention (2603–2608)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Current consensus for defining sarcopenia (loss of muscle mass and strength with aging) and sarcopenic obesity (SO, sarcopenia with obesity) suggests combining measures of strength and physical function with body composition parameters. Limited evidence suggests that SO is associated with knee osteoarthritis (KOA), moreso than either sarcopenia or obesity alone. However, previous studies often defined SO using only body composition or clinical measures, rather than a combination of both. Therefore, this study examined the relationship between KOA and sarcopenia, obesity, and SO utilizing a definition of sarcopenia, obesity, and SO that combined body composition and clinical definitions.

Methods: The sample was drawn from participants enrolled in the Johnston County Osteoarthritis Project (JoCoOA) with available whole body dual energy x-ray absorptiometry (DXA) scans, along with data on anthropometric, knee symptoms and radiographic, and physical function measures from one visit occurring between 1999-2010. Obesity was defined using cutoffs based on body fat % and either BMI, waist-to-height, or waist circumference (Table 1). Sarcopenia was defined as

Table 1. Normative data for identification of obesity, sarcopenia, and sarcopenic obesity.

Assessment	Definition	PMID
Obesity		
BMI	Compared to sex-matched normative data	36719951
Waist to height	Compared to sex-matched normative data	36719951
Waist circumference	Compared to sex-matched normative data	36719951
Percent body fat	Compared to sex, age, and race-matched normative data	10966886
Sarcopenia		
Chair stand	Compared to sex and age-matched normative data	35000330; 3491815
Hand grip strength	Compared to sex and age-matched normative data	25474696
Appendicular lean mass	Lowest quintile of appendicular lean mass percent	

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

low fat-free mass with either low grip strength or poor chair stand time when compared to age and sex-matched normative values (Table 1). SO was defined as having both obesity and sarcopenia. Outcomes included radiographic KOA (rKOA) defined by a Kellgren-Lawrence grade ≥2 and symptomatic knee OA (sxKOA) defined by rKOA and symptoms (pain, aching, stiffness on most days) in the same knee. Logistic regression models assessed cross-sectional associations among obesity, sarcopenia, and SO and rKOA or sxKOA, adjusting for age, sex, race (Black/White), education level, smoking status(never/former/current), number of chronic conditions, and prior knee injury.

Results: A total of 1878 participants (mean age 63.6±10.4 years, 1/3 male, 1/3 Black) were included (Table 2). Individuals were classified as having neither obesity nor sarcopenia (64%), obesity only (23%), sarcopenia without obesity (2%), and SO (10%). Approximately 1/3 of the sample had rKOA and 2/5 had sxKOA. Compared to the referent group of no obesity or sarcopenia, obesity only and SO were associated with more than double the odds of rKOA and sxKOA (Table 3). Compared to obesity only, SO was related to sxKOA but not rKOA, and compared to sarcopenia only, SO was associated with rKOA and sxKOA.

Table 2. Descriptive statistics for JbCoOA with available DXA, N=1878.

Characteristics	n or mean	% or ±S
Age, mean±SD years, range=45-95	63.6	±10

rKOA (KLG=2)	639	34
sxKOA (KLG=2 and symptoms in same knee)	386	20

SD=standard deviation; OA=osteoarthritis; rKOA=radiographic knee OA; sxKOA=symptomatic knee OA; symptoms=pain, aching, or stiffness on most days

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 3. Cross-sectional associations between main effect and knee osteoarthritis (KOA) outcomes, adjusted* odds ratios (aOR) and 95% confidence intervals (CI).

	Radiographic KOA	Symptomatic KOA
Main effect	aOR (95% CI)	aOR (95% CI)
Mutually-exclusive comparisons		
obesity only (vs no obesity or sarcopenia)	**2.16 (1.67, 2.79)**	**2.08 (1.56, 2.79)**
sarcopenia only (vs no obesity or sarcopenia)	0.86 (0.42, 1.74)	1.51 (0.69, 3.29)
sarcopenic obesity (vs no obesity or sarcopenia)	**2.40 (1.70, 3.40)**	**3.38 (2.34, 4.88)**
sarcopenic obesity (vs obesity only)	1.11 (0.76, 1.63)	**1.62 (1.08, 2.43)**
sarcopenic obesity (vs sarcopenia only)	**2.81 (1.31, 6.03)**	2.24 (0.98, 5.11)

Using 10 multiple imputed datasets. Logistic regression modeling log odds for KOA outcome.
*Adjusted for: age, sex, race, education, smoking, multimorbidities, and knee injury
Shown **BOLD** when significant at 0.05 level.

Conclusion: These findings suggest that SO is strongly related to sxKOA when compared to obesity only or normal cutoffs of fat-free and fat mass. Both sarcopenia and obesity are related to changes in body composition and metabolic function associated with aging and the combination of sarcopenia and obesity (i.e. SO) works synergistically in its relationship with KOA, as the odds are higher than both conditions in isolation. Future research using current definitions of SO should investigate longitudinal relationships to inform interventions to address SO and KOA.

Do Patients Recall Their Rheumatic Diagnoses Accurately? A Comparison by Disease Type

Sydney Liles[1], Samantha Namit[2], Jennifer Copson[3], Matthew Librizzi[2], Sophia Baionno[2], Nurten Gizem Tore[2], Yvonne Lee[4] and Daniel K. White[1], [1]University of Delaware, Newark, DE, [2]University of Delaware, Newark, [3]University of Delaware, Wilmington, DE, [4]Northwestern University, Chicago, IL

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: ARP II: Perception, Prediction, and Prevention (2603–2608)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Rheumatic diseases represent a major public health concern in the United States due to their high prevalence and their association with disability. Observational studies are an essential tool in understanding the distribution and impact of these conditions. Such studies often rely on patients to recall their physician provided diagnosis. However, previous research has shown mixed results on this agreement. The purpose of this study was to assess the preliminary agreement of patient-recalled diagnosis type with a physician diagnosis in an online cohort of adults with rheumatic disease in the United States.

Methods: We used cross-sectional data from the Observational Arthritis Foundation Internet Study. Participants were recruited online using advertisements on Meta. Those who were ≥ 18 years old, lived in the US, and had a patient-recalled rheumatic condition were included in the study. Demographic information was collected using questionnaires. Study

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1: Percentage of agreement, Kappa values (K) and 95% confidence intervals, sensitivity, specificity for Osteoarthritis, Gout, Fibromyalgia, Rheumatoid Arthritis, Psoriatic Arthritis, Lupus, and other

Rheumatic Disease Type	Percentage of agreement of patient-recalled diagnosis with physician reported diagnosis	K (95% CI)	Sensitivity	Specificity
Osteoarthritis (n = 78*)	88.0%	0.69 (0.53, 0.85)	0.90	0.81
Gout (n = 9*)	98.2%	0.88 (0.71, 1.00)	0.89	0.99
Fibromyalgia (n = 45*)	92.6%	0.85 (0.75, 0.95)	0.91	0.94
Rheumatoid Arthritis (n = 22*)	93.5%	0.80 (0.65, 0.94)	0.86	0.95
Psoriatic Arthritis (n = 8*)	98.2%	0.88 (0.71, 1.00)	0.80	1.00
Lupus (n = 7*)	99.1%	0.93 (0.79, 1.00)	0.88	1.00
Other (n = 8*)	88.0%	0.25 (-0.03, 0.54)	0.27	0.95

*Participants could report more than one diagnosis and be counted in multiple diagnoses

participants were asked what "Type(s) of Arthritis you have been diagnosed with:". Response options included Osteoarthritis (OA), Fibromyalgia, Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA), Gout, Lupus, and/or Other. We compared patient-recalled diagnoses with health records/provider report. Health record/provider reported diagnoses were collected through uploaded documentation from an electronic medical record or receiving a completed form specifying rheumatic diagnoses completed by a physician. We assessed agreement by calculating percent agreement, kappa coefficients (κ) with 95% confidence intervals (CI), sensitivity, and specificity for each diagnosis. Kappa coefficients were interpreted using 0 no agreement, 0.1-0.2 slight, 0.21-0.4 fair, 0.41-0.6 moderate, 0.61-0.8 substantial, 0.81-0.99 near perfect, and 1.0 perfect agreement.

Results: 108 participants (mean age = 57.3 years old, 85.2% female, mean BMI =34.1 kg/m^2, mean Charleson Comorbidity Index Score 3.4, 18.5% non-White, 78.7% with at least an associate's degree) were included in the analysis. Percentages of agreement between physician diagnoses and patient-recalled ranged from 88% to 99%, with corresponding kappa coefficients ranging from 0.25 to 0.93 (Table 1). Lupus showed the highest agreement (99.1%) and a kappa coefficient of 0.93 95% CI (0.79, 1.00). Osteoarthritis and the "Other" category each had agreement percentages of 88.0% with kappa values of 0.69 (0.53, 0.85) and 0.25 (-0.03, 0.54), reflecting substantial and fair agreement, respectively. Specificity scores ranged from 0.81 to 1.00, while sensitivity scores ranged from 0.80 to 0.90 for all conditions except "Other" (sensitivity 0.27). Examples of reported "Other" diagnoses include ankylosing spondylitis, Sjogren's arthritis, or scleroderma.

Conclusion: We found, in our preliminary study, that patient-recalled diagnoses of specific rheumatic conditions have substantial agreement with physician diagnoses. However, patient-recalled diagnoses of 'Other' have fair agreement with physician report. Patient-recalled diagnoses may serve as a reasonable proxy for provider-confirmed diagnoses. These findings need to be replicated in larger and more diverse samples.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: ARP II: Perception, Prediction, and Prevention (2603–2608)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Social media (SM) and Artificial Intelligence (AI) are common sources of health information for patients with chronic diseases. Seeking medical information from unreliable sources can negatively affect the health perspective of patients with rheumatic diseases and their treatment adherence. We aimed to determine the influence of SM and AI on disease perception and treatment adherence in patients with rheumatic diseases.

Methods: We conducted an observational, cross-sectional study at an outpatient rheumatology clinic. Patients >18 years and with at least one rheumatologic diagnosis were included. Electronic health literacy was assessed with eHEALS higher scores indicating better electronic medical understanding. The impact of SM on daily life was evaluated with social media

Table 1. Social Media and Artificial Intelligence perception for rheumatic disease knowledge

a Fisher´s exact test; b Chi-square test; c Mann-Whitney´s U test; SM: Social media; AI: Artificial Intelligence; eHEALS: eHealth literacy scale; SMEQ: Social media engagement questionnaire; AIAS-4: Artificial Intelligence Attitude Scale

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

engagement questionnaire (SMEQ), higher scores indicating more involvement of SM. Morisky-Green test was used to evaluate treatment adherence, with a score > 3 indicating adherence. To assess the perspective of AI, Artificial Intelligence Attitude Scale (AIAS-4) was utilized. A comparison was done between two groups of ages (< 45 and >45 years). Descriptive analysis was performed. Chi-square test and Mann-Whitney´s U test were utilized, as appropriate. A p-value < 0.05 was considered significant.

Results: A total of 95 patients were included, of whom 88 patients were women (92.6%), with a median age of 50 (IQR: 39-60). The most common diagnoses were rheumatoid arthritis (n=46/48.4%) and systemic lupus erythematous (n=27/28.5%). The most common duration of disease was 1-4 years (n=39/41.4%). Most patients use smartphones (96.8%), and 58.9% use computers. In addition, 94.7% of patients use SM daily, with Facebook being the most common (n=68/71.6%) and spending less than two hours seeking information about their disease (n=80/84.3). Regarding the use of AI, 45 patients (47.4%) use AI, and 29 patients (30.5%) have used AI to seek information about their disease. Half of the patients (56.8%) believe that the internet has changed their perspective of their disease, making them more interested in their condition (n=23/24.3%). Most patients consider that their doctor is open to talking about the information found on internet platforms (n=80/84.2%) and would use SM if their doctor recommended it (n=87/91.6%). Patients < 45 years (n=39) were less likely to modify their treatment based on information found on SM and tend to use more AI to seek information about their disease, compared to patients >45 years (n=56) (p= 0.043, p=0.047, respectively). Regarding eHEALS, patients < 45 years have more electronic health literacy than patients > 45 years (p=0.010) and tend to be more involved in SM (p= < 0.001). There were no significant differences between treatment adherence and the perspective of their disease based on the information from SM or AI (Table 1).

Conclusion: More than half of our patients believe that the internet has changed their perspective of their disease, making them more interested in their condition. Younger patients have greater electronic health literacy, are more engaged in social media, and are more likely to use AI for health information. However, they are less prone to modifying their treatment based on this information.

Background/Purpose: The Expanded Risk Model for Rheumatoid Arthritis (ERS-RA) incorporates traditional CV risk factors and RA-related measures of disease activity and has demonstrated better performance compared to a traditional cardiovascular (CV) risk factor model. Additional external validations are needed to better understand the utility of ERS-RA in different patient groups with RA.

Methods: We used data from the longitudinal Brigham and Women's Hospital Rheumatoid Arthritis Sequential Study (BRASS). We obtained CV endpoints from three data sources: 1) self-reported CV events in BRASS, assessed annually, 2) linkage to Medicare/Medicaid claims, and 3) linkage to electronic health records (EHR). We used validated algorithms to define CV events in claims. We searched for and adjudicated CV events in EHRs with diagnosis and procedure codes. Due to uncertainty in accuracy of self-reported CV events, we included events from claims and EHR in primary analyses (narrow definition) and integrated self-reported events as a third source (broad definition). We defined follow-up as time from enrollment until first CV event or last study visit and truncated at 10 years. For the narrow CV definition, participants were censored at the visit prior to their self-reported CV event. We restricted to participants aged 20-80 years at enrollment and excluded participants with prevalent CV at baseline. We used multiple imputations with fully conditional specification to impute missing covariates. Model performance was assessed by evaluating discrimination (C-statistic) and visual inspection of calibration plots. Additionally, model performance was evaluated by dichotomizing predicted 10-year risk as < 7.5% vs. ≥7.5% and < 10% vs. ≥10%.

Results: We identified 1,332 participants in BRASS without evidence of CV events at baseline. The cohort had a mean age of 54 years; 16% were male; 8% current smokers; 6% diabetes; 22% hyperlipidemia; and 30% hypertension. RA duration was < 5 years in 37%; and 71% were rheumatoid factor positive. The mean follow-up was 81 (SD 41) months [approximately 6.8 (3.4) years]. We observed 71 (5%) participants with a CV event (narrow definition) and 166 (12%; broad definition). We observed c-statistics of 0.659 (broad definition) and 0.810 (narrow definition) (**Table 1)**. Calibration curves (**Figure 1**) indicated slight overprediction of CV risk using the narrow definition, with tighter calibration for lower predicted risk values. Conversely, using the broad definition, we observed slight underprediction of CV risk and less precision. Using a cut-point of <

Table 1. Model Performance of the ERS-RA for Broad and Narrow CV Definitions

Metric	CV Event Definitions	
	Broad definition	Narrow definition
Number of patients with a CV event	166	71
Observed %	12.5	5.3
Predicted %	31.8	31.8
Absolute difference, %	19.4	26.5
C-statistic	0.659	0.810
Predicted 10-year risk: <7.5% vs. ≥7.5% predicted risk		
Participants with ≥7.5% predicted risk, n (%)	424 (31.8)	424 (31.8)
Sensitivity, %	54.2	78.9
Specificity, %	71.4	70.8
Positive Predictive Value, PPV, %	21.2	13.2
Negative Predictive Value, NPV, %	91.6	98.4
Predicted 10-year risk: <10% vs. ≥10% predicted risk		
Participants with ≥10% predicted risk, n (%)	307 (23.1)	307 (23.1)
Sensitivity, %	41.6	63.4
Specificity, %	79.6	79.2
Positive Predictive Value, PPV, %	22.5	14.7
Negative Predictive Value, NPV, %	90.5	97.5

Abbreviations: CV = cardiovascular; Broad CV definition = events from Medicare/Medicaid claims, electronic health records and/or self-reported. Narrow CV definition= events from Medicare/Medicaid and/or electronic health records.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

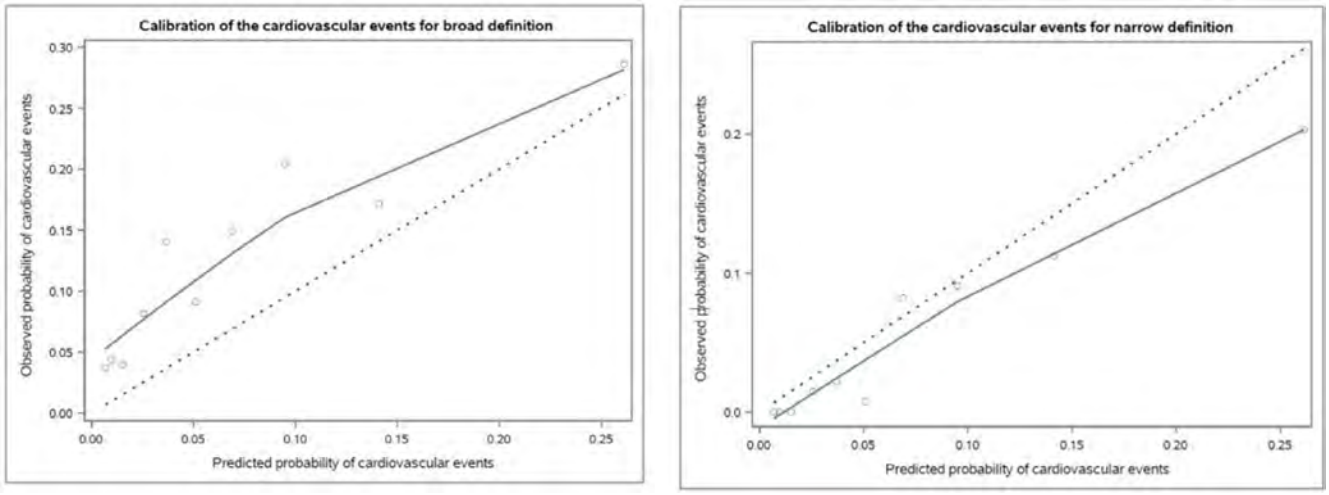

Figure 1. Calibration Curves for Broad and Narrow CV Definitions

7.5% we observed sensitivity (0.542 vs. 0.789), specificity (0.714 vs. 0.708), positive predictive value (PPV, 0.212 vs. 0.132), and negative predictive value (NPV, 0.916 vs. 0.984) for broad and narrow definitions, respectively. Results were similar for a cut-point of 10% predicted risk.

Conclusion: In this cohort of individuals with established RA the ERS-RA generally demonstrated good discrimination and calibration for CV events defined using validated algorithms in claims and EHR; however, its precision was lower when self-reported CV events were included.

SESSION INFORMATION

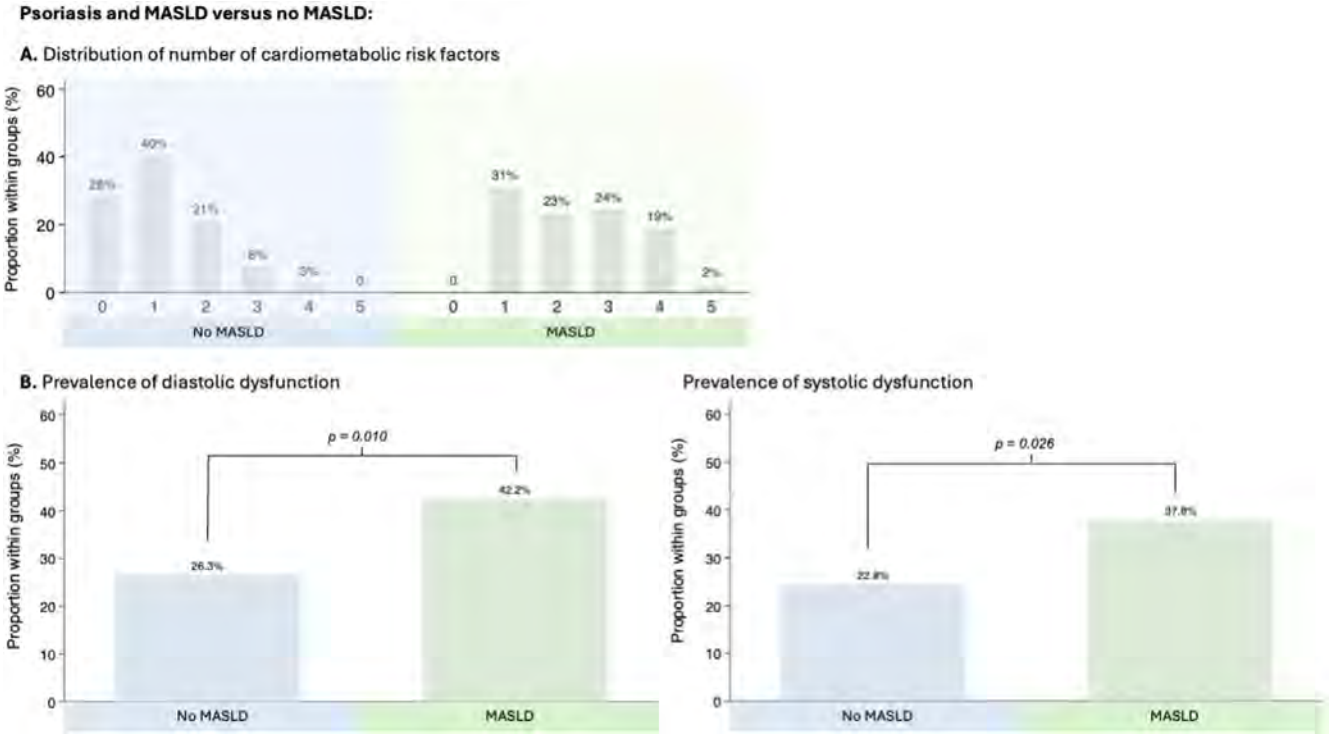
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: ARP II: Perception, Prediction, and Prevention (2603–2608)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Metabolic dysfunction-associated steatotic liver disease (MASLD) is increasingly recognized as a cardiometabolic risk factor. Individuals with psoriasis have a high prevalence of MASLD, yet the association between MASLD and cardiac manifestations in this population remains unclear.

We aimed to evaluate associations between MASLD, cardiovascular risk factors, and cardiac structure and function in adults with psoriasis.

Methods: A total of 261 adults with psoriasis were consecutively enrolled in the PSOCADIA study (Prevalence and risk factors asSOciated with CArdiac comorbiDIty in psoriAsis, ClinTrials.gov: NCT04950218) from the Copenhagen Translational Skin Immunology Biobank and Research Programme (BIOSKIN). Participants underwent clinical assessment, transthoracic echocardiography, transient elastography (TE), and blood withdrawal. MASLD was defined as hepatic steatosis on TE with controlled attenuation parameter ≥ 250 dB and presence of ≥ 1 cardiometabolic risk factor(s), excluding other causes of liver disease. Measures of cardiac structure and function were compared between psoriasis patients with MASLD and those without MASLD. Associations between MASLD, diastolic and systolic dysfunction were assessed in uni- and multivariable regression models.

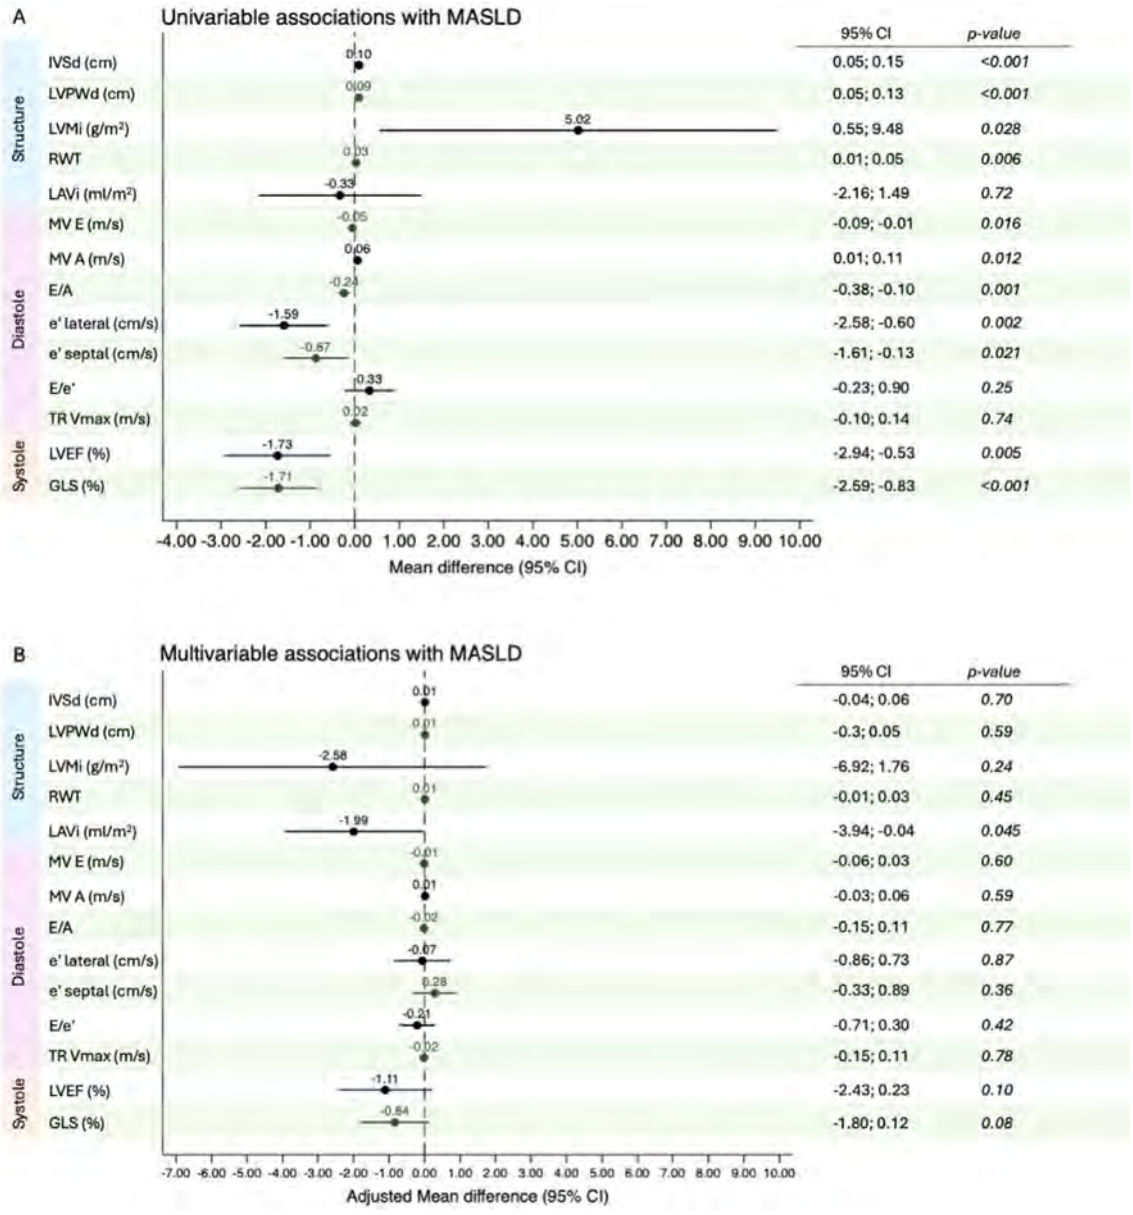
Results: We prospectively enrolled 261 individuals with psoriasis (median age 53.5 years, 46.4% women), whereof 20.7% had psoriatic arthritis. MASLD was present in 90 patients (34.5%) of whom 7 (8%) had possible advanced fibrosis. Compared to individuals without MASLD, those with MASLD exhibited higher blood pressure, higher body mass index (BMI),



Cardiometabolic risk factors and myocardial dysfunction in adults with psoriasis with and without MASLD. A) Distribution of the number of cardiometabolic risk factors and B) Prevalence of diastolic and systolic dysfunction in individuals with psoriasis with and without MASLD. Bars represent the proportion of individuals (%) within each group. Cardiometabolic risk factors included obesity, hypertension, dyslipidemia, diabetes, and metabolic syndrome. Abbreviations: MASLD, metabolic dysfunction-associated liver disease.

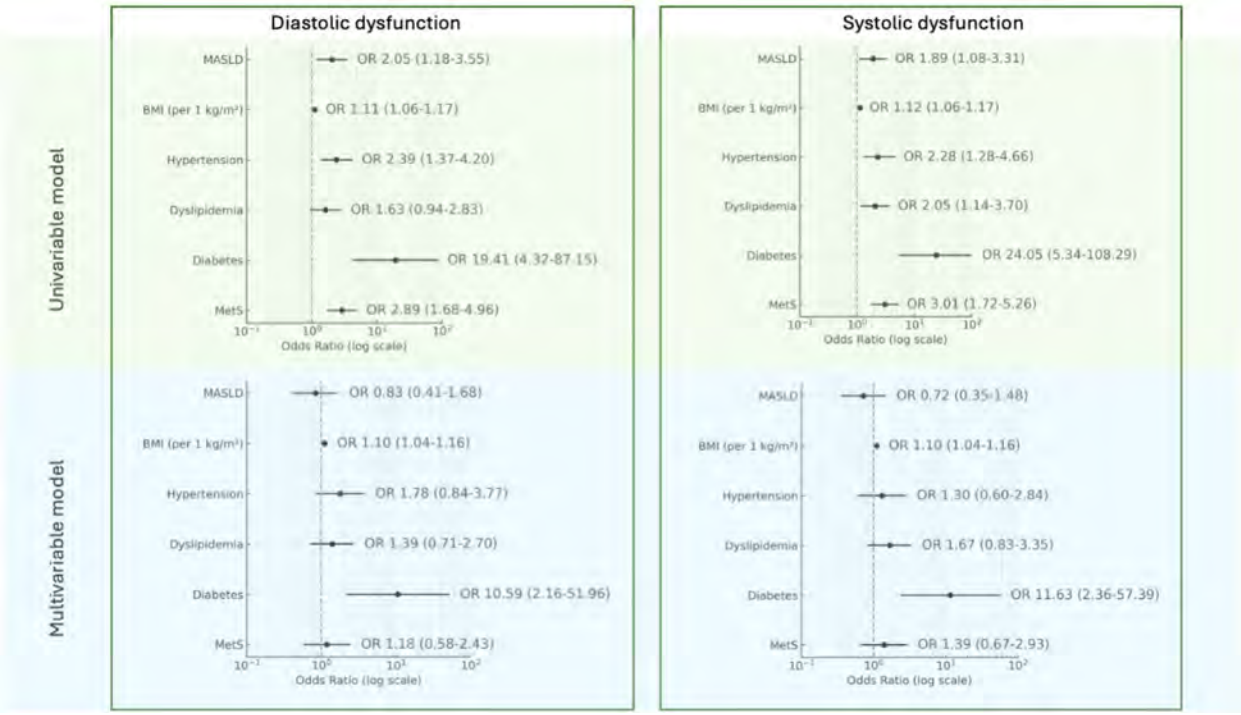
23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

and more adverse cardiometabolic profiles including more prevalent diabetes (14.4% vs. 1.9%, $p < 0.001$). MASLD was associated with structural measures indicative of cardiac hypertrophy and worse measures of diastolic and systolic function. However, after adjusting for age, sex, and BMI, these associations were no longer statistically significant. In fully adjusted models, MASLD was not associated with diastolic or systolic dysfunction. In contrast, higher BMI and diabetes remained independently associated with myocardial dysfunction.



Association between MASLD and cardiac structure and function in A) uni- and B) multivariable models adjusted for age, sex, and BMI. Mean differences (x-axis) in echocardiographic measures of cardiac structure, diastolic and systolic function (y-axis) in MASLD compared to no MASLD in the study population. Mean differences plotted with 95% confidence intervals in A) univariable linear regression models and B) multivariable linear regression models adjusted for age, sex, and BMI. Abbreviations: IVSd, Interventricular septum diameter; LVPWd, Left ventricular posterior wall diameter; LVMi, Left ventricular mass index; RWT, Relative wall thickness; LAVi, Left atrial volume index; MV E, Mitral valve early filling velocity; MV A, Mitral valve atrial contraction velocity; E/A, Ratio of early to late mitral inflow velocities; e', Early diastolic mitral annular velocity; E/e', Ratio of early mitral inflow to mitral annular velocity; TR Vmax, Tricuspid regurgitation peak velocity; LVEF, Left ventricular ejection fraction; GLS, Global longitudinal strain.

23265203, 2025, 59, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Associations between MASLD, cardiometabolic risk factors and myocardial dysfunction in psoriasis. Uni- and multivariable associations between risk factors and diastolic and systolic dysfunction. Forest plots display odds ratios (OR) for diastolic dysfunction (left panels) and systolic dysfunction (right panels) on logarithmic scale with 95% confidence intervals for MASLD and other key cardiometabolic risk factors. Top panels show univariable models for each risk factor, while bottom panels show fully adjusted models for age, sex, and all risk factors. Abbreviations: MASLD, metabolic dysfunction-associated steatotic liver disease; BMI, body mass index; MetS, metabolic syndrome.

Conclusion: In adults with psoriasis, associations between MASLD and abnormal cardiac structure and function were attenuated after adjustment for cardiometabolic risk factors, underscoring the importance of risk factor control in individuals with psoriasis and concomitant MASLD. This may also reflect that most adults with psoriasis and MASLD did not have hepatic fibrosis in this cohort.

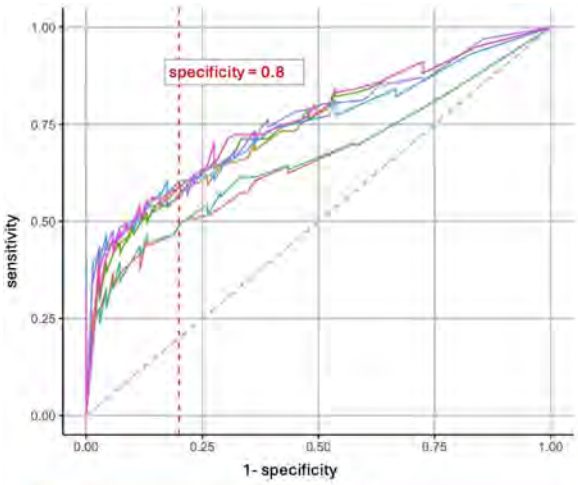
Abstract Number: 2609

Evaluation of the Performance of Candidate Enthesitis Ultrasound Scoring Systems for Psoriatic Arthritis Diagnosis – DUET Study

Nam Nguyen[1], Mu Yang[2], Sibel Aydin[3], Gurjit Kaeley[4], Richard Cook[2] and Lihi Eder[1], [1]University of Toronto, Toronto, ON, Canada, [2]University of Waterloo, Waterloo, Canada, [3]Department of Medicine, University of Ottawa, The Ottawa Hospital Research Institute, Ottawa, ON, Canada, [4]UF COM-J, Ponte Vedra Beach, FL

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Imaging of Rheumatic Diseases (2609–2614)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Psoriatic arthritis (PsA) is often diagnosed late, leading to worse outcomes. Enthesitis is a key feature that can aid in early detection, but its clinical assessment is unreliable. Ultrasound (US) offers a more objective method for evaluating enthesitis, yet standardization remains a challenge. The GRAPPA Ultrasound Working Group is developing the Diagnostic Ultrasound Enthesitis Tool (DUET), a PsA-specific sonographic enthesitis scoring system to distinguish PsA from non-inflammatory conditions. While DUET has been derived from a discovery cohort, external validation is needed before its clinical adoption. In this study, we aimed to evaluate the discriminative ability of candidate DUET scores using independent data to inform the selection of a DUET scoring system.



Risk score	Sites included	Formula	AUC
1	Pat, Ach	0.154*(PD+Hypo+Thick)+0.093*(Enth+3*Eros)-0.105	0.66
3	Pat, Ach, Tric	0.109*(PD+Hypo+Thick)+0.069*(Enth+3*Eros)-0.152	0.74
10	Pat, Ach, Tib, Tric	0.082*(PD+Hypo+Thick)+0.061*(Enth+3*Eros)-0.192	0.75
33	Pat, Ach	0.142*(2*PD+Hypo+Thick)+0.091*(Enth+3*Eros)-0.133	0.66
35	Pat, Ach, Tric	0.095*(2*PD+Hypo+Thick)+0.068*(Enth+3*Eros)-0.187	0.75
40	Pat, Ach, Quad, Tric	0.066*(2*PD+Hypo+Thick)+0.037*(Enth+3*Eros)-0.131	0.76
42	Pat, Ach, Tib, Tric	0.066*(2*PD+Hypo+Thick)+0.064*(Enth+3*Eros)-0.204	0.76

Pat: patellar tendon origin at patella; Ach: Achilles tendon; Tric: tricep tendon; Quad: quadricep tendon insertion at patella; Tib: patellar tendon insertion at tibial tuberosity; PD: Power doppler grade (0-3); Hypo: hypoechogenicity (0-1); Thick: Thickening (0-1); Enth: Enthesophyte (0-3); Eros: erosion (0-1).

Figure 1. ROC curve of candidate DUET scores

Figure 2. Discriminative ability of candidate DUET scores stratified by age groups

Methods: This retrospective cross-sectional study analyzed US scans from PsA patients and non-psoriatic controls collected in a single centre following standard protocol. All PsA patient met the DUET enrollment criteria including PsA duration < 5 years and were not using biologics. Controls had no psoriasis or other autoimmune disease. Enthesis US scans of the quadriceps, proximal and distal patellar tendons, triceps and Achilles were scored by a single reader blinded to the diagnosis for entheseal elementary lesions including hypoechogenicity, thickening, Doppler signal, enthesophytes, calcifications and erosions. We evaluated seven candidate DUET scores, each incorporating different combinations of entheseal sites and elementary lesions. Models were refitted using coefficients estimated in the discovery cohort. Model performance was also stratified by age group.

Results: In our validation cohort of 102 PsA patients and 69 controls, the seven candidate DUET risk scores yielded areas under the curve (AUCs) ranging from 0.660 to 0.764 (Figure 1). Stratifying the risk scores by age with a cutoff of 55 years enhanced AUCs to 0.781 (under 55) and 0.753 (over 55) (Figure 2).

Conclusion: The candidate DUET scores demonstrated discriminative ability in an external validation cohort, with additional improvement following age stratification. These findings will guide further refinement of the selected DUET score and inform its integration into clinical and research settings.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Imaging of Rheumatic Diseases (2609–2614)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Aortitis is a frequent and potential severe complication of giant cell arteritis (GCA)(GCA-aortitis). Tocilizumab (TCZ) was approved for the treatment of GCA, but its efficacy in GCA-aortitis has not been specifically studied in randomized clinical trials. GCA-aortitis may be more refractory to TCZ than classic cranial GCA phenotype.

Our aim was to assess the effectiveness and safety of TCZ in monotherapy (TCZmono) compared to TCZ combined with conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs)(TCZcombo) in GCA-aortitis in clinical practice. To study associative factors associated with imaging remission.

Methods: Comparative multicenter observational study of GCA-aortitis treated with TCZcombo vs TCZmono. Outcomes, at 12 and 24 months, were: clinical, EULAR, and imaging remission (^{18}F-FDG PET/CT vascular uptake lower than liver uptake), glucocorticoid-sparing effect and safety data. Associative factors associated with imaging remission (multivariable logistic regression) were determined at 24 months.

Results: 196 patients (148 female/48 male) with GCA-aortitis treated with TCZ (136 TCZmono/60 TCZcombo) (**Table 1**). After 24 months since the initiation of TCZ, imaging remission (50% vs.15.8%; p=0.026) was higher with TCZcombo (**Figure**). In contrast, there were no differences in EULAR and clinical remission. Prednisone sparing effect was higher in TCZcombo. In addition, a non-statistically lower adverse events rate was observed in TCZcombo (8.7 vs. 13.2 vs. adverse

Table 2. Multivariable analysis through stepwise logistic regression of associative factors with imaging remission at 24 months of initiation of TCZ.

IMAGING REMISSION at 24 month	Univariable		Multivariable

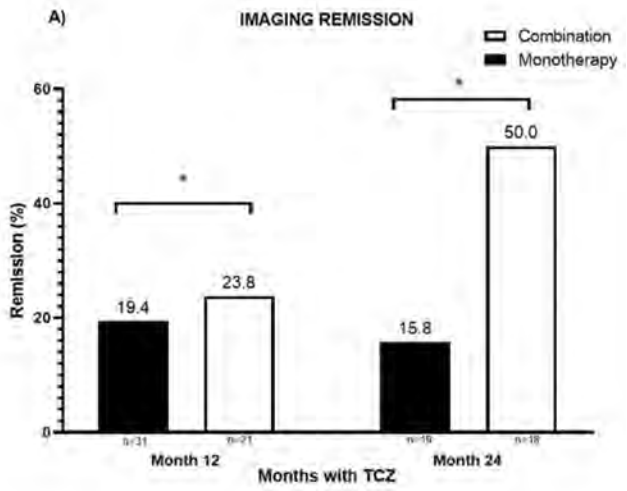
Figure 1. Imaging remission at 12 and 24 months after initiation of tocilizumab in a wide series of GCA-aortitis patients. Comparison between tocilizumab in monotherapy vs. tocilizumab combined with disease-modifying antirheumatic drugs.



+ No significant differences; *p<0.05
GCA: giant cell arteritis; TCZ: tocilizumab.

events 100 patients/year; p=0.21). In a multivariable logistic study TCZcombo vs TCZmono increases the imaging remission 5.26-fold (OR 5.26 (95% CI: 1.03-26.85; p=0.046) at 24-month follow-up (**Table 2**).

Conclusion: In GCA-aortitis, TCZ therapy combined with csDMARDs may be more effective than TCZmono in imaging remission without increasing adverse events.

Check the corresponding score at each site and then calculate the total score. Total score = Sum of 14 sites scores (B line score+ pleural line score) +Am-line score + pleural effusion score (range 0-93)

*: For the pleural effusion score of 5 to be considered, the presence of either B lines or pleural lines score is required.

Figure 1.The bilateral anterolateral posterior chest wall 14 intercostal lung ultrasound scanning method (A) and a lung ultrasound scoring system (B) for connective tissue disease related interstitial lung disease.

Background/Purpose: The role of lung ultrasound (LUS) in assessing disease severity of interstitial lung disease (ILD) remains unclear. We employed a semiquantitative scoring system to evaluate the ability of a LUS score to assess disease severity in patients with connective tissue disease (CTD) related ILD.

Methods: This study involved individuals from a prospective cohort of patients with CTD exhibiting respiratory symptoms or clinical suspicion of ILD who attended our hospital from December 2023 to December 2024. All patients underwent LUS, high-resolution CT (HRCT), and pulmonary function test (PFT) within one week. LUS was performed using a 14 intercostal scanning protocol, and the total LUS score was calculated using a semiquantitative scoring system (Figure 1). HRCT results were evaluated by two experienced radiologists and analyzed a commercial quantitative computed tomography (QCT) software. According to the Goh staging system, ILD was categorized as limited or extensive if < 20% or >20%, respectively, of the total lung area was affected. Differences in LUS scores across ILD severity groups were compared, and correlations between LUS scores and QCT and PFT results were analyzed. The stratification efficacy of the LUS score was evaluated using the area under of the receiver operating characteristic curve (AUC) with 95% confidence intervals (CI).

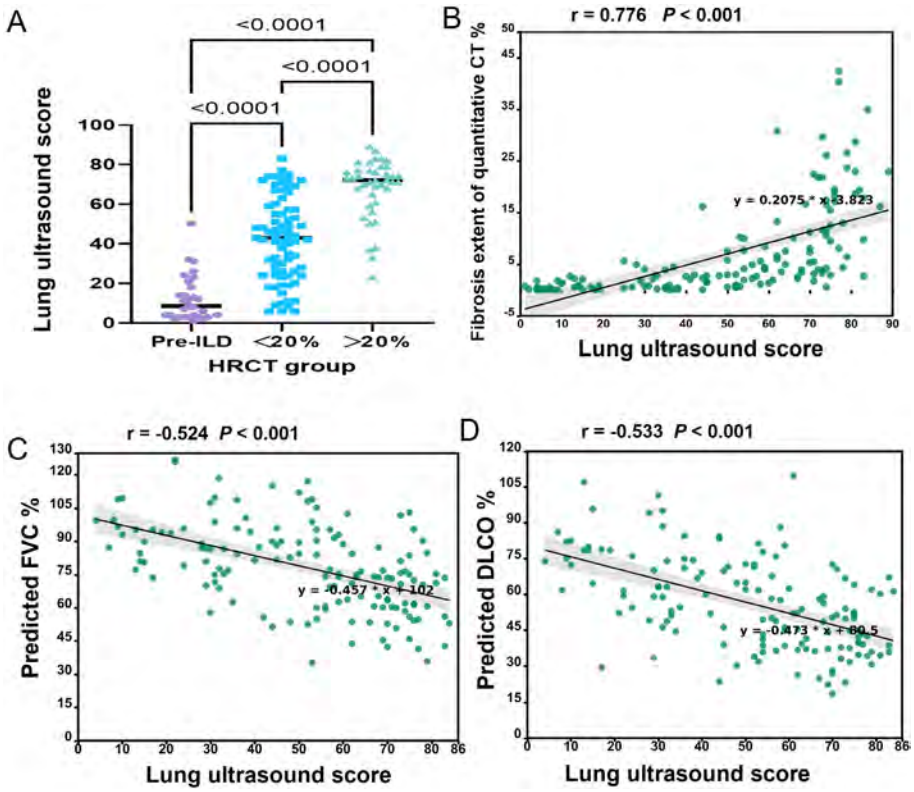

Figure 2. Differences in lung ultrasound scores among patients with connective tissue diseases related interstitial lung diseases of varying HRCT severity grading (A), as well as correlation between lung ultrasound scores and fibrosis extent on quantitative HRCT (B), predicted percentage of forced vital capacity (C), and predicted percentage of diffusing capacity of the lungs for carbon monoxide (D) in patients.

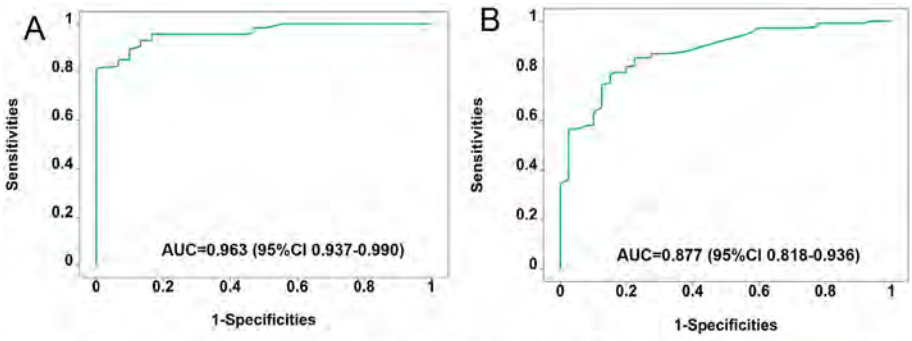
Results: A total of 146 patients with CTD-ILD were enrolled (mean age 56.1 ± 11.7 years; 108 [74.0%] female). Among these patients, 50 (34.2%) were diagnosed with idiopathic inflammatory myopathy; 35 with rheumatoid arthritis; 27 with Sjögren's disease; 20 with systemic sclerosis; 11 with systemic lupus erythematosus; and 3 with mixed connective tissue



C

Predictions of lung ultrasound score versus gradings of HRCT						
ILD		Lung ultrasound score grading			Total	Accuracy
HRCT grading		1(<20)	2(20-55)	3 (>55)		(%)
Preclinical	1	25	5	0	30	83.3
Limited (<20%)	2	5	46	25	76	60.5
Extensive (>20%)	3	0	6	34	40	85.0
	Total	30	57	58	146	71.9

quadratic weighted kappa = 0.736; 95% CI: 0.621–0.850

Figure 3. Receiver operating characteristic curves of lung ultrasound scores for distinguishing between preclinical ILD and ILD (A), as well as between limited and extensive ILD (B); and the predictions of lung ultrasound score versus HRCT gradings (C). AUC: area under the receiver operating characteristic curve.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

disease. The cohort comprised 30 individuals classified with preclinical ILD, 76 with limited ILD, and 40 with extensive ILD. Patients with extensive ILD exhibited higher QCT parameters but lower PFT results than those with limited ILD or preclinical ILD. The median LUS scores in patients with extensive ILD were significantly higher (72, IQR 62–77) compared with those in the limited ILD (43, IQR 24.5–58.5) and preclinical ILD groups (8.5, IQR 3.0–18.75) ($P < 0.001$). Furthermore, LUS scores exhibited a positive correlation with fibrosis extent assessed by QCT ($r = 0.776$, $P < 0.001$) and negative correlations with diffusion capacity for carbon monoxide (DLCO) ($r = -0.533$, $P < 0.001$) and forced vital capacity (FVC) ($r = -0.524$, $P < 0.001$) (Figure 2). At cutoffs of 19.5 and 55.5, LUS distinguished preclinical ILD from limited ILD and extensive ILD, with sensitivities of 95.7% and 89.7% and specificities of 83.3% and 73.8%, respectively (AUC 0.963 and 0.877) (Figure 3). The agreement between LUS and HRCT severity stratification was good (quadratic weighted kappa = 0.736; 95% CI: 0.621–0.850), and interoperator consistency was excellent (intra-class correlation coefficient: 0.971, 95% CI: 0.965–0.980, $P < 0.001$).

Conclusion: LUS exhibited favorable sensitivity and specificity for distinguishing between CTD-ILD patients of varying severity grades. Moreover, LUS presents a promising imaging modality for disease severity stratification and longitudinal monitoring of disease progression.

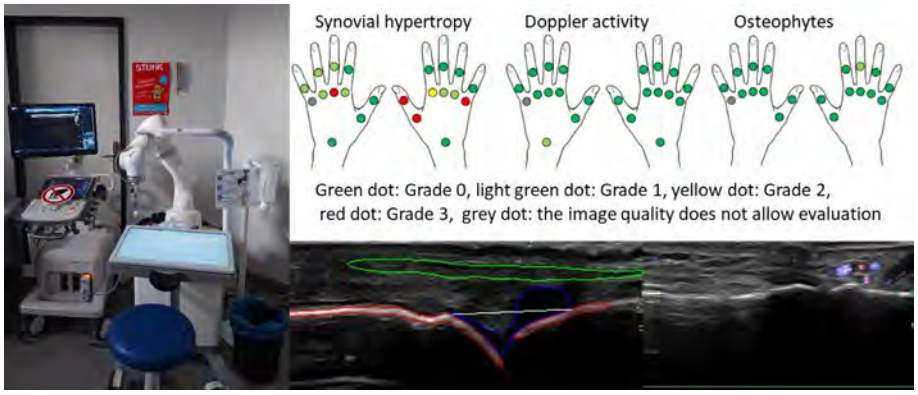
SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Imaging of Rheumatic Diseases (2609–2614)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: The integration of artificial intelligence (AI) in combination with robotics into clinical diagnostics has the potential to increase precision and efficiency and relieve increasingly scarce staff. Rheumatoid arthritis (RA), hand osteoarthritis (HOA), and psoriatic arthritis (PsoA) are common or relevant causes of hand complaints and impending functional limitations. The aim of the pilot phase is to introduce and test the safety, reliability, and acceptance of the hand examination using the ultrasound robot ARTHUR and the AI DIANA (both ROPCA Denmark) in an university outpatient clinic.

Methods: ARTHUR and DIANA offer automated scanning and evaluation of the wrists, all MCP, IP/PiP, and the DiP joints for synovial thickening, increased perfusion, and osteophytes based on the OMERACT guidelines. CANON aplio a ultrasound scanner with an 18L7 UHF ultra-wide linear probe was used. Procedures, reasons for discontinuation, and satisfaction were recorded in a standardized manner.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



ARTHUR diagnostic unit and DIANA report

Results: Within the first 12 weeks of use, 10,000 joints in 500 patients were examined (200 patients with RA, 100 PsoA, 50 HOA, 150 with other conditions). 5 examinations were discontinued without data transfer. 16 examinations were transferred but not read; all other examinations were completed successfully. No discontinuations for safety reasons were necessary. The average time for examiation of both hands took 20 minutes. Patient satisfaction was high: 92% reported being "very satisfied," 8% described themselves as "satisfied," and one patient rated the experience as "undecided." No one expressed dissatisfaction. The willingness to participate in a follow-up examination was 99.7%. Five patients reported mild pain during the examination but would still undergo the procedure again.

The figure shows the ARTHUR diagnostic unit on the left, a DIANA report on the top, and the corresponding image documentation below (red bone, blue synovium, green tendon in the example of an MCP joint, and Doppler of an IP joint).

In 91% of joints examined by ARTHUR documentation and recognizability of the joint structures was good or very. Difficulties were encountered with pronounced deformities or extension deficits. In the AI-supported interpretation of the stored images, DIANA shows a fair detection and differentiation of synovitis, with a relevant error rate of < 5%, but the detection of osteophytes is still unsatisfactory.

Conclusion: The implementation of a new AI-supported technology is associated with administrative hurdles and requirements. Technically, the robot demonstrates good performance, including robust image acquisition for synovitis and effusion. The joint-related correction rate for gross deviations exceeding at least 2 score points for synovitis by the experienced rheumatologist was below 5%. Currently, parallel evaluation and approval by experienced examiners is still necessary. Further training of the evaluation AI promises to further increase reliability and thus significantly improve the patient experience. Patient acceptance of the examination was very high.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Imaging of Rheumatic Diseases (2609–2614)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: ^{68}Ga-FAPI-04 PET/CT reveals fibroblast activation in vivo and is increasingly used to assess rheumatic diseases, including inflammatory arthritides. (1,2) We previously demonstrated that the synovio-entheseal ^{68}Ga-FAPI-04 uptake is increased in psoriasis (PsO) patients with arthralgia. (3) We now report the risk of PsA development with ^{68}Ga-FAPI-04 uptake in a longitudinal cohort of PsO patients at risk.

Methods: PsO patients with arthralgia but without arthritis/enthesitis underwent a whole-body ^{68}Ga-FAPI-04 PET/CT scan. We evaluated 34 synovial, 34 enthesial and 5 axial sites for ^{68}Ga-FAPI-04 uptake using the maximal standardized uptake value (SUVmax) and PET/CT Joint Index (PET-JI) (2), both calculated at each site individually and cumulatively at all sites. Patients were considered "^{68}Ga-FAPI-04 positive" when a PET-JI ≥2 was detected at least at one site.

Subsequently, patients were examined by a rheumatologist every 3 months or in case of symptoms worsening or reported joint swelling. Only patients with a ≥6 months of follow-up were included in the evaluation. PsA diagnosis was based on the fulfillment of CASPAR criteria. We described sites and intensity of ^{68}Ga-FAPI-04 uptake, compared the characteristics of ^{68}Ga-FAPI-04 positive vs negative patients and performed survival analyses to estimate the risk of PsA development.

Results: We included 44 patients, 59% were male, the mean age was 50 years (IQR 42-58). Further baseline characteristics are summarized in table 1. We found relevant ^{68}Ga-FAPI-04 uptake in 36 (81.8%) patients with a mean cumulative SUVmax of 22.4 (±23.8) and PET-JI of 13.6 (±13.8), most commonly around mechanically challenged large joints: greater trochanter (n=15), shoulder (n=14), ankle (n=13), knee (n=13) and acromioclavicular joints (n=12), spinous process of the L5 vertebra (n=10). ^{68}Ga-FAPI-04 positive patients had significantly higher BMI (p=0.023) and DAS28-CRP (p=0.04), driven by higher patient global VAS and CRP levels.

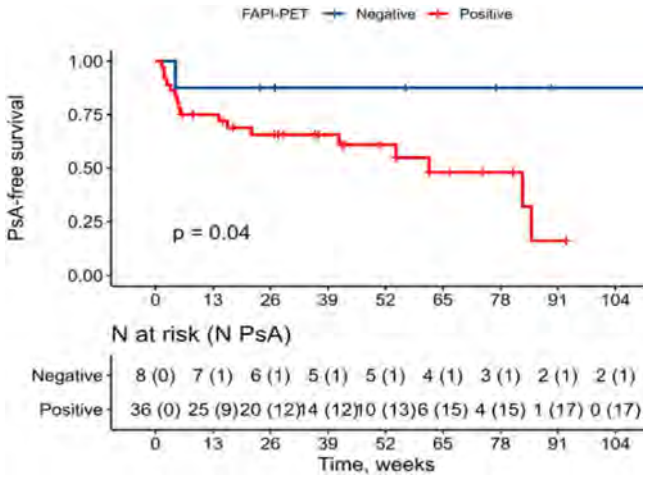
bDMARD, biological disease-modifying antirheumatic drugs; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BMI, body mass index; cDMARD, conventional antirheumatic drugs; CRP, C-reactive protein; DAS28-ESR, Disease Activity Score based on Erythrocyte Sedimentation Rate; HAQ, Health Assessment Questionnaire; LEI, Leeds Enthesitis Index; MASES, Maastricht Ankylosing Spondylitis Enthesitis Score; PASI, Psoriasis Area and Severity Index; VAS, Visual Analogue Scale.



Kaplan-Meyer curves of PsA-free survival in PsO patients with positive 68Ga-FAPI-04-PET/CT scans (blue line) vs. negative 68Ga-FAPI-04-PET/CT scans (red line) at synovial and entheseal sites

During a mean follow-up of 42 (±41) weeks, 18 patients (41%) developed PsA. 17/36 (47%) patients with a ^{68}Ga-FAPI-04 positive scan at baseline were PsA progressors, whereas only 1/8 (13%) without FAPI uptake developed PsA ((HR 6.55, 95%CI 0.85-50.8), log-rank p-value=0.04). Although not statistically significant (p=0.33 and 0.34), PsA progressors had higher mean cumulative SUV-max (27.0 ±26.8) and PET-JI (16.0 ±15.6) compared to non-progressors (SUVmax: 19.4 ± 21.6) (PET-JI: 11.9 ±12.3).

Conclusion: This prospective study shows that fibroblast activation detected by ^{68}Ga-FAPI-04-PET/CT is linked to a 6-fold higher risk of PsA development in PsO patients. Our data suggest that this imaging technique may be useful in identifying PsO patients at risk of PsA development, who may benefit from close monitoring and possible preventive interventions.

Abstract Number: 2614

Impact of Vagus Nerve-Mediated Neuroimmune Modulation on structural joint damage using Gd-MRI RAMRIS imaging in Biologic-Experienced Patients with Rheumatoid Arthritis

Charles Peterfy, MD, PhD[1], John Tesser[2], Yaakov Levine[3], Melissa Evangelista[4], Vibeke Strand[5], Michael Weinblatt[6] and David Chernoff[7], [1]Spire Sciences, Inc., Boca Raton, FL, [2]Arizona Arthritis & Rheumatology Associates, Phoenix, AZ, [3]SetPoint Medical, Valencia, CA, [4]SetPoint Medical Corporation, Valencia, CA, [5]Stanford University School of Medicine, Palo Alto CA, Portola Valley, CA, [6]Brigham and Women's Hospital/ Harvard Medical School, Waban, MA, [7]SetPoint Medical, Sausalito, CA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Imaging of Rheumatic Diseases (2609–2614)

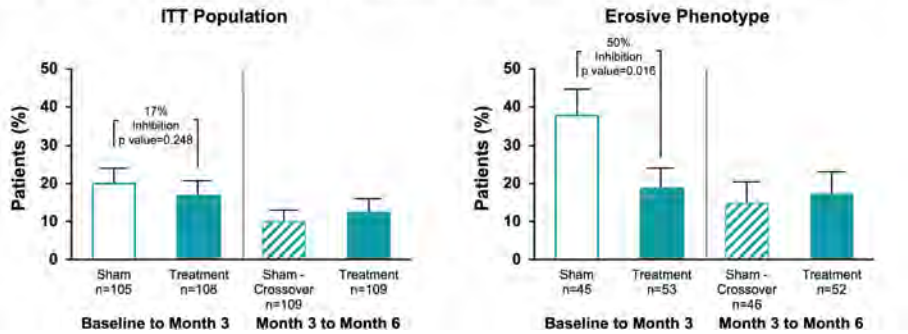
Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Previously reported results from RESET-RA (ClinicalTrials.gov, NCT04539964) showed neuroimmune modulation via electrical stimulation of the left vagus nerve using an implantable device to treat RA provided clinical efficacy compared to sham at 3 months. Further improvement was observed in both groups, after sham crossover to stimulation.

Vagus nerve stimulation may directly impact bone turnover via release of specialized pro-resolving mediators (SPMs) and neurotransmitters that act through ChemR23 receptors, nicotinic acetylcholine receptors and adrenergic receptors on osteoblasts and osteoclasts to reduce RANKL pathways and increase OPG, leading to inhibition of osteoclast activity.

Figure 1: Percentage of patients with bone erosion progression from baseline to Month 3 and Month 3 to Month 6 for ITT population and erosive phenotype subgroup.



23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2: Cumulative distribution of change in RAMRIS erosion scores from baseline to Month 3 and Month 3 to Month 6 for ITT population (top) and erosive phenotype (bottom) subgroup.

To objectively evaluate treatment effect of neuroimmune modulation on joint erosions, we report results from RESET-RA, which employed an OMERACT-validated imaging method using gadolinium-enhanced MRI of the hand and wrist, called RAMRIS (Rheumatoid Arthritis MRI Scoring system).

Methods: Adults with moderate-to-severe, active RA despite prior exposure to one or more biologic or targeted synthetic DMARDs (b/tsDMARDs) underwent outpatient surgery to implant the integrated neurostimulator, followed by 1:1 randomization to treatment (stimulation) or sham. MRIs were obtained at baseline, 3 months and 6 months after randomization and evaluated to assess progression of bone erosions. Images were scored centrally by two independent radiologists blinded to treatment allocation, clinical information, and the order in which images were acquired to ensure objective, unbiased scoring.

While active synovitis was not required for eligibility, prespecified analyses included an enriched subgroup of patients with erosive phenotype, i.e., patients at higher risk of erosion progression based on active, intra-articular synovitis at baseline (score ≥ 2 on any individual joint, at least 4 joints with a synovitis score of 1, or any joint with osteitis).

Results: Baseline RAMRIS scores were comparable between treatment and sham for both the ITT population and enriched subgroup. The non-enriched, ITT population showed that at 3 months, treatment had fewer patients with erosion progression (>0.5 increase in erosion score) compared to sham, but differences were not statistically significant. However, in the enriched subgroup, the proportion of patients with erosion progression at 3 months was significantly lower for treatment (18.9%) compared to sham (37.8%, p=0.0156) (**Figure 1**). After sham crossed over to treatment and received stimulation for 3 months, the proportion of patients with erosion progression reduced to levels comparable to the treatment group (17.0% treatment, 21.7% sham-crossover, (**Figure 1**). The cumulative distribution of change in erosion scores also showed greater inhibition of erosion progression with stimulation that was more pronounced in the enriched subgroup (**Figure 2**).

Conclusion: Neuroimmune modulation using an implantable device is effective in inhibiting progression of structural damage as early as 3 months in adults with active RA and active synovitis at baseline who previously had inadequate response or intolerance to at least one b/tsDMARD.

The Cost of Complexity: Financial Toxicity in Rheumatic Disease, Cancer, and Their Intersection

Manush Sondhi[1], Bhavik Bansal[2], Hemant Khandelia[1], Jiha Lee[3], Sebastian E Sattui[4], Siddharth Singh[5] and Namrata Singh[6], [1]University of Washington, Seattle, WA, [2]UT Southwestern Medical Center, Dallas, [3]University of Michigan, Ann Arbor, MI, [4]Division of Rheumatology and Clinical Immunology, University of Pittsburgh, Pittsburgh, PA, [5]University of California San Diego, San Diego, CA, [6]University of Washington, Bellevue, WA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Measures & Measurement of Healthcare Quality (2615–2620)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Financial toxicity (FT) is the financial burden of accessing health care, well known in cancer and increasingly seen in rheumatic disease (RD). We compared FT among adults with neither condition, RD only, cancer only, and both.

Methods: We used the National Health Interview Survey, a nationally representative sample of US adults from 2019-2023. Adults were categorized by self-reported RD, including arthritis, rheumatoid arthritis, gout, lupus, or fibromyalgia, and/or cancer. FT was defined as the presence of one or more of the following: financial distress, difficulty paying bills, delayed or forgone care, cost-related medication non-adherence, and food insecurity. Weighted logistic regressions were used to examine associations between disease groups and FT components, adjusting for demographics, comorbidities, and insurance status. To account for baseline differences and insurance coverage, analyses were stratified by age (< 65 versus ≥65 years). Analyses were conducted in RStudio v4.4.1; significance was set at $p < 0.05$.

Results: A total of 149,905 adults were included, of whom 10,094 (weighted prevalence: 6.3% [95% CI: 6.1%–6.5%]) had cancer only, 30,446 (18.5% [95% CI: 18.2%–18.8%]) had rheumatic disease (RD) only, and 8,713 (4.7% [95% CI: 4.6%–4.9%]) had both RD and cancer. These correspond to approximately 80.5, 235.6, and 59.9 million U.S. adults, respectively. Adults with both RD and cancer were more likely to be aged ≥65 years (70.5%) and had the highest rates of multimorbidity (62.1% with ≥2 comorbidities). Most adults across groups were female and insured, with higher educational attainment in the cancer-only and neither condition **(Table 1)**.

[†] n (unweighted) (%)

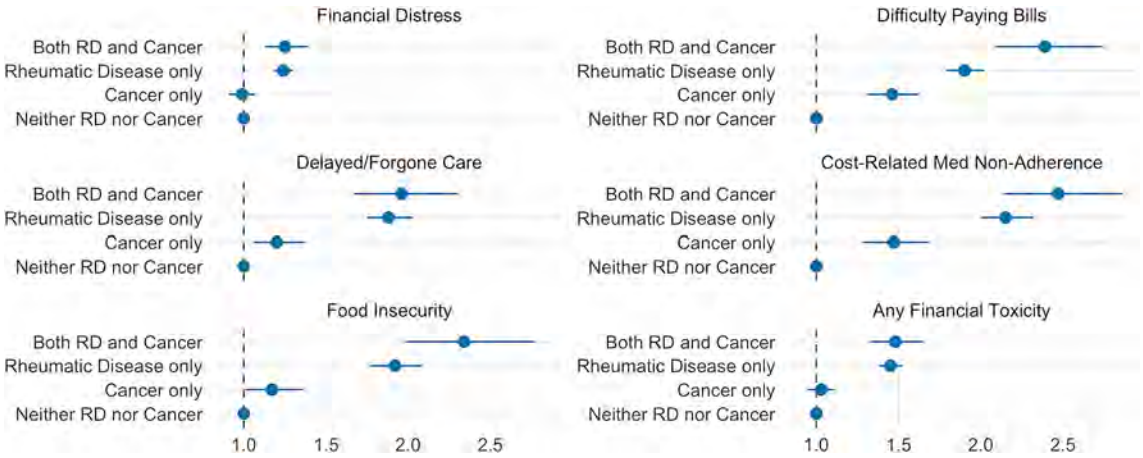

Figure 1: Adjusted Odds Ratios for Financial Toxicity Outcomes Among Younger Adults (<65 years) by Disease Group

In adults under 65, FT was highest in those with RD alone (63.9%) or RD plus cancer (64.3%), compared to 54% in those without either condition. Medication non-adherence was higher in RD groups (16.3% RD only, 19.2% RD with cancer). In adults over 65, FT was most prevalent in those with RD only (41.4%), with financial distress highest in this group (35.1%).

Among adults < 65 years, compared to those with neither RD nor cancer, persons with RD alone or in combination with cancer were consistently associated with increased FT across all domains **(Figure 1)**. Among adults ≥65 years, RD remained associated with higher odds of difficulty paying bills, cost-related medication non-adherence, and food insecurity, while cancer alone was not associated with increased financial toxicity and appeared protective in some domains compared to those with neither condition. The combined burden of RD and cancer conferred a similar level of risk as RD alone **(Figure 2)**.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

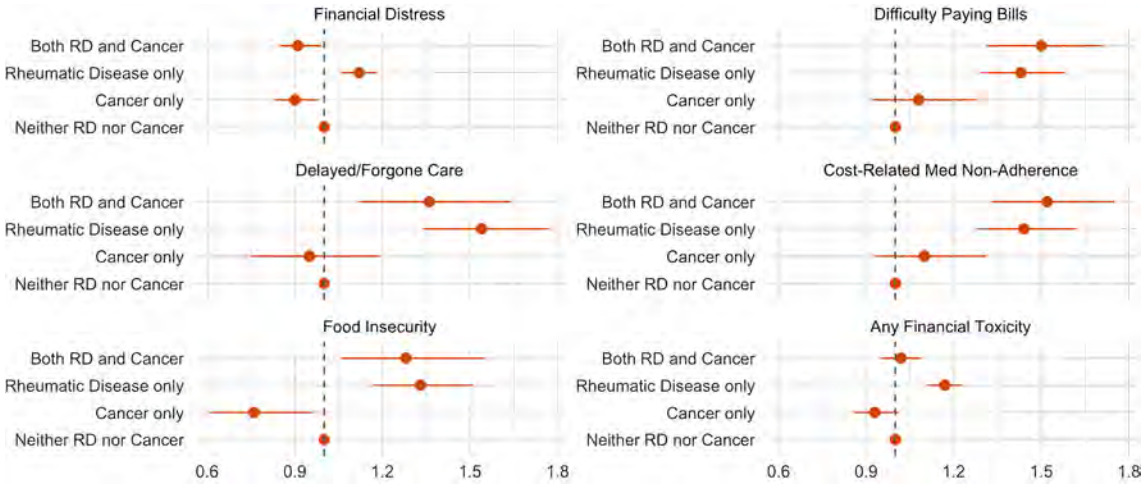

Figure 2: Adjusted Odds Ratios for Financial Toxicity Outcomes Among Older Adults (≥65 years) by Disease Group

Conclusion: Among younger adults, RD had a stronger association with FT than cancer, with the highest burden seen in those with both. Similar trends were observed among older adults, though with more modest effect sizes. While cancer may lead to short-term high costs, RD imposes a chronic financial burden from ongoing treatment and care. Even among Medicare-insured older adults, FT persists. These findings underscore the need for RD-specific FT assessment tools and greater clinical attention to financial burden, particularly as longer life expectancy amplifies the long-term economic impact of chronic RDs.

Real-World Implication of Clinical Disease Activity Index (CDAI) Utilization on Treatment Decisions and Clinical Outcomes in Rheumatoid Arthritis

Ryan Clark[1], Sally Almahdawi[1], Carolina Alvarez[2], Rumey Ishizawar[3] and Thuyvan Phan[4], [1]UNC Eshelman School of Pharmacy, Chapel Hill, NC, [2]University of North Carolina at Chapel Hill, Miami, FL, [3]UNC Division of Rheumatology, Allergy and Immunology and TARC, Chapel Hill, NC, [4]UNC Health, Chapel Hill, NC

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Measures & Measurement of Healthcare Quality (2615–2620)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: The University of North Carolina (UNC) Hospitals Rheumatology Clinic is utilizing the Clinical Disease Activity Index (CDAI) in patients with rheumatoid arthritis (RA) per the American College of Rheumatology (ACR) recommendation to guide therapeutic decisions in a treat-to-target approach. Through quality initiatives in clinic, approximately 70% of RA encounters now capture CDAI. This study was designed to understand covariables impacting CDAI over time and treatment actions, as well as determine generalizable applicability in clinical practice.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: This was a single-center, retrospective cohort study evaluating the use of CDAI to monitor disease activity and treatment response for adult patients (≥18 years) with RA, defined by treating rheumatologist from 10/01/2022 to 09/30/2023. Patients were included if they had three documented CDAI scores within the study period. Analyses included associations between CDAI with sex, race, insurance, income, steroid use, steroid sparing agents (conventional and targeted DMARDs and/or biologics) over time. The utility of the CDAI was examined by assessing whether provider's treatment actions were associated with CDAI scores vs other reasons such as patient's preference, medication side effect profile, or insurance coverage. Mixed linear (random intercept and linear time, other covariables as fixed effects, and unstructured covariance) and population-averaged logistic regression, using generalized estimating equations, were used to produce betas or odds ratios (OR), respectively, and 95% confidence intervals (CI) for these associations.

Results: A total of 234 patients had three CDAI scores within 12 months. Mean baseline CDAI score was 15.5 ± 12. The mean time from visit 1 to visit 2 and 3 was 15.1 weeks and 31.8 weeks, respectively (Table 1). CDAI score significantly decreased over time, on average 2.9 units (95% CI -4.0, -1.8) after 15 weeks and 3.5 units (95% CI -4.8, -2.1) after 30 weeks from baseline. CDAI score was significantly higher for those with no insurance vs private insurance by 3.9 units (95% CI -0.0, 7.8). Patients with Medicare or other government insurances (vs private) had lower odds of escalation or switch in therapy, OR 0.57 (95% CI 0.33, 0.98) and OR 0.50 (95% CI 0.28, 0.90), respectively (Table 2). Patients with moderate or high CDAI

Figure 1: Percent of treatment action by CDAI score group

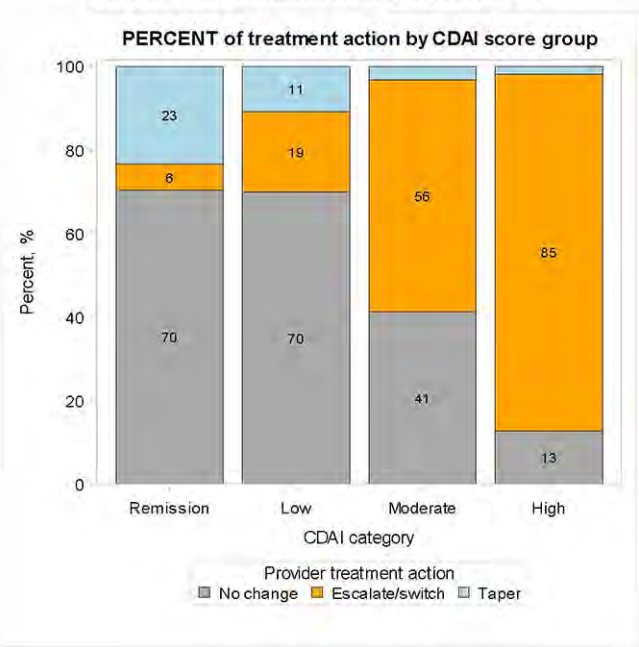

Figure 1 - Percent of treatment action by CDAI score group

(compared to low/remission) had higher odds of escalation or switch in therapy and lower odds of no change or taper therapy (Figure 1, Table 2). Treatment actions guided by CDAI scores had higher odds of escalation or switch in therapy, OR 2.83 (95% CI 1.47, 5.46) and lower odds for tapering therapy, OR 0.15 (95% CI 0.06, 0.33) compared to other reasons (Table 2).

Conclusion: Within the UNC Rheumatology Clinic, treatment changes were guided by CDAI scores. Other factors (e.g., access to insurance or insurance types, income, and race/ethnicity) may also play a role in treatment decisions and degree of disease activity. Therefore, other clinic resources may need to be utilized to bridge gaps between these disparities

Design and Initial Results from a Cluster Randomized Trial of a Provider-Facing Immunization Dashboard to Improve Shingrix Vaccination in the Veterans Health Administration

Jing Li[1], Cherish Wilson[2], Gary Tarasovsky[3], Sooyeon Kwon[4], Mary Whooley[3] and **gabriela Schmajuk**[5], [1]University of California, San Francisco, San Francisco, CA, [2]UCSF / SFVA, San Francisco, CA, [3]SFVA, San Francisco, [4]Albany Stratton VAMC, Loudonville, NY, [5]University of California, San Francisco, and San Francisco Veterans Affairs Medical Center, San Francisco, CA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Measures & Measurement of Healthcare Quality (2615–2620)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Patients prescribed immunosuppressive medications are at increased risk for herpes zoster and related complications, and the American College of Rheumatology recommends the recombinant zoster vaccine (Shingrix) for most patients receiving these treatments. However, fewer than half of Veterans in the VHA receiving immunosuppressive therapy have received even one dose of the Shingrix vaccine. To address this gap, we developed a national EHR-based dashboard to promote guideline-concordant Shingrix vaccination across the VHA and deployed it using a wait-list randomized control trial design.

Methods: Using data from the VHA Corporate Data Warehouse, we identified patients eligible for Shingrix according to ACR vaccination guidelines. A PowerBI dashboard was created to display patient-level information (immunosuppressant use, vaccination status) and facility-level vaccination rates (**Figure 1**).

All 131 VHA facilities were invited to participate in a waitlist-randomized trial of dashboard access. Seventy-three facilities responded to the invitation, and they were randomized to either "early access" (September 2024) or "late access" (Summer 2025), stratified by facility size and baseline percentage of patients vaccinated. Dashboard use was tracked using PowerBI user logs. The main outcome was the percentage of eligible patients with at least one dose of Shingrix, calculated weekly between June 2024 and March 2025 (38 weeks). A two-group interrupted time series (ITS) analysis was conducted to compare rates of improvement in early-access vs. late-access (control) sites.

Table. Percentage of patients with at least one Shingrix vaccine, overall and by groups at the beginning and the end of the study period

	All facilities included in the study (N=79357 pts)	Early-access facilities (38 facilities) (n=41191 pts)	Late-access (control) facilities (35 facilities) (n= 38166 pts)
Beginning of the study period (Week 1), mean (SD)	57.1 (8.1)	57.0 (8.1)	57.2 (8.1)
End of the study period (Week 38), mean (SD)	59.5 (7.8)	59.5 (7.7)	59.5 (7.6)
Post-linear trends from Interrupted Time Series analysis, coef. (95%CI)	-	0.07 (0.04, 0.09)	0.05 (0.03, 0.07)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: The 73 participating facilities served 79,357 Veterans prescribed immunosuppressive medications at baseline; 87% were age ≥50, 88% male, 73% white, and 89% non-Hispanic. The most common regimens were csDMARD monotherapy (37%) and biologic monotherapy (20%).

Most facilities (79%) were high-complexity sites located in the North Atlantic (23%) or Southeast (25%) regions. At the 38 early-access sites, 71% (27/38) had at least one clinician access the dashboard at least once during the study period. Access peaked in the first month after launch and was more sporadic thereafter (median (IQR) number of sessions over the study period: 38 (38 – 114)).

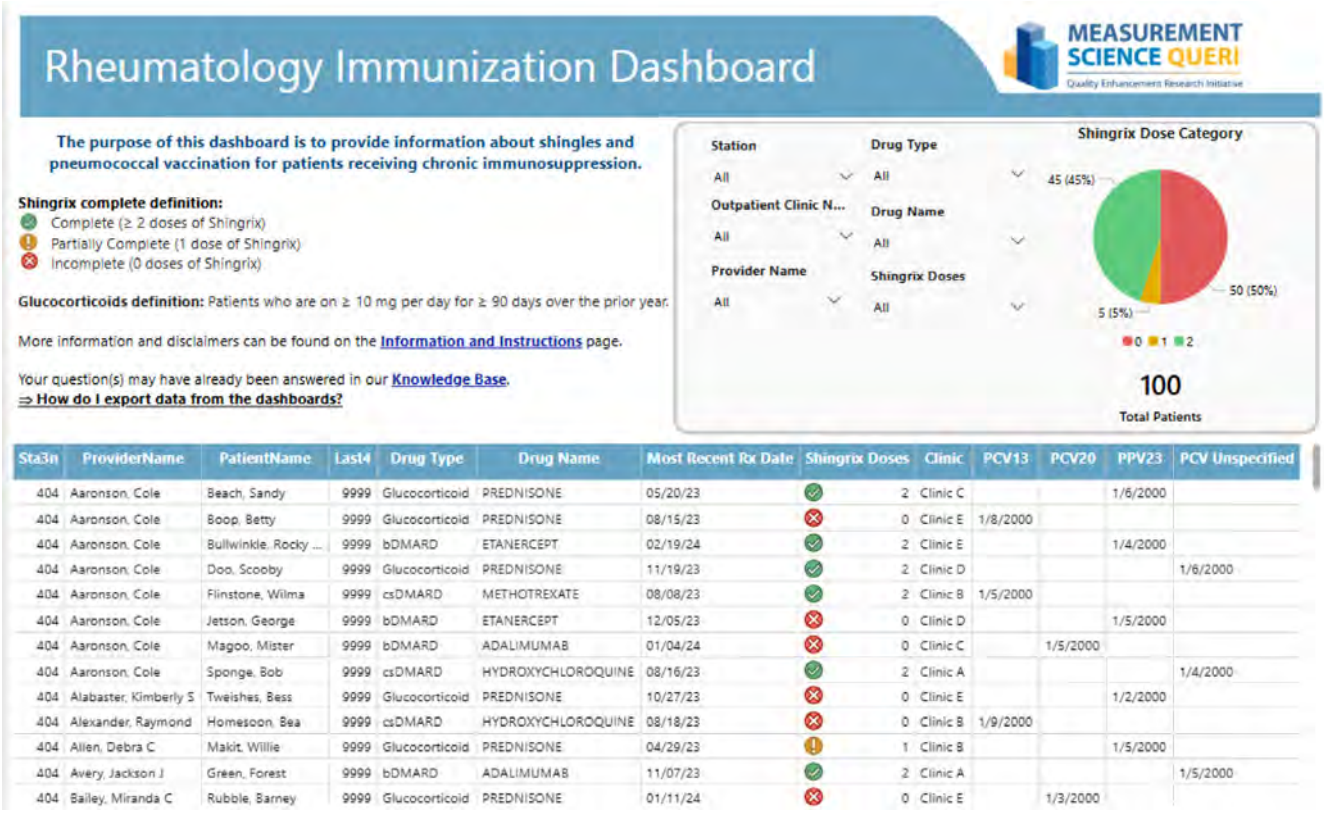

Figure 1. Screenshot of the Shingrix immunization dashboard (fictitious data)

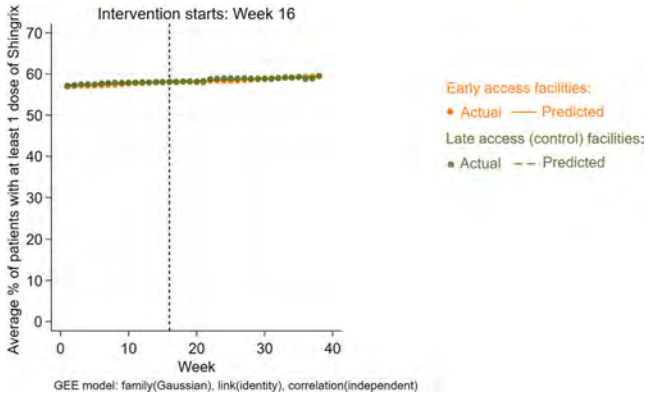

Figure 2. Interrupted time series (ITS) analysis assessing Shingrix vaccination pre- and post-dashboard access for "early access" versus "late access" (control) facilities

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

In this analysis of the first 38 weeks post-launch, Shingrix vaccination increased modestly from 57.1% to 59.5% across all sites. Early-access facilities saw a post-intervention increase of 0.07 percentage points (pp) per week, compared to 0.05 pp/week at control sites. The difference in trends was not statistically significant (difference: 0.02 pp/week; 95% CI: –0.01 to 0.05) (**Table; Figure 2**).

Conclusion: We designed an innovative wait-list randomized control trial of a provider-facing immunization dashboard to improve Shingrix vaccination. After 4 months of implementation, we observed no significant difference in Shingrix vaccination rates between early-access and control sites. This may reflect the typical 3–4 month interval between rheumatology visits. Longer follow-up, enhanced promotion of the dashboard, and additional clinician and patient education may be needed to realize te full impact of this intervention.

Abstract Number: 2618

Effect of Implementing a Dashboard with or without a Best Practice Alert on HLA-B*58:01 Testing Rates among Allopurinol Users at VA Medical Centers

Abimbola Fadairo-Azinge[1], gabriela Schmajuk[2], Sristi Sharma[3], Colleen Flanagan[4], Sara Faghihi-Kashani[5] and Mary Whooley[6], [1]UNIVERSITY OF CALIFORNIA SAN-FRANCISCO, SAN FRANCISCO, [2]University of California, San Francisco, and San Francisco Veterans Affairs Medical Center, San Francisco, CA, [3]UNIVERSITY OF CALIFORNIA SAN FRANCISCO, SAN FRANCISCO, [4]UNIVERSITY OF CALIFORNIA SAN FRANCISCO, SAN FRANCISO, [5]UCSF, Mountain View, CA, [6]SFVA, San Francisco

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Measures & Measurement of Healthcare Quality (2615–2620)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: The American College of Rheumatology recommends HLA-B*58:01 allele testing before the initiation of allopurinol, specifically among Asian and Black/African American patients, due to their increased risk for severe hypersensitivity reactions. However, testing rates remain low at many healthcare facilities. This study aimed to determine whether the introduction of a clinician-facing dashboard, with or without a Best Practice Alert (BPA), would increase HLA-B*58:01 testing rates among eligible patients at two Veterans Health Administration (VA) medical centers.

Methods: In October 2022, we launched a clinician-facing dashboard that displayed HLA-B*58:01 testing results for all patients prescribed allopurinol at two VA Medical Centers. In January 2023, we added a synchronous BPA that appeared at one of the two medical centers whenever a provider entered a prescription for allopurinol. The BPA was presented as blue text on the medication order entry form and stated "HLA-B*58:01 genotyping recommended before rx for Asian or African American." Using data from the electronic health record, we compared the change in proportion of patients receiving allopurinol prescriptions who had HLA-B*58:01 genotype testing done after implementation of the dashboard (± BPA) at the two VA medical centers.All statistical analyses were conducted using R (R Foundation for Statistical Computing, Vienna, Austria). A p-value of < 0.05 was considered statistically significant.

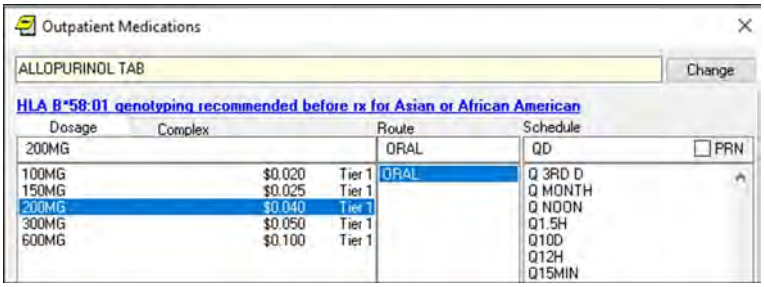

Figure 1. Interventions: Blue Text alert encountered by providers when entering an order for allopurinol at the BPA+DASHBOARD SITE

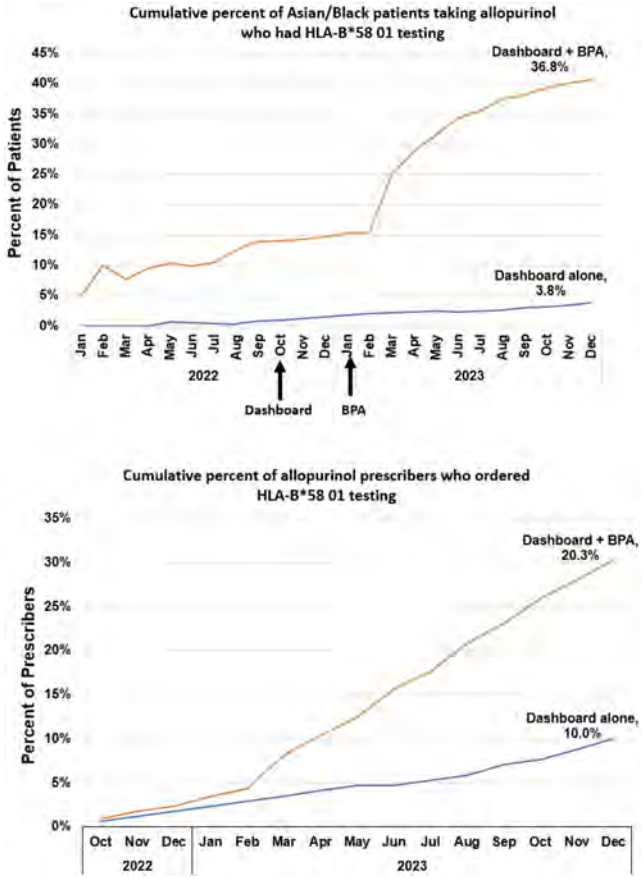
Results: From October 2022 through December 2023, the number of Asian or African American/Black patients who filled one or more prescriptions for allopurinol was 448 at the BPA + dashboard site and 499 at the dashboard only site. The two sites were similar in complexity, patient volume, location, and academic affiliation (Table 1). Between October 2022 and December 2023, the cumulative percentage of patients who had HLA-B*58:01 testing increased from 13.1% to 36.8% at the dashboard + BPA site and from 1.0% to 3.8% at the dashboard only site (Figure 2A, $p< 0.05$). Between January and December 2023, the number of Asian or African American/Black patients who had HLA-B*58:01 testing during a single month increased from an average of three per month to ten per month at the dashboard + BPA medical center and from one to three patients per month at the dashboard only medical center ($p< 0.05$). Allopurinol prescribers at the dashboard + BPA facility were more likely to order at least one HLA-B*58:01 test during the observation period than those at the dashboard only medical center (Figure 2B, 20.3% vs. 10.0%; $p=0.003$). However, this varied by provider type. Although

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



2a. Percent of Asian or African American/Black patients prescribed allopurinol who had HLA-B*58:01 testing 2b. Percent of prescribers who ordered one or more HLA-B*58:01 tests for Asian or African American/Black patients on allopurinol

there was a significant difference in the proportion of non-rheumatologists who ordered genotyping at the dashboard + BPA vs. dashboard alone facilities (15.4% vs. 4.3%; p=0.0004), there was no significant difference in the proportion of rheumatologists who ordered HLA-B*58:01 testing at the two facilities (83.3% vs. 88.9%; p=0.70).

Conclusion: Implementing a dashboard plus simple text BPA was associated with a greater increase in the proportion of patients who completed guideline-recommend HLA-B*58:01 testing compared to implementing a dashboard alone.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Measures & Measurement of Healthcare Quality (2615–2620)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Despite widespread recognition of persistent patient safety challenges in the U.S. health care system, the development of feasible and scalable solutions has lagged, particularly for ambulatory patients receiving immunosuppressive therapies. In this qualitative study we interviewed stakeholders across a diverse group of rheumatology practices to identify barriers and facilitators of high performance on four national patient safety measures, including screening for Hepatitis B and Tuberculosis prior to initiating immunosuppressive therapy, recommended Hydroxychloroquine dosing, and osteoporosis assessment for high-risk populations.

Table 2: Key Opportunities, Innovations, and Best Practices aligned with CFIR, with Supporting Quotes.

CFIR Domain	Opportunities	Exemplary Quotes
Process	1. Preventive care protocol 2. Risk screening	"I made a letter template that anyone in the health system can use for vaccination recommendations for immunosuppressed patients. I fill it out and send it to the patient. Or fax it into the pharmacy or the PCP." (P150)
Intervention characteristics	1. Medication monitoring system 2. EHR based alerts and reminders 3. Automatic data integration 4. EHR synopsis and customization	"Wherever we start immunosuppressives or biologic .... it's a communication order embedded within MyChart... It automatically takes it to my enrollment team and that will give them clear instructions on whether I need pre-labs." (P149) "If they're on HCQ, we have a pop-up on the side that reminds them to do their eye exams every six months." (P58) "Labs get sent out. They automatically flow in with a HL7 message, then they just flow right into the chart." (P25)
Individual characteristics	1. Commitment to safety and quality improvement	"It happened because I'm interested in quality of care and I like standardization. I like things to be easier and to be efficient." (P142)
Inner Setting	1. Staff training and education 2. Interdisciplinary collaboration 3. Monitoring and evaluation	"I created a laminated Excel spreadsheet, and it'll say the name of the measure, and then what is required of the measure, and what they're needing to do." (P5) "We have a close relationship with our pharmacy team, and I appreciated the Swiss cheese model that they provide. 'Hey, you ordered this, but they haven't had this test in quite a long time. Consider repeating the latent TB test.'" (P144)
Outer Setting	1. External reporting and compliance 2. Regular performance review	"I take a look and see how I'm performing, where I'm performing, and what's going on, and then try to look and do the deeper dive." (P13)

Methods: We identified 139 practices participating in the ACR's RISE registry with above-average performance on ≥1 of the 4 patient safety measures for interviews. Since RISE practices are largely community-based, we also invited 6 academic (AMCs) and 5 Veterans Affairs (VA) medical centers. Rheumatologists and key staff members involved in patient safety measure workflows were invited to take part in virtual semi-structured interviews. Guided by the concepts of the Consolidated Framework for Implementation Research (CFIR), the recorded interviews were transcribed verbatim and analyzed thematically using deductive and inductive techniques to generate themes.

Table 3: Major Challenges Faced by Practices Aligned with CFIR, with Supporting Quotes

CFIR Domain	Barriers	Exemplary Quotes
Process	1. Cumbersome workflow 2. Documentation gaps	"There are instances where there's a weight missing, was incorrectly entered, kilograms are put in for pounds. That's the biggest thing for the hydroxychloroquine– the absence of a reliable or recent weight." (P145)
Innovation	1. Limited EHR data integration 2. Unstructured EHR fields	"Part of the problem is, if it's not discrete data, it doesn't get counted." (P7) "PPD results, we've saved in many different fields, we don't have a great one-stop solution. We have some on the problem list...some saved in notes and carried forward with the date. That's been a challenge." (P140)
Individual characteristics	1. Clinician/staff noncompliance with workflow 2. Patient health literacy	"We're not part of a bigger clinic system. Our doctors are the board members, and they are all very independent and kind of stubborn. So, each one of them does things the way that they want to." (P108) "Another barrier is health literacy in patients. So I often have to find words on how I describe these situations so that the patient can understand at their level." (P150)
Inner Setting	1. Time constraints 2. Structural and logistics barriers 3. Increased workload	"We used to have a DEXA scanner in-house. We haven't had that for several years. So, we send the patient out." (P108) "It's one of my jobs, along with 27,000 others. If I tried to give it to a clinician, it would never get done either." (P58)
Outer Setting	1. Inaccurate data in RISE 2. Insurance and financial constraints	"Our measure is around 40% for Plaquenil, but there's no way it's 40% because most of my patients, regardless of weight, are on 200 mg daily at this point... It's closer to 70." (P14) "Your insurance company doesn't want to pay it but once a year. All of a sudden, we need to put in an order. Sometimes those don't coincide, so a little problematic." (P24)

Results: We conducted 19 interviews with 21 participants across 11 RISE practices, 5 AMCs, and 3 VAs. Participants included 11 rheumatologists, 6 practice managers, 2 pharmacists, 1 nurse, and 1 quality and compliance manager (Table 1). Practices described several innovative workflows that supported high performance on quality measures. These included standardized screening protocols and safety monitoring tools, often incorporating EHR-based alerts, integrated screening data, performance dashboards, and customized EHR fields for documentation. High performance was commonly attributed to clinicians' strong commitment to patient safety, ongoing staff training on clinical guidelines, and interdisciplinary collaboration, particularly with pharmacists (Table 2).

Respondents also identified persistent challenges including inefficient workflows for repatriating external lab data, inconsistent or missing documentation of screening information in structured EHR fields, non-standardized workflows and logistical difficulties in tracking the implementation and performance of safety measures (Table 3).

Conclusion: This study provided critical insights into key barriers and facilitators affecting rheumatology practices' performance on patient safety measures. Qualitative interviews revealed strategies associated with higher performance on safety measures, such as EHR-supported protocols and collaboration with pharmacists, but also highlighted challenges like inefficient workflows for data entry and data integration issues. These findings have laid the foundation for the development of the Rheum Safe Patient Safety Toolkit, currently in development. The toolkit will guide RISE practices in implementing patient safety measures and optimizing workflows for scalable and sustained improvement.

Transition Success of Pediatric Rheumatology Patients: A Novel Scoring System

Kyla Blasingame[1], David McDonald[1], Karissa Chesky[1], Jimin Kim[1], charles lee[1], Constance Wiemann[1], Blanca Sanchez-Fournier[1], Miriah Gillispie-Taylor[2] and Tiphanie Vogel[1], [1]Baylor College of Medicine, Houston, TX, [2]Baylor College of Medicine/Texas Children's Hospital, Houston, TX

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Measures & Measurement of Healthcare Quality (2615–2620)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Success of transition from pediatric to adult care depends on many factors. Various scores for transition readiness have been developed, including some designed to capture patient self-reported readiness and others that focus on program specific parameters. However, few patient-level transition success scores exist. Without such a score, it is difficult to assess the impact of programmatic interventions to improve the process of transition on transition outcomes. We created a novel transition success score for pediatric rheumatology patients.

Methods: Pediatric rheumatologists and adolescent health experts were consulted. Four components were included in the score: attending the first adult appointment in the time frame designated by the pediatric rheumatologist (component 1), refilling medications within 3 months of the first adult appointment (component 2), attending a second adult appointment (component 3), and no rheumatology-related emergency department visits in the first year after transition (component 4).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Scores were determined via electronic medical record (EMR) review. Each component was weighted as one-quarter of the total transition success score. The few patients who transitioned off medications were scored successfully for component 2.

Results: From 2017-2024, we identified 357 patients with a final visit to pediatric rheumatology using direct provider notification of transition to adult rheumatology clinic and EMR review. Of those, 199 were able to be scored for transition success. Some patients were unable to be scored due to subsequent healthcare details being inaccessible via EMR (n=73), others because it was still < 1 year since the final pediatric appointment (n=59), and others for various reasons such as dismissal from the need for future rheumatology followup (n=26). The average age at transition was 18.6 years. 73/199 (37%) patients scored 100 (ie achieved all 4 components of successful transition) and 77/199 (39%) scored 75. Only 3 patients (1.5%) scored 0. The average score was 74.3%. When considered by component, 114 patients (57%) met component 1, 151 (76%) met component 2, 160 (80%) met component 3, and 166 (83%) met component 4.

Conclusion: We developed a transition success score and applied it to patients who had transitioned from our pediatric rheumatology clinic. Although 150/199 patients (75%) fulfilled 3 or 4 out of 4 components of successful transition, we were unable to document attendance at a second adult rheumatology appointment for a surprising 20% of transitioned patients. Our next steps include correlating components of our transition program, including demographics, transition planning, self-reported transition readiness, and receipt of a transition summary letter, with the transition success score to better understand what factors predict successful transition.

Abstract Number: 2621

Erosive Hand Osteoarthritis Is Associated With Increased Risk of Incident Osteoporotic Fractures In Post-menopausal Women (QUALYOR Cohort)

MAXIME AUROUX[1], MERCIER-GUERY Alexandre[1], PIOT Anne[2], MERLE Blandine[3], PRORIOL Mathilde[1], FONTANGES Elisabeth[1], DUVERT Florence[1], Eric LESPESSAILLES[4] and CHAPURLAT Roland[1], [1]Hospices Civils de Lyon, LYON, France, [2]Centre Hospitalier Lucien Hussel, VIENNE, France, [3]INSERM U1033, LYON, France, [4]University Hospital of Orléans, Orleans, France

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Osteoarthritis – Clinical (2621–2626)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Erosive hand osteoarthritis (ErHOA) is a severe form of hand osteoarthritis (HOA) characterized by greater inflammation and higher burden of disease. In this more inflammatory form of HOA, we wanted to explore bone loss and fracture

Methods: We used data from the prospective QUALYOR study that enrolled 1575 postmenopausal women, aged at least 55 years, followed prospectively for 12 years.

At the 5-year visit (baseline of this work), we evaluated HOA using hand radiographs and clinical examination. HOA status was defined as follows:

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

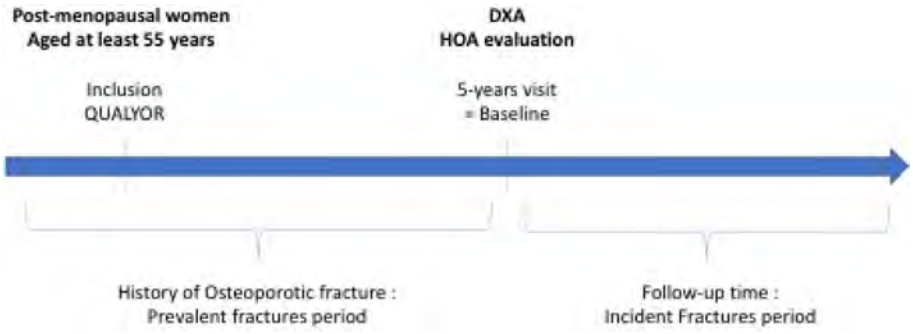

Figure 1. Study design

- No HOA : no pain AND no radiographic sign
- Radiographic HOA (RxHOA) : at least 2 joints graded KL ≥ 2 AND no symptoms
- Symptomatic HOA (SyHOA) : ACR criteria for HOA (no eroded joints)
- Erosive HOA (ErHOA) : SyHOA with at least one eroded joint

Osteoporotic (OP) status was evaluated at the 5-year visit by DXA (BMD at lumbar spine and hip) and history of fractures (medically confirmed) was recorded. Incident OP fractures at each subsequent follow-up visit were medically ascertained. OP status was defined as follows:

- No OP: All T-scores above -2.5 AND no history of OP fractures
- OP DXA: At least one T-score bellow -2.5 AND no history of OP fracture
- OP fracture: History of at least one OP fracture (regardless of T-scores)

Table 1. Characteristics of the total population and according to HOA status

Population		Total Population	No HOA	RxHOA	Sy HOA no Er	ErHOA	p-value

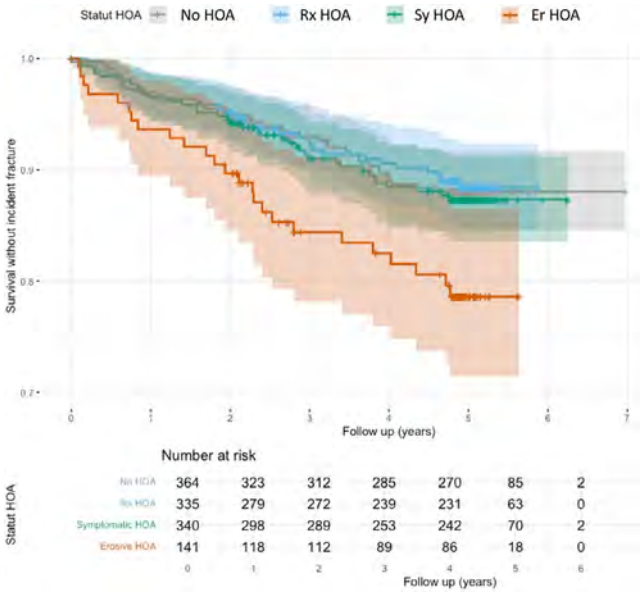

Figure 2. Kaplan-Meier curves representation the survival without incident fracture according to HOA status

We investigated the association between HOA status and incidence of OP fractures using a Cox model with adjustment for age, history of fractures, T-scores and obesity. Kaplan Meier curves representing survival without incident fractures were obtained according to HOA status. We also conducted a subgroup analysis stratifying patient by prevalent fracture at baseline combined with HOA status.

Results: We have analyzed data from 1180 patients. The mean age was 71.7(± 6.41) years and the mean follow-up time was 4.6 (±0.85) years. Among them, 364 (30.8%) had no HOA, 335 (28.4%) had RxHOA, 340 (28.8%) had SyHOA and 141 (11.9%) had ErHOA. Patients with HOA were older than patients without HOA (Table 1)

During follow-up, 131 patients (11.1%) experienced 166 incident OP fractures with a mean follow-up time to event of 2.2 (±1.42) years. Patients with incident OP fractures were older and had lower BMD. Among them 19.1% had ErHOA compared to 11.1% in those without incident OP fracture ($p< 0.05$). Kaplan-Meier curves depicting the survival without incident fracture according to HOA status is provided in Figure 2. The HR for incident fracture in patients with ErHOA compared to patients without HOA was 1.93 (CI95% 1.12-3.32, $p< 0.05$), whereas the HR was 1.1 (CI95% 0.69-1.77) for SyHOA and HR 0.95 (CI95% 0.59-1.57) for RxHOA compared with patients without HOA.

Patients with ErHOA and no history of OP fracture had an increased risk of incident fractures with a HR of 1.95 (CI95% 1.07-3.5, $p< 0.05$) compared to patient without HOA and no history of fracture. Of note, patients without HOA but prevalent OP fracture – a recognized strong risk factor for fracture – had a HR of 1.41 (CI95% 0.62-3.23) when compared with those without prevalent fracture.

Conclusion: In conclusion, erosive HOA is a strong predictor of incident osteoporotic fracture, in postmenopausal women, independently of various classical risk factors for fracture. Exploring the sources of bone loss distinguishing erosive HOA from other types of HOA is warranted.

Oral Microbiome Dysbiosis and Oral-gut Microbial Network Disruption in Hand Osteoarthritis: Data from the Xiangya Osteoarthritis Study

Jiatian Li[1], Yadan Xiao[2], Tuo Yang[1], david Hunter[3], Weiya Zhang[4], Michael Doherty[4], Yuqing Zhang[5], Zidan Yang[1], Yilun Wang[1], Dongxing Xie[1], Changjun Li[1], Wei Li[1], Zeqin Wen[1], Chao Zeng[1], Guanghua Lei[1] and **Jie Wei[1]**, [1]Xiangya Hospital, Central South University, Changsha, Hunan, China (People's Republic), [2]Xiangya School of Public Health, Central South University, Changsha, Hunan, China (People's Republic), [3]Sydney Musculoskeletal Health, University of Sydney, St Leonards, New South Wales, Australia, [4]School of Medicine, University of Nottingham, Nottingham, United Kingdom, [5]Massachusetts General Hospital, Quincy, MA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Osteoarthritis – Clinical (2621–2626)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: The oral microbiome plays a critical role in modulating systemic inflammation and maintaining immune homeostasis, partly through its interactions with the gut microbiome. Although gut microbiome dysbiosis has been implicated in symptomatic hand osteoarthritis (SHOA), the role of oral microbiome dysbiosis in SHOA and its potential correlation with gut microbiome remains unclear. Elucidation these relationships may provide novel insights into the pathogenesis of SHOA and inform future treatment strategies.

Methods: Participants were recruited from the Xiangya Osteoarthritis (OA) Study, a community-based cohort study. SHOA was defined as the presence of both self-reported pain and radiographic OA in at least one hand. The control group comprised participants without hand pain or radiographic OA. Among the 764 participants included in this study, 52 (6.8%) had SHOA. Saliva samples were analyzed using 16S rRNA gene sequencing. Oral microbial richness (α-diversity, measured by Shannon index) and composition (β-diversity, measured by Bray-Curtis distance) were compared between SHOA and control groups. Associations of the relative abundance of oral microbiome genera with SHOA and its severity were examined. Functional alterations in the oral microbiome were inferred using Kyoto Encyclopedia of Genes and Genomes (KEGG) level 3 pathways analysis. Gut microbiome data from a previous study conducted within the same cohort were

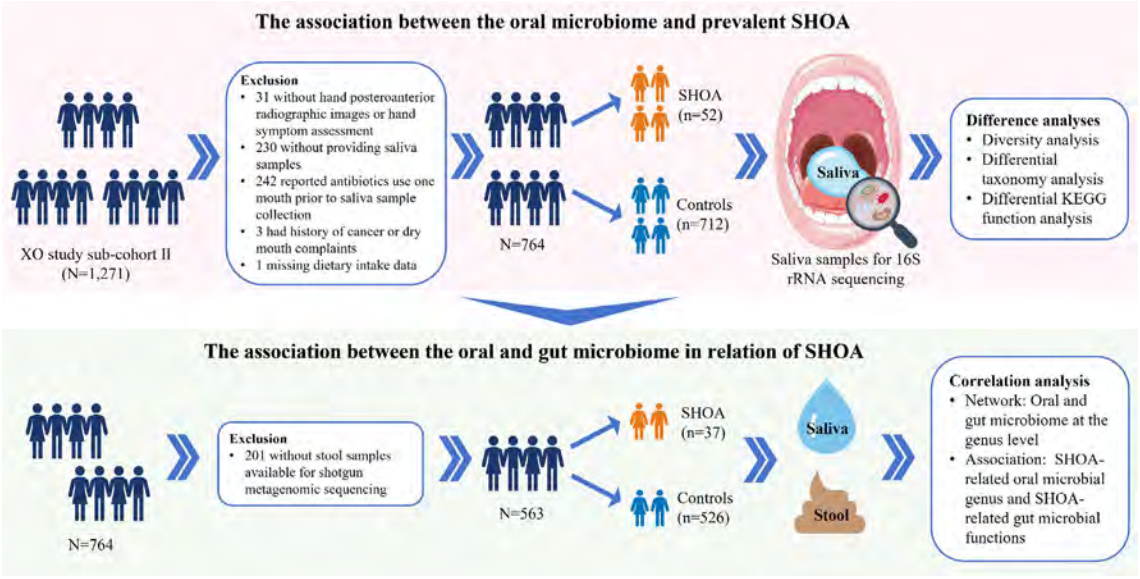

Figure 1. Summary of the present study. SHOA, symptomatic hand osteoarthritis; KEGG, Kyoto Encyclopedia of Genes and Genomes.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

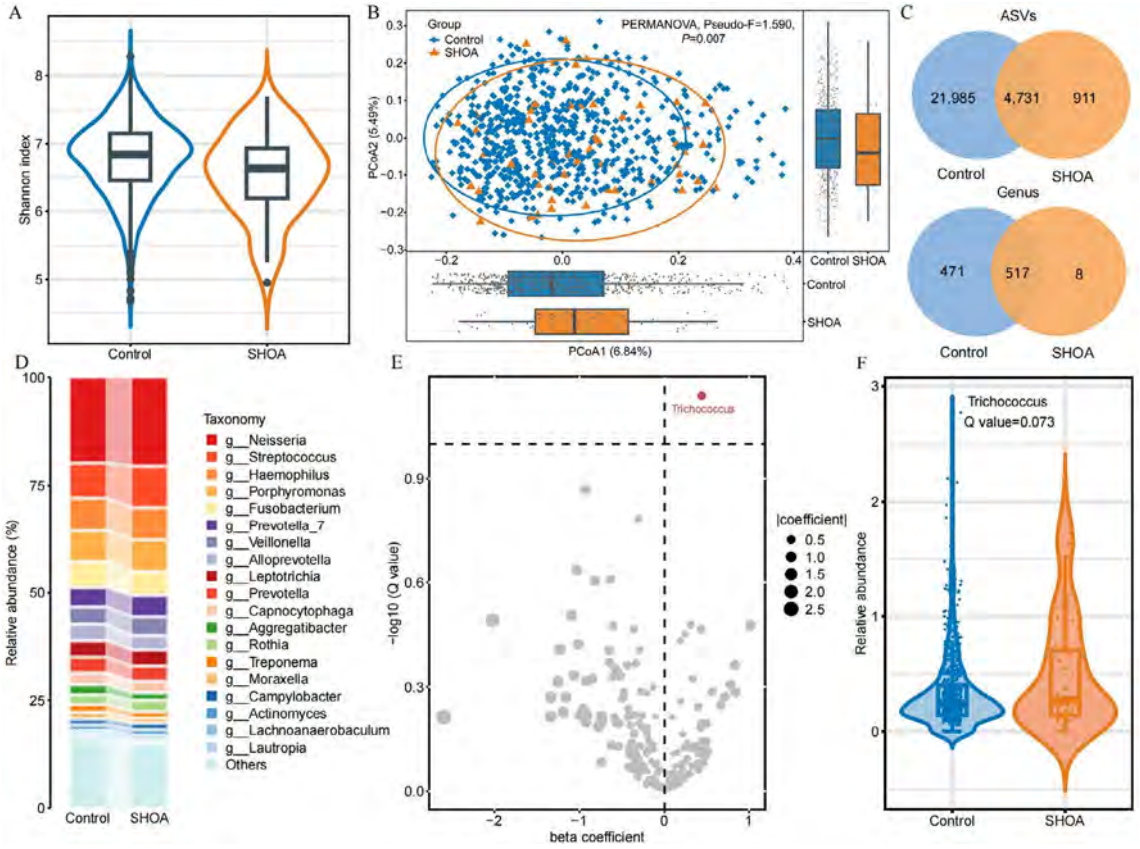

Figure 2. Comparison of oral microbiome diversity and composition between participants with SHOA and controls. (A) Violin plots showing α-diversity measured by the Shannon index between participants with SHOA and controls. (B) PCoA plots comparing β-diversity measured by Bray-Curtis distance between participants with SHOA and controls. (C) Venn diagram illustrating shared and exclusive ASVs and microbial genera between participants with SHOA and controls. (D) Relative abundance of the top 20 microbial genera in the oral microbiome composition of participants with SHOA and controls. (E) Volcano plot depicting differences in the microbial genera between participants with SHOA and controls. The red region indicates statistically significant differences (Q<0.1). (F) Relative abundance of differential microbial genus between participants with SHOA and controls. SHOA, symptomatic hand osteoarthritis; PCoA, principal coordinates analysis; ASVs, amplicon sequence variants.

integrated to examine ecological links between the oral and gut microbiomes.[1] Correlations between SHOA-associated oral microbial genera and SHOA-associated gut microbial functions were also assessed. A workflow is presented in **Fig. 1**.

Results: Compared with controls, participants with SHOA exhibited significantly lower oral microbial α-diversity (P=0.007, **Fig. 2A**) and altered β-diversity (P=0.007, **Fig. 2B**). A total of 911 amplicon sequence variants and eight genera were uniquely identified in the SHOA group (**Fig. 2C**). In both the SHOA and control groups, the oral microbiome was predominantly composed of the genera *Neisseria*, *Streptococcus*, *Haemophilus*, *Porphyromonas*, *Fusobacterium***(Fig. 2D)**. The relative abundance of the genus *Trichococcus* was significantly higher in SHOA participants (P=0.001, Q=0.073, **Fig. 2E-F**), and was positively correlated with SHOA severity. Oral microbiome KEGG level 3 pathways involved in tropane, piperidine, and pyridine alkaloid biosynthesis (P=0.006, Q=0.084), as well as indole alkaloid biosynthesis (P=0.006, Q=0.090), were significantly inversely associated with SHOA. Furthermore, the number of correlations in the oral-gut microbiome network was significantly reduced in SHOA participants compared with controls (**Fig. 3A)**. Additionally, a positive correlation was observed between oral microbiota *Trichococcus* and the gut microbiome KEGG pathway of tyrosine metabolism, both of which were significantly associated with SHOA (P=0.001, Q=0.047, **Fig. 3B-C**).

Conclusion: Oral microbiome dysbiosis and the disrupted oral-gut microbiome network are associated with prevalent SHOA, suggesting a potential role for oral-gut microbiome interactions in disease pathogenesis.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Osteoarthritis – Clinical (2621–2626)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Barriers to developing effective osteoarthritis (OA) therapies include the lack of standardized definitions for disease progression and structural endpoints that reliably predict changes in symptoms (e.g., pain). We recently developed a "disease activity" composite metric that combines bone marrow lesion (BML) and effusion-synovitis volumes on magnetic resonance (MR) imaging into a standardized definition of disease progression related to pain. While many imaging biomarkers are associated with pain, the clinically meaningful magnitude of change in these measures remains unclear. We aimed to examine the association between 2-year changes in disease activity and 2-year changes in knee pain and quantify thresholds of clinically meaningful change for our novel disease activity composite metric.

Methods: We conducted a longitudinal nested cohort study within the Osteoarthritis Initiative, including participants with at least possible radiographic knee OA (Kellgren-Lawrence grade ≥ 1) and mild knee pain (WOMAC pain score ≥ 10/100). We measured BML and effusion-synovitis volumes on MR images (intraclass correlation coefficients > 0.95). We assessed 4 methods to calculate the disease activity metric: 1) sum of standardized volumes, 2) z-score, 3) percentile, and 4) adjusted

Table. The distribution and association of 2-year changes in disease activity (DA) metrics with categories of 2-year changes in knee pain.

	2-year changes of WOMAC				
2-year change	Pain Improvement < -20 (n = 139) median (25th, 75th)	No Change -20 to 20 (Reference) (n = 1081) median (25th, 75th)	Pain Worsening > 20 (n = 75) median (25th, 75th)	OR (95% CI)* Pain Improvement	OR (95% CI)* Pain Worsening
DA	-0.07 (-1.26, 0.86)	0.32 (-0.33, 1.24)	1.18 (-0.06, 2.64)	0.87 (0.82, 0.93)	1.16 (1.05, 1.27)
DA z-score	-0.05 (-0.43, 0.32)	0.15 (-0.13, 0.46)	0.43 (-0.03, 0.88)	0.46 (0.34, 0.63)	2.09 (1.32, 3.32)
DA percentile	-0.73 (-10.84, 8.85)	3.21 (-3.18, 13.17)	11.81 (-1.00, 27.78)	0.79 (0.72, 0.87)	1.29 (1.13, 1.47)
Adjusted DA percentile	-1.11 (-14.86, 8.57)	2.53 (-4.14, 12.81)	11.05 (-1.06, 27.66)	0.79 (0.72, 0.87)	1.30 (1.14, 1.48)

* Footnote: Odds ratio (OR) per unit increase of DA and DA z-score; OR per 10 percent increase of percentiles.

percentile. We used established cut-points to categorize 2-year change in pain: 1) pain improvement (< - 20), 2) minimal change (-20 to 20), and 3) worsening (> 20). We calculated the distribution of each disease activity metric across categories of changes in WOMAC knee pain. We then used multinomial logistic regression to explore the association between 2-year changes in disease activity and categories of changes in WOMAC knee pain (3-level outcome, reference = minimal change).

Results: Among 1,295 knees (641 participants), 139 knees had meaningful pain improvement (71% female, 53% obese, 81% radiographic knee OA), 75 knees had worsening (70% female, 62% obese, 79% radiographic knee OA), and 1,081 had no meaningful change (58% female, 45% obese, 79% radiographic knee OA). Changes in each disease activity metric were associated with both pain improvement (OR= 0.46 to 0.87; Table) and pain worsening (OR= 1.16 to 2.09; Table). Among knees with minimal change in pain, most knees experienced worsening disease activity scores (Table). Median disease activity changes among participants with pain improvement or worsening may serve as a threshold for defining minimally clinically important changes to effectively distinguish most knees with minimal pain changes as having minimal disease activity changes (Table, Figure).

Conclusion: All disease activity metrics were associated with knee pain, underscoring their utility in monitoring disease activity as an indicator of pain. Most knees with minimal changes in pain had subtly worsening disease activity, which reflects the natural history of OA progression. Most knees showing clinically meaningful improvement in pain experienced improved

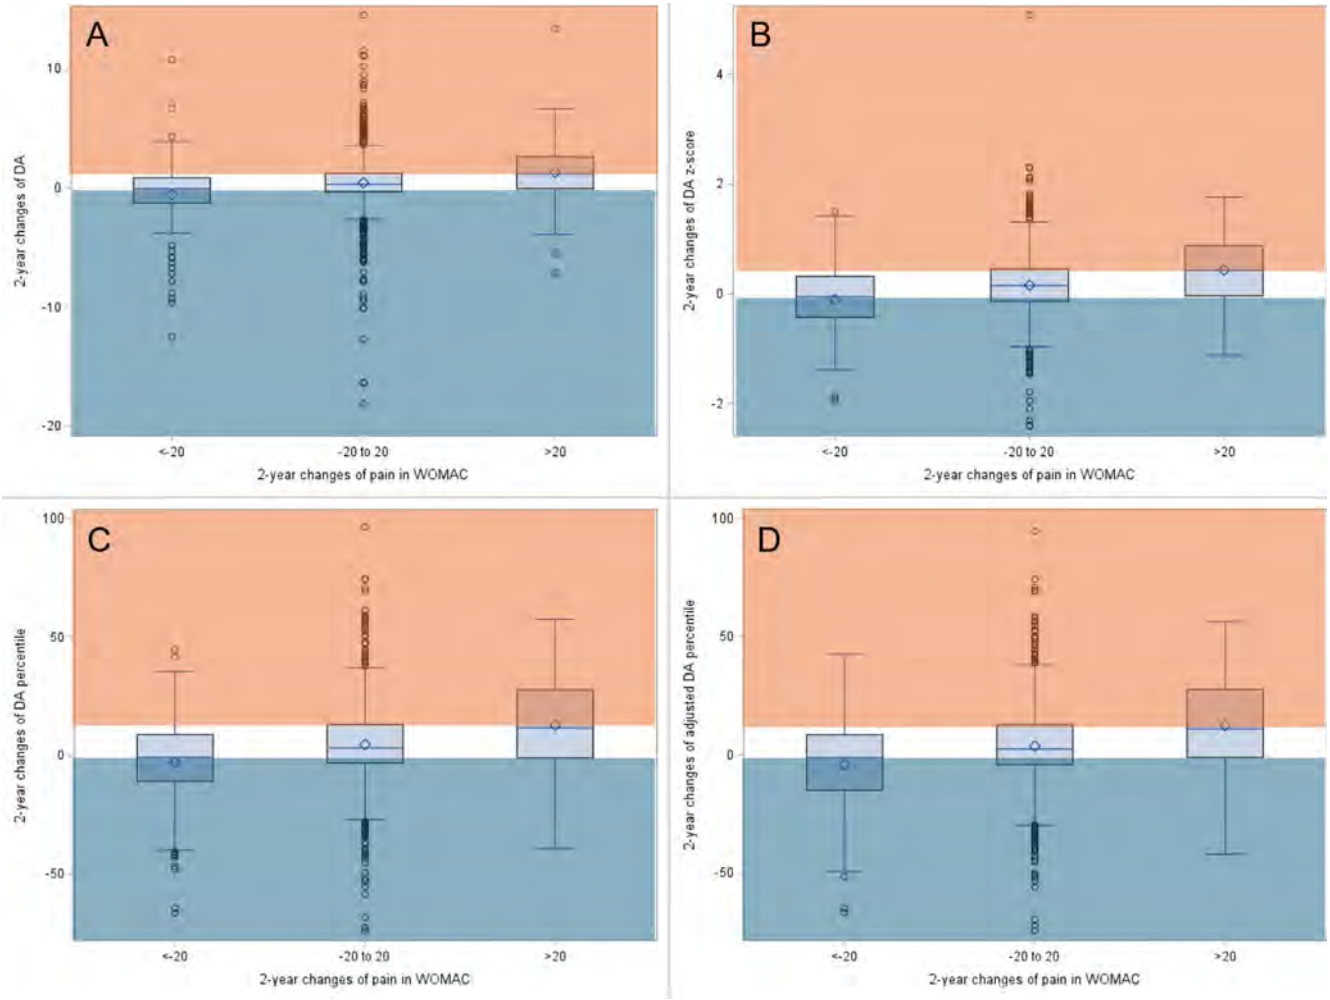

Figure. The distribution of 2-year changes in disease activity (DA) metrics across categories of 2-year changes in WOMAC knee pain scores, with orange reflecting clinically meaningful worsening in disease activity and blue representing clinically meaningful improvement in disease activity. Note. A. Disease activity score, B. Disease activity z-score, C. Disease activity percentile, and D. Disease activity adjusted percentile.

disease activity; in contrast, knees with worsening knee pain had worsening disease activity. Our composite disease activity metric shows promise as a biomarker for defining structural progression in knee OA that is clinically relevant to pain outcomes.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Osteoarthritis – Clinical (2621–2626)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Intra-articular corticosteroids are widely used for routine management of chronic pain from knee osteoarthritis (KOA), though estimates of their benefit vary widely. We aimed to quantify the short-term benefit of corticosteroid injections in reducing symptoms of KOA in a large, pragmatic, multi-site clinical trial.

Methods: This was a factorially-designed crossover randomized trial among patients with KOA across 4 Veteran Affairs Medical Centers. Participants were 40-80 years of age, had a clinical diagnosis of KOA, a Kellgren-Lawrence X-ray grade > or = 1, and a clinical indication for joint injection according to the treating provider. Participants were randomized to an incentive arm to promote physical activity, or an attention control. Within these arms, participants were further randomized to receive blinded injections with corticosteroid plus lidocaine (40 mg methylprednisolone) or lidocaine-only in a crossover design over 28 weeks. The primary outcome was the change in the Knee Osteoarthritis Outcome Score (KOOS) (range 0-100). A change of $\geq$10 was considered the minimal clinically important difference (MCID). Linear or generalized mixed-effects models were used to evaluate the effect of the corticosteroid injection over all outcomes between 2-12 weeks. We also performed a crossover analysis among 196 participants that received a second injection at week 16 (N=392). Sensitivity analyses included a last-observation-carried-forward approach to account for missingness as well as sub-group analyses.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2: Subgroup analyses for primary outcome comparing corticosteroid plus lidocaine to lidocaine-only. Point estimates and confidence intervals shown are the estimates of difference betweenc corticosteroid and lidocaine-only groups from time-averaged mixed-effects models within each subgroup of interest. Abbreviations: KL, Kellgren-Lawrence; KOOS, Knee Osteoarthritis Outcome Score; LOCF, last observation carried forward.

Results: Of 231 enrolled, 221 were randomized (mean age 64 years; 84% male, median K-L grade of 3). 176 (80%) had received a prior injection. Those randomized to initial corticosteroids showed no improvement in total KOOS scores compared to lidocaine-only at any time point or when evaluating all outcomes over 12-weeks [B: 1.72 (95% CI: -1.08, 4.52) p=0.23] (**Figure 1a**, **Table 1**). The probability of achieving KOOS MCID was 20.9% v. 16.8% for the lidocaine-only arm (Risk Difference [RD] = 0.041 (95% CI: -4.1, 12.3); Number Needed to Treat [NNT] = 24 (95% CI: 8, ∞). A crossover analysis comparing 196 participants to themselves demonstrated no benefit over 12-weeks [B: 0.36 (95% CI: -1.17, 1.90) p=0.29] (**Figure 1b**). The probability of achieving MCID was 19.7% v. 15.3% for lidocaine-only (RD=0.044 [95% CI: -0.011, 0.10]; NNT=23 [95% CI: 10, ∞]). There were no carryover effects. Results were similar for secondary outcomes, in sensitivity analysis, and across subgroups (**Table 1; Figure 2**). There was no interaction with the exercise incentive arm. Among those receiving both injections, only 55% correctly guessed the order of their injections. Rescue injections were infrequent (n=6 during lidocaine-only; n=7 during corticosteroid).

Conclusion: In this well-powered, blinded, pragmatic, randomized trial, corticosteroid injections provided no significant benefit over 12 weeks compared to lidocaine-only injections. These findings, in the context of the existing literature, suggest limited benefit of this commonly performed procedure in real-world practice and raise new questions about whether this intervention should be widely used for routine management of KOA symptoms.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Osteoarthritis – Clinical (2621–2626)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Bone marrow lesions (BMLs) and effusion-synovitis are frequent and dynamic disease processes detected from early- to late-stage knee OA. These processes are associated with knee symptoms, representing the primary clinical manifestations of OA. Through a systematic and iterative process, we previously developed and validated a composite biomarker – the disease activity metric – that combines BML and effusion-synovitis volumes throughout a knee into an efficient continuous single score. It remains unclear whether this composite score represents clinically meaningful pathways to early stages of OA and if it could detect people early, before the onset of OA. We evaluated whether these dynamic disease processes (effusion-synovitis volume and BMLs), summarized by a validated efficient continuous composite score, are present in early OA and prognostic of incident symptomatic knee OA over the subsequent three years.

Methods: We analyzed a convenience sample within the Osteoarthritis Initiative (OAI) of participants without symptomatic knee OA. Pain assessments and radiographs were collected annually. Using magnetic resonance images from the initial visit, we combined effusion-synovitis and BML volumes (intra-reader ICCs ≥ 0.95) to calculate a composite score, referred to as the disease activity metric. A disease activity metric of 0 corresponded to the average in a reference sample (n=197, 53% with moderate-severe radiographic knee OA, average [SD] WOMAC pain score = 5.0 [3.6]); lower (negative) values indicate milder disease, while greater values indicate worse disease. The outcome was incident symptomatic knee OA (the combined state of frequent knee pain and radiographic OA [Kellgren-Lawrence Grade ≥ 2]) within three years after the disease activity measurement. We used logistic regression with repeated measures to examine the association between disease activity (continuous and tertiles) and incident symptomatic knee OA, adjusting for gender, age, and body mass index.

Results: Among 913 knees (n=572 participants), most were female (56%), white (82%), and had a mean age of 61 (SD=9) and body mass index of 29.4 (SD=4.5) kg/m^2. Disease activity ranged from -3.8 to 24.8 (lower values = smaller effusion-synovitis and BML volumes). Knees that developed incident symptomatic OA had a greater mean disease activity metric compared to those that did not (-0.3 [2.7] vs. -1.4 [2.7]). The adjusted relative risk of incident symptomatic OA per 1 unit

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table. Worse Disease Activity is Associated with a Greater Chance of Incident Symptomatic or Radiographic OA

	Incident Symptomatic OA			
Overall Study Sample	Absent n= 630	Present n = 283	Unadjusted Relative Risk (RR) (95% CI)	Adjusted RR[a] (95% CI)
Disease Activity (mean (SD))	-1.37 (2.68)	-0.30 (2.66)	**1.07 (1.03 - 1.11)**[b]	**1.08 (1.04 - 1.11)**[b]
Disease Activity –Tertiles Low (-3.83 to -2.46)	253 (40%)	48 (17%)	REFERENCE	
Moderate (-2.44 to -1.05)	207 (33%)	99 (35%)	**2.05 (1.50 - 2.80)**	**1.99 (1.46 - 2.71)**
High (-1.04 to 24.79)	170 (27%)	136 (48%)	**2.89 (2.14 - 3.91)**	**2.79 (2.06 – 3.78)**
No Symptoms, No Radiographic OA (n = 277)	Incident Symptomatic OA			
	Absent n= 259	Present n = 18	Unadjusted RR* (95% CI)	
Disease Activity (continuous)	-1.94 (1.96)	-1.77 (1.29)	1.05 (0.93 - 1.19)	
Disease Activity –Tertiles Low (-3.83 to -2.46)	128 (49%)	7 (39%)	REFERENCE	
Moderate (-2.44 to -1.05)	84 (32%)	7 (39%)	1.23 (0.50 - 3.03)	
High (-1.04 to 24.79)	47 (18%)	4 (22%)	1.49 (0.50 - 4.42)	
Radiographic OA Only (No Symptoms) (n = 459)	Incident Symptomatic OA			
	Absent n= 211	Present n = 248	Unadjusted RR* (95% CI)	
Disease Activity (continuous)	-0.62 (3.43)	-0.22 (2.71)	1.02 (0.99 - 1.05)	
Disease Activity –Tertiles Low (-3.83 to -2.46)	58 (27%)	38 (15%)	REFERENCE	
Moderate (-2.44 to -1.05)	70 (33%)	87 (35%)	**1.42 (1.07 - 1.89)**	
High (-1.04 to 24.79)	83 (39%)	123 (50%)	**1.56 (1.19 - 2.05)**	
Symptoms Only (No Radiographic OA) (n = 175)	Incident Symptomatic OA			
	Absent n= 158	Present n = 17	Unadjusted RR* (95% CI)	
Disease Activity (continuous)	-1.43 (2.34)	0.03 (2.64)	**1.16 (1.05 - 1.29)**	
Disease Activity –Tertiles Low (-3.83 to -2.46)	66 (42%)	3 (18%)	REFERENCE	
Moderate (-2.44 to -1.05)	53 (34%)	5 (29%)	2.04 (0.78 - 45.37)	
High (-1.04 to 24.79)	39 (25%)	9 (53%)	**5.65 (1.85 - 17.30)**	

Notes. (a). Relative risks adjusted for age, gender, and body mass index. (b). Relative risks for disease activity as a continuous measurement are per 1 unit. Bold = statistically significant associations. * Only unadjusted relative risks are reported because of the limited sample size within each stratum.

increase in disease activity was 1.08 (95% confidence interval: 1.04-1.11). Stratified analyses suggested that the association was driven by knees with either radiographic OA only or symptoms only at baseline.

Conclusion: Our findings underscore the critical role of the composite disease activity metric in the early detection of knee OA. By integrating BMLs and effusion-synovitis volumes, this metric provides a powerful prognostic tool, enabling earlier detection and potential intervention to alter disease progression. These results also support the development of targeted therapies that address inflammation and bone turnover in early OA.

Lorecivivint Delayed Time to Pain and Function Worsening Compared to Placebo: Evaluation of Knee OA Symptom Progression Outcomes in a Phase 3 Trial (OA-07)

Yusuf Yazici[1] and Christopher Swearingen[2], [1]NYU Grossman School of Medicine, La Jolla, CA, [2]Biosplice Therapeutics, Inc, San Diego, CA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Osteoarthritis – Clinical (2621–2626)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Increased pain and decreased function are hallmarks of knee OA progression. Lorecivivint (LOR), an intra-articular CLK/DYRK inhibitor thought to modulate inflammatory and Wnt pathways, appeared safe, improved pain and function outcomes and maintained radiographic medial joint space width (JSW) compared with placebo (PBO) in clinical trials to date. A Phase 3 trial, OA-07 (NCT04520607), evaluated LOR's safety and assessed WOMAC Pain and Function and JSW outcomes. A post-hoc analysis assessed whether LOR could delay pain and function worsening, proposed predictors of future knee replacement surgery[1].

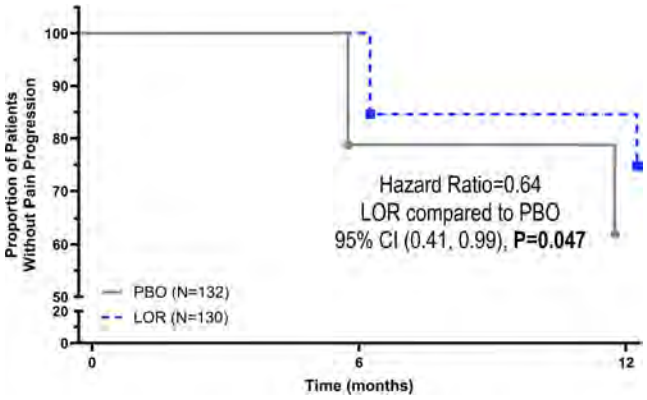

Figure 1. Analysis of LOR compared to PBO in Time to Progression in WOMAC Pain [0-100]

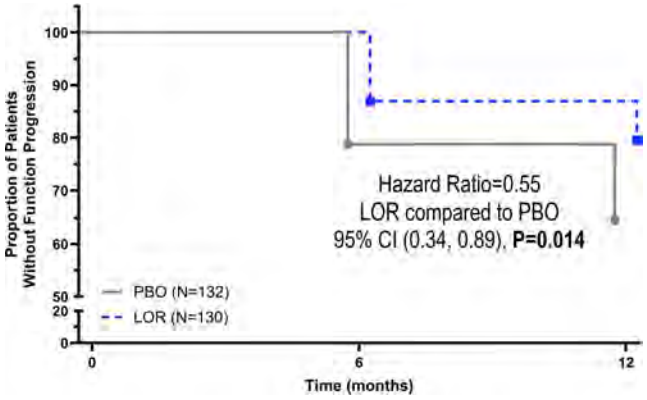

Figure 2. Analysis of LOR compared to PBO in Time to Progression in WOMAC Function [0-100]

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

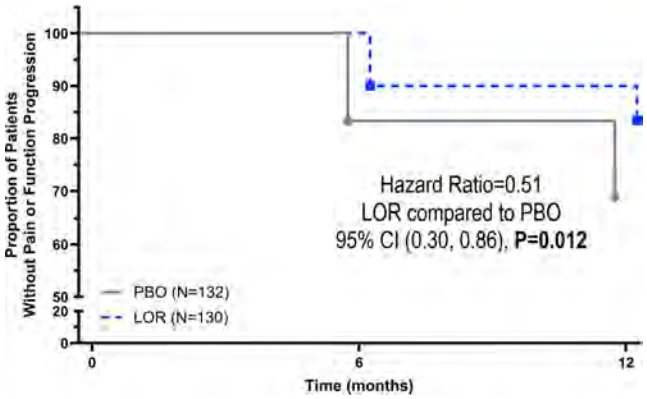

Figure 3. Analysis of LOR compared to PBO in Time to Coincident Progression of WOMAC Pain and Function

Methods: Patients who had completed the year-long, single-injection LOR trial Study OA-11 (NCT03928184), were invited to enroll into Study OA-07. At OA-07 baseline, patients received the same randomized study injection originally received in Study OA-11 and patients and investigators remained blind to treatment allocation. At the end of OA-07's first year, all patients were treated with open-label LOR.

In this post-hoc analysis, worsening in WOMAC Pain (WOMAC Pain [0-100] increase by 10+ points), worsening in WOMAC Function (> 9 points), and worsening in coincident WOMAC Pain and Function were explored using multivariable Logistic and Cox regression to assess differences between LOR and PBO in the first year of OA-07 in the Full Analysis Set. Progression in PBO patients during the first year was analyzed compared to their second year after cross-over to LOR, so that each patient served as their own control. The PBO-LOR crossover analysis was analyzed using repeated measures multivariable logistic and Cox regression in the Per-Protocol Analysis Set for complete Year 1 and Year 2 assessments.

Results: 276 patients were enrolled (LOR N=138, PBO N=138, 62.7% female, mean age 61.0 ± 8.2 years, mean BMI 31.8 ± 4.9 kg/m^2, 45.3% Kellgren-Lawrence Grade 3, average medial JSW 2.63 ± 0.69 mm). LOR appeared safe and well-tolerated with no adverse event rate differences compared to PBO.

Significant reduction in the progression of WOMAC Pain (LOR n=38 [29.2%], PBO n=57 [43.2%], OR=1.86, 95% CI [1.12, 2.12], P=0.018), progression of WOMAC Function (LOR n=35 [26.9%], PBO n=52 [39.4%], OR=1.82, 95% CI [1.07, 3.08], P=0.026), and progression in composite Pain and Function (n=28 [21.5%]) PBO (n=45 [34.1%]) (OR=1.90, 95% CI [1.09, 3.31], P=0.023), adjusting for age and KL Grade, were seen with LOR compared to PBO. Time to progression was also significantly reduced in LOR compared to PBO for WOMAC Pain (**Figure 1**), WOMAC Function (**Figure 2**), the combined Pain and Function progression (**Figure 3**). LOR also reduced progression in WOMAC Pain (OR=1.73, 95% CI (0.88, 3.04), P=0.054) and WOMAC Function (OR=2.12, 95% CI (1.16, 3.87), P=0.015) in PBO patients crossed over to LOR.

Conclusion: LOR was shown to be safe and efficacious in Study OA-07. Significant reduction in pain and function progression was seen for LOR compared to PBO, with LOR delaying time to progression. PBO patients who crossed to LOR treatment also demonstrated reduced progression. LOR continues to show promise as a safe, disease-modifying knee OA treatment.

Abstract Number: 2627

Risk of Adverse Pregnancy Outcomes in Individuals with Rheumatic Diseases Using Prenatal Antirheumatic Drugs: a Population-Based Cohort Study

Shenthuraan Tharmarajah[1], Dharini Mahendira[2], Swaleh Hussain[1], Howard Berger[3], Sara Guilcher[4], Lisa McCarthy[4] and Mina Tadrous[1], [1]University of Toronto, Toronto, ON, Canada, [2]St Michael's Hospital, Toronto, Canada, [3]St. Michael's Hospital, Toronto, Canada, [4]University of Toronto, Toronto, Canada

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Reproductive Issues in Rheumatic Disorders (2627–2632)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Disease-modifying antirheumatic drugs (DMARDs) are the primary class of drug therapies generally used to treat rheumatic diseases, such as rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), psoriatic arthritis (PsA), and ankylosing spondylitis (AS). However, the safety effects of DMARD use during pregnancy remain largely understudied, despite many individuals continuing some form of DMARD therapy during pregnancy to control maternal disease activity. Within Canada, past observational studies have leveraged claims data from the provinces of Quebec and British Columbia to study DMARD safety in pregnancy. This study aimed to assess the risk of severe maternal morbidity (SMM) and severe neonatal morbidity (SNM) in individuals with rheumatic diseases using DMARDs during pregnancy in Ontario, Canada's most populous province.

Methods: Leveraging routinely collected population-based healthcare administrative claims data at ICES in Ontario, Canada, we included pregnant individuals with RA, SLE, PsA, and/or AS who delivered a liveborn or stillborn singleton infant after 20 weeks of gestation between April 1, 2006, and March 31, 2021. DMARD exposure was defined as having at least one conventional synthetic or biological DMARD dispensation reimbursed from estimated conception to delivery. To adjust for confounders such as maternal age, rheumatic conditions and comorbidities, healthcare utilization, and concomitant medication use, propensity scores were calculated to estimate the probability of DMARD exposure. Stabilized inverse probability of treatment weights were derived from propensity scores and used in logistic regression modelling to estimate the odds ratios (ORs) and 95% confidence intervals (95% CIs) for SMM and SNM in the DMARD-exposed cohort versus unexposed comparators.

Results: There were 836 pregnant individuals with rheumatic conditions, with 302 exposed to DMARDs and 534 unexposed. Most individuals had a diagnosis of RA (n=396, 47.4%), followed by SLE (n=357, 42.7%), AS (n=86, 10.3%), and PsA (n=48, 5.7%), with 49 (5.9%) individuals having more than one of these conditions. In unadjusted analyses, DMARD exposure was associated with SMM (OR: 1.81, 95% CI: 1.11–2.96) but not associated with SNM (OR: 0.97, 95% CI: 0.62–1.51). After adjusting for confounders, DMARD exposure was not associated with SMM (OR: 1.47, 95% CI: 0.86-2.51) or SNM (OR: 0.94, 95% CI: 0.59-1.49). Sensitivity analyses using overlap weights, entropy weights, and a longer exposure window from six months before estimated conception to delivery did not yield significant changes in point estimates and confidence intervals.

Conclusion: These findings suggest that DMARD use before and during pregnancy is not associated with an increased risk of SMM or SNM. Further studies with larger sample sizes are needed to better understand the long-term maternal and neonatal outcomes associated with prenatal DMARD use and develop real-world evidence-based clinical guidelines for safe prescribing during pregnancy.

Calprotectin and Anti-CCP Antibodies Predict Development of Preeclampsia

Daniele Marcy[1], Nanette Santoro[2], Claudia Lugo[3], Kristin Sturm[2] and Kristen Demoruelle[4], [1]University of Colorado, Northglenn, CO, [2]University of Colorado Anschutz Medical Campus, Aurora, CO, [3]University of Colorado, Denver, CO, [4]University of Colorado Anschutz Medical Campus, Golden, CO

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Reproductive Issues in Rheumatic Disorders (2627–2632)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Several systemic autoimmune diseases are associated with an increased risk of preeclampsia. Preeclampsia is a pregnancy complication characterized by new-onset hypertension after 20 weeks of gestation. Neutrophil extracellular trap (NET) formation is a process during which activated neutrophils externalize nuclear and cytoplasmic proteins in net-like structures. NETosis is increased in several systemic autoimmune diseases and has also been implicated in the pathogenesis of preeclampsia. Yet, there are limited data examining whether peripheral blood measures of NETosis can serve as predictive biomarkers for preeclampsia. In addition, autoantibodies to cyclic citrullinated peptide (anti-CCP) can target proteins externalized during NETosis, and preeclampsia is a risk factor for future development of rheumatoid arthritis (RA). In this study, we evaluated the relationship between preeclampsia, NETosis and anti-CCP antibodies in pregnant women without a history of autoimmune disease.

Methods: We included stored serum from Baby Blanket, a single-center, prospective pregnancy cohort (2011-2013) that collected maternal blood during pregnancy and obtained delivery outcomes by medical chart review. We included samples collected after 20 weeks gestation (median 33.4, IQR 27.0-35.5 weeks) in all women who later developed preeclampsia (N=35) and in 35 controls matched on age, parity, and history of diabetes who did not develop preeclampsia. No women had an underlying history of RA or lupus. Serum was tested for calprotectin (Werfen), anti-CCP-IgG (CCP3, Werfen), and anti-CCP-IgA (CCP3.1 plate with research modification to detect IgA only). Calprotectin is an S100A8/A9 heterodimer released from neutrophils upon NET formation and can be used to quantify NETosis. Levels were compared between women who did vs. did not develop preeclampsia by Wilcoxon ranked sum test.

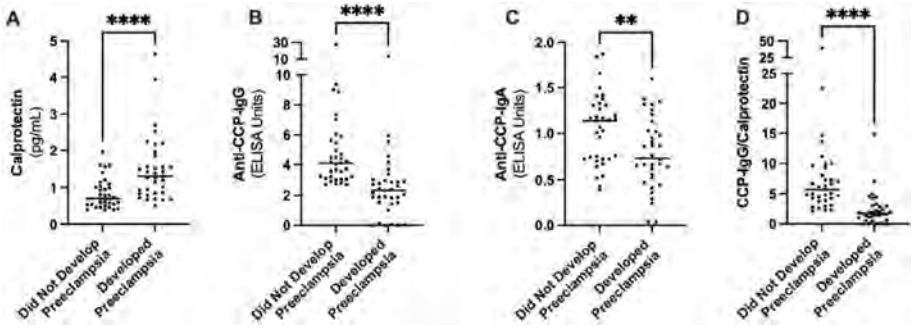

Figure 1. Serum levels of Calprotectin and Anti-CCP in pregnant women. The figure depicts serum levels of calprotectin (A), anti-CCP-IgG (B), anti-CCP-IgA (C) and that ratio of anti-CCP-IgG/calprotectin in pregnant women after 20 weeks gestation who either did or did not later develop preeclampsia. P-values calculated by Wilcoxon ranked sum test.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Results: Serum calprotectin levels were significantly higher in individuals who later developed preeclampsia compared to control pregnancies (p=0.008, Figure 1A). Paradoxically, serum anti-CCP-IgG and anti-CCP-IgA levels were significantly lower in individuals who later developed preeclampsia compared to controls (p< 0.001, Figure 1B-C). Notably, an anti-CCP-IgG/calprotectin ratio < 2 was 62.8% sensitive and 100% specific for developing preeclampsia.

Conclusion: Higher serum calprotectin and lower serum anti-CCP levels were strongly associated with increased risk of preeclampsia in women without autoimmune disease and may serve as novel clinical biomarkers for risk prediction. The finding that women who developed preeclampsia had lower anti-CCP levels and lower anti-CCP-IgG/calprotectin ratios suggests a potential protective effect of anti-CCP antibodies during pregnancy, perhaps buffering pathogenic effects of NET-associated proteins. While most anti-CCP levels in this study were not above the diagnostic level of positivity used in RA, low levels of anti-CCP antibodies can still be biologically relevant. Future studies are needed to determine whether anti-CCP could also be a predictive biomarker for preeclampsia in women with autoimmune diseases, particularly RA.

Predictors of 30-day Readmissions in Pregnant Patients with Systemic Lupus Erythematosus: The Impact of Social Determinants of Health.

Sandhya Kannayiram[1], Yiyuan Wu[2], Lisa Sammaritano[3], Michael Lockshin[4], Rich Caruana[5], Ware Branch[6], Jane Salmon[3] and Bella Mehta[7], [1]Hospital for Special Surgery, Weill Cornell Medicine, New York, [2]Weill Cornell Medicine, New York, NY, [3]Hospital for Special Surgery, New York, NY, [4]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY, [5]Microsoft, Redmond, WA, [6]University of Utah Health Sciences Center, Salt Lake City, UT, [7]Hospital for Special Surgery, Weill Cornell Medicine, Jersey City, NJ

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Reproductive Issues in Rheumatic Disorders (2627–2632)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Social Determinants of Health (SDOH) are increasingly recognized as significant contributors to adverse outcomes in pregnant patients with SLE. This study aims to evaluate the impact of SDOH on 30-day readmissions during pregnancy- and delivery-related hospitalizations in SLE patients, hypothesizing that incorporating SDOH into predictive models will enhance understanding of readmission risks and outcomes.

Methods: We conducted a retrospective analysis using the National Readmissions Database (NRD) from 2011 to 2021, which covers 28 states and represents 60% of U.S. hospitalizations. We identified adult pregnant patients with SLE using ICD-9 and 10 codes and categorized them into pregnancy- and delivery-related hospitalizations, including delivery cases within the pregnancy cohort. Our primary outcome was 30-day all-cause readmissions, and secondary outcomes included length of stay(LOS) and total hospitalization charges(THC). The SDOH evaluated in the study consists of income by zip code and insurance type. Descriptive analyses compared age, SDOH, clinical factors, LOS, and THC between initial hospitalizations and 30-day readmissions. We employed an Explainable Boosting Machine (EBM) model, using a 70-30 train-test split to predict readmissions based on features including comorbidities and SDOH. Weighted Mean absolute scores were aggregated globally to measure variable importance.

Table : A Comparative Analysis of Demographics and Social Determinants of Health for Pregnant Patients with Systemic Lupus Erythematosus during Initial Hospitalizations and 30-Day Readmissions.

Variables	Pregnancy including delivery related hospitalizations in SLE		Delivery related hospitalizations in SLE	
	Initial admission N (%) = 66,301	Readmission within 30 days N (%) = 2,469	Initial admission N (%) = 57,820	Readmission within 30 days N (%) =1,267
Age in years [Median (IQR)] *	30 (26, 34)	29 (25, 33)	31 (27, 34)	30 (26, 35)
Median household income by zip code (Qnartiles)*				
• 0-25th	18,848 (29%)	876 (36%)	15,249 (27%)	439 (35%)
• 26-50th	16,032 (24%)	608 (25%)	13,565 (24%)	313 (25%)
• 51-75th	16,266 (25%)	572 (23%)	14,138 (25%)	309 (25%)
• 76-100th	14,552 (22%)	391 (16%)	13,078 (23%)	194 (15%)
Insurance*				
• Medicaid	3,950 (6.0%)	307 (12%)	2,906 (5.1%)	127 (10%)
• Medicare	25,452 (38%)	1,160 (47%)	20,775 (37%)	560 (44%)
• Private/Self-pay	33,466 (51%)	865 (35%)	30,112 (53%)	506 (40%)
• Others	3,319 (5.0%)	136 (5.5%)	2,666 (4.7%)	73 (5.8%)
Discharge location*				
• Home discharge	64,075 (97%)	2,209 (89%)	55,246 (98%)	1,163 (92%)
• Location other than Home	2,226 (3.4%)	261 (11%)	1,307 (2.3%)	104 (8.2%)
Hospital Location+				
• Large metropolitan areas (≥ 1million residents)	43,648 (66%)	1,675 (68%)	36,779 (65%)	858 (68%)
• Small metropolitan areas (< 1 million residents)	19,792 (30%)	717 (29%)	17,200 (30%)	370 (29%)
• Micropolitan and non-urban residual areas	2,861 (4.3%)	77 (3.1%)	2,574 (4.6%)	39 (3.1%)
Hospital Bed size*				
• Large	44,760 (68%)	1,812 (73%)	37,572 (66%)	928 (73%)
• Medium	14,735 (22%)	489 (20%)	12,856 (23%)	251 (20%)
• Small	6,806 (10%)	169 (6.8%)	6,125 (11%)	87 (6.9%)
Length of Stay in days [Median (IQR)] *	3 (2, 4)	3 (2, 6)	3 (2, 4)	3 (2, 6)
Total Hospitalization charges [Median (IQR)] *	$19,408 (12,157- 32,338)	$22,952 (12,422- 45,499)	$19,497 (12,403-31,876)	$24,767 (13,286- 48,413)

*P value <0.05 was considered statistically significant; + - non-significant p value. Statistical analysis with Wilcoxon rank-sum test for complex survey samples; chi-squared test with Rao & Scott's second-order correction.

Results: Among pregnancy- and delivery-related hospitalizations, 3.6% resulted in readmissions, while 2.2% of delivery-related hospitalizations led to readmissions. Patients in the lowest income quartile (0–25th percentile) faced nearly double the readmission rates compared to the highest quartile (36% vs. 16% for pregnancy and delivery; 35% vs. 15% for delivery-related hospitalizations). Similarly, patients with public insurance (Medicare/Medicaid) were more likely to be readmitted, while those with private insurance/self-pay were less likely, underscoring systemic inequities **(Table)**.

SLE patients with thrombocytopenia (8.6% vs. 6.2%), hypertension (11% vs. 3.8%), pre-eclampsia/eclampsia (19% vs. 15%), or Acute kidney injury (6.4% vs. 1.7%) during pregnancy and those with pre-eclampsia/eclampsia (24% vs. 15%), renal failure (19% vs. 9.5%), pulmonary edema (3.9% vs. 1.1%), sepsis (3.6% vs. 1.1%), or thromboembolism (4.9% vs. 2.9%) during delivery had higher 30-day readmission rates[p value < 0.05].

Importance analysis **(AUROC ≃0.68)** identified LOS, insurance type, comorbidities, hospital characteristics, income, and age as key predictors for pregnancy and delivery-related readmissions, with LOS and insurance showing the highest predictive value. Comorbidities, LOS, insurance, hospital characteristics, income, and age were top predictors for delivery-related admissions.

Conclusion: SDOH are an important predictor of readmissions in SLE patients during pregnancy and delivery. Targeted strategies focusing on improving access to resources and healthcare and addressing income disparities within disadvantaged communities may help reduce readmission rates and improve outcomes for this high-risk group.

Background/Purpose: Systemic Lupus Erythematosus (SLE) primarily affects females of childbearing age and increases the risk of adverse pregnancy outcomes (APOs), particularly in non-White individuals and those with active disease. This study leveraged an urban multi-ethnic longitudinal SLE pregnancy cohort to evaluate predictors of APOs, with a focus on DORIS remission and outcomes across multiple pregnancies—two underexplored areas in SLE pregnancy research. The incidence of intrahepatic cholestasis of pregnancy, a rare condition not well-characterized in SLE that may increase the risk of preeclampsia, was also assessed.

Table 1. Characteristics and Outcomes in the Pregnancy Cohort. A. N is specified where it differs from the overall sample size. Data is represented as N (%) for categorical variables and median (IQR) for continuous variables. *Low complements, thrombocytopenia, anti-dsDNA (crithidia), DORIS, and cholestasis were considered if present at any time during pregnancy. **The highest SELENA SLEPDAI during pregnancy is represented as well as the measure taken during each trimester. Medications include those taken at any time during pregnancy. B. Pregnancy outcomes in the SLE cohort (N=95), also stratified by DORIS remission status.

Methods: The cohort includes 114 pregnancies in 95 consecutively consented SLE patients classified by ACR, SLICC and/or EULAR criteria. Clinical and laboratory data were collected during routine rheumatology visits. The primary outcome was a composite of APOs using modified PROMISSE definitions, which included preeclampsia, preterm premature rupture of membranes (PPROM), preterm birth (PTB) < 36 weeks, small for gestational age (SGA) birth, fetal death >10 weeks' gestation, and neonatal death within 28 days of birth. Logistic regression assessed predictors including race/ethnicity, history of lupus nephritis, autoantibodies, disease activity measured by SLEPDAI, DORIS remission, and medications. For patients with >1 pregnancy, only the first was included in regression analyses; a descriptive analysis examined the impact of prior APOs on future pregnancy outcomes.

Results: Among 95 pregnant SLE patients, 28% were Hispanic, 44% White, 32% Black, and 13% Asian. APOs occurred in 57%, most commonly preeclampsia (27%), SGA < 5th percentile (20%), and PTB (18%) (Table 1A). Significant predictors included antihypertensive use (OR 10.2, p=0.029), prior lupus nephritis (OR 2.5, p=0.034), non-White race (OR 2.4, p=0.039), Black race (OR 2.8, p=0.003), higher SLEPDAI (OR 1.11, p=0.022), and anti-Sm positivity (OR 3.3, p=0.01) (Table 2). LAC was associated with neonatal death. All APOs occurred with higher frequency in those who were not in sustained DORIS remission and significantly associated with PTB and preeclampsia (Tables 1B, 2). Notably, all 4 neonatal deaths occurred in patients not in DORIS remission. In the 16 patients with multiple pregnancies, the proportion in DORIS remission improved from 62% in the first pregnancy to 81% in the second pregnancy. While 8 of these 16 (50%) had an APO in the first pregnancy, only 3 had recurrent APOs, and 1 developed a new APO in pregnancy 2 (Figure 1A-B). Compared to the reported frequency of intrahepatic cholestasis in 0.2 to 2% percent of healthy pregnancies, it occurred in 8/114 pregnancies (7%, one patient twice, one with APO).

Conclusion: In this diverse SLE cohort, known predictors of APOs – including antihypertensive use, prior nephritis and active disease – were confirmed. The absence of DORIS remission was associated with preeclampsia and PTB. Prior pregnancy morbidity did not predict future APOs. These findings highlight the relevance of DORIS remission to maternal-fetal outcomes. The high prevalence (7%) of cholestasis of pregnancy in this cohort warrants further attention given its known fetal risks.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Reproductive Issues in Rheumatic Disorders (2627–2632)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Dapirolizumab pegol (DZP) is a novel CD40L inhibitor with broad modulatory effects on SLE immunopathology;[1,2] it consists of a polyethylene glycol (PEG)-conjugated antigen-binding fragment (Fab'), which lacks an Fc domain. DZP demonstrated efficacy in the phase 3 PHOENYCS GO trial (NCT04294667).[3] SLE predominantly affects women of childbearing age, conferring potential maternal and fetal risks.[4] Here, DZP reprotoxicity was studied *in vivo* in non-human primates (NHPs; cynomolgus monkeys), and DZP transfer across human placentas was evaluated *ex vivo*.

Methods: In an enhanced pre/postnatal development (ePPND) study, pregnant NHPs (N=14) received weekly intravenous DZP 27 or 50 mg/kg from gestation Day 20 to birth. Infant development was monitored for 9 months. *Ex vivo* dual perfusion of human placentas (N=22) assessed DZP and control IgG full monoclonal antibody transfer over up to 6 hours.

Results: In the ePPND study, pregnancy outcomes, embryofetal development, and infant postnatal development to 9 months post-birth were not affected by DZP. DZP induced expected decreases in B cells, IgG, and IgM in pregnant mothers, with no evidence of these effects in infants, nor altered development of infant immune systems to 9 months post-birth. Post-birth, DZP transfer from mother to infant (< 0.3% infant:mother plasma ratio) and mother plasma to milk (< 0.08% mother milk:plasma ratio) were very low. In the human *ex vivo* placental model, DZP was below quantification (minimal to none) in human placental fetal perfusate, in contrast to IgG full antibody control.

Conclusion: DZP showed no adverse outcomes on pregnancy or infant development post-birth in NHPs. In the *ex vivo* human placental model, DZP transfer was below the level of detection. These data align with lack of active placental transfer via the neonatal Fc receptor, causing minimal to no DZP transfer from mother to fetus, and suggest DZP may not be anticipated to cross the placenta to significant levels. These findings support further investigation of DZP in the setting of human pregnancy.

Maternal vascular malperfusion: association with adverse perinatal outcomes in lupus pregnancies

ANA JIMENA LOPEZ DIAZ[1], **MARIA DEL CARMEN ZAMORA MEDINA**[2], Mario Isaac Lumbreras Márquez[1], Diana Yazmin Copado mendoza[1], Oralia Alejandra Orozco Guillén[1], Maria José rodríguez Sibaja[1], Martha Leticia Palafox Vargas[1] and Sandra Acevedo gallegos[1], [1]Instituto Nacional de Perinatología, Mexico City, Distrito Federal, Mexico, [2]Instituto Nacional de Perinatologia, Mexico City, Distrito Federal, Mexico

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Reproductive Issues in Rheumatic Disorders (2627–2632)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is associated with increased risk of adverse perinatal outcomes (APOs), including preeclampsia, preterm birth, fetal growth restriction, and stillbirth. Placental findings of maternal vascular malperfusion (MVM), particularly intervillous fibrin deposition (IVFD), are more frequently observed in patients with SLE and antiphospholipid syndrome (APS). While IVFD has been linked to small-for-gestational-age (SGA) neonates in SLE pregnancies, its association with other severe APOs remains poorly characterized. The aim of our study is t compare the incidence of high-grade MVM between pregnant individuals with and without SLE and to evaluate the association between these placental lesions and APOs.

Methods: We included women aged ≥18 years with singleton pregnancies and a preexisting diagnosis of SLE (2012 SLICC criteria), managed at the National Institute of Perinatology between January 2016 and May 2024, with available placental histopathology. Placental lesions were assessed using the 2016 Amsterdam Working Group criteria and classified based on Freedman's phenotypes incorporating lesion severity. Exclusion criteria included other autoimmune diseases (except APS), pregnancies in women ≤18 years, multiple gestations, assisted reproduction, absence of prenatal care, or SLE diagnosed during pregnancy. The control group comprised healthy pregnant women matched 1:1 by maternal and gestational age. The primary outcome was the frequency of high-grade MVM. Associations between high-grade MVM and APOs—fetal or neonatal death, preterm birth < 37 weeks due to placental insufficiency (i.e., preeclampsia, hypertension, fetal growth restriction), and SGA neonates (birthweight < 10th percentile)—were assessed using univariable logistic regression, with odds ratios (ORs) and 95% confidence intervals (CIs). $P < 0.05$ was considered statistically significant.

Results: Among 130 SLE patients (mean age 28.0 ± 5.5 years; gestational age 36.5 ± 3.4 weeks), 25.4% had APS and 23.8% experienced an SLE flare during pregnancy. APOs occurred in 31.5%, including SGA (19%), fetal/neonatal death (3.8%), and preterm birth (19.2%). Placental weight was significantly lower in SLE patients compared to controls (388.9 ± 102.7 g vs. 440.4 ± 81.1 g; $P < 0.001$), particularly in those with flares ($P = 0.014$). High-grade MVM was significantly more

Table 1. Placental morphological characteristics and histopathological lesions.

Characteristic	Total N = 130	Flare during pregnancy N = 31	No flare during pregnancy N = 99	P value

Abstract Number: 2633

Comparative 3-year Safety Outcomes in Patients with Ankylosing Spondylitis Initiating JAK Inhibitor or TNF Inhibitor Therapy

Hsin-Hua Chen, Taichung Veterans General Hospital, Taichung, Taiwan (Republic of China)

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes II: Advances in Axial Spondyloarthritis (2633–2638)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: To compare safety outcomes in patients with ankylosing spondylitis (AS) initiating Janus kinase inhibitors (JAKi) versus tumor necrosis factor inhibitors (TNFi).

Methods: This retrospective cohort study utilized data from the TriNetX Global Collaborative Network, comparing patients initiating JAKi (n=299) versus TNFi (n=299) after propensity score matching for age, sex, race, diabetes mellitus, hypertension, psoriasis, inflammatory bowel disease, uveitis, and hyperlipidemia, . Patients were followed for up to three years.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1: Baseline Characteristics Before and After PSM (JAKi vs TNFi).

Table 1. Baseline Characteristics before and after propensity score matching in patients with ankylosing spondylitis initiating JAK inhibitors or TNF inhibitors (JAKi vs TNFi).

Baseline Variable	Pre-match JAKi (n=300)	Pre-match TNFi (n=12,443)	p-value	Std diff.	Post-match JAKi (n=299)	Post-match TNFi (n=299)	p-value	Std diff.
Age at index, years	49.0 ± 15.9	42.8 ± 15.5	<0.001	0.390	48.9 ± 15.9	49.0 ± 14.8	0.915	0.009
White race	74.7%	66.0%	0.002	0.191	74.9%	75.3%	0.925	0.008
Female	55.0%	38.2%	<0.001	0.342	54.8%	52.5%	0.566	0.047
Diabetes mellitus	8.0%	5.5%	0.064	0.099	8.0%	8.0%	1.000	<0.001
Hypertension	23.7%	14.5%	<0.001	0.234	23.4%	26.1%	0.448	0.062
Psoriasis	10.3%	4.6%	<0.001	0.220	10.0%	9.4%	0.782	0.023
Inflammatory bowel disease	17.0%	8.3%	<0.001	0.263	16.7%	17.4%	0.828	0.018
Uveitis (iritis)	3.3%	8.5%	0.001	0.220	3.3%	3.3%	1.000	<0.001
Hyperlipidemia	16.3%	10.8%	0.003	0.161	16.1%	16.7%	0.825	0.018

Footnotes: PSM – propensity score matching; JAKi – Janus kinase inhibitor; TNFi – tumor necrosis factor inhibitor. Values are presented as mean ± standard deviation or % of patients. *Std diff.* – standardized difference (absolute difference in means or percentages divided by pooled standard deviation), used to assess balance between groups (imbalances defined by |Std diff.| > 0.10). Pre-match columns reflect the original unmatched cohorts (JAKi n=300, TNFi n=12,443), while post-match columns reflect the propensity score-matched sample (n=299 in each group).

Table 2. Three-year safety outcomes in patients with ankylosing spondylitis initiating JAK inhibitors or TNF inhibitors after propensity score matching shown as hazard ratios with 95% confidence intervals (JAKi vs. TNFi)

Outcomes included mortality, major adverse cardiovascular events (MACE), venous thromboembolism (VTE), malignancy, gastrointestinal bleeding, hepatitis (non-infectious), serious infections (sepsis, pneumonia, herpes zoster), dermatologic events, and neuropsychiatric disorders. Kaplan–Meier analysis provided hazard ratios (HRs) with 95% confidence intervals (CIs).

Results: JAKi initiation was associated with significantly increased all-cause mortality (4.3% vs. 3.3%; HR 4.94, 95% CI 1.59–15.37) and gastrointestinal bleeding (3.4% vs. 0%; p=0.002). Conversely, malignancy occurred exclusively among TNFi initiators (3.4% vs. 0%; p=0.001). Herpes zoster infection showed a non-significant trend toward higher incidence in JAKi users (6.0% vs. 5.0%; HR 1.90, 95% CI 0.95–3.83). No significant differences emerged in MACE, VTE, serious bacterial infections (including pneumonia and sepsis), dermatologic events, or hepatitis. Anxiety/insomnia diagnoses were numerically lower with JAKi (14.3% vs. 24.1%), but without statistical significance.

Conclusion: Compared with TNFi, JAKi therapy in AS was associated with increased mortality and gastrointestinal bleeding, but lower short-term malignancy incidence. Infection-related outcomes were similar, aside from a potential herpes zoster risk. These findings highlight distinct safety trade-offs, underscoring the need for individualized treatment choices in AS.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes II: Advances in Axial Spondyloarthritis (2633–2638)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Women with axial spondyloarthritis (axSpA) tend to report worse outcomes and greater functional impairment than men. They may also respond less favorably to medication, though most data focus on tumor necrosis factor inhibitors (TNFi). Less is known about their response to interleukin-17 inhibitors (IL-17i) and Janus kinase inhibitors (JAKi), particularly in real-world settings. We assessed sex differences in medication discontinuation among U.S. adults with axSpA using the Rheumatology Informatics System for Effectiveness (RISE) registry.

Methods: We conducted a retrospective cohort study using RISE from 2000–2022, identifying new users of TNFi, IL-17i, and JAKi with axSpA. Patients had ≥2 consecutive prescriptions for the same drug. Discontinuation was defined as a stop date or ≥90-day gap without prescription (≥60 days for infliximab). Cox proportional hazards models assessed sex differences in discontinuation, adjusting for demographics, body mass index, area deprivation index, insurance type, and visit frequency. Multiple imputation addressed missingness. Sensitivity analyses included requiring only 1 prescription, requiring medication stop dates, and adjusting for disease activity using the Multi-Dimensional Health Assessment Questionnaire (MDHAQ). We also examined drug continuation by sex and age (18–64 vs ≥65) using Kaplan Meier curves.

Results: Among 4,799 axSpA patients (mean age 49.7 years; 54.3% female), 90% used TNFi, 7.4% IL-17i, and 2.6% JAKi (**Table 1**). Women had a higher adjusted risk of TNFi discontinuation than men (N=4,320, aHR 1.24, 95% CI: 1.15–1.35), which persisted across sensitivity models (**Table 2**). Adjustment for MDHAQ attenuated the association (aHR 1.16, 95% CI: 0.92–1.46). No significant sex differences were seen for IL-17i (N=356, aHR 1.21, 95% CI: 0.92–1.60) or JAKi (N=123, aHR 0.89, 95% CI: 0.47–1.66), though sample sizes were small. Among TNFi users, women under 65 had the lowest probability of medication continuation (**Figure**). There were no differences by sex and age in the IL17i and JAKi groups.

Conclusion: In this national axSpA cohort, women were more likely than men to discontinue TNFi therapy. This was not observed for IL-17i or JAKi, and larger studies are needed to confirm these results. These findings highlight the importance of investigating sex-based differences in axSpA treatment response.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes II: Advances in Axial Spondyloarthritis (2633–2638)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: The difference in spinal structural lesions and their progression over time between chronic back pain (CBP) patients with and without early axSpA is unknown. We aimed to compare structural lesions of the spine on conventional radiographs (CR) and magnetic resonance imaging (MRI) over 2 years (2Y), as well as their 2Y-change, between patients with early axSpA and non-axSpA CBP.

Methods: Patients included in the Spondyloarthritis Caught Early cohort (CBP ≥3 months and ≤2 years, starting < 45 years), were diagnosed with axSpA or non-axSpA CBP by their rheumatologist at 2Y follow-up (1). Only patients with available imaging (CR or MRI) at both baseline (BL) and 2Y were included. Spinal lesions on CR were assessed by three central readers using the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS). Structural lesions on spinal MRIs were assessed by two central readers using the Canada-Denmark scoring system. Readers made assessments independently, and they were blinded to demographic, clinical data and to the chronological order. BL spinal structural lesions and 2Y changes were compared between axSpA and non-axSpA. Generalized Estimating Equations models were used to assess the progression of structural lesions over 2Y, adjusting for age, sex, NSAID use, and diagnosis.

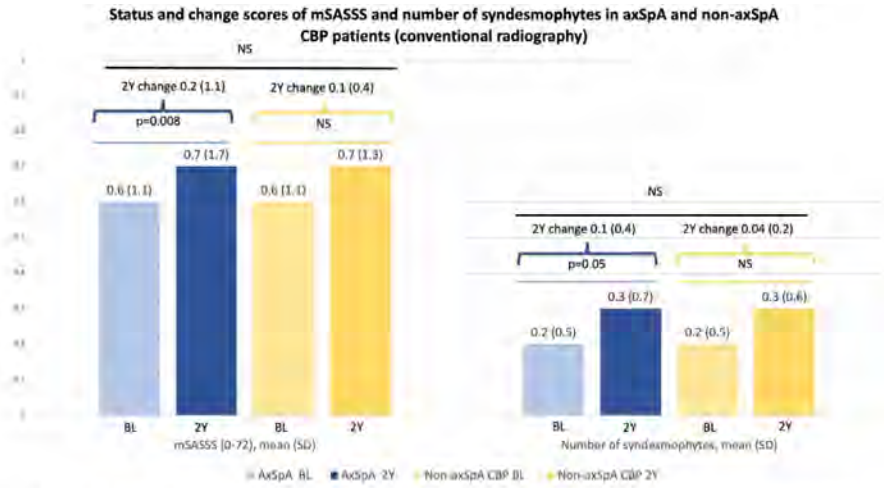

Figure 1. Status and change scores of mSASSS and number of syndesmophytes in axSpA and non-axSpA CBP patients.

- *Lines indicate p-values for BL to 2Y differences within groups and between-group differences in 2Y change scores. No significant difference was observed at BL and 2Y between axSpA and non-axSpA. BL, Baseline; 2Y, 2-years; CBP, Chronic back pain; NS, Non-significant*

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

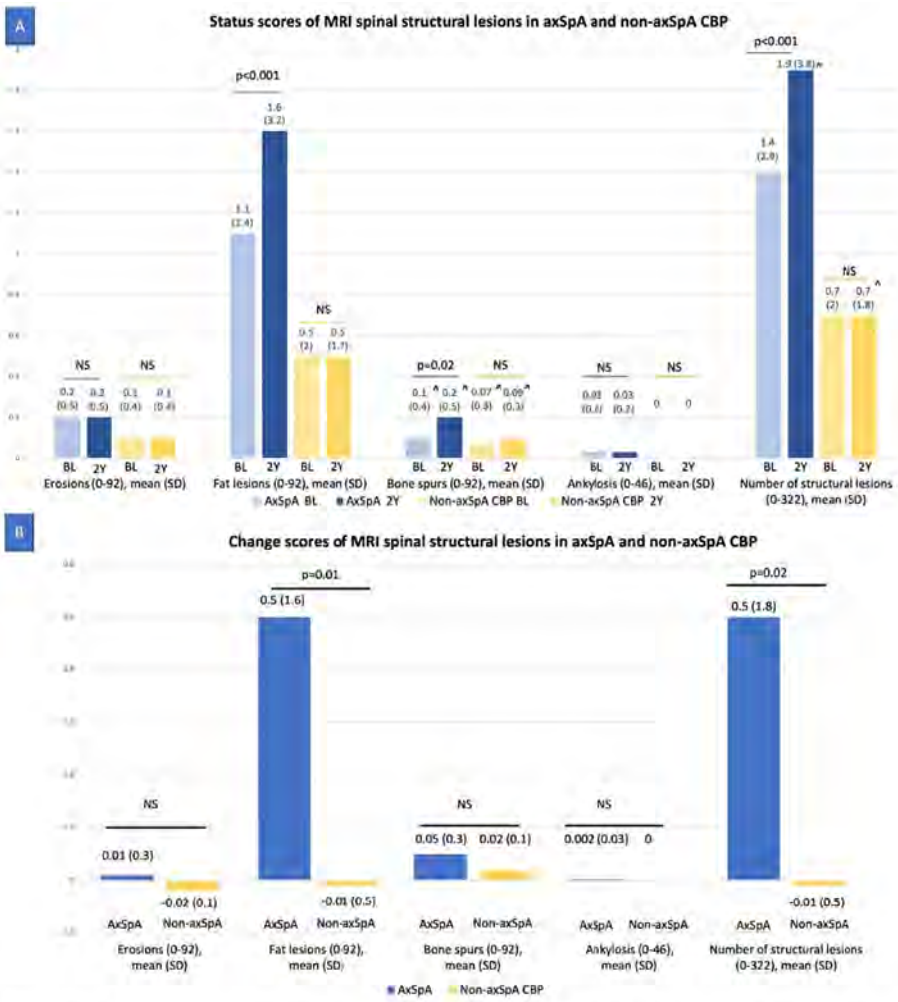

Figure 2. A. Status scores of MRI spinal structural lesions in axSpA and non-axSpA CBP. **B.** 2Y change scores of MRI spinal structural lesions in axSpA and non-axSpA CBP.

- *In Figure 2A, Lines indicate p-values for BL to 2Y differences within groups. Significant differences between the axSpA and non-axSpA groups at BL or 2Y for individual lesions are marked with a superscript (^).*
- *In Figure 2B, lines indicate p-values between the axSpA and non-axSpA -. BL, Baseline; 2Y, 2-years, Chronic back pain; NS, Non-significant*

Results: CR data from 318 patients (67% axSpA) and MRI data from 351 patients (69% axSpA) were included. Overall, 278 patients had both CR and MRI available at BL and 2Y [mean (SD) age 30 (8) years, 46% males, 61% HLA-B27+]. On CR, the mean (SD) BL mSASSS was 0.6 (1.1) for both axSpA and non-axSpA (Figure 1). Over 2Y, the progression of spinal structural lesions was similar between the axSpA and non-axSpA groups on CR, with overall mSASSS progression being minimal, specifically 0.01 mSASSS units per year. Mean number of syndesmophytes at BL and 2Y change scores between patients with axSpA and non-axSpA were similar. On MRI, axSpA patients had a mean of 1.4 (2.9) total structural lesions compared to 0.7 (2) in non-axSpA at BL (p=0.12) (Figure 2A). The 2Y increase in the mean total number of structural lesions [0.5 (1.8)] was mainly driven by the increase in fat lesions [0.5 (1.6)] in the axSpA group and was significantly higher than in non-axSpA (Figure 2B). The proportion of patients with ≥3 fat lesions both at BL and 2Y was higher in the axSpA group (BL: 9% vs 1%, p=0.004, 2Y: 15% vs 1%, p< 0.001). On MRI, fat lesions progressed at a rate of 0.16 units/year in axSpA (p=0.002) and -0.02 units/year in non-axSpA (p=0.7). The remaining lesions showed no significant progression.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Over 2 years, there is minimal progression of spinal structural damage typical for axSpA on CR in both early axSpA and non-axSpA CBP. On MRI, there is a significant increase in the number of fat lesions in axSpA, contrasting with non-axSpA in which no progression is observed. Fat lesions may be important to assess spinal disease progression from early disease onwards.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes II: Advances in Axial Spondyloarthritis (2633–2638)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: People with axial spondyloarthritis (axSpA), typically present with persistent back pain and experience up to a 10-year diagnostic delay that may lead to irreversible spinal damage. Earlier diagnosis and treatment may prevent this damage. As such, there is a high clinical unmet need in primary care, to differentiate patients with axSpA who require a referral to a rheumatologist from those with mechanical backpain (MBP). According to the Spondyloarthritis Research and Treatment Network (SPARTAN), identifying 1 axSpA patient of 3 referred, could meaningfully reduce diagnostic delay. This study examines the discriminative performance of 14-3-3η AAbs in patients with axSpA, including those with radiographic (r-) and non-radiographic (nr-) disease, compared to people with MBP.

Methods: Patient serum (n=160) from the Bath Spondyloarthritis Biobank, a repository collected during routine clinical visits, were selected based on sample availability. Patients had a rheumatologist confirmed diagnosis and met classification criteria for r-axSpA (modified New York criteria, n=55), nr-axSpA (ASAS 2009 criteria, n=54) or MBP (n=51). 14-3-3η AAb levels were measured using the Health Canada and UKCA approved multiplex assay.

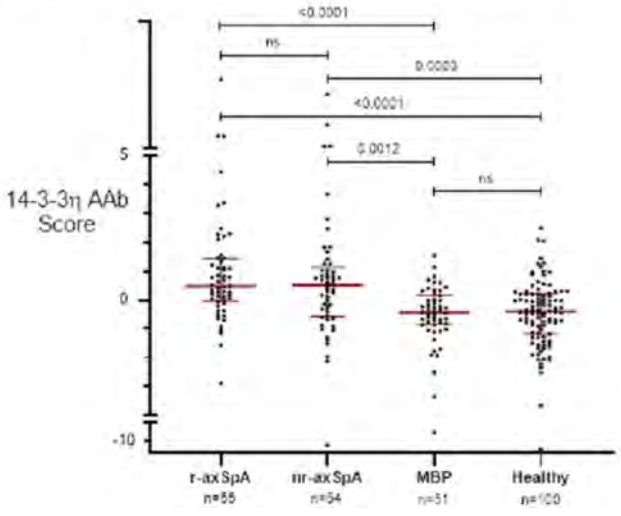
PPV	83%	87%	88%	90%
NPV	59%	70%	71%	83%
DxOR (95% CI)	7.12 (2.2 – 22.7)	14.6 (5.3 – 40.4)	17.5 (5.9 – 51.9)	44.0 (13.6 – 141.7)

Figure 1. 14-3-3η AAb Score Distribution r-axSpA versus MBP Model



Nominal regression was performed to model the relationship between predictor variables and diagnosis. The probability formula generated from this regression was used to calculate a linear score for three models alongside variables of age, sex, CRP and HLA-B27: 1) all patients with axSpA (n=109), 2) r-axSpA, and 3) nr-axSpA versus MBP as a control group. This score quantifies the likelihood of a diagnosis based on model predictors. The r-axSpA versus MBP regression was used to calculate 14-3-3η AAb scores in banked serum samples from healthy individuals (n=100) for comparison. Statistical significance was set at $p < 0.05$.

Results: Mean age (SD) was 55 (23) yrs for r-axSpA, 42 (14) yrs for nr-axSpA, and 30 (14) yrs for MBP. Gender distribution (% male) was respectively 67%, 41%, and 59%. Disease duration (SD) was 13 (27) yrs for r-axSpA, and 5 (5) yrs for nr-axSpA. HLA-B27+ status was: 69% for r-axSpA, 72% for nr-axSpA, and 18% for MBP. 14-3-3η AAb predictive model

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

ROC AUCs for all axSpA versus MBP were 0.77, r-axSpA of 0.78 and nr-axSpA 0.73 (Table 1). Selecting the best sensitivity (SN) for ~90% specificity (SP) returned SP & SN for all axSpA of 90% & 42%, r-axSpA of 92% & 47% and nr-axSpA of 92% & 38%. Corresponding Positive Predictive Values (PPV) were 88%, 83% and 83%, exceeding the SPARTAN target 33.3% PPV. In the All axSpA model, adding age and sex variables to the 14-3-3η AAb score, improved the diagnostic odds ratio (DxOR) from 5.4 to 18.4 and increased to 23.4 with CRP added and to 63.7 with HLA-B27 added. Scores for healthy controls were similar to patients with MBP, p >0.99 (Figure 1).

Conclusion: The 14-3-3η AAb biomarker differentiates radiographic and non-radiographic-axSpA from MBP, achieves a high PPV and its discrimination improves when age, sex, CRP, and HLA-B27 are added. Alongside these easily accessible patient variables at primary care, 14-3-3η AAb may reduce diagnostic delay and complement HLA-B27.

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes II: Advances in Axial Spondyloarthritis (2633–2638)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: The pathophysiology of axial spondyloarthritis (axSpA) involves the gut-joint axis. Recent studies suggest more active disease in cases of gut involvement.

The objective of this study is to evaluate the impact of bacterial translocation levels at baseline in the DESIR cohort on 5-year outcomes in patients.

Methods: We included patients from the DESIR cohort meeting the 2009 ASAS criteria, for whom serum samples at baseline and 5-year follow-up data were available. Gut permeability was assessed by measuring serum zonulin levels using ELISA. Bacterial translocation was evaluated by quantifying serum levels of lipopolysaccharides (LPS) and their esterified free fatty acid components (3OHC10, 12, 14, 16, and 18) using liquid chromatography coupled with mass spectrometry. Phospholipid transfer protein (PLTP) activity, which plays a role in LPS transfer, was also measured. We analyzed these biomarkers concerning the occurrence of extra-articular manifestations (psoriasis, IBD, and uveitis), radiographic spinal

* P < 0,05 ; ** p<0,01

progression assessed by mSASS, sacroiliac joint radiographic progression evaluated by the change in sacroiliitis grade (NYm), and the transition from non-radiographic to radiographic axSpA over 5 years.

Results: Out of 708 patients in the DESIR cohort, 319 met the inclusion criteria. The mean age was 31.7 (±7.3) years, with 49.2% male, 82% HLA-B27 positive, 27% with radiographic axial involvement, and symptom duration of 1.6 (±0.9) years. The cohort included 15% with psoriasis, 6% with IBD, 9% with uveitis, 55% with enthesitis, and 12% with dactylitis. Baseline disease activity scores included a BASDAI of 42 (±20), an ASDAS-CRP of 2.6 (±1), and a CRP of 8.4 (±13) mg/L. At baseline, LPS levels (and their fatty acid subgroups), zonulin levels, and PLTP activity were not associated with the presence of extra-musculoskeletal manifestations or disease activity. These levels also did not differ between patients who developed extra-musculoskeletal manifestations at 5 years and those who did not. In patients with sacroiliac progression, lower total LPS levels (716 ± 199 pmol/mL vs. 656 ± 200 pmol/mL; p = 0.036), lower 3OHC18 levels (252.5 ± 116.8 pmol/mL vs. 205.9 ± 119 pmol/mL; p = 0.007), and lower zonulin levels (147 ± 155 ng/mL vs. 104 ± 103 ng/mL; p = 0.01) were observed. PLTP activity was higher in patients with sacroiliac progression (5.2 ± 1.6 nmol/h/mL vs. 5.8 ± 1.7 nmol/h/mL). In multivariate analysis accounting for age, sex, smoking, and ASDAS-CRP, PLTP activity remained significantly associated with sacroiliac progression (p = 0.028). Finally, in patients transitioning from non-radiographic to radiographic axSpA, lower 3OHC16 levels (290 ± 71 pmol/mL vs. 252 ± 48 pmol/mL) and lower zonulin levels (156 ± 157 ng/mL vs. 72 ± 84 ng/mL; p = 0.003) were noted.

Conclusion: In early axial spondyloarthritis, baseline PLTP activity was associated with sacroiliac radiographic progression at 5 years

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

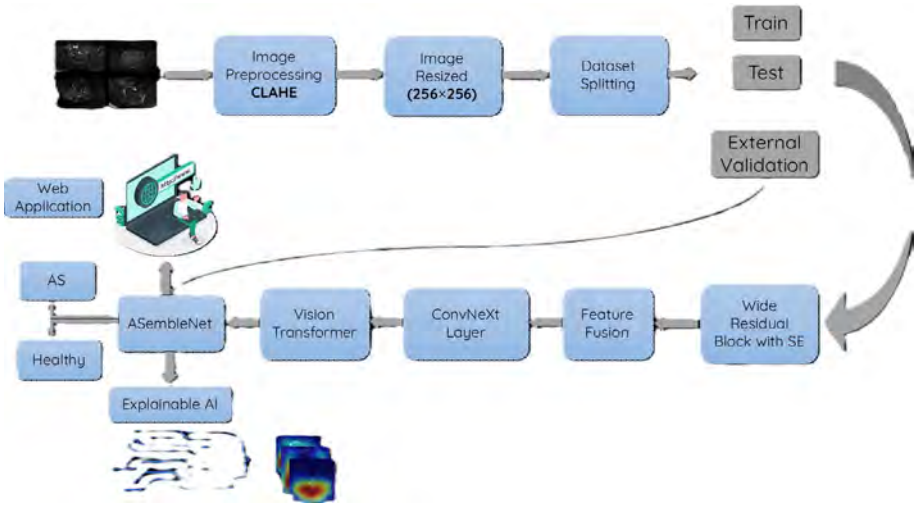
Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes II: Advances in Axial Spondyloarthritis (2633–2638)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Ankylosing spondylitis (AS) is a progressive inflammatory disease with delayed diagnosis due to subtle early imaging findings. We present ASembleNet, a deep learning model integrating convolutional and transformer-based architectures for accurate AS classification on MRI. The model was developed using multi-institutional, publicly available datasets and externally validated with expert-reviewed cases.

Methods: Three datasets were used for model development. Dataset 1 consisted of 4,115 axial and coronal MRI images from AS patients and healthy controls collected at Elazığ Fethi Sekin City Hospital (2018–2023). Dataset 2 included 213 expert-annotated MRI images from the Assessment of Spondyloarthritis International Society (ASAS) Online Case Library for external validation. Dataset 3 comprised 102 normal MRIs sourced from Radiopaedia.org to augment healthy control data. All images underwent standardized preprocessing: cropping of artifacts, resizing to 256×256 pixels, and contrast enhancement via CLAHE. ASembleNet architecture (Figure 1) combines wide residual blocks, ConvNeXt layers, and



Methodology of our proposed model

Table 1: Dataset distribution for axial and coronal MRI from three public sources.

Dataset	Category	Source	Training Set	Validation Set	Total
Axial MRI	Ankylosing Spondylitis	Dataset 1	1000 images	-	1000 images
	Ankylosing Spondylitis	ASAS Online Case Library	56 images (5 cases)	56 images (4 cases)	112 images
	Healthy Controls	Dataset 1	1110 images	-	1110 images
	Healthy Controls	Radiopaedia.org	-	51 images	51 images
Coronal MRI	Ankylosing Spondylitis	Dataset 1	1000 images	-	1000 images

Table 2: Performance comparison of ASembleNet and other deep learning models.

Model	Accuracy (Axial)	Precision (Axial)	F1-score (Axial)	Recall (Axial)	Accuracy (Coronal)	Precision (Coronal)	F1-score (Coronal)	Recall (Coronal)
IRv2	96.26%	96.26%	96.26%	96.26%	95%	95%	95%	95%
InceptionV3	98.13%	98.13%	98.13%	98.13%	96%	96%	96%	96%
Xception	98.13%	98.13%	98.13%	98.13%	98%	98%	98%	98%
ResNet50	97.19%	97.19%	97.19%	97.19%	97%	97%	97%	97%
ASembleNet	98.13%	98.13%	98.13%	98.13%	99%	99%	99%	99%

Table: Performance comparison of ASembleNet and benchmark deep learning models on Axial and Coronal MRI images. Metrics include Accuracy, Precision, Recall, and F1-score. ASembleNet demonstrates superior performance.

Axial MRI Metrics Coronal MRI Metrics

Vision Transformer encoders with Squeeze-and-Excitation modules for attention calibration and Grad-CAM for interpretability. The dataset distribution is detailed in Table 1. Training-validation split ensured ASAS cases were used solely for external testing. Performance metrics included accuracy, precision, recall, F1-score, AUC, and confusion matrix analysis.

Results: ASembleNet achieved 99% classification accuracy for coronal MRI and 98.13% for axial MRI, outperforming Xception, ResNet50, and InceptionV3 models. The model consistently showed high sensitivity and specificity across all classes. External validation on ASAS cases confirmed generalizability. Model performance across architectures is summarized in Table 2. Grad-CAM visualizations demonstrated clinically relevant feature localization, aligning with expert interpretations. A publicly accessible web-based platform was developed to facilitate real-time AS classification by clinicians.

Conclusion: ASembleNet demonstrates high accuracy in detecting AS on MRI using a hybrid deep learning approach trained on diverse, real-world datasets. Its strong performance on external validation and integration with explainable AI tools underscore its potential as a reliable clinical decision-support tool for early AS diagnosis.

Session Date: Wednesday, October 29, 2025
Session Title: Abstracts: Rheumatoid Arthritis – Treatment II: Phenotyping and Personalization (2639–2644)
Session Type: Abstract Session
Session Time: 9:30AM–11:00AM

Background/Purpose: Oral methotrexate (MTX) is the cornerstone treatment for newly diagnosed rheumatoid arthritis (RA), yet up to 50% of patients do not respond adequately. Early prediction of MTX response is crucial to prevent disease progression and promptly initiate alternative therapies. Recent studies suggest a link between the gut microbiome and MTX efficacy in treatment-naïve RA patients. However, the use of 16S rRNA sequencing in these studies limits taxonomic resolution in identifying gut microbial relationships with treatment response; and the response criteria applied were arbitrary, as

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. acknowledged by the investigators. To enhance clinical applicability, our study used whole genome shotgun metagenome sequencing and the standardized EULAR response criteria to rigorously investigate associations between pre-treatment gut microbiome and MTX response.

Methods: A cohort of 60 treatment-naïve RA patients (mean age 51.2 years) initiated treatment with oral MTX at a low dose (15 mg/week). Of these, 43 were female, 6 were current smokers, and 14 were on prednisone (**Table 1**). Stool samples collected at baseline and after 3–3.5 months of treatment underwent metagenomic sequencing. Patients were classified as MTX responders (n = 37) or non-responders (n = 23) based on the EULAR response criteria. Response was defined as a decrease in DAS28-CRP (ΔDAS28-CRP) > 1.2, or ΔDAS28-CRP > 0.6 with a follow-up DAS28-CRP ≤ 5.1. Differential abundance and prevalence analyses identified microbiome features distinguishing the two groups. A gradient-boosting linear regression model using baseline gut microbiome and clinical data (BMI, DAS28-CRP, ACPA status, and prednisone dose) was developed to predict MTX response.

Results: Baseline microbiome analysis revealed significant differences between responders and non-responders, with five species and nine metabolic pathways having differential abundance (**Fig. 1**). Additionally, clinical response correlated strongly with the presence of specific species, such as *Bacteroides fragilis* and *Eubacterium* sp. AF16-48 (**Fig. 1**). Additionally, the odds of MTX response increased ten-fold in patients harboring any of the top ten differentially prevalent gut microbial species (OR = 10.4). Moreover, genes of the dihydrofolate reductase (DHFR) enzyme were significantly less abundant in responders (P = 0.031). Finally, our machine learning model using baseline gut microbiome and clinical data demonstrated an AUC of 0.83 in leave-one-out cross-validation, outperforming an AUC of 0.72 from clinical data alone. Our model achieved an AUC of 0.77 in an external validation cohort of 38 treatment-naïve RA patients (**Fig. 2**).

Conclusion: We identified gut microbiome features associated with MTX response in early RA patients. Our machine learning model suggests the potential of gut microbiome profiling as a personalized predictive tool for MTX outcomes.

[a] positive rheumatoid factor or anti-citrullinated cyclic peptide antibody

Number (%) or median (interquartile range) are reported. RA, rheumatoid arthritis; eGFR, estimated glomerular filtration rate; bDMARDs, biologic disease-modifying antirheumatic drugs; csDMARDs, conventional synthetic disease-modifying antirheumatic drugs; TNFi, tumor necrosis factor inhibitors; CTLA4-Ig, cytotoxic T-lymphocyte-associated protein 4 immunoglobulin; IL-6i, interleukin-6 inhibitors; BCDT, B cell depletion therapy; JAKi, Janus kinase inhibitors; BMI, body mass index; NSAIDs, nonsteroidal anti-inflammatory drugs; CDAI, Clinical Disease Activity Index; mHAQ, modified Health Assessment Questionnaire.

Background/Purpose: Kidney dysfunction is common in patients with rheumatoid arthritis (RA). However, there has been limited and conflicting evidence on the effectiveness of biologic and targeted synthetic disease-modifying antirheumatic drugs (b/tsDMARDs) in RA patients with kidney dysfunction.

Methods: This study used the CorEvitas RA registry, a large prospective registry of RA patients from multiple US institutions. We included patients with moderate-to-high clinical disease activity index (CDAI) who newly initiated each class of b/tsDMARDs (TNFi, CTLA4-Ig, IL-6i, BCDT, or JAKi) during the registry follow-up from Oct 2001 to Dec 2023. The index date was set at the b/tsDMARDs initiation. The exposure of interest was a reduced estimated glomerular filtration rate (eGFR < 60 mL/min/1.73m^2) at the index date, in comparison to non-reduced eGFR (≥60 mL/min/1.73m^2). Outcomes included CDAI remission (REM), CDAI-remission or low disease activity (REM/LDA), and each outcome without concomitant glucocorticoid (GC) use. The patients were followed until the first occurrence of an outcome or the last study visit. Propensity scores (PS) for baseline reduced eGFR were used for overlap weighting. Kaplan-Meier curves and Cox proportional hazards models before and after weighting examined the association between baseline reduced eGFR and treatment outcomes. Sensitivity analysis using an alternative exposure of chronic kidney disease (CKD) G3a or worse (eGFR ≤ 60 mL/min/1.73m^2 for ≥3 months) was also performed. Given that low eGFR may potentially lead to more MTX discontinuation, four-way decomposition causal mediation analysis evaluated whether MTX discontinuation mediated the association among those who used MTX at baseline.

Results: We identified 12,076 new b/tsDMARDs treatment courses (TNFi 5,318; CTLA4-Ig 2,265; IL-6i 1,679; BCDT 1,059; JAKI 1,755) among 9,569 patients. At baseline, median age was 59.0 years, 80.2% were female, and median eGFR was 52.3 mL/min/1.73m^2 in the reduced eGFR group and 92.8 mL/min/1.73m^2 in the non-reduced eGFR group. Patients with low eGFR were older, had more comorbidities, and used NSAIDs less often (**Table 1**). After PS overlap weighting, patient

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Achievement of CDAI-REM and CDAI-REM/LDA after initiating b/tsDMARDs by baseline eGFR: Kaplan–Meier cumulative incidence curves (95% CI) for (A) CDAI-REM, (B) CDAI-REM/LDA, (C) CDAI-REM without GC use, and (D) CDAI-REM/LDA without GC use are visualized by reduced eGFR (<60) versus non-reduced eGFR (≥60) at baseline. Time zero represents initiation of b/tsDMARDs. Crude HR (95% CI) and HR (95% CI) after propensity-score overlap weighting (weighted HR) of reduced eGFR for achieving outcomes are described. CDAI, Clinical Disease Activity Index; REM, remission; REM/LDA, remission or low disease activity; GC, glucocorticoid; b/tsDMARDs, biologic or targeted synthetic disease-modifying antirheumatic drugs; eGFR, estimated glomerular filtration rate; HR, hazard ratio; CI, confidence interval

characteristics were well-balanced. Reduced eGFR was associated with less achievement of CDAI-REM (crude HR 0.71 [95% CI: 0.62, 0.82]) and CDAI-LDA/REM (crude HR, 0.88 [95% CI: 0.81, 0.95]). Restricting the outcomes to those without GC use modestly strengthened these associations. These results were similar after weighting (**Figure 1**). Sensitivity analyses using CKD G3a as the exposure demonstrated comparable results. Among baseline MTX users, MTX discontinuation did not completely explain the association between kidney dysfunction and less CDAI-REM achievement.

Conclusion: Although b/tsDMARDs remain effective treatments for RA with kidney dysfunction, patients with reduced eGFR are approximately 30% less likely to achieve remission. Tailored treatment strategies are therefore required to optimize disease control in this high-risk population.

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Rheumatoid Arthritis – Treatment II: Phenotyping and Personalization (2639–2644)

Session Type: Abstract Session

Session Time: 9:30AM–11:00AM

Background/Purpose: Emerging data show the potential of T-cell engagers (TCEs) for deep B cell depletion to treat autoimmune diseases. Cizutamig is a purposefully designed BCMAxCD3 TCE based on the FIT-Ig® platform and an optimized CD3 binding affinity to reduce cytokine release while maintaining killing of BCMA-expressing B cells, plasmablasts and plasma cells. This study aimed to evaluate the translatability of TCE design from preclinical data to clinical activity in patients.

Methods: Previous in vitro methods on plasma cell killing, T cell activation, and cytokine release comparing cizutamig to benchmark BCMA TCEs have been previously described. To assess in vivo preclinical activity, immunodeficient mice reconstituted with peripheral blood mononuclear cells (PBMCs) from a patient with systemic lupus erythematosus (SLE) were treated with 3 weekly doses of vehicle, isotype (1 mg/kg), or 0.1, 0.3, or 1 mg/kg of cizutamig (n=10 per group). Levels of human serum IgG, anti-dsDNA antibodies, splenic B cells and kidney immune complexes were measured. A Phase 1 dose

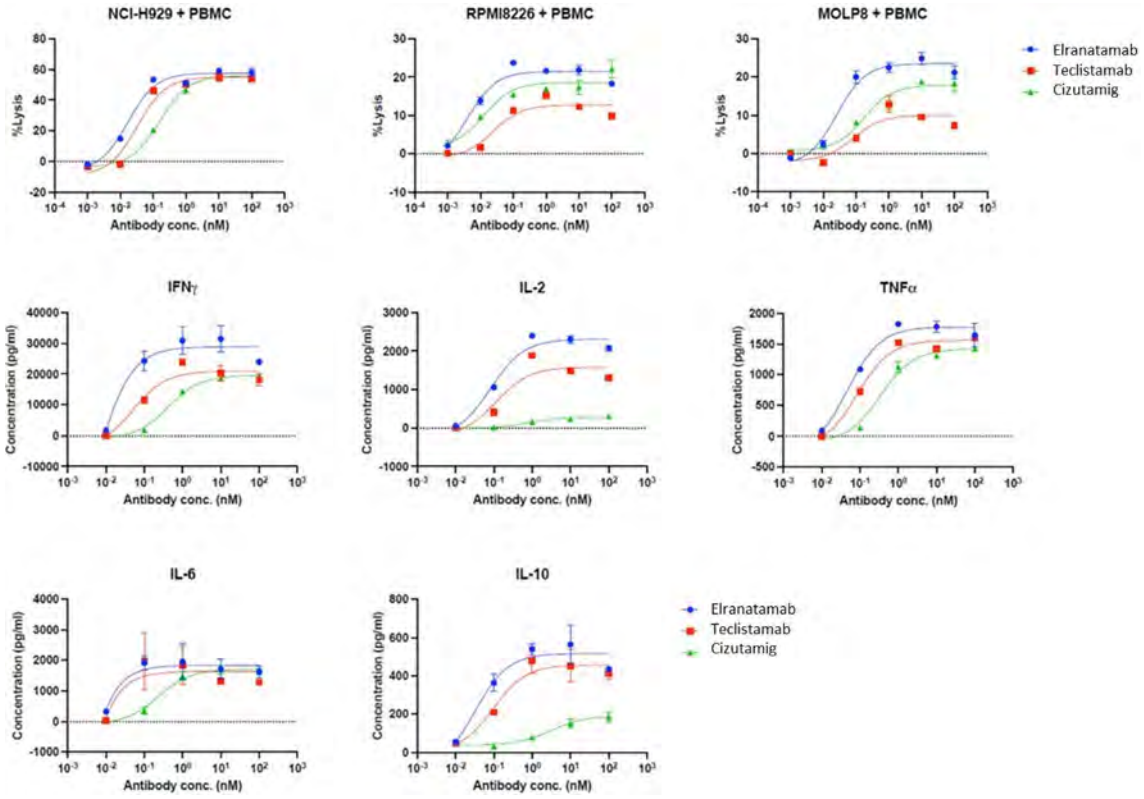

Fig 1. T cell mediated killing and cytokine release by healthy donor PBMCs co-cultured with BCMA-expressing cell lines in the presence of cizutamig or benchmark BCMAxCD3 TCEs (elranatamab, teclistamab).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. escalation study to assess safety and efficacy was completed in patients with relapsed/refractory multiple myeloma (RRMM) in which cizutamig was administered weekly with step-up dosing. A patient with rheumatoid arthritis (RA) refractory to 5 targeted synthetic and biologic DMARDs including rituximab was the first non-oncology patient treated with weekly doses of cizutamig.

Results: In vitro, cizutamig showed comparable T cell dependent cytotoxicity of BCMA-expressing cell lines with lower cytokine release compared to benchmark BCMA TCEs (Fig 1). In the SLE mouse model, cizutamig showed complete depletion of serum IgG and anti-dsDNA antibodies, splenic B cells, and IgG deposits in the kidneys (Fig 2). In the Phase 1 study, 40 RRMM patients were treated with cizutamig at doses from 0.2 mg to 300 mg. For those who received ≥ 60mg dose, the objective response rate was 66% (12 of 18 patients) with minimal residual disease achieved in 42% of responders. Across all doses, only Grade 1 (18%) or Grade 2 (8%) cytokine release syndrome (CRS) per ASTCT criteria was seen with a median onset time and duration of 1 day (range 1-2) and 3 days (range 1-6), respectively. No immune effector cell-associated neurotoxicity syndrome (ICANS) was observed. In the refractory RA patient, after 3 weeks of treatment, near complete depletion of serum plasma light chains, bone marrow CD138+ plasma cells, and lymph node CD19+ and CD20+ B cells and CD138+ plasma cells were observed (Fig 3). Clinical response was achieved with DAS28 score decreasing from 6.3 to 2.7 units 5 weeks after treatment initiation. No CRS or ICANS was observed.

Conclusion: Cizutamig was designed to mitigate cytokine release while preserving cytotoxicity of BCMA-expressing cells. Preclinical and clinical data demonstrate a differentiated safety profile with signs of clinical activity in RRMM patients and a patient with refractory RA. Further clinical evaluation of cizutamig in autoimmune diseases is being explored.

Abstract Number: 2642

Impact of Rheumatoid Arthritis Therapeutic Classes on Risk of Major Adverse Cardiovascular Events and Venous Thromboembolism: A Population-Based Cohort Study

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025
Session Title: Abstracts: Rheumatoid Arthritis – Treatment II: Phenotyping and Personalization (2639–2644)
Session Type: Abstract Session
Session Time: 9:30AM–11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) are at increased risk of major adverse cardiovascular events (MACE) and venous thromboembolism (VTE). Inflammation is a driver of vascular risk, but specific RA therapeutic classes may differentially influence this risk, especially among older patients with additional risk factors. We aimed to evaluate the association between RA medications and advanced therapy (AT) classes and the incidence of MACE and VTE.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table. Adjusted hazard ratios (HR) and 95% confidence intervals for healthcare utilization due to major adverse cardiovascular events (MACE) or venous thromboembolism (VTE) by RA therapeutic class and baseline cardiovascular (CVD) risk.

	High Risk CVD cohort	Low Risk CVD cohort
	N=8,016 (person-years 69,638)	N=2,004 (person-years 20,353)
MACE		
csDMARD prescription (reference)		
No csDMARD/AT prescription	13.3 (11.9, 14.8)	17.2 (12.9, 23.0)
Oral GC prescription	1.54 (1.26, 1.88)	2.05 (1.14, 3.69)
AT prescription	0.63 (0.41, 0.99)	0.36 (0.11, 1.26)
VTE		
csDMARD prescription (reference)		
No csDMARD/AT prescription	25.8 (19.2, 34.8)	23.0 (14.0, 38.1)
Oral GC prescription	3.20 (1.81, 5.65)	3.60 (1.56, 8.32)
AT prescription	2.11 (0.88, 5.03)	0.39 (0.04, 4.10)

csDMARD: conventional synthetic disease modifying antirheumatic drug; AT: advanced therapy; GC: glucocorticoid.

Methods: RA patients were identified from the Ontario Rheumatoid Arthritis Database, a population-based registry derived using a validated algorithm and maintained at ICES. We included patients aged >67 years diagnosed between January 1, 2008, and December 30, 2013, and followed them through to December 30, 2023, with a minimum of 6 months follow-up. The primary outcome was healthcare utilization related to MACE (composite of myocardial infarction, stroke, congestive heart failure, and coronary artery bypass grafting) and/or VTE (deep vein thrombosis or pulmonary embolism), requiring hospital admission, emergency department (ED) visits, or physician encounters. RA therapeutic class was obtained from prescription data (Ontario Drug Benefit) and treated as a time-varying exposures into 4 mutually exclusive groups: (1) No csDMARDs or AT, (2) oral glucocorticoid (GC), (3) csDMARDs only (reference), or (4) b/tsSMARD (AT). The cohort was stratified by CVD risk, with high-risk individuals defined by the presence of established CVD, diabetes mellitus, or hypertension at RA diagnosis. The association between therapeutic class and recurrent healthcare encounters was assessed using the Andersen-Gill, an extension of the Cox model, adjusted for baseline covariates including concomitant csDMARD.

Results: A total of 10,020 RA patients were included and 80% had high CVD risk (n= 8,016). Over a median follow-up of 10.9 (IQR: 5.9-12.7) years, 16,468 MACE and 2,326 VTE events occurred in the high-risk group, compared to 2,965 MACE and 495 VTE events in the low CVD risk cohort. Compared to csDMARDs, there was a significant positive association between no csDMARD/AT (adjusted hazard ratio [aHR]: 13.3; 95% CI: 11.9, 14.8), oral GC (HR: 1.54; 95% CI: 1.26, 1.88), and higher hazard of MACE in the high-risk CVD cohort, while AT was associated with a lower hazard (adj HR: 0.63; 95% CI: 0.41, 0.99) (Table). Similar results were observed for no csDMARD/AT and oral GC in the low-risk CVD cohort. No csDMARD/AT and oral GC prescription were significantly associated with higher hospitalization/ED or physician visits for VTE compared to csDMARDs in both low and high CVD risk cohorts (Table). VTE events were numerically higher for AT users in the high CVD risk cohort, but this was not statistically significant.

Conclusion: In this study, therapeutic choice significantly influenced MACE and VTE outcomes. Compared to csDMARDs, advanced therapies were associated with a lower hazard, while GC and lack of RA treatment were associated with a higher hazard. These findings highlight the importance of integrating cardiovascular and thrombotic risk assessment into RA treatment decisions to optimize both disease and safety outcomes.

Microbiome Signatures in RA Treatment: Personalizing Methotrexate Therapy

Rahul Bodkhe[1], Kai Trepka[1], Diego Orellana[1], Rebecca Blank[2], Peter Turnbaugh[3], Jose Scher[4] and **Renuka Nayak**[5], [1]University of California San Francisco, San Francisco, CA, [2]NYU Langone Health, New York, NY, [3]University of California, San Francisco, San Francisco, CA, [4]New York University School of Medicine, New York, NY, [5]University of California, San Francisco (UCSF), San Francisco, CA

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Rheumatoid Arthritis – Treatment II: Phenotyping and Personalization (2639–2644)

Session Type: Abstract Session

Session Time: 9:30AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a common systemic autoimmune disease that targets the joints, causing persistent pain and swelling. Oral methotrexate (MTX) remains first-line therapy and an anchor drug for RA. However, up to 50% of patients do not achieve a clinically adequate outcome, and there is a lack of prognostic tools to predict MTX response. Variations in clinical outcomes may stem from interindividual differences in the gut microbiome. We and others have found differences in the pre-treatment microbiome of MTX responders (MTX-R) and non-responders (MTX-NR). However, whether there are consistent microbiome features associated with response in multiple cohorts remains unknown. Identification of cross-cohort features would enable development of a generalizable predictive model. Here, we investigate the microbiomes of 3 diverse patient cohorts and their associations with MTX response.

Methods: Three metagenomic datasets comprising fecal samples from 86 treatment-naïve RA subjects were analyzed. Two cohorts (Cohort 1, n=32; Cohort 2, n=25) were recruited from rheumatology clinics at New York University and University of California, San Francisco. Data for a third cohort (Cohort 3, n=29) was publicly available from Sequence Read Archive. Participants were new-onset RA patients. MTX response was defined as an improvement of ≥1.8 in the DAS28 at 12 to 16 weeks post-MTX monotherapy. MMUPHin was employed for metagenomic batch correction and data harmonization. Microbiome differences were assessed using PERMANOVA.

Results: After batch correction, when examining all three cohorts, we confirmed that the pretreatment gut microbiome community composition differed between MTX-R and MTX-NR patients. Of 2,386 strains observed, 95 were differentially abundant ($p_{unadj} < 0.05$), with 24 increased and 71 decreased in MTX-NR. Key gut commensal strains were decreased in MTX-NR, including multiple strains from the *Faecalibacterium*, *Clostridium*, and *Bacteroides* genera. Functional profiling of the microbiome identified 8,895 KEGG Orthologs (KOs), of which 252 were associated with response. Intriguingly, we observed decreased abundance of 231 KOs in MTX-NR that are likely direct and indirect targets of MTX, including dihydrofolate reductase (K00287), methylenetetrahydrofolate dehydrogenase (K01491), and genes associated with metabolism of pyrimidines (K01591), purines (K01939), and histidine (K00013) ($p_{unadj} < 0.05$). Of 601 pathways examined, 19 differed by MTX response status. Biosynthesis pathways for L-histidine, L-tyrosine, L-lysine, and inosine-5'-phosphate and the superpathway for pyrimidine salvage were reduced in MTX-NR ($p_{unadj} < 0.05$). Finally, we applied machine learning techniques to the metagenomic data, resulting in a model that predicted response to MTX.

Conclusion: Our study confirms that the pretreatment gut microbiome is associated with response to MTX in new-onset RA across multiple diverse cohorts. We identify multiple taxa, microbial functions, and pathways that are reproducibly associated with clinical response in patients. Development of a robust predictive model will bring us closer to the goal of advancing precision medicine for patients with RA.

Background/Purpose: TNF inhibitors (TNFi) are the most common biologic DMARD used to treat RA; however, no robust biomarkers have been established to predict likelihood of a good response to them. We hypothesized that detailed cellular profiling on blood samples from RA patients can identify specific immune cell features in baseline samples that are associated with TNFi treatment response. We assessed blood samples from 97 RA patients from a randomized trial to identify cellular features associated with response to TNFi or triple therapy.

Methods: We utilized PBMCs collected as part of the TARGET trial (Solomon et al., Ann Rheum Dis, 2023), which randomized RA patients with an inadequate response to methotrexate to either TNFi (adalimumab or etanercept; n=51) or triple therapy (sulfasalazine and hydroxychloroquine; n = 47). Patients were 72% female with a median age of 60. Treatment response was determined by DAS28 EULAR response criteria at 24 weeks (66% responders in TNFi arm, 69% responders in triple therapy arm). We performed scRNA-seq on PBMCs from baseline and week 24 followed by unsupervised clustering. Data were analyzed using covarying neighborhood analysis (CNA), mixed effects association of single cell analysis (MASC), Wilcoxon paired tests, and differential gene expression analyses.

Results: To define cellular phenotypes affected by TNFi therapy, we compared baseline and week 24 samples. TNFi induced substantial changes in phenotypes of every major immune cell lineage (Fig1). Our analyses highlighted shifts in phenotypes of classical CD14+ CD16- monocytes comparing baseline and week 24 TNFi samples. These changes were observed in TNFi treated patients and not in the triple therapy group (Fig2A-B). To identify cellular features in baseline samples associated with subsequent response to TNFi, we compared immune profiles of baseline samples from TNFi responders and non-responders. Abundance of a monocyte phenotype which corresponded precisely to the monocytes strongly reduced by TNFi in longitudinal analyses differed significantly between TNFi responders and non-responders (Fig2C). These monocytes express inflammatory factors including IL1b and CCL2 and several chemokines are more highly

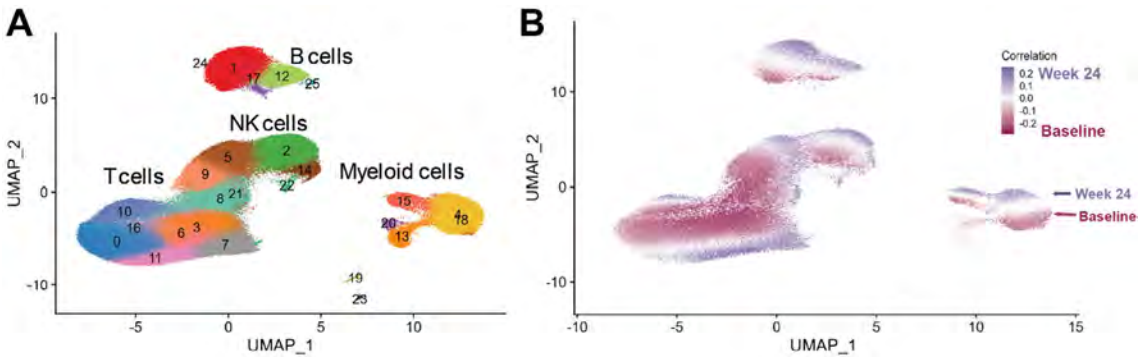

Figure 1. A) scRNAseq of PBMCs from TNFi-treated RA patients, including cells from baseline (pre-treatment) and week 24 post-treatment samples (~355K cells). B) Covarying neighborhood analysis (CNA) showing changes in all major PBMC populations associated with TNFi therapy. p <0.01 and FDR < 0.1 and adjusted for age and sex.

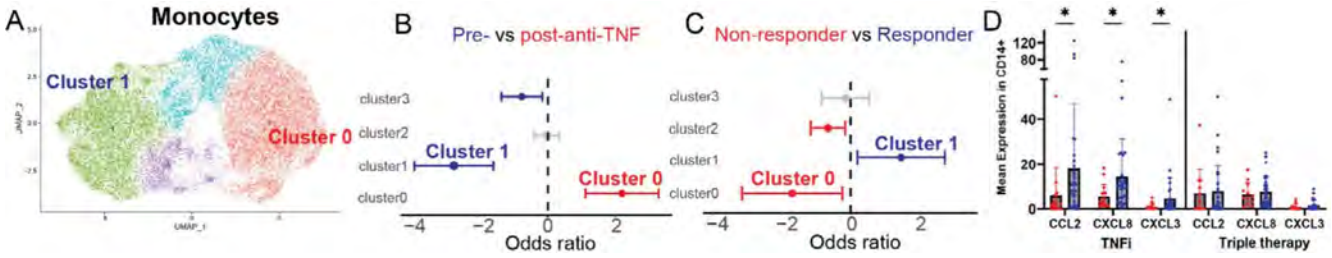

Figure 2. Identification of a monocyte population associated with TNFi treatment response. A) UMAP of monocytes from scRNAseq of TNFi-treated patients in TARGET. B) MASC analysis demonstrating clusters associated with baseline (pre-treatment) or week 24 (post-treatment) samples in the TNFi treated cohort. C) MASC analysis demonstrating clusters in baseline (pre-treatment) samples associated with responders or non-responders to TNFi therapy. D) Mean expression of CCL2, CXCL8 and CXCL3 at baseline in responders and non-responders to TNFi or triple therapy.

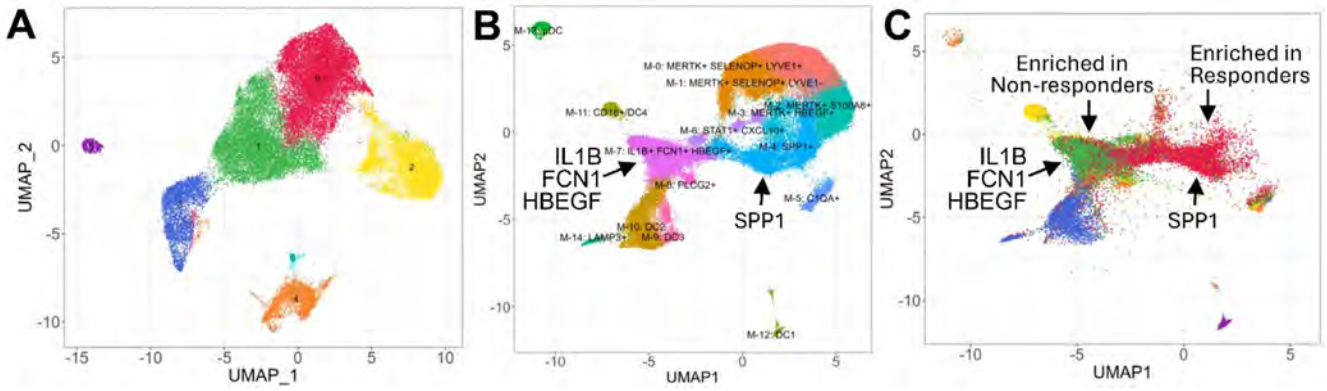

Figure 3. Mapping TNFi treatment-response associated monocytes in blood to RA synovial myeloid populations. A) Myeloid cells from TARGET PBMCs. The red cluster indicates the cluster associated with TNFi response. B) UMAP of RA synovial myeloid cells from synovial tissue generated through AMP (Zhang et al, Nature, 2023). C) Mapping of TARGET myeloid cells to AMP synovial myeloid cells. The colors match the cluster source of each cell shown in A.

expressed in baseline monocytes of TNFi responders as compared to non-responders (Fig2D). Transcriptomic mapping of myeloid cells from this blood scRNA-seq to myeloid cells from RA synovial tissue revealed similarities of the TNFi response-associated monocytes to inflammatory macrophages in RA synovial tissue (Fig3). Analysis of differentially expressed genes encoding surface proteins yielded a candidate list of surface factors, which we validated by flow cytometry. Cytometry quantification of these markers correlated with change in DAS28 in TNFi treated patients and successfully reproduced the discrimination of TNFi responders and non-responders in a subset of TARGET patients (n=18).

Conclusion: Immune profiling of blood from RA patients by scRNA-seq has identified monocytes in blood that are expanded pre-treatment in responders to TNFi. These monocytes can be quantified in blood using a simple cytometry test, which may facilitate translation of a predictive biomarker test to clinical application.

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes III (2645–2650)

Session Type: Abstract Session

Session Time: 9:30AM–11:00AM

Background/Purpose: Current estimates for age of SLE onset are limited, particularly for males and racial/ethnic groups in the United States. Leveraging five Centers for Disease Control and Prevention population-based SLE surveillance registries, which were developed to provide epidemiologic data for SLE across diverse regions of the US, we performed meta-analyses to estimate the age-specific incidence of SLE, overall and by sex and race/ethnicity.

Methods: The registries in Georgia, California, New York and the Indian Health Service (IHS) used the 1997 revised ACR classification criteria while the registry in Minnesota used the EULAR/ACR classification criteria for SLE as their primary case definitions. The surveillance periods ranged from 2002 to 2018. Age-specific incidence of SLE stratified by sex and race/ethnicity was obtained from each registry. Given the small number of registries and near-complete case ascertainment from each site, we performed a fixed-effects meta-analysis to estimate the pooled incidence using inverse-variance weighting, stratified by sex and race/ethnicity (females only due to small sample sizes for males), across the four state sites. Given the IHS registry focused solely on the American Indian/Alaska Native (AI/AN) population, their data was included separately in the female racial/ethnic estimates and not as part of the pooled estimates. To examine age-specific patterns of diagnoses, we then estimated the percentage of all SLE patients diagnosed among each age group, 0-19, 20-29, 30-39, 40-49, 50-59, 60-69, ≥70 years, from all the registries, weighted by the number of person-years contributed by the five sites.

Results: The registries contributed 939 incident classified cases of SLE from a mix of urban and rural areas. The fixed-effects model yielded overall incidence rates of 9.6 (95%CI: 8.9-10.3) and 1.7 (95%CI: 1.4-2.0) per 100,000 person-years among females and males, respectively, Figure 1. Incidence rates among females were highest for those aged 30-39 (13.8, 95%CI: 12.0-16.0), while rates among males were highest for those aged 60-69 (3.1, 95%CI: 1.9-5.0). Black females aged 20-39 and 40-59 had the highest SLE incidence rates (24.2, 95%CI: 20.5-28.6) and (24.3, 95% CI: 20.3-29.3), Figure 2. Among females diagnosed with SLE before age 20, incidence was highest among Asian (7.2, 95%CI: 3.8-13.5) and Black (6.4, 95%CI: 4.5-9.1) individuals. Among females diagnosed with SLE after age 60, incidence was highest among Black (13.8, 95%CI: 9.5-20.0) and AI/AN (9.4, 95%CI: 3.4-15.4) individuals. Weighted percentages (Table 1) show that 7.8% of those with SLE were diagnosed before age 20, while 17.9% were diagnosed after age 60. The largest proportion of individuals with SLE, 22.2%, were diagnosed between 30 and 39 years.

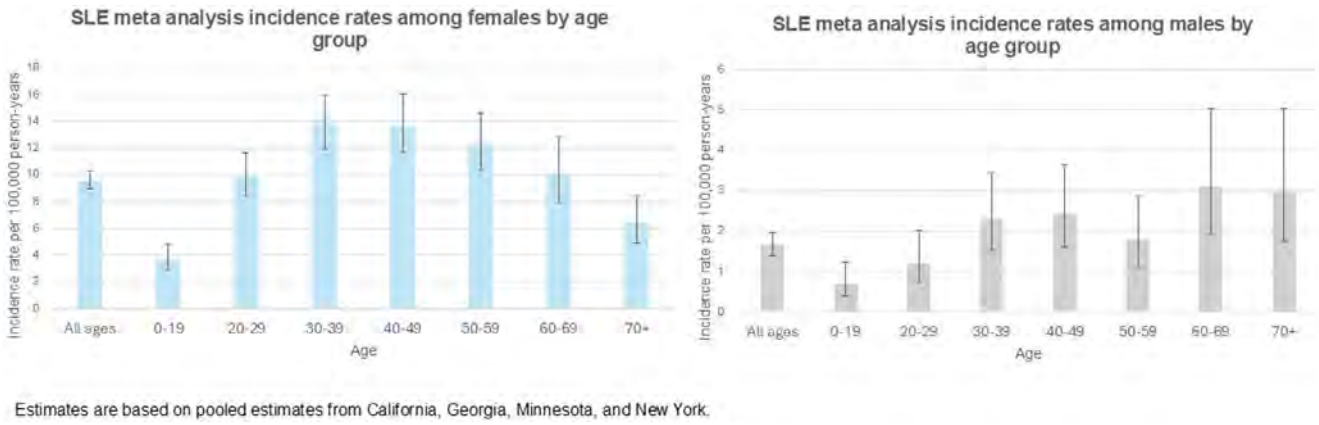

Figure 1. SLE meta analysis incidence rates among females and males by age group.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. SLE meta-analysis incidence rates by race and ethnicity and age group among females.

Age range	Weighted Average by Person-Years (%)
0-19 years	7.8
20-29 years	17.7
30-39 years	22.2
40-49 years	19.9
50-59 years	16.0
60-69 years	9.7
≥70 years	8.3

Age-Specific Patterns of Diagnoses

Conclusion: In this coordinated network of population-based SLE registries, age-specific incidence rates were obtained, and data were provided on males and previously understudied age groups. While female incidence rates were highest during the reproductive years, the incidence rates for males increased with age with the highest rates at ages 60-69. Overall, 18% of patients with SLE were diagnosed after age 60 and nearly 8% before age 20.

Abstract Number: 2646

DNA methylation-based clustering reveals clinically distinct subtypes of systemic lupus erythematosus

Meghan Nelson[1], Mary Horton[2], Joanne Nititham[2], Jinoos Yazdany[3], Maria Dall'Era[4], Cristina Lanata[5] and Lindsey Criswell[2], [1]NIH/NIAMS/NHGRI, Bethesda, MD, [2]NIH/NHGRI, Bethesda, MD, [3]UCSF, San Francisco, CA, [4]Division of Rheumatology, University of California, San Francisco, CA, [5]NIH/NHGRI, Bethesda

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes III (2645–2650)

Session Type: Abstract Session

Session Time: 9:30AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a heterogenous autoimmune disease with significant variability in clinical presentation. DNA methylation has been associated with lupus risk and heterogeneity. In order to identify biologically relevant molecular subtypes, we leveraged genome-wide methylation profiles to cluster patients and evaluate associations between methylation-based clusters and SLE clinical characteristics.

Methods: We analyzed methylation profiles from 1,882 multi-ancestry SLE patients. Clinical data was collected at enrollment and time of peripheral blood collection. Genome-wide methylation profiles were generated using Illumina's EPICv2 BeadChip (n= 937,690 CpG sites). Normalization and quality control were performed using *minfi*. CpGs with high detection p-values and cross-reactive probes were excluded, and missing methylation values imputed using methyLImp2. We selected the top 5% most variable CpGs (~60,000) by beta value standard deviation and performed unsupervised k-means clustering using *ConsensusClusterPlus* across multiple CpG sets (n = 5,000; 10,000; 25,000; 60,000 CpGs). The most distinct clustering was observed with 60,000 CpGs and k=4. Differentially methylated positions (DMPs) by cluster

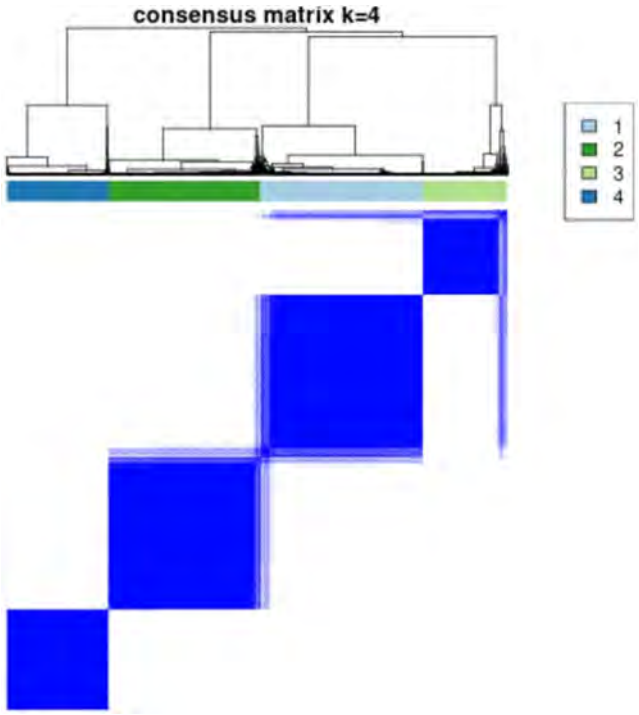

Figure 1. Consensus Plot (k=4) of Patient Clusters based off methylation beta values.

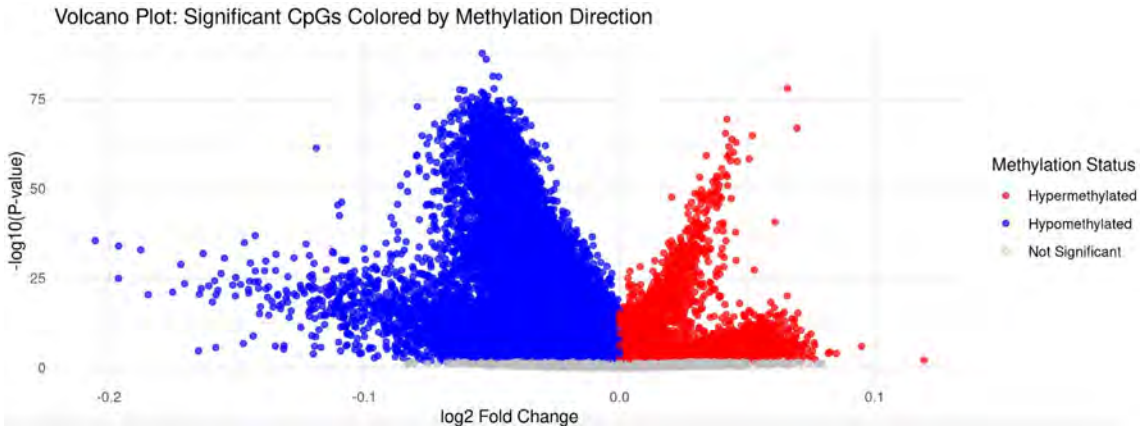
23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



were identified using *limma*, with beta values used for coefficient interpretation and M values to determine statistical significance. Models adjusted for genetic principal components, Houseman estimated blood cell proportions, batch, age, disease duration, sex. DMPs with FDR q< 0.05 were considered statistically significant.

Results: We identified 4 distinct clusters based on methylation beta values (Figure 1). Clusters 1 and 2 reflected milder disease with discoid rash (p=0.002); Cluster 3 exhibited older age at enrollment (p=0.001); Cluster 4 was associated with more severe disease as reflected by younger age of diagnosis (p=0.006), serositis (p< 0.001), nephritis (p< 0.001), higher proportion of males (p=0.006) and hematologic abnormalities (p< 0.001). 2,569 CpGs with FDR q< 0.05 were identified across all cross-comparisons between clusters (Figure 2). Significant CpGs annotated to *ZFP36L1* (an RNA-binding protein that plays a role in post-transcriptional gene regulation), *DOCK9* (involved in intracellular signaling networks), and *NEK8* (protein kinase involved in cell cycle regulation, DNA damage response, and mitosis). Of the significant CpG sites, the absolute change in methylation between clusters ranged from -4.6% to 3.8 %. A majority of these were hypomethylated; 267 were located within genes, and 322 were in promoter regions. Gene set enrichment analysis (GSEA) revealed cluster-specific enrichment: Cluster 1 in leukocyte cell adhesion (FDR q=0.025) and leucocyte activation involved in immune response (FDR q=0.025); Cluster 2 in positive regulation of *MAPK* (FDR q=0.0003); Cluster 3 in neutrophil degranulation (FDR q=0.001); and Cluster 4 in pattern specification (FDR q=1e-5) and cell adhesion (FDR q=1e-5).

Conclusion: We identified 2,569 differentially methylated CpGs across 4 distinct SLE clusters. These results support the potential of DNA methylation profiling to reveal molecular subtypes of SLE and improve risk stratification.

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025
Session Title: Abstracts: Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes III (2645–2650)
Session Type: Abstract Session
Session Time: 9:30AM–11:00AM

Background/Purpose: The aetiopathogenesis of SLE encompasses genetic and epigenetic factors, including hypomethylation of type I interferon (IFN) regulated genes (1) and the HLA-DRB1*03:01 haplotype, linked to *C4A* copy numbers and associated with anti-SSA/SSB antibodies (2). Further, a non-HLA SLE polygenic risk score (SLE-PRS) has been linked to a more severe disease (3). This study aimed to investigate the relationship between a methylation-based SLE risk score (MRS), an SLE-PRS, an HLA-DRB1*03:01 tag SNP, serum IFN-α levels and clinical phenotype.

Methods: DNA methylation levels in whole blood from patients fulfilling ≥4 ACR-82 criteria (n=547) and controls matched for age and sex (n=587) were investigated by the Illumina HM450K methylation array. Significant differentially methylated CpGs with a $\Delta\beta$ of ≥0.1 between cases and controls and located at independent genetic loci (n=17) were selected for calculation of the MRS. Clinical data were collected from patient charts. Serum IFN-α2 levels were measured in a subgroup of patients (n=85) using Simoa.

We analysed if the MRS was associated with the SLE-PRS including 57 non-HLA SLE risk loci (3), with the HLA-DRB1*03:01 tag SNP rs1269852 and with levels of IFN-α using linear regression models. Associations between the MRS, SLE-PRS and HLA-DRB1*03:01 tag SNP and clinical variables were assessed applying logistic regression. Models were adjusted for age and sex, $p< 0.05$ was considered significant.

Results: The MRS was associated with high disease activity (SLEDAI >4 or SLAM >6) (OR=1.01, $p=2.0\times10^{-4}$), higher IFNα levels (Exp(B)=1.03, $p=8.1x10^{-13}$) and low complement (OR=1.01, $p=2.2\times10^{-3}$), while the SLE-PRS was not (all $p >0.05$). Further, no significant correlation between the MRS and the SLE-PRS was observed ($p >0.05$).

The MRS was associated with discoid rash (OR=1.02, $p=3.5x10^{-4}$), hematologic criteria (OR=1.02, $1.6x10^{-7}$) and immunologic criteria (OR=1.01, $p=1.4x10^{-4}$), while the SLE-PRS was associated with the nephritis (OR=1.19, p=0.04) and the immunologic criteria (OR=1.40, $p=1.1x10^{-4}$). Further, the MRS, but not the SLE-PRS, associated with anti-SSA and anti-RNP antibodies (OR=1.03, $p=1.1x10^{-12}$ and OR=1.02, $p=8.2x10^{-11}$).

The HLA-DRB1*03:01 tag SNP was significantly associated with higher MRS (B=7.22, $p=8.6x10^{-4}$) and with anti-SSA and anti-SSB antibodies (OR 3.09 and 4.75, both $p< 1x10^{-10}$).

Conclusion: The lack of correlation between the MRS and SLE-PRS suggests that they reflect distinct, yet complementary, aspects of SLE pathogenesis. The association between the MRS, high disease activity, higher levels of IFN-α2 in serum, anti-SSA antibodies and the HLA-DRB1*03:01 tag SNP implies that an epigenetic predisposition for IFN-α signalling might be of particular importance in HLA-DRB1*03:01 positive patients. These results underscore the relevance of integrating epigenetic profiling with genetic data to better understand disease heterogeneity and mechanisms in SLE.

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes III (2645–2650)

Session Type: Abstract Session

Session Time: 9:30AM–11:00AM

Background/Purpose: Unpredictability is a major challenge in systemic lupus erythematosus (SLE). Routinely used clinical and laboratory parameters fail to predict the risk of and time to flare. We hypothesise that gene signatures may better predict flaring and might thus have merit in disease monitoring.

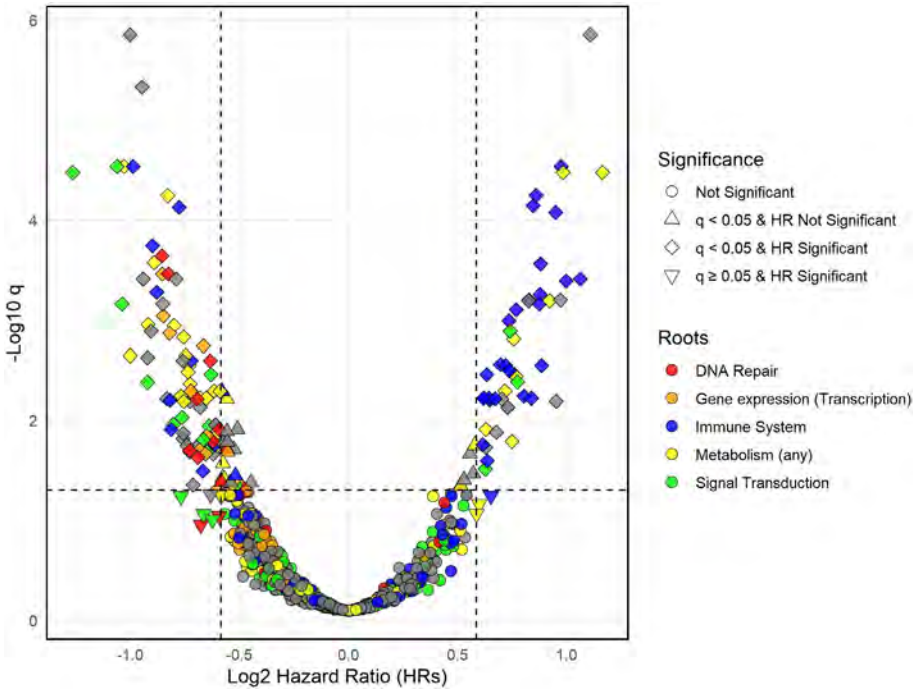

Figure 1

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Heatmap

Methods: Eligible for this analysis were SLE patients from the European multicenter PRECISESADS project (NCT02890121) with available transcriptome data and long-term follow-up including disease flares. The analysis was restricted to patients with quiescent disease at baseline, defined as a clinical SLEDAI-2K score < 6. Flare was defined as any increase in disease activity resulting in a change of therapy. For each patient Reactome pathways according to the Functional Analysis of Individual Microarray Expression (FAIME) algorithm, were calculated. Time-dependent analysis for interval censored data was conducted with parametric models correcting for relevant confounding covariates associated with flares and individual regression weights. Q value < 0.05 and a hazard ratio (HR) >1.5 for causative pathways or < 0.667 for protective ones were considered significant.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Survival Clusters

Results: Long-term data were available in 131 patients, including 85 with quiescent disease at baseline. At the time of blood sampling, those patients had a mean (SD) age of 47.5 (13.9) years and a mean disease duration of 15.7 (9.7) years, and they were mostly women (n=84, 98.8%). The mean clinical SLEDAI-2K was 1.5 (1.5). At baseline, 59 (69.4%) patients were treated with hydroxychloroquine, 25 (29%) with synthetic immunosuppressants, and 36 (42.3%) with glucocorticoids at a mean daily dose of 2.3 (0.5) mg of prednisone equivalent. After a mean observation time of 6.9 (2.6) years, flares occurred in 30 patients (35%).

Among those 30 patients, the first flare was developed after a mean time of 3.0 (2.0) years, and the non-cumulative count of those flares per domain was 18 articular, 9 cutaneous, 5 constitutional, 4 haematological, 3 vascular, and 2 renal.

Overall, 1265 Reactome pathways were explored, of those 83 and 48 pathways were significantly associated with increased or reduced flaring hazards, respectively (Figure 1).

Flaring patients had a reduced capability of DNA repair, increased DNA damage due to impaired telomere function, an increased activity interferon-related pathways, an increased activity of the complement system, an increased inflammasome, reduced CTLA4 and CD28 inhibitory mechanisms, a disrupted circadian clock and several metabolic alterations.

Conclusion: Our findings reveal that specific pathway deregulations linked to SLE pathogenesis may herald the occurrence of flares in quiescent patients. Impaired DNA repair, increased interferon signaling, complement activation, inflammasome upregulation, and reduced CTLA4/CD28 inhibitory mechanisms suggest a predisposition to immune dysregulation preceding clinical flares. These insights highlight potential molecular predictors of flaring and suggest that targeted immunomodulation or specific interventions may be warranted in selected patients to prevent flares and mitigate the risk of long-term damage accrual, ultimately improving disease monitoring strategies in SLE.

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes III (2645–2650)

Session Type: Abstract Session

Session Time: 9:30AM–11:00AM

Background/Purpose: Immune dysregulation propels systemic lupus erythematosus (SLE) pathogenesis. Capturing it as lab-based screening tests could help prioritize SLE patients for early intervention and proactive disease management. This study ascertained the usefulness of simultaneous Lupus Flare Risk Index (L-FRI) and Lupus Disease Activity Index (L-DAI) assessment to determine parallel risk of *future* clinical disease flare and *concurrent* disease activity.

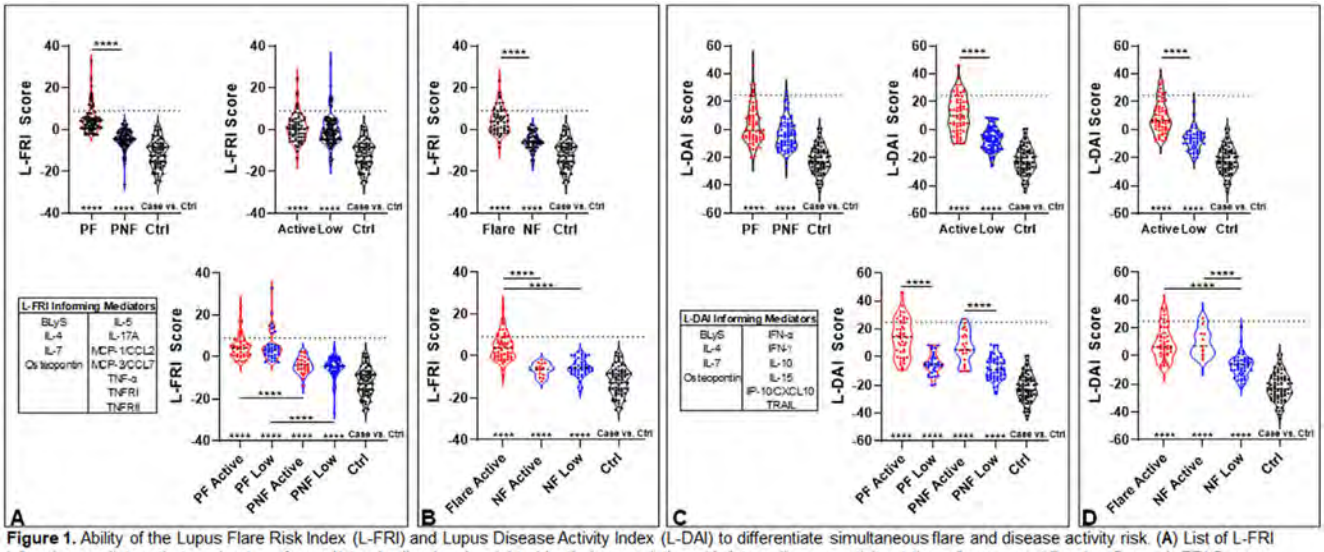

Figure 1. Ability of the Lupus Flare Risk Index (L-FRI) and Lupus Disease Activity Index (L-DAI) to differentiate simultaneous flare and disease activity risk. (**A**) List of L-FRI informing mediators that are log-transformed/standardized and weighted by their association with future disease activity at time of concurrent flare/nonflare + L-FRI Scores comparing Pre-flare (PF) vs. Pre-Nonflare (PNF), Active (hSLEDAI ≥ 4) vs Low (hSLEDAI < 4) disease activity, and comparisons of flare/disease activity risk status, each vs. healthy controls (Ctrl). (**B**) L-FRI scores comparing concurrent SFI-defined Flare vs. Nonflare (NF), and comparisons of flare/disease activity status, each vs. Ctrls. **A-B**. Visits above the dashed line are in the "high" risk category and are enriched for severe pre-flare/flare status. (**C**) List of L-DAI informing mediators that are log-transformed/standardized and compositely weighted by their association with concurrent disease activity and SLE-associated autoantibody specificities + L-DAI Scores comparing PF vs. PNF, Active vs Low disease activity, and comparisons of flare/disease activity risk status, each vs. Ctrl. (**D**) L-DAI scores comparing Active vs. Low disease activity at time of concurrent SFI-defined Flare/NF, and comparisons of flare/disease activity status, each vs. Ctrl. **C-D**. Visits above the dashed line are in the "high" risk category and are enriched for active disease with renal features. ****p<0.0001 Kruskal-Wallis test with Dunn's multiple comparison. Graphs = mean ± SEM.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

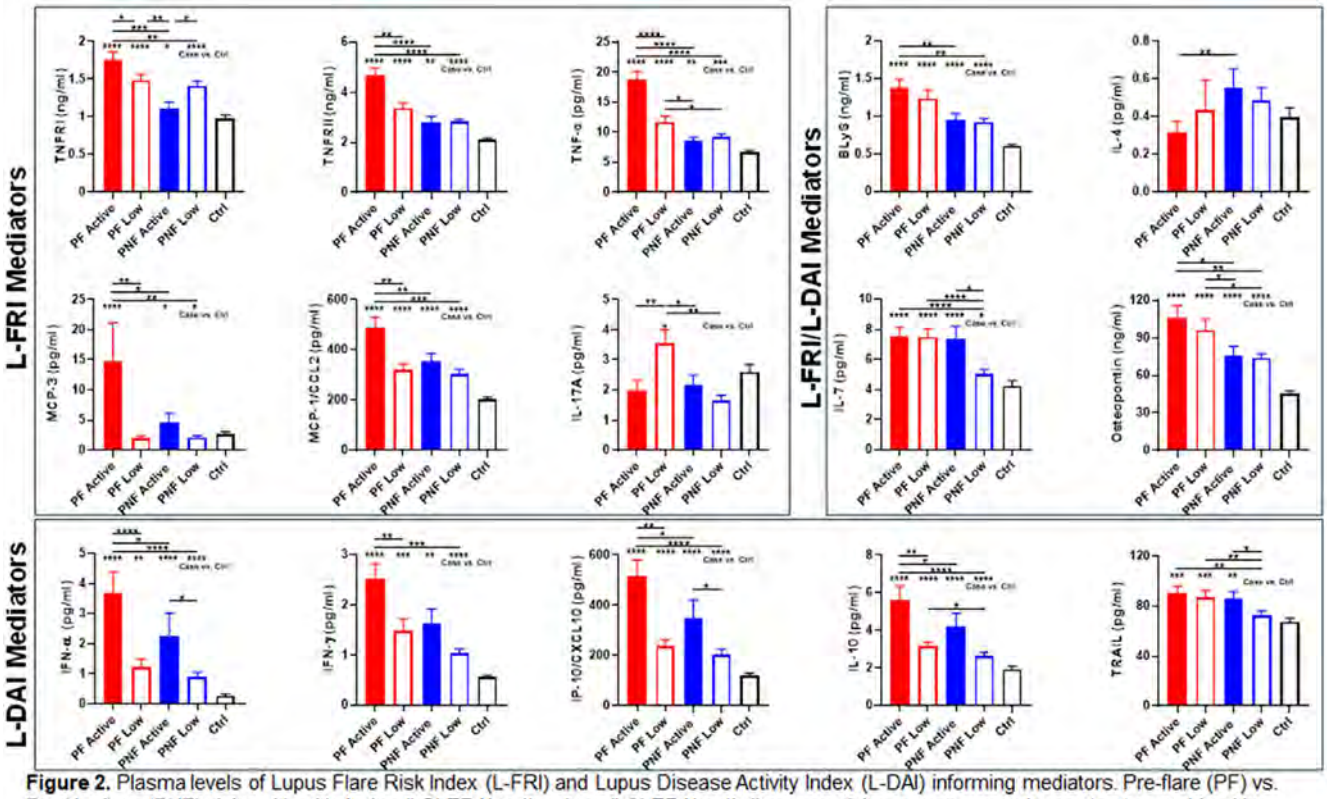

Figure 2. Plasma levels of Lupus Flare Risk Index (L-FRI) and Lupus Disease Activity Index (L-DAI) informing mediators. Pre-flare (PF) vs. Pre-Nonflare (PNF) visits with with Active (hSLEDAI ≥ 4) or Low (hSLEDAI < 4) disease activity were compared to each other and healthy controls (Ctrl). *$p<0.05$, **$p<0.01$, ***$p<0.001$, ****$p<0.0001$ Kruskal-Wallis test with Dunn's multiple comparison. Graphs = mean ± SEM.

Methods: L-FRI and L-DAI scores were calculated from 11 and 10 informing plasma mediators, respectively (**Fig. 1**) in 86 preflare (PF) vs. 87 prenonflare (PNF) visits, and 60 flare vs. 62 nonflare (NF) follow-up visits with available samples from a unique cohort of prospectively followed SLE patients. The algorithms reflect the sum of log-transformed/standardized informing immune mediators, weighted by their association with either ensuing disease activity at the time of *future* flare/NF (L-FRI) or a composite of *current* disease activity and SLE-associated autoantibody specificities (L-DAI). Hybrid SLEDAI (hSLEDAI) scores, clinical features, medication usage, and the presence of autoantibody specificities to dsDNA, chromatin, Ro/SSA, La/SSB, Sm, SmRNP, and RNP were also determined.

Results: Forty-three of 86 (50%) PF vs. 26 of 87 (30%) PNF visits were associated with active disease (hSLEDAI≥4; *p=0.0084*). The 43 PF and 61 PNF visits with low disease activity included 16 (PF)/10 (PNF) LLDAS and 14 (PF)/30 (PNF) in DORIS remission. The L-FRI did not differentiate disease activity itself (**Fig 1A**), but discerned flare risk in PF vs. PNF (**Fig. 1A**) and Flare vs. NF visits (**Fig. 1B**), irrespective of disease activity state. The L-DAI did not differentiate flare risk itself (**Fig. 1C**), but differentiated concurrent active vs. low (hSLEDAI< 4) disease activity, irrespective of flare risk status (**Fig.1C-D**). All SLE scores were higher than matched controls (*p< 0.0001*, **Fig. 1**). Plasma levels of osteopontin and BLyS (L-FRI, L-DAI), as well as other L-FRI informing mediators TNF-α, TNFRI, TNFRII, MCP-1, and MCP-3, were highest in PF visits with active disease (*p< 0.05*), while IL-17A levels were highest in PF visits with low disease activity and IL-4 highest in PNF visits with active disease (*p< 0.05*), **Fig. 2**. IL-7 (L-FRI, L-DAI) and TRAIL (L-DAI) levels were increased with both flare and disease activity risk (*p< 0.05*), while L-DAI informing mediators IFN-α, IFN-γ, IP-10, and IL-10 were highest in active disease (PF >PNF levels, *p< 0.05*), **Fig 2**. Of note, the L-FRI and L-DAI performed well at assessing flare and disease activity risk, respectively (AUC >0.8), yet parallel assessment of L-FRI and L-DAI performed better than either alone to identify simultaneous risk of concurrent active disease and imminent flare risk, **Table 1**.

Table 1. Combination of L-FRI and L-DAI Tests Optimally Informs *Future* Flare and *Concurrent* Disease Activity Risk

Comparison	Variables	Test	AUC	95% CI	p-value
Flare Risk Status	Pre-Flare (PF) vs. Pre-Nonflare (PNF)[a]	L-FRI[b]	0.942	0.910-0.974	***<0.0001***
		L-DAI[c]	0.646	0.558-0.734	***0.0023***
		L-FRI + L-DAI	0.951	0.921-0.981	***<0.0001***
Disease Activity Risk Status	Active (Act) vs. Low Disease Activity[d]	L-FRI	0.569	0.480-0.657	*0.1315*
		L-DAI	0.884	0.831-0.937	***<0.0001***
		L-FRI + L-DAI	0.899	0.849-0.949	***<0.0001***
Pre-Flare Disease Activity Risk	PF/Act vs. PNF/Act	L-FRI	0.527	0.398-0.656	*0.6769*
		L-DAI	0.891	0.821-0.961	***<0.0001***
		L-FRI + L-DAI	0.925	0.868-0.981	***<0.0001***
Pre-Nonflare Disease Activity Risk	PF/Low vs. PNF/Low	L-FRI	0.530	0.395-0.666	*0.6586*
		L-DAI	0.865	0.775-0.955	***<0.0001***
		L-FRI + L-DAI	0.868	0.780-0.956	***<0.0001***
Active Disease Flare Risk	PF/Act vs. PNF/Act	L-FRI	0.931	0.871-0.990	***<0.0001***
		L-DAI	0.651	0.515-0.786	***0.0459***
		L-FRI + L-DAI	0.930	00.868-0.992	***<0.0001***
Low Disease Activity Flare Risk	PF/Low vs. PNF/Low	L-FRI	0.943	0.901-0.985	***<0.0001***
		L-DAI	0.607	0.489-0.725	*0.0874*
		L-FRI + L-DAI	0.956	0.919-0.994	***<0.0001***
Moderate Flare/Disease Activity Risk	PF/Low vs. PNF/Act	L-FRI	0.924	0.862-0.986	***<0.0001***
		L-DAI	0.794	0.669-0.920	***0.0002***
		L-FRI + L-DAI	0.950	0.891-1.000	***<0.0001***
Highest vs. Lowest Flare/Disease Activity Risk	PF/Act vs. PNF/Low	L-FRI	0.953	0.917-0.990	***<0.0001***
		L-DAI	0.921	0.871-0.973	***<0.0001***
		L-FRI + L-DAI	0.989	0.974-1.000	***<0.0001***

[a]Pre-Flare/Pre-Nonflare visits occurred within 12 weeks of SELENA-SLEDAI Flare Index (SFI) defined Flare/Comparable Nonflare

[b]Lupus Flare Risk Index (L-FRI) informs flare risk within next 12 weeks

[c]Lupus Disease Activity Index (L-DAI) informs concurrent SLE disease activity risk

[d]Disease Activity: Active (hSLEDAI≥4); Low (hSLEDAI<4)

Conclusion: Simultaneous use of the L-FRI and L-DAI optimally identified risk of imminent lupus disease flare and concurrent active disease to identify SLE patients who may benefit from early intervention strategies. Such an approach would improve disease management and be advantageous in prospective clinical trials for study participant recruitment and assessment.

Abstract Number: 2650

LFA-REAL Outperforms SLEDAI and BILAG in Detecting Clinical Change in Lupus Activity

Alberto Nordmann-Gomes[1], Leila Khalili[2], Cynthia Aranow[3], Meghan mackay[4], Mimi Kim[5], Diane Kamen[6], Cristina Arriens[7], Maya Souvignier[8], Wei Tang[9], Stephen Suh[8], Maria Dall'Era[10], Joan Merrill[11] and Anca Askanase[2], [1]Columbia University Irving Medical Center, New York, NY, [2]Columbia University Medical Center, New York, NY, [3]Institute of Molecular Medicine, Feinstein Institutes for Medical Research, Manhasset, NY, [4]Feinstein Institutes for Medical Research, Manhasset, NY, [5]Albert Einstein College of Medicine, Bronx, NY, [6]Medical University of South Carolina, Johns Island, SC, [7]Oklahoma Medical Research Foundation, Oklahoma City, OK, [8]Columbia University Irving Medical Center, New York City, NY, [9]Westchester Medical Center, Valhalla, NY, [10]Division of Rheumatology, University of California, San Francisco, CA, [11]Oklahoma Medical Research Foundation, Oklahoma

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes III (2645–2650)

Session Type: Abstract Session

Session Time: 9:30AM–11:00AM

Background/Purpose: Disease activity measures in SLE have important limitations that restrict their performance in clinical practice and research. The Lupus Foundation of America-Rapid Evaluation of Activity in Lupus (LFA-REAL) is a novel and simple SLE disease activity instrument. Each organ and active symptom/sign receives a unique visual analog score (0-100mm each), allowing sensitive detection and granular understanding of disease fluctuations. The system allows rapid yet versatile evaluation of progress at the level of symptoms, organs, or overall disease, and addresses pitfalls in glossary defined cutoffs for scoring that limit the utility of the SLE Disease Activity Index (SLEDAI) and British Isles Lupus Assessment Group Index (BILAG). Here, we evaluate the sensitivity of the LFA-REAL to detect changes in the clinician's global Impression of clinically significant change (CGIC) compared to the SLEDAI and BILAG.

Methods: An observational, longitudinal, prospective study of SLE patients was conducted at four lupus centers. Each study participant was evaluated at a baseline and follow-up visit. The same clinician scored the SLEDAI, BILAG, and LFA-REAL. At the follow-up visit, the physician also rated the CGIC, which rates no change vs clinically significant change compared to the previous visit. Agreement between changes in disease activity scores and CGIC was analyzed, generating ROC curves to assess the accuracy of each instrument to detect the clinician's overall conclusion about the degree of change.

Results: Of 163 patients enrolled, 145 completed follow-up visits, 124 (85%) were women, mean age was 41.4 +/- 12.9 years (Table 1). Among the 145 patients with follow-up, 33 (23%) had CGIC clinically significant disease improvement, 25 (17%) worsening, and 87 (60%) no change. For the CGIC improvement group the median change in LFA-REAL from visit 1 to visit 2 (V2-V1) (ΔLFA-REAL) was -36 (IQR: -62 ; -20), for the group with no change in CGIC the median change in LFA-REAL was 0 (IQR: -20 ; 10), and for those who worsened: 27 (6 ; 34) (Figure 1). Compared to BILAG and SLEDAI, LFA-REAL demonstrated the greatest sensitivity for clinical change in either direction, with area under the curve (AUC) of 0.8385 for improvement and 0.8305 for worsening. BILAG AUCs were 0.7461 and 0.7553, and SLEDAI AUCs were 0.7385 and 0.7362, respectively (Figure 2). Using DeLong's test, the AUC for LFA-REAL was significantly greater than that of SLEDAI for detecting improvement ($p = 0.042$) and trended towards greater sensitivity than BILAG ($p = 0.073$). Detection of worsening was similar compared to SLEDAI ($p = 0.093$) and BILAG ($p = 0.188$). Of the 25 patients classified as having clinical worsening by CGIC, 8 (32%) required a change in treatment. LFA-REAL identified all 8 of these patients as having clinically significant worsening, compared to 4 (50%) detected by BILAG and 2 (25%) by SLEDAI.

Session Title: Abstracts: Systemic Sclerosis & Related Disorders – Clinical III (2651–2656)

Session Type: Abstract Session

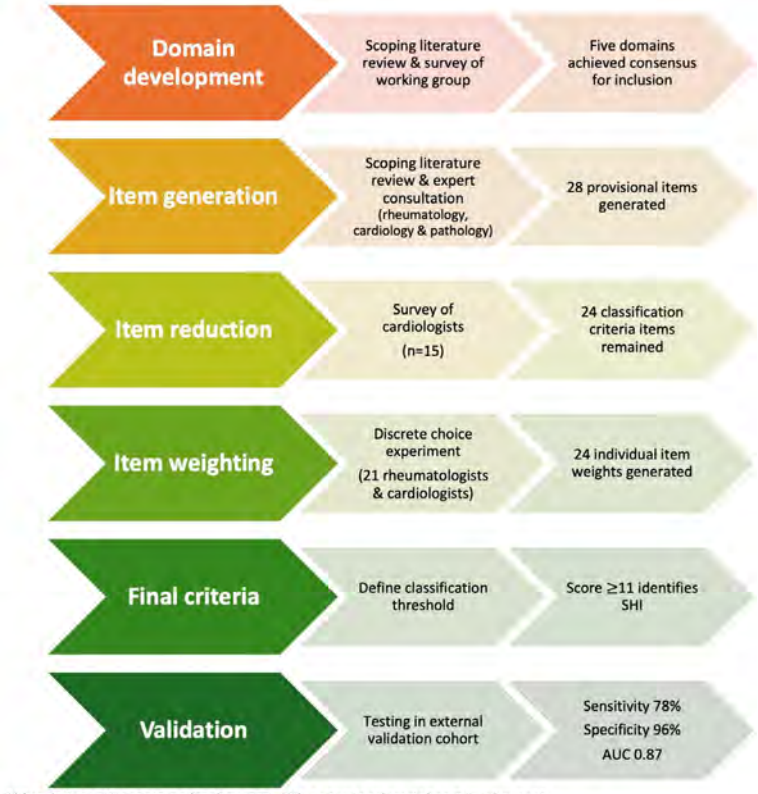
Session Time: 9:30AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) heart involvement (SHI) is a serious disease manifestation associated with high mortality. This study presents newly developed classification criteria to enable standardised identification of SHI in clinical studies.

Methods: An international inter-disciplinary working group including rheumatology, cardiology and anatomical pathology members was assembled. Consensus methods were applied to determine the domains of cardiac disease to be included in the criteria and generate provisional items (Figure 1).

Repeated consensus exercises and a discrete choice experiment were performed to reduce and weight items. A classification threshold was defined in a single centre derivation cohort (n=20), with emphasis placed on the specificity of the

Figure 1: Development of Systemic Sclerosis Heart Involvement Classification Criteria



Abbreviations: AUC: area under the curve; SHI: systemic sclerosis heart involvement

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1: SCTC Systemic Sclerosis Heart Involvement Classification Criteria

- A diagnosis of systemic sclerosis heart involvement (SHI) can only be made in the setting of an established diagnosis of systemic sclerosis
- SHI can only be diagnosed when other causes of cardiomyopathy, particularly infiltrative diseases, have been reasonably excluded. Other causes of cardiomyopathy to be excluded include:
  - Cardiac disease secondary to pulmonary vascular disease
  - Ischaemic heart disease
  - Hypertensive heart disease
  - Cardiac disease secondary to renal disease
  - Dilated cardiomyopathy (e.g. genetic, post non-systemic sclerosis myocarditis, alcohol etc)
  - Cardiac sarcoidosis, cardiac amyloidosis, iron overload, Fabry's disease

Classification score ≥11 indicates presence of SHI

Classification criteria item	Item weight
Endomyocardial biopsy	
Perivascular and/or interstitial mononuclear inflammatory infiltrate adjacent to areas of myocyte necrosis and/or degeneration, with or without myocardial fibrosis	6
Perivascular and/or interstitial inflammatory infiltrate without myocyte necrosis	5
Pathological degree of interstitial fibrosis with or without replacement fibrosis	6
Fibrous or fibrinous pericarditis or pericardial adhesions	5
Cardiac magnetic resonance imaging	
Evidence of myocarditis as per Lake Louise Criteria	5
Abnormalities on T2 sequences (including T2 mapping) or post-contrast imaging suggestive of myocardial oedema that do not meet Lake Louise criteria for diagnosis of myocarditis	5
Epicardial or mid-wall late gadolinium enhancement in a non-ischaemic pattern	6
Abnormal T1 mapping time	5
Focal thinning or akinesis of myocardial wall or wall motion abnormalities	4
Evidence of thickened pericardium on either CMR, cardiac CT, TTE	4
Objective evidence of myocardial ischaemia in the absence of epicardial coronary artery disease (e.g. transmural scarring on CMR and patent coronary arteries)	4
Echocardiography	
Acute or subacute onset global or regional left and, or right ventricular dysfunction / reduced ventricular ejection fraction	4
Grade II or Grade III left ventricular diastolic dysfunction, according to ASE/EACVI criteria	4
Chronic non-trivial pericardial effusion	3
Electrocardiography	
Unexplained 2nd degree Mobitz type II conduction defect or complete heart block	4
Multifocal or complex ventricular ectopics	4
Sustained or non-sustained ventricular tachyarrhythmia	5
Right heart catheterisation	
Unexplained post capillary wedge pressure >15mmHg or left ventricular end diastolic pressure >12mmHg	4
Serum biomarkers	
Elevated troponin (above upper limit of normal)	3
Elevated serum BNP / NT-proBNP (above upper limit of normal)	3
Clinical features	
New onset heart failure	3
Signs, symptoms, investigation findings of cardiac constriction	3
Acute pericarditis indicated by clinical symptoms and either typical ECG changes or imaging evidence of pericardial inflammation	4

Note: Patients do not have to complete all investigations to secure a diagnosis of systemic sclerosis heart involvement. If a particular investigation has not been performed or the described abnormality is not observed, the patient scores zero for that item.

Abbreviations: ASE: American Society of Echocardiography; BNP: B-type natriuretic peptide; CMR: cardiac magnetic resonance imaging; CT: computed tomography; EACVI: European Association of Cardiovascular Imaging; ECG: electrocardiography; NT-proBNP: N-terminal pro B-type natriuretic peptide; TTE: transthoracic echocardiography; SCTC: Scleroderma Clinical Trials Consortium; SHI: systemic sclerosis heart involvements

classification criteria. Performance of the criteria were tested against physician-diagnosed SHI, the current diagnostic gold standard.

External validation studies were performed in a multi-centre validation cohort (n=168) to determine the sensitivity, specificity and discriminant validity of criteria by calculating the areas under receiver operator curves (AUC). Logistic regression analysis was performed to calculate the diagnostic odds ratio (OR) of the criteria classifying a patient as positive for SHI.

Results: The working group achieved consensus that criteria should be developed to identify the direct effects of SSc on the heart and discriminate SHI from cardiac complications of other disease manifestations, e.g. pulmonary arterial hypertension, renal disease. It was agreed that criteria should reflect the pathogenic changes of fibrosis, inflammation and vasculopathy known to affect the myocardium and pericardium in SSc.

Five domains of cardiac disease reached the *a priori* threshold of 70% agreement for inclusion in the classification criteria. Twenty-eight provisional items were generated from the results of a literature review and expert consultation. Four items were omitted following item reduction survey, with the remaining 24 items weighted using the results of the discrete choice experiment (Table 1).

A classification criteria score was calculated for each patient in the derivation cohort by summing individual criterion weights. A SHI classification score of ≥11 was chosen as it defined the the presence of SHI with a sensitivity of 100% and specificity of 82%. Application of this score to the validation cohort correctly classified 91% of cases, with a sensitivity of 78% and specificity of 96% and AUC of 0.87 (95%CI 0.80-0.93), compared to physician-diagnosed SHI (the current gold standard). A classification criteria score ≥11 gave an OR 82.60 (95%CI 26.47-257.72) for the presence of SHI.

Conclusion: These newly developed classification criteria are the first clinical criteria that can identify SHI with good sensitivity and excellent specificity. Their implementation in future studies will further validate their use and encourage systematic investigation of this important disease manifestation.

Anti-mitochondrial Antibodies in Systemic Sclerosis Target Enteric Neurons and Are Associated with GI Dysmotility

Zsuzsanna McMahan[1], Srinivas Puttapaka[2], Livia Casciola-Rosen[3], Timothy Kaniecki[3], Laura Gutierrez[3], Su Hong MIng[2], Philippa Seika[2] and **Subhash Kulkarni**[4], [1]UT Health Houston, Houston, TX, [2]BIDMC/Harvard, Boston, MA, [3]Johns Hopkins University, Baltimore, MD, [4]BIDMC, Boston, MA

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025
Session Title: Abstracts: Systemic Sclerosis & Related Disorders – Clinical III (2651–2656)
Session Type: Abstract Session
Session Time: 9:30AM–11:00AM

Background/Purpose: Most patients with systemic sclerosis (SSc) experience gastrointestinal (GI) dysmotility. The enteric nervous system (ENS) regulates GI motility, and its dysfunction causes dysmotility. A subset of SSc patients harbor autoantibodies against the M2 mitochondrial antigen (AM2A). Here, we investigate whether M2 is expressed by specific ENS cells, and if AM2A associate with GI dysmotility in SSc patients.

Methods: Patients with SSc were prospectively enrolled from a large Scleroderma Center into the NIH-funded cohort based on ACR/EULAR criteria or CREST features and GI symptomatology. Clinical phenotyping, including Medsger Severity Scores, autoantibody profiles, and overlap diagnoses (e.g., PBC), was performed at enrollment and during routine follow-up. Whole gut transit (WGT) scintigraphy was conducted using radiolabeled meals to evaluate GI motility. AM2A autoantibodies were assessed by ELISA, and their uptake was studied via immunostaining in HepG2 cells, human intestinal tissue, and neural-crest lineage mouse models using confocal microscopy. Functional effects of AM2A were

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Figure 3: A subset of mesoderm-derived enteric neurons (MENs) are enriched in mitochondria. Immunostaining of adult murine small intestinal longitudinal muscle - myenteric plexus (LM-MP) tissue with ANNA1 antisera containing antibodies against Hu (green) and antibodies against the pan-mitochondrial antigen TOM20 (cyan). LM-MP is derived from an neural crest lineage-specific adult mouse Wnt1-cre:tdTomato, where tdTomato (red) labels neural crest-derived cells. The representative image shows that tdTomato- Hu+ neurons (MENs, yellow arrows) are enriched in TOM20, while the neural crest-derived neurons (NENs, red arrow) and a subset of MENs (green arrow) are not. Nuclei are labeled with DAPI (blue). Scale bar = 10 m.

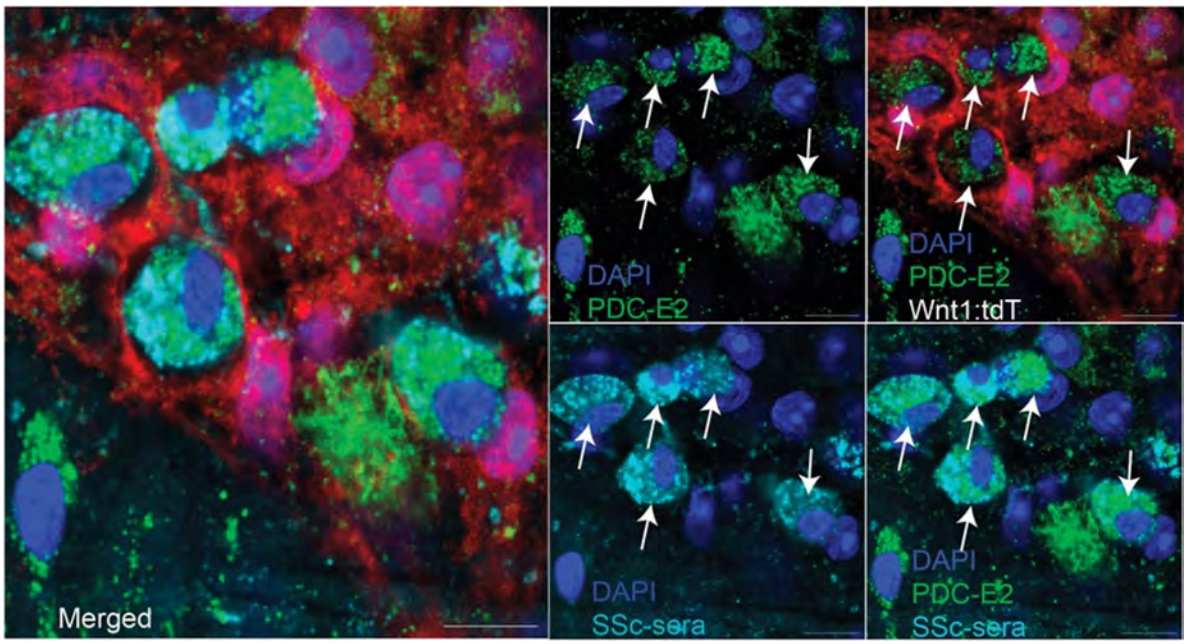

Figure 2. SSc-AM2A penetrate viable MENs ex vivo. Adult murine small intestinal LM-MP tissues from the Wnt1-cre:tdTomato lineage fate mapping mouse when cultured with SSc patient sera containing AM2A (FW-2530), and immunostained with commercially available anti-DLAT antibodies post-culture show that tdTomato-negative myenteric neurons or MENs show presence of SSc autoantibodies (AM2A; cyan) within their soma which co-localizes with the presence of DLAT (green) immunostaining (white arrows). Nuclei are labeled with DAPI (blue). Scale bar = 10 m.

tested with Seahorse assays. Immunoprecipitation and Western blot confirmed antibody-protein interactions. All protocols were IRB-approved, and statistical analyses included t-tests, chi-square, regression, and Spearman correlation, with significance set at $p < 0.05$.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

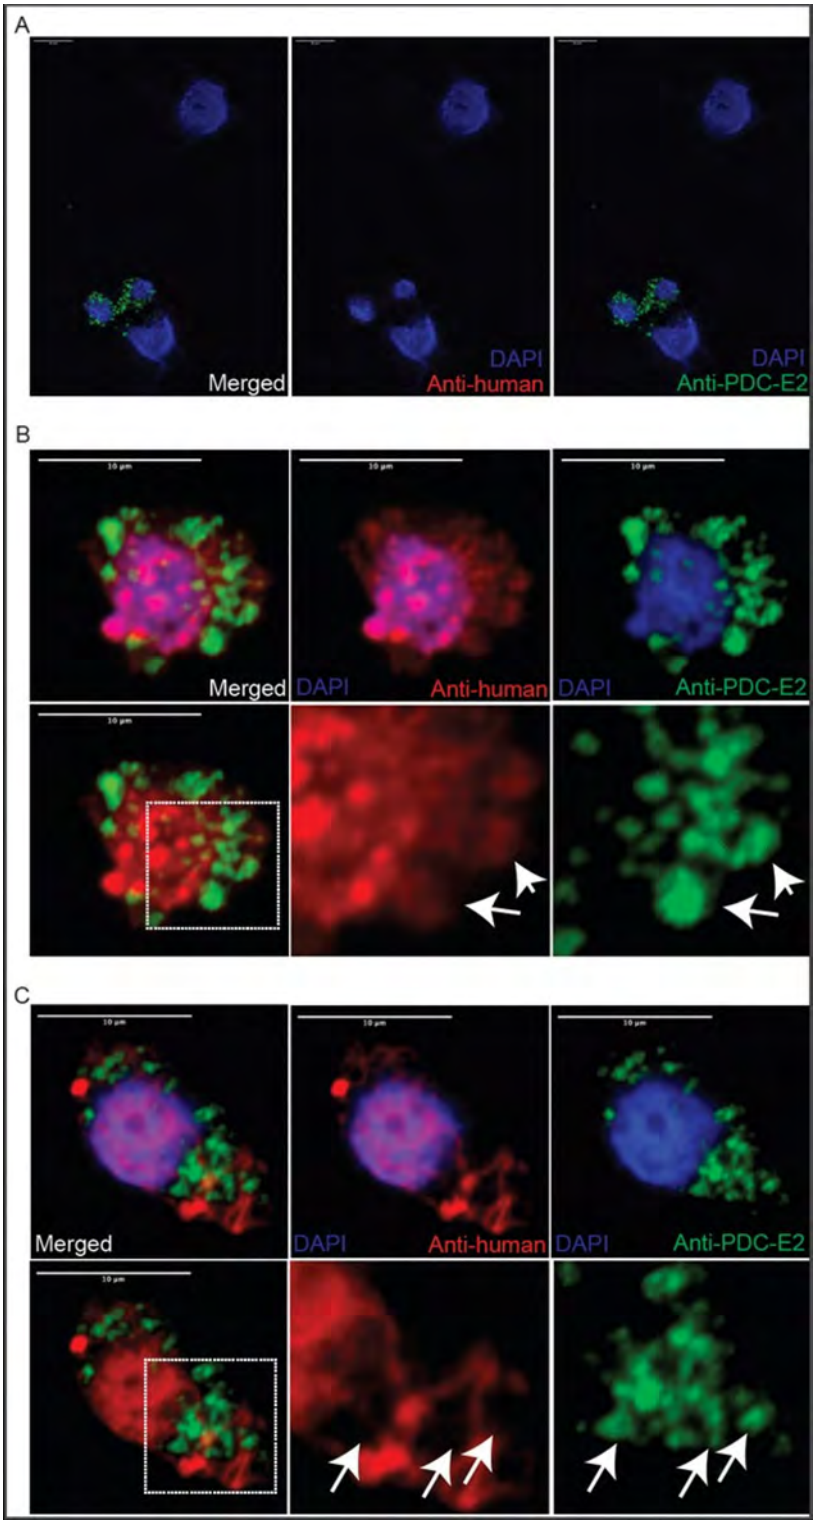

Figure 3. SSc autoantibodies penetrate viable cells and engage intracellular targets upon uptake. HepG2 cells when cultured with and without SSc antisera (red) can be used to test intracellular uptake. Live HepG2 cells cultured (A) without SSc antisera, and with (B) AM2A+ SSc antisera (patient FW-2530), and (C) AM2A- SSc antisera (patient FW-2340), were subsequently fixed and immunostained with commercially available anti-M2/PDC-E2 antibody (green) and imaged to observe that SSc autoantibodies were present within cells cultured with SSc patient antisera. Furthermore, AM2A+ antisera was detected in PDC-E2- expressing mitochondria (B, white arrow), but the AM2A- antisera labeled cellular compartments other than the PDC-E2-expressing mitochondria (C, white arrows). Nuclei are labeled with DAPI (blue). Scale bar = 10 μm.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Nineteen of 147 patients (12.9%) were AM2A positive. AM2A positivity was significantly associated with slower transit in the esophagus (β -14.4, 95%CI -26.2, -2.6) and stomach (β -7.9, 95% CI -14.1, -1.6). Immunostaining demonstrated pan-mitochondrial antigens TOM-20 and M2 enrichment in human ENS neurons, specifically in mesoderm-derived enteric neurons (MENS). Autoantibodies in SSc sera penetrated live adult murine MENs and HepG2 cells, when adult murine longitudinal muscle containing myenteric plexus (LM-MP) tissue and HepG2 cells were cultured with SSc sera. Upon penetrating live cells, AM2A localized to mitochondria, and immunoprecipitation demonstrated binding to the M2 antigen. Seahorse assays show that penetration of HepG2 cells with SSc-AM2A altered cellular respiration suggesting that penetrating AM2A are pathogenic.

Conclusion: AM2A in SSc patients associate with slower GI transit. SSc autoantibodies penetrate live cells in vitro, and SSc-AM2A penetrate live cells to target the mitochondrial M2 antigen and cause functional deficits in cellular respiration. Since a subset of enteric neurons (MENs) is enriched in mitochondria, which are similarly penetrated by SSc-AM2A ex vivo, the presence of GI dysmotility in SSc patients harboring AM2A suggests that SSc-AM2A may penetrate MENs in vivo, driving ENS and GI dysfunction. Further studies are warranted to test how AM2A alter ENS function in vivo to contribute to GI dysmotility in SSc.

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025
Session Title: Abstracts: Systemic Sclerosis & Related Disorders – Clinical III (2651–2656)
Session Type: Abstract Session
Session Time: 9:30AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) patients are at higher risk of herpes zoster (HZ) due to underlying immune dysregulation and immunosuppressive therapies. Vaccination is a key strategy for preventing HZ. Although the recombinant zoster vaccine (RZV/Shingrix®) is approved for immunocompromised individuals, its immunogenicity, safety, and impact on disease activity (DA) have not been specifically evaluated in SSc patients. This study aimed to evaluate the humoral immune response to RZV in immunosuppressed SSc patients compared to healthy controls, to identify factors influencing vaccine

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Humoral response rates at V3 (D84) and anti-gE IgG titers before (D0) and after two doses (D84) of RZV in SSc patients and CG.

	Humoral response	Geometric mean titer		*p value*	Factor increase in GMT
	D84	D0	D84	D0 vs. D84	
SSc, n=68	63 (92.6)	0.19 (0.14-0.25)	5.81 (4.41-7.65)	**< 0.001**	31.0 (20.64-46.56)
CG, n= 299	298 (99.7)	0.21 (0.18-0.24)	12.56 (11.63-13.56)	**< 0.001**	59.44 (51.37-68.78)
p (SSc vs CG)	**0.001**	0.463	**< 0.001**	-	**< 0.001**

SSc - systemic sclerosis; CG – control group; GMTs – Geometric mean titers (AU/mL); Frequencies of humoral response are presented as number (%) and they were compared using two-sided chi-square test between SSc and CG at D84 (12-week after first vaccine dose). Ig-gE IgG titers and factor increase in GMT are expressed as geometric means with 95% confidence interval (95%CI). Data regarding anti-gE titers were analyzed using ANOVA with repeated measures and 2 factors [2 groups (SSc vs. CG), at 2 time points (D0 and D84)], followed by Bonferroni's multiple comparisons at neperian logarithm (ln)-transformed data. GMT and factor increase in GMT were compared using Mann-Whitney test for intergroup comparisons in ln-transformed data at pre-specified time points (D0 and D84). All analyses were two-side

response, and to assess RZV safety profile and impact on patient-reported outcome measure (PROM) using validated scores.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: In this randomized, double-blind, placebo-controlled trial, 76 immunosuppressed SSc patients (≥18 years) and 304 healthy individuals (≥50 years) in control group (CG) received two RZV doses. SSc patients were randomized to vaccine (P1) or placebo (P2) at D0 and D42, with unblinding at D84, after which P2 also received RZV (D84, D126). Anti-glycoprotein E antibody (Anti-gE) levels were measured at baseline and 6-week visit after vaccination using an in-house GlaxoSmithKline (GSK)'s enzyme-linked immunosorbent assay (ELISA). A humoral response was defined as ≥4-fold the pre-vaccination concentration. Geometric mean titers (GMTs) and factor increase (FI) were calculated. PROM and DA was assessed by EULAR Systemic Sclerosis Impact of Disease (ScleroID), Modified Medical Research Council (mMRC) Dyspnea Scale, Clinical Disease Activity Index (CDAI), and patient/provider's global assessments

Results: Female sex was similar between groups ($p > 0.05$). SSc patients were younger [53.0 (46.0-61.0) vs 55.0 (52.0-61.0), $p=0.002$] years, more often Black (44.1 vs 19.4%, $p< 0.001$), had lower body mass index ($p=0.005$), and more chronic kidney disease ($p=0.001$). At 6-week visit after the 2nd dose, humoral response was observed in 92.6% of SSc and 99.7% of CG ($p=0.001$). SSc had a significantly lower GMT [5.8 (95% CI 4.4-7.7) vs 12.6 (95% CI 11.6-13.6), $p< 0.001$], and FI at D84 [31.0 (95% CI 20.6-46.6) vs 59.4 (95% CI 51.4-68.8), $p< 0.001$] compared to CG (table 1). No demographic or immunosuppressive therapy predicted impaired vaccine response. Local adverse events were less frequent in SSc patients (73.7 vs 86.5%, $p=0.024$) with significantly low rates of pain, erythema and edema at injection sites ($p< 0.05$). Systemic reactions were comparable overall (59.2 vs 61.5%, $p=0.712$), although dyspnea ($p< 0.001$), tremor ($p=0.018$) and vomiting ($p=0.032$) were more common among SSc patients. DA parameters and PROM (ScleroID, mMRC, CDAI, and patient/provider's global assessments) showed no significant differences between vaccinated (P1) and placebo (P2) groups at baseline, D42, D84 ($p >0.05$). Rates of worsening across validated DA measures were similar between groups at all time points ($p >0.05$) (Table 2).

Conclusion: RZV is safe and highly immunogenic in immunosuppressed SSc patients, without affecting DA as measured by validated scores. However, lower antibody titers raise concerns about long-term protection, underscoring the need for ongoing monitoring in this population (ClinicalTrials NCT05879419).

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Systemic Sclerosis & Related Disorders – Clinical III (2651–2656)

Session Type: Abstract Session

Session Time: 9:30AM–11:00AM

Background/Purpose: To determine the frequency and extent of discordance between patient and physician global assessments of disease in early systemic sclerosis and identify factors associated with discordance.

Methods: Adult patients with early systemic sclerosis from the COllaborative National QUality and Efficacy Registry (CONQUER) were included. Global disease assessments by patients and physicians (0-10, higher is worse, 7-day recall), clinical evaluations, and patient-reported outcomes were collected at enrollment and every 6 months. Score concordance was defined as patient and physician global scores within 1 point, and discordance as a difference of ≥ 2 points, creating 3 categories: concordance, patient scores worse, and physician scores worse. The frequency of discordance and correlation between global assessments were determined for the enrollment visit, and factors associated with discordance were assessed using multivariable mixed-effects proportional odds regression with concordance as the reference category.

Results: 956 patients (83% female, 33% limited cutaneous disease, 19% with disease duration < 1 year) with both global assessments available were included **(Table 1)**. The correlation between patient and physician global assessments was weak (Pearson's *r*=0.28) **(Figure 1)**. Discordance between global assessments was present in 510 (53%) of patients (35% patient score worse; 19% physician score worse)**(Figure 2)**. In the multivariable model, compared to score concordance, physicians tended to report global scores worse than patient scores when there was a higher modified Rodnan skin score (mRSS)(odds ratio (OR), [95% confidence interval (CI)]: 1.03 [1.01, 1.05]), worse New York Heart Association (NYHA) functional Class (Class II OR 1.78 [1.20, 2.65]; Class III/IV: 2.83 [1.07, 7.46]), and higher PROMIS Pain Interference (OR 1.03, [1.00, 1.05]), while higher diffusing capacity of the lung for carbon monoxide (DLCO) %-predicted (OR 0.94 [0.90, 0.98]) was associated with lower likelihood of discordance with physician scores worse. Patients tended to report global scores worse than physician scores when there was higher overall pain/discomfort (OR 1.29 [1.18, 1.42]), while decreased likelihood of discordance with the patient scores worse was observed for limited vs. diffuse cutaneous subtype (OR 0.45 [0.28, 0.71]), higher mRSS (OR 0.97 [0.95, 0.99]), and worse NYHA functional Class (Class III/IV OR 0.29 [0.13, 0.66]).

Conclusion: Discordance between global assessments is present in over half of cases in systemic sclerosis, with patients tending to rate their condition worse compared to their physician's rating. Discordance in which physician scores are worse is associated with disease characteristics and measures of severity, while discordance in which patient scores are worse is associated with increased pain and lower likelihood of severe manifestations. Physicians may underestimate disease impact when disease manifestations are less severe. These results highlight differing perceptions of disease severity and emphasize the need for comprehensive approaches to symptom management and measurement of disease burden in this complex disease.

Table 1. Characteristics of patients with systemic sclerosis and frequency at enrollment of patient-physician discordance of global assessments

	Patient characteristics	Difference between patient and physician global assessment		
	Overall	Physician score worse	Concordance (+/- 1 point)	Patient score worse
Overall	N = 956	177 (19%)	446 (47%)	333 (35%)
Subgroups				
Age at baseline visit (years)	52.7 (13.5)	53.5 (13.4)	52.9 (14.2)	52.1 (12.7)
Female sex	794 (83%)	134 (17%)	371 (47%)	289 (36%)
Disease duration at enrollment less than 1 year	179 (19%)	36 (20%)	74 (41%)	69 (39%)
Limited cutaneous subtype	318 (33%)	44 (14%)	150 (47%)	124 (39%)
ILD status				
ILD status unknown (no HRCT)	316 (33%)	50 (16%)	155 (49%)	111 (35%)
No ILD	280 (29%)	45 (16%)	123 (44%)	112 (40%)
ILD present	360 (38%)	82 (23%)	168 (47%)	110 (31%)
Abnormal gastrointestinal tract	676 (71%)	113 (17%)	316 (47%)	247 (37%)
Renal crisis	35 (4%)	15 (43%)	15 (43%)	5 (14%)

Values presented as n (%) or mean (standard deviation). Patient characteristics in the overall cohort are displayed as column percentages. The frequency of discordance and concordance is displayed as row percentages to allow comparison of discordance rates by subgroups. Abnormal gastrointestinal tract is based on the Gastrointestinal Medsger Severity Scale. ILD, interstitial lung disease; HRCT, high-resolution computed tomography chest imaging.

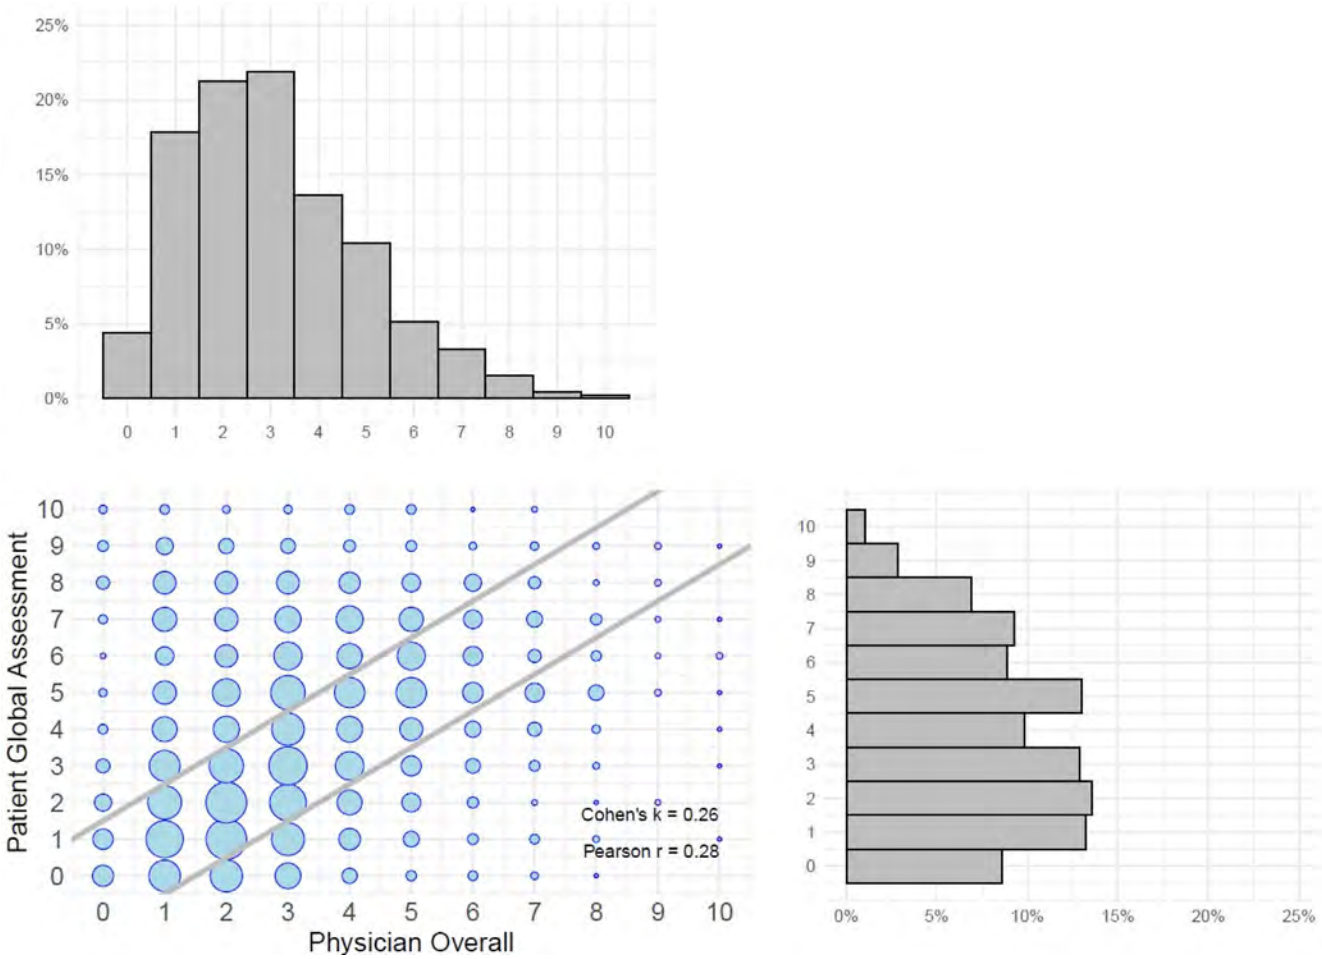

Figure 1. Scatterplot and distributions of patient and physician global assessments of overall disease activity in systemic sclerosis at enrollment visit. The size of the blue circles represents the number of patients with each score combination. Points above the gray lines indicate discordance with the patient score worse, while points below the gray lines indicate discordance with the physician score worse. Points between the gray lines are concordant. Mean (standard deviation) global assessments at enrollment were 4.2 (2.6) and 3.5 (2.0) among patients and physicians, respectively. The distributions demonstrate that patients are more likely to utilize the full range of scores compared to physicians.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

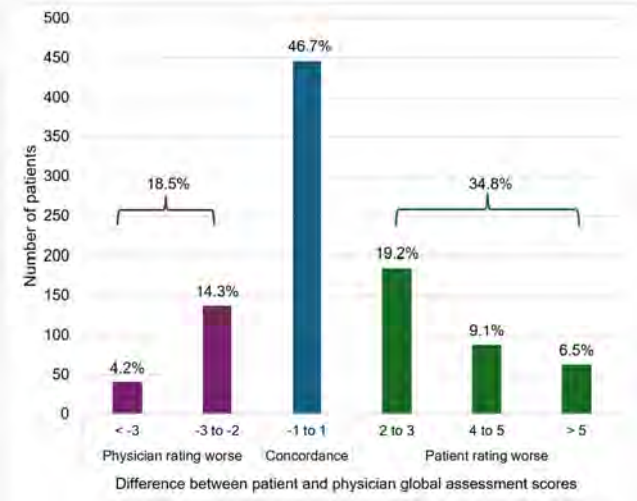

Figure 2. Distribution of differences between patient and physician global assessment scores among patients with systemic sclerosis at enrollment visit. Global assessment score concordance (+/- 1 point) was present in 47% of patient-physician assessments at the enrollment visit (blue). Discordance (≥ 2-point difference) was present in 53%. Patient global assessment scores were worse than the physician scores in 35% (green), while physician global assessment scores were worse than the patient scores in 19% (purple). Patient scores were more likely to show high discordance, with 15% of scores 4 or more points higher than the corresponding physician scores.

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Systemic Sclerosis & Related Disorders – Clinical III (2651–2656)

Session Type: Abstract Session

Session Time: 9:30AM–11:00AM

Background/Purpose: Pregnancy in women with systemic sclerosis (SSc) is considered high-risk due to complications like scleroderma renal crisis and preeclampsia, related to vasculopathy. Prospective data on pregnancy outcomes in SSc are lacking. We aimed to describe adverse pregnancy outcomes (APOs), disease course, and associated factors in SSc pregnancies, and to compare APO rates to the general population.

Methods: We included all pregnancies in women with SSc (ACR/EULAR 2013 criteria) or very early SSc (VEDOSS) enrolled in the French prospective GR2 study (2014–2020). We analyzed pregnancies beyond 22 weeks for APOs: fetal demise, preterm delivery≤34 weeks, placental insufficiency complications (preeclampsia, HELLP, fetal growth restriction [FGR], placental abruption), and small for gestational age (SGA, < 10th percentile using AUDIPOG curves). Disease worsening was defined as the appearance or progression of vascular manifestations (cutaneous ulcers, pulmonary arterial hypertension, or renal crisis), interstitial lung disease, worsening of skin fibrosis, calcinosis, joint involvement, or gastrointestinal tract involvement (excluding gastroesophageal reflux disease). Adverse pregnancy outcome rates were compared to those of age-matched controls from the 2016 French perinatal survey.

Results: Fifty-eight pregnancies (52 women) were included: 16 diffuse SSc (27.5%), 34 limited (58.6%), and 8 VEDOSS (13.8%). None had prior pulmonary arterial hypertension or renal crisis. Among 53 pregnancies beyond 22 weeks, 14 (26.4%) had APOs: 2 preterm deliveries (3.8%), 12 placental complications (22.6%; 7 preeclampsia, 5 FGR), and 6 SGA (11.3%). Six women (11.3%) had severe postpartum hemorrhage. Rates of preeclampsia, preterm birth, birth weight < 2500g, and postpartum hemorrhage were significantly higher than in the general population (13.2% vs 3.0%, p=0.001; 13.2% vs 5.8%, p< 0.047; 21.1% vs 4.3%, p< 0.0001; 11.3% vs 1.4%, p< 0.0001). No factors were significantly associated with APO in univariate analysis.

Table 3. Factors associated with worsening of systemic sclerosis or very early diagnosis of systemic sclerosis during pregnancy and one year postpartum (n=58) – univariate analysis

	Disease worsening (n=23)	No disease worsening (n=35)	Crude Odds Ratio [95%IC]	p**
VEDOSS	1 (4.3%)	7 (20.0%)	0.2 [0.02-1.6]	0.13
dcSSc	10 (43.5%)	6 (17.1%)	**3.7 [1.1-12.4]**	**0.028**
lcSSc	12 (52.2%)	22 (62.9%)	0.6 [0.2-1.9]	0.42
Anti-topoisomerase I Ab	10 (43.5%)	9 (25.7%)	2.2 [0.7-6.8]	0.16
Anti-centromere Ab	4 (17.4%)	17 (48.6%)	**0.2 [0.1-0.8]**	**0.016**
Disease duration < 3 years	14 (60.9%)	14 (40.0%)	2.3 [0.8-6.8]	0.12
Prior cutaneous vascular manifestation**	13 (56.5%)	9 (25.7%)	**3.7 [1.2-11.5]**	**0.018**

Data are n (%)
* Prior cutaneous vascular manifestation: fingertip lesions (digital ulcers, pitting scars), before pregnancy
** Chi2 test or fisher exact test if needed.
Abbreviations: Ab: antibody; dcSSc: diffuse cutaneous systemic sclerosis; lcSSc: limited cutaneous systemic sclerosis; SSc: systemic sclerosis; VEDOSS: very early diagnosis of systemic sclerosis.

Conclusion: In this prospective cohort of 58 pregnancies in women with SSc or VEDOSS and no prior severe organ involvement, 91.4% resulted in live births. Despite a relatively low incidence of severe complications, SSc pregnancies were associated with significantly higher rates of APOs and severe postpartum hemorrhage compared to the general population. Disease progression occurred in nearly 40% of cases, particularly affecting skin vascular manifestations during the postpartum period, and was more frequent in women with diffuse cutaneous SSc, prior vascular involvement, and antibodies other than anti-centromere.

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Systemic Sclerosis & Related Disorders – Clinical III (2651–2656)

Session Type: Abstract Session

Session Time: 9:30AM–11:00AM

Background/Purpose: Digital ulcers (DUs) affect approximately 50% of SSc patients, causing significant pain and disability. Current management involves both systemic and local therapies. However, the burden in terms of pain and quality of life due to refractory DUs remains heavy. Indeed, over 67% of SSc patients experience >5 DUs in their disease course, reflecting the high burden of this disease domain. While selexipag, an oral selective IP prostacyclin receptor agonist, is approved for the treatment of SSc-associated pulmonary arterial hypertension (PAH), its potential in healing DUs is largely unexplored. We aimed at evaluating the long-term efficacy of selexipag compared to iloprost in treating SSc-DUs.

Methods: This retrospective multicentre study included 96 SSc patients with refractory DUs, 32 treated with selexipag (median dose of 1600mg/day- IQR1100mg) and 64 with intravenous iloprost (0.5–2ng/kg/min), matched for gender, disease subset, and age at diagnosis (Table 1). Both groups were concomitantly treated with conventional vascular therapies (i.e. calcium channel blockers, endothelin receptor antagonists and phosphodiesterase 5- inhibitors). DUs number, ischemic pain and Raynaud phenomenon (RP) severity were assessed at baseline, 6,12, and 24 months. Pain and RP were evaluated using Likert Pain Scale (LPS) and Raynaud Condition Score (RCS), respectively. Additionally, DUs recurrence and new onset were recorded. Healing rates were estimated using Kaplan-Meier analysis.

Results: DUs healing rate was significantly higher in selexipag-treated patients in comparison with iloprost-treated ones (87% vs 28%) at 96 weeks, with the formers achieving faster healing (75% vs 18% by week 40) ($p< 0.001$) (Figure1). DUs number, RCS and LPS scores showed significant improvement in selexipag-treated group compared to iloprost ($p< 0.001$ for all) throughout the 24-month follow-up (Figure 2 A-B-C). Repeated measures analysis demonstrated significant changes over time for all three outcomes. The difference in treatment effect was supported by Mann-Whitney U analyses, showing comparable baseline measures (DUs: $p=0.901$; RCS: $p=0.561$; LPS: $p=0.708$) significant differences emerged by 6 months (DUs: $p=0.001$; RCS: $p< 0.001$; LPS: $p< 0.001$) and were maintained through 12 and 24 months (all $p< 0.001$). Additionally, selexipag-treated patients experienced significantly lower relapse rates (5% vs 45% at 24 months, $p< 0.001$) (Figure2D). Consistently, DUs formation remained lower with selexipag (5% vs 40% at 24 months, $p< 0.001$)(Figure 2E).

Demographics and clinical characteristics of patients treated with iloprost or selexipag.

Conclusion: Our study shows that SSc patients treated with selexipag have a better sustained outcome of DUs compared to those treated with intravenous iloprost over 24 months. Furthermore, oral administration and good tolerability profile make selexipag a promising alternative option to standard therapy for SSc-related DUs, overcoming challenges such as difficult venous access, high hospitalization costs, and lost work productivity associated with IV administration. Prospective studies are needed to confirm a wider use of selexipag other than PAH.

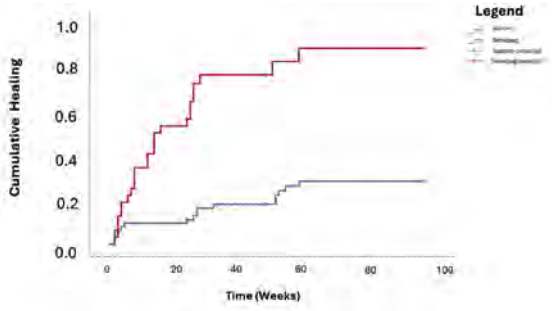

Figure 1. Kaplan-Meier analysis showing cumulative healing rates of DUs in SSc patients treated with selexipag versus iloprost over 96 weeks of follow-up. The vertical dashed line indicates week 40. Censored events are indicated by vertical marks on the curves.

Background/Purpose: GLP-1 receptor agonists (GLP-1RAs) are increasingly utilized in diabetes mellitus management due to their glucose-lowering and cardiovascular benefits. However, the effect of GLP-1RAs on rheumatic disease incidence is not well defined. This study evaluates the incidence of rheumatic diseases in patients treated with GLP-1RAs, using patients receiving DPP-4 inhibitors (DPP-4i) as a comparator group.

Methods: We conducted a propensity score-matched cohort study utilizing the TriNetX Analytics Network database, comprising anonymized patient data from healthcare institutions worldwide. Adult patients (≥18 years) initiating treatment with GLP-1RAs were matched 1:1 with those initiating DPP-4i therapy based on age, sex, race, hemoglobin A1c levels, BMI, underlying comorbidities, commonly used medications, and diabetes medications to ensure baseline comparability. The primary outcomes included the incidence rates of rheumatoid arthritis, gout, systemic lupus erythematosus, ankylosing

Table 2. Incidence of rheumatic diseases among patients with GLP-1RA vs DPP-4i group

Table 2. Mortality and incidences of rheumatic disease among patients with GLP-1RA vs DPP-4i group								
Outcomes	GLP1-RA Group			DPP4i Group			Hazard Ratio (CI 95%)	P-value (log rank)
	Cases with outcome	Patient Number at Risk	Incidence rates (per 1000 patient-years)	Cases with outcome	Patient Number at Risk	Incidence rates (per 1000 patient-years)		
Rheumatoid arthritis	485	217,302	2.23	542	217,302	2.49	0.87 (0.77, 0.98)	0.026
Gout	1,827	217,302	8.4	2,157	217,302	9.92	0.82 (0.77, 0.87)	<0.001
SLE	93	217,302	0.42	103	217,302	0.49	0.87 (0.66, 1.16)	0.362
Ankylosing spondylitis	59	217,302	0.27	46	217,302	0.21	1.24 (0.84, 1.83)	0.261
Scleroderma	21	217,302	0.09	23	217,302	0.1	0.88 (0.49, 1.60)	0.693
Psoriatic arthritis	78	217,302	0.35	64	217,302	0.29	1.18 (0.85, 1.64)	0.316
Osteoarthritis	11,700	217,302	53.84	12,367	217,302	56.91	0.91 (0.89, 0.94)	<0.001

spondylitis, scleroderma, psoriatic arthritis, and osteoarthritis within 1 year after the index date. Cox proportional hazards models were employed to assess and compare the risk (hazard ratios [HRs]) of developing various rheumatic diseases between the groups. Statistical significance was set at a p-value < 0.05.

Results: After matching, each group comprised 217,302 patients. Mean age (59.5±12.5 vs. 59.6±13.3 years), sex (50.9% vs. 51.2% males), mean hemoglobin A1c (8.4 ± 2.0 vs. 8.4 ± 2.1), and BMI (33.5 ± 7.6 vs. 32.7 ± 7.3) were similar between groups. Additionally, the GLP-1RA group showed significantly reduced risks of rheumatoid arthritis (HR 0.87; 95% CI 0.77–0.98; p=0.026), gout (HR 0.82; 95% CI 0.77–0.88; p< 0.001), and osteoarthritis (HR 0.92; 95% CI 0.89–0.94; p< 0.001). No significant differences were noted for systemic lupus erythematosus, ankylosing spondylitis, scleroderma, or psoriatic arthritis.

Conclusion: In this propensity score-matched study, GLP-1RA therapy was associated with a significantly reduced incidence of rheumatoid arthritis, gout, osteoarthritis, compared to DPP-4i treatment. These findings suggest beneficial effects of GLP-1RAs on rheumatological outcomes, supporting their broader therapeutic implications in diabetes management.

Abstract Number: 2658

Risk of Immune-Mediated Inflammatory Diseases and Other Safety Outcomes in Patients with T2DM and Obesity Initiating GLP-1 RA: A Propensity Score-Matched Multi-center Study using the TriNetX Global Network

Hsin-Hua Chen and Wen-Cheng Chao, Taichung Veterans General Hospital, Taichung, Taiwan (Republic of China)

SESSION INFORMATION
Session Date: Wednesday, October 29, 2025
Session Title: Abstracts: Epidemiology & Public Health I (2657–2662)
Session Type: Abstract Session
Session Time: 11:30AM–1:00PM

Background/Purpose: Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) are increasingly prescribed for type 2 diabetes mellitus (T2DM) and obesity due to their beneficial metabolic effects. However, real-world evidence on whether GLP-1 RAs affect the incidence of immune-mediated inflammatory diseases (IMIDs), neurologic conditions, psychiatric

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

disorders, or other safety outcomes remains limited. This study evaluated the associations of initiating GLP-1 RAs with the incidence of IMIDs and various clinically important outcomes, including gout, osteoarthritis, and neurodegenerative disorders (dementia, Parkinson disease) in adults with T2DM or obesity.

Methods: We conducted a propensity score-matched retrospective cohort study utilizing data from the global TriNetX federated electronic health records network. Two separate analyses were performed: adults with T2DM (n=793,873) and non-diabetic adults with obesity or overweight (N=79,148). Patients initiating GLP-1 RAs (≥3 prescriptions) were matched 1:1 to comparable patients initiating non-GLP-1 medications based on demographics, BMI, comorbidities, and medication history. Outcomes assessed were new-onset IMIDs, gout, osteoarthritis, and neurodegenerative diseases (dementia, Parkinson's disease). Hazard ratios (HRs) with 95% confidence intervals (CIs) were estimated using Cox regression. Kaplan-Meier analyses and E-values assessed robustness, and multiple comparison corrections were applied using Bonferroni and False Discovery Rate (FDR).

Results: GLP-1 RA initiation was not associated with increased risk of IMIDs, and musculoskeletal diseases (gout or osteoarthritis) in either cohort. Notably, GLP-1 RA use was associated with significantly lower incidence of all-cause mortality in both T2DM (HR 0.38, 95% CI 0.36-0.40; p< 0.001; E-value=4.70) and obesity cohorts (HR 0.23, 95% CI 0.18-0.30; p< 0.001; E-value=8.16) lower dementia incidence in both T2DM (HR 0.51, 95% CI 0.47–0.55; p< 0.001; E-value=3.33) and obesity cohorts (HR 0.21, 95% CI 0.12–0.36; p< 0.001; E-value=9.99). Parkinson's disease incidence was significantly lower only in the obesity cohort (HR 0.27, 95% CI 0.12–0.58; p< 0.001), but not after adjustment in the T2DM cohort. Use of GLP1 RA was also associated with a lower risk of cardiovascular diseases (heart failure, cerebral infarction and pulmonary embolism/deep vein thrombosis in both T2DM and obesity cohorts.

Conclusion: In patients with T2DM or with overweight/obesity, real-world initiation of GLP-1 receptor agonist therapy was **not associated with an increased risk of autoimmune or inflammatory diseases**. We found no signal that GLP-1 RAs precipitate IMIDs such as RA, lupus, or IBD. Conversely, GLP-1 RA use was linked to significant reductions in all-cause mortality, heart failure, stroke, chronic kidney disease, severe infections, and even dementia, without new safety concerns.

Background/Purpose: Treatment with dipeptidyl peptidase-4 inhibitors (DPP4i) have been shown to reduce the risk of systemic autoimmune rheumatic diseases (SARD) in patients with type 2 diabetes (T2D). This study aimed to evaluate the effect of treatment with sodium-glucose cotransporter-2 inhibitors (SGLT2i) on the risk of new-onset SARD.

Methods: This emulated target trial used electronic health records of adults with T2D who initiated either an SGLT2i (canagliflozin, dapagliflozin, empagliflozin, or ertugliflozin) or a DPP4i (alogliptin, saxagliptin, linagliptin, or sitagliptin) between 2016 and 2024 from 101 U.S. healthcare organizations. Propensity score matching was used to balance baseline characteristics. Outcomes included new-onset rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), ankylosing spondylitis (AS), systemic sclerosis (SSc), Sjögren's syndrome (SjS), mixed connective tissue disease (MCTD), Behcet's disease, polymyalgia rheumatica (PMR), and vasculitis. Patients were followed from initial prescription through incident SARD, end of prescription or switch to the other drug class, death or end of follow-up. Cox proportional hazards models and the log-rank test were used to evaluate the effect of SGLT2i on SARD over time.

Results: A total of 699,1977 pairs of SGLT2i and matched-DPP4i initiators were included. SGLT2i initiators had a significantly lower risk of RA (hazard ratio [HR] 0.77, 95% confidence interval [CI] 0.54-0.58), SLE (HR=0.85, 95% CI 0.79-0.92), SSc (HR 0.80, 95% CI=0.66-0.96), MCTD (HR=0.83, 95% CI=0.80-0.87), PMR (HR=0.67, 95% CI=0.62-0.72), and vasculitis (HR=0.79, 95% CI=0.70-0.89). Risks of Sjögren's and AS were not significantly reduced. Overall risk of any SARD was HR (95%CI). Among the SGLT2i studied, dapagliflozin and empagliflozin showed the most pronounced reductions in the risk of new-onset SARD. Canagliflozin was associated with a reduced risk of new-onset RA and vasculitis.

Conclusion: Treatment with SGLT2i, especially dapagliflozin and empagliflozin, was associated with reduced risks of developing various SARD compared to DPP4i. These findings provide evidence for the broader immunomodulatory effects of SGLT2i. Prospective studies on the roles of SGLT2i in attenuating inflammation and autoimmunity are warranted to validate the finding.

Background/Purpose: Understanding longitudinal changes in serum urate (SU) allows for the development of evidence-based interventions for gout. Post-menopausal women, who are at risk of gout, have increased SU levels. This increase is partially attributed to the loss of estrogen's protective effect on kidney function. While cross-sectional studies have been conducted, longitudinal SU changes during the menopausal transition and interactions with coexisting conditions that modify SU, such as BMI and estimated glomerular filtration rate (eGFR), are not well studied.

Methods: This retrospective longitudinal cohort study included Japanese women who underwent annual medical examinations from April 2004 to September 2024. Each woman had at least one visit before and after a self-report of menopause. Women with possible surgical menopause and those who received hormonal therapy were excluded. The median date between the two consecutive visits before and after menopause was considered the date of menopause for statistical analyses. Menopausal transition stages were temporally categorized as pre-menopause (>5 years before menopause), peri-menopause (from 5 years before up until menopause), and post-menopause (after menopause). Longitudinal changes in SU and hyperuricemia (HU: SU ≥6.8 mg/dL or taking medications for gout/HU) were examined by interrupted time-series

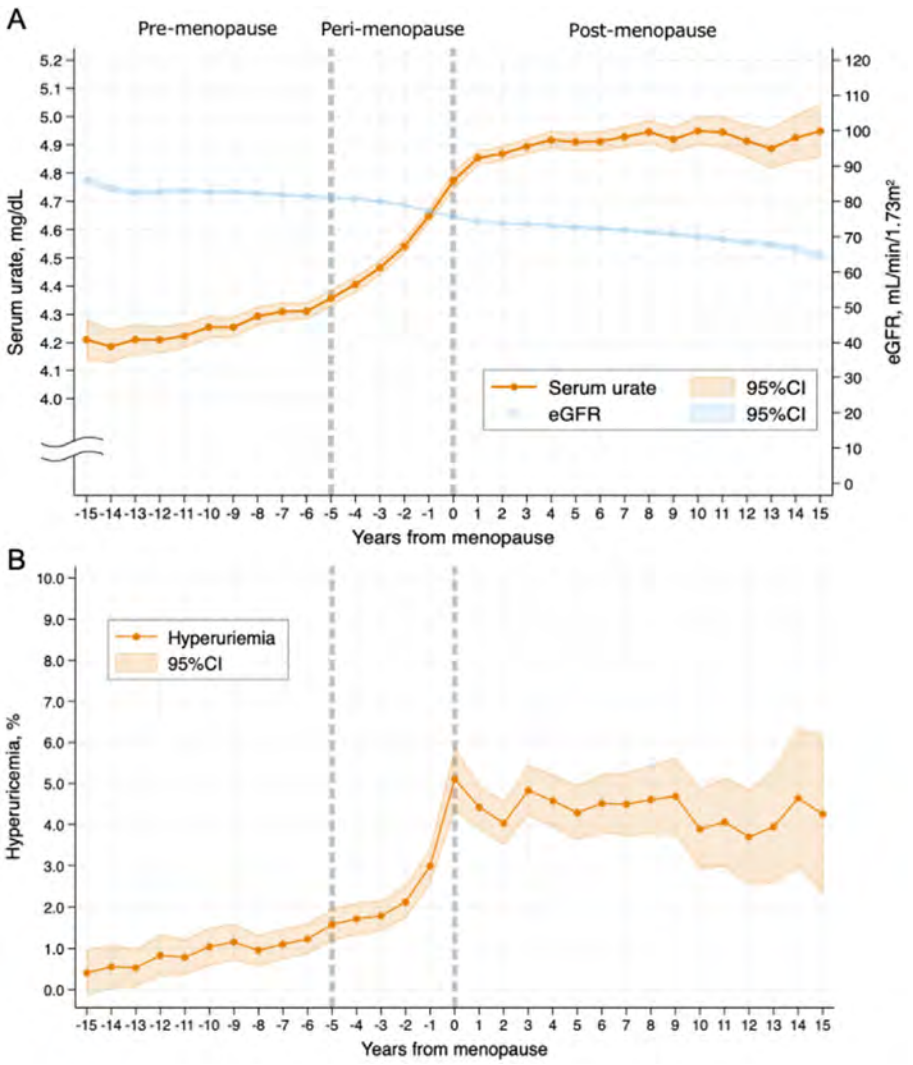

Figure 1. Longitudinal trends in serum urate and hyperuricemia observed in women. Mean serum urate levels (A) and the proportion who had hyperuricemia (B) with a 95% CI were described. The date of menopause was defined as the median date between the two consecutive visits immediately before and after the self-reported menopause occurrence. The time from menopause was calculated for each visit. Participant data was then summarized by years since menopause. eGFR, estimated glomerular filtration rate; CI, confidence intervals

*Difference in SU mean relative to the reference (pre-menopausal stage)
**Change in SU relative to the annual change in SU of the reference (pre-menopausal stage)
***Change in SU for each unit of change in eGFR or BMI relative to the reference (pre-menopausal stage)

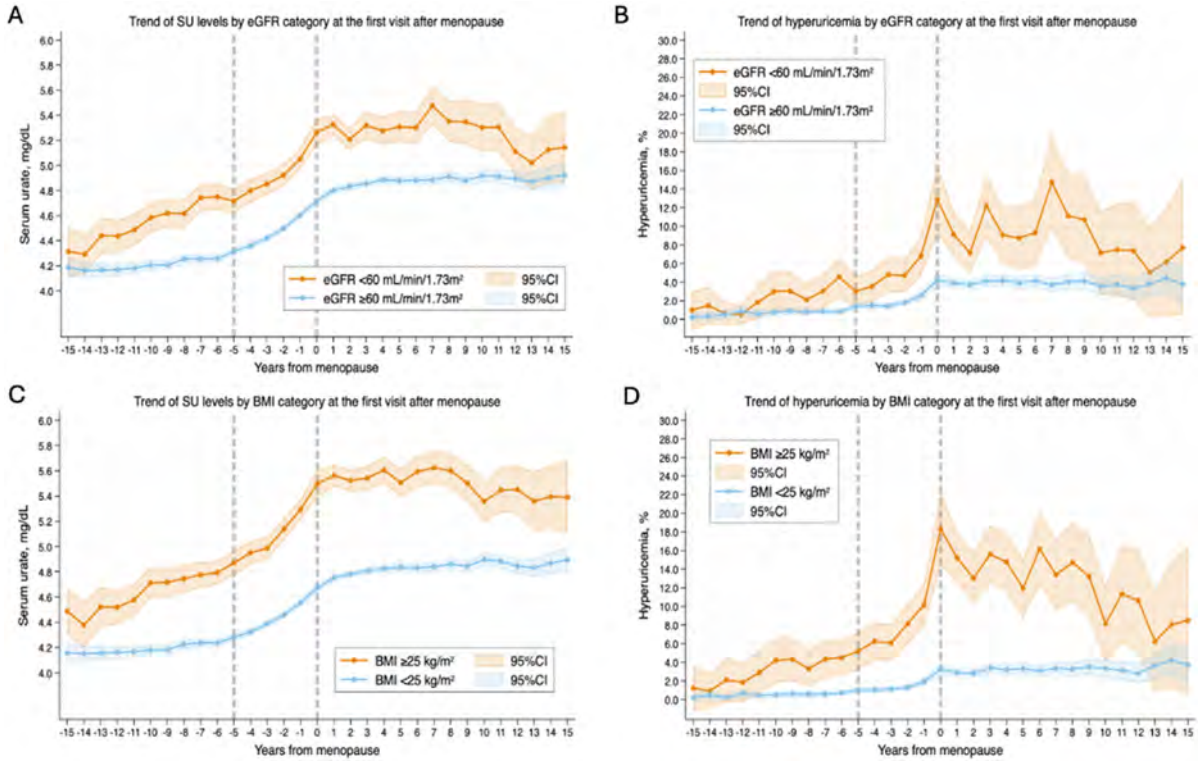

Figure 2. Longitudinal trends in serum urate by subgroups of women. Mean serum urate levels (A, C) and the proportion who had hyperuricemia (B, D) with a 95% CI were described by stratified subgroups of eGFR (A, B) and BMI (C, D) The date of menopause was defined as the median date between the two consecutive visits immediately before and after the self-reported menopause occurrence. The time from menopause was calculated for each visit. Participant data was then summarized by years since menopause. The information at the first visit after menopause was used for stratification. eGFR, estimated glomerular filtration rate; BMI, body mass index; CI, confidence intervals

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

analyses and evaluated across subgroups stratified by median menopausal age, kidney function (eGFR < 60 or ≥ 60 mL/min/1.73 m^2), BMI (< 25 or ≥ 25 kg/m^2), and alcohol intake (≥1 drink/day or no drinks) at the first visit after menopause.

Results: We analyzed 8,169 eligible participants with 93,511 visits over a median follow-up of 13.8 years. SU gradually increased during pre-menopause, rose rapidly during peri-menopause, and stabilized post-menopause (**Figure 1**). Compared to pre-menopause, the mean SU level was 0.41 mg/dL (95% CI: 0.38, 0.43) higher during post-menopause. SU increased by 0.033 mg/dL per year (95% CI: 0.030, 0.035) during pre-menopause. The slope changed to 0.095 mg/dL (+0.062 mg/dL [95% CI: 0.057, 0.067]) during peri-menopause and 0.016 mg/dL (–0.017 mg/dL [95% CI: –0.021, –0.014]) during post-menopause (**Table 1**). HU prevalence was < 1.0% during pre-menopause, began to increase approximately 2-3 years before menopause, and was 4-5% during post-menopause (**Figure 1**). Association of SU levels with eGFR and BMI were also larger during peri-menopause and post-menopause compared to pre-menopause (**Table 1**). Women with an eGFR < 60 mL/min/1.73 m^2 and a BMI ≥ 25 kg/m^2 had a greater rise in SU during peri-menopause: HU was observed in approximately 18% of overweight or obese women at menopause (**Figure 2**).

Conclusion: This longitudinal study found that SU levels and HU prevalence drastically increase several years before menopause and are already elevated by the time of menopause. Maintaining a healthy body weight and preserving kidney function prior to menopause may decrease post-menopausal HU and potentially control subsequent gout in women.

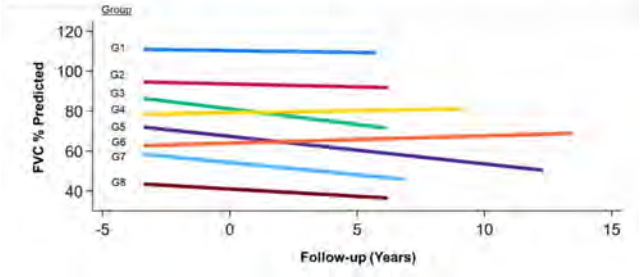
Background/Purpose: Forced vital capacity (FVC) is one of the primary disease measures monitored in RA-associated interstitial lung disease (RA-ILD). While prior studies have suggested a minority of RA-ILD patients fulfill a progressive phenotype specified for inclusion in antifibrotic clinical trials, the trajectories of FVC over time in large, real-world RA-ILD populations are not well described. We investigated FVC trajectories among RA-ILD patients within the Veterans Health Administration, the largest integrated healthcare system in the U.S.

Methods: We performed a cohort study of RA-ILD patients within the Veterans Health Administration between 1999 and 2021. RA-ILD patients were identified using validated RA and ILD algorithms (>80% PPV for RA-ILD), then followed until death or end of study. FVC values were obtained from VA databases of pulmonary function test (PFT) results and also extracted from clinical notes (when primary PFT results were not available) using a validated natural language processing tool. All available FVC values were utilized. Group based trajectory modeling was utilized to derive unique longitudinal trajectories of FVC values, with selection of the optimal numbers of trajectories determined by model fit characteristics (AIC/BIC), group size, and clinical interpretability. Trajectory group membership was used to predict survival and respiratory hospitalization following RA-ILD index date in Cox regression models that included age, sex, race, smoking status, comorbidity burden, and calendar year.

Results: We studied 5,172 RA-ILD patients (92.3% male, mean age 68.8 years) with 18,007 FVC values and identified eight unique FVC trajectories (**Figure 1**). While initial FVC values were a major determinant of group membership, four of eight trajectory groups (54% of patients) were characterized by a mean FVC % predicted decline >0.7%/year during follow-up (range -0.73 to -1.56%/year). Over 24,780 patient-years of follow-up, 3,400 deaths and 2,763 respiratory hospitalizations occurred. Survival significantly differed across FVC trajectory groups, with trajectory groups characterized by greater FVC decline being associated with poorer survival (adjusted HR 1.56 [1.45-1.67] for groups 3, 5, 7, and 8 combined progressive vs. groups 1, 2, 4, and 6 combined non-progressive) (**Figure 2A-B**). Progressive trajectory groups were also associated with respiratory hospitalization risk (**Figure 3A**) with the combined progressive FVC trajectory groups having a >1.6-fold higher risk than the combined non-progressive groups (**Figure 3B**). Findings persisted when adjusting for baseline FVC (not shown).

Conclusion: Within a large, national RA-ILD population, we identified eight unique trajectories of the RA-ILD disease course characterized by differing patterns of longitudinal FVC values. A progressive RA-ILD disease course (mean decline in FVC % predicted of 0.7 to 1.6 per year) occurred amongst 54% of RA-ILD patients and was predictive of poorer survival and respiratory hospitalization. These findings highlight RA-ILD heterogeneity and the prognostic value of monitoring disease trajectories with longitudinal FVC measurements.

Figure 1. Unique trajectories of forced vital capacity measurements among patients with RA-ILD.



Group	% of RA-ILD patients	FVC % pred. Intercept	ΔFVC%/year (Std. Error)
1	2.3	110.3	-0.19 (0.11)
2	20.5	93.5	-0.29 (0.08)
3*	8.7	81.1	**-1.56 (0.14)**
4	20.1	79.1	0.21 (0.09)
5*	23.9	67.3	**-1.38 (0.09)**
6	3.2	63.9	0.36 (0.09)
7*	18.1	54.2	**-1.22 (0.07)**
8*	3.3	40.9	**-0.73 (0.11)**

*Denotes groups considered progressive

Target trial emulation of biologic and targeted synthetic disease-modifying antirheumatic drugs in rheumatoid arthritis-associated interstitial lung disease

Gregory McDermott[1], Daniel Solomon[2], Jeffrey Sparks[3] and Rishi Desai[3], [1]Brigham and Women's Hospital, Brookline, MA, [2]Division of Rheumatology, Inflammation, and Immunity, Brigham and Women's Hospital, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Wednesday, October 29, 2025
Session Title: Abstracts: Epidemiology & Public Health I (2657–2662)
Session Type: Abstract Session
Session Time: 11:30AM–1:00PM

Background/Purpose: RA-ILD is associated with high mortality, but the optimal treatment approach is unclear. While immunosuppressants may treat inflammatory components of ILD, there are concerns about pro-fibrotic effects and increased infection risk. Prior studies investigating specific biologic or targeted synthetic DMARDs (b/tsDMARDs) in RA-ILD had small sample size, and no randomized trials have been performed. Despite this limited evidence, the 2023 ACR/CHEST guideline conditionally recommended rituximab as initial RA-ILD therapy.

Methods: Nationwide data from Medicare Parts A/B/D from 1/1/2006 to 12/31/2019 (n=7,993,101 patients) served as the data source. We identified patients with RA-ILD to emulate target trials comparing b/tsDMARDs. RA-ILD patients had ≥2 RA ICD-9/10 codes, ≥1 DMARD prescription 7-365 days after RA ICD code, and ≥2 ILD ICD codes, including ≥1 ILD ICD code from a pulmonologist (PPV 81%). We emulated target trials comparing patients with RA-ILD initiating abatacept, tocilizumab, JAK inhibitors, or TNF inhibitors, each compared to rituximab. The index date was first b/tsDMARD after RA-ILD diagnosis. The primary outcome was a composite of respiratory hospitalization (including respiratory infections), lung transplant, or death. We constructed propensity scores (PS) for treatment selection using 46 pre-exposure variables including year of enrollment, demographic factors, RA-related factors (including line of therapy and oral glucocorticoids), pulmonary factors, comorbidities, medications, healthcare utilization, and Medicare low-income subsidy eligibility. After 1:1 PS matching and using an intention-to-treat follow up, we constructed Kaplan-Meier curves and used Cox regression to estimate hazard ratios for the composite outcome and its components.

Results: After PS matching, we analyzed RA-ILD patients (mean age 74 years, 70% female) initiating abatacept (n=701), JAK inhibitor (n=152), tocilizumab (n=390), or TNFi (n=773), each compared to an equal number of rituximab initiators. Separate emulated target trials were used for each two-way comparison. PS matching successfully achieved balance in baseline covariates between treatment groups. Comparing each b/tsDMARD to rituximab, there were no significant differences in the risk of the composite outcome of respiratory hospitalization, lung transplant, or death: abatacept (HR 0.88 95%CI 0.76-1.02), JAK inhibitor (HR 0.75 95%CI 0.51-1.11), tocilizumab (HR 1.03 95%CI 0.84-1.28), or TNF inhibitor (HR 1.01 95%CI 0.88-1.16), each compared to rituximab (**Figure 1**). Separate analyses found no statistically significant differences between b/tsDMARDs and rituximab for respiratory hospitalization or death (**Figure 2**).

Conclusion: Despite rituximab being conditionally recommended as first line treatment for RA-ILD in the recent ACR/CHEST guideline, we found no significant differences between rituximab and other b/tsDMARDs in the risk of respiratory hospitalization, lung transplant, or death. There were nonsignificant findings of decreased mortality in RA-ILD patients treated with abatacept or JAK inhibitors compared to rituximab. These findings highlight the need for randomized controlled trials in RA-ILD.

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases III: End Organ Focus on Heart, Lung and Eye (2663–2668)

Session Type: Abstract Session

Session Time: 11:30AM–1:00PM

Background/Purpose: VEXAS syndrome (Vacuoles, E1 ubiquitin-activating enzyme, X-linked, Autoinflammatory, Somatic) is a systemic disorder characterized by an overlap of hematologic and inflammatory features. Treatment poses a challenge, as most immunomodulators fail to control the disease, resulting in a requirement for moderate to high doses of glucocorticoids (GCs). Pacritinib, an oral inhibitor of IRAK1, JAK2, and ACVR1, is FDA-approved for myelofibrosis with severe thrombocytopenia (platelets < 50 x 10^9/L) and has emerged as a potential treatment for VEXAS syndrome.

Methods: PAXIS is an international, randomized, multicentre, double-blind, placebo-controlled phase 2 dose finding trial. It is designed to assess pacritinib in adult patients with VEXAS syndrome. Inclusion criteria include documented evidence of past inflammatory involvement and ongoing GCs for ≥4 consecutive weeks at a baseline dose of 15-45 mg/day. Previous exposure to non-GC therapies is allowed, but patients must undergo a washout period. Exclusion criteria include prior allogeneic hematopoietic stem cell transplantation, receiving ≥9 units of red blood cell transfusion in the prior 90 days,

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1: PAXIS Study Design

concurrent myelodysplastic syndrome requiring antineoplastic treatment, and exposure to any HMAs in the previous 6 months or exposure to more than 4 cycles of HMAs at any time.

The study will consist of a screening period, a double-blind period (up to end of week 24), an open-label period (up to end of week 48), and a 30-day post-end of treatment period (**Figure 1**). Patients (n=78) will be randomized 1:1:1 to receive pacritinib 200 mg twice daily (BID), pacritinib 100 mg BID, or placebo (26 per arm). All patients will follow a fixed GC taper.

Results: The primary endpoint (assessed during the double-blind period) is the proportion of patients who achieve Overall Clinical Response, defined as having a flare-free interval lasting ≥8 weeks following a GC taper, and a GC dose during the interval of ≤10 mg/day. Secondary endpoints include number of flare free days with GC dose < 10 mg/day, hematologic improvement (in platelets and hemoglobin), change in quality-of-life measures, and safety. Exploratory endpoints include change in symptoms based on the VEXAS-symptom assessment form (VEXAS-SAF), change in disease activity measured by the Clinical Global Impression of Change (CGI-C) and the VEXAS-disease activity index (VEXAS-DAI), change in variant allele frequency (VAF) of *UBA1* by next generation sequencing (NGS), and improvement in GC toxicity as measured by the glucocorticoid toxicity index (GTI). PAXIS is anticipated to enroll at 40 sites across 8 countries.

Conclusion: The PAXIS study represents a significant step forward in the treatment of VEXAS syndrome. As the first randomized, double-blind placebo-controlled pharmacotherapy trial for this disease, it has the potential to redefine treatment and address unmet needs for this complex, refractory, and sometimes fatal condition.

Neutrophil-to-Lymphocyte Ratio (NLR) as a Clinically Accessible Marker for Interferon Signatures in Autoimmune Diseases

YOSHINOBU KOYAMA[1], KENTA SHIDAHARA[2], YU NAKAI[2], YOSHIHARU SATO[3] and YOSHINORI NISHIURA[2], [1]Japanese Red Cross Okayama Hospital, Okayama, Okayama, Japan, [2]Japan Red Cross Okayama Hospital, Okayama-shi, Okayama, Japan, [3]DNA Chip Research Inc., Kawasaki-shi, Kanagawa, Japan

SESSION INFORMATION
Session Date: Wednesday, October 29, 2025
Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases III: End Organ Focus on Heart, Lung and Eye (2663–2668)
Session Type: Abstract Session
Session Time: 11:30AM–1:00PM

Background/Purpose: Interferons (IFNs) play critical roles in systemic autoimmune diseases, particularly systemic lupus erythematosus (SLE), where heightened type I IFN signaling is a hallmark. Elevated IFN activity is also observed in rheumatoid arthritis (RA), systemic sclerosis (SSc), and idiopathic inflammatory myopathy (IIM), making IFNs promising therapeutic targets. However, their pathogenic involvement varies among patients. In the TULIP trial, anifrolumab showed greater efficacy in SLE patients with elevated type I IFN signatures. Although IFN signatures derived from transcriptomic profiles are valuable biomarkers, their clinical utility is limited by cost. At ACR 2024, we reported a strong correlation between the neutrophil-to-lymphocyte ratio (NLR) and IFN signatures in patients with SLE. This study investigated whether the NLR can serve as a practical surrogate for IFN signatures in SLE, RA, SSc, and IIM patients.

Methods: We enrolled 236 patients with autoimmune diseases: 36 with SLE, 31 with RA, 95 with SSc, and 74 with IIM. Whole-blood RNA was subjected to transcriptome analysis. Seventy-three genes were assigned as type I IFN-related, 94 as type II, and 10 as type III. The IFN signature score was calculated as the sum of the Z scores for each group. The $\log_2$-transformed NLR ($\log_2$NLR) was derived from clinical blood data obtained at the time of RNA sampling. Correlations between the Log_2NLR and type I–III IFN scores were evaluated.

Results: Log_2NLR significantly correlated with all three IFN signatures across diseases.

In **SLE**, strong correlations were observed with type I IFN ($R^2 = 0.40$, $P = 5.99\times10^{-12}$), type II IFN ($R^2 = 0.29$, $P = 2.77\times10^{-8}$), and type III IFN ($R^2 = 0.57$, $P = 1.32\times10^{-7}$).

In **SSc**, the correlations were even stronger: type I IFN ($R^2 = 0.57$, $P = 1.74\times10^{-7}$), type II IFN ($R^2 = 0.36$, $P = 1.74\times10^{-7}$), and type III IFN ($R^2 = 0.63$, $P = 9.79\times10^{-22}$).

In **RA**, the associations were weaker but significant: type I IFN ($R^2 = 0.19$, $P = 0.013$), type II IFN ($R^2 = 0.13$, $P = 0.042$), and type III IFN ($R^2 = 0.44$, $P = 5.00\times10^{-5}$).

In **IIM**, correlations were also significant: type I IFN ($R^2 = 0.17$, $P = 0.0002$), type II IFN ($R^2 = 0.06$, $P = 0.032$), and type III IFN ($R^2 = 0.37$, $P = 1.01\times10^{-8}$).

Conclusion: The NLR was significantly correlated with type I, II, and III IFN signatures in patients with SLE, SSc, RA, and IIM. The strongest associations were observed in SLE and SSc patients, indicating a more consistent IFN-driven pathogenesis in these diseases. In contrast, RA and IIM showed weaker associations, possibly reflecting greater disease heterogeneity and variable IFN involvement. Among the IFN types, the type III IFN signature showed the most consistent and strongest

correlation with the NLR. Given its simplicity and availability, the NLR has emerged as a practical and cost-effective surrogate biomarker for IFN activation, with potential utility in clinical decision-making across autoimmune diseases.

Session Time: 11:30AM–1:00PM

Background/Purpose: Ianalumab, an afucosylated mAb, depletes B cells via enhanced antibody (Ab)-dependent cellular cytotoxicity and blocks B cell-activating factor (BAFF): BAFF-receptor (BAFF-R) mediated signals.[1] It is currently being assessed for the treatment of immune-mediated diseases. Given its novel mode of action, it is crucial to assess the effects of ianalumab on preexisting Abs against vaccine antigens (Ags). We evaluated the impact of ianalumab treatment vs placebo on pre-existing Ab levels against 7 pathogens in patients with SLE and Sjögren's disease (SjD).

Methods: A retrospective analysis was conducted on serum samples from 2 randomized, double-blind (DB), placebo-controlled, phase 2 studies in patients with SjD (NCT02962895) or SLE (NCT03656562). Patients received either placebo or ianalumab 300 mg subcutaneously monthly for 24 weeks (79 with SjD) or for 28 weeks (40 with SLE). In SjD study, patients on 300 mg ianalumab at Week (W) 24 were re-randomized to receive DB monthly ianalumab 300 mg or placebo until W52. Patients on placebo at W24 were switched to a lower ianalumab dose and were excluded from further analysis. In the SLE study, all the patients switched from DB to open label ianalumab up to W52. Abs (IgG isotypes) to vaccine Ags and auto-Abs were measured at baseline (BL), W24 (SjD) or W28 (SLE), and W52. Changes in Ab levels from BL and proportions of patients maintaining protective levels at W52 were assessed. Three patients (2 SjD and 1 SLE) received booster doses against diphtheria and tetanus toxoid (TTd) under ianalumab treatment.

Results: The proportion of patients with SjD and SLE maintaining protective Ab levels against TTd, measles, mumps, varicella, rubella, diphtheria, and influenza remained stable after 52 weeks of ianalumab treatment. In SjD, changes from BL to W24 were < 6% for all Ags in both groups. In SLE, changes from BL to W28 were < 10% in both groups for all Ags besides diphtheria (**Fig. 1**). For diphtheria, up to 18% changes were seen with ianalumab treatment, likely due to the low preexisting protection (< 50% of patients had protective levels at BL). By contrast, several auto-Abs showed a significant reduction in ianalumab-treated patients (e.g. up to 60% reduction of anti-ribosomal P Abs at W28) compared with placebo (**Fig. 1**). These results align with ianalumab's ability to deplete memory and Ab-producing cells,[2] while likely not affecting the long-

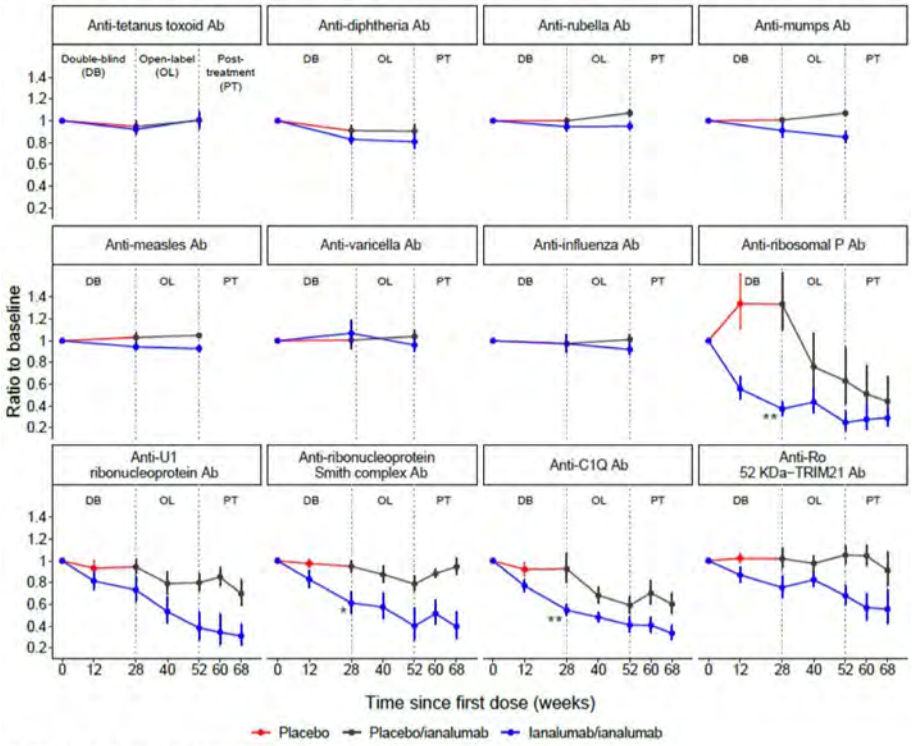

Figure 1. Titers from vaccine antigens and auto-antibody titers following treatment with ianalumab or placebo over time in patients with SLE.
Ratio to baseline of antibodies to vaccine antigens and autoantibodies were measured over time in patients with SLE treated with placebo vs ianalumab. All antibodies measured were IgG.

Significance values were calculated at the end of the double-blind period (28 weeks). *P<0.05; **P<0.01.
Ab, antibody; IgG, immunoglobulin G; SLE, systemic lupus erythematosus.

lived bone marrow plasma cells that do not express BAFF-R.[3] Among the 3 patients who received booster doses against diphtheria and TTd during ianalumab treatment, 2 showed a subsequent increase in corresponding titers, whereas the other patient received the booster only 10 days before W52 sampling, which explains no increase in titers.

Conclusion: Treatment with ianalumab up to 52 weeks did not result in a reduction of the Ab titers to previous immunizations against tetanus, varicella, measles, mumps, rubella, diphtheria, and influenza while having a clear impact on auto-Ab levels.

Rare *TNFAIP3* Hypomorphic Variants are a Massively Underestimated Driver of Human Autoinflammatory Disease

Danica Lee[1], Urekha Karri[2], Yiming Luo[3], Kader Cetin Gedik[4], Manuel Carpio Tumba[5], Prabal Chhibbar[6], Priyamvada Roy[6], Guido Falduto[7], Jishnu Das[5] and Daniella Schwartz[5], [1]University of Pittsburgh School of Medicine, Pittsburgh, PA, [2]School of public health, Pittsburgh, PA, [3]Columbia University, New York, NY, [4]UPMC Children's Hospital of Pittsburgh/ University of Pittsburgh, Pittsburgh, PA, [5]University of Pittsburgh, Pittsburgh, PA, [6]University of Pittsburgh School of Medicine, Pittsburgh, [7]University of Pittsburgh Medical Center, Pittsburgh, PA

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases III: End Organ Focus on Heart, Lung and Eye (2663–2668)

Session Type: Abstract Session

Session Time: 11:30AM–1:00PM

Background/Purpose: *TNFAIP3* encodes the ubiquitin editing enzyme A20, which inhibits multiple proinflammatory signaling pathways. Heterozygous germline mutations in *TNFAIP3* cause the autoinflammatory disease Haploinsufficiency of A20 (HA20). The prevalence of HA20 is thought to be low, with only 200 reported cases, yet HA20 is clinically heterogeneous and has variable severity. The full spectrum of disease-causing and disease-modifying *TNFAIP3* variants is unknown. Therefore, we hypothesized that HA20 prevalence is underestimated due to ascertainment bias.

Methods: To better understand HA20 prevalence and ascertain its full phenotypic spectrum, we analyzed three large population databases with whole genome sequencing data: gnomad v4 (730,947 exomes; 76,215 genomes), All of Us v7 (244,845 genomes and electronic health records (EHR) data), and UK BioBank (500,000 genomes and EHR data). We identified individuals harboring rare (MAF< 0.01%) predicted loss-of-function (pLOF) variants (frameshift, truncating, splice null) or rare predicted pathogenic missense (pPM) variants (CADD≥30; SIFT=deleterious; PolyPhen=probably damaging). Phenome-wide association studies (PheWAS) determined conditions that were significantly associated with pLOFs and pPMs. We then functionally validated the variants by performing luciferase assays to measure TNF-induced NF-kB activation, Western blot to measure basal A20 expression, and cycloheximide assays to measure protein stability. Lastly, we compared our results from these "virtual" cohorts to a "referral" cohort of patients seen at our medical center who harbor LOF (48 subjects, 17 variants) or missense (14 subjects, 9 variants) *TNFAIP3* mutations.

Results: pLOF variants had a mean prevalence of 1:14,403, while pPM variants had a mean prevalence of 1:2,782, suggesting that ~100,000 to 2.9 million individuals worldwide may suffer from A20-insufficient disease. *TNFAIP3* variants conferred a 164-fold risk of Behcet's disease and a 14-fold to 138-fold risk of other HA20-associated phenotypes like

Table 1. Prevalence estimates of pLOF or missense TNFAIP3 variants in the US (AoU), UK (UKBB), and globally (gnomAD). Number of individuals harboring pLOF variants, or pPM variants (missense variants with CADD^{3}30; SIFT=deleterious; PolyPhen=probably damaging; MAF<0.01%). Mean prevalence of the variants and affected number of individuals were estimated based on the 2024 U.S. Census count of 340.1 million.

	GnomAD v4	All of Us v7	UKBB

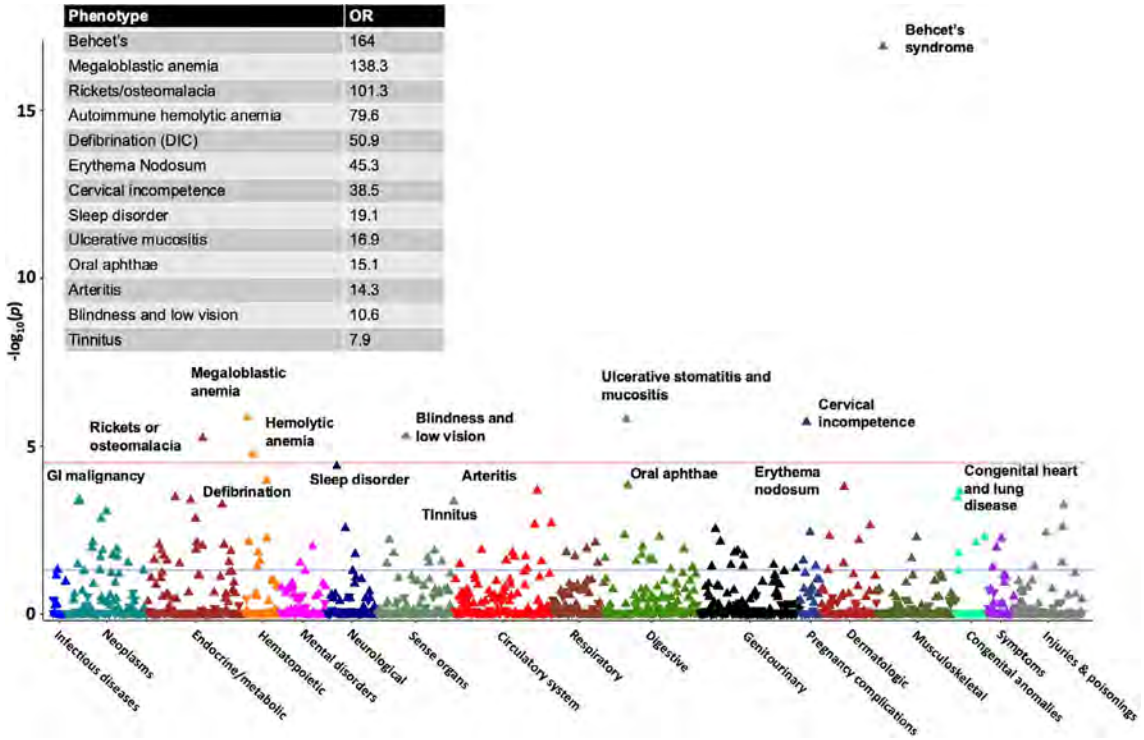

Figure 1. Inflammatory conditions are significantly associated with pathogenic TNFAIP3 variants. Manhattan plot of conditions that are significantly associated with rare pathogenic TNFAIP3 variants in meta-PheWAS of AoU and UKBB data. Each data point represents one condition. Blue line represents uncorrected p-value and red line represents Bonferroni adjusted p-value. The table above reports odds ratio (OR) for top associated conditions compared to control cohort.

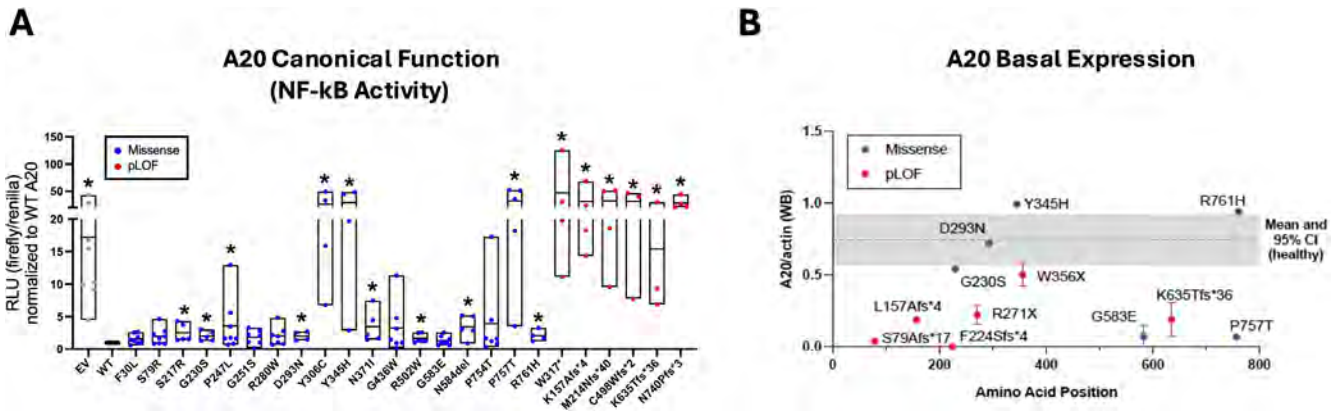

Figure 2. Hypomorphic TNFAIP3 variants can affect A20 function and/or expression. (A) Over-expressed mutant A20 proteins fail to suppress TNF-induced NF-kB activity in A20-deficient HEK293 cells transfected with the luciferase reporter plasmid (*p<0.05, ratio paired t-test); WT = wild-type, EV = empty vector. (B) Basal A20 expression (Western blot) of A20 variants, expression normalized to actin.

stomatitis/mucositis, vasculitis, and autoimmune hemolytic anemia (PheWAS, p < 1e-5, Bonferroni). *In vitro*, variants reduced A20 stability, expression, and/or TNF-induced NF-kB activation. In our Pittsburgh cohort, patients exhibited clinical autoinflammation and/or autoimmunity as well as evidence of basally activated TNF-NFκB, inflammasome-IL-1β, and/or Type I interferon signaling. LOF and missense variants either increased A20 protein degradation, resulted in production of an A20 protein unable to suppress TNF-induced NFkB activation, or reduced both protein stability and function. Patients exhibited >90% response to therapies targeting A20-regulated pathways such as TNF, IL-1, and JAK inhibitors.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Together, these data suggest that hypomorphic *TNFAIP3* variants are a massively underrecognized cause of autoinflammation with high disease burden. Increased recognition and expanded genetic testing could potentially improve health outcomes by directing these patients towards more precise immune-targeting therapies.

Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases III: End Organ Focus on Heart, Lung and Eye (2663–2668)

Session Type: Abstract Session

Session Time: 11:30AM–1:00PM

Background/Purpose: Familial Mediterranean Fever (FMF) is a monogenic autoinflammatory disease caused by MEFV mutations. Amyloidosis remains its most serious complication, with several risk factors reported in the literature. Traditional models, used to identify these factors, are limited by their reliance on linearity and inability to capture complex patterns in high-dimensional datasets. Machine learning ensemble models have not yet been applied to predict amyloidosis in FMF. This study aimed to develop and compare the performance of logistic regression, Random Forest and Gradient Boosting models.

Methods: From a database of 920 FMF patients diagnosed and followed at our rheumatology department between 1990–2022, records were retrieved. Patients without available documents or those followed elsewhere were excluded. Diagnoses were validated using Tel-Hashomer criteria and patients later found to have other diseases were excluded. Biopsy-confirmed amyloid fibrils were required to classify patients as having amyloidosis. Demographic, clinical, genetic, and laboratory data were recorded.

Imputation with MICE method was done in R in respect to alignment of imputed dataset to original dataset. The imputed dataset loaded into Python and training-test sets (0.8:0.2) were created (random state=42). Logistic Regression, Random Forest, Gradient Boosting models were created thereafter. Recursive feature elimination was applied for logistic regression and Synthetic Minority Oversampling Technique (SMOTE) was used to oversample amyloidosis cases and prevent overfitting. Mann-Whitney and chi-squared tests were used for comparisons.

Results: Of 920 FMF patients, 615 with available data were included, 58 (9.4%) of whom had biopsy-confirmed amyloidosis. Variable comparisons between patients with and without amyloidosis are shown in Table 1. Age at symptom onset, diagnostic delay, disease duration, M694V homozygosity, frequent infections, arthritis, erysipelas-like erythema, myalgia, protracted febrile myalgia, and median CRP were significantly associated with amyloidosis ($p < 0.001$).

Table 1: Characteristics of the Patients with and without Amyloidosis

	FMF (n=557)	FMF with Amyloidosis (n=58)	p value
Age at Symptom Onset, median (IQR)	11 (7-20)	7 (4.5-12.5)	**<0.001**
Diagnostic Delay, years, median (IQR)	3 (0-11)	10 (2.5-18)	**<0.001**
Disease Duration, years, median (IQR)	24 (20-31)	35 (26-43)	**<0.001**
Female Gender, n (%)	347 (62)	27 (47)	**0.028**
Higher Educational Status, n (%)	208 (37)	23 (40)	0.104
M694V Homozygous, n (%)	133 (24)	34 (59)	**<0.001**
Presence of Comorbidity, n (%)	180 (32)	34 (59)	**0.003**
Consanguinity in Parents, n (%)	87 (16)	18 (31)	**0.01**
Family History of FMF, n (%)	311 (56)	41 (71)	0.125
Family History of other rheumatic/inflammatory disease, n (%)	183 (33)	25 (43)	0.27
Malignancy, n (%)	9 (1.6)	3 (5)	0.41
Frequent Infection, n (%)	67 (12)	18 (31)	**<0.001**
Clinical Features, n (%)			
• Fever	433 (78)	50 (86)	0.61
• Abdominal Pain	471 (85)	50 (86)	0.32
• Chest Pain	202 (36)	31 (53)	**0.029**
• Arthralgia	381 (68)	53 (91)	**0.002**
• Arthritis	220 (39)	37 (64)	**<0.001**
• Erysipelas Like Erythema	83 (15)	28 (48)	**<0.001**
• Myalgia	185 (33)	37 (64)	**<0.001**
• Protracted Febrile Myalgia	44 (8)	18 (31)	**<0.001**
Age at Colchicine Initiation, median (IQR)	20 (12-29.5)	21 (14.5-31)	0.23
Regular Follow-up, n (%)	281 (50)	35 (60)	0.59
Irregular Use of Colchicine	238 (43)	21 (36)	0.08
Median CRP, median (IQR)	2.31 (0.77-5.54)	5.34 (1.41-9.27)	**<0.001**

Among the models, Random Forest performed best (AUC: 0.70, F1: 0.3, Precision: 0.375, Recall:0.25), followed by Gradient Boosting (AUC: 0.65, F1: 0.2, Precision: 0.17, Recall:0.25) and Logistic Regression (AUC: 0.60, F1: 0.17, Precision: 0.13, Recall:0.25). AUC curves and Shapley Additive Explanations (SHAP) values for the Random Forest model are shown in Figure 1 and Figure 2, respectively.

Conclusion: To our knowledege, this is the first study showing that ensemble machine learning models outperform logistic regression in predicting amyloidosis in FMF patients. Despite inherently "opaque" machinary and lower interpretability, these ensemble models are valuable given their superior performance. Furhtermore, increasing the Random Forest decision threshold to 0.6 raised precision to 0.75, enabling more efficient patient screening, especially in underserved areas. Advancing these models requires continued collaboration and a multidisciplinary approach. We invite the healthcare community to join in this effort to achieve meaningful progress and improved patient outcomes.

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases III: End Organ Focus on Heart, Lung and Eye (2663–2668)

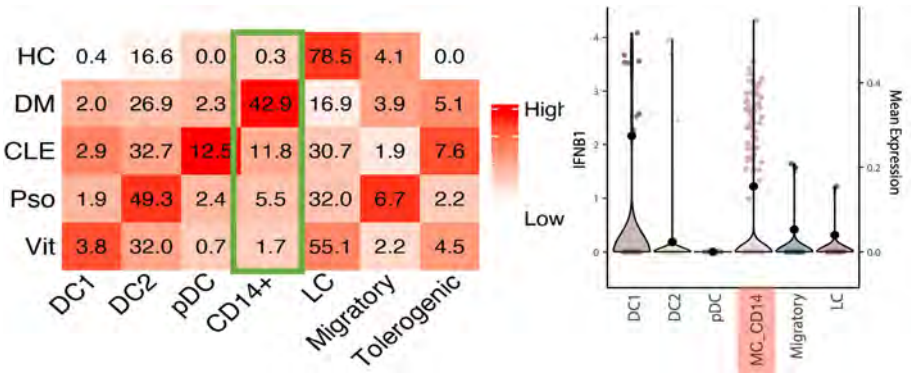
Session Type: Abstract Session

Session Time: 11:30AM–1:00PM

Background/Purpose: Inflammatory skin diseases vary widely in symptoms and causes. While ultraviolet (UV) light helps treat some like vitiligo and psoriasis, in conditions like cutaneous lupus erythematosus (CLE) and dermatomyositis (DM), UV exposure can worsen disease. The biological basis for this photosensitivity remains unclear.

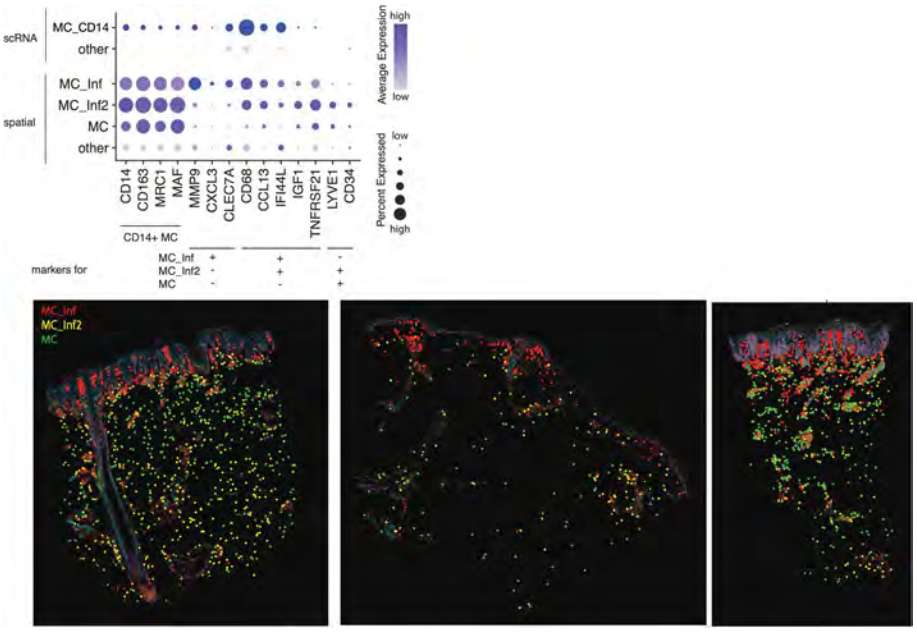
Methods: We used a multi-omics approach—single-cell RNA sequencing (scRNA-seq), spatial transcriptomics, and proteomics—to analyze lesional and non-lesional skin from patients with DM, CLE, vitiligo, psoriasis, and healthy controls. In vivo, a photoprovocation test was performed on sun-protected skin of healthy volunteers, DM, and CLE patients; post-irradiation biopsies were analyzed by flow cytometry and spatial transcriptomics. In vitro, keratinocytes were treated with UVB ± IFN-β. Supernatants were applied to monocyte-derived dendritic cells (moDCs) generated from PBMCs, and their activation was assessed.

Results: CD14$^+$ myeloid cells, which resembled monocyte-derived dendritic cells (moDCs) in culture, were the only immune population distinguishing photosensitive (CLE, DM) from photoresponsive (psoriasis, vitiligo) diseases. These cells were enriched in lesional DM (43%) and CLE (12%) compared to controls (< 0.3%) and localized near the dermo-epidermal junction, adjacent to cytotoxic CD4$^+$ T cells. CD14$^+$ myeloid cells expressed IFNB1 and MMP9, suggesting involvement in IFN-I signaling and tissue remodeling. UVB photoprovocation confirmed increased recruitment of CD14$^+$ myeloid cells to the skin,

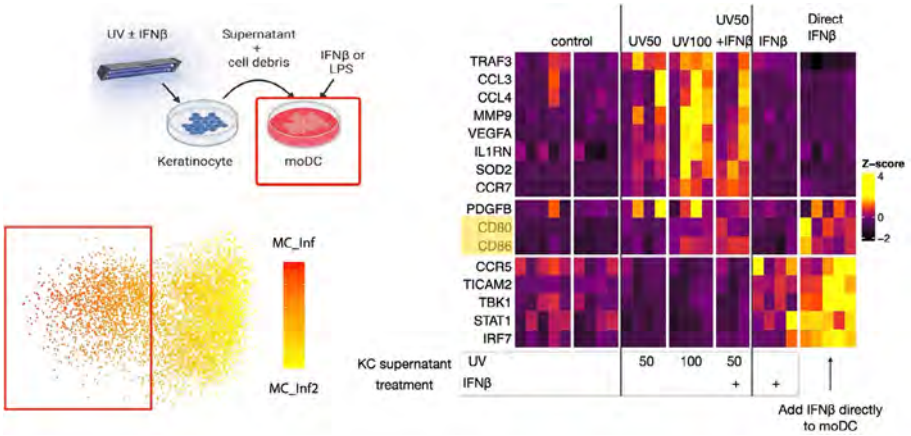


CD14$^+$ myeloid cells (MC_CD14) are expanded in dermatomyositis and lupus skin in our single-cell RNA sequencing dataset (heatmap, left) and show the highest IFNB1 expression among dendritic cell subsets (violin plot, right).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



The dot plot (top) shows shared marker expression between CD14$^+$ myeloid subsets identified by scRNA-seq and spatial single-cell transcriptomics (SeqFISH+). The MC_Inf transcriptional signature aligns with the scRNA-seq-defined CD14$^+$ myeloid profile and maps to cells spatially enriched near the dermo-epidermal junction, as illustrated in the bottom panels.



Schematic and heatmaps showing moDCs stimulated with supernatants from UV-treated keratinocytes. Exposure to supernatants from UVB-damaged keratinocytes, particularly in the presence of IFN-β, induced a transcriptional program enriched for MC_Inf markers (e.g., CD80, CD86, CCL4, MMP9), consistent with acquisition of a pro-inflammatory phenotype.

more so in DM and CLE patients. IFN-β priming sensitized keratinocytes to UVB-induced death and enhanced secretion of TNF-α and IL-6, which activated moDCs. Upon activation, moDCs release chemokines promoting immune cell recruitment, amplified in the presence of IFN-β.

Conclusion: Our findings reveal a UVB-induced inflammatory circuit driven by IFN-β–primed keratinocytes and CD14$^+$ myeloid cells in CLE and DM. By defining this keratinocyte–myeloid interaction, we highlight new opportunities for targeted therapies that may prevent lesion flares in photosensitive patients.

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science I: Diagnostics & Therapeutics (2669–2674)

Session Type: Abstract Session

Session Time: 11:30AM–1:00PM

Background/Purpose: The goals of treatment for idiopathic inflammatory myopathy (IIM) are to eliminate or reduce inflammation, restore muscle performance, reduce morbidity, and improve a patient's quality of life. Therapies providing durable meaningful clinical responses without requiring chronic administration are lacking. Rese-cel (formerly CABA-201), is a fully human, autologous 4-1BB CD19-CAR T cell therapy, designed to deeply and transiently deplete CD19 positive cells following a weight-based, single infusion with the potential to enable an "immune system reset" with durable responses. RESET-Myositis™ (NCT06154252) is an ongoing Phase 1/2 trial evaluating rese-cel in 3 independent cohorts of adults with dermatomyositis [DM], antisynthetase syndrome [ASyS] and immune mediated necrotizing myopathy [IMNM].

Methods: Patients were 18 to 75 years with refractory IIM per 2017 ACR/EULAR classification criteria, with myositis specific autoantibody (MSA), manual muscle test ≤142, at least moderate disease activity on 2 or more core set measures (CSMs). A weight-based infusion of $1x10^6$ CAR T cells/kg was given following preconditioning with fludarabine and cyclophosphamide. All non-glucocorticoid (GC) IM agents were discontinued by Day –5. Adverse events, use of IM medications and efficacy

Cabaletta Bio; Data on file

measurements to calculate the TIS were collected. CAR T cells and B cells were profiled in peripheral blood pre- and post-infusion by digital PCR and flow cytometry, respectively. Serum cytokines were measured using the mesoscale discovery platform.

Results: As of 31 March 2025, 6 patients have been infused with rese-cel and have at least 1 month of follow-up (Table 1). Additional patients were recently infused and are in early follow-up.

Rese-cel was well-tolerated in all 6 patients with Grade 1 cytokine release syndrome (CRS) in 3 of 6 patients, and no Grade 2 or higher CRS, dose-limiting toxicity or immune effector cell-associated neurotoxicity syndrome (ICANS). IMNM-2 with multiple risk factors, experienced a pulmonary embolism (PE) on Day 38, which was assessed as unrelated to rese-cel.

Five out of 6 patients achieved a drug-free clinical response on TIS (Table 2).

Rese-cel expanded rapidly in all patients and peaked between days 8 and 14 after infusion. Serum IFNγ levels increased post-infusion and peaked prior to rese-cel peak expansion. Rese-cel contracted quickly and was undetectable peripherally within the first 8 weeks in most patients. B cells ($CD19^{+}CD20^{+}$) were rapidly reduced to undetectable levels by 14 days and through the first month post rese-cel infusion in all patients. B cell reconstitution occurred as early as 8 weeks after infusion in 4 patients and 12 weeks in 1 patient. Reemergent B cells had predominantly transitional naïve phenotype (CD19+CD20+CD38++CD24++).

Conclusion: Data from IIM patients infused with rese-cel show early drug-free clinical responses in most patients and acceptable safety in the setting of rese-cel expansion and peripheral B cell depletion. DM & ASyS patients achieved a higher threshold of response than IMNM which is not unexpected. These initial data suggest the potential for rese-cel to reset the immune system, allowing patients to achieve meaningful drug-free clinical responses.

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science I: Diagnostics & Therapeutics (2669–2674)

Session Type: Abstract Session

Session Time: 11:30AM–1:00PM

Background/Purpose: Dermatomyositis (DM) is a systemic autoimmune disease marked by muscle weakness and characteristic cutaneous manifestations. Dysregulation of the Type I interferon (IFN-I) pathway plays a crucial role in its pathogenesis. Anifrolumab (ANI), an anti-IFNAR1 monoclonal antibody approved for the treatment of lupus, is a potential treatment for IFN-I–mediated diseases. This study aims to assess the efficacy and safety of ANI in patients with refractory DM.

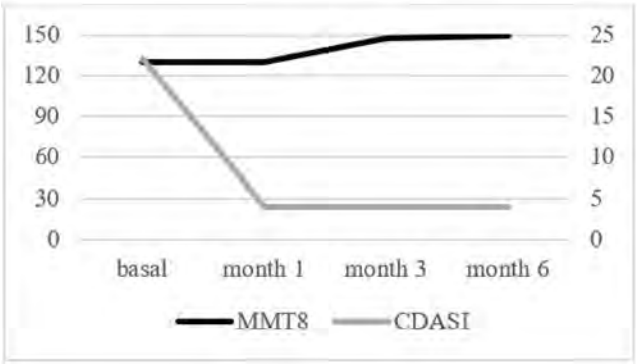

Figure 1. Evolution of CDASI and MMT8 after initiation of anifrolumab over a 6-month follow-up period.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We performed a multicenter, multidisciplinary, retrospective study involving 24 DM patients treated with ANI under compassionate use. Data collected included demographics, clinical features, serology, prior treatments, and concomitant medications. Efficacy was measured using the Cutaneous Dermatomyositis Disease Area and Severity Index (CDASI) and the Manual Muscle Test 8 (MMT8). Safety was evaluated based on adverse events (AEs).

Results: Of the 24 patients, 83% were female, with a mean age of 58.1±21.1 years at DM diagnosis and 53.9±19.8 years at ANI initiation. The majority were Caucasian (79%). DM subtypes included classic (9), amyopathic (10), juvenile (3), and antisynthetase syndrome (2); 21% had a paraneoplastic origin. Common cutaneous manifestations included Gottron's papules (100%), pruritus (92%), periorbital erythema (83%), periungual erythema (79%), alopecia (46%), and calcinosis (38%). Musculoskeletal involvement was observed in 58%, dysphagia in 42%, arthritis in 50%, and interstitial lung disease in 21%. Myositis-specific antibodies were detected in 19 patients: anti-TIF1γ (8), anti-MDA5 (3), anti-SAE (4), anti-ARS (3), anti-Mi-2 (1); 5 patients were seronegative. Anti-Ro52 was present in 9 (38%). Prior treatments included oral CS (100%), HCQ (88%), MTX (88%), AZA (25%), TAC (21%), MMF (67%), IVIG (79%), RTX (29%), TOFA (42%), BARI (8.3%), RUXO (4.1%), and others.

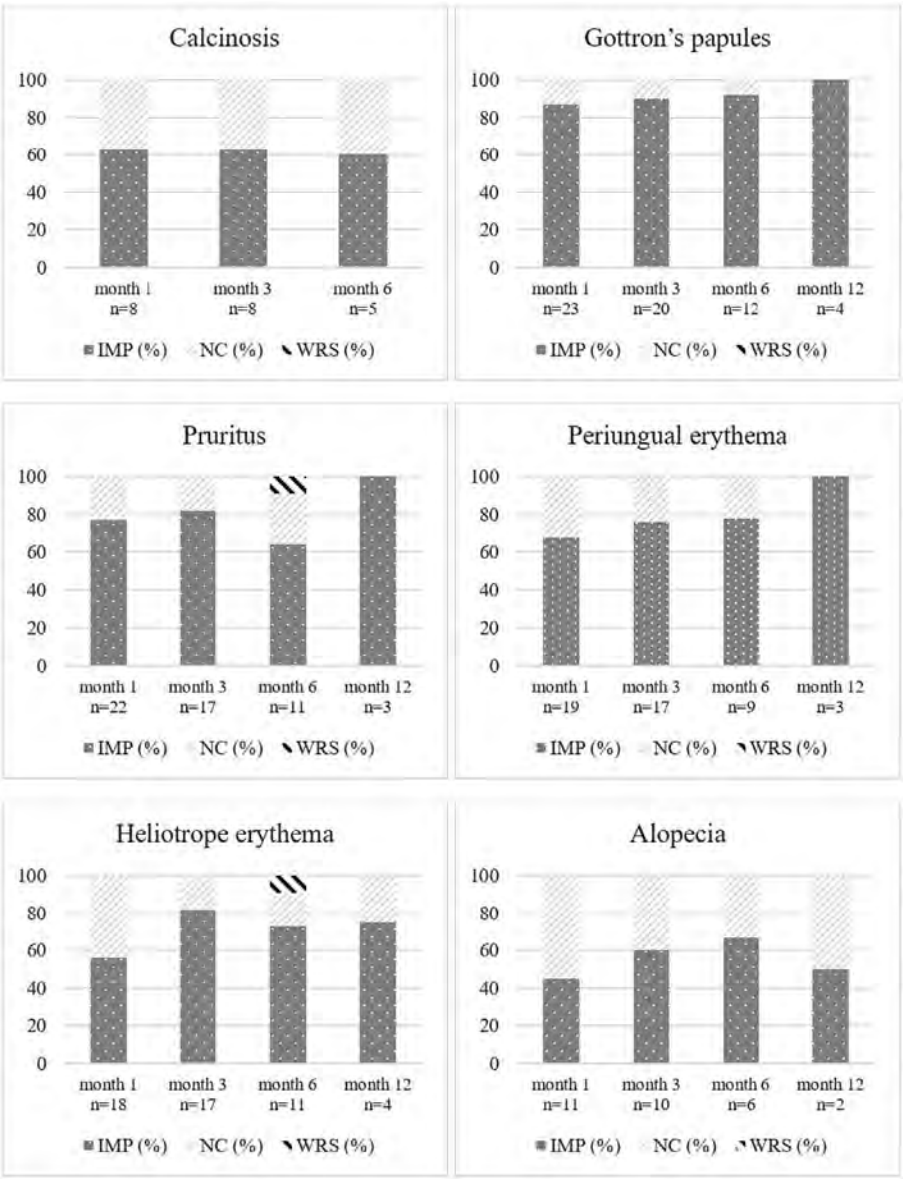

Figure 2. Impact of anifrolumab on different cutaneous manifestations over 12 months of follow-up.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 3. Significant improvement in facial and upper chest erythema observed following three doses of anifrolumab.

ANI was initiated mainly for cutaneous refractoriness (91.6%) and musculoskeletal activity (8.4%). It was administered at 300 mg every 4 weeks, except in one juvenile DM patient, who received 150 mg every 4 weeks. Half of the patients received concomitant csDMARDs: MTX (4), MMF (4), TAC (2), AZA (1), and TAC + MMF (1). After a mean follow-up of 7.5±4.2 months, most patients showed marked cutaneous improvement (CDASI) and muscle stability (MMT8) (Figure 1). The impact of ANI on cutaneous manifestations over 12 months is shown in Figure 2. In two patients, the IVIG intervals were successfully spaced due to clinical improvement. One juvenile DM patient had a flare, with CK elevation (450 UI/L) and a positive Gowers' sign after discontinuing MTX. AEs included impetigo (1), arthralgia/myalgia (1), urinary tract infections (2), and herpes zoster (1). No AEs led to ANI discontinuation, although one patient stopped treatment due to loss to follow-up.

Conclusion: Anifrolumab demonstrated early efficacy in dermatomyositis, with a favorable safety profile in refractory DM. This is the largest real-world series of DM patients treated with ANI to date, supporting its role in IFN-I–mediated dermatomyositis.

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science I: Diagnostics & Therapeutics (2669–2674)

Session Type: Abstract Session

Session Time: 11:30AM–1:00PM

Background/Purpose: Idiopathic inflammatory myopathy (IIM) is a rare, systemic, autoimmune, rheumatic disease, with different subtypes, characterized by muscle weakness and extra-muscular involvement. There are no approved targeted treatments indicated for multiple IIM subtypes. Efgartigimod is an IgG1 antibody Fc fragment engineered for high neonatal Fc receptor (FcRn) affinity. ALKIVIA evaluates the safety and efficacy of subcutaneous (SC) efgartigimod PH20 (coformulation of efgartigimod and recombinant human hyaluronidase PH20; EFG) plus standard of care (SOC) vs placebo PH20 (PBO) plus SOC in patients with IIM.

Methods: ALKIVIA (NCT05523167) is an operationally seamless phase 2/3, randomized, double-blinded, PBO-controlled, parallel-group, multicenter study in adults with IIM. The completed phase 2 randomized 89 patients (1:1) with immune-mediated necrotizing myopathy, dermatomyositis, polymyositis, or anti-synthetase syndrome, meeting ACR/EULAR classification criteria to receive weekly EFG or PBO alongside SOC for IIM. The primary endpoint was the 2016 ACR/EULAR Total Improvement Score (TIS) at Week 24, a composite endpoint based on improvement in Physician's Global Disease Activity (MDGA), manual muscle testing-8 (MMT8), muscle enzymes, Patient Global Disease Activity (PGA), Health Assessment Questionnaire Disability Index (HAQ-DI), and Extra-muscular Global Disease Activity. Key secondary endpoints were time to TIS, proportion of patients with TIS ≥20 and ≥40, changes in MMT8, PGA, and MDGA at Week 24.

Results: Of the 89 participants, 76.4% were female and 71.8% white, with a mean (SD) age of 56.6 (13.3) years. Least-squares mean TIS at Week 24 was statistically significantly higher in the EFG than the PBO arm (50.45 vs 35.65; *P*=0.0004). EFG-treated participants showed significant improvement in all key secondary endpoints compared with PBO, including the proportion of participants with minimal (≥20) and moderate (≥40) TIS, and the exploratory endpoint of major (≥60) TIS (91.5 vs 73.8%; 78.7 vs 47.6%, *P*=0.0029; and 34.0 vs 9.5%, *P*=0.0055, respectively) (**Figure 1**). Median times to TIS ≥20 and ≥40 were shorter with EFG compared to PBO (30 vs 71.5 days, *P*=0.0020; 113 days vs not estimable, *P*=0.0293). EFG treatment improved all 6 core set measures (**Figure 2A**). Both Patient and Clinician Global Impression of Change "much/moderately better" were improved at Week 24 with EFG vs PBO (54.4% vs 40.4%, and 60.8% vs 38.1%, respectively; **Figure 2B**). Significant improvements were seen in MMT8 (LSM 15.16 vs 7.60, *P*=0.0011), PGA (LSM –2.72 vs –1.03, *P*=0.0015), and MDGA (LSM –2.88 vs –1.94, *P*=0.0379). Safety was comparable between treatment arms (**-Table 1**), with the most common AEs in the EFG arm being injection site erythema (23.4%), rash (17.0%), bruising (10.6%) or reaction (10.6%), and diarrhea (12.8%). Two deaths occurred in the EFG arm (both unrelated to study drug) and none in the PBO arm.

Conclusion: ALKIVIA, the first FcRn inhibitor study in IIM, established proof of concept and highlights the mechanistic relevance of FcRn inhibition in IIM. Results support further evaluation of efgartigimod PH20 SC in patients with IIM in the ongoing phase 3 part of the study.

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science I: Diagnostics & Therapeutics (2669–2674)

Session Type: Abstract Session

Session Time: 11:30AM–1:00PM

Background/Purpose: Anti-melanoma differentiation-associated protein 5 (MDA5) antibody-positive dermatomyositis (MDA5+DM) is a distinct and severe subtype of dermatomyositis, frequently complicated by interstitial lung disease (ILD). Among these patients, rapid progressive ILD (RP-ILD) is the leading cause of high mortality, often resulting in severe respiratory failure within a short time frame. Despite available treatments, managing MDA5+ DM-associated ILD (MDA5+DM-ILD) remains a significant clinical challenge, with first-year mortality rates reported as high as 40%. Therefore, exploring effective therapeutic options is crucial. This cohort study aims to evaluate the efficacy and safety of Upadacitinib (UPA) in patients with MDA5+ DM-ILD, assessing its potential to improve clinical outcomes.

Methods: All patients with MDA5+DM-ILD who were admitted to Renji Hospital, affiliated with Shanghai Jiao Tong University School of Medicine, between 2013 and 2024 were included in the study. The primary efficacy endpoint was the 1-year survival rate. Secondary efficacy endpoints included the dosage of glucocorticoid usage, changes in lung function, and relevant laboratory parameters. Propensity score matching (PSM) was applied to minimize confounding biases and enhance intergroup comparability.

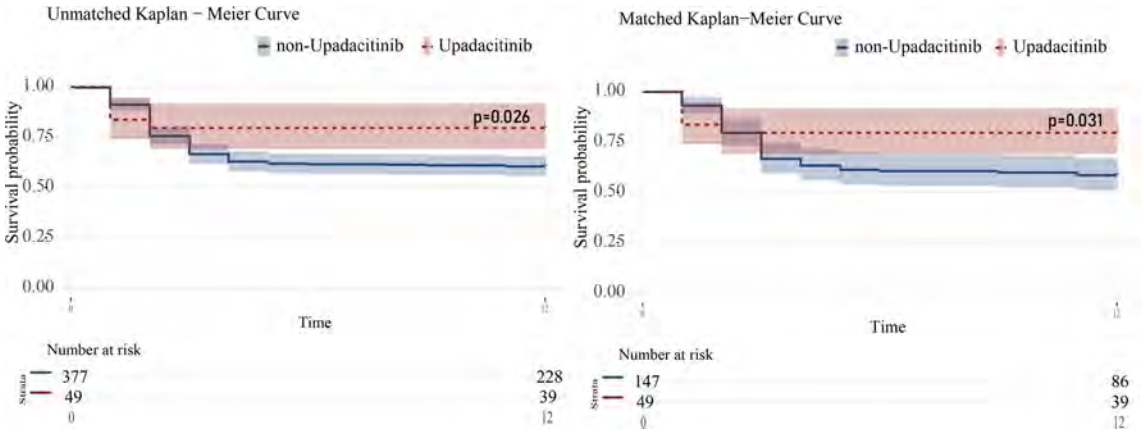

Figure 1 Kaplan-Meier survival curves comparing UPA group and non-UPA group patients before and after PSM.

Results: In the eligible cohort, a total of 49 patients received UPA treatment, while 377 patients were in the non-UPA group, of whom 78.5% received tofacitinib. After propensity score matching (PSM), baseline differences between the two groups were reduced (Table 1). The 1-year survival rates were 79.6% (39/49) in the UPA group and 60.5% (228/377) in the non-UPA group. Following PSM, the 1-year survival rate of the non-UPA group was 58.5%, with the difference remaining statistically significant (P=0.031) (Figure 1). Multivariate Cox regression analysis after PSM indicated that UPA treatment was associated with a significantly lower mortality risk, with a hazard ratio (HR) of 0.491 (95% confidence interval: 0.251-0.960) compared to the non-UPA group (Figure 2A). Subgroup analyses further demonstrated that UPA provided greater therapeutic benefits in patients with PaO_2/FiO_2 ratios between 200-300 mmHg (Figure 2B).

Conclusion: In this cohort study, UPA demonstrated a superior ability to improve the survival of patients with MDA5+DM-ILD compared to the non-UPA treatment regimen.

SUVmax: Maximum Standardized Uptake Value, **MLV:** Metabolic Lesion Volume, **TLG:** Total Lesion Glycolysis, **SCM:** Sternocleidomastoid Muscle

Background/Purpose: To characterize muscle involvement in idiopathic inflammatory myopathies (IIMs) using detailed anatomical segmentation and volumetric 18F-FDG PET/CT analysis, and to evaluate the prognostic value of global metabolic burden compared to SUVmax.

Methods: Patients with IIMs undergoing baseline 18F-FDG PET/CT were retrospectively analyzed. Clinical and laboratory data (CK, AST, LDH, CRP, ESR) were collected. Severe or refractory disease was defined clinically. Each muscle group was individually assessed, then categorized into five regions (head/neck, thorax, abdomen, upper and lower extremities) based on anatomical curricula. PET parameters included SUVmax (peak activity), metabolic lesion volume (MLV), and total lesion glycolysis (TLG; SUVmean × MLV). Log-transformation normalized data. Pearson correlations and nonparametric tests assessed associations. ROC analysis after logistic regression evaluated prognostic performance.

Results: Twenty-one patients [median age 62 (range 22–77); 76.2% female] were included. Diagnoses were dermatomyositis (71.4%), polymyositis (23.8%), and antisynthetase syndrome (4.8%). Median follow-up was 11.5 months. Detailed anatomical segmentation (Table 1) revealed that thoracic muscles, particularly autochthonous thoracic and thoracic wall muscles, had the highest MLV and TLG values (median TLG: 115.99 thorax vs. 127.5 lower extremities). Lower extremities also showed significant burden, whereas abdominal and head/neck muscles were less involved (Figure 1). At follow-up, 33.3% (7/21) developed severe disease and 42.9% (9/21) were refractory. SUVmax did not correlate significantly with baseline laboratory markers or outcomes. In contrast, TLG demonstrated strong correlations with AST (r=0.657, p=0.003), LDH (r=0.663, p=0.003), CRP (r=0.598, p=0.009), and ESR (r=0.549, p=0.018). ROC analysis showed that TLG (AUC 0.821) and MLV (AUC 0.803) outperformed SUVmax (AUC 0.652) in predicting severe/refractory disease (Figure 2).

Conclusion: This study provides the first detailed volumetric map of muscle inflammation in IIMs using 18F-FDG PET/CT.

Thoracic and paraspinal muscles were major sites of involvement, challenging the classical focus on proximal muscles. Volumetric PET parameters, particularly TLG and MLV, more effectively captured the global inflammatory load and correlated with severe or refractory disease. These findings suggest that comprehensive volumetric PET/CT analysis may enhance diagnostic precision and risk stratification in IIMs.

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science I: Diagnostics & Therapeutics (2669–2674)

Session Type: Abstract Session

Session Time: 11:30AM–1:00PM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are a group of diseases characterized by muscular and systemic involvement, with interstitial lung disease (ILD) being a challenging problem. High-resolution tomography (HRCT) is the current reference standard for diagnosing ILD; however, there are limitations related to its cost, accessibility, and the use of ionizing radiation. Lung ultrasound (LUS) has recently been used to detect ILD associated with other rheumatic diseases, which may justify its use as a screening method for clinical suspicion of ILD. However, evidence on using LUS in ILD associated with IIM is limited. We aimed to characterize the LUS findings in patients with IIM and their relationship with clinical features and antibodies.

Methods: Patients diagnosed with IIM according to the ACR/EULAR 2017 Classification Criteria were included, and they underwent HRCT, LUS, and pulmonary function tests (PFT). The Warrick score was used to assess the severity and extent of ILD. Ultrasound was performed using a LOGIQTMe device with a 4-12 MHz linear probe, applying two scanning methods (14 predetermined intercostal space (ICS) and 12 posterior-basal ICS). "B" lines (BL) and pleural abnormalities (PA) were documented for each ICS. Descriptive statistics were used based on the distribution of the variables, ROC curve analysis was conducted, and the sensitivity and specificity of LUS for detecting ILD compared to HRCT were calculated. Correlations were analyzed using the Spearman correlation coefficient between the ultrasound findings, the Warrick score, and the PFT.

Results: We included 59 patients diagnosed with IIM, mostly women (79.7%). The median and interquartile range (IQR) of age enrolment was 52 years (39.0-60.5). The most common diagnoses were dermatomyositis (72.9%) and antisynthetase syndrome (15.3%). The most frequent antibodies in the recruited patients were Ro-52 (30.5%), Mi-2 (23.7%), and MDA-5 (16.9%). The prevalence of ILD was 64.4%. Relevant baseline characteristics are shown in Table 1.

Table 2. Correlations between ultrasonographic findings and Warrick score

Table 2			
Variable	**Lines B 14 ICS >5**	**Lines B 12 ICS >2**	**Alteration in the pleural line >1**
Warrick gravity	r = 0.641 p = < 0.0001	r = 0.55 p = < 0.0001	r = 0.60 p = < 0.001
Warrick extension	r = 0.65 p = < 0.0001	r = 0.54 p = < 0.0001	r = 0.59 p = < 0.001
Warrick total	r = 0.64 p = < 0.0001	r = 0.54 p = < 0.0001	r = 0.59 p = < 0.001

Intercostal spaces: ICS

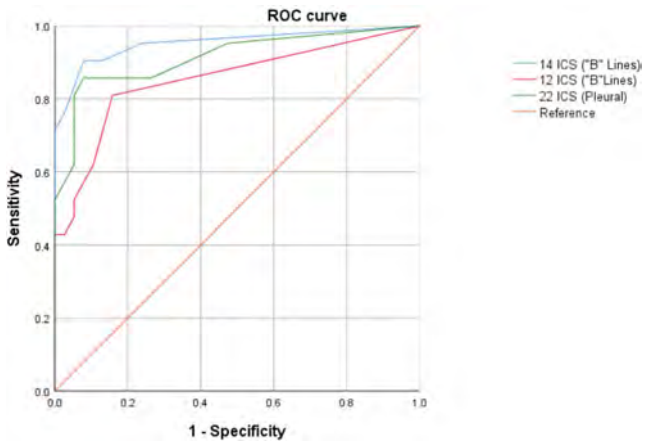

Image 1. ROC curve of ultrasonographic findings

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

A positive, strong correlation was demonstrated between the Warrick score and B-line count in 14 ICS (rho= 0.64, p< 0.0001) and 12 ICS (rho=0.54, p< 0.0001). Also, a positive correlation was observed between pleural line abnormalities and the Warrick score (rho=0.59,p< 0.0001). Table 2.

The AUCs were 0.95 (95% CI, 0.88-1.00), 0.85 (95% CI, 0.74-0.96), and 0.91 (95% CI, 0.82-0.99) for the evaluation of the number of B-lines in 14 ICS, 12 ICS, and the number of ICS with pleural abnormalities (22 EIC), respectively. Image 1

Conclusion: Our study confirms that LUS is a valuable tool for detecting ILD in patients with IIM. It offers real-time visualization and high diagnostic accuracy by quantifying B-lines and evaluating pleural abnormalities using either of the two scanning protocols (14 and 12 ICS). The method demonstrates strong diagnostic performance and a good correlation with the Warrick scores.

RANTES and CXCL10 as Potential Tear-Based Biomarkers Associated with Ocular Damage in Pediatric Chronic Anterior Uveitis

Ilaria Maccora[1], Mariia Pavlenko[2], Mekibib Altaye[3], Hermine Brunner[4], Alexandra Duell[4], Megan Quinlan-Waters[5], Alyssa Sproles[6], Sherry Thornton[4], Grant Schulert[4], Virginia Miraldi Utz[4] and Sheila Angeles-Han[6], [1]Rheumatology Unit, ERN ReCoNNET Center, Meyer Children's Hospital IRCCS, Florence, Italy, Firenze, Florence, Italy, [2]Rheumatology Division, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, USA, Cincinnati, OH, [3]Cincinnati Children's Hospital, Cincinnati, [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [5]Cincinnati Children's Hospital Medical Center, CCHMC, [6]Cincinnati Children's Hospital, Cincinnati, OH

SESSION INFORMATION
Session Date: Wednesday, October 29, 2025
Session Title: Abstracts: Pediatric Rheumatology – Clinical III (2675–2680)
Session Type: Abstract Session
Session Time: 11:30AM–1:00PM

Background/Purpose: Pediatric chronic anterior uveitis (CAU) leads to sight-threatening complications in approximately 50% of affected children. Among complications, cataract and glaucoma are among the most common ocular complications of CAU. We aim to identify tear-based biomarkers associated with ocular damage in pediatric CAU.

Methods: This cross-sectional study included children ≥5 years old diagnosed with CAU (juvenile idiopathic arthritis-associated (JIA-U) or idiopathic (iCAU)) from our registry at CCHMC. Tear samples were collected from both eyes by Schirmer strips. Ocular complications included cataract, glaucoma, synechiae, band keratopathy, macular edema, epiretinal membrane, and optic disc oedema. Levels of S100A8, A9, and A12 were measured by ELISA, and IL-18, IL-8, CXCL10 (IP-10), MCP-1, RANTES, and sICAM-1 by Luminex assays. Biomarker levels were compared by the number of ocular complications (0, 1, >1). An exploratory Spearman correlation (ρ) analysis was performed and a Heatmap was developed to identify potential significant associations. A p-value < 0.05 was considered significant.

Results: Forty-one children (29 JIA-U; 12 iCAU) with CAU contributed 121 tear samples (86 JIA-U; 35 iCAU) (Table 1), of whom 77 samples are from eyes with complications (51 by JIA-U and 26 by iCAU, $\chi^2$2.41, p=0.088). We observed significant differences regarding the number of complications between JIA-U vs iCAU (mean 1.88 vs 2.15, p< 0.001).

*One patient could contribute to both active and inactive uveitis/arthritis groups; List of abbreviations: JIA-U-Juvenile Idiopathic Arthritis-associated uveitis; CAU - Chronic Anterior Uveitis; iCAU - Idiopathic CAU; N number; N/A not applicable

We observed an increased level of RANTES in children with complications compared to those without complications (0.752 vs 0.389, p=0.028), and when considering the number of complications [0, 1, or >1] (0.389 vs 0.675 vs 0.824 respectively, p=0.022) (Figure 1A). Conversely, CXCL10 was decreased in children with complications (2.82 vs 2.99, p=0.010), and when stratified by the number of complications (2.991 vs 2.881 vs 2.785 respectively, p=0.004, Figure 1B).

As shown in Figure 2, there were several significant correlations between the level of candidate biomarkers and ocular parameters: RANTES was positively correlated with the presence of complications (ρ=271, p=0.005) and glaucoma (ρ=306,p=0.015), while CXCL10 was negatively correlated with the presence of complications(ρ=0.27, p=0.005, the number of complications (ρ=0.31,p=0.006), and the presence of macular oedema/and papillitis (ρ=245,p=0.031). Moreover we found a positive correlation between S100A9 and the presence of cataract (ρ=384,p=0.003) and a negative correlation with uveitis activity (ρ=292,p=0.007).

Conclusion: We identified RANTES, CXCL10 and S100A9 as potential tear-based biomarkers associated with ocular damage in pediatric patients with CAU. RANTES appears to be elevated with ocular complications, whereas CXCL10 is decreased. The role of RANTES has been demonstrated in experimental autoimmune uveitis models and patients with

Abstract Number: 2676

Tofacitinib in Juvenile spondyloarthropathy: clinical efficacy, impact on biomarkers and comparison with Adalimumab

Anu Balakrishnan[1], Asif Khan[2], Shivika Guleria[3], Fareha Umam[4], Naveen R[5], Priyansh Jain[2], Lekshmi Minikumari Rahulan[2], Rudrarpan Chatterjee[6] and **Amita Aggarwal**[7], [1]Sanjay Gandhi Post Graduate Institute, India, Lucknow, Uttar Pradesh, India, [2]Sanjay Gandhi Postgraduate Institute of Medical sciences Lucknow, Lucknow, Uttar Pradesh, India, [3]SGPGIMS, Lucknow, Lucknow, Uttar Pradesh, India, [4]Dept of Clinical Immunology and Rheumatology, SGPGIMS, Lucknow, Uttar Pradesh, India, [5]Sanjay Gandhi Post graduate institute of medical sciences, Lucknow, Uttar Pradesh, India, [6]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow., Lucknow, Uttar Pradesh, India, [7]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India, Lucknow, Uttar Pradesh, India

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Pediatric Rheumatology – Clinical III (2675–2680)

Session Type: Abstract Session

Session Time: 11:30AM–1:00PM

Background/Purpose: Tofacitinib is a JAK inhibitor that has been approved for treatment of polyarticular Juvenile idiopathic arthritis. However, data on its use in juvenile spondyloarthropathy including Enthesitis related arthritis is limited. MRP8/14 and MMP3 are good biomarkers of activity in Juvenile spondyloarthropathy[1,2]. Thus, we studied the effect of Tofacitinib on disease activity, biomarkers and compared that with treatment with adalimumab.

Methods: Patients with juvenile spondyloarthropathy (onset < 18 years), and having poor response to NSAIDs and/or methotrexate/Sulphasalazine were included in the study. Patients were given a choice of tofacitinib(tofa) or Adalimumab (ADA) and based on preference, the availability of cold chain to store ADA patients were treated with either ADA or tofacitinib.

Table 1: Baseline characteristics of two groups

Characteristics	Tofacitinib group (n=29)	TNF inhibitor group (n=24)
Male: female	28:1	22:2
Age at the onset of disease	12.6+3.61	11.7+3.57
Age at inclusion (years)	17.8+3.54	17.9+3.81
Duration of disease (years)	5.21+3.25	6.02+3.84
Clinical features (N)		
Arthritis	25	25
Enthesitis	21	21
IBP	20	20
Sacroiliitis	21	21
Uveitis	02	02
Hip disease	19	19
Tarsitis	10	10
HLA B27		13/14
Disease activity parameters		
ESR	46.78+29.28	65.68+41.01
JSpADA	4.12+1.26	5.06+1.18
BASDAI	4.39+1.89	5.76+1.74
BASMI	2.03+1.25	3.58+1.86
BASFI	3.49+2.45	5.77+2.42
ASDAS ESR	3.61+1.04	4.51+0.90

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

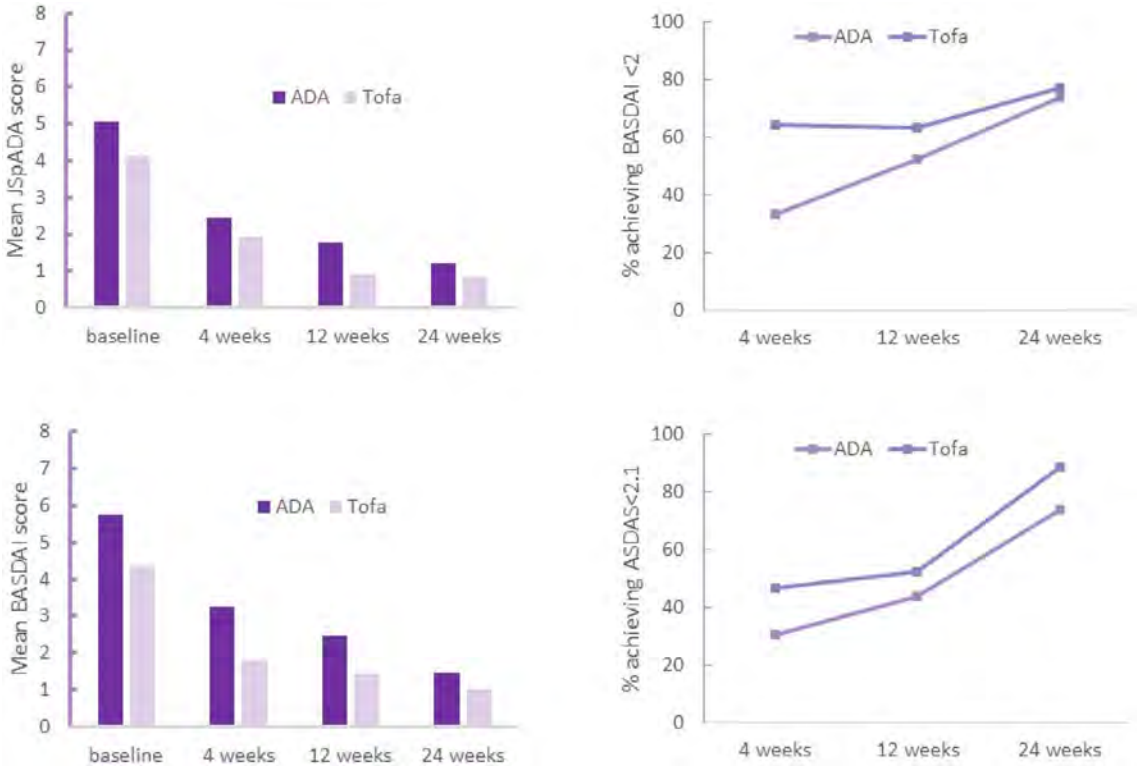

Figure 1: Effect of ADA and Tofa on JSpADA, BASDAI, ASDAS at different time points

Drugs were provided free of cost and were supported by a foundation. The disease activity was assessed using JSpADA, BASDAI, BASFI, BASMI and ASDAS at baseline, 4 weeks, 16 weeks and 24 weeks. ESR, CRP, MMP3, MRP 8/14, were measured at 0 and 4 weeks. The study was approved by institutional ethics committee and consent was taken from patient/guardian.

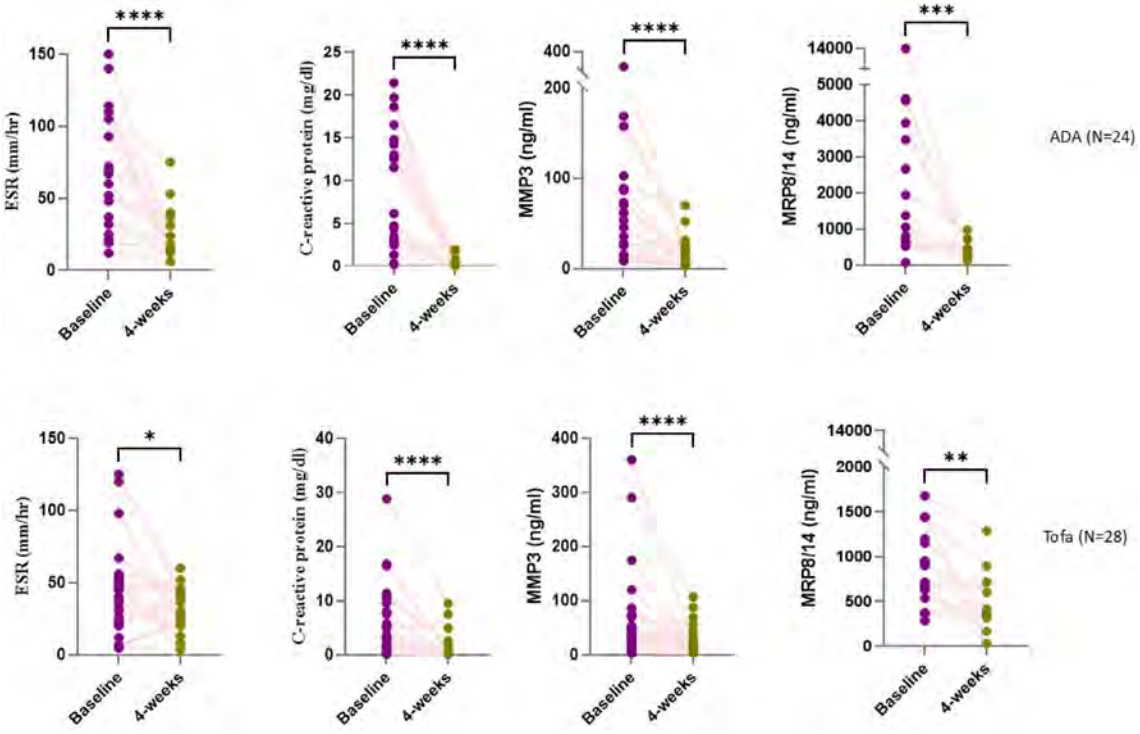

Figure 2: Effect of ADA and Tofa on ESR, CRP, MMP3 and MRP8/14

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: The study included 53 patients with JSpA (29 on Tofacitinib and 24 on ADA). The clinical features of the two groups showed that the mean age of onset, duration of disease and clinical features were similar in both the groups however disease activity was higher in ADA group. (Table 1). In ADA group 1 patient had transaminitis at 12 weeks, 1 had flare after 16 weeks, 1 had anemia and GI infection and one each was lost to follow up at 16 and 24 weeks. In Tofa group 1 patient each was lost to follow up at 4, 12 and 24 weeks thus 26 complete the 24 week follow up.

Both JSpADA score and BASDAI reduced after 4 weeks and over the next 24 weeks there was further reduction of the score (figure 1). Both groups had a similar reduction in scores. BASDAI remission (< 2) was seen in 14/19 (73.7%) in ADA group and 20/26 (76.9%) patients in Tofa group. ASDAS based low disease activity was achieved by 73.6% in ADA group and in 88.4% in tofa group ($p < 0.05$) (figure 1).

The blood biomarkers i.e. ESR, CRP, MMP and MRP8/14 showed a significant fall at 4 weeks, however the degree of fall was similar between ADA and Tofa.(Figure 2)

Conclusion: Tofacitinib shows similar efficacy, reduction in markers of inflammation as adalimumab in JSpA. It has a good safety profile and also has rapid onset of action.

Quantified Imaging Response at the Sacroiliac Joints to TNF-Inhibitor Therapy in Youth with Axial Disease

Timothy Brandon[1], Rui Xiao[2], Daniel Lovell[3], Edward Oberle[4], Matthew Stoll[5], Nancy A. Chauvin[6], Michael Francavilla[7], Walter P. Maksymowych[8] and **Pamela Weiss**[9], [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA, [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [4]Nationwide Children's Hospital, Columbus, OH, [5]University of Alabama at Birmingham, Birmingham, AL, [6]The Cleveland Clinic, Hummelstown, PA, [7]Department of Pediatric Radiology, Children's Hospital Philadelphia, Philadelphia, PA, [8]Department of Medicine, University of Alberta, 568 Heritage Building, Edmonton, AB, Canada, [9]Childrens Hospital of Philadelphia, Philadelphia, PA

SESSION INFORMATION
Session Date: Wednesday, October 29, 2025
Session Title: Abstracts: Pediatric Rheumatology – Clinical III (2675–2680)
Session Type: Abstract Session
Session Time: 11:30AM–1:00PM

Background/Purpose: This study assessed the timeline for the resolution of inflammation, changes in structural lesions at the sacroiliac joints (SIJ), and their correlation with patient-reported outcomes in youth with spondyloarthritis and axial disease (axJSpA) starting tumor necrosis factor inhibitor (TNFi) therapy.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: This prospective, observational, multicenter study included youth aged 8 to 18 years with a clinical diagnosis of axJSpA starting TNFi therapy. TNFi therapy continued through the observation window as part of ongoing standard of care. Assessments at baseline and 12 weeks included a questionnaire, clinical exam, and MRI. Those with persistent SIJ inflammation at 12 weeks were invited for repeat MRI and questionnaires at 24 weeks. Imaging was independently assessed by 3 reviewers, blinded to timepoint and clinical details, using the Spondyloarthritis Research Consortium of Canada (SPARCC) SIJ inflammation and structural scores (SIS and SSS). Patient-reported outcomes included PROMIS pain interference and global health scores, self-rated pain (neck/back/hip), and global change assessment (improved, stable, or worsened); Associations between imaging scores and patient-reported outcomes were analyzed using Spearman's correlation.

Results: Seventy-five participants enrolled; 73 (97.3%) completing the baseline visit. Among those, 62 (84.9%) had MRI findings consistent with axJSpA, and 57 of 62 (91.9%) completed the 12-week visit. Subject baseline characteristics are shown in Table 1. The median baseline SIS was 11 (IQR 5-20), and 89% of participants had ≥ 1 structural lesion, most commonly erosion. Change in imaging lesions from baseline to 12 and 24 weeks are illustrated in Figure 1. At 12 weeks, 89% improved in SIS (median change: -8 [IQR -18 to -3]); 63% achieved resolution of inflammation (SIS < 2). Of 26 with persistent inflammation and available global change data, 85% reported at least moderate improvement. At 24 weeks, 14 of 25 (25% of total) had ongoing inflammation with a median SIS of 1 (IQR 0-2). Erosion and sclerosis scores declined, increased or stayed the same in 58/25/17% and 21/9/70% of participants, respectively. Structural changes that reflect a tissue response to resolution of inflammation (fat metaplasia and backfill) demonstrated increased scores in 30% and 28%, respectively at week 12. Correlations between imaging outcomes and patient-reported measures at 12 weeks are shown in Figure 2.

Table 1. Subjects

	Median (IQR) or n (%)
Criteria fulfilled	
ESSG	48 (84.2%)
ILAR ERA	49 (86.0%)
ILAR PsA	3 (5.3%)
Age at baseline, years	15.3 (13.5-16.9)
Sex, male	39 (68.4%)
HLA-B27+	22 (41.5%)
Family history of SpA	5 (9.3%)
Peripheral arthritis	16 (28.1%)
Enthesitis	31 (54.4%)
Psoriasis	6 (10.5%)
Inflammatory Bowel disease	9 (15.8%)
TNFi therapy	
Adalimumab	49 (86.0%)
Etanercept	5 (8.8%)

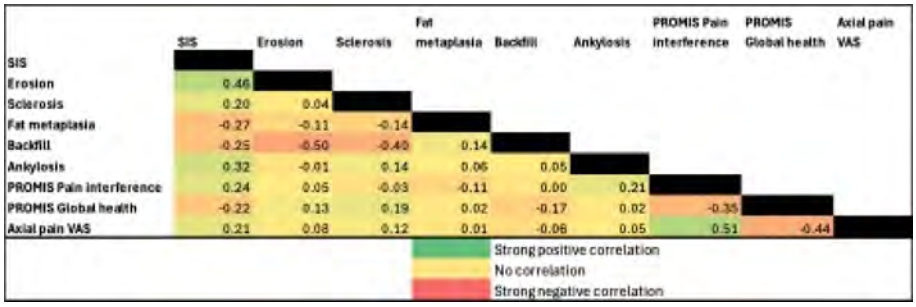

Figure 2. Correlation matrix of patient-reported and imaging outcomes after 12 weeks of TNFi therapy. All raw scores generated from PROMIS instruments are translated into standardized T-scores with a population mean of 50 and standard deviation of 10. Higher scores in a domain represent more of the trait being measured; higher T-scores indicate a worse outcome in pain interference; lower T-scores indicate a worse outcome global health.

Conclusion: Approximately half of participants had persistent SIJ inflammation on MRI at 12 weeks, yet 85% of those reported meaningful clinical improvement. Reductions in certain structural lesion scores were observed, and there was some evidence of early reparative changes, such as fat metaplasia or backfill. These findings underscore variability in therapeutic response to TNFi and indicate that significant clinical and imaging improvements may occur early in treatment, although a subset of patients may continue to exhibit active inflammation beyond 12 weeks. The modest correlations observed between imaging findings and patient-reported outcomes highlight the need for a multimodal approach to assessing treatment response in axJSpA.

The Association Between Medication Taper Duration and Time to JIA Disease Flare: A Retrospective Cohort Study

Christian-Immanuel Oliveros[1], Kelly Rouster-Stevens[2], Laura Johnson[3] and Sampath Prahalad[4], [1]Emory University / Children's Healthcare of Atlanta, Atlanta, GA, [2]Emory University/Children's Healthcare of Atlanta, Peachtree Corners, GA, [3]Emory University, Atlanta, GA, [4]Emory + Children's Pediatric Institute, Atlanta, GA

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025
Session Title: Abstracts: Pediatric Rheumatology – Clinical III (2675–2680)
Session Type: Abstract Session
Session Time: 11:30AM–1:00PM

Background/Purpose: Once clinically inactive, many patients with oligoarticular (oligoJIA) or polyarticular JIA (polyJIA) are interested in de-escalating therapy in a safe and successful manner.

Many studies have attempted to answer questions regarding JIA medication withdrawal such as priority of medication to wean on those using combination therapy or recapturing patients who flare. However, no studies to date have attempted to determine if there is an association between duration of medication taper and time to relapse should it occur.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: This is a single site, retrospective cohort study. Eligible subjects included all pediatric patients with oligoJIA or polyJIA seen between January 1, 2015, and August 31, 2023, who tapered off a unique conventional disease-modifying antirheumatic drug (cDMARD), which included methotrexate or leflunomide, and/or biologic disease-modifying antirheumatic drug (bDMARD), which included adalimumab, infliximab or etanercept, as directed by their rheumatology provider or on their own accord.

The primary objective was to determine if there was an association between length of medication taper and time to disease relapse should it occur. The secondary objective was to identify risk factors for JIA disease relapse.

Kaplan-Meier survival curves were used to illustrate the observed probability of flare-free survival over time. To explore Unadjusted Cox proportional hazards regressions were used to estimate the association between exposures of interest and time to flare, using robust (sandwich) standard errors clustered by participant (due to multiple tapers within certain subjects). Variables that were statistically significant in the unadjusted models were entered into a final multivariable model.

Results: Among oligoJIA subjects (n = 67), there were 60 unique cDMARD tapers, 17 unique bDMARD tapers, and one patient simultaneously tapered cDMARD and bDMARD, who was excluded from the analysis. Risk factors ($p< 0.05$) for oligoJIA flare included tapering off a bDMARD, having more than 1 joint affected, HLA-B27 and RF positivity. Subjects with longer tapers (>6 months, > 12 months) of either medication class demonstrated increased risk for disease relapse compared to shorter taper durations (HR of 2.29 (95%CI: 1.23-4.26, p=0.009) for >6 months, HR of 6.41 (95% CI: 3.47-11.76, $p< 0.001$) for > 12 months).

Among polyJIA subjects (n = 41), there were 41 unique cDMARD tapers and 10 unique bDMARD tapers. Risk factors for polyJIA flare included tapering off a bDMARD and abruptly stopping either JIA medication (versus tapering over time). Subjects with longer taper durations (≥1 day) demonstrated a protective effect against disease relapse compared to subjects who immediately stopped (aHR: 0.41; 95% CI: 0.016-1.07, p=0.035).

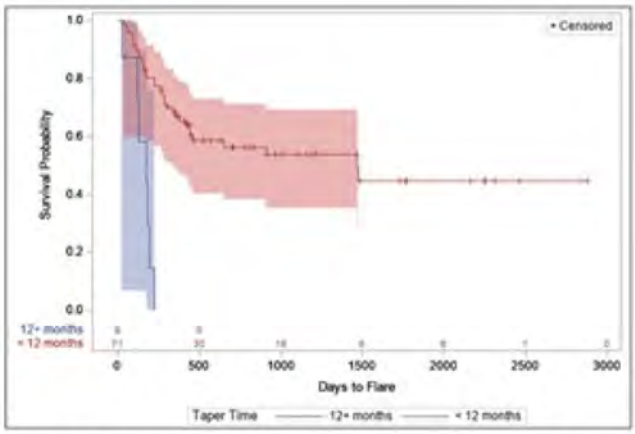

Figure 1a. Oligo JIA Cohort: Kaplan Meier Curve Estimating Survival Curves, Stratified by Taper Time (<12 months vs. 12+ months)

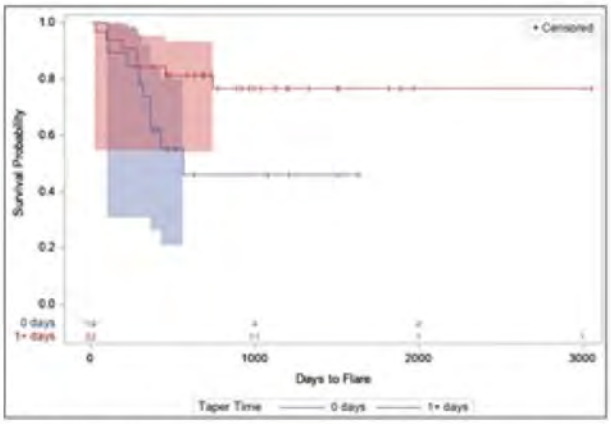

Figure 1b. Poly JIA Cohort: Kaplan Meier Curve Estimating Survival Curves, Stratified by Taper Time (0 days vs. 1+ days)

Figures 1a and 1b.

Conclusion: For oligoJIA patients, there was an inverse association between duration of medication taper and time to relapse. This suggests that children with clinically inactive oligoJIA and particularly those with favorable factors (negative RF or HLA-B27 status, cDMARD monotherapy, only one joint affected) could undergo faster tapers. However, in those with polyJIA, children may benefit from a taper over time versus abruptly stopping their medication.

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025
Session Title: Abstracts: Pediatric Rheumatology – Clinical III (2675–2680)
Session Type: Abstract Session
Session Time: 11:30AM–1:00PM

Background/Purpose: Early-life nutrition may influence the risk of immune-mediated diseases like juvenile idiopathic arthritis (JIA). The benefits of breastfeeding are well established, but findings related to JIA have been inconsistent and mainly based on small case-control studies (1). Early introduction of solid food may promote immune tolerance (2), which could reduce the risk of immune-mediated diseases like JIA, but this has not been studied. We aimed to investigate the association

≥6 months	58 (24.3) / 13,462 (18.8)	**1.42 (1.05-1.92)**	**1.48 (1.09-2.00)**

between breastfeeding duration, age at introduction of solid food, and risk of JIA in a large population-based pregnancy cohort, including possible gene-environment interactions.

Methods: We used The Norwegian Mother, Father, and Child Cohort Study (MoBa), a cohort that recruited pregnant women from 1999-2008, with data from >114 000 mother-infant pairs. A JIA case was, as previously validated (3), defined as having at least two ICD-10 codes (M08/M09) by linking the cohort to the Norwegian Patient Registry. At 6 months post-partum, mothers completed a questionnaire reporting infant feeding practices. Full breastfeeding was defined as receiving only breast milk without any formula or solid food. We categorized breastfeeding and age at solid food introduction as: < 4 months, 4–5 months (reference), and ≥6 months.

We used multivariable logistic regression and estimated odds ratios (aORs) adjusted for: maternal history of inflammatory rheumatic disease, age, education, BMI, parity, mode of delivery, preterm birth and gestational smoking. Umbilical cord blood sampling at birth allowed genotyping of a subsample of the children. We calculated polygenic risk scores (PRSs) using summary statistics from a large genome-wide association study (GWAS) to estimate the children's genetic risk of JIA (4). By using these PRSs, we assessed gene-environment interactions.

Results: Our final analytical sample included 239 infants who later developed JIA and 71,761 infants who did not, with genotyping data on 169 cases and 39,488 non-cases. The risk of JIA was non-significantly higher in those with a full breastfeeding duration ≥6 months (aOR 1.39, 95% CI 0.98-1.99) **(Table 1)**. We identified interactions between genetic susceptibility to JIA and both short (< 4 months) and prolonged (≥6 months) breastfeeding (p = 0.02 and 0.04).

Additionally, delayed introduction of solid food (≥6 months) was associated with an increased risk of JIA (aOR 1.48, 95% CI 1.09-2.00) **(Table 1)**, with no evidence of gene-environment interaction.

Conclusion: Our findings suggest that later introduction of solid food is associated with an increased risk of JIA, supporting the hypothesis that earlier dietary exposures may promote immune tolerance. Additionally, we observed interactions between genetic susceptibility to JIA and breastfeeding duration, indicating that genetic predisposition may modify the association between breastfeeding and disease risk, which warrants further investigation.

High Health Care Utilization Preceding Diagnosis of Juvenile Idiopathic Arthritis

Anna Costello[1], Rui Xiao[1], Jahan Jazayeri[1], Timothy Brandon[1], Xuemei Zhang[1], Irit Rasooly[1] and **Pamela Weiss**[2], [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]Childrens Hospital of Philadelphia, Philadelphia, PA

SESSION INFORMATION
Session Date: Wednesday, October 29, 2025
Session Title: Abstracts: Pediatric Rheumatology – Clinical III (2675–2680)
Session Type: Abstract Session
Session Time: 11:30AM–1:00PM

Background/Purpose: Timely diagnosis of Juvenile Idiopathic Arthritis (JIA) enables early initiation of therapy and improves outcomes, yet JIA patients often experience circuitous pathways to diagnosis. We aimed to characterize the healthcare utilization in the year preceding JIA diagnosis.

Methods: We used deidentified administrative data from the Truven Marketscan commercial and Medicaid databases (2014 to 2022). Inclusion criteria for the study were: (1) age 1-17 years and (2) diagnosis of JIA as defined by (a) ≥2 International Classification of Disease (ICD)-9 or 10 JIA codes within 6 months, (b) ≥1 JIA code from a rheumatologist, or (c) ≥1 JIA

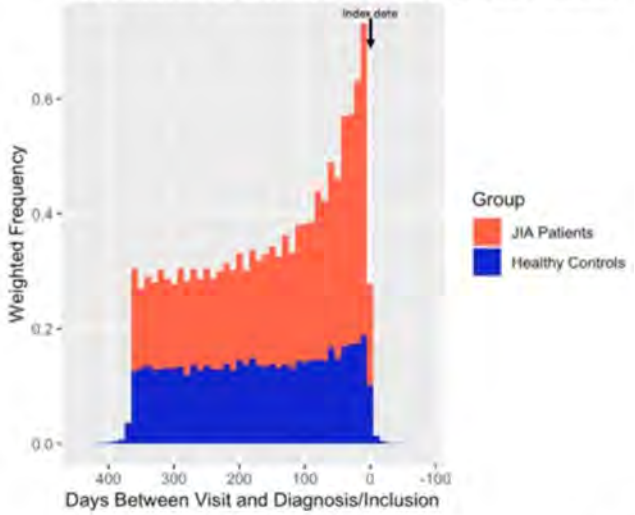
Table 2: Healthcare Utilization 12 months prior to index date

	JIA cohort n=10021 Mean (SD)	Healthy Control n=20042 Mean (SD)	Incident Rate Ratio (95% CI)	p-value
Total Healthcare Utilization	13.43 (14.68)	5.26 (8.52)	2.55 (2.53-2.57)	**<0.001**
Number of Outpatient visits	11.78 (13.73)	4.60 (8.21)	2.56 (2.54-2.58)	**<0.001**
Number of ED/Urgent Care visits	1.54 (2.76)	0.64 (1.46)	2.42 (2.36-2.47)	**<0.001**
Number of Inpatient Hospitalizations	0.11 (0.52)	0.02 (0.20)	4.48 (4.04-4.97)	**<0.001**

Legend. The index date for JIA patients was defined as the date of the first JIA code that they received. The index date for healthy controls was defined as the date of an outpatient visit occurring within two months of the index date of the matched JIA patient. Visit numbers presented as mean (standard deviation). p-value calculated using manual Wald test. JIA, Juvenile Idiopathic Arthritis, CI, confidence interval.

Figure 1: Time Between Visits and Diagnosis/Inclusion



Legend. This figure demonstrates the frequency of healthcare utilization in the outpatient, inpatient, or ED settings as patients approach the date of diagnosis (day 0) for JIA patients or inclusion in the cohort for healthy controls. The visit frequencies are weighted to account for the numbers of patients versus controls.

code with a claim for a JIA directed therapy or intraarticular steroid injection within 6 months. Patients were excluded if they did not have continuous enrollment in the database for 12 months prior to the index date or if they had a claim with a JIA code during that period. Age- and sex-matched controls were identified at a 2:1 ratio. The index date for JIA patients was defined as the date of the first JIA code. The index date for controls was defined as the date of a visit occurring within two months of the index date of the matched JIA patient. Healthcare utilization was defined as any inpatient admission, emergency department or urgent care visit, and outpatient claim for a billing visit with a physician or advanced practice provider. Incidence rate ratios (IRRs) were calculated to compare healthcare between JIA patients and controls in the 12 months prior to the index date, and the manual Wald test was used to calculate the relevant p-values.

Results: 10,021 children, ages 1-18 years, had an incident diagnosis of JIA in the years of study. Median age in both JIA patients and controls was 13 (interquartile range 9-16), and there was no significant difference in insurance type or prevalence of chronic conditions between the JIA patients and controls (**Table 1)**. Healthcare utilization in the year preceding

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

the index date was significantly higher for JIA patients versus controls (**p< 0.001**). JIA patients had a median of 10 healthcare encounters (interquartile range [IQR] 5 to 17) while controls had a median of 3 visits (IQR 1 to 7). This increased utilization was consistent for outpatient (IRR 2.56, p< 0.001), inpatient (IRR 4.48, p< 0.001), and emergency room/urgent care encounters (IRR 2.42, p< 0.001) (**Table 2**). Healthcare utilization for JIA patients escalated as the index date approached (**-Figure 1**). JIA outpatient encounters were most frequent with generalists (74.8% of visits) and orthopedists (4.9%) in the pre-diagnosis period. Further, 22.9% of children with JIA saw an orthopedist in the year preceding JIA diagnosis, with most receiving non-specific diagnosis codes for joint pain or effusion.

Conclusion: Children with JIA have significantly higher health care utilization in comparison to age- and sex- matched healthy peers in the 12 months preceding JIA diagnosis. This pattern suggests that there may be opportunities, particularly in primary care and orthopedics, to identify JIA earlier. Understanding the patterns of utilization could help target interventions to improve the time to diagnosis, and ultimately the experiences and outcomes, for these patients.

Derivation and Validation of Inflammation-Adjusted Lipid Measures to Improve Cardiovascular Risk Prediction in Rheumatoid Arthritis

Tate Johnson[1], George Reed[2], Joel Kremer[3], Dimitrios Pappas[4], Punyasha Roul[5], Grant Cannon[6], Gail Kerr[7], Andreas Reimold[8], Katherine Liao[9], Michael George[10], Jon Giles[11], Christina Charles-Schoeman[12], Joshua Baker[10], Ted Mikuls[1] and Bryant England[1], [1]University of Nebraska Medical Center, Omaha, NE, [2]University of Massachusetts Chan Medical School, Worcester, MA, [3]The Corrona Research Foundation, Delray Beach, FL, [4]CorEvitas, New York, NY, [5]UNMC, Omaha, NE, [6]University of Utah and Salt Lake City VA, Salt Lake City, UT, [7]Washington DC VAMC/Georgetown and Howard Universities, Washington, DC, [8]Dallas VA Medical Center, Dallas, TX, [9]Brigham and Women's Hospital, Boston, MA, [10]University of Pennsylvania, Philadelphia, PA, [11]Cedars Sinai Medical Center, Los Angeles, CA, [12]UCLA Medical Center, Santa Monica, CA

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes III: Long Live (Comorbidity and Outcomes) (2681–2686)

Session Type: Abstract Session

Session Time: 11:30AM–1:00PM

Background/Purpose: Total cholesterol (TC) and low-density lipoprotein (LDL) are critical measures of atherosclerotic cardiovascular disease (ASCVD) risk. However, the lipid paradox in RA, whereby systemic inflammation reduces lipid levels despite an increased risk of ASCVD, renders TC and LDL unreliable. To account for the lipid paradox, we derived and externally validated inflammation adjusted lipid measures in RA and tested the hypothesis that inflammation adjusted lipids would be more strongly associated with incident ASCVD than unadjusted lipid levels.

Methods: Derivation occurred using baseline data in CERTAIN, a prospective cohort of active RA patients initiating or switching a biologic DMARD. Participants with high sensitivity C-reactive protein (hsCRP) and serum lipids available were included. Statin, JAK inhibitor, and IL-6 inhibitor use were exclusion criteria. Linear spline regression with a single knot was executed using log-transformed hsCRP as a predictor of lipid levels, adjusting for age, sex, smoking status, BMI, diabetes, hypothyroidism, and DMARD use. External validation was conducted in the Veterans Affairs RA registry, a multicenter, prospective RA cohort, with identification of ASCVD events (myocardial infarction, stroke) in linked VA, Medicare, and National

[c] LDL_{adj} = Unadjusted LDL + (5.8 x log-hsCRP)
Abbreviations:; Ref, reference; VA, Veterans Affairs

Death Index data. The magnitude of the estimated β for hsCRP was used as a correction factor for baseline TC and LDL levels in VARA (TC_{adj} *[or* LDL_{adj}*]* = *Unadjusted TC [or LDL]* + β**log-hsCRP*). The association between hsCRP and lipid levels, before and after inflammation adjustment, was illustrated with Lowess smoothing. The association of unadjusted lipids, TC_{adj} and LDL_{adj} values (categorical and dichotomous cutoffs) with incident ASCVD were compared using multivariable Cox regression.

Results: Among 1,663 patients in CERTAIN (mean age 54.4, 81.2% female, mean hsCRP 10.7 mg/L), an inverse U-shaped relationship was observed between hsCRP and unadjusted lipids. A linear spline with a knot at log-hsCRP = 0 yielded the best model fit, leading to a correction factor of 11.4 (TC) and 5.8 (LDL) for each log unit increase in hsCRP above 0 (**Figure 1**). Adjusting lipid levels for log-hsCRP >0 among 2,106 VARA registry participants (mean age 61.7, 86.4% male, mean hsCRP 11.1 mg/L) corrected the U-shaped relationship (**Figure 2**) and recategorized a greater proportion of participants into higher TC_{adj} and LDL_{adj} categories (**Table 2**). Over 17,701 person-years, we observed 371 incident ASCVD events. The associations between categorical and dichotomous TC_{adj} (range aHR 1.35-1.80) and LDL_{adj} (range aHR 1.22-1.56) cutoffs with ASCVD events were stronger than for unadjusted lipids (**Table 2**).

Conclusion: Compared to unadjusted lipids, inflammation-adjusted TC and LDL identified a larger number of RA patients with high-risk lipid levels and strengthened the association between serum lipids and ASCVD risk. This approach may identify patients with a statin indication who are otherwise missed using current guidelines. Though a critical first step in overcoming challenges to care posed by the lipid paradox, additional study is required to integrate these results into risk calculators to optimize CVD prevention in RA.

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes III: Long Live (Comorbidity and Outcomes) (2681–2686)

Session Type: Abstract Session

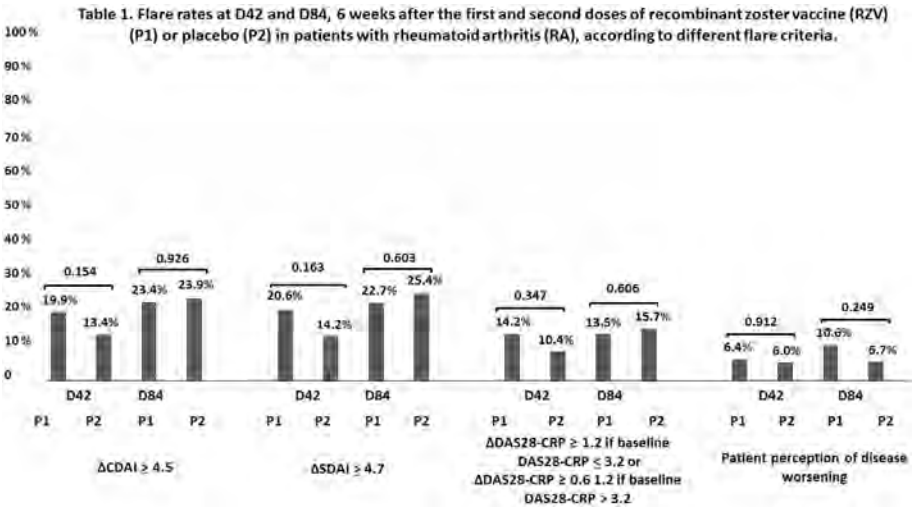
Session Time: 11:30AM–1:00PM

Background/Purpose: The recombinant vaccine against herpes zoster (HZ) (RZV) is recommended by ACR and EULAR for immunocompromised individuals. Short-term observational data from RA cohorts aged ≥50 years supports its overall reactogenicity and possible safety in non-randomized designs. However, the specific impact of different immunosuppressive drugs or combinations on vaccine immunogenicity is limited to small sample sizes or selected groups of patients, hampering conclusions about the effect of specific therapies. Moreover, new flare definition criteria using CDAI/SDAI were recently validated but the effect of vaccination using these new criteria were not evaluated. To address these gaps, we conducted a large prospective, randomized controlled trial to evaluate safety and assess humoral immunogenicity induced by RZV in RA adult (≥18 years) patients.

Methods: RA patients were randomized to receive RZV (P1) or placebo (P2) at D0 and D42. Groups were blindly evaluated for disease activity (CDAI, SDAI and DAS28-CRP) at D0, D42 and D84. P2 group was vaccinated with a similar schedule at D84 and D126. Immunogenicity was evaluated in patients (P1+ P2) and compared to non-immunosuppressed control group (CG) at 1st RZV dose and 6 weeks post-vaccination. Anti-gE antibody concentrations (ELISA) were assessed at 1st RZV dose and six weeks after the second dose. Pre and post vaccination geometric mean titers (GMTs) and soroconversion (SC) were calculated. Adverse events (AE) were monitored for 3 months through scheduled visits and phone contacts.

Results: A total of 320 RA patients were randomized at D0: 165 in P1 and 155 in P2. The groups were balanced for age (p=0.562), sex (p=0.331), previous HZ infections (p=0.580), disease duration (p=0.838), rheumatoid factor (p=0.411) and anti-CCP (p=0.456) positivity, disease-modifying antirheumatic drugs (p >0.05), CDAI (p=0.268), SDAI (p= 0.343)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



For safety analyses, all patients who adhered to protocol were included (n=275: 141 in P1 and 134 in P2). Results are expressed in % and compared with the chi-square or Fisher's exact test, as appropriate, as two-sided analyses; CDAI (Clinical Disease Activity Index), SDAI (Simplified Disease Activity Index), DAS28-CRP (Disease Activity Score using 28-joint count and C-reactive protein) and patient perception of disease worsening at D42 and D84 were compared to baseline status (D0). P1: pacients vaccinated with recombinant zoster vaccine (RZV) at D0 and D42; P2: patients who received placebo at DO and D42.

and DAS28-CRP (p=0.268). After 2 vaccine doses, SC (96.6% vs. 100%, p=0.030) and GMT [8.3 (7.2-9.5) vs 12.9 (11.5-14.5 mUI/mL; p< 0.001] were significantly reduced in patients compared to CG. Linear regression corrected for pre-vaccination GMT linked older age (p=0.032), higher disease activity (p=0.042), MTX (p< 0.001), and prednisone use (p=0.045) with lower post-vaccination GMT. The concomitant use of MTX reduced post-vaccination GMT among bDMARD (p< 0.001) users (mainly TNFi users, p=0.003) and sDMARD users (p< 0.001). In multivariate analysis, higher pre-vaccination GMT persisted associated with higher post-vaccination GMT (p< 0.001), while older age (p=0.033) and MTX use (p< 0.001) remained associated with lower post-vaccination GMT. No HZ cases occurred by D84. Flare rates were comparable (p >0.05) between P1 and P2 (Figure 1) both at D42 and D84. No moderate/severe AEs were observed.

Conclusion: This large study showed that RZV was safe in immunosuppressed RA patients, with no evidence of increased flare rate using validated measures in comparison to placebo. Importantly, we identified MTX and older age as key factors that significantly impair humoral immune response. Although the humoral correlates of protection are not established, new strategies may be recommended for these patients (ClinicalTrials NCT05879419).

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes III: Long Live (Comorbidity and Outcomes) (2681–2686)

Session Type: Abstract Session

Session Time: 11:30AM–1:00PM

Background/Purpose: Guidelines recommend the use of composite scores to evaluate disease activity in RA and inform a treat-to-target approach. It is recognised that patient-reported components of these scores are influenced by factors unrelated to inflammation such as other chronic pain conditions. We assessed whether those with a higher genetic predisposition to pain had higher disease activity scores and which components of disease activity were most affected.

Methods: Participants from the Veterans Affairs RA registry, a longitudinal cohort of veterans with RA, were genotyped using the Infinium Global Screening Array-24 v2.0; imputation was performed using the TOPMed server. We applied two existing polygenic risk scores (PGS) including: 1) pain intensity (PI-PGS) and 2) chronic back pain (CBP-PGS). Scores were normalized and standardized within participants of similar genetic backgrounds. Disease activity components were recorded by treating providers during routine clinical encounters and extracted from the electronic health record. We

Figure 1: Standardized effect of the pain intensity polygenic score on disease activity scores within VARA. Table and forest plot demonstrating standardised effect size of 1SD increase in PI-PGS on disease activity scores. Similar standardized effects are observed on the traditional disease activity scores; the PI-PGS had a lower standardized effect in the scores modified to remove some patient-reported aspects. Absolute effect sizes are included on the scale of the individual disease activity score. Abbreviations DAS28 – disease activity score-28 CDAI – clinical disease activity index SDAI - simplified disease activity index HAQ – health activity questionnaire RAPID3 – routine assessment of patient index data 3 M-SDAI – modified simplified disease activity index M-DAS28 – modified disease activity score-28 VARA – Veterans Affairs Rheumatoid Arthritis Registry PI-PGS – pain intensity polygenic score

Table 1: Absolute effect of pain intensity and chronic back pain polygenic scores on components of disease activity scores grouped by patient-reported and objective aspects of disease activity. The PGS demonstrate statistically significant effects on patient-reported aspects of disease activity. The effect of 1 standard deviation change in the PGS on components of disease activity scores was determined through generalized linear models using all available longitudinal data, adjusting for age, sex, and five principal components of population structure. Abbreviations: PI-PGS – pain intensity polygenic score CBP-PGS – chronic back pain polygenic score TJC – tender joint count (0-28) Pt global – patient global assessment (0-100) Prov global – provider global assessment (0-100) SJC – swollen joint count (0-28) CRP – C-reactive protein, log-transformed ESR – erythrocyte sedimentation rate, log-transformed

Component	PI-PGS (95% CI)	p-value	CBP-PGS (95% CI)	p-value
Subjective				
Pain	0.26 (0.17-0.35)	<0.001	0.14 (0.05-0.22)	0.002
TJC	0.46 (0.29-0.64)	<0.001	0.22 (0.05-0.39)	0.011
Pt global	1.88 (1.07-2.68)	<0.001	1.33 (0.57-2.09)	0.001
Prov global	1.22 (0.59-1.84)	<0.001	0.41 (-0.21-1.03)	0.198
HAQ	0.06 (0.04-0.08)	<0.001	0.03 (0.005 – 0.05)	0.015
Objective				
SJC	0.09 (-0.02-0.2)	0.123	0.06 (-0.06-0.18)	0.32
CRP	0.04 (-0.004-0.08)	0.075	0.04 (0.004-0.09	0.033
ESR	0.04 (0.009-0.08)	0.015	0.04 (-0.0002-0.07)	0.051

assessed common disease activity scores including the DAS28, Clinical Disease Activity Index (CDAI), and Routine Assessment of Patient Index Data 3 (RAPID3), as well as modified disease activity scores (M-DAS28, M-SDAI) that replace patient global assessment with provider global assessment and removes tender joint count (TJC). The effect of PI-PGS and CBP-PGS on disease activity scores and their individual components was evaluated with generalized estimating equations to use all available longitudinal data, adjusted for sex, age, and five principal components of population structure and clustered by participant with an exchangeable correlation structure. We evaluated the effect of the genetic risk as a continuous measure and by quartile.

Results: A 1 standard deviation (SD) higher PI-PGS and CBP-PGS were each associated with significantly higher DAS28, CDAI, SDAI, and RAPID3. The strength of the association was more modest for the M-DAS28 and M-SDAI (Fig. 1). A 1 SD increase in each PGS was associated with significantly higher pain score, TJC, patient global scores and HAQ (Table 1). There was no association between a 1SD increase in either PGS and SJC or CRP. A dose-dependent effect of PI-PGS on disease activity scores was observed; there were significant differences between 1st and 4th quartile of PI-PGS for all disease activity scores (Fig 2). The highest quartile had a 0.29 higher average DAS28 compared to the lowest quartile. This difference represents 24% of the minimal clinically important difference described for the DAS28.

Conclusion: Higher genetic predisposition to pain is associated with higher disease activity scores in a dose dependent manner with an effect size that may have clinical relevance. The consistency of the findings using a risk score developed for back pain suggests an association through mechanisms unrelated to RA inflammation. Our study suggests commonly

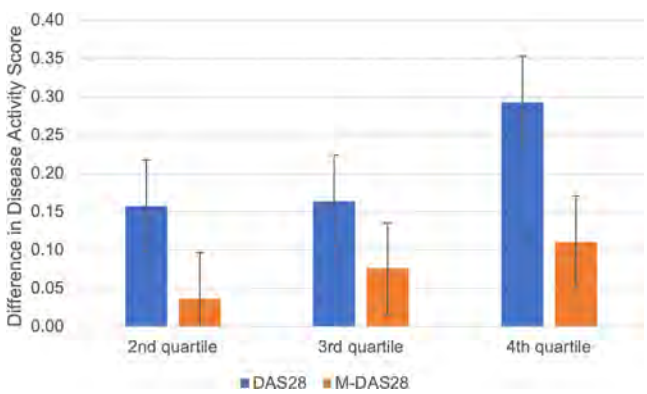

Figure 2. Absolute effect of quartile of pain-intensity polygenic score on DAS28 and M-DAS28. A dose effect is observed from increasing quartile of PI-PGS as compared to 1st quartile on DAS28 and to a more modest extent on M-DAS28. Absolute effect sizes are shown. Abbreviations: DAS28 – disease activity score-28 M-DAS28 – modified disease activity score-28

used disease activity scores, especially components related to patient global and TJC, are biased in the setting of chronic pain. Clinicians should interpret disease activity in the context of the presence of other chronic pain conditions and consider using M-DAS28 and M-SDAI in those with chronic pain.

Session Type: Abstract Session

Session Time: 11:30AM–1:00PM

Background/Purpose: Despite advances in rheumatoid arthritis (RA) treatment, 5–20% of patients experience persistent symptoms, particularly pain, and are classified as difficult-to-treat (D2T). Factors such as treatment resistance, comorbidities, and central pain sensitization may contribute; however, the exact mechanisms remain unclear. This study focused on investigating the underlying factors of the D2T condition and revealing the connections between pain and inflammation with a multimodal approach.

Methods: 31 D2T RA (determined by the 2020 EULAR definition), 18 non-D2T RA patients, and 32 healthy controls (HCs) were included. All participants underwent a clinical assessment, psychological analysis (including in-depth interviews, the Rorschach test, and questionnaires), two resting-state functional MRI (fMRI) scans with standardized heat pain stimulation in between, as well as peripheral blood transcriptomic analysis and plasma metabolomics.

Results: Resting-state fMRI revealed significantly reduced intrinsic connectivity of the posterior cingulate cortex (PCC) in RA patients, especially in D2T RA. Following acute painful stimulation, intrinsic connectivity of the PCC increased in D2T RA, in contrast to the decreased connectivity observed in non-D2T RA patients and healthy controls (HCs). *(Figure 1.)* Seed-based analysis of the postcentral gyrus (PCG) revealed a reduction in connectivity strength across many connections within the somatosensory area, which were significantly altered after pain stimulation in all RA patients compared to HCs. Fractional amplitude of low-frequency fluctuations (fALFF) analysis revealed significantly reduced activity in several brain regions (e.g., lateral occipital cortex, middle frontal gyrus, medial prefrontal cortex, and frontal pole) in RA, with D2T patients showing the most significant reductions. Compared to non-D2T RA, D2T patients also exhibited lower fALFF in additional brain regions, indicating more complex alterations in pain and somatosensory processing, behavior, and cognitive functions, which aligns with our psychological results showing increased relational and decision-making inhibition, reduced motivation, and impaired mental control in RA. *(Figure 2.)* Transcriptomic analysis showed 70 downregulated and 17 upregulated differentially expressed (DE) mRNAs in D2T RA compared to the non-D2T RA group (e.g., neuregulin-1 (NRG1) or S100B). Functional analysis demonstrated a direct link of DE mRNAs to neuronal differentiation processes, neuroinflammation, or neuroplasticity. *(Figure 3.)* Metabolomic analysis revealed significant differences in amino acid and sphingolipid metabolism.

Conclusion: Teveal a novel neuroimmune signature of D2T RA, characterized by altered brain connectivity patterns, psychological disturbances, and distinct transcriptomic and metabolomic profiles. These results may lead to new opportunities for patient stratification, biomarker development, and personalized interventions targeting central mechanisms.

Abstract Number: 2685

Assessing for Racial/ethnic Variability in U.s.-frax^{tm} Performance Among Older Adult Women with Rheumatoid Arthritis in the United States

Rachel Elam[1], Jing Li[2], Angel Paul[3], Emma Kersey[4], gabriela Schmajuk[5], William Leslie[6] and Laura Carbone[1], [1]Augusta University, Augusta, GA, [2]University of California, San Francisco, San Francisco, CA, [3]University of California San Francisco, Berkeley, CA, [4]University of California San Francisco, San Francisco, CA, [5]University of California, San Francisco, and San Francisco Veterans Affairs Medical Center, San Francisco, CA, [6]University of Manitoba, Winnipeg, MB, Canada

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes III: Long Live (Comorbidity and Outcomes) (2681–2686)

Session Type: Abstract Session

Session Time: 11:30AM–1:00PM

Background/Purpose: Women with rheumatoid arthritis (RA) have 1.5- and 2-fold higher risk of major osteoporotic fracture (MOF: first of distal forearm, hip, humerus, or clinical vertebral fracture) and hip fracture, respectively. Most fractures occur in women with osteopenia, where fracture risk stratification with FRAX^{TM} guides drug therapy initiation in the United States. U.S.-FRAX was calibrated using mainly White cohorts, and its performance across racial/ethnic groups with RA is uncertain. We assessed racial/ethnic differences in U.S.-FRAX performance in predicting imminent (2-year) MOF and hip fracture risk in older U.S. women with RA.

Methods: We retrospectively analyzed RISE registry data linked to Medicare claims (2016-2018). We included women ≥ 65 years old with RA (≥ 2 RA-coded RISE visits ≥ 30 days apart by 1/1/2017) and Medicare coverage throughout 2016 and extending into 2017. Only participants identified as Asian, Black, Hispanic, or White race/ethnicity in Medicare were included as we used these four race/ethnicity-specific U.S.-FRAX models. We used Fine-Gray competing risk models to assess associations between U.S.-FRAX 10-year MOF and hip fracture probabilities and imminent fracture risk, with separate analyses overall and in each racial/ethnic group. Variables to compute U.S.-FRAX were obtained from RISE and Medicare at or before 1/1/2017. Bone mineral density (BMD) and parental hip fracture were not available. U.S.-FRAX without BMD was used, adjusting with age- and sex-specific estimates of the effect of affirming a parental hip fracture. Incident MOF and hip fracture were identified using validated claims-based definitions starting 1/1/2017. Observed absolute 2-year fracture incidence per 1,000 person-years was compared across FRAX risk categories (low: < 10% MOF, < 1%

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Subhazard ratios from Fine-Gray competing risk models for incident major osteoporotic fracture and incident hip fracture per 10% increase in U.S.-FRAX major osteoporotic fracture or hip fracture probability score, respectively, among women with rheumatoid arthritis[1]

	Overall (n = 14,533)	Asian (n = 159)	Black/African American (n = 1,127)	Hispanic/ Latina (n = 683)	White (n = 12,564)
	sHR (95% CI)	sHR (95% CI)[2]	sHR (95% CI)[2]	sHR (95% CI)[2]	sHR (95% CI)[2]
MOF Probability Score[3]	1.58 (1.52 - 1.64)	2.64 (1.59 - 4.39)	2.21 (1.60 - 3.07)	2.05 (1.64 - 2.57)	1.57 (1.51 - 1.64)
Hip Fracture Probability Score[3]	1.76 (1.66 - 1.88)	1.12 (0.68 - 1.84)	3.81 (2.19 - 6.63)	2.51 (1.80 - 3.50)	1.73 (1.62 - 1.85)

sHR: subhazard ratio; CI: confidence interval; MOF: major osteoporotic fracture

[1]The data presented here was supported by the American College of Rheumatology's RISE Registry. However, the views expressed represent those of the authors and do not necessarily represent the views of the American College of Rheumatology. The study protocol was prepared by Rachel E. Elam, MD. The data analysis was executed by the UCSF Data Analytic Center. Funding for this project was provided by the Rheumatology Research Foundation Scientist Development Award.

[2]For each U.S.-FRAX race/ethnicity group, the subhazard ratios and 95% confidence intervals presented here are derived from a competing risk model fit on just the population of women in that race/ethnicity group (i.e. a separate model was constructed for each race/ethnicity group)

[3]U.S.-FRAX 10-year fracture risk probability score was modeled here in decimal form (range of probability score 0 to 1.0)

Table 2. Areas under the curve (AUCs) for 2-year prediction of incident fracture by site by U.S.-FRAX 10-year site-specific fracture probability score[1] in women with rheumatoid arthritis, overall and by U.S.-FRAX race/ethnicity group

		Number of Fractures[2]	Cross-validated AUC[3] (95% CI)	P value[4]
MOF	Overall (n = 14,533)	1477	0.66 (0.65 - 0.68)	—
	Asian (n = 159)	13	0.71 (0.47 - 0.90)	0.78
	Black/African American (n = 1,127)	55	0.63 (0.57 - 0.66)	0.22
	Hispanic/Latina (n = 683)	69	0.69 (0.64 - 0.76)	0.56
	White (n = 12,564)	1340	0.67 (0.65 - 0.69)	Ref
Hip fracture	Overall (n = 14,533)	419	0.71 (0.69 - 0.73)	—
	Asian (n = 159)	<10	0.48 (0.23 - 0.66)	0.27
	Black/African American (n = 1,127)	<20	0.72 (0.60 - 0.84)	0.81
	Hispanic/Latina (n = 683)	21	0.75 (0.62 - 0.86)	0.51
	White (n = 12,564)	381	0.70 (0.68 - 0.72)	Ref

AUC: Area under the curve; CI: confidence interval; Ref: reference group

[1]U.S.-FRAX 10-year fracture risk probability score was modeled here in decimal form (range of probability score 0 to 1.0)

[2]Cell values and aggregate statistics that correspond to fewer than 10 participants are obscured to protect participant privacy in accordance with RISE policy

[3]Cross-validation was performed using a 10-fold cross-validation method of each AUC estimate

[4]P values are derived from a Z-test for independent AUCs comparing the AUC estimate for each U.S.-FRAX race/ethnicity group to the AUC in White women (reference group), separately for each fracture site (MOF or hip fracture)

hip; moderate: 10-20% MOF, 1-3% hip; high: >20% MOF, >3% hip) using the Cochran-Armitage trend test. Discrimination was measured via cross-validated Areas Under the Curve (AUCs) in racial/ethnic groups, with comparison to White women.

Results: Among 14,533 women with RA (mean age: 73.8±6.4 years; 1% Asian; 8% Black; 5% Hispanic; 86% White), we observed 1,477 MOFs and 419 hip fractures. FRAX scores were statistically significantly associated with corresponding fracture risk at both sites overall, and in Black, Hispanic, and White women (Table 1). FRAX MOF, but not hip fracture, scores were statistically significantly associated with fracture risk in Asian women (Table 1). Observed MOF incidence increased significantly across FRAX risk categories overall and in all racial/ethnic groups ($P \leq 0.01$). For hip fracture, the trend was statistically significant overall and in White women ($P < 0.01$), and approached significance in Black ($P=0.09$) and Hispanic ($P=0.07$) women. FRAX discrimination for imminent MOF and hip fracture was fair, and AUCs did not differ by race/ethnicity (Table 2).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: U.S.-FRAX without BMD predicted imminent MOF and hip fracture risk in older women with RA, and showed similar discrimination across racial/ethnic groups. Future studies with longer follow-up are needed to assess calibration by race/ethnicity and evaluate performance within RA-specific subgroups, such as stratifying by RA disease activity.

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Rheumatoid Arthritis – Diagnosis, Manifestations, and Outcomes III: Long Live (Comorbidity and Outcomes) (2681–2686)

Session Type: Abstract Session

Session Time: 11:30AM–1:00PM

Background/Purpose: RA and PsA follow different pathomechanisms and incur disease-specific erosive and osteoproliferative bone changes. We used data from a large cohort of RA and PsA patients who underwent high-resolution peripheral quantitative computed tomography (HR-pQCT) imaging and analyzed the impact of the primary disease, disease activity and exposure to targeted treatments on bone density, structure and biomechanics over time.

Methods: The study included RA patients fulfilling the 2010 ACR/EULAR criteria and PsA patients fulfilling the CASPAR criteria in University Hospital Erlangen with ethics approval (324_16B) and written informed consent of the participants. HR-pQCT of the distal radius and 2nd and 3rd metacarpal heads (MCP) was performed bi/annually measuring volumetric bone density (vBMD), trabecular and cortical microstructure, bone stiffness and failure load. Cohort follow-up started at the earliest HR-pQCT and ended at the latest. Imaging episodes between consecutive imaging dates were classified based on the type of coinciding targeted treatments and using time-weighted average DAS-28 as the disease activity exposed. HR-pQCT measurements at the beginning and end of an episode were the episode baseline and outcome values. We used mixed-effects/additive regression to model episode outcome as a function of the episode baseline, episode duration, gender, age and weight of the patients and calculated adjusted marginal means at yearly intervals by diagnosis, and at fixed DAS-28 ESR values representing continuous remission (2.0) and continuous high disease activity (6.0). btsDMARD effects were summarized using their regression coefficients comparing to no use.

Results: We included 946 radius and 916 MCP scans from 482 patients with PsA (n=175), RA- (n=86) and RA+ (n=221) over a median (IQR) follow-up of 28 months (12 to 50). Glucocorticoid exposure was similar in RA+ and RA- patients (Table-1). Measurements at radius showed a total vBMD deterioration in a similar fashion for both RA and PsA while RA+

patients show lower total vBMD at all timepoints. This separation was prominent in trabecular vBMD (Fig1A) trabecular microstructure (Fig1B) and biomechanics (Fig1C). Patients with PsA showed higher cortical vBMD and a numerically slower rate of cortical bone loss compared to RA (Fig1A) and a stable trabecular count (Fig1B). Patterns at the MCP region were grossly similar. Disease activity comparisons indicate deteriorating radial trabecular vBMD in PsA patients after 1 year under high disease activity and in all vBMDs in RA+ patients after 1 year including stiffness and failure load (Fig2A). TNF blockers, baricitinib and rituximab use improved bone density at the MCP in RA+ patients (Fig2B) , no particular pattern was discernible at the radius and for RA- and PsA.

Conclusion: Seropositive RA patients show worse bone density and microstructure across the board, which is also affected by disease activity, segregating from seronegative RA despite similar glucocorticoid use. Intervention with TNF-blockers, rituximab and baricitinib seem beneficial for bone density at the MCP, possibly indicating interception of local inflammation.

Glucagon-like peptide-1 receptor agonists therapy is associated in improvement in psoriatic arthritis-related and metabolic outcomes: A retrospective analysis of two cohorts

Lihi Eder[1], Uma Scher[2], Kyra Chen[3], Alexandra L. Rice[3], Sydney Thib[4] and Rebecca Haberman[5], [1]University of Toronto, Toronto, ON, Canada, [2]NYU School of Medicine, Scarsdale, NY, [3]NYU Grossman School of Medicine and NYU Langone Health Psoriatic Arthritis Center, New York, [4]Women's College Research Institute, Women's College Hospital, Toronto, Canada, [5]NYU Langone Health, New York, NY

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment II: Pathogenesis, Exercise, and Dietary Interventions (2687–2692)

Session Type: Abstract Session

Session Time: 11:30AM–1:00PM

Background/Purpose: Obesity is highly prevalent in psoriatic arthritis (PsA) and is associated with reduced therapeutic response, worse disease outcomes, and increased cardiometabolic risk. Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) are being increasingly used for weight loss and diabetes, but their impact on PsA outcomes remains unclear. We aimed to characterize patients with PsA initiating GLP-1 RAs and assess longitudinal changes in weight, psoriatic disease activity and cardiometabolic parameters.

Methods: We conducted a retrospective analysis of PsA patients from two academic cohorts (Toronto and NYU, PPACMAN sites) who initiated GLP-1 RAs (semaglutide, liraglutide, or tirzepatide) for weight loss or diabetes. Data from clinic visits within 1 year before and after GLP-1 RA initiation were extracted, including joint counts, skin involvement, enthesitis, CRP, and patient-reported outcomes. Disease Activity in PsA (DAPSA) scores were calculated. Cardiometabolic data (weight, blood pressure, lipids) were also collected. Within-patient changes were assessed using the Wilcoxon signed-rank test. Linear regression models, adjusting for baseline outcome values, were used to examine the association between percent weight change and change in outcomes.

Results: A total of 48 patients (18 Toronto, 30 NYU; median age 52.7 years; 60.4% female; median BMI 34.9, **Table 1**) were included. Cardiometabolic and other comorbidities were common: obesity (64.6%), diabetes (35.4%), hypertension (50%), cardiovascular disease (12.5%), fatty liver (20.8%), depression (39.6%), sleep apnea (35.4%), and osteoarthritis (27.1%). Sixty percent had ≥3 comorbidities. Significant weight loss was observed post-treatment (-6.43 kg (95% CI -9.5, -2.0), $p<$ 0.0001, **Table 2**), with 35.4% losing 5–10% and 25% losing >10% of their baseline weight. CRP levels decreased significantly (-1.1 mg/L (95% CI: -2.0, -0.2), p=0.002), as did pain scores (-1.0 (95% CI: -1.75, 0), p=0.01). DAPSA (-3.52, p=0.11) and patient global assessment (-0.5, p=0.08) showed numerical improvements. A significant reduction in triglycerides (-0.35 mmol/L, p=0.02) was also noted. Regression analyses revealed that each 1% reduction in body weight was associated with significant improvements in DAPSA (β=-0.49 (95% CI: -0.94, -0.03), **Table 3**), tender joint count (β=-0.18 (95% CI: -0.32, -0.05)), EQ-5D (β=0.0016 (95% CI: 0.008, 0.023)), LDL (β=-0.05 (95% CI: -0.10, -0.003)), and systolic blood pressure (β=-0.67 (95% CI: -1.18, -0.15)).

*Wilcoxon Signed-Rank test for paired samples

BSA - Body surface area of psoriasis; CRP- C-reactive protein; DAPSA - Disease activity in psoriatic arthritis; FACIT- Functional Assessment of Chronic Illness Therapy; HAQ-DI - health assessment questionnaire disability index; AST- alanine transaminase

Conclusion: In this initial analysis of a real-world study conducted in dual psoriasis-PsA PPACMAN clinics, GLP-1 RA therapy in patients with PsA was associated with clinically meaningful weight loss and improvements in systemic inflammation, pain, and cardiometabolic markers. Improvements in PsA outcomes were proportional to the degree of weight loss. These findings warrant further investigation in prospective controlled studies to evaluate the therapeutic role of GLP-1 RAs in PsA management and its frequent comorbidities.

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment II: Pathogenesis, Exercise, and Dietary Interventions (2687–2692)

Session Type: Abstract Session

Session Time: 11:30AM–1:00PM

Background/Purpose: The use of IL-23 inhibitors (IL-23i) for psoriatic diseases resulted in significant improvement in disease symptoms for many patients. Whether any blood immune cell profiles can predict clinical response to IL-23 blockade has not been examined, however. Here, we applied single cell RNA-seq immune profiling to blood samples from 27 PsO/A patients to identify cellular features associated with response to IL-23 blockade by tildrakizumab in the setting of a clinical trial.

Methods: PBMCs from psoriasis (n = 21) and psoriatic arthritis (n=6) patients were collected as part of the MINIMA study (NCT04271540) at Brigham and Women's Hospital before (following washout) and after 24 weeks of treatment with tildrakizumab. Patients currently had moderate or severe PsO. PASI scores were recorded before and after treatment, and % improvement of 50% or 70% was calculated. 48% of participants had a PASI improvement of 70% or greater, and 78% PASI improvement of 50% or greater. Table 1 denotes the disease characteristics and demographics of the patients. Single-cell RNA sequencing was conducted on baseline samples before treatment and on follow-up samples, followed by

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Description of patients included in the scRNAseq from the MINIMA trial.

Patients	Pre/Post paired samples	FollowUP	Female median (%)	Age median (range)	PsA	Medication	DeltaPASI median (range)	PASI improved by 50%	PASI improved by 70%
27		26~6mo	10(37%)	63(31-79)	6(22%)	Tildrekizumab (anti-P19)	-7.8 (-0.9--17.7)	21 (78%)	13 (48%)

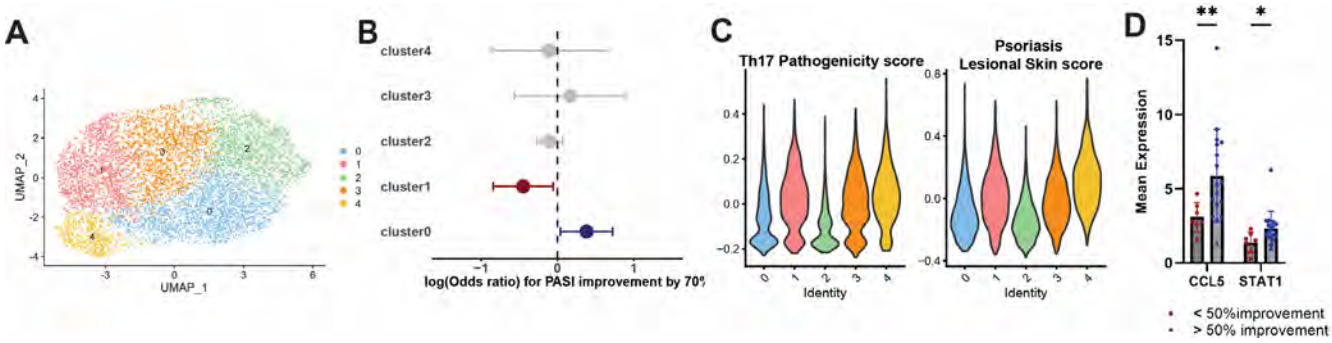

Figure 1. A) scRNAseq of PBMCs from IL-23i-treated patients, including cells from baseline (pre-treatment) and week 24 post-treatment samples (~136K cells). B) Mixed effects association of single cell analysis demonstrates a lack of association of PBMC clusters with pre- or post-IL-23i. C) CD4 T cells subset from PBMCs. D) IL23R, IL17A, and IFN expression in CD4 T cells.

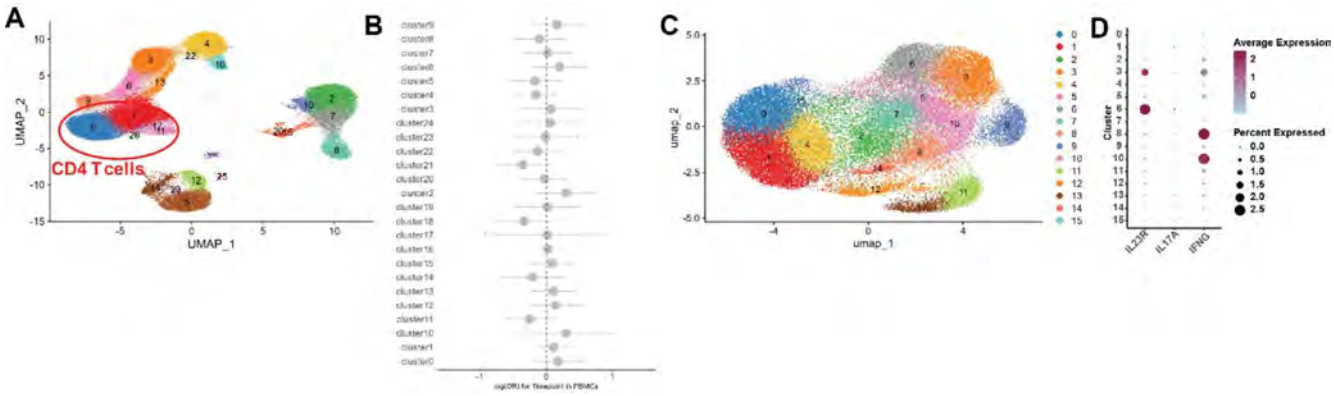

Figure 2. A) Subcluster of CD4+IL23R+ clusters. B) MASC analysis of pre-treatment samples demonstrating CD4+IL23R+ subclusters associated with baseline (pre-treatment) or week 24 (post-treatment). C) Module scores of genes that predict Th17 cell pathogenicity and genes highly expressed in psoriasis lesional skin. Both scores are higher in the better improvement-associated cluster than the lesser improvement-associated cluster. D) Mean expression of CCL5 and STAT1 in pre-treatment samples is higher in those who have greater than 50% improvement from IL-23i at week 24.

QC, batch correction, and unsupervised clustering. Analyses were performed using Wilcoxon paired tests, covarying neighborhood analysis (CNA), mixed effects association of single cell analysis (MASC), and differential gene expression analysis.

Results: We compared baseline samples from patients with greater or less than 70% improvement to identify baseline immune features associated with response. Assessment of PBMCs at a broad level did not reveal associations of any major immune cell populations with better or worse response to IL-23i. We then focused on T cell populations likely to be affected by IL-23i especially IL-23R+ T cells (**Fig 1**). The IL23R+ CD4 T cell had phenotypes consistent with Th17 and Th1 cells, including expression of IFNG, CXCR3, and IL17A, CCR6 and RORC. As a whole, the proportion of these cells in blood did not change following IL-23i. Further subcluster analysis of the IL23R+ CD4 T cell clusters revealed an association of a subcluster of cells with 70% clinical improvement and a separate subcluster of cells associated with lesser clinical improvement (**Fig 2**). Response-associated CD4+ T cells had a gene signature which corresponded to pathogenic Th17 cells (Hu et al,

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Nat. Commun. 2017). Additionally, patients with improvement >50% had higher expression of CCL5 and STAT1 in the IL23R+ CD4 T cells. To understand relevance of these cells to cells that are expanded in psoriasis skin, we applied a gene module score of genes associated with IFNg+ IL-17A+ cells from psoriasis skin (Kim et al, J. Allergy Clin. Immunol., 2021). This gene score was also higher in the response-associated cluster.

Conclusion: We have identified a subset of CD4+ T cells whose abundance in circulation before treatment is associated with response to IL-23i in skin disease severity. This T cell population demonstrates transcriptomic features that correspond to those expanded in psoriasis lesional skin. These results suggest that cellular features detectable in blood may be informative in predicting clinical response to IL-23 blockade.

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment II: Pathogenesis, Exercise, and Dietary Interventions (2687–2692)

Session Type: Abstract Session

Session Time: 11:30AM–1:00PM

Background/Purpose: Biologic therapies for moderate to severe psoriasis (PsO) include inhibitors of IL-17 (IL-17i), IL-23i, IL-12/23i, and tumor necrosis factor (TNFi). Previous studies that assessed whether biologic treatments can prevent inflammatory arthritis (IA; including PsA) in patients with PsO have not accounted for potential confounders such as PsO severity, PsA/IA-related therapy, and physician preference. This study compared incident PsA/IA among patients with PsO who newly initiated IL-17i, IL-23i, IL-12/23i, or TNFi therapy.

Methods: Adults with ≥2 PsO diagnosis codes (International Classification of Disease [ICD] codes) ≥30 days apart who newly initiated an IL-17i, IL-23i, IL-12/23i, or TNFi between January 1, 2019, and April 17, 2024 (index date = first record), were included in this retrospective cohort analysis of electronic health records (EHR). Exclusion criteria included missing age/sex information, any diagnosis code for IA (PsA or other IA) any time before or within 14 days after the index date, or NSAID prescriptions in 12 months prior to (pre-index period) or on the index date to mitigate protopathic bias. Patient demographics, clinical characteristics, past treatments, and comorbidities in the pre-index period or at index were descriptively reported. We used the Kaplan-Meier (KM) method to estimate the cumulative incidence of PsA or other IA during the follow-up period, and a 2-sample test with Greenwood plug-in estimator for variance to compare the area under the curve (AUC; ie, restricted mean time lost [RMTL]) between cohorts up to the last common time point. Propensity score matching (PSM) was used to attempt to balance covariates for each pairwise comparison. Covariates included key disease and demographic characteristics (including but not limited to those in **Table 1**) from both structured and natural language processing–derived EHR data.

Table 1. Baseline Demographics and Clinical Characteristics of Patients Treated with Interleukin-17, Interleukin-23, Interleukin 12/23, or Tumor Necrosis Factor Inhibitors[a,b]

Characteristic	IL-17i vs IL-23i		IL-17i vs IL-12/23i		IL-17i vs TNFi

Results: Before PSM, the most common biologics by class were secukinumab (IL-17i), risankizumab (IL-23i), ustekinumab (IL-12/23i), and adalimumab (TNFi; **Table 2**). After PSM, 1444 patients were included in the IL-17i vs IL-23i cohort, 765 patients were in the IL-17i vs IL-12/23i cohort, and 1476 patients were in the IL-17i vs TNFi cohort (**Table 1**). Patient demographics, past treatment, clinical characteristics, and mean times from PsO onset to index and follow-up were balanced across cohorts. KM analysis revealed a trend toward lower RMTL for time with PsA/IA through 57 months in patients treated with IL-17i vs IL-23i (P=.052; **Figure 1**). RMTL for time with PsA/IA through 57 months was significantly lower in patients treated with IL-17i vs IL-12/23i (P< .05) and in those treated with IL-17i vs TNFi through 58 months(P< .01). On average, patients treated with IL-17i had a 45% reduction in time with PsA/IA vs those treated with IL-23i, a 61% reduction in time with PsA/IA vs those treated with IL-12/23i, and a 74% reduction in time with PsA/IA vs those treated with TNFi over the available follow-up.

Conclusion: In this retrospective cohort analysis of EHR data employing PSM, patients with PsO treated with IL-17i had lower incidence of PsA/IA development through 5 years post-treatment initiation than patients treated with IL-23i, IL-12/23i, or TNFi therapies.

SESSION INFORMATION

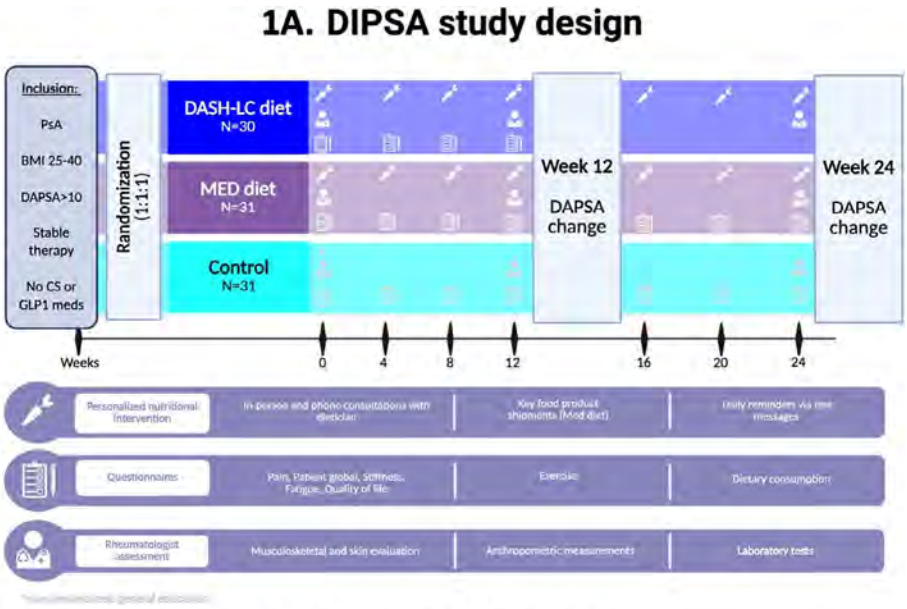
Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment II: Pathogenesis, Exercise, and Dietary Interventions (2687–2692)

Session Type: Abstract Session

Session Time: 11:30AM–1:00PM

Background/Purpose: The Dietary Interventions in Psoriatic Arthritis (DIPSA) study is a multicentre randomized controlled trial (RCT) designed to evaluate the efficacy of two personalized dietary interventions in improving clinical outcomes in patients with active psoriatic arthritis (PsA), compared to standard of care.



1B. Baseline variable of study participants

Variable	MED N=31	DASH-LC N=30	Control N=31
Age (mean, SD)	57 (13)	52 (13)	56 (13)
Sex: Female (N, %)	18 (58%)	22 (73%)	24 (77%)
Race: White (N, %)	25 (81%)	26 (87%)	23 (74%)
BMI (mean, SD)	32 (4.5)	34 (4)	32 (4.3)
DAPSA (mean, SD)	17 (7.2)	21 (15)	21 (8.8)
Tender joints (mean, SD)	6.2 (6.6)	8.7 (13)	7.7 (5.9)
Swollen joints (mean, SD)	0.7 (1.3)	1.5 (3.1)	1.7 (3.6)
Patient global (mean, SD)	5.1 (1.7)	5.2 (2.2)	5.4 (2)
Pain (mean, SD)	4.8 (1.9)	5.2 (1.9)	5.5 (2.1)
Physician global (mean, SD)	2.5 (1.3)	2.6 (1.6)	2.4 (1.6)
hsCRP (mg/L) (mean, SD)	4.9 (5.7)	5.1 (4.1)	4.2 (4.3)
PASI (mean, SD)	1.3 (2.4)	1.2 (1.7)	0.5 (0.8)

Figure 1: 1A. DIPSA study design, enrolment criteria and study procedures; 1B. Baseline characteristics by arm. BMI- Body mass area; DAPSA - Disease activity in Psoriatic Arthritis; PASI - Psoriasis Area and Severity Index

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Adults with moderately active PsA (Disease Activity index for PsA (DAPSA) >10), BMI 25–40, and stable drug therapy were recruited from 3 centres. Participants were randomized to one of 3 arms: (1) a Mediterranean (Med) diet focused on healthy food composition; (2) a low-calorie Dietary Approaches to Stop Hypertension (DASH-LC) diet targeting weight reduction; or (3) a standard-of-care control arm receiving general, non-personalized dietary advice. Interventions were delivered by registered dietitians through 2 in-person consultations and 7 structured telephone sessions. Clinical evaluations were performed at baseline, 12, and 24 weeks by rheumatologists. Patient-reported outcomes were collected from weeks 0 to 24. The primary outcome was change in DAPSA at week 12. Secondary outcomes included DAPSA change at week 24, as well as changes in pain, PROMIS fatigue, Psoriatic Arthritis Impact of Disease (PsAID), tender/swollen joint

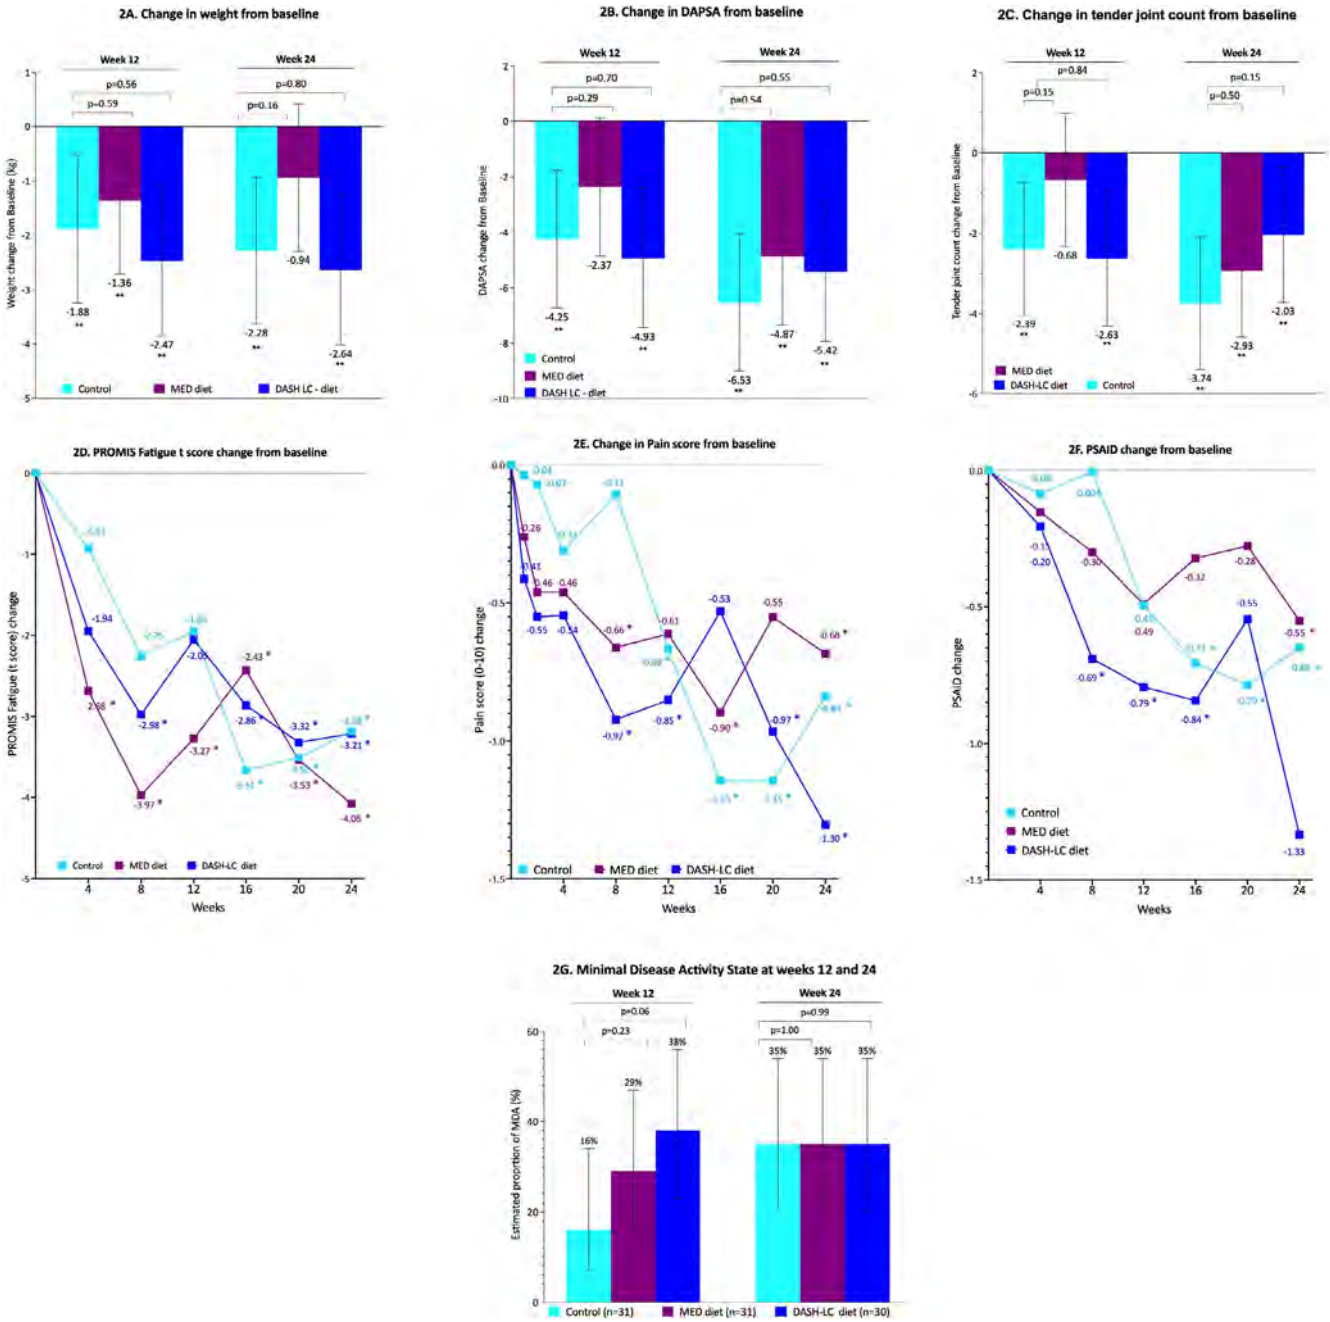


Figure 2: Change in study outcome by study arm. 2A. Weight; 2B. DAPSA; 2C. Tender joint count; 2D. PROMIS Fatigue (t score); Pain score; 2E. PSAID; Minimal Disease Activity state. * indicates p<0.05 compared to baseline. DAPSA - Disease activity in Psoriatic Arthritis; PSAID - Psoriatic Arthritis Impact of Disease.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 3. 3A-E. The correlation between study outcomes and weight change from baseline with splines; 3F-3J. The estimated mean change (95% CI) in study outcomes by the extent of weight reduction (none, <5% and >5% reduction in body weight) for each study arm.

counts, anthropometric measures, and inflammatory markers. Missing data were managed using last observation carried forward and multiple imputation. Changes across study arms and from baseline were assessed using random-effects regression models.

Results: Of 92 randomized patients (Med: n=31, DASH-LC: n=30, Control: n=31), 12 withdrew post-randomization. Baseline characteristics were comparable across arms (**Fig. 1**). All groups experienced significant, yet modest, weight loss by week 12 (Med: –1.36 kg; DASH-LC: –2.47 kg; Control: –1.88 kg, **Fig. 2A**), with small additional reductions by week 24. No significant differences in weight loss were observed between arms. At week 12, significant reductions in DAPSA were observed in the DASH-LC (–4.93) and control (–4.25) groups; by week 24, all groups showed improvement (Med: –4.87; DASH-LC: –5.42; Control: –6.53, **Fig. 2B**), without significant between-group differences. Minimal Disease Activity (MDA) was achieved at week 12 by 38% in DASH-LC and 29% in Med versus 16% in control (p=0.23 and p=0.06, respectively), though week 24 rates were similar across groups. Improvements in pain, fatigue, PsAID, and tender joint counts were observed across all arms (**Fig. 2C-G**). Notably, weight loss magnitude was significantly associated with improvement in clinical outcomes—including DAPSA, pain, fatigue, PsAID, and tender joint count—independent of treatment group (**Fig. 3**).

Conclusion: Both personalized dietary interventions and standard dietary advice led to modest weight loss and improvements in PsA disease activity. The degree of weight loss, rather than the specific dietary strategy, was the primary determinant of clinical benefit.

Abstract Number: 2691

Understanding the Impact of Overweight and Obesity on Treatment Response in Psoriatic Arthritis: Results from a Longitudinal Cohort Study

Pankti Mehta[1], Mu Yang[2], Virginia Carrizo Abarza[3], Fadi Kharouf[4], Richard Cook[2], Dafna D. Gladman[5], Vinod Chandran[6] and Denis Poddubnyy[7], [1]University of Toronto, Gladman Krembil Psoriatic Arthritis Research Program, Toronto, ON, Canada, [2]University of Waterloo, Waterloo, Canada, [3]University of Toronto, Toronto, [4]University Health Network and University of Toronto, Toronto, ON, Canada, Toronto, ON, Canada, [5]Schroeder Arthritis Institute, Krembil Research Institute, Toronto Western Hospital, Division of Rheumatology, Toronto, ON, Canada, [6]University of Toronto, Toronto, ON, Canada, [7]Division of Rheumatology, Department of Medicine, University Health Network and University of Toronto, Toronto, Ontario, Canada, and Department of Gastroenterology, Infectious Diseases and Rheumatology, Charité – Universitätsmedizin Berlin, Berlin, Germany; Department of Epidemiology, German Rheumatism Research Centre, Berlin, Germany

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment II: Pathogenesis, Exercise, and Dietary Interventions (2687–2692)

Session Type: Abstract Session

Session Time: 11:30AM–1:00PM

Background/Purpose: Overweight and obesity is associated with poor outcomes in Psoriatic Arthritis (PsA), with reduced odds of achieving minimal disease activity (MDA). Whether this effect is mediated by direct inflammation or psychosocial factors such as pain perception and mood remains unclear. This study aimed to assess the influence of body mass index (BMI) on components of treatment response in patients with PsA.

Methods: Patients with available body mass index (BMI) values were selected from a large longitudinally assessed PsA cohort followed from 1978. These patients are followed every six months with comprehensive documentation of demographic data, clinical and patient-reported outcomes, and treatment details.

Generalized estimating equations (GEE) were used to assess the association of BMI with MDA and its subcomponents, adjusting for age, sex, anxiety, depression, fibromyalgia, smoking, radiographic damage (modified Steinbrocker score), and use of TNFi and PDE4i.

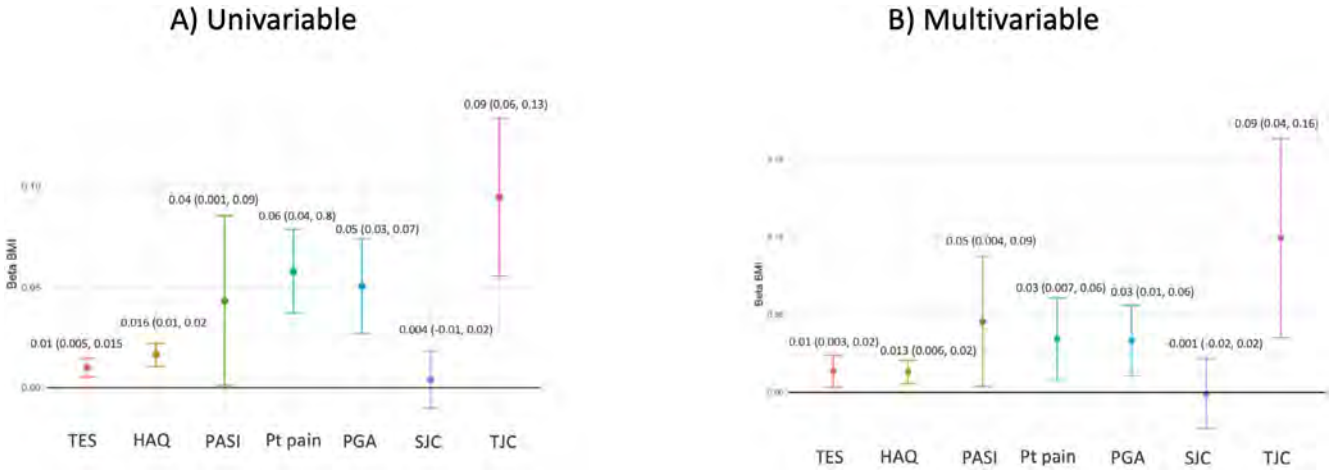

Figure 1: Association of BMI with components of MDA *TES: total entheseal score, HAQ- Health Assessment Questionnaire, Pt- patient, PGA- Patient Global Assessment, SJC_ Swollen Joint Count, TJC- Tender Joint Count

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

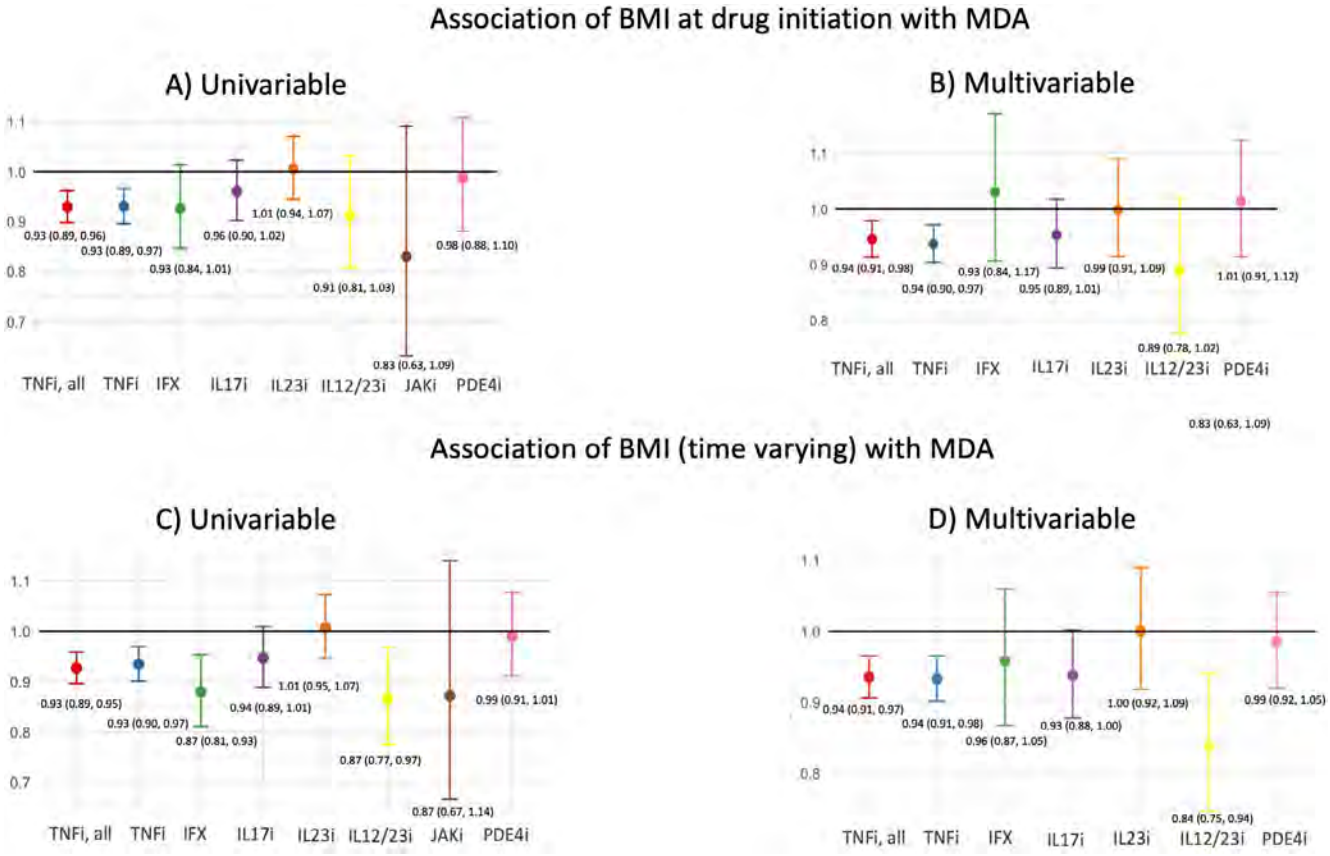

Figure 2: Drug-stratified analyses of BMI at drug initiation and BMI as a time time-varying variable with MDA *TNFi- Tumor Necrosis Factor, i- inhibitor, IL-interleukin, JAK- Janus Kinase, PDE4-Phosphodiesterase 4

We also evaluated the effect of baseline BMI at drug initiation and time-varying BMI (to incorporate effects of drugs on BMI) on treatment response across six drug classes (TNFi, IL-17i, IL-23i, IL-12/23i, JAKi, PDE4i) using univariable and multivariable GEE. The multivariable model was adjusted for age, sex, anxiety, depression, fibromyalgia, smoking, radiographic damage (modified Steinbrocker score), and line of treatment. Missing data were addressed using multiple imputation (MICE).

Results: Of 1291 patients included, the mean age was 44.9 (SD 13.3) years, and 55% were males. The mean BMI was 28.8 (SD 6.34) kg/m2. 428 patients received b- and/or tsDMARDs (40 patients - infliximab, 288 - other TNFis, 113 - IL17i, 36 - IL12/23i, 43 - IL23i, 14 - JAKi, and 30 - PDE4i).

Higher BMI was significantly associated with lower odds of achieving MDA [OR 0.95; 95% CI 0.94–0.97], and worse outcomes across multiple MDA subcomponents, including enthesitis, tender joint count, PASI, patient pain, global assessments, and HAQ, but not swollen joint count (Figure 1).

This association was sustained in the multivariable GEE analyses with reduced odds for MDA with increasing BMI [OR 0.96 (0.93-0.98) with similar effects on the subcomponents (Figure 1).

In drug stratified analyses, BMI at drug initiation was significantly associated with reduced MDA [0.93 (0.89-0.97)] in the TNFi group, and TNFi group excluding infliximab [0.93 (0.89-0.97)]. BMI did not impact the response across other drug groups. This association was sustained also in the multivariable analyses (Figure 2).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Obesity is independently associated with poorer treatment outcomes and reduced odds of achieving MDA in PsA, largely driven by subjective and skin-related domains. The impact appears most pronounced among patients treated with TNFis. These findings highlight the need for tailored therapeutic strategies in obese PsA patients and the potential importance of addressing psychosocial factors and weight management in clinical care.

Individualized Strength, Mobility and Aerobic Rehabilitation Training in axial Spondyloarthritis (iSMART in axSpA)

Sophie De Mits[1], Tine Willems[2], Lieven Danneels[2], Patrick Calders[2], Gaëlle Varkas[3], Filip Van den Bosch[4], Dirk Elewaut[5] and Philippe Carron[6], [1]Ghent University Hospital, Gent, Belgium, [2]Ghent University, Gent, Belgium, [3]Department of Rheumatology, Ghent University Hospital, Ghent, Belgium, [4]Department of Internal Medicine and Pediatrics, Ghent University and VIB Center for Inflammation Research, Ghent, Belgium, [5]VIB Center for Inflammation Research, and Ghent University Hospital, Department of Rheumatology, Ghent, Belgium, [6]Ghent University and VIB Center for Inflammation Research, Ghent, Belgium

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment II: Pathogenesis, Exercise, and Dietary Interventions (2687–2692)

Session Type: Abstract Session

Session Time: 11:30AM–1:00PM

Background/Purpose: AxSpA primarily affects the sacroiliac joints and spine, reducing trunk strength, mobility, and cardiorespiratory fitness. While exercise is a key treatment, few studies have examined combined trunk mobility and strength training with cardiorespiratory training. This prospective interventional study assessed the benefits of a combined and personalized exercise intervention based on baseline physical tests.

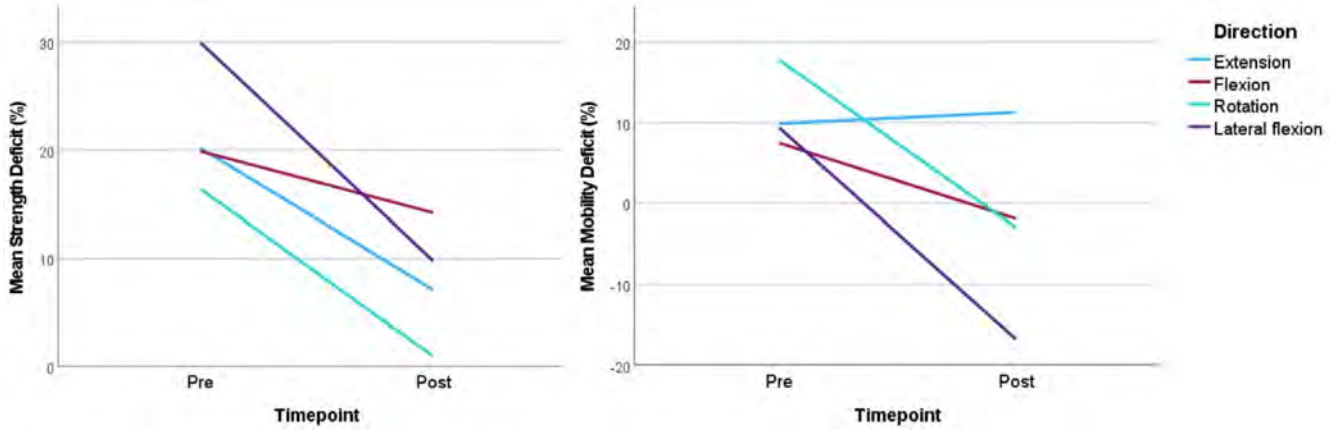

Fig.1: Mean strength (A) and mobility (B) deficit before and after the training program for the different directions.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1: cardiorespiratory parameters before and after intervention

	Pre		Post		Estimated time effect		
	Mean	SD	Mean	SD	Mean	95% CI	p-value
anaerobic threshold, % (VO2VT1/VO2pred)	58.1	17.7	72.2	21.6	13.81	5.40 – 22.23	0.002
oxygen pulse, % (VO2/HR)	12.9	3.5	14.4	3.4	1.39	0.48 – 2.31	0.004
ventilatory efficiency (VE/VCO2)	24.7	2.5	26.4	2.5	1.65	0.82 – 2.47	<0.001
respiratory condition, % (PeakVO2/VO2pred)	94.8	22.2	103	25.7	8.37	-2.63 – 19.36	0.13

Table 2: clinical parameters before and after intervention

	Pre		Post		Estimated time effect		
	Mean	SD	Mean	SD	Mean	95% CI	p-value
BASFI-score	2.8	2.2	2.4	2.1	-0.448	-0.974 – 0.079	0.092
BASDAI-score	3.5	2.1	2.9	2.2	-0.579	-1.066 – -0.092	0.021
Total BASMI score	2.0	1.1	1.8	1.0	-0.285	-0.574 – 0.004	0.053
Chest expansion	4.5	1.9	5	2.1	0.586	-0.060 – 1.231	0.073

Methods: Participants with AxSpA completed a baseline maximal Cardiopulmonary Exercise Test (CPET) and trunk strength/mobility tests using David Back Concept (DBC) devices. Strength and mobility deficits were calculated as: (Reference – Patient value) × 100 / Reference. BASDAI, BASFI, BASMI, and chest expansion (CE) were registered pre- and post-intervention. The 8-week program consists of two weekly sessions of two 10-minute intervals of cardiorespiratory training at a set heart rate (HR), followed by DBC device exercises. Cardiorespiratory intensity was based on ventilatory threshold 1 (VT1) and monitored via a Polar HR device. Trunk training focused on mobility and resistance using each patient's one-repetition-maximum and maximal range of motion at baseline. All sessions were supervised to ensure correct execution and safety. Post-intervention, CPET and DBC tests were repeated. Linear mixed models analyzed changes over time.

Results: Thirty axSpA patients (14M/16F, age 42±11.2 years; BASDAI 3.5±2.1, BASFI 2.8±2.2, BASMI 2.0±1.1, CE 4.5 ±2.0 cm) participated; 2 patients were lost to follow-up (1: flare, 2: personal reasons). Strength increased on average by 14.1% ($p< 0.001$), and mobility improved by 14.9% ($p< 0.001$) on average, with significant time and direction effects.(See Fig.1) Cardiorespiratory parameters improved significantly: oxygen pulse ($p=0.004$), ventilatory efficiency ($p< 0.001$), anaerobic threshold ($p=0.002$), and mechanical efficiency ($p=0.021$), but not efficiency slope ($p=0.888$). (See Table 1) BASDAI (2.9 ±2.2, $p=0.021$) and CE (5.0±2.1 cm, $p=0.020$) showed significant improvement, while BASMI (1.8±1.0, $p=0.053$) showed a borderline significant decrease and BASFI (2.4±2.1, $p=0.092$) did not differ significantly. (See Table 2)

Conclusion: A combined, individually tailored exercise program, dependent on baseline objectively measured physical parameters, significantly improved cardiorespiratory fitness, trunk strength, and mobility in AxSpA patients. These results support the role of individualized exercise interventions in enhancing patient outcomes and reducing functional limitations.

CAR T-cell Therapy in SLE: A Systematic Review

Alberto Nordmann-Gomes[1], Leila Khalili[2], Wei Tang[3], Laura Geraldino-Pardilla[4], Yevgeniya Gartshteyn[5], Robert Clancy[4], Stephen Suh[6], Maya Souvignier[6], Michel Sadelain[6] and Anca Askanase[2], [1]Columbia University Irving Medical Center, New York, NY, [2]Columbia University Medical Center, New York, NY, [3]Westchester Medical Center, Valhalla, NY, [4]Columbia University, New York, NY, [5]Columbia University Medical Center, Glen Rock, NJ, [6]Columbia University Irving Medical Center, New York City, NY

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Systemic Lupus Erythematosus – Treatment II (2693–2698)

Session Type: Abstract Session

Session Time: 11:30AM–1:00PM

Background/Purpose: CAR T-cell therapy is poised to revolutionize the treatment of systemic lupus erythematosus (SLE). Recently, several authors have reported their experience using CAR T-cell therapy for patients with SLE; nonetheless, all studies are limited by a reduced sample size. Here, we review and summarize the available clinical evidence published or presented to date on the use of CAR therapy in SLE.

Methods: We conducted a systematic review to evaluate all clinical studies assessing safety and efficacy outcomes of CAR therapy in SLE. MEDLINE (PubMed), Embase, Scopus, and CENTRAL were consulted, as well as the ACR Convergence 2024 Archives.

Results: The search strategy yielded 4,943 results, of which 14 studies were included in the analysis (including 8 from the consulted databases and 6 from the 2024 ACR Archives). The studies had a combined population of 98 participants. All studies included patients with refractory and active SLE who had failed at least 2 immunosuppressive therapies. Most studies (n=12 [85%]) used a CD19-targetted CAR, with only 2 groups (15%) assessing bispecific CD19-BCMA CAR T-cells. Two studies (15%) evaluated allogeneic CAR products. All groups reported successful B-cell depletion, typically achieved within 1–3 weeks, and B-cell reconstitution was observed after 2-3 months by most groups. Pooled analysis of the 63 individual SLEDAI scores available showed a median decrease in SLEDAI of 6 points (IQR: 3.5 - 8.5) at month 1, 8 points (IQR: 6 -

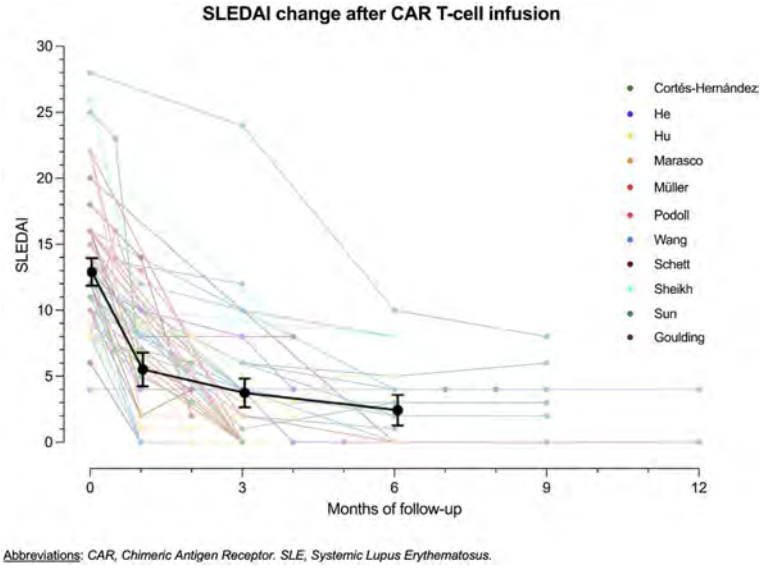

Figure 1. SLEDAI reduction in studies evaluating CAR T-cell therapy in patients with SLE

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Safety outcomes of CAR T-cell therapy in patients with SLE

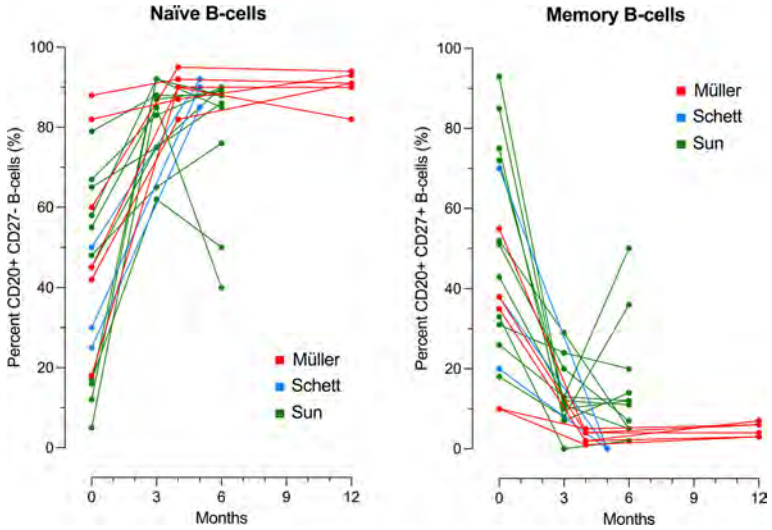

Figure 3. B-cell phenotypes after CAR T-cell infusion in patients with SLE

9.3) at month 3, and 8 points (IQR: 6 - 12) at month 6. The mean baseline SLEDAI of 12.8 (95% CI 11.7-13.8) decreased to 3.6 (95% CI 2.5-4.7), and 2.3 (95% CI 1.1-3.5) after 3 and 6 months; respectively. Thirty-one (48%) patients had a SLEDAI score of 0 at their last follow-up, and 59 (91%) had a score of 4 or less. There was no difference in efficacy between autologous vs allogeneic products, or between CD19-targeted vs CD19- and BCMA-targeted therapies. Cytokine release syndrome (CRS) occurred in 56 (57%) participants, of which 50 (89%) were grade 1, 5 (9%) grade 2, and 1 (2%) grade 3. Immune effector cell-associated neurotoxicity syndrome (ICANS) was reported in 3 patients (3%), 1 grade 1, 1 grade 3, and 1 grade 4. Twenty-one patients (21%) developed infections, of which six (28%) were severe. Severe (grade 3 or 4) and prolonged (>28 days) hematologic toxicity was observed in 17 (17%) and 8 (8%) patients; respectively. Among the 5 studies analyzing B-cell phenotypes, all reported a marked increase in naïve B-cell populations (CD20+, CD27–) alongside a significant reduction in memory B-cells (CD20+, CD27+). Among the 40 patients in which serum biomarkers were measured, anti-dsDNA levels decreased in 36 (90%) patients and normalized in 29 (73%). Complement levels normalized in 37 (93%) patients.

Conclusion: This systematic review showed consistent efficacy with decrease in SLEDAI from 12.8 at baseline to 2.3 at 6 months after CAR T-cell. CRS and ICANS were milder and less frequent than expected from oncology data. The findings further support the efficacy and safety of this treatment modality while highlighting the need for additional research to better define its role in SLE management.

Effect of Deucravacitinib Treatment on Renal Dysfunction–Associated Plasma Biomarkers From a Phase 2 Study in Patients With Systemic Lupus Erythematosus

Amit Saxena[1], Chun Wu[2], Brad Rovin[3], Zahi Touma[4], Xueer Chen[5], Ilias Kouris[6] and Jinqi Liu[5], [1]Division of Rheumatology, Department of Medicine, NYU Grossman School of Medicine, New York, NY, [2]Bristol Myers Squibb, Princeton, [3]The Ohio State University, Columbus, OH, [4]University of Toronto, Toronto, ON, Canada, [5]Bristol Myers Squibb, Princeton, NJ, [6]Bristol Myers Squibb, Boudry, Switzerland

SESSION INFORMATION
Session Date: Wednesday, October 29, 2025
Session Title: Abstracts: Systemic Lupus Erythematosus – Treatment II (2693–2698)
Session Type: Abstract Session
Session Time: 11:30AM–1:00PM

Background/Purpose: Plasma biomarkers may play a role in understanding kidney health in patients with lupus, particularly in terms of early detection of lupus nephritis (LN), monitoring for disease progression, and predicting treatment responses. Deucravacitinib is a first-in-class, oral, selective, allosteric tyrosine kinase 2 (TYK2) inhibitor that has shown clinical efficacy in the 48-week, double-blind, placebo-controlled, phase 2 PAISLEY SLE study (NCT03252587).[1] In this post hoc analysis, we investigated circulating proteins associated with kidney dysfunction at baseline (BL) by analyzing proteomic profiles of patients with higher BILAG renal scores and urine protein-to-creatinine ratios (UPCRs) in PAISLEY SLE and assessed the impact of deucravacitinib on these biomarkers throughout the course of the study.

Methods: Patients with SLE were randomized 1:1:1:1 to placebo (n = 90) or deucravacitinib 3 mg twice daily (BID; n = 91), 6 mg BID (n = 93), or 12 mg once daily (n = 89). Proteomic profiles of 1187 clinical samples, collected longitudinally from 351 patients at BL and 268 patients at W12, W32, and W48, were evaluated using Olink Explore HT assays. Using DREAM, genome-wide statistical analyses were conducted to identify differentially expressed proteins associated with a higher BILAG renal score and UPCR at BL and W32. Pharmacodynamics in the intent-to-treat population were analyzed using linear mixed-effects models adjusted for stratum and batch. Pathway enrichment analyses using the Gene Ontology database identified biological pathways that were significantly represented among differentially expressed proteins. Protein biomarkers associated with low estimated glomerular filtration rate (eGFR) identified at BL in the phase 3 abatacept LN study (NCT01714817) were also evaluated for changes throughout the PAISLEY SLE study.

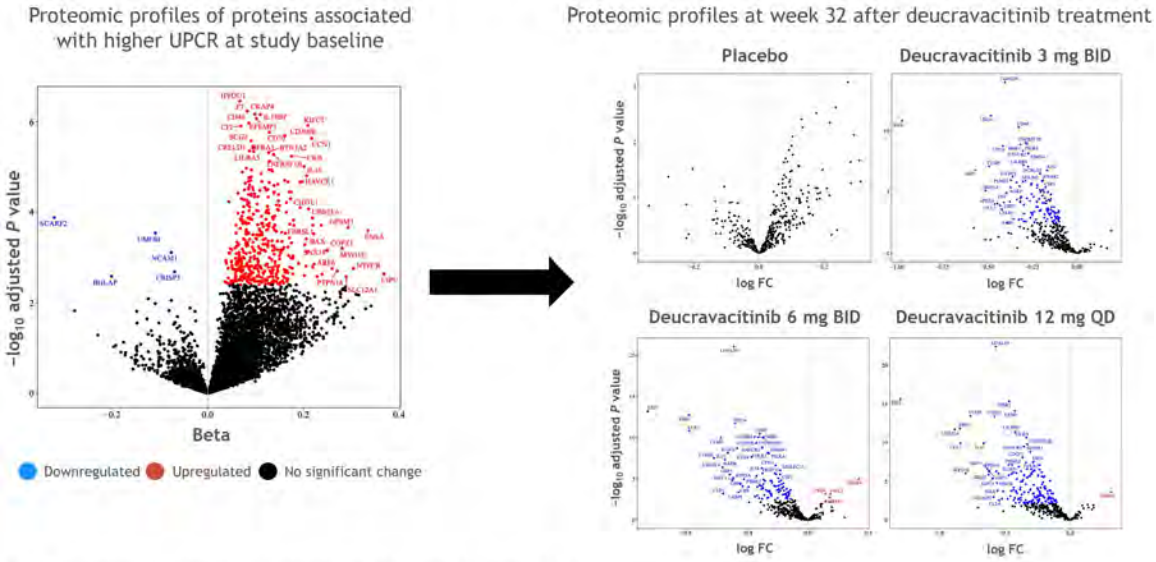
Figure 1. Identification of dysregulated plasma proteins associated with higher UPCR at baseline and the effects of deucravacitinib treatment at week 32 for patients treated in the phase 2 PAISLEY SLE study



Cutoff criteria at BL and week 32 were determined by an adjusted $P < 0.05$.
BID, twice daily; BL, baseline; FC, fold change; QD, once daily; UPCR, urine protein-to-creatinine ratio.

Figure 1. B-cell phenotypes after CAR T-cell infusion in patients with SLE

Results: Plasma proteins significantly associated with higher BILAG renal scores (n = 72) or UPCR (n = 420) were identified; pathway analyses indicated dysregulated immune responses, including leukocyte activation, cytokine production, and cell adhesion regulation. At W32, deucravacitinib vs placebo significantly reduced expression of several biomarkers (eg, CD27, AXL, EPHB6, IL-18BP) associated with higher BILAG renal domain score at BL. Similarly, deucravacitinib significantly

Figure 2. Biomarkers associated with abnormal eGFR at baseline in the abatacept phase 3 lupus nephritis study and effects of deucravacitinib treatment on these biomarkers in patients treated in the phase 2 PAISLEY SLE study

Biomarkers associated with abnormal eGFR in patients with LN treated in the abatacept phase 3 trial (NCT01714817)

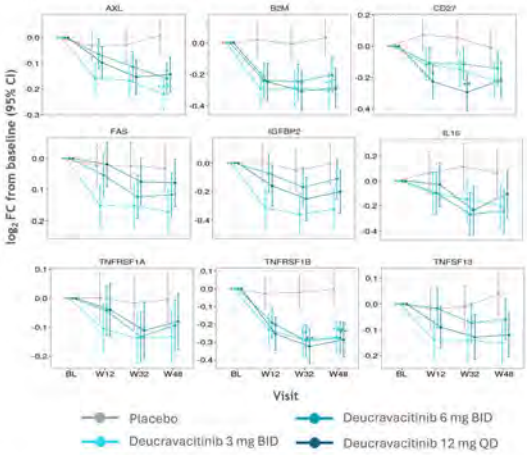
Reduction of representative LN-relevant biomarkers with deucravacitinib treatment in the phase 2 PAISLEY SLE study



Analytes with eGFR ρ > 0.25 and adjusted $P < 0.05$ are shown. The BH method was used to correct for multiple comparisons for *P* values.
*Adjusted $P < 0.05$; **Adjusted $P < 0.01$; ***Adjusted $P < 0.001$ vs placebo; error bars denote the 95% CI.
BH, Benjamini-Hochberg; BID, twice daily; eGFR, estimated glomerular filtration rate; FC, fold change; LN, lupus nephritis; QD, once daily; SLE, systemic lupus erythematosus; W, week.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

reduced expression of biomarkers associated with increasing UPCR at W32 vs placebo (**Figure 1**). Furthermore, biomarkers negatively associated with eGFR in the abatacept LN study were reduced with deucravacitinib vs placebo (**Figure 2**).

Conclusion: Deucravacitinib treatment demonstrated significant reduction of proteins associated with renal dysfunction in patients treated in the PAISLEY SLE study. Further investigation of the effects of deucravacitinib on renal biomarkers and attenuation of renal disease progression in the phase 3 POETYK SLE-1 and SLE-2 studies is warranted.

Background/Purpose: Advanced protein-based therapies targeting B-cells, including glycoengineered CD20 monoclonal antibody obinutuzumab (OBI) and the CD19/CD3 T-cell engager blinatumumab (BLI), show promise for managing severe autoimmune diseases (AIDs). These innovative agents are believed to offer more effective B-cell depletion compared to rituximab (RTX), potentially enabling the elimination of B-cells within affected tissues.

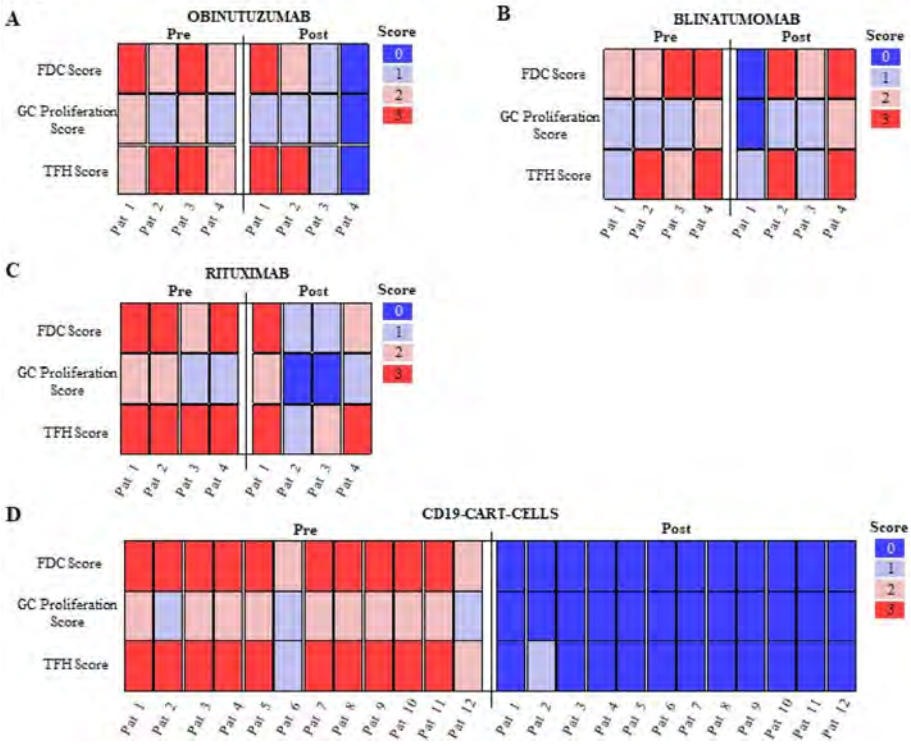
Methods: We performed sequential US-guided inguinal lymph node (LN) biopsies before and after OBI-, BLI-, RTX- and CD19 chimeric antigen receptor T-cell treatment (CAR) in AID patients. Immunohistochemistry (IHC) staining was performed to quantify the number of B cells, plasma cells, follicular dendritic cells (FDCs), follicular T helper cells (TFH), proliferating germinal centre B cells, T cells and macrophages.

Results: Baseline and follow-up LN biopsies from 24 AID patients (7 SLE, 7 SSc, 4 Idiopathic Inflammatory Myositis [IIM], 6 RA) were analysed. Four patients received OBI (3 SLE, 1 IIM), 4 BLI (4 RA), 4 RTX (2 IIM, 2 RA) and 12 CAR (4 SLE, 7 SSc, 1 IIM).

Peripheral blood B-cell depletion occurred in all but one BLI-treated patient.

IHC quantification of B cells in LNs by CD19 and CD20 staining was performed. In all 12 CAR-treated patients, B cells were completely depleted (p-value for CD19+ and CD20+ cell before vs after CAR = 0.0005). In contrast, in all but one (OBI-treated) patients, B cells were not depleted. OBI showed robust (CD20+: -92%; CD19+: -96%) LN reduction of B-cells. Reduction was less pronounced in BLI-treated patients (CD20+: -69%; CD19+: -47%) and RTX- treated patients (CD20+: -86%; CD19+: -86%). CD138+ plasmablast/plasma depletion was incomplete across all treatments: CAR -59%, OBI -54%, RTX -32% and BLI -7%.

Figure 1



Heatmap scoring of follicular dendritic cell (FDC) score, germinal centre proliferation score (GC proliferation score) and the T follicular helper cell score (TFH score) for each treatment.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Changes in the follicular structure in the LNs were also assessed, including the number of CD23+ FDCs, PD-1+ TFH cells and the proliferation rate in the follicles (Ki67+) before and after treatment. These data were integrated into a combined B-cell compartment architecture score (score range 0 – 9). In all CAR-treated patients the follicular LN architecture was completely disrupted (median B-cell compartment score post-treatment [IQR]: 0.0 [0 – 0]). Among patients treated with protein-based B-cell depleting agents, only one (OBI-treated) exhibited dissolution of the follicular architecture in the LNs, while all others retained some degree of follicular structure. In OBI-treated patients the median [IQR] B-cell compartment score was 4.5 [0.75 – 6.75], in the BLI-treated patients 5.5 [1.75 – 7.75] and RTX- treated patients 4.5 [2.25 – 7.5], all showing maintained follicular structures (Figure 1). Neither T-cell nor macrophages numbers were affected by any of the B-cell targeted treatment agents. Complete depletion was associated with stable drug-free remission, while incomplete depletion required re-treatment with immunomodulatory drugs.

Conclusion: Protein-based B-cell depletion reduces but rarely deplete B cells in LNs leaving the follicular architecture intact and being associated with disease recurrence, whereas CAR ensures consistent full B-cell depletion and follicular structural disruption enabling sustained remission.

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025
Session Title: Abstracts: Systemic Lupus Erythematosus – Treatment II (2693–2698)
Session Type: Abstract Session
Session Time: 11:30AM–1:00PM

Background/Purpose: Current evidence suggests that B cell depletion through CD19-directed chimeric antigen receptor T cell (CAR-T) therapies may offer promise in improving outcomes in severe refractory systemic lupus erythematosus (srSLE).[1] YTB323 (rapcabtagene autoleucel) is a rapidly manufactured, autologous CD19 CAR-T therapy that is also being investigated in hematological malignancies.[2] Herein, we report interim biomarker data from a phase 1/2 open-label study investigating YTB323 in patients with srSLE.[3]

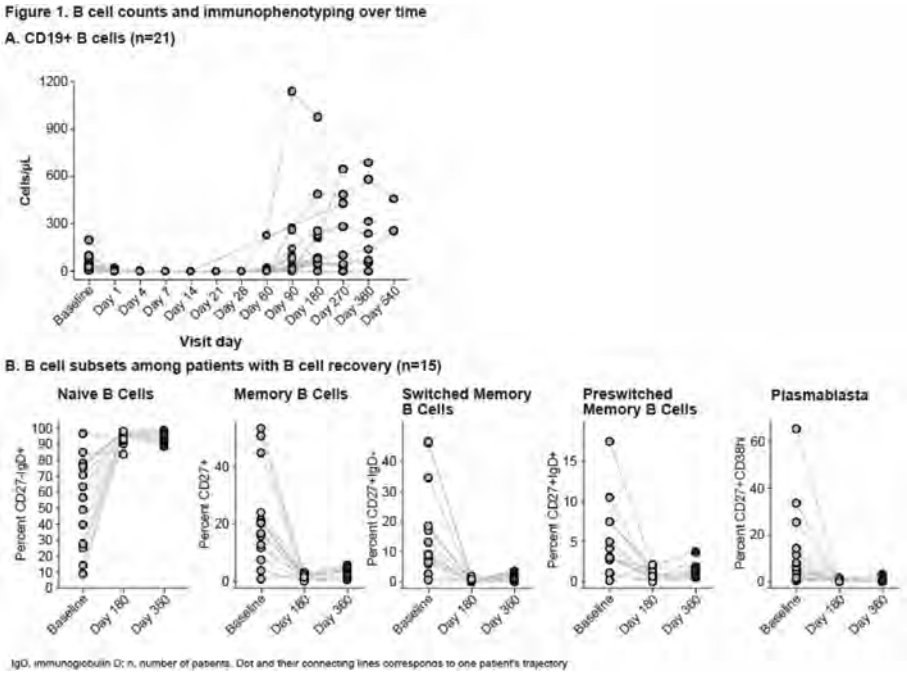
Methods: This ongoing open-label, single-arm, multicenter phase 1/2 study (NCT05798117) assesses the safety, efficacy and cellular kinetics of YTB323 in patients with srSLE (defined as SLE Disease Activity Index 2000 [SLEDAI-2K] ≥8 with major organ involvement, having failed ≥2 standard immunosuppressive therapies and ≥1 biological agent).[3] YTB323 treatment was administered as a single dose of 12.5×10^6 CAR-positive viable T cells, following lymphodepletion. Cellular kinetics, quantified by polymerase chain reaction and flow cytometry, and biomarkers, measured by transcriptome analysis, were assessed. Assessments of B cell counts and B cell subsets after recovery were monitored via flow cytometry.

Table 1. Patient baseline characteristics (n=21)

Age, years, mean (SD)	36.6 (10.60)
Female sex, n (%)	19 (90.5)
SLE duration, years, mean (SD)	13.6 (8.07)
SLEDAI -2K at baseline, mean (SD)	14.1 (5.37)
Duration of follow-up, months, mean (SD)	11.2 (4.50)

n, number of patients; SD, standard deviation; SLE, systemic lupus erythematosus; SLEDAI-2K, SLE disease activity index 2000

Figure 1. B cell counts and immunophenotyping over time



IgD, immunoglobulin D; n, number of patients. Dot and their connecting lines corresponds to one patient's trajectory

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Changes in type I IFN inducible gene expression (21-IFNGS) after YTB323 treatment, (n=10)

The lower and upper hinges of each box correspond to the first and third quartiles (25th and 75th), respectively; Black horizontal line in each box corresponds to the median 21-IFNGS expression.
The upper whisker extends from the hinge to the largest value no further than 1.5 * IQR from the hinge (where IQR is the inter-quartile range, or distance between the first and third quartiles).
The lower whisker extends from the hinge to the smallest value at most 1.5 * IQR of the hinge.
The individual dots correspond to the median normalized expression of the 21 IFN gene signature.
Each dot corresponds to one patient

CPM, counts per million; FC, fold change; IFN, interferon; IFNGS, interferon gene signature; IQR, interquartile range, n, number of patients

Results: Data from all enrolled patients in the study (n=21) were analyzed. At baseline, mean (standard deviation [SD]) age was 36.6 years (10.6), and 90.5% of patients were female. The mean (SD) duration of follow-up was 11.2 months (4.5; **Table 1**). Cellular kinetics and pharmacodynamics data revealed peak expansion of CAR-T cells (median time to peak concentration [Tmax]) 2 weeks post-infusion and median time of clearance from peripheral blood of 2 months. YTB323 treatment induced a rapid, complete, and sustained depletion of CD19-positive B cells, with subsequent B cell recovery occurring at a median of 90 days post-infusion (**Figure 1A**). Analysis of B cell subsets at days 180 and 360 in patients with B cell recovery (n =15) showed that returning B cells had a predominantly naïve phenotype (CD27-IgD+), with a decrease in the proportion of other B cell subsets (**Figure 1B**). Expression of type I interferon (IFN) inducible genes was downregulated after YTB323 treatment (n =10; **Figure 2**).

Conclusion: Interim biomarker data from this phase 1/2 trial show complete CD19 B cell depletion and IFN pathway suppression, followed by repopulation with a naïve B cell phenotype. These findings support the concept of an immune "reset" of the B cell compartment via CD19 CAR-T therapy in srSLE.

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Systemic Lupus Erythematosus – Treatment II (2693–2698)

Session Type: Abstract Session

Session Time: 11:30AM–1:00PM

Background/Purpose: Tacrolimus (TAC) and glucocorticoid as continuous induction-maintenance therapy for lupus nephritis (LN) has never been investigated. We conducted a prospective randomized open-label multicenter study to evaluate its efficacy and safety against standard-of-care mycophenolate mofetil (MMF) and glucocorticoid dual immunosuppression in Asian patients with active severe LN.

Methods: Patients with biopsy-proven Class III/IV±V LN were randomized to receive pulse methylprednisolone (500mg/500mg/150mg) for 3 days followed by oral prednisolone (0.7 mg/kg/day, then taper) in combination with either TAC (initial dose 2 mg bid; target trough level 6-8 ng/mL) or MMF (1 g bid), then followed for 96 weeks. Primary endpoint was sustained renal response (SRR) [defined as proteinuria reduced by $\geq$50% compared with baseline and 24-hr urine protein < 1 g and serum creatinine not higher than 15% above baseline and no disease flare or rescue therapies] at Week 96.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Sustained renal response (SRR) rate in patients with active lupus nephritis treated with tacrolimus (TAC) or mycophenolate mofetil (MMF) in combination with glucocorticoid.

Key secondary endpoints included rates of complete renal response (CR), adverse events, and time-to-renal related adverse events/death.

Results: A total of 130 patients were randomized (65 in each group). TAC and MMF treatment groups showed similar rates of SRR (58.5% vs. 69.2%, OR 0.62; 95% CI 0.29-1.29; p=0.2) and CR (55.4% vs. 63.1%, OR 0.72; p=0.36) at Week 96. SRR rates for TAC and MMF groups were 53.8% vs 52.3% at Week 24, and 63.1% vs. 66.2% at Week 48 respectively (Figure 1). Time-to-renal related adverse events/death were similar in both groups (HR 0.70; 95% CI 0.37-1.35; p=0.29). Overall adverse event rates were 69.2% and 70.8% in TAC and MMF groups respectively (p=1.00), while serious adverse events were more frequent in the MMF group (12.3% vs. 30.8%, p=0.02). Acute kidney injury (16.9% vs. 3.1%) and tremor (16.9% vs. 0%) were more frequent in TAC-treated patients, while leucopoenia (1.5% vs. 12.3%) was more frequent in the MMF group. Three patients in the MMF group died.

Conclusion: Immunosuppressive regimen with TAC combined with glucocorticoid showed comparable efficacy as MMF with glucocorticoid, as continuous induction-maintenance treatment for active LN over 96 weeks, with similar overall adverse event rate but different safety profile between the two treatments.

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025
Session Title: Abstracts: Systemic Lupus Erythematosus – Treatment II (2693–2698)
Session Type: Abstract Session
Session Time: 11:30AM–1:00PM

Background/Purpose: The efficacy of calcineurin inhibitors in the induction treatment of lupus nephritis (LN) has been increasingly supported by recent studies. Based on these findings, current guidelines recommend a combination of tacrolimus (TAC), mycophenolate mofetil (MMF), and glucocorticoids (GC) as an option for the first-line induction therapy. However, several studies have also demonstrated that TAC + GC therapy is effective for induction therapy, with favorable safety profile. Therefore, our study aimed to compare the efficacy of TAC + GC versus TAC + MMF + GC for remission induction in patients with proliferative LN.

Methods: This multicenter retrospective cohort study, designed as a target trial emulation, included patients with biopsy proven proliferative LN who received either TAC + GC or TAC + MMF + GC as induction therapy between September 2007 and July 2023. Based on the induction regimen, patients were classified into the TAC + GC and TAC + MMF + GC groups. The primary outcome was 12-month total renal response, defined as achieving either complete or partial renal response after 12 months. To address the baseline imbalances between the two groups, inverse probability of treatment weighting (IPTW) was applied. The comparative efficacy of TAC + MMF + GC compared to TAC + GC was estimated by

Table 1

Table 1. Baseline characteristics of the study population.

	Original population			IPTW-adjusted population		
	TAC+GC (n=48)	TAC+MMF+ GC (n=67)	SMD	TAC+GC (%)	TAC+MMF+ GC (%)	SMD
Age, year	35.6 ± 12.0	31.5 ± 11.2	0.356	33.4 ± 11.2	33.2 ± 12.6	0.017

Figure 1. Serial change of albumin, GFR, and UPCR in the study population

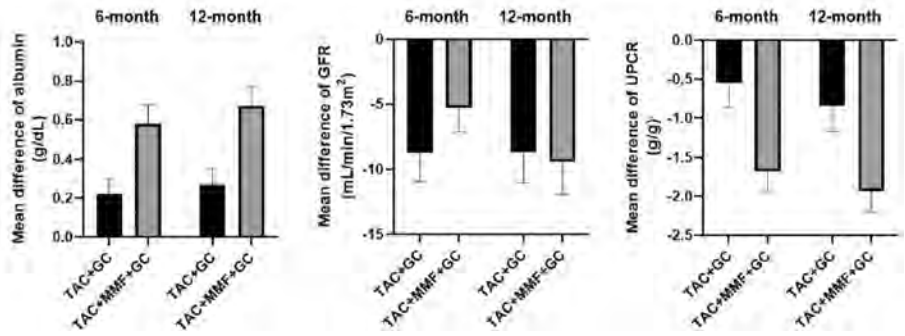

Figure 1

Table 2

Table 2. Comparative efficacy of TAC + MMF + GC regimen compared to TAC + GC regimen

	As-started analysis[a]			On-treatment analysis[b]		
	TAC+GC (n=48)	TAC+MMF+ GC (n=67)	p	TAC+GC (n=40)	TAC+MMF+ GC (n=55)	p
12-month TR, n (%)	16 (33.3)	40 (59.7)	0.009	16 (40.0)	40 (72.7)	0.003
12-month TR, OR[c] [95% CI]						
Crude	2.96 [1.38-6.54]		0.006	4.00 [1.71-9.75]		0.002
IPTW-adjusted	2.85 [1.32-6.33]		0.010	3.01 [1.29-7.23]		0.014

CI, confidence interval; CR, complete renal response; GC, glucocorticoid; IPTW, inverse probability treatment weighting; MMF, mycophenolate mofetil; OR, odds ratio; TAC, tacrolimus; TR, total renal response.
[a], analogous to intention-to-treat approach
[b], analogous to per-protocol approach
[c], OR is calculated using the TAC + GC group as the reference

using binary logistic regression, based on both as-started (corresponding to intention-to-treat) and on-treatment (corresponding to per-protocol) analyses.

Results: A total of 115 patients (48 in TAC + GC group and 67 in TAC + MMF + GC group) were included in the analysis. The baseline characteristics of the study population is shown in Table 1. The 12-month total renal response was achieved in 16 (33.3%) patients in the TAC + GC group and 40 (59.7%) patients in the TAC + MMF + GC group. Both groups showed improvements in serum albumin and proteinuria, while renal function declined (Figure 1). Compared to the TAC + GC group, the TAC + MMF + GC group showed significantly higher 12-month total renal response in both as-started and on-treatment analyses (Table 2). Adverse drug reactions occurred in 7 (14.6%) patients in the TAC + GC group and 11 (16.4%) patients in the TAC + MMF + GC group.

Conclusion: Compared to TAC + GC, TAC + MMF + GC therapy showed significantly higher renal response and comparable adverse drug reactions in patients with proliferative LN. These findings support TAC + MMF + GC as the preferred TAC-based induction regimen for proliferative LN.

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders II (2699–2704)

Session Type: Abstract Session

Session Time: 11:30AM–1:00PM

Background/Purpose: Immunoglobulin A vasculitis (IgAV) is a small vessel vasculitis marked by IgA, deposition, palpable purpura with lower body predilection and variable joints, kidney and gastrointestinal tract involvement. In 2018, the addendum to the 2012 Chapel Hill Consensus Conference established the recognition of an exclusively or predominantly cutaneous form of the disease, more common in adults. Despite its frequency, standardized management of cutaneous IgA vasculitis remains elusive. The objective of this study was to compare colchicine, dapsone and glucocorticoids (GCs) to induce remission in newly diagnosed or relapsing skin-limited/dominant IgA vasculitis.

Methods: Patients with cutaneous IgAV treated with colchicine, dapsone, or GCs were included between January 1, 2014, and May 1, 2024. Data were collected retrospectively from 38 tertiary centers across eight countries in Europe. Inclusion criteria were age >8 years, biopsy-proven diagnosis of IgAV with evidence of IgA deposition in the skin and/or other organs, newly diagnosed or relapsing IgAV with active skin manifestations; absence of severe organ involvement; and a minimum follow-up of 3 months. The primary endpoint was to evaluate the proportion of patients achieving sustained remission of cutaneous involvement at day 90 (SRD90). Treatments were compared pairwise using inverse probability treatment weighting with the propensity score to adjust for confounders. Variables differing between responders and non-responders and susceptible to be associated with the endpoint were included in the propensity score. Patients receiving multiple therapies were counted per treatment line. Missing data were addressed with multiple imputation by chained equations.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Of the 407 cases identified, 208 patients (114 males, 89 females; median age 44.9 years) were included in the study. Most were enrolled at initial diagnosis (174). At day 90, 109 patients (52.4%) had achieved sustained remission of cutaneous involvement. A total of 164 patients contributing to 216 therapeutic lines were analysed: 113 corresponded to colchicine, 83 to GCs, 20 to dapsone. Variables included in the propensity score were age at diagnosis, gender, necrotic lesions, myalgia and number of therapeutic lines. In the univariate analysis, no significant difference but trends were observed in the proportion of patients with SRD90 when comparing GCs vs colchicine (odds ratio [OR] 1.77 95% CI [0.97 - 3.20], p=0.059) and GCs vs dapsone (OR 1.82 95%CI [0.67 - 4.93], p=0.235). No difference was observed between colchicine and dapsone (OR 0.55 95% CI [1.68 - 5.15], p=0.360]). After weighting, GCs vs. colchicine showed balanced covariates (standardized mean differences < 0.10) and the proportion of SRD90 in the GCs group was higher (OR 1.88, 95%CI [1.04 - 3.41], p=0.034). No balance was achieved in comparisons involving dapsone due to low sample size.

Conclusion: GCs were significantly associated with a more favorable outcome than colchicine in achieving sustained remission of cutaneous involvement. The efficacy of dapsone versus colchicine or GCs could not be assessed using propensity scores, but suggests a similar response rate to colchicine and a lower efficacy compared to GCs.

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders II (2699–2704)

Session Type: Abstract Session

Session Time: 11:30AM–1:00PM

Background/Purpose: VEXAS (vacuoles, E1 enzyme, X-linked, autoinflammatory, somatic) syndrome is a severe adult-onset inflammatory disease caused by somatic mutations of the ubiquitin-like modifier activating enzyme 1 (*UBA1*) gene. Expansion of *UBA1* mutated hematopoietic stem cells in the bone marrow of patients produces skewing towards the myeloid compartment. Neutrophils are enriched at sites of inflammation, yet prior functional studies in VEXAS have not focused on neutrophils. The aim of this study was to examine the transcriptomes and maturation of neutrophils in peripheral blood and marrow from patients with VEXAS.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We collected paired bone marrow and peripheral blood samples from 26 VEXAS patients with somatic pathogenic variants in *UBA1* at p.Met41 for single-cell RNA sequencing (scRNA-seq). Negatively isolated neutrophils were captured using 10X Genomics Chromium 3' Kits. Libraries were sequenced on the Illumina Novaseq 6000/X plus. Reads were aligned and quantified using Cell Ranger v8.0.0; dimensional reduction, clustering, and gene expression analysis was conducted using R package Seurat v5.2.1. Trajectory analysis and lineage differential expression tests were performed by R packages slingshot v3.20 and tradeSeq v1.23.0. Longitudinal analyses were performed in patients who were treated with hypomethylating agents, where one patient achieved molecular remission (i.e. eradication of the mutant clone).

Results: Canonical mutation types were proportional among the cohort (p.Met41Thr (n=10), p.Met41Leu (n=8), and p.Met41Val (n=8)) with median variant allele fraction 74% (range 24-89%). Circulating neutrophil counts were preserved to elevated in patients with VEXAS, while lymphocyte, monocyte, and natural killer cell counts were typically reduced. Immature granulocytes were commonly detected in peripheral blood and confirmed by scRNA-seq. Upregulation of genes related to neutrophil survival and inflammation were seen in neutrophils from patients with VEXAS. In particular, interferon response genes were highly upregulated in VEXAS neutrophils. Trajectory analysis identified two pathways of neutrophil differentiation in VEXAS: traditional development and an atypical pathway where myeloid-committed stem cells rapidly differentiated into mature neutrophils. Over-expression of genes associated with emergency granulopoiesis and immune metabolism defined the atypical pathway. Mutational burden in blood and bone marrow was eradicated in one patients with VEXAS following treatment with azacytidine. Comparing neutrophils before and after molecular remission revealed with significant reduction in interferon response gene expression, elimination of the atypical trajectory in peripheral blood, and normalization of neutrophil maturity subsets relative to healthy controls in both blood and bone marrow.

Conclusion: Neutrophils are critical effector cells in VEXAS syndrome, with distinct inflammatory transcriptomic profiles that normalize in molecular remission. These results are informative about the heterogeneity of neutrophils in VEXAS syndrome and may lead to discovery of novel myeloid-directed therapeutic targets.

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders II (2699–2704)

Session Type: Abstract Session

Session Time: 11:30AM–1:00PM

Background/Purpose: The prevalence of ocular involvement (OI) in patients with relapsing polychondritis (RP) has not been well defined. This study aimed to describe ocular manifestations, other clinical features, and use of immunosuppressive agents (IS), in patients with RP with and without OI.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

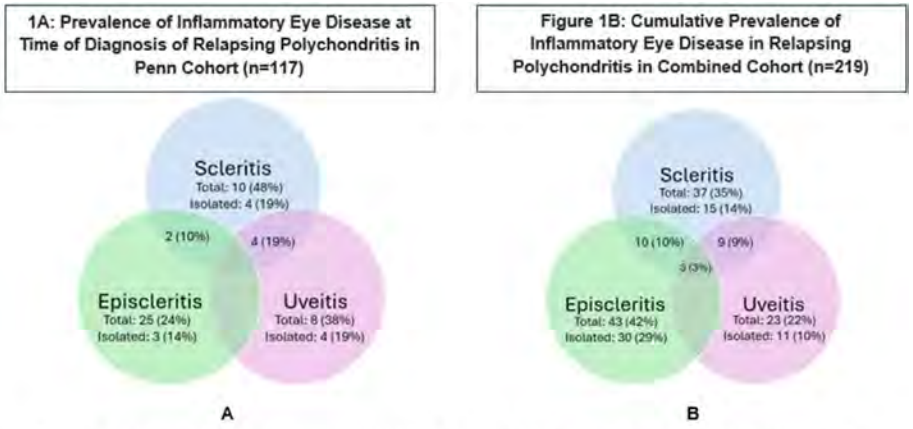

Figure 1. Prevalence of types of inflammatory eye disease in patients with relapsing polychondritis.

Methods: The study included adult patients with physician-diagnosed RP enrolled in a multicenter prospective observational cohort [University of Pennsylvania (Penn) and the National Institutes of Health (NIH)]. Data on demographics, clinical presentations, including OI, and use of IS [glucocorticoids (GC), non-biologic, and biologic IS] were collected. Means with standard deviation (SD) were calculated for continuous variables. Fischer's exact test was used to compare patients with and without OI.

Results: A total of 219 patients with RP (Penn=117; NIH=102) were included; of which, 185 (84%) were female, 194 (89%) were white, average age was 43 (SD 12.9) and average disease duration was 6.9 (SD 10) years. One hundred five (48%) had an OI during their disease course: episcleritis (n=43, 41%), scleritis (n=37, 35%), and uveitis (n=23, 22%), and recorded only in the Penn cohort were conjunctivitis (n=5, 9%) and eyelid swelling (3, 5%). Some patients had more than one OI (**Figure 1**). Clinical data at the time of diagnosis of RP was available in 117 patients (Penn cohort); 21 (18%) patients had an OI at the time of diagnosis, and the remaining 35 (30%) patients developed OI later. Among the patients with OI, scleral thinning and blindness were observed in 3 (7%) and 1 (2%) patients, respectively.

Table 1. Medication use in patients with relapsing polychondritis with and without ocular disease

Medication	Patients with eye involvement ever (n=90)	Patients without eye involvement ever (n=129)	p-value
Glucocorticoid	82 (91%)	121 (94%)	0.560
Non-biologic IS	79 (88%)	95 (74%)	0.011
Biologic IS	53 (59%)	60 (47%)	0.076
Methotrexate	63 (70%)	77 (60%)	0.152
Mycophenolate	22 (24%)	15 (12%)	0.016
Azathioprine	16 (18%)	12 (9%)	0.098
Leflunomide	12 (13%)	2 (2%)	0.001
Cyclophosphamide	5 (6%)	2 (2%)	0.126
Hydroxychloroquine	10 (11%)	18 (14%)	0.681
TNF inhibitors	28 (31%)	26 (20%)	0.080
Infliximab	22 (24%)	10 (8%)	<0.001
Adalimumab	19 (21%)	17 (13%)	0.139
Etanercept	6 (7%)	3 (2%)	0.166
Certolizumab	3 (3%)	3 (2%)	0.691
Golimumab	2 (2%)	3 (2%)	1.0
IL6 inhibitors	10 (11%)	9 (7%)	0.332
Ustekinumab	2 (2%)	2 (2%)	1.0
Secukinumab	2 (2%)	2 (2%)	1.0
Rituximab	5 (6%)	3 (2%)	0.278
Tofacitinib	2 (2%)	6 (5%)	0.476

23265203, 2025, 59, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Compared to patients without OI, those with OI had higher rates of fever (n=24, 27%; vs n=15, 12%; p=0.007), arthritis (n=57, 63%; vs n=61, 47%; p=0.020), rash (n=32, 36%; n=15, 12%, p< 0.001), oral ulcers (n=29, 32%; n=25, 19%; p=0.038), genital ulcers (n=20, 22%; n=10, 8%; p=0.003), cough (n=56, 62%; n=58, 45%, p=0.010), and wheezing (n=31, 34%; n=26, 20%, p=0.020). OI was also associated with increased rates of sensorineural hearing loss (SNHL) (n=30, 33%; n=26, 20%, p=0.040), auricular deformity (n=16, 18%; n=7, 5%; p=0.006), and nasal bridge collapse (n=16, 18%; n=8, 6%; p=0.009). Coexisting autoimmune diseases were reported in 32 (27%) patients in the Penn Cohort, with no significant difference between those with and without OI (n=10, 24%; n=22, 29%; p=0.650).

Use of non-biologic IS was significantly higher (n=79, 88%; n=95, 74%; p=0.010) in those with OI compared to those without OI. Patients with OI were more likely to receive infliximab compared to those without OI (n=22, 24%; n=10, 8%; p< 0.001). There was no significant difference in the use of GC in patients with and without OI (n=82, 91%; n=121, 94%, p=0.560). (**Table 1**).

Conclusion: OI is common in RP and often develops after diagnosis, with many patients experiencing multiple ocular manifestations. OI is associated with a higher burden of systemic disease, greater risk of organ damage, and frequent use of non-biologic IS and select biologic IS. These findings underscore the importance of monitoring for OI in RP, which may indicate severe disease and influence treatment decisions.

Diagnostic Performance of Vascular Ultrasound in Giant Cell Arteritis – A Single Center Experience

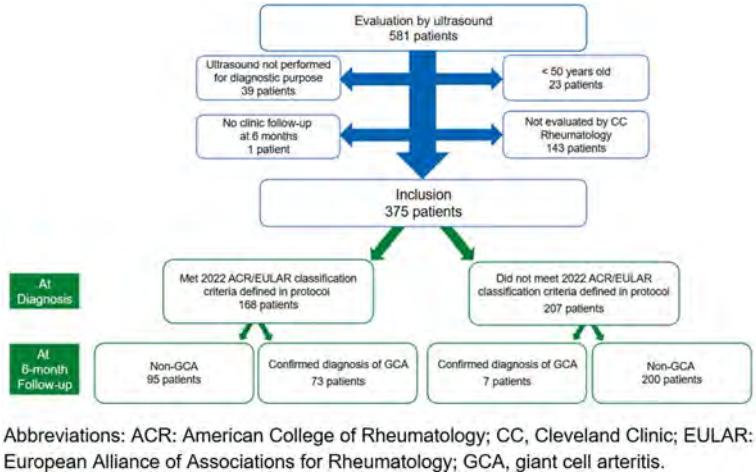
Ruoning Ni[1], Carol Langford[2], Minna Kohler[3], amne Dargham[1], Irene Katzan[1], Chao Zhang[4] and Rula Hajj-Ali[1], [1]Cleveland Clinic, Cleveland, [2]Cleveland Clinic, Moreland Hills, OH, [3]Massachusetts General Hospital, Harvard Medical School, Boston, MA, [4]Cleveland Clinic, Cleveland Heights, OH

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025
Session Title: Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders II (2699–2704)
Session Type: Abstract Session
Session Time: 11:30AM–1:00PM

Background/Purpose: Diagnostic approaches to giant cell arteritis (GCA) differ between the United States (U.S.) and Europe, with Europe favoring rheumatologist-performed ultrasound and the U.S. relying on temporal artery biopsy (TAB). Limited U.S. data on ultrasound use in GCA and lack of vascular ultrasound (VUS) training among U.S. rheumatologists constrains clinical decision-making. We aim to evaluate the diagnostic performance of VUS, including temporal, axillary and vertebral artery ultrasound at Cleveland Clinic (CC) for the diagnosis of GCA.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

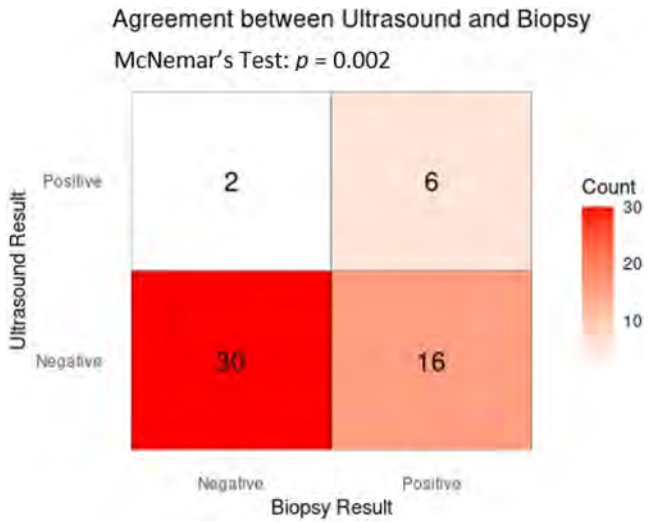


Abbreviations: ACR: American College of Rheumatology; CC, Cleveland Clinic; EULAR: European Alliance of Associations for Rheumatology; GCA, giant cell arteritis.

Algorithm of patient population

Methods: Patients aged ≥ 50 years old with suspected GCA who underwent radiology-performed VUS and were evaluated at the CC rheumatology clinic on at least two visits, with a 6-month interval between visits from 12/2020 to 12/2024, were included in this retrospective cohort analysis. Patient demographics, clinical manifestations, and final diagnosis were extracted. At the 6-month follow-up, a confirmed clinical diagnosis of GCA was established by the clinician based on a combination of clinical symptoms, laboratory markers, imaging and/or pathological findings, exclusion of other potential diagnoses, and treatment response. Operating characteristics of VUS, including sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were calculated and compared to a diagnosis of GCA, using the 2022 ACR/EULAR classification criteria for GCA (as defined in this protocol) and with a confirmed clinical diagnosis of GCA at 6-month follow-up. The correlation coefficient of VUS and TAB was generated in patients with a confirmed diagnosis of GCA at 6-month follow-up.

Results: In total, 581 patients underwent VUS of whom 375 patients met the inclusion criteria. Of these, 168 (44.8%) met the 2022 ACR/EULAR classification criteria and 80 (21.3%) had a confirmed clinical diagnosis of GCA at 6-month follow-up (Table 1). Patients diagnosed with GCA more commonly presented with positive VUS, higher scores on 2022 ACR/EULAR classification criteria, compared to those without GCA, while the occurrence of abrupt headache did not differ



Heatmap for positive temporal, axillary or vertebral artery ultrasound and positive temporal artery biopsy, indicative of a statistically significant asymmetry in the discordant classifications between ultrasound and temporal artery biopsy.

Time from initiation of glucocorticoids to biopsy (days) [Median (IQR)]	7.0 [3.0;13.0]	5.0 [3.0;12.0]	9.0 [3.0;13.8]	0.183
Giant cell arteritis on biopsy – n (%)	22 (23.9%)	0 (0.00%)	22 (47.8%)	<0.001
*Increased uptake of large vessels on PET-CT – n (%)	3 (10.0%)	2 (7.7%)	1 (25.0%)	0.360
Bilateral axillary involvement – n (%)	7 (1.9%)	0 (0.0%)	7 (8.8%)	<0.001
Scores of 2022 ACR/EULAR criteria (points) [Median (IQR)]	5.0 [4.0;7.0]	5.0 [4.0;6.0]	9.00 [7.0;11.0]	<0.001
2022 ACR criteria met per protocol – n (%)	168 (44.8%)	95 (32.2%)	73 (91.2%)	<0.001

* PET-CTs were performed on a total of 30 patients.
Abbreviations: ACR: American College of Rheumatology; CRP: C-reactive protein; ESR: erythrocyte sedimentation rate; EULAR: European Alliance of Associations for Rheumatology; IQR, interquartile range; PET-CT: Positron Emission Tomography - Computed Tomography; SD: standard deviation.

Characteristics of patients with/without confirmed diagnosis of giant cell arteritis at 6-month follow up

between the two groups (Table 1). The sensitivity, specificity, PPV and NPV of VUS compared to the 2022 ACR/EULAR classification criteria were 9.5%, 99.5%, 94.1% and 57.5%, respectively. When compared to the confirmed diagnosis of GCA at 6-month follow-up, the sensitivity, specificity, PPV, and NPV of VUS were 21.3%, 100.0%, 100.0%, and 82.4% respectively. A total of 135 patients (36.0%) underwent TAB, of which 22 biopsies confirmed GCA. The Cohen's Kappa coefficient between VUS and TAB results was 0.64, indicating fair agreement (Figure 2).

Conclusion: In this cohort, VUS demonstrated low sensitivity but high specificity in patients with a confirmed diagnosis of GCA at 6-month follow-up; there was a fair agreement between VUS and TAB. Compared to reported sensitivity rates in existing studies, our findings indicate a lower sensitivity, underscoring the variability of VUS performance across different settings. Future work should aim to refine VUS protocols and acquisition techniques to assess performance across varied settings to ensure more consistent diagnostic outcomes.

Abstract Number: 2703

Longitudinal Changes on Cranial Magnetic Resonance Imaging in Relapsing Giant Cell Arteritis

Ruoheng Zeng[1], Ryan Rebello[2], Konstanze Guggenberger[3], Joshua Baker[4], Shubhasree Banerjee[4], Robert Kurtz[4], Naomi Amudala[4], Peter Merkel[4] and Rennie Rhee[4], [1]University of Pennsylvania School of Medicine, Philadelphia, PA, [2]St. Joseph's Hospital at McMaster University, Hamilton, ON, Canada, [3]University Hospital of Wuerzburg, Wuerzburg, Germany, [4]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders II (2699–2704)

Session Type: Abstract Session

Session Time: 11:30AM–1:00PM

Background/Purpose: There is a need for better tools to monitor disease activity in giant cell arteritis (GCA). Prior studies demonstrated that vascular enhancement on cranial vessel wall magnetic resonance imaging (vw-MRI) decreases with treatment of GCA, but whether enhancement increases during relapse is not well known. This study examined changes on vw-MRI during relapse of cranial GCA.

Methods: Patients were prospectively enrolled in the study after receiving a diagnosis of GCA by a rheumatologist. All patients met the 2022 American College of Rheumatology/EULAR classification criteria for GCA. Enrolled patients underwent cranial vw-MRIs at enrollment, month 1, month 6, and month 12. Additional imaging was acquired in the setting of suspected relapse, defined as recurrence or worsening of symptoms of GCA felt to require escalation of immunosuppressive therapies. Neuroradiologists masked to disease activity and other clinical data graded vw-MRI enhancement for several cranial arteries and ocular structures using a previously-validated semiquantitative scoring system. Changes in MRI scores were compared with clinically-determined disease activity and acute phase reactants (APRs).

Results: Fourteen patients were included in the study, all of whom underwent a temporal artery biopsy (TAB), of which 12 (86%) had histologic evidence of GCA. All patients were treated with both high-dose glucocorticoids and adjunctive immunosuppressive therapies (10 treated with tocilizumab, 2 with tocilizumab and methotrexate, and 2 with trial-related study drug). Over the course of the study 4 patients experienced a cranial or ocular relapse, 2 patients experienced a relapse with polymyalgia rheumatica (PMR) without cranial symptoms, and 8 patients were in sustained remission. All 4 patients with

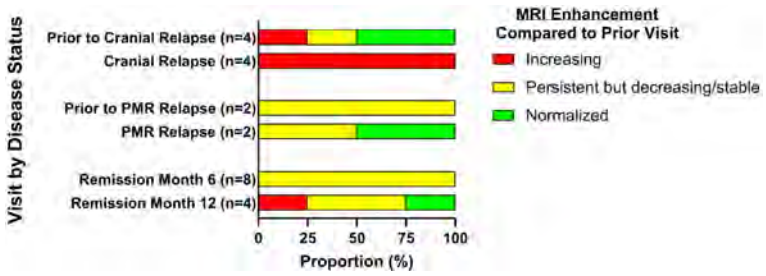

Figure 1. Changes on magnetic resonance imaging prior to and during relapse of giant cell arteritis. Graphs reflect changes in magnetic resonance imaging (MRI) enhancement from most recent visit. MRI enhancement increased during cranial relapse in 4 patients, including 1 patient who experienced increasing enhancement prior to clinical presentation of relapse. MRI enhancement decreased or became normal in 2 patients with a relapse of polymyalgia rheumatica only (non-cranial disease) and in most visits among 8 patients with non-relapsing giant cell arteritis. One patient classified as having non-relapsing giant cell arteritis and who remained in remission during the study period was noted to have increased MRI enhancement at month 12; several months after completion of the study, this patient experienced a relapse, although repeat MRI was not performed at the time of relapse.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

a cranial or ocular relapse had increased vw-MRI enhancement in at least one cranial structure. Two patients experiencing relapse of PMR had persistent, but not increased enhancement, while 7 of 8 patients in sustained remission had decreased or normal enhancement on follow-up. In 2 patients experiencing relapse, increased vw-MRI enhancement was seen months prior to clinical signs of relapsing disease. Cranial structures that showed increased enhancement at relapse included the occipital artery, optic nerve sheath, and maxillary artery. Levels of APRs remained normal in most patients, likely impacted by use of tocilizumab.

Conclusion: This study serves as proof-of-concept that vw-MRI may be potentially useful to monitor for relapse in GCA. Abnormal vw-MRI enhancement of cranial and orbital structures is responsive to change and correlates with clinical disease activity. Moreover, vw-MRI is more sensitive to changes in disease activity compared to APRs, suggesting that vw-MRI provides additive information to current biomarkers of GCA. A non-invasive method for accurately assessing disease activity is imperative for high-quality longitudinal care of patients with GCA. These findings expand the repertoire of imaging modalities to study for use in assessing disease activity for GCA.

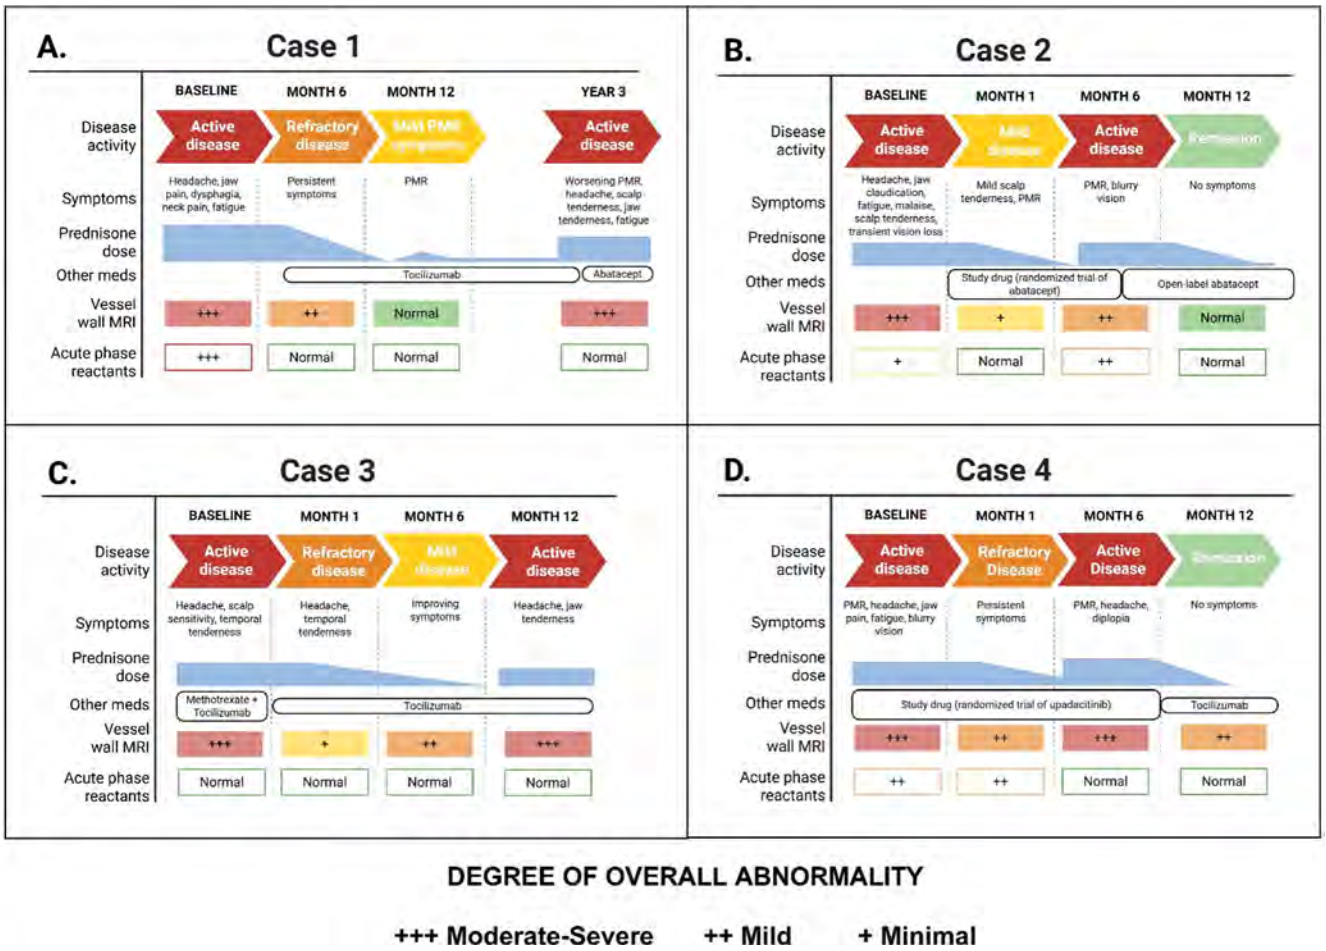

Figure 2. Longitudinal changes in disease activity measures of four patients with relapsing giant cell arteritis (GCA). Figures depict chronological changes in clinical status, medications, combined orbital and cranial vessel wall MRI (vw-MRI), and acute phase reactants (APRs) during enrollment in the 4 patients who experienced cranial or ocular relapse of GCA. (A) In Case 1, although APRs normalized, vw-MRI at month 6 showed persistent abnormal vascular enhancement similar to the patient's refractory clinical symptoms. Then relapse in year 3 was associated with worsening changes on vw-MRI whereas APRs remained normal, likely due to use of tocilizumab. (B) In Case 2, both vw-MRI and APRs tracked with disease activity in patient enrolled in clinical trial of abatacept. (C) In Case 3, worsening changes on vw-MRI were observed at month 6 prior to developing clinical manifestations of relapse at month 12 whereas APRs were normal throughout likely due to use of tocilizumab. (D) In Case 4, relapse at month 6 was associated with worsening changes on vw-MRI whereas APRs were normal.

Abstract Number: 2704

Complete metabolic response on PET/CT in giant-cell arteritis-related large vessel vasculitis : comparison of two strategies using glucocorticoids or glucocorticoids + tocilizumab

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025
Session Title: Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders II (2699–2704)
Session Type: Abstract Session
Session Time: 11:30AM–1:00PM

Background/Purpose: Persistent large-vessel vasculitis (LVV) on PET/CT in giant-cell arteritis (GCA) is associated with a higher risk of aortic dilation. Few data are available on complete metabolic response under treatment (i.e., total extinction of vascular uptakes). This study compared the ability of glucocorticoids (GC) alone and GC + tocilizumab (TCZ) to obtain a complete metabolic response on repetitive PET/CT.

GCA: Giant Cell Arteritis; LVV: Large Vessel Vasculitis; FU: follow-up; TCZ: Tocilizumab; GC: glucocorticoids; PET/CT: positrons emission tomography coupled with a computed tomography

Methods: Through the French Large-Vessel Vasculitis Study Group (GEFA), we retrospectively enrolled all GCA patients who satisfied the following criteria: 1) a LVV was evidenced on PET/CT; 2) all patients were treated either with GC alone or GC+TCZ; and 3) at least a second PET/CT was repeated under the same initial treatment. Patients who received another treatment between the two repeated PET/CT were excluded.

Patients who showed a total vascular extinction on repeated PET/CT without LVV relapse during follow-up were considered as a success. Patients with still positive PET/CT or with LVV relapse during follow-up were considered as failures.

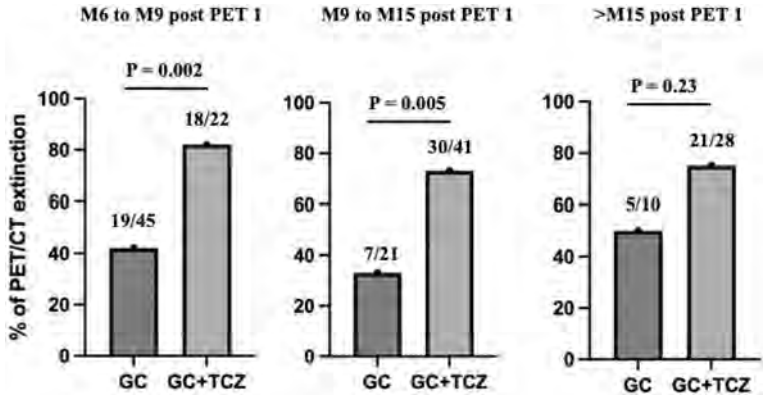

Figure 1. Proportion of negative PET/CT in the two groups according to the time of control.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: A total of 167 patients were enrolled, 76 treated with GC alone and 91 treated with GC + TCZ. Their characteristics at baseline are shown and compared in Table 1. LVV was diagnosed on PET/CT at GCA diagnosis in 66% and 71% (p=ns) of patients in the GC and GC+TCZ groups, respectively. A second PET/CT was repeated at 8 [IQR 25-75, 6–11] months in the GC group and 12 [10–20] months in the GC+TCZ group (p< 0.0001). Under GC alone, 41% of PET/CT showed a total extinction of vascular uptakes versus 76% in the TCZ group (p< 0.0001). Figure 1 shows the proportion of negative PET/CT in the two groups according to the time of control. LVV relapse on a third PET/CT was diagnosed in 5% of patients treated with GC alone and 12% of patients treated with GC+TCZ (p=0.17). At last follow-up, more patients treated with GC+TCZ had discontinued GC (79% vs. 61% in patients treated with GC alone, p=0.009).

Conclusion: This study suggests that the combination of GC+TCZ is more efficient than GC alone to obtain a complete metabolic extinction on repeated PET/CT in GCA-related large vessel vasculitis. A further longitudinal study is required to analyze the impact on the risk of aortic dilation.

Low-dose Interleukin-2 Therapy in Systemic Lupus Erythematosus: a double-blind, randomised, placebo-controlled, phase IIb trial

Xia Zhang[1], Ruiling Feng[1], Zhanguo Li[2] and Jing He[1], [1]Peking University People's Hospital, Beijing, China (People's Republic), [2]Peking Univeristy People's Hospital, Beijing, China (People's Republic)

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (LB01–LB18) Late-Breaking Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Low-dose Interleukin-2 (Ld-IL2) has shown therapeutic effect in autoimmune diseases, particularly systemic lupus erythematosus (SLE). Various doses from 0.33 to 3.0 million units of IL-2 have been used widely in clinics. As

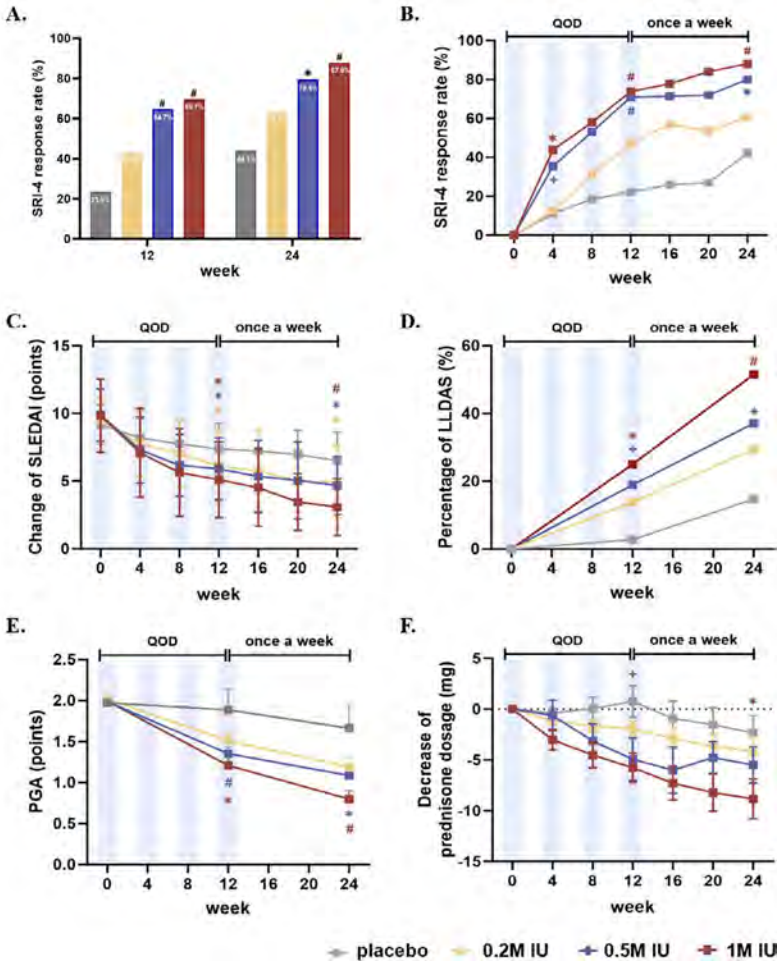

Figure 1. The clinical efficacy through 48 weeks in overall study population (A) Efficacy of Ld-IL2 assessed by SRI-4 during 24 weeks. (B) Percentage of SRI-4 responders at week 12 and 24. (C) Change of SLEDAI from baseline to 24 weeks. (D) Proportion of LLDAS responders at week 12 and 24. (E) Improvement with Ld-IL2 determined by PGA. (F) Change of prednisone dose from baseline to week 24. Red represents Ld-IL2 1M IU versus placebo group; blue Ld-IL2 0.5M IU versus placebo group; yellow represents Ld-IL2 0.2M IU versus placebo group. Ld-IL-2, low-dose interleukin 2. SRI-4: Systemic Lupus Erythematosus Responder Index 4; PGA: physician's global assessment. + P<0.05; *P<0.01; # P<0.001

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. far, the optimal dose in SLE treatment has not been evaluated, which leads to uncertainty of efficacy and causes difficulty of dose decision in practice.

Methods: In this multicenter, randomized, double-blind, Phase IIb trial, 152 active SLE patients were randomized (1:1:1:1) to receive subcutaneous IL2 (0.2, 0.5, or 1.0 million IU) or placebo every other day for 12 weeks, then weekly for further 12 weeks.

Results: At week 12, significantly higher SRI-4 response rates were demonstrated in IL2 1M IU (69.7%), 0.5M IU (64.7%), and 0.2M IU (42.9%) than in placebo (23.5%). Notably, these significant differences proceeded until the end of treatment period at week 24 ($p < 0.001$). Secondary outcomes revealed SLE patients achieving LLDAS at doses of 1M IU, 0.5M, and 0.2M (51.5%, 37.1%, and 28.5% respectively) at week 24. In the 1M IU Ld-IL2 group, significant reductions were observed in PGA scores, anti-dsDNA antibody, and prednisone dosages, accompanied by remarkable increases in serum C3 and C4 levels. Infection rates were lower in IL2 groups compared to placebo. Ld-IL2 drives expansion of Tregs and rebalance of Tregs/Teff ratio.

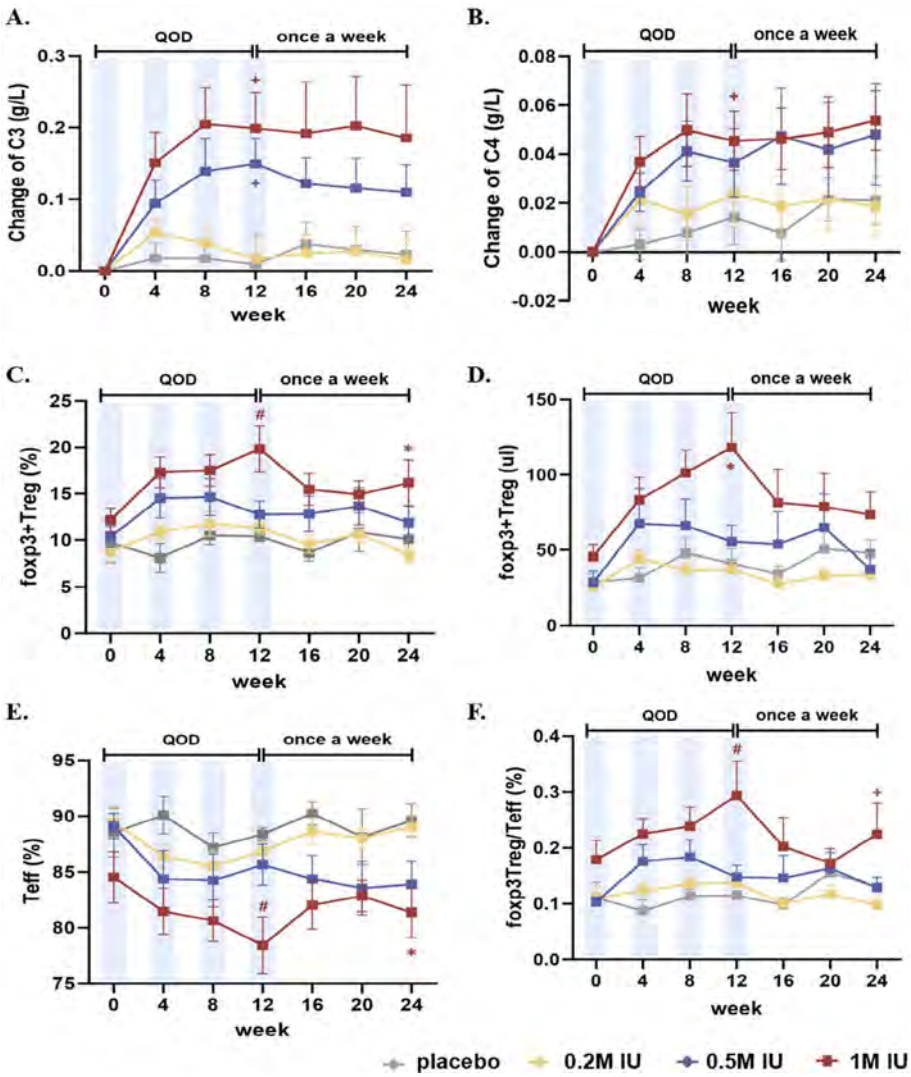

Figure 2. Dynamics of laboratory and immunological responses after IL2 treatment (A-B) Change in C3 and C4 concentrations from baseline over time. (C-F) Changes of the percentage and the number of foxp3+ CD127loCD25hi regulatory T cells (foxp3+Treg) and effector T (Teff) cells. Red represents Ld-IL2 1M IU versus placebo group; blue Ld-IL2 0.5M IU versus placebo group; yellow represents Ld-IL2 0.2M IU versus placebo group. Ld-IL-2, low-dose interleukin 2. SRI-4: Systemic Lupus Erythematosus Responder Index 4; PGA: physician's global assessment. + P<0.05; *P<0.01; # P<0.001

with 54.16% (13/24) in the monotherapy group ($p < 0.0001$) (Fig 2). No significant difference was observed in the change of IgG4-RD RI between the combination group and the monotherapy group (5.64±2.97 vs. 5.17±3.47, p=0.619). The proportion of Th2 cells decreased more significantly in the combination therapy group than in the GCs monotherapy group (-0.71 [-1.41, 0.42] vs. 0.11 [-0.10, 0.69], p=0.032). Changes in IgG4 levels did not differ significantly between the two groups (p=0.389). Four infections occurred in the combination group, (two urinary tract infection, one herpes zoster and one pulmonary infection), but the overall incidence of adverse events did not differ significantly between the groups (p = 0.311). No serious adverse events occurred.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (LB01–LB18) Late-Breaking Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Fibromyalgia (FM) is characterized by chronic widespread pain that is often exacerbated by movement. FM is associated with enhanced central pain transmission, while transcutaneous electrical nerve stimulation (TENS) delivers electrical current through surface electrodes to counteract this central excitability. We previously showed the efficacy of TENS in reducing movement-evoked pain (MEP) and fatigue in individuals with FM in a double-blind, randomized controlled trial; however, effectiveness of TENS in a real-world setting has not previously been tested. As physical therapists are trained to use TENS for pain management, we examined if addition of TENS to outpatient physical therapy (PT) would reduce MEP using a pragmatic trial design.

Methods: The Fibromyalgia TENS in Physical Therapy Study (FM-TIPS) was a cluster-randomized pragmatic trial conducted at 28 outpatient PT clinics from 6 healthcare systems. Each clinic was randomized to TENS+PT or PT-Only. Potential participants were screened at their first PT visit and were eligible if they had been diagnosed with FM and no contraindications to TENS. Consented participants were instructed on TENS use at PT visit 2. The intervention consisted of 2 TENS devices used daily for 2 hours during physical activity that delivered a waveform with a modulating frequency of 2-125 Hz and duration between 100-180 μs at a strong but comfortable intensity through butterfly electrodes placed on the upper and lower back. Data was captured via REDCap on days (d) 1, 30, 60, 90 and 180. The primary outcome was MEP during a sit-to-stand test at d60 (randomized phase) modeled as a between-group comparison of change in MEP from d1 pre-TENS to d60 post-TENS using linear mixed-effects models. Following d60, the PT-Only group received TENS units along with virtual instructions (extension phase).

Pain duration (yrs)	14.5 ± 10.9	14.4 ± 10.9	14.6 ± 11.0

FIQR: Fibromyalgia impact questionnaire revised, WPI: Widespread pain index, SSS: Symptom severity scale, PSD: Polysymptomatic distress, PSD: Polysymptomatic distress

Results: We enrolled 459 participants, of whom 384 completed baseline data and were randomized to the TENS+PT (191) or PT-Only groups (193). Baseline characteristics are shown in **Table 1**. MEP at d60 was significantly lower (-1.1, CI= -1.58 to -0.7; Cohen's d=0.46) in the TENS+PT compared to the PT-Only group during the randomized phase. Within-group comparisons showed TENS+PT reduced post-TENS MEP by d30 and effectiveness persisted to d180 (**Figure 1**), a result also seen in the PT-Only group during the extension phase. Movement-evoked fatigue and resting pain/fatigue demonstrated a similar pattern. There was a dose-response for measured TENS use, and the patient global impression of change favored TENS+PT (p=0.001) (**Figure 2**). There were more participants in the TENS+PT than the PT-Only group who demonstrated at least 30% reduction in MEP (41% vs 13%, p=0.0001) and resting pain (39% vs 21%, p=0.004). At d180, 81% of

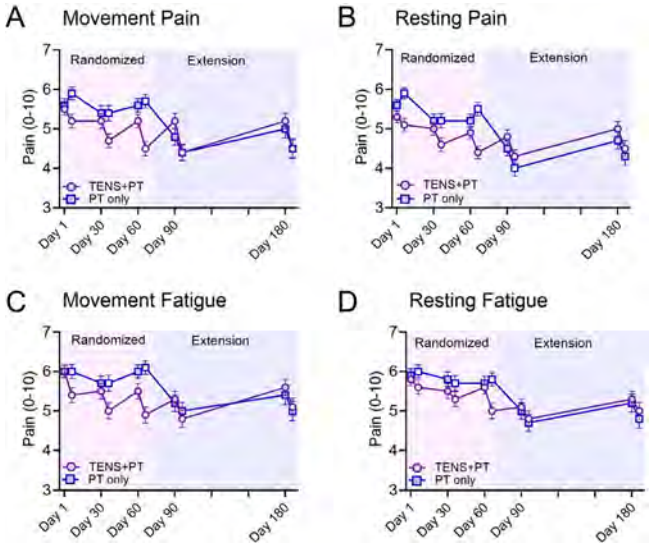

Figure 1. Changes in A) movement-evoked pain, B) resting pain, C) movement-evoked fatigue, and D) resting fatigue before and after TENS through Day 180. Measures were assessed before (pink circles) and after 30 min application of TENS (white circles) on each day. The PT-only group tested all measures before (blue squares) and after 30 minutes of rest (white squares) on each day through day 60 (randomized phase), and before and after TENS during the extension phase on Day 90 and day 180. There were significant decreases in all measures after 30 minutes of TENS treatment for both pain and fatigue beginning on Day 30 and persisting through Day 180 for the TENS+PT group. There was no change in the measures for the PT-only group during the first 60 days, the randomized phase. However, after receiving TENS, the PT-only group showed a significant decrease 30 days later that lasted through the Day 180 test period (4 months). Data are mean and S.E.M.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

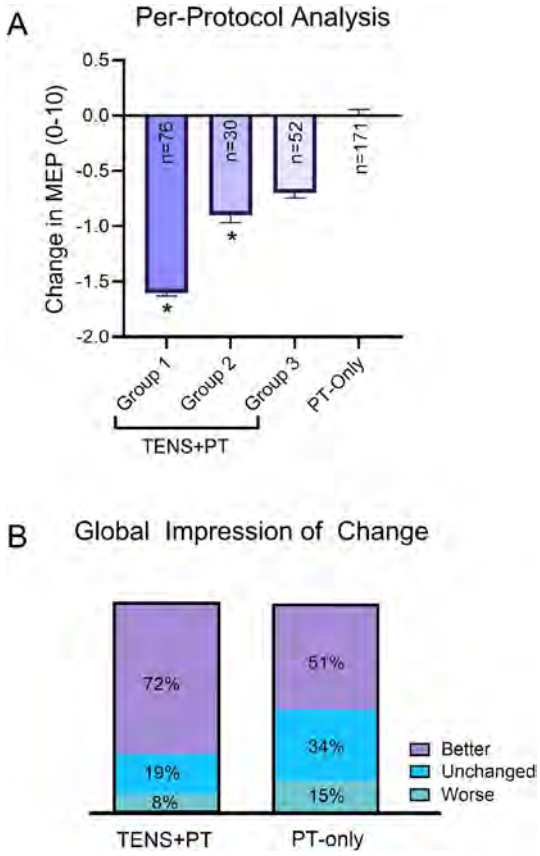

Figure 2. A. Per protocol analysis shows a dose-response effect for change in movement-evoked pain on Day 60 during the randomized phase. Group 1 used TENS 8x/month and a total of 900 min/mo for both the first and the second 30-day period. Group 2 used TENS 8x/month and a total of 900 min/mo for the first 30 days. Group 3 used TENS less than the minimal dose. The PT-only group did not use TENS. Groups 1 and 2 showed a greater reduction in movement-evoked pain when compared to the PT-Only group. *, $p<0.05$. B. The global impression of change showed a greater number of individuals reported improvement in MEP when compared to those in the PT-only group ($\square$=16.7, p=0.001).

respondents that remained in the study found TENS helpful and 55% used TENS daily. There were no treatment-related serious adverse events and minor adverse events related to TENS were all ≤ 7.5%.

Conclusion: TENS meaningfully reduces FM pain and fatigue. Effectiveness persists for at least 180 days. Treatment effect size is comparable to other FM therapies even in this heterogeneous real-world population. TENS is a safe, inexpensive, and readily available treatment for FM.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (LB01–LB18) Late-Breaking Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Refractory autoimmune diseases with progressive organ damage remain a major unmet medical need. C-CAR168 is an autologous anti-CD20/BCMA bispecific CAR-T therapy designed to simultaneously target autoantibody-producing plasma cells and their B-cell precursors, aiming to achieve a complete "immune reset". This first-in-human Phase I trial (NCT06249438) evaluates C-CAR168 in patients with treatment-refractory autoimmune diseases. Here, we report the trial's safety data and preliminary efficacy in the lupus nephritis (LN) and multiple sclerosis (MS) cohorts.

Methods: This Phase I, open-label study enrolled patients with refractory SLE (±LN), immune mediated necrotizing myositis (IMNM), neuromyelitis optica spectrum disorder (NMOSD), and MS, who had failed ≥2 standard immunosuppressive therapies. After lymphodepletion, patients received a single C-CAR168 infusion at either 0.75×10^6 or 1.5×10^6 CAR-T cells/kg.

Results: As of September 10, 2025, 16 patients were treated: 11 SLE (9 proliferative LN), 2 NMOSD, 2 progressive MS and 1 IMNM, with a median follow-up of 177 days. C-CAR168 was well tolerated. Grade 1-2 CRS occurred in 11/16 patients (68.8%) and resolved with supportive care. No ICANS or DLTs were observed. Grade ≥3 AEs were primarily hematologic and transient. Prolonged cytopenia and Grade 3 treatment-emergent infections each occurred in 2 patients (12.5%) and were successfully managed with standard therapies. All patients discontinued immunosuppressants (IS) / biologic agents, 12 (75%) achieved steroid discontinuation and 4 remained on corticosteroids ≤10 mg/day.

Robust efficacy was observed in the LN and SPMS patients. In proliferative LN (median 4 prior IS/ biologic agents, excluding steroids/HCQ), 7/9 patients achieved a renal response (77.8%), including 3 CR, 1 PERR and 3PR. Improvement in proteinuria was rapid (median 1M [range 1–3]), and continued to improve with longer follow-up. Improvement in extrarenal SLE activity, as measured by SRI-4, was achieved in 6/7 (85.7%) proliferative LN patients with ≥3M follow-up. The first SPMS patient showed significant improvement in gait and orbital movement, EDSS score, reductions in MRI lesion burden, and normalization of serum neurofilament light chain.

C-CAR168 expansion was accompanied by rapid depletion of $CD20^+$ B cells and plasma cells in blood, followed by naïve-dominant B-cell reconstitution in most patients by months 2-3, along with reductions in the type I IFN gene signature score. In one patient, bone marrow biopsy confirmed complete plasma cell depletion. Longitudinal examination of the B cell receptor repertoire (BCR) in 3 LN patients revealed a loss of clonally expanded BCRs with subsequent emergence of a naïve repertoire after treatment.

Conclusion: C-CAR168 therapy demonstrated durable treatment-free disease control in refractory autoimmune diseases. Its favorable safety profile, together with a renal response rate of 77.8% in refractory proliferative LN and rapid neurological improvement in SPMS, both achieved without background standard of care medications, coupled with mechanistic evidence of immune reset, provides a compelling rationale for further clinical evaluation of C-CAR168.

Abstract Number: LB05

ER Stress-Induced ATP2A3 Drives Rheumatoid Arthritis via Activation of STING Signaling

yujie cai, Nanfang hospital, Guangzhou, China (People's Republic)

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (LB01–LB18) Late-Breaking Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease characterized by persistent synovial inflammation and joint bone destruction. Endoplasmic reticulum (ER) stress plays an important role in the pathogenesis of autoimmune diseases such as RA, yet the specific mechanism through which ER stress contributes to RA remains unclear. This study aims to investigate the role and mechanism of ER stress-related genes in promoting RA, with the goal of identifying novel therapeutic targets.

Methods: Transcriptomic data from six RA datasets were analyzed using Least Absolute Shrinkage and Selection Operator (LASSO) regression, Support Vector Machine-Recursive Feature Elimination (SVM-RFE), and Random Forest (RF) to identify ER stress-related genes (ERSRGs). Protein-level validation was conducted via Immunohistochemistry (IHC) on RA synovial tissues and control synovial tissues.The expression levels of ATP2A3, STING, TBK1, IRF3, and NF-κB in fibroblast-like synoviocytes (FLS) were detected by Western blot (WB).Cell invasion and migration abilities were assessed using Transwell assays. The levels of inflammatory cytokines IL-6, IL-1β, TNF-α, and IFN-γ were measured by ELISA.

Results: Seventeen ERSRGs were identified by intersecting differentially expressed genes (DEGs; n=1433) between RA and control samples with ERSRGs (n=267) from the Gene Ontology Consortium.Among the differentially expressed genes, ATP2A3—an ER stress-induced gene—was found to be significantly upregulated in RA. Overexpression of ATP2A3 in FLS promoted cell migration, invasion, and the release of inflammatory cytokines including IL-6, IL-1β, TNF-α, and IFN-γ. Furthermore, ATP2A3 facilitated the phosphorylation of STING, thereby activating the STING signaling pathway, which enhanced FLS invasion, migration, and inflammatory cytokine secretion.

Conclusion: This study demonstrates that the ER stress-induced gene ATP2A3 plays a crucial role in RA pathogenesis. ATP2A3 promotes the development and progression of RA by activating the STING signaling pathway. These findings highlight ATP2A3 as a potential therapeutic target for the treatment of RA.

Welcker GmbH, Planegg, Germany, [3]Rheumatologisches Praxiszentrum, München, Germany, [4]Novartis Pharma GmbH, Nürnberg, Germany

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (LB01–LB18) Late-Breaking Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Psoriatic arthritis (PsA) patients with prior failure or intolerance to TNFα inhibitors (TNFi) represent a clinically challenging population with limited therapeutic options. The AgAIN study (CAIN457FDE04; NCT04632927) is the first randomized, double-blind, active-controlled, multicenter trial directly comparing secukinumab (SEC) and ustekinumab (UST) in this population.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: A total of 119 patients (pts) were randomized (SEC: 56, UST: 63; see Fig. 1 for Study Design) at 28 clinical centers in Germany. The mean age was 53.5 ± 11.0 years, with 15.1% of pts aged over 65. Female pts comprised 69.6% in the SEC group and 65.1% in the UST group. Body weight over 100 kg was observed in 30.4% of SEC pts and 22.2% of UST pts. All pts met the CASPAR criteria for PsA diagnosis (score ≥3). Key CASPAR features included current psoriasis (91.1% SEC, 82.5% UST), negative rheumatoid factor (100.0% SEC, 96.8% UST), and juxta-articular new bone formation (37.5% SEC, 31.7% UST). All pts had prior TNFi exposure and failed TNFi, with adalimumab (68.9%) being the most commonly used. Treatment discontinuation rates were notably higher in the UST group (25.4% vs. 3.6% SEC), primarily due to lack/loss of efficacy, with a mean ± SD duration of exposure of 24.3 ± 2.0 weeks for SEC vs. 21.5 ± 6.8 weeks for UST. Despite recruitment issues resulting in early recruitment termination, the study was successfully completed, offering descriptive analysis of comparative efficacy and safety.

Results: For the primary endpoint, HAQ-DI© response increased continuously over time in SEC group and was numerically higher than in UST group at all analyzed time points (see Figure 1), with a notably greater response rate of 57.1% (32/56 pts) for SEC vs. 27.0% (17/63 pts) for UST at week 28 [OR=3.647, 95% CI: 1.601–8.311; p=0.002;]. Further, SEC showed qualitatively better outcomes across all secondary and exploratory endpoints, see Table 1 for details. No new safety signals of secukinumab were identified. Treatment emergent adverse events (TEAEs) occurred in 76.8% (SEC; 43/56 pts) vs. 81.0% (UST; 51/63 pts); SAEs in 8.9% (SEC; 5/56 pts) vs. 3.2% (UST; 2/63 pts). TEAEs leading to discontinuation were seen in 3.6% in SEC arm (2/56 pts) and 12.7% in UST arm (8/63 pts).

Conclusion: AgAIN is the first study to provide head-to-head data comparing SEC and UST in TNFi-experienced PsA patients. SEC showed qualitatively better efficacy across all clinical and patient-reported outcomes (PRO), and safety signals in line with known safety profile. Notably, improvements in key clinical endpoints and PROS—including HAQ-DI, joint

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (LB01–LB18) Late-Breaking Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Knee osteoarthritis (KOA) is a leading cause of disability, with no available disease-modifying treatments. While Hyaluronic Acid (HA) remains widely used, there is little to no head-to-head randomised evidence comparing HA with adipose-derived mesenchymal stem cells (AdMSC) therapy. This evaluator-blinded, phase IIb trial compared the efficacy, safety and dose response of autologous adipose-derived mesenchymal stem cells (AdMSC) versus intermediate molecular-weight HA in patients with refractory primary KOA in Bangladesh.

Methods: Seventy-three participants with Kellgren-Lawrence grade ≥2 KOA on standard conservative care were randomised to receive HA injection (n=31), a single-dose AdMSC injection (n=21), or two-dose AdMSC injections (n=21, dose interval 3 months). Primary outcomes included pain on VAS, knee-related problems on KOOS, femoral cartilage thickness utilising ultrasound scan, and MRI-assessed cartilage defects (MOAKS) at baseline, 6, and 12 months involving a multidisciplinary clinical team.

Table 1: Summary of the baseline clinical characteristics of the study population (N=73). SD, standard deviation, VAS, visual analogue scale (0-10; 0 indicates no pain and 10 indicates worst pain), KOOS, The Knee Injury and Osteoarthritis Outcome Score (0-100 with 0 representing extreme knee problems and 100 representing no knee problems).

Table 1: Summary of the baseline clinical characteristics of the study population (N=73)

Clinical Characteristics		Active Control HA (n=31)	Single-dose AdMSC (n=21)	Two-dose AdMSC (n=21)
Mean Age in years		60.81±8.14	60.76±6.69	58.10±5.67
Female (n, %)		10 (32.26)	10 (46.62)	12 (57.14)
Height in centimetres		161.65±4.31	160.90±6.27	158.24±5.42
Weight in kg		68.10±6.06	71.33±5.29	66.81±10.41
Body Mass Index (BMI) kg/meter²		26.12±2.73	27.65±2.76	26.84±4.93
Presence of any Comorbidity (n, %)		19 (61.29)	11 (52.38)	14 (66.67)
KL grade in the Right Knee (n, %)	Grade 2	6 (19.35)	4 (19.05)	4 (19.05)
	Grade 3	22 (70.97)	13 (61.90)	16 (76.19)
	Grade 4	3 (9.68)	4 (19.05)	1 (4.76)
KL grade in the Left Knee (n, %)	Grade 2	7 (22.58)	4 (19.05)	7 (33.33)
	Grade 3	23 (74.19)	13 (61.90)	14(66.67)
	Grade 4	1 (3.23)	4 (19.05)	0 (0.00)
Baseline pain intensity on the visual analogue scale (VAS, 0-10) in the Right Knee		5.32±0.87	5.29±0.64	5.67±0.58
Baseline pain intensity on the visual analogue scale (VAS, 0-10) in the Left Knee		5.35±0.88	5.52±0.51	5.29±0.78
Baseline total KOOS score (0-100) in the Right Knee		45.55±8.19	44.86±9.85	45.52±5.29
Baseline total KOOS score (0-100) in the Left Knee		45.87±8.72	44.76±8.47	46.29±5.84
Mean Femoral Cartilage Thickness on HFUS in the Right Knee in millimetres		1.71±0.27	1.68±0.25	1.78±0.28
Mean Femoral Cartilage Thickness on HFUS in the Left Knee in millimetres		1.80±0.23	1.65±0.24	1.77±0.33
Right Knee's Mean Cartilage Defect in MRI in per cent	Medial Tibiofemoral Joint	49.03±6.38	54.52±10.94	50.95±7.35
	Lateral Tibiofemoral Joint	49.35±5.74	54.05±11.02	51.67±8.11
	Patellofemoral Joint	19.19±5.10	21.43±4.23	20.48±4.98
Left Knee's Mean Cartilage Defect in MRI in per cent	Medial Tibiofemoral Joint	49.35±6.16	54.52±10.94	50.95±7.35
	Lateral Tibiofemoral Joint	49.52±4.72	53.81±10.36	51.19±7.23
	Patellofemoral Joint	19.74±5.36	22.38±4.07	21.43±6.55

Changes in pain on VAS, knee damage on KOOS, femoral cartilage thickness on ultrasound, and cartilage defect on MOAKS at 6 months

Results: Interim analysis revealed significant, dose-dependent improvements. Two-dose AdMSC resulted in greater pain reduction (3.2 vs. 1.3 points) and functional improvement (21.24 vs. 11.31 points) compared to HA at 6 months ($p < 0.001$). Cartilage thickness increased (0.25±0.18mm) and defects improved (9.13%) with two-dose AdMSC, whereas the HA group showed deterioration (-0.06±0.14mm; 0.75%). Single-dose AdMSC also showed better outcomes than HA. No baseline predictors were identified, and all treatments were well-tolerated.

Conclusion: Two-dose AdMSC therapy significantly outperformed HA and single-dose AdMSC in improving pain, function, and cartilage structure, indicating its potential as a disease-modifying treatment for KOA. These results support advancing to larger phase III trials, particularly in South Asia, where KOA is a growing health burden. (www.clinicaltrials.gov: NCT05783154, IRB approval reference: BSMMU/2024/1192/registration/742).

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (LB01–LB18) Late-Breaking Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: PsA is a chronic, systemic, inflammatory musculoskeletal disease in which dysregulated IL-17A activity plays a pivotal role in disease pathogenesis. Izokibep (IZO) is an Affibody® molecule (small protein therapeutic; 18.6 kDa) designed to inhibit IL-17A with high potency through tight selective binding. In a phase 2b/3 study in patients (pts) with active PsA, IZO was well tolerated and demonstrated improved efficacy vs placebo (PBO) across multiple disease domains including the study primary endpoint of ACR50 at week (wk) 16. Here, we report the efficacy and safety of IZO from the phase 2b/3 study through wk 52.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. ACR50 Response Over 52 Weeks

Full analysis set; nonresponse imputation. Dashed line and gray shading indicate crossover from PBO to active treatment (IZO QW).

Statistical significance per the prespecified testing hierarchy: ‡‡‡ P<0.001 vs PBO. Nominal P-value: * P<0.05, *** P<0.001 vs PBO.

IZO, izokibep; PBO, placebo; Q2W, every 2 weeks; QW, every week.

Methods: In this study (NCT05623345; Study 22104), eligible pts had adult-onset active PsA (duration ≥6 months and ≥3 tender/swollen joints) and an inadequate response, intolerance, or contraindication to an NSAID, conventional synthetic DMARD, and/or TNF inhibitor. During the 16-wk PBO-controlled treatment period, pts were equally randomized to IZO 160 mg every 2 wks (Q2W), IZO 160 mg every wk (QW), or PBO QW. At wk 16, pts originally randomized to IZO kept receiving IZO per their original dose and schedule; pts receiving placebo were switched to IZO 160 mg QW. Wk 52 results are reported.

Results: A total of 343 pts were included (IZO Q2W, n = 113; IZO QW, n = 112; PBO→IZO QW, n = 118). The mean (SD) age was 49.5 (13.3), 51.8 (12.2), and 52.6 (11.7) years, BMI was 30.5 (6.6), 29.1 (5.9), and 29.7 (6.0) kg/m^2, and time

Table 1. Efficacy Results

	IZO 160 mg Q2W (n = 113)		IZO 160 mg QW (n = 112)		PBO QW→IZO 160 mg QW (n = 118)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

since diagnosis was 6.2 (6.8), 6.9 (8.0), and 7.1 (6.9) years for IZO Q2W, IZO QW, and PBO→IZO QW, respectively; 59%, 57%, and 43% of pts were male. Baseline (BL) disease characteristics were generally similar across groups. After wk 16, continued improvement was seen for pts randomized to either IZO group and rapid improvement was observed in pts following crossover from PBO (**Figure 1**); by wk 52, approximately half of pts achieved ACR50 (IZO Q2W, 50%; IZO QW, 57%; PBO→IZO QW, 51%). Notable percentages of pts in all groups also achieved the high-hurdle endpoints of ACR70 (36%, 42%, 42%), PASI90 (63%, 69%, 65%), PASI100 (55%, 64%, 58%), and minimal disease activity (MDA; 47%, 52%, 47%) at wk 52 (**Table 1**). Improvements in quality of life measures were also observed across groups (**Table 1**). Overall, more than half of pts with BL enthesitis achieved resolution at wk 52 (**Table 1**). Treatment-emergent adverse events (TEAEs) occurred in 81%, 88%, and 82% of pts receiving IZO Q2W, IZO QW, and PBO→IZO QW, respectively, through wk 52; the most common TEAEs were injection-site erythema and pruritus and nasopharyngitis. The majority of TEAEs were mild to moderate in severity, with serious TEAEs reported at low rates (IZO Q2W 7%; IZO QW 4%; PBO→IZO QW 4%). Rates of ulcerative colitis (0%, 1%, 0%) and oral candidiasis (1%, 1%, 0%) were also low. There were no deaths or reports of suicidal ideation.

Conclusion: IZO demonstrated durable efficacy across several measures of PsA disease activity over 52 wks. Substantial percentages of pts originally randomized to IZO or switching from PBO to IZO achieved ACR50/70, PASI 90/100, and MDA by the end of the study. IZO treatment was well tolerated, with a safety profile generally consistent with that of legacy IL-17A inhibitors.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (LB01–LB18) Late-Breaking Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Axial spondyloarthritis (axSpA) is initially treated with non-steroidal anti-inflammatory drugs. In case of inadequate response, ACR/EULAR recommend biological disease-modifying antirheumatic drugs (bDMARDs). Up to 2015, TNF inhibitors (TNFi) were the only available option. Since then, IL-17A inhibitors (IL-17Ai) have also demonstrated efficacy. The 2022 ASAS-EULAR guidance proposes switching an alternative bDMARD after TNF inhibitors failure without mandating a change of mechanism of action. Therefore, we designed a randomized multicenter clinical trial to identify the most effective treatment after a first TNFi failure in axSpA, comparing an IL-17Ai to a second TNFi.

Methods: The ROC-SpA (Rotation Or Change of biologics after first TNFi treatment failure in axSpA patients) study is a prospective, randomized, multicenter, open-label, superiority, phase IV trial. Patients with active axSpA (BASDAI >4 or ASDAS >3.5), an inadequate 3-month response to a first TNFi, and stable doses of conventional synthetic (cs)DMARDs, oral corticosteroids, and/or NSAIDs for at least one month were enrolled across 31 centers in France and Monaco. Patients were randomized to receive either an IL-17Ai or a second TNFi. The primary outcome was the ASAS40 response at week 24. Secondary outcomes were ASAS 40 at weeks 12 and 52, other clinical assessments (ASAS20, partial remission rate, ASDAS major improvement rate) at weeks 12, 24, and 52. The primary analysis was performed at the end of the study according to the intent-to-treat principle.

Results: Baseline characteristics of the enrolled patients are shown in Table 1. Both drug options led to similar rates of response ASAS40 at week 24 (15.2% for IL-17Ai and 14.5% for TNFi (14.5%), thus the primary outcome assessing the superiority of IL-17Ai was not achieved (Figure 1). No statistically significant difference was observed between groups for other secondary endpoints. ASDAS declined similarly in both groups to 2.6 (1.0) at week 12, 2.5 (0.9) at week 24, and 2.3 (1.0) at the end of follow-up. On-treatment maintenance at week 54 was 62.8% with IL-17Ai and 54.9% with TNFi. No

SD: standard deviation, HLA: human leucocyte antigen, axSpA: axial spondyloarthritis, nr: non-radiographic, AS: ankylosing spondylitis, BASDAI: Bath Ankylosing Spondylitis Disease Activity Index, ASDAS: Ankylosing Spondylitis Disease Activity Score, BASFI: Bath Ankylosing Spondylitis Functional Index, CRP: C-reactive protein, BMI, body mass index.

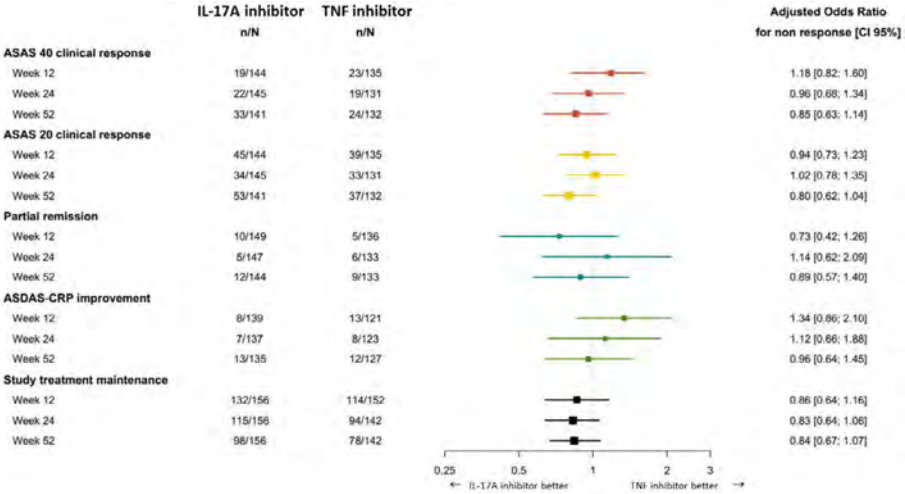

Figure 1. Clinical responses with adjusted odds ratio in IL-17i and TNFi groups at weeks 12, 24, and 52

new safety signals were identified, and adverse-event rates were comparable between groups. Exploratory, non-significant trends favored an IL-17Ai after primary nonresponse and in patients with cutaneous psoriasis, HLA-B27 negativity, or CRP < 5 mg/L. Conversely, when the first TNFi was discontinued for an adverse event, cycling to another TNFi appeared more favorable.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: In this randomized trial of axSpA patients with inadequate response to a first TNFi, switching to an IL-17Ai was not superior to cycling to a second TNFi for the primary endpoint. These findings directly inform treatment sequencing after TNFi failure and support individualized, shared decision-making in axSpA. They also align with current recommendations that, for the axial symptom control, the choice among available bDMARDs should not be based on anticipated efficacy differences.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (LB01–LB18) Late-Breaking Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: There is a substantial unmet need for effective, well-tolerated therapies for patients with SLE. Deucravacitinib is an oral, selective tyrosine kinase 2 (TYK2) inhibitor approved in moderate to severe plaque psoriasis and under evaluation in phase 3 SLE studies. Deucravacitinib demonstrated superior efficacy vs placebo (PBO) in the phase 2 PAISLEY SLE study. Here, we report integrated analyses from the PAISLEY SLE (parent; NCT03252587) and PAISLEY long-term extension (LTE; NCT03920267) studies.

Methods: Patients completing the 48-week parent study while on study drug (deucravacitinib 3 mg twice daily [BID], 6 mg BID, or 12 mg once daily [QD] or PBO) were enrolled in the 3-year LTE study (**Figure 1**). Patients on PBO were rerandomized 1:1:1 in the LTE study to 1 of the 3 deucravacitinib doses (blinded), while those already on deucravacitinib continued their

Table 1. Safety summary[a] for patients treated in the PAISLEY SLE and LTE studies

Patients with an adverse event	Placebo[f] (to week 48) n = 90	Total deucravacitinib[b] 3 mg BID n = 112		Total deucravacitinib[b] 6 mg BID n = 114		Total deucravacitinib[b] 12 mg QD n = 110		Total deucravacitinib[b] n = 336	
	n (%)	n (%)	EAIR[c] (95% CI)	n (%)	EAIR[c] (95% CI)	n (%)	EAIR[c] (95% CI)	n (%)	EAIR[c] (95% CI)
AEs	79 (87.8)	104 (92.9)	280.8 (229.4, 340.2)	107 (93.9)	246.7 (202.2, 298.1)	103 (93.6)	228.3 (186.4, 276.9)	314 (93.5)	250.2 (223.3, 279.4)
Treatment-related AEs	30 (33.3)	54 (48.2)	30.5 (22.9, 39.8)	47 (41.2)	23.0 (16.9, 30.6)	41 (37.3)	23.6 (16.9, 32.0)	142 (42.3)	25.6 (21.5, 30.2)
Serious AEs	11 (12.2)	19 (17.0)	7.1 (4.3, 11.1)	17 (14.9)	5.7 (3.3, 9.2)	24 (21.8)	10.7 (6.9, 16.0)	60 (17.9)	7.6 (5.8, 9.8)
AEs leading to treatment discontinuation	3 (3.3)	15 (13.4)	5.2 (2.9, 8.5)	13 (11.4)	4.1 (2.2, 7.1)	19 (17.3)	7.4 (4.4, 11.5)	47 (14.0)	5.5 (4.0, 7.3)
Deaths	0	1[d] (0.9)	0.3 (0.0, 1.9)	0	0	0	0	1 (0.3)	0.1 (0, 0.6)

[a]MedDRA: 28.0. Includes all patients who received deucravacitinib (parent plus LTE studies). AEs are defined as treatment-emergent AEs that occurred on or after the first treatment dose in the PAISLEY SLE or LTE study, whichever is earlier, and up to 30 days after the last treatment date. [b]In patients who received at least 1 dose of deucravacitinib in either the PAISLEY SLE or LTE study. [c]Incidence rate per 100 person-years of exposure (IR/100 P-Y): 100 × 365.25 × (total number of patients with the AE) / total exposure time for the selected AE under each treatment. 95% CI for incidence rate is calculated based on Garwood 1936.[7] [d]A 54-year-old postmenopausal woman had an acute ST-segment elevation myocardial infarction and Killip class IV cardiogenic shock. She had been on deucravacitinib 3 mg BID for 57.5 weeks (48 weeks in the parent study and 9.5 weeks in the LTE study). Risk factors included postmenopausal status, SLE, and 30 years of corticosteroid use. Both the principal investigator and the study sponsor assessed this event as unrelated to the investigative treatment.

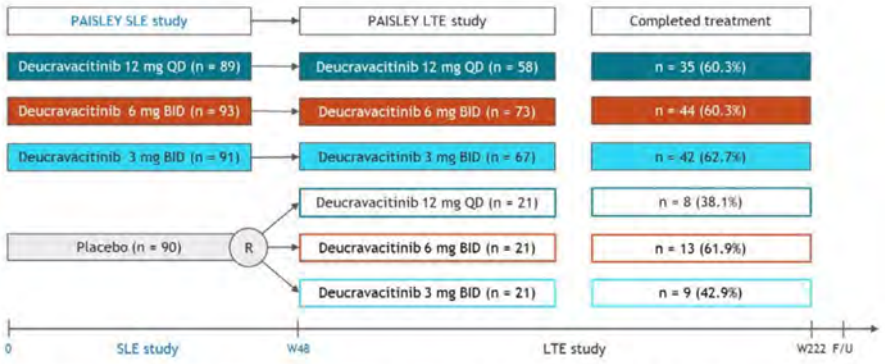
AE, adverse event; BID, twice daily; CI, confidence interval; EAIR, exposure-adjusted incidence rate; LTE, long-term extension; MedDRA, Medical Dictionary for Regulatory Activities; PBO, placebo; QD, once daily; SLE, systemic lupus erythematosus.

Figure 1. PAISLEY SLE and LTE studies



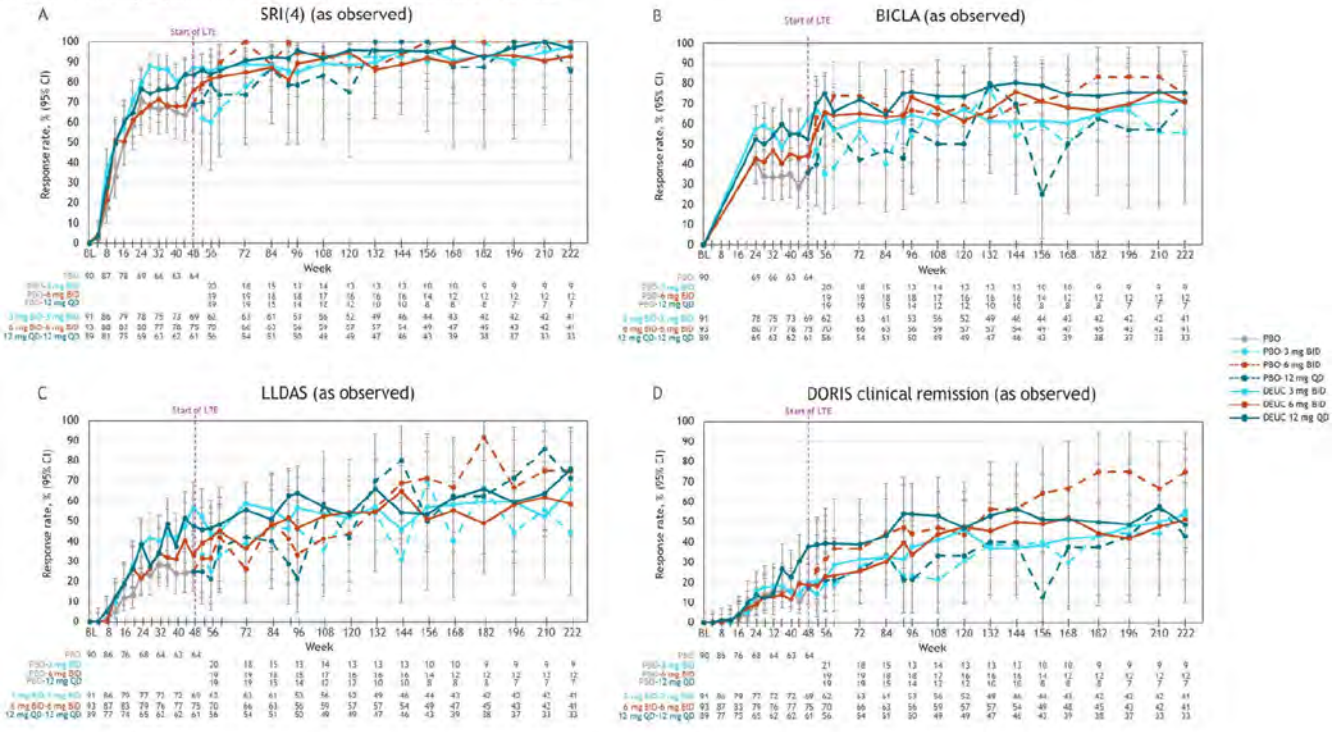
Timeline is not drawn to scale. The LTE study enrolled patients who completed the parent PAISLEY SLE study (to week 48).
BID, twice daily; F/U, follow-up; LTE, long-term extension; QD, once daily; R, randomize; SLE, systemic lupus erythematosus.

regimen for up to 4+ years of treatment (222 weeks). The LTE study allowed greater flexibility in adjustments to background treatment. Databases of the parent and LTE studies were integrated for analyses of safety through W226 and efficacy through W222. Efficacy analyses using composite measures of disease activity were summarized descriptively without formal statistical comparisons; additional efficacy results based on imputation for missing data to minimize survivor bias will be presented. For binary endpoints, 95% CIs were obtained using the Clopper-Pearson method.

Results: Of 363 patients from the parent study, 261 (72%) were enrolled in the LTE study; 151/261 patients (57.9%) completed the study. Adverse events (AEs) with up to 4+ years of treatment are shown in **Table 1**; serious AEs occurred in 17%, 14.9%, and 21.8% of patients who received deucravacitinib 3 mg BID, 6 mg BID, and 12 mg QD, respectively, and AEs leading to treatment discontinuation occurred in 13.4%, 11.4%, and 17.3%, respectively. One death deemed unrelated to study treatment occurred in the deucravacitinib 3-mg BID arm. SRI(4), BICLA, LLDAS, and DORIS remission rates were maintained over time (**Figure 2**); patients in the PBO arm in the parent study who switched to deucravacitinib achieved improvements that were broadly comparable to those of continuously treated patients from ≈W72 (**Figure 2**). CLASI-50/70 and JC-50/100 responses were maintained consistently throughout the LTE study, with increased responses seen in the PBO-switch arm. The incidence of moderate to severe flares was low across all treatment arms.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 2. Efficacy in patients treated in the PAISLEY SLE and LTE studies



Integrated analysis of the PAISLEY SLE and LTE studies was based on observed data for patients who enrolled in the LTE study. 95% CIs were obtained using the Clopper-Pearson method. BICLA responses were not evaluated prior to week 24 per the requirement that corticosteroid dose be ≥ 7.5 mg/day after week 20. LLDAS responses were evaluated using the 2019 definition.
BICLA, British Isles Lupus Assessment Group-based Composite Lupus Assessment; BID, twice daily; CI, confidence interval; DEUC, deucravacitinib; DORIS, Definitions Of Remission In Systemic Lupus Erythematosus; LLDAS, Lupus Low Disease Activity State; LTE, long-term extension; PBO, placebo; QD, once daily; SLE, systemic lupus erythematosus; SRI(4), SLE Responder Index-4.

Conclusion: Integrated analysis of the PAISLEY SLE and LTE studies confirmed the consistent safety profile and sustained efficacy of deucravacitinib in SLE with up to 4+ years of drug exposure, with no new safety signals despite complex background therapies. Patients who switched from PBO during the LTE study achieved outcomes comparable to those treated from baseline. These data represent the longest follow-up of a TYK2 inhibitor in SLE to date, supporting the potential of deucravacitinib as a durable future treatment option, currently under evaluation in phase 3 POETYK SLE trials (NCT05617677; NCT05620407).

Efficacy and Safety of Telitacicept in Patients with Sjögren's Disease: Results from a Multicenter, Randomized, Double-blind, Placebo-controlled, Phase 3 Clinical Study

Dong Xu[1], Shangzhu Zhang[1], Lin Qiao[1], Li Zhang[1], Wenxiang Wang[2], Lin Li[2], Binghua Xiao[2], Jing Zhang[2], Qing Zuraw[3], Jianmin Fang[2] and Xiaofeng Zeng[1], [1]Department of Rheumatology and Clinical Immunology, Peking Union Medical College Hospital (PUMCH), Chinese Academy of Medical Sciences & Peking Union Medical College; National Clinical Research Center for Dermatologic and Immunologic Diseases (NCRC-DID), Ministry of Science & Technology; State Key Laboratory of Complex Severe and Rare Diseases; Key Laboratory of Rheumatology and Clinical Immunology, Ministry of Education, Beijing, China (People's Republic), [2]RemeGen Co., Ltd., Rheumatology, Yantai, China (People's Republic), [3]Vor Biopharma Inc., Boston

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (LB01–LB18) Late-Breaking Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Sjögren's disease (SjD) is a chronic autoimmune disease whose pathogenesis is associated with aberrant activation of B-lymphocytes. Telitacicept, a novel fusion protein, dually targets and neutralizes B-lymphocyte stimulator (BLyS) and a proliferation-inducing ligand (APRIL), and has previously demonstrated efficacy and safety in a phase 2 study in patients with SjD.

Methods: This randomized, double-blind, placebo-controlled, phase 3 study (NCT05673993) was conducted in 79 research centers in China. Participants aged 18–70 years meeting the 2016 ACR/EULAR criteria for SjD who were anti-SSA antibody positive with EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI)≥5 were eligible. Eligible participants were randomized (1:1:1) to telitacicept 160 mg, telitacicept 80 mg, or placebo groups to receive weekly subcutaneous injection for 48 weeks. During the period from Week 24–48, participants with inadequate response to treatment in the placebo group could switch to telitacicept 160 mg or telitacicept 80 mg at a ratio of 1:1 under blind conditions. The primary efficacy endpoint was the change from baseline in ESSDAI score at Week 24. Secondary endpoints included change from baseline in ESSDAI score at Week 48; proportion of participants with: ≥3-point reduction from baseline in ESSDAI score; ESSDAI score < 5; ≥1-point or ≥15% reduction from baseline in EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI); and change from baseline in ESSPRI total score (all at Week 24 and Week 48). The proportion of Sjögren's Tool for Assessing Response (STAR) responders was also assessed, along with adverse events (AEs) and immunological parameters.

Results: A total of 381 eligible participants were randomly assigned to telitacicept 160 mg (N=127), telitacicept 80 mg (N=127), and placebo (N=127). One participant in the telitacicept 80 mg group who prematurely withdrew before receiving study treatment was excluded from the estimand population and safety set. Compared with placebo, a statistically

Table 1. Efficacy analysis.

Endpoint	Telitacicept 160 mg (N=127)	Telitacicept 80 mg (N=126)	Placebo (N=127)
Primary endpoint			
Change from baseline in ESSDAI score at Week 24, LS mean (95% CI)[a]	-4.4 (-5.0, -3.8)	-3.0 (-3.6, -2.4)	-0.6 (-1.2, -0.0)
LS mean difference (95% CI)	-3.8 (-4.6, -3.0)	-2.4 (-3.2, -1.6)	
P-value	<0.0001	<0.0001	
Secondary endpoint			
Change from baseline in ESSDAI score at Week 48, LS mean (95% CI)[a]	-4.6 (-5.3, -4.0)	-3.2 (-3.9, -2.6)	-0.4 (-1.1, 0.2)
LS mean difference (95% CI)	-4.2 (-5.1, -3.3)	-2.8 (-3.7, -1.9)	
P-value	<0.0001	<0.0001	
Proportion of participants with a ≥3-point reduction in ESSDAI score[b]			
Week 24, n (%)	84 (71.8%)	56 (47.1%)	23 (19.3%)
Difference in proportion (95% CI)	52.3% (41.53%, 63.09%)	27.9% (16.77%, 39.06%)	
P-value	<0.0001	<0.0001	
Week 48, n (%)	81 (73.0%)	56 (49.1%)	19 (16.5%)
Difference in proportion (95% CI)	56.4% (45.72%, 67.09%)	32.7% (21.51%, 43.88%)	
P-value	<0.0001	<0.0001	
Proportion of participants with an ESSDAI score <5 points[b]			
Week 24, n (%)	58 (49.6%)	34 (28.8%)	13 (10.9%)
Difference in proportion (95% CI)	39.2% (29.13%, 49.23%)	17.8% (8.20%, 27.41%)	
P-value	<0.0001	0.0004	
Week 48, n (%)	61 (55.0%)	37 (32.7%)	14 (12.2%)
Difference in proportion (95% CI)	43.0% (32.38%, 53.57%)	20.6% (10.41%, 30.71%)	
P-value	<0.0001	0.0001	
Proportion of participants with a ≥1 point or ≥15% reduction in ESSPRI score[b]			
Week 24, n (%)	100 (86.2%)	75 (63.0%)	38 (32.2%)
Difference in proportion (95% CI)	54.0% (43.45%, 64.64%)	30.8% (18.69%, 42.96%)	
P-value	<0.0001	<0.0001	
Week 48, n (%)	98 (89.1%)	86 (75.4%)	38 (33.3%)
Difference in proportion (95% CI)	55.7% (45.31%, 66.18%)	42.1% (30.39%, 53.82%)	
P-value	<0.0001	<0.0001	
Exploratory endpoint			
Proportion of participants who achieved STAR response[b]			
Week 24, n (%)	96 (82.1%)	68 (57.1%)	29 (24.4%)
Difference in proportion (95% CI)	57.7% (47.33%, 68.12%)	32.9% (21.13%, 44.59%)	
P-value	<0.0001	<0.0001	
Week 48, n (%)	91 (82.7%)	73 (64.6%)	27 (25.0%)
Difference in proportion (95% CI)	57.7% (46.90%, 68.51%)	39.5% (27.52%, 51.85%)	
P-value	<0.0001	<0.0001	
Other efficacy endpoints			
Change from baseline in ESSPRI score[a]			
Week 24, LS mean (95% CI)	-1.88 (-2.13, -1.63)	-1.31 (-1.56, -1.06)	-0.36 (-0.60, -0.11)
LS mean difference (95% CI)	-1.52 (-1.87, -1.17)	-0.95 (-1.30, -0.60)	
P-value	<0.0001	<0.0001	
Week 48, LS mean (95% CI)	-2.56 (-2.84, -2.27)	-1.74 (-2.03, -1.46)	-0.41 (-0.69, -0.13)
LS mean difference (95% CI)	-2.15 (-2.55, -1.75)	-1.34 (-1.74, -0.94)	
P-value	<0.0001	<0.0001	

The efficacy analysis was based on the estimand population.
[a]This analysis was performed using a MMRM, with group, visit, the group-by-visit interaction, and baseline score as variables in the model; the MMRM analysis model already includes handling of missing data. The post-switching data for the two telitacicept groups and the placebo group were handled with the LOCF method, i.e., imputing all the post-switching values with the most recent pre-switching results.
[b]The stratum-adjusted between-group difference was tested with the CMH method. The post-switching data for the two telitacicept groups and the placebo group were handled with the LOCF method, i.e., imputing all the post-switching values with the most recent pre-switching results. Missing data were not imputed.
CI, confidence interval; CMH, Cochran–Mantel–Haenszel; ESSDAI, EULAR Sjögren's Syndrome Disease Activity Index; ESSPRI, EULAR Sjögren's Syndrome Patient Reported Index; LOCF, last observation carried forward; LS, least square; MMRM, mixed-effects model for repeated measures; STAR, Sjögren's Tool for Assessing Response.

significant decrease in ESSDAI score from baseline at Week 24 was observed with telitacicept 160 mg (least square [LS] mean change: -4.4 vs -0.6, p< 0.0001) and telitacicept 80 mg (LS mean change: -3.0 vs -0.6, p< 0.0001) (Table 1). The efficacy in both telitacicept groups was maintained through Week 48 compared with placebo, with telitacicept 160 mg having a better reduction than 80 mg at Week 48 (LS mean change: -4.6 vs -3.2) (Figure 1a). Other efficacy endpoints, including proportion of participants who achieved ≥3-point reduction in ESSDAI score, proportion of participants with ESSDAI score < 5, proportion of participants who achieved ≥1-point or ≥15% reduction in ESSPRI score, change from baseline in ESSPRI score, and proportion of participants who achieved STAR response, showed consistent results with the primary endpoint (Table 1 and Figure 1). The majority of treatment-emergent AEs were mild or moderate (Table 2).

Conclusion: The primary efficacy endpoint was reached in this study. Compared with placebo, both telitacicept 160 mg and 80 mg demonstrated consistent clinical symptom improvement through 48 weeks and a favorable safety profile, with greater improvements observed with the telitacicept 160 mg dose.

Table 2. Overview of adverse events.

Event, n (%)	Telitacicept 160 mg (N=127)	Telitacicept 80 mg (N=126)	Placebo (N=127)
TEAEs	122 (96.1)	119 (94.4)	112 (88.2)
TRAEs	107 (84.3)	106 (84.1)	74 (58.3)
TESAEs	11 (8.7)	14 (11.1)	10 (7.9)
TRSAEs	2 (1.6)	5 (4.0)	4 (3.1)
Severe TEAEs	3 (2.4)	5 (4.0)	3 (2.4)
Severe TRAEs	0	1 (0.8)	1 (0.8)
Death	0	0	0
Common TEAE (incidence ≥10% in any group)			
Upper respiratory tract infection	80 (63.0)	85 (67.5)	74 (58.3)
Urinary tract infection	8 (6.3)	15 (11.9)	7 (5.5)
Cough	11 (8.7)	14 (11.1)	8 (6.3)
Hepatic function abnormal	7 (5.5)	16 (12.7)	7 (5.5)
Injection site reaction	53 (41.7)	51 (40.5)	5 (3.9)
Pyrexia	4 (3.1)	14 (11.1)	4 (3.1)

TEAE, treatment emergent adverse event; TRAE, treatment related adverse event; TESAE, treatment emergent serious adverse event; TRSAE, treatment related serious adverse event.

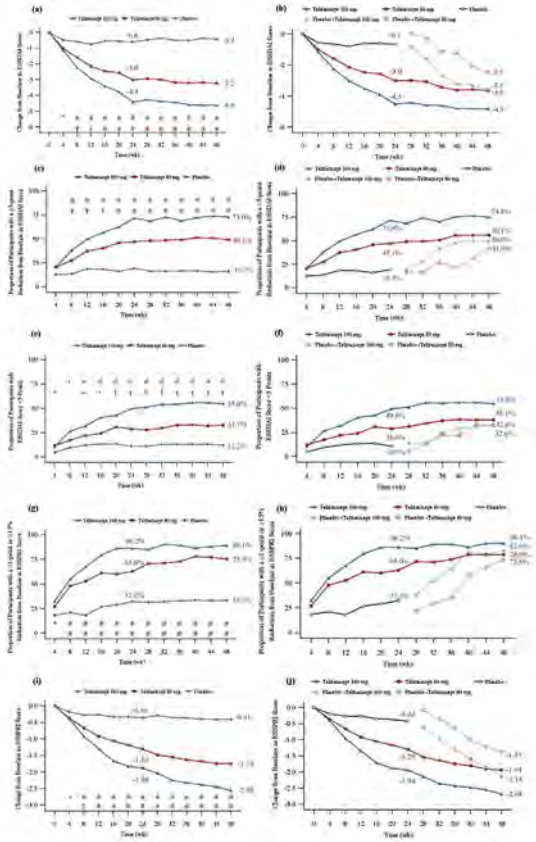

Figure 1. Efficacy outcomes over time by treatment group.
(a) LS mean change from baseline in ESSDAI score.
(b) Mean change of measure values from baseline in ESSDAI score.
(c) Proportion of participants with a ≥3-point reduction from baseline in ESSDAI score.
(d) Observed proportion of participants with a ≥3-point reduction from baseline in ESSDAI score.
(e) Proportion of participants with ESSDAI score <5 points.
(f) Observed proportion of participants with ESSDAI score <5 points.
(g) Proportion of participants with a ≥1-point or ≥15% reduction from baseline in ESSPRI score.
(h) Observed proportion of participants with a ≥1-point or ≥15% reduction from baseline in ESSPRI score.
(i) LS mean change from baseline in ESSPRI score.
(j) Mean change of measure values from baseline in ESSPRI score.
(a) and **(i)**: For continuous variables, the analyses between each telitacicept group and placebo group used MMRM method. MMRM analysis had already accounted for missing data. The post-switching data for the two telitacicept groups and the placebo group were handled with the LOCF method, i.e., imputing all the post-switching values with the most recent pre-switching results.
(c), **(e)**, and **(g)**: For categorical variables, the stratum-adjusted between-group difference was tested with the CMH method. Missing data were not imputed. The post-switching data for the two telitacicept groups and the placebo group were handled with the LOCF method, i.e., imputing all the post-switching values with the most recent pre-switching results.
*: P<0.05, †: P<0.01, ‡: P<0.001, #: P<0.0001.
(b), **(d)**, **(f)**, **(h)**, and **(j)**: A descriptive analysis was performed on the observed data, and missing data were not imputed.
CMH, Cochran–Mantel–Haenszel; ESSDAI, EULAR Sjögren's Syndrome Disease Activity Index; ESSPRI, EULAR Sjögren's Syndrome Patient Reported Index; LOCF, last observation carried forward; LS, least square; MMRM, mixed-effects model for repeated measures; wk, Week.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (LB01–LB18) Late-Breaking Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: OA is a prevalent disabling disease growing globally due to aging populations and rising obesity. In primary OA, the effects of joint tissue damage accumulate with age, with low-grade inflammation and decline in the joint regenerative capacity.

A novel cell therapy of apoptotic PBMCs has been developed for OA based on robust pre-clinical data on their pro-resolution modulation of macrophage-mediated inflammation. Following a Phase I safety run-in, in which participants demonstrated favorable tolerability, we now report the pre-planned 3-month analysis results of a randomized controlled Phase IIa assessing safety and efficacy of apoptotic cell therapy in knee OA, as well as identifying a responder population based on baseline covariates.

Methods: ENX-CL-05-001 is a multicenter, randomized, double-blind, placebo-controlled Phase IIa in moderate–severe knee OA (NCT06233474). Participants received 3 knee injections on Days 0/14/28 and are followed to Month 12. Primary objectives were safety/tolerability; key secondary endpoints included changes in NRS and WOMAC pain scores and MRI semi-quantitative evaluations. Innovative machine-learning methods explored heterogeneity and high-responder populations.

Results: 134 patients were randomized and treated. Baseline characteristics were well balanced between the arms (mean age 61, 55% female, mean BMI 29). No treatment-related SAEs occurred. AEs were more frequent with apoptotic cell therapy vs placebo (89.6% [60/67] vs 71.6% [48/67]), driven by transient local reactions (typically resolving ~6 days vs ~10 days with placebo); noncompliance with treatments was uncommon (7.5% elected to forego subsequent injections due to AEs).

In the mITT population, pain NRS improvement was 24% higher with apoptotic cell therapy vs placebo; and WOMAC pain and function improvements were also numerically higher, however these did not reach statistical significance. An age-related responder population enriching for primary/idiopathic OA was identified (≥60 years; 69/129, 53.5% of study

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1: Results of WOMAC pain change at 3 months for the mITT overall population and Age-related Responder Population ≥ 60 years and ≥ 65 years

population) demonstrating significant improvements with apoptotic cell therapy: WOMAC Pain –27.82 (SD 20.76) vs –16.22 (SD 22.54), 72% relative improvement (p=0.03); WOMAC Total –26.43 vs –13.75, 92% relative improvement (p=0.012), including WOMAC Function –26.45 vs –12.63, 109% relative improvement (p=0.007). The 3-month pain NRS group difference (-0.98; 0-10), 48% relative improvement (p=0.07), was clinically meaningful and consistent with weekly pain reporting. Ongoing Month-6 readouts indicate potentially durable results. Moreover, pain improvement results were associated with more severe baseline imaging markers, including bone marrow lesions, Hoffa synovitis and radiographic structural damage.

Conclusion: Intra-articular apoptotic cell therapy was well tolerated without treatment-related SAEs and produced clinically meaningful and statistically significant improvements in pain and function endpoints in participants ≥60 years—consistent with an age-linked, macrophage-mediated OA phenotype. These findings support advancement into advanced trials program targeting older, primary/idiopathic knee OA.

Session Time: 10:30AM–12:30PM

Background/Purpose: B cells infiltrate the kidneys in lupus nephritis (LN) and likely contribute to the pathogenesis of kidney injury. The REGENCY trial (NCT04221477) showed that depletion of B cells with the anti-CD20 monoclonal antibody, obinutuzumab, increased the proportion of clinical complete responses when added to standard therapy compared with standard therapy alone.

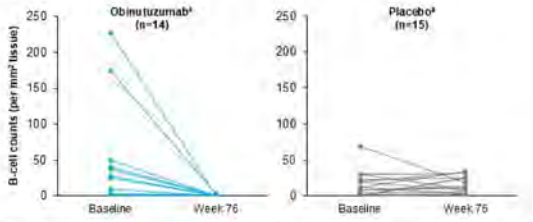
Figure 1. Tissue CD79a+/CD138- B cells at baseline and Week 76 in the REGENCY longitudinal kidney biopsy B-cell cohort



B-cell count per mm² tissue, median (min, max)	Obinutuzumab[a] (n=14)	Placebo[a] (n=15)
Baseline	16.76 (0.35, 226.73)	12.15 (0.00, 68.85)
Week 76	0.31 (0.00, 3.31)	13.27 (2.15, 34.77)

In cases of replicates (more than one slide stained for the same participant), single value is calculated as sum of B cells divided by the sum of areas.
CRR was achieved by seven participants (50%) in the obinutuzumab group and three (20%) in the placebo group.
CRR, complete renal response; MMF, mycophenolate mofetil; ST, standard therapy.
[a]Plus ST consisting of MMF plus glucocorticoids.

We postulated that obinutuzumab may deplete B cells in the kidney in addition to the periphery. Given the potential importance of deep, tissue B-cell depletion in LN, participants in the REGENCY trial were offered a post-Week 76 kidney biopsy to evaluate histologic changes over time. Here we present the results of kidney B-cell dynamics from participants with both biopsies.

Methods: Blinded, central reads of baseline and post-Week76 (obtained between Week 76 and Week 80) biopsies were performed by nephropathologists at Arkana Laboratories using the 2018 ISN/RPS LN classification criteria. All participants met the American College of Rheumatology classification criteria for systemic lupus erythematosus and had biopsy-proven proliferative LN. CD79a+/CD138- B cells were quantified on formalin-fixed, paraffin-embedded tissue sections by immunofluorescence microscopy and digital whole-slide image analysis for participants with paired baseline and post-Week 76 biopsies with remaining material for tissue staining (N=29 participants; 14 obinutuzumab plus standard therapy [OBI+ST] and 15 placebo plus standard therapy [PBO+ST]). Raw analysis data generation was performed blinded to treatment; data were unblinded for statistical evaluation. Treatment group comparison of absolute change from baseline at Week 76 in B-cell counts was assessed using ANCOVA model with baseline B-cell counts and stratification factor (Black vs Other) as independent variables.

Results: Baseline characteristics were generally balanced and consistent with the overall REGENCY population; however, the baseline level of tissue CD79a+/CD138- B cells was higher in the OBI+ST group compared with the PBO+ST group (**-Table 1**). Spatial frequency of tissue CD79a+/CD138- B cells at baseline and Week 76 was similar in PBO+ST participants, whereas there was a highly significant decline of B-cell counts per mm^2 at Week 76 vs baseline in OBI+ST participants, with measurements at or near zero (**Figure 1**). ANCOVA analysis showed that at Week 76, the adjusted mean change from baseline in B-cell counts was –28.5 (95% CI, –33.3 to –23.6) in OBI+ST and –11.9 (95% CI, –16.6 to –7.2) in PBO+ST, with a difference of –16.6 (95% CI, –23.4 to –9.7; P< 0.0001) between treatment groups.

Conclusion: These findings demonstrate that obinutuzumab potently depletes B cells in the kidneys of individuals with LN. These data represent the first demonstration of kidney tissue-level B-cell depletion by an anti-CD20 agent in any glomerular disease. Given the possible association of deep, tissue B-cell depletion and prolonged disease control in LN, the clearing of B cells from the kidneys by obinutuzumab may contribute to the improvement in kidney function and decline in LN flares observed in the obinutuzumab-treated patients during the REGENCY trial.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (LB01–LB18) Late-Breaking Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Idiopathic inflammatory myopathies (IIMs) are systemic autoimmune diseases affecting muscles, skin, lungs, joints, and several other organs; many patients are refractory to available therapy, highlighting the need for novel treatments. BMS-986353 is an investigational CD19-directed autologous chimeric antigen receptor (CAR) T cell therapy being studied in autoimmune diseases. We present the first report on the tolerability and efficacy of BMS-986353 in patients with severe refractory IIMs from Breakfree-1 (NCT05869955).

Methods: Patients with IIM with severe muscle involvement (manual muscle test [MMT]-8 < 130) despite treatment with glucocorticoids and ≥2 immunosuppressants (ISTs) were treated with a single BMS-986353 infusion of 10×10^6 CAR T cells following lymphodepletion. All patients discontinued IIM-specific therapies and steroids (≥5 mg prednisone equivalent, except when directed for adrenal insufficiency) before lymphodepletion. Primary endpoint was safety.

Table

Table. CRS and ICANS

	CRS	ICANS
Any grade,[a] n (%)	6 (46.2)	1 (7.7)
Grade 1	5 (38.5)	0
Grade 2	1 (7.7)	0
Grade 3	0	1 (7.7)
Median time to onset (range), days	5.0 (5–10)	9
Median duration[b] (range), days	4.0 (1–11)	3
Treatments, n (%)		
Tocilizumab	5 (38.5)	0
Paracetamol	2 (15.4)	0
Steroids	0	1 (7.7)
Anakinra	0	0

[a]No grade 4 or 5 events were observed. [b]Multiple events occurring within 7 days of each other are considered as 1 episode.
CRS, cytokine release syndrome; ICANS, immune effector cell-associated neurotoxicity syndrome.

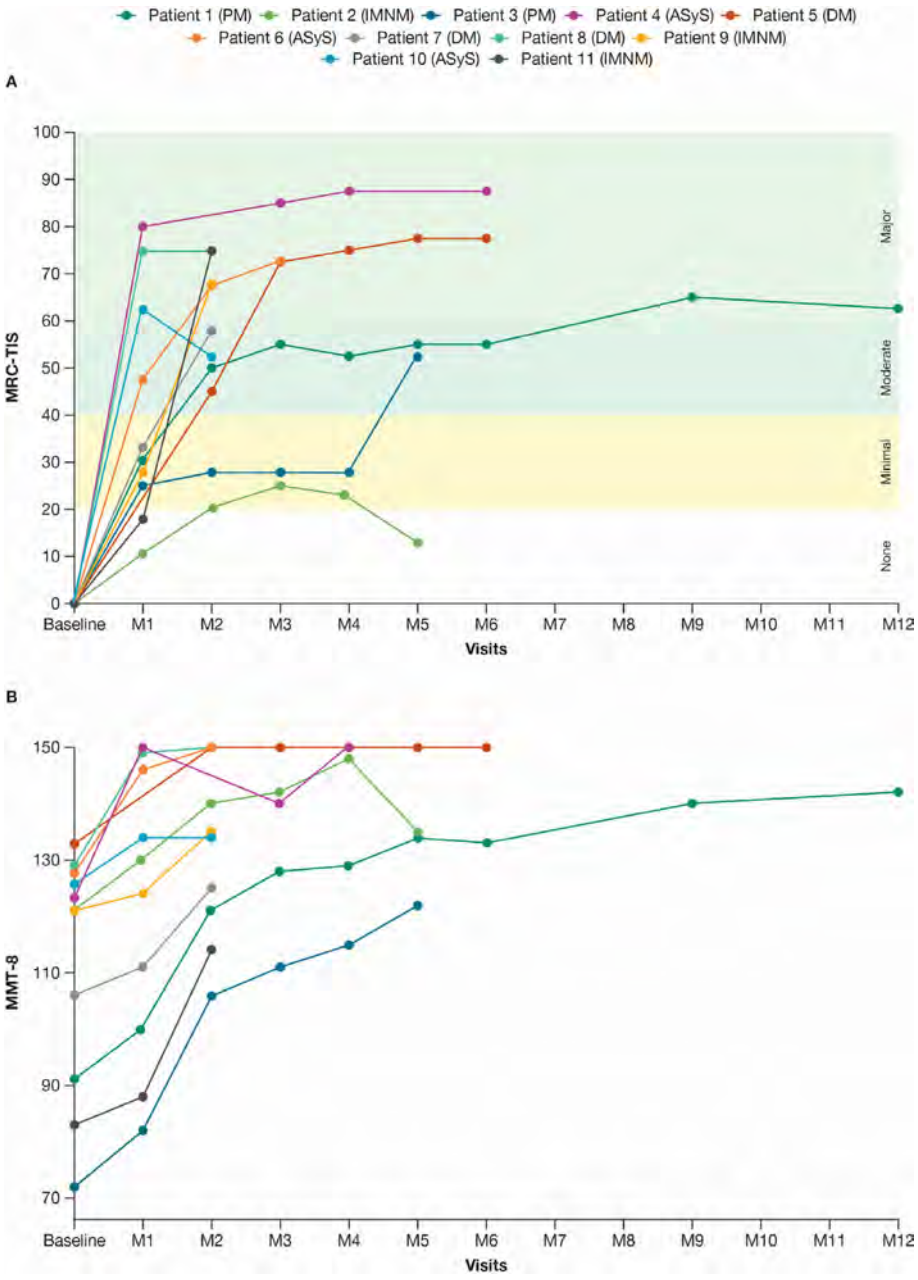

Figure 1. MRC-TIS (A) and MMT-8 (B) following BMS-986353 infusion in efficacy-evaluable IIM population. ASyS, antisynthetase syndrome; IMNM, immune-mediated necrotizing myopathy; M, month.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

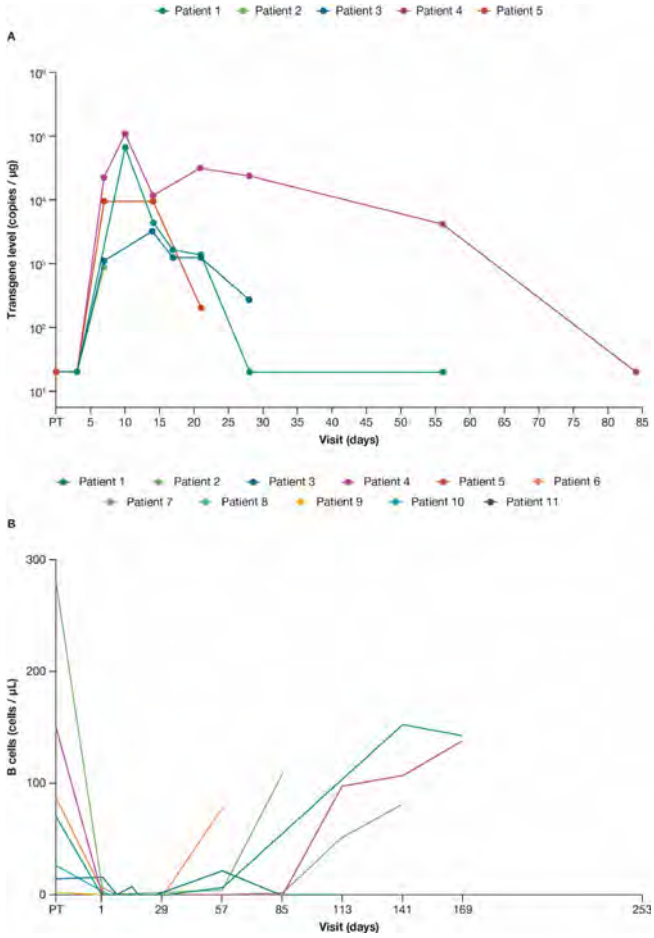

Figure 2. CAR transgene levels (A) and peripheral blood B cell depletion/reconstitution (B) in evaluable IIM population. Transgene levels refer to the number of genetic copies of the engineered CAR construct present in a patient's blood, as measured by droplet digital PCR. CAR, chimeric antigen receptor; PT, pre-treatment.

Results: As of August 14, 2025, 13 patients were evaluable for safety. Before enrollment, patients received a median 6 (range 3–9) prior ISTs. Eleven patients were evaluable for efficacy (antisynthetase syndrome, n=3; DM, n=3; PM, n=2; immune-mediated necrotizing myopathy [IMNM], n=3), with median baseline MMT-8 score of 121 (range 72–133). Median follow-up was 87 days (range 4–375).

Six of 13 (46.2%) patients developed low-grade (Gr) cytokine release syndrome (Gr 1, n=5; Gr 2, n=1; **Table**). One patient had immune effector cell-associated neurotoxicity syndrome (Gr 3) characterized by decreased level of consciousness and aphasia, which resolved in 3 days with dexamethasone. Two transient hematologic treatment-emergent adverse events of Gr ≥3 (neutropenia, n=1; anemia, n=1) were reported. There were no prolonged cytopenias (lasting >28 days) or treatment-emergent serious infections.

Of the 11 efficacy-evaluable patients, 7 (63.6%) achieved a major response and 3 (27.3%) a moderate response based on Myositis Response Criteria—Total Improvement Score (MRC-TIS). All 11 patients experienced a rapid and significant improvement in muscle strength; median increase in MMT-8 score from baseline was 22.0 points at day 85 (n=6) and 27 points at day 169 (n=3). One patient with IMNM with a >10-year disease duration and minimally elevated baseline creatine kinase had an improved MMT-8 without achieving ≥moderate MRC-TIS response (**Figure 1**). Ten of 11 efficacy-evaluable patients remained off IIM-directed therapy at last follow-up, with 1 patient empirically restarting IVIG for elevated creatine kinase despite improvement in MMT-8 score.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

All patients had robust CAR T cell expansion and achieved complete peripheral blood B-cell depletion (**Figure 2**). IIM-related autoantibody levels decreased post-infusion.

Conclusion: Findings from Breakfree-1 demonstrate a manageable safety profile, robust CAR T cell expansion, complete B-cell depletion, and promising efficacy of BMS-986353 without IIM-directed therapies in >90% of patients with severe refractory IIMs.

Abstract Number: LB15

Dietary Fiber Supplementation Enhances Methotrexate Response and Restores Th17/Treg Balance in Rheumatoid Arthritis: Results from the Superfibre Randomized Trial

Claire Immediato Daien[1], Jean-Pierre Hellier[2], Zübeyir Salis[3], Gaël Mouterde[4], Jacques Morel[5], Laurence Macia[6] and Rachel audo[4], [1]CHU and Univesrity of Montpellier, Montpellier, France, [2]CHU Montpellier, Arles, France, [3]University of Montpellier, Montpellier, France, [4]CHU Montpellier, Montpellier, France, [5]CHU and University of Montpellier, Montpellier, France, [6]Sydney University, Brisbane, Australia

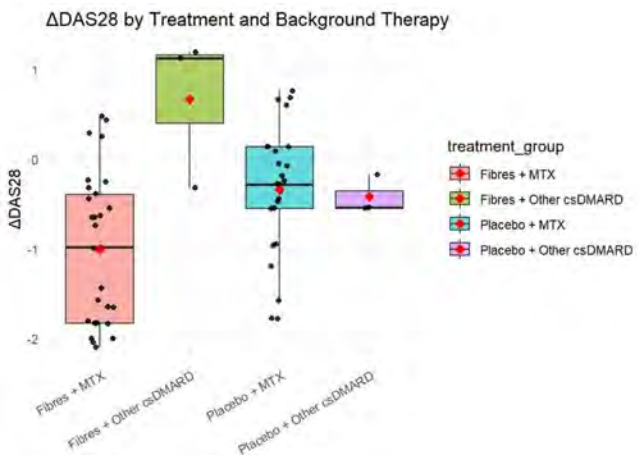
SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (LB01–LB18) Late-Breaking Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Gut dysbiosis and Th17/Treg imbalance contribute to rheumatoid arthritis (RA). Additionally, methotrexate (MTX) efficacy depends on gut microbiota composition, especially on the presence of B. fragilis and butyrate (Zhou B, et al. Front Microbiol. 2022). Dietary fibres improve gut microbiota composition and increase microbiota-derived short-chain fatty acids including butyrate, that may restore immune tolerance.

We aimed to evaluate whether dietary fiber supplementation in patients with RA improves disease activity, Th17/Treg balance and response to MTX.

Methods: Superfibres was a randomized, double-blind, placebo-controlled trial, including patients with active RA despite stable doses of csDMARDs. Patients were randomized 1:1 to inulin (12 g/day) or placebo for 30 days. EULAR response and change in peripheral Th17/Treg subsets (flow cytometry) were compared. Subgroup analyses compared MTX vs. non-MTX patients.

Results: A total of 49 patients were included (26 in the fiber group, 23 in the placebo group) with 85.7% women, a mean age of 62 ± 10 years and a mean DAS28 was 3.86 ± 0.61. Odds of EULAR response were markedly higher with fiber (OR 4.65, 95% CI 1.15–18.9; p=0.03). Fiber reduced circulating Th17 cells and the Th17/Treg ratio compared with placebo (p < 0.02). A significant treatment × MTX interaction was observed (p=0.011). In MTX users, mean ΔDAS28 was –1.00 with fiber vs –0.34 with placebo (Fig. 1). No effect was seen in non-MTX patients (n=6). Intervention was well tolerated, with >90% compliance.



DeltaDAS28 by treatment and background therapy.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: This first placebo-controlled RCT of dietary fiber in RA shows that supplementation significantly increases EULAR response rates and improves Th17/Treg balance. This may be explained by an enhanced MTX efficacy These findings establish the gut–immune axis as a novel therapeutic target and identify dietary fiber as a safe, inexpensive adjunct to MTX in RA. If confirmed, our results have the potential to change clinical practice and improve MTX efficacy in daily practice.

Mepolizumab Reduces End-Organ Manifestations Compared with Standard of Care in Patients with EGPA and HES: A US Real-world Analysis

David Silverman[1], Timothy Barnes[2], Nnaemeka Odo[2], Jared Silver[3], Lisa Le[2], Amy Edgecomb[4] and Hitesh Patel[5], [1]Rheumatology Department, Kaiser Permanente Colorado Medical Group, Denver, Colorado, [2]Value and Evidence Solutions, Optum Life Sciences, Eden Prairie, Minnesota, [3]Clinical Development, Amgen, Thousand Oaks, California, [4]Anti-infectives and Respiratory, GSK, Philadelphia, Pennsylvania, [5]US Medical Affairs, GSK, Durham, North Carolina

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (LB01–LB18) Late-Breaking Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Eosinophilic granulomatosis with polyangiitis (EGPA) and hypereosinophilic syndrome (HES) are rare systemic diseases characterized by persistent eosinophilia and tissue infiltration, resulting in end-organ dysfunction (EOD)[(1)]. Standard of care (SOC) includes corticosteroids, immunosuppressives, disease-modifying antirheumatic drugs and biologics[(2)]. Mepolizumab, an anti-interleukin-5 monoclonal antibody, reduces disease manifestations and corticosteroid dependence[(3,4)]. Real-world evidence on EOD outcomes following mepolizumab initiation in EGPA and HES is limited. This study evaluated mepolizumab impact on EOD compared with other SOC therapies in a US real-world setting.

Methods: This retrospective cohort study used administrative claims and EHR data from Optum's Market Clarity database. Patients with EGPA (≥18 years) or HES (≥12 years) were identified at mepolizumab or SOC initiation (index). Patients were classified as mepolizumab users or chronic SOC users (≥6 months of >7.5 mg prednisone equivalent and/or ≥2 records of immunosuppressants or other disease-modifying antirheumatic drugs from index). Baseline sociodemographic characteristics, SOC use, comorbidities, and prior end-organ procedures were captured in the 6-months pre-index. Inverse probability of treatment weighting was used to balance the covariates between patient cohorts. EOD proportion, rate, and status were assessed ≥12 months post-index. Z-test compared weighted groups. Analyses were performed separately for EGPA and HES.

Results: Among 1102 patients with EGPA, 375 received mepolizumab and 727 received chronic SOC. Weighted analyses demonstrated numerical improvements in 14 distinct EOD conditions across multiple organ systems in those treated with mepolizumab vs chronic SOC. Significant improvements in EOD status were observed in acute kidney failure in mepolizumab vs chronic SOC (63.4% vs 23.4%, p=0.026) **(Table)**.

Patients are grouped according to treatment received during the landmark period (within 6 months of index date) – mepolizumab vs chronic SOC[2]. Only the proportion of patients with improvement of EOD status[1] is reported as the remainder of patients experienced worsening of EOD status. [1]Improvement of EOD status: no evidence of hospitalization or emergency room visit linked to ICD-10 code for EOD condition AND treatment change defined as a removal of new SOC medication or decrease in SOC medication dose. [2]Chronic SOC user: ≥6 months of >7.5 mg prednisone equivalent and/or ≥2 records of immunosuppressants or other disease-modifying antirheumatic drugs (DMARDs). The earliest record and date of this continuous use period of SCS and/or immunosuppressants or DMARDS will be defined as the index date. [3]p-values are calculated from standardized differences between mepolizumab and chronic SOC users using z-test. Significant p-values are highlighted in bold. EGPA, eosinophilic granulomatosis with polyangiitis; EOD, end-organ dysfunction; HES, hypereosinophilic syndrome; ICD, International Classification of Diseases; Mepo, mepolizumab; SOC, standard of care; SCS, systemic corticosteroid; TIA, transient ischemic attack.

Among 784 patients with HES, 198 received mepolizumab and 586 received chronic SOC. Weighted analyses showed numerical improvement across 12 distinct EOD conditions among those treated with mepolizumab vs chronic SOC. Significant improvements in EOD status were observed in mepolizumab vs chronic SOC in mitral regurgitation (90.9% vs 29.4%, p< 0.001), and venous thrombosis (69.5% vs 8.1%, p=0.009) **(Table)**.

Conclusion: In this large real-world analysis, mepolizumab was associated with clinically meaningful improvements across multiple end-organ systems in both EGPA and HES, including cardiac, renal, and vascular conditions. These findings represent a potential signal of multisystem benefit and support further research to explore the durability and clinical significance of these effects.

Circulating biomarkers for organ involvement in systemic lupus erythematosus: a series of systematic reviews and meta-analyses

Sitian Zang[1], Ranran Yao[1], Yan Wang[1], Danxue Zhu[1], Jing He[1] and Zhanguo Li[2], [1]Peking University People's Hospital, Beijing, China (People's Republic), [2]Peking Univeristy People's Hospital, Beijing, China (People's Republic)

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (LB01–LB18) Late-Breaking Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) features heterogeneous clinical manifestations. The identification of biomarkers that facilitate initial disease recognition is a cornerstone of optimized clinical management. This study was aimed at summarizing and providing an exhaustive and penetrating exploration of biomarkers associated with organ involvement.

Methods: Embase, PubMed and Web of Science were systematically searched from inception through June 1, 2023. Effect estimates were pooled by the DerSimonian-Laird random-effects model in the presence of substantial heterogeneity (I^2 >50% or the p-value for Q was < 0·1). Fixed-effects models were not used when heterogeneity criteria were not met. Bivariate models were employed for summarizing diagnostic accuracy parameters when ≥4 datasets were available. Univariate models were used for three or fewer datasets or when bivariate models failed to converge.

Results: A total of 698 studies were included in the analysis and comprised 114,457 lupus patients from 55 countries and territories. The most commonly involved organ and system were renal, neuropsychiatric, hematologic, cardiopulmonary, and cutaneous, corresponding to five distinct lupus phenotypes: lupus nephritis (LN), neuropsychiatric SLE (NPSLE), hematologic involvement, cardiopulmonary involvement, and cutaneous lupus erythematosus (CLE). Thirty-seven biomarkers were significantly associated with the risk of multi-organ involvement. We further analyzed the specific biomarkers for the five phenotypes. It showed that 71 circulating biomarkers were significantly related to an increased risk of LN. Among them, the most frequently reported biomarker was anti-complement 1q (anti-C1q) (odds ratio [OR] 3.76, 95% confidence interval [CI] 2.50–5.64, p< 0.0001). Of the 43 circulating biomarkers correlated with an increased risk of NPSLE, anti-ribosomal P protein (anti-Rib-P) isotypes (anti-Rib-P IgG [OR 1.93, 95% CI 1.10–3.39, p=0.023]) and subtypes (anti-Rib-P0 [OR 2.28, 95% CI 1.20–4.33, p< 0.0001] and anti-neuronal antibodies (OR 6.10, 95% CI 1.65–22.59, p=0.0070) were most frequently reported. The most frequently reported biomarkers for hematologic involvement were platelet-related and coagulation-associated antibodies, as well as non-criteria anti-phospholipid antibodies. High-sensitivity C-reactive protein (hsCRP) levels

differed greatly between patients with and without serositis, pericarditis, myocarditis and pleuritis. Anti-nuclear ribonucleoprotein (anti-nRNP) antibodies (OR 3.66, 95% CI 1.94–6.89, p< 0.0001) were the most commonly reported biomarker showing a relationship with a higher risk of pulmonary arterial hypertension. Among the eight specific biomarkers for CLE in SLE patients, anti-SSA60 was significantly associated with increased risk of CLE with the largest number of involved patients (OR 1.30, 95% CI 1.05–1.62, p=0.017).

Conclusion: This large-scale analysis revealed biomarker profiles associated with organ involvement in SLE and provided a clinically actionable non-invasive tool for the risk prediction of organ damage.

Abstract Number: LB18

Transcriptomic Signatures of ANA+ and ANA- B Cells Reveal Shifts from Active Disease to Remission in Systemic Lupus Erythematosus

Rita Pozovskiy[1], Yemil Atisha-Fregoso[2] and Betty Diamond[3], [1]Zucker School of Medicine, New York, New York, [2]Feinstein Institutes for Medical Research, New York, New York, [3]The Feinstein Institutes for Medical Research, Manhasset, New York

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (LB01–LB18) Late-Breaking Posters
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: In systemic lupus erythematosus (SLE), IgG antibodies that target nuclear antigens (ANA) are pathogenic and part of the diagnostic criteria for SLE. Healthy individuals (HC) possess ANA^+ mature B cells but these cells do not differentiate into IgG+ plasma cells and do not produce pathogenic antibodies. This study aimed to identify differential activation and regulatory mechanisms of ANA^+ B cells in patients with SLE and HC. To gain insight into immune homeostasis during remission, we included patients with active disease (SLE-A) and those in remission (SLE-R).

Methods: We profiled the transcriptomes of ANA^+ and ANA^- B cells using single-cell RNA sequencing (scRNA-seq). Samples were obtained from 7 patients with SLE-A, 5 SLE-R, and 7 HC. Three B cell subsets were isolated (ANA^+ and ANA^-): (1) $CD19^+$ $CD27^-$ CD38^int (encompassing naïve B cells and age-associated B cells [ABCs]), (2) $CD19^+$ $CD27^+$ IgM^+ (including circulating marginal zone B cells [MZB] and IgM memory B cells), and (3) $CD19^+$ $CD27^+$ IgG^+ (IgG memory B cells).

Results: We identified seven transcriptionally distinct B cell clusters defined by canonical lineage and activation markers: naïve, activated naïve, marginal zone B cells (MZB), IgM memory, memory (predominantly IgG^+), activated memory (also predominantly IgG^+), and age-associated B cells (ABCs). Minimal overlap in cluster composition was observed between SLE-A and HC, while SLE-R exhibited a unique intermediate profile.

Pathway analysis revealed that activated clusters were enriched for interferon (IFN) and TNF-α and oxidative phosphorylation signatures compared to quiescent clusters. Using a published compendium of scRNA-seq profiles of immune cells in response to cytokines, we confirmed an IFN signature across all SLE patients, with higher expression in SLE-A relative to SLE-R. TNF signaling was consistently present in activated clusters from both SLE-A and SLE-R, with comparable magnitude.

To identify differentially expressed genes in ANA^+ B cells, we applied a zero-inflated model to pseudobulk data, stratified by cluster and cohort. ANA^+ B cells showed enrichment of B cell receptor (BCR) signaling pathways, consistent with chronic antigen exposure. Notably, Fc receptor signaling was upregulated in ANA^+ B cells from HC and SLE-R, but absent in SLE-A.

Conclusion: Our findings highlight the relevance of activated memory B cell subsets and ABCs in SLE pathogenesis, with SLE-R marked by a persistent activated naïve B cell population enriched for TNF signaling. We identified a regulatory checkpoint in ANA^+ memory B cells that is impaired in SLE-A. Activated B cell clusters in SLE exhibited reduced oxidative phosphorylation, suggesting a metabolic shift toward glycolysis. Differential regulation of Fcgr2b between ANA+ and ANA- in SLE-A suggests that Fcgr2b may modulate ANA^+ B cell activation in health and remission but is dysregulated during active disease. This further implicates Fc receptor signaling as a potential therapeutic target to promote or sustain remission in SLE.

SESSION INFORMATION
Session Date: Wednesday, October 29, 2025
Session Title: (LB19–LB24) Late-Breaking Abstracts
Session Type: Late-Breaking Abstract Session
Session Time: 8:00AM–9:30AM

Background/Purpose: Over 50% of RA patients require multiple b/tsDMARD classes due to inadequate or lost response. Rosnilimab, an investigational monoclonal antibody that selectively targets and depletes pathogenic T cells of interest (i.e., PD-1^{high} Tph/Tfh, Teff), is upstream of several clinically validated targets in RA and offers potential advantages as a new treatment modality.

Methods: This multicenter, randomized, double-blind, placebo-controlled Phase 2B trial (NCT06041269) enrolled adults with moderate to severe (≥6 tender and ≥6 swollen joints) seropositive RA on concurrent csDMARDs and < 3 previous b/tsDMARDs. Participants were randomized 1:1:1:1 to receive SC rosnilimab 100mg Q4W, 400mg Q4W, 600mg Q2W or placebo. Primary endpoint was at Wk 12. Participants randomized to rosnilimab were required to achieve CDAI LDA (≤10) at Wk 14 to continue in the Blinded All-Active Treatment Period through Wk 28, with subsequent off-drug follow-up to Wk 38.

Results: 424 participants were randomized; 41% had prior b/tsDMARD exposure; 95.0% and 86.6% were RF and CCP positive, respectively. At baseline, participants had a mean DAS28-CRP of 5.6, mean CDAI of 37.7 and mean CRP of 18mg/L.

The primary endpoint, mean change from baseline in DAS28-CRP at Wk 12, was met by all rosnilimab doses (-2.06, -2.12, -2.06 in 100mg, 400mg and 600mg arms) versus placebo (-1.69) ($p < 0.01$). At Wk 12, all rosnilimab dose arms had significantly greater changes in ACR20 and mean change in CRP versus placebo. ACR 50, ACR70, CDAI LDA and patient reported outcomes (PROs) consistently demonstrated higher responses over placebo (Fig 1a).

ITT population; MMRM used for continuous measures at Week 12, MI-LMCF at Week 28, NRI used for dichotomous measures at Week 12 and 28
*P<0.05; **P<0.01; ***P<0.001.

b. **Proportion of Week 28 Responders Completing Week 38 and Maintaining Response Off-Drug at Week 38**

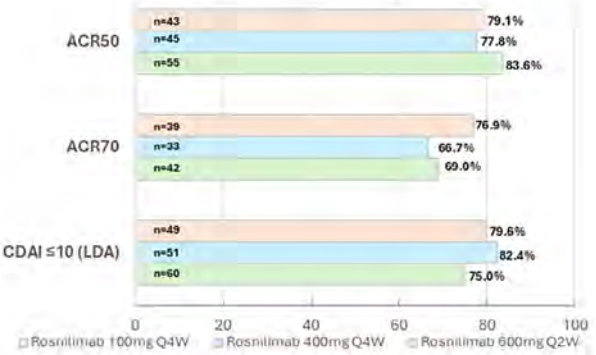

Figure 1. Clinical Efficacy Measures. a) Primary, Selected Secondary and Exploratory Endpoints at Week 12 and Week 28; MMRM = Mixed model repeated measures; used for continuous measures at week 12. MI-LMCF = Multiple imputations with last mean carried forward; used for continuous efficacy measures at Week 28. NRI = nonresponder imputation (NRI); used for dichotomous endpoints at Week 12 and 28. *p<0.05; **p<0.01; ***p<0.001. b) Proportion of Week 28 Responders Completing Week 38 and Maintaining Response Off-Drug at Week 38.

220 (69%) rosnilimab-treated participants reached CDAI LDA at Wk 14 and were eligible to continue into the All-Active Period. Those not eligible for the All-Active Period were imputed as nonresponders at all future visits, although many would be considered responders by other criteria (60% achieved ACR20 and 18% achieved ACR50). In the All-Active cohort, response rates substantially increased from Wk 12 to Wk 28 for secondary endpoints (ACR 50,70, LDA) and PROs (HAQ, pain VAS) (Fig 1a). After Wk 26, during the 12-14 week off drug period, responses were generally maintained (Fig 1b). Results were similar in b/tsDMARD naïve and experienced participants.

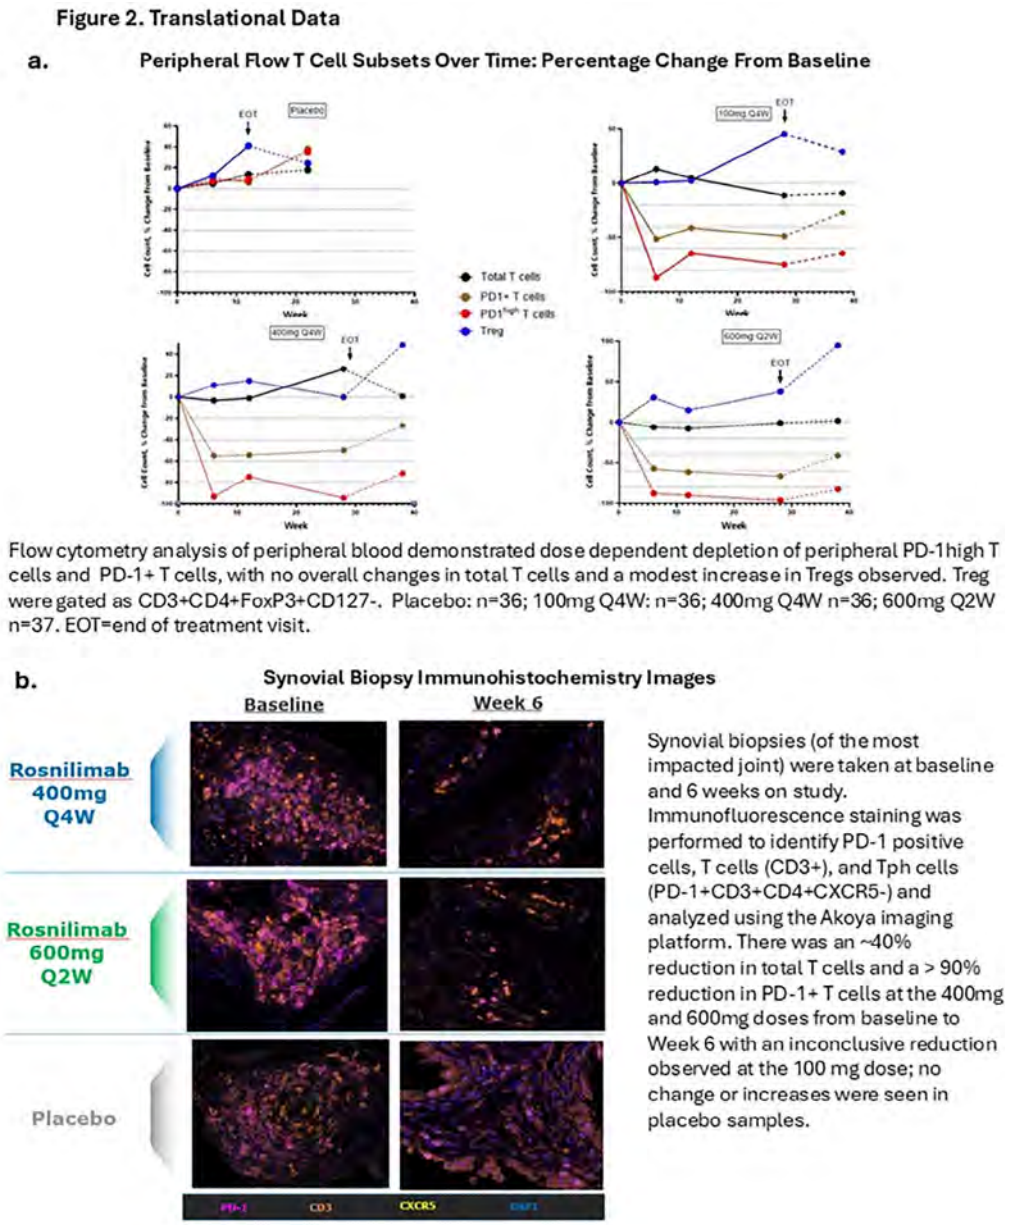

Figure 2. Translational Data. a) Peripheral Flow T Cell Subsets Over Time: Percent Change from Baseline; b) Synovial Biopsy Immunohistochemistry Images

Translational data showed rapid depletion (>90%) of pathogenic T cells of interest in blood with preservation of the total T cell numbers through the 28 Wk treatment period, consistent with the durability of clinical outcomes (Fig 2a). Synovial biopsies at Wk 6 (n = 24 evaluable pairs) demonstrated similar >90% depletion of pathogenic T cells of interest (Fig 2b) and broad downregulation of gene signatures including T cell, B cell, and myeloid activation.

Rosnilimab was well tolerated. 28/424 (7%) participants discontinued prior to Wk 12. 8/220 (4%) participants discontinued during the All-Active Period. No deaths or malignancies were reported. No serious or severe infections leading to treatment withdrawal were reported in rosnilimab-treated participants (Table 1).

Conclusion: Rosnilimab selectively and potently depletes pathogenic T cells in RA leading to clinically meaningful and durable responses. These data support further exploration of rosnilimab in RA.

N=Total number of subjects in the defined analysis set in the period
n=Total number of subjects in the specific category
Rate=Exposure-adjusted incidence rate per 100 person-year = 100 x (Number of subjects with AE in the given period/Total years of exposure in the given period across all subjects at risk for the treatment). Total years of exposure at risk in the given period is sum of individual time (years) to first episode of AE in the given period if subject was event free. Placebo subjects received treatment for maximum of 12 weeks.
[a] TEAE=Treatment-Emergent Adverse Event. An adverse event is considered treatment-emergent if the date of onset is during or after the first dose of study treatment, or if the AE was present at baseline and worsens in either intensity or frequency after the first dose of study treatment.
[b] Related=Possibly related, related, or missing.
[c] Values shown are for herpes zoster, the only opportunistic infection reported.

Background/Purpose: Deucravacitinib is an oral, selective tyrosine kinase 2 (TYK2) inhibitor being investigated in active PsA in the global, randomized, double-blind, placebo (PBO)-controlled, phase 3 POETYK PsA-1 (NCT04908202) and PsA-2 (NCT04908189) studies. Deucravacitinib has an established clinical profile in moderate to severe plaque psoriasis (PsO), with over 5 years of data, and is approved in multiple countries for PsO. We report efficacy and safety of deucravacitinib up to W52 in POETYK PsA-1.

Methods: Patients had a PsA diagnosis for ≥ 3 mo, met CASPAR criteria, were naive to biologic DMARDs, and had active or documented PsO, active arthritis (≥ 3 swollen and ≥ 3 tender joints), a high-sensitivity CRP level of ≥ 3 mg/L, and ≥ 1 PsA-related hand and/or foot joint erosion on radiographs at screening. Patients (N = 670) were randomized 1:1 to receive deucravacitinib 6 mg QD (n = 336) or PBO (n = 334) through W16. From W16 to W52, those randomized to PBO were switched to deucravacitinib 6 mg QD. The primary endpoint was ACR 20 at W16. Secondary endpoints included measurements of

Table 1. Efficacy endpoints at weeks 16 and 52

Endpoint	Week 16[a]		Week 52

Radiographic progression (as observed, post hoc analysis)				
Nonprogressors (95% CI), %[f]	71.5 (66.1 to 76.5)[g]	82.0 (77.3 to 86.2)[g]	66.5 (60.5 to 72.2)[h]	73.3 (67.6 to 78. 4)[h]

A Cochran-Mantel-Haenszel test stratified by screening hsCRP concentration (< 10 mg/L vs ≥ 10 mg/L) and csDMARD use at baseline (yes/no) was used to compare the response rates of deucravacitinib 6 mg QD vs placebo. Nonresponder imputation was used for missing data for binary variables. CfB was analyzed using ANCOVA with treatment, randomization stratification variables, and baseline value as independent variables. Control-based pattern multiple imputation was used for missing data for continuous variables.

[a]Patients were randomized 1:1 to receive placebo or deucravacitinib 6 mg QD through W16. At W16, patients initially randomized to receive placebo were switched to deucravacitinib 6 mg QD through W52. Patients initially randomized to receive deucravacitinib 6 mg QD continued to receive deucravacitinib 6 mg QD through W52; [b]Assessed in patients with ≥ 3% BSA and an sPGA score of ≥ 2 at baseline (placebo, n = 170; deucravacitinib, n = 162); [c]Assessed in randomized patients with enthesitis by LEI at baseline (placebo to deucravacitinib, n = 317; deucravacitinib to deucravacitinib, n = 318); [d]Assessed in randomized patients with enthesitis by SPARCC at baseline (placebo to deucravacitinib, n = 407; deucravacitinib to deucravacitinib, n = 393); [e]Assessed in randomized patients with dactylitis at baseline (placebo to deucravacitinib, n = 188; deucravacitinib to deucravacitinib, n = 210); [f]Nonprogressors were patients who had a CfB to W16 or W52 in modified SvdH total score ≤ 0. Response rate 95% CI was based on the Clopper-Pearson exact method; [g]Assessed in randomized patients with available, observed SvdH total scores collected at baseline and W16 nominal visits (placebo, n = 305; deucravacitinib, n = 306); [h]Assessed in randomized patients with available, observed SvdH data collected at baseline and W52 nominal visits (placebo to deucravacitinib, n = 266; deucravacitinib to deucravacitinib, n = 273). The total number of patients is randomized patients with nonmissing baseline and W52 SvdH total scores based on purely observed data.

ANCOVA, analysis of covariance; BSA, body surface area; CfB, change from baseline; csDMARD, conventional disease-modifying antirheumatic drug; FACIT-Fatigue, Functional Assessment of Chronic Illness Therapy–Fatigue Scale; HAQ-DI, Health Assessment Questionnaire Disability Index; hsCRP, high sensitivity C-reactive profile; LEI, Leeds Enthesitis Index; MDA, minimal disease activity; NRI, nonresponder imputation; PASI 75, ≥ 75% improvement in the Psoriasis Area and Severity Index; PCS, physical component score; PsA, psoriatic arthritis; QD, once daily; SF-36, 36-Item Short Form Survey; SPARCC, Spondylarthritis Research Consortium of Canada; sPGA, static Physician Global Assessment; SvdH, Sharp-van der Heijde; W, week.

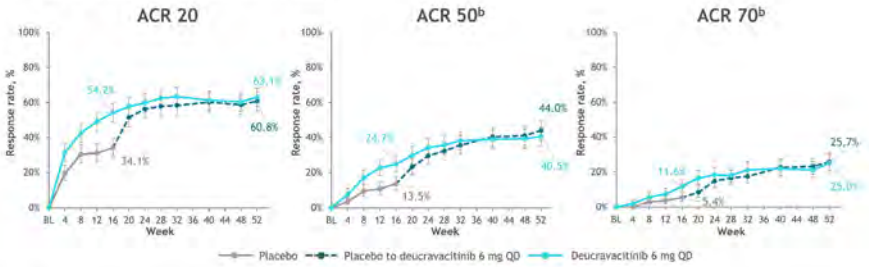
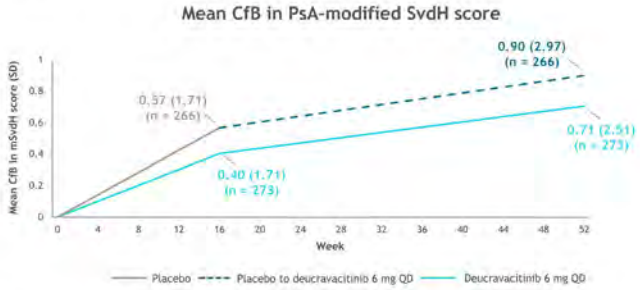
Figure 1. ACR 20/50/70 and radiographic progression analyses through week 52

A. ACR 20/50/70 kinetics (NRI)[a]



B. Radiographic progression: sustained inhibition of progression of structural damage (as observed, post hoc analysis)[c]



[a]All randomized patients were assessed. Treatment discontinuations prior to week 16 were considered treatment failures (composite variable strategy). All rescue medication–related intercurrent events were treated with a treatment policy–estimand strategy. The Clopper-Pearson exact method was used to estimate CI. Nonresponder imputation was used to handle missing data; [b]Additional secondary endpoint up to week 16 and exploratory endpoint up to week 52; [c]The population was based on randomized patients with available, observed SvdH total score, which was collected only at screening, W16, and W52 nominal visits. ACR 20, American College of Rheumatology 20% improvement in response; ACR 50, American College of Rheumatology 50% improvement in response; ACR 70, American College of Rheumatology 70% improvement in response; BL, baseline; CfB, change from baseline; mSvdH, modified Sharp-van der Heijde; NRI, nonresponder imputation; QD, once daily; SD, standard deviation; SvdH, Sharp-van der Heijde.

PsA disease activity, joint and extraarticular clinical responses, radiographic progression, and quality of life. Treatment discontinuation prior to W16 was considered an intercurrent event and imputed as a nonresponse. Nonresponder imputation and control-based pattern imputation were used for the remaining missing binary and continuous data, respectively. Post hoc analyses of radiographic data included all available assessments at baseline, W16, and W52, without imputation. Safety was evaluated through W52.

Results: Demographics and baseline characteristics were balanced across arms. The study met the primary endpoint (ACR 20; $P < 0.0001$).[1] Responses continued to improve through W24 and were maintained with deucravacitinib

Table 2. Overall safety summary: cumulative treatment period (weeks 0-52)

Safety parameter	Placebo to deucravacitinib 6 mg QD (n = 306)		Deucravacitinib to deucravacitinib 6 mg QD (n = 332)	
	n (%)	IR/100 PY	n (%)	IR/100 PY
Any AEs	206 (67.3)	196.0	262 (78.9)	218.7
Treatment-related AEs	54 (17.6)	31.2	92 (27.7)	38.0
Serious AEs	17 (5.6)	9.0	26 (7.8)	8.9
AEs leading to discontinuation	10 (3.3)	5.2	18 (5.4)	6.0
Deaths	0	0	0	0
Most frequent AEs (≥ 5%) in any arm by PT				
Upper respiratory tract infection	33 (10.8)	18.0	46 (13.9)	15.6
Nasopharyngitis	26 (8.5)	14.2	30 (9.0)	10.6
Hypertension	14 (4.6)	7.4	26 (7.8)	9.1
COVID-19	9 (2.9)	4.7	24 (7.2)	8.4
Urinary tract infection	7 (2.3)	3.7	19 (5.7)	6.5

AEs are defined as treatment-emergent AEs with an onset date on or after the first dose date of study treatment up to 30 days after the last dose date of treatment in the study. MedDRA: 28.0.
AE, adverse event; COVID-19, coronavirus disease 2019; IR, incidence rate; MedDRA, Medical Dictionary for Regulatory Activities; PsA, psoriatic arthritis. PT, preferred term; PY, patient-year; QD, once daily.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. through W52; similar results were seen for ACR 50/70 (**Figure 1A)**. Clinical responses and patient-reported outcomes (PROs) were met at W16, continued to improve, and were maintained through W52 with deucravacitinib (**Table 1**). Inhibition of radiographic progression observed at W16 with deucravacitinib[1] was sustained through W52 (**Figure 1B**). Patients who switched from PBO to deucravacitinib at W16 had reduced radiographic progression after switching (-**Figure 1B**). Few serious adverse events (AEs) and discontinuations due to AEs occurred; deucravacitinib was well tolerated through W52 (**Table 2**). No new safety signals related to adjudicated MACE, VTE, or opportunistic infections were observed. No deaths occurred.

Conclusion: Deucravacitinib was efficacious in patients with PsA based on clinical responses, PROs, and inhibition of radiographic progression, which continued to improve after W16 and were durable through W52. Responses at W52 were comparable in patients who switched from PBO to deucravacitinib at W16. Safety was consistent with the known deucravacitinib profile, with no new signals. Data were consistent with findings from POETYK PsA-2, reinforcing deucravacitinib as efficacious in PsA and underscoring its favorable safety profile as the first selective TYK2 inhibitor evaluated in PsA.

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025

Session Title: (LB19–LB24) Late-Breaking Abstracts

Session Type: Late-Breaking Abstract Session

Session Time: 8:00AM–9:30AM

Background/Purpose: Recently, somatic mutations in hematopoietic stem and progenitor cells (HSPCs) have been proposed as a novel mechanism driving systemic inflammation. *UBA1* somatic variants in HSPCs cause VEXAS (Vacuoles, E1 enzyme, X-linked, Autoinflammatory, Somatic) syndrome, a late onset, systemic autoinflammatory disease (SAID) with elevated morbidity and mortality. We hypothesized that additional somatic variants may underlie inflammation in undiagnosed SAID.

Methods: We performed unbiased mutation enrichment analysis in 265 UBA1-negative adults with VEXAS-like SAID versus matched controls. Associations between identified genes with autoimmune phenotypes were assessed in UK Biobank (N=454,218), All of Us (N=414,830), and a Mayo Clinic cohort of clonal cytopenia of uncertain significance (CCUS, N=275). Finally, inflammatory outcomes in carriers were evaluated in a clinical trial of targeted treatment.

Results: Unbiased gene burden analysis identified *IDH1/2* and *SRSF2*, frequently co-mutated, as significantly enriched in the SAID cohort. *IDH1/2* hotspot mutations were observed in 5.7% of patients overall, and were the most recurrent impactful variants among patients without hematologic malignancy (N=193, 2.1%). All of these individuals (N=4) exhibited recurrent fevers, skin inflammation and cytopenia, with most (N=3) having inflammatory arthritis requiring multiple DMARDs, supporting a role for *IDH1/2* in driving inflammation outside of the established role of inflammation in overt malignancy.

To explore the association between *IDH*-mutant clonal hematopoiesis (CH) or CCUS and autoimmune disease, we analyzed two large cohorts, identifying 264 individuals with *IDH1/2*-mutant CH without hematologic malignancy. *IDH1/2* CH was associated with autoimmune disease (OR=1.8, p=4e-3), with the strongest associations for polymyalgia rheumatica (OR=4.0, p=1e-3) and giant cell arteritis (OR=8.1, p=1e-6). Carriers had elevated CRP versus other CH-carriers (p=1e-2) and altered myeloid counts. Findings were corroborated in the Mayo clinic CCUS cohort, where 8/275 patients (2.9%) carried IDH1 mutations, half of which exhibited autoimmune manifestations—including seronegative rheumatoid arthritis and

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Sweet syndrome – highlighting the clinical relevance of *IDH* mutations in the context of cytopenia.

We then evaluated the effect of *IDH1* inhibition on inflammation in a clinical trial of ivosidenib in *IDH1* carriers with CCUS. Most (58%, 11/19) had elevated hsCRP (>=5; range 6.91–46.2 mg/L) including 4 with autoimmune disorders—all with episodic joint pain and half with skin manifestations. Most patients with elevated hsCRP at baseline normalized (< 5 mg/L) on treatment (7/9). All four individuals with autoimmune disorders had subjective improvement in symptoms with ivosidenib.

Conclusion: Together, our results point to IDH1/2 CH as a driver of autoinflammation, particularly in patients with cytopenia. Their presence in SAID cases without hematologic malignancy supports their role as drivers of inflammation. The efficacy of IDH1 inhibition in improving inflammatory manifestations in the ongoing IDH1-carrier trial underscores the potential for a therapeutic approach.

SESSION INFORMATION
Session Date: Wednesday, October 29, 2025
Session Title: (LB19–LB24) Late-Breaking Abstracts
Session Type: Late-Breaking Abstract Session
Session Time: 8:00AM–9:30AM

Background/Purpose: Excessive formation and impaired clearance of Neutrophil Extracellular Traps (NETs) have been linked to autoimmune and inflammatory diseases, notably systemic lupus erythematosus (SLE). DNASE1-like 3 (DNASE1L3) is a circulating endonuclease that degrades NETs, and loss-of-function mutations are associated with severe autoimmune phenotypes in patients, including childhood-onset SLE, vasculitis, and systemic sclerosis. Based on this biology, Neutrolis developed a platform of engineered recombinant DNASE1L3 analogues, including NTR-441, a DNASE1L3 analogue fused to human serum albumin. In this first-in-human study, we aimed to validate the novel approach of NET inactivation by DNASE1L3 as a therapeutic strategy with three main objectives:

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(1) assess safety, tolerability, and pharmacokinetics (PK) in healthy subject lacking the pharmacological target (NETs)
(2) evaluate safety, tolerability, PK, and target engagement in patients with a high NET burden
(3) establish pharmacodynamic and clinical proof-of-concept in a patient with SLE and congenital DNASE1L3 deficiency

Methods: A first-in-human Phase 1a/b, placebo-controlled, double-blind trial was conducted, including a single ascending dose study in 35 healthy adults and 12 hospitalized patients with severe COVID-19, representing a high NET burden disease (NCT04941183) across dose levels of 0.01–10 mg/kg. Proof-of-concept was investigated in a 16.5-year-old male with a homozygous DNASE1L3 loss-of-function mutation (c.643del) and severe, longstanding, treatment-refractory monogenic SLE, who received weekly doses of NTR-441 (3 mg/kg) as add-on therapy to corticosteroids, antimalarials, and tofacitinib through a compassionate use protocol (Ethics Committee approval no. 0120-553/2024-2711-8).

Results: NTR-441 was well tolerated across all studies and produced robust increases in DNASE1L3 levels that remained supraphysiologic for >48 hours (Fig. 1). Infusion reactions occurred in one healthy subject at the highest dose and at the fifth dose in the patient with SLE, the latter linked to anti-drug antibodies but managed with desensitization and adjusted dosing. Target engagement was demonstrated in patients with COVID-19 and SLE by rises in NET-degradation products (MPO–DNA complexes, cell-free DNA) peaking 4–8 hours post-infusion, while absent in healthy volunteers (Fig. 2). In the SLE patient, the first dose of NTR-441 resulted in a rapid (≤6 hours) and sustained clinical improvement across multiple organ systems, including urticarial rash, episcleritis, and arthritis except for a transient rash recurrence that subsequently subsided (Fig. 3).

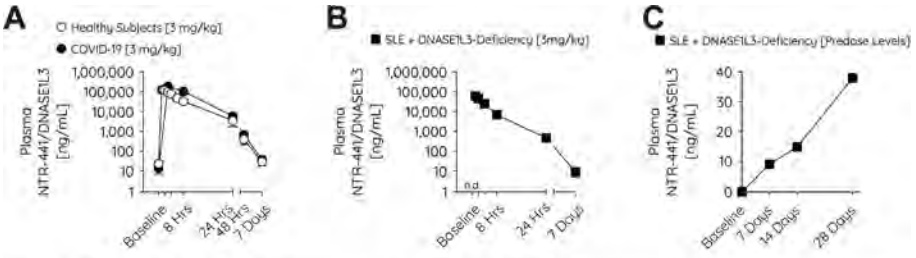

Figure 1. Pharmacokinetics of NTR-441. Plasma concentrations of DNASE1L3/NTR-441 were measured by electrochemiluminescence immunoassay using monoclonal antibodies against DNASE1L3 cross-reactive with NTR-441. Panels A–B: Plasma concentrations after a single 3 mg/kg infusion in (A) healthy subjects (N=6, open circles) and COVID-19 patients (N=3, closed circles), and (B) a patient with DNASE1L3-deficient SLE. Panel C: Pre-dose plasma concentrations prior to five weekly NTR-441 infusions in the DNASE1L3-deficient SLE patient.

Figure 1

FIGURE 2: NET-DEGRADATION PRODUCTS IN CIRCULATION

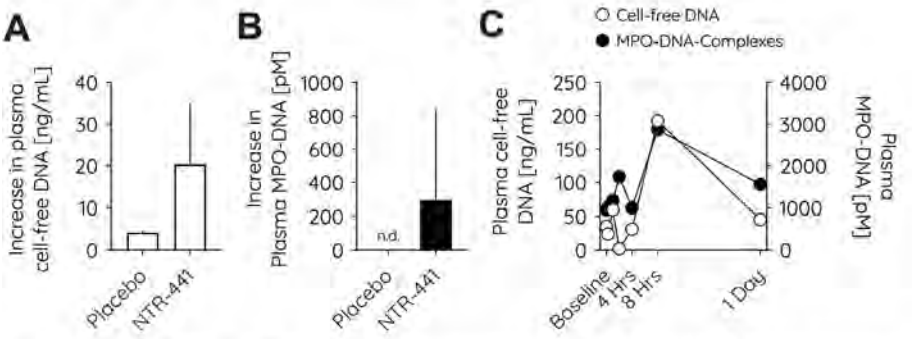

Figure 2. Changes in NET-Degradation Products. Plasma concentrations of cell-free DNA and MPO–DNA complexes were measured by qPCR and ELISA, respectively. Panels A–B: Maximal increases in (A) cell-free DNA and (B) MPO–DNA complexes in COVID-19 patients receiving placebo or NTR-441 (0.3–3 mg/kg, pooled data). Panel C: Plasma concentrations of cell-free DNA (open circles) and MPO–DNA complexes (closed circles) in a DNASE1L3-deficient SLE patient following the first NTR-441 infusion (3 mg/kg).

Figure 3. Clinical Manifestations and Response to NTR-441 Treatment.
Panels A–D: Images of clinical manifestations at pre-dose: (A) episcleritis, (B) urticarial rash on the back, (C) wrist arthritis, and (D) arthritis in the proximal interphalangeal (PIP) joint of the index finger. Panels E–H: Same manifestations within 6 hours after NTR-441 infusion showing resolution or improvement. (I) Quantification of clinical manifestations over a 4-week treatment course, including urticarial rash as % body surface area (BSA), Urticaria Activity Score (UAS), number of active joints, and episcleritis severity.

Figure 3

Conclusion: These combined studies validate DNASE1L3 as a therapeutic strategy to inactivate NETs. In a patient with treatment-refractory SLE with DNASE1L3-deficiency, pharmacologic degradation of NETs with NTR-441 induced rapid, sustained remission, providing the first clinical proof-of-concept for this approach. The temporal link between NET clearance and clinical benefit supports NETs as a central pathogenic driver in autoimmunity. These findings warrant broader trials in SLE and other autoimmune disorders.

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025
Session Title: (LB19–LB24) Late-Breaking Abstracts
Session Type: Late-Breaking Abstract Session
Session Time: 8:00AM–9:30AM

Background/Purpose: Regulatory T cells (Tregs) modulate inflammation, maintain self-tolerance, promote tissue repair, and hold promise as a versatile therapeutic. Autologous polyclonal Tregs have a favorable safety profile but limited efficacy in autoimmunity.

Engineered Tregs offer a novel approach by introducing a chimeric antigen receptor (CAR) specific for tissue- or disease-associated antigens. SBT777101 is an autologous Treg product transduced with a CAR specific for citrullinated proteins (CitP), which are present in the inflamed synovium of rheumatoid arthritis (RA) patients. Unlike cytotoxic CAR-T therapies, SBT777101 may restore balance to the immune system without target cell destruction. Potential mechanisms of action include direct and bystander suppression of antigen presenting cells and effector T cells, IL-2 consumption, and immunomodulatory cytokine production, promoting immune homeostasis and tissue repair.

Regulate-RA is an ongoing first-in-human, phase 1 study evaluating the safety and tolerability of SBT777101 in patients with refractory RA. Exploratory endpoints include assessment of SBT777101's pharmacokinetic (PK) profile, pharmacodynamic (PD) parameters, mechanism of action (MOA), and potential efficacy.

Table 1: Overview of (A) patient demographics and disease activity at screening for cohorts 1 and 2, and (B) safety events to date. AI or AN: American Indian or Alaska native; TEAE: Treatment-Emergent Adverse Event; MSK: Musculoskeletal; ICANS: Immune effector cell-associated neurotoxicity syndrome ; N: the number of subjects in the Safety Evaluable Set; n: the number of subjects in each category. Data cut 8/15/2025

Table 1

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

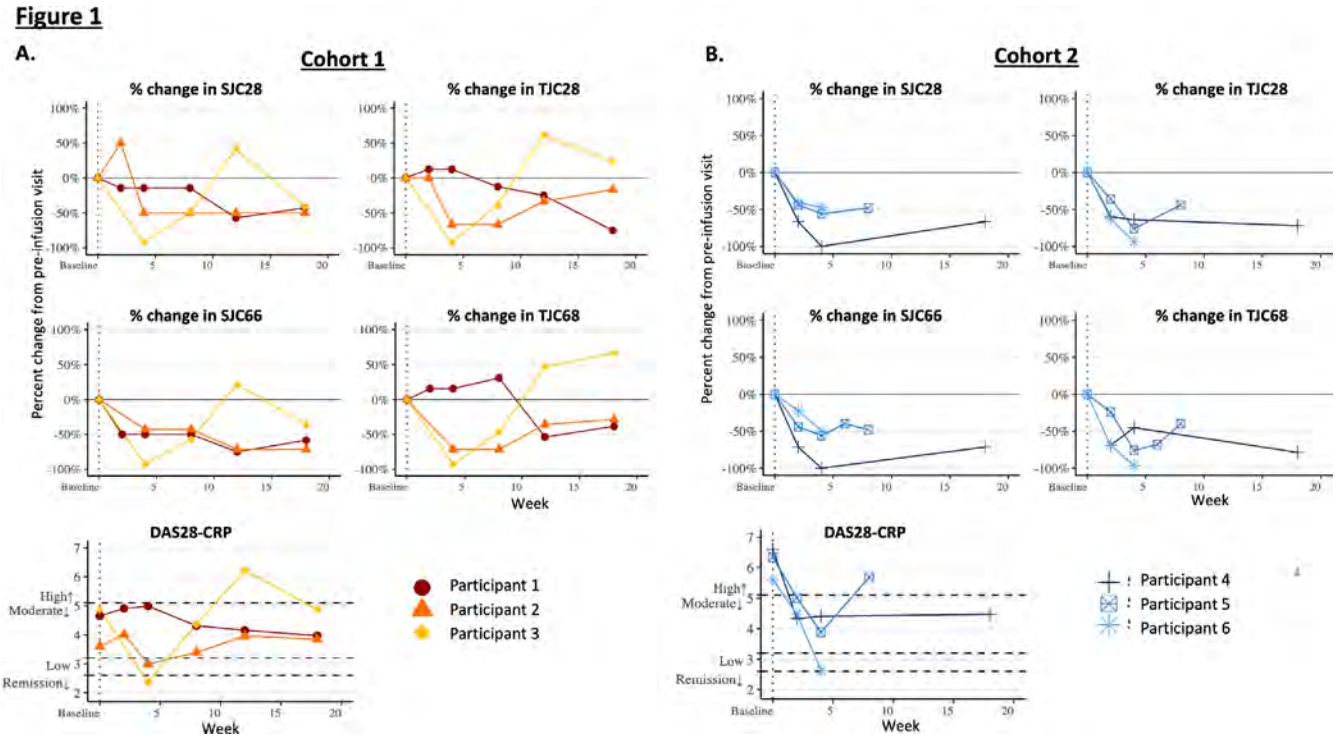

Figure 1: Preliminary efficacy of SBT777101. (A) Cohort 1 showed modest improvement in disease activity within 4 weeks of infusion, but this was of variable duration. (B) By week 4, Cohort 2 showed more consistent improvements of both tender and swollen joint counts, as well as DAS28-CRP. SJC: swollen joint count; TJC: tender joint count; DAS: Disease Activity Score.

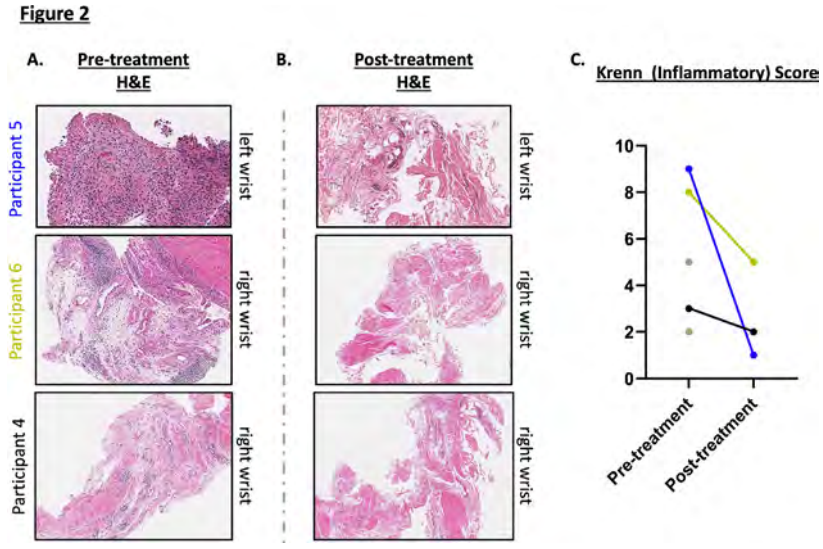

Figure 2: Reduced inflammation in post-treatment synovial biopsies: 20X images A) show pre- and B) post-treatment biopsies on the indicated joint with the patient number color represented in the dot-plot C) of Krenn inflammatory score as assessed by an independent, blinded, pathologist. Two participants only provided pre-treatment biopsies and are only shown in the plot.

Methods: Adults aged 18-70 with active RA (Disease Activity Score (DAS28-CRP) ≥ 3.2) and failure of ≥3 prior classes of biologic or targeted synthetic DMARDs are eligible.

SBT777101 is prepared by transduction of autologous Tregs with a CitP-specific CAR expressing vector followed by ex vivo expansion and is administered intravenously as a single dose in a 3-cohort, 3+3 dose-escalation design, with no preparative lymphodepletion. Participants are monitored for adverse events and clinical responses through 48 weeks. PK, PD, and MOA are assessed in blood and synovial biopsies.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: As of August 2025, six participants have received SBT777101 (table 1). Infusions were well-tolerated, without cytokine release syndrome, neurotoxicity, or dose limiting toxicities.

Across both dose levels, 4/6 participants (67%) had a ≥ 50% reduction from baseline swollen and tender joint counts by week 4, and 4/6 (67%) had a reduction of DAS28-CRP score by ≥ 2 (figure 1). Participants in Cohort 2, who received a higher dose of SBT777101, showed a more rapid onset and consistent reduction in joint count compared to Cohort 1. All participants in Cohort 2 showed clinically meaningful improvements in disease activity by week 4 with continued reduction in disease activity for as long as 18 weeks. Additionally, all post-infusion biopsies collected to date demonstrated decreases in inflammatory score (Figure 2). SBT777101 cells can be transiently detected in blood within the first month following infusion.

Clinical assessments and biomarker analyses are ongoing to assess changes in disease activity, systemic inflammation and Treg activity; additional participants are being enrolled.

Conclusion: In this ongoing phase 1 study, Cit-P–targeted CAR-Tregs demonstrate a favorable early safety profile, with preliminary clinical and mechanistic evidence of therapeutic activity in highly refractory RA participants.

SESSION INFORMATION

Session Date: Wednesday, October 29, 2025
Session Title: (LB19–LB24) Late-Breaking Abstracts
Session Type: Late-Breaking Abstract Session
Session Time: 8:00AM–9:30AM

Background/Purpose: Sjögren's disease (SjD) is a systemic, heterogeneous, autoimmune disease with substantial disease burden, high unmet need, and no approved systemic treatments. B cell hyperactivity and dysregulated B cell–activating factor/receptor (BAFF/BAFF-R) signalling are a hallmark of SjD pathogenesis. Ianalumab is a fully human IgG1 mAb with a novel dual mechanism of action that depletes B cells through enhanced antibody-dependent cellular cytotoxicity (ADCC) and also inhibits their activation and survival via BAFF-R blockade. NEPTUNUS-1 (NCT05350072) and NEPTUNUS-2 (NCT05349214) are Phase 3 studies designed to assess the efficacy and safety of ianalumab in patients with active SjD.

Methods: NEPTUNUS-1 and NEPTUNUS-2 are complementary, 52-week (Wk), global, multicenter, randomized, double-blind, placebo-controlled studies that enrolled adult patients with SjD meeting ACR/EULAR 2016 classification criteria with a EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI) score ≥5 across 8 pre-selected domains, and stimulated salivary flow rate of ≥0.05 mL/min. Background immunosuppressants, including MTX (≤25 mg/Wk), HCQ (≤400 mg/day), AZA (≤150 mg/day), and prednisone ≤10 mg/day were allowed alone or in combination in both studies. In NEPTUNUS-1, patients were randomized (1:1) to monthly (QM) subcutaneous (s.c.) ianalumab 300 mg or placebo (PBO); in NEPTUNUS-2, patients were randomized (1:1:1) to either ianalumab 300 mg QM, every 3 months (Q3M) or PBO. The primary objective of both studies was to demonstrate superiority of ianalumab over PBO based on change from baseline (CFB) in ESSDAI at Wk 48. Key secondary endpoints included disease activity measures as well as physician- and patient-reported outcomes at Wk 48. Safety was assessed up to Wk 52.

Results: In NEPTUNUS-1, 275 patients and in NEPTUNUS-2, 504 patients were randomized. In both studies, baseline characteristics were generally balanced across treatment arms. Both studies met their primary objective. Ianalumab QM demonstrated statistically significant improvement in ESSDAI CFB at Wk 48 compared to PBO (**Fig 1)**. Patient's Global Assessment (PaGA; LS mean difference [Δ]: -6.6; 95% CI: -11.4, -1.8, p=0.007) and Physician's Global Assessment (PhGA; Δ: -5.5; 95% CI: -10.1, -0.9, p=0.018) reached nominal statistical significance in NEPTUNUS-1. Additional secondary endpoints showed a trend towards improvement in both studies. Ianalumab showed favorable safety with an overall incidence of adverse events and serious adverse events comparable to placebo in both studies (**Table 1**).

Conclusion: NEPTUNUS-1 and NEPTUNUS-2 are the first replicate Phase 3 studies in SjD to meet their primary endpoint, with ianalumab 300 mg QM demonstrating significant improvement in disease activity measured by ESSDAI. In addition, secondary endpoints including PaGA and PhGA indicate symptom reduction and patient benefit beyond improvement in

Patient Perspective (PP 01-13)

Abstract Number: PP01

When You Become the Story: A Journalist's Approach to Managing Complex Care

Lindsay Guentzel[1], [1]Freelance Journalist

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (PP01-PP08) Patient Perspectives Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: As a journalist, I've spent my career digging for answers. But when I became the story, I had to learn how to ask the right questions – about my care, my symptoms, and the system that wasn't built for someone like me.

In March 2023, I was diagnosed with dermatomyositis (DM) associated with antisynthetase syndrome and Sjögren's syndrome (SS). The lead-up to those diagnoses was complicated and full of frustration. I quickly realized that if I wanted answers, I had to push for them – and once I had them, I had to lead. These were skills I fine-tuned in newsrooms, and I began to approach my health like a full-time job. That shift, while often overwhelming, reshaped how I engaged with my care.

Intervention: I applied the systems and storytelling skills I developed as a journalist: setting aside time weekly to manage appointments, organize records, and prepare questions. I recorded visits and used transcripts to track details and keep my family informed. Sharing my story publicly helped me develop clearer language around my symptoms—improving communication with my care team and strengthening our partnership.

That storytelling practice has grown into national advocacy work. I was invited to speak at the National Institutes of Health for Rare Disease Day 2025, delivered the keynote at the TMA *We Care for Rare Summit*, and led a storytelling workshop for nearly 100 people affected by myositis.

Maintenance: By treating my health like a full-time job, I've seen measurable improvements in how I manage my care. My missed appointment rate is under 5%, compared to nearly 40% at my clinic – something I attribute to the systems I've built. Staff has expressed appreciation for my follow-ups, which encourages me to advocate without hesitation. Staying informed also paid off: tracking CAR T-cell research allowed me to have early, informed conversations with my rheumatologist, so I was ready when a trial opened. I've seen similar transformations in the myositis community—when patients build storytelling skills, their confidence grows, and with it, a renewed sense of control and emotional well-being.

Quality of Life: Taking ownership of my care and embracing my story helped reduce the anxiety and helplessness I felt early in my diagnosis. I began to feel more in control of my health and my daily life.[1] That shift made it easier to manage the emotional toll of chronic illness and advocate for what I needed.[2] It also strengthened my relationships with my care team – our interactions now feel more collaborative, and I'm treated as a partner in decision-making.[3]

Papers Cited

Takeaway: As a journalist, I was trained to research, ask tough questions, and communicate clearly – skills that became essential when I had to start managing my own care. But patients shouldn't need a background in storytelling or investigative work to feel confident navigating their health. Medical providers can play a powerful role in helping patients step into that leadership (Fig. 1). By normalizing organization, curiosity, and follow-up, you can show patients that their engagement is not only welcome – it's valuable.

Encourage them to treat their care as something they can manage, not just endure. Patients who feel supported are more likely to stay informed, speak up, and follow through.[1] When providers support that shift, care becomes a true partnership [2] – where communication is clearer, collaboration is stronger, and outcomes improve on both sides of the relationship.[3]

Abstract Number: PP02

When The Body Speaks But No One Listens: A Dermatomyositis Story Through a Public Health Lens

Kyanna Johnson[1], Lynn Wilson[1], Manuel Lubinus[1], Elisa Glass[1], [1]Myositis Support and Understanding

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (PP01-PP08) Patient Perspectives Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: My journey with dermatomyositis (DM) began abruptly in July 2024, when I was hit by sudden, severe muscle weakness after a GI infection. I couldn't stand or move my legs- I was terrified, my body was failing, and I didn't know why. I was admitted to the hospital for inpatient rehabilitation for 2–3 weeks. Despite lab results suggesting myositis, I was discharged without a diagnosis or treatment plan. I felt invisible. I was advised to follow up with a neurological clinic, but after multiple unreturned calls, I decided to take control.

As a public health professional and medical student, I knew how to navigate healthcare systems, but nothing prepared me for how dehumanizing it would be to have my symptoms dismissed. I was scared and exhausted—not just physically, but emotionally. However, with my primary care provider's help, I was prescribed prednisone. My strength returned briefly, and with it, hope. But when the taper ended, so did my progress. My body was falling apart again, which prompted me to seek a more comprehensive diagnosis.

Intervention: Determined not to be ignored, I became relentless. I used Myositis Support and Understanding (MSU) resources to advocate for myself. I had to educate doctors, those I trusted with my care, about how DM presents, especially in people with darker skin. At one point, a specialist brushed off my symptoms—my fear turned to fury. I knew something was wrong, and I wouldn't let their indifference invalidate my lived reality.

Finally, I found someone who listened who was out of state. Under Dr. Arash Hassan's care, guided by labs, clinical presentation, previous skin biopsy, and dilated capillaries, I was formally diagnosed with DM and referred to NIH for further evaluation. That moment was a turning point for my health and my spirit.

Maintenance: The emotional toll remains. I still grapple with fatigue, fear of flare-ups, and the memory of being dismissed. That experience changed me. It motivated me to advocate for myself and to ensure no other patient has to fight this hard to be heard. I am now MSU's Director of Public Health and Policy, where I intend to enhance policy and research around chronic diseases like myositis.

Quality of Life: I'm no longer bed-bound. Through physical therapy, prednisone, azathioprine, IVIG, and continued care, I'm slowly rebuilding my strength. More importantly, I've transformed pain into purpose. Through MSU, I'm advocating for reproductive rights, equitable access to care, and better provider education about rare diseases like DM.

Takeaway: This journey taught me the importance of self-advocacy and the need for providers to listen to patients who are navigating rare, complex diseases like DM. Diagnostic delays don't just harm the body—they fracture trust and deepen emotional suffering. My story is one of resilience, but it shouldn't have required so much self-advocacy to be believed. We

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. must build a healthcare system that centers the patient's voices. When we listen, we heal more than just symptoms; we restore dignity, trust, and hope. By empowering patients and fostering a strong doctor-patient relationship, we can improve outcomes for those with rare diseases like mine.

Abstract Number: PP03

My Journey of Risk, Loss, and Hope: The Role of Multidisciplinary Collaboration in Managing Pregnancy with Takayasu Arteritis

Tugce Turten Kaymaz[1], [1]Ankara Yildirim Beyazit University

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (PP01-PP08) Patient Perspectives Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: At the age of 26, the same month I got married, I was diagnosed with Takayasu Arteritis following severe chest and back pain. Hypertension was added to my condition two years later. My treatment varied but included deltacortril, PULSE, methotrexate, infliximab, and tocilizumab. As a result, I had to avoid pregnancy from the beginning of my marriage. Four years after the diagnosis, I experienced pregnant unexpectedly while using tocilizumab. What should have been joyful news became a source of fear and uncertainty for us. After my rheumatologist explained the risks, we decided to continue the pregnancy at 10 weeks. However, at the first perinatologist visit, anomaly was suspected, followed by a trisomy 21 diagnosis, and the pregnancy was terminated at week 16. Five months later, I had a planned pregnancy that ended in miscarriage due to an ectopic pregnancy. Both pregnancies ended in loss. I experienced bleeding, and curettage was done without any anesthesia, increasing my fear of gynecology clinics. After these experiences, my husband and I silently closed the door on having children.

Intervention: During the COVID-19 pandemic, I couldn't access tocilizumab for six months. At the check-up six months later, my doctor informed me that my condition was stable enough to go without medication for a period and try for a baby. A month later, I went to the ER with severe groin pain and learned I was pregnant again. What followed were weeks filled with fear: suspicions of ectopic pregnancy, then heterotopic pregnancy, and bleeding. I found myself once again face-to-face with the very fears I had hoped to avoid. Until I found my perinatologist.

Maintenance: I had check-ups every three weeks in the first two trimesters, and every two weeks in the third. The communication and coordination between my rheumatologist and perinatologist were crucial components of my pregnancy care. My anxiety decreased thanks to my doctor's clear, calming communication without overemphasizing risks. Working from home due to the pandemic also reduced physical stress and allowed me to have a rest-focused, and calm pregnancy. My third pregnancy ended happily with the birth of a healthy baby girl in the 41st week.

Quality of Life: The key to a healthy pregnancy and baby was my rheumatologist's accurate evaluation of my condition and reassurance that my health was suitable for pregnancy. The patient's trust that the doctor will make the best decision for her makes it easier to make difficult decisions and accept negativities during the process. At this point, clinical expertise alone is not enough. The physician's communication, long-term follow-up, and interdisciplinary coordination are all crucial for the patient's acceptance of the disease, adherence to treatment, and overall adjustment. In addition to the professionalism of

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

my doctors, their coordination, patient communication and the decrease in my daily stress level increased my quality of life during pregnancy and allowed me to have a healthy pregnancy and birth without complications at age 34.

Takeaway:

- Effective communication and a trusting doctor–patient relationship improve patient adherence and emotional resilience.
- Interdisciplinary coordination is essential, especially in pregnancies complicated by rheumatologic disease.
- A personalized approach that considers the patient's life circumstances enhances treatment success.

Abstract Number: PP04

MCTD and Aging – Resilience Required

Carol Kaminski[1], [1]HP

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (PP01-PP08) Patient Perspectives Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: I was diagnosed with MCTD at age 25. My priorities were understanding a disease I had trouble pronouncing, and trying to learn to live with it, not die from it. I did not think I would live to an old age. 40 years on, here are my strategies on aging well with MCTD that may help rheumatic disease patients and professionals who treat them, to either avoid my errors or employ helpful behaviors. I've learned these through trial and error and also observed them in others "chronically managing."

Intervention: Since I did not believe I would *definitely* reach old age my lifestyle reflected that. I was told, "Some patients do very well; others live only a few years." That conversation couldn't be unheard. Why plan for an uncertain future?

As each year brought improvements in the care of autoimmune diseases, and the chance I would have a future, my hope increased. One pivotal period for me was when histamine-2 blockers and proton-pump inhibiters were developed. I feel such gratitude for those involved in the development of gastrointestinal motility and acid-suppressing drugs. My quality of life improved overnight. *Any* medical improvement may be "right around the corner" so why not plan for that? I began to contribute to a retirement account at work. Once I felt I might have a future, I began to plan for one.

A doctor said to me "some things take a "tincture of time" to resolve. Along with managing MCTD, I am subject to everyday problems and unrelated diseases. I appreciated this concept while waiting for hydroxychloroquine to kick in; By simply resting joints or muscles before deciding I am flaring gave me time for clarity. Although not appropriate for all situations, there are times to wait.

When in pain, I move slower, and my focus lessens. I mitigate by managing my calendar better, so I am not overbooked or hurried. I leave earlier for appointments. With joints damaged from years of swelling and arthritis, when I rush, I drop or forget things. Others' time is valuable too, so I strive to be on time. I cancel plans when rest is required, something not always understood by others.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Early in my chronic illness journey I found myself relying on and at times being disappointed by friends and family. Experiencing a lack of understanding and even denial at diagnosis, I learned the reality no one person can always be there for me. Sometimes, I'd call only to find others caught up in their own situations, not tuned into me. This is normal. How happy it makes me when I get help, a listening ear, or a sense of understanding. But maturity allows me to let it go when I don't. Adding frustration and disappointment to things doesn't help. The process also developed my resilience and allows me to empathize with others.

Alongside the emotional work of understanding, forgiving, or choosing to move on, I began to simply increase my support system. Online and in-person support groups. Viewing close friends/partner as *adjunct* support, rather than primary. These actions release those closest to me from the pressure of being "always on."

Maintenance: Today, I prioritize activities and investments that promote health, physical, mental, emotional and spiritual.

Quality of Life: By doing so, I am able to live a better, fuller and perhaps even a healthier life.

Takeaway: May more of us live healthier years *with, even in spite of* chronic illness, even into older age.

Disclosure: C. Kaminski: None.

Abstract Number: PP05

Mastering a Rare, Autoimmune Disease: My Journey Regaining Agency Through Education, Collaboration, and Community

Mustafa Shameem[1], [1]The Myositis Association

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (PP01-PP08) Patient Perspectives Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: After a complex diagnostic journey, my PCP working on a rheumatological theory ordered a myositis-specific autoantibody (MSA) panel. It revealed the presence of an antisynthetase autoantibody, and a very rare one. A serious diagnosis—and one that is rare and rheumatological like dermatomyositis/anti-synthetase syndrome—can be devastating and leave one in the unknown. As a young professional facing this exact situation, I remembered a piece of wisdom: dignity is affirmed by facing reality as it is, and responding responsibly.

Intervention: Nature had dealt a harsh blow. However, I attempted to restore some personal agency. I immersed myself in the science of myositis. I collected dozens of relevant research papers, carefully read through, annotated, and extracted points to help reason about my own situation. Aside from research, I tapped into the Myositis Association (TMA), the leading, global, myositis non-profit. Of the range of TMA services, I leveraged a subset: lectures from experts, online forum, and conferences. I discovered and selected my myositis-expert rheumatologist thanks to TMA, along with large parts of my broader care team.

Maintenance: Through education, my condition was no longer a black box that could only be deciphered through an expert. For patients without the relevant professional backgrounds or comfort with research, patient organizations like TMA provide the accessible, expert-crafted resources needed for patients to become fluent in their condition. No small

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

contribution considering the larger information ecosystem in which predatory actors are eager to provide 'solutions' to fearful, vulnerable patients.

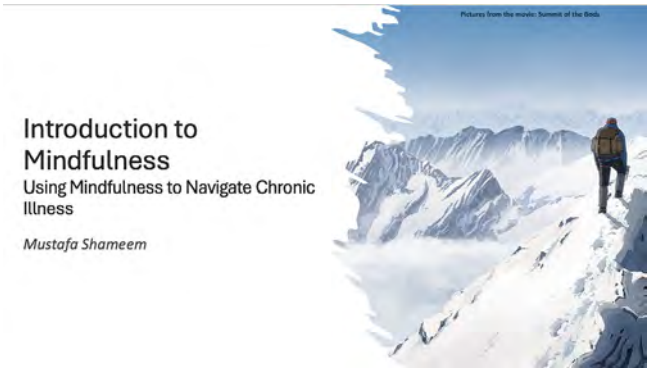
The patient-as-subject approach yielded other benefits: I understood tradeoffs of different treatments or why a particular test (e.g. CK, AST, ALT, pulmonary function) was being done. And I could interpret each of these at a fine-grained level, their implications, and have more sophisticated provider conversations as a result. I also found mindfulness, adapted for dealing with illness, helpful in navigating many stormy, difficult situations associated with my journey.

Quality of Life: Resuming my normal activities, and engaging in the myositis community have been the two elements that have been personally meaningful.

I was the beneficiary of the vision and generosity of patient and provider leaders at The Myositis Association. I would, in my small way, repay this forward by joining the board of directors and applying my professional experiences to advance the needs of the myositis community.

From consuming and applying myositis research, I've now become a contributor to a number of myositis research efforts. For example, I've joined one study as a technical advisor, applying my professional background in product management to enable telemedicine myositis research. My experiences navigating a rare condition and applying mindfulness practices, which I had learned from the Sōtō Zen and other traditions, were articulated into an 'Applying Mindfulness to Navigate

TMA board members, medical advisory board member, staff, and executive director at the Global Conference on Myositis (GCOM); Mustafa on far left.



23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Chronic Illness' class. I was privileged to teach this in a number of settings from small patient groups to large conferences. And the positive response and value others have gained has been a deep source of personal satisfaction.

Takeaway: 1. Importance of autoantibody testing - Myositis autoantibody testing should be considered in a wider range of scenarios from isolated, RA seronegative arthritis to partial, or atypical presentations. This wider testing may enable more accurate diagnosis, earlier detection, and better outcomes.

2. Patient-as-subject approach - Due to the complexity and challenges of the myositis family of conditions, providers should encourage patients to be as agentic as possible. This could include educating themselves on their conditions, engaging with patient organizations, shaping their treatments, and contributing back.

Disclosure: M. Shameem: None.

Abstract Number: PP06

Co-Creation of Exercise Videos by Patients and Professionals to Support Patient Empowerment

Noriko Okochi[1], Eiji Oishi[1], Yoshifumi Hitoe[2], Hitomi Koshi[2], Hajime Kono[2], [1]Rheumatic Disease and Vasculitis Support Network Japan, [2]Teikyo University School of Medicine

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (PP01-PP08) Patient Perspectives Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatic and musculoskeletal diseases (RMDs) cause chronic pain, joint deformities, and reduced mobility, significantly limiting patients' daily activities and social participation. Physical inactivity can also lead to secondary risks such as cardiovascular disease and depression, worsening quality of life (QOL). EULAR(2021) recommends exercise as an effective non-pharmacological therapy, which can reduce pain and fatigue and improve mental health. However, many Japanese patients express uncertainty about how to exercise and fear worsening symptoms. The spread of online exercise support remains limited, contributing to an information gap. In response, a patient-led project was launched to create and distribute exercise videos accessible to all, involving patients, families, and healthcare professionals.

Ten videos and flyers that reached our patients.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Intervention: The project consisted of three steps. In Step 1, an on-demand seminar was held in May 2024 to coincide with World Lupus Day, gathering insights on patients' interests, concerns, and challenges related to exercise. In Step 2, a multidisciplinary team—including doctors, physical therapists, nurses, psychologists, and patient representatives—was formed to develop ten exercise videos based on these insights. In Step 3, the videos were released on the patient group's website and social media (X and Instagram), with flyers distributed at medical institutions and academic conferences.

Maintenance: All ten videos are designed to be easy to follow and sustainable, minimizing joint strain. The video titles and content are:

1. Lower Body Exercises While Seated: Safe movements to strengthen thighs and calves.
2. Shoulder Stretches for Tension Relief: Simple stretches for stiff shoulders and neck.
3. Improving Sit-to-Stand Movements: Exercises to assist rising from a chair.
4. Ankle Mobility Training: Movements to increase flexibility and prevent falls.
5. Back and Lower Back Stretching: Exercises to loosen tension from prolonged sitting.
6. Finger Exercises and Relaxation: Improve hand flexibility and reduce stiffness.
7. Relaxation through Breathing: Deep breathing to regulate the autonomic nervous system.
8. Balance Training: Exercises to improve balance and core stability.
9. Full-Body Stretching: Warm-up and cool-down stretches for the whole body.
10. Daily Exercise Habits: Tips to maintain and incorporate exercise into daily life.

Quality of Life: The flyers introducing the exercise program were distributed through public health centers and medical institutions across Japan, reaching patients directly. Additionally, some patients accessed the exercise videos via the internet, using websites and social media platforms such as X and Instagram. When the program was introduced to patients shortly after discharge from the hospital, it received positive feedback, including comments such as "This is the perfect exercise for me right now." These responses suggest that the program provides a feasible way for patients with illnesses to continue exercising without overexertion. It not only supports the maintenance and recovery of physical function, but also helps foster a sense of self-efficacy and optimism, thereby potentially contributing to improved mental well-being.

Takeaway: By regularly promoting the videos through social media and the website, and incorporating them as references during rehabilitation, patients are likely to feel more familiar and comfortable with the exercises.

Abstract Number: PP07

Beyond the Medication: Creating a Toolbox of Complementary Therapies

Brittany Murray[1], [1]Chronic Disease Diary, LLC

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (PP01-PP08) Patient Perspectives Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: For over 30 years, I have been living with Psoriatic Disease, diagnosed with Psoriasis at 2 years old and Psoriatic Arthritis at 14. My disease has progressed, luckily with the advancement of treatments. With chronic diseases, you get used to treating with pharmaceuticals, and at the beginning, you are sometimes spoiled with the ability to take a single medication, but usually not. I progressed from creams and ointments and phototherapy to DMARDs to biologics. I was

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

lucky for 7 years to use one biologic to treat both my psoriasis and psoriatic arthritis. Those 7 years convinced me that I could always manage my disease with one medication. Of course, that has not been true since. I tried for many years to find another medication that worked as well as that one biologic did, but had no success. I have seen some that treat most of my symptoms or give me more good days than bad, but nothing is 100%, and nothing relieves all of the pain.

Intervention: After several years of exploring biologic after biologic and JAK 2 inhibitors with my rheumatologist, we turned to functional medicine and complementary therapies. For two years, I have been trying various other treatments to not only see what works but to see if any of my symptoms are actually unrelated to Psoriatic Arthritis and have just been lumped in over the years or due to overcompensating for pain. On this journey, I have tried chiropractic care, massage therapy, acupuncture, functional medicine interviews, autoimmune protocol diet, food sensitivity testing, CBD topicals, traditional Chinese medicine, supplements, herbs, and physical therapy. I have also come to terms with the need for assistive devices such as compression gloves, ergonomic accessories like a mouse, cushions for my workstation, and a plethora of kitchen gadgets.

Maintenance: This complementary therapy journey, although years long already, will never be over. Depending on the state of my disease, different therapies will be needed and effective. Sometimes I do chiropractic care every day, sometimes it's once a week, or once a month. Sometimes I do physical therapy, chiropractic care, supplements, and massage all in one day or week. What I have developed is a toolbox of complementary therapies that I know work sometimes for certain flares that I can pull from when I need them. I know that some of my pain can be better managed and even eliminated by relearning how to use all of my muscles properly in physical therapy and reducing stress and tension with regular acupuncture and massage.

Quality of Life: Simply knowing there are other options to relieve symptoms and improve my day without adding more drugs has improved my outlook on my disease and, therefore, my mental health. I can better cope in a flare, accomplish more, and feel more productive. I can say yes to more opportunities and more fun things. The only drawback is the number of activities I have to juggle to maintain my version of good. Keeping the pills and doctors' appointments straight with work is hard enough, and sometimes adding in PT and other appointments is too much, and I have to pick and choose which, in the short term, gives me more free time or mental capacity, but backfires in flares or pain.

Takeaway: Adding in complementary therapies might seem like a no-brainer, but it took me almost 20 years for a rheumatologist to suggest it and help me find options. I had brought it up a few times over the years, "should I try changing my diet" "should I try PT" and was met every time with no, I don't think that will make a difference for you and then we would proceed to chase the next biologic that hit the market. I would like to see both patients and rheumatologists find a balance in therapy options and regularly challenge the status quo. We are taught in Western medicine to treat with drugs or to dismiss problems and say exercise more or eat better. While all of those things can be helpful, they can be more of a hammer approach. Each symptom needs to be examined and determine possible root causes and offer multiple ways to treat them, especially with the rate of comorbidities in chronic disease.

Disclosure: B. Murray: None.

Abstract Number: PP08

Living Well Despite the Challenges of Sjögren's Disease and Systemic Lupus Erythematous: My Perspective as a Health Care Provider and Patient

Casey Hogan[1], [1]Advanced Eye Care Professionals & Sjogren's Foundation

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: (PP01-PP08) Patient Perspectives Poster
Session Type: Poster Session A
Session Time: 10:30AM–12:30PM

Background/Purpose: Typically, the diagnosis of any autoimmune condition can be challenging and take years. In my case, my diagnosis of Sjögren's disesase (SjD) was established while hospitalized in cardiac intensive care due to renal failure and cardiomyopathy as a young patient. Over time and years later, my health landscape evolved to an additional diagnosis of systemic lupus erythematous (SLE) with kidney involvement, specifically lupus nephritis. My career as an optometrist allows me a unique perspective on not only understanding the clinical aspects and management of my conditions, but also gives me the knowledge and compassion to treat my patients and advocate for increased awareness of SjD and its multi-systemic nature within the healthcare community.

I was 23 years old and a 3rd year optometry student when I was first diagnosed. I initially presented to my local emergency room with mental confusion, significant tachycardia, nausea, and lethargy. Clinical examination revealed metabolic acidosis secondary to type 1 distal renal tubular acidosis, hypokalemia, renal failure, and metabolic encephalopathy and cardiomyopathy. The diagnosis was SjD w/Type 1 renal tubular acidosis based on clinical laboratory studies. We were just learning about autoimmune disease in our courses, and I recall the immediate concern of being so young and so sick, and the uncertainty of the disease.

Intervention: Management of any systemic autoimmune disease requires a team approach and collaborative care and the number of subspecialties who are a part of my healthcare team has grown over the last thirty years. This is a key reason that I believe in staying educated on my disease by utilizing reliable resources such as PubMed to review current literature pertaining to my disease. This, in turn, helps ensure that I'm able to communicate with my health care team and that they're kept up to date on best practices and considerations for my optimal care.

An important example of these collaborative efforts was educating my urologist on the complex nature of my simple lithotripsy procedure for nephrolithiasis and the risk for urinary tract infections that had led to sepsis and multiple hospitalizations for me in the past. This education and awareness was much appreciated by my healthcare team, who often times mistakenly think of SjD as "just dry eye disease".

Maintenance: Continuing my own education and communicating and advocating for myself with my healthcare team to ensure we're on the same page is an ongoing effort. My ocular complications have led to a lifelong journey of specializing in the management of ocular surface disease and my continued education and interest in this field facilitated becoming a Diplomat of the American Academy of Optometry in anterior segment disease, which has helped both myself as individual as well as the many patients I treat.

Quality of Life: While education and stronger communication have helped improve care and **Quality of Life**, there are still gaps in knowledge, management, and treatment options that influence how I'm able to live in a given period.

Takeaway: My efforts to stay educated on my disease and openly communicate with my healthcare team have helped strengthen these relationships and provided a degree of confidence in my own understanding of the disease and what I'm experiencing as well as those who I trust with caring for me. My perspective as an eye care specialist has helped me in my pursuit of quality of life, and ultimately my empathy and true understanding has helped countless patients and other healthcare providers understand this complex disease.

Disclosure: C. Hogan: None.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Abstract Number: PP09

The Role of a Palliative Care Support Team to Optimize Outcomes for Patients with Airway Involvement from Relapsing Polychondritis

Joshua Sparks

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Patient Perspectives (PP09-PP13)
Session Type: Poster Session C
Session Time: 8:15AM–9:30AM

Background/Purpose: Relapsing polychondritis (RP) is an inflammatory condition with a variable phenotype thought to be due to autoimmunity towards cartilage, particularly, that found in the airway. It can be challenging to diagnose and lead to symptoms that can have a profound effect on quality of life (QOL) and is one of the leading causes of morbidity and mortality for this condition. I was diagnosed with RP after over a decade with "challenging asthma." In addition to progressive diffuse airway malacia (figure 1), I had auricular chondritis, migratory polyarthritis, episcleritis, and sicca syndrome. After an extended period of steroids and multiple medications, partial remission was achieved with low dose prednisone, IV tocilizumab, methotrexate, and hydroxychloroquine. Despite adequate immune control, the residual airway damage resulted in nearly constant air hunger, dyspnea, and cough. After 1 year, I was barely able to walk, talk, or work requiring intermittent positive airway pressure (PAP) and cough suppressants during the day. Intervention: Once on immunotherapy, the persistent air hunger led to poor mental health and fear. As a physician involved in the care of very complex diseases, I work alongside palliative care (PC) teams, and I thought they might be able to help. Against the advice of my primary doctor, I sought consultation with my local PC program. After assessment, we worked to establish goals and a plan.; specifically, time free from air hunger, reduced cough, and to be able to continue working. Maintenance: Unfortunately, things were more complicated than I was prepared for which led to the first and most important intervention: acknowledging the severity of my illness. In addition to the airway symptoms, I was obese with low muscle mass from steroids and the situation was untenable. Working was unrealistic, especially in my chosen career, and continuing likely increased risk of complications and death. I was totally disabled. Step one, I had to quit working. Next, though I was skeptical, I start extended release morphine for air hunger. Despite my skepticism, this proved to be highly effective and I was able to breathe comfortably resulting in an immediate and significant improvement in my QOL. Quality of Life: After an adjustment period, I began trauma and grief counseling and refocused on my QOL with the goal to get back to work. I began moving some every day. This wasn't simple or easy requiring mobility aids and portable PAP (See figure 2). Over time, I was able to take walks and travel. After 2+ years, I lost 125 lbs and increased my strength (See figure 3). After 4 years, I was finally able to go back to work. I have kept off the weight and have strategies in place to focus on living day to day. Without PC's unique expertise directing focus toward goals and QOL, I would be more likely to be a statistic than writing this abstract. Takeaway: In conclusion, airway involvement from RP leads to symptoms of severe cough, dyspnea, and air hunger compounded by the debilitating effects of steroids. These symptoms are complex and challenging and can persist despite remission of the disease. PC provides unique expertise in the treatment of respiratory symptoms and poor QOL commonly found in advanced stages of disease. Though traditionally associated with the end of life, when a PC team is utilized to focus on a patient's symptom control and QOL, it can help to optimize rehabilitation and maintenance of overall health thereby improving outcomes for patients with advanced airway involvement from RP.

Abstract Number: PP10

Breaking Through Scleroderma's Invisible Struggles: From Isolation to Connection

Sheri Hicks[1], Mary Alore[1], Yen Chen[1], Susan Murphy[1], [1]University of Michigan

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Patient Perspectives (PP09-PP13)
Session Type: Poster Session C
Session Time: 8:15AM–9:30AM

Background/Purpose: While living in Tucson, Arizona in 2006, and caring to our 1-year-old son, I noticed painful ulcers on my red, swollen, and tight fingertips. The pain became unbearable, and it took nearly 6 months before I finally diagnosed with scleroderma in 2007. I could hardly pronounce or understand the word, but I knew I couldn't ignore it. After reaching a point of exhaustion, we relocated to Michigan to be with family and friends. That move became a turning point. In Michigan, I found a supportive community and discovered a new purpose. Although I can no longer work full-time, I became a patient partner in research to help make sure patients' voices are reflected in studies. I am also a trained peer mentor and find joy in connecting with others living with scleroderma. By sharing my experiences, I hope others feel less alone in what can be an isolating journey. This work has given me a renewed purpose, and I am dedicated to supporting others on their journey with scleroderma. Intervention: Living with a rare disease like scleroderma can be isolating, especially when symptoms are invisible to others and we "don't look sick." This invisibility can make it hard to manage daily life and feel understood. I've found that combining peer support and building a strong community connections help address not just the physical symptoms, but also the emotional and social toll of living with scleroderma. As a trained peer mentor and a peer health coach in the RENEW (Resilience-building Energy management to Enhance Well-being) intervention, I've supported others in building resilience and managing energy to improve their quality of life. I also co-founded Scleroderma Backers, an online community that support patients with nearly 900 members, which offers a safe space for connection, questions, and shared understanding. Through RENEW and Scleroderma Backers, I've seen how support from those who "get it" can foster hope and promote health behaviors. Maintenance: Through ongoing connections, whether in RENEW, the Scleroderma Backers, or extended community, I've learned to better advocate for myself, adjust to changing roles, and stay engaged in my care. These non-clinical approaches have strengthened my well-being, increased my confidence in navigating daily challenges, and reduced feelings of isolation. Quality of Life: Today, my quality of life is much more balanced and fulfilling than it was at the time of my diagnosis. While I still face daily challenges from scleroderma, I've learned how to manage my symptoms, set realistic goals, and lean on a strong support system. Being actively involved in peer support and patient-centered research gives me purpose and connection that empowers and inspires me to help others on their journey. Takeaway: This abstract highlights the importance of integrating peer support into care to inspire self-care, foster meaningful connections, and reduce isolation. It also emphasizes the value of comprehensive care that support overall well-being. As patients find innovative ways to manage their conditions, healthcare providers are crucial in promoting these strategies. These insights benefit various rheumatic conditions, strengthening support systems that empower patients and enhance overall well-being.

Abstract Number: PP11

Lived Experience in Action: How Co-Creating a Psoriatic Arthritis Project Empowered My Journey as a Patient Advocate

Kathleen Gallant[1], Sicily Mburu[1], [1]IFPA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Patient Perspectives (PP09-PP13)
Session Type: Poster Session C
Session Time: 8:15AM–9:30AM

Background/Purpose: I am a person living with Psoriatic Arthritis (PsA) since the age of 20. I have spent decades working in advocacy. On my 'good days,' I focus on outreach to change national health policy. I have participated in various advisory boards, most recently in the GoodCare Campaign for PsA, a global, patient-driven project to address unmet needs in the PsA community. Having experienced the challenges patients face—misdiagnosis, delayed treatment, lack of awareness, and isolation, has motivated me to contribute to initiatives that bridge the gap between lived experience and clinical care. Intervention: The GoodCare Campaign for PsA project was launched by the International Federation of Psoriasis Associations (IFPA) in 2022 to raise awareness of the need for PsA treatment guidelines and their integration into care pathways. I served on the steering committee helping to ensure that the patient voice remained central. Together with patients, clinicians and member associations, we co-created tools like the lived-experience illustration booklets, webinars, podcasts, social media materials, communication guides and a downloadable "treat-to-target" patient checklist. These resources support early symptom recognition and help patients, and their loved ones, navigate conversations with healthcare providers. Materials were translated into 9 languages and shared in global campaigns such as World Psoriasis Day, World Arthritis Day, and at international congresses including the European League Against Rheumatism (EULAR) and American College of Rheumatology (ACR).Maintenance: Since its launch, the project has achieved measurable reach. The resources were shared globally via live podcasts recorded at major congresses reaching listeners in over 25 countries. A global survey conducted by IFPA showed over 50% of organizations advocating for people living with PsA had received and used the co-created materials - especially in under-resourced areas. Many, including myself, have emphasized the need for culturally adaptable formats to make the content inclusive. A key outcome was an engaging webinar with a rheumatologist exploring how treatment guidelines can be used as patient education tools. Quality of Life: Co-leading this project has been personally empowering. Seeing patient insights transformed into tools and educational content gives me hope. Knowing my peers feel less alone has deepened my resilience and commitment, furthermore, sharing tailored resources with the medical community and advocating for shared decision-making is impactful. Among the many meaningful conversations I have been part of, one that stands out is this: Importance of shared decision making around therapeutic choice Takeaway: This project shows the power of patient-physician collaboration. I encourage patient leaders and healthcare professionals to adopt co-creation models, use shared decision-making tools and embrace communication strategies that work for both. This will not just change clinical outcomes—it changes lives.

Abstract Number: PP12

From Invisibility to Advocacy: A Gout Patient's Journey to Validation and Systemic Change

Gary Ho[1], [1]Gout Support Group of America

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: Patient Perspectives (PP09-PP13)
Session Type: Poster Session C
Session Time: 8:15AM–9:30AM

Background/Purpose: In 1994, at 24 years old, I felt a sudden, sharp pain in my right ankle while crossing campus. My father shared that both he and my grandfather lived with gout and urged me to see a physician. But my concern was dismissed with: "You're too young for gout." This began a 16-year journey through pain, misdiagnosis, and dismissal. Flares would vanish before appointments. Without visible signs, I was told it was overuse or that I was too active. I used crutches, then a wheelchair. I was prescribed nonsteroidal antiinflammatory drugs (NSAIDs) and steroids, but no one searched for the cause. By the time I was properly tested, I had lost 20% of my kidney function, and my serum uric acid (UA) level was over 10 mg/dL—far exceeding the 6.8 mg/dL threshold for gout diagnosis. Each time I left a medical appointment without answers, I felt more invisible. Over time, I started questioning if anyone would ever believe the pain I was living through. Intervention: In 2010, I finally saw a rheumatologist. For the first time, a physician listened. A simple blood test confirmed chronic gout. That diagnosis wasn't the end of my story—it was the beginning. For the first time, I felt validated—my pain had a name, and with that came hope for healing. I started UA-lowering therapy, but after years of unmanaged disease, my levels remained high. I joined a clinical trial for an intravenous UA-lowering therapy. The treatments were grueling—six-hour infusions every two weeks for nine months. The first three months were the hardest as my body expelled years of UA crystals. With support from my medical team and family, I endured. By the end, my UA stabilized, my mobility returned, and I have not had a gout attack since. Maintenance: Today, medication keeps my UA below 6 mg/dL. I exercise regularly, stay active, and enjoy foods I once avoided. My 16-year struggle was isolating. I battled pain and mental health challenges brought on by dismissal and stigma. In 2015, after reclaiming my life, I helped establish a patient support group. What began as a small effort now reaches over 16,000 people, offering education, resources, and support to help others advocate for their health. Through this community, we've connected patients with trusted specialists and empowered them to speak up, ask better questions, and demand the care they deserve. Quality of Life: I am living fully and without limitations. I can travel freely, stay active, and enjoy everyday moments without fear of flares. I no longer schedule my life around my disease. Instead, I plan my future with confidence, knowing that gout no longer controls me. Emotionally, I found freedom through advocacy. Helping others has restored hope and brought new purpose. For people living with gout, this quality of life means everything: living without pain, without fear, and with the confidence to fully participate in life. Takeaway: Listen first. Create space for patients to fully share their experiences. Simple diagnostic tests, such as serum uric acid (UA) measurement, can prevent years of unnecessary suffering. Recognize the mental health impact. Include mental health check-ins for patients with chronic disease. Acknowledging emotional well-being improves outcomes and strengthens trust. Address stigma head-on. Educate patients and care teams that gout is a complex, chronic disease requiring proactive, long-term management. Correcting misinformation can be the first step toward treatment adherence. Partner with patients. Use shared decision-making to set treatment goals, establish UA targets, and provide regular follow-up support. Patients who feel heard are more engaged and committed to their care."

Abstract Number: PP13

Life Transitions and Their Impact on Patients

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Patient Perspectives (PP09-PP13)
Session Type: Poster Session C
Session Time: 8:15AM–9:30AM

Background/Purpose: I was diagnosed with systemic lupus erythematosus (SLE) when I was 14, and then eventually with CNS lupus when I was 17. My doctors have found a treatment plan that works really well for me. Due to being diagnosed at such a young age, I have gone through many life transitions while dealing with my autoimmune diseases. These transitions include: advancing from pediatric to adult care, moving to college, medical insurance changes, and getting married. Life transitions can lead to health issues as a result of medical care team changes, insurance changes, and difficulties with access to medications and treatments. Changing doctors in the move from pediatric to adult care can introduce difficulties in ensuring that the new health care provider is willing to maintain that same treatment plan. Moving to college can also introduce challenges, especially if you are in a new state and need a local physician for your prescriptions and infusions. Getting married also led to medical insurance challenges, resulting in changing infusion companies and restarting the approval process. For many of these life transitions, I had a period of usually 3 to 6 months going without the treatments that worked for me, which always led to a flare. Intervention: To help prevent discontinuity of care and treatments during life transitions, it is important to plan ahead. Preparing for these changes can prevent some of the common, preventable issues that can occur. The healthcare system can be difficult to navigate, especially if you add in healthcare insurance. Ensuring that the patient learns about their health insurance and prepares for changes before they occur is important. This includes understanding the new coverage and beginning the process of finding covered healthcare providers before the change happens. When choosing where to attend college, planning ahead for treatment is crucial, especially if the college is in another state. Ultimately, I determined that it would not be possible to maintain my treatment plan as it was if I did this, so I chose a college in the same state. Maintenance: Once I was educated on how to navigate medical insurance and the healthcare system in general, it was much easier to prepare for and overcome challenges that arose when I went through another life transition and will be in the future as well. Quality of Life: Maintaining my treatment plan through these life transitions has allowed me to finish my bachelor's and master's degrees, walk across the stage at both graduations, and walk down the aisle at my wedding. These were things that were not initially possible, but through preparing for these life transitions and maintaining my treatment plan, they were able to happen. Takeaway: To ensure there is no disruption in the care and treatments of rheumatic patients during life transitions: It is critical that the patient and their family understand their health insurance coverage, including which healthcare providers (HCPs), facilities, and services are covered. HCPs should be aware of possible life changes and situations to expect ahead of time. HCPs should know and be able to provide available resources such as handouts, links to resources, and information that can be added to the after-visit summary that would help patients navigate these challenges. Potential life transitions to consider are moving from pediatric to adult care, beginning college, moving to a different state or country, healthcare insurance changes, marriage, divorce, and death. Preparing a patient and their family for potential challenges from life transitions can result in better care, health outcomes, and quality of life.
